For example, consider a cluster with three nodes. You create a nodegroup NG0 that includes node n1 and another nodegroup NG1 that includes n2 and n3. Bind load balancing virtual servers .77 to NG0 and load balancing virtual server .69 to NG1.

This means that virtual server .77 will be active only on n1 and consequently only n1 will receive traffic that is directed to .77. Similarly, virtual server .69 will be active only on nodes n2 and n3 and consequently only n2 and n3 will receive traffic that is directed to .69.

Figure 1. Citrix ADC cluster with nodegroups configured for spotted and partial-striped configurations

The entities or configurations that you can bind to a nodegroup are:

- Load balancing, content switching, cache redirection, authentication, authorization, and auditing virtual servers

### Note

FTP load balancing virtual servers cannot be bound to nodegroups.

- VPN virtual server (Supported from NetScaler 10.5 Build 50.10 onwards)
- Global Server Load Balancing (GSLB) sites and other GSLB entities (Supported from NetScaler 10.5 Build 52.11 onwards)
- Limit identifiers and stream identifiers

## Behavior of nodegroups

September 21, 2020

Due to the interoperability of nodegroups with different Citrix ADC features and entities, there are some behavioral aspects to be noted. Nodes in a nodegroup can also be backed up. Read on for more information.

### General behavior of a cluster nodegroup

- A nodegroup that has entities bound to it cannot be removed.
- A cluster node that belongs to a nodegroup with entities bound to it, cannot be removed.
- A cluster instance that has nodegroups with entities bound to it, cannot be removed.
- You cannot add an entity that has a dependency on another entity that is not part of the nodegroup. If you need to do so, first remove the dependency. Then, add both the entities to the nodegroup and reassociate the entities.

#### Examples:

- Assume you have a virtual server, VS1, whose backup is virtual server VS2. To add VS1 to a nodegroup, first make sure that VS2 is removed as the backup server of VS1. Then, bind each server individually to the nodegroup, and then configure VS2 as the backup for VS1.
  - Assume you have a content switching virtual server, CSVS1, whose target load balancing virtual server is LBVS1. To add CSVS1 to a nodegroup, first remove LBVS1 as the target. Then, bind each server individually to the nodegroup, and then configure LBVS1 as the target.
  - Assume you have a load balancing virtual server, LBVS1, that has a policy which invokes another load balancing virtual server, LBVS2. To add either one of the virtual servers, first remove the association. Then, bind each server individually to the nodegroup, and then reassociate the virtual servers.
- You cannot bind an entity to a nodegroup that has no nodes and that has the strict option enabled. Consequently, you cannot unbind the last node of a nodegroup that has entities bound to it and that has the strict option enabled.
  - The strict option cannot be modified for a nodegroup that has no nodes but has entities bound to it.

### Backing up nodes in a nodegroup

By default, a nodegroup is designed to provide back up nodes for members of a nodegroup. If a nodegroup member goes down, a cluster node that is not a member of the nodegroup dynamically replaces

the failed node. This node is called the replacement node.

**Note**

For a single-member nodegroup, a backup node is automatically preselected when an entity is bound to the nodegroup.

When the original member of the nodegroup comes up, the replacement node, by default, is replaced by the original member node.

From NetScaler 10.5 Build 50.10 onwards, however, the Citrix ADC allows you to change this replacement behavior. When you enable the sticky option, the replacement node is retained even after the original member node comes up. The original node takes over only when the replacement node goes down.

You can also disable the backup functionality. To do this, you must enable the strict option. In this scenario, when a nodegroup member goes down, no other cluster node is picked up as a backup node. The original node continues being part of the nodegroup when it comes up. This option ensures that entities bound to a nodegroup are active only on nodegroup members.

**Note**

The strict and sticky option can be set only when creating a nodegroup.

## Configuring nodegroups for spotted and partially-stripped configurations

September 21, 2020

To configure a nodegroup for spotted and partially-stripped configurations you must first create a nodegroup and then bind the required nodes to the nodegroup. You must then associate the required entities to that nodegroup. The entities that are bound to the nodegroup will be:

- **Spotted** - If bound to a nodegroup that has a single node.
- **Partially Striped** - If bound to a nodegroup that has more than one node.

**Some points to remember:**

- GSLB is supported on a cluster only when GSLB sites are bound to nodegroups that have a single cluster node. For more information, see [Setting Up GSLB in a Cluster](#).
- Citrix Gateway is supported on a cluster only when the VPN virtual servers are bound to nodegroups that have a single cluster node. The sticky option must be enabled on the nodegroup.
- For versions prior to NetScaler 11, application firewall is supported only on individual cluster nodes (spotted configuration). Application firewall profiles can be associated only with virtual

servers that are bound to nodegroups that have a single cluster node. This means that application You are not allowed to do the following:

- Bind application firewall profiles to striped or partially striped virtual servers.
- Bind the policy to a global bind point or to user-defined policy labels.
- Unbind, from a nodegroup, a virtual server that has application firewall profiles.
- NetScaler 11 introduced application firewall support for striped and partially-striped configurations. For more information, see [Application Firewall Support for Cluster Configurations](#).

Check [Citrix ADC Features Supported in a Cluster](#) to see the NetScaler versions from which GSLB, Citrix Gateway, and application firewall are supported in a cluster.

### To configure a nodegroup by using the command line interface

1. Log on to the cluster IP address.

2. Create a nodegroup. Type:

```
add cluster nodegroup <name> -strict (YES | NO)<!--NeedCopy-->
```

#### Example

```
1 add cluster nodegroup NG0 -strict YES
```

3. Bind the required nodes to the nodegroup. Type the following command for each member of the nodegroup:

```
bind cluster nodegroup <name> -node <nodeId><!--NeedCopy-->
```

#### Example

To bind nodes with IDs 1, 5, and 6.

```
1 > bind cluster nodegroup NG0 -node 1
2 > bind cluster nodegroup NG0 -node 5
3 > bind cluster nodegroup NG0 -node 6
```

4. Bind the entity to the nodegroup. Type the following command once for every entity that you want to bind:

```
bind cluster nodegroup <name> (-vServer <string> | -identifierName <string> | -gslbSite <string> -service <string>)<!--NeedCopy-->
```

#### Note

The gslbSite and service parameters are available from NetScaler 10.5 onwards.

#### Example

To bind virtual servers VS1 and VS2 and rate limit identifier named identifier1.

```
1 > bind cluster nodegroup NG0 -vServer VS1
2 > bind cluster nodegroup NG0 -vServer VS2
3 > bind cluster nodegroup NG0 -identifierName identifier1
```

5. Verify the configurations by viewing the details of the nodegroup. Type:

```
show cluster nodegroup <name><!--NeedCopy-->
```

**Example**

```
1 > show cluster nodegroup NG0
```

**To configure a nodegroup by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Node Groups**.
3. In the details pane, click **Add**.
4. In the **Create Node Group** dialog box, configure the nodegroup:
  - a) Under **Cluster Nodes**, click the **Add** button.
    - The Available list displays the nodes that you can bind to the nodegroup and the Configured list displays the nodes that are bound to the nodegroup.
    - Click the + sign in the Available list to bind the node. Similarly, click the - sign in the Configured list to unbind the node.
  - b) Under **Virtual Servers**, select the tab corresponding to the type of virtual server that you want to bind to the nodegroup. Click the **Add** button.
    - The Available list displays the virtual servers that you can bind to the nodegroup and the Configured list displays the virtual servers that are bound to the nodegroup.
    - Click the + sign in the Available list to bind the virtual server. Similarly, click the - sign in the Configured list to unbind the virtual server.

**Configuring redundancy for nodegroups**

September 21, 2020

**Note**

Supported from NetScaler 10.5 Build 52.1115.e onwards.

Nodegroups can be configured such that when one nodegroup goes down, another nodegroup can take over and process traffic. For example, when a nodegroup NG1 goes down, NG2 takes over.

**Note**

This functionality can be used to configure datacenter redundancy where each nodegroup is configured as a datacenter.

To achieve this use case, cluster nodes must be logically grouped into nodegroups, where some nodegroups must be configured as ACTIVE and others as SPARE. The active nodegroup with the highest priority (that is, the lowest priority number) is made operationally active and therefore serves traffic. When a node from this operationally active nodegroup goes down, the node count of this nodegroup is compared with the node count of the other active nodegroups in order of their priority. If a nodegroup has a higher or equal node count, that nodegroup is made operationally active. Else, the spare nodegroups are checked.

**Note**

- Only one state-specific nodegroup can be active at a given point in time.
- A cluster node inherits the state of the nodegroup. So, if a node with “SPARE” state is added to nodegroup with state as “ACTIVE”, the node automatically behaves as an active node.
- The preemption parameter that is defined for the cluster instance decides whether the initial active nodegroup will take control when the it comes up again.
- A spare node group can take up a node group and host active traffic when an active node group goes down.

The following figure shows a nodegroup setup that has nodegroup redundancy defined. NG1 is initially the active nodegroup. When it loses one of the nodes, the spare nodegroup (NG3) with the highest priority starts serving traffic.

Figure 1. Citrix ADC cluster with nodegroup redundancy configured

## Configuring redundancy for nodegroups

1. Log on to the cluster IP address.
2. Create the active nodegroup and bind the required cluster nodes.

```

1 > add cluster nodegroup NG1 -state ACTIVE
2 > bind cluster nodegroup NG1 -node n1
3 > bind cluster nodegroup NG1 -node n2
4 > bind cluster nodegroup NG1 -node n3

```

3. Create the spare nodegroup and bind the requisite nodes.

```

1 > add cluster nodegroup NG2 -state SPARE -priority 20
2 > bind cluster nodegroup NG2 -node n4
3 > bind cluster nodegroup NG2 -node n5
4 > bind cluster nodegroup NG2 -node n6

```

4. Create another spare nodegroup and bind the requisite nodes.

```

1 > add cluster nodegroup NG3 -state SPARE -priority 10
2 > bind cluster nodegroup NG3 -node n7

```

```
3 > bind cluster nodegroup NG3 -node n8
4 > bind cluster nodegroup NG3 -node n9
```

## Disabling steering on the cluster backplane

September 21, 2020

### Note

Supported from NetScaler 11 onwards.

The default behavior of a Citrix ADC cluster is to direct the traffic that it receives (flow receiver) to another node (flow processor) that must then process the traffic. This process of directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

If required, you can disable steering so that the process becomes local to the flow receiver and therefore makes the flow receiver as the flow processor. Such a configuration setup can come handy when you have a high latency link.

### Note

This configuration is applicable only for striped virtual servers.

- For partially striped virtual servers, if the flow receiver is a non-owner node, the traffic is steered to a owner node. If however, the flow receiver is a owner node, then steering is disabled.
- For spotted virtual servers, flow receiver is the flow processor, and hence there is no need for steering.

Some points to remember when disabling the steering mechanism:

- Striped SNIPs are not supported as steering is disabled.
- MPTCP and FTP does not work.
- L2 mode must be disabled.
- If USIP is enabled, traffic may not reach back to the same node as the steering is disabled.
- Traffic that is directed to the cluster IP address is steered to the configuration coordinator.
- When a node joins or leaves a cluster, it is possible that more than 1/N connections will be affected. This is due to the fact that a change in the nodes available, may cause the routes to be rehashed. As a result, the traffic will be routed to another node and due to the non-availability of steering, the traffic will not be processed.

Steering can be disabled at the individual virtual server level or at the global level. The global configuration takes precedence over the virtual server setting.

- Disabling backplane steering for all striped virtual servers

Configured at cluster instance level. Traffic meant for any striped virtual server will not be steered on cluster backplane.

```
add cluster instance \<clId\> -processLocal ENABLED<!--NeedCopy-->
```

- Disabling backplane steering for a specific striped virtual server

Configured on a striped virtual server. Traffic meant for the virtual server will not be steered on cluster backplane.

```
add lb vserver <name> <serviceType> -processLocal ENABLED<!--NeedCopy-->
```

## Synchronizing cluster configurations

September 21, 2020

Citrix ADC configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

- A node joins the cluster
- A node rejoins the cluster
- A new command is executed through the cluster IP address.

Additionally, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

### To synchronize cluster configurations by using the command line interface

At the command prompt of the appliance on which you want to synchronize the configurations, type:

```
1 force cluster sync
```

### To synchronize cluster configurations by using the configuration utility

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click Force cluster sync.
4. Click **OK**.

## Synchronizing time across cluster nodes

September 21, 2020

The cluster uses Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

### To enable/disable PTP by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 set ptp -state disable
```

### To enable/disable PTP by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click **Configure PTP Settings**.
4. In the **Enable/Disable PTP** dialog box, select whether you want to enable or disable PTP.
5. Click **OK**.

## Synchronizing cluster files

September 21, 2020

The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Additionally, you can manually synchronize the cluster files.

The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netscaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/htmlinjection/
- /netscaler/htmlinjection/ens/
- /nsconfig/monitors/
- /nsconfig/nstemplates/

- /nsconfig/ssh/
- /nsconfig/rc.netscaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd\_config
- /nsconfig/hosts
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab
- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java\_home/lib/security/cacerts
- /var/wi/java\_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

**Tip**

Files (certificates and key files) that are copied to the cluster configuration coordinator manually (or through the shell) are not automatically available on the other cluster nodes. You must execute the “sync cluster files” command from the cluster IP address before executing a command that depends on these file(s).

**To synchronize cluster files by using the command line interface**

At the command prompt of the cluster IP address, type:

```
1 sync cluster files <mode>
```

**To synchronize cluster files by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click Synchronize cluster files.

4. In the **Synchronize** cluster files dialog box, select the files to be synchronized in the Mode drop-down box.
5. Click **OK**.

## Viewing the statistics of a cluster

September 21, 2020

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

### To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 stat cluster instance <clId>
```

### To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 stat cluster node <nodeid>
```

#### Note

When executed from the cluster IP address, this command displays the cluster level statistics. However, when executed from the NSIP address of a cluster node, the command displays node level statistics.

### To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, in the center of the page, click **Statistics**.

### To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, select a node and click **Statistics** to view the statistics of the node. To view the statistics of all the nodes, click **Statistics** without selecting a specific node.

## Discovering Citrix ADC appliances

September 21, 2020

You can discover the appliances present in the same subnet as the current node. The required discovered appliances can then be selectively added to the cluster. This operation can be performed to either create a new cluster or to add nodes to an existing cluster.

### Note

- The discover operation can be performed only through the configuration utility.
- This operation cannot discover Citrix ADC appliances from different networks.
- When performing this operation to add nodes to an existing cluster, the L3 VLAN configurations will be cleared from the node. You must make sure to define these configurations once the appliance is added to the cluster.

### To discover appliances by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, at the bottom of the page, click **Discover NetScalers**.
4. In the **Discover NetScalers** dialog box, set the following parameters:
  - **IP address range** - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
  - **Backplane interface** - Specify the interfaces to be used as the backplane interface. This is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.
5. Click **OK**.
6. Select the appliances that you want to add to the cluster.
7. Click **OK**.

## Disabling a cluster node

September 21, 2020

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations. When the node is enabled again, the cluster configurations are automatically synchronized on it. For more information, see [Synchronization across cluster nodes](#).

A disabled node cannot serve traffic and all existing connections on this node are terminated.

**Note**

If the configurations of a disabled non-configuration coordinator node are modified (through the NSIP address of the node), the configurations are not automatically synchronized on that node. You must manually synchronize the configurations as described in [Synchronizing Cluster Configurations](#).

**To disable a cluster node by using the command line interface**

At the command prompt of the node that you want to disable, type:

```
1 disable cluster instance <clId>
```

**Note**

To disable the cluster, run the `disable cluster instance` command on the cluster IP address.

**To disable a cluster node by using the configuration utility**

1. On the node that you want to disable, navigate to **System > Cluster**, and click **Manage Cluster**.
2. In the **Configure** cluster instance dialog box, unselect the **Enable** cluster instance check box.

**Note**

To disable the cluster instance on all the nodes, perform the above procedure on the cluster IP address.

**Removing a cluster node**

March 10, 2021

When a node is removed from the cluster, the cluster configurations are cleared from the node (by internally running the `clear ns config -extended` command). The SNIP addresses, **MTU** settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

**Note**

- If the deleted node was the cluster configuration coordinator (CCO), another node is automatically selected as the CCO, and the cluster IP address is assigned to that node. All the

- current cluster IP address sessions are invalid and you have to start a new session.
- To delete the whole cluster, you must remove each node individually. When you remove the last node, the cluster IP addresses are deleted.
  - When an active node is removed, the traffic serving capability of the cluster is reduced by one node. Existing connections on this node are terminated.

## To remove a cluster node by using the CLI

### For NetScaler 10.1 and later versions

1. Log on to the cluster IP address and at the command prompt, type:

```
1 rm cluster node <nodeId>
2
3 save ns config
```

2. Log on to the removed node, NSIP address, and at the command prompt, type:

```
1 save ns config
```

### Note

If the cluster IP address is unreachable from the node, run the `rm cluster instance` command on the NSIP address of that node itself.

### For NetScaler 10

1. Log on to the node that you want to remove from the cluster and remove the reference to the cluster instance.

```
1 rm cluster instance <clId>
2
3 save ns config
```

2. Log on to the cluster IP address and remove the node from which you removed the cluster instance.

```
1 rm cluster node <nodeId>
2
3 save ns config
```

Make sure you do not run the `rm cluster node` command from the local node. It results in inconsistent configurations between the CCO and the node.

## To remove a cluster node by using the GUI

On the cluster IP address, navigate to **System > Cluster > Nodes**, select the node you want to remove and click **Remove**.

## Removing a node from a cluster deployed using cluster link aggregation

September 21, 2020

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see [Using Cluster Link Aggregation](#).

### To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to PASSIVE.

```
1 set cluster node <nodeId> -state PASSIVE
```

3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.

#### Note

You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.

4. Remove the node from the cluster.

```
1 rm cluster node <nodeId>
```

## Detecting jumbo probe on a cluster

September 21, 2020

If a Jumbo frame is enabled on a Cluster interface, the backplane interface should be large enough to support the all packets in the Jumbo frame. This is achieved by setting the Maximum Transmission Unit (MTU) of the backplane as:

Backplane\_MTU = maximum (all cluster interface MTU's) + 78

To verify the above configuration, you must send a jumbo probe (of the above computational size) to all peer nodes of a Cluster setup. If the probe does not succeed, the appliance displays a warning message in the output of the “show cluster instance” command.

In the command interface mode, type the following command:

```

1      > show cluster instance
2      Cluster ID: 1
3      Dead Interval: 3 secs
4      Hello Interval: 200 msec
5      Preemption: DISABLED
6      Propagation: ENABLED
7      Quorum Type: MAJORITY
8      INC State: DISABLED
9      Process Local: DISABLED
10     Cluster Status: ENABLED(admin),      ENABLED(operational), UP

```

### Warning

The MTU for a backplane interface must be large enough to handle all packets in the frame. It must be equal to <MTU\\_VAL>. If the recommended value is not user configurable, you must review the MTU value of jumbo interfaces.

| Sl. no | Member Nodes                       | Health | Admin State | Operation State                    |
|--------|------------------------------------|--------|-------------|------------------------------------|
| 1      | Node ID: 1; Node IP: 10.102.53.167 | UP     | Active      | ACTIVE (Configuration Coordinator) |
| 2      | Node ID: 2; Node IP: 10.102.53.168 | UP     | Active      | Active                             |

## Route monitoring for dynamic routes in cluster

September 21, 2020

You can use a route monitor to make a Cluster node dependent on the internal routing table whether it contains or does not contain dynamically learnt route. In a Cluster system, a route monitor on each node checks the internal routing table to ensure there is a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

In a cluster deployment, if the client-side or server side-link of a node goes down, traffic is steered to this node through the peer nodes for processing. The steering of traffic is implemented by configuring

dynamic routing and adding static ARP entries, pointing to the special MAC address of each node, on all the nodes. If there are a large number of nodes in a cluster deployment, adding and managing static ARP entries with special MAC addresses on all the nodes is a cumbersome task. Now, nodes implicitly use special MAC addresses for steering packets. Therefore, static ARP entries pointing to special MAC addresses are no longer required to be added to the cluster nodes.

## To bind a cluster node using the command line interface

At the command prompt, type:

```
1 bind cluster node <nodeId> (-routeMonitor <ip_addr|ipv6_addr|*> [<
  netmask>])
2 unbind cluster node <nodeId> (-routeMonitor <ip_addr|ipv6_addr|*> [<
  netmask>])
```

Consider a scenario where Node 1 is bound to route monitor 1.1.1.0 255.255.255.0. When a dynamic route fails, Node 1 become INACTIVE. Health status is available in the Show Cluster Node command by node id as show below.

```
1 Node ID: 1
2 IP: 10.102.169.96
3 Backplane: 1/1/2
4 Health: NOT UP
5 Reason(s): Route Monitor(s) of the node have failed
6 Route Monitor - Network: 1.1.1.0 Netmask: 255.255.255.0 State:
  DOWN
```

## Monitoring cluster setup using SNMP MIB with SNMP link

February 5, 2021

SNMP mib is device specific information that has been configured on the SNMP agent for the purpose of identifying a Citrix ADC appliance, such as appliance name, administrator, location. In a cluster setup, you can now configure the SNMP MIB in any node by including the “ownerNode” parameter in the set snmp mib command. Without this parameter, the set snmp mib command applies only to the Cluster Coordinator (CCO) node.

To display the MIB configuration for a cluster node other than the CCO, include the “ownerNode” parameter in the show snmp mib command

## Configuring SNMP MIB on CLIP

To configure and view MIB configuration on CLIP by using the command line interface.

```
1 set snmp mib [-contact <string>] [-name <string>] [-location <string>]
2     [-customID <string>] [-ownerNode <positive_integer>]
3 Done
4 show snmp mib [-ownerNode <positive_integer>]
5
6 > set mib -contact John -name NS59 -location San Jose -customID 123 -
   ownerNode 3
7 Done
8 > sh mib -ownerNode 3
9     -----
10     Cluster Node ID: 3
11     -----
12     NetScaler system MIB:
13     sysDescr:    NetScaler NS11.1: Build 46.4.a.nc, Date: Jun 7
2016, 10:27:29
14     sysUpTime:   124300
15     sysObjectID: .1.3.6.1.4.1.5951.1.1
16     sysContact:  John
17     sysName:     NS59
18     sysLocation: San Jose
19     sysServices: 72
20     Custom ID:  123
21 Done
22
23 > unset mib -contact -name -location -customID -ownerNode 3
24 Done
25 > sh mib -ownerNode 3
26     -----
27     Cluster Node ID: 3

## Monitoring command propagation failures in a cluster deployment

September 21, 2020

In a cluster deployment of Citrix ADC appliances, you can use the new command “show prop status” for faster monitoring and troubleshooting of issues related to command-propagation failure on non-CCO nodes. This command displays up to 20 of the most recent command propagation failures on all non-CCO nodes. You can use either the Citrix ADC command line or the Citrix ADC GUI to perform this operation after accessing them through the CLIP address or through the NSIP address of any node in the cluster deployment.

## Graceful shutdown of nodes

September 21, 2020

In a cluster setup, some of the existing connections (1/Nth connections, where N is the cluster size) at the cluster level or specific virtual server level are lost. This behavior is observed if a node leaves or joins the system. To address the loss, you must gracefully handle the existing connections. Graceful handling is done by configuring “retain connections on cluster” option in the CLIP address and specifying timeout interval in the node’s NSIP.

Graceful handling of connections is applicable in two scenarios:

1. Cluster upgrade
2. New node addition

## Graceful handling of Nodes in cluster upgrade

To upgrade a cluster, you must upgrade one node at a time. Before upgrading a node, you must set it to passive state and then set it to active state after the upgrade. To avoid terminating existing connections when upgrading the node, shut it down gracefully with a configured timeout interval. Otherwise, 1/Nth (where N is the cluster size) of the cluster’s connections are terminated.

### Note

If existing sessions are not completed within the configured timeout interval, they get terminated after the grace time.

Following are the steps to gracefully handle nodes in a cluster upgrade scenario:

1. Consider a cluster setup of five nodes (n0, n1, n2, n3, n4).

2. Before you shut down a node, you must configure “retainConnectionsOnCluster” option to retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

**Example**

On CLIP

```
“set cluster instance -retainConnectionsOnCluster YES
```

```
1 OR
2
3 ``set lb vserver <vserver name> - retainConnectionsOnCluster Yes
  <!--NeedCopy-->
```

3. Now, log on to the NSIP address of node n3 and set the node n3 to PASSIVE with a timeout interval.

**Example**

```
“set cluster node n3 -state PASSIVE -delay 60
```

```
1 ``saveconfig<!--NeedCopy-->
```

4. After the grace period expires, close all connections, shut down n3 and reboot the Citrix ADC appliance.
5. Upgrade the appliance. Then, with the CLI connected to the appliance’s NSIP address, set the node to ACTIVE.

**Example**

```
“set cluster node n3 -state ACTIVE
```

```
1 ``saveconfig<!--NeedCopy-->
```

6. Repeat steps 4–6 for all nodes in the cluster.
7. After all nodes are upgraded and set to ACTIVE, reset the retainConnectionsOnCluster option from the CLIP address.

**Example**

```
“set cluster instance -retainConnectionsOnCluster NO
```

```
1 OR
2
3 ``set lb vserver <vserver name> - retainConnectionsOnCluster NO
  <!--NeedCopy-->
```

**Note**

If there is a version mismatch when upgrading a cluster, cluster propagation is automatically disabled and no commands are allowed on the CLIP.

**Graceful handling of nodes during a new node addition**

The graceful handling of nodes describes how a new node can be added to the existing Citrix ADC cluster. Consider you have a Citrix ADC cluster that is already serving traffic. And you want to add an extra appliance as a node to the cluster without terminating its existing connections. To accomplish the preceding scenario, set the option to retain existing connections either at a Global level or at a specific virtual server level. Once done, save the configuration. Now set the option to retain connections to NO, to allow existing connections from other nodes to be reassigned to the new node.

Following are the steps to gracefully handle nodes if a node newly added:

1. Save the existing configuration that has “retainConnectionsOnCluster” option enabled to retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

On CLIP

```
set cluster instance x - retainConnectionsOnCluster YES
```

OR

```
set lb vserver xxxx -retainConnectionsOnCluster Yes
```

2. Add a node ‘n5’ to the cluster setup.
3. Disable “the retainConnectionOnCluster” option to “NO” for distributing existing connections from other nodes to the newly added node n5.

On CLIP

```
set cluster instance x - retainConnectionsOnCluster NO
```

OR

```
set lb vserver xxxx -retainConnectionsOnCluster NO
```

**Note**

The backplane steering depends on the type of traffic distribution mechanism (ECMP, CLAG, and USIP) on a cluster setup. The increase in backplane steering is based on the traffic type.

## Configuring graceful shutdown of nodes in a cluster

To configure graceful shutdown of nodes in a cluster, do the following:

1. Configure “retainConnectionsOnCluster” option at Global (Cluster) level.
2. Configure “retainConnectionsOnCluster” option at the virtual server level.
3. Set the node (leaving the system) to the passive state with a graceful timeout interval specified in the node’s NSIP address.
4. Monitor the existing connections to make sure all transactions are completed within the grace period.

### To retain existing connections at the global (cluster) level by using the command line

You can retain existing connections either at a global level or at a specific virtual server level. This option is configured to retain all existing connections at the global level. By default, this option is disabled.

At the command prompt type:

```
1 - set cluster instance <clusterID> - retainConnectionsOnCluster YES
2
3 - set cluster instance 60 - retainConnectionsOnCluster YES
```

### To retain existing connections of a specific virtual server in the cluster by using the command line

This option is configured to retain existing connections specific to a load balancing virtual server. To retain those connections, we enable this option at the virtual server level. By default, this option is disabled.

At the command prompt, type:

```
1 - set lb vserver <clusterID> - retainConnectionsOnCluster Yes
2
3 - set lb vserver v1 - retainConnectionsOnCluster Yes
```

### To set a cluster node to passive state by using the command line

To set a cluster node to passive state with a graceful timeout interval. This setting is performed in the node’s NSIP as propagation is disabled during cluster upgrade.

At the command prompt, type:

```
1 - set cluster node <clusterID> -state passive
2 -backplane <interface_name>@
3 -priority <positive_integer>
4 -delay <mins>
5
6 - set cluster node 4 - state PASSIVE -delay 60
7
8 - set cluster instance 60 - retainConnectionsOnCluster YES
9 - set lb vserver v1 - retainConnectionsOnCluster Yes
10 - set cluster node 4 - state PASSIVE -delay 60
```

**Note**

You might observe the following behavior on a cluster node when it is set to passive with delay option configured from a CLIP:

- After the timeout, the node shows as passive from the NSIP of the node.
- The **show cluster instance** command on CLIP displays the node as active from the CLIP. Whereas the **show cluster node** command on the CLIP displays the node as passive.

**To configure graceful shutdown of nodes by using the Citrix ADC GUI**

1. Navigate to **Configuration > System > Cluster** and click **Manage Cluster**.
2. On the **Manage Cluster** page, select **Retain Connections on Cluster** option.
3. Click **OK**, and then click **Done**.

**Graceful shutdown of services**

September 21, 2020

Starting with NetScaler 12.1 build 49.xx, Citrix ADC clusters support graceful shutdown of services. To gracefully shutdown the services, you can perform one of the following tasks.

- Explicitly disable the service, and
  - Set a delay (in seconds).
  - Enable graceful shutdown.
- Add a TROFS code or string to the monitor.

For more details, see [Graceful shutdown of services](#).

## To configure graceful shutdown for a service by using the CLI

### Disable with graceful option only:

At the command prompt, type:

```
1 disable service <name> [-graceFul (YES|NO)]
2
3 show service <name>
4 <!--NeedCopy-->
```

### Example

```
1 disable service svc1 -graceFul YES
2 Done
3 sh service svc1
4          svc1 (10.102.225.11:80) - HTTP
5          State: GOING OUT OF SERVICE   Graceful (number of
6          active clients: 1)
7          Last state change was at Wed Jul 25 10:46:29 2018
8          Time since last state change: 0 days, 00:00:02.680
9          .....
10         Traffic Domain: 0
11
12 1)          Monitor Name: tcp-default
13             State: UP                               Weight: 1
14             Probes: 26                               Failed [Total: 0
15             Current: 0]
16             Last response: Success - TCP syn+ack
17             Response Time: 0.0 millisec
18 <!--NeedCopy-->
```

### Disable with timeout and graceful option:

At the command prompt, type:

```
1 disable service <name> [<delay>] [-graceFul (YES|NO)]
2
3 show service <name>
4 <!--NeedCopy-->
```

### Example

```
1 disable service svc1 2000 -graceFul YES
```

```

2
3 Done
4 > sh service svc1
5         svc1 (10.102.225.11:80) - HTTP
6         State: GOING OUT OF SERVICE (Graceful (number of active
7             clients: 1), Out Of Service in 1998 seconds)
8         Last state change was at Wed Jul 25 10:49:08 2018
9         Time since last state change: 0 days, 00:00:01.710
10        ... .. .
11        Traffic Domain: 0
12
13 1)          Monitor Name: tcp-default
14                State: UP                Weight: 1
15                Passive: 0
16                Probes: 57                Failed [Total: 0
17                Current: 0]
18                Last response: Success - TCP syn+ack
19                received.
20                Response Time: 0.0 millisec
21 Done
22 <!--NeedCopy-->

```

### Disable service group with timeout and graceful option:

At the command prompt, type:

```

1 disable serviceGroup <serviceName>@ [<serverName>@ <port>] [-delay
2 <secs>] [-graceFul ( YES | NO )]
3 Show service group <serviceName>
4 <!--NeedCopy-->

```

Example:

```

1 disable servicegroup sg -delay 2000 -graceFul yes
2 sh servicegroup sg
3         sg - HTTP
4         State: DISABLED                Effective State: OUT OF
5             SERVICE Monitor Threshold : 0
6         Max Conn: 0                Max Req: 0                Max Bandwidth: 0
7             kbits
8         Use Source IP: NO
9         Client Keepalive(CKA): NO
10        ... .. .
11        ... .. .

```

```

11
12          1) 200.200.10.21:80      Server Name: server3
              Server ID: None Weight: 1
13              State: GOING OUT OF SERVICE (learnt
                  from node:2 ) Graceful (number
                  of active clients: 6), Out Of
                  Service in 1993 seconds
14              Last state change was at Mon Aug 13
                  15:15:11 2018
15              ... ..
16
17          2) 200.200.10.22:80      Server Name: server4
              Server ID: None Weight: 1
18              State: GOING OUT OF SERVICE (learnt
                  from node:2 ) Graceful (number
                  of active clients: 7), Out Of
                  Service in 1993 seconds
19              Last state change was at Mon Aug 13
                  15:15:11 2018
20 <!--NeedCopy-->

```

Note: CLIP displays the aggregated value of all active clients connections from all cluster nodes.

### To configure graceful shutdown for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

### To configure a TROFS code or string in a monitor by using the CLI

At the command prompt, type one of the following commands:

```

1 add lb monitor <monitor-name> HTTP -trofsCode <respcode>
2 add lb monitor <monitor-name> HTTP-ECV -trofsString <resp string>
3 add lb monitor <monitor-name> TCP-ECV -trofsString <resp string>
4 <!--NeedCopy-->

```

### To configure a TROFS code or string in a monitor by using the GUI

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following steps:
  - Select Type as HTTP, and specify a TROFS Code.

- Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

## IPv6 ready logo support for clusters

September 21, 2020

You can test clustered appliances for IPv6 Ready Logo certification. Modified commands for testing IPv6 core protocols, such as for ND test cases, Router Solicitation processing, and sending route advertisement and router redirection messages are available in a clustered setup. Following are the IPv6 functionalities available for testing the IPv6 core protocols.

Following are the modified functionalities available to pass IPv6 core protocols, such as ND test cases, Router Solicitation processing and sending Route advertisement and router redirection messaging in IPv6readylogo phase2 test suite.

- Link Local SNIPs
- Address Resolution and Neighbor Unreachability
- Router and Prefix Discovery
- Router Redirection
- DoDAD

With these modified commands, the following configurations are supported in a clustered appliance.

### Supportable configurations for testing IPv6 core protocols

For a clustered setup to pass IPv6 Ready Logo test cases, you can execute the following configurations on the Cluster Management IP address (CLIP).

- global IP6 configuration
- basic IPv6 configuration
- additional IPv6 configurations

#### Global configuration

A global IPv6 configuration enables you to set the global IPv6 parameters (such as relearning, routeRedirection, ndBasereachTime, nRetransmissionTime, natprefix, td, and doodad) to run the basic IPv6 configuration.

At the command prompt, type the following:

```
1 set ipv6 [-relearning ( ENABLED | DISABLED )] [-routerRedirection (
    ENABLED | DISABLED )] [-ndBasereachTime<positive_integer>][-
```

```
ndRetransmissionTime <positive_integer>] [-natprefix <ipv6_addr|*>[-td<positive_integer>]] [-doDAD ( ENABLED | DISABLED )]
```

### Basic IPv6 configuration

The basic IPv6 configuration enables you to create an IPv6 address and bind to a VLAN interface. You must perform the following configurations to test the IPv6 core protocols.

To add a VLAN to the clustered setup by using the NetScaler command line

At the command prompt, type:

```
1 add vlan <id>
```

To add another VLAN to the clustered set up by using the NetScaler command line

At the command prompt, type:

```
1 add vlan <id>
```

To bind an interface to a VLAN by using the NetScaler command line

At the command prompt, type:

```
1 bind vlan <id> -ifnum <interface_name>
```

To bind an interface to a VLAN by using the NetScaler command line

This command adds the global prefix as on-link prefix into RA information for subsequent Router Advertisements. At the command prompt, type:

```
1 bind vlan <id> -ifnum <interface_name>
```

To add IPv6 SNIP address on a VLAN by using the NetScaler command line

At the command prompt, type the following:

```
1 add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To add IPv6 address on VLAN by using the NetScaler command line

At the command prompt, type the following:

```
1 add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To bind IPv6 address to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
1 bind vlan <id> [-ifnum <interface_name> [-tagged]] [-IPAddress <ip_addr |
  ipv6_addr |
```

To bind IPv6 address to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
1 bind vlan <id> [-ifnum <interface_name> [-tagged]] [-IPAddress <ip_addr |
  ipv6_addr |
```

To display link local IPv6 address attached to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
1 sh VLAN
```

### Example 1

```
1 add vlan 2
2 add vlan 3
3 bind vlan 2 -ifnum 1/2
4 bind vlan 3 -ifnum 1/3
5 add ip6 fe80::9404:60ff:fedd:a464/64 -vlan 2 -scope link-local -type
  SNIP
6 add ip6 fe80::c0ee:7bff:fede:263f/64 -vlan 3 -scope link-local -type
  SNIP
7 add ip6 3ffe:501:ffff:100:9404:60ff:fedd:a464/64 -vlan 2
8 add ip6 3ffe:501:ffff:101:c0ee:7bff:fede:263f/64 -vlan 3
9 bind vlan 2 -ipAddress 3ffe:501:ffff:100:9404:60ff:fedd:a464/64
10 bind vlan 3 -ipAddress 3ffe:501:ffff:101:c0ee:7bff:fede:263f/64
```

### Example 2

```
1 sh vlan
2 1)      VLAN ID: 2      VLAN Alias Name:
3         Interfaces : 1/6
4         IPs :
5         3ffe:501:ffff:100:2e0:edff:fe15:ea2a/64
6 3)      VLAN ID: 3      VLAN Alias Name:
7         Link-local IPv6 addr: fe80::9404:60ff:fedd:a464/64
```

```

8      Interfaces : 1/5
9      IPs :
10         3ffe:501:ffff:101:2e0:edff:fe15:ea2b/64
11 Done

```

### Additional IPv6 cluster configuration

To test IPv6 core protocols, you can use the following new or modified IPv6 configurations.

To set VLAN specific Router Advertisement parameters by using the NetScaler command line

At the command prompt, type:

```

1 set nd6RAvariables -vlan <positive_integer> [-ceaseRouterAdv ( YES | NO
   )] [-sendRouterAdv ( YES | NO )] [-srcLinkLayerAddrOption ( YES | NO
   )] [-onlyUnicastRtAdvResponse ( YES | NO )] [-managedAddrConfig (
   YES | NO)] [-otherAddrConfig ( YES | NO )] [-currHopLimit <
   positive_integer>] [-maxRtAdvInterval <positive_integer>] [-
   minRtAdvInterval<positive_integer>] [-linkMTU <positive_integer>] [-
   reachableTime<positive_integer>] [-retransTime <positive_integer>]
   [-defaultLifeTime<integer>]

```

To set an on-link global prefix's configurable parameters by using the NetScaler command line

At the command prompt, type:

```

1 set onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )] [-
   autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )] [-
   decrementPrefixLifeTimes ( YES | NO )] [-prefixValideLifeTime <
   positive_integer>] [-prefixPreferredLifeTime <positive_integer>]

```

To add configurable parameters to an on-link global prefix by using the NetScaler command line

At the command prompt, type:

```

1 add onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )] [-
   autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )] [-
   decrementPrefixLifeTimes ( YES | NO )] [-prefixValideLifeTime <
   positive_integer>] [-prefixPreferredLifeTime <positive_integer>]

```

To set on-link link IPv6 prefix's configurable parameters by using the NetScaler command line

At the command prompt, type the following:

```

1 help set onLinkIPv6Prefix

```

To bind an on-link link IPv6 prefix's configurable parameters by using the NetScaler command line

At the command prompt, type:

```
1 help bind nd6RAvariables
```

To show nd6RAvariables by using the NetScaler command line

At the command prompt, type:

```
1 help sh nd6RAvariables
```

### Example

```
1 > sh nd6RAvariables
2 1) Vlan : 1
3   SendAdvert      : NO   CeaseAdv      : NO   SourceLLAddress:
   YES
4   UnicastOnly    : NO   ManagedFlag  : NO   OtherConfigFlag:
   NO
5   CurHopLimit    : 64   MaxRtrAdvInterv: 600  MinRtrAdvInterv:
   198
6   LinkMTU        : 0    ReachableTime : 0    RetransTimer   :
   0
7   DefaultLifetime: 1800 LastRASentTime : 0    NextRAdelay    :
   0
8
9 2) Vlan : 2
10  SendAdvert      : NO   CeaseAdv      : NO   SourceLLAddress:
   YES
11  UnicastOnly    : NO   ManagedFlag  : NO   OtherConfigFlag:
   NO
12  CurHopLimit    : 64   MaxRtrAdvInterv: 600  MinRtrAdvInterv:
   198
13  LinkMTU        : 0    ReachableTime : 0    RetransTimer   :
   0
14  DefaultLifetime: 1800 LastRASentTime : 0    NextRAdelay    :
   0
15 Done
16 >
17 > sh nd6RAvariables - vlan 2
18 1) Vlan : 2
19  SendAdvert      : NO   CeaseAdv      : NO   SourceLLAddress:
   YES
```

```
20   UnicastOnly      : NO   ManagedFlag       : NO       OtherConfigFlag:
    NO
21   CurHopLimit     : 64   MaxRtrAdvInterv: 600     MinRtrAdvInterv:
    198
22   LinkMTU         : 0    ReachableTime    : 0       RetransTimer    :
    0
23   DefaultLifetime: 1800 LastRAsentTime   : 0       NextRAdelay     :
    0
24   Prefix         :
25   3ffe:501:ffff:100::/64
26   Done
```

## Managing cluster heartbeat messages

September 21, 2020

Managing heartbeat messages in a cluster is similar to managing them in a high availability (HA) configuration. Nodes can send and receive heartbeat messages to and from each other on all interfaces that are enabled. To avoid increased traffic resulting from heartbeat messages, you can now disable the heartbeat option on node interfaces. However, the heartbeat option on the backplane interface cannot be disabled, because it is required for maintaining connectivity among the cluster nodes.

For more information about managing heart messages, see [Managing High Availability Heartbeat Messages on a NetScaler Appliance](#).

### To manage heartbeat messages on a node interface by using the Citrix ADC CLI

At the command prompt, type:

```
1 set interface <ID> [-HAHeartBeat (ON | OFF)]
2 Show interface <ID>
```

## Configuring owner node response status

September 21, 2020

In a cluster setup, on a node has a spotted SNIP address, you can configure the ownerDownResponse option. By default, the option is enabled, allowing the spotted IP address to respond to PING or ARP

requests (coming from the upstream router) when the node is inactive. If you disable the option, the IP address cannot respond to the router requests when the owner node is inactive.

To know how this feature is used for monitoring static routes in ECMP deployment, see [Using Equal Cost Multiple Path \(ECMP\)](#) topic.

### To set owner node response status by using the Citrix ADC CLI

At the command prompt, type:

```
1 add ns ip <IPAddress> [-ownerNode <positive_integer>] [-ownerDownResponse (YES | NO)] [-td <positive_integer>]
```

### Example

```
1 add ns ip 2.2.2.2 255.255.255.0 -ownernode 6 -ownerdownResponse YES
```

### To set owner node response status by using the Citrix ADC GUI

1. Navigate to **System > Network > IPs** and click **Add** to create a spotted SNIP address.
2. On the **Create IP Address** page, select or clear the **ownerDownResponse** check box.

### To edit owner node response status by using the Citrix ADC GUI

Navigate to **System > Network > IPs**, select an IP address, and click **Edit** to select or clear the **ownerDownResponse** check box.

## Monitor static route (MSR) support for inactive nodes in a spotted cluster configuration

September 21, 2020

In a cluster set up with MSR option enabled on the route, only active nodes can probe to a static route and reach a network while inactive and spare nodes have no link to the route and cannot probe to it. You can now configure an inactive or spare node to send PING and ARP probe to IPv4 route and send ping6 and nd6 probe to IPv6 route. You can perform this only in a Spotted Cluster configuration in which the SNIP address is active and owned exclusively only by one node.

## VRRP interface binding in a single node active cluster

September 21, 2020

When you migrate a high availability (HA) setup to a cluster setup, all configurations must be compatible and must be supportable in the cluster. To achieve this, you can now configure virtual router IDs (VRIDs and VRID6s) on a node interface.

Important: Currently, only a single-node active cluster system supports VRIDs and VRID6s.

For instructions for configuring VRIDs and VRID6s, see [Configuring Virtual MAC Addresses](#).

To configure a virtual router ID on a single-node active cluster, add the VRID or VRID6 and bind it to the cluster-node interface.

To add a VRID by using the Citrix ADC CLI

At the command prompt, type:

```
1 add vrid <ID>
```

To bind a VRID to the cluster-node interface by using the Citrix ADC CLI

At the command prompt, type:

```
1 Bind vrid <ID> -ifnum <interface_name> | -trackifNum <interface_name>
2
3 Add vrid 100
4 Bind vrid 100 - ifnum 1/1 1/2
5 done
```

To add a VRID6 by using the Citrix ADC CLI

At the command prompt, type:

```
1 add vrid6 <ID>
```

To bind a VRID6 to cluster node interface by using the Citrix ADC CLI

At the command prompt, type:

```
1 bind vrid6 <ID> -ifnum <interface_name> | -trackifNum <interface_name>
2
3 Add vrid6 100
4 Bind vrid6 100 - ifnum 1/1 1/2
5 Done
```

## Cluster setup and usage scenarios

September 21, 2020

This section explains some scenarios in which the Citrix ADC cluster can be set up, and configured for different features and network topologies. Provide feedback if you want any other scenarios to be documented.

### Creating a two-node cluster

September 21, 2020

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of  $(n/2 + 1)$  nodes, where  $n$  is the number of cluster nodes, are able to serve traffic. If that formula were applied to a two-node cluster, the cluster would fail if one node went down ( $n/2 + 1 = 2$ ).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You must add one node as the configuration coordinator and the other node as the other cluster node.

#### Note

Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

### Migrating an HA setup to a cluster setup

September 21, 2020

Migrating an existing high availability (HA) setup to a cluster setup requires you to first remove the Citrix ADC appliances from the HA setup and create a backup of the HA configuration file. You must then use the two appliances to create a cluster and upload the backed-up configuration file to the cluster.

#### Note

- Before uploading the backed-up HA configuration file to the cluster, you must modify it to make it cluster compatible. Refer to the relevant step of the procedure below.
- Use the **batch -f <backup\_filename>** command to upload the backed-up configuration file.

The above approach is a very basic migration solution which results in downtime for the deployed application. As such, it must be used only in deployments where there is no consideration to application availability.

However, in most deployments, the availability of the application is of paramount importance. For such cases, you must use the approach where an HA setup can be migrated to a cluster setup without any resulting downtime. In this approach, an existing HA setup is migrated to a cluster setup by first removing the secondary appliance and using that appliance to create a single-node cluster. After the cluster becomes operational and serves traffic, the primary appliance of the HA setup is added to the cluster.

### **To convert a HA setup to cluster setup (without any downtime) by using the command line interface**

Let us consider the example of a HA setup with primary appliance (NS1) - 10.102.97.131 and secondary appliance (NS2) - 10.102.97.132.

1. Make sure the configurations of the HA pair are stable.
2. Log on to any one of the HA appliances, go to the shell, and create a copy of the ns.conf file (for example, ns\_backup.conf).
3. Log on to the secondary appliance, NS2, and clear the configurations. This operation removes NS2 from the HA setup and makes it a standalone appliance.

```
1 > clear ns config full
```

#### **Note**

- This step is required to make sure that NS2 does not start owning VIP addresses, now that it is a standalone appliance.
- At this stage, the primary appliance, NS1, is still active and continues to serve traffic.

4. Create a cluster on NS2 (now no longer a secondary appliance) and configure it as a PASSIVE node.

```
1 > add cluster instance 1
2
3 > add cluster node 0 10.102.97.132 -state PASSIVE -backplane
    0/1/1
4
5 > add ns ip 10.102.97.133 255.255.255.255 -type CLIP
6
7 > enable cluster instance 1
8
9 > save ns config
```

```
10
11 > reboot -warm
```

5. Modify the backed-up configuration file as follows:

- Remove the features that are not supported on a cluster. For the list of unsupported features, see [Citrix ADC Features Supported by a Cluster](#). This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.
- Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

**Example**

```
1 > add vlan 10 -ifnum 0/1
```

should be changed to

```
1 > add vlan 10 -ifnum 0/0/1 1/0/1
```

- The backup configuration file can have SNIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

**Example**

```
1 > add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
2
3 > add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

- Update the hostname to specify the owner node.

**Example**

```
1 > set ns hostname ns0 -ownerNode 0
2
3 > set ns hostname ns1 -ownerNode 1
```

- Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).

6. On the cluster, do the following:

- Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.
- Apply configurations from the backed-up and modified configuration file to the configuration coordinator through the cluster IP address.

```
1 > batch -f ns_backup.conf
```

- Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.

7. Switch the traffic from the HA setup to the cluster.

- Log on to the primary appliance, NS1, and disable all the interfaces on it.

```
1 > disable interface <interface_id>
```

- Log on to the cluster IP address and configure NS2 as an ACTIVE node.

```
1 > set cluster node 0 -state ACTIVE
```

#### Note

There might be a small amount (in the order of seconds) of downtime between disabling the interfaces and making the cluster node active.

8. Log on to the primary appliance, NS1, and remove it from the HA setup.

- Clear all the configurations. This operation removes NS1 from the HA setup and makes it a standalone appliance.

```
1 > clear ns config full
```

- Enable all the interfaces.

```
1 > enable interface <interface_id>
```

9. Add NS1 to the cluster.

- Log on to the cluster IP address and add NS1 to the cluster.

```
1 > add cluster node 1 10.102.97.131 -state PASSIVE -backplane  
1/1/1
```

- Log on to NS1 and join it to the cluster by sequentially executing the following commands:

```
1 > join cluster -clip 10.102.97.133 -password nsroot  
2  
3 > save ns config  
4  
5 > reboot -warm
```

10. Log on to NS1 and perform the required topological and configuration changes.

11. Log on to the cluster IP address and set NS1 as an ACTIVE node.

```
1 > set cluster node 1 -state ACTIVE
```

## Transitioning between a L2 and L3 Cluster

September 21, 2020

### Note

Supported from NetScaler 11 onwards.

An L2 cluster is one where all the nodes are from the same network and an L3 cluster is one that can include nodes from different networks. You can seamlessly transition from one type of cluster to the other without any downtime for the applications that are deployed on the Citrix ADC.

### Transitioning a cluster from L2 to L3

You can transition to an L3 cluster when you want the cluster to include nodes from other networks.

On the cluster IP address, do the following:

1. Create a nodegroup.

#### Example

```
1 > add cluster nodegroup NG0
```

This nodegroup is used in the next step to group all the nodes from the existing L2 cluster.

2. Transition the L2 cluster to an L3 cluster.

#### Example

```
1 > set cluster instance 1 -inc ENABLED -nodegroup NG0
```

This command achieves the dual purpose of transitioning to L3 cluster and also adding all the nodes of the L2 cluster to the nodegroup.

3. Now, you can add more nodes to the cluster as explained in [“Adding a Node to the Cluster”](#).

### Transitioning a cluster from L3 to L2

You can transition to an L2 cluster when you want to retain nodes that belong to a single network.

On the cluster IP address, do the following:

1. Remove the cluster nodes from the networks that you do not want to retain.

**Example**

```
1 > rm cluster node <nodeId>
```

2. Transition the L3 cluster to a L2 cluster.

**Example**

```
1 > set cluster instance 1 -inc DISABLED
```

The cluster now includes nodes only of a single network.

## Setting up GSLB in a cluster

October 30, 2020

**Note**

Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

**Notes**

- If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. It happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than `/var/netscaler/locdb/`, you must manually synchronize the file to all the cluster nodes.
- The “show gslb domain” command is not supported in a cluster setup.

**To set up GSLB in a cluster by using the command line interface:**

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see [GSLB Configuration Entities](#).

**Note**

When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address (needed only when the cluster is deployed behind a NAT device). While configuring a GSLB site, you must use the cluster IP address of the same site. These parameters are required to ensure the availability of the GSLB auto-sync functionality.

```
add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr>
  -clip <ip_addr> <publicCLIP><!--NeedCopy-->
```

2. Create a cluster node group.

```
add cluster nodegroup <name> [-sticky ( YES | NO )]<!--NeedCopy-->
```

**Note**

Enable the sticky option if you want to set up GSLB based on VPN users.

3. Bind a single cluster node to the node group.

```
bind cluster nodegroup <name> -node <nodeId><!--NeedCopy-->
```

4. Bind the local GSLB site to the nodegroup.

```
bind cluster nodegroup <name> -gslbSite <string><!--NeedCopy-->
```

**Note**

Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

**To bind the ADNS service:**

```
“bind cluster nodegroup -service
```

```
1  **To bind the DNS load balancing virtual server:**
2
3  ``bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
```

6. Bind the GSLB virtual server to the node group.

```
bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
```

7. [Optional] To set up GSLB based on VPN users, bind the VPN virtual server to the GSLB node group.

```
bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
```

8. Verify the configurations.

```
show gslb runningConfig<!--NeedCopy-->
```

**To set up GSLB in a cluster by using the graphical user interface:**

Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.

Navigate to **Traffic Management > GSLB** to perform the required configurations.

2. Create a node group and perform other node group related configurations.

Navigate to **System > Cluster > Node Groups** to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the preceding CLI procedure.

### Support for GSLB parent-child topology in a cluster

Starting with NetScaler 12.1 build 49.xx, GSLB parent-child topology is supported in cluster.

For more information about the parent-child topology, see [Parent-child topology deployment using the MEP protocol](#).

### To set up GSLB parent-child topology in a cluster by using the CLI

#### Parent site

Perform the following configuration:

1. Create a cluster node group.

```
1 add cluster nodegroup <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 add cluster nodegroup parentng
2 <!--NeedCopy-->
```

- 2./ Bind a single cluster node to the node group.

```
1 bind cluster nodegroup <name> -node <nodeId>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind cluster nodegroup parentng -node n2
2 <!--NeedCopy-->
```

- 3./ Bind the local GSLB site to the nodegroup.

```
1 bind cluster nodegroup <name> -gslbSite <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind cluster nodegroup parentng -gslbSite site1
2 <!--NeedCopy-->
```

4./ Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

```
1 bind cluster nodegroup <name> -service <string>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind cluster nodegroup parentng - service ADNS
2 <!--NeedCopy-->
```

5./ Bind the GSLB virtual server to the node group.

```
1 bind cluster nodegroup <name> -vServer <string>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind cluster nodegroup parentng -vService gslbvs1
2 <!--NeedCopy-->
```

**Child site**

Perform the following configuration:

1./ Create a cluster node group.

```
1 add cluster nodegroup <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 add cluster nodegroup childng
2 <!--NeedCopy-->
```

2./ Bind a single cluster node to the node group.

```
1 bind cluster nodegroup <name> -node <nodeId>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind cluster nodegroup childng -node -n3
2 <!--NeedCopy-->
```

3./ Bind the local GSLB site to the nodegroup.

```
1 bind cluster nodegroup <name> -gslbSite <string>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind cluster nodegroup childng -gslbSite site1
2 <!--NeedCopy-->
```

**Note**

For parent and child sites to exchange aggregated statistics in metric-based load balancing methods, you must add local GSLB services on the child site. The metric-based load balancing methods are least connection, least bandwidth, and least packets.

**To set up GSLB parent-child topology in a cluster by using the GUI**

1./ Configure the GSLB entities.

Navigate to **Traffic Management > GSLB** to perform the required configurations.

2./ Create a node group.

Navigate to **System > Cluster > Node Groups** to perform the required configurations.

3./ In the Node Group page, select the node group to which you want to bind a node, click **Edit**, and perform the following tasks. You can also perform these tasks when adding a node group.

- Bind a node to the node group.

In **Advance Settings**, click **Cluster Nodes** and perform the following tasks:

- In **Cluster Nodes** section, click **No Cluster Node**.
- In **Select Cluster Node**, click > and select the node that you want to bind to the node group. You can also add a new cluster node.

- Bind the local GSLB site to the nodegroup.

In **Advance Settings**, click **GSLB Sites** and perform the following tasks:

- In the **GSLB Sites** section, click No GSLB Site.
- In **Select GSLB Site**, click > and select the GSLB site that you want to bind to the node group. You can also add a new GSLB site.

- Bind the GSLB virtual server to the node group.

In **Advance Settings**, click **Virtual Servers** and perform the following task:

- In the **Virtual Servers** pane, click +.
  - In **Choose Virtual Server**, select the server that you want to bind to the node group.
- Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

In **Advance Settings**, click **Services** and perform the following tasks:

- In **Services** section, click No Service.
- In **Select Service**, select the service that you want to bind to the node group. You can also add a new service.

#### Note

For child sites, you only have to bind a cluster node and local GSLB site to the node group.

## Using cache redirection in a cluster

September 21, 2020

Cache redirection in a cluster works in the same way as it does on a standalone Citrix ADC appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see “[Cache Redirection](#).”

### Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests will be dropped.
- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the enable ns mode MBF command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

## Using L2 mode in a cluster setup

September 21, 2020

#### Note

Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.

## Using cluster LA channel with linksets

September 21, 2020

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

### Note

Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

Figure 1. Linksets and cluster LA channel topology

## To configure cluster LA channel and linksets by using the Citrix ADC command line

1. Log on to the cluster IP address.
2. Bind the connected interfaces to a cluster LA channel.

```
1 add channel CLA/1 - ifnum 0/1/2 1/1/2
```

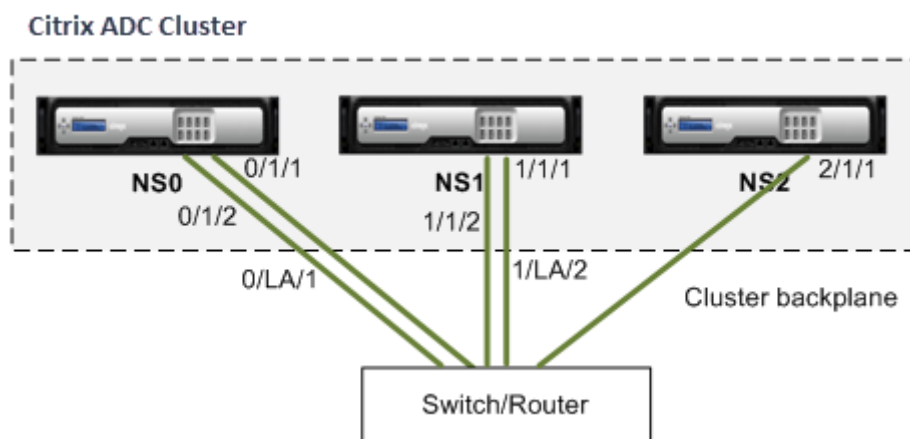

3. Bind the cluster LA channel to the linkset.

```
1 add linkset LS/1 -ifnum CLA/1
```

## Backplane on LA channel

September 21, 2020

In this deployment, LA channels are used for the cluster backplane.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

## To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.
  - a) Log on to the first node that you want to add to the cluster and do the following:

```
1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE
3 > enable cluster instance 1
```

```
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm
```

b) Log on to the cluster IP address and do the following:

```
1 > add cluster node 1 10.102.29.70 -state ACTIVE
2 > add cluster node 2 10.102.29.80 -state ACTIVE
```

c) Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:

a) Create the LA channels for nodes NS0 and NS1.

```
1 > add channel 0/LA/1 -ifnum 0/1/1 0/1/2
2 > add channel 1/LA/2 -ifnum 1/1/1 1/1/2
```

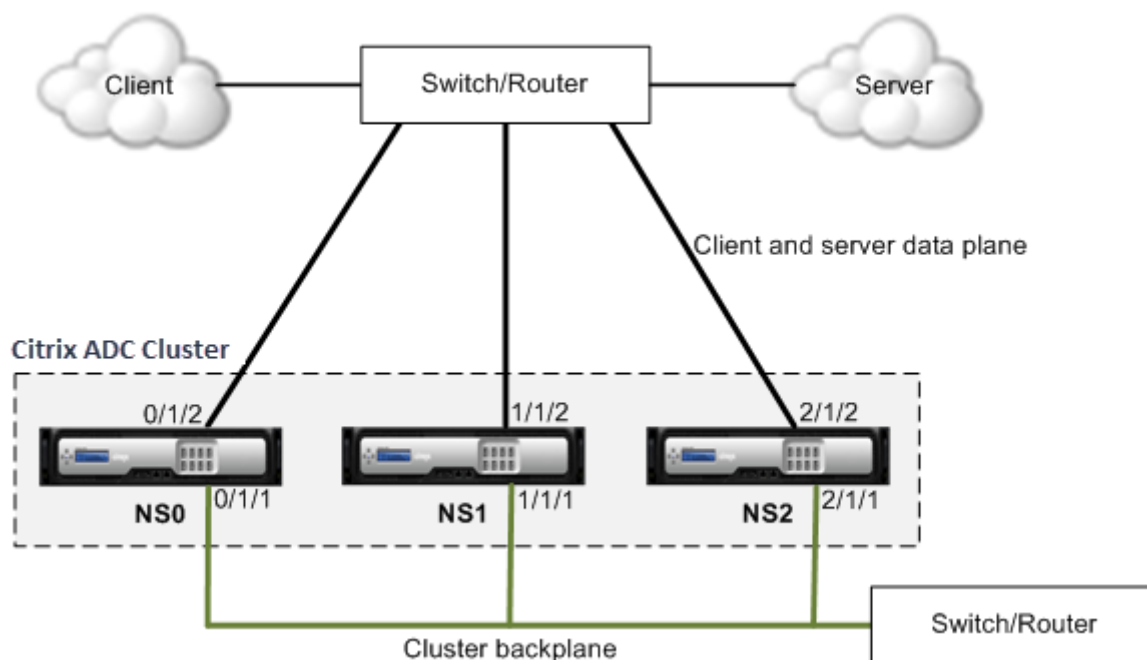

b) Configure the backplane for the cluster nodes.

```
1 > set cluster node 0 -backplane 0/LA/1
2 > set cluster node 1 -backplane 1/LA/2
3 > set cluster node 2 -backplane 2/1/1
```

## Common interfaces for client and server and dedicated interfaces for backplane

September 21, 2020

This is a one-arm deployment of the Citrix ADC cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

**To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane**

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane
    0/1/1
3 > enable cluster instance 1
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm

```

3. Log on to the cluster IP address and do the following:

```

1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane
    1/1/1
2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane
    2/1/1

```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

//For the backplane interfaces

```
1 > add vlan 10
2 > bind vlan 10 0/1/1 1/1/1 2/1/1
```

//For the interfaces that are connected to the client and server networks.

```
1 > add vlan 20
2 > bind vlan 20 0/1/2 1/1/2 2/1/2
```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface...

```
1 > interface Ethernet2/47
2   switchport access vlan 100
3   switchport mode access
4   end
```

//For the interfaces connected to the client and server networks. Repeat for each interface...

```
1 > interface Ethernet2/47
2   switchport access vlan 200
3   switchport mode access
4   end
```

## Common switch for client, server, and backplane

September 21, 2020

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the Citrix ADC cluster.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

**To deploy a cluster with a common switch for the client, server, and backplane**

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane
    0/1/1
3 > enable cluster instance 1
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm

```

3. Log on to the cluster IP address and do the following:

```

1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane
    1/1/1
2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane
    2/1/1

```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```

1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm

```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

//For the backplane interfaces

```

1 > add vlan 10
2 > bind vlan 10 0/1/1 1/1/1 2/1/1

```

//For the client-side interfaces

```

1 > add vlan 20
2 > bind vlan 20 0/1/2 1/1/2 2/1/2

```

//For the server-side interfaces

```

1 > add vlan 30
2 > bind vlan 30 0/1/3 1/1/3 2/1/3

```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface...

```
1 > interface Ethernet2/47
2   switchport access vlan 100
3   switchport mode access
4   end
```

//For the client interfaces. Repeat for each interface...

```
1 > interface Ethernet2/48
2   switchport access vlan 200
3   switchport mode access
4   end
```

//For the server interfaces. Repeat for each interface...

```
1 > interface Ethernet2/49
2   switchport access vlan 300
3   switchport mode access
4   end
```

## **Common switch for client and server and dedicated switch for backplane**

September 21, 2020

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the Citrix ADC cluster. The cluster backplane uses a dedicated switch for inter-node communication.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

**To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane**

1. Create a cluster of nodes NS0, NS1, and NS2.
  - Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane
    0/1/1
3 > enable cluster instance 1
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm

```

- Log on to the cluster IP address and do the following:

```

1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane
    1/1/1
2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane
    2/1/1

```

- Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```

1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm

```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

//For the backplane interfaces

```

1 > add vlan 10
2 > bind vlan 10 0/1/1 1/1/1 2/1/1

```

//For the client-side interfaces

```

1 > add vlan 20
2 > bind vlan 20 0/1/2 1/1/2 2/1/2

```

//For the server-side interfaces

```

1 > add vlan 30
2 > bind vlan 30 0/1/3 1/1/3 2/1/3

```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface...

```
1 > interface Ethernet2/47
2 > switchport access vlan 100
3 > switchport mode access
4 > end
```

//For the client interfaces. Repeat for each interface...

```
1 > interface Ethernet2/48
2 > switchport access vlan 200
3 > switchport mode access
4 > end
```

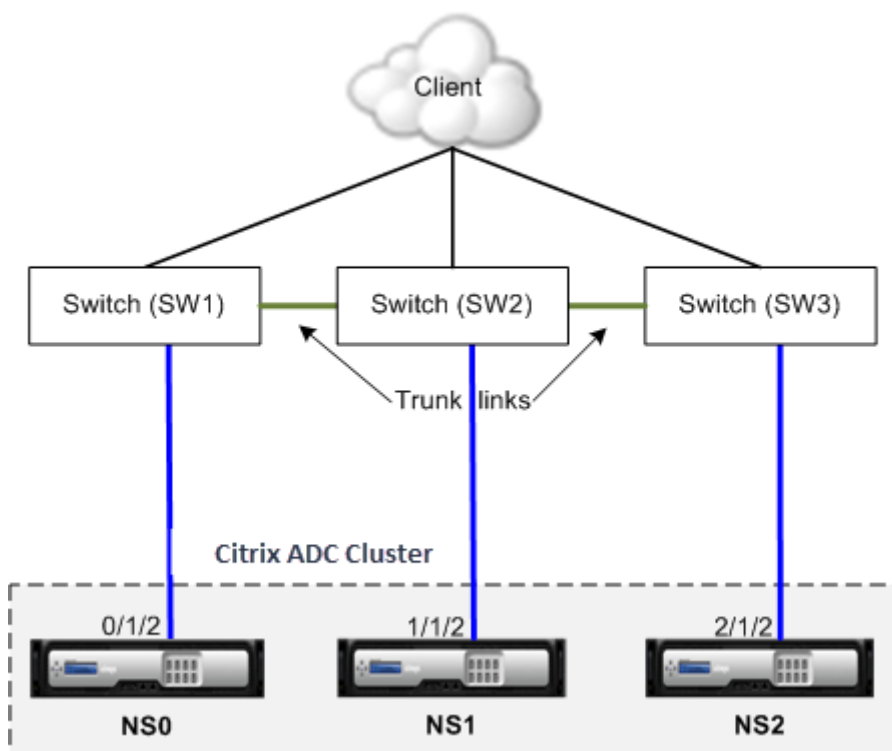

//For the server interfaces. Repeat for each interface...

```
1 > interface Ethernet2/49
2 > switchport access vlan 300
3 > switchport mode access
4 > end
```

## Different switch for every node

September 21, 2020

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.

The cluster configurations will be the same as the other deployments scenarios. Most of the client-side configurations will be done on the client-side switches.

## Sample cluster configurations

September 21, 2020

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.

1. Create the cluster.

- Log on to first node.
- Add the cluster instance.

```
1 > add cluster instance 1
```

- Add the first node to the cluster.

```
1 > add cluster node 0 10.102.33.184 -backplane 0/1/1
```

- Enable the cluster instance.

```
1 > enable cluster instance 1
```

- Add the cluster IP address.

```
1 > add ns ip 10.102.33.185 255.255.255.255 -type CLIP
```

- Save the configurations.

```
1 > save ns config
```

- Warm reboot the appliance.

```
1 > reboot -warm
```

## 2. Add the other three nodes to the cluster.

- Log on to cluster IP address.
- Add the second node to the cluster.

```
1 > add cluster node 1 10.102.33.187 -backplane 1/1/1
```

- Add the third node to the cluster.

```
1 > add cluster node 2 10.102.33.188 -backplane 2/1/1
```

- Add the fourth node to the cluster.

```
1 > add cluster node 3 10.102.33.189 -backplane 3/1/1
```

## 3. Join the added nodes to the cluster. This step is not applicable for the first node.

- Log on to each newly added node.
- Join the node to the cluster.

```
1 > join cluster -clip 10.102.33.185 -password nsroot
```

- Save the configuration.

```
1 > save ns config
```

- Warm reboot the appliance.

```
1 > reboot -warm
```

4. Configure the Citrix ADC cluster through the cluster IP address.

// Enable load balancing feature

```
1 > enable ns feature lb
```

// Add a load balancing virtual server

```
1 > add lb vserver first_lbvserver http
2 ....
3 ....
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

#### **ECMP**

- Log on to the cluster IP address.
- Enable the OSPF routing protocol.

```
1 > enable ns feature ospf
```

- Add a VLAN.

```
1 > add vlan 97
```

- Bind the interfaces of the cluster nodes to the VLAN.

```
1 > bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
```

- Add a spotted SNIP on each node and enable dynamic routing on it.

```
1 > add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -
  dynamicRouting ENABLED
2 > add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -
  dynamicRouting ENABLED
3 > add ns ip 1.1.1.12 255.255.255.0 -ownerNode 2 -
  dynamicRouting ENABLED
4 > add ns ip 1.1.1.13 255.255.255.0 -ownerNode 3 -
  dynamicRouting ENABLED
```

- Bind one of the SNIP addresses to the VLAN.

```
1 > bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
```

- Configure the routing protocol on ZebOS by using vtysh shell.

### Static cluster LA

- Log on to the cluster IP address.
- Add a cluster LA channel.

```
1 > add channel CLA/1 -speed 1000
```

- Bind the interfaces to the cluster LA channel.

```
1 > bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
```

- Perform equivalent configuration on the switch.

### Dynamic cluster LA

- \* Log on to the cluster IP address.
- \* Add the interfaces to the cluster LA channel.

```
1 > set interface 0/1/5 -lacpmode active -lacpkey 5 -  
lagtype cluster  
2 > set interface 1/1/5 -lacpmode active -lacpkey 5 -  
lagtype cluster  
3 > set interface 2/1/5 -lacpmode active -lacpkey 5 -  
lagtype cluster  
4 > set interface 3/1/5 -lacpmode active -lacpkey 5 -  
lagtype cluster
```

- \* Perform equivalent configuration on the switch.

**Linksets.** Assume that the node with nodeld 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

- a) Log on to the cluster IP address.
- b) Add a linkset.

```
1 > add linkset LS/1
```

- c) Bind the connected interfaces to the linkset.

```
1 > bind linkset LS/1 -ifnum 0/1/6 1/1/6 2/1/6
```

6. Update the state of the cluster nodes to ACTIVE.

```
1 > set cluster node 0 -state ACTIVE
2 > set cluster node 1 -state ACTIVE
3 > set cluster node 2 -state ACTIVE
4 > set cluster node 3 -state ACTIVE
```

## Using VRRP in a cluster setup

September 21, 2020

Virtual Router Redundancy Protocol (VRRP) is supported in a cluster setup for both IPv4 and IPv6. The two VRRP features supported in a cluster setup are Interface based VRRP and IP based VRRP.

### IP based VRRP

In IP based VRRP, striped VIP addresses bound to the same VRID are configured on all nodes of a cluster setup. These VIP addresses are active on all the nodes

One of the cluster nodes acts as the VRID owner and sends out the VRRP advertisement to other nodes. If there is failure of the VRID owner node, another node in the cluster assumes the ownership of the VRID and starts sending VRRP advertisements. You can also assign a specific cluster node as the owner of the VRID.

#### Note

Citrix recommends you to use the IP based method for VRRP deployment in cluster.

### Configuring IP based VRRP for IPv4

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a virtual MAC address. The generic VMAC address is in the form of 00:00:5e:00:02:<VRID>.
- **(Optional) Assign a node as the owner of the virtual MAC address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC address. You can set the owner node using the `set vrID <id> -ownerNode <positive_integer>` command.
- **Bind the VRID to the VIP address of the nodes.** Bind the created VRID to the striped VIP address.

### To add a VRID by using the CLI

At the command prompt, type:

```
1 add vrid <ID> [-ownerNode <positive_integer>]
2 show vrid <ID>
```

### To bind the VRID to VIP address by using the CLI

At the command prompt, type:

```
1 set ns ip <IPv4Address> -vrid <ID>
2 show vrid <ID>
```

### To add a VRID by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the Create **VMAC** page, specify a value in the **Virtual Router ID** field and then click **Create**.

### To bind the VRID to a VIP address by using the GUI

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP configuration.

```
1 add vrid 90
2 Done
3 set ns ip 192.0.2.90 - vrid 90
4 Done
```

## Configuring IP based VRRP for IPv6

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:02:<VRID6>.
- **(Optional) Assign a node as the owner of the virtual MAC6 address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC6 address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC6 address.
- **Bind the VRID6 to the VIP6 address of the nodes.** Bind the created VRID6 to the striped VIP6 address.

### To add a VRID6 by using the CLI

At the command prompt, type:

```
1 add vrid6 <ID> [-ownerNode <positive_integer>]
2 show vrid6 <ID>
```

### To bind the VRID6 to VIP6 address by using the CLI

At the command prompt, type:

```
1 set ns ip6 <IPv6Address> -vrid6 <ID>
2 show vrid6 <ID>
```

### To add a VRID6 by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field and then click **Create**.

### To bind the VRID6 to a VIP6 address by using the GUI

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP6 configuration.

```
1 add vrid6 90
2 Done
3 set ns ip6 2001:db8::5001 - vrid6 90
4 Done
```

### Interface based VRRP

In the interface based VRRP feature, the same virtual MAC address is configured on both the nodes of the cluster. This virtual MAC address is used in GARP advertisements and ARP responses for the IP addresses configured on a node. This feature is useful in an active-spare two-node cluster setup that has external devices/routers that do not accept GARP advertisements.

#### Note

The interface based VRRP feature is applicable only to a two-node cluster with one node in active state and the other node serving as a spare.

With the same virtual MAC address on both cluster nodes, when the active node goes down and the spare node takes over as active, the MAC address for the IP addresses on the new active node remain unchanged and the ARP tables on the external devices/routers do not need to be updated.

## Configuring interface based VRRP for IPv4

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a virtual MAC address.
- **Bind the VRID to node interfaces.** Bind the interfaces to the created VRID. The bound interfaces (in the current active node) use the virtual MAC address in GARP advertisements and ARP responses for its IPv4 addresses. You must associate the VRID to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

### To add a VRID by using the CLI

At the command prompt, type:

```
1 add vrid <ID>
2 show vrid <ID>
```

### To bind the VRID to an interface by using the CLI

At the command prompt, type:

```
1 bind vrid <ID> -ifnum <interface_name>
2 show vrid <ID>
```

### To add a VRID and bind it to interfaces by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the **Create virtual MAC** page, specify a value in the **Virtual Router ID\*** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
1 add vrid 300
2 Done
3 bind vrid 300 -ifnum 1/1/2 2/1/3
4 Done
```

## Configuring interface based VRRP for IPv6

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:01:<VRID6>.
- **Bind the VRID6 to node interfaces.** Bind the interfaces to the created VRID6. The bound interfaces (in the current active node) use the virtual MAC6 address in GARP advertisements and ARP responses for its IPv6 addresses. You must associate the VRID6 to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

### To add a VRID6 by using the CLI

At the command prompt, type:

```
1 add vrid6 <ID>
2 show vrid6 <ID>
```

### To bind the VRID6 to an interface by using the CLI

At the command prompt, type:

```
1 bind vrid6 <ID> -ifnum <interface_name>
2 show vrid6 <ID>
```

### To add a VRID6 and bind it to interfaces by using the GUI

1. Navigate **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
1 add vrid6 100
2 Done
3 bind vrid6 100 -ifnum 0/1/1 1/1/2 2/1/3
4 Done
```

## Monitoring services in a cluster using path monitoring

September 25, 2020

In a cluster setup, ownership for monitoring services is distributed among the nodes. Therefore, different nodes monitor different services. The node that monitors a service is called the service owner. Only the service owner probes the server to monitor the status of the services assigned to it. It further communicates the status of the services to all other nodes within the cluster. The drawback with distributed monitoring is that the network connectivity and link state between all nodes and the server is not determined. To overcome this drawback, you can use path monitoring.

#### Note

You cannot select a node to monitor a service. The selection of nodes to monitor a service is done through an internal mechanism. You can see the owner node to monitor services by using the `show service <service name>` and `show serviceGroup <service group name>` command.

Path monitoring checks the network connectivity and link state between a node and the service provided by the server. A node sends ICMP pings to verify whether the server is reachable or not.

### How path monitoring works

Consider an example of a Citrix ADC cluster consisting of three nodes N1, N2, and N3. N2 is the service owner that monitors the state of HTTP services (S1). It advertises the service state to other nodes in the cluster. Path monitoring is enabled on all nodes in the cluster, for all the services. Each node sends only an ICMP ping to the server. The service owner sends both the HTTP service request and an ICMP ping. Each node reports its path monitoring state to the service owner.

The following two parameters determine the service state of a node:

- S = service state advertised by the service owner
- P = path monitoring state of each node

Whether a node can reach a server or not, determines the path monitoring state for that node.

The following table shows the service state set based on the path monitoring state, when the pathMonitorIndv parameter is enabled or disabled.

| Parameter                                           | Path monitoring state | Service state |
|-----------------------------------------------------|-----------------------|---------------|
| pathMonitorIndv = NO; Is the default configuration. | P1 = DOWN             | S1 = DOWN     |
|                                                     | P2 = UP               | S1 = DOWN     |
|                                                     | P3 = UP               | S1 = DOWN     |
| pathMonitorIndv = YES                               | P1 = DOWN             | S1 = DOWN     |
|                                                     | P2 = UP               | S1 = UP       |
|                                                     | P3 = UP               | S1 = UP       |

In this example, the service owner decides the service state for all the nodes based on the node whose path monitoring state is set to DOWN. If the path monitoring state for any of the nodes is DOWN, then the service owner sets the service state for all the nodes as DOWN. The service state for all the nodes is set to UP only if the path monitoring state for each of the node is UP.

You can use path monitoring for individual nodes by enabling the pathMonitorIndv parameter. This parameter enables the service owner to set the service state for each node based on the path monitoring state of that respective node.

#### Note

If the pathMonitorIndv parameter is set, some features like persistence might break.

## Configuring path monitoring

Path monitoring is applicable for all the services and service groups. Path monitoring parameter is disabled by default.

### To enable path monitoring for services/service groups by using the CLI

At the command prompt, type:

```

1 add service <service name> <IP address> <service type> <port> [-
  pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]
2
3 add servicegroup <servicegroup name> <service type> [-pathMonitor <YES
  | NO>] [-pathMonitorIndv <YES | NO>]
```

```
4 <!--NeedCopy-->
```

**Example:**

```
1 add service s1 1.1.1.1 HTTP 80 -pathMonitor YES
2 add servicegroup sg_1 HTTP -pathMonitor YES
3
4 add service s1 1.1.1.1 HTTP 80 -pathMonitor YES -pathMonitorIndv YES
5 add servicegroup sg_1 HTTP -pathMonitor YES -pathMonitorIndv YES
6 <!--NeedCopy-->
```

You can also set the path monitoring parameter from the set command, as follows:

```
1 set service <service name> [-pathMonitor <YES | NO>] [-pathMonitorIndv
  <YES | NO>]
2 set servicegroup <servicegroup name> [-pathMonitor <YES | NO>] [-
  pathMonitorIndv <YES | NO>]
3 <!--NeedCopy-->
```

**Example:**

```
1 set service s1 -pathMonitor YES
2 set servicegroup sg_1 -pathMonitor YES
3
4
5 set service s1 -pathMonitorIndv YES
6 set servicegroup sg_1 -pathMonitorIndv NO
7 <!--NeedCopy-->
```

**To enable path monitoring for services/service groups by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.  
For service groups, navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In the **Services/Service Groups** pane, select a service/service group from the list, and then double-click to open it.
3. On the **Service Settings** tab, click **Edit**.
4. Select **Path Monitoring**.
5. Select **Individual Path Monitoring**, if you want to apply it, and then click **OK**.

**Note**

You can enable Individual Path Monitoring only if you enable Path Monitoring.

## Backup and restore of cluster setup

September 21, 2020

You can back up the current state of a Citrix ADC cluster node, and later use the backed-up files to restore the node to the same cluster state. As a precautionary measure, you must use this feature before performing an upgrade on the cluster nodes.

### Backup a Cluster Setup

Depending on the type of data to be backed up and the frequency at which you will create a backup, you can take a basic or a full backup.

- **Basic back up.** Backs up only configuration files. You might want to perform this type of backup frequently, because the files it backs up change constantly. The files that are backed up are listed in the table.

Directory

Sub-Directory or Files

/nsconfig/

- ns.conf
- ZebOS.conf
- rc.netscaler
- snmpd.conf
- nsbefore.sh
- nsafter.sh
- inetd.conf
- ntp.conf
- syslog.conf
- newsyslog.conf
- crontab
- host.conf
- hosts
- ttys
- sshd\_config

- httpd.conf
- monitrc
- rc.conf
- ssh\_config
- localtime
- issue
- issue.net

/var/

- download/\*
- log/wicmd.log
- wi/tomcat/webapps/\*
- wi/tomcat/logs/\*
- wi/tomcat/conf/catalina/localhost/\*
- nslw.bin/etc/krb.conf
- nslw.bin/etc/krb.keytab
- netscaler/locdb/\*
- lib/likewise/db/\*
- vpn/bookmark/\*
- netscaler/crl
- nstemplates/\*
- learnt\_data/\*

/netscaler/

- custom.html
- vsr.html
- **Full back up.** In addition to the files that are backed up by a basic backup, a full backup backs up some less frequently updated files. The files that are backed up when using the full backup option are listed in the table.

Directory

Sub-Directory or Files

/nsconfig/

- ssl/\*
- license/\*
- fips/\*

/var/

- netscaler/ssl/\*

- `wi/java_home/jre/lib/security/cacerts/*`
- `wi/java_home/lib/security/cacerts/*`

### Important

The backup and restore does not work if CLAG is configured on a cluster setup.

The backup is stored as a compressed TAR file in the `/var/ns_sys_backup/` directory. To avoid issues due to non-availability of disk space, you can store a maximum of 50 backup files in this directory. You can use the `rm system backup` command to delete existing backup files so that you can create more backups.

When you perform back up operation on a CLIP of a cluster setup, back up files are created on each of the cluster nodes.

### How to backup a cluster setup

To backup the cluster setup on CLIP by using Citrix ADC command line interface

#### At the command prompt, do the following:

- Save the configuration.

```
save ns config<!--NeedCopy-->
```

- Create the backup file (basic or full).

```
“create system backup [[-level (basic | full)][-comment ]
```

```
1  **Example**
2
3  ``create system backup cluster-backup-1 - level basic<!--
   NeedCopy-->
```

After you run this command, back up TAR files are created on each of the cluster nodes with the specified file name. For example, CLUSTER-backup-1.tgz file is created on each of the cluster node.

### Note

If the filename is not specified, back up TAR files are created on each of the cluster nodes with the following naming convention:

- `backup_<level>_<nsip_address of the cluster node 0>_<date-timestamp>.tgz<!--NeedCopy-->`
- `backup_<level>_<nsip_address of the cluster node 1>_<date-timestamp>.tgz<!--NeedCopy-->`

For example, on a three node cluster setup,

- `backup_<level>_<nsip_address of the cluster node 0>_<date-timestamp>.tgz<!--NeedCopy-->` is created on node0
- `backup_<level>_<nsip_address of the cluster node 1>_<date-timestamp>.tgz<!--NeedCopy-->` is created on node1
- `backup_<level>_<nsip_address of the cluster node 2>_<date-timestamp>.tgz<!--NeedCopy-->` is created on node2

- Verify the created backup files on CLIP.

```
show system backup<!--NeedCopy-->
```

## Restore a cluster setup

When a cluster node becomes faulty, you can replace this node with a new node and set the new node for a cluster using a backup file of the faulty node.

For example, in a three-node cluster setup, if node1 becomes faulty, you can replace this faulty node with a new node as node1. Using the restore operation, you can restore one of the faulty node's backup files on the new node.

### Note

The restore operation does not succeed if the backup file is renamed or if the contents of the file are modified.

## How to restore a cluster node

### To restore a cluster node by using Citrix ADC command line interface

#### At the command prompt, do the following:

- Obtain a list of the backup files available on CLIP.

```
show system backup<!--NeedCopy-->
```

- Copy the backup tar file to `/var/ns_sys_backup` directory of the cluster node, which is to be restored.
- Add the backup tar file to the cluster node memory by running the following command on the cluster node.

```
“add system backup
```

```
1  **Example**
2
3  `` `add system backup CLUSTER-BACKUP-1.tgz<!--NeedCopy-->
```

**Note**

The command must be run on the cluster node to be restored.

- Restore the cluster node by specifying the backup file.

“restore system backup

```
1  **Example**
2
3  `` `restore system backup CLUSTER-BACKUP-1.tgz<!--NeedCopy-->
```

**Note**

The command must be run on the cluster node to be restored.

- Reboot the cluster node.

reboot

**Note**

The command must be run on the cluster node to be restored.

## Upgrading or downgrading the Citrix ADC cluster

September 21, 2020

All the nodes of a Citrix ADC cluster must be running the same software version. Therefore, to upgrade or downgrade the cluster, you must upgrade or downgrade each Citrix ADC appliance of the cluster, one node at a time.

A node that is being upgraded or downgraded is not removed from the cluster. The node continues to be a part of the cluster and serves traffic uninterrupted, except for the down-time when the node reboots after it is upgraded or downgraded.

However, due to software version mismatch among the cluster nodes, configuration propagation is disabled on the cluster and is enabled only after all the cluster nodes are of the same version. Since configuration propagation is disabled during upgrading or downgrading a cluster, you cannot perform any configurations through the cluster IP address during this time.

**Important**

- Configurations can be lost on downgrading the cluster.
- When you are upgrading a cluster to NetScaler 11.0 build 64.x from an earlier NetScaler 11.0 build, cluster configuration propagation is disabled. This exception arises because the

cluster version in build 64.x is different from the one in previous NetScaler 11.0 builds.

Traditionally, this issue occurred only during an upgrade of a cluster to a different NetScaler version (for example, from 10.5 to 11.0). It must be noted that normally the cluster version matches the NetScaler version.

**Note**

Configuration propagation remains disabled until all the cluster nodes are upgraded to Build 64.x.

**Points to note before upgrading or downgrading the cluster**

- You cannot add cluster nodes while upgrading or downgrading the cluster software version.
- You can perform node-level configurations through the NSIP address of individual nodes, but make sure to perform the same configurations on all the nodes to maintain them in synch.
- You cannot execute the “start nstrace” command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes through their NSIP address.
- Owing to changes in cluster licensing that were made in NetScaler 10.5 Build 52.11 see [Prerequisites for cluster nodes](#), look into the following:
  - If the cluster is setup in a build prior to NetScaler 10.5 Build 52.11, the cluster will work with the separate cluster license file. No changes are required.
  - If the cluster is setup in NetScaler 10.5 Build 52.11 or later releases and then downgraded to a build prior to NetScaler 10.5 Build 52.11, the downgraded cluster will not work as it now expects a separate cluster license file.
- While upgrading from any NetScaler 10.1 build to a later release, syncookie must be disabled on all TCP profiles (using the “set ns tcpProfile <name> -synCookie DISABLED” command) and after that a striped SNIP must be added on the CLIP subnet. Once upgraded, syncookie can be enabled again.
- While upgrading the Citrix ADC appliance from a NetScaler 10.1 build to a NetScaler 10.5 build, do not execute the “show audit messages” command as this can cause the Citrix ADC appliance to become unresponsive.
- NetScaler 10.5 54.x and 55.x builds are not suitable for cluster deployment. This is because, for services that need probing, SYN packets are processed locally (on the flow receiver) even though syncookie is disabled.
- When a cluster is being upgraded, it is possible that the upgraded nodes have some additional features activated that are not available on the nodes that are not upgraded. This results in a

license mismatch warning while the cluster is being upgraded. This warning will be automatically resolved when all the cluster nodes are upgraded.

**Important**

- Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.
- Citrix recommends that the cluster configuration node must be upgraded/downgraded last to avoid multiple disconnect of cluster IP sessions.

**To upgrade or downgrade the software of the cluster nodes**

1. Make sure the cluster is stable and the configurations are synchronized on all the nodes.
2. Access each node through its NSIP address and perform the following:
  - Upgrade or downgrade the cluster node. For detailed information about upgrading and downgrading the software of an appliance, see [Upgrade and downgrade a NetScaler appliance](#).
  - Save the configurations.
  - Reboot the appliance.
3. Repeat step 2 for each of the other cluster nodes.

**Operations supported on individual cluster nodes**

September 21, 2020

As a rule, Citrix ADC appliances that are a part of a cluster cannot be individually configured from their NSIP address. However, there are some operations that are an exception to this rule. These operations, when executed from the NSIP address, are not propagated to other cluster nodes.

The operations are:

---

|                       |    |        |          |
|-----------------------|----|--------|----------|
| cluster instance (set | rm | enable | disable) |
|-----------------------|----|--------|----------|

---

•

---

|                   |     |
|-------------------|-----|
| cluster node (set | rm) |
|-------------------|-----|

---

- 

---

|                |      |       |
|----------------|------|-------|
| nstrace (start | show | stop) |
|----------------|------|-------|

---

- 

---

|                |        |          |
|----------------|--------|----------|
| interface (set | enable | disable) |
|----------------|--------|----------|

---

- 

---

|            |    |     |        |
|------------|----|-----|--------|
| route (add | rm | set | unset) |
|------------|----|-----|--------|

---

- 

---

|          |    |            |
|----------|----|------------|
| arp (add | rm | send -all) |
|----------|----|------------|

---

- 

- force cluster sync
- sync cluster files
- disable ntp sync
- save ns config
- reboot
- shutdown

For example, when you execute the command `disable interface 1/1/1` from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

## Support for heterogeneous cluster

September 21, 2020

Citrix ADC appliance now supports heterogeneous cluster in a cluster deployment. A heterogeneous cluster spans nodes of different Citrix ADC hardware and you can have a combination of different platforms in the same cluster.

**Important**

The formation or supportability of a heterogeneous cluster is possible and limited only to MPX hardware platforms.

The supportability and formation of the heterogeneous cluster depend on certain Citrix ADC models. The following table lists the platforms that are supported in the formation of a heterogeneous cluster.

| Number of Packet Engines | MPX Hardware Platforms | Supported MPX Hardware Platforms to form Heterogeneous Cluster |
|--------------------------|------------------------|----------------------------------------------------------------|
| 5                        | MPX 11500              | MPX 14020                                                      |
| 7                        | MPX 11515              | MPX 14040                                                      |
| 9                        | MPX 11530              | MPX 14060                                                      |

**Note**

If you run the “join cluster” command from the node that has an unequal number of packet engines, the following error message appears: “Mismatch in the number of active PPEs between CCO and local node”.

**Limitations of using heterogeneous cluster**

1. The number of packet engines present on all of the MPX hardware appliances should be same in the cluster deployment.
2. The extra management CPU setting should be same on all the cluster nodes.
3. The newly added node should have the same capacity on the data planes and backplane, as that of existing cluster nodes.
4. If there are mixed platform devices supporting different ciphers, then the cluster would agree upon a common cipher list.

**FAQs**

September 21, 2020

A list of the frequently asked questions about clustering.

### **How many Citrix ADC appliances can be included in a single Citrix ADC cluster?**

A Citrix ADC cluster can include one appliance or as many as 32 Citrix ADC nCore hardware or virtual appliances. Each of these nodes must satisfy the criteria specified in [Prerequisites for Cluster Nodes](#).

### **Can a Citrix ADC appliance be a part of multiple clusters?**

No. A Citrix ADC appliance can belong to one cluster only.

### **What is a cluster IP address? What is its subnet mask?**

The cluster IP address is the management address of a Citrix ADC cluster. All cluster configurations must be performed by accessing the cluster through this address. The subnet mask of the cluster IP address is fixed at 255.255.255.255.

### **How can I make a specific cluster node as the cluster configuration coordinator?**

To manually set a specific node as the cluster configuration coordinator, you must set the priority of that node to the lowest numeric value (highest priority). To understand, let us consider a cluster with three nodes that have the following priorities:

n1 - 29, n2 - 30, n3 - 31

Here, n1 is the configuration coordinator. If you want to make n2 the configuration coordinator, you must set its priority to a value that is lower than n1, for example, 28. On saving the configuration, n2 becomes the configuration coordinator.

#### **Note**

n2 with its original priority value of 30 will also become the configuration coordinator when n1 goes down, as the node with the next lowest priority value is selected in the event that the configuration coordinator goes down.

### **Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation?**

When a Citrix ADC appliance is part of a cluster, you must be able to identify the node to which the interface belongs. Therefore, the network interface naming convention for cluster nodes is modified from u/c to n/u/c, where n denotes the node Id.

### **How can I set the hostname for a cluster node?**

The hostname of a cluster node must be specified by executing the **set ns hostname** command through the cluster IP address. For example, to set the hostname of the cluster node with ID 2, the command is:

```
set ns hostname hostName1 -ownerNode 2
```

### **Can I automatically detect Citrix ADC appliances so that I can add them to a cluster?**

Yes. The configuration utility allows you to discover appliances that are present in the same subnet as the NSIP address of the configuration coordinator. For more information, see [Discovering NetScaler Appliances](#).

### **Is the traffic serving capability of a cluster affected if a node is removed or disabled or reboot or shutdown or made inactive?**

Yes. When any of these operations are performed on an active node of the cluster, the cluster will have one less node to serve traffic. Also, existing connections on this node are terminated.

### **I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster?**

Yes. You can add appliances that have different configurations to a single cluster. However, when the appliance is added to the cluster, the existing configurations are cleared. To use the configurations that are available on each of the individual appliances, you must:

1. Create a single \*.conf file for all the configurations.
2. Edit the configuration file to remove features that are not supported in a cluster environment.
3. Update the naming convention of interfaces from 2-tuple (u/c) format to 3-tuple (n/u/c) format.
4. Apply the configurations to the configuration coordinator node of the cluster by using the batch-command.

### **Can I migrate the configurations of a standalone Citrix ADC appliance or an HA setup to the clustered setup?**

No. When a node is added to a clustered setup, its configurations are implicitly cleared by using the **clear ns config** command (with the **extended** option). In addition, the SNIP addresses and all VLAN configurations (except default VLAN and NSVLAN) are cleared. Therefore, it is recommended that you back up the configurations before adding the appliance to a cluster. Before using the backed-up configuration file for the cluster, you must:

1. Edit the configuration file to remove features that are not supported in a cluster environment.
2. Update the naming convention of interfaces from two-tuple (x/y) format to three-tuple (x/y/z) format.
3. Apply the configurations to the configuration coordinator node of the cluster by using the **batch** command.

### **Are backplane interfaces part of the L3 VLANs?**

Yes, by default, backplane interfaces have presence on all the L3 VLANs that are configured on the cluster.

### **How can I configure a cluster that includes nodes from different networks?**

#### **Note**

Supported from NetScaler 11.0 onwards.

A cluster that includes nodes from different networks is called a L3 cluster (sometimes referred to as a cluster in INC mode). In an L3 cluster, all nodes that belong to a single network must be grouped together in a single nodegroup. Therefore, if a cluster includes two nodes each from three different networks, you will have to create 3 nodegroups (one for each network) and associate each of these nodegroups with the nodes that belong to that network. For configuration information, see the steps to setup a cluster.

### **How can I configure/un-configure the NSVLAN on a cluster?**

Do either one of the following:

- To make the NSVLAN available in a cluster, make sure that each appliance has the same NSVLAN configured before it is added to cluster.
- To remove the NSVLAN from a cluster node, first remove the node from the cluster and then delete the NSVLAN from the appliance.

### **I have a cluster setup where some Citrix ADC nodes are not connected to the external network. Can the cluster still function normally?**

Yes. The cluster supports a mechanism called linksets, which allows unconnected nodes to serve traffic by using the interfaces of connected nodes. The unconnected nodes communicate with the connected nodes through the cluster backplane. For more information, see [Using Linksets](#).

## **How can deployments that require MAC-Based Forwarding (MBF) be supported in a clustered setup?**

Deployments that use MBF must use linksets. For more information, see [Using Linksets](#).

## **Can I execute commands from the NSIP address of a cluster node?**

No. Access to individual cluster nodes through the NSIP addresses is read-only. Therefore, when you log on to the NSIP address of a cluster node you can only view the configurations and the statistics. You cannot configure anything. However, there are some operations you can execute from the NSIP address of a cluster node. For more information, see [Operations Supported on Individual Nodes](#).

## **Can I disable configuration propagation among cluster nodes?**

No, you cannot explicitly disable the propagation of cluster configurations among cluster nodes. However, during a software upgrade or downgrade, a version mismatch error can automatically disable configuration propagation.

## **Can I change the NSIP address or change the NSVLAN of a Citrix ADC appliance when it is a part of the cluster?**

No. To make such changes you must first remove the appliance from the cluster, perform the changes, and then add the appliance to the cluster.

## **Does the Citrix ADC cluster support L2 and L3 VLANs?**

Yes. A cluster supports VLANs between cluster nodes. The VLANs must be configured on the cluster IP address.

- **L2 VLAN.** You can create a layer2 VLAN by binding interfaces that belong to different nodes of the cluster.
- **L3 VLAN.** You can create a layer3 VLAN by binding IP addresses that belong to different nodes of the cluster. The IP addresses must belong to the same subnet. Make sure that one of the following criteria is satisfied. Otherwise, the L3 VLAN bindings can fail.
  - All nodes have an IP address on the same subnet as the one bound to the VLAN.
  - The cluster has a striped IP address and the subnet of that IP address is bound to the VLAN.

When you add a new node to a cluster that has only spotted IPs, the sync happens before spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings on the NSIP of the newly added node.

### How can I configure SNMP on a Citrix ADC cluster?

SNMP monitors the cluster, and all the nodes of the cluster, in the same way that it monitors a standalone appliance. The only difference is that SNMP on a cluster must be configured through the cluster IP address. When generating hardware specific traps, two additional varbinds are included to identify the node of the cluster: node ID and NSIP address of the node.

### What details must I have available when I contact technical support for cluster-related issues?

The Citrix ADC appliance provides a **show techsupport -scope cluster** command that extracts configuration data, statistical information, and logs of all the cluster nodes. You must run this command on the cluster IP address.

The output of this command is saved in a file named *collector\_cluster\_<nsip\_CCO>\_P\_<date-timestamp>.tar.gz* which is available in the */var/tmp/support/cluster/* directory of the configuration coordinator.

Send this archive to the technical support team to debug the issue.

### Can I use striped IP addresses as the default gateway of servers?

In case of cluster deployments, make sure the default gateway of the server points to a striped IP address (if you are using a Citrix ADC-owned IP address). For example, in case of LB deployments with USIP enabled, the default gateway must be a striped SNIP address.

### Can I view routing configurations of a specific cluster node from the cluster IP address?

Yes. You can view and clear the configurations specific to a node by specifying the owner node while entering the vtysh shell.

For example, to view the output of a command on nodes 0 and 1, the command is as follows:

```
1 \> vtysh
2 ns# owner-node 0 1
3 ns(node-0 1)\# show cluster state
4 ns(node-0 1)\# exit-cluster-node
5 ns\#
```

### How can I specify the node for which I want to set the LACP system priority?

**Note**

Supported from NetScaler 10.1 onwards.

In a cluster, you must set that node as the owner node by using the **set lacp** command.

**For example:** To set the LACP system priority for node with ID 2:

```
set lacp -sysPriority 5 -ownerNode 2<!--NeedCopy-->
```

**How are IP tunnels configured in a cluster setup?****Note**

Supported from NetScaler 10.1 onwards.

Configuring IP tunnels in a cluster is the same as on a standalone appliance. The only difference is that in a cluster setup, the local IP address must be a striped SNIP address.

**How can I add a failover interface set (FIS) on the nodes of a Citrix ADC cluster?****Note**

Supported from NetScaler 10.5 onwards.

On the cluster IP address, specify the ID of the cluster node on which the FIS must be added, using the command as follows:

```
add fis <name> -ownerNode <nodeId>
```

**Notes**

- The FIS name for each cluster node must be unique.
- A cluster LA channel can be added to a FIS. You must make sure that the cluster LA channel has a local interface as a member interface.

For more information on FIS, see [Configuring failover interface set](#).

**How are net profiles configured in a cluster setup?****Note**

Supported from NetScaler 10.5 onwards.

You can bind spotted IP addresses to a net profile. This net profile can then be bound to spotted load balancing virtual server or service (that is defined using a nodegroup). The following recommendations must be followed, failing which, the net profile configurations are not honored and the USIP/US-NIP settings will be used:

#### Note

- If the **strict** parameter of the nodegroup is set to **Yes**, the net profile must contain a minimum of one IP address from each nodegroup member.
- If the **strict** parameter of the nodegroup is set to **No**, the net profile must include at least one IP address from each of the cluster nodes.

### How can I configure WlonNS in a cluster setup?

#### Note

Supported from NetScaler 11.0 Build 62.x onwards.

To use WlonNS on a cluster, you must do the following:

1. Make sure that the Java package and the WI package are present in the same directory on all the cluster nodes.
2. Create a load balancing virtual server that has persistency configured.
3. Create services with IP addresses as the NSIP address of each of the cluster nodes that you want to serve WI traffic. This step can only be configured using the Citrix ADC CLI.
4. Bind the services to the load balancing virtual server.

#### Note

If you are using WlonNS over a VPN connection, make sure that the load balancing virtual server is set as WIHOME.

### Can the cluster LA channel be used for management access?

No. Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down and therefore loses management access.

### How cluster nodes communicate to each other and what are the different types of traffic that goes through backplane?

A backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through backplane, which is used by internode communication are:

- Node to Node Messaging (NNM)
- Steered traffic
- Configuration propagation and synchronization

Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: **0x02 0x00 0x6F <cluster\_id> <node\_id> <reserved>**, where <cluster\_id> is the cluster instance ID, <node\_id> is the node number of the Citrix ADC appliance that are added to a cluster.

**Note**

The amount of traffic that is handled by a backplane will have negligible CPU overhead.

### **What gets routed over GRE tunnel for Layer 3 cluster?**

Only steered data traffic goes over the GRE tunnel. The packets are steered through the GRE tunnel to the node on the other subnet.

### **How Node to Node Messaging (NNM) and heartbeat messages are exchanged, and how are they routed?**

The NNM, heartbeat messages, and cluster protocol are non-steering traffic. These messages are not sent through the tunnel, but they are routed directly.

### **What are the MTU recommendations when Jumbo frames are enabled for layer 3 cluster tunneled traffic?**

The following are the layer 3 cluster recommendations of Jumbo MTU over GRE tunnel:

- The Jumbo MTU can be configured among cluster nodes across the L3 path to accommodate GRE tunnel overhead.
- The fragmentation does not happen for full sized packets which need to be steered.
- Steering of traffic continues to work even if Jumbo frames are not allowed, but with more overhead due to fragmentation.

### **How the global hash key is generated and shared across all nodes?**

The rsskey for a standalone appliance is generated at the boot time. In a cluster setup, the first node holds the rsskey of the cluster. Every new node joining to the cluster will synchronize the rsskey.

### **What is the need of “set rsskeytype –rsskey symmetric” command for \*\*\*, USIP on, useproxyport off, topologies?**

This is not specific to cluster, applies to a standalone appliance as well. With USIP ON, and use proxy port disabled, symmetric rsskey reduces both Core to Core (C2C) steering and node to node steering.

## Troubleshooting the Citrix ADC cluster

September 21, 2020

If a failure occurs in a Citrix ADC cluster, the first step in troubleshooting is to get information on the cluster instance and the cluster nodes by running the `show cluster instance <clld>` and `show cluster node <nodeid>` commands respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.
- **Check the commands recently executed.** Run the `history` command to check the recent configurations performed on the cluster. You can also review the `ns.conf` file to verify the configurations that have been implemented.
- **Check the ns.log files.** Use the log files, available in the `/var/log/` directory of each node, to identify the commands executed, status of commands, and the state changes.
- **Check the newslog files.** Use the newslog files, available in the `/var/nslog/` directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple newslog files as a single file, by copying the files to a single directory, and then running the following command:

```
1 nsconmsg -K newslog-node<id> -K newslog.node<id> -d current
```

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the `show techsupport -scope cluster` command to send the report to the technical support team.

## Tracing the packets of a Citrix ADC cluster

September 21, 2020

The Citrix ADC operating system provides a utility called `nstrace` to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the Wireshark application.

Some salient aspects of the `nstrace` utility are:

- Can be configured to trace packets selectively by using classic expressions and default expressions.

- Can capture the trace in multiple formats: nstrace format (.cap) and TCP dump format (.pcap).
- Can aggregate the trace files of all cluster nodes on the configuration coordinator.
- Can merge multiple trace files into a single trace file (only for .cap files).

You can use the nstrace utility from the Citrix ADC command line or the Citrix ADC shell.

### **To trace packets of a standalone appliance**

Run the start nstrace command on the appliance. The command creates trace files in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>.cap.

You can view the status by executing the show nstrace command. You can stop tracing the packets by executing the stop nstrace command.

#### **Note**

You can also run the nstrace utility from the Citrix ADC shell by executing the nstrace.sh file. However, it is recommended that you use the nstrace utility through the Citrix ADC command line interface.

### **To trace packets of a cluster**

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the start nstrace command on the cluster IP address. The command is propagated and executed on all the cluster nodes. The trace files are stored in individual cluster nodes in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>\_node<id>.cap.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the stop nstrace command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the /var/nstrace/<date-timestamp> directory as follows:

### Merge multiple trace files

You can prepare a single file from the trace files (supported only for .cap files) obtained from the cluster nodes. The single trace files gives you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the Citrix ADC shell, type:

```
1 > nstracemerge.sh -srcdir \<DIR\> -dstdir \<DIR\> -filename \<name\> -  
    filesize \<num\>
```

where,

- srcdir is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- dstdir is the directory where the merged trace file are created.
- filename is the name of the trace file that is created.
- filesize is the size of the trace file.

## Examples

Following are some examples of using the nstrace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:

### Using classic expressions:

```
1 > start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF == 2/1/1"
```

### Using default expressions:

```
1 > start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") && CONNECTION.INTF.EQ("1/1/1") && CONNECTION.INTF.EQ("2/1/1")"
```

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not "s1":

### Using classic expressions

```
1 > start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME != s1 && SOURCEPORT > 80)"
```

### Using default expressions

```
1 > start nstrace -filter "CONNECTION.SRCIP.EQ(10.102.34.201) || (CONNECTION.SVCNAME.NE("s1") && CONNECTION.SRCPORT.GT(80))"
```

#### Note

For more information about filters used in nstrace, see [nstrace](#).

## Capturing SSL Session Keys During a Trace

When you run the "start nstrace" command, you can set the new "capsslkeys" parameter to capture the SSL master keys for all SSL sessions. If you include this parameter, a file named nstrace.sslkeys is generated along with the packet trace. This file can be imported into Wireshark to decrypt the SSL traffic in the corresponding trace file.

This functionality is similar to web browsers exporting session keys that can later be imported into Wireshark for decrypting SSL traffic.

## Advantages of using SSL session keys

Following are the advantages of using SSL session keys:

1. Generates smaller trace files that do not include the extra packets created by the SSLPLAIN mode of capturing.
2. Provides the ability to view plaintext [SP(1)] from the trace and choose whether to share the master keys file or protect sensitive data by not sharing it.

### Limitations of using SSL session keys

Following are the limitations of using SSL session keys:

1. SSL sessions cannot be decrypted if initial packets of the session are not captured.
2. SSL sessions cannot be captured if the Federal Information Processing Standard (FIPS) mode is enabled.

### To capture SSL session keys by using the command line interface (CLI)

At the command prompt, type the following commands to enable or disable SSL session keys in a trace file and verify trace operation.

```
1 > start nstrace -capsslkeys ENABLED
2 > show nstrace
3 Example
4 > start nstrace -capsslkeys ENABLED
5 > show nstrace
6     State:  RUNNING           Scope:  LOCAL           TraceLocation:

```

### To configure SSL session keys by using the Citrix ADC GUI

1. Navigate to **Configuration > System > Diagnostics > Technical Support Tools** and click **Start new Trace** to start tracing encrypted packets on an appliance.
2. On the **Start Trace** page, select the **Capture SSL Master Keys** check box.
3. Click **OK** and **Done**.

## To import the SSL Master Keys into Wireshark

On the Wireshark GUI, navigate to **Edit > Preferences > Protocols > SSL > (Pre)-Master-Secret log filename** and specify the master key files obtained from the appliance.

## Troubleshooting common issues

September 21, 2020

### **While joining a node to the cluster, I get the following message, “ERROR: Invalid interface name/number.” What must I do to resolve this error?**

This error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance’s management interface as the backplane interface, and that the <nodeId> bit of the interface is the same as the node’s Id. For example, if the nodeId is 3, the backplane interface must be 3/<c>/<u>.

### **While joining a node to the cluster, I get the following message, “ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster.” What must I do to resolve this error?**

This error occurs when you try to join a node without adding the node’s NSIP to the cluster. To resolve this error, you must first add the node’s NSIP address to the cluster by using the **add cluster node** command and then execute the **join cluster** command.

### **While joining a node to the cluster, I get the following message, “ERROR: Connection refused.” What must I do to resolve this error?**

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.
- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a new cluster IP address and try re-joining the cluster.

**While joining a node to the cluster, I get the following message, “ERROR: License mismatch between the configuration coordinator and the local node.” What must I do to resolve this error?**

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

**From the command line:**

- `show ns hardware`
- `show ns license`

**From the shell:**

- `nsconmsg -g feature -d stats`
- `ls /nsconfig/license`
- View the contents of the `/var/log/license.log` file

**What must I do when the configurations of a cluster node are not in synch with the cluster configurations?**

In most cases, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by executing the `force cluster sync` command from the node that you want to synchronize. For more information, see [Synchronizing Cluster Configurations](#).

When configuring a cluster node, I get the following message, “ERROR: Session is read-only; connect to the cluster IP address to modify the configuration.”

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NSIP address of individual nodes are read-only.

**Why does the node state show “INACTIVE” when the node health shows “UP”?**

A healthy node can be in the INACTIVE state for a number of reasons. A scan of `ns.log` or error counters can help you determine the exact reason.

**How can I resolve the health of a node when its health shows “NOT UP”?**

Node health “**Not UP**” indicates that there are some issues with the node. To know the root cause, you must run the `show cluster node` command. This command displays the node properties and the

reason for the node failure.

### **What must I do when the health of a node shows as “NOT UP” and the reason indicates that configuration commands have failed on a node?**

This issue arises when some commands are not executed on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see [Synchronizing Cluster Configurations](#).
- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.

### **When I run the set vserver command, I get the following message, “No such resource.” What must I do to resolve this issue?**

The **set vserver** command is not supported in clustering. The **unset vserver**, **enable vserver**, **disable vserver**, and **rm vserver** commands are also not supported. However, the **show vserver** command is supported.

### **I cannot configure the cluster over a Telnet session. What must I do?**

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

### **I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?**

When PTP packets are dropped due to backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized.

To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.

**set ptp -state disable**

2. Configure Network Time Protocol (NTP) for the cluster. For more information, see [Setting up Clock Synchronization](#).

## What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?

If you cannot access to the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by executing the following command at the shell prompt:

```
“# ssh nsroot@
```

```

1  ## What must I do to recover a cluster node that has connectivity
   issues?
2
3  To recover a node that has connectivity issues:
4
5  1.  Disable the cluster instance on that node (since you cannot execute
   commands from the NSIP of a cluster node).
6
7  1.  Execute the commands required to recover the node.
8
9  1.  Enable the cluster instance on that node.
10
11 ## Some nodes of the cluster have two default routes. How can I remove
   the second default route from the cluster node?
12
13 To delete the additional default route, do the following on each node
   that has the extra route:
14
15 1.  Disable the cluster instance.
16
17  ``disable cluster instance <clId><!--NeedCopy-->
```

1. Remove the route.

```
rm route <network> <netmask> <gateway><!--NeedCopy-->
```

2. Enable the cluster instance.

```
enable cluster instance <clId><!--NeedCopy-->
```

## The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue?

If RPC password of node is changed from the cluster IP address when that node is out of the cluster, then, when the node comes online, there is a mismatch in rpc credentials and this could affect cluster functionality. To solve this issue, use the set ns rpcNode command to update the password on the NSIP of the node which has come online.

## Content Switching

September 21, 2020

In today's complex Web sites, you may want to present different content to different users. For example, you may want to allow users from the IP range of a customer or partner to have access to a special Web portal. You may want to present content relevant to a specific geographical area to users from that area. You may want to present content in different languages to the speakers of those languages. You may want to present content tailored to specific devices, such as smartphones, to those who use the devices. The Citrix ADC content switching feature enables the appliance to distribute client requests across multiple servers on the basis of specific content that you wish to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.

### How Content Switching Works

Content Switching enables the Citrix ADC appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content on the basis of various client attributes. Some of those client attributes are:

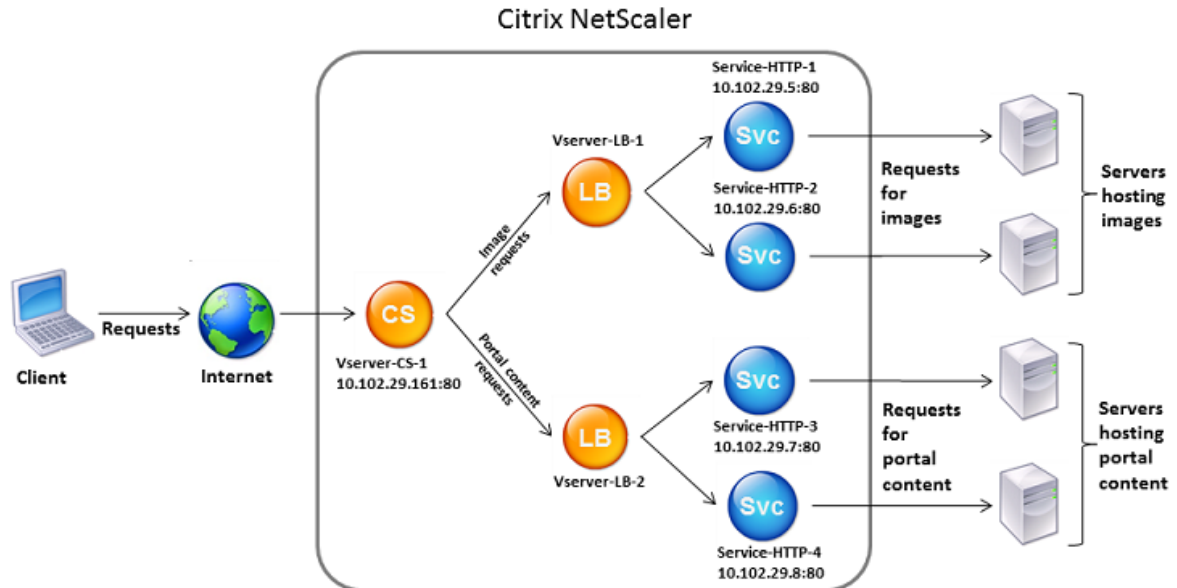

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server that is capable of serving content that the user can view on his or her cell phone. A request from a computer is directed to a different server that is capable of serving content designed for a computer screen.
- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client's browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in

French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.

- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.
- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to a faster server that handles dynamic content.
- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

Figure 1. Content Switching Architecture

A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a *content group*—a group of all virtual servers

and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using Citrix ADC classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the Citrix ADC appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see [“Configuring Default Syntax Policies.”](#)

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer, you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.

## Configuring Basic Content Switching

October 14, 2020

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of web sites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy

labels. If you create additional content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

**Note**

After creating a content group, you can modify its content switching virtual server to customize the configuration.

## Enabling Content Switching

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.

### To enable content switching by using the command line interface

At the command prompt, type the following commands to enable content switching and verify the configuration:

- `enable ns feature CS`
- `show ns feature`

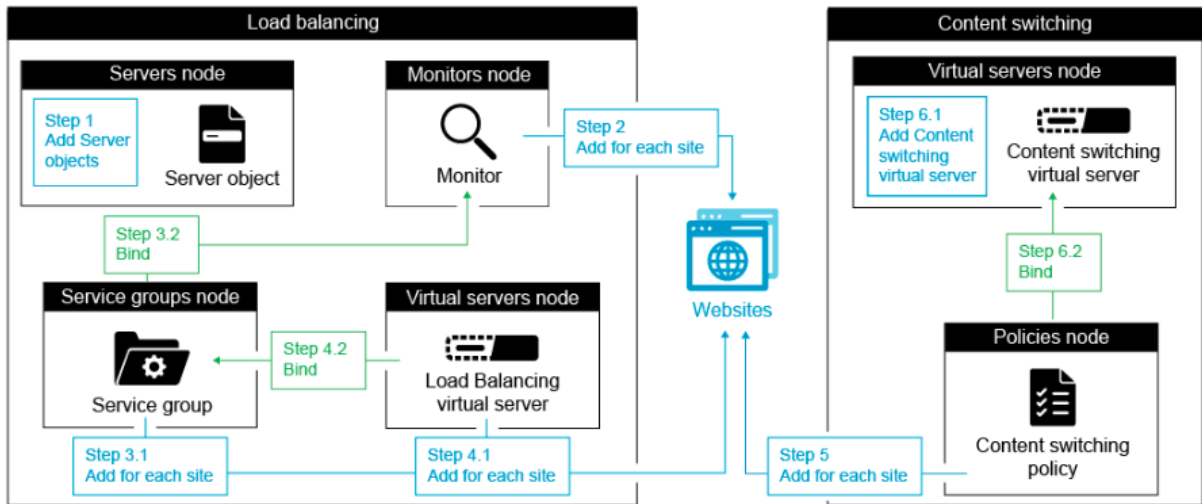

**Example**

```
1 > enable feature ContentSwitch
2 Done
3 > show feature
4
5 Feature                               Acronym           Status
6 -----                               -
7 1) Web Logging                         WL                OFF
8 2) Surge Protection                    SP                ON
9 3) Load Balancing                      LB                ON
10 4) Content Switching                  CS                ON
11 .
12 .
13 .
14 22) Responder                          RESPONDER         ON
15 23) HTML Injection                     HTMLInjection     ON
16 24) NetScaler Push                     push              OFF
17 Done
18 <!--NeedCopy-->
```

## To enable content switching by using the configuration utility

Navigate to **System > Settings** and, in the **Modes and Features** group, select **Configure Basic Features**, and select **Content Switching**.

The following figure illustrates the step wise configuration of Content Switching.

## Creating Content Switching Virtual Servers

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

### To create a virtual server by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <protocol> <IPAddress> <port>
```

Example

```
1 add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
2 <!--NeedCopy-->
```

### To add a content switching virtual server by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and add a virtual server.
2. Specify a name for Content Switching virtual server.

**Note**

There are different Content Switching virtual server for each protocol. (For example, HTTP and SSL).

3. Populate the relevant fields and click **OK**.

## Configuring a Load Balancing Setup for Content Switching

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. This is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see [How load balancing works](#). For detailed instructions on setting up a basic load balancing configuration, see [Set up basic load balancing](#).

## Configuring a Content Switching Action

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Consequently, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an

action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

**Note**

You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server.

**Configuring an Action that Specifies the Name of the Target Load Balancing Virtual Server**

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

**To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the command line interface**

At the command prompt, type:

- `add cs action <name> -targetLBVserver <string> [-comment <string>]`
- `show cs action <name>`

**Example**

```
1 > add cs action mycsaction -targetLBVserver mylbvserver -comment "
    Forwards requests to mylbvserver."
2 Done
3 > show cs action mycsaction
4 Name: mycsaction
5 Target LB Vserver: mylbvserver
6 Hits: 0
7 Undef Hits: 0
```

```
8     Action Reference Count: 0
9     Comment: "Forwards requests to mylbvserver."
10
11    Done
12    >
13    <!--NeedCopy-->
```

### **To configure a content switching action that specifies the name of the target load balancing virtual server, by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify the name of the target load balancing virtual server.

### **Configuring an Action that Specifies an Expression for Selecting the Target at Run Time**

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests on the basis of the URL suffix (file extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as `mylb_`. For example, load balancing virtual servers for HTML pages and PDF files could be named `mylb_html` and `mylb_pdf`, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is `"mylb_" + HTTP.REQ.URL.SUFFIX`. If the content switching virtual server receives a request for an HTML page, the expression returns `mylb_html`, and the request is switched to virtual server `mylb_html`.

## To create a content switching action that specifies an expression, by using the command line interface

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

- `add cs action <name> -targetVserverExpr <expression>)[-comment <string>]`
- `show cs action <name>`

### Example

```
1 > add cs action mycsaction1 -targetvserverExpr '"mylb_" + HTTP.REQ.URL.SUFFIX'
2 Done
3 > show cs action mycsaction1
4 Name: mycsaction1
5 Target Vserver Expression: "mylb_" + HTTP.REQ.URL.SUFFIX
6 Target LB Vserver: No_Target
7 ...
8 Done
9 >
10 <!--NeedCopy-->
```

## To configure a content switching action that specifies an expression by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify an expression that will dynamically compute the name of the target load balancing virtual server.

## Configuring Content Switching Policies

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using Citrix ADC classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The Citrix ADC appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate con-

tent. Domain-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.

- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.
- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

#### Note

A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about Citrix ADC classic policies and expressions, see [“Configuring Classic Policies and Expressions.”](#) For information about Default Syntax policies, see [“Configuring Default Syntax Expressions.”](#)

## To create a content switching policy by using the command line interface

At the command prompt, type one of the following commands:

- `add cs policy <policyName> -domain <domain>`
- `add cs policy <policyName> -url <URLValue>`
- `add cs policy <policyName> -rule <RULEValue>`
- `add cs policy <policyName> -rule <RULEValue> -action <actionName>`

### Example:

```
1 add cs policy Policy-CS-1 -url `http://example.com`
2
3 add cs policy Policy-CS-1 -domain "example.com"
4
5 add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ
  (10.217.84.0)"
6
7 add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009
  Dec)"
```

```
8
9 add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1
10 <!--NeedCopy-->
```

## To rename a content switching policy by using the command line interface

At the command prompt, type:

```
rename cs policy <policyName> <newName>
```

### Example:

```
1 rename cs policy myCSPolicy myCSPolicy1
2 <!--NeedCopy-->
```

## To rename a content switching policy by using the configuration utility

Navigate to **Traffic Management > Content Switching > Policies**, select a policy and, in the Action list, select Rename.

## To create a content switching policy by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Policies**, and click **Add**.
2. Populate the relevant fields and click **Create**.

## Configuring Content Switching Policy Labels

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a

gotoPriorityExpression option and/or an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and/or the invoke option. Additionally, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the Citrix ADC CLI or the configuration utility to configure content switching policy labels. In the Citrix ADC CLI, you first create a policy label by using the add cs policylabel command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policylabel command. In the Citrix ADC GUI, you perform both tasks in a single dialog box.

### To create a content switching policy label by using the command line interface

At the command prompt, type:

```
add cs policylabel <labelName> <cspolicylabelType>
```

#### Example

```
1 add cs policylabel testpollab http
2 <!--NeedCopy-->
```

### To rename a content switching policy label by using the command line interface

At the command prompt, type:

```
rename cs policylabel <labelName> <newName>
```

#### Example

```
1 rename cs policylabel oldPolicyLabelName newPolicyLabelName
2 <!--NeedCopy-->
```

### To rename a content switching policy label by using the configuration utility

Navigate to **Traffic Management > Content Switching > Policy Labels**, select a policy label and, in the Action list, select Rename.

## To bind a policy to a content switching policy label by using the command line interface

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

- `bind cs policylabel <labelName> <policyName> <priority>[-targetVserver <string>] | [-gotoPriorityExpression <expression>] | [-invoke <labeltype> <labelName>] ]`
- `show cs policylabel <labelName>`

### Example

```
1 bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
2 show cs policylabel testpollab
3     Label Name: testpollab
4     Label Type: HTTP
5     Number of bound policies: 1
6     Number of times invoked: 0
7     Policy Name: test_Pol
8     Priority: 100
9     Target Virtual Server: LBVIP
10 <!--NeedCopy-->
```

#### Note

If a policy is configured with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configured with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

## To unbind a policy from a policy label by using the command line interface

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

- `unbind cs policylabel <labelName> <policyName>`
- `show cs policylabel <labelName>`

### Example

```
1 unbind cs policylabel testpollab test_Pol
2 show cs policylabel testpollab
```

```

3      Label Name: testpollab
4      Label Type: HTTP
5      Number of bound policies: 0
6      Number of times invoked: 0
7 <!--NeedCopy-->

```

### To remove a policy label by using the command line interface

At the command prompt, type:

```
rm cs policylabel <labelName>
```

### To manage a content switching policy label by using the configuration utility

Navigate to **Traffic Management > Content Switching > Policy Labels**, configure a policy label, bind policies to the label, and optionally specify a priority, gotoPriority expression, and an invoke option.

### Binding Policies to a Content Switching Virtual Server

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

#### Note

If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see [Configuring a Content Switching Action](#) section.

### To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the command line interface

At the command prompt, type:

```

1 bind cs vserver <name>[-lbvserver<string> -targetLBVServer<string> -
  policyname <string> -priority <positive_integer>] [-
  gotoPriorityExpression <expression>] [-type ( REQUEST | RESPONSE )]
  [-invoke (<labelType> <labelName>)]
2 <!--NeedCopy-->

```

Example

```
1 bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -
   gotoPriorityExpression NEXT
2
3 bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -
   gotoPriorityExpression
4 'q.header("a").count' -flowtype REQUEST -invoke policylabel label1
5
6 bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -
   priority 20
7 <!--NeedCopy-->
```

**Note**

The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.

**To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the configuration utility**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, open a virtual server and, in the Content Switching Policy Binding section, bind a policy to the virtual server, and specify a target load balancing virtual server.

**Configuring Policy Based Logging for Content Switching**

You can configure policy based logging for a content switching policy. Policy based logging enables you to specify a format for log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified in the policy is performed, the Citrix ADC appliance constructs the log message from the expression and writes the message to the log file. Policy based logging is particularly useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.

**Note**

If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, the Citrix ADC appliance does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.

To configure policy based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see [Configuring](#)

[the Citrix ADC appliance for audit logging](#). After you configure the audit message action, you specify the action in a content switching policy.

### **To configure policy based logging for a content switching policy by using the command line interface**

At the command line, type the following commands to configure policy based logging for a content switching policy and verify the configuration:

- `set cs policy <policyName> -logAction <string>`
- `show cs policy <policyName>`

#### **Example**

```
1 > set cs policy cspol1 -logAction csLogAction
2   Done
3 > show cs policy cspol1
4
5   Policy: cspol1 Rule: TRUE Action: csact1
6   LogAction: csLogAction
7   Hits: 0
8
9 1) CS Vserver: csvs1
10   Priority: 10
11   Done
12 >
13 <!--NeedCopy-->
```

### **To configure policy based logging for a content switching policy by using the configuration utility**

Navigate to **Traffic Management > Content Switching > Policies**, open a policy and, in the Log Action list, select a log action for the policy.

#### **Verifying the Configuration**

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

## Viewing the Properties of Content Switching Virtual Servers

You can view the properties of content switching virtual servers that you have configured on the Citrix ADC appliance. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

### Note

If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

## To view the properties of content switching virtual servers by using the command line interface

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

- `show cs vserver`
- `show cs vserver <name>`

## Example

```
1 1.  
2 show cs vserver Vserver-CS-1  
3 Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT  
4 State: UP  
5 Last state change was at Thu Jun 30 10:48:59 2011  
6 Time since last state change: 6 days, 20:03:00.760  
7 Client Idle Timeout: 180 sec  
8 Down state flush: ENABLED  
9 Disable Primary Vserver On Down : DISABLED  
10 Appflow logging: DISABLED  
11 Port Rewrite : DISABLED  
12 State Update: DISABLED  
13 Default: Content Precedence: RULE

```

## Viewing Content Switching Policies

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it should.

### To view the properties of content switching policies by using the command line interface

To list either basic properties of all content switching policies in your configuration or detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

- `show cs policy`
- `show cs policy <PolicyName>`

### Example

```
1 show cs policy
2
3 show cs policy Policy-CS-1
4 <!--NeedCopy-->
```

### To view the properties of content switching policies by using the configuration utility

Navigate to **Traffic Management > Content Switching > Policies**, select a policy and, in the Action list, select **Show Bindings**.

## Viewing a Content Switching Virtual Server Configuration by Using the Visualizer

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

**Note**

The Visualizer requires a graphical interface, so it is available only through the configuration utility.

**To view a content switching configuration by using the Visualizer in the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.
3. In the **Content Switching Visualizer** window, you can adjust the viewable area as follows:
  - Click the **Zoom In** and **Zoom Out** icons to increase or decrease the viewable area.
  - Click the **Save Image** icon to save the graph as an image file.
  - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.
4. To view configuration details for entities that are bound to this virtual server, you can do the following:
  - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
  - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
  - To view the configuration details for a monitor, click the icon for the monitor, click the **Related Tasks** tab, and then click **View Monitor**.
5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click **Statistics**.

6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the **Related Tasks** tab, and then click **Service Attributes Diff**.
7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click **Details**. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.
8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It has to be refreshed manually. To refresh the information, click Refresh Stats.

**Note**

This option is available only on Citrix ADC nCore builds.

9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.
10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information about creating the application template file and configuring variables for a template, see [AppExpert](#).

## Customizing the Basic Content Switching Configuration

September 8, 2021

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. You can configure HTTP and SSL content switching virtual servers to listen on multiple ports instead of creating separate virtual servers. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.

## Configuring Case Sensitivity for Policy Evaluation

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the Citrix ADC appliance considers case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

### To configure case sensitivity by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -caseSensitive (ON|OFF)
```

#### Example:

```
1 set cs vserver Vserver-CS-1 -caseSensitive ON
2 <!--NeedCopy-->
```

### To configure case sensitivity by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select Case Sensitive.

## Setting the Precedence for Policy Evaluation

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You do not normally have to configure precedence: the default precedence works correctly in many cases. If you want to make sure that one policy or set of policies is applied first, however, and another policy or set of policies is applied only if the first set does not match a request, you can configure either URL-based precedence or rule-based precedence.

### Precedence with URL-Based Policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only

6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an “HTTP 404 Not Found” error message is sent to the client.

**Note**

You should configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served based on client attributes (such as Accept-Language), you must use rule-based precedence.

**Precedence with Rule-Based Policies**

If you configure precedence based on rules, which is the default setting, the request is tested on the basis of the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an “HTTP 404 Not Found” error message is sent to the client.

**To configure precedence by using the command line interface**

At the command prompt, type:

```
set cs vserver \<name\> -precedence ( RULE | URL )
```

**Example:**

```
set cs vserver Vserver-CS-1 -precedence RULE
```

**To configure precedence by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and then specify Precedence.

**Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers**

You can configure the Citrix ADC so that HTTP and SSL content switching virtual servers listen on multiple ports, without having to configure separate virtual servers. This feature is especially useful if you want to base a content switching decision on a part of the URL and other L7 parameters. Instead of configuring multiple virtual servers with the same IP address and different ports, you can configure one IP address and specify the port as \*. As a result, the configuration size is also reduced.

**To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line**

At the command prompt, type:

```
add cs vserver \<name\> \<serviceType\> \<IPAddress\> Port \*
```

**Example**

```
1 > add cs vserver cs1 HTTP 10.102.92.215 *
2 Done
3 > sh cs vserver cs1
4     cs1 (10.102.92.215:*) - HTTP      Type: CONTENT
5     State: UP
6     Last state change was at Tue May 20 01:15:49 2014
7     Time since last state change: 0 days, 00:00:03.270
8     Client Idle Timeout: 180 sec
9     Down state flush: ENABLED
10    Disable Primary Vserver On Down : DISABLED
11    Appflow logging: ENABLED
12    Port Rewrite : DISABLED
13    State Update: DISABLED
14    Default:          Content Precedence: RULE
15    Vserver IP and Port insertion: OFF
16    L2Conn: OFF      Case Sensitivity: ON
17    Authentication: OFF
18    401 Based Authentication: OFF
19    Push: DISABLED  Push VServer:
20    Push Label Rule: none
```

```

21      IcmpResponse: PASSIVE
22      RHISate: PASSIVE
23      TD: 0
24 Done
25 <!--NeedCopy-->

```

### To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and create a virtual server of type HTTP or SSL.
2. Use an asterisk (\*) to specify the port.

### Configuring per-VLAN Wildcarded Virtual Servers

If you want to configure content switching for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

### To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```

1      add cs vsver \<name> \<serviceType> IPAddress `* Port *` -
      listenpolicy \<expression> \[-listenpriority \<positive\
      _integer\>\]
2 <!--NeedCopy-->

```

#### Example:

```

1 add cs vsver Vserver-CS-vlan1 ANY * *
2   -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
3 <!--NeedCopy-->

```

### To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, and configure a virtual server. Specify a listen policy that restricts it to processing traffic only on the specified VLAN.

After you have created this virtual server, you bind it to one or more services as described in [Set up basic load balancing](#).

## Configuring the Microsoft SQL Server Version Setting

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

### To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- `set cs vserver \<name\> -mssqlServerVersion \<mssqlServerVersion\>`
- `show cs vserver \<name\>`

### Example

```
1 > set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2 Done > show cs
   vserver myMSSQLcsvip myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type:
   CONTENT State: UP . . . . . Mssql Server Version: 2008R2 . . . . .
   . Done >
2 <!--NeedCopy-->
```

### To set the Microsoft SQL Server version parameter by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server and specify the protocol as MSSQL.
2. In **Advanced Settings**, specify the **Server Version**.

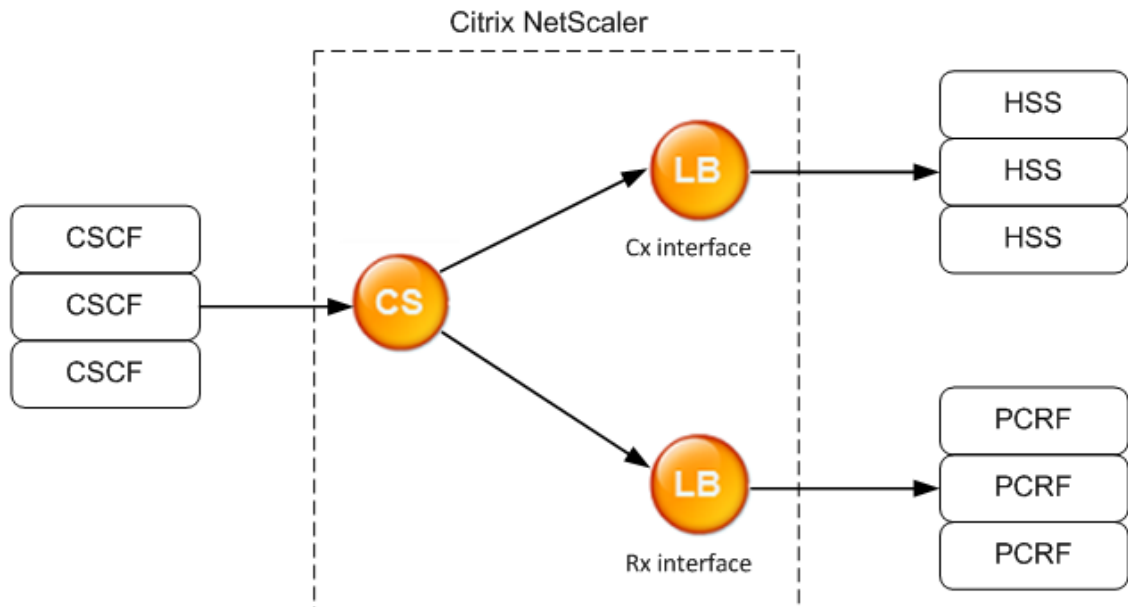

## Content Switching for Diameter Protocol

September 21, 2020

For Diameter-protocol traffic, you can configure the Citrix ADC appliance (or virtual appliance) to act as a relay agent that load balances and forwards a packet to the appropriate destination on the basis of the message content (AVP value in the message). Since the appliance does not perform any

application-level processing, it provides relaying services for all diameter applications as specified by the configured content switching policies. Therefore, the appliance advertises the Relay Application ID in the capability exchange answer (CEA) message when the client establishes a diameter connection. You must configure a content switching virtual server, load balancing virtual servers, and services to represent the diameter nodes. When a request reaches the content switching virtual server, the virtual server applies the content switching policies associated with that type of request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

A diameter interface provides a connection between the different diameter nodes. The following sample deployment uses Cx and Rx interfaces. A Cx interface provides a connection between a CSCF and an HSS. An Rx interface provides a connection between a CSCF and a PCRF. All the messages reach the Citrix ADC appliance. Depending on whether the message is for a Cx or an Rx interface, and on the content switching policies defined, the Citrix ADC selects an appropriate load balancing server pool.

CSCF=Call Session Control Function  
HSS=Home Subscriber Server  
PCRF=Policy and Charging Rules Function

### Sample Configuration

1. For each entity, create a service, a load balancing server, and bind the service to the virtual server.

```
1 add service svc_pcrf[1-3] 1.1.1.1[1-3] DIAMETER 3868
2 add service svc_hss[1-3] 1.1.1.2[1-3] DIAMETER 3868
```

```
3 add lb vserver vs_rx DIAMETER -persistenceType DIAMETER -
  persistavpno 263
4 add lb vserver vs_cx DIAMETER -persistenceType DIAMETER -
  persistavpno 263
5 bind lb vserver vs_rx svc_pcrf[1-3]
6 bind lb vserver vs_cx svc_hss[1-3]
7 <!--NeedCopy-->
```

2. Create a content switching virtual server and two actions (one for each load balancing virtual server). Create two content switching policies and bind these policies to the content switching virtual server, specifying a priority for each policy.

```
1 add cs vserver cs_diameter DIAMETER 10.1.1.10 3868
2 add cs action cx_action -targetLBVserver vs_cx
3 add cs action rx_action -targetLBVserver vs_rx
4 add cs policy cx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ
  (16777216)" -action cx_action
5 add cs policy rx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ
  (16777236)" -action rx_action
6 bind cs vserver cs_diameter -policyName rx_policy -priority 100
7 bind cs vserver cs_diameter -policyName cx_policy -priority 110
8 <!--NeedCopy-->
```

## Protecting the Content Switching Setup against Failure

September 21, 2020

Content switching may fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

### Configuring a Backup Virtual Server

If the primary content switching virtual server is marked DOWN or DISABLED, the Citrix ADC appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter `Disable Primary When Down` to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. This is useful if you want to ensure that

any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

**Note**

If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the redirect URL. The redirect is used when the primary and backup virtual servers are down.

**To set up a backup content switching virtual server by using the command line interface**

At the command prompt, type:

```
1 set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON
  |OFF)
2 <!--NeedCopy-->
```

**Example**

```
1 set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -
  disablePrimaryOnDown ON
2 <!--NeedCopy-->
```

**To set up a backup content switching virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Protection**, and specify a **Backup Virtual Server**.

**Diverting Excess Traffic to a Backup Virtual Server**

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you

can set the value. The number of established connections (in case of TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

### **To configure a content switching virtual server to divert new connections to a backup virtual server by using the command line interface**

At the command prompt, type:

```
1 set cs vserver \<name\> -soMethod \<methodType\> -soThreshold \<
  thresholdValue\> -soPersistence \<persistenceValue\> -
  soPersistenceTimeout \<timeoutValue\>
2 <!--NeedCopy-->
```

### **Example**

```
1 set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -
  soPersistence enabled -soPersistenceTimeout 2
2 <!--NeedCopy-->
```

### **To set a content switching virtual server to divert new connections to a backup virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Protection**, and configure spillover.

### **Configuring a Redirection URL**

You can configure a redirect URL to communicate the status of the Citrix ADC appliance in the event that a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL),

the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example `www.example.com/` instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

**Note**

If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.

When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user's browser.

**To configure a redirect URL for when the content switching virtual server is unavailable by using the command line interface**

At the command prompt, type:

```
1 set cs vserver \<name\> -redirectURL \<URLValue\>
2 <!--NeedCopy-->
```

**Example**

```
1 set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/
  mysite/maintenance
2 <!--NeedCopy-->
```

**To configure a redirect URL for when the content switching virtual server is unavailable by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Protection**, and specify a Redirect URL.

**Configuring the State Update Option**

The content switching feature enables the distribution of client requests across multiple servers on the basis of the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the

content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

**When State Update is disabled:**

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

**When State Update is enabled:**

When you add a new content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

**To configure the state update option by using the command line interface**

At the command prompt, type:

```
1 add cs vserver \<name\> \<protocol\> \<ipAddress\> \<port\> -  
   stateUpdate ENABLED  
2 <!--NeedCopy-->
```

**Example**

```
1 add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED  
   -cltTimeout 180  
2 <!--NeedCopy-->
```

**To configure the state update option by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server and specify the protocol as MYSQL.

2. In **Advanced Settings**, select **Traffic Settings**, and then select **State Update**.

## Flushing the Surge Queue

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

### Note

You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

### To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
1 flush ns surgeQ [-name <name>] [-serverName <serverName> <port>].  
2 <!--NeedCopy-->
```

### Examples

```
1 1. flush ns surgeQ - name SVC1ANZGB - serverName 10.10.10.1 80  
2 The above command flushes the surge queue of the service or virtual  
   server that is named SVC1ANZGB and has IP address as 10.10.10  
3  
4 2. flush ns surgeQ  
5 The above command flushes all the surge queues on the appliance.  
6 <!--NeedCopy-->
```

### To flush a surge queue by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

## Managing a Content Switching Setup

September 21, 2020

After a content switching setup is configured, it may require periodic changes. When operating systems or software are updated, or hardware wears out and is replaced, you may need to take down your setup. Load on your setup may increase, requiring additional resources. You may also modify the configuration to improve performance.

These tasks may require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have made changes to your setup, you may need to re-enable servers and rebind policies. You might also want to rename your virtual servers.

### Unbinding Policies from the Content Switching Virtual Server

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

#### To unbind a policy from a content switching virtual server by using the command line interface

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

#### Example:

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

#### To unbind a policy from a content switching virtual server by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open the virtual server.
2. Click **Policies** section, select the policy, and click **Unbind**.

### Removing Content Switching Virtual Servers

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the Citrix ADC appliance first unbinds all policies from the content switching virtual server, and then removes it.

### To remove a content switching virtual server by using the command line interface

At the command prompt, type:

```
rm cs vserver <name>
```

#### Example:

```
rm cs vserver Vserver-CS-1
```

### To remove a content switching virtual server by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server, and click **Delete**.

### Disabling and Re-Enabling Content Switching Virtual Servers

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

### To disable or re-enable a virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `disable cs vserver <name>`
- `enable cs vserver <name>`

#### Example:

```
1 `disable cs vserver Vserver-CS-1`  
2  
3 `enable cs vserver Vserver-CS-1`
```

### To disable or re-enable a virtual server by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the **Action** list, select **Enable** or **Disable**.

### Renaming Content Switching Virtual Servers

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the Citrix ADC configuration.

**To rename a virtual server by using the command line interface**

At the command prompt, type:

```
rename cs vserver <name> <newName>
```

**Example:**

```
1 `rename cs vserver Vserver-CS-1 Vserver-CS-2`
```

**To rename a virtual server by using the configuration utility**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the **Action** list, select **Rename**.

**Managing Content Switching Policies**

You can modify an existing policy by configuring rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

For more information, see [Examples of URL-Based Policies](#) pdf.

**Note**

You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

**To modify, remove, or rename a policy by using the command line interface**

At the command prompt, type one of the following commands:

- `set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]`
- `rm cs policy <policyName>`
- `rename cs policy <policyName> <newPolicyName>`

**Example:**

```
1 set cs policy Policy-CS-1 -domain "www.domainxyz.com"  
2  
3 set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ  
   (10.100.148.0)"  
4
```

```
5 set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010
  Jul)"
6
7 set cs policy Policy-CS-1 -url /sports/*
8
9 rename cs policy Policy-CS-1 Policy-CS-11
10
11 rm cs policy Policy-CS-1
```

### To modify, remove, or rename a policy by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Policies**.
2. Select the policy, and either delete it, edit it or, in the **Action** list, click **Rename**.

## Managing Client Connections

September 21, 2020

To ensure efficient management of client connections, you can configure the content switching virtual servers on the Citrix ADC appliance to use the following features:

- **Configuring the ICMP Response.** You can configure the Citrix ADC appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, the Citrix ADC appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, the ADC appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, ADC appliance responds even if one virtual server set to ACTIVE is UP.

### Redirecting Client Requests to a Cache

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see “[Cache Redirection](#).”

### To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cacheable <Value>
```

#### Example

```
set cs vserver Vserver-CS-1 -cacheable yes
```

### To configure cache redirection on a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Cacheable**.

### Enabling Delayed Cleanup of Virtual Server Connections

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

### To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver \
```

#### Example

```
1 set cs vserver Vserver-CS-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

**To configure the down state flush setting on a virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **Down State Flush**.

**Rewriting Ports and Protocols for Redirection**

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you may need to configure the Citrix ADC appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do this by enabling and configuring the `redirectPortRewrite` setting.

**To configure HTTP redirection on a virtual server by using the command line interface**

At the command prompt, type:

```
set cs vserver \<name\> -redirectPortRewrite \<Value\>
```

**Example**

```
1 set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
2 <!--NeedCopy-->
```

**To configure HTTP redirection on a virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Rewrite**.

**Inserting the IP Address and Port of a Virtual Server in the Request Header**

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

**Note**

This option is not supported for wildcarded virtual servers or dummy virtual servers.

**To insert the IP address and port of the virtual server in the client requests by using the command line interface**

At the command prompt, type:

```
set cs vserver \<name\> -insertVserverIPPort \<vServerIPPORT\>
```

**Example**

```
1 set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
2 <!--NeedCopy-->
```

**To insert the IP address and port of the virtual server in the client requests by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings** and, in the Virtual Server IP Port Insertion list, select VIPADDR or V6TOV4MAPPING, and specify a port header in Virtual Server IP Port Insertion Value.

**Setting a Time-out Value for Idle Client Connections**

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

**To set a time-out value for idle client connections by using the command line interface**

At the command prompt, type:

```
set cs vserver \<name\> -cltTimeout \<Value\>
```

**Example**

```
1 set cs vserver Vserver-CS-1 -cltTimeout 100
2 <!--NeedCopy-->
```

### To set a time-out value for idle client connections by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and specify a **Client Idle Time-Out** value.

### Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

### To set the L2Conn option for a content switching virtual server by using the command line interface

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

```
1 - set cs vserver \<name\> -l2Conn (**ON** | **OFF**)  
2 - show cs vserver \<name\>
```

### Example

```
1 > set cs vserver mycsvserver -l2Conn ON  
2 Done  
3 > show cs vserver mycsvserver  
4     mycsvserver (192.0.2.56:80) - HTTP   Type: CONTENT  
5     State: UP  
6         . . .  
7         . . .  
8     L2Conn: ON Case Sensitivity: ON  
9         . . .  
10        . . .  
11 Done  
12 >  
13 <!--NeedCopy-->
```

## To set the L2Conn option for a content switching virtual server by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **Layer 2 Parameters**.

## Troubleshooting

September 21, 2020

If the content switching feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

### Resources for Troubleshooting Content Switching

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Configuration file
- Relevant newnslog file
- Trace files
- Network topology diagram for the network setup of the customer
- Citrix documentation, such as release notes, Knowledge Center articles, and eDocs

In addition to the above resources, the following tools expedite troubleshooting:

- The `iehttpheaders` or a similar utility
- The Wireshark application customized for the Citrix ADC trace files
- An SSH utility for command line access
- A HyperTerminal utility to access the console

### Troubleshooting Content Switching Issues

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

- **Issue**

The content switching feature is not functioning.

- **Resolution**

Check the configuration as follows:

- Verify that the appliance is licensed for content switching.
- Verify that the feature is enabled.
- From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.

- **Issue**

Client receives a 503 - Service Unavailable response.

**Resolution**

- Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
- From the configuration, verify the policies and URL being accessed by the client.
- Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy expression and update it if necessary.
- Verify the URL and HTTP request and response headers. To do so, record an HTTPHeader trace and, if necessary, record the packet traces on the appliance and the client.

- **Issue**

Intermittently, the content switching feature is not working as expected.

**Resolution**

- Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the server(s).
- Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
- Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
- Run the following commands to verify the bindings and the values of the policy hit counters in the output of the commands:  

```
show cs vserver <CS VServer>
```

```
show cs policy <CS Policy>
```

```
stat cs vserver <CS VServer>
```
- Using `iehttpheaders` or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
- Check the release notes and Knowledge Center articles.
- If the issue is still not resolved, contact Citrix Technical Support with appropriate data for further investigation.

## DataStream

January 20, 2021

The Citrix ADC DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a Citrix ADC appliance ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and based on database names, user names, character sets, and packet size.

You can configure load balancing to switch requests based on load balancing algorithms. Alternately, you can elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameter. You can further configure monitors to track the state of database servers.

**Note:**

Citrix ADC DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

### How DataStream works

In DataStream, the ADC appliance is placed in-line between the application or web servers and the database servers. On the appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

Figure 1. DataStream Entity Model

As shown in this figure, a DataStream configuration can consist of:

- An optional content switching virtual server (CS).
- A load balancing setup consisting of load balancing virtual servers (LB1 and LB2).
- Services (Svc1, Svc2, Svc3, and Svc4).
- Content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the Citrix ADC appliance. The appliance, then, authenticates the clients using the database user credentials configured on the appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2). Then, the load balancing virtual server distributes the requests to the appropriate database servers (represented by services on the appliance) based on the load balancing algorithm. The Citrix ADC appliance uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the appliance, the clients (application or Web servers) send their requests to a load balancing virtual server configured on the appliance. The Citrix ADC appliance authenticates the client by using the database user credentials configured on the ap-

pliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set

## Configuring Database Users

September 21, 2020

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler appliance. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.

### Note

Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

### To add a database user by using the command line interface

At the command prompt, type

```
add db user <username> - password <password>
```

#### Example:

```
1 add db user nsdbuser -password dd260427edf
2 <!--NeedCopy-->
```

### To add a database user by using the configuration utility

Navigate to **System > User Administration > Database Users**, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the ADC appliance.

### To reset the password of a database user by using the command line interface

At the command prompt, type

```
1 set db user <username> -password <password>
2 <!--NeedCopy-->
```

#### Example:

```
1 set db user nsdbuser -password dd260538abs
2 <!--NeedCopy-->
```

### To reset the password of database users by using the configuration utility

Navigate to **System > User Administration > Database Users**, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

### To remove a database user by using the command line interface

At the command prompt, type

```
1 rm db user <username>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm db user nsdbuser
2 <!--NeedCopy-->
```

### To remove a database user by using the configuration utility

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

## Configuring a Database Profile

September 21, 2020

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

### To create a database profile by using the command line interface

At the command line, type the following commands to create a database profile and verify the configuration:

```
1 add db dbProfile <name> [-interpretQuery ( YES | NO )] [-stickiness (
    YES | NO )] [-kcdAccount <string>]
2
3 show db dbProfile
4 <!--NeedCopy-->
```

### Example:

```
1 > add dbProfile myDBProfile -interpretQuery YES -stickiness YES -
    kcdAccount mykcdacct
2 Done
3 > show dbProfile myDBProfile
4 Name: myDBProfile
5 Interpret Query: YES
6 Stickyness: YES
7 KCD Account: mykcdacct
8 Reference count: 0
9
10 Done
11 >
12 <!--NeedCopy-->
```

### To create a database profile by using the configuration utility

Navigate to **System > Profiles** and, on the **Database Profiles** tab, configure a database profile.

## To bind a database profile to a load balancing or content switching virtual server by using the command line interface

At the command line, type:

```
1 set (lb | cs) vserver <name> -dbProfileName <string>
2 <!--NeedCopy-->
```

## To bind a database profile to a load balancing or content switching virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** or **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Profiles** and, in the **DB Profile** list, select a profile to bind to the virtual server. To create a new profile, click plus (+).

## Configuring Load Balancing for DataStream

September 21, 2020

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

### Note:

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The Citrix ADC appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

## Parameter values specific to DataStream

- Protocol

Use the MySQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see <http://dev.mysql.com/doc/internals/en/client-server-protocol.html>. For information about the TDS protocol, see [http://msdn.microsoft.com/en-us/library/dd304523\(v=prot.13\).aspx](http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx).

- Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- Method

It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

Note: URL Hash method is not supported for DataStream.

- MS SQL Server Version

If you are using the Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL server version setting](#).

- MySQL Server Version

If you are using the MySQL Server, and you expect some clients to not be running the same version as your MySQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL server version setting](#).

## Configuring Content Switching for DataStream

September 21, 2020

You can segment traffic according to information in the SQL query, on the basis of database names, user names, character sets, and packet size.

You can configure content switching policies with default syntax expressions to switch content based on connection properties, such as user name and database name, command parameters, and the SQL query to select the server.

The default syntax expressions evaluate traffic associated with MYSQL and MS SQL database servers. You can use request-based expressions in default syntax policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

For information about default syntax expressions, see

[Default Syntax Expressions: DataStream](#).

**Note:**

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The Citrix ADC appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

### Parameter values specific to DataStream

- Protocol

Use the

MYSQL protocol type for MySQL databases and

MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see

<http://dev.mysql.com/doc/internals/en/client-server-protocol.html>. For information about the TDS protocol, see

[http://msdn.microsoft.com/en-us/library/dd304523\(v=prot.13\).aspx](http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx).

- Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- MS SQL Server Version

If you are using Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the Microsoft SQL Server Version Setting](#).

## Configuring Monitors for DataStream

September 21, 2020

To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service. (This is sometimes referred to as performing a health check.) If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors, MYSQL-ECV and MSSQL-ECV. This monitor provides the ability to send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler appliance. For information about configuring monitors, see [Configure monitors in a load balancing setup](#).

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run an SQL query to the database server and evaluate the server response to check whether it matches the configured rule.

The following examples are for MYSQL servers.

### Examples:

In the following example, the value of the error message is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon1 MYSQL-ECV -sqlQuery "select * from
```

```
2 table2;" -evalrule "mysql.res.error.message.contains("Invalid
3 User")"-database "NS" -userName "user1"
4 <!--NeedCopy-->
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon4 MYSQL-ECV -sqlQuery "select * from
2 table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -
  userName "user2"
3 <!--NeedCopy-->
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon3 MYSQL-ECV
2 -sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem
  (2) == 345.12"
3 -database "NS" -userName "user3"
4 <!--NeedCopy-->
```

The following examples are for MSSQL servers.

**Examples:**

In the following example, the value of the error message is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon1 MSSQL-ECV -sqlQuery "select * from
2 table2;" -evalrule "mssql.res.error.message.contains("Invalid
3 User")"-database "NS" -userName "user1"
4 <!--NeedCopy-->
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon4 MSSQL-ECV -sqlQuery "select * from
2 table4;" -evalrule "mssql.res.atleast_rows_count(7)" -database "NS" -
  userName "user2"
3 <!--NeedCopy-->
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon3 MSSQL-ECV
```

```
2 -sqlQuery "select * from ABC;" -evalrule "mssql.res.row(1).double_elem  
   (2) == 345.12"  
3 -database "NS" -userName "user3"  
4 <!--NeedCopy-->
```

## Use Case 1: Configure DataStream for a primary/secondary database architecture

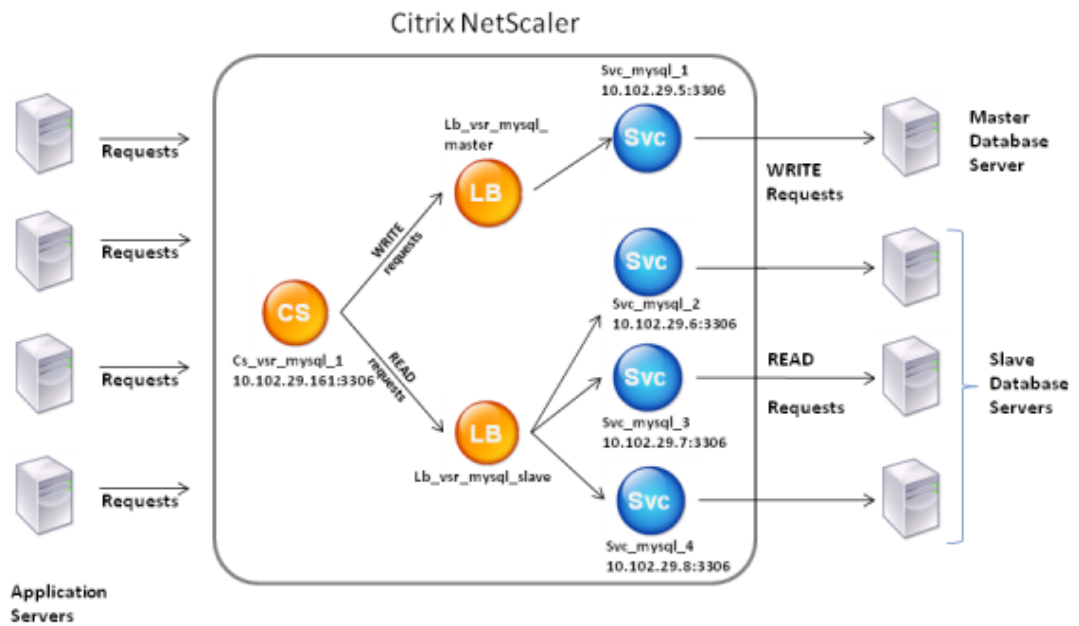

January 20, 2021

A commonly used deployment scenario is the primary/secondary database architecture where the primary database replicates all information to the secondary databases.

For primary/secondary database architecture, you might want all WRITE requests to be sent to the primary database and all READ requests to the secondary databases.

The following figure shows the entities and the values of the parameters you need to configure on the appliance.

Figure 1. DataStream Entity Model for Primary/Secondary Database Setup

In this example scenario, a service (Svc\_mysql\_1) is created to represent the primary database and is bound to a load balancing virtual server (Lb\_vsr\_mysql\_primary). Three more services (Svc\_mysql\_2, Svc\_mysql\_3, and Svc\_mysql\_4) are created to represent the three secondary databases, and they are bound to another load balancing virtual server (Lb\_vsr\_mysql\_secondary).

A content switching virtual server (Cs\_vsr\_mysql\_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server, Lb\_vsr\_mysql\_primary. All READ requests are sent to the load balancing virtual server, Lb\_vsr\_mysql\_secondary.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the Citrix ADC appliance.

| Entity Type | Name        | IP Address   | Protocol | Port | Expression |
|-------------|-------------|--------------|----------|------|------------|
| Services    | Svc_mysql_1 | 198.51.100.5 | MYSQL    | 3306 | NA         |

| Entity Type                      | Name          | IP Address     | Protocol | Port | Expression                                                 |
|----------------------------------|---------------|----------------|----------|------|------------------------------------------------------------|
|                                  | Svc_mysql_2   | 198.51.100.6   | MYSQL    | 3306 | NA                                                         |
|                                  | Svc_mysql_3   | 198.51.100.7   | MYSQL    | 3306 | NA                                                         |
|                                  | Svc_mysql_4   | 198.51.100.8   | MYSQL    | 3306 | NA                                                         |
| Load balancing virtual servers   | Lb_vsr_mysql_ | 198.51.100.201 | MYSQL    | 3306 | NA                                                         |
|                                  | Lb_vsr_mysql_ | 198.51.100.202 | MYSQL    | 3306 | NA                                                         |
| Content switching virtual server | Cs_vsr_mysql_ | 198.51.100.161 | MYSQL    | 3306 | NA                                                         |
| Content switching policy         | Cs_select     | NA             | NA       | NA   | <code>MYSQL.REQ. QUERY. COMMAND. contains("select")</code> |

Table 1. Entity and Policy Names and Values

### To configure DataStream for a primary/secondary database setup by using the command line interface

At the command prompt, type

```

1 add service Svc_mysql_1 198.51.100.5 mysql 3306
2
3 add service Svc_mysql_2 198.51.100.6 mysql 3306
4
5 add service Svc_mysql_3 198.51.100.7 mysql 3306
6
7 add service Svc_mysql_4 198.51.100.8 mysql 3306
8
9 add lb vserver Lb_vsr_mysql_primary mysql 198.51.100.201 3306
10
11 add lb vserver Lb_vsr_mysql_secondary mysql 198.51.100.202 3306
12
13 bind lb vserver Lb_vsr_mysql_primary svc_mysql_1

```

```

14
15 bind lb vserver Lb_vsr_mysql_secondary svc_mysql_2
16
17 bind lb vserver Lb_vsr_mysql_secondary svc_mysql_3
18
19 bind lb vserver Lb_vsr_mysql_secondary svc_mysql_4
20
21 add cs vserver Cs_vsr_mysql_1 mysql 198.51.100.161 3306
22
23 add cs policy Cs_select - rule "MYSQL.REQ.QUERY.COMMAND.contains(\"
    select"\)"
24
25 bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_primary
26
27 bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_secondary - policy
    Cs_select - priority 10
28 <!--NeedCopy-->

```

## Use Case 2: Configuring the Token Method of Load Balancing for DataStream

September 21, 2020

You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the Citrix ADC appliance sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

| MySQL                   | MS SQL                  |
|-------------------------|-------------------------|
| MYSQL.REQ.QUERY.TEXT    | MSSQL.REQ.QUERY.TEXT    |
| MYSQL.REQ.QUERY.TEXT(n) | MSSQL.REQ.QUERY.TEXT(n) |
| MYSQL.REQ.QUERY.COMMAND | MSSQL.REQ.QUERY.COMMAND |
| MYSQL.CLIENT.USER       | MSSQL.CLIENT.USER       |
| MYSQL.CLIENT.DATABASE   | MSSQL.CLIENT.DATABASE   |

MySQL

MS SQL

MYSQL.CLIENT.CAPABILITIES

The following example shows how the Citrix ADC DataStream feature works when you configure the token method of load balancing.

Figure 1. How DataStream Works with the Token Method of Load Balancing

In this example, the token is the name of the database. A request with token books is sent to Database Server1 and a request with token music is sent to Database Server2. All subsequent requests with token books are sent to Database Server1 and requests with token music are sent to Database Server2. This configuration provides pseudo persistence with the database servers.

### To configure this example by using the command line interface

At the command prompt, type:

```

1 add service Service1 192.0.2.9 MYSQL 3306
2
3 add service Service2 192.0.2.11 MYSQL 3306
4
5 add lb vserver token_lb_vserver MYSQL 192.0.2.15 3306 -lbmethod token -
  rule MYSQL.CLIENT.DATABASE
6
7 bind lb vserver token_lb_vserver Service1
8
9 bind lb vserver token_lb_vserver Service2

```

### To configure this example by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. Click in the Service section, and configure two services specifying the protocol as MYSQL. Bind these services to the virtual server.
3. In Advanced Settings, click Method and, in the Load Balancing Method list, select TOKEN and specify the expression as MYSQL.CLIENT.DATABASE.

## Use Case 3: Logging MSSQL Transactions in Transparent Mode

September 21, 2020

You can configure the Citrix ADC appliance to operate transparently between MSSQL clients and servers, and to only log or analyze details of all client-server transactions. Transparent mode is designed so that the Citrix ADC appliance only forwards MSSQL requests to the server, and then relays the server's responses to the clients. As the requests and responses pass through the appliance, the appliance logs information gathered from them, as specified by the audit logging or AppFlow configuration, or collects statistics, as specified by the Action Analytics configuration. You do not have to add database users to the appliance.

When operating in transparent mode, the Citrix ADC appliance does not perform load balancing, content switching, or connection multiplexing for the requests. However, it responds to a client's pre-login packet on behalf of the server so that it can prevent encryption from being agreed upon during the pre-login handshake. The login packet and subsequent packets are forwarded to the server.

### Summary of Configuration Tasks

For logging or analyzing MSSQL requests in transparent mode, you have to do the following:

- Configure the Citrix ADC appliance as the default gateway for both clients and servers.
- Do one of the following on the Citrix ADC appliance:
  - **If you can configure the use source IP address (USIP) option globally**, create a load balancing virtual server with a wildcard IP address and the port number on which the MSSQL servers listen for requests (a port-specific wildcard virtual server). Then, enable the USIP option globally. If you configure a port-specific wildcard virtual server, you do not have to create MSSQL services on the appliance. The appliance discovers the services on the basis of the destination IP address in the client requests.

- **If you do not want to configure the USIP option globally**, create MSSQL services with the USIP option enabled on each of them. If you configure services, you do not have to create a port-specific wildcard virtual server.
- Configure audit logging, AppFlow, or Action Analytics to log or collect statistics about the requests. If you configure a virtual server, you can bind your policies either to the virtual server or to the global bind point. If you do not configure a virtual server, you can bind your policies to only the global bind point.

## Configuring Transparent Mode by Using a Wildcard Virtual Server

You can configure transparent mode by configuring a port-specific wildcard virtual server and enabling Use Source IP (USIP) mode globally. When a client sends its default gateway (the Citrix ADC appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance checks whether the destination IP address is available. If the IP address is available, the virtual server forwards the request to the server. Otherwise, it drops the request.

### To create a wildcard virtual server by using the command line

At the command prompt, type the following commands to create a wildcard virtual server and verify the configuration:

```
1 add lb vserver <name> <serviceType> <IPAddress> <port>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Example:

```
1 > add lb vserver wildcardLbVs MSSQL * 1433
2 Done
3 > show lb vserver wildcardLbVs
4   wildcardLbVs (*:1433) - MSSQL   Type: ADDRESS
5   State: UP
6   . . .
7
8 Done
9 >
10 <!--NeedCopy-->
```

### To create a wildcard virtual server by using the GUI

Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server. Specify MSSQL as the protocol and \* as the IP address.

### To enable Use Source IP (USIP) mode globally by using the CLI

At the command prompt, type the following commands to enable USIP mode globally and verify the configuration:

```
1 enable ns mode USIP
2
3 show ns mode
4 <!--NeedCopy-->
```

### Example:

```
1 > enable ns mode USIP
2 Done
3 > show ns mode
4
5 Mode                               Acronym
6   Status                               -----
7   . . .
8 3) Use Source IP                     USIP                                ON
9   . . .
10 Done
11 >
12 <!--NeedCopy-->
```

### To enable USIP mode globally by using the GUI

1. Navigate to **System > Settings** and, in Modes and Features, select **Configure Modes**.
2. Select **Use Source IP**.

### Configuring Transparent Mode by Using MSSQL Services

You can configure transparent mode by configuring MSSQL services and enabling USIP on each service. When a client sends its default gateway (the Citrix ADC appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance forwards the request to the destination server.

### To create an MSSQL service and enable USIP mode on the service by using the command line interface

At the command prompt, type the following commands to create an MSSQL service, with USIP enabled, and verify the configuration:

```

1 add service <name> (<IP> | <serverName>) <serviceType> <port> -usip YES
2
3 show service <name>
4 <!--NeedCopy-->

```

### Example

```

1 > add service myDBservice 192.0.2.0 MSSQL 1433 -usip YES
2 Done
3 > show service myDBservice
4 myDBservice (192.0.2.0:1433) - MSSQL
5 State: UP
6
7 Use Source IP: YES Use Proxy Port: YES
8
9 Done
10 >
11 <!--NeedCopy-->

```

### To create an MSSQL service, with USIP enabled, by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and configure a service.
2. Specify protocol as MSSQL and, in Settings, select Use Source IP.

## Use Case 4: Database Specific Load Balancing

September 21, 2020

A database server farm must be load balanced not only based on the states of the servers, but also based on the availability of the database on each server. A service might be up, and a load balancing device might show it as being in the UP state, but the requested database might be unavailable on that service. The request is not served if a query is forwarded to a service on which the database is unavailable. Therefore, a load balancing device must be aware of the availability of a database on

each service. And when making a load balancing decision, it must consider only those services on which the database is available.

As an example, consider that database servers server1, server2, and server3 host databases mydatabase1 and mydatabase2. If mydatabase1 becomes unavailable on server2, the load balancing device must be aware of that change in state. It must load balance requests for mydatabase1 across only server1 and server3. After mydatabase1 becomes available on server2, the load balancing device must include server2 in load balancing decisions. Similarly, if mydatabase2 becomes unavailable on server3, the device must load balance requests for mydatabase2 across only server1 and server2. It must include server3 in its load balancing decisions only when mydatabase2 becomes available. This load balancing behavior must be consistent across all the databases that are hosted on the server farm.

The Citrix ADC appliance implements this behavior by retrieving a list of all the databases that are active on a service. To retrieve the list of active databases, the appliance uses a monitor that is configured with an appropriate SQL query. If the requested database is unavailable on a service, the appliance excludes the service from load balancing decisions until it becomes available. This behavior ensures uninterrupted service to clients.

**Note**

Database specific load balancing is supported for only MSSQL and MySQL service types. This support is also available for Microsoft SQL Server 2012 high availability deployment.

To set up database specific load balancing, you must configure the following:

- Enable the load balancing feature, and configure a load balancing virtual server of type MSSQL or MySQL.
- Configure the services that host the database, and bind the services to the virtual server. The monitor needs valid user credentials to log on to the database server, so you must configure a database user account on each of the servers and then add the user account to the Citrix ADC appliance.
- Then, you configure an MSSQL-ECV or MYSQL-ECV monitor and bind the monitor to each service.
- Finally, you must test the configuration to ensure that it is working as intended. Before you perform these configuration tasks, make sure you understand how database specific load balancing works.

**How Database Specific Load Balancing Works**

For database specific load balancing, you configure a monitor that periodically queries each database server for the names of all the active databases on it. The Citrix ADC appliance stores the results, and regularly updates the records based on the information retrieved through monitoring. When a client queries a particular database, the appliance uses the configured load balancing method to select a

service, and then checks its records to determine whether the database is available on that service. If the records indicate that the database is not available, it uses the configured load balancing method to select the next available service, and then repeats the check. The appliance forwards the query to the first available service on which the database is active.

## Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled. The entities do not function until you enable the feature.

### To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2
3 show ns feature
4 <!--NeedCopy-->
```

### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5         Feature                Acronym        Status
6         -----                -
7 1)    Web Logging              WL             OFF
8 2)    Surge Protection         SP             ON
9 3)    Load Balancing          LB             ON
10 .
11 .
12 .
13 24)   NetScaler Push          push           OFF
14 Done
15 <!--NeedCopy-->
```

### To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

## Configuring a Load Balancing Virtual Server for Database Specific Load Balancing

To configure a virtual server to load balance databases based on availability, you enable the database specific load balancing parameter on the virtual server. Enabling the parameter modifies the load balancing logic that the Citrix ADC appliance refers the results of the monitoring probe sent to the selected service, before forwarding the query to that service.

### To configure a load balancing virtual server for database specific load balancing

At the command prompt, type the following command to configure a load balancing virtual server for database specific load balancing and verify the configuration:

```
1 add lb vserver <name> <serviceType> <ipAddress> <port> -dbsLb ENABLED
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

## Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

## Configuring Database Users

In databases, a connection is always stateful, which means that when a connection is established, it must be authenticated.

You need to configure your database user name and password on the Citrix ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, the same are added to the nsconfig file.

### Note

Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

### To add a database user by using the command line interface

At the command prompt, type

```
1 add db user <username> - password <password>
2 <!--NeedCopy-->
```

#### Example:

```
1 add db user nsdbuser -password dd260427edf
2 <!--NeedCopy-->
```

### To add a database user by using the configuration utility

Navigate to **System > User Administration > Database Users**, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the Citrix ADC appliance.

### To reset the password of a database user by using the command line interface

At the command prompt, type

```
1 set db user <username> -password <password>
2 <!--NeedCopy-->
```

#### Example:

```
1 set db user nsdbuser -password dd260538abs
2 <!--NeedCopy-->
```

### To reset the password of database users by using the configuration utility

Navigate to **System > User Administration > Database Users**, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the Citrix ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated. Therefore, the user name does not get routed to the database server.

### To remove a database user by using the command line interface

At the command prompt, type

```
1 rm db user <username>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm db user nsdbuser
2 <!--NeedCopy-->
```

### To remove a database user by using the configuration utility

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

### Configuring a Monitor to Retrieve the Names of Active Databases

You can create a monitor to retrieve the list of all active databases on a database instance. The monitor logs on to the database server by using a valid user credentials and runs an appropriate SQL query. The SQL query you need to use depends on your SQL server deployment. For example, in an MSSQL database mirroring setup, you can use the following query to retrieve a list of active databases available on a server instance.

```
1 select name from sys.databases where state=0
2 <!--NeedCopy-->
```

In a MySQL database setup you can use the following queries to retrieve a list of active databases available on a server instance.

#### Show databases:

You also configure the monitor to evaluate the response for an error condition, and to store the results if there is no error. If the response contains an error, the monitor marks the service as DOWN. The appliance excludes the service from load balancing decisions until an error is no longer returned.

#### Note

The database specific load balancing feature is supported only for the MSSQL and MySQL service types. Therefore, the monitor type must be MSSQL-ECV or MYSQL-ECV.

**To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line**

At the command prompt, type the following commands to retrieve the names of all the active databases hosted on a service and verify the configuration:

```
1 add lb monitor <monitorName> <type> -userName <string> -sqlQuery <text>
   -evalRule <expression> -storedb ENABLED
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

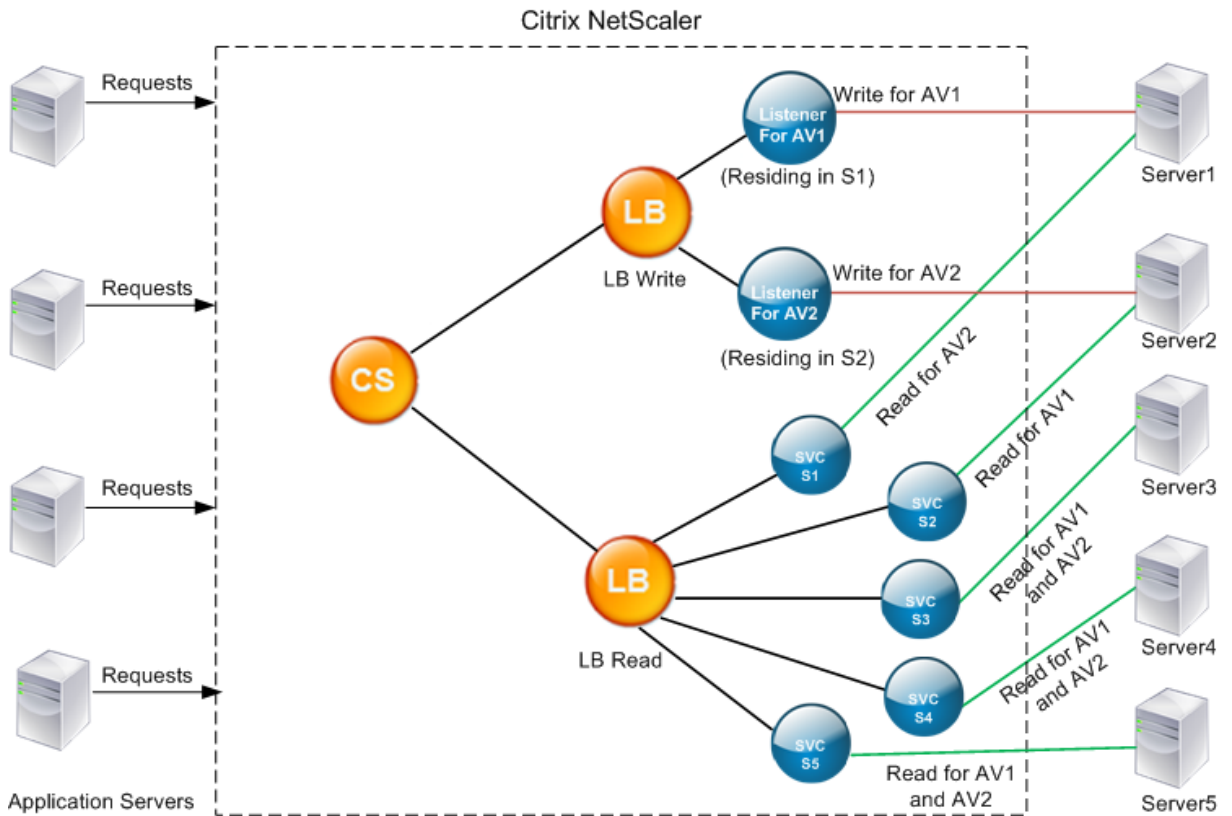

**To configure a monitor to retrieve the names of all the active databases hosted on a service by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Monitors** and configure a monitor of type MSSQL-ECV or MYSQL-ECV.
2. In **Special Parameters**, specify a user name, query, and a rule. For example, for MSSQL-ECV, the query must be “select name from sys.databases where state=0”), and a rule must be MSSQL.RES.TYPE.NE(ERROR). For MYSQL-ECV, the query must be “show databases” and a rule must be MYSQL.RES.TYPE.NE(ERROR).

**Availability Groups Deployment Support for MSSQL**

Consider the following scenario in which database specific load balancing is configured in a high availability group deployment. S1 through S5 is the services on the ADC appliance. DB1 through DB4 is the databases on the servers represented by the services S1 through S5. AV1 and AV2 are the availability groups. Each availability group contains up to one primary database server instance and up to four secondary database server instances. A service, representing the servers in the availability group, can be primary for one availability group and secondary for another availability group. Each availability group contains different databases and one listener, which is a service. All requests arrive on the listener service that resides on the primary database. AV1 contains databases DB1 and DB2. AV2 contains databases DB3 and DB4. L1 and L2 are the listeners on AV1 and AV2 respectively. S1 is the primary service for AV1 and S2 is the primary service for AV2.

| Service | List of Active Databases on the Service |
|---------|-----------------------------------------|
| S1      | DB1, DB2, DB3, DB4                      |
| S2      | DB3, DB4                                |
| S3      | DB3, DB4                                |
| S4      | DB1, DB2                                |
| S5      | DB1, DB2                                |

| Availability Group | Databases | Services representing the Servers in Availability Group |
|--------------------|-----------|---------------------------------------------------------|
| AV1                | DB1, DB2  | S1, S4, S5                                              |
| AV2                | DB3, DB4  | S1, S2, S3                                              |

Queries flow as follows:

1. A READ query for AV1 is load balanced between S4 and S5. S1 is the primary for AV1.
2. A WRITE query for AV1 is directed to L1.

3. A READ query for AV2 is load balanced between S1 and S3. S2 is the primary for AV2.
4. A WRITE query for AV1 is directed to L2.

### Sample Configuration

1. Configure load balancing and content switching virtual servers.
  - `add lb vserver lbwrite -dbslb enabled`
  - `add lbvserver lbread MSSQL -dbslb enabled`
  - `add csvserver csv MSSQL 1.1.1.10 1433`
2. Configure two listener services, one for each availability group, and five services S1 through S5 representing databases DB1 through DB4.
  - `add service L1 1.1.1.11 MSSQL 1433`
  - `add service L2 1.1.1.12 MSSQL 1433`
  - `add service s1 1.1.1.13 MSSQL 1433`
  - `add service s2 1.1.1.14 MSSQL 1433`
  - `add service s3 1.1.1.15 MSSQL 1433`
  - `add service s4 1.1.1.16 MSSQL 1433`
  - `add service s5 1.1.1.17 MSSQL 1433`
3. Bind the services to the load balancing virtual servers.
  - `bind lbvserver lbwrite L1`
  - `bind lbvserver lbwrite L2`
  - `bind lbvserver lbread s1`
  - `bind lbvserver lbread s2`
  - `bind lbvserver lbread s3`
  - `bind lbvserver lbread s4`
  - `bind lbvserver lbread s5`
4. Configure database users.
  - `add db user nsdbuser1 -password dd260427edf`
  - `add db user nsdbuser2 -password ccd1234xyzw`
5. Configure two monitors, monitor\_L1 and monitor\_L2 for each listener service, to retrieve the list of active databases in that availability group. Add a monitor, monitor1 to retrieve the list of databases for the secondary database server instance.
  - `add lb monitor monitor_L1 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_a d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address like '1.1.1.11'" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED`
  - `add lb monitor monitor_L2 MSSQL-ECV -userName user1 -sqlQuery "`

```
SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica
  b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners
  c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_a
  d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address
  like '1.1.1.12'"-evalRule "MSSQL.RES.TYPE.NE(ERROR)"-storedb
ENABLED
```

- add lb monitor monitor1 MSSQL-ECV -userNameuser1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm\_hadr\_availability\_replica\_states b ON a.replica\_id=b.replica\_id WHERE b.role = 2"-evalRule "MSSQL.RES.TYPE.NE(ERROR)"-storedb ENABLED

#### 6. Configure read and write policies.

- add cs policy pol\_write -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS("insert")"
- add cs policy pol\_read -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS("select")"

#### 7. Bind the policies to the content switching virtual server.

- bind csvserver csv -targetLBVserver lbwrite -policyName pol\_write -priority 11
- bind csvserver csv -targetLBVserver lbread -policyName pol\_read -priority 12

#### 8. Bind monitors to the services. Bind monitors to services L1 and L2 to get the list of active databases for the availability group for which it is the listener. Bind monitors to all the services that are bound to the read-only virtual server.

- bind service L1 -monitorName monitor\_L1
- bind service L2 -monitorName monitor\_L2
- bind service s1 -monitorName monitor1
- bind service s2 -monitorName monitor1
- bind service s3 -monitorName monitor1
- bind service s4 -monitorName monitor1
- bind service s5 -monitorName monitor1

## Configuration examples for MSSQL virtual server

### To configure a load balancing virtual server for database specific load balancing:

```
1 add lb vserver DBSpecificLB1 MSSQL 192.0.2.10 1433 -dbsLb ENABLED
2
3 Done
4
5 show lb vserver DBSpecificLB1
6
```

```
7 DBSpecificLB1 (192.0.2.10:1433) - MSSQL Type: ADDRESS
8 . . .
9 DBS_LB: ENABLED
10
11 Done
12 <!--NeedCopy-->
```

**To configure services:**

**add service** msservice1 5.5.5.5 MSSQL 1433

**To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:**

```
1 add lb monitor mssql-monitor1 MSSQL-ECV -userName user1 -sqlQuery "
  select name from sys.databases where state=0" -evalRule "MSSQL.RES.
  TYPE.NE(ERROR)" -storedb EN
2
3 Done
4
5 show lb monitor mssql-monitor1
6
7 1) Name.....: mssql-monitor1    Type.....: MSSQL-ECV
8
9 ...
10
11 Special parameters: Database.....:""
12
13 User name.....:"user1"
14
15 Query...:select name from sys.databases where state=0 EvalRule...:MSSQL.
  RES.TYPE.NE(ERROR)
16
17 Version...:70 STORE_DB...:ENABLED
18
19 Done
20 <!--NeedCopy-->
```

**Configuration examples for MySQL virtual server**

**To configure a load balancing virtual server for database specific load balancing:**

```
1 add lb vserver DBSpecificLB1 MYSQL 192.0.2.10 3306 -dbsLb ENABLED
2
3 Done
```

```
4
5 show lb vserver DBSpecificLB1
6
7 DBSpecificLB1 (192.0.2.10:3306) - MYSQL Type: ADDRESS
8
9 . . .
10
11 DBS_LB: ENABLED
12
13 Done
14 <!--NeedCopy-->
```

**To configure services:**

```
1 add service msservice1 5.5.5.5 MYSQL 3306
2 <!--NeedCopy-->
```

**To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:**

```
1 add lb monitor mysql-monitor1 MYSQL-ECV -userName user1 -sqlQuery "show
   databases" -evalRule "MYSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
2
3 Done
4
5 show lb monitor mysql-monitor1
6
7 1)      Name.....: mysql-monitor1  Type.....: MYSQL-ECV  State.....:
   ENABLED
8
9 ...
10
11 Special parameters: Database.....:""
12
13 User name.....:"user1" Query...:show databases
14
15 EvalRule...:MYSQL.RES.TYPE.NE(ERROR)  STORE_DB...:ENABLED
16
17 Done
18 <!--NeedCopy-->
```

## DataStream Reference

September 21, 2020

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how the Citrix ADC handles transaction requests and special queries that modify the state of a connection.

You can also configure the Citrix ADC appliance to generate audit log messages for the DataStream feature.

### Supported Database Versions, Protocols, and Authentication Methods

|                        | MySQL Database                                                                                                        | MS SQL Database                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Database Versions      | MySQL database versions 4.1, 5.0, 5.1, 5.4, 5.5, and 5.6.                                                             | MS SQL database versions 2000, 2000SP1, 2005, 2008, 2008R2, and 2012.                                                                               |
| Protocols              | MySQL protocol version 10. For information about the MySQL protocol, see <a href="#">MySQL Client/Server Protocol</a> | Tabular Data Stream (TDS) protocol version 7.1 and higher. For information about the TDS protocol, see <a href="#">Tabular Data Stream Protocol</a> |
| Authentication Methods | MySQL native authentication is supported.                                                                             | SQL server authentication and Windows Authentication (Kerberos/NTLM) are supported.                                                                 |

### Character Sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request may be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set cannot be multiplexed onto a connection with a different character set.

The Citrix ADC appliance parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

```
1 SET NAMES <charset> COLLATION <collation>
2
3 SET CHARACTER SET <charset>
4 <!--NeedCopy-->
```

## Transactions

In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the query SET AUTOCOMMIT.

The Citrix ADC appliance explicitly parses each and every query to determine the beginning and end of a transaction.

In MySQL protocol, the response contains two flags to indicate whether the connection is a transaction, the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag is not set. The ADC appliance parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag is not set, it does not do connection multiplexing. When these conditions are no longer true, the ADC appliance begins connection multiplexing.

### Note

Transactions are also supported for MS SQL.

## Special Queries

There are special queries, such as SET and PREPARE, that modify the state of the connection and may break request switching, and therefore, these need to be handled differently.

On receiving a request with special queries, the Citrix ADC appliance sends an OK response to the client and additionally, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the Citrix ADC appliance first, looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, the ADC appliance creates a new connection, and sends the stored query first, and then, sends the request with the non-special query.

In case of SET, USE db, and INIT\_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which the ADC appliance has a modified behavior.

- SET query

The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, the ADC appliance is unable to differentiate between local and global variables. For this query, the ADC appliance uses the 'store and forward' mechanism.

- USE <db> query

Using this query, the user can change the database associated with a connection. In this case, the ADC appliance parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

- INIT\_DB command

Using this query, the user can change the database associated with a connection. In this case, ADC appliance parses the value sent and modifies a field in the server side connection to reflect the new database to be used.

- COM\_PREPARE

The ADC appliance stops request switching on receiving this command.

- PREPARE query

This query is used to create prepared statements that are associated with a connection. For this query, the ADC appliance uses the 'store and forward' mechanism.

## **Audit Log Message Support**

You can now configure the Citrix ADC appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with "CS" and error messages for server-side connections begin with "SS." Additional information is provided where necessary. For example, log messages for closed connections (CS\_CONN\_CLOSED) include only the connection ID. However, log messages for established connections (CS\_CONN\_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.

## **Domain Name System**

September 21, 2020

You can configure the Citrix ADC appliance to function as an authoritative domain name server (ADNS server) for a domain. You can add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the Citrix ADC appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within your network or outside your network. You can configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the Citrix ADC appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the Citrix ADC appliance as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the Transmission Control Protocol (TCP) for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).

### **How DNS Works on the Citrix ADC**

You can configure the Citrix ADC appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the Citrix ADC appliance, including service (SRV) records, IPv6 (AAAA) records, address (A) records, mail exchange (MX) records, canonical name (CNAME) records, pointer (PTR) records, start of authority (SOA) records, and text (TXT) records. Also, you can configure the Citrix ADC to load balance external DNS name servers.

The Citrix ADC appliance can be configured as the authority for a domain. To do this, you add valid SOA and NS records for the domain.

An ADNS server is a DNS server that contains complete information about a zone.

To configure the Citrix ADC appliance as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a client sends a DNS request, the Citrix ADC appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the Citrix ADC Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the Citrix ADC authoritative for the subdomain, by adding a “glue record” for each of the subdomain name servers. If GSLB is configured, the Citrix ADC makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server. The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.

Figure 1. DNS Proxy Entity Model

The Citrix ADC appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the Citrix ADC appliance. This enables the Citrix ADC appliance to provide quick responses for repeated translations. You must also create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The Citrix ADC provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The Citrix ADC checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The Citrix ADC also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called *negative caching*. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- NXDOMAIN error message - If a negative response is present in the local cache, the Citrix ADC returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the Citrix ADC. The Citrix

ADC caches the response locally, then returns the error message to the client.

- NODATA error message - The Citrix ADC sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.

The Citrix ADC supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the Citrix ADC queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the Citrix ADC as a DNS forwarder. A forwarder passes DNS requests to external name servers. The Citrix ADC allows you to add external name servers and provides name resolution for domains outside the network. The Citrix ADC also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).

### **Round Robin DNS**

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when a large number of requests arrive.

When the Citrix ADC receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The Citrix ADC performs this function automatically. You do not have to configure this behavior.

### **Functional Overview**

If the Citrix ADC is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. If the Citrix ADC is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The Citrix ADC then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, the third response contains the third record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

## Round Robin DNS Example

As an example of round robin DNS, consider DNS records that have been added as follows:

```
1   add dns addRec ns1 1.1.1.1  add dns addRec ns1 1.1.1.2  add dns
    addRec ns1 1.1.1.3  add dns addRec ns1 1.1.1.4
2   <!--NeedCopy-->
```

The domain, abc.com is linked to an NS record as follows:

```
1   add dns nsrec abc.com. ns1
2   <!--NeedCopy-->
```

When the Citrix ADC receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

```
1   ns1.                1H IN A      1.1.1.1 ns1.
                        1H IN A      1.1.1.2 ns1.
                        1H IN A      1.1.1.3 ns1.
                        1H IN A      1.1.1.4
2   <!--NeedCopy-->
```

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

```
1   ns1.                1H IN A      1.1.1.2 ns1.
                        1H IN A      1.1.1.3 ns1.
                        1H IN A      1.1.1.4 ns1.
                        1H IN A      1.1.1.1
2   <!--NeedCopy-->
```

In the third DNS response, the third IP address, 1.1.1.3 is served as the first record:

```
1   ns1.                1H IN A      1.1.1.3 ns1.
                        1H IN A      1.1.1.4 ns1.
                        1H IN A      1.1.1.1 ns1.
                        1H IN A      1.1.1.2
2   <!--NeedCopy-->
```

## Configure DNS resource records

September 21, 2020

You configure resource records on the Citrix® ADC appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource

records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records
- Mail Exchange records
- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records

The following table lists the record types that you can configure for a domain name record on the Citrix ADC appliance. For example, you can configure a maximum of 25 IP addresses for one record.

Table 1. Record Type and Number Configurable

| Record Type                      | Number of Records |
|----------------------------------|-------------------|
| Address (A)                      | 25                |
| IPv6 (AAAA)                      | 5                 |
| Mail exchange (MX)               | 12                |
| Name server (NS)                 | 16                |
| Service (SRV)                    | 8                 |
| Pointer (PTR)                    | 20                |
| Canonical name (CNAME)           | 1                 |
| Start of Authority (SOA)         | 1                 |
| Text (TXT)                       | 20                |
| Naming Authority Pointer (NAPTR) | 20                |

**Note:**

The maximum number of IP addresses for a specific hostname is 25. However, the number of different address records can be more than 25.

## Create SRV records for a service

September 21, 2020

The SRV record provides information about the services available on the Citrix ADC appliance. An SRV record contains the following information: name of the service and the protocol, domain name, TTL, DNS class, priority of the target, weight of records with the same priority, port of the service, and host name of the service. The Citrix ADC chooses the SRV record that has the lowest priority setting first. If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

### Add an SRV record by using the CLI

At the command prompt, type the following commands to add an SRV record and verify the configuration:

```
1 - add dns srvRec <domain> <target> -priority <positive_integer> -
   weight <positive_integer> -port <positive_integer> [-TTL <secs>]
2 - sh dns srvRec <domain>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -
   weight 1 -port 80
2 Done
3 > show dns srvRec _http._tcp.example.com
4 1)      Domain Name : _http._tcp.example.com
5         Target Host : nameserver1.com
6         Priority   : 1      Weight   : 1
7         Port      : 80      TTL     : 3600 secs
8 Done
9 <!--NeedCopy-->
```

### Modify or remove an SRV record by using the CLI

- To modify an SRV record, type the `set dns srvRec` command, the name of the domain for which the SRV record is configured, the name of the target host that hosts the associated service, and the parameters to be changed, with their new values.
- To remove an SRV record, type the `rm dns srvRec` command, the name of the domain for which the SRV record is configured, and the name of the target host that hosts the associated service.

## Configure an SRV record by using the GUI

Navigate to Traffic Management > DNS > Records > SRV Records and create an SRV record.

## Creating AAAA Records for a Domain Name

September 21, 2020

An AAAA resource record stores a single IPv6 address.

### Add an AAAA record by using the CLI

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

```
1 - add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
2 - show dns aaaaRec <hostName>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57
   ab
2 Done
3 > show dns aaaaRec www.example.com
4 1)      Host Name : www.example.com
5         Record Type : ADNS                TTL : 5 secs
6         IPV6 Address : 2001:db8::1428:57ab
7 Done
8 <!--NeedCopy-->
```

To remove an AAAA record and all of the IPv6 addresses associated with the domain name, type the `rm dns aaaaRec` command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the

`rm dns aaaaRec` command, the domain name for which the AAAA record is configured, and the IPv6 addresses that you want to remove.

### Add an AAAA record by using the GUI

Navigate to Traffic Management > DNS > Records > AAAA Records and create an AAAA record.

## Creating address records for a Domain Name

September 21, 2020

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the Citrix ADC deletes Address records added for GSLB domains when you unbind the domain from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.

### Add an Address record by using the CLI

At the command prompt, type the following commands to add an Address record and verify the configuration:

```
1 - add dns addRec <hostName> <IPAddress> [-TTL <secs>]
2 - show dns addRec <hostName>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns addRec ns.example.com 192.0.2.0
2 Done
3 > show dns addRec ns.example.com
4 1) Host Name : ns.example.com
5 Record Type : ADNS TTL : 5 secs
6 IP Address : 192.0.2.0
7 Done
8 <!--NeedCopy-->
```

To remove an Address record and all of the IP addresses associated with the domain name, type the `rm dns addRec` command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the `rm dns addRec` command, the domain name for which the Address record is configured, and the IP addresses that you want to remove.

### Add an Address record by using the GUI

Navigate to Traffic Management > DNS > Records > Address Records and create an Address record.

## Create MX records for a mail exchange server

September 21, 2020

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0 through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.

### Add an MX record by using the CLI

At the command prompt, type the following commands to add an MX record and verify the configuration:

```
1 - add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]
2 - show dns mxRec <domain>
3 <!--NeedCopy-->
```

#### Example:

```
1 > add dns mxRec example.com -mx mail.example.com -pref 1
2 Done
3 > show dns mxRec example.com
4 1)      Domain : example.com      MX Name : mail.example.com
5        Preference : 1             TTL : 5 secs
6 Done
7 <!--NeedCopy-->
```

### Modify or remove an MX record by using the CLI

- To modify an MX record, type the set dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.
- To set the TTL parameter to its default value, type the unset dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and -TTL without any TTL value. You can use the unset dns mxRec command to unset only the TTL parameter.

- To remove an MX record, type the `rm dns mxRec` command, the name of the domain for which the MX record is configured, and the name of the MX record.

### Add an MX record by using the GUI

Navigate to Traffic Management > DNS > Records > Mail Exchange Records and create an MX record.

## Create NS Records for an authoritative server

September 21, 2020

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.

### Create an NS record by using the CLI

At the command prompt, type the following commands to create an NS record and verify the configuration:

```
1 - add dns nsRec <domain> <nameServer> [-TTL <secs>]
2 - show dns nsRec <domain>
3 <!--NeedCopy-->
```

#### Example:

```
1 > add dns nsRec example.com nameserver1.example.com
2 Done
3 > show dns nsRec example.com
4 1)      Domain : example.com      NameServer : nameserver1.example.com
5        TTL : 5 sec
6 Done
7 <!--NeedCopy-->
```

To remove an NS record, type the `rm dns nsRec` command, the name of the domain to which the NS record belongs, and the name of the name server.

### Create an NS record by using the GUI

Navigate to Traffic Management > DNS > Records > Name Server Records and create an NS record.

## Create CNAME records for a subdomain

September 21, 2020

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

In some cases, a Citrix ADC appliance in proxy mode requests an address record from the cache instead of the server.

### Add a CNAME record by using the CLI

At the command prompt, type the following commands to create a CNAME record and verify the configuration:

```
1 - add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]
2 - show dns cnameRec <aliasName>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns cnameRec www.example.com www.examp1enw.com
2 Done
3 > show dns cnameRec www.example.com
4      Alias Name      Canonical Name  TTL
5 1)    www.example.com      www.examp1enw.com      5 secs
6 Done
7 <!--NeedCopy-->
```

To remove a CNAME record for a given domain, type the `rm dns cnameRec` command and the alias of the domain name.

### Add a CNAME record by using the GUI

Navigate to Traffic Management > DNS > Records > Canonical Records and create a CNAME record.

### Cache CNAME records

Citrix ADC when deployed in a proxy mode does not always send the query for an address record to the back-end server. This happens when for an answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache. Following are the conditions:

- Citrix ADC should be deployed in a proxy mode
- The response from the back-end server should have a CNAME chain, for which the record type of last entry in the answer section must be a CNAME and the question type not a CNAME
- The response from the back-end server cannot be a No-data or NX-Domain
- The response from the back-end server has to be a authoritative response

## Create NAPTR records for telecommunications domain

September 21, 2020

NAPTR (Naming Address Pointer) is one of the most commonly used DNS record in telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

Citrix ADCs support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in Citrix ADC. Citrix ADC caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record is served from the cache.

### Create a NAPTR record by using CLI

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

```
add dns naptrRec <order> <preference>[flags<string>][services<string>](  
regex<expressions>|-replacement<string>)[-TTL<secs>]
```

### Remove a NAPTR record by using CLU

```
rm dns naptrRec<domain> (<order> <preference> [-flags <string>] [-services  
<string>] (-regex <expression> | -replacement <string>))| -recordId <  
positive_integer>@)
```

### Configure a NAPTR record using GUI

Navigate to Traffic Management > DNS > Records > NAPTR Records and create an NAPTR record.

## Create PTR records for IPv4 and IPv6 addresses

September 21, 2020

A pointer (PTR) record translates an IP address to its domain name. IPv4 PTR records are represented by the octets of an IP address in reverse order with the string “in-addr.arpa.” appended at the end. For example, the PTR record for the IP address 1.2.3.4 is 4.3.2.1.in-addr.arpa.

IPv6 addresses are reverse mapped under the domain IP6.ARPA. IPv6 reverse-maps use a sequence of nibbles separated by dots with the suffix “.IP6.ARPA” as defined in RFC 3596. For example, the reverse lookup domain name corresponding to the address, 4321:0:1:2:3:4:567:89ab would be b.a.9.8.7.6.5.0.4.0.0.3.0.0.0.2.0.0.0.1.0.0.0.0.0.0.1.2.3.4.IP6.ARPA.

### Add a PTR record by using the CLI

At the command prompt, type the following commands to add a PTR record and verify the configuration:

```
1 - add dns ptrRec <reverseDomain> <domain> [-TTL <secs>]
2 - show dns ptrRec <reverseDomain>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns ptrRec 0.2.0.192.in-addr.arpa example.com
2 Done
3 > show dns ptrRec 0.2.0.192.in-addr.arpa
4 1)      Reverse Domain Name : 0.2.0.192.in-addr.arpa
5         Domain Name : example.com                TTL : 3600 secs
6 Done
7 <!--NeedCopy-->
```

To remove a PTR record, type the `rm dns ptrRec` command and the reverse domain name associated with the PTR record

### Add a PTR record by using the GUI

Navigate to Traffic Management > DNS > Records > PTR Records and create a PTR record.

## Create SOA records for authoritative information

September 21, 2020

A Start of Authority (SOA) record is created only at the zone apex and contains information about the zone. The record includes, among other parameters, the primary name server, contact information (e-mail), and default (minimum) time-to-live (TTL) values for records.

### Create an SOA record by using the CLI

At the command prompt, type the following commands to add an SOA record and verify the configuration:

```
1 - add dns soaRec \<domain\> -originServer \<originServerName\> -
   contact \<contactName\>
2 - sh dns soaRec \<do main\>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns soaRec example.com -originServer nameserver1.example.com -
   contact admin.example.com
2 Done
3 > show dns soaRec example.com
4 1) Domain Name : example.com
5 Origin Server : nameserver1.example.com
6 Contact : admin.example.com
7 Serial No. : 100 Refresh : 3600 secs Retry : 3 secs
8 Expire : 3600 secs Minimum : 5 secs TTL : 3600 secs
9 Done
10 <!--NeedCopy-->
```

### Modify or remove an SOA record by using the CLI

- To modify an SOA record, type the `set dns soaRec` command, the name of the domain for which the record is configured, and the parameters to be changed, with their new values.
- To remove an SOA record, type the `rm dns soaRec` command and the name of the domain for which the record is configured.

### Configure an SOA record by using the GUI

Navigate to Traffic Management > DNS > Records > SOA Records and create an SOA record.

## Create TXT records for holding descriptive text

September 21, 2020

Domain hosts store TXT records for informative purposes. A TXT record's RDATA component, which consists of one or more character strings of variable length, can store practically any information that a recipient might need to know about the domain, including information about the service provider, contact person, email addresses, and associated details. SPF (Sender Policy Framework) protection has been the most prominent use case for the TXT record.

All configuration types (authoritative DNS, DNS proxy, end resolver, and forwarder configurations) on the Citrix ADC appliance support TXT records. You can add a maximum of 20 TXT resource records to a domain. Each resource record is stored with a unique, internally generated record ID. You can view the ID of a record and use it to delete the record. However, you cannot modify a TXT resource record.

### Create a TXT resource record by using the CLI

At the command prompt, type the following commands to create a TXT resource record and verify the configuration:

```
1 - add dns txtRec <domain> <string> ... [-TTL <secs>]
2 - show dns txtRec [<domain> | -type <type>]
3 <!--NeedCopy-->
```

#### Example:

```
1 > add dns txtRec www.example.com "Contact: Mark" "Email: mark@example.
  com" -TTL 36000
2 Done
3 > show dns txtRec www.example.com
4 1) Domain : www.example.com      Record id: 13783      TTL : 36000 secs
   Record Type : ADNS
5     "Contact: Mark"
6     "Email: mark@example.com"
7 Done
8 <!--NeedCopy-->
```

### Remove a TXT resource record by using the CLI

At the command prompt, type the following commands to remove a TXT resource record and verify the configuration:

```
1 - rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>)
2 - show dns txtRec [<domain> | -type <type>]
3 <!--NeedCopy-->
```

**Example:**

You can use the show dns txtRec command first to view the record ID of the TXT resource record that you want to remove, as shown:

```
1 > show dns txtRec www.example.com
2 1) Domain : www.example.com      Record id: 36865      TTL : 36000 secs
   Record Type : ADNS
3     "Contact: Evan"
4     "Email: evan@example.com"
5 2) Domain : www.example.com      Record id: 14373      TTL : 36000 secs
   Record Type : ADNS
6     "Contact: Mark"
7     "Email: mark1@example.com"
8 Done
9 <!--NeedCopy-->
```

The simpler method of deleting a TXT record is to use the record ID. If you want to provide the strings, enter them in the order in which they are stored in the record. In the following example, the TXT record is deleted by using its record ID.

```
1 >rm dns txtRec www.example.com -recordID 36865
2 Done
3 > show dns txtRec www.example.com
4 1) Domain : www.example.com      Record id: 14373      TTL : 36000 secs
   Record Type : ADNS
5     "Contact: Mark"
6     "Email: mark1@example.com"
7 Done
8 <!--NeedCopy-->
```

**Configure a TXT record by using the GUI**

Navigate to Traffic Management > DNS > Records > TXT Records and create a TXT record.

**Viewing DNS statistics**

September 21, 2020

You can view the DNS statistics generated by the Citrix ADC appliance. The DNS statistics include runtime, configuration, and error statistics.

### View DNS records statistics by using the CLI

At the command prompt, type:

```
stat dns
```

#### Example:

```
1 > stat dns
2 DNS Statistics
3
4 Runtime Statistics
5 Dns queries                21
6 NS queries                  8
7 SOA queries                18
8 .
9 .
10 .
11 Configuration Statistics
12 AAAA records              17
13 A records                 36
14 MX records                9
15 .
16 .
17 .
18 Error Statistics
19 Nonexistent domain        17
20 No AAAA records           0
21 No A records              13
22 .
23 .
24 .
25 Done
26 <!--NeedCopy-->
```

### View DNS records statistics by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Statistics.

## Configure a DNS zone

September 21, 2020

A DNS zone entity on the Citrix ADC appliance facilitates the ownership of a domain on the appliance. A zone on the appliance also enables you to implement DNS Security Extensions (DNSSEC) for the zone, or to offload the zone's DNSSEC operations from the DNS servers to the appliance. DNSSEC sign operations are performed on all the resource records in a DNS zone. Therefore, if you want to sign a zone, or if you want to offload DNSSEC operations for a zone, you must first create the zone on the Citrix ADC appliance.

You must create a DNS zone on the appliance in the following scenarios:

- The Citrix ADC appliance owns all the records in a zone, that is, the appliance is operating as the authoritative DNS server for the zone. The zone must be created with the proxyMode parameter set to NO.
- The Citrix ADC appliance owns only a subset of the records in a zone, and all the other resource records in the zone are hosted on a set of back-end name servers for which the appliance is configured as a DNS proxy server. A typical configuration where the Citrix ADC appliance owns only a subset of the resource records in the zone is a global server load balancing (GSLB) configuration. Only the GSLB domain names are owned by the Citrix ADC appliance, while all the other records are owned by the back-end name servers. The zone must be created with the proxyMode parameter set to YES.
- You want to offload DNSSEC operations for a zone from your authoritative DNS servers to the appliance. The zone must be created with the proxyMode parameter set to YES. You might need to configure additional settings for the zone.

The current topic describes how to create a zone for the first two scenarios. For more information about how to configure a zone for offloading DNSSEC operations to the appliance, see [Offload DNSSEC operations to the Citrix ADC appliance](#).

### Note

If the Citrix ADC is operating as the authoritative DNS server for a zone, you must create Start of Authority (SOA) and name server (NS) records for the zone before you create the zone. If the Citrix ADC is operating as the DNS proxy server for a zone, SOA and NS records must not be created on the Citrix ADC appliance. For more information about creating SOA and NS records, see [Configure DNS resource records](#).

When you create a zone, all existing domain names and resource records that end with the name of the zone are automatically treated as a part of the zone. Additionally, any new resource records created with a suffix that matches the name of the zone are implicitly included in the zone.

## Create a DNS zone on the Citrix ADC appliance by using the CLI

At the command prompt, type the following command to add a DNS zone to the Citrix ADC appliance and verify the configuration:

```
1 - add dns zone <zoneName> -proxyMode ( YES | NO )
2 - show dns zone [<zoneName> | -type <type>]
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns zone example.com -proxyMode Yes
2 Done
3 > show dns zone example.com
4     Zone Name : example.com
5     Proxy Mode : YES
6 Done
7 <!--NeedCopy-->
```

## Modify or remove a DNS zone by using the CLI

- To modify a DNS zone, type the `set dns zone` command, the name of the DNS zone, and the parameters to be changed, with their new values.
- To remove a DNS zone, type the `rm dns zone` command and the name of the dns zone.

## Configure a DNS zone by using the GUI

Navigate to Traffic Management > DNS > Zones and create a DNS zone.

## Configure the Citrix ADC as an ADNS server

September 21, 2020

You can configure the ADC appliance to function as an authoritative domain name server (ADNS) for a domain. As an ADNS server for a domain, the Citrix ADC resolves DNS requests for all types of DNS records that belong to the domain. To configure the Citrix ADC to function as an ADNS server for a domain, you must create an ADNS service and configure NS and Address records for the domain on the Citrix ADC. The ADNS service can be configured using the subnet IP address (SNIP) or a separate IP address. The following topology diagram shows a sample configuration and the flow of requests and responses.

Figure 1. Citrix ADC as an ADNS

The following table shows the parameters that are configured for the ADNS service illustrated in the preceding topology diagram.

| Entity type  | Name           | IP address   | Type | Port |
|--------------|----------------|--------------|------|------|
| ADNS Service | Service-ADNS-1 | 10.102.29.51 | ADNS | 53   |

Table 1. Example of ADNS Service Configuration

To configure an ADNS setup, you must configure the ADNS service. For instructions on configuring the ADNS service, see “[Load balancing](#)”.

During DNS resolution, the ADNS server directs the DNS proxy or local DNS server to query the Citrix ADC for the IP address of the domain. Because the Citrix ADC is authoritative for the domain, it sends the IP address to the DNS proxy or local DNS server. The following diagram describes the placement and role of the ADNS server in a GSLB configuration.

Figure 2. GSLB Entity Model

Note: In ADNS mode, if you remove SOA and ADNS records, the following do not function for the domain hosted by the Citrix ADC: ANY query (for more information about the ANY query, see [DNS ANY query](#)), and negative responses, such as NODATA and NXDOMAIN.

### Create an ADNS service

An ADNS service is used for global service load balancing. For more information about creating a GSLB setup, see “[Global server load balancing](#)”. You can add, modify, enable, disable, and remove an ADNS service. For instructions on creating an ADNS service, see [Configure services](#).

**Note:** You can configure the ADNS service to use SNIP or any new IP address.

When you create an ADNS service, the Citrix ADC responds to DNS queries on the configured ADNS service IP and port.

You can verify the configuration by viewing the properties of the ADNS service. You can view properties such as name, state, IP address, port, protocol, and maximum client connections.

### Configure the ADNS setup to use TCP

By default, some clients use the User Datagram Protocol (UDP) for DNS, which specifies a limit of 512 bytes for the payload length of UDP packets. To handle payloads that exceed 512 bytes in size, the

client must use the Transmission Control Protocol (TCP). To enable DNS communications over TCP, you must configure the Citrix ADC appliance to use the TCP protocol for DNS. The Citrix ADC then sets the truncation bit in the DNS response packets. The truncation bit specifies that the response is too large for UDP and that the client must send the request over a TCP connection. The client then uses the TCP protocol on port 53 and opens a new connection to the Citrix ADC. The Citrix ADC listens on port 53 with the IP address of the ADNS service to accept the new TCP connections from the client.

To configure the Citrix ADC to use the TCP protocol, you must configure an ADNS\_TCP service. For instructions on creating an ADNS\_TCP service, see

[Load balancing](#).

#### **Important**

To configure the Citrix ADC to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure the ADNS and ADNS\_TCP services. The IP address of the ADNS\_TCP service must be same as the IP address of the ADNS service.

### **Add DNS resource records**

After you create an ADNS service, you can add DNS records. For instructions on adding DNS records, see [Configure DNS resource records](#).

### **Remove ADNS services**

For instructions on removing services, see [Load balancing](#)

### **Configure domain delegation**

Domain delegation is the process of assigning responsibility for a part of the domain space to another name server. Therefore, during domain delegation, the responsibility for responding to the query is delegated to another DNS server. Delegation uses NS records.

In the following example, sub1.abc.com is the subdomain for abc.com. The procedure describes the steps to delegate the subdomain to the name server ns2.sub1.abc.com and add an Address record for ns2.sub1.abc.com.

To configure domain delegation, you need to perform the following tasks, which are described in the sections that follow:

1. Create an SOA record for a domain.
2. Create an NS record to add a name server for the domain.
3. Create an Address record for the name server.
4. Create an NS record to delegate the subdomain.
5. Create a glue record for the name server.

### **Create an SOA record**

For instructions on configuring SOA records, see [Create SOA records for authoritative information](#).

### **Create an NS record for a name server**

For instructions on configuring an NS record, see [Create NS records for an authoritative server](#). In the Name Server drop-down list, select the primary authoritative name server, for example, ns1.abc.com.

### **Create an address record**

For instructions on configuring Address records, see [Create address records for a domain name](#). In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns1.abc.com and 10.102.11.135, respectively.

### **Create an NS record for domain delegation**

For instructions on configuring NS records, see [Create NS records for an authoritative server](#). In the Name Server drop-down list, select the primary authoritative name server, for example, ns2.sub1.abc.com.

### **Create a glue record**

NS records are usually defined immediately after the SOA record (but this is not a restriction.) A domain must have at least two NS records. If an NS record is defined within a domain, it must have a matching Address record. This Address record is referred to as a glue record. Glue records speed up DNS queries.

For instructions on adding glue records for a subdomain, see the procedure for adding an Address (A) record, [Configure DNS resource records](#).

For instructions on configuring Address records, see [Create address records for a domain name](#). In Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns2.sub1.abc.com and 10.102.12.135, respectively.

## **Configure the Citrix ADC appliance as a DNS proxy server**

September 21, 2020

As a DNS proxy server, the ADC appliance can function as a proxy for either a single DNS server or a group of DNS servers. The flow of requests and responses is illustrated in the following sample topology diagram.

Figure 1. Citrix ADC as DNS proxy

By default, the Citrix ADC appliance caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the Citrix ADC returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the Citrix ADC. The Citrix ADC then returns the address to the client.

For requests for a domain that has been cached earlier, the Citrix ADC serves the Address record of the domain from the cache without querying the configured DNS server.

The appliance discards a record stored in its cache when the time-to-live (TTL) value of the record reaches the configured value. A client that requests an expired record has to wait until the Citrix ADC retrieves the record from the server and updates its cache. To avoid this delay, the Citrix ADC proactively updates the cache by retrieving the record from the server before the record expires.

The following table lists sample names and the values of the entities that need to be configured on the Citrix ADC.

Table 1. Example of DNS Proxy Entity Configuration

| Entity type       | Name          | IP address   | Type | Port |
|-------------------|---------------|--------------|------|------|
| LB virtual server | Vserver-DNS-1 | 10.102.29.40 | DNS  | 53   |

```
|Services|Service-DNS-1|10.102.29.50|DNS|53|  
|Services|Service-DNS-2|10.102.29.51|DNS|53|
```

The following diagram shows the entities of a DNS Proxy and the values of the parameters to be configured on the Citrix ADC.

Figure 2. DNS Proxy Entity Model

#### Note

To configure DNS proxy, you need to know how to configure load balancing services and virtual servers.

### Create a load balancing virtual server

To configure a DNS Proxy on the Citrix ADC, configure a load balancing virtual server of type DNS. To configure a DNS virtual server to load balance a set of DNS servers that support recursive queries, you must set the Recursion Available option. With this option, the RA bit is set to ON in the DNS replies from the DNS virtual server.

For instructions on creating a load balancing virtual server, see [“Load Balancing”](#).

### Create DNS services

After creating a load balancing virtual server of type DNS, you must create DNS services. You can add, modify, enable, disable, and remove a DNS service. For instructions on creating a DNS service, see [“Load Balancing”](#).

## Bind a load balancing virtual server to DNS services

To complete the DNS Proxy configuration, you must bind the DNS services to the load balancing virtual server. For instructions on binding a service to a load balancing virtual server, see [“Load Balancing”](#).

## Configure the DNS proxy setup to use TCP

Some clients use the User Datagram Protocol (UDP) for DNS communications. However, UDP specifies a maximum packet size of 512 bytes. When payload lengths exceed 512 bytes, the client must use the Transmission Control Protocol (TCP). When a client sends the Citrix ADC appliance a DNS query, the appliance forwards the query to one of the name servers. If the response is too large for a UDP packet, the name server sets the truncation bit in its response to the Citrix ADC. The truncation bit indicates that the response is too large for UDP and that the client must send the query over a TCP connection. The Citrix ADC relays the response to the client with the truncation bit intact and waits for the client to initiate a TCP connection with the IP address of the DNS load balancing virtual server, on port 53. The client sends the request over a TCP connection. The Citrix ADC appliance then forwards the request to the name server and relays the response to the client.

To configure the Citrix ADC to use the TCP protocol for DNS, you must configure a load balancing virtual server and services, both of type `DNS_TCP`. You can configure monitors of type `DNS_TCP` to check the state of the services. For instructions on creating `DNS_TCP` virtual servers, services, and monitors, see [“Load Balancing.”](#)

For updating the records proactively, the Citrix ADC uses a TCP connection to the server to retrieve the records.

**Important** To configure the Citrix ADC to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure DNS and `DNS_TCP` services. The IP address of the `DNS_TCP` service must be same as that of the DNS service.

## Configure time-to-live values for DNS entries

The TTL is the same for all DNS records with the same domain name and record type. If the TTL value is changed for one of the records, the new value is reflected in all records of the same domain name and type. The default TTL value is 3600 seconds. The minimum is 0, and the maximum is 604800. If a DNS entry has a TTL value less than the minimum or greater than the maximum, it is saved as the minimum or maximum TTL value, respectively.

## Specify the minimum and/or maximum TTL by using the CLI

At the Citrix ADC command prompt, type the following commands to specify the minimum and maximum TTL and verify the configuration:

```
1 - set dns parameter [-minTTL <secs>] [-maxTTL <secs>]
2 - show dns parameter
3 <!--NeedCopy-->
```

**Example:**

```
1 > set dns parameter -minTTL 1200 -maxTTL 1800
2 Done
3 > show dns parameter
4     DNS parameters:
5     DNS retries: 5
6     Minimum TTL: 1200           Maximum TTL: 1800
7     .
8     .
9     .
10 Done
11 >
12 <!--NeedCopy-->
```

**Specify the minimum and/or maximum TTL by using the GUI**

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in TTL, in the Minimum and Maximum text boxes, type the minimum and maximum time to live (in seconds), respectively, and then click OK.

**Note:** When the TTL expires, the record is deleted from the cache. The Citrix ADC proactively contacts the servers and obtains the DNS record just before the DNS record expires.

**Flush DNS records**

You can delete all DNS records present in the cache. For example, you might want to flush DNS records when a server is restarted after modifications are made.

**Delete all proxy records by using the CLI**

At the Citrix ADC command prompt, type:

```
flush dns proxyRecords
```

**Delete all proxy records by using the GUI**

1. Navigate to Traffic Management > DNS > Records.

2. In the details pane, click Flush Proxy Records.

### **Add DNS resource records**

You can add DNS records to a domain for which the Citrix ADC appliance is configured as a DNS proxy server. For information about adding DNS records, see [Configuring DNS Resource Records](#).

### **Remove a load balancing DNS virtual server**

For information about removing a load balancing virtual server, see [Load Balancing](#).

### **Limit the number of concurrent DNS requests on a client connection**

You can limit the number of concurrent DNS requests on a single client connection, which is identified by the <clientip:port>-<vserver ip:port> tuple. Concurrent DNS requests are those requests that the Citrix ADC appliance has forwarded to the name servers and for which the appliance is awaiting responses. Limiting the number of concurrent requests on a client connection enables you to protect the name servers when a hostile client attempts a Distributed Denial of Service (DDoS) attack by sending a flood of DNS requests. When the limit for a client connection is reached, subsequent DNS requests on the connection are dropped till the outstanding request count goes below the limit. This limit does not apply to the requests that the NetScCitrix ADCaler appliance serves out of its cache.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve a large number of concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This is a global parameter and applies to all the DNS virtual servers that are configured on the Citrix ADC appliance.

### **Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the CLI**

At the command prompt, type the following commands to specify the maximum number of concurrent DNS requests allowed on a single client connection and verify the configuration:

```
1 - set dns parameter -maxPipeline <positive_integer>
2 - show dns parameter
3 <!--NeedCopy-->
```

### **Example:**

```
1 > set dns parameter -maxPipeline 1000
2 Done
3 > show dns parameter
4     DNS parameters:
5     DNS retries: 5
6     .
7     .
8     .
9     Max DNS Pipeline Requests: 1000
10 Done
11 <!--NeedCopy-->
```

### **Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the GUI**

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, specify a value for Max DNS Pipeline Requests.
4. Click OK.

## **Configure the Citrix ADC as an end resolver**

September 21, 2020

A resolver is a procedure that is invoked by an application program that translates a domain/host name to its resource record. The resolver interacts with the LDNS, which looks up the domain name to obtain its IP address. The Citrix ADC can provide end-to-end resolution for DNS queries.

In recursive resolution, the Citrix ADC appliance queries different name servers recursively to access the IP address of a domain. When the Citrix ADC receives a DNS request, it checks its cache for the DNS record. If the record is not present in the cache, it queries the root servers configured in the ns.conf file. The root name server reports back with the address of a DNS server that has detailed information about the second-level domain. The process is repeated until the required record is found.

When you start the Citrix ADC appliance for the first time, 13 root name servers are added to the ns.conf file. The NS and Address records for the 13 root servers are also added. You can modify the ns.conf file, but the Citrix ADC does not allow you to delete all 13 records; at least one name server entry is required for the appliance to perform name resolution. The following diagram illustrates the process of name resolution.

Figure 1. Recursive resolution

In the process shown in the diagram, when the name server receives a query for the address of `s1.s2.s3.com`, it first checks the root name servers for `s1.s2.s3.com`. A root name server reports back with the address of the `.com` name server. If the address of `s1.s2.s3.com` is found in the name server, it responds with a suitable IP address. Otherwise, it queries other name servers for `s3.com`, then for `s2.s3.com` to retrieve the address of `s1.s2.s3.com`. In this way, resolution always starts from root name servers and ends with the domain's authoritative name server.

Note: For recursive resolution functionality, caching should be enabled.

### Enable recursive resolution

To configure the Citrix ADC appliance to function as an end resolver, you must enable recursive resolution on the appliance.

#### Enable recursive resolution by using the CLI

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

```
1 - set dns parameter -recursion ENABLED
2 - show dns parameter
3 <!--NeedCopy-->
```

**Example:**

```
1 > set dns parameter -recursion ENABLED
2 Done
3 > show dns parameter
4     DNS parameters:
5     .
6     .
7     .
8     Recursive Resolution : ENABLED
9     .
10    .
11    .
12 Done
13 <!--NeedCopy-->
```

**Enable recursive resolution by using the GUI**

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable recursion check box, and then click OK.

**Set the Number of Retries**

The Citrix ADC appliance can be configured to make a preconfigured number of attempts (called DNS retries) when it does not receive a response from the server to which it sends a query. By default, the number of DNS retries is set to 5.

**Set the number of DNS retries by using the CLI**

At the command prompt, type the following commands to set the number of retries and verify the configuration:

```
1 - set dns parameter -retries <positive_integer>
2 - show dns parameter
3 <!--NeedCopy-->
```

**Example:**

```
1 > set DNS parameter -retries 3
2 Done
3 > show dns parameter
4     DNS parameters:
5     DNS retries: 3
6     .
7     .
8     .
9 Done
10 <!--NeedCopy-->
```

**Set the number of retries by using the GUI**

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in the DNS Retries text box, type the DNS resolver request retry count, and then click OK.

**Configure the Citrix ADC appliance as a forwarder**

January 6, 2021

A forwarder is a server that forwards DNS queries to DNS servers that are outside the forwarder server's network. Queries that cannot be resolved locally are forwarded to other DNS servers. A forwarder accumulates external DNS information in its cache as it resolves DNS queries. To configure the Citrix ADC appliance as a forwarder, you must add an external name server.

The Citrix ADC appliance allows you to add external name servers to which it can forward the name resolution queries that cannot be resolved locally. To configure the Citrix ADC appliance as a forwarder, you must add the name servers to which it must forward name resolution queries. You can specify the lookup priority to specify the name service that the Citrix ADC appliance must use for name resolution.

**Note:**

The Citrix ADC appliance in forwarder mode supports TCP, UDP, and UDP-TCP name servers.

- If you have configured a TCP name server, then the Citrix ADC appliance sends the DNS request over TCP.
- If you have configured a UDP name server, then the Citrix ADC appliance sends the DNS request over UDP.

- If you have configured a UDP-TCP name server, then the Citrix ADC appliance sends the DNS request over UDP. However if the truncated bit is set in the DNS response, the appliance sends such DNS requests over TCP.

## Add a name server

September 21, 2020

You can create a name server by specifying its IP address or by configuring an existing virtual server as the name server.

- **IP address-based name server** - An external name server to contact for domain name resolution. If multiple IP address-based name servers are configured on the appliance, and the local parameter is not set on any of them, incoming DNS queries are load balanced across all the name servers, in round robin fashion.
- **Virtual server-based name server** - A DNS virtual server configured in the Citrix ADC. If you want more fine-grained control on how external DNS name servers are load balanced (for example, you want a load balancing method other than round robin), do the following:
  - Configure a DNS virtual server on the appliance
  - Bind the external name servers as its services
  - Specify the name of the virtual server in this command.

To verify the configuration, you can use the `show dns nameServer` command.

To remove a name server, at the Citrix ADC CLI, type the `rm dns nameServer` command followed by the IP address of the name server.

To view the details of the DNS nameserver, at the Citrix ADC CLI, type `show dns nameServer` command followed by the IP address of the name server.

### Add a name server (when the Citrix ADC appliance acts as a forwarder) by using the CLI

At the command prompt, type;

```
1 add dns nameServer ((<IP> | <dnsVserverName>)
2 <!--NeedCopy-->
```

or

```
1 add dns nameServer ((<IP> | <dnsVserverName>) [-type <type>]
2 <!--NeedCopy-->
```

### Examples:

```
1 add dns nameServer dnsVirtualNS
2
3 add dns nameServer 192.0.2.11 -type TCP
4
5 add dns nameServer 192.0.2.12 -type UDP_TCP
6
7
8 add dns nameServer 192.0.2.10
9 show dns nameServer 192.0.2.10
10
11 1) 192.0.2.10 - State: UP Protocol: UDP
12 Done
13 <!--NeedCopy-->
```

**Note:**

If the name server type is not specified, a UDP name server is created by default. To create a name server of type TCP or UDP\_TCP, you must specify the type.

When you specify the type as UDP\_TCP, two name servers (one UDP name server and one TCP name server) are created for the given IP address.

**Add a name server (when the Citrix ADC appliance acts as a resolver) by using the CLI**

At the command prompt, type:

```
1 add dns nameServer ((<IP> [-local]) | <dnsVserverName>)
2 <!--NeedCopy-->
```

**Example:**

```
1 add dns nameServer 10.102.9.19 -local
2 show dns nameServer
3 1) 10.102.9.19 LOCAL - State: UP Protocol: UDP
4 Done
5 <!--NeedCopy-->
```

**local** - Mark the IP address as one that belongs to a local recursive DNS server on the Citrix ADC appliance. The appliance recursively resolves queries received on an IP address that is marked as being local.

For recursive resolution to work, the global DNS parameter, *recursion*, must also be set.

If no name server is marked as being local, the appliance functions as a stub resolver and load balances the name servers.

## Add a name server by using the GUI

Navigate to **Traffic Management > DNS > Name Servers** and create a name server.

## Set DNS lookup priority

September 21, 2020

You can set the lookup priority to either DNS or WINS. This option is used in the SSL VPN mode of operation.

### Set the lookup priority to DNS by using the CLI

At the command prompt, type the following commands to set the lookup priority to DNS and verify the configuration:

```
1 - set dns parameter -nameLookupPriority (DNS | WINS)
2 - show dns parameter
3 <!--NeedCopy-->
```

#### Example:

```
1 > set dns parameter -nameLookupPriority DNS
2 Done
3 > show dns parameter
4      .
5      .
6      .
7      Name lookup priority : DNS
8      .
9      .
10     .
11 Done
12 <!--NeedCopy-->
```

### Set lookup priority to DNS by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under **Settings**, click Change DNS settings.
3. In the **Configure DNS Parameters** dialog box, under **Name Lookup Priority**, select DNS or WINS, and then click OK.

**Note**

If the DNS virtual server that you have configured is DOWN and if you set the `-nameLookupPriority` to DNS, the Citrix ADC does not attempt WINS lookup. Therefore, if a DNS virtual server is not configured or is disabled, set the `-nameLookupPriority` to WINS.

## Disable and enable name servers

September 21, 2020

The following procedure describes the steps to enable or disable an existing name server.

### Enable or disable a name server by using the CLI

At the command prompt, type the following commands to enable or disable a name server and verify the configuration:

```
1 - (enable | disable) dns nameServer <IPAddress>
2 - show dns nameServer <IPAddress>
3 <!--NeedCopy-->
```

**Example:**

```
1 > disable dns nameServer 10.102.9.19
2 Done
3 > show dns nameServer 10.102.9.19
4 1)      10.102.9.19: LOCAL - State: OUT OF SERVICE
5 Done
6 <!--NeedCopy-->
```

### Enable or disable a name server by using the GUI

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, select the name server that you want to enable or disable.
3. Click Enable or Disable. If a name server is enabled, the Disable option is available. If a name server is disabled, the Enable option is available.

## Configure Citrix ADC as a non-validating security aware stub-resolver

September 21, 2020

Starting with Citrix ADC 12.1 build 49.xx, Citrix ADC acts as anon-validating security aware stub-resolver. To enable this support, the AD bit is set in the DNS header and the DO bit is unset in the OPT header. When the AD bit is set and DO bit is unset, the upstream recursive resolver validates the DNSSEC response. If the validation is successful, the recursive resolver responds without DNSSEC RRs. If the DNSSEC validation fails, then the recursive resolver returns with a SERVFAIL response.

**Important:** The AD bit is set by default in the ADC forwarder. The AD bit is not set for DBS initiated queries.

## Jumbo frames support for DNS to handle responses of large sizes

September 21, 2020

Starting with Citrix ADC 12.1 build 49.xx, DNS supports jumbo frames for handling UDP responses greater than 1,280 bytes. Previously, the Citrix ADC appliance only supported UDP packet size only up to 1,280 bytes.

You can set the maximum UDP packet size that the appliance can handle in proxy, ADNS, and forwarder modes by configuring the Maximum UDP Packet Size parameter value. For example, if the Maximum UDP Packet Size parameter value is set to 4096, the appliance can handle DNS response of size 4,096 bytes.

### Important

- In proxy mode, the least size between the client request OPT payload size and the Maximum UDP Packet Size value is considered for sending DNS queries to the backend. For example, if the client request OPT payload size is 3000, and the Maximum UDP Packet Size parameter value is set to 4096, DNS queries of size 3,000 bytes are sent to the backend.  
  
Also, from the backend, appliance can receive responses of large sizes and process responses of large sizes.
- In forwarder mode, the appliance sets the OPT payload size equal to the UDP packet size parameter value.
- If the DNS records are local to the appliance, then the appliance can compose response sizes as large as the Maximum UDP Packet Size parameter value. This is applicable for ADNS, proxy, and recursive resolvers.

## To configure the maximum UDP packet size using the CLI

At the command prompt, type:

```
1 set dns parameter [-maxUDPPacketSize <positive_integer>]
2 <!--NeedCopy-->
```

### Example:

```
1 set dns parameter -maxUDPPacketSize 10000
2 <!--NeedCopy-->
```

**Note:** The minimum and maximum value that you can set for the Maximum UDP Packet Size parameter is 512 and 16384 respectively. Default value is 1280.

## To configure the maximum UDP packet size using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click **Change DNS settings**.
3. In Maximum UDP Packet Size, specify the maximum UDP packet size.
4. Click **OK**.

## Configure DNS logging

January 6, 2021

You can configure the Citrix ADC appliance to log the DNS requests and responses that it handles. The appliance logs the DNS requests and responses in SYSLOG format. You can choose to log either DNS requests or DNS responses, or both, and send the syslog messages to a remote log server. The log messages can be used to:

- Audit the DNS responses to the client
- Audit DNS clients
- Detect and prevent DNS attacks
- Troubleshoot

A Citrix ADC appliance can log the following sections in the DNS request or response, based on your configuration:

- Header Section
- Questions Section
- Answer Section

- Authority Section
- **Additional** Section

## DNS profiles

You can use a DNS profile to configure the various DNS parameters that you want the DNS endpoint to apply to the DNS traffic. In the profile, you can enable logging, caching, and negative caching.

**Important:** From the NetScaler 11.0 release, enabling DNS caching using global DNS parameters have been deprecated. You can enable or disable DNS caching using DNS profiles. You can now enable DNS caching for an individual virtual server by enabling DNS caching in a DNS profile and setting the DNS profile to the individual virtual server.

DNS profiles support the following types of DNS logging:

- DNS Query Logging
- DNS Answer Section Logging
- DNS Extended Logging
- DNS Error Logging

## DNS query logging

You can configure a Citrix ADC appliance to log only the DNS queries received by the DNS endpoints on the appliance.

**Note:** If errors occur during processing of a query, they are logged if this option is set in the DNS profile.

Following is an example of a query log message:

```
1 DNS DNS_QUERY 143 0 : U:10.102.27.70#61297:10.102.27.73#53/22142/Q/  
2 (RD)/NO/1/0/0/0#test.com./1#  
3 <!--NeedCopy-->
```

## DNS answer section logging

You can configure a Citrix ADC appliance to log all the **Answer** sections in the DNS responses that the appliance sends to the client. DNS Answer Section logging is useful when the Citrix ADC is configured as a DNS resolver, or in GLSB use cases.

Following is an example of a DNS answer section log:

```
1 DNS DNS_RESPONSE 6678 0 : U:100.100.100.210#32776:100.100.100.10#  
2 53/61373/Q/(RD,AA,RA,R)/NO/1/1/2/4#n1.citrix.com1./  
3 28#ANS#AAAA/120/1111:2345:6789:ffab:abcd:effa:1234:3212##  
4 <!--NeedCopy-->
```

## DNS extended logging

To configure a Citrix ADC appliance to log Authority and **Additional** sections in the DNS responses, enable Extended logging with Answer Section logging.

**Note:** If errors occur during processing of either queries or responses, the errors are logged if this option is set in the DNS profile.

Following is an example of a message logged when the cache lookup is completed and the response is embedded in the packet:

```
1 DNS DNS_RESPONSE 2252 0 : T:100.100.100.118#21411:100.100.100.10
2 #53/48537/Q/(RD,AA,CD,RA,R)/NO/1/1/2/6#a1.citrix.com1./1#ANS#A/
3 120/1.1.1.1##AUTH#citrix.com1/NS/120/n2.citrix.com1#n1.citrix.com1##ADD
4 #n1.citrix.com1
5 /A/120/1.1.1.1#1.1.1.2##n1.citrix.com1/AAAA/120/
6 1111:2345:6789:ffab:abcd:effa:1234:3212##n2.citrix.com1/A/120/2.1.1.2
7 ##n2.citrix.com1/AAAA/120/2222:faff:3212:8976:123:1241:64:ff9b##OPT
8 /0/1280/DO##
9 <!--NeedCopy-->
```

## DNS error logging

You can configure a Citrix ADC appliance to log the errors or failures that occur when it processes a DNS query or response. For these errors, the appliance logs the DNS header, **Question** sections and OPT records.

Following is an example of a message logged when an error occurs during processing of a DNS request or response:

```
1 DNS DNS_ERROR 149 0 : U:10.102.27.70#27832:10.102.27.73#53/61153/Q/
2 (RD)/NO/1/0/0/0#test.com./1140#Packet Dropped
3 <!--NeedCopy-->
```

## Policy based logging

You can configure custom logging based on DNS expressions by configuring the logAction on DNS policies, Rewrite, or Responder policies. You can specify that logging occurs only when a particular DNS policy evaluates to true. For more information, see Configure policy based logging for DNS.

## Understand the Citrix ADC syslog log message format

Citrix ADC appliance log DNS requests and responses in the following Syslog format:

```
1 <transport> :<client IP>#<client ephemeral port>:<DNS endpoint IP>#<
  port>
2 : <query id> /opcode/header flags/rcode/question section count/answer
  section count
3 / auth section count / additional section count #<queried domain name>
4 /<queried type>#...
5 <!--NeedCopy-->
```

- **<transport>:**

- T = TCP
- U = UDP

- **<client IP>#< client ephemeral port >:**

DNS client IP address and port number

- **<DNS endpoint IP>#<port>:**

Citrix ADC DNS endpoint IP address and port number

- **<query id>:**

Query ID

- **<opcode>:**

Operation code. Supported Values:

- Q: query
- I: inverse query
- S: status
- X0: unassigned
- N: notify
- U: update
- X1-10: unassigned values

- **<header flags>:**

Flags. Supported Values:

- RD: recursion desired
- TC: truncated
- AA: authoritative response
- CD: check disabled
- AD: authenticated data
- Z: unassigned
- RA: recursion available
- R: response

- **<rcode>:**

Response Code. Supported Values:

- NO: no error
- F: format error
- S: server failure
- NX: non-existent domain
- NI: not implemented
- R: query refused
- YX: Name Exists when it must not
- YXR: RR Set Exists when it must not
- NXR: RR Set that must exist does not
- NAS: Server Not Authoritative for zone
- NA: Not Authorized
- NZ: Name not contained in zone
- X1-5: unassigned

- **/question section count/answer section count/auth section count/additional section count:**

Question section, Authority section count, and **Additional** section count in the DNS request

- **<queried domain name>/<queried type>:**

Queried domain and queried type in the DNS request

- **#ANS#<record type>/<ttd>/.. #AUTH#<domain name>/<record type>/<ttd>.. #ADD#<domain name>/<record type>/<ttd>...:**

In DNS responses:

Answer Section is logged if answer section logging is enabled in the DNS profile.

Authority and **Additional** sections are logged if extended logging is enabled in the DNS profile.

The log format would differ depending on the type of record. For more information see Understanding the Record Logging Format.

- ANS: Answer section
- AUTH: Authority
- ADD: **Additional** section

- **OPT/<edns version>/UDP max payload size/DO:**

OPT record format in the DNS log

- **OPT/<EDNS version>/<UDP payload size>/<“DO”or empty based on whether DNSSEC OK bit is set or not>/<value of RDLEN>/ECS/<Q/R>/<option length>/<Family>/<Source Prefix-Length>/<Scope Prefix-Length>/<ECS Address>:**

If the DNS query or response includes the EDNS Client Subnet (ECS) option, then that is also logged in the OPT record format in the DNS log file.

When a DNS query with an ECS option that includes either an IPv4 or IPv6 address is sent, the ECS option is logged with either of the following options;

- “ECS/Q” indicating that the values in the log are from the query
- “ECS/R” indicating that the values in the log are from the response.

The value of Scope Prefix-Length is also set appropriately. In the DNS Query, it is set to zero, and for response, it is set to the calculated value.

The following table describes the logged details in various scenarios:

| Scenario                                                      | ECS option set in the DNS Query | ECS option set in the DNS Response | Logged Details                                                                                            |
|---------------------------------------------------------------|---------------------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Both query logging and extended logging enabled               | Yes                             | Yes                                | ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value. |
| Both query logging and extended logging enabled               | Yes                             | No                                 | ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.                 |
| Query logging is enabled, but extended logging is not enabled | Yes                             | Yes                                | ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.                 |
| Query logging & extended logging are not enabled              | Yes                             | Yes                                | ECS option is not logged.                                                                                 |
| Query logging is enabled, but extended logging is not enabled | Yes                             | No                                 | ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.                 |

| Scenario                                                      | ECS option set in the DNS Query | ECS option set in the DNS Response | Logged Details                                                                                            |
|---------------------------------------------------------------|---------------------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Query logging is not enabled, but extended logging is enabled | Yes                             | Yes                                | ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value. |
| Query logging is not enabled, but extended logging is enabled | Yes                             | No                                 | ECS option is not logged.                                                                                 |

### Understand the record logging format

Following is an example of the record logging format in a Syslog message:

```

1 <domainname>/<record type>/ <record ttl> / <resource record data>#<
  resource record data>#.....##
2 <!--NeedCopy-->

```

Where:

| Record Type          | Sample Format                                             | Resource Record Data / Format                                                                                                                                      |
|----------------------|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address (A) record   | A/5/1.1.1.1#1.1.1.2#1.1.1.3##                             | IPv4 address                                                                                                                                                       |
| AAAA record          | AAAA/5/1::1#1::2#1::3##                                   | IPv6 address                                                                                                                                                       |
| SOA record           | SOA/3600/ns1.dnslogging.test./                            | Origin server, contact, and other details. Resource record format is:<br>< originServer<br>>/<contact>/<serial number>/<refresh rate>/<retry>/<expire>/<minimum>## |
| NS record            | NS/5/ns1.dnslogging.test                                  | Host name of the nameserver.                                                                                                                                       |
| MX record            | #MX/5/10/host1.dnslogging.test.#1#host2.dnslogging.test## | exchange server host name                                                                                                                                          |
| CNAME record logging | CNAME/5/host1.dnslogging.test                             | Canonical name                                                                                                                                                     |

| Record Type   | Sample Format                                                   | Resource Record Data / Format                                                                          |
|---------------|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| SRV record    | SRV/5/1/2/3/host1.dnslogging.test#4/5/6/host2.dnslogging.test## | <priority>/<weight>/<port>/<target>#                                                                   |
| TXT record    | TXT/5/dns+logging##                                             | Data comprises all the texts.                                                                          |
| NAPTR record  | NAPTR/5/10/11////dnslogging#202101/54/54/dnslogging.test##      | <order>/<preference>/<flags>/<services>/<regex-expression>/<replacement string>#                       |
| DNSKEY record | DNSKEY/5/1/3/5/AwEAAanP0K+                                      | Resource record format: JZgiDBZhSON<br><flags>/<protocol>/<algorithm>/<public key in base64 encoding># |
| PTR record    | PTR/3600/test.com.#test4.com.#                                  | Domain name                                                                                            |

## Limitations of DNS logging

DNS logging has the following limitations:

- If response logging is enabled, only the following record types are logged:
  - Address (A) record
  - AAAA record
  - SOA record
  - NS record
  - MX record
  - CNAME record
  - SRV record
  - TXT record
  - NAPTR record
  - DNSKEY record
  - PTR record

For all other record types, only L3/L4 parameters, DNS Header, and Question section are logged.

- RRSIG records are not logged even if response logging is enabled.
- DNS64 is not supported.
- DNS proactive update requests or responses are logged according to the settings in the default profile.

- On the virtual server, if sessionless option and response logging is enabled, L3/L4 parameters, DNS Header, and DNS Question section are logged instead of the response.
- The maximum size of the syslog message is 1024 bytes.
- If you have set a DNS profile for a DNS policy with action type Rewrite Response, the Citrix ADC appliance does not log the query or the manipulated responses. To log the required information you must use the audit message action in the DNS policy.
- DNS transactions that are due to DNS monitoring traffic are not logged.

## Configuring DNS logging

Following is an overview of configuring DNS logging:

1. Create a Syslog action and enable DNS in the action.
2. Create a Syslog policy and specify the Syslog action in the policy.
3. Globally bind the Syslog policy to enable logging of all Citrix ADC system events. Or, bind the Syslog policy to a specific load balancing virtual server.
4. Create a DNS profile and define any of the following types of logging that you want to enable:
  - DNS Query Logging
  - DNS Answer Section Logging
  - DNS Extended Logging
  - DNS Error Logging
5. Configure any of the following, based on your requirement:
  - DNS service and virtual server for DNS
  - ADNS service
  - Citrix ADC as a forwarder
  - Citrix ADC as a resolver
6. Set the created DNS profile to one of the DNS entities.

## Configure DNS logging for Citrix ADC configured as DNS Proxy by using the CLI

1. Add a syslog action and enable DNS in the action. At the command prompt, type:

```
1 add audit syslogAction <name> (<serverIP> | -lbVserverName <string>
  >) [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat <
  dateFormat>] [-logFacility <logFacility>] [-tcp ( NONE | ALL )]
  [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME |
  LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-
  appflowExport ( ENABLED |DISABLED )] [-lsn ( ENABLED | DISABLED
  )] [-alg ( ENABLED | DISABLED )] [-transport ( TCP | UDP )] [-
  tcpProfileName <string>] [-maxLogDataSizeToHold <
  positive_integer>] [-dns ( ENABLED | DISABLED)]
```

```
2 <!--NeedCopy-->
```

**Example:**

```
add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL  
ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone  
LOCAL_TIME -dns ENABLED
```

2. Create a syslog policy and specify the created syslog action in the policy. At the command prompt, type:

```
add audit syslogPolicy <name> <rule> <action>
```

**Example:**

```
add audit syslogPolicy syslogpol1 ns_true nssyslogact1
```

3. Bind the syslog policy globally. At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>]]
```

**Example:**

```
bind system global syslogpol1
```

4. Create a DNS profile and enable any of the following type of logs that you want to configure:

- DNS Query Logging
- DNS Answer Section Logging
- DNS Extended Logging
- DNS Error Logging

At the command prompt, type:

```
add dns profile <dnsProfileName> [-dnsQueryLogging ( ENABLED | DISABLED  
) ] [-dnsAnswerSecLogging ( ENABLED | DISABLED )] [-dnsExtendedLogging  
( ENABLED | DISABLED )] [-dnsErrorLogging ( ENABLED | DISABLED )] [-  
cacheRecords ( ENABLED | DISABLED )] [-cacheNegativeResponses ( ENABLED  
| DISABLED )]
```

**Example:**

```
add dns profile dnsprofile1 -dnsQueryLogging ENABLED
```

5. Configure service of type DNS. At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
```

**Example:**

```
add service svc1 10.102.84.140 dns 53
```

6. Configure a load balancing virtual server of service type DNS.

```
add lb vserver <name> <serviceType> <ip> <port>
```

**Example:**

```
add lb vserver lb1 dns 100.100.100.10 53
```

7. Bind the service to the virtual server. At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

**Example:**

```
bind lb vserver lb1 svc1
```

8. Set the created DNS profile to the virtual server. At the command prompt, type:

```
set lb vserver <name> [ - dnsProfileName <string>]
```

**Example:**

```
set lb vserver lb1 -dnsProfileName dnsprofile1
```

**Sample DNS logging configuration for Citrix ADC appliance configured as DNS proxy**

```
1 > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel
2 CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -
   timeZone
3 LOCAL_TIME -dns ENABLED
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add lb vserver lb1 dns 100.100.100.10 53 - dnsProfileName dnsprofile1
12 Done
13 > add service svc1 10.102.84.140 dns 53
14 Done
15 > bind lb vserver lb1 svc1
16 Done
17 <!--NeedCopy-->
```

**Sample DNS logging configuration for Citrix ADC appliance configured as ADNS**

```
1 > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
2 ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
   LOCAL_TIME

4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add lb vserver lb1 dns 100.100.100.10 53 - dnsProfileName dnsprofile1
12 Done
13 > add service svc1 10.102.84.140 dns 53
14 Done
15 > bind lb vserver lb1 svc1
16 Done
17 <!--NeedCopy-->
```

### Sample DNS logging configuration for Citrix ADC appliance configured as a forwarder

```
1 > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
2 ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
   LOCAL_TIME
3 -dns ENABLED
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add dns nameserver 8.8.8.8 - dnsProfileName dnsprofile1
12 Done
13 <!--NeedCopy-->
```

### Sample DNS logging configuration for Citrix ADC appliance configured as a resolver

```
1 > add audit syslogAction nssyslogact1 10.102.151.136
2 -logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -
   logFacility LOCAL4
3 -timeZone LOCAL_TIME -dns ENABLED
```

```
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > set dns parameter -recursion enabled
12 Done
13 > add nameserver 1.1.1.100 -local dnsProfileName dnsprofile1
14 Done
15 <!--NeedCopy-->
```

## Configure policy based logging for DNS

Policy based logging enables you to specify a format for log messages. The contents of a log message are defined by using a default syntax expression. When the message action specified in the policy is performed, the Citrix ADC appliance constructs the log message from the expression and writes the message to the log file. You can configure the appliance to log only when a particular DNS policy evaluates to True.

### Note

If you have set a DNS policy with a DNS profile for the request side, a Citrix ADC appliance logs only the query.

To configure policy based logging for a DNS policy, you must first configure an audit message action. For more information about configuring an audit message action, see [Configure the NetScaler appliance for audit logging](#). After configuring the audit message action, specify the message action in a DNS policy.

## Configure policy based logging for a DNS policy by using the CLI

At the command prompt, type the following commands to configure policy based logging for a DNS policy and verify the configuration:

```
1 - add dns action <actionName> <actionType> [-IPAddress <ip_addr|
    ipv6_addr> ... | -viewName <string> | -preferredLocList <string>
    ...] [-TTL <secs>] [-dnsProfileName <string>]
2 - set dns policy <name> [<rule>] [-actionName <string>] [-logAction <
    string>]
3 - show dns policy [<name>]
4 <!--NeedCopy-->
```

**Example 1:**

In a GSLB deployment, if you want to respond with different IP addresses to the client requests coming from a particular subnet, instead of responding with IP addresses used for general purposes (such as the IP addresses of internal users), you can configure a DNS policy with the action type as DNS view. In this case, you can configure DNS logging on the specified DNS action such that you can log the specific responses.

```

1 > add dns profile dns_prof1 -dnsqueryLogging enABLED -
   dnsanswerSecLogging enABLED
2 Done
3 > add dns view dns_view1
4 Done
5 > add dns action dns_act1 viewName -view dns_view1 - dnsprofileName
   dns_prof1
6 Done
7 > add dns policy dns_pol1 "CLIENT.IP.SRC.APPLY_MASK(255.255.255.0).EQ
   (100.100.100.0)"
8 dns_act1
9 Done
10 > bind dns global dns_pol1 100 -gotoPriorityExpression END -type
   REQ_DEFAULT
11 Done
12 > bind gslb service site_1_svc -viewName dns_view1 123.1.1.1
13 Done
14 > bind gslb service site_5_svc -view dns_view1 132.1.1.1
15 Done
16 <!--NeedCopy-->

```

**Note:** In the preceding configuration, if you query for the domain configured on a GSLB virtual server, for example, *sampletest.com*, all the internal users of subnet 100.100.100.0/24 are served with the DNS view IP addresses, and the responses are logged. Client requests for other subnets are not logged.

**Example 2:**

If you want to log only the queries for the domain *example.com*, you can create a DNS profile with query logging enabled and set the DNS profile to a DNS action with the action type **NOOP**, and then create a DNS policy and set the DNS action. For example:

```

1 >add dns profile query_logging -dnsqueryLogging ENABLED
2 Done
3 >add dns action dns_act1 NOOP -dnsprofileName query_logging
4 Done

```

```
5 >add dns policy dns_pol1 DNS.REQ.QUESTION.DOMAIN.EQ("example.com")
   dns_act1
6 Done
7 <!--NeedCopy-->
```

## Configuring DNS suffixes

January 6, 2021

You can configure DNS suffixes that enable the Citrix ADC appliance to complete non-fully qualified domain names during name resolution. For example, while resolving a not fully qualified domain name abc, if a DNS suffix example.com is configured, the appliance appends the suffix to the domain name. Then it resolves the domain name. In this case, it would resolve abc.example.com. If DNS suffixes are not configured, the appliance appends a period to the non-fully qualified domain names and resolves the domain name.

### Create DNS suffixes

DNS suffixes have significance and are valid only when the Citrix ADC is configured as an end resolver or forwarder. You can specify a suffix of up to 127 characters.

**Note:** The order of DNS suffixes is important. The ADC appliance tries the configured suffixes in a serial order and stops when it gets a successful response for a suffix.

### Create DNS suffixes by using the CLI

At the command prompt, type the following commands to create a DNS suffix and verify the configuration:

```
1 - add dns suffix <dnsSuffix>
2 - show dns suffix <dnsSuffix>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns suffix example.com
2 Done
3 > show dns suffix example.com
4 1)      Suffix: example.com
5 Done
6
```

```
7 <!--NeedCopy-->
```

To remove a DNS suffix by using the Citrix ADC command line, at the command prompt, type the `rm dns suffix` command and the name of the DNS suffix.

### **Create DNS suffixes by using the GUI**

Navigate to **Traffic Management > DNS > DNS Suffix** and create DNS suffixes.

## **DNS ANY query**

September 21, 2020

An ANY query is a type of DNS query that retrieves all records available for a domain name. The ANY query must be sent to a name server that is authoritative for a domain.

### **Behavior in ADNS mode**

In the ADNS mode, the Citrix ADC appliance returns the records held in its local cache. If there are no records in the cache, the appliance returns the NXDOMAIN (negative) response.

If the Citrix ADC can match the domain delegation records, it returns the NS records. Otherwise, it returns the NS records of the root domain.

### **Behavior in DNS proxy mode**

In proxy mode, the Citrix ADC appliance checks its local cache. If there are no records in the cache, the appliance passes the query to the server.

### **Behavior for GSLB domains**

If a GSLB domain is configured on the Citrix ADC appliance and an ANY query is sent for the GSLB domain (or GSLB site domain), the appliance returns the IP address of the GSLB service that it selects through the Load Balancing decision. If the multiple IP response (MIR) option is enabled, the IP addresses of all GSLB services are sent.

For the Citrix ADC to return these records when it responds to the ANY query, all records corresponding to a GSLB domain must be configured on the Citrix ADC.

**Note**

If records for a domain are distributed between the Citrix ADC and a server, only records configured on the Citrix ADC are returned.

The Citrix ADC provides the option to configure DNS views and DNS policies. These are used for performing global server load balancing. For more information, see [Global Server Load Balancing](#).

## Configure negative caching of DNS records

September 21, 2020

The Citrix ADC appliance supports caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called negative caching. Negative caching helps speed up responses to queries about a domain.

**Note:**

Negative caching is supported only when the back-end server is configured as an authoritative DNS (ADNS) server for the queried domain.

A negative response can be one of the following:

- NXDOMAIN error message—If a negative response is present in the local cache, the Citrix ADC returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the Citrix ADC appliance. The appliance caches the response locally, then returns the error message to the client.
- NODATA error message—If the domain name in query is valid but records of the given type are not available, the appliance sends a NODATA error message.

When negative caching is enabled, the appliance caches the negative response from the DNS server and serves the future requests from the cache only. This helps speed up responses to queries and also to reduce the DNS traffic. Negative caching can be used in all deployments, that is, when a Citrix ADC appliance is serving as a proxy, as an end resolver, or as a forwarder.

You can enable or disable negative caching using DNS profile, for more information see, [DNS profiles](#). By default, negative caching is enabled in the default DNS profile (*default-dns-profile*) that are bound by default to a DNS virtual server or in the newly created DNS profile.

### Enable or disable negative caching by using the CLI

At the command prompt, type the following commands to enable or disable negative caching and verify the configuration:

```

1 - add dns profile <dnsProfileName> [-cacheRecords ( ENABLED | DISABLED
    )] [-cacheNegativeResponses (ENABLED | DISABLED )]
2 - show dns profile [<dnsProfileName>]
3 <!--NeedCopy-->

```

**Example of a default DNS profile:**

```

1 > sh dns profile default-dns-profile
2     1) default-dns-profile
3         Query logging : DISABLED           Answer section logging :
           DISABLED
4         Extended logging : DISABLED       Error logging : DISABLED
5         Cache Records : ENABLED          Cache Negative Responses: ENABLED
6 Done
7 <!--NeedCopy-->

```

**Example of a newly created DNS profile:**

```

1 > add dnsprofile dns_profile1 -cacheRecords ENABLED -
    cacheNegativeResponses ENABLED
2 Done
3 > show dns profile dns_profile1
4     1) dns_profile1
5         Query logging : DISABLED           Answer section logging :
           DISABLED
6         Extended logging : DISABLED       Error logging : DISABLED
7         Cache Records : ENABLED          Cache Negative Responses: ENABLED
8 Done
9 <!--NeedCopy-->

```

**Specify service or virtual server level DNS parameters by using the CLI**

At the command prompt, perform the following:

1. Configure the DNS profile.

```

add dns profile <dnsProfileName> [-cacheRecords ( ENABLED | DISABLED )]
[-cacheNegativeResponses (ENABLED | DISABLED )]

```

2. Bind the DNS profile to the service or virtual server.

To bind the DNS profile to the service:

```

set service <name> [-dnsProfileName <string>]

```

**Example:**

```
1 >set service service1 -dnsProfileName dns_profile1
2 Done
3 <!--NeedCopy-->
```

To bind the DNS profile to the virtual server:

```
set lb vserver <name> [-dnsProfileName <string>]
```

**Example:**

```
1 >set lb vserver lbvserver1 -dnsProfileName dns_profile1
2 Done
3 <!--NeedCopy-->
```

## Specify service or virtual server level DNS parameters by using the GUI

1. Configure the HTTP profile.  
Navigate to **System > Profiles > DNS Profile**, and create the DNS profile.
2. Bind the HTTP profile to the service or virtual server.  
Navigate to **Traffic Management > Load Balancing > Services/Virtual Servers**, and create the DNS profile, which should be bound to the service/virtual server.

## Cache EDNS0 client subnet data when the Citrix ADC appliance is in proxy mode

September 21, 2020

In Citrix ADC Proxy mode, if a back-end server that supports EDNS0 Client Subnet (ECS) sends a response containing the ECS option, the Citrix ADC appliance forwards the response as-is to the client and stores it in the cache, along with the client subnet information. Further DNS requests that are from the same subnet of the same domain, and for which the server would send the same response, are then served from the cache instead of being directed to the server.

**Note:**

- ECS caching is disabled by default. You have to enable caching of EDNS0 client-subnet data in the associated DNS profile.
- The number of subnets that you can cache for a domain is limited to the available subnet IDs, that is, 1270 in the Citrix ADC appliance. Optionally, you can set the limit to a lower number (minimum value: 1 ipv4/ipv6).

## Enable caching of ECS responses by using the CLI

At the command prompt, type:

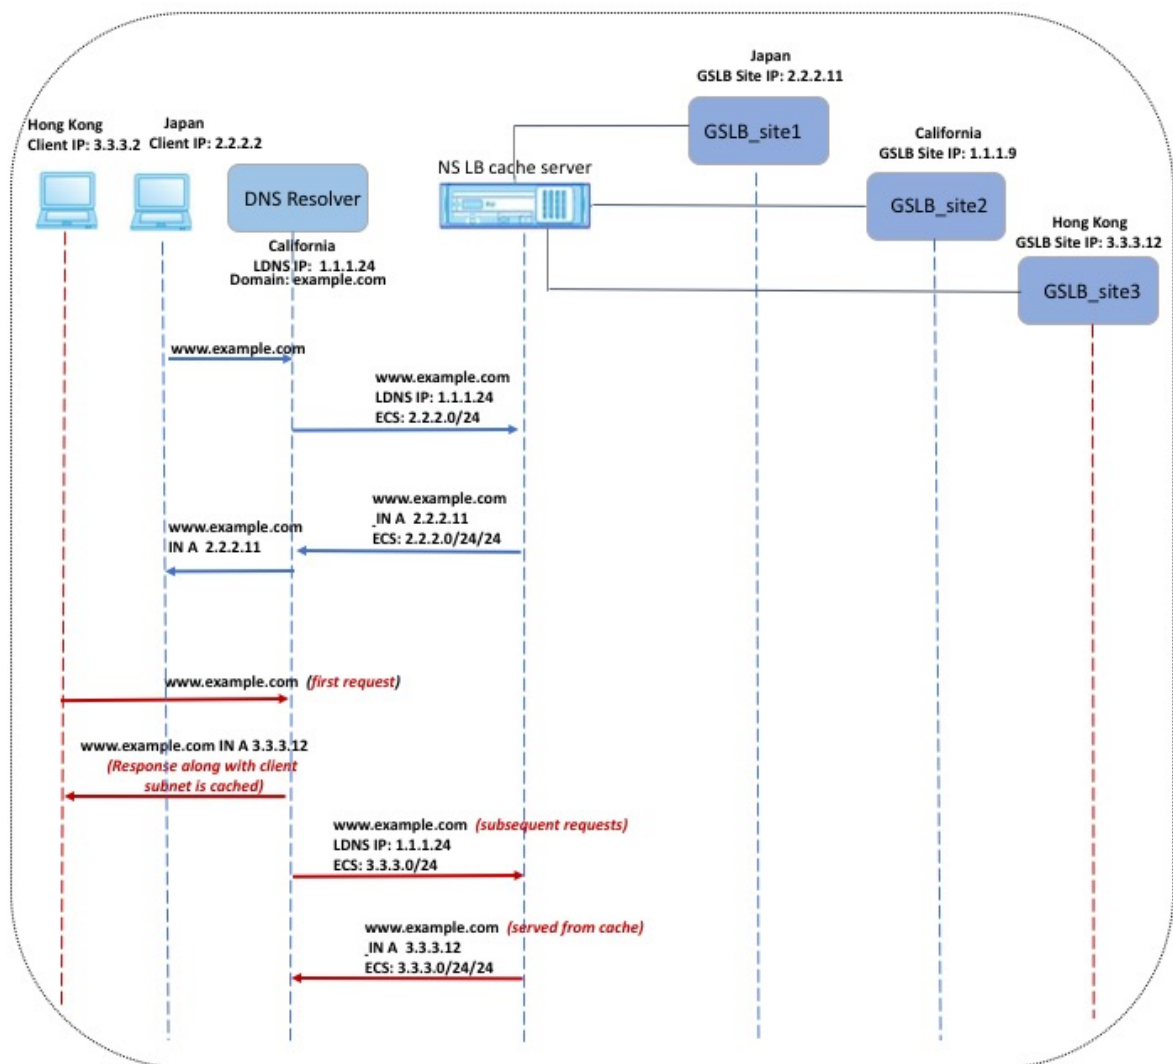

```
set dns profile <dnsProfileName> -cacheECSSubnet ( ENABLED | DISABLED )
```

## Limit the number of subnets that can be cached per domain by using the CLI

At the command prompt, type:

```
set dns profile <dnsProfileName> -maxSubnetsPerDomain <positive_integer>
```

### Example:

In the example shown in the above figure, the client at IP address 2.2.2.2 sends a query for `www.example.com` to the DNS resolver, and the DNS resolver sends the following response:

`www.example.com IN A, IP is 2.2.2.11, and ECS 2.2.2.0/24/24`

At this point, the response and the client-subnet identifier (2.2.2.0/24) are cached. Further requests from the same subnet and domain will be served from the cache.

For example, if the client's IP address is 2.2.2.100 and the query is for www.example.com, the query is served from the cache instead of being sent to the backend server.

## Domain name system security extensions

September 21, 2020

DNS Security Extensions (DNSSEC) is an Internet Engineering Task Force (IETF) standard that aims to provide data integrity and data origin authentication in communications between name servers and clients while still transmitting User Datagram Protocol (UDP) responses in clear text. DNSSEC specifies a mechanism that uses asymmetric key cryptography and a set of new resource records that are specific to its implementation.

The DNSSEC specification is described in RFC 4033, "DNS Security Introduction and Requirements," RFC 4034, "Resource Records for the DNS Security Extensions," and RFC 4035, "Protocol Modifications for the DNS Security Extensions." The operational aspects of implementing DNSSEC within DNS are discussed in RFC 4641, "DNSSEC Operational Practices."

You can configure DNSSEC on the Citrix ADC. You can generate and import keys for signing DNS zones. You can configure DNSSEC for zones for which the Citrix ADC is authoritative. You can configure the ADC as a DNS proxy server for signed zones hosted on a farm of backend name servers. If the ADC is authoritative for a subset of the records belonging to a zone for which the ADC is configured as a DNS proxy server, you can include the subset of records in the DNSSEC implementation.

## Configure DNSSEC

September 21, 2020

Configuring DNSSEC involves enabling DNSSEC on the Citrix ADC appliance, creating a Zone Signing Key and a Key Signing Key for the zone, adding the two keys to the zone, and then signing the zone with the keys.

The Citrix ADC appliance does not act as a DNSSEC resolver. DNSSEC on the ADC is supported only in the following deployment scenarios:

1. ADNS—Citrix ADC is the ADNS and generates the signatures itself.

2. Proxy—Citrix ADC acts as a DNSSEC proxy. It is assumed that the Citrix ADC is placed in front of the ADNS/LDNS servers in a trusted mode. The ADC acts only as a proxy caching entity and does not validate any signatures.

## Enable and disable DNSSEC

You must enable DNSSEC on the Citrix ADC for the ADC to respond to DNSSEC-aware clients. By default, DNSSEC is enabled.

You can disable the DNSSEC feature if you do not want the Citrix ADC to respond to clients with DNSSEC-specific information.

## Enable or disable DNSSEC by using the CLI

At the command prompt, type the following commands to enable or disable DNSSEC and verify the configuration:

```
1 - set dns parameter -dnssec ( ENABLED | DISABLED )
2 - show dns parameter
3 <!--NeedCopy-->
```

## Example:

```
1 > set dns parameter -dnssec ENABLED
2 Done
3 > show dns parameter
4     DNS parameters:
5     DNS retries: 5
6     .
7     .
8     .
9     DNSSEC Extension: ENABLED
10    Max DNS Pipeline Requests: 255
11 Done
12
13 <!--NeedCopy-->
```

## Enable or disable DNSSEC by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select or clear the Enable DNSSEC Extension check box.

## Create DNS keys for a zone

For each DNS zone that you want to sign, you must create two pairs of asymmetric keys. One pair, called the Zone Signing Key, is used to sign all the resource record sets in the zone. The second pair is called the Key Signing Key and is used to sign only the DNSKEY resource records in the zone.

When the Zone Signing Key and Key Signing Key are created, the suffix `.key` is automatically appended to the names of the public components of the keys and the suffix `.private` is automatically appended to the names of their private components.

Additionally, the Citrix ADC also creates a Delegation Signer (DS) record and appends the suffix `.ds` to the name of the record. If the parent zone is a signed zone, you must publish the DS record in the parent zone to establish the chain of trust.

When you create a key, the key is stored in the `/nsconfig/dns/` directory, but it is not automatically published in the zone. After you create a key by using the `create dns key` command, you must explicitly publish the key in the zone by using the `add dns key` command. The process of generating a key has been separated from the process of publishing the key in a zone to enable you to use alternative means to generate keys. For example, you can import keys generated by other key-generation programs (such as `bind-keygen`) by using Secure File Transfer Protocol (SFTP) and then publish the keys in the zone. For more information about publishing a key in a zone, see [Publish a DNS key in a zone](#).

Perform the steps described in this topic to create a Zone Signing Key and then repeat the steps to create a Key Signing Key. The example that follows the command syntax first creates a Zone Signing Key pair for the zone `example.com`. The example then uses the command to create a Key Signing Key pair for the zone.

### Create a DNS key by using the CLI

At the Citrix ADC command prompt, type the following command to create a DNS key:

```
create dns key -zoneName <string> -keyType <keyType> -algorithm RSASHA1 -
keySize <positive_integer> -fileNamePrefix <string>
```

#### Example:

```
1 > create dns key -zoneName example.com -keyType zsk -algorithm RSASHA1
   -keySize 1024 -fileNamePrefix example.com.zsk.rsasha1.1024
2 File Name: /nsconfig/dns/example.com.zsk.rsasha1.1024.key (public); /
   nsconfig/dns/example.com.zsk.rsasha1.1024.private (private); /
   nsconfig/dns/example.com.zsk.rsasha1.1024.ds (ds)
3 This operation may take some time, Please wait...
4 Done
5 > create dns key -zoneName example.com -keyType ksk -algorithm RSASHA1
   -keySize 4096 -fileNamePrefix example.com.ksk.rsasha1.4096
```

```
6 File Name: /nsconfig/dns/example.com.ksk.rsasha1.4096.key (public); /
   nsconfig/dns/example.com.ksk.rsasha1.4096.private (private); /
   nsconfig/dns/example.com.ksk.rsasha1.4096.ds (ds)
7 This operation may take some time, Please wait...
8 Done
9 <!--NeedCopy-->
```

### Create a DNS key by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details area, click **Create DNS Key** and create a DNS key.

Note: For

File Name Prefix, if you want to modify the file name prefix of an existing key, click the arrow next to the

Browse button, click either

Local or

Appliance (depending on whether the existing key is stored on your local computer or in the /nsconfig/dns/ directory on the appliance), browse to the location of the key, and then double-click the key. The

File Name Prefix box is populated with only the prefix of the existing key. Modify the prefix accordingly.

### Publish a DNS key in a zone

A key (Zone Signing Key or Key Signing Key) is published in a zone by adding the key to the Citrix ADC. A key must be published in a zone before you sign the zone.

Before you publish a key in a zone, the key must be available in the /nsconfig/dns/ directory. Therefore, if you used other means to generate the key—means other than the create dns key command on the Citrix ADC (for example, by using the bind-keygen program on another computer)—make sure that the key is added to the /nsconfig/dns/ directory before you publish the key in the zone.

If the key has been generated by another program, you can import the key to your local computer and use the Citrix ADC configuration utility to add the key to the /nsconfig/dns/ directory. Or, you can use other means to import the key to the directory, such as the Secure File Transfer Protocol (SFTP).

You must use the add dns key command for each public-private key pair that you want to publish in a given zone. If you created a Zone Signing Key pair and a Key Signing Key pair for a zone, use the add dns key command to first publish one of the key pairs in the zone and then repeat the command to publish the other key pair. For each key that you publish in a zone, a DNSKEY resource record is created in the zone.

The example that follows the command syntax first publishes the Zone Signing Key pair (that was created for the example.com zone) in the zone. The example then uses the command to publish the Key Signing Key pair in the zone.

### Publish a key in a zone by using the CLI

At the command prompt, type the following command to publish a key in a zone and verify the configuration:

```
1 - add dns key <keyName> <publickey> <privatekey> [-expires <
    positive_integer> [<units>]] [-notificationPeriod <positive_integer>
    [<units>]] [-TTL <secs>]
2 - show dns zone [<zoneName> | -type <type>]
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.
    com.zsk.rsasha1.1024.private
2 Done
3 > add dns key example.com.ksk example.com.ksk.rsasha1.4096.key example.
    com.ksk.rsasha1.4096.private
4 Done
5 > show dns zone example.com
6     Zone Name : example.com
7     Proxy Mode : NO
8     Domain Name : example.com
9         Record Types : NS SOA DNSKEY
10    Domain Name : ns1.example.com
11        Record Types : A
12    Domain Name : ns2.example.com
13        Record Types : A
14 Done
15 <!--NeedCopy-->
```

### Publish a key in a DNS zone by using the GUI

Navigate to

Traffic Management > DNS > Keys.

#### **Note:** For

Public Key and

Private Key, to add a key that is stored on your local computer, click the arrow next to the

Browse button, click

Local, browse to the location of the key, and then double-click the key.

## Configure a DNS key

You can configure the parameters of a key that has been published in a zone. You can modify the key's expiry time period, notification period, and time-to-live (TTL) parameters. If you change the expiry time period of a key, the Citrix ADC automatically re-signs all the resource records in the zone with the key, provided that the zone is currently signed with the particular key.

## Configure a key by using the CLI

At the command prompt, type the following command to configure a key and verify the configuration:

```
1 - set dns key <keyName> [-expires <positive_integer> [<units>]] [-  
    notificationPeriod <positive_integer> [<units>]] [-TTL <secs>]  
2 - show dns key [<keyName>]  
3 <!--NeedCopy-->
```

### Example:

```
1 > set dns key example.com.ksk -expires 30 DAYS -notificationPeriod 3  
    DAYS -TTL 3600  
2 Done  
3 > show dns key example.com.ksk  
4 1) Key Name: example.com.ksk  
5 Expires: 30 DAYS Notification: 3 DAYS TTL: 3600  
6 Public Key File: example.com.ksk.rsasha1.4096.key  
7 Private Key File: example.com.ksk.rsasha1.4096.private  
8 Done  
9 <!--NeedCopy-->
```

## Configure a key by using the GUI

1. Navigate to Traffic Management > DNS > Keys.
2. In the details pane, click the key that you want to configure, and then click Open.
3. In the Configure DNS Key dialog box, modify the values of the following parameters as shown:
  - Expires—expires
  - Notification Period—notificationPeriod
  - TTL—TTL
4. Click OK.

## Sign and unsign a DNS zone

To secure a DNS zone, you must sign the zone with the keys that have been published in the zone. When you sign a zone, the Citrix ADC creates a Next Secure (NSEC) resource record for each owner name. Then, it uses the Key Signing Key to sign the DNSKEY resource record set. Finally, it uses the Zone Signing Key to sign all the resource record sets in the zone, including the DNSKEY resource record sets and NSEC resource record sets. Each sign operation results in a signature for the resource record sets in the zone. The signature is captured in a new resource record called the RRSIG resource record.

After you sign a zone, you must save the configuration.

### Sign a zone by using the CLI

At the command prompt, type the following command to sign a zone and verify the configuration:

```
1 - sign dns zone <zoneName> [-keyName <string> ...]
2 - show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
3 - save config
4 <!--NeedCopy-->
```

### Example:

```
1 > sign dns zone example.com -keyName example.com.zsk example.com.ksk
2 Done
3 > show dns zone example.com
4     Zone Name : example.com
5     Proxy Mode : NO
6     Domain Name : example.com
7         Record Types : NS SOA DNSKEY RRSIG NSEC
8     Domain Name : ns1.example.com
9         Record Types : A RRSIG NSEC
10    Domain Name : ns2.example.com
11        Record Types : A RRSIG
12    Domain Name : ns2.example.com
13        Record Types : RRSIG NSEC
14 Done
15 > save config
16 Done
17 <!--NeedCopy-->
```

### Unsign a zone by using the CLI

At the command prompt, type the following command to unsign a zone and verify the configuration:

```
1 -  unsign dns zone <zoneName> [-keyName <string> ...]
2 -  show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
3 <!--NeedCopy-->
```

**Example:**

```
1 > unsign dns zone example.com -keyName example.com.zsk example.com.ksk
2 Done
3 > show dns zone example.com
4     Zone Name : example.com
5     Proxy Mode : NO
6     Domain Name : example.com
7         Record Types : NS SOA DNSKEY
8     Domain Name : ns1.example.com
9         Record Types : A
10    Domain Name : ns2.example.com
11        Record Types : A
12 Done
13 <!--NeedCopy-->
```

**Sign or unsign a zone by using the GUI**

1. Navigate to Traffic Management > DNS > Zones.
2. In the details pane, click the zone that you want to sign, and then click Sign/Unsign.
3. In the Sign/Unsign DNS Zone dialog box, do one of the following:
  - To sign the zone, select the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to sign the zone.  
You can sign the zone with more than one Zone Signing Key or Key Signing Key pair.
  - To unsign the zone, clear the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to unsign the zone.  
You can unsign the zone with more than one Zone Signing Key or Key Signing Key pair.
4. Click OK.

**View the NSEC records for a given record in a zone**

You can view the NSEC records that the Citrix ADC automatically creates for each owner name in the zone.

**View the NSEC record for a given record in a zone by using the CLI**

At the command prompt, type the following command to view the NSEC record for a given record in a zone:

```
show dns nsecRec [<hostName> | -type (ADNS | PROXY | ALL)]
```

**Example:**

```
1 > show dns nsecRec example.com
2 1)      Domain Name : example.com
3         Next Nsec Name: ns1.example.com
4         Record Types : NS SOA DNSKEY RRSIG NSEC
5 Done
6 <!--NeedCopy-->
```

**View the NSEC record for given record in a zone by using the GUI**

1. Navigate to Traffic Management > DNS > Records > Next Secure Records.
2. In the details pane, click the name of the record for which you want to view the NSEC record. The NSEC record for the record you select is displayed in the Details area.

**Remove a DNS key**

You remove a key from the zone in which it is published when the key has expired or if the key has been compromised. When you remove a key from the zone, the zone is automatically unsigned with the key. Removing the key with this command does not remove the key files present in the /nsconfig/dns/ directory. If the key files are no longer needed, they have to be explicitly removed from the directory.

**Remove a key from the Citrix ADC by using the CLI**

At the command prompt, type the following command to remove a key and verify the configuration:

```
1 - rm dns key <keyName>
2 - show dns key <keyName>
3 <!--NeedCopy-->
```

**Example:**

```
1 > rm dns key example.com.zsk
2 Done
3 > show dns key example.com.zsk
4 ERROR: No such resource [keyName, example.com.zsk]
5
```

## Remove a key from the Citrix ADC by using the GUI

1. Navigate to **Traffic Management > DNS > Keys**.
2. In the details pane, click the name of the key that you want to remove from the ADC, and then click Remove.

## Configure DNSSEC when the Citrix ADC is authoritative for a zone

September 21, 2020

When the Citrix ADC is authoritative for a given zone, all the resource records in the zone are configured on the ADC. To sign the authoritative zone, you must create keys (the Zone Signing Key and the Key Signing Key) for the zone, add the keys to the ADC, and then sign the zone, as described in [Create DNS keys for a zone](#), [Publish a DNS key in a zone](#), and [Sign and unsign a DNS zone](#), respectively.

If any global server load balancing (GSLB) domains configured on the ADC belong to the zone being signed, the GSLB domain names are signed along with the other records that belong to the zone.

After you sign a zone, responses to requests from DNSSEC-aware clients include the RRSIG resource records along with the requested resource records. DNSSEC must be enabled on the ADC. For more information about enabling DNSSEC, see [Enable and disable DNSSEC](#).

Finally, after you configure DNSSEC for the authoritative zone, you must save the Citrix ADC configuration.

## Configure DNSSEC for a zone for which the Citrix ADC is a DNS proxy server

September 21, 2020

The procedure for signing a zone for which the Citrix ADC is configured as a DNS proxy server depends on whether or not the ADC owns a subset of the zone information owned by the backend name servers. If it does, the configuration is considered a *partial zone ownership configuration*. If the ADC does not own a subset of the zone information, the Citrix ADC configuration for managing the backend servers is considered a *zone-less DNS proxy server configuration*. The basic DNSSEC configuration tasks for both Citrix ADC configurations are the same. However, signing the partial zone on the Citrix ADC requires some additional configuration steps.

**Note:** The terms

*zone-less proxy server configuration* and

*partial zone* are used only in the context of the Citrix ADC appliance.

**Important:** When configured in proxy mode, the ADC does not perform signature verification on DNSSEC responses before updating the cache.

If you configure the ADC as a DNS proxy to load balance DNSSEC aware resolvers (servers), you must set the Recursion Available option while configuring the DNS virtual server. If a DNSSEC query arrives with Checking Disabled (CD) bit set, the query is passed on to the server with the CD bit retained, and the response from the server is not cached. In releases prior to 10.5.e build xx.x, the ADC unset the CD bit before passing it to the server and also cached the server response.

### **Configure DNSSEC for a zone-less DNS proxy server configuration**

For a zone-less DNS proxy server configuration, zone signing must be performed on the backend name servers. On the Citrix ADC, you configure the ADC as a DNS proxy server for the zone. You create a load balancing virtual server of protocol type DNS, configure services on the ADC to represent the name servers, and then bind the services to the load balancing virtual server. For more information about these configuration tasks, see [Configure the NetScaler as a DNS proxy server](#).

When a client sends the ADC a DNS request with the DNSSEC OK (DO) bit set, the ADC checks its cache for the requested information. If the resource records are not available in its cache, the ADC forwards the request to one of the DNS name servers, and then relays the response from the name server to the client. Additionally, the ADC caches the RRSIG resource records along with the response from the name server. Subsequent requests from DNSSEC-aware clients are served from the cache (including the RRSIG resource records), subject to the time-to-live (TTL) parameter. If a client sends a DNS request without setting the DO bit, the ADC responds with only the requested resource records, and does not include the RRSIG resource records that are specific to DNSSEC.

### **Configure DNSSEC for a partial zone ownership configuration**

In some Citrix ADC configurations, even though the authority for a zone lies with the backend name servers, a subset of the resource records that belong to the zone might be configured on the Citrix ADC. The ADC owns (or is authoritative for) only this subset of records. Such a subset of records can be considered to constitute a *partial zone* on the ADC. The ADC owns the partial zone. All other records are owned by the backend name servers.

A typical partial zone configuration on the Citrix ADC is seen when global server load balancing (GSLB) domains are configured on the ADC, and the GSLB domains are a part of a zone for which the backend name servers are authoritative.

Signing a zone that includes only a partial zone on the ADC involves including the partial zone information in the backend name server zone files, signing the zone on the backend name servers, and then signing the partial zone on the ADC. The same key set must be used to sign the zone on the name servers and the partial zone on the ADC.

### **Sign the zone on the backend name servers**

1. Include the resource records that are contained in the partial zone, in the zone files of the name servers.
2. Create keys and use the keys to sign the zone on the backend name servers.

### **Sign the partial zone on the Citrix ADC**

1. Create a zone with the name of the zone that is owned by the backend name servers. When configuring the partial zone, set the proxyMode parameter to YES. This zone is the partial zone that contains the resource records owned by the ADC.

For example, if the name of the zone that is configured on the backend name servers is example.com, you must create a zone named example.com on the ADC, with the proxyMode parameter set to YES. For more information about adding a zone, see [Configure a DNS zone](#).

#### **Note**

Do not add SOA and NS records for the zone. These records should not exist on the ADC for a zone for which the ADC is not authoritative.

2. Import the keys (from one of the backend name servers) to the ADC and then add them to the /n-sconfig/dns/ directory. For more information about how you can import a key and add it to the ADC, see [Publish a DNS key in a zone](#).
3. Sign the partial zone with the imported keys. When you sign the partial zone with the keys, the ADC generates RRSIG and NSEC records for the resource record sets and individual resource records in the partial zone, respectively. For more information about signing a zone, see [sign and unsign a DNS zone](#).

## **Configure DNSSEC for GSLB domain names**

September 21, 2020

If global server load balancing (GSLB) is configured on the Citrix ADC and the ADC is authoritative for the zone to which the GSLB domain names belong, all GSLB domain names are signed when the zone

is signed. For more information about signing a zone for which the ADC is authoritative, see [Configure DNSSEC when the Citrix ADC appliance is authoritative for a zone](#).

If the GSLB domains belong to a zone for which the backend name servers are authoritative, you must first sign the zone on the name servers, and then sign the partial zone on the ADC to complete the DNSSEC configuration for the zone. For more information, see [Configure DNSSEC for a partial zone ownership configuration](#).

## Zone Maintenance

September 21, 2020

From a DNSSEC perspective, zone maintenance involves rolling over zone signing keys and key signing keys when key expiry is imminent. These zone maintenance tasks must be performed manually. The zone is re-signed automatically and does not require any manual intervention.

### Re-sign an updated zone

When a zone is updated (add a record or modify an existing record), the appliance automatically re-signs the new (or modified) record. If a zone contains multiple zone signing keys, the appliance re-signs the new (or modified) record with the key used to sign the zone.

### Roll over DNSSEC keys

**Note:** Manually roll over the DNSSEC keys (KSK, ZSK) before they expire.

On the Citrix ADC, you can use the prepublish and double signature methods to perform a rollover of the zone signing key and key signing key. More information about these two rollover methods is available in RFC 4641, “DNSSEC Operational Practices.”

The following topics map commands on the ADC to the steps in the rollover procedures discussed in RFC 4641.

The key expiry notification is sent through an SNMP trap called `dnskeyExpiry`. Three MIB variables, `dnskeyName`, `dnskeyTimeToExpire`, and `dnskeyUnitsOfExpiry` are sent along with the `dnskeyExpiry` SNMP trap. For more information, see *Citrix NetScaler SNMP OID Reference* at [NetScaler 12.0 SNMP OID Reference](#).

### Prepublish key rollover

RFC 4641, “DNSSEC Operational Practices” defines four stages for the prepublish key rollover method: initial, new DNSKEY, new RRSIGs, and DNSKEY removal. Each stage is associated with a set of tasks

that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both key signing keys and zone signing keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

**Example:**

Consider the key, `example.com.zsk1`, with which the zone `example.com` is signed. The zone contains only those RRSIGs generated by the `example.com.zsk1` key, which is due for expiry. The key signing key is `example.com.ksk1`.

- **Stage 2: New DNSKEY.** A new key is created and published in the zone (that is, the key is added to the ADC), but the zone is not signed with the new key until the pre-roll phase is complete. In this stage, the zone contains the old key, the new key, and the RRSIGs generated by the old key. Publishing the new key for the complete duration of the pre-roll phase gives the DNSKEY resource record (that corresponds to the new key) enough time to propagate to the secondary name servers.

**Example:**

A new key `example.com.zsk2` is added to the `example.com` zone. The zone is not signed with `example.com.zsk2` until the pre-roll phase is complete. The `example.com` zone contains DNSKEY resource records for both `example.com.zsk1` and `example.com.zsk2`.

**Citrix ADC commands:**

Perform the following tasks on the ADC:

- Create a DNS key by using the `create dns key` command.

For more information about creating a DNS key, including an example, see [Create DNS keys for a zone](#).

- Publish the new DNS key in the zone by using the `add dns key` command.

For more information about publishing the key in the zone, including an example, see [Publish a DNS key in a zone](#).

- **Stage 3: New RRSIGs.** The zone is signed with the new DNS key and then unsigned with the old DNS key. The old DNS key is not removed from the zone and remains published until the RRSIGs generated by the old key expire.

**Example:**

The zone is signed with `example.com.zsk2` and then unsigned with `example.com.zsk1`. The zone continues to publish `example.com.zsk1` until the RRSIGs generated by `example.com.zsk1` expire.

**Citrix ADC commands:**

Perform the following tasks on the ADC:

- Sign the zone with the new DNS key by using the `sign dns zone` command.
- Unsign the zone with the old DNS key by using the `unsign dns zone` command.

For more information about signing and unsigning a zone, including examples, see [Sign and unsign a DNS zone](#).

- **Stage 4: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

**Example:**

The old DNS key `example.com.zsk1` is removed from the `example.com` zone.

**Citrix ADC commands**

On the ADC, you remove the old DNS key by using the `rm dns key` command. For more information about removing a key from a zone, including an example, see [Remove a DNS key](#).

**Double signature key rollover**

RFC 4641, “DNSSEC Operational Practices” defines three stages for double signature key rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both key signing keys and zone signing keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

**Example:**

Consider the key, `example.com.zsk1`, with which the zone `example.com` is signed. The zone contains only those RRSIGs generated by the `example.com.zsk1` key, which is due for expiry. The key signing key is `example.com.ksk1`.

- **Stage 2: New DNSKEY.** The new key is published in the zone and the zone is signed with the new key. The zone contains the RRSIGs that are generated by the old and the new keys. The minimum duration for which the zone must contain both sets of RRSIGs is the time required for all the RRSIGs to expire.

**Example:**

A new key `example.com.zsk2` is added to the `example.com` zone. The zone is signed with `example.com.zsk2`. The `example.com` zone now contains the RRSIGs generated from both keys.

**Citrix ADC commands**

Perform the following tasks on the ADC:

- Create a DNS key by using the `create dns key` command.

For more information about creating a DNS key, including an example, see [Create DNS keys for a zone](#).

- Publish the new key in the zone by using the `add dns key` command.

For more information about publishing the key in the zone, including an example, see [Publish a DNS key in a zone](#).

- Sign the zone with the new key by using the `sign dns zone` command.

For more information about signing a zone, including examples, see [Sign and unsign a DNS zone](#).

- **Stage 3: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

**Example:**

The old DNS key `example.com.zsk1` is removed from the `example.com` zone.

**Citrix ADC commands:**

On the ADC, you remove the old DNS key by using the `rm dns key` command.

For more information about removing a key from a zone, including an example, see [Remove a DNS key](#).

## Offload DNSSEC operations to the Citrix ADC

September 21, 2020

For DNS zones for which your DNS servers are authoritative, you can offload DNSSEC operations to the Citrix ADC. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response on the fly before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see [Configure a DNS zone](#).

You must create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see [Domain name system security extensions](#).

After you configure DNS offloading, you must flush the DNS cache on the Citrix ADC. Flushing the DNS cache ensures that any unsigned records in the cache are removed and subsequently replaced by signed records. For information about flushing the DNS cache, see [Flush DNS records](#).

### Enable DNSSEC offloading for a zone by using the CLI

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

```
1 - add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec
    ( ENABLED | DISABLED )
2 - show dns zone
3 <!--NeedCopy-->
```

#### Example:

```
1 > add dns zone example.com -proxyMode YES -dnssecOffload ENABLED nsec
    ENABLED
2 Done
3 > show dns zone example.com
4     Zone Name : example.com
5     Proxy Mode : YES
6     DNSSEC Offload: ENABLED     NSEC: ENABLED
7 Done
8 <!--NeedCopy-->
```

### Enable DNSSEC offloading for a zone by using the GUI

1. Navigate to **Traffic Management > DNS > Zones**.

2. In the details pane, do one of the following:
  - To create a zone on the Citrix ADC, click Add.
  - To configure DNSSEC offloading for an existing zone, double-click the zone.
3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.
4. Optionally, if you want the Citrix ADC to generate NSEC records for the zone, select the NSEC check box.

## Admin partition support for DNSSEC

September 21, 2020

In a partitioned Citrix ADC appliance, the DNS keys that are generated are stored in the following locations:

- Default partition: `/nsconfig/dns/`
- Non-default partition: `/nsconfig/partitions/<partitionname>/dns/`

You can now add a password to the DNS key. To add a password to the DNS key, you must first add the password in the `create dns key` command and then provide the same password in the `add dns key` command when adding the DNS key to the Citrix ADC appliance. For example:

```
create dns key -zoneName com -keytype ksK -algorithm rsASHA1 -keysize 4096
- fileNamePrefix com.ksk.rsasha1.4096 -password 1jsfd3Wa
add dns key com.zsk.4096 /nsconfig/dns/com.zsk.rsasha1.4096.private -
password 1jsfd3Wa
```

### Note:

- For default partitioned environment, the keys are read from default location `/nsconfig/dns/`. However, if the keys are stored in a different location, the path name has to be provided in the `add dns key -private` command. Example, `add dns key -private <path name>`.
- For non-default partitioned environment, the keys are read from the default location `/nsconfig/partitions/<partitionname>/dns/`.

## Supporting wildcard DNS domains

September 21, 2020

Wildcard DNS domains are used to handle requests for nonexistent domains and subdomains. In a zone, if you want to redirect queries for all nonexistent domains or subdomains to a particular server,

you can use wildcard domains rather than creating a separate Resource Record (RR) for each such domain. The most common use of a wildcard DNS domain is to create a zone that can be used to forward mail from the internet to some other mail system.

In DNS resolution, the wildcard domain is supported by wildcard RRs. The wildcard RRs are used to synthesize the responses to queries for a nonexistent domain name. For example, if you queried <http://image.example.com>, and the subdomain “image” did not exist, you could be redirected to [example.com](http://example.com).

A wildcard record has an asterisk (\*) character as the leftmost label of a domain name. For example, \*.example.com. An asterisk at any other place in the domain name does signify a wildcard DNS record. For example, new\*.example.com is not a valid wildcard DNS record.

**Note**

- Wildcard domain is supported only when the Citrix ADC appliance is authoritative for the zone and is configured as an ADNS or a DNS proxy server.
- Wildcard domain is not supported for NS and SOA records.
- Wildcard domain cannot be applied when the query is in another zone.
- Wildcard domain cannot be applied when the QNAME or a name between the wildcard domain and the QNAME is known to exist.

**Example configuration**

```
1 add dns soaRec example.com -originServer n1.example.com -contact admin.  
  example.com  
2  
3 add dns nsRec example.com n1.example.com  
4  
5 add dns nsRec example.com n2.example.com  
6  
7 add dns zone example.com -proxyMode no  
8  
9 add dns addrec www.example.com 2.2.2.2  
10  
11 add dns addrec *.example.com 10.10.10.10  
12  
13 add dns addrec *.example.com 10.10.10.11  
14  
15 add dns aaaarec *.example.com 2001::1  
16 <!--NeedCopy-->
```

In the example, wildcard domain name is added for A and AAAA record.

When a query is received for a domain name that exists in the zone, say [www.example.com](http://www.example.com), the Citrix ADC appliance responds with the corresponding response; that is 2.2.2.2 in the example.

For a nonexistent domain name that matches with a wildcard type, a synthesized response is delivered.

In the example, the Citrix ADC appliance responds with 10.10.10.10 and 10.10.10.11 for domain name [nonexist.example.com](http://nonexist.example.com) or [xyz.example.com](http://xyz.example.com).

Wildcard synthesize is not applicable for a domain name that exists in the zone.

For example, for the query [www.example.com](http://www.example.com) and type AAAA, the Citrix ADC appliance does not synthesize with wildcard, because [www.example.com](http://www.example.com) exists with type A. In the example, the Citrix ADC appliance responds with a NODATA response.

For a query say [abc.example.com](http://abc.example.com) and type AAAA, the Citrix ADC appliance responds with a synthesized response; that is 2001::1 in the example.

## Mitigate DNS DDoS attacks

January 6, 2021

DNS servers are one of the most critical components of a network, and they must be defended against attacks. One of the most basic types of DNS attacks is the DDoS attack. Attacks of this type are on the rise and can be destructive. You can do the following to mitigate DDoS attacks:

- Flush negative records.
- Restrict the time to live (TTL) of negative records.
- Preserve Citrix ADC memory by limiting the memory consumed by the DNS cache.
- Retain DNS records in the cache.
- Enable DNS cache bypass.

You can also limit DNS queries to a single packet and thus prevent [Slowloris](#) attacks.

### Flush negative records

A DNS attack fills the cache with negative records (NXDOMAIN and NODATA). As a result, responses to legitimate requests are not cached, so new requests are sent to a back-end server for DNS resolution. Responses are therefore delayed.

You can now flush the negative DNS records from the Citrix ADC appliance's DNS cache.

### Flush negative cache records by using the CLI

At the command prompt, type:

```
flush dns proxyrecords -type (dnsRecordType | negRecType)NXDOMAIN | NODATA
```

#### Example:

```
flush dns proxyrecords -negRecType NODATA
```

### Flush of negative cache records by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS > Records**.
2. In the details pane, click **Flush Proxy Records**.
3. In the **Flush Type** box, select **Negative Records**.
4. In the **Negative Records Type** box, select either **NXDOMAIN** or **NODATA**.

### Protection against random subdomain and NXDOMAIN attacks

To prevent random subdomain and NXDOMAIN attacks, you can restrict the DNS cache memory, and you can adjust the TTL values for negative records.

To limit the amount of memory consumed by the DNS cache, you can specify the maximum cache size and the cache size (in MB) for storing negative responses. When either limit is reached, no more entries are added to the cache. Also, syslog messages are logged and, if you have configured SNMP traps, SNMP traps are generated. If these limits are not set, caching continues until the system memory is exhausted.

A higher TTL value for negative records can result in storing records that are not valuable for a long time. A lower TTL value results in sending more requests to the back-end server.

The TTL of the negative record is set to a value that can be the lesser of the TTL value or the "Expires" value of the SOA record.

#### Note:

- This limitation is added per packet engine. For example, if the maxCacheSize is set to 5 MB and the appliance has 3 packet engines, the total cache size is 15 MB.
- The cache size for the negative records must be less than or equal to the maximum cache size.
- If you reduce the DNS cache memory limit to a value lower than the amount of data already cached, the cache size remains above the limit until the data ages out. That is, exceeds its TTL or is flushed (`flush dns proxyrecords` command, or Flush Proxy Records in the Citrix ADC GUI).
- To configure SNMP traps, see [Configuring the NetScaler to Generate SNMP Traps](#).

### Limit the memory consumed by the DNS Cache by using the CLI

At the command prompt, type:

```
set dns parameter -maxCacheSize <MBytes> -maxNegativeCacheSize <MBytes>
```

#### Example:

```
set dns parameter - maxCacheSize 100 -maxNegativeCacheSize 25
```

### Limit the memory consumed by the DNS Cache by using the GUI

Navigate to **Configuration > Traffic Management > DNS**, click **Change DNS Settings**, and set the following parameters:

- Max Cache Size in MB
- Max Negative Cache Size in MB

### Restrict the TTL of negative records by using the CLI

At the command prompt, type:

```
set dns parameter -maxnegcacheTTL <secs>
```

#### Example:

```
set dns parameter -maxnegcacheTTL 360
```

### Restrict the TTL of negative records by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS**.
2. Click **Change DNS Settings** and set the **Max Negative Cache TTL in sec** parameter.

### Retain DNS records in the cache

An attack can flood the DNS cache with non-important entries but can cause flushing of the already cached legitimate records to make room for the new entries. To prevent attacks from filling the cache with invalid data, you can retain the legitimate records even after they exceed their TTL values.

If you enable the `cacheNoExpire` parameter, the records currently in the cache are retained until you disable the parameter.

#### Note:

- This option can be used only when the maximum cache size is specified (`maxCacheSize` parameter).
- If `maxnegcacheTTL` is configured and `cacheNoExpire` is enabled, `cacheNoExpire` takes priority.

### Retain DNS records in the cache by using the CLI

At the command prompt, type:

```
set dns parameter -cacheNoExpire ( ENABLED | DISABLED )
```

#### Example:

```
set dns parameter -cacheNoExpire ENABLED
```

### Retain DNS records in the cache by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. Select **Cache No Expire**.

### Enable DNS cache bypass

For greater visibility and control of DNS requests, set the `cacheHitBypass` parameter to forward all requests to the back-end servers and allow the cache to be built but not used. After the cache is built, you can disable the parameter so that requests are served from the cache.

### Enable DNS cache bypass by using the CLI

At the command prompt, type:

```
set dns parameter -cacheHitBypass ( ENABLED | DISABLED )
```

#### Example:

```
set dns parameter -cacheHitBypass ENABLED
```

### Enable DNS cache bypass by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. Select **Cache Hit Bypass**.

### Prevent the Slowloris attack

A DNS query spanning multiple packets, presents the potential threat of a `Slowloris` attack. The Citrix ADC appliance can silently drop DNS queries that are split into multiple packets.

You can set the `splitPktQueryProcessing` parameter to `ALLOW` or `DROP` a DNS query if the query is split into multiple packets.

**Note:** This setting is applicable only for DNS TCP.

### Limit the DNS queries to a single packet by using the CLI

At the command prompt, type:

```
set dns parameter -splitPktQueryProcessing ( ALLOW | DROP )
```

#### Example:

```
set dns parameter -splitPktQueryProcessing DROP
```

### Limit DNS queries to a single packet by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. In the **Split Packet Query Processing** box, choose **ALLOW** or **DROP**.

### Collect statistics of the DNS responses served from the cache

You can collect statistics of the DNS responses served from the cache. Then use these statistics to create a threshold beyond which more DNS traffic is dropped, and enforce this threshold with a bandwidth based policy. Previously, bandwidth calculation for a DNS load balancing virtual server was not accurate, because the number of requests served from the cache was not reported.

In proxy mode, the statistics for Request bytes, Response bytes, Total Packets received, and Total Packets sent statistics are continuously updated. Previously, these statistics were not always updated, particularly for a DNS load balancing virtual server.

Proxy mode also now enables you to determine the number of DNS responses served from the cache. To collect these statistics, the following options have been added to the `stat lb vserver <DNSvirtualServerName>` command:

- **Requests** – Total number of requests received by the DNS or DNS\_TCP virtual server. Includes the requests forwarded to the back end and the requests answered from the cache.
- **Vserver hits** – Total number of requests forwarded to the back end. The number of requests served from the cache is the difference between the total number of requests and the number of requests served from the virtual server.
- **Responses** – Total number of responses sent by this virtual server. For example, if a DNS LB virtual server received 5 DNS requests, forwarded 3 of them to the back end, and served 2 of them from the cache, the corresponding value of each of these statistics would be as follows:
  - **Vserver hits:** 3
  - **Requests:** 5
  - **Responses:** 5

## Service discovery using DNS SRV records

September 21, 2020

An SRV record (service record) is a specification of data in the Domain Name System that defines the location, that is the hostname and the port number of servers for specified services. The record also defines the weight and priority of each server.

### Example of an SRV record:

`_http._tcp.example.com. 100 IN SRV 10 60 5060 a.example.com.`

The following table describes each item in an SRV record:

| Service | Protocol | Name        | TTL | Class | SRV | Priority | Weight | Port | Target        |
|---------|----------|-------------|-----|-------|-----|----------|--------|------|---------------|
| HTTP    | TCP      | example.com | 100 | IN    | SRV | 10       | 60     | 5060 | a.example.com |

You can use the DNS SRV records to discover the service endpoints. Citrix ADC appliance is configured to periodically query the DNS servers with the SRV record associated with a service. On receiving the SRV record, each of the target host published in the SRV record is bound to a service group associated with the service. Each of the bindings inherits the port, priority, and weight from the SRV record. For each service deployment the user has to configure the Citrix ADC appliance once while bringing it up, thus making it a single touch deployment for applications.

### Use case: Load balancing microservices

Applications are moving toward microservice architecture from monolithic architectures. Movement to microservice architecture along with backend server autoscale solution, is making application deployment more dynamic. To support such a dynamic deployment, proxies or ADC must be able to dynamically detect the backend application or service instances and absorb them into proxy configuration.

The service discovery using DNS SRV records feature aids configuration of Citrix ADC appliance in such a dynamic deployment scenario. Application developers can use some of the orchestration platforms to deploy the application. Orchestration platforms while instantiating containers during application deployment, might not assign protocol specific standard port for each of these containers. In such scenarios, discovering the port information becomes the key to configuring the Citrix ADC appliance. SRV records are helpful in such a scenario. SRV record parameters such as the priority and weight can be used for better load balancing of applications.

- Priority parameter can be used to dictate the priority of the server pool.
- Weight parameter can be used to dictate the capacity of the backend service instances and hence can be used for weighted load balancing.

- Whenever there is a change in the back-end server pool, for example a backend instance is removed from the pool, the instance is removed gracefully only after all the existing client connections are honored.

**Note:**

- An A/AAAA records based service discovery, all resolved IP addresses have the same weight because you assign the weight to the domain being resolved.
- If the weight in SRV response is greater than 100, then services are not created.

## Priority based load balancing using SRV records

You can use SRV records to perform priority-based load balancing. The priority based server pool can be an alternative for the backup virtual servers. The ns.conf file requires minimal configuration compared to the backup virtual servers.

In priority based load balancing using SRV records, a priority number is assigned to each of the server pool. Lesser the number, higher is the priority. One of the servers in the highest priority pool is selected for load balancing based on the server's health and availability. If all the servers in the highest priority server pool are down, then the servers that have the next highest priority are selected for load balancing. However, if the servers in the highest priority server pool are up again, then the servers are selected from the highest priority pool again.

Switching from one priority server pool to another server pool occurs gracefully by bleeding the existing client transactions. Therefore, the current clients do not see any break in the application access.

### To enable querying for SRV records using the CLI

You must perform the following tasks to enable querying for SRV records:

1. Create a server by specifying the query type parameter as SRV.

At the command prompt, type:

```
1 add server <name> <domain> [-queryType <queryType>])
2 <!--NeedCopy-->
```

**Example:**

```
1 add server web_serv example.com -queryType SRV
2 <!--NeedCopy-->
```

**Note:**

- By default, IPv4 queries are sent. To send IPv6 queries, you must enable the IPv6 domain.

- The SRV target domain name must not exceed 127 characters.
2. Create a service group with the autoscale mode as DNS.

At the command prompt, type:

```
1 add serviceGroup <serviceName> <serviceType> [-autoScale <
  autoScale>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add servicegroup svc_grp_1 http -autoscale dns
2 <!--NeedCopy-->
```

3. Bind the server created in step 1 to the service group as a member.

At the command prompt, type:

```
1 bind serviceGroup <serviceName> <serverName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv
2 <!--NeedCopy-->
```

**Note:**

- When binding servers to service group members, you do not have to enter the port number for SRV server types. In case you specify a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

**To enable querying for SRV records using the GUI****Create a server**

1. Navigate to **Traffic Management > Load Balancing > Servers** and click **Add**.

## ← Create Server

4. Click **OK**.

## Bind server to the service group member

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Close**.

### Note:

- While binding, you do not have to enter the port number for SRV server types. In case you enter a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

## Overwriting TTL values

Citrix ADC appliance is configured to periodically query the DNS server for any update in SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding service group member and also globally, then the TTL value specified while binding the service group member takes precedence.

If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

## Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```

1 bind serviceGroup <serviceName> (<serverName> [-dbsTTL <secs>])
2 <!--NeedCopy-->

```

**Example:**

```

1 bind servicegroup svc_grp_1 web_serv -dbsTTL 10
2 <!--NeedCopy-->

```

- To overwrite the TTL value globally, at the command prompt, type:

```

1 set lb parameter [-dbsTTL <secs>]
2 <!--NeedCopy-->

```

**Example:**

```

1 set lb parameter -dbsTTL 15
2 <!--NeedCopy-->

```

**Overwriting the TTL values using the GUI****To overwrite the TTL value while binding:**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

**To overwrite the TTL value at the global level:**

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

**Note:** If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

**Specifying different name servers for service group and domain name bindings**

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

## Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
1 bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
    ip_addr>] [-dbsTTL <secs>])
2 <!--NeedCopy-->
```

Example:

```
1 bind servicegroup svc_grp_1 web_serv -ns.nameserver.com 10.102.27.155
    -dbsTTL 10
2 <!--NeedCopy-->
```

## Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for bound domain needs to be sent.

## Firewall Load Balancing

March 29, 2021

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput. Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a Citrix ADC appliance for firewall load balancing is similar to configuring load balancing, with the following exceptions:

- The recommended service type is ANY.
- The recommended monitor type is PING.
- The load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration.

- The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet. The configuration involves two Citrix ADC appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet.
- The enterprise environment involves configuring a single Citrix ADC appliance between the internal network and the firewalls that provide access to the Internet.
- The multiple-firewall environment is used for load balance traffic coming from another firewall. Firewall load balancing enabled on both the sides of the Citrix ADC appliance improves the traffic flow in both the egress and ingress direction. It also ensures faster processing of the traffic. The multiple-firewall environment involves configuring a Citrix ADC appliance sandwiched between two firewalls.

**Important:** If you configure static routes on the Citrix ADC appliance for the destination IP address and enable L3 mode, the Citrix ADC appliance uses its routing table to route the traffic instead of sending the traffic to the load balancing virtual server.

**Note:** For FTP to work, an extra virtual server or service must be configured on the Citrix ADC appliance with IP address and port as \* and 21 respectively, and the service type specified as FTP. In this case, the Citrix ADC appliance manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.

Firewall Load Balancing supports only some of the load balancing methods supported on the Citrix ADC appliance. Also, you can configure only a few types of persistence and monitors.

## **Firewall Load Balancing Methods**

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
- Least Bandwidth
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

## Firewall Persistence

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

## Firewall Server Monitoring

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the back-end service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.

## Sandwich Environment

March 29, 2021

A Citrix ADC deployment in a sandwich mode can load balance network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

In this setup, a Citrix ADC is located on each side of a set of firewalls. The Citrix ADC placed between the firewalls and the Internet, called the external Citrix ADC that handles ingress traffic selects the best firewall, based on the configured method. The Citrix ADC between the firewalls and the private network, called the internal Citrix ADC tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal Citrix ADC can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.

Figure 1. Firewall Load Balancing (Sandwich)

The service type ANY configures the Citrix ADC to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

### Configuring the External Citrix ADC in a Sandwich Environment

Perform the following tasks to configure the external Citrix ADC in a sandwich environment

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

## Enable the load balancing feature

### To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2 show ns feature
3 <!--NeedCopy-->
```

### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 -----
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 .
11 .
12 .
13 24) NetScaler Push push OFF
14 Done
15 <!--NeedCopy-->
```

### To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

## Configure a wildcard service for each firewall

### To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
1 add service <name> <serverName> ANY *
2 <!--NeedCopy-->
```

### Example:

```
1 add service Service-HTTP-1 10.102.29.5 ANY *
2 <!--NeedCopy-->
```

**To configure a wildcard service for each firewall by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Services** and add a service. Specify **ANY** in the **Protocol** field and \* in the Port field.

**Configure a monitor for each wildcard service**

A PING monitor is bound by default to the service. Configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

**To configure a transparent monitor by using the command line interface**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

**Example:**

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 To bind a PING monitor, type the following command:
4 bind monitor PING fw-svc1
5 <!--NeedCopy-->
```

**To create and bind a transparent monitor by using the configuration utility**

Navigate to

**Traffic Management > Load Balancing > Monitors**, and then create and bind a transparent monitor.

### Configure a wildcard virtual server for traffic coming from the Internet

#### To configure a wildcard virtual server for traffic coming from the Internet by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> ANY * *
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

#### To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers** and create a wildcard virtual server. Specify **ANY** in the **Protocol** field and \* in the Port field.

### Configure the virtual server in MAC rewrite mode

#### To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

#### To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section, and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

## Bind services to the wildcard virtual server

### To bind a service to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To bind a service to the wildcard virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server for which you want to bind the service.
2. Click in the **Services** section and select a service to bind.

### Save and verify the configuration

When you've finished the configuration tasks, be sure to save the configuration. You can also check to make sure that the settings are correct.

### To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 save ns config
2 show vserver
3 <!--NeedCopy-->
```

#### Example:

```
1 save config
2 sh lb vserver FWLBVIP1
3 FWLBVIP1 (*:*) - ANY      Type: ADDRESS
4      State: UP
5      Last state change was at Mon Jun 14 06:40:14 2010
6      Time since last state change: 0 days, 00:00:11.240
7      Effective State: UP  ARP:DISABLED
8      Client Idle Timeout: 120 sec
```

```
9      Down state flush: ENABLED
10     Disable Primary Vserver On Down : DISABLED
11     No. of Bound Services : 2 (Total)      2 (Active)
12     Configured Method: SRCIPDESTIPHASH
13     Mode: MAC

15     Connection Failover: DISABLED
16
17  1) fw_svc_1 (10.102.29.251: *) - ANY State: UP  Weight: 1
18  2) fw_svc_2 (10.102.29.18: *) - ANY State: UP  Weight: 1
19  Done
20  show service fw-svc1
21      fw-svc1 (10.102.29.251:*) - ANY
22      State: DOWN
23      Last state change was at Thu Jul  8 10:04:50 2010
24      Time since last state change: 0 days, 00:00:38.120
25      Server Name: 10.102.29.251
26      Server ID : 0  Monitor Threshold : 0
27      Max Conn: 0  Max Req: 0  Max Bandwidth: 0 kbits
28      Use Source IP: NO
29      Client Keepalive(CKA): NO
30      Access Down Service: NO
31      TCP Buffering(TCPB): YES
32      HTTP Compression(CMP): NO
33      Idle timeout: Client: 120 sec  Server: 120 sec
34      Client IP: DISABLED
35      Cacheable: NO
36      SC: OFF
37      SP: OFF
38      Down state flush: ENABLED
39
40  1)  Monitor Name: monitor-HTTP-1
41      State: DOWN  Weight: 1
42      Probes: 5  Failed [Total: 5 Current: 5]
43      Last response: Failure - Time out during TCP connection
44      establishment stage
45      Response Time: 2000.0 millisec
46  2)  Monitor Name: ping
47      State: UP  Weight: 1
48      Probes: 3  Failed [Total: 0 Current: 0]
49      Last response: Success - ICMP echo reply received.
50      Response Time: 1.415 millisec
51  Done
52  <!--NeedCopy-->
```

## Configuring the Internal Citrix ADC in a Sandwich Environment

Perform the following tasks to configure the internal Citrix ADC in a sandwich environment

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

### Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

#### To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2 show ns feature
3 <!--NeedCopy-->
```

#### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 -----
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
```

```

 9  3)      Load Balancing          LB          ON
10  .
11  .
12  .
13  24)    NetScaler Push          push        OFF
14  Done
15  <!--NeedCopy-->

```

### To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in Configure Basic Features, select **Load Balancing**.

### Configure a wildcard service for each firewall

#### To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```

1  add service <name> <serverName> ANY *
2  <!--NeedCopy-->

```

#### Example:

```

1  add service Service-HTTP-1 10.102.29.5 ANY *
2  <!--NeedCopy-->

```

### To configure a wildcard service for each firewall by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services** and add a service. Specify **ANY** in the **Protocol** field and \* in the Port field.

### Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. Configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the

firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

### To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 <!--NeedCopy-->
```

### To create and bind a transparent monitor by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors** and create a monitor.
2. In the **Create Monitor** dialog box, enter the required parameters, and select **Transparent**.

### Configure a wildcard virtual server to load balance the traffic sent to the firewalls

#### To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> ANY * *
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Virtual Servers** and create a wildcard virtual server. Specify **ANY** in the Protocol field and \* in the Port field.

**To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select \*.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

**Configure the virtual server in MAC rewrite mode****To configure the virtual server in MAC rewrite mode by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

**To configure the virtual server in MAC rewrite mode by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

**To configure the virtual server in MAC rewrite mode by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click **Open**.
3. On the Advanced tab, under Redirection Mode, click **MAC-Based**.
4. Click **OK**.

### Bind firewall services to the wildcard virtual server

#### To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

#### To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

### Configure a service for each virtual server

#### To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
1 add service <name> <serverName> HTTP <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-HTTP-1 10.102.29.5 HTTP 80
2 <!--NeedCopy-->
```

#### To configure a service for each virtual server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services** and configure a service for each virtual server. Specify **HTTP** in the **Protocol** field and select **HTTP** under **Available Monitors**.

**To configure a service for each virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
  - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

**Configure a monitor for each service****To bind a monitor to a service by using the command line interface**

At the command prompt, type:

```
1 bind lb monitor <monitorName> <ServiceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind mon monitor-HTTP-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To bind a monitor to a service by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Services**, double-click a service, and add a monitor.

**Configure an HTTP virtual server to balance traffic sent to the servers****To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface**

At the command prompt, type:

```
1 add lb vserver <name> HTTP <ip> <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
2 <!--NeedCopy-->
```

**To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Virtual Services** and configure an HTTP virtual server. Specify **HTTP** in the **Protocol** field.

**To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
  - IP Address—IP Address  
Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).
  - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

**Save and Verify the Configuration**

When you've finished the configuration tasks, be sure to save the configuration. You can also check to make sure that the settings are correct.

**To save and verify the configuration by using the command line interface**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 - save ns config
2 - show vservers
3 <!--NeedCopy-->
```

**Example:**

```
1 save config
2 show lb vservers FWLBVIP2
3          FWLBVIP2 (*:*) - ANY      Type: ADDRESS
```

```
4      State: UP
5      Last state change was at Mon Jun 14 07:22:54 2010
6      Time since last state change: 0 days, 00:00:32.760
7      Effective State: UP
8      Client Idle Timeout: 120 sec
9      Down state flush: ENABLED
10     Disable Primary Vserver On Down : DISABLED

50          Response Time: 1.275 millisec
51 Done
52 <!--NeedCopy-->
```

### **To save and verify the configuration by using the configuration utility**

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
4. In the details pane, select the virtual server that you created in step 5, verify that the settings displayed in the Details pane are correct.
5. Navigate to **Traffic Management > Load Balancing > Services**.
6. In the details pane, select the service that you created in step 5, verify that the settings displayed in the Details pane are correct.

### **Monitoring a Firewall Load Balancing Setup in a Sandwich Environment**

After the configuration is up and running, you can view the statistics for each service and virtual server to check for possible problems.

#### **Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of requests

#### **To display virtual server statistics by using the command line interface**

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC, or for a single virtual server, at the command prompt, type:

```

1 stat lb vserver [-detail] [<name>]
2 <!--NeedCopy-->

```

**Example:**

```

1 >stat lb vserver -detail
2 Virtual Server(s) Summary
3
4      vsvrIP  port  Protocol  State  Req/s
5      Hits/s
6 One          *    80      HTTP     UP     5/s
7          0/s
8 Two          *    0       TCP     DOWN   0/s
9          0/s
10 Three        * 2598     TCP     DOWN   0/s
11          0/s
12 dnsVirtualNS 10.102.29.90 53      DNS     DOWN   0/s
13          0/s
14 BRVSRV       10.10.1.1   80      HTTP     DOWN   0/s
15          0/s
16 LBVIP        10.102.29.66 80      HTTP     UP     0/s
17          0/s
18 Done
19
20
21
22 <!--NeedCopy-->

```

**To display virtual server statistics by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click **Statistics**.

**Viewing the Statistics of a Service**

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

**To view the statistics of a service by using the command line interface**

At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

**To view the statistics of a service by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click **Statistics**.

## Enterprise Environment

March 29, 2021

In the enterprise setup, the Citrix ADC is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The Citrix ADC selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)

The service type ANY configures the Citrix ADC to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

## Configuring the Citrix ADC in an Enterprise Environment

Perform the following tasks to configure a Citrix ADC in an enterprise environment.

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.

- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

### Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they do not function until you enable the feature.

### To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5     Feature                Acronym        Status
6     -----                -
```

|        |                  |      |     |
|--------|------------------|------|-----|
| 7 1)   | Web Logging      | WL   | OFF |
| 8 2)   | Surge Protection | SP   | ON  |
| 9 3)   | Load Balancing   | LB   | ON  |
| 10 .   |                  |      |     |
| 11 .   |                  |      |     |
| 12 .   |                  |      |     |
| 13 24) | NetScaler Push   | push | OFF |

```
14 Done
15 <!--NeedCopy-->
```

### To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in Configure Basic Features, select **Load Balancing**.

### Configure a wildcard service for each firewall

#### To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
1 add service <name> <serverName> ANY *
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-HTTP-1 10.102.29.5 ANY *
2 <!--NeedCopy-->
```

#### To configure a wildcard service for each firewall by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
4. In Protocol, select ANY, and in Port, select \*.
5. Click Create, and then click Close. The service you created appears in the Services pane.

### Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. Configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

### To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 <!--NeedCopy-->
```

### To create and bind a transparent monitor by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify the values as shown:
  - Name\*
  - Type\*—type
  - Destination IP
  - Transparent

-\* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you configured and verify that the settings displayed at the bottom of the screen are correct.

### Configure a wildcard virtual server to load balance the traffic sent to the firewalls

#### To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> ANY * *
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select \*.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

**Configure the virtual server in MAC rewrite mode****To configure the virtual server in MAC rewrite mode by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

**To configure the virtual server in MAC rewrite mode by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

## Bind firewall services to the wildcard virtual server

### To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

## Configure a service for each virtual server

### To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
1 add service <name> <serverName> HTTP <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-HTTP-1 10.102.29.5 HTTP 80
2 <!--NeedCopy-->
```

### To configure a service for each virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
  - Port—port

4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

### Configure a monitor for each service

#### To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
1 bind lb monitor <monitorName> <ServiceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind mon monitor-HTTP-1 Service-HTTP-1
2 <!--NeedCopy-->
```

#### To bind a monitor to a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service, and add a monitor.

### Configure an HTTP virtual server to balance traffic sent to the servers

#### To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
1 add lb vsrver <name> HTTP <ip> <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb vsrver Vserver-LB-1 HTTP 10.102.29.60 80
2 <!--NeedCopy-->
```

#### To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
  - IP Address—IP address  
Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).
  - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

### **Bind HTTP services to the HTTP virtual server**

#### **To bind HTTP services to the wildcard virtual server by using the command line interface**

At the command prompt, type:

```
1 bind lb vservice <name> <serviceName>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 bind lb vservice Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

#### **To bind HTTP services to the wildcard virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

### **Save and Verify the Configuration**

When you've finished the configuration tasks, be sure to save the configuration. You can also check to make sure that the settings are correct.

#### **To save and verify the configuration by using the command line interface**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 - save ns config
2 - show vserver
3 <!--NeedCopy-->
```

**Example:**

```
1 save config
2 show lb vserver FWLBVIP2
3     FWLBVIP2 (*:*) - ANY    Type: ADDRESS
4     State: UP
5     Last state change was at Mon Jun 14 07:22:54 2010
6     Time since last state change: 0 days, 00:00:32.760
7     Effective State: UP
8     Client Idle Timeout: 120 sec
9     Down state flush: ENABLED
10    Disable Primary Vserver On Down : DISABLED
11    No. of Bound Services : 2 (Total)      2 (Active)
12    Configured Method: LEASTCONNECTION
13    Current Method: Round Robin, Reason: A new service is bound
14    Mode: MAC
15    Persistence: NONE
16    Connection Failover: DISABLED
17

42          State: DOWN      Weight: 1
43          Probes: 9        Failed [Total: 9 Current: 9]
44          Last response: Failure - Time out during TCP connection
                        establishment stage
45          Response Time: 2000.0 millisec
46 2)      Monitor Name: ping
47          State: UP        Weight: 1
48          Probes: 3        Failed [Total: 0 Current: 0]
49          Last response: Success - ICMP echo reply received.
50          Response Time: 1.275 millisec
51 Done
52 <!--NeedCopy-->
```

### To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
4. In the details pane, select the virtual server that you created in step 5, verify that the settings displayed in the Details pane are correct.
5. Navigate to **Traffic Management > Load Balancing > Services**.
6. In the details pane, select the service that you created in step 5, verify that the settings displayed in the Details pane are correct.

## Monitoring a Firewall Load Balancing Setup in an Enterprise Environment

After the configuration is up and running, you can view the statistics for each service and virtual server to check for possible problems.

### Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port

- Protocol
- State of the virtual server
- Rate of requests received
- Rate of requests to the virtual server

### To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC appliance, or for a single virtual server, at the command prompt, type:

```
1 stat lb vsrver [-detail] [<name>]
2 <!--NeedCopy-->
```

### Example:

```
1 >stat lb vsrver -detail
2 Virtual Server(s) Summary
3
4      vsvrIP  port  Protocol  State  Req/s
5      Hits/s
6 One          *    80      HTTP     UP     5/s
7           0/s
8 Two          *    0       TCP     DOWN   0/s
9           0/s
10 Three        * 2598    TCP     DOWN   0/s
11           0/s
12 dnsVirtualNS 10.102.29.90 53     DNS     DOWN   0/s
13           0/s
14 BRVSRV       10.10.1.1   80     HTTP     DOWN   0/s
15           0/s
16 LBVIP        10.102.29.66 80     HTTP     UP     0/s
17           0/s
18 Done
19
20
21
22 <!--NeedCopy-->
```

### To display virtual server statistics by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

### To view the statistics of a service by using the command line interface

At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

### To view the statistics of a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

## Multiple-Firewall Environment

March 29, 2021

In a multiple-firewall environment, the Citrix ADC appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a Citrix ADC appliance. Having firewall load balancing enabled on both the sides of the Citrix ADC appliance improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

The following figure shows a multiple-firewall load balancing environment

Figure 1. Firewall Load Balancing (multiple-firewall)

With a configuration like the one shown in Figure 1, you can configure the Citrix ADC to load balance

the traffic through an internal firewall even if it is load balanced by an external firewall. For example, with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and conversely.

Firewall load balancing is supported only for MAC mode LB virtual server.

The service type ANY configures the Citrix ADC to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

## Configuring the Citrix ADC in a Multiple-Firewall Environment

To configure a Citrix ADC appliance in a multiple-firewall environment, you need to;

1. Enable the load balancing feature.
2. Configure a virtual server to load balance the egress traffic across the external firewalls.
3. Configure a virtual server to load balance the ingress traffic across the internal firewalls.
4. Enable firewall load balancing on the Citrix ADC appliance.

To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. Configure a wildcard service for each firewall
2. Configure a monitor for each wildcard service
3. Configure a wildcard virtual server to load balance the traffic sent to the firewalls
4. Configure the virtual server in MAC rewrite mode
5. Bind firewall services to the wildcard virtual server

### Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the Citrix ADC device.

#### To enable load balancing by using the CLI:

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature <featureName>
2 show ns feature
3 <!--NeedCopy-->
```

#### Example:

```
1 enable ns feature LoadBalancing
```

```

2 Done
3 show ns feature
4 Feature Acronym Status
5 -----
6 1) Web Logging WL OFF
7 2) Surge Protection SP ON
8 3) Load Balancing LB ON
9 .
10 .
11 .
12 24) NetScaler Push push OFF
13 Done
14 <!--NeedCopy-->

```

### To enable load balancing by using the GUI:

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the Settings pane, under Modes and Features, click **Change basic features**.
3. In the Configure Basic Features dialog box, select the **Load Balancing** check box, and then click **OK**.

### Configuring a wildcard service for each firewall

To accept traffic from all the protocols, you need to configure a wildcard service for each firewall by specifying support for all the protocols and ports.

#### To configure a wildcard service for each firewall by using the CLI:

At the command prompt, type the following command to configure support for all the protocols and ports:

```

1 add service <name>@ <serverName> <serviceType> <port_number>
2 <!--NeedCopy-->

```

#### Example:

```

1 add service fw-svc1 10.102.29.5 ANY *
2 <!--NeedCopy-->

```

#### To configure a wildcard service for each firewall by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click **Add**.
3. In the Create Services dialog box, specify values for the following parameters as shown:

- Service name
  - Server name
- \* A required parameter
4. In Protocol, select **Any** and in Port, select **\***.
  5. Click **Create**, and then click **Close**. The service you created appears in the Services pane.

### Configuring a monitor for each service

A PING monitor is bound by default to the service. Configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

#### To configure a transparent monitor by using the CLI:

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 <!--NeedCopy-->
```

The Citrix ADC appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of

the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.

### To configure a receive string by using the CLI:

At the command prompt, type the following command:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )] [-send <string>] [-recv <string>]
2 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor monitor-udp-1 udp-ecv -destip 10.10.10.11 -transparent YES - send "test message" - recv "site_is_up"
2 <!--NeedCopy-->
```

### To create and bind a transparent monitor by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. In the details pane, click **Add**.
3. In the Create Monitor dialog box, specify values for the following parameters as shown:
  - Name\*
  - Type\*—type
  - Destination IP
  - Transparent

-\* A required parameter
4. Click **Create**, and then click **Close**.

In the **Monitors** pane, select the monitor that you configured and verify that the settings displayed at the bottom of the screen are correct.

### Configuring a virtual server to load balance the traffic sent to the firewalls

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.

### To configure a virtual server to load balance the traffic sent to the firewalls by using the CLI:

At the command prompt, type the following command:

```
1 add lb vsriver <name>@ <serviceType> <IPAddress> <port_number>
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a virtual server to load balance the traffic sent to the firewalls by using the GUI:**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click **Add**.
3. In Protocol, select **Any**, and in IP Address and Port, select **\***.
4. Click **Create**, and then click **Close**. The virtual server you created appears in the Load Balancing Virtual Servers pane.

**Configuring the virtual server to the MAC rewrite mode**

To configure the virtual server to use the MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.

**To configure the virtual server in MAC rewrite mode by using the CLI:**

At the command prompt, type the following command:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

**To configure the virtual server in MAC rewrite mode by using the GUI:**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click **Open**.
3. On the Advanced tab, under the Redirection Mode mode, click **Open**.
4. Click **OK**.

**Binding firewall services to the virtual server**

To access a service on the Citrix ADC appliance, you need to bind it to a wildcard virtual server.

**To bind firewall services to the virtual server by using the CLI:**

At the command prompt, type the following command:

```
1 bind lb vserver <name>@ <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To bind firewall services to the virtual server by using the GUI:**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click **Open**.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the **Active** check box next to the service that you want to bind to the virtual server (for example, Service-HTTP-1).
4. Click **OK**.

**Configuring the multiple-firewall load balancing on the Citrix ADC appliance**

To load balance traffic on both the sides of a Citrix ADC using firewall load balancing, you need to enable multiple firewall load balancing by using the vServerSpecificMac parameter.

**To configure multiple-firewall load balancing by using the CLI:**

At the command prompt, type the following command:

```
1 set lb parameter -vServerSpecificMac <status>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb parameter -vServerSpecificMac ENABLED
2 <!--NeedCopy-->
```

**To configure multiple-firewall load balancing by using the GUI:**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click **OK**.

## Saving and Verifying the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You can also check to make sure that the settings are correct.

### To save and verify the configuration by using the CLI:

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 - save ns config
2 - show vserver
3 <!--NeedCopy-->
```

### Example:

```
1 save config
2 show lb vserver FWLBVIP2
3     FWLBVIP2 (*:*) - ANY      Type: ADDRESS
4     State: UP
5     Last state change was at Mon Jun 14 07:22:54 2010
6     Time since last state change: 0 days, 00:00:32.760
7     Effective State: UP
8     Client Idle Timeout: 120 sec
9     Down state flush: ENABLED
10    Disable Primary Vserver On Down : DISABLED
11    No. of Bound Services : 2 (Total)      2 (Active)
12    Configured Method: LEASTCONNECTION
13    Current Method: Round Robin, Reason: A new service is bound
14    Mode: MAC
15    Persistence: NONE
16    Connection Failover: DISABLED
17
18 1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
19 2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
20 Done
21 show service fw-int-svc1
22     fw-int-svc1 (10.102.29.5:*) - ANY
23     State: DOWN
24     Last state change was at Thu Jul  8 14:44:51 2010
25     Time since last state change: 0 days, 00:01:50.240
26     Server Name: 10.102.29.5
27     Server ID : 0   Monitor Threshold : 0
28     Max Conn: 0   Max Req: 0   Max Bandwidth: 0 kbits
29     Use Source IP: NO
30     Client Keepalive(CKA): NO
```

```
31      Access Down Service: NO
32      TCP Buffering(TCPB): NO
33      HTTP Compression(CMP): NO
34      Idle timeout: Client: 120 sec   Server: 120 sec
35      Client IP: DISABLED
36      Cacheable: NO
37      SC: OFF
38      SP: OFF
39      Down state flush: ENABLED
40
41 1)      Monitor Name: monitor-HTTP-1
42          State: DOWN      Weight: 1
43          Probes: 9        Failed [Total: 9 Current: 9]
44          Last response: Failure - Time out during TCP connection
45                          establishment stage
46          Response Time: 2000.0 millisec
46 2)      Monitor Name: ping
47          State: UP        Weight: 1
48          Probes: 3        Failed [Total: 0 Current: 0]
49          Last response: Success - ICMP echo reply received.
50          Response Time: 1.275 millisec
51 Done
52 <!--NeedCopy-->
```

### To save and verify the configuration by using the GUI:

1. In the details pane, click **Save**.
2. In the Save Config dialog box, click **Yes**.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
4. In the details pane, select the virtual server that you created in step 5, verify that the settings displayed in the Details pane are correct.
5. Navigate to **Traffic Management > Load Balancing > Services**.
6. In the details pane, select the service that you created in step 5, verify that the settings displayed in the Details pane are correct.

### Monitoring a Firewall Load Balancing Setup in a Multiple-Firewall Environment

After the configuration is up and running, you can view the statistics for each service and virtual server to check for possible problems.

## Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

### To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC appliance, or for a single virtual server, at the command prompt, type:

```
1 stat lb vserver [-detail] [<name>]
2 <!--NeedCopy-->
```

### Example:

```
1 >stat lb vserver -detail
2 Virtual Server(s) Summary
3
4      vsvrIP  port  Protocol  State  Req/s
5      Hits/s
6 One          *    80      HTTP     UP     5/s
7          0/s
8 Two          *    0       TCP     DOWN   0/s
9          0/s
10 Three        * 2598    TCP     DOWN   0/s
11          0/s
12 dnsVirtualNS 10.102.29.90 53     DNS     DOWN   0/s
13          0/s
14 BRVSRV       10.10.1.1   80     HTTP     DOWN   0/s
15          0/s
16 LBVIP        10.102.29.66 80     HTTP     UP     0/s
17          0/s
18 Done
19
20
```

```
13 <!--NeedCopy-->
```

**To display virtual server statistics by using the GUI:**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click **Statistics**.

**Viewing the Statistics of a Service**

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

**To view the statistics of a service by using the CLI:**

At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

**To view the statistics of a service by using the GUI:**

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click **Statistics**.

## Global Server Load Balancing

November 9, 2020

**Note**

The GSLB feature is included with the Citrix ADC Advance and Premium edition licenses. The Citrix ADC option license is supported with the Standard edition.

Citrix ADC appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a WAN. GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers if there is an outage.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server's IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.

**Note**

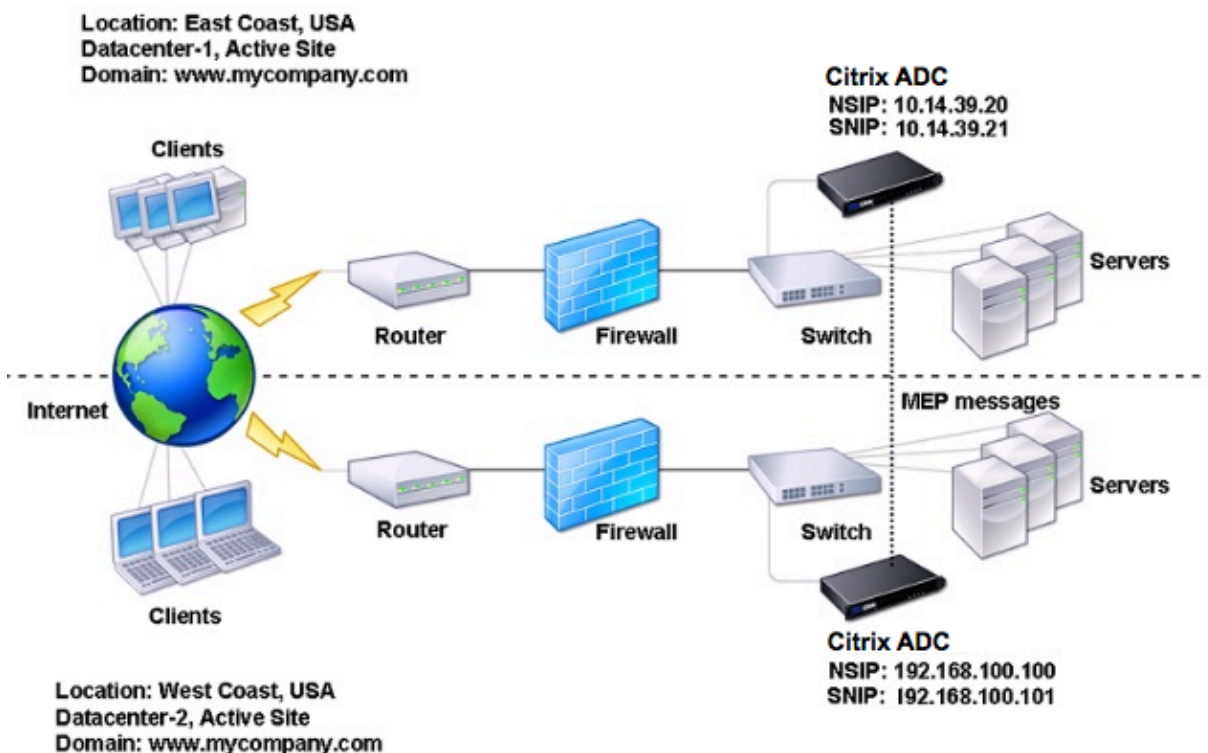

To take full advantage of the Citrix ADC GSLB features, you should use Citrix ADC appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary Metric Exchange Protocol (MEP) to exchange site metrics.

**How GSLB works**

With ordinary DNS, when a client sends a domain name system (DNS) request, it receives a list of IP addresses of the domain or service. Generally, the client chooses the first IP address in the list and initiates a connection with that server. The DNS server uses a technique called DNS round robin to rotate through the IPs on the list, sending the first IP address to the end of the list and promoting the others after it responds to each DNS request. This technique ensures equal distribution of the load, but it does not support disaster recovery, load balancing based on load or proximity of servers, or persistence.

When you configure GSLB on Citrix ADC appliances and enable Metric Exchange Protocol (MEP), the appliances use the DNS infrastructure to connect the client to the data center that best meets the criteria that you set. The criteria can designate the least loaded data center, the closest data center, the data center that responds most quickly to requests from the client's location, a combination of those metrics, and SNMP metrics. An appliance keeps track of the location, performance, load, and availability of each data center and uses these factors to select the data center to which to send a client request.

The following figure illustrates a basic GSLB topology.

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB service groups, GSLB virtual servers, load balancing servers, content switching servers, and ADNS services.

## GSLB deployment types

September 21, 2020

Citrix ADC appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

The following are some of the typical GSLB deployment types:

- [Active-active site deployment](#)
- [Active-passive site deployment](#)
- [Parent-child topology deployment](#)

## Active-active site deployment

September 21, 2020

An active-active site consists of multiple active data centers. Client requests are load balanced across active data centers. This deployment type can be used when you have a need for global distribution of traffic in a distributed environment.

All the sites in an active-active deployment are active, and all the services for a particular application/-domain are bound to the same GSLB vserver. Sites exchange metrics through the Metrics Exchange Protocol (MEP). Site metrics exchanged between the sites include the status of each load balancing and content switching virtual server, current number of connections, current packet rate, and current bandwidth usage. The Citrix ADC appliance needs this information to perform load balancing across the sites.

An active-active deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites. No backup sites are configured in this deployment type.

The Citrix ADC appliance sends client requests to the appropriate GSLB site as determined by the GSLB method specified in the GSLB configuration.

For an active-active deployment, you can configure the following GSLB methods.

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

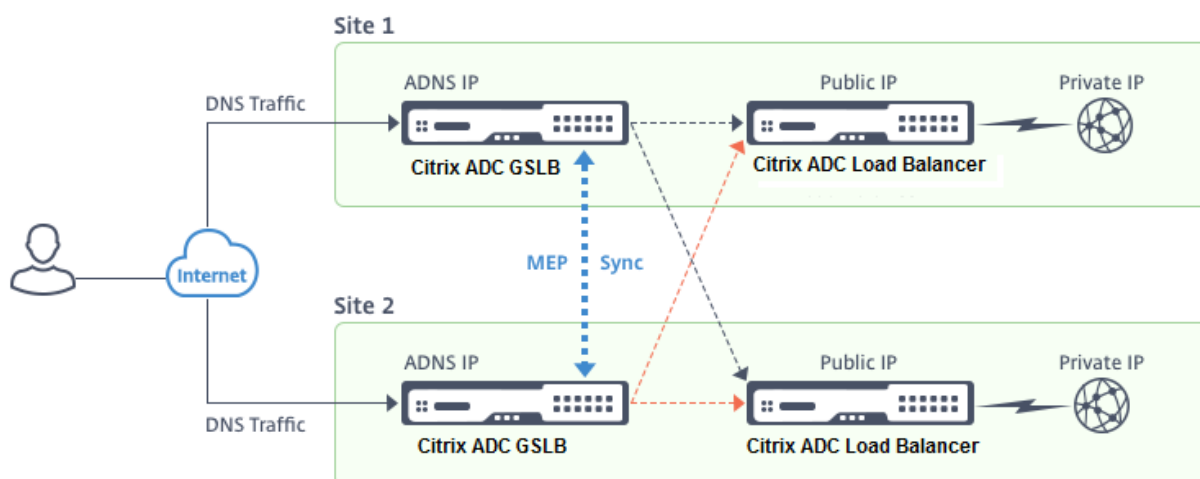

Note:

- If MEP is disabled, the following algorithm methods default to Round Robin.
  - RTT
  - Least Connections
  - Least Bandwidth
  - Least Packets
  - Least Response Time
- In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.

- In the Round Trip Time method, the dynamic round trip time (RTT) values are used to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client's local DNS server and a data resource.

## GSLB active-active datacenter topology

In the diagram, Site 1 and Site 2 are active GSLB sites.

When the client sends a DNS request, it lands in one of the active sites.

If Site 1 receives the client request, the GSLB virtual server in Site 1 selects a load balancing or content switching virtual server and sends the virtual server's IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP address.

As both sites are active, the GSLB algorithm evaluates the services at both sites when making a selection as determined by the configured GSLB method.

## Active-passive site deployment

September 21, 2020

An active-passive site consists of an active and a passive data center. This deployment type is ideal for disaster recovery.

In this type of deployment, some of the sites (remote sites) are reserved only for disaster recovery. These sites do not participate in any decision making until all the active sites are DOWN. A passive site does not become operational unless a disaster event triggers a failover.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the passive GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

An active-passive deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites.

For an active-passive deployment, you can configure the following GSLB methods.

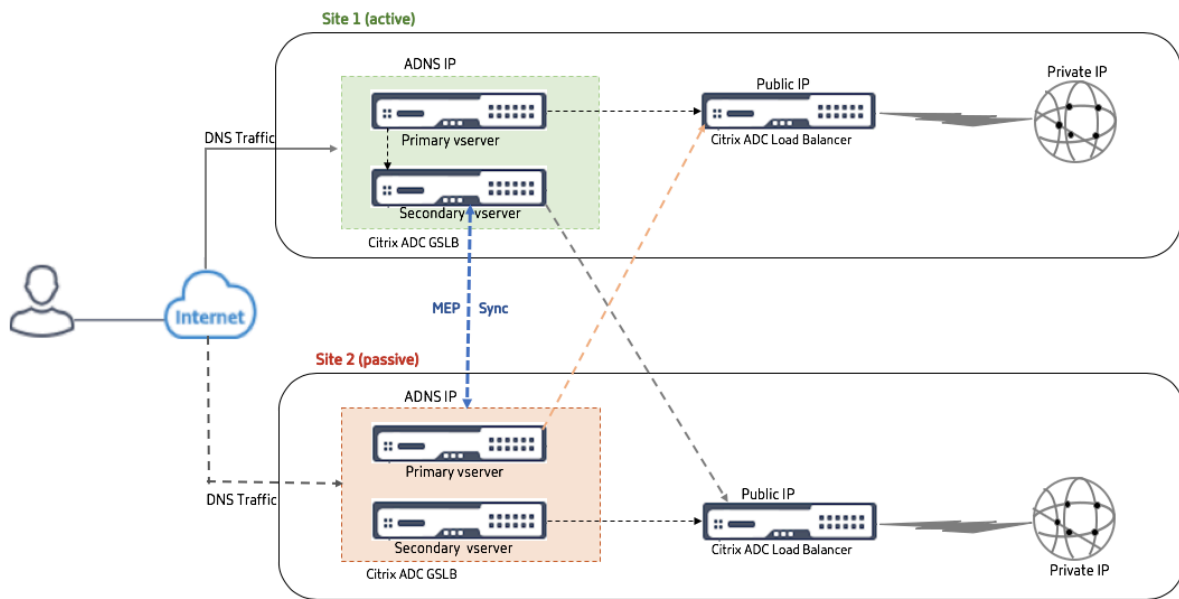

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

**Note:**

- If MEP is disabled, the following algorithm methods default to Round Robin.
  - RTT
  - Least Connections
  - Least Bandwidth
  - Least Packets
  - Least Response Time
- In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.
- In the Round Trip Time method, the dynamic round trip time (RTT) values are used to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client's local DNS server and a data resource.

### **GSLB active-passive datacenter topology**

In the diagram, Site 1 is an active site and Site 2 is a passive site, which has the same configuration as that of Site 1.

If Site 1 goes DOWN, Site 2 becomes operational.

When the client sends a DNS request, the request can land in any of the sites. However, the services are selected only from the active site (Site1) as long as it is UP.

Services from the passive site (Site 2) are selected only if the active site (Site 1) is DOWN.

## Parent-child topology deployment using the MEP protocol

November 2, 2020

Citrix ADC GSLB provides global server load balancing and disaster recovery by creating mesh connections between all the involved sites and making intelligent load balancing decisions. Each site communicates with the others to exchange server and network metrics through Metric Exchange Protocol (MEP), at regular intervals. However, with the increase in number of peer sites, the volume of MEP traffic increases exponentially because of the mesh topology. To overcome this, you can use a parent-child topology. The parent-child topology also supports larger deployments. In addition to the 32 parent sites, you can configure 1024 child sites.

The GSLB parent-child topology is a two-level hierarchical design with the following characteristics:

- At the top level are parent sites, which have peer relationships with other parents.
- Each parent can have multiple child sites.
- Each parent site exchanges health information with its child sites and with other parent sites.
- A child site communicates only with its parent site.

- In a parent-child relationship for GSLB, only the parent site responds to ADNS queries. The child sites act as normal load balancing sites.
- An ADNS service or DNS load balancing virtual servers should be configured only in the parent site.
- A parent site can have a normal GSLB configuration, that is, services from local and all remote sites, but a child site can have local services only. Also, only the parent sites have GSLB virtual servers configured.

#### Note

- In a parent-child topology, the exchange of site metrics is initiated from the lower of two IP addresses. However, from Citrix ADC release 11.1 build 51.x, the parent sites initiate connections to the child sites, and not vice versa, because the parent sites have information about all the child sites in the GSLB setup.
- In a parent-parent connection, the exchange of site metrics is still initiated from the lower IP of two IP addresses.
- In a parent-child topology, GSLB services are not always required to be configured on a child site. However, if you have additional configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the child site and configure it accordingly.
- In a parent-child topology, the parent site and the child site can be on different Citrix ADC software versions. However, to use the GSLB automaticConfigSync option to synchronize the configuration across the parent sites, all parent sites must be on the same Citrix ADC software versions. If you are not using the automaticConfigSync option, then the parent site and the child site can be on different Citrix ADC software versions but make sure that you are not using any of the new features in the latest release. This is also applicable, in general, to two Citrix ADC nodes participating in GSLB.

### Basic parent-child topology

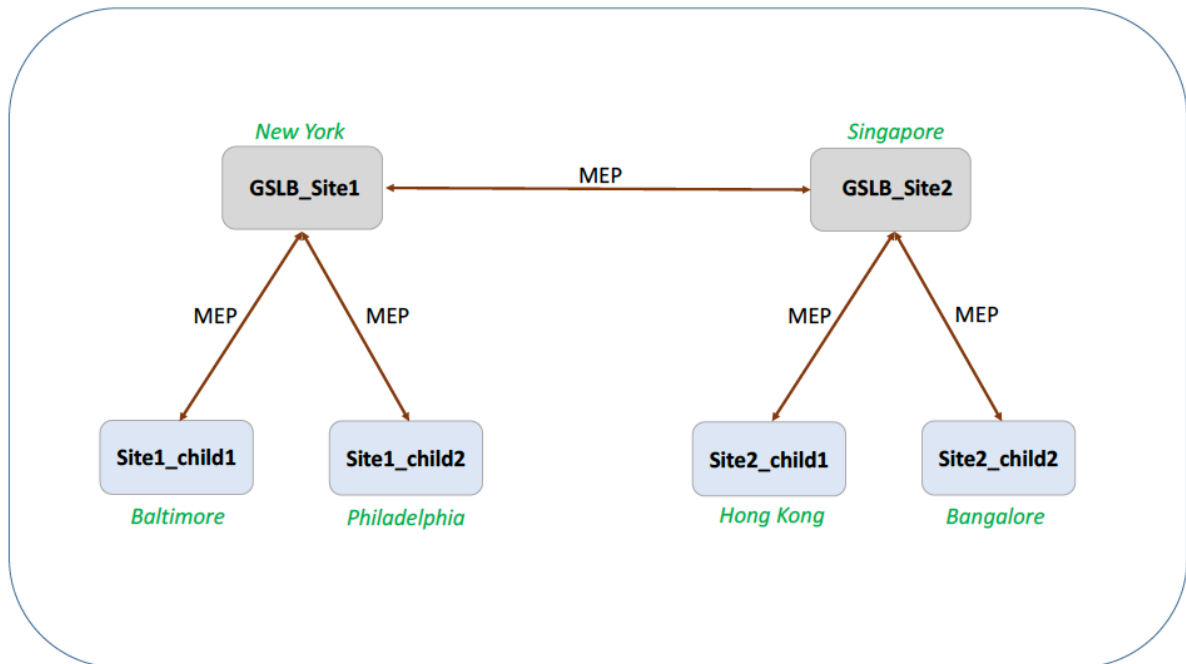

In the diagram, Site P1 and Site P2 are parent sites in a peer relationship. Site P1C1 and P2C1 are the child sites of P1 and P2 respectively.

### Setting up a parent-child configuration for GSLB

If you have a firewall configured at a GSLB site, make sure that port 3011 is open.

The following diagram displays a sample parent-child configuration.

- The configuration of a child site includes the child site and its parent site, but no other parent or child sites.
- Network metrics, such as RTT and persistence session information, are synchronized only across the parent sites. Therefore, parameters such as `nwMetricExchange` and `sessionExchange` are disabled by default on all the child sites.
- To verify correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

**To set up a parent-child configuration for GSLB by using the CLI:**

1. On each parent site, enter the following commands:

```
1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr
  |*>]
2 <!--NeedCopy-->
```

```
1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr
  |*>] [-parentSite <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add gslb site GSLB_Site1 10.1.1.1 - publicIP 10.1.1.1
2 <!--NeedCopy-->
```

```
1 add gslb site Site1_child1 1 10.1.1.2 -publicIP 10.1.1.2 -parentSite
  GSLB_Site1
2 <!--NeedCopy-->
```

2. On each child site, enter the following commands:

```
1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr
  |*>]
2
3 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr
  |*>] [-parentSite <string>]
4 <!--NeedCopy-->
```

**Example:**

```
1 add gslb site GSLB_Site1 10.1.1.1 - publicIP 10.1.1.1
2
3 add gslb site Site1_child1 1 10.1.1.2 -publicIP 10.1.1.2 -parentSite
  GSLB_Site1
4 <!--NeedCopy-->
```

For a complete example of a parent-child configuration, using the command line interface, see [Example of a Complete Parent-Child Configuration, Using the CLI](#)

**Note**

If the load balancing virtual server IP address is a private IP address and the public IP address is different from this IP address, you need to configure a GSLB service for the local load balancing

virtual server on the child site. This is required for statistics collection between the parent and the child site.

On the child site, at the command prompt, type:

```
add gslb service <name> <private IP/lb vserver IP> http 80 -sitename <
childsite name> -publicip <public IP of LB vserver><!--NeedCopy-->
```

**Example:**

```
add gslb service Service-GSLB 192.168.1.3 http 80 -GSLB_Site11 site 11_lb1 172.16.1.1
```

Where 192.168.1.3 is a private IP address of the load balancing virtual server and 172.16.1.1 is a public IP address of the load balancing virtual server.

## Backing up a parent site

**Note:** This feature was introduced in Citrix ADC release 11.1 build 51.x. To use the backup parent site topology, make sure that the parent site and the child sites are on Citrix ADC 11.1 build 51.x and later.

The backup parent site topology is useful in scenarios wherein a large number of child sites are associated with a parent site. If this parent site goes DOWN, all of its child sites become unavailable. To prevent this, you can now configure a backup parent site to which the child sites can connect if the original parent site is DOWN. The parent site sends the backup parent list to the child sites through the MEP messages.

When a parent site is DOWN, the other parent sites in the GSLB get to know that a particular parent site is DOWN through MEP because MEP to that parent site is DOWN. The other parent sites in the GSLB setup look up the backup chain of the peer parent. The parent site with the highest preference adopts the child sites of the parent that went DOWN. The new parent then initiates a connection with the child site. A child site can accept or reject the connection after evaluating its existing connections and the information in the backup list.

When the original parent site is back UP, it tries to establish connections with its child sites that have migrated to a different parent. When a connection attempt is successful, the child site is reassigned to its original parent site.

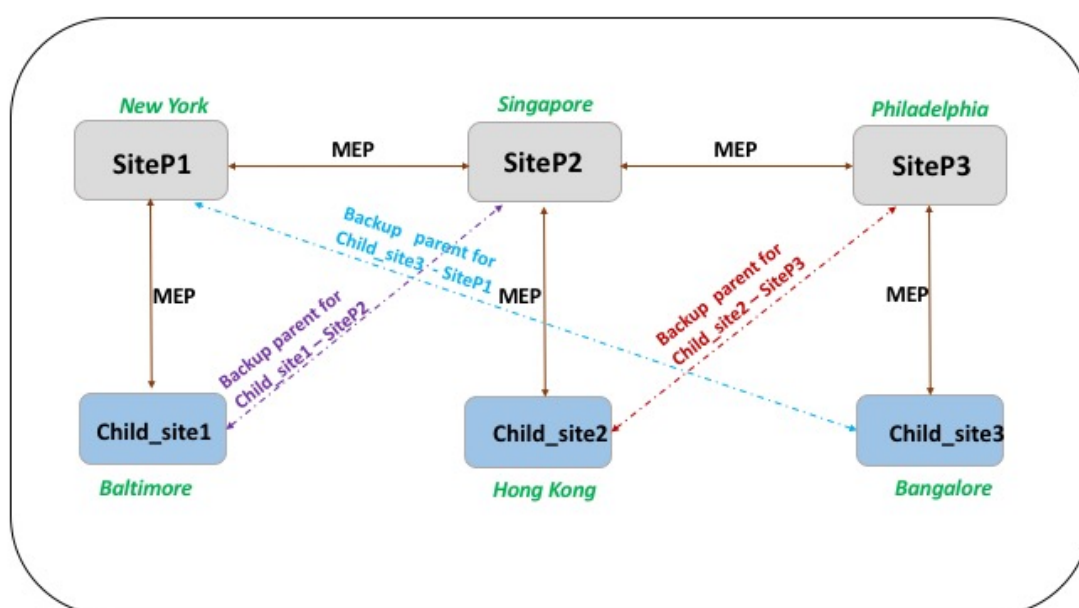

**Note:**

- Only parent sites can be configured as backups, and this configuration can only be done at the parent site.
- All child sites use the backup parent set.
- Synchronization is done only on the parent sites. GSLB child sites' configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.

Consider the configuration shown in the following figure, in which:

- SiteP1, SiteP2, and SiteP3 are the parent sites.
- Child\_site1, Child\_site2, and Child\_site3 are the child sites of SiteP1, SiteP2, and Site P3 respectively.
- Backup parent sites;
  - SiteP1 backup parents - SiteP2 (higher preference) and SiteP3
  - SiteP2 backup parents – SiteP3 (higher preference) and SiteP1
  - SiteP3 backup parents – SiteP1 (higher preference) and SiteP2

**Note:** For illustration purposes, the figure shows only one backup parent for each parent site.

The following list summarizes the behavior of the parent and child sites under various scenarios:

- Scenario 1: SiteP1 goes DOWN.
  - SiteP2 and SiteP3 detect that SiteP1's MEP connection is DOWN. SiteP2 is higher in the preference list of backup parents for SiteP1, so it tries to initiate a connection to Child\_site1. SiteP3 assumes that Child\_site1 is now the child site of parent SiteP2.
  - SiteP2 sends Child\_Site1 the list of SiteP1's backup parents (SiteP2 and SiteP3) to Child\_site1. Child\_site1 uses the list to decide whether to accept or reject the connection from SiteP2. It accepts the connection and becomes a child of SiteP2.
  - When SiteP1 is back UP, it sends Child\_site1 a connection request. The new request takes precedence and Child\_site 1 migrates to SiteP1.
- Scenario 2: Only the MEP connection between SiteP1 and SiteP2 has gone DOWN. Child\_site1 rejects SiteP2's connection request, because its parent, SiteP1, is still UP.

- Scenario 3: SiteP3 and Child\_Site1 detect that SiteP1 is DOWN, and the MEP connection between SiteP3 and SiteP2 is also DOWN. However, SiteP2 detects that SiteP1 is UP, and the MEP connection between SiteP1 and SiteP2 is UP.
  - SiteP2 does not take any action.
  - SiteP3 checks SiteP1's backup list and finds that SiteP2 has a higher preference than SiteP3. But SiteP2 is DOWN, so SiteP3 tries to establish a connection with Child\_site1. Child\_site1 has detected that SiteP1 is DOWN, so it accepts SiteP3's connection request.
  - Now the connection between SiteP1 and SiteP2 goes DOWN. SiteP2 checks SiteP1's backup list and finds itself as the most preferred backup, so it tries to connect to Child\_site1. Child\_site1 evaluates the new connection request based on SiteP1's list and finds SiteP2 as the most preferred backup, so it migrates to SiteP2 from SiteP3.

### To configure a backup parent site by using the command line interface

At the command prompt type:

```
1 set gslb site <sitename> -backupParentlist <bkp_site1> <bkp_site2> ... <
  bkp_site5>
2 <!--NeedCopy-->
```

<**sitename**> is the current parent site.

#### Example:

For the parent site (SiteP1), the sites (SiteP2 and SiteP3) are configured as the backup parent sites.

```
1 set gslb site SiteP1 -backupParentlist SiteP2 SiteP3
2 <!--NeedCopy-->
```

#### Note:

- You cannot add a new site as a backup parent. You must first add all the sites, and then configure the site as a backup parent.
- To remove a backup parent, you must use the unset command, which unsets all the sites that were previously configured as backup parent sites.

### To configure a backup parent site by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Sites**.
2. Add a new site or select an existing site.
3. Choose the **Backup Parent Sites** option box while creating or configuring the GSLB site.

## **GSLB configuration entities**

September 21, 2020

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include the following:

- GSLB Sites
- GSLB Services
- GSLB Virtual Servers
- Load Balancing or Content Switching Virtual Servers
- ADNS Services
- DNS VIPs

### **GSLB Sites**

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be Citrix ADC appliances. The data centers are called GSLB sites. Each GSLB site is managed by a Citrix ADC appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only Citrix ADC appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.

### **Relationships among GSLB Sites**

The concept of sites is central to Citrix ADC GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be;

- To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.
- To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites.

## GSLB Services

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server's IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the Citrix ADC appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in a different data center is remote from that GSLB virtual server.

### Note

Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

## GSLB Virtual Servers

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a Citrix ADC appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

## Load Balancing or Content Switching Virtual Servers

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server's virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server's VIP address.

For more information about load balancing or content switching virtual servers and services, see [Load Balancing](#) or [Content Switching](#).

## **ADNS Services**

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the Citrix ADC appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

## **DNS VIPs**

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the Citrix ADC appliance. DNS requests for domains for which the Citrix ADC appliance is authoritative can be sent to a DNS VIP.

## **GSLB methods**

September 21, 2020

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a Citrix ADC appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the appliance responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The Citrix ADC appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least

Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

### Specifying a GSLB method other than static proximity or dynamic RTT

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see “[Load Balancing](#).”

#### To change the GSLB method by using the CLI

At the command prompt, type:

```
1 set gslb vserver <name> -lbMethod GSLBMethod
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
2 <!--NeedCopy-->
```

#### To change the GSLB method by using the GUI

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In the details pane, select a GSLB virtual server and click **Open**.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.
4. Click **OK**, and verify that the method you selected appears under Details at the bottom of the screen.

## GSLB algorithms

September 21, 2020

The following algorithm are supported for GSLB.

- **Round Robin:** When a GSLB virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

- **Least Response Time:** When the GSLB virtual server is configured to use the least response time method, it selects the service with the lowest value. Where, lowest value = current active connections X average response time.  
You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.
- **Least Connections:** When a GSLB virtual server is configured to use the least connection GSLB algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.
- **Least Bandwidth:** A GSLB virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps).
- **Least Packets:** A GSLB virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.
- **Source IP Hash:** A GSLB virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.
- **Custom Load:** Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all of the services in the GSLB setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the GSLB decision when those services are not UP.

For more details, see [Load Balancing](#).

## Static proximity

September 21, 2020

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The Citrix ADC appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the Citrix ADC appliance maintains a database of IP address ranges and uses the database for decisions about the

GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

For details about configuring static proximity, see [Configuring Static Proximity](#).

## Dynamic round trip time method

November 13, 2020

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the Citrix ADC appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client's DNS request for a domain comes to the Citrix ADC appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The Citrix ADC appliance uses different mechanisms, such as ICMP echo request / reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the Citrix ADC appliance as Load Balancing Monitors and are easily identified due to their use of the "ldns" prefix. The three monitors, in their default order, are:

- ldns-ping
- ldns-dns
- ldns-tcp

These monitors are built in to the appliance and are set to safe defaults, but may be customized just like any other monitor on the appliance.

The default order may also be changed by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```
set gslb parameter -ldnsprobeOrder DNS PING TCP
```

Unless they have been customized, the Citrix ADC appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful in order to

provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the appliance uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric.”

If RTT information is not available (for example, when a client’s local DNS server accesses the site for the first time), the Citrix ADC appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site’s GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

### **Configure a GSLB virtual server for dynamic RTT**

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The Citrix ADC appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all Citrix ADC appliances deployed in the GSLB domain.

#### **To configure a GSLB virtual server for dynamic RTT by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver <name> -lbMethod RTT -tolerance <value>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10
2 <!--NeedCopy-->
```

#### **To configure a GSLB virtual server for dynamic RTT by using the configuration utility**

Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server.

## Set the probing interval of local DNS servers

The Citrix ADC appliance uses different mechanisms, such as ICMP echo request / reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response and, if a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

### To modify the probing interval by using the command line interface

At the command prompt, type:

```
1 set lb monitor <monitorName> <type> -interval <integer> <units> -  
   resptimeout <integer> <units>  
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb monitor ldns-tcp LDNS-TCP -interval 10 sec -resptimeout 5 sec  
2 <!--NeedCopy-->
```

### To modify the probing interval by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Monitors**, and double-click the monitor that you want to modify (for example, ping).

## Configure static proximity

September 21, 2020

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

This document includes the following information:

- [Adding a Location File to Create a Static Proximity Database](#)
- [Adding Custom Entries to a Static Proximity Database](#)

- [Setting the Location Qualifiers](#)
- [Specifying the Proximity Method](#)
- [Synchronizing GSLB Static Proximity Database](#)

## Add a location file to create a static proximity database

September 21, 2020

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a Citrix ADC appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the Citrix ADC appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as [www.maxmind.com](http://www.maxmind.com) and [www.ip2location.com](http://www.ip2location.com)).

The Citrix ADC appliance includes the following two IP geolocation database files. These are GeoLite2 files, published by MaxMind.

- Citrix\_Netscaler\_InBuilt\_GeoIP\_DB\_IPv4
- Citrix\_Netscaler\_InBuilt\_GeoIP\_DB\_IPv6

These database files are available in a format supported by the Citrix ADC appliance in the directory `/var/netscaler/inbuilt_db`.

You can use these IP geolocation databases as the location file for the static proximity based GSLB method, or in location based policies.

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the Citrix ADC appliance. Specifying an incorrect value for the format option can corrupt the internal data.

### Note

- After an upgrade, if the `/var/netscaler/inbuilt_db/` directory contains the database file (Citrix\_Netscaler\_InBuilt\_GeoIP\_DB.csv) from the earlier Citrix ADC software versions, the file is retained.
- The default location of the database file is `/var/netscaler/locdb`, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both Citrix

ADC appliances.

- If the location file is stored in a location other than the default location, then specify the path of the location file.
- For admin partitions, the default path is: `/var/partitions/<partitionName>/netscaler/locdb`.
- Some databases provide short country names according to ISO-3166 and long country names as well. The Citrix ADC uses short names when storing and matching qualifiers.
- To create a static proximity database, log on to the UNIX shell of the Citrix ADC appliance and use an editor to create a file with the location details in one of the Citrix ADC supported formats.

### To add a static location file by using the CLI

At the command prompt, type:

```
1 add locationFile <locationFile> [-format <format>]
2 - show locationFile
3 <!--NeedCopy-->
```

#### Example:

```
1 add locationFile /var/netscaler/locdb/nsgeo1.0 -format netscaler
2 Done
3
4 show locationFile
5 Location File: /var/netscaler/locdb/nsgeo1.0
6 Format: netscaler
7 Done
8 >
9 <!--NeedCopy-->
```

#### Example:

```
1 add locationFile /var/netscaler/inbuilt_db/
   Citrix_Netscaler_InBuilt_GeoIP_DB_IPv4 -format netscaler
2
3 add locationFile6 /var/netscaler/inbuilt_db/
   Citrix_Netscaler_InBuilt_GeoIP_DB_IPv6 -format netscaler
4 <!--NeedCopy-->
```

### To add a static location file by using the GUI:

1. Navigate to **AppExpert > Location**, click the **Static Database** tab.

2. Click **Add** to add a static location file.

You can view an imported location file database by using the **View Database** dialog box in the configuration utility. There is no CLI equivalent.

**To view a static location file by using the GUI:**

1. Navigate to **AppExpert > Location**, click the **Static Database** tab.
2. Select a static location file, and from the **Action** list, click **View Database**.

**To convert a location file into the Citrix ADC format:**

By default, when you add a location file, it is saved in the Citrix ADC format. You can convert a location file of other formats into the Citrix ADC format.

**Note:** The `nsmmap` option can be accessed only from the command line interface. The conversion is possible only into the Citrix ADC format.

**To convert the static database format, at the CLI prompt, type the following command:**

```
1 nsmmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
2 <!--NeedCopy-->
```

**Example:**

```
1 nsmmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.
   csv
2 <!--NeedCopy-->
```

**Script to convert Maxmind GeoLite2 database format to Citrix ADC database format**

MaxMind GeoIP database cannot be used directly in Citrix ADC. The MaxMind GeoIP database must be converted into Citrix ADC format and then loaded for IP location detection in GSLB static proximity method and other features like policies.

You can use a script to convert the GeoLite2 database format to Citrix ADC database format. This script can be used to convert both IPv4 and IPv6 files.

The script is available in the location: <https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format>

**Steps to convert GeoIP2 database to Citrix ADC format**

1. Download the GeoLite2 City or GeoLite2 Country database in .csv format from <https://dev.maxmind.com/geoip/geoip2/geolite2/>.
2. Copy the file in a Citrix ADC directory (say /var). Unzip the file using the following shell command, which would create a directory with the same name.

```
1 tar -xf <filename>
2 <!--NeedCopy-->
```

3. Download the script `Convert_GeoIPDB_To_Netscaler_Format.pl` from <https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format> and copy it to the directory created in step #2.

4. To check the acceptable options for the script execution, run the following command:

```
1 perl Convert_GeoIPDB_To_Netscaler_Format.pl - help
2 <!--NeedCopy-->
```

Various options available are;

- `<filename>`  
IPv4 output file.  
Default output file name: `Netscaler_Maxmind_GeoIP_DB_IPv4.csv`
- `-p <filename>`  
IPv6 output file.  
Default output file name: `Netscaler_Maxmind_GeoIP_DB_IPv6.csv`
- `-logfile <filename>`  
File containing list of events/messages
- `-debug`  
Prints all the messages to STDOUT

4. Execute the following command to convert the GeoLite2 database format to Citrix ADC database format.

```
1 perl Convert_GeoIPDB_To_Netscaler_Format.pl
2 <!--NeedCopy-->
```

**Note:** The operation can take up to 5 minutes.

The default file names used in the script are that of the Maxmind GeoLite2 City based database. If you have downloaded GeoLite2 Country database, you must provide the input file names accordingly as listed.

- `-b <filename>` name of IPv4 block file to be converted.  
Default file name: `GeoLite2-City-Blocks-IPv4.csv`
- `-i <filename>` name of IPv6 block file to be converted.  
Default file name: `GeoLite2-City-Blocks-IPv6.csv`
- `-l <filename>` name of location file to be converted.  
Default file name: `GeoLite2-City-Locations-en.csv`

**Example:**

```
1 perl Convert_GeoIPDB_To_Netscaler_Format.pl -b GeoLite2-Country-Blocks-
   IPv4.csv -i GeoLite2-Country-Blocks-IPv6.csv -l GeoLite2-Country-
   Locations-en.cs
2 <!--NeedCopy-->
```

The following are the output files generated after running the script.

- Netscaler\_Maxmind\_GeoIP\_DB\_IPv4.csv
- Netscaler\_Maxmind\_GeoIP\_DB\_IPv6.csv

5. Once the conversion of the database into Citrix ADC format is complete, use the following command to start using it.

```
1 add locationFile <locationFile>
2 <!--NeedCopy-->
```

**Add a third-party static database file on a Citrix ADC appliance**

Perform the following steps to add a third-party static database file on a Citrix ADC appliance.

1. Obtain the location database file from a third-party vendor, such as [www.maxmind.com](http://www.maxmind.com) or [www.ip2location.com](http://www.ip2location.com).
2. Copy the location database file to the Citrix ADC appliance using the WinSCP utility.

**Note**

The default location of the database file on the appliance is **`/var/netscaler/locdb`**.

3. Execute the following command to add a static location file:

```
1 add location file <locationfile Name> -format LocationFormat
2 <!--NeedCopy-->
```

4. Execute the following command to ensure that the location database is loaded:

```
1 show location parameter
2 <!--NeedCopy-->
```

This command displays the parameters, such as number of static entries. If the database is not loaded correctly, this command also displays an error message. A maximum of 3M-1 (3 million minus one) entries can be loaded.

5. Execute the following command to view the location of the GSLB site:

```
1 show gslb service
2 <!--NeedCopy-->
```

**Note**

- If the database is loaded correctly, the location of the GSLB sites is automatically populated in the database.
- You can specify only one location file in the configuration on the appliance.
- If the appliances are in a high availability setup, then one appliance must copy the database from the other appliance.
- If no match is found for an incoming IP address, the request is processed using the Round Robin method.

6. Execute the following command to configure the GSLB method on the appliance:

```
1 set gslb vserver GSLBVserverName -lbMethod MethodType
2 <!--NeedCopy-->
```

## Add custom entries to a static proximity database

September 21, 2020

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 500 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (\*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

### To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration:

```
1 add location < IPfrom> < IPto> <preferredLocation> [-longitude <integer>
   >[-latitude <integer>]]
2 show location
3 <!--NeedCopy-->
```

**Example:**

```
1 >add location 192.168.100.1 192.168.100.100 *.us.ca.mycity
2 <!--NeedCopy-->
```

```
1 >show location
2 <!--NeedCopy-->
```

### Parameters for adding custom entries

- IPfrom  
First IP address in the range, in dotted decimal notation. This is a mandatory argument.
- IPTo  
Last IP address in the range, in dotted decimal notation. This is a mandatory argument.
- preferredLocation  
String of qualifiers, in dotted notation, describing the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example, "NA.US.CA.San Jose.ATT.citrix".  
Note: A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks.  
This is a mandatory argument. Maximum Length: 197
- longitude  
Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range.  
Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.  
Maximum value: 180
- latitude  
Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range.  
Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.  
Maximum value: 180

### To add custom entries by using the configuration utility

Navigate to **AppExpert > Location**, click the **Custom Entries** tab, and add the custom entries.

## Set location qualifiers

September 21, 2020

The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The meaning of the qualifiers (context) is defined by the qualifier labels, which are user defined. Citrix ADC has two built-in contexts:

Geographic context, which has the following qualifier labels:

- Qualifier 1 – “Continent”
- Qualifier 2 – “Country”
- Qualifier 3 – “State”
- Qualifier 4 – “City”
- Qualifier 5 – “ISP”
- Qualifier 6 – “Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 – “Qualifier 1”
- Qualifier 2 – “Qualifier 2”
- Qualifier 3 – “Qualifier 3”
- Qualifier 4 – “Qualifier 4”
- Qualifier 5 – “Qualifier 5”
- Qualifier 6 – “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the Citrix ADC appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

### To set the location qualifiers by using the command line interface

At the command prompt, type:

---

```
1 set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 set locationparameter -context custom -q1label asia
2 <!--NeedCopy-->
```

**To set the location qualifiers by using the configuration utility**

1. Navigate to **AppExpert > Location**.
2. From the **Action** list, click **Location Parameters** and set the location qualifiers.

**Specify proximity method**

September 21, 2020

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

**To specify static proximity by using the command line interface**

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
1 set gslb vserver <name> -lbMethod STATICPROXIMITY
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
2 show gslb vserver
3 <!--NeedCopy-->
```

**To specify static proximity by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server.

2. Click the **Method** section and from the **Choose Method** drop-down list, select **STATICPROXIMITY**.

## Synchronize GSLB static proximity database

September 21, 2020

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the `/var/netscaler/locdb` directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the `rsync` program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the `rsync` program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the **sync gslb config** command on Site1:

```
1 sync gslb config -nowarn
2 Sync Time: Feb 24 2014 14:56:16
3 Retrieving local site info: ok
4 Retrieving all participating gslb sites info:
5 0 bytes in 0 blocks
6 ok
7 site1[Master]:
8     Getting Config: ok
9 site2[Slave]:
10     Syncing gslb static proximity database: ok
11     Getting Config: ok
12     Comparing config: ok
13     Applying changes: ok
14 Done
15 <!--NeedCopy-->
```

## Configure site-to-site communication

September 21, 2020

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The Citrix ADC appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a Citrix ADC owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use a subnet IP (SNIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the Citrix ADC appliance:

### Changing the password of an RPC node

Citrix recommends you to secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the `show rpcNode` command to compare the encrypted form of the password before and after the change.

### To change the password of an RPC node by using the command line interface

At the command line, type the following commands to change the password of an RPC node:

```
1 set ns rpcNode <IPAddress> {
2   -password }
3
4 show ns rpcNode
5 <!--NeedCopy-->
```

### Example:

```
1 > set rpcNode 192.0.2.4 -password mypassword
2 Done
```

```
3 > show rpcNode
4 .
5 .
6 .
7 2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e
8     SrcIP: *           Secure: OFF
9 Done
10 >
11
12 <!--NeedCopy-->
```

### **To unset the password of an RPC node by using the command line interface**

To unset the password of an RPC node by using the CLI, type the `unset rpcNode` command, the IP address of the RPC node, and the password parameter, without a value.

### **To change the password of an RPC node by using the configuration utility**

Navigate to System > Network > RPC, select the RPC node, and change the password.

### **Encrypt the exchange of site metrics**

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the Citrix ADC appliance encrypts all communication sent from the node to other RPC nodes.

### **To encrypt the exchange of site metrics by using the command line interface**

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

```
1 set ns rpcNode <IPAddress> [-secure ( YES | NO )]
2 show rpcNode
3 <!--NeedCopy-->
```

### **Example:**

```
1 > set rpcNode 192.0.2.4 -secure YES
2 Done
3 >
4 > show rpcNode
5 .
```

```
6 .
7 .
8 3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP:
    192.0.2.3      Secure: ON
9 Done
10 >
11 <!--NeedCopy-->
```

### To unset the secure parameter by using the command line interface

To unset the secure parameter by using the CLI, type the `unset rpcNode` command, the IP address of the RPC node, and the `secure` parameter, without a value.

### To encrypt the exchange of site metrics by using the Citrix ADC configuration utility

1. Navigate to **System > Network > RPC** and double-click a RPC node.
2. Select the **Secure** option, and click **OK**.

### Configure source IP address for an RPC node

By default, the Citrix ADC appliance uses a Citrix ADC owned subnet IP (SNIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address. If a SNIP address is not available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NSIP address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address.

#### Note

From NetScaler 11.0.64.x release onwards, you can configure the appliance to use GSLB Site IP address as the source IP address for an RPC node.

### To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

```
1 set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr|*>]
2 show ns rpcNode
3 <!--NeedCopy-->
```

**Example:**

```
1 set rpcNode 192.0.2.4 -srcIP 192.0.2.3
2 Done
3 show rpcNode
4 <!--NeedCopy-->
```

```
1 IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3
   Secure: OFF
2 Done
3 <!--NeedCopy-->
```

**To unset the source IP address parameter by using the command line interface**

To unset the source IP address parameter by using the CLI, type the `unset rpcNode` command, the IP address of the RPC node, and the `srcIP` parameter, without a value.

**To specify a source IP address for an RPC node by using the Citrix ADC configuration utility**

1. Navigate to System > Network > RPC and double-click a RPC node.
2. In the Source IP Address field, enter the IP address that you want the RPC node to use as the source IP address and click OK.

**Important**

The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each Citrix ADC appliance. Therefore, after you force a synchronization (using the `sync gslb config -forceSync` command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other Citrix ADC appliances.

## Configure metrics exchange protocol

November 2, 2020

The data centers in a GSLB setup exchange metrics with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for Citrix ADC appliance. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metric (round-trip time) can be initiated by either of the data centers involved in

the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, virtual IP (VIP) address, or the NSIP address, as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the Citrix ADC appliances.

Note: You can configure a SNIP or a GSLB site IP address as the source IP address for metrics exchange. For more information, see [Configure source IP address for an RPC node](#).

If the source and target sites (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services as described in “[Monitoring GSLB Services](#).” When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metric exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service enables the Citrix ADC appliance to interact with a non-citrix ADC load balancing device. The Citrix ADC appliance can monitor non-citrix ADC devices but cannot perform load balancing on them unless monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.

With NetScaler release 11.1.51.x or later, to avoid unnecessary disruption of services, you can set a time delay for marking GSLB services as DOWN when a MEP connection goes DOWN.

### **MEP state in a high availability setup**

In a high availability setup, the primary node establishes connections with the remote sites and the MEP state is not synchronized from the primary node to secondary nodes. Therefore, the MEP state in secondary node remains DOWN. When the secondary node becomes primary, it establishes MEP connections with the new GSLB site and updates the MEP state accordingly.

### **Enable site metrics exchange**

Site metrics exchanged between the GSLB sites include the status of each load balancing, or content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The Citrix ADC appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

**To enable or disable site metrics exchange by using the command line interface**

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

```
1 set gslb site <siteName> -metricExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
4 <!--NeedCopy-->
```

**To enable or disable site metric exchange by using the GUI**

1. Navigate to **Traffic Management > GSLB > Sites**, and select the site.
2. In the **Configure GSLB Site** dialog box, select the **Metric Exchange** option.

**Enable network metric exchange**

If your GSLB sites use the round-trip time (RTT) load balancing method, you can enable or disable the exchange of RTT information about the client's local DNS service. This information is exchanged every 5 seconds.

For details about changing the GSLB method to a method based on RTT, see "[GSLB Methods](#)."

**To enable or disable network metric information exchange by using the command line interface**

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

```
1 set gslb site <siteName> -nwmetricExchange (ENABLED|DISABLED)
2 show gslb site <<siteName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
```

```
4 <!--NeedCopy-->
```

### To enable or disable network metric information exchange by using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**.
2. In the **Configure GSLB Site** dialog box, select the **Network Metric Exchange** option.

### Configuring a time delay for the GSLB services to be marked as DOWN when a MEP connection goes DOWN

If the status of a MEP connection to a remote site changes to DOWN, the status of every GSLB service on that remote site is marked as DOWN, although the site might not actually be DOWN.

You can now set a delay to allow some time for reestablishment of the MEP connection before the site is marked as DOWN. If the MEP connection is back UP before the delay expires, the services are not affected.

For example, if you set the delay 10, the GSLB services are marked as DOWN until the MEP connection has been DOWN for 10 seconds. If the MEP connection is back UP within 10 seconds, the GSLB services remain in the UP state.

**Note:** This delay is applicable only to services not bound to a monitor. The delay does not affect the trigger monitors.

### To set a time delay by using the command line interface

At the command prompt, type the following command:

```
1 set gslb parameter** - GSLBSvcStateDelayTime <sec>
2 <!--NeedCopy-->
```

#### Example:

**set gslb parameter - GSLBSvcStateDelayTime 10**

#### Note

In a hierarchical deployment (parent-child topology), if you configure the GSLB service on both the parent and child sites, set the GSLB parameter on both the parent and child sites. If you do not configure the GSLB service on the child site, set the GSLB parameter only on the parent site.

### To set a time delay by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Change GSLB Settings**.
2. In the **GSLB Service State Delay Time (secs)** box, type the time delay in seconds.

### Enable persistence information exchange

You can configure Citrix ADC appliance to provide persistent connections, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

You can enable or disable the exchange of persistence information at each site. This information is exchanged once every 5 seconds between Citrix ADC appliances participating in GSLB.

For details about configuring persistence, see [Configuring Persistent Connections](#).

### To enable or disable persistence information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable persistence-information exchange and verify the configuration:

```
1 set gslb site <siteName> -sessionExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb site Site-GSLB-East-Coast -sessionExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -sessionExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
4 <!--NeedCopy-->
```

### To enable or disable persistence information exchange by using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**, and double-click the site.
2. In the **Configure GSLB Site** dialog box, select or clear the **Persistence Session Entry Exchange** check box.

## Configure GSLB by using a wizard

September 21, 2020

You can now use a wizard to configure the GSLB deployment types: active-active, active-passive, and parent-child.

This wizard is available in the GUI. To access the wizard, navigate to **Configuration > Traffic Management > GSLB** and click **Get Started**.

You can also access this wizard from the GSLB dashboard. Navigate to **Configuration > Traffic Management > GSLB > Dashboard** and click **Configure GSLB**.

**Note:** You can also configure the GSLB entities individually.

- [Active-Active Site Configuration](#)
- [Active-Passive Site Configuration](#)
- [Parent-Child Topology Configuration](#)

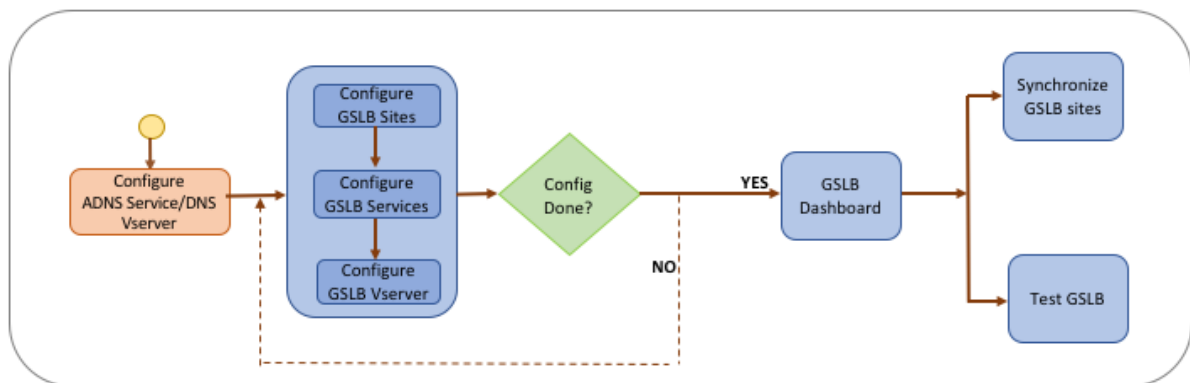

### Important

This feature is supported in High Availability deployment and not in Admin Partition and Cluster deployments.

## Configure active-active site

September 21, 2020

The following figure shows the workflow involved in a GSLB active-active site configuration.

Before you begin configuring an active-active site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.

- The master and slave Citrix ADC appliances are running the same Citrix ADC software versions.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

### To configure an active-active site by using the wizard

On the Configuration tab, do the following:

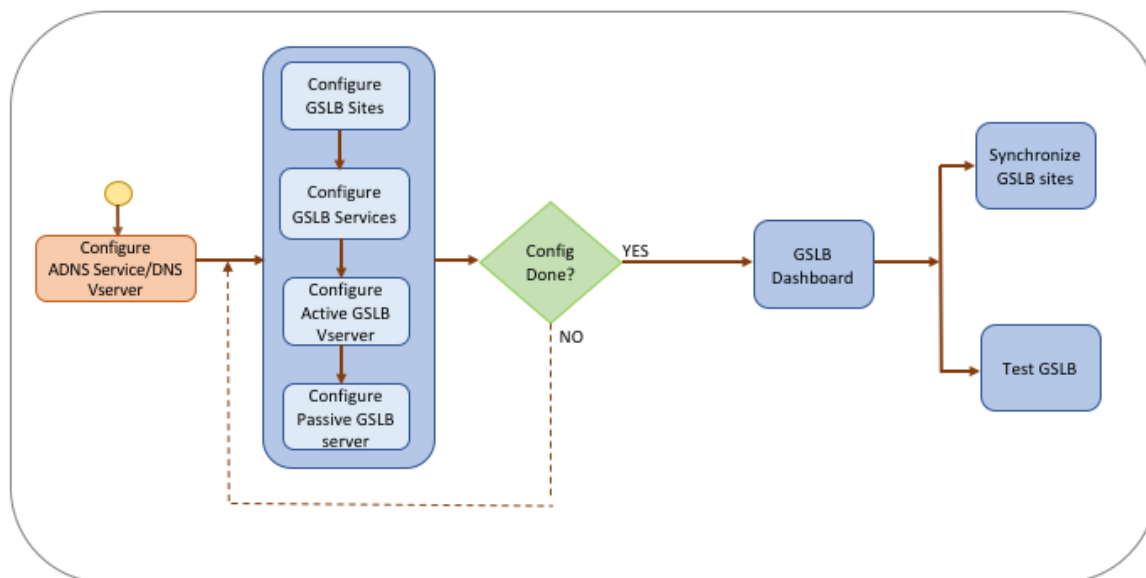

1. Navigate to **Traffic Management > GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
  - a) Click **View** and then click **Add**.
  - b) Enter the service name, IP address and select the protocol (ADNS/ADNS\_TCP) through which the data is exchanged with the service.
3. Select **Active-Active Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
  - a) Enter the site details, such as the site name and site IP address.
  - b) Select either REMOTE or LOCAL site type.
  - c) Optionally, change the RPC password and, if necessary, secure it.
  - d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
    - **ALWAYS**. Monitor the GSLB service at all times.
    - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
    - **MMEP Fails and Service ID Down**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services. To create an active-active site you must add at least two GSLB services.
  - a) Enter the service details, such as service name, service type, and port number.
  - b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
  - c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
  - d) To associate an existing server, select the server name. The service IP address is automatically populated.

- If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
  - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
  - To associate a virtual server, select an already existing virtual server, or click + and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.
7. Configure the GSLB virtual servers.
    - a) Enter the name of the GSLB virtual server name and select the DNS record type.
    - b) Click > in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
    - c) Click > in the **Domain Binding** box to select the domain to be bound to this GSLB virtual server.
    - d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      - If you choose **the Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
      - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
      - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.
  8. Click **Done** if the configuration is complete. The GSLB dashboard appears.
  9. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
    - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other Citrix ADC appliances.
    - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
      - a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
      - b) Select the **Automatic Config Sync** check box.
  10. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

## Configure active-passive site

September 21, 2020

The following figure shows the workflow involved in the active-passive site configuration.

Before you begin configuring an active-passive site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave Citrix ADC appliances are running the same Citrix ADC software versions.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

### To configure an active-passive site by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management** > **GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
  - a) Click **View** and then click **Add**.

- b) Enter the service name, IP address and select the protocol (ADNS/ADNS\_TCP) through which the data is exchanged with the service.
3. Select **Active-Passive Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
  - a) Enter the site details, such as the site name and site IP address.
  - b) Select either REMOTE or LOCAL site type.
  - c) Optionally, change the RPC password and, if necessary, secure it.
  - d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
    - **ALWAYS**. Monitor the GSLB service at all times.
    - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
    - **MEP Fails and Service ID Down**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services.
  - a) Enter the service details, such as service name, service type, and port number.
  - b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
  - c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
  - d) To associate an existing server, select the server name. The service IP address is automatically populated.
    - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
    - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
    - To associate a virtual server, select an already existing virtual server, or click **+** and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.
7. Configure the GSLB backup virtual servers. The GSLB backup virtual servers become operational only when the primary GSLB virtual servers is inaccessible or it is marked DOWN for any reason.
  - a) Enter the name of the GSLB virtual server name and select the DNS record type.
  - b) Click **>** in **Service Binding**, and choose the GSLB services that must be bound to the GSLB

virtual server.

- c) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
  - If you choose the **Algorithm based** method, select the primary and backup methods.
  - If you choose the **Static Proximity** method, select the backup method and provide the location of the database file.
  - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.
8. Configure the GSLB virtual servers.
  - a) Enter the name of the GSLB virtual server name and select the DNS record type.
  - b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
  - c) Click **>** in the **Domain Binding** box to select the domain to be bound to this GSLB virtual server.
  - d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
    - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
    - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the **>** icon or add a new location by clicking **+** in the Select a location database box.
    - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.
9. Click **Done** if the configuration is complete. The GSLB dashboard appears.
10. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
  - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other Citrix ADC appliances.
  - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
    - a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
    - b) Select the **Automatic Config Sync** check box.

- Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

**Note**

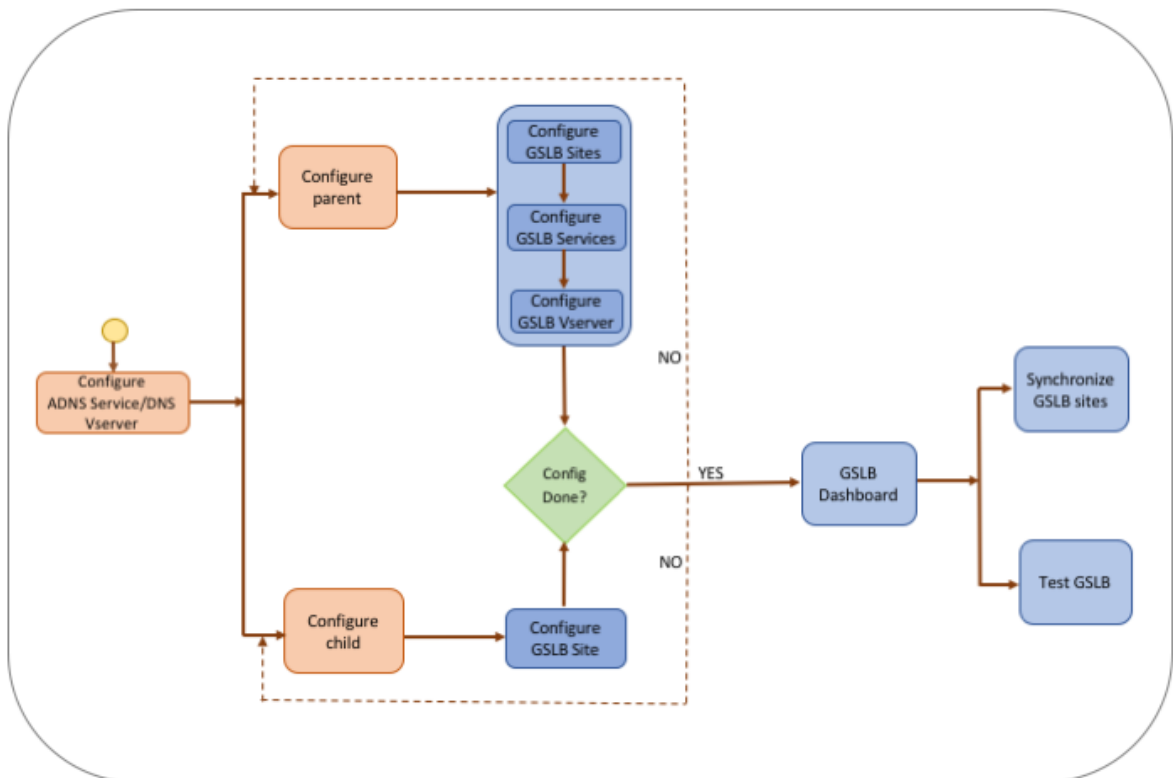

For details about configuring GSLB entities of an active-passive GSLB setup for disaster recovery, see [Configuring GSLB for Disaster Recovery](#).

## Configure parent-child topology

September 21, 2020

In a parent-child topology, at the top level are parent sites, which have peer relationships with other parents. Each parent can have multiple child sites, and each parent site exchanges health information with its child sites and with other parent sites. However, a child site communicates only with its parent site.

The following figure shows the workflow involved in a GSLB parent-child topology configuration.

Before you begin configuring the parent-child topology deployment, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

### To configure a parent-child deployment by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management > GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS server or a DNS virtual server for the site, you can do it now.
  - a) Click **View** and then click **Add**.
  - b) Enter the service name, IP address and select the protocol (ADNS/ADNS\_TCP) through which the data is exchanged with the service.
3. Select **Parent-Child Topology**.
4. In the Select the site type field, choose;
  - **Parent** – When configuring the parent site, you must configure its associated child sites and also configure the other parent sites in the GSLB setup.
  - **Child** – When configuring the child site, you must configure only the child site and its parent site.

### To configure a parent site

1. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
2. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site. All other sites are remote sites. If the specified site IP address is owned by the appliance (for example, a MIP address or SNIP address), the site is a local site. Otherwise, it is a remote site.
3. Enter the site details, such as the site name and site IP address.
  - a) Select the site type.
  - b) Optionally, change the RPC password and, if necessary, secure it.
  - c) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:

- **Always.** Monitor the GSLB service at all times.
  - **MEP Fails.** Monitor the GSLB service only when the exchange of metrics through MEP fails.
  - **MEP Fails and Service is DOWN.** Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
4. Configure the GSLB services.
    - a) Enter the service details such as service name, service type, and port number.
    - b) Associate the service with a site (local or remote) by selecting the GSLB site to which the GSLB service belongs.
    - c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
      - To associate an existing server, select the server name. The service IP address is auto-populated.
      - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      - To associate a virtual server, select an already existing virtual server or click **+** and add a new virtual server. This vserver is the load balancing vserver to which this GSLB service will be associated. If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the public port number.
  5. Configure the GSLB virtual servers.
    - a) Enter the name of the GSLB virtual server name and select the DNS record type.
    - b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
    - c) Click **>** in the **Domain Binding** box to view the domain name that is bound to the GSLB virtual server.
    - d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are automatically populated by default. You can change them if required.
      - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
      - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the **>** icon or add a new location by clicking **+** in the Select a location database box.
      - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.
  6. Click **Done** if the configuration is complete. The GSLB dashboard appears.
  7. If you have modified the GSLB parent-site configuration, click **Auto Synchronize GSLB** to syn-

chronize the configuration to the other parent sites in the GSLB setup. In a parent-child topology, synchronization for the child sites is skipped.

- Before synchronization, make sure that the local site's configuration includes information about the remote sites.
  - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
    - a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
    - b) Select the **Automatic Config Sync** check box.
8. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

### To configure a child site

1. Configure the GSLB sites.
  - a) Enter the site details, such as the site name and site IP address.
  - b) Select the site type.
  - c) Optionally, change the RPC password and, if necessary, secure it. 4. If a monitor is bound to the GSLB service, select the condition under which the monitor is to monitor the service. The possible conditions are:
    - **Always**. Monitor the GSLB service at all times.
    - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
    - **MEP Fails and Service is DOWN**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
2. Click **Done** if the configuration is complete. The GSLB dashboard appears.
3. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

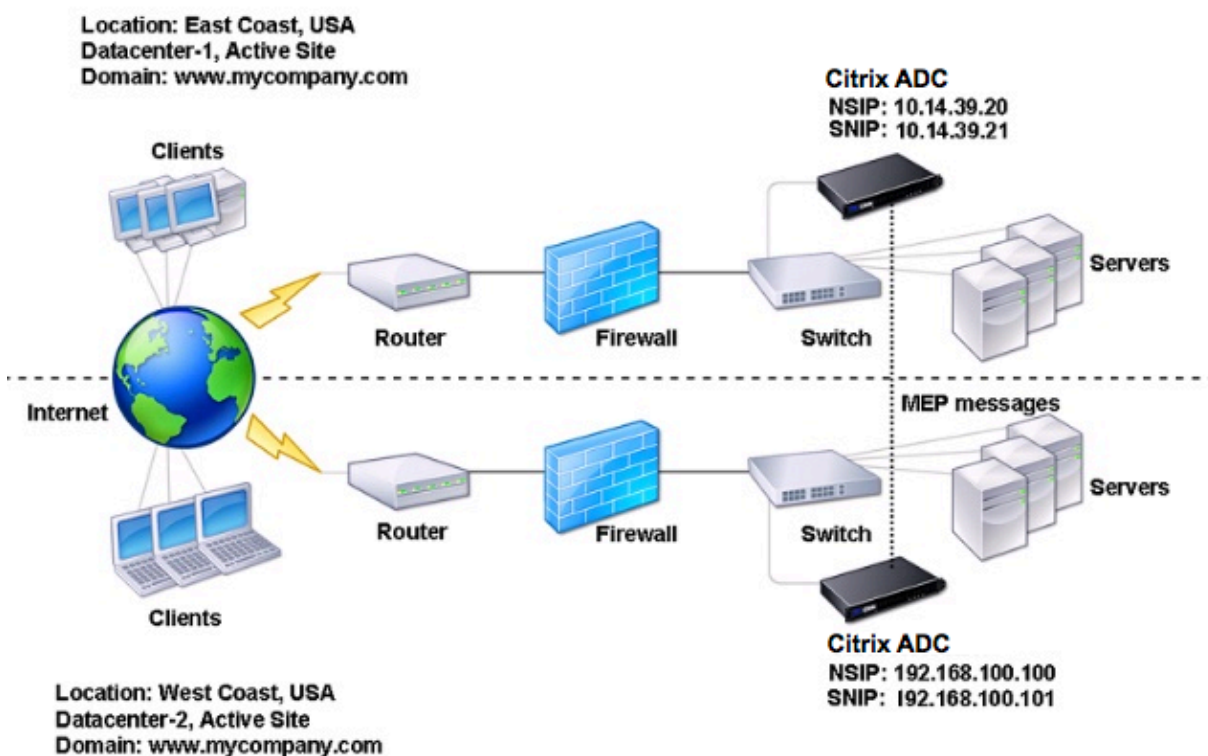

## Configure GSLB entities individually

September 21, 2020

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, [www.mycompany.com](http://www.mycompany.com), which is hosted on two geographically separated server farms or data centers. Both server farms use Citrix ADC appliances. The Citrix ADC appliances in these server farms

are set up in one-arm mode and function as authoritative DNS servers for the `www.mycompany.com` domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology

To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both Citrix ADC appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a Citrix ADC cluster setup, see [Setting Up GSLB in a Cluster](#).

### Configuring a Standard Load Balancing Setup

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the Citrix ADC appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see [Load Balancing](#).

## Configure an authoritative DNS service

September 21, 2020

When you configure the Citrix ADC appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the Citrix ADC appliance to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see

[Domain Name System](#).

### To create an ADNS service by using the command line interface

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

```
1 add service <name> <IP>@ ADNS <port>
2
3 show service <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-ADNS-1 10.14.39.21 ADNS 53
2
3 show service Service-ADNS-1
4 <!--NeedCopy-->
```

### To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

```
1 set service <name> <IPAddress> ADNS <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-ADNS-1 10.14.39.21 ADNS 53
2 <!--NeedCopy-->
```

## To remove an ADNS service by using the command line interface

At the command prompt, type the following command:

```
1 rm service <name>
2 <!--NeedCopy-->
```

### Example:

```
1 rm service Service-ADNS-1
2 <!--NeedCopy-->
```

## To configure an ADNS service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Add a new ADNS service, or select an existing service and edit its settings.

## Configure a basic GSLB site

September 21, 2020

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB set up, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every Citrix ADC appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the Citrix ADC appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

## To create a GSLB site by using the command line interface

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

```
1 add gslb site <siteName> <siteIPAddress>
2 show gslb site <siteName>
3 <!--NeedCopy-->
```

### Example:

```
1 add gslb site Site-GSLB-East-Coast 10.14.39.21
2 show gslb site Site-GSLB-East-Coast
3 <!--NeedCopy-->
```

### To modify or remove a GSLB Site by using the command line interface

- To modify a GSLB site, use the `set gslb site` command, which is just like using the `add gslb site` command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the `unset gslb site` command, followed by the `siteName` value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the `rm gslb site` command, which accepts only the `<name>` argument.

### To configure a basic GSLB site by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**.
2. Add a new GSLB site, or select an existing GSLB site and edit its settings.

### To view the statistics of a GSLB site by using the command line interface

At the command prompt, type:

```
1 stat gslb site <siteName>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb site Site-GSLB-East-Coast
2 <!--NeedCopy-->
```

### To view the statistics of a GSLB site by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**.
2. Select the GSLB site and click **Statistics**.

## Configure a GSLB service

September 21, 2020

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

**Important**

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

The GSLB service IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

**To create a GSLB service by using the command line interface**

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

```
1 add gslb service <serviceName> <serverName | IP> <serviceType> <port>-
  siteName <string>
2 show gslb service <serviceName>
3 <!--NeedCopy-->
```

**Example:**

```
1 add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 - siteName Site-
  GSLB-East-Coast
2 show gslb service Service-GSLB-1
3 <!--NeedCopy-->
```

**To modify or remove a GSLB service by using the command line interface**

- To modify a GSLB service, use the `set gslb service <serviceName>` command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the `add gslb service` command for details about the parameters. Example

```
1 > set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandWidth 25 -
  maxClient 8
2 Done
3 > sh gslb service SKP_GSLB_NOTCNAME_SVC2
4 SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
```

```
5 ...
6 Max Conn: 8 Max Bandwidth: 25 kbits
7 <!--NeedCopy-->
```

- To reset a parameter to its default value, you can use the `unset gslb service <serviceName>` command and the parameters to be unset. Example

```
1 > unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandwidth
2 Done
3 > sh gslb service SKP_GSLB_NOTCNAME_SVC2
4 SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
5 ...
6 Max Conn: 8 Max Bandwidth: 0 kbits
7 <!--NeedCopy-->
```

- To remove a GSLB service, use the `rm gslb service <serviceName>` command.

### To create a GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**.
2. Add a new GSLB service, or select an existing service and edit its settings.

### To view the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
1 stat gslb service <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb service Service-GSLB-1
2 <!--NeedCopy-->
```

### To view the statistics of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**.
2. Select the GSLB Service and click **Statistics**.

## Configure a GSLB service group

September 21, 2020

Service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable an option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled or disabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to the service groups.

### Important

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

The GSLB service group IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

The Citrix ADC supports the following types of GSLB service groups.

- IP address based service groups
- Domain name based service groups
- Domain name based autoscale service groups

### GSLB domain name based autoscale service groups

The Citrix ADC hybrid and multi-cloud global server load balancing (GSLB) solution enables customers to distribute application traffic across multiple data centers in hybrid clouds, multiple clouds, and on premises. The Citrix ADC GSLB solution supports various load balancing solutions, such as the Citrix ADC load balancer, Elastic Load Balancing (ELB) for Amazon Web Services (AWS), and other third-party load balancers. Also, the GSLB solution performs global load balancing even if the GSLB and load balancing layers are independently managed.

In cloud deployments, users are given a domain name as a reference when accessing the load balancing solution for management purposes. It is recommended that external entities do not use the IP addresses that these domain names resolve to. Also, the load balancing layers scale up or down based on the load, and the IP addresses are not guaranteed to be static. Therefore, it is recommended to use the domain name to refer to the load balancing endpoints instead of IP addresses. This requires the GSLB services to be referred using the domain name instead of IP addresses and it must consume all the IP addresses returned for the load balancing layer domain name and have a representation for the same in GSLB.

To use domain names instead of IP addresses when referring to the load balancing endpoints, you can use the domain name based service groups for GSLB.

### **Monitor GSLB domain name based service groups**

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications; tcp-default and ping-default. The tcp-default monitor is bound to all TCP services and the ping-default monitor is bound to all non-TCP services. The built-in monitors are bound by default to the GSLB service groups. However, it is recommended to bind an application specific monitor to the GSLB service groups.

### **Recommendation for setting the trigger monitors option to MEPDOWN**

The Trigger Monitors option can be used to indicate if the GSLB site must use the monitors always, or use monitors when metrics exchange protocol (MEP) is DOWN.

The Trigger Monitors option is set to ALWAYS by default.

When the Trigger Monitors option is set to ALWAYS, each GSLB node triggers the monitors independently. If each GSLB node triggers the monitors independently, then each GSLB node might operate on different set of GSLB services. This might result in discrepancies in the DNS responses for the DNS requests landing on these GSLB nodes. Also, if each GSLB node is monitoring independently, then the number of monitor probes reaching the load balancer entity increases. The persistence entries also become incompatible across the GSLB nodes.

Therefore, it is recommended that the Trigger Monitors option on GSLB site entity is set to MEPDOWN. When the Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and monitoring ownership lies with the local GSLB node. When Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and subsequent monitoring is done by the local GSLB node of a GSLB service group. The results are then propagated to all other nodes participating in GSLB by using the metrics exchange protocol (MEP).

Also, whenever the set of IP addresses associated with a load balancing domain are updated, it is notified through MEP.

### **Limitations of GSLB service groups**

- For a load balancing domain, the IP address that is returned in the DNS response is generally the public IP address. The private IP address cannot be applied dynamically when the load balancing domain is resolved. Therefore, public IP port and private IP port for the GSLB domain name based autoscale service groups IP port bindings are the same. These parameters cannot be set explicitly for the domain name based autoscale service groups.
- Site persistence, DNS views, and clustering are not supported for GSLB service groups.

## Configure and manage GSLB service groups by using the CLI

|Operation|CLI Command|

|--|

|To add a GSLB service group|`add gslb serviceGroup <serviceName>@ <serviceType> [-autoScale ( DISABLED | DNS )] -siteName <string>`

||Example: **add gslb serviceGroup** Service-Group-1 http -siteName Site1 -autoScale DNS

|To bind a GSLB service group to a virtual server|`bind gslb serviceGroup <serviceName> > ((<IP>@ <port>)| <serverName>@ | ((-monitorName <string>@`

||Example: **bind gslb serviceGroup** Service-Group-1 203.0.113.2; **bind gslb serviceGroup** Service-Group-1 S1 80; **bind gslb serviceGroup** Service-Group-1 -monitorName Mon1

|To unbind a GSLB service group to a virtual server|`unbind gslb serviceGroup <serviceName> > ((<IP>@ <port>)| <serverName>@ | -monitorName <string>@)`

||Example:**unbind gslb serviceGroup** Service-Group-1 -monitorName Mon1

|To set parameters for a GSLB service group|`set gslb serviceGroup <serviceName>@ [(<serverName>@ <port> [-weight <positive_integer>] [-hashId <positive_integer>] [-publicIP <ip_addr|ipv6_addr|*>] [-publicPort <port>])| -maxClient <positive_integer> | -cip ( ENABLED | DISABLED )| <cipHeader> | -cltTimeout <secs> | -svrTimeout <secs> | -maxBandwidth <positive_integer> | -monThreshold <positive_integer> | -downStateFlush ( ENABLED | DISABLED )] [-monitorName <string> -weight <positive_integer>] [-healthMonitor ( YES | NO )] [-comment <string>] [-appflowLog ( ENABLED | DISABLED )]`

|To unset parameters from a GSLB service group|`unset gslb serviceGroup <serviceName>@ [<serverName>@ <port> [-weight] [-hashId] [-publicIP] [-publicPort]] [-maxClient] [-cip] [-cltTimeout] [-svrTimeout] [-maxBandwidth] [-monThreshold] [-appflowLog] [-monitorName] [-weight] [-healthMonitor] [-cipHeader] [-downStateFlush] [-comment]`

|To enable a GSLB service group|`enable gslb serviceGroup <serviceName>@ [<serverName>@ <port>]`

||Example:**enable gslb serviceGroup** SG1 S1 80

|To disable a GSLB service group|`“disable gslb serviceGroup @ [@ ] [-delay] [-graceFul ( YES // NO )]`

```

1 ||Example:disable gslb serviceGroup SRG2 S1 80
2 ||Note: The service group that has to be disabled must be a DBS
   service group and not an autoscale service group.
3 |To remove a GSLB service group|`rm gslb serviceGroup <
   serviceName>`
4 ||Example:rm gslb serviceGroup Service-Group-1
5 |To view the statistics of a GSLB service group|`stat gslb
   serviceGroup [<serviceName>`
6 ||Example:stat gslb serviceGroup Service-Group-1
7 |To view the properties of a GSLB service group|`show gslb

```

```

    serviceGroup [<serviceGroupName> -includeMembers]``
8  ||Example: **show gslb serviceGroup** SG1; **show gslb serviceGroup** -
    includeMembers
9
10 ### Changes to the existing GSLB CLI commands
11
12 The following table lists some of the changes that are done to the
    existing GSLBs commands after the introduction of the GSLB service
    groups.
13
14 |CLI Command|Change
15 |--|--|
16 |bind gslb vserver|The service group name is added to the bind command.
17 ||Example:``bind gslb vserver <name> ((-serviceName <string> [-weight
    <positive_integer>] ) | <serviceGroupName>@ | | (-domainName <string>
    > [-TTL <secs>] [-backupIP<ip_addr|ipv6_addr|*>] [-cookieDomain <
    string>] [-cookieTimeout <mins>][-sitedomainTTL <secs>]) | (-
    policyName <string>@ [-priority<positive_integer>] [-
    gotoPriorityExpression <expression>] [-type REQUEST | RESPONSE ]))
    <!--NeedCopy-->

```

|unbind gslb vserver|The service group is added to the unbind command.

|Example:|“unbind gslb vserver (-serviceName @ /(-domainName [-backupIP] [-cookieDomain]) | -policyName @)

```

1  |show gslb site|When this command is executed, the GSLB service groups
    are also displayed.
2  |show gslb vs|When this command is executed, the GSLB service groups
    are be displayed.
3  |stat gslb vs|When this command is executed, the GSLB service groups
    statistics are also displayed.
4  |show lb monitor bindings|When this command is executed the GSLB
    service group bindings are also displayed.
5
6  ### Configure GSLB service groups by using the GUI
7
8  1.  Navigate to **Traffic** **Management** > **GSLB** > **Service** **
    Groups.**
9  1.  Create a service group and set the AutoScale Mode to DNS.
10
11 ### Configure site persistence for the GSLB service groups
12
13 You can configure site persistence for the IP address based and domain
    name based service groups. Site persistence is not supported for
    domain name based autoscale service groups.

```

```
14
15 ##### To set site persistence based on HTTP cookies by using the CLI
16
17 - For connection proxy persistence, you do not have to set the site
    prefix.
18
19 At the command prompt, type:
```

```
set gslb service group [-sitePersistence ]
```

```
1 - For HTTP redirect persistence, you must first set the site prefix
    for a member of the service group and then set the HTTPRedirect
    persistence parameter for the service group.
2
3 At the command prompt, type:
```

```
set gslb servicegroup <serviceGroup member name|Ip> [-sitePrefix ]
```

```
set gslb servicegroup [-sitePersistence ]
```

““

#### Examples:

- Connection proxy persistence

```
set gslbservicegroup sg1 -sitePersistence connectionProxy
```
- HTTPRedirect persistence

```
set gslb servicegroup sg2 test1 80 -sitePrefix vserver-GSLB-1
set gslb servicegroup sg2 -sitePersistence HTTPRedirect
```

#### To set site persistence based on cookies by using the GUI

1. Navigate to **Traffic Management > GSLB > Services Groups** and select the service group that you want to configure for site persistence (for example, servicegroup-GSLB-1).
2. Click the **Site Persistence** section and set the persistence that meets your requirement.

#### Tip

For deployment scenario and example configuration of GSLB service groups, see the following topics:

- [Use Case: Deployment of Domain Name Based Autoscale Service Group](#)
- [Use Case: Deployment of IP Address Based Autoscale Service Group](#)

## Configure a GSLB virtual server

September 21, 2020

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

### Note

A GSLB virtual server protocol requirement is mainly to create a relation between the virtual server and the services that are bound to the virtual server. This also keeps CLI/APIs consistent for other types of virtual servers. The Service Type parameter on a service or a virtual server is not used while serving the DNS requests. It is instead referenced during site persistence, monitoring, and for doing lookups via MEP.

### To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

```
1 - add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)
2 - show gslb vserver <name>
3 <!--NeedCopy-->
```

### Example:

```
1 add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
2 add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
3 show gslb vserver Vserver-GSLB-1
4 show gslb vserver Vserver-GSLB-2
5 <!--NeedCopy-->
```

### To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the `set gslb vserver` command. This command works similar to the `add gslb vserver` command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to its default value, you can use the `unset gslb vserver` command followed by the `vserverName` value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the `rm gslb vserver` command, which accepts only the name argument.

**To configure a GSLB virtual server by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

**To view the statistics of a GSLB virtual server by using the command line interface**

At the command prompt, type:

```
1 stat gslb vserver <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat gslb vserver Vserver-GSLB-1
2 <!--NeedCopy-->
```

**To view the statistics of a GSLB virtual server by using the configuration utility**

Navigate to **Traffic Management > GSLB > Virtual Servers**, select the virtual server and click **Statistics**.

**GSLB virtual server statistics**

Starting from Citrix ADC version 12.1 build 51.xx and later, the GSLB virtual server statistics also display the following information in addition to details such as; vserver hits, current persistence session, request bytes, response bytes, spillover threshold, spillover hits, current client established connections, and vserver down backup hits.

- **Primary LB method failures:** Number of times the primary GSLB method has failed.
- **Backup LB method failures:** Number of times the backup GSLB method has failed.
- **Vserver persistence hits:** The number of times the request is served through the persistence sessions.

**Note:**

The primary or the backup method can fail when the primary method is static proximity and the backup method is RTT. In this scenario, if there is no location corresponding to LDNS IP, the static proximity fails and backup method is attempted. The statistics are updated based on the following:

- If the backup method is successful, only primary method failure statistics are incremented.
- If RTT calculation is not successful, then backup method also fails. In this case, both primary and backup method failure statistics are incremented.

When the backup method fails, the last resort method of round robin is used.

The following image is a sample of GSLB virtual server statistics from CLI.

```
Gslb Vserver Summary
      Protocol      State  Health  actSvcs  inactSvc
gslbvip      HTTP      DOWN    0         0         0

VServer Stats:
                Rate (/s)                Total
Vserver hits                0                0
Primary LB Method Failures  --                0
Backup LB Method Failures  --                0
Current Persistence Sessions --                0
Vserver Persistence Hits   --                0
Request bytes                0                0
Response bytes               0                0
Current Client Est connections --                0
Spill Over Threshold        --                0
Spill Over Hits             --                0
Vserver Down Backup Hits    --                0

Note: The above counters are the sum of all bound GSLB services
Done
```

The following image is a sample of GSLB virtual server statistics from GUI.

The screenshot displays the 'GSLB Virtual Servers' configuration page for a specific virtual server named 'stat'. The page is titled 'GSLB Virtual Servers Statistics [ stat ]'. Under the 'Gslb Vserver Summary' section, there is a table with two columns: 'Name' and 'Vserver protocol'. The row for 'stat' shows the protocol as 'HTTP'. Below the table are 'Enable' and 'Disable' buttons. The 'VServer Stats:' section lists various performance metrics:

| Name | Vserver protocol |
|------|------------------|
| stat | HTTP             |

Buttons:

**VServer Stats:**

- Vserver hits
- Primary LB Method Failures
- Backup LB Method Failures
- Current Persistence Sessions
- Vserver Persistence Hits
- Request bytes
- Response bytes
- Current Client Est connections
- Spill Over Threshold
- Spill Over Hits
- Vserver Down Backup Hits

### GSLB service statistics

When you run the `stat gslb service` command from the command line or click the **Statistics link** from the configuration utility, the following details of the service are displayed:

- **Request bytes.** Total number of request bytes received on this service or virtual server.
- **Response bytes.** Number of response bytes received by this service or virtual server.
- **Current client established connections.** Number of client connections in ESTABLISHED state.
- **Current load on the service.** Load on the service (Calculated from the load monitor bound to the service).

The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

## Clearing the GSLB virtual server or service statistics

Note: This feature is available in NetScaler release 10.5.e.

You can now clear the statistics of a GSLB virtual server and service. Citrix ADC provides the following two options to clear the statistics:

- **Basic:** Clears the statistics that are specific to the virtual server but retains the statistics that are contributed by the bound GLSB service.
- **Full:** Clears both the virtual server and the bound GSLB service statistics.

### To clear the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 stat gslb vserver <name> -clearstats <basic | full>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb vserver Vserver-GSLB-1 - clearstats basic
2 <!--NeedCopy-->
```

### To clear the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
1 stat gslb service <name> -clearstats <basic | full>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb service service-GSLB-1 - clearstats basic
2 <!--NeedCopy-->
```

### To clear the statistics of a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Select the GSLB virtual server and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

**To clear the statistics of a GSLB service by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Services**.
2. Select the GSLB service and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

**Enabling and Disabling GSLB Virtual Servers**

When you create a GSLB virtual server, it is enabled by default. If you disable the GSLB virtual server, upon receiving a DNS request, the Citrix ADC appliance does not make any GSLB decision based on the GSLB method that is configured. Instead, the response to the DNS query contains the IP addresses of all the services bound to the virtual server.

**To enable or disable a GSLB virtual server by using the command line interface**

At the command prompt, type one of the following commands:

```
1 enable gslb vserver <name>@
2
3 disable gslb vserver <name>@
4 <!--NeedCopy-->
```

**Example:**

```
1 enable gslb vserver Vserver-GSLB-1
2 disable gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

**To enable or disable a GSLB virtual server by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Select a virtual server and, from the **Action** list, select **enable** or **disable**.

**Bind GSLB services to a GSLB virtual server**

September 21, 2020

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

### To bind a GSLB service to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

```
1 bind gslb vserver <name> -serviceName <string>
2
3 show gslb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
2 show gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To unbind a GSLB service from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 unbind gslb vserver <name> -serviceName <string>
2 <!--NeedCopy-->
```

### To bind GSLB services by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click a virtual server.
2. Click in the **Domains** section, and configure a domain and bind the domain.

### Bind a domain to a GSLB virtual server

September 21, 2020

To make a Citrix ADC appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the Citrix ADC appliance adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see [Domain Name System](#).

### To bind a domain to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

```
1 bind gslb vserver <name> -domainName <string>
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
2 show gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To unbind a GSLB domain from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 unbind gslb vserver <name> -domainName <string>
2 <!--NeedCopy-->
```

### To bind a domain to a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
  - To create a new Domain, click **Add**.
  - To modify an existing Domain, select the domain, and then click **Open**.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:
  - Domain Name\*—domainName (for example, www.mycompany.com)

/\* A required parameter
5. Click Create.
6. Click OK.

## To view the statistics of a domain by using the command line interface

At the command prompt, type:

```
1 stat gslb domain <name>
2 <!--NeedCopy-->
```

### Example:

```
1 stat gslb domain www.mycompany.com
2 <!--NeedCopy-->
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the Citrix ADC appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

## To view the statistics of a domain by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click **Statistics**.

## To view the configuration details of the entities bound to a GSLB domain using the command line

Note: This feature is available in NetScaler release 10.5.e.

At the command prompt, type:

```
1 show gslb domain <name>
2 <!--NeedCopy-->
```

### Example:

```
1 show gslb domain gslb1.com
2     gslb1.com
3     gvs1 - HTTP      state: DOWN
4     DNS Record Type: A
5     Configured Method: LEASTCONNECTION
6     Backup Method: ROUNDROBIN
7     Persistence Type: NONE
8     Empty Down Response: DISABLED
```

```
9      Multi IP Response: DISABLED
10     Dynamic Weights: DISABLED
11
12     gsvc1 (10.102.239.165: 80)- HTTP State: DOWN   Weight: 1
13         Dynamic Weight: 0   Cumulative Weight: 1
14         Effective State: DOWN
15         Threshold : BELOW
16
17         Monitor Name : http
18             State: DOWN   Weight: 1
19             Probes: 144   Failed [Total: 144 Current: 144]
20             Last response: Failure - TCP syn sent, reset
21                 received.
22             Response Time: 2000 millisec
23
24     gsvc2 (10.102.239.179: 80)- HTTP State: DOWN   Weight: 1
25         Dynamic Weight: 0   Cumulative Weight: 1
26         Effective State: DOWN
27         Threshold : BELOW
28
29         Monitor Name : http-ecv
30             State: DOWN   Weight: 1
31             Probes: 141   Failed [Total: 141 Current: 141]
32             Last response: Failure - TCP syn sent, reset
33                 received.
34             Response Time: 2000 millisec
35 Done
36 <!--NeedCopy-->
```

### To view the configuration details of the entities bound to a GSLB domain by using the configuration utility

Note: This feature is available in NetScaler release 10.5.e.

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click a virtual server.
2. Click the field below the **Domains** pane.
3. In the **GSLB Virtual Server Domain Binding** dialog box, select a domain, and then click **Show Bindings**.

## Example of a GSLB setup and configuration

September 21, 2020

An organization has a geographically dispersed network and has three data centers located in the United States, Mexico, and Colombia. In the configuration related to these locations, these are referred to as US, MX, and CO respectively. At each location, the company has a server farm, which provides the same content and the setup is working as expected. The Citrix ADC appliance at each location is configured through a virtual server with the HTTP protocol on port 80.

The organization has implemented the GSLB setup by adding a site identifier at each site. The site identifier includes a site name and an IP address that is owned by the Citrix ADC appliance and is used for the GSLB communications.

Each site has a site local to the appliance. Also, each site has two sites remote to the local appliance. On each site, a GSLB virtual server is created with the same name. This virtual server identifies the website of the organization globally and does not have any IP address associated with it.

The setup also has GSLB services configured that point to the load balancing virtual servers configured on each GSLB site by specifying the IP address, protocol, and port number of the respective virtual server. These services are bound to the GSLB virtual server.

**Note:** In the procedure below, the commands use private IP addresses for the GSLB sites. For public sites and GSLB services, ensure that you use public IP addresses for these sites.

The following table lists the IP addresses and locations used in the example:

| IP Address    | Location                               |
|---------------|----------------------------------------|
| 10.3.1.101    | Site IP of local Citrix ADC.           |
| 172.16.1.101  | Site IP of remote location site-MX.    |
| 192.168.1.101 | Site IP of remote location site-CO.    |
| 172.16.1.100  | Service IP of remote location site-MX. |
| 10.3.1.100    | Service IP of local Citrix ADC.        |
| 192.168.1.100 | Service IP of remote location site-CO. |

When adding a GSLB site, if the site communicates over the internet only then use the “Public IP” field. For example, when there is no site to site VPN connectivity between the GSLB sites.

### To configure the GSLB setup with Citrix ADC appliances by using the CLI commands

1. Enable the GSLB feature, if not already done.

```
1 enable ns feature gslb
2 <!--NeedCopy-->
```

2. Identify a SNIP that for adding local GSLB site.
3. Add the GSLB site for the local Citrix ADC appliance.

```
1 add gslb site site-US 10.3.1.101
2 <!--NeedCopy-->
```

4. Add the GSLB sites for the remote Citrix ADC appliances.

```
1 add gslb site site-MX 172.16.1.101
2 add gslb site site-CO 192.168.1.101
3 <!--NeedCopy-->
```

5. Add the GSLB virtual server that references a service being used in the GSLB setup:

```
1 add gslb vserver gslb-lb HTTP
2 <!--NeedCopy-->
```

6. Add the GSLB services for each site participating in the GSLB setup:

```
1 add gslb service gslb_SVC30 172.16.1.100 HTTP 80 -siteName site-MX
2 add gslb service gslb_SVC10 10.3.1.100 HTTP 80 -siteName site-US
3 add gslb service gslb_SVC20 192.168.1.100 HTTP 80 -siteName site-
  CO
4 <!--NeedCopy-->
```

7. Bind the GSLB services to the GSLB virtual server:

```
1 bind gslb vserver gslb-lb -serviceName gslb_SVC10
2 bind gslb vserver gslb-lb -serviceName gslb_SVC20
3 bind gslb vserver gslb-lb -serviceName gslb_SVC30
4 <!--NeedCopy-->
```

8. Bind the domain to the GSLB virtual server.

```
1 bind gslb vserver gslb-lb -domainName www.mycompany.com -TTL 30
2 <!--NeedCopy-->
```

9. Add an ADNS service that listens to the DNS queries.

```
1 set service Service-ADNS-1 10.14.39.21 ADNS 53
2 <!--NeedCopy-->
```

## Synchronize the configuration in a GSLB setup

July 9, 2021

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each Citrix ADC, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point, you must ensure that the configuration across all GSLB sites is identical. You can use the Citrix ADC's GSLB configuration synchronization option to synchronize the configuration across the GSLB sites.

The Citrix ADC appliance from which you use the synchronization option is referred to as the 'main node' and the GSLB sites on which the configuration is copied as 'subordinate nodes'. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to that on the main node.

Synchronization (also referred to as 'auto sync') is carried out in the following manner:

- The main node finds the differences between the configuration of the main node and subordinate node, and changes the configuration of the subordinate node to make it similar to the main node.  
If you force a synchronization (use the 'force sync' option), the appliance deletes the GSLB configuration from the subordinate node and then configures the subordinate to make it similar to the main node.
- During synchronization, if a command fails, synchronization is not aborted and the error message are logged into a **.err** file in the **/var/netScaler/gslb** directory.
- Synchronization is done only on the parent sites. GSLB child sites' configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.
- If you disable the internal user login, the GSLB auto sync uses the SSH keys to synchronize the configuration. But, to use GSLB auto sync in a partition environment, you must enable the internal user login and make sure that the partition user name in the local and remote GSLB sites is the same.
- For enhanced security, Citrix recommends that you change the internal user account and RPC node passwords. Internal user account password is changed through RPC node password. For details, see [Change an RPC node password](#).

### Note

- On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). If the default route to reach the remote sites is in an management

subnet, as in most cases, then NSIP is used as the source IP address.

To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through the GSLB site IP subnet.

- The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for an RPC node is specific to each Citrix ADC appliance. Therefore, after you force a synchronization (using the `sync gslb config -forceSync` command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other Citrix ADC appliances.
- Port 22 is also required for synchronizing the database files to the remote site.

If you use the `saveconfig` option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

1. The main node saves its configuration immediately before it initiates the process of synchronization.
2. After the process of synchronization is complete, the subordinate nodes save their configuration. A subordinate node saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a subordinate node, you must manually investigate the cause of the failure and take corrective action.

### To improve the time taken for configuration synchronization on all GSLB sites

Configure the TCP profile settings at the command prompt as follows:

```
1 set tcpprofile nstcp_internal_apps -bufferSize 4194304 -sendBuffsize
   4194304 -tcpmode ENDPOINT
2 <!--NeedCopy-->
```

### Limitations of synchronization

- On the main node, the names of the remote GSLB sites must be identical to the names of sites configured on the Citrix ADC appliances hosting those sites.
- During the synchronization, traffic disruptions may occur.
- Citrix ADC is tested to synchronize up to 200,000 lines of the configuration.
- Synchronization may fail:
  - If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
  - If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the main node and then try to synchronize.
  - If the RPC node passwords are different for NSIP and loopback IP address.

- If you perform synchronization on GSLB sites that are configured in different partitions of the same Citrix ADC appliance.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes must be the same.
- If you rename any GLSB entity that is part of your GSLB configuration (use “show gslb running-Config” command to display the GSLB configuration). You must use the force sync option to synchronize the configuration to other GSLB sites.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and readded to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

### **Points to note before starting the synchronization of a GSLB setup**

Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the main node, management access and SSH should be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the Citrix ADC appliance. For more information about adding the GSLB site IP addresses and enabling Management Access, see “[Configuring a Basic GSLB Site](#)”.
- The GSLB configuration on the Citrix ADC appliance that is considered as the main node is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB must have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.
- The main node and the subordinate nodes run the same Citrix ADC versions. Starting from release 12.1, build 50.x, the appliance checks for the firmware version on main and subordinate nodes before initiating synchronization. If the main and the subordinate nodes run different versions, the synchronization is aborted for that remote site to avoid pushing any incompatible changes across the versions. Also, an error message displaying the site details on which the synchronization aborted appears.

The following figures display sample error messages from the CLI and the GUI.

```
> sh gslb syncStatus -summary
```

Displaying the status summary of the manual GSLB configuration synchronization:

| Site Name | Status  | Reason                                                                                     |
|-----------|---------|--------------------------------------------------------------------------------------------|
| s2        | Failure | Error: Different netscaler release on the remote site. Local Site: 13.0, Remote Site: 12.1 |
| s1        | Success | All Done                                                                                   |
| s3        | Success | All Done                                                                                   |

Done

```
>
```

```
> sh gslb syncStatus -summary
```

Displaying the status summary of the manual GSLB configuration synchronization:

| Site Name | Status  | Reason                                                                                     |
|-----------|---------|--------------------------------------------------------------------------------------------|
| s2        | Failure | Error: Different netscaler release on the remote site. Local Site: 13.0, Remote Site: 12.1 |
| s1        | Success | All Done                                                                                   |
| s3        | Success | All Done                                                                                   |

Done

```
>
```

### Important

The following directories are synchronized as part of the GSLB configuration synchronization.

- /var/netscaler/locdb/
- /var/netscaler/ssl/
- /var/netscaler/inbuilt\_db/

## Manual synchronization between sites participating in GSLB

September 21, 2020

**Important:** After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Perform the synchronization only if you are sure that the synchronization process will not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, and can lead to site outage. If some commands fail and some commands succeed, the successful commands cannot be rolled back.

### To synchronize a GSLB configuration by using the CLI:

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

```
1 sync gslb config [-preview | -forceSync <string> | -nowarn | -
  saveconfig] [-debug]
```

```
2 show gslb syncStatus
3 <!--NeedCopy-->
```

**Example:**

```
1 sync gslb config
2
3 [WARNING]: Syncing config may cause configuration loss on other site.
4
5 Please confirm whether you want to sync-config (Y/N)? [N]:y
6
7 Sync Time: Dec 9 2011 10:56:9
8
9 Retrieving local site info: ok
10
11 Retrieving all participating gslb sites info: ok
12
13 Gslb_site1[Master]:
14
15 Getting Config: ok
16
17 Gslb_site2[Slave]:
18
19 Getting Config: ok
20
21 Comparing config: ok
22
23 Applying changes: ok
24
25 Done
26 <!--NeedCopy-->
```

**To synchronize a GSLB configuration by using the GUI:**

1. Navigate to **Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **ForceSyn**.
3. In **GSLB Site Name**, select the GSLB sites that are to be synchronized with the master node configuration.

**Previewing GSLB synchronization**

By previewing the GSLB synchronization operation, you can see the differences between the master node and each slave node. If there are any discrepancies, you can troubleshoot before synchronizing the GSLB configuration.

**To preview the GSLB synchronization output by using the CLI:**

At the command prompt, type the following command:

```
1 sync gslb config -preview
2 <!--NeedCopy-->
```

**To preview the GSLB synchronization output by using the GUI:**

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **Preview**.
3. Click **Run**.

A progress window displays any discrepancies in the configuration.

**Debugging the commands triggered during synchronization process**

You can view the status (success or failure) of each command triggered during the synchronization process and troubleshoot accordingly.

**To debug the GSLB synchronization commands by using the CLI:**

At the command prompt, type the following command:

```
1 sync gslb config -debug
2 <!--NeedCopy-->
```

**To debug the GSLB synchronization commands by using the GUI:**

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **Debug**.
3. Click **Run**.

A progress window displays the status of each command triggered during synchronization.

## Real-time synchronization between sites participating in GSLB

September 21, 2020

If you want to synchronize GSLB configuration across slave sites automatically when the commands are executed on master sites, you can now use the AutomaticConfigSync option to automatically synchronize the real-time GSLB configuration. You do not have to manually trigger the AutoSync option to synchronize the configuration.

If you attempt to manually synchronize (with the sync gslb config command) a site while it is being autosynchronized, a “Sync in progress” error message appears. Autosynchronization cannot be triggered for a site that is in the process of being synchronized manually.

**Attention:**

Starting with Citrix ADC 12.1 build xx.xx, SNMP traps are generated when you synchronize the GSLB configuration. Note that in real-time synchronization, the synchronization status in the first SNMP trap is captured as failure. You can ignore this status because a second SNMP trap is automatically generated immediately after the first trap with the actual synchronization status. However, if the synchronization failed in the second attempt also, SNMP trap is not generated because the synchronization status has not changed from the previous synchronization status.

For details on configuring Citrix ADC appliance to generate traps, see [Configuring the Citrix ADC to generate SNMP traps](#).

**Notes:**

- All logs related to real-time sync are stored in the `/var/netScaler/gslb/periodic_sync.log` file.
- The sync status file and default configuration file are stored in the location `/var/netScaler/gslb_sync`.
- Enabling `AutomaticConfigSync` from default partition of a partitioned appliance is not supported. However, it can be enabled from all other partitions. The sync status file and default configuration file are stored in the location `/var/partitions/<partition name>/netScaler/gslb_sync`.

**Best practices for using the real-time synchronization feature**

- It is recommended that all the Citrix ADC appliances participating as sites have the same Citrix ADC software version.
- To change the RPC node password, first change the password on the slave site and then on the master site.
- Configure local GSLB sites on each site participating in GSLB.
- Enable `automaticConfigSync` on one of the sites where the configuration is performed. This site eventually gets synchronized to other GSLB sites.
- If there is a new configuration or changes are made to the existing configuration, make sure to check the status using the “`show gslb syncStatus`” command to confirm if the changes are synchronized across all sites or if there was any error.

**To enable real-time synchronization by using the CLI**

At the command prompt, type:

```
1 set gslb parameter - automaticConfigSync (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb parameter - automaticConfigSync ENABLED
2 <!--NeedCopy-->
```

### To enable real-time synchronization by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Change GSLB Settings**.
2. Select **Automatic ConfigSync**.

**Note:** This option must be enabled only in the site where the configuration is performed.

#### Tip

For information on the following topics, see [Manual synchronization between sites participating in GSLB](#).

- Previewing GSLB synchronization
- Debugging the commands triggered during synchronization process

## View GSLB synchronization status and summary

September 21, 2020

After the GSLB configuration is synchronized across the GSLB sites, you can view the detailed status and the summary of the last GSLB sync operation. This is applicable to both manual and real-time GSLB synchronization.

### To view the GSLB synchronization status or summary by using the CLI

At the command prompt, type:

```
1 show gslb sync status
2 <!--NeedCopy-->
```

or

```
1 show gslb syncStatus -summary
2 <!--NeedCopy-->
```

The following figure displays a sample GSLB configuration synchronization status.

```

> sh gslb syncStatus
Displaying the status of the manual GSLB configuration synchronization:

gslb_site1[Master]:
  Getting Config: ok
gslb_site2[Slave]:
  Syncing gslb static proximity database: ok
  Syncing inbuilt gslb static proximity database : ok
  Getting Config: ok
  Comparing config: ok
  Applying changes: ok
gslb_natsite1[Slave]:
  Syncing gslb static proximity database: ok
  Syncing inbuilt gslb static proximity database : ok
  Getting Config: ok
  Comparing config: ok
  Applying changes: ok

Done
> █

```

The following figure displays a sample GSLB configuration synchronization summary.

```

> sh gslb syncStatus -summary
Displaying the status summary of the manual GSLB configuration synchronization:

-----
  Site Name      Status      Reason
-----
  gslb_site1    Success    All Done
  gslb_site2    Failure    Error executing command on gslb site...ERROR: Connection failed
  gslb_natsite1 Success    All Done
Done
>

```

### To view the GSLB synchronization status or summary by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard**.
2. Click **View Synchronization Summary** or **View Synchronization Status**, as required.

## SNMP traps for GSLB configuration synchronization

September 21, 2020

Starting with Citrix ADC 12.1 build 49.xx, the Citrix ADC appliance generates SNMP traps for both local and remote sites when you synchronize the GSLB configuration. SNMP traps are generated for both manual synchronization and real-time synchronization.

When you synchronize the GSLB configuration for the first time, SNMP traps are generated. In the subsequent synchronization attempts, the SNMP traps are generated only if there is a change in the synchronization status from the previous synchronization status. Also, the SNMP traps are generated only for sites for which the synchronization status changed from the previous state.

For example, consider that the first GSLB configuration synchronization is successful. When you synchronize the configuration for the second time and if the synchronization is successful again, then SNMP traps are not generated because the status is not changed. However, in the third attempt, if the synchronization fails for one of the sites, then SNMP trap is generated for that site alone.

In a high availability and a cluster setup, the appliance generates the SNMP traps when you synchronize the GSLB configuration from the new node irrespective of the previous synchronization status. Also, if SNMP trap option was previously disabled and then enabled, SNMP traps are generated from that point onwards irrespective of previous synchronization status.

The following figure displays sample SNMP traps of GSLB configuration synchronization.

```

2018-05-22 09:53:06 10.102.82.11 [10.102.82.11]:

```

## GSLB dashboard

September 21, 2020

You can view the overall status of the GSLB sites participating in GSLB on the GSLB dashboard.

You can access the GSLB settings from the dashboard. You can also start the GSLB configuration wizard from the dashboard. Additionally, you can perform the synchronization and test the GSLB setup from the dashboard.

To access the GSLB dashboard, navigate to **Configuration > Traffic Management > GSLB > Dashboard**.

## Monitor GSLB services

September 21, 2020

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric information, which is the round-trip-time and persistence information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The Citrix ADC appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the Citrix ADC appliance uses the state of the service reported by the monitor. However, you can configure the Citrix ADC appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the appliance to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN

because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.

### Configure monitor trigger

You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the Citrix ADC appliance stops monitoring when MEP returns to the UP state.

#### To configure monitor triggering by using the command line interface

At the command prompt, type:

```
1 set gslb site <siteName> - triggerMonitor (ALWAYS | MEPDOWN |
   MEPDOWN_SVCDOWN)
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb site Site-GSLB-North-America - triggerMonitor Always
2 <!--NeedCopy-->
```

#### To configure monitor triggering by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**, and double-click the site.
2. In the **Trigger Monitors** drop-down list, select an option for when to trigger monitoring.

### Add or remove monitors

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

#### To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

```
1 add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

**Example:**

```
1 add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
2 show lb monitor monitor-HTTP-1
3 <!--NeedCopy-->
```

**To remove a monitor by using the command line interface**

At the command prompt, type:

```
1 rm lb monitor <monitorName>
2 <!--NeedCopy-->
```

**To add a monitor by using the configuration utility**

Navigate to

Traffic Management > Load Balancing > Monitors, and add or delete a monitor.

**Bind monitors to a GSLB service**

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service's monitoring threshold.

**To bind the monitor to the GSLB service by using the command line interface**

At the command prompt, type:

```
1 bind monitor <name> <serviceName> [ -state (Enabled | Disabled) ] -
  weight <positiveInteger>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
2 <!--NeedCopy-->
```

**To set the monitoring threshold for a GSLB service by using the command line interface**

At the command prompt, type:

```
1 set gslb service <ServiceName> -monThreshold <PositiveInteger>
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb service service-GSLB-1 -monThreshold 9
2 <!--NeedCopy-->
```

**To bind the monitor to the GSLB service by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor** section and bind the monitor to the GSLB service.

**To set the monitoring threshold for a GSLB service by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor Threshold** section and enter a threshold value.

## Upgrade recommendations for GSLB deployment

September 16, 2021

This section provides recommendations on the sequence in which GSLB nodes need to be upgraded in various GSLB setups. It also addresses a few FAQs.

**Note:** The Citrix ADC appliance from which the GSLB synchronization is started is referred to as the 'main site' and the GSLB sites on which the configuration is copied as the 'subordinate sites'.

Before you start the upgrade process, read the prerequisites mentioned in the following topics:

- [Before you begin](#)
- [Upgrade a high availability pair.](#)
- [Upgrade a cluster.](#)

## Points to note when upgrading GSLB setups

- In an HA setup, first upgrade the subordinate sites and then the main site.
- In an HA setup, service states might not propagate from an older build primary node to a newer build secondary node. However, if the builds are of different versions, but have the same HA version, the service state might still propagate.
- If GSLB is configured within a cluster, first upgrade the non-owner nodes, and then upgrade the owner node. If there is one site or multiple sites in a cluster, follow the same upgrade sequence in each of the site.
- Enable new GSLB features only after you upgrade all nodes to a newer build.
- Upgrade all GSLB nodes to the latest build. There is no functional impact on the available features when some of the GSLB nodes are using an older version and some of the GSLB nodes are upgraded to a newer version.

## FAQs

### • **Are GSLB service states propagated when instances run different software versions?**

GSLB MEP is functional when instances run on different versions and GSLB service states are propagated across GSLB sites. There is no impact on the MEP communication when instances run different versions after an upgrade.

### • **Is it recommended to do configuration changes during an upgrade?**

In a GSLB setup, when a main site is being upgraded, it is not recommended to do configuration changes on any other GSLB nodes.

## Related resources

The following resources provide information about upgrading a Citrix ADC instance using Citrix ADM:

- [10 ways Citrix ADM service supports easier Citrix ADC upgrades](#)

- [Use Citrix ADM software to upgrade Citrix ADC instances](#)

## Use case: Deployment of domain name based autoscale service group

September 21, 2020

**Tip**

For information about the GSLB service groups, see [Configuring a GSLB Service Group](#)

**Deployment scenario**

Two datacenters are deployed in two AWS regions, one in Sydney and one in North Virginia. Another datacenter is deployed in Azure. An AWS ELB in each AWS region is used to load balance the application servers. ALB is used for Azure to load balancing the application server. The Citrix ADC appliances are configured for GSLB for the ELBs and ALB using GSLB domain name based autoscale service group.

**Important**

You must configure the required security groups in AWS and attach it to the GSLB instance. Port 53 must be allowed in the security group inbound and outbound rules. Also, ports (3009 or 3011 depending on secure MEP configuration) for MEP communication must be open. For application monitoring, the corresponding ports must be allowed in the security group outbound rules.

The configuration steps for the above deployment scenario and the corresponding CLI commands are as follows:

1. Create datacenters (represented by GSLB sites).

```
1 add gslb site aws-sydney 192.0.2.2
2
3 add gslb site aws-nvirginia 198.51.100.111
4
5 add gslb site alb-southindia 203.0.113.6
```

2. Add a name server with the DNS gateway IP address where the GSLB node is added. This must be done in all datacenters.

```
1 add dns nameServer 8.8.8.8
```

3. Add servers for ELB and ALB.

```
1 add server aws-sydney_server lb-sydney-1052691850.ap-southeast-2.elb.
  amazonaws.com
2
3 add server aws-nvirginia_server LB-nvirginia-860559595.us-east-1.elb.
  amazonaws.com
4
5 add server alb-southindia_server alb.southindia.cloudapp.azure.com
```

4. Add GSLB autoscale service groups for each ELB and ALB and bind each server to the respective service group.

```
1 add gslb serviceGroup aws-nvirginia_sg HTTP -autoScale DNS -siteName
  aws-nvirginia
2
3 add gslb serviceGroup aws-sydney_sg HTTP -autoScale DNS -siteName aws-
  sydney
4
5 add gslb serviceGroup alb-southindia_sg HTTP -autoScale DNS -siteName
  alb-southindia
6
7 bind gslb serviceGroup aws-nvirginia_sg aws-nvirginia_server 80
8
9 bind gslb serviceGroup aws-sydney_sg aws-sydney_server 80
10
11 bind gslb serviceGroup alb-southindia_sg alb-southindia_server 80
```

5. Add a GSLB virtual server and bind the application domain and the service groups to this virtual server.

```
1 add gslb vserver gv1 HTTP
2
3 bind gslb vserver gv1 -serviceName aws-nvirginia_sg
4
5 bind gslb vserver gv1 -serviceName aws-sydney_sg
6
7 bind gslb vserver gv1 -serviceName alb-southindia_sg
```

## Use case: Deployment of IP address based GSLB service group

March 9, 2021

### Tip

For information about the GSLB service groups, see [Configuring a GSLB Service Group](#).

### Deployment scenario

If there are multiple applications hosted on the same application server, the GSLB should probe these applications to see if the applications are responding or not. If an application is not responding, the user must be directed to the server on which the application is UP. Also, if one of the applications is DOWN, then the server should not be marked DOWN, because the other applications are UP.

In the following example, multiple applications (HTTPS) are hosted on one server in each GSLB site and hence all these applications resolve to one IP address of the respective site.

Using the GSLB service groups, you can have the same server with an IP address and port bound to multiple service groups where each service group represents a different application.

An application specific monitor is bound to the service groups that marks the service group as DOWN if the application is DOWN. Thus, whenever an application is DOWN, only that application is taken out from the setup and not the server.

```
1 add gslb serviceGroup app1_site1 HTTP -maxClient 0 -cip DISABLED -
  cltTimeout 180 -svrTimeout 360 -siteName s1
2
3 add gslb serviceGroup app2_site1 HTTP -maxClient 0 -cip DISABLED -
  cltTimeout 180 -svrTimeout 360 -siteName s1
4
5 add gslb serviceGroup app1_site2 HTTP -maxClient 0 -cip DISABLED -
  cltTimeout 180 -svrTimeout 360 -siteName s2
6
7 add gslb serviceGroup app2_site2 HTTP -maxClient 0 -cip DISABLED -
  cltTimeout 180 -svrTimeout 360 -siteName s2
8
9 add lb monitor http_app2 HTTP -respCode 200 -httpRequest "GET /testsite
  /app2.html"
10
11 add lb monitor http_app1 HTTP -respCode 200 -httpRequest "GET /testsite
  /app1.html"
12
13 bind gslb serviceGroup app1_site1 192.0.2.140 80
14
15 bind gslb serviceGroup app1_site1 -monitorName http_app1
16
17 bind gslb serviceGroup app2_site1 192.0.2.140 80
18
19 bind gslb serviceGroup app2_site1 -monitorName http_app2
20
21 bind gslb serviceGroup app1_site2 192.0.2.142 80
22
23 bind gslb serviceGroup app1_site2 -monitorName http_app1
24
25 bind gslb serviceGroup app2_site2 192.0.2.142 80
26
27 bind gslb serviceGroup app2_site2 -monitorName http_app2
```

## How-to articles

September 21, 2020

The GSLB how-to articles contain information about some of the important GSLB configurations such as customizing GSLB configuration, configuring persistent connections, disaster recovery, and so on.

[Customizing Your GSLB Configuration](#)

[Configuring Persistent Connections](#)

[Managing Client Connections](#)

[Configuring GSLB for Proximity](#)

[Using the EDNS0 Client Subnet Option for Global Server Load Balancing](#)

[Example of a Complete Parent-Child Configuration Using the Metrics Exchange Protocol](#)

## Customize your GSLB configuration

September 21, 2020

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.

### Modify maximum connections or maximum bandwidth for a GSLB service

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

### To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

```
1 set gslb service <serviceName> [-maxClients <positive_integer>] [-  
    maxBandwidth <positive_integer>]  
2 show gslb service <serviceName>  
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service Service-GSLB-1 -maxBandwidth 100 -maxClients 100  
2 show gslb service Service-GSLB-1  
3 <!--NeedCopy-->
```

### To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**, and double-click a service.
2. Click in the **Other Settings** section and set the following parameters:
  - Max Clients—maxClients
  - Max Bandwidth—maxBandwidth

### Create CNAME-based GSLB services

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMES) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the Citrix ADC appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the Citrix ADC appliance provides the CNAME with the corresponding A record (IP address). The Citrix ADC appliance handles the final resolution of the DNS

query, as determined by the GSLB method. The CNAME records can be maintained on a different Citrix ADC appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a Citrix ADC appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The

Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the

Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

### **To create a CNAME-based GSLB service by using the command line interface**

At the command prompt, type:

```
1 add gslb service <serviceName> -cnameEntry <string> -siteName <string>
2 <!--NeedCopy-->
```

### **Example:**

```
1 add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -
   siteName Site-GSLB-East-Coast
2 add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -
   siteName Site-GSLB-West-Coast
3 <!--NeedCopy-->
```

### To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**.
2. Create a service, and set the **Type to Canonical Name Based**.

### Configure transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

### Configure dynamic weights for services

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore, when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see “[Assigning Weights to Services](#)”.

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled:** The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.
- **SERVICECOUNT:** The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWEIGHT:** The dynamic weight is the sum of the weights of services bound to the load balancing virtual servers corresponding to the GSLB service (3), and the cumulative weight is the product of the dynamic weight (3) and the weight of the GSLB service (3), which is 9.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

### To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

```
1 set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT
2 <!--NeedCopy-->
```

### To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list, select **SERVICE-COUNT** or **SERVICWEIGHT**.

## How to configure persistence in GSLB

January 4, 2021

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. You can use persistence for deployments where an information related to a client transaction is stored locally on an instance, which has served the initial requests. For example, the deployments for e-commerce that uses a shopping cart, where the server needs to maintain the state of the connection to track the transaction. The Citrix ADC appliance selects a data center to process a client request. With persistence enabled, it forwards the same IP address of the selected data center for all subsequent Domain Name System (DNS) requests. If a persistence session points to a data center that is DOWN, the Citrix ADC appliance uses the configured GSLB method to select a new data center. It then becomes persistent for subsequent requests from the client.

For persistence in GSLB, the same set of persistence identifiers (persistID) must be configured on the GSLB virtual servers in all data centers. The GSLB module uses the persistence identifier to uniquely identify a GSLB virtual server. When Source IP persistence is enabled on the GSLB virtual server, the persistence sessions are also exchanged as part of the metrics exchange. For the Citrix ADC appliance to support persistence across sites, persistence related configuration must be done on all the participating GSLB sites. Citrix recommends persistence in GSLB for stateful applications, which requires clients to reconnect to the same application instance for the subsequent requests.

You can achieve persistence in GSLB by the following ways:

- Persistence on GSLB virtual server
- Site persistence on GSLB services

### Persistence on GSLB virtual server

Persistence on GSLB virtual server is used during the DNS requests. The Source IP address of the DNS request is used to create persistence session between the client and the data center. DNS clients are generally the Local DNS (LDNS) or DNS gateways proxying a set of clients sitting behind them (in ISPs). Persistence on a GSLB virtual server is application protocol agnostic.

In general, multiple DNS gateways or Local Domain Name Servers (LDNS) are configured in the client network. Citrix recommends you to configure an appropriate persistence mask because for the subsequent DNS requests, irrespective of the upstream LDNS devices used to connect to the ADC appliance, the client is able to persist to the same data center, which had served the earlier requests. After the persistence session is created for an LDNS IP address, all the end clients connecting using that LDNS are given the same data center IP address.

### **Site persistence on GSLB services**

Site persistence becomes effective while processing the application requests. Site persistence works only for HTTP and HTTPS traffic because the persistency is achieved using HTTP cookie. As cookies are maintained on HTTP clients (browsers), it gives visibility into the clients sitting behind the DNS gateways. When you use cookies to achieve persistency for clients, no resources are consumed on the ADC appliance for each incoming client. When you bring a GSLB service DOWN with a delay time, the service goes into the transition to out of service (TROFS) state. Persistence is supported as long as the service is in the UP or TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

If you access an application through an alias, ensure that the CNAME record is also configured on the Citrix ADC appliance. In a parent-child topology, site persistence does not work when you access an application through an alias.

#### Note

If the connection proxy is specified as the site persistence method and you also want to configure persistence on LB virtual servers, source IP persistence is not recommended. When the connection is proxied, an IP address owned by the ADC appliance is used, and not the actual IP address of the client.

Configure an appropriate persistence, which does not use source IP of the HTTP(S) request to identify the client, for example, cookie persistence or rule-based persistence.

### **Configure persistence based on source IP address**

If source IP persistence is configured on GSLB virtual server, persistence sessions are created for the source IP address of the DNS request. Depending on the Extended Client Subnet (ECS) feature, the source IP address of the DNS request is taken from any of the following:

- The source IP in the IP header of the incoming DNS request packet
- The ECS option in the DNS request For more information on ECS, see [Use the EDNS0 client subnet option for Global Server Load Balancing](#).

Persistence sessions for a client last until the persistence timeout. After the timeout period expires, existing persistence sessions are cleared. For subsequent requests, a new GSLB decision is made and a different GSLB service IP address might be selected.

The source IP persistence on GSLB virtual server and site persistence on GSLB service complements each other. If source IP persistence is disabled on GSLB virtual server, the GSLB virtual server chooses a different GSLB service each time the DNS tries to do the resolution. The client also connects to a different GSLB service and the data center which receives the application request proxy the connection to the data center which served the client first. This might add some latency. So by enabling source IP persistence on GSLB virtual server can avoid frequent such multiple hops for application requests. If the source IP persistence session has expired and the client reconnects after that, the site persistence connects the client back to the data center, which had served the client initially. Also, if the client connects back through a DNS gateway, which does not fall within the persistence mask range configured, then as well site persistence helps clients stick to the data center that served the first request.

### To configure persistence based on source IP address by using the CLI

At the command prompt, type:

```
1 set gslb vserver <name> -persistenceType (SOURCEIP|NONE) -persistenceId
   <positive_integer> [-persistMask <netmask>] - [timeout <mins>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -
   persistenceId 23 -persistMask 255.255.255.255 - timeout 2
2 <!--NeedCopy-->
```

### To configure persistence based on source IP address by using the GUI

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Persistence** section and, from the **Persistence** drop-down list, select **SOURCEIP** and set the following parameters:
  - Persistence Id—persistenceId
  - Time-out—timeout
  - IPv4 Netmask or IPv6 Mask length—persistMask

## Configure site persistence based on HTTP cookies

Site persistence is achieved using HTTP cookies (known as a “site cookie”) to reconnect the client to the same server. When the GSLB appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. Application endpoint in that GSLB site adds a site cookie to the HTTP header, and site persistence is in effect.

If the client sends a DNS query after the client cache is expired, the DNS request might be directed to a different GSLB site. The new GSLB site uses the site cookie present in the client request header to implement persistence. Site persistence feature becomes active under the following conditions:

- When the domain name in the host header matches one of the GSLB domains
- When site persistence is enabled on the GSLB service that represents the virtual server receiving the application traffic.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. If the GSLB service pointed by the cookie is DOWN or removed from the GSLB configuration, then the virtual server that receives the traffic continues to process the traffic. The cookie expiration is based on the cookie timeout configured on the Citrix ADC appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

Citrix ADC supports two types of site persistence:

- Connection Proxy
- HTTP redirect

### Connection Proxy

In the Connection Proxy mode of site persistence, the data center that receives the subsequent application request performs the following tasks to establish a connection:

1. Creates a connection to the GSLB site that inserted the site cookie.
2. Proxies the client request to the original site.

**Note:**

The proxy server establishes connection with the original site using the following details:

- The SNIP of the new site is the source IP address.
- The GSLB service public IP address of the original site is the destination IP address.
- An ephemeral port is the source port and GSLB service port is the destination port.
- Uses either HTTP or HTTPS protocols depending on the GSLB service type.

3. Receives a response from the original GSLB site.
4. Relays that response back to the client.

5. Closes the connection.

## HTTP redirect

If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie. Domain name in the redirect URL is the site domain. Ensure that both cookies and SSL certificates are applicable to both GSLB domain and site domain. To apply cookies for both GSLB and site domain, the cookie domain must be the site to GSLB domain. To apply SSL certificates to both GSLB and site domain, certificate bound to the SSL virtual server must be a wildcard certificate.

Connection proxy occurs when the following conditions are satisfied:

- Requests are sent for a domain participating in GSLB. The domain is obtained from the URL/Host header.
- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

### Note

In a GSLB parent-child configuration, the connection proxy works as intended even when a GSLB service is not configured on a child site. However, if you have extra configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the site and configure it accordingly.

For more information about parent-child topology, see [Parent-Child Topology Deployment Using the MEP Protocol](#).

## To set persistence based on HTTP cookies by using the CLI

At the command prompt, type:

```
1 set gslb service <serviceName> -sitePersistence (ConnectionProxy [-
    sitePrefix <prefix>] | HTTPRedirect -sitePrefix <prefix>)
2 <!--NeedCopy-->
```

### Example:

```
1 set gslb service service-GSLB-1 -sitePersistence ConnectionProxy
2 set gslb service service-GSLB-1 -sitePersistence HTTPRedirect -
    sitePrefix vserver-GSLB-1
3 <!--NeedCopy-->
```

### To set persistence based on cookies by using the GUI

1. Navigate to **Traffic Management > GSLB > Services** and select the service that you want to configure for site persistence (for example, service-GSLB-1).
2. Click the **Site Persistence** section and set persistence based on cookies.

## Manage client connections

September 21, 2020

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

### Enable delayed cleanup of virtual server connections

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the Citrix ADC appliance performs a delayed cleanup of connections to a GSLB service that is down.

### To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

```
1 set gslb service <name> -downStateFlush (ENABLED | DISABLED)
2 show gslb service <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service Service-GSLB-1 -downStateFlush ENABLED
2 Done
3
4 show gslb service Service-GSLB-1
5 Done
6 <!--NeedCopy-->
```

### To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services** and double-click the service.
2. Click the **Other Settings** section and select the **Down State Flush** option.

### Manage local DNS traffic by using DNS policies

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the Citrix ADC appliance.

#### DNS expressions

The Citrix ADC appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called *rules*) are combined to create DNS policies that are then bound globally on the Citrix ADC appliance.

Following is the list of predefined DNS qualifiers available on the Citrix ADC appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
- CLIENT.UDP.DNS.IS\_AREC
- CLIENT.UDP.DNS.IS\_AAAAREC
- CLIENT.UDP.DNS.IS\_SRVREC
- CLIENT.UDP.DNS.IS\_MXREC
- CLIENT.UDP.DNS.IS\_SOAREC
- CLIENT.UDP.DNS.IS\_PTRREC
- CLIENT.UDP.DNS.IS\_CNAME
- CLIENT.UDP.DNS.IS\_NSREC
- CLIENT.UDP.DNS.IS\_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH("abc.com.")

### To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).

4. In the Value box, type a value (for example, Asia, Japan...).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

### Configure DNS actions

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see [Adding DNS Views](#).
- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see [Overriding Static Proximity Behavior by Configuring Preferred Locations](#).
- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
- Forward a request to the name server without performing a lookup in the appliance's DNS cache.
- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, `dns_default_act_Drop`. If you want to bypass the DNS cache, use the built-in action, `dns_default_act_Cachebypass`. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

### To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

```
1 add dns action <actionName> <actionType> (-IPAddress <ip_addr |  
    ipv6_addr> ... | -viewName <string> | -preferredLocList <string>  
    ...) [-TTL <secs>]  
2  
3 show dns action [<actionName>]  
4 <!--NeedCopy-->
```

### Examples

**Example 1: Configuring DNS Response Rewrite.** The following DNS action sends the client a pre-configured IP address when the policy to which the action is bound evaluates to true:

```
1 add dns action dns_act_response_rewrite Rewrite_Response -IPAddress
   192.0.2.20 192.0.2.56 198.51.100.10
2 Done
3
4 show dns action dns_act_response_rewrite
5 1) ActionName: dns_act_response_rewrite ActionType: Rewrite_Response
   TTL: 3600 IPAddress: 192.0.2.20 192.0.2.56
   198.51.100.10
6 Done
7 <!--NeedCopy-->
```

**Example 2: Configuring a DNS-View Based Response.** The following DNS action sends the client an IP address for which you have configured a DNS view:

```
1 add dns action send_ip_from_view_internal_ip ViewName -viewName
   view_internal_ip
2 Done
3
4 show dns action send_ip_from_view_internal_ip
5 1) ActionName: send_ip_from_view_internal_ip ActionType: ViewName
   ViewName: view_internal_ip
6 Done
7 <!--NeedCopy-->
```

**Example 3: Configuring a Response Based on a Preferred Location List.** The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```
1 add dns action send_preferred_location GslbPrefLoc -preferredLocList NA
   .tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
2 Done
3
4 show dns action send_preferred_location
5 1) ActionName: send_preferred_location ActionType: GslbPrefLoc
   PreferredLocList: "NA.tx.ns1.*.*.*" "NA.tx.ns2.*.*.*" "NA.tx.ns3
   *.*.*.*"
6 Done
7 <!--NeedCopy-->
```

### To configure a DNS action by using the Citrix ADC configuration utility

1. Navigate to Traffic Management > DNS > Actions, create or edit a DNS action.
2. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:

- Action Name (cannot be changed for an existing DNS action)
- Type (cannot be changed for an existing DNS action)

To set the

Type parameter, do one of the following:

- To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
  - To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
  - To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.
- TTL (applicable only to the Rewrite Response action type)

### **Configure DNS policies**

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks (") as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the Citrix ADC appliance.

- A maximum of 64 policies are supported.
- DNS policies are global to the Citrix ADC appliance and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see “Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol” in [“Policy Configuration and Reference”](#).

### **To add a DNS policy by using the command line interface**

At the command prompt, type the following commands to create a DNS policy and verify the configuration:

```
1 add dns policy <name> <rule> <actionName>
2 show dns policy <name>
3 <!--NeedCopy-->
```

#### **Example:**

```
1 > add dns policy policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ("domainname")'
   my_dns_action
2 Done
3 > show dns policy policy-GSLB-1
```

```
4     Name: policy-GSLB-1
5     Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
6     Action Name: my_dns_action
7     Hits: 0
8     Undef Hits: 0
9
10    Done
11 <!--NeedCopy-->
```

### To remove a configured DNS policy by using the command line interface

At the command prompt, type:

```
1  rm dns policy <name>
2  <!--NeedCopy-->
```

### To configure a DNS policy by using the Citrix ADC configuration utility

1. Navigate to Traffic Management > DNS > Policies and create a DNS policy.
2. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
  - Policy Name (cannot be changed for an existing policy)
  - Action
  - ExpressionTo specify an expression, do the following:
  - a) Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the first expression element.
  - b) In the second list, select the expression element that you want, and then enter a period.
  - c) After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.
3. Click Create or OK, and then click Close.

### Bind DNS policies

DNS policies are bound globally on the Citrix ADC appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the bind dns global command accepts

REQ\_OVERRIDE and

RES\_OVERRIDE as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the

REQ\_DEFAULT and

RES\_DEFAULT bind points.

### To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

```
1 bind dns global <policyName> <priority> [-gotoPriorityExpression <
    string>] [-type <type>]
2 show dns global -type <type>
3 <!--NeedCopy-->
```

#### Example:

```
1 bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
2 Done
3 show dns global -type REQ_DEFAULT
4 1) Policy Name: policy-GSLB-1
5     Priority: 10
6     GotoPriorityExpression: END
7 Done
8 <!--NeedCopy-->
```

### To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.

8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.

### To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

```
show dns global
```

### To view the global bindings of a DNS policy by using the configuration utility

1. Navigate to **Traffic Management > DNS > Policies**.
2. In the details pane, click **Global Bindings**. The global bindings of all DNS policies appear in this dialog box.

## Adding DNS Views

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company's domain and have the server hosted in your company's network, clients querying for the domain from within your company's internal network can be provided with the server's internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain's public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ \_ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see **Managing Local DNS Traffic by Using DNS Policies**.

### To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

```
1 add dns view <viewName>
2 show dns view <viewName>
3 <!--NeedCopy-->
```

**Example:**

```
1 add dns view PrivateSubnet
2 show dns view PrivateSubnet
3 <!--NeedCopy-->
```

**To remove a DNS view by using the command line interface**

At the command prompt, type:

```
1 rm dns view <viewName>
2 <!--NeedCopy-->
```

**To add a DNS view by using the configuration utility**

Navigate to Traffic Management > DNS > Views and add a DNS view.

For details on how to create a DNS policy and how to bind DNS policies globally, see **Managing Local DNS Traffic by Using DNS Policies**.

## Configure GSLB for proximity

September 21, 2020

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

**Configure dynamic round trip time (RTT) method**

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the Citrix ADC appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see [Configuring Dynamic RTT](#).

### **Configure static proximity**

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The Citrix ADC appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the Citrix ADC appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB set up and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see [Configuring Static Proximity](#).

### **Configure static proximity and dynamic RTT**

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed

to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see [Configuring Static Proximity](#) and for details on how to configure dynamic RTT, see [Configuring Dynamic RTT](#).

## Protect the GSLB setup against failure

June 7, 2021

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring a backup GSLB virtual server, configuring the Citrix ADC appliance to respond with multiple IP addresses, or configuring a Backup IP address for a GSLB domain. You can also divert excess traffic to a backup virtual server by using spillover.

### Configure a backup GSLB virtual server

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what should happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the `disablePrimaryOnDown` option).

Note: You can configure a single backup entity as a backup for multiple GSLB virtual server.

### To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as a backup virtual server and verify the configuration:

```
1 set gslb vserver <name> -backupVServer <name> [-disablePrimaryOnDown (
    ENABLED | DISABLED)]
2
3 show gslb vserver <name>
4 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -
    disablePrimaryOnDown ENABLED
2 show gslb vserver vserver-GSLB-1
3 <!--NeedCopy-->
```

**To set GSLB virtual server as a backup virtual server by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**, and double-click the GSLB virtual server.
2. Click the **Backup Virtual Server** section and select the backup virtual server.

**Configure a GSLB setup to respond with multiple IP addresses**

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP response (MIR), the Citrix ADC appliance sends the best GSLB service as the first record in the response and adds the remaining active services as additional records. If MIR is disabled (the default), the Citrix ADC appliance sends the best service as the only record in the response.

**To configure a GSLB virtual server for multiple IP responses by using the command line interface**

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

```
1 set gslb vserver<name> -MIR (ENABLED | DISABLED)
2 - show gslb vserver <name>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver vserver-GSLB-1 -MIR ENABLED
2 show gslb vserver <vserverName>
3 <!--NeedCopy-->
```

**To set a GSLB virtual server for multiple IP responses by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “UP,” select the Send all “active” service IP in response (MIR) check box, and click OK.

**Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN**

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.

**To configure a GSLB virtual server for empty down responses by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver<name> -EDR (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

**Example:**

```
1 > set gslb vserver vserver-GSLB-1 -EDR ENABLED
2 Done
3 <!--NeedCopy-->
```

**To set a GSLB virtual server for empty down responses by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “Down,” select the Do not send any service’s IP address in response (EDR) check box.

3. Click **OK**.

### Configure a backup IP address for a GSLB domain

You can configure a backup site for your GSLB configuration. With this configuration in place, if all of the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site's IP address.

Note: When a backup IP address is sent, persistence is not honored.

### To set a backup IP address for a domain by using the command line interface

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

```
1 set gslb vserver <name> -domainName <string> -backupIP <IPAddress>
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

### Example:

```
1 set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP
   10.102.29.66
2 show gslb vserver vserver-GSLB-1
3 <!--NeedCopy-->
```

### To set a backup IP address for a domain by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
2. Click the **Domains** section, configure the GSLB domain and specify the IP address of the backup domain in the **Backup IP** field.

### Divert excess traffic to a backup virtual server

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to

the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured by the number of connections, bandwidth, and health of the services.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments will have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIP(s) is absent or down, the effective state is set to DOWN.
- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.

- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

### To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup GSLB virtual server and verify the configuration:

```
1 set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -
   soPersistence ( **ENABLED** | **DISABLED** ) -soPersistenceTimeout <
   timeout>
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000
   -soPersistence ENABLED -soPersistenceTimeout 2
2 show gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To configure a backup GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server that you want to configure as a backup (for example, Vserver-LB-1).
2. Click the **SpillOver** section and set the following parameters:
  - Method— soMethod
  - Threshold— soThreshold
  - Persistence Time-out (min) — soPersistenceTimeout
3. Select the Persistence option and click **OK**.

## Configure GSLB for disaster recovery

September 21, 2020

Disaster recovery capability is critical, because downtime is costly. A Citrix ADC appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

## Configure GSLB for disaster recovery in an active-standby data center setup

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
  - Add a local GSLB site.
  - Add a GSLB vserver, which represents the active data center.
  - Bind the domain to the GSLB virtual server.
  - Add gslb services and bind the services to active GSLB virtual server.
- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

### To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

```
1 set gslb vserver <name> -backupVserver <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
2 <!--NeedCopy-->
```

### To configure the standby site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for the primary site.
2. Click the **Backup Virtual Server** section and select a backup virtual server.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the 'disable primary on down' option.

### **Configure for disaster recovery in an active-active data center setup**

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

### **Configuring for Disaster Recovery with Weighted Round Robin**

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the Citrix ADC appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual server. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

### **To configure a virtual server to assign weights to services by using the command line interface**

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

```
1 add lb vserver <name>@ -weight <WeightValue> <ServiceName>
2 set lb vserver <name>@ -weight <WeightValue> <ServiceName>
3 <!--NeedCopy-->
```

#### **Example:**

```
1 add lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
2 set lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
3 <!--NeedCopy-->
```

### **To set dynamic weight by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver <name> -dynamicWeight DynamicWeightType
2 <!--NeedCopy-->
```

#### **Example:**

```
1 set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight
2 <!--NeedCopy-->
```

### **To add weights to the GSLB services by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver <name> -serviceName GSLBServiceName -weight
  WeightValue
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1
2 <!--NeedCopy-->
```

**To configure a virtual server to assign weights to services by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and double-click the virtual server (for example, Vserver-LB-1).
2. Click the Services section and set the weight of a service.

**To add weights to the GSLB services by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1)
2. Click the Services section and set the weight of the service in the Weight field.

**To set dynamic weight by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list select **SERVICEWEIGHT**.

**Configuring for Disaster Recovery with Data Center Persistence**

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB set up and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the Citrix ADC appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

### To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

```
1 set gslb service <serviceName> -sitePersistence <sitePersistence> -
   sitePrefix <string>
2 show gslb service <serviceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -
   sitePrefix vserver-GSLB-1
2 show gslb service Service-GSLB-1
3 <!--NeedCopy-->
```

### To configure HTTP redirect by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the GSLB service to be configured.
2. Click the **Site Persistence** section, select the **HTTPRedirect** option, and in the **Site Prefix** text box, enter the site prefix (for example, vserver-GSLB-1).

#### Note

When site persistence is not configured and if a load balancing virtual server that is configured as a local GSLB service is DOWN, the HTTP requests are redirected to other healthy GSLB sites using a 302 redirect.

## Override static proximity behavior by configuring preferred locations

September 21, 2020

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a *preferred location* for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see [Configuring a DNS Action](#).
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see [Adding Custom Entries to a Static Proximity Database](#). When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to

TRUE, the Citrix ADC appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of `.UK.*` or `Europe.UK..` is a perfect match for the preferred location `.UK.*`.
- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of `Europe.EG` is a partial match for the preferred location `Europe.UK`.

When a DNS policy evaluates to

TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

## Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```
1 > add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "  
    Europe.UK"  
2 Done  
3 > add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION("*.ZMB  
    *.*")" prefLoc11  
4 Done  
5 <!--NeedCopy-->
```

When the appliance receives a request from the location `.ZMB.*`, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.

4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.

## Configure GSLB service selection using content switching

September 21, 2020

In a typical GSLB deployment, you can prioritize the selection of a set of GSLB services bound to a GSLB virtual server, but you cannot do the following:

- Restrict the selection of a GSLB service from a subset of GSLB services bound to a GSLB virtual server for the given domain.
- Apply different load balancing methods on the different subsets of GSLB services in the deployment.
- Apply spillover policies on a subset of GSLB services, and you cannot have a backup for a subset of GSLB services.
- Configure a subset of GSLB services to serve different content. That is, you cannot content switch between servers in different GSLB sites. The GSLB configuration assumes that the servers contain the same content.
- Define a subset GSLB services with different priorities and specify an order in which the services in the subset are applied to a request.

You can now configure a content switching (CS) policy to customize the GSLB deployment. First configure a set of GSLB services and bind it to a GSLB virtual server. Then, configure a CS virtual server of target type GSLB, define a CS policy and action with the GSLB virtual server as target virtual server, and bind the CS policy to CS virtual server.

### Important

- Only CS policies with DNS based expressions can be bound to a CS virtual server of target type GSLB.
- If a GSLB service is bound to a CS virtual server through a GSLB virtual server, you cannot bind another GSLB virtual server bound with the same GSLB service to the CS virtual server.

### Example

Consider a GSLB deployment that includes two GSLB sites. At each site, four GSLB services (S-1, S-2, S-3, and S-4) are bound to GSLB virtual server VS-1. You can configure a content switching (CS) virtual

server of target type GSLB and define a CS policy and action with VS-1 as the target virtual server, so that requests for content in English are served only by S-1 and S-2, and requests for content in the local language are served only by S-3 and S-4.

You could give S-1 priority by configuring a backup virtual server to VS-1 and binding S-2 to the backup virtual server. Client requests would then be served by S-1 unless the server it represents went down, in which case the requests would be served by S-2. If both S-1 and S-2 were down, clients would receive an empty response.

### To configure GSLB Service Selection using Content Switching:

1. Configure GSLB. For instructions, see [Configuring Global Server Load Balancing](#).
2. Configure a Content Switching (CS) virtual server of target type GSLB. For more information, see [Creating Content Switching Virtual Servers](#).
3. Configure Content Switching (CS) policies. For more information, see [Configuring Content Switching Policies](#).
4. Configure CS actions that designate a GSLB virtual server as the target virtual server. For more information, see [Configuring a Content Switching Action](#).
5. Bind the CS policies to the CS virtual server. For more information, see [Binding Policies to a Content Switching Virtual Server](#).
6. Bind the domain to the CS virtual server instead of the GSLB virtual server.

### Sample Configuration

The following sample configuration sends requests from the client with IP address 5.5.5.5 to SERVICE\_GSLB1 and SERVICE\_GSLB2. SERVICE\_GSLB1 has a higher priority than SERVICE\_GSLB2, and SERVICE\_GSLB2 serves the client requests only when SERVICE\_GSLB1 is down. If both SERVICE\_GSLB1 and SERVICE\_GSLB2 are down, SERVICE\_GSLB3 and service-GSLB4 are not considered, and a blank response is sent to the client.

```
1 add cs vs CSVSERVER_GSLB http - targettype GSLB
2 Done
3 add gslb vs VSERVER_GSLB1 http
4 Done
5 add gslb vs VSERVER_GSLB2 http
6 Done
7 add gslb vs VSERVER_GSLB_BACKUP1 http
8 Done
9 set gslb vs VSERVER_GSLB1 -backupvserver VSERVER_GSLB_BACKUP1
10 Done
11 add gslb service SERVICE_GSLB1 1.1.1.1 HTTP 80 -sitename site1
12 Done
13 add gslb service SERVICE_GSLB2 1.1.1.2 HTTP 80 -sitename site1
14 Done
```

```
15 add gslb service SERVICE_GSLB3 1.1.1.3 HTTP 80 -sitename site2
16 Done
17 add gslb service SERVICE_GSLB4 1.1.1.4 HTTP 80 -sitename site2
18 Done
19 bind gslb vs VSERVER_GSLB1 -servicename SERVICE_GSLB1
20 Done
21 bind gslb vs VSERVER_GSLB_BACKUP1 -servicename SERVICE_GSLB2
22 Done
23 bind gslb vs VSERVER_GSLB2 -servicename SERVICE_GSLB3
24 Done
25 bind gslb vs VSERVER_GSLB2 -servicename SERVICE_GSLB4
26 Done
27 add cs action a1 -targetvserver VSERVER_GSLB1
28 Done
29 add cs policy p1 -rule "CLIENT.IP.SRC.EQ(5.5.5.5)" -action a1
30 Done
31 bind cs vs CSVSERVER_GSLB -domainName www.abc.com
32 Done
33 bind cs vs CSVSERVER_GSLB -policyname p1 -priority 1
34 Done
35 add cs action a2 -targetvserver VSERVER_GSLB2
36 Done
37 add cs policy p2 -rule "CLIENT.IP.SRC.EQ(6.6.6.6)" -action a2
38 Done
39 bind cs vs CSVSERVER_GSLB -policyname p2 -priority 2
40 Done
41 <!--NeedCopy-->
```

## Configure GSLB for DNS queries with NAPTR records

September 21, 2020

In a typical Global Server Load Balancing (GSLB) deployment, the Citrix ADC appliance receives DNS queries for A/AAAA records, selects the most appropriate GSLB service according to the configured load balancing method, and returns the service's IP address as a reply to the DNS query. You can now configure the appliance to receive DNS queries for NAPTR records and respond with the list of services configured for a domain. The appliance also monitors the health of the services, and in the response it provides a list of only the services that are up.

### Example:

In Telco deployments, you can configure a Citrix ADC appliance to receive DNS queries with NAPTR records from clients such as mobile management entities (MMEs), which play the role of a DNS re-

solver to discover all the services that are offered by the domain name. The appliance responds to the query with NAPTR records for all the services that are up. The MME can use this NAPTR response to run the S-NAPTR procedure to select the nodes on the basis of the service offered, colocation, topological closeness, and so on.

If multiple nodes qualify for selection, the MME can use the preference field in the NAPTR record from the Citrix ADC appliance to determine the node.

### **NAPTR Record Format**

While responding to a DNS query with NAPTR record, a Citrix ADC appliance constructs a response NAPTR record for each GSLB service.

The following table lists the fields in the NAPTR record:

---

| Field              |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Domain             | The GSLB domain                                                                                                                                                                                               |
| TTL                | The amount of time for which the NAPTR record can be cached.                                                                                                                                                  |
| Class              | The class of the record. By default, this value is set to IN.                                                                                                                                                 |
| Type               | The DNS record type.                                                                                                                                                                                          |
| Order              | Specifies the order in which the NAPTR record MUST be processed. You can specify the order in the GSLB service. Otherwise, it is set to 1.                                                                    |
| Preference         | Specifies the order in which NAPTR records with equal "order" values SHOULD be processed, low numbers being processed before high numbers. If the order is not specified in the GSLB service, it is set to 1. |
| Flags              | Controls the aspects of the rewriting and interpretation of the fields in the record. The Citrix ADC appliance sets this value to A.                                                                          |
| Service            | Specifies the available service(s).                                                                                                                                                                           |
| Regular Expression | Regular expressions are not supported, so this value is set to NULL.                                                                                                                                          |
| Replacement        | The domain name of the node that hosts the services.                                                                                                                                                          |

---

## Configuration procedure

For detailed GSLB configuration instructions, see [Configuring Global Server Load Balancing \(GSLB\)](#). Make sure that you do the following:

- Set the following parameters while adding the GSLB virtual server:
  - serviceType: ANY
  - dnsRecordType: NAPTR
  - lbMethod: CUSTOMLOAD

### Example:

```
1 add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
2 <!--NeedCopy-->
```

- While adding a GSLB site, set the *naptrReplacementSuffix* parameter to the domain name that you want to embed in the NAPTR records.

### Example:

```
1 add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
2 <!--NeedCopy-->
```

- Set the following parameters while adding the GSLB service:
  - naptrreplacement
  - naptrOrder
  - naptrServices
  - naptrDomainTTL
  - naptrPreference

## Sample configuration

```
1 add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
2
3 Done
4
5 add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
6
7 Done
8
9 add gslb service sgw1 3.3.3.13 ANY * -siteName site1 -naptrreplacement
   sgw1.site1. -naptrOrder 2 -naptrServices x-3gpp-sgw:x-s5-gtp -
   naptrDomainTTL 20 -naptrPreference 200
10
11 Done
```

```
12
13 add gslb service sgw2 3.3.3.11 ANY * -siteName site1 -naptrreplacement
    sgw2.site1. -naptrOrder 5 -naptrServices x-3gpp-sgw:x-s5-gtp -
    naptrDomainTTL 20 naptrPreference 100
14
15 Done
16
17 add gslb service sgw3 3.3.3.12 ANY * -siteName site2 -naptrreplacement
    sgw3.site1. -naptrOrder 10 -naptrServices x-3gpp-sgw:x-s5-gtp -
    naptrDomainTTL 20 naptrPreference 300
18
19 bind gslb vserver gslb_vs -serviceName sgw1
20
21 Done
22
23 bind gslb vserver gslb_vs -serviceName sgw2
24
25 Done
26
27 bind gslb vserver gslb_vs -serviceName sgw3
28
29 Done
30
31 bind gslb service sgw1 -monitorName ping
32
33 Done
34
35 bind gslb service sgw2 -monitorName ping
36
37 Done
38
39 bind gslb service sgw3 -monitorName ping
40
41 Done
42
43 bind gslb vserver gslb_vs -domainName gslb.com -TTL 5
44
45 Done
46 <!--NeedCopy-->
```

**Note**

DNS queries with NAPTR records are not supported in parent-child configuration.

## Use the EDNS0 client subnet option for Global Server Load Balancing

September 21, 2020

EDNS Client Subnet (ECS) is a Domain Name Server (DNS) header extension that provides the client subnet details. You can use these details to improve the accuracy of Citrix ADC Global Server Load Balancing (GSLB) by using the client network location rather than the DNS resolver location to determine the topological closeness of the client.

### Note

Citrix ADC supports only EDNS0.

### Important:

Make sure that the Local Domain Name Server (LDNS) in your deployment supports the EDNS0 Client Subnet so that the incoming DNS queries contain the EDNS0 Client Subnet option. The Citrix ADC appliance uses the ECS address while processing the DNS query.

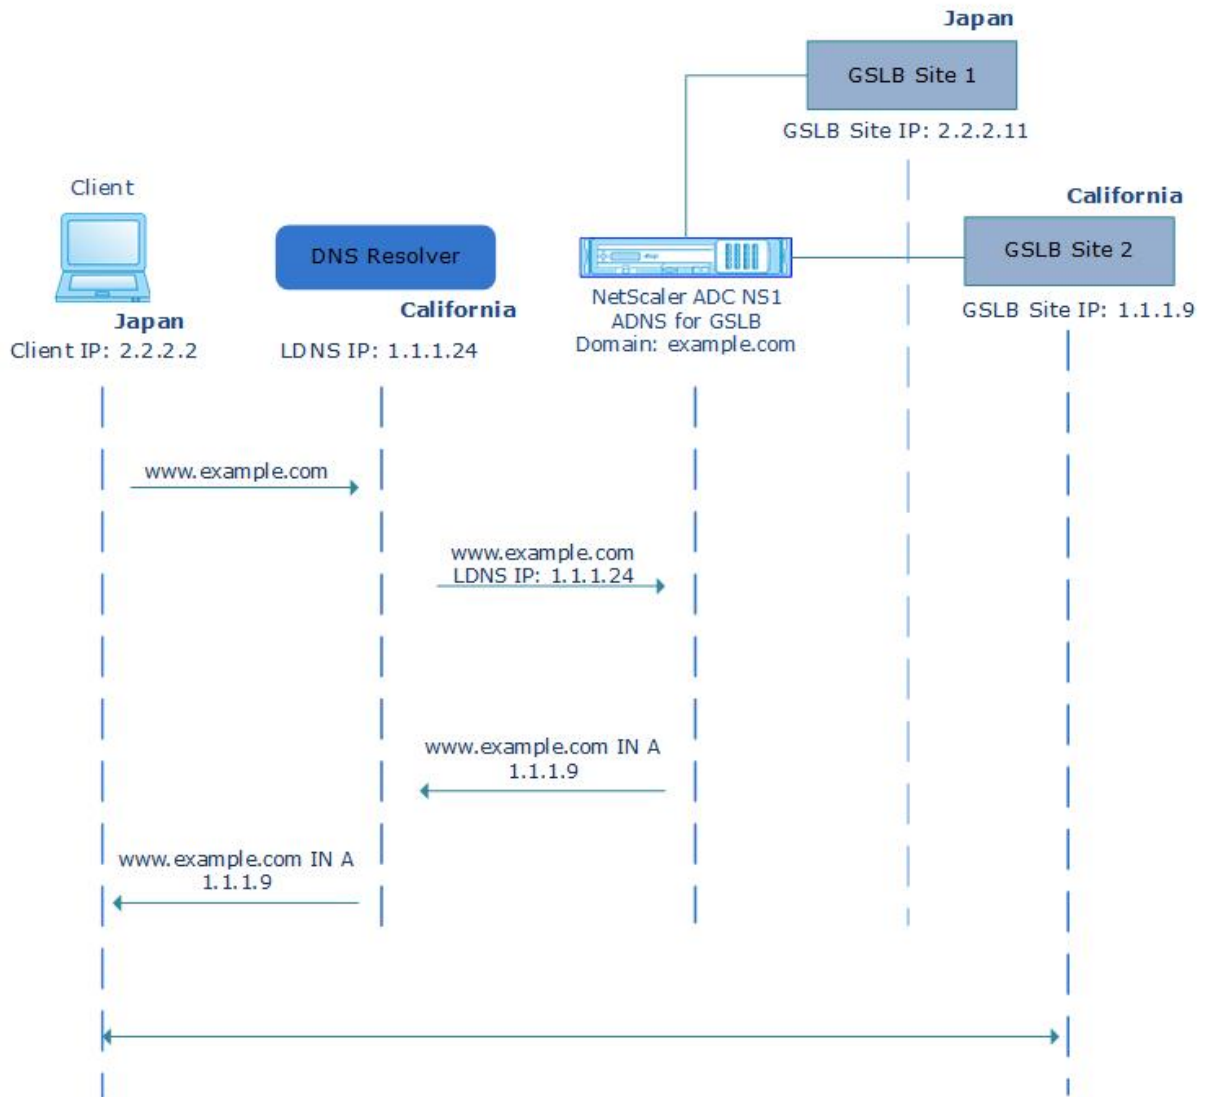

The Citrix ADC appliance uses the LDNS IP address for determining the topological closeness of the client and performs GSLB so, when you use proximity-based load balancing methods like static proximity or dynamic round-trip time (RTT). It happens in a typical GSLB deployment. But when a centralized DNS resolver, such as Google DNS or OpenDNS, is involved in the deployment, the Citrix ADC appliance sends the DNS request to a data center close to the centralized DNS resolver, which might not be close to the client. For example, in a typical Citrix ADC GSLB deployment using the static proximity load balancing method, an end-user request from Japan is sent to a data center in Japan. And an end user request from California is sent to a data center in California. But if a centralized DNS resolver is involved, the Citrix ADC appliance might send a request from Japan to a data center in California.

You can use the ECS option in deployments that include the Citrix ADC appliance configured as an Authoritative DNS (ADNS) server for a GSLB domain. If you use static proximity as the load balancing method, you can use the IP subnet in the EDNS header instead of the LDNS IP address. This helps to determine the geographical proximity of the client. In proxy mode deployment, the Citrix ADC appliance forwards an ECS-enabled DNS query as-is to the back-end servers. The appliance does not cache ECS-enabled DNS responses.

### Note

The ECS option is not applicable for all other deployment modes, such as ADNS mode for non-GSLB domains, resolver mode, and forwarder mode. The ECS option is ignored by the Citrix ADC appliance in the preceding mentioned modes. Also, by default, ECS is disabled for GSLB deployment.

### Without EDNS0 Client Subnet Option

### With EDNS0 Client Subnet Option

### To enable the EDNS0 Client Subnet option by using the command line interface:

At the command prompt, type:

```

1 set gslb vserver <vserver_name> **-ECS ENABLED
2
3 set gslb vserver vserver-GSLB-1 -ECS ENABLED
4 <!--NeedCopy-->

```

## Address validation

You can configure a GSLB virtual server to verify that the address returned by the EDNS0 ECS option of the DNS query is not a private or an unroutable IP address. With address validation enabled, the Citrix ADC appliance ignores the ECS address in the DNS query if it is listed in the following table. It instead uses the LDNS IP address for global server load balancing.

### Note

By default, address validation is disabled.

| Address Type | Address            | Description                                                                   |
|--------------|--------------------|-------------------------------------------------------------------------------|
| IPv4         | 10.0.0.0/8         | For private use                                                               |
|              | 172.16.0.0/12      | For private use                                                               |

### To enable address validation by using the command line interface

At the command prompt, type:

```
1 set gslb vserver <vserver_name> -ecsAddrValidation ENABLED
2
3 set gslb vserver vserver-GSLB-1 -ecsAddrValidation ENABLED
4 <!--NeedCopy-->
```

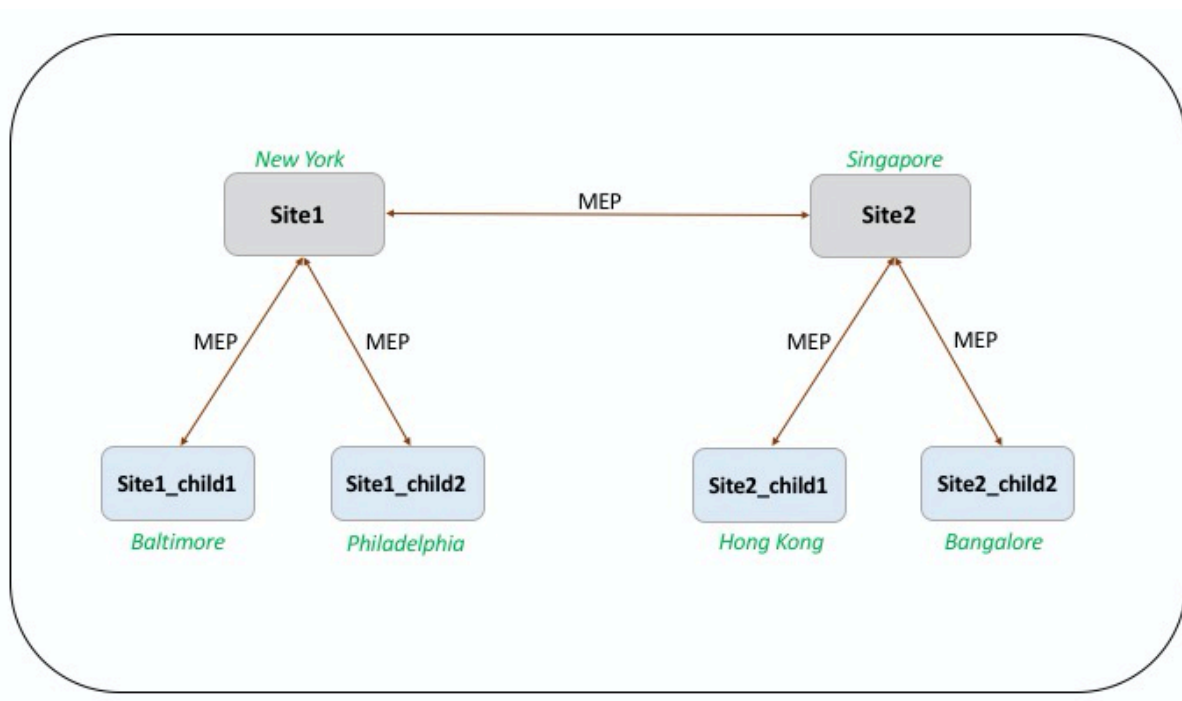

### Example of a complete parent-child configuration using the metrics exchange protocol

September 21, 2020

Consider the following parent-child topology in which the GSLB sites are distributed globally.

- Site1 and Site2 are the parent sites.

- Site1\_child1 and Site1\_child2 are the child sites of Site1.
- Site2\_child1 and Site2\_child2 are the child sites of Site2.

The following commands illustrate the complete configuration of the parent-child topology.

### site1

```

1 add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2
3 add gslb site site2 10.106.24.164 -publicIP 10.106.24.164
4
5 add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -
  nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
  site1
6
7 add gslb site site1_child2 10.102.82.67 -publicIP 10.102.82.67 -
  nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
  site1
8
9 add gslb site site2_child1 10.106.24.132 -publicIP 10.106.24.132 -
  nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
  site2
10
11 add gslb site site2_child2 10.106.24.67 -publicIP 10.106.24.67 -
  nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
  site2
  
```

```
12
13 add gslb service site1_child1_http_gsvc1 10.102.82.132 HTTP 80 -
    publicIP 10.102.82.132 -publicPort 80 -maxClient 0 -siteName
    site1_child1 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
14
15 add gslb service site1_child2_http_gsvc1 10.102.82.68 HTTP 80 -publicIP
    10.102.82.68 -publicPort 80 -maxClient 0 -siteName site1_child2 -
    cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
16
17 add gslb service site2_child1_http_gsvc1 10.106.24.134 HTTP 80 -
    publicIP 10.106.24.134 -publicPort 80 -maxClient 0 -siteName
    site2_child1 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
18
19 add gslb service site2_child2_http_gsvc1 10.106.24.68 HTTP 80 -publicIP
    10.106.24.68 -publicPort 80 -maxClient 0 -siteName site2_child2 -
    cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
20
21 add gslb vserver gv1 HTTP -backupLBMethod ROUNDROBIN -tolerance 0 -
    appflowLog DISABLED
22
23 bind gslb vserver gv1 -serviceName site1_child1_http_gsvc1
24
25 bind gslb vserver gv1 -serviceName site1_child2_http_gsvc1
26
27 bind gslb vserver gv1 -serviceName site2_child2_http_gsvc1
28
29 bind gslb vserver gv1 -serviceName site2_child1_http_gsvc1
30
31 bind gslb vserver gv1 -domainName www.gslb.com -TTL 5
32 <!--NeedCopy-->
```

### site1\_child1

```
1 add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2
3 add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site1
4 <!--NeedCopy-->
```

You can add the following commands for load balancing configuration:

```
1 add service svc1 10.102.82.25 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0
    -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -
```

```
    svrTimeout 360 -CKA NO -TCPB NO -CMP NO
2
3 add lb vserver lb1 HTTP 10.102.82.132 80 -persistenceType NONE -
    cltTimeout 180
4
5 bind lb vserver lb1 svc1
6 <!--NeedCopy-->
```

## site1\_child2

```
1 add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2
3 add gslb site site1_child2 10.102.82.67 -publicIP 10.102.82.67 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site1
4
5 You can add the following commands for load balancing configuration:
6
7 add service svc1 10.102.82.25 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0
    -cip DISABLED -usip NO -useproxyport YES -sp OFF -cltTimeout 180 -
    svrTimeout 360 -CKA NO -TCPB NO -CMP NO
8
9 add lb vserver lb1 HTTP 10.102.82.68 80 -persistenceType NONE -
    cltTimeout 180
10
11 bind lb vserver lb1 svc1
12 <!--NeedCopy-->
```

## site2

```
1 add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2
3 add gslb site site2 10.106.24.164 -publicIP 10.106.24.164
4
5 add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site1
6
7 add gslb site site1_child2 10.102.82.67 -publicIP 10.102.82.67 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site1
8
```

```
9 add gslb site site2_child1 10.106.24.132 -publicIP 10.106.24.132 -
  nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
  site2
10
11 add gslb site site2_child2 10.106.24.67 -publicIP 10.106.24.67 -
  nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
  site2
12
13 add gslb service site1_child1_http_gsvc1 10.102.82.132 HTTP 80 -

  svrTimeout 360 -CKA NO -TCPB NO -CMP NO
2
3 add lb vserver lb1 HTTP 10.106.24.68 80 -persistenceType NONE -
  cltTimeout 180
4
5 bind lb vserver lb1 svc1
6 <!--NeedCopy-->
```

## Link load balancing

September 25, 2020

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the Citrix ADC appliance to monitor and control traffic so

that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the Citrix ADC appliance and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. Configuring a basic setup involves configuring services, virtual servers, monitors, routes, an LLB method, and, optionally, configuring persistence. Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.

## Configuring a Basic LLB Setup

September 21, 2020

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical routers represented by the services. The virtual server selects a router by using the load balancing method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.

To configure a basic LLB setup, do the following:

- Configure services
- Configure an LLB virtual server and binding a service
- Configure the LLB method and persistence
- Configure an LLB route
- Create and bind a transparent monitor

### Configure services

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in “

Creating and Binding a Transparent Monitor.”

### To create a service by using the command line interface

At the command prompt, type:

```
1 add service <name> <IP> <serviceType> <port>
2
3 show service <name>
4 <!--NeedCopy-->
```

### Example:

```
1 add service ISP1R_svc_any 10.10.10.254 any *
2 show service ISP1R_svc_any
3     ISP1R_svc_any (10.10.10.254:*) - ANY
4     State: DOWN
5     Last state change was at Tue Aug 31 04:31:13 2010
6     Time since last state change: 2 days, 05:34:18.600
7     Server Name: 10.10.10.254
8     Server ID : 0   Monitor Threshold : 0
9     Max Conn: 0     Max Req: 0     Max Bandwidth: 0 kbits
10    Use Source IP: NO
11    Client Keepalive(CKA): NO
12    Access Down Service: NO
13    TCP Buffering(TCPB): YES
14    HTTP Compression(CMP): NO
15    Idle timeout: Client: 120 sec   Server: 120 sec
16    Client IP: DISABLED
17    Cacheable: NO
18    SC: OFF
19    SP: OFF
20    Down state flush: ENABLED
21
22 1)    Monitor Name: ping
23        State: UP     Weight: 1
24        Probes: 244705   Failed [Total: 0 Current: 0]
25        Last response: Success - ICMP echo reply received.
26        Response Time: 1.322 millisec
27 Done
28 <!--NeedCopy-->
```

**To create services by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Services, and create a service.

**To create services by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
  - Service Name\*—name
  - Server—IP
  - Protocol\*—serviceType (Select ANY from the drop-down list.)
  - Port\*—port

A required parameter

1. Click Create.
2. Repeat Steps 2-4 to create another service.
3. Click Close.
4. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

**Configure an LLB virtual server and bind a service**

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method, see “[Configuring the LLB Method and Persistence.](#)”

**To create a link load balancing virtual server and bind a service by using the command line interface**

At the command prompt, type:

```
1 add lb vserver <name> <serviceType>
2
3 bind lb vserver < name> <serviceName>
4
5 show lb vserver < name>
6 <!--NeedCopy-->
```

**Example:**

```

1 add lb vserver LLB-vip any
2 bind lb vserver LLB-vip ISP1R_svc_any
3 sh lb vserver LLB-vip
4     LLB-vip (0.0.0.0:0) - ANY    Type: ADDRESS
5     State: DOWN
6     Last state change was at Thu Sep  2 10:51:32 2010
7     Time since last state change: 0 days, 17:51:46.770
8     Effective State: DOWN
9     Client Idle Timeout: 120 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    No. of Bound Services :  1 (Total)      0 (Active)
13    Configured Method: ROUNDROBIN
14    Mode: IP
15    Persistence: NONE
16    Connection Failover: DISABLED
17
18 1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN    Weight: 1
19 Done
20 <!--NeedCopy-->

```

**To create a link load balancing virtual server and bind a service by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
2. In the **IP Address Type** drop-down list, select the desired option. Select **Non Addressable** to create a virtual server that is not directly accessible.
3. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

**Configure the LLB method and persistence**

By default, the Citrix ADC appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

**To configure the LLB method and/or persistence by using the command line interface**

At the command prompt, type the following command:

```
1 set lb vserver <name> -lbMethod <lbMethod> -persistenceType <
   persistenceType>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver LLB-vip -lbmethod ROUNDROBIN -persistencetype SOURCEIP
2
3 show lb vserver LLB-vip
4     LLB-vip (0.0.0.0:0) - ANY      Type: ADDRESS
5     State: DOWN
6     Last state change was at Fri Sep  3 04:46:48 2010
7     Time since last state change: 0 days, 00:52:21.200
8     Effective State: DOWN
9     Client Idle Timeout: 120 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    No. of Bound Services :  0 (Total)      0 (Active)
13    Configured Method: ROUNDROBIN
14    Mode: IP
15    Persistence: SOURCEIP
16    Persistence Mask: 255.255.255.255      Persistence v6MaskLength:
17    128 Persistence Timeout: 2 min
18    Connection Failover: DISABLED
18 <!--NeedCopy-->
```

**To configure the link load balancing method and/or persistence by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the load balancing method and/or persistence settings.
2. In the **Advanced Settings** section, select Method and configure the load balancing method.
3. In the **Advanced Settings** section, select **Persistence** and configure the persistence parameters.

## Configure an LLB route

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the LLB virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the LLB virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

### To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

```
1 add lb route <network> <netmask> <gatewayName>
2
3 show lb route [<network> <netmask>]
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb route 0.0.0.0 0.0.0.0 LLB-vip
2 show lb route 0.0.0.0 0.0.0.0
3      Network          Netmask          Gateway/VIP          Flags
4      -----          -
5 1)  0.0.0.0          0.0.0.0          LLB-vip              UP
6 <!--NeedCopy-->
```

### To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

```
1 add lb route6 <network> <gatewayName>
2
3 show lb route6
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb route6 ::/0 llb6_vs show lb route6 Network VIP Flags -----
   ----- 1) ::/0 llb6_vs UP
2 <!--NeedCopy-->
```

### To configure an LLB route by using the configuration utility

Navigate to System > Network > Routes, and select **LLB**, and configure the LLB route.

**Note:** Select LLBV6 to configure an IPV6 route.

### To configure an LLB route by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the details pane, select one of the following:
  - Click LLB to configure an IPv4 route.
  - Click LLBV6 to configure an IPv4 route.
3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:
  - Network\*
  - Netmask\*—Required for IPV4 routes.
  - Gateway Name\*—gatewayName

A required parameter

1. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.

Figure 1. Basic LLB Setup

**Note**

If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

**Create and bind a transparent monitor**

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor,

if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

### To create a transparent monitor by using the command line interface

At the command prompt, type:

```

1 add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent
  YES
2
3 show lb monitor [<monitorName>]
4 <!--NeedCopy-->

```

### Example:

```

1 add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
2 > show lb monitor monitor-1
3 1) Name.....: monitor-1 Type.....: PING State.....:
  ENABLED
4 Standard parameters:
5 Interval.....: 5 sec Retries.....:
  3
6 Response timeout.: 2 sec Down time.....:
  30 sec
7 Reverse.....: NO Transparent.....:
  YES
8 Secure.....: NO LRTM.....:
  ENABLED
9 Action.....: Not applicable Deviation.....:
  0 sec
10 Destination IP...: 10.10.10.11
11 Destination port.: Bound service
12 Iptunnel.....: NO
13 TOS.....: NO TOS ID.....:
  0
14 SNMP Alert Retries: 0 Success Retries...:
  1
15 Failure Retries...: 0
16 <!--NeedCopy-->

```

### To create a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors and configure a transparent monitor.

**To create a transparent monitor by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:
  - Name\*
  - Type\*
  - Destination IP
  - Transparent

A required parameter

1. Click Create, and then click Close.
2. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

**To bind a monitor to a service by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the **Monitors** tab, under **Available**, select the monitor that you want to bind to the service, and then click **Add**.

**To bind a monitor to a service by using the command line interface**

At the command prompt, type:

```
1 bind lb monitor <monitorName> <serviceName>
2
3 show service <name>
4 <!--NeedCopy-->
```

**Example:**

```
1 bind lb monitor monitor-HTTP-1 ISP1R_svc_any
2 Done
3 > show service ISP1R_svc_any
4     ISP1R_svc_any (10.10.10.254:*) - ANY
5     State: UP
6     Last state change was at Thu Sep  2 10:51:07 2010
7     Time since last state change: 0 days, 18:41:55.130
8     Server Name: 10.10.10.254
9     Server ID : 0     Monitor Threshold : 0
10    Max Conn: 0     Max Req: 0     Max Bandwidth: 0 kbits
```

```
11      Use Source IP: NO
12      Client Keepalive(CKA): NO
13      Access Down Service: NO
14      TCP Buffering(TCPB): YES
15      HTTP Compression(CMP): NO
16      Idle timeout: Client: 120 sec   Server: 120 sec
17      Client IP: DISABLED
18      Cacheable: NO
19      SC: OFF
20      SP: OFF
21      Down state flush: ENABLED
22
23 1)      Monitor Name: monitor-HTTP-1
24          State: UP   Weight: 1
25          Probes: 1256           Failed [Total: 0 Current: 0]
26          Last response: Success - ICMP echo reply received.
27          Response Time: 1.322 millisec
28      Done
29 <!--NeedCopy-->
```

### To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select a service to which you want to bind a monitor, and then click Open.
3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.
4. Click OK.
5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.

## Configuring RNAT with LLB

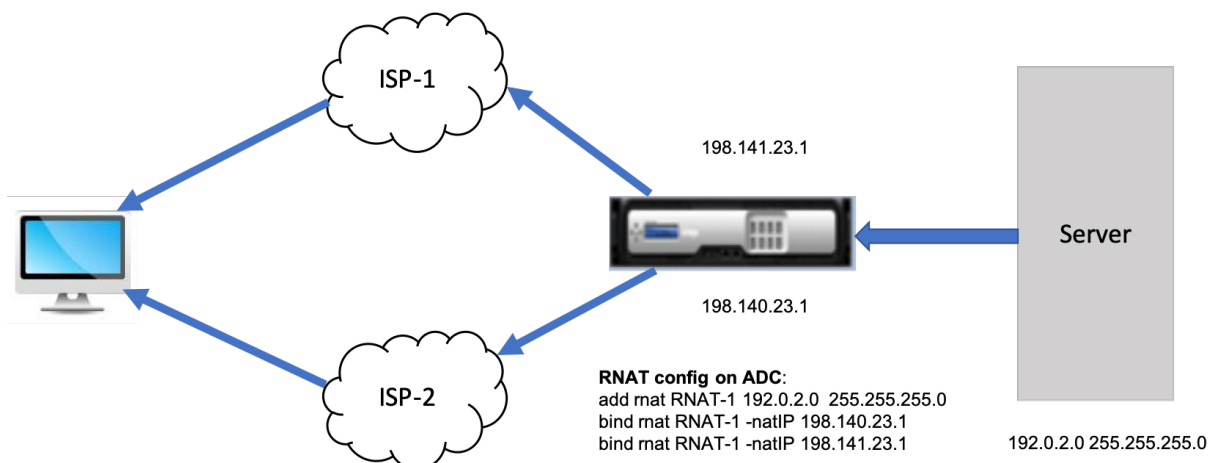

September 21, 2020

### To configure RNAT by using the command line interface

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. This ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in

“[Configuring a Basic LLB Setup](#)”, and then configure RNAT as described in [Configure RNAT](#). You must then enable use subnet IP (USNIP) mode.

In the following diagram, the Citrix ADC appliance uses LLB to route outbound traffic to different links. During the RNAT operation, the ADC appliance replaces the source IP addresses of the outbound traffic with the public NAT IP address (198.141.23.1) to route the traffic through ISP-1. Similarly, the ADC appliance replaces the source IP addresses with 198.140.23.1 to route the traffic through ISP-2.

### To add SNIPs for ISP routers by using the command line interface

At the command prompt, type:

```
1 add NS IP <subnet of first ISP in the IP router> <subnet mask> -type
  SNIP
2
3 add NS IP <subnet of second ISP in the IP router> <subnet mask> -type
  SNIP
4 <!--NeedCopy-->
```

#### Example:

```
1 add ns ip 10.140.23.1 255.255.255.0 -type snip
2
3 add ns ip 10.141.23.1 255.255.255.0 -type snip
4 <!--NeedCopy-->
```

### To configure RNAT by using the command line interface

At the command prompt, type:

```
1 set rnat <network> <netmask>
```

```

2
3 show rnat
4 <!--NeedCopy-->

```

**Example:**

```

1 set rnat 10.102.29.0 255.255.255.0 -natIP 10.140.23.1
2 set rnat 10.102.29.0 255.255.255.0 -natIP 10.141.23.1
3 show rnat
4     1) Network: 10.102.29.0           Netmask: 255.255.255.0
5       NatIP: 10.140.23.1
6     2) Network: 10.102.29.0           Netmask: 255.255.255.0
7       NatIP: 10.141.23.1
8 <!--NeedCopy-->

```

**To configure RNAT by using the configuration utility**

1. Navigate to **System > Network > NATs**.
2. On the **RNAT** tab, click **Configure RNAT**.
3. Specify the network on which to perform RNAT.

**Note**

You can also configure RNAT by using Access Control Lists (ACLs). Refer [Configuring RNAT](#) for details.

**To enable Use Subnet IP mode by using the command line interface**

At the command prompt, type:

```

1 enable ns mode USNIP
2
3 show ns mode
4 <!--NeedCopy-->

```

**Example:**

```

1 enable ns mode USNIP
2
3 show ns mode
4     Mode                               Acronym           Status
5     -----                               -
6     1) Fast Ramp                         FR                ON
7     2) ... .

```

```

8 8)      Use Subnet IP          USNIP          ON
9 9)      ...
10 <!--NeedCopy-->

```

### To enable Use Subnet IP mode by using the configuration utility

1. Navigate to **System > Settings** and, under **Modes and Features**, click **Configure Modes**.
2. In the **Configure Modes** dialog box, select **Use Subnet IP**, and then click **OK**.

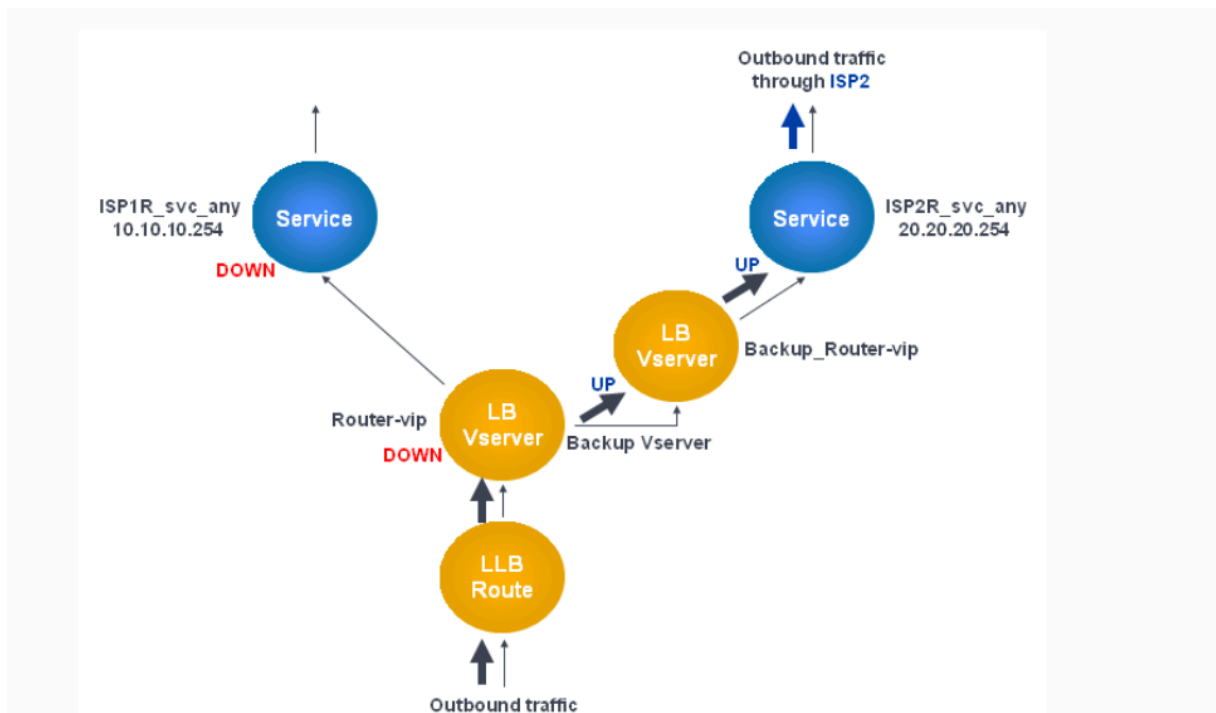

## Configuring a Backup Route

September 21, 2020

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the Citrix ADC appliance automatically uses it when the primary route fails. First create a primary virtual server as described in “[Configuring an LLB Virtual Server and Binding a Service](#).” To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup\_Router-vip** is the secondary virtual server designated as the backup virtual server.

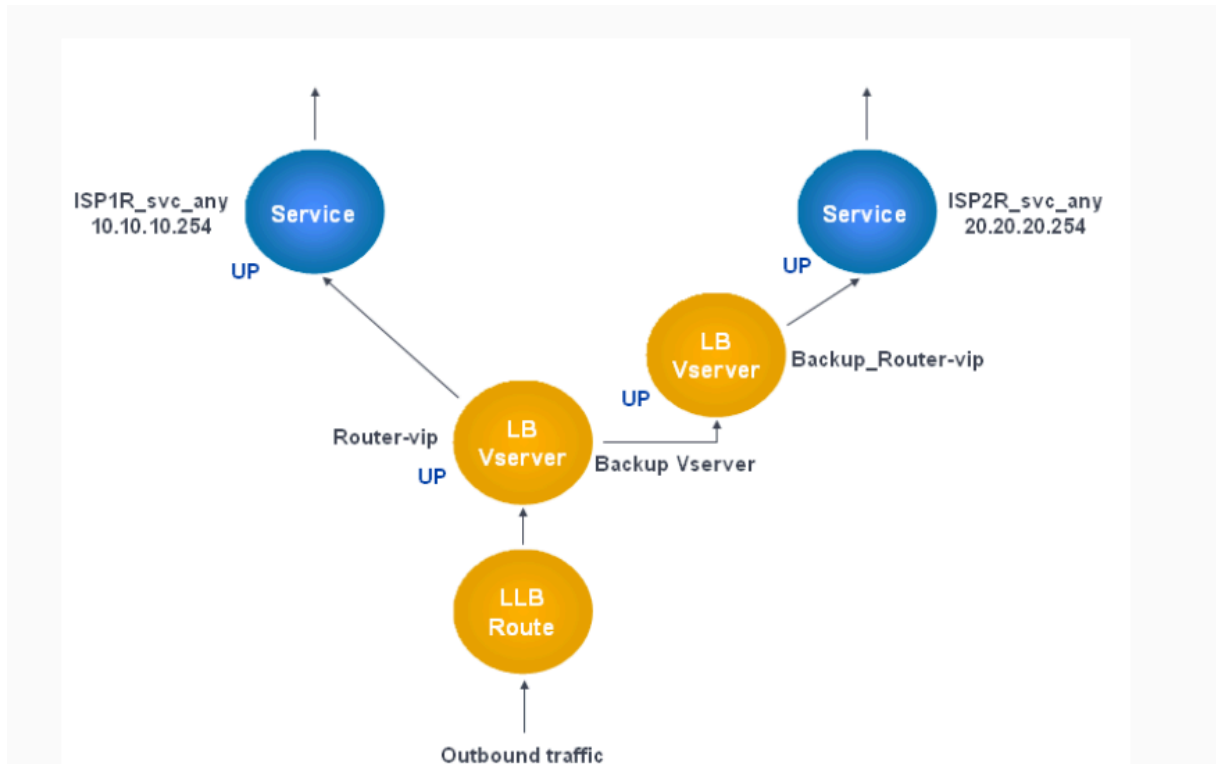

Figure 1. Backup Route Setup

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Backup Routing in Operation

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

### To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

```

1 set lb vserver <name> -backupVserver <string>
2 <!--NeedCopy-->

```

#### Example:

```

1 set lb vserver Router-vip -backupVServer Backup_Router-vip
2 > show lb vserver Router-vip
3     Router-vip (0.0.0.0:0) - ANY      Type: ADDRESS
4     State: UP

```

```
5      Last state change was at Fri Sep  3 04:46:48 2010
6      Time since last state change: 0 days, 03:09:45.600
7      Effective State: UP
8      Client Idle Timeout: 120 sec
9      Down state flush: ENABLED
10     Disable Primary Vserver On Down : DISABLED
11     No. of Bound Services : 1 (Total)          1 (Active)
12     Configured Method: ROUNDROBIN
13     Mode: IP
14     Persistence: DESTIP      Persistence Mask: 255.255.255.255
15           Persistence v6MaskLength: 128      Persistence Timeout: 2
16           min
17     Backup: Router2-vip
18     Connection Failover: DISABLED
19     Done
20     <!--NeedCopy-->
```

### To set the secondary virtual server as the backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the secondary virtual server for which you want to configure the backup virtual server.
2. In the **Load Balancing Virtual Server** dialog box, under **Advanced**, select **Protection**.
3. In the **Backup Virtual Server** drop-down list, select the secondary backup virtual server, and then click **OK**.

## Resilient LLB Deployment Scenario

September 21, 2020

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways **Router1-vip** and **Router2-vip**, respectively. **Router1-vip** is configured as a backup to **Router2-vip** and vice versa. All traffic with the destination IP specified as 30.30.30.30 is sent through **Router1-vip** and traffic with the destination IP specified as 30.30.31.31 is sent through **Router2-vip**.

Figure 1. Resilient LLB Deployment Setup

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

However, if any one of the gateways (**Router1-vip** or **Router2-vip**) is DOWN, traffic is routed through the backup router. In the following diagram, **Router1-vip** for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

## Monitoring an LLB Setup

September 21, 2020

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

### Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name

- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

### To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC, or for a single virtual server, at the command prompt, type:

```
1 stat lb vserver -detail] [<name>]
2 <!--NeedCopy-->
```

### Example:

```
1 stat lb vserver -detail
2 Virtual Server(s) Summary
3
4      vsvrIP  port  Protocol  State  Req/s
5      Hits/s
6 One          *    80      HTTP     UP     5/s
7           0/s
8 Two          *     0      TCP      DOWN   0/s
9           0/s
10 Three        * 2598     TCP      DOWN   0/s
11           0/s
12 dnsVirtualNS 10.102.29.90 53      DNS      DOWN   0/s
13           0/s
14 BRVSERVER    10.10.1.1   80      HTTP     DOWN   0/s
15           0/s
16 LBVIP        10.102.29.66 80      HTTP     UP     0/s
17           0/s
18 Done
19 <!--NeedCopy-->
```

### To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

### To view the statistics of a service by using the command line interface

At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

### To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

## Load Balancing

September 21, 2020

The load balancing feature distributes user requests for web pages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance; when one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to;

- Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
- Use any of several different algorithms to determine which server should receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the Citrix ADC appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

## How load balancing works

September 21, 2020

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the Citrix ADC appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. In some cases, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see **Global HTTP Ports**.

### Load balancing basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture

The load balancing virtual server can use any of a number of algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the Citrix ADC appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical Citrix ADC load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the local area network (LAN) or wide area network (WAN), the VIP is usually a private (ICANN non-routable) IP address.
- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.
- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the

server's IP address when you create a service, and the IP address becomes the name of the server.

- **Monitor.** An entity on the Citrix ADC appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The Citrix ADC appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

For variations in the load balancing setup, see the following use cases:

- [Configuring Load Balancing in Direct Server Return Mode](#)
- [Configuring LINUX Servers in DSR Mode](#)
- [Configuring DSR Mode When Using TOS](#)
- [Configuring Load Balancing in DSR Mode by Using IP Over IP](#)
- [Configuring Load Balancing in One-arm Mode](#)
- [Configuring Load Balancing in the Inline Mode](#)
- [Load Balancing of Intrusion Detection System Servers](#)
- [Load balance remote desktop protocol servers](#)

## Understanding the topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the Citrix ADC appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The Citrix ADC appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.

| Entity         | Name           | IPAddress    | Port | Protocol |
|----------------|----------------|--------------|------|----------|
| Virtual server | Vserver-LB-1   | 10.102.29.60 | 80   | HTTP     |
| Services       | Service-HTTP-1 | 10.102.29.5  | 80   | HTTP     |
|                | Service-HTTP-2 | 10.102.29.6  | 80   | HTTP     |
| Monitors       | Default        | None         | None | None     |

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model

## Use of wildcards instead of IP addresses and ports

In some cases you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases may require using a wildcard:

- If the Citrix ADC appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single Citrix ADC appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the Citrix ADC appliance determines the actual IP address or port and creates new records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server

receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each should be used.

| IP | Port | Protocol | Description                                                                                                                                                                                                                                                                             |
|----|------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *  | *    | TCP      | A general wildcard virtual server that accepts traffic sent to any IP address and port on the Citrix ADC appliance. When using a wildcarded virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic. |
| *  | *    | TCP      | A firewall load balancing virtual server. You can bind firewall services to this virtual server, and the Citrix ADC appliance passes traffic through the firewall to the destination.                                                                                                   |

---

| IP         | Port | Protocol         | Description                                                                                                                                                                                                                                             |
|------------|------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Address | *    | TCP,UDP, and ANY | A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It will not dynamically learn them. |

**Note:** You do not configure services or virtual servers for a global HTTP port. In this case, you configure a specific port as a global HTTP port (for example, set ns param -httpPort 80). The appliance then accepts all traffic that matches the port number, and processes it as HTTP traffic. The appliance dynamically learns and creates services for this traffic.

| IP | Port | Protocol       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----|------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *  | port | SSL, SSL_TCP   | A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it should use. If -cleartext is not specified, the Citrix ADC appliance uses end-to-end SSL. |
| *  | port | Not applicable | All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers; the Citrix ADC appliance learns them dynamically.                                                                                                                                                                                                                                                                                                    |

Note: If you have configured your Citrix ADC appliance as a transparent pass through that makes use of global (wildcard) ports, you may want to turn on Edge mode.

For more information, see [“Configuring Edge Mode.”](#)

The Citrix ADC appliance attempts to locate virtual servers and services by first attempting an exact

match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a \* (wildcard) port
3. • (wildcard) IP address and a specific port
4. • (wildcard) IP address and a \* (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server on the basis of the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

## Configuring global HTTP ports

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the `set ns param` command. After configuring this port, the Citrix ADC appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single `set ns param` command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the `show ns param` command to view the ports that are currently configured.

### To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

```
1 set ns param - httpPort <port>
2
3 show ns param
4 <!--NeedCopy-->
```

### Example 1: Configuring a port as a global HTTP port

In this example, port 80 is configured as a global HTTP port.

```
1 set ns param -httpPort 80
2 Done
3 show ns param
4     Global configuration settings:
5         HTTP port(s): 80
6         Max connections: 0
7         Max requests per connection: 0
8         Client IP insertion: DISABLED
9         Cookie version: 0
10        Persistence Cookie Secure Flag: ENABLED
11        ...
12        ...
13 <!--NeedCopy-->
```

**Example 2: Adding ports when one or more global HTTP ports are already configured\*\***

In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
1 > show ns param
2     Global configuration settings:
3         HTTP port(s): 80
4         Max connections: 0
5         Max requests per connection: 0
6         Client IP insertion: DISABLED
7         Cookie version: 0
8         Persistence Cookie Secure Flag: ENABLED
9         Min Path MTU: 576
10        ...
11        ...
12 Done
13 > set ns param -httpPort 80 8888
14 Done
15 > show ns param
16
17     Global configuration settings:
18         HTTP port(s): 80,8888
19         Max connections: 0
20         Max requests per connection: 0
21         Client IP insertion: DISABLED
22         Cookie version: 0
23         Persistence Cookie Secure Flag: ENABLED
24         Min Path MTU: 576
```

```
25
26     ...
27     ...
28 Done
29 >
30 <!--NeedCopy-->
```

### To configure a global HTTP port by using the configuration utility

1. Navigate to System > Settings > Change HTTP Parameters, and then add an HTTP port number.

## Set up basic load balancing

January 20, 2021

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

### Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

### To enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example

```
1     > enable ns feature LoadBalancing
2
3     Done
4
```

```

5 > show ns feature
6
7
8
9         Feature                               Acronym           Status
10        -----                               -
11
12
13     1)    Web Logging                           WL                OFF
14
15     2)    Surge Protection                       SP                ON
16
17     3)    Load Balancing LB ON
18
19     .
20
21     .
22
23     .
24
25     24)   NetScaler Push                        push              OFF
26
27         Done
28 <!--NeedCopy-->

```

### To enable load balancing by using the GUI

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

### Configuring a Server Object

Create an entry for your server on the Citrix ADC appliance. The Citrix ADC appliance supports IP address based servers and domain-based servers. If you create an IP address based server, you can specify the name of the server instead of its IP address when you create a service. For information about setting up DNS for a domain-based server, see [Domain Name System](#).

### To create a server object by using the CLI

At the command prompt, type:

```

1 add server `<name>`@ `<IPAddress>`@ | `<domain>`
2 <!--NeedCopy-->

```

**Example for adding IP address-based name server:**

```
1 add server web_serv 10.102.27.150
2 <!--NeedCopy-->
```

**Example for adding domain-based server:**

```
1 add server web_serv test.com
2 <!--NeedCopy-->
```

**To create a server object by using the GUI**

Navigate to **Traffic Management > Load Balancing > Servers**, and add a server object.

**Configuring Services**

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP\_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

**Creating a Service**

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the Citrix ADC appliance.

**HTTP**

Used for load-balanced servers that accept HTTP traffic, such as standard websites and web applications. The HTTP service type enables the Citrix ADC appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also

supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the Citrix ADC appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 supports described earlier.

## **SSL**

Used for servers that accept HTTPS traffic, such as ecommerce websites and shopping cart applications. The SSL service type enables the Citrix ADC appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL\_BRIDGE, SSL\_TCP, or TCP service types. If you do so, however, the appliance performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 supports described above.

## **FTP**

Used for servers that accept FTP traffic. The FTP service type enables the Citrix ADC appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service types for FTP servers.

## **TCP**

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

## **SSL\_TCP**

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the Citrix ADC appliance performs both the Layer 4 load balancing and SSL offloading.

## **UDP**

Used for servers that accept UDP traffic. You can also use the ANY service type.

### **SSL\_BRIDGE**

Used for servers that accept SSL traffic when you do not want the Citrix ADC appliance to perform SSL offloading. Alternatively, you can use the SSL\_TCP service type.

### **NNTP**

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

### **DNS**

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the Citrix ADC appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the Citrix ADC appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

### **ANY**

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

### **SIP-UDP**

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the Citrix ADC appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

### **DNS-TCP**

Used for servers that accept DNS traffic, where the Citrix ADC appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the Citrix ADC appliance validates the packet format of each DNS request and response and can cache DNS responses, as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the Citrix ADC appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

## **RTSP**

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

You can also use the TCP service type for these services. If you do, however, the Citrix ADC appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NATting.

## **DHCPRA**

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

## **DIAMETER**

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

## **SSL\_DIAMETER**

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the Citrix ADC appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the Citrix ADC appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

Note: You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in case of an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

## **QUIC**

Used by load balancing servers that accept UDP based QUIC video traffic. The service enables the Citrix ADC appliance to optimize encrypted ABR video traffic over UDP protocol.

### To create a service by using the CLI

At the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2
3 add service Service-HTTP-1 192.0.2.5 HTTP 80
4 <!--NeedCopy-->
```

### To create a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click **Add**.
3. In the Create Service dialog box, specify values for the following parameters:
  - Service Name—name
  - Server—serverName
  - Protocol—serviceType
  - Port—port
4. Click **Create**, and then click **Close**. The service you created appears in the Services pane.

### Creating a Virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced websites, applications, or servers. Once load balancing is configured, users connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.

#### Note:

- Virtual server names prefixed with “app\_” do not appear in the GUI though they are present in the ns.conf file and are displayed when you run the show command. However, virtual server names prefixed with “app” are displayed in the GUI.
- The virtual server is designated as DOWN until you bind the services that you created to it, and until the Citrix ADC appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.

### To create a virtual server by using the CLI

At the command prompt, type:

```
1 add lb vserver <name> <serviceType> <ip> <port>
2
```

```

3 add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
4 <!--NeedCopy-->

```

### To create a virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then create a virtual server.

### Binding Services to the Virtual Server

Note: A service can be bound to a maximum of 500 virtual servers.

After you have created services and a virtual server, you must bind the services to the virtual server. In most cases, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

| Virtual Server Type | Service Type | Comment                                                                                                                                           |
|---------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTP                | SSL          | You would normally bind an SSL service to an HTTP virtual server to do encryption.                                                                |
| SSL                 | HTTP         | You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.                                                            |
| SSL_TCP             | TCP          | You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness). |

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

### To bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```

1 bind lb vserver <name> <serviceName>
2 bind lb vserver Vserver-LB-1 Service-HTTP-1

```

```
3 <!--NeedCopy-->
```

### To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the **Service** section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

### Verifying the Configuration

After finishing your basic configuration, you should view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you should view the statistics for each service and load balancing virtual server to check for possible problems.

### Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your Citrix ADC appliance configuration.

### To view the properties of server objects by using the command line interface

At the command prompt, type:

```
1 show server <serverName>
2
3 show server server-1
4 <!--NeedCopy-->
```

### To view the properties of server objects by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Servers**. The parameter values of the available servers appear in the details pane.

### Viewing the Properties of a Virtual Server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies

that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

### To view the properties of a load balancing virtual server by using the CLI

At the command prompt, type:

```
1 show lb vserver <name>
2
3 show lb vserver Vserver-LB-1
4 <!--NeedCopy-->
```

### To view the properties of a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.
3. To view cache redirection and content switching virtual servers that are bound to this virtual server, click **Show CS/CR Bindings**.

### Viewing the Properties of a Service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

### To view the properties of services by using the CLI

At the command prompt, type:

```
1 show service <name>
2
3 show service Service-HTTP-1
4 <!--NeedCopy-->
```

### To view the properties of services by using the GUI

Navigate to **Traffic Management > Load Balancing > Services**. The details of the available services appear on the Services pane.

## Viewing the Bindings of a Service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

### To view the bindings of a service by using the CLI

At the command prompt, type:

```
1 show service bindings <name>
2
3 show service bindings Service-HTTP-1
4 <!--NeedCopy-->
```

### To view the bindings of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose binding information you want to view.
3. In the **Action** tab, click **Show Bindings**.

## Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

### To display virtual server statistics by using the CLI

To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

stat lb vserver [<name>]

**Example:**

```
1 stat lb vserver server-1
2 <!--NeedCopy-->
```

The following figure displays a sample statistic page.

```
> stat lbvserver
[
Virtual Server(s) Summary
vserver1      vsvrIP  port  Protocol  State  Req/s
10.102.20.200 80     SSL      DOWN      0/s

lb1           203.1.113.5 443     DTLS     DOWN      0/s

vicap         *        0       TCP      DOWN      0/s

lbicap        2.2.3.4 1344    TCP      DOWN      0/s

app_...stest  0.0.0.0 0       HTTP     DOWN      0/s
app_...ttest  0.0.0.0 0       HTTP     DOWN      0/s
app_...fault  0.0.0.0 0       HTTP     DOWN      0/s
app_...test1  0.0.0.0 0       HTTP     DOWN      0/s
app_...1test  0.0.0.0 0       HTTP     DOWN      0/s
app_...fault  0.0.0.0 0       HTTP     DOWN      0/s

```

### To display virtual server statistics by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click **Statistics**.

### Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

### To view the statistics of a service by using the CLI

At the command prompt, type:

```
1 stat service `<name>`  
2 <!--NeedCopy-->
```

#### Example:

```
1 stat service Service-HTTP-1  
2 <!--NeedCopy-->
```

### To view the statistics of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click **Statistics**. The statistics appear in a new window.

## Load balance virtual server and service states

September 21, 2020

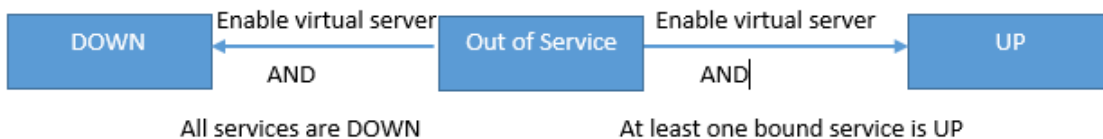

A load balancing virtual server that does not have a backup virtual server can take the following states, depending on the states of the service(s) bound to it and whether it is administratively disabled:

- **UP**: At least one of the services bound to the virtual server is UP.

- **DOWN:** All the services bound to the virtual server are DOWN, or the load balancing feature is not enabled.
- **Out of Service (OFS):** If you administratively disable the virtual server, it enters the OFS state but its effective state is DOWN. Transitioning to the OFS state from the DOWN or UP state, or to the DOWN or UP state from the OFS state, is controlled by the administrator.

The state and effective state of a virtual server are the same if a backup virtual server is not configured. However, if a backup virtual server or a chain of backup virtual servers is configured, the effective state is derived from the states of the services that are bound to the primary virtual server and the backup virtual server(s). If any of the backup virtual servers in the chain is UP, the effective state of the primary virtual server is UP, even if all the services bound to the primary virtual server are DOWN.

The following diagrams show the conditions under which a virtual server transitions from one state to another.

A service can take the following states:

- **UP:** If probes from all the monitors bound to the service are successful.
- **DOWN:** If monitoring probes to the service are not answered within the configured time limit.
- **OUT OF SERVICE:** If you administratively disable the service, or if you gracefully shut down the service and there are no active transactions to the service

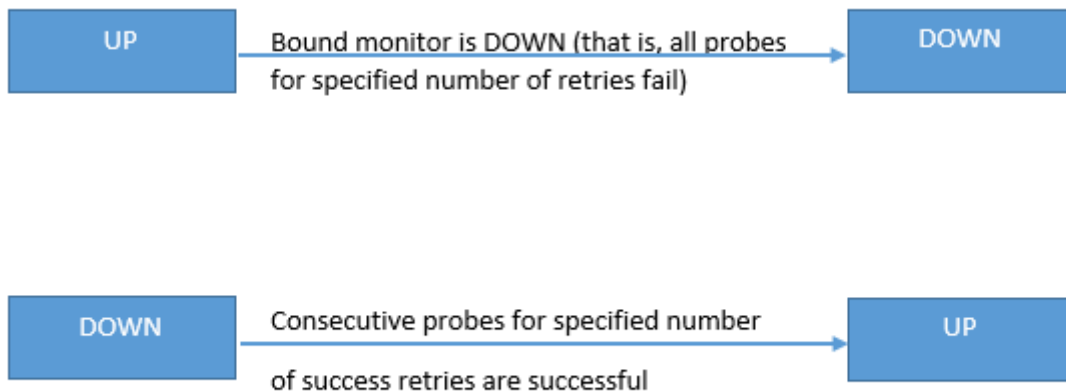

- **GOING OUT OF SERVICE (TROFS):** If you administratively disable the service with delay, or gracefully shut down the service and there are active transactions to the service. For more information, see [Graceful Shut down of Services](#).
- **DOWN WHEN GOING OUT OF SERVICE (TROFS\_DOWN)[ ]** A monitoring probe fails while the service is in the GOING OUT OF SERVICE state.

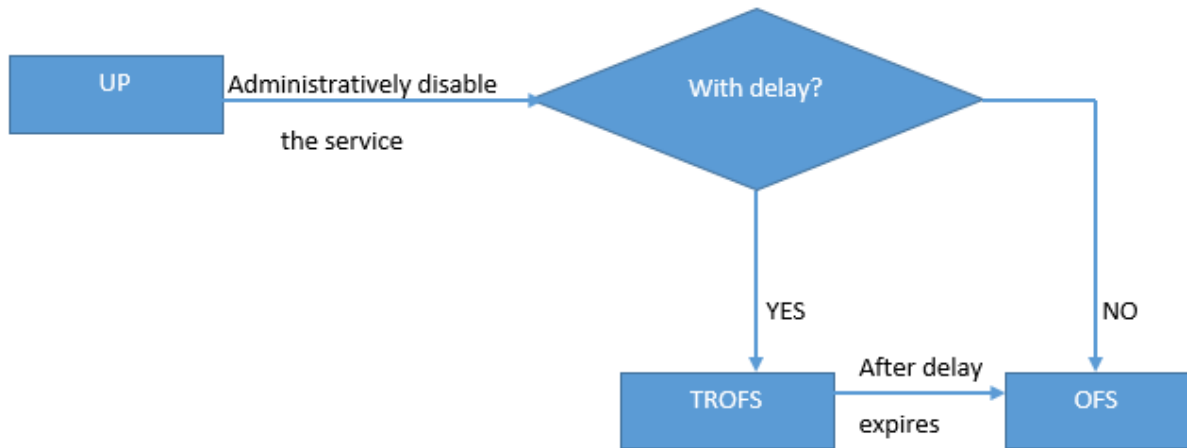

A service in the process of transitioning from UP to OFS is in the GOING OUT OF SERVICE state. A service transitioning from DOWN to OFS is in the DOWN WHEN GOING OUT OF SERVICE state. For example, if a service is DOWN and you disable it with delay, the service transitions to DOWN WHEN GOING OUT OF SERVICE and then to the OUT OF SERVICE state. If a service is UP and you disable it with delay, the service transitions to GOING OUT OF SERVICE. During this time, if a monitoring probe to the server fails, the service transitions to DOWN WHEN GOING OUT OF SERVICE and, after the delay time expires, enters the OFS state.

**Note**

You can configure spillover to a backup virtual server by setting the “healthThreshold” parameter to a non-zero positive value. Then, if a single service bound to the primary virtual server transitions to the DOWN WHEN GOING OUT OF SERVICE state and the health threshold is not reached, the primary virtual server is marked DOWN and new connections are directed to the backup virtual server.

The following diagrams show the conditions under which a service transitions from one state to another.

## Support for load balancing profile

September 21, 2020

A load balancing configuration has a large number of parameters, so setting the same parameters on a number of virtual servers can become tedious. From release 11.1, a load balancing (LB) profile makes

this task easier. You can now set load balancing parameters in a profile and associate this profile with virtual servers, instead of setting these parameters on each virtual server.

The following parameters are presently supported in an LB profile:

- HTTPOnlyflag—Include the HttpOnly attribute in persistence cookies. The HttpOnly attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.
- UseSecuredPersistenceCookie—Encrypt the persistence cookie values by using a SHA2 hash algorithm.
- Cookiepassphrase—Specify the passphrase used to generate a secured persistence cookie value.
- DBS\_LB—Enable database specific load balancing for MySQL and MSSQL service types.
- Cl\_process\_local—Packets destined to a virtual server in a cluster are not steered. Enable option for single packet request response mode or when the upstream device is performing a proper RSS for connection based distribution.

#### Note

You can set DBS\_LB and Cl\_process\_local parameters on a virtual server and in the profile. If you enable these parameters on a virtual server and then set a profile to this virtual server, the parameters appear as disabled in the output of the “show lb vserver” command for that virtual server. Check the profile to see the actual status of these parameters. In addition, if you set and then unset a profile to a virtual server, the parameters will be set with default values for that virtual server.

### To create an LB profile by using the CLI

At the command prompt, type:

```
1 add lb profile <lbprofilename> -dbsLb ( ENABLED | DISABLED ) -
   processLocal ( ENABLED | DISABLED ) -httpOnlyCookieFlag ( ENABLED |
   DISABLED ) -cookiePassphrase -useSecuredPersistenceCookie ( ENABLED
   | DISABLED )
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb profile p1
2
3 Done
4
5 show lb profile p1
6
7 LB Profile name:          p1
```

```
8
9 DBS LB : DISABLED          Process Local: DISABLED
10
11 Persistence Cookie HttpOnly Flag: ENABLED
12
13 Use Secured Persistence Cookie Flag: DISABLED
14
15 No of vservers bound: 0
16
17 Done
18 <!--NeedCopy-->
```

### To create an LB profile by using the GUI

Navigate to **System > Profiles > LB Profile**, and add a profile.

### To associate an LB profile with an LB virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -lbprofilename <string>
2 <!--NeedCopy-->
```

### Example

```
1 set lbvserver lbvip1 -lbprofile p1
2
3 Done
4
5 sh lb vserver lbvip1
6
7 lbvip1 (203.0.113.1:80) - HTTP          Type: ADDRESS
8 State: UP
9 Last state change was at Wed May 25 12:36:20 2016
10 Time since last state change: 0 days, 00:01:26.140
11 Effective State: UP ARP:DISABLED
12 Client Idle Timeout: 180 sec
13 Down state flush: ENABLED
14 Disable Primary Vserver On Down : DISABLED
15 Appflow logging: ENABLED
16 Port Rewrite : DISABLED
17 No. of Bound Services : 2 (Total)      2 (Active)
18 Configured Method: LEASTCONNECTION    BackupMethod: ROUNDROBIN
19 Mode: IP
```

```
20 Persistence: NONE
21 Vserver IP and Port insertion: OFF
22 Push: DISABLED Push VServer:
23 Push Multi Clients: NO
24 Push Label Rule: none
25 L2Conn: OFF
26 Skip Persistency: None
27 Listen Policy: NONE
28 IcmpResponse: PASSIVE
29 RHlstate: PASSIVE
30 New Service Startup Request Rate: 0 PER_SECOND, Increment Interval: 0
31 Mac mode Retain Vlan: DISABLED
32 DBS_LB: DISABLED
33 Process Local: DISABLED
34 Traffic Domain: 0
35 LB Profile: p1
36 Done
37 <!--NeedCopy-->
```

### To associate an LB profile with an LB virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server, and click **Edit**.
3. In **Advanced Settings**, click **Profiles**.
4. In the **LB Profile** list, select the profile to associate with this virtual server.

## Load balancing algorithms

September 21, 2020

The load balancing algorithm defines the criteria that the Citrix ADC appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the Citrix ADC appliance supports, with a brief description of how each operates.

| Name              | Server selection based on                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| LEASTCONNECTION   | Which service currently has the fewest client connections. This is the default load balancing algorithm.                                |
| ROUNDROBIN        | Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list. |
| LEASTRESPONSETIME | Which load balanced server currently has the quickest response time.                                                                    |
| URLHASH           | A hash of the destination URL.                                                                                                          |
| DOMAINHASH        | A hash of the destination domain.                                                                                                       |
| DESTINATIONIPHASH | A hash of the destination IP address.                                                                                                   |
| SOURCEIPHASH      | A hash of the source IP address.                                                                                                        |
| SRCIPDESTIPHASH   | A hash of the source and destination IP addresses.                                                                                      |
| CALLIDHASH        | A hash of the call ID in the SIP header.                                                                                                |
| SRCIPSRCPORHASH   | A hash of the client's IP address and port.                                                                                             |
| LEASTBANDWIDTH    | Which service currently has the fewest bandwidth constraints.                                                                           |
| LEASTPACKETS      | Which service currently is receiving the fewest packets.                                                                                |
| CUSTOMLOAD        | Data from a load monitor.                                                                                                               |
| TOKEN             | The configured token.                                                                                                                   |
| LRTM              | Fewest active connections and the lowest average response time.                                                                         |

Depending on the protocol of the service that it is load balancing, the Citrix ADC appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

| Granularity      | Types of Load Balanced Service              | Specifies                                                                                                                                                                                                                                                                                                              |
|------------------|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Request -based   | HTTP or HTTPS                               | A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.                                                                                                                                         |
| Connection-based | TCP and TCP-based protocols other than HTTP | A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.                                                                                                                                                                                        |
| Time-based       | UDP and other IP protocols                  | A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period of time. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client. |

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin*, helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the appliance switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, the appliance uses the round robin method for the specified number of requests before switching to the specified load balancing method.

method.

- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the Citrix ADC appliance.

### To set the startup round-robin factor by using the CLI

At the command prompt, type:

```
set lb parameter -startupRRFactor
```

Example

```
set lb parameter -startupRRFactor 25000
```

### To set the startup round-robin factor by using the GUI

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters, and set the Startup RR Factor.

## Least connection method

September 21, 2020

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL\_TCP services, the Citrix ADC appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.
- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.

- The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server’s connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the Citrix ADC appliance creates a session between the source IP address and port and the destination IP address and port.

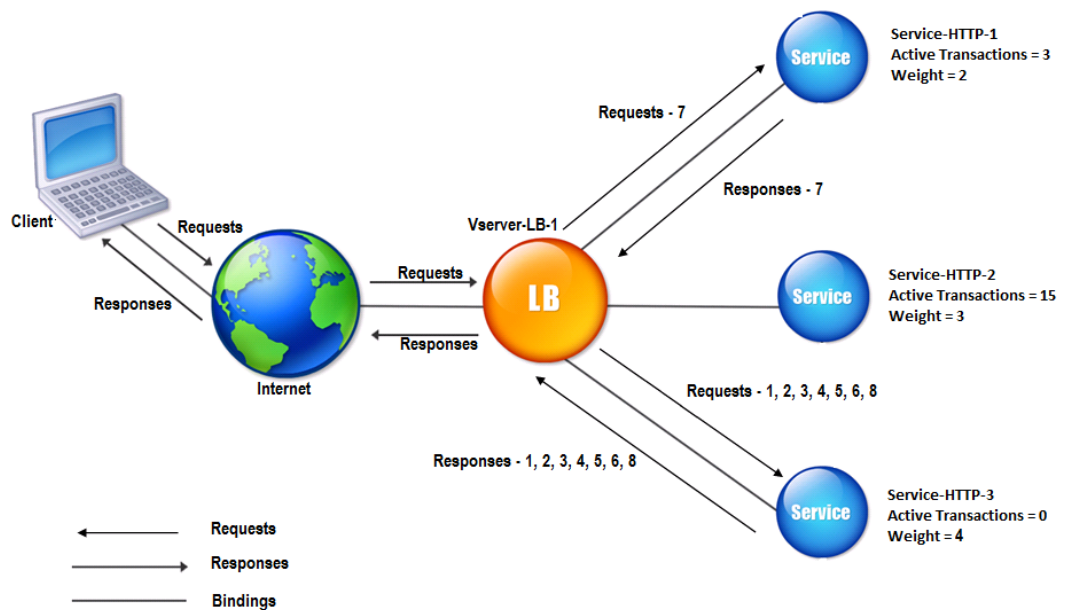

For Real-Time Streaming Protocol (RTSP) connections, the Citrix ADC appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the Citrix ADC appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method

In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.  
Note: The service with no active transaction is selected first.
- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
- Service-HTTP-1 receives the fourth request Because Service-HTTP-1 and Service-HTTP-3 have same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. At that time, the Citrix ADC appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

Note: If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing setup described above.

| Incoming Connection | Service Selected        | Current Number of Active Connections | Remarks                                                                       |
|---------------------|-------------------------|--------------------------------------|-------------------------------------------------------------------------------|
| Request-1           | Service-HTTP-3; (N = 0) | 1                                    | Service-HTTP-3 has the fewest active connections.                             |
| Request-2           | Service-HTTP-3; (N = 1) | 2                                    | Service-HTTP-3 has the fewest active connections.                             |
| Request-3           | Service-HTTP-3; (N = 2) | 3                                    | -                                                                             |
| Request-4           | Service-HTTP-1; (N = 3) | 4                                    | Service-HTTP-1 and Service-HTTP-3 have the same number of active connections. |

| Incoming Connection | Service Selected        | Current Number of Active Connections | Remarks                                                                       |
|---------------------|-------------------------|--------------------------------------|-------------------------------------------------------------------------------|
| Request-5           | Service-HTTP-3; (N = 3) | 4                                    | Service-HTTP-1 and Service-HTTP-3 have the same number of active connections. |
| Request-6           | Service-HTTP-1;(N = 4)  | 5                                    | -                                                                             |
| Request-7           | Service-HTTP-3; (N = 4) | 5                                    | -                                                                             |
| Request-8           | Service-HTTP-1; (N = 5) | 6                                    | -                                                                             |

Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.

The Citrix ADC appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

$$Nw = (\text{Number of active transactions}) * (10000 / \text{weight})$$

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.  
Note: If services are not handling any active transactions, the Citrix ADC appliance uses the round robin method regardless of the weights assigned to each of the services.
- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has lowest Nw value.
- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described above.

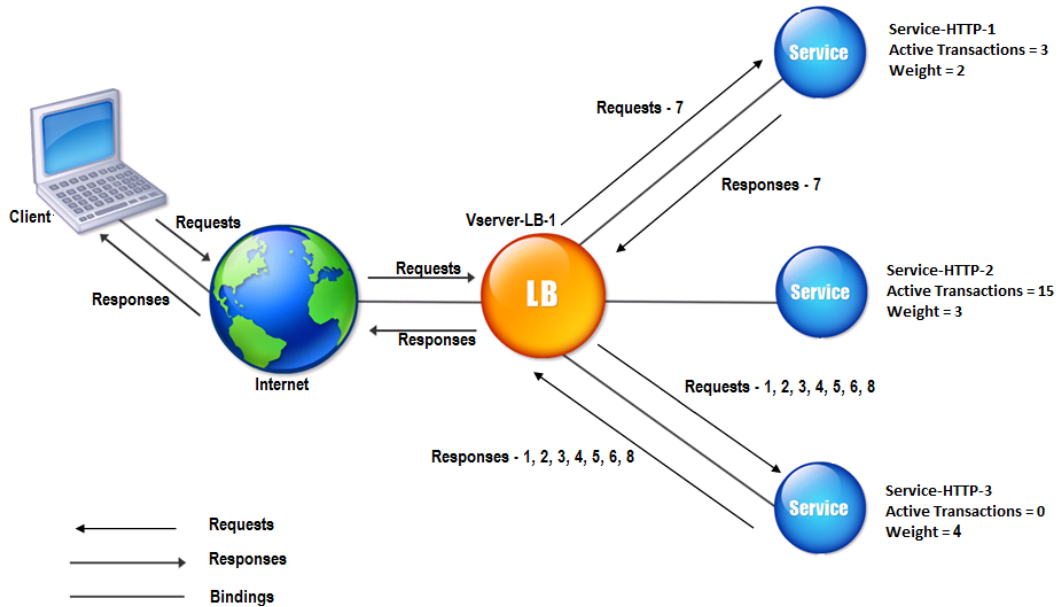

| Request Received | Service Selected             | Current Nw (Number of active transactions) * (10000 / weight) value | Remarks                                                   |
|------------------|------------------------------|---------------------------------------------------------------------|-----------------------------------------------------------|
| Request-1        | Service-HTTP-3; (Nw = 0)     | Nw = 2500                                                           | Service-HTTP-3 has the lowest Nw value.                   |
| Request-2        | Service-HTTP-3; (Nw = 2500)  | Nw = 5000                                                           |                                                           |
| Request-3        | Service-HTTP-3; (Nw = 5000)  | Nw = 7500                                                           |                                                           |
| Request-4        | Service-HTTP-3; (Nw = 7500)  | Nw = 10000                                                          |                                                           |
| Request-5        | Service-HTTP-3; (Nw = 10000) | Nw = 12500                                                          |                                                           |
| Request-6        | Service-HTTP-3; (Nw = 12500) | Nw = 15000                                                          |                                                           |
| Request-7        | Service-HTTP-1; (Nw = 15000) | Nw = 20000                                                          | Service-HTTP-1 and Service-HTTP-3 have the same Nw values |
| Request-8        | Service-HTTP-3; (Nw = 15000) | Nw = 17500                                                          |                                                           |

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the Citrix ADC appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned

To configure the least connection method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Round robin method

September 21, 2020

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the Citrix ADC appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works

If you assign a different weight to each service, the Citrix ADC appliance performs weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

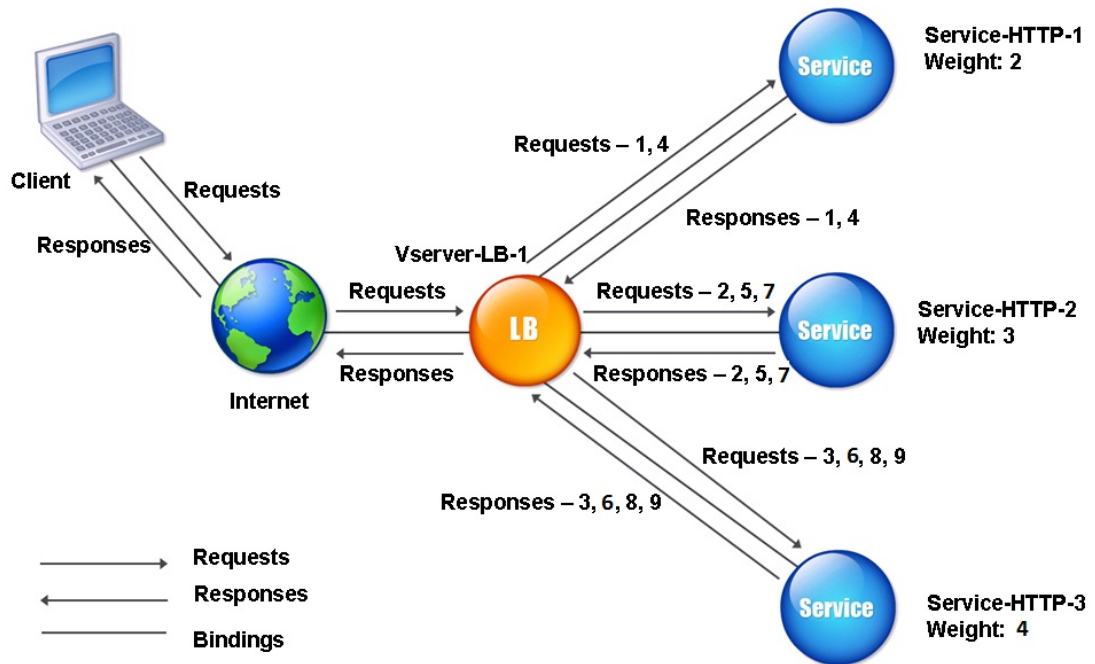

- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

**Note:** You can also configure weights on services to prevent multiple services from using the same server and overloading the server.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

Figure 2. How the Round Robin Load Balancing Method Works with Weighted Services

To configure the round robin method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Least response time method

September 21, 2020

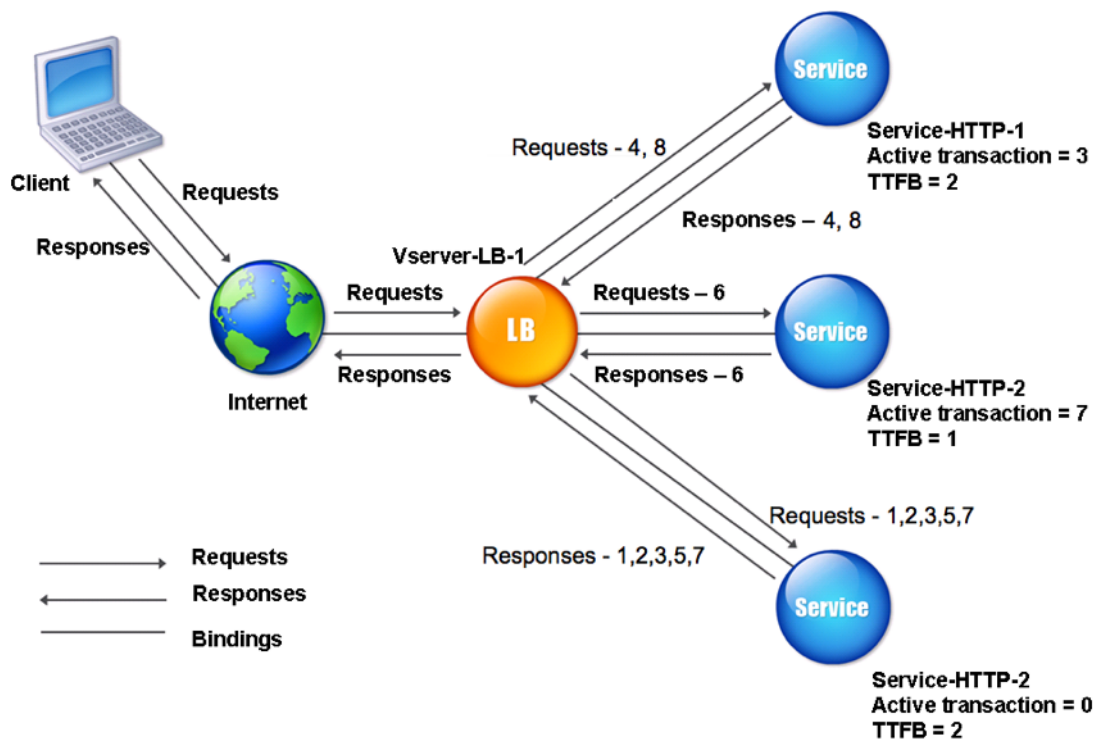

When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) load balancing virtual servers only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The Citrix ADC appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works

The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the Citrix ADC appliance chooses between them by applying the Round Robin

method.

- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the appliance switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described above.

| Request Received | Service Selected        | Current N Value<br>(Number of Active<br>Transactions * TTFB) | Remarks                                                                                                                         |
|------------------|-------------------------|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Request-1        | Service-HTTP-3;(N = 0)  | N = 2                                                        | Service-HTTP-3 has the lowest N value.                                                                                          |
| Request-2        | Service-HTTP-3; (N = 2) | N = 4                                                        | Service-HTTP-3 has the lowest N value.                                                                                          |
| Request-3        | Service-HTTP-3; (N = 4) | N = 6                                                        | Service-HTTP-3 has the lowest N value.                                                                                          |
| Request-4        | Service-HTTP-1; (N = 6) | N = 8                                                        | Service-HTTP-1 and Service-HTTP-3 have the same N values. The appliance uses the round robin method to distribute the requests. |
| Request-5        | Service-HTTP-3; (N = 6) | N = 8                                                        | Service-HTTP-1 and Service-HTTP-3 have the same N values.                                                                       |
| Request-6        | Service-HTTP-2; (N = 7) | N = 8                                                        | Service-HTTP-2 has the lowest N value.                                                                                          |

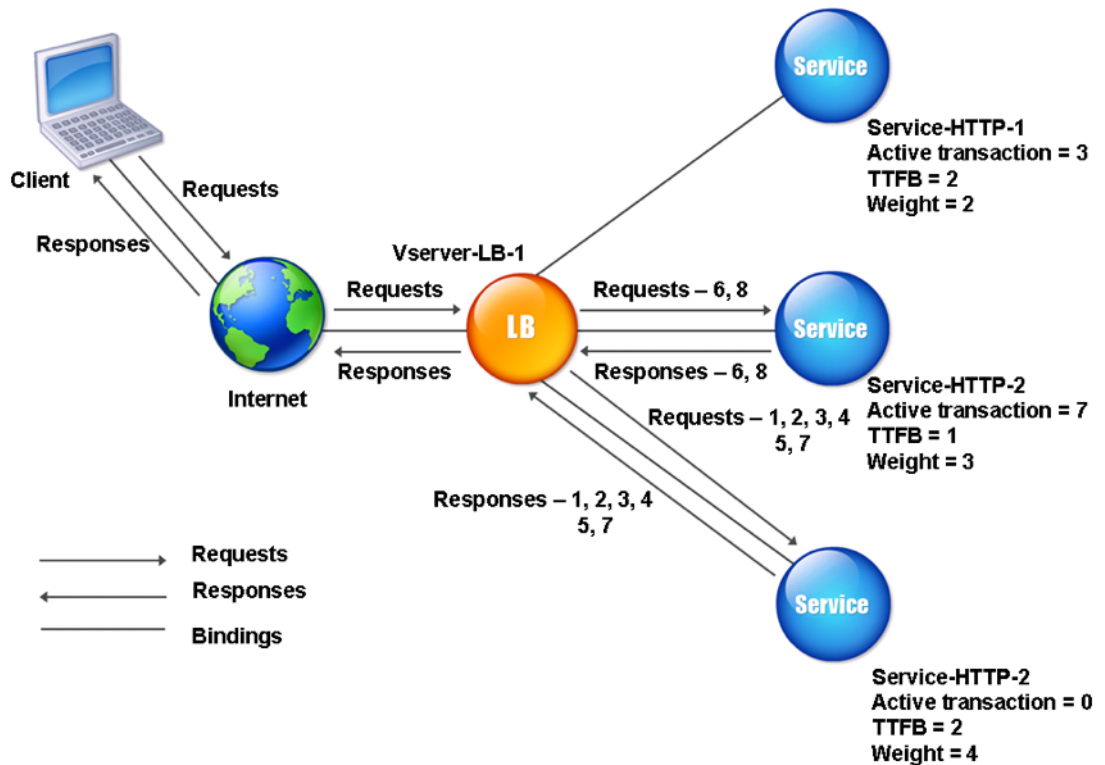

| Request Received | Service Selected        | Current N Value<br>(Number of Active<br>Transactions * TTFB) | Remarks                                                                                                                                                    |
|------------------|-------------------------|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Request-7        | Service-HTTP-3; (N = 8) | N = 10                                                       | Service-HTTP-1, Service-HTTP-2 and Service-HTTP-3 have the same N values. The Citrix ADC appliance uses the round robin method to distribute the requests. |
| Request-8        | Service-HTTP-1; (N = 8) | N = 10                                                       | Service-HTTP-1 and Service-HTTP-2 have the same N values, the appliance uses the round robin method to distribute the requests.                            |

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

### Selection of services when weights are assigned

The following diagram illustrates how the Citrix ADC appliance uses the least response time method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

The virtual server selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

Where N = (number of active transactions \* TTFB)

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The Citrix ADC appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions. If services are not handling any active transactions, the appliance selects them regardless of the weights assigned to them.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

The following table explains how connections are distributed in the three-service load balancing setup described above.

| Request Received | Service Selected                | Current Nw Value =<br>(N) * (10000 / Weight) | Remarks                                 |
|------------------|---------------------------------|----------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3; (Nw = 0)        | Nw = 5000                                    | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3; (Nw = 5000)     | Nw = 10000                                   | Service-HTTP-3 has the lowest Nw value. |
| Request-3        | Service-HTTP-3; (Nw = 10000)    | Nw = 15000                                   | Service-HTTP-3 has the lowest Nw value. |
| Request-4        | Service-HTTP-3; (Nw = 15000)    | Nw = 20000                                   | Service-HTTP-3 has the lowest Nw value. |
| Request-5        | Service-HTTP-3; (Nw = 20000)    | Nw = 25000                                   | Service-HTTP-3 has the lowest Nw value. |
| Request-6        | Service-HTTP-2; (Nw = 23333.34) | Nw = 26666.67                                | Service-HTTP-2 has the lowest Nw value. |
| Request-7        | Service-HTTP-3; (Nw = 25000)    | Nw = 30000                                   | Service-HTTP-3 has the lowest Nw value. |
| Request-8        | Service-HTTP-2; (Nw = 26666.67) | Nw = 30000                                   | Service-HTTP-2 has the lowest Nw value. |

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

### To configure the least response time load balancing method by using the CLI

At the command prompt type;

```
1 set lb vserver <name> -lbMethod LEASTRESPONSETIME
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -lbMethod LEASTRESPONSETIME
2 <!--NeedCopy-->
```

## To configure the least response time load balancing method by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LEASTRESPONSETIME**.

For more information about configuring monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## LRTM method

September 21, 2020

**Note:** LRTM stands for Least response time method using monitors (LRTM).

When a load balancing virtual server is configured to use the LRTM method, it uses the existing monitoring infrastructure to get the fastest response time. The load balancing virtual server then selects the service with the smallest number of active transactions and lowest response time. Before you use the LRTM method, you must bind application-specific monitors to each service and enable LRTM mode on these monitors. The Citrix ADC appliance then makes load balancing decisions based on the response times it calculates from monitoring probes.

You can use the LRTM method to load balance non-HTTP and non-HTTPS services also. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for various monitors.

| Monitor | Response time calculation                                                                                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PING    | Time difference between the ICMP ECHO request and the ICMP ECHO response.                                                                                                                                       |
| TCP     | Time difference between the SYN request and the SYN+ACK response.                                                                                                                                               |
| HTTP    | Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.                                                                                                       |
| TCP-ECV | Time difference between the time the data send string is sent and the data receive string is returned. A tcp-ecv monitor without the send and receive strings is considered to have an incorrect configuration. |

| Monitor                             | Response time calculation                                                                                                                                              |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTP-ECV                            | Time difference between the HTTP request and the HTTP response.                                                                                                        |
| UDP-ECV                             | Time difference between the UDP send string and the UDP receive string. A UDP-ECV monitor without the receive string is considered to have an incorrect configuration. |
| DNS                                 | Time difference between a DNS query and the DNS response.                                                                                                              |
| TCPS                                | Time difference between a SYN request and the SSL handshake completion.                                                                                                |
| FTP                                 | Time difference between the sending of the user name and the completion of user authentication.                                                                        |
| HTTPS (monitors HTTPS requests)     | Time difference is same as for the HTTP monitor.                                                                                                                       |
| HTTPS-ECV (monitors HTTPS requests) | Time difference is same as for the HTTP-ECV monitor                                                                                                                    |
| USER                                | Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.                                       |

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the LRTM method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the Citrix ADC appliance follows when it forwards requests.

Figure 1. How the LRTM Method Works

The virtual server selects a service by using the value (N) in the following expression:

$$N = (\text{Number of active transactions} * \text{Response time that is determined by the monitor})$$

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
- Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the Citrix ADC appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the Citrix ADC appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

| Request Received | Service Selected        | Current N Value<br>(Number of Active<br>Transactions * TTFB) | Remarks                                                                                                                                      |
|------------------|-------------------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Request-1        | Service-HTTP-3;(N = 0)  | N = 2                                                        | Service-HTTP-3 has the lowest N value.                                                                                                       |
| Request-2        | Service-HTTP-3; (N = 2) | N = 4                                                        | Service-HTTP-3 has the lowest N value.                                                                                                       |
| Request-3        | Service-HTTP-3; (N = 4) | N = 6                                                        | Service-HTTP-3 has the lowest N value.                                                                                                       |
| Request-4        | Service-HTTP-3; (N = 6) | N = 8                                                        | Service-HTTP-3 has the lowest N value.                                                                                                       |
| Request-5        | Service-HTTP-2; (N = 7) | N = 8                                                        | Service-HTTP-2 has the lowest N value..                                                                                                      |
| Request-6        | Service-HTTP-3; (N = 8) | N = 10                                                       | Service-HTTP-2 and Service-HTTP-3 have the same N values. Citrix ADC appliance switches to the round robin method and selects Service-HTTP-3 |
| Request-7        | Service-HTTP-2; (N = 8) | N = 9                                                        | Service-HTTP-2 has the lowest N value.                                                                                                       |
| Request-8        | Service-HTTP-2; (N = 9) | N = 10                                                       | Service-HTTP-2 has the lowest N value.                                                                                                       |

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

### Selection of services when weights are assigned

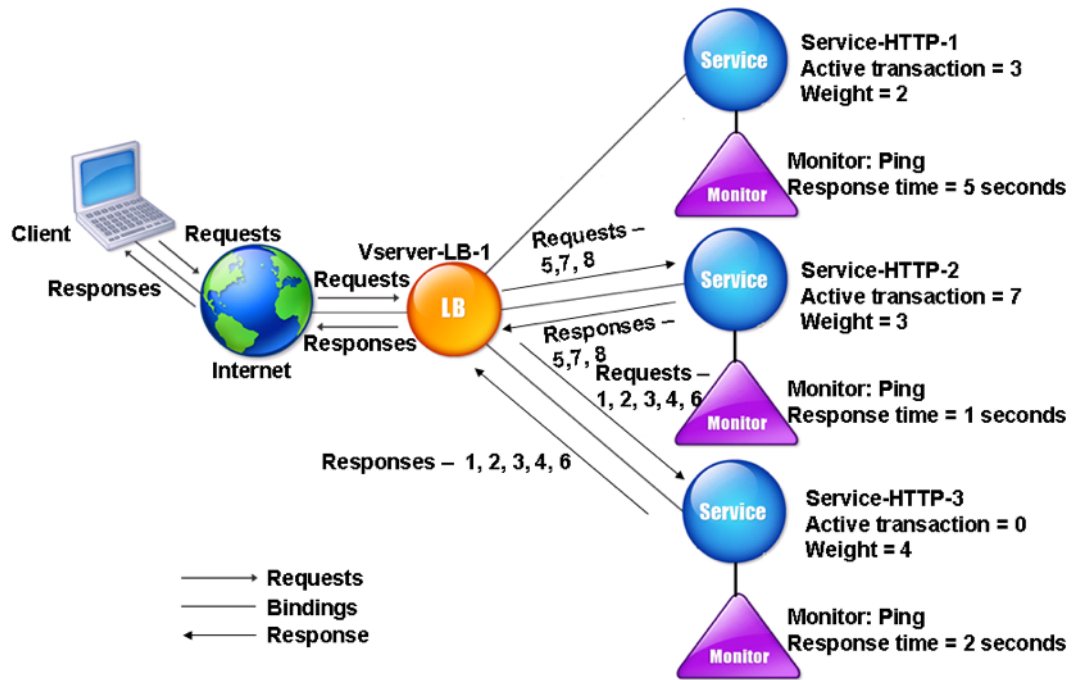

The Citrix ADC appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The Citrix ADC appliance selects the service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

Where N = (Number of active transactions \* Response time that is determined by the monitor)

The following diagram illustrates how the virtual server uses the LRTM method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

In this example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, fourth and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the Citrix ADC appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

| Request Received | Service Selected                | Current Nw Value (N)<br>* (10000 / Weight) | Remarks                                 |
|------------------|---------------------------------|--------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-3; (Nw = 0)        | Nw = 5000                                  | Service-HTTP-3 has the lowest Nw value. |
| Request-2        | Service-HTTP-3; (Nw = 5000)     | Nw = 10000                                 | Service-HTTP-3 has the lowest Nw value. |
| Request-3        | Service-HTTP-3; (Nw = 10000)    | Nw = 15000                                 | Service-HTTP-3 has the lowest Nw value. |
| Request-4        | Service-HTTP-3; (Nw = 15000)    | Nw = 20000                                 | Service-HTTP-3 has the lowest Nw value. |
| Request-5        | Service-HTTP-3; (Nw = 20000)    | Nw = 25000                                 | Service-HTTP-3 has the lowest Nw value. |
| Request-6        | Service-HTTP-2; (Nw = 23333.34) | Nw = 26666.67                              | Service-HTTP-2 has the lowest Nw value. |
| Request-7        | Service-HTTP-3; (Nw = 25000)    | Nw = 30000                                 | Service-HTTP-3 has the lowest Nw value. |
| Request-8        | Service-HTTP-2; (Nw = 26666.67) | Nw = 30000                                 | Service-HTTP-2 has the lowest Nw value. |

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

### To configure the LRTM load balancing method by using the CLI

At the command prompt type;

```
1 set lb vservers <name> [-lbMethod <lbMethod>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vservers Vserver-LB-1 -lbMethod LRTM
2 <!--NeedCopy-->
```

### To configure the LRTM load balancing method by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LRTM**.

### To enable the LRTM option in monitors by using the CLI

At the command prompt type;

```
1 set lb monitor <monitorName> <type> [-LRTM ( ENABLED | DISABLED )]  
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb monitor monitor-HTTP-1 HTTP -LRTM ENABLED  
2 <!--NeedCopy-->
```

### To enable the LRTM option in monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**, and open a monitor.
2. In Advanced Parameters, select **LRTM (Least Response Time using Monitoring)**.

For more information about configuring monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## Hashing methods

September 21, 2020

Load balancing methods based on hashes of certain connection information or header information constitute the majority of the Citrix ADC appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used Web sites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The Citrix ADC appliance provides the following hashing methods:

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method

- Source IP Source Port hash method
- Call ID hash method
- Token method

These hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup. Most of them calculate two hash values:

- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The Citrix ADC appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with highest hash value. As the appliance computes a hash value for each request and selects the service that will process the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

Figure 1. How the Hashing Methods Distribute Requests

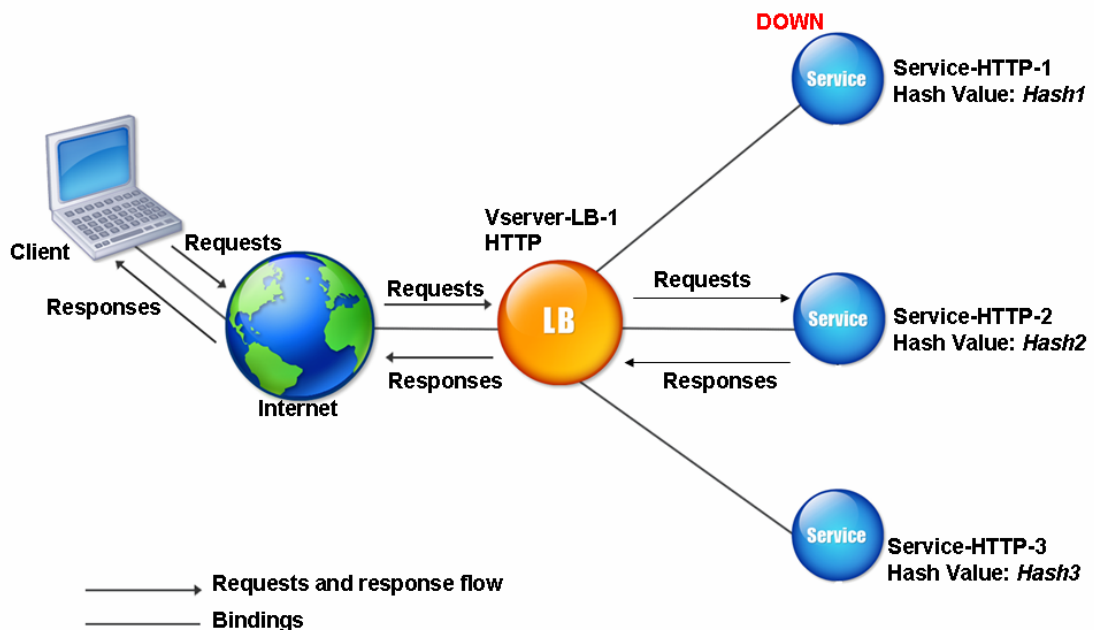

Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the Citrix ADC appliance calculates the hash value for the last log of the number of services. The appliance then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods

Note: If the Citrix ADC appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. You should adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

### The URL Hash Method

When you configure the Citrix ADC appliance to use the URL hash method for load balancing the services, for selecting a service, the appliance generates a hash value of the HTTP URL present in the incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The appliance caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the appliance cannot parse an incoming request, it uses the round robin method for load

balancing instead of the URL hash method.

For generating the hash value, the appliance uses a specific algorithm and considers a part of the URL. By default, the appliance considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 to 4096 bytes. Generally, if long URLs are used where only a small number of characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. appliance selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the appliance selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates

If both Service-HTTP-1 and Service-HTTP-2 are DOWN, appliance sends requests with hash value U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to Service-HTTP-3. If these services are UP, requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#). Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash value.

### **The Domain Hash Method**

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the appliance gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the Citrix ADC appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the Citrix ADC appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

### **The Destination IP Hash Method**

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the Destination IP Hash method.

To configure the destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## **The Source IP Hash Method**

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the `netMask` parameter. For IPv6 addresses, use the `v6NetMaskLength` parameter.

To configure the source IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## **The Source IP Destination IP Hash Method**

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric; the hash-value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the `netMask` parameter. For IPv6 addresses, use the `v6NetMaskLength` parameter.

To configure the source IP destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## **The Source IP Source Port Hash Method**

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see [Connection Failover](#).

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the `netMask` parameter. For IPv6 addresses, use the `v6NetMaskLength` parameter.

To configure the source IP source port hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

To configure the call ID hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Least bandwidth method

September 21, 2020

A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.

Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works

The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

| Request Received | Service Selected        | Current N Value | Remarks                                |
|------------------|-------------------------|-----------------|----------------------------------------|
| Request-1        | Service-HTTP-3; (N = 2) | N = 3           | Service-HTTP-3 has the lowest N value. |

| Request Received | Service Selected        | Current N Value | Remarks                                                                    |
|------------------|-------------------------|-----------------|----------------------------------------------------------------------------|
| Request-2        | Service-HTTP-1; (N = 3) | N = 4           | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-3        | Service-HTTP-3; (N = 3) | N = 4           | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-4        | Service-HTTP-1; (N = 4) | N = 5           | -                                                                          |
| Request-5        | Service-HTTP-3; (N = 4) | N = 5           | -                                                                          |
| Request-6        | Service-HTTP-1; (N = 5) | N = 6           | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-7        | Service-HTTP-2; (N = 5) | N = 6           | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-8        | Service-HTTP-3; (N = 5) | N = 6           | -                                                                          |

Note: If you enable the RTSP NAT option on the virtual server, the Citrix ADC appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about RTSP NAT option, see [Managing RTSP Connections](#).

The Citrix ADC appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.

- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

| Request Received | Service Selected                | Current Nw Value<br>(Number of Active<br>Transactions) *<br>(10000 / Weight) | Remarks                                                   |
|------------------|---------------------------------|------------------------------------------------------------------------------|-----------------------------------------------------------|
| Request-1        | Service-HTTP-3; (Nw = 5000)     | Nw = 5000                                                                    | Service-HTTP-3 has the lowest Nw value.                   |
| Request-2        | Service-HTTP-3; (Nw = 5000)     | Nw = 7500                                                                    | -                                                         |
| Request-3        | Service-HTTP-3; (Nw = 7500)     | Nw = 10000                                                                   | -                                                         |
| Request-4        | Service-HTTP-3; (Nw = 10000)    | Nw = 12500                                                                   | -                                                         |
| Request-5        | Service-HTTP-3; (Nw = 12500)    | Nw = 15000                                                                   | -                                                         |
| Request-6        | Service-HTTP-1; (Nw = 15000)    | Nw = 20000                                                                   | Service-HTTP-1 and Service-HTTP-3 have the same Nw value. |
| Request-7        | Service-HTTP-3; (Nw = 15000)    | Nw = 17500                                                                   | Service-HTTP-1 and Service-HTTP-3 have the same Nw value. |
| Request-8        | Service-HTTP-2; (Nw = 16666.67) | Nw = 20000                                                                   | Service-HTTP-2 has the lowest Nw value.                   |

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned

To configure the least bandwidth method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Least packets method

September 21, 2020

A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in last 14 seconds.
- Service-HTTP-2 has handled five packets in last 14 seconds.
- Service-HTTP-3 has handled two packets in last 14 seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works

The Citrix ADC appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

| Request Received | Service Selected        | Current N Value | Remarks                                |
|------------------|-------------------------|-----------------|----------------------------------------|
| Request-1        | Service-HTTP-3; (N = 2) | N = 3           | Service-HTTP-3 has the lowest N value. |

| Request Received | Service Selected        | Current N Value | Remarks                                                                    |
|------------------|-------------------------|-----------------|----------------------------------------------------------------------------|
| Request-2        | Service-HTTP-1; (N = 3) | N = 4           | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-3        | Service-HTTP-3; (N = 3) | N = 4           | Service-HTTP-1 and Service-HTTP-3 have the same N values.                  |
| Request-4        | Service-HTTP-1; (N = 4) | N = 5           | -                                                                          |
| Request-5        | Service-HTTP-3; (N = 4) | N = 5           | -                                                                          |
| Request-6        | Service-HTTP-1; (N = 5) | N = 6           | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-7        | Service-HTTP-2; (N = 5) | N = 6           | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |
| Request-8        | Service-HTTP-3; (N = 5) | N = 6           | -                                                                          |

Note: If you enable the RTSP NAT option on the virtual server, the appliance uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about RTSP NAT option, see [Managing RTSP Connections](#).

The Citrix ADC appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.

- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

| Request Received | Service Selected                | Current Nw Value<br>(Number of Active<br>Transactions) *<br>(10000 / weight) | Remarks                                                   |
|------------------|---------------------------------|------------------------------------------------------------------------------|-----------------------------------------------------------|
| Request-1        | Service-HTTP-3; (Nw = 5000)     | Nw = 5000                                                                    | Service-HTTP-3 has the lowest Nw value.                   |
| Request-2        | Service-HTTP-3; (Nw = 5000)     | Nw = 7500                                                                    | -                                                         |
| Request-3        | Service-HTTP-3; (Nw = 7500)     | Nw = 10000                                                                   | -                                                         |
| Request-4        | Service-HTTP-3; (Nw = 10000)    | Nw = 12500                                                                   | -                                                         |
| Request-5        | Service-HTTP-3; (Nw = 12500)    | Nw = 15000                                                                   | -                                                         |
| Request-6        | Service-HTTP-1; (Nw = 15000)    | Nw = 20000                                                                   | Service-HTTP-1 and Service-HTTP-3 have the same Nw value. |
| Request-7        | Service-HTTP-3; (Nw = 15000)    | Nw = 17500                                                                   | Service-HTTP-1 and Service-HTTP-3 have the same Nw value. |
| Request-8        | Service-HTTP-2; (Nw = 16666.67) | Nw = 20000                                                                   | Service-HTTP-2 has the lowest Nw value.                   |

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.

Figure 2. How the Least Packets Method Works When Weights Are Assigned

To configure the least packets method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Custom load method

September 21, 2020

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all of the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see [Understanding Load Monitors](#). The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate

The load monitor uses Simple Network Management Protocol (SNMP) probes to calculate load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics, described below, to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

- Metrics values retrieved through SNMP probes that exist as tables in the Citrix ADC appliance.
- Threshold value set for each metric.
- Weight assigned to each metric.

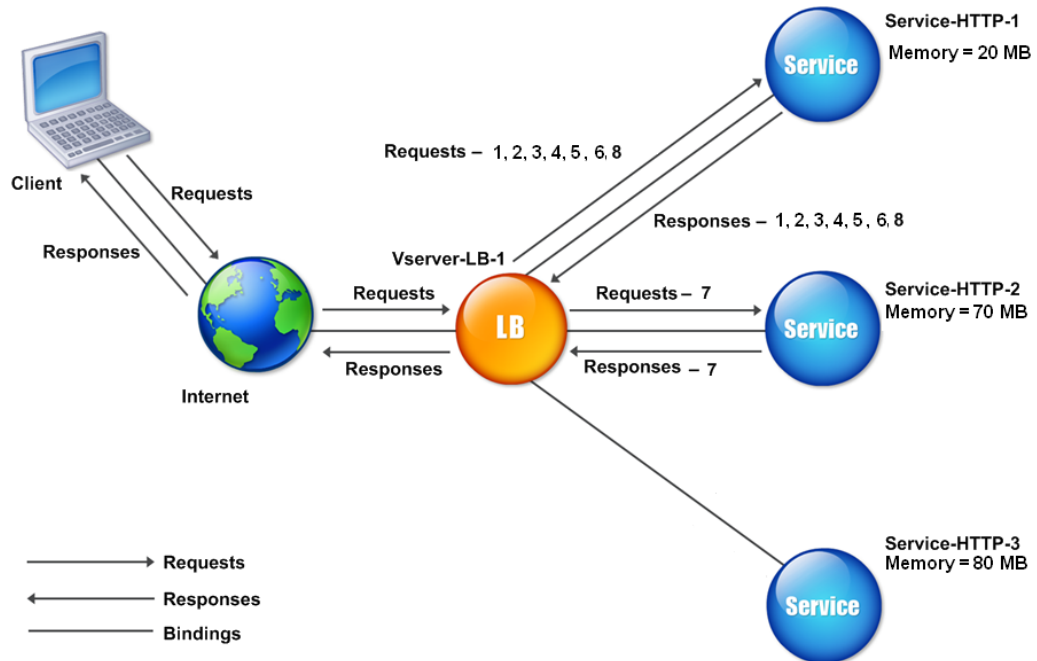

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 megabytes (MB) of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by

using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The three services respond to the request. The Citrix ADC appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works

If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

| Request received | Service selected         | Current N Value<br>(Number of Active<br>Transactions) | Remarks                                                                    |
|------------------|--------------------------|-------------------------------------------------------|----------------------------------------------------------------------------|
| Request-1        | Service-HTTP-1; (N = 20) | N = 30                                                | Service-HTTP-3 has the lowest N value.                                     |
| Request-2        | Service-HTTP-1; (N = 30) | N = 40                                                | -                                                                          |
| Request-3        | Service-HTTP-1; (N = 40) | N = 50                                                | -                                                                          |
| Request-4        | Service-HTTP-1; (N = 50) | N = 60                                                | -                                                                          |
| Request-5        | Service-HTTP-1; (N = 60) | N = 70                                                | -                                                                          |
| Request-6        | Service-HTTP-1; (N = 70) | N = 80                                                | Service-HTTP-2 and Service-HTTP-3 have the same N values.                  |
| Request-7        | Service-HTTP-2; (N = 70) | N = 80                                                | Service-HTTP-3 have the same N values.                                     |
| Request-8        | Service-HTTP-1; (N = 80) | N = 90                                                | Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values. |

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

The following table summarizes how Nw is calculated.

| Request received | Service selected                 | Current Nw Value (Number of Active Transactions) * (10000 / Weight) | Remarks                                 |
|------------------|----------------------------------|---------------------------------------------------------------------|-----------------------------------------|
| Request-1        | Service-HTTP-1; (Nw = 50000)     | Nw = 75000                                                          | Service-HTTP-1 has the lowest Nw value. |
| Request-2        | Service-HTTP-1; (Nw = 5000)      | Nw = 100000                                                         | -                                       |
| Request-3        | Service-HTTP-1; (Nw = 15000)     | Nw = 125000                                                         | -                                       |
| Request-4        | Service-HTTP-1; (Nw = 20000)     | Nw = 150000                                                         | -                                       |
| Request-5        | Service-HTTP-1; (Nw = 23333.34)  | Nw = 175000                                                         | -                                       |
| Request-6        | Service-HTTP-1; (Nw = 25000)     | Nw = 200000                                                         | -                                       |
| Request-7        | Service-HTTP-1; (Nw = 23333.34)  | Nw = 225000                                                         | -                                       |
| Request-8        | Service-HTTP-1; (Nw = 25000)     | Nw = 250000                                                         | -                                       |
| Request-9        | Service-HTTP-2; (Nw = 233333.34) | Nw = 266666.67                                                      | Service-HTTP-2 has the lowest Nw value. |

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the Citrix ADC appliance uses the custom load method when weights are assigned.

Figure 3. How the Custom Load Method Works When Weights Are Assigned

To configure the custom load method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Static proximity method

September 21, 2020

When a virtual server is configured to use the static proximity method, it selects the service that best matches the proximity criteria.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the load balancing method.

For more details, see the following topics.

- [Adding a Location File to Create a Static Proximity Database](#)
- [Adding Custom Entries to a Static Proximity Database](#)
- [Setting the Location Qualifiers](#)

- Specifying the Static Proximity method

## Specifying the Proximity Method

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

### To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
1 set lb vserver <name> -lbMethod STATICPROXIMITY
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -lbMethod STATICPROXIMITY
2
3 show lb vserver
4 <!--NeedCopy-->
```

### To specify static proximity by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server.
2. Click **Edit** and expand the **Method** section.
3. In the **Load Balancing Method** list, select **STATICPROXIMITY**.

## Token method

September 21, 2020

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

This method is content aware; it operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see [Policy Configuration and Reference](#).

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL\_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the appliance searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the Citrix ADC appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works

### To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

```

1 set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length>
   -dataoffset <offset>
2
3 show lb vserver <name>
4 <!--NeedCopy-->

```

#### Example:

```

1 set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -
   dataoffset 25
2
3 show lb vserver LB-VServer-1
4 <!--NeedCopy-->

```

## To configure the token load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Method
3. In the Load Balancing Method list, select Token, and specify an expression.

## Configure a load balancing method that does not include a policy

September 21, 2020

After you select a load balancing algorithm for your load balancing setup, you must configure the Citrix ADC appliance to use that algorithm. You can configure it by using the CLI or by using the configuration utility.

Note:

The token method is policy based and requires more configuration than is described here. To configure the token method, see [Token method](#).

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see [Hashing methods](#).

## To set the load balancing method by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name> -lbMethod <method>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -lbMethod LeastConnection
2 <!--NeedCopy-->
```

## To set the load balancing method by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, click **Method**, and in the Load Balancing Method list, select a method.

## Persistence and persistent connections

September 21, 2020

Unless you configure persistence, a load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections. Different transmissions from the same client might be directed to different servers even though all of the transmissions are part of the same session. You must configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what the implications of each type is. You then need to configure the Citrix ADC appliance to provide persistent connections for those Web sites and Web applications that require them.

You can also configure backup persistence, which takes effect in the event that the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see [Configuring RADIUS Load Balancing with Persistence](#).

### About Persistence

September 21, 2020

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, Web-based email, or other network application. The persistence session remains in effect for a period of time, which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the Citrix ADC appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie

issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and be used as the basis for persistence.

The following table summarizes the persistence types available on the Citrix ADC appliance.

| Persistence Type           | Description                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Source IP                  | SOURCEIP. Connections from the same client IP address are parts of the same persistence session.                                                    |
| HTTP Cookie                | COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.                                          |
| SSL Session ID             | SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.                                                |
| URL Passive                | URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.                                                       |
| Custom Server ID           | CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.                                    |
| Destination IP             | DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.                                                |
| Source and Destination IPs | SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP are treated as parts of the same persistence session. |
| SIP Call ID                | CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session.                              |
| RTSP Session ID            | RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.                                       |

| Persistence Type  | Description                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------|
| User-Defined Rule | RULE. Connections that match a user-defined rule are treated as parts of the same persistence session. |

Table 1. Types of Persistence

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

| Persistence Type                                                                                        | Number of Simultaneous Persistent Connections Supported                                                     |
|---------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID | 250 K                                                                                                       |
| Cookie, URL Server ID, Custom Server ID                                                                 | Memory limit. In case of CookieInsert, if timeout is not 0, the number of connections is limited by memory. |

Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

| Persistence Type    | HTTP | HTTPS | TCP | UDP/IP | SSL_Bridge | SSL_TCP | RTSP | SIP_UDP |
|---------------------|------|-------|-----|--------|------------|---------|------|---------|
| <b>SOURCEIP</b>     | YES  | YES   | YES | YES    | YES        | YES     | NO   | NO      |
| <b>COOKIEINSERT</b> |      | YES   | NO  | NO     | NO         | NO      | NO   | NO      |
| <b>SSLSESS</b>      | NO   | YES   | NO  | NO     | YES        | YES     | NO   | NO      |
| <b>URLPASSIVE</b>   |      | YES   | NO  | NO     | NO         | NO      | NO   | NO      |
| <b>CUSTOMRULE</b>   | YES  | YES   | NO  | NO     | NO         | NO      | NO   | NO      |
| <b>RULE</b>         | YES  | YES   | YES | NO     | NO         |         | NO   | NO      |
| <b>SRCIPDE</b>      | YES  | YES   | YES | YES    | YES        | YES     | NO   | NO      |

| Persistence   |      |       |     |        |            |         |      |         |
|---------------|------|-------|-----|--------|------------|---------|------|---------|
| Type          | HTTP | HTTPS | TCP | UDP/IP | SSL_Bridge | SSL_TCP | RTSP | SIP_UDP |
| <b>DESTIP</b> | YES  | YES   | YES | YES    | YES        | YES     | NO   | NO      |
| <b>CALLID</b> | NO   | NO    | NO  | NO     | NO         | NO      | NO   | YES     |
| <b>RTSPID</b> | NO   | NO    | NO  | NO     | NO         | NO      | YES  | NO      |

Table 3. Relationship of Persistence Type to Virtual Server Type

## Source IP address persistence

September 21, 2020

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

**Caution:** In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single Web site or application are routed through the single gateway to the Citrix ADC appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session should be created. This issue is called the “Mega Proxy problem.” You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see [Configuring Persistence Types That Do Not Require a Rule](#).

**Note:** If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the Citrix ADC appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.

## HTTP cookie persistence

September 21, 2020

When HTTP cookie persistence is configured, the Citrix ADC appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the Citrix ADC appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any appliance resources and therefore can accommodate an unlimited number of persistent clients.

Note: If the client's Web browser is configured to refuse cookies, HTTP cookie-based persistence will not work. It might be advisable to configure a cookie check on the Web site, and warn clients that do not appear to be storing cookies properly that they will need to enable cookies for the Web site if they want to use it.

The format of the cookie that the Citrix ADC appliance inserts is:

```
NSC_XXXX=<ServiceIP ><ServicePort>
```

where:

- NSC\_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period of time, the Citrix ADC appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the Citrix ADC appliance does not specify an expiration time, but sets a session cookie that is not saved when the client's browser is shut down.

By default, the Citrix ADC appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the "Max-Age" attribute of the HTTP cookie. In this case, the client's browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see [Configuring Persistence Types That Do Not Require a Rule](#).

In the HTTP cookie, the appliance by default sets the `httponly` flag to indicate that the cookie is non-scriptable and should not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the `httponly` flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the `httponly` flag in the persistence cookie.

### To change the `httponly` flag setting by using the command line interface

At the command prompt, type:

```
set lb parameter -httpOnlyCookieFlag      DISABLED)
(ENABLED
```

#### Example:

```
1 > set lb parameter -httpOnlyCookieFlag disabled
2   Done
3 > show lb parameter
4   Global LB parameters:
5       Persistence Cookie HttpOnly Flag: DISABLED
6       Use port for hash LB: YES
7   Done
8 <!--NeedCopy-->
```

### To change the `httponly` flag setting by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters, and select or clear the Persistence Cookie HTTPOnly Flag.

### Encrypting the Cookie

From release 10.5 build 55.8, you can encrypt the cookie in addition to any SSL encryption.

### To encrypt the cookie by using the command line interface, at the command prompt, type

```
1 set lb parameter -UseEncryptedPersistenceCookie ENABLED -
   cookiePassphrase test
2 <!--NeedCopy-->
```

### To encrypt the cookie by using the configuration utility

1. Navigate to **Traffic Management > Change Load Balancing Parameters**, and select **Encode Persistence Cookie Values** and enter a passphrase in **Cookie Passphrase**.

## SSL session ID persistence

September 21, 2020

When SSL session ID persistence is configured, the Citrix ADC appliance uses the SSL session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

### Note:

There are two issues that users should consider before choosing this type of persistence. First, this type of persistence consumes resources on the Citrix ADC appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support a very large number of concurrent persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server should renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client's next request is received. This may result in the client's activity on the website being interrupted and the client might be asked to reauthenticate or restart the session. It may also result in large numbers of abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see [Configuring Persistence Types That Do Not Require a Rule..](#)

### Note

SSL session ID persistence is not supported with session tickets.

### Backup Persistence Support for SSL session ID

From NetScaler release 12.0 build 56.20, source IP persistence is supported as a backup persistence type for SSL session ID persistence. If the client and load-balanced server renegotiate the session, and source IP persistence is configured as the backup persistence, client requests are forwarded to the same server.

To support backup persistence for SSL session ID, the Citrix ADC appliance creates session entries for both source IP and SSL session ID when a client request is received for the first time. For the subsequent requests containing the same session ID, the SSL session ID is used. However, when the client

and the load-balanced server renegotiate the session, the client request is forwarded to the same server by using the Source IP persistence and a new SSL Session ID persistence entry is created.

For information about configuring backup persistence, see [Configuring Backup Persistence](#).

## Diameter AVP number persistence

September 21, 2020

You can use persistence based on the Attribute-Value Pair (AVP) number of a Diameter message to create persistent Diameter sessions. When the Citrix ADC appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

### To configure Diameter-based persistence on a virtual server by using the command line interface

At the command prompt, type the following command:

```
1 set lb vserver <name> -PersistenceType <type-> persistAVPno <
   positive_integer>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
2 <!--NeedCopy-->
```

## Custom server ID persistence

September 21, 2020

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services.

The Citrix ADC appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider should make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the Citrix ADC appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

**Note:** The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

**Example:**

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
1 set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789
2
3 set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
4 <!--NeedCopy-->
```

On virtual server Web11, enable Custom Server ID persistence.

Create the following expression so that all URL queries containing the string “sid=” are examined.

HTTP.REQ.URL.AFTER\_STR(“sid=”)

**Example:**

```
1 set lb vserver Web11 -persistenceType customserverID -rule "HTTP.REQ.
  URL.AFTER_STR("sid=")"
2
3 bind lb vserver Web11 Service-[1-2]
4 <!--NeedCopy-->
```

When a client sends a request with the following URL to the IP address of Web11, the appliance directs the request to Service-2 and honors persistence.

**Example:**

<http://www.example.com/index.asp?&sid=2345-drawing-abb123>

For more information about default-syntax policy expressions, see the [Policy Configuration and Reference](#).

**To configure custom server ID persistence by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service and set a server ID.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
4. In Advanced Settings, select Persistence.
5. Select CUSTOMESERVERID, and specify an expression.

**IP address persistence**

September 21, 2020

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

**Persistence Based on Destination IP Addresses**

With destination IP address-based persistence, when the Citrix ADC appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see [Link Load Balancing](#).

The time-out value for destination IP persistence is the same as that for source IP persistence, described in [Persistence Based on Source IP Address](#).

To configure persistence based on the destination IP address, see [Configuring Persistence Types That Do Not Require a Rule..](#)

**Persistence Based on Source and Destination IP Addresses**

With source and destination IP address-based persistence, when the Citrix ADC appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address).

Subsequently, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in [Persistence Based on Source IP Address](#).

To configure persistence based on both source and destination IP addresses, see [Configuring Persistence Types That Do Not Require a Rule](#).

## SIP Call ID persistence

September 21, 2020

With SIP Call ID persistence, the Citrix ADC appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

To configure persistence based on SIP Call ID, see [Configuring Persistence Types That Do Not Require a Rule](#).

## RTSP session ID persistence

September 21, 2020

With RTSP Session ID persistence, when the Citrix ADC appliance receives a request from a new client, it creates a new persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

**Note:** RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting.

Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that may issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see [Configuring Persistence Types That Do Not Require a Rule](#).

**Important:** If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

## Configure URL passive persistence

September 21, 2020

With URL Passive persistence, when the Citrix ADC appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see [Policies and Expressions](#).

The following expression configures the appliance to examine requests for URL queries that contain the string “urlp=”, extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

```
HTTP.REQ.URL.AFTER_STR("urlp=")
```

If URL passive persistence is enabled and the above expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

```
http://www.example.com/index.asp?urlp=0A661D0A0050
```

The persistence time-out value does not affect this persistence type; persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any appliance resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in [Configuring Persistence Types That Do Not Require a Rule](#). You set the persistence type to URLPASSIVE. You then perform the procedures provided below.

### To configure URL passive persistence by using the CLI

At the command prompt, type:

```

1 set lb vserver <vserverName> [-persistenceType <persistenceType>] [-
  rule <expression>]
2 <!--NeedCopy-->

```

**Example:**

```

1 set lb vserver LB-VServer-1 -persistenceType URLPASSIVE - rule HTTP.REQ
  .URL.AFTER_STR( "urlp=" )
2 <!--NeedCopy-->

```

**To configure persistence on a virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

**Persistence** [X]

Configure persistence to route all connections from the same user to the same service, such as an application that includes a shopping cart or that handles banking transactions. With some persistence types, you can configure backup persistence, which takes effect if the primary persistence type fails.

**Note**

Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

## Configure persistence based on user-defined rules

September 20, 2021

**Warning:**

The use of Classic expressions for the persistence rule in the load balancing feature is deprecated. However Classic expressions are removed and no longer available for the filter rule on the Citrix ADC appliance release 13.1 onwards.

When rule based persistence is configured, the Citrix ADC appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Subsequently, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL\_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you could use a classic expression to configure persistence based on the contents of the HTTP Host header. You could also use a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see [Policies and Expressions](#).

The expressions that you can configure depends on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL\_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

Note: For a use case that involves configuring rule based persistence on the basis of Financial Information eXchange (“FIX”) Protocol data transmitted over TCP, see [Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream](#).

Rule based persistence can be used for maintaining persistence with entities such as Branch Repeater appliances, Branch Repeater plug-ins, cache servers, and application servers.

**Note:** On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in [Configuring Persistence Types That Do Not Require a Rule](#), and set the persistence type to RULE. You then perform the procedures provided below. You can configure rule based persistence by using the configuration utility or the CLI.

## To configure persistence based on user-defined rules by using the CLI

At the command prompt, type:

```
1 set lb vserver <vserverName> [-rule <expression>][-resRule <expression
   >]
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver vsvr_name - rule http.req.header("cookie").value(0).
   typecast_nvlist_t('=', ';').value("server")
2
3 set lb vserver vsvr_name - resrule http.res.header("set-cookie").value
   (0).typecast_nvlist_t('=', ';').value("server")
4
5 <!--NeedCopy-->
```

## To configure persistence based on user-defined rules by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

✕
**Persistence**

**Note**

Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

**Example: Classic Expression for a Request Payload**

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, “MyBrowser”, and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

http header User-Agent contains MyBrowser

**Example: Default syntax Expression for a Request Header**

The following default syntax expression does exactly the same thing as the previous classic expression.

```
HTTP.REQ.HEADER("User-Agent").CONTAINS ("MyBrowser")
```

**Example: Default syntax Expression for a Response Cookie**

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

```
HTTP.RES.HEADER("SET-COOKIE").VALUE(0).TYPECAST_NVLIST_T(“=;”).VALUE(“server”)
```

## Configure persistence types that do not require a rule

September 21, 2020

To configure persistence, you must first set up a load balancing virtual server, as described in [Setting Up Basic Load Balancing](#). You then configure persistence on the virtual server.

**To configure persistence on a virtual server by using the CLI**

At the command prompt, type the following commands to configure persistence and verify the configuration:

```
1 set lb vserver <name> -PersistenceType <type> [-timeout <integer>]
2
3 show lb vserver
4 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -persistenceType SOURCEIP -timeout 60
2
3 show lb vserver
4 <!--NeedCopy-->
```

Timeout is the time period for which a persistence session is in effect. The timeout default and minimum values (in minutes) vary based on the persistence type as listed in the following table.

| persistence type                  | Default value | Minimum value | Maximum value |
|-----------------------------------|---------------|---------------|---------------|
| Cookie insert/group cookie insert | 2             | 0             | 1440          |
| Other persistence types           | 2             | 2             | 1440          |

**Note**

- Group cookie insert persistence type can be set on the load balancing group.
- For IP-based persistence, you can also set the persistMask parameter.
- The persistence type by default is set to NONE.

**To configure persistence on a virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the **Others** list.

**Persistence** ×

Configure persistence to route all connections from the same user to the same service, such as an application that includes a shopping cart or that handles banking transactions. With some persistence types, you can configure backup persistence, which takes effect if the primary persistence type fails.

**Select Persistence Type\***

SOURCEIP  
  COOKIEINSERT  
  OTHERS ?

**OK**

**Note** Prior to Citrix ADC release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

## Configure backup persistence

September 21, 2020

You can configure a virtual server to use source IP persistence type when the primary persistence type fails.

The following table describes the combinations of primary and secondary backup persistence types, and the conditions when the backup persistence is used.

| Primary persistence | Backup persistence | When the primary persistence lookup fails...                                                                                                                                                                                                                                                                     |
|---------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cookie Insert       | Source IP          | The appliance falls back to source-IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered. |
| Rule                | Source IP          | The appliance uses source-IP based persistence when the parameter specified in the rule is missing in the incoming request.                                                                                                                                                                                      |

### Note

- If the primary persistence type is HTTP-Cookie based persistence, and the backup persistence type is Source IP-based, you can set a timeout value for backup persistence. For instructions, see [Setting a Timeout Value for Idle Client Connections](#).
- You cannot set a timeout value for backup persistence when the primary persistence is rule based, because in that case the timeout value for secondary persistence must be the same as for the primary persistence. Therefore, the primary and secondary expire at the same time.

## To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name> -persistenceType <PersistenceType> -  
   persistenceBackup <BackupPersistenceType>  
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -persistenceType CookieInsert -  
   persistenceBackup SourceIP  
2  
3 set lb vserver Vserver-LB-1 -persistenceType sslsession -  
   persistenceBackup SourceIP  
4  
5 set lb vserver Vserver-LB-1 - persistenceType RULE - rule http.req.  
   header("User-Agent").value(0).contains("MyBrowser") -  
   persistenceBackup SOURCEIP  
6  
7 set lb vserver Vserver-LB-1 -persistenceType sslsession -  
   persistenceBackup SourceIP  
8 <!--NeedCopy-->
```

## To set backup persistence for a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In **Advanced Settings**, select **Persistence**, and specify a backup persistence type.

**Note:** The primary persistence must be set to COOKIEINSERT, RULE, or SSLSESSION.

## Configure persistence groups

September 21, 2020

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

When you add a virtual server that has persistence sessions to a load balancing group with a different persistence type, the existing persistent sessions specific to an old persistence type are deleted. The persistent sessions decide whether the traffic must go to the same virtual server or to a different server. Therefore, existing established connections are not impacted.

The persistence type of a load balancing group is applied to all the virtual servers bound to that group, irrespective of the virtual servers' protocol type. A load balancing group supports the following persistence types:

- SourceIP
- CookieInsert
- Rule

Some virtual servers support only certain persistence types. For example, a virtual server of type SSL\_BRIDGE can use only SourceIP persistence type for an LB group.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see [Persistence Based on HTTP Cookies](#).

### **To create a virtual server persistency group by using the command line interface**

At the command prompt, type:

```
1 bind lb group <vServerGroupName> <vServerName> -persistenceType <
  PersistenceType>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType
  CookieInsert
2 <!--NeedCopy-->
```

## To modify a virtual server group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Persistency Groups**, create a persistency group, and specify the virtual servers that must be part of this group.

## To modify a virtual server group by using the command line interface

At the command prompt, type:

```
1 set lb group <vServerGroupName> -PersistenceBackup <
  BackupPersistenceType> -persistMask <SubnetMaskAddress>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask
  255.255.255.255
2 <!--NeedCopy-->
```

## Share persistent sessions between virtual servers

September 21, 2020

In some customer environments (telecom and ISP), a single server handles both control and data traffic. For a given client IP address, both control and data traffic have to be directed to the same back-end server. For this, one virtual server is required for handling client authentication traffic, and usually rule based persistency is configured on it. For example, Radius.req.avp(8).value.typecast\_text\_t'. The second virtual server for handling data traffic. Usually, SourceIP persistence is configured on it.

Previously, persistence entries were local to the vserver. If you had to apply persistence across multiple vservers, you had to add the vservers to a load balancing group and then apply a common persistence type to the group. The above requirement could not be achieved, because all the vservers bound to a load balancing group inherited the persistency configured on the group.

With the persistency sharing between vservers feature, you can set the new useVserverPersistency parameter for a load balancing group to allow the vservers in the group to use their own persistency parameters instead of inheriting them from the group settings. You can configure separate rule-based persistency on each vserver.

Optionally, you can also designate one of the vservers in the group as a master vserver. When a vserver is designated as a master vserver, only that vserver creates the persistence entries, which are used by

all the vservers in the group. If the master vserver is down, the Citrix ADC appliance does not create any new persistence entries.

**Note:** Persistence sharing across vservers is supported only for rule based persistency methods. You must configure compatible rule based persistence parameters on the member virtual servers.

**Example:**

Assume v1 and v2 are bound to a load balancing group, v1 is a RADIUS type vserver and v2 is an HTTP type vserver. 'Radius.req.avp(8).value.typecast\_text\_t' persistency is configured on v1 and 'client.ip.src' is configured on v2.

When traffic flows through the RADIUS vserver v1, it creates a persistent entry based on the evaluated rule string. Later, when traffic reaches the HTTP type vserver v2, v2 checks for the persistence entries on the load balancing group and uses the same persistence session to direct traffic to the same back-end server.

## Configuring Sharing of Persistent Sessions

To share persistency parameters across vservers in a load balancing group, you must first enable the useVserverPersistency parameter and then designate one of the vservers in the group as a master server.

### To enable the useVserverPersistency parameter by using the command line interface

At the command prompt, type:

```
1 set lb group <name> -useVserverPersistency ( ENABLED)
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb group lb_grp1 -useVserverPersistency ENABLED
2 <!--NeedCopy-->
```

### To enable the useVserverPersistency parameter by using the GUI

1. Navigate to **Configuration > Traffic Management > Load Balancing > Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.

## To designate a vserver as a master vserver by using the command line interface

At the command prompt, type:

```
1 set lb group <name> -useVserverPersistency ( ENABLED ) -masterVserver <
   string>
2 <!--NeedCopy-->
```

Example:

```
1 set lb group lb_grp1 -useVserverPersistency ENABLED -masterVserver vs1
2 <!--NeedCopy-->
```

## To designate a vserver as a master vserver by using the GUI

1. Navigate to **Configuration > Traffic Management > Load Balancing > Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.
4. In the **Virtual Server Name** box, click **+** to add the vservers to the group. You can select the available vservers or create new vservers.
5. Click **Create** if you are adding a new group or **Close** if you are modifying an existing group.
6. Select the group for which you have enabled the useVserverPersistency parameter and click **Edit** to set a vserver as a master to create persistence entries.
7. From the **Master vServer** list, select the vserver that has to be designated as a master vserver.

## Arguments

### useVserverPersistency

Allow the virtual servers in a group to use their own persistency parameters to create persistent sessions, instead of inheriting the persistency settings from the group settings. When this parameter is enabled, persistence cannot be set on the load balancing group.

When this parameter is disabled, the group's virtual servers inherit the persistency parameters from the group settings.

When this parameter is toggled on the load balancing group, the Citrix ADC appliance flushes all the corresponding persistence entries of the group and the member virtual servers.

Possible values: ENABLED, DISABLED

Default: DISABLED

### Example:

```
1 set lb group lb_grp1 -useVserverPersistency ENABLED
2 <!--NeedCopy-->
```

### masterVserver

Designate a virtual server as a master virtual server in its load balancing group. Once designated, only the master virtual server can create the persistent entries used by the group.

**Note:** This parameter can be set only if the useVserverPersistency parameter is enabled.

### Example:

```
1 set lb group lb_grp1 - masterVserver vs1
2 <!--NeedCopy-->
```

### Example Configuration of Sharing Persistent Sessions by Using the Command Line Interface

The virtual servers are created

```
1 add lb vs vs1 http 10.1.10.11 80 - persistence rule - rule 'client.ip.
  src'
2
3 add lb vs vs2 radius 10.2.2.2 1812 - persistenceType rule - rule '
  Radius.req.avp(8).value.typecast_text_t'
4 <!--NeedCopy-->
```

The groups are created.

```
1 add lb group lb_grp1 - persistenceType NONE - useVserverPersistency
  ENABLED
2 <!--NeedCopy-->
```

A virtual server in a group is designated as master vserver.

```
1 set lb group lb_grp1 - masterVserver vs1
2 <!--NeedCopy-->
```

The virtual servers are bound to the group.

```
1 bind lb group lb_grp1 vs1
2 bind lb group lb_grp1 vs2
3 <!--NeedCopy-->
```

For more details, see [Setting Up Basic Load Balancing](#) and [Configuring Persistence Groups](#).

## Configure RADIUS load balancing with persistence

September 21, 2020

Today's complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users may connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the Citrix ADC appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in [AAA Application Traffic](#). You must also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

### Enabling the Load Balancing or Content Switching Feature

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new Citrix ADC appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a Citrix ADC appliance with a previous configuration on it, and you are not certain that the feature you will use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see [Enabling Load Balancing](#).
- For instructions on enabling the content switching feature, see [Enabling Content Switching](#).

## Configuring Virtual Servers

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service will handle authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service will handle accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user's activities on your protected application or VPN.

**Important:** You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

### To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a new load balancing virtual server and verify the configuration:

```
1 add lb vsrver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
  <rule>
2
3 show lb vsrver <name>
4 <!--NeedCopy-->
```

To configure an existing load balancing virtual server, replace the above add lb virtual server command with the set lb vsrver command, which takes the same arguments.

### To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a new content switching virtual server and verify the configuration:

```
1 add cs vsrver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
  <rule>
2
3 show cs vsrver <name>
4 <!--NeedCopy-->
```

To configure an existing content switching virtual server, replace the above add cs vsrver command with the set cs vsrver command, which takes the same arguments.

#### Example:

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
  TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2
3 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
  TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
4
5 set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
  TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
6

### **To configure a load balancing or content switching virtual server by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Virtual Servers or navigate to Traffic Management > Content Switching > Virtual Servers», and configure a virtual server.

### **Configuring Services**

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created.

Note: Once configured, these services are in the DISABLED state until the Citrix ADC appliance can connect to your RADIUS server's authentication and accounting IPs and monitor their status. For instructions, see [Configuring Services](#).

### **Binding Virtual Servers to Services**

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service. For instructions, see [Binding Services to the Virtual Server](#).

### **Configuring a Persistency Group for Radius**

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. A persistency group is required because the authentication and accounting virtual servers are different and both the authentication & accounting message for a single user should reach the same RADIUS server. By configuring a

persistence group, the same session is used for both virtual servers. For instructions, see [Configuring Persistence Groups](#).

## Configuring RADIUS Shared Secret

From release 12.0, a Citrix ADC appliance supports RADIUS shared secret. A RADIUS client and server communicate with each other by using a shared secret that is configured on the client and on the server. Transactions between a RADIUS client and server are authenticated through the use of a shared secret. This secret is also used to encrypt some of the information in the RADIUS packet.

### RADIUS shared secret key validation scenarios

The validation of the RADIUS shared secret key happens in the following scenarios:

- **RADIUS shared secret key is configured for both the radius client and the radius server:** The Citrix ADC appliance uses the RADIUS secret key for both the client side and the server side. If the verification succeeds, the appliance allows the RADIUS message to go through. Otherwise, it drops the RADIUS message.
- **RADIUS shared secret key is not configured for either the radius client or the radius server:** The Citrix ADC appliance drops the RADIUS message, because shared-secret-key validation cannot be performed on a node that has no radkey configured.
- **RADIUS shared secret key is not configured for both the RADIUS client and the RADIUS server:** The Citrix ADC appliance bypasses the RADIUS secret key validation and allows the RADIUS messages to go through.

You can configure a default RADIUS shared secret or configure on a per client or a subnet basis. It is recommended to add a RADIUS shared secret key for all deployments with RADIUS policy configured. The appliance uses the source IP address of the RADIUS packet to decide which shared secret to use. You may configure a RADIUS client and server and the corresponding shared secret as follows:

At the CLI prompt, type:

```
1 add radiusNode <clientPrefix/Subnet> -radKey <Shared_secret_key>
2 <!--NeedCopy-->
```

### Arguments

#### IPaddress

IP address or subnet of the RADIUS client in CIDR format. The appliance uses the source IP address of an incoming request packet to match the client IP address. Instead of configuring a client IP address, you can configure the client network address. Longest prefix is matched to identify the shared secret for an incoming client request.

## Radkey

Shared secret between the client, Citrix ADC appliance, and the server. Maximum length: 31.

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
  TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2
3 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
  TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
4
5 add service radius_auth_service1 192.168.41.68 RADIUS 1812
6
7 add service radius_acct_service1 192.168.41.70 RADIUS 1813
8
9 bind lb vserver radius_auth_vs1 radius_auth_service1
10
11 bind lb vserver radius_acct_vs1 radius_acct_service[1-3]
12
13 add radiusNode 192.168.41.0/24 -radKey serverkey123
14
15 add radiusNode 203.0.113.0/24 -radkey clientkey123
16 <!--NeedCopy-->
```

A shared secret must be configured both for a RADIUS client and server. The command is the same. The subnet determines whether the shared secret is for a client or for a server.

For example, if the subnet specified is a client subnet, the shared secret is for the client. If the subnet specified is a server subnet (192.168.41.0/24 in the above example), the shared secret is for the server.

A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients and servers.

### Note

Only the PAP and CHAP authentication methods are supported with RADIUS shared secret.

## View persistence sessions

September 21, 2020

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

Note: A Citrix ADC nCore appliance uses multiple CPU cores for packet handling. Every session on the appliance is owned by a CPU core. If the appliance receives a request for which a session does

not already exist, a session is created, and one of the cores is designated as the owner of that session. Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current. However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session. Consequently, in the output of successively executed `show lb persistentSessions` commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session continues to be active.

### To view a persistence session by using the command line interface

At the command prompt, to view all persistence sessions type:

```
1 show lb persistentSessions [<vServer>]
2 <!--NeedCopy-->
```

#### Example:

```
1 show lb persistentSessions myVserver
2 <!--NeedCopy-->
```

### To view persistence sessions by using the configuration utility

Navigate to Traffic Management > Virtual server persistent sessions.

## Clear persistence sessions

September 21, 2020

You might need to clear persistence sessions from the Citrix ADC appliance if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

### To clear a persistence session by using the command line interface

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

```
1 clear lb persistentSessions [<vServer> [-persistenceParam <string>]]
2
3 show persistentSessions <vServer>
4 <!--NeedCopy-->
```

**Examples:**

Example 1 clears all persistence sessions for load balancing virtual server lbvip1.

Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

**Example 1:**

```
1 > clear persistentSessions lbvip1
2 Done
3 > show persistentSessions
4 Done
5 >
6 <!--NeedCopy-->
```

**Example 2:**

```
1 > show persistentSessions lbvip1
2 Type          SRC-IP      ...    PERSISTENCE-PARAMETER
3 RULE          0.0.0.0    ...    xls
4 RULE          0.0.0.0    ...    txt
5 RULE          0.0.0.0    ...    html
6 Done
7 > clear persistentSessions lbvip1 -persistenceParam xls
8 Done
9 > show persistentSessions lbvip1
10 Type         SRC-IP      ...    PERSISTENCE-PARAMETER
11 RULE         0.0.0.0    ...    txt
12 RULE         0.0.0.0    ...    html
13 Done
14 >
15 <!--NeedCopy-->
```

**To clear persistence sessions by using the configuration utility**

1. Navigate to Traffic Management > Clear Persistent Sessions.

## Override persistence settings for overloaded services

September 21, 2020

When a service is loaded or is otherwise unavailable, service to clients is degraded. To work around this situation, you might have to configure the Citrix ADC appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the skip-persistency parameter. With the parameter set, when the virtual server receives new connections for an overloaded service, the virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests. Persistence sessions associated with other services are not affected. The functionality is available for only virtual servers whose type is ANY or UDP.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see [Understanding Load Monitors](#).

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services on the basis of the configured load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.

Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server on the basis of the destination IP address in the request.

Only wildcard virtual servers of type ANY and UDP support the bypass option. Wildcard virtual servers have a : IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the Citrix ADC appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. If you configure the virtual server to bypass the virtual server–service configuration for overloaded services, if a Branch Repeater appliance or firewall gets overloaded, the virtual server bridges requests di-

rectly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

### To override persistence settings for overloaded services by using the command line interface

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

```
1 set lb vserver <name> -skippersistency <skippersistency>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Example

```
1 > set lb vserver mylbvserver -skippersistency ReLb
2 Done
3 > show lb vserver mylbvserver
4 mylbvserver (*:*) - ANY Type: ADDRESS
5 . . .
6 . . .
7 Skip Persistence: ReLb
8 . . .
9 Done
10 >
11 <!--NeedCopy-->
```

### To override persistence settings for overloaded services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server of type UDP or ANY.
2. In the Advanced Settings pane, select Traffic Settings, and specify the type of Skip Persistence.

## Troubleshooting

September 21, 2020

- **The statistics from the Citrix ADC VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?**

**Cause:** The Citrix ADC appliance has the system limit of 250,000 persistence session for a core.

**Resolution:** To resolve this issue, you can perform any of the following tasks:

- Reduce the time out value for persistence
- Increase the number of cores for the appliance

- **After configuring Cookie Insert persistence on the Citrix ADC appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?**

**Cause:** By default, the time-out value for Cookie Insert persistence is 120 seconds.

**Resolution:** When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

- **After configuring an HTTP virtual server on the Citrix ADC appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?**

**Resolution:** Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

- **After configuring Cookie Insert persistence on the Citrix ADC appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.**

**Cause:** Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and Citrix ADC appliance are in different time zones, the cookie is not valid. For example, when a client in EST time zone sends a cookie at 11:00 AM EST to a Citrix ADC appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

**Resolution:** Set the time-out value for Cookie Insert persistence to 0.

- **A Citrix ADC appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and,**

**as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?**

**Cause:** The Citrix ADC appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

**Resolution:** To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

- **The Citrix ADC appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the “State Error” error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.**

**Cause:** Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

**Resolution:** Citrix recommends that you specify the Cookie Insert persistence method on the Citrix ADC appliance when load balancing Web Interface servers.

## Insert cookie attributes to ADC generated cookies

September 21, 2020

The web administrators can insert additional cookie attributes to the cookies generated by Citrix ADC appliance. These additional cookie attributes help in enforcing the required policies for the ADC generated cookies based on the application access pattern.

The following features use the ADC generated cookies to achieve persistency.

- Load balancing cookie persistence
- Load balancing group cookie persistence
- GSLB site persistence

You can insert additional cookie attributes to the ADC generated cookies using the following parameters:

- **LiteralADCCookieAttribute:** Append additional cookie attributes to the ADC generated cookie, as a string.

- **ComputedADCCookieAttribute:** Use an ADC ns variable to conditionally append cookie attributes to the ADC generated cookie, based on the client or server attributes, for example, user agent version.

**Note**

You cannot configure both Literal ADC Cookie Attribute and Computed ADC Cookie Attribute, simultaneously on the load balancing parameter or in a single load balancing profile.

**Use case: Configure SameSite cookie attribute**

Every cookie has a domain associated with it. When a cookie's domain matches the website domain in the user's address bar, this is considered a same-site (or first party) context. If the domain associated with a cookie matches an external service and not the website in the user's address bar, this is considered a cross-site (or third party) context.

The SameSite attribute indicates the browser whether the cookie can be used for cross-site context or only for same-site context. Also, if an application intends to be accessed in cross-site context then it can do so only via HTTPS connection. For details, see [RFC6265](#).

Until Feb 2020, the SameSite property was not explicitly set in Citrix ADC. The browser took the default value as None, and did not impact the Citrix ADC deployments.

However with certain browsers upgrade, such as Google Chrome 80, there is a change in the default cross-domain behavior of cookies. The SameSite attribute can be set to one of the following values. Default value for Google Chrome is set to Lax.

- **None:** Indicates the browser to use cookie in cross-site context only on secure connections.
- **Lax:** Indicates the browser to use cookie for requests in the same-site context. In cross-site context, only safe HTTP methods like GET request can use the cookie.
- **Strict:** Use the cookie only in the same-site context.

If there is no SameSite attribute in the cookie, the Google Chrome assumes the functionality of SameSite=Lax.

**Note**

For certain version of other browsers, the default value for SameSite attribute might be set to **None**. In some browser versions, "SameSite = none" can be treated differently. For example, the following browsers reject a cookie with "SameSite = none":

- Versions of Chrome from Chrome 51 to Chrome 66 (inclusive on both ends)
- Versions of UC browser on Android prior to version 12.13.2

**Configure ADC generated cookies**

To configure ADC generated cookie attributes, you must perform the following:

1. Create a load balancing virtual server
2. Set the ADC Cookie attributes for the load balancing virtual server, either through LB parameters or LB profile.
3. If you use an LB profile, set the LB profile to a load balancing virtual server.
4. If you choose to use the Computed ADC Cookie Attribute, configure the related rewrite policy.

**Note**

If an LB profile is bound to an LB virtual server, then the profile parameter configuration is considered instead of global LB parameter configuration.

You can set the ADC generated cookie attributes by the following methods:

- Setting the ADC cookie attributes in LB parameters
- Setting the ADC cookie attributes in LB profile

**Setting the ADC cookie attributes in LB parameters by using the CLI**

To apply a policy uniformly to ADC generated cookies of all applications configured on Citrix ADC appliance, you can set the ADC cookie attribute in the global LB parameters.

The **Literal ADC Cookie Attribute** setting allows you to unconditionally insert the cookie attributes to the ADC generated cookie.

At the command prompt, type:

```
1 set lb parameter -LiteralADCCookieAttribute <string>
2 <!--NeedCopy-->
```

Example:

```
1 set lb parameter -LiteralADCCookieAttribute SameSite=None
2 <!--NeedCopy-->
```

The **Computed ADC Cookie Attribute** setting allows you to conditionally insert the cookie attributes, based on the client or server attributes, to the ADC generated cookie.

At the command prompt, type:

```
1 set lb parameter -ComputedADCCookieAttribute <ns variable>
2 <!--NeedCopy-->
```

Example:

```
1 add ns variable cookieattribute_var -type "text(100)" -scope
  transaction
2 set lb parameter -ComputedADCCookieAttribute "$cookieattribute_var"
```

```
3 add ns assignment samesiteassign -variable "$cookieattribute_var" -set
  "\"SameSite=None\""
4
5 add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
  CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
  /OS \\d+\\_/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).EQ(12).
  typecast_text_t ALT \"false\").eq(\"true\"))"
6 add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
  CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
  (re/Chrom.*\\d+/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).
  BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
7 add rewrite policy exception_samesite_insert "pol_iphone || pol_chrome
  " NOREWRITE
8 add rewrite policy append_samesite_attribute true samesiteassign
9
10 bind rewrite global exception_samesite_attribute 90 110 -type
  RES_OVERRIDE
11 bind rewrite global append_samesite_attribute 100 110 -type
  RES_OVERRIDE
12
13 <!--NeedCopy-->
```

### Setting the ADC cookie attributes in LB parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters.**

[Traffic Management](#) / [Load Balancing](#)

## Load Balancing

The load balancing feature distributes user requests for applications among multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages, and ensuring that users can seamlessly access your applications. Load balancing also provides fault tolerance: when a server that hosts an application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

To set up load balancing:

- Configure a virtual server.
- Configure a service representing the application running on the server.
- Bind the service to the virtual server.
- Optionally, configure a monitor and bind it to the service.
- Optionally, configure persistence and a load balancing method.

### Settings

- [Change SIP settings](#)
- [Change Load Balancing parameters](#)
- [Change SMPP Parameters](#)

### Configuration Summary

- 2 Load Balancing Virtual Servers
- 1 Service
- No Service Group
- 24 Monitors
- 6 Metric Tables
- 1 Server
- 1 Persistency Group

- In the **Configure Load Balancing Parameters** pane, enter appropriate values for either one of the fields based on your requirement:
  - **Literal ADC Cookie Attribute**
  - **Computed ADC Cookie Attribute**

Dashboard Configuration Reporting Documentation

3. Click **OK**.

### Setting the ADC cookie attributes in LB profile by using the CLI

To apply a policy for a specific application that is configured on Citrix ADC appliance, you can set the cookie attribute parameters in the LB profile bound to the application-specific LB virtual server.

The **Literal ADC Cookie Attribute** setting in the LB profile allows you to unconditionally insert the

cookie attributes to the ADC generated cookie that is specific to a virtual server.

At the command prompt, type:

```
1 add lb profile <profile name> -LiteralADCCookieAttribute <string>
2 <!--NeedCopy-->
```

Example:

```
1 add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
  =None
2 add lb vservice LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
  COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
3 <!--NeedCopy-->
```

The **Computed ADC Cookie Attribute** setting in the LB profile allows you to conditionally insert the cookie attributes based on the client or server attributes, to the ADC generated cookie. Then, set this LB profile to an LB virtual server.

At the command prompt, type:

```
1 add lb profile <profile name> -ComputedADCCookieAttribute <ns variable>
2 <!--NeedCopy-->
```

Example:

```
1 add ns variable cookieattribute_var -type "text(100)" -scope
  transaction
2 add ns assignment samesiteassign -variable "$cookieattribute_var" -set
  "\"SameSite=None\""
3 add lb profile LB-Vserver-Profile-1 -ComputedADCCookieAttribute "$
  cookieattribute_var"
4
5 add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
  CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
  /OS \\d+\\_/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).EQ(12).
  typecast_text_t ALT \"false\").eq(\"true\"))"
6 add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
  CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
  (re/Chrom.*\\d+/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).
  BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
7 add rewrite policy exception_samesite_attribute "pol_iphone ||
  pol_chrome " NOREWRITE
8 add rewrite policy append_samesite_attribute true samesiteassign
9
10 add lb vservice LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
  COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
```

```

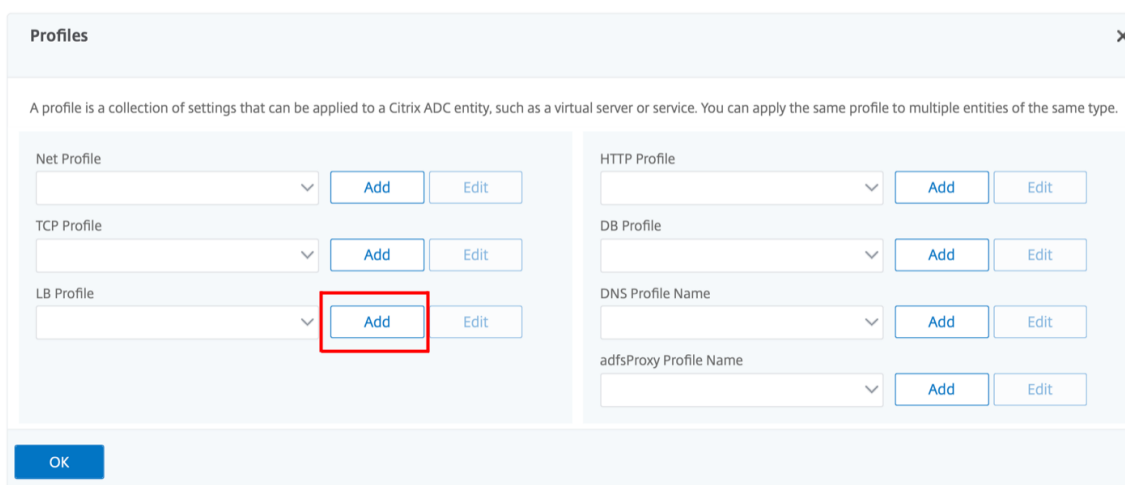

11 bind lb vserver LB-VServer-1 -policyName exception_samesite_attribute -
    priority 90 -gotoPriorityExpression 110 -type RESPONSE
12 bind lb vserver LB-VServer-1 -policyName append_samesite_attribute -
    priority 100 -gotoPriorityExpression 110 -type RESPONSE
13 <!--NeedCopy-->
    
```

### Setting the ADC Cookie attributes in LB profile by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers**.
2. Select a virtual server and click **Edit**.
3. Under **Advanced Settings** section, click **Add profiles**.

4. In the **Profiles** section, click **Add** to create an LB Profile.  
If you have already created a profile, choose it from the **LB Profile** drop-down menu.

5. In the **LB Profile** pane, enter appropriate values for either one of the fields based on your requirement:

- **Literal ADC Cookie Attribute**
- **Computed ADC Cookie Attribute**

The screenshot shows the 'LB Profile' configuration page in the Citrix ADC management console. The page has a navigation bar with 'Dashboard', 'Configuration', and 'Rep' tabs. Below the navigation bar, there is a back arrow and the title 'LB Profile'. The main configuration area contains several fields and checkboxes:

- LB Profile Name:** A text input field containing 'lbprof1'.
- DBS LB:** A checkbox that is unchecked.
- Process Local:** A checkbox that is unchecked.
- Persistence Cookie HttpOnly Flag:** A checkbox that is unchecked.
- Encode Persistence Cookie Values:** A checkbox that is unchecked.
- Cookie Passphrase:** A text input field that is empty.
- Literal ADC Cookie Attribute:** A text input field that is empty and highlighted with a red rectangular box.
- Computed ADC Cookie Attribute:** A text input field containing 'Slbvar'.

At the bottom of the configuration area, there are two buttons: 'OK' (a blue button) and 'Close' (a white button with a grey border).

1. Click **OK**.
2. Set the created LB profile to the LB virtual server created in **Step 1**.

### Verify ns variable configuration

To verify that the ADC ns variable is configured appropriately in LB parameters or LB profile, use the show lb parameter or show lb profile commands.

The following table lists the various warning messages and its cause, when the ns variable is not cor-

rectly configured.

| Warning message                                                                                 | Reasons                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NS Variable is not configured. Configure it with type text() and scope transaction for variable | NS variable is not yet configured.                                                                                                                                                                                            |

| Type of variable is not Text().                                                                 | Variable is configured but type is not set to "Text".                                                                                                                                                                         |
| Configured value-max-size for NS Variable is greater than 255.                                  | The value configured for NS variable is greater than 255 characters. <b>Note:</b> A maximum length of 255 characters can be appended to an ADC generated cookie. The characters that exceed the maximum length are truncated. |

### Sample output

In the following example, the warning message is displayed when the ns variable is not configured.

```

1 set lb parameter -ComputedADCCookieAttribute "$lbvar"
2
3 Warning: NS Variable is not configured. Please configure it with type
  text() and scope transaction
4 Done
5 <!--NeedCopy-->
```

The warning message is displayed in the following output of the `show lb parameter` command.

```

1 show lb parameter
2
3 Global LB parameters:
4 Persistence Cookie HttpOnly Flag: ENABLED
5 Use Encrypted Persistence Cookie: DISABLED
6 Use Port For Hash LB: YES
7 Prefer direct route: YES
8 Retain Service State: OFF
9 Start RR Factor: 0
10 Skip Maxclient for Monitoring: DISABLED
11 Monitor Connection Close: FIN
12 Use consolidated stats for LeastConnection: YES
```

```

13 Allow mac mode based vserver to pick thereturn traffic from services:
    DISABLED
14 Allow bound service removal: ENABLED
15 TTL for Domain Based Server: 0 secs
16
17 Citrix ADC Cookie Variable Name: $lbvar(NS Variable is not configured.
    Please configure it with type text() and scope transaction)
18
19 Done
20 <!--NeedCopy-->

```

### Sample configuration for inserting cookie attributes in GSLB deployment

The following sample configuration applies to site persistence configured on GSLB services corresponding to an LB virtual server. To append some additional cookie attributes to the GSLB cookies, perform the following configuration.

- Set the ADC cookie attributes in the LB profile (LB-Vserver-Profile-1).
- Set the Literal ADC Cookie Attribute value, for example “SameSite=None”, in the LB profile.
- Set the LB profile to the load balancing virtual server (LB-VServer-1), which represents the GSLB service.

```

1 add gslb vserver GSLB-VServer-1 SSL -backupLBMethod ROUNDROBIN -
    tolerance 0 -appflowLog DISABLED
2 add gslb site site1 10.102.148.4 -publicIP 10.102.148.4
3 add gslb service site1_gsvc1 10.102.148.35 SSL 443 -publicIP
    10.102.148.35 -publicPort 443 -maxClient 0 -siteName site1 -
    sitePersistence HTTPRedirect -sitePrefix ssl -cltTimeout 180 -
    svrTimeout 360 -downStateFlush ENABLED
4
5 bind gslb vserver GSLB-VServer-1 -serviceName site1_gsvc1
6 bind gslb vserver GSLB-VServer-1 -domainName www.gslb.com -TTL 5
7
8 add service service-1 10.102.84.140 SSL 443
9
10 add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
    =None
11 add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
    COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
12
13 bind lb vserver LB-VServer-1 service-1
14 <!--NeedCopy-->

```

**Note**

You can also conditionally insert the cookie attributes using the Computed ADC Cookie Attribute.

**Sample configuration for inserting cookie attribute in content switching deployment**

The following sample configuration applies when multiple applications are hosted behind a content switching virtual server. To apply the same policy to all the applications, bind the rewrite policies to content switching virtual server instead of LB virtual server, as follows:

- Set the ADC cookie attributes in the LB parameters.

**Note:**

You can set the ADC cookie attributes in the LB profile as well.

- Configure the ns variable (cookieattribute\_var) of Type set to Text and Scope set to Transaction.
- Set the Computed ADC Cookie Attribute in the global LB parameters using the ns variable.
- Set the rewrite policies (exception\_samesite\_attribute and append\_samesite\_attribute) to the content switching virtual servers for inserting the cookie attributes.

```

1 add ns variable cookieattribute_var -type "text(100)" -scope
  transaction
2 set lb parameter -ComputedADCCookieAttribute "$cookieattribute_var"
3 add ns assignment samesiteassign -variable "$cookieattribute_var" -set
  "\"SameSite=None\""
4
5 add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
  CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
  /OS \\d+\\_/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).EQ(12).
  typecast_text_t ALT \"false\").eq(\"true\"))"
6 add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
  CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
  (re/Chrom.*\\d+/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).
  BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
7 add rewrite policy exception_samesite_insert "pol_iphone || pol_chrome
  " NOREWRITE
8 add rewrite policy append_samesite_attribute true samesiteassign
9
10 add lb vserver LB-VServer-1 SSL 10.102.148.35 443
11 add lb vserver LB-VServer-2 SSL 10.102.148.36 443
12
13 add cs vserver CS-VServer-1 SSL 10.102.148.42 443 -persistenceType
  COOKIEINSERT
14

```

```
15 add cs action act1 -targetLBVserver v1
16 add cs action act2 -targetLBVserver v2
17 add cs policy CS-policy-1 -rule "HTTP.REQ.URL.CONTAINS(\"file1.html\")"
    -action act1
18 add cs policy CS-policy-2 -rule "HTTP.REQ.URL.CONTAINS(\"file2.html\")"
    -action act2
19
20 bind cs vserver CS-VServer-1 -policyName CS-policy-1 -priority 1
21 bind cs vserver CS-VServer-1 -policyName CS-policy-2 -priority 2
22
23 bind cs vserver -policyname exception_samesite_attribute 90 110 -type
    RES_OVERRIDE
24 bind cs vserver -policyname append_samesite_attribute 100 110 -type
    RES_OVERRIDE
25 <!--NeedCopy-->
```

## Customize a load balancing configuration

September 21, 2020

After you configure a basic load balancing setup, you can make a number of modifications to it so that it distributes load exactly as you need. The load balancing feature is complex. You can modify the basic elements by changing the load balancing algorithm, configuring load balancing groups and using them to create your load balancing configuration, configuring persistent client-server connections, configuring the redirection mode, and assigning different weights to different services that have different capacities.

The default load balancing algorithm on the Citrix ADC appliance is the least connection method, which configures the appliance to send each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers, causing the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can assign weights to different services, specifying what percentage of incoming load should be directed to each service, so that you

can include servers with different capacities in the same load balancing setup without overloading the lower-capacity servers or allowing the higher-capacity servers to sit idle.

This section includes the following details:

- [Customizing the Hash Algorithm for Persistence across Virtual Servers](#)
- [Configuring the Redirection Mode](#)
- [Configuring per-VLAN Wildcarded Virtual Servers](#)
- [Assigning Weights to Services](#)
- [Configuring the MySQL and Microsoft SQL Server Version Setting](#)

## Customize the hash algorithm for persistence across virtual servers

September 21, 2020

The Citrix ADC appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the CLI to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

### To change the use-port-number global setting by using the CLI

At the command prompt, type:

```
set lb parameter -usePortForHashLb (YES NO)
```

**Example:**

```
1 > set lb parameter -usePortForHashLb NO
2 Done
3 >show lb parameter
4 Global LB parameters:
5     Persistence Cookie HttpOnly Flag: DISABLED
6     Use port for hash LB: NO
7 Done
8 <!--NeedCopy-->
```

**To change the use-port-number global setting by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing parameters.
2. Select or clear Use Port for Hash Based LB Methods.

**To create a new service and specify a hash identifier for a service by using the CLI**

At the command prompt, type the following commands to set the hash ID and verify the setting:

```
add service < name > (< ip > < serverName >) < serviceType > < port >
                                     -hashId < positive_integer >
```

```
1 show service <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 > add service flbkng 10.101.10.1 http 80 -hashId 12345
2 Done
3 >show service flbkng
4     flbkng (10.101.10.1:80) - HTTP
5     State: DOWN
6     Last state change was at Thu Nov  4 10:14:52 2010
7     Time since last state change: 0 days, 00:00:15.990
8     Server Name: 10.101.10.1
9     Server ID : 0   Monitor Threshold : 0
10
```

```

11      Down state flush: ENABLED
12      Hash Id: 12345
13
14 1)      Monitor Name: tcp-default
15          State: DOWN      Weight: 1
16
17 Done
18 <!--NeedCopy-->

```

### To specify a hash identifier for an existing service by using the CLI

Type the set service command, the name of the service, and **-hashID** followed by the ID value.

### To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

```

1 bind servicegroup <serviceName> <memberName> <port> -hashId <
  positive_integer>
2
3 show servicegroup <serviceName>
4 <!--NeedCopy-->

```

### Example:

```

1 bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222
2
3 >show servicegroup SRV
4      SRV - HTTP
5      State: ENABLED  Monitor Threshold : 0
6      ...
7
8      1)          1.1.1.1:80  State: DOWN      Server Name: 1.1.1.1
9                  Server ID: 123  Weight: 1
10     Hash Id: 32211
11
12             Monitor Name: tcp-default      State: DOWN
13     ...
14
15     2)          2.2.2.2:80  State: DOWN      Server Name: 2.2.2.2
16             Server ID: 123  Weight: 1

```

```
15      Hash Id: 12345
16
17      Monitor Name: tcp-default      State: DOWN
18      ...
19 Done
20
21 <!--NeedCopy-->
```

### To specify a hash identifier for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a new service, or open an existing service and specify the hash ID.

### To specify a hash identifier for an already configured service group member by using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a member and type a unique hash ID.

## Configure the redirection mode

September 30, 2021

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The Citrix ADC appliance supports the following redirection modes. Before forwarding the request to a server, the redirection modes function as follows:

- IP-Based forwarding (the default): The destination IP address is changed to the server's IP address.
- MAC-Based forwarding: The destination MAC address is changed to the server's MAC address. However, the destination IP address is not changed. MAC-based redirection mode is used mostly in firewall load balancing deployments.
- IP TUNNEL Based: An IP-in-IP encapsulation is performed for the client IP packets. In the outer IP headers, the destination IP address is set to the IP address of the server and the source IP address is set to the subnet IP (SNIP). The client IP packets are not modified. This is applicable to both IPv4 and IPv6 packets.
- TOS ID Based: The virtual server's TOS ID is encoded in the TOS field of the IP header.

You can use either the IP TUNNEL or the TOS option to implement Direct Server Return (DSR). For more information see:

- [Configure DSR mode when using TOS](#)
- [Configure load balancing in DSR mode for IPv6 networks by using the TOS field](#)
- [Configure load balancing in DSR mode by using IP Over IP](#)

You can configure MAC-Based forwarding on networks that use DSR topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding for load balancing, see [Configure MBF for load balancing configuration](#).

### To configure the redirection mode by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -m <RedirectionMode>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

#### Note

For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

### To configure the redirection mode by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and select the redirection mode.

## Configure per-VLAN wildcarded virtual servers

September 21, 2020

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

### To configure a wildcarded virtual server that listens to a specific VLAN by using the CLI

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

```
1 add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <
  expression> [-listenpriority <positive_integer>]
2
3 show vserver
4 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)
  " -listenpriority 10
2
3 show vserver Vserver-LB-vlan1
4 <!--NeedCopy-->
```

**To configure a wildcarded virtual server that listens to a specific VLAN by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a new virtual server or open an existing virtual server.
3. Specify a listen policy priority and expression.

After you have created this virtual server, you bind it to one or more services as described in [Setting Up Basic Load Balancing](#).

**Assign weights to services**

September 21, 2020

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the Citrix ADC appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

| Load Balancing Methods                                            | Service Selection with Weights                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Round Robin                                                       | The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see <a href="#">The Round Robin Method</a> . |
| Least Connection                                                  | The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see <a href="#">The Least Connection Method</a> .                                                                                                                |
| Least Response Time and Least Response Time Method using Monitors | The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see <a href="#">The Least Response Time Method</a> .                                                                                              |
| Least Bandwidth                                                   | The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see <a href="#">The Least Bandwidth Method</a> .                                                                                                                           |
| Least Packets                                                     | The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see <a href="#">The Least Packets Method</a> .                                                                                                                               |
| Custom Load                                                       | The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see <a href="#">The Custom Load Method</a> .                                                                                                                                    |
| Hashing methods and Token method                                  | Weighting is not supported by these load balancing methods.                                                                                                                                                                                                                                                     |

### To configure a virtual server to assign weights to services by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -weight <Value> <ServiceName>
```

```
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
2 <!--NeedCopy-->
```

**To configure a virtual server to assign weights to services by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and then click in the **Services** section.
3. In the weight column for the service, assign a weight to the service.

**Configure the MySQL and Microsoft SQL server version setting**

September 21, 2020

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

**To set the Microsoft SQL server version parameter by using the CLI**

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

```
1 set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Example**

```
1 > set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
2 Done
3 > show lb vserver myMSSQLvip
4 myMSSQLvip (190.0.2.12:1433) - MSSQL Type: ADDRESS
5 . . .
```

```
6   . . .
7     Mssql Server Version: 2008R2
8     . . .
9     . . .
10  Done
11  >
12  <!--NeedCopy-->
```

### To set the MySQL server version parameter by using the CLI

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

```
1  set lb vserver <name> -mysqlServerVersion <string>
2
3  show lb vserver <name>
4  <!--NeedCopy-->
```

### Example

```
1  > set lb vserver mysqlsvr -mysqlserverversion 5.5.30
2  Done
3  > sh lb vserver mysqlsvr
4     mysqlsvr (2.22.2.222:3306) - MYSQL      Type: ADDRESS
5     . . .
6     . . .
7     Mysql Server Version: 5.5.30
8     . . .
9     . . .
10  Done
11  >
12  <!--NeedCopy-->
```

### To set the MySQL or Microsoft SQL server version parameter by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server of type MySQL or MSSQL, and set the server version.

## Multi-IP virtual servers

September 21, 2020

The Citrix ADC supports creating a single load balancing virtual server with multiple non-consecutive/consecutive IPv4 and IPv6 addresses of type VIP. Each VIP address bound to a virtual server is treated as an individual virtual server. These virtual servers have the same protocol and other virtual server level settings. A virtual server with multiple VIP addresses is also called multi-IP virtual server.

The following are some advantages of using multi-IP virtual servers:

- A multi-IP virtual server offloads the work of creating many virtual servers with the same settings and service bindings.
- Multi-IP virtual servers effectively reduces the possibility of reaching the maximum limit on virtual server entities.
- One multi-IP virtual server can be used for clients in different subnets to connect to the same set of servers.
- Only one multi-IP virtual server can be used for IPv6 and IPv4 clients to connect to the same set of servers.

### Configure a multi-IP virtual server

Configuring a multi-IP virtual server consists of the following tasks:

- Create an IPset and bind multiple IP addresses to it.
- Bind the IPset to load balancing virtual servers.

Note the following points related to IPset configuration:

- An IPset can have:
  - non-consecutive/consecutive IPv4 addresses and IPv6 addresses
  - combinations of IPv4 and IPv6 addresses.
- All IPv4/IPv6 addresses to be associated with virtual servers using IPset must be of type VIP.
- A single IPset can be bound to multiple virtual servers.
- IPv4/IPv6 addresses can be bound/unbound to/from IPset irrespective any existing IPset bindings to virtual servers.
- You must unset the IPset binding to a virtual server before binding a new IPset to it.

### To add an IPset and bind multiple VIP addresses to it by using the CLI

At the command prompt, type:

```
1 add ipset <name>
2
3 bind ipset <name> <IPaddress1 ... >
4
5 bind ipset <name> <IPaddress2... >
6
7 show ipset <name>
8 <!--NeedCopy-->
```

### To bind the IPset to a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -ipset <ipset name>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### To add an IPset and bind multiple VIP addresses to it by using the GUI

Navigate to **System > Network > IPSets**, and create an IPset with multiple VIP addresses.

### To bind the IPSet to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server to which you want to bind the created IPset.
2. In **Basic Settings**, set the **IPset** parameter to the name of the created IPset.

```
1 > add ipset IPSET-1
2
3
4 Done
5
6 > bind ipset IPSET-1 9.9.9.10
7
8
9 Done
10
11 > bind ipset IPSET-1 1000::20
12
13
14 Done
```

```
15
16 > add lb vserver LBVS-1 HTTP 8.8.8.10 80 - ipset IPSET-1
17
18
19 Done
20
21 > add service SVC-1 3.3.3.10 HTTP 80
22
23
24 Done
25
26 > add service SVC-2 3.3.3.100 HTTP 80
27
28
29 Done
30
31 > bind lb vserver LBVS-1 SVC-1
32
33
34 Done
35
36 > bind lb vserver LBVS-1 SVC-2
37
38
39 Done
```

### **GSLB support for multi-IP virtual servers**

In cloud deployments, floating IP addresses are not supported. These IP addresses are required for high availability deployments. With IPset support, you can associate a private IP address to each of the primary and secondary instances. One of the private IP addresses is added when creating the virtual server. The other IP address is bound to an IPset. This IPset is then associated with the virtual server. Typically a public IP is mapped to one of the private IPs based on which appliance is taking the traffic. During failover, this mapping changes dynamically to route the traffic to the new primary.

In GSLB deployments, the GSLB service represents the virtual server's IP address, port number, and service type. This IP address can be the IP address that is configured while adding the virtual server or it can be one of the IP addresses in the IPset. Irrespective of the IP address used in GSLB service, statistics and state are inherited from the same load balancing virtual server entity.

Parent child topology is also supported with IPset. The load balancing virtual servers on the child sites can have the IPset associated with it. Communication between the parent and the child sites is always using public IP address and the public port of the GSLB service

Also, with IPset support, you can have a single virtual server endpoint for both IPv4 and IPv6 traffic. Previously, you had to configure different virtual servers for IPv4 and IPv6 traffic. With IPset support, you can associate IPv4 and IPv6 IP addresses to the same IP set. You can add different GSLB services representing the IPv4 and IPv6 endpoints.

**Note:** Only one IP address is associated with a GSLB service. You cannot associate an IPset with a GSLB service.

For details on configuring GSLB entities, see the topic [Configure GSLB entities individually](#).

## Configure diameter load balancing

September 21, 2020

The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a Citrix ADC deployment:

A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices situated at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The Citrix ADC appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The Citrix ADC uses message based load balancing.

#### Example:

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there

is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

### **How diameter load balancing works**

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

### **Load balancing diameter traffic**

When a client sends a request to the Citrix ADC appliance, the appliance parses the request and contextually load balances it to a Diameter server on the basis of a persist AVP. The appliance has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the appliance maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- The Citrix ADC appliance adds a route entry by putting its identity, because the client sees the appliance as a relay agent.

Note: If a Diameter message spans more than one packet, the appliance accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the appliance splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

## Disconnect a session

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the Citrix ADC appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

## Configure load balancing for diameter traffic

To configure the Citrix ADC appliance to load balance diameter traffic, you must first set the Diameter parameters on the appliance, then add the diameter monitor, add the diameter services, bind the services to the monitor, add the diameter load balancing virtual server, and bind the services to the virtual server.

### To configure load balancing for diameter traffic by using the command line interface

Configure the diameter parameters.

```
1 set ns diameter -identity <string> -realm <string> -
   serverClosePropagation <YES|NO>
2 <!--NeedCopy-->
```

#### Example:

```
1 set ns diameter -identity mydomain.org -realm org -
   serverClosePropagation YES
2 <!--NeedCopy-->
```

Add a Diameter monitor.

```
1 add lb monitor <monitorName> DIAMETER -originHost <string> -
   originRealm <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb monitor diameter_mon DIAMETER -originHost mydomain.org -
  originRealm org
2 <!--NeedCopy-->
```

Create the Diameter services.

```
1 add service <name> <IP> DIAMETER <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add service diameter_svc0 10.102.82.86 DIAMETER 3868
2
3 add service diameter_svc1 10.102.82.87 DIAMETER 3868
4
5 add service diameter_svc2 10.102.82.88 DIAMETER 3868
6
7 add service diameter_svc3 10.102.82.89 DIAMETER 3868
8 <!--NeedCopy-->
```

Bind the Diameter services to the Diameter monitor.

```
1 bind service <name>@ monitorName <monitorName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind service diameter_svc0 -monitorName diameter_mon
2
3 bind service diameter_svc1 -monitorName diameter_mon
4
5 bind service diameter_svc2 -monitorName diameter_mon
6
7 bind service diameter_svc3 -monitorName diameter_mon
8 <!--NeedCopy-->
```

Add a Diameter load balancing virtual server with Diameter persistence.

```
1 add lb vserver <name> DIAMETER <IPAddress> <port> -
  persistenceType DIAMETER -persistAVPno <positive_integer>
2 <!--NeedCopy-->
```

**Example:**

---

```
1 add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -
   persistenceType DIAMETER -persistAVPno 263
2 <!--NeedCopy-->
```

Bind the Diameter services to the Diameter load balancing virtual server.

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver diameter_vs diameter_svc0
2
3 bind lb vserver diameter_vs diameter_svc1
4
5 bind lb vserver diameter_vs diameter_svc2
6
7 bind lb vserver diameter_vs diameter_svc3
8 <!--NeedCopy-->
```

Save the configuration.

```
1 save ns config
2 <!--NeedCopy-->
```

**Note:** You can also configure load balancing of Diameter traffic over SSL by using the **SSL\_DIAMETER** service type.

**To configure load balancing for Diameter traffic by using the configuration utility**

1. Navigate to **System > Settings > Change Diameter Parameters** and set the diameter parameters.
2. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a load balancing virtual server of type Diameter.
3. Create a service of type Diameter.
4. Create a monitor of type Diameter. In Special parameters, set the origin host and origin realm.
5. Bind the monitor to the service, and bind the service to the Diameter virtual server.
6. In Advanced Settings, click **Persistence**, specify Diameter and enter a persistence AVP number.
7. Click **Save**, and click **Done**.

## Configure FIX load balancing

September 21, 2020

Financial Information eXchange (FIX) protocol is an open message standard used in financial industry for electronic exchange of information related to securities transaction between trading partners. FIX/SSL\_FIX protocol is used extensively by buy-side and sell-side firms, trading platforms, and regulators for communicating trade information.

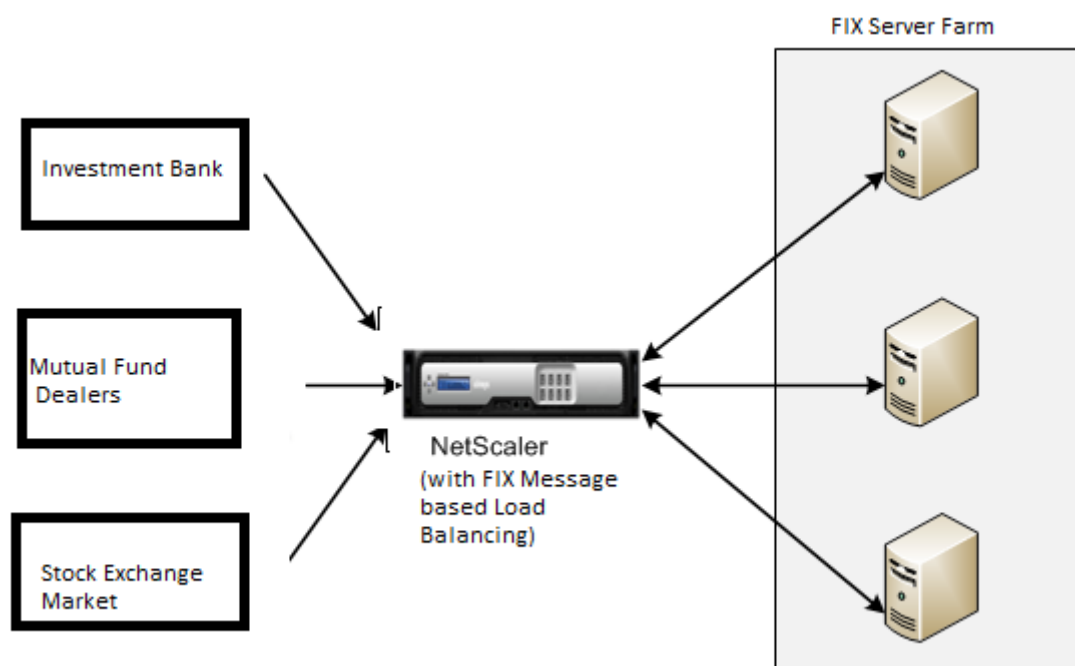

This feature enables you to configure a FIX or SSL\_FIX load balancing virtual server to distribute incoming FIX messages and provide security in FIX messaging. Citrix ADC supports FIX message based load balancing (MBLB) for FIX 4.1, FIX 4.2, FIX 4.3 and FIX 4.4 versions.

FIX MBLB on a Citrix ADC appliance provides the following benefits:

1. Efficient management of FIX or SSL\_FIX servers with superior HA and health monitoring.
2. SYN protection to all FIX or SSL\_FIX servers.
3. FIX session persistence.

### How FIX load balancing works

A FIX MBLB setup includes a FIX load-balancing virtual server and multiple load-balanced FIX servers. The FIX virtual server receives incoming client traffic, parses the incoming traffic into FIX messages, selects a FIX server for each FIX message and forwards the message to the selected FIX server. The following conceptual drawing illustrates a typical FIX load balancing set up.

In a basic FIX MBLB setup, the FIX virtual server distributes FIX messages coming from clients to the load-balanced FIX servers using the round robin load-balancing method. With persistence of type FIXSESSION enabled, the FIX virtual server selects the same server for different FIX messages belonging to the same FIX session. The FIX session is determined based on the values of FIX fields SenderCompID (tag 49) and TargetCompID (tag 56).

## Configure and monitor load balancing for FIX traffic

Following are the configurations that you must do to load balance FIX message traffic:

1. Configuring FIX load balancing virtual server
2. Configuring SSL\_FIX load balancing virtual server
3. Configuring FIX load balancing service
4. Configuring SSL\_FIX load balancing service
5. Configuring FIXSESSION persistence
6. Setting persistence timeout
7. Displaying FIX/SSL\_FIX stats
8. Monitoring FIX/SSL\_FIX persistent sessions

### To configure a FIX load balancing server by using the command line interface

At the command prompt, type:

```
1 add lb vsriver <name> FIX <IP> <PORT>
2 <!--NeedCopy-->
```

Example

```
1 add lb vsriver vs1 FIX 10.102.82.86 3868
2 <!--NeedCopy-->
```

### To configure a SSL\_FIX load balancing virtual server by using the command line interface

At the command prompt, type:

```
1 add lb vsriver <name> SSL_FIX <IP> <PORT>
2 <!--NeedCopy-->
```

Example

```
1 add lb vsriver vs1 SSL_FIX 10.102.82.86 3868
2 <!--NeedCopy-->
```

### To configure a FIX service by using the command line interface

At the command prompt, type:

```
1 add service <name> <ip-addr> FIX <port>
2 <!--NeedCopy-->
```

Example

```
1 add service_svc1 10.102.82.86 FIX 3868
2 <!--NeedCopy-->
```

### To configure a SSL\_FIX service by using the command line interface

At the command prompt, type:

```
1 add service <name> <ip-addr> SSL_FIX <port>
2 <!--NeedCopy-->
```

Example

```
1 add service_svc1 10.102.82.86 SSL_FIX 3868
2 <!--NeedCopy-->
```

### To configure FIXSESSION persistence by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name> -persistenceType FIXSESSION
2 <!--NeedCopy-->
```

Example

```
1 set lb vserver vs1 -persistenceType FIXSESSION
2 <!--NeedCopy-->
```

### To set persistence timeout by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name> -timeout <value>
2 <!--NeedCopy-->
```

### Example

```
1 set lb vserver vs1 - timeout 2
2 <!--NeedCopy-->
```

### To display FIX stats by using the command line interface

At the command prompt, type:

```
1 stat lb vserver <name>
2 <!--NeedCopy-->
```

### Example

```
1 stat lb vserver_svc1
2 <!--NeedCopy-->
```

### To bind FIX service to FIX virtual server by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name> <service name>
2 <!--NeedCopy-->
```

### Example

```
1 bind lb vserver vs1 svc1
2 <!--NeedCopy-->
```

### To display FIX persistent sessions by using the command line interface

At the command prompt, type:

```
1 show lb persistentSessions <name>
2 <!--NeedCopy-->
```

### Example

```
1 show lb persistentSessions vs1
2 <!--NeedCopy-->
```

### Note

Note: You can now configure the load balancing of FIX traffic over SSL by using the SSL\_FIX service type. This service provides secured communication for FIX messages.

## To configure FIX load balancing virtual server by using the GUI

1. Navigate to the **Configuration > Traffic Management > Load Balancing > Virtual Servers** page and click **Add** to create a FIX Load Balancing virtual server.
2. On the **Load Balancing Virtual Server** page, set the server parameters:
  - a) Virtual Server Name
  - b) Protocol type as “FIX”
  - c) Server IP Address Type
  - d) Server IP Address
  - e) Server Port Number
3. Click **OK** and **Continue** to set additional parameters.
4. In the **Services** section, select or add a new FIX load balancing virtual service, and bind it to the FIX server.
5. In the **Persistence** section, set the following parameters:
  - a) Persistence type as ‘FIXSESSION’
  - b) Time-out interval
6. Click **OK** and then **Done**.

## To edit a FIX load balancing virtual server by using the GUI

Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** page, select a FIX server and click **Edit**.

## To delete a FIX load balancing virtual server by using the GUI

Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** page, select a FIX server and click **Delete**.

## To configure FIX Load Balancing Virtual Service by using the GUI

1. Navigate to **Configuration > Traffic Management > Load Balancing > Services** page and click **Add** to create a FIX Load Balancing virtual service.
2. On the **Services** page, set the following parameters. You can click the ‘More’ arrow to set additional parameters such as Traffic Domain, Hash ID, Server ID, Cache Type, and Number of Active Connections.

- a) Service Name – FIX Virtual Service Name
  - b) Choose Virtual Server type as (New or Existing)
  - c) Protocol – Protocol Type as 'FIX'
  - d) Server – Virtual Server IP address
  - e) Port – Server Port Number
3. Click **OK** and **Continue** to set other parameters such as Monitors, Threshold & Timeout, Profiles, and Policies.
  4. Click **OK** and then **Done**.

### **To edit a FIX load balancing virtual service by using the GUI**

Navigate to **Configuration > Traffic Management > Load Balancing > Services** page, select a **FIX service** and click **Edit**.

### **To delete a FIX load balancing virtual service by using the GUI**

Navigate to **Configuration > Traffic Management > Load Balancing > Services** page, select a FIX service and click **Delete**.

### **To display FIX load balancing server statistics**

Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** page and then click **Statistics** to display the FIX server statistics.

### **To display Persistent sessions for a FIX server by using the GUI**

Navigate to **Configuration > Traffic Management** page and, under **Monitor Sessions** click **Virtual Server Persistent Sessions**.

### **To clear Persistent sessions for a FIX server by using the GUI**

1. Navigate to **Configuration > Traffic Management** page and, under **Monitor Sessions** click **Clear Persistent Sessions**.
2. On the **Clear Persistent Sessions** page, set the following parameters:
  - a) Virtual Server – Choose a FIX virtual server
  - b) Persistence Parameter – Choose a FIX persistence parameter
3. Click **OK**.

## Protect a load balancing configuration against failure

September 21, 2020

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring the Citrix ADC appliance to redirect excess traffic to an alternate URL, configuring a backup load balancing virtual server, and configuring stateful connection failover.

## Redirect client requests to an alternate URL

September 21, 2020

In the event that a load balancing virtual server of type HTTP or type HTTPS goes DOWN or is disabled, you can redirect requests to an alternate URL by using an HTTP 302 redirect. The alternate URL can provide information about the status of the server.

You can redirect to a page on the local server or a remote server. You can redirect to a relative URL or an absolute URL. If you configure a redirect to a relative URL consisting of a domain name with no path, the Citrix ADC appliance appends the path of the incoming URL to the domain. If you use an absolute URL, the HTTP redirect is sent to that URL with no modification.

**Note:** If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

## To configure a virtual server to redirect the client request to a URL by using the CLI

At the command prompt, type:

```
1 set lb vserver <vServerName> -redirectURL <URLValue>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -redirectURL http://www.newdomain.com/
  mysite/maintenance
2 <!--NeedCopy-->
```

## To configure a virtual server to redirect the client request to a URL by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and specify a redirect URL.

## Configure a backup load balancing virtual server

March 9, 2021

You can configure the Citrix ADC appliance to direct requests to a backup virtual server in the event that the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

Note:

The backup virtual server continues to handle the existing connections, even after the primary virtual server is deleted or disabled.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you may want to configure the backup virtual server to remain in control in the event that it takes over. For example, you may want to sync updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control in the event that the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

**Note:** If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

## To set a backup virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <vServerName> -backupVserver <BackupVServerName> [-  
    disablePrimaryOnDown]  
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -  
    disablePrimaryOnDown  
2 <!--NeedCopy-->
```

## To set a backup virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and select a backup virtual server.
3. If you want the backup virtual server to remain in control until you manually enable the primary virtual server even if the primary virtual server comes back up, select **Disable Primary When Down**.

**Note:** Starting from Citrix ADC version 12.1 build 51.xx, the GUI displays the effective state of that server indicating if the backup is active or not.

The effective state of the current server can be one of the following:

- **UP** – Indicates that the server is UP
- **DOWN** – Indicates that the server is DOWN
- **UP (Backup Active)** – Indicates that either the primary or the secondary virtual server is UP and traffic is directed to the backup virtual server.
- **DOWN (Backup Active)** – Indicates that both the primary and the backup virtual servers are down and traffic is routed to the backup virtual server.

When the **Disable Primary When Down** option is enabled on the primary virtual server and the primary server goes DOWN and is back UP again, the traffic is still served by the backup virtual server until the primary virtual server is re-enabled explicitly. You can use the command `**enable lb vserver **` command to re-enable the primary virtual server.

## Configure spillover

September 21, 2020

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period after the load on the primary falls below the threshold.

**Note:** Usually, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). However with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.

You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, use a Citrix ADC rule to specify the conditions for the spillover to occur. Citrix ADC rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

For instructions for assigning a virtual server as the backup for another virtual server, see [Configuring a Backup Load Balancing Virtual Server](#).

## Configure a predefined spillover method

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the Citrix ADC appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP, it diverts new requests to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the Citrix ADC appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

**Note:** With RTSP virtual servers, the Citrix ADC appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

### To configure a predefined spillover method for a virtual server by using the command line interface

At the command prompt, type:

```
1 set lb vserver <vServerName> -soMethod <spillOverType> -soThreshold <
   positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <
   positiveInteger>
2 <!--NeedCopy-->
```

### Example

```
1 set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -
   soPersistence enabled -soPersistenceTimeout 2
2 <!--NeedCopy-->
```

### To configure a predefined spillover method for a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and set the spillover parameters.

## Configure policy based spillover

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover on the basis of the virtual server's response time, or based on number of connections in the virtual server's surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy, configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all the backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

### Configuring a Spillover Action

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

#### To configure policy based spillover by using the command line interface

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
1 add spillover action <name> -action SPILLOVER
2
3 show spillover action <name>
4 <!--NeedCopy-->
```

#### Example

```
1 add spillover action mySoAction -action SPILLOVER
2 Done
3 <!--NeedCopy-->
```

```
1 show spillover action mySoAction
2 1) Name: mySoAction Action: SPILLOVER
3 Done
4 <!--NeedCopy-->
```

### Selecting an Expression for the Spillover Policy

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you can use one of the following expressions:

```
1 SYS.VSERVER("vserver").RESPTIME.GT(<int>)
2 SYS.VSERVER("vserver").STATE.EQ(" <string> "), and
3 SYS.VSERVER("vserver").THROUGHPUT.LT (<int>)
4 <!--NeedCopy-->
```

In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

#### Averagesurgecount

Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

#### Activeservices

Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

#### Activetransactions

Returns the value of the virtual-server-level counter for current active transactions.

#### is\_dynamic\_limit\_reached

Returns a Boolean TRUE if the number of connections that the virtual server manages is equal to the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

Table 1. Converting predefined spillover methods to policy expressions

| Predefined spillover method | Corresponding expression                                                                                                                                                                                                                                                                                             |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONNECTION                  | SYS.VSERVER("<vserver-name>").CONNECTIONS, used with the GT(int) arithmetic function.                                                                                                                                                                                                                                |
| BANDWIDTH                   | SYS.VSERVER("<vserver-name>").THROUGHPUT, used with the GT(int) arithmetic function.                                                                                                                                                                                                                                 |
| HEALTH                      | SYS.VSERVER("<vserver-name>").HEALTH, used with the LT(int) arithmetic function.                                                                                                                                                                                                                                     |
| DYNAMICCONNECTION           | SYS.VSERVER("<vserver-name>").IS_DYNAMIC_LIMIT_REACHED <b>Note:</b> If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that statistics required for spillover to work are collected. |

### Configuring a Spillover Policy

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

#### To configure a spillover policy by using the command line interface

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```

1 add spillover policy <name> -rule <expression> -action <string> [-
  comment <string>]
2
3 show spillover policy <name>
4 <!--NeedCopy-->
```

#### Example

```

1 > add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT
  (50) -action mySoAction -comment "Triggers spillover when the
  vserver's response time is greater than 50 ms."
```

```

2 Done
3
4 > show spillover policy mySoPolicy
5
6 1) Name: mySoPolicy Rule: "SYS.VSERVER("v1").RESPTIME.GT(50)" Action:
   mySoAction Hits: 0 ActivePolicy: 0
7 Comment: "Triggers spillover when the vserver's response time is
   greater than 50 ms."
8 Done
9 >
10 <!--NeedCopy-->

```

### Binding a Spillover Policy to a Virtual Server

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers). You can bind multiple policies to a virtual server, with Goto expressions controlling the flow of evaluation.

#### To bind a spillover policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

```

1 bind (lb | cs | gslb) vserver <name> -policyName <string> -priority <
   positive_integer> [-gotoPriorityExpression <expression>]
2
3 show (lb | cs | gslb) vserver <name>
4 <!--NeedCopy-->

```

### Example

```

1 > bind lb vserver vserver1 -policyName mySoPolicy -priority 5
2 Done
3 > show lb vserver vserver1
4 vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS
5 . . .
6
7 1) Spillover Policy Name: mySoPolicy Priority: 5
8 GotoPriority Expression: END
9 Flowtype: REQUEST
10 Done
11 >

```

```
12 <!--NeedCopy-->
```

### Configuring a Backup Action for a Spillover Event

A backup action specifies what to do when the spillover threshold is reached but one or more backup virtual servers are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests even before establishing TCP or SSL connections until the number of requests falls below the threshold. Therefore, lesser memory resources are utilized as the connections are reset even before allocating any data structures.

### To configure a backup action for spillover by using the CLI

At the command prompt, type the following commands to configure a backup action and verify the configuration:

```
1 set lb vserver <name> -soBackupAction <soBackupAction>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Example

```
set lb vserver vs1 -soBackupAction REDIRECT -redirectURL http://www.mysite.com/
maintenance
Done
show lb vserver vs1
vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
State: UP
...
Redirect URL: http://www.mysite.com/maintenance
...
Done
```

### To configure a backup action for spillover by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and then specify a spillover backup action.

## Connection failover

May 24, 2021

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a Citrix ADC High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary Citrix ADC appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

#### Note:

Consider a HA setup, where a client establishes a session with the primary node, which in turn establishes a session with the back end server. When a failover is triggered in this state, the packets received on a new primary from the existing client and server nodes are treated as stale packets, and the client and server connections are reset. Whereas if stateless connection failover is enabled (USIP is ON), after the failover, the connections are not reset when you receive packets from client or server nodes. Instead, the client and server connections are created dynamically.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

Connection failover is helpful if your deployment has long lasting connections. For example, if you are downloading a large file over FTP and a failover occurs during the download, the connection breaks and the download is aborted. However, if you configure connection failover in stateful mode, the download continues even after the failover.

### How connection failover works on Citrix ADC appliances

In stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

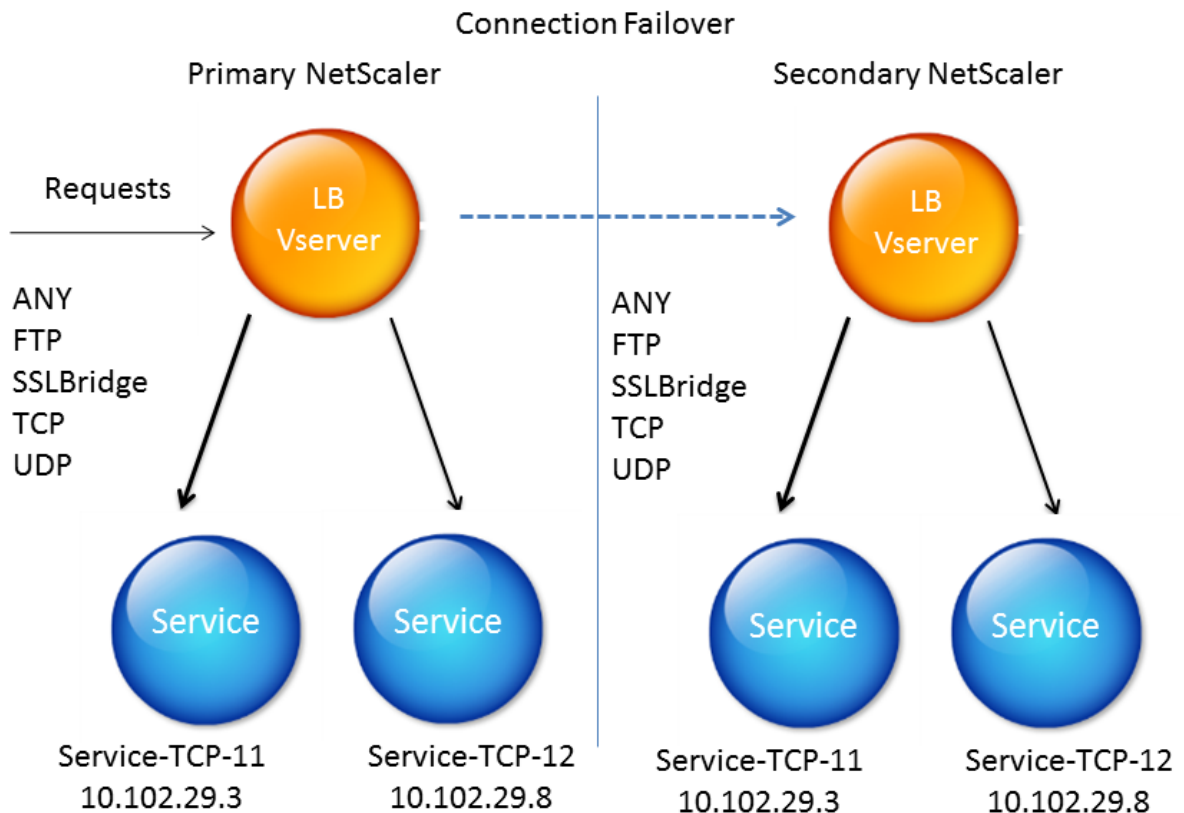

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server may experience a brief disruption and retransmissions.

Note:

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify correct configuration of the passwords, use the show rpcnode command from command line or use the RPC option of the Network menu in GUI.

A basic HA configuration with connection failover contains the entities shown in the following figure.

Figure 1. Connection Failover Entity Diagram

**Note**

Connection failover is not supported after either of the following events:

- 1 - An upgrade to a later release.
- 2 - An upgrade to a later build within the same release, **if** the **new** build uses a different HA version.

**Supported setup**

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content switching virtual servers. If you enable connection failover on load balancing virtual servers that are attached to a content switching virtual server, connection failover will not work because the load balancing virtual servers do not initially accept the traffic.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

| Setting                         | Stateless                                                                                                                              | Stateful                                                           |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| Service type                    | ANY.                                                                                                                                   | ANY, UDP, TCP, FTP, SSL_BRIDGE.                                    |
| Load balancing methods          | All methods supported for the service type ANY. However, if Source IP persistence is not set, the SRCIPSRCPORHASH method must be used. | All methods applicable to the supported service types.             |
| Persistence types               | SOURCEIP persistence.                                                                                                                  | All types applicable to the supported service types are supported. |
| USIP                            | Must be ON.                                                                                                                            | No restriction. It can be ON or OFF.                               |
| Service bindings                | Service can be bound to only one virtual server.                                                                                       | Service can be bound to one or more virtual servers.               |
| Internet Protocol (IP) versions | IPv4 and IPv6                                                                                                                          | IPV4 and IPV6                                                      |
| Redundancy support              | Clustering and high availability                                                                                                       | High availability                                                  |

**Note:**

Stateful connection failover is supported only for connection-based switching services, for example, TCP. Because HTTP uses request-based switching, it does not support connection failover. In SSL, the existing connections are reset after the failover.

**Features affected by connection failover**

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects Citrix ADC Features

| Feature              | Impact of Connection Failover                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SYN protection       | For any connection, if a failover occurs after the appliance issues SYN-ACK but before it receives the final ACK, the connection is not supported by connection failover. The client must reissue the request to establish the connection. |
| Surge protection     | If the failover occurs before a connection with the server is established, the new primary appliance tries to establish the connection with the server. It also retransmits all the packets held in the course of surge protection.        |
| Access down          | If enabled, the access-down functionality takes precedence over connection failover.                                                                                                                                                       |
| Application firewall | The Application firewall feature is not supported.                                                                                                                                                                                         |
| INC                  | Independent network configuration is not supported in the high availability (HA) mode.                                                                                                                                                     |
| TCP buffering        | TCP buffering is not compatible with connection mirroring.                                                                                                                                                                                 |
| Close on response    | After failover, the NATPCBs may not be closed on response.                                                                                                                                                                                 |

**To configure connection failover by using GUI**

Navigate to **Traffic Management > Load Balancing > Virtual Servers**. Open the virtual server, and in **Advanced Settings**, click **Protection**, and select **Connection Failover** as **Stateful**.

### To configure connection failover by using CLI

At the command prompt:

```
1 set lb vserver <vServerName> -connFailover <Value>
2 show lb vserver <vServerName>
```

#### Example:

```
set lb vserver Vserver-LB-1 -connFailover stateful
Done
```

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

### To disable connection failover by using CLI

At the command prompt:

```
1 set lb vserver <vServerName> -connFailover <Value>
2 show lb vserver <vServerName>
```

#### Example:

```
set lb vserver Vserver-LB-1 -connFailover disable
Done
```

### To disable connection failover by using GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**. Open the virtual server, in **Protection**, select **Connection Failover** as Disabled.

## Flush the surge queue

September 21, 2020

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

### **To flush a surge queue by using the CLI**

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.

- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
1 flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
2 <!--NeedCopy-->
```

### Examples

```
1 flush ns surgeQ - name SVC1ANZGB - serverName 10.10.10.1 80
2 <!--NeedCopy-->
```

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

```
1 flush ns surgeQ
2 <!--NeedCopy-->
```

The above command flushes all the surge queues on the appliance.

### To flush a surge queue by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

## Manage a load balancing setup

September 21, 2020

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced

servers and eventually new Citrix ADC appliances, which must be configured and added to the existing setup. Old servers wear out and need to be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology may also require modifications to your load balancing setup. Therefore, you will need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of a number of other features that facilitate management of the traffic through your load balancing setup.

## Manage server objects

September 21, 2020

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not already exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the Citrix ADC appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

### To enable a server by using the CLI

At the command prompt, type:

```
1 enable server <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 enable server 10.102.29.5
2 <!--NeedCopy-->
```

### To enable or disable a server object by using the GUI

1. Navigate to Traffic Management > Load Balancing > Servers.
2. Select the server and, in the Action list, select Enable or Disable.

## To disable a server object by using the CLI

At the command prompt, type:

```
1 disable server <name> <delay>
2 <!--NeedCopy-->
```

### Example:

```
1 disable server 10.102.29.5 30
2 <!--NeedCopy-->
```

## To remove a server object by using the CLI

At the command prompt, type:

```
1 rm server <name>
2 <!--NeedCopy-->
```

### Example:

```
1 rm server 10.102.29.5
2 <!--NeedCopy-->
```

## To remove a server object by using the GUI

1. Navigate to Traffic Management > Load Balancing > Servers.
2. Select a server, and click Remove.

## Manage services

September 21, 2020

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service's state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the Citrix ADC configuration.

## To enable or disable a service by using the command line interface

At the command prompt, type:

```
1 enable service <name>
2
3 disable service <name> <DelayInSeconds>
4 <!--NeedCopy-->
```

### Examples:

```
1 enable service Service-HTTP-1
2 disable service Service-HTTP-1 30
3 <!--NeedCopy-->
```

## To enable or disable a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service and, in the Action list, select Enable or Disable.

## Manage a load balancing virtual server

September 21, 2020

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual service's state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the downStateFlush parameter. If downStateFlush is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

## To enable or disable a virtual server by using the command line interface

At the command prompt, type:

```
1 enable lb vserver <name>
2 <!--NeedCopy-->
```

```
1 disable lb vserver <name>
2 <!--NeedCopy-->
```

**Examples:**

```
1 enable lb vserver Vserver-LB-1
2 disable lb vserver Vserver-LB-1
3 <!--NeedCopy-->
```

**To enable or disable a virtual server by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select a virtual server, and in the Action list, select Enable or Disable.

**To unbind a service from a virtual server by using the command line interface**

At the command prompt, type:

```
1 unbind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 unbind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To unbind a service from a virtual server by using the configuration utility**

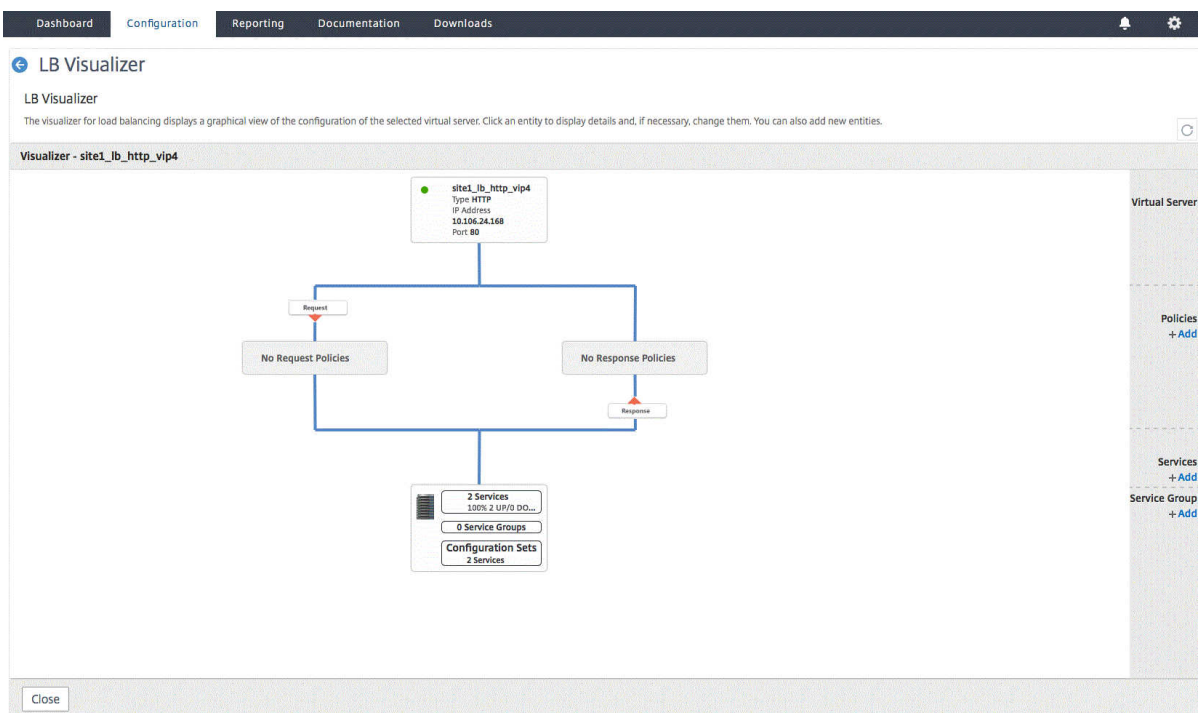

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services section.
3. Select a service and click Unbind.

## Load balancing visualizer

September 21, 2020

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in a graphical format. Following is an example of the Visualizer display.

Figure 1. Load Balancing Visualizer Display

You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. The services in the container have the same properties, with the exception of the name, IP address, and port, and their monitor bindings should have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services; otherwise, it is placed in its own container.

The following procedures provide only basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all of the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration utility.

### **To view load balancing virtual server properties by using the Visualizer**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

### **To view configuration details for services, service groups, and monitors by using the Visualizer**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click the entity to view the configuration details of the entity that is bound to this virtual server, you can do the following:

### **To view configuration details for policies and policy labels by using the Visualizer in the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click policies entity to view policies that are bound to this virtual server.

### **To modify a resource in a load balancing configuration by using the Visualizer**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.

### **To add a load balancing configuration by using the Visualizer**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click + to add the resource.

## Manage client traffic

September 21, 2020

Managing client connections properly helps to ensure that your applications remain available to users even when your Citrix ADC appliance is experiencing high loads. A number of load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.
- **SureConnect.** You can use load balancing with the SureConnect feature to redirect important requests to a custom Web page, insulating them from delays due to network congestion.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the Citrix ADC appliance is experiencing high loads.
- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response.** You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, appliance responds even if one virtual server set to ACTIVE is UP.

## Configure sessionless load balancing virtual servers

September 21, 2020

When the Citrix ADC appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the appliance resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

### Supported setup

Citrix ADC sessionless load balancing supports the following service types and load balancing methods:

#### Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

#### Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

## Limitations

Sessionless load balancing has the following limitations:

- The appliance must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.
- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address will not be changed.

### Note:

- While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.
- To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the Citrix ADC appliance.

## To add a sessionless virtual server by using the CLI

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

```
1 add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -m <
  redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <
  load_balancing_method>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -
  lbMethod roundrobin -m ip
2 Done
3 show lb vserver sesslessv1
4 sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
5 State: DOWN
6 ...
```

```
7     Effective State: DOWN
8     Client Idle Timeout: 120 sec
9     Down state flush: ENABLED
10    ...
11    Persistence: NONE
12    Sessionless LB: ENABLED
13    Connection Failover: DISABLED
14    L2Conn: OFF
15    1) Policy : cmp_text Priority:8680 Inherited
16    2) Policy : cmp_nocmp_ie60 Priority:8690 Inherited
17 <!--NeedCopy-->
```

### To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

```
1 set lb vserver <name>@ -m <redirectionMode> --sessionless <(ENABLED|
   DISABLED)> -lbMethod <load_balancing_method>
2 <!--NeedCopy-->
```

### Example

```
1 set lb vserver sesslessv1 -m mac --sessionless ENABLED -lbmethod lrtm
2 Done
3 <!--NeedCopy-->
```

#### Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

### To configure a sessionless virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and in Advanced Settings, click Traffic Settings, and then select Sessionless Load Balancing.

## Redirect HTTP requests to a cache

September 21, 2020

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

### To configure cache redirection on a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vservers <name> -cacheable <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vservers Vserver-LB-1 -cacheable yes
2 <!--NeedCopy-->
```

### To configure cache redirection on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Cacheable.

## Direct requests according to priority

September 16, 2021

#### Warning:

Priority Queuing (PQ) deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. However, Priority Queuing (PQ) is removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see [AppQoE](#) topic.

The Citrix ADC appliance supports prioritization of client requests with its priority queuing feature. This feature allows you to designate certain requests, such as those from important clients, as priority requests and sends them to the “front of the line,” so that the appliance responds to them first. This allows you to provide uninterrupted service to those clients through demand surges or DDoS attacks on your web site.

## To configure priority queuing on a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -pq <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -pq yes
2 <!--NeedCopy-->
```

## To configure priority queuing on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Priority Queuing.

**Note:** You must configure priority queuing globally for it to function correctly.

## Direct requests to a custom web page

September 16, 2021

### Warning:

SureConnect is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. However, SureConnect is removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see [AppQoE](#) topic.

The Citrix ADC appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative web page of your choice when the server that hosts the primary web page is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see [SureConnect](#). After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom web page in use.

Note: For SureConnect to function correctly, you must configure it globally.

## To enable SureConnect on a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -sc <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -sc yes
2 <!--NeedCopy-->
```

## To enable SureConnect on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select SureConnect.

## Enable cleanup of virtual server connections

September 21, 2020

Under certain conditions, you can configure the `downStateFlush` setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

You must not enable the `downStateFlush` setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, `Vserver-LB-1`, with one service bound to it, `Service-TCP-1`. In the table, E and D denote the state of the `downStateFlush` setting: E means Enabled, and D means Disabled.

| Vserver-LB-1 | Service-TCP-1 | State of connections                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E            | E             | Both client and server connections are terminated.                                                                                                                                                                                                                                                                                                                                                                                |
| E            | D             | For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated. |
| D            | E             | For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated. |
| D            | D             | Neither client nor server connections are terminated.                                                                                                                                                                                                                                                                                                                                                                             |

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see

[Graceful Shutdown of Services](#).

### **To configure the down state flush setting on a virtual server by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -downStateFlush <Value>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 set lb vserver Vserver-LB-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

### **To configure the down state flush setting on a virtual server by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Down State Flush.

## **Rewrite ports and protocols for HTTP redirection**

September 21, 2020

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the Citrix ADC appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the `redirectPortRewrite` setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The `redirectPortRewrite` setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.

- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

*Only SSL redirect is enabled. The virtual server can be configured on any port. See the following table:*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a> |

*SSL redirect and port rewrite are enabled. The virtual server is configured on port 80. See the following table:*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com/">https://domain.com/</a>         |

*SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080. See the following table:*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled,

only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

*SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table.*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                                 |
|---------------------------------------------------------------|-----------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="https://domain.com/">https://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="https://domain.com:8080/">https://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>           |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a>   |

*SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a> |

*SSL redirect and port rewrite are enabled. The virtual server is configured on port 444. See the following table:*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="https://domain.com:444/">https://domain.com:444/</a> |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:445/">https://domain.com:445/</a> | <a href="https://domain.com:445/">https://domain.com:445/</a> |

**Scenario 3:** The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

*The virtual server is configured on port 80. See the following table:*

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a> |

The virtual server is configured on port 8080. See the following table:

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:445/">https://domain.com:445/</a> | <a href="https://domain.com:445/">https://domain.com:445/</a> |

Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table:

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a>         |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a> |

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |

| Redirect URL from the Server                                  | Redirect URL sent to the Client                       |
|---------------------------------------------------------------|-------------------------------------------------------|
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com/">https://domain.com/</a> |
| <a href="https://domain.com:444/">https://domain.com:444/</a> | <a href="https://domain.com/">https://domain.com/</a> |

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444. See the following table:

| Redirect URL from the Server                                  | Redirect URL sent to the Client                               |
|---------------------------------------------------------------|---------------------------------------------------------------|
| <a href="http://domain.com/">http://domain.com/</a>           | <a href="http://domain.com/">http://domain.com/</a>           |
| <a href="http://domain.com:8080/">http://domain.com:8080/</a> | <a href="http://domain.com:8080/">http://domain.com:8080/</a> |
| <a href="https://domain.com/">https://domain.com/</a>         | <a href="https://domain.com:444/">https://domain.com:444/</a> |
| <a href="https://domain.com:445/">https://domain.com:445/</a> | <a href="https://domain.com:444/">https://domain.com:444/</a> |

### To configure HTTP redirection on a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -redirectPortRewrite (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
2 <!--NeedCopy-->
```

### To configure HTTP redirection on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Rewrite.

### To configure SSL Redirect on an SSL virtual server or service by using the CLI

At the command prompt, type:

```
1 set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)
2
```

```
3 set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)
4 <!--NeedCopy-->
```

**Example:**

```
1 set ssl vserver Vserver-SSL-1 -sslRedirect enabled
2
3 set ssl service service-SSL-1 -sslRedirect enabled
4 <!--NeedCopy-->
```

**To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click SSL Parameters, and select SSL Redirect.

**Insert IP address and port of a virtual server in the request header**

September 21, 2020

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

**Note:** This option is not supported for wild card virtual servers or dummy virtual servers.

**To insert the IP address and port of the virtual server in the client requests by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -insertVserverIPPort <insertVserverIPPort> [<
  vipHeader>]
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr
2 <!--NeedCopy-->
```

**To insert the IP address and port of the virtual server in the client requests by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Virtual Server IP Port Insertion and specify a virtual server IP port header.

**Use a specified source IP for back-end communication**

July 28, 2021

For communication with the physical servers or other peer devices, the Citrix ADC appliance uses an IP address owned by it as the source IP address. The Citrix ADC appliance maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, the appliance decides which IP address to use. This address pool is used for sending traffic and monitor probes.

In many situations, you want the appliance to use a specific IP address or any IP address from a specific set of IP addresses for back-end communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server may be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the appliance can use only the IP addresses accepted by the server as the source IP address.
- The appliance can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the appliance to use a specified source IP address, create net profiles (network profiles) and configure the appliance entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, Citrix Gateway VPN virtual servers, services, service groups, or monitors. A net profile has Citrix ADC owned IP addresses (SNIPs and VIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, the appliance dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile is used for sending traffic to all the services bound to it. If a net profile is bound to a service group, the appliance uses the profile for all the members of the service group. If a net profile is bound to a monitor, the appliance uses the profile for all the probes sent from the monitor.

Note:

- When a Citrix ADC appliance uses a VIP address to communicate with a server, it uses session entries to identify whether the traffic destined to the VIP address is a response from a server or a request from a client
- You can bind a net profile to Citrix Gateway VPN virtual servers. However, you need to note some points when binding a net profile. For more information, see [Points to note when binding a net profile to VPN virtual server](#).

### **Usage of a net profile for sending traffic**

If the Use Source IP Address (USIP) option is enabled, the appliance uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, the appliance selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, the appliance uses the default method.
- If there is a net profile only on the service/service group, the appliance uses that net profile.
- If there is a net profile only on the virtual server, the appliance uses the net profile.
- If there is a net profile both on the virtual server and service/service group, the appliance uses the net profile bound to the service/service group.

### **Usage of a net profile for sending monitor probes:**

For monitor probes, the appliance selects the source IP in the following manner:

- If there is a net profile bound to the monitor, the appliance uses the net profile of the monitor. It ignores the net profiles bound to the virtual server or service/service group.
- If there is no net profile bound to the monitor,
  - If there is a net profile on the service/service group, the appliance uses the net profile of the service/service group.
  - If there is no net profile even on the service/service group, the appliance uses the default method of selecting a source IP.

Note: If there is no net profile bound to a service, the appliance looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs and VIPs owned by the Citrix ADC appliance. An IP set can consist of both SNIP and VIP addresses. For instructions, see [Creating IP Sets](#).

2. Create net profiles. For instructions, see [Creating a Net Profile](#).
3. Bind the net profiles to the appliance entities. For instructions, see [Binding a Net Profile to a Citrix ADC Entity](#).

**Note:**

- A net profile can have only the IP addresses specified as SNIP and VIP on the Citrix ADC appliance.
- Source IP persistence is not honored for Citrix ADC initiated packets.

## Manage net profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the Citrix ADC appliance uses the addresses specified in the profile as the source IP address.

- For instructions on creating a network profile, see [Creating a Network Profile](#).
- For instructions on binding a network profile to a Citrix ADC entity, see [Binding a Net Profile to a Citrix ADC Entity](#).

## Create an IP set

An IP set is a set of IP addresses, which are configured on the Citrix ADC appliance as Subnet IP addresses (SNIPs) or Virtual IP addresses (VIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set and bind Citrix ADC owned IP addresses to it. SNIP addresses and VIP addresses can be present in the same IP set.

### To create an IP set by using the CLI

At the command prompt, type the following commands:

```
1 add ipset <name>
2
3 bind ipset <name> <IPAddress>
4 <!--NeedCopy-->
```

or

```
1 bind ipset <name> <IPAddress>
2
3 show ipset [<name>]
4 <!--NeedCopy-->
```

The above command shows the names of all the IP sets on the appliance if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

### Examples

```
1 1.
2 > add ipset skpnwipset
3 Done
4 > bind ipset skpnwipset 21.21.20.1
5 Done
6
7 2.
8 > add ipset testnwipset
9 Done
10 > bind ipset testnwipset 21.21.21.[21-25]
11 IPAddress "21.21.21.21" bound
12 IPAddress "21.21.21.22" bound
13 IPAddress "21.21.21.23" bound
14 IPAddress "21.21.21.24" bound
15 IPAddress "21.21.21.25" bound
16 Done
17
18 3.
19 > bind ipset skipipset 11.11.11.101
20 ERROR: Invalid IP address
21 [This IP address could not be added because this is not an IP address
22 owned by the Citrix ADC appliance]
23 > add ns ip 11.11.11.101 255.255.255.0 -type SNIP
24 ip "11.11.11.101" added
25 Done
26 > bind ipset skipipset 11.11.11.101
27 IPAddress "11.11.11.101" bound
28 Done
29 4.
30 > sh ipset
31 1) Name: ipset-1
32 2) Name: ipset-2
33 3) Name: ipset-3
34 4) Name: skpnewipset
35 Done
36
37 5.
38 > sh ipset skpnewipset
39 IP:21.21.21.21
```

```
39 IP:21.21.21.22
40 IP:21.21.21.23
41 IP:21.21.21.24
42 IP:21.21.21.25
43 Done
44 <!--NeedCopy-->
```

### To create an IP set by using the GUI

Navigate to **System > Network > IP Sets**, and create an IP set.

### Create a net profile

A net profile (network profile) consists of one or more SNIP or VIP addresses of the Citrix ADC appliance.

### To create a net profile by using the CLI

At the command prompt, type:

```
1 add netprofile <name> [-srcIp <srcIpVal>]
2 <!--NeedCopy-->
```

If the srcIpVal is not provided in this command, it can be provided later by using the set net profile command.

### Examples

```
1 add netprofile skpnetprofile1 -srcIp 21.21.20.1
2 Done
3
4 add netprofile baksnp -srcIp bakipset
5 Done
6
7 set netprofile yahnp -srcIp 12.12.23.1
8 Done
9
10 set netprofile citkbnp -srcIp citkbipset
11 Done
12 <!--NeedCopy-->
```

## Bind a net profile to a Citrix ADC entity

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor.

Note: You can bind a net profile at the time of creating a Citrix ADC entity or bind it to an existing entity.

### To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

```
1 set lb vserver <name> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

or

```
1 set cs vserver <name> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

### Examples

```
1 set lb vserver skpnwvs1 -netProfile gntnp
2 Done
3 set cs vserver mmdcsv -netProfile mmdnp
4 Done
5 <!--NeedCopy-->
```

### To bind a net profile to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Profiles**, and set a net profile.

### To bind a net profile to a service by using the CLI

At the command prompt, type:

```
1 set service <name> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

**Example**

```
1 set service brnssvc1 -netProfile brnsnp
2 Done
3 <!--NeedCopy-->
```

**To bind a net profile to a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, click **Profiles**, and set a net profile.

**To bind a net profile to a service group by using the CLI**

At the command prompt, type:

```
1 set servicegroup <serviceName> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

**Example**

```
1 set servicegroup ndhsvcgrp -netProfile ndhnp
2 Done
3 <!--NeedCopy-->
```

**To bind a net profile to a service group by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and open a service group.
2. In Advanced Settings, click **Profiles**, and set a net profile.

**To bind a net profile to a monitor by using the CLI**

At the command prompt, type:

```
set monitor -netProfile
```

**Example**

```
1 set monitor brnsecvmon1 -netProfile brnsmonnp
2 Done
3 <!--NeedCopy-->
```

### To bind a net profile to a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Open a monitor, and set the net profile.

## Set a time-out value for idle client connections

April 6, 2021

You can configure a virtual server to terminate any idle client connections after a configured time-out period (in seconds) elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection. By default, the client idle time-out value is set to 180 seconds.

### To set a time-out value for idle client connections by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -cltTimeout <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -cltTimeout 100
2 <!--NeedCopy-->
```

### To set a time-out value for idle client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, click **Traffic Settings**, and set the client idle time-out value in seconds.

## Manage RTSP connections

September 21, 2020

The Citrix ADC appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see [“IP Addressing.”](#)

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see [“Configuring Load Balancing in Direct Server Return Mode.”](#) For more information about configuring DNS, see [“Domain Name System.”](#) In either case, when you configure RTSP load balancing, you must also configure `rtspNat` to match the topology of your load balancing setup.

### To configure RTSP NAT by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> - RTSPNAT <ValueOfRTSPNAT>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver vserver-LB-1 - RTSPNAT ON
2 <!--NeedCopy-->
```

### To configure RTSP NAT by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server of type RTSP.
2. In Advanced Settings, click **Traffic Settings**, and select **RTSP Natting**.

## Manage client traffic on the basis of traffic rate

September 21, 2020

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the Citrix ADC appliance based on the traffic rate. You can throttle the traffic flow if it is too high, cache information based on the traffic rate, and if the traffic rate is too high redirect excess traffic to a different load balancing virtual server. You can apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see [Rate Limiting](#).

## Identify a connection with layer 2 parameters

September 21, 2020

Generally, to identify a connection, Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) to co-exist on the Citrix ADC appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the Citrix ADC appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore Citrix ADC appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

### To configure the L2 connection option by using the CLI

At the command prompt, type:

```
1 add lb vserver <name> <serviceType> <IPAddress>@ <port> -l2Conn ON
2 <!--NeedCopy-->
```

#### Example

```
1 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
2 <!--NeedCopy-->
```

### To configure the L2 connection option by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Layer 2 Parameters.

## Configure the prefer direct route option

September 21, 2020

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the Citrix ADC appliance forwards traffic according to the configured route. If you want the appliance to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a Citrix ADC appliance, the appliance directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, in some cases, you may want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the Citrix ADC appliance.

### To set the prefer direct route option by using the CLI

At the command prompt, type:

```
1 set lb parameter -preferDirectRoute (YES | NO)
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -preferDirectRoute YES
2 <!--NeedCopy-->
```

### To set the prefer direct route option by using the GUI

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing parameters.
2. Select Prefer Direct Route.

## Use a source port from a specified port range for backend communication

September 21, 2020

By default, for configurations with USIP option disabled or with USIP and use proxy port options enabled, the Citrix ADC appliance communicates to the servers from a random source port (greater than 1024).

The appliance supports using a source port from a specified port range for communicating to the servers. One of the use case of this feature is for servers that are configured to identify received traffic belonging to a specific set on the basis of source port for logging and monitoring purposes. For example, identifying internal and external traffic for logging purpose.

Configuring the Citrix ADC appliance to use a source port from a port range for communicating to the servers consists of the following tasks:

- **Create a net profile and set the source port range parameter.** A source port range parameter specifies one or more port ranges. The appliance randomly selects one of the free ports from the specified port ranges and used it as the source port for each connection to servers.
- **Bind the net profile to load balancing virtual servers, services, or service groups:** A net profile with source port range setting can be bound to a virtual server, service, or a service group of a load balancing configuration. For a connection to a virtual server, the appliance randomly selects one of the free ports from the specified port ranges of a net profile and use this port as the source port for connecting to one of the bound server.

### To specify a source port range or ranges by using the CLI

At the command prompt, type:

```
1 bind netProfile <name> (-srcPortRange <int[-int]> ...)  
2  
3 show netprofile <name>  
4 <!--NeedCopy-->
```

### To specify a source port range or ranges by using the GUI

1. Navigate to **System > Network > Net Profiles**.
2. Set the **Source Port Range** parameter while adding or modifying NetProfiles.

### Sample Configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has partial NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1 > add netprofile CUSTOM-SRCPORT-NP-1  
2 Done  
3 > bind netprofile CUSTOM-SRCPRT-NP-1 - srcportrange 2000-3000
```

```
4
5 Done
6 > bind netprofile CUSTOM-SRCPRT-NP-1 - srcportrange 5000-6000
7
8 Done
9 > add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
10
11 Done
```

## Configure source IP persistency for backend communication

September 21, 2020

By default, for a load balancing configuration with the USIP option disabled and a net profile bound to a virtual server or services or service groups, the Citrix ADC appliance uses the round robin algorithm to select an IP address from the net profile for communicating with the servers. Because of this selection method, the IP address selected can be different for different sessions of a specific client.

Some situations require that the Citrix ADC appliance send all of a specific client's traffic from the same IP address when sending the traffic to servers. The servers can then, for example, identify traffic belonging to a specific set for logging and monitoring purposes.

The source IP persistency option of a net profile enables the Citrix ADC appliance to use the same address, specified in the net profile, to communicate with servers about all sessions initiated from a specific client to a virtual server.

### To enable source IP persistency in a net profile by using the CLI

To enable source IP persistency while adding a net profile, at the command prompt, type:

```
1 add netProfile <name> -srcippersistency ( ENABLED | DISABLED )
2
3 show netprofile <name>
4 <!--NeedCopy-->
```

To enable source IP persistency in an existing net profile, at the command prompt, type:

```
1 set netProfile <name> -srcippersistency ( ENABLED | DISABLED )
2
3 show netprofile <name>
4 <!--NeedCopy-->
```

## To enable source IP persistency in a net profile by using the GUI

1. Navigate to **System > Network > Net Profiles**.
2. Select **Source IP Persistency** while adding or modifying a net profile.

### Example

In the following sample configuration, net profile NETPROFILE-IPPRSTNCY-1 has the source IP persistency option enabled and is bound to load balancing virtual server LBVS-1.

The Citrix ADC appliance always use the same IP address (in this example, 192.0.2.11) to communicate with servers bound to LBVS-1, for all sessions initiated from a specific client to the virtual server.

```
1 > add ipset IPSET-1
2
3 Done
4 > bind ipset IPSET-1 192.0.2.[11-15]
5   IPAddress "192.0.2.11" bound
6   IPAddress "192.0.2.12" bound
7   IPAddress "192.0.2.13" bound
8   IPAddress "192.0.2.14" bound
9   IPAddress "192.0.2.15" bound
10 Done
11 > add netprofile NETPROFILE-IPPRSTNCY-1 -srcIp IPSET-1 -
    srcippersistency ENABLED
12
13 Done
14 > set lb vserver LBVS-1 -netprofile NETPROFILE-IPPRSTNCY-1
15
16 Done
```

## Use IPv6 link local addresses on server side of a load balancing setup

September 21, 2020

IPv6 link local address is supported for services, service groups, and servers of a load balancing configuration. You can specify a link local IPv6 address along with the associated VLAN ID in services, service groups, and servers configurations. The Citrix ADC appliance uses the link local SNIP6 address from the same VLAN as specified in the services, service groups, and servers configurations to communicate with them.

A link local IPv6 address and the associated VLAN ID are specified in the following format in services, service groups, and servers configurations: %

For example, fe80:123:4567::a%2048:, fe80:123:4567::a is the link local address AND 2048 is the VLAN ID.

```
1 > add service SERVICE-1 fe80:123:4567::a%2048 HTTP 80
2
3 Done
4 > bind servicegroup SERVICE-GROUP-1 fe80::1%24 80
5
6 Done
7 > add server SERVER-1 fe80:b:c:d::e:f:a/64%1028
8
9 Done
```

## Advanced load balancing settings

September 21, 2020

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

- [Gradually step up the load on a new service with virtual server-level slow start](#)
- [The no-monitor option for services](#)
- [Protect applications on protected servers against traffic surges](#)
- [Enable cleanup of virtual server and service connections](#)
- [Graceful shutdown of services](#)
- [Enable or disable persistence session on TROFS services](#)
- [Direct requests to a custom web page](#)
- [Enable access to services when down](#)
- [Enable TCP buffering of responses](#)
- [Enable compression](#)
- [Maintain client connection for multiple client requests](#)
- [Insert IP address of the client in the request header](#)
- [Retrieve location details from user IP address using geolocation database](#)
- [Use the source IP address of the client when connecting to the server](#)
- [Configure the source port for server-side connections](#)
- [Set a limit on the number of client connections](#)
- [Set a limit on the number of requests per connection to the server](#)
- [Set a threshold value for the monitors bound to a service](#)

- [Set a timeout value for idle client connections](#)
- [Set a timeout value for idle server connections](#)
- [Set a limit on the bandwidth usage by clients](#)
- [Redirect client requests to a cache](#)
- [Retain the VLAN identifier for VLAN transparency](#)
- [Configure automatic state transition based on percentage health of bound services](#)

## **Gradually step up the load on a new service with virtual server-level slow start**

September 21, 2020

You can configure the Citrix ADC appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (hereafter, the term “new service” is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

Note: In automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

### **Manual slow start**

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and “per second,” respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

Table 1. Parameter Values

| Parameter                              | Value                                           |
|----------------------------------------|-------------------------------------------------|
| Interval in seconds                    | 0                                               |
| New service request rate               | 10, 20, 40, and 0, at intervals that you choose |
| Units for the new service request rate | Requests per second                             |

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

Table 2. Load Distribution on Services when Manually Stepping Up the Load

|                                                           | new service<br>request rate = 10<br>req/sec<br>(Service3added) | new service<br>request rate = 20<br>req/sec | new service<br>request rate = 40<br>req/sec<br>(Service4added) | new service<br>request rate = 0<br>req/sec (new<br>services exit<br>slow start mode) |
|-----------------------------------------------------------|----------------------------------------------------------------|---------------------------------------------|----------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <b>Service1</b>                                           | 115                                                            | 110                                         | 80                                                             | 60                                                                                   |
| <b>Service2</b>                                           | 115                                                            | 110                                         | 80                                                             | 60                                                                                   |
| <b>Service3</b>                                           | 10                                                             | 20                                          | 40                                                             | 60                                                                                   |
| <b>Service4</b>                                           | -                                                              | -                                           | 40                                                             | 60                                                                                   |
| <b>Total req/sec<br/>(load on the<br/>virtual server)</b> | 240                                                            | 240                                         | 240                                                            | 240                                                                                  |

### Automated slow start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving its full share of the load.

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 3. Parameter Values

| Parameter                              | Value               |
|----------------------------------------|---------------------|
| Interval in seconds                    | 10                  |
| Increment value                        | 4                   |
| Units for the new service request rate | Requests per second |

With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second, the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

|                            | 0 sec | 10 sec | 20 sec | 30 sec | 40 sec | 50 sec |
|----------------------------|-------|--------|--------|--------|--------|--------|
| <b>Req/sec forService1</b> | 25    | 24     | 23     | 22     | 21     | 20     |
| <b>Req/sec forService2</b> | 25    | 24     | 23     | 22     | 21     | 20     |
| <b>Req/sec forService3</b> | 25    | 24     | 23     | 22     | 21     | 20     |
| <b>Req/sec forService4</b> | 25    | 24     | 23     | 22     | 21     | 20     |
| <b>Req/sec forService5</b> | 0     | 4      | 8      | 12     | 16     | 20     |

|                                                   | 0 sec | 10 sec | 20 sec | 30 sec | 40 sec | 50 sec |
|---------------------------------------------------|-------|--------|--------|--------|--------|--------|
| <b>Total req/sec (load on the virtual server)</b> | 100   | 100    | 100    | 100    | 100    | 100    |

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

Table 5. Parameter Values

| Parameter                              | Value   |
|----------------------------------------|---------|
| Interval in seconds                    | 5       |
| Increment value                        | 25      |
| Units for the new service request rate | Percent |

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the

ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”

### Set the slow start parameters

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

### To configure stepwise load increments for a new service by using the command line interface

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

```
1 add lb vserver <name> <serviceType> <IPAddress> <port> [-
    newServiceRequest <positive_integer>] [<newServiceRequestUnit>] [-
    newServiceRequestIncrementInterval <positive_integer>]
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Example

```
1 set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -
    newServiceRequestIncrementInterval 10
2 Done
3
4 show lb vserver BR_LB
5 BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
6 State: UP
7 ...
8 ...
9 New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
10 ...
11 ...
12 Done
13 <!--NeedCopy-->
```

### To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Method, and set the following slow start parameters:

- New Service Startup Request Rate.
- New Service Request Unit.
- Increment Interval.

## The no-monitor option for services

September 21, 2020

If you use an external system to perform health checks on the services and do not want the Citrix ADC appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the appliance continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports that a service that is DOWN, remove the service from the Citrix ADC configuration.
- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

### To set the no-monitor option for a new service by using the CLI

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```
1 add service <serviceName> <IP | serverName> <serviceType> <port> -  
   healthMonitor (YES|NO)  
2 <!--NeedCopy-->
```

#### Example:

```
1 add service nomonsrv 10.102.21.21 http 80 -healthMonitor no
2 Done
3
4 show service nomonsrv
5 nomonsrv (10.102.21.21:80) - HTTP
6 State: UP
7 Last state change was at Mon Nov 15 22:41:29 2010
8 Time since last state change: 0 days, 00:00:00.970
9 Server Name: 10.102.21.21
10 Server ID : 0 Monitor Threshold : 0
11 ...
12 Access Down Service: NO
13 ...
14 Down state flush: ENABLED
15 Health monitoring: OFF
16
17 1 bound monitor:
18 1) Monitor Name: tcp-default
19 State: UNKNOWN Weight: 1
20 Probes: 3 Failed [Total: 3 Current: 3]
21 Last response: Probe skipped - Health monitoring is turned off.
22 Response Time: N/A
23 Done
24 <!--NeedCopy-->
```

### To set the no-monitor option for an existing service by using the CLI

At the command prompt, type the following command to set the health monitor option:

```
1 set service <name> -healthMonitor (YES|NO)
2 <!--NeedCopy-->
```

### Example:

```
1 By default, the state of a service and the state of the corresponding
   monitor are UP.
2 >show service LB-SVC1
3 LB-SVC1 (10.102.29.5:80) - HTTP
4 State: UP
5
6
7 1) Monitor Name: http-ecv
8 State: UP Weight: 1
```

```
9 Probes: 99992 Failed [Total: 0 Current: 0]
10 Last response: Success - Pattern found in response.
11 Response Time: 3.76 millisec
12 Done
13
14 When the no-monitor option is set on a service, the state of the
    monitor changes to UNKNOWN.
15 set service LB-SVC1 -healthMonitor NO
16 Done
17
18 show service LB-SVC1
19 LB-SVC1 (10.102.29.5:80) - HTTP
20 State: UP
21 Last state change was at Fri Dec 10 10:17:37 2010.
22 Time since last state change: 5 days, 18:55:48.710
23 Health monitoring: OFF
24
25 1) Monitor Name: http-ecv
26   State: UNKNOWN Weight: 1
27     Probes: 100028 Failed [Total: 0 Current: 0]
28     Last response: Probe skipped - Health monitoring is turned off.
29     Response Time: 0.0 millisec
30   Done
31 When the no-monitor option is removed, the earlier state of the monitor
    is resumed.
32 > set service LB-SVC1 -healthMonitor YES
33 Done
34 >show service LB-SVC1
35 LB-SVC1 (10.102.29.5:80) - HTTP
36 State: UP
37 Last state change was at Fri Dec 10 10:17:37 2010
38 Time since last state change: 5 days, 18:57:47.880
39 1) Monitor Name: http-ecv
40   State: UP Weight: 1
41     Probes: 100029 Failed [Total: 0 Current: 0]
42     Last response: Success - Pattern found in response.
43     Response Time: 5.690 millisec
44   Done
45 <!--NeedCopy-->
```

### To set the no-monitor option for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and clear Health Monitoring.

## Protect applications on protected servers against traffic surges

September 21, 2020

The Citrix ADC appliance provides the surge protection option to maintain the capacity of a server or cache. The appliance regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The appliance blocks any surges passed to the server, thereby preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see [“Surge Protection.”](#)

### To set surge protection on the service by using the CLI

At the command prompt, type:

```
1 set service <name> -sp <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -sp ON
2 <!--NeedCopy-->
```

### To set surge protection on the service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a source.
2. In Advanced Settings, select Traffic Settings, and select Surge Protection.

## Enable cleanup of virtual server and service connections

September 21, 2020

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes or health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN. If a service or virtual server are marked DOWN, the server and client side connections must be flushed. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

Under certain conditions, you can configure the **downStateFlush** setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. You must not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

| Vserver-LB-1 | Service-1 | State of Connections                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E            | E         | Both client and server connections are terminated.                                                                                                                                                                                                                                                                                                                                                                                |
| E            | D         | For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated. |

| Vserver-LB-1 | Service-1 | State of Connections                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D            | E         | For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated. |
| D            | D         | Neither client nor server connections are terminated.                                                                                                                                                                                                                                                                                                                                                                             |

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see

[Graceful Shutdown of Services](#).

### To set down state flush on the service by using the CLI

At the command prompt, type:

```
1 set service <name> -downStateFlush (ENABLED | DISABLED )
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

### To set down state flush on the service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Down State Flush.

### To set down state flush on the virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -downStateFlush (ENABLED | DISABLED )
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver vsvr1 -downStateFlush enabled
2 <!--NeedCopy-->
```

### To set down state flush on the virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Down State Flush.

## Graceful shutdown of services

September 21, 2020

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. You can later enable the service by using the “enable service <name>” command.

To avoid disrupting established sessions, you can place a service in the Transition Out of Service (TROFS) state by doing one of the following:

- Adding a TROFS code or string to the monitor—Configure the server to send a specific code or string in response to a monitor probe.
- Explicitly disable the service and:
  - Set a delay (in seconds).
  - Enable graceful shut down.

## Adding a TROFS Code or String

If you bind only one monitor to a service, and the monitor is TROFS-enabled, it can place the service in the TROFS state on the basis of the server's response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the persistent connections.

If multiple monitors are bound to a service, the effective state of the service is calculated on the basis of the state of all the monitors that are bound to the service. Upon receiving a TROFS response, the state of the TROFS-enabled monitor is considered as UP for the purpose of this calculation. For more information about how a Citrix ADC appliance designates a service as UP, see [Setting a Threshold Value for the Monitors Bound to a Service](#).

### Important:

- You can bind multiple monitors to a service, but must not TROFS-enable more than one of them.
- You can convert a TROFS-enabled monitor to a monitor that is not TROFS-enabled, but not vice versa.

### To configure a TROFS code or string in a monitor by using the command line interface

At the command prompt, type one of the following commands:

```
1 add lb monitor <monitor-name> HTTP -trofsCode <respcode>
2
3 add lb monitor <monitor-name> HTTP-ECV -trofsString <resp string>
4
5 add lb monitor <monitor-name> TCP-ECV -trofsString <resp string>
6 <!--NeedCopy-->
```

### To modify the TROFS code or string by using the command line interface

At the command prompt, type one of the following commands:

```
1 set lb monitor <trofs monitorname> HTTP -trofscode <newcode>
2
3 set lb monitor <trofs monitorname> HTTP-ECV -trofsstring <new string>
4
5 set lb monitor <trofs monitorname> TCP-ECV -trofsstring <new string>
6 <!--NeedCopy-->
```

**Note:** You can use the set command only if a TROFS-enabled monitor was added earlier. You cannot use this command to set the TROFS code or string for a monitor that is not TROFS-enabled.

### To configure a TROFS code or string in a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following:
  - Select Type as HTTP, and specify a TROFS Code.
  - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

### Disabling a Service

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes graceful shut down options.

| State                                                       | Results                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Graceful shutdown is enabled and a wait time is specified.  | Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed. |
| Graceful shutdown is disabled and a wait time is specified. | Service is shut down only after the wait time expires, even if all established connections are served before expiration.                                                                                                                                     |
| Graceful shutdown is enabled and no wait time is specified. | Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.                                                                                                     |

| State                                                        | Results                                                                                                                                                              |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Graceful shutdown is disabled and no wait time is specified. | No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.) |

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see [Enabling Cleanup of Virtual Server Connections](#).

### To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

```

1  disable service <name> [<delay>] [-graceful (YES|NO)]
2
3  show service <name>
4  <!--NeedCopy-->

```

#### Example:

```

1  > disable service svc1 6000 -graceful YES
2  Done
3  >show service svc1
4  svc1 (10.102.80.41:80) - HTTP
5  State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
6  Last state change was at Mon Nov 15 22:44:15 2010
7  Time since last state change: 0 days, 00:00:01.160
8  ...
9  Down state flush: ENABLED
10
11  1 bound monitor:
12  1) Monitor Name: tcp-default
13  State: UP           Weight: 1
14  Probes: 13898      Failed [Total: 0 Current: 0]
15  Last response: Probe skipped - live traffic to service.
16  Response Time: N/A
17  Done
18
19  >show service svc1
20  svc1 (10.102.80.41:80) - HTTP
21  State: OUT OF SERVICE

```

```
22 Last state change was at Mon Nov 15 22:44:19 2010
23 Time since last state change: 0 days, 00:00:03.250
24 Down state flush: ENABLED
25
26 1 bound monitor:
27 1) Monitor Name: tcp-default
28 State: UNKNOWN           Weight: 1
29 Probes: 13898    Failed [Total: 0 Current: 0]
30 Last response: Probe skipped - service state OFS.
31 Response Time: N/A
32 Done
33 <!--NeedCopy-->
```

### **To configure graceful shutdown for a service by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

### **Enable or disable persistence session on TROFS services**

September 21, 2020

You can set the `trofsPersistence` flag to specify whether a service in the transition out of service (TROFS) state should maintain persistent sessions. When a monitor is TROFS enabled, it can place a service in the TROFS state on the basis of the server's response to a monitor probe. This response is compared with the value in the `trofsCode` parameter for an HTTP monitor or the `trofsString` parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the active client connections. In some cases, the honored active sessions might have to include persistent sessions. But in other cases, especially those involving long-lived persistence sessions or persistence methods such as custom server ID, honoring the persistent sessions could prevent the service from transitioning to the out-of-service state.

If you set the `trofsPersistence` flag to `ENABLED`, persistent sessions are honored. If you set it to `DISABLED`, they are not.

### **To set the `trofsPersistence` flag by using the command line interface**

At the command prompt, type one of the following commands to set the `trofsPersistence` flag for a new virtual server or an existing virtual server, or to return the setting to its default value:

```
1 **add lb vserver** <name> [-trofsPersistence ( ENABLED | DISABLED )]  
2  
3 **set lb vserver** <name> [-trofsPersistence ( ENABLED | DISABLED )]  
4  
5 **unset lb vserver** <name> [-trofsPersistence]  
6 <!--NeedCopy-->
```

### Argument

**trofsPersistence.** Honor current active client connections and new requests on persistence sessions when the service is in TROFS state.

Possible values: ENABLED, DISABLED. Default: ENABLED.

### Examples:

```
1 add lb vserver v1 http 10.102.217.42 80 -persistencetype SOURCEIP -  
   trofsPersistence ENABLED  
2  
3 set lb vserver v1 -trofsPersistence DISABLED  
4  
5 unset lb vserver v1 -trofsPersistence  
6 <!--NeedCopy-->
```

## Direct requests to a custom web page

March 30, 2021

### Warning

SureConnect (SC) is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. For more information, see [AppQoE](#).

For SureConnect to function correctly, you must set it globally. The Citrix ADC provides the SureConnect option to ensure the response from an application.

For more information about the SureConnect option, see [Sure Connect](#).

For SureConnect to function correctly, you must set it globally. The Citrix ADC provides the SureConnect option to ensure the response from an application.

For more information about the SureConnect option, see “[Sure Connect](#).”

## To set SureConnect on the service by using the CLI

At the command prompt, type:

```
1 set service <name> -sc <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -sc ON
2 <!--NeedCopy-->
```

## To set SureConnect on the service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Sure Connect.

## Enable access to services when down

September 21, 2020

You can enable access to a service when it is disabled or in a DOWN state by configuring the Citrix ADC appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the Access Down setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see [IP Addressing](#).

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the access-Down parameter.

## To enable access down on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -accessDown <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -accessDown YES
2 <!--NeedCopy-->
```

## To enable access down on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Access Down.

## Enable TCP buffering of responses

September 21, 2020

The Citrix ADC appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 megabytes (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting. For more information about configuring TCP buffering globally, see [“TCP Buffering.”](#)

## To enable TCP Buffering on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -TCPB <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -TCPB YES
2 <!--NeedCopy-->
```

## To enable TCP Buffering on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select TCP Buffering.

## Enable compression

September 21, 2020

The Citrix ADC appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and

can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally.

For more information about configuring compression globally, see [Compression](#).

### To enable compression on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -CMP <YES | NO>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -CMP YES
2 <!--NeedCopy-->
```

### To enable compression on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Compression.

## Maintain client connection for multiple client requests

September 21, 2020

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a Web site open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the Citrix ADC appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client will open a new connection for every request that it sends to the Web site. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see [Client Keep-Alive](#).

## To enable client keep-alive on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -CKA <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -CKA YES
2 <!--NeedCopy-->
```

## To enable client keep-alive on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Client Keep-Alive.

## Insert the IP address of the client in the request header

September 21, 2020

A Citrix ADC uses the subnet IP (SNIP) address to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the appliance inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

**Note:** To insert multiple headers, you need to perform one of the following:

- Add rewrite policies to check CLIENT.IS\_SSL and insert appropriate header.
- Bind the appropriate rewrite policy for each virtual server based on the type.

## To insert client IP address in the client request by using the CLI

At the command prompt, type:

```
1 set service <name> -CIP <Value> <cipHeader>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -CIP enabled X-Forwarded-For
2 <!--NeedCopy-->
```

### To insert client IP address in the client request by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and edit a service.
2. In the **Service Settings** pane, click the **edit icon**.
3. In the **Load Balancing Service** pane, select the **Insert Client IP Address** check box.

## Retrieve location details from user IP address using geolocation database

September 21, 2020

**Note:** This feature is available from Citrix ADC release 12.1 build 50.x and later.

The Citrix ADC appliance can now get user location details like continent, county, and city. For any public IP address from a geo location database. This is performed using the advanced policy infrastructure. The retrieved location details are then used in a rewrite action or a responder action for performing the following use cases.

- Insert an HTTP header with user location details (such as country, city information) when sending the client request to the back-end server.
- Add country name in the HTML page response for an invalid user.

The appliance can also log the location details using the audit logging mechanism.

### Getting user location details using geolocation functions

The components interact as given below:

1. User sends a client request from a particular geographic location.
2. The Citrix ADC appliance looks for the user IP address from the client request and retrieves the geo location details (such as continent, country, region, city, ISP, organization, or custom details) from a geolocation database.
3. Once the location details are retrieved, the appliance uses either a responder policy or a rewrite policy to evaluate the request.
4. In a rewrite policy, the appliance adds a new header with the geo location details and sends it to the back-end server. For example, insert a custom HTTP header with country information.

- In a responder policy, the appliance evaluates the HTTP request and based on policy evaluation, the appliance allows access to the users or redirects the user to an error page stating the region from where they are accessing the application does not have access

## Setting up geolocation database

As a pre-requisite, you must have a geolocation database to run on the Citrix ADC appliance. The geolocation database files are available with Citrix ADC firmware. To download the database files from a vendor, convert it into Citrix ADC format and import it into your appliance.

For more information about geolocation database, see [Add a location file to create static proximity database](#) topic.

## Geolocation functions

The following table gives a list of geolocation functions that retrieves location details of any public IP address. These functions can be used in rewrite or responder policies.

| Geolocation function                            | Example                                                   |
|-------------------------------------------------|-----------------------------------------------------------|
| CLIENT.IP.SRC.LOCATION                          | Asia.In.Karnataka.Bangalore                               |
| CLIENT.IP.SRC.LOCATION.GET<br>(1).LOCATION_LONG | India                                                     |
| CLIENT.IP.SRC.LOCATION(3)                       | Asia.In.Karnataka                                         |
| CLIENT.IP.SRC.LAT_LONG                          | 12,77                                                     |
| CLIENT.IPV6.SRC.LOCATION                        | North America.US.California.Santa<br>Clara.Verizon.Citrix |
| CLIENT.IPV6.SRC.LOCATION(3)                     | North America.US.California                               |
| CLIENT.IPV6.SRC.LOCATION.GET(1).LOCATION_L      | United States                                             |
| CLIENT.IPV6.SRC.LOCATION.GET(3)                 | California                                                |
| CLIENT.IPV6.SRC.LAT_LONG                        | 36, -119                                                  |

## Configuring geolocation functions

To configure geolocation functions using advanced policy infrastructure, you must enable the load balancing, rewrite and responder features and then complete the following use cases.

## Enable load balancing, responder, rewrite features

If you want Citrix ADC appliance to authorize user access from a particular geo location, you must enable the load balancing, rewrite and responder features.

```
1 enable ns feature loadbalancing rewrite responder
2 <!--NeedCopy-->
```

## Use case 1: Configuring geolocation function for redirecting invalid users outside geo location

When a user from India is requesting access to a webpage, block the request and respond with an HTML page with country name.

Follow the steps given below to complete the configuration for this use case.

- Add responder action
- Add responder policy
- Bind responder policy to load balancing server

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see [Responder](#) topic

### Add responder action

Add a responder action to respond with HTML page with country name.

At the command prompt, type:

```
1 add responder action <name> <type> (<target> | <htmlpage>) [-comment <
  string>] [-responseStatusCode <positive_integer>][-reasonPhrase <
  string>]
2 <!--NeedCopy-->
```

### Example:

```
1 add responder action responder_act respondwith "CLIENT.REQ.VERSION + \"
  304 Requested Page not allowed in your country - \" + CLIENT.IP.SRC
  .LOCATION.GET (1).LOCATION_LONG + \"\r\n\""
2 <!--NeedCopy-->
```

### Add auditlog message action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newslog formats. Audit-message actions use expressions to specify the

format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

```
add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewslog  
(YES|NO)] [-bypassSafetyCheck (YES|NO)]
```

**Example:**

```
1 add audit messageaction msg1 DEBUG "\"Request Location: \"+CLIENT.IP.  
SRC.LOCATION"  
2 <!--NeedCopy-->
```

**Add responder policy**

Add a responder policy to identify requests coming from India and associate the responder action to this policy.

At the command prompt, type:

```
1 add responder policy <name> <rule> <action> [<undefAction>] [-comment <  
string>] [-logAction <string>] [-appflowAction <string>]  
2 <!--NeedCopy-->
```

**Example:**

```
1 add responder policy responder_pol CLIENT.IP.SRC.MATCHES_LOCATION("Asia  
.India.*.*.*.*") responder_act -logaction log_act  
2 <!--NeedCopy-->
```

**Bind responder policy to load balancing server**

Bind the responder policy to a load balancing virtual server of type HTTP/SSL.

At the command prompt, type:

```
1 bind lb vserver <vserver name> -policyName < policy_name > -priority  
<> -type <L7InlineREQUEST | L4Inline-REQUEST>  
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver http_vserver -policyName responder_pol -priority 100 -  
type REQUEST  
2 <!--NeedCopy-->
```

## Use case 2: Configuring geolocation function for inserting new HTTP header with location details for back-end to respond

Consider a scenario, where a Citrix ADC appliance must insert the user location in HTTP header of a request sent to the application server so that the server can use the information for some business logic.

Follow the steps given below to complete the configuration for this use case:

- Add rewrite action
- Add rewrite policy
- Bind rewrite policy to load balancing

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see [Responder](#) topic.

### Add rewrite action

Add a rewrite action to insert a custom HTTP header with user geolocation details in the request and send it back-end servers.

At the command prompt, type:

```
1 add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-  
    pattern <expression> | -search <expression>] [-refineSearch <string  
    >] [-comment <string>]  
2 <!--NeedCopy-->
```

### Example:

```
1 add rewrite action rewrite_act insert_http_header "User_location"  
    CLIENT.IP.SRC.LOCATION  
2 <!--NeedCopy-->
```

### Add rewrite policy

Add a rewrite policy to evaluate if the rewrite action should be executed. In this case, all requests going to the application server must have a custom HTTP header, so the rule can be “true.”

At the command prompt, type:

```
1 add rewrite policy <name> <rule> <action> [<undefAction>] [-comment <  
    string>] [-logAction <string>]  
2 <!--NeedCopy-->
```

### Example:

```
1 add rewrite policy rewrite_pol true rewrite_act -logaction log_act
2 <!--NeedCopy-->
```

### Bind rewrite policy to load balancing

Bind the rewrite policy to the required load balancing virtual server of type HTTP/SSL.

At the command prompt, type:

```
1 bind lb vserver <vserver name> -policyName < policy_name > -priority
   <> -type <L7InlineREQUEST | L4Inline-REQUEST>
2 <!--NeedCopy-->
```

### Example:

```
1 bind lb vserver http_vserver -policyName rewrite_pol -priority 100 -
   type REQUEST
2 <!--NeedCopy-->
```

### Syslog support for logging geolocation details (optional)

If you prefer to log the user's geolocation details, you must specify the SYSLOG action to be performed when a request matches the policy. The appliance stores the details as a log message in the ns.log file. For more information about SYSLOG and NSLOG auditing, see [Audit logging](#) topic.

### Output for user geolocation details

If a user is trying to access an application from Bangalore location and if the appliance uses geolocation function, "CLIENT.IP.SRC.LOCATION" then the following output is logged in the appliance using SYSLOG or newslog action.

```
1 Asia.India.Karnataka.Banglore
2 <!--NeedCopy-->
```

### Sample output log:

```
1 07/23/2018:19:03:54 GMT Debug 0-PPE-0 : default REWRITE Message 22 0 :
   "Request Location: asia.in.karnataka.bangalore.*.*"
2 07/23/2018:19:23:55 GMT Debug 0-PPE-0 : default RESPONDER Message 32 0
3 Done
4 <!--NeedCopy-->
```

## Use source IP address of the client when connecting to the server

September 21, 2020

You can configure the Citrix ADC appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see [“Enabling Use Source IP Mode.”](#)

### To enable USIP mode for a service by using the CLI

At the command prompt, type:

```
1 set service <name> -usip (YES | NO)
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -usip YES
2 <!--NeedCopy-->
```

### To enable USIP mode for a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, in the Service Settings section, select **Use Source IP Address**.

## Use client source IP address for backend communication in a v4-v6 load balancing configuration

September 21, 2020

In a v4-to-v6 load balancing configuration, for services with USIP disabled, the Citrix ADC appliance communicates to the related servers from one of the configured IPv6 SNIP (SNIP6) addresses.

For services with USIP enabled, you must set the global USIP NAT prefix parameter for making the related servers aware of the client's IP address of the request packets. USIP NAT prefix is a global IPv6 prefix of length 32/40/48/56/64/96 bits configured on the Citrix ADC appliance.

For a load balancing service that has USIP enabled, the appliance translates the IPv4 request packet to an IPv6 packet and sets the source IP address of the translated IPv6 packet to a concatenation of:

- the USIP NAT prefix of length of 32/40/48/56/64/96 bits.
- zeros padded if the USIP NAT prefix length is less than 96 bits. Number of bits padded with zeros = 96-USIP NAT prefix length. For example, if the USIP NAT prefix length is 64, then the number of bits padded with zeros = 96-64 = 32.
- the IPv4 source address [32 bits] that was received in the request packet. In other words, the last 32 bits of the source IPv6 address is set to the IPv4 address of the client.

On receiving an IPv6 response packet from the server, the Citrix ADC appliance translates the IPv6 packet to an IPv4 packet and sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

**Note:** This feature is not supported for Citrix Gateway configuration and, content switching and cache redirection load balancing configurations.

## Configuration Steps

Configuring USIP for a v4-to-v6 load balancing configuration consists of the following tasks:

- **Add global USIP NAT prefix.** It is a global IPv6 prefix of length 32/40/48/56/64/96 bits to be configured on the appliance.
- **Enable global USIP mode.** For more information, see [Enable Use Source IP Mode](#).
- **Enable USIP mode for load balancing services.** For more information, see [Use source IP address of the client when connecting to the server](#).

### To add a global USIP NAT prefix by using the CLI:

- set ipv6 -usipnatprefix <prefix/prefix\_length>
- show ipv6

### To add a global USIP NAT prefix by using the GUI:

1. Navigate to **System > Network**, and click **Change IPv6 Settings**.
2. On the **Configure Configuration for IPV6** screen, set the **USIP NAT Prefix** parameter.

## Sample configuration

```
1 > set ipv6 -usipnatprefix 2001:DB8:90::/64
2 Done
3
4 > enable ns mode USIP
5 Done
6
7 > add lb vserver LBVS-1 HTTP 203.0.113.90 80
8 Done
9
```

```
10 > add service SVC-1 2001:DB8:5001::30 HTTP 80 -usip yes
11 Done
12
13 > add service SVC-2 2001:DB8:5001::60 HTTP 80 -usip yes
14 Done
15
16 > bind lb vserver LBVS-1 SVC-1
17 Done
18
19 > bind lb vserver LBVS-1 SVC-2
20 Done
21
22 <!--NeedCopy-->
```

## Configure the source port for server-side connections

September 21, 2020

When the Citrix ADC appliance connects to a physical server, it can use the source port from client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The Citrix ADC appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- Req1 is received by LBVS1 and Req2 is received by LBVS2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, they forward the response to the client.
- Consider two cases:
  - Use the client port. When the appliance uses the client port, both the virtual servers use the client's IP address (because USIP is ON) and the client's port when connecting to the server. Therefore, when the service sends the response, the appliance cannot determine which virtual server should receive the response.
  - Use proxy port. When the appliance uses a proxy port, the virtual servers use the client's IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that should receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the Citrix ADC appliance can use

the source port from the client's request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see [“Enabling Use Source IP Mode.”](#)

You can configure the Use Proxy Port setting either globally or on a given service.

### **Configure the use proxy port setting on a service**

You configure the Use ProxyPort setting on the service if you want to override the global setting.

#### **To configure the Use Proxy Port setting on a service by using the CLI**

At the command prompt, type:

```
1 set service <name> -useProxyPort (YES | NO)
2 <!--NeedCopy-->
```

#### **Example:**

```
1 set service svc1 -useproxyport YES
2 Done
3
4 show service svc1
5 svc1 (10.102.29.30:80) - HTTP
6 State: UP
7 . . .
8 Use Source IP: YES Use Proxy Port: YES
9 . . .
10 Done
11 <!--NeedCopy-->
```

#### **To configure the Use Proxy Port setting on a service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Use Proxy Port.

### **Configure the use proxy port setting globally**

You configure the Use Proxy Port setting globally if you want to apply the setting to all the services on the Citrix ADC appliance. The global setting is overridden by service-specific Use Proxy Port settings.

### To configure the Use Proxy Port setting globally by using the CLI

At the command prompt, type the following commands to configure the Use Proxy Port setting globally and verify the configuration:

```
set ns param -useproxyport ( ENABLED          DISABLED )
```

- 
- show ns param

#### Example:

```
1 set ns param -useproxyport ENABLED
2
3 Done
4
5 show ns param
6 Global configuration settings:
7 . . .
8 Use Proxy Port: ENABLED
9 Done
10 <!--NeedCopy-->
```

### To configure the Use Proxy Port setting globally by using the GUI

Navigate to System > Settings > Change global system settings, and select or clear Use Proxy Port.

## Set a limit on the number of client connections

September 21, 2020

You can specify a maximum number of client connections that each load balanced server can handle. The Citrix ADC appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the Maximum Client setting, see [Load Balancing Domain-Name Based Services](#).

Note: Connections that are in the process of closing are not considered for this limit.

## To set a limit to the number of client connections by using the CLI

At the command prompt, type:

```
1 set service <name> -maxclient <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -maxClient 1000
2 <!--NeedCopy-->
```

## To set a limit to the number of client connections by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Clients.

## Set a limit on number of requests per connection to the server

September 21, 2020

The Citrix ADC appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers may have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

## To limit the number of client requests per connection by using the CLI

At the command prompt, type:

```
1 set service <ServiceName> -maxReq <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -maxReq 100
2 <!--NeedCopy-->
```

## To limit the number of client requests per connection by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Requests.

## Set a threshold value for the monitors bound to a service

September 21, 2020

The Citrix ADC appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

By default, the monitor threshold is set to 0 and monitor weights are set to 1. All monitors have equal weightage then and a service can go DOWN when any one of the monitors goes DOWN.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

## To set the monitor threshold value on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -monThreshold <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -monThreshold 100
2 <!--NeedCopy-->
```

### To set the monitor threshold value on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Monitor Threshold.

## Set a timeout value for idle client connections

September 21, 2020

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the Citrix ADC appliance closes the client connection.

### To set a timeout value for idle client connections by using the CLI

At the command prompt, type:

```
1 set service <name> -cltTimeout <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -cltTimeout 100
2 <!--NeedCopy-->
```

### To set a timeout value for idle client connections by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Client Idle Time-out.

## Set a timeout value for idle server connections

September 21, 2020

You can configure a service with a timeout value to terminate any idle server connections when the configured time (in seconds) elapses. If the server is idle for the configured amount of time, the Citrix ADC appliance closes the server connection.

## To set a timeout value for idle server connections by using the CLI

At the command prompt, type:

```
1 set service <name> -svrTimeout <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -svrTimeout 100
2 <!--NeedCopy-->
```

## To set a timeout value for idle server connections by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Server Idle Time-out.

## Set a limit on the bandwidth usage by clients

September 21, 2020

In some cases, servers may have limited bandwidth to handle client requests and may become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth, in Kbps, processed by the server. The Citrix ADC appliance forwards requests to a load balanced server only until this limit is reached.

## To set a maximum bandwidth limit on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -maxBandwidth <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -maxBandwidth 100
2 <!--NeedCopy-->
```

## To set a maximum bandwidth limit on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.

2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Bandwidth.

## Redirect client requests to a cache

September 21, 2020

You can configure a service to redirect client requests to a cache, and forward the non-cacheable requests to a service chosen by the configured load balancing method.

### To set cache redirection on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -cacheable <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -cacheable YES
2 <!--NeedCopy-->
```

### To set cache redirection on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and set the Cache Type.

## Retain the VLAN identifier for VLAN transparency

September 21, 2020

You can configure a load balancing virtual server to retain the client's VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

### To configure a load balancing virtual server to retain the client VLAN ID by using the CLI

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

```
1 set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Note**

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

**To configure a load balancing virtual server to retain the client VLAN ID by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Retain VLAN ID.

**Configure automatic state transition based on percentage health of bound services**

September 21, 2020

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.

You can also enable an SNMP alarm called ENTITY-STATE if you want the Citrix ADC appliance to notify you when the percentage health of bound services causes a virtual server to change state.

**To configure percentage based automatic state transition by using the CLI**

At the command prompt, type the following commands to configure automatic state transition for a virtual server and verify the configuration:

```
1 set lb vserver <name> -healthThreshold <positive_integer>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### To configure percentage based automatic state transition by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and set a Health Threshold.

### To enable the ENTITY-STATE alarm by using the CLI

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

```
1 enable snmp alarm ENTITY-STATE
2
3 show snmp alarm
4 <!--NeedCopy-->
```

### To enable the ENTITY-STATE alarm by using the GUI

1. Navigate to System > SNMP > Alarms.
2. Select ENTITY-STATE and, in the Action list, select Enable.

## Built-in monitors

July 15, 2021

The Citrix ADC appliance contains various built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. They provide options to modify some parameters, such as interval, response time-out to meet your requirements. However, you cannot modify the monitor name and protocol. For more information, see [Modifying Monitors](#). You can also bind a built-in monitor to a service and unbind it from the service.

#### Note

You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## TCP-based application monitoring

September 21, 2020

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications: tcp-default and ping-default. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services; the ping-default monitor is bound to all non-TCP services.

You cannot delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

| Monitor type | Specific parameters                                                                                                                             | Process                                                                                                                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcp          | Not applicable                                                                                                                                  | The Citrix ADC appliance establishes a 3-way handshake with the monitor destination, and then closes the connection. If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor. |
| http         | httprequest ["HEAD /"] - HTTP request that is sent to the service. respcode [200] - A set of HTTP response codes are expected from the service. | The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.                                                             |

| Monitor type | Specific parameters                                                                                                                                                                                                                        | Process                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcp-ecv      | <p>send ["] - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes.</p> <p>recv ["] - expected response from the service. The maximum permissible length of the string is 128 K bytes.</p> | <p>The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.</p>                                                                               |
| http-ecv     | <p>send ["] - HTTP data that is sent to the service; recv ["] - the expected HTTP response data from the service</p>                                                                                                                       | <p>The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data may be anywhere in the first 24K bytes of the HTTP body of the response.</p> |

| Monitor type | Specific parameters | Process                                                                                                                  |
|--------------|---------------------|--------------------------------------------------------------------------------------------------------------------------|
| ping         | Not Applicable      | The Citrix ADC appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response. |

To configure built-in monitors for TCP-based applications, see [Configuring Monitors in a Load Balancing Setup](#).

## SSL service monitoring

September 21, 2020

The Citrix ADC appliance has built-in secure monitors, TCPS and HTTPS. You can use the secure monitors to monitor HTTP as well as non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and then set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and then set the secure flag. The secure monitors work as described below:

- **Secure TCP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.
- **Secure HTTP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

| Monitor type | Probe                         | Success criteria (Direct condition)                                 |
|--------------|-------------------------------|---------------------------------------------------------------------|
| TCP          | TCP connection; SSL handshake | Successful TCP connection established and successful SSL handshake. |

| Monitor type | Probe                                                               | Success criteria (Direct condition)                                                                                                                    |
|--------------|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTP         | TCP connection; SSL handshake; Encrypted HTTP request               | Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted. |
| TCP-ECV      | TCP connection; SSL handshake (Data sent to a server is encrypted.) | Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.                    |
| HTTP-ECV     | TCP connection; SSL handshake (Encrypted HTTP request)              | Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.                   |

### Sample configuration for HTTPS-ECV health check monitor

HTTP services have predefined monitors capable of Extended Content Verification (ECV). These monitors are used when a validation is required beyond a successful TCP connection. These monitors validate the service as UP, when all the following criteria are met:

- A successful TCP connection.
- A particular type of request must be generated.
- A specific message is expected in reply from the **Receive String**.

For these monitors, a request string is configured along with a reply string. If the reply string received by the Citrix ADC monitor matches the configured string, then the service is marked UP.

### Bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, create a service, and specify the protocol as **SSL**. Click **OK**.
2. Click in the **Service to Load Balancing Monitor Binding** pane, and click **Add Binding**.
3. Choose the monitor type as **HTTPS-ECV** and click **Edit**.

4. In the **Configure Monitor** pane under **Basic Parameters** tab, enter values for the following parameters:

- **Send String** – The string that the monitor must send to the service.
- **Receive String** – The string that the monitor must receive to mark the service as UP.

Service Load Balancing Monitor Binding / Load Balancing Monitor Binding / Monitors / Configure Monitor

### Configure Monitor

Name  
https-ecv

Type  
HTTP-ECV

#### Basic Parameters

Interval  
5 Second

Response Time-out  
2 Second

Custom Header

Send String  
GET /testserver/test.html

Receive String  
Hello

Secure  
SSL Profile  
Add Edit

Bind Delete

| Certificate Name |
|------------------|
| No items         |

Advanced Parameters

OK Close

5. Click **OK** to complete the monitor configuration.
6. Click **Select**.
7. Click **Bind** to bind the **HTTPS-ECV** monitor to the service.
8. Click **Close**.

## Bind a monitor to a service by using the CLI

At the command prompt, type:

```
1 bind service <servicename> -monitorName https-ecv
2 <!--NeedCopy-->
```

### Example:

```
1 bind services1 -monitorName https-ecv
2 <!--NeedCopy-->
```

## FTP service monitoring

September 21, 2020

To monitor FTP services, the Citrix ADC appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected, on both the connections, it is marked UP.

Note: Monitor probes originate from the NSIP address.

The Citrix ADC appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP-EXTENDED monitor is a scriptable monitor. It uses the nsftp.pl script. The FTP-EXTENDED monitor script is enhanced to send secure probes to FTP services. You can create a monitor of type FTP-EXTENDED. The nsftp.pl script is automatically taken from the default directory.

## To send secure FTP probes to FTP services by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -username <string> -password <
  string> -filename <filename>
2 <!--NeedCopy-->
```

### Example

```
1 add monitor mon1 FTP-EXTENDED -username root -password freebsd -
  filename fsdf
2 <!--NeedCopy-->
```

### To send secure FTP probes to FTP services by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Specify the monitor type as **FTP-EXTENDED**, and set the parameters.
3. In **Special Parameters**, specify a **File Name**, **User Name**, and **Password**.

To configure built-in monitors to check the state of FTP services, see [Configuring Monitors in a Load Balancing Setup](#).

## Secure monitoring of servers by using SFTP

September 21, 2020

A user script 'nssftp.pl' is added to support SSH File Transfer Protocol (SFTP) monitoring. It is available in the current list of in-built Citrix ADC user monitors and is located in the /netscaler/monitors directory. The SFTP monitor uses the specified username and password to check if the file is present on the server.

### To configure secure monitoring using SFTP by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
  string> -secure ( YES | NO )
2 <!--NeedCopy-->
```

#### Example:

```
1 add monitor SFTP_MON USER - scriptname nssftp.pl - scriptargs "file=
  example.txt;user=sam;password=sam_passwd"
2 <!--NeedCopy-->
```

### To configure secure monitoring using SFTP by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors** and in **Type** specify **USER**.
2. In **Special Parameters**, in **Script Name**, select nssftp.pl.
3. Specify the **Script Arguments**.

## Set SSL parameters on a secure monitor

September 21, 2020

### Important

This feature is supported only on the new Default profiles. For more information about these profiles, see [Enhanced SSL Profiles Infrastructure Overview](#).

A monitor inherits either the global settings or the settings of the service to which it is bound. If a monitor is bound to a non-SSL or non-SSL\_TCP service, such as SSL\_BRIDGE, you cannot configure it with SSL settings such as the protocol version or the ciphers to be used. Therefore, if your deployment requires SSL-based monitoring of the back-end servers, the monitoring is ineffective.

You can have more control over SSL-based monitoring of back-end servers, by binding an SSL profile to a monitor. An SSL profile contains SSL parameters, cipher bindings, and ECC bindings. For example, you can set server authentication, ciphers, and protocol version in an SSL profile and bind the profile to a monitor. Note that to perform server authentication, you must also bind a CA certificate to a monitor. To perform client authentication, you must bind a client certificate to the monitor. New parameters for the “bind lb monitor” command enable you to do so.

### Note

The SSL settings take effect only if you add a secure monitor. Also, the SSL profile type must be **BackEnd**.

## Monitor Types that Support SSL Profiles

SSL profiles can be bound to the following monitor types:

- HTTP
- HTTP-ECV
- TCP
- TCP-ECV
- HTTP-INLINE

### To specify an SSL profile while adding a monitor by using the command line

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -secure YES -sslprofile <string>
2
3 set lb monitor <monitorName> <type> -secure YES -sslprofile <string>
4 <!--NeedCopy-->
```

**Example:**

```

1 add ssl profile prof1 -sslProfileType BackEnd
2
3 add lb monitor mon1 HTTP -secure YES -sslprofile prof1
4 <!--NeedCopy-->

```

**To bind a certificate-key pair to a monitor by using the command line**

At the command prompt, type:

```

1 bind monitor <monitor name> -certkeyName <string> [(-CA [-crlCheck (
    Mandatory | Optional ) | -ocspCheck ( Mandatory | Optional )]
2 <!--NeedCopy-->

```

**SIP service monitoring**

September 21, 2020

A Citrix ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

| Parameter | Specifies                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------|
| sipURI    | SIP addressing schema of the SIP server.                                                                                        |
| sipmethod | Type of SIP request used to probe the SIP service. Specify one of the following methods: INVITE, OPTION (the default), REGISTER |
| respcode  | SIP response code with which the SIP service responds the probe request. Default: 200.                                          |

**RADIUS service monitoring**

September 21, 2020

The Citrix ADC appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

---

| Parameter | Specifies                                                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| userName  | User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.                                                                                                                      |
| password  | Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.                                                                                                                                          |
| radKey    | Shared secret key value that the RADIUS server uses during client authentication.                                                                                                                                          |
| radNASid  | NAS-ID that is encapsulated in the payload when an access request is made.                                                                                                                                                 |
| radNASip  | The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the Citrix ADC appliance sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address. |

---

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor will use for authentication to the RADIUS authentication database.
2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the Citrix ADC appliance has more than one mapped IP address, or if a subnet IP address (SNIP)

is used, you must add the same secret key for all of the IP addresses.

**Caution:** If the IP address used by the appliance are not added to the RADIUS database, the RADIUS server will discard all packets.

To configure built-in monitors to check the state of RADIUS server, see [Configuring Monitors in a Load Balancing Setup](#).

## Monitor accounting information delivery from a RADIUS server

September 21, 2020

You can configure a monitor called a *RADIUS accounting* monitor to determine whether the Radius server used for Authentication, Authorization, and Accounting (AAA) is delivering accounting information as expected. The monitor is of type RADIUS\_ACCOUNTING. The probe is generated by a Perl script called nsbmradius.pl, which is located in the /nsconfig/monitors/ directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as Acct-Status-Type and Framed-IP-Address. For information about these attributes, see RFC 2865, “Remote Authentication Dial In User Service (RADIUS),” and RFC 2866, “RADIUS Accounting.”

### To configure a RADIUS accounting monitor by using the command line interface

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

```
1 add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {
2   -password }
3   {
4   -radKey }
5   [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-
6     radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-
7     radAccountSession <string>]
8 show lb monitor <monitorName>
9 <!--NeedCopy-->
```

**Example**

```

1 add lb monitor radAccntMon RADIUS_ACCOUNTING -radKey "8d#>9jr4rV)L7%a2-
  zW13sM"
2 <!--NeedCopy-->

```

**DNS and DNS-TCP service monitoring**

September 21, 2020

The Citrix ADC appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| query     | The DNS query (domain name) sent to the DNS service that is being monitored. Default value: "\007" If the DNS query succeeds, the service is marked as UP; otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN; otherwise, it is marked as UP. If no response is received, the service is marked as DOWN. |
| queryType | The type of DNS query that is sent. Possible values: Address, Zone.                                                                                                                                                                                                                                                                                                    |
| IPAddress | List of IP addresses that are checked against the response to the DNS monitoring probe.                                                                                                                                                                                                                                                                                |
| IPv6      | Select this check box if the IP address uses IPv6 format.                                                                                                                                                                                                                                                                                                              |

To configure the built-in DNS or DNS-TCP monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## LDAP service monitoring

June 24, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

Configure the LDAP monitor to define the search that it must perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server must start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NSIP address.

| Parameter | Specifies                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| baseDN    | Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=netScaler, dc=com.                                                                                                  |
| bindDN    | BDN name for the LDAP monitor.                                                                                                                                                                                                                                   |
| filter    | Filter for the LDAP monitor. Use the filter parameter in a query to limit the number of results. If you do not specify this parameter in the query, the filter applies for the entire object class, which might be a costly operation, such as a high CPU usage. |
| password  | Password used in monitoring LDAP servers.                                                                                                                                                                                                                        |
| attribute | Attribute for the LDAP monitor.                                                                                                                                                                                                                                  |

To configure the built-in LDAP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## MySQL service monitoring

September 21, 2020

The Citrix ADC appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search

query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

---

| Parameter | Specifies                                     |
|-----------|-----------------------------------------------|
| database  | Database that is used for the MySQL monitor.  |
| sqlQuery  | SQL query that is used for the MySQL monitor. |

---

To configure built-in MySQL monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## SNMP service monitoring

September 21, 2020

The Citrix ADC appliance has one built-in monitor that can be used to monitor SNMP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NSIP address.

---

| Parameter     | Specifies                                                                  |
|---------------|----------------------------------------------------------------------------|
| SNMPOID       | OID that is used for the SNMP monitor.                                     |
| snmpCommunity | Community that is used for the SNMP monitor.                               |
| snmpThreshold | Threshold that is used for the SNMP monitor.                               |
| snmpVersion   | SNMP version that is used for load monitoring.<br>Possible Values: V1, V2. |

---

To configure the built-in SNMP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## NNTP service monitoring

September 21, 2020

The Citrix ADC appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

| Parameter | Specifies                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------|
| userName  | User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe. |
| password  | Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.                     |
| group     | Group name to be queried for NNTP monitor.                                                            |

To configure the built-in NNTP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## POP3 service monitoring

September 21, 2020

The Citrix ADC appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

| Parameter      | Specifies                                                    |
|----------------|--------------------------------------------------------------|
| userName       | User name POP3 server. This user name is used in the probe.  |
| password       | Password used in monitoring POP3 servers.                    |
| scriptName     | The path and name of the script to execute.                  |
| dispatcherIP   | The IP address of the dispatcher to which the probe is sent. |
| dispatcherPort | The port of the dispatcher to which the probe is sent.       |

To configure the built-in POP3 monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## SMTP service monitoring

June 15, 2021

The Citrix ADC appliance has a built-in monitor that can be used to monitor SMTP services: the SMTP monitor. It periodically checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. Else, if the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

| Parameter      | Specifies                                                    |
|----------------|--------------------------------------------------------------|
| scriptName     | The path and name of the script to run.                      |
| dispatcherIP   | The IP Address of the dispatcher to which the probe is sent. |
| dispatcherPort | The port of the dispatcher to which the probe is sent.       |

To configure the built-in SMTP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## RTSP service monitoring

September 21, 2020

The Citrix ADC appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The Citrix ADC appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
  - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
  - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.
4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
  - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
  - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.
4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.
5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

---

| Parameter   | Specifies                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rtspRequest | The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters. |
| respCode    | Set of response codes that are expected from the service.                                                                                                            |

---

For instructions on configuring an RTSP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## XML broker service monitoring

September 21, 2020

The Citrix ADC appliance has a built-in monitor type, CITRIX-XML-SERVICE, with which you can create monitors to monitor the XML Broker services. The XML Broker services are used by Citrix XenApp. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a CITRIX-XML-SERVICE monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker service. The default application is Notepad.

To configure monitors for XML Broker services, see [“Configuring Monitors in a Load Balancing Setup.”](#)

### Note

The parameter “Application Name” for Citrix-XML-Service monitor is invalid for XA and XD versions 7 and later. It is recommended not to use this parameter in XA/XD 7. In case you configure this parameter, this parameter is not used internally. The probing criteria is different starting XA/XD 7. However, you can use the “Application Name” parameters in versions earlier to XA/XD 7.

## ARP request monitoring

September 21, 2020

The Citrix ADC appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP works with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see [Configuring Monitors in a Load Balancing Setup.](#)

## XenDesktop Delivery Controller service monitoring

September 21, 2020

In desktop virtualization, the Citrix ADC appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by Citrix XenDesktop environment. The Citrix ADC appliance provides a built-in monitor, CITRIX-XD-DDC monitor, which monitors the XenDesktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.

The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether or not the user credentials (user name, password and domain) are specified on the

CITRIX-XD-DDC monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the XenDesktop servers, the CITRIX-XD-DDC monitor is automatically created and bound to the XenDesktop Delivery Controller services.

### To add an XD-DDC monitor with the validate credentials option by using the command line interface

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

```
1 add lb monitor <monitorName> <monitorType> -userName <userName> -
   password <password> -ddcDomain <ddc_domain_name> -validateCred YES
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

#### Example:

```
1 > add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -
   password E12Dc35450a1 -ddcDomain dhop -validateCred YES
```

```

2 Done
3 > show lb monitor xdddcmon
4 1) Name.....:xdddcmon Type.....:CITRIX-XD-DDC State.....: ENABLED
5
6 Standard parameters:
7 Interval.....:..5 sec...Retries.....:..3
8 Response timeout.....:..2 sec...Down time.....:..30 sec
9 Reverse.....:..NO...Transparent.....:..NO
10 Secure.....:..NO...LRTM.....:..ENABLED
11 Action.....:..Not applicable...Deviation.....:..0 sec
12 Destination IP.....:..Bound service
13 Destination port.....:..Bound service
14 Iptunnel.....:..NO
15 TOS.....:..NO...TOS ID.....:..0
16 SNMP Alert Retries.....:..0...Success Retries.....:..1
17 Failure Retries.....:..0
18
19 Special parameters:
20 User Name.....:"Administrator"
21 Password.....:*****
22 DDC Domain.....: "dhop"
23 Done
24 <!--NeedCopy-->

```

### To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

```

1 set lb monitor <monitorName> <monitorType> -userName -password -
   ddcDomain <ddc_domain_name> -validateCred YES
2 <!--NeedCopy-->

```

#### Example:

```

1 set lb monitor XD_DDC_21.21.21.22_443_mn CITRIX-xd-ddc -userName
   Administrator -password D123S1R2A123 -ddcDomain dhop -validateCred
   YES
2 Done
3 <!--NeedCopy-->

```

## **To configure an XD-DDC monitor with the validate credentials option by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type Citrix-XD-DDC.

## **Citrix StoreFront stores monitoring**

September 21, 2020

You can configure a user monitor for a Citrix Storefront store. The monitor determines the state of the StoreFront store by successively probing the account service, discovery service, and authentication endpoint (if the Citrix Storefront Store is an authenticated store). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service. For more information, see [Citrix StoreFront Store Services API](#).

Note: Monitor probes originate from the NSIP address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.

Beginning with release 10.1 build 120.13, you can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member's IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

In earlier releases, the StoreFront monitor tried to authenticate anonymous stores. As a result, a service could be marked as DOWN and you could not launch XenApp or XenDesktop by using the URL of the load balancing virtual server.

From build 64.x, the probe order has changed. The monitor now determines the state of the StoreFront store by successively probing the account service, the discovery document, and then the authentication service, and skips authentication for anonymous stores.

The hostname parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

## **To create a StoreFront monitor by using the command line interface**

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

```
1 add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-  
    storefrontacctservice ( YES | NO )] -secure ( YES | NO )  
2  
3 show lb monitor <monitorName>  
4 <!--NeedCopy-->
```

### Example

```
1 add lb monitor storefront_ssl STOREFRONT -storename myStore -  
    storefrontacctservice YES -secure YES  
2 <!--NeedCopy-->
```

### To create a StoreFront monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type STOREFRONT.

#### Note

For more information about the StoreFront monitors, see [Load balancing with Citrix ADC](#).

## Custom monitors

September 21, 2020

In addition to built-in monitors, you can use custom monitors to check the state of your services. The Citrix ADC appliance provides several types of custom monitors based on scripts that are included with the Citrix ADC operating system that can be used to determine the state of services based on the load on the service or network traffic sent to the service. These are the inline monitors, user monitors, and load monitors.

With any of these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

This section includes the following details:

- [Configuring HTTP-Inline Monitors](#)
- [Understanding User Monitors](#)
- [How to Use a User Monitor to Check Web Sites](#)
- [Understanding the Internal Dispatcher](#)
- [Configuring a User Monitor](#)

- [Understanding Load Monitors](#)
- [Configuring Load Monitors](#)
- [Unbinding Metrics from a Metrics Table](#)
- [Configuring Reverse Monitoring for a Service](#)

## Configure HTTP-inline monitors

September 21, 2020

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured to work with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the Citrix ADC appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured down time. After the DOWN time elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

To configure inline monitors, see [Configuring Monitors in a Load Balancing Setup](#).

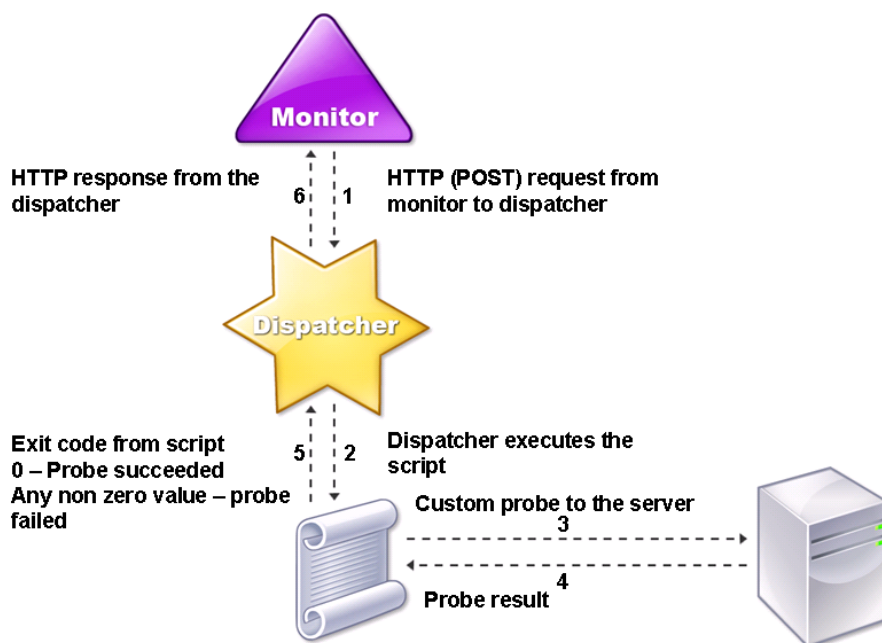

## Understand user monitors

September 21, 2020

User monitors extend the scope of custom monitors. You can create user monitors to track the health

of customized applications and protocols that the Citrix ADC appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors

A user monitor requires the following components.

- **Dispatcher.** A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

Note: You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the “secure” option on the monitor and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

In a HA setup, the dispatcher runs on both the primary and secondary Citrix ADC appliances. The dispatcher remains inactive on the secondary appliance.

**Script.** The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe

succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

The Citrix ADC appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the `/nsconfig/monitors` directory. If you want to add a new script, add it there. If you want to customize an existing script, create a copy with a new name and modify it.

**Important:** Starting with release 10.1 build 122.17, the script files for user monitors are in a new location.

If you upgrade an MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

- A new directory named `conflicts` is created in `/nsconfig/monitors/` and all the built-in scripts of the previous builds are moved to this directory.
- All new built-in scripts are available in the `/netscaler/monitors/` directory. All custom scripts are available in the `/nsconfig/monitors/` directory.
- You must save a new custom script in the `/nsconfig/monitors/` directory.
- After the upgrade is completed, if a custom script is created and saved in the `/nsconfig/monitors/` directory, with the same name as that of a built-in script, the script in the `/netscaler/monitors/` directory takes priority. That is, the custom script does not run.

If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:

- All built-in scripts are available in the `/netscaler/monitors/` directory.
- The `/nsconfig/monitors/` directory is empty.
- If you create a new custom script, you must save it in the `/nsconfig/monitors/` directory.

For the scripts to function correctly:

- The maximum number of characters in the name of the script must not exceed 63.
- The maximum number of script arguments that can be provided to a script must not exceed 512.
- The maximum number of characters that can be provided in the parameter script arguments must not exceed 639.

To debug the script, you must run it by using the `nsumon-debug.pl` script from the CLI. You use the script name (with its arguments), IP address, and the port as the arguments of the `nsumon-debug.pl` script. Users must use the script name, IP address, port, time-out, and the script arguments for the `nsumon-debug.pl` script.

At the CLI, type:

```
1 nsumon-debug.pl <scriptname> <IP> <port> <timeout> <partitionID> [  
    scriptarguments] [is_secure]  
2 <!--NeedCopy-->
```

**Important:** Starting with release 10.5 build 57.x, and 11.0 script files for user monitors support IPv6 addresses and include the following changes:

- For the following protocols, new pm files have been included for IPv6 support.
  - Radius
  - NNTP
  - POP3
  - SMTP
- The following sample scripts in `/netscaler/monitors/` has been updated for IPv6 support:
  - `nsbmradius.pl`
  - `nsldap.pl`
  - `nsnntp.pl`
  - `nspop3 nssf.pl`
  - `nssnmp.pl`
  - `nswi.pl`
  - `nstftp.pl`
  - `nssmtp.pl`
  - `nsrdp.pl`
  - `nsntlm-lwp.pl`
  - `nsftp.pl`
  - `nsappc.pl`

After upgrading to release 10.5 build 57.x, or 11.0, if you want to use your existing custom scripts with IPv6 services, make sure that you update the existing custom scripts with the changes provided in the updated sample scripts in `/netscaler/monitors/`.

Note: The sample script `nsmysql.pl` does not support IPv6 address. If an IPv6 service is bound to a user monitor that uses `nsmysql.pl`, the probe will fail.

- The following LB monitor types have been updated to support IPv6 addresses:
  - USER
  - SMTP
  - NNTP
  - LDAP

- SNMP
- POP3
- FTP\_EXTENDED
- STOREFRONT
- APPC
- CITRIX\_WI\_EXTENDED

If you are creating a new custom script that uses one of these LB monitors types, make sure that you include IPv6 support in the custom script. Refer to the associated sample script in `/netscaler/monitors/` for the changes that you have to make in the custom script for IPv6 support.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be executed. The dispatcher executes the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The appliance logs the error messages to the `/var/nslog/nsumond.log` file when user monitor probes fail. The following table lists the user monitors and the possible reasons for failure.

| User monitor type | Probe failure reasons                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| SMTP              | Monitor fails to establish a connection to the server.                                                    |
| NNTP              | Monitor fails to establish a connection to the server.                                                    |
|                   | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                   | Monitor fails to find the NNTP group.                                                                     |
| LDAP              | Monitor fails to establish a connection to the server.                                                    |
|                   | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                   | Monitor fails to bind to the LDAP server.                                                                 |

| User monitor type | Probe failure reasons                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------|
|                   | Monitor fails to locate an entry for the target entity in the LDAP server.                                |
| FTP               | The connection to the server times out.                                                                   |
|                   | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                   | Logon fails.                                                                                              |
| POP3              | Monitor fails to find the file on the server.                                                             |
|                   | Monitor fails to establish a connection to the database.                                                  |
|                   | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                   | Logon fails.                                                                                              |
| POP3              | Monitor fails to establish a connection to the database.                                                  |
|                   | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                   | Logon fails.                                                                                              |
|                   | Preparation of SQL query fails.                                                                           |
|                   | Execution of SQL query fails.                                                                             |
| SNMP              | Monitor fails to establish a connection to the database.                                                  |
|                   | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                   | Logon fails.                                                                                              |
|                   | Monitor fails to create the SNMP session.                                                                 |
|                   | Monitor fails to find the object identifier.                                                              |
|                   | The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.      |

| User monitor type             | Probe failure reasons                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------|
| RDP (Windows Terminal Server) | Missing or invalid script arguments, which can include an invalid number of arguments or argument format. |
|                               | Monitor fails to create a socket.                                                                         |
|                               | Mismatch in versions.                                                                                     |
|                               | Monitor fails to confirm connection.                                                                      |

You can view the log file from the CLI by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the CLI:

```

1 > shell
2 root@ns# cat /var/nslog/nsumond.log
3 root@ns# exit
4 >
5 <!--NeedCopy-->

```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

#### Note

For scriptable monitors, the response timeout must be configured to a value equal to expected timeout + 1 second.

For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.

#### Example command:

```

1 add lb monitor <name> USER - scriptname <script-name> -resptimeout 5
   seconds
2 <!--NeedCopy-->

```

## How to use a user monitor to check web sites

September 21, 2020

You can configure a user monitor to check for specific Web site problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

| HTTP response code          | Meaning                                                                                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200 - success               | Probe success.                                                                                                                                                           |
| 503 - service unavailable   | Probe failure.                                                                                                                                                           |
| 404 - not found             | Script not found or cannot execute.                                                                                                                                      |
| 500 - Internal server error | Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN. |
| 400 - bad request           | Error parsing HTTP request.                                                                                                                                              |
| 502 - bad gateway           | Error decoding script's response.                                                                                                                                        |

You configure the user monitor for HTTP by using the following parameters.

| Parameter      | Specifies                                                                                  |
|----------------|--------------------------------------------------------------------------------------------|
| scriptName     | The path and name of the script to execute.                                                |
| scriptArgs     | The strings that are added in the POST data. They are copied to the request verbatim.      |
| dispatcherIP   | The IP address of the dispatcher to which the probe is sent.                               |
| dispatcherPort | The port of the dispatcher to which the probe is sent.                                     |
| localfileName  | The name of a monitor script file on the local system.                                     |
| destPath       | A particular location on the Citrix ADC appliance where the uploaded local file is stored. |

To create a user monitor to monitor HTTP, see [Configuring Monitors in a Load Balancing Setup](#).

## Understand the internal dispatcher

September 21, 2020

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

Figure 1. Using a user monitor with the internal dispatcher

A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The Citrix ADC appliance includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a user monitor with an external dispatcher

A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

## Configure a user monitor

September 21, 2020

To configure a user monitor, you must write a script that the monitor uses to check the services that are bound to it. Upload the script to the `/nsconfig/monitors` directory on the Citrix ADC appliance. Give executable permission to the script. If the monitor type is a protocol that the Citrix ADC appliance does not support, only then you must use the monitor of type **USER**. The user monitors support Perl and Bash scripts. Python scripts are not supported.

### Note

Monitor probes originate from the NSIP address. The `scriptargs` configured for the monitor of type **USER** is displayed in the running configuration and `ns.conf` files.

## To configure a user monitor by using the command line interface

At the command prompt, type:

```
1 add lb monitor <monitorName> USER -scriptname <NameOfScript> -  
   scriptargs <Arguments>  
2 <!--NeedCopy-->
```

### Example:

```
1 add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file  
   =/home/user/  
2 sample.txt;user=root;password=passwd"  
3 <!--NeedCopy-->
```

## Understand load monitors

September 21, 2020

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The Citrix ADC appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in [Setting Up Basic Load Balancing](#).

Figure 1. Operation of Load Monitors

Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL
- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing,

as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

| Metric name | OIDs    | Weight | Threshold |
|-------------|---------|--------|-----------|
| CPU         | 1.2.3.4 | 2      | 70        |
| Memory      | 4.5.6.7 | 3      | 80        |
| Connections | 5.6.7.8 | 4      | 90        |

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

## Configure load monitors

September 21, 2020

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see [Creating Monitors](#). Next, select or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

### To create a metric table by using the command line interface

At the command prompt, type the following commands:

```
1 add lb metricTable <metricTableName>
2
3 bind lb metricTable <metricTableName> <metric> <SNMPOID>
4 <!--NeedCopy-->
```

#### Example:

```
1 add metricTable Table-Custom-1
2
3 bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
4 <!--NeedCopy-->
```

## To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables and create a metric table.
2. To bind metrics, click Bind and specify a metric and an SNMP OID.

## Unbind metrics from a metrics table

September 21, 2020

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

### To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

```
1 unbind lb metricTable <metricTable> <metric>
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5
2 <!--NeedCopy-->
```

### To unbind metrics from a metric table by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Metric Tables**.
2. Open a metric table, select a metric, and click **Delete**.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

## Configure reverse monitoring for a service

September 21, 2020

A reverse monitor marks a service as DOWN if the probe criteria are satisfied and UP if they are not satisfied. For example, if you want a backup service to receive traffic only when the primary service is DOWN, you can bind a reverse monitor to the secondary service but configure it to probe the primary service.

The Citrix ADC appliance supports the following reverse monitors:

- HTTP
- ICMP
- TCP (from release 11.1 build 49.x)

### Configuring HTTP Reverse Monitoring for a Service

The following table describes the conditions of HTTP direct and reverse monitoring for a service:

| Condition                                                     | Direct  | Reverse |
|---------------------------------------------------------------|---------|---------|
| Connection not established.                                   | Fail    | Fail    |
| HTTP response code matches the probe's specifications.        | Success | Fail    |
| HTTP response code does not match the probe's specifications. | Fail    | Success |
| Probe timed out.                                              | Fail    | Fail    |

### To configure HTTP reverse monitoring for a service by using the CLI

At the command prompt, type:

```

1 add lb monitor <Monitor_Name> HTTP -respCode 200 -httpRequest "HEAD /"
   -destIP <Primary_Service_IP_Address> -destPort 80 -reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
4 <!--NeedCopy-->

```

### Configuring ICMP Reverse Monitoring for a Service

The following table describes the conditions of ICMP direct and reverse monitoring for a service:

| Condition                    | Direct  | Reverse |
|------------------------------|---------|---------|
| ICMP echo reply is received. | Success | Fail    |

---

---

|                  |      |         |
|------------------|------|---------|
| Probe timed out. | Fail | Success |
|------------------|------|---------|

---

### To configure ICMP reverse monitoring for a service by using the CLI

At the command prompt, type:

```

1 add lb monitor <Monitor_Name> PING -destIP <Primary_Service_IP_Address>
   -reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
4 <!--NeedCopy-->

```

### Configuring TCP Reverse Monitoring for a Service

If a direct TCP monitor receives a RESET in response to a monitor probe, the service is marked DOWN. However, if a reverse TCP monitor receives a RESET response, the probe is considered successful, and the service is marked UP.

The following table describes the conditions of TCP reverse monitoring for a service:

---

| Condition                      | Direct  | Reverse |
|--------------------------------|---------|---------|
| TCP connection is established. | Success | Fail    |
| Probe timed out.               | Fail    | Fail    |
| Response to probe is RESET.    | Fail    | Success |

---

### To configure TCP reverse monitoring for a service by using the CLI

At the command prompt, type:

```

1 add lb monitor <Monitor_Name> TCP - destip <Primary_Service_IP_Address>
   -destport <primary_service_port> - reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
4 <!--NeedCopy-->

```

**To configure reverse monitoring by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create an HTTP, ICMP, or TCP monitor and select **Reverse**.

**Configure monitors in a load balancing setup**

September 21, 2020

To configure monitors on a website, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see [Custom Monitors](#). Once you have chosen or created a monitor, you then bind it to the appropriate service. The monitor names can be up to 63 characters in length. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How monitors operate

As shown in the diagram, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server fails to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

- [Creating Monitors](#)
- [Configuring Monitoring Parameters to Determine the Service Health](#)
- [Binding Monitors to Services](#)
- [Modifying Monitors](#)
- [Enabling and Disabling Monitors](#)
- [Unbinding Monitors](#)
- [Removing Monitors](#)
- [Viewing Monitors](#)
- [Closing Monitor Connections](#)
- [Ignoring the Upper Limit on Client Connections for Monitor Probes](#)

## Create monitors

September 21, 2020

The Citrix ADC appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

### To create a monitor by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <monitorType> [<interval>]
2
3 add lb mon monitor-HTTP-1 HTTP
4
5 add lb mon monitor-HTTP-2 TCP 2
6 <!--NeedCopy-->
```

### To create a monitor by using the GUI

1. Navigate to **Traffic Management> Load Balancing> Monitors**.
2. Click **Add** and create a monitor type that meets your requirement.

The Create Monitor screen contains two sections, **Basic Parameters** and **Advanced Parameters**.

Depending on the monitor type, the **Basic Parameters** section contains the parameters that must be set for each monitor. The **Advanced Parameters** section contains the parameters that can be used in advanced use cases.

The following figure is a sample of a Create Monitor page of the ARP monitor type.

The screenshot displays the 'Configure Monitor' page for an ARP monitor. The navigation bar at the top includes 'Dashboard', 'Configuration', 'Reporting', 'Documentation', and 'Downloads'. The main heading is 'Configure Monitor'. The form is divided into two sections: 'Basic Parameters' and 'Advanced Parameters'.

**Basic Parameters:**

- Name: arp
- Type: ARP
- Interval: 5 (Second)
- Response Time-out: 2 (Second)

**Advanced Parameters:**

- Destination IP: (empty)
- Destination Port: Bound Service
- Down Time: 30 (Second)
- TROFS Code: 0
- TROFS String: (empty)
- Dynamic Time-out: 0
- Deviation: 0 (Second)
- Dynamic Interval: 0

#### Note

Prior to NetScaler release 12.0 build 56.20, Basic Parameters and Advanced Parameters are named Standard Parameters and Special Parameters respectively.

## Configure monitor parameters to determine the service health

September 21, 2020

You can configure the following monitoring parameters to mark a service as DOWN on the basis of the monitoring probes.

### Retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe fails.

### failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the ten probes sent, at least six probes must fail if the service is to be marked as DOWN.

### alertRetries

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

### Setting alertRetries to a Value Higher than the Retries Value

The alertRetries parameter, which specifies the maximum number of consecutive monitoring-probe failures after which the Citrix ADC appliance generates an SNMP trap called monProbeFailed, can now be set to a value higher than the Retries value (which specifies the maximum number of probes to send to establish the state of a service for which a monitoring probe failed). If the alertRetries value is higher than the Retries value, the SNMP trap is not sent until after the service is DOWN.

For example, if you set Retries to 3, alertRetries to 12, and the time interval to 5 seconds, the service is marked DOWN after 15 seconds (35), *but no alert is generated. If the monitor probes are still failing*

after 60 seconds (125), the Citrix ADC appliance generates a monProbeFailed trap. If a probe succeeds at some time between 15 and 60 seconds, the service is marked UP and no alert is generated.

Setting the alertRetries value to a value higher than the Retries value helps in generating only genuine alerts and avoid false positives during scheduled restarts.

### **To set the alertRetries parameter value to a higher value than the Retries value by using the command line interface**

At the command prompt, type:

```
1 add lb monitor <monitorName> [-retries <integer>] [-alertRetries <
   integer>]
2 <!--NeedCopy-->
```

#### **Example:**

```
add lb monitor monitor-HTTP-1 HTTP -retries 3 -alertRetries 12
```

### **To set the alertRetries parameter value to a higher value than the Retries value by using the GUI**

1. Navigate to **Configuration > Traffic Management > Load Balancing > Monitors**.
2. Click **Add** to add a new monitor or select an existing monitor and click **Edit**.
3. In the **Retries** box, type the value for the Retries parameter.
4. In the **SNMP Alert Retries** box, type the value for the alertRetries parameter.

## **Bind monitors to services**

September 21, 2020

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN.

If you bind multiple monitors to a service, the Citrix ADC appliance checks the state of all the monitors and then decides the state of the service. You can configure different weights to a monitor. The weight of a monitor specifies how much that monitor contributes to designating the service as UP or DOWN. A monitor with a greater weight has a higher preference in marking the service UP or DOWN. Default weight is 1. Therefore, even if one of the monitors fails, the service is marked as DOWN. For more information, see [Set a threshold value for the monitors bound to a service](#).

**Note:** The destination IP address of a monitor probe can be different than the server IP address and port.

### To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
1 bind service <name> (-monitorName <string>)
2 <!--NeedCopy-->
```

#### Example:

```
1 bind service s1 -monitorName tcp
2 <!--NeedCopy-->
```

### To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

## Modify monitors

September 21, 2020

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

### To modify an existing monitor by using the command line interface

At the command prompt, type:

```
1 set lb monitor <monitorName> <type> -interval <interval> -resptimeout <
  resptimeout>
2 <!--NeedCopy-->
```

#### Example:

```
1 set mon monitor-HTTP-1 HTTP -interval 50 milli
2 -resptimeout 20 milli
3 <!--NeedCopy-->
```

### **To modify an existing monitor by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Monitors, and open a monitor to modify.

## **Enable and disable monitors**

September 21, 2020

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

### **To enable a monitor by using the command line interface**

At the command prompt, type:

```
1 enable lb monitor <monitorName>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 enable lb mon monitor-HTTP-1
2 <!--NeedCopy-->
```

### **To enable a monitor by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and from the Action list, select Enable or Disable.

### **To disable a monitor by using the command line interface**

At the command prompt, type:

```
1 disable lb monitor <monitorName>
2 <!--NeedCopy-->
```

**Example:**

```
1 disable lb mon monitor-HTTP-1
2 <!--NeedCopy-->
```

## Unbind monitors

September 21, 2020

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

### To unbind a monitor from a service by using the command line interface

At the command prompt, type:

```
1 unbind lb monitor <monitorName>
2 <!--NeedCopy-->
```

**Example:**

```
1 unbind mon monitor-HTTP-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To unbind a monitor from a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click Unbind.

## Remove monitors

September 21, 2020

After you unbind a monitor that you created from its service, you can remove that monitor from the Citrix ADC configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

### To remove a monitor by using the command line interface

At the command prompt, type:

```
1 rm lb monitor <monitorName> <type>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm lb monitor monitor-HTTP-1 HTTP
2 <!--NeedCopy-->
```

### To remove a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and click Delete.

## View monitors

September 21, 2020

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your Citrix ADC configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

### To view monitor bindings by using the command line interface

At the command prompt, type:

```
1 show lb monbindings <MonitorName>
2 <!--NeedCopy-->
```

**Example:**

```
1 show lb monbindings monitor-HTTP-1
2 <!--NeedCopy-->
```

**To view monitor bindings by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and in the Action list, click Show Bindings.

**To view monitors by using the command line interface**

At the command prompt, type:

```
1 show lb monitor <monitorName>
2 <!--NeedCopy-->
```

**Example:**

```
1 show lb mon monitor-HTTP-1
2 <!--NeedCopy-->
```

**To view monitors by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors. The details of the available monitors appear in the Monitors pane.

**Close monitor connections**

September 21, 2020

The Citrix ADC appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the appliance and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and may not be always necessary.

For the TCP type monitor, you can configure the appliance to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

**Note:** The monitorConnectionClose setting is applicable only for type TCP and TCP-Default monitors.

**To configure monitor-connection closure by using the command line interface:**

At the command prompt, type:

```
1 set lb parameter -monitorConnectionClose <monitor_conn_close_option>
2 <!--NeedCopy-->
```

**Example**

```
1 set lb parameter -monitorConnectionClose RESET
2 <!--NeedCopy-->
```

**To configure monitor-connection closure by using the configuration utility:**

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters.
2. Select FIN or Reset.

**Closing Monitor Connections at the Service or Service Group Level**

You can also configure the appliance to close a monitor-probe connection at the service and service group level by setting the monConnectionClose parameter. If this parameter is not set, the monitor connection is closed by using the value set in the global load balancing parameters. If this parameter is set at the service or service group level, the monitor connection is closed by sending a connection termination message, with the FIN or RESET bit set, to the service or service group.

**To configure monitor-connection closure at the service level by using the CLI**

At the command prompt, type:

```
1 set service <service_name> -monConnectionClose ( RESET | FIN )
2 <!--NeedCopy-->
```

**To configure monitor-connection closure at the service group level by using the CLI**

At the command prompt, type:

```
1 set serviceGroup <service_name> -monConnectionClose ( RESET | FIN )
2 <!--NeedCopy-->
```

**To configure monitor-connection closure at the service level by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Add or edit a service, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

**To configure monitor-connection closure at the service group level by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Add or edit a service group, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

**Ignore the upper limit on client connections for monitor probes**

September 21, 2020

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the Citrix ADC appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the appliance to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the Citrix ADC appliance.

**To set the Skip MaxClients for Monitor Connections option by using the command line interface**

At the command prompt, type:

```
1 set lb parameter -monitorSkipMaxClient (ENABLED|DISABLED)
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb parameter -monitorSkipMaxClient enabled
2 <!--NeedCopy-->
```

## To set the Skip MaxClients for Monitor Connections option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters.
2. Select Skip MaxClients for Monitoring Connections.

## Manage a large scale deployment

September 21, 2020

The Citrix ADC appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure, which significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services, and make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

## Ranges of virtual servers and services

September 21, 2020

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, all of the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this

example, five virtual servers will be created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

Note: The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

For example, if you have three virtual servers named Vserver-x, Vserver-y, and Vserver-z, instead of configuring them separately, you can type vserver [x-z] to configure them all.

## Creating a range of virtual servers

You create a range of virtual servers as described below.

### To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
1 add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
  port>]
2
3 add lb vserver <name>@[<rangeValue>]> <protocol> <IPAddress[<rangeValue
  >]> [<port>]
4 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
2 <!--NeedCopy-->
```

OR

```
1 add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
2
3 vserver "vserverP" added
4
5 vserver "vserverQ" added
6
7 vserver "vserverR" added
8
9 Done
10 <!--NeedCopy-->
```

### To create range of virtual servers by using the command line interface

At the command prompt, type one of the following commands:

```

1 add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
  port>]
2
3 add lb vserver <name>@**[**<rangeValue>**]** <protocol> <IPAddress[<
  rangeValue>]> [<port>]
4 <!--NeedCopy-->

```

#### Example:

```

1 add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
2 <!--NeedCopy-->

```

OR

```

1 add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
2 vserver "vserverP" added
3 vserver "vserverQ" added
4 vserver "vserverR" added
5 Done
6 <!--NeedCopy-->

```

### To create range of virtual servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Add a virtual server, and specify a range.

### Creating a range of services

You create a range of services as described below. If you specify a range for the service name, specify a range for the IP address too.

### To create range of services by using the command line interface

At the command prompt, type the command:

```

1 add service <name>@ <IP>@ <protocol> <port>
2 <!--NeedCopy-->

```

#### Example:

```
1 > add service serv[1-3] 10.102.29.[102-104] http 80
2 service "serv1" added
3 service "serv2" added
4 service "serv3" added
5 Done
6 <!--NeedCopy-->
```

## Configure service groups

September 21, 2020

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group can be identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not re-configure the member on the Citrix ADC appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is particularly useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the appliance learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the Citrix ADC appliance. A domain name will be resolved into an IP address only if the corresponding address record is present on the appliance or the name server.

### Create service groups

You can configure up to 8192 service groups on the Citrix ADC appliance.

#### To create a service group by using the command line

At the command prompt, type:

```
1 add servicegroup <ServiceGroupName> <Protocol>
2 <!--NeedCopy-->
```

**Example:**

```
1 add servicegroup Service-Group-1 HTTP
2 <!--NeedCopy-->
```

**To create a service group by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Service Groups**, and add a service group.

**Bind a service group to a virtual server**

When you bind a service group to a virtual server, the member services are bound to the virtual server.

**To bind a service group to a virtual server by using the command line interface**

At the command prompt, type:

```
1 bind lb vserver <name>@ <serviceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
bind lb vserver Vserver-LB-1 Service-Group-1
```

**To bind a service group to a virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Service Groups**.

**Bind a member to a service group**

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the configuration utility, if you want to add a domain-name based service group member, select Server Based.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

## To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
1 bind servicegroup <serviceName> (<IP>@ | <serverName>) <port>
2 <!--NeedCopy-->
```

### Examples:

```
1 bind servicegroup Service-Group-1 10.102.29.30 80
2
3 bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a
   :888b 80
4
5 bind servicegroup CitrixEdu s1.citrite.net
6 <!--NeedCopy-->
```

## To add members to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups and open a service group.
2. Click in the Service Group section, and do one of the following:
  - To add a new IP based service group member, select IP Based.
  - To add a server-name based service group member, select Server Based.

If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box  
Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.
4. Click Create.

## Bind a monitor to a service group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

## To bind a monitor to a service group by using the command line interface

At the command prompt, type:

```
1 bind serviceGroup <serviceName> -monitorName <string> -monState (
    ENABLED | DISABLED)
2 <!--NeedCopy-->
```

### Example:

```
1 bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
2 <!--NeedCopy-->
```

## To a bind monitor to a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Open a service group and, in Advanced Settings, click **Monitors**.

## Retain the original state of a service group member after disabling and enabling a virtual server

From build 64.x, a new global option, `-retainDisableServer`, enables you to retain a service-group member's state when a server is disabled and reenabled.

Previously, a member's state would change from DISABLED to ENABLED under the following set of conditions:

- Two applications are deployed on the same port on a virtual server.
- Two service groups with a common member are bound to this virtual server, and the common member is enabled in one group and disabled in the other.
- The server is disabled and then reenabled.

Under these conditions, disabling the server disables all the service group members, and re enabling the server enables all the members, by default, regardless of their earlier states. To bring the members back to the original states, you must manually disable those member(s) in the service group. This is a cumbersome task and prone to errors.

## Manage service groups

September 21, 2020

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group. For more information about service groups, see [Configure service groups](#).

## Modify a service group

You can modify attributes of service group members. You can set several attributes of the service group, such as maximum client, SureConnect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

### To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

```
1 set servicegroup <serviceName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES|NO)] [-cip (ENABLED|DISABLED)] [-cipHeader <cipHeader>] [-usip (YES|NO)] [-sc (ON|OFF)] [-sp (ON|OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES|NO)] [-TCPB (YES|NO)] [-CMP (**YES**|**NO**)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED|DISABLED)] [-downStateFlush (ENABLED|DISABLED)]
2 <!--NeedCopy-->
```

### Example:

```
1 set servicegroup Service-Group-1 -type TRANSPARENT
2
3 set servicegroup Service-Group-1 -maxClient 4096
4
5 set servicegroup Service-Group-1 -maxReq 16384
6
7 set servicegroup Service-Group-1 -cacheable YES
8 <!--NeedCopy-->
```

### To modify a service group by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Service Groups**, and open the service group to modify.

## Remove a service group

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the Citrix ADC appliance.

### To remove a service group by using the command line interface

At the command prompt, type:

```
1 rm servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm servicegroup Service-Group-1
2 <!--NeedCopy-->
```

### To remove a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and click **Delete**.

## Unbind a member from a service group

When you unbind a member from the service group, the attributes set on the service group will no longer apply to the member that you unbound. The member services retain its individual settings, however, and continue to exist on the Citrix ADC appliance.

### To unbind members from a service group by using the command line interface

At the command prompt, type:

```
1 unbind servicegroup <serviceGroupName> <IP>@ [<port>]
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind servicegroup Service-Group-1 10.102.29.30 80
2 <!--NeedCopy-->
```

**To unbind members from a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click **Unbind**.

**Unbind a service group from a virtual server**

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the Citrix ADC appliance.

**To unbind a service group from a virtual server by using the command line interface**

At the command prompt, type:

```
1 unbind lb vserver <name>@ <ServiceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
1 unbind lb vserver Vserver-LB-1 Service-Group-1
2 <!--NeedCopy-->
```

**To unbind a service group from a virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click **Unbind**.

**Unbind monitors from service groups**

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

**To unbind a monitor from a service group using the command line interface**

At the command prompt, type:

```
1 unbind serviceGroup <serviceName> -monitorName <string>
2 <!--NeedCopy-->
```

**Example:**

```
1 unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
2 <!--NeedCopy-->
```

### To unbind a monitor from a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click **Unbind**.

### Enable or Disable a service group

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

### To disable a service group by using the command line interface

At the command prompt, type:

```
1 disable servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

#### Example:

```
1 disable servicegroup Service-Group-1
2 <!--NeedCopy-->
```

### To disable a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Disable**.

### To enable a service group by using the command line interface

At the command prompt, type:

```
1 enable servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
1 enable servicegroup Service-Group-1
2 <!--NeedCopy-->
```

**To enable a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Enable**.

**View the status of service groups members**

Navigate to **Traffic Management > Load Balancing > Service Groups**.

In the Service Groups page, the **Effective State** column displays the status of the service groups. Status UP/DOWN in the **Effective State** column is clickable. You can click the status and get the list of members along with their status in the same view. Select a member and click the **Monitor Details** button to view the reason for the status being DOWN.

**Note:** Before NetScaler release 12.0 build 56.20, the status in the **Effective State** column was not clickable.

|                          | Service Group Name | State   | Effective State | Protocol | Max Clients | Max Requests | Maximum Bandwidth (Kbps) |
|--------------------------|--------------------|---------|-----------------|----------|-------------|--------------|--------------------------|
| <input type="checkbox"/> | sg1                | ENABLED | DOWN            | HTTP     | 0           | 0            | 0                        |
| <input type="checkbox"/> | ssl-sg             | ENABLED | DOWN            | SSL      | 0           | 0            | 0                        |

**Viewing the properties of a service group**

You can view the following settings of the configured service groups:

- Name
- IP address
- State
- Protocol
- Maximum client connections
- Maximum requests per connection
- Maximum bandwidth
- Monitor threshold

Viewing the details of the configuration can be helpful for troubleshooting your configuration.

**To view the properties of a service group by using the command line interface**

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

```
1 show servicegroup <ServiceGroupName>
2
3 show servicegroup <ServiceGroupName> -includemembers
4 <!--NeedCopy-->
```

**Example:**

```
1 show servicegroup Service-Group-1
2 <!--NeedCopy-->
```

**To view the properties of a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Click the arrow next to the service group.

**Viewing service group statistics**

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The Citrix ADC appliance uses the statistics of a service group to balance the load on the services.

**To view the statistics of a service group by using the command line interface**

At the command prompt, type:

```
1 stat servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat servicegroup Service-Group-1
2 <!--NeedCopy-->
```

**To view the statistics of a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and click **Statistics**.

## Load balancing virtual servers bound to a service group

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

### To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
1 show servicegroupbindings <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 > show servicegroupbindings SVCGRPDTLS
2 SVCGRPDTLS - State :ENABLED
3 1) Test-pers (10.10.10.3:80) - State : DOWN
4 2) BRVSERV (10.10.1.1:80) - State : DOWN
5 3) OneMore (10.102.29.136:80) - State : DOWN
6 4) LBVIP1 (10.102.29.66:80) - State : UP
7 Done
8 >
9 <!--NeedCopy-->
```

### To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Show Bindings**.

## Configure automatic domain based service group scaling

January 20, 2021

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind additional domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically on the basis of the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see [Adding a Name Server](#).
- Add a domain based server. For information about adding a domain-based server, see [Configuring a server object](#).
- Add a service group and associate the domain based server to the service group, with the autoscale option set to DNS. For information about adding a service group, see [Configuring Service Groups](#).

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain

name that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

### To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

```
1 add serviceGroup <serviceName> -autoScale (YES | NO)
2
3 show serviceGroup <serviceName>
4 <!--NeedCopy-->
```

### Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
1 > add serviceGroup servGroup server1 80 -autoScale YES
2 Done
3 > sh servicegroup servGroup
4     servGroup - HTTP
5     State: ENABLED Monitor Threshold : 0
6         . . .
7         . . .
8     1) 192.0.2.31:80 State: UP Server Name: server1 (Auto
          scale) Server ID: None Weight: 1
9
10         Monitor Name: tcp-default State: UP
11         Probes: 2 Failed [Total: 0 Current: 0]
12         Last response: Success - TCP syn+ack received.
13
14     2) 192.0.2.32:80 State: UP Server Name: server1 (Auto
          scale) Server ID: None Weight: 1
15
```

```

16         Monitor Name: tcp-default           State: UP
17         Probes: 2           Failed [Total: 0 Current: 0]
18         Last response: Success - TCP syn+ack received.
19
20     3)   192.0.2.36:80   State: UP           Server Name: server1 (Auto
         scale)       Server ID: None Weight: 1
21
22         Monitor Name: tcp-default           State: UP
23         Probes: 2           Failed [Total: 0 Current: 0]
24         Last response: Success - TCP syn+ack received.
25
26     4)   192.0.2.55:80   State: UP           Server Name: server1 (Auto
         scale)       Server ID: None Weight: 1
27
28         Monitor Name: tcp-default           State: UP
29         Probes: 2           Failed [Total: 0 Current: 0]
30         Last response: Success - TCP syn+ack received.
31
32     5)   192.0.2.80:80   State: UP           Server Name: server1 (Auto
         scale)       Server ID: None Weight: 1
33
34         Monitor Name: tcp-default           State: UP
35         Probes: 2           Failed [Total: 0 Current: 0]

```

## To configure a service group to scale automatically by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Create a service group, and set the autoscale mode to DNS.

## Overwriting TTL values

**Note:** This option is supported from Citrix ADC 12.1 build 51.xx and later.

Citrix ADC appliance is configured to periodically query the DNS server for any update in SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding service group member and also globally, then the TTL value specified while binding the service group member takes precedence.

If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

### Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```
1 bind serviceGroup <serviceGroupName> (<serverName> [-dbstTL <secs>])
2 <!--NeedCopy-->
```

#### Example:

```
1 bind servicegroup svc_grp_1 web_serv -dbstTL 10
2 <!--NeedCopy-->
```

- To overwrite the TTL value globally, at the command prompt, type:

```
1 set lb parameter [-dbstTL <secs>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -dbstTL 15
2 <!--NeedCopy-->
```

### Overwriting the TTL values using the GUI

#### To overwrite the TTL value while binding:

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

#### To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

**Note:** If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

### Specifying different name servers for service group and domain name bindings

**Note:** This option is supported from Citrix ADC 12.1 build 51.xx and later.

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

### Specifying name servers while binding a server to service groups using the CLI

**At the command prompt, type:**

```
1 bind serviceGroup <serviceName> (<serverName> [-nameServer <
    ip_addr>] [-dbsTTL <secs>])
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv -ns.nameserver.com 10.102.27.155
    -dbsTTL 10
2 <!--NeedCopy-->
```

### Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for bound domain needs to be sent.

## Service discovery using DNS SRV records

September 21, 2020

An SRV record (service record) is a specification of data in the Domain Name System that defines the location, that is the hostname and the port number of servers for specified services. The record also defines the weight and priority of each server.

### Example of an SRV record:

`_http._tcp.example.com. 100 IN SRV 10 60 5060 a.example.com.`

The following table describes each item in an SRV record:

| Service | Protocol | Name        | TTL | Class | SRV | Priority | Weight | Port | Target        |
|---------|----------|-------------|-----|-------|-----|----------|--------|------|---------------|
| HTTP    | TCP      | example.com | 100 | IN    | SRV | 10       | 60     | 5060 | a.example.com |

You can use the DNS SRV records to discover the service endpoints. Citrix ADC appliance is configured to periodically query the DNS servers with the SRV record associated with a service. On receiving the SRV record, each of the target host published in the SRV record is bound to a service group associated with the service. Each of the bindings inherits the port, priority, and weight from the SRV record. For each service deployment the user has to configure the Citrix ADC appliance once while bringing it up, thus making it a single touch deployment for applications.

### Use case: Load balancing microservices

Applications are moving toward microservice architecture from monolithic architectures. Movement to microservice architecture along with backend server autoscale solution, is making application deployment more dynamic. To support such a dynamic deployment, proxies or ADC must be able to dynamically detect the backend application or service instances and absorb them into proxy configuration.

The service discovery using DNS SRV records feature aids configuration of Citrix ADC appliance in such a dynamic deployment scenario. Application developers can use some of the orchestration platforms to deploy the application. Orchestration platforms while instantiating containers during application deployment, might not assign protocol specific standard port for each of these containers. In such scenarios, discovering the port information becomes the key to configuring the Citrix ADC appliance. SRV records are helpful in such a scenario. SRV record parameters such as the priority and weight can be used for better load balancing of applications.

- Priority parameter can be used to dictate the priority of the server pool.
- Weight parameter can be used to dictate the capacity of the backend service instances and hence can be used for weighted load balancing.

- Whenever there is a change in the back-end server pool, for example a backend instance is removed from the pool, the instance is removed gracefully only after all the existing client connections are honored.

**Note:**

- An A/AAAA records based service discovery, all resolved IP addresses have the same weight because you assign the weight to the domain being resolved.
- If the weight in SRV response is greater than 100, then services are not created.

## Priority based load balancing using SRV records

You can use SRV records to perform priority-based load balancing. The priority based server pool can be an alternative for the backup virtual servers. The ns.conf file requires minimal configuration compared to the backup virtual servers.

In priority based load balancing using SRV records, a priority number is assigned to each of the server pool. Lesser the number, higher is the priority. One of the servers in the highest priority pool is selected for load balancing based on the server's health and availability. If all the servers in the highest priority server pool are down, then the servers that have the next highest priority are selected for load balancing. However, if the servers in the highest priority server pool are up again, then the servers are selected from the highest priority pool again.

Switching from one priority server pool to another server pool occurs gracefully by bleeding the existing client transactions. Therefore, the current clients do not see any break in the application access.

### To enable querying for SRV records using the CLI

You must perform the following tasks to enable querying for SRV records:

1. Create a server by specifying the query type parameter as SRV.

At the command prompt, type:

```
1 add server <name> <domain> [-queryType <queryType>])
2 <!--NeedCopy-->
```

**Example:**

```
1 add server web_serv example.com -queryType SRV
2 <!--NeedCopy-->
```

**Note:**

- By default, IPv4 queries are sent. To send IPv6 queries, you must enable the IPv6 domain.

- The SRV target domain name must not exceed 127 characters.
2. Create a service group with the autoscale mode as DNS.

At the command prompt, type:

```
1 add serviceGroup <serviceName> <serviceType> [-autoScale <
  autoScale>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add servicegroup svc_grp_1 http -autoscale dns
2 <!--NeedCopy-->
```

3. Bind the server created in step 1 to the service group as a member.

At the command prompt, type:

```
1 bind serviceGroup <serviceName> <serverName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv
2 <!--NeedCopy-->
```

**Note:**

- When binding servers to service group members, you do not have to enter the port number for SRV server types. In case you specify a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

## To enable querying for SRV records using the GUI

### Create a server

1. Navigate to **Traffic Management > Load Balancing > Servers** and click **Add**.

## ← Create Server

4. Click **OK**.

## Bind server to the service group member

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Close**.

### Note:

- While binding, you do not have to enter the port number for SRV server types. In case you enter a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

## Overwriting TTL values

Citrix ADC appliance is configured to periodically query the DNS server for any update in SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding service group member and also globally, then the TTL value specified while binding the service group member takes precedence.

If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

## Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```

1 bind serviceGroup <serviceName> (<serverName> [-dbsTTL <secs>])
2 <!--NeedCopy-->

```

**Example:**

```

1 bind servicegroup svc_grp_1 web_serv -dbsTTL 10
2 <!--NeedCopy-->

```

- To overwrite the TTL value globally, at the command prompt, type:

```

1 set lb parameter [-dbsTTL <secs>]
2 <!--NeedCopy-->

```

**Example:**

```

1 set lb parameter -dbsTTL 15
2 <!--NeedCopy-->

```

**Overwriting the TTL values using the GUI****To overwrite the TTL value while binding:**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

**To overwrite the TTL value at the global level:**

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

**Note:** If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

**Specifying different name servers for service group and domain name bindings**

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

## Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
1 bind serviceGroup <serviceName> (<serverName> [-nameServer <
    ip_addr>] [-dbstTL <secs>])
2 <!--NeedCopy-->
```

Example:

```
1 bind servicegroup svc_grp_1 web_serv -ns.nameserver.com 10.102.27.155
    -dbstTL 10
2 <!--NeedCopy-->
```

## Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for bound domain needs to be sent.

## Translate the IP address of a domain-based server

September 21, 2020

To simplify maintenance on the Citrix ADC appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address in the event that you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks

particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

### **To configure a translation IP address for a server by using the command line interface**

At the command prompt, type:

```
1 add server <name>@ <serverDomainName> -translationIp <
  translationIPAddress> -translationMask <netMask> -state <ENABLED|
  DISABLED>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 add server myMaskedServer www.example.com -translationIp 10.10.10.10 -
  translationMask
2 255.255.0.0 -state ENABLED
3 <!--NeedCopy-->
```

### **To configure a translation IP address for a server by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Servers, create a domain-based server, and specify a translation IP address.

## **Mask a virtual server IP address**

September 17, 2021

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works differently from the IP pattern definition for a server described in [Translating the IP Address of a Domain-Based Server](#). For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Also, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The Citrix ADC appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers.

When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it is sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

### To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

```
1 add lb vsriver <name>@ http -ipPattern <ipAddressPattern> -ipMask <
  ipMask> <listenPort>
2 <!--NeedCopy-->
```

#### Example:

Pattern matching based on prefix octets:

```
1 add lb vsriver myLBVserver http -ippattern 10.102.0.0 -ipmask
  255.255.0.0 80
2 <!--NeedCopy-->
```

Pattern matching based on trailing octets:

```
1 add lb vsriver myLBVserver1 http -ippattern 0.0.22.74 -ipmask
  0.0.255.255 80
2 <!--NeedCopy-->
```

Modify a pattern-based virtual server:

```
1 set lb vsriver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
2 <!--NeedCopy-->
```

If you configure the Virtual Server 1 as follows:

```
1 add lb vsriver vs1 HTTP -ippattern 100.1.1.0 -ipmask 255.255.255.0 80
2 <!--NeedCopy-->
```

The Citrix ADC appliance will not respond to an ARP request on all the IP addresses. However, it responds to the virtual server traffic routed to all the IP addresses in that pattern.

### To configure a virtual server IP address mask by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

## Configure load balancing for commonly used protocols

September 21, 2020

In addition to Web sites and Web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your Citrix ADC appliance to use domain names for your servers rather than IPs, you may also need to set up IP translation and masking for those servers.

### Load balance a group of FTP servers

September 21, 2020

The Citrix ADC appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers

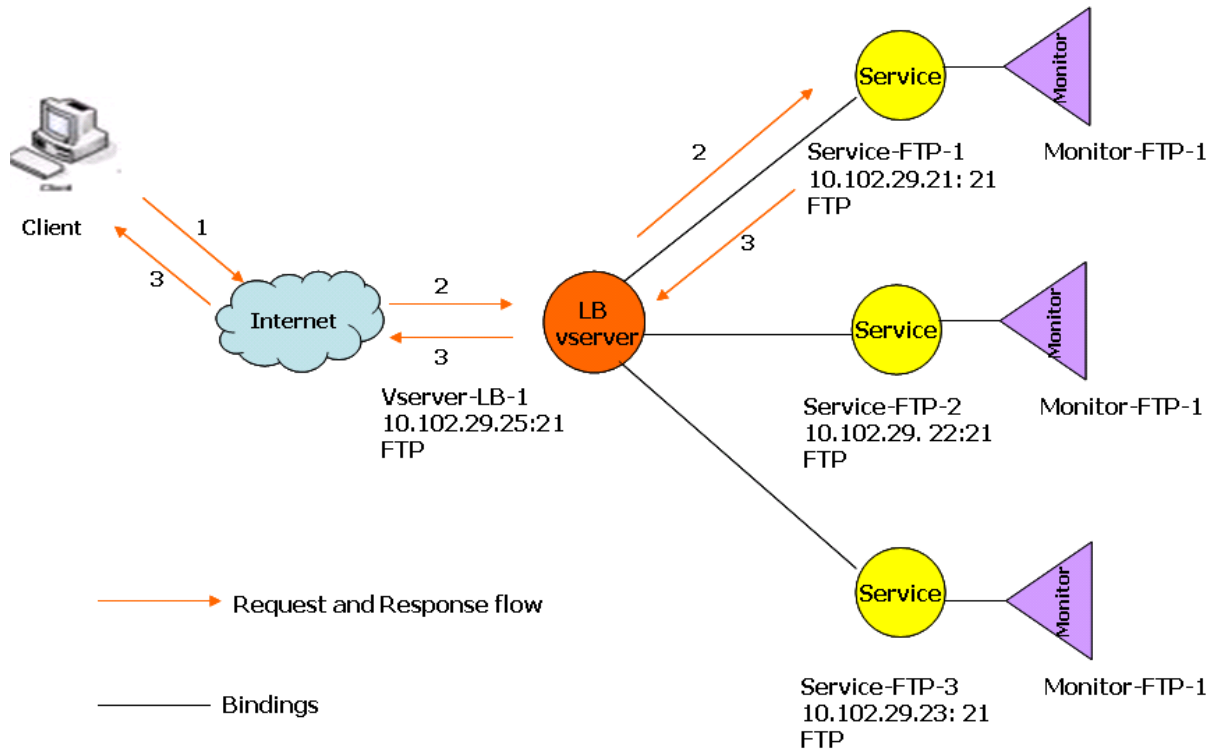

In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client’s connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

The following table lists the names and values of the basic entities configured on the appliance.

| Entity type | Name          | IP address   | Port | Protocol |
|-------------|---------------|--------------|------|----------|
| Vserver     | Vserver-LB-1  | 10.102.29.25 | 21   | FTP      |
| Services    | Service-FTP-1 | 10.102.29.21 | 21   | FTP      |
|             | Service-FTP-2 | 10.102.29.22 | 21   | FTP      |
|             | Service-FTP-3 | 10.102.29.23 | 21   | FTP      |
| Monitors    | FTP           | None         | None | None     |

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model

The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section [Binding Monitors to Services](#).

### To create FTP monitors by using the command line interface

At the command prompt, type:

```
1 add lb monitor <MonitorName> FTP -interval <Interval> -userName <
  UserName> -password <Password>
2 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password
   User
2 <!--NeedCopy-->
```

### To create FTP monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.

## Load balance DNS servers

September 21, 2020

When you request DNS resolution of a domain name, the Citrix ADC appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improves DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

| Entity type    | Name          | IP address   | Port | Protocol |
|----------------|---------------|--------------|------|----------|
| Virtual Server | Vserver-LB-1  | 10.102.29.13 | 53   | DNS      |
| Services       | Service-DNS-1 | 10.102.29.14 | 53   | DNS      |
|                | Service-DNS-2 | 10.102.29.15 | 53   | DNS      |
|                | Service-DNS-3 | 10.102.29.16 | 53   | DNS      |
| Monitors       | monitor-DNS-1 | None         | None | None     |

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model

To configure a basic DNS load balancing setup, see [Setting Up Basic Load Balancing](#). Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see [Binding Monitors to Services](#).

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

### To configure DNS monitors by using the command line interface

At the command prompt, type:

```
1 add lb monitor <monitorName> DNS -query <domainName> -queryType <
  Address|ZONE> -IPAddress <ipAddress>
2 <!--NeedCopy-->
```

Example:

```
1 add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType
  Address -IPAddress 10.102.29.66
```

```
2
3 add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType
   Address -IPAddress
4 1000:0000:0000:0000:0005:0600:700a::888b-888d
5 <!--NeedCopy-->
```

## To configure DNS monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

## Load balance domain-name based services

September 21, 2020

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the Citrix ADC configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor could be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

**Note:** When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.

- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error” (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers

The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The vserver Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

| Entity type    | Name           | IP address     | Port | Protocol |
|----------------|----------------|----------------|------|----------|
| Virtual Server | Vserver-LB-1   | 10.102.29.17   | 80   | HTTP     |
|                | Vserver-LB-2   | 10.102.29.20   | 53   | DNS      |
| Servers        | server-1       | 10.102.29.18   | 80   | HTTP     |
|                | server-2       | www.citrix.com | 80   | HTTP     |
| Services       | Service-HTTP-1 | server-1       | 80   | HTTP     |
|                | Service-HTTP-2 | server-2       | 80   | HTTP     |
|                | Service-HTTP-2 | 10.102.29.19   | 80   | HTTP     |
| Monitors       | Default        | None           | None | None     |
| Name Server    | None           | 10.102.29.19   | None | None     |

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model

To configure a basic load balancing setup, see [Setting Up Basic Load Balancing](#). Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

### To add a name server by using the command line interface

At the command prompt, type:

```
1 add dns nameServer <dnsVserverName>
2 <!--NeedCopy-->
```

#### Example:

```
1 add dns nameServer Vserver-LB-2
2 <!--NeedCopy-->
```

### To add a name server by using the configuration utility

1. Navigate to **Traffic Management > DNS > Name Servers**.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

You can also add an authoritative name server that resolves the domain name to an IP address.

#### Note

You can add a name server of type TCP, UDP or UDP\_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with truncated bit, this response is not retried over TCP name server.

## Load balance a group of SIP servers

September 21, 2020

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System

A Citrix ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the Citrix ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the Citrix ADC appends RPORT to the via header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

## Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the Citrix ADC so that the private IP addresses used by the clients are translated into public IP addresses.

If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the Citrix ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named **nsrnatsip-127.0.0.1-5061**.

## Support for Policies and Expressions

The Citrix ADC default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip\_udp, sip\_tcp or sip\_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

## Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The Citrix ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- SIP\_UDP – Used when SIP servers send SIP messages over UDP.
- SIP\_TCP – Used when SIP servers send SIP messages over TCP.
- SIP\_SSL – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The Citrix ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 2. SIP Load Balancing Topology

| Entity type    | Name          | IP address   | Port | Service type / Protocol           |
|----------------|---------------|--------------|------|-----------------------------------|
| Virtual Server | Vserver-LB-1  | 10.102.29.65 | 80   | SIP_UDP /<br>SIP_TCP /<br>SIP_SSL |
| Services       | Service-SIP-1 | 192.168.1.6  | 80   | SIP_UDP /<br>SIP_TCP /<br>SIP_SSL |
|                | Service-SIP-2 | 192.168.1.5  | 80   | SIP_UDP /<br>SIP_TCP /<br>SIP_SSL |
| Monitors       | Default       | None         | 80   | SIP_UDP /<br>SIP_TCP /<br>SIP_SSL |

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:
  - **SIP\_UDP** – If you are load balancing the SIP traffic over UDP.
  - **SIP\_TCP** – If you are load balancing the SIP traffic over TCP.
  - **SIP\_SSL** – If you are load balancing and securing the SIP traffic over TCP.

Note: If you use SIP\_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.
2. Bind the services to the virtual servers.
3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The Citrix ADC provides two custom monitor types, **SIP\_UDP** and **SIP\_TCP**, for monitoring SIP services.
4. If using a SIP\_SSL virtual server, bind an SSL certificate-key pair to the virtual server.
5. If you are using the Citrix ADC as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

### To configure a basic load balancing setup for SIP traffic by using the command line interface

Create one or more services. At the command prompt, type:

```
1 add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
2 <!--NeedCopy-->
```

Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you will bind to it. At the command prompt, type:

```
1 add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
2 <!--NeedCopy-->
```

Bind each service to a virtual server. At the command prompt, type:

```
1 bind lb vserver <name> <serverName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
2 <!--NeedCopy-->
```

(Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:

```
1 add lb monitor <monitorName> <monitorType> [<interval>]
2
3 bind lb monitor <monitorName> <ServiceName>
4 <!--NeedCopy-->
```

**Example:**

```
1 add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipURI sip:mon@test.
   com -sipregURI sip:mon@test.com -respcode 200
2
3 bind monitor mon1 Service-SIP-UDP-1
4 <!--NeedCopy-->
```

If you created a SIP\_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:

```
1 bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -
   CA - skipCAName
2 <!--NeedCopy-->
```

**Example:**

```
1 bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
2 <!--NeedCopy-->
```

Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

```
1 set rnat <IPAddress> <netmask>
2
3 set rnat <IPAddress> <netmask> -natip <NATIPAddress>
4
5 set rnat <aclname> [-redirectPort <port>]
6
7 set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>
8 <!--NeedCopy-->
```

**Example:**

```
1 set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
2 <!--NeedCopy-->
```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named nsrnatsip-127.0.0.1-5061.

```
1 add ssl certKey <certkeyName> -cert <string> [-key <string>]
2
3 bind ssl service <serviceName> -certkeyName <string>
4 <!--NeedCopy-->
```

**Example:**

```
1 add ssl certKey c1 -cert cert.epm -key key.ky
2
3 bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
4 <!--NeedCopy-->
```

If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:

```
1 set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<
   rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -
   sip503RateThreshold <sip503_rate_threshold_value>
2 <!--NeedCopy-->
```

**Sample Configuration for load balancing the SIP traffic over UDP**

```
1 add service service-UDP-1 10.102.29.5 SIP_UDP 80
2
3 Done
4
```

```
5 add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80
6
7 Done
8
9 bind lb vserver vserver-LB-1 service-UDP-1
10
11 Done
12
13 add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -
    sipregURI sip:mon@test.com -respcode 200
14
15 Done
16
17 bind mon mon1 service-UDP-1
18
19 Done
20
21 set rnat 192.168.1.0 255.255.255.0
22
23 Done
24
25 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
    -addRportVip ENABLED -sip503RateThreshold 1000
26
27 Done
28 <!--NeedCopy-->
```

### Sample Configuration for load balancing the SIP traffic over TCP

```
1 add service service-TCP-1 10.102.29.5 SIP_TCP 80
2
3 Done
4
5 add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80
6
7 Done
8
9 bind lb vserver vserver-LB-1 service-TCP-1
10
11 Done
12
13 add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -
    sipregURI sip:mon@test.com -respcode 200
14
```

```
15 Done
16
17 bind mon mon1 service-TCP-1
18
19 Done
20
21 set rnat 192.168.1.0 255.255.255.0
22
23 Done
24
25 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
    -addRportVip ENABLED -sip503RateThreshold 1000
26
27 Done
28 <!--NeedCopy-->
```

### Sample Configuration for load balancing and securing SIP traffic over TCP

```
1 add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80
2
3 Done
4
5 add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80
6
7 Done
8
9 bind lb vserver vserver-LB-1 service-SIP-SSL
10
11 Done
12
13 add lb mon mon1 sip-tCP -sipMethod REGISTER -sipuRI sip:mon@test.com -
    sipregURI sip:mon@test.com -respcode 200
14
15 Done
16
17 bind mon mon1 service-SIP-SSL
18
19 Done
20
21 bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
22
23 Done
24
25 set rnat 192.168.1.0 255.255.255.0
```

```
26
27 Done
28
29 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
    -addRportVip ENABLED -sip503RateThreshold 1000
30
31 Done
32 <!--NeedCopy-->
```

## To configure a basic load balancing setup for SIP traffic by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SIP\_UDP, SIP\_TCP, or SIP\_SSL.
2. Click the Service section, and add a service of type SIP\_UDP, SIP\_TCP, or SIP\_SSL.
3. (Optional) Click the Monitor section, and add a monitor of type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP\_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
  - a) Navigate to System > Network > Routes.
  - b) On the Routes page, click the RNAT tab.
  - c) In the details pane, click Configure RNAT.
  - d) In the Configure RNAT dialog box, do one of the following:
    - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
      - Network
      - Netmask
    - If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
      - ACL Name
      - Redirect Port
  - e) To set a SNIP address as a NAT IP address, skip to step 7.
  - f) To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.
  - g) Click Create, and then click Close.

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

- a) Navigate to Traffic Management > Load Balancing > Services and click the Internal Services tab.
  - b) Select nsrnatsip-127.0.0.1-5061 and click **Edit**.
  - c) Click the **Certificates** section and bind a certificate key pair to the internal service.
7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to Traffic Management > Load Balancing and click Change SIP settings, set the various SIP parameters.

### SIP Expression and Policy Example: Compression Enabled in Client Requests

A Citrix ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with “400 Bad Request,” so that the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
1 add responder action sipaction1 respondwith q{
2   "SIP/2.0 400 Bad Request\r\n\r\n" }
3
4
5 Done
6
7 add responder policy sippol1
8
9 add responder policy sippol1 "SIP.REQ.METHOD.EQ("NEGOTIATE")&&SIP.REQ.
   HEADER("Compression").EXISTS" sipaction1
10 <!--NeedCopy-->
```

## Load balance RTSP servers

September 21, 2020

The Citrix ADC appliance can balance load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of a load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

| Entity type    | Name           | IP address    | Port | Protocol |
|----------------|----------------|---------------|------|----------|
| Virtual Server | Vserver-LB-1   | 10.102.29.100 | 554  | RTSP     |
| Services       | Service-RTSP-1 | 10.102.29.101 | 554  | RTSP     |
|                | Service-RTSP-2 | 10.102.29.102 | 554  | RTSP     |
|                | Service-RTSP-3 | 10.102.29.103 | 554  | RTSP     |
| Monitors       | Monitor-RTSP-1 | None          | 554  | RTSP     |

The following diagram shows the load balancing entities used in RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model

To configure a basic load balancing setup for RTSP servers, see [Setting Up Basic Load Balancing](#). Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see [Binding Monitors to Services](#). The following procedure describes how create a monitor that checks RTSP servers.

### To configure RTSP monitors by using the command line interface

At the command prompt, type:

```
1 add lb monitor <monitorName> <type>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb monitor Monitor-RTSP-1 RTSP
2 <!--NeedCopy-->
```

## **To configure RTSP monitors by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.

## **Load balance remote desktop protocol (RDP) servers**

October 23, 2020

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a graphical user interface to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the Citrix ADC appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). In some cases, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user should be able to continue with the remote application. To provide this functionality, the Citrix ADC RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the Citrix ADC applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the Citrix ADC appliance forwards the response to the client.

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as routing token) with the details of the active session and returns the packets to the Citrix ADC appliance, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the Citrix ADC reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

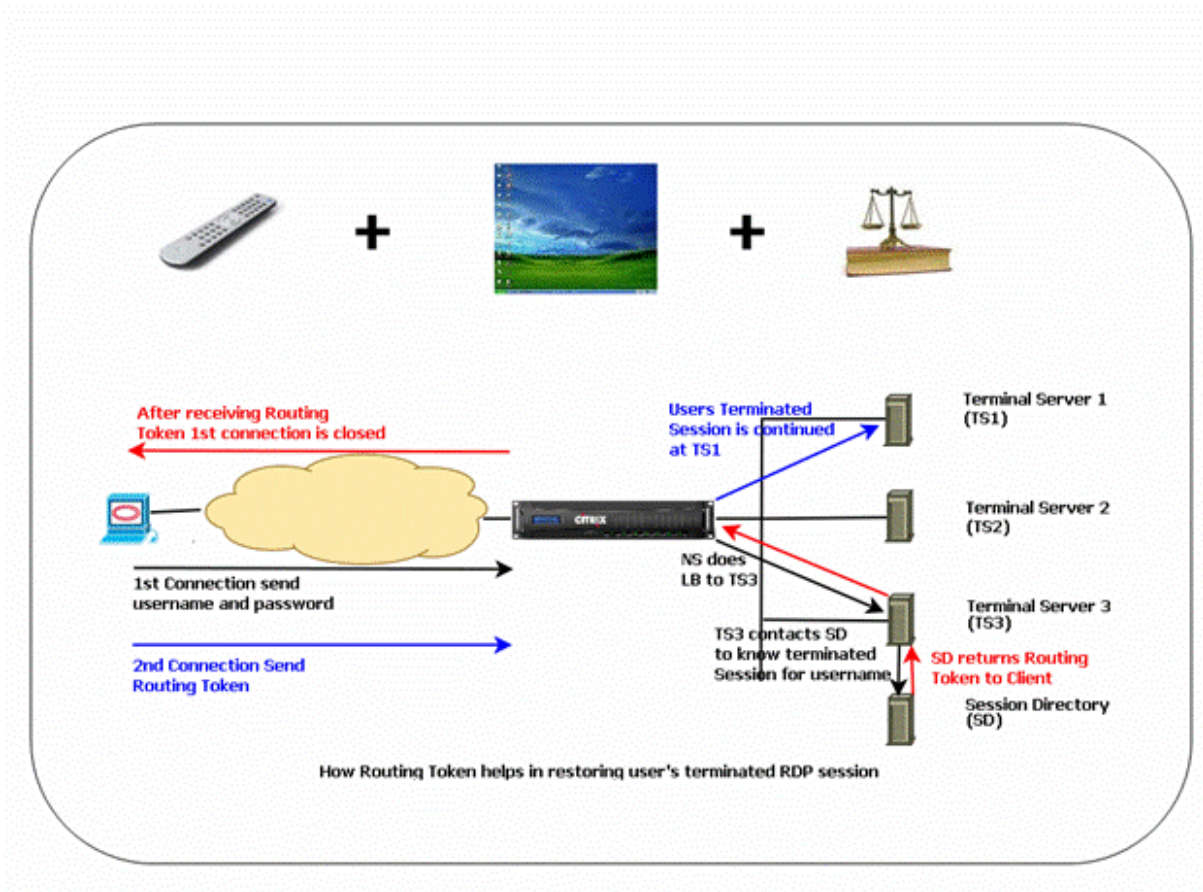

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.

The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP

**Note**

- When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
- The Citrix ADC appliance supports only IP-based cookies.
- The nsrdp.pl script is not supported on any current version of Windows servers.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the backend to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see [https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2003/cc758177\(v=ws.10\)##BKMK\\_2](https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2003/cc758177(v=ws.10)##BKMK_2)

When you add an RDP service, by default, Citrix ADC adds a monitor of the type TCP and binds it to the

service. The default monitor is a simple TCP monitor that checks whether or not a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, Citrix ADC marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a scripting monitor that is meant for the RDP protocol. When you configure the scripting monitor, the Citrix ADC opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the Citrix ADC can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the Citrix ADC at `/nsconfig/monitors/n-srdp.pl`. When you configure the user monitor, the Citrix ADC runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

### To configure RDP load balancing services by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

```
1 add service <name>@ <serverName> <serviceType> <port>
2 <!--NeedCopy-->
```

Note: Repeat the above command to add more services.

#### Example

```
1 > add service ser1 10.102.27.182 RDP 3389
2 Done
3 > add service ser2 10.102.27.183 RDP 3389
4 Done
5 >show service ser1
6 ser1 (10.102. 27.182:3389) - RDP
7     State: UP
8 ...
9     Server Name: 10.102.27.182
10    Server ID : 0           Monitor Threshold : 0

### To configure RDP load balancing services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create services of type RDP.

### To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

```
1 add lb vserver <name>@ <serviceType> <ipAddress> <port>
2
3 bind lb vserver <name>@ <serviceName>
4
5 Bind all the RDP services to be load balanced to the virtual server.
6 <!--NeedCopy-->
```

#### Example:

This example has two RDP services bound to the RDP virtual server.

```
1 add lb vs v1 rDP 10.102.27.186 3389
2 Done
3
4 bind lb vs v1 ser1
5 service "ser1" bound
6
7 bind lb vs v1 ser2
8 service "ser2" bound
9 Done
10
11 sh lb vs v1
12 v1 (10.102.27.186:3389) - RDP Type: ADDRESS
13 State: UP
14 ...
15 No. of Bound Services : 2 (Total)          2 (Active)
16 Configured Method: LEASTCONNECTION
17 Current Method: Round Robin, Reason: A new service is bound
18 Mode: IP
19 Persistence: NONE
20 L2Conn: OFF
21
```

```
22 1) ser1 (10.102.27.182: 3389) - RDPState: UP Weight: 1
23 2) ser2 (10.102.27.183: 3389) - RDPState: UP Weight: 1
24 Done
25 <!--NeedCopy-->
```

### To configure an RDP load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server of type RDP, and bind RDP services to this virtual server.

### To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

```
1 add lb monitor <monitorName> USER -scriptName nsrdp.pl
2
3 bind lb monitor <monitorName> <rdpServiceName>
4 <!--NeedCopy-->
```

#### Example:

```
1 add service ser1 10.102.27.182 RDP 3389
2
3 add lb monitor RDP_MON USER -scriptName nsrdp.pl
4
5 bind lb monitor RDP_MON ser1
6
7 <!--NeedCopy-->
```

### To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type USER.
2. In Special Parameters, in the Script Name list, select nsrdp.pl, and then bind this monitor to an RDP service.

## Use case 1: SMPP load balancing

September 21, 2020

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The Citrix ADC supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

The Citrix ADC performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.

Load balancing of SMPP messages by the Citrix ADC provides the following benefits:

- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

### **Introduction to SMPP**

SMPP is an application layer protocol for transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections. It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.

The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.

### Architecture Overview of the Different SMPP Entities in a Mobile Network

Note: The terms client and ESME are used interchangeably throughout the document.

An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receives messages. The ESME sends the MC one of the three messages (also known as PDUs): `bind_transmitter`, `bind_receiver`, or `bind_transceiver`. The MC responds with a `bind_transmitter_resp`, `bind_receiver_resp`, or `bind_transceiver_resp`, as appropriate for the request.

After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a `submit_sm` or `data_sm` message, receive a `deliver_sm` or `data_sm` message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as `query_sm`, `replace_sm`, and `cancel_sm`, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends

an alert\_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.

Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.

**Limitation:**

The Citrix ADC appliance does not support outbind operations. That is, a message center cannot initiate an SMPP session with an ESME through the Citrix ADC appliance.

## **How SMPP Load Balancing Works on the Citrix ADC**

An ESME (client) sends a bind message to open a connection to the Citrix ADC. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The Citrix ADC establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

### **Messages Originating from the ESMEs**

Each ESME must be added as a user on the Citrix ADC for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center.

Before forwarding the response (`submit_sm_resp` or `data_sm_resp`) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding `deliver_sm` or `data_sm` messages from the message centers to the clients.

### **Messages Originating from a Message Center**

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a `deliver_sm` message to the Citrix ADC. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve `deliver_sm` messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

The following diagram illustrates the internal flow of PDUs between ESMEs, Citrix ADC, and the message centers. For simplicity, only two ESMEs and two message centers are shown.

Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit\_sm(1) to NetScaler
6. ESME1 sends submit\_sm(2) to NetScaler
7. NetScaler forwards submit\_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit\_sm(2) to MC2
11. MC1 sends submit\_sm\_resp(1) to NetScaler
12. MC2 sends submit\_sm\_resp(2) to NetScaler
13. NetScaler forwards submit\_sm\_resp(1) to ESME1
14. NetScaler forwards submit\_sm\_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler
16. NetScaler sends bind response to ESME2
17. ESME2 sends submit\_sm(3) to NetScaler

18. NetScaler forwards submit\_sm(3) to MC1
19. MC2 sends deliver\_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit\_sm\_resp(3) to NetScaler
21. NetScaler forwards submit\_sm\_resp(3) to ESME2
22. NetScaler forwards deliver\_sm to ESME2
23. ESME2 sends deliver\_sm\_resp to NetScaler
24. MC1 sends alert\_notification to NetScaler (ESME1 serves the address range specified in the message)
25. NetScaler forwards deliver\_sm\_resp to MC2
26. NetScaler forwards the alert\_notification to ESME1

### Health Monitoring of Message Centers

By default, a TCP\_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire\_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

### Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the Citrix ADC to content switch these requests on the basis of the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.

**Example:**

```
SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS("^988")
```

- Based the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.

**Example:**

```
SMPP.BINDINFO.SYSTEM_ID.EQ("ESME1")
```

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.

**Example:**

```
SMPP.BINDINFO.SYSTEM_TYPE.EQ("VMS")
```

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)

**Example:**

SMPP.BINDINFO.ADDR\_TON.EQ(1)

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)

**Example:**

SMPP.BINDINFO.ADDR\_NPI.EQ(0)

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)

**Example:**

SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)

## Concatenated Message Handling

An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The Citrix ADC forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

## Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the Citrix ADC responds with an error message.

## Configuring SMPP Load Balancing on the Citrix ADC

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.

4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.

### To configure SMPP load balancing by using the command line

At the command prompt, type:

```
1 add smpp user <username> -password <password>
2 add service <name> <IP> SMPP <port> - customserverID <customserverID>
3 add lb vserver <name> <IP> SMPP <port>
4 bind lb vserver <name> <service name>
5 set smpp param
6 <!--NeedCopy-->
```

### Example

```
1 add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -
  encrypted -encryptmethod ENCMTHD_2
2 add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -
  encrypted -encryptmethod ENCMTHD_2
3 add service smmpsvc 10.102.84.140 SMPP 2775 -gslb NONE -maxClient 0 -
  maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
  180 -svrTimeout 360 -CustomServerID ab -CKA NO -TCPB NO -CMP NO
4 add service smmpsvc2 10.102.81.175 SMPP 2775 -gslb NONE -maxClient 0 -
  maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
  180 -svrTimeout 360 -CustomServerID xy -CKA NO -TCPB NO -CMP NO
5 add lb vserver smppvs SMPP 10.102.239.179 2775 -persistenceType NONE -
  cltTimeout 180
6 bind lb vserver smppvs smmpsvc2
7 bind lb vserver smppvs smmpsvc
8 set smpp param -addrange "d*"
9 <!--NeedCopy-->
```

### To configure SMPP load balancing by using the configuration utility

1. Navigate to System > User Administration > SMPP Users, and add an SMPP user.
2. Navigate to Traffic Management > Load Balancing > Configure SMPP Parameters, and set the parameters as required by your deployment.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SMPP.

4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

## Use case 2: Configure rule based persistence based on a name-value pair in a TCP byte stream

September 21, 2020

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In its traditional, non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called “FIX fields”). The field format is `<tag>=<value><delimiter>`. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. For example, the tag 35 indicates the message type. The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. For example, a value of A for the tag 35 indicates that the message is a logon message. The delimiter is the nonprinting “Start of Header” (SOH) ASCII character (0x01), which is the caret symbol (^). Each field is also assigned a name. For example, the field with tag 35 is the msgType field. Following is an example of a logon message.

```
8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157
```

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another (depending on the message type, the preceding fields, and the lengths of the preceding values) and from one implementation to another (depending on whether custom fields have been defined). Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application, and that you want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the

SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule "CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T('=', '^').VALUE("49")
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the Citrix ADC appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET\_TEXT\_MODE(IGNORECASE) function if you want the appliance to ignore case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET\_TEXT\_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=', '^').SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace

<tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression CLIENT.TCP.PAYLOAD(300).BEFORE\_STR("^").AFTER\_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPECAST\_NVLIST\_T('=', '^').VALUE("<tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).TYPECAST\_NVLIST\_T('=', '^').VALUE("<tag>",2).

Note: If the second argument that is passed to the

VALUE() function is

n, the appliance extracts the value of the

(n+1)

<sup>th</sup> instance of the field because the count starts from zero (

0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)

- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

### **Use case 3: Configure load balancing in direct server return mode**

September 21, 2020

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the Citrix ADC appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not completely shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the Citrix ADC appliance does not replace the load balancing virtual server's IP address with the destination server's IP address. Instead, it forwards packets to a service by using the server's MAC address. The VIP must be configured on the server and ARP must be disabled for the VIP which is configured on the server to prevent the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user needs to configure VIP in the loopback interface and disable the ARP for the same VIP.
- The appliance obtains the server's MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the Citrix ADC appliance, do not learn a server's MAC address. If you use only custom monitors in a DSR con-

figuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the Citrix ADC appliance, the ARP requests always resolve to the MAC address of the Citrix ADC interface. Consequently, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.

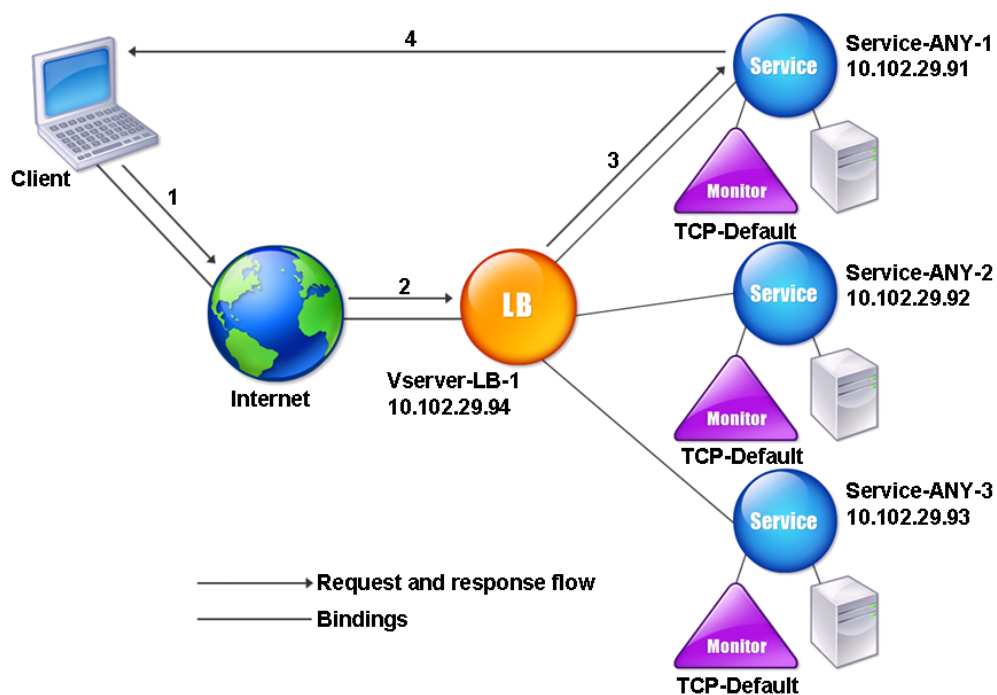

- The Citrix ADC appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the Citrix ADC appliance. The following table lists the names and values of the entities configured on the Citrix ADC appliance in DSR mode.

| Entity type    | Name          | IP address   | Protocol |
|----------------|---------------|--------------|----------|
| Virtual server | Vserver-LB-1  | 10.102.29.94 | ANY      |
| Services       | Service-ANY-1 | 10.102.29.91 | ANY      |
|                | Service-ANY-2 | 10.102.29.92 | ANY      |
|                | Service-ANY-3 | 10.102.29.93 | ANY      |
| Monitors       | TCP           | None         | None     |

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model

For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server.

Next, you configure a basic load balancing setup as described in [Setting Up Basic Load Balancing](#), naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

### **To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:

---

```
1 set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
  RedirectionMode> -sessionless <Value>
2 <!--NeedCopy-->
```

### Example

```
1 set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless
  enabled
2 <!--NeedCopy-->
```

### Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

## To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.
3. In Traffic Settings, select Sessionless Load Balancing.

## To configure a service to use source IP address by using the command line interface

At the command prompt, type:

```
1 set service <ServiceName> -usip <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-ANY-1 -usip yes
2 <!--NeedCopy-->
```

## To configure a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Traffic Settings, select Use Source IP Address.

Some additional steps are required in certain situations, which are described in the succeeding sections.

## Use case 4: Configure LINUX servers in DSR mode

September 21, 2020

The LINUX operating system requires that you set up a loopback interface with the Citrix ADC appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

### To configure LINUX server in DSR mode

To create a loop back interface with the Citrix ADC appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
1 ifconfig dummy0 up
2
3 ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up
4
5 echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore
6
7 echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
8 <!--NeedCopy-->
```

Then, run the software that re-maps the TOS id to VIP.

Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

## Use case 5: Configure DSR mode when using TOS

September 21, 2020

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the IPv4 packet header. The equivalent field in the IPv6 header is Traffic Class. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the Citrix ADC appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the **TOS** field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The Citrix ADC appliance in DSR mode with TOS

The TOS feature is customized for a controlled environment as follows:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client does not understand the message, as the source IP address is the IP address of the load balanced server and not the Citrix ADC VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

| Entity Type    | Name          | IP Address    | Protocol |
|----------------|---------------|---------------|----------|
| Virtual server | Vserver-LB-1  | 10.102.33.91  | ANY      |
| Services       | Service-ANY-1 | 10.102.100.44 | ANY      |
| Monitors       | PING          | None          | None     |

DSR with TOS requires that load balancing is set up on layer 3. To configure a basic load balancing setup for Layer 3, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

### To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

```
1 set lb vserver <vServerName> -m <Value> -tosId <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -m TOS -tosId 3
2 <!--NeedCopy-->
```

### To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and in Redirect Mode, select TOS ID.

### To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

```
1 add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -
  tosId <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosId 3
2 <!--NeedCopy-->
```

**To create the transparent monitor for TOS by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

**Wildcard TOS Monitors**

In a load balancing configuration in DSR mode using TOS field, monitoring its services requires a TOS monitor to be created and bound to these services. A separate TOS monitor is required for each load balancing configuration in DSR mode using TOS field, because a TOS monitor requires the VIP address and the TOS ID to create an encoded value of the VIP address. The monitor creates probe packets in which the **TOS** field is set to the encoded value of the VIP address. It then sends the probe packets to the servers represented by the services of a load balancing configuration.

With many load balancing configurations, creating a separate custom TOS monitor for each configuration is a significant, cumbersome task. Managing these TOS monitors is also a significant task. Now, you can create wildcard TOS monitors. Create only one wildcard TOS monitor for all load balancing configurations that use the same protocol (for example, TCP or UDP).

A wildcard TOS monitor has the following mandatory settings:

- Type = <protocol>
- TOS = Yes

The following parameters can be set to a value or can be left blank:

- Destination IP
- Destination Port
- TOS ID

A wildcard TOS monitor (with destination IP, Destination port, and TOS ID not set) bound to a DSR service automatically learns the TOS ID and the VIP address of the load balancing virtual server. The monitor creates probe packets with TOS field set to the encoded VIP address and then sends the probe packets to the server represented by the DSR service.

**To create a wildcard TOS monitor by using the CLI**

At the command prompt, type:

```
1 add lb monitor <monitorName> <Type> -tos YES
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

**To bind a wildcard TOS monitor to a service by using the CLI**

At the command prompt, type:

```
1 bind lb monitor <monitorName> <serviceName>
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

**To create a wildcard TOS monitor by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Add a monitor with the following parameter settings:
  - Type = <protocol>
  - TOS = YES

**To bind a wildcard TOS monitor to a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service and bind a wildcard TOS monitor to it.

In the following sample configuration, V1, V2, and V3 are load balancing virtual servers of type ANY and has TOS ID set to 1, 2, and 3 respectively. S1, S2, S3, S4, and S5 are services of type ANY. S1 and S2 are bound to both V1 and V2. S3, S4, and S5 and bound to both V1 and V3. WLCD-TOS-MON is a wildcard TOS monitor with type TCP and is bound to S1, S2, S3, S4, and S5.

WLCD-TOS-MON automatically learns the TOD ID and VIP address of virtual servers bound to S1, S2, S3, S4, and S5.

Because S1 is bound to V1 and V2, WLCD-TOS-MON creates two types of probe packets for S1, one with TOS field set to the encoded VIP address (203.0.113.1) of V1 and the other with the VIP address (203.0.113.2) of V2. The Citrix ADC then sends these probe packets to the server represented by S1. Similarly, WLCD-TOS-MON creates probe packets for S2, S3, S4, and S5.

```
1 add lb monitor WLCD-TOS-MON TCP -tos YES
2
3 Done
4
5 add lb vserver V1 ANY 203.0.113.1 * -m TOS - tosID 1
6
7 Done
8
9 add lb vserver V2 ANY 203.0.113.2 * -m TOS - tosID 2
10
11 Done
12
13 add lb vserver V3 ANY 203.0.113.3 * -m TOS - tosID 3
14
15 Done
16
17 add service S1 198.51.100.1 ANY *
18
19 Done
20
21 add service S2 198.51.100.2 ANY *
22
23 Done
24
25 add service S3 198.51.100.3 ANY *
26
27 Done
28
29 add service S4 198.51.100.4 ANY *
30
31 Done
32
33 add service S5 198.51.100.5 ANY *
34
35 Done
36
37 bind lb monitor WLCD-TOS-MON S1
38
39 Done
40
41 bind lb monitor WLCD-TOS-MON S2
42
43 Done
44
```

```
45 bind lb monitor WLCD-TOS-MON S3
46
47 Done
48
49 bind lb monitor WLCD-TOS-MON S4
50
51 Done
52
53 bind lb monitor WLCD-TOS-MON S5
54
55 Done
56
57 bind lb vserver V1 S1, S2, S3, S4, S5
58
59 Done
60
61 bind lb vserver V2, S1, S2
62
63 Done
64
65 bind lb vserver V3 S3, S4, S5
66
67 Done
68 <!--NeedCopy-->
```

## Use case 6: Configure load balancing in DSR mode for IPv6 networks by using the TOS field

September 21, 2020

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the Citrix ADC appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a Citrix ADC appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the appliance.

Consider an example where a load balancing virtual server LBVS1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The Citrix ADC appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.

The following table lists the settings used in this example.

| Entities                             | Name                                         |
|--------------------------------------|----------------------------------------------|
| IPv6 address of client C1            | C1_IP (for reference purposes only)          |
| Load balancing virtual server on NS1 | LBVS1                                        |
| IPv6 address of LBVS1                | LBVS1_VIP6 (for references purpose only)     |
| TOS value                            | TOS_LBVS1_VIP6 (for references purpose only) |
| Service for server S1 on NS1         | SVC_S1                                       |
| IPv6 address for server S1           | S1_IP (for references purpose only)          |
| Service for server S2 on NS1         | SVC_S2                                       |
| IPv6 address for server S1           | S2_IP (for references purpose only)          |
| Service for server S3 on NS1         | SVC_S3                                       |
| IPv6 address for server S1           | S3_IP (for references purpose only)          |

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.

2. LBVS1's load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
  - TOS field set to TOS\_LBVS1\_VIP6.
  - Source IP address as C1\_IP.
3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1\_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the appliance, with:
  - Source IP address set to the derivedLBVS1\_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

### **To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance**

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

### **To configure load balancing in DSR Mode using TOS by using the command line interface**

At the command prompt, type:

```
1 enable ns mode USIP
2
3 add service <serviceName> <IP> <serviceType> <port>
4 <!--NeedCopy-->
```

Repeat the above command as many times as necessary to add each server as a service on the Citrix ADC appliance.

```
1 add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -
  tosId <positive_integer>
2
3 bind lb vserver <vserverName> <serviceName>
4 <!--NeedCopy-->
```

### **To enable USIP mode by using the configuration utility**

Navigate to System > Settings > Configure Modes, and select Use Source IP Address.

### **To create services by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Services, and create a service.

### **To create a load balancing virtual server and bind services by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server.
2. Click in the Service section to bind a service to this virtual server.

## **Use case 7: Configure load balancing in DSR mode by using IP Over IP**

January 22, 2021

You can configure your Citrix ADC appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the Citrix ADC appliance, improving response times and throughput. As with standard DSR mode, the Citrix ADC appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the Citrix ADC appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the Citrix ADC appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client.

To configure IP over IP DSR mode on your Citrix ADC appliance, you must do the following:

- Create a load balancing virtual server. Set the protocol to ANY and set the mode to IPTUNNEL.
- Create services. Create a service for each of your back-end applications. Bind the services that you created to the virtual server.
- Configure for decapsulation. You can configure either a Citrix ADC appliance or a back-end server to act as a decapsulator.

### **Configure a load balancing virtual server**

Configure a virtual server to handle requests to your applications. Assign a service type of ANY and set the forwarding method to IPTUNNEL. Optionally, configure the virtual server to operate in sessionless mode. You can configure any load balancing method that you want to use.

### To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

```
1 add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <
  port> -lbMethod <method> -m <ipTunnelTag> -sessionless <sessionless>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

In the following example, we have selected the load balancing method as sourceIPHash and configured sessionless load balancing.

```
1 add lb vserver Vserver-LB-1 ANY 10.102.29.60 * -lbMethod SourceIPHash -
  m IPTUNNEL -sessionless enabled
2 <!--NeedCopy-->
```

### To create and configure a load balancing virtual server for IP over IP DSR by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Create a virtual server, and specify Redirection Mode as IP Tunnel Based.

### Configure services for IP over IP DSR

After creating your load-balanced server, You must configure one service for each of your applications. The service handles traffic from the Citrix ADC appliance to those applications, and allows the Citrix ADC appliance to monitor the health of each application.

You assign a service type of ANY and configure it for USIP mode. Optionally, you can also bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

### To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

```
1 add service <serviceName> <serverName> <serviceType> <port> -usip <usip
  >
2
```

```
3 add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <
  iptunnel>
4
5 bind service <serviceName> -monitorName <monitorName>
6 <!--NeedCopy-->
```

**Example:**

In the following example, we are creating a monitor of type IPTUNNEL:

```
1 add monitor mon-1 PING -destip 10.102.29.60 -iptunnel yes
2 add service Service-DSR-1 10.102.30.5 ANY * -usip yes
3 bind service Service-DSR-1 -monitorName mon-1
4 <!--NeedCopy-->
```

**To configure a monitor by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, and select **IP Tunnel**.

**To create and configure a service for IP over IP DSR by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a service and, in Settings, select Use Source IP Address.

**To bind a service to a load balancing virtual server by using the command line interface**

At the command prompt type the following command:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-DSR-1
2 <!--NeedCopy-->
```

**To bind a service to a load balancing virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section to bind a service to the virtual server.

## Using the Client IP address in the Outer Header of Tunnel Packets

The Citrix ADC supports using the client IP address as the source IP address in the outer header of tunnel packets related to direct server return mode using IP tunneling. This feature is supported for DSR with IPv4 and DSR with IPv6 tunneling modes. For enabling this feature, enable the **use client source IP address** parameter for IPv4 or IPv6. This setting is applied globally to all the DSR configurations that use IP tunneling.

### To use client IP address as the source IP address on outer header of IPv4 tunnel packets by using the CLI

At the command prompt, type:

```
set iptunnelparam -useclientsourceip [YES NO]
```

- 
- **show iptunnelparam**

### To use client IP address as the source IP address on outer header of IPv4 tunnel packets by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv4 Tunnel Global Settings**.
3. In the **Configure IPv4 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

### To use client source IP address as the source IP address on outer header of IPv6 tunnel packets by using the CLI

At the command prompt, type:

```
set ip6tunnelparam -useclientsourceip [YES NO]
```

- 
- **show ip6tunnelparam**

**To use client IP address as the source IP address on outer header of IPv6 tunnel packets by using the GUI**

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv6 Tunnel Global Settings**.
3. In the **Configure IPv6 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

Following is a sample load balancing configuration in DSR mode using IPv4 tunneling. LBVS-IPIP-1 is the load balancing virtual server, and services SERVICE-DSR-IPIP-1 and SERVICE-DSR-IPIP-2 are bound to LBVS-IPIP-1.

```
1      > set iptunnelparam -useclientsourceip YES
2
3
4      Done
5
6      >add service SERVICE-DSR-IPIP-1 192.0.2.91 ANY * -usip yes
7
8
9      Done
10
11     > add service SERVICE-DSR-IPIP-2 192.0.2.92 ANY * -usip yes
12
13
14     Done
15
16     >add lb vserver LBVS-IPIP-1 ANY 203.0.113.9 * -m IPTUNNEL
17
18
19     Done
20
21     >bind lb vserver LBVS-IPIP-1 Service-DSR-1
22
23
24     Done
25
26     >bind lb vserver LBVS-IPIP-1 Service-DSR-2
27
28
29     Done
30 <!--NeedCopy-->
```

## Decapsulator configuration

- When a Citrix ADC appliance is used as a decapsulator, an IP tunnel must be created in the Citrix ADC appliance. For details, see [Configuring IP Tunnels](#).

### Example configuration:

```

1  add lb vserver v1 any 1.1.1.1 * -m IPTUNNEL
2
3  add service s1 2.2.2.2 ANY *
4
5  bind lb vserver v1 s1
6
7  add iptunnel tun1 <snip_in_encap> netmask *
8
9  add ns ip 1.1.1.1 255.255.255.255 - type vip - arp disabled
10
11 add lb vserver v1 any 1.1.1.1 *
12
13 add service s1 <actualserverip> ANY *
14
15 bind lb vserver v1 s1
16 <!--NeedCopy-->

```

- When a back-end server is used as a decapsulator, the back-end configuration varies depending on the server type. The steps involved in configuring a back-end server as a decapsulator are:
  1. Configure a loop back interface.
  2. Add a route through tunnel interface.

**Note:** Make sure that the tunnel modules are installed in the system.

### Example configuration:

In this example, 1.1.1.1 is the Citrix ADC virtual IP (VIP) address and 2.2.2.2 is the back end server IP address.

The VIP address is configured in the loopback interface and a route is added through the tunnel interface. The `modprobe ipip` command is used for enabling the tunnel interface.

```

1  add lb vserver v1 ANY 1.1.1.1 80 -m IPTUNNEL
2
3  add service svc1 2.2.2.2 ANY 80 -usip YES -useproxyport NO
4
5  bind lb vserver v1 svc1
6
7  ifconfig lo inet 1.1.1.1 netmask 255.255.255.255
8

```

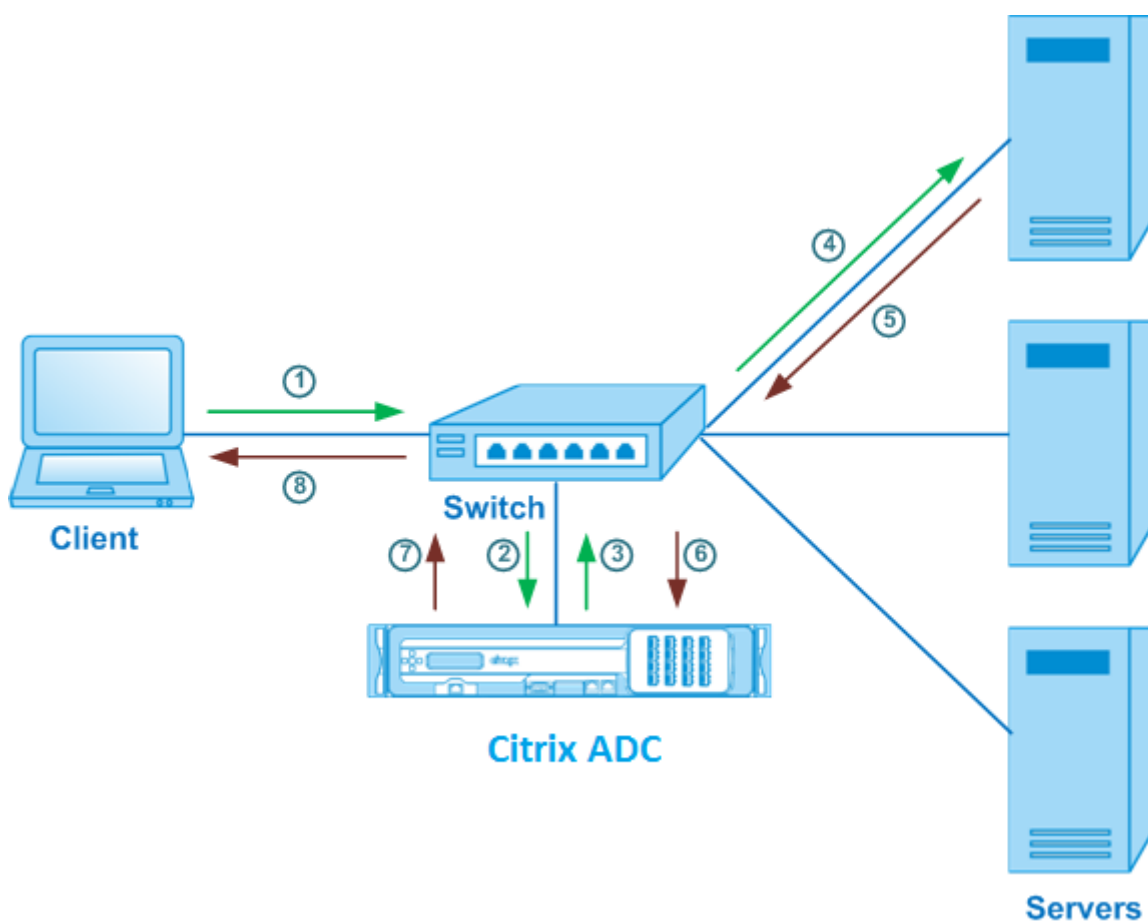

```
9     modprobe ipip
10
11     echo 1 > /proc/sys/net/ipv4/conf/tunl0/arp_ignore
12
13     echo 2 > /proc/sys/net/ipv4/conf/tunl0/arp_announce
14
15     ifconfig tunl0 1.1.1.1 netmask 255.255.255.255 up
16
17     route add -host 1.1.1.1 dev tunl0
18 <!--NeedCopy-->
```

## Use case 8: Configure load balancing in one-arm mode

September 21, 2020

In a one-arm setup, you connect the Citrix ADC appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service, as is shown in the following diagram.

Figure 1. Load balancing in one-arm mode

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

| Entity type    | Name          | IP address   | Protocol |
|----------------|---------------|--------------|----------|
| Virtual server | Vserver-LB-1  | 10.102.29.94 | ANY      |
| Services       | Service-ANY-1 | 10.102.29.91 | ANY      |
|                | Service-ANY-2 | 10.102.29.92 | ANY      |
|                | Service-ANY-3 | 10.102.29.93 | ANY      |
| Monitors       | TCP           | None         | None     |

To configure a load balancing setup in one-arm mode, see [“Setting Up Basic Load Balancing.”](#)

## Use case 9: Configure load balancing in the inline mode

September 21, 2020

In an inline mode (also called two-arm mode) setup, you connect the Citrix ADC appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service. This is shown in the following diagram.

Figure 1. Load balancing in inline mode

The configuration and the entity diagram for inline mode are the same as described in [Configuring Load Balancing in One-arm Mode](#).

## Use case 10: Load balancing of intrusion detection system servers

September 21, 2020

To enable the Citrix ADC appliance to support load balancing of intrusion detection system (IDS)

servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the Citrix ADC appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers

Note: Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.

Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

| Entity type    | Name          | IP address    | Port | Protocol |
|----------------|---------------|---------------|------|----------|
| Virtual server | Vserver-LB-1  | *             | *    | ANY      |
| Services       | Service-ANY-1 | 10.102.29.101 | *    | ANY      |
|                | Service-ANY-2 | 10.102.29.102 | *    | ANY      |
|                | Service-ANY-3 | 10.102.29.103 | *    | ANY      |
| Monitors       | Ping          | None          | None | None     |

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers

To configure an IDS load balancing setup, you must first enable MAC-based forwarding. You must also disable layer 2 and layer 3 modes on the appliance.

### To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
1 enable ns mode <ConfigureMode>
2 <!--NeedCopy-->
```

#### Example:

```
1 enable ns mode MAC
2 <!--NeedCopy-->
```

### To enable MAC-based forwarding by using the configuration utility

Navigate to System > Settings > Configure Modes, and select MAC Based Forwarding.

Next, see [“Setting Up Basic Load Balancing”](#), to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

### **To configure LB method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
   RedirectionMode> -sessionless <Value>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -
   sessionless enabled
2 <!--NeedCopy-->
```

#### **Note**

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

### **To configure LB method and redirection mode for a sessionless virtual server by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

### **To set a service to use source IP address by using the command line interface**

At the command prompt, type:

```
1 set service <ServiceName> -usip <Value>
2 <!--NeedCopy-->
```

#### **Example:**

```
1 set service Service-ANY-1 -usip yes
2 <!--NeedCopy-->
```

### To set a service to use source IP address by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and in Settings select **Use Source IP Address**.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see “[IP Addressing](#).”

## Use case 11: Isolating network traffic using listen policies

September 21, 2020

### Note

The traffic isolation solution using shadow virtual servers to simulate multitenant isolation is no more recommended. Alternatively, Citrix recommends you to use the Citrix ADC Admin Partitioning feature for such deployments. For more information, see [Admin Partitioning](#).

A common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant’s traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department’s applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IdP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multitenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a Citrix ADC appliance identifies network domains and controls the traffic across the domains. The Citrix ADC solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on several client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

| Category          | Parameters                                                                      |
|-------------------|---------------------------------------------------------------------------------|
| Ethernet protocol | Source MAC address, destination MAC address                                     |
| Network interface | Network ID, receiving throughput, sending throughput, transmission throughput   |
| IP protocol       | Source IP address, destination IP address                                       |
| IPv6 protocol     | Source IPv6 address, destination IPv6 address                                   |
| TCP protocol      | Source port, destination port, maximum segment size, payload, and other options |
| UDP protocol      | Source port, destination port                                                   |
| VLAN              | ID                                                                              |

Table 1. Client Parameters Used to Define Listen Policies

On the Citrix ADC appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (\*) IP address and port, and its service type is set to ANY.

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

### How network paths are isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path

### Traffic within network domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.

- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the Citrix ADC for all the traffic that originates from a client.

### **Traffic between network domain 1 and network domain 2**

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANs: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VLAN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

### **Configuration Steps**

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic.
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create a new expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (\*). Enable MAC-based forwarding on this virtual server.

- Enable the L2 Connection option on both the virtual servers.

Generally, to identify a connection, the Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all the firewall services to the shadow virtual server.

### To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

```
1 add policy expression <expressionName> <listenPolicyExpression>
2
3 add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -
  listenPolicy <expressionName>
4 <!--NeedCopy-->
```

Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.

```
1 add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <
  expressionName>
2 <!--NeedCopy-->
```

Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

#### Example:

```
1 add policy expression e110 client.vlan.id==110
2 add policy expression e210 client.vlan.id==210
3 add policy expression e310 client.vlan.id==310
4 add policy expression e11 client.vlan.id==11
5 add policy expression e22 client.vlan.id==22
6 add policy expression e33 client.vlan.id==33
7
8 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -
  listenPolicy e11
9 -cltTimeout 180 -l2Conn ON
10
11 add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE -
  listenPolicy e22
```

```
12 -cltTimeout 180 -l2Conn ON
13
14 add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE -
    listenPolicy e33
15 -cltTimeout 180 -l2Conn ON
16
17
18 add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod
    ROUNDROBIN - listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout
    120
19
20 add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod
    ROUNDROBIN - listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout
    120
21
22 add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod
    ROUNDROBIN - listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout
    120
23
24
25 add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
    DISABLED
26 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
    NO -TCPB NO -CMP NO
27
28 add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
    DISABLED
29 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
    NO -TCPB NO -CMP NO
30
31 add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
    DISABLED
32 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
    NO -TCPB NO -CMP NO
33
34
35 bind lb vserver FW-VIP-1 RD-1
36
37 bind lb vserver FW-VIP-2 RD-2
38
39 bind lb vserver FW-VIP-3 RD-3
40 <!--NeedCopy-->
```

### To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in [Creating a Service](#).
2. Add each firewall as a service:
  - a) Navigate to **Traffic Management > Load Balancing > Services**.
  - b) Create a service, specifying protocol as ANY, server as firewall's IP address, and port as 80.
3. Configure a load balancing virtual server.
4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

## Use case 12: Configure XenDesktop for load balancing

September 21, 2020

For an improved performance in the delivery of virtual desktop applications, you can integrate the Citrix ADC appliance with Citrix XenDesktop and use the Citrix ADC load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or XenApp, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user's device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a Citrix ADC appliance working with XenDesktop.

Figure 1. Load Balancing of XenDesktop

**Note**

Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC appliance. You can use the HTTP protocol for communication between the Citrix ADC and the DDC servers even though you use the SSL protocol for communication with the client.

**To configure load balancing for XenDesktop by using the GUI**

1. Create a service.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Services** and click **Add**.
  - b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and click **Add**.
  - b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and

then click **OK**.

3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and select a server.
  - a) Click **Edit**.
  - b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
  - c) Select the service you want to bind and enter the weight value.
  - d) Click **Bind**.

### To configure load balancing for XenDesktop by using the command line interface

- To create a service, at the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-HTTP-1 192.0.2.5 HTTP 80
2 <!--NeedCopy-->
```

- To create a virtual server, at the command prompt, type:

```
1 add lb vserver <name> <serviceType> <ip> <port>
2 <!--NeedCopy-->
```

#### Example:

**add lb vserver** Vserver-LB-1 HTTP 10.102.29.60 80

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

## Use case 13: Configure XenApp for load balancing

September 21, 2020

For efficient delivery of applications, you can integrate the Citrix ADC appliance with Citrix XenApp and use the Citrix ADC load balancing feature to distribute the load across the XenApp server farms. The following figure is a topology diagram of such a setup.

Figure 1. Load Balancing of XenApp

The Web Interface servers provide secure access to XenApp application resources through the user's Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the XenApp server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users

with access to applications, and the XML Broker evaluates the user's permissions to determine which applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. On the basis of the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using the Citrix ADC appliance. Configure one virtual server to load balance all of the Web Interface servers and another for all of the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

**Note**

Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC. You can use the HTTP protocol for communication between the Citrix ADC and the WI servers even though you use the SSL protocol for communication with the client.

**To configure load balancing for XenApp by using the GUI**

1. Create a service.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Services** and click **Add**.
  - b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and click **Add**.
  - b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and select a server.
  - a) Click **Edit**.
  - b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
  - c) Select the service you want to bind and enter the weight value.
  - d) Click **Bind**.

**To configure load balancing for XenApp by using the command line interface**

- To create a service, at the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add service Service-HTTP-1 192.0.2.5 HTTP 80
2 <!--NeedCopy-->
```

- To create a virtual server, at the command prompt, type:

```
1 add lb vserver <name> <serviceType> <ip> <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
2 <!--NeedCopy-->
```

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

## Use case 14: ShareFile wizard for load balancing Citrix ShareFile

September 21, 2020

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up load balancing configuration for ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS or SharePoint. The content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the diagram below.

Figure 1. ShareFile Data Load Balancing

You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to Traffic Management > Virtual Servers and Services > Virtual Servers. You cannot manually remove the virtual servers created using the ShareFile wizard. Use the wizard to remove the virtual servers.

Citrix ADC uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

## To configure a Citrix ADC appliance for load balancing Citrix ShareFile

1. In the navigation pane, click Load Balancing.
2. Navigate to Traffic Management > Load Balancing.
3. Under Citrix ShareFile, click Setup NetScaler for ShareFile.
4. On the Setup Load Balancing for ShareFile page, provide the following information:
  - Name: Name of the content switching virtual server.
  - IP Address: IP address of the content switching virtual server.
  - If you want to setup load balancing for CIFS or SharePoint, click the StorageZone Connector for Network File Shares/SharePoint checkbox and then click Continue. By default **ShareFile Data** checkbox is selected.

5. Provide a valid certificate. If you have a certificate, click Choose Certificate and from the drop-down list select the certificate. If you have to install a certificate, click Install Certificate and provide the Certificate-Key pair.

| Name                        | IP Address   | Port | Protocol | Selected                                       |
|-----------------------------|--------------|------|----------|------------------------------------------------|
| ShareFile CS Virtual Server | 10.102.29.96 | 443  | SSL      | Sharefile Data, Network File Shares/SharePoint |

6. Click Continue.
7. In the Add New StorageZone Controller dialog box, specify the values of the following parameters:
  - StorageZone Controller IP Address— IP address
  - Port— Port number. The default value is 443.
  - Protocol— Select from HTTPS or HTTP

ShareFile StorageZone Controller Configuration

Add New StorageZone Controller X Add From Existing

StorageZone Controller IP Address\*  +

Port\* 443

Protocol\* https

Create Cancel

Done

8. Click Create and then click Done. The wizard automatically creates a service and autogenerate the name of the service.
9. If you chose load balancing for CIFS or SharePoint in step 4.c, then specify the values for LDAP Authentication Settings:
  - AAAServer IP Address— IP address of AAA virtual server
  - LDAP Server IP Address— IP Address of the LDAP server
  - Port— Port number. The default value is 389
  - Time out— The time out value in minutes
  - Single Sign-on Domain— Single sign-on domain name
  - Base DN— Base domain name
  - Administrator Bind DN— LDAP account name with the domain name, for example, administrator@domainname.com
  - Logon Name— Logon name is the sAMAccount name
  - Password and Confirm Password— Enter the password and confirm the password

### LDAP Authentication Settings

**Configure New**

|                              |                                                         |
|------------------------------|---------------------------------------------------------|
| AAAVServer IP Address*       | <input type="text" value=" . . ."/>                     |
| LDAP Server IP Address*      | <input type="text" value=" . . ."/>                     |
| Port*                        | <input type="text" value="389"/>                        |
| Time out*                    | <input type="text" value="3"/>                          |
| Single Sign-on Domain*       | <input type="text"/>                                    |
| Base DN (location of users)* | <input type="text" value="Cn=Users,dc=example,dc=com"/> |
| Administrator Bind DN*       | <input type="text" value="administrator@example.com"/>  |
| Logon Name*                  | <input type="text" value="sAMAccountName"/>             |
| Password*                    | <input type="password"/>                                |
| Confirm Password*            | <input type="password"/>                                |

10. Click Continue and then click Done.

### To remove load balancing configuration for ShareFile

1. Click on Configuration > Traffic Management > Load Balancing.
2. On the Load Balancing page, under Citrix ShareFile click on Remove ShareFile Configuration.

## Troubleshooting

September 21, 2020

If the load balancing does not work as expected after you have configured it, you can use some com-

mon tools to access Citrix ADC resources and diagnose the problem.

## Resources for Troubleshooting Load Balancing

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Latest ns.conf file
- Relevant newnslog files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistence related issues.
- The Wireshark application customized for the Citrix ADC trace files.

## Troubleshooting Load Balancing Issues

- **Issue**

CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which -m MAC option is enabled.

- **Resolution**

Bind a non-user monitor to the service.

- **Issue**

I created a user script for monitoring, but it is not working.

- **Resolution**

Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the CLI to debug the script.

- **Issue**

I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to turn off the monitor probes?

- **Resolution**

You can turn off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

- **Issue**

I have set up monitors for services, but connections are still directed to servers that are DOWN.

**Resolution**

You probably need to decrease the monitor probe intervals. The Citrix ADC appliance does not detect the DOWN state until the monitor sends a probe.

- **Issue**

A metric bound to the monitor is present in the local and custom metric tables.

**Resolution**

Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don't need to add any prefix.

- **Issue**

The monitor probes to a service are not reaching the service.

**Resolution**

Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the monitorSkipMaxClient parameter to ENABLED.

- **Issue**

I am able to ping the servers, but the state of the services is always shown as DOWN.

**Resolution**

Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor should change the state of the service to UP.

- **Issue**

Setting a weight for load monitors does not help in deciding the state of the service.

**Resolution**

Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- **Issue**

A service is not stable.

**Resolution**

Consider troubleshooting the following components:

- Verify that a correct server is bound to the service.
- Verify the type of monitor bound to the service.
- Verify the reasons for the monitor failures. You can open service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
- If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- You can record packet traces on the Citrix ADC appliance and verify the monitor probes and server response for further investigation.

- **Issue**

The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

**Resolution**

Consider troubleshooting the following components:

- Verify that the load balancing feature is licensed.
- Verify that the feature is enabled.
- Verify that an appropriate service is bound to the virtual server.
- If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service should be Out-Of-Service. In such as case, you must enable the service and verify if the issue is resolved.
- Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
- If the VIP address is not stable, all the services bound to the virtual server should fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the Citrix ADC appliance and the servers.

- **Issue**

The site is experiencing uneven load balancing.

**Resolution**

Consider troubleshooting the following components:

- Verify the load balancing method configured on the appliance.
- Verify weights associated with the services are as expected.
- If the load balancing method is other than round robin, verify the number of connections to the server logged in the newslog file. You can run the following command to verify the number on the newslog file:

```
## nsconmsg -K <newslog_file> -s ConLb=2 -d oldconmsg
```

Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), Hits, Persistent Hits and persistent rate (P) to troubleshoot the issue further.

- If the load balancing method is round robin, verify the persistent Hits as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue
- Verify if persistency is configured on the appliance.
- Verify if any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

- **Issue**

The service status is displayed as DOWN.

- **Resolution**

Consider troubleshooting the following components:

- Verify whether a SNIP address is configured.
- Verify that appropriate monitors are bound to the service.
- If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this could be due to the MIP address being unable to communicate to the server.

- **Issue**

There is an issue with the response time.

- **Resolution**

Consider troubleshooting the following components:

- Verify the server response time from the service stats either by running the following command:

```
## nsconmsg -K <newslog_file> -s ConLb=2 -d oldconmsg
```

- Check for service not stable and service status being displayed as DOWN issues.

- **Issue**

One of the servers is serving more requests than the other load balanced servers.

- **Resolution**

Consider troubleshooting the following components:

- Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
- Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given servers might be carrying a heavier load to maintain its session, especially If the persistence sessions are long.
- Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

• **Issue**

Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

**Resolution**

Consider troubleshooting the following components:

- Verify the load balance method. If it is round robin, consider changing the method to least connections.
- Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to server which is functional.
- If the connections are stalled for a long period, surge-queue might build. Consider flushing the surge-queue to avoid a sudden spike in load on the server.
- If the servers are working at their maximum level, consider adding a new server for better performance.

• **Issue**

A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.

**Resolution**

Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server's IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

• **Troubleshooting Tips**

For other issues, consider following tips to troubleshoot an issue not listed above:

- If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.

- If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
- When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if status of at least one of the custom load monitors is not UP.
- All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
- The CUSTOMLOAD load balancing method also follows startup round robin.
- If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
- When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message “5xx - server busy error” is displayed.
- A maximum of 10 metrics from a custom table can be bound to the monitor.
- The OIDs must be scalar variables.
- For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
- A user cannot modify the local table.

## Load balancing FAQs

September 21, 2020

### What are the various load balancing policies I can create on the Citrix ADC appliance

You can create the following types of load balancing policies on the Citrix ADC appliance:

- 1 - Least Connections
- 2 - Round Robin
- 3 - Least response time
- 4 - Least bandwidth
- 5 - Least packets
- 6 - URL hashing
- 7 - Domain name hashing
- 8 - Source IP address hashing
- 9 - Destination IP address hashing

- 10 - Source IP - Destination IP hashing
- 11 - Token
- 12 - LRTM

### **Can I achieve the Web farm security by implementing load balancing using the Citrix ADC appliance?**

Yes. You can achieve Web farm security by implementing load balancing using the Citrix ADC appliance. Citrix ADC appliance enables you to implement the following options of the load balancing feature:

- 1 - **IP Address hiding:** Enables you to install the actual servers to be on **private** IP address space **for** security reasons and **for** IP address conservation. This process is transparent to the end-user because the Citrix ADC appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the **private** subnet, such as FTP or a Telnet server, through a different VIP on the appliance **for** that service.
- 2 - **Port Mapping:** Enables the actual TCP services to be hosted on non-standard ports **for** security reasons. This process is transparent to the end-user as the Citrix ADC appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

### **What are various devices that I can use to load balance with a Citrix ADC appliance?**

You can load balance following devices with a Citrix ADC appliance:

- 1 - Server farms
- 2 - Caches or Reverse Proxies
- 3 - Firewall devices
- 4 - Intrusion detection systems
- 5 - SSL offload devices
- 6 - Compression devices
- 7 - Content Inspection servers

### **Why should I implement the load balancing feature for the website?**

You can implement the Load balancing feature for the website to take the following advantages:

---

- 1 - Reduce the response time: When you implement the load balancing feature **for** the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.
- 2 - Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, **if** the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors **do** not even notice any downtime. Any load balancing solution immediately stops sending traffic to the backend server that is not available.

### Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?

- 1 - If you enable the MBF option, the Citrix ADC appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires that the best path be chosen **for** the **return** traffic.
- 2 - Enabling the MBF option breaks **this** topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

## Networking

September 21, 2020

The following topics provide a conceptual reference and instructions for configuring the various networking components on the Citrix ADC appliance.

---

IP Addressing

Learn the various types of Citrix ADC owned IP addresses and how to create, customize, and remove them.

## IP Addressing

September 21, 2020

Before you can configure the Citrix ADC appliance, you must assign the NSIP address, also known as the Management IP address. You can also create other Citrix ADC-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (NAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

## Configuring Citrix ADC-owned IP addresses

September 21, 2020

The Citrix ADC-owned IP addresses—NSIP address, Virtual IP Addresses (VIPs), Subnet IP Addresses

(SNIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the Citrix ADC appliance. The NSIP uniquely identifies the Citrix ADC on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The Citrix ADC terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP. You can configure some Citrix ADC-owned IP addresses to provide access for management applications.

## Configuring the NSIP address

September 21, 2020

The NSIP address is the IP address at which you access the Citrix ADC appliance for management purposes. The appliance can have only one NSIP, which is also called the management IP address. You must add this IP address when you configure the Citrix ADC for the first time. You cannot remove an NSIP address. For security reasons, the NSIP should be a non-routable IP address on your organization's LAN.

If you modify this address, you must reboot the Citrix ADC appliance. If the subnet address of the new NSIP address is different from the previous one, you must add a default route for this subnet so that the new NSIP address becomes reachable from other networks on the LAN.

### Important

Configuring the NSIP address is mandatory.

Changing the NSIP address of a Citrix ADC appliance consists of the following tasks:

- Change the NSIP address.
- Add a default route for the subnet address of the NSIP address, if one is not present.
- Save the configuration.
- Restart the appliance.

## Command Line Procedures

To change the NSIP address by using the CLI:

At the command prompt, type:

- **set ns config -IPAddress** <ip\_addr> **-netmask** <netmask>
- **show ns config**

To add a default route by using the CLI:

At the command prompt, type:

- **add route 0 0** <gateway IP address>
- **show route**

To save the configuration by using the CLI:

At the command prompt, type:

- **save config**

To restart the Citrix ADC appliance by using the CLI:

At the command prompt, type:

- **reboot**

## GUI Procedures

To configure the NSIP address by using the GUI:

1. Click the gear icon in the top-right corner of the **Configuration** page.
2. Click the **NSIP address** pane.
3. On the **NSIP address** page, set the following parameters, and then click **Done**:
  - NSIP address
  - Netmask

To add a default route by using the GUI:

Navigate to **System** > **Network** > **Routes** and, on the **Basic** tab, add a default route with the following parameter settings, and then click **Create**.

- Network (set to zero)
- Netmask (set to zero)
- Gateway (IP address of the gateway)

To restart the Citrix ADC by using the GUI:

1. On the **System Information** tab page of the **System** node, click **Reboot**.
2. When prompted to reboot, select **Save Configuration** to make sure that you do not lose any configurations.

## Sample configuration

In the following example, the NSIP address of a Citrix ADC appliance is changed to 192.0.2.90, which has a different subnet address (192.0.2.0/24) than the previous NSIP address. Therefore, a default route is added for this subnet, so that the new NSIP address becomes reachable from other networks.

```
1 > set nsconfig -ipAddress 192.0.2.90 -netmask 255.255.255.0
2
```

```
3  Warning: The configuration must be saved and the system rebooted for
   these settings to take effect
4  > add route 0 0 192.0.2.1
5
6  Warning: The configuration must be saved and the system rebooted for
   these settings to take effect
7  > save config
8
9  Done
10 > reboot
```

## Configuring and Managing Virtual IP (VIP) Addresses

September 21, 2020

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the Citrix ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see [Load Balancing](#).

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple Citrix ADC appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the appliance sends, and then responds to, ARP requests. VIPs are the only Citrix ADC-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests. As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

### Example:

```
1  > add ns ip 10.102.29.59 255.255.255.0 -type VIP
2  Done
3  <!--NeedCopy-->
```

To create a range of VIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
2 ip "10.102.29.60" added
3 ip "10.102.29.61" added
4 ip "10.102.29.62" added
5 ip "10.102.29.63" added
6 ip "10.102.29.64" added
7 Done
8 <!--NeedCopy-->
```

To enable or disable an IPv4 VIP address by using the CLI:

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

**Example:**

```
1 > enable ns ip 10.102.29.79
2 Done
3 > show ns ip 10.102.29.79
4
5 IP: 10.102.29.79
6 Netmask: 255.255.255.255
7 Type: VIP
8 state: Enabled
9 arp: Enabled
10 icmp: Enabled
11 vserver: Enabled
12 management access: Disabled
13 telnet: Disabled
14 ftp: Disabled
15 ssh: Disabled
16 gui: Disabled
17 snmp: Disabled
18 Restrict access: Disabled
19 dynamic routing: Disabled
20 hostroute: Disabled
```

```
21 Done
22 > disable ns ip 10.102.29.79
23 Done
24 > show ns ip 10.102.29.79
25
26     IP: 10.102.29.79
27     Netmask: 255.255.255.255
28     Type: VIP
29     state: Disabled
30     arp: Enabled
31     icmp: Enabled
32     vserver: Enabled
33     management access: Disabled
34     telnet: Disabled
35     ftp: Disabled
36     ssh: Disabled
37     gui: Disabled
38     snmp: Disabled
39     Restrict access: Disabled
40     dynamic routing: Disabled
41     hostroute: Disabled
42
43 Done
44 <!--NeedCopy-->
```

To configure a VIP address by using the GUI:

Navigate to **System > Network > IPs > IPV4s**, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. In the **Action** list, select **Add Range**.

To enable or disable a VIP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Do one of the following:
  - Select a VIP address.
  - Hold down the **Ctrl** key and select multiple server address entries.
  - Hold down the **Shift** key and select a range of server address entries.
  - Select all the addresses by selecting the checkbox on the left side of the header row.
3. From the **Action** list, select **Disable** or **Enable**.

## Detecting a Citrix ADC Appliance in a UDP Load Balancing Setup through TTL Updates

The following table displays how a Citrix ADC appliance handles the TTL value of received packets in different functionalities.

| Functionality  | TTL value                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual Server | TTL is set to 255 when forwarding the request to the backend servers. TTL is decremented by 1 when forwarding the response to the client. |
| L2 Mode        | TTL is not changed.                                                                                                                       |
| L3 Mode        | TTL is set to 255.                                                                                                                        |
| INAT           | TTL is set to 255 when forwarding the request to the backend server. TTL is decremented by 1 when forwarding the response to the client.  |

Some enterprises/scenarios running a monitoring application requires the Citrix ADC appliance of a load balancing setup to be detected as one of the hop in a traceroute. A Citrix ADC appliance of a load balancing setup is not detected in a traceroute because the appliance, by default, sets the TTL value to 255 instead of decrementing it when forwarding the request to a backend server.

To meet this requirement, **Decrement TTL** parameter of a VIP address can be used. This parameter applies to all UDP virtual servers using this VIP.

When you enable the **Decrement TTL** parameter of a VIP, the Citrix ADC appliance decrements the TTL value by 1 instead of setting it to 255 when forwarding requests, which are received on the UDP virtual servers that uses this VIP.

Monitoring applications using traceroute data can now detect the presence of a Citrix ADC appliance of a UDP load balancing setup.

### Before You Begin

Before you begin configuring a Citrix ADC appliance to be detected in a traceroute of a load balancing setup, note the following points:

- Decrement TTL parameter is supported only for UDP load balancing virtual servers.
- Decrement TTL parameter is supported for IPv4 VIP as well as IPv6 VIP (VIP6) addresses.
- Decrement TTL parameter is supported for standalone Citrix ADC appliances as well as for high availability (HA) and cluster setups.

## Configuration Steps

Configuring a Citrix ADC appliance to be detected in a traceroute of a UDP load balancing setup consists of the following tasks:

- Create a UDP load balancing configuration
- Enable the Decrement TTL parameter for the VIP address

## CLI Procedures

To enable the decrement TTL option for a VIP address by using the CLI:

- To enable the decrement TTL option for a VIP address while adding the VIP address, at the command prompt, type:
  - **add ns ip** <ip> <mask> **-type VIP -decrementTTL ENABLED**
  - **show ns ip** <VIP address>
- To enable the decrement TTL option for an existing VIP address, at the command prompt, type:
  - **set ns ip** <ip> <mask> **-decrementTTL ENABLED**
  - **show ns ip** <VIP address>

To enable the decrement TTL option for a VIP6 address by using the CLI:

- To enable the decrement TTL option for a VIP6 address while adding the VIP6 address, at the command prompt, type:
  - **add ns ip6** <IP6/prefix> <mask> **-type VIP -decrementTTL ENABLED**
  - **show ns ip6** <VIP6/prefix>
- To enable the decrement TTL option for an existing VIP6 address, at the command prompt, type:
  - **set ns ip6** <ip6/prefix> <mask> **-decrementTTL ENABLED**
  - **show ns ip6** <VIP6 address>

```
1 > add ns ip 203.0.113.30 -type VIP -decrementTTL ENABLED
2 Done
3
4 > add ns ip6 2001:DB8:5001::30 -type VIP -decrementTTL ENABLED
5 Done
```

## GUI Procedures

To enable the decrement TTL option for a VIP address by using the GUI:

Navigate to **System > Network > IPs > IPv4s**, and enable the **Decrement TTL** parameter while adding a new VIP address or editing an existing address.

To enable the decrement TTL option for a VIP6 address by using the GUI:

Navigate to **System > Network > IPs > IPv6s**, and enable the **Decrement TTL** parameter while adding a new VIP6 address or editing an existing address.

## Configuring ARP response Suppression for Virtual IP addresses (VIPs)

September 21, 2020

You can configure the Citrix ADC appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a Citrix ADC appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE.** The Citrix ADC appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER.** The Citrix ADC appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER.** The Citrix ADC appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of Citrix ADC appliance for a VIP configured with two virtual servers:

| Associated virtual servers for a VIP    | STATE 1 | STATE 2 | STATE 3 | STATE 4 |
|-----------------------------------------|---------|---------|---------|---------|
| <b>NONE</b>                             |         |         |         |         |
| V1                                      | UP      | UP      | DOWN    | DOWN    |
| V2                                      | UP      | DOWN    | UP      | DOWN    |
| Respond to an ARP request for this VIP? | Yes     | Yes     | Yes     | Yes     |
| <b>ONE VSERVER</b>                      |         |         |         |         |
| V1                                      | UP      | UP      | DOWN    | DOWN    |
| V2                                      | UP      | DOWN    | UP      | DOWN    |

| Associated virtual servers for a VIP    | STATE 1 | STATE 2 | STATE 3 | STATE 4 |
|-----------------------------------------|---------|---------|---------|---------|
| Respond to an ARP request for this VIP? | Yes     | Yes     | Yes     | No      |
| <b>ALL VSERVER</b>                      |         |         |         |         |
| V1                                      | UP      | UP      | DOWN    | DOWN    |
| V2                                      | UP      | DOWN    | UP      | DOWN    |
| Respond to an ARP request for this VIP? | Yes     | No      | No      | No      |

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on Citrix ADC appliances NS1 and NS2. Let's call the shared VIP address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for *VIP1*, the ARP suppression parameter is set to *ALL\_VSERVER*. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for *VIP1*.

Figure 1.

The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.
8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request

for VIP1.

10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the CLI:

At the command prompt, type:

- **set ns ip -arpResponse** <arpResponse>]
- **sh ns ip** <IPAddress>

**Example:**

```
1 > set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
2 Done
3 <!--NeedCopy-->
```

To configure ARP response suppression by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Open an IP address entry and select the type of ARP Response.

## Configuring Subnet IP Addresses (SNIPs)

September 21, 2020

A subnet IP address (SNIP) is a Citrix ADC owned IP address that is used by the Citrix ADC to communicate with the servers.

The Citrix ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers. Depending on your network topology, you might have to configure one or more SNIPs for different scenarios.

To configure a SNIP address on a Citrix ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode. As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the CLI:

At the command prompt, type:

- **add ns ip** <IPAddress> <netmask> -type SNIP
- **show ns ip** <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.203 255.255.255.0 -type SNIP
2 Done
3 <!--NeedCopy-->
```

To create a range of SNIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
2 ip "10.102.29.205" added
3 ip "10.102.29.206" added
4 ip "10.102.29.207" added
5 ip "10.102.29.208" added
6 ip "10.102.29.209" added
7 Done
8 <!--NeedCopy-->
```

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the GUI:

Navigate to System > Network > IPs > IPv4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the GUI:

1. Navigate to System > Network > IPs > IPv4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns mode USNIP
- disable ns mode USNIP

To enable or disable USNIP mode by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

## Using SNIPs for a Directly Connected Server Subnet

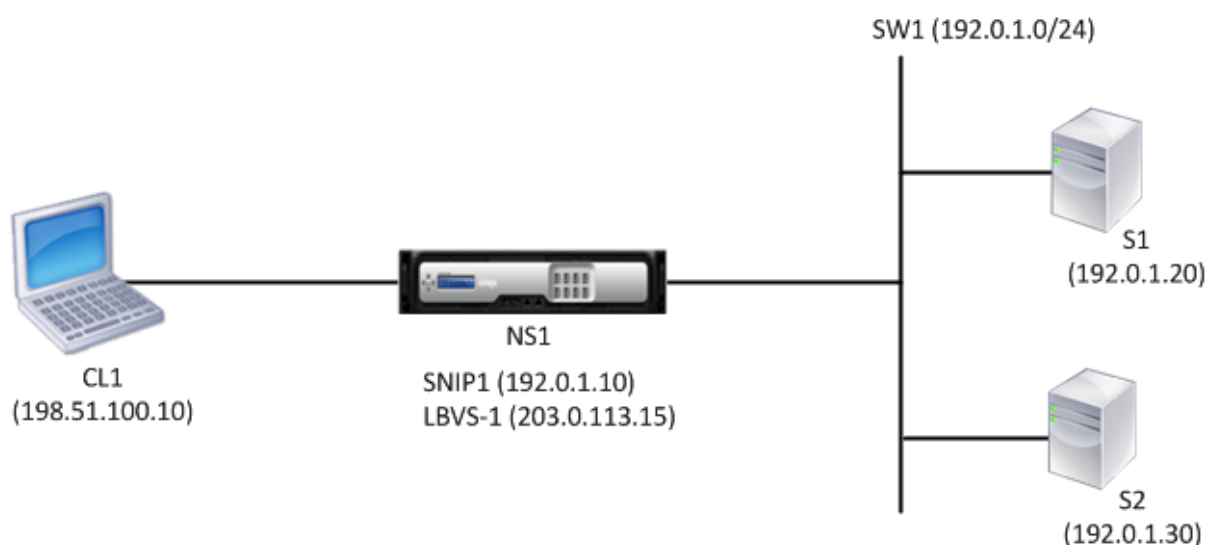

To enable communication between the Citrix ADC and a server that is either connected directly to the Citrix ADC or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a Citrix ADC, see [Load Balancing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
  - Source IP = IP address of the client (198.51.100.10)
  - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.
5. NS1 sends the request packet to S2 from SNIP1. The request packet has:

- Source IP = SNIP1 (192.0.1.10)
  - Destination IP = IP address of S2 (192.0.1.30)
6. S2's response returns by the same path.

### **Using SNIPs for Server Subnets Connected through a Router**

To enable communication between the Citrix ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

Citrix ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

For more information about configuring load balancing on a Citrix ADC, see [Load Balancing](#).

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables, that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a Citrix ADC, see [IP Routing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
  - Source IP = IP address of the client (198.51.100.10)
  - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
  - Source IP address = SNIP1 (192.0.1.10)
  - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3's response returns by the same path.

### Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a Citrix ADC, you must configure at least one SNIP address for each of the server subnets, so that the Citrix ADC can communicate with these server subnets.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a Citrix ADC, see [Load Balancing](#).

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a Citrix ADC, see [Configuring a VLAN](#).

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
  - Source IP = IP address of the client (198.51.100.10)
  - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.
 

Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.
5. NS1 sends the request packet to S2 from SNIP2. The request packet has:
  - Source IP = SNIP1 (192.0.2.10)
  - Destination IP = IP address of S2 (192.0.2.20)
6. S2's response returns by the same path.

## Configuring GSLB Site IP Addresses (GSLBIP)

September 21, 2020

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the Citrix ADC appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see [Global Server Load Balancing](#).

## Removing a Citrix ADC-owned IP address

September 21, 2020

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

| IP address type                 | Implications                                                                                                                                                                                                                                                                                  |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Subnet IP address (SNIP)        | If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another Citrix ADC-owned IP address. |
| Virtual Server IP address (VIP) | Before removing a VIP, you must first remove the virtual server associated with it. For information about removing the virtual server, see <a href="#">Load Balancing</a> .                                                                                                                   |
| GSLB-Site-IP address            | Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see <a href="#">Global Server Load Balancing</a> .                                                                                                              |

To remove an IP address by using the CLI:

At the command prompt, type:

rm ns ip <IPAddress>

**Example:**

```
1 > rm ns ip 10.102.29.54
2 Done
3 <!--NeedCopy-->
```

To remove an IP address by using the GUI:

Navigate to **System > Network > IPs > IPv4s**, delete the IP address.

## Configuring Application Access Controls

September 21, 2020

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see [Access Control Lists \(ACLs\)](#).

The Citrix ADC appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

| Management Access | Telnet (State Configured on the Citrix ADC) | Telnet (Effective State at the IP Level) |
|-------------------|---------------------------------------------|------------------------------------------|
| Enable            | Enable                                      | Enable                                   |
| Enable            | Disable                                     | Disable                                  |
| Disable           | Enable                                      | Disable                                  |
| Disable           | Disable                                     | Disable                                  |

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

| Application/ IP     | NSIP | SNIP | VIP |
|---------------------|------|------|-----|
| ARP                 | Yes  | Yes  | No  |
| Server side traffic | No   | Yes  | No  |
| RNAT                | No   | Yes  | Yes |
| ICMP PING           | Yes  | Yes  | No  |
| Dynamic routing     | Yes  | Yes  | Yes |

The following table provides an overview of the applications available on these IP addresses.

| Application/ IP | NSIP | SNIP | VIP |
|-----------------|------|------|-----|
| SNMP            | Yes  | Yes  | Yes |
| System access   | Yes  | Yes  | No  |

You can access and manage the Citrix ADC by using applications such as Telnet, SSH, GUI, and FTP.

**Note:** Telnet and FTP are disabled on the Citrix ADC for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the Citrix ADC to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the Citrix ADC appliance's attack prevention capabilities.

You can block access to these non-management applications on a SNIP or NSIP. When access is blocked, a user connecting to a Citrix ADC by using the SNIP or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the CLI:

At the command prompt, type:

```
set ns ip <IPAddress> -mgmtAccess <value> -telnet <value> -ftp <value> -gui <value> -ssh <value>
-snmp <value> -restrictAccess (ENABLED | DISABLED)
```

**Example:**

```
1 To enable management access and restrict access for a Citrix ADC owned IP address:
```

```
2
3 > set ns ip 192.0.2.20 -mgmtAccess enabled -restrictAccess ENABLED
4 Done
5
6 To disable GUI access for a NSIP or SNIP address:
7
8 > set ns ip 192.0.2.10 -gui disabled
9 Done
10
11 <!--NeedCopy-->
```

To enable management access for an IP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Open an IP address entry, and select the **Enable Management Access control** to support the listed applications option.

## How the Citrix ADC Proxies Connections

September 21, 2020

When a client initiates a connection, the Citrix ADC appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

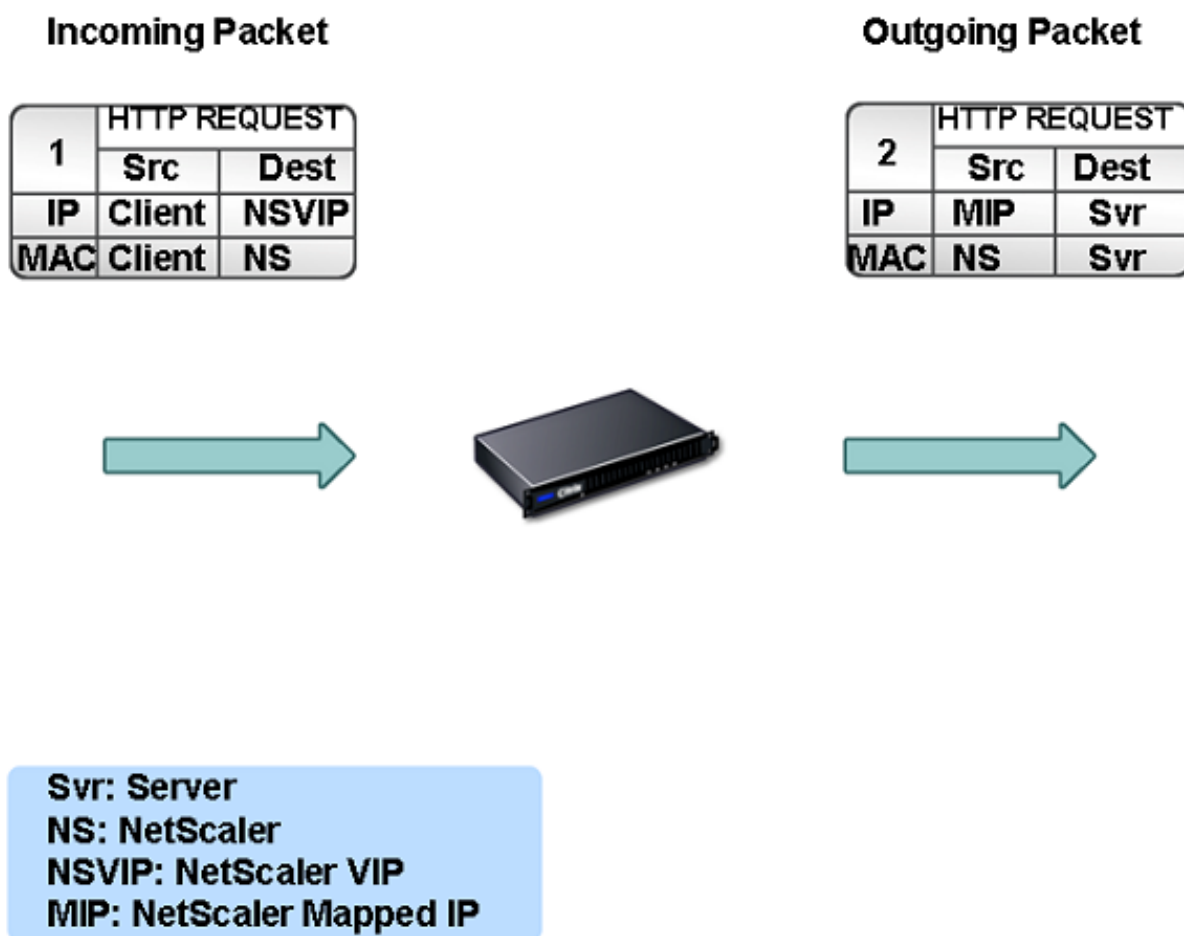

For more information about service types, see [Load Balancing](#).

You can configure the Citrix ADC to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the Citrix ADC to retain the source IP address of the packets by enabling Use Source IP mode.

### How the Destination IP Address Is Selected

Traffic sent to the Citrix ADC appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The Citrix ADC terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

Figure 1. Proxying Connections to VIPs

Packets destined for a service are sent directly to the appropriate server, and the Citrix ADC does not modify the destination IP addresses. In this case, the Citrix ADC functions as a proxy.

### How the Source IP Address Is Selected

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. Citrix ADC maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, Citrix ADC selects a specific SNIP address.

**Note:** If the Use Source IP (USIP) option is enabled, appliance uses the IP address of the client.

## Enable Use Source IP Mode

September 21, 2020

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of selecting a SNIP address depends on the subnet in which the physical server resides.

If necessary, you can configure the Citrix ADC appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Google provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the Citrix ADC may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want the Citrix ADC to use the client's IP address for communication with the servers.

The following figure shows how the appliance uses IP addresses in USIP mode.

## Before you begin

Before you enable USIP mode, note the following points:

- Enable USIP in the following situations:
  - Load balancing of Intrusion Detection System (IDS) servers
  - SMTP load balancing
  - Stateless connection failover
  - Sessionless load balancing
  - If you use the Direct Server Return (DSR) mode
- The USIP global setting applies only to services that are created after the USIP global setting is made. In other words, the USIP global setting does not apply to the existing services when the USIP global setting is made. For example, Disabling USIP globally does not disable USIP on the existing services. But it stops the subsequently created services from having USIP enabled automatically.

To enable or disable USIP on a set of existing services, you need to enable or disable USIP on each of these services.

- When USIP is enabled, you must set server's gateway to one of the Citrix ADC owned IP addresses (of type Subnet IP (SNIP)) so that server's response always go through the Citrix ADC appliance.
- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.
- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.
- As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.
- In earlier Citrix ADC releases, USIP mode had the following source-port options for server-side connections:
  - **Use the client's port.** With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.
  - **Use proxy port.** With this option, connection reuse is possible for all requests from the same client.

In the later Citrix ADC releases, if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

**Note:** If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

For more information about the Use Proxy Port option, see [Configure the source port for server-side connections](#).

## Configuration Steps

Enable Use Source IP mode (USIP) mode if you want Citrix ADC to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the Citrix ADC or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

### CLI procedures

To globally enable or disable USIP mode by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns mode USIP**
- **disable ns mode USIP**

To enable USIP mode for a service by using the CLI:

At the command prompt, type:

**set service <name>@ -usip (YES | NO)**

#### Example:

```
1 > set service Service-HTTP-1 -usip YES
2 Done
3 <!--NeedCopy-->
```

### GUI procedures

To globally enable or disable USIP mode by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change Modes**.
2. Select or clear the **Use Source IP** option.

To enable USIP mode for a service by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Services**, and edit a service.
2. In **Advanced Settings**, select **Service Settings**, and select **Use Source IP Address**.

## Configuring Network Address Translation

September 21, 2020

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the Citrix ADC appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the Citrix ADC. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The Citrix ADC supports the following types of network address translation:

- **Inbound NAT (INAT)**. The Citrix ADC replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- **Reverse NAT (RNAT)**. The Citrix ADC replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

### INAT

September 21, 2020

When a client sends a packet to a Citrix ADC appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping**: A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.
- **IPv4-IPv6 Mapping**: A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.

- **IPv6-IPv4 Mapping:** A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping:** A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the appliance uses a subnet IP address (SNIP) as the source IP address.
- If USNIP mode is disabled and USIP mode is disabled, the appliance uses a mapped IP address (MIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the appliance uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the Citrix ADC to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the Citrix ADC attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the Citrix ADC from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you may want to disable them.

## Configure INAT

You can create, modify, or remove an INAT entry.

### CLI procedures

To create an INAT entry by using the CLI:

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- **add inat** <name> <publicIP> <privateIP> [-tcpproxy ( **ENABLED** | **DISABLED** )] [-ftp ( **ENABLED** | **DISABLED** )] [-usip ( **ON** | **OFF** )] [-usnip ( **ON** | **OFF** )] [-proxyIP <ip\_addr|ipv6\_addr>]
- **show inat** [<name>]

### Example:

```
1 > add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
2 Done
3 <!--NeedCopy-->
```

To modify an INAT entry by using the CLI:

To modify an INAT entry, type the **set inat** command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the CLI:

At the command prompt, type:

- **rm inat** <name>

**Example:**

```
1 > rm inat ip4-ip4
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To configure an INAT entry by using the GUI:

Navigate to **System > Network > Routes > INAT**, and add a new INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the GUI:

Navigate to **System > Network > Routes > INAT**, delete the INAT configuration.

## Coexistence of INAT and Virtual Servers

September 21, 2020

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the Citrix ADC device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

| Case                                                                                                                                                                                                                                                                                                                                                 | Result                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| You have configured a virtual server and a service to send all data packets received on a specific Citrix ADC port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.                                    | All packets received on the Citrix ADC, except those received on the specified port, pass through the TCP engine. |
| You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the Citrix ADC, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server. | Only packets received on the specified port pass through the TCP engine.                                          |
| You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.                                                                                                                                         | The INAT configuration is not allowed.                                                                            |
| You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.                                                                                                                                          | The vserver configuration is not allowed.                                                                         |

## Stateless NAT46

September 21, 2020

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the Citrix ADC appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

A stateless NAT46 configuration on the Citrix ADC appliance has the following components:

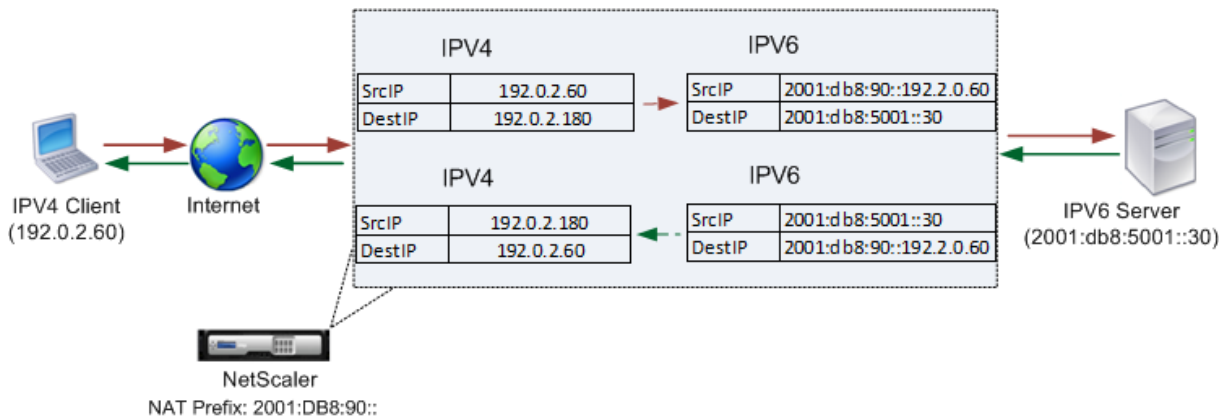

- **IPv4-IPv6 INAT entry.** An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.

The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.

- **NAT46 IPv6 prefix.** A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.

During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site `www.example.com` on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, Citrix ADC appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.

The following table lists the settings used in this example:

| Entities                   | Name                                      | Value             |
|----------------------------|-------------------------------------------|-------------------|
| IP address of the client   | Client_IPv4 (for reference purposes only) | 192.0.2.60        |
| IPv6 address of the server | Sevr_IPv6 (for reference purposes only)   | 2001:DB8:5001::30 |

| Entities                                                  | Name                                        | Value         |
|-----------------------------------------------------------|---------------------------------------------|---------------|
| IPv4 address defined in the INAT entry for IPv6 server S1 | Map-Sevr-IPv4 (for reference purposes only) | 192.0.2.180   |
| IPv6 prefix for NAT 46 translation                        | NAT46_Prefix (for reference purposes only)  | 2001:DB8:90:: |

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the Citrix ADC appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
  - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
  - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client\_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the Citrix ADC appliance with:
  - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client\_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60
  - Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30
6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30 ). It finds the Map-Sevr-IPv4 address (192.0.2.180).
7. The appliance creates an IPv4 response packet with:
  - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client\_IPv4 (192.0.2.60)
  - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
8. The appliance sends the translated IPv4 response to client CL1.

### Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.

- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

## Configure Stateless NAT46

Creating the required entities for stateless NAT46 configuration on the Citrix ADC appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Create a NAT46 IPv6 prefix.

### CLI procedures

To configure an INAT mapping entry by using the CLI:

At the command prompt, type:

- `add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS`
- `show inat <name>`

To create an NAT46 prefix by using the CLI:

At the command prompt, type:

```
set inatparam -nat46v6Prefix <ipv6_addr *>
```

- 
- `show inatparam`

### Example:

```
1 > add inat exmpl-com-stls-nat46 192.0.2.180
2 2001:DB8:5001::30 -mode stateless
3 Done
4
5 > set inatparam -nat46v6Prefix 2001:DB8:90::/96
6 Done
7 <!--NeedCopy-->
```

## GUI procedures

To create an INAT mapping entry by using the GUI:

1. Navigate to System > Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
  - Name\*
  - Public IP Address\*
  - Private IP Address\* (Select the IPv6 check box and enter the address in IPv6 format.)
  - Mode (Select Stateless from the drop down list.)

\* A required parameter

To create a NAT46 prefix by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure INAT Parameters**, and set the **Prefix** parameter.

## Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the CLI:

At the command prompt, type:

```

set inatparam NO )] [- DISABLED )] DISABLED )]
[-nat46IgnoreTOS ( nat46ZeroChecksum [-nat46v6Mtu
YES ( ENABLED <positive_integer>]
[-nat46FragHeader (
ENABLED

```

•

- **show inatparam**

### Example:

```

1 > set inatparam -nat46IgnoreTOS YES -nat46ZeroChecksum DISABLED -
    nat46v6Mtu 1400 -nat46FragHeader DISABLED
2 Done
3 <!--NeedCopy-->

```

To set global parameters for stateless NAT46 by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure INAT Parameters**.

## DNS64

September 21, 2020

The Citrix ADC DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery of the IPv4 domain by the IPv6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the Citrix ADC appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the Citrix ADC appliance. The Citrix ADC appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a Citrix ADC appliance with DNS64 and NAT64 configuration can be deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the Citrix ADC appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the Citrix ADC appliance is deployed on the client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a Citrix ADC appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site `www.example.com` on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, and DNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

The global DNS parameter `cacherecords` is enabled on the Citrix ADC appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example: [DNS64 example settings](#).

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site www.example.com.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on Citrix ADC appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site www.example.com does not exist in the DNS cache.
4. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site www.example.com is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site www.example.com.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.
7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of www.example.com.
8. DNS-1 responds by sending the DNS A record for www.example.com to LBVS-DNS64-1. The A record includes the IPv4 address for www.example.com.
9. NS1 synthesizes an AAAA record for the site www.example.com with:
  - IPv6 address for site www.example.com = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = 2001:DB8:300::192.0.2.60
10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

### **Points to Consider for a DNS64 Configuration**

Before configuring DNS64 on a Citrix ADC appliance, consider the following points:

- The DNS64 feature of the Citrix ADC appliance is compliant with RFC 6174.
- The DNS64 feature of the Citrix ADC appliance does not support DNSSEC. The Citrix ADC appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.
- The Citrix ADC appliance supports DNS64 prefix of length of only 96 bits.
- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the Citrix ADC appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a Citrix ADC appliance, see [Stateful NAT64](#).
- The following are the different cases of DN64 processing by the Citrix ADC appliance:

- If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the Citrix ADC appliance for the particular DNS64 configuration. The Citrix ADC removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the Citrix ADC appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
  - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.
  - If the response from the DNS server includes RCODE=1 (format error), the Citrix ADC appliance forwards the same to the client. If there is no response before the timeout, the Citrix ADC appliance sends a response with RCODE=2 (server failure) to the client.
  - If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the Citrix ADC appliance fetches the DNS A record to be used for synthesizing AAAA record. The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.
- The DNS64 feature of the Citrix ADC appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping the IP6-ARPA domain into the corresponding IN-ADDR.ARPA domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The Citrix ADC appliance uses the response from the DNS server to synthesize response for the initial PTR request.

## Configuration Steps

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the Citrix ADC appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see [Load Balancing](#).
- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing accord-

ing to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.

- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see [Load Balancing](#).

**Note:** The CLI has separate commands for these two tasks, but the GUI combines them in a single dialog box.

**Enable caching of DNS records.** Enable the global parameter for the Citrix ADC appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see [Domain Name System](#).

</div>

## CLI procedures

To create a service of type DNS by using the CLI:

At the command prompt, type:

- `add service <name> <IP> <serviceType> <port> ...`

To create a DNS64 action by using the CLI:

At the command prompt, type:

- `add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule <expression>] [-excludeRule <expression>]`

To create a DNS64 policy by using the CLI:

At the command prompt, type:

- `add dns policy64 <name> -rule <expression> -action <string>`

To create a DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- `add lb vserver <name> DNS <IPAddress> <port> -dns64 ( ENABLED | DISABLED ) [-bypassAAAA ( YES | NO )] ...`

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- bind lb vserver <name> <serviceName> ...
- bind lb vserver <name> -policyName <string> -priority <positive\_integer> ...

## GUI procedures

To create a service of type DNS by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
  - Service Name\*
  - Server\*
  - Protocol\* (Select DNS from the drop down list.)
  - Port\*

To create a DNS64 action by using the GUI:

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the GUI:

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
  - Name\*
  - IP Address\*
  - Protocol\* (Select DNS from the drop down list.)
  - Port\*
3. Select the Enable DNS64 option.
4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

## Sample Configuration

```
1 > add service SVC-DNS-1 203.0.113.50 DNS 53
2 Done
3
4 > add service SVC-DNS-2 203.0.113.60 DNS 53
5 Done
6
7 > add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
8 Done
```

```
9
10 > add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET
    (2001:DB8:5001::/64)"
11 -action DNS64-Action-1
12 Done
13
14 > add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
15 Done
16
17 > bind lb vserver LBVS-DNS64-1 SVC-DNS-1
18 Done
19
20 > bind lb vserver LBVS-DNS64-1 SVC-DNS-2
21 Done
22
23 > bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
24 Done
25
26 <!--NeedCopy-->
```

## Stateful NAT64 Translation

September 21, 2020

The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the Citrix ADC appliance.

A stateful NAT64 configuration on the Citrix ADC appliance has the following components:

- **NAT64 rule**— An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of Citrix ADC owned SNIP Addresses.
- **NAT64 IPv6 Prefix**— A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance.

Note: Currently the Citrix ADC appliance supports only one prefix to be used commonly with all NAT 64 rules.

The Citrix ADC appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

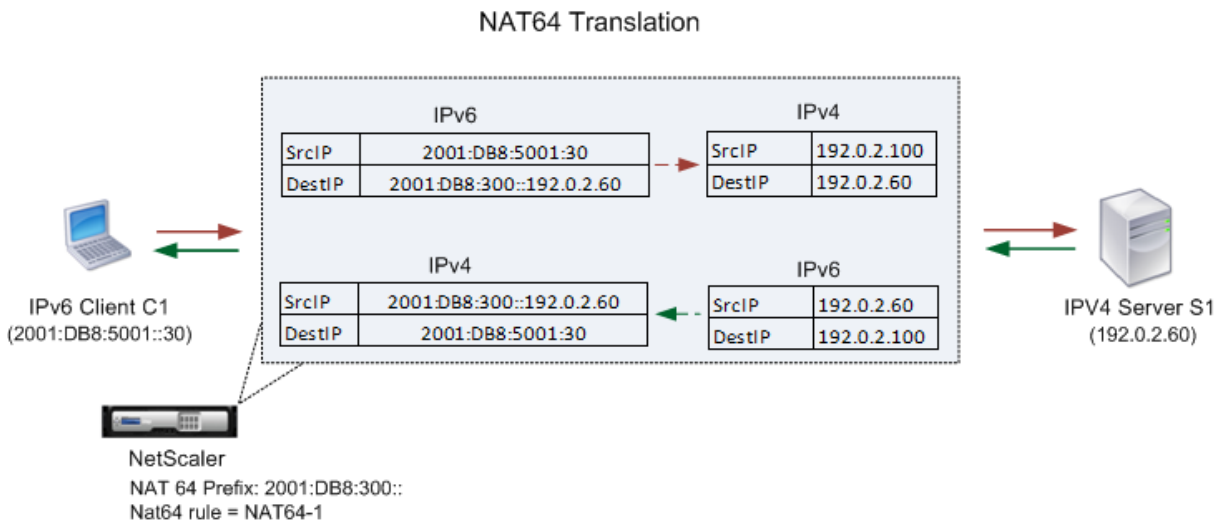

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the Citrix ADC appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the Citrix ADC appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The Citrix ADC appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site `www.example.com` on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate with IPv4 server S1.

The following table lists the settings used in this example: [Stateful NAT64 translation example settings](#).

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The Citrix ADC appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the Citrix ADC considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
  - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr\_IPv4 = 192.0.2.60)

- Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)
4. The Citrix ADC appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
  5. IPv4 server S1 responds by sending an IPv4 packet to the Citrix ADC appliance with:
    - Destination IP address field containing 192.0.2.100
    - Source IP address field containing the address of Sevr\_IPv4(192.0.2.60)
  6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv4 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.
  7. The appliance creates a translated IPv6 response packet with:
    - Destination IP address field=Client\_IPv6=2001:DB8:5001::30
    - Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr\_IPv4 (last 32 bits) =2001:DB8:300::192.0.2.60
  8. The appliance sends the translated IPv6 response to client CL1.

### **Limitations of Stateful NAT64**

The following limitations apply to stateful NAT64:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

### **Configuring Stateful NAT64**

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACL6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

**CLI procedures**

To add an ACL6 rule by using the CLI:

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> ...

To add an IPset and bind multiple IPs to it by using the CLI:

At the command prompt, type:

- add ipset <name>
- bind ipset <name> <IPaddress ...>

To add a netprofile by using the CLI:

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the CLI:

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the CLI:

At the command prompt, type:

---

```
set ipv6 -natprefix <ipv6_addr          *>
```

---

•

**Example:**

```
1 > add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
2 Done
3
4 > apply acIs6
5 Done
6
7 > add ip 192.0.2.100 255.255.255.0 - type SNIP
8 Done
9
10 > add ip 192.0.2.102 255.255.255.0 - type SNIP
11 Done
12
13 > add ipset IPset-1
```

```
14 Done
15
16 > bind ipset IPset-1 192.0.2.100 192.0.2.102
17 IPAddress "192.0.2.100" bound
18 IPAddress "192.0.2.102" bound
19 Done
20
21 > add netprofile Netprofile-1 -srcIP IPset-1
22 Done
23
24 > add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
25 Done
26
27 > set ipv6 -natprefix 2001:DB8:300::/96
28 Done
29 <!--NeedCopy-->
```

## GUI procedures

To add a NAT64 rule by using the GUI:

Navigate to System > Network > Routes > NAT64, and add a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

## RNAT

September 21, 2020

In Reverse Network Address Translation (RNAT), the Citrix ADC appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a SNIP address as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

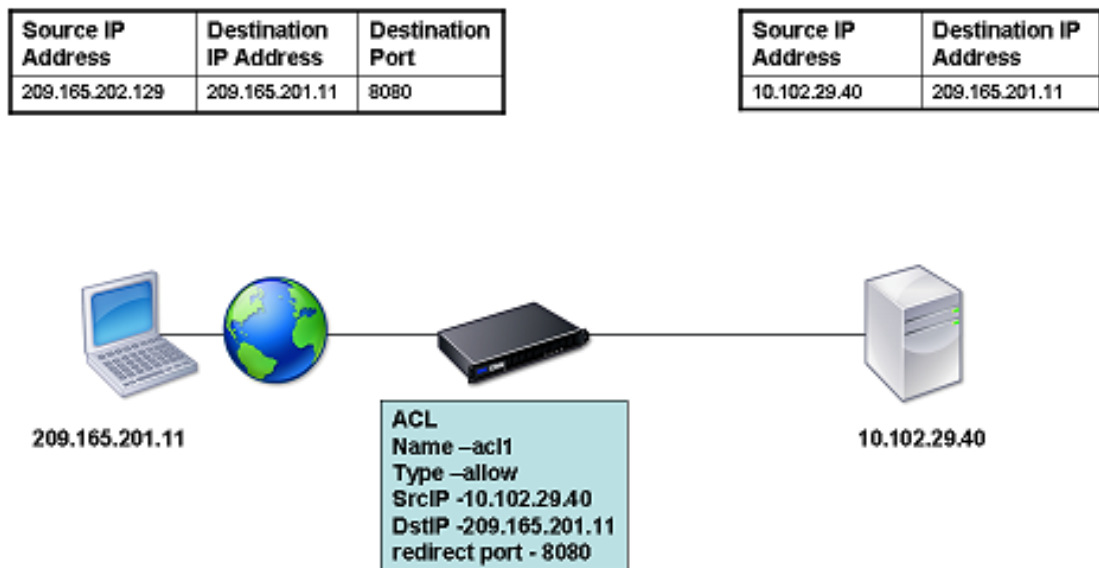

**Note:** The ephemeral port range for RNAT on the Citrix ADC appliance is 1024-65535.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the Citrix ADC appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:
  1. Configure the ACL.
  2. Configure RNAT to change the source IP address and Destination Port.
  3. Apply the ACL.

The following diagram illustrates RNAT configured with an ACL.

Figure 1. RNAT with an ACL

You have the following basic choices for the type of NAT IP address:

- **Using a SNIP as the NAT IP Address.** When using a SNIP as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the a SNIP. Therefore, the SNIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the Citrix ADC can use a subnet IP address (SNIP) as the NAT IP address.
- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public Citrix ADC-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

This configuration is illustrated in the following diagram.

Figure 2. Using a Unique IP Address as the NAT IP Address

## Before you begin

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the Citrix ADC appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- In a topology where the Citrix ADC appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see [Link Load Balancing](#).

## Configure RNAT

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the GUI, all of the variations can be configured in the same dialog box, so there is only one procedure for GUI users.

## CLI procedures

To create an RNAT entry by using the CLI:

At the command prompt, type one the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

- **set rnat** <IPAddress> <netmask>
- **set rnat IPAddress** <netMask> **-natip** <NATIPAddress>
- **set rnat** <aclname> [**-redirectPort** <port>]
- **set rnat** <aclname> [**-redirectPort** <port>] **-natIP** <NATIPAddress>

Use the following command to verify the configuration:

- **show rnat**

## Examples:

```
1 A network address as the condition and a SNIP as the NAT IP address:
2
3 > set rnat 192.168.1.0 255.255.255.0
4 Done
5
6 A network address as the condition and a unique IP address as the NAT
  IP address:
7
8 > set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
9 Done
10
11 If instead of a single NAT IP address you specify a range, RNAT entries
    are created with all the Citrix ADC-owned IP addresses, except the
    NSIP, that fall within the range specified:
12
13 > set rnat 192.168.1.0 255.255.255.0 -natIP 10.102.29.[50-110]
14 Done
15
16 An ACL as the condition and a SNIP as the NAT IP address:
17
18 > set rnat acl1
19 Done
20
21 An ACL as a condition and a unique IP address as the NAT IP address:
22
23 > set rnat acl1 -natIP 209.165.202.129
```

```

24 Done
25
26 If instead of a single NAT IP address you specify a range, RNAT entries
    are created with all the Citrix ADC-owned IP addresses, except the
    NSIP, that fall within the range specified:
27
28 > set rnat acl1 -natIP 10.102.29.[50-70]
29 Done
30
31 <!--NeedCopy-->

```

## GUI procedures

To create an RNAT entry by using the GUI:

1. Navigate to **System > Network > NATs**, and then click the **RNAT** tab.
2. In the **Action list**, select **Configure RNAT** to create or modify an RNAT entry.

## Monitor RNAT

You can display RNAT statistics to troubleshoot issues related to IP address translation.

The following table describes the statistics associated with RNAT and RNAT IP.

| Statistic        | Description                                        |
|------------------|----------------------------------------------------|
| Bytes received   | Bytes received during RNAT sessions                |
| Bytes sent       | Bytes sent during RNAT sessions                    |
| Packets received | Packets received during RNAT sessions              |
| Packets sent     | Packets sent during RNAT sessions                  |
| Syn sent         | Requests for connections sent during RNAT sessions |
| Current sessions | Currently active RNAT sessions                     |

To view RNAT statistics by using the CLI:

At the command prompt, type:

- **stat rnat**

### Example:

```

1 > stat rnat
2
3 RNAT summary
4
5                               Rate (/s)           Total
6 Bytes Received                0                0
7 Bytes Sent                     0                0
8 Packets Received               0                0
9 Packets Sent                   0                0
10 Syn Sent                      0                0
11 Current RNAT sessions         --                0
12 Done
13 >
14 <!--NeedCopy-->

```

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

## Configure RNAT6

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the Citrix ADC owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address.** When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s.** When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of Citrix ADC owned SNIP6 and VIP6 addresses for an RNAT6 rule. The Citrix ADC appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any Citrix ADC owned SNIP6 or VIP6 address for an RNAT6 rule. The Citrix ADC appliance uses any one of the Citrix ADC owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

## CLI procedures

To create an RNAT6 rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- **add rnat6** <name> (<network> | (<acl6name> [-**redirectPort** <port>]))
- **bind rnat6** <name> <natIP6>@ ...
- **show rnat6**

To modify or remove an RNAT6 rule by using the CLI:

- To modify an RNAT6 rule whose condition is an ACL6, type the **set rnat6** <name> command, followed by a new value for the **redirectPort** parameter.
- To remove an RNAT6 rule, type the **clear rnat6** <name> command.
- **show rnat6**

### GUI procedures

To configure an RNAT6 rule by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT6** tab, and add a new RNAT6 rule, or edit an existing rule.

### Monitor RNAT6

You can display statistics related to the RNAT6 feature to monitor the performance or to troubleshoot problems related to RNAT6 feature. You can display a summary of statistics of the RNAT6 rules or of a particular RNAT6 rule. The statistical counters reflect events since the Citrix ADC appliance was last restarted. All these counters are reset to 0 when the Citrix ADC appliance is restarted.

The following lists some of the statistics counters associated with the RNAT6 feature:

- **Bytes received** - Total bytes received during RNAT6 sessions.
- **Bytes sent** - Total number of bytes sent during RNAT6 sessions.
- **Packets received** - Total number of packets received during RNAT6 sessions.
- **Packets sent** - Total number of packets sent during RNAT6 sessions.
- **Syn sent** - Total number of requests for connections sent during RNAT6 sessions
- **Current sessions** - Currently active RNAT6 sessions

To display a summarized statistics of all RNAT6 rules by using the CLI:

At the command prompt, type:

- **stat rnat6**

To display statistics for a specified RNAT6 rule by using the CLI:

At the command prompt, type:

- **stat rnat6** [<rnat6 rule name>]

To display RNAT6 statistics by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT6** tab, and then click **Statistics**.

```
1 > stat rnat6
2
3 RNAT6 summary
4
5                               Rate (/s)                Total
6
7 Bytes Received                178                20644
8
9 Bytes Sent                     178                20644

21 <!--NeedCopy-->
```

### Log Start Time and Connection Closure Reasons in RNAT Log Entries

For diagnosing or troubleshooting problems related to RNAT, the Citrix ADC appliance logs RNAT sessions whenever they are closed.

A log message for an RNAT session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp of log creation
- Protocol of the RNAT session
- Source IP address
- RNAT IP address
- Destination IP address
- Start time of the RNAT session
- Closing time of the RNAT session
- Total bytes sent by the Citrix ADC appliance for this RNAT session
- Total bytes received by the Citrix ADC appliance for this RNAT session

- Reason for closure of the RNAT session. The Citrix ADC appliance logs closure reason for TCP RNAT sessions that do not use the TCP proxy (TCP proxy disabled) of the appliance. The following are the type of closure reasons that are logged for TCP RNAT sessions:
  - **TCP FIN.** The RNAT session was closed because of a TCP FIN sent by either the source or destination device.
  - **TCP RST.** The RNAT session was closed because of a TCP Reset that was sent by either the source or destination device.
  - **TIMEOUT.** The RNAT session timed out.

The following table shows some sample log entries for RNAT sessions.

| Type of Entry                                                                                           | Sample Log Entry                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sample log entry for UDP RNAT session                                                                   | Dec 1 15:28:12 10.102.53.114<br>12/01/2015:15:28:12 GMT 0-PPE-0 : default<br>UDP NAT_OTHERCONN_DELINK 154 0 : Source<br>1.2.2.5:23431 - Destination 192.168.123.122:22<br>- NatIP 192.168.123.1:4045 - Destination<br>192.168.123.122:22 - Start Time<br>12/01/2015:15:26:58 GMT - Delink Time<br>12/01/2015:15:28:12 GMT - Total_bytes_send<br>2511 - Total_bytes_rcv 3725                             |

### Stateful Connection Failover for RNAT

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. The Citrix ADC appliance now supports stateful connection failover for connections related to RNAT rules in a Citrix ADC High Availability (HA) setup. In an HA setup, connection failover (or connection mirroring) refers to the process of keeping an established TCP or UDP connection active when a failover occurs.

The primary appliance sends messages to the secondary appliance to synchronize current information about the RNAT connections. The secondary appliance uses this connection information only in the event of a failover. When a failover occurs, the new primary Citrix ADC appliance has information about the connections established before the failover and hence continues to serve those connections even after the failover. From the client's perspective this failover is transparent. During the transition period, the client and server may experience a brief disruption and retransmissions.

Connection failover can be enabled per RNAT rule. For enabling connection failover on an RNAT rule, you enable the `connFailover` (Connection Failover) parameter of that specific RNAT rule by using either CLI or GUI.

To enable connection failover for a RNAT rule by using the CLI:

At the command prompt, type:

- **set rnat** <name> **-connfailover (ENABLED | DISABLED)**
- **show rnat**

To enable connection failover for a RNAT rule by using the GUI:

1. Navigate to **System > Network > NATs**, and then click the **RNAT** tab.
2. Select **Connection Failover** while adding a new RNAT rule, or while editing an existing rule.

## Removing RNAT Sessions

You can remove any unwanted or inefficient RNAT sessions from the Citrix ADC appliance. The appliance immediately releases resources (such as the port of the NAT IP address, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected RNAT sessions from the Citrix ADC appliance.

To clear all RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession**

To clear selective RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession** ((-network <ip\_addr> -netmask <netmask>) | -natIP <ip\_addr> | -aclname <string>)

To clear all or selective RNAT sessions by using the GUI:

1. Navigate to **System > Network > NATs**, and then click the **RNAT** tab.
2. In the **Actions** Menu, click **Flush RNAT Sessions** to remove all or selective RNAT sessions (for example, removing RNAT sessions with a specific RNAT IP, or belonging to a specific Network or ACL based RNAT rule).

### Sample Configurations:

```
1 Clear all RNAT sessions existing on a Citrix ADC appliance
2
3 > flush rnatsession
4
5 Done
6
7 Clear all RNAT sessions belonging to network based RNAT rules that has
   203.0.113.0/24 network as the matching condition.
8
9 > flush rnatsession -network 203.0.113.0 -netmask 255.255.255.0
10
11 Done
12
13 Clear all RNAT sessions with RNAT IP 192.0.2.90.
14
15 > flush rnatsession -natIP 192.0.2.90
16
17 Done
18
```

```
19 Clear all RNAT sessions belonging to ACL based RNAT rules that has ACL-
    RNAT-1 as the matching condition.
20
21 > flush rnatsession -aclname ACL-RNAT-1
22
23 Done
24 <!--NeedCopy-->
```

## Configuring Prefix-Based IPv6-IPv4 Translation

September 21, 2020

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the Citrix ADC appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The Citrix ADC appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the Citrix ADC appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the Citrix ADC so that the IPv6-IPv4 translation is done by the Citrix ADC.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on Citrix ADC NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation

To configure prefix-based IPv6-IPv4 translation by using the CLI:

At the command prompt, type:

```
set ipv6 [-natprefix <ipv6_addr *>]
```

- 
- show ipv6

#### Example:

```
1 > set ipv6 -natprefix 3ffe::/96
2 Done
3 <!--NeedCopy-->
```

To configure prefix-based IPv6-IPv4 translation by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

## IP Prefix NAT

September 21, 2020

The Citrix ADC appliance supports translating a part of the source IP address instead of the complete address of packets received on the appliance. IP prefix NAT includes changing one or more octets or bits of the source IP address.

The Citrix ADC appliance supports IP prefix NAT for load balancing configurations of the following types: ANY, UDP, DNS, TCP, and HTTP.

### **Use Case: Zonification of Clients for a Deployment of a Citrix ADC appliance and an Optimization Device**

IP prefix NAT is very useful in a deployment that includes a Citrix ADC appliance and an optimization device (for example, Citrix ByteMobile). This type of deployment has different geographically located client networks, which share the same network address. The Citrix ADC appliance must send the traffic received from each of the client networks to the optimization device before forwarding to the destination.

The device sends the optimized traffic back to the Citrix ADC appliance. Because the optimization requirement is different for traffic from each client network, the optimization device must recognize the client network of each packet that it receives. The solution is to segregate traffic from each client network into a different zone by using VLANs. IP prefix NAT with a different setting is configured for each zone. The Citrix ADC appliance translates the last octet of the source IP address of every packet, and the translated octet value is different for each zone.

Consider an example of two zones, Z1 and Z2, sharing network address 192.0.2.0/24. On the Citrix ADC appliance, IP prefix NAT entities named `natrule-1` and `natrule-2` are configured for these two zones. Before the appliance forwards a packet from Z1, `natrule-1` translates the last octet of the packet's source IP address to 100. Similarly, for packets from Z2, `natrule-2` translates the last octet of the source IP address to 200. For two clients, CL1-Z1 in zone Z1 and CL1-Z2 in zone Z2, each with IP address 192.0.2.30, the Citrix ADC appliance translates the source IP address of CL1-Z1's packets to 100.0.2.30 and of CL1-Z2's packets to 200.0.2.30. The optimization device to which the Citrix ADC appliance sends the translated packets is configured to use a packet's source IP address to recognize the zone, so it applies the appropriate optimization configured for the zone from which the packet originated.

### **Configuration Steps**

Configuring IP prefix NAT consists of the following steps:

- **Create a net profile and set the NAT Rule parameter of a net profile.** A NAT rule specifies two IP addresses and a net mask. The first IP address (specified by IP Address parameter) is the source IP address that is to be translated with the second one (specified by IP Rewrite parameter). The net mask specifies the part of the source IP address that is to be translated with the same part of the second IP address.

- **Bind the net profile to load balancing virtual servers or services.** A net profile with NAT rule setting can be bound to a virtual server or service of type ANY, UDP, DNS, TCP, and HTTP. After binding a net profile to a virtual server or service, the Citrix ADC appliance matches the source IP address of the incoming packets related to the virtual server or service with the NAT rule setting. The Citrix ADC then performs IP prefix NAT for packets that match the NAT rule.

To configure IP prefix NAT translation by using the command line:

At the command prompt, type:

- **bind netProfile** <name> (-natRule <ip\_addr> <netmask> <rewritelp>)
- **show netprofile** <name>

To configure IP prefix NAT by using the GUI:

1. Navigate to **System > Network > Net Profiles**.
2. Set the following parameters under NAT Rules while adding or modifying NetProfiles.
  - IP Address
  - Netmask
  - Rewrite IP

## Sample configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has IP prefix NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1 > add netprofile PARTIAL-NAT-1
2 Done
3
4 > bind netprofile PARTIAL-NAT-1 -natrule 192.0.0.0 255.0.0.0 100.0.0.0
5 Done
6
7 > add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
8 Done
9 <!--NeedCopy-->
```

## Static ARP

September 21, 2020

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip\_addr> **-mac**<mac\_addr> **-ifnum** <interface\_name>
- **show arp** <IPAddress>

**Example:**

```
1 > add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
2 Done
3 <!--NeedCopy-->
```

To remove a static ARP entry by using the CLI:

At the command prompt, type the **rm arp** command and the IP address.

To add a static ARP entry by using the GUI:

Navigate to **System > Network > ARP Table**, and add a static ARP entry.

### Specify a VLAN in a Static ARP Entry

In a static ARP entry, you can specify the VLAN through which the destination device is accessible. This feature is useful when the interface specified in the static ARP entry is part of multiple tagged VLANs and the destination is accessible through one of the VLANs. The Citrix ADC appliance includes the specified VLAN ID in the outgoing packets matching the static ARP entry. If you don't specify a VLAN ID in an ARP entry, and the specified interface is part of multiple tagged VLANs, the appliance assigns the interface's native VLAN to the ARP entry.

For example, say Citrix ADC interface 1/2 is part of native VLAN 2 and of tagged VLANs 3 and 4, and you add a static ARP entry for network device A, which is part of VLAN 3 and is accessible through interface 1/2. You must specify VLAN 3 in the ARP entry for network device A. The Citrix ADC appliance then includes tagged VLAN 3 in all the packets destined to network device A, and sends them from interface 1/2.

If you don't specify a VLAN ID, the Citrix ADC appliance assigns native VLAN 2 for the ARP entry. Packets destined to device A are dropped in the network path, because they do not specify tagged VLAN 3, which is the VLAN for device A.

To specify a VLAN in a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip\_addr> **-mac** <mac\_addr> **-ifnum** <interface\_name> [**-vlan** <positive\_integer>]
- **show arp** <IPAddress>

**Example:**

```
1 > add arp -ip 198.51.100.91 -mac 36:db:4b:f6:12:15 -ifnum 1/2 -vlan 3
2 Done
3 <!--NeedCopy-->
```

## Set the Timeout for Dynamic ARP Entries

September 21, 2020

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time. You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the CLI:

At the command prompt, type:

- **set arpparam -timeout** <positive\_integer>]
- **show arpparam**

**Example:**

```
1 > set arpparam -timeout 500
2 Done
3 <!--NeedCopy-->
```

To set the time-out for dynamic ARP entries to its default value by using the CLI:

At the command prompt, type:

- **unset arpparam**
- **show arpparam**

**Example:**

```
1 > unset arpparam
2 Done
3 <!--NeedCopy-->
```

To set the time-out for dynamic ARP entries by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure ARP Global Parameters**, and set the **ARP Table Entry Timeout** parameter.

## Neighbor Discovery

September 21, 2020

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

- **Router Discovery:** Enables a host to discover the local routers on an attached link and automatically configure a default router.
- **Prefix Discovery:** Enables the host to discover the network prefixes for local destinations.  
**Note:** The Citrix ADC appliance does not support Prefix Discovery.
- **Parameter Discovery:** Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.
- **Address Autoconfiguration:** Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The Citrix ADC does not support Address Autoconfiguration for Global IPv6 addresses.
- **Address Resolution:** Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.
- **Neighbor Unreachability Detection:** Enables a node to determine the reachability state of a neighbor.
- **Duplicate Address Detection:** Enables a node to determine whether an NSIP address is already in use by a neighboring node.
- **Redirect:** Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

**Note:** The Citrix ADC appliance does not support IPv6 Redirect.

## Configuration Steps

Configuring neighbor discovery consists of the following tasks:

- Adding IPv6 neighbors
- (Optional) Removing IPv6 neighbors

### CLI procedures

To add an IPv6 neighbor by using the CLI:

At the command prompt, type:

- **add nd6** <neighbor> <mac> <ifnum> [-vlan <integer>]
- **sh nd6**

#### Example:

```

1 > add nd6 2001::1 00:04:23:be:3c:06 1/1 -vlan 1
2 Done
3
4 > show nd6
5 Neighbor                               MAC-Address(Vlan, Interface)         State
6 -----                               -
7 1) ::1                                00:d0:68:0b:58:da( 1, LO/1)        REACHABLE
8     PERMANENT
9 2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da( 1, LO/1)        REACHABLE
10    PERMANENT
11 3) 2001::1                            00:04:23:be:3c:06( 1, 1/1)        REACHABLE
12    STATIC
13 Done
14 <!--NeedCopy-->

```

To remove a neighbor discovery entry by using the CLI:

At the command prompt, type:

- **rm nd6** <Neighbor> -vlan <VLANID>

#### Example:

```

1 rm nd6 3ffe:100:100::1 -vlan 1
2 <!--NeedCopy-->

```

To remove all neighbor discovery entries by using the CLI:

At the command prompt, type:

- **clear nd6**

## GUI procedures

To add an IPv6 neighbor by using the GUI:

Navigate to **System > Network > IPv6 Neighbors**, and add a new IPv6 neighbor.

To remove a neighbor discovery entry by using the GUI:

Navigate to **System > Network > IPv6 Neighbors**, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the GUI:

Navigate to **System > Network > IPv6 Neighbors**, and click **Clear**.

## IP Tunnels

September 21, 2020

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The Citrix ADC appliance implements IP Tunneling in the following ways:

- **Citrix ADC as an Encapsulator (Load Balancing with DSR Mode):** Consider an organization that has multiple data centers across different countries, where the Citrix ADC maybe at one location and the back-end servers are located in a different country. In essence, the Citrix ADC and the back-end servers are on different networks and are connected via a router.

When you configure Direct Server Return (DSR) on this Citrix ADC, the packet sent from the source subnet is encapsulated by the Citrix ADC and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the Citrix ADC.

- **Citrix ADC as a Decapsulator:** Consider an organization having multiple data centers each having Citrix ADCs and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another Citrix ADC. The Citrix ADC processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the Citrix ADC must be able to decapsulate the packet before sending it to the back-end servers. To enable the Citrix ADC to function as a decapsulator, a tunnel is added between the router and the Citrix ADC. When the encapsulated packet, with additional header information, reaches the Citrix ADC, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

The Citrix ADC can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the

new connections are then diverted to a back-up vserver.

## Configure IP Tunnels

Configuring IP tunnels on a Citrix ADC appliance consists of creating IP tunnel entities. An IP tunnel entity specifies the local and remote tunnel end-point IP addresses and the protocol to be used for the IP tunnel.

**Note:** While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP address.

### CLI procedures

To create an IP tunnel by using the CLI:

At the command prompt type:

- **add iptunnel** <name> <remote> <remoteSubnetMask> <local> -**type -protocol** (ipoverip | GRE)
- **show iptunnel**

To remove an IP tunnel by using the CLI:

To remove an IP tunnel, type the **rm iptunnel** command and the name of the tunnel.

To create an IPv6 tunnel by using the CLI:

At the command prompt type:

- **add ip6tunnel** <name> <remotelp> <local>
- **show ip6tunnel**

To remove an IPv6 tunnel by using the CLI:

To remove an IPv6 tunnel, type the **rm ip6tunnel** command and the name of the tunnel.

### GUI procedures

To create an IP Tunnel by using the GUI:

Navigate to **System > Network > IP Tunnels**, add a new IP tunnel.

To create an IPv6 Tunnel by using the GUI:

Navigate to **System > Network > IP Tunnels > IPv6 Tunnels**, and add a new IPv6 tunnel.

## Customizing IP Tunnels Globally

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the Citrix ADC appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

### CLI procedures

To globally customize IP tunnels by using the CLI:

At the command prompt, type:

- **set iptunnelparam -srcIP** <sourceIPAddress> **-srcIPRoundRobin** ( YES | NO ) **-dropFrag** [YES | NO] **-dropFragCpuThreshold** <Positive integer>
- **show iptunnelparam**

### Example:

```
1 > set iptunnelparam -srcIP 12.12.12.22 -dropFrag Yes -
    dropFragCpuThreshold 50
2 Done
3
4 > set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes -
    dropFragCpuThreshold 50
5 Done
6 <!--NeedCopy-->
```

To globally customize IPv6 tunnels by using the CLI:

At the command prompt, type:

- **set ip6tunnelparam -srcIP** <IPv6Address> **-srcIPRoundRobin** ( YES | NO ) **-dropFrag** [YES | NO] **-dropFragCpuThreshold** <Positive integer>
- **show ip6tunnelparam**

### GUI procedures

To globally customize IP tunnels by using the GUI:

Navigate to **System > Network**, in the Settings group, click **IPv4 Tunnel Global Settings**.

1. Navigate to **System > Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

To globally customize IPv6 tunnels by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

## GRE Payload Options in a GRE IP Tunnel

For a configured GRE IP tunnel, the Citrix ADC appliance encapsulates the entire Layer 2 packet, including the Ethernet header and the VLAN header (dot1q VLAN tag). IP GRE tunnels between Citrix ADC appliances and some 3rd party devices might not be stable, because these 3rd party devices are not programmed to process some or the Layer 2 packet headers. To configure a stable IP GRE tunnel between a Citrix ADC appliance and a 3rd party device, you can use the GRE payload parameter of the GRE IP tunnel command set. GRE payload setting can also be applied to a GRE with IPsec tunnel.

You can set the GRE payload parameter to do one of the following before the packet is sent through the GRE tunnel:

- **Ethernet with DOT1Q.** Carry the Ethernet header as well the VLAN header. This is the default setting. For a tunnel bound to a netbridge, inner Ethernet header and VLAN header contains information from the ARP and bridge table of the Citrix ADC appliance. For a tunnel set as a next hop to a PBR rule, Inner Ethernet destination MAC address is set to zero and the VLAN header specifies the default VLAN. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

| Outer Ethernet Header | Outer IP Header | GRE Header | Inner Ethernet | Inner VLAN header | Inner IP/IPv6/ARP header | Inner TCP/UDP Header | Payload |
|-----------------------|-----------------|------------|----------------|-------------------|--------------------------|----------------------|---------|
|                       |                 |            |                |                   |                          |                      |         |

- **Ethernet.** Carry the Ethernet header but drop the VLAN header. Because the packets do not carry any VLAN information in the tunnel, for a tunnel with this setting and bound to a netbridge, you must bind an appropriate VLAN to the netbridge so that on receiving any packets on the tunnel, the Citrix ADC can forward these packet to the specified VLAN. If the tunnel is set as a next hop in a PBR rule, the Citrix ADC routes the packets that are received on the tunnel. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

| Outer Ethernet header | Outer IP header | GRE Header | Inner Ethernet header | Inner IP/IPv6/ARP header | Inner TCP/UDP header | Payload |
|-----------------------|-----------------|------------|-----------------------|--------------------------|----------------------|---------|
|                       |                 |            |                       |                          |                      |         |

- **IP.** Drop the Ethernet header as well as the VLAN header. Because tunnels with this setting do not carry Layer 2 headers, these tunnels cannot be bound to a netbridge but can be set as a next hop in a PBR rule. The peer tunnel endpoint device on receiving the packet either consumes or routes it. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

|                              |                        |                   |                             |                             |                |
|------------------------------|------------------------|-------------------|-----------------------------|-----------------------------|----------------|
| <b>Outer Ethernet header</b> | <b>Outer IP header</b> | <b>GRE header</b> | <b>Inner IP/IPv6 header</b> | <b>Inner TCP/UDP header</b> | <b>Payload</b> |
|------------------------------|------------------------|-------------------|-----------------------------|-----------------------------|----------------|

To drop Layer 2 headers of packets in a GRE IP tunnel by using the CLI:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> [-**protocol** <GRE> [-**vlan** <positive\_integer>]] [-**grepayload** <grepayload>] [-**ipsecProfileName** <string>]
- **show ipTunnel** <tunnelname>

#### Example:

```

1 > add iptunnel IPTUNNEL-1 203.0.113.133 255.255.255.0 198.51.100.15 -
   protocol GRE - grepayload Ethernet -ipsecProfileName IPTUNNEL-IPSEC
   -1
2 Done
3 <!--NeedCopy-->

```

## IPv6 Traffic through GRE IPv4 Tunnels

The Citrix ADC appliance supports transferring IPv6 traffic through an IPv4 GRE tunnel. This feature can be used for enabling communication between Isolated IPv6 networks without upgrading the IPv4 infrastructure between them.

For configuring this feature, you associate a PBR6 rule with the configured IPv4 GRE tunnel through which you want the Citrix ADC to send and receive IPv6 traffic. The source IPv6 address and destination IPv6 address parameters of the PBR6 rule specify the IPv6 networks whose traffic is to traverse the IPv4 GRE tunnel.

**Note:** IPsec protocol is not supported on GRE IPv4 tunnels that are configured to transfer IPv6 packets.

To create a GRE IPv4 tunnel by using the CLI:

At the command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -**protocol GRE**
- **show ipTunnel** <name>

To associate a PBR6 rule with a GRE IPv4 tunnel by using the CLI:

- **add ns pbr6** <pbrName> **ALLOW** -**srcIPv6** <network-range> -**dstIPv6** <network-range> -**ipTunnel** <tunnelName>
- **show pbr**

### Sample configuration

In the following sample configuration, GRE IP tunnel TUNNEL-V6onV4 is created with remote tunnel endpoint IP address 10.10.6.30 and local tunnel endpoint IP address 10.10.5.30. The tunnel is then bound to pbr6 PBR6-V6onV4. The srcIPv6 specifies the IPv6 network connected to the local endpoint and destIPv6 specifies the IPv6 network connected to the remote endpoint. The traffic from these Ipv6 networks are allowed to traverse through the GRE IPv4 tunnel.

```
1 > add ipTunnel TUNNEL-V6onV4 10.10.6.30 255.255.255.255 10.10.5.30 -  
    protocol GRE  
2 -ipsecProfileName None  
3 Done  
4 > add ns pbr6 PBR6-V6onV4 ALLOW -srcIPv6 = 2001:0db8:1::1-2001:0db8  
    :1::255 -destIPv6 =  
5 1-2001:0db8:4::255 -ipTunnel TUNNEL-V6onV4  
6 <!--NeedCopy-->
```

### Send Response Traffic Through an IP-IP Tunnel

You can configure a Citrix ADC appliance to send response traffic through an IP-IP tunnel instead of routing it back to the source. By default, when the appliance receives a request from another Citrix ADC or a third-party device through an IP-IP tunnel, it routes the response traffic instead of sending it through the tunnel. You can use policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) to send the response through the tunnel.

In a PBR rule, specify the subnets at both end points whose traffic is to traverse the tunnel. Also set the next hop as the tunnel name. When response traffic matches the PBR rule, the Citrix ADC appliance sends the traffic through the tunnel.

Alternatively, you can enable MBF to meet this requirement, but the functionality is limited to traffic for which the Citrix ADC appliance stores session information (for example, traffic related to load balancing or RNAT configurations). The appliance uses the session information to send the response traffic through the tunnel.

### CLI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the CLI:

At the command prompt, type:

- **add ns pbr** <pbr\_name> **ALLOW** -**srcIP** = <local\_subnet\_range> -**destIP** = <remote\_subnet\_range> -**ipTunnel** <tunnel\_name>
- **apply ns pbrs**
- **show ns pbr** <pbr\_name>

To enable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **show ns mode**

### GUI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the GUI:

1. Navigate to **System > Network > PBRs**. On the **PBRs** tab, create a **PBR** rule.
2. While creating the PBR, set the **Next Hop Type** to **IP tunnel** and **IP Tunnel Name** to the configured IP-IP tunnel name.

To enable MAC-based forwarding by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features**, click **Configure Modes**.
2. On the **Configure Modes** page, select **MAC-based forwarding**.

### Sample configuration

Consider an example of an IPIP tunnel, NS1-NS2-IPIP, which is set up between two Citrix ADC appliances NS1 and NS2.

By default, for any request that NS2 receives through the tunnel, it routes the response traffic to the source instead of sending it (to NS1) through the tunnel.

You can configure policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) on NS2 for enabling it to send the response through the tunnel.

In the following sample configuration on NS2, NS1-NS2-IPIP is an IPIP tunnel and NS1-NS2-IPIP-PBR is a PBR rule. For requests (with inner source IP address in the range 10.102.147.0-10.102.147.255 and inner destination IP address in the range 10.102.147.0-10.102.147.255) received by NS2 through the tunnel, NS2 sends the corresponding response through the tunnel (to NS1) instead of routing it to the source. The functionality is limited to the traffic that matches the PBR rule.

```
1 > add iptunnel NS1-NS2-IPIP 192.0.2.99 255.255.255.255 203.0.113.99 -
    protocol IPIP
2
3 Done
4 > add pbr NS1-NS2-IPIP-PBR -srcIP 10.102.147.0-10.102.147.255 -destIP
    10.20.1.0-10.20.1.255 - ipTunnel NS1-NS2-IPIP
5
6 Done
7 > apply pbrs
```

```
8  
9 Done
```

Alternatively, MBF can be enabled on NS2. The functionality is limited to traffic for which NS2 stores session information (for example, traffic related to load balancing or RNAT configurations).

```
1 > enable ns mode MBF  
2  
3 Done
```

## Class E IPv4 packets

September 21, 2020

By default, the Citrix ADC appliance drops any packets if they contain any class E IPv4 address in the source IP or the destination IP fields. If your setup is using class E IPv4 addresses, you can configure the Citrix ADC appliance to process class E IPv4 packets.

### Before you begin

Before you begin configuring a Citrix ADC appliance to process class E IPv4 packets, note the following points:

- Citrix ADC appliances do not support configuring any Citrix ADC owned IPv4 address (for example, SNIP and VIP) in the class E range. Citrix ADC appliances only support processing of class E IPv4 packets.
- A Citrix ADC appliance internally uses class E IPv4 addresses for the IPv6 feature. The Citrix ADC appliance does not support both features (processing class E IPv4 packets and IPv6 support) working at the same time. The Citrix ADC appliance imposes a restriction to not enable the IPv6 feature when processing of class E IPv4 packets is enabled, and vice versa.

### Configuration steps

Configuring a Citrix ADC appliance to process class E IPv4 packets consist of the task of enabling the **IPv4 Class E address clients (allowClassEIPv4)** Layer 3 parameter.

### CLI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the CLI:

At the command prompt, type:

---

---

|                                                             |
|-------------------------------------------------------------|
| <b>set l3param -allowClassEIPv4 (ENABLED      DISABLED)</b> |
|-------------------------------------------------------------|

---

---

- 

- **show l3param**

**Sample Configuration:**

```
1 > set l3param -allowClassEIPv4 ENABLED
2
3 Done
4
5 > sh l3param
6
7     Network L3 related Configuration Parameters
8
9     icmpgen_rate_threshold      : 100
10
11     srcnat                      : ENABLED
12
13     override_rnat              : DISABLED
14
15     drop_df_flag               : DISABLED
16
17     .
18
19     .
20
21     .
22
23     IPv6DynamicRouting         : DISABLED
24
25     allowClassEIPv4            : ENABLED
26
27 Done
28 <!--NeedCopy-->
```

**GUI procedures**

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the GUI:

1. Navigate to **System > Network**, and then in the **Settings** section, click **Configure Layer 3 Parameters**.
2. Select **IPv4 Class E address clients** and click **OK**.

## Interfaces

September 21, 2020

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix ADC appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC (VMAC) address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. Citrix ADC appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. You can use the Network Visualizer tool to view the network configuration of a Citrix ADC deployment and configure interfaces, channels, VLANs, and bridge groups.

## Configuring MAC-Based Forwarding

September 21, 2020

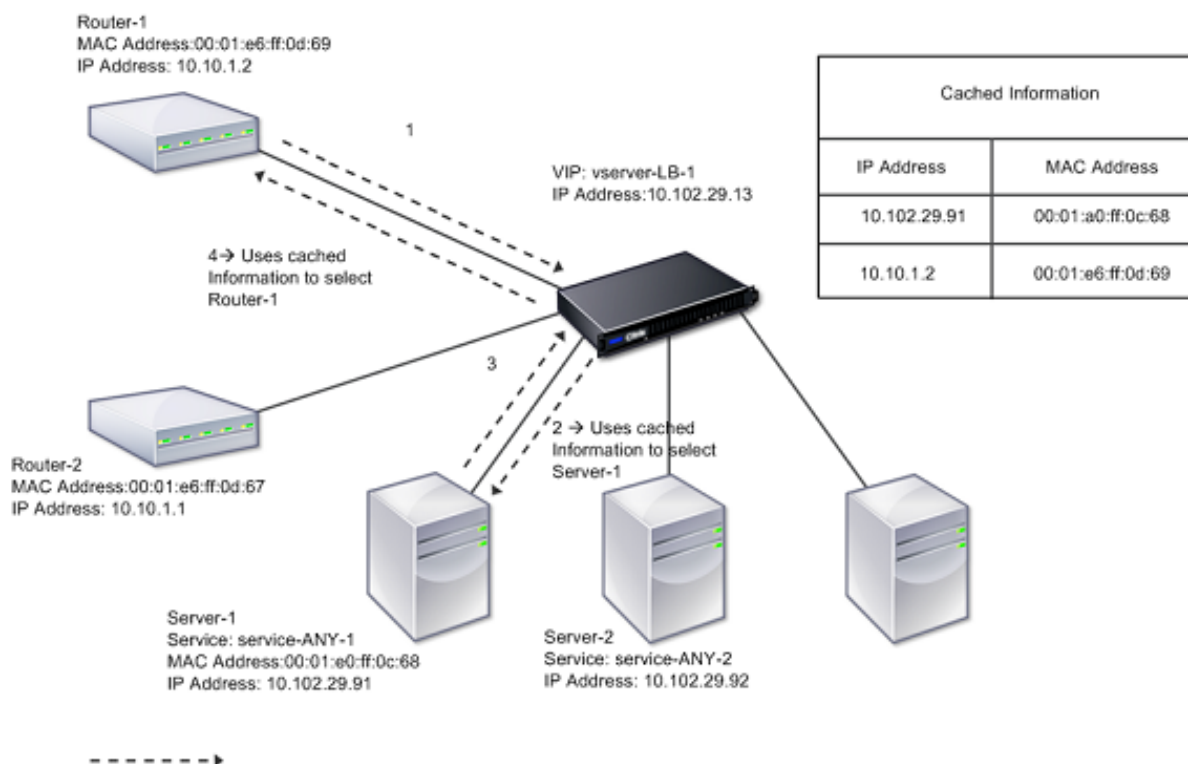

With MAC-based forwarding (MBF) enabled, when a request reaches the Citrix ADC appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the Citrix ADC is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode

When MAC-based forwarding (MBF) is enabled, the Citrix ADC caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the Citrix ADC appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the Citrix ADC initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see [Load Balancing](#).

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When you configure link load balancing.** In this case, asymmetric traffic flows are desirable because of link costs.
- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the Citrix ADC and server.

Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.

- **When firewall clustering is used.** Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the appliance uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the appliance uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the Citrix ADC looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the Citrix ADC requests the ARP entries.

To enable or disable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **disable ns mode MBF**

To enable or disable MAC-based forwarding by using the GUI:

1. Navigate to **System > Settings**, in the **Modes and Features** group, click **Configure modes**.
2. Select or clear the **MAC-based forwarding** option.

## MAC based forwarding for a load balancing setup

Some load balancing setups require that the Citrix ADC appliance bypasses the global MBF (if enabled) for these setups and instead use the route/ARP lookups for sending packets to the destination.

The MBF parameter of a net profile is used to enable or disable MBF for a specific load balancing configuration. MBF can be set for the client side as well as the server side of a load balancing configuration by binding net profiles (MBF enabled or disabled) to the virtual server and the services.

For example, if a net profile with MBF disabled is bound to the virtual server of a load balancing configuration, the Citrix ADC appliance bypasses the global MBF (if enabled) and instead use the route/ARP lookups for sending response packets to clients.

## Before you begin

Before you begin configuring MBF for a load balancing configuration, note the following points:

- In a load balancing configuration, the client side (virtual server) and the server side (service/service groups) can have different MBF settings.

- A load balancing configuration inherits global MBF setting if MBF is not set explicitly in the net profiles bound to the virtual server and the services.
- In a load balancing configuration, server side (service) inherits client side MBF setting of net profile bound to the virtual server if no net profile is bound to the service.
- In a load balancing configuration with direct server return mode, client side inherits the MBF setting in the net profile bound to the service.
- In a content switching configuration, client side takes the MBF setting in the net profile bound to the content switching virtual server instead of from the target load balancing virtual server.

## Limitations

Before you begin configuring MBF for a load balancing configuration, note the following limitations:

- MBF setting for load balancing configurations is not supported in a cluster setup.
- For a load balancing virtual server with MAC mode or L2Conn settings, MBF is enabled irrespective of the MBF setting in the bound net profile to the virtual server.
- The Citrix ADC appliance does not support setting MBF for load balancing monitors using net profile. In other words, the MBF setting of a net profile is not applied to the monitors to which the net profile is bound. The global MBF setting is applied to monitors irrespective of the MBF setting of the bound net profile.

## Configure MBF for load balancing configuration

Configuring MBF for a load balancing configuration consists of the following tasks:

- Enable MBF parameter in a net profile.
- Bind the net profile to a load balancing virtual server or services.

To enable MBF in a net profile by using the CLI:

- To enable MBF while adding a net profile, at the command prompt, type:
  - **add netProfile** <name> -**MBF ( ENABLED | DISABLED )**
  - **show netprofile** <name>
- To enable MBF in an existing net profile, at the command prompt, type:
  - **set netProfile** <name> -**MBF ( ENABLED | DISABLED )**
  - **show netprofile** <name>

To enable MBF in a net profile by using GUI\*\*

1. Navigate to **System > Network > Net Profiles**.
2. Enable the **MBF** parameter while adding or modifying a net profile.

```
1 In the following sample configuration, net profile NETPROFILE-MBF-LBVS
  has MBF enabled and is bound to load balancing virtual server LBVS
  -1. Also, net profile NETPROFILE-MBF-SVC has MBF enabled and is
  bound to a load balancing service SVC-1.
2
3 > add netprofile NETPROFILE-MBF-LBVS -MBF ENABLED
4
5 Done
6
7 > add netprofile NETPROFILE-MBF-SVC -MBF ENABLED
8
9 Done
10
11 > set lb vserver LBVS-1 -netprofile NETPROFILE-MBF-LBVS
12
13 Done
14
15 > set service SVC-1 -netprofile NETPROFILE-MBF-SVC
16
17 Done
18
19 <!--NeedCopy-->
```

## Configuring Network Interfaces

September 21, 2020

Network interfaces in the Citrix ADC appliance are numbered in `<slot>/<port>` notation. After configuring your interfaces, display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you might have to enable some interfaces and disable others. You can reset an interface to renegotiate its settings. You can clear the accumulated statistics for an interface. To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

### Set the network interface parameters

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

To set the network interface parameters by using the CLI:

At the command prompt, type:

```

1 - set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl
   <flowControl>] [-autoneg ( DISABLED | ENABLED )] [-haMonitor ( ON |
   OFF )] [ ( ON | OFF )] [-tagall ( ON | OFF )] [-lacpMode <lacpMode
   >] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>]
   [-lacpTimeout (LONG | SHORT )] [-ifAlias <string>] [-throughput <
   positive_integer>][-bandwidthHigh <positive_integer> [-
   bandwidthNormal <positive_integer>]]
2 - show interface [<id>]
3 <!--NeedCopy-->

```

### Example:

```

1 > set interface 1/8 -duplex full
2 Done
3 <!--NeedCopy-->

```

To set the network interface parameters by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface that you want to modify (for example, 1/8), click **Edit**, and then set the parameters.

### Set the receive ring size and ring type for an interface

You can increase the receive ring size and ring type for IX, F1X, F2X, or F4X interfaces on Citrix ADC MPX and SDX platforms.

An increased ring size provides more cushion to handle burst traffic, but might impact the performance. A ring size of up to 8192 is supported for IX interfaces. A ring size of up to 4096 is supported for F1X, F2X, and F4X interfaces. The default ring size remains 2048.

Interface ring types are elastic by default. They increase or decrease in size based on packet arrival rate. You can configure the ring type as “fixed” in which case the ring size does not change based on traffic rate.

**Note:** This feature is supported from release 13.0 build 41.x, and supported on platforms that have IX, F1X, F2X, or F4X interfaces.

Use the `show hardware` command to identify whether your appliance has IX, F1X, F2X, or F4X interfaces.

### Examples:

The following model has 16 F1X (10G) interfaces and 4 F4X (40G) interfaces.

```

1 > sh hardware

```

```

2      Platform: NSMPX-25000-40G 20*CPU+16*F1X+4*F4X+2*E1K+2*CVM N3
      250040
3      Manufactured on: 12/16/2016
4      CPU: 2800MHZ
5      Host Id: 234913926
6      Serial no: N43RJCRV3X
7      Encoded serial no: N43RJCRV3X
8      Netscaler UUID: 336a32d6-2cfa-11e8-bf01-00e0ed5dd23c
9      BMC Revision: 4.08
10     Done
11     <!--NeedCopy-->

```

The following model has 2 1X (10G) interfaces.

```

1 > sh hardware
2      Platform: NSMPX-10500 8*CPU+2*E1K+8*E1K+2*IX+8*CVM 1620 760100
3      Manufactured on: 12/27/2010
4      CPU: 2832MHZ
5      Host Id: 1707114630
6      Serial no: 7VZZV1ZXJ4
7      Encoded serial no: 7VZZV1ZXJ4
8      Netscaler UUID: eb1bfd72-5176-11e7-ba18-00e0ed1b0d12
9      Done
10     <!--NeedCopy-->

```

To configure ring size and ring type by using the CLI

At the command line, type:

```

1 set interface <id> -ringsize <positive_integer> -ringtype ( Elastic |
      Fixed )
2 <!--NeedCopy-->

```

#### Parameters:

##### ringsize:

The receive ring size of the interface. A higher number provides more buffers to handle incoming traffic.

Default value: 2048

Minimum value: 512

Maximum value: 16384

##### ringtype:

The receive ring type of the interface. A fixed ring type preallocates the configured number of buffers

irrespective of traffic rate. In contrast, an elastic ring, expands and shrinks based on incoming traffic rate.

Possible values: Elastic, Fixed

Default value: Elastic

**Example:**

```
1 > set interface 40/2 -ringsize 4096 -ringtype Fixed
2 Done
3 > show interface 40/2
4
5 1)      Interface 40/2 (40G Ethernet, CR4, 40 Gbit) #21 flags=0xc020 <
        ENABLED, UP, UP, autoneg, HAMON, HEARTBEAT, 802.1q> MTU=1500, native
        vlan=10, MAC=00:e0:ed:75:14:2a, uptime 119h26m32s
6         Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,
           throughput 0
7         Actual: media UTP, speed 40000, duplex FULL, fctl OFF,
           throughput 40000
8         LLDP Mode: NONE, LR Priority: 1024
9         RX: Pkts(1443972660032) Bytes(1457207315336105) Errs(0) Drops
           (53319) Stalls(0)
10        TX: Pkts(1452311431262) Bytes(1458534011197761) Errs(0) Drops
           (788) Stalls(0)
11        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
12        Bandwidth thresholds are not set.
13        Rx Ring: Configured size=4096, Actual size=4096, Type: Fixed
14 Done
15 <!--NeedCopy-->
```

The last line shows the configured and actual ring size, and the ring type.

To configure ring size and ring type by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select your interface and click **Edit**.
3. In **Ring Size**, specify one of the following:
  - **IX interfaces:** 512, 1024, 2048, 4096, or 8192.
  - **F1X, F2X, or F4X interfaces:** 512, 1024, 2048, or 4096.
4. In **Ring Type**, select Elastic or Fixed.
5. Click **OK**.

## Enabling and Disabling Network Interfaces

By default, the network interfaces are enabled. You must disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause a failover.

For more information about high availability, see [High Availability](#).

To enable or disable a network interface by using the CLI:

At the command prompt, type:

- enable interface
- show interface
- disable interface
- show interface

### Example:

```
1 > enable interface 1/8
2 Done
3 > show interface 1/8
4     Interface 1/8 (Gig Ethernet 10/100/1000 Mbits) #2
5     flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg,
6         802.1q>
7     MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
8     Requested: media UTP, speed AUTO, duplex FULL, fctl OFF,
9         throughput 0
10    RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
11    TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
12    NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
13    Bandwidth thresholds are not set.
14 Done
15 <!--NeedCopy-->
```

To enable or disable a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the Action list, select Enable or Disable.

## Resetting Network Interfaces

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the CLI:

At the command prompt, type:

- reset interface
- show interface

**Example:**

```
1 > reset interface 1/8
2 Done
3 <!--NeedCopy-->
```

To reset a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the Action list, select Reset Interface.

**Monitoring a Network Interface**

You can display network interface statistics to monitor parameters such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors, and use the information to check the health of the network interface. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the CLI:

At the command prompt, type:

- **stat interface**

**Example:**

```
1 > stat interface 1/8
2 Done
3 <!--NeedCopy-->
```

To clear a network interface's statistics by using the CLI:

At the command prompt, type:

- **clear interface**

**Example:**

```
1 > clear interface 1/8
2 Done
3 <!--NeedCopy-->
```

To display the statistics of an Interface by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface, and click **Interface Statistics**.

To clear a network interface's statistics by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the Action list, select Clear Statistics.

## Configuring Forwarding Session Rules

September 21, 2020

By default, the Citrix ADC appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the Citrix ADC. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address.** When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule.** When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix.** When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule.** When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the CLI:

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- `add forwardingSession <name> [<network> <netmask> ] | [-aclname <string>] -connfailover (ENABLED | DISABLED)`
- `show forwardingSession`

### Example:

```
1 A network address as the condition:
2
3 > add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
4 Done
5
6 An ACL as the condition:
7
8 > add forwardingSession fs-acl-1 acl1
9 Done
10 <!--NeedCopy-->
```

To configure an IPv4 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the CLI:

- At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:
  - add forwardingSession <name> [<IPv6 prefix>] | [-acl6name <string>]
  - show forwardingSession

**Example:**

```
1 An IPv6 prefix as the condition:
2
3 > add forwardingSession fsv6-pfx-1 3ffe::/64
4 Done
5
6 An ACL6 rule as the condition:
7
8 > add forwardingSession fsv6-acl6-1 - acl6name ACL6-FS
9 Done
10 <!--NeedCopy-->
```

To configure an IPv6 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

### Assigning an ACL rule to an Existing Forwarding Session Rule

You can assign an ACL rule to a Network-address/IPv6-prefix based forwarding session rule, in which case it becomes an ACL based forwarding session rule. You can also change an existing ACL rule to

another ACL rule in an ACL based forwarding session rule. After the existing related forwarding session entries (if any) have timed out, the rules start using the newly assigned ACL to identify IPv4/IPv6 traffic for which to create a forwarding-session entry.

To assign an extended ACL rule to an existing IPv4 forwarding session rule by using the CLI:

At the command prompt, type

- **set forwardingSession** <name> [-aclname <string>]
- **show forwardingSession** <name>

To assign an ACL6 rule to an existing IPv6 forwarding session rule by using the CLI:

At the command prompt, type

- **set forwardingSession** <name> [-acl6name <string>]
- **show forwardingSession** <name>

**Example:**

```
1 > add forwardingSession FS-1 -aclname ACL-9
2 Done
3
4 > add forwardingSession FS6-1 -acl6name ACL6-9
5 Done
```

## Disabling Steering for Forwarding Sessions on a Cluster Setup

The default behavior of a Citrix ADC cluster is for the node that receives traffic (flow receiver) to direct the traffic to another node (flow processor), which processes the traffic. Directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

Steering can be an overhead for real-time processing or when the setup includes high-latency links.

Steering for forwarding sessions can now be disabled so that the processing becomes local to the flow receiver. That is, the flow receiver becomes the flow processor.

### Before you begin

Note the following points before configuring forwarding session rules in a cluster setup:

- You must configure linksets to be used for forwarding sessions.
- You must enable MAC Based Forwarding (MBF) on the cluster setup.

## Configuring Forwarding Session Rules in a Cluster Setup

Disabling steering for forwarding session rules in a cluster setup can be done at the following two levels:

- **Specific forwarding session rule level.** Enable the Process Local parameter while adding a new forwarding session rule or editing an existing forwarding session rule.
- **Global level.** Enable the Process Local parameter while adding a new cluster instance or editing an existing cluster instance. The global setting takes precedence over the forwarding session rule setting.

### CLI procedures

To disable steering for a forwarding session rule on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new forwarding session rule:
  - **add forwardingSession** <name> ((<network> [<netmask>]) | **-acl6name** <string> | **-aclname** <string>) **-processLocal ENABLED**
  - **show forwardingSession** <name>
- If reconfiguring an existing forwarding session rule:
  - **set forwardingSession** <name> **-processLocal ENABLED**
  - **show forwardingSession** <name>

To disable steering for all (global level) forwarding session rules on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new cluster instance:
  - **add cluster instance** <clid> **-processLocal Enabled**
  - **show cluster instance** <clid>
- If reconfiguring an existing cluster instance:
  - **set cluster instance** <clid> **-processLocal Enabled**
  - **show cluster instance** <clid>

### Sample configuration:

Following are two examples of disabling steering at the forwarding session rule level, and an example of disabling steering at the global level.

```
1 An IPv4 forwarding session rule:  
2
```

```
3 > add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV4-1 10.102.105.51
   255.255.255.255 -processLocal Enabled
4 Done
5
6 An IPv6 forwarding session rule:
7
8 > add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV6-1 - acl6name ACL6-
   FWD-SESSN-1 -processLocal Enabled
9 Done
10
11 A cluster setup, with an instance ID 10, has steering disabled at
   global level:
12
13 > set cluster instance 10 -processLocal Enabled
14 Done
15 <!--NeedCopy-->
```

### GUI procedures

To disable steering for a forwarding session rule on a cluster setup by using the GUI:

Navigate to **System > Network > Forwarding Sessions**, select **Process Local** while adding a new forwarding session rule or editing an existing forwarding session rule.

To disable steering for all (global level) forwarding session rules on a cluster setup by using the GUI:

Navigate to **System > Cluster**, and select **Process Local** while adding a cluster configuration or modifying an existing cluster configuration.

## Understanding VLANs

September 21, 2020

A Citrix ADC appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The Citrix ADC then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The Citrix ADC supports the following types of VLANs:

- **Port-Based VLANs.** The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple

port-based VLANs. By default, all network interfaces on the Citrix ADC are members of VLAN 1.

If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

- **Default VLAN.** By default, the network interfaces on the Citrix ADC are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

When you add a network interface to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

- **Tagged VLANs.** 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the Citrix ADC) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the Citrix ADC connects must be on the same VLAN as the Citrix ADC network interface.

**Note:** This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

## Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

- **Ingress rules.** Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:
  - If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)

- If frame has a tag value equal to FFF, the frame is dropped.
- If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.
- **Egress Rules.** The following egress rules are applied:
  - If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
  - During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the Citrix ADC.
  - A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

## **VLANs and Packet Forwarding on the Citrix ADC**

The forwarding process on the Citrix ADC appliance is similar to that on any standard switch. However, the Citrix ADC performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the Citrix ADC. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the Citrix ADC are processed at the upper layers.
- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs

are common to IPv4 and IPv6. For IPv6, the Citrix ADC supports prefix-based VLANs.

## Configuring a VLAN

September 21, 2020

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the Citrix ADC. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the Citrix ADC to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other Citrix ADC appliances. The Citrix ADC forwards packets between configured IP subnets (VLANs).

When you configure the Citrix ADC, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the Citrix ADC appliance.

### Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the Citrix ADC appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the Citrix ADC appliances. The result is identical actions on all the appliances. For example,

adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other Citrix ADC appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

## Creating or Modifying a VLAN

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

### CLI procedures

To create a VLAN by using the CLI:

At the command prompt, type:

- `add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED|DISABLED)]`
- `sh vlan <id>`

#### Example:

```
1 > add vlan 2 -aliasName "Network A" Done
2 <!--NeedCopy-->
```

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -ifnum <slot/port>`
- `sh vlan <id>`

#### Example:

```
1 > bind vlan 2 -ifnum 1/8 Done
2 <!--NeedCopy-->
```

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -IPAddress <IPAddress> <netMask>`
- `sh vlan <id>`

#### Example:

```
1 > bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0 Done
2 <!--NeedCopy-->
```

To remove a VLAN by using the CLI:

At the command prompt, type:

- `rm vlan <id>`

### GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

### Monitoring VLANs

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the CLI:

At the command prompt, type:

- `stat vlan <vlanID>`

### Example:

```
1 stat vlan 2
2 <!--NeedCopy-->
```

To view the statistics of a VLAN by using the GUI:

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.

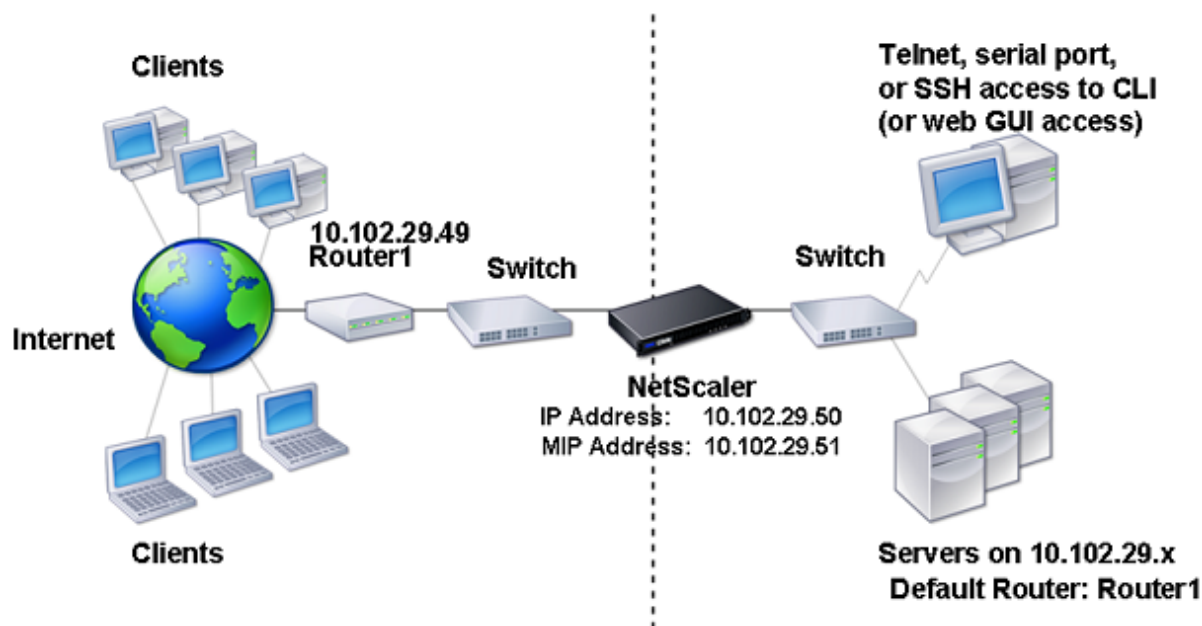

## Configuring VLANs on a Single Subnet

September 21, 2020

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet

In the above figure:

1. The default router for the Citrix ADC and the servers is Router 1.
2. Layer 2 mode must be enabled on the Citrix ADC for the Citrix ADC to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the Citrix ADC appliance.

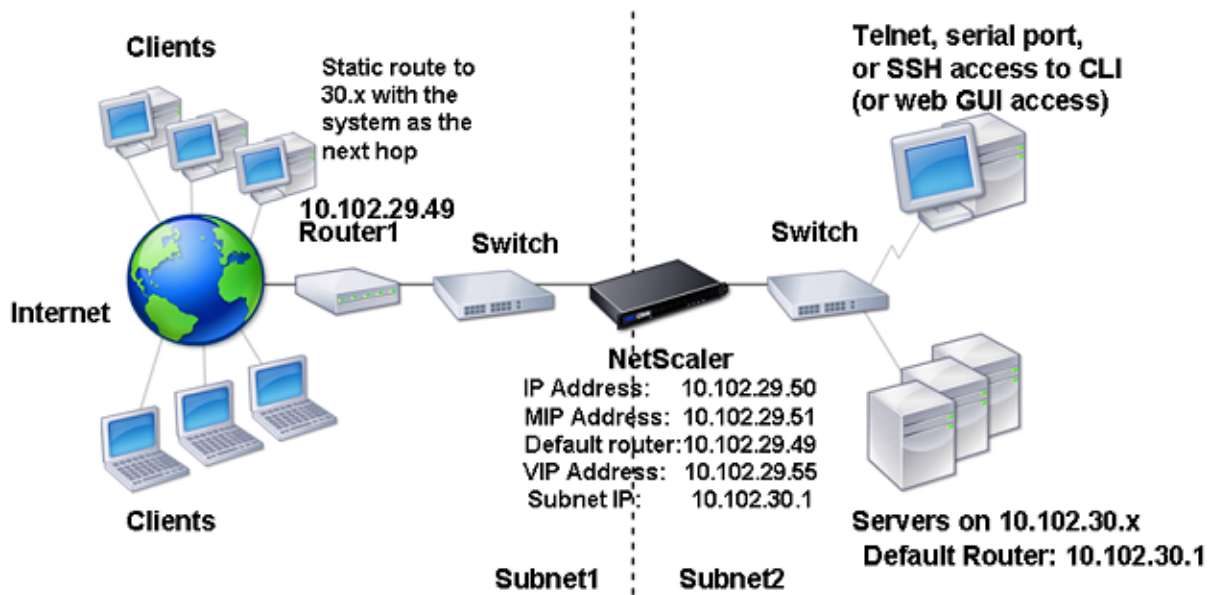

To configure a VLAN on a single subnet, follow the procedures described in [Configuring a VLAN](#).

## Configuring VLANs on Multiple Subnets

September 21, 2020

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN

To configure a single VLAN across multiple subnets, perform the following tasks:

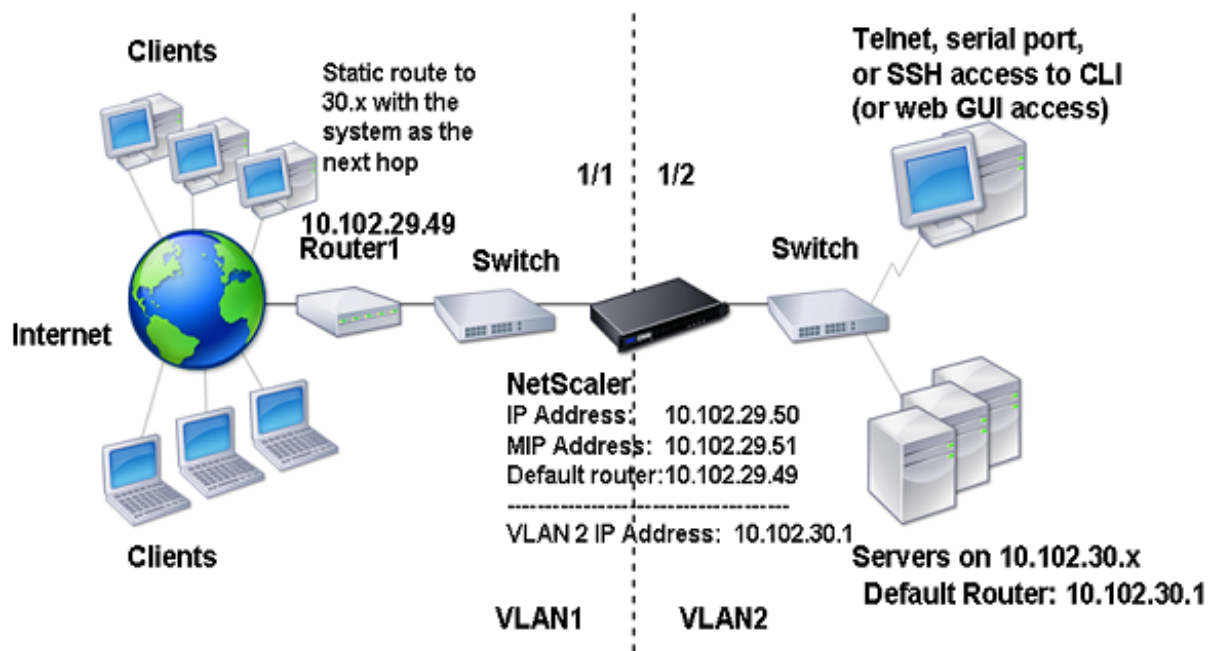

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see [Packet forwarding modes](#).
2. Add a VIP address. For the procedure to add a VIP address, see [Configuring and Managing Virtual IP Addresses \(VIPs\)](#).
3. Configure RNAT rule. For the procedure to configure the RNAT ID, see [Configuring RNAT](#).

## Configuring Multiple Untagged VLANs across Multiple Subnets

September 21, 2020

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

Figure 1. Multiple Subnets with VLANs - No Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and subnet mask to VLAN 2.

For procedures on these tasks, see [Configuring a VLAN](#).

## Configuring Multiple VLANs with 802.1q Tagging

September 21, 2020

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

Figure 1. Multiple VLANs with IEEE 802.1q Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and netmask to VLAN 2.
4. Add VLAN 3.
5. Bind the 1/2 network interface of the Citrix ADC to VLAN 3 as a tagged network interface.
6. Bind the IP address and netmask to VLAN 3.

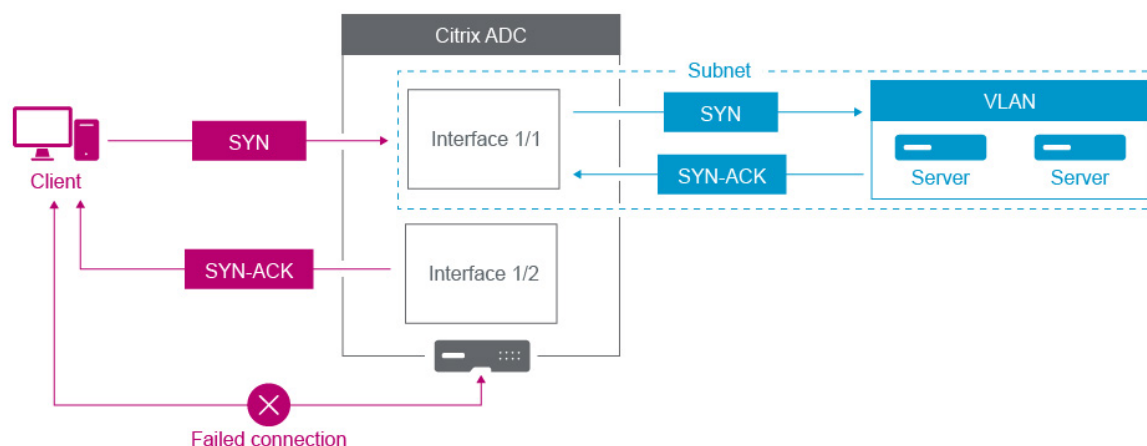

For procedures on these tasks, see [Configuring a VLAN](#).

## Associate an IP Subnet with a Citrix ADC Interface by Using VLANs

April 13, 2021

By default, a Citrix ADC appliance does not provide any differentiation between network interfaces. The appliance functions more like a network hub than a switch. This can lead to Layer 3 network loops where duplicated traffic is transmitted on multiple interfaces.

In such scenarios, depending on network design, it is possible that a request might be transmitted on one interface and the corresponding response is received on a different interface.

For example, a SYN packet sent on one interface and the SYN-ACK response received on a different interface can result in a failed connection, as the appliance expects to receive the SYN-ACK on the same interface that sent the original SYN packet.

To resolve such issues, the appliance can use internal or external VLANs, to associate specific subnets with interfaces.

### Before you begin

Before you begin associating an IP Subnet with a Citrix ADC interface by using VLANs, note the following points:

- The network connectivity might be accidentally lost when associating a VLAN to the subnet or interface that is currently being used to access the Citrix ADC GUI or command line interface. Therefore, in such scenarios, it is highly recommended that the change is made by accessing the command line interface through the serial console of a physical Citrix ADC appliance or through the virtual serial console of a Citrix ADC VPX.
- Citrix ADC management interfaces lack certain hardware optimization features which make them less desirable for use with production data traffic. As such, it is recommended that the Citrix ADC be configured to only use the management interfaces for management (NSIP) traffic. In the default configuration, there is no logical differentiation between the management interfaces and data interfaces on a hardware NetScaler. To accomplish this goal, it is recommended that the NSIP be on a separate VLAN from data traffic, which allows management traffic to be on a separate interface.

Although the concept is the same, to change the VLAN associations of the subnet that contains the NSIP address, you must configure NSVLAN instead of the below instructions. Such changes will also require a reboot of the Citrix ADC to take effect. For more information, see [Configuring NSVLAN](#).

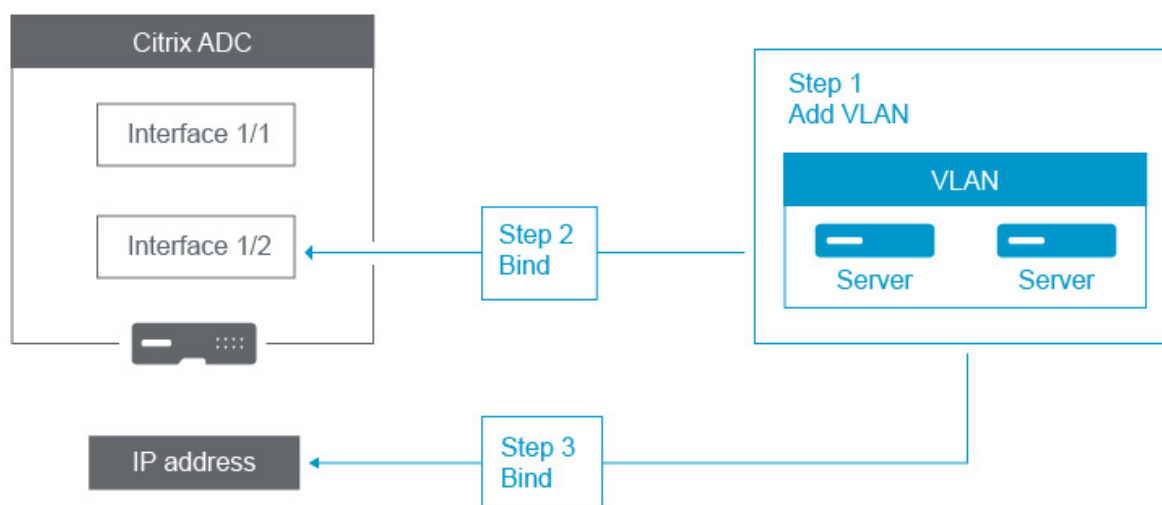

- On Citrix ADC SDX, it is highly recommended that the NSIP of each instance be on the same

subnet and VLAN as the SDX's SVM (Management Service GUI) and XenServer. The SVM communicates with instances via the network. If the SVM, XenServer, and instances are not on the same VLAN and subnet, management traffic must flow outside of the SDX. In this situation, network issues can cause Instance state to show up as yellow or red and can prevent the management and configuration changes of the Citrix ADC instances.

## Configuration Steps

Associate an IP subnet with a Citrix ADC Interface consists of the following tasks:

**Add a VLAN.** While adding a VLAN, if you are tagging the VLAN, then you must select a VLAN number that is defined in the network switch for the associated switch port. If the VLAN is untagged and is internal to the appliance, then it is recommended that you select the VLAN number that is available in the switch configuration for easy reference.

**Bind an interface to the VLAN.** While binding, if you are using Link Aggregation, associate the VLAN with the LA channel (for example, LA/1) instead of the physical interface. The VLAN must be associated with only one network interface.

If you want to tag the traffic on the interface, use the tagged (Tag) option. Else, the traffic leaves the appliance untagged and is associated with the native VLAN of the switch port.

**Bind an IP address to the VLAN.** While binding, if you bind more than one IP address from the same subnet, an error occurs. When an IP address is associated with a VLAN, all IP addresses in that subnet are automatically associated with the VLAN.

### Note:

In a high availability (HA) setup, these VLAN configurations are added automatically from the primary node to the secondary node during HA synchronization. For more information about

high availability setups, see [High Availability](#).

### CLI procedures

To add a VLAN by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **sh vlan** <id>

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> -**ifnum** <slot/port>
- **sh vlan** <id>

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> -**IPAddress** <IPAddress> <netMask>
- **sh vlan** <id>

### Example:

```
1 > add vlan 100
2
3 > bind vlan 100 -ifnum 1/1
4
5 > bind vlan 100 -ipAddress 10.0.1.0 255.255.255.0
6 <!--NeedCopy-->
```

### GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to **System > Network > VLANs**, add a new VLAN.
2. To bind a network interface to a VLAN, under **Interface Bindings**, select the **Active** option corresponding to the interface that you want to bind to the VLAN.
3. To bind an IP address to a VLAN, under **IP Bindings**, select the **Active** option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The **Type** column displays the IP address type for each IP address in the **IP Address** column.

## Configuring NSVLAN

September 21, 2020

NSVLAN is a VLAN to which the Citrix ADC management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN 1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the Citrix ADC appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the Citrix ADC IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface. If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN 1, restoring the default NSVLAN.

To configure NSVLAN by using the CLI:

At the command prompt, type:

- `set ns config -nsvlan <positive_integer> -ifnum <interface_name> ... [-tagged (YES|NO)]`
- `show ns config`

Note: The configuration takes effect after the Citrix ADC appliance is rebooted.

### Example:

```
1 > set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged NO
2   Done
3
4 > save config
5   Done
6 <!--NeedCopy-->
```

To restore the default NSVLAN configuration by using the CLI:

At the command prompt, type:

- `unset ns config -nsvlan`
- `show ns config`

### Example:

```
1 > unset ns config -nsvlan
2   Done
3 <!--NeedCopy-->
```

To configure NSVLAN by using the GUI:

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

### Setting the MTU on the NSVLAN

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throughput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the CLI:

At the command prompt, type:

- **set vlan** <id> **-mtu** <positive\_integer>
- **show vlan** <id>

To set the MTU of the NSVLAN by using the GUI:

Navigate to **System > Network > VLANs**, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

#### Sample configuration:

In the following sample configuration, VLAN 100 is the NSVLAN.

```
1 > set ns config -nsvlan 100 -ifnum 1/1 -tagged no
2
3   Warning: The configuration must be saved and the system rebooted for
4         these settings to take effect
5 > set vlan 100 -mtu 1600
6
7   Done
8
9 > sh vlan
10
11  1)  VLAN ID: 1
12
13      Link-local IPv6 addr:
14      fe80::947b:52ff:fead:12d5/64
15
16      Interfaces : 1/2 L0/1
17
18  2)  VLAN ID: 100   VLAN Alias Name:
19
20      MTU: 1600
21
22      Interfaces : 1/1
23
24      IPs :
```

```
25
26          10.102.53.114      Mask: 255.255.255.0
27
28   Done
29
30 > save config
31
32   Done
33 <!--NeedCopy-->
```

## Configuring Allowed VLAN List

September 21, 2020

Citrix ADC accepts and sends tagged packets of a VLAN on an interface if the VLAN is explicitly configured on the Citrix ADC appliance and the interface is bound to the VLAN. Some deployments (for example, Bump in the wire) require the Citrix ADC appliance to function as a transparent device to accept and forward tagged packets related to a large number of VLANs. For this requirement, configuring and managing a large number of VLANs is not a feasible solution.

Allowed VLAN list on an interface specifies a list of VLANs. The interface transparently accepts and sends tagged packets related to the specified VLANs without the need for explicitly configuring these VLANs on the appliance.

### Points to Consider before Configuring Allowed VLAN List

Consider the following points before configuring allowed VLAN list

- In a high availability setup, allowed VLAN list is not propagated or synchronized. Therefore, you have to configure allowed VLAN list on both the nodes.
- The traffic of a native VLAN might leak to the non-member interfaces that specifies the native VLAN in its allowed VLAN list.
- A Maximum of 60 VLAN ranges can be specified as part of allowed VLAN list for an interface.
- The Citrix ADC appliance does not support allowed VLAN list on interfaces that are part of link aggregation channels or redundant interface sets. For more information on redundant interface set, see [Redundant Interface Set](#).
- Allowed VLAN list is not supported on a Citrix ADC cluster configuration.
- The Citrix ADC appliance does not support allowed VLAN list for Bridge groups.
- The Citrix ADC appliance does not support allowed VLAN list for VXLANS.

## Configuring Allowed VLAN List

To configure allowed VLAN list by using the CLI:

At the command prompt, type:

- **set interface** <id> **-trunkmode** (ON|OFF) **-trunkAllowedVlan** <int[-int]> ...
- **show interface** <id>

To configure allowed VLAN list by using the GUI:

Navigate to **System > Network > Interfaces**, select a network interface, click **Edit**, and then set the following parameters:

- Trunk Mode
- Trunk Allowed VLAN

### Sample Configuration:

In the following sample configuration, VLANs in the ranges 100-120, 190-200, and 300-330 are specified as part of allowed VLAN list for interface 1/2.

```
1 > set int 1/2 -trunkmode on -trunkallowedVlan 100-120 190-200 300-330
2
3 Done
4
5 > sh int 1/2
6
7 1)      Interface 1/2 (Gig Ethernet 10/100/1000 Mbits) #6
8         flags=0xc020
9
10        <ENABLED, UP, UP, AUTONEG OFF, HEARTBEAT, 802.1q, trunkmode>
11
12        Trunk Allowed Vlans:  100-120 190-200 300-330
13
14 Done
15
16 <!--NeedCopy-->
```

## Configuring Bridge Groups

September 21, 2020

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANs can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the Citrix ADC appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The Citrix ADC accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

**Note**

Bridge Group feature and Bridge BPDU mode cannot work together.

## Configuration steps

Perform the following steps to configure a bridge group:

- Enable Layer 2 mode
- Add a bridgegroup and bind VLANs to the bridgegroup

## CLI procedures

To enable Layer 2 mode by using the CLI:

At the command prompt, type:

- **enable ns mode l2**
- **show ns mode**

To add a bridge group and bind VLANs by using the CLI:

At the command prompt, type:

- **add bridgegroup** <id> [-**ipv6DynamicRouting** ( **ENABLED** | **DISABLED** )]
- **bind bridgegroup** <id> -**vlan** <positive\_integer>
- **show bridgegroup** <id>

## Example:

```
1 > add bridgegroup 12
2 Done
3 <!--NeedCopy-->
```

To remove a bridge group by using the CLI:

At the command prompt, type:

- **rm bridgegroup** <id>

**Example:**

```
1  rm bridgegroup 12
2  <!--NeedCopy-->
```

### GUI Procedures

To configure a bridge group by using the GUI:

Navigate to **System > Network > Bridge Groups**, add a new bridge group and bind VLANs to the bridgegroup, or edit an existing bridge group.

## Configuring Virtual MACs

September 21, 2020

The primary and secondary nodes in a high availability (HA) setup share the Virtual MAC address (VMAC) floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a Virtual MAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a Virtual MAC, see [Configuring Virtual MAC Addresses](#).

## Configuring Link Aggregation

September 21, 2020

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the Citrix ADC appliance and other connected devices. An aggregated link is also referred to as a “channel.” You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

### Configuring Link Aggregation Manually

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

#### CLI procedures

To create a link aggregation channel by using the CLI:

At the command prompt, type:

- `add channel <id> [-ifnum <interfaceName> ...] [-state ( ENABLED | DISABLED )] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor ( ON | OFF )] [-tagall ( ON | OFF )] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer>] [-bandwidthNormal <positive_integer>]]`
- `show channel`

#### Example:

```
1 > add channel LA/1 -ifnum 1/8
2 Done
3 <!--NeedCopy-->
```

To bind an interface to or unbind an interface from an existing link aggregation channel by using the CLI:

At the command prompt, type one of the following commands:

- `bind channel <id> <interfaceName>`
- `unbind channel <id> <interfaceName>`

**Example:**

```
1 bind channel LA/1 1/8
2 <!--NeedCopy-->
```

To modify a link aggregation channel by using the CLI:

At the command prompt, type the `set channel` command, the channel ID, and the parameters to be changed, with their new values.

To remove a link aggregation channel by using the CLI:

**Important:** When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

- `rm channel <id>`

**Example:**

```
1 > rm channel LA/1
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To configure a link aggregation channel by using the GUI:

Navigate to **System > Network > Channels**, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the GUI:

**Important:**

When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Navigate to **System > Network > Channels**, select the channel that you want to remove and click **Delete**.

## Configuring Link Aggregation by Using the Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

**Note:** In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

### Configuring the LACP System Priority

The LACP system priority determines which peer device of an LACP LA channel can have control over the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the value, the higher the priority.

To configure the LACP system priority by using the CLI:

At the command prompt, type the following commands to set the priority for a standalone appliance and verify the configuration:

- `set lacp -sysPriority <positive_integer>`
- `show lacp`

#### Example:

```
1 set lacp -sysPriority 50
2 <!--NeedCopy-->
```

To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

- `set lacp -sysPriority <positive_integer> -ownerNode <positive_integer>`
- `show lacp`

#### Example:

```
1 set lacp -sysPriority 50 -ownerNode 2
2 <!--NeedCopy-->
```

To configure the LACP system priority by using the GUI:

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

## Creating Link Aggregation Channels

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

### Note:

- When enabling LACP on a network interface, you must specify the LACP Key.
- By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the CLI:

At the command prompt, type:

- `set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT )]`
- `show interface [<id>]`

To create an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.

## Modifying Link aggregation Channels

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel by using the CLI:

At the command prompt, type:

- `set channel <id> [-ifnum <interfaceName> ...] [-state ( ENABLED | DISABLED )] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor ( ON | OFF )] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer>] [-bandwidthNormal <positive_integer>]]`
- `show channel`

### Example:

```
1 > set channel LA/3 -state ENABLED -speed 10000
2 Done
3 <!--NeedCopy-->
```

To modify an LACP channel by using the GUI:

Navigate to System > Network > Channels, and modify an existing LACP channel.

## Removing a Link Aggregation Channel

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the CLI:

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

To remove an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

## Link Redundancy using LACP channels

Link Redundancy using LACP channels enables the Citrix ADC to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.

A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a Citrix ADC, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.

To configure link redundancy for an LACP channel, set the `lrMinThroughput` parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the `lrMinThroughput` value, link failover occurs and a standby subchannel becomes active.

If you unset the `lrMinThroughput` parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

### Example

Consider an example of link redundancy configured between Citrix ADC NS1 and switches SW1 and SW2.

NS1 is connected to network device NW-A through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.

When the `lrMinThroughput` parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the `lrMinThroughput` value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

### Link Redundancy using LACP channels in a High Availability setup

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (`lrMinThroughput` parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the `lrMinThroughput` parameter.

The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the `lrminthroughput` parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels' maximum supported throughput meet the `lrMinThroughput` parameter value.

- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has Citrix ADCs NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.

Following are the LACP-parameter settings in this example:

| Parameter       | Value |
|-----------------|-------|
| Throughput      | 2000  |
| lrminthroughput | 2000  |

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2's maximum supported throughput also falls below the lrminthroughput value (for

example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:

### Configure Link Redundancy using LACP channels

To configure link redundancy for a LACP channel by using the CLI:

At the command prompt, type the following commands to configure the channel and verify the configuration:

- **set channel** <id> -lrMinThroughput <positive\_integer>
- **show channel**

#### Example:

```
1 > set channel la/1 -lrMinThroughput 2000
2 Done
3 > set channel la/2 -throughput 2000 -lrMinThroughput 2000
4 Done
5 <!--NeedCopy-->
```

To configure link redundancy for a LACP channel by using GUI

1. Navigate to System > Network > Channels.
2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.
3. In the Configure LACP channel dialog box, set the lrMinThroughput parameter.
4. Click Close.

## Redundant Interface Set

September 21, 2020

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the Citrix ADC appliance and a peer device by providing back up links between them.

- Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, redundant interface set appear as individual interfaces and not as a set or collection.
- In an high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

**Note**

Redundant Interface Set was formerly known as 'NIC bundling' when first introduced in 10.5 release.

### How Redundant Interface Set Works

For a redundant interface set, the Citrix ADC appliance derives a MAC address on the basis of an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contains the MAC address assigned to the redundant interface set and not the interface's own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority.** This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.
- **Binding order of the member interfaces.** If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.

## Points to Consider for Configuring Redundant Interface Sets

Consider the following points before you configure a redundant interface set:

- In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.
- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- You can configure a maximum of four redundant interface sets on a Citrix ADC appliance.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a link aggregate (LA) channel.
- LA channels cannot be bound to a redundant interface set.
- Redundant interface sets cannot be bound to an LA channel.
- In a cluster setup:
  - Redundant interface sets cannot be bound to a cluster link aggregation.
  - A link redundant set is specified in N/LR/X notation (for example, 1/LR/3). Where:  
N is the ID of the cluster node on which the redundant interface set is to be created.  
X is a link-redundant set identifier on a cluster node. X can range from 1-4.
  - A cluster link aggregation cannot be bound to a redundant interface set.
  - A redundant interface set can include only the interfaces of the node to which the redundant interface set belongs.
  - An Existing elink redundancy set configuration on a standalone appliance automatically changes to cluster notation (N/LR/X) after the appliance is added to a cluster setup.

## Configuration Steps

Configuring redundant interface set on a Citrix ADC appliance consists of the following tasks:

- **Create a redundant interface set.** Use the channel command operation for creating a redundant interface set.

In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

In a cluster setup, a link redundant set is specified in N/LR/X (for example, 1/LR/3), where: N is the ID of the cluster node on which the redundant interface set is to be created, X is link redundant set identifier on a cluster node. X can range from 1-4.

- **Bind interfaces to the redundant interface set.** Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.

- **(Optional) Set a redundant interface priority on the member interface.** Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the CLI:

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the CLI:

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the CLI:

At the command prompt:

- set interface <ID> -lrsetpriority <positive\_integer>
- show interface <ID>

### Sample configuration 1:

In the following example, redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command displays that the interface 1/1 is the current active interface for the redundant interface set lr/1.

```
1 > add channel lr/1
2 Done
3 > bind channel lr/1 1/1 1/2 1/3 1/4
4 Done
5 > show channel
6 1) Interface LR/1 (Link Redundant) #23
7     flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
8     MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
9     Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
10             throughput 0
11     Actual: throughput 1000
12     LLDP Mode: NONE,
13     RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
14     TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
15     NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
16     Bandwidth thresholds are not set.
```

```

17          1/1: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Active Member
18          1/2: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Inactive Member
19          1/3: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Inactive Member
20          1/4: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Inactive Member
21 Done
22 <!--NeedCopy-->

```

**Sample configuration 2:**

In the following example, redundant interface priority of the member interface 1/4 is set to 100, which is lower than the set redundant interface priority of all the other member interfaces of LR/1.

Output of the show channel command displays that the interface 1/4 is the current active interface for the redundant interface set LR/1.

```

1 > set interface 1/4 -lrsetPriority 100
2 Done
3 > show channel
4 1)      Interface LR/1 (Link Redundant) #23
5         flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
6         MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
7         Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
8             throughput 0
9         Actual: throughput 1000
10        LLDP Mode: NONE,
11        RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
12        TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
13        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
14        Bandwidth thresholds are not set.
15          1/1: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Inactive Member
16          1/2: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Inactive Member
17          1/3: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Inactive Member
18          1/4: UTP-1000-FULL-OFF          UP  0h14m06s  LR
           Active Member
19 Done
20 <!--NeedCopy-->

```

**Sample configuration 3:**

Consider a cluster setup of four nodes N1, N2, N3, and N4. In this example, redundant interface set 1/LR/3 is created on node N1, and interfaces 1/1/1, 1/1/2, and 1/1/3 are bound to it. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command indicates that interface 1/1/1 is the current active interface for redundant interface set 1/LR/3.

```
1 > add channel 1/LR/3
2
3 Done
4 > bind channel 1/LR/3 1/1/1 1/1/2 1/1/3
5
6 Done
7 > show channel

## Binding an SNIP address to an Interface

September 21, 2020

You can now bind a Citrix ADC owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation

channels and you want the Citrix ADC appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.

The following tables describe the example settings for the scenario:

| Entity                | Name                               | Value      |
|-----------------------|------------------------------------|------------|
| SNIP addresses on NS1 | SNIP2 (for reference purpose only) | 10.10.10.2 |
|                       | SNIP3 (for reference purpose only) | 10.10.10.3 |
|                       | SNIP4 (for reference purpose only) | 10.10.10.4 |
|                       | SNIP5 (for reference purpose only) | 10.10.10.5 |

---

| Entity                              | Name                                     | Value             |
|-------------------------------------|------------------------------------------|-------------------|
| LLB virtual server on NS1           | LLB_VSERVER1                             | -                 |
| Transparent monitor on NS1          | TRANS_MON                                | -                 |
| LLB services on NS1                 | LLB_SVC2                                 | 10.10.10.240      |
|                                     | LLB_SVC3                                 | 10.10.10.120      |
|                                     | LLB_SVC4                                 | 10.10.10.60       |
|                                     | LLB_SVC5                                 | 10.10.10.30       |
| MAC address of interface 1/2 on NS1 | NS_MAC_2 (for reference purpose only)    | 00:e0:ed:0f:bc:e0 |
| MAC address of interface 1/3 on NS1 | NS_MAC_3 (for reference purpose only)    | 00:e0:ed:0f:bc:df |
| MAC address of interface 1/4 on NS1 | NS_MAC_4 (for reference purpose only)    | 00:e0:ed:0f:bc:de |
| MAC address of interface 1/5 on NS1 | NS_MAC_5 (for reference purpose only)    | 00:e0:ed:1c:89:53 |
| IP address of Router R1             | Router_IP (for reference purpose only)   | 10.10.10.1        |
| MAC address of interface of R1      | ROUTER_MAC1 (for reference purpose only) | 00:21:a1:2d:db:cc |

---

To configure the example settings:

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see [Configuring Subnet IP Addresses \(SNIPs\)](#).

**CLI example:**

```
1 > add ns ip 10.10.10.2 255.255.255.0 -type SNIP
2 Done
3 > add ns ip 10.10.10.3 255.255.255.128 - type SNIP
4 Done
5 > add ns ip 10.10.10.4 255.255.255.192 - type SNIP
6 Done
7 > add ns ip 10.10.10.5 255.255.255.224 - type SNIP
8 Done
9 <!--NeedCopy-->
```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see [Set up basic load balancing](#).

**CLI example:**

```
1 > add service LLB_SVC2 10.10.10.240 any *
2 Done
3 > add service LLB_SVC3 10.10.10.120 any *
4 Done
5 > add service LLB_SVC4 10.10.10.60 any *
6 Done
7 > add service LLB_SVC5 10.10.10.30 any *
8 Done
9 <!--NeedCopy-->
```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see [Configure monitors in a load balancing setup](#).

**CLI example:**

```
1 > add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
2 Done
3 > bind monitor TRANS_MON LLB_SVC2
4 Done
5 > bind monitor TRANS_MON LLB_SVC3
6 Done
7 > bind monitor TRANS_MON LLB_SVC4
8 Done
9 > bind monitor TRANS_MON LLB_SVC5
10 Done
11 <!--NeedCopy-->
```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see [Configuring a Basic LLB Setup](#).

**CLI example:**

```
1 > add lb vserver LLB_VSERVER1 any
2 Done
3 > set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
4 Done
5 > bind lb vserver LLB_VSERVER1 LLB_SVC2
6 Done
7 > bind lb vserver LLB_VSERVER1 LLB_SVC2
```

```

8 Done
9 > bind lb vserver LLB_VSERVER1 LLB_SVC2
10 Done
11 > bind lb vserver LLB_VSERVER1 LLB_SVC2
12 Done
13 <!--NeedCopy-->

```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see [Configuring a Basic LLB Setup](#).

**CLI example:**

```

1 > add lb route 0.0.0.0 0.0.0.0 LLB_VSERVER1
2 Done
3 <!--NeedCopy-->

```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see [Configuring Static ARP](#).

**CLI example:**

```

1 > add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum
  1/2
2 Done
3 > add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum
  1/3
4 Done
5 > add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4
6 Done
7 > add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5
8 Done
9 <!--NeedCopy-->

```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see [Configuring Static ARP](#).

**CLI example:**

```

1 > add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
2 Done
3 > add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
4 Done
5 > add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
6 Done

```

```
7 > add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
8 Done
9 <!--NeedCopy-->
```

## Monitor the Bridge Table and Changing the Aging time

September 21, 2020

Citrix ADC appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics. All the MAC entries in the bridge table are updated with the aging time.

To set the aging time of bridge table entries by using the CLI:

At the command prompt, type:

- **set l2param -bridgeage timeout** <positive\_integer>
- **show l2param**

### Example:

```
1 > set l2param -bridgeage timeout 90
2 Done
3 <!--NeedCopy-->
```

To view the statistics of a bridge table by using the CLI:

At the command prompt, type:

- **stat bridge**

To set the aging time of bridge table entries by using the GUI:

Navigate to **System > Network**. On the **Network** page, in the **Settings** section, click **Configure Layer2 Parameters** and set the **Timeout Value For The Bridge Table Entries (seconds)** parameter.

To view the statistics of a bridge table by using the GUI:

Navigate to **System > Network > Bridge Table**, select the MAC address, and click **Statistics**.

## Citrix ADC Appliances in Active-Active Mode Using VRRP

September 21, 2020

An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all Citrix ADC appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

The active VIP is called the master VIP, and the corresponding VIPs on the other Citrix ADC appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the Citrix ADC appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

Citrix ADC appliances in active-active mode can be configured so that no Citrix ADC is idle. In this configuration, different sets of VIPs are active on each Citrix ADC. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration

The Citrix ADC appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an ARP entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the Virtual MAC (for example VMAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with VMAC1 and VIP1.

6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2.
8. S2 replies to the SNIP on the Citrix ADC.
9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the Citrix ADC appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, VMAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for VMAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

## Health Tracking

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.
- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP  $(1 - K/N)$ , where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

**Note:** If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

## Preemption

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

## Sharing

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure **An Active-Active Configuration** VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

## Configuring Active-Active Mode

September 21, 2020

On each Citrix ADC appliance that you want to deploy in active-active mode, you must add a Virtual MAC (VMAC) and bind the Virtual MAC to a VIP. The Virtual MAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID (VRID) must be created on each Citrix ADC and bound to VIP 10.102.29.5 on each Citrix ADC. When you bind a Virtual MAC to a VIP, the appliance sends VRRP advertisements to each VLAN that is bound to that VIP. The Virtual MAC can be shared by different VIPs configured on the same Citrix ADC.

## Configuring IPv4 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a Virtual MAC address.** Add a Virtual MAC address by adding a VRID. You can also specify a priority and enable or disable preemption and sharing on this VRID address.

- **Add a VIP address and associate the Virtual MAC's VRID.** Add a VIP address and set the VRID parameter to the newly created VRID. The attributes of the VRID (for example, priority and pre-emption) are bound to this VIP address.

**Note:** The same VIP address must be added to all the other Citrix ADC appliances.

To add a Virtual MAC address by using the CLI

At the command prompt, type:

- **add vrid** <id> [-**priority** <positive\_integer>] [-**preemption** (ENABLED|DISABLED)][-**sharing** (ENABLED|DISABLED)] [-**tracking** <tracking>]
- **show vrid**

To add a VIP address by using the CLI:

At the command prompt, type:

- **add ns ip** <IPv4Address> -type VIP -vrid <value>
- **show ns ip**

To configure a Virtual MAC by using the GUI:

1. Navigate to **System > Network > VMAC**, on the **VMAC** tab, add a new Virtual MAC, or edit an existing Virtual MAC.
2. Set the following parameters:
  - Virtual Router ID
  - Priority
  - Tracking
  - Preemption
  - Sharing

To configure a VIP address and associate the VRID to it by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, add an IP address of type VIP.
2. While adding the IP address, select the virtual router ID from the **Virtual Router Id** drop down box.

### Sample Configuration:

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv4 active-active mode. VIP address 203.0.113.10 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP address is bound to a Virtual MAC address. 203.0.113.10 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100).

```

1      Settings on NS1
2
3      > add vrid 10 - Priority 100 - Preemption Enabled - sharing Enabled
4

```

```
5     Done
6
7     > add ns ip 203.0.113.10 - type VIP - vrid 10
8
9     Done
10
11    Settings on NS2
12
13    > add vrid 10 - Priority 200 - Preemption Enabled - sharing Enabled
14
15    Done
16
17    > add ns ip 203.0.113.10 - type VIP - vrid 10
18
19    Done
20 <!--NeedCopy-->
```

## Configuring IPv6 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a Virtual MAC6 address.** Add a Virtual MAC6 address by adding a VRID6. You can also specify a priority and enable or disable preemption and sharing on this VRID6 address.
- **Add a VIP6 address.** Add a VIP6 address. Set the VRID6 parameter to the VRID6 of the newly created Virtual MAC6. The attributes of the Virtual MAC6 (for example, priority and preemption) are bound to this VIP6 address.

**Note:** The same VIP6 address must be added to all the other Citrix ADC appliances.

To add a Virtual MAC6 address by using the CLI:

At the command prompt, type:

- **add vrid6** <id> [-**priority** <positive\_integer>] [-**preemption** ( **ENABLED** | **DISABLED** )] [-**sharing** ( **ENABLED** | **DISABLED** )]
- **show vrid6**

To add a VIP6 address by using the CLI:

At the command prompt, type:

- **add ns ip6** <IPv6Address> -**type** VIP -**vrid** <value>
- **show ns ip6**

To configure a Virtual MAC6 by using the GUI:

1. Navigate to **System > Network > VMAC**, on the **VMAC6** tab, add a new Virtual MAC6, or edit an existing **Virtual MAC**.
2. Set the following parameters:
  - Virtual Router ID
  - Priority
  - Preemption
  - Sharing

To configure a VIP6 address and associate the VRID to it by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, add an IPv6 address of type VIP.
2. While adding the VIP6 address, select the VRID6 from the **Virtual Router Id** drop down box.

### Sample Configuration:

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv6 active-active mode. VIP6 address 2001:db8::5001 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP6 address is bound to a Virtual MAC6 address. 2001:db8::5001 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100).

```
1 Settings on NS1
2 > add vrid6 10 - Priority 100 - Preemption Enable - sharing Enable
3
4 Done
5 > add ns ip6 2001:db8::5001 - type VIP - vrid6 10
6
7 Done
8 Settings on NS2
9 > add vrid6 10 - Priority 200 - Preemption Enable - sharing Enable
10
11 Done
12 > add ns ip6 2001:db8::5001 - type VIP - vrid6 10
13
14 Done
15 <!--NeedCopy-->
```

## Configuring Send to Master

September 21, 2020

Usually, the traffic destined to a VIP reaches the Citrix ADC appliance on which the VIP is active, because an ARP request with the VIP and a Virtual MAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet,

or a topology that blocks this route, the traffic can reach a Citrix ADC appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled

To enable send to master by using the CLI:

At the command prompt, type:

```
set vrIDParam -sendToMaster (ENABLED | DISABLED)
```

**Example:**

```
1 > set vrIDParam -sendToMaster ENABLED
2 Done
3 <!--NeedCopy-->
```

To enable send to master by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. Select the **Send to Master** option.

## Configuring VRRP Communication Intervals

September 21, 2020

In an active-active deployment, all Citrix ADC nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval.** Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.
- **Dead Interval.** Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

To configure VRRP communication intervals by using the CLI:

At the command prompt, type:

- **set vrIDParam** [-helloInterval <msecs>] [-deadInterval <secs>]
- **sh vrIDParam**

### Example:

```
1 > set vrIDParam -helloInterval 500 -deadInterval 2
2 Done
3 <!--NeedCopy-->
```

To configure VRRP communication intervals by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. In **Configure Virtual Router Parameter**, set the **Hello Interval** and **Dead Interval** parameters.

3. Click **OK**.

### **Example 1: Nodes with the Same VRRP Dead Intervals**

Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes. The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn, apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node. Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: [VRRP interval example 1 settings](#).

The execution flow is as follows:

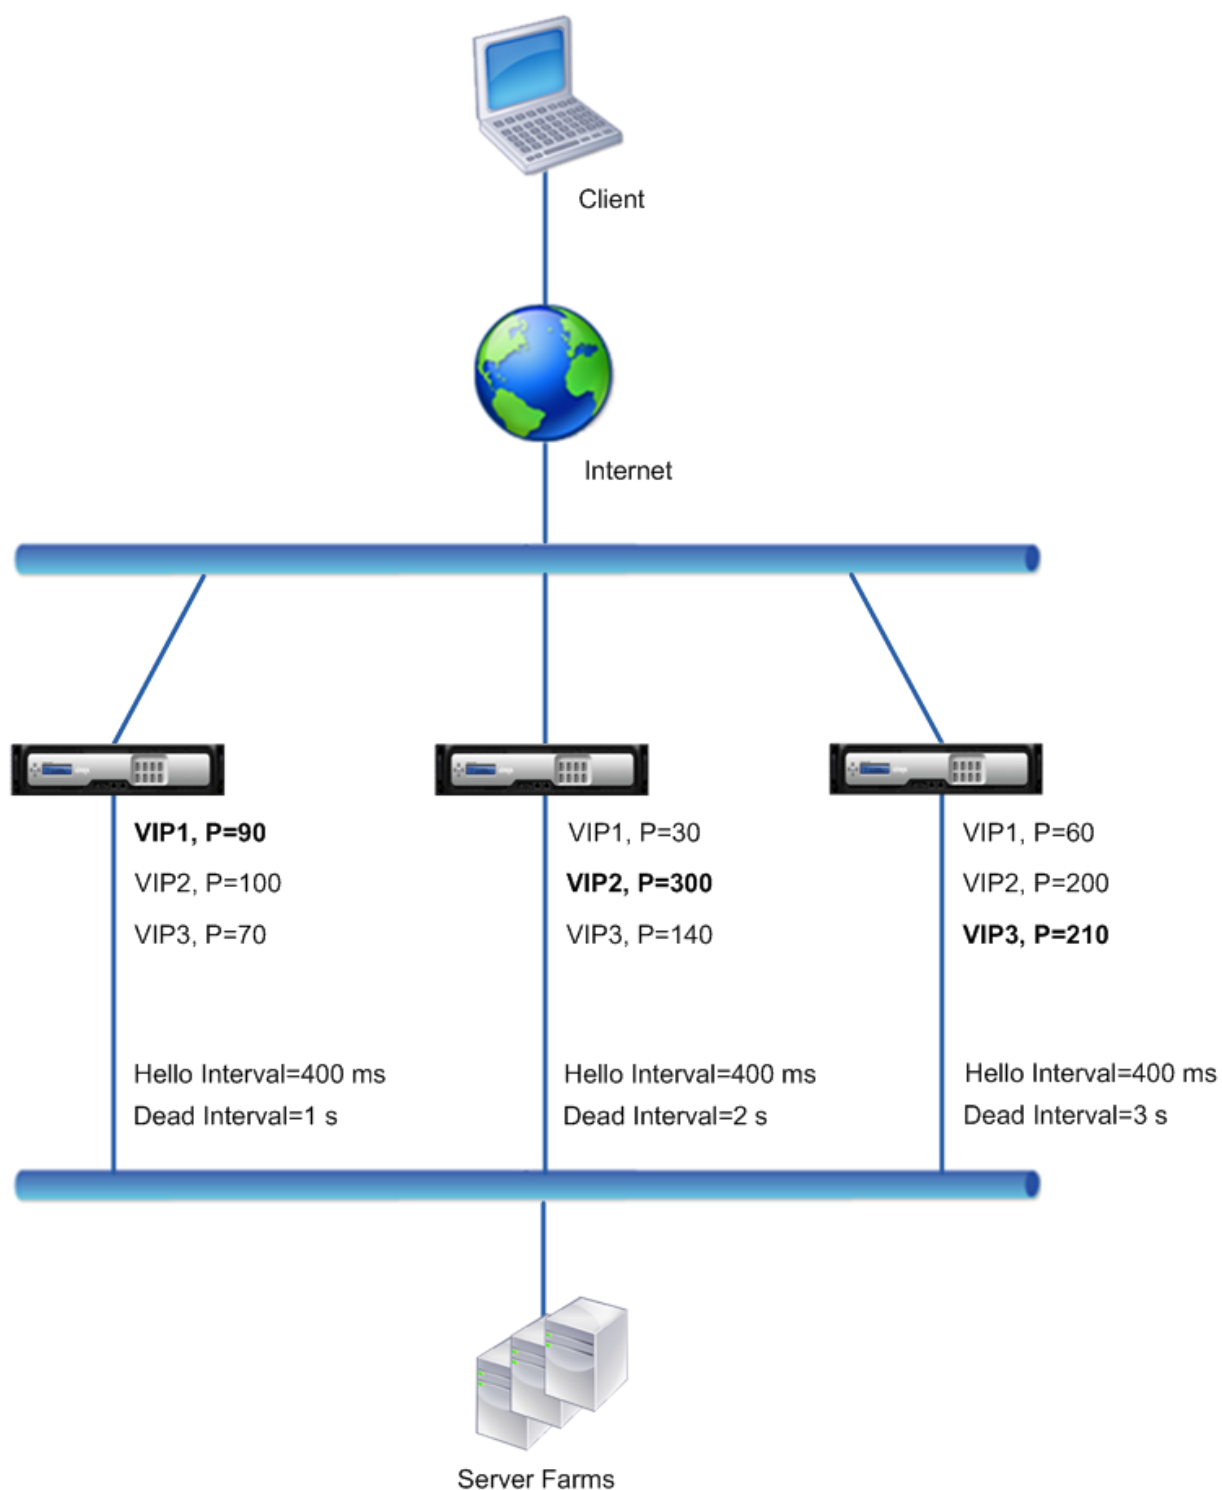

1. NS1 sends hello messages at a set hello interval of 400 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages for VIP2, and NS3 sends hello messages for VIP3.

2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master) because its VRID priority (60) is higher than that of VIP1 of NS2 (30).

### **Example 2: Nodes with Different VRRP Dead Intervals**

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: [VRRP interval example 2 settings](#).

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages

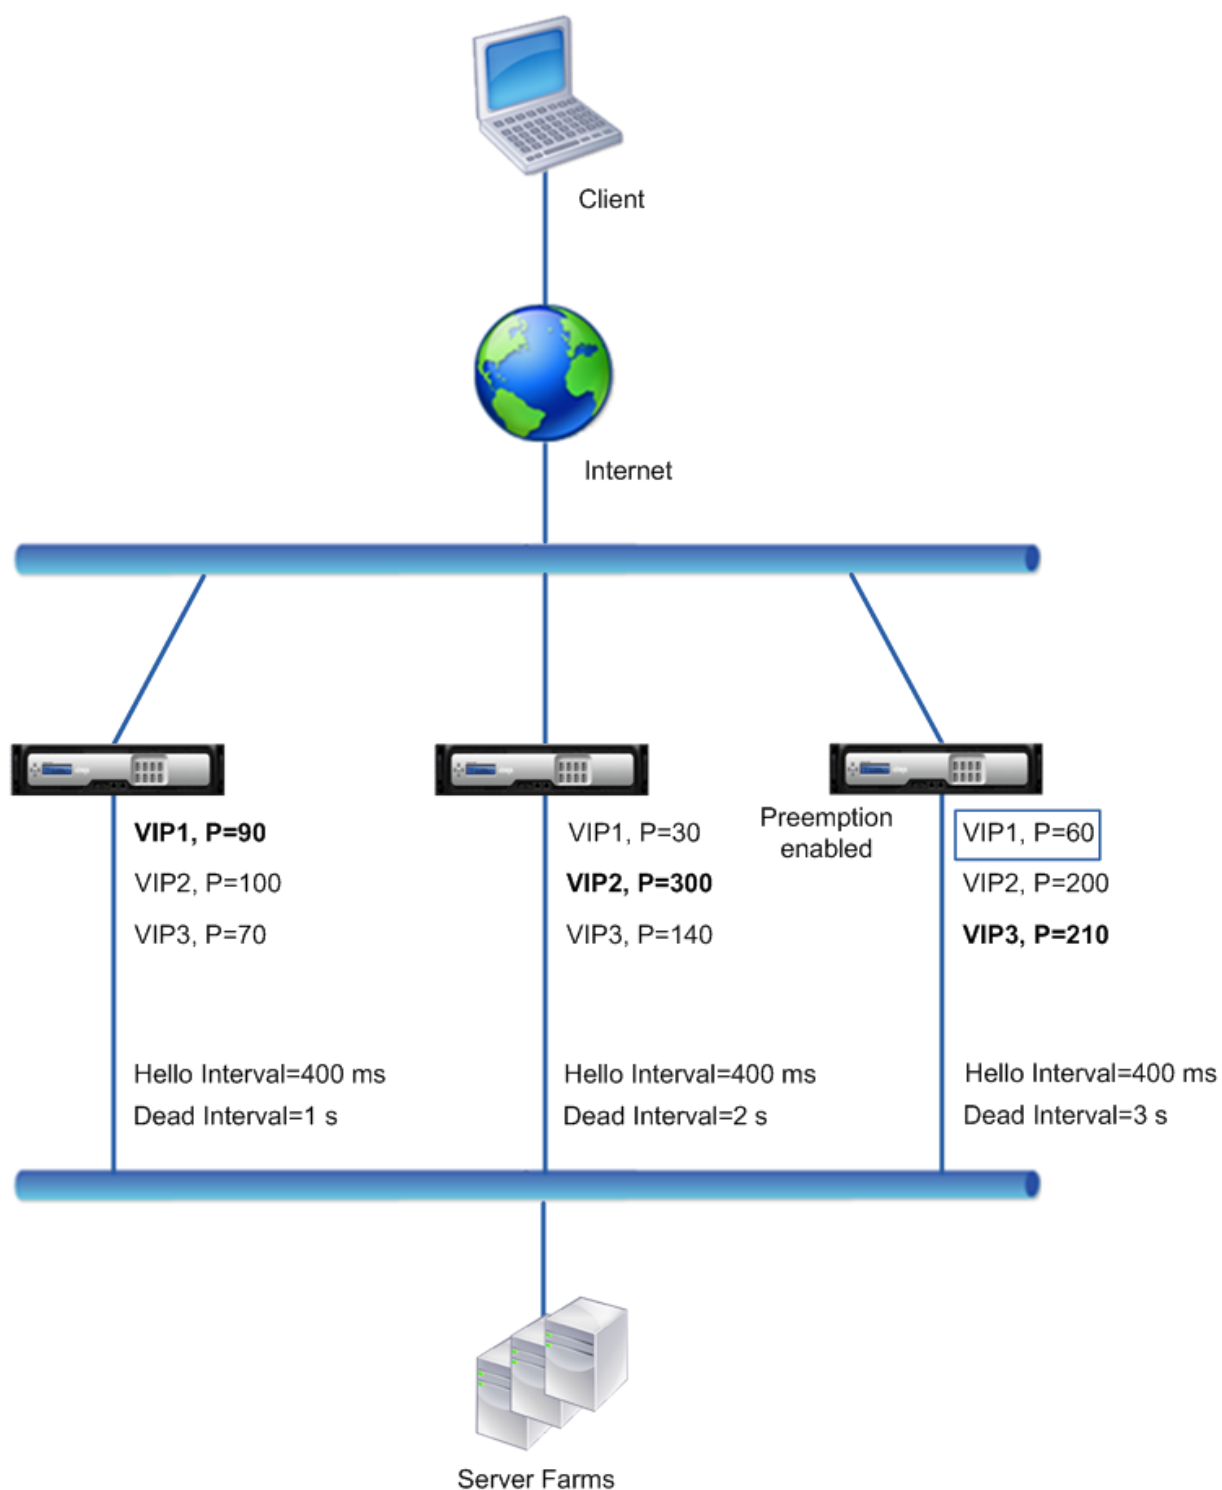

for VIP1.

Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3's larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

### **Example 3: Nodes with Different Dead Intervals and Preemption Enabled**

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example: [VRRP interval example 3 settings](#).

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.

2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

## Configuring Health Tracking based on Interface State

September 21, 2020

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address when the state of an interface on the node changes. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP. This feature is a per node configuration for each VIP address.

### Example

Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (`trackifNumPriority`) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example: [Health tracking example settings](#).

\* Packet Interfaces = 1/2, 1/3, 1/5  
Reduced Priority = 20

\*\* Packet Interfaces = 1/5, 1/7  
Reduced Priority = 55

The execution flow is as follows on NS1 when multiple interface on NS1 goes down:

1. If interface 1/3 goes down, the priority of address VIP1 is reduced by 20 (VIP1's reduced priority value), because interface 1/3 is associated with VIP1:
  - Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of address VIP1 is further reduced:
  - Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4's reduced priority value (55).
  - Effective priority of VIP4 = (250 - 55) = 195
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
  - Effective priority of VIP4 = (Current priority - reduced priority) = (195-55) = 145
6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

### Configuration Steps for IPv4 Active-Active Mode

To configure this feature on a node for a VIP address, you set the Reduced Priority (`trackifNumPriority`) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (`trackifNumPriority`) value.

To set reduced priority and bind interfaces to the virtual router ID by using the CLI:

At the command prompt, type:

- **set vrID** <id> [-**trackifNumPriority** <positive\_integer>]
- **bind vrID** <id> -**trackifNum** <interface\_name>
- **show vrID** <id>

#### Example:

```
1 > set vrID 125 -trackifNumPriority 10
2 Done
3
4 > bind vrID 125 -trackifNum 1/4 1/5
5 Done
6 <!--NeedCopy-->
```

To set reduced priority and bind interfaces to the virtual router ID by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMACs** tab, select a virtual router ID, and click **Edit**.
3. Under **Configure Virtual MAC**, set the **Reduced Priority** parameter.
4. Select the **Interfaces tracked for the VRID** option and, under **Associate Interfaces**, add interfaces to the virtual router ID.

## Configuration Steps for IPv6 Active-Active Mode

To configure this feature on a node for a VIP6 address, you set the Reduced Priority (`trackifNumPriority`) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP6 address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP6 address by the configured Reduced Priority (`trackifNumPriority`) value.

To change the priority of a VIP address automatically by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new Virtual MAC6:
  - **add vrID6** <id> [-**trackifNumPriority** <positive\_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface\_name>
  - **show vrID6** <id>
- If reconfiguring an existing Virtual MAC6:
  - **set vrID6** <id> [-**trackifNumPriority** <positive\_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface\_name>
  - **show vrID6** <id>

### Example:

```
1 > set vrID6 130 -trackifNumPriority 10
2 Done
3
4 > bind vrID6 130 -trackifNum 1/4 1/5
5 Done
6 <!--NeedCopy-->
```

## Delaying Preemption

September 21, 2020

By default, a backup VIP address preempts the master VIP address immediately after its priority becomes higher than that of the master VIP. When configuring a backup VIP address, you can specify an amount of time by which to delay the preemption. Preemption delay time is a per-node setting for each backup VIP address.

The preemption delay setting for a backup VIP does not apply in the following conditions:

- The node of the master VIP goes down. In this case, the backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.
- The priority of the master VIP is set to zero. The backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.

### Example: Delaying Preemption

Consider an active-active deployment consisting of Citrix ADC appliances NS1 and NS2. Virtual IP address VIP1 is configured on each of these appliances. Because of their priorities, VIP1 is master on NS2. Preemption is enabled and preemption delay time is set for VIP1 on these two nodes.

The following table lists the settings used in this example.

| Entity and Parameters              | Settings on NS1                                                                                                                              | Settings on NS2                                                                                                                              |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| VIP1 (for reference purposes only) | <b>IP address:</b> 192.0.1.10, <b>VRID:</b> 10, <b>Priority:</b> 100, <b>Preemption:</b> Enabled, <b>Preemption delay time:</b> 1000 seconds | <b>IP address:</b> 192.0.1.10, <b>VRID:</b> 10, <b>Priority:</b> 200, <b>Preemption:</b> Enabled, <b>Preemption delay time:</b> 2000 seconds |
| Dead Interval                      | 1 Seconds                                                                                                                                    | 2 Seconds                                                                                                                                    |

Following are some examples of possible preemption behavior in this setup:

- If the priority of VIP1 on NS1 is set to a value (for example, 210) higher than that of VIP1 on NS2, VIP1 on NS1 takes over as master after its set preemption delay time (1000 secs).
- If a third node NS3 with the following VRRP settings is added to this deployment, VIP1 on NS3 becomes master after its set preemption delay time (3000 secs).
  - VIP1
    - \* VRID: 30
    - \* IP address:
    - \* Priority = 300
    - \* Preemption delay time = 3000 seconds
- If NS2 goes down, VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

- If NS2 goes down and NS1 restarts, VIP1 on NS1 becomes master 1 second (set dead interval on NS1) after NS1 comes up. Preemption delay time for VIP1 on NS1 does not apply in this case.
- If the priority of VIP1 on NS2 is set to zero, VIP1 goes to standby mode. VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

## Configuring Delay Preemption for IPv4 Active-Active Mode

To configure preemption delay time for a VIP address, you set the preemption delay timer parameter of the associated Virtual MAC address. You can set this parameter when you add the address, or you can modify an existing Virtual MAC address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a Virtual MAC, at the command prompt, type:
  - **add vrid** <id> **-preemptiondelaytimer** <secs>
  - **show vrid**
- To set the preemption delay time while modifying a Virtual MAC, at the command prompt, type:
  - **set vrid** <id> **-preemptiondelaytimer** <secs>
  - **show vrid**

To configure preemption delay time by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMAC** tab. While adding a new Virtual MAC, or editing an existing Virtual MAC, set the **Preemption Delay Timer** parameter.

### Sample configuration:

The following configuration uses the settings listed in table in section Example: Delaying Preemption.

```
1      Settings on NS1
2
3      > set vrid param - deadInterval 1
4
5      Done
6
7      > add ns ip 192.0.1.10 255.255.255.255 - type VIP
8
9      Done
10
11     > add vrid 10 - Priority 100 - Preemption Enable -
12         preemptiondelaytimer 1000
13
14     Done
```

```
14
15 > bind ns ip 192.0.1.10 255.255.255.255 - vrid 10
16
17 Done
18
19 Settings on NS2
20
21 > set vrid param - deadInterval 2
22
23 Done
24
25 > add ns ip 192.0.1.10 255.255.255.255 - type VIP
26
27 Done
28
29 > add vrid 20 - Priority 200 - Preemption Enable -
    preemptiondelaytimer 2000
30
31 Done
32
33 > set ns ip 192.0.1.10 255.255.255.255 - vrid 10
34
35 Done
36 <!--NeedCopy-->
```

## Configuring Delay Preemption for IPv6 Active-Active Mode

To configure preemption delay time for a VIP6 address, you set the preemption delay timer parameter of the associated Virtual MAC6 address. You can set this parameter when you add the Virtual MAC6 address, or you can modify an existing Virtual MAC6 address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a Virtual MAC6, at the command prompt, type:
  - **add vrid6 *\*\*<id>* -preemptiondelaytimer\*\*** <secs>
  - **show vrid6**
- To set the preemption delay time while modifying a Virtual MAC6, at the command prompt, type:
  - **set vrid6 <id> -preemptiondelaytimer** <secs>
  - **show vrid6**

To configure preemption delay time by using the GUI:

1. Navigate to **System > Network > VMAC**.

2. On the **VMAC6** tab. While adding a Virtual MAC6 address, or editing an existing Virtual MAC6 address, set the **Preemption Delay Timer** parameter.

## Keeping a VIP Address in the Backup State

September 21, 2020

You can force a VIP address to always stay in backup state. This operation is helpful in maintenance or testing of a VRRP deployment.

When a VIP address is forced to stay in backup state, it does not participate in VRRP state transitions. Also, it cannot become master even if all other nodes go down.

To force a VIP address to stay in backup state, you set the priority of the associated Virtual MAC address to zero. To ensure that none of the VIP addresses of a node handle traffic during a maintenance process on the node, set all the priorities to zero.

You can set the priority of a Virtual MAC address while adding or modifying the address.

To force a VIP address to stay in the backup state by using the CLI:

- To set the priority while adding a Virtual MAC, at the command prompt, type:
  - **add vrid <id> -priority 0**
  - **show vrid**
- To set the priority while modifying a Virtual MAC, at the command prompt, type:
  - **set vrid <id> -priority 0**
  - **show vrid**

To force a VIP address to stay in backup state by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMAC** tab, while adding a new Virtual MAC or editing an existing Virtual MAC, set the **Priority** parameter to zero.

## Network Visualizer

September 21, 2020

The network visualizer shows a graphical view of all the interfaces, channels, VLANs, IP addresses, and bindings to VLANs on a Citrix ADC appliance. An enabled interface or channel has a black label. A disabled interface or channel has a red label.

This complete picture of the appliance's network connections can be useful for detecting flaws in the network design and for optimizing the network. It can also help a new administrator easily understand the appliance's network configuration.

To open the Network Visualizer:

Navigate to **System > Network**. In **Monitor Connections**, click **Network Visualizer**.

## Configuring Link Layer Discovery Protocol

September 21, 2020

The Citrix ADC supports the industry standard (IEEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the Citrix ADC to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbor devices.

### Note:

Link Layer Discovery Protocol (LLDP) is supported only in Citrix ADC MPX platforms.

Using LLDP, the Citrix ADC transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs). An LLDPDU is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The Citrix ADC sends the following TLVs in each LLDPDU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

**Note:** You cannot specify the TLVs to be sent in LLDP messages.

Citrix ADC interfaces support the following LLDP modes:

- **NONE.** The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER.** The interface transmits LLDP messages to the directly connected device but does not receive LLDP messages from the directly connected device.

- **RECEIVER.** The interface receives LLDP messages from the directly connected device but does not transmit LLDP messages to the directly connected device.
- **TRANSCEIVER.** The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings: [Interface and global level LLDP modes](#).

Note the following points related to LLDP messages transmitted or received by the Citrix ADC:

- **Transmitting LLDP messages.** The Citrix ADC transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

Following are the global LLDP transmitting parameters on the Citrix ADC:

- **Timer.** Interval, in seconds, between LLDPUs that the Citrix ADC sends to a directly connected device.
- **Holdtime Multiplier.** A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the **Holdtime Multiplier** parameter value multiplied by the Timer parameter value.
- **Receiving LLDP Messages.** The Citrix ADC stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The Citrix ADC retains this LLDP information for the duration specified in the received LLDPDU.

If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.

## Configuration Steps

Configuring LLDP on a Citrix ADC appliance consists of the following tasks:

1. **Set global level LLDP parameters.** In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.
2. **Set the interface level LLDP parameters.** In this task, you set the LLDP mode for an interface.
3. **(Optional) Display neighbor-device information.** You can display the neighbor-device LLDP information collected on all of the Citrix ADC's interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a Citrix ADC:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).
2. Verify that you have configured LLDP on the desired directly connected devices.

### CLI procedures

To set global level LLDP parameters by using the CLI:

At the command prompt, type:

- **set lldp param** [-[-holdtimeTxMult <positive\_integer>][-timer <positive\_integer>] [-Mode <Mode>]
- **show lldp param**

To configure an interface for LLDP by using the CLI:

At the command prompt, type:

- **set interface** <id> -lldpmode <lldpmode>
- **show interface** <id>

To display neighbor device information by using the CLI:

At the command prompt, type one of the following commands:

- **show lldp neighbors**
- **show lldp neighbors** <ifnum>

### GUI procedures

To set the global level LLDP parameters by using the GUI:

1. Navigate to **System > Network**, and click Configure LLDP Parameters.
2. Set the following parameters:
  - Hold Timer Multiplier
  - Timer
  - Mode

To configure an interface for LLDP by using the GUI:

Navigate to **System > Network > Interfaces**, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the GUI:

Navigate to **System > Network > Interfaces** and, in the Action list, select **View LLDP Neighbors**.

## LLDP Support in a Cluster Setup

In a cluster setup, the GUI and the CLI display the LLDP neighbor configuration of all or specific cluster nodes when the GUI or CLI is accessed through the Cluster IP address (CLIP). Any change made to the global level LLDP mode is applied to the global level on each of the cluster nodes.

Consider an example of a cluster setup of three nodes, NS1, NS2, and NS3. Each of these nodes are connected to both routers Router-1 and Router-2. The following output is displayed when the **show lldp neighbor -summary** operation is performed on the Cluster CLI that is accessed through the Cluster IP address (CLIP) of the cluster setup. The output shows the LLDP neighbor information of all these nodes.

```
1 > show lldp neighbor -summary
2
3 Node Id: 1
4 -----
5      Interface      ChassisId          PortId      System name
6 -----
7 1      1/1/1          fe:c7:3b:13:bd:11  1/1         Router-1
8
9 2      1/1/2          12:68:7b:9e:4c:11  1/1         Router-2
10
11 Node Id: 2
12 -----
13      Interface      ChassisId          PortId      System name
14 -----
15 1      2/1/1          fe:c7:3b:13:bd:12  1/2         Router-1
16
17 2      2/1/2          12:68:7b:9e:4c:12  1/2         Router-2
18
19 Node Id: 3
20 -----
21      Interface      ChassisId          PortId      System name
22 -----
23
24 1      3/1/1          fe:c7:3b:13:bd:13  1/3         Router-1
25
26 2      3/1/2          12:68:7b:9e:4c:13  1/3         Router-2
27
28 Done
29 <!--NeedCopy-->
```

## Jumbo Frames

September 21, 2020

Citrix ADC appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A Citrix ADC appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The Citrix ADC appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS

## Configuring Jumbo Frames Support on a Citrix ADC Appliance

October 20, 2020

To enable the Citrix ADC appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the Citrix ADC appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a Citrix ADC appliance

1. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
2. The MTU for a channel is propagated to all the bound interfaces.
3. When an interface is bound to the channel whose MTU is different from the interface's MTU, the interface goes onto the inactive list.
4. When you change the MTU of a member interface, the interface goes onto the inactive list.

5. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
6. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
7. You cannot set the MTU on the default VLAN. The Citrix ADC appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
8. For TCP based traffic on a load balancing configuration on a Citrix ADC appliance, MSSs are set accordingly at each end point for supporting jumbo frames:
  - For a connection between a client and a load balancing virtual server on the Citrix ADC appliance, the MSS on the Citrix ADC appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
  - For a connection between the Citrix ADC appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the Citrix ADC appliance.
  - By default, a TCP profile `nstcp_default_profile` is bound to all TCP based load balancing servers and services on the Citrix ADC appliance.
  - For supporting jumbo frames, you can either change the MSS value of the TCP profile `nstcp_default_profile`, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.
  - The default MSS value of any TCP profile is 1460.

## CLI procedures

To set the MTU of an interface by using the CLI:

At the command prompt, type:

- `set interface <id> -mtu <positive_integer>`
- `show interface <id>`

### Example:

```
1 > set interface 10/1 - mtu 9000
2 Done
3 <!--NeedCopy-->
```

To set the MTU of a channel by using the CLI:

At the command prompt, type:

- `set channel <id> -mtu <positive_integer>`
- `show channel <id>`

### Example:

```
1 > set channel LA/1 - mtu 9000
2 Done
3 <!--NeedCopy-->
```

To set the MTU of a VLAN by using the CLI:

At the command prompt, type:

- add vlan <id> -mtu <positive\_integer>
- show vlan <id>

**Example:**

```
1 > set vlan 20 - mtu 9000
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To set the MTU of an interface by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the GUI:

Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the GUI:

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

## Use Case 1 – Jumbo to Jumbo Setup

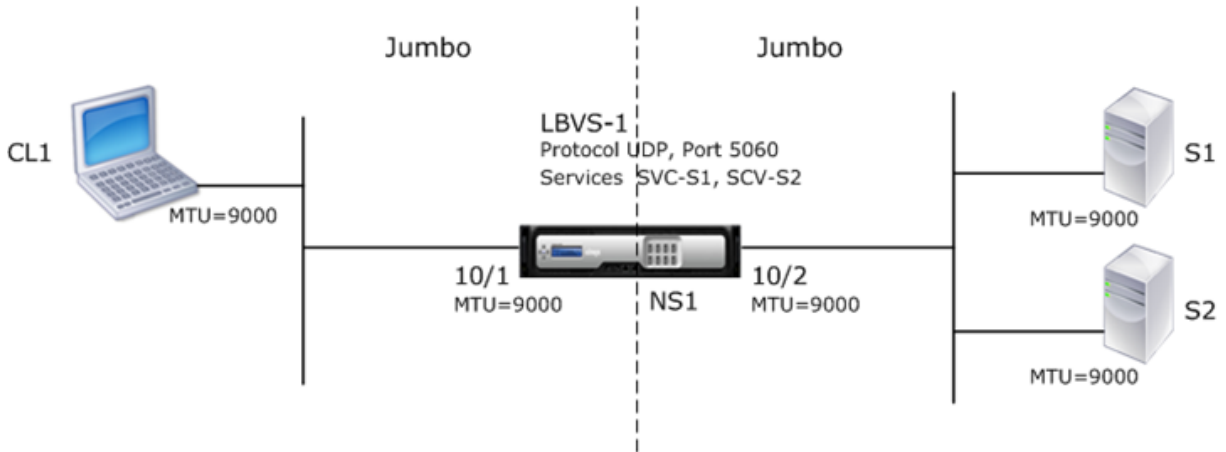

September 21, 2020

Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on Citrix ADC appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.

The following table lists the settings used in the example.

| Entity                                        | Name    | Details                                                                      |
|-----------------------------------------------|---------|------------------------------------------------------------------------------|
| IP address of client CL1                      | -       | 192.0.2.10                                                                   |
| IP address of servers                         | S1      | 198.51.100.19                                                                |
|                                               | S2      | 198.51.100.20                                                                |
| SNIP address on NS1                           |         | 198.51.100.18                                                                |
| MTU specified for interfaces and VLANs on NS1 | 10/1    | 9000                                                                         |
|                                               | 10/2    | 9000                                                                         |
|                                               | VLAN 10 | 9000                                                                         |
|                                               | VLAN 20 | 9000                                                                         |
| Services on NS1 representing servers          | SVC-S1  | <b>IP address:</b> 198.51.100.19,<br><b>Protocol:</b> SIP, <b>Port:</b> 5060 |
|                                               | SVC-S2  | <b>IP address:</b> 198.51.100.20,<br><b>Protocol:</b> SIP, <b>Port:</b> 5060 |

| Entity                                   | Name   | Details                                                                                                                  |
|------------------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------|
| Load balancing virtual server on VLAN 10 | LBVS-1 | <b>IP address:</b> 203.0.113.15,<br><b>Protocol:</b> SIP, <b>Port:</b> 5060,<br><b>Bound services:</b> SVC-S1,<br>SVC-S2 |

Following is the traffic flow of CL1's request to NS1:

1. CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
2. CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
  - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
  - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
  - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 2048] = 2068
3. NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
4. NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
5. LBVS-1's load balancing algorithm selects server S1.
6. NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal to or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.
  - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
  - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
  - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 2048] = 2068

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.
2. S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.
  - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000

- Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
  - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088
3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.
  4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.
  5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1's IP address.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

## Configuration Tasks

The following table list the tasks, Citrix ADC commands, and examples for creating the required configuration on the Citrix ADC appliance.

| Task                                                                          | Citrix ADC Command Syntax                                       | Example                                           |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------|---------------------------------------------------|
| Set the MTU of the desired interfaces for supporting jumbo frames             | set interface <id> -mtu <positive_integer>, show interface <id> | set int 10/1 -mtu 9000 set int 10/2 -mtu 9000     |
| Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames | add vlan <id> -mtu <positive_integer>, show vlan <id>           | add vlan 10 -mtu 9000 add vlan 20 -mtu 9000       |
| Bind interfaces to VLANs                                                      | bind vlan <id> -ifnum <interface_name>, show vlan <id>          | bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2 |
| Add a SNIP address                                                            | add ns ip <IPAddress> <netmask> -type SNIP, show ns ip          | add ns ip 198.51.100.18 255.255.255.0 -type SNIP  |

| Task                                                                  | Citrix ADC Command Syntax                                                                                                 | Example                                                                                                              |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Create services representing SIP servers                              | add service <serviceName><br><ip> SIP_UDP <port>, show<br>service <name>                                                  | add service SVC-S1<br>198.51.100.19 SIP_UDP 5060<br>add service SVC-S2<br>198.51.100.20 SIP_UDP 5060                 |
| Create SIP load balancing virtual servers and bind the services to it | add lb vserver <name><br>SIP_UDP <ip> <port> bind lb<br>vserver <vserverName><br><serviceName>, show lb<br>vserver <name> | add lb vserver LBVS-1<br>SIP_UDP 203.0.113.15 5060<br>bind lb vserver LBVS-1 SVC-S1<br>bind lb vserver LBVS-1 SVC-S2 |
| Save the configuration                                                | save ns config, show ns config                                                                                            |                                                                                                                      |

## Use Case 2 – Non-Jumbo to Jumbo Setup

September 21, 2020

Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.

Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S1 ) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp\_default\_profile is used that is by default bound to LBVS-1 and

has the MSS set to the default value of 1460.

The following table lists the settings used in this example.

| Entity                                        | Name                  | Details                                                                                         |
|-----------------------------------------------|-----------------------|-------------------------------------------------------------------------------------------------|
| IP address of client CL1                      |                       | 192.0.2.10                                                                                      |
| IP address of servers                         | S1                    | 198.51.100.19                                                                                   |
|                                               | S2                    | 198.51.100.20                                                                                   |
| SNIP address on NS1                           |                       | 198.51.100.18                                                                                   |
| MTU specified for interfaces and VLANs on NS1 | 10/1                  | 1500                                                                                            |
|                                               | 10/2                  | 9000                                                                                            |
|                                               | VLAN 10               | 1500                                                                                            |
|                                               | VLAN 20               | 9000                                                                                            |
| Default TCP profile                           | nstcp_default_profile | MSS:1460                                                                                        |
| Custom TCP profile                            | NS1-SERVERS-JUMBO     | MSS: 8960                                                                                       |
| Services on NS1 representing servers          | SVC-S1                | IP address: 198.51.100.19, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960) |

| Entity                                      | Name   | Details                                                                                                                                          |
|---------------------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
|                                             | SVC-S2 | IP address: 198.51.100.20,<br>Protocol: HTTP, Port: 80, TCP<br>profile: NS1-SERVERS-JUMBO<br>(MSS: 8960)                                         |
| Load balancing virtual server<br>on VLAN 10 | LBVS-1 | IP address = 203.0.113.15,<br>Protocol: HTTP, Port:80,<br>Bound services: SVC-S1,<br>SVC-S2, TCP Profile:<br>nstcp_default_profile<br>(MSS:1460) |

Following is the traffic flow of CL1's request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1's MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.

Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240

4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
6. Because S1's MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.

Size of the request packet = [IP Header + TCP Header + [TCP Request] = [20 + 20 + 200] = 240

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.

- Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000

- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
3. NS1 receives the response packets at interface 10/2.
  4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.
  5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
    - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
    - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

## Configuration Tasks

The following table lists the tasks, Citrix ADC commands, and examples for creating the required configuration on the Citrix ADC appliance.

| Tasks                                                                         | CLI Syntax                                                      | Examples                                                                           |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------|------------------------------------------------------------------------------------|
| Set the MTU of the desired interfaces for supporting jumbo frames             | set interface <id> -mtu <positive_integer>, show interface <id> | set int 10/1 -mtu 1500 set int 10/2 -mtu 9000                                      |
| Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames | add vlan <id> -mtu <positive_integer>, show vlan <id>           | add vlan 10 -mtu 1500 add vlan 20 -mtu 9000                                        |
| Bind interfaces to VLANs                                                      | bind vlan <id> -ifnum <interface_name>, show vlan <id>          | bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2                                  |
| Add a SNIP address                                                            | add ns ip <IPAddress> <netmask> -type SNIP, show ns ip          | add ns ip 198.51.100.18 255.255.255.0 -type SNIP                                   |
| Create services representing HTTP servers                                     | add service <serviceName> <ip> HTTP <port>, show service <name> | add service SVC-S1 198.51.100.19 http 80, add service SVC-S2 198.51.100.20 http 80 |

| Tasks                                                                   | CLI Syntax                                                                                                  | Examples                                                                                                   |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Create HTTP load balancing virtual servers and bind the services to it  | add lb vserver <name> HTTP <ip> <port>, bind lb vserver <vserverName> <serviceName>, show lb vserver <name> | add lb vserver LBVS-1 http 203.0.113.15 80, bind lb vserver LBVS-1 SVC-S1, bind lb vserver LBVS-1 SVC-S2   |
| Create a custom TCP profile and set its MSS for supporting jumbo frames | add tcpProfile <name> -mss <positive_integer>, show tcpProfile <name>                                       | add tcpprofile NS1-SERVERS-JUMBO -mss 8960                                                                 |
| Bind the custom TCP profile to the desired services                     | set service <Name> -tcpProfileName <string>, show service <name>                                            | set service SVC-S1 -tcpProfileName NS1-SERVERS-JUMBO, set service SVC-S2 -tcpProfileName NS1-SERVERS-JUMBO |
| Save the configuration                                                  | save ns config, show ns config                                                                              |                                                                                                            |

### Use Case 3 – Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

September 21, 2020

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on Citrix ADC appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.

CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

The effective MTU on a Citrix ADC interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.

The following table lists the settings used in this example: [Jumbo frames use case 3 example settings](#).

Following is the traffic flow of CL1's request to S1:

- Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
- CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.
- Because NS1's MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 10 to NS1.
  - Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
- NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
- From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
- LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
- NS1 segments the request data into multiples of S1's MSS and sends these segments in IP pack-

ets tagged as VLAN 20 to S1.

- Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1's response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
  - Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS's IP address and destined to CL1's IP address.
  - Size of first three packet = [IP Header + TCP Header + ((TCP payload=CL1's MSS size))] = [20 + 20 + 8960] = 9000
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

## Configuration Tasks

Following table lists tasks, commands, and examples for creating the required configuration on the Citrix ADC appliance: [Jumbo frames use case 3 configuration tasks](#).

## Citrix ADC Support for Microsoft Direct Access Deployment

September 21, 2020

Microsoft Direct Access is a technology that enables remote users to seamlessly and securely connect to the enterprise's internal networks, without the need to establish a separate VPN connection. Un-

like VPN connections, which require user intervention to open and close connections, a Direct Access-enabled client connects automatically to the enterprise's internal networks whenever the client connects to the Internet.

Manage-Out is a Microsoft Direct Access feature that allows administrators inside the enterprise network to connect to Direct Access clients outside the network and manage them (for example, performing administration tasks, such as scheduling service updates, and providing remote support).

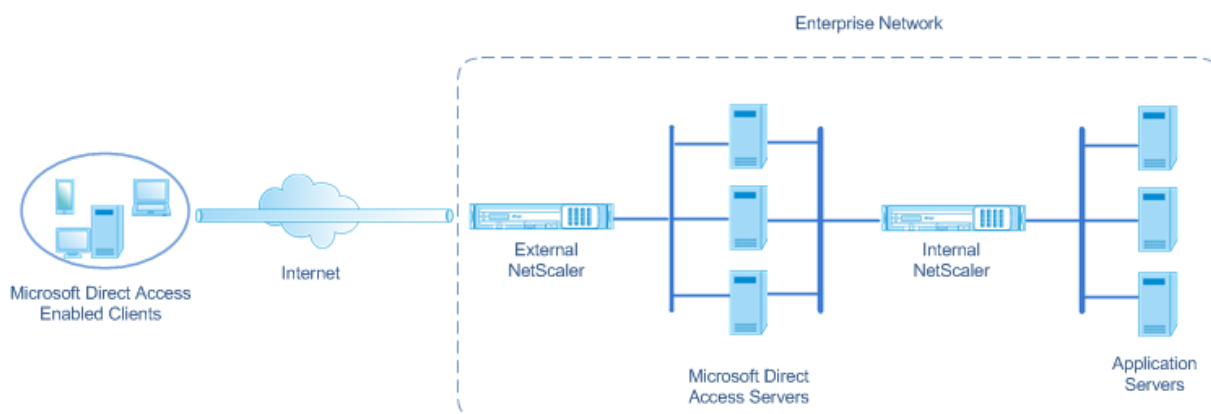

In a Direct Access deployment, Citrix ADC appliances provide high availability, scalability, high performance, and security. Citrix ADC load balancing functionality sends client traffic through the most appropriate server. The appliances can also forward Manage-Out traffic through the right path to reach the client.

## Architecture

The architecture of a Microsoft Direct Access deployment consists of Direct Access enabled clients, Direct Access servers, application servers, and internal and external Citrix ADC appliances. Clients connect to an application server through a Direct Access server. An external Citrix ADC appliance load balance the client traffic to a Direct Access server, and an Internal Citrix ADC appliance forwards the client traffic from the Direct Access server to the destination application server. Direct Access is used for tunneling the client's IPv6 traffic over the IPv4 network. An IPv4 load balancing virtual server on the external Citrix ADC appliance load balances the client's tunneled traffic to one of the Direct Access servers. The Direct Access server extracts the IPv6 packets from the received client's IPv4 packets and sends them to the destination application server through the internal Citrix ADC appliance. The Internal Citrix ADC appliance has forwarding session rules with the source route cache option enabled for storing Layer 2 and Layer 3 connection information about the client's traffic from the Direct Access Server. The Citrix ADC appliance stores the following Layer 2 and Layer 3 information in a table called the source route cache table:

- Source IP address of the received packet
- MAC address of the Direct Access server that sent the packet
- VLAN ID of the Citrix ADC appliance that received the packet
- Interface ID of the Citrix ADC appliance that received the packet

The Citrix ADC appliance uses the information in the source route cache table for forwarding a response to the same Direct Access server because it has the tunneling information to reach the client. Also, the Internal appliance uses the source route cache table to forward application server's Manage-out traffic to the appropriate Direct Access server to reach a particular client.

## Configuring the Internal Citrix ADC Appliance in a Microsoft Direct Access Deployment

To configure the Internal Citrix ADC appliance for forwarding an application server's response and manage-out traffic to the appropriate Direct Access Gateway, configure forwarding session rules. In each rule, set the `sourceroutecache` parameter to `ENABLED`.

To create a forwarding session rule by using the CLI:

At the command prompt, type:

- **add forwardingSession** <name> ((<network> [<netmask>]) | **-acl6name** <string> | **-aclname** <string>) **-sourceroutecache** ( **ENABLED** | **DISABLED** )
- **show forwardingSession** <name>

### Sample configuration:

In the following example, forwarding-session rule `MS-DA-FW-1` is created on the internal Citrix ADC appliance. The forwarding session stores Layer 2 and Layer 3 information for any incoming IPv6 packets from a Direct Access server that matches source IPv6 prefix `2001:DB8::/96`.

```
1 > add forwardingSession MS-DA-FW-1 2001:DB8::/96 -sourceroutecache -
   ENABLED
2 Done
```

## Displaying the Source Route Cache Table

You can display the source route cache table for monitoring or detecting any unwanted connections between direct access servers and application servers.

To display the source route cache table by using the CLI:

At the command prompt, type:

- **show sourceroutecachetable**

**Example:**

```
1 > show sourceroutecachetable
2 SOURCEIP          MAC          VLAN    INTERFACE
3 2001:DB8:5001:10  56:53:24:3d:02:eb  30      1/2
4 2001:DB8:5003:30  60:54:35:3e:04:bd  60      1/3
5 Done
```

## Clearing the Source Route Cache Table

You can clear all the entries from the source route cache table on a Citrix ADC appliance.

To clear the source route cache table by using the CLI:

At the command prompt, type:

- **flush ns sourceroutecachetable**

## Access Control Lists

September 21, 2020

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the Citrix ADC evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the Citrix ADC receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- **ALLOW**—Process the packet.
- **BRIDGE**—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- **DENY**—Drop the packet.

ACL rules are the first level of defense on the Citrix ADC.

Citrix ADC supports the following types of ACLs:

- **Simple ACLs** filter packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.

- **Extended ACLs** filter data packets on the basis of various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the Citrix ADC to process the packet, bridge the packet, or drop the packet.

## Nomenclature

In the Citrix ADC user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.

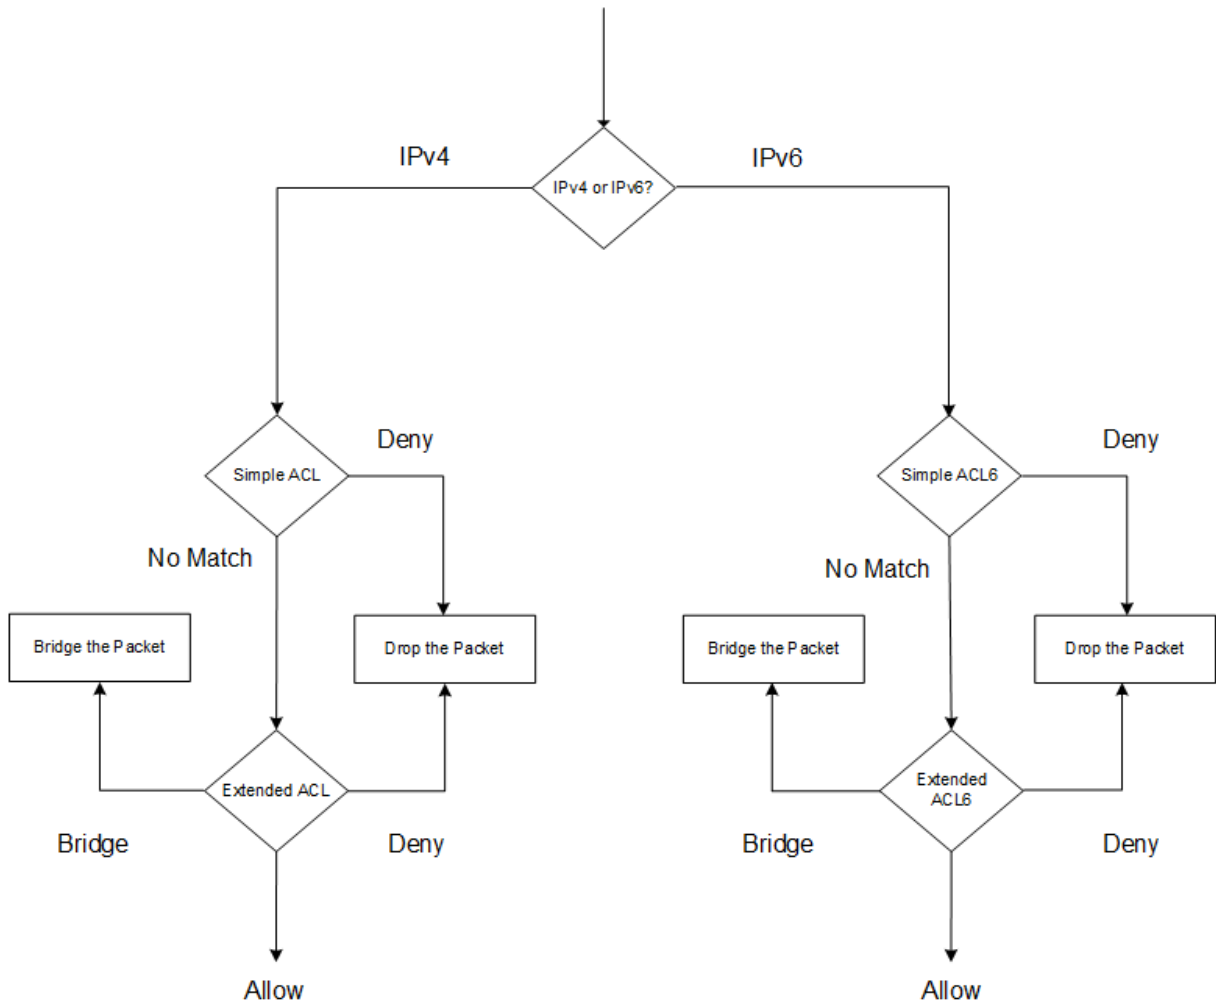

## ACL Precedence

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The Citrix ADC first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s. If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence

## Simple ACLs and Simple ACL6s

September 21, 2020

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

### Configuring Simple ACLs and Simple ACL6s

Configuring a simple ACL or simple ACL6 on a Citrix ADC can include the following tasks.

- **Create simple ACLs or simple ACL6s.** Creating simple ACLs or simple ACL6s to drop (deny) packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.
- **Remove simple ACLs or simple ACL6s.** These ACLs cannot be modified once created. If you need to modify a simple ACL or simple ACL6, you must remove it and create a new one.

### CLI procedures

To create a simple ACL by using the CLI:

At the command prompt, type:

- **add ns simpleacl** <aclname> DENY -srcIP <ip\_addr> [-destPort<port> -protocol ( TCP | UDP )] [-TTL <positive\_integer>]
- **show ns simpleacl** [<aclname>]

#### Example:

```
1 > add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
2 Done
3 <!--NeedCopy-->
```

To create a simple ACL6 by using the CLI:

At the command prompt, type:

- **add ns simpleacl6** <aclname> DENY -srcIPv6 <ipv6\_addr|null> [-destPort<port> -protocol ( TCP | UDP )] [-TTL <positive\_integer>]
- **show ns simpleacl6** [<aclname>]

#### Example:

```
1 > add ns simpleacl6 rule1 DENY - srcIPv6 3ffe:192:168:215::82 -
    destPort 80 -Protocol TCP -TTL 9000
2 Done
3 <!--NeedCopy-->
```

To remove a single simple ACL by using the CLI:

At the command prompt, type:

- **rm ns simpleacl** <aclname>
- **show ns simpleacl**

To remove a single simple ACL6 by using the CLI:

At the command prompt, type:

- **rm ns simpleacl6**<aclname>

- **show ns simpleacl6**

To remove all simple ACLs by using the CLI:

At the command prompt, type:

- **clear ns simpleacl**
- **show ns simpleacl**

To remove all simple ACL6s by using the CLI:

At the command prompt, type:

- **clear ns simpleacl6**
- **show ns simpleacl6**

### GUI procedures

To create a simple ACL by using the GUI:

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, add a new simple ACL.

To create a simple ACL6 by using the GUI:

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, add a new simple ACL6.

To remove a single simple ACL by using the GUI:

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, delete the simple ACL.

To remove a single simple ACL6 by using the GUI:

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, delete the simple ACL6.

To remove all simple ACLs by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Clear**.

To remove all simple ACL6s by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Clear**.

### Displaying Simple ACL and Simple ACL6 Statistics

You can display the simple ACL (or simple ACL6) statistics, which include the number of hits, the number of misses, and the number of simple ACLs configured.

The following table describes statistics you can display for simple ACLs and simple ACL6s.

| Statistics | Indicates                    |
|------------|------------------------------|
| ACL hits   | Packets matching an ACL      |
| ACL misses | Packets not matching any ACL |
| ACL count  | Number of ACLs configured    |

### CLI procedures

To display simple ACL statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl**

#### Example:

```

1 > stat ns simpleacl
2
3 SimpleACL Statistics
4
5                                     Rate (/s)
6 SimpleACL hits                       Total
7 SimpleACL misses                       0
   51872
8 SimpleACLs count                       --
   2
9 Done
10 <!--NeedCopy-->

```

To display simple ACL6 statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl6**

### GUI procedures

To display simple ACL statistics by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, select the ACL and click **Statistics**.

To display simple ACL6 statistics by using the GUI:

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, select the simple ACL6 and click **Statistics**.

## Terminating Established Connections

For a simple ACL or simple ACL6, the Citrix ADC blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the CLI or the GUI.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the Citrix ADC. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate a large number of connections from a particular network without taking the time to terminate them one by one.

## Before you begin

- When you run flush, the Citrix ADC searches through all of its established connections and terminates those that match conditions specified in any of the simple ACLs configured on the ADC.
- If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all of the simple ACLs and then running flush only once.

## CLI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the CLI:

At the command prompt, type:

- **flush simpleacl -estSessions**

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the CLI:

At the command prompt, type:

- **flush simpleacl6 -estSessions**

## GUI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.

## Extended ACLs and Extended ACL6s

August 31, 2021

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data on the basis of parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

**Note:** If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.

The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the Citrix ADC to log details for packets that match an extended ACL.

**Applying Extended ACLs and Extended ACL6s:** Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the Citrix ADC do not work until they are applied. Also, if you make any modifications to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must reapply the extended ACLs or ACL6s. You must also reapply them after enabling logging. The procedure to apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the Citrix ADC starts comparing incoming packets against them. However, if you disable them, they are not used until you

reenable them, even if they are reapplied.

**Renumbering the priorities of Extended ACLs and Extended ACL6s:** Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the Citrix ADC automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

## Configuring Extended ACLs and Extended ACL6s

Configuring an extended ACL or ACL6 on a Citrix ADC consists of the following tasks.

- **Create an extended ACL or ACL6.** Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.
- (Optional) **Modify an extended ACL or ACL6.** You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenale it.
- **Apply extended ACLs or ACL6s.** After you create, modify, disable or reenale, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.
- (Optional) **Renumber the priorities of extended ACLs or ACL6s.** If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

## CLI procedures

To create an extended ACL by using the CLI:

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive\_integer>] [-**srcMac** <mac\_addr>] [(**-protocol** <protocol> [-established]) | **-protocolNumber** <positive\_integer>] [-**vlan** <positive\_integer>] [-**interface** <interface\_name>] [-**icmpType** <positive\_integer> [-**icmpCode** <positive\_integer>]] [-**priority** <positive\_integer>] [-**state** ( ENABLED | DISABLED )] [-**logstate** ( ENABLED | DISABLED )] [-**ratelimit** <positive\_integer>]]
- **show ns acl** [<aclName>]

**Example:**

```
1 > add ns acl restrict DENY -srcport 45-1024 -destIP 192.168.1.1 -
   protocol TCP
2 Done
3 <!--NeedCopy-->
```

To create an extended ACL6 by using the CLI:

At the command prompt, type:

- **add ns acl6** <acl6name> <acl6action> [-**srcIPv6** [<operator>] <srcIPv6Val>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIPv6** [<operator>] <destIPv6Val>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive\_integer>] [-**srcMac** <mac\_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive\_integer>] [-**vlan** <positive\_integer>] [-**interface** <interface\_name>] [-**icmpType** <positive\_integer> [-icmpCode <positive\_integer>]] [-**priority** <positive\_integer>] [-**state** ( ENABLED | DISABLED )]
- **show ns acl6** [<aclName>]

**Example:**

```
1 > add ns acl6 rule6 DENY -srcport 45-1024 -destIPv6 2001::45 -protocol
   TCP
2 Done
3 <!--NeedCopy-->
```

**To modify an extended ACL by using the CLI:**

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

**To modify an extended ACL6 by using the CLI:**

To modify an extended ACL6, type the **set ns acl6** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

**To disable or enable an extended ACL by using the CLI:**

At the command prompt, type one of the following commands:

- **disable ns acl** <aclname>
- **enable ns acl** <aclname>

**To disable or enable an extended ACL6 by using the CLI:**

At the command prompt, type one of the following commands:

- **disable ns acl6** <aclname>
- **enable ns acl6** <aclname>

**To apply extended ACLs by using the CLI:**

At the command prompt, type:

- **apply ns acls**

**To apply extended ACL6s by using the CLI:**

At the command prompt, type:

- **apply ns acls6**

**To renumber the priorities of extended ACLs by using the CLI:**

At the command prompt, type:

- **renumber ns acls**

**To renumber the priorities of extended ACL6s by using the CLI:**

At the command prompt, type:

- **renumber ns acls6**

**GUI procedures**

**To configure an extended ACL by using the GUI:**

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

**To configure an extended ACL6s by using the GUI:**

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL6 or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

**To apply extended ACLs by using the GUI:**

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

**To apply extended ACL6s by using the GUI:**

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Apply**.

**To renumber the priorities of extended ACLs by using the GUI:**

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

**To renumber the priorities of extended ACL6s by using the GUI:**

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Renumber Priority (s)**.

## Sample Configurations

The following table shows examples of configuring extended ACL rules through the command line interface: [ACLs sample configurations](#).

## Logging Extended ACLs

You can configure the Citrix ADC to log details for packets that match extended ACLs.

**Note:** You cannot enable logging for extended ACL6s.

In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the nslog file, depending on the type of global logging (syslog or nslog) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence. For more information about enabling logging globally, see “.”

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the Citrix ADC performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

**Note:** You must apply ACLs after you enable logging.

## CLI procedures

To configure extended ACL Logging by using the CLI:

At the command prompt, type the following commands to configure logging and verify the configuration:

- **set ns acl** <aclName> [-logState (ENABLED | DISABLED)] [-rateLimit <positive\_integer>]
- **show ns acl** [<aclName>]

### Example:

```
1 > set ns acl restrict -logstate ENABLED -ratelimit 120
2 Warning: ACL modified, apply ACLs to activate change
3 <!--NeedCopy-->
```

## GUI procedures

To configure extended ACL Logging by using the GUI:

1. Navigate to System > Network > ACLs and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
  - **Log State**—Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.
  - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

## Extended ACL6 Logging

You can configure the Citrix ADC appliance to log details for packets that match an extended ACL6 rule. In addition to the ACL6 name, the logged details include packet-specific information, such as the source and destination IP addresses. The information is stored either in a syslog or nslog file, depending on the type of logging (syslog or nslog) that you have configured in the Citrix ADC appliance.

To optimize logging, when multiple packets from the same flow match an ACL6, only the first packet's details are logged. The counter is incremented for every other packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the following parameters:

- Source IP
- Destination IP
- Source port
- Destination port
- Protocol (TCP or UDP)

If an incoming packet is not from the same flow, a new flow is created. The total number of different flows that can be logged at any given time is limited to 10,000.

## CLI procedures

To configure logging for an extended ACL6 rule by using the CLI:

- To configure logging while adding the extended ACL6 rule, at the command prompt, type:
  - **add acl6** <acl6Name> <acl6action> [-logState (ENABLED | DISABLED)] [-rateLimit <positive\_integer>]
  - **show acl6** [<acl6Name>]
  - **apply acls6**
- To configure logging for an existing extended ACL6 rule, at the command prompt, type:
  - **set acl6** <acl6Name> [-logState (ENABLED | DISABLED)] [-rateLimit <positive\_integer>]
  - **show acl6** [<acl6Name>]

## - apply acls6

### GUI procedures

To configure extended ACL6 Logging by using the GUI:

1. Navigate to **System > Network > ACLs** and, then click the **Extended ACL6s** tab.
2. Set the following parameters while adding, or modifying an existing extended ACL6 rule.
  - **Log State**—Enable or disable logging of events related to the extended ACL6s rule. The log messages are stored in the configured syslog or auditlog server.
  - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the **Log State** parameter.

### Example:

```

1 > set acl6 ACL6-1 -logstate ENABLED -ratelimit 120
2 Done
3
4 > apply acls6
5 Done
6 <!--NeedCopy-->

```

### Displaying Extended ACL and Extended ACL6s Statistics

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

| Statistic       | Specifies                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------|
| Allow ACL hits  | Packets matching ACLs with processing mode set to ALLOW. The Citrix ADC processes these packets. |
| NAT ACL hits    | Packets matching a NAT ACL, resulting in a NAT session.                                          |
| Deny ACL hits   | Packets dropped because they match ACLs with processing mode set to DENY.                        |
| Bridge ACL hits | Packets matching a bridge ACL, which in transparent mode bypasses service processing.            |
| ACL hits        | Packets matching an ACL.                                                                         |

ACL misses

Packets not matching any ACL.

### CLI procedures

To display the statistics of all extended ACLs by using the CLI:

At the command prompt, type:

- **stat ns acl**

To display the statistics of all extended ACL6s by using the CLI:

At the command prompt, type:

- **stat ns acl6**

### GUI procedures

To display the statistics of an extended ACL by using the GUI:

Navigate to System > Network > ACLs, on the **Extended ACLs** tab, select the extended ACL, and click **Statistics**.

To display the statistics of an extended ACL6 by using the GUI:

Navigate to System > Network > ACLs, on the **Extended ACL6s** tab, select the extended ACL, and click **Statistics**.

### Stateful ACLs

A stateful ACL rule creates a session when a request matches the rule and allows the resulting responses even if these responses matches a deny ACL rule in Citrix ADC appliance. A stateful ACL offloads the work of creating additional ACL rules/forwarding session rules for allowing these specific responses.

Stateful ACLs can be best used in an edge firewall deployment of a Citrix ADC appliance having the following requirements:

- The Citrix ADC appliance must allow requests initiated from internal clients and the related responses from the Internet.
- The appliance must drop the packets from the Internet that are not related to any client connections.

## Before you begin

Before you configure stateful ACL rules, note the following points:

- The Citrix ADC appliance supports stateful ACL rules as well as stateful ACL6 rules.
- In a high availability setup, the sessions for a stateful ACL rule are not synchronized to the secondary node.
- You cannot configure an ACL rule as stateful if the rule is bound to any Citrix ADC NAT configuration. Some examples of Citrix ADC NAT configurations are:
  - RNAT
  - Large Scale NAT (large scale NAT44, DS-Lite, large scale NAT64)
  - NAT64
  - Forwarding session
- You cannot configure an ACL rule as stateful if TTL and Established parameters are set for this ACL rule.
- The sessions created for a stateful ACL rule continue to exist till timeout irrespective of the following ACL operations:
  - Remove ACL
  - Disable ACL
  - Clear ACL
- Stateful ACLs are not supported for the following protocols:
  - Active FTP
  - TFTP

## Configure stateful IPv4 ACL rules

Configuring a stateful ACL rule consists of enabling the stateful parameter of an ACL rule.

To enable the stateful parameter of an ACL rule by using the CLI:

- To enable the stateful parameter while adding an ACL rule, at the command prompt, type:
  - add acl <lname> ALLOW -stateful ( **ENABLED** | **DISABLED** )
  - apply acls
  - show acl <name>
- To enable the stateful parameter of an existing ACL rule, at the command prompt, type:
  - set acl <name> -stateful ( **ENABLED** | **DISABLED** )
  - apply acls
  - show acl <name>

To enable the stateful parameter of an ACL rule by using the GUI:

1. Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL rule.

```
1 > add acl ACL-1 allow -srcIP 1.1.1.1 -stateful Yes
2
3 Done
4
5 > apply acls
6
7 Done
8
9 > show acl
10
11 1)          Name: ACL-1
12
13 Action: ALLOW                               Hits: 0
14
15 srcIP = 1.1.1.1
16
17 destIP
18
19 srcMac:
20
21 Protocol:
22
23 Vlan:   Interface:
24
25 Active Status: ENABLED                       Applied Status: NOTAPPLIED
26
27 Priority: 10                                  NAT: NO
28
29 TTL:
30
31 Log Status: DISABLED
32
33 Forward Session: NO
34
35 Stateful: YES
36
37 <!--NeedCopy-->
```

### Configure stateful ACL6 rules

Configuring a stateful ACL6 rule consists of enabling the stateful parameter of an ACL6 rule.

To enable the stateful parameter of an ACL6 rule by using the CLI:

- To enable the stateful parameter while adding an ACL6 rule, at the command prompt, type:
  - add acl6 <name> ALLOW -stateful ( **ENABLED** | **DISABLED** )
  - apply acls6
  - show acl6 <name>
- To enable the stateful parameter of an existing ACL6 rule, at the command prompt, type:
  - set acl6 <name> -stateful ( **ENABLED** | **DISABLED** )
  - apply acls6
  - show acl6 <name>

To enable the stateful parameter of an ACL6 rule by using the CLI:

1. Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL6 rule.

```
1 > add acl6 ACL6-1 allow -srcip6 1000::1 - stateful Yes
2
3 Done
4
5 > apply acls6
6
7 Done
8
9 > show acl6
10
11 1)      Name: ACL6-1
12
13      Action: ALLOW                               Hits: 0
14
15      srcIPv6 = 1000::1
16
17      destIPv6
18
19      srcMac:
20
21      Protocol:
22
23      Vlan:                                       Interface:
24
25      Active Status: ENABLED                     Applied Status: NOTAPPLIED
26
27      Priority: 10                               NAT: NO
28
29      TTL:
30
31      Forward Session: NO
```

```
32
33     Stateful: YES
34 <!--NeedCopy-->
```

## MAC Address Wildcard Mask for ACLs

September 21, 2020

A wildcard mask parameter has been introduced for extended ACLs and ACL6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of incoming packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an ACL, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the incoming packets.

To specify a range of source MAC addresses in an ACL rule by using the CLI:

At the command prompt, type:

- **add ns acl** <name> <action> **-srcMac** <mac\_addr> **-srcMacMask** <string>

- **show ns acl** <aclname>

**Example:**

```
1 > add ns acl ACL-1 ALLOW - protocol TCP - srcport 2000-3000 -srcMac 96:
   fa:95:1d:67:4a
2   - srcMacMask 000000111111
3 Done
4 <!--NeedCopy-->
```

To specify a range of source MAC addresses in an ACL6 rule by using the CLI:

At the command prompt, type:

- **add ns acl6** <name> <action> **-srcMac** <mac\_addr> **-srcMacMask** <string>
- **show ns acl6** <acl6name>

**Example:**

```
1 > add ns acl6 ACL6-1 ALLOW -destIPv6 2001::45 -srcMac 96:fa:90:1d:67:4a
2   - srcMacMask 000000001111
3 Done
4 <!--NeedCopy-->
```

## Blocking Traffic on Internal Ports

September 21, 2020

The Citrix ADC appliance does not block traffic that matches an ACL rule if the traffic is destined to the appliance's NSIP address, or one of its SNIP addresses, and a port in the 3008-3011 range.

This behavior is now specified by the default setting of the new Implicit ACL Allow (implicitACLAllow) parameter (of the L3 param command). You can disable this parameter if you want to block traffic to ports in the 3008-3011 range. An appliance in a high availability configuration makes an exception for its partner (primary or secondary) node. It does not block traffic from that node.

To disable or enable this parameter by using the CLI:

At the command prompt, type:

---

```
set l3param -implicitACLAllow [ENABLED    DISABLED]
```

---

-

- **sh l3param**

**Note:** The parameter `implicitACLAllow` is enabled by default.

**Example:**

```
1 > set l3param -implicitACLAllow DISABLED
2 Done
3 <!--NeedCopy-->
```

## IP Routing

September 21, 2020

Citrix ADC appliances support both dynamic and static routing. Because simple routing is not the primary role of a Citrix ADC, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most Citrix ADC implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

## Configuring Dynamic Routes

September 21, 2020

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone Citrix ADC appliances. Dynamic routing on a Citrix ADC appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see [Dynamic Routing Protocol Command Reference Guides and Unsupported Commands](#).

The Citrix ADC supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2

- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

## **Routing Tables in Citrix ADC**

In a Citrix ADC appliance, the Citrix ADC kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

### **NS Kernel Routing Table**

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the `add ns ip` command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the CLI (CLI). The entries in this table are used by the Citrix ADC in packet forwarding. From the CLI, they can be inspected with the `show route` command.

### **FreeBSD Routing Table**

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a Citrix ADC appliance, these applications are tightly coupled to FreeBSD, and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the Citrix ADC establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the `route` command. The FreeBSD routing table can be inspected by using the `netstat` command from any UNIX shell.

### **Network Services Module (NSM) FIB**

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

- **Connected routes.** IP subnets that are directly reachable from the Citrix ADC. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.
- **Kernel routes.** All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the CLI that have the - advertise option enabled. Alternatively, if the Citrix ADC is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.
- **Static routes.** Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.
- **Learned routes.** If the Citrix ADC is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTYSH.

## Dynamic Routing in a High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

## Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

## Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

## Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the GUI or a command-line interface. The Citrix ADC supports two independent command-line interfaces: the CLI and the Virtual Teletype Shell (VTYSH). The CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The Citrix ADC routing suite is based on ZebOS, the commercial version of GNU Zebra.

### Note:

Citrix recommends that you use VTYSH for all commands except those that can be configured only on the CLI. Use of the CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

## Dynamic Routing Protocol Command Reference Guides and Unsupported Commands

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the Citrix ADC appliance: [Dynamic routing protocol reference guides and unsupported commands](#).

## Configuring RIP

September 21, 2020

Routing Information Protocol (RIP) is a Distance Vector protocol. The Citrix ADC supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

### Enabling and Disabling RIP

Use either of the following procedures to enable or disable RIP. After you enable RIP, the Citrix ADC appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the CLI:

At the command prompt, enter one of the following commands to enable or disable RIP:

- **enable ns feature RIP**
- **disable ns feature RIP**

To enable or disable RIP routing by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change advanced features**.

2. Select or clear the **RIP Routing** option.

## Advertising Routes

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

To configure RIP to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command             | Specifies                                                                           |
|---------------------|-------------------------------------------------------------------------------------|
| VTYSH               | Display VTYSH command prompt.                                                       |
| configure terminal  | Enter global configuration mode.                                                    |
| router rip          | Start the RIP routing process and enter configuration mode for the routing process. |
| redistribute static | Redistribute static routes.                                                         |
| redistribute kernel | Redistribute kernel routes.                                                         |

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router rip
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->
```

## Limiting RIP Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                       | Specifies                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------|
| VTYSH                         | Display VTYSH command prompt.                                                       |
| configure terminal            | Enter global configuration mode.                                                    |
| router rip                    | Start the RIP routing process and enter configuration mode for the routing process. |
| passive-interface <vlan_name> | Suppress routing updates on interfaces bound to the specified VLAN.                 |

**Example:**

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router rip
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

**Verifying the RIP Configuration**

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line:

At the command prompt, type the following commands in the following order:

| Command                      | Specifies                                        |
|------------------------------|--------------------------------------------------|
| VTYSH                        | Display VTYSH command prompt.                    |
| sh rip                       | Display updated RIP routing table.               |
| sh rip interface <vlan_name> | Displays RIP information for the specified VLAN. |

**Example:**

```

1 NS# VTYSH
2 NS# sh rip
3 NS# sh rip interface VLAN0
4 <!--NeedCopy-->

```

## Configuring OSPF

September 21, 2020

The Citrix ADC supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the Citrix ADC are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the Citrix ADC.
- The Citrix ADC can advertise Type-1 or Type-2 external metrics for all routes.
- The Citrix ADC can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the Citrix ADC.
- The Citrix ADC supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

### Enabling and Disabling OSPF

To enable or disable OSPF, you must use either the CLI or the GUI. When OSPF is enabled, the Citrix ADC starts the OSPF process. When OSPF is disabled, the Citrix ADC stops the OSPF routing process.

To enable or disable OSPF routing by using the CLI:

At the command prompt, type one of the following commands:

1. **enable ns feature OSPF**
2. **disable ns feature OSPF**

To enable or disable OSPF routing by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change advanced features**.

2. Select or clear the **OSPF Routing** option.

## Advertising OSPF Routes

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure OSPF to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                               | Specifies                                                                        |
|---------------------------------------|----------------------------------------------------------------------------------|
| VTYSH                                 | Display VTYSH command prompt.                                                    |
| configure terminal                    | Enters global configuration mode.                                                |
| router OSPF                           | Start OSPF routing process and enter configuration mode for the routing process. |
| network A.B.C.D/M area <0-4294967295> | Enable routing on an IP network.                                                 |
| redistribute static                   | Redistribute static routes.                                                      |
| redistribute kernel                   | Redistribute kernel routes.                                                      |

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router OSPF
4 NS(config-router)# network 10.102.29.0/24 area 0
5 NS(config-router)# redistribute static
6 NS(config-router)# redistribute kernel
7 <!--NeedCopy-->
```

## Limiting OSPF Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                       | Specifies                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------|
| VTYSH                         | Display VTYSH command prompt.                                                     |
| configure terminal            | Enter global configuration mode.                                                  |
| router OSPF                   | Start OSPF routing process and enters configuration mode for the routing process. |
| passive-interface <vlan_name> | Suppress routing updates on interfaces bound to the specified VLAN.               |

**Example:**

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router OSPF
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

**Verifying the OSPF Configuration**

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command          | Specifies                     |
|------------------|-------------------------------|
| VTYSH            | Display VTYSH command prompt. |
| sh OSPF neighbor | Displays current neighbors.   |
| sh OSPF route    | Displays OSPF routes.         |

**Example:**

```

1 >VTYSH
2 NS# sh ip OSPF neighbor
3 NS# sh ip OSPF route
4 <!--NeedCopy-->

```

## Configuring Graceful Restart for OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning takes some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

| Command                            | Example                                   | Command Description                                                                                                                                                                                                                                       |
|------------------------------------|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VTYSH                              | VTYSH                                     | Enters VTYSH command prompt.                                                                                                                                                                                                                              |
| configure terminal                 | NS# configure terminal                    | Enters global configuration mode.                                                                                                                                                                                                                         |
| router-id <id>                     | NS(config)# router-id 1.1.1.1             | Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA setup. |
| ospf restart grace-period <1-1800> | NS(config)# ospf restart grace-period 170 | Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.                                                                                                                       |

| Command                                          | Example                                                 | Command Description                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ospf restart helper<br>max-grace-period <1-1800> | NS(config)# ospf restart<br>helper max-grace-period 180 | This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode. |
| router ospf                                      | NS(config)# router ospf                                 | Starts OSPF routing process and enter configuration mode for the routing process.                                                                                                                                                                                                                                     |
| network A.B.C.D/M area<br><0-4294967295>         | NS(config-router)# network<br>192.0.2.0/24 area 0       | Enables routing on an IP network.                                                                                                                                                                                                                                                                                     |
| capability restart graceful                      | NS(config-router)# capability<br>restart graceful       | Enables graceful restart on the OSPF routing process.                                                                                                                                                                                                                                                                 |
| redistribute kernel                              | NS(config-router)#<br>redistribute kernel               | Redistributes kernel routes.                                                                                                                                                                                                                                                                                          |

## Configuring BGP

September 21, 2020

The Citrix ADC appliance supports BGP (RFC 4271). The features of BGP on the Citrix ADC are:

- The Citrix ADC advertises routes to BGP peers.
- The Citrix ADC injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The Citrix ADC generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.
- As-Override Support in Border Gateway Protocol

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

## Enabling and Disabling BGP

To enable or disable BGP, you must use either the CLI or the GUI. When BGP is enabled, the Citrix ADC appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the CLI:

At the command prompt, type one of the following commands:

- enable ns feature BGP
- disable ns feature BGP

To enable or disable BGP routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

## Advertising IPv4 Routes

You can configure the Citrix ADC appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                                         | Specifies                                                                                                               |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>VTYSH</b>                                    | Display VTYSH command prompt.                                                                                           |
| configure terminal                              | Enter global configuration mode.                                                                                        |
| router BGP < ASnumber>                          | BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.                        |
| Neighbor < IPv4 address> remote-as < as-number> | Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system. |
| Address-family ipv4                             | Enter address family configuration mode.                                                                                |
| Neighbor < IPv4 address> activate               | Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.       |
| redistribute kernel                             | Redistribute kernel routes.                                                                                             |
| redistribute static                             | Redistribute static routes.                                                                                             |

**Example:**

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router BGP 5
4 NS(config-router)# Neighbor 10.102.29.170 remote-as 100
5 NS(config-router)# Address-family ipv4

7 NS(config-router)# redistribute kernel
8 NS(config-router)# redistribute static
9 <!--NeedCopy-->

```

**Prerequisites for IPv6 BGP**

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Enable the IPv6 feature.

**Advertising IPv6 BGP Routes**

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure BGP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                                         | Specifies                                                                                                               |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| VTYSH                                           | Display VTYSH command prompt.                                                                                           |
| configure terminal                              | Enter global configuration mode.                                                                                        |
| router BGP < ASnumber>                          | BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.                        |
| Neighbor < IPv6 address> remote-as < as-number> | Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system. |
| Address-family ipv6                             | Enter address family configuration mode.                                                                                |

---

| Command                           | Specifies                                                                                                         |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Neighbor < IPv6 address> activate | Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address. |
| redistribute kernel               | Redistribute kernel routes.                                                                                       |
| redistribute static               | Redistribute static routes.                                                                                       |

---

**Example:**

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router BGP 5
4 NS(config-router)# Neighbor a1bc::102 remote-as 100
5 NS(config-router)# Address-family ipv6
6 NS(config-router-af)# Neighbor a1bc::102 activate
7 NS(config-router)# redistribute kernel
8 NS(config-router)# redistribute static
9 <!--NeedCopy-->
```

**Verifying the BGP Configuration**

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
1 VTYSH
2 You are now in the VTYSH command prompt. An output similar to the
  following appears:
3 NS170#
4 At the VTYSH command prompt, type:
5 NS170# sh ip BGP
6 NS170# sh BGP
7 NS170# sh ip BGP neighbors
8 NS170# sh ip BGP summary
9 NS170# sh ip BGP route-map <map-tag>
10 <!--NeedCopy-->
```

## As-Override Support in Border Gateway Protocol

As a part of BGP loop prevention functionality, if a router receives a BGP packet containing the router's Autonomous System Number (ASN) in the Autonomous Systems (AS) path, the router drops the packet. The assumption is that the packet originated from the router and has reached the place from where it originated.

If an enterprise has several sites with a same ASN, BGP loop prevention causes the sites with an identical ASN to not get linked by another ASN. Routing updates (BGP packets) are dropped when another site receives them.

To solve this issue, BGP AS-Override functionality has been added to the ZebOS BGP routing module of the Citrix ADC.

With AS-Override enabled for a peer device, when the Citrix ADC appliance receives a BGP packet for forwarding to the peer, and the ASN of the packet matches that of the peer, the appliance replaces the ASN of the BGP packet with its own ASN number before forwarding the packet.

You can enable AS-Override for a specific neighbor or a group of neighbors (peer group) by using the VTYSH command line.

To configure BGP AS-Override for a IPv4 neighbor by using the VTYSH command line:

| Command                                              | Specifies                                                                                                    |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>configure terminal</b>                            | Enter global configuration mode.                                                                             |
| <b>router BGP</b> <ASnumber>                         | BGP autonomous system. <ASnumber> is a required parameter.                                                   |
| <b>Neighbor</b> <IPv4 address> remote-as <as-number> | Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system. |
| <b>Neighbor</b> <IPv4 address> as-override           | Enable BGP as-override for the specified neighbor.                                                           |

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# Neighbor 192.0.2.100 remote-as 100
4 NS(config-router)# Neighbor 10.102.29.100 as-override
5 <!--NeedCopy-->

```

To configure BGP AS-Override for a IPv4 BGP peer group by using the VTYSH command line:

| Command                                                            | Specifies                                                                                                    |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>configure terminal</b>                                          | Enter global configuration mode.                                                                             |
| <b>router BGP</b> <ASnumber>                                       | BGP autonomous system. <ASnumber> is a required parameter.                                                   |
| <b>Neighbor</b> <peer group name> <b>peer-group</b>                | Create a BGP peer group.                                                                                     |
| <b>Neighbor</b> <IPv4 address> <b>peer-group</b> <peer group name> | Associate neighbors to the specified peer group.                                                             |
| <b>Neighbor</b> <peer group name> remote-as <as-number>            | Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system. |
| <b>Neighbor</b> <peer group name> as-override                      | Enable BGP as-override for all the neighbors that are associated with the specified peer group.              |

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# neighbor external-peers-1 peer-group
4 NS(config-router)# neighbor 192.0.2.101 peer-group external-peers-1
5 NS(config-router)# neighbor 192.0.2.102 peer-group external-peers-1
6 NS(config-router)# neighbor 192.0.2.103 peer-group external-peers-1
7 NS(config-router)# Neighbor external-peers-1 remote-as 100
8 NS(config-router)# Neighbor external-peers-1 as-override
9 <!--NeedCopy-->

```

To configure BGP AS-Override for an IPv6 neighbor by using the VTYSH command line:

| Command                                              | Specifies                                                                                                    |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>configure terminal</b>                            | Enter global configuration mode.                                                                             |
| <b>router BGP</b> <ASnumber>                         | BGP autonomous system. <ASnumber> is a required parameter.                                                   |
| <b>Neighbor</b> <IPv6 address> remote-as <as-number> | Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system. |
| <b>Neighbor</b> <IPv6 address> as-override           | Enable BGP as-override for the specified neighbor.                                                           |
| <b>Address-family ipv6</b>                           | Enter address family configuration mode.                                                                     |

| Command                                    | Specifies                                                                                                                       |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Neighbor</b> <IPv6 address> activate    | Exchange prefixes for the IPv6 router family between the specified neighbor and the Citrix ADC by using the link local address. |
| <b>Neighbor</b> <IPv6 address> as-override | Enable BGP as-override for the specified neighbor.                                                                              |

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# Neighbor a1bc::102 remote-as 100
4 NS(config-router)# Neighbor a1bc::102 as-override
5 NS(config-router)# Address-family ipv6
6 NS(config-router-af)# Neighbor a1bc::102 activate
7 NS(config-router)# Neighbor a1bc::102 as-override
8 <!--NeedCopy-->

```

To configure BGP AS-Override for IPv6 peer group by using the VTYSH command line:

| Command                                                            | Specifies                                                                                                                                          |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>configure terminal</b>                                          | Enter global configuration mode.                                                                                                                   |
| <b>router BGP</b> <ASnumber>                                       | BGP autonomous system. <ASnumber> is a required parameter.                                                                                         |
| <b>Neighbor</b> <peer group name> <b>peer-group</b>                | Create a BGP peer group.                                                                                                                           |
| <b>Neighbor</b> <IPv6 address> <b>peer-group</b> <peer group name> | Associate a neighbor with the specified peer group.                                                                                                |
| <b>Neighbor</b> <peer group name> remote-as <as-number>            | Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.                                       |
| <b>Neighbor</b> <peer group name> as-override                      | Enable BGP as-override for all the neighbors that are associated with the specified peer group.                                                    |
| <b>Address-family ipv6</b>                                         | Enter address family configuration mode.                                                                                                           |
| <b>Neighbor</b> <peer group name> activate                         | Exchange prefixes for the IPv6 router family between the neighbors of the specified peer group and the Citrix ADC by using the link local address. |

| Command                                       | Specifies                                                                                       |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>Neighbor</b> <peer group name> as-override | Enable BGP as-override for all the neighbors that are associated with the specified peer group. |

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# neighbor external-peers-2 peer-group
4 NS(config-router)# neighbor 2001::1 peer-group external-peers-2
5 NS(config-router)# neighbor 2001::2 peer-group external-peers-2
6 NS(config-router)# Neighbor external-peers-2 remote-as 100
7 NS(config-router)# Neighbor external-peers-2 as-override
8 NS(config-router)# Address-family ipv6
9 NS(config-router-af)# Neighbor external-peers-2 activate
10 NS(config-router)# Neighbor external-peers-2 as-override
11 <!--NeedCopy-->

```

## Graceful Restart

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped. Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

### Configuring Graceful Restart for BGP

To configure graceful restart for BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

| Command            | Example                | Command Description               |
|--------------------|------------------------|-----------------------------------|
| VTYSH              | VTYSH                  | Enters VTYSH command prompt.      |
| configure terminal | NS# configure terminal | Enters global configuration mode. |

| Command                                                                | Example                                                            | Command Description                                                                                                                                                                                                                         |
|------------------------------------------------------------------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| router-id <ID>                                                         | NS(config)# router-id 1.1.1.1                                      | A router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same identifier must be specified on the other node in a high availability setup for graceful restart to work properly. |
| router bgp <AS-number>                                                 | NS(config)# router bgp 5                                           | Enters BGP configuration mode.                                                                                                                                                                                                              |
| bgp graceful-restart                                                   | NS(config)# bgp graceful-restart                                   | Enables graceful restart on the BGP routing process.                                                                                                                                                                                        |
| bgp graceful-restart restart-time <1-1800>                             | NS(config-router)# bgp graceful-restart restart-time 170           | Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes.                                     |
| bgp graceful-restart stalepath-time <1-1800>                           | NS(config-router)# bgp graceful-restart stalepath-time 180         | Specifies the time, in seconds, that the Citrix ADC appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.                                                                    |
| neighbor <IPv4 address of the peer router> remote-as <AS-number>       | NS(config-router)# neighbor 192.0.2.30 remote-as 2                 | Establishes BGP peering with the specified neighbor router device.                                                                                                                                                                          |
| neighbor <IPv4 address of the peer router> capability graceful-restart | NS(config-router)# neighbor 192.0.2.30 capability graceful-restart | Enables graceful restart with the specified neighbor.                                                                                                                                                                                       |
| redistribute kernel                                                    | NS(config-router)# redistribute kernel                             | Redistributes kernel routes.                                                                                                                                                                                                                |

## Configuring Graceful Restart for IPv6 BGP

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning takes some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for IPv6 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

| Command                | Example                          | Command Description                                                                                                                                                                                                                      |
|------------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VTYSH                  | VTYSH                            | Enters VTYSH command prompt.                                                                                                                                                                                                             |
| configure terminal     | NS# configure terminal           | Enters global configuration mode.                                                                                                                                                                                                        |
| router-id <id>         | NS(config)# router-id 1.1.1.1    | Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability setup for graceful restart to work properly. |
| router bgp <AS-number> | NS(config)# router bgp 5         | Enters configuration mode for BGP protocol.                                                                                                                                                                                              |
| bgp graceful-restart   | NS(config)# bgp graceful-restart | Enables graceful restart on the BGP routing process.                                                                                                                                                                                     |

| Command                                                                   | Example                                                                       | Command Description                                                                                                                                                                                                                       |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bgp graceful-restart<br>restart-time <1-1800>                             | NS(config-router)# bgp<br>graceful-restart restart-time<br>170                | Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes. The default value is 360 seconds. |
| bgp graceful-restart<br>stalepath-time <1-1800>                           | NS(config-router)# bgp<br>graceful-restart<br>stalepath-time 180              | Specifies the time, in seconds, that the Citrix ADC appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.                                                                  |
| neighbor <IPv6 address><br>remote-as <AS-number>                          | NS(config-router)# neighbor<br>2001:db8::10 remote-as 2                       | Establishes BGP peering with the specified neighbor router device.                                                                                                                                                                        |
| address-family ipv6                                                       | NS(config-router)#address-<br>family ipv6                                     | Enters address family configuration mode.                                                                                                                                                                                                 |
| neighbor <IPv6 address of the<br>neighbor> activate                       | NS(config-router-<br>af)#neighbor 2001:db8::10<br>activate                    | Enables the exchange of address family routes with the specified neighbor router device.                                                                                                                                                  |
| neighbor <IPv6 address of the<br>neighbor> capability<br>graceful-restart | NS(config-router-<br>af)#neighbor 2001:db8::10<br>capability graceful-restart | Enables graceful restart with the specified neighbor router device.                                                                                                                                                                       |
| redistribute kernel                                                       | NS(config-router-<br>af)#redistribute kernel                                  | Redistributes kernel routes.                                                                                                                                                                                                              |
| exit-address-family                                                       | NS(config-router-af)#exit-<br>address-family                                  | Exits address family configuration mode.                                                                                                                                                                                                  |

## Configuring MD5 Authentication for IPv4 BGP

The Citrix ADC appliance supports MD5 authentication for Border Gateway Protocol (BGP). When authentication is enabled, any TCP segment belonging to BGP exchanged between the Citrix ADC appliance and its peer device is verified and accepted only if authentication is successful. For authentication to be successful, both the peers must be configured with the same MD5 password. If authentication fails, the BGP neighbor relationship is not being established. MD5 authentication support for BGP in the Citrix ADC appliance is compliant with RFC 2385.

### Before you Begin

Before you start configuring BGP MD5 authentication, consider the following points:

- Make sure that you understand the different components of BGP MD5 authentication, described in RFC 2385.
- BGP MD5 authentication is not supported for Citrix ADC admin partitions.
- BGP MD5 authentication is not supported for IPv6 BGP configurations.
- BGP MD5 authentication is supported for Citrix ADC cluster configurations as well as for high availability configurations.
- Because of the following issue in FreeBSD, Citrix recommends to set a low keep-live and hold-time values (for example, 5 and 15) and configure graceful restart for a BGP session in a Layer 2 high availability configuration. Otherwise, with MD5 authentication enabled, BGP might take a longer time to re-establish a connection with the neighbour after a failover.
  - Last ACK from FreeBSD does not contain md5 digest:
    - \* <https://forums.freebsd.org/threads/11170/>
    - \* <http://support.pfsense.narkive.com/povrH5HI/bgp-md5-weird-behavior-when-connection-closes>

## Configuring MD5 Authentication for IPv4 BGP

To configure MD5 authentication for IPv4 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

| Command                             | Specifies                                                                                                              |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>vtysh</b>                        | Displays VTYSH command prompt.                                                                                         |
| <b>configure terminal</b>           | Enters global configuration mode.                                                                                      |
| <b>router bgp &lt;AS-number&gt;</b> | Enters configuration mode for BGP protocol. <AS-number> is a BGP autonomous system number and is a required parameter. |

| Command                                                                                          | Specifies                                                                                                                                                                                                                             |
|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>neighbor &lt;neighbour IPv4 address&gt;<br/>remote-as &lt;AS-number &gt;</b>                  | Updates the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.                                                                                                                                  |
| <b>neighbor &lt; neighbour IPv4 address &gt;<br/>password &lt; password in double quotes&gt;</b> | Configures MD5 authentication for the specified neighbour with the specified MD5 password. For MD5 authentication to be successful, you must configure the same MD5 password on the Citrix ADC appliance and the neighbour appliance. |

```
1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)#router bgp 5
6
7 ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9 ns(config-router)#neighbor 20.20.20.138 password "secret"
10
11 ns(config-router)#redistribute kernel
12
13 ns(config-router)#exit
14
15 <!--NeedCopy-->
```

## Configuring IPv6 RIP

September 21, 2020

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

## Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

## Advertising IPv6 RIP Routes

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command             | Specifies                                                                            |
|---------------------|--------------------------------------------------------------------------------------|
| VTYSH               | Display VTYSH command prompt.                                                        |
| configure terminal  | Enter global configuration mode.                                                     |
| router ipv6 rip     | Start IPv6 RIP routing process and enter configuration mode for the routing process. |
| redistribute static | Redistribute static routes.                                                          |
| redistribute kernel | Redistribute kernel routes.                                                          |

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 rip
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->
```

## Limiting IPv6 RIP Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                       | Specifies                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------|
| VTYSH                         | Display VTYSH command prompt.                                                        |
| configure terminal            | Enter global configuration mode.                                                     |
| router ipv6 rip               | Start IPv6 RIP routing process and enter configuration mode for the routing process. |
| passive-interface <vlan_name> | Suppress routing updates on interfaces bound to the specified VLAN.                  |

### Example:

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 rip
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

### Verifying the IPv6 RIP Configuration

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Commands                          | Specifies                                            |
|-----------------------------------|------------------------------------------------------|
| VTYSH                             | Display VTYSH command prompt.                        |
| sh ipv6 rip                       | Display updated IPv6 RIP routing table.              |
| sh ipv6 rip interface <vlan_name> | Display IPv6 RIP information for the specified VLAN. |

### Example:

```

1 NS# VTYSH
2 NS# sh ipv6 rip
3 NS# sh ipv6 rip interface VLAN0

## Configuring IPv6 OSPF

September 21, 2020

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

### Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

### Advertising IPv6 Routes

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Commands            | Specifies                                                                             |
|---------------------|---------------------------------------------------------------------------------------|
| VTYSH               | Display VTYSH command prompt.                                                         |
| configure terminal  | Enter global configuration mode.                                                      |
| router ipv6 OSPF    | Start IPv6 OSPF routing process and enter configuration mode for the routing process. |
| redistribute static | Redistribute static routes.                                                           |
| redistribute kernel | Redistribute kernel routes.                                                           |

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 OSPF
```

```

4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->

```

## Limiting IPv6 OSPF Propagations

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Commands                        | Specifies                                                                             |
|---------------------------------|---------------------------------------------------------------------------------------|
| VTYSH                           | Display VTYSH command prompt.                                                         |
| configure terminal              | Enter global configuration mode.                                                      |
| router ipv6 OSPF                | Start IPv6 OSPF routing process and enter configuration mode for the routing process. |
| passive-interface < vlan_name > | Suppress routing updates on interfaces bound to the specified VLAN.                   |

### Example:

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 OSPF
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

## Verifying the IPv6 OSPF Configuration

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command | Specifies                     |
|---------|-------------------------------|
| VTYSH   | Display VTYSH command prompt. |

| Command               | Specifies                  |
|-----------------------|----------------------------|
| sh ipv6 OSPF neighbor | Display current neighbors. |
| sh ipv6 OSPF route    | Display IPv6 OSPF routes.  |

**Example:**

```
1 >VTYSH
2 NS# sh ipv6 OSPF neighbor
3 NS# sh ipv6 OSPF route
4 <!--NeedCopy-->
```

**OSPFv3 Authentication**

To ensure the integrity, data origin authentication, and data confidentiality of OSPFv3 packets, OSPFv3 authentication must be configured on OSPFv3 peers.

The Citrix ADC appliance supports OSPFv3 authentication and is partially compliant with RFC 4552. OSPFv3 authentication is based on the two IPsec protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP). The Citrix ADC appliance supports only the AH protocol for OSPFv3 authentication.

OSPFv3 authentication uses manually defined IPsec Security Associations (SAs) between the OSPFv3 peers and does not rely on IKE protocol for forming dynamic SAs. Manual SAs define the security parameter Index (SPI) values, algorithms, and keys to be used between the peers. Manual SAs require no negotiation between the peers; therefore, the same SA must be defined on both the peers.

You can configure OSPFv3 authentication on a VLAN or for an OSPFv3 area. When you configure for a VLAN, the settings are applied to all the interfaces that are members of the VLAN. When you configure OSPFv3 authentication for an OSPF area, the settings are applied to all the VLANs in that area. The settings are in turn applied to all the interfaces that are members of these VLANs. These settings do not apply to member VLANs on which you have configured OSPFv3 authentication directly.

Consider the following points and limitations before configuring OSPFv3 authentication on a Citrix ADC appliance:

- Make sure that you understand the different components of OSPFv3 authentication, described in RFC 4552.
- Only Authentication Header protocol is supported for OSPFv3 authentication. Encapsulating Security Payload (ESP) is not supported.
- You must define an SA with the same setting on the peer interface.
- Rekeying of manual keys is not supported.

To configure OSPFv3 authentication on a VLAN by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: [OSPFv3 authentication VLAN commands](#).

**Example:**

```

1 > VTYSH NS# configure terminal
2 NS(config)# interface vlan2
3 NS(config-if)# ipv6 ospf authentication ipsec spi 256 md5 123456789
   ABCDEF0123456789ABCDEF0
4 <!--NeedCopy-->

```

To configure OSPFv3 authentication on an OSPF area by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: [OSPFv3 authentication OSPF area commands](#).

**Example:**

```

1 > VTYSH NS# configure terminal
2 ns(config)#router ipv6 ospf 30
3 ns(config-router)# area 1 authentication ipsec spi 256
   md5123456789ABCDEF0123456789ABCDEF0
4 <!--NeedCopy-->

```

## Configuring Graceful Restart for IPv6 OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for IPv6 OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

| Command | Example | Command Description          |
|---------|---------|------------------------------|
| VTYSH   | > VTYSH | Enters VTYSH command prompt. |

| Command                                            | Example                                                   | Command Description                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| configure terminal                                 | NS# configure terminal                                    | Enters global configuration mode.                                                                                                                                                                                                                                                                                     |
| router-id id>                                      | NS(config)#router-id 1.1.1.1                              | Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA set up.                                                            |
| IPv6ospf restart grace-period <1-1800>             | NS(config)# IPv6ospf restart grace-period 170             | Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.                                                                                                                                                                                   |
| IPv6 ospf restart helper max-grace-period <1-1800> | NS(config)# IPv6 ospf restart helper max-grace-period 180 | This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode. |
| interface <VLANID>                                 | NS(config)#interface vlan3                                | Enters VLAN configuration mode.                                                                                                                                                                                                                                                                                       |
| ipv6 router ospf area tag                          | NS(config-if)#ipv6 router ospf area 0 tag 1               | Starts IPv6 OSPF routing process on a VLAN.                                                                                                                                                                                                                                                                           |
| exit                                               | NS(config-if)#exit                                        | Exits VLAN configuration mode.                                                                                                                                                                                                                                                                                        |

| Command                     | Example                                       | Command Description                                                                     |
|-----------------------------|-----------------------------------------------|-----------------------------------------------------------------------------------------|
| router ipv6 ospf            | NS(config)# router ipv6 ospf 1                | Starts IPv6 OSPF routing process and enters configuration mode for the routing process. |
| capability restart graceful | NS(config-router)#capability restart graceful | Enables graceful restart on the IPv6 OSPF routing process.                              |
| redistribute kernel         | NS(config-router)# redistribute kernel        | Redistributes kernel routes.                                                            |

## Configuring ISIS

September 21, 2020

The Citrix ADC appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

### Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

### Enabling ISIS

Use either of the following procedures to enable the ISIS routing feature on the Citrix ADC appliance.

To enable ISIS routing by using the CLI:

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

### Creating an ISIS Routing Process and Starting It on a VLAN

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

| Command                                        | Description                                                                                                                                                                                                                                                                                            |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VTYSH                                          | Displays VTYSH command prompt.                                                                                                                                                                                                                                                                         |
| configure terminal                             | Enters the global configuration mode.                                                                                                                                                                                                                                                                  |
| router ISIS [tag]                              | Creates an ISIS routing process and configuration mode for the routing process.                                                                                                                                                                                                                        |
| net<br>XX...XXXX.YYYY.YYYY.YYYY                | Specifies a NET value for the routing process, where: <ul style="list-style-type: none"> <li>· <b>XX</b>.</li> <li>· <b>.. .XXXX</b> is the Area Address (can be 1-13 bytes),</li> <li>· <b>YYYY.YYYY.YYYY</b> is the System ID (6 bytes),</li> <li>· <b>00</b> is the N-selector (1 byte).</li> </ul> |
| is-type (level-1<br>level-1-2<br>level-2-only) | Sets the ISIS routing process to the specified level of routing. Default: level-1-2.                                                                                                                                                                                                                   |
| ns IPv6-routing                                | Starts the IPv6 dynamic routing daemon.                                                                                                                                                                                                                                                                |

| Command          | Description                                                            |
|------------------|------------------------------------------------------------------------|
| interface        | Enters the VLAN configuration mode.                                    |
| ip router ISIS   | Enables the ISIS routing process on the VLAN for IPv4 route exchanges. |
| ipv6 router ISIS | Enables the ISIS routing process on the VLAN for IPv6 route exchanges. |

**Example:**

```

1 > VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11
4 NS(config-router)# net 15.aabb.ccdd.0097.00
5 NS(config-router)# is-type level-1
6 NS(config-router)# exit
7 NS(config)# ns IPv6-routing
8 NS(config)# interface vlan0
9 NS(config-if)# ip router isis 11
10 NS(config-if)# ipv6 router isis 11
11 <!--NeedCopy-->

```

**Advertising Routes**

Route advertisement enables an upstream router to track network entities located behind the Citrix ADC appliance.

To configure ISIS to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command            | Description                           |
|--------------------|---------------------------------------|
| VTYSH              | Displays the VTYSH command prompt.    |
| configure terminal | Enters the global configuration mode. |

| Command                                                  | Description                                                                                                                                                                                                                                 |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| router ISIS [tag]                                        | Starts the ISIS routing instance and enter configuration mode for the routing process.                                                                                                                                                      |
| redistribute connected (level-1 or level-1-2 or level-2) | Redistributes connected routes, where:<br><b>level-1:</b> Redistribute connected routes into Level-1, <b>level-1-2:</b> Redistribute connected routes into Level-1 and Level-2, <b>level-2:</b> Redistribute connected routes into Level-2. |
| redistribute kernel (level-1 or level-1-2 or level-2)    | Redistributes kernel routes, where: <b>level-1:</b> Redistribute kernel routes into Level-1, <b>level-1-2:</b> Redistribute kernel routes into Level-1 and Level-2, <b>level-2:</b> Redistribute kernel routes into Level-2.                |

**Example:**

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11
4 NS(config-router)# redistribute connected level-1
5 NS(config-router)# redistribute kernel level-1
6 <!--NeedCopy-->

```

**Limiting ISIS Propagations**

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command            | Description                                            |
|--------------------|--------------------------------------------------------|
| VTYSH              | Displays the VTYSH command prompt.                     |
| configure terminal | Enters the global configuration mode.                  |
| router isis [tag]  | Enters the configuration mode for the routing process. |

| Command                                          | Description                                                           |
|--------------------------------------------------|-----------------------------------------------------------------------|
| <code>passive-interface &lt;vlan_name&gt;</code> | Suppresses routing updates on interfaces bound to the specified VLAN. |

**Example:**

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

**Verifying the ISIS Configuration**

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Commands                                         | Description                                            |
|--------------------------------------------------|--------------------------------------------------------|
| VTYSH                                            | Displays the VTYSH command prompt.                     |
| <code>show ip isis route</code>                  | Displays updated IPv4 ISIS routing table.              |
| <code>show ipv6 isis route</code>                | Displays updated IPv6 ISIS routing table.              |
| <code>sh isis interface &lt;vlan_name&gt;</code> | Displays IPv6 ISIS information for the specified VLAN. |

**Example:**

```

1 NS# VTYSH
2 NS# show ip isis route
3 NS# show ipv6 isis route
4 NS# sh isis interface VLAN0
5 <!--NeedCopy-->

```

## Install Routes to the Citrix ADC Routing Table

September 21, 2020

The Citrix ADC appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line:

At the CLI, type the following commands as appropriate for the routes that you want to install:

| Commands                      | Specifies                                                        |
|-------------------------------|------------------------------------------------------------------|
| VTYSH                         | Display VTYSH command prompt.                                    |
| configure terminal            | Enter global configuration mode.                                 |
| ns route-install Default      | Install IPv4 default routes to the internal routing table.       |
| ns route-install RIP          | Install IPv4 RIP specific routes to the internal routing table.  |
| ns route-install BGP          | Install IPv4 BGP specific routes to the internal routing table.  |
| ns route-install OSPF         | Install IPv4 OSPF specific routes to the internal routing table. |
| ns route-install IPv6 Default | Install IPv6 default routes to the internal routing table.       |
| ns route-install IPv6 RIP     | Install IPv6 RIP specific routes to the internal routing table.  |
| ns route-install IPv6 BGP     | Install IPv6 BGP specific routes to the internal routing table.  |
| ns route-install IPv6 OSPF    | Install IPv6 OSPF specific routes to the internal routing table. |

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS# ns route-install Default
4 NS(config)# ns route-install RIP
5 NS(config)# ns route-install BGP
6 NS(config)# ns route-install OSPF
```

```
7 NS# ns route-install IPv6 Default
8 NS(config)# ns route-install IPv6 RIP
9 NS(config)# ns route-install IPv6 BGP
10 NS(config)# ns route-install IPv6 OSPF
11 <!--NeedCopy-->
```

## Advertisement of SNIP and VIP Routes to Selective Areas

September 21, 2020

To advertise some SNIP addresses to selective areas, enabling DRADV mode or redistribute connect ZebOS operations cannot be used. This is because these operations send all the connected routes to ZebOS. Also, adding dummy static routes in ZebOS for the required subnets, or adding ACLs in ZebOS to filter unwanted connected routes, is a cumbersome and tedious task.

The Network Route and the Tag options address this issue. You can enable the Network Route option for only one SNIP address per subnet. The connected route for that SNIP address is sent as a kernel route to ZebOS.

For VIP and SNIP addresses, Tag, can be assigned an integer from 1 to 4294967295. This parameter can be set only when Host Route or Network Route is enabled for VIP or SNIP addresses. The tag value associated with VIP and SNIP addresses are also sent along with their routes to ZebOS. Tags with different values can be set for VIP and SNIP routes. These tag values can then be matched in route maps in ZebOS and advertised to selective areas.

### Advertise SNIP Routes to Selective Areas

To configure the network route and tag parameters of a SNIP address by using the CLI:

At the command prompt, type:

- If adding a new SNIP address:
  - **add ns ip** <IPAddress>@ <netmask> **-type SNIP -networkroute ( ENABLED | DISABLED )**
  - **tag** <positive\_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing SNIP address:
  - **set ns ip** <IPAddress>@ <netmask> **-type SNIP - networkroute ( ENABLED | DISABLED )**
  - **tag** <positive\_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a SNIP address by using GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Set the **Network Route** and **Tag** parameters while adding a Subnet IP (SNIP) address or modifying an existing Subnet IP address.

### Advertise VIP Routes to Selective Areas

To configure the host route and tag parameters of a VIP address by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new VIP address:
  - **add ns ip** <IPAddress>@ <netmask> **-type VIP -hostRoute ( ENABLED | DISABLED ) -tag** <positive\_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing VIP address:
  - **set ns ip** <IPAddress>@ <netmask> **-type VIP -hostRoute ( ENABLED | DISABLED ) -tag** <positive\_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a VIP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Set the **Host Route** and **Tag** parameters while adding a VIP address or modifying an existing VIP address.

## Configuring Bidirectional Forwarding Detection

September 21, 2020

Bidirectional Forwarding Detection (BFD) protocol is a mechanism for fast detection of failures of forwarding paths. BFD detects path failures in the order of milliseconds. BFD is used with dynamic routing protocols.

In BFD operation, routing peers exchange BFD packets at a negotiated interval. If a packet is not received from a peer within the negotiated interval plus grace interval, the peer is considered to be dead and a notification will be sent to the set of registered routing protocols. In turn, the routing protocols recalculate the best path and reprogram the routing table.

BFD supports smaller time interval, when compared to the timers provided by the routing protocols, thus resulting in faster detection of failures.

The Citrix ADC appliance supports BFD for the following routing protocols: BGP (IPv4 and IPv6), OSPFv2 (IPv4), and OSPFv3 (IPv6). BFD support in the Citrix ADC appliance is compliant with RFCs 5880, 5881, and 5883.

## Points to Consider for Configuring Bidirectional Forwarding Detection

Before you start configuring BFD, consider the following points:

- Make sure that you understand the different components of BFD, described in RFCs 5880, 5881, and 5883.
- BFD on a Citrix ADC appliance is supported for the following routing protocols:
  - BGP (IPv4 and IPv6)
  - OSPFv2 (IPv4)
  - OSPFv3 (IPv6)
- BFD on a Citrix ADC appliance is not supported for the following routing protocols:
  - ISIS
  - RIP (IPv4)
  - RIPng (IPv6)
- The following BFD features are not supported on a Citrix ADC appliance:
  - BFD Echo mode
  - BFD Authentication
  - BFD Demand asynchronous mode
- The minimum values for BFD interval and BFD Rx timers are 100 milliseconds.
- When BFD is used in a topology with shared IP addresses (for example, Layer 2 high availability setup with SNIP addresses or a cluster setup with striped IP addresses), BFD brings down the active sessions during a failover because the BFD failure detection time (order of milliseconds) is lesser than the HA failover detection interval (3–4 seconds). Therefore, Citrix recommends usage of Graceful restart in layer-2 HA topologies as the routes are retained during the failover process.

## Configuration Steps

Configuring BFD on a Citrix ADC appliance consists of the following tasks:

- Configure BFD Parameters
- Configure BFD Support for Dynamic Routing Protocols

## Configure BFD Parameters

The Citrix ADC appliance provides separate BFD session parameters for:

- single hop sessions

- IPv4 multiple hop sessions
- IPv6 multiple hop sessions

If you do not configure BFD parameters for a type of session, the default values are applied for that session.

The default value of each BFD parameter is same for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. The following table displays the default value of each BFD parameter.

| BFD Parameter Name | Default Value    |
|--------------------|------------------|
| Interval           | 750 milliseconds |
| Minimum Rx         | 500 milliseconds |
| Multiplier         | 3                |

#### IMPORTANT:

Mellanox NICs in a Citrix appliance take around 1500 ms to initialize. You must set the BFD timers to more than 1500 ms for a Citrix ADC appliance with Mellanox NICs. Citrix recommends setting the BFD timers to 3000 ms:

- Interval Tx = 600 ms
- Minimum Rx = 600 ms
- Multiplier = 5

### Configuring BFD Parameters for a Single Hop Session

To configure BFD parameters for a single hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

| Command                                                                                           | Specifies                                                |
|---------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <code>vttysh</code>                                                                               | Display <b>VTYSH</b> command prompt.                     |
| <code>configure terminal</code>                                                                   | Enter global configuration mode.                         |
| <code>interface &lt;vlan ID&gt;</code>                                                            | Enter the interface configuration mode.                  |
| <code>bfd singlehop-peer interval &lt;num&gt;<br/>minrx &lt;num&gt; multiplier &lt;num&gt;</code> | Configure the BFD parameters on the specified interface. |

#### Sample configuration:

```
1 > vtysh
```

```

2
3 ns# configure terminal
4
5 ns(config)# interface vlan3
6
7 ns(config-if)# bfd singlehop-peer interval 200 minrx 200 multiplier 5
8
9 ns(config-if)# exit
10 <!--NeedCopy-->

```

### Configuring BFD Parameters for IPv4 Multiple Hop Sessions

To configure BFD parameters for IPv4 multiple hop sessions by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

| Command                                                                                                               | Specifies                                                    |
|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <code>vtysh</code>                                                                                                    | Display <b>VTYSH</b> command prompt.                         |
| <code>configure terminal</code>                                                                                       | Enter global configuration mode.                             |
| <code>bfd multihop-peer &lt;ipv4addr&gt;<br/>interval &lt;num&gt; minrx &lt;num&gt;<br/>multiplier &lt;num&gt;</code> | Configure the BFD parameters for IPv4 multiple hop sessions. |

### Sample configuration:

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# bfd multihop-peer 20.20.20.138 interval 300 minrx 300
6 multiplier 5
7
8 ns(config)# exit
9 <!--NeedCopy-->

```

### Configuring BFD Parameters for IPv6 Multiple Hop Sessions

To configure BFD parameters for IPv6 multiple hop sessions by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

| Command                                                                                                                    | Specifies                                                    |
|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <code>vtysh</code>                                                                                                         | Display <code>VTYSH</code> command prompt.                   |
| <code>configure terminal</code>                                                                                            | Enter global configuration mode.                             |
| <code>bfd multihop-peer ipv6 &lt;ipv6addr&gt;<br/>interval &lt;num&gt; minrx &lt;num&gt;<br/>multiplier &lt;num&gt;</code> | Configure the BFD parameters for IPv6 multiple hop sessions. |

**Sample configuration:**

```

1    > vtysh
2
3    ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx
        500 multiplier 5
4
5    ns(config)# exit
6    <!--NeedCopy-->

```

**Configure BFD Support for Dynamic Routing Protocols**

You can enable BFD for a dynamic routing protocol for a type of session with a peer. For example, single hop and multiple hops. The Citrix ADC appliance applies the relevant BFD parameter settings to the session.

**Configuring BFD for an IPv4 BGP Single Hop Session**

To configure BFD for an IPv4 BGP single hop session by using the `VTYSH` command line, at the command prompt, type the following commands, in the order shown:

| Command                                                      | Specifies                                                                                           |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>vtysh</code>                                           | Display <code>VTYSH</code> command prompt.                                                          |
| <code>configure terminal</code>                              | Enter global configuration mode.                                                                    |
| <code>router bgp &lt;asnumber&gt;</code>                     | BGP autonomous system. <code>asnumber</code> is a required parameter.                               |
| <code>neighbor &lt;ipv4addr&gt; remote-as &lt;num&gt;</code> | Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system. |

| Command                                              | Specifies                              |
|------------------------------------------------------|----------------------------------------|
| <code>neighbor &lt;ipv4addr&gt; fall-over bfd</code> | Enable BFD for the specified neighbor. |

**Sample configuration:**

```

1    > vtysh
2
3    ns# configure terminal
4
5    ns(config)#router bgp 1
6
7    ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9    ns(config-router)#neighbor 20.20.20.138 fall-over bfd
10
11   ns(config-router)#redistribute kernel
12
13   ns(config-router)#exit
14 <!--NeedCopy-->

```

**Configuring BFD for an IPv4 BGP Multiple Hop Session**

To configure BFD for an IPv4 BGP multiple hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

| Command                                                       | Specifies                                                                                           |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>vtysh</code>                                            | Display <b>VTYSH</b> command prompt.                                                                |
| <code>configure terminal</code>                               | Enter global configuration mode.                                                                    |
| <code>router bgp &lt;asnumber&gt;</code>                      | BGP autonomous system. <code>asnumber</code> is a required parameter.                               |
| <code>neighbor &lt;ipv4addr&gt; remote-as &lt;num&gt;</code>  | Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system. |
| <code>neighbor &lt;ipv4addr&gt; fall-over bfd multihop</code> | Enable BFD for the specified neighbor.                                                              |

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)#router bgp 1
6
7 ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9 ns(config-router)#neighbor 20.20.20.138 fall-over bfd multihop
10
11 ns(config-router)#redistribute kernel
12
13 ns(config-router)#exit
14 <!--NeedCopy-->

```

### Configuring BFD for an IPv6 BGP Single Hop Session

To configure BFD for an IPv6 BGP single hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

| Command                                                      | Specifies                                                                                                         |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>vtysh</code>                                           | Display <b>VTYSH</b> command prompt.                                                                              |
| <code>configure terminal</code>                              | Enter global configuration mode.                                                                                  |
| <code>router bgp &lt;asnumber&gt;</code>                     | BGP autonomous system. <code>asnumber</code> is a required parameter.                                             |
| <code>neighbor &lt;ipv6addr&gt; remote-as &lt;num&gt;</code> | Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.    |
| <code>neighbor &lt;ipv6addr&gt; fall-over bfd</code>         | Enable BFD for the specified neighbor.                                                                            |
| <code>address-family ipv6</code>                             | Enter address family configuration mode.                                                                          |
| <code>neighbor &lt;ipv6addr&gt; activate</code>              | Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address. |

### Sample configuration:

```

1 > vtysh
2

```

```

3 ns# configure terminal ns(config)#router bgp 1
4
5 ns(config-router)#neighbor 30fe:123::124 remote-as 1
6
7 ns(config-router)#neighbor 30fe:123::124 fall-over bfd
8
9 ns(config-router)#address-family ipv6
10
11 ns(config-router-af)#neighbor 30fe:123::124 activate
12
13 ns(config-router-af)#redistribute kernel
14
15 ns(config-router-af)#exit
16
17 <!--NeedCopy-->

```

### Configuring BFD for an IPv6 BGP Multiple Hop Session

To configure BFD for an IPv6 BGP multiple hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

| Command                                                       | Specifies                                                                                                         |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>vtysh</code>                                            | Display <b>VTYSH</b> command prompt.                                                                              |
| <code>configure terminal</code>                               | Enter global configuration mode.                                                                                  |
| <code>router bgp &lt;asnumber&gt;</code>                      | BGP autonomous system. <code>asnumber</code> is a required parameter.                                             |
| <code>neighbor &lt;ipv6addr&gt; remote-as &lt;num&gt;</code>  | Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.    |
| <code>neighbor &lt;ipv6addr&gt; fall-over bfd multihop</code> | Enable BFD for the specified neighbor.                                                                            |
| <code>address-family ipv6</code>                              | Enter address family configuration mode.                                                                          |
| <code>neighbor &lt;ipv6addr&gt; activate</code>               | Exchange prefixes for the IPv6 router family between the peer and the local node by using the link-local address. |

### Sample configuration:

```
1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx 500
   multiplier 5
6
7 ns(config)#router bgp 1
8
9 ns(config-router)#neighbor 20fe:125::138 remote-as 1
10
11 ns(config-router)#neighbor 20fe:125::138 fall-over bfd multihop
12
13 ns(config-router)#address-family ipv6
14
15 ns(config-router-af)#neighbor 20fe:125::138 activate
16
17 ns(config-router-af)#redistribute kernel
18
19 ns(config-router-af)#end
20
21 <!--NeedCopy-->
```

### Configuring BFD for OSPFv2 (IPv4) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv2 protocol.

#### To configure BFD for OSPFv2 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                                      | Specifies                                     |
|----------------------------------------------|-----------------------------------------------|
| <code>vtysh</code>                           | Display VTYSH command prompt.                 |
| <code>configure terminal</code>              | Enter global configuration mode.              |
| <code>router ospf &lt;process tag&gt;</code> | Enter OSPFv2 configuration mode.              |
| <code>bfd all-interfaces</code>              | Enable BFD on all interfaces that use OSPFv2. |

#### Sample configuration:

```
1 > vtysh
2
```

```

3     ns# configure terminal
4
5     ns(config)#router ospf 1
6
7     ns(config-router)#bfd all-interfaces
8
9     ns(config-router)#redistribute kernel
10
11    ns(config-router)#exit
12 <!--NeedCopy-->

```

### To configure BFD for OSPFv2 on a specific interface by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                                | Specifies                                               |
|----------------------------------------|---------------------------------------------------------|
| <code>vtysh</code>                     | Display VTYSH command prompt.                           |
| <code>configure terminal</code>        | Enter global configuration mode.                        |
| <code>interface &lt;vlan ID&gt;</code> | Enter the interface configuration mode.                 |
| <code>ip ospf bfd</code>               | Enable BFD on the specified interface that uses OSPFv2. |

### Sample configuration:

```

1     > vtysh
2
3     ns# configure terminal
4
5     ns(config)# interface vlan5
6
7     ns(config-if)# ip ospf bfd
8
9     ns(config-if)# exit
10 <!--NeedCopy-->

```

### Configuring BFD for OSPFv3 (IPv6) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv3 protocol.

### To configure BFD for OSPFv3 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

| Command                                           | Specifies                                     |
|---------------------------------------------------|-----------------------------------------------|
| <code>vtysh</code>                                | Display <b>VTYSH</b> command prompt.          |
| <code>configure terminal</code>                   | Enter global configuration mode.              |
| <code>router ipv6 ospf &lt;process tag&gt;</code> | Enter OSPFv3 configuration mode.              |
| <code>bfd all-interfaces</code>                   | Enable BFD on all interfaces that use OSPFv3. |

**Sample configuration:**

```

1    > vtys
2
3    ns# configure terminal
4
5    ns(config)#router ipv6 ospf 10
6
7    ns(config-router)#bfd all-interfaces
8
9    ns(config-router)#redistribute kernel
10
11   ns(config-router)#exit
12 <!--NeedCopy-->

```

**To configure BFD for OSPFv3 on a specific interface by using the VTYSH command line:**

At the command prompt, type the following commands, in the order shown:

| Command                         | Specifies                                               |
|---------------------------------|---------------------------------------------------------|
| <code>vtysh</code>              | Display <b>VTYSH</b> command prompt.                    |
| <code>configure terminal</code> | Enter global configuration mode.                        |
| <b>interface</b> <vlan ID>      | Enter the interface configuration mode.                 |
| <code>ipv6 ospf bfd</code>      | Enable BFD on the specified interface that uses OSPFv3. |

**Sample configuration:**

```

1    > vtys
2
3    ns# configure terminal
4

```

```
5     ns(config)# interface vlan15
6
7     ns(config-if)# ipv6 ospf bfd
8
9     ns(config-if)# exit
10 <!--NeedCopy-->
```

## Configuring Static Routes

September 21, 2020

Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

**Monitored Static Routes.** If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the Citrix ADC appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the Citrix ADC. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

**Note:** In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.

Consider the following simple topology, in which a Citrix ADC is load balancing traffic to a site across multiple servers.

Router R1 moves traffic between the client and the Citrix ADC appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers'

subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the Citrix ADC points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the Citrix ADC marks it as DOWN. The Citrix ADC now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The Citrix ADC supports monitoring of IPv4 and IPv6 static routes. You can configure the Citrix ADC to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the Citrix ADC to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

**Weighted Static Routes.** When the Citrix ADC appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The Citrix ADC then uses both the weight and the hashed value for balancing the load.

**Null Routes.** If the route chosen in a routing decision is inactive, the Citrix ADC appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

## Configuring IPv4 Static Routes

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

### CLI procedures

To create a static route by using the CLI:

At the command prompt, type:

- `add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise ( DISABLED | ENABLED )]`
- `show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]`

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise
    ENABLED
2 Done
3 <!--NeedCopy-->
```

To create a monitored static route by using the CLI:

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive\_integer>] [-weight <positive\_integer>][-msr ( ENABLED | DISABLED ) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6
    -msr ENBLED -monitor PING
2 Done
3 <!--NeedCopy-->
```

To create a null route by using the CLI:

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 null
2 Done
3 <!--NeedCopy-->
```

To remove a static route by using the CLI:

At the command prompt, type:

```
rm route <network> <netmask> <gateway>
```

**Example:**

```
1 > rm route 10.102.29.0 255.255.255.0 10.102.29.3
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To configure a static route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

## Configuring IPv6 Static Routes

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

## CLI procedures

To create an IPv6 route by using the CLI:

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- `add route6 <network> <gateway> [-vlan <positive_integer>]`
- `show route6 [<network> [<gateway>]`

### Example:

```
1 > add route6 ::/0 FE80::67 -vlan 5
2 Done
3 <!--NeedCopy-->
```

To create a monitored IPv6 static route by using the CLI:

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the configuration:

- `add route6 <network> <gateway> [-msr ( ENABLED | DISABLED ) ] [-monitor <string>]`
- `show route6 [<network> [<gateway>]`

### Example:

```
1 > add route6 ::/0 2004::1 -msr ENABLED -monitor PING
2 Done
3 <!--NeedCopy-->
```

To remove an IPv6 route by using the CLI:

At the command prompt, type:

```
rm route6 <network> <gateway>
```

**Example:**

```
1 > rm route6 ::/0 FE80::67
2 Done
3 <!--NeedCopy-->
```

### GUI procedures

To configure an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

## Route Health Injection Based on Virtual Server Settings

September 21, 2020

The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the Citrix ADC appliance for advertising the route of a VIP address.

- **VSVR\_CNTRLD**. It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.
- **RHI STATE**. It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR\_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the Citrix ADC always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.

- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The Citrix ADC appliance has two virtual servers V1 and V2 associated with the VIP address:

| Associated virtual servers for a VIP                                          | State 1 | State 2 | State 3 | State 4 |
|-------------------------------------------------------------------------------|---------|---------|---------|---------|
| <b>RHI State set to PASSIVE on all virtual servers</b>                        |         |         |         |         |
| V1                                                                            | UP      | UP      | DOWN    | DOWN    |
| V2                                                                            | UP      | DOWN    | UP      | DOWN    |
| Advertise the route for this VIP address?                                     | Yes     | Yes     | Yes     | Yes     |
| <b>RHI State set to ACTIVE on all virtual servers</b>                         |         |         |         |         |
| V1                                                                            | UP      | UP      | DOWN    | DOWN    |
| V2                                                                            | UP      | DOWN    | UP      | DOWN    |
| Advertise the route for this VIP address?                                     | Yes     | Yes     | Yes     | No      |
| <b>RHI State set to ACTIVE on one virtual server and PASSIVE on the other</b> |         |         |         |         |
| V1 (RHI State = ACTIVE)                                                       | UP      | UP      | DOWN    | DOWN    |
| V2 (RHI State = PASSIVE)                                                      | UP      | DOWN    | UP      | DOWN    |

| Associated virtual servers for a VIP      | State 1 | State 2 | State 3 | State 4 |
|-------------------------------------------|---------|---------|---------|---------|
| Advertise the route for this VIP address? | Yes     | Yes     | No      | No      |

To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to `VSVR_CNTRLD` for the VIP address.
- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using the CLI:

At the command prompt, type:

- **set ns ip** <IPAddress> [-**vserverRHILevel** <vserverRHILevel>]

To set the RHI State parameter of a virtual server by using the CLI:

At the command prompt, type:

- **set lb vsver** <name> [-**RHIstate** ( **PASSIVE** | **ACTIVE** )]

To set the vServer RHI Level for a VIP address by using GUI

1. Navigate to **System > Network > IPs**.
2. Select a VIP address, and then click **Edit**.
3. Set the **Vserver RHI Level** parameter to **VSVR\_CNTRLD**, and then click **OK**.

To set the RHI State parameter of a virtual server by using GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a load balancing virtual server, and then click **Edit**.
3. Set the **RHI State** parameter, and then click **OK**.

## Configuring Policy-Based Routes

September 21, 2020

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the Citrix ADC appliance to route outgoing packets from a specific

IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the Citrix ADC applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the Citrix ADC to route the packet. These actions are known as “processing modes.” The processing modes are:

- **ALLOW.** The appliance sends the packet to the designated next-hop router.
- **DENY.** The Citrix ADC applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

## Policy-Based Routes (PBR) for IPv4 Traffic

March 16, 2021

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

### Creating or Modifying a PBR

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBRs. When you create a PBR without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR, the Citrix ADC compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the Citrix ADC and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

### CLI procedures

To create a PBR by using the CLI:

At the command prompt, type:

- `add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-state ( ENABLED | DISABLED )]`
- `show ns pbr`

#### Example:

```
1 > add ns pbr pbr1 allow -srcip 10.102.37.252 -destip 10.10.10.2 -
    nexthop 10.102.29.77
2 Done
3 <!--NeedCopy-->
```

To modify the priority of a PBR by using the CLI:

At the command prompt, type the following commands to modify the priority and verify the configuration:

- `set ns pbr <name> [-action ( ALLOW | DENY )] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-state ( ENABLED | DISABLED )]`
- `show ns pbr [<name>]`

#### Example:

```
1 > set ns pbr pbr1 -priority 23
2 Done
```

```
3 <!--NeedCopy-->
```

To remove one or all PBRs by using the CLI:

At the command prompt, type one of the following commands:

- `rm ns pbr <name>`
- `clear ns pbrs`

**Example:**

```
1 > rm ns pbr pbr1
2 Done
3
4 > clear ns PBRs
5 Done
6 <!--NeedCopy-->
```

### GUI procedures

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

### Applying a PBR

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

**Note:** PBRs created on the Citrix ADC appliance do not work until they are applied.

To apply a PBR by using the CLI:

At the command prompt, type:

```
apply ns PBRs
```

To apply a PBR by using the GUI:

1. Navigate to System > Network > PBRs.

2. On the PBRs tab, select the PBR, in the Action list, select Apply.

## Enabling or Disabling PBRs

By default, the PBRs are enabled. This means that when PBRs are applied, the Citrix ADC appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the Citrix ADC does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the CLI:

At the command prompt, type one of the following commands:

- `enable ns pbr <name>`
- `disable ns pbr <name>`

### Example:

```
1 > enable ns PBR pbr1
2 Done
3 > show ns PBR pbr1
4 1)      Name: pbr1
5         Action: ALLOW                               Hits: 0
6         srcIP = 10.102.37.252
7         destIP = 10.10.10.2
8         srcMac:                                     Protocol:
9         Vlan:                                       Interface:
10        Active Status: ENABLED                       Applied Status: APPLIED
11        Priority: 10
12        NextHop: 10.102.29.77
13
14 Done
15
16 > disable ns PBR pbr1
17 Warning: PBR modified, use 'apply pbrs' to commit this operation
18
19 > apply pbrs
20 Done
21
22 > show ns PBR pbr1
23 1)      Name: pbr1
24         Action: ALLOW                               Hits: 0
25         srcIP = 10.102.37.252
26         destIP = 10.10.10.2
27         srcMac:                                     Protocol:
```

```

28      Vlan:                               Interface:
29      Active Status: DISABLED             Applied Status:
      NOTAPPLIED
30      Priority: 10
31      NextHop: 10.102.29.77
32 Done
33 <!--NeedCopy-->

```

To enable or disable a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

## Renumbering PBRs

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the CLI:

At the command prompt, type:

- renumber ns pbrs

To renumber PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

## Use Case - PBR with Multiple Hops

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on Citrix ADC appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The Citrix ADC appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.

- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - ROUNDROBIN
  - DESTINATIONIPHASH
  - SOURCEIPHASH
  - SRCIPDESTIPHASH
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - LTRM
  - CALLIDHASH
  - CUSTOM LOAD
- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDESTIP

The following table lists the names and values of the entities configured on the Citrix ADC appliance:

| Entity Type                        | Name    | IP Address |
|------------------------------------|---------|------------|
| Link load balancing virtual server | LLB1    | NA         |
| Services (next hops)               | Router1 | 1.1.1.254  |
|                                    | Router2 | 2.2.2.254  |
|                                    | Router3 | 3.3.3.254  |
| PBRs                               | PBR1    | NA         |
|                                    | PBR2    | NA         |

Table 1. Sample Values for Creating Entities

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

**Example:**

```
1 > add service Router1 1.1.1.254 ANY *
2 Done
3 > add service Router2 2.2.2.254 ANY *
4 Done
5 > add service Router3 3.3.3.254 ANY *
6 Done
7 <!--NeedCopy-->
```

To create a service by using the GUI:

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

**Example:**

```
1 > add lb vserver LLB1 ANY
2 Done
3 > bind lb vserver LLB1 Router1 Router2 Router3
4 Done
5 <!--NeedCopy-->
```

To create a link load balancing virtual server and bind a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.

Note: Make sure that

**Directly Addressable** is unchecked.

2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

**Example:**

```
1 > add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
2   Done
3 > add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
4   Done
5 <!--NeedCopy-->
```

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

## Policy-Based Routes (PBR6) for IPv6 Traffic

September 21, 2020

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

### Creating or Modifying a PBR6

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR6, the Citrix ADC compares the packet against the PBR6 with the next highest priority.

### CLI procedures

To create a PBR6 by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>]

```
[-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state ( ENABLED | DISABLED)] [-msr ( ENABLED | DISABLED)] [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]
```

- `show ns pbr`

To modify or remove a PBR6 by using the CLI:

To modify a PBR6, type the **set pbr6** <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the CLI:

At the command prompt, type one of the following commands:

- **rm ns pbr6** <name>
- **clear ns pbr6**

## GUI procedures

To create or modify a PBR6 by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

## Applying PBR6s

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6\_1 - p6\_10), and then you create another PBR6 (p6\_11) and apply it, all of the PBR6s (p6\_1 - p6\_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

**Note:** PBR6s created on the Citrix ADC appliance do not work until they are applied.

To apply PBR6s by using the CLI:

At the command prompt, type:

- **apply ns PBR6**

To apply PBR6s by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

### Enabling or Disabling a PBR6

By default, the PBR6s are enabled. This means that when PBR6s are applied, the Citrix ADC appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the Citrix ADC does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns pbr** <name>
- **disable ns pbr** <name>

To enable or disable a PBR6 by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

### Renumbering PBR6s

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the CLI:

At the command prompt, type:

- **renumber ns pbr6**

To renumber PBR6s by using the GUI:

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

### MAC Address Wildcard Mask for PBRs

September 21, 2020

A wildcard mask parameter has been introduced for extended PBRs and PBR6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of outgoing packets.

Wildcard masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an PBR rule, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the outgoing packets.

To specify a range of source MAC addresses in a PBR rule by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> <action> **-srcMac** <mac\_addr> **-srcMacMask** <string>
- **show ns pbr** <pbrname>

**Example:**

```
1 > add ns pbr PBR-1 ALLOW -srcip 192.0.2.34 -srcMac 96:fa:95:1d:67:4a
   - srcMacMask 000000111111 -nextHop 198.51.100.1
2
3 Done
```

To specify a range of source MAC addresses in an PBR6 rule by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> **-srcMac** <mac\_addr> **-srcMacMask** <string>
- **show pbr6** <pbr6name>

**Example:**

```
1 > add ns pbr6 PBR6-1 ALLOW - srcipv6 2001:db8:0::7 -srcMac 96:fa:95:1d
   :67:4a - srcMacMask 000000001111 -nexthop 2001:db8:0::1
2 Done
```

## Using NULL Policy Based Routes to Drop Outgoing Packets

September 21, 2020

Some situations might demand that the Citrix ADC appliance drops specific outgoing packets instead of routing them, for example, in testing cases and during deployment migration.

NULL policy based routes can be used to drop specific outgoing packets. A NULL PBR is a type of PBR that has the nexthop parameter set to NULL. The Citrix ADC appliance drops outgoing packets that match a NULL PBR.

### Configuring NULL PBRs for IPv4 Packets

To create a NULL PBR by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> ALLOW [-td <positive\_integer>] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] (-nextHop NULL) [srcMac <mac\_addr> [-srcMacMask <string>]] [-protocol <protocol> | -protocolNumber <positive\_integer>] [-vlan <positive\_integer> | -vxlan <positive\_integer>] [-interface <interface\_name>] [-priority <positive\_integer>] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-state ( ENABLED | DISABLED )][-ownerGroup <string>]
- **apply ns pbrs**
- **show ns pbr**<id>

To configure a NULL PBR by using the GUI:

Navigate to **System > Network > PBRs**, on the **PBRs** tab, add a **new NULL PBR**, or edit an existing NULL PBR.

### Sample configuration

In the following sample configuration, NULL PBR6 PBR6-NULL-EXAMPLE-1 is configured for dropping any outgoing IPv6 packets from interface 1/5.

```
1 > add ns pbr PBR6-NULL-EXAMPLE-1 ALLOW - nextHop NULL -interface 1/5
2   Done
3
4 > apply ns pbr6
5   Done
```

## Troubleshooting Routing Issues

September 21, 2020

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the Citrix ADC appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr\_error.log and dr\_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

## Generic Routing FAQs

September 21, 2020

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from CLI to save both ns.conf and ZebOS.conf files.

- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

- How do I block the advertisement of default routes?

The default route is not injected into ZebOS.

- How do I view the debug output of networking daemons?

You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

```
1 ns(config)# log file /var/ZebOS.log
2 <!--NeedCopy-->
```

You can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

```
1 ns# terminal monitor
2 <!--NeedCopy-->
```

- How do I collect cores of running daemons?

You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

```
1 gcore [-s] [-c core] [executable] pid
2 <!--NeedCopy-->
```

The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

```
1 root@ns#gcore -s -c nsm.core /netscaler/nsm 342
2 <!--NeedCopy-->
```

- How do I run a batch of ZebOS commands?

You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

```
1  !
2  router bgp 234
3  network 1.1.1.1 255.255.255.0
4  !
5  route-map bgp-out2 permit 10
6   set metric 9900
7   set community 8602:300
8  !
9  <!--NeedCopy-->
```

## Troubleshooting OSPF-Specific Issues

September 21, 2020

Before you start debugging any OSPF specific issue, you must collect information from the Citrix ADC appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
  - If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
  - If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

```
1 gcore -s -c xyz.core /netscaler/ospfd <pid>
```

**Note:** The gcore command is non-disruptive.

Collect additional information from the Citrix ADC as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

```
1 ns(config)# log file /var/ospf.log
2 <!--NeedCopy-->
```

2. Enable debugging ospf events and log them by using the following command:

```
1 ns(config) #log file /var/ospf.log
2 <!--NeedCopy-->
```

Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

## Internet protocol version 6 (IPv6)

September 21, 2020

A Citrix ADC appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services.

The following table lists some of the IPv6 features that the Citrix ADC appliance supports.

Table 1. Some Supported IPv6 Features

---

IPv6 features

---

IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)

Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)

Management Applications (ping6, telnet6, ssh6)

Static Routing and Dynamic routing (OSPF, BGP, RIPng, and ISIS)

Port Based VLANs

Access Control Lists for IPv6 addresses (ACL6)

---

---

## IPv6 features

---

IPv6 Protocols (TCP6, UDP6, ICMP6)

Server Side Support (IPv6 addresses for virtual server, services)

USIP (Use source IP) and DSR (Direct Server Return) for IPv6

SNMP and Clientless VPN for IPv6

High Availability with native IPv6 node address

IPv6 addresses for MIPs

Path-MTU discovery for IPv6

---

## Implementing IPv6 support

You must enable IPv6 feature on a Citrix ADC appliance before you can use or configure it. If IPv6 is disabled, the Citrix ADC does not process IPv6 packets. It displays the following warning when you run an unsupported command:

```
1 "Warning: Feature(s) not enabled [IPv6PT]"
2 <!--NeedCopy-->
```

Use either of the following procedures to enable or disable IPv6.

### CLI procedures

To enable or disable IPv6 by using the CLI:

At the command prompt, type one of the following commands:

- `enable ns feature ipv6pt`
- `disable ns feature ipv6pt`

### GUI procedures

To enable or disable IPv6 by using the GUI:

1. Navigate to **System > Settings**, in the **Modes and Features** group, click **Configure Advanced Features**.
2. Select or clear the **IPv6 Protocol Translation** option.

## VLAN support

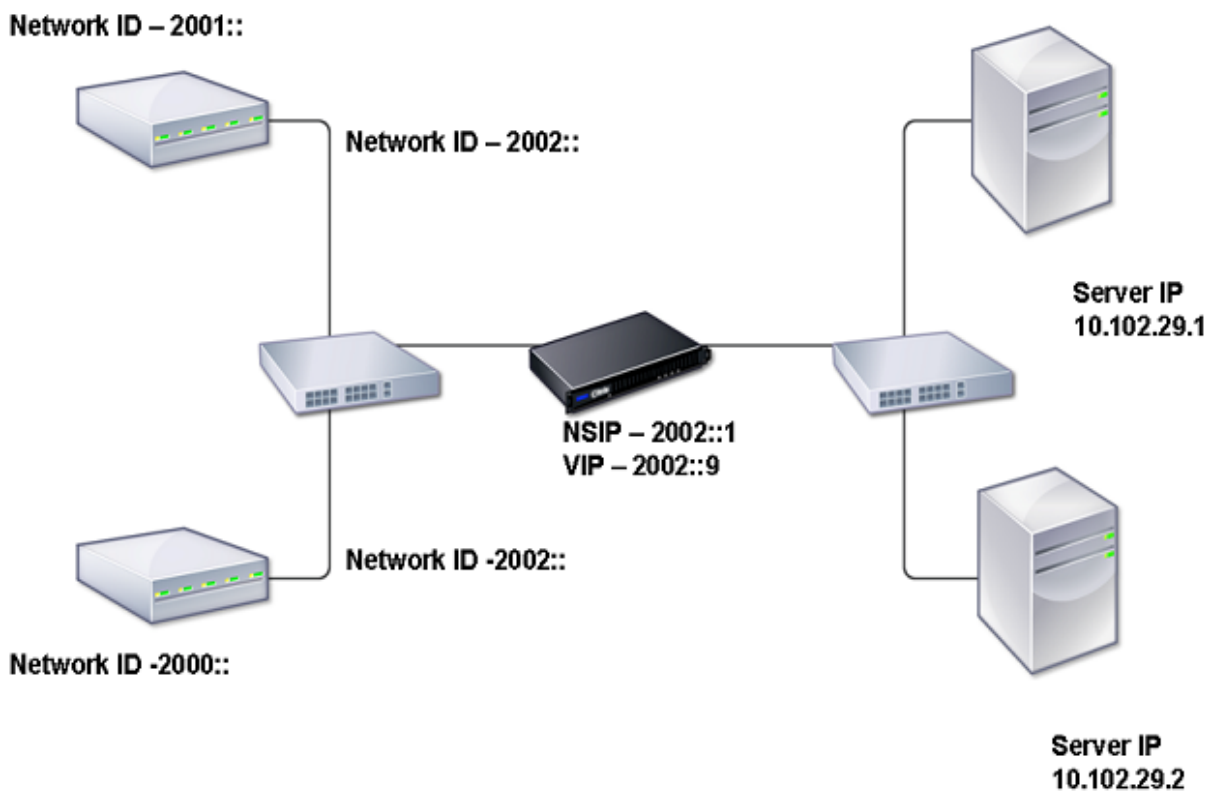

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the Citrix ADC appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN. For more information about ND6 and VLANs, see [Configuring Neighbor Discovery](#).

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

## Simple deployment scenario

Following is an example of a simple load balancing set-up consisting of an IPv6 virtual server and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology

The following table summarizes the names and values of the entities that must be configured on the Citrix ADC.

Table 2. Sample Values for Creating Entities

| Entity type       | Name     | Value       |
|-------------------|----------|-------------|
| LB virtual server | VS1_IPv6 | 2002::9     |
| Services          | SVC1     | 10.102.29.1 |
|                   | SVC2     | 10.102.29.2 |

The following figure shows the entities and values of the parameters to be configured on the Citrix ADC.

Figure 2. IPv6 Entity Diagram

To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB virtual server.
3. Bind the services to the virtual server.

#### **CLI procedures**

To create IPv4 services by using the CLI:

At the command prompt, type:

- **add service** <Name> <IPAddress> <Protocol> <Port>
- **show service** <Name>

**Example:**

```
1 add service SVC1 10.102.29.1 HTTP 80
2
3 add service SVC2 10.102.29.2 HTTP 80
4
5 <!--NeedCopy-->
```

To create IPv6 virtual server by using the CLI:

At the command prompt, type:

- **add lb vsrver** <Name> <IPAddress> <Protocol> <Port>
- **sh lb vsrver** <Name>

**Example:**

```
1 add lb vsrver VS1_IPv6 2002:::9 HTTP 80
2
3 <!--NeedCopy-->
```

To bind a service to an LB virtual server by using the CLI:

At the command prompt, type:

- **bind lb vsrver** <name> <service>
- **sh lb vsrver** <name>

**Example:**

```
1 bind lb vsrver VS1_IPv6 SVC1
2
3 <!--NeedCopy-->
```

**GUI procedures**

To create IPv4 services by using the GUI:

Navigate to **Traffic Management > Load Balancing > Services**, click **Add**, and then set the following parameters:

- Service Name
- IP Address
- Protocol

- Port

To create IPv6 virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, click **Add**, and select the **IPv6** check box.
2. Set the following parameters:
  - Name
  - Protocol
  - IP Address Type
  - IP Address
  - Port

To bind a service to an LB virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the **Load Balancing Virtual Servers** page, select the virtual server for which you want to bind the service (for example, VS1\_IPv6).
3. Click **Open**.
4. In the **Configure Virtual Server (Load Balancing)** dialog box, on the **Services** tab, select the **Active** check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click **OK**.
6. Repeat steps 1-4 to bind the service (for example, SVC2 to the virtual server).

## Host header modification

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the virtual server.

## CLI procedures

To change the IPv6 address in the host header to an IPv4 address by using the CLI:

At the command prompt, type:

- **set ns ip6** <IPv6Address> **-map** <IPAddress>
- **sh ns ip6** <IPv6Address>

### Example:

```
1 set ns ip6 2002::9 -map 200.200.200.200
2
3 <!--NeedCopy-->
```

## GUI procedures

To change the IPv6 address in the host header to an IPv4 address by using the GUI:

1. Navigate to **System > Network > IPs** and, on the **IPv6s** tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:9, and click Edit.
2. In the **Mapped IP** text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

## VIP insertion

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP. Then, you can enable VIP insertion feature to enable insertion of the IPv4 VIP address and port number in the HTTP requests sent to the servers.

## CLI procedures

To configure a map IPv6 address by using the CLI:

At the command prompt, type:

```
set ns ip6 <IPv6Address> -map <IPAddress>
```

### Example:

```
1 set ns ip6 2002::9 -map 200.200.200.200
2
3 <!--NeedCopy-->
```

To enable VIP insertion by using the CLI:

At the command prompt, type:

- **set lb vsrver** <name> **-insertVserverIPPort** <Value>
- **sh lb vsrver** <name>

### Example:

```
1 set lb vsrver VS1_IPv6 -insertVserverIPPort ON
2
3 <!--NeedCopy-->
```

## GUI procedures

To configure a map IPv6 address by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPv6s** tab, select the IP address for which you want to configure a map IP address, for example, 2002:0:0:0:0:0:9, and click **Edit**.
2. In the **Mapped IP** text box, type the map IP address that you want to configure, for example, 200.200.200.200.

To enable VIP insertion feature by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select the virtual server that you want to enable port insertion, and select **Edit**.
2. In the **Advanced** tab, under **Traffic Settings**, in the **Vserver IP Port Insertion** list, click **VIPADDR**.
3. In the **Vserver IP Port Insertion** text box, type the vip header.

## Traffic Domains

March 16, 2021

### Warning

Citrix recommends you to use Admin Partitions instead of using Traffic Domains. For more information, see [Admin Partitioning](#) page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a Citrix ADC appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

### Benefits of using Traffic Domains

The main benefits of using traffic domains on a Citrix ADC appliance are the following:

- **Use of duplicate IP addresses in a Network.** Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a Citrix ADC appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the Citrix ADC appliance.** Traffic domains also allow you to use duplicate Citrix ADC feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.  
Note: Duplicate entities with same name are not supported.
- **Multitenancy.** Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANs configured on the appliance.

## Default Traffic Domain

A Citrix ADC appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the Citrix ADC appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

**Note:** Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see Supported Citrix ADC Features in Traffic Domains.

## How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1.

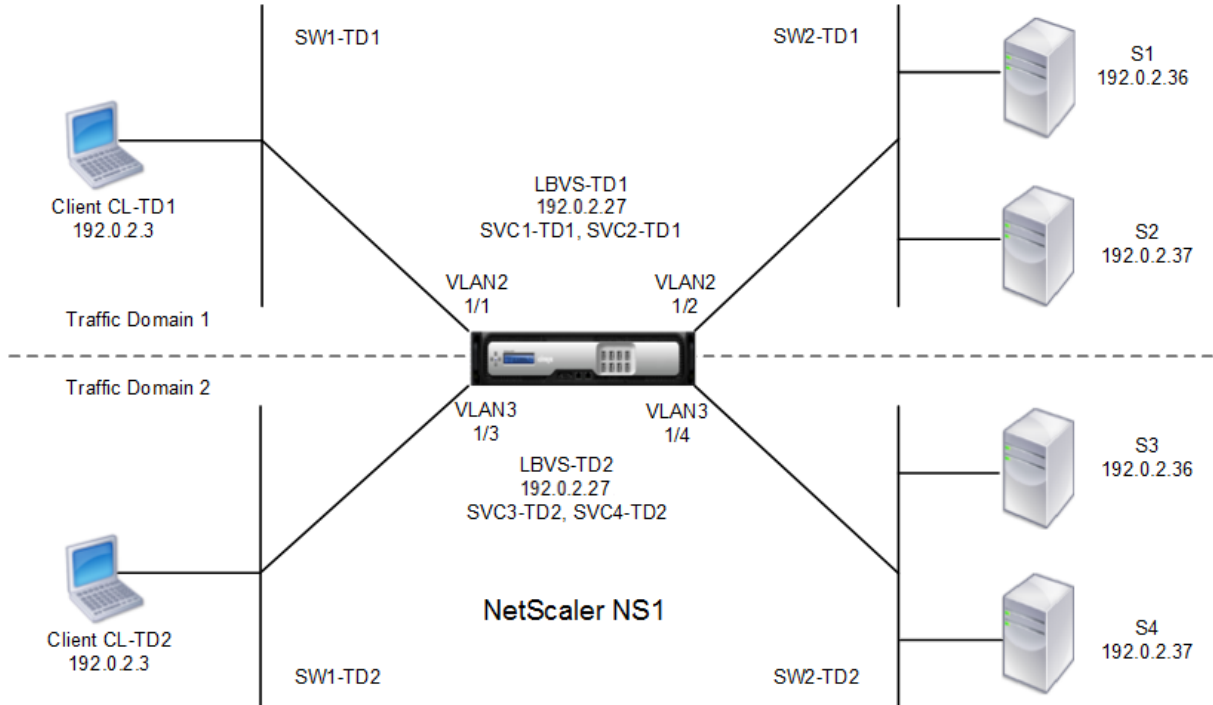

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the Citrix ADC appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work

The following table lists the settings used in the example.

| Entity                                   | Name                                   | Details                               |
|------------------------------------------|----------------------------------------|---------------------------------------|
| <b>Settings in traffic domain 1</b>      |                                        |                                       |
| VLANs bound to traffic domain 1          | VLAN 2                                 | VLAN Id: 2 Interfaces bound: 1/1, 1/2 |
| Client connected to TD1                  | CL-TD1 (for reference purposes only)   | IP address: 192.0.2.3                 |
| Load balancing virtual server in TD1     | LBVS-TD1                               | IP address: 192.0.2.27                |
| Service bound to virtual server LBVS-TD1 | SVC1-TD1                               | IP address: 192.0.2.36                |
| Service bound to virtual server LBVS-TD1 | SVC2-TD1                               | IP address: 192.0.2.37                |
| SNIP                                     | SNIP-TD1 (for reference purposes only) | IP address: 192.0.2.27                |
| <b>Settings in traffic domain 2</b>      |                                        |                                       |

| Entity                                   | Name                                   | Details                               |
|------------------------------------------|----------------------------------------|---------------------------------------|
| VLAN bound to traffic domain 2           | VLAN 3                                 | VLAN Id: 3 Interfaces bound: 1/3, 1/4 |
| Client connected to TD2                  | CL-TD2 (for reference purposes only)   | IP address: 192.0.2.3                 |
| Load balancing virtual server in TD2     | LBVS-TD2                               | IP address: 192.0.2.27                |
| Service bound to virtual server LBVS-TD2 | SVC3-TD2                               | IP address: 192.0.2.36                |
| Service bound to virtual server LBVS-TD2 | SVC4-TD2                               | IP address: 192.0.2.37                |
| SNIP in TD2                              | SNIP-TD2 (for reference purposes only) | IP address: 192.0.2.29                |

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD1.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.27. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.27.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.27. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD2.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is

bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.

3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.27. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.27. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.27. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

## Supported Citrix ADC Features in Traffic Domains

The Citrix ADC features in the following list are supported in all traffic domains.

### Important

Any Citrix ADC feature not listed below is supported only in the default traffic domain.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6
- MSR
- MSR6
- Net profiles
- SNMP MIBs
- Fragmentation
- Monitors (Scriptable monitors are not supported)

- Content Switching
- Cache Redirection
- Persistency (Persistency groups are not supported)
- Service (Domain based services are not supported)
- Service group (Domain based service groups are not supported)
- Policies (\*)
- PING
- TRACEROUTE
- PMTU
- High Availability (connection mirroring is not supported)
- Cluster (Supported on L2 clusters. Not supported on L3 clusters)
- Cookie Persistency
- MSS
- Logging (Syslog is not supported)
- Priority Queuing
- Surge Protection
- HTTP DOSP (\*\*)
- Load balancing (The following types are not supported:)
  - TFTP
  - RTSP
  - Diameter
  - SIP
  - SMPP
- NAT46
- NAT64
- DNS64
- Forwarding Session Rules
- SNMP

**Note**

- \* Policies do not have global binding points for traffic domains. However, policies can be bound to a specific load balancing virtual server of a traffic domain.
- \*\* HTTP DOSP policies do not have global binding points for traffic domains. However, HTTP DOSP policies can be bound to a specific load balancing service of a traffic domain.
- Global Server Loading Balancing (GSLB) and ADNS features in Citrix ADC are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see <http://support.citrix.com/article/CTX202277>.

## Configuring Traffic Domains

Configuring a traffic domain on the Citrix ADC appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
