Citrix ADC 13.0

Contents

Citrix ADC Release Notes

November 15, 2021

Release notes describe how the software has changed in a particular build, and the issues known to exist in the build.

The release notes document includes all or some of the following sections:

- **What's New**: The enhancements and other changes released in the build.
- **Fixed Issues**: The issues that are fixed in the build.
- **Known Issues**: The issues that exist in the build.
- **Points to Note**: The important aspects to keep in mind while using the build.
- **Limitations**: The limitations that exist in the build.

> **Note**
>
> - The [# XXXXXX] labels under the issue descriptions are internal tracking IDs used by the Citrix ADC team.
> - These release notes do not document security related fixes. For a list of security related fixes and advisories, see the Citrix security bulletin.

To view the release notes document for a specific build, click the corresponding link in the following table. When the release notes are updated for a build, the version number of the release notes and the publish date are also updated. The release notes publish date might not be the same as the build GA date.

Release notes for Citrix ADC release 13.0	Release notes publish date	Release notes version
Build 83.29	November 15, 2021	1.0
Build 82.45	July 19, 2021	2.0
Build 79.64	April 28, 2021	3.0
Build 76.31	April 06, 2021	3.0
Build 71.44	February 19, 2021	4.0
Build 67.43	November 26, 2020	2.0
Build 64.35	January 21, 2021	4.0
Build 61.48	September 04, 2020	3.0
Build 58.32	July 07, 2020	1.0
Build 52.24	July 20, 2020	4.0
Build 47.24	April 20, 2020	2.0

Build 41.28	April 20, 2020	3.0

Getting started with Citrix ADC

September 14, 2021

This topic describes the basic features and configuration details of a Citrix ADC appliance. System and network administrators who install and configure network equipment can refer to the content.

Understanding Citrix ADC

The Citrix ADC appliance is an application switch which performs application-specific traffic analysis to intelligently distribute, optimize, and secure Layer 4-Layer 7 (L4–L7) network traffic for web applications. For example, a Citrix ADC appliance load balances decisions on individual HTTP requests instead of long-lived TCP connections. The load balancing feature helps slowing down the failure of a server with less disruption to clients. The ADC features can be broadly classified as:

1. Data switching
2. Firewall security
3. Optimization
4. Policy infrastructure
5. Packet flow
6. System limitation

Data switching

When deployed in front of application servers, a Citrix ADC ensures optimal distribution of traffic by how it directs client requests. Administrators can segment application traffic according to information in the body of an HTTP or TCP request, and based on L4–L7 header information such as URL, application data type, or cookie. Numerous load balancing algorithms and extensive server health checks improve application availability by ensuring that client requests are directed to the appropriate servers.

Firewall security

The Citrix ADC security and protection protect web applications from Application Layer attacks. An ADC appliance allows legitimate client requests and can block malicious requests. It provides built-in

defenses against denial-of-service (DoS) attacks and supports features that protect against legitimate surges in application traffic that would otherwise overwhelm the servers. An available built-in firewall protects web applications from Application Layer attacks, including buffer overflow exploits, SQL injection attempts, cross-site scripting attacks, and more. In addition, the firewall provides identity theft protection by securing confidential corporate information and sensitive customer data.

Optimization

Optimization offloads resource-intensive operations, such as Secure Sockets Layer (SSL) processing, data compression, client keep-alive, TCP buffering, and the caching of static and dynamic content from servers. This improves the performance of the servers in the server farm and therefore speeds up applications. An ADC appliance supports several transparent TCP optimizations which mitigate problems caused by high latency and congested network links. Thereby accelerating the delivery of applications while requiring no configuration changes to clients or servers.

Policy infrastructure

A policy defines specific details of traffic filtering and management on a Citrix ADC. It consists of two parts: the expression and the action. The expression defines the types of requests that the policy matches. The action tells the ADC appliance what to do when a request matches the expression. For example, the expression might be to match a specific URL pattern for a security attack with the configured to drop or reset the connection. Each policy has a priority, and the priorities determine the order in which the policies are evaluated.

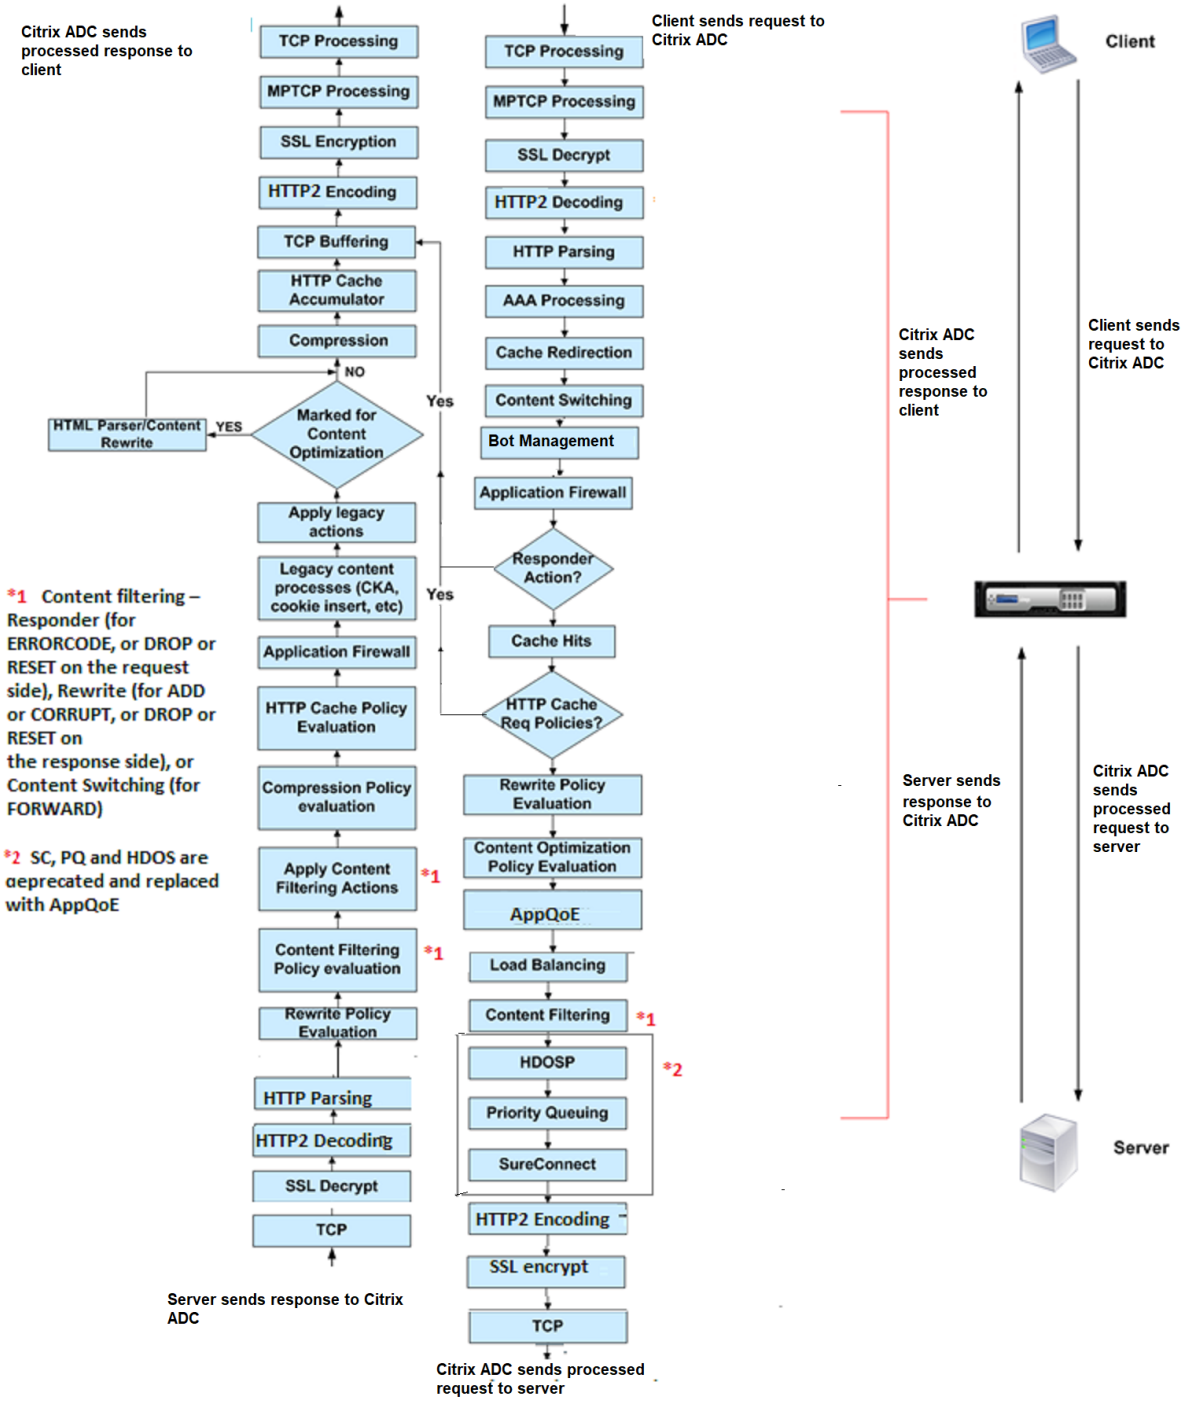
When an ADC appliance receives traffic, the appropriate policy list determines how to process the traffic. Each policy on the list contains one or more expressions, which together define the criteria that a connection must meet to match the policy.

For all policy types except rewrite, the appliance implements only the first policy that has a request match. For Rewrite policies, the ADC appliance evaluates the policies in order and performs the associated actions in the same order. Policy priority is important for getting the results you want.

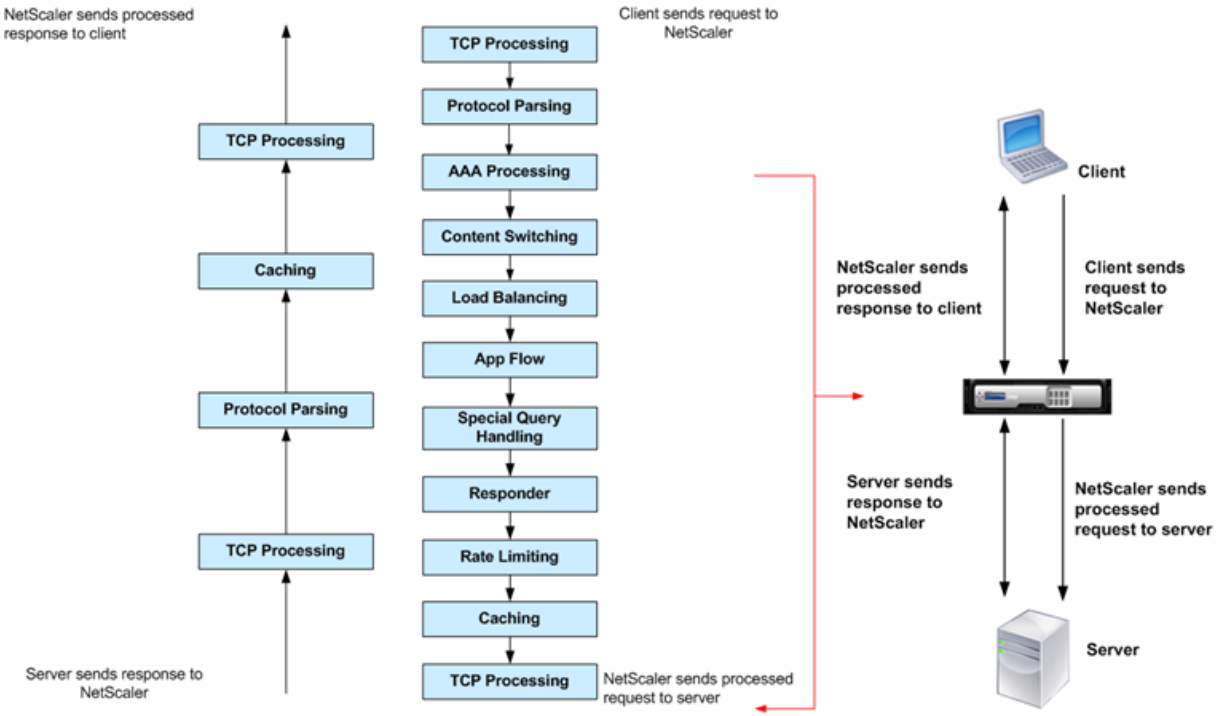
Packet flow

Depending on requirements, you can choose to configure multiple features. For example, you might choose to configure both compression and SSL offload. As a result, an outgoing packet might be compressed and then encrypted before being sent to the client.

The following figure shows the DataStream packet flow in the Citrix ADC appliance. DataStream is supported for MySQL and MS SQL databases.



The following figure shows the DataStream packet flow in the Citrix ADC appliance. DataStream is supported for MySQL and MS SQL databases. For information about the DataStream feature, see DataStream.



> **Note:** If the traffic is for a content switching virtual server, the appliance evaluates policies in the following order:
>
> 1. bound to global override.
> 2. bound to load balancing virtual server.
> 3. bound to content switching virtual server.
> 4. bound to global default.
>
> This way, if a policy rule is true and gotopriorityexpression is END, we stop further policy evaluation.
> In content switching, if no load balancing virtual server is selected or bound to the content switching virtual server, then we evaluate responder policies bound only to the content switching virtual server.

System limitation

There are system limitations for each Citrix ADC feature when you install Citrix ADC software 9.2 or later. For more information, see Citrix article, CTX118716.

Where does a Citrix ADC appliance fit in the network?

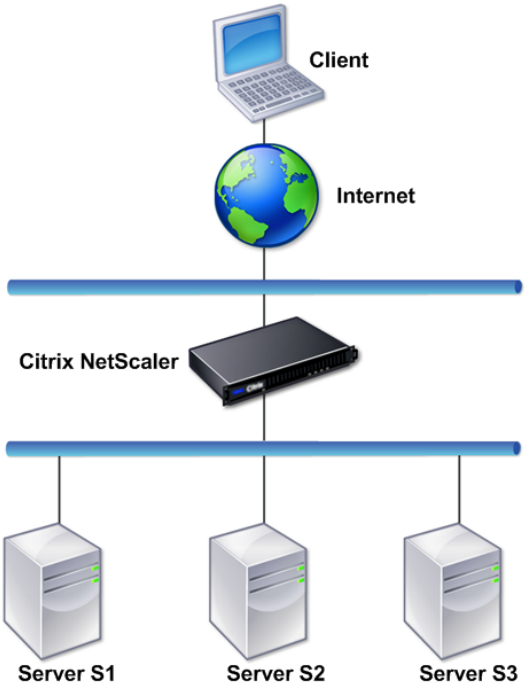
September 14, 2021

A Citrix ADC appliance resides between the clients and the servers, so that client requests and server responses pass through it. In a typical installation, virtual servers configured on the appliance provide connection points that clients use to access the applications behind the appliance. In this case, the appliance owns public IP addresses that are associated with its virtual servers, while the real servers are isolated in a private network. It is also possible to operate the appliance in a transparent mode as an L2 bridge or L3 router, or even to combine aspects of these and other modes.

Physical deployment modes

A Citrix ADC appliance logically residing between clients and servers can be deployed in either of two physical modes: inline and one-arm. In inline mode, multiple network interfaces are connected to different Ethernet segments, and the appliance is placed between the clients and the servers. The appliance has a separate network interface to each client network and a separate network interface to each server network. The appliance and the servers can exist on different subnets in this configuration. It is possible for the servers to be in a public network and the clients to directly access the servers through the appliance, with the appliance transparently applying the L4-L7 features. Usually, virtual servers (described later) are configured to provide an abstraction of the real servers. The following figure shows a typical inline deployment.

Figure 1. Inline Deployment



In one-arm mode, only one network interface of the appliance is connected to an Ethernet segment. The appliance in this case does not isolate the client and server sides of the network, but provides access to applications through configured virtual servers. One-arm mode can simplify network changes needed for Citrix ADC installation in some environments.

For examples of inline (two-arm) and one-arm deployment, see Understanding Common Network Topologies.

Citrix ADC as an L2 device

A Citrix ADC appliance functioning as an L2 device is said to operate in L2 mode. In L2 mode, the ADC appliance forwards packets between network interfaces when all of the following conditions are met:

- The packets are destined to another device's media access control (MAC) address.
- The destination MAC address is on a different network interface.
- The network interface is a member of the same virtual LAN (VLAN).

By default, all network interfaces are members of a pre-defined VLAN, VLAN 1. Address Resolution Protocol (ARP) requests and responses are forwarded to all network interfaces that are members of the same VLAN. To avoid bridging loops, L2 mode must be disabled if another L2 device is working in parallel with the Citrix ADC appliance.

For information about how the L2 and L3 modes interact, see Packet forwarding modes.

For information about configuring L2 mode, see the “Enable and disable layer 2 mode” section in Packet forwarding modes.

Citrix ADC as a packet forwarding device

A Citrix ADC appliance can function as a packet forwarding device, and this mode of operation is called L3 mode. With L3 mode enabled, the appliance forwards any received unicast packets that are destined for an IP address that does not belong to the appliance, if there is a route to the destination. The appliance can also route packets between VLANs.

In both modes of operation, L2 and L3, the appliance generally drops packets that are in:

- Multicast frames
- Unknown protocol frames destined for an appliance’s MAC address (non-IP and non-ARP)
- Spanning Tree protocol (unless BridgeBPDUs is ON)

For information about how the L2 and L3 modes interact, see Packet forwarding modes.

For information about configuring the L3 mode, see Packet forwarding modes.

How a Citrix ADC appliance communicates with clients and servers

September 14, 2021

A Citrix ADC appliance is usually deployed in front of a server farm and functions as a transparent TCP proxy between clients and servers, without requiring any client-side configuration. This basic mode of operation is called Request Switching technology and is the core of Citrix ADC functionality. Request Switching enables an appliance to multiplex and offload the TCP connections, maintain persistent connections, and manage traffic at the request (application layer) level. This is possible because the appliance can separate the HTTP request from the TCP connection on which the request is delivered.

Depending on the configuration, an appliance might process the traffic before forwarding the request to a server. For example, if the client attempts to access a secure application on the server, the appliance might perform the necessary SSL processing before sending traffic to the server.

To facilitate efficient and secure access to server resources, an appliance uses a set of IP addresses collectively known as Citrix ADC-owned IP addresses. To manage your network traffic, you assign Citrix ADC-owned IP addresses to virtual entities that become the building blocks of your configuration. For example, to configure load balancing, you create virtual servers to receive client requests and distribute them to services, which are entities representing the applications on your servers.

Understanding Citrix ADC-owned IP addresses

To function as a proxy, a Citrix ADC appliance uses a variety of IP addresses. The key Citrix ADC-owned IP addresses are:

- Citrix ADC IP (NSIP) address

  The NSIP address is the IP address for management and general system access to the appliance itself, and for communication between appliances in a high availability configuration.

- Virtual server IP (VIP) address

  A VIP address is the IP address associated with a virtual server. It is the public IP address to which clients connect. An appliance managing a wide range of traffic may have many VIPs configured.

- Subnet IP (SNIP) address

  A SNIP address is used in connection management and server monitoring. You can specify multiple SNIP addresses for each subnet. SNIP addresses can be bound to a VLAN.

- IP Set

  An IP set is a set of IP addresses, which are configured on the appliance as SNIP . An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it.

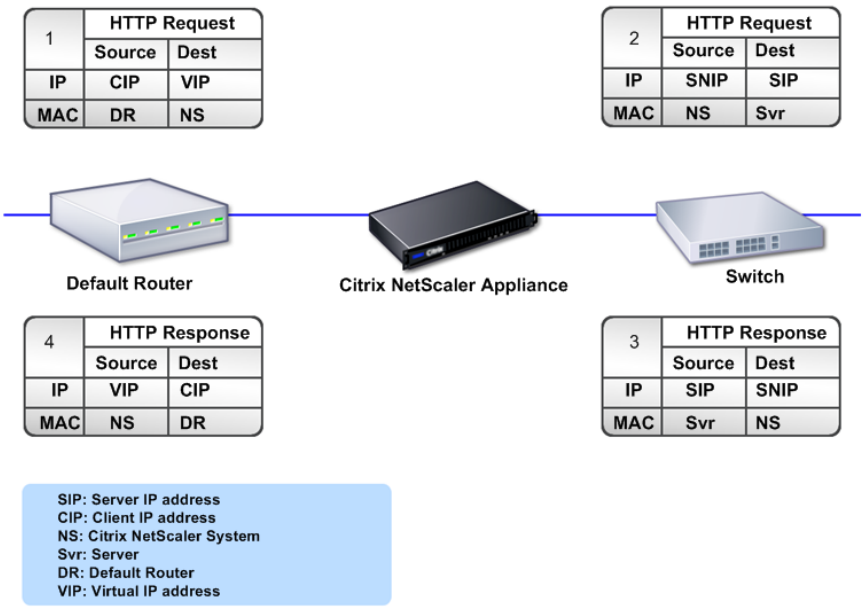
- Net Profile

  A net profile (or network profile) contains an IP address or an IP set. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. During communication with physical servers or peers, the appliance uses the addresses specified in the profile as source IP addresses.

How Traffic flows are managed

Because a Citrix ADC appliance functions as a TCP proxy, it translates IP addresses before sending packets to a server. When you configure a virtual server, clients connect to a VIP address on the Citrix ADC appliance instead of directly connecting to a server. As determined by the settings on the virtual server, the appliance selects an appropriate server and sends the client's request to that server. By default, the appliance uses a SNIP address to establish connections with the server, as shown in the following figure.

Figure 1. Virtual Server Based Connections



In the absence of a virtual server, when an appliance receives a request, it transparently forwards the request to the server. This is called the transparent mode of operation. When operating in transparent mode, an appliance translates the source IP addresses of incoming client requests to the SNIP address but does not change the destination IP address. For this mode to work, L2 or L3 mode has to be configured appropriately.

For cases in which the servers need the actual client IP address, the appliance can be configured to modify the HTTP header by inserting the client IP address as an additional field, or configured to use the client IP address instead of a SNIP address for connections to the servers.

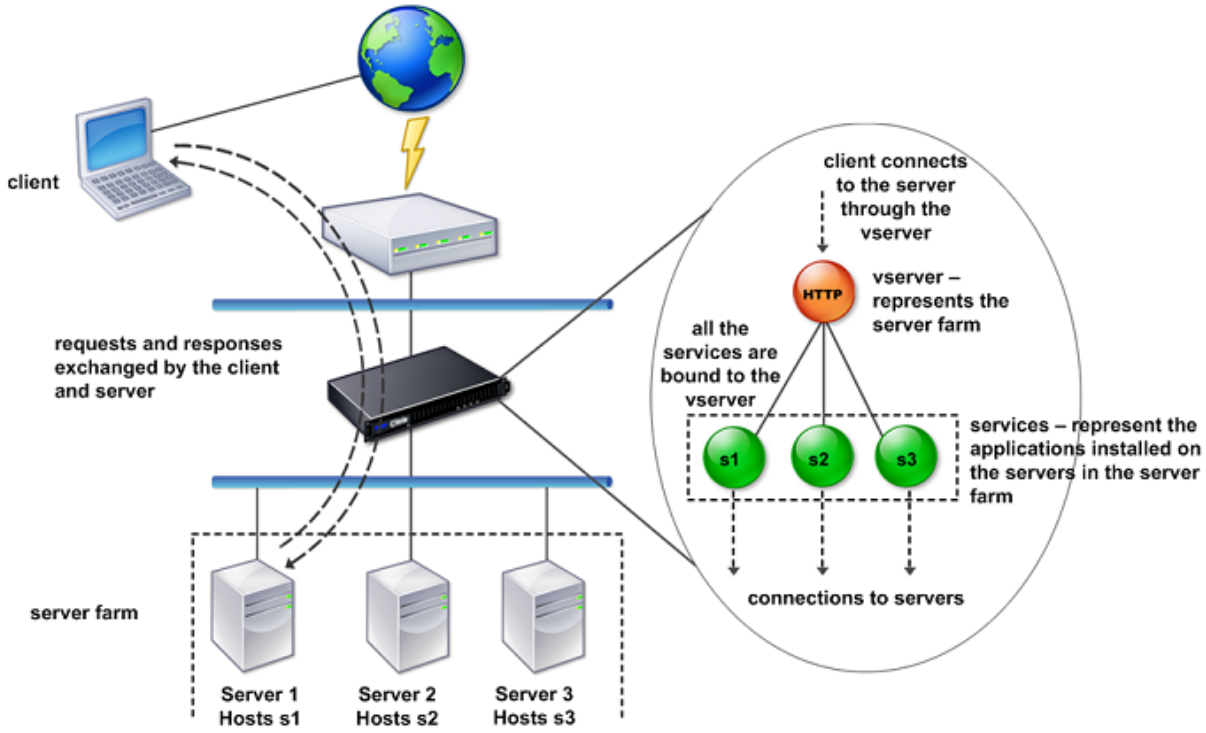
Traffic management building blocks

The configuration of a Citrix ADC appliance is typically built up with a series of virtual entities that serve as building blocks for traffic management. The building block approach helps separate traffic flows. Virtual entities are abstractions, typically representing IP addresses, ports, and protocol handlers for processing traffic. Clients access applications and resources through these virtual entities. The most commonly used entities are virtual servers and services. Virtual servers represent groups of servers in a server farm or remote network, and services represent specific applications on each server.

Most features and traffic settings are enabled through virtual entities. For example, you can configure

an appliance to compress all server responses to a client that is connected to the server farm through a particular virtual server. To configure the appliance for a particular environment, you need to identify the appropriate features and then choose the right mix of virtual entities to deliver them. Most features are delivered through a cascade of virtual entities that are bound to each other. In this case, the virtual entities are like blocks being assembled into the final structure of a delivered application. You can add, remove, modify, bind, enable, and disable the virtual entities to configure the features. The following figure shows the concepts covered in this section.

Figure 2. How traffic management building blocks work



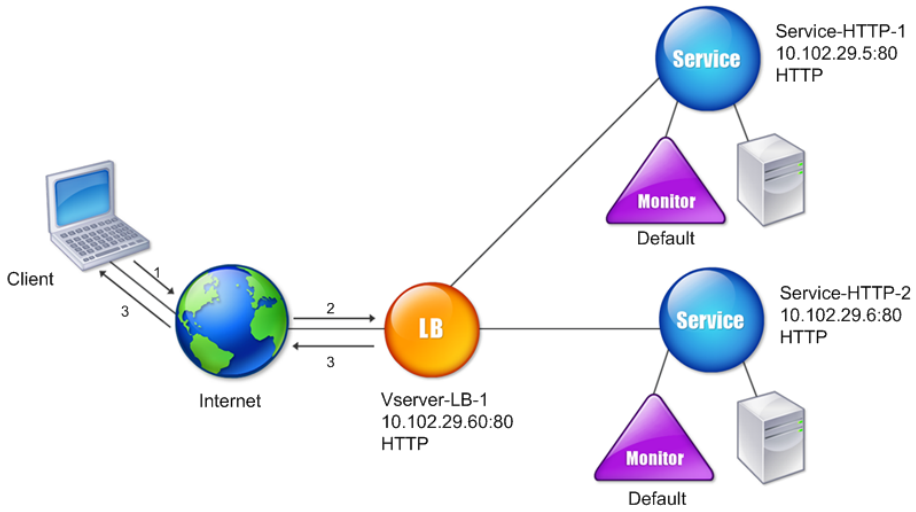
A simple load balancing configuration

In the example shown in the following figure, the Citrix ADC appliance is configured to function as a load balancer. For this configuration, you need to configure virtual entities specific to load balancing and bind them in a specific order. As a load balancer, an appliance distributes client requests across several servers and thus optimizes the utilization of resources.

The basic building blocks of a typical load balancing configuration are services and load balancing virtual servers. The services represent the applications on the servers. The virtual servers abstract the servers by providing a single IP address to which the clients connect. To ensure that client requests are sent to a server, you need to bind each service to a virtual server. That is, you must create services for every server and bind the services to a virtual server. Clients use the VIP address to connect to a Citrix ADC appliance. When the appliance receives client requests sent to the VIP address, it sends

them to a server determined by the load balancing algorithm. Load balancing uses a virtual entity called a monitor to track whether a specific configured service (server plus application) is available to receive requests.

Figure 3. Load balancing virtual server, services, and monitors



In addition to configuring the load balancing algorithm, you can configure several parameters that affect the behavior and performance of the load balancing configuration. For example, you can configure the virtual server to maintain persistence based on source IP address. The appliance then directs all requests from any specific IP address to the same server.

Understanding virtual servers

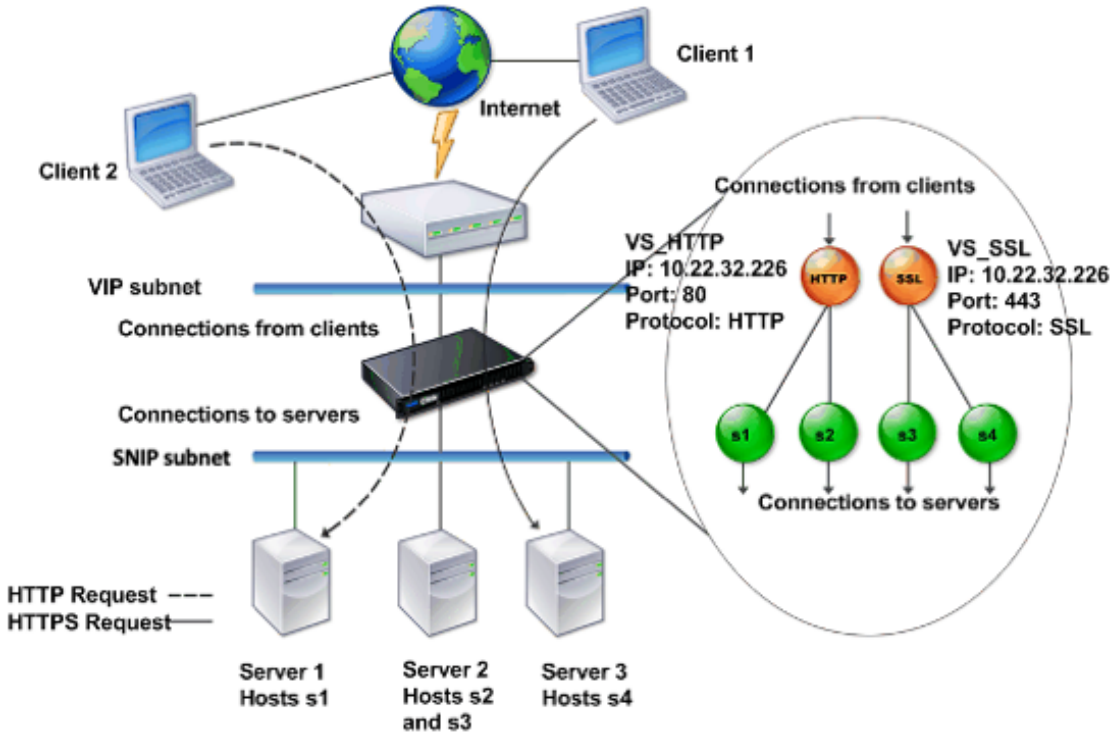
A virtual server is a named Citrix ADC entity that external clients can use to access applications hosted on the servers. It is represented by an alphanumeric name, virtual IP (VIP) address, port, and protocol. The name of the virtual server is of only local significance and is designed to make the virtual server easier to identify. When a client attempts to access applications on a server, it sends a request to the VIP instead of the IP address of the physical server. When the appliance receives a request at the VIP address, it terminates the connection at the virtual server and uses its own connection with the server on behalf of the client. The port and protocol settings of the virtual server determine the applications

that the virtual server represents. For example, a web server can be represented by a virtual server and a service whose port and protocol are set to 80 and HTTP, respectively. Multiple virtual servers can use the same VIP address but different protocols and ports.

Virtual servers are points for delivering features. Most features, like compression, caching, and SSL offload, are normally enabled on a virtual server. When the appliance receives a request at a VIP address, it chooses the appropriate virtual server by the port on which the request was received and its protocol. The appliance then processes the request as appropriate for the features configured on the virtual server.

In most cases, virtual servers work in tandem with services. You can bind multiple services to a virtual server. These services represent the applications running on physical servers in a server farm. After the appliance processes requests received at a VIP address, it forwards them to the servers as determined by the load balancing algorithm configured on the virtual server. The following figure illustrates these concepts.

Figure 4. Multiple Virtual Servers with a Single VIP Address



The preceding figure shows a configuration consisting of two virtual servers with a common VIP address but different ports and protocols. Each of the virtual servers has two services bound to it. The services s1 and s2 are bound to VS_HTTP and represent the HTTP applications on Server 1 and Server 2. The services s3 and s4 are bound to VS_SSL and represent the SSL applications on Server 2 and Server 3 (Server 2 provides both HTTP and SSL applications). When the appliance receives an HTTP

request at the VIP address, it processes the request as specified by the settings of VS_HTTP and sends it to either Server 1 or Server 2. Similarly, when the appliance receives an HTTPS request at the VIP address, it processes it as specified by the settings of VS_SSL and it sends it to either Server 2 or Server 3.

Virtual servers are not always represented by specific IP addresses, port numbers, or protocols. They can be represented by wildcards, in which case they are known as wildcard virtual servers. For example, when you configure a virtual server with a wildcard instead of a VIP, but with a specific port number, the appliance intercepts and processes all traffic conforming to that protocol and destined for the predefined port. For virtual servers with wildcards instead of VIPs and port numbers, the appliance intercepts and processes all traffic conforming to the protocol.

Virtual servers can be grouped into the following categories:

- Load balancing virtual server

  Receives and redirects requests to an appropriate server. Choice of the appropriate server is based on which of the various load balancing methods the user configures.

- Cache redirection virtual server

  Redirects client requests for dynamic content to origin servers, and requests for static content to cache servers. Cache redirection virtual servers often work in conjunction with load balancing virtual servers.

- Content switching virtual server

  Directs traffic to a server on the basis of the content that the client has requested. For example, you can create a content switching virtual server that directs all client requests for images to a server that serves images only. Content switching virtual servers often work in conjunction with load balancing virtual servers.

- Virtual private network (VPN) virtual server

  Decrypts tunneled traffic and sends it to intranet applications.

- SSL virtual server

  Receives and decrypts SSL traffic, and then redirects to an appropriate server. Choosing the appropriate server is similar to choosing a load balancing virtual server.

Understanding services

Services represent applications on a server. While services are normally combined with virtual servers, in the absence of a virtual server, a service can still manage application-specific traffic. For example, you can create an HTTP service on a Citrix ADC appliance to represent a web server application. When the client attempts to access a web site hosted on the web server, the appliance intercepts the HTTP requests and creates a transparent connection with the web server.

In service-only mode, an appliance functions as a proxy. It terminates client connections, uses a SNIP address to establish a connection to the server, and translates the source IP addresses of incoming client requests to a SNIP address. Although the clients send requests directly to the IP address of the server, the server sees them as coming from the SNIP address. The appliance translates the IP addresses, port numbers, and sequence numbers.

A service is also a point for applying features. Consider the example of SSL acceleration. To use this feature, you must create an SSL service and bind an SSL certificate to the service. When the appliance receives an HTTPS request, it decrypts the traffic and sends it, in clear text, to the server. Only a limited set of features can be configured in the service-only case.

Services use entities called monitors to track the health of applications. Every service has a default monitor, which is based on the service type, bound to it. As specified by the settings configured on the monitor, the appliance sends probes to the application at regular intervals to determine its state. If the probes fail, the appliance marks the service as down. In such cases, the appliance responds to client requests with an appropriate error message or re-routes the request as determined by the configured load balancing policies.

Introduction to the Citrix ADC product line

September 14, 2021

The Citrix ADC product line optimizes delivery of applications over the internet and private networks, combining application-level security, optimization, and traffic management into a single, integrated appliance. You can install a Citrix ADC appliance in your server room and route all connections to your managed servers through it. The Citrix ADC features that you enable and the policies you set are then applied to incoming and outgoing traffic.

A Citrix ADC appliance can be integrated into any network as a complement to existing load balancers, servers, caches, and firewalls. It requires no additional client or server side software, and can be configured using the Citrix ADC web-based GUI and CLI configuration utilities.

This topic includes the following sections:

- Citrix ADC Hardware Platforms
- Citrix ADC Editions
- Supported Releases on ADC Hardware
- Supported Browsers

Citrix ADC Hardware Platforms

Citrix ADC hardware is available in a variety of platforms that have a range of hardware specifications:

Citrix ADC MPX hardware platform

Citrix ADC SDX hardware platform

Citrix ADC Editions

The Citrix ADC operating system is available in three editions:

- Standard
- Advanced
- Premium

The Standard and Advanced editions have limited features available. Feature licenses are required for all editions.

For more information about Citrix ADC software editions, see the Citrix ADC Editions datasheet.

For information about how to obtain and install licenses, see Licensing.

Supported releases on Citrix ADC hardware

See the following compatibility matrix tables for all Citrix ADC hardware platforms and the software releases supported on these platforms:

Citrix ADC MPX Hardware-Software Compatibility Matrix

Citrix ADC SDX Hardware-Software Compatibility Matrix

Supported browsers

To access the Citrix ADC GUI, your workstation must have a supported web browser.

The following table lists the compatible browsers for NetScaler GUI version 12.0, 12.1, and 13.0:

Operating System	Browser	Versions
Windows 7 & later	Internet Explorer	11, Edge, & later
Windows 7 & later	Mozilla Firefox	45 & later
Windows 7 & later	Chrome	60 & later
MAC	Mozilla Firefox	45 & later
MAC	Safari	10.1.1 & later

The compatible browser versions for Citrix ADC 11.1 are as follows:

Operating System	Browser	Versions
Windows 7 & later	Internet Explorer	8,9,10, 11, Edge
Windows 7 & later	Mozilla Firefox	45 & later
Windows 7 & later	Chrome	60 & later
MAC	Mozilla Firefox	45 & later
MAC	Safari	10.1.1 & later

Install the hardware

September 14, 2021

Before installing a Citrix ADC appliance, review the pre-installation checklist.

To use the SDX appliance, you must complete the following tasks by following the instructions given in the resources provided in table. Complete the tasks in the sequence given.

Task

Description

1. Read safety, cautions, warnings, and other information

   Read the caution and danger information you need to know, before installing the product.

2. Prepare for installation

   Unpack your appliance and ensure all parts were delivered, prepare the site and rack, and follow basic electrical safety precautions before you install your new appliance.

3. Install the hardware

   Rack mount the appliance, install transceivers (if available), and connect the appliance to the network and a power source.

4. Configure the appliance.

   Configure the initial settings of the Citrix ADC appliance by using the GUI or the serial console.

   Follow the steps given in the following documentations to complete these tasks:

   - Citrix ADC MPX hardware documentation
   - Citrix ADC SDX hardware documentation

Access a Citrix ADC appliance

September 14, 2021

A Citrix ADC appliance has both a command line interface (CLI) and a GUI. The GUI includes a configuration utility for configuring the appliance and a statistical utility, called Dashboard. For initial access, all appliances ship with the default Citrix ADC IP address (NSIP) of 192.168.100.1 and the default subnet mask of 255.255.0.0. You can assign a new NSIP and an associated subnet mask during initial configuration.

If you encounter an IP address conflict when deploying multiple Citrix ADC units, check for the following possible causes:

- Did you select an NSIP that is an IP address already assigned to another device on your network?
- Did you assign the same NSIP to multiple Citrix ADC appliances?
- The NSIP is reachable on all physical ports. The ports on a Citrix ADC are host ports, not switch ports.

The following table summarizes the available access methods.

Access Method	Port	Default IP Address Required? (Y/N)
CLI	Console	N
CLI and GUI	Ethernet	Y

Command line interface

Access the CLI locally by connecting a workstation to the console port, or remotely by connecting through the secure shell (SSH) from any workstation on the same network.

Log on to the Command Line Interface through the Console Port

The appliance has a console port for connecting to a computer workstation. To log on to the appliance, you need a serial crossover cable and a workstation with a terminal emulation program.

To log on to the CLI through the console port, follow these steps:

1. Connect the console port to a serial port on the workstation. For more information, see Connect the console cable.
2. On the workstation, start HyperTerminal or any other terminal emulation program. If the logon prompt does not appear, you might have to press ENTER one or more times to display it.

3. In User Name, type nsroot. In Password, type nsroot and if that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance.

Log on to the Command Line Interface by using SSH

The SSH protocol is the preferred remote access method for accessing an appliance remotely from any workstation on the same network. You can use either SSH version 1 (SSH1) or SSH version 2 (SSH2.)

If you do not have a working SSH client, you can download and install any of the following SSH client programs:

- PuTTY

  Open Source software supported on multiple platforms. Available at:

  http://www.chiark.greenend.org.uk/~sgtatham/putty/

- Vandyke Software SecureCRT

  Commercial software supported on the Windows platform. Available at:

  http://www.vandyke.com/products/securecrt/

These programs are tested by the Citrix ADC team, who have verified that they work correctly with a Citrix ADC appliance. Other programs might also work correctly, but have not been tested.

To verify that the SSH client is installed properly, use it to connect to any device on your network that accepts SSH connections.

To log on to a Citrix ADC appliance by using an SSH client, follow these steps:

1. On your workstation, start the SSH client.
2. For initial configuration, use the default IP address (NSIP), which is 192.168.100.1. For subsequent access, use the NSIP that was assigned during initial configuration. Select either SSH1 or SSH2 as the protocol.
3. In User Name, type nsroot. In Password, type nsroot and if that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance. For example.

```
login as: nsroot

Using keyboard-interactive authentication.

Password:

```

Citrix ADC GUI

> **Important:**
>
> A certificate-key pair is required for HTTPS access to the Citric ADC GUI. On the ADC, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Also, if a license is not present on an MPX appliance when it starts, and you add a license later and restart the appliance, you might lose the certificate binding.

Citrix recommends that you install a certificate-key pair of at least 1024 bytes on the appliance for HTTPS access to the GUI. Also, install an appropriate license before starting the appliance.

The GUI includes a configuration utility and a statistical utility, called Dashboard, either of which you access through a workstation connected to an Ethernet port on the appliance.

The system requirements for the workstation running the GUI are as follows:

- For Windows-based workstations, a Pentium 166 MHz or faster processor.
- For Linux-based workstations, a Pentium platform running Linux kernel v2.2.12 or above, and `glibc` version 2.12–11 or later. A minimum of 32 MB RAM is required, and 48 MB RAM is recommended. The workstation must support 16-bit color mode, KDE, and KWM window managers used in conjunction, with displays set to local hosts.
- For Solaris-based workstations, a Sun running either Solaris 2.6, Solaris 7, or Solaris 8.

Your workstation must have a supported web browser to access the configuration utility and Dashboard.

The following browsers are supported.

Operating System: Windows 7

Browser: Internet Explorer (version 9, 10, and 11), Mozilla Firefox (version 3.6.25 and above), Google Chrome (latest).

Operating System: Windows 64 bit

Browser: Internet Explorer (version 8, 9, 10, and 11), Google Chrome (version latest)

Operating System: MAC
Browser: Mozilla Firefox (version 3.6.25 and above), Safari (version 5.1.3 and above), Google Chrome (version latest)

Use the Citrix ADC GUI

Once you log on to the configuration utility, you can configure the appliance through a graphical interface that includes context-sensitive help.

To log on to the GUI, follow these steps:

1. Open your web browser and enter the Citrix ADC IP (NSIP) as an HTTP address. If you have not yet set up the initial configuration, enter the default NSIP (http://192.168.100.1). The Citrix Logon page appears.

   Note: If you have two Citrix ADC appliances in a high availability setup, do not access the GUI by entering the IP address of the secondary Citrix ADC appliance. If you do so and use the GUI to configure the secondary appliance, your configuration changes are not applied to the primary Citrix ADC appliance.

2. In the User Name text box, type `nsroot`.
3. In the Password text box, type the administrative password you assigned to the `nsroot` account during initial configuration and click **Login**. If that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance.

   To access the online help, select Help from the Help menu at the top right corner.

Use the Statistical Utility

Dashboard, the statistical utility, is a browser-based application that displays charts and tables on which you can monitor the performance of a Citrix ADC appliance.

To log on to Dashboard, follow these steps:

1. Open your web browser and enter the NSIP as an HTTP address. The Citrix Logon page appears.
2. In the User Name text box, type `nsroot`.

3. In the Password text box, type the administrative password you assigned to the `nsroot` account during initial configuration. If that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance.

Configure the ADC for the first time

September 14, 2021

For initial configuration of a Citrix ADC MPX appliance, see Initial Configuration of a Citrix MPX appliance.

For initial configuration of a Citrix SDX appliance, see Initial Configuration of a Citrix SDX appliance.

NITRO API

You can use the NITRO API to configure the Citrix ADC appliance. NITRO exposes its functionality through Representational State Transfer (REST) interfaces. Therefore, NITRO applications can be developed in any programming language. Additionally, for applications that must be developed in Java or .NET or Python, NITRO APIs are exposed through relevant libraries that are packaged as separate Software Development Kits (SDKs). For more information, see NITRO API.

Secure your Citrix ADC deployment

September 14, 2021

To maintain security through the deployment life cycle of Citrix ADC appliance, Citrix recommends you to consider the following security aspects:

- Physical Security
- Appliance Security
- Network Security
- Administration and Management

Different deployments might require different security considerations. The Citrix ADC secure deployment guidelines provide general security guidance to help you decide on an appropriate secure deployment based on your specific security requirements.

For more information on guidelines for securely deploying the Citrix ADC appliance, see Citrix ADC secure deployment guidelines.

Configure high availability

September 14, 2021

You can deploy two Citrix ADC appliances in a high availability configuration, where one unit actively accepts connections and manages servers while the secondary unit monitors the first. The Citrix ADC appliance that is actively accepting connections and managing the servers is called a primary unit and the other one is called a secondary unit in a high availability configuration. If there is a failure in the primary unit, the secondary unit becomes the primary and begins actively accepting connections.

Each Citrix ADC appliance in a high availability pair monitors the other by sending periodic messages, called heartbeat messages or health checks, to determine the health or state of the peer node. If a health check for a primary unit fails, the secondary unit retries the connection for a specific time period. For more information about high availability, see High Availability. If a retry does not succeed by the end of the specified time period, the secondary unit takes over for the primary unit in a process called failover. The following figure shows two high availability configurations, one in one-arm mode and the other in two-arm mode.

Figure 1. High availability in one-arm mode

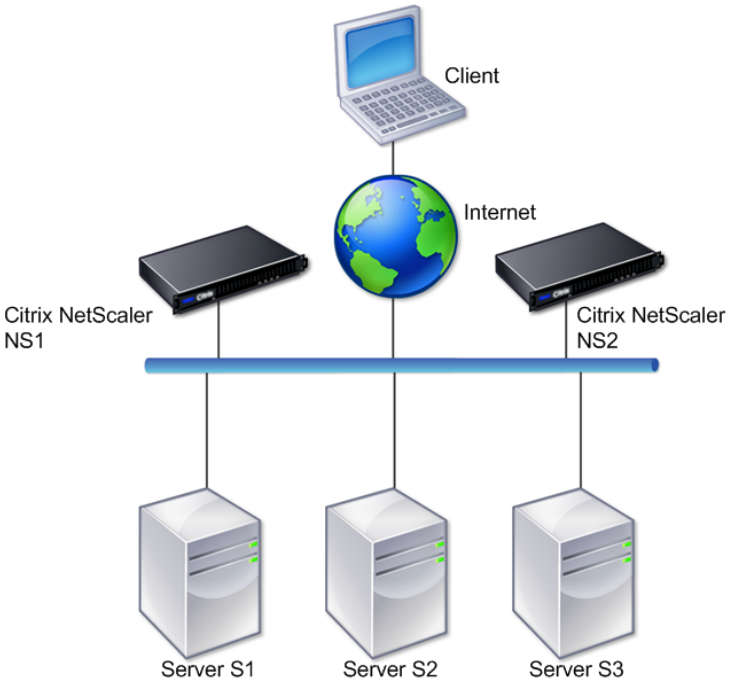

Figure 2. High availability in two-arm mode

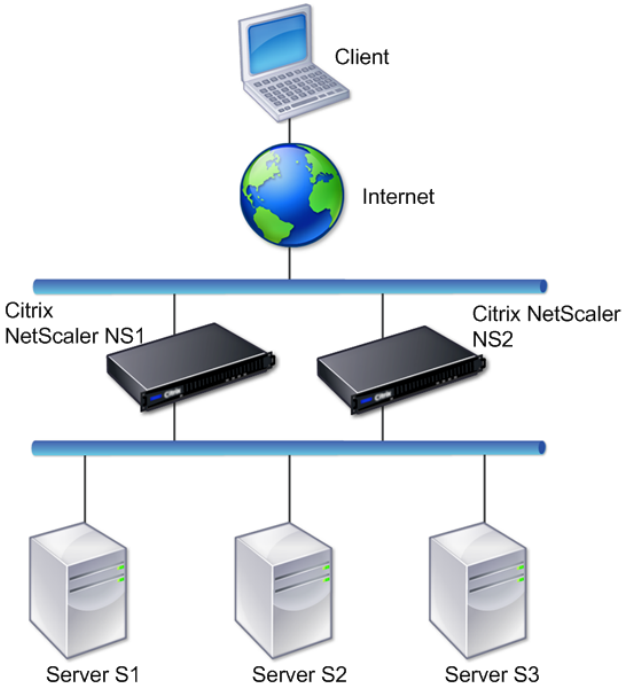


In one-arm configuration, both NS1 and NS2 and servers S1, S2, and S3 are connected to the switch.

In two-arm configuration, both NS1 and NS2 are connected to two switches. The servers S1, S2, and S3 are connected to the second switch. The traffic between client and the servers passes through either NS1 or NS2.

To set up a high availability environment, configure one ADC appliance as primary and another as secondary. Perform the following tasks on each of the ADC appliances:

- Add a node.
- Disable high availability monitoring for unused interfaces.

Add a Node

A node is a logical representation of a peer Citrix ADC appliance. It identifies the peer unit by ID and NSIP. An appliance uses these parameters to communicate with the peer and track its state. When you add a node, the primary and secondary units exchange heartbeat messages asynchronously. The node ID is an integer that must not be greater than 64.

Through CLI

To add a node by using the command line interface, follow these steps:

At the command prompt, type the following commands to add a node and verify that the node has been added:

- add HA node <id> <IPAddress>
- show HA node <id>

Example

```
add HA node 0 10.102.29.170
 Done
> show HA node 0
1)      Node ID:      0
        IP:   10.102.29.200 (NS200)
        Node State: UP
        Master State: Primary
        SSL Card Status: UP
        Hello Interval: 200 msecs
        Dead Interval: 3 secs
        Node in this Master State for: 1:0:41:50 (days:hrs:min:
           sec)
<!--NeedCopy-->
```

Through GUI

To add a node by using the GUI, follow these steps:

1. Navigate to **System** > **High Availability**.
2. Click **Add** on the **Nodes** tab.
3. On the **Create HA Node** page, in the **Remote Node IP Address** text box, type the NSIP Address (for example, 10.102.29.170) of the remote node.
4. Ensure that the **Configure remote system to participate in High Availability setup** check box is selected. Provide the login credentials of the remote node in the text boxes under **Remote System Login Credentials**.
5. Select the **Turn off HA monitor on interfaces/channels that are down** check box to disable the HA monitor on interfaces that are down.

Verify that the node you added appears in the list of nodes in the Nodes tab.

Disable high availability monitoring for unused interfaces

The high availability monitor is a virtual entity that monitors an interface. You must disable the monitor for interfaces that are not connected or being used for traffic. When the monitor is enabled on an interface whose status is DOWN, the state of the node becomes NOT UP. In a high availability configuration, a primary node entering a NOT UP state might cause a high availability failover. An interface is marked DOWN under the following conditions:

- The interface is not connected
- The interface is not working properly
- The cable connecting the interface is not working properly

Through CLI

To disable the high availability monitor for an unused interface by using the command line interface, follow these steps:

At the command prompt, type the following commands to disable the high availability monitor for an unused interface and verify that it is disabled:

- set interface <id> -haMonitor OFF
- show interface <id>

  Example

```
1  > set interface 1/8 -haMonitor OFF
2   Done
3  > show interface 1/8
4          Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2
5          flags=0x4000 <ENABLED, DOWN, down, autoneg, 802.1q>
6          MTU=1514, native vlan=1, MAC=00:d0:68:15:fd:3d, downtime
               238h55m44s
7          Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,
8                    throughput 0
9
10         RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
11         TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
12         NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0)
               Muted(0)
13         Bandwidth thresholds are not set.
14 <!--NeedCopy-->
```

  When the high availability monitor is disabled for an unused interface, the output of the show interface command for that interface does not include “HAMON.”

Through GUI

To disable the high availability monitor for unused interfaces by using the GUI, follow these steps:

1. Navigate to System > Network > Interfaces.
2. Select the interface for which the monitor must be disabled.
3. Click Open. The Modify Interface dialog box appears.
4. In HA Monitoring, select the OFF option.
5. Click OK.
6. Verify that, when the interface is selected, “HA Monitoring: OFF” appears in the details at the bottom of the page.

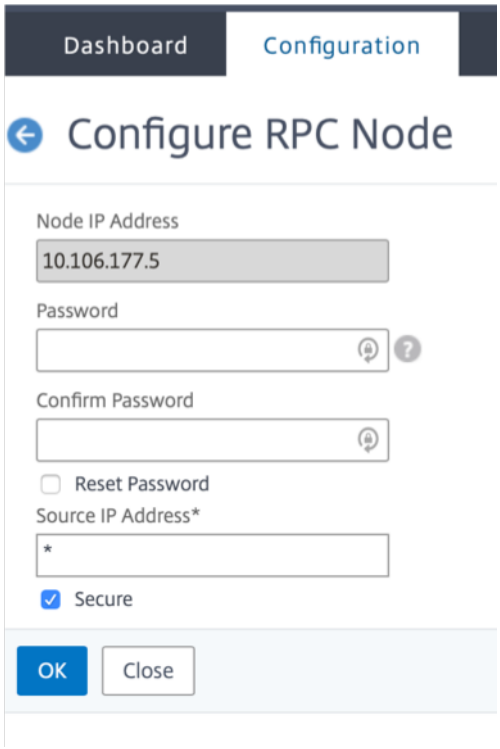
Change an RPC node password

September 14, 2021

To communicate with other Citrix ADC appliances, each appliance requires knowledge of the other appliances, including how to authenticate on Citrix ADC appliance. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. One RPC node exists on each Citrix ADC appliance and stores information, such as the IP addresses of the other Citrix ADC appliance and the passwords used for authentication. The Citrix ADC appliance that contacts the other Citrix ADC appliance checks the password within the RPC node.

To change an RPC node password by using the GUI

1. Navigate to **System** > **Network** > **RPC**.
2. In the **RPC** pane, select the node and then click **Edit**.
3. In **Configure RPC Node**, type the new password.
4. In **Source IP Address**, type the existing node’s IP address to be used to communicate with the peer system node.



5. Select **Secure** and then click **OK**.

> **Note**
>
> For enhanced security, Citrix recommends you to enable the **Secure** option on RPC nodes. When you enable the **Secure** option, the appliance encrypts all the RPC communication sent from one ADC node to other ADC nodes thus securing the RPC communication. This secure communication uses the port number 3008. If the firewall between the ADC nodes blocks the port number 3008, unblock it and proceed. Otherwise, configuration synchronization and configuration propagation might fail.

To change an RPC node password by using the CLI

At the command line, type the following commands:

```
set ns rpcNode <IPAddress> {
 -password }
  [-secure ( YES | NO )]
show ns rpcNode
<!--NeedCopy-->
```

Example:

```
> set ns rpcNode 192.0.2.4 -password mypassword -secure YES
 Done
```

```
> show rpcNode
.
.
.
 IPAddress:  192.0.2.4 Password:  d336004164d4352ce39e
     SrcIP:  *           Secure:  ON
Done
>

<!--NeedCopy-->
```

Configure a FIPS appliance for the first time

October 14, 2021

> **Note**
>
> - FIPS FAQ can be found here: FIPS FAQ.

A certificate-key pair is required for HTTPS access to the configuration utility and for secure remote procedure calls. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. One RPC node exists on each appliance. This node stores the password, which is checked against the one provided by the contacting appliance. To communicate with other Citrix ADC appliances, each appliance requires knowledge of the other appliances, including how to authenticate on the other appliance. RPC nodes maintain this information, which includes the IP addresses of the other Citrix ADC appliances and the passwords used to authenticate on each.

On a Citrix ADC MPX appliance virtual appliance, a certificate-key pair is automatically bound to the internal services. On a FIPS appliance, a certificate-key pair must be imported into the hardware security module (HSM) of a FIPS card. To do so, you must configure the FIPS card, create a certificate-key pair, and bind it to the internal services.

Configure secure HTTPS by using the CLI

To configure secure HTTPS by using the CLI, follow these steps

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see Configure the HSM.
2. If the appliance is part of a high availability setup, enable the SIM. For information about enabling the SIM on the primary and secondary appliances, see Configure FIPS appliances in a high availability setup.

3. Import the FIPS key into the HSM of the FIPS card of the appliance. At the command prompt, type:

   ```
   import ssl fipskey serverkey -key ns-server.key -inform PEM
   ```

4. Add a certificate-key pair. At the command prompt, type:

   ```
   add certkey server -cert ns-server.cert -fipskey serverkey
   ```

5. Bind the certificate-key created in the previous step to the following internal services. At the command prompt, type:

   ```
   bind ssl service nshttps-127.0.0.1-443 -certkeyname server
   ```

   ```
   bind ssl service nshttps-::11-443 -certkeyname server
   ```

Configure secure HTTPS by using the GUI

To configure secure HTTPS by using the GUI, follow these steps:

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see Configure the HSM.
2. If the appliance is part of a high availability setup, enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. For more information about importing a FIPS key, see the Import an existing FIPS key section.
4. Navigate to **Traffic Management > SSL > Certificates**.
5. In the details pane, click Install.
6. In the Install Certificate dialog box, type the certificate details.
7. Click Create, and then click Close.
8. Navigate to **Traffic Management > Load Balancing > Services**.
9. In the details pane, on the Action tab, click Internal Services.
10. Select `nshttps-127.0.0.1-443` from the list, and then click Open.
11. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
12. Select `nshttps-::11-443` from the list, and then click Open.
13. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
14. Click OK.

Configure secure RPC by using the CLI

To configure secure RPC by using the CLI, follow these steps:

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see Configure the HSM.
2. Enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. At the command prompt, type:

   ```
   import ssl fipskey serverkey -key ns-server.key -inform PEM
   ```

4. Add a certificate-key pair. At the command prompt, type:

   ```
   add certkey server -cert ns-server.cert -fipskey serverkey
   ```

5. Bind the certificate-key pair to the following internal services. At the command prompt, type:

   ```
   bind ssl service nsrpcs-127.0.0.1-3008 -certkeyname server
   ```

   ```
   bind ssl service nskrpcs-127.0.0.1-3009 -certkeyname server
   ```

   ```
   bind ssl service nsrpcs-::1l-3008 -certkeyname server
   ```

6. Enable secure RPC mode. At the command prompt, type:

   ```
   set ns rpcnode \<IP address\> -secure YES
   ```

   For more information about changing an RPC node password, see Change an RPC node password.

Configure secure RPC by using the GUI

To configure secure RPC by using the GUI, follow these steps:

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see Configure the HSM.
2. Enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. For more information about importing a FIPS key, the Import an existing FIPS key section.
4. Navigate to **Traffic Management > SSL > Certificates**.
5. In the details pane, click Install.
6. In the Install Certificate dialog box, type the certificate details.
7. Click Create, and then click Close.
8. Navigate to **Traffic Management > Load Balancing > Services**.

9. In the details pane, on the Action tab, click Internal Services.
10. Select `nsrpcs-127.0.0.1-3008` from the list, and then click Open.
11. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
12. Select `nskrpcs-127.0.0.1-3009` from the list, and then click Open.
13. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
14. Select `nsrpcs-::11-3008` from the list, and then click Open.
15. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
16. Click OK.
17. Navigate to **System > Network > RPC**.
18. In the details pane, select the IP address, and click Open.
19. In the Configure RPC Node dialog box, select Secure.
20. Click OK.

Common network topologies

September 14, 2021

As described in the "Physical deployment mode" section in Where does a Citrix ADC appliance fit in the network?, you can deploy the Citrix ADC appliance either inline between the clients and servers or in one-arm mode. Inline mode uses a two-arm topology, which is the most common type of deployment.

Set up a common two-arm topology

In a two-arm topology, one network interface is connected to the client network and another network interface is connected to the server network, ensuring that all traffic flows through the appliance. This topology might require you to reconnect your hardware and also might result in a momentary downtime. The basic variations of two-arm topology are multiple subnets, typically with the appliance on a public subnet and the servers on a private subnet, and transparent mode, with both the appliance and the servers on the public network.

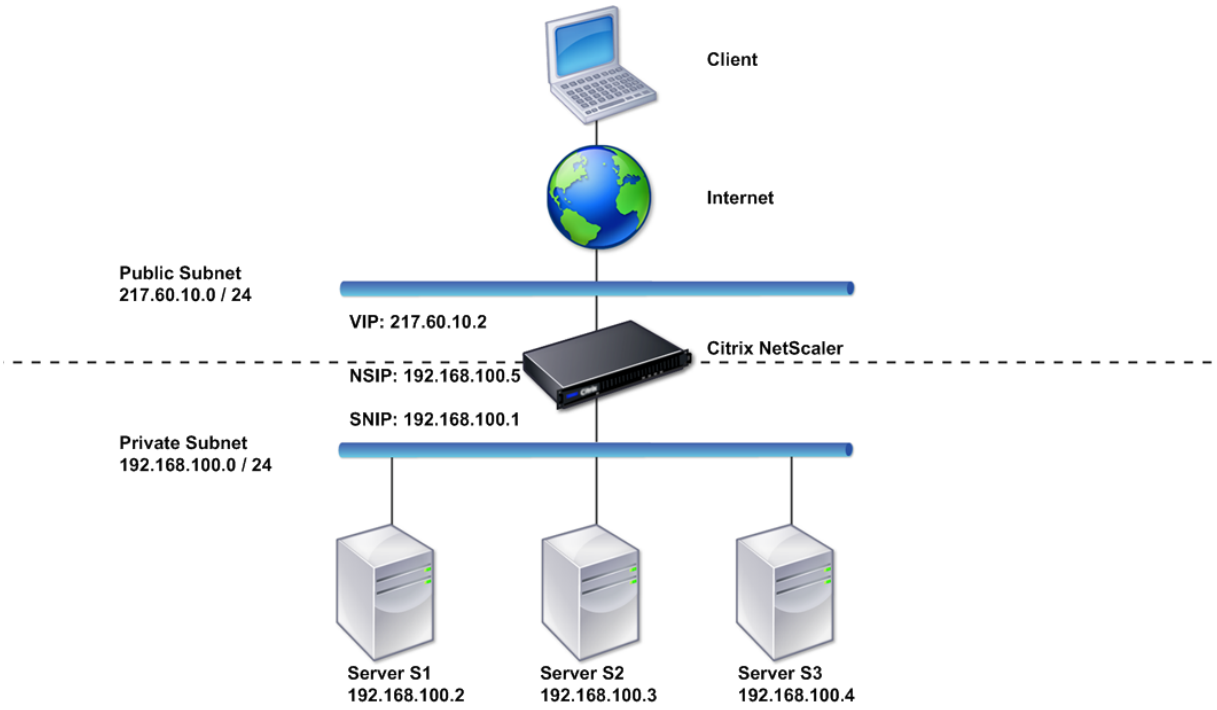
Set up a simple two-arm multiple subnet topology

One of the most commonly used topologies has the Citrix ADC appliance inline between the clients and the servers, with a virtual server configured to handle the client requests. This configuration is used when the clients and servers reside on different subnets. In most cases, the clients and servers reside on public and private subnets, respectively.

For example, consider an appliance deployed in two-arm mode for managing servers S1, S2, and S3, with a virtual server of type HTTP configured on the appliance, and with HTTP services running on the servers. The servers are on a private subnet and a SNIP is configured on the appliance to communicate with the servers. The Use SNIP (USNIP) option must be enabled on the appliance so that it uses the SNIP instead of the MIP.

As shown in the following figure, the VIP is on public subnet 217.60.10.0, and the NSIP, the servers, and the SNIP are on private subnet 192.168.100.0/24.

Figure 1. Topology Diagram for Two-Arm Mode, Multiple Subnets



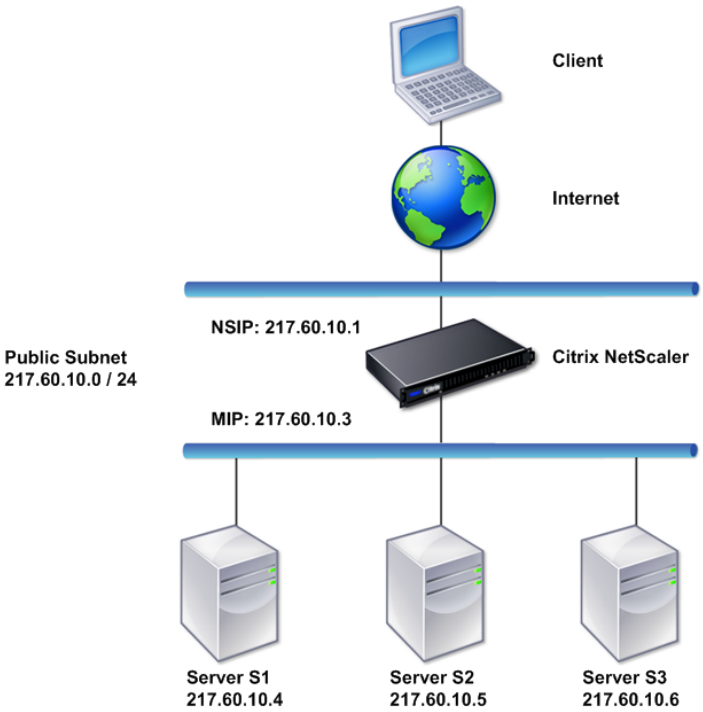
To deploy a Citrix ADC appliance in two-arm mode with multiple subnets, follow these steps:

1. Configure the NSIP and default gateway, as described in Configuring the NetScaler IP Address (NSIP).
2. Configure the SNIP, as described in Configuring Subnet IP Addresses.
3. Enable the USNIP option, as described in To enable or disable USNIP mode section.
4. Configure the virtual server and the services, as described in Creating a Virtual Server section and Configuring Services section.
5. Connect one of the network interfaces to a private subnet and the other interface to a public subnet.

Set up a simple two-arm transparent topology

Use transparent mode if the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them. In the example shown in the following figure, a Citrix ADC appliance is placed between the client and the server, so the traffic must pass through the appliance. You must enable L2 mode for bridging the packets. The NSIP and MIP are on the same public subnet, 217.60.10.0/24.

Figure 2. Topology Diagram for Two-Arm, Transparent Mode



To deploy a Citrix ADC appliance in two-arm, transparent mode, follow these steps

1. Configure the NSIP and default gateway, as described in Configuring the NetScaler IP Address (NSIP).
2. Enable L2 mode, as described in Enabling and Disabling Layer 2 Mode.
3. Configure the default gateway of the managed servers as the MIP.
4. Connect the network interfaces to the appropriate ports on the switch.

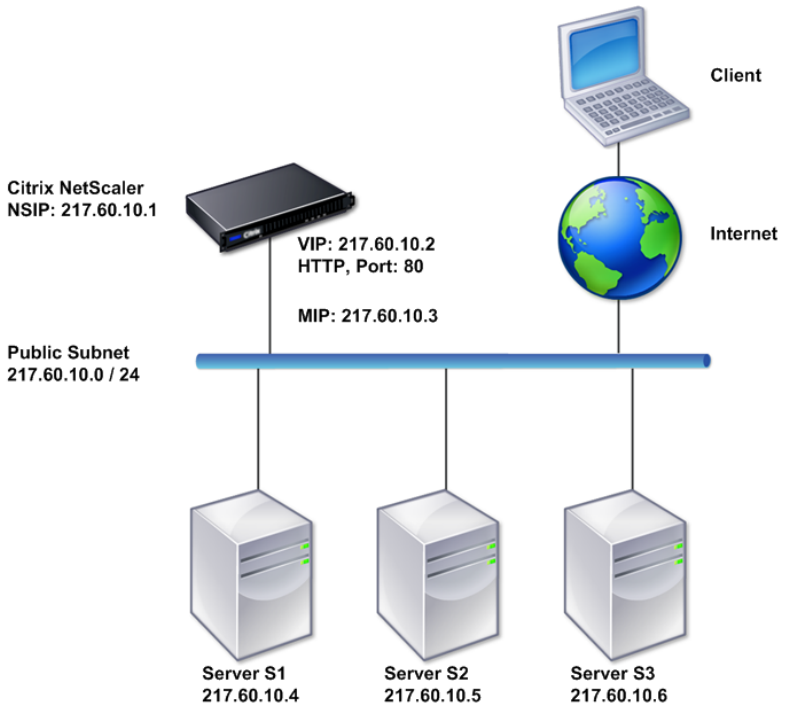
Set up common one-arm topologies

The two basic variations of one-arm topology are with a single subnet and with multiple subnets.

Set up a simple one-arm single subnet topology

You can use a one-arm topology with a single subnet when the clients and servers reside on the same subnet. For example, consider a Citrix ADC appliance deployed in one-arm mode for managing servers S1, S2, and S3. A virtual server of type HTTP is configured on an ADC appliance, and HTTP services are running on the servers. As shown in the following figure, the Citrix ADC IP address (NSIP), the Mapped IP address (MIP), and the server IP addresses are on the same public subnet, 217.60.10.0/24.

Figure 3. Topology Diagram for One-Arm Mode, Single Subnet



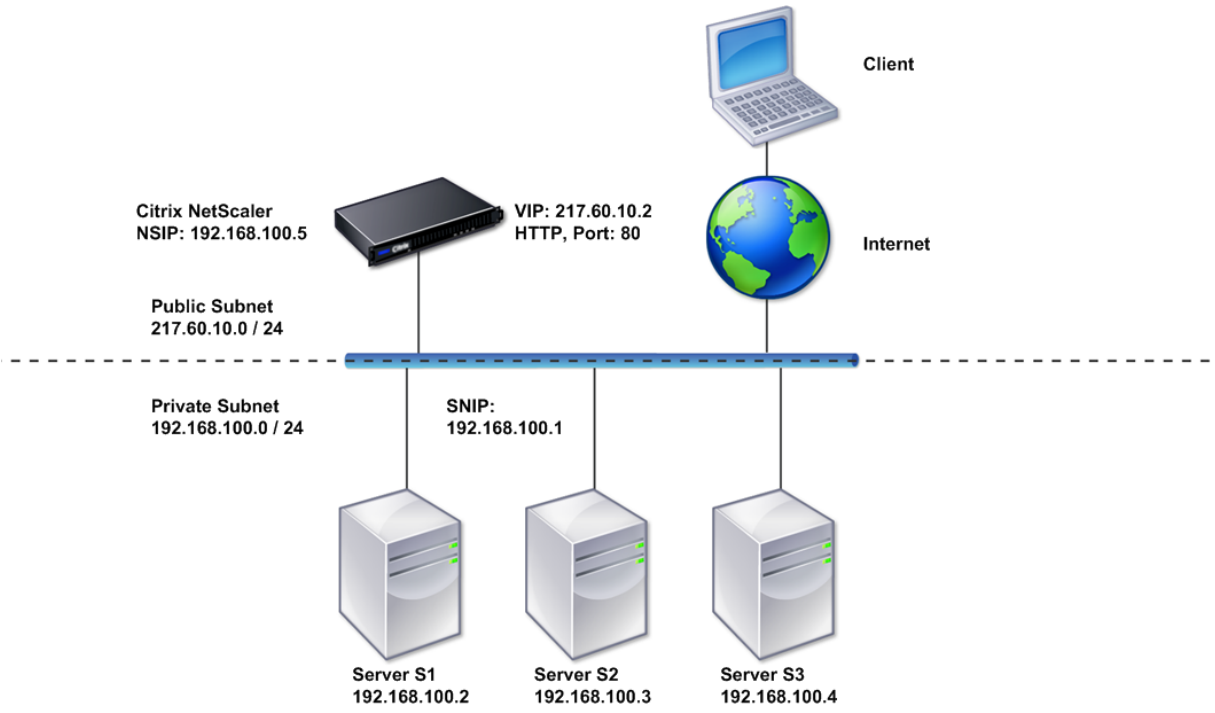
To deploy a Citrix ADC appliance in one-arm mode with a single subnet, follow these steps:

1. Configure the NSIP and the default gateway, as described in, as described in Configuring the Citrix ADC IP Address (NSIP).
2. Configure the virtual server and the services, as described in Creating a Virtual Server section and Configuring Services section.
3. Connect one of the network interfaces to the switch.

Set up a simple one-arm multiple subnet topology

You can use a one-arm topology with multiple subnets when the clients and servers reside on the different subnets. For example, consider a Citrix ADC appliance deployed in one-arm mode for managing servers S1, S2, and S3, with the servers connected to switch SW1 on the network. A virtual server of type HTTP is configured on the appliance, and HTTP services are running on the servers. These three servers are on the private subnet, so a subnet IP address (SNIP) is configured to communicate with them. The Use Subnet IP address (USNIP) option must be enabled so that the appliance uses the SNIP instead of a MIP. As shown in the following figure, the virtual IP address (VIP) is on public subnet 217.60.10.0/24; the NSIP, SNIP, and the server IP addresses are on private subnet 192.168.100.0/24.

Figure 4. Topology Diagram for One-Arm Mode, Multiple Subnets



To deploy a Citrix ADC appliance in one-arm mode with multiple subnets, follow these steps:

1. Configure the NSIP and the default gateway, as described in Configuring the NetScaler IP Address (NSIP).
2. Configure the SNIP and enable the USNIP option, as described in Configuring Subnet IP Addresses.
3. Configure the virtual server and the services, as described in Creating a Virtual Server section and Configuring Services section.

4. Connect one of the network interfaces to the switch.

System management settings

September 14, 2021

Once your initial configuration is in place, you can configure settings to define the behavior of the Citrix ADC appliance and facilitate connection management. You have a number of options for handling HTTP requests and responses. Routing, bridging, and MAC based forwarding modes are available for handling packets not addressed to the Citrix ADC appliance. You can define the characteristics of your network interfaces and can aggregate the interfaces. To prevent timing problems, you can synchronize the Citrix clock with a Network Time Protocol (NTP) server. The Citrix ADC appliance can operate in various DNS modes, including as an authoritative domain name server (ADNS). You can set up SNMP for system management and customize syslog logging of system events. Before deployment, verify that your configuration is complete and correct.

System settings

September 14, 2021

Configuration of system settings includes basic tasks such as configuring HTTP ports to enable connection keep-alive and server offload, setting the maximum number of connections for each server, and setting the maximum number of requests per connection. You can enable client IP address insertion for situations in which a proxy IP address is not suitable, and you can change the HTTP cookie version.

You can also configure a Citrix ADC appliance to open FTP connections on a controlled range of ports instead of ephemeral ports for data connections. This improves security, because opening all ports on the firewall is insecure. You can set the range anywhere from 1,024 to 64,000.

Before deployment, go through the verification checklists to verify your configuration. To configure HTTP parameters and the FTP port range, use the Citrix ADC GUI.

You can modify the types of HTTP parameters described in the following table.

Parameter Type: HTTP Port Information

Specifies: The web server HTTP ports used by your managed servers. If you specify the ports, the appliance performs request switching for any client request that has a destination port matching a specified port.

> Note: If an incoming client request is not destined for a service or a virtual server that is specifically configured on the appliance, the destination port in the request must match one of the globally configured HTTP ports. This allows the appliance to perform connection keep-alive and server off-load.

Parameter Type: Limits

Specifies: The maximum number of connections to each managed server, and the maximum number of requests sent over each connection. For example, if you set Max Connections to 500, and the appliance is managing three servers, it can open a maximum of 500 connections to each of the three servers. By default, the appliance can create an unlimited number of connections to any of the servers it manages. To specify an unlimited number of requests per connection, set Max Requests to 0.

> Note: If you are using the Apache HTTP server, you must set Max Connections equal to the value of the MaxClients parameter in the Apache httpd.conf file. Setting this parameter is optional for other web servers.

Parameter Type: Client IP Insertion

Specifies: Enable/disable insertion of the client's IP address into the HTTP request header. You can specify a name for the header field in the adjacent text box. When a web server managed by an appliance receives a subnet IP address, the server identifies it as the client's IP address. Some applications need the client's IP address for logging purposes or to dynamically determine the content to be served by the web server.

You can enable insertion of the actual client IP address into the HTTP header request sent from the client to one, some, or all servers managed by the appliance. You can then access the inserted address through a minor modification to the server (using an Apache module, ISAPI interface, or NSAPI interface).

Parameter Type: Cookie Version

Specifies: The HTTP cookie version to use when COOKIEINSERT persistence is configured on a virtual server. The default, version 0, is the most common type on the Internet. Alternatively, you can specify version 1.

Parameter Type: Requests/Responses

Specifies: Options for handling certain types of requests, and enable/disable logging of HTTP error responses.

Parameter Type: Server Header Insertion

Specifies: Insert a server header in Citrix ADC-generated HTTP responses.

To configure HTTP parameters by using the GUI, follow these steps:

1. In the navigation pane, expand **System**, and then click **Settings**.

2. In the details pane, under **Settings**, click **Change HTTP parameters**.
3. In the **Configure HTTP parameters** dialog box, specify values for some or all of the parameters that appear under the headings listed in the table above.
4. Click **OK**.

To set the FTP port range by using the GUI, follow these steps:

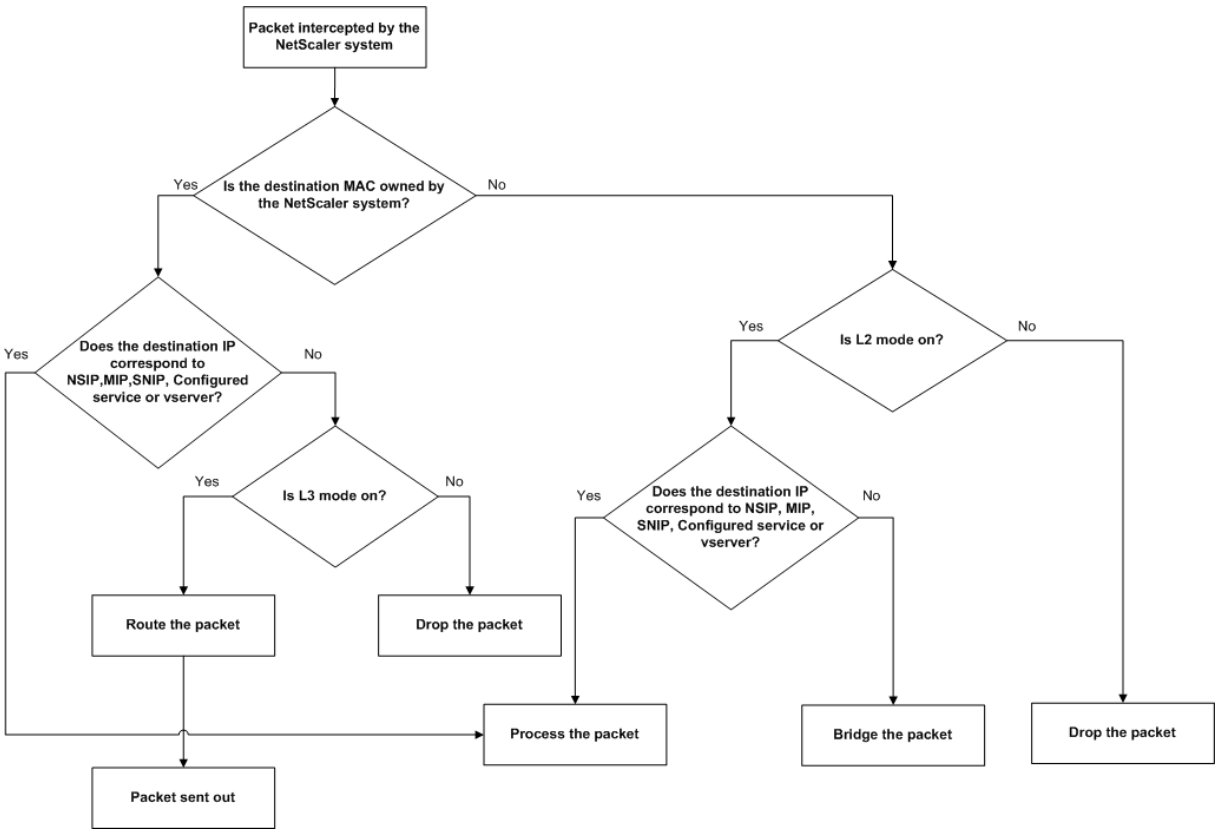
1. In the navigation pane, expand **System**, and then click **Settings**
2. In the details pane, under **Settings**, click **Change global system settings**.
3. Under **FTP Port Range,** in the **Start Port** and **End Port** text boxes, type the lowest and highest port numbers, respectively, for the range you want to specify (for example, 5000 and 6000).
4. Click **OK**.

Packet forwarding modes

September 14, 2021

The Citrix ADC appliance can either route or bridge packets that are not destined for an IP address owned by the appliance (that is, the IP address is not the NSIP, a MIP, a SNIP, a configured service, or a configured virtual server). By default, L3 mode (routing) is enabled and L2 mode (bridging) is disabled, but you can change the configuration. The following flow chart shows how the appliance evaluates packets and either processes, routes, bridges, or drops them.

Figure 1. Interaction between Layer 2 and Layer 3 Modes



An appliance can use the following modes to forward the packets it receives:

- Layer 2 (L2) Mode
- Layer 3 (L3) Mode
- MAC-Based Forwarding Mode

Enable and disable layer 2 mode

Layer 2 mode controls the Layer 2 forwarding (bridging) function. You can use this mode to configure a Citrix ADC appliance to behave as a Layer 2 device and bridge the packets that are not destined for it. When this mode is enabled, packets are not forwarded to any of the MAC addresses, because the packets can arrive on any interface of the appliance and each interface has its own MAC address.

With Layer 2 mode disabled (which is the default), the appliance drops packets that are not destined for one of its MAC address. If another Layer 2 device is installed in parallel with the appliance, Layer 2 mode must be disabled to prevent bridging (Layer 2) loops. You can use the configuration utility or the command line to enable Layer 2 mode.

Note: The appliance does not support spanning tree protocol. To avoid loops, if you enable L2 mode, do not connect two interfaces on the appliance to the same broadcast domain.

To enable or disable Layer 2 mode by using the CLI

At the command prompt, type the following commands to enable/disable Layer 2 mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Examples

```
    \> enable ns mode l2
    Done
    \> show ns mode

    Mode Acronym Status
    \------- ------- ------
    1\) Fast Ramp FR ON
    2\) Layer 2 mode L2 ON
    .
    .
    .
    Done
    \>

    \> disable ns mode l2
    Done
    \> show ns mode

    Mode Acronym Status
    \------- ------- ------
    1\) Fast Ramp FR ON
    2\) Layer 2 mode L2 OFF
    .
    .
    .
    Done
    \>
<!--NeedCopy-->
```

To enable or disable Layer 2 mode by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes** and **Features**, click **Configure modes**.

3. In the **Configure Modes** dialog box, to enable Layer 2 mode, select the **Layer 2 Mode** check box. To disable Layer 2 mode, clear the check box.
4. Click **OK**. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click **Yes**.

Enable and disable layer 3 mode

Layer 3 mode controls the Layer 3 forwarding function. You can use this mode to configure a Citrix ADC appliance to look at its routing table and forward packets that are not destined for it. With Layer 3 mode enabled (which is the default), the appliance performs route table lookups and forwards all packets that are not destined for any appliance-owned IP address. If you disable Layer 3 mode, the appliance drops these packets.

To enable or disable Layer 3 mode by using the CLI

At the command prompt, type the following commands to enable/disable Layer 3 mode and verify that it has been enabled/disabled:

- enable ns mode <Mode>
- disable ns mode <Mode>
- show ns mode

Examples

```
\> enable ns mode l3
Done
\> show ns mode

Mode Acronym Status
\------- ------- ------
1\) Fast Ramp FR ON
2\) Layer 2 mode L2 OFF
.
.
.
9\) Layer 3 mode (ip forwarding) L3 ON
.
.
.
Done
\>

\> disable ns mode l3
```

```
20      Done
21      \> show ns mode
22
23      Mode Acronym Status
24      \------- ------- ------
25      1\) Fast Ramp FR ON
26      2\) Layer 2 mode L2 OFF
27      .
28      .
29      .
30      9\) Layer 3 mode (ip forwarding) L3 OFF
31      .
32      .
33      .
34      Done
35      \>
36  <!--NeedCopy-->
```

To enable or disable Layer 3 mode by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In the Configure Modes dialog box, to enable Layer 3 mode, select the Layer 3 Mode (IP Forwarding) check box. To disable Layer 3 mode, clear the check box.
4. Click OK. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click Yes.

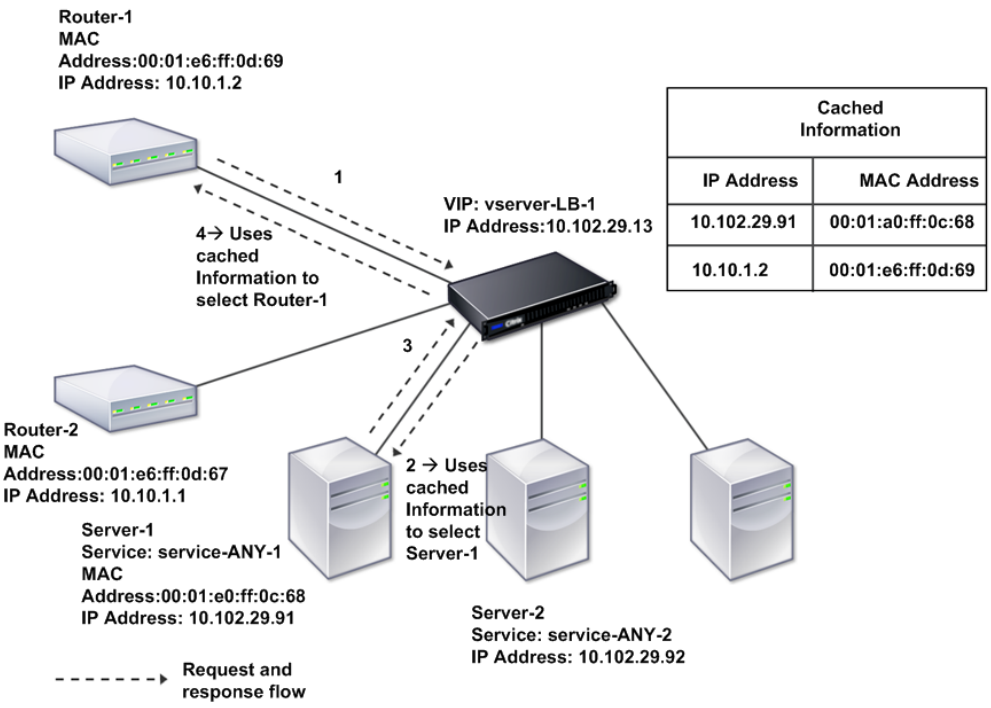
Enable and disable MAC based forwarding mode

You can use MAC-based forwarding to process traffic more efficiently and avoid multiple-route or ARP lookups when forwarding packets, because the Citrix ADC appliance remembers the MAC address of the source. To avoid multiple lookups, the appliance caches the source MAC address of every connection for which it performs an ARP lookup, and it returns the data to the same MAC address.

MAC-based forwarding is useful when you use VPN devices because the appliance ensures that all traffic flowing through a particular VPN passes through the same VPN device.

The following figure shows the process of MAC-based forwarding.

Figure 2. MAC-Based Forwarding Process



When MAC-based forwarding is enabled, the appliance caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server responds through an appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when an appliance initiates a connection, it uses the route and ARP tables for the lookup function. To enable MAC-based forwarding, use the configuration utility or the command line.

Some deployments require the incoming and outgoing paths to flow through different routers. In these situations, MAC-based forwarding breaks the topology design. For a global server load balancing (GSLB) site that requires the incoming and outgoing paths to flow through different routers, you must disable MAC-based forwarding and use the appliance's default router as the outgoing router.

With MAC-based forwarding disabled and Layer 2 or Layer 3 connectivity enabled, a route table can specify separate routers for outgoing and incoming connections. To disable MAC-based forwarding, use the configuration utility or the command line.

To enable or disable MAC-based forwarding by using the CLI

At the command prompt, type the following commands to enable/disable MAC-based forwarding mode and verify that it has been enabled/disabled:

- <enable ns mode <Mode>
- <disable ns mode <Mode>
- <show ns mode
  Example

  “‘ pre codeblock

  ```
  enable ns mode mbf
  Done
  show ns mode
  ```

  ```
  1   Mode                          Acronym           Status
  2   -------                       -------           ------   1)  Fast
      Ramp                     FR                ON   2)  Layer 2
      mode                  L2                OFF   .   .   .   6)
      MAC-based forwarding        MBF               ON   .   .   .
        Done  >
  ```

  ```
  disable ns mode mbf
  Done
  show ns mode
  ```

  ```
  1   Mode                          Acronym           Status
  2   -------                       -------           ------   1)  Fast
      Ramp                     FR                ON   2)  Layer 2
      mode                  L2                OFF   .   .   .   6)
      MAC-based forwarding        MBF               OFF   .   .   .
         Done  >  <!--NeedCopy--> ```
  ```

To enable or disable MAC-based forwarding by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes and Features** group, click **Configure modes**.
3. In the **Configure Modes** dialog box, to enable MAC-based forwarding mode, select the **MAC Based Forwarding** check box. To disable MAC-based forwarding mode, clear the check box.
4. Click **OK**. The Enable/Disable Mode(s)? message appears in the details pane.
5. Click **Yes**.

Network interfaces

September 14, 2021

The Citrix ADC interfaces are numbered in slot/port notation. In addition to modifying the characteristics of individual interfaces, you can configure virtual LANs to restrict traffic to specific groups of hosts. You can also aggregate links into high-speed channels.

Virtual LANs

The Citrix ADC appliance supports (Layer 2) port and IEEE802.1Q tagged virtual LANs (VLANs). VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface to belong to multiple VLANs by using IEEE 802.1q tagging.

You can bind your configured VLANs to IP subnets. The ADC appliance (if it is configured as the default router for the hosts on the subnets) then performs IP forwarding between these VLANs.

The Citrix ADC appliance supports the following types of VLANs.

- Default VLAN

  By default, the network interfaces on a Citrix ADC appliance are included in a single, port-based VLAN as untagged network interfaces. This default VLAN has a VID of 1 and exists permanently. It cannot be deleted, and its VID cannot be changed.

- Port-Based VLANs

  A set of network interfaces that share a common, exclusive, Layer 2 broadcast domain define the membership of a port-based VLAN. You can configure multiple port-based VLANs. When you add an interface to a new VLAN as an untagged member, it is automatically removed from the default VLAN.

- Tagged VLAN

  A network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of only one VLAN (its native VLAN). The untagged network interface forwards the frames for the native VLAN as untagged frames. A tagged network interface can be a part of more than one VLAN. When you configure tagging, be sure that both ends of the link have matching VLAN settings. You can use the configuration utility to define a tagged VLAN (nsvlan) that can have any ports bound as tagged members of the VLAN. Configuring this VLAN requires a reboot of the ADC appliance and therefore must be done during initial network configuration.

Link aggregate channels

Link aggregation combines incoming data from multiple ports into a single high speed link. Configuring the link aggregate channel increases the capacity and availability of the communication channel between a Citrix ADC appliance and other connected devices. An aggregated link is also referred to as a channel.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to only one channel. Binding a network interface to a link aggregate channel changes the VLAN configuration. That is, binding network interfaces to a channel removes them from the VLANs that they originally belonged to and adds them to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you have bound network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then you bind them to link aggregate channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them to VLAN 2.

Note: You can also use Link Aggregation Control Protocol (LACP) to configure link aggregation. For more information, see Configuring Link Aggregation by Using the Link Aggregation Control Protocol.

Clock synchronization

September 14, 2021

You can configure your Citrix ADC appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network. NTP uses User Datagram Protocol (UDP) port 123 as its transport layer. You have to add NTP servers in the NTP configuration file so that the appliance periodically gets updates from these servers.

If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site at http://www.ntp.org.

To configure clock synchronization on your appliance, follow these steps:

1. Log on to the command line and enter the shell command.
2. At the shell prompt, copy the ntp.conf file from the /etc directory to the /nsconfig directory. If the file already exists in the /nsconfig directory, make sure that you remove the following entries from the ntp.conf file:

   ```
   restrict localhost

   restrict 127.0.0.2
   ```

These entries are required only if you want to run the device as a time server. However, this feature is not supported on the Citrix ADC appliance.

3. Edit /nsconfig/ntp.conf by typing the IP address for the desired NTP server under the file's server and restrict entries.
4. Create a file named rc.netscaler in the /nsconfig directory, if the file does not already exist in the directory.
5. Edit /nsconfig/rc.netscaler by adding the following entry: `/usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ntpd.log &`

   This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory.

   Note: If the time difference between the Citrix ADC appliance and the time server is more than 1000 sec, the ntpd service terminates with a message to the ADC log. To avoid this, you need to start ntpd with the -g option, which forcibly syncs the time. Add the following entry in /nsconfig/rc.netscaler:

   ```
   /usr/sbin/ntpd -g -c /nsconfig/ntp.conf -l /var/log/ntpd.log &
   ```

   If you do not want to forcibly sync the time when there is a large difference, you can set the date manually and then start ntpd again. You can check the time difference between the appliance and the time server by running the following command in the shell:

   ```
   1 ntpdate -q <IP address or domain name of the NTP server>
   2 <!--NeedCopy-->
   ```

6. Reboot the appliance to enable clock synchronization.

   Note: If you want to start time synchronization before you restart the appliance, enter the following command (which you added to the rc.netscaler file in step 5) at the shell prompt:

   ```
   1 /usr/sbin/ntpd -c /nsconfig/ntp.conf -l /var/log/ ntpd.log &
   2 <!--NeedCopy-->
   ```

DNS configuration

September 14, 2021

You can configure a Citrix ADC appliance to function as an Authoritative Domain Name Server (ADNS), DNS proxy server, End Resolver, or Forwarder. You can add DNS resource records such as SRV Records, AAAA Records, A Records, MX Records, NS Records, CNAME Records, PTR Records, and SOA Records. Also, the appliance can balance the load on external DNS servers.

A common practice is to configure an appliance as a forwarder. For this configuration, you need to add external name servers. After you have added the external servers, you should verify that your configuration is correct.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

When adding name servers, you can specify IP addresses or virtual IP addresses (VIPs). If you use IP addresses, the appliance load balances requests to the configured name servers in a round robin manner. If you use VIPs, you can specify any load balancing method.

Add a name server by using the CLI

At the command prompt, type the following commands to add a name server and verify the configuration:

- <add dns nameServer <IP>
- <show dns nameServer <IP>

  Example

  “‘ pre codeblock

  ```
  add dns nameServer 10.102.29.10
  Done
  show dns nameServer 10.102.29.10
  1) 10.102.29.10 - State: DOWN
  Done
  “‘
  ```

Add a name server by using the GUI

1. Navigate to **Traffic Management** > **DNS** > **Name Servers**.
2. In the details pane, click **Add**.
3. In the **Create Name Server** dialog box, select **IP Address**.
4. In the **IP Address** text box, type the IP address of the name server (for example, 10.102.29.10). If you are adding an external name server, clear the **Local** check box.
5. Click **Create**, and then click **Close**.
6. Verify that the name server you added appears in the **Name Servers** pane.

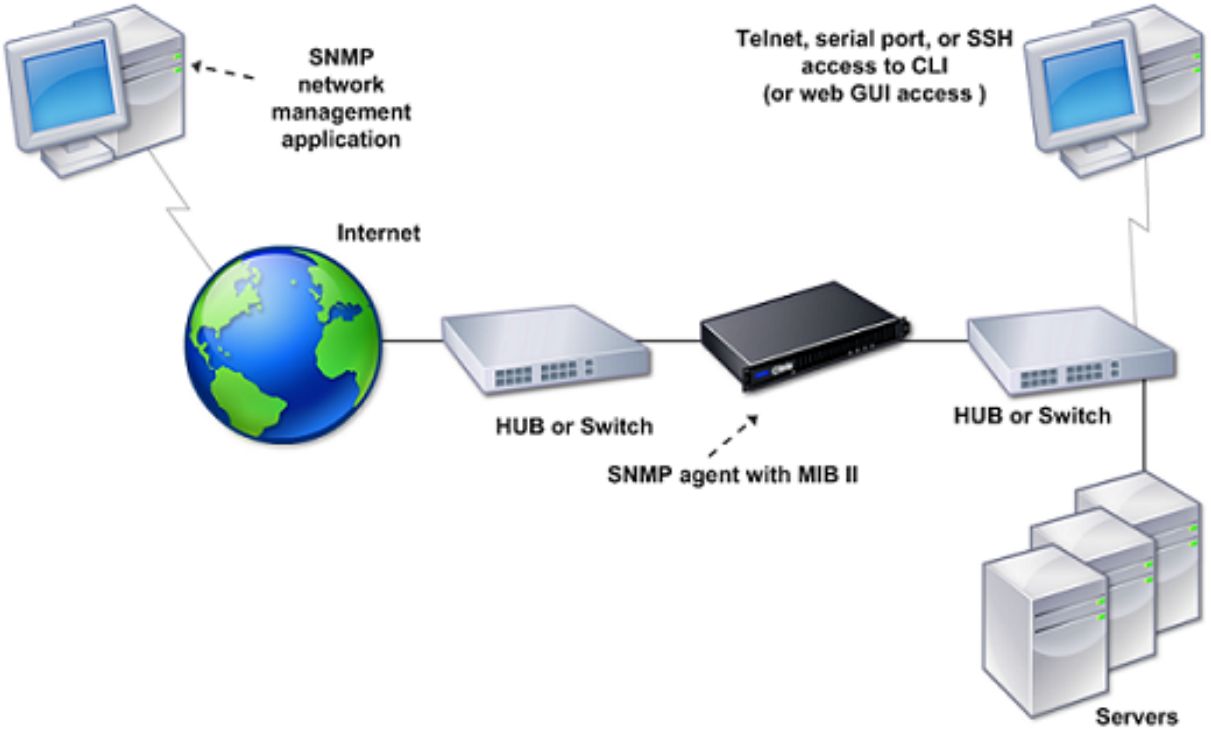
SNMP configuration

September 14, 2021

The Simple Network Management Protocol (SNMP) network management application, running on an external computer, queries the SNMP agent on the Citrix ADC appliance. The agent searches the management information base (MIB) for data requested by the network management application and sends the data to the application.

SNMP monitoring uses traps messages and alarms. SNMP traps messages are asynchronous events that the agent generates to signal abnormal conditions, which are indicated by alarms. For example, if you want to be informed when CPU utilization is above 90 percent, you can set up an alarm for that condition. The following figure shows a network with a Citrix ADC appliance that has SNMP enabled and configured.

Figure 1. SNMP on the Citrix ADC appliance



The SNMP agent on a Citrix ADC appliance supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3). Because it operates in bilingual mode, the agent can handle SNMPv2 queries, such as Get-Bulk, and SNMPv1 queries. The SNMP agent also sends traps compliant with SNMPv2 and supports SNMPv2 data types, such as counter64. SNMPv1 managers (programs on other servers that request SNMP information from the ADC appliance) use the NS-MIB-smiv1.mib file when processing SNMP queries. SNMPv2 managers use the NS-MIB-smiv2.mib file.

The Citrix ADC appliance supports the following enterprise-specific MIBs:

- A subset of standard MIB-2 groups. Provides MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.
- A system enterprise MIB. Provides system-specific configuration and statistics.

To configure SNMP, you specify which managers can query the SNMP agent, add SNMP trap listeners that will receive the SNMP trap messages, and configure SNMP Alarms.

Add SNMP managers

You can configure a workstation running a management application that complies with SNMP version 1, 2, or 3 to access an appliance. Such a workstation is called an SNMP manager. If you do not specify an SNMP manager on the appliance, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds to SNMP queries from only those specific IP addresses. When specifying the IP address of an SNMP manager, you can use the netmask parameter to grant access from entire subnets. You can add a maximum of 100 SNMP managers or networks. To add an SNMP manager by using the CLI

At the command prompt, type the following commands to add an SNMP manager and verify the configuration:

```
add snmp manager <IPAddress> ... [-netmask <netmask>]
show snmp manager <IPAddress>
```

Example:

```
1 add snmp manager 10.102.29.5 -netmask 255.255.255.255
2 Done
3 show snmp manager 10.102.29.5
4 10.102.29.5 255.255.255.255
5 Done
6 <!--NeedCopy-->
```

To add an SNMP manager by using the GUI:

1. In the navigation pane, expand **System**, expand **SNMP**, and then click **Managers**.
2. In the details pane, click **Add**.
3. In the **Add SNMP Manager** dialog box, in the **IP Address** text box, type the IP address of the workstation running the management application (for example, 10.102.29.5).
4. Click **Create**, and then click **Close**.
5. Verify that the SNMP manager you added appears in the **Details** section at the bottom of the pane.

Add SNMP traps listeners

After configuring the alarms, you need to specify the trap listener to which the appliance will send the trap messages. Apart from specifying parameters like IP address and the destination port of the trap

listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

To add an SNMP trap listener by using the CLI

At the command prompt, type the following command to add an SNMP trap and verify that it has been added:

- `add snmp trap specific <IP>`
- `show snmp trap`

Example:

```
Trap type: SPECIFIC
Destination IP: 10.102.29.3
TD: 0
Destination Port: 162
Source IP: NetScaler IP
Version: V2
Min-Severity: -
AllPartition: DISABLED
Community: public
<!--NeedCopy-->
```

To add an SNMP trap listener by using the GUI

1. In the navigation pane, expand System, expand **SNMP**, and then click **Traps**.
2. In the details pane, click **Add**.
3. In the **Create SNMP Trap Destination** dialog box, in the **Destination IP Address** text box, type the IP address (for example, 10.102.29.3).
4. Click **Create** and then click **Close**.
5. Verify that the SNMP trap you added appears in the **Details** section at the bottom of the pane.

Configure SNMP alarms

You configure alarms so that the appliance generates a trap message when an event corresponding to one of the alarms occurs. Configuring an alarm consists of enabling the alarm and setting the severity level at which a trap is generated. There are five severity levels: Critical, Major, Minor, Warning, and Informational. A trap is sent only when the severity of the alarm matches the severity specified for the trap.

Some alarms are enabled by default. If you disable an SNMP alarm, the appliance will not generate trap messages when corresponding events occur. For example, if you disable the Login-Failure SNMP alarm, the appliance will not generate a trap message when a login failure occurs.

To enable or disable an alarm by using the CLI

At the command prompt, type the following commands to enable or disable an alarm and verify that it has been enabled or disabled:

```
set snmp alarm <trapName> [-state ENABLED      DISABLED ]
```

-
- show snmp alarm <trapName>

  Example

```
set snmp alarm LOGIN-FAILURE -state ENABLED
Done
show snmp alarm LOGIN-FAILURE
Alarm Alarm Threshold Normal Threshold Time State Severity Logging
\----- --------------- ---------------- ---- -------- ---------
   --------
LOGIN-FAILURE N/A N/A N/A ENABLED - ENABLED
Done
<!--NeedCopy-->
```

To set the severity of the alarm by using the CLI

At the command prompt, type the following commands to set the severity of the alarm and verify that the severity has been set correctly:

- `set snmp alarm <trapName> [-severity <severity>]`
- `show snmp alarm <trapName>`

Example:

```
set snmp alarm LOGIN-FAILURE -severity Major
Done
show snmp alarm LOGIN-FAILURE
Alarm Alarm Threshold Normal Threshold Time State Severity Logging
\----- --------------- ---------------- ---- -------- ---------
   --------
LOGIN-FAILURE N/A N/A N/A ENABLED Major ENABLED
```

```
7 Done
8 <!--NeedCopy-->
```

To configure alarms by using the GUI

1. In the navigation pane, expand **System**, expand SNMP, and then click **Alarms**.
2. In the details pane, select an alarm (for example, LOGIN-FAILURE), and then click **Open**.
3. In the **Configure SNMP Alarm** dialog box, to enable the alarm, select Enabled in the **State** drop-down list. To disable the alarm, select Disabled.
4. In the **Severity** drop-down list, select a severity option (for example, Major).
5. Click **OK**, and then click **Close**.
6. Verify that the parameters for the SNMP alarm you configured are correctly configured by viewing the **Details** section at the bottom of the pane.

Verify configuration

September 14, 2021

After you've finished configuring your system, complete the following checklists to verify your configuration.

Configuration checklist

- The build running is:
- There are no incompatibility issues. (Incompatibility issues are documented in the build's release notes.)
- The port settings (speed, duplex, flow control, monitoring) are the same as the switch's port.
- Enough SNIP IP addresses have been configured to support all server-side connections during peak times.
  - The number of configured SNIP IP addresses is:____
  - The expected number of simultaneous server connections is:
    [ ] 62,000 [ ] 124,000 [ ] Other____

Topology configuration checklist

The routes have been used to resolve servers on other subnets.

The routes entered are:

_____

- If the Citrix ADC appliance is in a public-private topology, reverse NAT has been configured.
- The failover (high availability) settings configured on the ADC appliance resolve in a one arm or two-arm configuration. All unused network interfaces have been disabled:

_____

- If the ADC appliance is placed behind an external load balancer, then the load balancing policy on the external load balancer is not “least connection”.

  The load balancing policy configured on the external load balancer is:

  _____

- If the ADC appliance is placed in front of a firewall, the session time-out on the firewall is set to a value greater than or equal to 300 seconds.

  Note: The TCP idle connection timeout on a Citrix ADC appliance is 360 seconds. If the timeout on the firewall is also set to 300 seconds or more, then the appliance can perform TCP connection multiplexing effectively because connections will not be closed earlier.

  The value configured for the session time-out is: _____

Server configuration checklist

- “Keep-alive” has been enabled on all the servers.

  The value configured for the keep-alive time-out is: _____

- The default gateway has been set to the correct value. (The default gateway should either be a Citrix ADC appliance or upstream router.) The default gateway is:

  _____

- The server port settings (speed, duplex, flow control, monitoring) are the same as the switch port settings.

  _____

- If the Microsoft® Internet Information Server is used, buffering is enabled on the server.
- If an Apache Server is used, the MaxConn (maximum number of connections) parameter is configured on the server and on the Citrix ADC appliance.

  The MaxConn (maximum number of connections) value that has been set is:

  _____

- If a Netscape Enterprise Server is used, the maximum requests per connection parameter is set on the Citrix ADC appliance. The maximum requests per connection value that has been set is:

  _____

Software features configuration checklist

- Does the Layer 2 mode feature need to be disabled? (Disable if another Layer 2 device is working in parallel with a Citrix ADC appliance.)

  Reason for enabling or disabling:

  _____

- Does the MAC-based forwarding feature need to be disabled? (If the MAC address used by return traffic is different, it should be disabled.)

  Reason for enabling or disabling:

  _____

- Does host-based reuse need to be disabled? (Is there virtual hosting on the servers?)

  Reason for enabling or disabling:

  _____

- Do the default settings of the surge protection feature need to be changed?

  Reason for changing or not changing:

  _____

Access checklist

- The system IPs can be pinged from the client-side network.
- The system IPs can be pinged from the server-side network.
- The managed server(s) can be pinged through the Citrix ADC.
- Internet hosts can be pinged from the managed servers.
- The managed server(s) can be accessed through the browser.
- The Internet can be accessed from managed server(s) using the browser.
- The system can be accessed using SSH.
- Admin access to all managed server(s) is working.

> Note: When you are using the ping utility, ensure that the pinged server has ICMP ECHO enabled, or your ping will not succeed.

Firewall checklist

The following firewall requirements have been met:

- UDP 161 (SNMP)
- UDP 162 (SNMP trap)

- TCP/UDP 3010 (GUI)
- HTTP 80 (GUI)
- TCP 22 (SSH)

Load balance traffic on a Citrix ADC appliance

September 14, 2021

The load balancing feature distributes client requests across multiple servers to optimize resource utilization. In a real-world scenario with a limited number of servers providing service to a large number of clients, a server can become overloaded and degrade the performance of the server farm. A Citrix ADC appliance uses load balancing criteria to prevent bottlenecks by forwarding each client request to the server best suited to handle the request when it arrives.

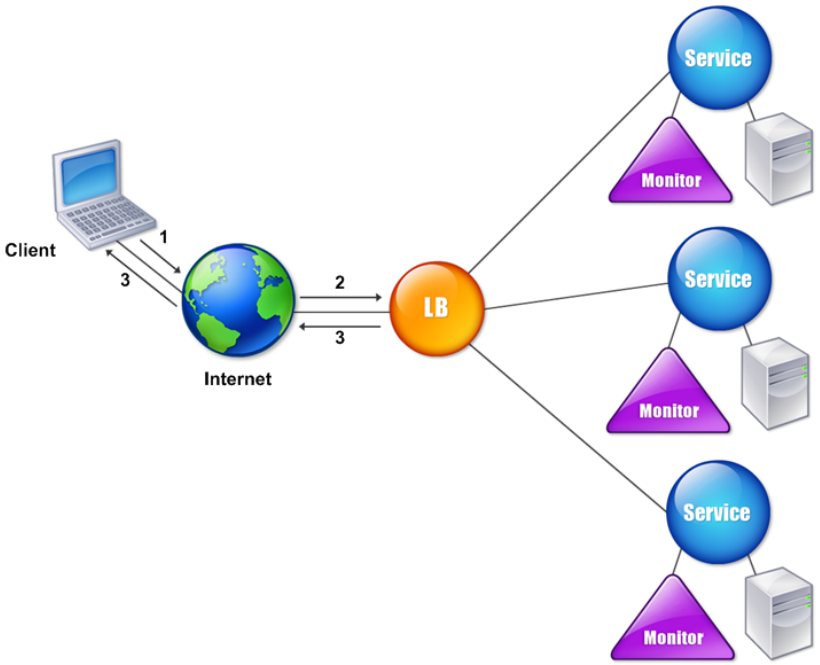
To configure load balancing, you define a virtual server to proxy multiple servers in a server farm and balance the load among them.

When a client initiates a connection to the server, a virtual server terminates the client connection and initiates a new connection with the selected server, or reuses an existing connection with the server, to perform load balancing. The load balancing feature provides traffic management from Layer 4 (TCP and UDP) through Layer 7 (FTP, HTTP, and HTTPS).

The Citrix ADC appliance uses a number of algorithms, called load balancing methods, to determine how to distribute the load among the servers. The default load balancing method is the Least Connections method.

A typical load balancing deployment consists of the entities described in the following figure.

Figure 1. Load Balancing Architecture



The entities function as follows:

- **Virtual server**. An entity that is represented by an IP address, a port, and a protocol. The virtual server IP address (VIP) is usually a public IP address. The client sends connection requests to this IP address. The virtual server represents a bank of servers.
- **Service**. A logical representation of a server or an application running on a server. Identifies the server's IP address, a port, and a protocol. The services are bound to the virtual servers.
- **Server object**. An entity that is represented by an IP address. The server object is created when you create a service. The IP address of the service is taken as the name of the server object. You can also create a server object and then create services by using the server object.
- **Monitor**. An entity that tracks the health of the services. The appliance periodically probes the servers using the monitor bound to each service. If a server does not respond within a specified response timeout, and the specified number of probes fails, the service is marked DOWN. The appliance then performs load balancing among the remaining services.

Load balancing

September 14, 2021

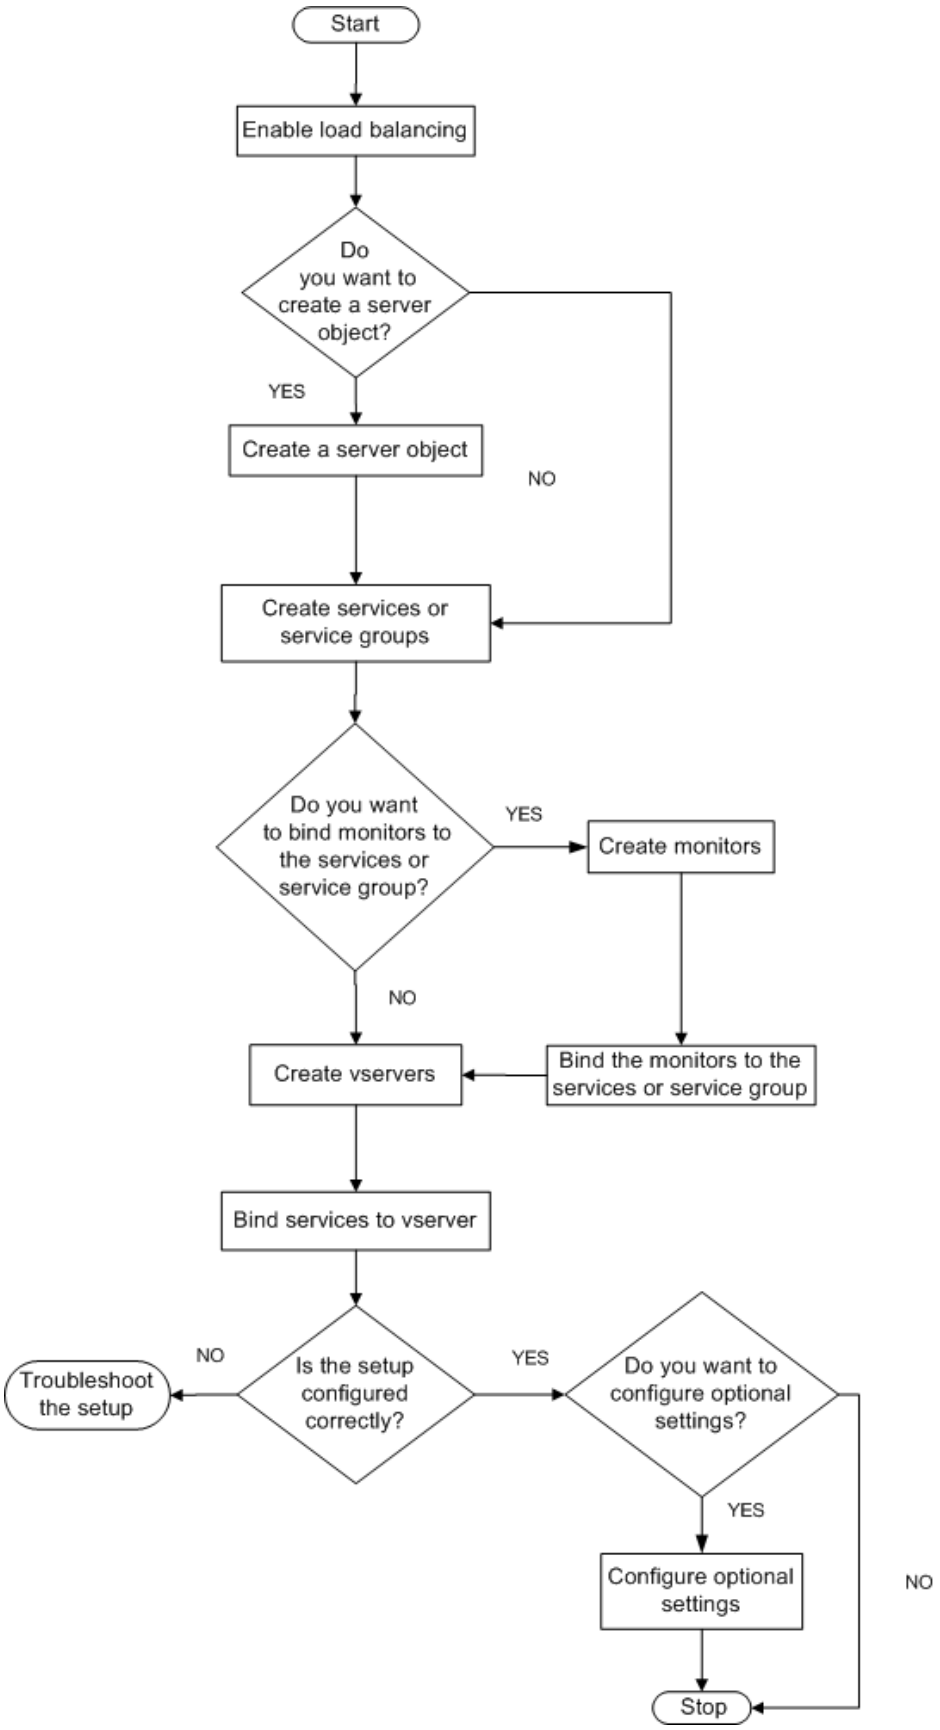
To configure load balancing, you must first create services. Then, you create virtual servers and bind the services to the virtual servers. By default, the Citrix ADC appliance binds a monitor to each service. After binding the services, verify your configuration by making sure that all of the settings are correct.

> Note: After you deploy the configuration, you can display statistics that show how the entities in the configuration are performing. Use the statistical utility or the stat lb vserver <vserverName> command.

Optionally, you can assign weights to a service. The load balancing method then uses the assigned weight to select a service. For getting started, however, you can limit optional tasks to configuring some basic persistence settings, for sessions that must maintain a connection to a particular server, and some basic configuration-protection settings.

The following flow chart illustrates the sequence of the configuration tasks.

Figure 1. Sequence of Tasks to Configure Load Balancing



Enable load balancing

Before configuring load balancing, make sure that the load balancing feature is enabled.

To enable load balancing by using the CLI

At the command prompt, type the following commands to enable load balancing and verify that it is enabled:

- enable feature lb
- show feature

Example

“‘ pre codeblock

> enable feature lb
> Done
> show feature

```
1   Feature                  Acronym          Status
2   -------                  -------          ------   1)  Web
       Logging               WL               OFF   2)  Surge
       Protection         SP               OFF   3)  Load Balancing
                 LB               ON   .   .   .   9)  SSL
       Offloading            SSL              ON   .   .   .  Done
       <!--NeedCopy--> ```
```

To enable load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message, click Yes.

Configure services and a virtual server

When you have identified the services you want to load balance, you can implement your initial load balancing configuration by creating the service objects, creating a load balancing virtual server, and binding the service objects to the virtual server.

To implement the initial load balancing configuration by using the CLI

At the command prompt, type the following commands to implement and verify the initial configuration:

- <add service <name> <IPaddress> <serviceType> <port>
- <add lb vserver <vServerName> <serviceType> [<IPaddress> <port>]
- <bind lb vserver <name> <serviceName>
- <show service bindings <serviceName>

Example

```
> add service service-HTTP-1 10.102.29.5 HTTP 80
 Done
> add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
 Done
> bind lb vserver vserver-LB-1 service-HTTP-1
 Done
> show service bindings service-HTTP-1
    service-HTTP-1 (10.102.29.5:80) - State : DOWN

      1)      vserver-LB-1 (10.102.29.60:80) - State : DOWN
 Done
<!--NeedCopy-->
```

To implement the initial load balancing configuration by using the GUI

1. Navigate to Traffic Management > Load Balancing.
2. In the details pane, under Getting Started, click Load Balancing wizard, and follow the instructions to create a basic load balancing setup.
3. Return to the navigation pane, expand Load Balancing, and then click Virtual Servers.
4. Select the virtual server that you configured and verify that the parameters displayed at the bottom of the page are correctly configured.
5. Click Open.
6. Verify that each service is bound to the virtual server by confirming that the Active check box is selected for each service on the Services tab.

Persistence settings

September 14, 2021

You must configure persistence on a virtual server if you want to maintain the states of connections on the servers represented by that virtual server (for example, connections used in e-commerce). The appliance then uses the configured load balancing method for the initial selection of a server, but forwards to that same server all subsequent requests from the same client.

If persistence is configured, it overrides the load balancing methods once the server has been selected. If the configured persistence applies to a service that is down, the appliance uses the load balancing methods to select a new service, and the new service becomes persistent for subsequent requests from the client. If the selected service is in an Out Of Service state, it continues to serve the outstanding requests but does not accept new requests or connections. After the shutdown period elapses, the existing connections are closed. The following table lists the types of persistence that you can configure.

Persistence Type	Persistent Connections
Source IP, SSL Session ID, Rule, DESTIP, SRCIPDESTIP	250K
CookieInsert, URL passive, Custom Server ID	Memory limit. In case of CookieInsert, if time out is not 0, any number of connections is allowed until limited by memory.

Table 1. Limitations on Number of Simultaneous Persistent Connections

If the configured persistence cannot be maintained because of a lack of resources on an appliance, the load balancing methods are used for server selection. Persistence is maintained for a configured period of time, depending on the persistence type. Some persistence types are specific to certain virtual servers. The following table shows the relationship.

Persistence TypeHeader 1	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge
Source IP	YES	YES	YES	YES	YES
CookieInsert	YES	YES	NO	NO	NO
SSL Session ID	NO	YES	NO	NO	YES
URL Passive	YES	YES	NO	NO	NO
Custom Server ID	YES	YES	NO	NO	NO
Rule	YES	YES	NO	NO	NO

Persistence TypeHeader 1	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge
SRCIPDESTIP	N/A	N/A	YES	YES	N/A
DESTIP	N/A	N/A	YES	YES	N/A

Table 2. Persistence Types Available for Each Type of Virtual Server

You can also specify persistence for a group of virtual servers. When you enable persistence on the group, the client requests are directed to the same selected server regardless of which virtual server in the group receives the client request. When the configured time for persistence elapses, any virtual server in the group can be selected for incoming client requests.

Two commonly used persistence types are persistence based on cookies and persistence based on server IDs in URLs.

Configure persistence based on cookies

When you enable persistence based on cookies, the the Citrix ADC appliance adds an HTTP cookie into the Set-Cookie header field of the HTTP response. The cookie contains information about the service to which the HTTP requests must be sent. The client stores the cookie and includes it in all subsequent requests, and the ADC uses it to select the service for those requests. You can use this type of persistence on virtual servers of type HTTP or HTTPS.

The Citrix ADC appliance inserts the cookie <NSC_XXXX>= <ServiceIP> <ServicePort>

where:

- <<NSC_XXXX> is the virtual server ID that is derived from the virtual server name.
- <<ServiceIP> is the hexadecimal value of the IP address of the service.
- <<ServicePort> is the hexadecimal value of the port of the service.

The ADC encrypts ServiceIP and ServicePort when it inserts a cookie, and decrypts them when it receives a cookie.

Note: If the client is not allowed to store the HTTP cookie, the subsequent requests do not have the HTTP cookie, and persistence is not honored.

By default, the ADC appliance sends HTTP cookie version 0, in compliance with the Netscape specification. It can also send version 1, in compliance with RFC 2109.

You can configure a timeout value for persistence that is based on HTTP cookies. Note the following:

- If HTTP cookie version 0 is used, the Citrix ADC appliance inserts the absolute Coordinated Universal Time (GMT) of the cookie's expiration (the expires attribute of the HTTP cookie), calculated as the sum of the current GMT time on an ADC appliance, and the timeout value.
- If an HTTP cookie version 1 is used, the ADC appliance inserts a relative expiration time (Max-Age attribute of the HTTP cookie). In this case, the client software calculates the actual expiration time.

Note: Most client software currently installed (Microsoft Internet Explorer and Netscape browsers) understand HTTP cookie version 0; however, some HTTP proxies understand HTTP cookie version 1.

If you set the timeout value to 0, the ADC appliance does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are not valid if that software is shut down. This persistence type does not consume any system resources. Therefore, it can accommodate an unlimited number of persistent clients.

An administrator can change the HTTP cookie version.

To change the HTTP cookie version by using the CLI

At the command prompt, type;

```
set ns param [-cookieversion ( 0 | 1 )]
<!--NeedCopy-->
```

Example:

```
set ns param -cookieversion 1
<!--NeedCopy-->
```

To change the HTTP cookie version by using the GUI

1. Navigate to System > Settings.
2. In the details pane, click Change HTTP Parameters.
3. In the Configure HTTP Parameters dialog box, under Cookie, select Version 0 or Version 1.

Note: For information about the parameters, see Configure persistence based on cookies.

To configure persistence based on cookies by using the CLI

At the command prompt, type the following commands to configure persistence based on cookies and verify the configuration:

```
set lb vserver <name> -persistenceType COOKIEINSERT

```

```
show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
Done
show lb vserver vserver-LB-1
    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
    .
    .
    .
    Persistence: COOKIEINSERT (version 0)
    Persistence Timeout: 2 min
    .
    .
    .
 Done
<!--NeedCopy-->
```

To configure persistence based on cookies by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select COOKIEINSERT.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. Click OK.
6. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configure persistence based on server IDs in URLs

The Citrix ADC appliance can maintain persistence based on the server IDs in the URLs. In a technique called URL passive persistence, the ADC extracts the server ID from the server response and embeds it in the URL query of the client request. The server ID is an IP address and port specified as a hexadecimal number. The ADC extracts the server ID from subsequent client requests and uses it to select the server.

URL passive persistence requires configuring either a payload expression or a policy infrastructure expression specifying the location of the server ID in the client requests. For more information about

expressions, see Policy Configuration and Reference.

Note: If the server ID cannot be extracted from the client requests, server selection is based on the load balancing method.

Example: Payload Expression

The expression, URLQUERY contains sid= configures the system to extract the server ID from the URL query of a client request, after matching token sid=. Thus, a request with the URL `http://www.citrix.com/index.asp?\\&sid;=c0a864100050` is directed to the server with the IP address10.102.29.10 and port 80.

The timeout value does not affect this type of persistence, which is maintained as long as the server ID can be extracted from the client requests. This persistence type does not consume any system resources, so it can accommodate an unlimited number of persistent clients.

> Note: For information about the parameters, see Load Balancing.

To configure persistence based on server IDs in URLs by using the CLI

At the command prompt, type the following commands to configure persistence based on server IDs in URLs and verify the configuration:

```
set lb vserver <name> -persistenceType URLPASSIVE

<show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
Done
show lb vserver vserver-LB-1
    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
    .
    .
    .
    Persistence: URLPASSIVE
    Persistence Timeout: 2 min
    .
    .
    .
Done
<!--NeedCopy-->
```

To configure persistence based on server IDs in URLs by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select URLPASSIVE.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. In the Rule text box, enter a valid expression. Alternatively, click Configure next to the Rule text box and use the Create Expression dialog box to create an expression.
6. Click OK.
7. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configure features to protect the load balancing configuration

September 14, 2021

You can configure URL redirection to provide notifications of virtual server malfunctions, and you can configure backup virtual servers to take over if a primary virtual server becomes unavailable.

Configure URL redirection

You can configure a redirect URL to communicate the status of the appliance in the event that a virtual server of type HTTP or HTTPS is down or disabled. This URL can be a local or remote link. The appliance uses HTTP 302 redirect.

Redirects can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. In this case, a redirect is used when both the primary and backup virtual servers are down.

To configure a virtual server to redirect client requests to a URL by using the CLI

At the command prompt, type the following commands to configure a virtual server to redirect client requests to a URL and verify the configuration:

```
set lb vserver <name> -redirectURL <URL>

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
    > set lb vserver vserver-LB-1 -redirectURL <http://www.newdomain.
       com/mysite/maintenance>
     Done
    > show lb vserver vserver-LB-1
        vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
        State: DOWN
        Last state change was at Wed Jun 17 08:56:34 2009 (+666 ms)
        .
        .
        .
        Redirect URL: <http://www.newdomain.com/mysite/maintenance>
        .
        .
        .
     Done
    >
<!--NeedCopy-->
```

To configure a virtual server to redirect client requests to a URL by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure URL redirection (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Redirect URL text box, type the URL (for example, `http://www.newdomain.com/mysite/maintenance`), and then click OK.
4. Verify that the redirect URL you configured for the server appears in the Details section at the bottom of the pane.

Configure backup virtual servers

If the primary virtual server is down or disabled, the appliance can direct the connections or client requests to a backup virtual server that forwards the client traffic to the services. The appliance can also send a notification message to the client regarding the site outage or maintenance. The backup virtual server is a proxy and is transparent to the client.

You can configure a backup virtual server when you create a virtual server or when you change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating a cascaded backup virtual server. The maximum depth of cascading backup virtual servers is 10. The appliance searches for a backup virtual server that is up and accesses that virtual server to deliver the content.

You can configure URL redirection on the primary for use when the primary and the backup virtual servers are down or have reached their thresholds for handling requests.

Note: If no backup virtual server exists, an error message appears, unless the virtual server is configured with a redirect URL. If both a backup virtual server and a redirect URL are configured, the backup virtual server takes precedence.

To configure a backup virtual server by using the CLI

At the command prompt, type the following commands to configure a backup server and verify the configuration:

```
set lb vserver <name> [-backupVserver <string>]

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
    > set lb vserver vserver-LB-1 -backupVserver vserver-LB-2
     Done
    > show lb vserver vserver-LB-1
        vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS
        State: DOWN
        Last state change was at Wed Jun 17 08:56:34 2009 (+661 ms)
        .
        .
        .
        Backup: vserver-LB-2
        .
        .
        .
     Done
    >
<!--NeedCopy-->
```

To set up a backup virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the backup virtual server (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Backup Virtual Server list, select the backup virtual server (for example, vserver-LB-2, and then click OK.
4. Verify that the backup virtual server you configured appears in the Details section at the bottom of the pane.

   Note: If the primary server goes down and then comes back up, and you want the backup virtual server to function as the primary server until you explicitly reestablish the primary virtual server, select the Disable Primary When Down check box.

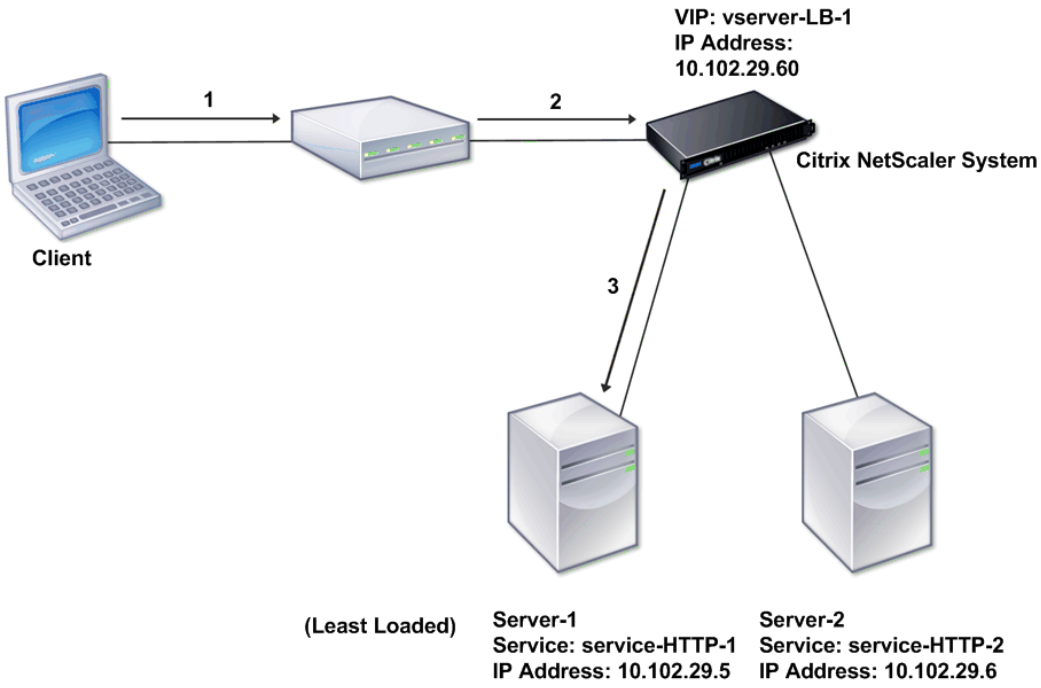
A typical load balancing scenario

September 14, 2021

In a load balancing setup, the Citrix ADC appliances are logically located between the client and the server farm, and they manage traffic flow to the servers.

The following figure shows the topology of a basic load balancing configuration.

Figure 1. Basic Load Balancing Topology

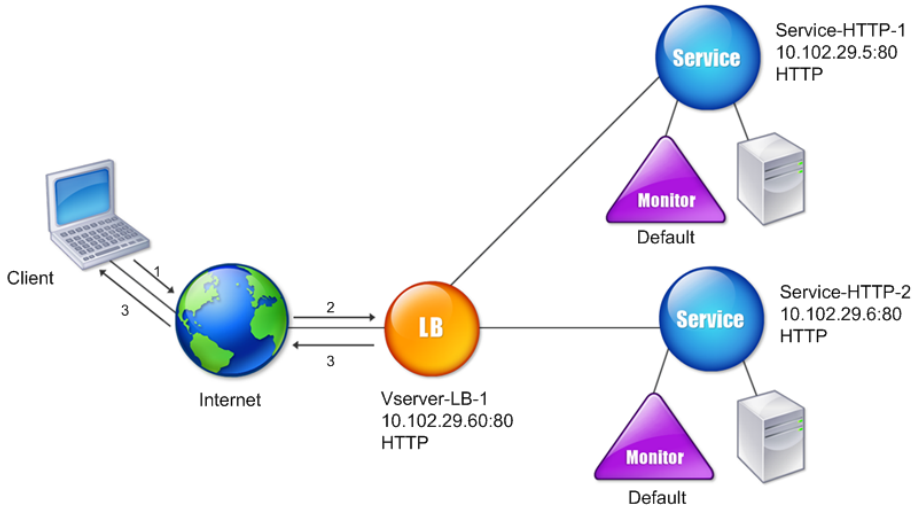


The virtual server selects the service and assigns it to serve client requests. Consider the scenario in the preceding figure, where the services service-HTTP-1 and service-HTTP-2 are created and bound to the virtual server named virtual server-LB-1. Virtual server-LB-1 forwards the client request to either service-HTTP-1 or service-HTTP-2. The system selects the service for each request by using the Least Connections load balancing method. The following table lists the names and values of the basic entities that must be configured on the system.

Table 1. LB Configuration Parameter Values

The following figure shows the load balancing sample values and required parameters that are described in the preceding table.

Figure 2. Load Balancing Entity Model



The following tables list the commands used to configure this load balancing setup by using the command line interface.

Task	Command
To enable load balancing	enable feature lb
To create a service named service-HTTP-1	add service service-HTTP-1 10.102.29.5 HTTP 80
To create a service named service-HTTP-2	add service service-HTTP-2 10.102.29.6 HTTP 80
To create a virtual server named vserver-LB-1	add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
To bind a service named service-HTTP-1 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-1
To bind a service named service-HTTP-2 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-2

Table 2. Initial Configuration Tasks

For more information about the initial configuration tasks, see Setting Up Basic Load Balancing.

Task	Command
To view the properties of a virtual server named vserver-LB-1	show lb vserver vserver-LB-1
To view the statistics of a virtual server named vserver-LB-1	stat lb vserver vserver-LB-1
To view the properties of a service named service-HTTP-1	show service service-HTTP-1
To view the statistics of a service named service-HTTP-1	stat service service-HTTP-1
To view the bindings of a service named service-HTTP-1	show service bindings service-HTTP-1

Table 3. Verification Tasks

Task	Command
To configure persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType SOURCEIP -persistenceMask 255.255.255.255 -timeout 2
To configure COOKIEINSERT persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
To configure URLPassive persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
To configure a virtual server to redirect the client request to a URL on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
To set a backup virtual server on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -backupVserver vserver-LB-2

Table 4. Customization Tasks

For more information about configuring persistence, see Choosing and Configuring Persistence Settings. For information about configuring a virtual server to redirect a client request to a URL and setting up a backup virtual server, see Configuring Features to Protect the Load Balancing Configuration.

Use case: How to force Secure and HttpOnly cookie options for websites using the Citrix ADC appliance

September 14, 2021

The web administrators may force the Secure, or HttpOnly, or both the flags on the Session ID and the authentication cookies that are generated by the web applications. You can modify the Set-cookie headers to include these two options by using an HTTP load balancing virtual server and rewrite policies on a Citrix ADC appliance.

- **HttpOnly** - This option on a cookie causes the web browsers to return the cookie using the HTTP or HTTPS protocol only. The non-HTTP methods such as JavaScript document.cookie references cannot access the cookie. This option helps in preventing cookie theft due to cross-site scripting.

  > NOTE
  >
  > You cannot use the HttpOnly option when a web application requires access to Cookie contents by using a client-side script, such as JavaScript or a client-side Java Applet. You can use the method mentioned in this document to rewrite only the server-generated cookies and not the cookies generated by Citrix ADC appliance. For example, AppFirewall, persistence, VPN session cookies and so on.

- **Secure** - This option on a cookie causes the web browsers to return only the cookie value when the transmission is encrypted by SSL. This option can be used to prevent cookie theft through connection eavesdropping.

> NOTE
>
> The following procedure is not applicable for VPN virtual servers.

To configure the Citrix ADC appliance to force the Secure and HttpOnly flags for an existing HTTP virtual server by using CLI

1. Create a rewrite action.

   This example is configured to set both Secure and HttpOnly flags. If either one is missing, modify it as necessary for other combinations.

```
1 add rewrite action act_cookie_Secure replace_all http.RES.
      full_Header "\"Secure; HttpOnly; path=/\"" -search "regex(re!(
      path=/\\; Secure; HttpOnly)|(path=/\\; Secure)|(path=/\\;
      HttpOnly)|(path=/)!)" -bypassSafetyCheck YES
2 <!--NeedCopy-->
```

This policy replaces all instances of “path=/”, “path=/; Secure”, “path=/; Secure; HttpOnly” and “path=/; HttpOnly” with “Secure; HttpOnly; path=/”. This regular expression (regex) fails if the case doesn’t match.

2. Create a rewrite policy to trigger the action.

```
add rewrite policy rw_force_secure_cookie "http.RES.HEADER(\"Set-Cookie\").EXISTS" act_cookie_Secure
<!--NeedCopy-->
```

3. Bind the rewrite policy to the virtual server to be secured. If `Secure` option is used, an SSL virtual server must be used.

```
bind lb vserver mySSLVServer -policyName rw_force_secure_cookie -priority 100 -gotoPriorityExpression NEXT -type RESPONSE
<!--NeedCopy-->
```

Examples:

The following example shows the cookie before setting the httpOnly flag

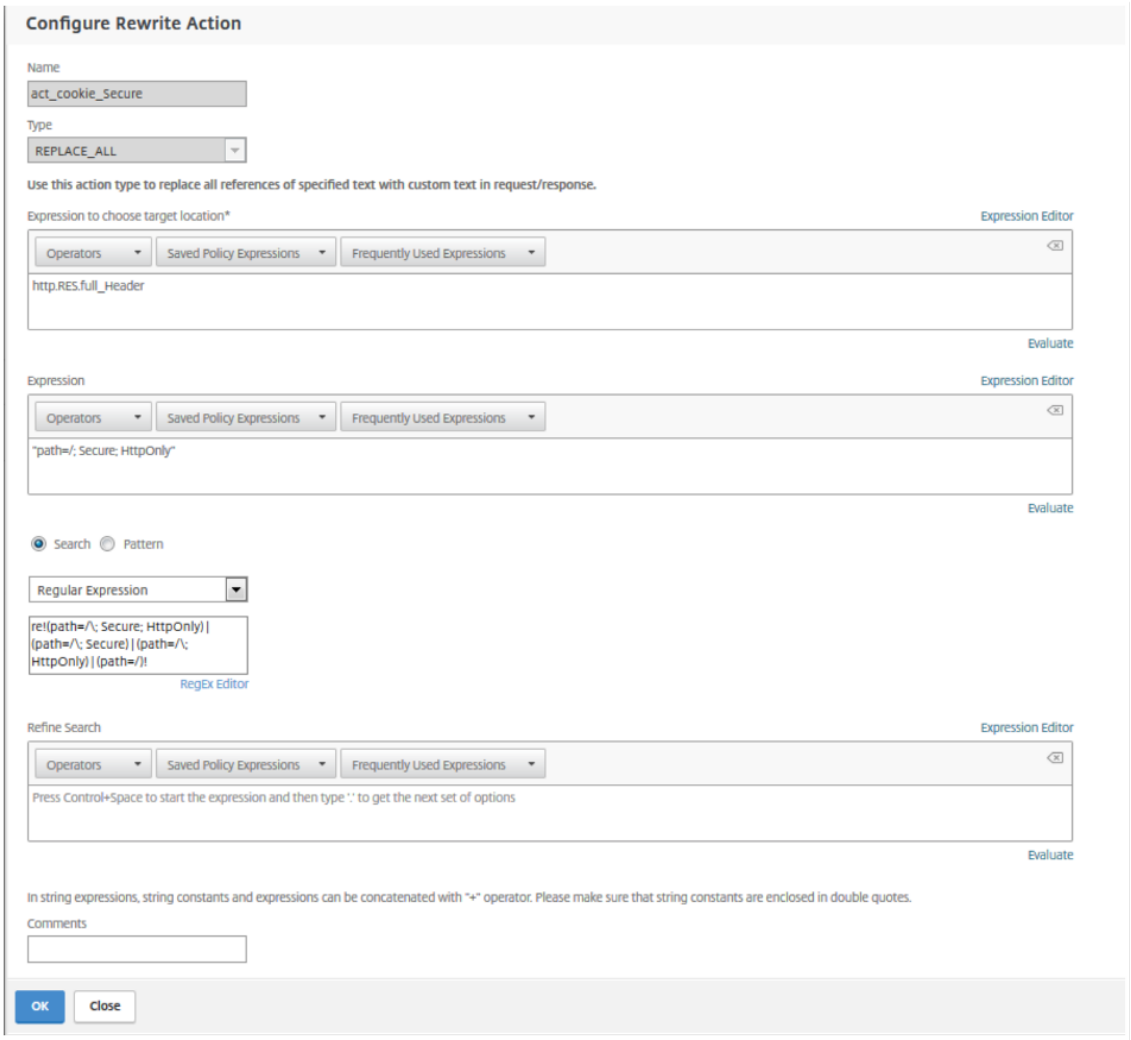
```
Set-Cookie: CtxsAuthId=C5614491; path=/Citrix/ProdWeb
<!--NeedCopy-->
```

The following example shows the cookie after setting the httpOnly flag

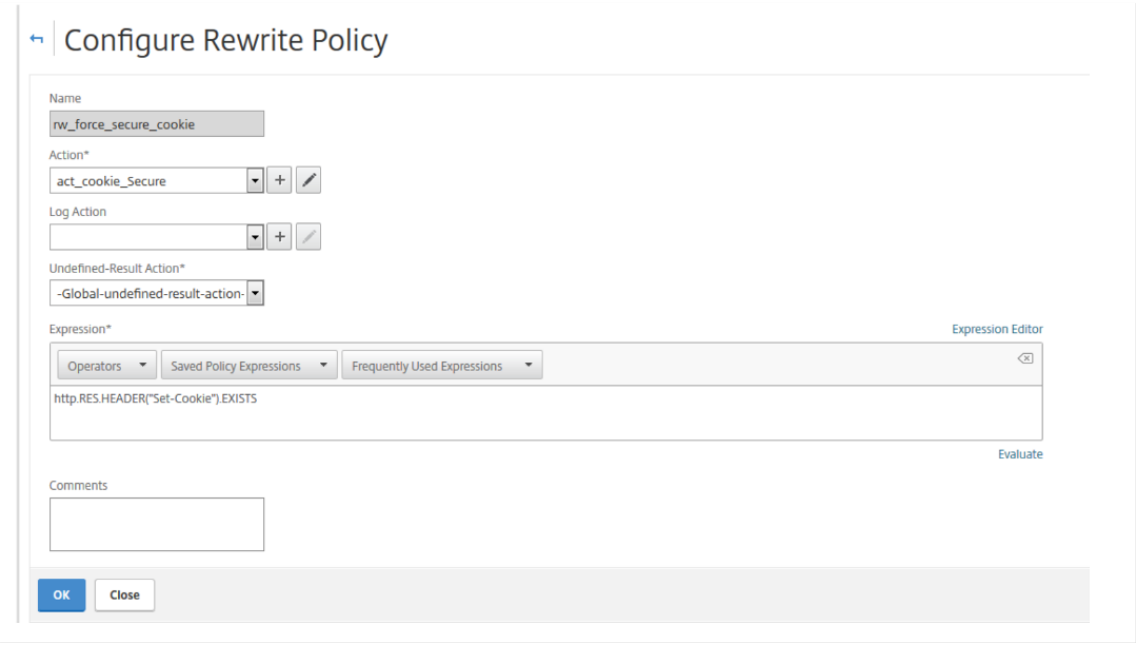
```
Set-Cookie: CtxsAuthId=C5614491; Secure; HttpOnly; path=/Citrix/ProdWeb/
<!--NeedCopy-->
```

To configure the Citrix ADC appliance to force the Secure and HttpOnly flags for an existing HTTP virtual server by using GUI

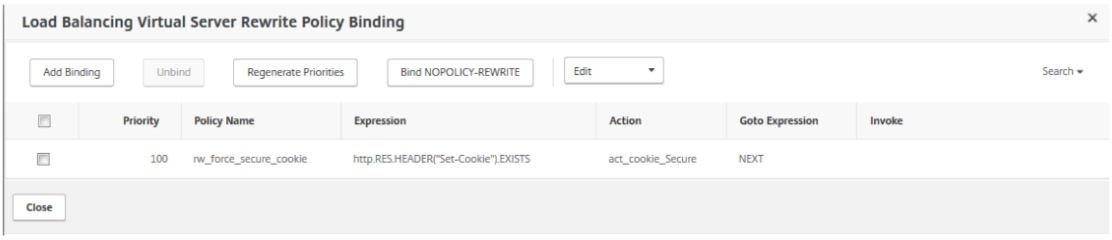
1. Navigate to **AppExpert > Rewrite > Actions**, and click **Add** to add a new rewrite action.



2. Navigate to **AppExpert > Rewrite > Policies**, and click **Add** to add a new rewrite policy.



3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then bind the rewrite (response) policy to the corresponding SSL virtual server.



Accelerate load balanced traffic by using compression

September 14, 2021

Compression is a popular means of optimizing bandwidth usage, and most web browsers support compressed data. If you enable the compression feature, the Citrix ADC appliance intercepts requests from clients and determines whether the client can accept compressed content. After receiving the HTTP response from the server, the appliance examines the content to determine whether it is compressible. If the content is compressible, the appliance compresses it, modifies the response header to indicate the type of compression performed, and forwards the compressed content to the client.

Citrix ADC compression is a policy-based feature. A policy filters requests and responses to identify responses to be compressed, and specifies the type of compression to apply to each response. The appliance provides several built-in policies to compress common MIME types such as text/html, text/plain,

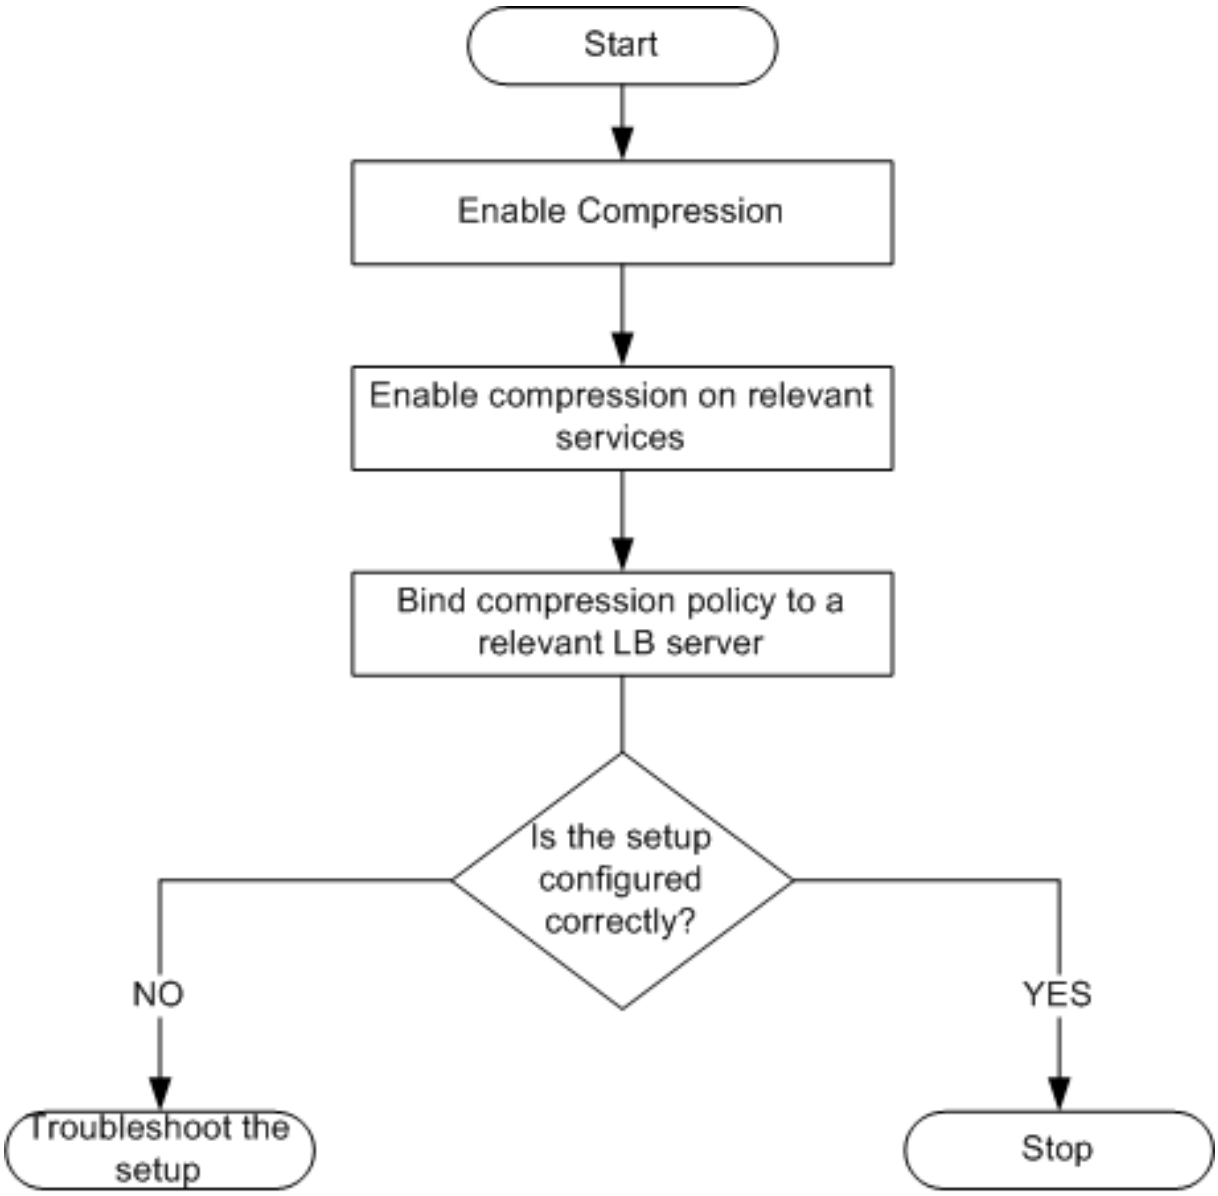
text/xml, text/css, text/rtf, application/msword, application/vnd.ms-excel, and application/vnd.ms-powerpoint. You can also create custom policies. The appliance does not compress compressed MIME types such as application/octet-stream, binary, bytes, and compressed image formats such as GIF and JPEG.

To configure compression, you must enable it globally and on each service that will provide responses that you want compressed. If you have configured virtual servers for load balancing or content switching, you should bind the polices to the virtual servers. Otherwise, the policies apply to all traffic that passes through the appliance.

Compression configuration task sequence

The following flow chart shows the sequence of tasks for configuring basic compression in a load balancing setup.

Figure 1. Sequence of Tasks to Configure Compression



Note: The steps in the above figure assume that load balancing has already been configured.

Enable compression

By default, compression is not enabled. You must enable the compression feature to allow compression of HTTP responses that are sent to the client.

To enable compression by using the CLI

At the command prompt, type the following commands to enable compression and verify the configuration:

- enable ns feature CMP
- show ns feature

```
    > enable ns feature CMP

    Done

    > show ns feature

           Feature                        Acronym              Status

           -------                        -------              ------

    1)     Web Logging                    WL                   ON

    2)     Surge Protection               SP                   OFF

    .

    7) Compression Control CMP ON

    8)     Priority Queuing               PQ                   OFF

    .

    Done
<!--NeedCopy-->
```

To enable compression by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Compression check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click Yes.

Configure services to compress data

In addition to enabling compression globally, you must enable it on each service that will deliver files to be compressed.

To enable compression on a service by using the CLI

At the command prompt, type the following commands to enable compression on a service and verify the configuration:

- set service <name> -CMP YES
- show service <name>

```
> show service SVC_HTTP1

SVC_HTTP1 (10.102.29.18:80) - HTTP

State: UP

Last state change was at Tue Jun 16 06:19:14 2009 (+737 ms)

Time since last state change: 0 days, 03:03:37.200

Server Name: 10.102.29.18

Done

<!--NeedCopy-->
```

To enable compression on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure compression (for example, service-HTTP-1), and then click Open.
3. On the Advanced tab, under Settings, select the Compression check box, and then click OK.
4. Verify that, when the service is selected, HTTP Compression(CMP): ON appears in the **Details** section at the bottom of the pane.

Bind a compression policy to a virtual server

If you bind a policy to a virtual server, the policy is evaluated only by the services associated with that virtual server. You can bind compression policies to a virtual server either from the Configure Virtual Server (Load Balancing) dialog box or from the Compression Policy Manager dialog box. This topic includes instructions to bind compression policies to a load balancing virtual server by using the Configure Virtual Server (Load Balancing) dialog box.

To bind or unbind a compression policy to a virtual server by using the command line

At the command prompt, type the following commands to bind or unbind a compression policy to a load balancing virtual server and verify the configuration:

(bind	unbind) lb vserver <name> -policyName <string>

-
- show lb vserver <name>

Example:

```
> bind lb vserver lbvip -policyName ns_cmp_msapp
Done
> showlbvserverlbvip
```

```
4
5  lbvip(8.7.6.6:80)-HTTPType:ADDRESS
6  State:UP

To bind or unbind a compression policy to a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind or unbind a compression policy (for example, Vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Policies tab, click Compression.
4. Do one of the following:
   - To bind a compression policy, click Insert Policy, and then select the policy you want to bind to the virtual server.
   - To unbind a compression policy, click the name of the policy you want to unbind from the virtual server, and then click Unbind Policy.

5. Click OK.

Secure load balanced traffic by using SSL

September 14, 2021

The Citrix ADC SSL offload feature transparently improves the performance of websites that conduct SSL transactions. By offloading CPU-intensive SSL encryption and decryption tasks from the local web server to the appliance, SSL offloading ensures secure delivery of web applications without the performance penalty incurred when the server processes the SSL data. Once the SSL traffic is decrypted, it can be processed by all standard services. The SSL protocol works seamlessly with various types of HTTP and TCP data and provides a secure channel for transactions using such data.

To configure SSL, you must first enable it. Then, you configure HTTP or TCP services and an SSL virtual server on the appliance, and bind the services to the virtual server. You must also add a certificate-key pair and bind it to the SSL virtual server. If you use Outlook Web Access servers, you must create an action to enable SSL support and a policy to apply the action. An SSL virtual server intercepts incoming encrypted traffic and decrypts it by using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the appliance for appropriate processing.

For detailed information about SSL offloading, see SSL offload and acceleration.

SSL configuration task sequence

To configure SSL, you must first enable it. Then, you must create an SSL virtual server and HTTP or TCP services on the Citrix ADC appliance. Finally, you must bind a valid SSL certificate and the configured services to the SSL virtual server.

An SSL virtual server intercepts incoming encrypted traffic and decrypts it using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the Citrix ADC appliance for appropriate processing.

The following flow chart shows the sequence of tasks for configuring a basic SSL offload setup.

Figure 1. Sequence of Tasks to Configure SSL Offloading

Enable SSL offload

First enable the SSL feature. You can configure SSL-based entities on the appliance without enabling the SSL feature, but they will not work until you enable SSL.

Enable SSL by using the CLI

At the command prompt, type the following commands to enable SSL Offload and verify the configuration:

```
-  enable ns feature SSL
-  show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature ssl

Done

> show ns feature

Feature Acronym Status

------- ------- ------

1) Web Logging WL ON

2) SurgeProtection SP OFF

3) Load Balancing LB ON . . .

 9) SSL Offloading SSL ON

10) Global Server Load Balancing GSLB ON . .

```

```
30 Done >
31 <!--NeedCopy-->
```

Enable SSL by using the GUI

Follow these steps:

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes and Features**, click **Change basic features**.
3. Select the **SSL Offloading** check box, and then click **OK**.
4. In the **Enable/Disable Feature(s)?** message box, click **Yes**.

Create HTTP services

A service on the appliance represents an application on a server. Once configured, services are in the disabled state until the appliance can reach the server on the network and monitor its status. This topic covers the steps to create an HTTP service.

Note: For TCP traffic, perform the following procedures, but create TCP services instead of HTTP services.

Add an HTTP service by using the CLI

At the command prompt, type the following commands to add an HTTP service and verify the configuration:

```
1 -  add service <name> (<IP> | <serverName>) <serviceType> <port>
2 -  show service <name>
3 <!--NeedCopy-->
```

Example:

```
1 > add service SVC_HTTP1 10.102.29.18 HTTP 80
2
3
4  Done
5
6
7 > show service SVC_HTTP1
8
9
10         SVC_HTTP1 (10.102.29.18:80) - HTTP
11
```

```

Add an HTTP service by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Services**.
2. In the details pane, click **Add**.
3. In the **Create Service** dialog box, type the name of the service, IP address, and port (for example, SVC_HTTP1, 10.102.29.18, and 80).
4. In the **Protocol** list, select the type of the service (for example, HTTP).
5. Click **Create**, and then click **Close**. The HTTP service you configured appears in the Services page.
6. Verify that the parameters you configured are correctly configured by selecting the service and viewing the Details section at the bottom of the pane.

Add an SSL based virtual server

In a basic SSL offloading setup, the SSL virtual server intercepts encrypted traffic, decrypts it, and sends the clear text messages to the services that are bound to the virtual server. Offloading CPU-intensive SSL processing to the appliance allows the back-end servers to process a greater number of requests.

Add an SSL-based virtual server by using the CLI

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

```
-  add lb vserver <name> <serviceType> [<IPAddress> <port>]
-  show lb vserver <name>
<!--NeedCopy-->
```

> **Caution:** To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Example:

```
> add lb vserver vserver-SSL-1 SSL 10.102.29.50 443
  Done

  > show lb vserver vserver-SSL-1

  vserver-SSL-1 (10.102.29.50:443) - SSL Type: ADDRESS

  State: DOWN[Certkey not bound] Last state change was at Tue Jun 16
     06:33:08 2009 (+176 ms)

  Time since last state change: 0 days, 00:03:44.120

```

Add an SSL-based virtual server by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. In the details pane, click **Add**.
3. In the **Create Virtual Server (SSL Offload)** dialog box, type the name of the virtual server, IP address, and port.
4. In the **Protocol** list, select the type of the virtual server, for example, SSL.
5. Click **Create**, and then click **Close**.
6. Verify that the parameters you configured are correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane. The virtual server is marked as DOWN because a certificate-key pair and services have not been bound to it.

> **Caution:** To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Bind services to the SSL virtual server

After decrypting the incoming data, the SSL virtual server forwards the data to the services that you have bound to the virtual server.

Data transfer between the appliance and the servers can be encrypted or in clear text. If the data transfer between the appliance and the servers is encrypted, the entire transaction is secure from end

to end. For more information about configuring the system for end-to-end security, see SSL offload and acceleration.

Bind a service to a virtual server by using the CLI

At the command prompt, type the following commands to bind a service to the SSL virtual server and verify the configuration:

```
-  bind lb vserver <name> <serviceName>
-  show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
> bind lb vserver vserver-SSL-1 SVC_HTTP1

  Done

  > show lb vserver vserver-SSL-1 vserver-SSL-1 (10.102.29.50:443) -
     SSL Type:

  ADDRESS State: DOWN[Certkey not bound]

  Last state change was at Tue Jun 16 06:33:08 2009 (+174 ms)

  Time since last state change: 0 days, 00:31:53.70

  Effective State: DOWN Client Idle

  Timeout: 180 sec

  Down state flush: ENABLED Disable Primary Vserver On Down :

46
47
48    Done
49  <!--NeedCopy-->
```

Bind a service to a virtual server by using the GUI

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. In the details pane, select a virtual server, and then click **Open**.
3. On the **Services** tab, in the **Active** column, select the check boxes next to the services that you want to bind to the selected virtual server.
4. Click **OK**.
5. Verify that the Number of Bound Services counter in the Details section at the bottom of the pane is incremented by the number of services that you bound to the virtual server.

Add a certificate-key pair

An SSL certificate is an integral element of the SSL Key-Exchange and encryption/decryption process. The certificate is used during an SSL handshake to establish the identity of the SSL server. You can use a valid, existing SSL certificate that you have on the Citrix ADC appliance, or you can create your own SSL certificate. The appliance supports RSA certificates of up to 4096 bits.

ECDSA certificates with only the following curves are supported:

- prime256v1 (P_256 on the ADC)
- secp384r1 (P_384 on the ADC)

- secp521r1 (P_521 on the ADC; supported on VPX only)
- secp224r1 (P_224 on the ADC; supported on VPX only)

> **Note:** Citrix recommends that you use a valid SSL certificate that has been issued by a trusted certificate authority. Invalid certificates and self-created certificates are not compatible with all SSL clients.

Before a certificate can be used for SSL processing, you must pair it with its corresponding key. The certificate key pair is then bound to the virtual server and used for SSL processing.

Add a certificate key pair by using the CLI

> **Note:** For information about creating an ECDSA certificate-key pair, see Create an ECDSA certificate-key pair.

At the command prompt, type the following commands to create a certificate key pair and verify the configuration:

```
1 -  add ssl certKey <certkeyName> -cert <string> [-key <string>]
2 -  show sslcertkey <name>
3 <!--NeedCopy-->
```

Example:

```
1  > add ssl certKey CertKey-SSL-1 -cert ns-root.cert -key ns-root.key
2
3   Done
4
5
6  > show sslcertkey CertKey-SSL-1

32
33   Done
34 <!--NeedCopy-->
```

Add a certificate key pair by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL > Certificates**.
2. In the details pane, click **Add**.
3. In the **Install Certificate** dialog box, in the Certificate-Key Pair Name text box, type a name for the certificate key pair you want to add, for example, Certkey-SSL-1.
4. Under **Details**, in Certificate File Name, click **Browse (Appliance)** to locate the certificate. Both the certificate and the key are stored in the /nsconfig/ssl/ folder on the appliance. To use a certificate present on the local system, select Local.
5. Select the certificate you want to use, and then click **Select**.
6. In Private Key File Name, click **Browse (Appliance)** to locate the private key file. To use a private key present on the local system, select Local.
7. Select the key you want to use and click **Select**. To encrypt the key used in the certificate key pair, type the password to be used for encryption in the Password text box.
8. Click **Install**.
9. Double-click the certificate key pair and, in the Certificate Details window, verify that the parameters have been configured correctly and saved.

Bind an SSL certificate key pair to the virtual server

After you pairing an SSL certificate with its corresponding key, bind the certificate-key pair to the SSL virtual server so that it can be used for SSL processing. Secure sessions require establishing a connection between the client computer and an SSL-based virtual server on the appliance. SSL processing

is then carried out on the incoming traffic at the virtual server. Therefore, before enabling the SSL virtual server on the appliance, you need to bind a valid SSL certificate to the SSL virtual server.

Bind an SSL certificate key pair to a virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL certificate key pair to a virtual server and verify the configuration:

```
-  bind ssl vserver <vServerName> -certkeyName <string>
-  show ssl vserver <name>
<!--NeedCopy-->
```

Example:

```
> bind ssl vserver Vserver-SSL-1 -certkeyName CertKey-SSL-1

Done

> show ssl vserver Vserver-SSL-1

     Advanced SSL configuration for VServer Vserver-SSL-1:

     DH: DISABLED

     Ephemeral RSA: ENABLED Refresh Count: 0

     Session Reuse: ENABLED Timeout: 120 seconds

     Cipher Redirect: ENABLED

     SSLv2 Redirect: ENABLED

     ClearText Port: 0

```

```

```

Bind an SSL certificate key pair to a virtual server by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. Select the virtual server to which you want to bind the certificate key pair, for example, Vserver-SSL-1, and click Open.
3. In the **Configure Virtual Server (SSL Offload)** dialog box, on the **SSL Settings** tab, under **Available**, select the certificate key pair that you want to bind to the virtual server. Then click **Add**.
4. Click **OK**.
5. Verify that the certificate key pair that you selected appears in the Configured area.

Configure support for Outlook web access

If you use Outlook Web Access (OWA) servers on your Citrix ADC appliance, you must configure the appliance to insert a special header field, FRONT-END-HTTPS: ON, in HTTP requests directed to the OWA servers, so that the servers generate URL links as `https://` instead of `http://`.

Note: You can enable OWA support for HTTP-based SSL virtual servers and services only. You cannot apply it for TCP-based SSL virtual servers and services.

To configure OWA support, do the following:

- Create an SSL action to enable OWA support.
- Create an SSL policy.
- Bind the policy to the SSL virtual server.

Create an SSL action to enable OWA support

Before you can enable Outlook Web Access (OWA) support, you must create an SSL action. SSL actions are bound to SSL policies and triggered when incoming data matches the rule specified by the policy.

Create an SSL action to enable OWA support by using the CLI

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

```
1 -  add ssl action <name> -OWASupport ENABLED
2 -  show SSL action <name>
3 <!--NeedCopy-->
```

Example:

```
1     > add ssl action Action-SSL-OWA -OWASupport enabled
2
3
4
5
6     Done
7
8
9     > show SSL action Action-SSL-OWA
10
11
12    Name: Action-SSL-OWA
13
14
```

```
    Data Insertion Action: OWA

    Support: ENABLED

    Done
<!--NeedCopy-->
```

Create an SSL action to enable OWA support by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL > Policies**.
2. In the details pane, on the **Actions** tab, click **Add**.
3. In the **Create SSL Action** dialog box, in the Name text box, type Action-SSL-OWA.
4. Under Outlook Web Access, select **Enabled**.
5. Click **Create**, and then click **Close**.
6. Verify that Action-SSL-OWA appears in the **SSL Actions** page.

Create SSL policies

SSL policies are created by using the policy infrastructure. Each SSL policy has an SSL action bound to it, and the action is carried out when incoming traffic matches the rule that has been configured in the policy.

Create an SSL policy by using the CLI

At the command prompt, type the following commands to configure an SSL policy and verify the configuration:

```
-  add ssl policy <name> -rule <expression> -reqAction <string>
-  show ssl policy <name>
<!--NeedCopy-->
```

Example:

```
> add ssl policy Policy-SSL-1 -rule ns_true -reqaction Action-SSL-OWA

Done

> show ssl policy Policy-SSL-1

```

```
Name: Policy-SSL-1 Rule: ns_true

Action: Action-SSL-OWA Hits: 0

Policy is bound to following entities

1) PRIORITY : 0

Done
<!--NeedCopy-->
```

Create an SSL policy by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL > Policies**.
2. In the details pane, click **Add**.
3. In the **Create SSL Policy** dialog box, in the Name text box, type the name of the SSL Policy (for example, Policy-SSL-1).
4. In **Request** Action, select the configured SSL action that you want to associate with this policy (for example, Action-SSL-OWA). The ns_true general expression applies the policy to all successful SSL handshake traffic. However, to filter specific responses, you can create policies with a higher level of detail. For more information about configuring granular policy expressions, see SSL actions and policies.
5. In **Named Expressions**, choose the built-in general expression ns_true and click **Add Expression**. The expression ns_true now appears in the Expression text box.
6. Click **Create**, and then click **Close**.
7. Verify that the policy is correctly configured by selecting the policy and viewing the Details section at the bottom of the pane.

Bind the SSL policy to the SSL virtual server

After you configure an SSL policy for Outlook Web Access, bind the policy to a virtual server that will intercept incoming Outlook traffic. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

Bind an SSL policy to an SSL virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL policy to an SSL virtual server and verify the configuration:

```
-  bind ssl vserver <vServerName> -policyName <string>
-  show ssl vserver <name>
<!--NeedCopy-->
```

Example:

```
> bind ssl vserver Vserver-SSL-1 -policyName Policy-SSL-1

 Done

> show ssl vserver Vserver-SSL-1

Advanced SSL configuration for VServer Vserver-SSL-1:

DH: DISABLED

Ephemeral RSA: ENABLED

Refresh Count: 0

Session Reuse: ENABLED

Timeout: 120 seconds

Cipher Redirect: ENABLED

SSLv2 Redirect: ENABLED

ClearText Port: 0

Client Auth: DISABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Policy Name: Policy-SSL-1 Priority: 0

1) Cipher Name: DEFAULT Description: Predefined Cipher Alias

```

```
Done
<!--NeedCopy-->
```

Bind an SSL policy to an SSL virtual server by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. In the details pane, select the virtual server (for example, Vserver-SSL-1), and then click **Open**.
3. In the **Configure Virtual Server (SSL Offload)** dialog box, click **Insert Policy**, and then select the policy that you want to bind to the SSL virtual server. Optionally, you can double-click the Priority field and type a new priority level.
4. Click **OK**.

Features at a glance

September 14, 2021

Citrix ADC features can be configured independently or in combinations to address specific needs. Although some features fit more than one category, the numerous Citrix ADC features can generally be categorized as application switching and traffic management features, application acceleration features, and application security and firewall features, and an application visibility feature.

To understand the order in which the features perform their processing, see Processing Order of Features section.

Application switching and traffic management features

September 14, 2021

Below are the application switching and traffic management features.

SSL Offloading

Transparently offloads SSL encryption and decryption from web servers, freeing server resources to service content requests. SSL places a heavy burden on an application's performance and can render many optimization measures ineffective. SSL offload and acceleration allow all the benefits of Citrix Request Switching technology to be applied to SSL traffic, ensuring secure delivery of web applications without degrading end-user performance.

For more information, see SSL offload and acceleration.

Access Control Lists

Compares incoming packets to Access Control Lists (ACLs). If a packet matches an ACL rule, the action specified in the rule is applied to the packet. Otherwise, the default action (ALLOW) is applied and the packet is processed normally. For the appliance to compare incoming packets to the ACLs, you have to apply the ACLs. All ACLs are enabled by default, but you have to apply them in order for the Citrix ADC appliance to compare incoming packets against them. If an ACL is not required to be a part of the lookup table, but still needs to be retained in the configuration, it should be disabled before the ACLs are applied. An ADC appliance does not compare incoming packets to disabled ACLs.

For more information, see Access Control List.

Load Balancing

Load balancing decisions are based on a variety of algorithms, including round robin, least connections, weighted least bandwidth, weighted least packets, minimum response time, and hashing based on URL, domain source IP, or destination IP. Both the TCP and UDP protocols are supported, so the Citrix ADC appliance can load balance all traffic that uses those protocols as the underlying carrier (for example, HTTP, HTTPS, UDP, DNS, NNTP, and general firewall traffic). In addition, the ADC appliance can maintain session persistence based on source IP, cookie, server, group, or SSL session. It allows users to apply custom Extended Content Verification (ECV) to servers, caches, firewalls and other infrastructure devices to ensure that these systems are functioning properly and are providing the right content to users. It can also perform health checks using ping, TCP, or HTTP URL, and the user can create monitors based on Perl scripts.
To provide high-scale WAN optimization, the CloudBridge appliances deployed at data centers can be load balanced through Citrix ADC appliances. The bandwidth and number of concurrent sessions can be improved significantly.

For more information, see Load Balancing.

Traffic Domains

Traffic domains provide a way to create logical ADC partitions within a single Citrix ADC appliance. They enable you to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments whose resources do not interact with each other. An application belonging to a specific traffic domain communicates only with entities, and processes traffic, within that domain. Traffic belonging to one traffic domain cannot cross the boundary of another traffic domain. Therefore, you can use duplicate IP addresses on the appliance as long as an addresses is not duplicated within the same domain.

For more information, see Traffic Domains.

Network Address Translation

Network address translation (NAT) involves modification of the source and/or destination IP addresses, and/or the TCP/UDP port numbers, of IP packets that pass through the Citrix ADC appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your network's source IP addresses when data passes through the Citrix ADC appliance.

The Citrix ADC appliance supports the following types of network address translation:

INAT: In Inbound NAT (INAT), an IP address (usually public) configured on the Citrix ADC appliance listens to connection requests on behalf of a server. For a request packet received by the appliance on a public IP address, the ADC replaces the destination IP address with the private IP address of the server. In other words, the appliance acts as a proxy between clients and the server. INAT configuration involves INAT rules, which define a 1:1 relationship between the IP address on the Citrix ADC appliance and the IP address of the server.

RNAT: In Reverse Network Address Translation (RNAT), for a session initiated by a server, the Citrix ADC appliance replaces the source IP address in the packets generated by the server with an IP address (type SNIP) configured on the appliance. The appliance thereby prevents exposure of the server's IP address in any of the packets generated by the server. An RNAT configuration involves an RNAT rule, which specifies a condition. The appliance performs RNAT processing on those packets that match the condition.

Stateless NAT46 Translation: Stateless NAT46 enables communication between IPv4 and IPv6 networks, by way of IPv4 to IPv6 packet translation and vice versa, without maintaining any session information on the Citrix ADC appliance. A stateless NAT46 configuration involves an IPv4-IPv6 INAT rule and an NAT46 IPv6 prefix.

Stateful NAT64 Translation: The stateful NAT64 feature enables communication between IPv4 clients and IPv6 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the Citrix ADC appliance. A stateful NAT64 configuration involves an NAT64 rule and an NAT64 IPv6 prefix.

For more information, see Configuring Network Address Translation.

Multipath TCP Support

Citrix ADC appliances support Multipath TCP (MPTCP). MPTCP is a TCP/IP protocol extension that identifies and uses multiple paths available between hosts to maintain the TCP session. You must enable MPTCP on a TCP profile and bind it to a virtual server. When MPTCP is enabled, the virtual server func-

tions as an MPTCP gateway and converts MPTCP connections with the clients to TCP connections that it maintains with the servers.

For more information, see MPTCP (Multi-Path TCP).

Content Switching

Determines the server to which to send the request on the basis of configured content switching policies. Policy rules can be based on the IP address, URL, and HTTP headers. This allows switching decisions to be based on user and device characteristics such as who the user is, what type of agent is being used, and what content the user requested.

For more information, see Content Switching.

Global Server Load Balancing (GSLB)

Extends the traffic management capabilities of a NetScaler to include distributed Internet sites and global enterprises. Whether installations are spread across multiple network locations or multiple clusters in a single location, the NetScaler maintains availability and distributes traffic across them. It makes intelligent DNS decisions to prevent users from being sent to a site that is down or overloaded. When the proximity-based GSLB method is enabled, the NetScaler can make load balancing decisions based on the proximity of the client's local DNS server (LDNS) in relation to different sites. The main benefit of the proximity-based GSLB method is faster response time resulting from the selection of the closest available site.

For more information, see Global Server Load Balancing.

Dynamic Routing

Enables routers to obtain topology information, routes, and IP addresses from neighboring routers automatically. When dynamic routing is enabled, the corresponding routing process listens to route updates and advertises routes. The routing processes can also be placed in passive mode. Routing protocols enable an upstream router to load balance traffic to identical virtual servers hosted on two standalone NetScaler units using the Equal Cost Multipath technique.

For more information, see Configuring Dynamic Routes.

Link Load Balancing

Load balances multiple WAN links and provides link failover, further optimizing network performance and ensuring business continuity. Ensures that network connections remain highly available, by applying intelligent traffic control and health checks to distribute traffic efficiently across upstream

routers. Identifies the best WAN link to route both incoming and outbound traffic based on policies and network conditions, and protects applications against WAN or Internet link failure by providing rapid fault detection and failover.

For more information, see Link Load Balancing.

TCP Optimization

You can use TCP profiles to optimize TCP traffic. TCP profiles define the way that NetScaler virtual servers process TCP traffic. Administrators can use the built-in TCP profiles or configure custom profiles. After defining a TCP profile, you can bind it to a single virtual server or to multiple virtual servers.

Some of the key optimization features that can be enabled by TCP profiles are:

- TCP keep-alive—Checks the operational status of the peers at specified time intervals to prevent the link from being broken.
- Selective Acknowledgment (SACK)— Improves the performance of data transmission, especially in long fat networks (LFNs).
- TCP window scaling— Allows efficient transfer of data over long fat networks (LFNs).

For more information on TCP Profiles, see Configuring TCP Profiles.

CloudBridge Connector

The Citrix NetScaler CloudBridge Connector feature, a fundamental part of the Citrix OpenCloud framework, is a tool used to build a cloud-extended data center. The OpenCloud Bridge enables you to connect one or more Citrix ADC appliances or NetScaler virtual appliances on the cloud-to your network without reconfiguring your network. Cloud hosted applications appear as though they are running on one contiguous enterprise network. The primary purpose of the OpenCloud Bridge is to enable companies to move their applications to the cloud while reducing costs and the risk of application failure. In addition, the OpenCloud Bridge increases network security in cloud environments. An OpenCloud Bridge is a Layer-2 network bridge that connects a Citrix ADC appliance or NetScaler virtual appliance on a cloud instance to a Citrix ADC appliance or NetScaler virtual appliance on your LAN. The connection is made through a tunnel that uses the Generic Routing Encapsulation (GRE) protocol. The GRE protocol provides a mechanism for encapsulating packets from a wide variety of network protocols to be forwarded over another protocol. Then Internet Protocol security (IPsec) protocol suite is used to secure the communication between the peers in the OpenCloud Bridge.

For more information, see CloudBridge.

DataStream

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests on the basis of the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.

You can configure load balancing to switch requests according to load balancing algorithms, or you can elaborate the switching criteria by configuring content switching to make a decision based on SQL query parameters, such as user name, database names, and command parameters. You can further configure monitors to track the states of database servers.

The advanced policy infrastructure on the Citrix ADC appliance includes expressions that you can use to evaluate and process the requests. The advanced expressions evaluate traffic associated with MySQL database servers. You can use request-based expressions (expressions that begin with MYSQL.CLIENT and MYSQL.REQ) in advanced policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

> Note: DataStream is supported for MySQL and MS SQL databases.

For more information, see DataStream.

Application acceleration features

September 14, 2021

- AppCompress

  Uses the gzip compression protocol to provide transparent compression for HTML and text files. The typical 4:1 compression ratio yields up to 50% reduction in bandwidth requirements out of the data center. It also results in significantly improved end-user response time, because it reduces the amount of data that must be delivered to the user's browser.

- Cache Redirection

  Manages the flow of traffic to a reverse proxy, transparent proxy, or forward proxy cache farm. Inspects all requests, and identifies non-cacheable requests and sends them directly to the origin servers over persistent connections. By intelligently redirecting non-cacheable requests back to the origin web servers, the Citrix ADC appliance frees cache resources and increases cache hit rates while reducing overall bandwidth consumption and response delays for these requests.

  For more information, see Cache Redirection.

- AppCache

  Helps optimize web content and application data delivery by providing a fast in-memory HTTP/1.1 and HTTP/1.0 compliant web caching for both static and dynamic content. This on-board cache stores the results of incoming application requests even when an incoming request is secured or the data compressed, and then reuses the data to fulfill subsequent requests for the same information. By serving data directly from the on-board cache, the appliance can reduce page regeneration times by eliminating the need to funnel static and dynamic content requests to the server.

  For more information, see Integrated Caching.

- TCP Buffering

  Buffers the server's response and delivers it to the client at the client's speed, thus offloading the server faster and thereby improving the performance of web sites.

Application security and firewall features

September 14, 2021

Below are the security and firewall features.

Denial of service (DoS) attack defense

Detects and stops malicious distributed denial-of-service (DDoS) attacks and other types of malicious attacks before they reach your servers, preventing them from affecting network and application performance. The Citrix ADC appliance identifies legitimate clients and elevates their priority, leaving suspect clients unable to consume a disproportionate percentage of resources and cripple your site. The appliance provides application-level protection from the following types of malicious attacks:

- SYN flood attacks
- Pipeline attacks
- Teardrop attacks
- Land attacks
- Fraggle attacks
- Zombie connection attacks

The appliance aggressively defends against these types of attacks by preventing the allocation of server resources for these connections. This insulates servers from the overwhelming flood of packets associated with these events.

The appliance also protects network resources from ICMP based attacks by using ICMP rate limiting and aggressive ICMP packet inspection. It performs strong IP reassembly, drops a variety of suspicious and malformed packets, and applies Access Control Lists (ACLs) to site traffic for further protection.

For more information, see HTTP Denial-of-Service Protection.

Content Filtering

Provides protection from malicious attacks for web sites at the Layer 7 level. The appliance inspects each incoming request according to user-configured rules based on HTTP headers, and performs the action the user configured. Actions can include resetting the connection, dropping the request, or sending an error message to the user's browser. This allows the appliance to screen unwanted requests and reduces your servers' exposure to attacks.

This feature can also analyze HTTP GET and POST requests and filter out known bad signatures, allowing it to defend your servers against HTTP-based attacks.

For more information, see Content Filtering.

Responder

Functions like an advanced filter and can be used to generate responses from the appliance to the client. Some common uses of this feature are generation of redirect responses, user defined responses, and resets.

For more information, see Responder.

Rewrite

Modifies HTTP headers and body text. You can use the rewrite feature to add HTTP headers to an HTTP request or response, make modifications to individual HTTP headers, or delete HTTP headers. It also enables you to modify the HTTP body in requests and responses.

When the appliance receives a request or sends a response, it checks for rewrite rules, and if applicable rules exist, it applies them to the request or response before passing it on to the web server or client computer.

For more information, see Rewrite.

Priority Queuing

Prioritizes user requests to ensure that the most important traffic is serviced first during surges in request volume. You can establish priority based on request URLs, cookies, or a variety of other fac-

tors. The appliance places requests in a three-tier queue based on their configured priority, enabling business-critical transactions to flow smoothly even during surges or site attacks.

For more information, see Priority Queuing.

Surge Protection

Regulates the flow of user requests to servers and controls the number of users that can simultaneously access the resources on the servers, queuing any additional requests once your servers have reached their capacity. By controlling the rate at which connections can be established, the appliance blocks surges in requests from being passed on to your servers, thus preventing site overload.

For more information, see Surge Protection.

Citrix Gateway

Citrix Gateway is a secure application access solution that provides administrators granular application-level policy and action controls to secure access to applications and data while allowing users to work from anywhere. It gives IT administrators a single point of control and tools to help ensure compliance with regulations and the highest levels of information security across and outside the enterprise. At the same time, it empowers users with a single point of access—optimized for roles, devices, and networks—to the enterprise applications and data they need. This unique combination of capabilities helps maximize the productivity of today's mobile workforce.

For more information, see Citrix Gateway.

Application Firewall

Protects applications from misuse by hackers and malware, such as cross site scripting attacks, buffer overflow attacks, SQL injection attacks, and forceful browsing, by filtering traffic between each protected web server and users that connect to any web site on that web server. The application firewall examines all traffic for evidence of attacks on web server security or misuse of web server resources, and takes the appropriate action to prevent these attacks from succeeding.

For more information, see Application Firewall.

Application visibility feature

September 14, 2021

- Citrix Application Delivery Management

  Citrix Application Delivery Management (ADM) is a high performance collector that provides end-to-end user experience visibility across Web and HDX (ICA) traffic. It collects HTTP and ICA AppFlow records generated by Citrix ADC appliances and populates analytical reports covering Layer 3 to Layer 7 statistics. Citrix ADM provides in-depth analysis for the last five minutes of real-time data, and for historical data collected for the last one hour, one day, one week, and one month.

  HDX (ICA) analytic dashboard enables you to drill down from HDX Users, Applications, Desktops, and even from gateway-level information. Similarly, HTTP analytics provide a bird's eye view of Web Applications, URLs Accessed, Client IP Addresses and Server IP Addresses, and other dashboards. The administrator can drill down and identify the pain points from any of these dashboards, as appropriate for the use case.

- Enhanced Application Visibility Using AppFlow

  The Citrix ADC appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. AppFlow transmits this information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information.

  Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

  AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

  To limit the types of flows to monitor, by sampling and filtering the application traffic, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

  You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

  For more information, see AppFlow.

- Stream Analytics

  The performance of your website or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help accelerate the delivery of services to clients, but you must be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify

the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed by those resources help you determine whether those resources must be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the website or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your website or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources based on the statistics. On the Citrix ADC appliance, this functionality is provided by the Stream Analytics feature. The feature operates on a single Citrix ADC appliance and collects run-time statistics based on the criteria that you define. When used with Citrix ADC policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

For more information, see Action Analytics.

Citrix ADC Solutions

September 14, 2021

Citrix ADC solutions simplify the task of setting up frequently deployed configurations. Check this space from time to time for additional solutions.

This section includes the following solutions.

- Setting up Citrix ADC for Citrix Virtual Apps and Desktops
- Global Server Load Balancing (GSLB) Powered Zone Preference
- Anycast support in Citrix ADC
- Deploy digital advertising platform on AWS with Citrix ADC
- Enhancing Clickstream analytics in AWS using Citrix ADC
- Citrix ADC in a Private Cloud Managed by Microsoft Windows Azure Pack and Cisco ACI

Setting up Citrix ADC for Citrix Virtual Apps and Desktops

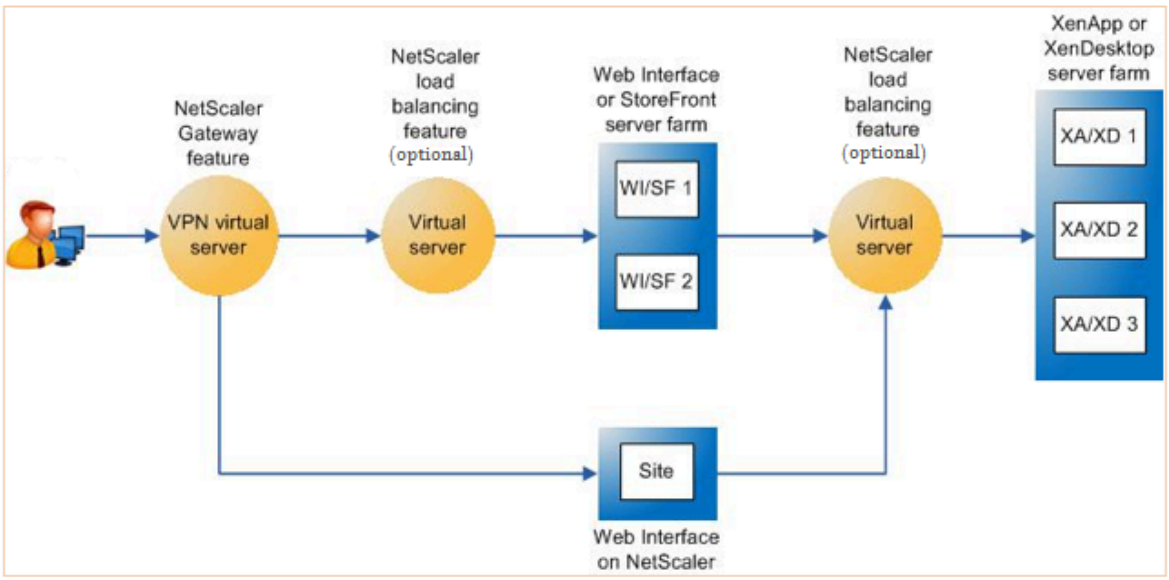
September 14, 2021

A Citrix ADC appliance can provide load balanced, secure remote access to your Citrix Virtual Apps and Desktops applications. You can use the Citrix ADC load balancing feature to distribute traffic across

the Citrix Virtual Apps and Desktops server. You can use the Citrix Gateway feature to provide secure remote access to the servers.

Citrix ADC can also accelerate and optimize the traffic flow and offer visibility features that are useful for Citrix Virtual Apps and Desktops deployments.

Figure 1. Citrix ADC appliance in Citrix Virtual Apps and Desktops setup



The preceding figure shows the components involved in this deployment:

- **NetScaler Gateway.** Provides the URL for user access, and provides security by authenticating the users.
- **Citrix ADC load balancing virtual server.** Load balances the traffic for the Web Interface or StoreFront servers. You can also deploy a load balancing virtual server in front of the Citrix Virtual Apps and Desktop servers to load balance key components such as XML Broker and Desktop Delivery Controller (DDC) server.
- **Web Interface or StoreFront or Web Interface on Citrix ADC.** Provides the interface through which you can access the applications.

  Note: Web Interface on Citrix ADC (WIonNS) is a customization of the Web Interface product, hosted on the Citrix ADC appliance.
- **Citrix Virtual Apps and Desktops.** Provides the applications that your users want to access.

To set up the Citrix ADC for Citrix Virtual Apps and Desktops by using the Citrix ADC GUI

Prerequisites

- Citrix Virtual Apps and Desktop servers are configured and available.
- Web Interface, StoreFront, or Web Interface on Citrix ADC servers are configured and available.
- You have a working knowledge of Citrix Gateway, Citrix ADC, Citrix Virtual Apps and Desktops, and StoreFront/Web Interface/Web Interface on Citrix ADC.
- Make sure that you have configured a virtual server and a service and bound the service to the virtual server. For more information, see:
  - Load balance XenDesktop
  - Load balance XenApp

Procedure:

1. Log on to the Citrix ADC appliance and on the **Configuration** tab click **XenApp and XenDesktop**.
2. On the **Details** pane, click **Get Started**. If the setup exists on the Citrix ADC, click the **Edit** link corresponding to each of the section that you want to modify.
3. Select the product (StoreFront, Web Interface, or Web Interface on Citrix ADC) that in your deployment provides the interface for access to the Citrix Virtual Apps and Desktops applications.
4. Set up secure remote access.
   a) In the **NetScaler Gateway Settings** section, specify the details for the VPN virtual server and click **Continue**.
   b) In the **Server Certificate** section, choose an existing certificate or install a new certificate and click **Continue**.
   c) In the **Authentication** section, configure the primary authentication mechanism to be used and specify the server details or use an existing server and click **Continue**.
   d) In the **StoreFront** section, specify the details of the server that provides the interface for accessing the applications and click **Continue**.
   e) You can use one of the following as your StoreFront server.
      i. LB virtual server pointing to multiple SF servers.
      ii. Web Interface or StoreFront server directly reachable from the Citrix ADC appliance.
      iii. Web Interface on Citrix ADC.
5. Click **Done** to complete the configuration.

Global Server Load Balancing (GSLB) Powered Zone Preference

September 14, 2021

GSLB powered zone preference is a feature that integrates Citrix Virtual Apps and Desktops, StoreFront, and Citrix ADC to provide clients access to the most optimized data center based on the client location.

In a distributed Citrix Virtual Apps and Desktops deployment, StoreFront might not select an optimal data center when multiple equivalent resources are available from multiple data centers. In such cases, StoreFront randomly selects a data center. It can send the request to any of the Citrix Virtual Apps and Desktops servers in any data center, regardless of proximity to the client making the request.

The client IP address is examined when an HTTP request arrives at the Citrix Gateway appliance. The real client IP address is used to create the data center preference list that is forwarded to StoreFront. If the Citrix ADC appliance is configured to insert the zone preference header, StoreFront 3.5 or later can use the information provided by the appliance to reorder the list of delivery controllers and connect to an optimal delivery controller in the same zone as the client. StoreFront selects the optimal gateway VPN virtual server for the selected data center zone, adds this information to the ICA file with appropriate IP addresses, and sends it to the client. StoreFront then tries to launch applications hosted on the preferred data center's delivery controllers before trying to contact equivalent controllers in other data centers.

For more information about configuring this solution, click here.

For a video overview about GSLB powered zone preference solution, click https://www.youtube.com/watch?v=Y8DELum0Xp0.

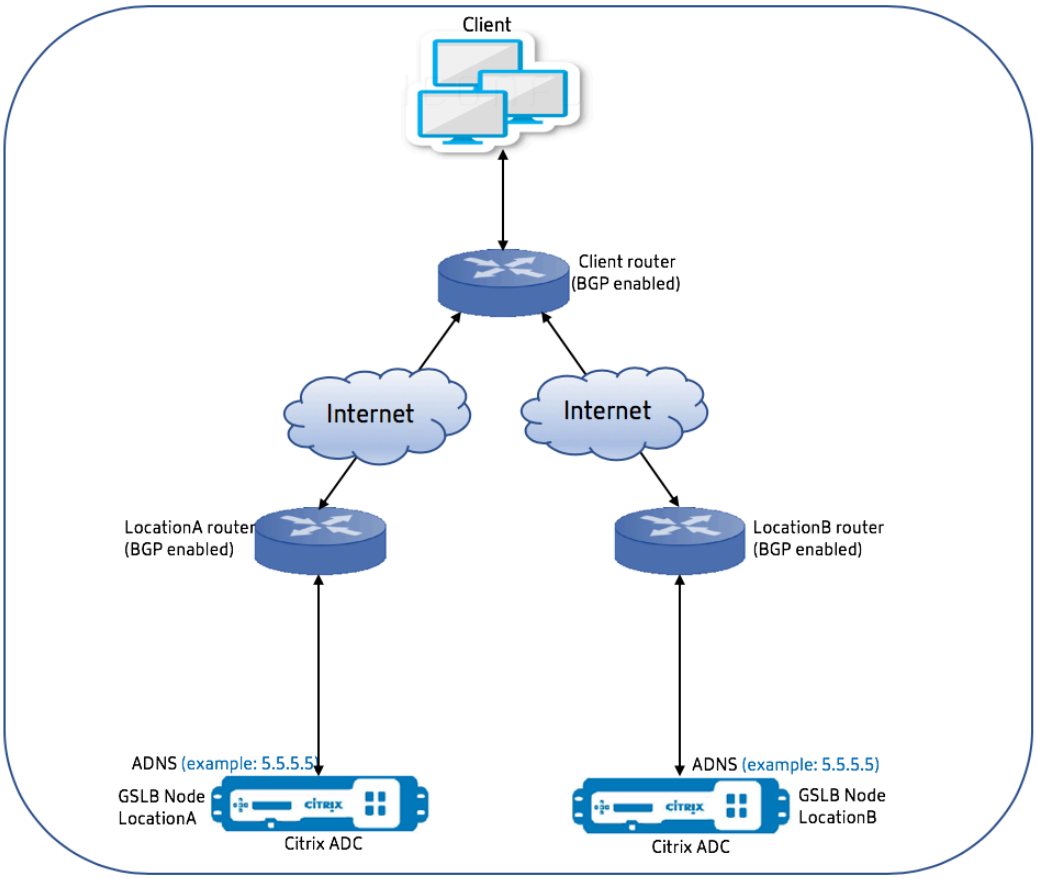
Anycast support in Citrix ADC

September 14, 2021

Anycast is a type of network where a set of servers shares an IP address. The client request is directed to the topographically closest server based on their routing tables. This routing reduces latency issues, ensures high availability, and minimizes downtime.

Citrix ADC supports anycast network with Global Server Load Balancing (GSLB) and DNS features.

The following diagram illustrates a topology diagram of Anycast in Citrix ADC.



Anycast GSLB

The Citrix ADC GSLB feature provides load balancing across globally distributed sites along with disaster recovery and ensures continuous availability of applications.

During an outage, GSLB provides immediate disaster recovery by routing traffic to the closest or the best performing data center. However, GSLB cannot control the following:

- How the DNS traffic is routed to GSLB nodes in different geographical locations.
- How much latency is getting added while DNS queries get routed to GSLB nodes.

In a typical GSLB setup, each data center has a GSLB node configured with the site-specific Authoritative Domain Name Server (ADNS) to receive DNS queries. Each site's ADNS is configured as the nameserver in the DNS resolver. As the number of GSLB nodes increases, the number of nameserver records also increase. In such cases, if there is a failure of a data center, LDNS has to retry resolution with a different nameserver. This retry adds to the latency in DNS resolution.
Also, every time a GSLB node is added, the nameserver records must be updated.

To overcome these drawbacks, you can use Anycast ADNS. In Anycast ADNS, a single ADNS IP address is used for all GSLB nodes and the DNS traffic is routed to GSLB nodes using dynamic routing.

For example, if a GSLB site is DOWN, the routing table is updated and route to this site is removed. As a result, The DNS queries are not sent to the sites that are DOWN. As a result, there are no retries.

If a new GSLB node is added, the new node is assigned the same ADNS IP address. The dynamic routing automatically updates the routing tables with routes to new sites based on the routing algorithms. Hence, you do not have to update the DNS name server records. The rollout of new GSLB sites is made simpler and faster with Anycast.

How to configure an ADNS IP address in an anycast mode

Enable host routing on the ADNS IP in a Citrix ADC appliance, and set the appropriate Route Health Injection (RHI) level. Mostly, there would not be any virtual servers on the ADNS IP and therefore RHI level must be selected as NONE. Enabling host route on the ADNS IP makes it a kernel route. You can then enable the dynamic routing of choice and configure the routing protocol to redistribute the kernel routes.

ADNS IP configuration – Example

At the command prompt, type;

```
add service adns_public 5.5.5.5 ADNS 53

set ip 5.5.5.5 -hostRoute ENABLED -vserverRHILevel ALL_VSERVERS
<!--NeedCopy-->
```

BGP configuration in GSLB site – Example

```
Site1#sh run
!
hostname Site1
!
log syslog
log record-priority
!
ns route-install bgp
!
interface lo0
 ip address 127.0.0.1/8
 ipv6 address fe80::1/64
 ipv6 address ::1/128
!
interface vlan0
 ip address 10.102.148.94/25
```

```
 ipv6 address fe80::e84c:f4ff:fe74:4588/64
!
interface vlan2
 ip address 172.18.30.15/24
!
router bgp 5
 redistribute kernel -----> redistributing the kernel routes
 neighbor 172.18.30.30 remote-as 4
 neighbor 172.18.30.30 advertisement-interval 1
 neighbor 172.18.30.30 timers 4 16
!
End

<!--NeedCopy-->
```

GSLB site routing table - Example

```
Site1#sh ip route
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, I - Intranet
       * - candidate default

K       5.5.5.5/32 via 0.0.0.0 ---------------------------------------->
    Kernel Route for ADNS
C       10.102.148.0/25 is directly connected, vlan0
C       127.0.0.0/8 is directly connected, lo0
B       172.18.10.0/24 [20/0] via 172.18.30.30, vlan2, 01w5d22h
B       172.18.20.0/24 [20/0] via 172.18.30.30, vlan2, 01w5d22h
C       172.18.30.0/24 is directly connected, vlan2
B       192.168.3.0/24 [20/0] via 172.18.30.30, vlan2, 01w5d22h
B       192.168.5.0/24 [20/0] via 172.18.30.30, vlan2, 01w5d22h
B       192.168.10.0/24 [20/0] via 172.18.30.30, vlan2, 01w5d22h

Gateway of last resort is not set
Site1#
<!--NeedCopy-->
```

Anycast DNS

You can use Anycast DNS for DNS proxy virtual servers on Citrix ADC. When there are multiple DNS name servers configured, the DNS resolver responds based on round robin method. For example, if the resolver does not receive any response from the first server, it switches to the second server after the configured timeout value expires. The switching from first server to second server adds to the latency in DNS resolution. If the DNS resolvers are configured with Anycast, then this latency can be eliminated.

DNS configuration – Example

At the command prompt, type;

```
add lb vserver dns DNS 5.5.5.50 53

set ip 5.5.5.50 -hostRoute ENABLED -vserverRHILevel ALL_VSERVERS
<!--NeedCopy-->
```

Deploy digital advertising platform on AWS with Citrix ADC

September 14, 2021

With the evolving nature of digital platforms, a wide range of advertising applications are available. For example, social media, direct mail, videos, banners, pops, interstitials, rich media and so on. Advertisers are embracing video advertising networks at a fast pace, constituting nearly 40% of the advertisement traffic. But with more usage of mobiles by the modern users, running video ads on the mobile platform has seen considerable surge.

The digital advertising platforms face several challenges. Some of the challenges are:

- Security threats
- High operational costs
- Wide range of devices are available to send traffic over the internet. The different protocols for real-time communication pose the following challenges:
  - webRTC
  - Adaptive streaming
  - UDP for video, where WebRTC uses UDP over HTTP

To deal with the complex behavior of advertising platforms, Citrix ADC solution with its whole suite of capabilities and features well integrated with AWS, provides an instant, secure, and reliable access to digital advertisement inventory, anywhere and anytime. Citrix ADC plays a critical role in delivering the SaaS and web apps for digital platforms.

Digital advertising platform integration with Citrix ADC

Digital advertising platform overview

The digital advertising platform consists of the following key components:

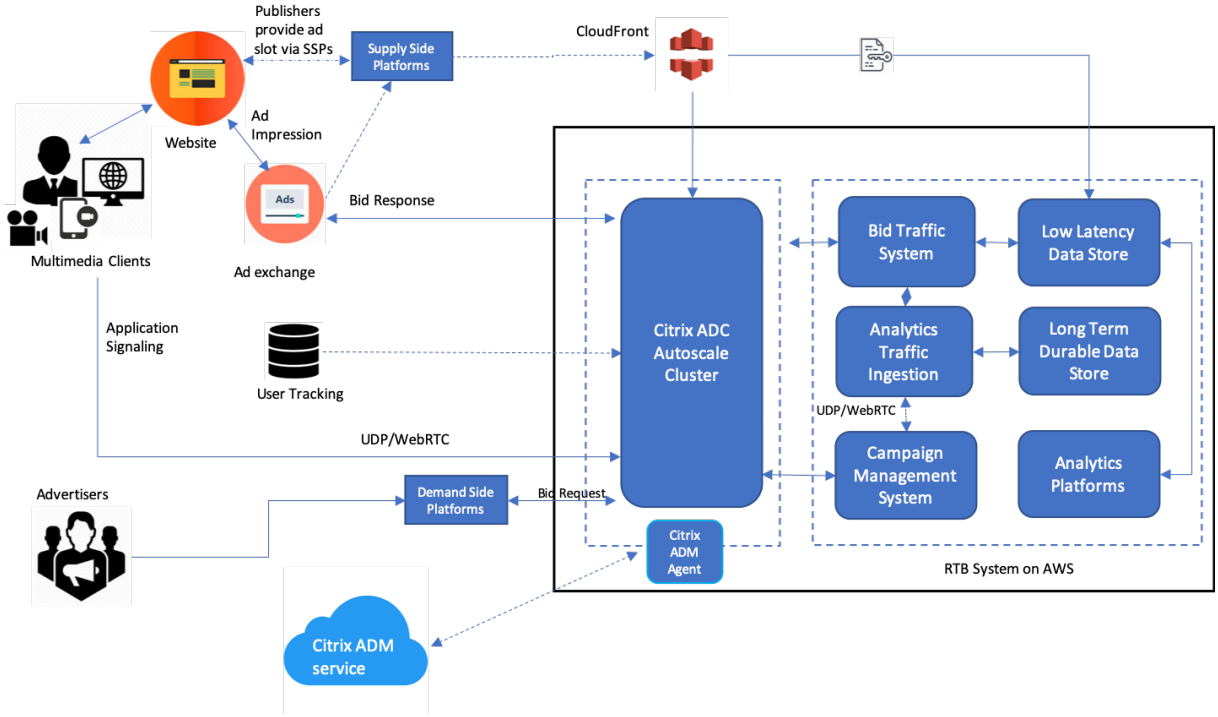
- Ad exchange
- Ad network
- Demand side platform (DSP)
- Supply side platform (SSP)
- Real time bidding (RTB) systems

An overview of the process followed in an advertising system is as follows.

- The first transaction happens when the user visits the website.
- This triggers a bid/advertisement request (including user's demographic information) that is sent to the ad server or publisher contacting an ad exchange.
- The Ad publishers send the advertisement request to an Ad exchange through SSPs.
- The Ad exchange submits this request and the accompanying data to DSP telling there is an impression or advertisement request available. Therefore, multiple advertisers can automatically submit bids in real time to place their advertisements.
- Meanwhile, the advertisers must set up their campaigns in DSP. Use the information about the user from Data Management Platform (DMP) to assess the amount they are willing to pay for delivering an advertisement to the user.
- DSPs submit these real-time bids on each advertisement impression because it is served to the advertisement exchange.
- Whichever bidder bids the most within a time period set by the Ad exchange or SSPs, gets an advertisement slot by the publishers to serve their advertisements. Otherwise, they lose the opportunity to get the right advertisement for their key demographic.

How digital advertising platform is integrated with Citrix ADC

The following diagram illustrates how the different components of advertising platform communicate with Citrix ADC and Citrix Application Delivery Management (ADM) to serve online advertisements.



How Citrix ADC contributes

In the advertisement publishing process, Citrix ADC solution helps in handling and processing the inconsistent influx of bid traffic. It acts as an entry point for all traffic to ensure scalability and availability across the availability zones. To cater to the elastic nature of advertising traffic, it is deployed in an autoscaling group in front of web applications and database servers.

The advertising platform on AWS with Citrix ADC solution allows you to get the real-time performance, high scalability, and high availability across the globe. You can buy and sell rich media, video, mobile, and native advertisements in real time. It reduces the overall operational cost and latency involved in running an Advertising platform. It is the best performing proxy with the rich capabilities of gracefully removing the back-end servers during Autoscale, connection multiplexing, and ensuring that the end-user traffic never gets impacted. Citrix ADC supports load balancing the HTTP, UDP, WebRTC, and RTSP protocols that are used in the advertising platforms.

Citrix ADC fits coherently into the AWS environment with the following key attributes:

- Content switching – Switch to the right platform based on host name.
- Security protection – Use web application firewall (WAF) functionality, rate limiting (through Client IP), and protection against DDoS attacks.
- Autoscaling of both front-end and back-end traffic.
- End-to-end visibility, and anomaly detection across ADC appliances by utilizing ADM.
- Low latency.

How Citrix ADM contributes

Citrix ADC utilizes Citrix ADM to overcome the following challenges faced by the digital advertising platforms:

- Identify the trend deviations from expected performance
- Real-time application performance analysis
- Capacity monitoring

Advantages of advertising platform integration with Citrix ADC and ADM

The Citrix ADC solution offers the following capabilities and benefits to a digital advertising platform vendor.

Low cost

- Integrated with AWS Autoscaling service, the Citrix ADC VPX instance can scale up or down your front-end and back-end resources automatically. This provides a zero-touch configuration catering to the elasticity of advertising platforms.
- Consolidation of delivering all types of traffic from a single point.

For more information on AWS autoscaling, see Add back-end AWS Autoscaling service.

High availability

- If one Availability Zone becomes unavailable, Citrix ADC applies its fault tolerance ability to autodetect the servers in another availability zone, without any traffic interruption.
- Also, It gracefully terminates servers avoiding the loss of client connections.

For more information, see How high availability on AWS works.

Application performance analytics

Citrix ADM intelligent analytics and application performance analytics ensures to:

- Gain visibility into the issues (server response anomalies, 5XX errors, and so on) plaguing the end user experience.
- Alert the administrator to take corrective actions immediately.

For more information, see Performance indicators for application analytics.

Rich firewall security

Most common security vulnerabilities occur in web applications rather in networks. It is vital to protect your web applications from unauthorized access such as bots, data thefts, and application layer attacks.

Citrix ADC provides comprehensive and integrated Layer 4 to Layer 7 security that includes:

- Web App Firewall (WAF) to protect your web applications, identify, and mitigate malicious bots with regularly updated bot signatures and behaviour-based detection.
- Rate limiting to prevent an advertising platform from being overwhelmed.

For more information, see Citrix Web App Firewall.

Select the right AWS instance type for advertising platform

Choose the right AWS instance type for ADC depending on the following two factors:

- Number of users simultaneously accessing the advertising platform.
- Average number of users on the platform.

The Citrix ADC can be deployed in various EC2 instances, which include c5, c5n, m5, and so on. For advertising platforms, use the following AWS instance types:

- c5 or c5n is appropriate for handling SSL heavy traffic.
- c5.large can handle up to 1000 SSL TPS.

For more information, see VPX-AWS support matrix.

Enhancing Clickstream analytics in AWS using Citrix ADC

September 14, 2021

Customers are increasingly accessing the company products through various applications such as Mobile apps, SaaS apps and so on. Therefore, applications can become a landmine of customer experience data. To track customer behavior online, customer-centric companies form data-driven profiles for each of their customers using this customer behavior data.

A clickstream is a sequence or stream of events that represent user actions (clicks) on a website or a mobile application. However, the scope of clickstream extends beyond clicks. It includes product searches, impressions, purchases, and any such events that might be of relevance to the business. Mere collecting and storing the customer experience data is not of much value. There is a need to distribute the highly complex data seamlessly to the right vendors at the right time. Businesses can derive value from the data and quickly take conscious decisions to improve upon their strategies. Therefore companies increasingly use clickstream analytics to glean insights into the customer experience journey of the apps.

This document provides you a good understanding on why Clickstream data is of utmost importance, how it is collected, stored, distributed, and transformed into meaningful and actionable analytics.

Citrix ADC integrates with Citrix ADM, and adds value to AWS services such as Amazon Kinesis Data Firehose to equip businesses with the best-in-class analytics solution that revolves around user's Clickstreams.

This Citrix ADC solution helps you to solve complex business issues efficiently and with extreme simplicity. Citrix ADC and AWS Kinesis help to capture the issues with the poorly designed workflow. Citrix ADM helps to capture web app and network performance related issues by applying relevant filters. Conjunction of Citrix ADC with Citrix ADM and AWS Kinesis helps you to manage and analyze the huge influx of clickstream data in each phase. This solution is highly available, scalable, robust, and ensures the delivery is continuous and secure. Thus, you can derive actionable insights.

Why businesses opt for Clickstream analytics?

Businesses opt for clickstream primarily to understand how users interact with the application, and to get insights on improving the goals of the application. Clickstream Analytics is an information retrieval use case that tracks your user's behavior, navigation habits, and so on. Clickstream analytics gives you information on:

- Which link your customers are clicking more often and at what point in time.
- Where was the visitor before reaching my website?
- How much time did the visitor spend on each page?
- When and where did the visitor click the "back" button on the web browser?
- What items did the visitor add to (or remove from) their shopping cart?
- From which page did the visitor exit my website?

Analytics service to manage Clickstream data using Amazon Kinesis

You can use Amazon Kinesis to perform clickstream analytics. Amazon kinesis enables clickstream analytics with the following services:

- Amazon Kinesis Data Firehose
- Amazon Kinesis Data Analytics
- Amazon Kinesis Data Streams

With Amazon Kinesis, you can collect and analyze your huge data sets at any scale. AWS Kinesis can handle data from various sources, such as:

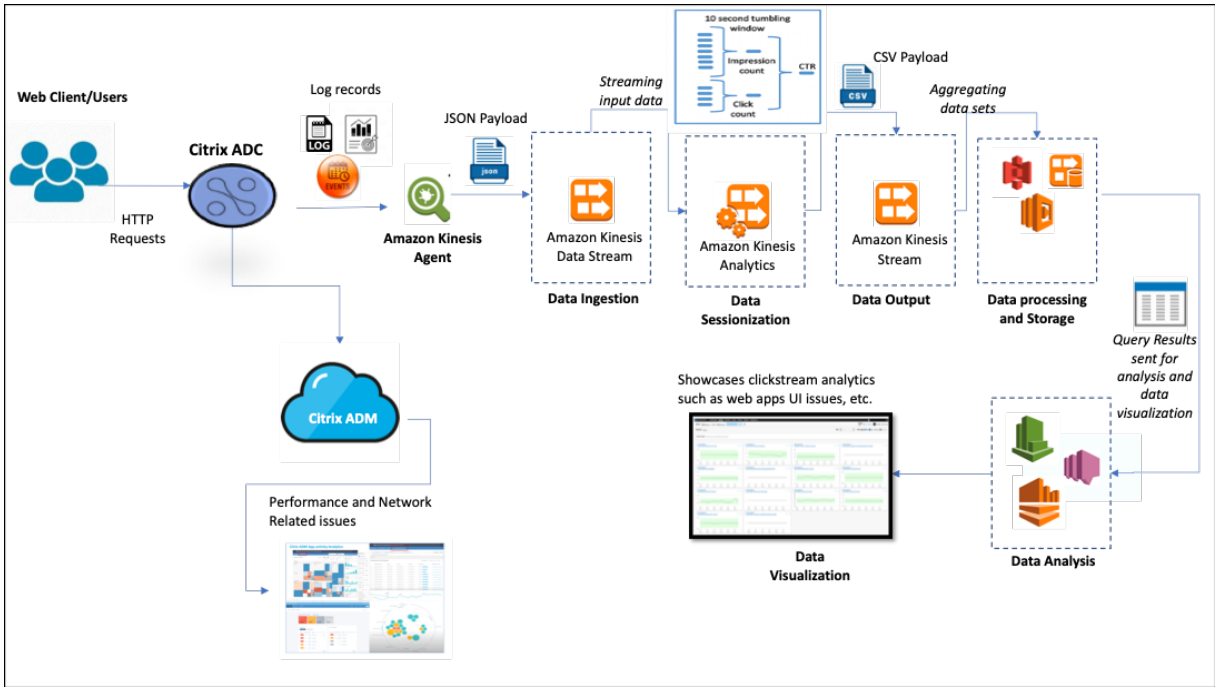
- Mobile and web applications (for example, Gaming, ecommerce)
- IoT devices
- Social networking applications
- Financial trading services

- Geospatial services

How Citrix ADC enables Clickstream analytics

The Citrix ADC solution collates and delivers information securely on the activities of users, such as, websites visited, the bandwidth spent, navigation flow. Companies analyze this high throughput and continuous clickstream data to corroborate the effectiveness of the following:

- Site layout
- Marketing campaigns
- New application features



With the Citrix ADC's ability to provide a resilient network protection for enterprise environments, the server cost is reduced manifolds by offloading computationally intensive tasks, and running sessions on this data. Thereby helping companies to identify events in real-time with high availability, security, and low latency always.

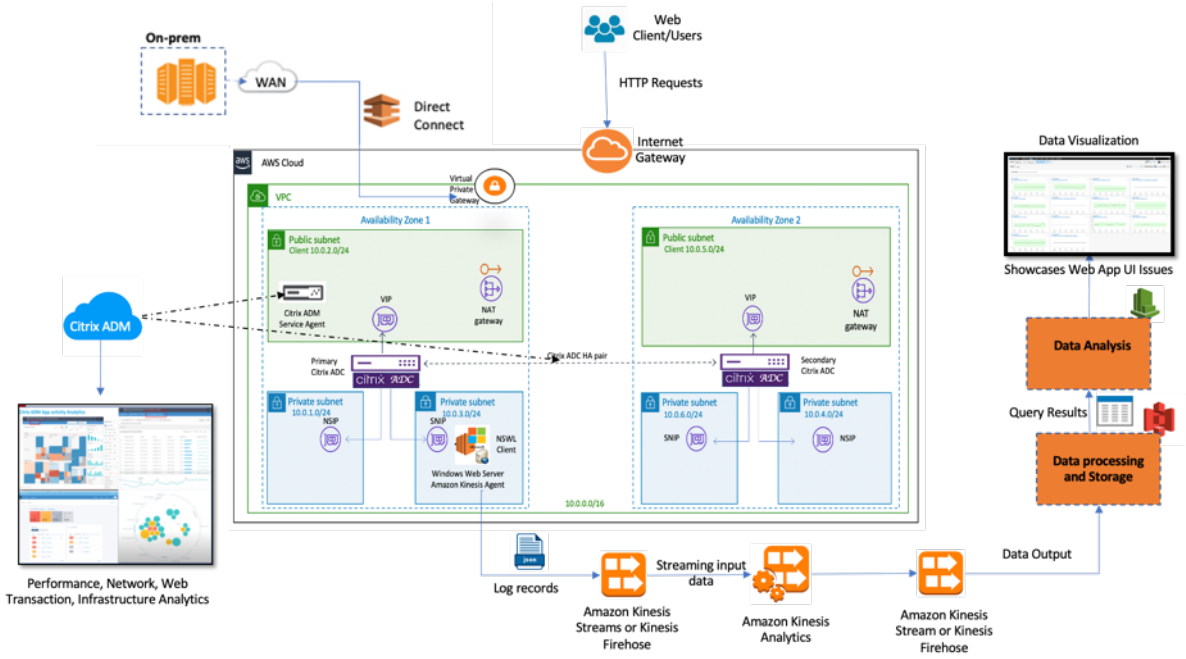
For configuration information, see Configure the Citrix ADC solution for clickstream analytics.

How Citrix ADC and Citrix ADM complement the AWS environment

The following diagram illustrates the end-to-end user workflow to perform Clickstream analytics in AWS infrastructure. This diagram helps you understand the following processes:

- How user interacts with Citrix ADC
- How Citrix ADC captures user's actions and generates clickstream data

- How the clickstream data is delivered to AWS services (Amazon Kinesis)
- How Amazon Kinesis processes the data logs and stores them to produce meaningful clickstream analytics



The Citrix ADC seamlessly integrates into the AWS environment and Citrix ADM that helps businesses to be compatible with variable volume and diverse nature of the clickstream data. It provides services to load and analyze streaming knowledge with simplicity. You can also create custom streaming knowledge applications for specialized desires.

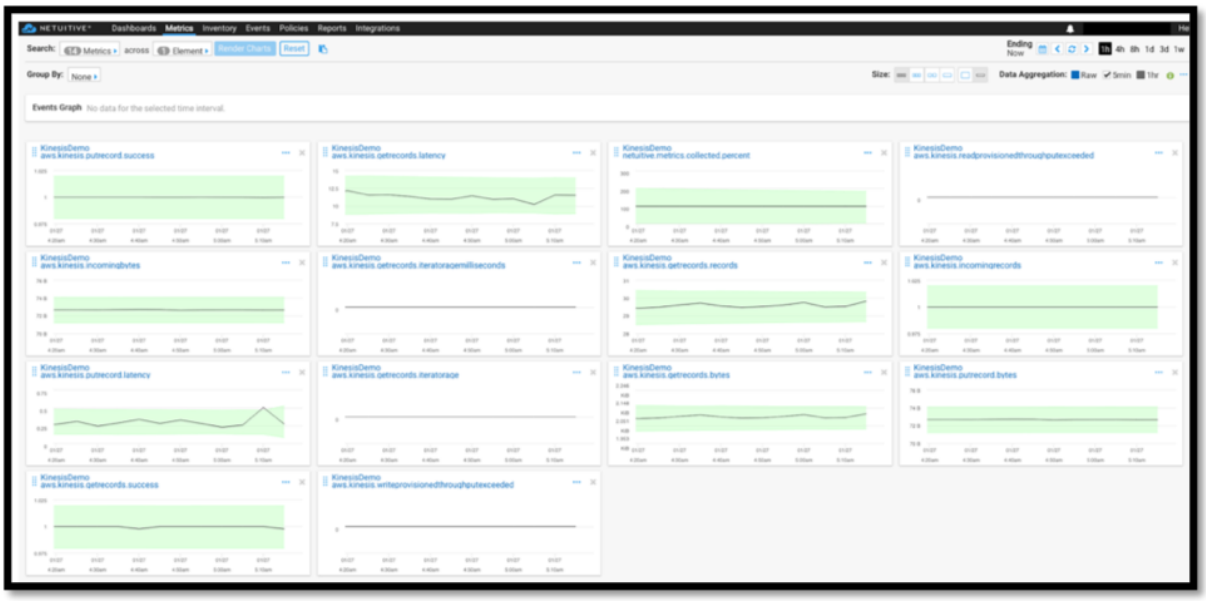
Amazon Kinesis

The AWS environment has different services that perform analytics on the user events, logs, and metrics captured by Citrix ADC. The data can be website clickstreams, financial transactions, social media feeds, IT logs, and location-tracking events.

- Amazon Kinesis Data Streams perform analytics in scenarios that involve scalable and durable real-time data streaming that can continuously capture GB of data per second from several sources.
- Amazon Kinesis Data Analytics can be used for scenarios with lower latency between the session generation because it takes less time to aggregate various data sets.
- Amazon Kinesis Agent for Microsoft Windows collects, parses, filters, and streams input data to Kinesis data streams.
- Once the data is up in the cloud, you can implement the exact data pipeline to get the results you want. For example, you can use this information in Amazon Quick Sight, which is a visualization tool that is used to build dashboards.

The AWS Kinesis dashboard provides the following offerings:

- Showcases web apps UI issues
- Near real-time visualizations of web usage metrics such as events per hour, visitor count, and referrers.
- Session-wise analysis



Citrix ADM Analytics

By utilizing Citrix ADM with Citrix ADC, you can get a single-pane-of-glass view across all the business environments. Citrix ADC captured logs are fed into Citrix ADM, that treats your individual applications as a single entity. You can gain valuable insights and effectively troubleshoot issues with the following ADM capabilities:

- Intelligent analytics
- Web transaction analytics
- Anomaly detection
- Performance and network-related issues

The following ADM service dashboard helps you gain valuable insights to effectively troubleshoot the issues.

How Citrix ADM correlates with Clickstream analytics

Clickstream analytics data can be correlated with ADM analytics to describe, predict, and improve application's performance.

For more information on Citrix ADM, see Citrix ADM

For example, an organization while analyzing their logs notice that most of the users are abandoning their sites. But to find the root cause behind this user behavior, they need to find out which part of their application is performing bad. With clickstream analytics data and ADM analytics, you can derive the following insights to analyze the reason behind users abandoning a site:

- Is the user abandoning due to latency, 5xx errors?
- Are there any SSL Handshake errors?
- Is there some part of the application that has performance or network related issues?
- Is there a 404 error, or the page loading time takes forever to respond, and so on.
- Are customers facing server response anomalies?

Citrix ADM service provides Web Insights that allow IT administrators to speed up solving issues with the following features:

- Provides integrated and real-time monitoring of all web applications that served by the Citrix

ADC.

- Get a holistic view on the application performance w.r.t. time, latency, and the usual user's behavior through observability tools (such as global service graph).
- Perform intelligent analytics to understand server response anomalies.
- SSL insights contribute towards resolving 5xx and 4xx errors.
- To maintain records of all web sessions that include:
  - Detailed logs of every web transaction
  - Search capability to find relevant logs
  - Ability to isolate an ADC-to-end user vs. ADC-to-server problem

Types of data exported by ADC for Clickstream analytics

Citrix ADC captures the different sources that generate varied forms of data, which are as follows:

- Web server logs

  Web server logging feature sends logs of HTTP and HTTPS requests to a client system for storage and retrieval. These logs contain huge amount of data, which is difficult to comprehend and make sense out of it. Analytical tools help in understanding and bring value from it. For configuration details, see the **Web logging configuration section** in this document.

- Syslogs

  The primary use of syslogs is for systems management. Proactive syslog monitoring pays off because it significantly reduces downtime of servers and other devices in your infrastructure. Syslog identifies critical network issues and reports them proactively.

- Access logs

  The access logs store information about events that occurred on your web server. For instance, when someone visits your website, a log is recorded and stored to provide the web server administrator with information such as the IP address of the visitor, what pages they were viewing, status codes, browser used. To access logs might be overwhelming, if there is lack of appropriate knowledge to understand them.
  You can program your system to integrate with:

  - Citrix ADC for seamless delivery
  - Kinesis for actionable insights that is useful for businesses

- Audit logs

  The Audit Logging feature enables you to log the Citrix ADC states and status information collected by various modules in the kernel and in the user-level daemons.

- Error logs

The error logs file is an aid for administrators to provide more information regarding a specific error that has occurred on the web server.

Configure the Citrix ADC solution for clickstream analytics

The Web server logging feature enables you to send logs of HTTP and HTTPS requests to a client system for storage and retrieval.

To configure the Citrix ADC for web server logging you must:

- Enable web logging feature
- Configure the size of the buffer to temporarily store the log entries because the Web log server runs on the Citrix ADC.

To configure web server logging by using CLI:

1. Enable the web server logging feature.

```
enable ns feature WL
<!--NeedCopy-->
```

2. [Optional] Modify/Configure the buffer size for storing the logged information.

```
set ns weblogparam -bufferSizeMB 60
<!--NeedCopy-->
```

3. Install the Citrix ADC web logging (NSWL) client. For more information, see Installing the Citrix ADC web logging (NSWL) client
4. Install the NSWL client on Windows by performing the following operations on the system where you downloaded the package.
   a) Extract and copy the nswl_win-< release number >-< build number >.zip file from the package to a Windows system on which you want to install the NSWL client.
   b) On the Windows system, unzip the file in a directory (referred as < NSWL-HOME>). Bin, samples, and other directories are extracted.
   c) At the command prompt, run the following command from the < NSWL-HOME >\bin directory:

```
nswl -install -f < path of the log.conf file >\log.conf
<!--NeedCopy-->
```

> **Note:**
>
> To uninstall the NSWL client, at the command prompt, run the following command from

the < NSWL-HOME >\bin directory:

```
nswl -remove
<!--NeedCopy-->
```

5. After you install the NSWL client, configure the NSWL client using the NSWL executable. These configurations are stored in the NSWL client configuration file (log.conf).

   Run the following commands from the directory in which the NSWL executable is located:

```
\ns\bin
<!--NeedCopy-->
```

6. In the NSWL client configuration file (log.conf), add the Citrix ADC IP address (NSIP) from which the NSWL client collects logs by running the following in the client system command prompt:

```
nswl -addns -f < Path to the configuration(log.conf) file >\log.
   conf
<!--NeedCopy-->
```

7. Input the Citrix ADC appliance's NSIP (IP address), user name as `nsroot` and password as "the instance id/your set password" so that:

   - NSWL client connects to the ADC after you add the NetScaler IP address (NSIP) to the NSWL configuration file
   - ADC buffers the HTTP and HTTPS request log entries before sending them to the client.
   - The client can filter the entries(by modifying log.conf file) before storing them.

Note

Change the default password for Citrix ADC and then proceed with the configuration. Type the following command to change the password:

```
set system user nsroot -password <your password>
<!--NeedCopy-->
```

Configuring the Amazon Kinesis agent

Perform the following steps in the AWS web console to configure the Amazon Kinesis agent:

1. Create a configuration file (appsettings.json) and deploy it. Configuration files define sets of sources, sinks, and pipes that connect sources to sinks, along with optional transformations.

   The following example is a complete `appsettings.json` configuration file that configures Kinesis Agent to stream Windows application log events to Kinesis Data Firehose.

```
{

"Sources": [
    {

        "Id": "NSWLog",
        "SourceType": "DirectorySource",
        "Directory": "C:\\Users\\Administrator\\Downloads\\
           nswl_win-13.0-52.24\\bin",
        "FileNameFilter": "*.log"
        "RecordParser": "TimeStamp",
        "TimestampFormat": "yyyy-MM-dddd HH:mm:ss.ffff", //
           Optional parameter required only by the timestamp
           record parser
        "TimeZoneKind": "UTC", //Local or UTC
        "SkipLines": 0 //Skip a number of lines at the beginning
           of each file
     }

    ],
"Sinks": [
    {

        "Id": "ApplicationLogKinesisFirehoseSink",
        "SinkType": "KinesisFirehose",
        "StreamName": "Delivery-ik-logs",
        "AccessKey": "Your Access Key",
        "SecretKey": "YourSecretKey",
        "Region": "ap-south-1"
     }

    ],
"Pipes": [
    {

    "Id": "ApplicationLogSourceToApplicationLogKinesisFirehoseSink
       ",
    "SourceRef": "ApplicationLogSource",
    "SinkRef": "ApplicationLogKinesisFirehoseSink"
     }

    ],
"Telemetrics":
    {
```

```
40
41      "off": "true"
42       }
43
44   }
45
46 <!--NeedCopy-->
```

2. Set up a Kinesis Agent on data sources to collect data and send it continuously to Amazon Kinesis Firehose/Kinesis Data Analytics. For more information, see Getting Started with Amazon Kinesis Agent for Microsoft Windows.
3. Create an end-to-end data delivery stream using Amazon Kinesis Firehose. The delivery stream transmits your data from the agent to the destination. The destination includes Amazon Kinesis Analytics, Amazon Redshift, Amazon Elasticsearch service, and Amazon S3. For the Source, choose **Direct PUT or other sources** to create a Kinesis Data Firehose delivery stream.
4. Process the incoming log data using SQL queries in Amazon Kinesis Analytics.
5. Load processed data from Kinesis Analytics to Amazon Elasticsearch Service to index the data.
6. Analyze and visualize the processed data using Visualization tools, such as Kibana and AWS QuickInsight Services.

Citrix ADC in a Private Cloud Managed by Microsoft Windows Azure Pack and Cisco ACI

September 14, 2021

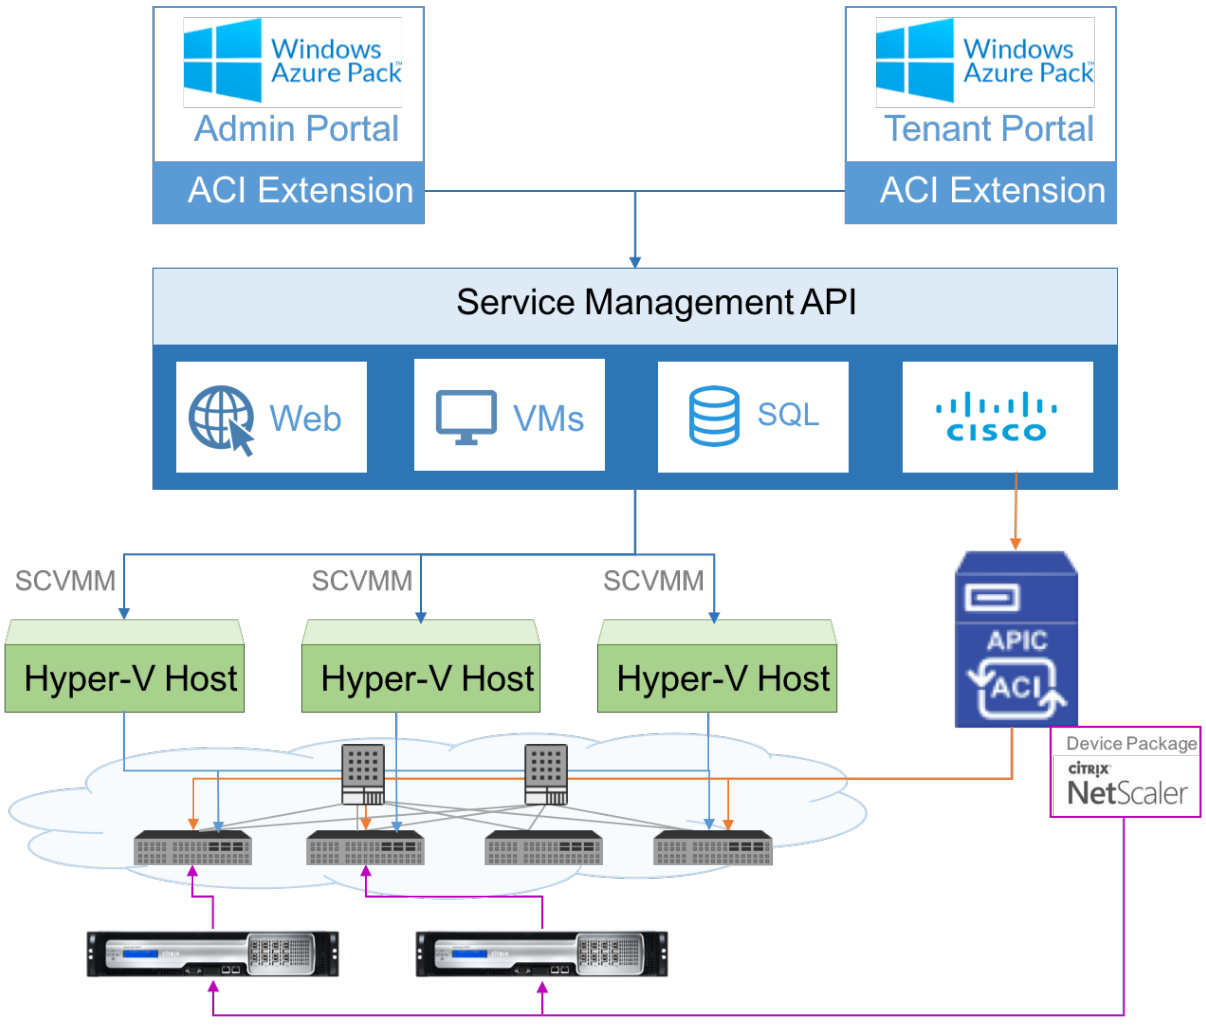
You can use a Citrix ADC appliance for load balancing in a private cloud that is managed through Microsoft Windows Azure Pack. The network for the private cloud is automated by using Cisco ACI and Citrix ADC.

This solution involves many integration points, such as Windows Azure Pack (WAP) to Cisco APIC, Cisco APIC to System Center Virtual Machine Manager (SCVMM), and Cisco APIC to Citrix ADC. As a tenant in the private cloud, you can enable NAT, provision network services, and add a load balancer.

WAP supports tenant and administrator portals where an administrator can perform administrative tasks such as ACI registration, VIP range, Citrix ADC device association with virtual machine cloud, tenant user account creation. Tenants can log on to the WAP Tenant Portal and configure the network, bridge domains, and Virtual Routing and Forwarding (VRFs), and make use of the Citrix ADC load balancing and RNAT features.

> **Important**
>
> - In this solution, the Citrix ADC appliance provides only basic load balancing.
> - Tenants can deploy multiple VIP addresses with different ports for the same network, but must ensure that the IP and port combination is unique.
> - The Citrix ADC device package supports only single-context deployment. Each Tenant gets a dedicated Citrix ADC instance.
> - WAP supports Citrix ADC MPX appliances and Citrix ADC VPX virtual appliances, including Citrix ADC VPX instances deployed on the Citrix ADC SDX platform.

The following illustration provides an overview of the solution:



Prerequisites

Make sure that:

- You have conceptual knowledge of Cisco ACI components and Citrix ADCs.
  - For more information about Cisco ACI and its components, see the product documentation at: http://www.cisco.com/c/en/us/support/cloud-systems-management/application-policy-infrastructure-controller-apic/tsd-products-support-series-home.html.
  - For more information about the Citrix ADCs, see the Citrix ADC product documentation at http://docs.citrix.com/.
- All the required components of Cisco ACI, including Cisco APIC in the data center, are set up and configured. For more information about Cisco ACI and its components, see the product documentation at: http://www.cisco.com/c/en/us/support/cloud-systems-management/application-policy-infrastructure-controller-apic/tsd-products-support-series-home.html.
- You know how to integrate Cisco ACI with Microsoft Windows Azure Pack. See the product documentation at: http://www.cisco.com/c/en/us/td/docs/switches/datacenter/aci/apic/sw/2-x/virtualization/b_ACI_Virtualization_Guide_2_2_1.html.
- You have conceptual knowledge of Microsoft Windows Azure Pack. See the product documentation at: https://www.microsoft.com/en-in/cloud-platform/windows-azure-pack.
- You have installed Citrix ADC software release 11.1 or later.
- You configure Citrix ADCs in Cisco ACI, so that they can be managed by using Cisco APIC.
- From Cisco APIC, make sure that:
  - Management connectivity of Cisco APIC to Citrix ADC is established.
  - You upload the Citrix ADC device package version *11.1–52.3* and register the Citrix ADC device in Cisco ACI by using Cisco APIC.
  - You configure the Citrix ADC appliance in Cisco APIC's common tenant and make sure that there are no faults in Cisco APIC.
  - You have configured all the APIC specific configurations such as, VLAN pool, L3OutServicesDom, L3ExtOUt, resource pool. For more information, see *Cisco documentation*.

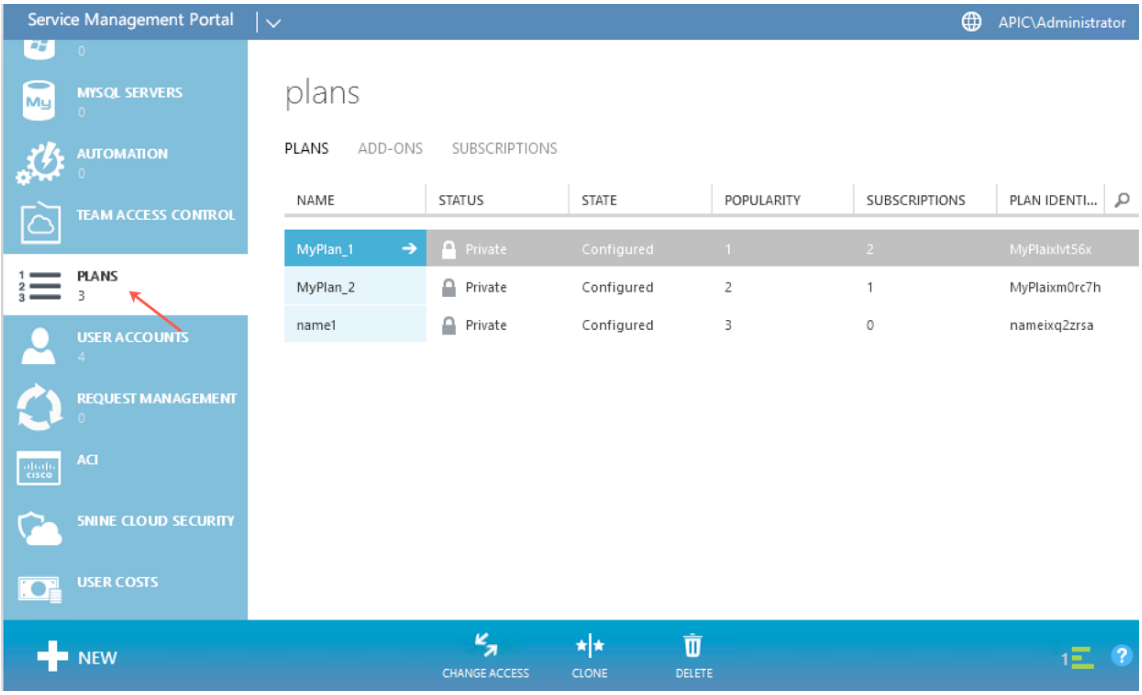
Creating a Citrix ADC Load Balancer in a Plan in the Service Management Portal (Admin Portal)

September 14, 2021

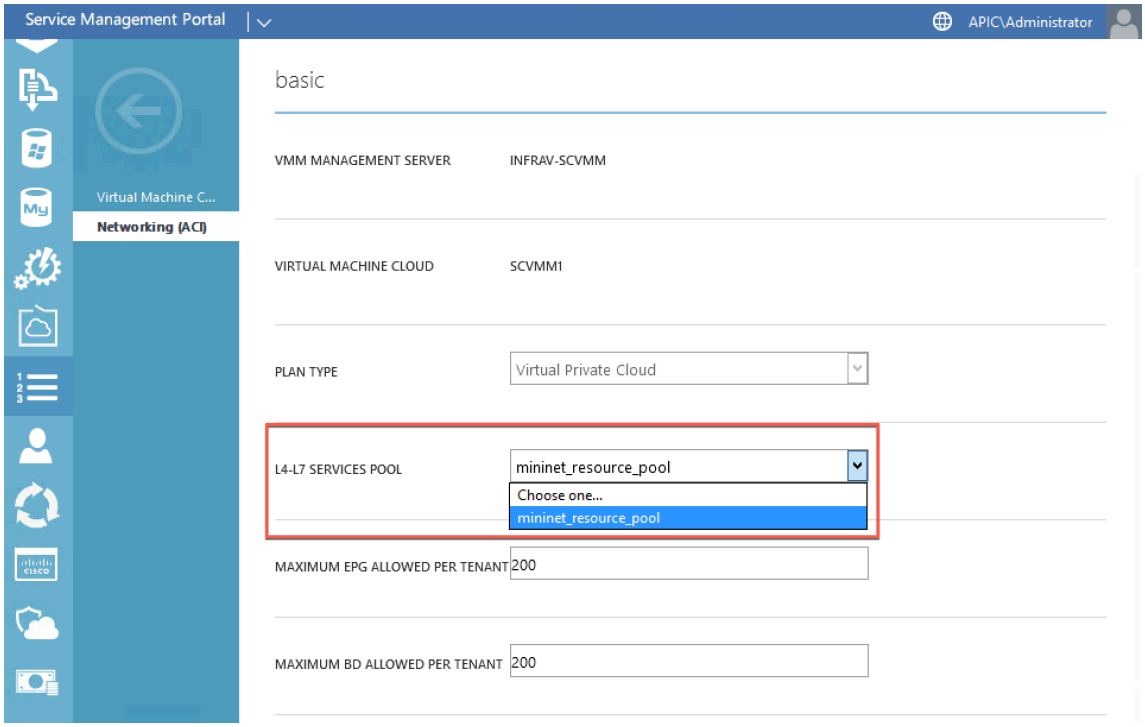
The Service Management Portal in WAP allows an administrator to register Cisco APIC with WAP and also create a hosting plan. As part of the plan, you can specify the VIP range, associate the Citrix ADC load balancer with the plan, and create tenant user accounts.

To create a Citrix ADC Load Balancer in a Plan in the Admin Portal:

1. Log in to the Service Management Portal (Admin Portal).
2. In the Navigation pane, select **PLANS**.



3. In the plans pane, select the plan that you want to add a load balancer.
4. In the selected plan's pane, select **Networking (ACI)**.
5. On the **Networking (ACI)** pane, in the **L4-L7 SERVICE POOL** drop-down list, select the L4-L7 resource pool that you had created in Cisco APIC.



6. Create a tenant user account and associate the user with the plan you have created.

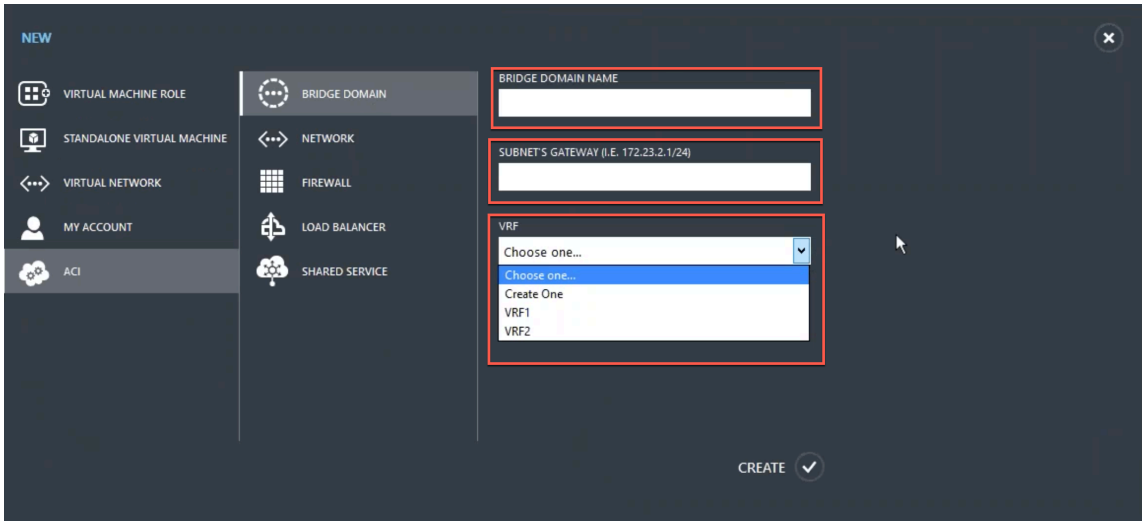
Configuring a Citrix ADC Load Balancer by Using the Service Management Portal (Tenant Portal)

September 14, 2021

In WAP, once the Tenant creates the Bridge Domain (BD), VRF, and a Network, the Tenant can configure a Citrix ADC Load Balancer through the Service Management Portal (Tenant Portal).

To configure Citrix ADC Load Balancer in Service Management Portal (Tenant Portal)

1. Log on to the Service Management Portal (Tenant Portal).
2. Create a bridge domain and VRF, as follows:
   a. In the navigation pane, select **ACI**.
   b. Click **NEW**.
   c. In the **NEW** pane, select **BRIDGE DOMAIN**.



d. In the **BRIDGE DOMAIN** field, enter the bridge domain name (for example, BD01).

e. (Optional) In the **SUBNET'S GATEWAY** field, enter the subnet's gateway (for example, 192.168.1.1/24).

f. In the **VRF** field, select a VRF that is already part of the subscription or select **Create One** to create a VRF.

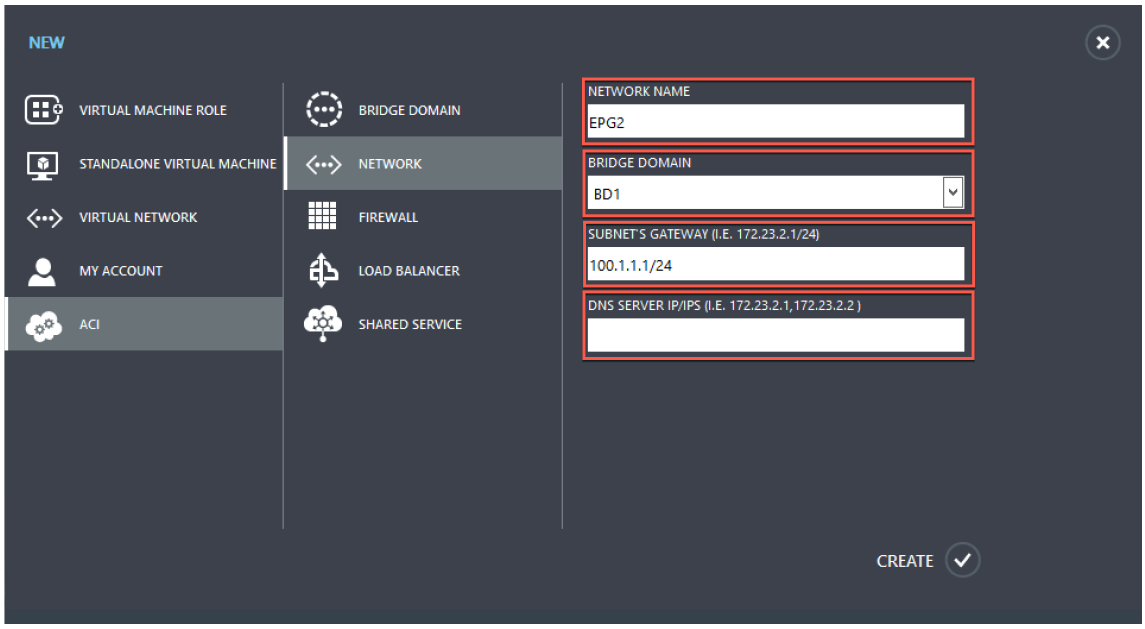
g. Click **CREATE**.

3. Create a network and associate it with the bridge domain that you created. Do the following:

a. In the navigation pane, select **ACI**.

b. Click **NEW**.

c. In the **NEW** pane, select **NETWORK**.



d. In the **NETWORK NAME** field, enter the network name (for example, S01).

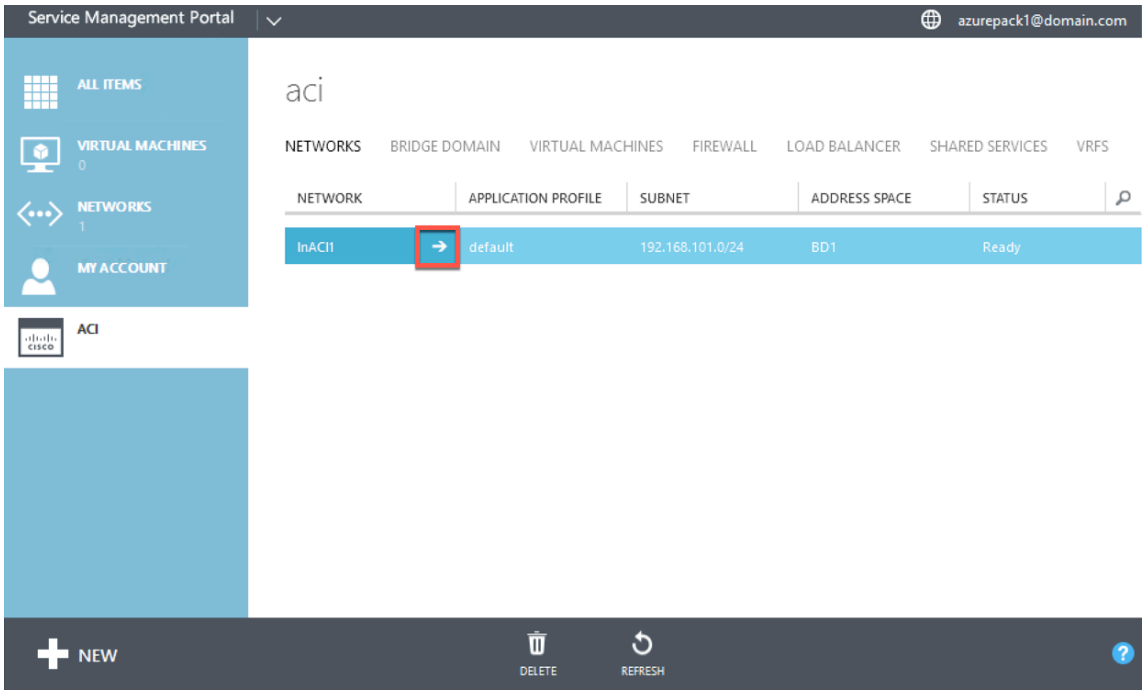
e. In the **BRIDGE DOMAIN** drop-down list, select the bridge domain you have created. (for example, BD01).

f. In the subnet's **GATEWAY** field, enter the subnet's gateway address (for example, 172.23.2.1/24).

g. (Optional) In the **DNS SERVER IP/IPS** field, enter the DNS server details.

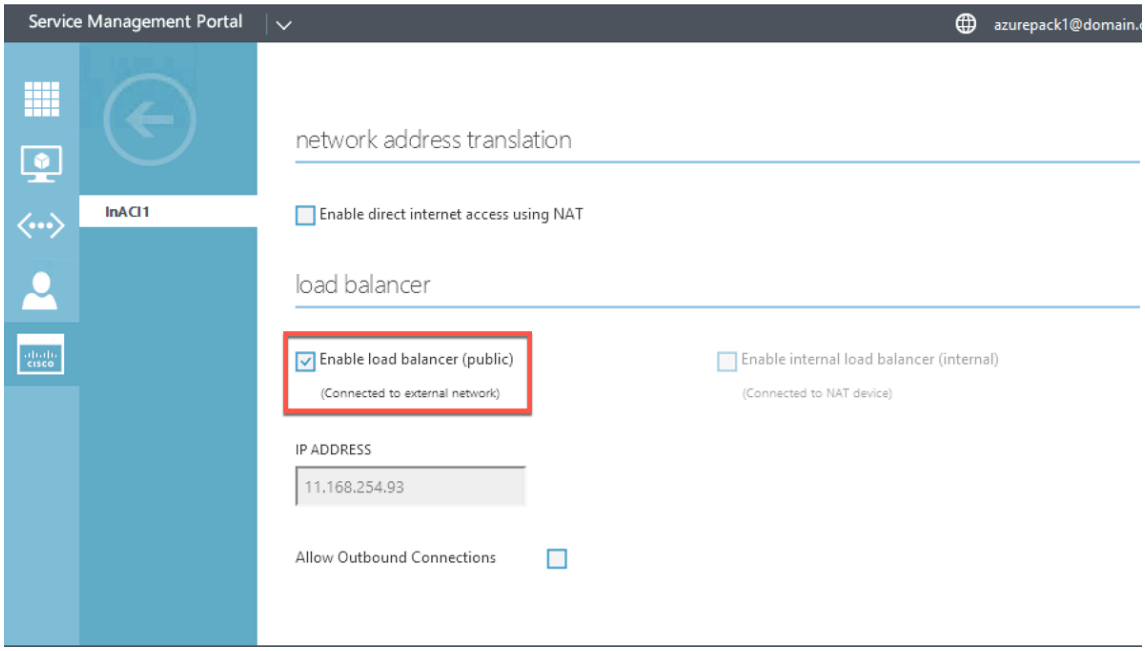
h. Click **CREATE**.

4. In the **ACI** pane, select **NETWORKS**.

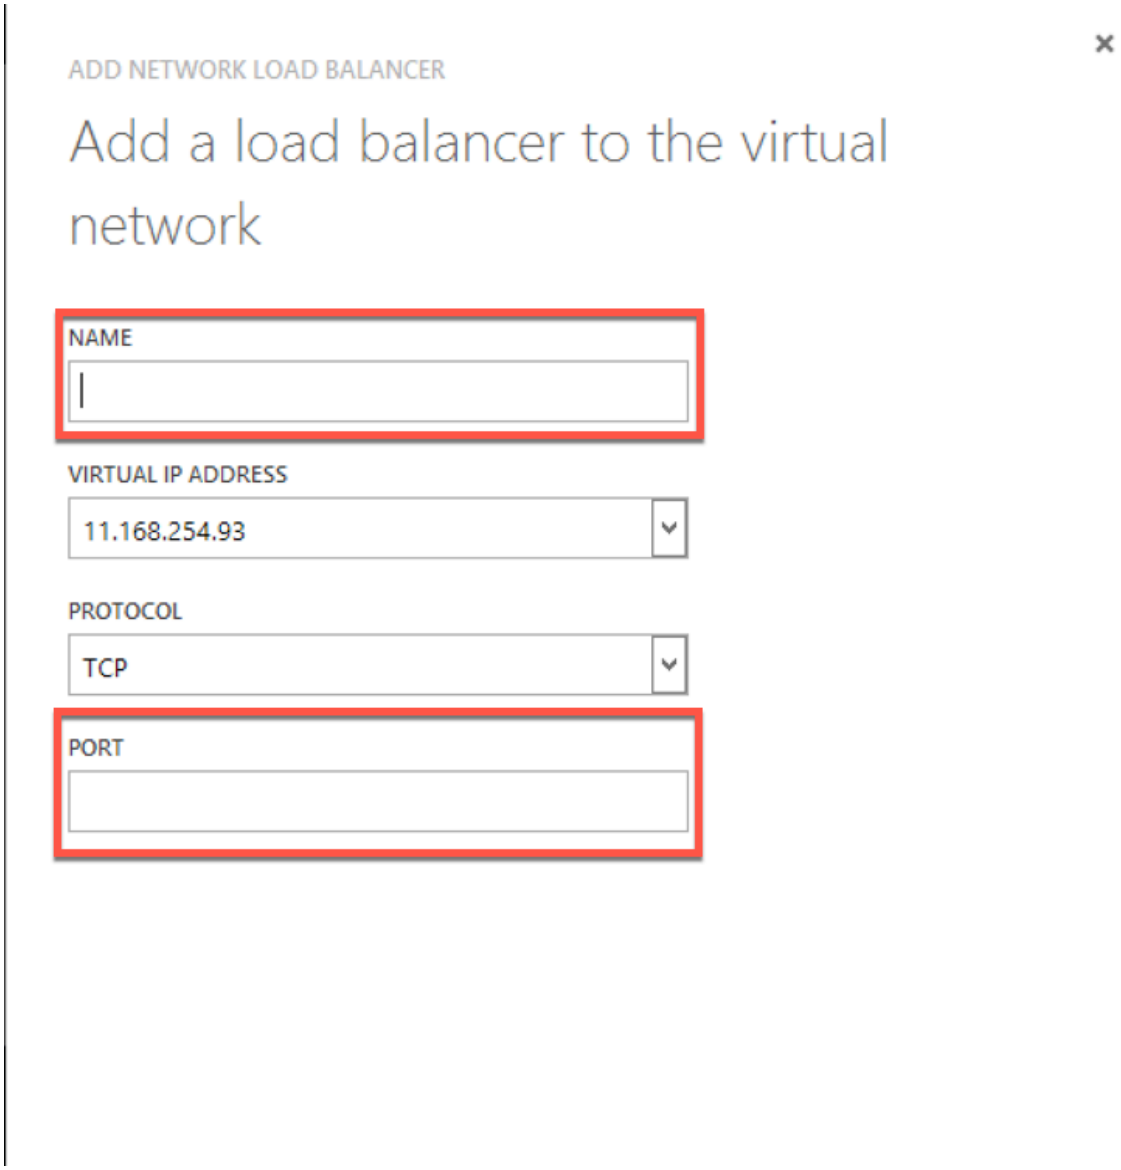


5. Double-click the network that you have created. Then, in the network pane, select **Enable load balancer (public)**. In the **IP ADDRESS** field, a VIP is automatically assigned from the VIP Range that the administrator configured in the Admin Portal. For more information, see Creating a Citrix ADC Load Balancer in a Plan in the Service Management Portal (Admin Portal).

6. Double-click the network that you have created. Then, in the network pane, select **Enable load balancer (public)**. In the **IP ADDRESS** field, a VIP is automatically assigned from the VIP Range that the administrator configured in the Admin Portal. For more information, see Creating a Citrix ADC Load Balancer in a Plan in the Service Management Portal (Admin Portal).



7. In the network pane, select the **Load Balancers** tab, and click **ADD**.



8. In the **ADD NETWORK LOAD BALANCER** pane, do the following:

   a. In the **NAME** field, enter the name for the load balancer.

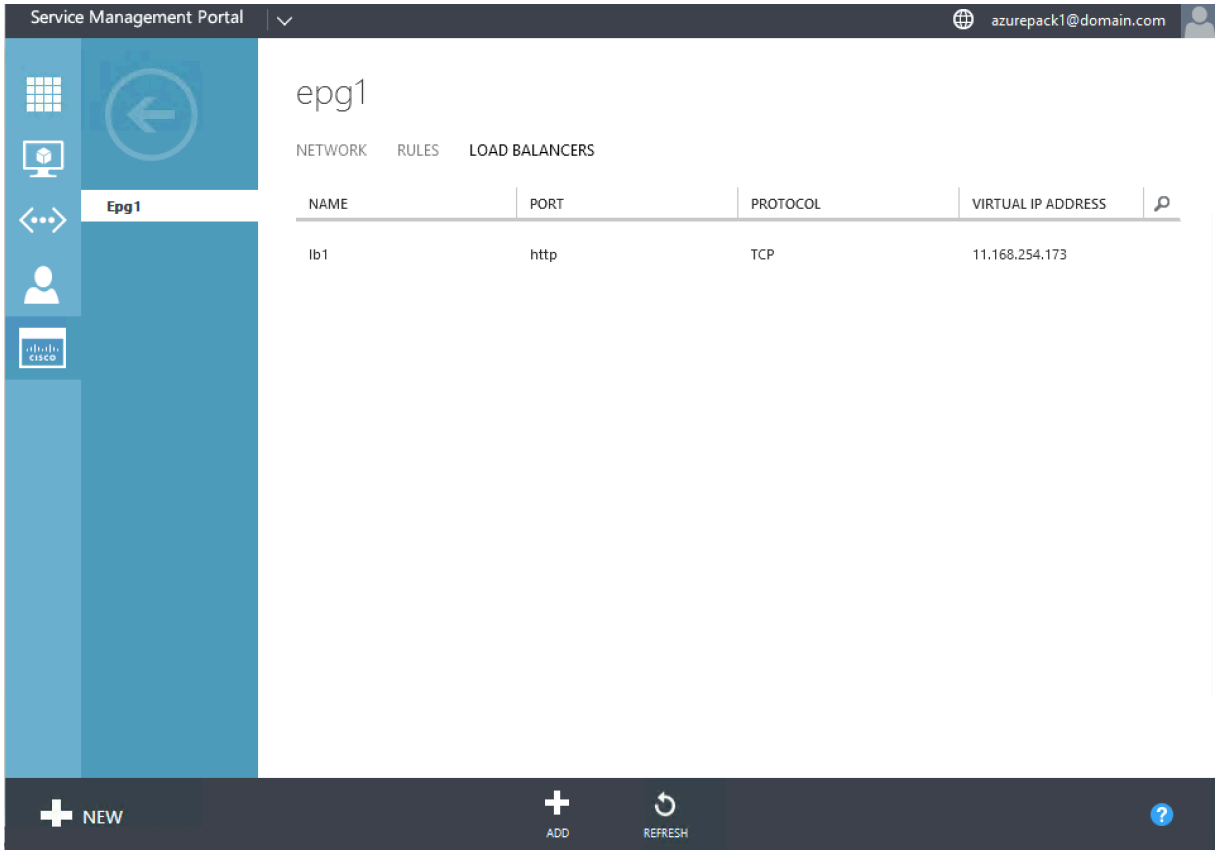
   b. Optionally, in the **VIRTUAL IP ADDRESS** field, assign the load balancer a VIP address from the VIP range that you defined earlier.

   c. Optionally, in the **PROTOCOL** field, select **TCP**.

   d. In the **PORT** field, enter the port number.

9. Click **CREATE**.

   The Citrix ADC Load Balancer is displayed in the **LOAD BALANCERS** tab and the Citrix ADC Load Balancer is data path ready.



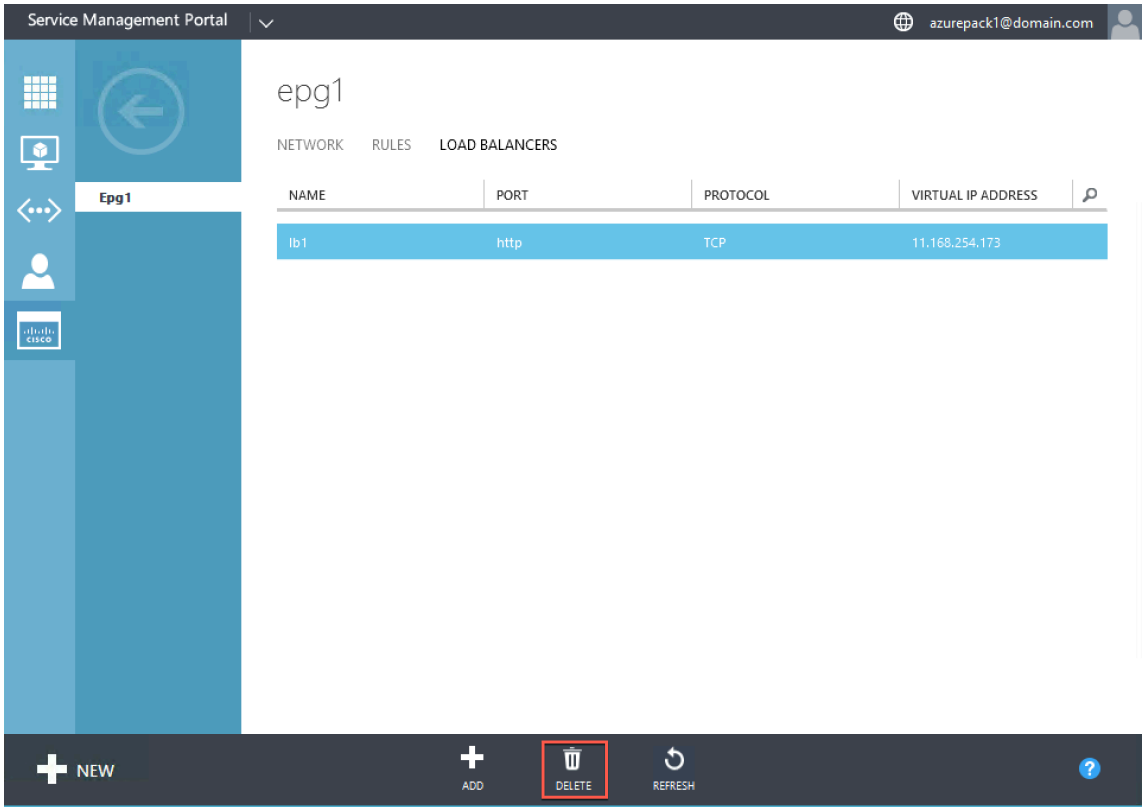
Deleting a Citrix ADC Load Balancer from the Network

September 14, 2021

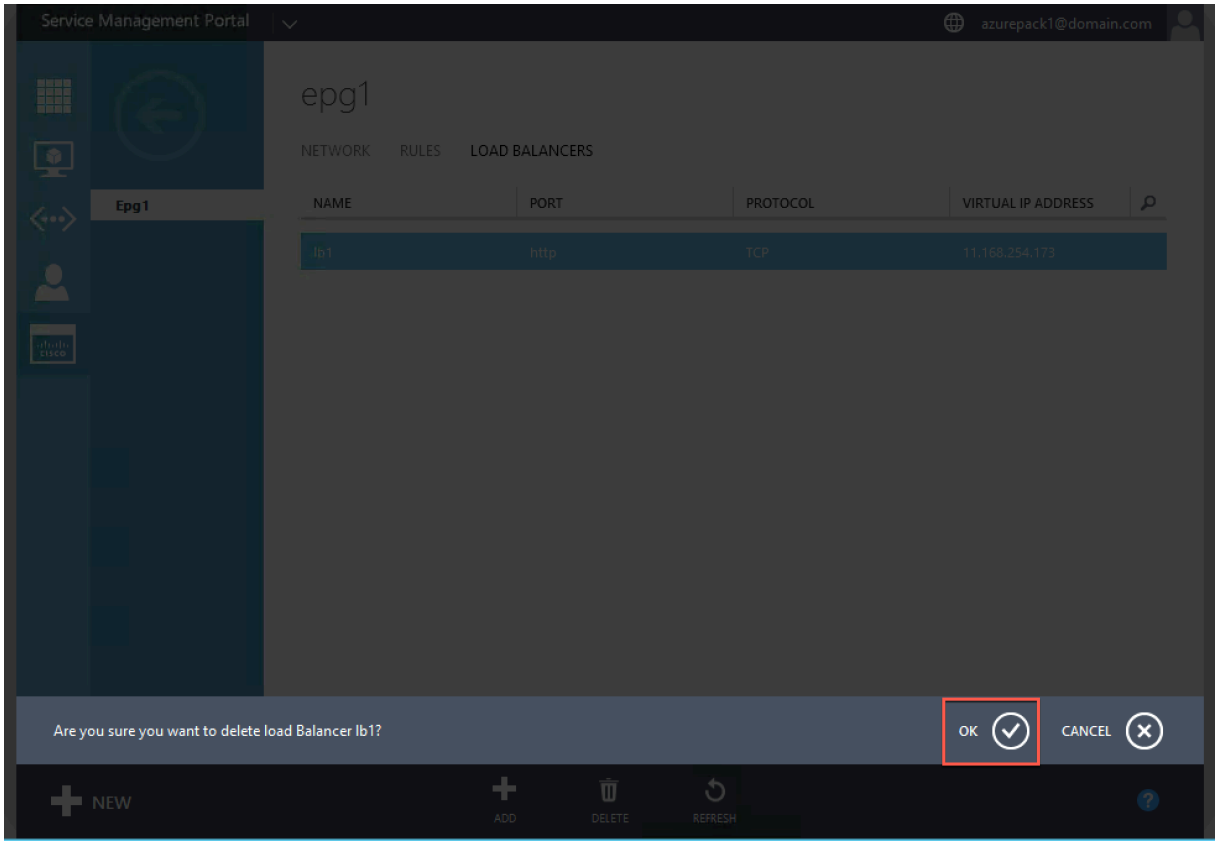
Using the Service Management Portal (Tenant Portal), from the Network, you can delete the Citrix ADC load balancer that you created.

To delete a Citrix ADC load balancer from the Network:

1. Log on to the Service Management Portal (Tenant Portal).
2. In the navigation pane, select **ACI**.
3. In the **ACI** pane, on the **NETWORKS** tab, click the network that you created.
4. In the selected network's pane, select the Citrix ADC load balancer and click **DELETE**.



5. Click **OK** to delete the Citrix ADC load balancer.



Citrix cloud native solution for microservices based on Kubernetes

September 14, 2021

As companies transform to innovate faster and get closer to customers, they are rearchitecting their internal process and breaking down boundaries within their organization. They are removing silos to pull together the right skill sets in the same team. One of the goals is to create and deliver software applications with speed, agility, and efficiency. In this regard, modern application architectures based on microservices are being adopted by a growing number of enterprises.
Using a microservices architecture, you can create applications as sets of loosely coupled services which can be deployed, updated, and scaled independently.

Cloud native is an approach that relies on the microservices architecture for building and deploying applications with the following key attributes:

- Deploys applications as loosely coupled microservices or containers
- Involves a very high degree of automation
- Implements agile DevOps processes and continuous delivery workflows
- Centers around APIs for interaction and collaboration

How does Kubernetes help in the cloud native journey?

To provide the desired levels of agility and stability, cloud native applications require high levels of infrastructure automation, security, networking, and monitoring. You need a container orchestration system that can efficiently manage containers at a large scale. Kubernetes has emerged as the most popular platform for container deployment and orchestration. Kubernetes abstracts the complex task of running, deploying, and managing containers from developers and operators and automatically schedules containers among a cluster of nodes. Kubernetes and the cloud native computing foundation (CNCF) ecosystem helps you to build a platform for cloud native solutions.

Some of the key benefits of using Kubernetes:

- Simplifies application deployment be it on-premises, hybrid, or public cloud infrastructure
- Accelerates application development and deployment
- Increases agility, flexibility, and scalability of applications

What is Citrix cloud native solution?

To maximize the benefits of using Kubernetes in production, you need to integrate Kubernetes with several tools, vendor-sourced, and open-source components. Ensuring production grade reliability and security for their cloud native application is a challenge faced by many organizations.

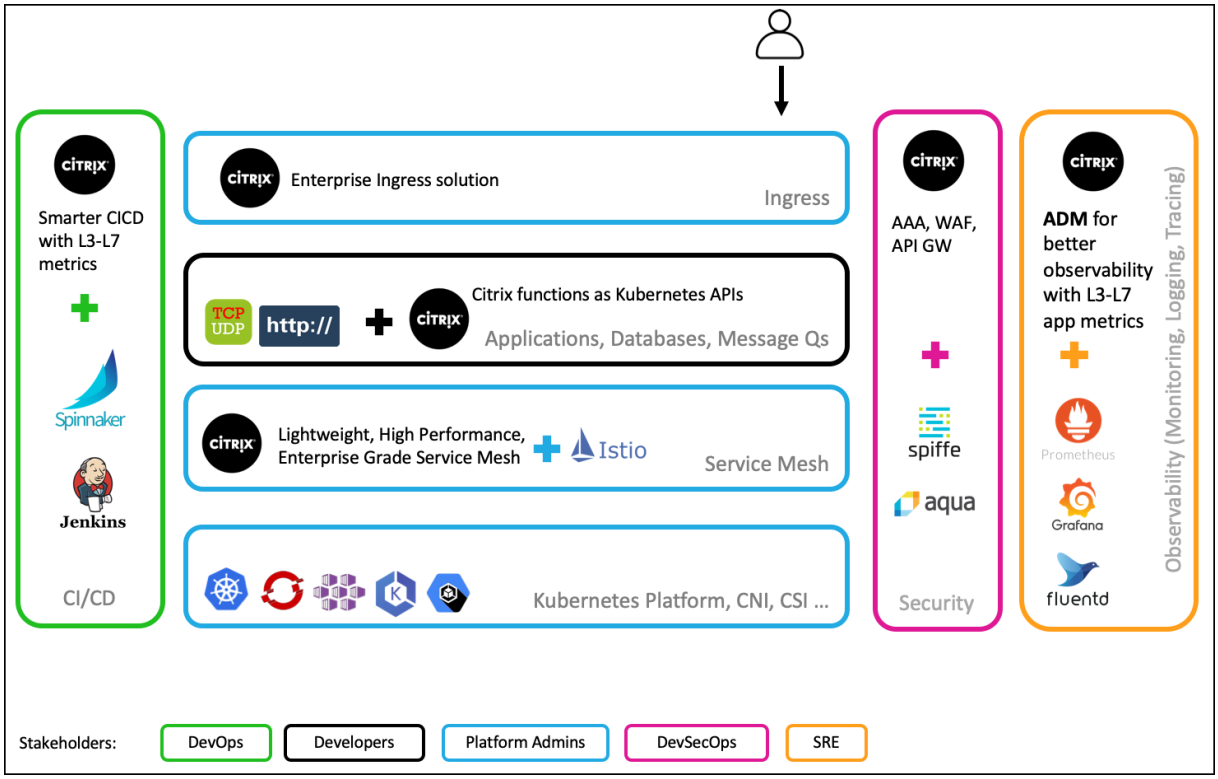
As the provider of industry-leading Citrix ADCs, Citrix offers a Citrix cloud native solution to address the challenges in a Kubernetes production environment.

Citrix cloud native solution leverages the advanced traffic management, observability, and comprehensive security features of Citrix ADCs to ensure enterprise grade reliability and security. It can provide complete visibility to application traffic in your Kubernetes environment, render immediate feedback, and help gain meaningful insights about the application performance.

The following table lists the key requirements of different stakeholders while implementing an Ingress solution.

Stakeholders	Job function	Needs
Platform administrators	Ensure availability of Kubernetes clusters	Simpler ways to manage applications deployed across multiple clusters, operation, and platform life cycle management
DevOps	Accelerate the deployment of applications to production	Integration with CI/CD pipeline, support for deployment techniques like Canary and blue-green for faster deployment
Developers	Develop and test microservices	Ways to bring traffic into the Kubernetes cluster, tracing and debugging, rate limiting for applications, and authentication for applications
SREs	Ensure availability of applications to meet service level agreements	Advanced telemetry for applications and infrastructure
SecOPs	Ensure security compliance	Secure Ingress traffic, API protection, service mesh for secure communication between microservices inside the Kubernetes cluster

The following diagram explains the Citrix cloud native solution and how it addresses the various challenges faced by stakeholders in their cloud native journey.



Citrix cloud native solution provides the following key benefits:

- Provides an advanced Kubernetes Ingress solution that caters to the needs of developers, SREs, devOps, and network or cluster administrators.
- Eliminates the need to rewrite legacy applications based on TCP or UDP traffic while moving them into a Kubernetes environment.
- Secures applications with Citrix ADC policies exposed as Kubernetes APIs.
- Helps to deploy high performing microservices for North-South traffic and East-West traffic.
- Provides an all-in-one view of all microservices using Citrix ADM service graph.
- Enables faster troubleshooting of microservices across different kinds of traffic including TCP, UDP, HTTP, HTTPS, and SSL.
- Secures APIs.
- Automates CI/CD pipeline for Canary deployments.
- Provides out of the box integrations with CNCF open-source tools.

For more information on different components of the Citrix cloud native solution, see the following links:

- Kubernetes Ingress solution
- Service mesh
- Solutions for observability
- API gateway for Kubernetes

Kubernetes Ingress solution

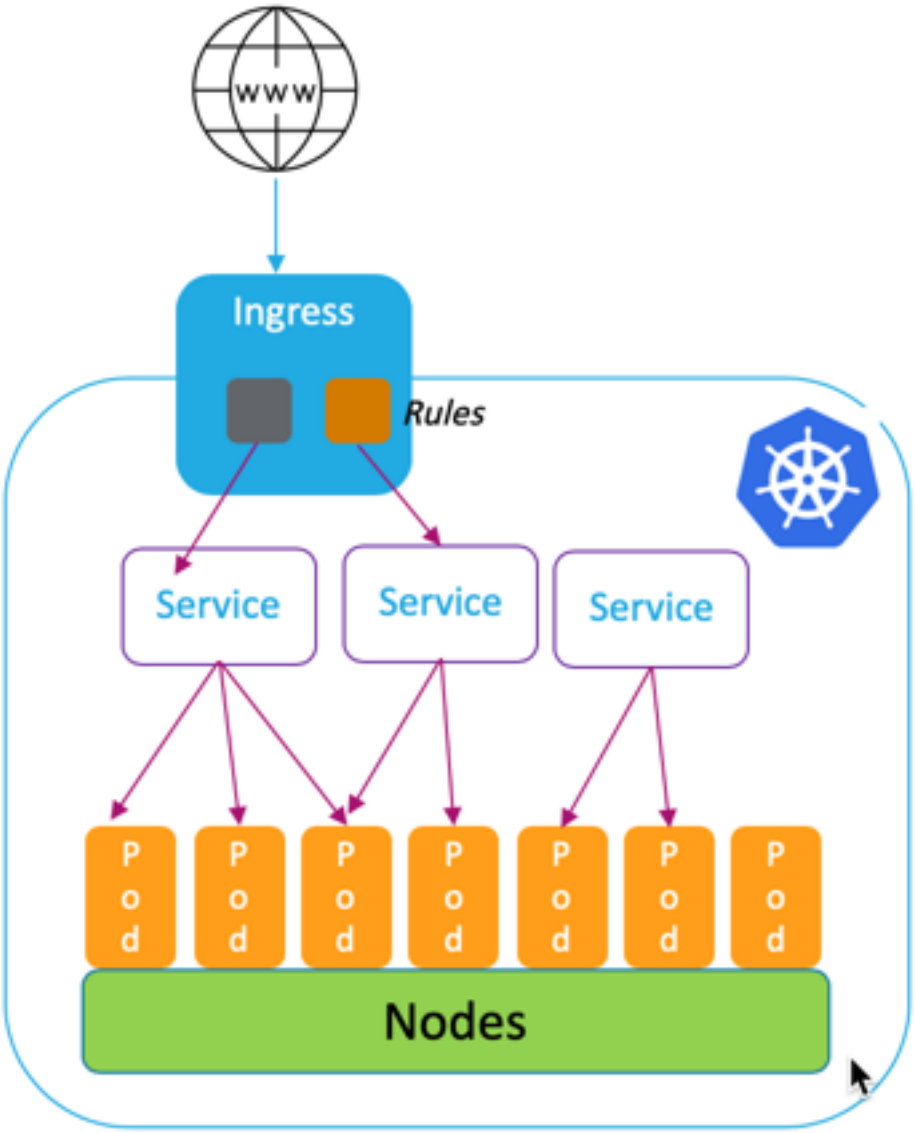
September 14, 2021

This topic provides an overview of the Kubernetes Ingress solution provided by Citrix and explains the benefits.

What is Kubernetes Ingress?

When you are running an application inside a Kubernetes cluster, you need to provide a way for external users to access the applications from outside the Kubernetes cluster. Kubernetes provides an object called Ingress that provides the most effective way to expose multiple services using a stable IP address. A Kubernetes ingress object is always associated with one or more services and acts as a single-entry point for external users to access services running inside the cluster.

The following diagram explains how Kubernetes Ingress works.



Kubernetes Ingress implementation consists of the following components:

- **Ingress resource**. An Ingress resource allows you to define rules for accessing the applications from outside of the cluster.
- **Ingress controller**. An Ingress controller is an application deployed inside the cluster that interprets rules defined in the Ingress. Ingress controller converts the Ingress rules into configuration instructions for a load balancing application integrated with the cluster. The load balancer can be a software application running inside your Kubernetes cluster or a hardware appliance running outside the cluster.
- **Ingress device**. An Ingress device is a load balancing application like Citrix ADC CPX, VPX, or

MPX which performs load balancing according to the configuration instructions provided by the Ingress controller.

What is the Kubernetes Ingress solution from Citrix?

In this solution, Citrix provides an implementation of Kubernetes Ingress controller to manage and route traffic into your Kubernetes cluster using Citrix ADCs (Citrix ADC CPX, VPX, or MPX). The Citrix ingress controller integrates Citrix ADCs with your Kubernetes environment and configures Citrix ADC CPX, VPX, or MPX according to the Ingress rules.

Standard Kubernetes Ingress solutions provide load balancing only at layer 7 (HTTP or HTTPS traffic). Some times, you need to expose many legacy applications which rely on TCP or UDP or applications and need a way to load balance those applications. Citrix Kubernetes Ingress solution provides TCP, TCP-SSL, and UDP traffic support apart from the standard HTTP or HTTPS Ingress. Also, it works seamlessly across multiple clouds or on-premises data centers.

Citrix ADC provides enterprise-grade traffic management policies like rewrite and responder policies for efficiently load balancing traffic at layer 7. However, Kubernetes Ingress lacks such enterprise-grade traffic management policies. With the Kubernetes Ingress solution from Citrix, you can apply rewrite and responder policies for application traffic in a Kubernetes environment using CRDs provided by Citrix.

The Kubernetes Ingress solution from Citrix also supports automated canary deployment for your CI/CD application pipeline. In this solution, Citrix ADC is integrated with the Spinnaker platform and acts as a source for providing accurate metrics for analyzing Canary deployment using Kayenta. After analyzing the metrics, Kayenta generates an aggregate score for the canary and decides to promote or fail the Canary version. You can also regulate traffic distribution to the Canary version using the Citrix ADC policy infrastructure.

The following table summarizes the benefits offered by the Ingress solution from Citrix over Kubernetes Ingress.

Features	Kubernetes Ingress	Ingress Solution from Citrix
HTTP and HTTPs support	Yes	Yes
URL routing	Yes	Yes
TLS	Yes	Yes
Load balancing	Yes	Yes
TCP, TCP-SSL	No	Yes
UDP	No	Yes
HTTP/2	Yes	Yes

Features	Kubernetes Ingress	Ingress Solution from Citrix
Automated canary deployment support with CI/CD tools	No	Yes
Support for applying Citrix ADC rewrite and responder policies	No	Yes
Authentication (Open Authorization (OAuth), mutual TLS (mTLS))	No	Yes
Support for applying Citrix Rate Limiting policies	No	Yes

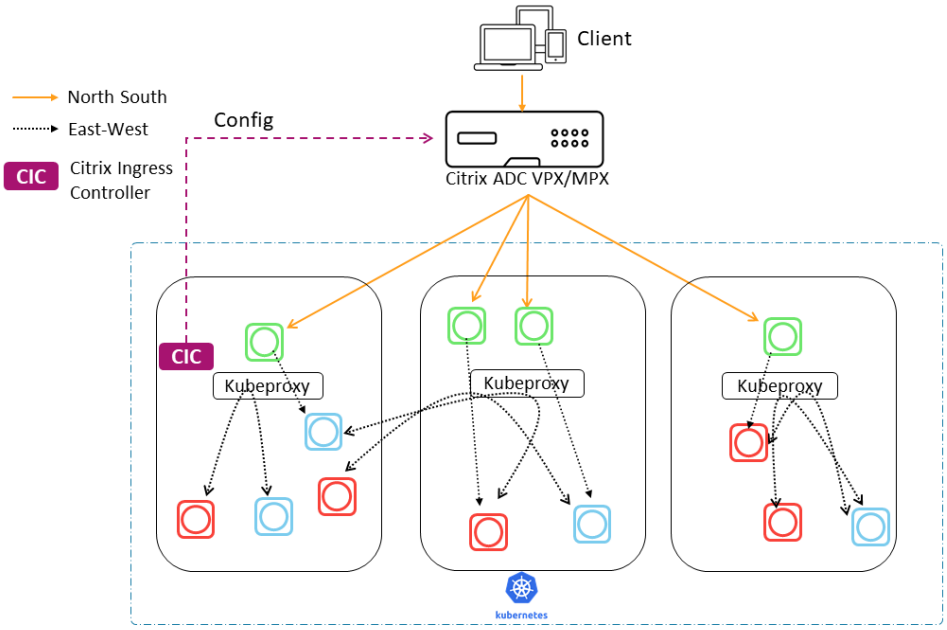
Deployment options for Kubernetes Ingress solution

Kubernetes Ingress solution from Citrix provides you flexible architecture depending on how you want to manage your Citrix ADCs and Kubernetes environment.

Unified Ingress (single-tier)

In a unified Ingress (single-tier) architecture, a Citrix MPX or VPX device deployed outside the Kubernetes cluster is integrated with the Kubernetes environment using the Citrix ingress controller. The Citrix ingress controller is deployed as a pod in the Kubernetes cluster and automates the configuration of Citrix ADCs based on changes to the microservices or the Ingress resources. The Citrix ADC device performs functions like load balancing, TLS termination, and HTTP or TCP protocol optimizations on inbound traffic and then routes the traffic to the correct microservice within a Kubernetes cluster. This architecture suits best in scenarios where the same team manages the Kubernetes platform and other networking infrastructure including application delivery controllers (ADCs).

The following diagram shows a deployment using the unified Ingress architecture.



A unified Ingress solution provides the following key benefits:

- Provides a way to extend the capabilities of your existing Citrix ADC infrastructure to the Kubernetes environment
- Enables you to apply traffic management policies for inbound traffic
- Provides a simplified architecture suitable for network-savvy DevOps teams
- Supports multitenancy

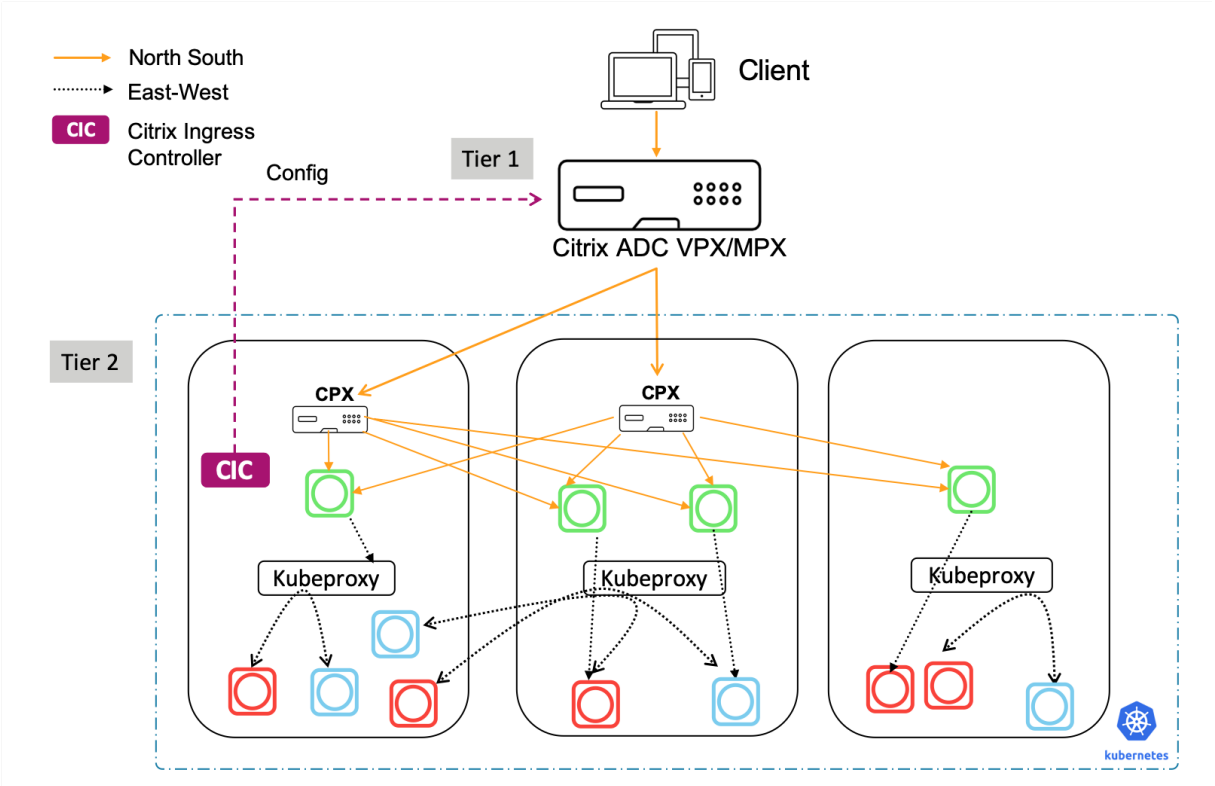
Dual-tier Ingress

In a dual-tier architecture, Citrix ADC (MPX or VPX) deployed outside the Kubernetes cluster acts at tier 1 and load balances North-South traffic to Citrix ADC CPXs running inside the cluster. Citrix ADC CPX acts at tier 2 and performs load balancing for microservices inside the Kubernetes cluster.

In scenarios where separate teams manage the Kubernetes platform and the network infrastructure, the dual-tier architecture is most suitable.

Networking teams use tier 1 Citrix ADC for use cases such as GSLB, TLS termination on the hardware platform, and TCP load balancing. Kubernetes platform teams can use tier 2 Citrix ADC (CPX) for Layer 7 (HTTP/HTTPS) load balancing, mutual TLS, and observability or monitoring of microservices. The tier 2 Citrix ADC (CPX) can have a different software release version than the tier 1 Citrix ADC to accommodate newly available capabilities.

The following diagram shows a deployment with dual-tier architecture.



A dual-tier Ingress provides the following key benefits:

- Ensures high velocity of application development for developers or platform teams
- Enables applying developer driven traffic management policies for microservices inside the Kubernetes cluster
- Enables cloud scale and multitenancy

For more information, see the Citrix ingress controller documentation.

Getting started

To get started with the Kubernetes Ingress solution from Citrix, you can try out the following examples:

- Load balance Ingress traffic with Citrix ADC CPX in Minikube
- Load balance North-South Ingress traffic using Citrix ADC CPX proxy
- Load balance East-West microservice traffic using Citrix ADC CPX proxy
- Deep dive on Kubernetes features with Citrix ADC CPX

Service mesh

September 14, 2021

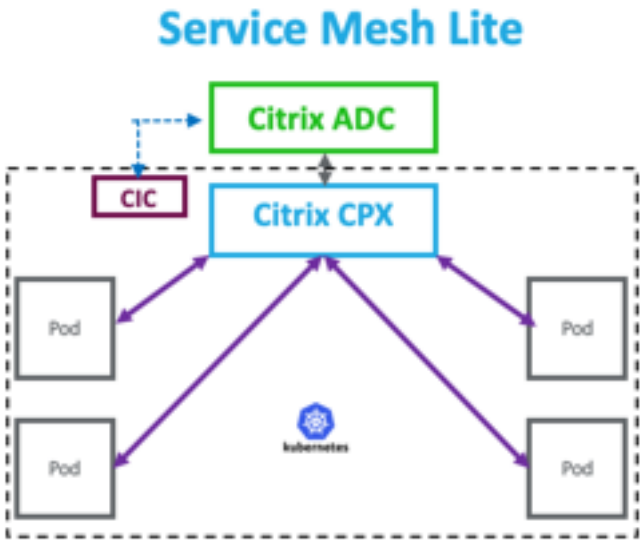
A service mesh is an infrastructure layer for handling service-to-service communication for cloud-native applications using APIs. It provides a way to connect, secure, and monitor your microservices. Citrix provides two solutions to meet your service mesh requirements:

- Service mesh lite
- Service mesh (Citrix ADC integration with Istio)

Service mesh lite

A full-fledged service-mesh implementation is complex and requires a steep learning curve. If you are looking for a simplified implementation of a service mesh with similar benefits, Citrix offers a solution called service mesh lite with lesser complexity. In this solution, a Citrix ADC CPX runs as a centralized load balancer in the Kubernetes cluster and load balances East-West traffic among microservices. Citrix ADC CPX enforces policies for inbound and inter-container traffic.

The following diagram shows a service mesh lite architecture.



For information, see the service mesh lite documentation.

Service mesh (Citrix ADC integration with Istio)

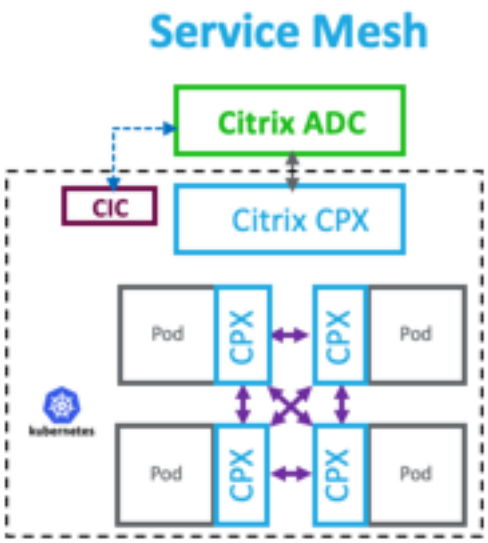
Citrix provides a service mesh solution by integrating Citrix ADC with Istio. Istio, an open source and platform-independent service mesh, is one of the most popular service mesh implementations. By integrating Citrix ADC with Istio, you can take advantage of the Citrix ADC features to secure and optimize the traffic for applications in the service mesh.

Citrix ADC can be integrated with Istio in the following ways:

- Citrix ADC MPX, VPX, or CPX as an Istio Ingress Gateway to the service mesh to expose traffic to the Kubernetes cluster.
- Citrix ADC CPX as a sidecar proxy with application containers in the service mesh to control communication between applications.

You can use either integration independently or you can combine both ways to have a unified data plane solution.

The following diagram shows a service mesh architecture.



Service mesh is ideal for highly secure applications and also offers the following benefits.

- Offers fine-grained (modularized) traffic management per container
- Ensures richer observability, analytics, and security (Mutual TLS) due to sidecar implementation
- Enables automated canary deployment for each container with embedded Citrix ADC CPX
- Supports cloud portability
- Allows offloading of some of the functions performed by applications to the sidecar
- Provides lower sidecar latency
- Provides integrations with open-source tools
- Offers scalability

For more information, see the Citrix ADC integration with Istio documentation.

Solutions for observability

September 14, 2021

In a microservices based architecture, visibility into service to service communications is critical to build an efficient and resilient architecture. Traditional ways for logging and monitoring is not capable of addressing the challenges of a microservices architecture. Observability solutions from Citrix provide you the ability to see what is happening when your services interact with each other and get meaningful insights about your system.

Citrix provides the following solutions to address the observability needs of your microservices architecture:

- Citrix ADM service graph and analytics
- Citrix ADC observability exporter

Citrix ADM service graph and analytics

Citrix Application Delivery Management (ADM) is a centralized management solution that provides enterprise-wide visibility and automation for management jobs that need to be run across multiple instances.

In a microservice architecture, troubleshooting is challenging because a single end-user request may span across multiple microservices.

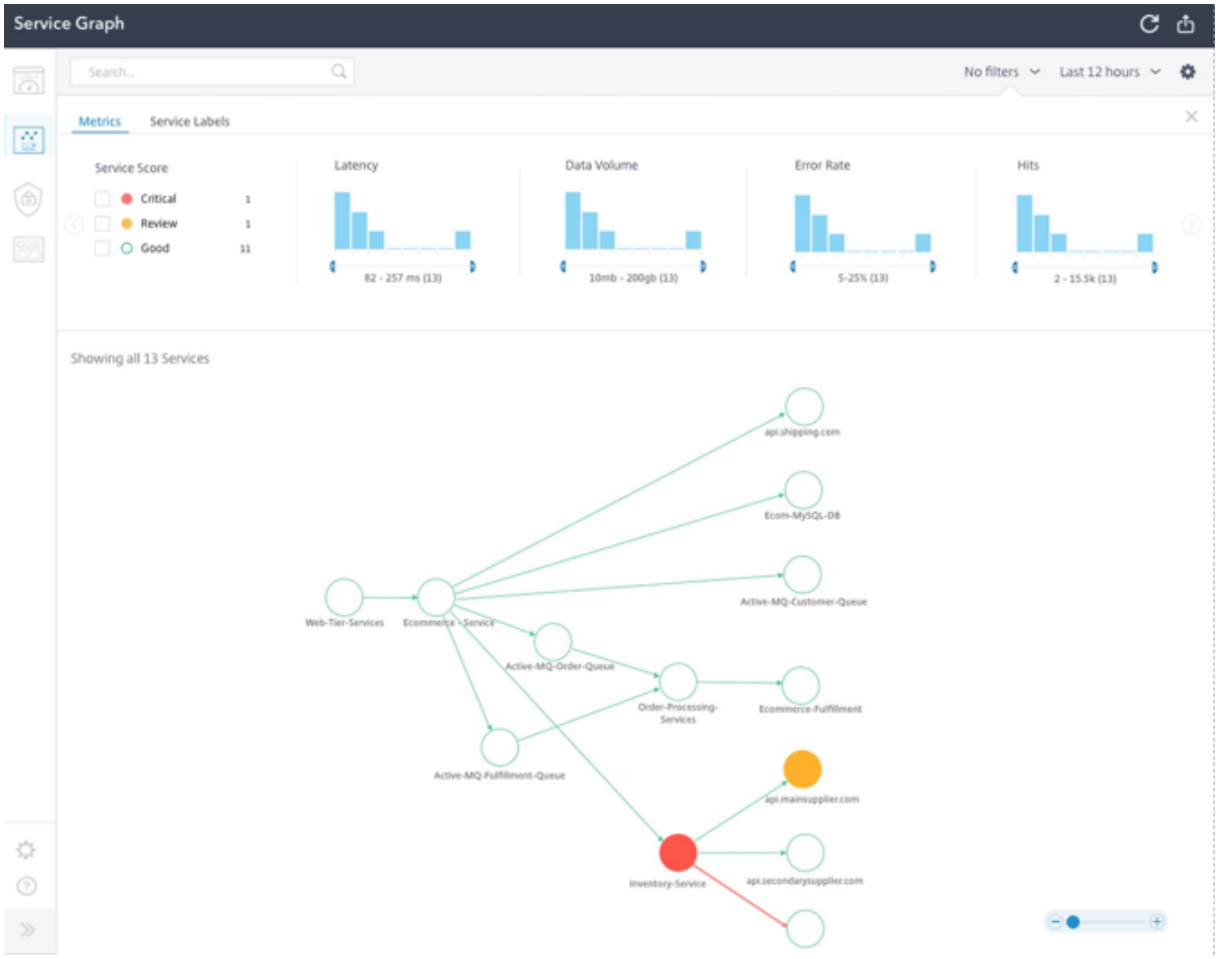
Citrix ADM's service graph and analytics provides visibility into interactions between microservices and helps to identify and fix issues based on various metrics such as latency and HTTP errors.

Citrix ADM also provides advanced analytics based on metrics and transaction logs collected from Citrix ADC.

Citrix ADM solution provides the following benefits:

- Provides a single pane of glass for applications across containers, on-premises, or cloud
- Provides better observability and faster troubleshooting for microservices
- Supports Canary deployment

The following diagram shows a sample service graph for an application which contains multiple microservices.



For more information on how to set up Citrix ADM service graph and analytics, see the Service graph and the Analytics documentation.

Citrix ADC observability exporter

Citrix ADC observability exporter is a container which collects metrics and transactions from Citrix ADCs and transforms them to suitable formats (such as JSON, AVRO) for supported endpoints. You can export the data collected by Citrix ADC observability exporter to the desired endpoint. By analyzing the data, you can get valuable insights at a microservices level for applications proxied by Citrix ADCs.

Distributed tracing support

Distributed tracers allow you to visualize the data flow between your microservices and helps to identify the bottlenecks in your microservices architecture. OpenTracing is a specification and standard set of APIs for designing and implementing distributed tracing.

Citrix observability exporter implements distributed tracing for Citrix ADC and currently supports Zipkin as the distributed tracer.

You can enhance the trace analysis by using Elasticsearch and Kibana with Zipkin. Elasticsearch provides long-term retention of the trace data. Kibana allows you to get much deeper insight into the data by providing a tool to explore, and visualize log messages.

Transaction collection and streaming support

Citrix ADC observability exporter supports collecting transactions and streaming them to endpoints. Currently, Citrix ADC observability exporter supports Elasticsearch and Kafka as transaction endpoints.

For more information, see the Citrix ADC observability exporter documentation.

Enable analytics using annotations in the Citrix ingress controller YAML file

You can enable analytics using the analytics profile which is defined as a smart annotation in Ingress or service of type LoadBalancer configuration. You can define the specific parameters you need to monitor by specifying them in the Ingress or service configuration of the application. For more information about enabling analytics using annotations, see Analytics using annotations.

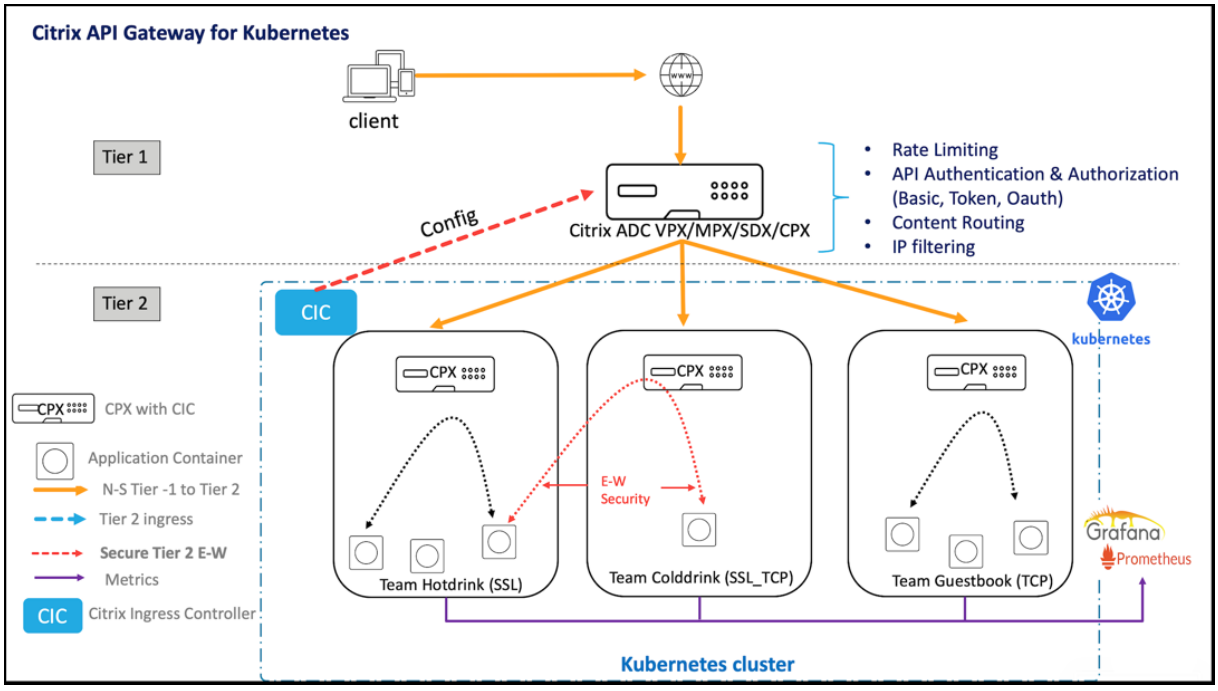
API gateway for Kubernetes

September 14, 2021

An API gateway acts as the single entry point for your APIs and ensures secure and reliable access to multiple APIs and microservices in your system.

Citrix provides an enterprise grade API gateway for North-South API traffic into the Kubernetes cluster. The
API gateway integrates with Kubernetes through the Citrix ingress controller and the Citrix ADC (Citrix ADC MPX, VPX, or CPX) deployed as the Ingress Gateway for on-premises or cloud deployments.

The following diagram shows a dual-tier topology for the API gateway.



Using the API gateway offered by Citrix, you can perform the following functionalities:

- Enforce authentication policies
- Rate limit access to services
- Advanced content routing
- Flexible and comprehensive transformation of HTTP transactions using the rewrite and responder policies
- Enforce web application firewall policies

How does the API gateway work

The API gateway is built on top of the Citrix ingress gateway and uses Kubernetes API extensions such as custom resource definitions (CRDs). Using CRDs, you can automatically configure the Citrix ADC and API gateway in the same instance.

Citrix provides the following CRDs for the API gateway:

- Auth CRD
- Rate limit CRD
- Content routing CRD
- Rewrite and responder CRD
- WAF CRD

Key benefits of using the API gateway

Following are the key benefits of the API gateway offered by Citrix:

- Uses the advanced traffic management and comprehensive security features of Citrix ADC.
- Optimizes your deployments by consolidating multiple network functions into a single component of the Citrix ingress gateway.
- Reduces the operational complexity and cost involved in deploying multiple components.
- Ensures better performance for your application traffic by reducing multiple hops of TCP or TLS decryption while using separate components.
- Simplifies deploy and integrate in your Kubernetes environments either by directly using YAMLs or helm charts.

Deploying the API gateway

For more information on how to configure the API gateway features using CRDs, see the Citrix ingress controller documentation:

- Authentication
- Rate limiting
- Advanced content routing
- Rewrite and responder policies
- Web application firewall policies

Deploy a Citrix ADC VPX instance

September 14, 2021

> **Note**
>
> Citrix ADM service connect is enabled by default, after you install or upgrade Citrix ADC or Citrix Gateway to release 13.0 build 61.xx and above. For more information see, Data governance and Citrix ADM service connect.

The Citrix ADC VPX product is a virtual appliance that can be hosted on a wide variety of virtualization and cloud platforms:

- Citrix Hypervisor
- VMware ESX
- Microsoft Hyper-V
- Linux KVM
- Amazon Web Services
- Microsoft Azure

- Google Cloud Platform

For more information, see the Citrix ADC VPX data sheet.

For more information about provisioning a Citrix ADC VPX instance on an SDX appliance, see Provisioning Citrix ADC instances.

Citrix Application Delivery Management for Citrix ADC VPX

Citrix Application Delivery Management software is a centralized management solution that simplifies operations by providing administrators with enterprise-wide visibility and automating management jobs that need to be run across multiple instances.

You can manage and monitor Citrix ADC VPX instances in addition to other Citrix application networking products such as Citrix Gateway, Citrix ADC SDX, Citrix ADC CPX, and Citrix SD-WAN. You can use the Application Delivery Management software to manage, monitor, and troubleshoot the entire global application delivery infrastructure from a single, unified console.

For more information, see Citrix Application Delivery Management documentation.

Support matrix and usage guidelines

October 7, 2021

This document lists the different hypervisors, and features supported on a Citrix ADC VPX instance, their usage guidelines, and known limitations.

Table 1. VPX instance on Citrix Hypervisor

Citrix Hypervisor version	SysID	VPX models
8.2 supported 13.0 64.x onwards, 8.0, 7.6, 7.1	450000	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G

Table 2. VPX instance on VMware ESXi server

ESXi version	ESXi release date in MM/DD/YYYY format	ESXi build number	Citrix ADC VPX version	SysID	VPX models
ESXi 7.0 update 2a	12/17/2020	17867351	13.0-82.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G
ESXi 7.0 update 1d	12/17/2020	17551050	13.0-82.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G
ESXi 7.0 update 1c	12/17/2020	17325551	13.0-82.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G

ESXi 6.7 Update 3	08/20/2019	14320388	13.0-58.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G
ESXi 6.7 U2	04/11/2019	13006603	13.0-47.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G

ESXi version	ESXi release date in MM/DD/YYYY format	ESXi build number	Citrix ADC VPX version	SysID	VPX models
ESXi 6.5 GA	11/15/2016	4564106	13.0-47.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G
ESXi 6.5 U1g	3/20/2018	7967591	13.0 47.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G
ESXi 6.0 Update 3	2/24/2017	5050593	12.0-51.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G

ESXi version	ESXi release date in MM/DD/YYYY format	ESXi build number	Citrix ADC VPX version	SysID	VPX models
ESXi 6.0 Express Patch 11	10/5/2017	6765062	12.0-56.x onwards	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G, VPX 25G, VPX 40G, VPX 100G

Table 3. VPX on Microsoft Hyper-V

Hyper-V version	SysID	VPX models
2012, 2012 R2, 2016, 2019	450020	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000

Table 4. VPX instance on generic KVM

Generic KVM version	SysID	VPX models
RHEL 7.4, RHEL 7.5 (from Citrix ADC version 12.1 50.x onwards), RHEL 7.6, RHEL 8.2, Ubuntu 16.04, Ubuntu 18.04, RHV 4.2	450070	VPX 10, VPX 25, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX 8000, VPX 10G, VPX 15G. VPX 25G, VPX 40G, VPX 100G

Points to note:

Consider the following points while using KVM hypervisors.

- The VPX instance is qualified for hypervisor release versions mentioned in table 1–4, and not for patch releases within a version. However, the VPX instance is expected to work seamlessly with patch releases of a supported version. If it does not, log a support case for troubleshooting and

debugging.

- Use the `ip link` commands to configure RHEL 8.2 network bridges.
- Before using RHEL 7.6, complete the following steps on the KVM host:
  1. Edit /etc/default/grub and append `"kvm_intel.preemption_timer=0"` to `GRUB_CMDLINE_LINUX` variable.
  2. Regenerate grub.cfg with the command `"## grub2-mkconfig -o /boot/grub2/grub.cfg"`.
  3. Restart the host machine.
- Before using Ubuntu 18.04, complete the following steps on the KVM host:
  1. Edit /etc/default/grub and append `"kvm_intel.preemption_timer=0"` to `GRUB_CMDLINE_LINUX` variable.
  2. Regenerate grub.cfg with the command `"## grub-mkconfig -o /boot/grub/grub.cfg "`.
  3. Restart the host machine.

Table 5. VPX instance on AWS

AWS version	SysID	VPX models
N/A	450040	VPX 10, VPX 200, VPX 1000, VPX 3000, VPX 5000, VPX BYOL(VPX 8000, VPX 10G, VPX 15G, and VPX 25G are available only with BYOL with EC2 instance types (C5, M5, and C5n)

> Note:
> The VPX 25G offering doesn't give the desired 25G throughput in AWS but can give higher SSL transactions rate compared to VPX 15G offering.

Table 6. VPX instance on Azure

Azure version	SysID	VPX models
N/A	450020	VPX 10, VPX 200, VPX 1000, VPX 3000, VPX BYOL

Table 7. VPX feature matrix

	VPX on XenServer		VPX on VMware ESX				VPX on Microsoft Hyper-V	VPX on generic KVM			VPX on AWS	VPX on Azure
Features	PV	SR-IOV	PV	SR-IOV	Emulated	PCI Passthrough	PV	PV	SR-IOV	PCI Passthrough		
Multi-PE Support	√	√	√	√	√	√	√	√	√	√	√	√
Clustering Support	√	*√	√	*√	√	√	√	√	*√	√	X	X
VLAN Tagging	√	√	√	√	√	√	√ ((Only on 2012R2))	√	√	√	X	X
Detecting Link Events	**X	***√	**X	***√	**X	***√	**X	**X	***√	***√	**X	**X
Interface Parameter Configuration	X	X	X	X	X	√	X	X	X	√	X	X
Static LA	**√	***√	**√	X	**√	***√	**√	**√	***√	***√	X	X
LACP	X	***√	**√	X	**√	***√	X	**√	***√	***√	X	X
Static CLAG	X	X	X	X	X	X	X	X	X	X	X	X
LACP CLAG	X	X	**√	X	**√	***√	X	**√	***√	***√	X	X
Hot-Plug	X	X	X	X	X	X	X	X	X	X	√	X

1. Clustering support is available on SRIOV for client and server facing interfaces and not for the backplane.
2. Interface DOWN events are not recorded in Citrix ADC VPX instances.
3. For Static LA, traffic might still be sent on the interface whose physical status is DOWN.
4. For LACP, the peer device knows the interface DOWN event based on the LACP timeout mechanism.
    - Short timeout: 3 seconds
    - Long timeout: 90 seconds
5. For LACP, do not share interfaces across VMs.
6. For Dynamic routing, convergence time depends on the Routing Protocol since link events are not detected.
7. Monitored static Route functionality fails if you do not bind monitors to static routes because the Route state depends on the VLAN status. The VLAN status depends on the link status.
8. Partial failure detection does not happen in high availability if there's link failure. High availability-split brain condition might happen if there's link failure.
    - When any link event (disable/enable, reset) is generated from a VPX instance, the physical status of the link does not change. For static LA, any traffic initiated by the peer gets dropped on the instance.

- For the VLAN tagging feature to work, do the following:

On the VMware ESX, set the port group's VLAN ID to 1–4095 on the vSwitch of the VMware ESX server. For more information about setting a VLAN ID on the vSwitch of the VMware ESX server, see VMware ESX Server 3 802.1Q VLAN Solutions.

Table 8. Supported browsers

Operating system	Browser and versions
Windows 7	Internet Explorer- 8, 9, 10, and 11; Mozilla Firefox 3.6.25 and above; Google Chrome- 15 and above
Windows 64 bit	Internet Explorer - 8, 9; Google Chrome - 15 and above
MAC	Mozilla Firefox - 12 and above; Safari - 5.1.3; Google Chrome - 15 and above

Usage guidelines

Follow these usage guidelines:

See the **VMware ESXi CPU Considerations** section in the document Performance Best Practices for VMware vSphere 6.5. Here's an extract:

- It is not recommended that virtual machines with high CPU/Memory demand sit on a Host/Cluster that is overcommitted.
- In most environments, ESXi allows significant levels of CPU overcommitment without impacting virtual machine performance. On a host, you can run more vCPUs than the total number of physical processor cores in that host.
- If an ESXi host becomes CPU saturated, that is, the virtual machines and other loads on the host demand all the CPU resources the host has, latency-sensitive workloads might not perform well. In this case you might want to reduce the CPU load, for example by powering off some virtual machines or migrating them to a different host (or allowing DRS to migrate them automatically).
- Citrix recommends the latest hardware compatibility version to avail latest feature sets of the ESXi hypervisor for the virtual machine. For more information about the hardware and ESXi version compatibility, see VMware documentation.
- The Citrix ADC VPX is a latency-sensitive, high-performance virtual appliance. To deliver its expected performance, the appliance requires vCPU reservation, memory reservation, vCPU pinning on the host. Also, hyper threading must be disabled on the host. If the host does not meet

these requirements, issues such as high-availability failover, CPU spike within the VPX instance, sluggishness in accessing the VPX CLI, pit boss daemon crash, packet drops, and low throughput occur.

A hypervisor is considered over-provisioned if one of the following two conditions is met:

- The total number of virtual cores (vCPU) provisioned on the host is greater than the total number of physical cores (pCPUs).
- The total number of provisioned VMs consume more vCPUs than the total number of pCPUs.

  If an instance is over-provisioned, the hypervisor might not guarantee the resources reserved (such as CPU, memory, and others) for the instance due to hypervisor scheduling over-heads, bugs, or limitations with the hypervisor. This behavior can cause lack of CPU resource for Citrix ADC and might lead to the issues mentioned in the first point under **Usage guidelines**. As administrators, you're recommended to reduce the tenancy on the host so that the total number of vCPUs provisioned on the host is lesser or equal to the total number of pCPUs.

  Example

  For ESX hypervisor, if the `%RDY%` parameter of a VPX vCPU is greater than 0 in the `esxtop` command output, the ESX host is said to be having scheduling overheads, which can cause latency related issues for the VPX instance.

  In such a situation, reduce the tenancy on the host so that `%RDY%` returns to 0 always. Alternatively, contact the hypervisor vendor to triage the reason for not honoring the resource reservation done.

- Hot adding is supported only for PV and SRIOV interfaces with Citrix ADC on AWS. VPX instances with ENA interfaces do not support hot-plug, and the behavior of the instances can be unpredictable if hot-plugging is attempted.
- Hot removing either through the AWS Web console or AWS CLI interface is not supported with PV, SRIOV, and ENA interfaces for Citrix ADC. The behavior of the instances can be unpredictable if hot-removal is attempted.

Commands to control the packet engine CPU usage

You can use two commands (`set ns vpxparam` and `show ns vpxparam`) to control the packet engine (non-management) CPU usage behavior of VPX instances in hypervisor and cloud environments:

- `set ns vpxparam [-cpuyield (YES | NO | DEFAULT)] [-masterclockcpu1 (YES | NO)]`

  Allow each VM to use CPU resources that have been allocated to another VM but are not being used.

`Set ns vpxparam` parameters:

-cpuyield: Release or do not release of allocated but unused CPU resources.

- **YES**: Allow allocated but unused CPU resources to be used by another VM.
- **NO**: Reserve all CPU resources for the VM to which they have been allocated. This option shows higher percentage in hypervisor and cloud environments for VPX CPU usage.
- **DEFAULT**: No.

> **Note**
>
> On all the Citrix ADC VPX platforms, the vCPU usage on the host system is 100 percent. Type the `set ns vpxparam -cpuyield YES` command to override this usage.

If you want to set the cluster nodes to "yield", you must perform the following extra configurations on CCO:

- If a cluster is formed, all the nodes come up with "yield=DEFAULT".
- If a cluster is formed using the nodes that are already set to "yield=YES", then the nodes are added to cluster using the "DEFAULT" yield.

> Note:
>
> If you want to set the cluster nodes to "yield=YES", you can perform suitable configurations only after forming the cluster but not before the cluster is formed.

-masterclockcpu1: You can move the main clock source from CPU0 (management CPU) to CPU1. This parameter has the following options:

- **YES**: Allow VM to move the main clock source from CPU0 to CPU1.
- **NO**: VM uses CPU0 for the main clock source. By default, CPU0 is the main clock source.

- `show ns vpxparam`

  Display the current `vpxparam` settings.

Optimize Citrix ADC VPX performance on VMware ESX, Linux KVM, and Citrix Hypervisors

September 29, 2021

The Citrix ADC VPX performance greatly varies depending on the hypervisor, allocated system resources, and the host configurations. To achieve the desired performance, first follow the recommendations in the VPX data sheet, and then further optimize it using the best practices provided in this document.

Citrix ADC VPX instance on VMware ESX hypervisors

This section contains details of configurable options and settings, and other suggestions that help you achieve optimal performance of Citrix ADC VPX instance on VMware ESX hypervisors.

- Recommended configuration on ESX hosts
- Citrix ADC VPX with E1000 network interfaces
- Citrix ADC VPX with VMXNET3 network interfaces
- Citrix ADC VPX with SR-IOV and PCI passthrough network interfaces

Recommended configuration on ESX hosts

To achieve high performance for VPX with E1000, VMXNET3, SR-IOV, and PCI passthrough network interfaces, follow these recommendations:

- The total number of virtual CPUs (vCPUs) provisioned on the ESX host must be less than or equal to the total number of physical CPUs (pCPUs) on the ESX host.
- Non-uniform Memory Access (NUMA) affinity and CPU affinity must be set for the ESX host to achieve good results.

  – To find the NUMA affinity of a Vmnic, log in to the host locally or remotely, and type:

```
1  #vsish -e get /net/pNics/vmnic7/properties | grep NUMA
2  Device NUMA Node: 0
3  <!--NeedCopy-->
```

  - To set NUMA and vCPU affinity for a VM, see VMware documentation.

Citrix ADC VPX with E1000 network interfaces

Perform the following settings on the VMware ESX host:

- On the VMware ESX host, create two vNICs from one pNIC vSwitch. Multiple vNICs create multiple Rx threads in the ESX host. This increases the Rx throughput of the pNIC interface.
- Enable VLANs on the vSwitch port group level for each vNIC that you have created.
- To increase vNIC transmit (Tx) throughput, use a separate Tx thread in the ESX host per vNIC. Use the following ESX command:
  - For ESX version 5.5:

```
esxcli system settings advanced set -o /Net/NetTxWorldlet -i
<!--NeedCopy-->
```

  - For ESX version 6.0 onwards:

```
esxcli system settings advanced set -o /Net/NetVMTxType -i 1
<!--NeedCopy-->
```

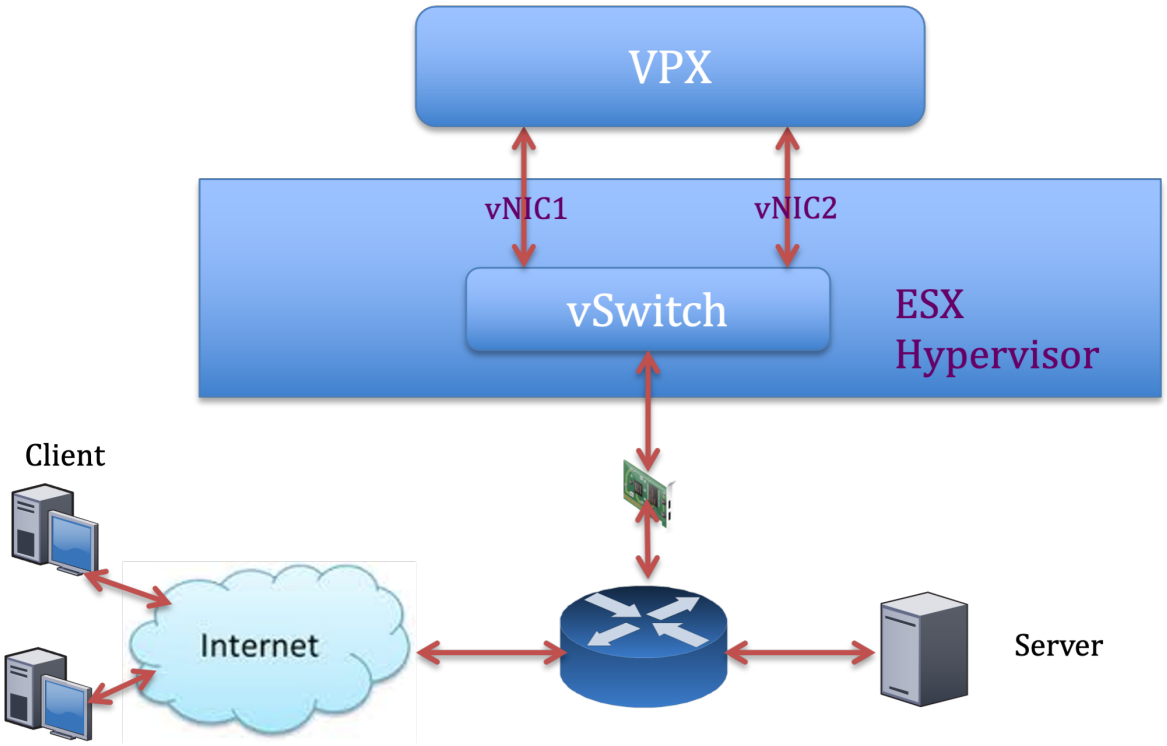
- To further increase the vNIC Tx throughput, use a separate Tx completion thread and Rx threads per device (NIC) queue. Use the following ESX command:

```
esxcli system settings advanced set -o /Net/
   NetNetqRxQueueFeatPairEnable -i 0
<!--NeedCopy-->
```

> Note:
>
> Make sure that you reboot the VMware ESX host to apply the updated settings.

Two vNICs per pNIC deployment

The following is a sample topology and configuration commands for the **Two vNICs per pNIC** model of deployment that delivers better network performance.



Citrix ADC VPX sample configuration:

To achieve the deployment shown in the preceding sample topology, perform the following configuration on the Citrix ADC VPX instance:

- On the client side, bind the SNIP (1.1.1.2) to network interface 1/1 and enable the VLAN tag mode.

```
1  bind vlan 2 -ifnum 1/1  - tagged
2  bind vlan 2 -IPAddress 1.1.1.2 255.255.255.0
3  <!--NeedCopy-->
```

- On the server side, bind the SNIP (2.2.2.2) to network interface 1/1 and enable the VLAN tag mode.

```
1  bind vlan 3 -ifnum 1/2  - tagged
2  bind vlan 3 -IPAddress 2.2.2.2 255.255.255.0
3  <!--NeedCopy-->
```

- Add an HTTP virtual server (1.1.1.100) and bind it to a service (2.2.2.100).

```
1  add lb vserver v1 HTTP 1.1.1.100 80 -persistenceType NONE -
       Listenpolicy None -cltTimeout 180
2  add service s1 2.2.2.100 HTTP 80 -gslb NONE -maxClient 0 -maxReq
       0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
       180 -svrTimeout 360 -CKA NO -TCPB NO -CMP NO
```

```
3  bind lb vserver v1 s1
4  <!--NeedCopy-->
```

> Note:
>
> Make sure that you include the following two entries in the route table:
>
> - 1.1.1.0/24 subnet with gateway pointing to SNIP 1.1.1.2
> - 2.2.2.0/24 subnet with gateway pointing to SNIP 2.2.2.2

Citrix ADC VPX with VMXNET3 network interfaces

To achieve high performance for VPX with VMXNET3 network interfaces, do the following settings on the VMware ESX host:

- Create two vNICs from one pNIC vSwitch. Multiple vNICs create multiple Rx threads in the ESX host. This increases the Rx throughput of the pNIC interface.
- Enable VLANs on the vSwitch port group level for each vNIC that you have created.
- To increase vNIC transmit (Tx) throughput, use a separate Tx thread in the ESX host per vNIC. Use the following ESX commands:
  - For ESX version 5.5:

```
1  esxcli system settings advanced set  -o /Net/NetTxWorldlet  -i
2  <!--NeedCopy-->
```

  - For ESX version 6.0 onwards:

```
1   esxcli system settings advanced set -o /Net/NetVMTxType  -i 1
2   <!--NeedCopy-->
```

On the VMware ESX host, perform the following configuration:

- On the VMware ESX host, create two vNICs from 1 pNIC vSwitch. Multiple vNICs create multiple Tx and Rx threads in the ESX host. This increases the Tx and Rx throughput of the pNIC interface.
- Enable VLANs on the vSwitch port group level for each vNIC that you have created.
- To increase Tx throughput of a vNIC, use a separate Tx completion thread and Rx threads per device (NIC) queue. Use the following command:

```
1  esxcli system settings advanced set -o /Net/
      NetNetqRxQueueFeatPairEnable -i 0
2  <!--NeedCopy-->
```

- Configure a VM to use one transmit thread per vNIC, by adding the following setting to the VM's configuration:

```
ethernetX.ctxPerDev = "1"
<!--NeedCopy-->
```

For more information, see Best Practices for Performance Tuning of Telco and NFV Workloads in vSphere

> Note:
>
> Make sure that you reboot the VMware ESX host to apply the updated settings.

You can configure VMXNET3 as a **Two vNICs per pNIC** deployment. For more information, see Two vNICs per pNIC deployment.

Citrix ADC VPX with SR-IOV and PCI passthrough network interfaces

To achieve high performance for VPX with SR-IOV and PCI passthrough network interfaces, see Recommended configuration on ESX hosts.

Citrix ADC VPX instance on Linux-KVM platform

This section contains details of configurable options and settings, and other suggestions that help you achieve optimal performance of Citrix ADC VPX instance on Linux-KVM platform.

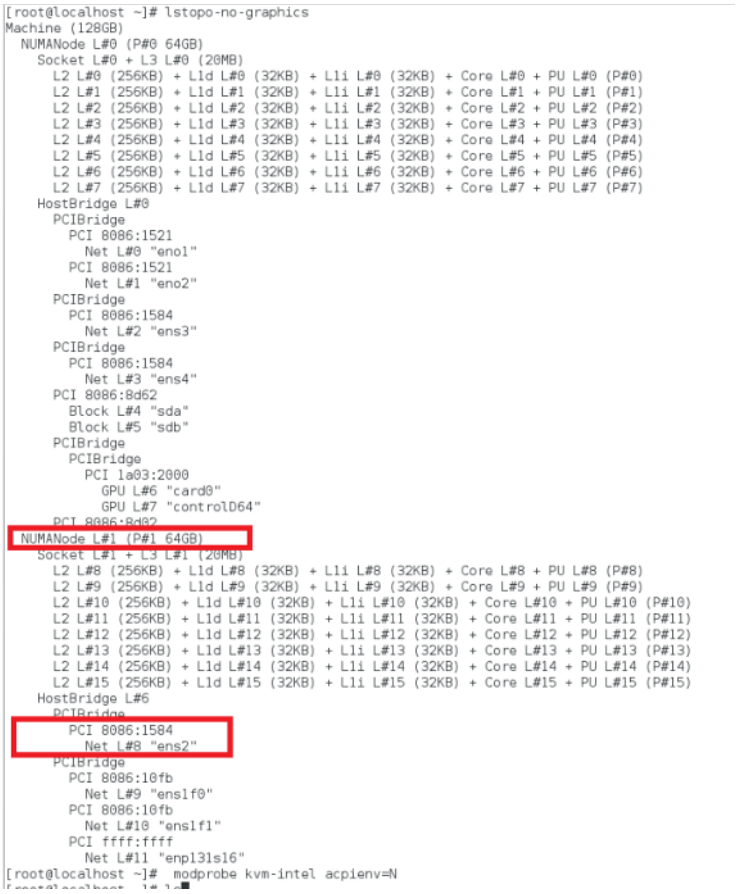
- Performance settings for KVM
- Citrix ADC VPX with PV network interfaces
- Citrix ADC VPX with SR-IOV and Fortville PCIe passthrough network interfaces

Performance settings for KVM

Perform the following settings on the KVM host:

Find the NUMA domain of the NIC using the `lstopo` command:

Make sure that memory for the VPX and the CPU is pinned to the same location.
In the following output, the 10G NIC “ens2” is tied to NUMA domain #1.



Allocate the VPX memory from the NUMA domain.

The `numactl` command indicates the NUMA domain from which the memory is allocated. In the following output, around 10 GB RAM is allocated from NUMA node #0.

```
[root@localhost ~]# numactl --hardware
available: 2 nodes (0-1)
node 0 cpus: 0 1 2 3 4 5 6 7
node 0 size: 65429 MB
node 0 free: 55854 MB
node 1 cpus: 8 9 10 11 12 13 14 15
node 1 size: 65536 MB
node 1 free: 52388 MB
node distances:
node   0   1
  0:  10  21
  1:  21  10
[root@localhost ~]#
```

To change the NUMA node mapping, follow these steps.

1. Edit the .xml of the VPX on the host.

```
1 /etc/libvirt/qemu/<VPX_name>.xml
2 <!--NeedCopy-->
```

2. Add the following tag:

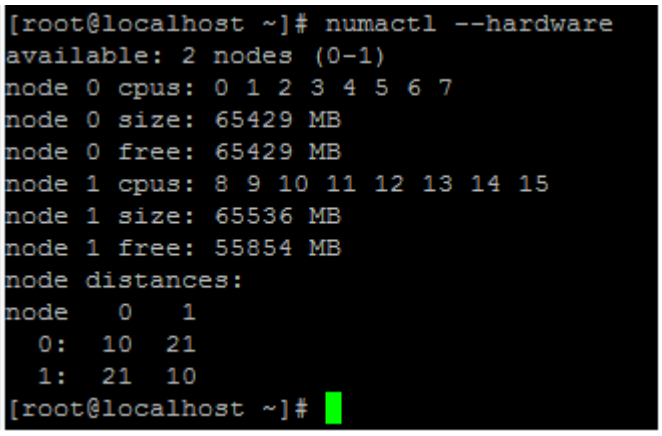
```
<numatune>
<memory mode="strict" nodeset="1"/>    This is the NUMA domain
   name
</numatune>
<!--NeedCopy-->
```

3. Shut down the VPX.
4. Run the following command:

```
virsh define /etc/libvirt/qemu/<VPX_name>.xml
<!--NeedCopy-->
```

   This command updates the configuration information for the VM with the NUMA node mappings.

5. Power on the VPX. Then check the `numactl -hardware` command output on the host to see the updated memory allocations for the VPX.



Pin vCPUs of VPX to physical cores.

- To view the vCPU to pCPU mappings of a VPX, type the following command

```
virsh vcpupin <VPX name>
<!--NeedCopy-->
```

```
root@localhost qemu]#  virsh vcpupin NS-VPX-DVR
CPU: CPU Affinity
----------------------------------
  0: 8
  1: 9
  2: 10
  3: 11
```

The vCPUs 0–4 are mapped to physical cores 8–11.

- To view the current pCPU usage, type the following command:

```
mpstat -P ALL 5
<!--NeedCopy-->
```

```
[root@localhost qemu]# mpstat -P ALL 5
Linux 3.10.0-123.el7.x86_64 (localhost.localdomain)     05/17/2016      _x86_64_        (16 CPU)

02:26:20 PM  CPU    %usr   %nice    %sys %iowait    %irq   %soft  %steal  %guest  %gnice   %idle
02:26:25 PM  all    0.24    0.00    1.67    0.00    0.00    0.00    0.00   17.32    0.00   80.78
02:26:25 PM    0    0.20    0.00    1.00    0.00    0.00    0.00    0.00    0.00    0.00   98.80
02:26:25 PM    1    0.20    0.00    0.20    0.00    0.00    0.00    0.00    0.00    0.00   99.60
02:26:25 PM    2    0.20    0.00    0.40    0.00    0.00    0.00    0.00    0.00    0.00   99.40
02:26:25 PM    3    0.00    0.00    0.20    0.00    0.00    0.00    0.00    0.00    0.00   99.80
02:26:25 PM    4    0.20    0.00    0.20    0.00    0.00    0.00    0.00    0.00    0.00   99.60
02:26:25 PM    5    0.60    0.00    0.20    0.00    0.00    0.00    0.00    0.00    0.00   99.20
02:26:25 PM    6    0.40    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00   99.60
02:26:25 PM    7    1.62    0.00    1.42    0.00    0.00    0.00    0.00    0.00    0.00   96.96
02:26:25 PM    8    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00  100.00
02:26:25 PM    9    0.00    0.00    7.60    0.00    0.00    0.00    0.00   92.40    0.00    0.00
02:26:25 PM   10    0.20    0.00    7.00    0.00    0.00    0.00    0.00   92.80    0.00    0.00
02:26:25 PM   11    0.00    0.00    8.60    0.00    0.00    0.00    0.00   91.40    0.00    0.00
02:26:25 PM   12    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00  100.00
02:26:25 PM   13    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00  100.00
02:26:25 PM   14    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00  100.00
02:26:25 PM   15    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00  100.00
```

In this output, 8 is management CPU, and 9–11 are packet engines.

- To change the vCPU to pCPU pinning, there are two options.
  - Change it at runtime after the VPX boots up using the following command:

```
virsh vcpupin <VPX name> <vCPU id>  <pCPU number>
virsh vcpupin NetScaler-VPX-XML 0 8
virsh vcpupin NetScaler-VPX-XML 1 9
virsh vcpupin NetScaler-VPX-XML 2 10
virsh vcpupin NetScaler-VPX-XML 3 11
<!--NeedCopy-->
```

  - To make static changes to the VPX, edit the `.xml` file as before with the following tags:
    1. Edit the .xml file of the VPX on the host

```
/etc/libvirt/qemu/<VPX_name>.xml
<!--NeedCopy-->
```

2. Add the following tag:

```
<vcpu placement='static' cpuset='8-11'>4</vcpu>
    <cputune>
        <vcpupin vcpu='0' cpuset='8'/>
        <vcpupin vcpu='1' cpuset='9'/>
        <vcpupin vcpu='2' cpuset='10'/>
        <vcpupin vcpu='3' cpuset='11'/>
    </cputune>
<!--NeedCopy-->
```

3. Shut down the VPX.
4. Update the configuration information for the VM with the NUMA node mappings using the following command:

```
virsh define /etc/libvirt/qemu/ <VPX_name>.xml
<!--NeedCopy-->
```

5. Power on the VPX. Then check the `virsh vcpupin <VPX name>` command output on the host to see the updated CPU pinning.

Eliminate host interrupt overhead.

- Detect VM_EXITS using the `kvm_stat` command.

  At the hypervisor level, host interrupts are mapped to the same pCPUs on which the vCPUs of the VPX are pinned. This might cause vCPUs on the VPX to get kicked out periodically.

  To find the VM exits done by VMs running the host, use the `kvm_stat` command.

```
[root@localhost ~]# kvm_stat -1  | grep EXTERNAL
kvm_exit(EXTERNAL_INTERRUPT)  1728349 27738
[root@localhost ~]#
<!--NeedCopy-->
```

  A higher value in the order of 1+M indicates an issue.

  If a single VM is present, the expected value is 30–100 K. Anything more than that can indicate that there are one or more host interrupt vectors mapped to the same pCPU.

- Detect host interrupts and migrate host interrupts.

  When you run the `concatenate` command for the “/proc/interrupts” file, it displays all the host interrupt mappings. If one or more active IRQs map to the same pCPU, its corresponding counter increments.

  Move any interrupts that overlap with your Citrix ADC VPX’s pCPUs to unused pCPUs:

```
echo 0000000f > /proc/irq/55/smp_affinity
0000000f - - > it is a bitmap, LSBs indicates that IRQ 55 can
   only be scheduled on pCPUs 0 - 3
<!--NeedCopy-->
```

- Disable IRQ balance.

  Disable IRQ balance daemon, so that no rescheduling happens on the fly.

```
service irqbalance stop
service irqbalance show - To check the status
service irqbalance start - Enable if needed
<!--NeedCopy-->
```

  Make sure you run the `kvm_stat` command to ensure that there are not many counters.

Citrix ADC VPX with PV network interfaces

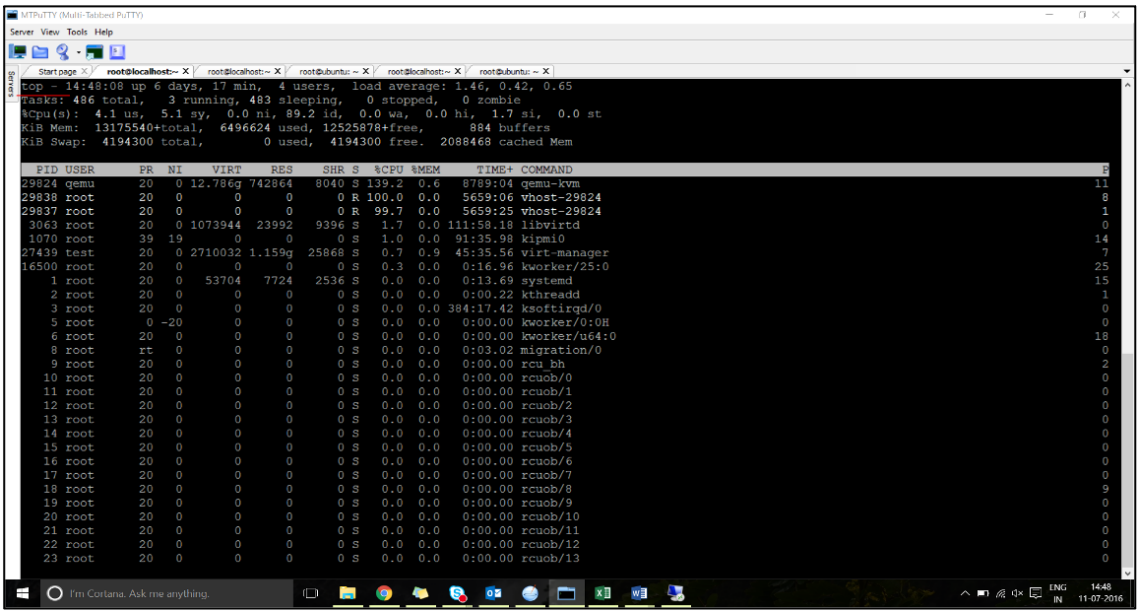
You can configure para-virtualization (PV), SR-IOV, and PCIe passthrough network interfaces as a **Two vNICs per pNIC** deployment. For more information, see Two vNICs per pNIC deployment.

For optimal performance of PV (virtio) interfaces, follow these steps:

- Identify the NUMA domain to which the PCIe slot/NIC is tied to.
- The Memory and vCPU for the VPX must be pinned to the same NUMA domain.
- Vhost thread must be bound to the CPUs in the same NUMA domain.

Bind the virtual host threads to the corresponding CPUs:

1. Once the traffic is started, run the `top` command on the host.



2. Identify the virtual host process (named as vhost-<pid-of-qemu>) affinity.
3. Bind the vHost processes to the physical cores in the NUMA domain identified earlier using the following command:

```
taskset -pc <core-id> <process-id>
<!--NeedCopy-->
```

Example:

```
taskset -pc 12 29838
<!--NeedCopy-->
```

4. The processor cores corresponding to the NUMA domain can be identified with the following command:

```
[root@localhost ~]# virsh capabilities | grep cpu
<cpu>
    </cpu>
        <cpus num='8'>
            <cpu id='0' socket_id='0' core_id='0' siblings='0'/>
            <cpu id='1' socket_id='0' core_id='1' siblings='1'/>
            <cpu id='2' socket_id='0' core_id='2' siblings='2'/>
            <cpu id='3' socket_id='0' core_id='3' siblings='3'/>
            <cpu id='4' socket_id='0' core_id='4' siblings='4'/>
            <cpu id='5' socket_id='0' core_id='5' siblings='5'/>
            <cpu id='6' socket_id='0' core_id='6' siblings='6'/>
            <cpu id='7' socket_id='0' core_id='7' siblings='7'/>
        </cpus>

        <cpus num='8'>
        <cpu id='8' socket_id='1' core_id='0' siblings='8'/>
        <cpu id='9' socket_id='1' core_id='1' siblings='9'/>
        <cpu id='10' socket_id='1' core_id='2' siblings='10'/>
        <cpu id='11' socket_id='1' core_id='3' siblings='11'/>
        <cpu id='12' socket_id='1' core_id='4' siblings='12'/>
        <cpu id='13' socket_id='1' core_id='5' siblings='13'/>
        <cpu id='14' socket_id='1' core_id='6' siblings='14'/>
        <cpu id='15' socket_id='1' core_id='7' siblings='15'/>
        </cpus>

    <cpuselection/>
    <cpuselection/>

<!--NeedCopy-->
```

Bind the QEMU process to the corresponding physical core:

1. Identify the physical cores on which the QEMU process is running. For more information, see the preceding output.
2. Bind the QEMU process to the same physical cores to which you bind the vCPUs, using the following command:

```
taskset -pc 8-11 29824
<!--NeedCopy-->
```

Citrix ADC VPX with SR-IOV and Fortville PCIe passthrough network interfaces

For optimal performance of the SR-IOV and Fortville PCIe passthrough network interfaces, follow these steps:

- Identify the NUMA domain to which the PCIe slot/NIC is tied to.
- The Memory and vCPU for the VPX must be pinned to the same NUMA domain.

Sample VPX XML file for vCPU and memory pinning for Linux KVM:

```
    <domain type='kvm'>
        <name>NetScaler-VPX</name>
        <uuid>138f7782-1cd3-484b-8b6d-7604f35b14f4</uuid>
        <memory unit='KiB'>8097152</memory>
        <currentMemory unit='KiB'>8097152</currentMemory>
        <vcpu placement='static'>4</vcpu>

    <cputune>
        <vcpupin vcpu='0' cpuset='8'/>
        <vcpupin vcpu='1' cpuset='9'/>
        <vcpupin vcpu='2' cpuset='10'/>
        <vcpupin vcpu='3' cpuset='11'/>
    </cputune>

    <numatune>
    <memory mode='strict' nodeset='1'/>
    </numatune>

    </domain>
<!--NeedCopy-->
```

Citrix ADC VPX instance on Citrix Hypervisors

This section contains details of configurable options and settings, and other suggestions that help you achieve optimal performance of Citrix ADC VPX instance on Citrix Hypervisors.

- Performance settings for Citrix Hypervisors
- Citrix ADC VPX with SR-IOV network interfaces
- Citrix ADC VPX with para-virtualized interfaces

Performance settings for Citrix Hypervisors

Find the NUMA domain of the NIC using the “xl” command:

```
xl info -n
<!--NeedCopy-->
```

Pin vCPUs of VPX to physical cores.

```
xl vcpu-pin <Netsclaer VM Name>  <vCPU id>  <physical CPU id>
<!--NeedCopy-->
```

Check binding of vCPUs.

```
xl vcpu-list
<!--NeedCopy-->
```

Allocate more than 8 vCPUs to Citrix ADC VMs.

For configuring more than 8 vCPUs, run the following commands from the Citrix Hypervisor console:

```
xe vm-param-set uuid=your_vms_uuid VCPUs-max=16
xe vm-param-set uuid=your_vms_uuid VCPUs-at-startup=16
<!--NeedCopy-->
```

Citrix ADC VPX with SR-IOV network interfaces

For optimal performance of the SR-IOV network interfaces, follow these steps:

- Identify the NUMA domain to which the PCIe slot or NIC is tied to.
- Pin the Memory and vCPU for the VPX to the same NUMA domain.
- Bind the Domain-0 vCPU to the remaining CPU.

Citrix ADC VPX with para-virtualized interfaces

For optimal performance, two vNICs per pNIC and one vNIC per pNIC configurations are advised, as in other PV environments.

To achieve optimal performance of para-virtualized (netfront) interfaces, follow these steps:

- Identify the NUMA domain to which the PCIe slot or NIC is tied to.
- Pin the memory and vCPU for the VPX to the same NUMA domain.
- Bind the Domain-0 vCPU to the remaining CPU of the same NUMA domain.
- Pin host Rx/Tx threads of vNIC to Domain-0 vCPUs.

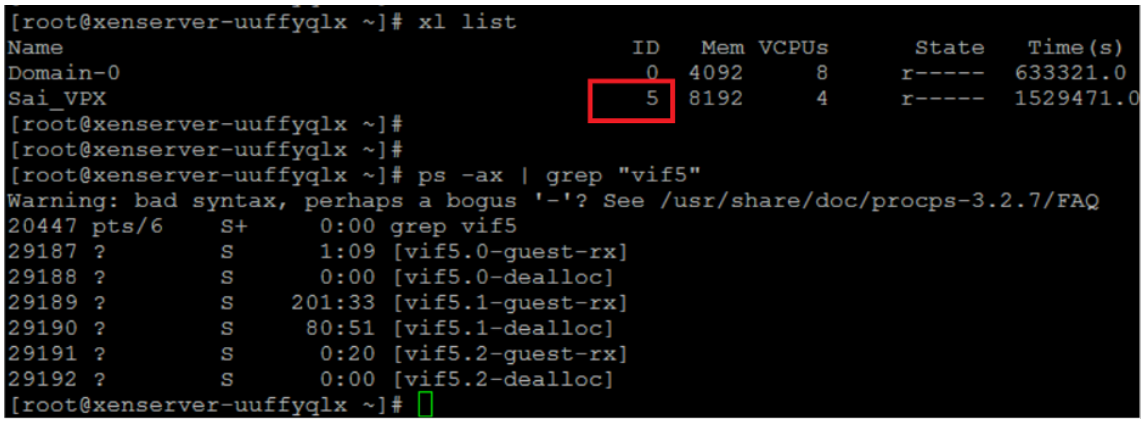
Pin host threads to Domain-0 vCPUs:

1. Find Xen-ID of the VPX by using the `xl list` command on the Citrix Hypervisor host shell.
2. Identify host threads by using the following command:

```
ps -ax | grep vif <Xen-ID>
<!--NeedCopy-->
```

   In the following example, these values indicate:

   - **vif5.0** - The threads for first interface allocated to VPX in XenCenter (management interface).
   - **vif5.1** - The threads for second interface assigned to VPX and so on.



3. Pin the threads to Domain-0 vCPUs using the following command:

```
taskset -pc <core-id> <process-id>
<!--NeedCopy-->
```

   Example:

```
taskset -pc 1 29189
<!--NeedCopy-->
```

Apply Citrix ADC VPX configurations at the first boot of the Citrix ADC appliance in cloud

September 17, 2021

You can apply the Citrix ADC VPX configurations during the first boot of the Citrix ADC appliance in a cloud environment. This stage is addressed as the **preboot** stage in this document. Therefore in certain cases like ADC pooled licensing, a specific VPX instance is brought up in much lesser time. This feature is available in Microsoft Azure, Google Cloud platform, and AWS clouds.

What is user data

When you provision a VPX instance in a cloud environment, you have the option of passing user data to the instance. The user data allows you to perform common automated configuration tasks, customize the startup behaviors of instances, and run scripts after the instance starts. At the first boot, the Citrix ADC VPX instance performs the following tasks:

- Reads the user data.
- Interprets the configuration provided in user data.
- Applies the newly added configuration as it boots up.

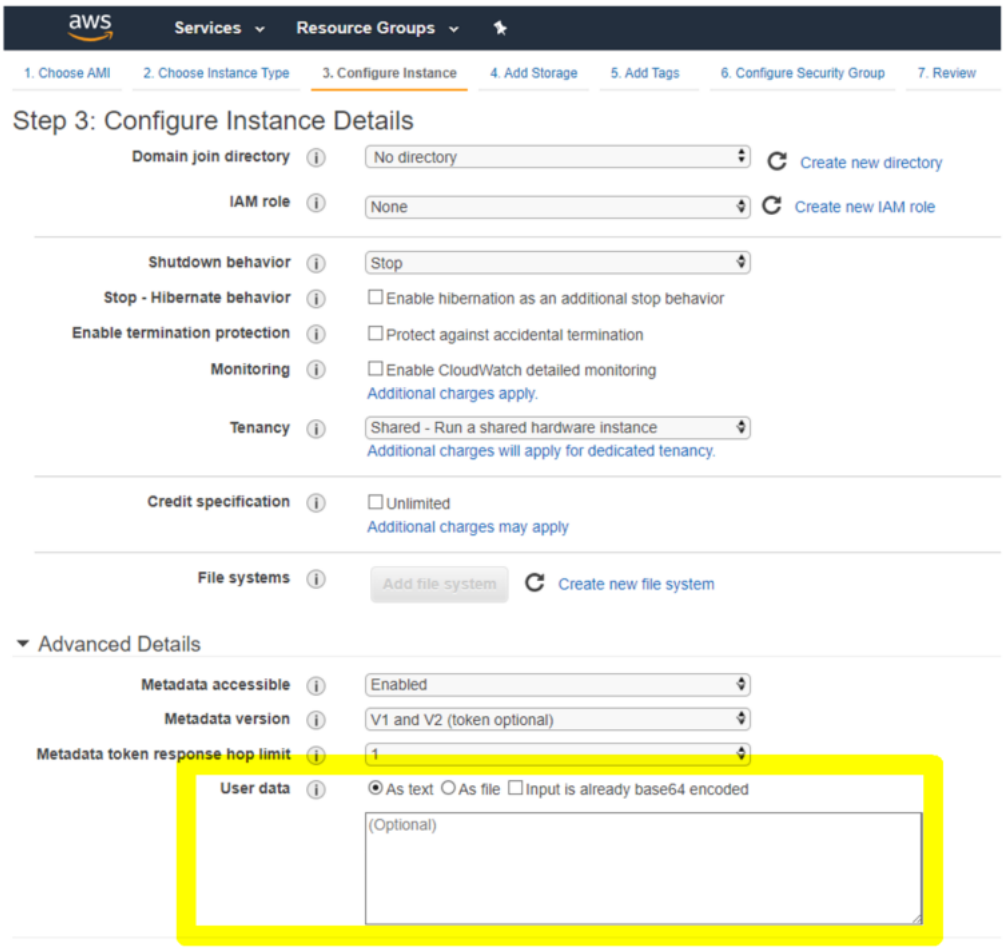
How to provide preboot user data in cloud instance

You can provide preboot user data to the cloud instance in XML format. Different clouds have different interfaces for providing user data.

Provide preboot user data using the AWS console

When you provision a Citrix ADC VPX instance using the AWS console, navigate to **Configure Instance Details > Advanced Details**, and provide the preboot user data configuration in the **User data** field.

For detailed instructions on each of the steps, see Deploy a Citrix ADC VPX instance on AWS by using the AWS web console.
For more information, see AWS documentation on Launching an instance.



Provide preboot user data using AWS CLI

Type the following command in the AWS CLI:

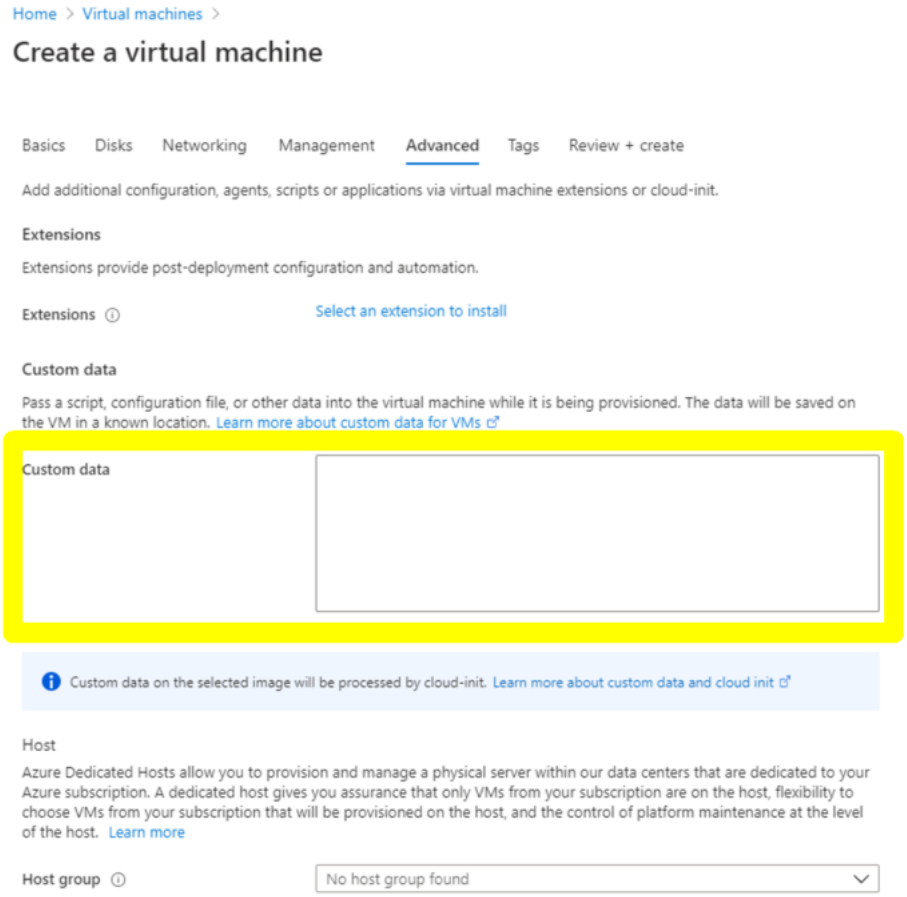
```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type t2.micro \
    --count 1 \
    --subnet-id subnet-08fc749671b2d077c \
    --key-name MyKeyPair \
    --security-group-ids sg-0b0384b66d7d692f9 \
    --user-data file://my_script.txt
<!--NeedCopy-->
```

For more information, see AWS documentation on Running instances.

For more information, see AWS documentation on Using instance user data

Provide preboot user data using the Azure console

When you provision a Citrix ADC VPX instance using Azure console, navigate to **Create a virtual machine > Advanced** tab. In the **Custom data** field, provide preboot user data configuration.



Provide preboot user data using the Azure CLI

Type the following command in the Azure CLI:

```
az vm create \
  --resource-group myResourceGroup \
  --name MyVm \
  --image debian \
  --custom-data MyCloudInitScript.txt \
<!--NeedCopy-->
```

Example:

```
az vm create --resource-group MyResourceGroup -name MyVm --image debian
    --custom-data MyCloudInitScript.txt
<!--NeedCopy-->
```

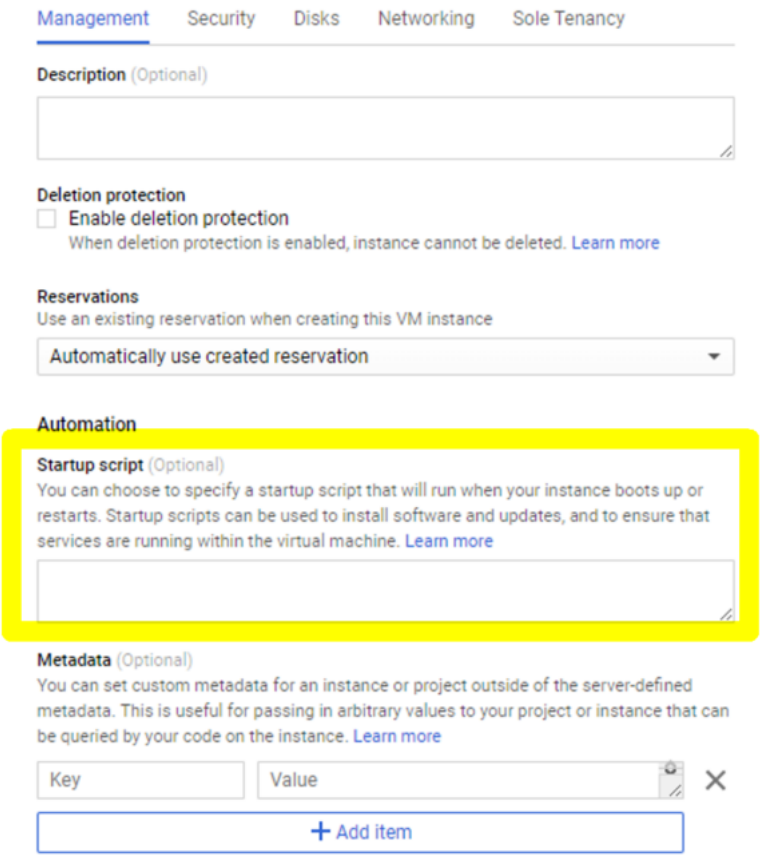
You can pass your custom data or preboot configuration as a file to "–custom-data" parameter. In this example, the file name is **MyCloudInitScript.txt**.

For more information, see Azure CLI documentation.

Provide preboot user data using the GCP console

When you provision a Citrix ADC VPX instance using GCP console, fill in the properties of instance. Expand **Management, security, disks, networking, sole tenancy**. Navigate to the **Management** tab. In the **Automation** section, provide preboot user data configuration in the **Startup Script** field.

For detailed information on creating the VPX instance using GCP, see Deploy a Citrix ADC VPX instance on Google Cloud Platform.



Provide preboot user data using the gcloud CLI

Type the following command in the GCP CLI:

```
gcloud compute instances create INSTANCE_NAMES --metadata-from-file=
   startup-script=LOCAL_FILE_PATH
<!--NeedCopy-->
```

metadata-from-file - Reads the value or user data from a file stored at the .

For more information, see gcloud CLI documentation

Preboot user data format

The preboot user data must be provided to the cloud instance in XML format. The Citrix ADC preboot user data that you provide through the cloud infrastructure during boot can comprise the following four sections:

- Citrix ADC configuration represented with the <NS-CONFIG> tag.
- Custom bootstrapping the Citrix ADC represented with the <NS-BOOTSTRAP> tag.
- Storing user-scripts in Citrix ADC represented with the <NS-SCRIPTS> tag.
- Pooled licensing configuration represented with the <NS-LICENSE-CONFIG> tag.

You can provide the preceding four sections in any order within the ADC preboot configuration. Ensure to strictly follow the formatting shown in the following sections while providing the preboot user data.

> Note:
>
> The entire preboot user data configuration must be enclosed in the <NS-PRE-BOOT-CONFIG> tag as shown in the following examples.

Example 1:

```
<NS-PRE-BOOT-CONFIG>
     <NS-CONFIG>          </NS-CONFIG>
     <NS-BOOTSTRAP>       </NS-BOOTSTRAP>
     <NS-SCRIPTS>         </NS-SCRIPTS>
     <NS-LICENSE-CONFIG>  </NS-LICENSE-CONFIG>
</NS-PRE-BOOT-CONFIG>
<!--NeedCopy-->
```

Example 2:

```
<NS-PRE-BOOT-CONFIG>
    <NS-LICENSE-CONFIG> </NS-LICENSE-CONFIG>
    <NS-SCRIPTS>        </NS-SCRIPTS>
    <NS-BOOTSTRAP>      </NS-BOOTSTRAP>
    <NS-CONFIG>         </NS-CONFIG>
</NS-PRE-BOOT-CONFIG>
```

```
<!--NeedCopy-->
```

Use the <NS-CONFIG> tag to provide the specific Citrix ADC VPX configurations that needs to be applied to the VPX instance at the preboot stage.

> NOTE:
>
> The <NS-CONFIG> section must have valid ADC CLI commands. The CLIs are not verified for the syntactic errors or format.

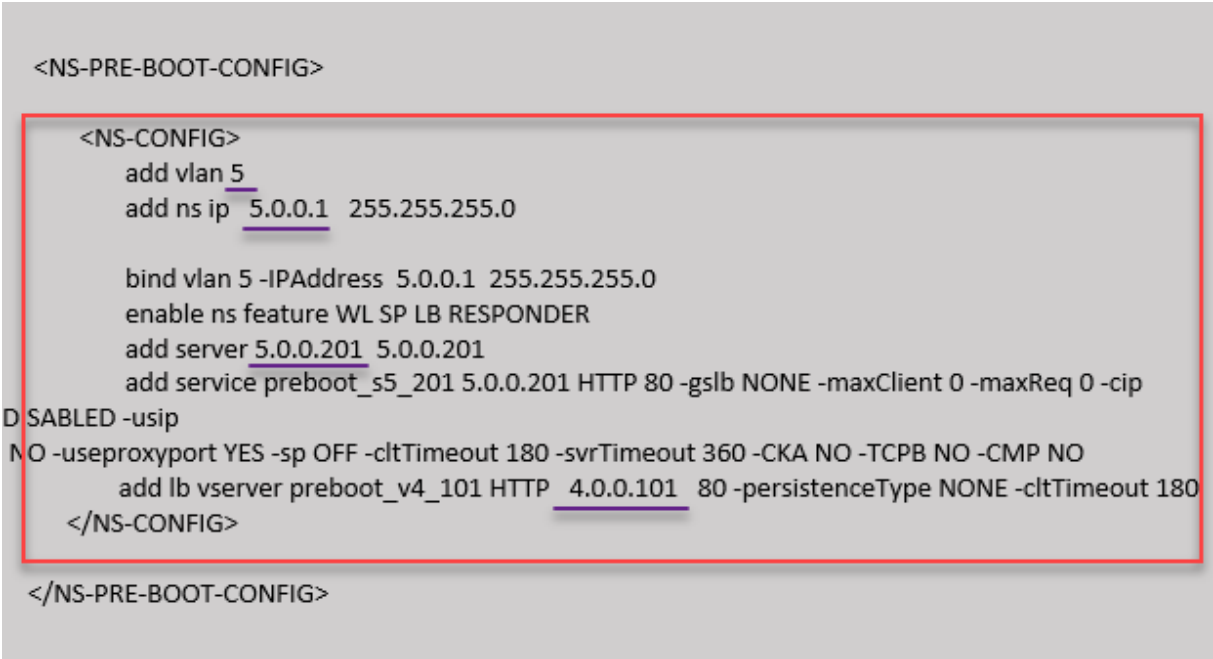
Citrix ADC configurations

Use the <NS-CONFIG> tag to provide the specific Citrix ADC VPX configurations that needs to be applied to the VPX instance at the preboot stage.

> NOTE:
>
> The <NS-CONFIG> section must have valid ADC CLI commands. The CLIs are not verified for the syntactic errors or format.

Example:

In the following example, the <NS-CONFIG> section has the details of the configurations. A VLAN of ID '5' is configured and bound to the SNIP (5.0.0.1). A load balancing virtual server (4.0.0.101) is also configured.

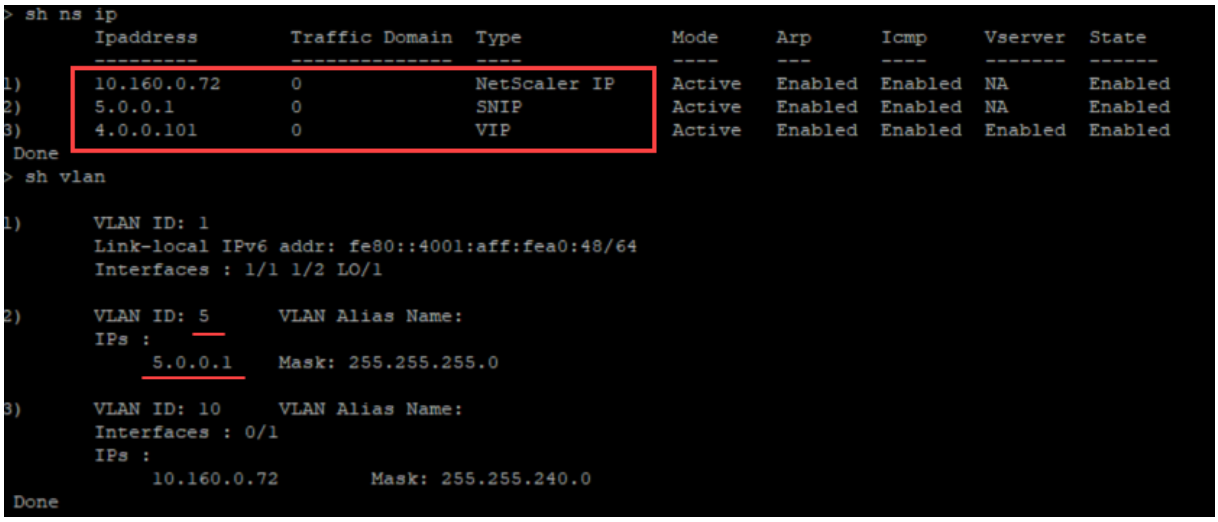


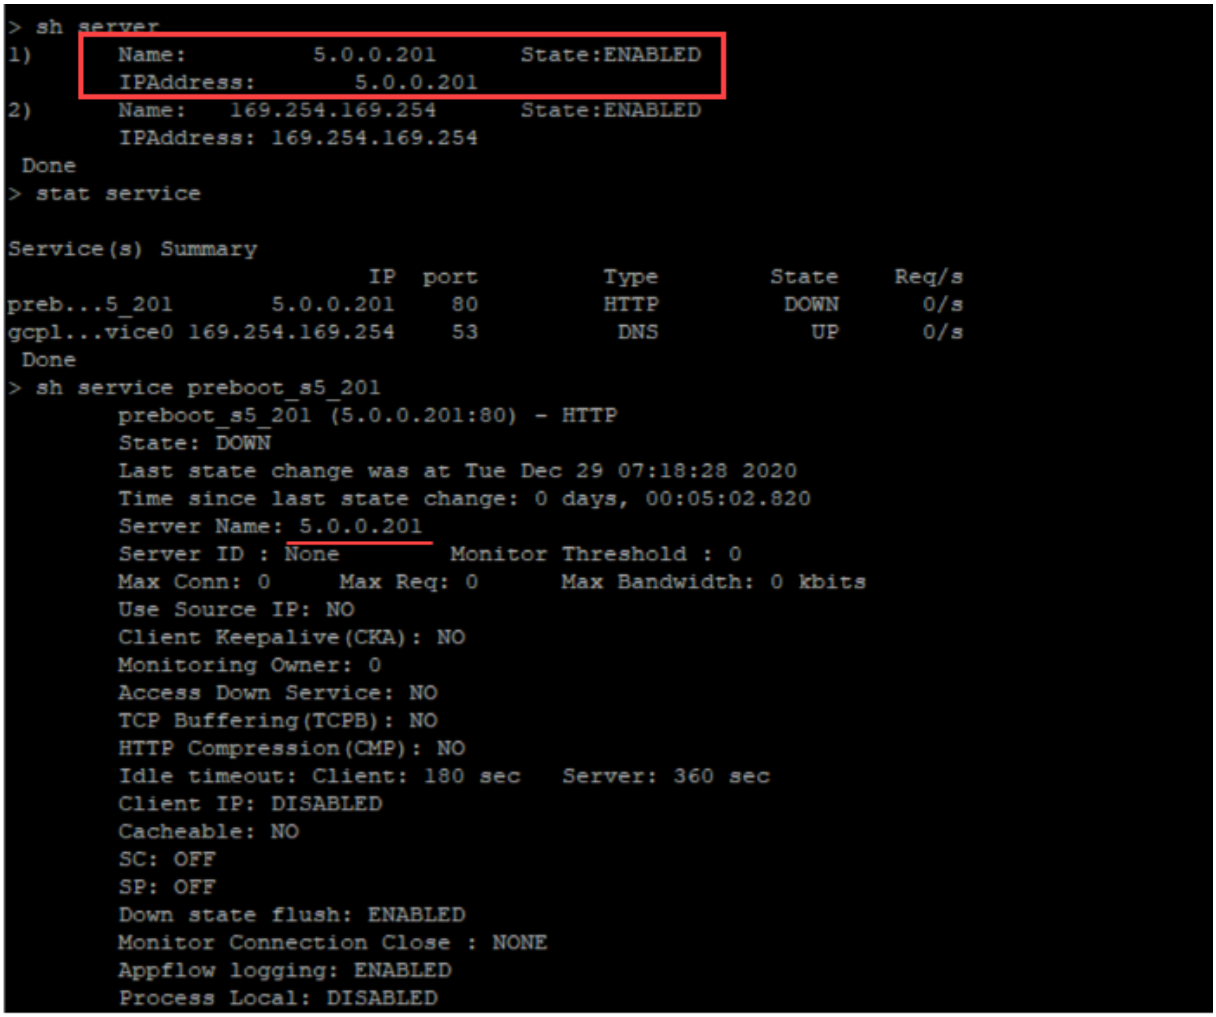
You can copy the configuration shown in the preceding screenshot from here:

```
<NS-PRE-BOOT-CONFIG>
```

```
      <NS-CONFIG>
          add vlan 5
          add ns ip 5.0.0.1 255.255.255.0
          bind vlan 5 -IPAddress 5.0.0.1 255.255.255.0
          enable ns feature WL SP LB RESPONDER
          add server 5.0.0.201 5.0.0.201
          add service preboot_s5_201 5.0.0.201 HTTP 80 -gslb NONE -
             maxClient 0 -maxReq 0 -cip DISABLED -usip
   NO -useproxyport YES -sp OFF -cltTimeout 180 -svrTimeout 360 -CKA NO -
      TCPB NO -CMP NO
          add lb vserver preboot_v4_101 HTTP 4.0.0.101 80 -
             persistenceType NONE -cltTimeout 180
      </NS-CONFIG>
</NS-PRE-BOOT-CONFIG>
<!--NeedCopy-->
```

The Citrix ADC VPX instance comes up with the configuration applied in the <NS-CONFIG> section as shown in the following illustrations.





User scripts

Use the <NS-SCRIPTS> tag to provide any script that must be stored and ran in Citrix ADC VPX instance.

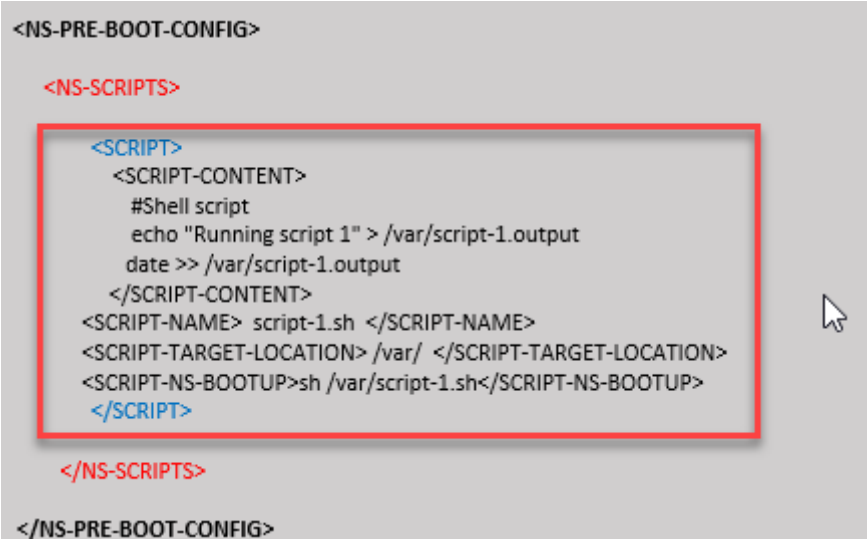
You can include many scripts within the <NS-SCRIPTS> tag. Each script must be included within the <SCRIPT> tag.
Each <SCRIPT> section corresponds to one script and contains all the details of the script using the following sub tags.

- **<SCRIPT-NAME>:** Indicates the name of the script file that must be stored.
- **<SCRIPT-CONTENT>:** Indicates the content of the file that must be stored.
- **<SCRIPT-TARGET-LOCATION>:** Indicates the designated target location where this file must be stored. If the target location is not provided, by default, the file, or script is saved in the "/nsconfig" directory.
- **<SCRIPT-NS-BOOTUP>:** Specify the commands that you use to run the script.

- If you use the <SCRIPT-NS-BOOTUP> section, the commands provided in the section are stored in "/nsconfig/nsafter.sh", and the commands are run after the packet engine boots up as part of "nsafter.sh" execution.
- If you do not use the <SCRIPT-NS-BOOTUP> section, the script file is stored in the target location that you specify.

Example 1:

In this example, the <NS-SCRIPTS> tag contains details of only one script: script-1.sh. The "script-1.sh" script is saved at the "/var" directory. The script is populated with the specified contents, and is run with the "sh /var/script-1.sh" command after packet engine boots up.



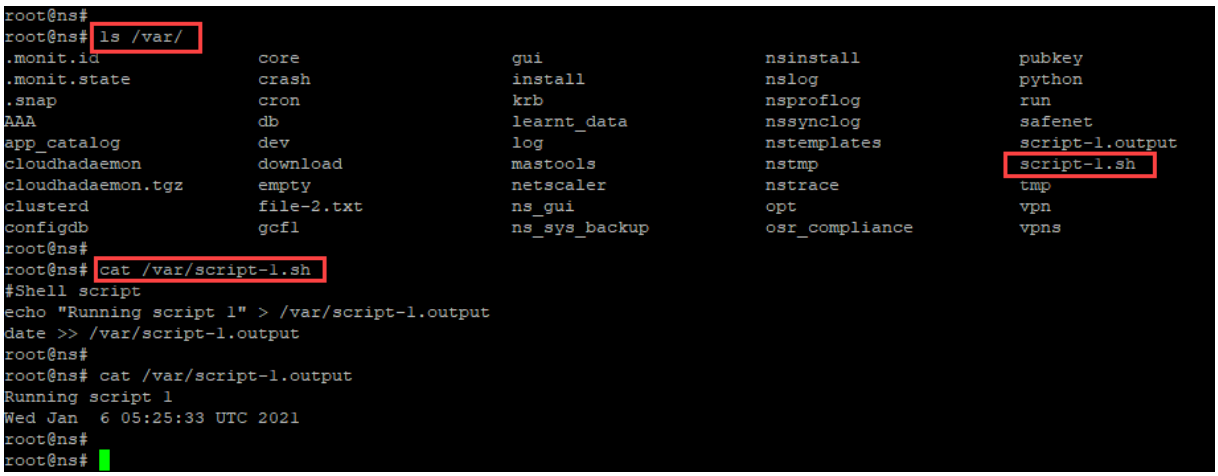
You can copy the configuration shown in the preceding screenshot from here:

```
<NS-PRE-BOOT-CONFIG>
    <NS-SCRIPTS>
    <SCRIPT>
            <SCRIPT-CONTENT>
                #Shell script
                echo "Running script 1" > /var/script-1.output
                date >> /var/script-1.output
            </SCRIPT-CONTENT>

                <SCRIPT-NAME> script-1.sh </SCRIPT-NAME>
                <SCRIPT-TARGET-LOCATION> /var/ </SCRIPT-TARGET-LOCATION
                    >
                <SCRIPT-NS-BOOTUP>sh /var/script-1.sh</SCRIPT-NS-BOOTUP
                    >
        </SCRIPT>
    </NS-SCRIPTS>
</NS-PRE-BOOT-CONFIG>
```

```
<!--NeedCopy-->
```

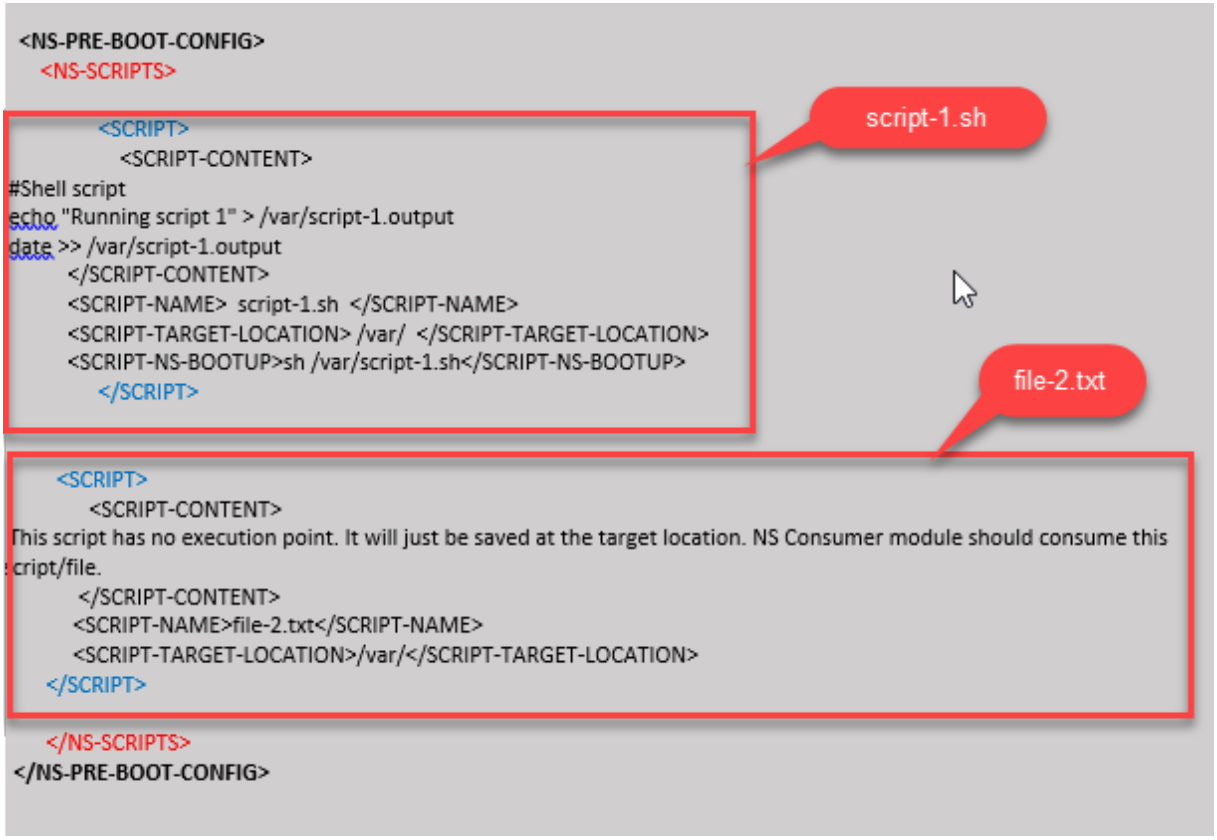
In the following snapshot, you can verify that “script-1.sh” script is saved in the “/var/” directory. The “Script-1.sh” script is run, and the output file is created appropriately.



Example 2:

In the following example, the <NS-SCRIPTS> tag contains details of two scripts.

- The first script is saved as “script-1.sh” at the “/var” directory. The script is populated with the specified contents, and is run with command “sh /var/script-1.sh” after packet engine boots up.
- The second script is saved as “file-2.txt” at the “/var” directory. This file is populated with the specified contents. But it is not run because the bootup execution command <SCRIPT-NS-BOOTUP> is not provided.



You can copy the configuration shown in the preceding screenshot from here:

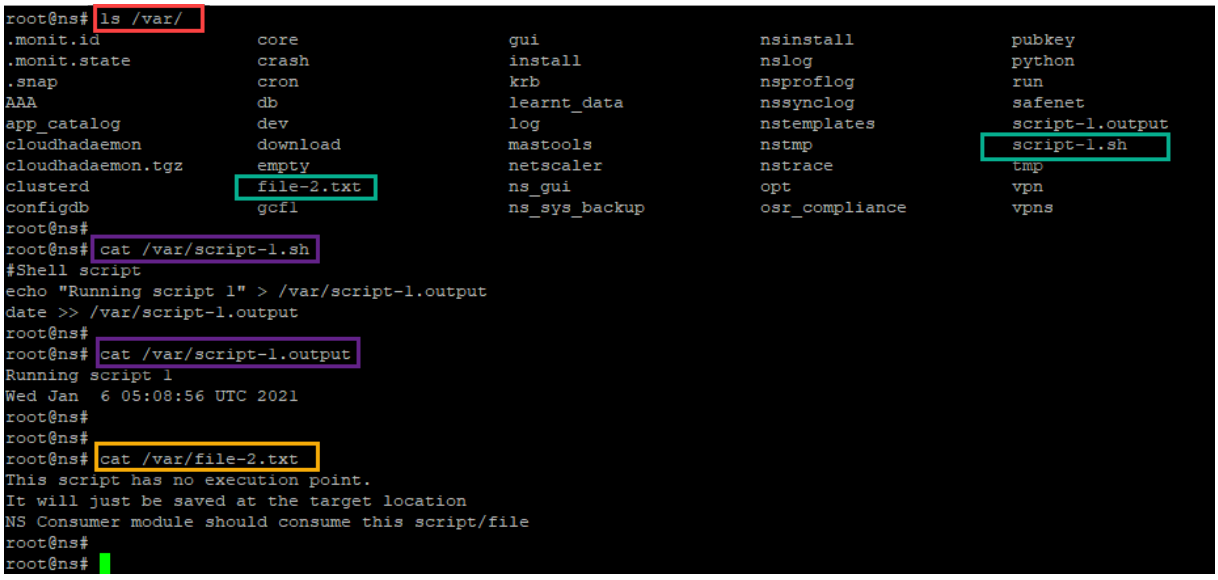
```
<NS-PRE-BOOT-CONFIG>
    <NS-SCRIPTS>
        <SCRIPT>
            <SCRIPT-CONTENT>
               #Shell script
               echo "Running script 1" > /var/script-1.output
               date >> /var/script-1.output
            </SCRIPT-CONTENT>

            <SCRIPT-NAME>  script-1.sh  </SCRIPT-NAME>
            <SCRIPT-TARGET-LOCATION> /var/  </SCRIPT-TARGET-LOCATION>
            <SCRIPT-NS-BOOTUP>sh /var/script-1.sh</SCRIPT-NS-BOOTUP>
            </SCRIPT>

        <SCRIPT>
            <SCRIPT-CONTENT>
                This script has no execution point.
                It will just be saved at the target location
                NS Consumer module should consume this script/file
            </SCRIPT-CONTENT>
```

```
            <SCRIPT-NAME>file-2.txt</SCRIPT-NAME>
            <SCRIPT-TARGET-LOCATION>/var/</SCRIPT-TARGET-LOCATION>
        </SCRIPT>
    </NS-SCRIPTS>
</NS-PRE-BOOT-CONFIG>
<!--NeedCopy-->
```

In the following snapshot, you can verify that script-1.sh and file-2.txt are created in the "/var/" directory. The Script-1.sh is run, and the output file is created appropriately.



Licensing

Use the <NS-LICENSE-CONFIG> tag to apply Citrix ADC pooled licensing while booting up the VPX instance. Use the <LICENSE-COMMANDS> tag within <NS-LICENSE-CONFIG> section to provide the pooled license commands. These commands must be syntactically valid.

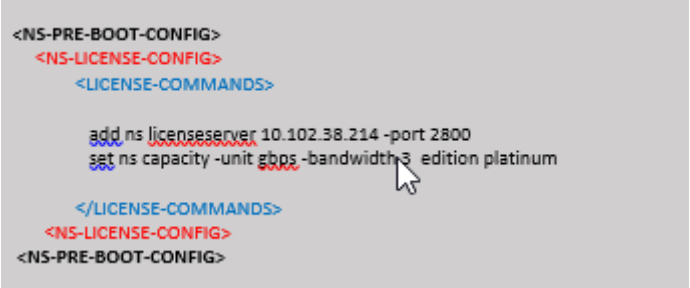
You can specify the pooled licensing details such as, license type, capacity, and license server in the <LICENSE-COMMANDS> section using the standard pooled licensing commands. For more information, see Configure Citrix ADC pooled capacity licensing.

After applying the <NS-LICENSE-CONFIG>, the VPX comes up with the requested edition upon boot, and VPX tries to check out the configured licenses from the license server.

- If the license checkout is successful, the configured bandwidth is applied to VPX.
- If the license checkout fails, the license is not retrieved from license server within 10–12 minutes approximately. As a result, the system reboots and enters an unlicensed state.

Example:

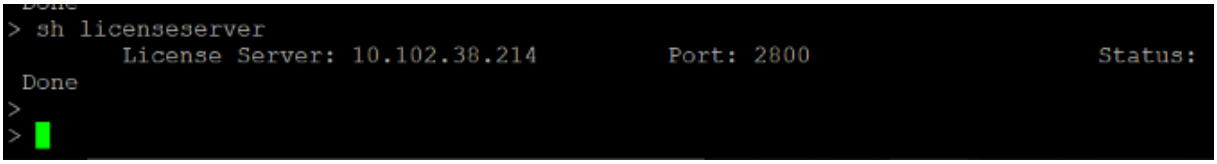
In the following example, after applying the <NS-LICENSE-CONFIG>, the VPX comes up with the Premium edition upon boot, and VPX tries to check out the configured licenses from the license server (10.102.38.214).



You can copy the configuration shown in the preceding screenshot from here:

```
<NS-PRE-BOOT-CONFIG>
   <NS-LICENSE-CONFIG>
        <LICENSE-COMMANDS>
            add ns licenseserver 10.102.38.214 -port 2800
            set ns capacity -unit gbps -bandwidth 3  edition platinum
        </LICENSE-COMMANDS>
    </NS-LICENSE-CONFIG>
</NS-PRE-BOOT-CONFIG>
<!--NeedCopy-->
```

As shown in the following illustration, you can run the "show license server" command, and verify that the license server (10.102.38.214) is added to the VPX.



Bootstrapping

Use the <NS-BOOTSTRAP> tag to provide the custom bootstrapping information. You can use the <SKIP-DEFAULT-BOOTSTRAP> and <NEW-BOOTSTRAP-SEQUENCE> tags within the <NS-BOOTSTRAP> section. This section informs Citrix ADC appliance whether to avoid the default bootstrap or not. If the default bootstrapping is avoided, this section provides you an option to provide a new bootstrapping sequence.

Default bootstrap configuration

The default bootstrap configuration in Citrix ADC appliance follows these interface assignments:

- **Eth0** - Management interface with a certain NSIP address.
- **Eth1** - Client-facing interface with a certain VIP address.
- **Eth2** - Server-facing interface with a certain SNIP address.

Customize bootstrap configuration

You can skip the default bootstrap sequence and provide a new bootstrap sequence for the Citrix ADC VPX instance. Use the <NS-BOOTSTRAP> tag to provide the custom bootstrapping information. For example, you can change the default bootstrapping, where the Management interface (NSIP), Client-facing interface (VIP), and server-facing interface (SNIP) are always provided in certain order.

The following table indicates the bootstrapping behavior with the different values that are allowed for <SKIP-DEFAULT-BOOTSTRAP> and <NEW-BOOTSTRAP-SEQUENCE> tags.

SKIP-DEFAULT-BOOTSTRAP	NEW-BOOTSTRAP-SEQUENCE	Bootstrap behavior
YES	YES	The default bootstrapping behavior is skipped, and a new custom bootstrap sequence provided in the <NS-BOOTSTRAP> section is run.
YES	NO	The default bootstrapping behavior is skipped. The bootstrap commands provided in the <NS-CONFIG> section is run.

You can customize the bootstrap configuration by the following three methods:

- Provide only the interface details
- Provide the interface details along with IP addresses and subnet mask
- Provide bootstrap related commands in the <NS-CONFIG> section

Method 1: Custom bootstrap by specifying only the interface details

You specify the management, client-facing and server-facing interfaces but not their IP addresses and subnet masks. The IP addresses and subnet masks are populated by querying the cloud infrastructure.

Custom bootstrap example for AWS

You provide the custom bootstrap sequence as shown in the following example. For more information, see How to provide preboot user data in cloud instance. Eth1 interface is assigned as the management interface (NSIP), Eth0 interface as the client interface (VIP), and Eth2 interface as the server interface (SNIP). The <NS-BOOTSTRAP> section contains only the interface details and not the details of IP addresses and subnet masks.

```
<NS-PRE-BOOT-CONFIG>
    <NS-BOOTSTRAP>
      <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
      <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>

      <MGMT-INTERFACE-CONFIG>
          <INTERFACE-NUM> eth1 </INTERFACE-NUM>
      </MGMT-INTERFACE-CONFIG>

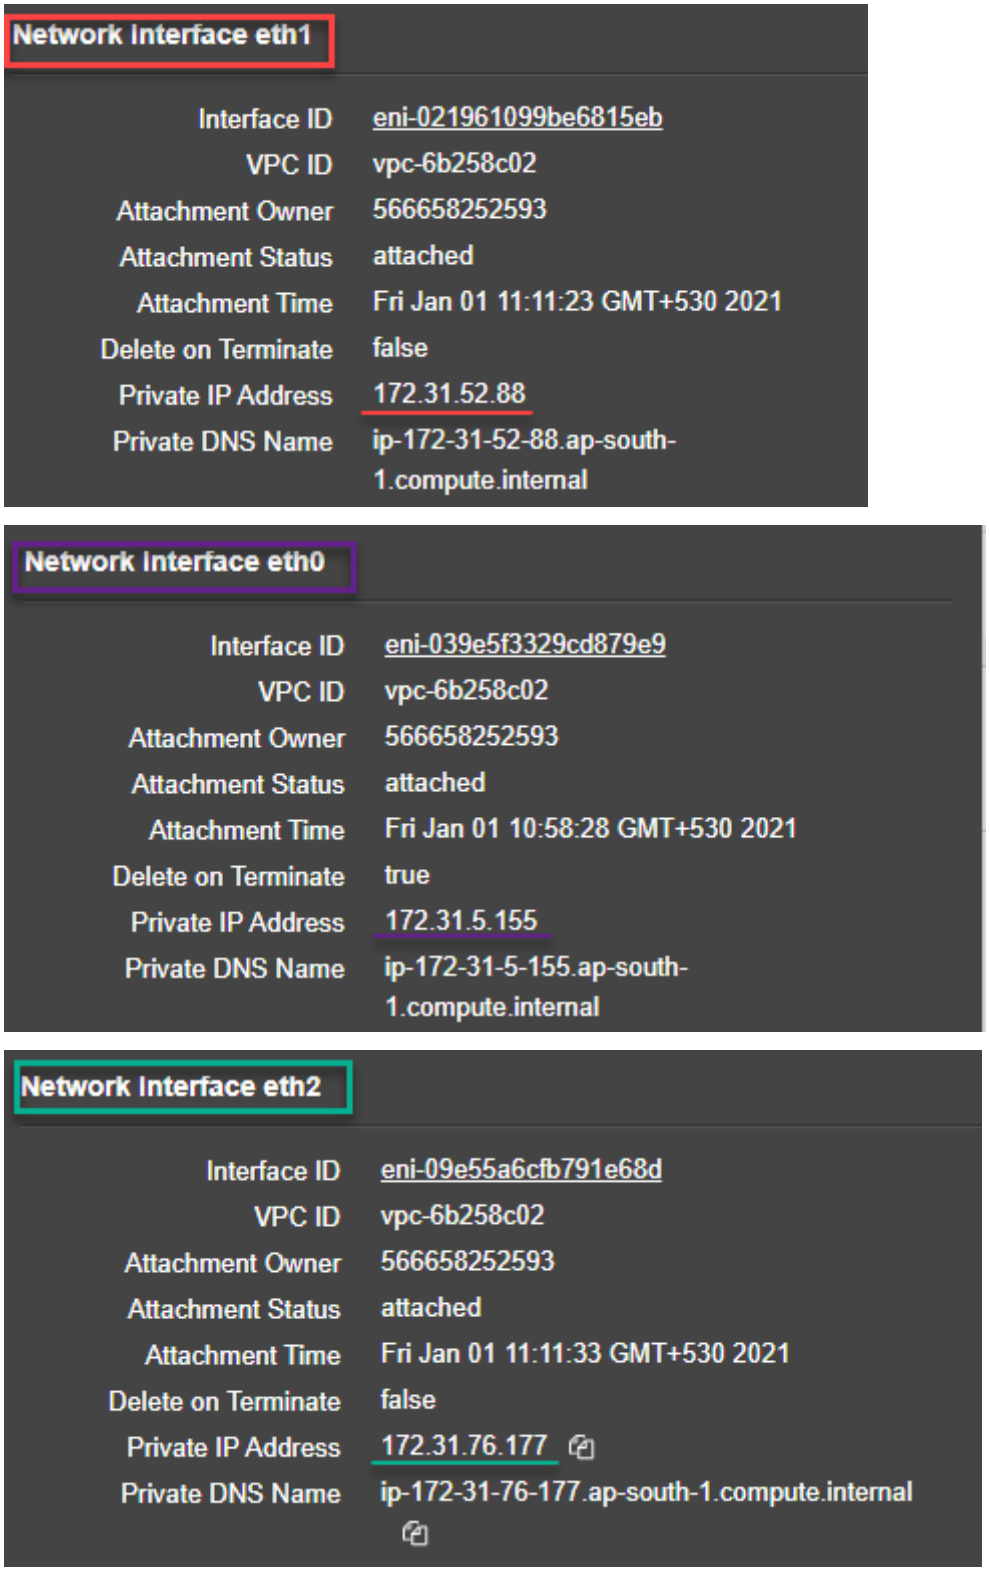
      <CLIENT-INTERFACE-CONFIG>
          <INTERFACE-NUM> eth0 </INTERFACE-NUM>
      </CLIENT-INTERFACE-CONFIG>

      <SERVER-INTERFACE-CONFIG>
          <INTERFACE-NUM> eth2 </INTERFACE-NUM>
      </SERVER-INTERFACE-CONFIG>

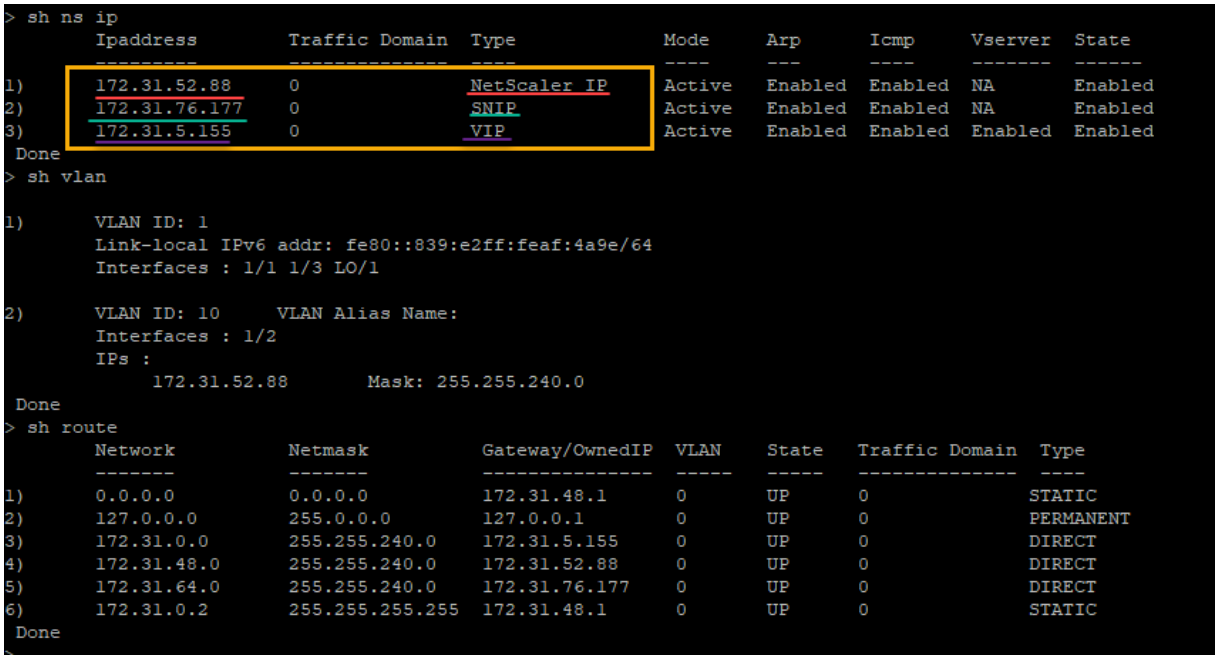
    </NS-BOOT STRAP>
</NS-PRE-BOOT-CONFIG>
```

After the VM instance is created, in the AWS portal, you can verify the network interface properties as follows:

1. Navigate to the **AWS Portal > EC2 instances**, and select the instance that you have created by providing the custom bootstrap information.
2. In the **Description** tab, you can verify the properties of each network interface as shown in the following illustrations.



You can run the `show nsip` command in **ADC CLI**, and verify the network interfaces applied to the ADC VPX instance during the first boot of the ADC appliance.



```
> sh ns ip
        Ipaddress        Traffic Domain  Type             Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----             ----     ---      ----     -------  ------
1)      172.31.52.88     0               NetScaler IP     Active   Enabled  Enabled  NA       Enabled
2)      172.31.76.177    0               SNIP             Active   Enabled  Enabled  NA       Enabled
3)      172.31.5.155     0               VIP              Active   Enabled  Enabled  Enabled  Enabled
 Done
> sh vlan

1)      VLAN ID: 1
        Link-local IPv6 addr: fe80::839:e2ff:feaf:4a9e/64
        Interfaces : 1/1 1/3 LO/1

2)      VLAN ID: 10     VLAN Alias Name:
        Interfaces : 1/2
        IPs :
             172.31.52.88       Mask: 255.255.240.0
 Done
> sh route
        Network          Netmask          Gateway/OwnedIP  VLAN    State   Traffic Domain  Type
        -------          -------          ---------------  -----   -----   --------------  ----
1)      0.0.0.0          0.0.0.0          172.31.48.1      0       UP      0               STATIC
2)      127.0.0.0        255.0.0.0        127.0.0.1        0       UP      0               PERMANENT
3)      172.31.0.0       255.255.240.0    172.31.5.155     0       UP      0               DIRECT
4)      172.31.48.0      255.255.240.0    172.31.52.88     0       UP      0               DIRECT
5)      172.31.64.0      255.255.240.0    172.31.76.177    0       UP      0               DIRECT
6)      172.31.0.2       255.255.255.255  172.31.48.1      0       UP      0               STATIC
 Done
```

Custom bootstrap example for Azure

You provide the custom bootstrap sequence as shown in the following example. For more information, see How to provide preboot user data in cloud instance. Eth2 interface is assigned as the management interface (NSIP), Eth1 interface as the client interface (VIP), and Eth0 interface as the server interface (SNIP). The <NS-BOOTSTRAP> section contains only the interface details and not the details of IP addresses and subnet masks.

```
<NS-PRE-BOOT-CONFIG>

    <NS-BOOTSTRAP>
        <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
        <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>

        <MGMT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth2 </INTERFACE-NUM>
        </MGMT-INTERFACE-CONFIG>

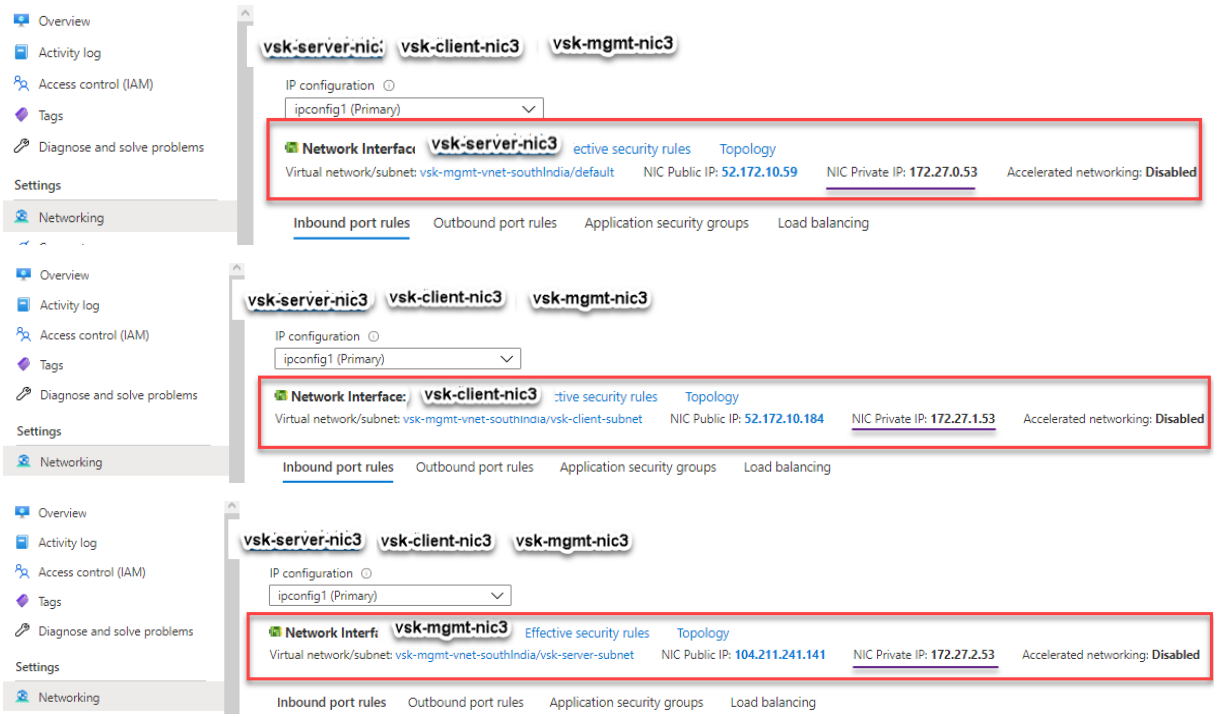
        <CLIENT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth1 </INTERFACE-NUM>
        </CLIENT-INTERFACE-CONFIG>

        <SERVER-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth0 </INTERFACE-NUM>
        </SERVER-INTERFACE-CONFIG>

    </NS-BOOTSTRAP>

</NS-PRE-BOOT-CONFIG>
```

You can see that the Citrix ADC VPX instance is created with three network interfaces. Navigate to the **Azure portal > VM instance > Networking**, and verify the networking properties of the three NICs as shown in the following illustrations.



You can run the “show nsip” command in the ADC CLI, and verify that the new bootstrap sequence

specified in the <NS-BOOTSTRAP> section is applied. You can run the "show route" command to verify the subnet mask.

```
> sh ns ip
        Ipaddress        Traffic Domain  Type             Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----             ----     ---      ----     -------  ------
1)      172.27.2.53      0               NetScaler IP     Active   Enabled  Enabled  NA       Enabled
2)      172.27.0.53      0               SNIP             Active   Enabled  Enabled  NA       Enabled
3)      172.27.1.53      0               VIP              Active   Enabled  Enabled  Enabled  Enabled
 Done
> sh vlan

1)      VLAN ID: 1
        Link-local IPv6 addr: fe80::20d:3aff:fec9:c26c/64
        Interfaces : 0/1 1/1 LO/1

2)      VLAN ID: 10     VLAN Alias Name:
        Interfaces : 1/2
        IPs :
             172.27.2.53        Mask: 255.255.255.0
 Done
> sh route
        Network          Netmask          Gateway/OwnedIP  VLAN    State   Traffic Domain  Type
        -------          -------          ---------------  -----   -----   --------------  ----
1)      0.0.0.0          0.0.0.0          172.27.2.1       0       UP      0               STATIC
2)      127.0.0.0        255.0.0.0        127.0.0.1        0       UP      0               PERMANENT
3)      172.27.0.0       255.255.255.0    172.27.0.53      0       UP      0               DIRECT
4)      172.27.1.0       255.255.255.0    172.27.1.53      0       UP      0               DIRECT
5)      172.27.2.0       255.255.255.0    172.27.2.53      0       UP      0               DIRECT

```

Custom bootstrap examples for GCP

You provide the custom bootstrap sequence as shown in the following example. For more information, see How to provide preboot user data in cloud instance. Eth1 interface is assigned as the management interface (NSIP), Eth0 interface as the client interface (VIP), and Eth2 interface as the server interface (SNIP). The <NS-BOOTSTRAP> section contains only the interface details and not the details of IP addresses and subnet masks.

```
<NS-PRE-BOOT-CONFIG>
    <NS-BOOTSTRAP>
        <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
        <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>

        <MGMT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth1 </INTERFACE-NUM>
        </MGMT-INTERFACE-CONFIG>

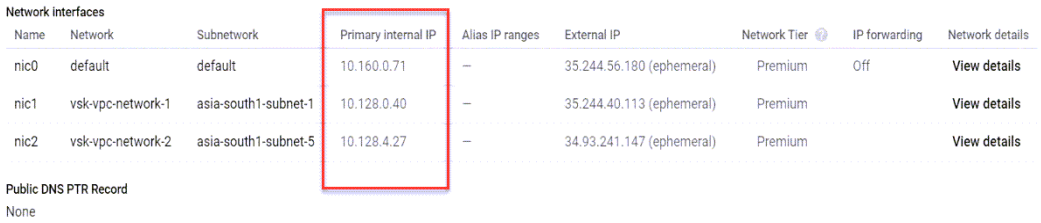
        <CLIENT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth0 </INTERFACE-NUM>
        </CLIENT-INTERFACE-CONFIG>

        <SERVER-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth2 </INTERFACE-NUM>
        </SERVER-INTERFACE-CONFIG>

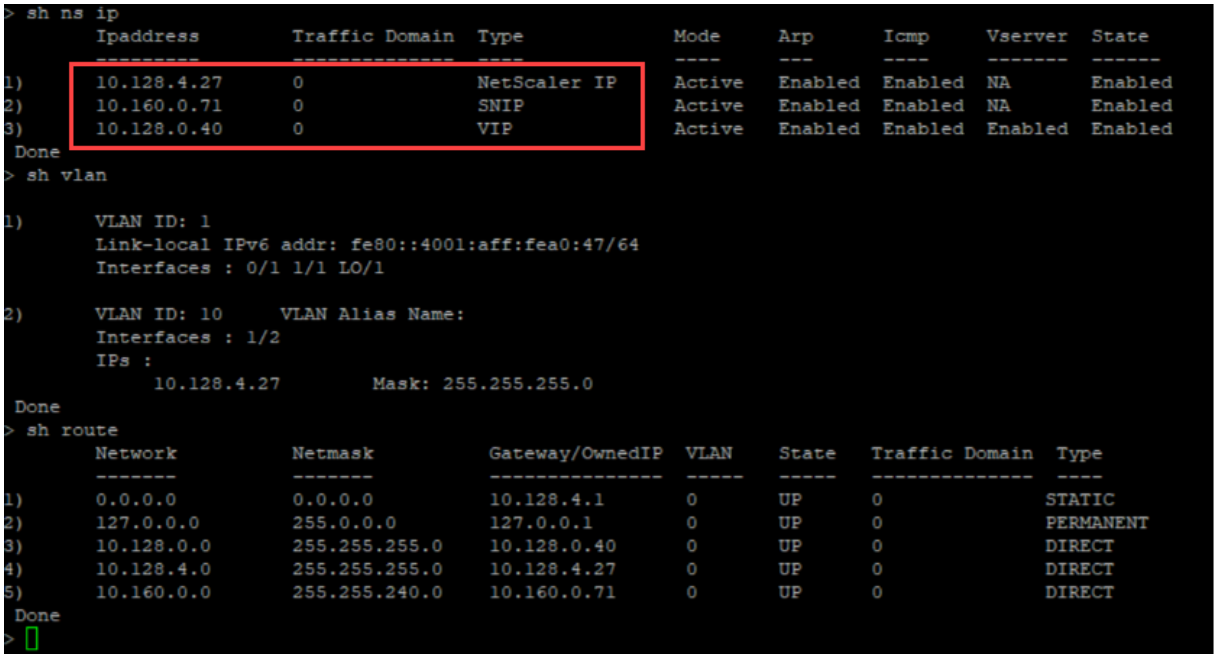
    </NS-BOOT STRAP>
</NS-PRE-BOOT-CONFIG>
```

After the VM instance is created in the GCP portal, you can verify the network interface properties as follows:

1. Select the instance that you have created by providing the custom bootstrap information.
2. Navigate to the Network interface properties and verify the NIC details as follows:



You can run the `show nsip` command in **ADC CLI**, and verify the network interfaces applied to the ADC VPX instance during the first boot of the ADC appliance.



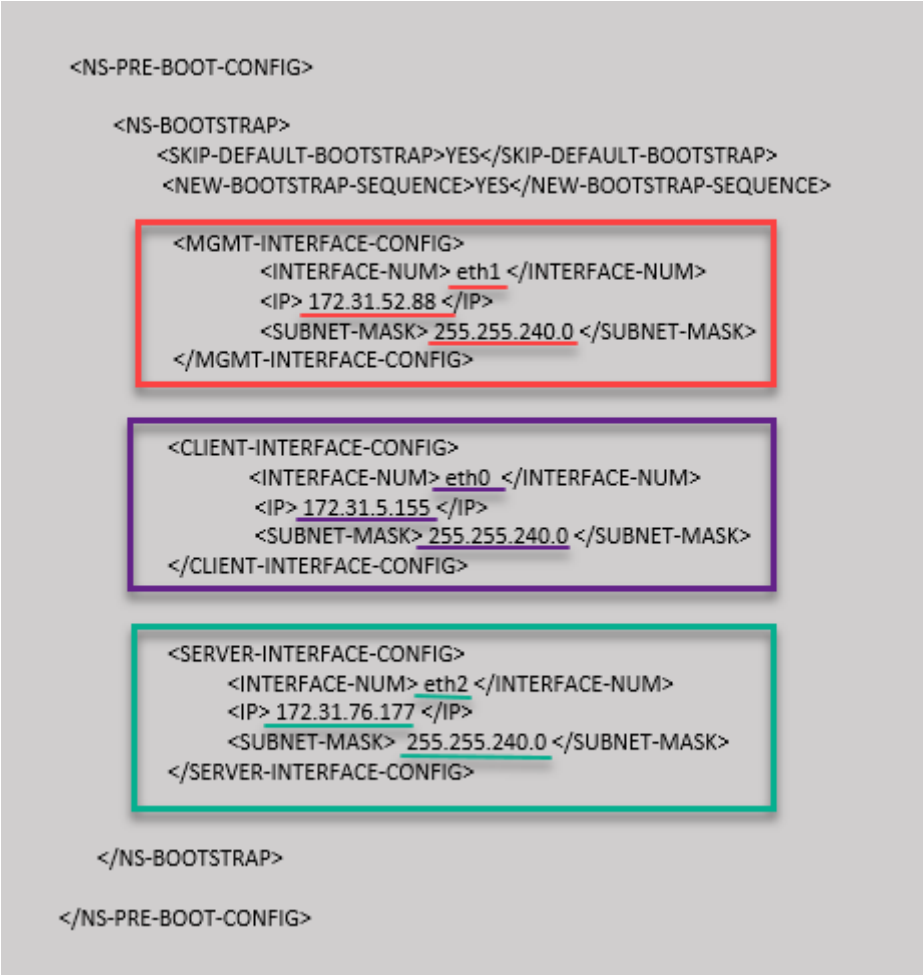
Method 2: Custom bootstrap by specifying the interfaces, IP addresses, and subnet masks

You specify the management, client-facing and server-facing interfaces along with their IP addresses and subnet mask.

Custom bootstrap examples for AWS

In the following example, you skip the default bootstrap and run a new bootstrap sequence for the Citrix ADC appliance. For the new bootstrap sequence, you specify the following details:

- **Management interface:** Interface - Eth1, NSIP - 172.31.52.88, and subnet mask - 255.255.240.0
- **Client facing interface:** Interface - Eth0, VIP - 172.31.5.155, and subnet mask - 255.255.240.0.
- **Server facing interface:** Interface - Eth2, SNIP - 172.31.76.177, and subnet mask - 255.255.240.0.



You can run the `show nsip` command in the ADC CLI, and verify that the new bootstrap sequence specified in the <NS-BOOTSTRAP> section is applied. You can run the “show route” command to verify the subnet mask.

```
> sh ns ip
        Ipaddress        Traffic Domain  Type             Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----             ----     ---      ----     -------  ------
1)      172.31.52.88     0               NetScaler IP     Active   Enabled  Enabled  NA       Enabled
2)      172.31.76.177    0               SNIP             Passive  Enabled  Enabled  NA       Enabled
3)      172.31.5.155     0               VIP              Passive  Enabled  Enabled  Enabled  Enabled
 Done
> sh vlan

1)      VLAN ID: 1

>
```

Custom bootstrap example for Azure

In the following example, a new bootstrap sequence for ADC is mentioned and default bootstrap is skipped. You provide the interface details along with the IP addresses and subnet masks as follows:

- Management interface (eth2), NSIP (172.27.2.53), and subnet mask (255.255.255.0)
- Client facing interface (eth1), VIP (172.27.1.53), and subnet mask (255.255.255.0)
- Server facing interface (eth0), SNIP (172.27.0.53), and subnet mask (255.255.255.0)

```
<NS-PRE-BOOT-CONFIG>

    <NS-BOOTSTRAP>
        <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
        <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>

        <MGMT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth2 </INTERFACE-NUM>
            <IP> 172.27.2.53 </IP>
            <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </MGMT-INTERFACE-CONFIG>

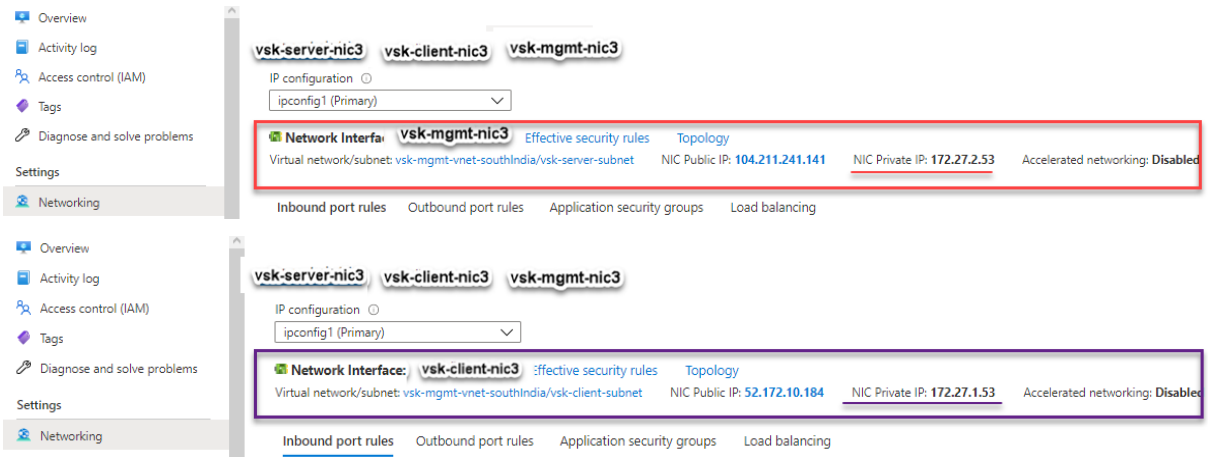
        <CLIENT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth1 </INTERFACE-NUM>
            <IP> 172.27.1.53 </IP>
            <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
            </CLIENT-INTERFACE-CONFIG>

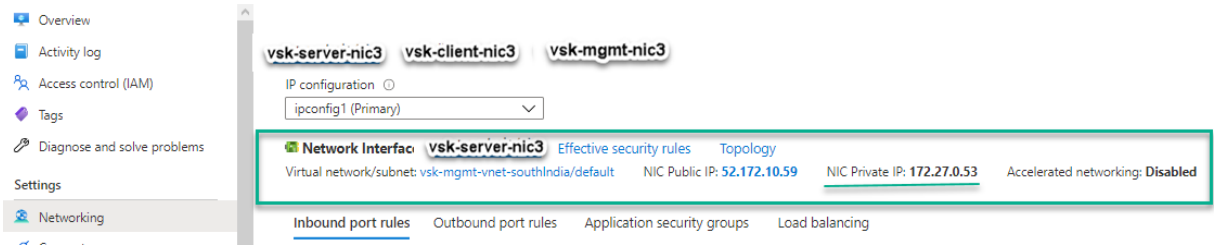
        <SERVER-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth0 </INTERFACE-NUM>
            <IP> 172.27.0.53 </IP>
            <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </SERVER-INTERFACE-CONFIG>

    </NS-BOOTSTRAP>

</NS-PRE-BOOT-CONFIG>
```

You can see that the Citrix ADC VPX instance is created with three network interfaces. Navigate to the **Azure portal > VM instance > Networking**, and verify the networking properties of the three NICs as shown in the following illustrations.





You can run the `show nsip` command in the ADC CLI, and verify that the new bootstrap sequence specified in the <NS-BOOTSTRAP> section is applied. You can run the "show route" command to verify the subnet mask.

```
> sh ns ip
        Ipaddress        Traffic Domain  Type             Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----             ----     ---      ----     -------  ------
1)      172.27.2.53      0               NetScaler IP     Active   Enabled  Enabled  NA       Enabled
2)      172.27.0.53      0               SNIP             Active   Enabled  Enabled  NA       Enabled
3)      172.27.1.53      0               VIP              Active   Enabled  Enabled  Enabled  Enabled
 Done
> sh vlan

1)      VLAN ID: 1
        Link-local IPv6 addr: fe80::20d:3aff:fec9:c26c/64
        Interfaces : 0/1 1/1 LO/1

2)      VLAN ID: 10     VLAN Alias Name:
        Interfaces : 1/2
        IPs :
             172.27.2.53        Mask: 255.255.255.0
 Done
> sh route
        Network          Netmask          Gateway/OwnedIP  VLAN    State   Traffic Domain  Type
        -------          -------          ---------------  -----   -----   --------------  ----

 Done
```

Custom bootstrap example for GCP

In the following example, a new bootstrap sequence for ADC is mentioned and default bootstrap is skipped. You provide the interface details along with the IP addresses and subnet masks as follows:

- Management interface (eth2), NSIP (10.128.4.31), and subnet mask (255.255.255.0)
- Client facing interface (eth1), VIP (10.128.0.43), and subnet mask (255.255.255.0)
- Server facing interface (eth0), SNIP (10.160.0.75), and subnet mask (255.255.255.0)

```
<NS-PRE-BOOT-CONFIG>
    <NS-BOOTSTRAP>
        <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
        <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>
        <MGMT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth2 </INTERFACE-NUM>
            <IP> 10.128.4.31 </IP>
            <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </MGMT-INTERFACE-CONFIG>
        <CLIENT-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth1 </INTERFACE-NUM>
            <IP> 10.128.0.43 </IP>
            <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </CLIENT-INTERFACE-CONFIG>
        <SERVER-INTERFACE-CONFIG>
            <INTERFACE-NUM> eth0 </INTERFACE-NUM>
            <IP> 10.160.0.75 </IP>
            <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </SERVER-INTERFACE-CONFIG>
    </NS-BOOTSTRAP>
</NS-PRE-BOOT-CONFIG>
```

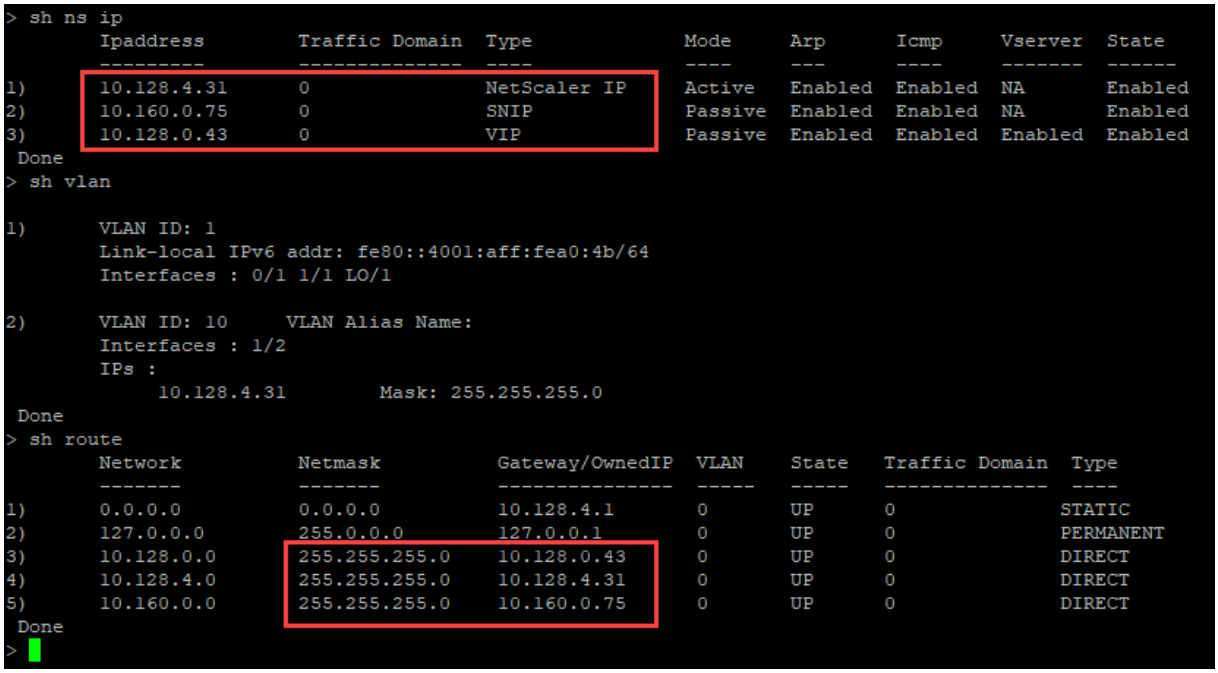
After the VM instance is created in the GCP portal with the custom bootstrap, you can verify the network interface properties as follows:

1. Select the instance that you have created by providing the custom bootstrap information.
2. Navigate to the Network interface properties and verify the NIC details as follows.

Network interfaces

Name	Network	Subnetwork	Primary internal IP	Alias IP ranges	External IP	Network Tier	IP forwarding	Network details
nic0	default	default	vsk-defnw-st-ip1 (10.160.0.75)	–	34.93.216.90 (ephemeral)	Premium	Off	View details
nic1	vsk-vpc-network-1	asia-south1-subnet-1	vsk-vpc-nw1-st-ip1 (10.128.0.43)	–	35.244.40.113 (ephemeral)	Premium		View details
nic2	vsk-vpc-network-2	asia-south1-subnet-5	vsk-nw2-st-ip-1 (10.128.4.31)	–	34.93.202.214 (ephemeral)	Premium		View details

You can run the `show nsip` command in the ADC CLI, and verify that the new bootstrap sequence specified in the <NS-BOOTSTRAP> section is applied. You can run the “show route” command to verify the subnet mask.



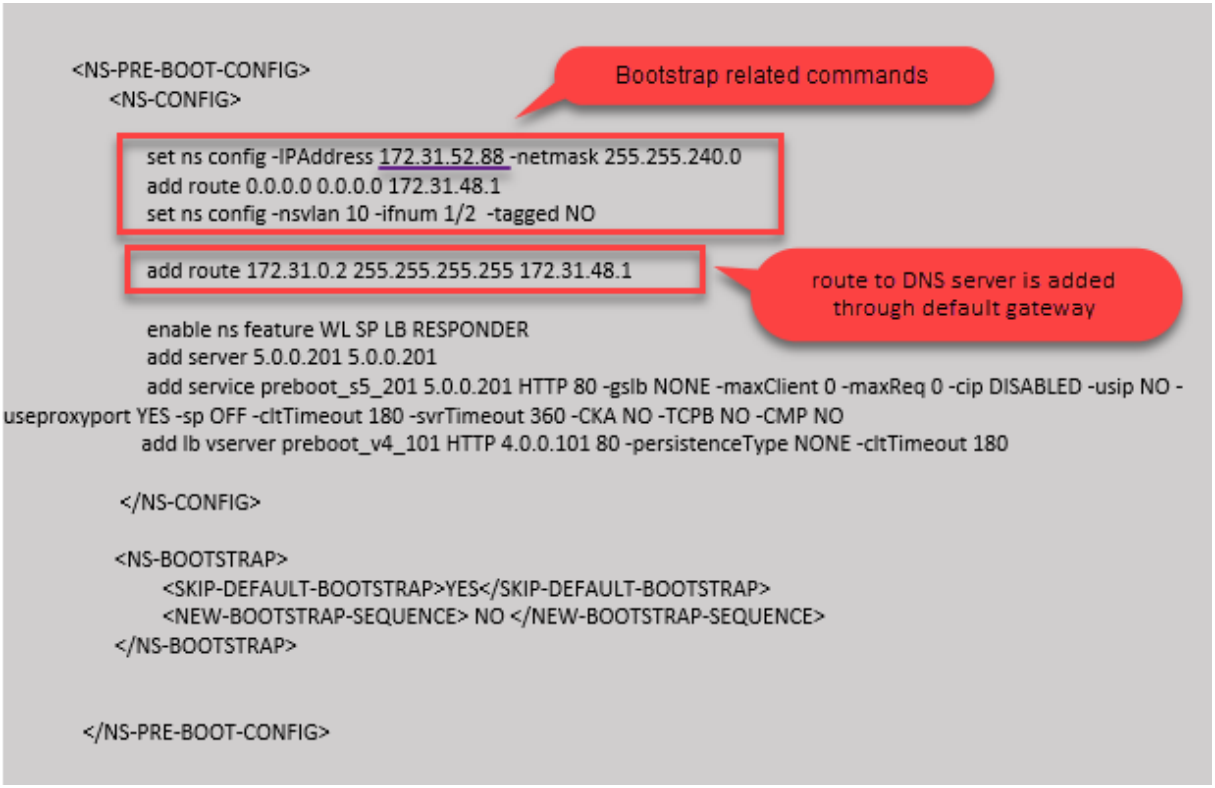
Method 3: Custom bootstrap by providing bootstrap related commands in the <NS-CONFIG> section

You can provide the bootstrap related commands in the <NS-CONFIG> section. In the <NS-BOOTSTRAP> section, you must specify the <NEW-BOOTSTRAP-SEQUENCE> as “No” to run the bootstrapping commands in the <NS-CONFIG> section. You must also provide the commands to assign NSIP, default route, and NSVLAN. In addition, provide the commands relevant for the cloud that you use.

Before providing a custom bootstrap, ensure that your cloud infrastructure supports a particular interface configuration.

Custom bootstrap example for AWS

In this example, bootstrap related commands are provided in the <NS-CONFIG> section. The <NS-BOOTSTRAP> section indicates that the default bootstrapping is skipped, and the custom bootstrap information provided in the <NS-CONFIG> section is run. You must also provide the commands to create NSIP, add default route, and add NSVLAN.



You can copy the configuration shown in the preceding screenshot from here:

```
<NS-PRE-BOOT-CONFIG>
    <NS-CONFIG>

        set ns config -IPAddress 172.31.52.88 -netmask 255.255.240.0
        add route 0.0.0.0 0.0.0.0 172.31.48.1
        set ns config -nsvlan 10 -ifnum 1/2  -tagged NO
        add route 172.31.0.2 255.255.255.255 172.31.48.1

        enable ns feature WL SP LB RESPONDER
        add server 5.0.0.201 5.0.0.201
        add service preboot_s5_201 5.0.0.201 HTTP 80 -gslb NONE -
            maxClient 0 -maxReq 0 -cip DISABLED -usip NO - useproxyport
            YES -sp OFF -cltTimeout 180 -svrTimeout 360 -CKA NO -TCPB NO
             -CMP NO
        add lb vserver preboot_v4_101 HTTP 4.0.0.101 80 -
            persistenceType NONE -cltTimeout 180

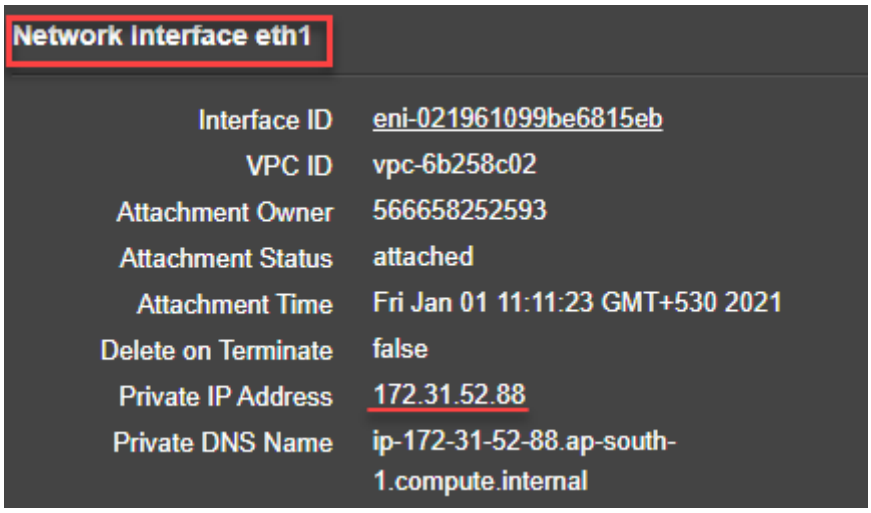
    </NS-CONFIG>

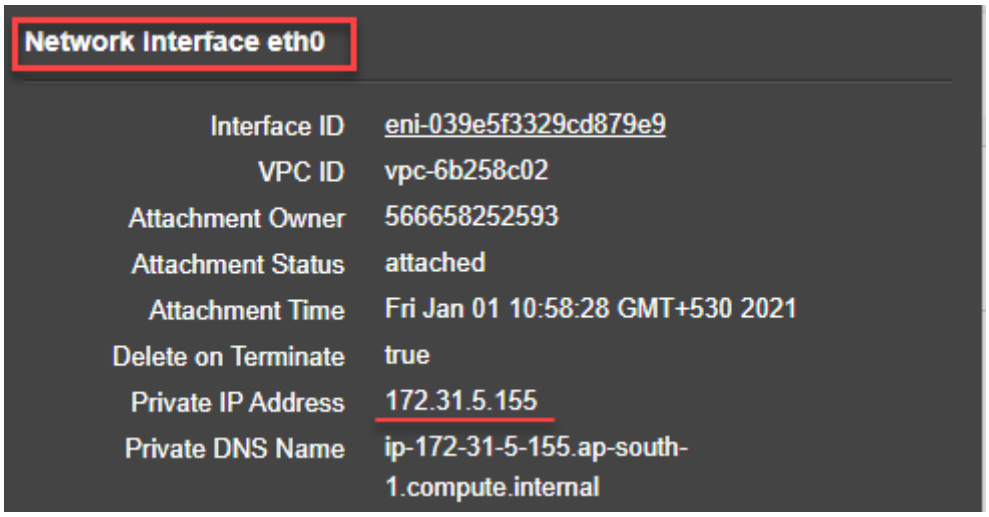
    <NS-BOOTSTRAP>
     <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
     <NEW-BOOTSTRAP-SEQUENCE> NO </NEW-BOOTSTRAP-SEQUENCE>
```

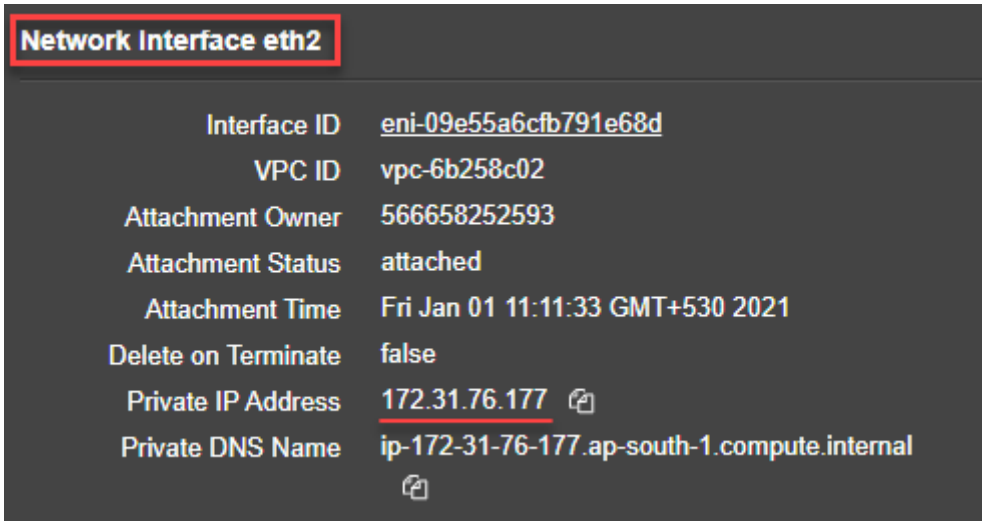
```
19      </NS-BOOTSTRAP>
20
21
22  </NS-PRE-BOOT-CONFIG>
23  <!--NeedCopy-->
```

After the VM instance is created, in the AWS portal, you can verify the network interface properties as follows:

1. Navigate to the **AWS Portal > EC2 instances**, and select the instance that you have created by providing the custom bootstrap information.
2. In the **Description** tab, you can verify the properties of each network interface as shown in the following illustrations.







You can run the `show nsip` command in **ADC CLI**, and verify the network interfaces applied to the ADC VPX instance during the first boot of the ADC appliance.

```
> sh ns ip
        Ipaddress        Traffic Domain  Type             Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----             ----     ---      ----     -------  ------
1)      172.31.52.88     0               NetScaler IP     Active   Enabled  Enabled  NA       Enabled
2)      4.0.0.101        0               VIP              Active   Enabled  Enabled  Enabled  Enabled
 Done
> sh vlan

1)      VLAN ID: 1
        Link-local IPv6 addr: fe80::839:e2ff:feaf:4a9e/64
        Interfaces : 1/1 1/3 LO/1

2)      VLAN ID: 10     VLAN Alias Name:
        Interfaces : 1/2
        IPs :

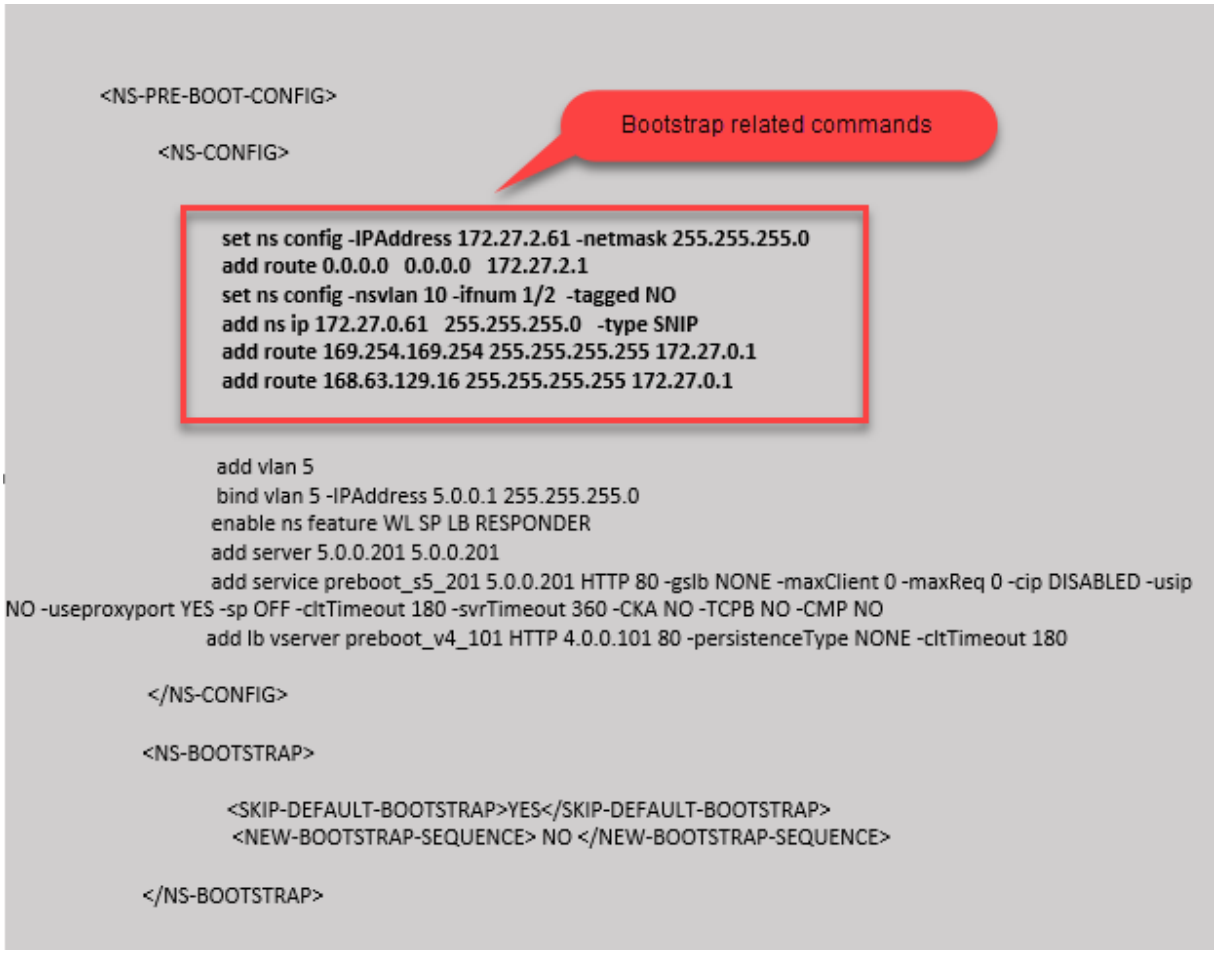
```

Custom bootstrap example for Azure

In this example, bootstrap related commands are provided in the <NS-CONFIG> section. The <NS-BOOTSTRAP> section indicates that the default bootstrapping is skipped, and the custom bootstrap information provided in the <NS-CONFIG> section is run.

> Note:
>
> For Azure cloud, Instance Metadata Server (IMDS) and DNS servers are accessible only through primary interface (Eth0). Therefore, if Eth0 interface is not used as management interface (NSIP),

> Eth0 interface must at least be configured as SNIP for IMDS or DNS access to work. The route to IMDS endpoint (169.254.169.254) and DNS endpoint (168.63.129.16) through Eth0's gateway must also be added.



```
<NS-PRE-BOOT-CONFIG>

   <NS-CONFIG>

        set ns config -IPAddress 172.27.2.61 -netmask 255.255.255.0
        add route 0.0.0.0   0.0.0.0   172.27.2.1
        set ns config -nsvlan 10 -ifnum 1/2  -tagged NO
        add ns ip 172.27.0.61   255.255.255.0   -type SNIP
        add route 169.254.169.254 255.255.255.255 172.27.0.1
        add route 168.63.129.16 255.255.255.255 172.27.0.1

        add vlan 5
        bind vlan 5 -IPAddress 5.0.0.1 255.255.255.0
        enable ns feature WL SP LB RESPONDER
        add server 5.0.0.201 5.0.0.201
```

```
16          add service preboot_s5_201 5.0.0.201 HTTP 80 -gslb NONE -
                maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport

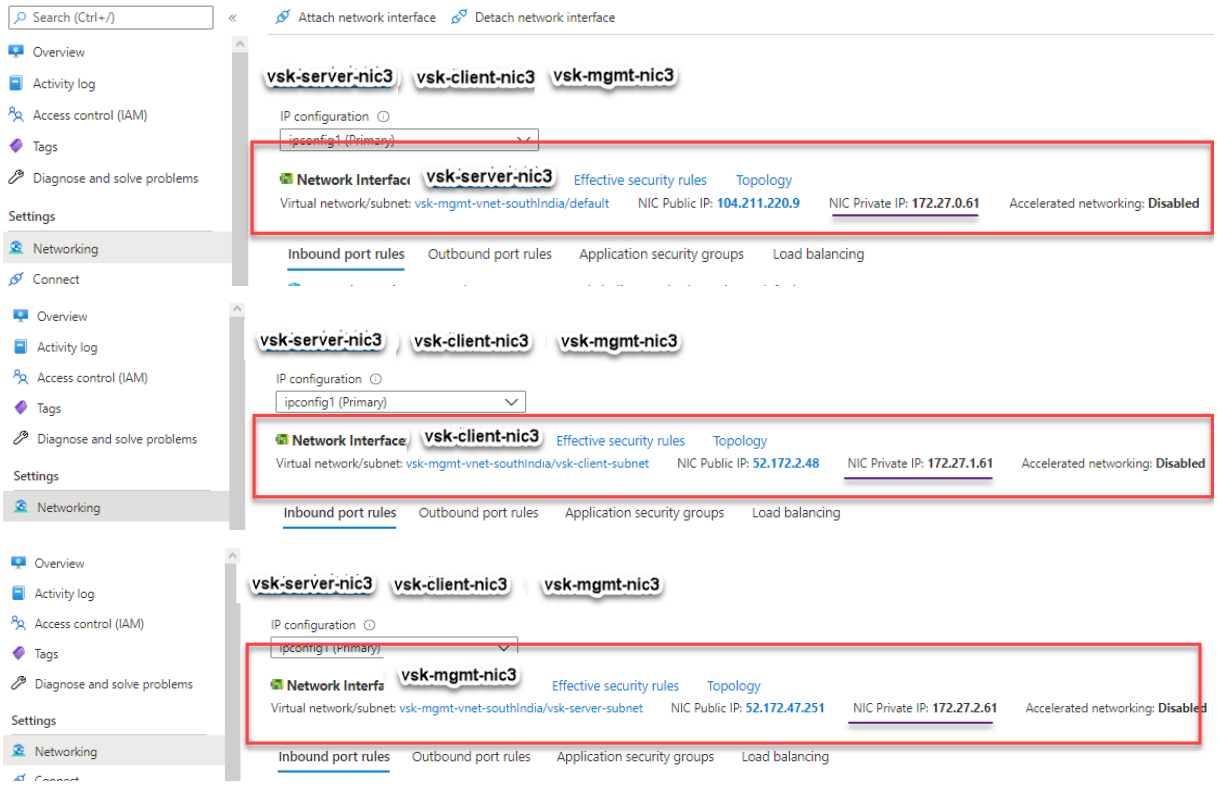
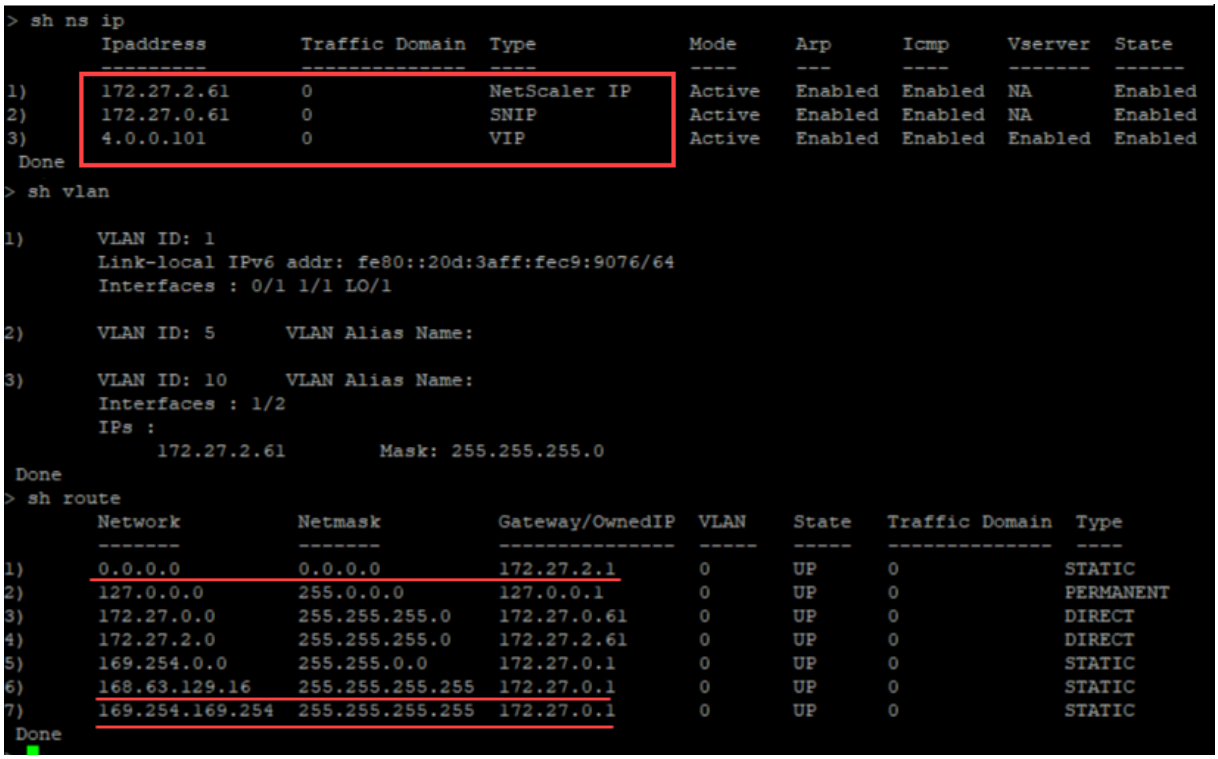
21      <NS-BOOTSTRAP>
22
23      <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
24      <NEW-BOOTSTRAP-SEQUENCE> NO </NEW-BOOTSTRAP-SEQUENCE>
25
26      </NS-BOOTSTRAP>
27
28  </NS-PRE-BOOT-CONFIG>
29  <!--NeedCopy-->
```

You can see that the Citrix ADC VPX instance is created with three network interfaces. Navigate to the **Azure portal > VM instance > Networking**, and verify the networking properties of the three NICs as shown in the following illustrations.



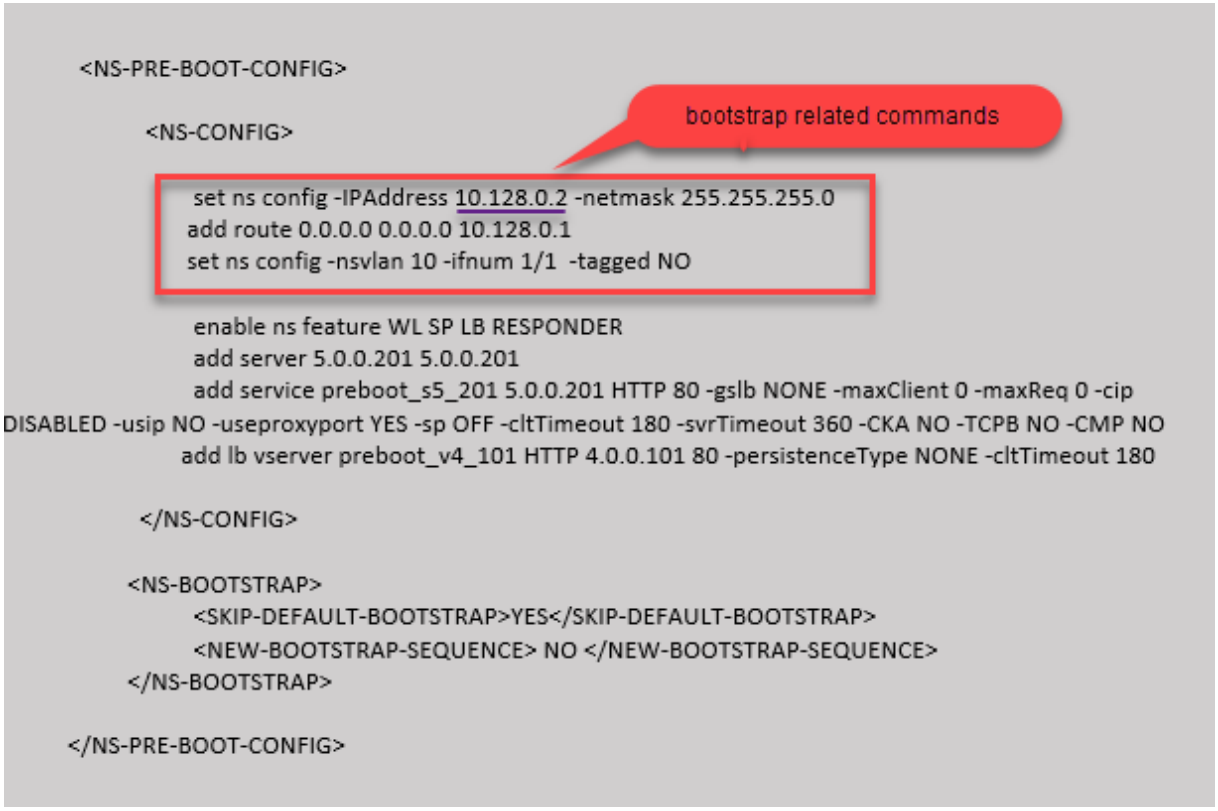
You can run the `show nsip` command in the ADC CLI, and verify that the new bootstrap sequence

specified in the <NS-BOOTSTRAP> section is applied. You can run the “show route” command to verify the subnet mask.



Custom bootstrap example for GCP

In this example, bootstrap related commands are provided in the <NS-CONFIG> section. The <NS-BOOTSTRAP> section indicates that the default bootstrapping is skipped, and the custom bootstrap information provided in the <NS-CONFIG> section is applied.



You can copy the configuration shown in the preceding screenshot from here:

```
<NS-PRE-BOOT-CONFIG>

    <NS-CONFIG>

        set ns config -IPAddress 10.128.0.2 -netmask 255.255.255.0
        add route 0.0.0.0 0.0.0.0 10.128.0.1
        set ns config -nsvlan 10 -ifnum 1/1  -tagged NO

        enable ns feature WL SP LB RESPONDER
        add server 5.0.0.201 5.0.0.201
        add service preboot_s5_201 5.0.0.201 HTTP 80 -gslb NONE -
            maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport
            YES -sp OFF -cltTimeout 180 -svrTimeout 360 -CKA NO -TCPB NO
             -CMP NO
        add lb vserver preboot_v4_101 HTTP 4.0.0.101 80 -
            persistenceType NONE -cltTimeout 180

    </NS-CONFIG>

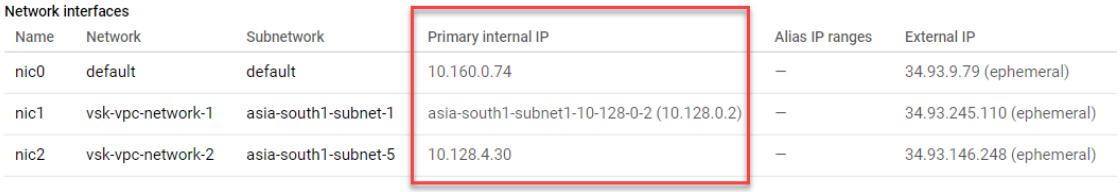
    <NS-BOOTSTRAP>
        <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
```

```
        <NEW-BOOTSTRAP-SEQUENCE> NO </NEW-BOOTSTRAP-SEQUENCE>
    </NS-BOOTSTRAP>

</NS-PRE-BOOT-CONFIG>
<!--NeedCopy-->
```

After the VM instance is created in the GCP portal with the custom bootstrap, you can verify the network interface properties as follows:

1. Select the instance that you have created by providing the custom bootstrap information.
2. Navigate to the Network interface properties and verify the NIC details as shown in the illustration.



You can run the `show nsip` command in **ADC CLI**, and verify that the configurations provided in the preceding <NS-CONFIG> section are applied at the first boot of the ADC appliance.

```
![Show NSIP output](/en-us/citrix-adc/media/gcp-show-nsip-method3.png)
```

Impact of attaching and detaching NICs in AWS and Azure

AWS and Azure provide the option to attach a network interface to an instance, and detach a network interface from an instance. Attaching or detaching interfaces might alter interface positions. Hence, Citrix recommends you to refrain from detaching interfaces from the ADC VPX instance. If you detach or attach an interface when custom bootstrapping is configured, Citrix ADC VPX instance reassigns the primary IP of the newly available interface in the management interface's position as NSIP. If no further interfaces are available after the one you detached, then the first interface is made the management interface for the ADC VPX instance.

For example, a Citrix ADC VPX instance is brought up with 3 interfaces: Eth0 (SNIP), Eth1 (NSIP), and Eth2 (VIP). If you detach Eth1 interface from the instance, which is a management interface, ADC configures the next available interface (Eth2) as the management interface. Thereby, the ADC VPX instance is still accessed through the primary IP of Eth2 interface. If Eth2 is also not available, then the remaining interface (Eth0) is made the management interface. Therefore, the access to ADC VPX instance continues to exist.

Let's consider a different assignment of interfaces as follows: Eth0 (SNIP), Eth1 (VIP), and Eth2 (NSIP). If you detach Eth2 (NSIP), because no new interface is available after Eth2, the first interface (Eth0) is made the management interface.

Install a Citrix ADC VPX instance on a bare metal server

September 14, 2021

A bare metal is a fully dedicated physical server that delivers physical isolation, fully integrated into the cloud environment. It is also known as a single-tenant server. Single tenancy allows you to avoid the noisy neighbor effect. With bare metal, you do not witness the noisy neighbor effect because you are the sole user.

A bare metal server installed with a hypervisor provides you a management suite to create virtual machines on the server. The hypervisor does not run applications natively. Its purpose is to virtualize your workloads into separate virtual machines to gain the flexibility and reliability of virtualization.

Prerequisites for installing Citrix ADC VPX instance on bare metal servers

A bare metal server must be obtained from a cloud vendor that meets all the system requirements for the respective hypervisor.

Install the Citrix ADC VPX instance on bare metal servers

To install Citrix ADC VPX instances on a bare metal server, you must first obtain a bare metal server with adequate system resources from a cloud vendor. On that bare metal server, any of the supported hypervisors such as Linux KVM, VMware ESX, Citrix Hypervisor, or Microsoft Hyper-V must be installed and configured before deploying the ADC VPX instance.

For more information on the list of different hypervisors and features supported on a Citrix ADC VPX instance, see Support matrix and usage guidelines.

For more information on installing Citrix ADC VPX instances on different hypervisors, see the respective documentation.

- **Citrix Hypervisor:** See Install a Citrix ADC VPX instance on Citrix Hypervisor.
- **VMware ESX:** See Install a Citrix ADC VPX instance on VMware ESX.
- **Microsoft Hyper-V:** See Install a Citrix ADC VPX instance on Microsoft Hyper-V server.
- **Linux KVM platform:** See Install a Citrix ADC VPX instance on Linux-KVM platform.

Install a Citrix ADC VPX instance on Citrix Hypervisor

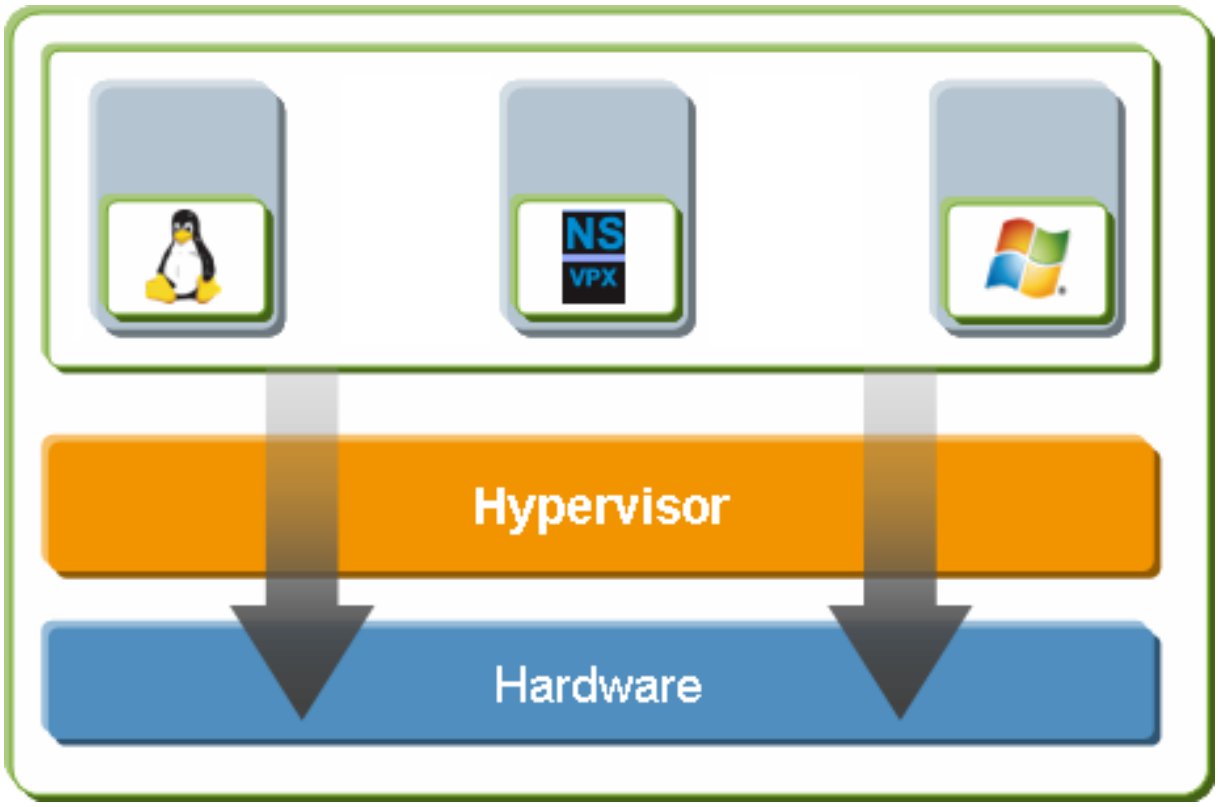
September 14, 2021

To install VPX instances on the Citrix Hypervisor, you must first install the Hypervisor on a machine with adequate system resources. To perform the Citrix ADC VPX instance installation, you use Citrix XenCenter, which must be installed on a remote machine that can connect to the Hypervisor host through the network.

For more information about Hypervisor, see Citrix Hypervisor documentation.

The following figure shows the bare-metal solution architecture of Citrix ADC VPX instance on Hypervisor.

Figure. A Citrix ADC VPX instance on Citrix Hypervisor



Prerequisites for installing a Citrix ADC VPX instance on Hypervisor

Before you begin installing a virtual appliance, do the following:

- Install Hypervisor version 6.0 or later on hardware that meets the minimum requirements.
- Install XenCenter on a management workstation that meets the minimum system requirements.
- Obtain virtual appliance license files. For more information about virtual appliance licenses, see the *Citrix ADC VPX Licensing Guide* at http://support.citrix.com/article/ctx122426.

Hypervisor hardware requirements

The following table describes the minimum hardware requirements for a Hypervisor platform running a Citrix ADC VPX instance.

Table 1. Minimum system requirements for Hypervisor running a nCore VPX instance

Component	Requirement
CPU	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT) enabled. AMD processor is not supported. To run the Citrix ADC VPX instance, hardware support for virtualization must be enabled on the Hypervisor host. Make sure that the BIOS option for virtualization support is not disabled. For more details, see BIOS documentation.
RAM	3 GB
Disk space	Locally attached storage (PATA, SATA, SCSI) with 40 GB of disk space. Note: Hypervisor installation creates a 4 GB partition for the Hypervisor host control domain. The remaining space is available for Citrix ADC VPX instance and other virtual machines.
NIC	One 1-Gbps NIC; recommended: two 1-Gbps NICs

For information about installing Hypervisor, see the Hypervisor documentation at http://support.citrix.com/product/xens/.

The following table lists the virtual computing resources that Hypervisor must provide for each nCore VPX virtual appliance.

Table 2. Minimum virtual computing resources required for running a nCore VPX instance

Component	Requirement
Memory	2 GB
Virtual CPU (vCPU)	2
Virtual network interfaces	2

> Note: For production use of
> Citrix ADC VPX instance, Citrix recommends that CPU priority (in virtual machine properties) be set to the highest level, to improve scheduling behavior and network latency.

XenCenter system requirements

XenCenter is a Windows client application. It cannot run on the same machine as the Hypervisor host. For more information about minimum system requirements and installing XenCenter, see the following Hypervisor documents:

- System requirements
- Install

Install Citrix ADC VPX instances on Hypervisor by using XenCenter

After you have installed and configured Hypervisor and XenCenter, you can use XenCenter to install virtual appliances on Hypervisor. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running Hypervisor.

After you have used XenCenter to install the initial Citrix ADC VPX instance (.xva image) on Hypervisor, you can use Command Center to provision Citrix ADC VPX instance. For more information, see the Command Center documentation.

To install Citrix ADC VPX instances on Hypervisor by using XenCenter, follow these steps:

1. Start XenCenter on your workstation.
2. On the Server menu, click Add.
3. In the Add New Server dialog box, in the host name text box, type the IP address or DNS name of the Hypervisor that you want to connect to.
4. In the User Name and Password text boxes, type the administrator credentials, and then click Connect. The Hypervisor name appears in the navigation pane with a green circle, which indicates that the Hypervisor is connected.
5. In the navigation pane, click the name of the Hypervisor on which you want to install the Citrix ADC VPX instance.
6. On the VM menu, click Import.
7. In the Import dialog box, in the Import file name, browse to the location at which you saved the Citrix ADC VPX instance .xva image file. Make sure that the Exported VM option is selected, and then click Next.
8. Select the Hypervisor on which you want to install the virtual appliance, and then click Next.

9. Select the local storage repository in which to store the virtual appliance, and then click Import to begin the import process.
10. You can add, modify, or delete the virtual network interfaces as required. When finished, click Next.
11. Click Finish to complete the import process.

    Note: To view the status of the import process, click the **Log** tab.
12. If you want to install another virtual appliance, repeat steps 5 through 11.

> **Note**
>
> After the initial configuration of the VPX instance, if you want to upgrade the appliance to the latest software release, see Upgrading or Downgrading the System Software.

Configure VPX instances to use single root I/O virtualization (SR-IOV) network interfaces

September 14, 2021

After you have installed and configured a Citrix ADC VPX instance on XenServer, you can configure the virtual appliance to use SR-IOV network interfaces.

Limitations

XenServer does not support the following features on SRIOV interfaces:

- L2 mode switching
- Clustering
- Admin partitioning [Shared VLAN mode]
- High Availability [Active - Active mode]
- Jumbo frames
- IPv6 protocol in Cluster environment

Prerequisites

On the XenServer host, ensure that you:

- Add the Intel 82599 NIC (NIC) to the host.
- Block list the `ixgbevf` driver by adding the following entry to the **/etc/modprobe.d/blacklist.conf** file:

blacklist ixgbevf

- Enable SR-IOV Virtual Functions (VFs) by adding the following entry to the **/etc/modprobe.d/ixgbe** file:

  options ixgbe max_vfs=<*number_of_VFs*>

  where <*number_VFs*> is the number of SR-IOV VFs that you want to create.

- Verify that SR-IOV is enabled in BIOS.

IXGBE driver version 3.22.3 is recommended.

Assign SR-IOV VFs to the VPX instance by using the XenServer host

To assign SR-IOV network interfaces to Citrix ADC VPX instance, follow these steps:

1. On the XenServer host, use the following command to assign the SR-IOV VFs to the Citrix ADC VPX instance:

   xe host-call-plugin plugin=iovirt host-uuid=<*Xen host UUID*> **fn=assign_free_vf args:uuid**=<*Netscalar VM UUID*> **args:ethdev**=<*interface name*> **args:mac=**<*Mac addr*>

   Where:

   - <*Xen host UUID*> is the UUID of the XenServer host.
   - <*NetScaler VM UUID*> is the UUID of the Citrix ADC VPX instance.
   - <*interface name*> is the interface for the SR-IOV VFs.
   - <*MAC address* > is the MAC address of the SR-IOV VF.

   > **Note**
   >
   > Specify the MAC address that you want use in the args:Mac= parameter, if not specified, the `iovirt` script randomly generates and assigns a MAC address. Also, if you want to use the SR-IOV VFs in Link Aggregation mode, make sure that you specify the MAC address as 00:00:00:00:00:00.

2. Boot the Citrix ADC VPX instance.

Unassign SR-IOV VFs to the VPX instance by using the XenServer host

If you have assigned an incorrect SR-IOV VFs or if you want to modify an assigned SR-IOV VFs, you need to unassign and reassign the SR-IOV VFs to the Citrix ADC VPX instance.

To unassign SR-IOV network interface assigned to a Citrix ADC VPX instance, follow these steps:

1. On the XenServer host, use the following command to assign the SR-IOV VFs to the Citrix ADC VPX instance and reboot the Citrix ADC VPX instance:

xe host-call-plugin plugin=iovirt **host-uuid**=<*Xen_host_UUID*> **fn**=unassign_all **args:uuid**=<*Netscalar_VM_*

Where:

- <*Xen_host_UUID*> - The UUID of the XenServer host.
- <*Netscalar_VM_UUID*> - The UUID of the Citrix ADC VPX instance

2. Boot the Citrix ADC VPX instance.

Configuring VLAN on the SR-IOV Interface

> **Important**
>
> While you are assigning the SR-IOV VFs to the Citrix ADC VPX instance, make sure that you specify MAC address 00:00:00:00:00:00 for the VFs.

To use the SR-IOV virtual functions in link aggregation mode, you need to disable spoof checking for virtual functions that you have created. On the XenServer host, use the following command to disable spoof checking:

ip link set <*interface_name*> **vf** <*VF_id*> **spoofchk** off

Where:

- <interface_name> is the interface name.
- <VF_id> is the virtual function ID.

After disabling spoof checking for all the Virtual Function that you have created, restart the Citrix ADC VPX instance and configure link aggregation. For instructions, see Configure link aggregation.

Configure VLAN on the SR-IOV interface

You can configure VLAN on the SR-IOV Virtual Functions, for instructions, see Configuring a VLAN.

> **Important**
>
> Make sure that the XenServer host does not contain VLAN settings for the VF interface.

Install a Citrix ADC VPX instance on VMware ESX

September 28, 2021

Before installing Citrix ADC VPX instances on VMware ESX, make sure that VMware ESX Server is installed on a machine with adequate system resources. To install a Citrix ADC VPX instance on VMware ESXi, you use the VMware vSphere client. The client or tool must be installed on a remote machine that can connect to VMware ESX through the network.

This section includes the following topics:

- Prerequisites
- Installing a Citrix ADC VPX instance on VMware ESX

> **Important**
>
> You cannot install standard VMware Tools or upgrade the VMware Tools version available on a Citrix ADC VPX instance. VMware Tools for a Citrix ADC VPX instance are delivered as part of the Citrix ADC software release.

Prerequisites

Before you begin installing a virtual appliance, do the following:

- Install VMware ESX on hardware that meets the minimum requirements.
- Install VMware Client on a management workstation that meets the minimum system requirements.
- Download the Citrix ADC VPX appliance setup files.
- Label the physical network ports of VMware ESX.
- Obtain VPX license files. For more information about Citrix ADC VPX instance licenses, see the *Citrix ADC VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

VMware ESX hardware requirements

The following table describes the minimum system requirements for VMware ESX servers running Citrix ADC VPX nCore virtual appliance.

Table 1. Minimum system requirements for a VMware ESX server running a Citrix ADC VPX instance

Component	Requirement
-	2 or more 64-bit x86 CPUs with virtualization assist (Intel-VT) enabled. To run Citrix ADC VPX instance, hardware support for virtualization must be enabled on the VMware ESX host. Make sure that the BIOS option for virtualization support is not disabled. For more information, see your BIOS documentation.
RAM	3 GB
Disk space	40 GB of disk space available

Component	Requirement
Network	One 1-Gbps NIC (NIC); Two 1-Gbps NICs recommended

For information about installing VMware ESX, see http://www.vmware.com/.

The following table lists the virtual computing resources that the VMware ESX server must provide for each VPX nCore virtual appliance.

Table 2. Minimum virtual computing resources required for running a Citrix ADC VPX instance

Component	Requirement
Memory	4 GB
Virtual CPU (vCPU)	2
Virtual network interfaces	1. In ESX, you can install a maximum of 10 virtual network interfaces if the VPX hardware is upgraded to version 7 or higher.
Disk space	20 GB

> Note
>
> This is in addition to any disk requirements for the hypervisor.

For production use of VPX virtual appliance, the full memory allocation must be reserved. CPU cycles (in MHz) equal to at least the speed of one CPU core of the ESX must be reserved.

VMware vSphere client system requirements

VMware vSphere is a client application that can run on Windows and Linux operating systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 3. Minimum system requirements for VMware vSphere client installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the “vSphere Compatibility Matrixes” PDF file at http://kb.vmware.com/.

Component	Requirement
CPU	750 MHz; 1 gigahertz (GHz) or faster recommended
RAM	1 GB; 2 GB recommended
NIC (NIC)	100 Mbps or faster NIC

OVF Tool 1.0 system requirements

OVF Tool is a client application that can run on Windows and Linux systems. It cannot run on the same machine as the VMware ESX server. The following table describes the minimum system requirements.

Table 4. Minimum system requirements for OVF tool installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.
CPU	750 MHz minimum, 1 GHz or faster recommended
RAM	1 GB Minimum, 2 GB recommended
NIC (NIC)	100 Mbps or faster NIC

For information about installing OVF, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.

Downloading the Citrix ADC VPX setup files

The Citrix ADC VPX instance setup package for VMware ESX follows the Open Virtual Machine (OVF) format standard. You can download the files from the Citrix website. You need a Citrix account to log on. If you do not have a Citrix account, access the home page at http://www.citrix.com, click the **New Users link**, and follow the instructions to create a new Citrix account.

Once logged on, navigate the following path from the Citrix home page:

Citrix.com > **Downloads > Citrix ADC > Virtual Appliances**.

Copy the following files to a workstation on the same network as the ESX server. Copy all three files into the same folder.

- NSVPX-ESX-<release number>-<build number>-disk1.vmdk (for example, NSVPX-ESX-13.0-71.44_nc_64-disk1.vmdk)
- NSVPX-ESX-<release number>-<build number>.ovf (for example, NSVPX-ESX-13.0-71.44_nc_64.ovf)
- NSVPX-ESX-<release number>-<build number>.mf (for example, NSVPX-ESX-13.0-71.44_nc_64.mf)

Label the physical network ports of VMware ESX

Before installing a VPX virtual appliance, label of all the interfaces that you plan to assign to virtual appliances, in a unique format, for example, NS_NIC_1_1, NS_NIC_1_2, and so on. In large deployments, labeling in a unique format helps in quickly identifying the interfaces that are allocated to the VPX virtual appliance among other interfaces used by other virtual machines, such as Windows and Linux. Such labeling is especially important when different types of virtual machines share interfaces.

To label the physical network ports of VMware ESX server, follow these steps:

1. Log on to the VMware ESX server by using the vSphere client.
2. On the vSphere client, select the Configuration tab, and then click Networking.
3. At the top-right corner, click Add Networking.
4. In the Add Network Wizard, for **Connection Type**, select **Virtual Machine**, and then click Next.
5. Scroll through the list of vSwitch physical adapters, and choose the physical port that maps to interface 1/1 on the virtual appliances.
6. Enter the label of the interface, for example, **NS_NIC_1_1** as the name of the vSwitch that is associated with interface 1/1 of the virtual appliances.
7. Click Next to finish the vSwitch creation. Repeat the procedure, beginning with step 2, to add any additional interfaces to be used by your virtual appliances. Label the interfaces sequentially, in the correct format (for example, NS_NIC_1_2).

Install a Citrix ADC VPX instance on VMware ESX

After you have installed and configured VMware ESX, you can use the VMware vSphere client to install virtual appliances on the VMware ESX server. The number of virtual appliances that you can install depends on the amount of memory available on the hardware that is running VMware ESX.

To install Citrix ADC VPX instances on VMware ESX by using VMware vSphere Client, follow these steps:

1. Start the VMware vSphere client on your workstation.
2. In the **IP address / Name** text box, type the IP address of the VMware ESX server that you want to connect to.
3. In the **User Name** and **Password** text boxes, type the administrator credentials, and then click Login.
4. On the **File** menu, click **Deploy OVF Template**.
5. In the **Deploy OVF Template** dialog box, in **Deploy from file**, browse to the location at which you saved the Citrix ADC VPX instance setup files, select the .ovf file, and click **Next**.

6. Map the networks shown in the virtual appliance OVF template to the networks that you configured on the ESX host. Click **Next** to start installing a virtual appliance on VMware ESX. When installation is complete, a pop-up window informs you of the successful installation.
7. You are now ready to start the Citrix ADC VPX instance. In the navigation pane, select the Citrix ADC VPX instance that you have installed and, from the right-click menu, select **Power On**. Click the **Console** tab to emulate a console port.
8. If you want to install another virtual appliance, repeat from Step 6.

> **Note**
>
> By default, the Citrix ADC VPX instance uses E1000 network interfaces.
>
> After the installation, you can use vSphere client or vSphere Web Client to manage virtual appliances on VMware ESX.
>
> For the VLAN tagging feature to work, on the VMware ESX, set the port group's VLAN ID to All (4095) on the vSwitch of VMware ESX server. For more information about setting a VLAN ID on the vSwitch of VMware ESX server, see http://www.vmware.com/pdf/esx3_vlan_wp.pdf.

Migrate a Citrix ADC VPX instance by using VMware vMotion

You can migrate a Citrix ADC VPX instance by using VMware vSphere vMotion.

Follow these usage guidelines:

- VMware does not support the vMotion feature on virtual machines configured with PCI Passthrough and SR-IOV interfaces.
- Supported interfaces are E1000 and VMXNET3. To use vMotion on your VPX instance, ensure that the instance is configured with a supported interface.
- For more information about how to migrate an instance by using VMware vMotion, see the VMware documentation.

Configure a Citrix ADC VPX instance to use VMXNET3 network interface

September 14, 2021

After you have installed and configured the Citrix ADC VPX instance on the VMware ESX, you can use the VMware vSphere web client to configure the virtual appliance to use VMXNET3 network interfaces.

To configure Citrix ADC VPX instances to use VMXNET3 network interfaces by using the VMware vSphere Web Client:

1. In the vSphere Web Client, select Hosts and Clusters.

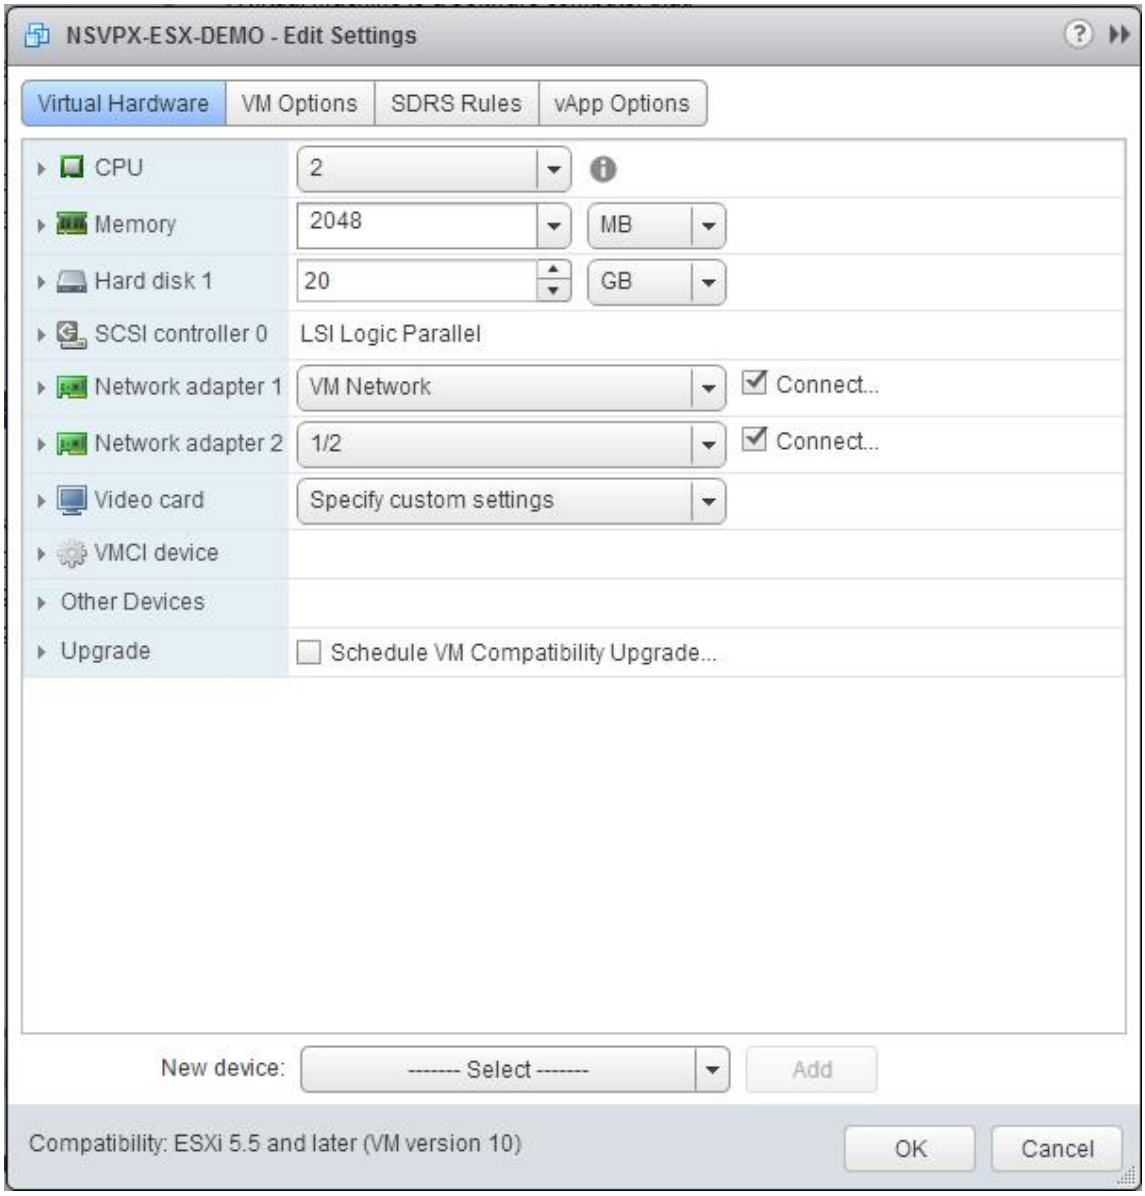
2. Upgrade the Compatibility setting of the Citrix ADC VPX instance to ESX, as follows:

   a. Power off the Citrix ADC VPX instance.

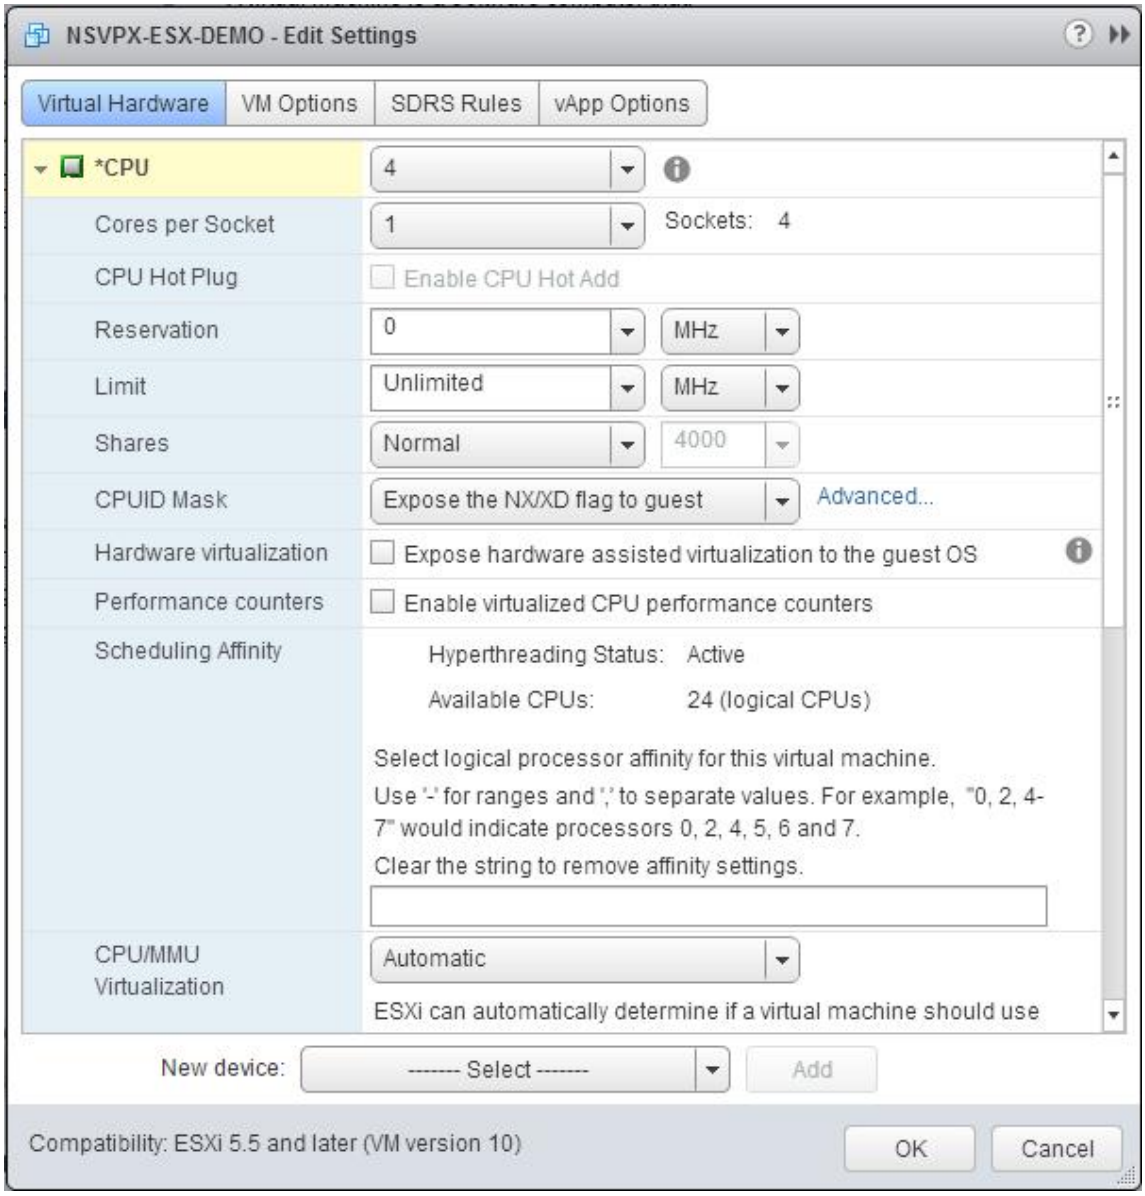
   b. Right-click the Citrix ADC VPX instance and select Compatibility > Upgrade VM Compatibility.

   c. In the Configure VM Compatibility dialog box, select ESXi 5.5 and later from the Compatible with drop-down list and click OK.

3. Right-click on the Citrix ADC VPX instance and click Edit Settings.



4. In the <virtual_appliance> - Edit Settings dialog box, click the CPU section.



5. In the CPU section, update the following:

   - Number of CPUs
   - Number of Sockets
   - Reservations
   - Limit
   - Shares

   Set the values as follows:

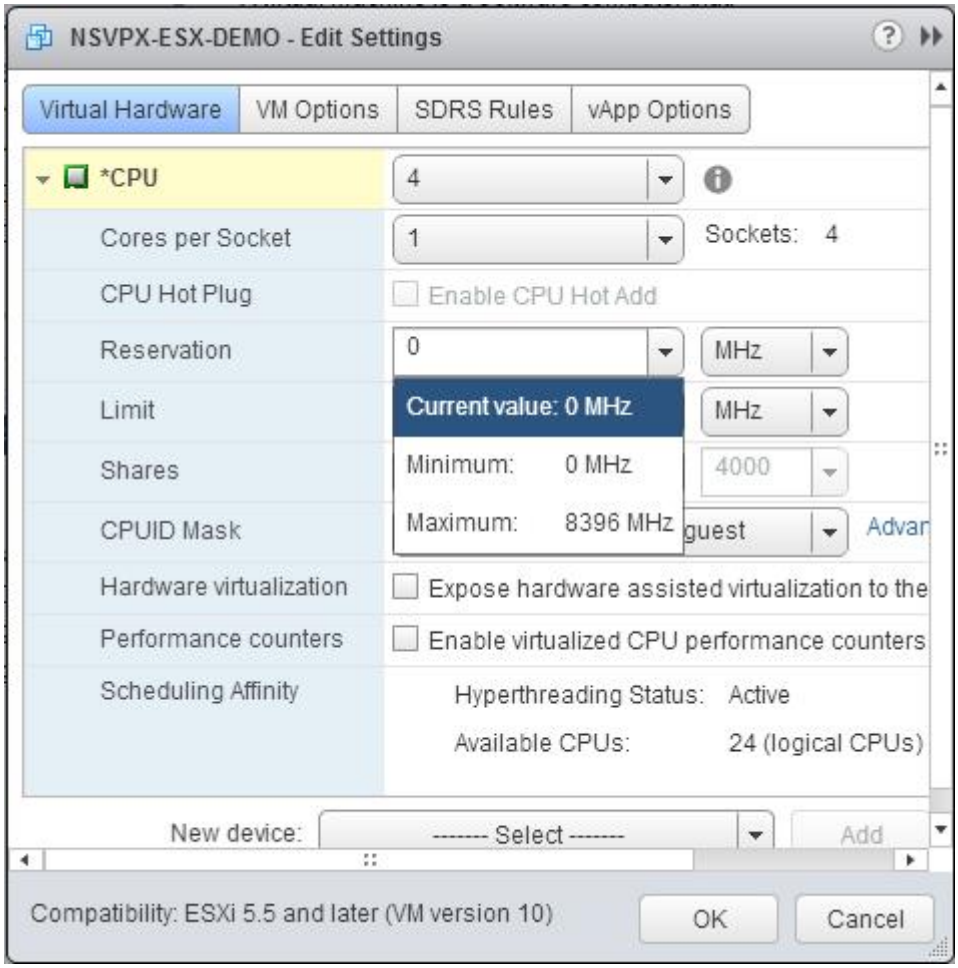
   a. In the CPU drop-down list, select the number of CPUs to assign to the virtual appliance.

   b. In the Cores per Socket drop-down list, select the number of sockets.

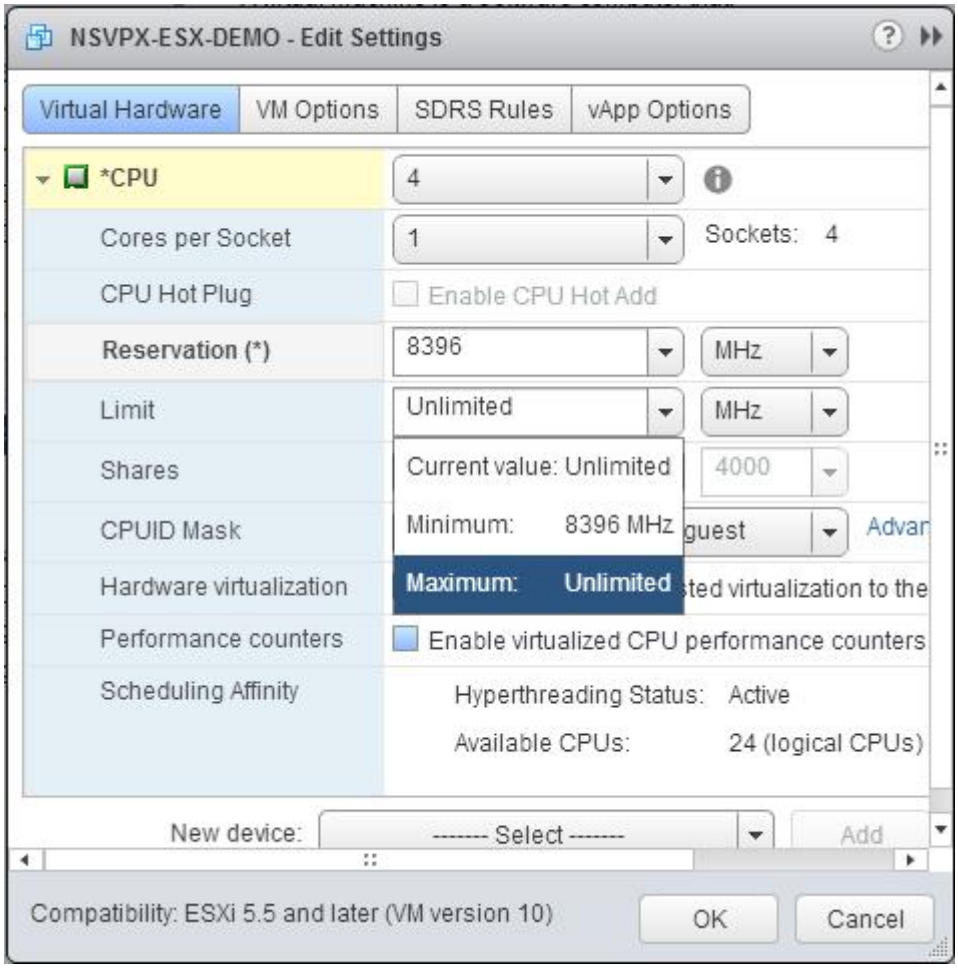
   c. (Optional) In the CPU Hot Plug field, select or unselect the Enable CPU Hot Add check box.

Note: Citrix recommends accepting the default (disabled).

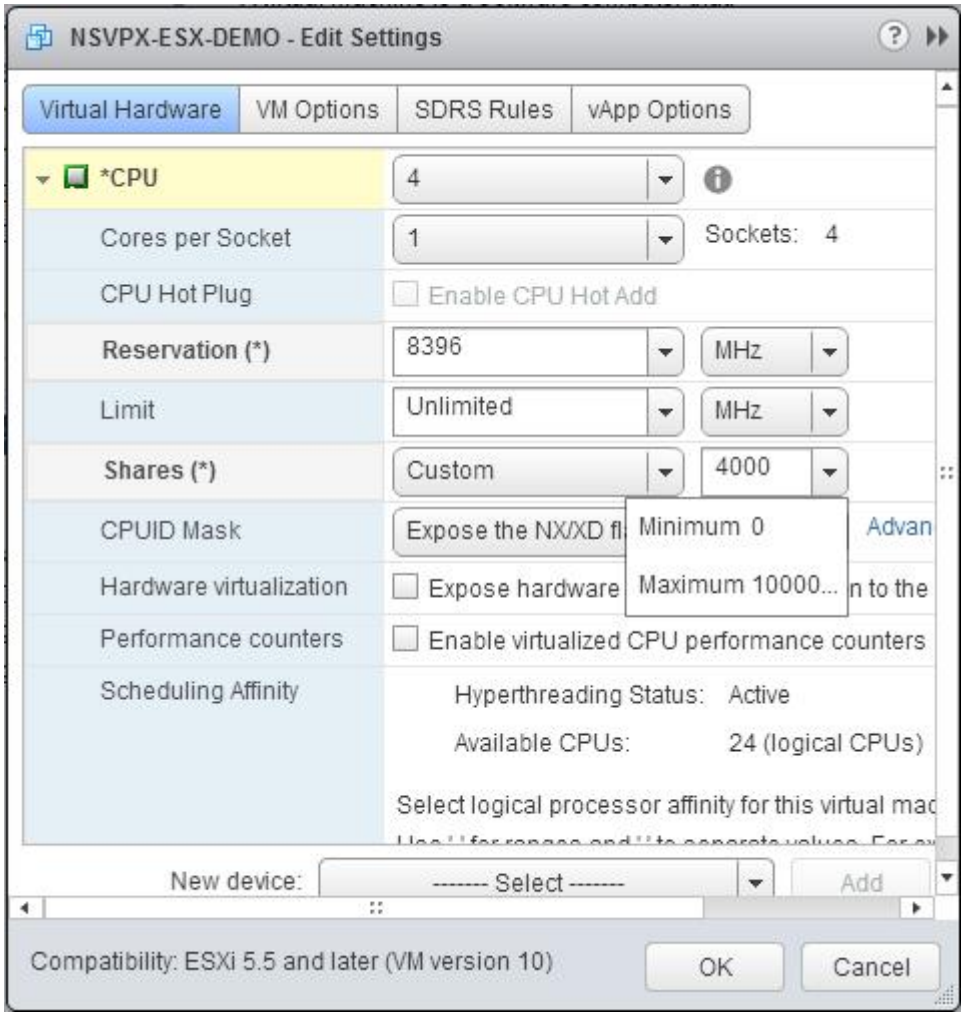
d. In the Reservation drop-down list, select the number that is shown as the maximum value.



e. In the Limit drop-down list, select the number that is shown as the maximum value.



f. In the Shares drop-down lists, select Custom and the number that is shown as the maximum value.



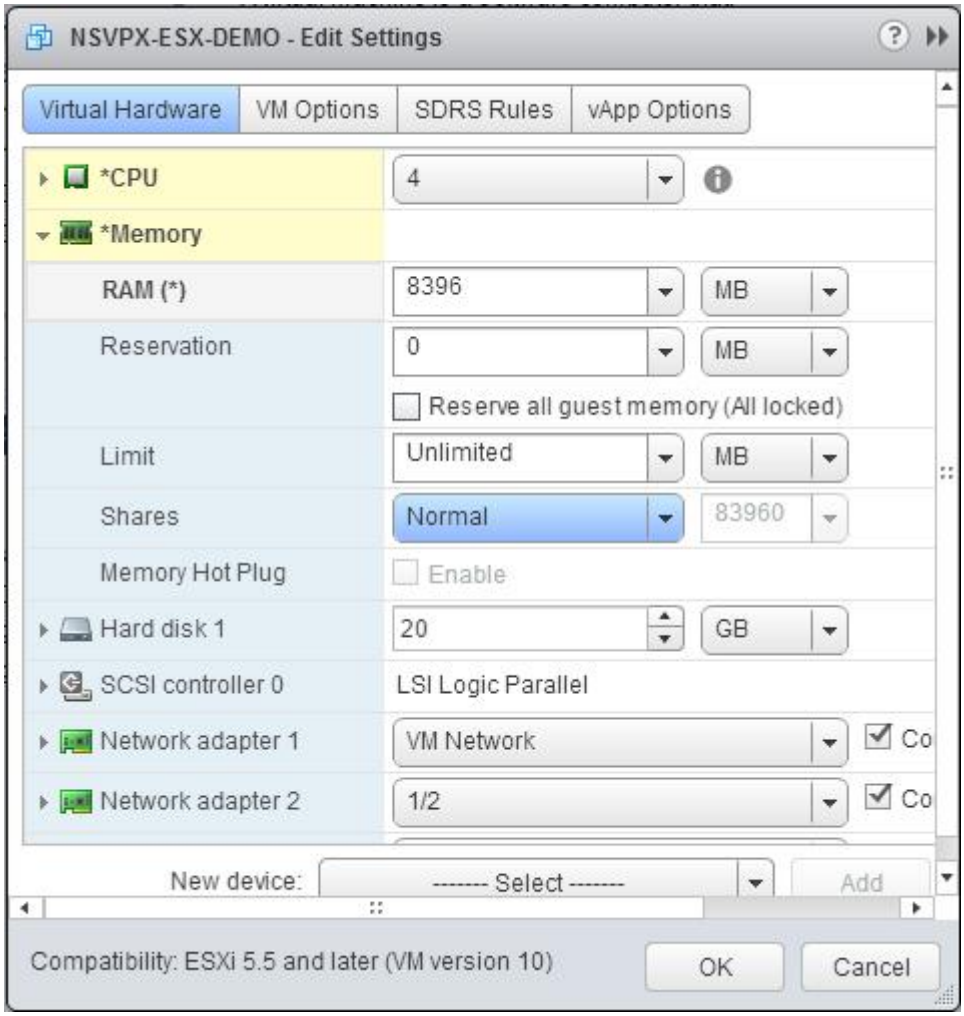
6. In the Memory section, update the following:

   - Size of RAM
   - Reservations
   - Limit
   - Shares

   Set the values as follows:

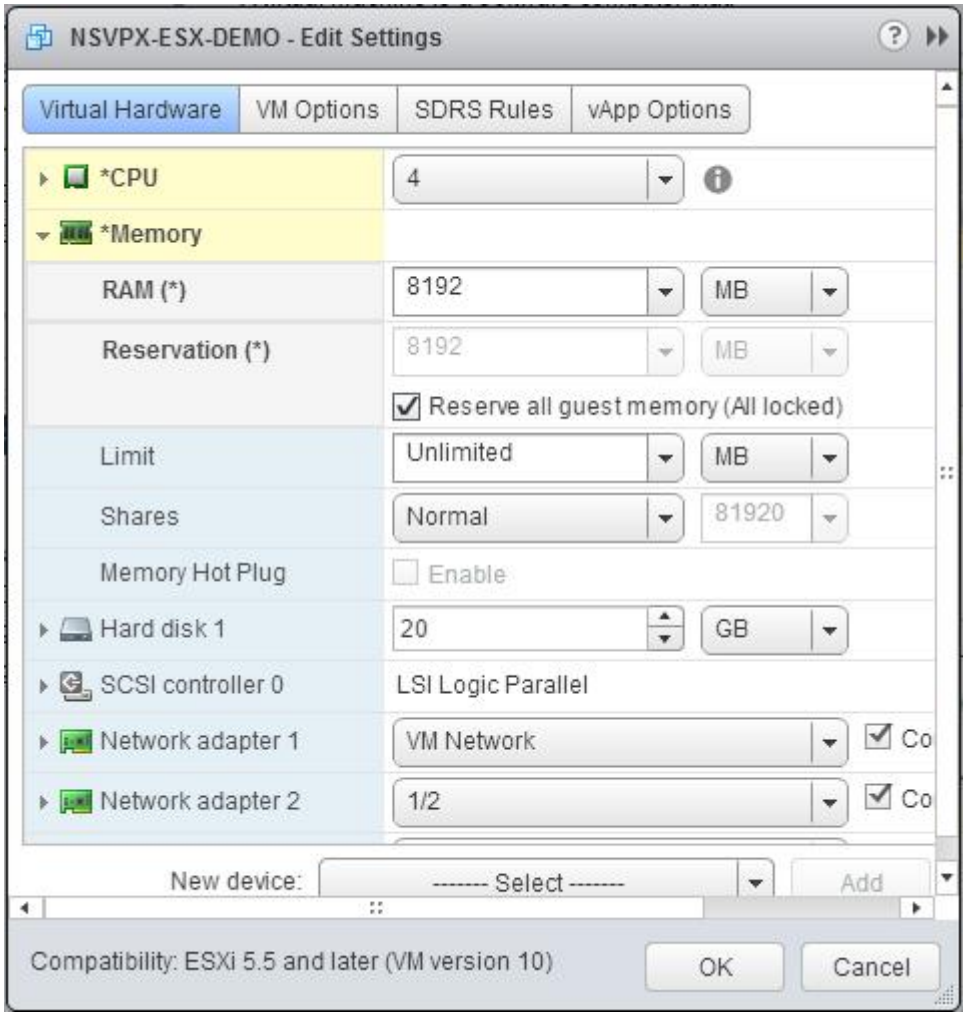
   a. In the RAM drop-down list, select the size of the RAM. It must be the number of vCPUs x 2 GB. For example, if the number of vCPUs is 4, the RAM must be 4 x 2 GB = 8 GB.

   Note: For an Advanced or Premium edition of the Citrix ADC VPX appliance, make sure that you allocate 4 GB of RAM to each vCPU. For example, if the number of vCPU is 4 then RAM = 4 x 4 GB = 16 GB.

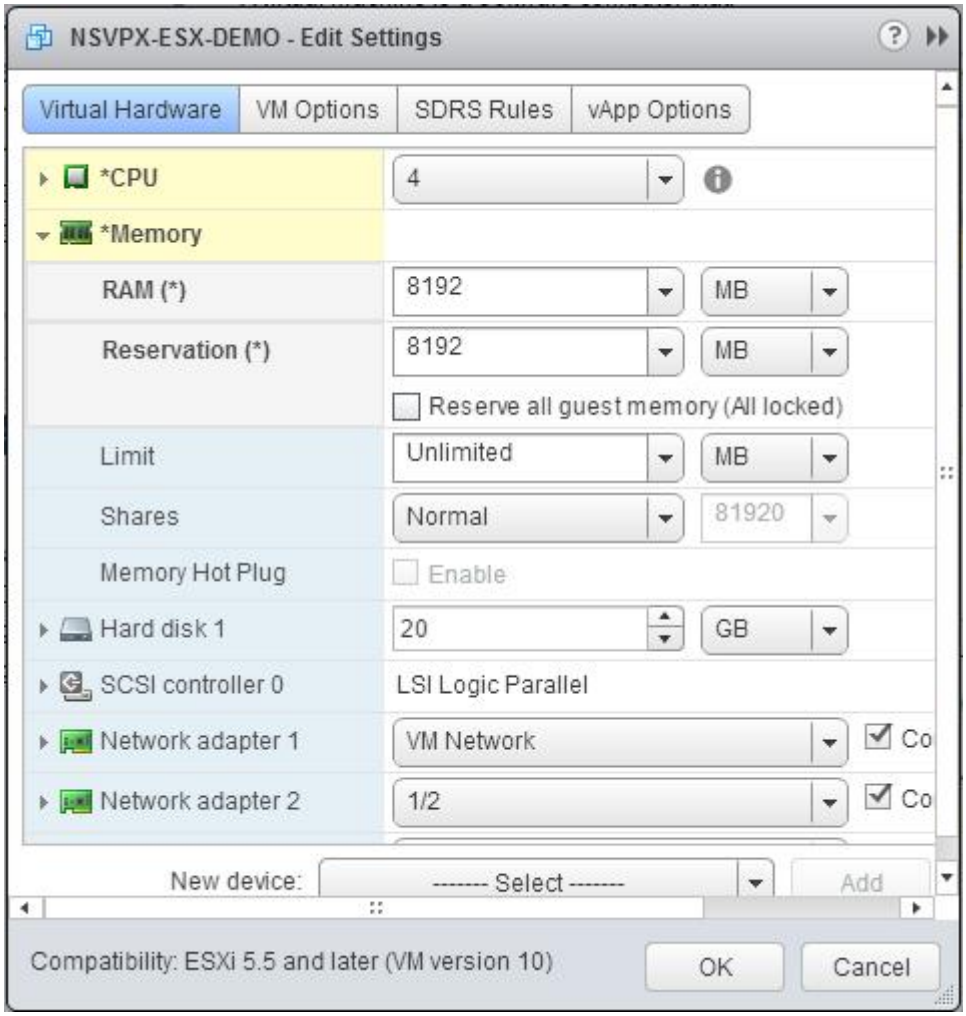


b. In the Reservation drop-down list, enter the value for the memory reservation, and select the Reserve all guest memory (All locked) check box. The memory reservation must be the number of vCPUs x 2 GB. For example, if the number of vCPUs is 4, the memory reservation must be 4 x 2 GB = 8 GB.

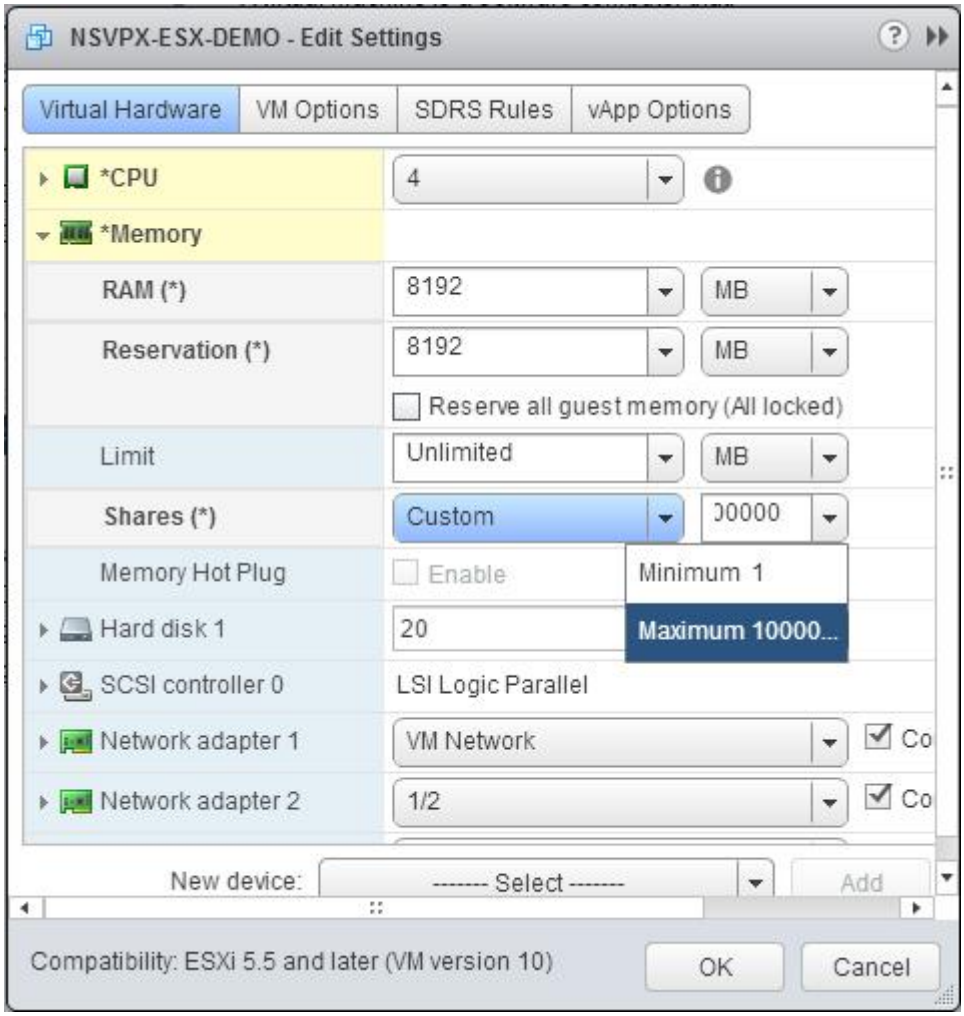
Note: For an Advanced or Premium edition of the Citrix ADC VPX appliance, make sure that you allocate 4 GB of RAM to each vCPU. For example, if the number of vCPU is 4 then RAM = 4 x 4 GB = 16 GB.



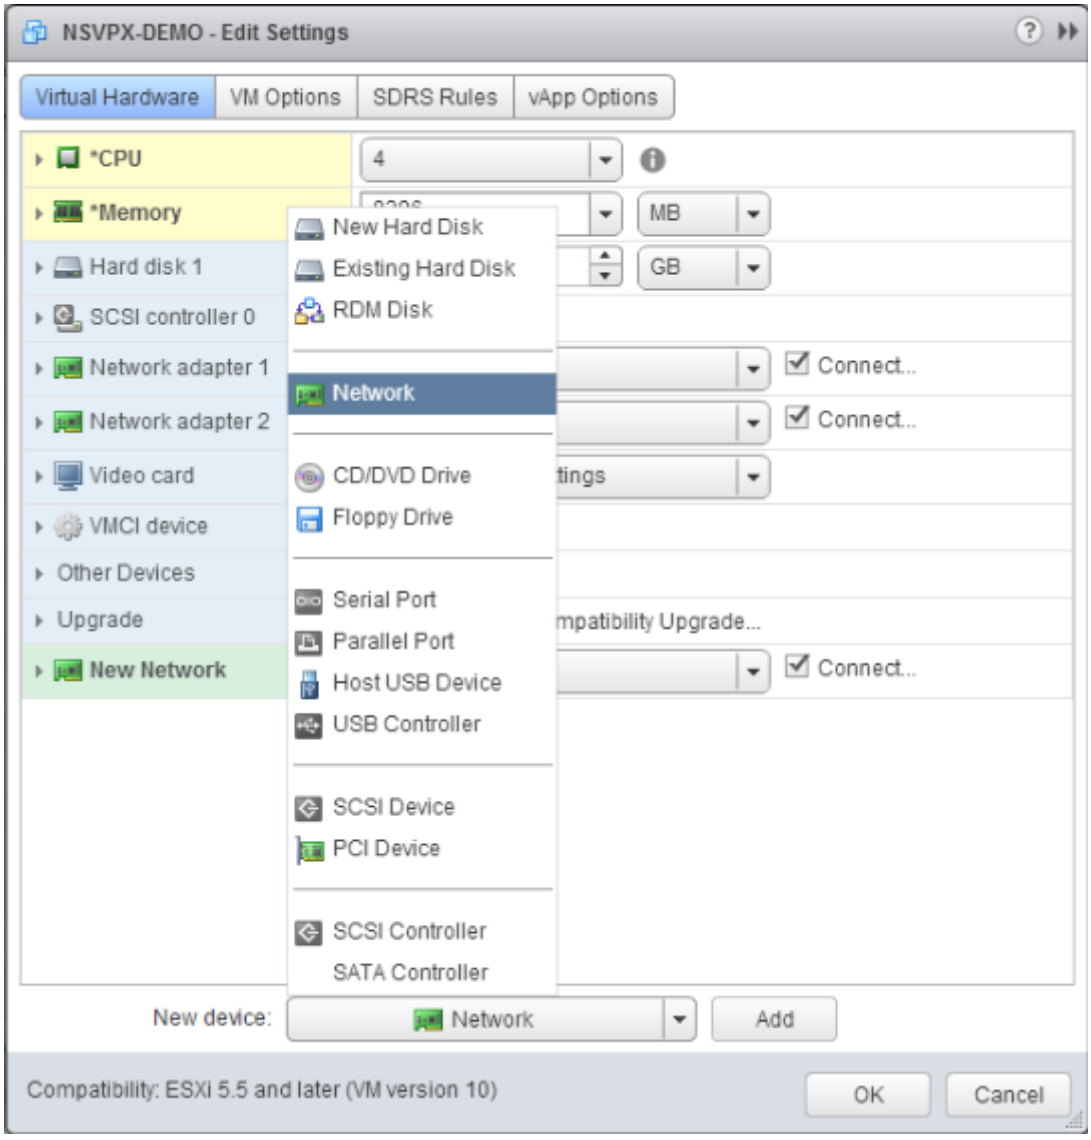
c. In the Limit drop-down list, select the number that is shown as the maximum value.



d. In the Shares drop-down lists, select Custom and the number that is shown as the maximum value.



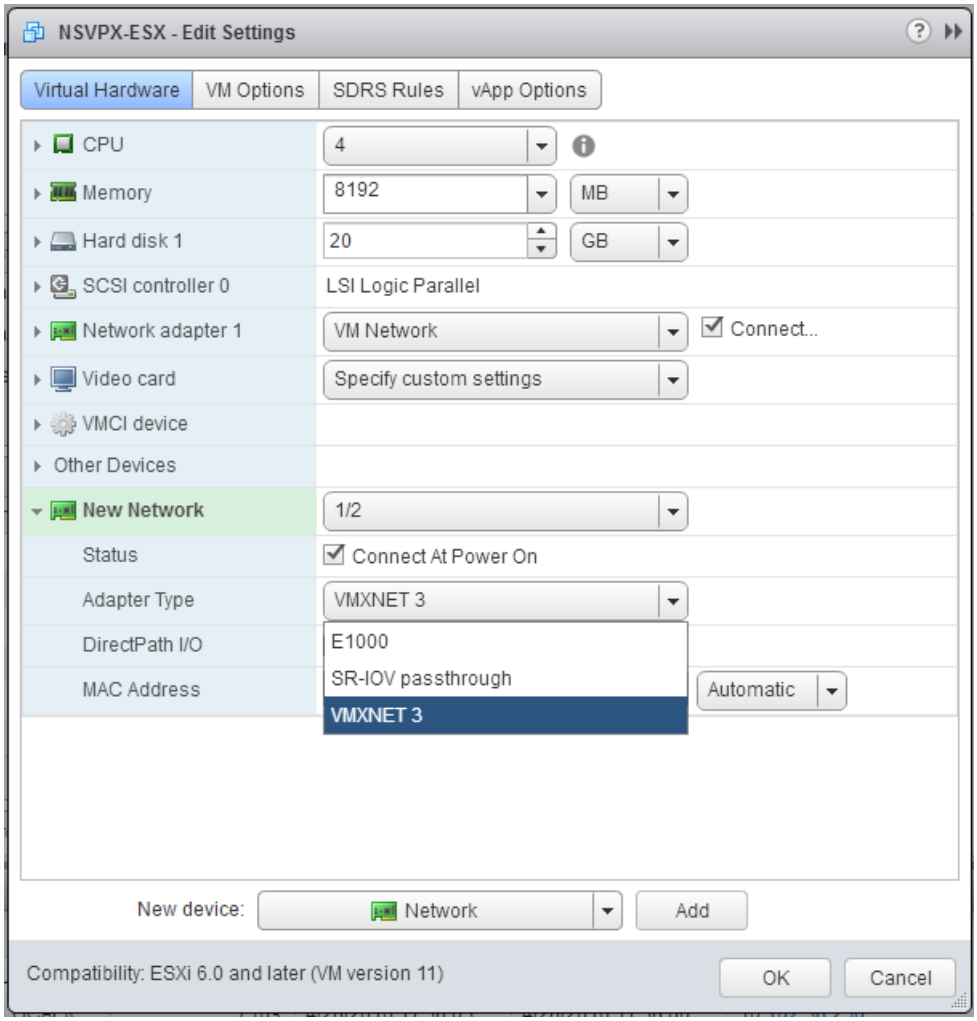
7. Add a VMXNET3 network interface. From the New device drop-down list, select Network and click Add.



8. In the New Network section, from the drop-down list, select the network interface, and do the following:

   a. In the Adapter Type drop-down list, select VMXNET3.

   > **Important**
   >
   > The default E1000 network interface and VMXNET3 cannot coexist, make sure that you remove the E1000 network interface and use VMXNET3 (0/1) as the management interface.



9. Click OK.
10. Power on the Citrix ADC VPX instance.
11. Once the Citrix ADC VPX instance powers on, you can use the following command to verify the configuration:

    ```
    show interface summary
    ```

The output must show all the interfaces that you configured:

```
> show interface summary
-------------------------------------------------------------------------

      Interface  MTU        MAC                Suffix
-------------------------------------------------------------------------

1     0/1        1500       00:0c:29:89:1d:0e  NetScaler Vir...rface,
    VMXNET3
```

```
6  2     1/1        9000       00:0c:29:89:1d:18    NetScaler Vir...rface,
       VMXNET3
7  3     1/2        9000       00:0c:29:89:1d:22    NetScaler Vir...rface,
       VMXNET3
8  4     LO/1       9000       00:0c:29:89:1d:0e    Netscaler Loopback
      interface
```

> **Note**
>
> After you add a VMXNET3 interface and restart the Citrix ADC VPX appliance, the VMware ESX hypervisor might change the order in which the NIC is presented to the VPX appliance. So, network adapter 1 might not always remain 0/1, resulting in loss of management connectivity to the VPX appliance. To avoid this issue, change the virtual network of the network adapter accordingly.
>
> This is a VMware ESX hypervisor limitation.

Configure a Citrix ADC VPX instance to use SR-IOV network interface

September 14, 2021

After you have installed and configured the Citrix ADC VPX instance on VMware ESX, you can use the VMware vSphere web client to configure the virtual appliance to use single root I/O v virtualization (SR-IOV) network interfaces.

Limitations

A Citrix ADC VPX configured with SR-IOV network interface has the following limitations:

- The following features are not supported on SR-IOV interfaces using the Intel 82599 10G NIC on ESX VPX:
  - L2 mode switching
  - Static Link Aggregation and LACP
  - Clustering
  - Admin partitioning [Shared VLAN mode]
  - High Availability [Active - Active mode]
  - Jumbo frames
  - IPv6
- The following features are not supported on the SR-IOV interface with an Intel 82599 10G NIC on KVM VPX:
  - Static Link Aggregation and LACP
  - L2 mode switching

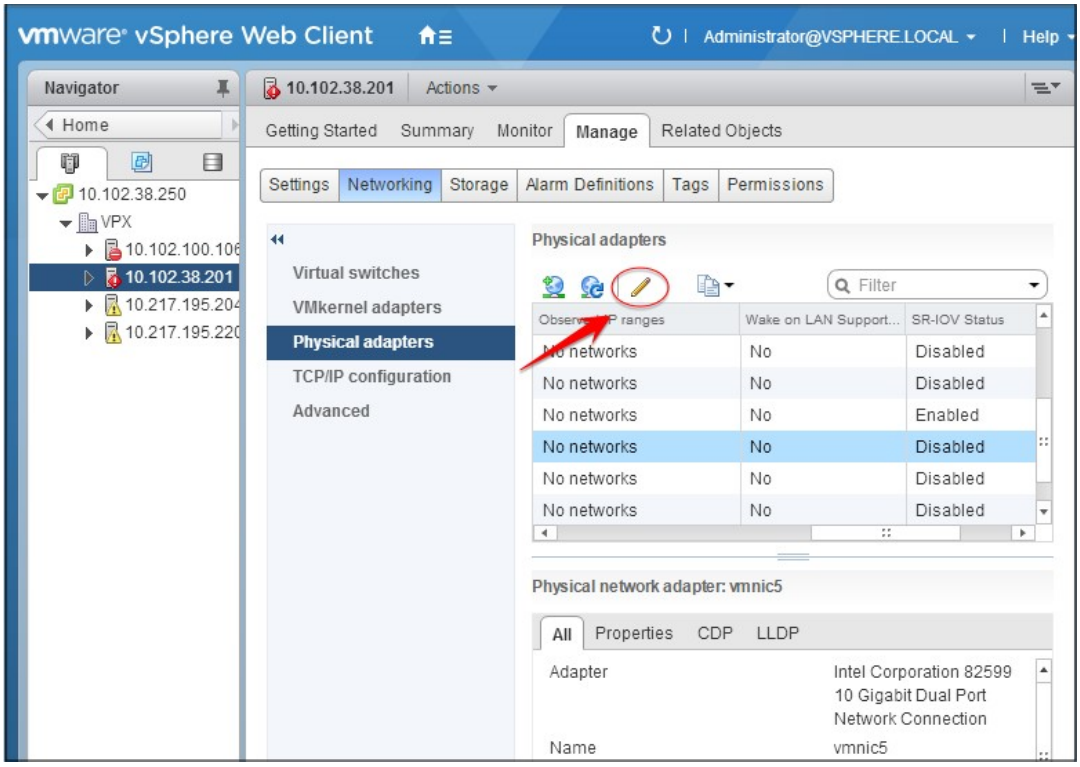
- Clustering
- Admin partitioning [Shared VLAN mode]
- High Availability [Active – Active mode]
- Jumbo frames
- IPv6
- VLAN configuration on Hypervisor for SR-IOV VF interface through `ip link` command is not supported

Prerequisite

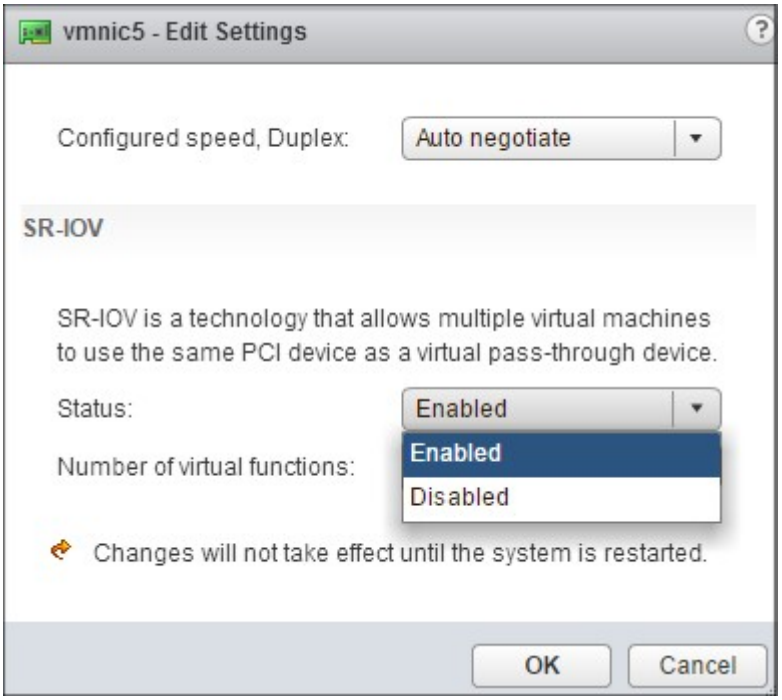
Make sure that you:

- Add the Intel 82599 NIC (NIC) to the ESX Host. IXGBE driver version 3.7.13.7.14iov is recommended.
- Enable SR-IOV on the host physical adapter, as follows:
  1. In the vSphere Web Client, navigate to the Host.
  2. On the **Manage > Networking** tab, select **Physical adapters**. The SR-IOV Status field shows whether a physical adapter supports SR-IOV.

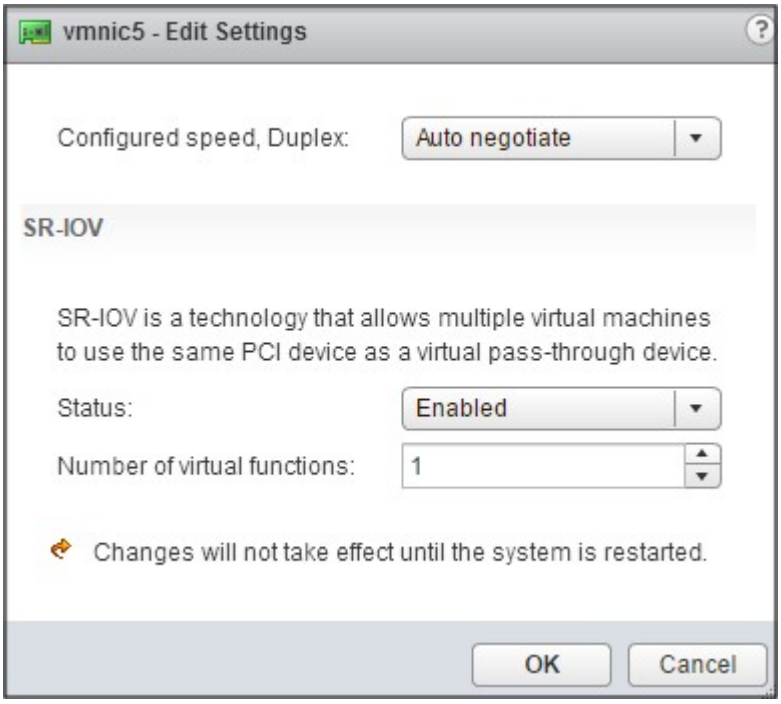
  3. Select the physical adapter, and then click the pencil icon to open the **Edit Settings** dialog box.



4. Under SR-IOV, select **Enabled** from the **Status** drop-down list.



5. In the **Number of virtual functions** field, enter the number of virtual functions that you want to configure for the adapter.



6. Click **OK**.
7. Restart the host.

- Create a Distributed Virtual Switch (DVS) and `Portgroups`. For instructions, see the VMware Documentation.

  > **Note**
  >
  > Citrix has qualified the SR-IOV configuration on DVS and `Portgroups` only.

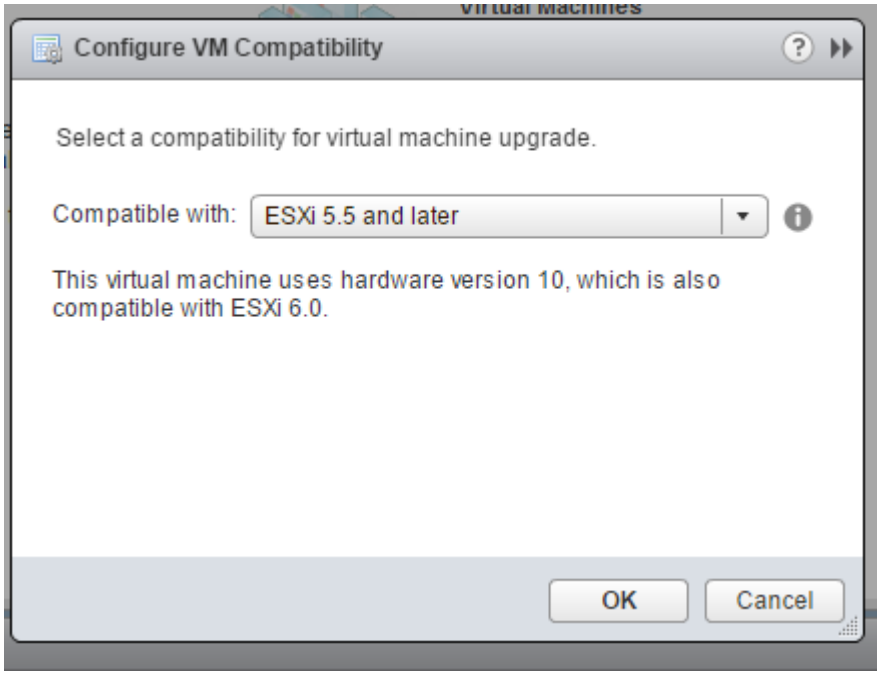
To configure Citrix ADC VPX instances to use SR-IOV network interface by using VMware vSphere Web Client:

1. In the vSphere Web Client, select **Hosts and Clusters**.
2. Upgrade the Compatibility setting of the Citrix ADC VPX instance to ESX 5.5 or later, as follows:

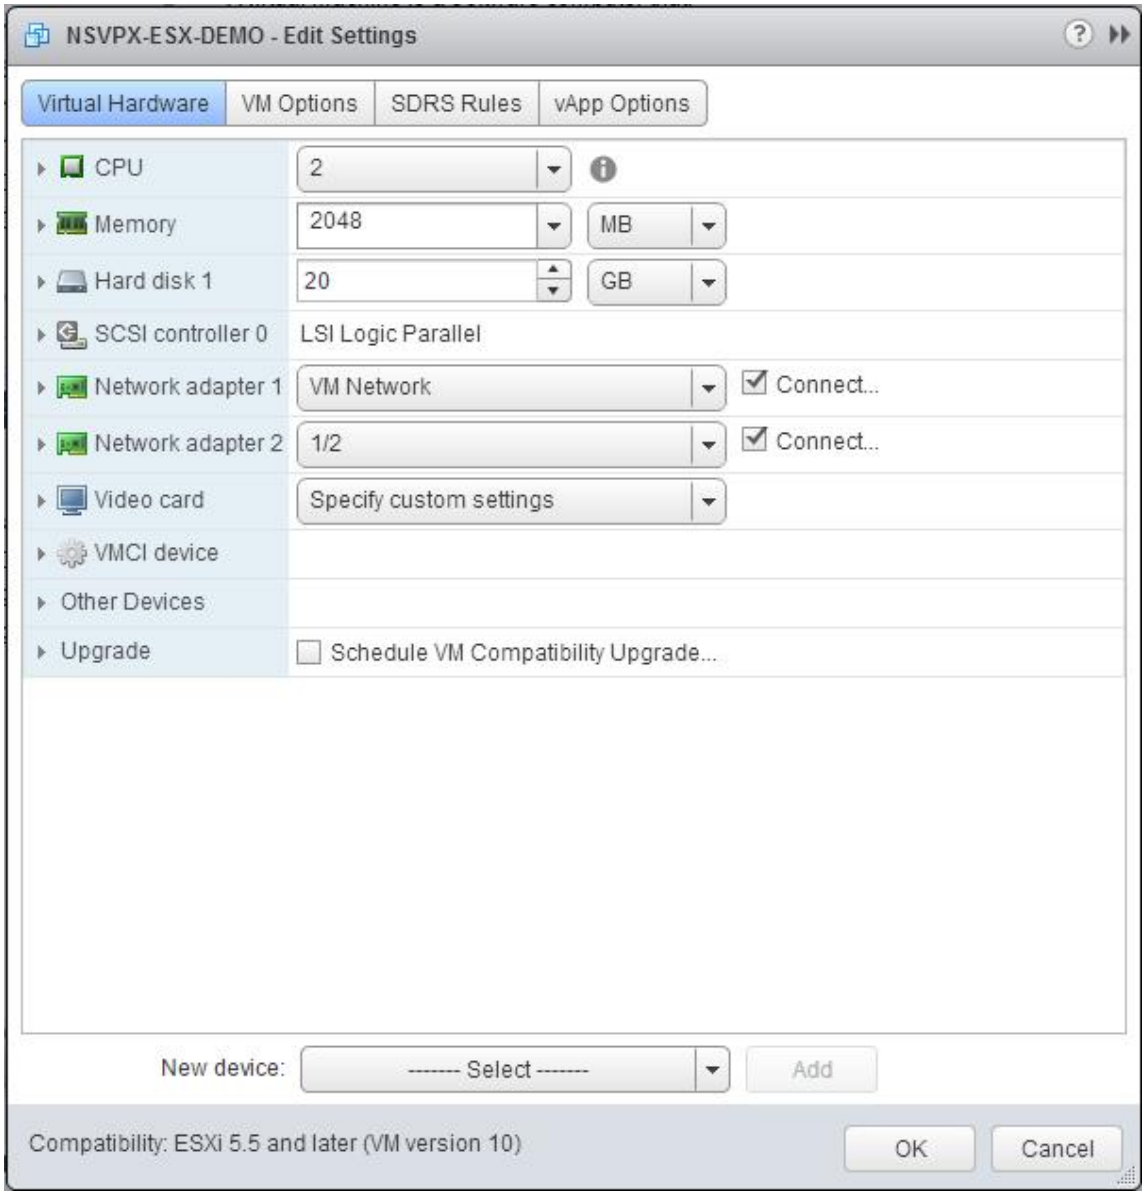
   a. Power off the Citrix ADC VPX instance.

   b. Right-click the Citrix ADC VPX instance and select **Compatibility > Upgrade VM Compatibility**.

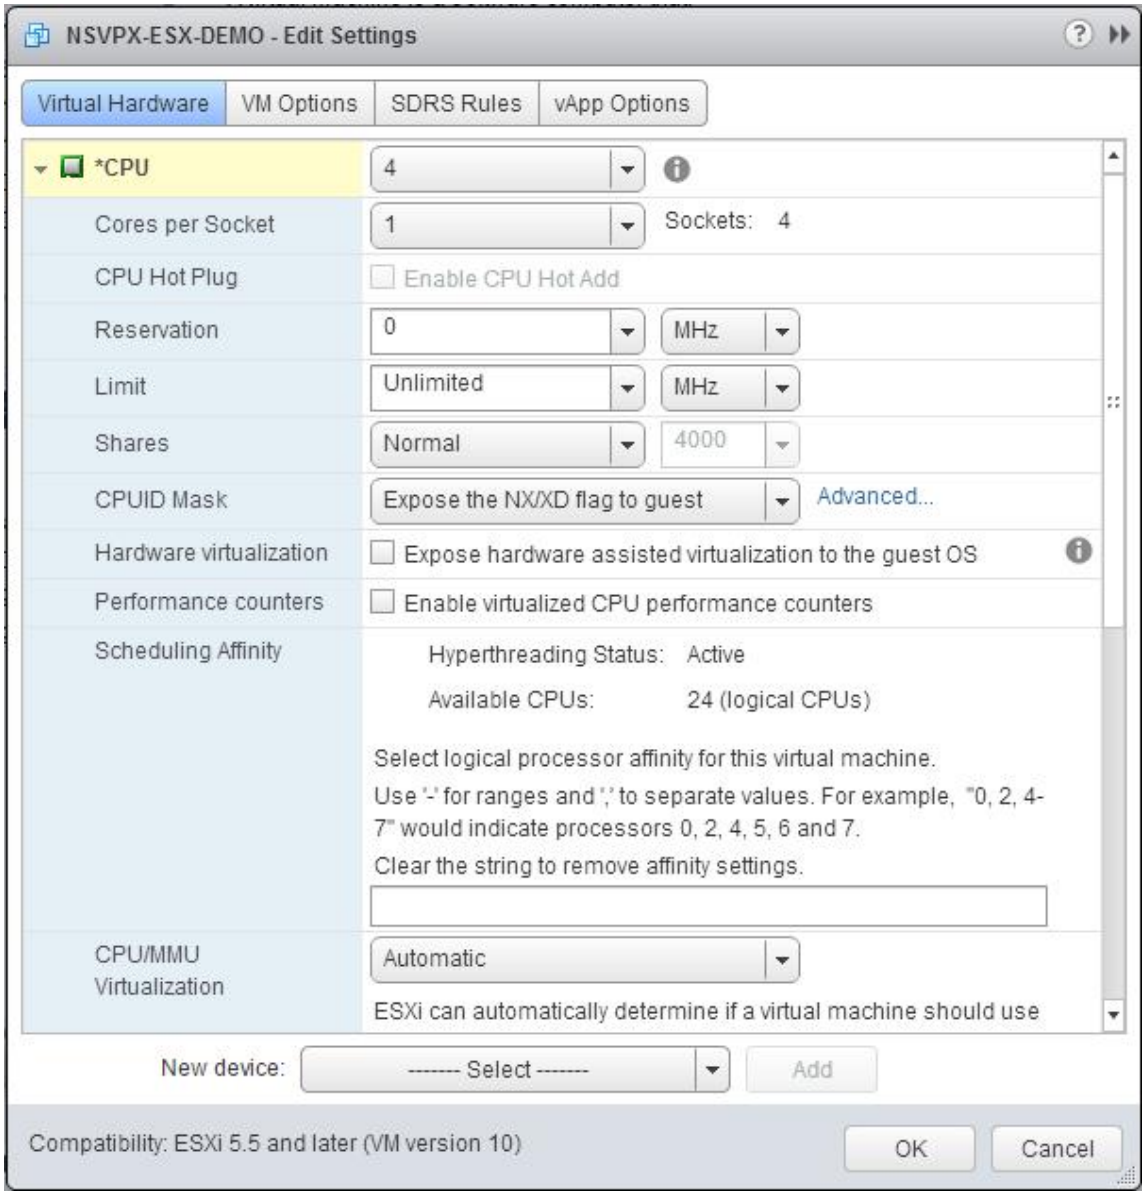
   c. In the **Configure VM Compatibility** dialog box, select **ESXi 5.5 and later** from the **Compatible with** drop-down list and click **OK**.



3. Right-click on the Citrix ADC VPX instance and click **Edit Settings**.



4. In the **<virtual_appliance> - Edit Settings** dialog box, click the **CPU** section.



5. In the **CPU** section, update the following settings:

   - Number of CPUs
   - Number of Sockets
   - Reservations
   - Limit
   - Shares

   Set the values as follows:

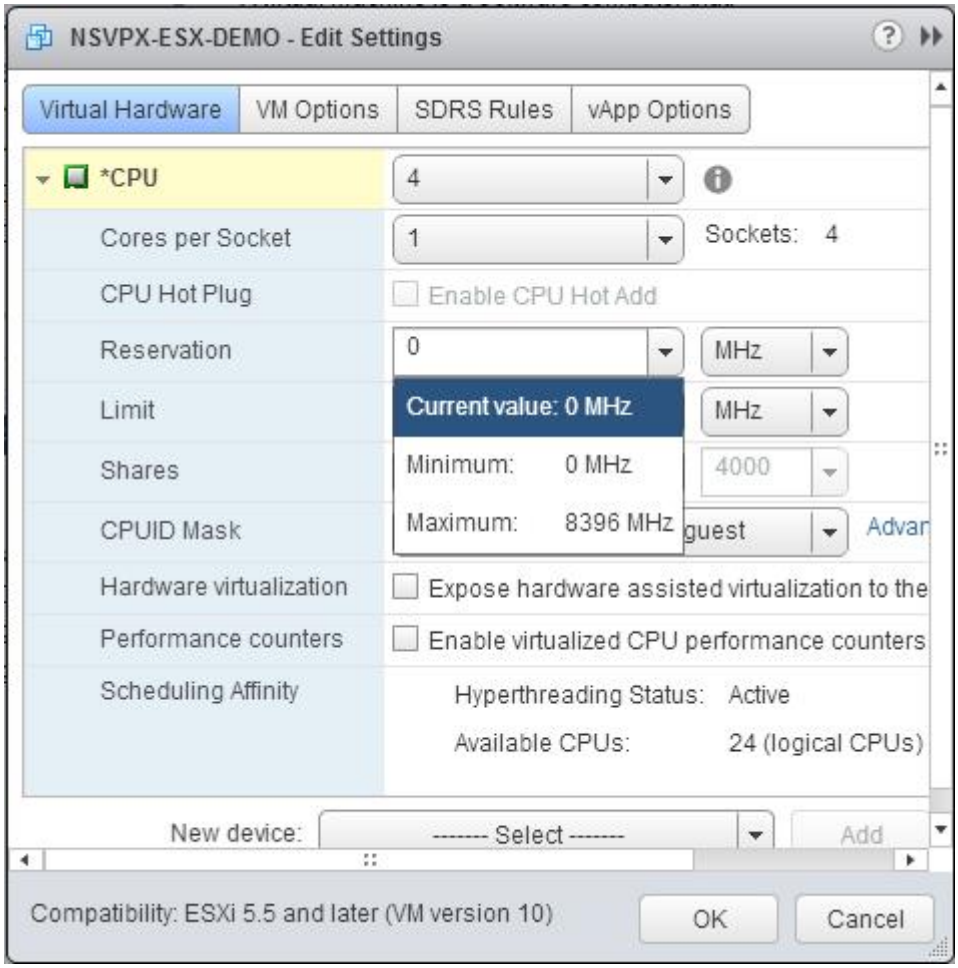
   a. In the **CPU** drop-down list, select the number of CPUs to assign to the virtual appliance.

   b. In the **Cores per Socket** drop-down list, select the number of sockets.

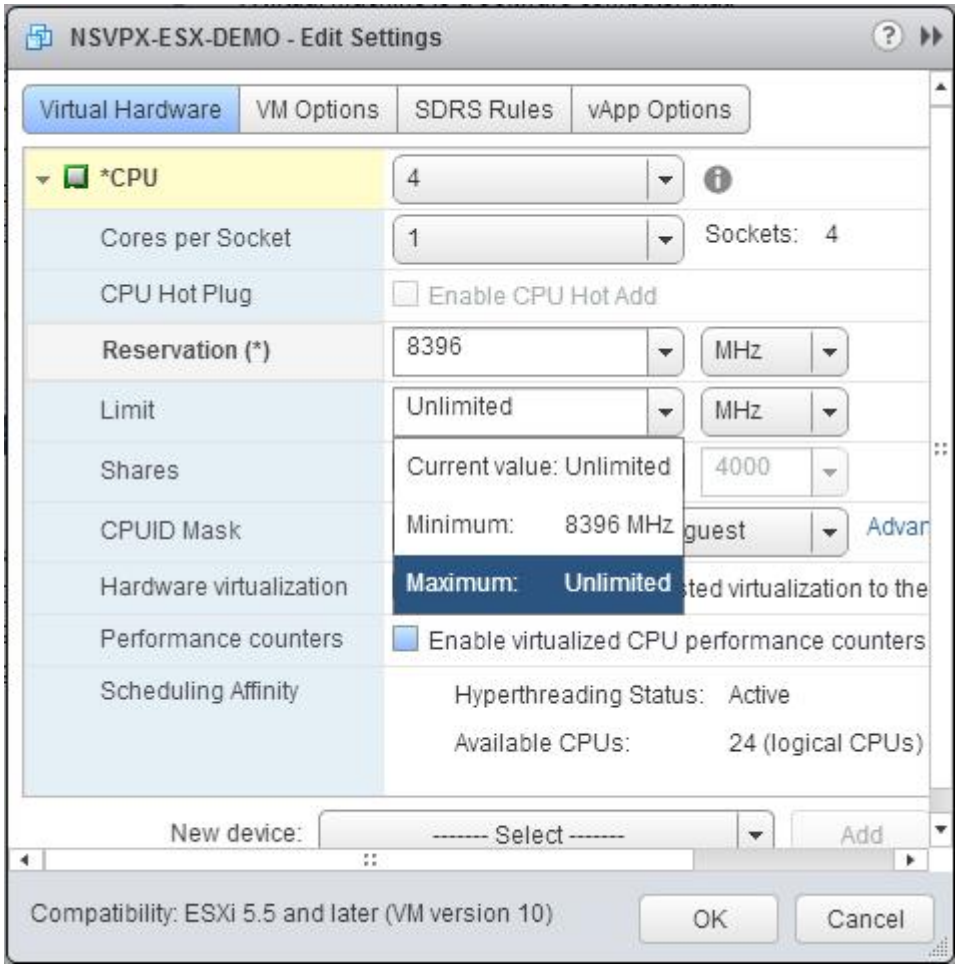
   c. (Optional) In the **CPU Hot Plug** field, select or clear the **Enable CPU Hot Add** check box.

Note: Citrix recommends accepting the default (disabled).

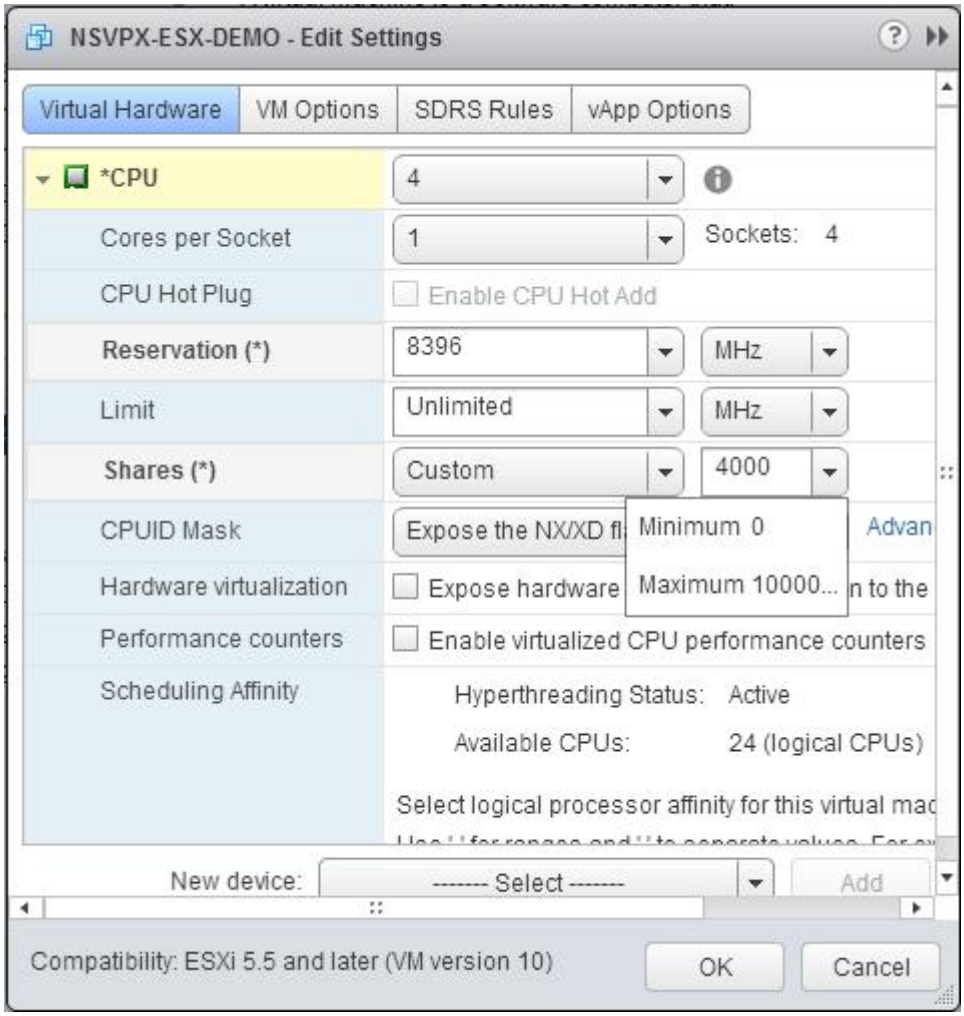
d. In the **Reservation** drop-down list, select the number that is shown as the maximum value.



e. In the **Limit** drop-down list, select the number that is shown as the maximum value.



f. In the **Shares** drop-down lists, select **Custom** and the number that is shown as the maximum value.



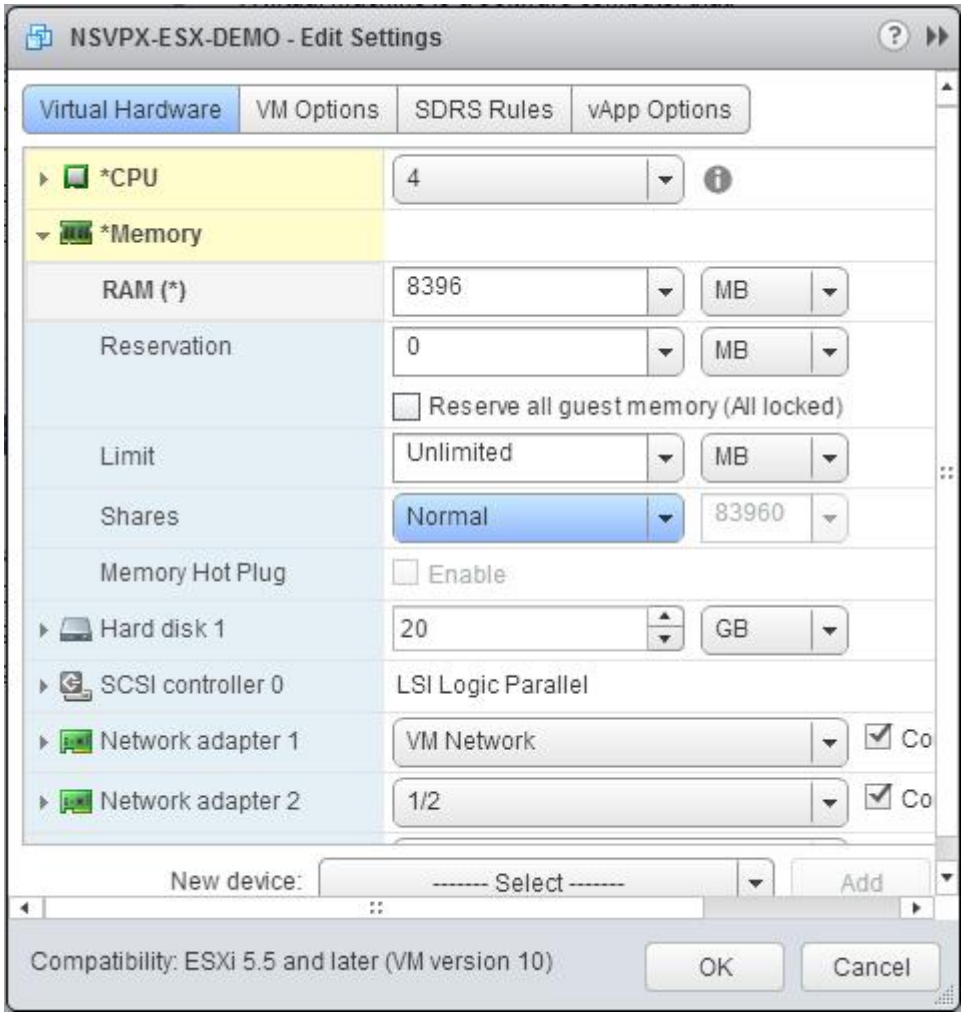
6. In the **Memory** section, update the following settings:

   - Size of RAM
   - Reservations
   - Limit
   - Shares

   Set the values as follows:

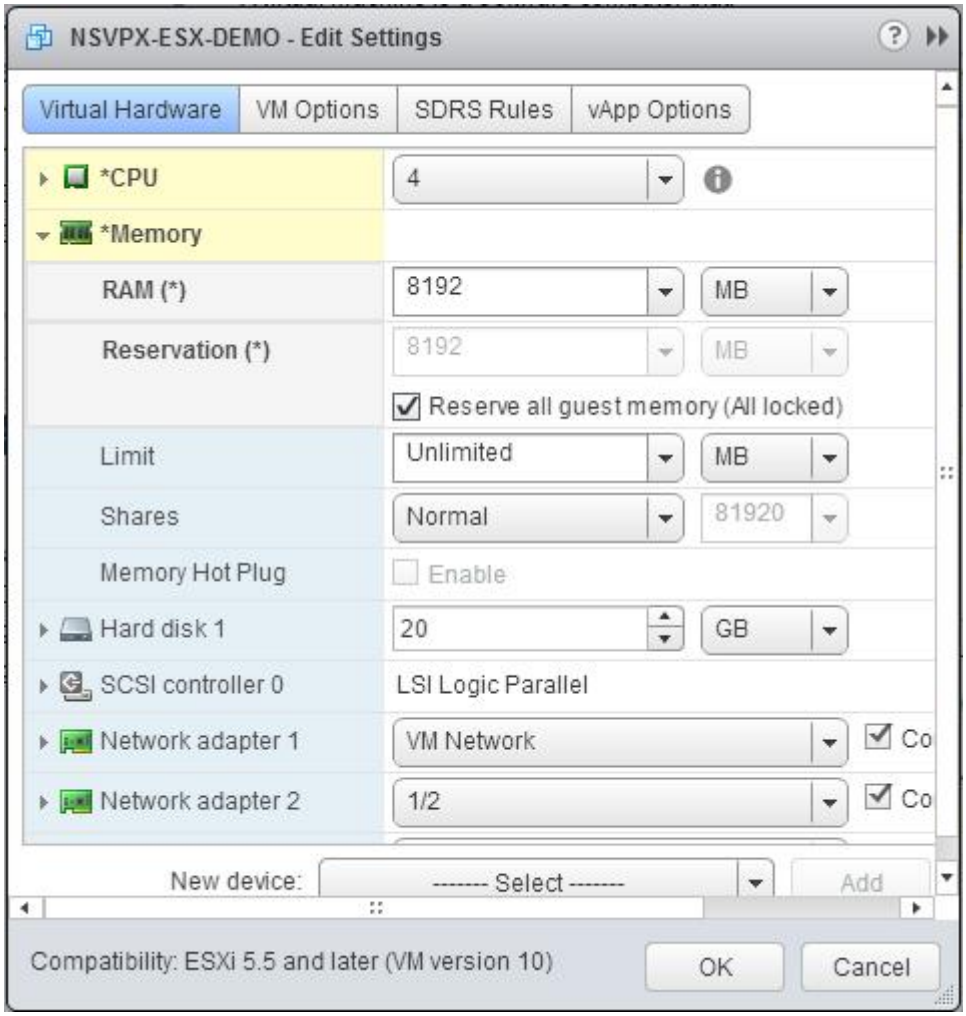
   a. In the **RAM** drop-down list, select the size of the RAM. It must be the number of vCPUs x 2 GB. For example, if the number of vCPU is 4 then RAM = 4 x 2 GB = 8 GB.

   Note: For Advanced or Premium edition of the Citrix ADC VPX appliance, make sure that you allocate 4 GB of RAM to each vCPU. For example, if the number of vCPU is 4 then RAM = 4 x 4 GB = 16 GB.

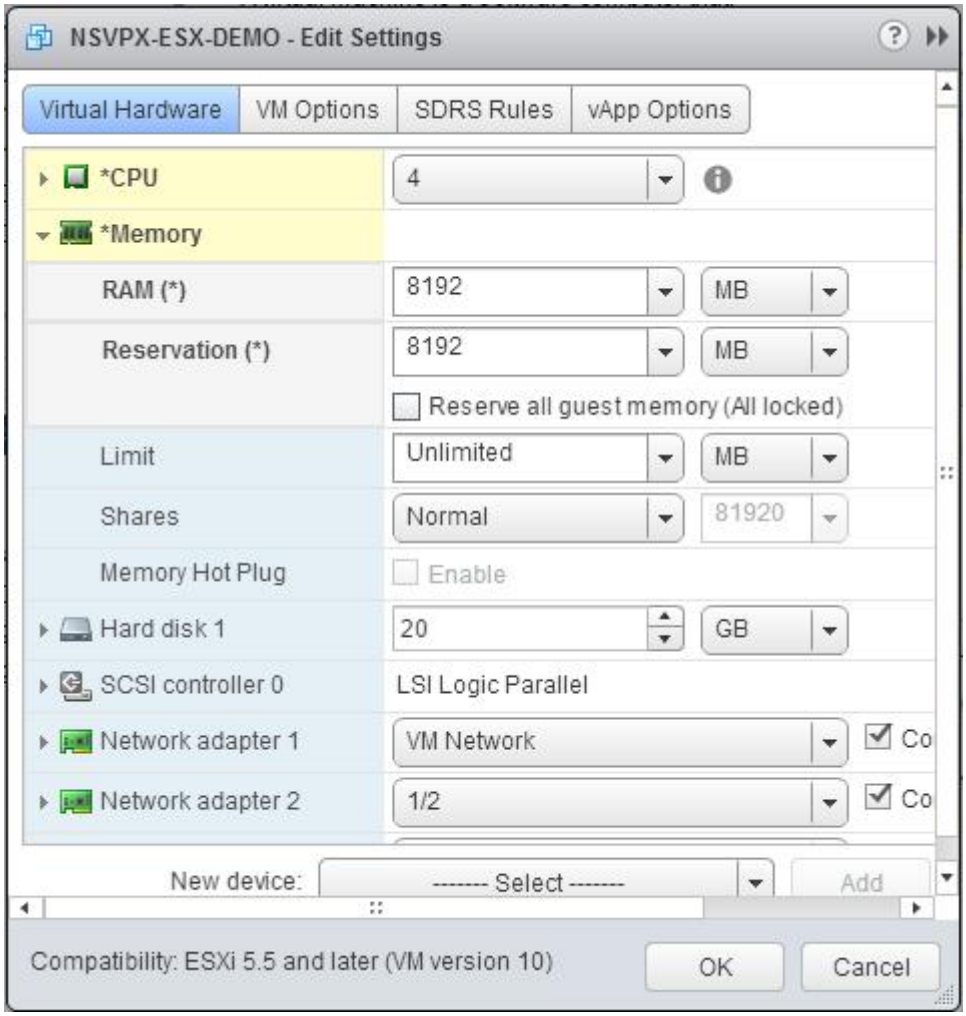


b. In the **Reservation** drop-down list, enter the value for the memory reservation, and select the **Reserve all guest memory (All locked)** check box. The memory reservation must be number of vCPUs x 2 GB. For example, if the number of vCPUs is 4, the memory reservation must be 4 x 2 GB = 8 GB.

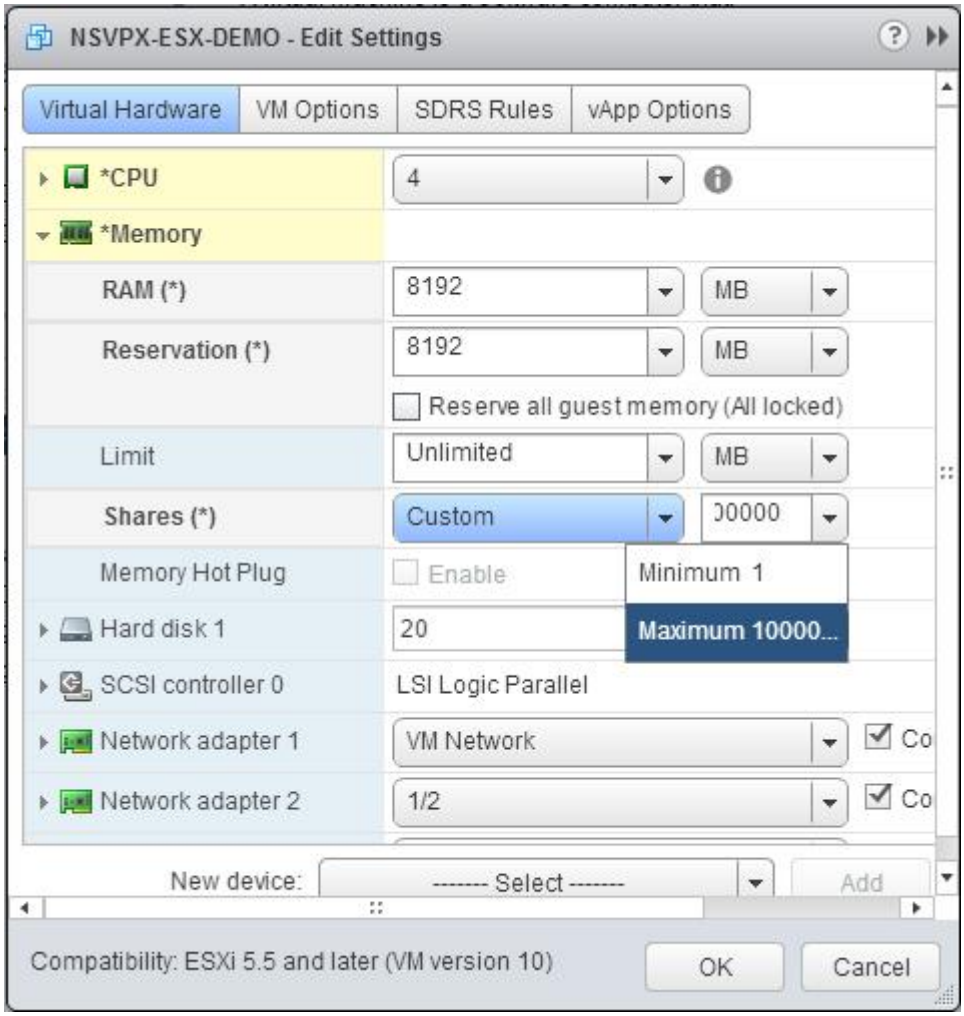
Note: For Advanced or Premium edition of the Citrix ADC VPX appliance, make sure that you allocate 4 GB of RAM to each vCPU. For example, if the number of vCPU is 4 then RAM = 4 x 4 GB = 16 GB.



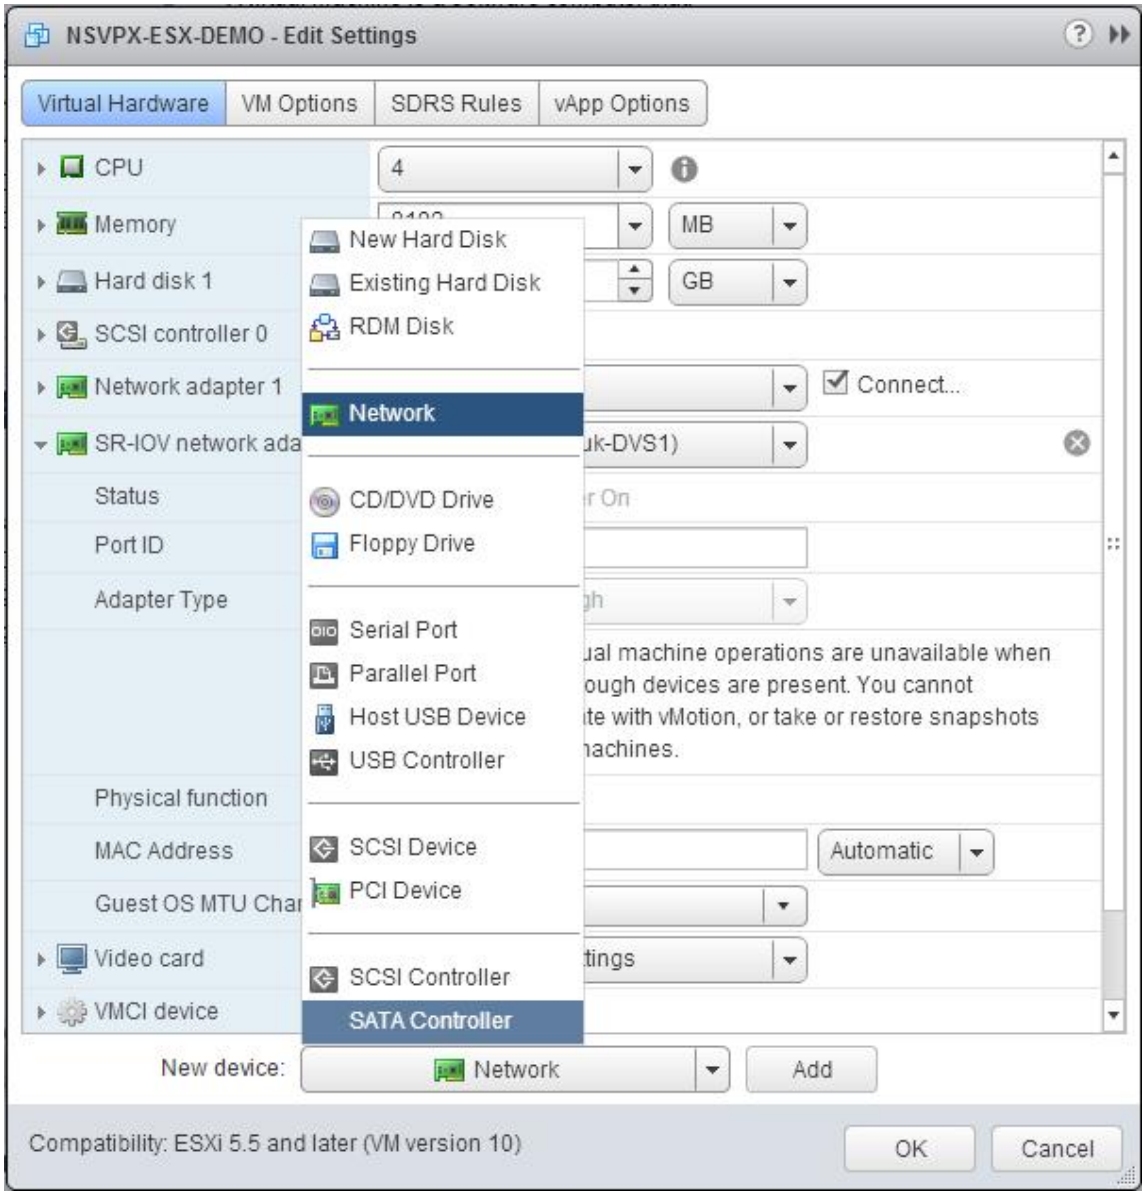
c. In the **Limit** drop-down list, select the number that is shown as the maximum value.



d. In the **Shares** drop-down lists, select **Custom**, and select the number that is shown as the maximum value.

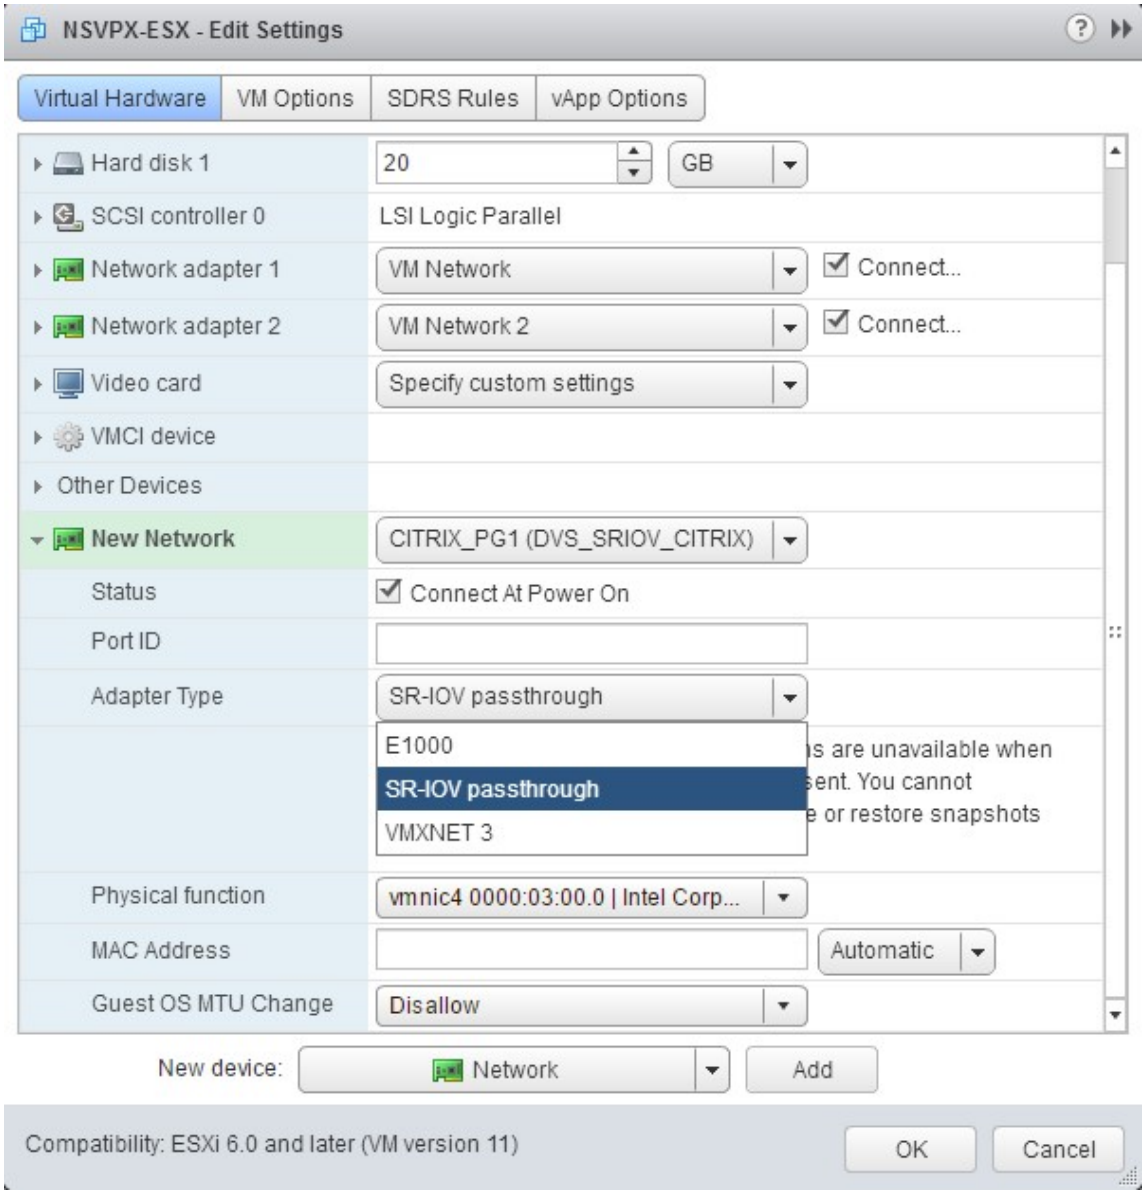


7. Add an SR-IOV network interface. From the **New device** drop-down list, select **Network** and click **Add**.

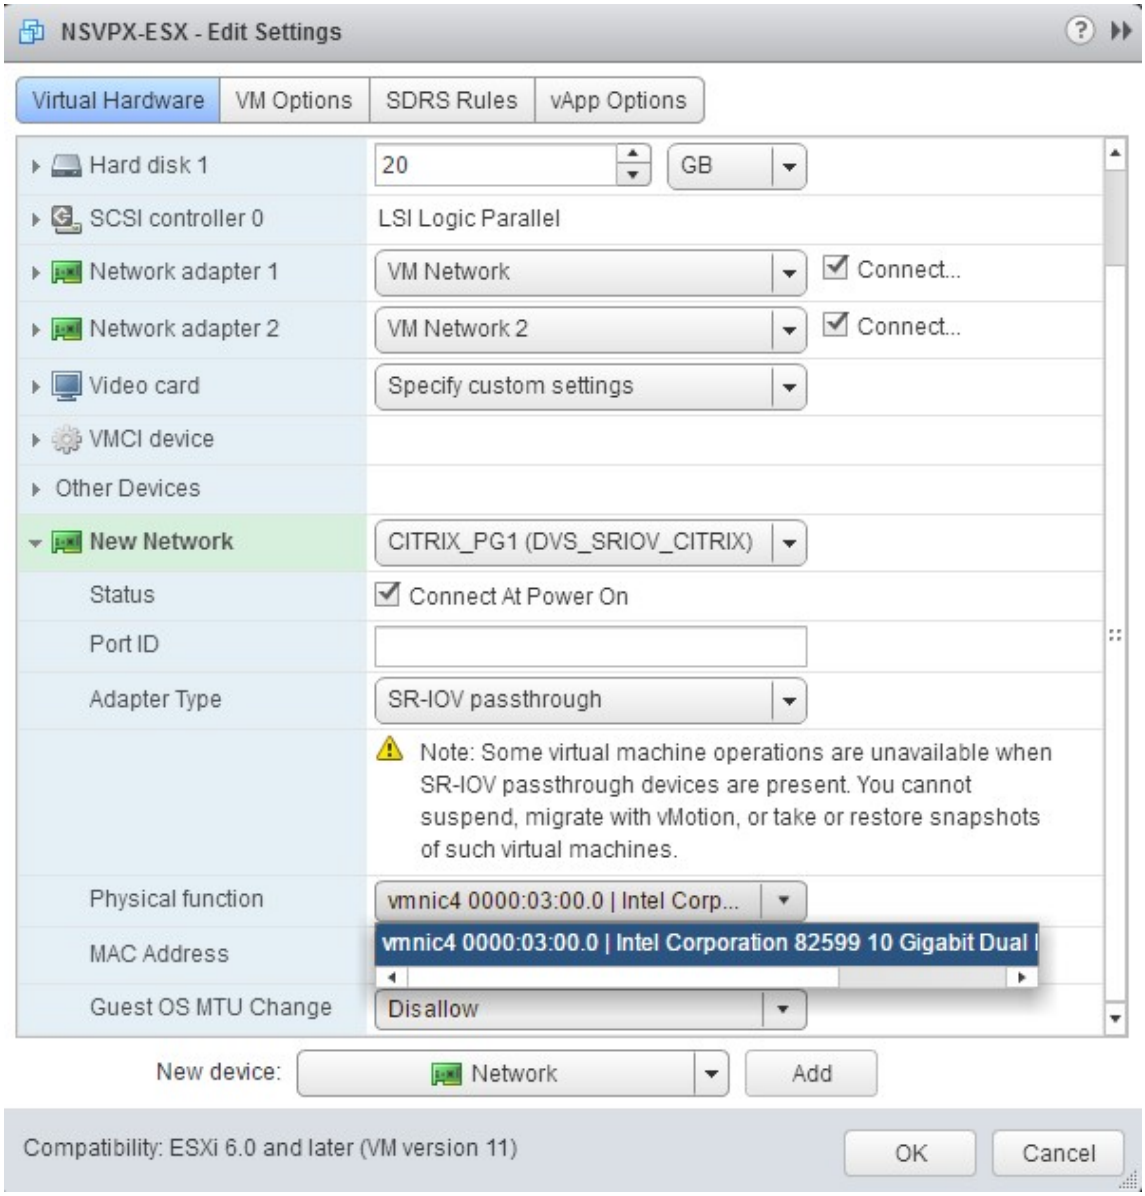


8. In the **New Network** section. From the drop-down list, select the `Portgroup` that you created, and do the following:

   a. In the **Adapter Type** drop-down list, select **SR-IOV passthrough**.

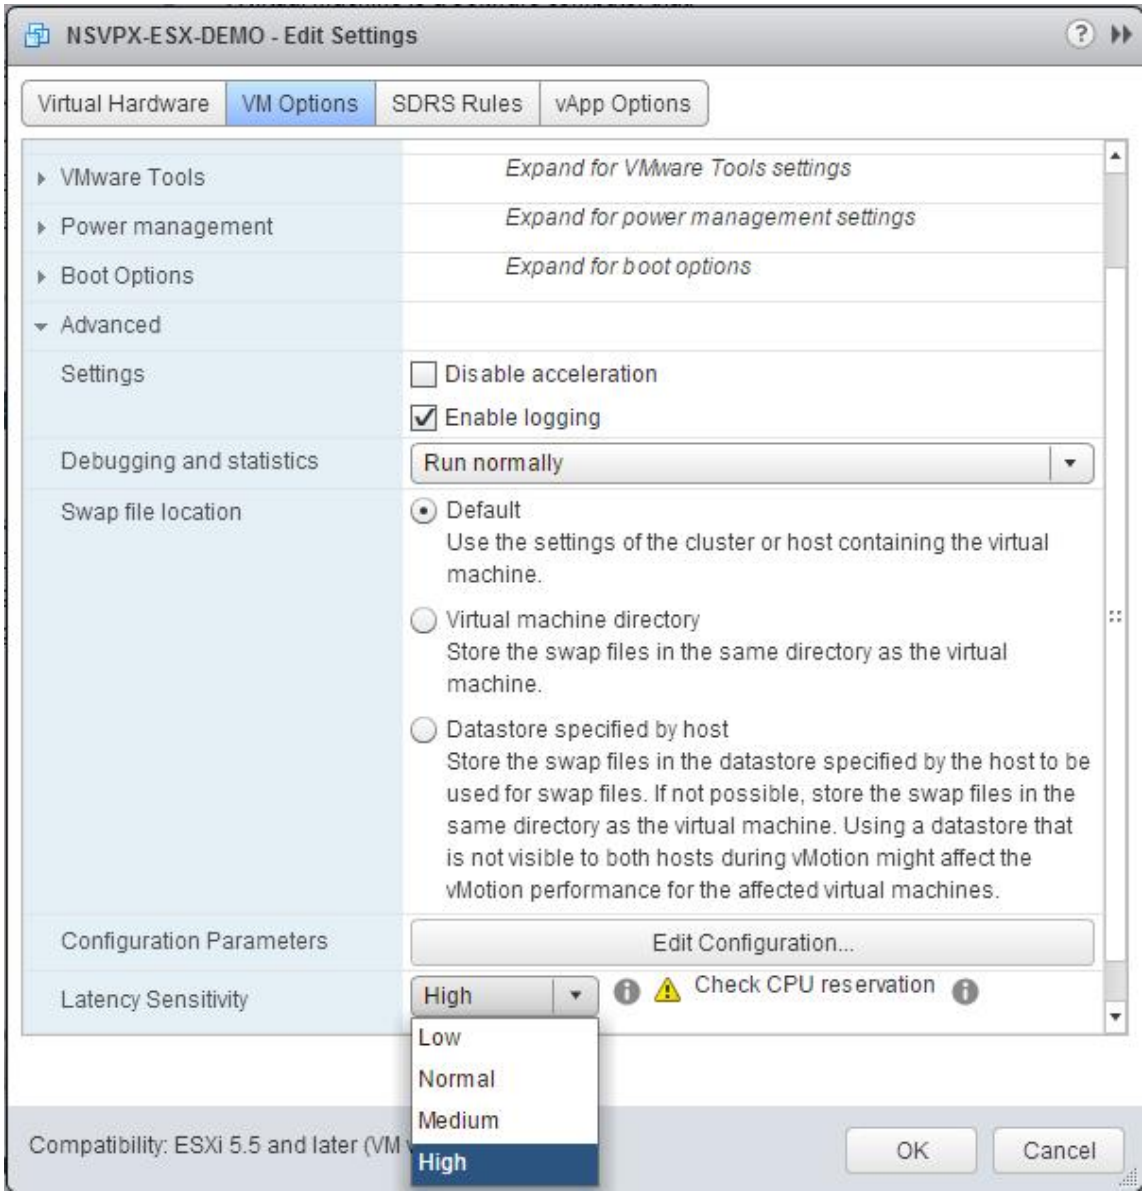


b. In the **Physical function** drop-down list, select the physical adapter mapped with the `Portgroup`.



c. In the **Guest OS MTU Change** drop-down list, select **Disallow**.

9. In the **<virtual_appliance> - Edit Settings** dialog box, click the **VM Options** tab.
10. On the **VM Options** tab, select the **Advanced** section. From the **Latency Sensitivity** drop-down list, select **High**.



11. Click **OK**.
12. Power on the Citrix ADC VPX instance.
13. Once the Citrix ADC VPX instance powers on, you can use the following command to verify the configuration:

    ```
    show interface summary
    ```

The output must show all the interfaces that you configured:

```
> show interface summary
-------------------------------------------------------------------------------

      Interface  MTU       MAC                Suffix
```

```
4 ----------------------------------------------------------------------------

5 1     0/1        1500       00:0c:29:1b:81:0b    NetScaler Virtual

```

Migrating the Citrix ADC VPX from E1000 to SR-IOV or VMXNET3 Network Interfaces

September 14, 2021

May 24, 2018

You can configure your exiting Citrix ADC VPX instances that use E1000 network interfaces to use SR-

IOV or VMXNET3 network interfaces.

To configure an existing Citrix ADC VPX instance to use SR-IOV network interfaces, see Configure a Citrix ADC VPX instance to use SR-IOV network interface.

To configure an existing Citrix ADC VPX instance to use VMXNET3 network interfaces, see Configure a Citrix ADC VPX instance to use VMXNET3 network interface.

Configure a Citrix ADC VPX instance to use PCI passthrough network interface

September 14, 2021

Overview

After you have installed and configured a Citrix ADC VPX instance on VMware ESX Server, you can use the vSphere Web Client to configure the virtual appliance to use PCI passthrough network interfaces.

The PCI passthrough feature allows a guest virtual machine to directly access physical PCI and PCIe devices connected to a host.

Prerequisites

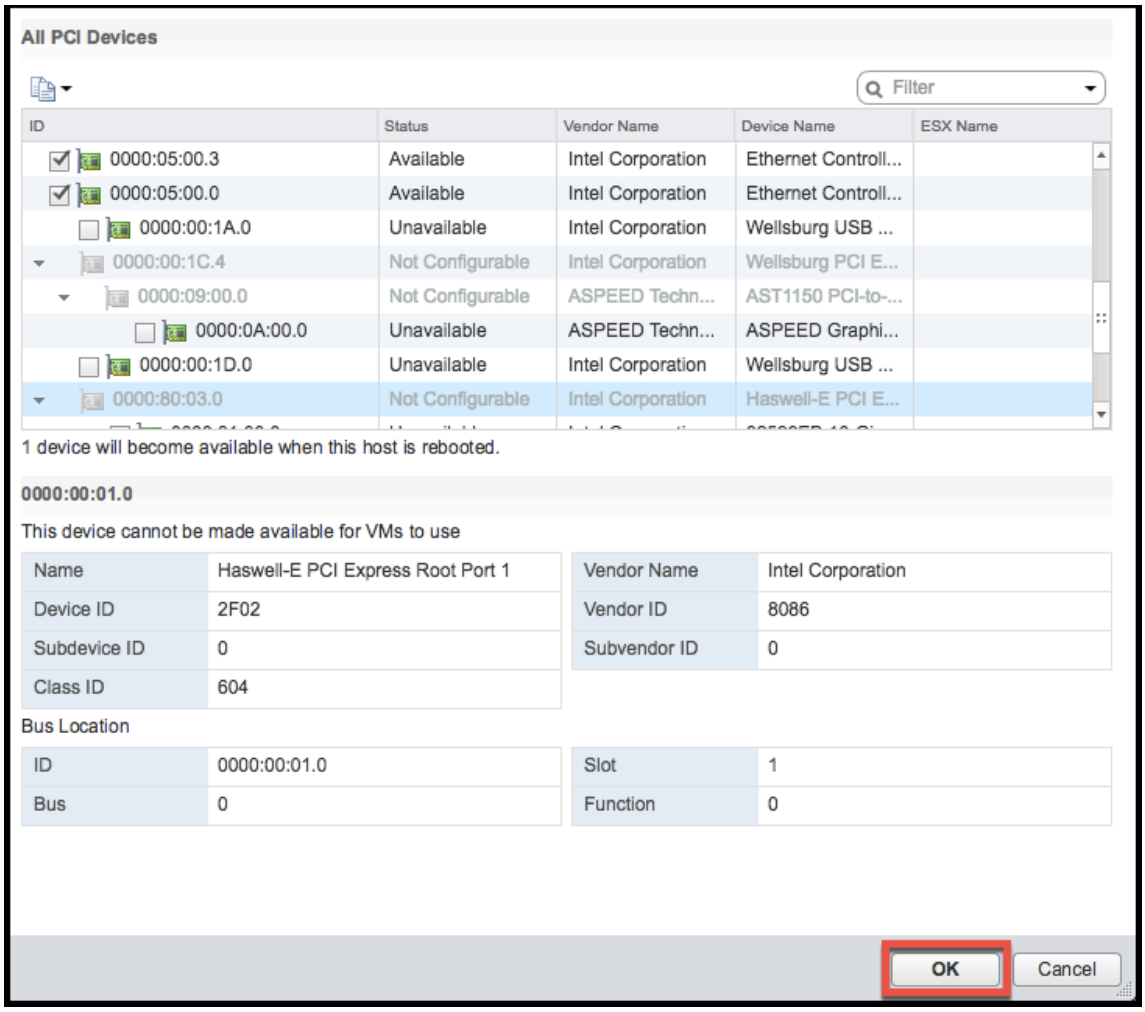
- The firmware version of the Intel XL710 NIC on the host is 5.04.
- A PCI passthrough device connected to and configured on the host
- Supported NICs:
  - Intel X710 10G NIC
  - Intel XL710 Dual Port 40G NIC
  - Intel XL710 Single Port 40G NIC

Configure passthrough devices on a host

Before configuring a passthrough PCI device on a virtual machine, you must configure it on the host machine. Follow these steps to configure passthrough devices on a host.

1. Select the host from the Navigator panel of the vSphere Web Client.
2. Click **Manage** > **Settings** > **PCI Devices**. All available passthrough devices are displayed.
3. Right-click the device that you want to configure and click **Edit**.
4. The **Edit PCI Device Availability** window appears.

5. Select the devices to be used for passthrough and click **OK**.

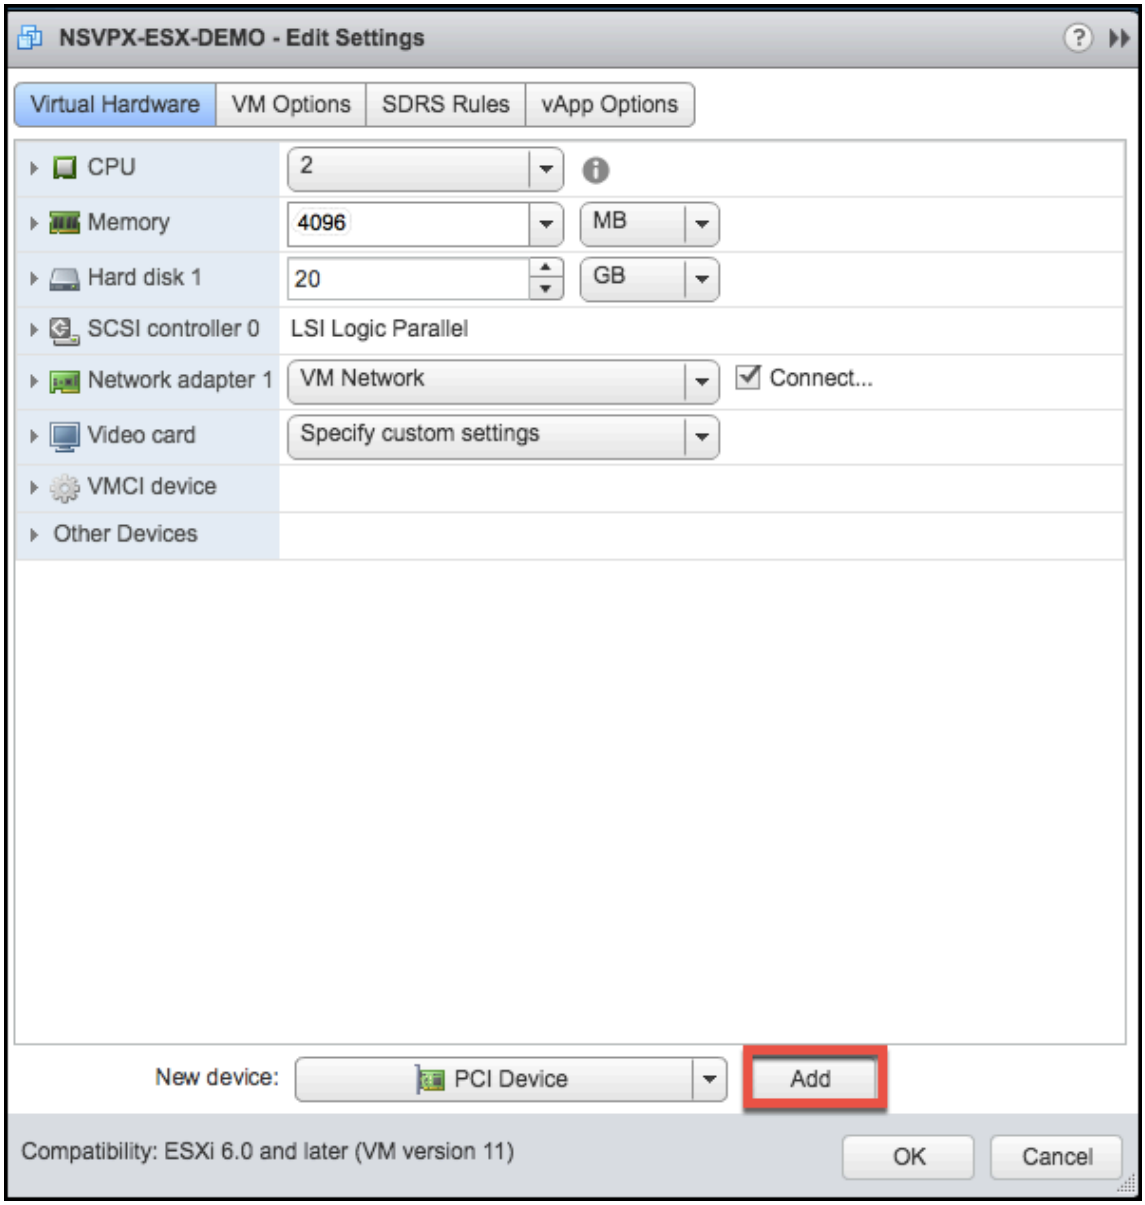


6. Restart the host machine.

Configure passthrough devices on a Citrix ADC VPX instance

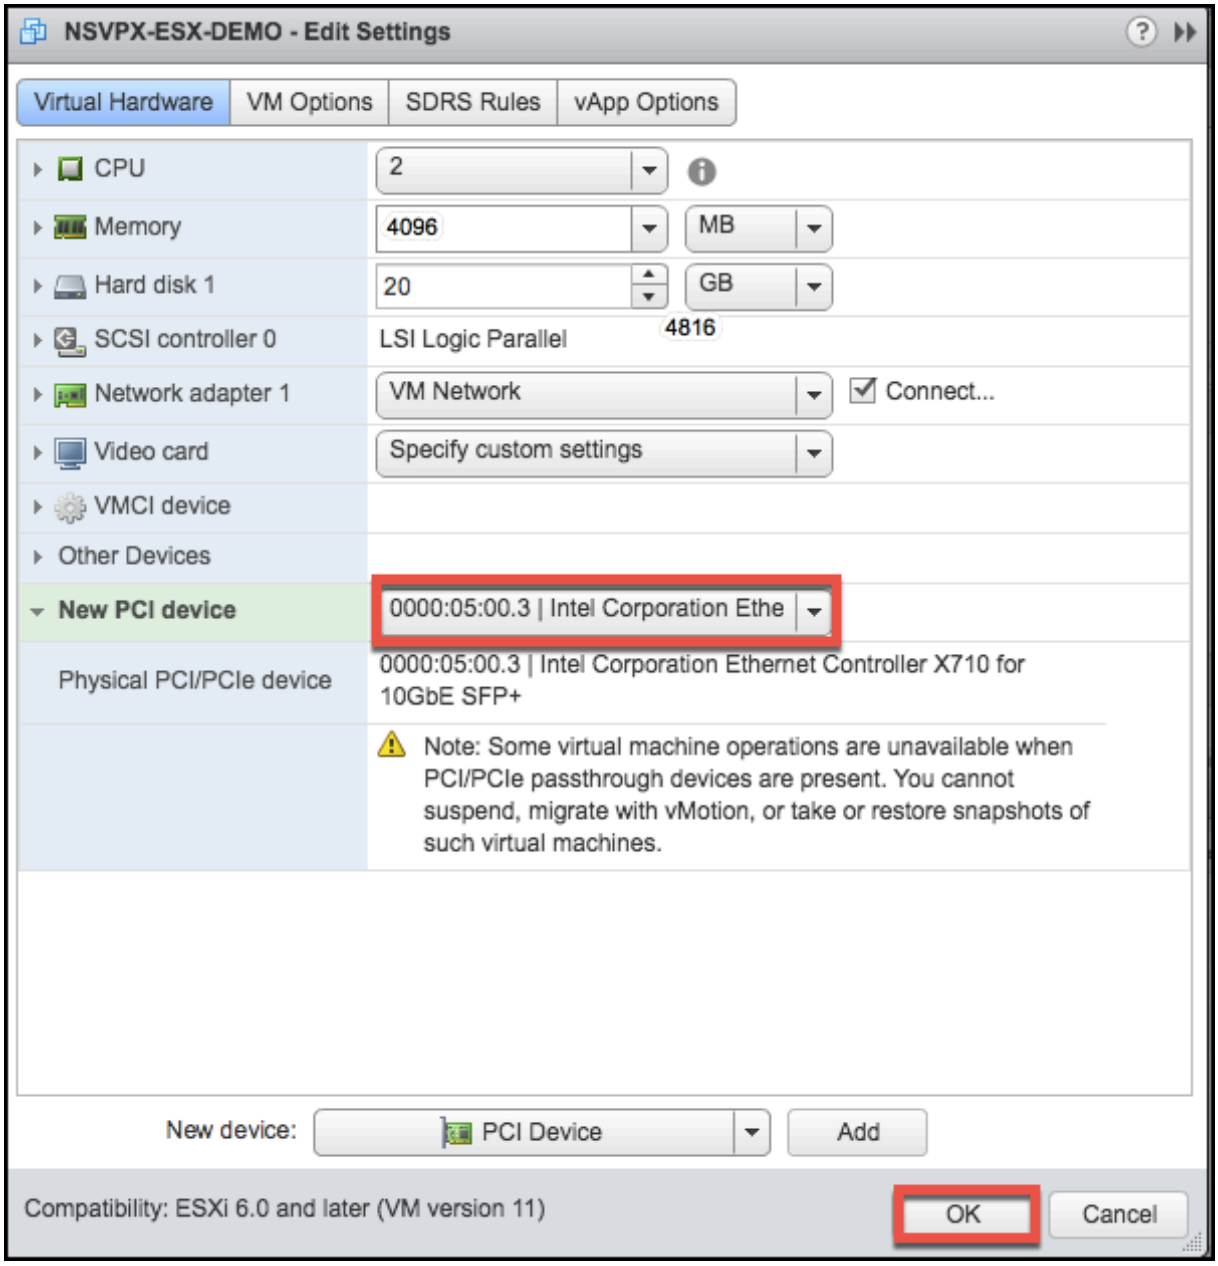
Follow these steps to configure a passthrough PCI device on a Citrix ADC VPX instance.

1. Power off the virtual machine.
2. Right-click the virtual machine and select **Edit Settings**.
3. On the **Virtual Hardware** tab, select **PCI Device** from the **New Device** drop-down menu, and click **Add**.



4. Expand **New PCI device** and select the passthrough device to connect to the virtual machine from the drop-down list and click **OK**.

> **Note**
>
> VMXNET3 network interface and PCI Passthrough Network Interface cannot coexist.



1. Power on the guest virtual machine.

You have completed the steps to configuring Citrix ADC VPX to use PCI passthrough network interfaces.

Apply Citrix ADC VPX configurations at the first boot of the Citrix ADC appliance on VMware ESX hypervisor

September 29, 2021

You can apply the Citrix ADC VPX configurations during the first boot of the Citrix ADC appliance on the VMware ESX hypervisor. Therefore in certain cases, a specific setup or VPX instance is brought up in much lesser time.

For more information on Preboot user data and its format, see Apply Citrix ADC VPX configurations at the first boot of the Citrix ADC appliance in cloud.

> Note:
>
> To bootstrap using preboot user data in ESX, default gateway config must be passed in <NS-CONFIG> section. For more information on the content of the <NS-CONFIG> tag, see Sample-<NS-CONFIG>-section.

Sample <NS-CONFIG> section:

```
<NS-PRE-BOOT-CONFIG>

    <NS-CONFIG>
        add route 0.0.0.0 0.0.0.0  10.102.38.1
    </NS-CONFIG>

    <NS-BOOTSTRAP>
            <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
            <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>

        <MGMT-INTERFACE-CONFIG>
                <INTERFACE-NUM> eth0 </INTERFACE-NUM>
                <IP> 10.102.38.216 </IP>
                <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </MGMT-INTERFACE-CONFIG>
    </NS-BOOTSTRAP>

</NS-PRE-BOOT-CONFIG>
<!--NeedCopy-->
```

How to provide preboot user data on ESX hypervisor

You can provide preboot user data on ESX hypervisor in the following two ways:

- Using CD/DVD ISO
- Using OVF Property

Provide user data using CD/DVD ISO

You can use VMware vSphere client to inject user data into the VM as an ISO image using the CD/DVD drive.

Follow these steps to provide user data using CD/DVD ISO:

1. Create a file with file name `userdata` that contains the preboot user data content. For more information on the content of the <NS-CONFIG> tag, see Sample <NS-CONFIG> section.

   > Note: File name must be strictly used as `userdata`.

2. Store the `userdata` file in a folder, and build an ISO image using the folder.

   You can build an ISO image with `userdata` file by the following two methods:

   - Using any image processing tool such as PowerISO.
   - Using `mkisofs` command in Linux.

   The following sample configuration shows how to generate an ISO image using the `mkisofs` command in Linux.

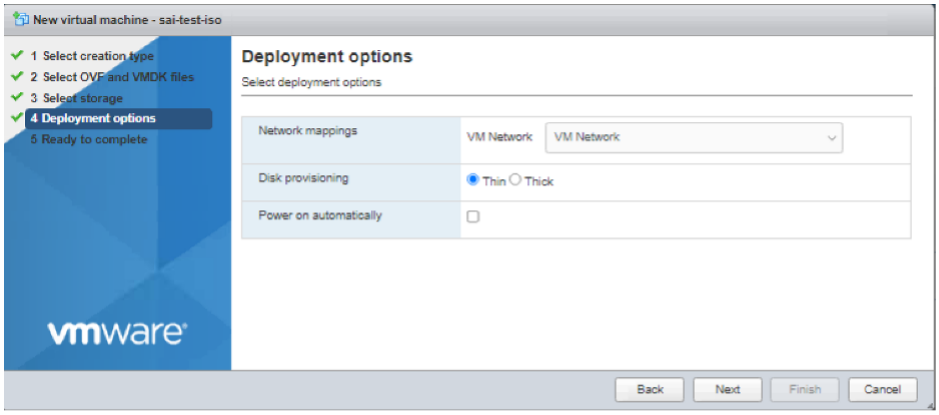
```
root@ubuntu:~/sai/14jul2021# ls -l total 4
drwxr-xr-x 2 root root 4096 Jul 14 12:32 esx_preboot_userdata
root@ubuntu:~/sai/14jul2021#
root@ubuntu:~/sai/14jul2021# ls -l esx_preboot_userdata/total 4
-rw-r--r-- 1 root root 3016 Jul 14 12:32 userdata
root@ubuntu:~/sai/14jul2021# mkisofs -o esx_preboot_userdata.iso
    ./esx_preboot_userdata
I: -input-charset not specified, using utf-8 (detected in locale
    settings)
Total translation table size: 0
Total rockridge attributes bytes: 0
Total directory bytes: 112
Path table size(bytes): 10
Max brk space used 0
176 extents written (0 MB)
root@ubuntu:~/sai/14jul2021# ls -lh
total 356K
drwxr-xr-x 2 root root 4.0K Jul 14 12:32 esx_preboot_userdata
-rw-r--r-- 1 root root 352K Jul 14 12:34 esx_preboot_userdata.iso

root@ubuntu:~/sai# ls preboot_userdata_155_193 userdata
root@ubuntu:~/sai# mkisofs -o preboot_userdata_155_193.iso ./
    preboot_userdata_155_193
I: -input-charset not specified, using utf-8 (detected in locale
    settings)
Total translation table size: 0
```

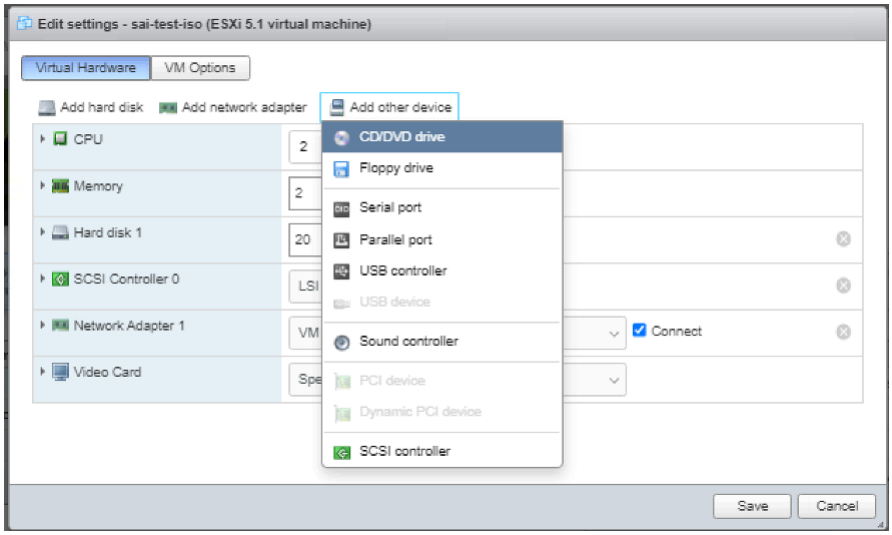
```
Total rockridge attributes bytes: 0
Total directory bytes: 112
Path table size(bytes): 10
Max brk space used 0
176 extents written (0 MB)

<!--NeedCopy-->
```

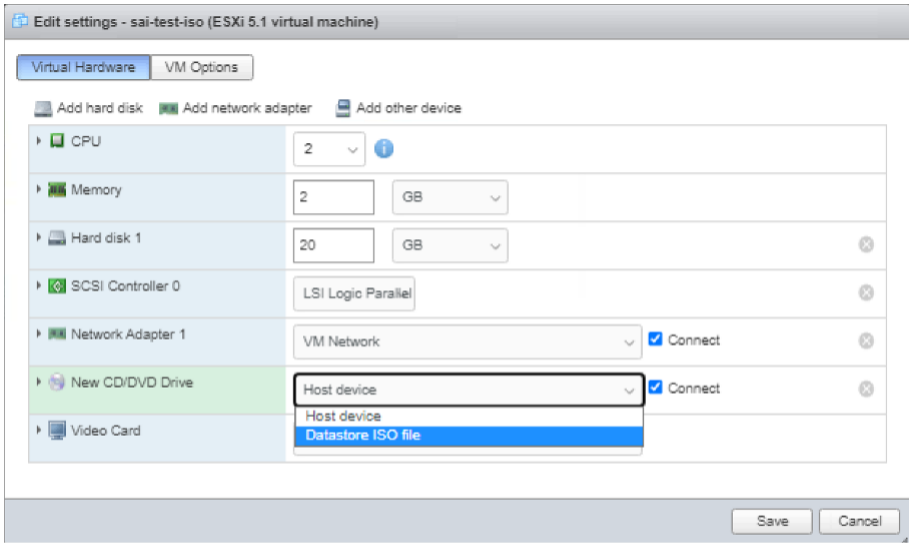
3. Provision the Citrix ADC VPX instance using standard deployment process to create the VM. But do not power on the VM automatically.



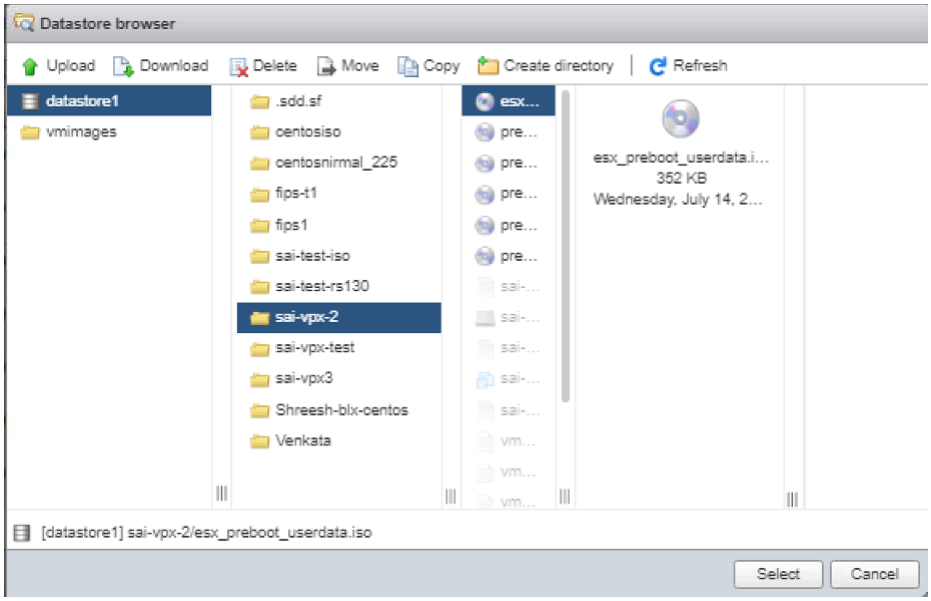
4. After the VM is successfully created, attach the ISO file as CD/DVD drive to the VM.



5. Navigate to **New CD/DVD Drive** and choose **Datastore ISO file** from the drop-down menu.



6. Select a Datastore in the vSphere Client.



7. Power on the VM.

Provide user data using OVF property

Follow these steps to provide user data using OVF property.

1. Create a file with user data content.

```
root@ubuntu:~/sai/14jul2021# cat esx_userdata.xml
<NS-PRE-BOOT-CONFIG>
    <NS-CONFIG>
        add route 0.0.0.0 0.0.0.0 10.102.38.1
    </NS-CONFIG>

    <NS-BOOTSTRAP>
            <SKIP-DEFAULT-BOOTSTRAP>YES</SKIP-DEFAULT-BOOTSTRAP>
            <NEW-BOOTSTRAP-SEQUENCE>YES</NEW-BOOTSTRAP-SEQUENCE>

        <MGMT-INTERFACE-CONFIG>
                <INTERFACE-NUM> eth0 </INTERFACE-NUM>
                <IP>    10.102.38.219 </IP>
                <SUBNET-MASK> 255.255.255.0 </SUBNET-MASK>
        </MGMT-INTERFACE-CONFIG>
    </NS-BOOTSTRAP>
</NS-PRE-BOOT-CONFIG>
```

2. Encode the user data content with Base64 encoding. You can perform the Base64 encoding using the following two methods:

   - In Linux, use the following command:

     ```
     base64 <userdata-filename>  >   <outuput-file>
     <!--NeedCopy-->
     ```

     Example:

     ```
     base64 esx_userdata.xml  > esx_userdata_b64
     <!--NeedCopy-->
     ```

     ```
     root@ubuntu:~/sai/14jul2021# base64 esx_userdata.xml > esx_userdata_b64
     root@ubuntu:~/sai/14jul2021#
     root@ubuntu:~/sai/14jul2021# cat esx_userdata_b64
     PE5TLVBSRS1CT09ULUNPTkZJRz4KICAgIDxOUy1DT05GSUc+CglhZGQgcm91dGUgMC4wLjAuMCAw
     LjAuMC4wIDEwLjEwMi4zOC4xCiAgICA8L05TLUNPTkZJRz4KCiAgICA8TlMtQk9PVFNUUkFQPgog
     ICAgICAgICAgICA8U0tJUC1ERUZBVUxULUJPT1RTVFJBUD5ZRVM8L1NLSVAtREVGQVVMVC1CT09U
     U1RSQVA+CiAgICAgICAgICAgIDxORVctQk9PVFNUUkFQLVNFUVVFTkNFPllFUzwvTkVXLUJPT1RT
     VFJBUC1TRVFVRU5DRT4KCiAgICAgICAgPE1HTVQtSU5URVJGQUNFLUNPTkZJRz4KICAgICAgICAg
     ICAgICAgIDxJTlRFUkZBQ0UtTlVNPiBldGgwIDwvSU5URVJGQUNFLU5VTT4KICAgICAgICAgICAg
     ICAgIDxJUD4gICAgMTAuMTAyLjM4LjIxOSA8L0lQPgogICAgICAgICAgICAgICAgPFNVQk5FVC1N
     QVNLPiAyNTUuMjU1LjI1NS4wIDwvU1VCTkVULU1BU0s+CiAgICAgICAgPC9NR01ULUlOVEVSRkFD
     RS1DT05GSUc+CiAgICA8L05TLUJPT1RTVFJBUD4KPC9OUy1QUkUtQk9PVC1DT05GSUc+Cg==
     ```

   - Use online tools to encode user data content, for example, Base64 Encode and Decode.

3. Include a **Product** section in the OVF template of a Citrix ADC VPX instance on ESX hypervisor.

   Sample Product section:

   ```
   <ProductSection>

     <Info>Information about the installed software</Info>
     <Product>NSVPX-VSK Template</Product>
   ```

```
  <Vendor>Citrix</Vendor>
  <VendorUrl>www.citrix.com</VendorUrl>
  <Category> Preboot Userdata </Category>

  <Property ovf:key="guestinfo.userdata" ovf:type="string" ovf:
     userConfigurable="true" ovf:value="">

    <Label>Userdata</Label>
    <Description> Userdata for ESX VPX </Description>
  </Property>

</ProductSection>
<!--NeedCopy-->
```

4. Provide the base64 encoded user data as the `ovf:value` for `guestinfo.userdata` property in the Product section.

```
<ProductSection>

  <Info>Information about the installed software</Info>
  <Product>NSVPX-VSK Template</Product>
  <Vendor>Citrix</Vendor>
  <VendorUrl>www.citrix.com</VendorUrl>
  <Category> Preboot Userdata </Category>
  <Property ovf:key="guestinfo.userdata" ovf:type="string" ovf:
     userConfigurable="true"
    ovf:value="PE5TLVBSRS1CT09ULUNPTkZJRz4KICAgIDxOUy1DT05GSUc+
       CglhZGQgcm91dGUgMC4wLjAuMCAw

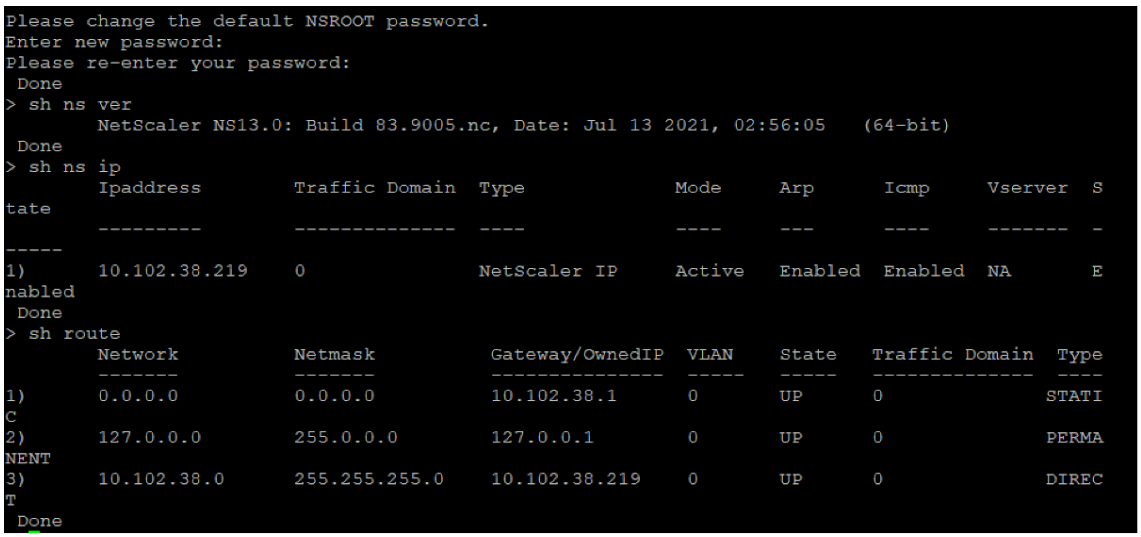
24  <!--NeedCopy-->
```

5. Use the modified OVF template with Product section for the VM deployment.



Install a Citrix ADC VPX instance on VMware cloud on AWS

September 14, 2021

The VMware Cloud (VMC) on AWS enables you to create cloud software-defined data centers (SDDC) on AWS with the desired number of ESX hosts. The VMC on AWS supports Citrix ADC VPX deployments. VMC provides a user interface same as on-prem vCenter. It functions identical to the ESX-based Citrix ADC VPX deployments.

Prerequisites

Before you begin installing a virtual appliance, do the following:

- One VMware SDDC must be present with at least one host.
- Download the Citrix ADC VPX appliance setup files.
- Create appropriate network segments on VMware SDDC to which the virtual machines connect.

- Obtain VPX license files. For more information about Citrix ADC VPX instance licenses, see the *Citrix ADC VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

VMware cloud hardware requirements

The following table lists the virtual computing resources that the VMware SDDC must provide for each VPX nCore virtual appliance.

Table 1. Minimum virtual computing resources required for running a Citrix ADC VPX instance

Component	Requirement
Memory	2 GB
Virtual CPU (vCPU)	2
Virtual network interfaces	In VMware SDDC, you can install a maximum of 10 virtual network interfaces if the VPX hardware is upgraded to version 7 or higher.
Disk space	20 GB

> Note
>
> This is in addition to any disk requirements for the hypervisor.

For production use of the VPX virtual appliance, the full memory allocation must be reserved.

OVF Tool 1.0 system requirements

OVF Tool is a client application that can run on Windows and Linux systems. The following table describes the minimum system requirements.

Table 2. Minimum system requirements for OVF tool installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the “OVF Tool User Guide” PDF file at http://kb.vmware.com/.
CPU	750 MHz minimum, 1 GHz or faster recommended
RAM	1 GB Minimum, 2 GB recommended
NIC	100 Mbps or faster NIC

For information about installing OVF, search for the "OVF Tool User Guide" PDF file at http://kb.vmware.com/.

Downloading the Citrix ADC VPX setup files

The Citrix ADC VPX instance setup package for VMware ESX follows the Open Virtual Machine (OVF) format standard. You can download the files from the Citrix website. You need a Citrix account to log on. If you do not have a Citrix account, access the home page at http://www.citrix.com. Click the **New Users link**, and follow the instructions to create a new Citrix account.

Once logged on, navigate the following path from the Citrix home page:

Citrix.com > **Downloads > Citrix ADC > Virtual Appliances**.

Copy the following files to a workstation on the same network as the ESX server. Copy all three files into the same folder.

- NSVPX-ESX-<release number>-<build number>-disk1.vmdk (for example, NSVPX-ESX-13.0-79.64-disk1.vmdk)
- NSVPX-ESX-<release number>-<build number>.ovf (for example, NSVPX-ESX-13.0-79.64.ovf)
- NSVPX-ESX-<release number>-<build number>.mf (for example, NSVPX-ESX-13.0-79.64.mf)

Install a Citrix ADC VPX instance on VMware cloud

After you have installed and configured VMware SDDC, you can use the SDDC to install virtual appliances on the VMware cloud. The number of virtual appliances that you can install depends on the amount of memory available on the SDDC.

To install Citrix ADC VPX instances on VMware cloud, follow these steps:

1. Open VMware SDDC on your workstation.
2. In the **User Name** and **Password** text boxes, type the administrator credentials, and then click Login.
3. On the **File** menu, click **Deploy OVF Template**.
4. In the **Deploy OVF Template** dialog box, in **Deploy from file**, browse to the location at which you saved the Citrix ADC VPX instance setup files, select the .ovf file, and click **Next**.

   > **Note:** By default, the Citrix ADC VPX instance uses E1000 network interfaces. To deploy ADC with the VMXNET3 interface, modify the OVF to use VMXNET3 interface instead of E1000.

5. Map the networks shown in the virtual appliance OVF template to the networks that you configured on the VMware SDDC. Click **Next** to start installing a virtual appliance on VMware SDDC.

6. You are now ready to start the Citrix ADC VPX instance. In the navigation pane, select the Citrix ADC VPX instance that you have installed and, from the right-click menu, select **Power On**. Click the **Console** tab to emulate a console port.
7. If you want to install another virtual appliance, repeat from Step 6.
8. Specify the management IP address from the same segment that is selected to be the management network. The same subnet is used for the Gateway.
9. The VMware SDDC requires that NAT and firewall rules are created explicitly for all private IP addresses belonging to network segments.

Install a Citrix ADC VPX instance on Microsoft Hyper-V server

September 14, 2021

To install Citrix ADC VPX instances on Microsoft Windows Server, you must first install Windows Server, with the Hyper-V role enabled, on a machine with adequate system resources. While installing the Hyper-V role, be sure to specify the NICs on the server that Hyper-V uses to create the virtual networks. You can reserve some NICs for the host. Use Hyper-V Manager to perform the Citrix ADC VPX instance installation.

Citrix ADC VPX instance for Hyper-V is delivered in virtual hard disk (VHD) format. It includes the default configuration for elements such as CPU, network interfaces, and hard-disk size and format. After you install Citrix ADC VPX instance, you can configure the network adapters on virtual appliance, add virtual NICs, and then assign the Citrix ADC IP address, subnet mask, and gateway, and complete the basic configuration of the virtual appliance.

After the initial configuration of the VPX instance, if you want to upgrade the appliance to the latest software release, see Upgrade a Citrix ADC VPX standalone appliance

> **Note**
>
> Intermediate System-to-Intermediate System (ISIS) protocol is not supported on the Citrix ADC VPX virtual appliance hosted on the HyperV-2012 platform.

Prerequisites for installing Citrix ADC VPX instance on Microsoft servers

Before you begin installing a virtual appliance, do the following:

- Enable the Hyper-V role on Windows Servers. For more information, see http://technet.microsoft.com/en-us/library/ee344837(WS.10).aspx.
- Download the virtual appliance setup files.

- Obtain Citrix ADC VPX instance license files. For more information about Citrix ADC VPX instance licenses, see the *Citrix ADC VPX Licensing Guide* at http://support.citrix.com/article/ctx131110.

Microsoft server hardware requirements

The following table describes the minimum system requirements for Microsoft servers.

Table 1. Minimum system requirements for Microsoft servers

Component	Requirement
CPU	1.4 GHz 64-bit processor
RAM	8 GB
Disk Space	32 GB or greater

The following table lists the virtual computing resources for each Citrix ADC VPX instance.

Table 2. Minimum virtual computing resources required for running a Citrix ADC VPX instance

Component	Requirement
RAM	4 GB
Virtual CPU	2
Disk Space	20 GB
Virtual Network Interfaces	1

Download the Citrix ADC VPX setup files

The Citrix ADC VPX instance for Hyper-V is delivered in virtual hard disk (VHD) format. You can download the files from the Citrix website. You need a Citrix account to log in. If you do not have a Citrix account, access the home page at http://www.citrix.com, click **Sign In > My account > Create Citrix Account**, and follow the instructions to create a Citrix account.

To download the Citrix ADC VPX instance setup files, follow these steps:

1. In a web browser, go to http://www.citrix.com/.
2. Sign in with your user name and password.
3. Click **Downloads**.

4. In **Select a Product** drop-down menu, select **Citrix ADC (NetScaler ADC)**.
5. Under **Citrix ADC Release X.X > Virtual Appliances**, click **Citrix ADC VPX Release X.X**
6. Download the compressed file to your server.

Install the Citrix ADC VPX instance on Microsoft servers

After you have enabled the Hyper-V role on Microsoft Server and extracted the virtual appliance files, you can use Hyper-V Manager to install Citrix ADC VPX instance. After you import the virtual machine, you need to configure the virtual NICs by associating them to the virtual networks created by Hyper-V.

You can configure a maximum of eight virtual NICs. Even if the physical NIC is DOWN, the virtual appliance assumes that the virtual NIC is UP, because it can still communicate with the other virtual appliances on the same host (server).

> **Note**
>
> You cannot change any settings while the virtual appliance is running. Shut down the virtual appliance and then make changes.

To install Citrix ADC VPX instance on Microsoft Server by using Hyper-V Manager:

1. To start Hyper-V Manager, click **Start**, point to **Administrative Tools**, and then click **Hyper-V Manager**.
2. In the navigation pane, under **Hyper-V Manage**r, select the server on which you want to install Citrix ADC VPX instance.
3. On the **Action** menu, click **Import Virtual Machin**e.
4. In the **Import Virtual Machine** dialog box, in **Location**, specify the path of the folder that contains the Citrix ADC VPX instance software files, and then select **Copy the virtual machine (create a new unique ID)**. This folder is the parent folder that contains the Snapshots, Virtual Hard Disks, and Virtual Machines folders.
5. Note: If you received a compressed file, make sure that you extract the files into a folder before you specify the path to the folder.
6. Click **Import**.
7. Verify that the virtual appliance that you imported is listed under **Virtual Machines**.
8. To install another virtual appliance, repeat steps **2** through **6**.

> **Important**
>
> Make sure that you extract the files to a different folder in step **4**.

Auto-provision a Citrix ADC VPX instance on Hyper-V

Auto-provisioning of Citrix ADC VPX instance is optional. If auto-provisioning is not done, the virtual appliance provides an option to configure the IP address and so on.

To auto-provision Citrix ADC VPX instance on Hyper-V, follow these steps.

1. Create an ISO9660 compliant ISO image using the xml file as depicted in the example. Make sure that the name of the xml file is **userdata**.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>

<Environment xmlns:oe=`"http://schemas.dmtf.org/ovf/environment/1`
    "

xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-instance`"

oe:id=""

xmlns=`"http://schemas.dmtf.org/ovf/environment/1`">

<PlatformSection>

<Kind>HYPER-V</Kind>

<Version>2013.1</Version>

<Vendor>CISCO</Vendor>

<Locale>en</Locale>

</PlatformSection>

<PropertySection>

<Property oe:key="com.citrix.netscaler.ovf.version" oe:value="1.0"
    />

<Property oe:key="com.citrix.netscaler.platform" oe:value="NS1000V
    "/>

<Property oe:key="com.citrix.netscaler.orch\_env" oe:value="cisco-
    orch-env"/>

<Property oe:key="com.citrix.netscaler.mgmt.ip" oe:value="
    10.102.100.122"/>

<Property oe:key="com.citrix.netscaler.mgmt.netmask" oe:value="
    255.255.255.128"/>

```

```
<Property oe:key="com.citrix.netscaler.mgmt.gateway" oe:value="
    10.102.100.67"/></PropertySection>

</Environment>
<!--NeedCopy-->
```

2. Copy the ISO image to hyper-v server.
3. Select the virtual appliance that you imported, and then on the **Action** menu, select **Settings**. You can also select the virtual appliance and then right click and select **Settings**. The **Settings** window for the selected virtual appliance is displayed.
4. In the **Settings** window, under the hardware section, click **IDE Controller**.
5. In the right window pane, select **DVD Drive** and click **Add**. The DVD Drive is added under the **IDE Controller** section in the left window pane.
6. Select the **DVD Drive** added in step 5. In the right window pane, select the **Image file radio** button and click **Browse** and select the ISO image that you copied on Hyper-V server, in step 2.
7. Click **Apply**.

> **Note**
>
> The virtual appliance instance comes up in the default IP address, when:
>
> - The DVD drive is attached and the ISO file is not provided.
> - The ISO file does not include the user data file.
> - The user data file name or format is not correct.

To configure virtual NICs on the Citrix ADC VPX instance, follow these steps:

1. Select the virtual appliance that you imported, and then on the **Action** menu, select **Settings**.
2. In the **Settings for <virtual appliance name>** dialog box, click **Add Hardware** in the left pane.
3. In the right pane, from the list of devices, select **Network Adapter**.
4. Click **Add**.
5. Verify that **Network Adapter (not connected)** appears in the left pane.
6. Select the network adapter in the left pane.
7. In the right pane, from the **Network** menu, select the virtual network to connect the adapter to.
8. To select the virtual network for other network adapters that you want to use, repeat steps **6** and **7**.
9. Click **Apply**, and then click **OK**.

To configure the Citrix ADC VPX instance:

1. Right-click the virtual appliance that you previously installed, and then select **Start**.
2. Access the console by double-clicking the virtual appliance.
3. Type the Citrix ADC IP address, subnet mask, and gateway for your virtual appliance.

You have completed the basic configuration of your virtual appliance. Type the IP address in a Web browser to access the virtual appliance.

> **Note**
>
> You can also use virtual machine (VM) template to provision Citrix ADC VPX instance using SCVMM.
>
> If you use Microsoft Hyper-V NIC teaming solution with NetScaler VPX instances, see article CTX224494 for more information.

Install a Citrix ADC VPX instance on Linux-KVM platform

September 14, 2021

To set up a Citrix ADC VPX for the Linux-KVM platform, you can use the graphical Virtual Machine Manager (Virtual Manager) application. If you prefer the Linux-KVM command line, you can use the `virsh` program.

The host Linux operating system must be installed on suitable hardware by using virtualization tools such as KVM Module and QEMU. The number of virtual machines (VMs) that can be deployed on the hypervisor depends on the application requirement and the chosen hardware.

After you provision a Citrix ADC VPX instance, you can add more interfaces.

Limitations and usage guidelines

General recommendations

To avoid unpredictable behavior, apply the following recommendations:

- Do not change the MTU of the VNet interface associated with the VPX VM. Shut down the VPX VM before modifying any configuration parameters, such as Interface modes or CPU.
- Do not force a shutdown of the VPX VM. That is, do not use the **Force off** command.
- Any configurations done on the host Linux might or might not be persistent, depending on your Linux distribution settings. You can choose to make these configurations persistent to ensure consistent behavior across reboots of host Linux operating system.
- The Citrix ADC package has to be unique for each of the Citrix ADC VPX instance provisioned.

Limitations

- Live migration of a VPX instance that runs on KVM is not supported.

Prerequisites for installing a Citrix ADC VPX instance on Linux-KVM platform

September 14, 2021

Check the minimum system requirements for a Linux-KVM server running on a Citrix ADC VPX instance.

CPU requirement:

- 64-bit x86 processors with the hardware virtualization feature included in Intel VT-X processors.

To test whether your CPU supports the Linux host, enter the following command at the host Linux shell prompt:

```
1 *.egrep '^flags.*(vmx|svm)' /proc/cpuinfo*
2 <!--NeedCopy-->
```

If the **BIOS** settings for the preceding extension are disabled, you must enable them in the BIOS.

- Provide at least 2 CPU cores to Host Linux.
- There is no specific recommendation for processor speed, but higher the speed, the better the performance of the VM application.

Memory (RAM) requirement:

Minimum 4 GB for the host Linux kernel. Add more memory as required by the VMs.

Hard disk requirement:

Calculate the space for Host Linux kernel and VM requirements. A single Citrix ADC VPX VM requires 20 GB of disk space.

Software requirements

The Host kernel used must be a 64-bit Linux kernel, release 2.6.20 or later, with all virtualization tools. Citrix recommends newer kernels, such as 3.6.11-4 and later.

Many Linux distributions such as Red Hat, CentOS, and Fedora, have tested kernel versions and associated virtualization tools.

Guest VM hardware requirements

Citrix ADC VPX supports IDE and virtIO hard disk type. The Hard Disk Type has been configured in the XML file, which is a part of the Citrix ADC package.

Networking requirements

Citrix ADC VPX supports virtIO para-virtualized, SR-IOV, and PCI Passthrough network interfaces.

For more information about the supported network interfaces, see:

- Provision the Citrix ADC VPX instance by using the Virtual Machine Manager
- Configure a Citrix ADC VPX instance to use SR-IOV network interfaces
- Configure a Citrix ADC VPX instance to use PCI passthrough network interfaces

Source Interface and Modes

The source device type can be either Bridge or MacVTap. In MacVTap, four modes are possible - VEPA, Bridge, Private, and Pass-through. Check the types of interfaces that you can use and the supported traffic types, as per the following:

Bridge:

- Linux Bridge.
- `Ebtables` and `iptables` settings on host Linux might filter the traffic on the bridge if you do not choose the correct setting or disable `IPtable` services.

MacVTap (VEPA mode):

- Better performance than a bridge.
- Interfaces from the same lower device can be shared across the VMs.
- Inter-VM communication using the same
- lower device is possible only if the upstream or downstream switch supports VEPA mode.

MacVTap (private mode):

- Better performance than a bridge.
- Interfaces from the same lower device can be shared across the VMs.
- Inter-VM communication using the same lower device is not possible.

MacVTap (bridge mode):

- Better as compared to bridge.
- Interfaces out of the same lower device can be shared across the VMs.
- Inter-VM communication using the same lower device is possible, if the lower device link is UP.

MacVTap (Pass-through mode):

- Better as compared to bridge.
- Interfaces out of the same lower device cannot be shared across the VMs.
- Only one VM can use the lower device.

> Note: For best performance by the VPX instance, ensure that the `gro` and `lro` capabilities are switched off on the source interfaces.

Properties of source interfaces

Make sure that you switch off the generic-receive-offload (`gro`) and large-receive-offload (`lro`) capabilities of the source interfaces. To switch off the `gro` and `lro` capabilities, run the following commands at the host Linux shell prompt.

```
ethtool -K eth6 gro off
ethool -K eth6 lro off
```

Example:

```
    [root@localhost ~]# ethtool -K eth6

                    Offload parameters for eth6:

                                        rx-checksumming: on

                                        tx-checksumming: on

                    scatter-gather: on

                    tcp-segmentation-offload: on

                    udp-fragmentation-offload: off

                    generic-segmentation-offload: on

                    generic-receive-offload: off

                    large-receive-offload: off

                    rx-vlan-offload: on

                    tx-vlan-offload: on

                    ntuple-filters: off

                    receive-hashing: on

    [root@localhost ~]#
<!--NeedCopy-->
```

Example:

If the host Linux bridge is used as a source device, as in the following example, and `lro` capabilities must be switched off on the VNet interfaces, which are the virtual interfaces connecting the host to the guest VMs.

```
    [root@localhost ~]# brctl show eth6_br

    bridge name     bridge  id               STP enabled interfaces

    eth6_br         8000.00e0ed1861ae          no         eth6

                                                          vnet0

                                                          vnet2

    [root@localhost ~]#
<!--NeedCopy-->
```

In the preceding example, the two virtual interfaces are derived from the eth6_br and are represented as vnet0 and vnet2. Run the following commands to switch off `gro` and `lro` capabilities on these interfaces.

```
    ethtool -K vnet0 gro off
            ethtool -K vnet2 gro off
            ethtool -K vnet0 lro off
                     ethtool -K vnet2 lro off
<!--NeedCopy-->
```

Promiscuous mode

The promiscuous mode must be enabled for the following features to work:

- L2 mode
- Multicast traffic processing
- Broadcast
- IPV6 traffic
- virtual MAC
- Dynamic routing

Use the following command to enable the promiscuous mode.

```
[root@localhost ~]# ifconfig eth6 promisc
[root@localhost ~]# ifconfig eth6
eth6       Link encap:Ethernet  HWaddr 78:2b:cb:51:54:a3
```

```
            inet6 addr: fe80::7a2b:cbff:fe51:54a3/64 Scope:Link
            UP BROADCAST RUNNING PROMISC MULTICAST  MTU:9000  Metric:1
            RX packets:142961 errors:0 dropped:0 overruns:0 frame:0
            TX packets:2895843 errors:0 dropped:0 overruns:0 carrier:0
            collisions:0 txqueuelen:1000
            RX bytes:14330008 (14.3 MB)  TX bytes:1019416071 (1.0 GB)

[root@localhost ~]#
<!--NeedCopy-->
```

Module required

For better network performance, make sure the vhost_net module is present in the Linux host. To check the existence of vhost_net module, run the following command on the Linux host:

```
lsmod | grep "vhost\_net"
<!--NeedCopy-->
```

If vhost_net is not yet running, enter the following command to run it:

```
modprobe vhost\_net
<!--NeedCopy-->
```

Provision the Citrix ADC VPX instance by using OpenStack

September 14, 2021

You can provision a Citrix ADC VPX instance in an OpenStack environment either by using the **Nova boot** command (OpenStack CLI) or Horizon (OpenStack dashboard) .

Provisioning a VPX instance, optionally involves using data from the config drive. Config drive is a special configuration drive that attaches to the instance as a CD-ROM device when it boots. This configuration drive can be used to pass networking configuration such as management IP address, network mask, default gateway, and to inject customer scripts.

In a Citrix ADC appliance, the default authentication mechanism is password based. Now, the SSH key-pair authentication mechanism is supported for Citrix ADC VPX instances on the OpenStack environment.

The key-pair (public key and private key) is generated before using the Public Key Cryptography mechanism. You can use different mechanisms, such as Horizon, Puttygen.exe for Windows, and `ssh-`

keygen for the Linux environment, to generate the key pair. Refer to online documentation of respective mechanisms for more information about generating key pair.

Once a key pair is available, copy the private key to a secure location to which authorized persons have access. In OpenStack, public key can be deployed on a VPX instance by using the Horizon or Nova boot command. When a VPX instance is provisioned by using OpenStack, it first detects that the instance is booting in an OpenStack environment by reading a specific BIOS string. This string is "OpenStack Foundation" and for Red Hat Linux distributions it is stored in /etc/nova/release. This is a standard mechanism that is available in all OpenStack implementations based on the KVM hypervisor platform. The drive must have a specific OpenStack label.

If the config drive is detected, the instance attempts to read the network configuration, custom scripts, and SSH key pair if provided.

User data file

The Citrix ADC VPX instance uses a customized OVF file, also known as the user data file, to inject network configuration, custom scripts. This file is provided as part of config drive. Here is an example of a customized OVF file.

```
```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<Environment xmlns:oe="http://schemas.dmtf.org/ovf/environment/1"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
oe:id=""
xmlns="http://schemas.dmtf.org/ovf/environment/1"
xmlns:cs="http://schemas.citrix.com/openstack">
<PlatformSection>
<Kind></Kind>
<Version>2016.1</Version>
<Vendor>VPX</Vendor>
<Locale>en</Locale>
</PlatformSection>
<PropertySection>
<Property oe:key="com.citrix.netscaler.ovf.version" oe:value="1.0"/>
<Property oe:key="com.citrix.netscaler.platform" oe:value="NSVPX"/>
<Property oe:key="com.citrix.netscaler.orch_env" oe:value="openstack-
   orch-env"/>
<Property oe:key="com.citrix.netscaler.mgmt.ip" oe:value="10.1.2.22"/>
<Property oe:key="com.citrix.netscaler.mgmt.netmask" oe:value="
   255.255.255.0"/>
<Property oe:key="com.citrix.netscaler.mgmt.gateway" oe:value="10.1.2.1
   "/>
</PropertySection>
```

 
```

```
<cs:ScriptSection>
  <cs:Version>1.0</cs:Version>
    <ScriptSettingSection xmlns="http://schemas.citrix.com/openstack"
       xmlns:i="http://www.w3.org/2001/XMLSchema-instance">
        <Scripts>
          <Script>
                <Type>shell</Type>
                <Parameter>X Y</Parameter>
               <Parameter>Z</Parameter>
               <BootScript>before</BootScript>
                 <Text>
                       #!/bin/bash
                       echo "Hi, how are you" $1 $2 >> /var/sample.txt
                 </Text>
          </Script>
          <Script>
                <Type>python</Type>
                <BootScript>after</BootScript>
                 <Text>
                     #!/bin/python
print("Hello");
                 </Text>
          </Script>
  <Script>
                <Type>perl</Type>
                <BootScript>before</BootScript>
                 <Text>
                     !/usr/bin/perl
my $name = "VPX";
print "Hello, World $name !\n" ;
                 </Text>
          </Script>
          <Script>
               <Type>nscli</Type>
               <BootScript>after</BootScript>
               <Text>
                add vlan 33
bind vlan 33 -ifnum 1/2
               </Text>
          </Script>
        </Scripts>
    </ScriptSettingSection>
</cs:ScriptSection>
</Environment>
<!--NeedCopy--> ```
```

In the OVF file preceding “PropertySection” is used for NetScaler networking configuration while <cs:ScriptSection> is used to enclose all scripts. <Scripts></Scripts> tags are used to bundle all scripts together. Each script is defined in between <Script> </Script> tags. Each script tag has following fields/tags:

a) <Type>: Specifies value for script type. Possible values: Shell/Perl/Python/NSLCI (for NetScaler CLI scripts)

b) <Parameter>: Provides parameters to the script. Each script can have multiple <Parameter> tags.

c) <BootScript>: Specifies script execution point. Possible values for this tag: before/after. “before” specifies script is run before PE comes up. “after” specifies that the script will be run after PE comes up.

d) <Text>: Pastes content of a script.

> **Note**
>
> Currently the VPX instance does not take care of sanitization of scripts. As an administrator, you must check the validity of the script.
>
> Not all sections need to be present. Use an empty “PropertySection” to only define scripts to run on first boot or an empty <cs:ScriptSection> to only define networking configuration.
>
> After the required sections of the OVF file (user data file) are populated, use that file to provision the VPX instance.

Network configuration

As part of the network configuration, the VPX instance reads:

- Management IP address
- Network mask
- Default gateway

After the parameters are successfully read, they are populated in the NetScaler configuration, to allow managing the instance remotely. If the parameters are not read successfully or the config drive is not available, the instance transitions to the default behavior, which is:

- The instance attempts to retrieve the IP address information from DHCP.
- If DHCP fails or times-out, the instance comes up with the default network configuration (192.168.100.1/16).

Customer script

The VPX instance allows to run a custom script during initial provisioning. The appliance supports script of type Shell, Perl, Python, and Citrix ADC CLI commands.

SSH key pair authentication

The VPX instance copies public key, available within the configuration drive as part of instance meta data, into its “authorized_keys” file. This allows the user to access the instance with private key.

> **Note**
>
> When an SSH key is provided, the default credentials (nsroot/nsroot) no longer work, if password-based access is needed, log on with the respective SSH private key and manually set a password.

Before you begin

Before you provision a VPX instance on OpenStack environment, extract the `.qcow2` file from the .tgz file and build

An OpenStack image from the qcow2 image. Follow these steps:

1. Extract the `.qcow2` file from the `.tqz` file by typing the following command

```
tar xvzf <TAR file>
tar xvzf <NSVPX-KVM-12.0-26.2_nc.tgz>
NSVPX-KVM.xml
NSVPX-KVM-12.0-26.2_nc.qcow2
```

2. Build an OpenStack image using the `.qcoz2` file extracted in step 1 by typing the following command.

```
openstack image create --container-format bare --property
   hw_disk_bus=ide --disk-format qcow2 --file <path to qcow2 file>
    --public <name of the OpenStack image>

glance image-create --name="NS-VPX-12-0-26-2" --property
   hw_disk_bus=ide --ispublic=
true --container-format=bare --disk-format=qcow2< NSVPX-KVM
   -12.0-26.2_nc.qcow2
```

Figure 1: The following illustration provides a sample output for the glance image-create command.

```
+------------------+--------------------------------------------------------+
| Field            | Value                                                  |
+------------------+--------------------------------------------------------+
| checksum         | 154ade3fc7dca7d1706b1d03d7d97552                       |

```

Provisioning the VPX instance

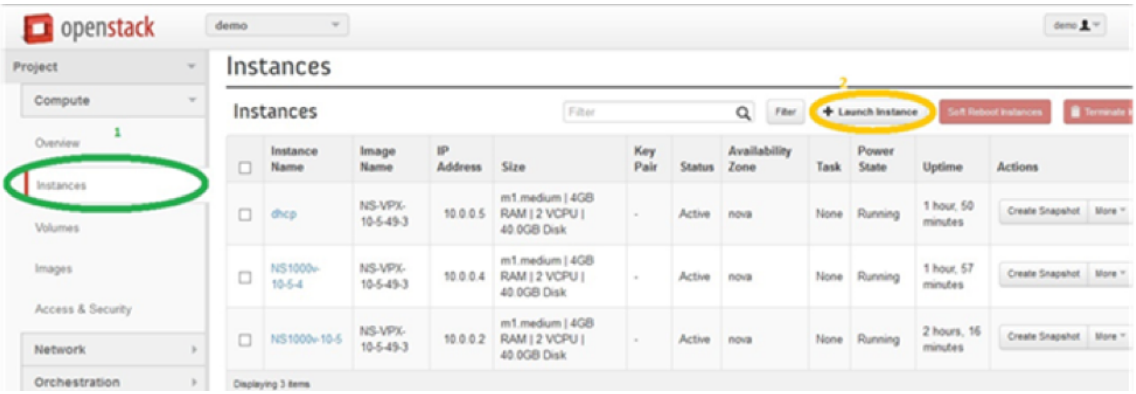
You can provision a VPX instance in two ways by using one of the options:

- Horizon (OpenStack dashboard)
- Nova boot command (OpenStack CLI)

Provision a VPX instance by using the OpenStack dashboard

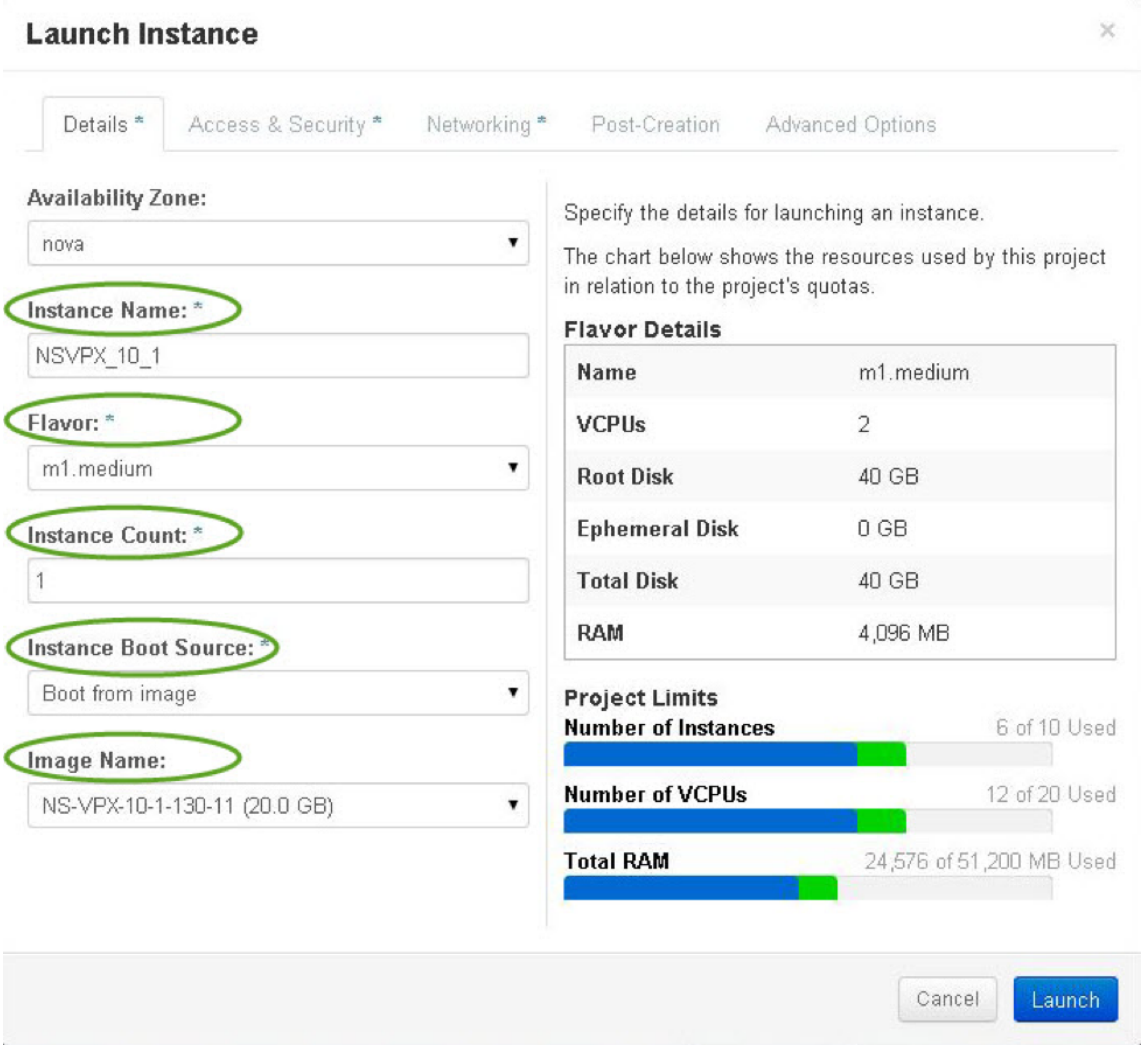
Follow these steps to provision the VPX instance by using Horizon:

1. Log on to the OpenStack dashboard.
2. In the Project panel on the left hand side of the dashboard, select **Instances**.
3. In the Instances panel, click **Launch Instance** to open the Instance Launching wizard.



4. In the Launch Instance wizard, fill in the details, like:

a) Instance Name
b) Instance Flavor
c) Instance Count
d) Instance Boot Source
e) Image Name



5. Deploy a new key pair or an existing key pair through Horizon by completing the following steps:

   a) If you don't have an existing key pair, create the key by using any existing mechanisms. If you've an existing key, skip this step.

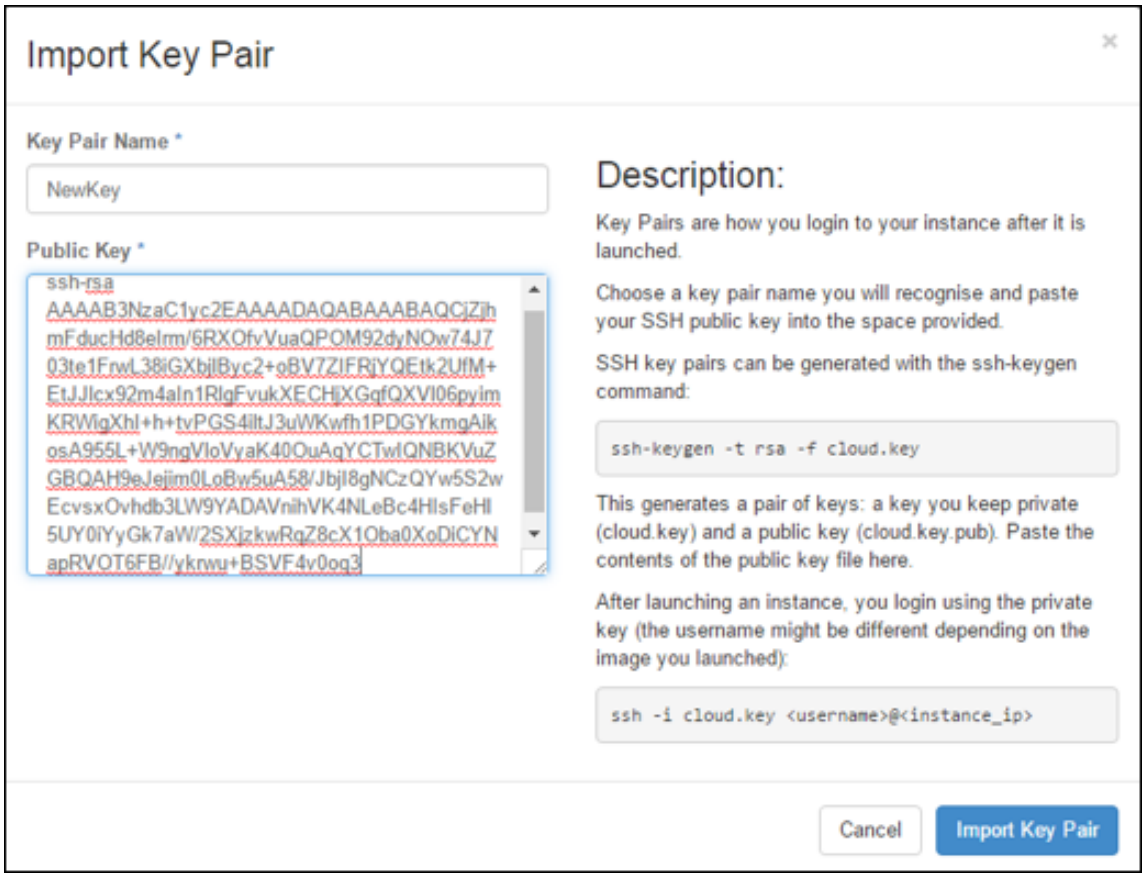
   b) Copy the content of public key.

   c) Go to **Horizon > Instances > Create New Instances**.

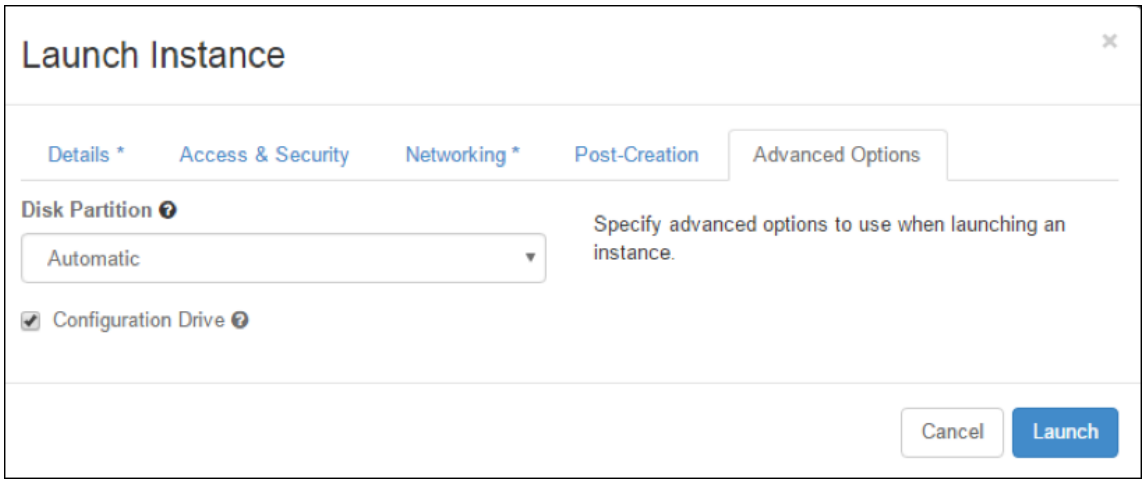
   d) Click **Access & Security**.

   e) Click the + sign next to the **Key Pair** drop-down menu and provide values for shown parameters.

f) Paste public key content in *Public key* box, give a name to the key and click **Import Key Pair**.



6. Click the **Post Creation** tab in the wizard. In Customization Script, add the content of the user data file. The user data file contains the IP address, Netmask and Gateway details, and customer scripts of the VPX instance.
7. After a key pair is selected or imported, check config-drive option and click **Launch**.



Provision the VPX instance by using OpenStack CLI

Follow these steps to provision a VPX instance by using OpenStack CLI.

1. To create an image from qcow2, type the following command:

   ```
   openstack image create --container-format bare --property hw_disk_bus=
   ide --diskformat qcow2 --file NSVPX-OpenStack.qcow2 --public VPX-ToT-
   Image
   ```

2. To select an image for creating an instance, type the following command:

   ```
   openstack image list | more
   ```

3. To create an instance of a particular flavor, type the following command to choose a flavor ID/-Name of from a list:

   ```
   openstack flavor list
   ```

4. To attach a NIC to a particular network, type the following command to choose a network ID from a network list:

   ```
   openstack network list
   ```

5. To create an instance, type the following command:

   ```
   1 openstack server create --flavor FLAVOR_ID --image IMAGE_ID --key-
       name KEY_NAME
   2 --user-data USER_DATA_FILE_PATH --config-drive True --nic net-id=
       net-uuid
   3 INSTANCE_NAME
   4 openstack server create --image VPX-ToT-Image --flavor m1.medium
       --user-data
   5 ovf.xml --config-drive True --nic net-id=2734911b-ee2b-48d0-a1b6-3
       efd44b761b9
   6 VPX-ToT
   ```

Figure 2: The following illustration provides a sample output.

```

Provision the Citrix ADC VPX instance by using the Virtual Machine Manager

September 14, 2021

The Virtual Machine Manager is a desktop tool for managing VM guests. It enables you to create new VM guests and various types of storage, and manage virtual networks. You can access the graphical console of VM guests with the built-in VNC viewer and view performance statistics, either locally or remotely.

After installing your preferred Linux distribution, with KVM virtualization enabled, you can proceed with provisioning virtual machines.

While using the Virtual Machine Manager to provision a Citrix ADC VPX instance, you have two options:

- Enter the IP address, gateway, and netmask manually
- Assign the IP address, gateway, and netmask automatically (auto-provisioning)

You can use two kinds of images to provision a Citrix ADC VPX instance:

- RAW
- QCOW2

You can convert a Citrix ADC VPX RAW image to a QCOW2 image and provision the Citrix ADC VPX instance. To convert the RAW image to a QCOW2 image, type the following command:

```
qemu-img convert -O qcow2 original-image.raw image-converted.qcow
```

For example:

```
qemu-img convert -O qcow2 NSVPX-KVM-11.1-12.5_nc.raw NSVPX-KVM-11.1-12.5_nc
.qcow
```

A typical Citrix ADC VPX deployment on KVM includes the following steps:

- Checking prerequisites for Auto-Provisioning a Citrix ADC VPX Instance
- Provisioning the Citrix ADC VPX Instance by Using a RAW Image
- Provisioning the Citrix ADC VPX Instance by Using a QCOW2 Image
- Adding Additional Interfaces to a VPX Instance by using Virtual Machine Manager

Check prerequisites for auto-provisioning a Citrix ADC VPX instance

Auto-provisioning is an optional feature, and it involves using data from the CDROM drive. If this feature is enabled, you need not enter the management IP address, network mask, and default gateway of the Citrix ADC VPX instance during initial setup.

You need to complete the following tasks before you can auto-provision a VPX instance:

1. Create a customized Open Virtualization Format (OVF) XML file or user data file.
2. Convert the OVF file into an ISO image by using an online application (for example PowerISO).
3. Mount the ISO image on the KVM host by using any secure copy (SCP)-based tools.

Sample OVF XML file:

Here's is an example of the contents an OVF XML file, which you can use as a sample to create your file.

```
1  <?xml version="1.0" encoding="UTF-8" standalone="no"?>
2
3  <Environment xmlns:oe="`http://schemas.dmtf.org/ovf/environment/1"`
4
5  xmlns:xsi="`http://www.w3.org/2001/XMLSchema-instance"`
6
7  oe:id=""
8
9  xmlns="`http://schemas.dmtf.org/ovf/environment/1"`
10
11 xmlns:cs="`http://schemas.citrix.com/openstack">`
12
13 <PlatformSection>
14
15 <Kind></Kind>
16
17 <Version>2016.1</Version>
```

```
18
19 <Vendor>VPX</Vendor>
20
21 <Locale>en</Locale>
22
23 </PlatformSection>
24
25 <PropertySection>
26
27 <Property oe:key="com.citrix.netscaler.ovf.version" oe:value="1.0"/>
28
29 <Property oe:key="com.citrix.netscaler.platform" oe:value="NSVPX"/>
30
31 <Property oe:key="com.citrix.netscaler.orch\_env" oe:value="KVM"/>
32
33 <Property oe:key="com.citrix.netscaler.mgmt.ip" oe:value="10.1.2.22"/>
34
35 <Property oe:key="com.citrix.netscaler.mgmt.netmask" oe:value="
      255.255.255.0"/>
36
37 <Property oe:key="com.citrix.netscaler.mgmt.gateway" oe:value="10.1.2.1
      "/>
38
39 </PropertySection>
40
41 </Environment>
42 <!--NeedCopy-->
```

In the OVF XML file preceding, “PropertySection” is used for NetScaler networking configuration. When you create the file, specify values for the parameters that are highlighted at the end of the example:

- Management IP address
- Netmask
- Gateway

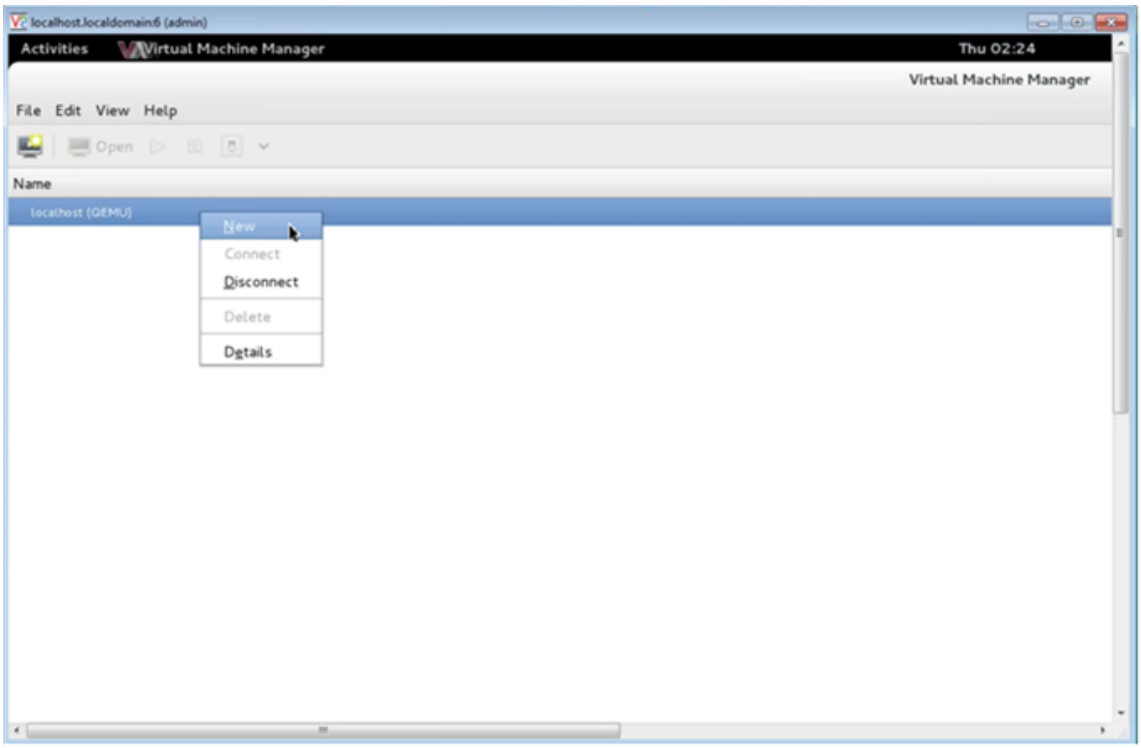
> **Important**
>
> If the OVF file is not properly XML formatted, the VPX instance is assigned the default network configuration, not the values specified in the file.

Provision the Citrix ADC VPX instance by using a RAW image

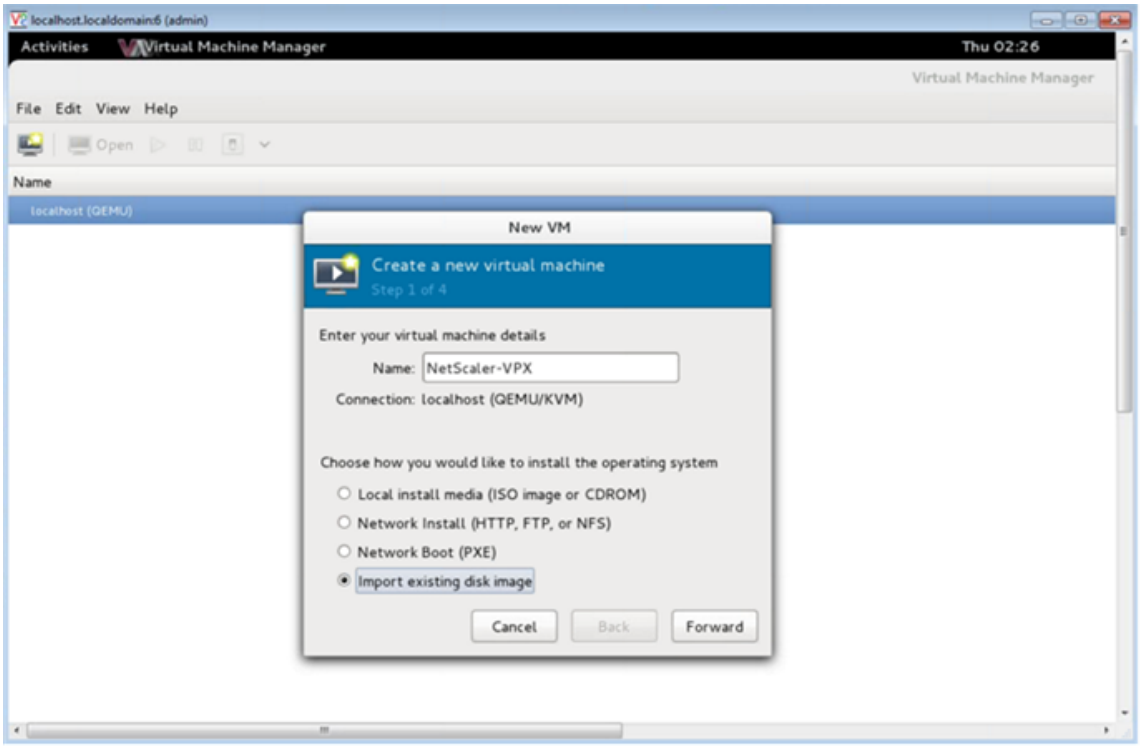
The Virtual Machine Manager enables you to provision a Citrix ADC VPX instancy by using a RAW image.

To provision a Citrix ADC VPX instance by using the Virtual Machine Manager, follow these steps:

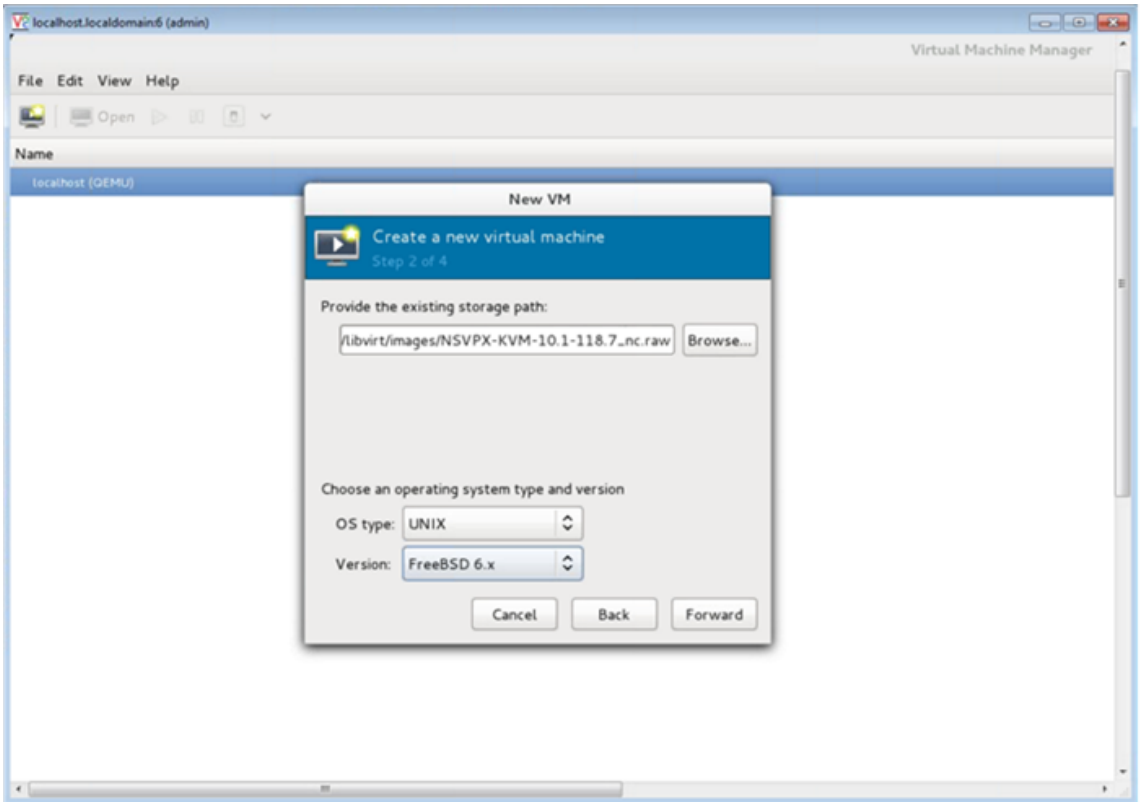
1. Open the Virtual Machine Manager (**Application** > **System Tools** > **Virtual Machine Manager**) and enter the logon credentials in the **Authenticate** window.
2. Click the  icon or right-click **localhost (QEMU)** to create a new Citrix ADC VPX instance.



3. In the **Name** text box, enter a name for the new VM (for example, NetScaler-VPX).
4. In the **New VM** window, under “Choose how you would like to install the operating system,” select **Import existing disk image**, and then and click **Forward**.

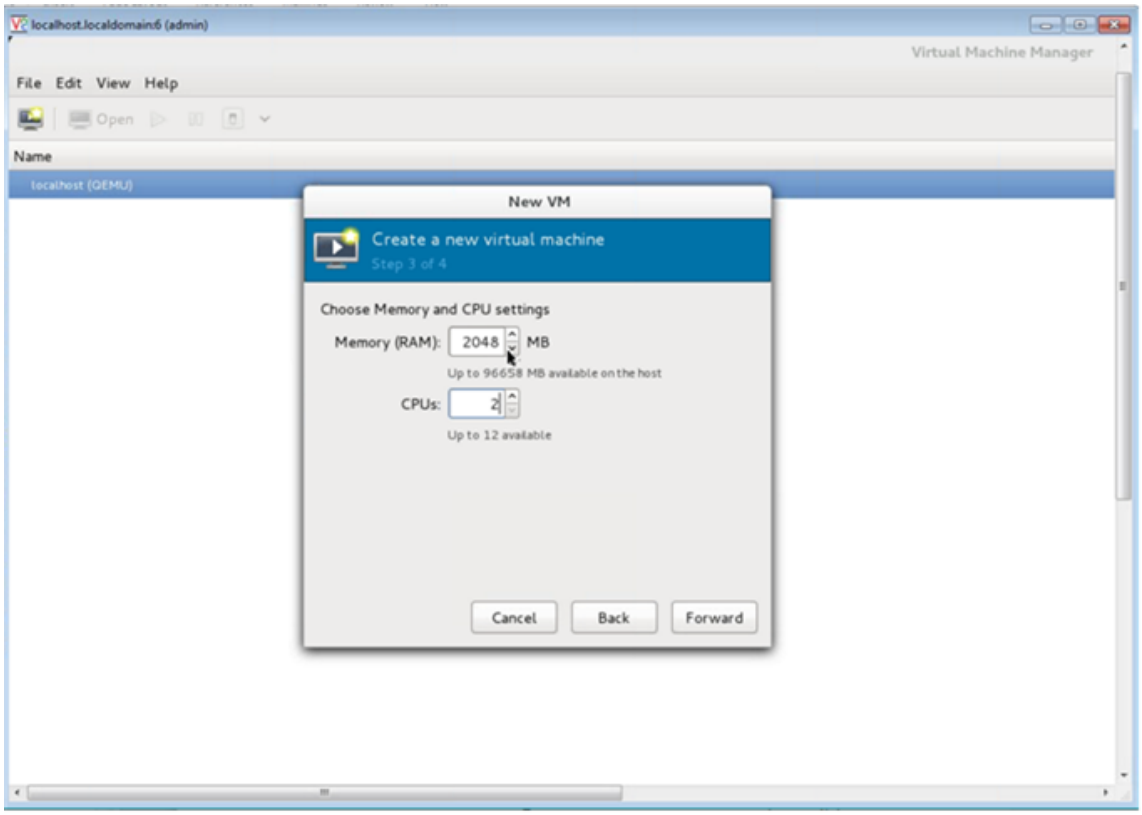


5. In the **Provide the existing storage path** field, navigate the path to the image. Choose the OS type as UNIX and Version as FreeBSD 6.x. Then, click **Forward**.

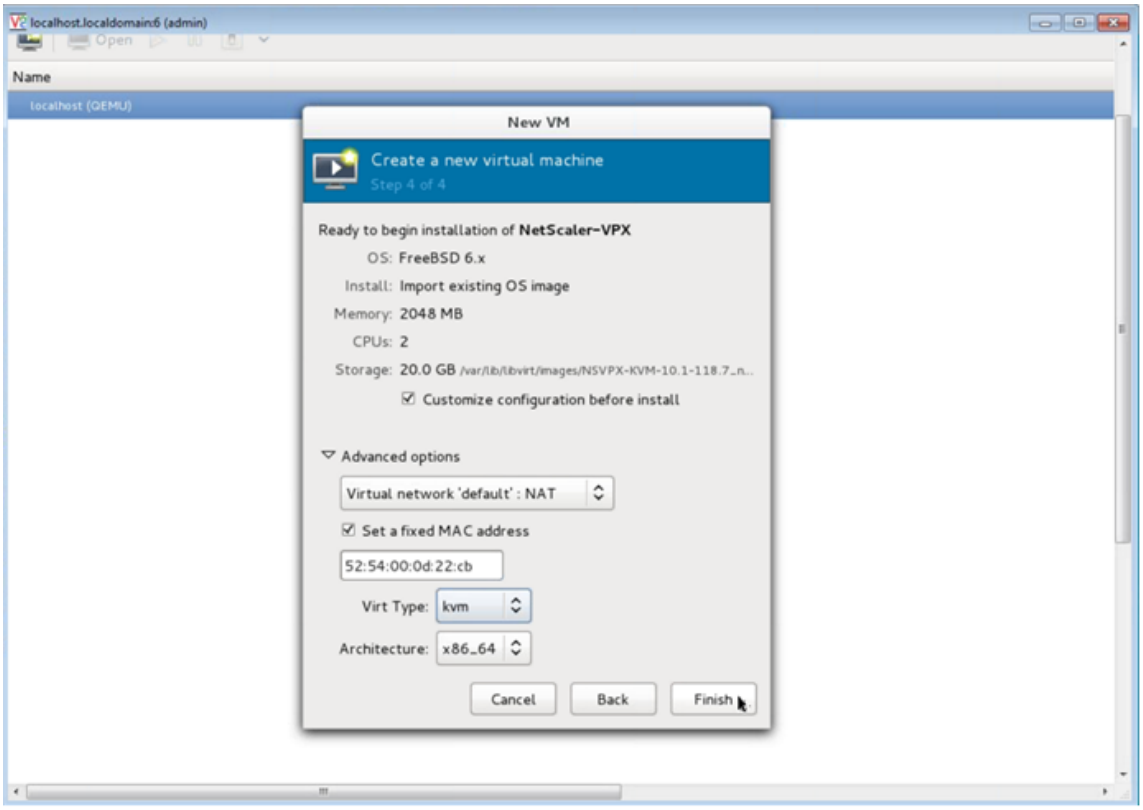


6. Under **Choose Memory and CPU** settings select the following settings, and then click **Forward**:

   - Memory (RAM)— 2048 MB
   - CPUs— 2

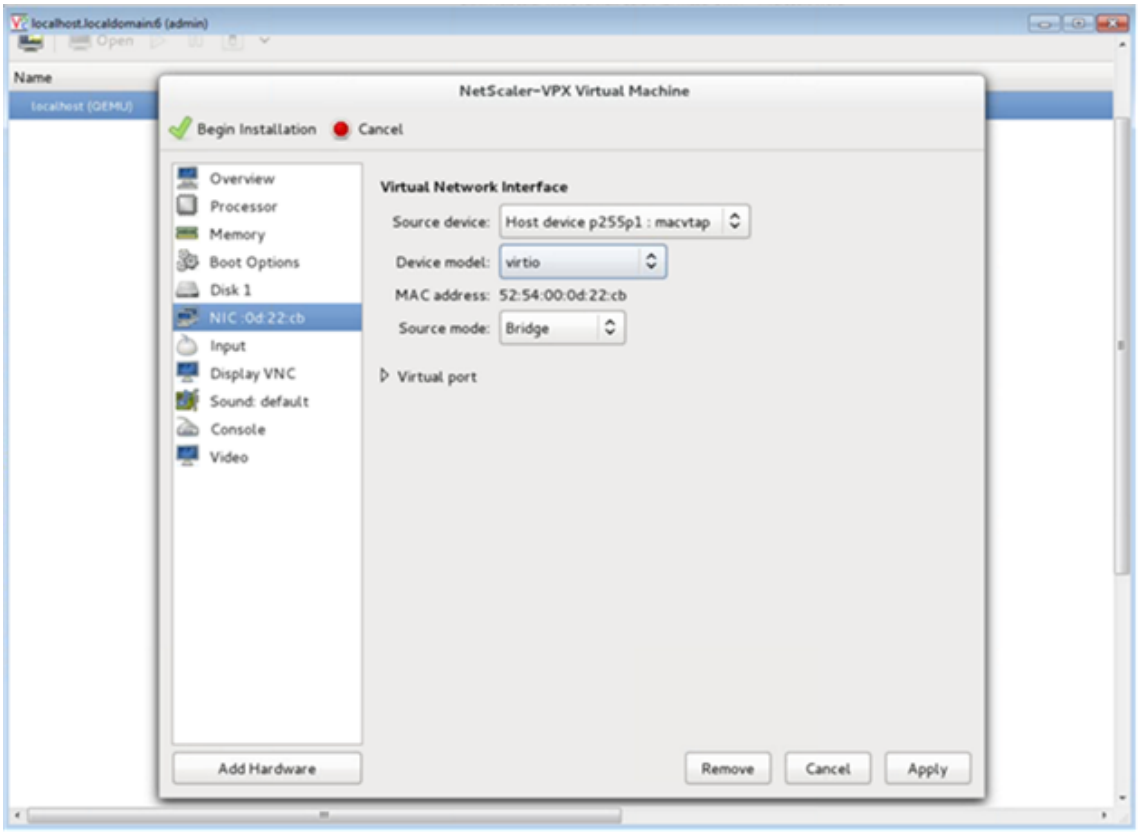


7. Select the **Customize configuration before install** check box. Optionally, under **Advanced options** you can customize the MAC address. Make sure the **Virt Type** selected is KVM and the Architecture selected is x86_64. Click **Finish**.



8. Select a NIC and provide the following configuration:

   - Source device— `ethX macvtap` or Bridge
   - Device model— `virtio`
   - Source mode— Bridge



9. Click **Apply**.
10. If you want to auto-provision the VPX instance, see the section **Enabling Auto-Provisioning by Attaching a CDROM Drive** in this document. Otherwise, click **Begin Installation**. After you have provisioned the Citrix ADC VPX on KVM, you can add more interfaces.

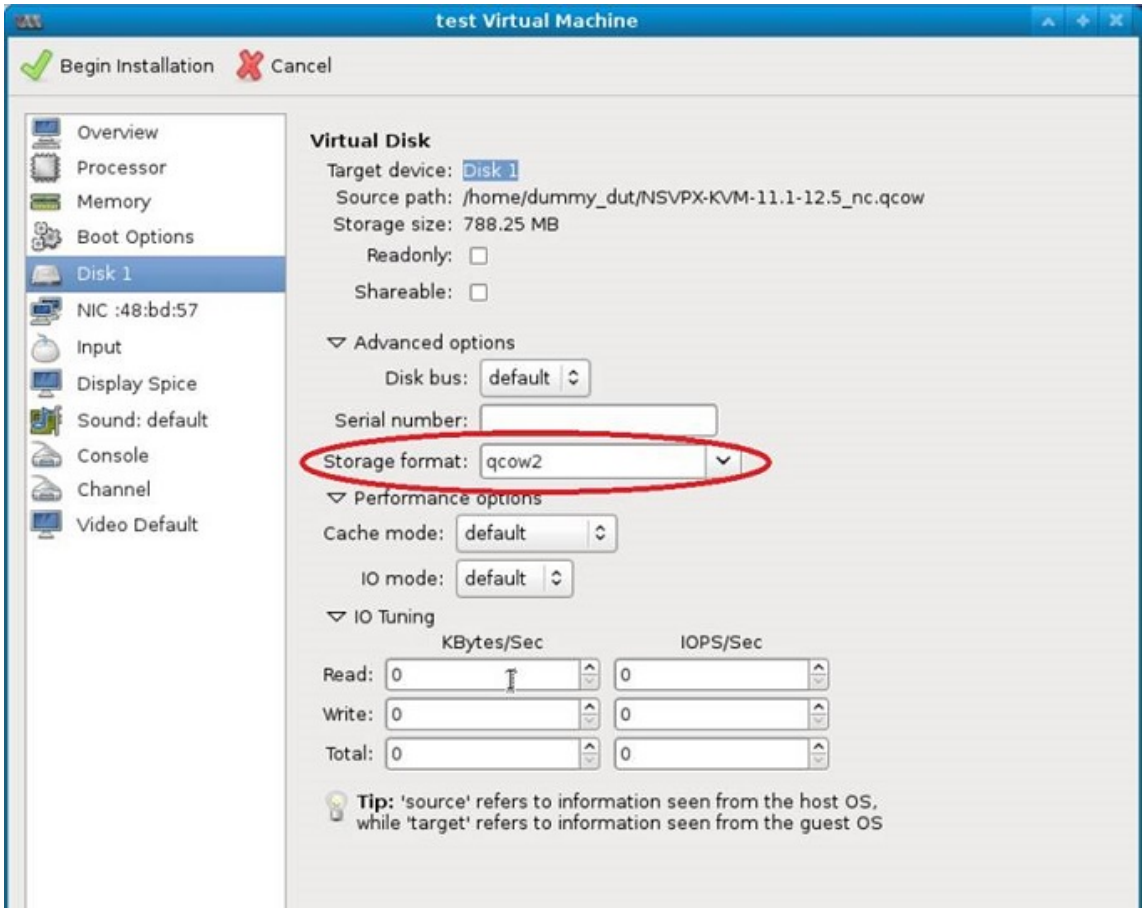
Provision the Citrix ADC VPX instance by using a QCOW2 image

Using the Virtual Machine Manager, you can provision the Citrix ADC VPX instance by using a QCOW2 image.

To provision a Citrix ADC VPX instance by using a QCOW2 image, follow these steps:

1. Follow **step 1** to **step 8** in Provision the Citrix ADC VPX instance by using a RAW image.

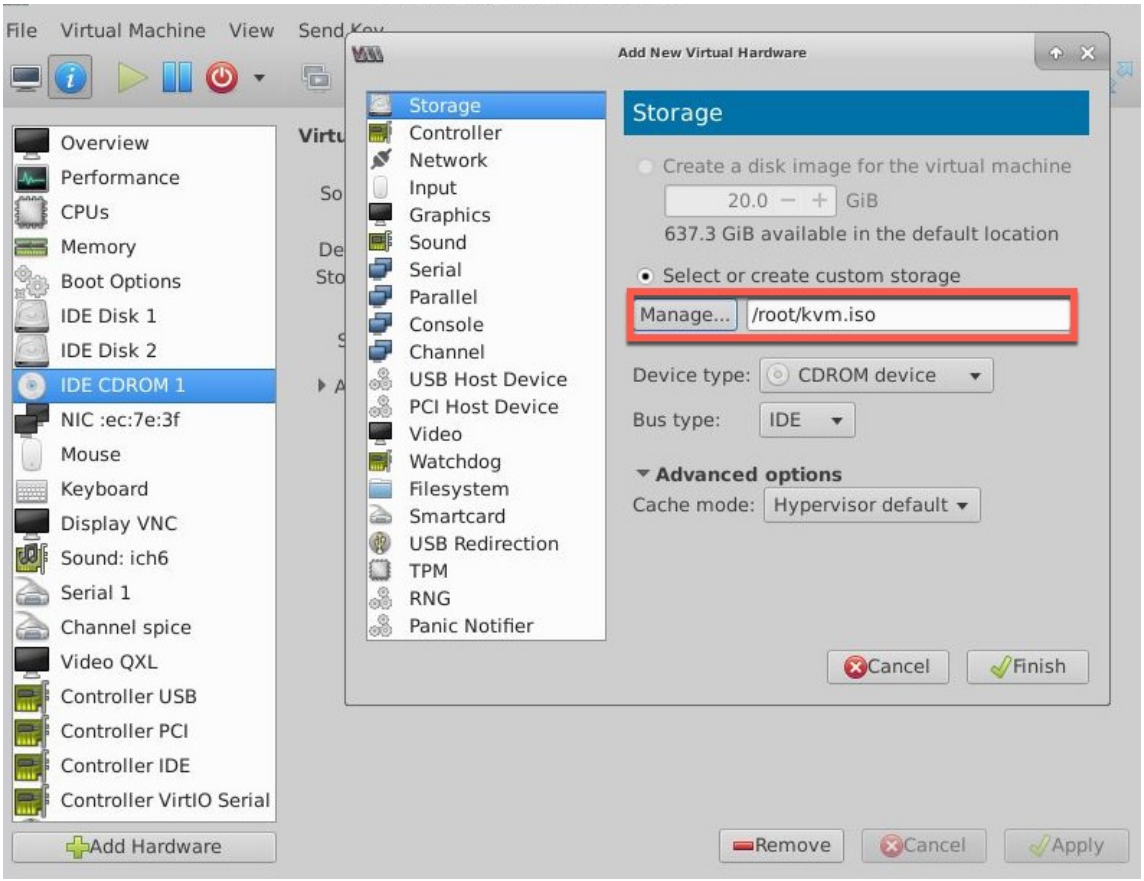
   Note: Ensure that you select **qcow2** image in **step 5**.
2. Select **Disk 1** and click **Advanced options**.
3. Select **qcow2** from the Storage format drop-down list.



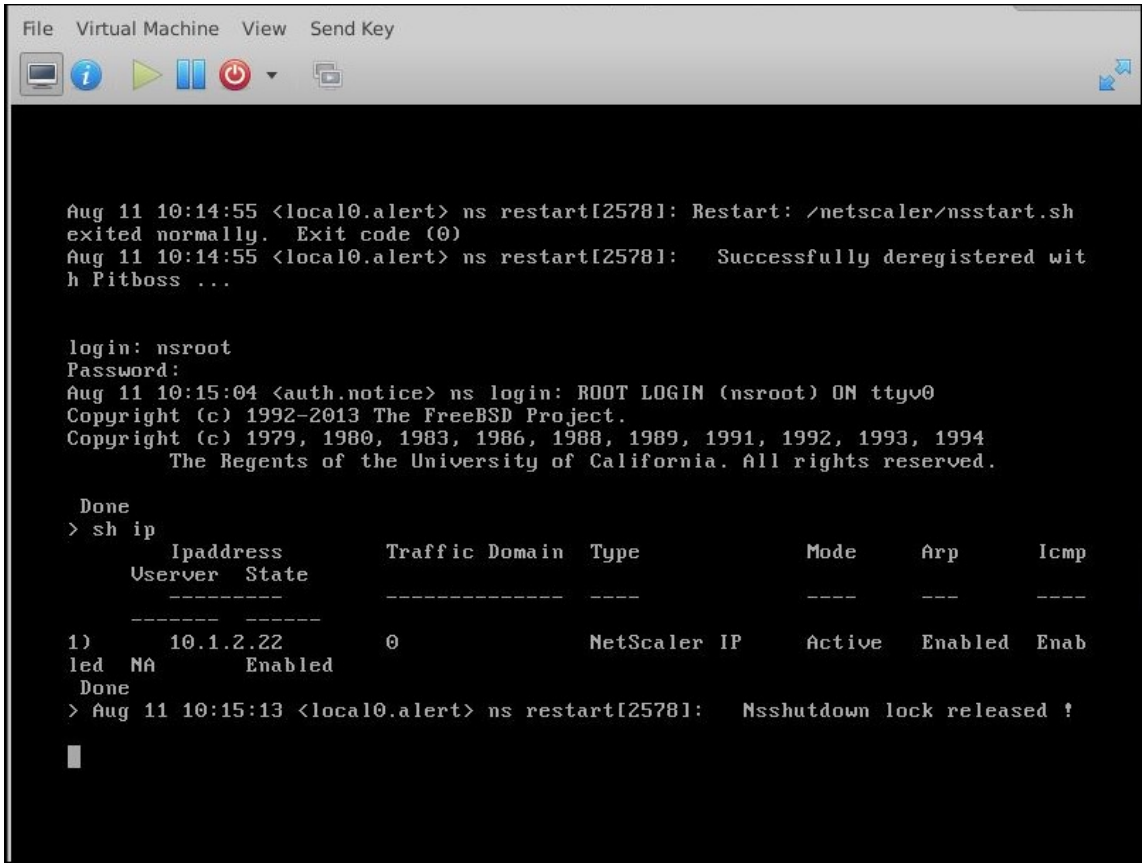
4. Click **Apply**, and then click **Begin Installation**. After you have provisioned the Citrix ADC VPX on KVM, you can add more interfaces.

Enable auto-provisioning by attaching a CDROM drive

1. Click Add **Hardware > Storage > Device type > CDROM device**.
2. Click **Manage** and select the correct ISO file that you mounted in the “Prerequisites for Auto-Provisioning a Citrix ADC VPX Instance” section, and click **Finish**. A new CDROM under Resources on your Citrix ADC VPX instance is created.



3. Power on the VPX instance, and it auto-provisions with the network configuration provided in the OVF file, as shown in the example screen capture.



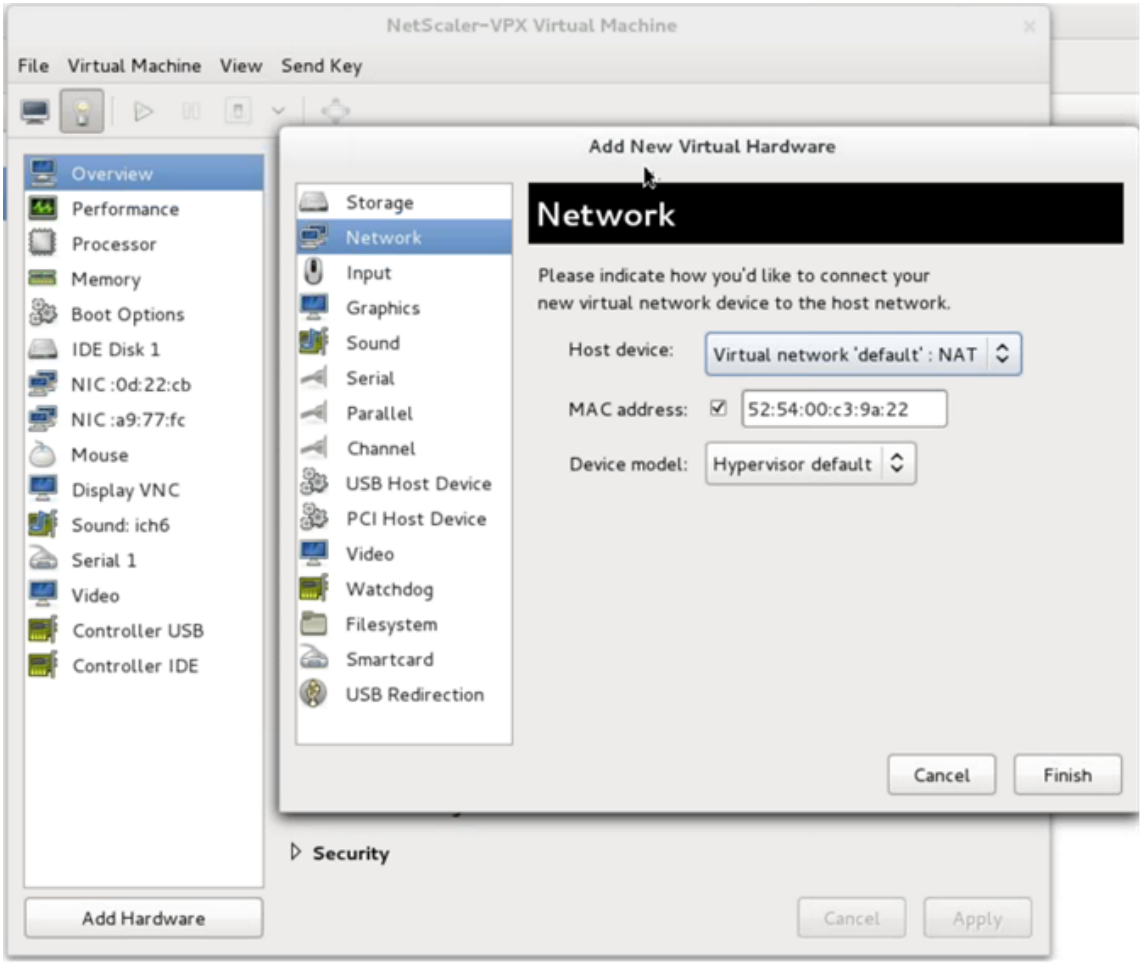
4. If auto-provision fails, the instance comes up with the default IP address (192.168.100.1). In that case, you must complete the initial configuration manually. For more information, see Configure the ADC for the first time.

Add more interfaces to the Citrix ADC VPX instance by using the Virtual Machine Manager

After you have provisioned the NetScaler VPX instance on KVM, you can add additional interfaces.

To add more interfaces, follow these steps.

1. Shut down the NetScaler VPX instance running on the KVM.
2. Right-click the VPX instance and choose **Open** from the pop-up menu.
3. Click the  icon in the header to view the virtual hardware details.
4. Click **Add Hardware**. In the **Add New Virtual Hardware window**, select **Network** from the navigation menu.



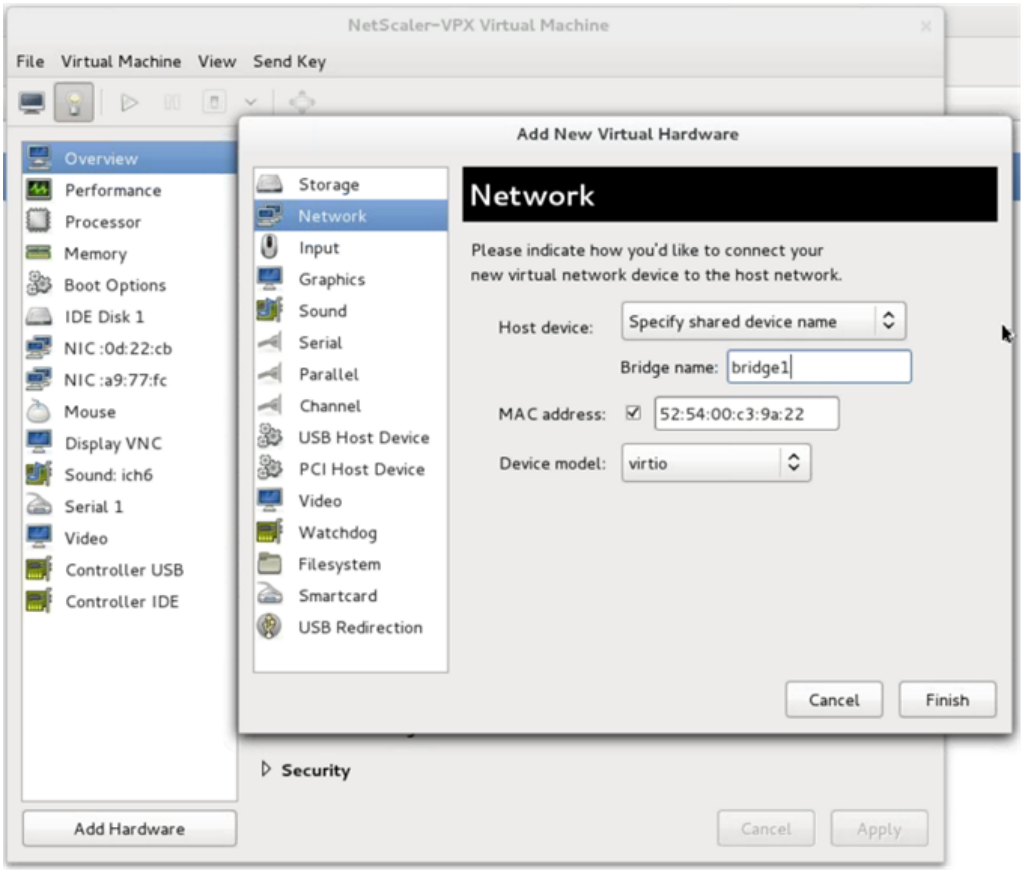
5. In **Host Device** field, select the physical interface type. The host device type can be either Bridge or MacVTap. In case of MacVTap, four modes possible are VEPA, Bridge, Private, and Pass-through.

    a) For Bridge

        i. Host device— Select the “Specify shared device name” option.

        ii. Provide the Bridge name that is configured in the KVM host.

        Note: Make sure that you have configured a Linux bridge in the KVM host, bound the physical interface to the bridge, and put the bridge in the UP state.



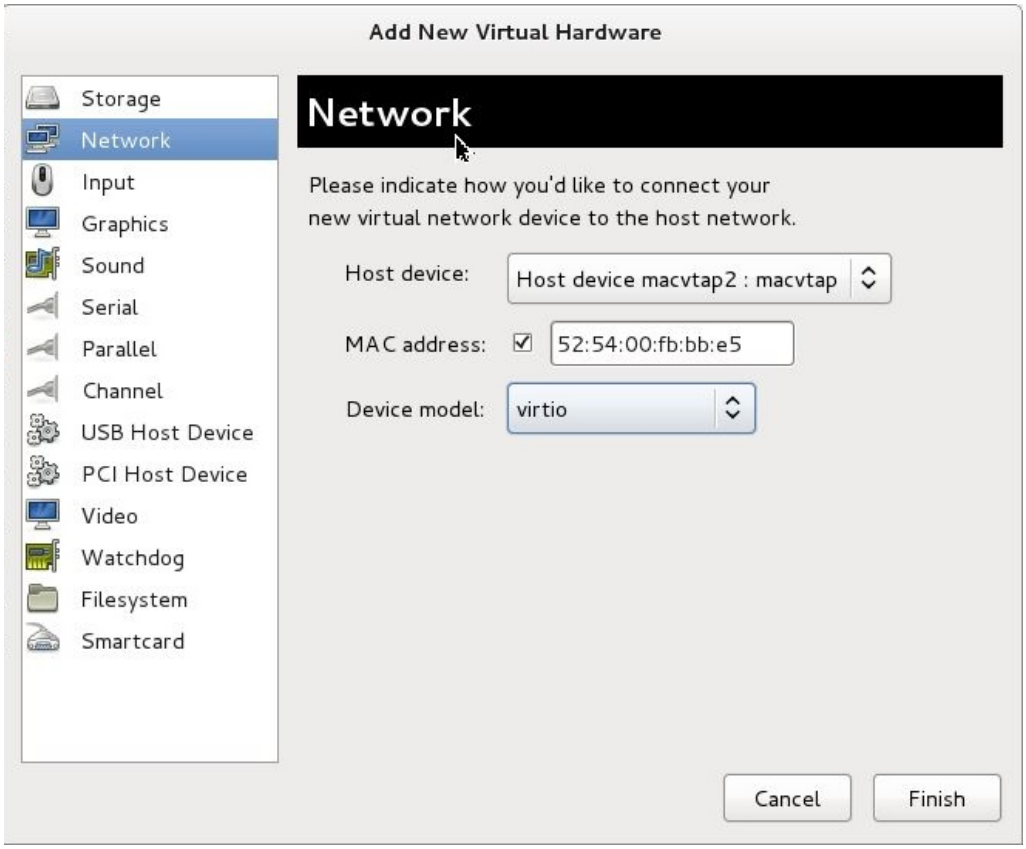
iii. Device model—`virtio`.

iv. Click Finish.

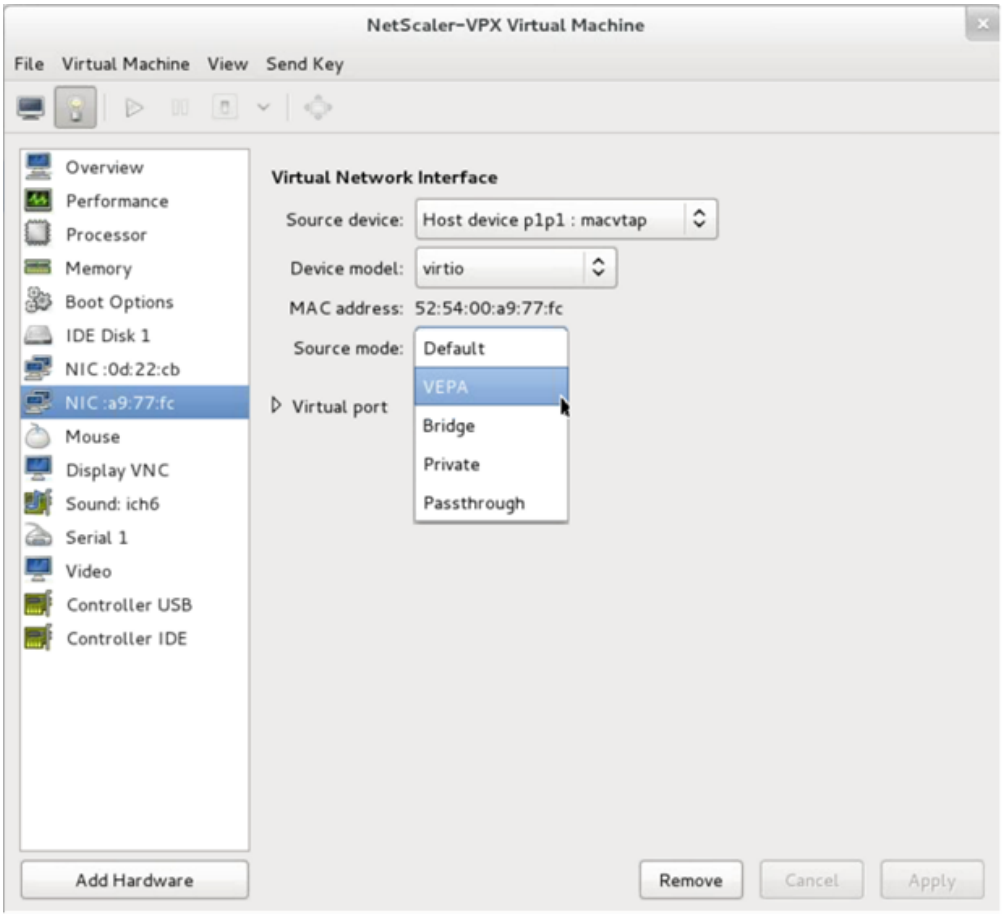
b) For MacVTap

i. Host device—Select the physical interface from the menu.

ii. Device model—`virtio`.



iii. Click Finish. You can view the newly added NIC in the navigation pane.



iv. Select the newly added NIC and select the Source mode for this NIC. The available modes are VEPA, Bridge, Private, and Passthrough. For more details on the interface and modes, see Source Interface and Modes.

v. Click Apply.

6. If you want to auto-provision the VPX instance, see the section “Adding a Config Drive to Enable Auto-Provisioning” in this document. Otherwise, power on the VPX instance to complete the initial configuration manually.

> **Important**
>
> Interface parameter configurations such as speed, duplex, and autonegotiation are not supported.

Configure a Citrix ADC VPX instance to use SR-IOV network interfaces

September 14, 2021

You can configure a Citrix ADC VPX instance running on Linux-KVM platform using single root I/O virtualization (SR-IOV) with the following NICs:

- Intel 82599 10G
- Intel X710 10G
- Intel XL710 40G
- Intel X722 10G

This section describes how to:

- Configure a Citrix ADC VPX Instance to Use SR-IOV Network Interface
- Configure Static LA/LACP on the SR-IOV Interface
- Configure VLAN on the SR-IOV Interface

Limitations

Keep the limitations in mind while using Intel 82599, X710, XL710, and X722 NICs. The following features not supported.

Limitations for Intel 82599 NIC:

- L2 mode switching.
- Admin partitioning (shared VLAN mode).
- High availability (active-active mode).
- Jumbo frames.
- IPv6: You can configure only up to 30 unique IPv6 addresses in a VPX instance if you've at least one SR-IOV interface.
- VLAN configuration on Hypervisor for SRIOV VF interface through `ip link` command is not supported.
- Interface parameter configurations such as speed, duplex, and autonegotiations are not supported.

Limitations for Intel X710 10G, Intel XL710 40G, and Intel X722 10G NICs:

- L2 mode switching.
- Admin partitioning (shared VLAN mode).
- In a cluster, Jumbo frames are not supported when the XL710 NIC is used as a data interface.
- Interface list reorders when interfaces are disconnected and reconnected.
- Interface parameter configurations such as speed, duplex, and auto negotiations are not supported.
- Interface name is 40/X for Intel X710 10G, Intel XL710 40G, and Intel X722 10G NICs
- Up to 16 Intel XL710/X710/X722 SRIOV or PCI passthrough interfaces can be supported on a VPX instance.

> **Note:** For Intel X710 10G, Intel XL710 40G, and Intel X722 10G NICs to support IPv6, you need to enable trust mode on the Virtual Functions (VFs) by typing the following command on the KVM host:
>
> ```
> ## ip link set <PNIC> <VF> trust on
> ```
>
> Example:
>
> ```
> ## ip link set ens785f1 vf 0 trust on
> ```

Prerequisites

Before you configure a Citrix ADC VPX instance to use SR-IOV network interfaces, complete the following prerequisite tasks. See the NIC column for details about how to complete the corresponding tasks.

Task	Intel 82599 NIC	Intel X710, XL710, and X722 NICs
1. Add the NIC to the KVM host.	-	-
2. Download and install the latest Intel driver.	IXGBE driver	I40E driver
3. Block list the driver on the KVM host.	Add the following entry in the /etc/modprobe.d/blacklist.conf file: `blacklist ixgbevf`. Use IXGBE driver version 4.3.15 (recommended).	Add the following entry in the /etc/modprobe.d/blacklist.conf file: `blacklist i40evf`. Use i40e driver version 2.0.26 (recommended).

Task	Intel 82599 NIC	Intel X710, XL710, and X722 NICs
4.Enable SR-IOV Virtual Functions (VFs) on the KVM host. In both the commands in the next two columns: `number_of_VFs` = the number of Virtual VFs that you want to create. `device_name` = the interface name.	If you are using earlier version of kernel 3.8, then add the following entry to the /etc/modprobe.d/ixgbe file and restart the KVM host: `options ixgbe max_vfs =<number_of_VFs>`. If you are using kernel 3.8 version or later, create VFs using the following command: `echo <number_of_VFs> > /sys/class/net/<device_name>/device/sriov_numvfs`. See example in figure 1.	If you are using earlier version of kernel 3.8, then add the following entry to the /etc/modprobe.d/i40e.conf file and restart the KVM host: `options i40e max_vfs=<number_of_VFs>`. If you are using kernel 3.8 version or later, create VFs using the following command: `echo<number_of_VFs> > /sys/class/net/<device_name>/device/sriov_numvfs`. See example in figure 2.
5. Make the VFs persistent by adding the commands that you used to create VFs, to the rc.local file.	See example in figure 3.	See example in figure 3.

> **Important**
>
> When you create the SR-IOV VFs, ensure that you do not assign MAC addresses to the VFs.

Figure 1: Enable SR-IOV VFs on the KVM host for Intel 82599 10G NIC.

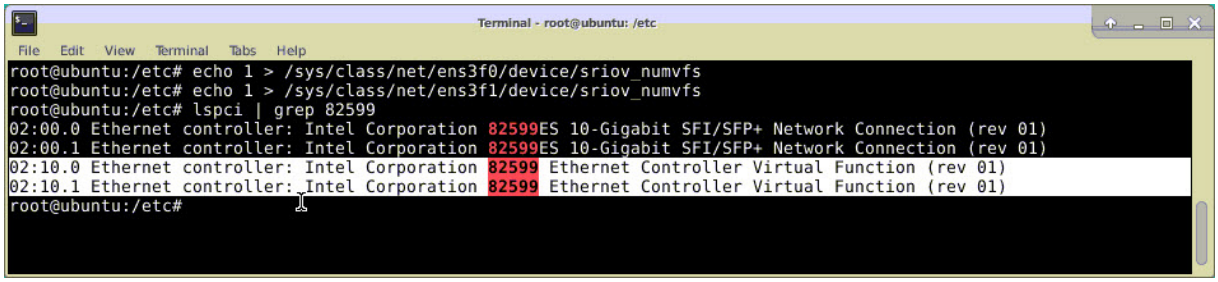


Figure 2: Enable SR-IOV VFs on the KVM host for Intel X710 10G and XL710 40G NICs.

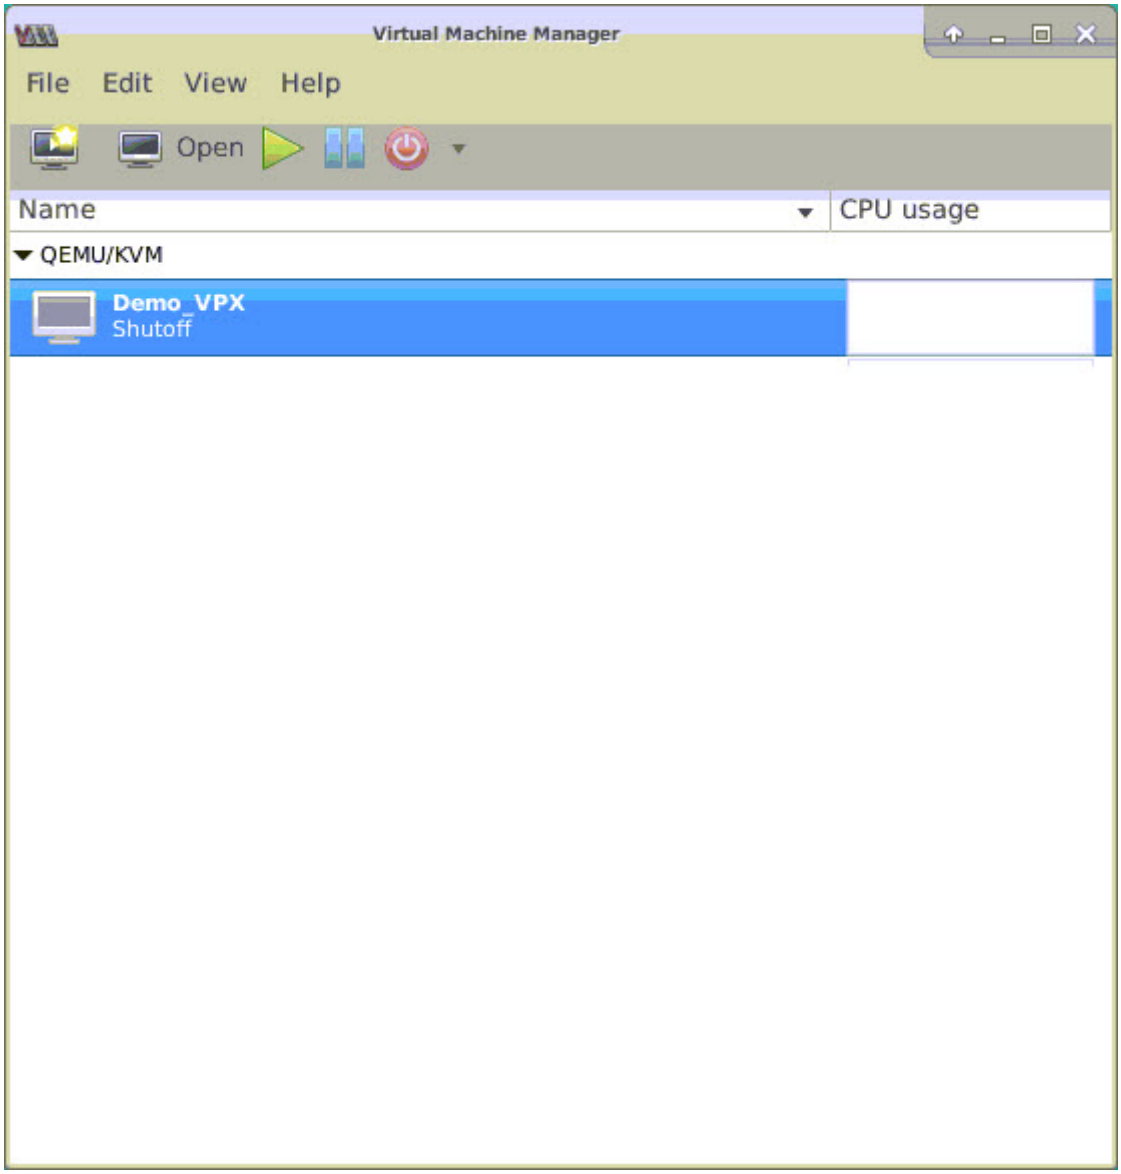
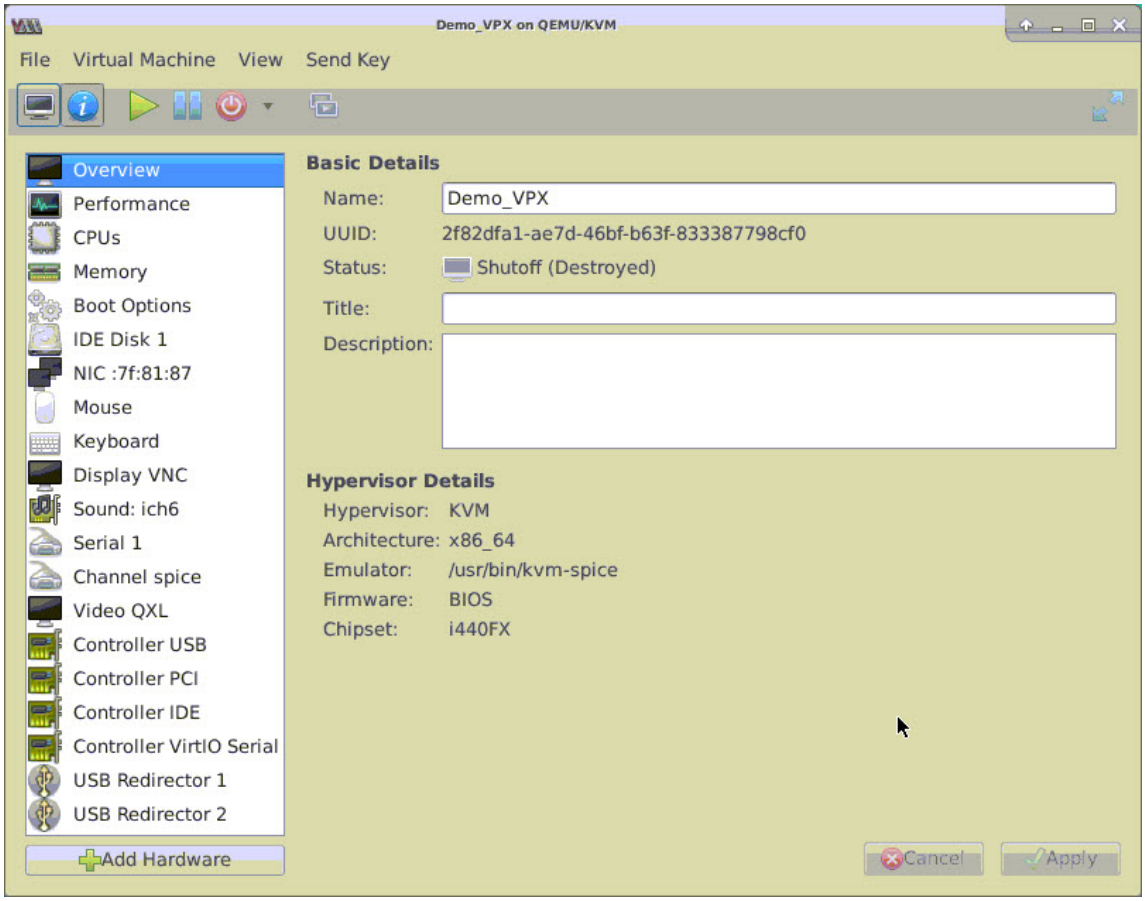
Configure a Citrix ADC VPX instance to use SR-IOV network interface

To configure the Citrix ADC VPX instance to use SR-IOV network interface by using Virtual Machine Manager, complete these steps:

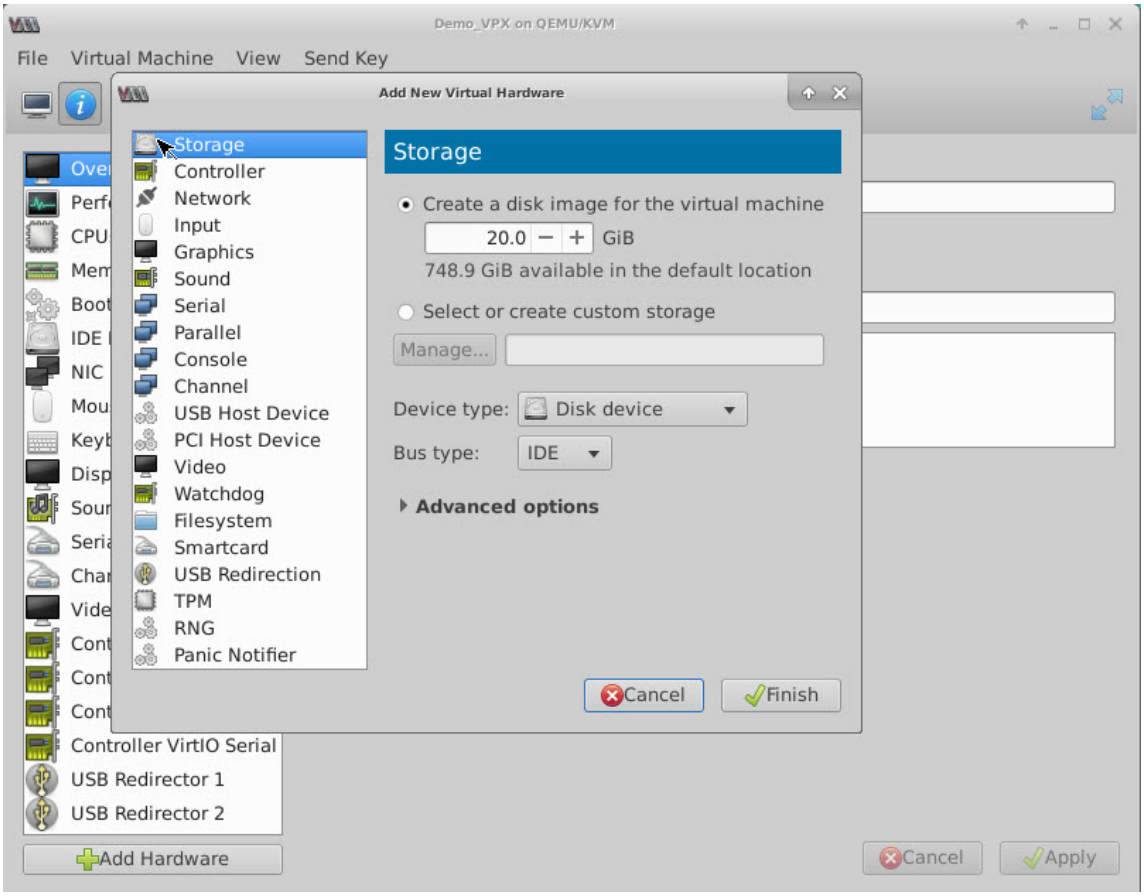
1. Power off the Citrix ADC VPX instance.
2. Select the Citrix ADC VPX instance and then select Open.



3. In the <virtual machine on KVM> window, select the **i** icon.



4. Select **Add Hardware**.



5. In the **Add New Virtual Hardware** dialog box, do the following:

   a) Select PCI Host Device.

   b) In the Host Device section, select the VF you have created and click Finish.

Figure 4: VF for Intel 82599 10G NIC

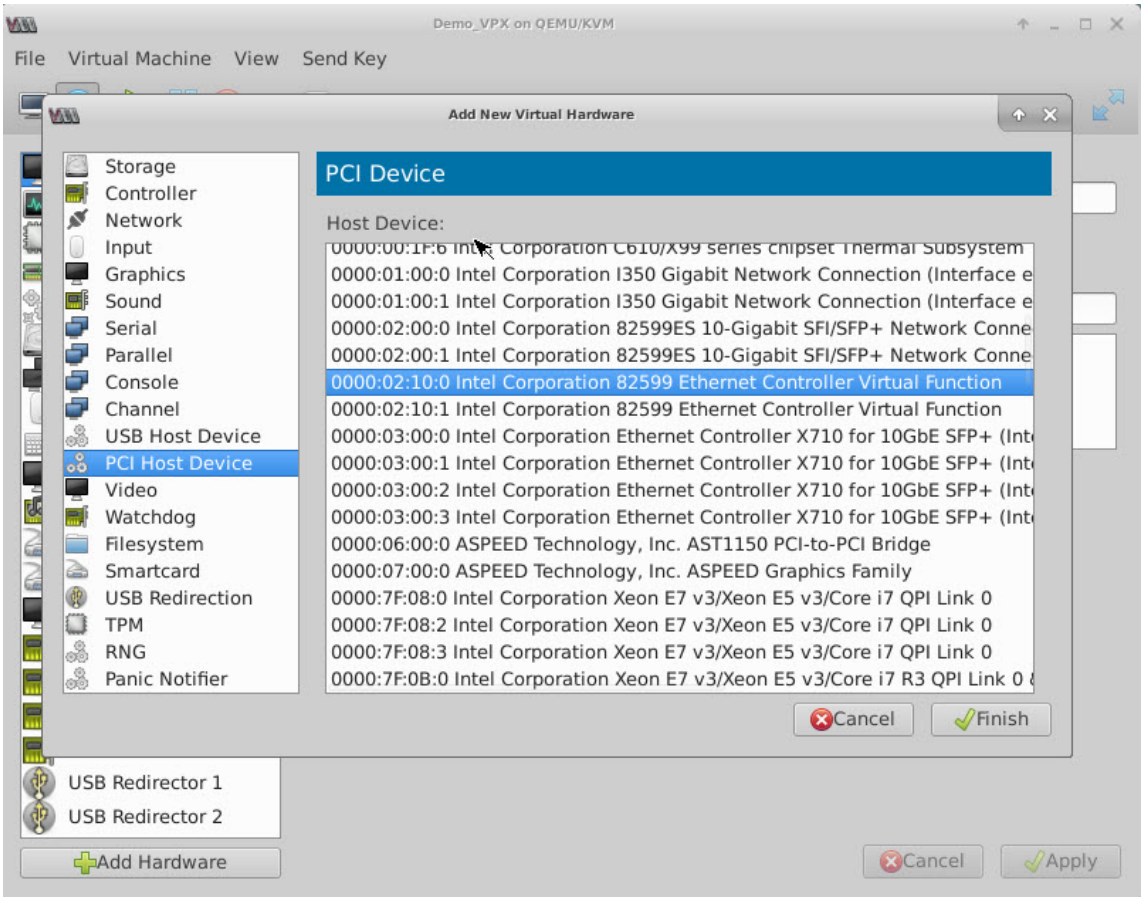


Figure 5: VF for Intel XL710 40G NIC

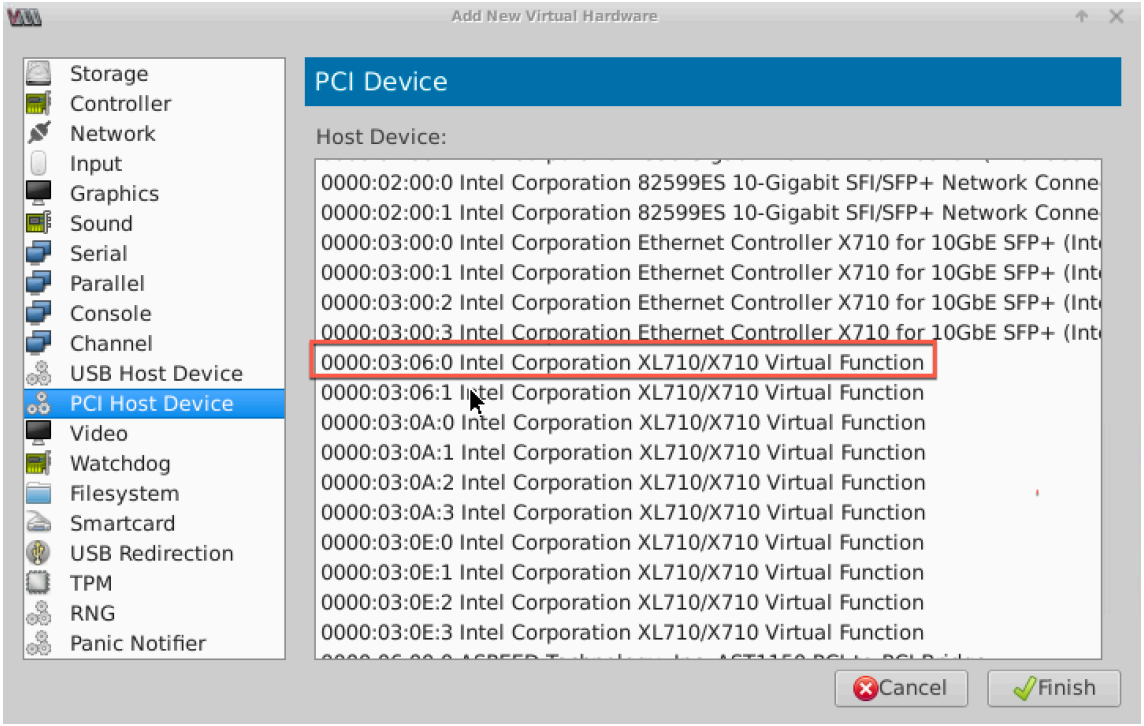

Figure 6: VF for Intel X722 10G NIC

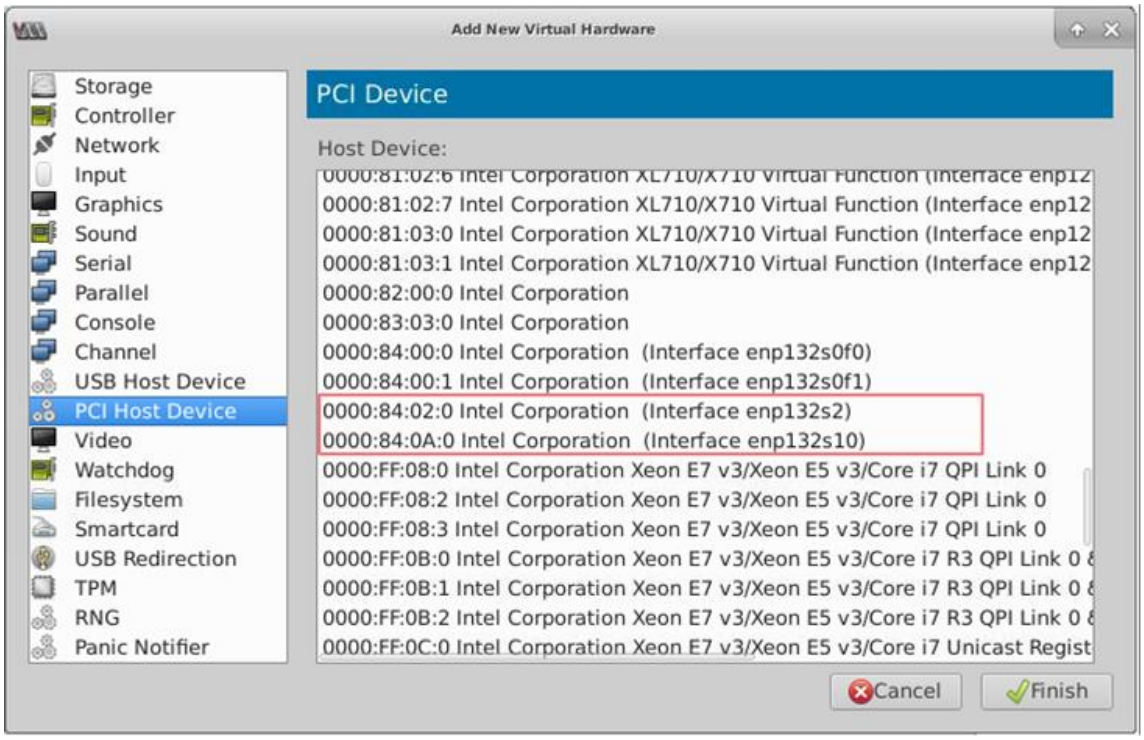


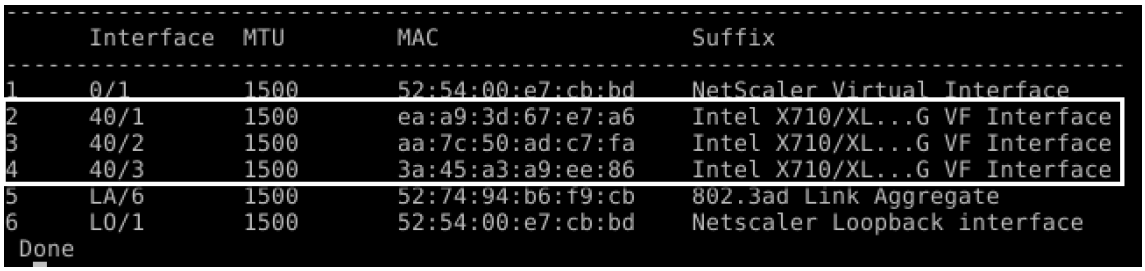
6. Repeat Step 4 and 5 to add the VFs that you have created.
7. Power on the Citrix ADC VPX instance.
8. After the Citrix ADC VPX instance powers on, use the following command to verify the configuration:

```
1 show interface summary
2 <!--NeedCopy-->
```

The output shows all the interfaces that you configured.

Figure 6: output summary for Intel 82599 NIC.

Figure 7. Output summary for Intel X710 and XL710 NICs.



Configure static LA/LACP on the SR-IOV interface

> **Important**
>
> When you are creating the SR-IOV VFs, ensure that you do not assign MAC addresses to the VFs.

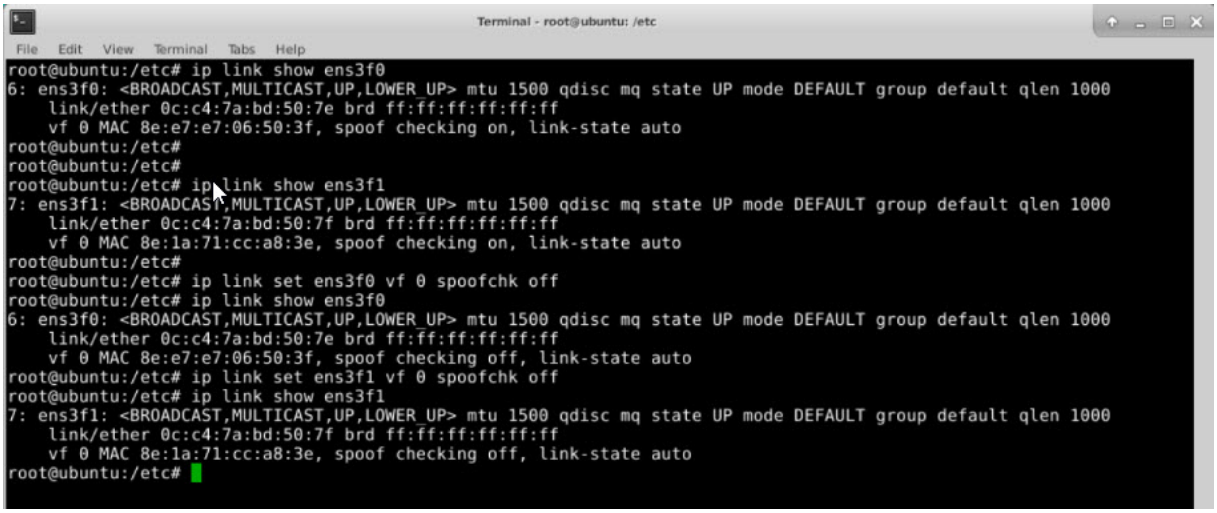
To use the SR-IOV VFs in link aggregation mode, disable spoof checking for VFs that you have created. On the KVM host, use the following command to disable spoof checking:

```
*ip link set \<interface\\_name\> vf \<VF\\_id\> spoofchk off*
```

Where:

- Interface_name – is the interface name.
- VF_id – is the Virtual Function id.

Example:



After you disable spoof checking for all the VFs that you have created. Restart the Citrix ADC VPX instance and configure link aggregation. For detailed instructions, see Configuring Link Aggregation.

Configuring VLAN on the SR-IOV Interface

You can configure VLAN on SR-IOV VFs. For detailed instructions, see Configuring a VLAN.

> **Important**
>
> Ensure that the KVM host does not contain VLAN settings for the VF interface.

Configure a Citrix ADC VPX instance to use PCI passthrough network interfaces

September 14, 2021

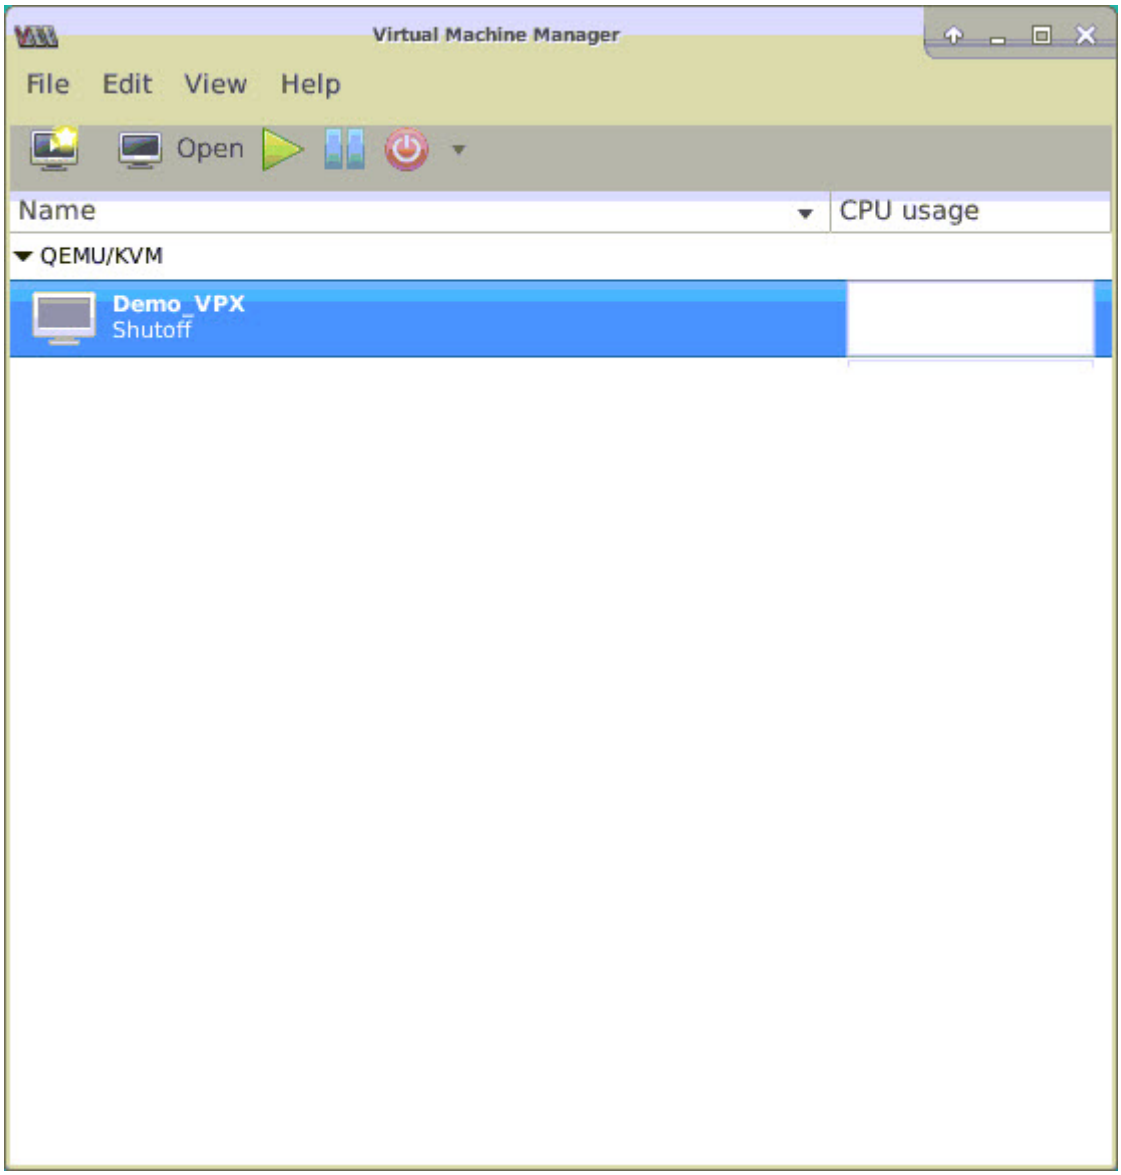
After you have installed and configured a Citrix ADC VPX instance on the Linux-KVM platform, you can use the Virtual Machine Manager to configure the virtual appliance to use PCI passthrough network interfaces.

Prerequisites

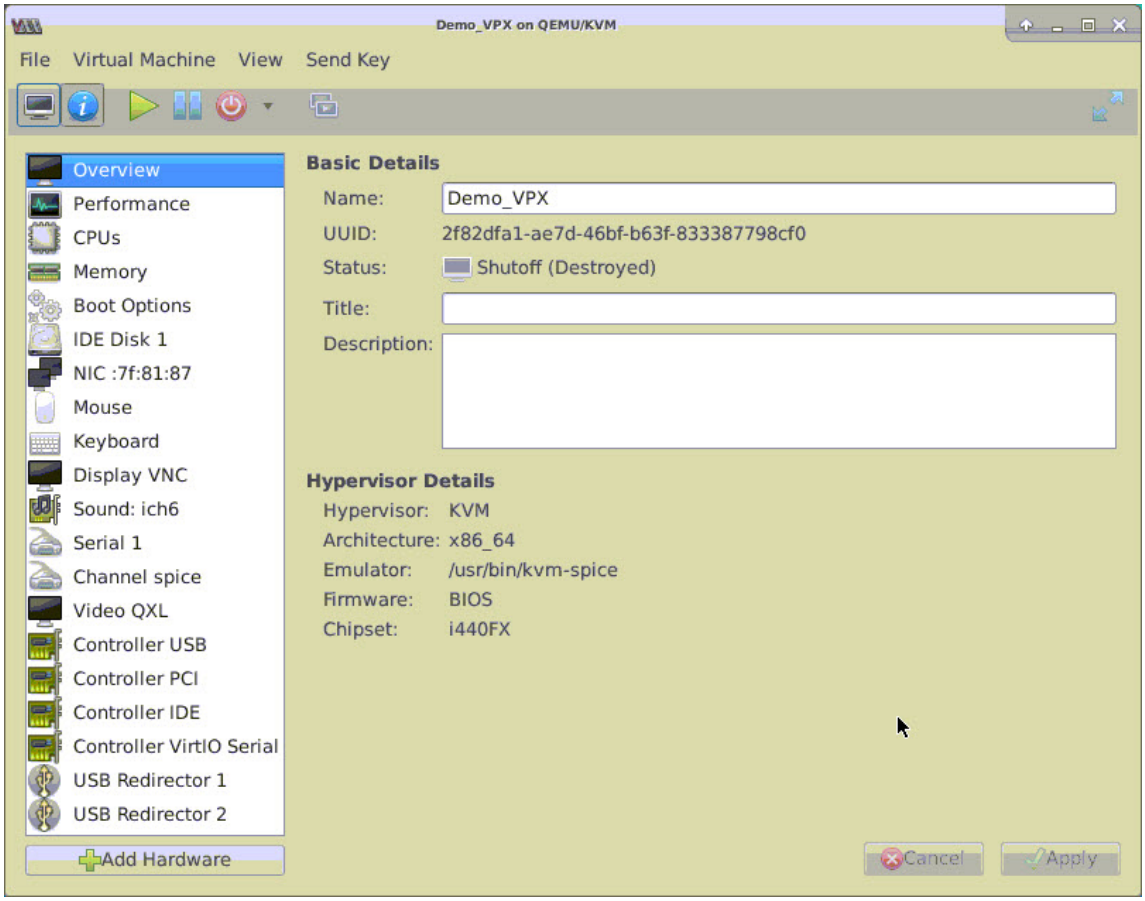
- The firmware version of the Intel XL710 NIC (NIC) on the KVM Host is 5.04.
- The KVM Host supports input–output memory management unit (IOMMU) and Intel VT-d, and they are enabled in the BIOS of the KVM Host. On the KVM Host, to enable IOMMU, add the following entry to the **/boot/grub2/grub.cfg** file: **intel_iommu=1**
- Run the following command and reboot the KVM Host: **Grub2-mkconfig –o /boot/-grub2/grub.cfg**

To configure Citrix ADC VPX instances to use PCI passthrough network interfaces by using the Virtual Machine Manager:

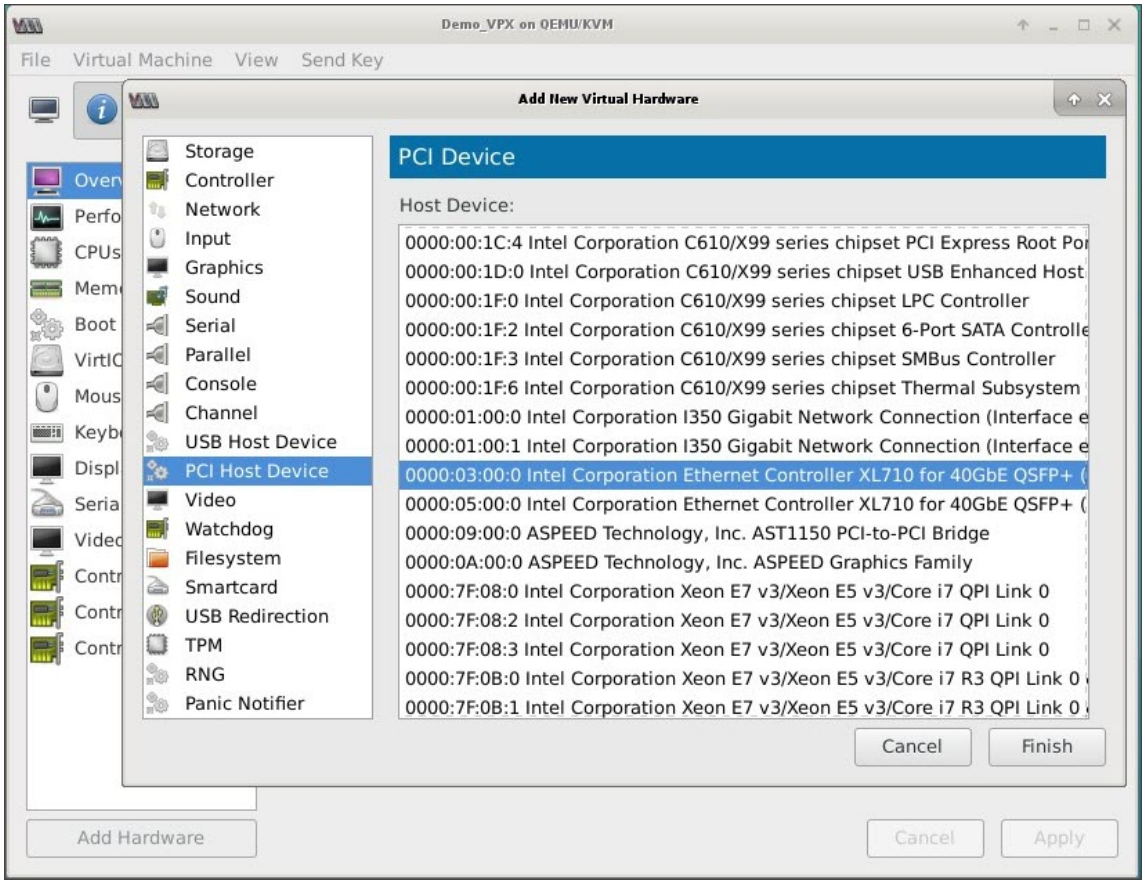
1. Power off the Citrix ADC VPX instance.
2. Select the Citrix ADC VPX instance and click **Open**.



3. In the **virtual_machine on KVM>** window, click the **i** icon.



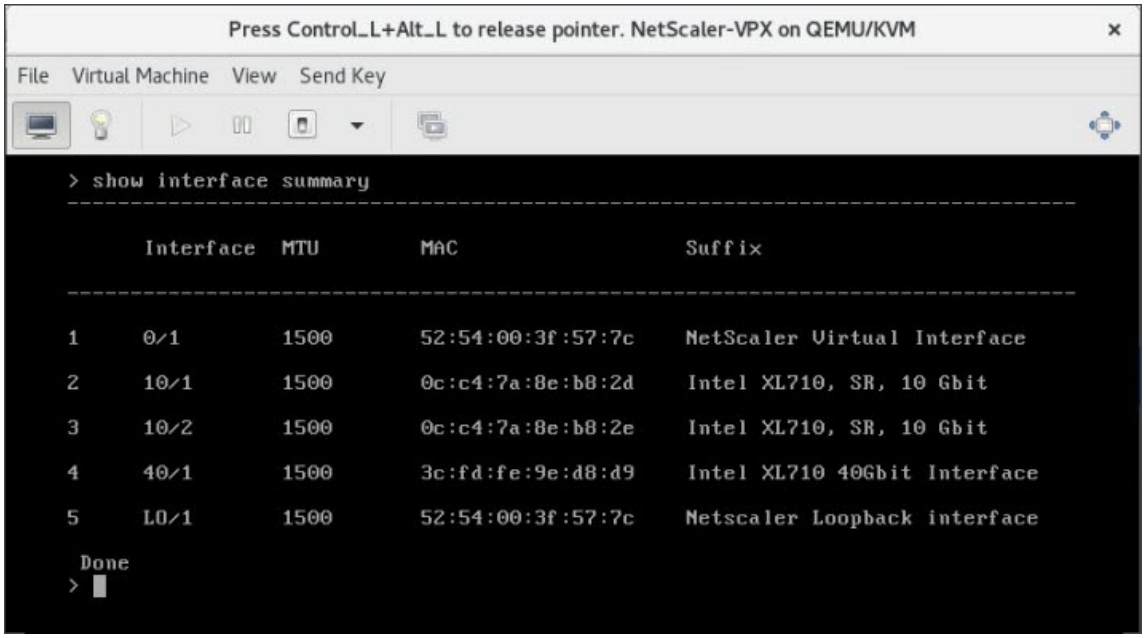
4. Click **Add Hardware**.
5. In the **Add New Virtual Hardware** dialog box, do the following:
   a. Select **PCI Host Device**.
   b. In the **Host Device** section, select the Intel XL710 physical function.
   c. Click **Finish**.



6. Repeat steps **4** and **5** to add any additional Intel XL710 physical functions.
7. Power on the Citrix ADC VPX instance.
8. Once the Citrix ADC VPX instance powers on, you can use the following command to verify the configuration:

```
COMMAND
> show interface summary
```

The output must show all the interfaces that you configured:



Provision the Citrix ADC VPX instance by using the virsh program

September 14, 2021

The `virsh` program is a command line tool for managing VM Guests. Its functionality is similar to that of Virtual Machine Manager. It enables you to change a VM Guest's status (start, stop, pause, and so on), to set up new Guests and devices, and to edit existing configurations. The `virsh` program is also useful for scripting VM Guest management operations.

To provision Citrix ADC VPX by using the `virsh` program, follow these steps:

1. Use the tar command to untar the Citrix ADC VPX package. The NSVPX-KVM-*_nc.tgz package contains the following components:

   - The Domain XML file specifying VPX attributes [NSVPX-KVM-*_nc.xml]
   - Check sum of NS-VM Disk Image [Checksum.txt]
   - NS-VM Disk Image [NSVPX-KVM-*_nc.raw]

   Example:

```
tar -xvzf NSVPX-KVM-10.1-117_nc.tgz
NSVPX-KVM-10.1-117_nc.xml
NSVPX-KVM-10.1-117_nc.raw
checksum.txt
<!--NeedCopy-->
```

2. Copy the NSVPX-KVM-*_nc.xml XML file to a file named <DomainName>-NSVPX-KVM-*_nc.xml. The <DomainName> is also the name of the virtual machine. Example:

```
cp NSVPX-KVM-10.1-117_nc.xml NetScaler-VPX-NSVPX-KVM-10.1-117_nc.
   xml
<!--NeedCopy-->
```

3. Edit the <DomainName>-NSVPX-KVM-*_nc.xml file to specify the following parameters:

   - name— Specify the name.
   - Mac— Specify the MAC address.
     Note: The domain name and the MAC address have to be unique.
   - source file— Specify the absolute disk-image source path. The file path has to be absolute. You can specify the path of the RAW image file or a QCOW2 image file.

     If you want to specify a RAW image file, specify the disk image source path as shown in the following example:

     Example:

```
<name>NetScaler-VPX</name>
<mac address='52:54:00:29:74:b3'/>
<source file='/root/NSVPX-KVM-10.1-117_nc.raw'/>
<!--NeedCopy-->
```

     Specify the absolute QCOW2 disk-image source path and define the driver type as **qcow2**, as shown in the following example:

     Example:

```
<name>NetScaler-VPX</name>
<mac address='52:54:00:29:74:b3'/>
<driver name ='qemu' type='qcow2'/>
<source file='/root/NSVPX-KVM-10.1-117_nc.qcow'/>*
<!--NeedCopy-->
```

4. Edit the <DomainName>-NSVPX-KVM-*_nc.xml file to configure the networking details:

   - source dev— specify the interface.
   - mode— specify the mode. The default interface is **Macvtap Bridge**.

   Example: Mode: MacVTap Bridge Set target interface as `ethx` and mode as bridge Model type as `virtio`

```
<interface type='direct'>
    <mac address='52:54:00:29:74:b3'/>
```

```
3        <source dev='eth0' mode='bridge'/>
4        <target dev='macvtap0'/>
5        <model type='virtio'/>
6        <alias name='net0'/>
7        <address type='pci' domain='0x0000' bus='0x00' slot='0x03'
             function='0x0'/>
8      </interface>
9  <!--NeedCopy-->
```

Here, eth0 is the physical interface attached to the VM.

5. Define the VM attributes in the <DomainName>-NSVPX-KVM-*_nc.xml file by using the following command: `virsh` define <DomainName>-NSVPX-KVM-*_nc.xml Example:

```
1 virsh define NS-VPX-NSVPX-KVM-10.1-117_nc.xml
2 <!--NeedCopy-->
```

Start the VM by entering the following command: `virsh` start [<DomainName> <DomainUUID>] Example:

```
1 virsh start NetScaler-VPX
2 <!--NeedCopy-->
```

Connect the Guest VM through the console `virsh` console [<DomainName> <DomainUUID> <DomainID>] Example:

```
1 virsh console NetScaler-VPX
2 <!--NeedCopy-->
```

Add more interfaces to Citrix ADC VPX instance using `virsh` program

After you have provisioned the Citrix ADC VPX on KVM, you can add additional interfaces.

To add more interfaces, follow these steps:

1. Shut down the Citrix ADC VPX instance running on the KVM.

Edit the <DomainName>-NSVPX-KVM-*_nc.xml <DomainUUID>]
file using the command: `virsh` edit
[<DomainName>

2.

3. In the <DomainName>-NSVPX-KVM-*_nc.xml file, append the following parameters:

   a) **For MacVTap**

   - Interface type— Specify the interface type as 'direct'.
   - MAC address— Specify the MAC address and make sure the MAC address is unique across the interfaces.
   - source dev— Specify the interface name.
   - mode— Specify the mode. The modes supported are - Bridge, VEPA, Private, and Pass-through
   - model type— Specify the model type as `virtio`

   Example:

   Mode: MacVTap Pass-through

   Set target interface as
   `ethx`, Mode as
   bridge, and model type as
   `virtio`

```
<interface type='direct'>
      <mac address='52:54:00:29:74:b3'/>
      <source dev='eth1' mode='passthrough'/>
      <model type='virtio'/>
 </interface>
<!--NeedCopy-->
```

   Here eth1 is the physical interface attached to the VM.

   b) **For Bridge Mode**

   Note: Make sure that you have configured a Linux bridge in the KVM host, bound the physical interface to the bridge, and put the bridge in the UP state.

   - Interface type— Specify the interface type as 'bridge'.
   - MAC address— Specify the MAC address and make sure the MAC address is unique across the interfaces.
   - source bridge— Specify the bridge name.

- model type— Specify the model type as `virtio`

Example: Bridge Mode

```
<interface type='bridge'>
      <mac address='52:54:00:2d:43:a4'/>
      <source bridge='br0'/>
      <model type='virtio'/>
 </interface>
<!--NeedCopy-->
```

Manage the Citrix ADC VPX guest VMs

September 14, 2021

You can use the Virtual Machine Manager and the `virsh` program to perform management tasks such as starting or stopping a VM Guest, setting up new guests and devices, editing existing configurations, and connecting to the graphical console through Virtual Network Computing (VNC).

Manage the VPX guest VMs by using Virtual Machine Manager

- List the VM guests

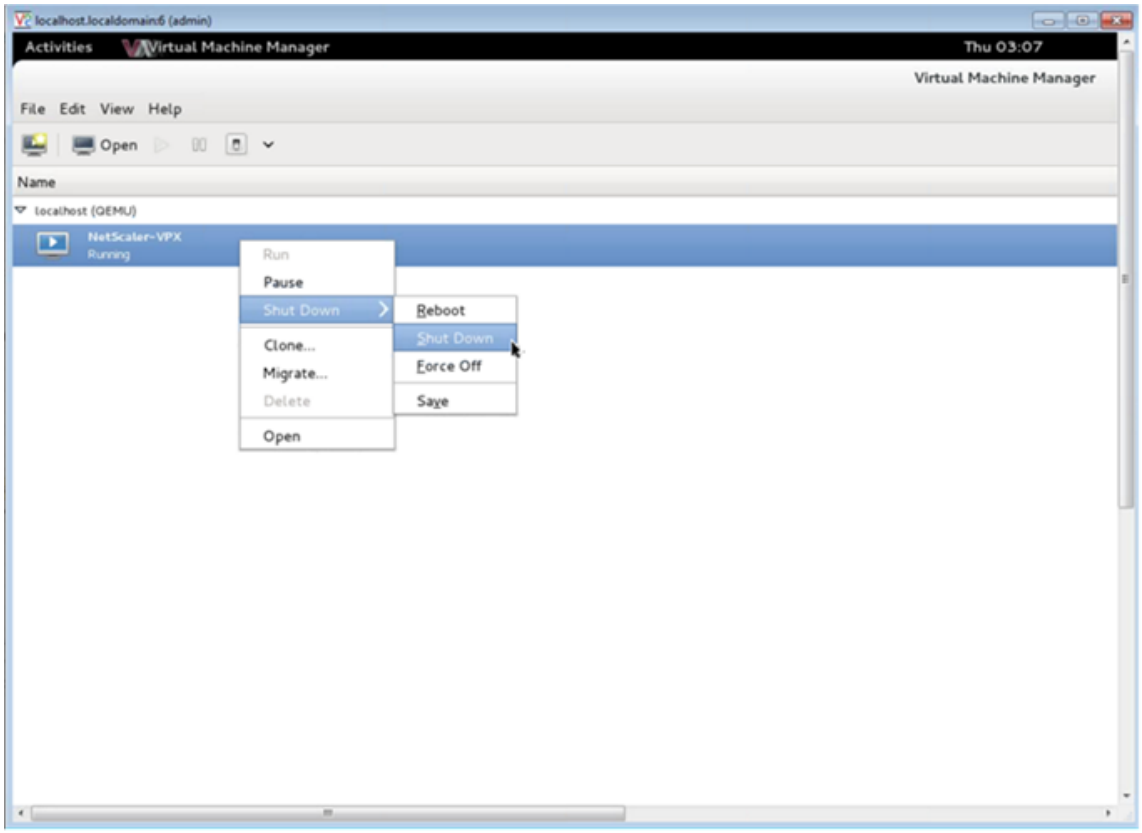
  The main Window of the Virtual Machine Manager displays a list of all the VM Guests for each VM host server it is connected to. Each VM Guest entry contains the virtual machine's name, along with its status (Running, Paused, or Shutoff) displayed as in the icon.

- Open a graphical console

  Opening a Graphical Console to a VM Guest enables you to interact with the machine like you would with a physical host through a VNC connection. To open the graphical console in the Virtual Machine Manager, right-click the VM Guest entry and select the Open option from the pop-up menu.

- Start and shut down a guest

  You can start or stop a VM Guest from the Virtual Machine Manager. To change the state of the VM, right-click the VM Guest entry and select Run or one of the Shut Down options from the pop-up menu.



- Reboot a guest

  You can reboot a VM Guest from the Virtual Machine Manager. To reboot the VM, right-click the VM Guest entry, and then select Shut Down > Reboot from the pop-up menu.

- Delete a guest

  Deleting a VM Guest removes its XML configuration by default. You can also delete a guest's storage files. Doing so completely erases the guest.

  1. In the Virtual Machine Manager, right-click the VM Guest entry.
  2. Select Delete from the pop-up menu. A confirmation window opens.
     Note: The Delete option is enabled only when the VM Guest is shut down.
  3. Click Delete.
  4. To completely erase the guest, delete the associated .raw file by selecting the Delete Associated Storage Files check box.

Manage the Citrix ADC VPX guest VMs using the `virsh` program

- List the VM Guests and their current states.

  To use `virsh` to display information about the Guests

  ```
  virsh list --all
  ```

The command output displays all domains with their states. Example output:

```
Id Name                 State
----------------------------------
  0 Domain-0           running
  1 Domain-1           paused
  2 Domain-2           inactive
  3 Domain-3           crashed
<!--NeedCopy-->
```

- Open a `virsh` console.

  Connect the Guest VM through the console

  `virsh console [<DomainID> | <DomainName> | <DomainUUID>]`

  Example:

  `virsh console NetScaler-VPX`

- Start and shut down a guest.

  Guests can be started using the DomainName or Domain-UUID.

  `virsh start [<DomainName> | <DomainUUID>]`

  Example:

  `virsh start NetScaler-VPX`

  To shut down a guest:

  `virsh shutdown [<DomainID> | <DomainName> | <DomainUUID>]`

  Example:

  `virsh shutdown NetScaler-VPX`

- Reboot a guest

  `virsh reboot [<DomainID> | <DomainName> | <DomainUUID>]`

  Example:

  `virsh reboot NetScaler-VPX`

  Delete a guest

  To delete a Guest VM you must shut down the Guest and undefine the <DomainName>-NSVPX-KVM-*_nc.xml before you run the delete command.

```
virsh shutdown [<DomainID> | <DomainName> | <DomainUUID>]
virsh undefine [<DomainName> | <DomainUUID>]
<!--NeedCopy-->
```

Example:

```
virsh shutdown NetScaler-VPX
virsh undefine NetScaler-VPX
<!--NeedCopy-->
```

> Note: The delete command doesn't remove disk image file which must be removed manually.

Provision the Citrix ADC VPX instance with SR-IOV, on OpenStack

September 14, 2021

You can deploy high-performance Citrix ADC VPX instances that use single-root I/O virtualization (SR-IOV) technology, on OpenStack.

You can deploy a Citrix ADC VPX instance that uses SR-IOV technology, on OpenStack, in three steps:

- Enable SR-IOV Virtual Functions (VFs) on the host.
- Configure and make the VFs available to OpenStack.
- Provision the Citrix ADC VPX on OpenStack.

Prerequisites

Ensure that you:

- Add the Intel 82599 NIC (NIC) to the host.
- Download and Install the latest IXGBE driver from Intel.
- Block list the IXGBEVF driver on the host. Add the following entry in the /etc/modprobe.d/blacklist.conf file: Block list `ixgbevf`

> **Note**
>
> The `ixgbe` driver version must be minimum 5.0.4.

Enable SR-IOV VFs on the host

Do one of the following steps to enable SR-IOV VFs:

- If you are using a kernel version earlier than 3.8, add the following entry to the /etc/modprobe.d/ixgbe file and restart the host: options ixgbe max_vfs=<number_of_VFs>
- If you are using kernel 3.8 version or later, create VFs by using the following command:

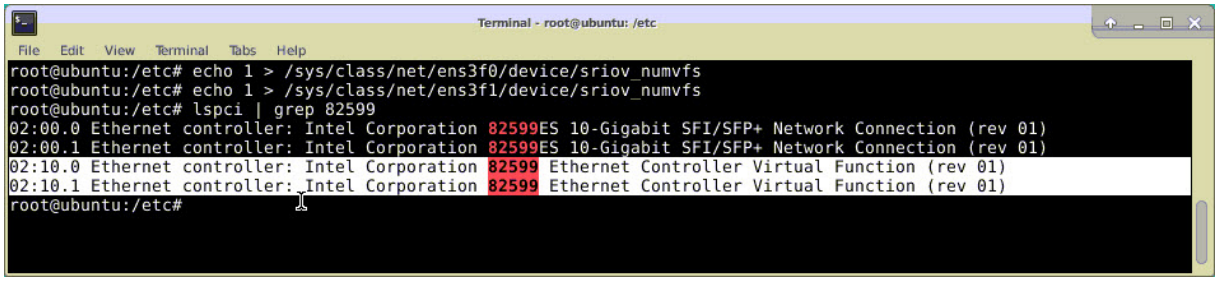
```
1     echo <number_of_VFs> > /sys/class/net/<device_name>/device/
         sriov_numvfs
2  <!--NeedCopy-->
```

Where:

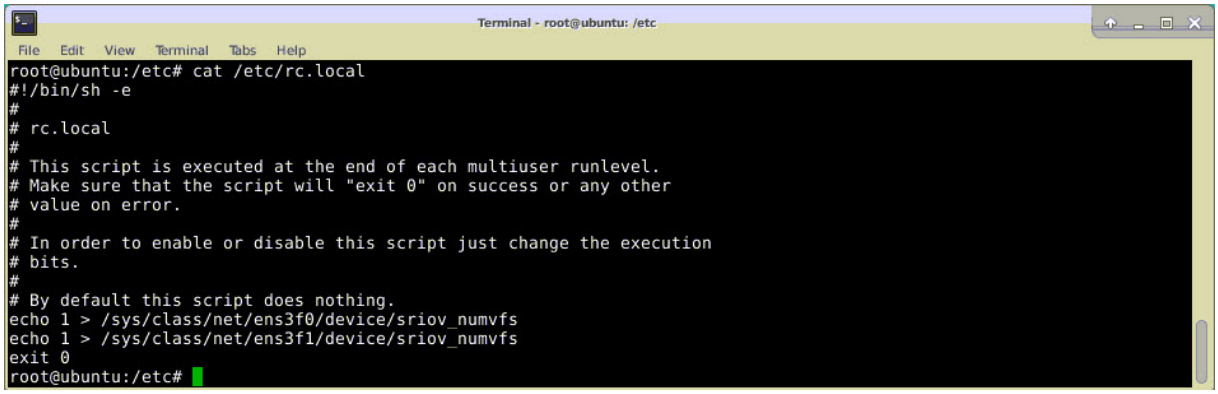
- number_of_VFs is the number of Virtual Functions that you want to create.
- device_name is the interface name.

> **Important**
>
> While you are creating the SR-IOV VFs, make sure that you do not assign MAC addresses to the VFs.

Here is an example of four VFs being created.



Make the VFs persistent, add the commands that you used to created VFs to the **rc.local** file. Here is an example showing content of rc.local file.



For more information, see this Intel SR-IOV Configuration Guide.

Configure and make the VFs available to OpenStack

Follow the steps given at the link below to configure SR-IOV on OpenStack: https://wiki.openstack.org/wiki/SR-IOV-Passthrough-For-Networking.

Provision the Citrix ADC VPX instance on OpenStack

You can provision a Citrix ADC VPX instance in an OpenStack environment by using the OpenStack CLI.

Provisioning a VPX instance, optionally involves using data from the config drive. The config drive is a special configuration drive that attaches to the instance when it boots. This configuration drive can be used to pass networking configuration information such as management IP address, network mask, and default gateway and so on to the instance before you configure the network settings for the instance.

When OpenStack provisions a VPX instance, it first detects that the instance is booting in an OpenStack environment, by reading a specific BIOS string (OpenStack Foundation) that indicates OpenStack. For Red Hat Linux distributions, the string is stored in /etc/nova/release. This is a standard mechanism that is available in all OpenStack implementations based on KVM hyper-visor platform. The drive must have a specific OpenStack label. If the config drive is detected, the instance attempts to read the following information from the file name specified in the `nova` boot command. In the procedures below, the file is called "userdata.txt."

- Management IP address
- Network mask
- Default gateway

Once the parameters are successfully read, they are populated in the NetScaler stack. This helps in managing the instance remotely. If the parameters are not read successfully or the config drive is not available, the instance transitions to the default behavior, which is:

- The instance attempts to retrieve the IP address information from DHCP.
- If DHCP fails or times-out, the instance comes up with default network configuration (192.168.100.1/16).

Provision the Citrix ADC VPX instance on OpenStack through CLI

You can provision a VPX instance in an OpenStack environment by using the OpenStack CLI. Here's the summary of the steps to provision a Citrix ADC VPX instance on OpenStack:

1. Extracting the `.qcow2` file from the .tgz file
2. Building an OpenStack image from the qcow2 image
3. Provisioning a VPX instance

To provision a VPX instance in an OpenStack environment, do the following steps.

1. Extract the. `qcow2` file from the `.tqz` file by typing the command:

```
tar xvzf <TAR file>
tar xvzf NSVPX-KVM-12.0-26.2_nc.tgz
```

```
NSVPX-KVM.xml
NSVPX-KVM-12.0-26.2_nc.qcow2
<!--NeedCopy-->
```

2. Build an OpenStack image using the `.qcoz2` file extracted in step 1 by typing the following command:

```
glance image-create --name="<name of the OpenStack image>" --
    property hw_disk_bus=ide --is-public=true --container-format=
    bare --disk-format=qcow2< <name of the qcow2 file>

glance image-create --name="NS-VPX-12-0-26-2" --property
    hw_disk_bus=ide --is-public= true --container-format=bare --
    disk-format=qcow2< NSVPX-KVM-12.0-26.2_nc.qcow2
<!--NeedCopy-->
```

The following illustration provides a sample output for the glance image-create command.

```
+------------------+--------------------------------------+
| Property         | Value                                |
+------------------+--------------------------------------+
| checksum         | 735dae4ea6e46e39ed3f0acfba02e755     |
| container_format | bare                                 |
| created_at       | 2017-02-16T10:03:29Z                 |
| disk_format      | qcow2                                |
| hw_disk_bus      | ide                                  |
| id               | aeaa13e9-b49b-411c-ab54-c61820a8e2f3 |
| min_disk         | 0                                    |
| min_ram          | 0                                    |

+------------------+--------------------------------------+
```

3. After an OpenStack image is created, provision the Citrix ADC VPX instance.

```
nova boot --image NSVPX-KVM-12.0-26.2 --config-drive=true --
    userdata
```

```
./userdata.txt --flavor m1. medium --nic net-id=3b258725-eaae-
455e-a5de-371d6d1f349f --nic port-id=218ba819-9f55-4991-adb6-
02086a6bdee2 NSVPX-10
<!--NeedCopy-->
```

In the preceding command, userdata.txt is the file which contains the details like, IP address, netmask, and default gateway for the VPX instance. The user data file is a user customizable file. NSVPX-KVM-12.0-26.2 is the name of the virtual appliance that you want to provision. –NIC port-id=218ba819-9f55-4991-adb6-02086a6bdee2 is the OpenStack VF.

The following illustration gives a sample output of the nova boot command.

Property	Value

```

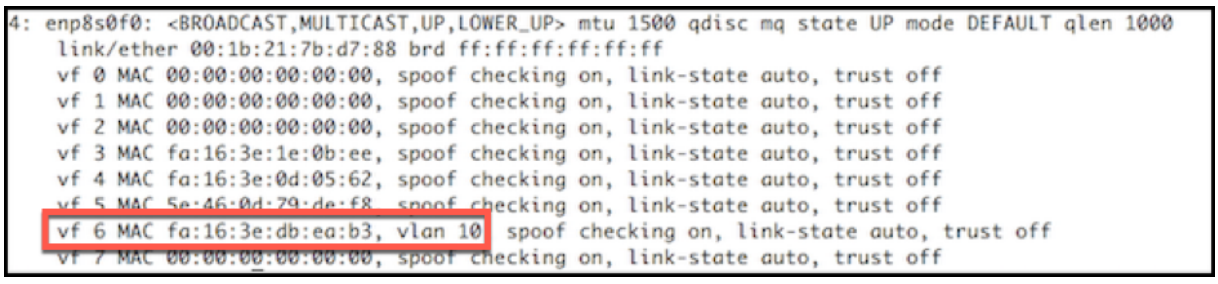
Additional supported Configurations: Creating and Deleting VLANs on SR-IOV VFs from the Host

Type the following command to create a VLAN on the SR-IOV VF:

```
ip link show enp8s0f0 vf 6 vlan 10
```

In the preceding command “enp8s0f0” is the name of the physical function.

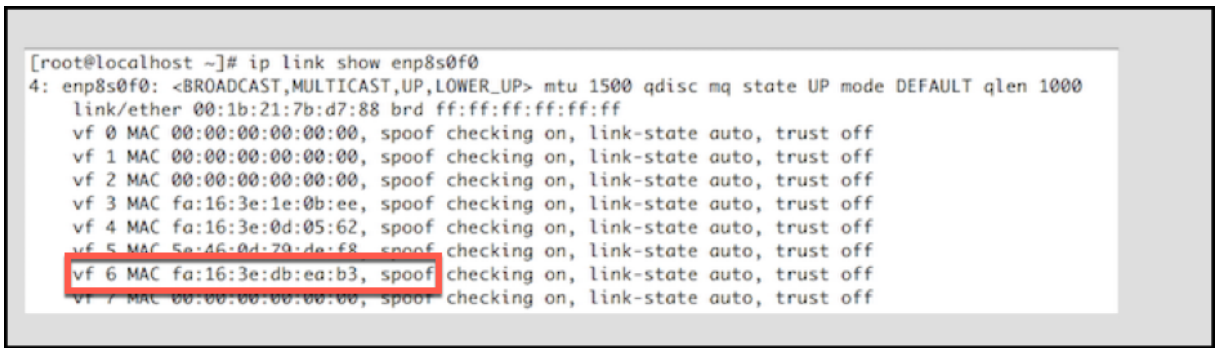
Example: VLAN 10, created on vf 6



Type the following command to delete a VLAN on the SR-IOV VF:

```
ip link show enp8s0f0 vf 6 vlan 0
```

Example: VLAN 10, removed from vf 6



These steps complete the procedure for deploying a Citrix ADC VPX instance that uses SRIOV technology, on OpenStack.

Configure a Citrix ADC VPX instance on KVM to use OVS DPDK-based host interfaces

September 14, 2021

You can configure a Citrix ADC VPX instance running on KVM (Fedora and RHOS) to use Open vSwitch (OVS) with Data Plane Development Kit (DPDK) for better network performance. This document describes how to configure the Citrix ADC VPX instance to operate on the `vhost-user` ports exposed by OVS-DPDK on the KVM host.

OVS is a multilayer virtual switch licensed under the open-source Apache 2.0 license. DPDK is a set of libraries and drivers for fast packet processing.

The following Fedora, RHOS, OVS, and DPDK versions are qualified for configuring a Citrix ADC VPX instance:

Fedora	RHOS
Fedora 25	RHOS 7.4
OVS 2.7.0	OVS 2.6.1
DPDK 16.11.12	DPDK 16.11.12

Prerequisites

Before you install DPDK, make sure the host has 1 GB huge pages.

For more information, see this DPDK system requirements documentation. Here is a summary of the steps required to configure a Citrix ADC VPX instance on KVM to use OVS DPDK-based host interfaces:

- Install DPDK.
- Build and Install OVS.
- Create an OVS bridge.
- Attach a physical interface to the OVS bridge.
- Attach `vhost-user` ports to the OVS data path.
- Provision a KVM-VPX with OVS-DPDK based `vhost-user` ports.

Install DPDK

To install DPDK, follow the instruction given at this Open vSwitch with DPDK document.

Build and install OVS

Download OVS from the OVS download page. Next, build, and install OVS by using a DPDK datapath. Follow the instructions given in the Installing Open vSwitch document.

For more detailed information, DPDK Getting Started Guide for Linux.

Create an OVS bridge

Depending on your need, type the Fedora or RHOS command to create an OVS bridge:

Fedora command:

```
1 > $OVS_DIR/utilities/ovs-vsctl add-br ovs-br0 -- set bridge ovs-br0
     datapath_type=netdev
2 <!--NeedCopy-->
```

RHOS command:

```
1 ovs-vsctl add-br ovs-br0 -- set bridge ovs-br0 datapath_type=netdev
2 <!--NeedCopy-->
```

Attach the physical interface to the OVS bridge

Bind the ports to DPDK and then attach them to the OVS bridge by typing the following Fedora or RHOS commands:

Fedora command:

```
1 > $OVS_DIR/utilities/ovs-vsctl add-port ovs-br0 dpdk0 -- set Interface
     dpdk0 type=dpdk  options:dpdk-devargs=0000:03:00.0
2
```

```
3 > $OVS_DIR/utilities/ovs-vsctl add-port ovs-br0 dpdk1 -- set Interface
     dpdk1 type=dpdk  options:dpdk-devargs=0000:03:00.1
4 <!--NeedCopy-->
```

RHOS command:

```
1 ovs-vsctl add-port ovs-br0 dpdk0 -- set Interface dpdk0 type=dpdk
     options:dpdk-devargs=0000:03:00.0
2
3
4 ovs-vsctl add-port ovs-br0 dpdk1 -- set Interface dpdk1 type=dpdk
     options:dpdk-devargs=0000:03:00.1
5 <!--NeedCopy-->
```

The `dpdk-devargs` shown as part of the options specifies the PCI BDF of the respective physical NIC.

Attach `vhost-user` ports to the OVS data path

Type the following Fedora or RHOS commands to attach `vhost-user` ports to the OVS data path:

Fedora command:

```
1 > $OVS_DIR/utilities/ovs-vsctl add-port ovs-br0 vhost-user1 -- set
     Interface vhost-user1 type=dpdkvhostuser -- set Interface vhost-
     user1  mtu_request=9000
2
3 > $OVS_DIR/utilities/ovs-vsctl add-port ovs-br0 vhost-user2 -- set
     Interface vhost-user2 type=dpdkvhostuser -- set Interface vhost-
     user2  mtu_request=9000
4
5 chmod g+w  /usr/local/var/run/openvswitch/vhost*
6 <!--NeedCopy-->
```

RHOS command:

```
1 ovs-vsctl add-port ovs-br0 vhost-user1 -- set Interface vhost-user1
     type=dpdkvhostuser -- set Interface vhost-user1  mtu_request=9000
2
3 ovs-vsctl add-port ovs-br0 vhost-user2 -- set Interface vhost-user2
     type=dpdkvhostuser -- set Interface vhost-user2  mtu_request=9000
4
5 chmod g+w /var/run/openvswitch/vhost*
6 <!--NeedCopy-->
```

Provision a KVM-VPX with OVS-DPDK-based vhost-user ports

You can provision a VPX instance on Fedora KVM with OVS-DPDK-based vhost-user ports only from the CLI by using the following QEMU commands:

Fedora command:

```
qemu-system-x86_64 -name KVM-VPX -cpu host -enable-kvm -m 4096M \

-object memory-backend-file,id=mem,size=4096M,mem-path=/dev/hugepages,
   share=on -numa node,memdev=mem \

-mem-prealloc -smp sockets=1,cores=2 -drive file=<absolute-path-to-disc
   -image-file>,if=none,id=drive-ide0-0-0,format=<disc-image-format> \

-device ide-drive,bus=ide.0,unit=0,drive=drive-ide0-0-0,id=ide0-0-0,
   bootindex=1 \

-netdev type=tap,id=hostnet0,script=no,downscript=no,vhost=on \

-device virtio-net-pci,netdev=hostnet0,id=net0,mac=52:54:00:3c:d1:ae,
   bus=pci.0,addr=0x3 \

-chardev socket,id=char0,path=</usr/local/var/run/openvswitch/vhost-
   user1> \

-netdev type=vhost-user,id=mynet1,chardev=char0,vhostforce -device
   virtio-net-pci,mac=00:00:00:00:00:01,netdev=mynet1,mrg_rxbuf=on \

-chardev socket,id=char1,path=</usr/local/var/run/openvswitch/vhost-
   user2> \

-netdev type=vhost-user,id=mynet2,chardev=char1,vhostforce -device
   virtio-net

pci,mac=00:00:00:00:00:02,netdev=mynet2,mrg_rxbuf=on \

--nographic
<!--NeedCopy-->
```

For RHOS, use the following sample XML file to provision the Citrix ADC VPX instance, by using virsh.

```
<domain type='kvm'>

  <name>dpdk-vpx1</name>

```

```
<uuid>aedb844b-f6bc-48e6-a4c6-36577f2d68d6</uuid>

```

To bring up the Citrix ADC VPX instance, start using the virsh command.

Citrix ADC VPX on AWS

October 14, 2021

You can launch a Citrix ADC VPX instance on Amazon Web Services (AWS). The Citrix ADC VPX appliance is available as an Amazon Machine Image (AMI) in AWS marketplace. A Citrix ADC VPX instance on AWS enables you to use AWS cloud computing capabilities and use Citrix ADC load balancing and traffic management features for their business needs. The VPX instance supports all the traffic management features of a physical Citrix ADC appliance, and it can be deployed as standalone instances or in HA pairs. For more information on VPX features, see the VPX data sheet.

Getting started

Before you get started with your VPX deployment, you must be familiar with the following information:

- AWS terminology
- AWS-VPX support matrix
- Limitations and usage guidelines
- Prerequisites
- How a Citrix ADC VPX instance on AWS works

Deploy a Citrix ADC VPX instance on AWS

In AWS, the following deployment types are supported for VPX instances:

- Standalone
- High availability (Acitve-Passive)
  - High availability within same zone
  - High availability across different zones using Elastic IP
  - High availability across different zones using Private IP
- Active-Active GSLB
- Autoscaling (Active-Active) using ADM

Hybrid Deployments

- Deploy Citrix ADC in AWS Outpost
- Deploy Citrix ADC in VMC in AWS

Licensing

A Citrix ADC VPX instance on AWS requires a license. The following licensing options are available for Citrix ADC VPX instances running on AWS:

- Free (unlimited)
- Hourly
- Annual
- BYOL
- Free Trial (all Citrix ADC VPX-AWS subscription offerings for 21 days free in AWS marketplace.)

Automation

- Citrix ADM: Smart Deployment
- AWS Quick Starts: Citrix ADC VPX for Web Applications on AWS
- GitHub CFTs: Citrix ADC templates and scripts for AWS deployment
- GitHub Ansible: Citrix ADC templates and scripts for AWS deployment
- GitHub Terraform: Citrix ADC templates and scripts for AWS deployment
- AWS Pattern Library (PL): Citrix ADC VPX

AWS terminology

September 14, 2021

This section describes the list of commonly used AWS terms and phrases. For more information, see AWS Glossary.

Term	Definition
Amazon Machine Image (AMI)	A machine image, which provides the information required to launch an instance, which is a virtual server in the cloud.
Elastic Block Store	Provides persistent block storage volumes for use with Amazon EC2 instances in the AWS Cloud.
Simple Storage Service (S3)	Storage for the Internet. It is designed to make web-scale computing easier for developers.
Elastic Compute Cloud (EC2)	A web service that provides secure, resizable compute capacity in the cloud. It is designed to make web-scale cloud computing easier for developers.
Elastic Load Balancing (ELB)	Distributes incoming application traffic across multiple EC2 instances, in multiple Availability Zones. This increases the fault tolerance of your applications.
Elastic network interface (ENI)	A virtual network interface that you can attach to an instance in a Virtual Private Cloud (VPC).

Term	Definition
Elastic IP (EIP) address	A static, public IPv4 address that you have allocated in Amazon EC2 or Amazon VPC and then attached to an instance. Elastic IP addresses are associated with your account, not a specific instance. They are elastic because you can easily allocate, attach, detach, and free them as your needs change.
Instance type	Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instance types comprise varying combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your applications.
Identity and Access Management (IAM)	An AWS identity with permission policies that determine what the identity can and cannot do in AWS. You can use an IAM role to enable applications running on an EC2 instance to securely access your AWS resources. IAM role is required for deploying VPX instances in a high-availability setup.
Internet Gateway	Connects a network to the Internet. You can route traffic for IP addresses outside your VPC to the Internet gateway.
Key pair	A set of security credentials that you use to prove your identity electronically. A key pair consists of a private key and a public key.
Route tables	A set of routing rules that controls the traffic leaving any subnet that is associated with the route table. You can associate multiple subnets with a single route table, but a subnet can be associated with only one route table at a time.
Security groups	A named set of allowed inbound network connections for an instance.

Term	Definition
Subnets	A segment of the IP address range of a VPC that EC2 instances can be attached to. You can create subnets to group instances according to security and operational needs.
Virtual Private Cloud (VPC)	A web service for provisioning a logically isolated section of the AWS cloud where you can launch AWS resources in a virtual network that you define.
Auto Scaling	A web service to launch or terminate Amazon EC2 instances automatically based on user-defined policies, schedules, and health checks.
CloudFormation	A service for writing or changing templates that create and delete related AWS resources together as a unit.

VPX-AWS support matrix

October 7, 2021

The following tables list the supported VPX model and AWS regions, instance types, and services.

Table 1: Supported VPX models on AWS

Supported VPX model
Citrix ADC VPX Standard/Advanced/Premium Edition - 200 Mbps
Citrix ADC VPX Standard/Advanced/Premium Edition - 1000 Mbps
Citrix ADC VPX Standard/Advanced/Premium Edition - 3 Gbps
Citrix ADC VPX Standard/Advanced/Premium Edition - 5 Gbps
Citrix ADC VPX Standard/Advanced/Premium - 10 Mbps
Citrix ADC VPX Express - 20 Mbps
Citrix ADC VPX - Customer Licensed
Citrix ADC (formerly NetScaler) VPX FIPS - Customer Licensed

Table: 2 Supported AWS regions

Supported AWS regions
US West (Oregon) Region
US West (N. California) Region
US East (Ohio) Region
US East (N. Virginia) Region
Asia Pacific (Mumbai) Region
Asia Pacific (Seoul) Region
Canada (Central) Region
Asia Pacific (Singapore) Region
Asia Pacific (Sydney) Region
Asia Pacific (Tokyo) Region
Asia Pacific (Hong Kong) Region
Canada (Central) Region
China (Beijing) Region
China (Ningxia) region
EU (Frankfurt) Region
EU (Ireland) Region
EU (London) Region
EU (Paris) Region
EU (Milan) Region
South America (São Paulo) Region
AWS GovCloud (US-East) Region
AWS GovCloud (US-West) Region
AWS Top Secret (C2S) Region
Middle East (Bahrain) Region
Africa (Cape Town)
C2S

Table 3: Supported AWS instance types

Supported AWS instance types
t2.medium, t2.large, t2.x large, t2.2x large
m3.large, m3.x large, m3.2x large
c4.large, c4.large, c4.2x large, c4.4x large, c4.8x large
m4.large, m4.large, m4.2x large, m4.4x large, m4.10x large
m5.large, m5.x large, m5.2x large, m5.4x large, m5.12x large, m5.24x large
c5.large, c5.x large, c5.2x large, c5.4x large, c5.9x large, c5.18x large, c5.24x large
C5n.large, C5n.x large, C5n.2x large, C5n.4x large, C5n.9x large, C5n.18x large
D2.x large, D2.2x large, D2.4x large, D2.8x large
m5a.large, m5a.xlarge, m5a.2xlarge, m5a.8xlarge, m5a.12xlarge, m5a.16xlarge, m5a.24xlarge
t3a.medium, t3a.large, t3a.xlarge, t3a.2xlarge

Table 4: Supported AWS Services

Supported AWS services
EC2: Launches ADC instances.
Lambda: Invokes Citrix ADC VPX NITRO APIs during provisioning of Citrix ADC VPX instances from CFT.
VPC and VPC ingress routing: VPC creates isolated networks in which ADC can be launched. VPC ingress routing is used in the firewall load balancing solution.
Route53: Distributes traffic across all the ADC VPX nodes in the Citrix ADC Autoscale solution.
ELB: Distributes traffic across all the ADC VPX nodes in the Citrix ADC Autoscale solution.
Cloudwatch: Monitors performance and system parameters for Citrix ADC VPX instance.
AWS Autoscaling: Used for back-end server autoscaling.
Cloud formation: CloudFormation templates are used to deploy Citrix ADC VPX instances.
Simple Queue Service (SQS): Monitors scale up and scale down events in back-end autoscaling.
Simple Notification Service (SNS): Monitors scale up and scale down events in back-end autoscaling.
Identity and Access Management (IAM): Provides access to AWS services and resources.
AWS Outposts: Provisions Citrix ADC VPX instances in AWS Outposts.

Citrix recommends the following AWS instance types:

- M5 and C5n series for marketplace editions or bandwidth-based pool licensing.
- C5n series for vCPU-based pool licensing.

VPX offering in AWS marketplace	AWS instance recommendation
VPX 10, VPX Express 20, VPX 200	M5.xLarge
VPX 1000, VPX 3G, VPX 5G	M5.2xLarge

Citrix recommends the following AWS instance types based on throughput.

VPX with Pooled licensing (Bandwidth licenses)	AWS instance recommendation
VPX 8G	C5n.4xLarge
VPX 10G, VPX 15G, VPX 25G	C5n.9xLarge

> Note:
>
> The VPX 25G offering doesn't give the desired 25G throughput in AWS but can give higher SSL transactions rate.

To achieve throughput more than 5G, do the following:

- Choose **Citrix ADC VPX - Customer Licensed (BYOL)** offering in AWS marketplace.
- Select **Pooled Licensing (Bandwidth licenses)** in Citrix ADC GUI or CLI.

To determine your instance based on different metrics such as packets per second, SSL transactions rate, reach out to your Citrix contact for guidance. For vCPU based Pool licensing and sizing guidance, reach out to Citrix support.

Limitations and usage guidelines

September 14, 2021

The following limitations and usage guidelines apply when deploying a Citrix ADC VPX instance on AWS:

- Before you start, read the AWS terminology section in Deploy a Citrix ADC VPX instance on AWS.
- The clustering feature is not supported for VPX.

- For the high availability setup to work effectively, associate a dedicated NAT device to management Interface or associate EIP to NSIP. For more information on NAT, in the AWS documentation, see NAT Instances.
- Data traffic and management traffic must be segregated with ENIs belonging to different subnets.
- Only the NSIP address must be present on the management ENI.
- If a NAT instance is used for security instead of assigning an EIP to the NSIP, appropriate VPC level routing changes are required. For instructions on making VPC level routing changes, in the AWS documentation, see Scenario 2: VPC with Public and Private Subnets.
- A VPX instance can be moved from one EC2 instance type to another (for example, from m3.large to an m3.xlarge).
- For storage options for VPX on AWS, Citrix recommends EBS, because it is durable and the data is available even after it is detached from the instance.
- Dynamic addition of ENIs to VPX is not supported. Restart the VPX instance to apply the update. Citrix recommends you to stop the standalone or HA instance, attach the new ENI, and then restart the instance.
- You can assign multiple IP addresses to an ENI. The maximum number of IP addresses per ENI is determined by the EC2 instance type, see the section "IP Addresses Per Network Interface Per Instance Type" in Elastic Network Interfaces. You must allocate the IP addresses in AWS before you assign them to ENIs. For more information, see Elastic Network Interfaces.
- Citrix recommends that you avoid using the enable and disable interface commands on Citrix ADC VPX interfaces.
- The Citrix ADC `set ha node \<NODE\_ID\> -haStatus STAYPRIMARY` and `set ha node \<NODE\_ID\> -haStatus STAYSECONDARY` commands are disabled by default.
- IPv6 is not supported for VPX.
- Due to AWS limitations, these features are not supported:
  - Gratuitous ARP(GARP)
  - L2 mode
  - Tagged VLAN
  - Dynamic Routing
  - virtual MAC
- For RNAT to work, ensure **Source/Destination Check** is disabled. For more information, see "Changing the Source/Destination Checking" in Elastic Network Interfaces.
- In a Citrix ADC VPX deployment on AWS, in some AWS regions, the AWS infrastructure might not be able to resolve AWS API calls. This happens if the API calls are issued through a nonmanage-

ment interface on the Citrix ADC VPX instance.
As a workaround, restrict the API calls to the management interface only. To do that, create an NSVLAN on the VPX instance and bind the management interface to the NSVLAN by using the appropriate command.
For example:

```
set ns config -nsvlan <vlan id> -ifnum 1/1 -tagged NO
save config
```

Restart the VPX instance at the prompt. For more information about configuring `nsvlan`, see Configuring NSVLAN.

- In the AWS console, the vCPU usage shown for a VPX instance under the **Monitoring** tab might be high (up to 100 percent), even when the actual usage is much lower. To see the actual vCPU usage, navigate to **View all CloudWatch metrics**. For more information, see Monitor your instances using Amazon CloudWatch.

Prerequisites

September 14, 2021

Before attempting to create a VPX instance in AWS, ensure you have the following:

- **An AWS account**: to launch a Citrix ADC VPX AMI in an Amazon Web Services (AWS) Virtual Private Cloud (VPC). You can create an AWS account for free at www.aws.amazon.com.
- **An AWS Identity and Access Management (IAM) user account**: to securely control access to AWS services and resources for your users. For more information about how to create an IAM user account, see the topic Creating IAM Users (Console).

An IAM role is mandatory for both standalone and high availability deployments. The IAM role must have the following privileges:

```
ec2:DescribeInstances
ec2:DescribeNetworkInterfaces
ec2:DetachNetworkInterface
ec2:AttachNetworkInterface
ec2:StartInstances
ec2:StopInstances
ec2:RebootInstances
ec2:DescribeAddresses
ec2:AssociateAddress
ec2:DisassociateAddress
ec2:AssignPrivateIpAddresses
ec2:UnAssignPrivateIpAddresses
autoscaling:*
```

```
14 sns:CreateTopic
15 sns:DeleteTopic
16 sns:ListTopics
17 sns:Subscribe
18 sqs:CreateQueue
19 sqs:ListQueues
20 sqs:DeleteMessage
21 sqs:GetQueueAttributes
22 sqs:SetQueueAttributes
23 iam:SimulatePrincipalPolicy
24 iam:GetRole
25 <!--NeedCopy-->
```

If you use the Citrix CloudFormation template, the IAM role is automatically created. The template does not allow selecting an already created IAM role.

> Note
>
> When you log on to the VPX instance through the GUI, a prompt to configure the required privileges for the IAM role appears. Ignore the prompt if you've already configured the privileges.

- **AWS CLI**: To use all the functionality provided by the AWS Management Console from your terminal program. For more information, see the AWS CLI user guide. You also need the AWS CLI to change the network interface type to SR-IOV.
- **Elastic Network Adapter (ENA)**: For ENA driver-enabled instance type, the firmware version must be 13.0 and above.

How a Citrix ADC VPX instance on AWS works

September 14, 2021

The Citrix ADC VPX instance is available as an AMI in AWS marketplace, and it can be launched as an EC2 instance within an AWS VPC. The Citrix ADC VPX AMI instance requires a minimum of 2 virtual CPUs and 2 GB of memory. An EC2 instance launched within an AWS VPC can also provide the multiple interfaces, multiple IP addresses per interface, and public and private IP addresses needed for VPX configuration. Each VPX instance requires at least three IP subnets:

- A management subnet
- A client-facing subnet (VIP)
- A back-end facing subnet (SNIP, MIP, and so on)

Citrix recommends three network interfaces for a standard VPX instance on AWS installation.

AWS currently makes multi-IP functionality available only to instances running within an AWS VPC. A VPX instance in a VPC can be used to load balance servers running in EC2 instances. An Amazon VPC allows you to create and control a virtual networking environment, including your own IP address range, subnets, route tables, and network gateways.

Note: By default, you can create up to 5 VPC instances per AWS region for each AWS account. You can request higher VPC limits by submitting Amazon's request form http://aws.amazon.com/contact-us/vpc-request.

Figure 1. A Sample Citrix ADC VPX Instance Deployment on AWS Architecture

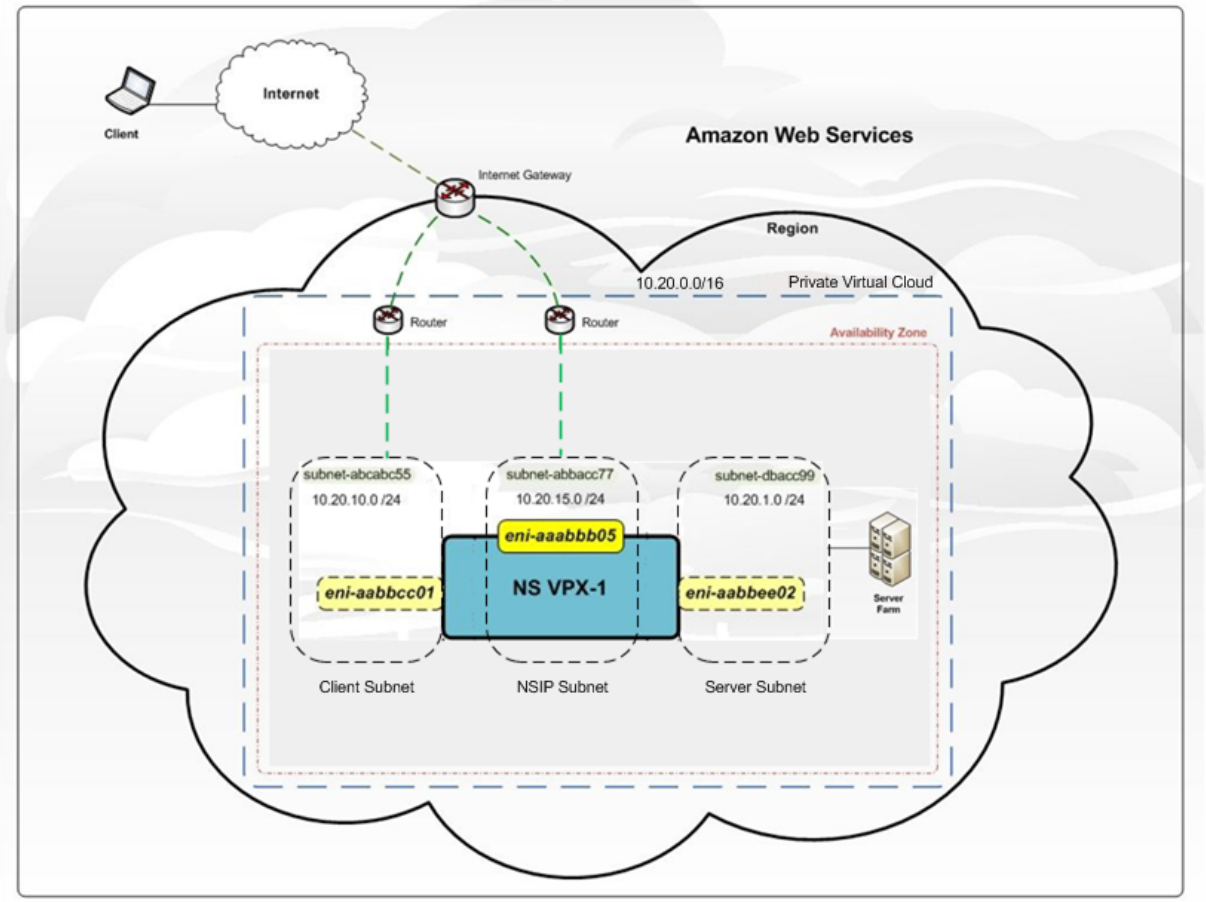

Figure 1 shows a simple topology of an AWS VPC with a Citrix ADC VPX deployment. The AWS VPC has:

1. A single Internet gateway to route traffic in and out of the VPC.
2. Network connectivity between the Internet gateway and the Internet.
3. Three subnets, one each for management, client, and server.
4. Network connectivity between the Internet gateway and the two subnets (management and client).
5. A standalone Citrix ADC VPX instance deployed within the VPC. The VPX instance has three ENIs,

one attached to each subnet.

Deploy a Citrix ADC VPX standalone instance on AWS

September 14, 2021

You can deploy a Citrix ADC VPX standalone instance on AWS by using the following options:

- AWS web console
- Citrix-authored CloudFormation template
- AWS CLI

This topic describes the procedure for deploying a Citrix ADC VPX instance on AWS.

Before you start your deployment, read the following topics:

- Prerequisites
- Limitation and usage guidelines

Deploy a Citrix ADC VPX instance on AWS by using the AWS web console

You can deploy a Citrix ADC VPX instance on AWS through the AWS web console. The deployment process includes the following steps:

1. Create a Key Pair
2. Create a Virtual Private Cloud (VPC)
3. Add more subnets
4. Create security groups and security rules
5. Add route tables
6. Create an internet gateway
7. Create a Citrix ADC VPX instance
8. Create and attach more network interfaces
9. Attach elastic IPs to the management NIC
10. Connect to the VPX instance

Step 1: Create a key pair.

Amazon EC2 uses a key pair to encrypt and decrypt logon information. To log on to your instance, you must create a key pair, specify the name of the key pair when you launch the instance, and provide the private key when you connect to the instance.

When you review and launch an instance by using the AWS Launch Instance wizard, you are prompted to use an existing key pair or create a new key pair. More more information about how to create a key pair, see Amazon EC2 Key Pairs.

Step 2: Create a VPC.

A Citrix ADC VPC instance is deployed inside an AWS VPC. A VPC allows you to define the virtual network dedicated to your AWS account. For more information about AWS VPC, see Getting Started With Amazon VPC.

While creating a VPC for your Citrix ADC VPX instance, keep the following points in mind.

- Use the VPC with a Single Public Subnet Only option to create an AWS VPC in an AWS availability zone.
- Citrix recommends that you create at least **three subnets**, of the following types:
  - One subnet for management traffic. You place the management IP(NSIP) on this subnet. By default elastic network interface (ENI) eth0 is used for management IP.
  - One or more subnets for client-access (user-to-Citrix ADC VPX) traffic, through which clients connect to one or more virtual IP (VIP) addresses assigned to Citrix ADC load balancing virtual servers.
  - One or more subnets for the server-access (VPX-to-server) traffic, through which your servers connect to VPX-owned subnet IP (SNIP) addresses. For more information about Citrix ADC load balancing and virtual servers, virtual IP addresses (VIPs), and subnet IP addresses (SNIPs), see:
  - All subnets must be in the same availability zone.

Step 3: Add subnets.

When you used the VPC wizard, only one subnet was created. Depending on your requirement, you might want to create more subnets. For more information about how to create more subnets, see Adding a Subnet to Your VPC.

Step 4: Create security groups and security rules.

To control inbound and outbound traffic, create security groups and add rules to the groups. For more information how to create groups and add rules, see Security Groups for Your VPC.

For Citrix ADC VPX instances, the EC2 wizard gives default security groups, which are generated by AWS Marketplace and is based on recommended settings by Citrix. However, you can create more security groups based on your requirements.

> **Note**
>
> Port 22, 80, 443 to be opened on the Security group for SSH, HTTP, and HTTPS access respectively.

Step 5: Add route tables.

Route table contains a set of rules, called routes, that are used to determine where network traffic is directed. Each subnet in your VPC must be associated with a route table. For more information about how to create a route table, see Route Tables.

Step 6: Create an internet gateway.

An internet gateway serves two purposes: to provide a target in your VPC route tables for internet-routable traffic, and to perform network address translation (NAT) for instances that have been assigned public IPv4 addresses.

Create an internet gateway for internet traffic. For more information about how to create an Internet Gateway, see the section Attaching an Internet Gateway.

Step 7: Create a Citrix ADC VPX instance by using the AWS EC2 service.

To create a Citrix ADC VPX instance by using the AWS EC2 service, complete the following steps.

1. From the AWS dashboard, go to **Compute > EC2 > Launch Instance > AWS Marketplace**.

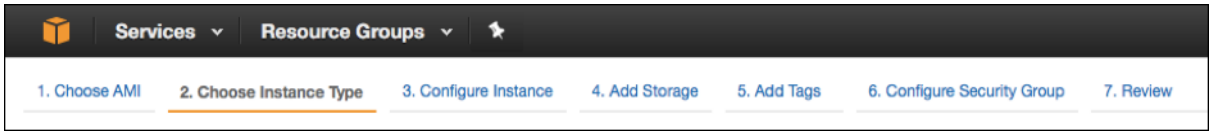
   Before you click **Launch Instance**, ensure your region is correct by checking the note that appears under **Launch Instance**.

2. In the Search AWS Marketplace bar, search with the keyword Citrix ADC VPX.
3. Select the version you want to deploy and then click **Select**. For the Citrix ADC VPX version, you have the following options:

   - A licensed version
   - Citrix ADC VPX Express appliance (This is a free virtual appliance, which is available from Citrix ADC 12.0 56.20.)
   - Bring your own device

The Launch Instance wizard starts. Follow the wizard to create an instance. The wizard prompts you to:

- Choose Instance Type
- Configure Instance
- Add Storage
- Add Tags
- Configure Security Group
- Review



Step 8: Create and attach more network interfaces.

Create two more network interfaces for VIP and SNIP. For more information about how to create more network interfaces, see the Creating a Network Interface section.

After you've created the network interfaces, you must attach them to the VPX instance. Before attaching the interface, shut down the VPX instance, attach the interface, and power on the instance. For more information about how to attach network interfaces, see the Attaching a Network Interface When Launching an Instance section.

Step 9: Allocate and associate elastic IPs.

If you assign a public IP address to an EC2 instance, it remains assigned only until the instance is stopped. After that, the address is released back to the pool. When you restart the instance, a new public IP address is assigned.

In contrast, an elastic IP (EIP) address remains assigned until the address is disassociated from an instance.

Allocate and associate an elastic IP for the management NIC. For more information about how to allocate and associate elastic IP addresses, see these topics:

- Allocating an Elastic IP Address
- Associating an Elastic IP Address with a Running Instance

These steps complete the procedure to create a Citrix ADC VPX instance on AWS. It can take a few minutes for the instance to be ready. Check that your instance has passed its status checks. You can view this information in the **Status Checks** column on the Instances page.

Step 10: Connect to the VPX instance.

After you've created the VPX instance, you connect the instance by using the GUI and an SSH client.

- GUI

The following are the default administrator credentials to access a Citrix ADC VPX instance

User name: `nsroot`

Password: The default password for the ns root account is set to the AWS instance-ID of the Citrix ADC VPX instance. On your first logon, you are prompted to change the password for security reasons. After changing the password, you must save the configuration. If the configuration is not saved and the instance restarts, you must log on with the default password. Change the password again at the prompt.

- SSH client

From the AWS management console, select the Citrix ADC VPX instance and click **Connect**. Follow the instructions given on the **Connect to Your Instance** page.

For more information about how to deploy a Citrix ADC VPX standalone instance on AWS by using the AWS web console, see:

- Scenario: standalone instance
- How to configure a Citrix NetScaler VPX instance on AWS by using Citrix CloudFormation template

Configure a Citrix ADC VPX instance by using the Citrix CloudFormation template

You can use the Citrix-provided CloudFormation template to automate VPX instance launch. The template provides functionality to launch a single Citrix ADC VPX instance, or to create a high availability environment with a pair of Citrix ADC VPX instances.

You can launch the template from AWS Marketplace or GitHub.

The CloudFormation template requires an existing VPC environment, and it launches a VPX instance with three elastic network interfaces (ENIs). Before you start the CloudFormation template, ensure that you complete the following requirements:

- An AWS virtual private cloud (VPC)
- Three subnets within the VPC: one for management, one for client traffic, and one for back-end servers
- An EC2 key pair to enable SSH access to the instance
- A security group with UDP 3003, TCP 3009–3010, HTTP, SSH ports open

See the "Deploy a Citrix ADC VPX Instance on AWS by Using the AWS Web Console" section or AWS documentation for more information about how to complete the prerequisites.

Watch this video to learn about how to configure and launch a Citrix ADC VPX standalone instance by using the Citrix CloudFormation template available in the AWS Marketplace.

Further, you configure and launch a Citrix ADC VPX Express standalone instance by using the Citrix CloudFormation template available in GitHub:

https://github.com/citrix/citrix-adc-aws-cloudformation/tree/master/templates/standalone/

An IAM role is not mandatory for a standalone deployment. However, Citrix recommends that you create and attach an IAM role with the required privileges to the instance, for future need. The IAM role ensures that the standalone instance is easily converted to a high availability node with SR-IOV, when required.

For more information about the required privileges, see Configuring Citrix ADC VPX instances to Use SR-IOV Network Interface.

> Note
> If you deploy a Citrix ADC VPX instance on AWS by using the AWS web console, the CloudWatch

> service is enabled by default. If you deploy a Citrix ADC VPX instance by using the Citrix CloudFormation template, the default option is "Yes." If you want to disable the CloudWatch service, select "No." For more information, see Monitor your instances using Amazon CloudWatch

Configure a Citrix ADC VPX instance by using the AWS CLI

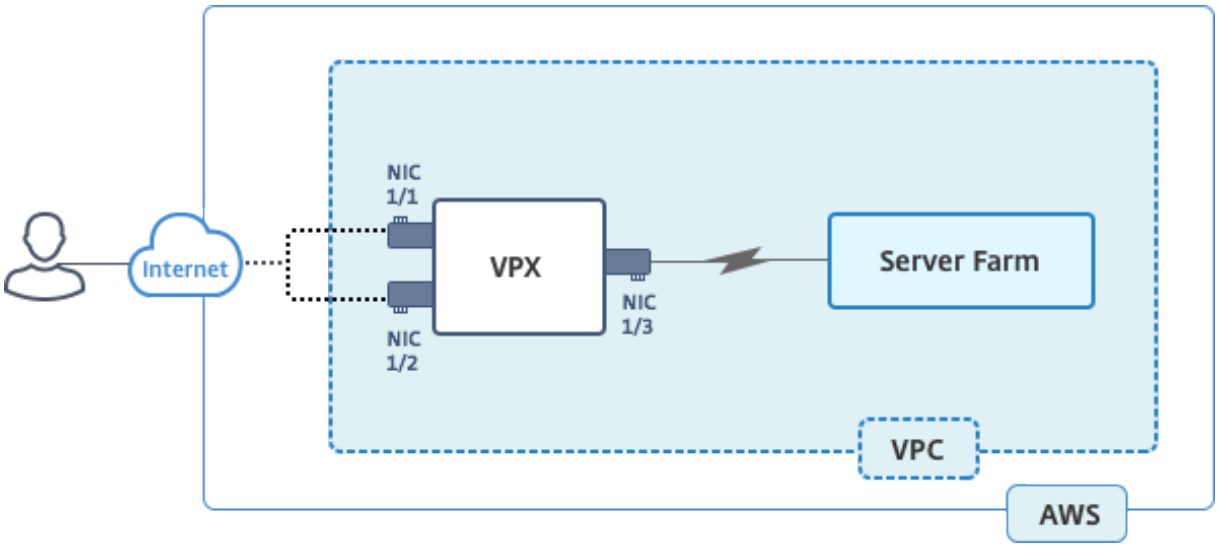
You can use the AWS CLI to launch instances. For more information, see the AWS Command Line Interface Documentation.

Scenario: standalone instance

September 14, 2021

This scenario illustrates how to deploy a Citrix ADC VPX standalone EC2 instance in AWS by using the AWS GUI. Create a standalone VPX instance with three NICs. The instance, which is configured as a load balancing virtual server, communicates with back-end servers (the server farm). For this configuration, set up the required communication routes between the instance and the back-end servers, and between the instance and the external hosts on the public internet.

For more details about the procedure for deploying a VPX instance, see Deploy a Citrix ADC VPX standalone instance on AWS.

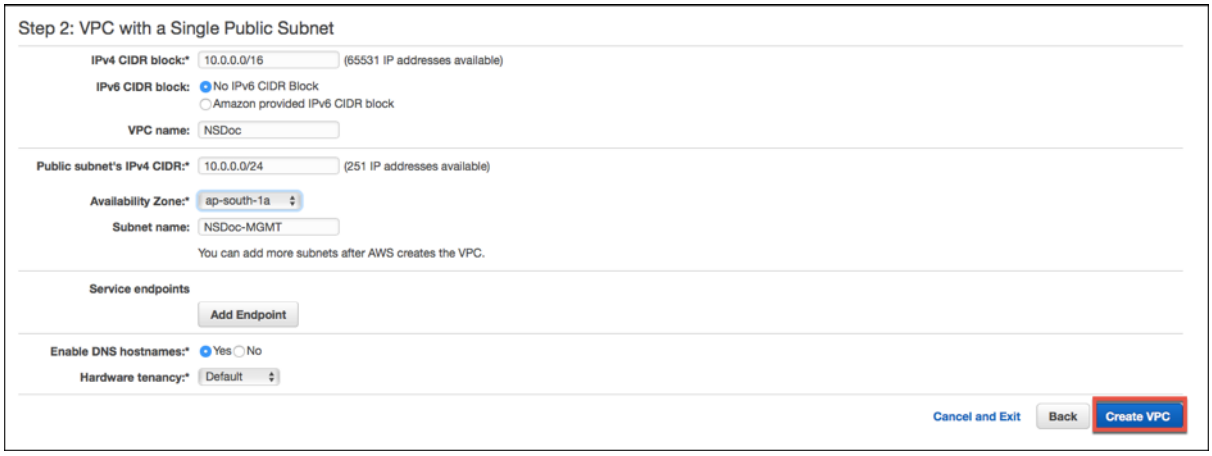


Create three NICs. Each NIC can be configured with a pair of IP addresses (public and private). The NICs serve the following purposes.

NIC	Purpose	Associated with
eth0	Serves management traffic (NSIP)	A public IP address and a private IP address
eth1	Serves client-side traffic (VIP)	A public IP address and a private IP address
eth2	Communicates with back-end servers (SNIP)	A public IP address (Private IP address not mandatory)

Step 1: Create a VPC.

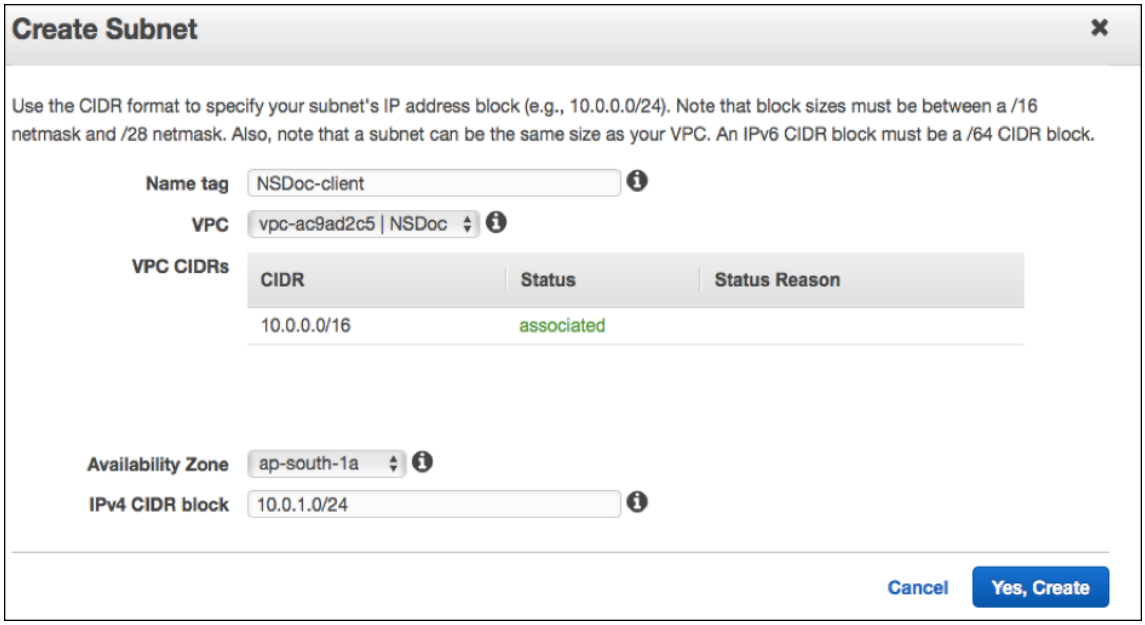
1. Log on to the AWS web console and navigate to **Networking & Content Delivery** > **VPC**. Click **Start VPC Wizard**.
2. Select **VPC with a Single Public Subnet** and click **Select**.
3. Set the IP CIDR Block to 10.0.0.0/16, for this scenario.
4. Give a name for the VPC.
5. Set the public subnet to 10.0.0.0/24. (This is the management network).
6. Select an availability zone.
7. Give a name for the subnet.
8. Click Create **VPC**.



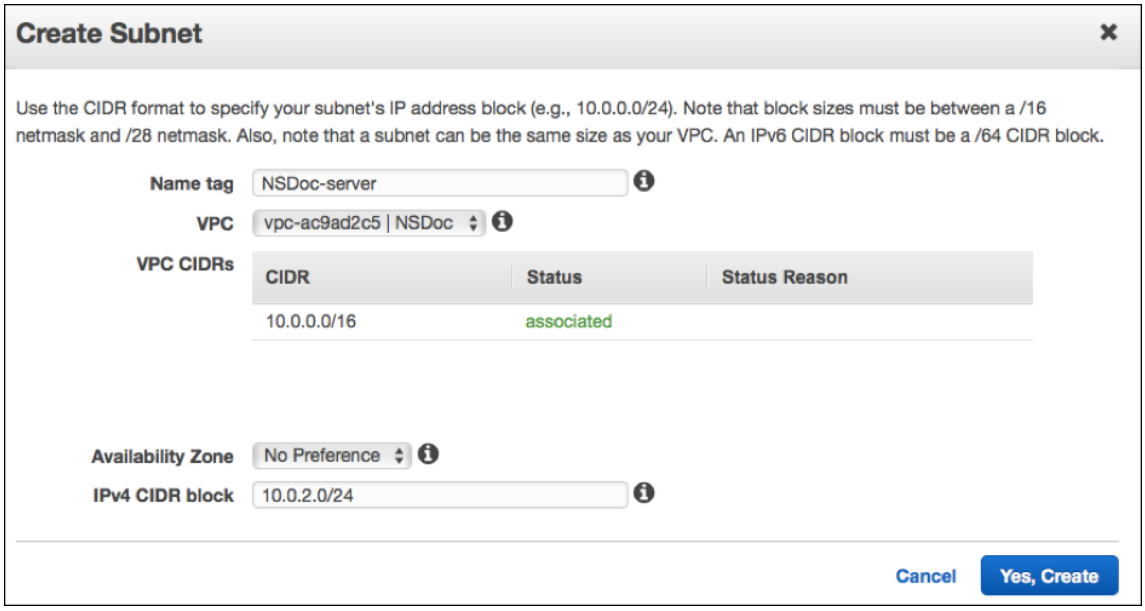
Step 2: Create extra subnets.

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets, Create Subnet after you enter the following details.
   - Name tag: Provide a name for your subnet.

- VPC: Choose the VPC for which you're creating the subnet.
- Availability Zone: Choose the availability zone in which you created the VPC in step 1.
- IPv4 CIDR block: Specify an IPv4 CIDR block for your subnet. For this scenario, choose 10.0.1.0/24.



3. Repeat the steps to create one more subnet for back-end servers.



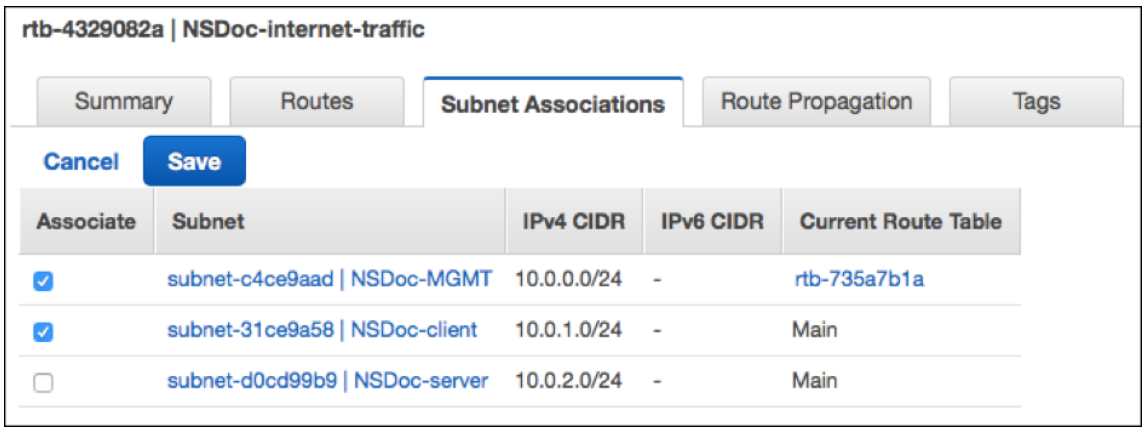
Step 3: Create a route table.

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Route Tables** > **Create Route Table.**
3. In the Create Route Table window, add a name and select the VPC that you created in step 1.

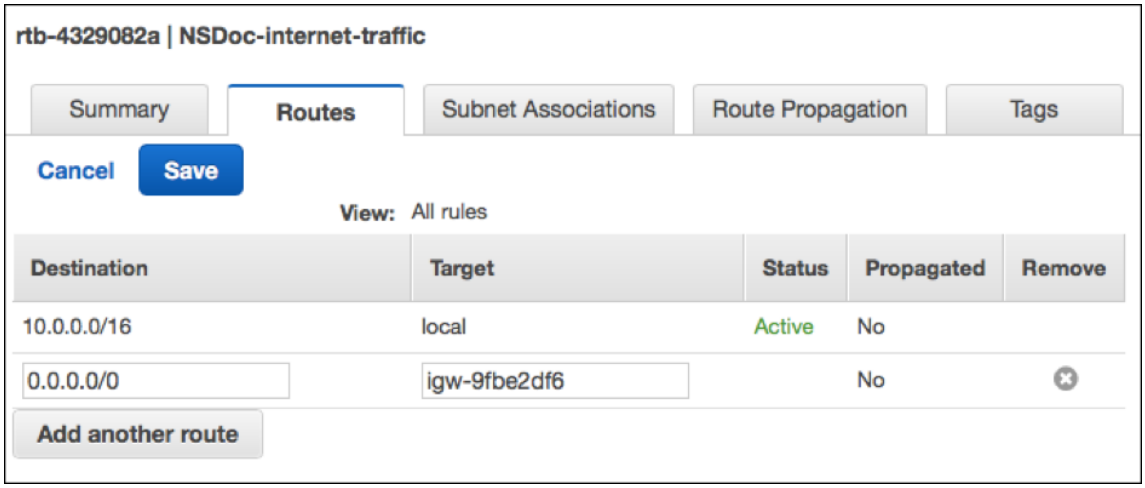
4. Click **Yes, Create**.

   The route table is assigned to all the subnets that you created for this VPC, so that routing of traffic from an instance in one subnet can reach an instance in another subnet.

5. Click Subnet Associations, and then click Edit.
6. Click the management and client subnet and click Save. This creates a route table for internet traffic only.



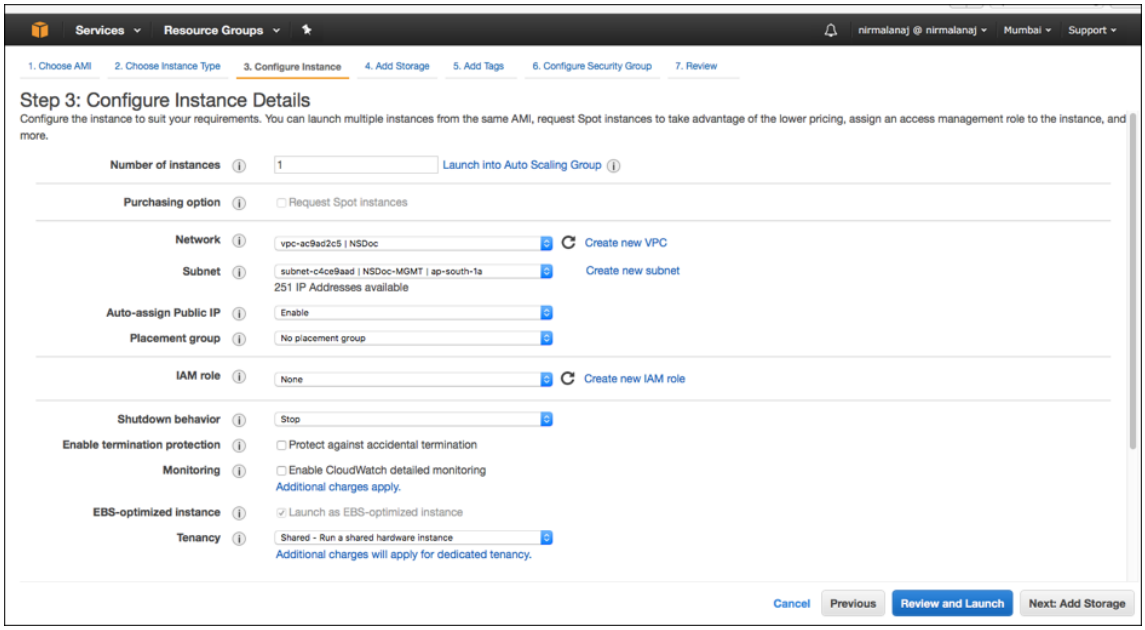
7. Click **Routes > Edit > Add another route**.
8. In the Destination field add 0.0.0.0/0, and click the Target field to select igw-<xxxx> the Internet Gateway that the VPC Wizard created automatically.
9. Click Save.



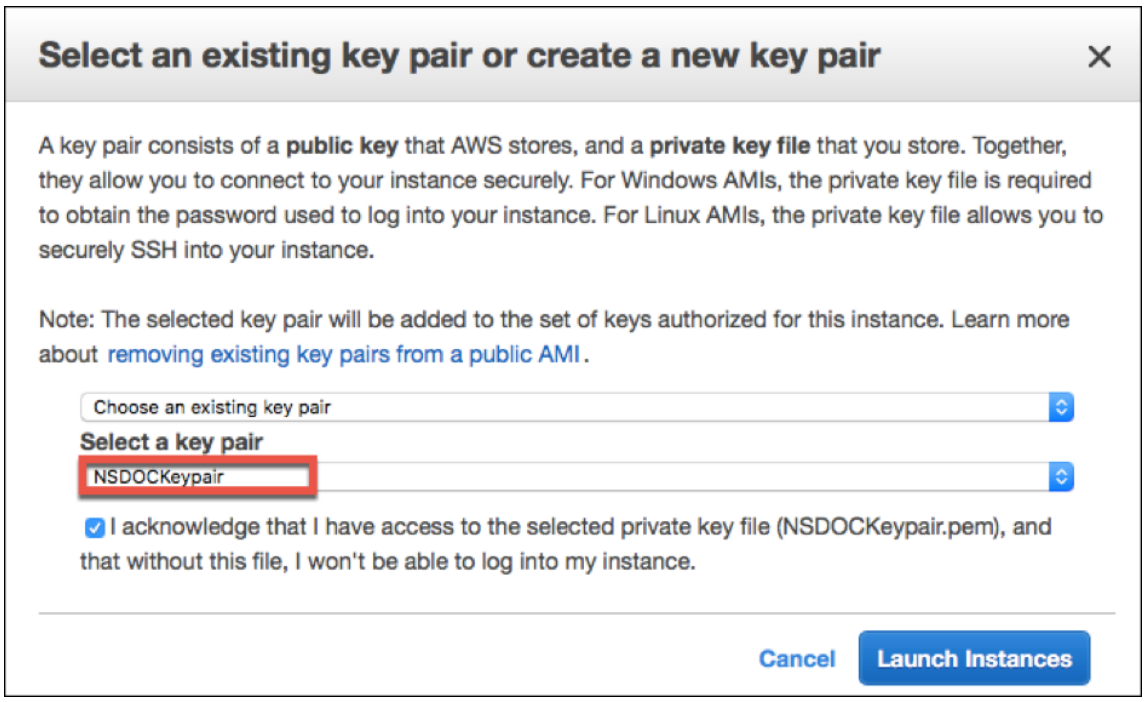
10. Follow the steps to create a route table for server-side traffic.

Step 4: Create a Citrix ADC VPX instance.

1. Log on the AWS management console and click **EC2** under **Compute**.
2. Click AWS Marketplace. In the Search AWS Marketplace bar, type Citrix ADC VPX and press Enter. The available Citrix ADC VPX editions are displayed.
3. Click **Select** to choose the desired Citrix ADC VPX edition. The EC2 instance wizard starts.
4. In the **Choose Instance Type** page, select **m4. Xlarge** (recommended) and click **Next: Configure Instance Details**.
5. In the Configure Instance Details page, select the following, and then click Next: Add Storage.
   - Number of instances: 1
   - Network: the VPC that created in Step 1
   - Subnet: the management subnet
   - Auto-assign Public IP: Enable



6. In the Add Storage page, select the default option, and click Next: Add Tags.
7. In the Add Tags page, add a name for the instance, and click Next: Configure Security Group.
8. In the Configure Security Group page, select the default option (which is generated by AWS Marketplace and is based on recommended settings by Citrix Systems) and then click **Review and Launch > Launch**.
9. You are prompted to select an existing key pair or create and new key pair. From the Select a key pair drop-down list, select the key pair that you created as a prerequisite (See the Prerequisite section.)
10. Check the box to acknowledge the key pair and click Launch Instances.



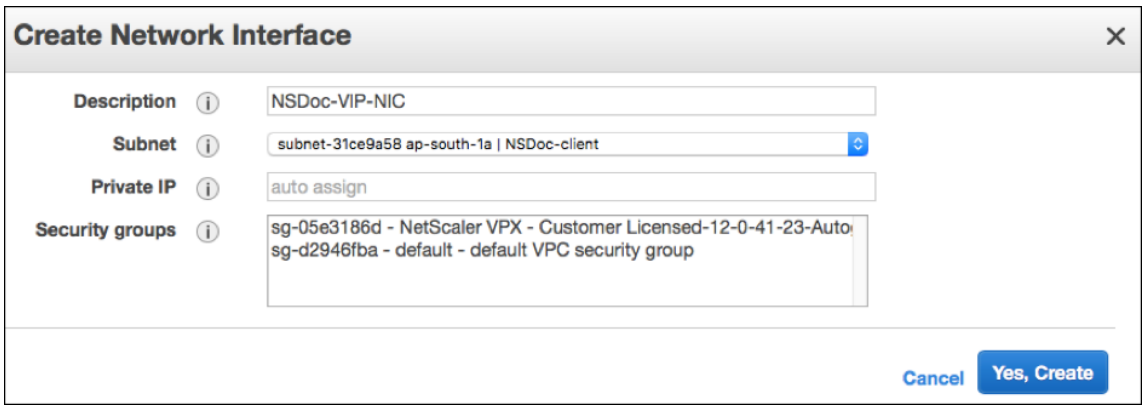
Launch Instance Wizard displays the Launch Status, and the instance appears in the list of instances when it is fully launched.

The check instance, go the AWS console click EC2 > Running Instances. Select the instance and add a name. Make sure the Instance State is running and Status Checks is complete.

Step 5: Create and attach more network interfaces.

When you created the VPC, only one network interface associated with it. Now add two more network interfaces to the VPC, for the VIP and SNIP.

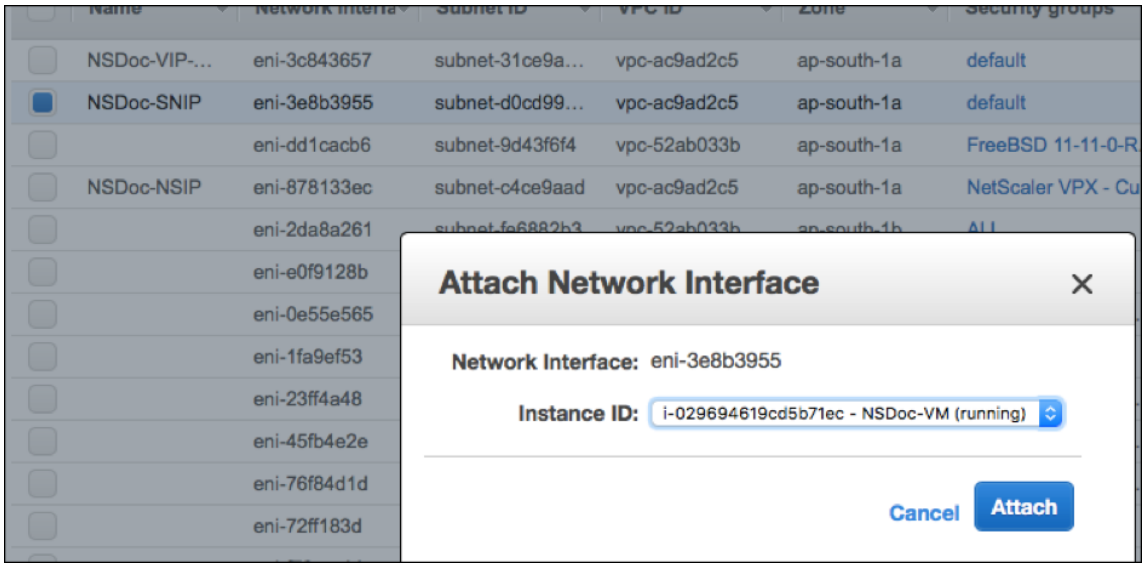
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose Create Network Interface.
4. For Description, enter a descriptive name.
5. For Subnet, select the subnet that you created previously for the VIP.
6. For Private IP, leave the default option.
7. For Security groups, select the group.
8. Click **Yes, Create**.



9. After the network interface is created, add a name to the interface.
10. Repeat the steps to create a network interface for server-side traffic.

Attach the network interfaces:

1. In the navigation pane, choose Network Interfaces.
2. Select the network interface and choose Attach.
3. In the Attach Network Interface dialog box, select the instance and choose Attach.



Step 6: Attach an elastic IP to the NSIP.

1. From the AWS management console, go to **NETWORK & SECURITY > Elastic IPs**.
2. Check for available free EIP to attach. If none, click **Allocate new address**.
3. Select the newly allocated IP address and choose **Actions > Associate address**.
4. Click the **Network interface** radio button.
5. From the Network interface drop-down list, select the management NIC.

6. From the **Private IP** drop-down menu, select the AWS-generated IP address.
7. Select the **Reassociation** check box.
8. Click **Associate**.

Access the VPX instance:

After you've configured a standalone Citrix ADC VPX instance with three NICs, log on to the VPX instance to complete the Citrix ADC-side configuration. Use of the following options:

- GUI: Type the public IP of the management NIC in the browser. Log on by using `nsroot` as the user name and the instance ID (i-0c1ffe1d987817522) as the password.

> Note
>
> On your first logon, you are prompted to change the password for security reasons. After changing the password, you must save the configuration. If the configuration is not saved and the instance restarts, you must log on with the default password. Change the password again at the prompt and save the configuration.

- SSH: Open an SSH client and type:

```
ssh -i \<location of your private key\> ns root@\<public DNS of the instance \>
```

To find the public DNS, click the instance, and click **Connect**.

Related information:

- To configure the Citrix ADC-owned IP addresses (NSIP, VIP, and SNIP), see Configuring Citrix ADC-Owned IP Addresses.
- You've configured a BYOL version of the Citrix ADC VPX appliance, for more information see the VPX Licensing Guide at http://support.citrix.com/article/CTX122426

Download a Citrix ADC VPX license

September 14, 2021

After the launch of Citrix ADC VPX-customer licensed instance from the AWS marketplace, a license is required. For more information on VPX licensing, see Licensing overview.

You have to:

1. Use the licensing portal within the Citrix website to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance activate automatically.

If you use a Citrix ADC VPX instance with a model number higher than VPX 5000, the network throughput might not be the same as specified by the instance's license. However, other features, such as SSL throughput and SSL transactions per second, might improve.

5 Gbps network bandwidth is observed in the `c4.8xlarge` instance type.

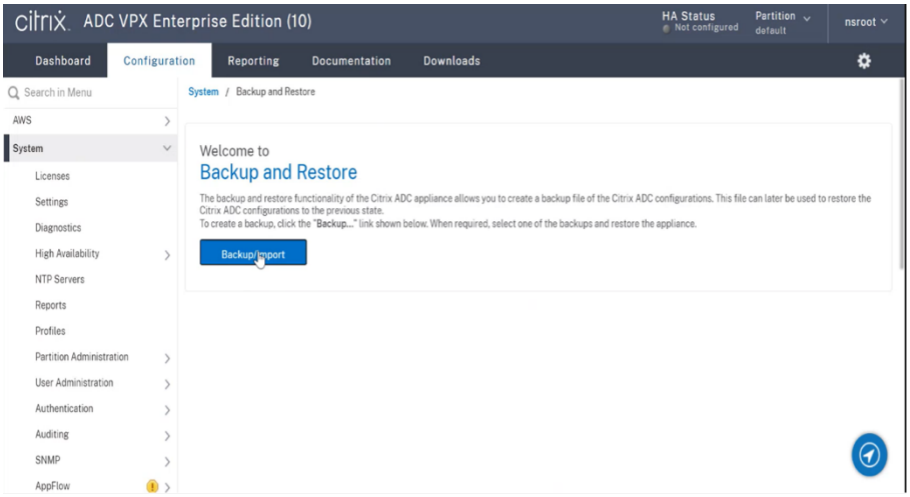
How to migrate the AWS subscription to BYOL

This section describes the procedure to migrate from AWS subscription to Bring your own license (BYOL), and conversely.

Do the following steps to migrate an AWS subscription to BYOL:

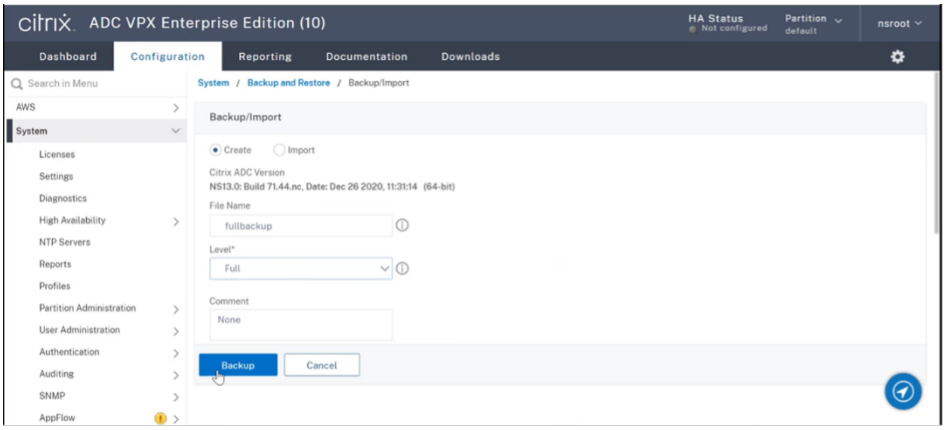
> Note
>
> The **Step 2** and **Step 3** are done on the Citrix ADC VPX instance, and all other steps are done on the AWS portal.

1. Create a BYOL EC2 instance using Citrix ADC VPX - Customer Licensed in the same availability zone as the old EC2 instance that has the same security group, IAM role, and subnet. The new EC2 instance must have only one ENI interface.
2. To back up the data on the old EC2 instance using the Citrix ADC GUI, follow these steps.
    a) Navigate to **System > Backup and Restore**.
    b) In the **Welcome** page, click **Backup/Import** to start the process.

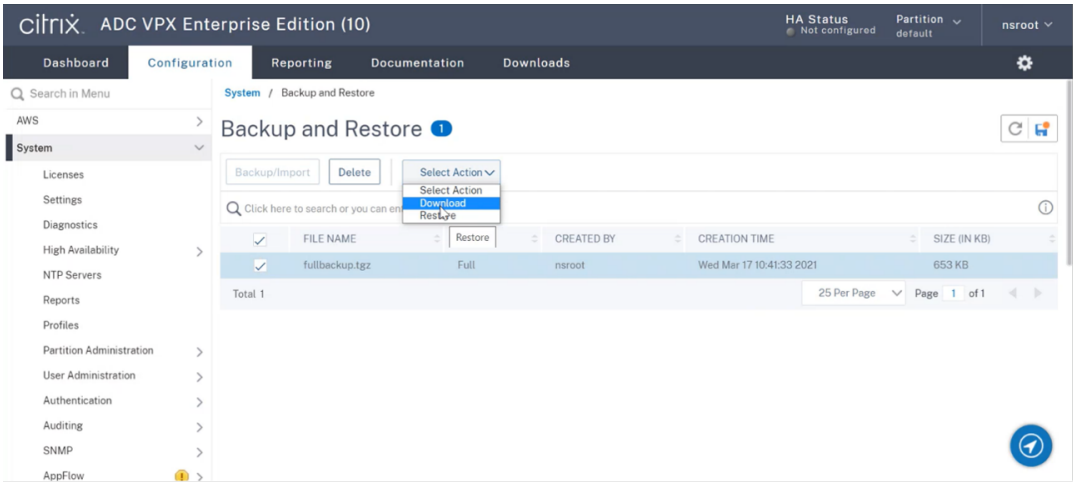


c) In the **Backup/Import** page, fill in the following details:

- **Name** – Name of the backup file.
- **Level** – Select the backup level as **Full**.
- **Comment** – Provide a brief description of the backup.



d) Click **Backup**. Once the backup is complete, you can select the file and download it to your local machine.



3. To restore the data on the new EC2 instance using the Citrix ADC GUI, follow these steps:

   a) Navigate to **System > Backup and Restore**.

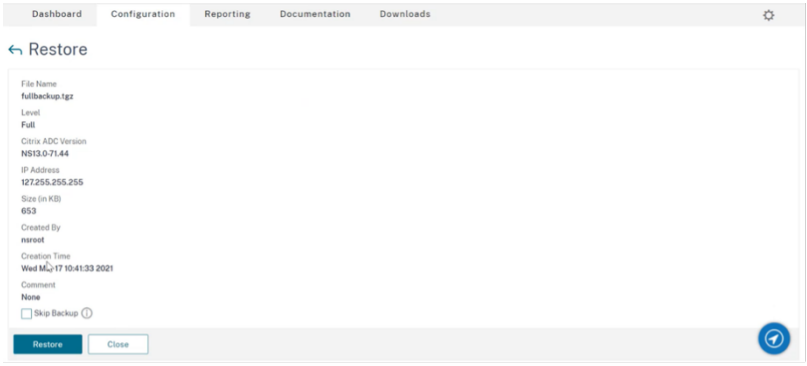
   b) Click **Backup/Import** to start the process.

   c) Select the **Import** option and upload the backup file.

   d) Select the file.

   e) From the **Select Action** drop-down menu, select **Restore**.

   f) On the **Restore** page, verify the file details, and click **Restore**.



g) After the restore, reboot the EC2 instance.

4. Move all interfaces (except the management interface to which the NSIP address is bound) from the old EC2 instance to the new EC2 instance. To move a network interface from one EC2 instance to another, follow these steps:

   a) In the **AWS Portal**, stop both the old and new EC2 instances.

   b) Navigate to **Network Interfaces**, and select the network interface attached to the old EC2 instance.

   c) Detach the EC2 instance by clicking **Actions > Detach**.

   d) Attach the network interface to the new EC2 instance by clicking **Actions > Attach**. Enter the EC2 instance name to which the network interface must be attached.

   e) Do the **Step 1** to **Step 4** for all other interfaces that are attached. Make sure to follow the sequence and maintain the interface order. That is, first detach interface 2 and attach it,

and then detach interface 3 and attach it, and so on.

5. You can't detach the management interface from an old EC2 instance. So, move all the secondary IP addresses (if any) on the management interface (primary network interface) of the old EC2 instance to the new EC2 instance. To move an IP address from one interface to another, follow these steps:

   a) In the **AWS Portal**, make sure that both the old and new EC2 instances are in **Stop** state.

   b) Navigate to **Network Interfaces**, and select the management network interface attached to the old EC2 instance.

   c) Click **Actions > Manage IP Address**, and make note of all the secondary IP addresses assigned (if any).

   d) Navigate to the management network interface or primary interface of the new EC2 instance.

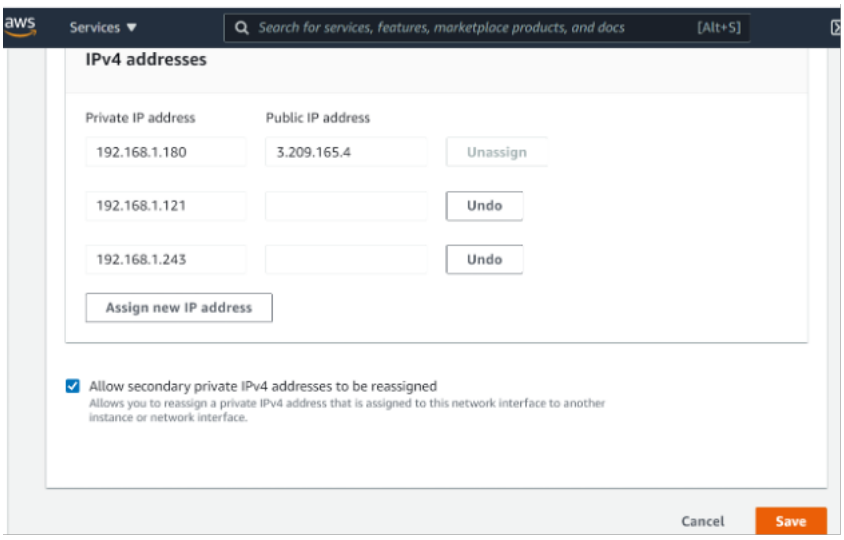
   e) Click **Actions > Manage IP Addresses**.

   f) Under **IPv4 Addresses**, click **Assign new IP address**.

   g) Enter the IP addresses, which are noted in the **Step 3**.

   h) Select **Allow secondary private IP addresses to be reassigned** check box.

   i) Click **Save**.



6. Start the new EC2 instance and verify the configuration. After all the configuration is moved, you can delete or keep the old EC2 instance as per your requirement.
7. If any EIP address is attached to the NSIP address of the old EC2 instance, move the old instance NSIP address to the new instance NSIP address.
8. If you want to revert to the old instance, then follow the same steps in the opposite way between the old and new instance.

9. After you move from subscription instance to BYOL instance, a license is required. To install a license follow these steps:
    - Use the licensing portal in the Citrix website to generate a valid license.
    - Upload the license to the instance. For more information, see VPX ADC - Install a new license.

> Note
>
> When you move BYOL instance to subscription instance (paid marketplace instance), you need not install the license. The correct feature set and performance is automatically activated.

Limitations

The management interface can't be moved to the new EC2 instance. So Citrix recommends you manually configure the management interface. For more information, see **Step 5** in the preceding procedure. A new EC2 instance is created with the exact replica of the old EC2 instance but only the NSIP address has a new IP address.

Load balancing servers in different availability zones

September 14, 2021

A VPX instance can be used to load balance servers running in the same availability zone, or in:

- A different availability zone (AZ) in the same AWS VPC
- A different AWS region
- AWS EC2 in a VPC

To enable a VPX instance to load balance servers running outside the AWS VPC that the VPX instance is in, configure the instance to use EIPs to route traffic through the Internet gateway, as follows:

1. Configure a SNIP on the Citrix ADC VPX instance by using the Citrix ADC CLI or the GUI.
2. Enable traffic to be routed out of the AZ, by creating a public facing subnet for the server-side traffic.
3. Add an Internet gateway route to the routing table, using the AWS GUI console.
4. Associate the routing table you updated with the server-side subnet.
5. Associate an EIP with the server-side private IP address that is mapped to a Citrix ADC SNIP address.

How high availability on AWS works

September 14, 2021

You can configure two Citrix ADC VPX instances on AWS as a high availability (HA) active-passive pair. When you configure one instance as the primary node and the other as the secondary node, the primary node accepts connections and manages servers. The secondary node monitors the primary. If for any reason, the primary node is unable to accept connections, the secondary node takes over.

In AWS, the following deployment types are supported for VPX instances:

- High availability within same zone
- High availability across different zones

> **Note**
>
> For high availability to work, ensure both the Citrix ADC VPX instances are attached with IAM roles and assigned with the Elastic IP (EIP) address to the NSIP. You need not assign an EIP on NSIP if the NSIP can reach internet through the NAT instance.

High availability within the same zones

In a high-availability deployment within the same zones, both VPX instances must have similar networking configurations.

Follow these two rules:

Rule 1. Any NIC on one VPX instance must be in the same subnet as the corresponding NIC in the other VPX. Both instances must have:

- Management interface on the same subnet (referred as management subnet)
- Client interface on the same subnet (referred as client subnet)
- Server interface on the same subnet (referred as server subnet)

Rule 2. Sequence of mgmt NIC, client NIC, and server NIC on both instances must be the same.
For example, the following scenario is not supported.

VPX instance 1

NIC 0: management
NIC 1: client
NIC 2: Server

VPX instance 2

NIC 0: management

NIC 1: server

NIC 2: client

In this scenario, NIC 1 of instance 1 is in client subnet while NIC 1 of instance 2 is in server subnet. For HA to work, NIC 1 of both the instances must be either in the client subnet or in the server subnet.

From 13.0 41.xx, high availability can be achieved by migrating secondary private IP addresses attached to the NICs (client and server-side NICs) of the primary HA node to the secondary HA node after failover. In this deployment:

- Both the VPX instances have the same number of NICs and subnet mapping according to NIC enumeration.
- Each VPX NIC has one extra private IP address, except the first NIC - which corresponds to the management IP address. The extra private IP address appears as the primary private IP address in the AWS web console. In our document, we refer to this extra IP address as the dummy IP address).
- The dummy IP addresses must be not configured on the Citrix ADC instance as VIP and SNIP.
- Other secondary private IP addresses must be created, as required, and configured as VIP and SNIP.
- On failover, the new primary node looks for configured SNIPs and VIPs and moves them from NICs attached to the previous primary to corresponding NICs on the new primary.
- Citrix ADC instances require IAM permissions for HA to work. Add the following IAM privileges to the IAM policy added to each instance.

```
"iam:GetRole"
"ec2:DescribeInstances"
"ec2:DescribeNetworkInterfaces"
"ec2:AssignPrivateIpAddresses"
```

> Note: `unassignPrivateIpAddress` is not required.

This method is faster than the legacy method. In the older method, HA depends on the migration of AWS elastic network interfaces of the primary node to the secondary node.

For a legacy method, the following policies are required:

```
"iam:GetRole"
"ec2:DescribeInstances"
"ec2:DescribeAddresses"
"ec2:AssociateAddress"
"ec2:DisassociateAddress"
```

For more information, see Deploy a high availability pair on AWS.

High availability across different zones

You can configure two Citrix ADC VPX instances on two different subnets or two different AWS availability zones, as a high availability active-passive pair in Independent Network Configuration (INC) mode. Upon failover, the EIP (Elastic IP) of the VIP of the primary instance migrates to the secondary, which takes over as the new primary. In the failover process, the AWS API:

- Checks the virtual servers that have `IPSets` attached to them.
- Finds the IP address that has an associated public IP, from the two IP addresses the virtual server is listening on. One that is directly attached to the virtual server, and one that is attached through the IP set.
- Reassociates the public IP (EIP) to the private IP belonging to the new primary VIP.

For HA across different zones, the following policies are required:

```
"iam:GetRole"
"ec2:DescribeInstances"
"ec2:DescribeAddresses"
"ec2:AssociateAddress"
"ec2:DisassociateAddress"
```

For more information, see High availability across AWS availability zones.

Before you start your deployment

Before you start any HA deployment on AWS, read the following document:

- Prerequisites
- Limitations and usage guidelines
- Deploy a Citrix ADC VPX instance on AWS
- High Availability

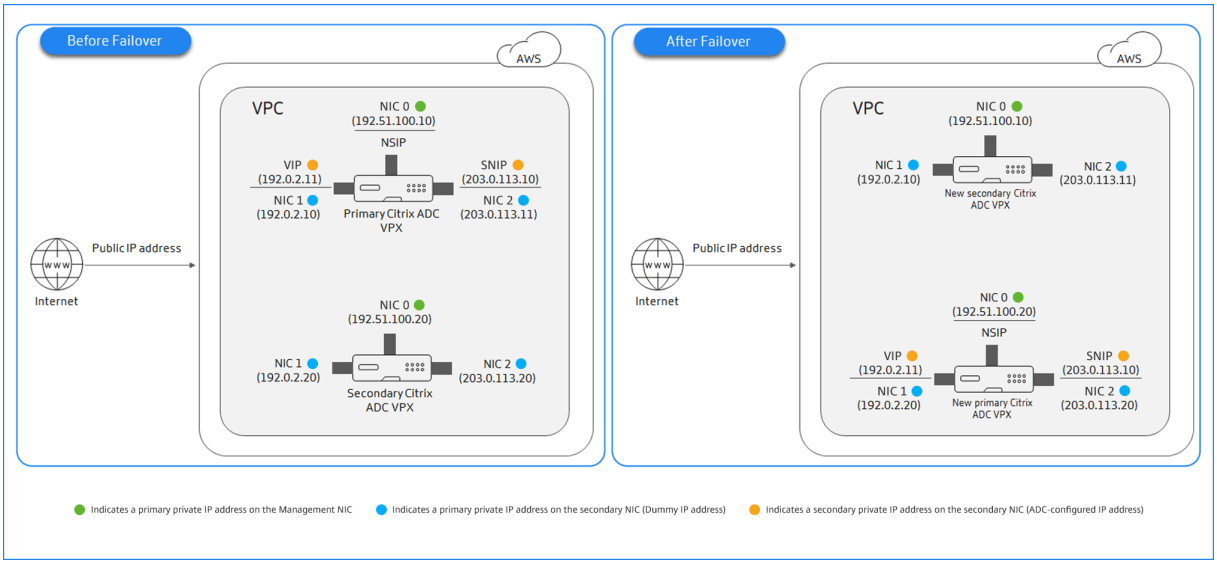
Deploy a high availability pair on AWS

October 27, 2021

You can configure two Citrix ADC VPX instances on AWS as a high-availability (HA) pair, in the same AWS zone where both VPX instances are on the same subnet. HA is achieved by migrating secondary private IP addresses attached to the NICs (client and server-side NICs) of the primary HA node to the secondary HA node after failover. All the Elastic IP addresses associated with the secondary private IP addresses are also migrated.

The following illustration depicts an HA failover scenario by migrating secondary private IP addresses.

Figure 1. A Citrix ADC VPX HA Pair on AWS, using private IP migration



Before you start your document, read the following docs:

- Prerequisites
- Limitations and usage guidelines
- Deploy a Citrix ADC VPX instance on AWS
- High Availability

How to deploy a VPX HA pair in the same zone

Here is the summary of the steps to deploy a VPX HA pair in the same zone:

1. Create two VPX instances on AWS, each with three NICs
2. Assign AWS secondary private IP address to VIP and SNIP of primary node
3. Configure VIP and SNIP on primary node using AWS secondary private IP addresses
4. Configure HA on both nodes

Step 1. Create two VPX instances (primary and secondary nodes) by using the same VPC, each with three NICs (Ethernet 0, Ethernet 1, Ethernet 2)

Follow the steps given in Deploy a Citrix ADC VPX instance on AWS by using the AWS web console.

Step 2. On the primary node, assign secondary private IP addresses for Ethernet 1 (client IP or VIP) and Ethernet 2 (back-end server IP or SNIP)

The AWS console automatically assigns primary private IP addresses to the configured NICs. Assign more private IP addresses to VIP and SNIP, known as secondary private IP addresses.

To assign a secondary private IPv4 address to a network interface, follow these steps:

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces, and then select the network interface attached to the instance.
3. Choose Actions, Manage IP Addresses.
4. Under IPv4 Addresses, choose Assign new IP.
5. Enter a specific IPv4 address that's within the subnet range for the instance, or leave the field blank to let Amazon select an IP address for you.
6. (Optional) Choose Allow reassignment to allow the secondary private IP address to be reassigned if it is already assigned to another network interface.
7. Choose Yes, Update.

Under the instance description, the assigned secondary private IP addresses appear.

Step 3. Configure VIP and SNIP on the primary node, using secondary private IP addresses

Access the primary node using SSH. Open an ssh client and type:

```
ssh -i <location of your private key> nsroot@<public DNS of the
   instance>
<!--NeedCopy-->
```

Next, configure VIP and SNIP.

For VIP, type:

```
add ns ip <IPAddress> <netmask> -type <type>
<!--NeedCopy-->
```

For SNIP, type:

```
add ns ip <IPAddress> <netmask> -type SNIP
<!--NeedCopy-->
```

Type `save config` to save.

To see the configured IP addresses, type the following command:

```
show ns ip
<!--NeedCopy-->
```

For more information, see the following topics:

- Configuring and Managing Virtual IP (VIP) Addresses
- Configuring the NSIP address

Step 4: Configure HA on both instances

On the primary node, open a Shell client and type the following command:

```
add ha node <id> <private IP address of the management NIC of the
   secondary node>
<!--NeedCopy-->
```

On the secondary node, type the following command:

```
add ha node <id> < private IP address of the management NIC of the
   primary node >
<!--NeedCopy-->
```

Type `save config` to save the configuration.

To see the configured HA nodes, type `show ha node`.

Upon failover, the secondary private IP addresses configured as VIP and SNIP on the previous primary node are migrated to the new primary node.

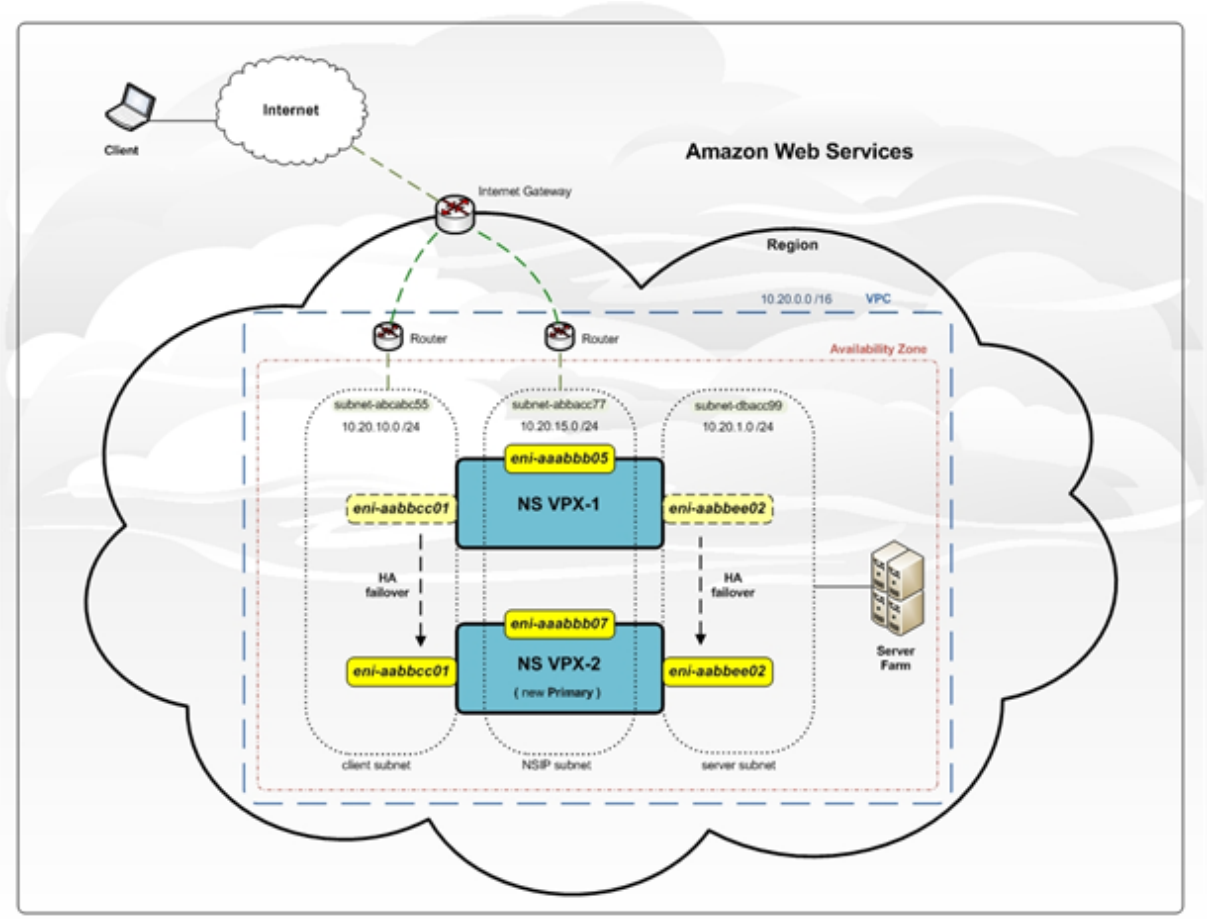
To force a failover on a node, type `force HA`failover.

Legacy method for deploying a VPX HA pair

Before 13.0 41.x release, HA within the same zone was achieved through AWS elastic network interface (ENI) migration. However, this method is slowly deprecated.

The following figure shows an example of the HA deployment architecture for Citrix ADC VPX instances on AWS.

Figure 1. A Citrix ADC VPX HA Pair on AWS, using ENI migration



You can deploy two VPX instances on AWS as an HA pair by using one of the following options:

- Create the instances with IAM Role manually by using the AWS Management Console and then configure HA on them.
- Or automate the high availability deployment by using the Citrix CloudFormation template.

The CloudFormation template significantly decreases the number of steps involved for creating an HA pair, and it automatically creates an IAM Role. This section shows how to deploy a Citrix ADC VPX HA (active-passive) pair by using the Citrix CloudFormation template.

Keep the following points in mind while deploying two Citrix ADC VPX instances as an HA pair.

Points to note

- HA on AWS requires the primary node to have at least two ENIs (one for management and the other for data traffic), and the secondary node to have one management ENI. However, for security purposes, create three ENIs on the primary node, because this setup allows you to segregate the private and public network (recommended).
- The secondary node always has one ENI interface (for management) and the primary node can have up to four ENIs.

- The NSIP addresses for each VPX instance in a high availability pair must be configured on the default ENI of the instance.
- Amazon does not allow any broadcast/multicast packets in AWS. As a result, in a HA setup, data-plane ENIs are migrated from the primary to the secondary VPX instance when the primary VPX instance fails.
- Because the default (management) ENI cannot be moved to another VPX instance, do not use the default ENI for client and server traffic (data-plane traffic).
- The message AWSCONFIG IOCTL NSAPI_HOTPLUG_INTF success output 0 in the /var/log/ns.log indicates that the two data ENIs have successfully attached to the secondary instance (the new primary).
- Failover might take up to 20 seconds due to the AWS detach/attach ENI mechanism.
- Upon failover, the failed instance always restarts.
- The heartbeat packets are received only on the management interface.
- The configuration file of the primary and secondary VPX instances is synchronized, including the `nsroot` password. The `nsroot` password of the secondary node is set to that of the primary node after the HA configuration synchronization.
- To have access to the AWS API servers, either the VPX instance must have a public IP address assigned or routing must be set up correctly at VPC subnet level pointing to the internet gateway of the VPC.
- Nameservers/DNS servers are configured at VPC level using DHCP options.
- The Citrix CloudFormation template does not create an HA setup between different availability zones.
- The Citrix CloudFormation template does not create an INC mode.
- The AWS debug messages are available in the log file, /var/log/ns.log, on the VPX instance.

Deploy a high availability pair by using the Citrix CloudFormation template

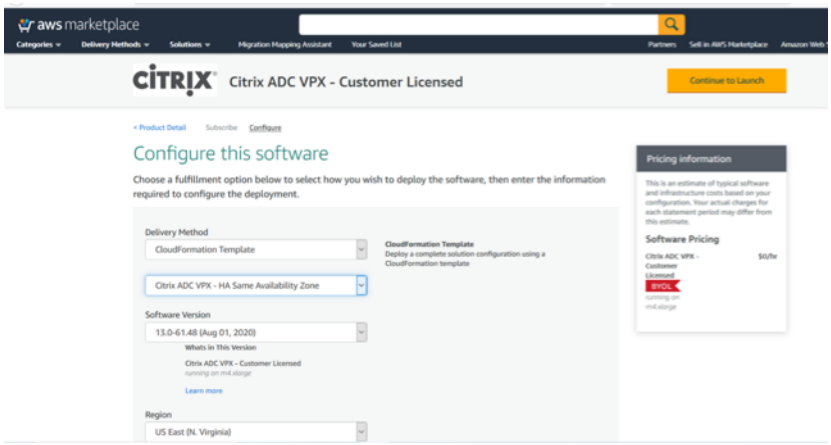
Before starting the CloudFormation template, ensure that you complete the following requirements:

- A VPC
- Three subnets within the VPC
- A security group with UDP 3003, TCP 3009–3010, HTTP, SSH ports open
- A key pair
- Create an internet gateway
- Edit route tables for client and management networks to point to the internet gateway

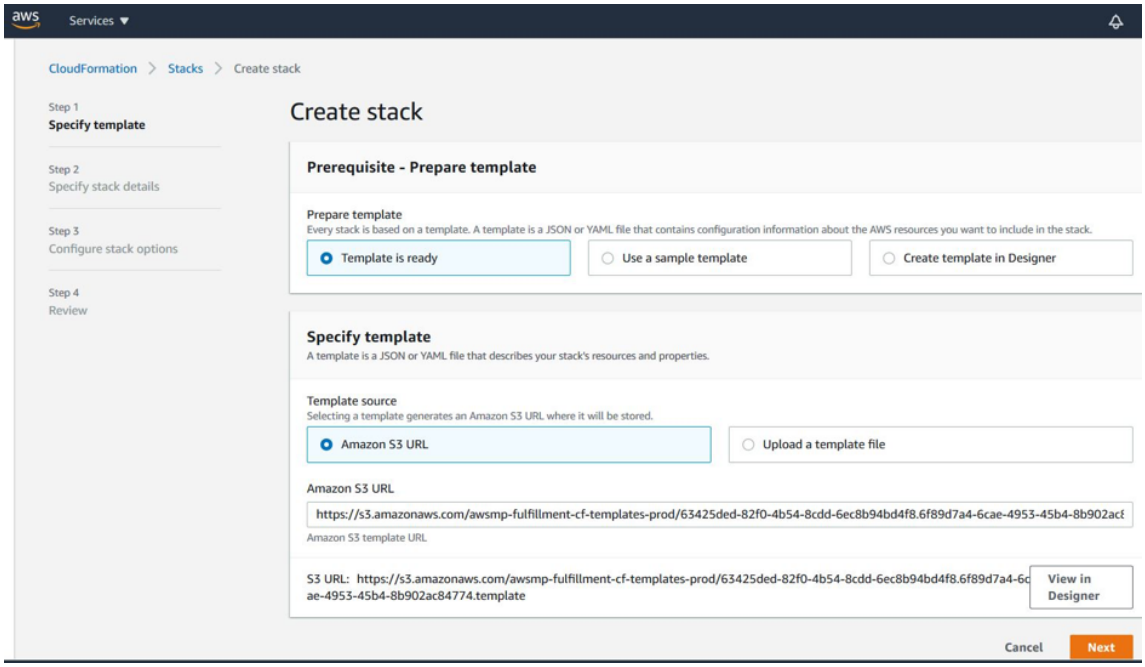
> **Note**
>
> The Citrix CloudFormation template automatically creates an IAM Role. Existing IAM Roles do not appear in the template.

To launch the Citrix CloudFormation template:

1. Log on to the AWS marketplace by using your AWS credentials.
2. In the search field, type **Citrix ADC VPX** to search for the Citrix ADC AMI, and click **Go**.
3. On the search result page, click the desired Citrix ADC VPX offering.
4. Click the **Pricing** tab, to go to **Pricing Information**.
5. Select the region and **Fulfillment Option** as **Citrix ADC VPX – Customer Licensed**.
6. Click **Continue to Subscribe**.
7. Check the details in the **Subscribe** page and click **Continue to Configuration**.
8. Select **Delivery Method** as **CloudFormation Template**.
9. Select the required CloudFormation template.
10. Select **Software Version** and **Region**, and click **Continue to Launch**.

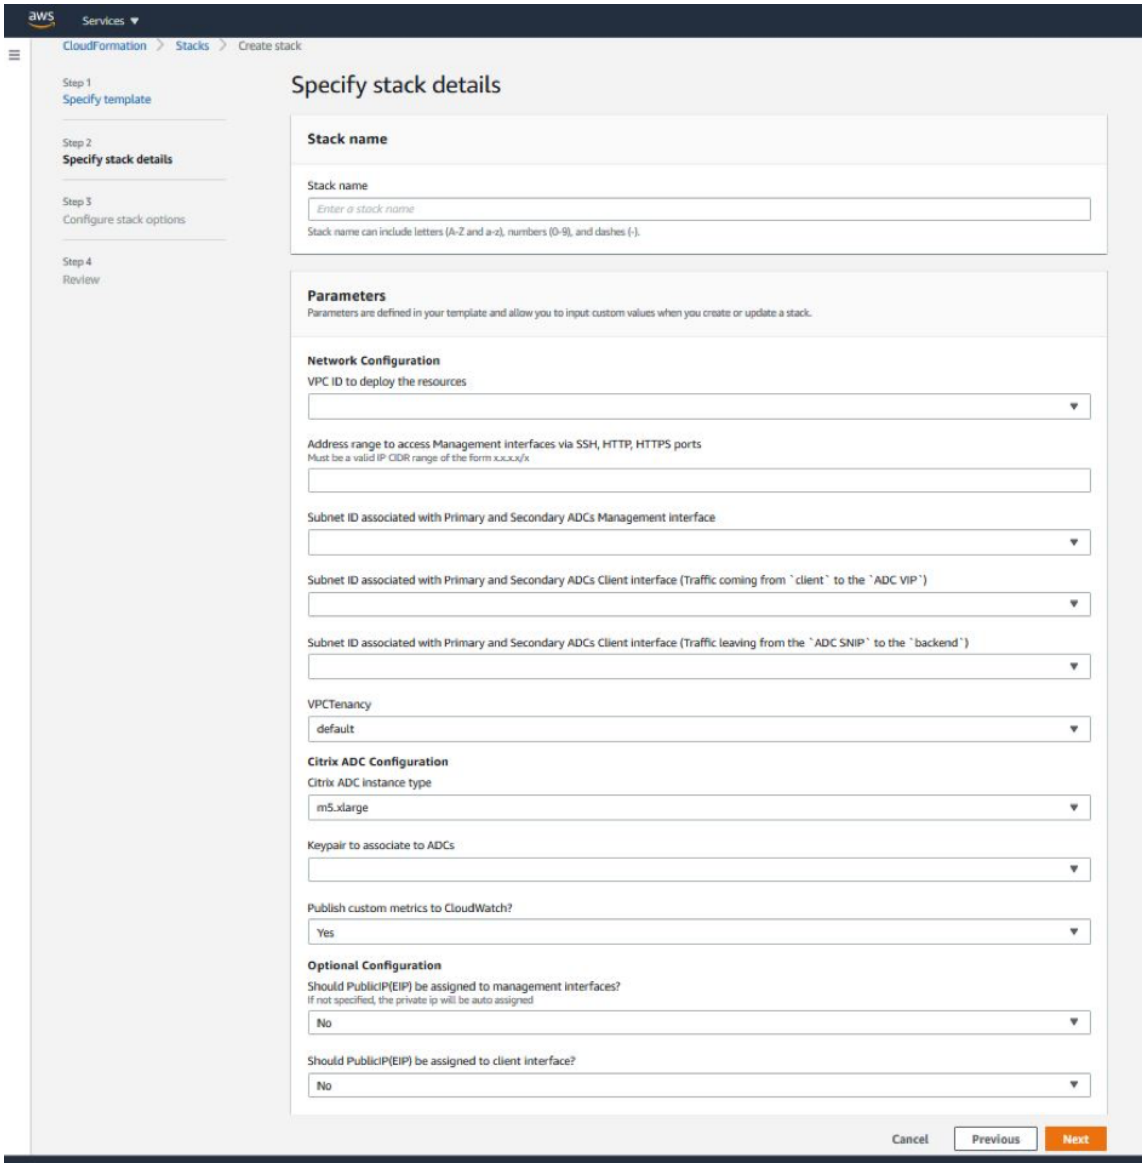


11. Under **Choose Action**, select **Launch CloudFormation**, and click **Launch**.
12. The **Create stack** page appears, and click **Next**.

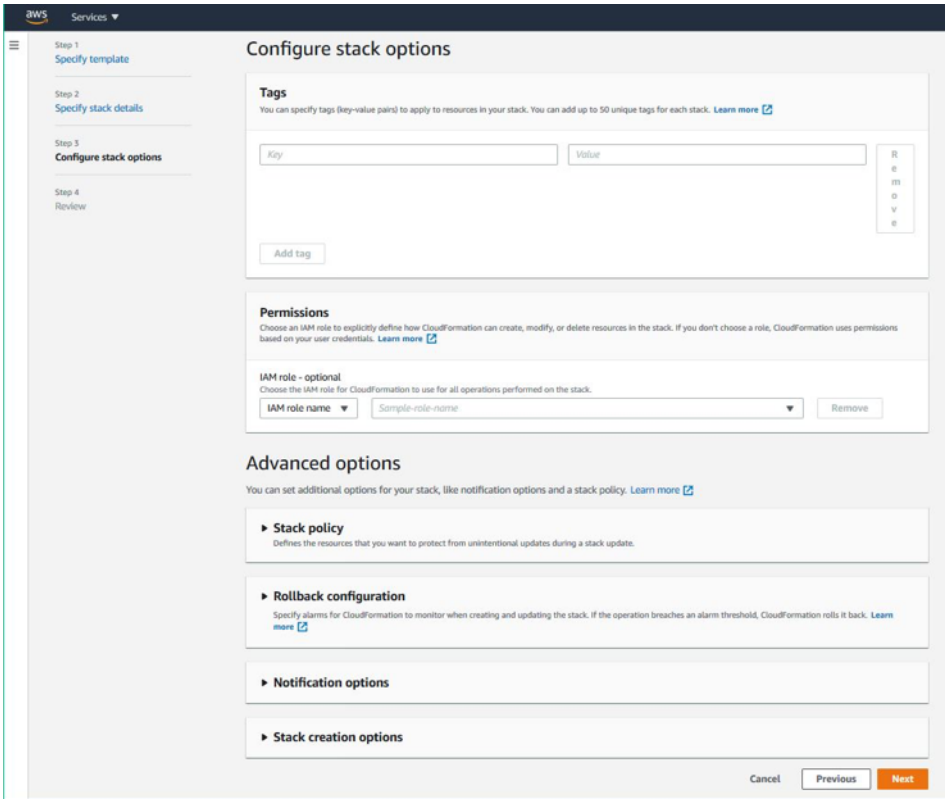


13. The **Specify stack details** page appears. Enter the following details.

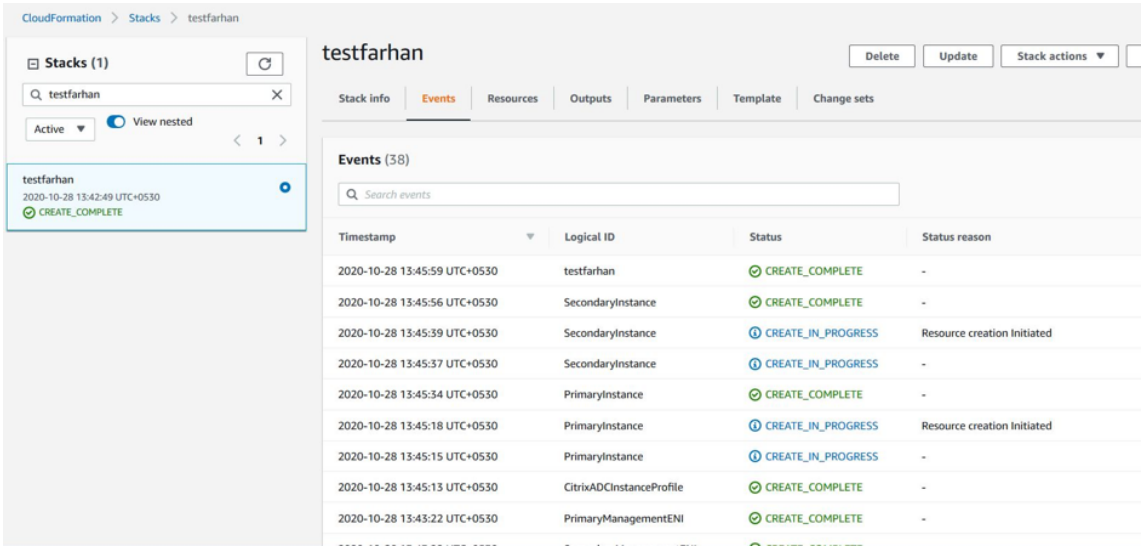
    - Type a **Stack name**. The name must be within 25 characters.
    - Under **Network Configuration**, perform the following:
        - Select **Management Subnetwork**, **Client Subnetwork**, and **Server Subnetwork**. Ensure that you select the correct subnetworks you created within the VPC that you selected under VPC ID.
        - Add **Primary Management IP**, **Secondary Management IP**, **Client IP**, and **Server IP**. The IP addresses must belong to the same subnets of the respective subnetworks. Alternatively, you can let the template assign the IP addresses automatically.
        - Select **default** for **VPCTenancy**.
    - Under **Citrix ADC Configuration**, perform the following:
        - Select **m5.xlarge** for **Instance type**.
        - Select the key pair that you've already created from the menu for **Key Pair**.
        - By default, the **Publish custom metrics to CloudWatch?** option is set to **Yes**. If you want to disable this option, select **No**.
          For more information about CloudWatch metrics, see Monitor your instances using Amazon CloudWatch.
    - Under **Optional Configuration**, perform the following:
        - By default, the **Should publicIP(EIP) be assigned to management interfaces?** option is set to **No**.
        - By default, the **Should publicIP(EIP) be assigned to client interface?** option is set to **No**.



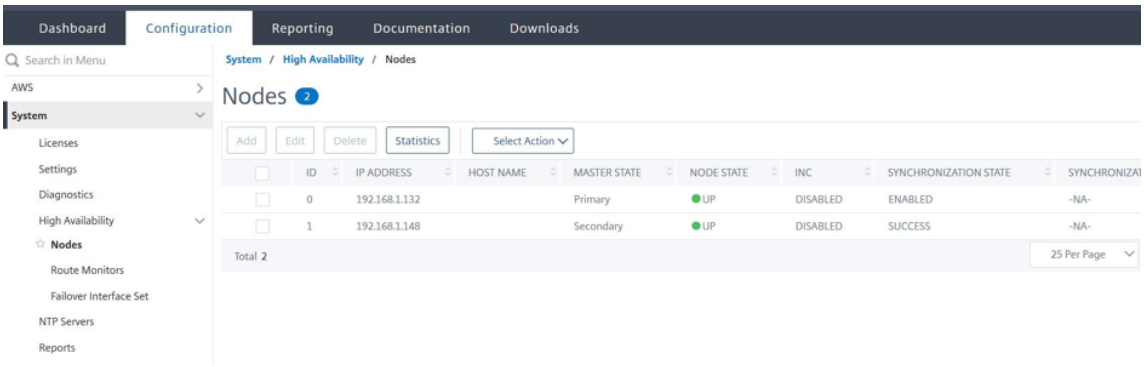
14. Click **Next**.
15. The **Configure stack options** page appears. This is an optional page.



16. Click **Next**.
17. The **Options** page appears. (This is an optional page.). Click **Next**.
18. The **Review** page appears. Take a moment to review the settings and make any changes, if necessary.
19. Select the **I acknowledge that AWS CloudFormation might create IAM resources.** check box, and then click **Create stack**.
20. The **CREATE-IN-PROGRESS** status appears. Wait until the status is **CREATE-COMPLETE**. If the status does not change to **COMPLETE**, check the **Events** tab for the reason of failure, and recreate the instance with proper configurations.



21. After an IAM resource is created, navigate to **EC2 Management Console > Instances**. You find two VPX instances created with IAM role. The primary and secondary nodes are created each with three private IP addresses and three network interfaces.
22. Log on to the primary node with user name `nsroot` and the instance ID as the password. From the GUI, navigate to **System > High Availability > Nodes**. The Citrix ADC VPX is already configured in HA pair by the CloudFormation template.
23. The Citrix ADC VPX HA pair appears.



Monitor your instances using Amazon CloudWatch

You can use the Amazon CloudWatch service to monitor a set of Citrix ADC VPX metrics such as CPU and memory utilization, and throughput. CloudWatch monitors resources and applications that run on AWS, in real time. You can access the Amazon CloudWatch dashboard by using the AWS Management console. For more information, see Amazon CloudWatch.

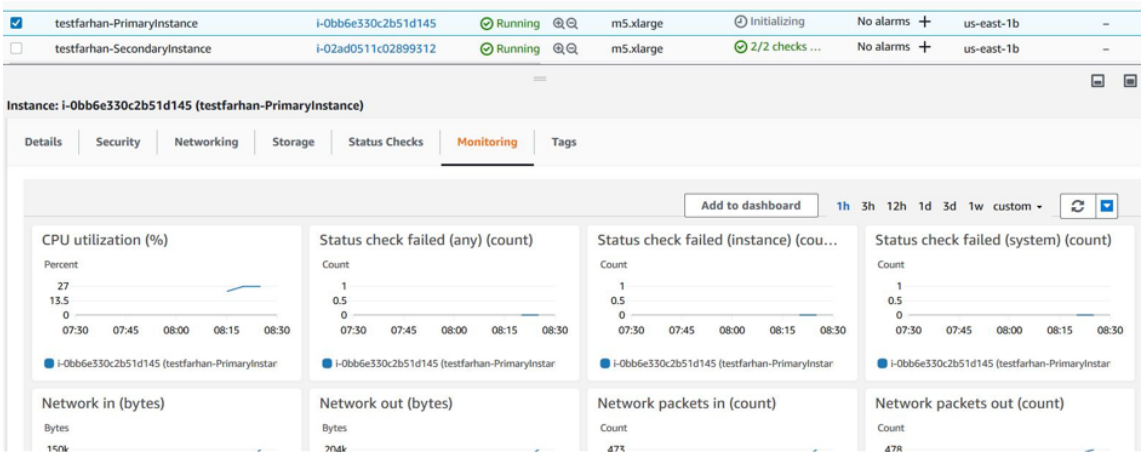
Points to note

- If you deploy a Citrix ADC VPX instance on AWS by using the AWS web console, the CloudWatch service is enabled by default.
- If you deploy a Citrix ADC VPX instance by using the Citrix CloudFormation template, the default option is “Yes.” If you want to disable the CloudWatch service, select “No.”
- Metrics are available for CPU (management and packet CPU usage), memory, and throughput (inbound and outbound).

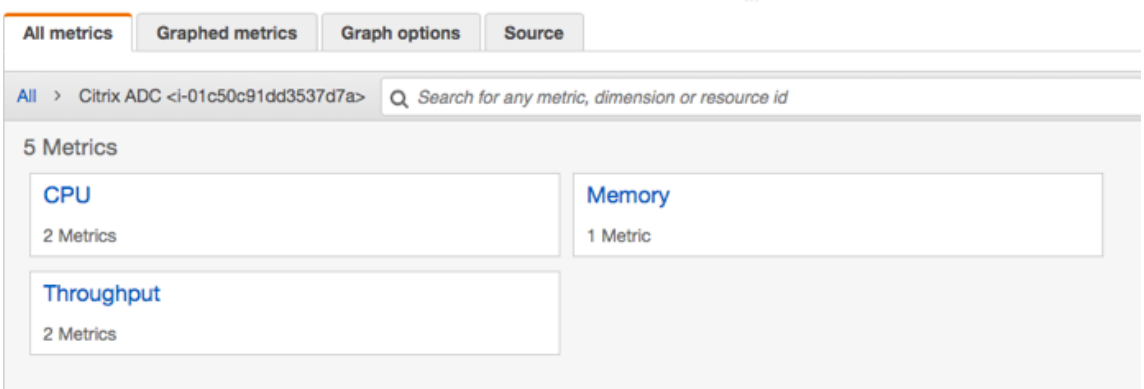
How to view CloudWatch metrics

To view CloudWatch metrics for your instance, follow these steps:

1. Log on to **AWS Management console > EC2 > Instances**.
2. Select the instance.
3. Click **Monitoring**.
4. Click **View all CloudWatch metrics**.



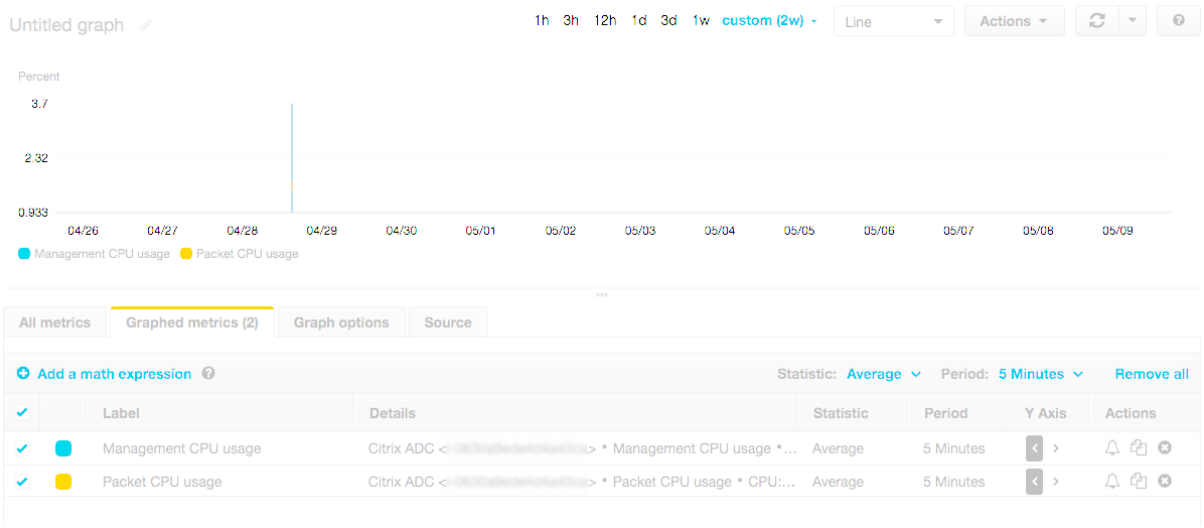
5. Under All metrics, click your instance ID.



6. Click the metrics you want to view, set the duration (by minutes, hours, days, weeks, months).

7. Click **Graphed metrics** to view the statistics of usage. Use the **Graph options** to customize your graph.

Figure. Graphed metrics for CPU usage



Configuring SR-IOV on a high availability setup

Support for SR-IOV interfaces in a high availability setup is available from Citrix ADC release 12.0 57.19 onwards. For more information about how to configure SR-IOV, see Configuring Citrix ADC VPX instances to Use SR-IOV Network Interface.

How high availability on AWS works

High availability across AWS availability zones

September 14, 2021

You can configure two Citrix ADC VPX instances on two different subnets or two different AWS availability zones, as a high availability active-passive pair in Independent Network Configuration (INC) mode. If for any reason, the primary node is unable to accept connections, the secondary node takes over.

For more information about high availability, see High availability. For more information about INC, see Configuring high availability nodes in different subnets.

Points to note

- Read the following documents before you start your deployment:
  - AWS terminology
  - Prerequisites
  - Limitations and usage guidelines
- The VPX high availability pair can either reside in the same availability zone in a different subnet or in two different AWS availability zones.
- Citrix recommends that you use different subnets for management (NSIP), client traffic (VIP), and back-end server (SNIP).
- High availability must be set in Independent Network Configuration (INC) mode for a failover to work.
- The two instances must have port 3003 open for UDP traffic as that is used for heartbeats.
- The management subnets of both the nodes must have access to internet or to AWS API server through internal NAT so that the rest APIs are functional.
- IAM role must have E2 permission for the public IP or elastic IP (EIP) migration and EC2 Route Table permissions for the private IP migration.

You can deploy high availability across AWS availability zones in the following ways:

- Using elastic IP addresses
- Using private IP addresses

How high availability across AWS availability zones works

Upon failover, the EIP of the VIP of the primary instance migrates to the secondary, which takes over as the new primary. In the failover process, AWS API

1. Checks the virtual servers that have `IPSets` attached to them.
2. Finds the IP address that has an associated public IP, from the two IP addresses the virtual server is listening on. One that is directly attached to the virtual server, and one that is attached through the IP set.
3. Reassociates the public IP (EIP) to the private IP belonging to the new primary VIP.

> **Note**
>
> To protect your network from attacks such as denial-of-service (DoS), when using an EIP, you can create security groups in AWS to restrict the IP access. For high availability, you can switch from EIP to a private IP movement solution as per your deployments.

Deploy a VPX high-availability pair with elastic IP addresses across different AWS zones

September 14, 2021

You can configure two Citrix ADC VPX instances on two different subnets or two different AWS availability zones using elastic IP addresses in the INC mode.

For more information about high availability, see High availability. For more information about INC, see Configuring high availability nodes in different subnets.

How to deploy a VPX high-availability pair with elastic IP addresses across different AWS zones

The following is the summary of steps for deploying a VPX pair on two different subnets or two different AWS availability zones.

1. Create an Amazon virtual private cloud.
2. Deploy two VPX instances in two different availability zones or in the same zone but in different subnets.
3. Configure high availability
    a) Set up high availability in INC mode in both the instances.
    b) Add an IP set in both the instances.
    c) Bind the IP set in both the instances to the VIP.
    d) Add a virtual server in the primary instance.

For steps 1 and 2, use the AWS console. For steps 3, use the Citrix ADC VPX GUI or the CLI.

Step 1. Create an Amazon virtual private cloud (VPC).

Step 2. Deploy two VPX instance in two different availability zones or in the same zone but in different subnets. Attach an EIP to the VIP of the primary VPX.

For more information about how to create a VPC and deploy a VPX instance on AWS, see Deploy a Citrix ADC VPX standalone instance on AWS and Scenario: standalone instance

Step 3. Configure high availability. You can use the Citrix ADC VPX CLI or the GUI to set up high availability.

Configure high availability by using the CLI

1. Set up high availability in INC mode in both the instances.

    On the primary node:

```
add ha node 1 <sec_ip> -inc ENABLED
```

On the secondary node:

```
add ha node 1 <prim_ip> -inc ENABLED
```

<sec_ip> refers to the private IP address of the management NIC of the secondary node

<prim_ip> refers to the private IP address of the management NIC of the primary node

2. Add the IP set in both the instances.

   Type the following command on both the instances.

   ```
   add ipset <ipsetname>
   ```

3. Bind the IP set to the VIP set on both the instances.

   Type the following command on both the instances:

   ```
   add ns ip <secondary vip> <subnet> -type VIP
   ```

   ```
   bind ipset <ipsetname> <secondary VIP>
   ```

   > **Note**
   >
   > You can bind the IP set to the primary VIP or to the secondary VIP. However, if you bind the IP set to the primary VIP, use the secondary VIP to add to the virtual server, and conversely.

4. Add a virtual server on the primary instance.

   Type the following command:

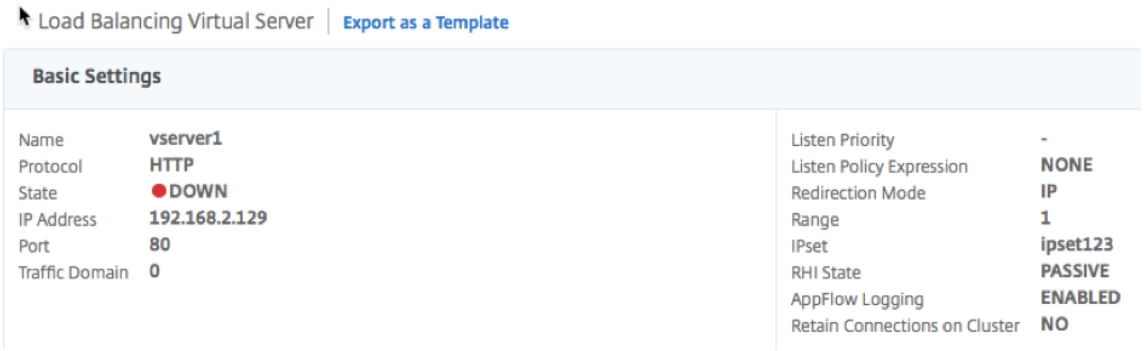
   ```
   add <server_type> vserver <vserver_name> <protocol> <primary_vip> <port
   > -ipset \<ipset_name>
   ```

Configure high availability by using the GUI

1. Set up high availability in INC mode on both the instances
2. Log on to the primary node with user name nsroot and instance ID as password.
3. From the GUI, go to **Configuration** > **System** > **High Availability**. Click **Add**.
4. At the **Remote Node IP address** field, add the private IP address of the management NIC of the secondary node.
5. Select **Turn on NIC (Independent Network Configuration)** mode on self-node.
6. Under **Remote System Login Credential**, add the user name and password for the secondary node and click **Create**.
7. Repeat the steps in the secondary node.

8. Add IP set and bind IP set to the VIP set on both the instances.
9. From the GUI, navigate to **System** > **Network** > **IPs** > **Add**.
10. Add the required values for IP Address, Netmask, IP Type (virtual IP) and click **Create**.
11. Navigate to **System** > **Network** > **IP Sets** > **Add**. Add an IP set name and click **Insert**.
12. From the IPV4s page, select the virtual IP and click **Insert**. Click **Create** to create the IP set.
13. Add a virtual server in the primary instance

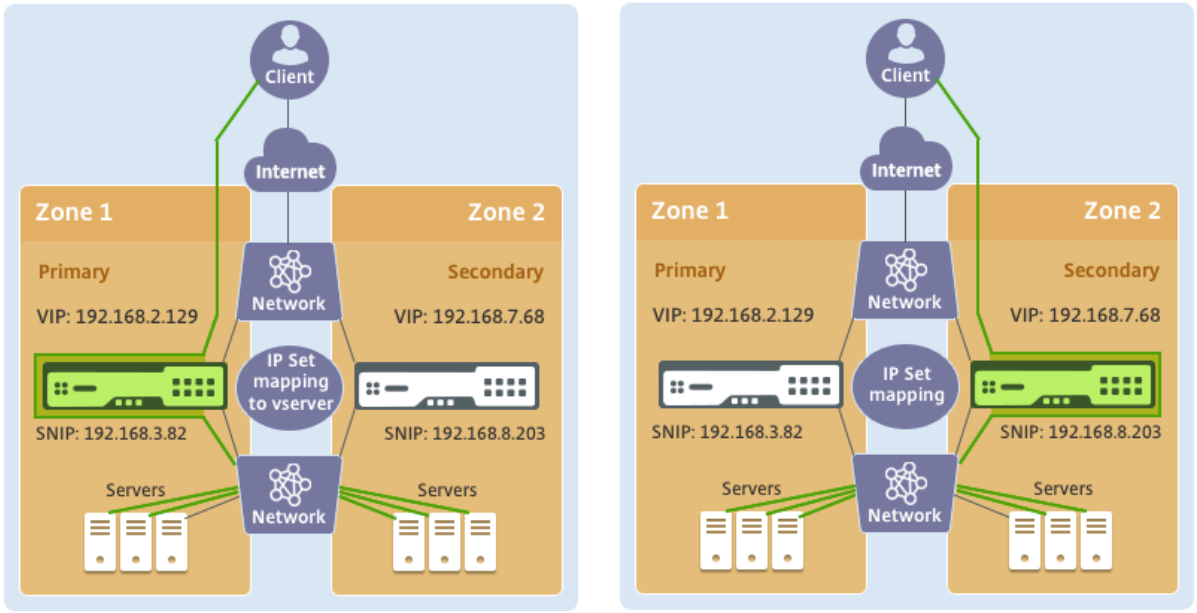
    From the GUI, go to **Configuration** > **Traffic Management** > **Virtual Servers** > **Add**.



Scenario

In this scenario, a single VPC is created. In that VPC, two VPX instances are created in two availability zones. Each instance has three subnets - one for management, one for client, and one for back-end server. An EIP is attached to the VIP of the primary node.

Diagram: This diagram illustrates the Citrix ADC VPX high availability setup in INC mode, on AWS



For this scenario, use CLI to configure high availability.

1. Set up high availability in INC mode on both the instances.

   Type the following commands on the primary and the secondary nodes.

   On primary:

   ```
   add ha node 1 192.168.6.82 -inc enabled
   ```

   Here, 192.168.6.82 refers to the private IP address of the management NIC of the secondary node.

   On secondary:

   ```
   add ha node 1 192.168.1.108 -inc enabled
   ```

   Here, 192.168.1.108 refers to the private IP address of the management NIC of the primary node.

2. Add an IP set and bind the IP set to the VIP on both the instances

   On primary:

   ```
   add ipset ipset123
   ```

   ```
   add ns ip 192.168.7.68 255.255.255.0 -type VIP
   ```

   ```
   bindipset ipset123 192.168.7.68
   ```

   On secondary:

   ```
   add ipset ipset123
   ```

   ```
   add ns ip 192.168.7.68 255.255.255.0 -type VIP
   ```

```
bind ipset ipset123 192.168.7.68
```

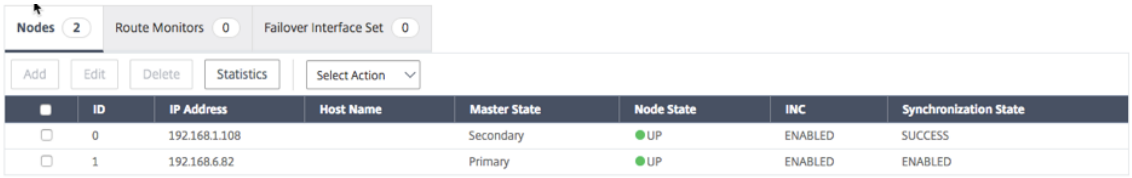
3. Add a virtual server on the primary instance.

   The following command:

   ```
   add lbvserver vserver1 http 192.168.2.129 80 -ipset ipset123
   ```

4. Save the configuration.

5. After a forced failover, the secondary becomes the new primary.



Deploy a VPX high-availability pair with private IP addresses across different AWS zones

September 17, 2021

You can configure two Citrix ADC VPX instances on two different subnets or two different AWS availability zones using private IP addresses in the INC mode. This solution can be easily integrated with the existing multizone VPX high-availability pair with elastic IP addresses. Therefore, you can use both the solutions together.

For more information about high availability, see High availability. For more information about INC, see Configuring high availability nodes in different subnets.

> Note:
>
> This deployment is supported from Citrix ADC release 13.0 build 67.39 onwards. This deployment is compatible with AWS Transit Gateway and VPC peering.

Prerequisites

Ensure that the IAM role associated with your AWS account has the following IAM permissions:

```
{

    "Version": "2012-10-17",
    "Statement": [
        {

            "Action": [
                "ec2:DescribeInstances",
                "ec2:DescribeAddresses",
                "ec2:AssociateAddress",
                "ec2:DisassociateAddress",
                "ec2:DescribeRouteTables",
                "ec2:DeleteRoute",
                "ec2:CreateRoute",
                "ec2:ModifyNetworkInterfaceAttribute",
                "iam:SimulatePrincipalPolicy",
                "iam:GetRole"
            ],
            "Resource": "*",
            "Effect": "Allow"
         }

    ]
 }

<!--NeedCopy-->
```

How to deploy a VPX high-availability pair with private IP addresses across different AWS zones

The following is the summary of steps for deploying a VPX pair on two different subnets or two different AWS availability zones using private IP addresses.

1. Create an Amazon virtual private cloud.
2. Deploy two VPX instances in two different availability zones.
3. Configure high availability
    a) Set up high availability in INC mode in both the instances.
    b) Add the respective route tables in the VPC that points to the client interface.
    c) Add a virtual server in the primary instance.

For steps 1 and 2, use the AWS console. For step 3, use the Citrix ADC VPX GUI or the CLI.

Step 1. Create an Amazon virtual private cloud (VPC).

Step 2. Deploy two VPX instance in two different availability zones with the same number of ENI (Network Interface).

For more information about how to create a VPC and deploy a VPX instance on AWS, see Deploy a Citrix ADC VPX standalone instance on AWS and Scenario: standalone instance

Step 3. Configure the ADC VIP addresses by choosing a subnet that does not overlap with the Amazon VPC subnets. If your VPC is 192.168.0.0/16, then to configure ADC VIP addresses, you can choose any subnet from these IP address ranges:

- 0.0.0.0 - 192.167.0.0
- 192.169.0.0 - 254.255.255.0

In this example, the chosen 10.10.10.0/24 subnet and created VIPs in this subnet. You can choose any subnet other than the VPC subnet (192.168.0.0/16).

Step 4. Add a route that points to the client interface (VIP) of the primary node from the VPC route table.

From the AWS CLI, type the following command:

```
aws ec2 create-route --route-table-id rtb-2272532 --destination-cidr-
    block 10.10.10.0/24 --gateway-id <eni-client-primary>
<!--NeedCopy-->
```

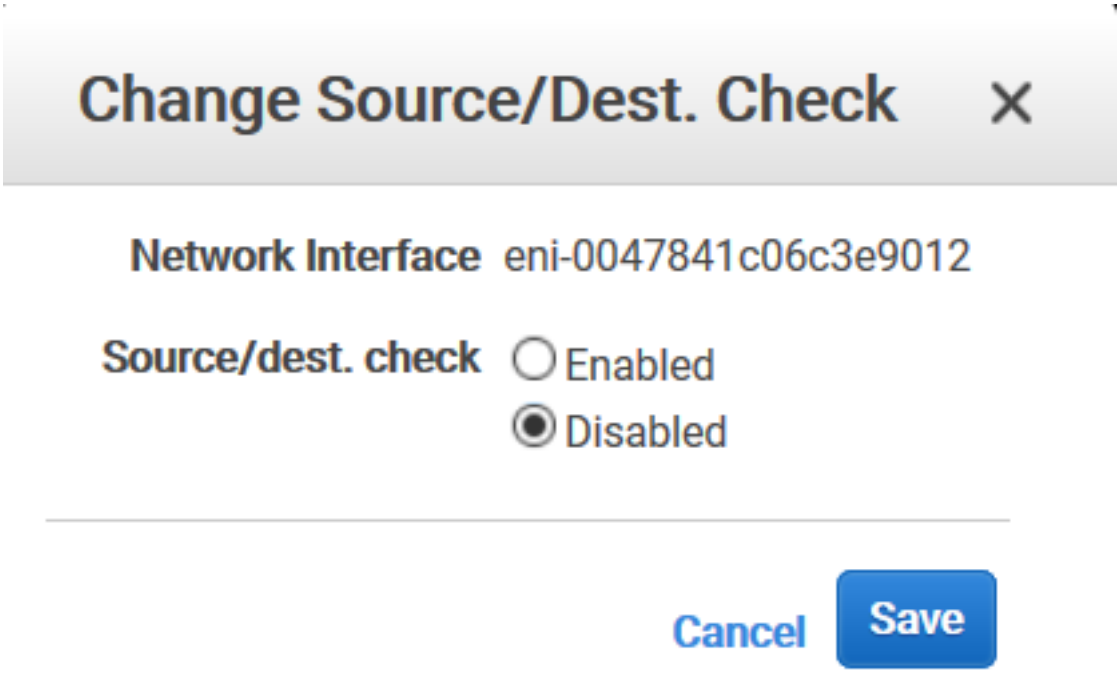
From the AWS GUI, perform the following steps to add a route:

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Route Tables**, and select the route table.
3. Choose **Actions**, and click **Edit routes**.
4. To add a route, choose **Add route**. For **Destination**, enter the destination CIDR block, a single IP address, or the ID of a prefix list. For gateway ID, select the ENI of a client interface of the primary node.

> Note
>
> You must disable **Source/Dest Check** on the client ENI of the primary instance.

To disable the source/destination checking for a network interface using the console, perform the following steps:

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface of a primary client interface, and choose **Actions**, and click **Change Source/Dest. Check**.
4. In the dialog box, choose **Disabled**, click **Save**.



Step 5. Configure high availability. You can use the Citrix ADC VPX CLI or the GUI to set up high availability.

Configure high availability by using the CLI

1. Set up high availability in INC mode in both the instances.

   On the primary node:

   ```
   1 add ha node 1 \<sec\_ip\> -inc ENABLED
   2 <!--NeedCopy-->
   ```

   On the secondary node:

```
1 add ha node 1 \<prim\_ip\> -inc ENABLED
2 <!--NeedCopy-->
```

<sec_ip> refers to the private IP address of the management NIC of the secondary node.

<prim_ip> refers to the private IP address of the management NIC of the primary node.

2. Add a virtual server on the primary instance. You must add it from the chosen subnet, for example, 10.10.10.0/24.

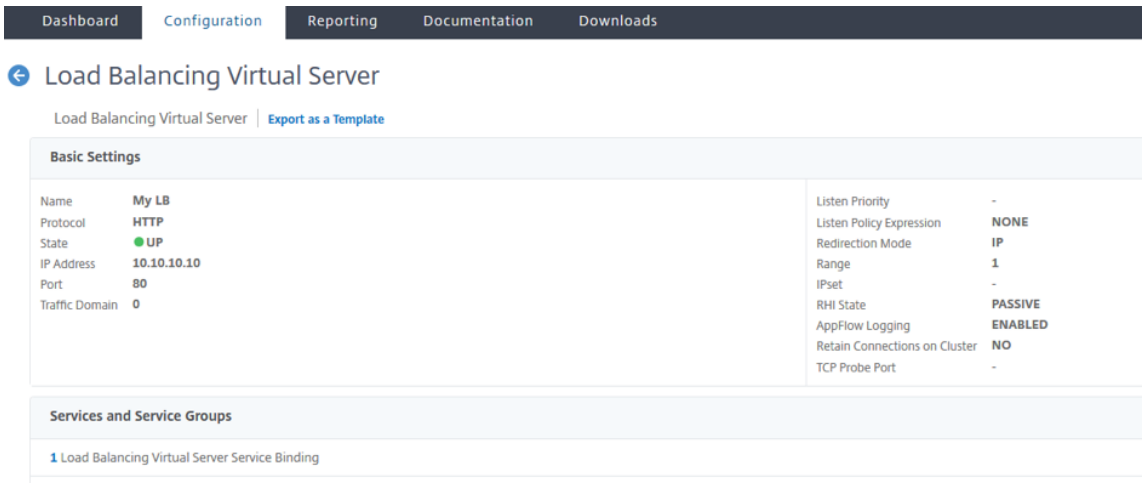
   Type the following command:

```
1 add \<server\_type\> vserver \<vserver\_name\> \<protocol\> \<
     primary\_vip\> \<port\>
2 <!--NeedCopy-->
```

Configure high availability by using the GUI

1. Set up high availability in INC mode on both the instances
2. Log on to the primary node with user name `nsroot` and instance ID as password.
3. Navigate to **Configuration** > **System** > **High Availability**, and click **Add**.
4. At the **Remote Node IP address** field, add the private IP address of the management NIC of the secondary node.
5. Select **Turn on NIC (Independent Network Configuration)** mode on self-node.
6. Under **Remote System Login Credential**, add the user name and password for the secondary node and click **Create**.
7. Repeat the steps in the secondary node.
8. Add a virtual server in the primary instance

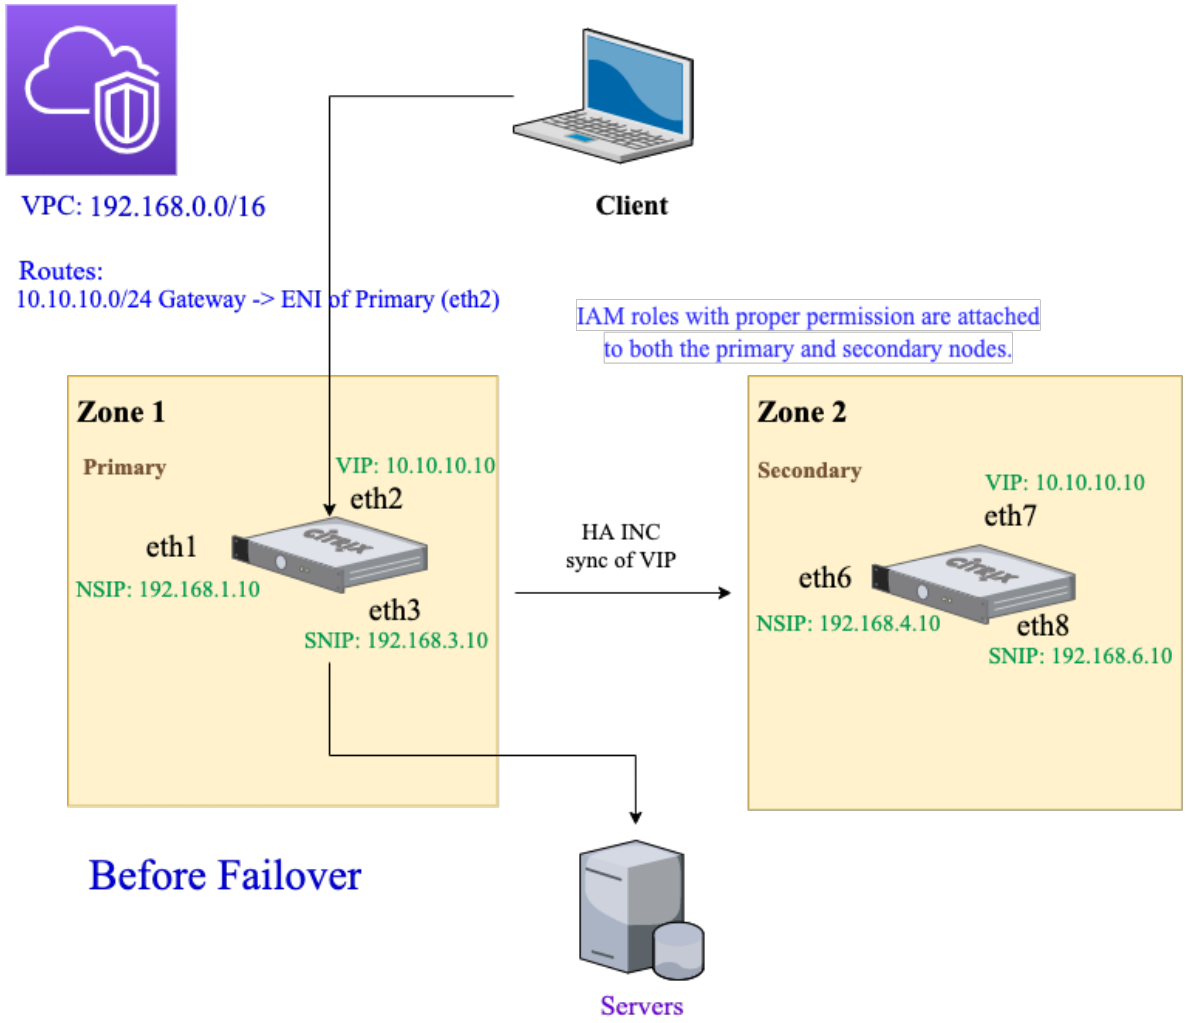
   Navigate to **Configuration** > **Traffic Management** > **Virtual Servers** > **Add**.

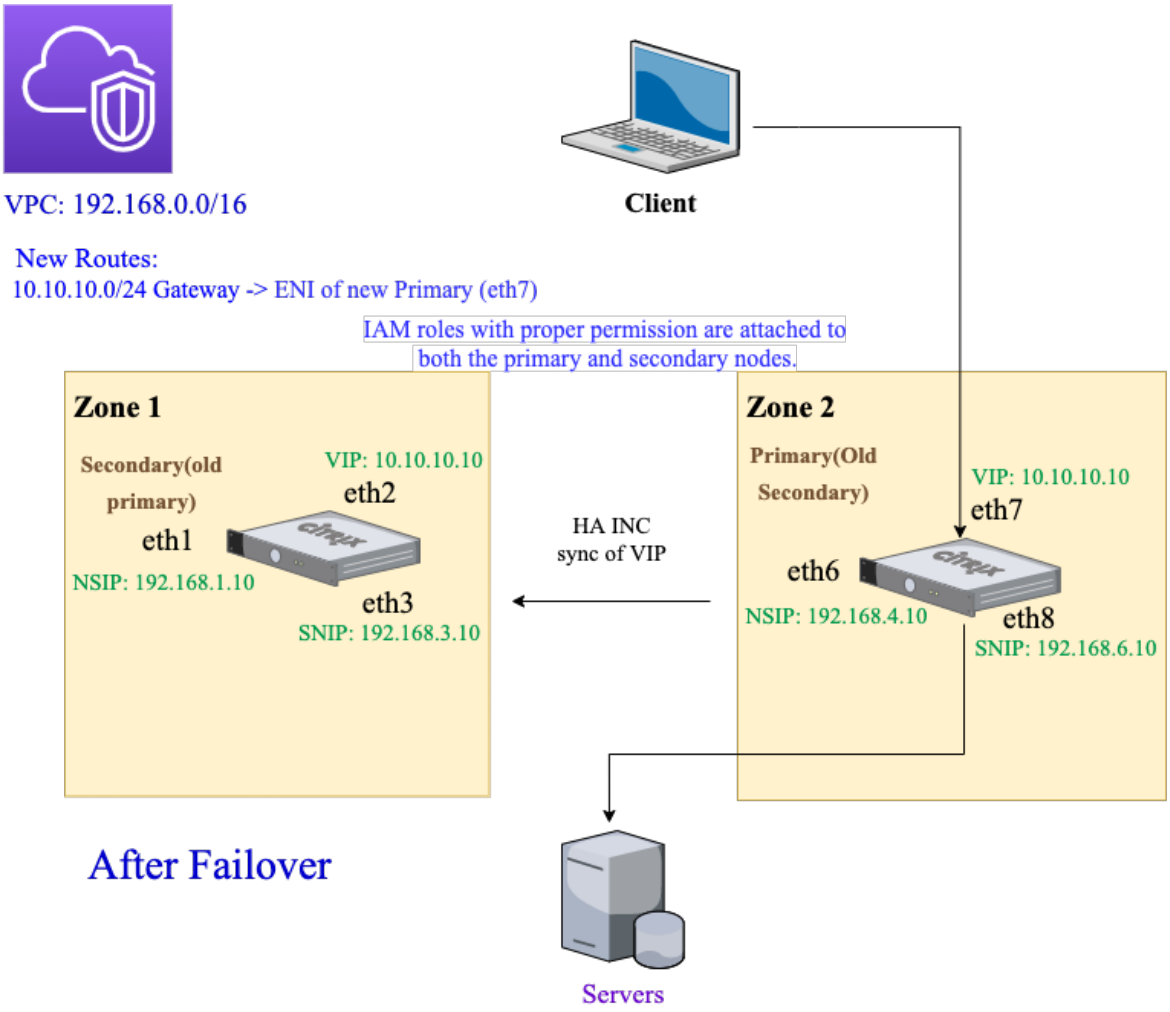


Scenario

In this scenario, a single VPC is created. In that VPC, two VPX instances are created in two availability zones. Each instance has three subnets - one for management, one for client, and one for back-end server.

The following diagrams illustrate the Citrix ADC VPX high availability setup in INC mode, on AWS. The custom subnet 10.10.10.10, which is not part of the VPC is used as VIP. Therefore, the 10.10.10.10 subnet can be used across availability zones.





For this scenario, use CLI to configure high availability.

1. Set up high availability in INC mode on both the instances.

   Type the following commands on the primary and the secondary nodes.

   On the primary node:

   ```
   add ha node 1 192.168.4.10 -inc enabled
   <!--NeedCopy-->
   ```

   Here, 192.168.4.10 refers to the private IP address of the management NIC of the secondary node.

   On the secondary node:

   ```
   add ha node 1 192.168.1.10 -inc enabled
   <!--NeedCopy-->
   ```

   Here, 192.168.1.10 refers to the private IP address of the management NIC of the primary node.

2. Add a virtual server on the primary instance.

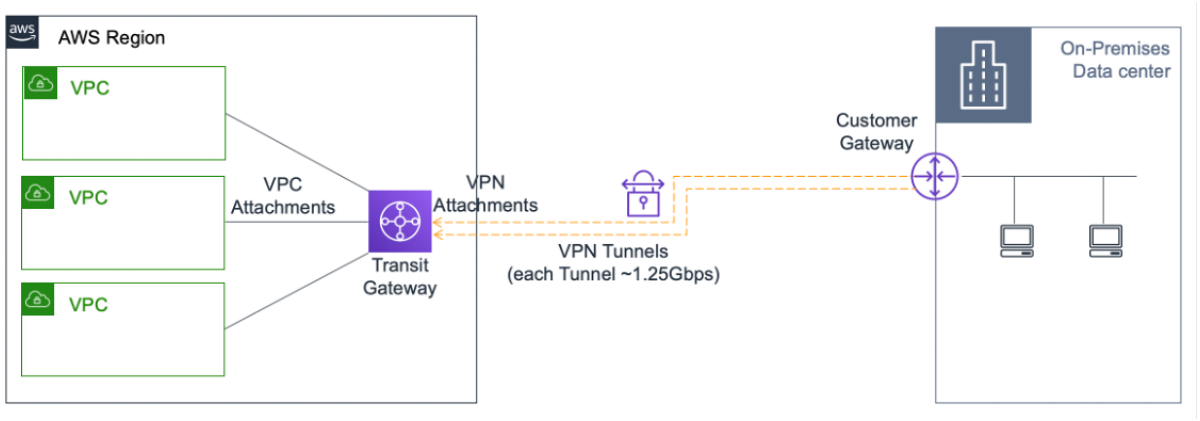
   Type the following command:

```
add lbvserver vserver1 http 10.10.10.10 80
<!--NeedCopy-->
```

3. Save the configuration.
4. After a forced failover:
   - The secondary instance becomes the new primary instance.
   - The VPC route pointing to the primary ENI migrates to the secondary client ENI.
   - Client traffic resumes to the new primary instance.

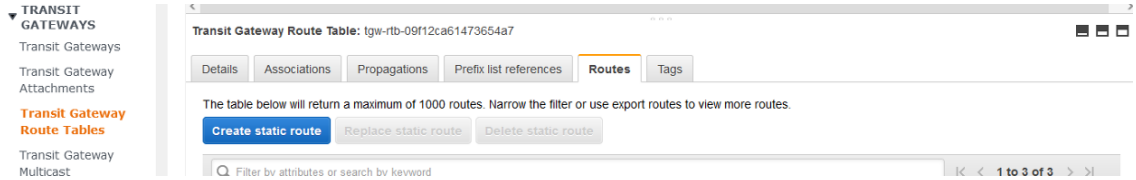
AWS Transit Gateway configuration for HA private IP solution

You need AWS Transit Gateway to make the private VIP subnet routable within the internal network, across AWS VPCs, regions, and On-premises networks. The VPC must connect to AWS Transit Gateway. A static route for the VIP subnet or IP pool inside the AWS Transit Gateway route table is created and pointed towards the VPC.

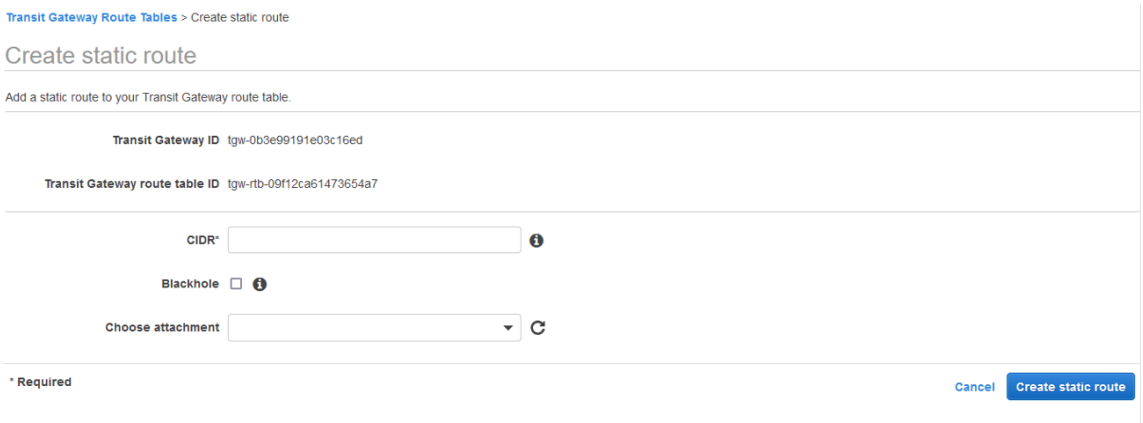


To configure AWS Transit Gateway, follow these steps:

1. Open the Amazon VPC console.
2. On the navigation pane, choose **Transit Gateway Route Tables**.
3. Choose the **Routes** tab, and click **Create static route**.



4. Create a static route where CIDR points to your private VIPS subnet and attachment points to the VPC having ADC VPX.



5. Click **Create static route**, then choose **Close**.

Deploy a Citrix ADC VPX instance on AWS Outposts

September 14, 2021

AWS Outposts is a pool of AWS compute and storage capacity deployed at your site. Outposts provides AWS infrastructure and services in your on-premises location. AWS operates, monitors, and manages this capacity as part of an AWS Region. You can use the same Citrix ADC VPX instances, AWS APIs, tools, and infrastructure across on-premises and the AWS cloud for a consistent hybrid experience.

You can create subnets on your Outposts and specify them when you create AWS resources such as EC2 instances, EBS volumes, ECS clusters, and RDS instances. Instances in the Outposts subnets communicate with other instances in the AWS Region using private IP addresses, all within the same Amazon Virtual Private Cloud (VPC).

For more information, see the AWS Outposts user guide.

How AWS Outposts works

AWS Outposts is designed to operate with a constant and consistent connection between your Outposts and an AWS Region. To achieve this connection to the Region, and to the local workloads in your on-premises environment, you must connect your Outpost to your on-premises network. Your on-premises network must provide WAN access back to the Region and to the internet. The internet must also provide LAN or WAN access to the local network where your on-premises workloads or applications reside.

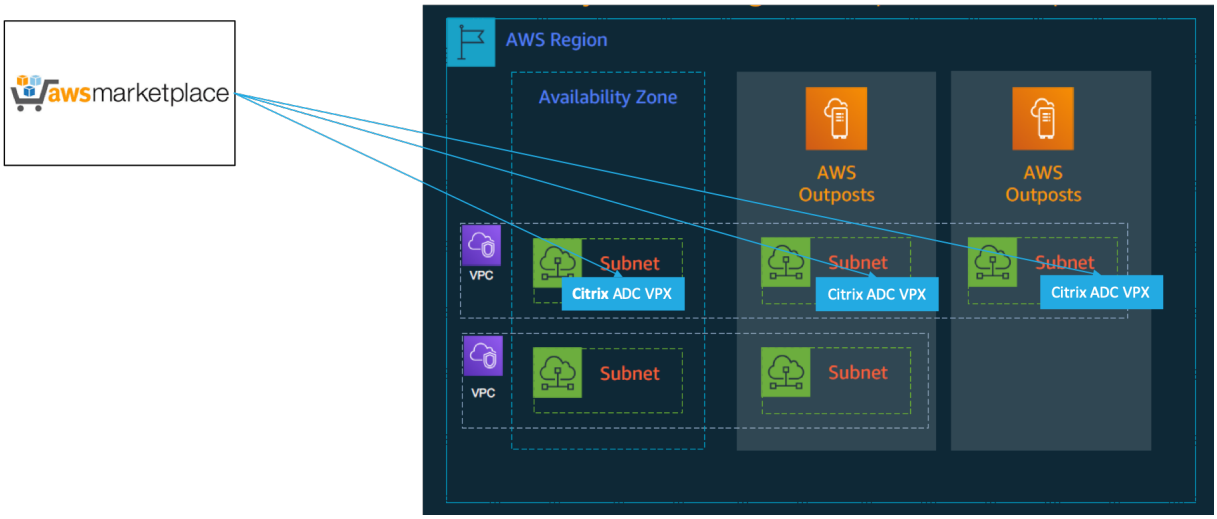
Prerequisite

- You must install an AWS Outposts at your site.
- The AWS Outposts' compute and storage capacity must be available for use.

For more information on how to place an order for AWS Outposts, see the following AWS documentation:
https://aws.amazon.com/blogs/aws/aws-outposts-now-available-order-your-racks-today/

Deploy a Citrix ADC VPX instance on AWS Outposts by using the AWS web console

The following figure depicts a simple deployment of Citrix ADC VPX instances on the Outposts. The Citrix ADC AMI present in the AWS Marketplace is also deployed in the Outposts.



Log in to the AWS web console and complete the following steps to deploy ADC VPX EC2 instances on your AWS Outposts.

1. Create a key pair.
2. Create a Virtual Private Cloud (VPC).
3. Add more subnets.
4. Create security groups and security rules.
5. Add route tables.
6. Create an internet gateway.
7. Create an ADC VPX instance by using the AWS EC2 service.
   From the AWS dashboard, navigate to **Compute > EC2 > Launch Instance > AWS Marketplace**.
8. Create and attach more network interfaces.
9. Attach elastic IPs to the management NIC.
10. Connect to the VPX instance.

For detailed instructions on each of the steps, see Deploy a Citrix ADC VPX instance on AWS by using the AWS web console.

For high availability within same availability zone deployment, see Deploy a high availability pair on AWS.

Add back-end AWS Autoscaling service

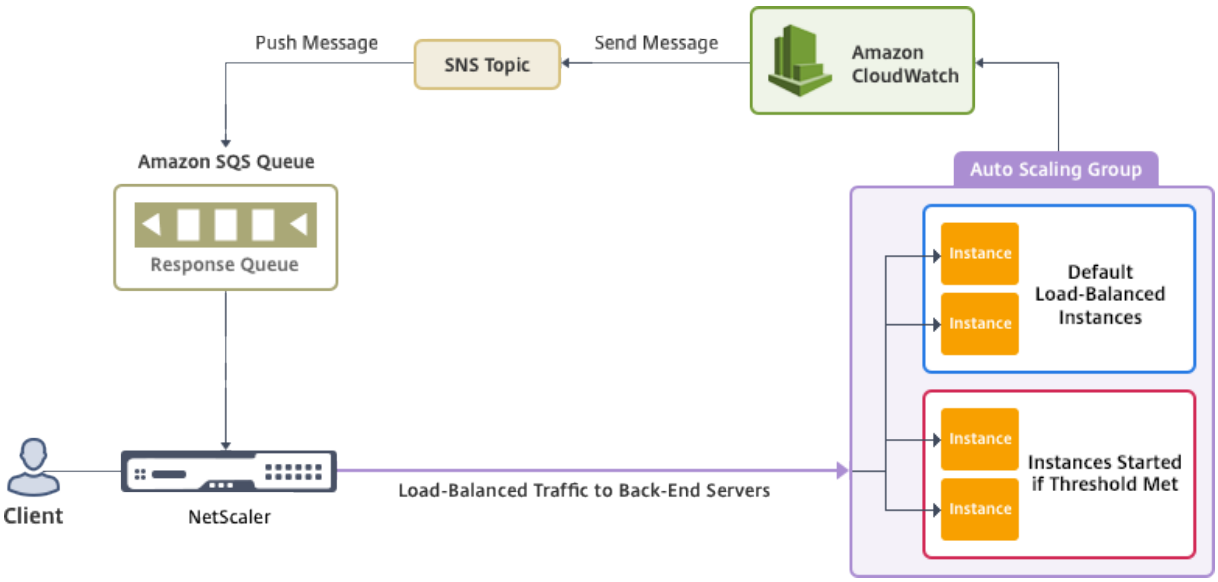
September 14, 2021

Efficient hosting of applications in a cloud involves easy and cost-effective management of resources depending on the application demand. To meet increasing demand, you have to scale network resources upward. Whether demand subsides, you need to scale down to avoid the unnecessary cost of idle resources. To minimize the cost of running the application by deploying only as many instances as are necessary during any given time, you constantly have to monitor traffic, memory and CPU use, and so on. However, monitoring traffic manually is cumbersome. For the application environment to scale up or down dynamically, you must automate the processes of monitoring traffic and of scaling resources up and down whenever necessary.

Integrated with the AWS Auto Scaling service, the Citrix ADC VPX instance provides the following advantages:

- **Load balance and management**: Auto configures servers to scale up and scale down, depending on demand. The VPX instance auto detects Autoscale groups in the back-end subnet and allows a user to select the Autoscale groups to balance the load. All of this is done by auto configuring the virtual and subnet IP addresses on the VPX instance.
- **High availability**: Detects Autoscale groups that span multiple availability zones and load-balance servers.
- **Better network availability**: The VPX instance supports:
  - Back-end servers on different VPCs, by using VPC peering
  - Back-end servers on same placement groups
  - Back-end servers on different availability zones
- **Graceful connection termination**: Removes Autoscale servers gracefully, avoiding loss of client connections when scale-down activity occurs, by using the Graceful Timeout feature.

Diagram: AWS Autoscaling service with a Citrix ADC VPX Instance



This diagram illustrates how the AWS Autoscaling service is compatible with a Citrix ADC VPX instance (Load balancing virtual server). For more information, see the following AWS topics.

- Autoscaling groups
- CloudWatch
- Simple Notification Service (SNS)
- Simple Queue Service (Amazon SQS)

Before you begin

Before you start using Autoscaling with your Citrix ADC VPX instance, you must complete the following tasks.

1. Read the following topics:
   - Prerequisites
   - Limitation and usage guidelines
2. Create a Citrix ADC VPX instance on AWS according to your requirement.
   - For more information about how to create a Citrix ADC VPX standalone instance, see Deploy a Citrix ADC VPX standalone instance on AWS and Scenario: standalone instance
   - For more information about how to deploy VPX instances in HA mode, see Deploy a high availability pair on AWS.

> **Note**
>
> Citrix recommends the CloudFormation template for creating Citrix ADC VPX instances on AWS.

> Citrix recommends you create three interfaces: one for management (NSIP), one for client-facing LB virtual server (VIP), and one for subnet IP (NSIP).

3. Create an AWS Autoscale group. If you don't have an existing Autoscaling configuration, you must:

   a) Create a Launch Configuration

   b) Create an Autoscaling Group

   c) Verify the Autoscaling Group

   For more information, see http://docs.aws.amazon.com/autoscaling/latest/userguide/GettingStartedTutorial.html.

4. In the AWS Autoscale group, you must specify at least one scale-down policy. The Citrix ADC VPX instance supports only the Step scaling policy. The Simple scaling policy and Target tracking scaling policy are not supported for Autoscale group.

Add the AWS Autoscaling service to a Citrix ADC VPX instance

You can add the Autoscaling service to a VPX instance with a single click by using the GUI. Complete these steps to add the Autoscaling service to the VPX instance:

1. Log on to the VPX instance by using your credentials for `nsroot`.
2. When you log on to the Citrix ADC VPX instance for the first time, you see the default Cloud Profile page. Select the AWS Autoscaling group from the drop-down menu and click **Create** to create a cloud profile. Click **Skip** if you want to create the cloud profile later.

   Points to keep in mind while creating a Cloud Profile: By default the CloudFormation Template creates and attaches the below IAM Role.

```
{

    "Version": "2012-10-17",

    "Statement": \[

     {

            "Action": \[

                "ec2:DescribeInstances",

                "ec2:DescribeNetworkInterfaces",
```

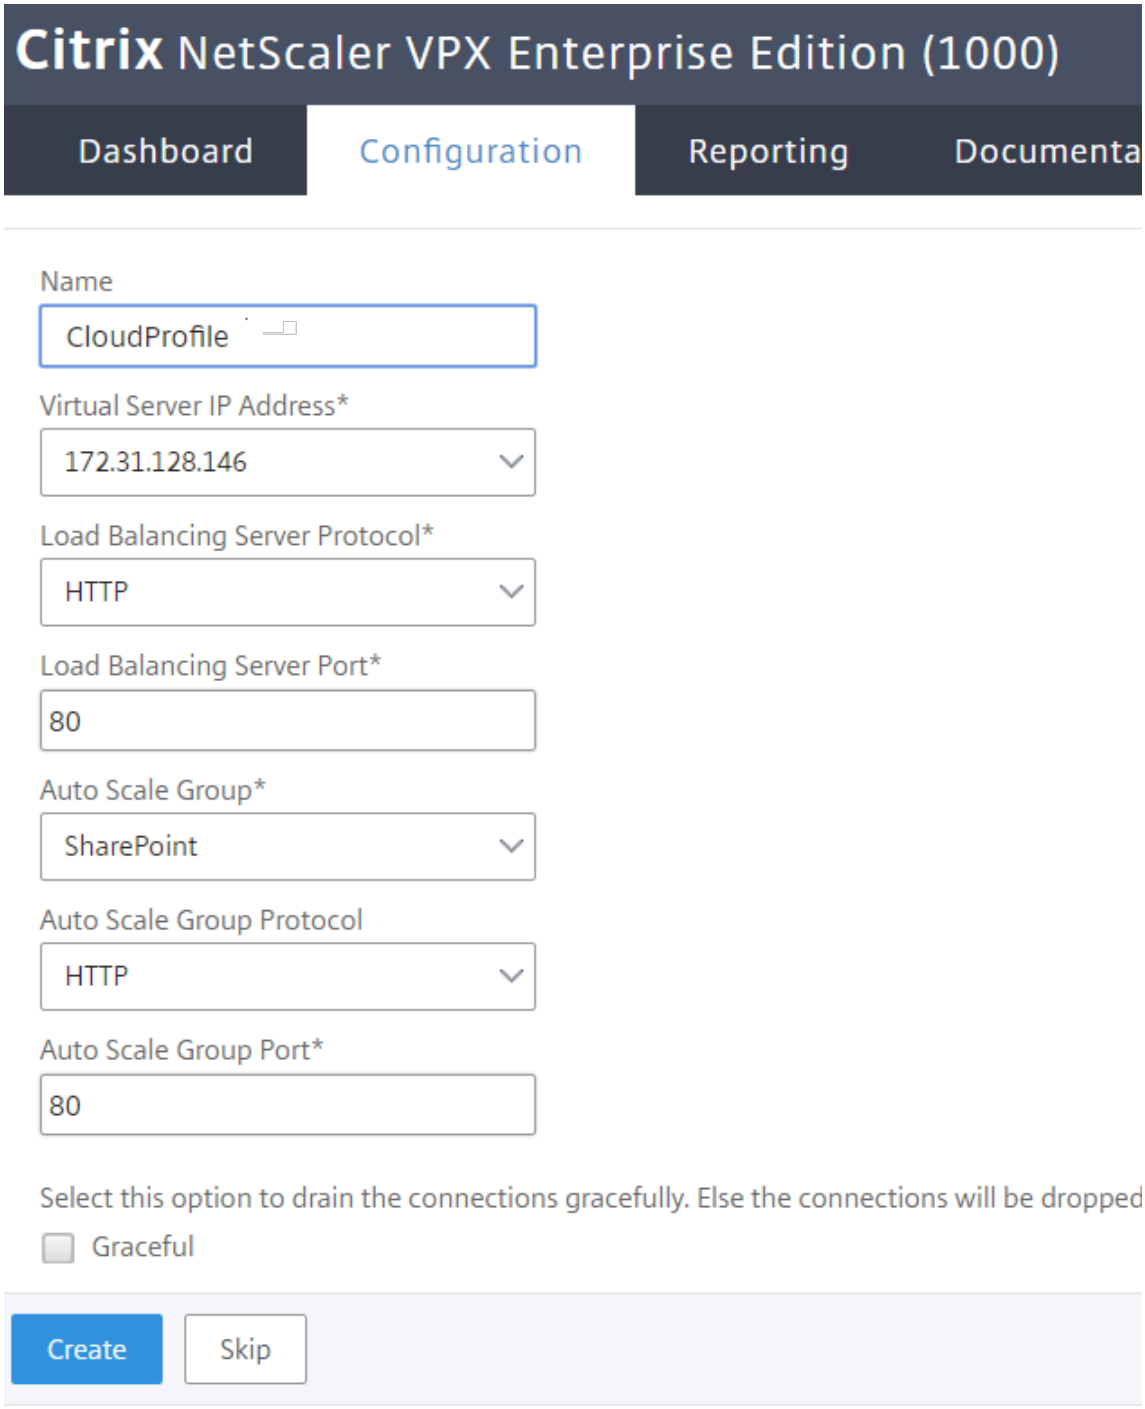
```
16
17                  "ec2:DetachNetworkInterface",
18
19                  "ec2:AttachNetworkInterface",
20
21                  "ec2:StartInstances",
22
23                  "ec2:StopInstances",
24
25                  "ec2:RebootInstances",
26
27                  "autoscaling:\*",
28
29                  "sns:\*",
30
31                  "sqs:\*"
32
33               “iam: SimulatePrincipalPolicy”
34
35               “iam: GetRole”
36
37              \],
38
39              "Resource": "\*",
40
41              "Effect": "Allow"
42
43           }
44
45
46      \]
47
48   }
49
50  <!--NeedCopy-->
```

Ensure the IAM Role of an instance has proper permissions.

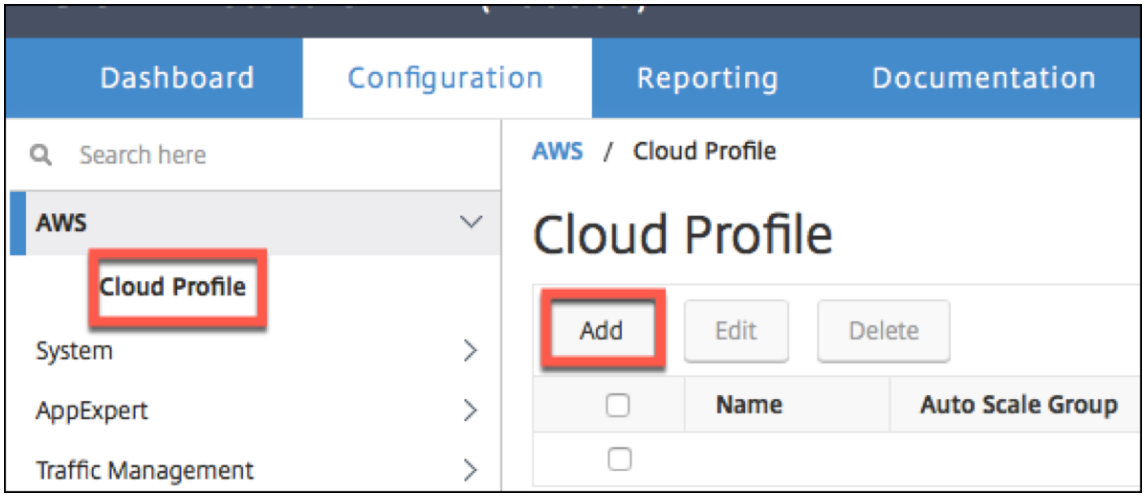
- The virtual server IP address is autopopulated from the free IP address available to the VPX instance. https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/MultipleIP.html#ManageMultipleIP
- Autoscale group is prepopulated from the Autoscale group configured on your AWS account. http://docs.aws.amazon.com/autoscaling/latest/userguide/AutoScalingGroup.html.

- While selecting the Autoscaling Group protocol and port, ensure your servers listen on those protocol and ports, and you bind the correct monitor in the service group. By default, the TCP monitor is used.
- For SSL Protocol type Autoscaling, after you create the Cloud Profile the load balance virtual server or service group is down because of a missing certificate. You can bind the certificate to the virtual server or service group manually.
- Select the Graceful Timeout option to remove Autoscale servers gracefully. If this option is not selected the server is the Autoscale group is removed immediately after the load goes down, which might cause service interruption for the existing connected clients. Selecting Graceful and giving a timeout means in the event of scale down. The VPX instance does not remove the server immediately but marks one of the servers for graceful deletion. During this period, the instance does not allow new connections to this server. Existing connection are served until the timeout occurs, and after a timeout, the VPX instance removes the server.

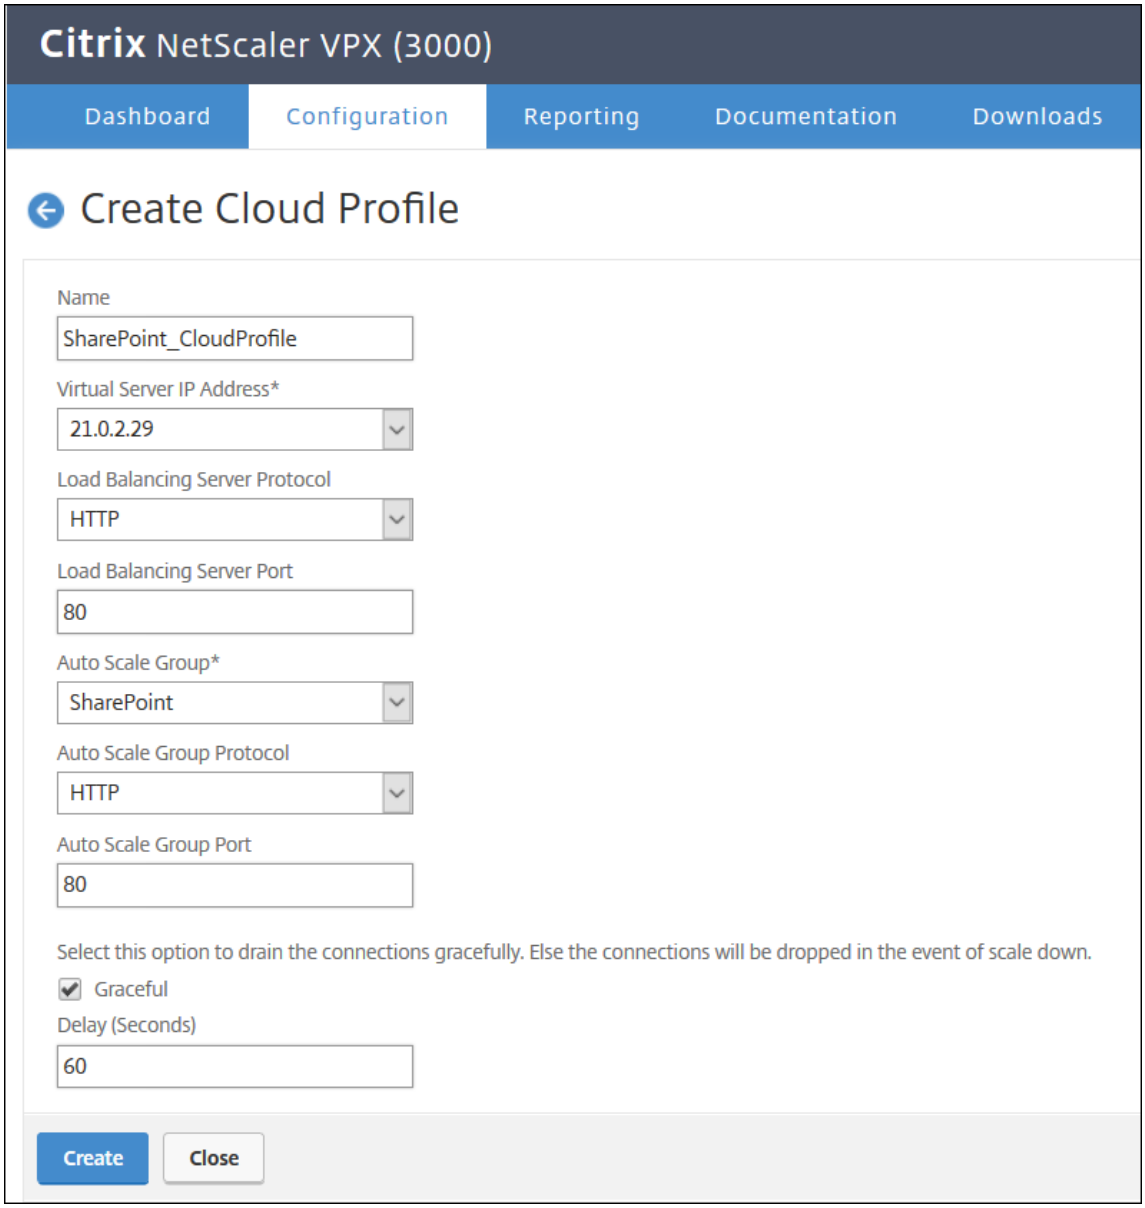
Figure: Default Cloud Profile page



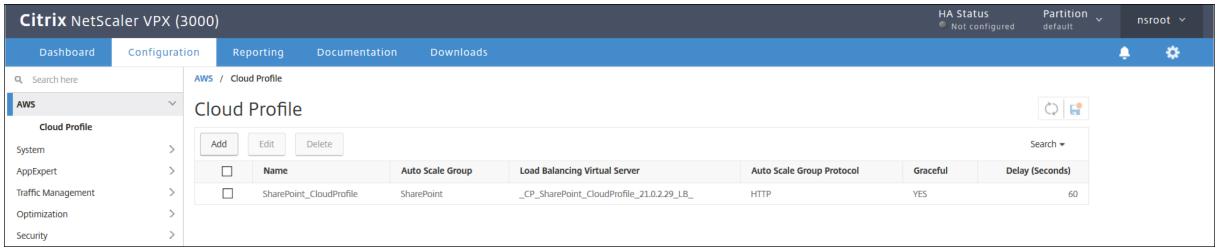
3. After the first time logon if you want to create Cloud Profile, on the GUI go to **System > AWS > Cloud Profile** and click **Add**.



The **Create Cloud Profile** configuration page appears.



Cloud Profile creates a Citrix ADC load-balancing virtual server and a service group with members as the servers of the Autoscaling group. Your back-end servers must be reachable through the SNIP configured on the VPX instance.



> **Note**
>
> To view Autoscale-related information in the AWS console, go to **EC2** > **Dashboard** > **Auto Scaling** > **Auto Scaling Group**.

Configure a Citrix ADC VPX instance to use SR-IOV network interface

September 14, 2021

> **Note**
>
> Support for SR-IOV interfaces in a high availability setup is available from Citrix ADC release 12.0 57.19 onwards.

After you have created a Citrix ADC VPX instance on AWS, you can configure the virtual appliance to use SR-IOV network interfaces, by using the AWS CLI.

In all Citrix ADC VPX models, except Citrix ADC VPX AWS Marketplace Editions of 3G and 5G, SR-IOV is not enabled in the default configuration of a network interface.

Before you start the configuration, read the following topics:

- Prerequisites
- Limitations and Usage Guidelines

This section includes the following topics:

- Change the Interface Type to SR-IOV
- Configure SR-IOV on a High Availability Setup

Change the interface type to SR-IOV

You can run the show interface summary command to check the default configuration of a network interface.

Example 1: The following CLI screen capture shows the configuration of a network interface where SR-IOV is enabled by default on Citrix ADC VPX AWS Marketplace Editions of 3G and 5G.

```
> show interface summary
-------------------------------------------------------------------------
      Interface  MTU       MAC                Suffix
-------------------------------------------------------------------------
1       1/1      1500      0a:1e:2e:17:a2:37  Intel 82599 10G VF Interface
2       LO/1     1500      0a:1e:2e:17:a2:37  Netscaler Loopback interface
 Done
```

Example 2: The following CLI screen capture shows the default configuration of a network interface where SR-IOV is not enabled.

```
 Done
> sh int s
-------------------------------------------------------------------------------
      Interface  MTU        MAC                Suffix
-------------------------------------------------------------------------------
1     1/1        1500       12:fc:04:c5:d0:12  NetScaler Virtual Interface
2     LO/1       1500       12:fc:04:c5:d0:12  Netscaler Loopback interface
 Done
>
```

For more information about changing the interface type to SR-IOV, see http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/sriov-networking.html

To change the interface type to SR-IOV

1. Shut down the Citrix ADC VPX instance running on AWS.
2. To enable SR-IOV on the network interface, type the following command in the AWS CLI.

   ```
   $ aws ec2 modify-instance-attribute --instance-id \<instance\\_id\> --sriov-net-support simple
   ```

3. To check if SR-IOV has been enabled, type the following command in the AWS CLI.

   ```
   $ aws ec2 describe-instance-attribute --instance-id \<instance\\_id\> --attribute sriovNetSupport
   ```

   Example 3: Network interface type changed to SR-IOV, by using the AWS CLI.

   ```
   aws ec2 modify-instance-attribute --instance-id i-008c1230aaf303bee --sriov-net-support simple
   aws ec2 describe-instance-attribute --instance-id   i-008c1230aaf303bee  --attribute sriovNetSupport
   {
       "InstanceId": "i-008c1230aaf303bee",
       "SriovNetSupport": {
           "Value": "simple"
       }
   }
   ```

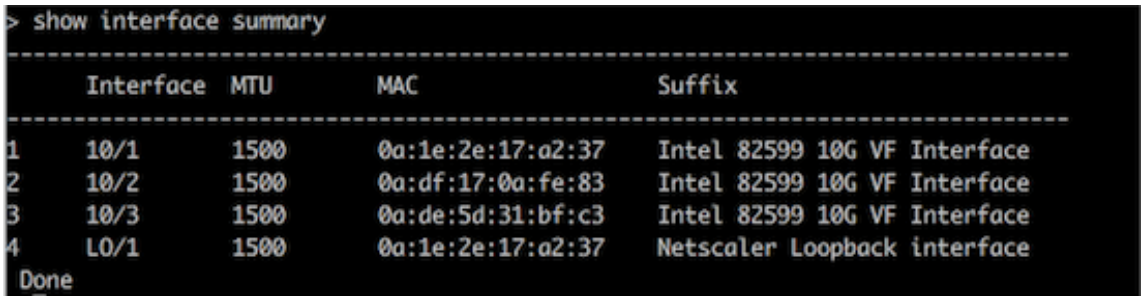
   If SR-IOV is not enabled, value for SriovNetSupport is absent.

   Example 4: In the following example, SR-IOV support is not enabled.

   ```
   {
       "InstanceId": "i-0c3e84cfa65b04cc8",
       "SriovNetSupport": {}
   }
   ```

4. Power on the VPX instance. To see the changed status of the network interface, type “show interface summary” in the CLI.

Example 5: The following screen capture shows the network interfaces with SR-IOV enabled. The interfaces 10/1, 10/2, 10/3 are SR-IOV enabled.



These steps complete the procedure to configure VPX instances to use SR-IOV network interfaces.

Configure SR-IOV on a high availability setup

High availability is supported with SR-IOV interfaces from Citrix ADC release 12.0 build 57.19 onwards.

If the high availability setup was deployed manually or by using the Citrix CloudFormation template for Citrix ADC version 12.0 56.20 and lower, the IAM role attached to the high availability setup must have the following privileges:

- ec2:DescribeInstances
- ec2:DescribeNetworkInterfaces
- ec2:DetachNetworkInterface
- ec2:AttachNetworkInterface
- ec2:StartInstances
- ec2:StopInstances
- ec2:RebootInstances
- autoscaling:*
- sns:*
- sqs:*
- IAM:SimulatePrincipalPolicy
- IAM:GetRole

By default, the Citrix CloudFormation template for Citrix ADC version 12.0 57.19 automatically adds the required privileges to the IAM role.

> **Note**
>
> A high availability setup with SR-IOV Interfaces takes around 100 seconds of downtime.

Related resources:

For more information about IAM roles, see AWS documentation.

Configure a Citrix ADC VPX instance to use Enhanced Networking with AWS ENA

September 14, 2021

After you have created a Citrix ADC VPX instance on AWS, you can configure the virtual appliance to use Enhanced Networking with AWS Elastic Network Adapter (ENA), by using AWS CLI.

Coupled with AWS ENA, enhanced networking provides higher bandwidth, higher packet-per-second (PPS) performance, and consistently lower inter-instance latencies.

Before you start the configuration, read the following topics:

- Prerequisites
- Limitations and Usage Guidelines

The following HA configurations are supported for ENA-enabled instances:

- Private IP addresses can be moved within the same availability zone.
- Elastic IP addresses can be moved across availability zones.

Upgrade a Citrix ADC VPX instance on AWS

September 14, 2021

You can upgrade the EC2 instance type, throughput, software edition, and the system software of a Citrix ADC VPX running on AWS. For certain types of upgrades, Citrix recommends using the High Availability Configuration method to minimize downtime.

> Note:
>
> - Citrix ADC software release 10.1.e-124.1308.e or later for a Citrix ADC VPX AMI (including both utility license and customer license) does not support the M1 and M2 instance families.
> - Because of changes in VPX instance support, downgrading from 10.1.e-124 or a later release to 10.1.123.x or an earlier release is not supported.
> - Most of the upgrades do not require the launch of a new AMI, and the upgrade can be done on the current Citrix ADC AMI instance. If you do want to upgrade to a new Citrix ADC AMI instance, use the high availability configuration method.

Change the EC2 instance type of a Citrix ADC VPX instance on AWS

If your Citrix ADC VPX instances are running release 10.1.e-124.1308.e or later, you can change the EC2 instance type from the AWS console as follows:

1. Stop the VPX instance.
2. Change the EC2 instance type from the AWS console.
3. Start the instance.

You can also use the above procedure to change the EC2 instance type for a release, earlier than 10.1.e-124.1308.e, unless you want to change the instance type to M3. In that case, you must first follow the standard Citrix ADC upgrade procedure, at, to upgrade the Citrix ADC software to 10.1.e-124 or a later release, and then follow the above steps.

Upgrade the throughput or software edition of a Citrix ADC VPX instance on AWS

To upgrade the software edition (for example, to upgrade from Standard to Premium edition) or throughput (for example, to upgrade from 200 Mbps to 1000mbps), the method depends on the instance's license.

Using a customer license (Bring-Your-Own-License)

If you are using a customer license, you can purchase and download the new license from the Citrix website, and then install the license on the VPX instance. For more information about downloading and installing a license from the Citrix website, see the VPX Licensing Guide.

Using a utility license (Utility license with hourly fee)

AWS does not support direct upgrades for fee-based instances. To upgrade the software edition or throughput of a fee based Citrix ADC VPX instance, launch a new AMI with the desired license and capacity and migrate the older instance configuration to the new instance. This can be achieved by using a Citrix ADC high availability configuration as described in Upgrade to a new Citrix ADC AMI instance by using a Citrix ADC high availability configuration subsection in this page.

Upgrade the system software of a Citrix ADC VPX instance on AWS

If you need to upgrade a VPX instance running 10.1.e-124.1308.e or a later release, follow the standard Citrix ADC upgrade procedure at Upgrade and downgrade a Citrix ADC appliance.

If you need to upgrade a VPX instance running a release older than 10.1.e-124.1308.e to 10.1.e-124.1308.e or a later release, first upgrade the system software, and then change the instance type to M3 as follows:

1. Stop the VPX instance.
2. Change the EC2 instance type from the AWS console.
3. Start the instance.

Upgrade to a new Citrix ADC AMI instance by using a Citrix ADC high availability configuration

To use the high availability method of upgrading to a new Citrix ADC AMI instance, perform the following tasks:

- Create a new instance with the desired EC2 instance type, software edition, throughput, or software release from the AWS marketplace.
- Configure high availability between the old instance (to be upgraded) and the new instance. After high availability is configured between the old and the new instance, configuration from the old instance is synchronized to the new instance.
- Force an HA failover from the old instance to the new instance. As a result, the new instance becomes primary and starts receiving traffic.
- Stop, and reconfigure or remove the old instance from AWS.

Prerequisites and points to consider

- Ensure you understand how high availability works between two Citrix ADC VPX instances on AWS. For more information about high availability configuration between two Citrix ADC VPX instances on AWS, see Deploy a high availability pair on AWS.
- You must create the new instance in the same availability zone as the old instance, having the exact same security group and subnet.
- High availability setup requires access and secret keys associated with the user's AWS Identity and Access Management (IAM) account for both instances. If the correct key information is not used when creating VPX instances, the HA setup fails. For more information about creating an IAM account for a VPX instance, see Prerequisites.
  - You must use the EC2 console to create the new instance. You cannot use the AWS 1-click launch, because it does not accept the access and secret keys as the input.
  - The new instance must have only one ENI interface.

To upgrade a Citrix ADC VPX Instance by using a high availability configuration, follow these steps:

1. Configure high availability between the old and the new instance. To configure high availability between two Citrix ADC VPX instances, at the command prompt of each instance, type:

   - `add ha node <nodeID> <IPaddress of the node to be added>`
   - `save config`

   Example:

   At the command prompt of the old instance, type:

   ```
   1 add ha node 30 192.0.2.30
   2 Done
   3 <!--NeedCopy-->
   ```

At the command prompt of the new instance, type:

```
add ha node 10 192.0.2.10
Done
<!--NeedCopy-->
```

Note the following:

- In the HA setup, the old instance is the primary node and the new instance is the secondary node.
- The NSIP IP address is not copied from the old instance to the new instance. Therefore, after the upgrade, your new instance has a different management IP address from the previous one.
- The `nsroot` account password of the new instance is set to that of the old instance after HA synchronization.

For more information about high availability configuration between two Citrix ADC VPX instances on AWS, see Deploy a high availability pair on AWS.

2. Force an HA failover. To force a failover in a high availability configuration, at the command prompt of either of the instances, type:

```
force HA failover
<!--NeedCopy-->
```

As the result of forcing a failover, the ENIs of the old instance are migrated to the new instance and traffic flows through the new instance (the new primary node). The old instance (the new secondary node) restarts.

If the following warning message appears, type N to abort the operation:

```
[WARNING]:Force Failover may cause configuration loss, peer health
    not optimum. Reason(s):
HA version mismatch
HA heartbeats not seen on some interfaces
Please confirm whether you want force-failover (Y/N)?
<!--NeedCopy-->
```

The warning message appears because the system software of the two VPX instances is not HA compatible. As a result, the configuration of the old instance cannot be automatically synced to the new instance during a forced failover.

Following is the workaround for this issue:

a) At the Citrix ADC shell prompt of the old instance, type the following command to create a backup of the configuration file (ns.conf):

```
copy /nsconfig/ns.conf to /nsconfig/ns.conf.bkp
```

b) Remove the following line from the backup configuration file (ns.conf.bkp):

- `set ns config -IPAddress <IP> -netmask <MASK>`

For example, `set ns config -IPAddress 192.0.2.10 -netmask 255.255.255.0`

c) Copy the old instance's backup configuration file (ns.conf.bkp) to the /nsconfig directory of the new instance.

d) At the Citrix ADC shell prompt of the new instance, type the following command to load the old instance's configuration file (ns.conf.bkp) on the new instance:

- `batch -f /nsconfig/ns.conf.bkp`

e) Save the configuration on the new instance.

- `save conifg`

f) At the command prompt of either of the nodes, type the following command to force a failover, and then type Y for the warning message to confirm the force failover operation:

- `force ha failover`

Example:

```
1         > force ha failover
2
3 WARNING]:Force Failover may cause configuration loss, peer health
     not optimum.
4         Reason(s):
5         HA version mismatch
6         HA heartbeats not seen on some interfaces
7         Please confirm whether you want force-failover (Y/N)? Y
8 <!--NeedCopy-->
```

3. Remove the HA configuration, so that the two instances are no longer in an HA configuration. First remove the HA configuration from the secondary node and then remove the HA configuration from the primary node.

   To remove an HA configuration between two Citrix ADC VPX instances, at the command prompt of each instance, type:

```
1     > remove ha node \<nodeID\>
2     >  save config
3 <!--NeedCopy-->
```

For more information about high availability configuration between two VPX instances on AWS, see Deploy a high availability pair on AWS.

Example:

At the command prompt of the old instance (new secondary node), type:

```
1          > remove ha node 30
2            Done
3          > save config
4            Done
5  <!--NeedCopy-->
```

At the command prompt of the new instance (new primary node), type:

```
1          > remove ha node 10
2            Done
3          > save config
4            Done
5  <!--NeedCopy-->
```

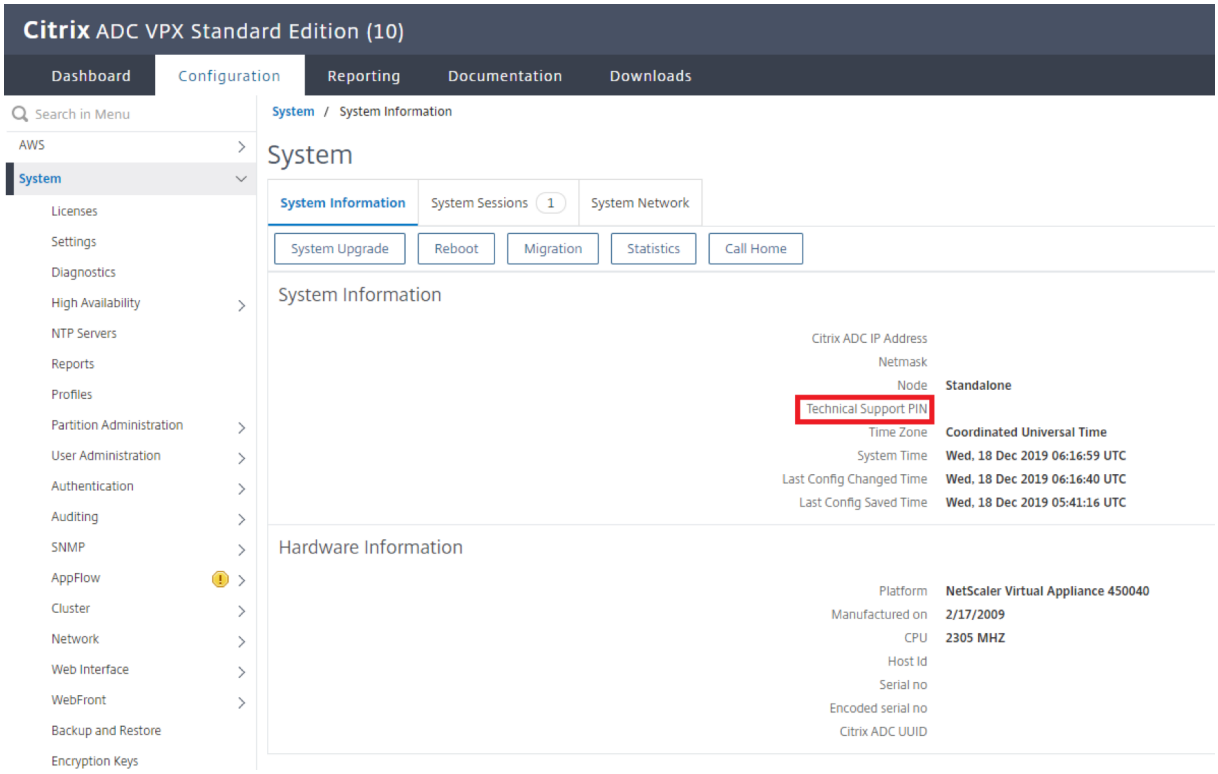
Troubleshoot a VPX instance on AWS

September 14, 2021

Amazon does not provide console access to a Citrix ADC VPX instance. To troubleshoot, you have to use the AWS GUI to view the activity log. You can debug only if the network is connected. To view an instance's System Log, right-click the instance and select System Log.

Citrix provides support for AWS Marketplace-licensed Citrix ADC VPX instances (utility license with hourly fee) on AWS. To file a support case, find your AWS account number and support PIN code, and call Citrix support. You will also be asked for your name and email address. To find the support PIN, log on to the VPX GUI and navigate to the System page.

Here is an example of a system page showing the support PIN.



AWS FAQs

September 14, 2021

- **Does a Citrix ADC VPX instance support the encrypted volumes in AWS?**

  Encryption and decryption happen at the hypervisor level, and hence it works seamlessly with any instance. For more information about the encrypted volumes see the following AWS document:

  https://docs.aws.amazon.com/kms/latest/developerguide/services-ebs.html

- **What is the best way to provision Citrix ADC VPX instance on AWS?**

  You can provision a Citrix ADC VPX instance on AWS by any of the following ways:

  - AWS CloudFormation Template (CFT) in AWS marketplace
  - Citrix ADM
  - AWS Quick Starts
  - Citrix AWS CFTs in GitHub
  - Citrix Terraform Scripts in GitHub
  - Citrix Ansible Playbooks in GitHub
  - AWS EC2 launch workflow

You can choose any of the listed options based on the automation tool that you use.

For more details about the options, see Citrix ADC VPX on AWS.

- **How to upgrade Citrix ADC VPX instance in AWS?**

  To upgrade the Citrix ADC VPX instance in AWS, you can upgrade the system software or upgrade to a new Citrix ADC VPX Amazon Machine Image (AMI) by following the procedure at Upgrade a Citrix ADC VPX instance on AWS.

  The recommended way to upgrade a Citrix ADC VPX instance is using the ADM service by following the procedure at Use jobs to upgrade Citrix ADC instances.

- **What is the HA failover time for Citrix ADC VPX in AWS?**

  - HA failover of Citrix ADC VPX within the AWS availability zone takes around 3 seconds.
  - HA failover of Citrix ADC VPX across AWS availability zones takes around 5 seconds.

- **What level of support is provided for Citrix ADC VPX marketplace subscription customers who provide the technical support PIN?**

  By default, the "Select for Software" service is provided to customers who provide the technical support PIN.

- **In High availability across different zones using Elastic IP deployment, do we need to create Multiple IPSets for each application?**

  Yes. If there are multiple applications with multiple VIPs mapped to multiple EIPs then multiple IPSets are required. Therefore during HA failover, all the primary VIP mappings of EIPs are changed to secondary (new primary) VIPs.

- **Why is INC mode enabled in high availability across different zone deployments?**

  HA pairs across availability zones are in different networks. For HA synchronization, network configuration must not be synchronized. This is achieved by enabling INC mode on HA pair.

- **Can HA node in one availability zone communicate with back-end servers in another availability zone, provided those availabilty zones are in same VPC?**

  Yes, subnets in different availability zones of the same VPC are reachable by adding an extra route pointing to the backend-server subnet via SNIP. For example, if the SNIP subnet of ADC in AZ1 is 192.168.3.0/24 and the backend-server subnet in AZ2 is 192.168.6.0/24, then a route must be added in the Citrix ADC appliance present in AZ1 as 192.168.6.0 255.255.255.0 192.168.3.1.

- **Can High availability across different zones using Elastic IP and High availability across different zones using Private IP deployments work together?**

  Yes, both the configurations can be applied on the same HA Pair.

- **In High availability across different zones using Private IP deployment, if there are multiple subnets with multiple route tables in a VPC, how does a secondary node in HA pair know about the route table to be checked during HA failover?**

  Secondary node is aware of the primary NICs and searches across all the route tables in a VPC.

- **What is the size of the /var partition when using the default image for VPX on AWS? How to increase the disk space?**

  The size of the root disk is limited to 20 GB to keep the disk image small.

  If you want to increase the /var/core/ or the /var/crash/ directory space, attach an extra disk. To increase the /var size, currently, you must attach an extra disk and create a symbolic link to /var, after copying the critical contents to the new disk.

- **How many packet engines are activated and allocated to vCPUs?**

  The packet engines (PEs) are limited by the number of licensed vCPUs. The Citrix ADC daemons are not pinned to any particular vCPU and might run on any of the non-PE vCPUs. According to AWS, the C5.9xlarge is a 36vCPU instance with 72 GB memory. With pooled licensing, the Citrix ADC VPX instance deploys with the maximum number of PEs. In this case, 19 PEs run on cores 1–19. However, ADC management processes run from CPUs 20–31.

- **How to decide the right AWS instance for ADC?**

  1. Understand your use case and requirements like throughput, PPS, SSL requirement, and average packet size.
  2. Choose the right ADC offering and licensing that meets your requirements, such as VPX bandwidth offerings or vCPU based licensing.
  3. Based on the chosen offering, decide on the AWS instance.

  Example:

  A 5 Gbps license enables 5 data packet engines. Hence, the vCPU requirement is 6 (5+1 for management). But 6 vCPU instance is not available. So an 8 vCPU is good enough to reach that throughput provided you choose a network that supports 5 Gbps bandwidth. For example, you must choose m5.2xlarge for a 5 Gbps bandwidth license to enable max PE allocation for 5 Gbps license. But if you use vCPU license that is not limited by throughput, you might get 5 Gbps throughput using the m5.xlarge instance itself.

Instance Size	vCPU	Memory (GiB)	Instance Storage (GiB)	Network Bandwidth (Gbps)	EBS Bandwidth (Mbps)
m5.large	2	8	EBS-Only	Up to 10	Up to 4,750
m5.xlarge	4	16	EBS-Only	Up to 10	Up to 4,750
m5.2xlarge	8	32	EBS-Only	Up to 10	Up to 4,750
m5.4xlarge	16	64	EBS-Only	Up to 10	4,750

- **Is three NICs-three subnets deployment mandatory for ADC in AWS**?

  `Three NICs-three subnets` is the recommended deployment, where each one for management, client and server network. This deployment gives better traffic isolation and VPX performance. Two NICs-two subnets, and one NIC-one subnet are the other available options. Citrix don't recommend multiple NICs sharing a subnet in AWS, such as two NICs–one subnet deployment. Because it might lead to networking issues such as asymmetric routing. For more information, see Best practices for configuring network interfaces in AWS.

Deploy a Citrix ADC VPX instance on Microsoft Azure

September 14, 2021

When you deploy a Citrix ADC VPX instance on Microsoft Azure Resource Manager (ARM), you can use both of the following feature sets to achieve your business needs:

- Azure cloud computing capabilities
- Citrix ADC load balancing and traffic management features

You can deploy Citrix ADC VPX instances on ARM either as standalone instances or as high availability pairs in active-standby modes.

You can deploy a Citrix ADC VPX instance on the Microsoft Azure in two ways:

- Through Azure Marketplace. The Citrix ADC VPX virtual appliance is available as an image in the Microsoft Azure Marketplace.
- Using the Citrix ADC Azure Resource Manager (ARM) json template available on GitHub.For more information, see the GitHub repository for Citrix NetScaler solution templates.

The Microsoft Azure stack is an integrated platform of hardware and software that delivers the Microsoft Azure public cloud services in a local data center to let organizations construct hybrid clouds. You can now deploy the Citrix ADC VPX instances on the Microsoft Azure stack.

Prerequisite

You need some prerequisite knowledge before deploying a Citrix VPX instance on Azure.

- Familiarity with Azure terminology and network details. For information, see Azure terminology.
- Knowledge of a Citrix ADC appliance. For detailed information the Citrix ADC appliance, see Citrix ADC
- Knowledge of Citrix ADC networking. See the Networking topic.

How a Citrix ADC VPX instance works on Azure

In an on-premises deployment, a Citrix ADC VPX instance requires at least three IP addresses:

- Management IP address, called NSIP address
- Subnet IP (SNIP) address for communicating with the server farm
- Virtual server IP (VIP) address for accepting client requests

For more information, see Network architecture for Citrix ADC VPX instances on Microsoft Azure.

> **Note**
>
> VPX virtual appliances can be deployed on any instance type that has two or more Intel VT-X cores and more than 2 GB memory. For more information on system requirements, see Citrix ADC VPX data sheet. Currently, Citrix ADC VPX instance supports only the Intel processors.

In an Azure deployment, you can provision a Citrix ADC VPX instance on Azure in three ways:

- Multi-NIC multi-IP architecture
- Single NIC multi IP architecture
- Single NIC single IP

Depending on your need, you can use any of these supported architecture types.

Multi-NIC multi-IP architecture

In this deployment type, you can have more than one network interfaces (NICs) attached to a VPX instance. Any NIC can have one or more IP configurations - static or dynamic public and private IP addresses assigned to it.

For more information, see the following use cases:

- Configure a high-availability setup with multiple IP addresses and NICs
- Configure a high-availability setup with multiple IP addresses and NICs by using PowerShell commands

> Note
>
> To avoid MAC moves and interface mutes on Azure environments, Citrix recommends you to create a VLAN per data interface (without tag) of ADC VPX instance and bind the primary IP of NIC in Azure. For more information, see CTX224626 article.

Single NIC multi IP architecture

In this deployment type, one network interfaces (NIC) associated with multiple IP configurations - static or dynamic public and private IP addresses assigned to it.
For more information, see the following use cases:

- Configure multiple IP addresses for a Citrix ADC VPX standalone instance
- Configure multiple IP addresses for a Citrix ADC VPX standalone instance by using PowerShell commands

Single NIC single IP

In this deployment type, one network interfaces (NIC) associated with a single IP address, which is used to perform the functions of NSIP, SNIP, and VIP.

For more information, see the following use case:

- Configure a Citrix ADC VPX standalone instance

> **Note**
>
> The single IP mode is available only in Azure deployments. This mode is not available for a Citrix ADC VPX instance on your premises, on AWS, or in other type of deployment.

Citrix ADC VPX licensing

A Citrix ADC VPX instance on Azure requires a license. The following licensing options are available for Citrix ADC VPX instances running on Azure.

- **Subscription-based licensing**: Citrix ADC VPX appliances are available as paid instances on Azure Marketplace. Subscription based licensing is a pay-as-you-go option. Users are charged hourly. The following VPX models and license types are available on Azure Marketplace.

VPX model	License type	Recommended instance
VPX10	Standard, Advanced, Premium	Standard_D2s_v4
VPX200	Standard, Advanced, Premium	Standard_D2s_v4
VPX1000*	Standard, Advanced, Premium	Standard_D4s_v4
VPX3000*	Standard, Advanced, Premium	Standard_D8s_v4

> *: For VPX 1000 and VPX 3000 models, you must enable Accelerated networking on Citrix ADC VPX instances to get the desired performance.

Citrix provides technical support for subscription-based license instances. To file a support case, see Support for Citrix ADC on Azure – Subscription license with hourly price.

- **Bring your own license (BYOL)**: If you bring your own license (BYOL), see the VPX Licensing Guide at http://support.citrix.com/article/CTX122426. You have to:
  - Use the licensing portal within Citrix website to generate a valid license.
  - Upload the license to the instance.

VPX model	License type	Recommended instance
VPX10	Standard, Advanced, Premium	Standard_D2s_v4
VPX200	Standard, Advanced, Premium	Standard_D2s_v4
VPX1000*	Standard, Advanced, Premium	Standard_D4s_v4
VPX3000*	Standard, Advanced, Premium	Standard_D8s_v4
VPX5000*	Standard, Advanced, Premium	Standard_D8s_v4
VPX8000*	Standard, Advanced, Premium	Standard_D8s_v4
VPX10000*	Standard, Advanced, Premium	Standard_D16s_v4

> *: From VPX 1000 to VPX 10000 models, you must enable Accelerated networking on Citrix ADC VPX instances to get the desired performance.

- **Citrix ADC VPX Check-In/Check-Out licensing**: For more information, see Citrix ADC VPX Check-In/Check-Out Licensing.

> **Note**
>
> In an Azure stack environment, **BYOL** is the only available licensing option.

Starting with NetScaler release 12.0 56.20, VPX Express for on-premises and cloud deployments does not require a license file. For more information on Citrix ADC VPX Express, see the "Citrix ADC VPX Express license" section in Citrix ADC licensing overview.

> **Note**
>
> Regardless of the subscription-based hourly license bought from Azure Marketplace, in rare cases, the Citrix ADC VPX instance deployed on Azure might come up with a default Citrix ADC license. This happens due to issues with the Azure Instance Metadata Service (IMDS).

> Do a warm restart before making any configuration change on the Citrix ADC VPX instance, to enable the correct Citrix ADC VPX license.

Limitations

Running the Citrix ADC VPX load balancing solution on ARM imposes the following limitations:

- The Azure architecture does not accommodate support for the following NetScaler features:
  - IPv6
  - Gratuitous ARP (GARP)
  - L2 Mode
  - Tagged VLAN
  - Dynamic Routing
  - virtual MAC
  - USIP
  - Jumbo Frames
  - Clustering

  > Note
  >
  > With the Citrix Application Delivery Management (ADM) Autoscale feature (cloud deployment), the ADC instances support clustering on all licenses. For information, see Autoscaling of Citrix ADC VPX in Microsoft Azure using Citrix ADM.

- If you expect that you might have to shut down and temporarily deallocate the Citrix ADC VPX virtual machine at any time, assign a static Internal IP address while creating the virtual machine. If you do not assign a static internal IP address, Azure might assign the virtual machine a different IP address each time it restarts, and the virtual machine might become inaccessible.
- In an Azure deployment, only the following Citrix ADC VPX models are supported: VPX 10, VPX 200, VPX 1000, and VPX 3000. For for information, see the Citrix ADC VPX Data Sheet.

  If you use a Citrix ADC VPX instance with a model number higher than VPX 3000, the network throughput might not be the same as specified by the instance's license. However, other features such as SSL throughput and SSL transactions per second might improve.
- The "deployment ID" that is generated by Azure during virtual machine provisioning is not visible to the user in ARM. You cannot use the deployment ID to deploy Citrix ADC VPX appliance on ARM.
- The Citrix ADC VPX instance supports 20 Mb/s throughput and standard edition features when it's initialized.
- The Citrix ADC VPX instances on Azure with accelerated networking enabled, provides better performance. Azure accelerated networking is supported on Citrix ADC VPX instances from release

13.0 build 76.x onwards. To enable accelerated networking on ADC VPX, Citrix recommends you to use an Azure instance type which supports accelerated networking.

- For a XenApp and XenDesktop deployment, a VPN virtual server on a VPX instance can be configured in the following modes:
  - Basic mode, where the `ICAOnly` VPN virtual server parameter is set to ON. The Basic mode works fully on an unlicensed Citrix ADC VPX instance.
  - SmartAccess mode, where the `ICAOnly` VPN virtual server parameter is set to OFF. The SmartAccess mode works for only five Citrix ADC AAA session users on an unlicensed Citrix ADC VPX instance.

> **Note**
>
> To configure the SmartControl feature, you must apply a Premium license to the Citrix ADC VPX instance.

Azure terminology

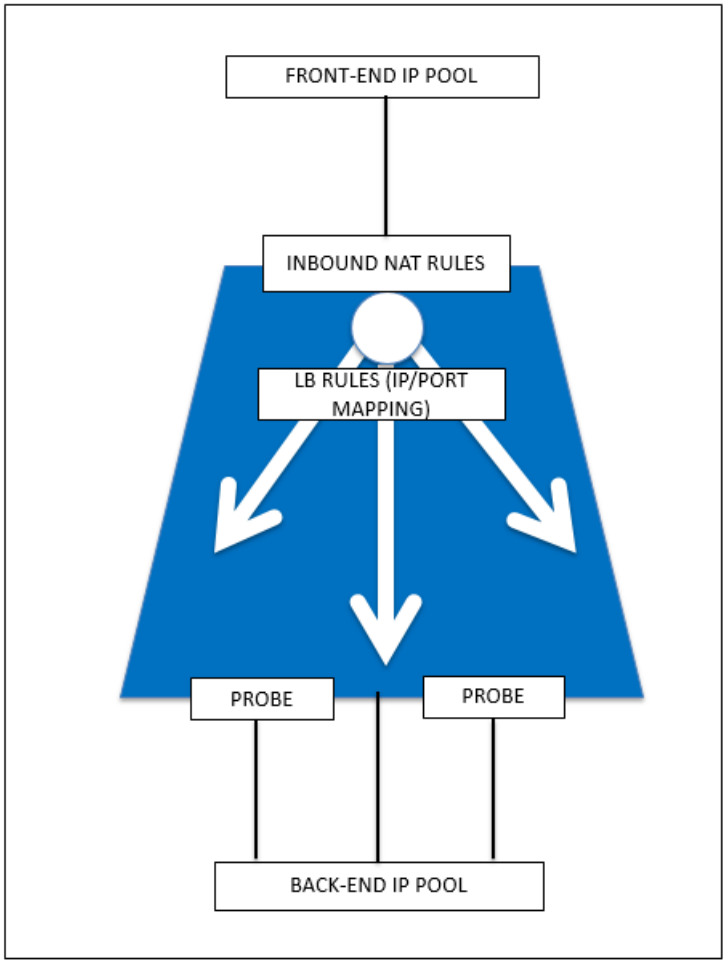
September 14, 2021

Some of the Azure terms that are used in the Citrix ADC VPX Azure documentation are listed below.

1. Azure Load Balancer – Azure load balancer is a resource that distributes incoming traffic among computers in a network. Traffic is distributed among virtual machines defined in a load-balancer set. A load balancer can be external or internet-facing, or it can be internal.
2. Azure Resource Manager (ARM) – ARM is the new management framework for services in Azure. Azure Load Balancer is managed using ARM-based APIs and tools.
3. Back-End Address Pool – These are IP addresses associated with the virtual machine NIC (NIC) to which load will be distributed.
4. BLOB - Binary Large Object – Any binary object like a file or an image that can be stored in Azure storage.
5. Front-End IP Configuration – An Azure Load balancer can include one or more front-end IP addresses, also known as a virtual IPs (VIPs). These IP addresses serve as ingress for the traffic.
6. Instance Level Public IP (ILPIP) – An ILPIP is a public IP address that you can assign directly to your virtual machine or role instance, rather than to the cloud service that your virtual machine or role instance resides in. This does not take the place of the VIP (virtual IP) that is assigned to your cloud service. Rather, it's an extra IP address that you can use to connect directly to your virtual machine or role instance.

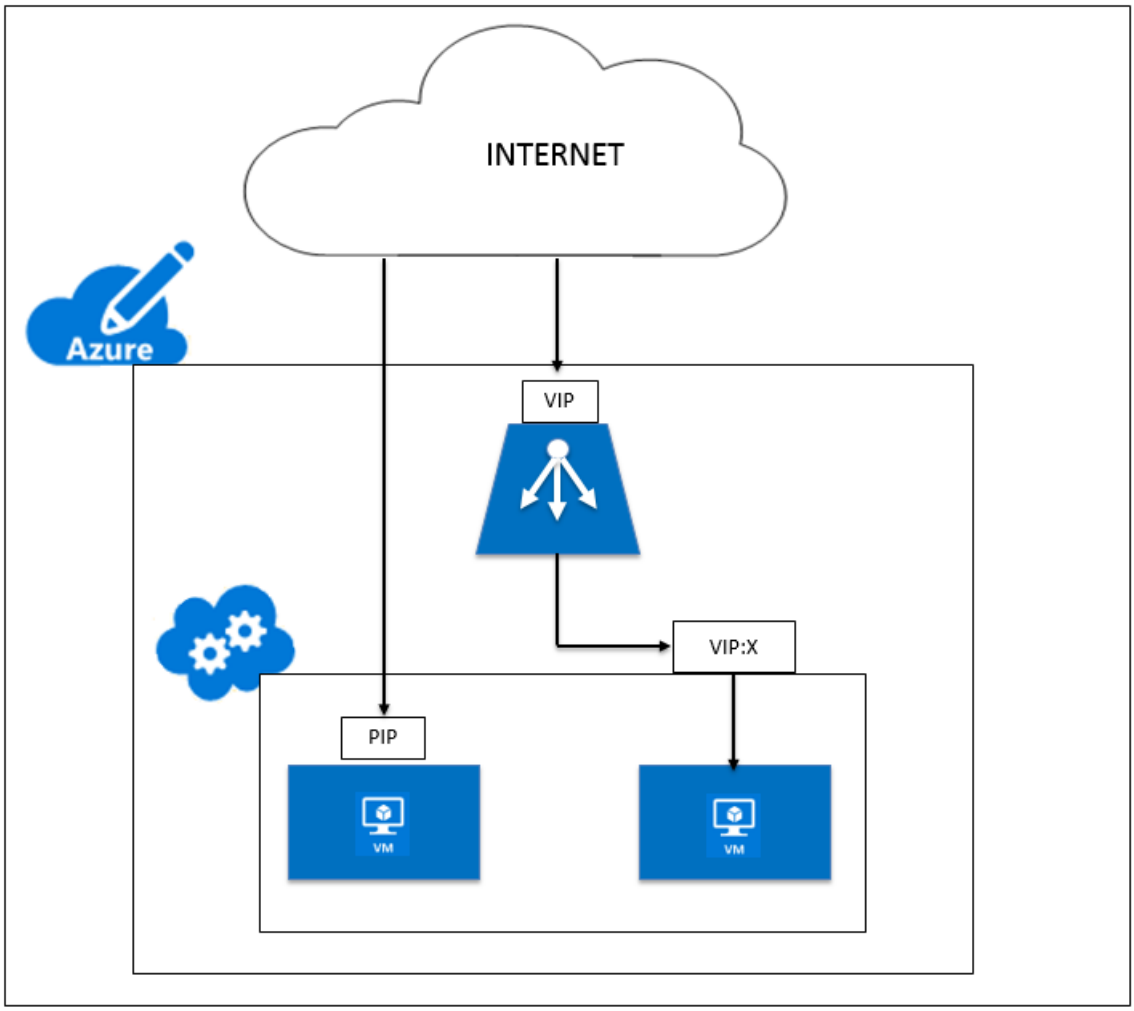
   Note: In the past, an ILPIP was referred to as a PIP, which stands for public IP.

7. Inbound NAT Rules – This contains rules mapping a public port on the load balancer to a port for a specific virtual machine in the back end address pool.
8. IP-Config - It can be defined as an IP address pair (public IP and private IP) associated with an individual NIC. In an IP-Config, the public IP address can be NULL. Each NIC can have multiple IP-Config associated with it, which can be up to 255.
9. Load Balancing Rules – A rule property that maps a given front-end IP and port combination to a set of back-end IP addresses and port combination. With a single definition of a load balancer resource, you can define multiple load balancing rules, each rule reflecting a combination of a front end IP and port and back end IP and port associated with virtual machines.



10. Network security group – Contains a list of Access Control List (ACL) rules that allow or deny network traffic to your virtual machine instances in a virtual network. NSGs can be associated with either subnets or individual virtual machine instances within that subnet. When a network security group is associated with a subnet, the ACL rules apply to all the virtual machine instances in that subnet. In addition, traffic to an individual virtual machine can be restricted further by associating a network security group directly to that virtual machine.

11. Private IP addresses – Used for communication within an Azure virtual network, and your on-premises network when you use a VPN gateway to extend your network to Azure. Private IP addresses allow Azure resources to communicate with other resources in a virtual network or an on-premises network through a VPN gateway or ExpressRoute circuit, without using an Internet-reachable IP address. In the Azure Resource Manager deployment model, a private IP address is associated with the following types of Azure resources – virtual machines, internal load balancers (ILBs), and application gateways.
12. Probes – This contains health probes used to check availability of virtual machines instances in the back end address pool. If a particular virtual machine does not respond to health probes for some time, then it is taken out of traffic serving. Probes enable you to keep track of the health of virtual instances. If a health probe fails, the virtual instance will be taken out of rotation automatically.
13. Public IP Addresses (PIP) – PIP is used for communication with the Internet, including Azure public-facing services and is associated with virtual machines, Internet-facing load balancers, VPN gateways, and application gateways.
14. Region - An area within a geography that does not cross national borders and that contains one or more data centers. Pricing, regional services, and offer types are exposed at the region level. A region is typically paired with another region, which can be up to several hundred miles away, to form a regional pair. Regional pairs can be used as a mechanism for disaster recovery and high availability scenarios. Also referred to generally as location.
15. Resource Group - A container in Resource Manager holds related resources for an application. The resource group can include all of the resources for an application, or only those resources that are logically grouped together
16. Storage Account – An Azure storage account gives you access to the Azure blob, queue, table, and file services in Azure Storage. Your storage account provides the unique namespace for your Azure storage data objects.
17. Virtual Machine – The software implementation of a physical computer that runs an operating system. Multiple virtual machines can run simultaneously on the same hardware. In Azure, virtual machines are available in a variety of sizes.
18. Virtual Network - An Azure virtual network is a representation of your own network in the cloud. It is a logical isolation of the Azure cloud dedicated to your subscription. You can fully control the IP address blocks, DNS settings, security policies, and route tables within this network. You can also further segment your VNet into subnets and launch Azure IaaS virtual machines and cloud services (PaaS role instances). Additionally, you can connect the virtual network to your on-premises network using one of the connectivity options available in Azure. In essence, you can expand your network to Azure, with complete control on IP address blocks with the benefit of enterprise scale Azure provides.



Network architecture for Citrix ADC VPX instances on Microsoft Azure

September 14, 2021

In Azure Resource Manager (ARM), a Citrix ADC VPX virtual machine (VM) resides in a virtual network. A single network interface can be created in a given subnet of the Virtual Network and can be attached to the VPX instance. You can filter network traffic to and from a VPX instance in an Azure virtual network with a network security group. A network security group contains security rules that allow or deny inbound network traffic to or outbound network traffic from a VPX instance. For more information, see Security groups.

Network security group filters the requests to the Citrix ADC VPX instance, and the VPX instance sends them to the servers. The response from a server follows the same path in reverse. The Network security group can be configured to filter a single VPX VM, or, with subnets and virtual networks, can filter

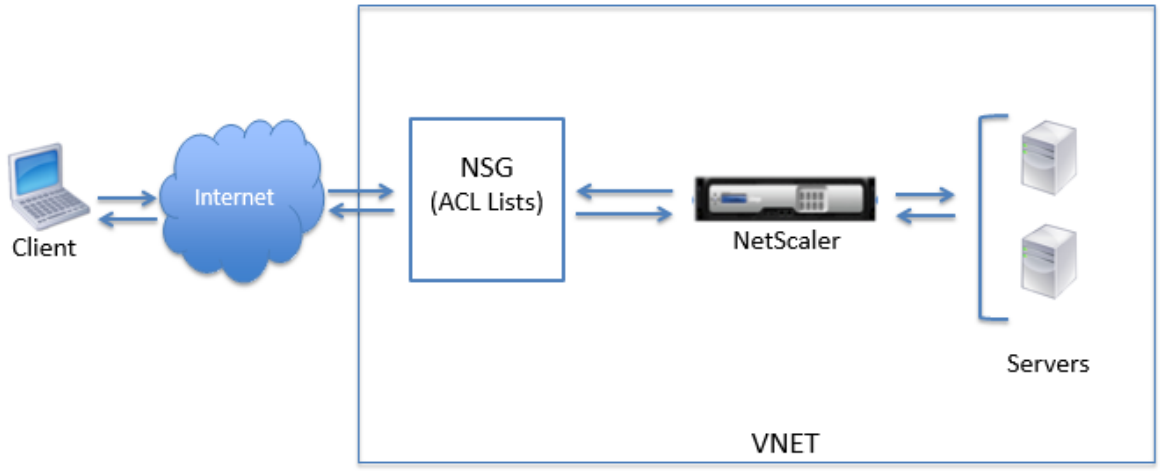
traffic in deployment of multiple VPX instances.

The NIC contains network configuration details such as the virtual network, subnets, internal IP address, and Public IP address.

While on ARM, it is good to know the following IP addresses that are used to access the VMs deployed with a single NIC and a single IP address:

- Public IP (PIP) address is the internet-facing IP address configured directly on the virtual NIC of the NetScaler VM. This allows you to directly access a VM from the external network.
- Citrix ADC IP (also known as NSIP) address is the internal IP address configured on the VM. It is non-routable.
- Virtual IP address (VIP) is configured by using the NSIP and a port number. Clients access NetScaler services through the PIP address, and when the request reaches the NIC of the NetScaler VPX VM or the Azure load balancer, the VIP gets translated to internal IP (NSIP) and internal port number.
- Internal IP address is the private internal IP address of the VM from the virtual network's address space pool. This IP address cannot be reached from the external network. This IP address is by default dynamic unless you set it to static. Traffic from the internet is routed to this address according to the rules created on the network security group. The network security group integrates with the NIC to selectively send the right type of traffic to the right port on the NIC, which depends on the services configured on the VM.

The following figure shows how traffic flows from a client to a server through a NetScaler VPX instance provisioned in ARM.

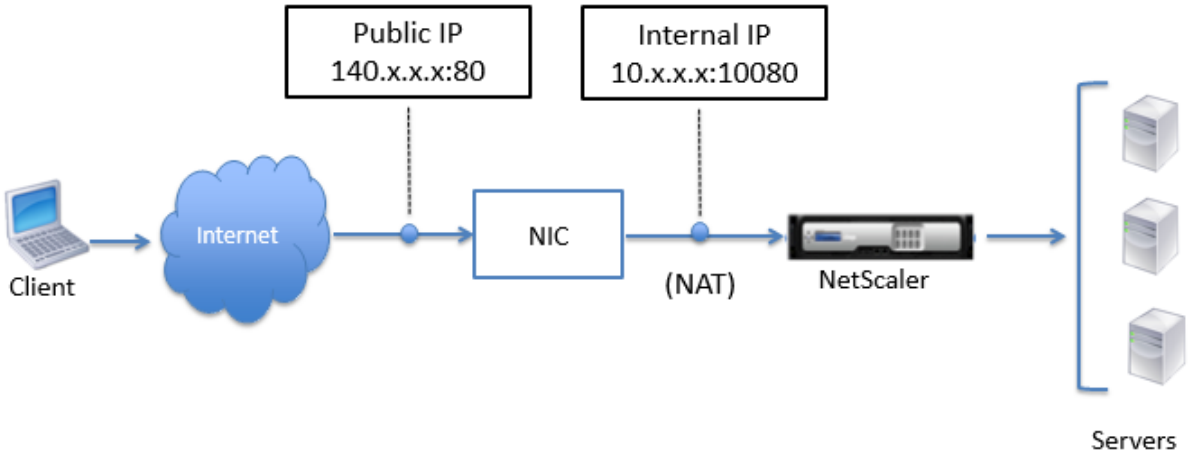


Traffic flow through network address translation

You can also request a public IP (PIP) address for your Citrix ADC VPX instance (instance level). If you use this direct PIP at the VM level, you need not define inbound and outbound rules to intercept the

network traffic. The incoming request from the Internet is received on the VM directly. Azure performs network address translation (NAT) and forwards the traffic to the internal IP address of the VPX instance.

The following figure shows how Azure performs network address translation to map the NetScaler internal IP address.



In this example, the Public IP assigned to the network security group is 140.x.x.x and the internal IP address is 10.x.x.x. When the inbound and outbound rules are defined, public HTTP port 80 is defined as the port on which the client requests are received, and a corresponding private port, 10080, is defined as the port on which the Citrix ADC VPX instance listens. The client request is received on the Public IP address (140.x.x.x). Azure performs network address translation to map the PIP to the internal IP address 10.x.x.x on port 10080, and forwards the client request.

> **Note**
>
> Citrix ADC VPX VMs in high availability are controlled by external or internal load balancers that have inbound rules defined on them to control the load balancing traffic. The external traffic is first intercepted by these load balancers and the traffic is diverted according to the load balancing rules configured, which has back-end pools, NAT rules, and health probes defined on the load balancers.

Port usage guidelines

You can configure more inbound and outbound rules n network security group while creating the Citrix ADC VPX instance or after the virtual machine is provisioned. Each inbound and outbound rule is associated with a public port and a private port.

Before configuring network security group rules, note the following guidelines regarding the port numbers you can use:

1. The Citrix ADC VPX instance reserves the following ports. You cannot define these as private ports when using the Public IP address for requests from the internet.

   Ports 21, 22, 80, 443, 8080, 67, 161, 179, 500, 520, 3003, 3008, 3009, 3010, 3011, 4001, 5061, 9000, 7000.

   However, if you want internet-facing services such as the VIP to use a standard port (for example, port 443) you have to create port mapping by using the network security group. The standard port is then mapped to a different port that is configured on the NetScaler for this VIP service.

   For example, a VIP service might be running on port 8443 on the VPX instance but be mapped to public port 443. So, when the user accesses port 443 through the Public IP, the request is directed to private port 8443.

2. Public IP address does not support protocols in which port mapping is opened dynamically, such as passive FTP or ALG.
3. High availability does not work for traffic that uses a public IP address (PIP) associated with a VPX instance, instead of a PIP configured on the Azure load balancer.

> **Note**
>
> In Azure Resource Manager, a Citrix ADC VPX instance is associated with two IP addresses - a public IP address (PIP) and an internal IP address. While the external traffic connects to the PIP, the internal IP address or the NSIP is non-routable. To configure VIP in VPX, use the internal IP address and any of the free ports available. Do not use the PIP to configure VIP.

Configure a Citrix ADC VPX standalone instance

September 14, 2021

You can provision a single Citrix ADC VPX instance in Azure Resource Manager (ARM) portal in a standalone mode by creating the virtual machine and configuring other resources.

Before you begin

Ensure that you have the following:

- A Microsoft Azure user account
- Access to Microsoft Azure Resource Manager
- Microsoft Azure SDK
- Microsoft Azure PowerShell

On the Microsoft Azure Portal page, log on to the Azure Resource Manager portal by providing your user name and password.

> **Note**
>
> In ARM portal, clicking an option in one pane opens a new pane to the right. Navigate from one pane to another to configure your device.

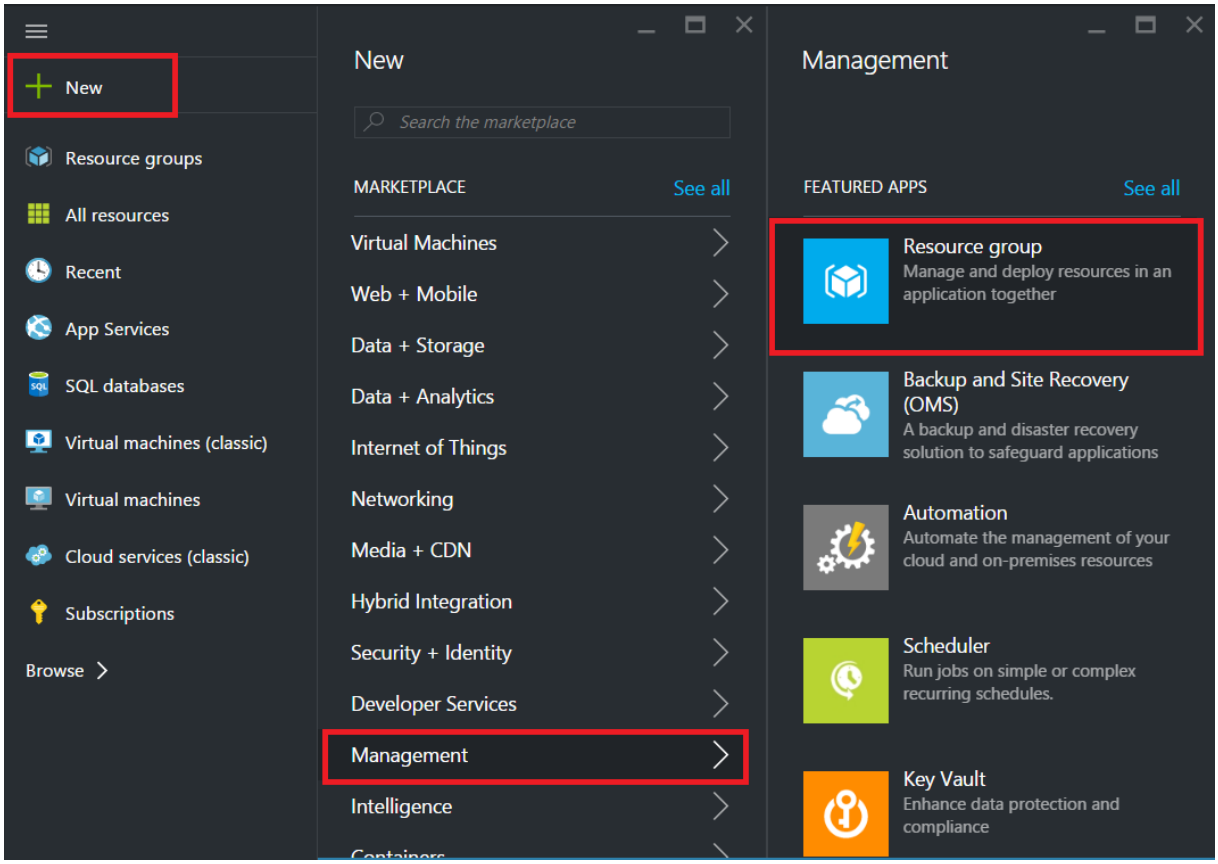
Summary of configuration steps

1. Configure a resource group
2. Configure a network security group
3. Configure virtual network and its subnets
4. Configure a storage account
5. Configure an availability set
6. Configure a Citrix ADC VPX instance.

Configure a resource group

Create a new resource group that is a container for all your resources. Use the resource group to deploy, manage, and monitor your resources as a group.

1. Click **New** > **Management** > **Resource group**.
2. In the **Resource group** pane, enter the following details:
   - Resource group name
   - Resource group location
3. Click **Create**.

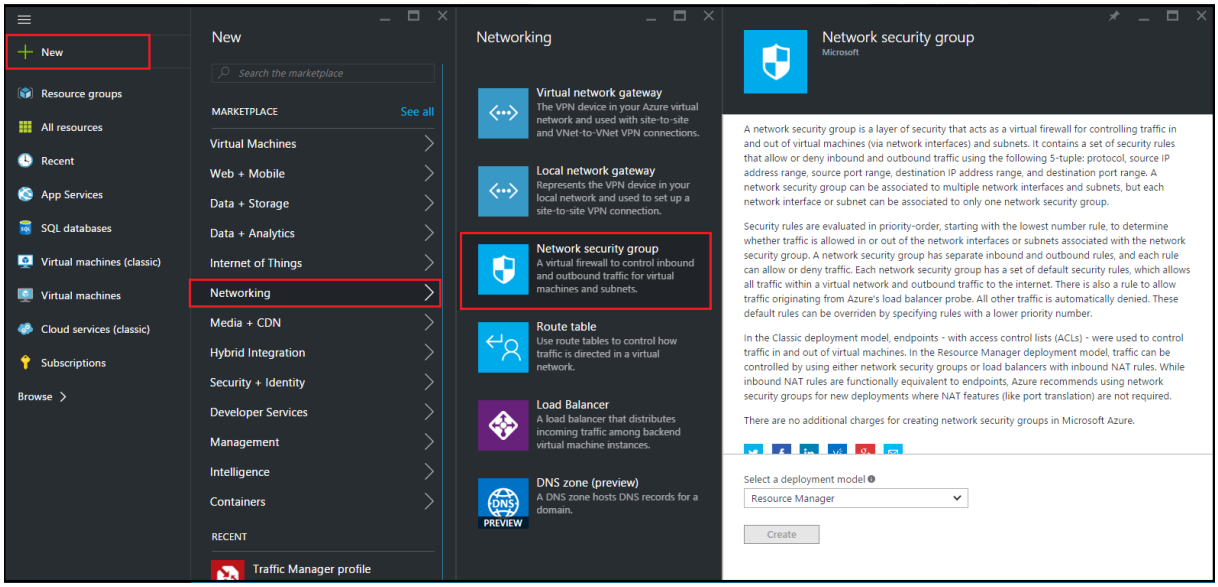


Configure a network security group

Create a network security group to assign inbound and outbound rules to control the incoming and outgoing traffic within the virtual network. Network security group allows you to define security rules for a single virtual machine and also to define security rules for a virtual network subnet.

1. Click **New** > **Networking** > **Network security group**.
2. In the **Create network security group** pane, enter the following details, and then click **Create**.
    - Name - type a name for the security group
    - Resource group - select the resource group from the drop-down list

> **Note**
>
> Ensure that you have selected the correct location. The list of resources that appear in the drop-down list is different for different locations.

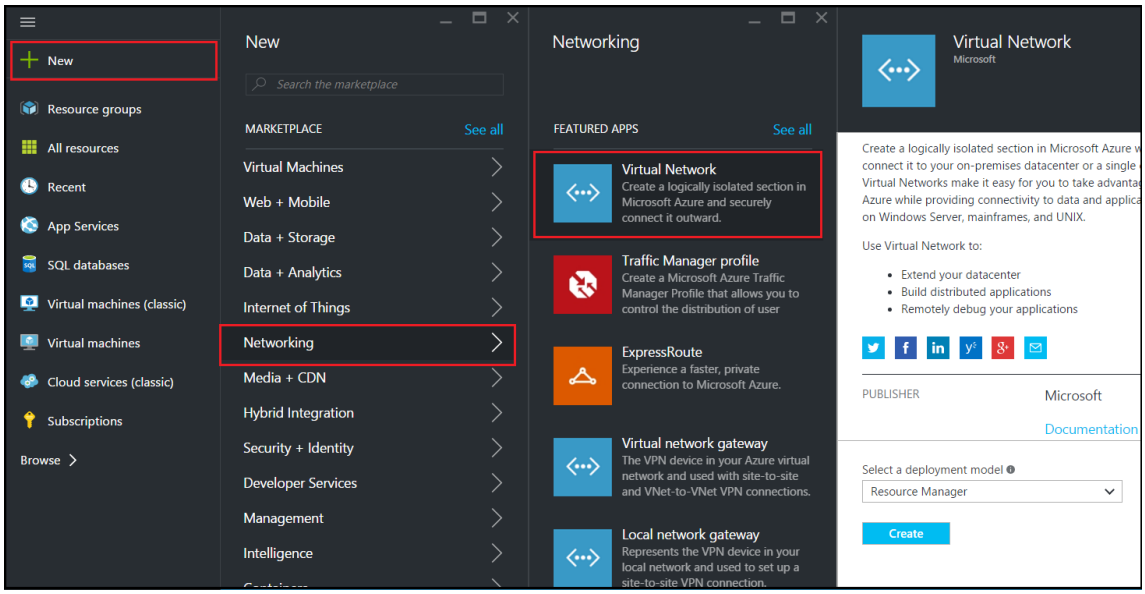


Configure a virtual network and subnets

Virtual networks in ARM provide a layer of security and isolation to your services. VMs and services that are part of the same virtual network can access each other.

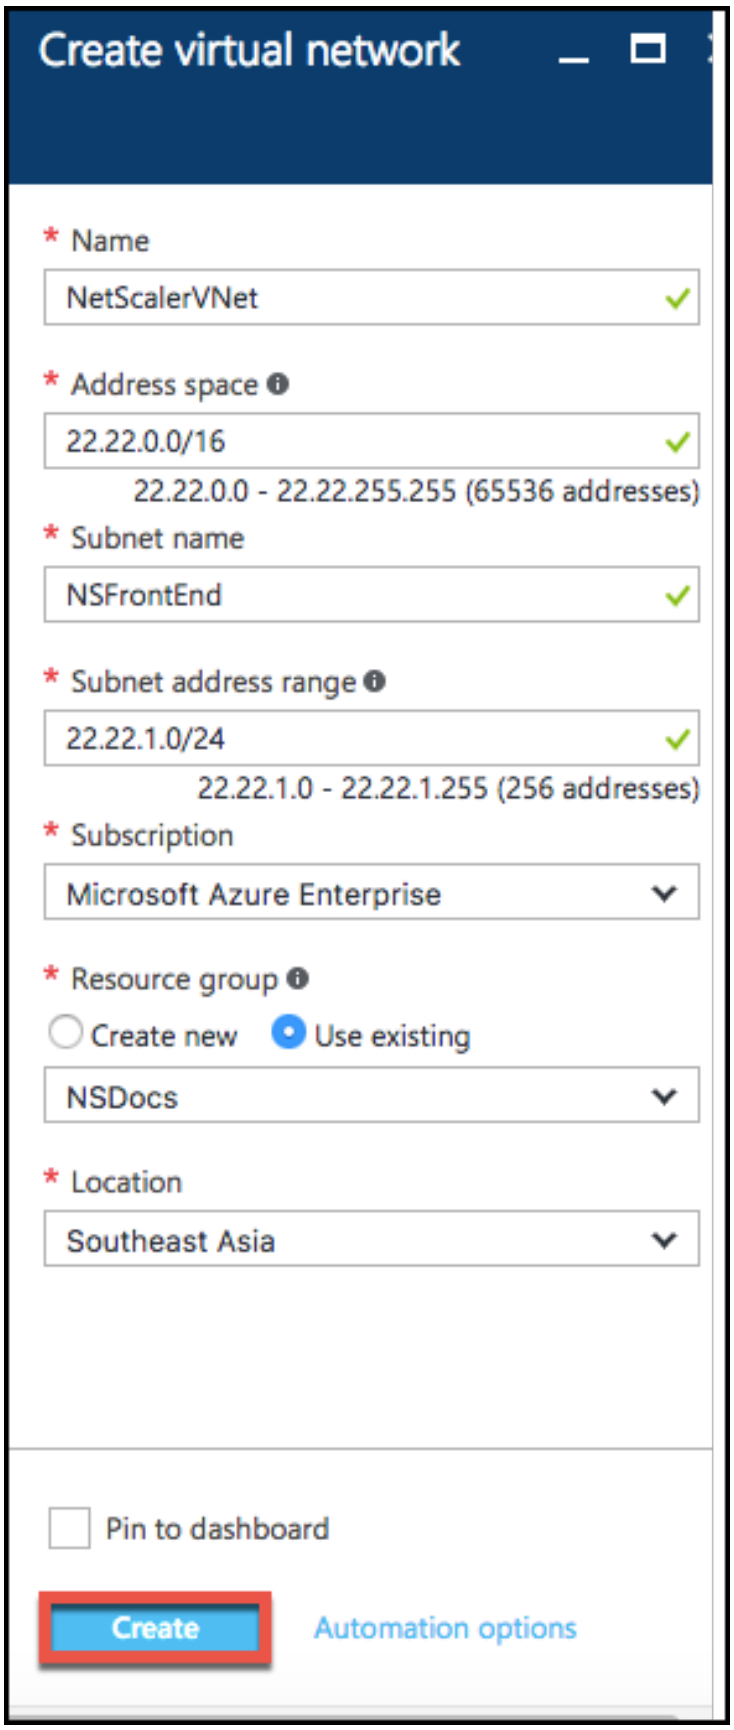
For these steps to create a virtual network and subnets.

1. Click **New** > **Networking** > **Virtual Network**.
2. In the **Virtual Network** pane, ensure the deployment mode is **Resource Manager** and click **Create**.



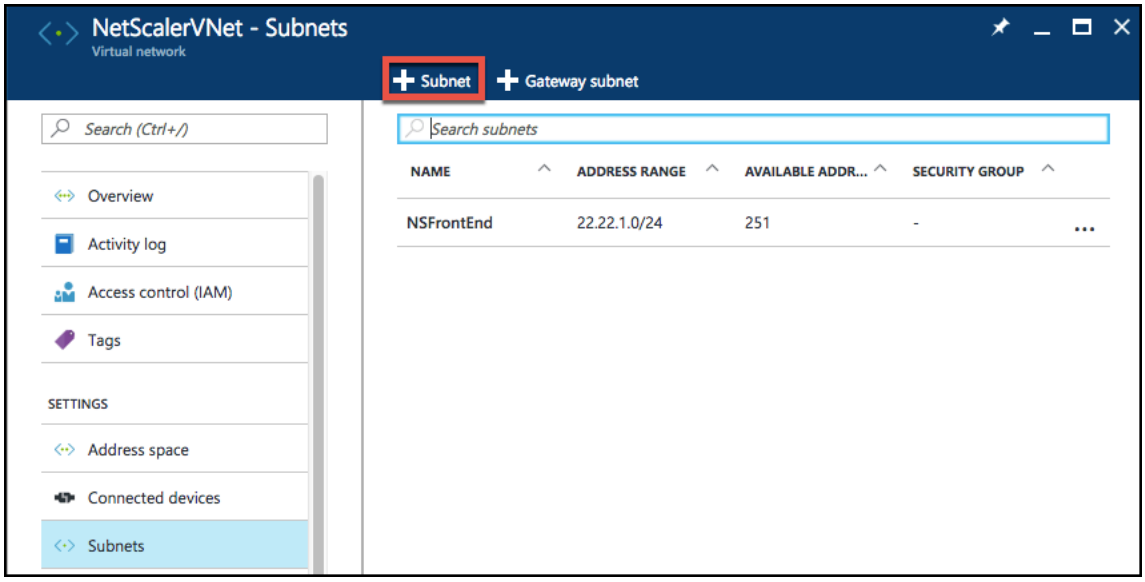
3. In the **Create virtual network** pane, enter the following values, and then click **Create**.
    - Name of the virtual network

- Address space - type the reserved IP address block for the virtual network
- Subnet - type the name of the first subnet (you create the second subnet later in this step)
- Subnet address range - type the reserved IP address block of the subnet
- Resource group - select the resource group created earlier from the drop-down list

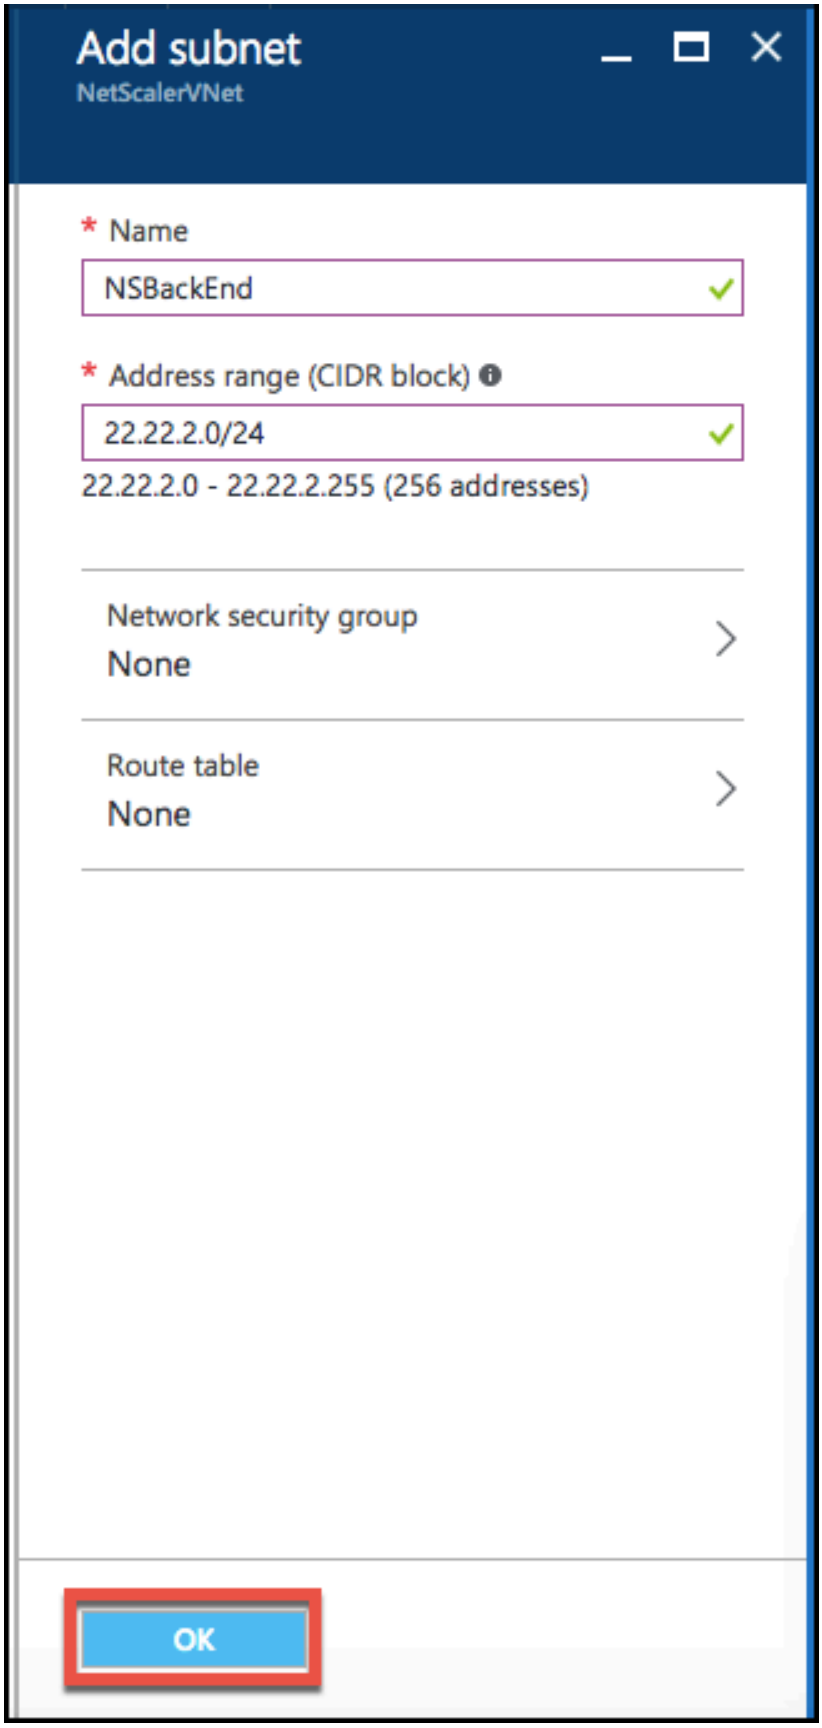


Configure the second subnet

1. Select the newly created virtual network from **All resources** pane and in the **Settings** pane, click **Subnets**.



2. Click **+Subnet** and create the second subnet by entering the following details.
   - Name of the second subnet
   - Address range - type the reserved IP address block of the second subnet
   - Network security group - select the network security group from the drop-down list
3. Click **Create**.

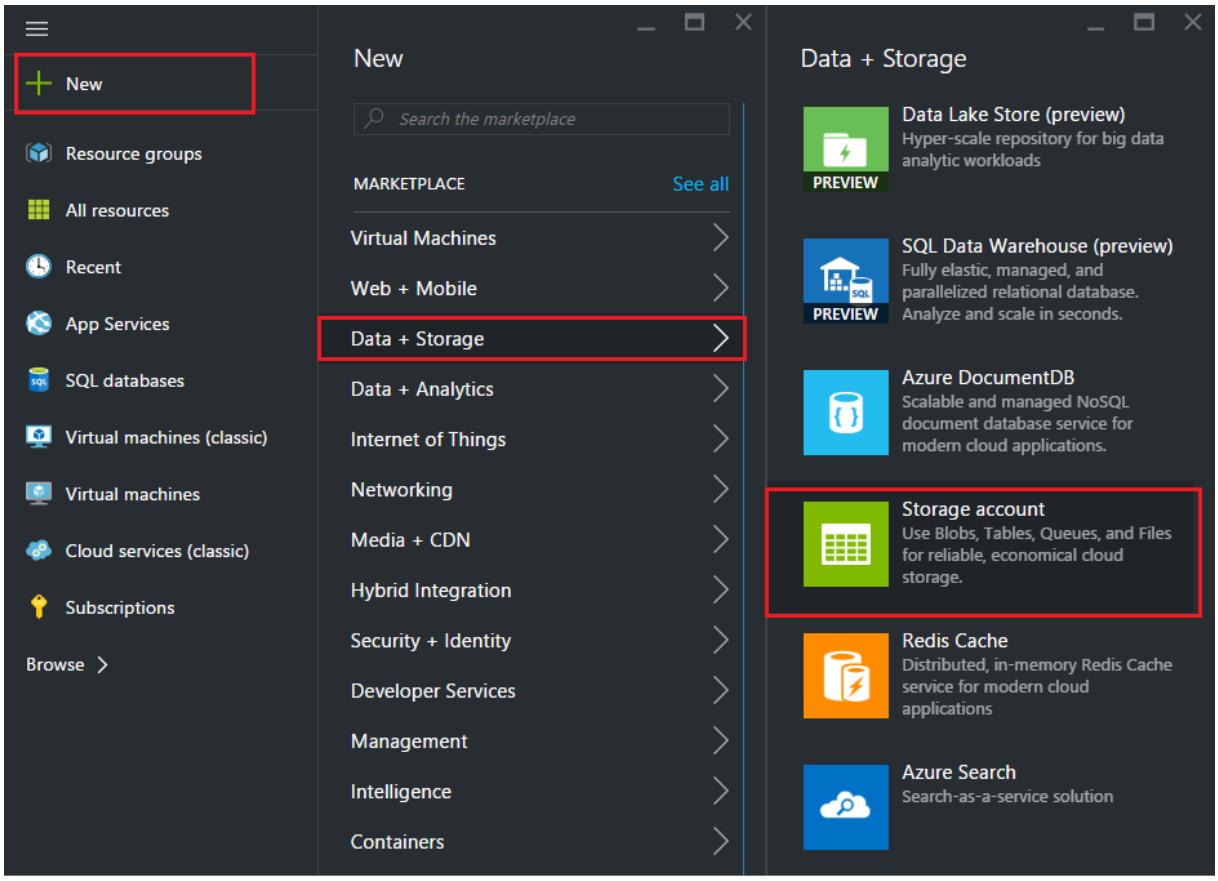


Configure a storage account

The ARM IaaS infrastructure storage includes all services where we can store data in the form of blobs, tables, queues, and files. You can also create applications using these forms of storage data in ARM.

Create a storage account to store all your data.

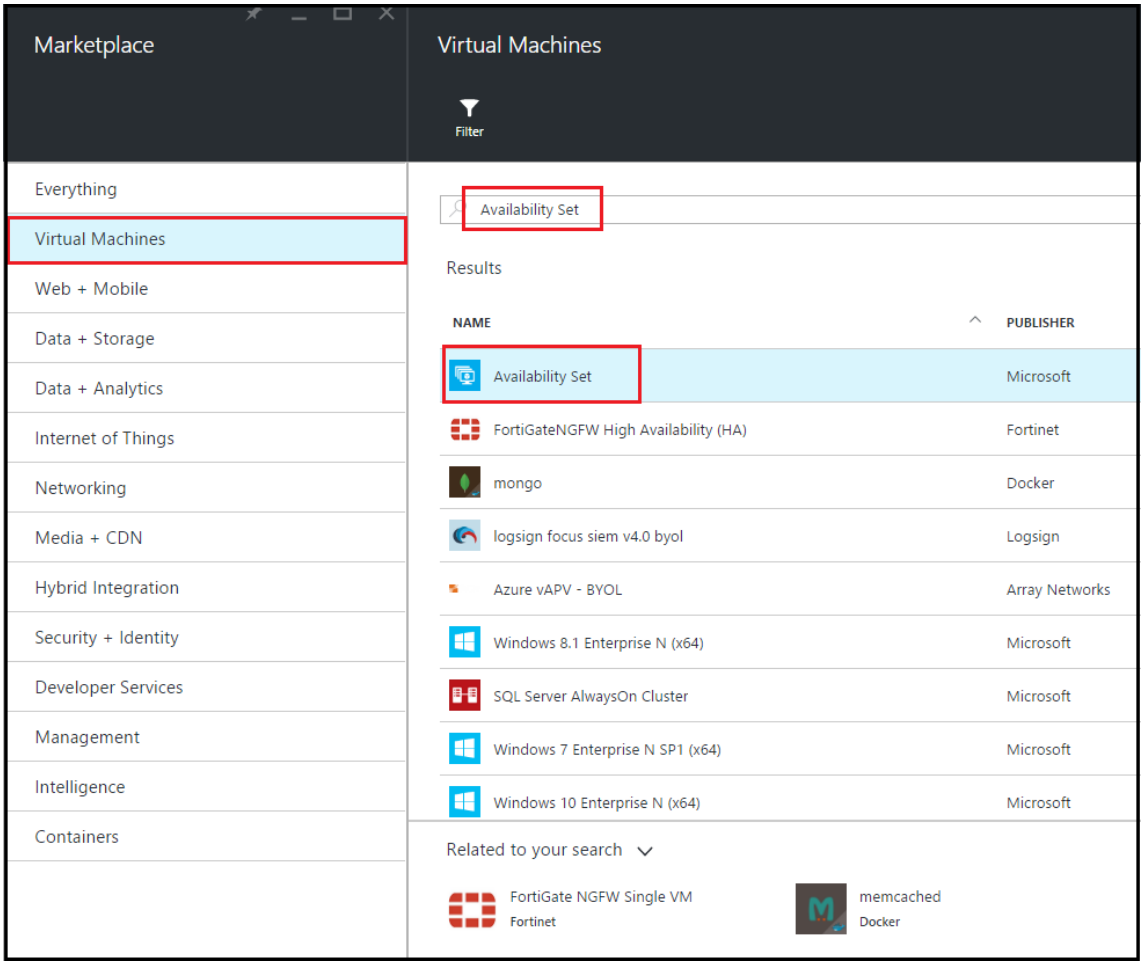
1. Click **+New** > **Data + Storage** > **Storage account**.
2. In the **Create storage account** pane, enter the following details:
    - Name of the account
    - Deployment mode - make sure to select **Resource Manager**
    - Account kind - select **General purpose** from the drop-down list
    - Replication - select **Locally redundant storage** from the drop-down list
    - Resource group - select the newly created resource group from the drop-down list
3. Click **Create**.



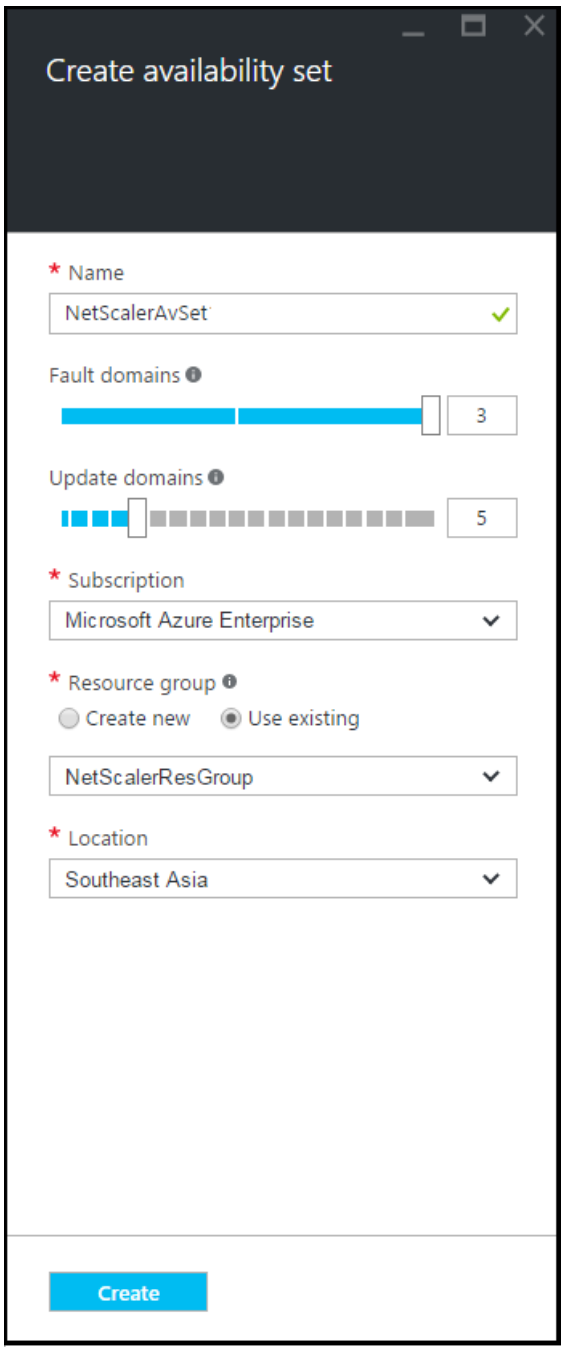
Configure an availability set

An availability set guarantee that at least one VM is kept up and running in case of planned or un-planned maintenance. Two or more VMs under the same 'availability set' are placed on different fault domains to achieve redundant services.

1. Click **+New**.
2. Click **See all** in the MARKETPLACE pane and click **Virtual Machines**.
3. Search for availability set, and then select **Availability set** entity from the list displayed.



4. Click **Create,** and in the **Create availability set** pane, enter the following details:
   - Name of the set
   - Resource group - select the newly created resource group from the drop-down list
5. Click **Create**.



Configure a Citrix ADC VPX instance

Create an instance of Citrix ADC VPX in the virtual network. Obtain the Citrix ADC VPX image from the Azure Marketplace, and then use the Azure Resource Manager portal to create a Citrix ADC VPX instance.

Before you begin creating the Citrix ADC VPX instance, make sure that you have created a virtual network with required subnets in which the instance resides. You can create virtual networks during

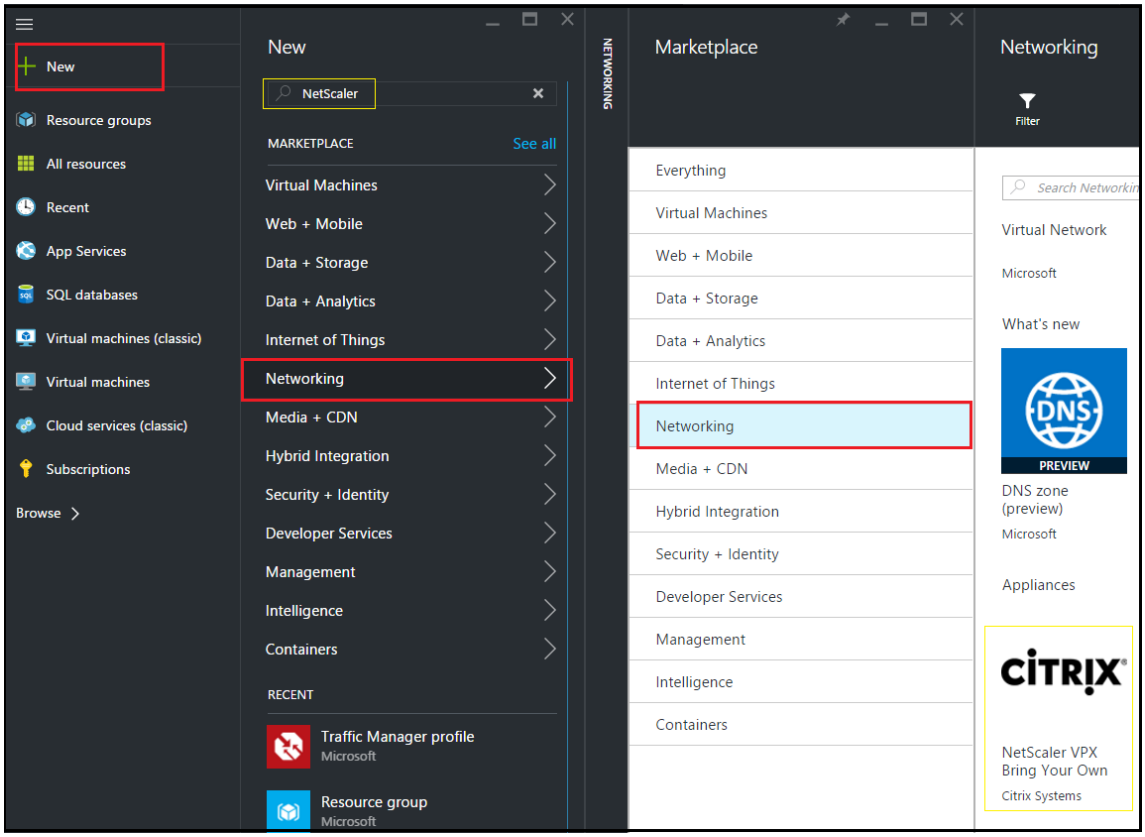
VM provisioning, but without the flexibility to create different subnets. For information about creating virtual networks, see http://azure.microsoft.com/en-us/documentation/articles/create-virtual-network/.

Optionally, configure DNS server and VPN connectivity that allows a virtual machine to access internet resources.

> **Note**
>
> Citrix recommends that you create resource group, network security group, virtual network, and other entities before you provision the Citrix ADC VPX VM, so that the network information is available during provisioning.

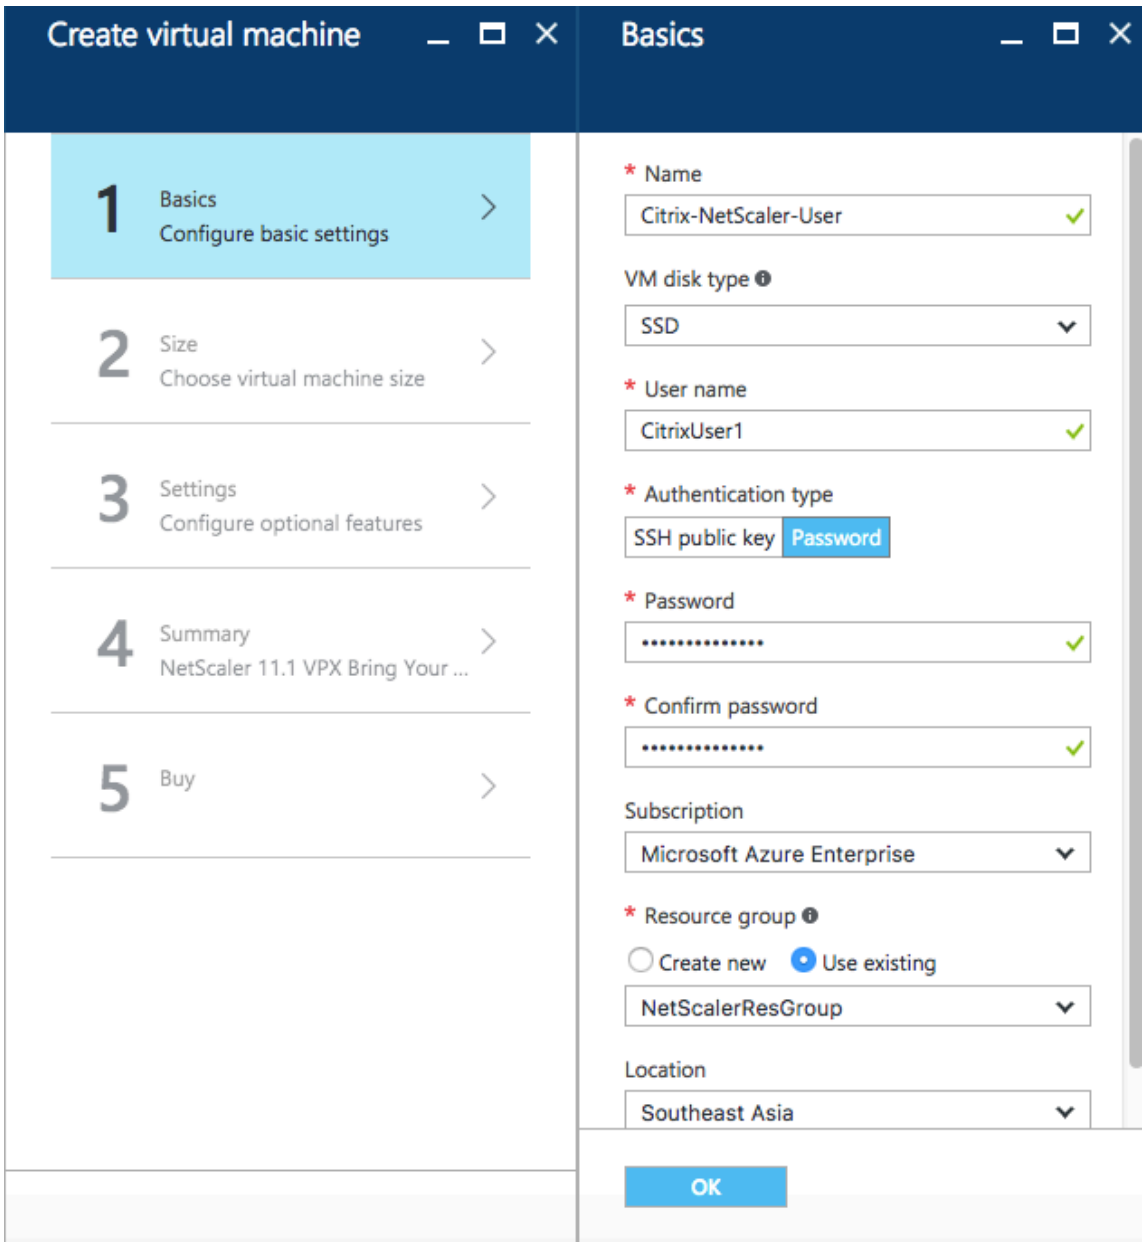
1. Click **+New** > **Networking**.
2. Click **See All** and in the Networking pane, click **Citrix ADC 13.0**.
3. Select **Citrix ADC 13.0 VPX Bring Your Own License** from the list of software plans.

   As a quick way to find any entity on ARM portal, you can also type the name of the entity in the Azure Marketplace search box and press <Enter>. Type NetScaler in the search box to find the Citrix NetScaler images.



> **Note**
>
> Ensure to select the latest image. Your Citrix NetScaler image might have the release number in the name.

4. On the **Citrix ADC VPX Bring Your Own License** page, from the drop-down list, select **Resource Manager** and click **Create**.



5. In the **Create virtual machine** pane, specify the required values in each section to create a virtual machine. Click **OK** in each section to save your configuration.

Basic:

- Name - specify a name for the Citrix ADC VPX instance

- VM disk type - select SSD (default value) or HDD from the drop-down menu
- User name and Password - specify a user name and password to access the resources in the resource group that you have created
- Authentication Type - select SSH Public Key or Password
- Resource group - select the resource group you have created from the drop-down list

You can create a resource group here, but Citrix recommends that you create a resource group from Resource groups in Azure Resource Manager and then select the group from the drop-down list.

> **Note**
>
> In an Azure stack environment, in addition to the basic parameters, specify the following parameters:
>
> - Azure stack domain
> - Azure stack tenant (Optional)
> - Azure client (Optional)
> - Azure client secret (Optional)

Size:

Depending on the VM disk type, SDD, or HDD, you selected in Basic settings, the disk sizes are displayed.

- Select a disk size according to your requirement and click **Select**.

Settings:

- Select the default (Standard) disk type
- Storage account - select the storage account
- Virtual network - select the virtual network
- Subnet - set the subnet address
- Public IP address - select the type of IP address assignment
- Network security group - select the security group that you have created. Ensure that inbound and outbound rules are configured in the security group.
- Availability Set - select the availability set from the drop-down menu box

Summary:

The configuration settings are validated and the Summary page displays the result of the validation. If the validation fails, the Summary page displays the reason of the failure. Go back to the particular section and make changes as required. If the validation passes, click **OK**.

Buy:

Review the offer details and legal terms on the Purchase page and click **Purchase**.

For high availability deployment, create two independent instances of Citrix ADC VPX in the same availability set and in the same resource group to deploy them in active-standby configuration.

Configure multiple IP addresses for a Citrix ADC VPX standalone instance

September 14, 2021

This section explains how to configure a standalone Citrix ADC VPX instance with multiple IP addresses, in Azure Resource Manager (ARM). The VPX instance can have one or more NIC attached to it, and each NIC can have one or more static or dynamic public and private IP addresses assigned to it. You can assign multiple IP addresses as NSIP, VIP, SNIP, and so on.

For more information, see the Azure documentation Assign multiple IP addresses to virtual machines using the Azure portal.

If you want to use PowerShell commands, see Configuring multiple IP addresses for a Citrix ADC VPX instance in standalone mode by using PowerShell commands.

Use case

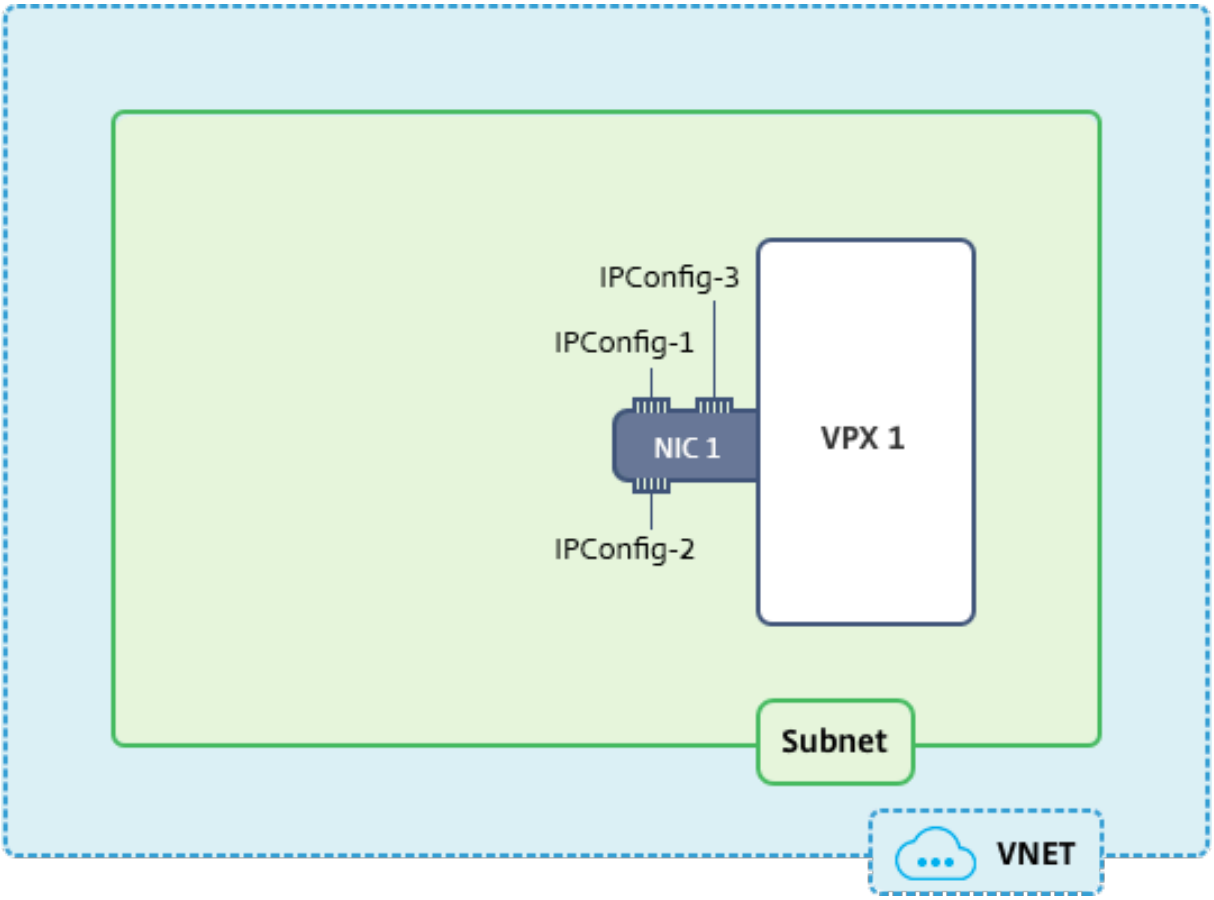
In this use case, a standalone Citrix ADC VPX appliance is configured with a single NIC that is connected to a virtual network (VNET). The NIC is associated with three IP configurations (ipconfig), each server a different purpose - as shown in the table.

IP config	Associated with	Purpose
ipconfig1	Static public IP address; static private IP address	Serves management traffic
ipconfig2	Static public IP address; static private address	Serves client-side traffic
ipconfig3	Static private IP address	Communicates with back-end servers

> **Note**
>
> `IPConfig-3` is not associated with any public IP address.

Diagram: Topology

Here is the visual representation of the use case.



> **Note**
>
> In a multi-NIC, multi-IP Azure Citrix ADC VPX deployment, the private IP associated with the primary (first) `IPConfig` of the primary (first) NIC is automatically added as the management NSIP of the appliance. The remaining private IP addresses associated with `IPConfigs` need to be added in the VPX instance as a VIP or SNIP by using the `add ns ip` command, according to your requirement.

Before you begin

Before you begin, create a VPX instance by following the steps given at this link:

Configure a Citrix ADC VPX standalone instance

For this use case, the NSDoc0330VM VPX instance is created.

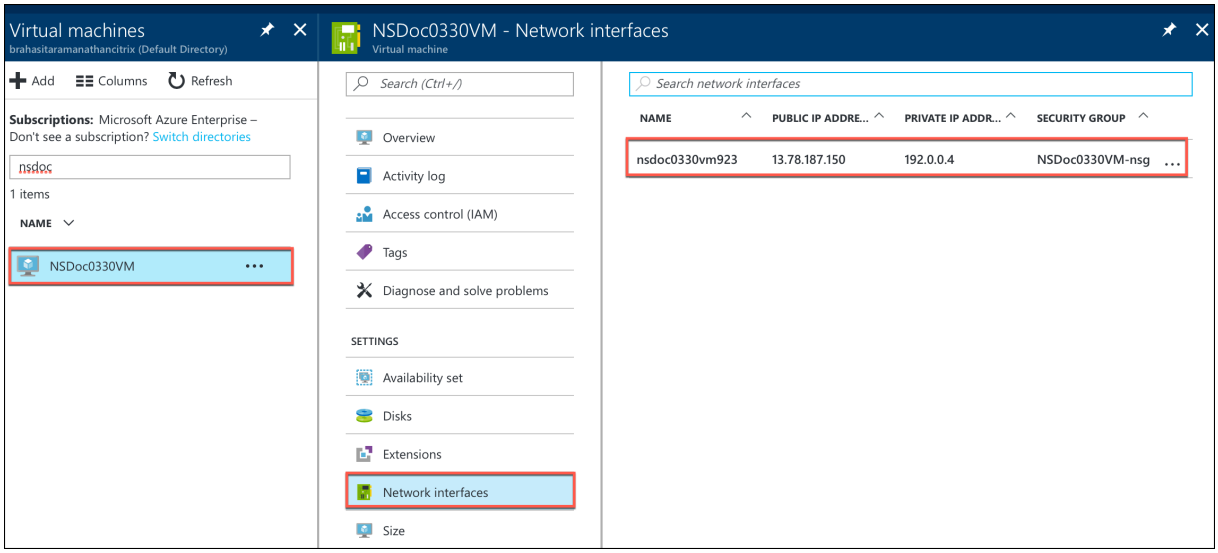
Procedure to configure multiple IP addresses for a Citrix ADC VPX instance in standalone mode.

For configuring multiple IP addresses for a Citrix ADC VPX appliance in standalone mode:

1. Add IP addresses to the VM
2. Configure Citrix ADC -owned IP addresses

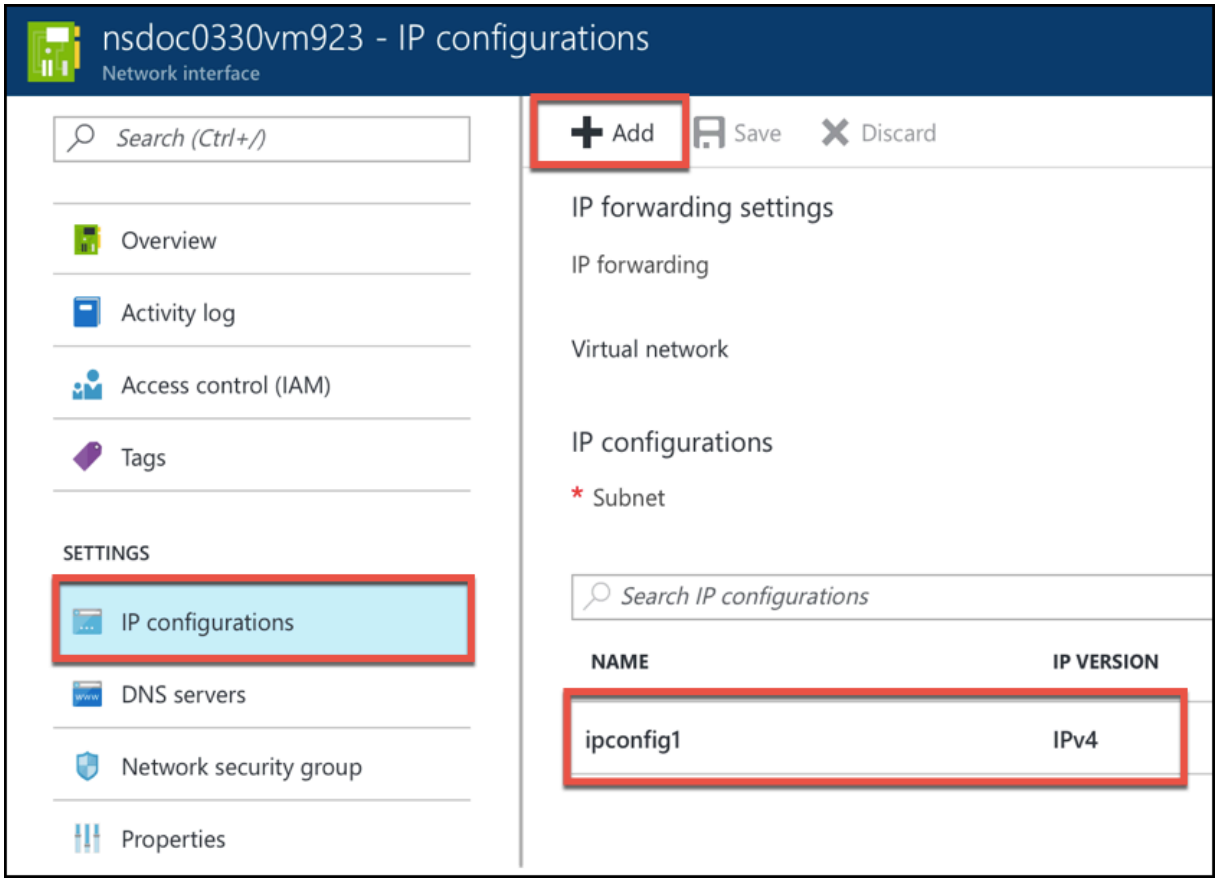
Step 1: Add IP addresses to the VM

1. In the portal, click **More services > type virtual machines** in the filter box, and then click **Virtual machines**.
2. In the **Virtual machines** blade, click the VM you want to add IP addresses to. Click **Network interfaces** in the virtual machine blade that appears, and then select the network interface.



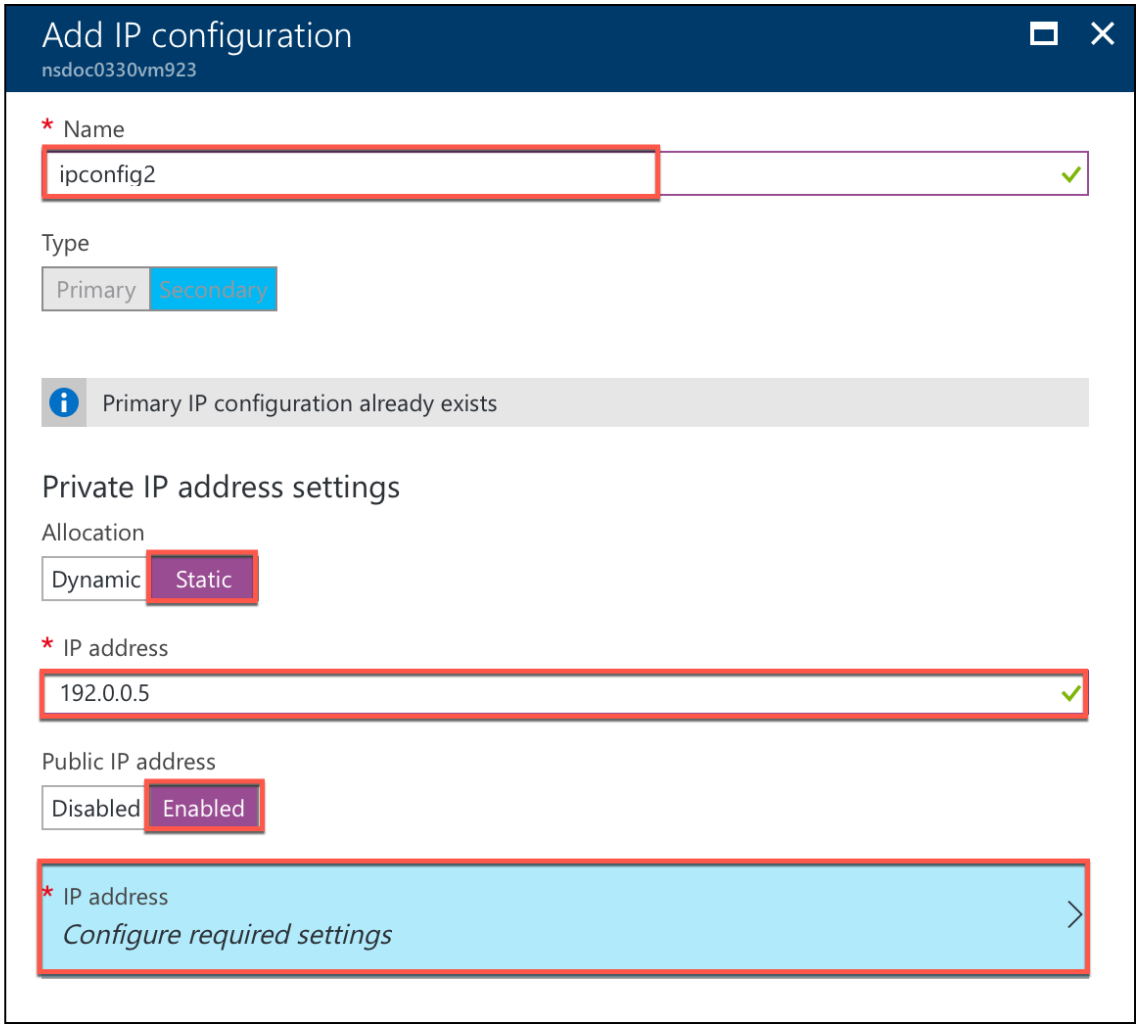
In the blade that appears for the NIC you selected, click **IP configurations**. The existing IP configuration that was assigned when you created the VM, **ipconfig1**, is displayed. For this use case, make sure the IP addresses associated with ipconfig1 are static. Next, create two more IP configurations: ipconfig2 (VIP) and ipconfig3 (SNIP).

To create more `ipconfigs`, create **Add**.



In the **Add IP configuration** window, enter a **Name**, specify allocation method as **Static**, enter an IP address (192.0.0.5 for this use case), and enable **Public IP address**.

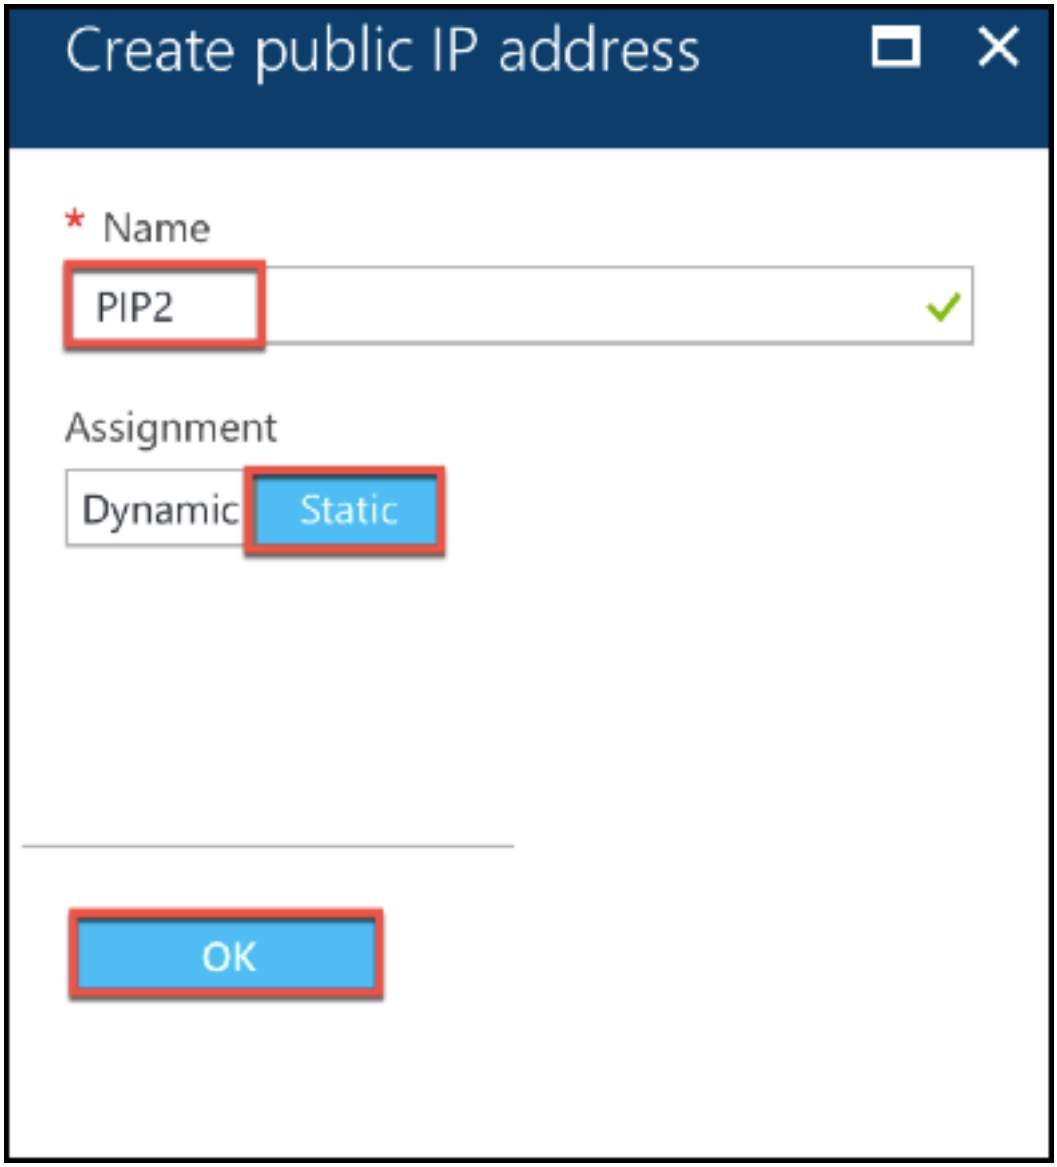
> **Note**
>
> Before adding a static private IP address, check for IP address availability and make sure the IP address belongs to the same subnet to which the NIC is attached.



Next, click **Configure required settings** to create a static public IP address for ipconfig2.

By default, public IPs are dynamic. To make sure that the VM always uses the same public IP address, create a static Public IP.

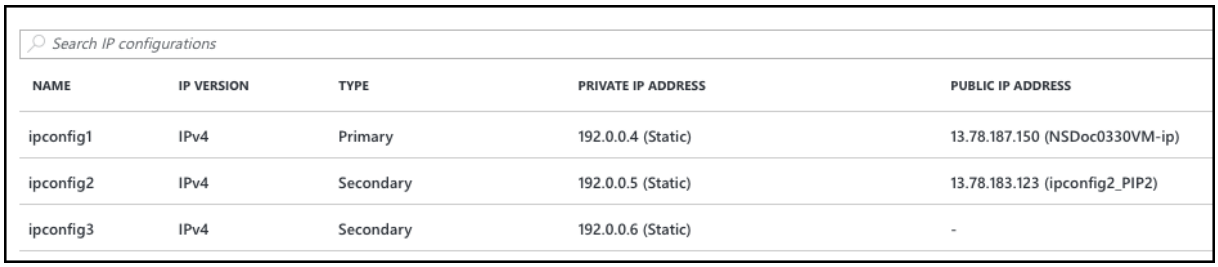
In the Create public IP address blade, add a Name, under Assignment click **Static**. And then click **OK**.



Note

Even when you set the allocation method to static, you cannot specify the actual IP address assigned to the public IP resource. Instead, it gets allocated from a pool of available IP addresses in the Azure location the resource is created in.

Follow the steps to add one more IP configuration for ipconfig3. Public IP is not mandatory.



Step 2: Configure Citrix ADC-owned IP addresses

Configure the Citrix ADC-owned IP addresses by using the GUI or the command `add ns ip`. For more information, see Configuring Citrix ADC-Owned IP Addresses.

Configure a high-availability setup with multiple IP addresses and NICs

September 14, 2021

In a Microsoft Azure deployment, a high-availability configuration of two Citrix ADC VPX instances is achieved by using the Azure Load Balancer (ALB). This is achieved by configuring a health probe on ALB, which monitors each VPX instance by sending a health probe at every 5 seconds to both primary and secondary instances.

In this setup, only the primary node responds to health probes and the secondary does not. Once the primary sends the response to the health probe, the ALB starts sending the data traffic to the instance. If the primary instance misses two consecutive health probes, ALB does not redirect traffic to that instance. On failover, the new primary starts responding to health probes and the ALB redirects traffic to it. The standard VPX high availability failover time is three seconds. The total failover time that might take for traffic switching can be a maximum of 13 seconds.

You can deploy a pair of Citrix ADC VPX instances with multiple NICs in an active-passive high availability (HA) setup on Azure. Each NIC can contain multiple IP addresses.

The following options are available for a multi-NIC high availability deployment:

- High availability using Azure availability set
- High availability using Azure availability zones

For more information about Azure Availability Set and Availability Zones, see the Azure documentation Manage the availability of Linux virtual machines.

High availability using availability set

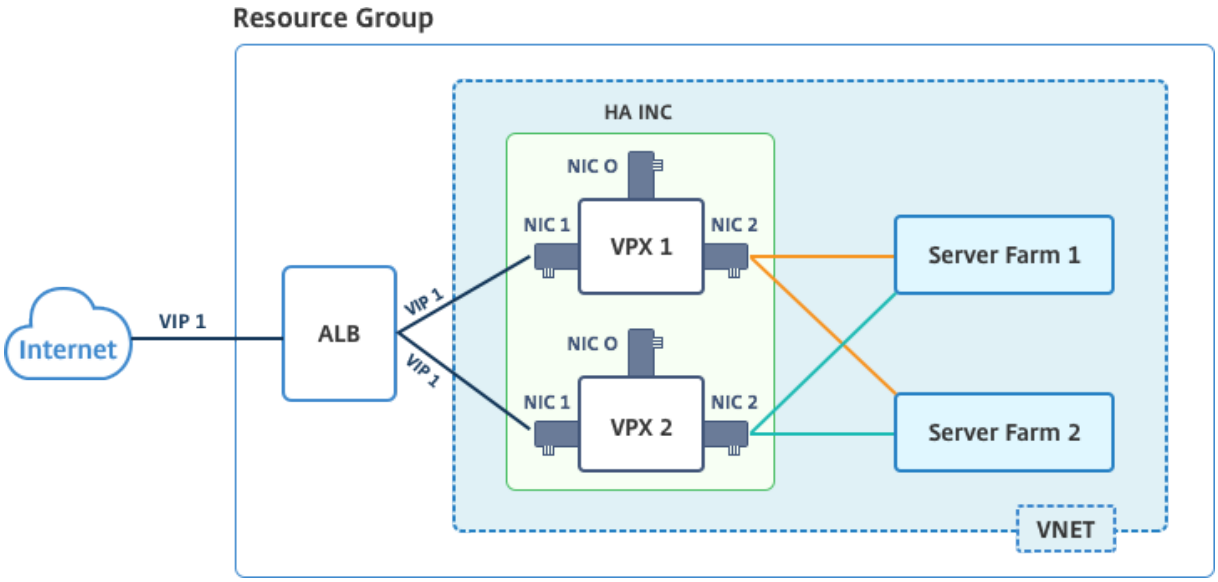
A high availability setup using a availability set must meet the following requirements:

- An HA Independent Network Configuration (INC) configuration
- The Azure Load Balancer (ALB) in Direct Server Return (DSR) mode

All traffic goes through the primary node. The secondary node remains in standby mode until the primary node fails.

> **Note**
>
> For a Citrix VPX high availability deployment on the Azure cloud to work, you need a floating public IP (PIP) that can be moved between the two VPX nodes. The Azure Load Balancer (ALB) provides that floating PIP, which is moved to the second node automatically in the event of a failover.

Diagram: Example of a high availability deployment architecture, using Azure Availability Set



In an active-passive deployment, the ALB front end public IP (PIP) addresses are added as the VIP addresses in each VPX node. In HA-INC configuration, the VIP addresses are floating and SNIP addresses are instance specific.

You can deploy a VPX pair in active-passive high availability mode in two ways by using:

- **Citrix ADC VPX standard high availability template**: use this option to configure an HA pair with the default option of three subnets and six NICs.
- **Windows PowerShell commands**: use this option to configure an HA pair according to your subnet and NIC requirements.

This topic describes how to deploy a VPX pair in active-passive HA setup by using the Citrix template. If you want to use PowerShell commands, see Configuring an HA Setup with Multiple IP Addresses and NICs by Using PowerShell Commands.

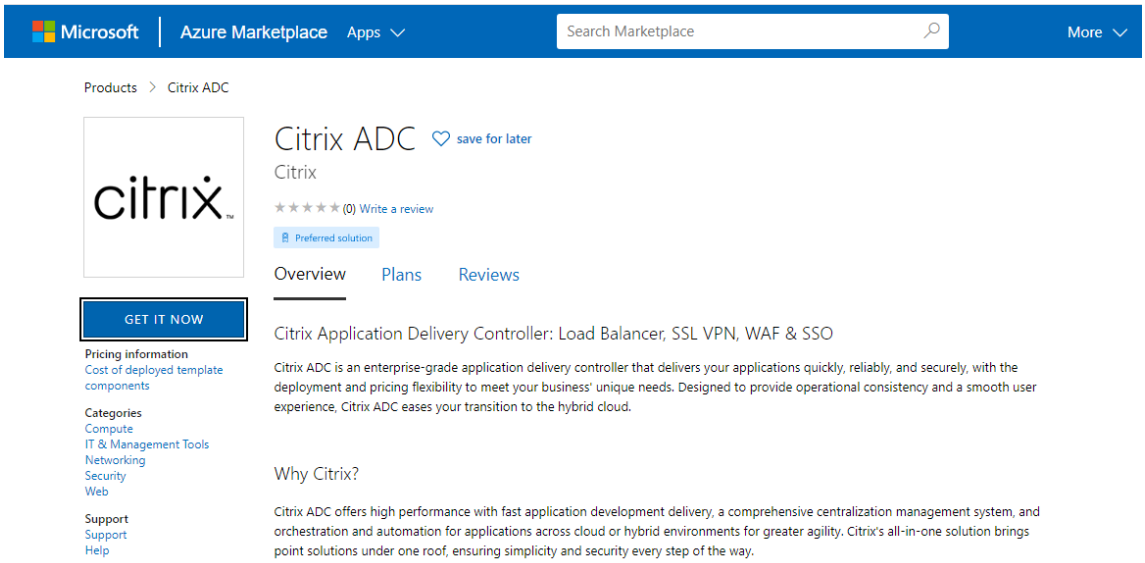
Configure HA-INC nodes by using the Citrix high availability template

You can quickly and efficiently deploy a pair of VPX instances in HA-INC mode by using the standard template. The template creates two nodes, with three subnets and six NICs. The subnets are for management, client, and server-side traffic, and each subnet has two NICs for both the VPX instances.

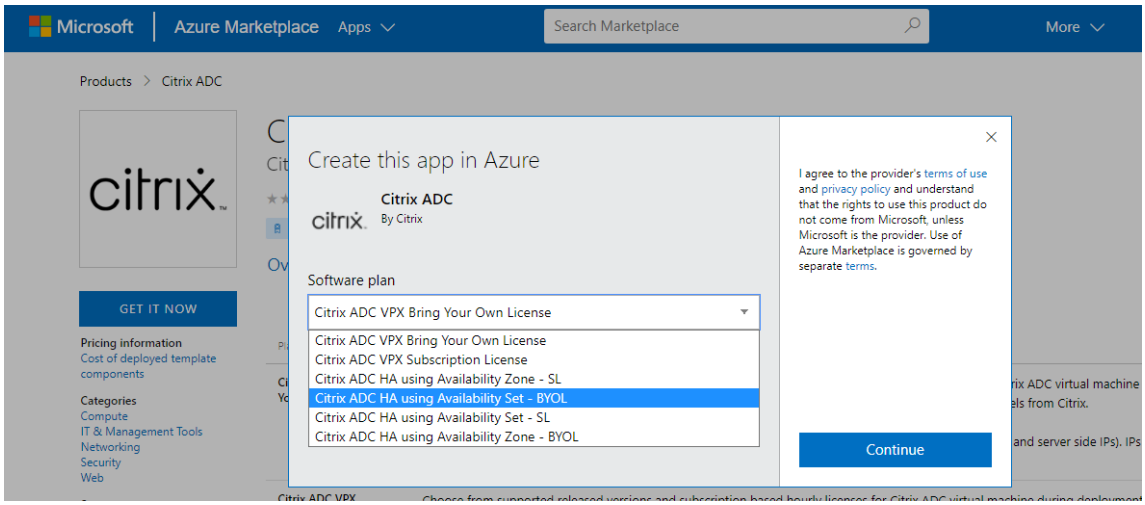
You can get the Citrix ADC HA Pair template at the Azure Marketplace.

Complete the following steps to launch the template and deploy a high availability VPX pair, by using Azure availability sets.

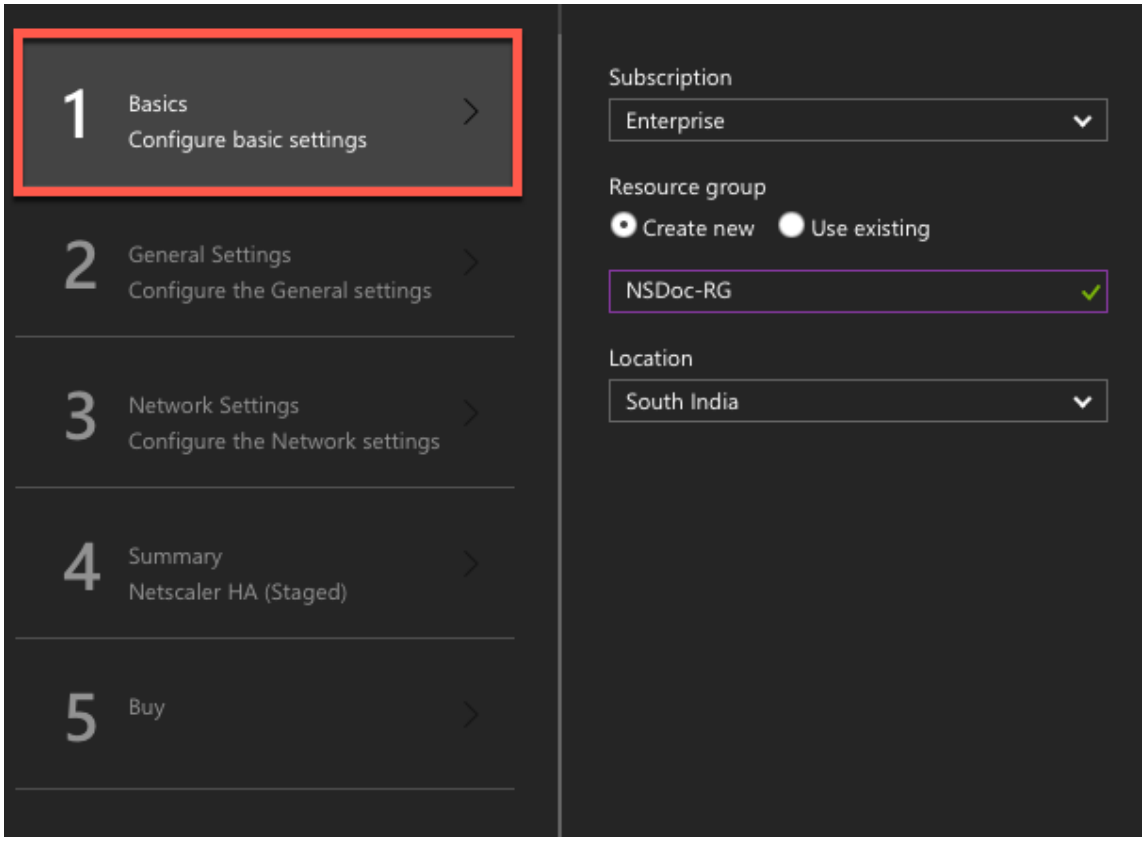
1. From Azure Marketplace, search **Citrix ADC**.



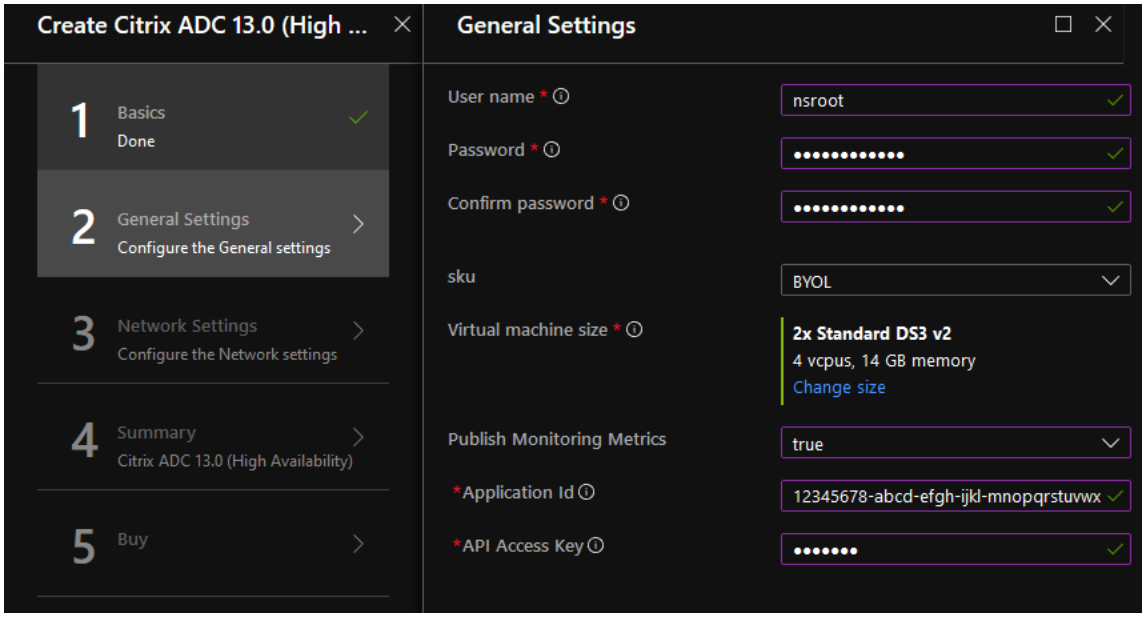
2. Click **GET IT NOW**.
3. Select the required HA deployment along with license, and click **Continue**.



4. The **Basics** page appears. Create a Resource Group and select **OK**.



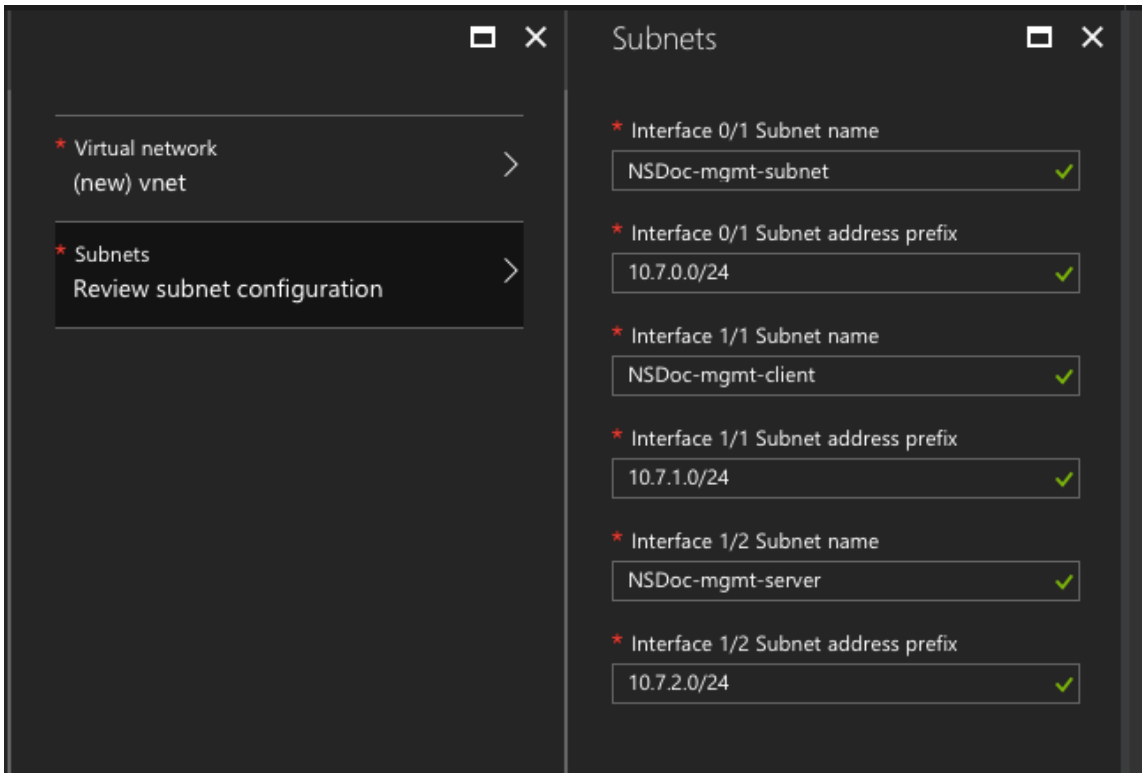
5. The **General Settings** page appears. Type the details and select **OK**.



> Note:
>
> By default, the **Publishing Monitoring Metrics** option is set to **false**. If you want to enable this option, select **true**.

> Create an Azure Active Directory (ADD) application and service principal that can access resources. Assign contributor role to the newly created AAD application. For more information, see Use portal to create an Azure Active Directory application and service principal that can access resources.

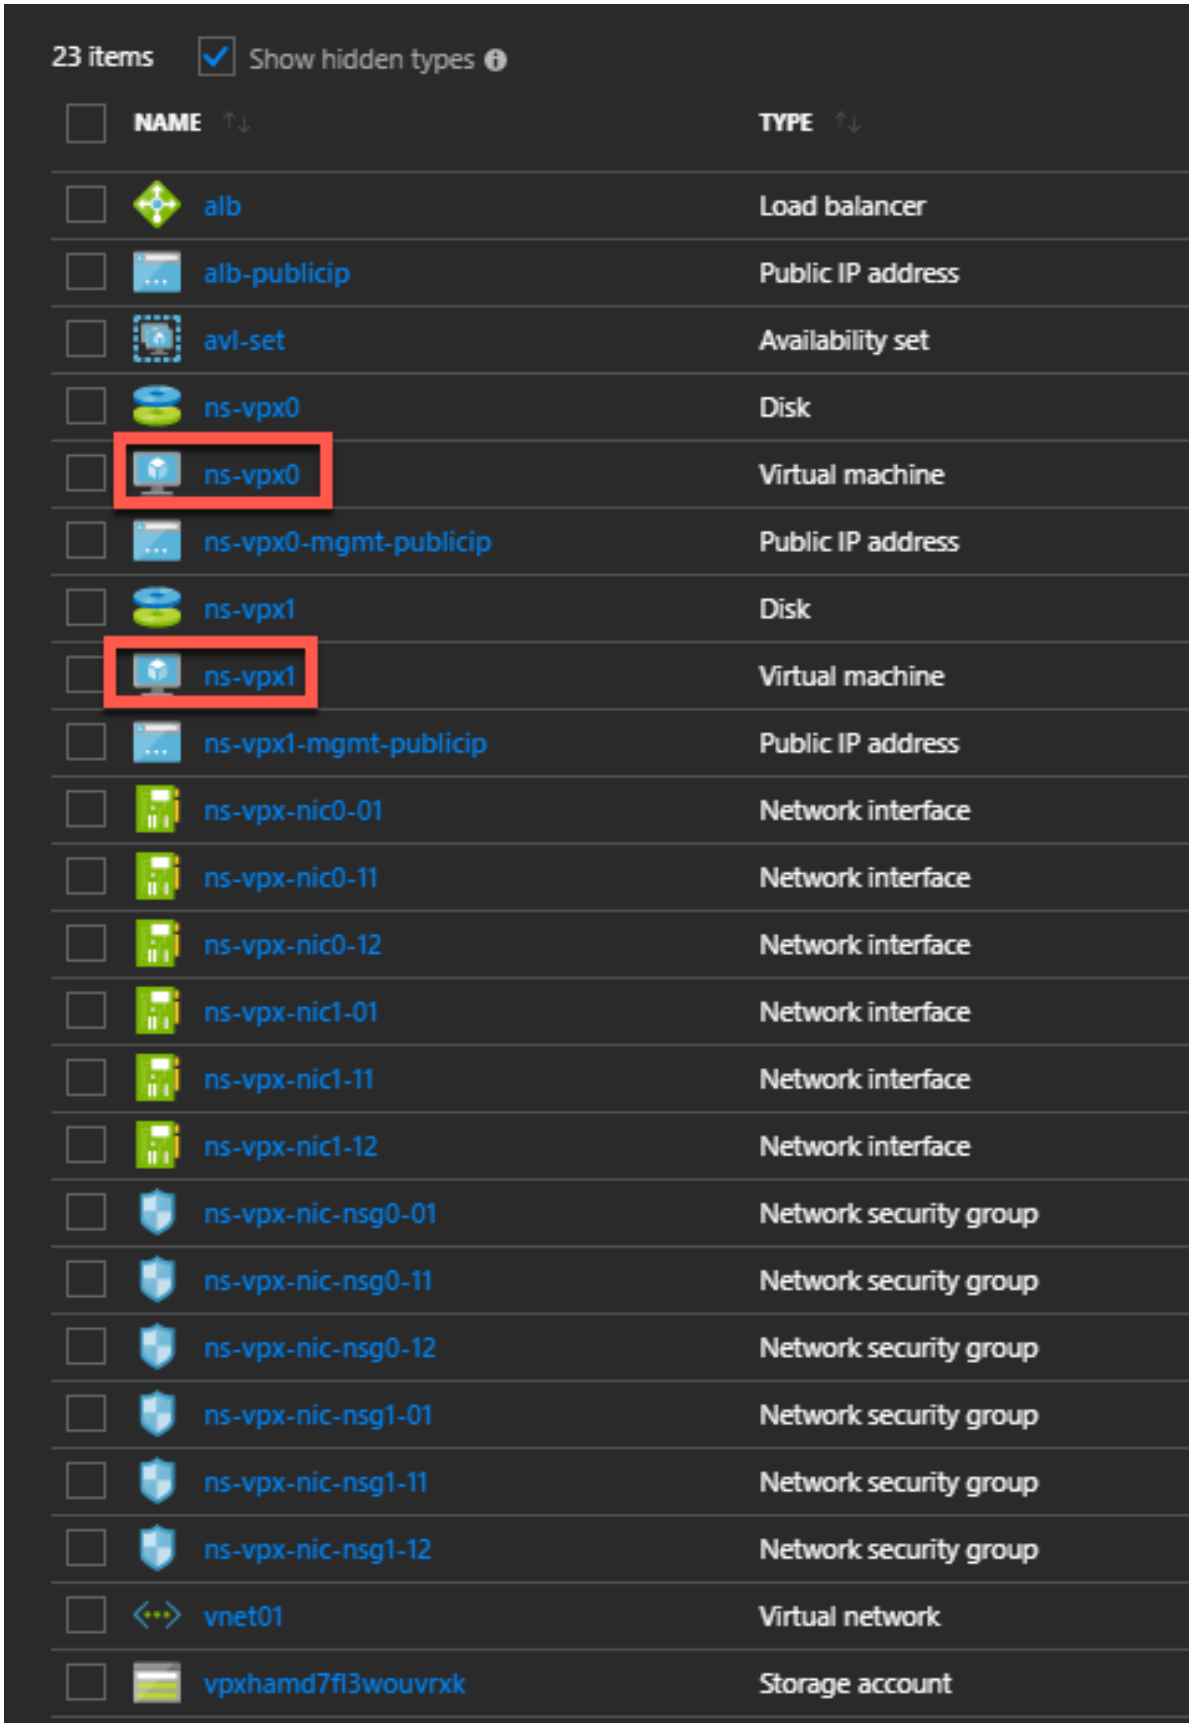
6. The **Network Settings** page appears. Check the VNet and subnet configurations, edit the required settings, and select **OK**.



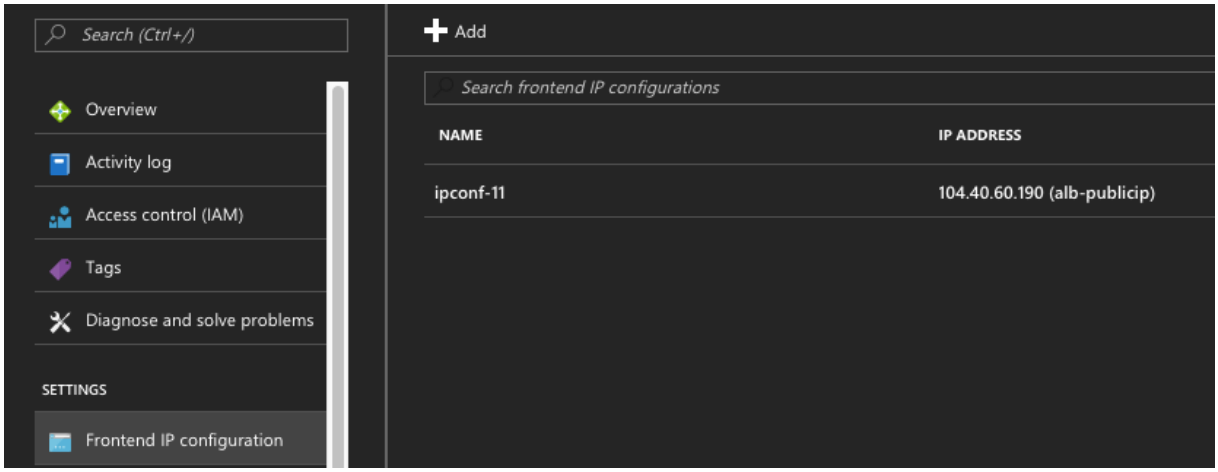
7. The **Summary** page appears. Review the configuration and edit accordingly. Select **OK** to confirm.
8. The **Buy** page appears. Select **Purchase** to complete the deployment.

It might take a moment for the Azure Resource Group to be created with the required configurations. After completion, select the **Resource Group** in the Azure portal to see the configuration details, such as LB rules, back-end pools, health probes. The high availability pair appears as ns-vpx0 and ns-vpx1.

If further modifications are required for your HA setup, such as creating more security rules and ports, you can do that from the Azure portal.



Next, you need to configure the load-balancing virtual server with the **ALB's Frontend public IP (PIP) address**, on primary node. To find the ALB PIP, select ALB > **Frontend IP configuration**.



See the **Resources** section for more information about how to configure the load-balancing virtual server.

Resources:

The following links provide additional information related to HA deployment and virtual server configuration:

- Configuring high availability nodes in different subnets
- Set up basic load balancing

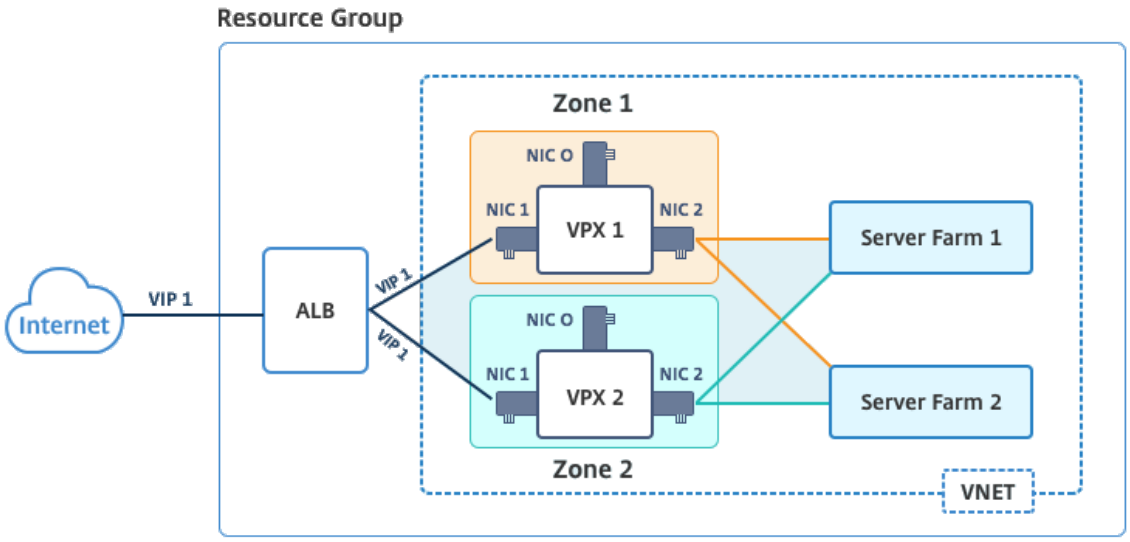
Related resources:

- Configure a high-availability setup with multiple IP addresses and NICs by using PowerShell commands
- Configuring GSLB on Active-Standby HA Deployment on Azure

High availability using availability zones

Azure Availability Zones are fault-isolated locations within an Azure region, providing redundant power, cooling, and networking and increasing resiliency. Only specific Azure regions support Availability Zones. For more information, see the Azure documentation [What are Availability Zones in Azure.

Diagram: Example of a high availability deployment architecture, using Azure Availability Zones



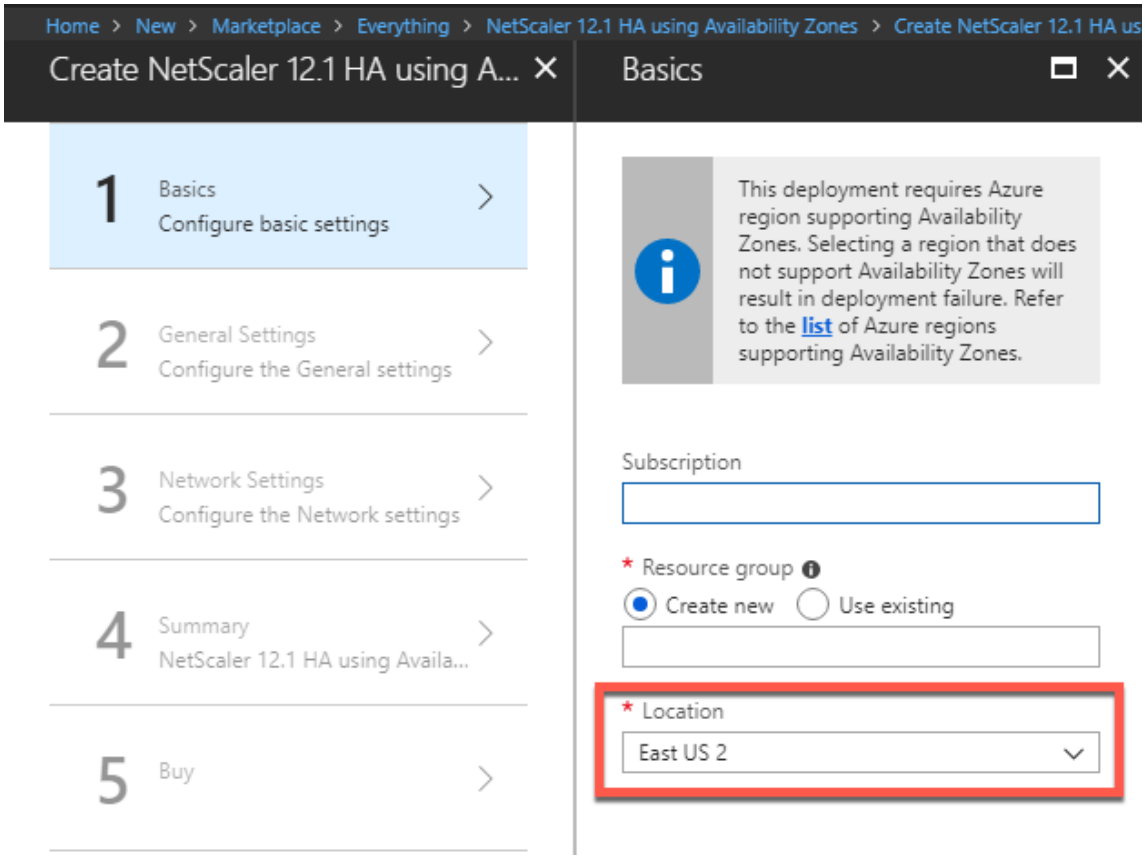
You can deploy a VPX pair in high availability mode by using the template called “NetScaler 13.0 HA using Availability Zones,” available in Azure Marketplace.

Complete the following steps to launch the template and deploy a high availability VPX pair, by using Azure Availability Zones.

1. From Azure Marketplace, select and initiate the Citrix solution template.

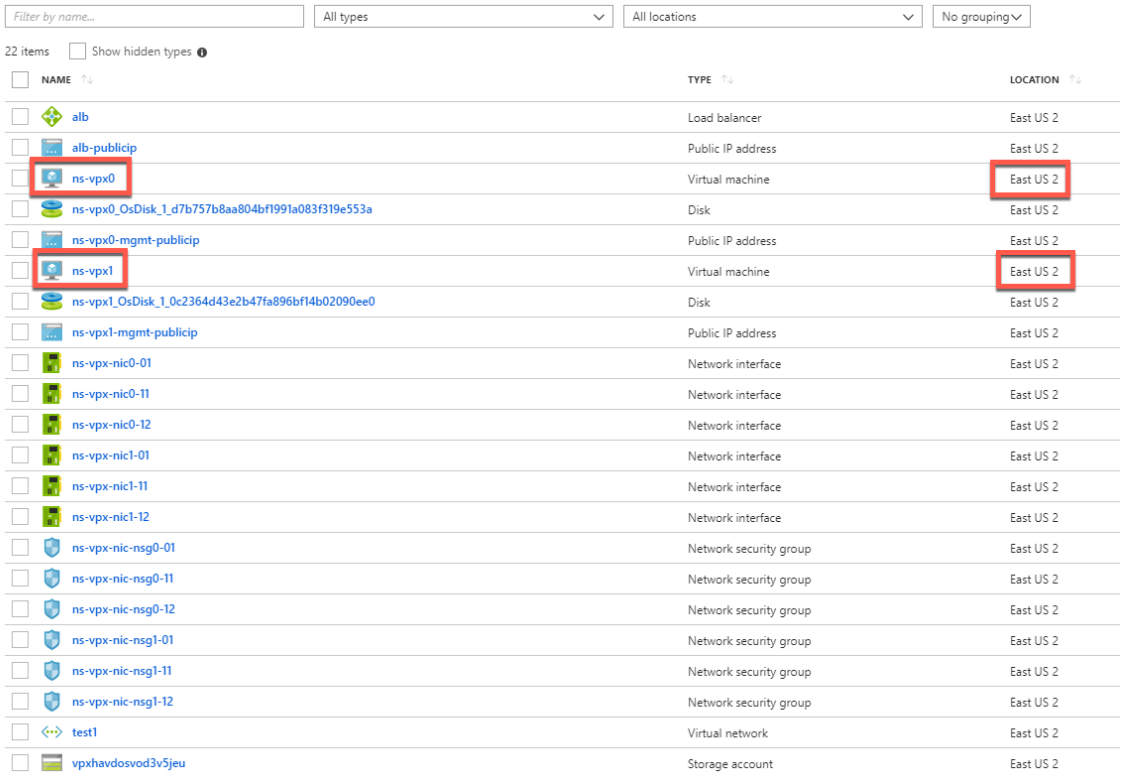
2. Ensure deployment type is Resource Manager and select **Create**.
3. The **Basics** page appears. Enter the details and click **OK**.

> Note: Ensure that you select an Azure region that supports Availability Zones. For more information about regions that support Availability Zones, see Azure documentation What are Availability Zones in Azure?



4. The **General Settings** page appears. Type the details and select **OK**.
5. The **Network Setting** page appears. Check the VNet and subnet configurations, edit the required settings, and select **OK**.
6. The **Summary** page appears. Review the configuration and edit accordingly. Select **OK** to confirm.
7. The **Buy** page appears. Select **Purchase** to complete the deployment.

   It might take a moment for the Azure Resource Group to be created with the required configurations. After completion, select the **Resource Group** to see the configuration details, such as LB rules, back-end pools, health probes, and so on, in the Azure portal. The high availability pair appears as ns-vpx0 and ns-vpx1. Also, you can see the location under the **Location** column.



If further modifications are required for your HA setup, such as creating more security rules and ports, you can do that from the Azure portal.

Monitor your instances using metrics in Azure monitor

You can use metrics in the Azure monitor data platform to monitor a set of Citrix ADC VPX resources such as CPU, memory utilization, and throughput. Metrics service monitors Citrix ADC VPX resources that run on Azure, in real time. You can use **Metrics Explorer** to access the collected data. For more information, see Azure Monitor Metrics overview.

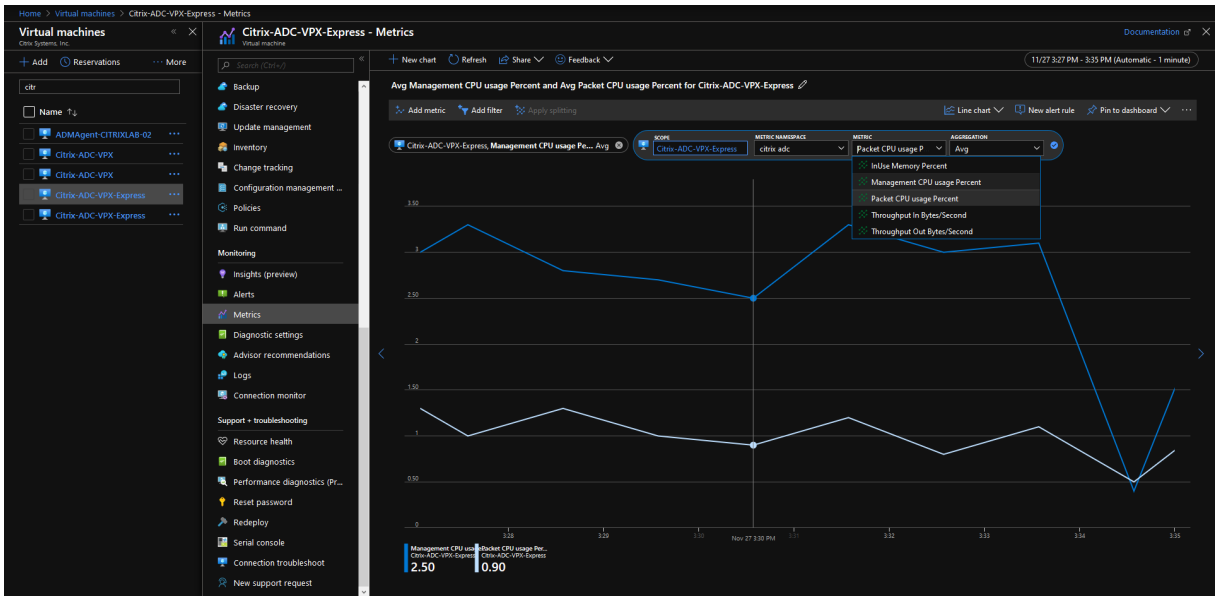
Points to note

- If you deploy a Citrix ADC VPX instance on Azure by using the Azure Marketplace offer, Metrics service is disabled by default.
- The Metrics service is not supported in Azure CLI.
- Metrics are available for CPU (management and packet CPU usage), memory, and throughput (inbound and outbound).

How to view metrics in Azure monitor

To view metrics in the Azure monitor for your instance, perform these steps:

1. Log on to **Azure Portal > Virtual Machines**.
2. Select the virtual machine that is the Primary Node.
3. In the **Monitoring** section, click **Metrics**.
4. From the **Metric Namespace** drop-down menu, click **Citrix ADC**.
5. Under **All metrics** in **Metrics** drop-down menu, click the metrics you want to view.
6. Click **Add metric** to view another metric on the same chart. Use the Chart options to customize your chart.



Configure a high-availability setup with multiple IP addresses and NICs by using PowerShell commands

September 14, 2021

You can deploy a pair of Citrix ADC VPX instances with multiple NICs in an active-passive high availability (HA) setup on Azure. Each NIC can contain multiple IP addresses.

An active-passive deployment requires:

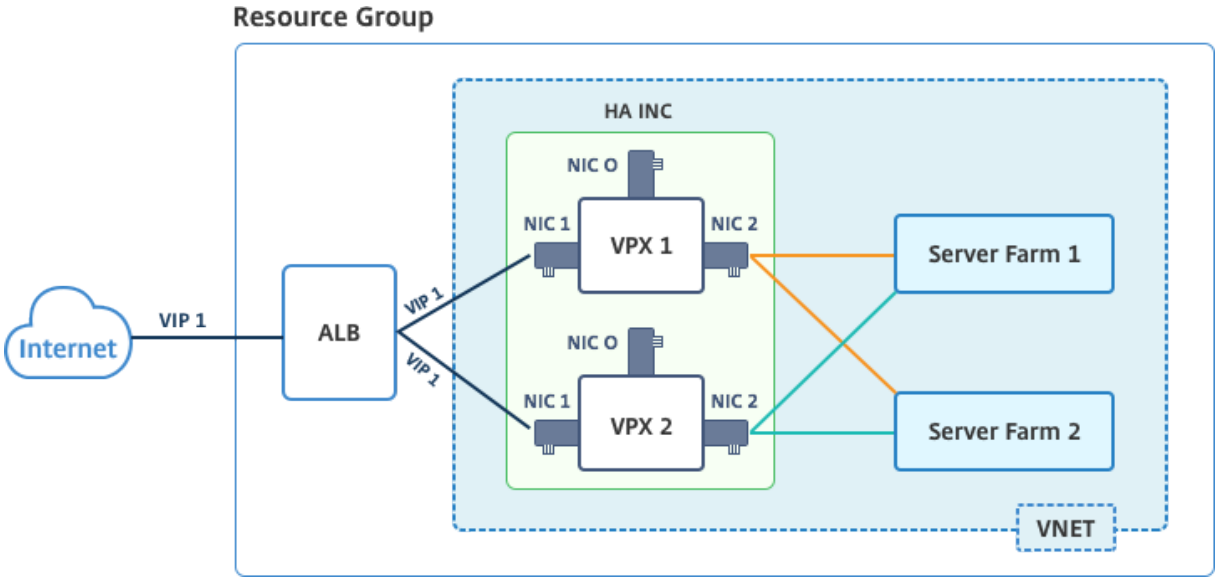
- An HA Independent Network Configuration (INC) configuration
- The Azure Load Balancer (ALB) in Direct Server Return (DSR) mode

All traffic goes through the primary node. The secondary node remains in standby mode until the primary node fails.

> **Note**
>
> For a Citrix ADC VPX high availability deployment on an Azure cloud to work, you need a floating

> public IP (PIP) that can be moved between the two high-availability nodes. The Azure Load Balancer (ALB) provides that floating PIP, which is moved to the second node automatically in the event of a failover.

Diagram: Example of an active-passive deployment architecture



In an active-passive deployment, the ALB floating public IP (PIP) addresses are added as the VIP addresses in each VPX node. In HA-INC configuration, the VIP addresses are floating and SNIP addresses are instance specific.

ALB monitors each VPX instance by sending health probe at every 5 seconds and redirects traffic to that instance only that sends health probes response on regular interval. So in an HA setup, the primary node responds to health probes and secondary does not. If the primary instances miss two consecutive health probes, ALB does not redirect traffic to that instance. On failover, the new primary starts responding to health probes and the ALB redirects traffic to it. The standard VPX high availability failover time is three seconds. The total failover time that might take for traffic switching can be maximum of 13 seconds.

You can deploy a VPX pair in active-passive HA setup in two ways by using:

- **Citrix ADC VPX Standard high availability template**: use this option to configure an HA pair with the default option of three subnets and six NICs.
- **Windows PowerShell commands**: use this option to configure an HA pair according to your subnet and NIC requirements.

This topic describes how to deploy a VPX pair in active-passive HA setup by using PowerShell commands. If you want to use the Citrix ADC VPX Standard HA template, see Configuring an HA Setup with Multiple IP Addresses and NICs.

Configure HA-INC nodes by using PowerShell Commands

Scenario: HA-INC PowerShell deployment

In this scenario, you deploy a Citrix ADC VPX pair by using the topology given in the table. Each VPX instance contains three NICs, with each NIC is deployed in a different subnet. Each NIC is assigned an IP configuration.

ALB	VPX1	VPX2
ALB is associated with public IP 3 (pip3)	Management IP is configured with IPConfig1, which includes one public IP (pip1) and one private IP (12.5.2.24); nic1; Mgmtsubnet=12.5.2.0/24	Management IP is configured with IPConfig5, which includes one public IP (pip3) and one private IP (12.5.2.26);nic4;Mgmtsubnet=12.5.2.0/24
LB rules and port configured are HTTP (80),SSL (443), health probe (9000)	Client-side IP is configured with IPConfig3, which includes one private IP(12.5.1.27);nic2; FrontEndsubet=12.5.1.0/24	Client-side IP is configured with IPConfig7, which includes one private IP (12.5.1.28);nic5;FrontEndsubet=12.5.1.0/24
-	Server-side IP is configured with IPConfig4, which includes one private IP(12.5.3.24); nic3;BackendSubnet=12.5.3.0/2	Server-side IP is configured with IPConfig8, which includes one private IP(12.5.3.28);nic6;BackendSubnet=12.5.3.0/2
-	Rules and ports for NSG are SSH (22),HTTP (80),HTTPS (443)	-

Parameter settings

The following parameter settings are used in this scenario.

$locName= “South east Asia”

$rgName = “MulitIP-MultiNIC-RG”

$nicName1= “VM1-NIC1”

$nicName2 = “VM1-NIC2”

$nicName3= “VM1-NIC3”

$nicName4 = “VM2-NIC1”

$nicName5= “VM2-NIC2”

$nicName6 = “VM2-NIC3”

$vNetName = “Azure-MultiIP-ALB-vnet”

$vNetAddressRange= “12.5.0.0/16”

$frontEndSubnetName= “frontEndSubnet”

$frontEndSubnetRange= “12.5.1.0/24”

$mgmtSubnetName= “mgmtSubnet”

$mgmtSubnetRange= “12.5.2.0/24”

$backEndSubnetName = “backEndSubnet”

$backEndSubnetRange = “12.5.3.0/24”

$prmStorageAccountName = “multiipmultinicbstorage”

$avSetName = “multiple-avSet”

$vmSize= “Standard_DS4_V2”

$publisher = “Citrix”

$offer = “netscalervpx-120”

$sku = “netscalerbyol”

$version=”latest”

$pubIPName1=”VPX1MGMT”

$pubIPName2=”VPX2MGMT”

$pubIPName3=”ALBPIP”

$domName1=”vpx1dns”

$domName2=”vpx2dns”

$domName3=”vpxalbdns”

$vmNamePrefix=”VPXMultiIPALB”

$osDiskSuffix1=”osmultiipalbdiskdb1”

$osDiskSuffix2=”osmultiipalbdiskdb2”

$lbName= “MultiIPALB”

$frontEndConfigName1= “FrontEndIP”

$backendPoolName1= “BackendPoolHttp”

$lbRuleName1= “LBRuleHttp”

$healthProbeName= “HealthProbe”

$nsgName=”NSG-MultiIP-ALB”

$rule1Name=”Inbound-HTTP”

$rule2Name=”Inbound-HTTPS”

$rule3Name=”Inbound-SSH”

To complete the deployment, complete the following steps by using PowerShell commands:

1. Create a resource group, storage account, and availability set
2. Create a network security group and add rules
3. Create a virtual network and three subnets
4. Create public IP addresses
5. Create IP configurations for VPX1
6. Create IP configurations for VPX2
7. Create NICs for VPX1
8. Create NICs for VPX2
9. Create VPX1
10. Create VPX2
11. Create ALB

Create a resource group, storage account, and availability set.

```
New-AzureRmResourceGroup -Name $rgName -Location $locName

$prmStorageAccount=New-AzureRMStorageAccount -Name
    $prmStorageAccountName -ResourceGroupName $rgName -Type Standard_LRS
     -Location $locName

$avSet=New-AzureRMAvailabilitySet -Name $avSetName -ResourceGroupName
    $rgName -Location $locName
```

Create a network security group and add rules.

```
$rule1 = New-AzureRmNetworkSecurityRuleConfig -Name $rule1Name -
    Description "Allow HTTP" -Access Allow -Protocol Tcp -Direction
    Inbound -Priority 101

```

```
-SourceAddressPrefix Internet -SourcePortRange * -
    DestinationAddressPrefix * -DestinationPortRange 80

$rule2 = New-AzureRmNetworkSecurityRuleConfig -Name $rule2Name -
    Description "Allow HTTPS" -Access Allow -Protocol Tcp -Direction
    Inbound -Priority 110

-SourceAddressPrefix Internet -SourcePortRange * -
    DestinationAddressPrefix * -DestinationPortRange 443

$rule3 = New-AzureRmNetworkSecurityRuleConfig -Name $rule3Name -
    Description "Allow SSH" -Access Allow -Protocol Tcp -Direction
    Inbound -Priority 120

-SourceAddressPrefix Internet -SourcePortRange * -
    DestinationAddressPrefix * -DestinationPortRange 22

$nsg = New-AzureRmNetworkSecurityGroup -ResourceGroupName $rgName -
    Location $locName -Name $nsgName -SecurityRules $rule1,$rule2,$rule3
```

Create a virtual network and three subnets.

```
$frontendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
    $frontEndSubnetName -AddressPrefix $frontEndSubnetRange (this
    parameter value should be as per your requirement)

$mgmtSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name $mgmtSubnetName
     -AddressPrefix $mgmtSubnetRange

$backendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
    $backEndSubnetName -AddressPrefix $backEndSubnetRange

$vnet =New-AzureRmVirtualNetwork -Name $vNetName -ResourceGroupName
    $rgName -Location $locName -AddressPrefix $vNetAddressRange -Subnet
    $frontendSubnet,$backendSubnet, $mgmtSubnet

```

```
$subnetName ="frontEndSubnet"

$subnet1=$vnet.Subnets|?{
 $_.Name -eq $subnetName }

$subnetName="backEndSubnet"

$subnet2=$vnet.Subnets|?{
 $_.Name -eq $subnetName }

$subnetName="mgmtSubnet"

$subnet3=$vnet.Subnets|?{
 $_.Name -eq $subnetName }
```

Create public IP addresses.

```
$pip1=New-AzureRmPublicIpAddress -Name $pubIPName1 -ResourceGroupName
    $rgName -DomainNameLabel $domName1 -Location $locName -
    AllocationMethod Dynamic

$pip2=New-AzureRmPublicIpAddress -Name $pubIPName2 -ResourceGroupName
    $rgName -DomainNameLabel $domName2 -Location $locName -
    AllocationMethod Dynamic

$pip3=New-AzureRmPublicIpAddress -Name $pubIPName3 -ResourceGroupName
    $rgName -DomainNameLabel $domName3 -Location $locName -
    AllocationMethod Dynamic
```

Create IP configurations for VPX1.

```
$IpConfigName1 = "IPConfig1"

$IPAddress = "12.5.2.24"

$IPConfig1=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName1 -
```

```
    Subnet $subnet3 -PrivateIpAddress $IPAddress -PublicIpAddress $pip1
    -Primary
8
9
10 $IPConfigName3="IPConfig-3"
11
12
13 $IPAddress="12.5.1.27"
14
15
16 $IPConfig3=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName3 -
    Subnet $subnet1 -PrivateIpAddress $IPAddress -Primary
17
18
19 $IPConfigName4 = "IPConfig-4"
20
21
22 $IPAddress = "12.5.3.24"
23
24
25 $IPConfig4 = New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName4 -
    Subnet $subnet2 -PrivateIpAddress $IPAddress -Primary
```

Create IP configurations for VPX2.

```
1  $IpConfigName5 = "IPConfig5"
2
3
4  $IPAddress="12.5.2.26"
5
6
7  $IPConfig5=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName5 -
    Subnet $subnet3 -PrivateIpAddress $IPAddress -PublicIpAddress $pip2
    -Primary
8
9
10 $IPConfigName7="IPConfig-7"
11
12
13 $IPAddress="12.5.1.28"
14
15
16 $IPConfig7=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName7 -
    Subnet $subnet1 -PrivateIpAddress $IPAddress -Primary
17
```

```
18
19 $IPConfigName8="IPConfig-8"
20
21
22 $IPAddress="12.5.3.28"
23
24
25 $IPConfig8=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName8 -
       Subnet $subnet2 -PrivateIpAddress $IPAddress -Primary
```

Create NICs for VPX1.

```
1 $nic1=New-AzureRmNetworkInterface -Name $nicName1 -ResourceGroupName
      $rgName -Location $locName -IpConfiguration $IpConfig1 -
      NetworkSecurityGroupId $nsg.Id
2
3
4 $nic2=New-AzureRmNetworkInterface -Name $nicName2 -ResourceGroupName
      $rgName -Location $locName -IpConfiguration $IpConfig3 -
      NetworkSecurityGroupId $nsg.Id
5
6
7 $nic3=New-AzureRmNetworkInterface -Name $nicName3 -ResourceGroupName
      $rgName -Location $locName -IpConfiguration $IpConfig4 -
      NetworkSecurityGroupId $nsg.Id
```

Create NICs for VPX2.

```
1 $nic4=New-AzureRmNetworkInterface -Name $nicName4 -ResourceGroupName
      $rgName -Location $locName -IpConfiguration $IpConfig5 -
      NetworkSecurityGroupId $nsg.Id
2
3
4 $nic5=New-AzureRmNetworkInterface -Name $nicName5 -ResourceGroupName
      $rgName -Location $locName -IpConfiguration $IpConfig7 -
      NetworkSecurityGroupId $nsg.Id
5
6
7 $nic6=New-AzureRmNetworkInterface -Name $nicName6 -ResourceGroupName
      $rgName -Location $locName -IpConfiguration $IpConfig8 -
      NetworkSecurityGroupId $nsg.Id
```

Create VPX1.

This step includes the following substeps:

- Create VM config object
- Set credentials, OS, and image
- Add NICs
- Specify OS disk and create VM

```
$suffixNumber = 1

$vmName=$vmNamePrefix + $suffixNumber

$vmConfig=New-AzureRMVMConfig -VMName $vmName -VMSize $vmSize -
    AvailabilitySetId $avSet.Id

$cred=Get-Credential -Message "Type the name and password for VPX
     login."

$vmConfig=Set-AzureRMVMOperatingSystem -VM $vmConfig -Linux -
    ComputerName $vmName -Credential $cred

$vmConfig=Set-AzureRMVMSourceImage -VM $vmConfig -PublisherName
    $publisher -Offer $offer -Skus $sku -Version $version

$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic1.
    Id -Primary

$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic2.
    Id

$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic3.
    Id

$osDiskName=$vmName + "-" + $osDiskSuffix1

$osVhdUri=$prmStorageAccount.PrimaryEndpoints.Blob.ToString() + "
    vhds/" + $osDiskName + ".vhd"

$vmConfig=Set-AzureRMVMOSDisk -VM $vmConfig -Name $osDiskName -
    VhdUri $osVhdUri -CreateOption fromImage

Set-AzureRmVMPlan -VM $vmConfig -Publisher $publisher -Product
    $offer -Name $sku

New-AzureRMVM -VM $vmConfig -ResourceGroupName $rgName -Location
    $locName
```

Create VPX2.

```
```
$suffixNumber=2

$vmName=$vmNamePrefix + $suffixNumber

$vmConfig=New-AzureRMVMConfig -VMName $vmName -VMSize $vmSize -
    AvailabilitySetId $avSet.Id

$cred=Get-Credential -Message "Type the name and password for VPX login
    ."

$vmConfig=Set-AzureRMVMOperatingSystem -VM $vmConfig -Linux -
    ComputerName $vmName -Credential $cred

$vmConfig=Set-AzureRMVMSourceImage -VM $vmConfig -PublisherName
    $publisher -Offer $offer -Skus $sku -Version $version

$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic4.Id -
    Primary

$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic5.Id

$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic6.Id

$osDiskName=$vmName + "-" + $osDiskSuffix2

$osVhdUri=$prmStorageAccount.PrimaryEndpoints.Blob.ToString() + "vhds/"
     + $osDiskName + ".vhd"

$vmConfig=Set-AzureRMVMOSDisk -VM $vmConfig -Name $osDiskName -VhdUri
    $osVhdUri -CreateOption fromImage

```

 
```

```
37
38 Set-AzureRmVMPlan -VM $vmConfig -Publisher $publisher -Product $offer -
       Name $sku
39
40
41 New-AzureRMVM -VM $vmConfig -ResourceGroupName $rgName -Location
       $locName
42 <!--NeedCopy--> ```
```

To view private and public IP addresses assigned to the NICs, type the following commands:

```
1 ```
2 $nic1.IPConfig
3
4
5 $nic2.IPConfig
6
7
8 $nic3.IPConfig
9
10
11 $nic4.IPConfig
12
13
14 $nic5.IPConfig
15
16
17 $nic6.IPConfig
18 <!--NeedCopy--> ```
```

Create Azure load balance (ALB).

This step includes the following substeps:

- Create front end IP config
- Create health probe
- Create back end address pool
- Create load-balancing rules (HTTP and SSL)
- Create ALB with front end IP config, back end address pool, and LB rule
- Associate IP config with back end pools

```
$frontEndIP1=New-AzureRmLoadBalancerFrontendIpConfig -Name $frontEndConfigName1
 -PublicIpAddress $pip3
```

```
$healthProbe=New-AzureRmLoadBalancerProbeConfig -Name $healthProbeName
-Protocol Tcp -Port 9000 -IntervalInSeconds 5 -ProbeCount 2

$beAddressPool1=New-AzureRmLoadBalancerBackendAddressPoolConfig -Name
$backendPoolName1

$lbRule1=New-AzureRmLoadBalancerRuleConfig -Name $lbRuleName1 -FrontendIpConfigur
 $frontEndIP1 -BackendAddressPool $beAddressPool1 -Probe $healthProbe -
Protocol Tcp -FrontendPort 80 -BackendPort 80 -EnableFloatingIP

$lb=New-AzureRmLoadBalancer -ResourceGroupName $rgName -Name $lbName -
Location $locName -FrontendIpConfiguration $frontEndIP1 -LoadBalancingRule
 $lbRule1 -BackendAddressPool $beAddressPool1 -Probe $healthProbe

$nic2.IpConfigurations[0].LoadBalancerBackendAddressPools.Add($lb.
BackendAddressPools[0])

$nic5.IpConfigurations[0].LoadBalancerBackendAddressPools.Add($lb.
BackendAddressPools[0])

$lb=$lb |Set-AzureRmLoadBalancer

$nic2=$nic2 | Set-AzureRmNetworkInterface

$nic5=$nic5 | Set-AzureRmNetworkInterface
```

After you've successfully deployed the Citrix ADC VPX pair, log on to each VPX instance to configure HA-INC, and SNIP and VIP addresses.

1. Type the following command to add HA nodes.

   ```
   add ha node 1 PeerNodeNSIP -inc Enabled
   ```

2. Add private IP addresses of client-side NICs as SNIPs for VPX1 (NIC2) and VPX2 (NIC5)

   ```
   add nsip privateIPofNIC2 255.255.255.0 -type SNIP
   add nsip privateIPofNIC5 255.255.255.0 -type SNIP
   ```

3. Add load-balancing virtual server on the primary node with front-end IP address (public IP) of ALB.

   ```
   add lb virtual server v1 HTTP FrontEndIPofALB 80
   ```

Configuring GSLB on Active-Standby HA Deployment on Azure

Configure a Citrix ADC VPX instance to use Azure accelerated networking

September 14, 2021

Accelerated networking enables the single root I/O virtualization (SR-IOV) virtual function (VF) NIC to a virtual machine, which improves the networking performance. You can use this feature with heavy workloads that need to send or receive data at higher throughput with reliable streaming and lower CPU utilization.
When a NIC is enabled with accelerated networking, Azure bundles the NIC's existing para virtualized (PV) interface with an SR-IOV VF interface. The support of SR-IOV VF interface enables and enhances the throughput of the Citrix ADC VPX instance.

Accelerated networking provides the following benefits:

- Lower latency
- Higher packets per second (pps) performance
- Enhanced throughput
- Reduced jitter
- Decreased CPU utilization

> Note
>
> Azure accelerated networking is supported on Citrix ADC VPX instances from release 13.0 build 76.29 onwards.

Prerequisites

- Ensure that your VM size matches the requirements for Azure accelerated networking.
- Stop VMs (individual or in an availability set) before enabling accelerated networking on any NIC.

Limitations

Accelerated networking can be enabled only on some instance types. For more information, see Supported instance types.

NICs supported for accelerated networking

Azure provides Mellanox ConnectX3 and ConnectX4 NICs in the SR-IOV mode for accelerated networking.

When accelerated networking is enabled on a Citrix ADC VPX interface, Azure bundles either ConnectX3 or ConnectX4 interface with the existing PV interface of a Citrix ADC VPX appliance.

For more information about enabling accelerated networking before attaching an interface to a VM, see Create a network interface with accelerated networking.

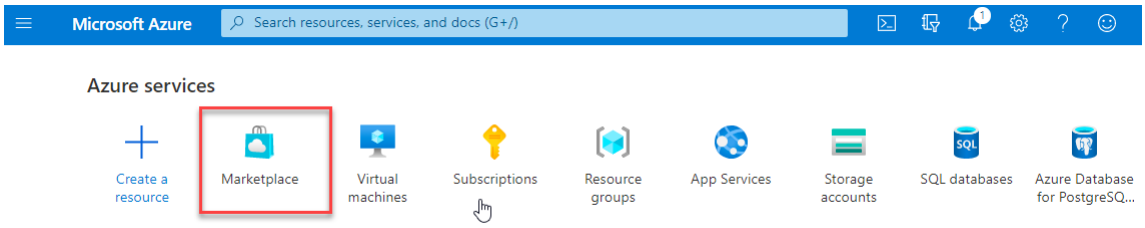
For more information about enabling accelerated networking on an existing interface on a VM, see Enable existing interfaces on a VM.

How to enable accelerated networking on Citrix ADC VPX instance using the Azure console

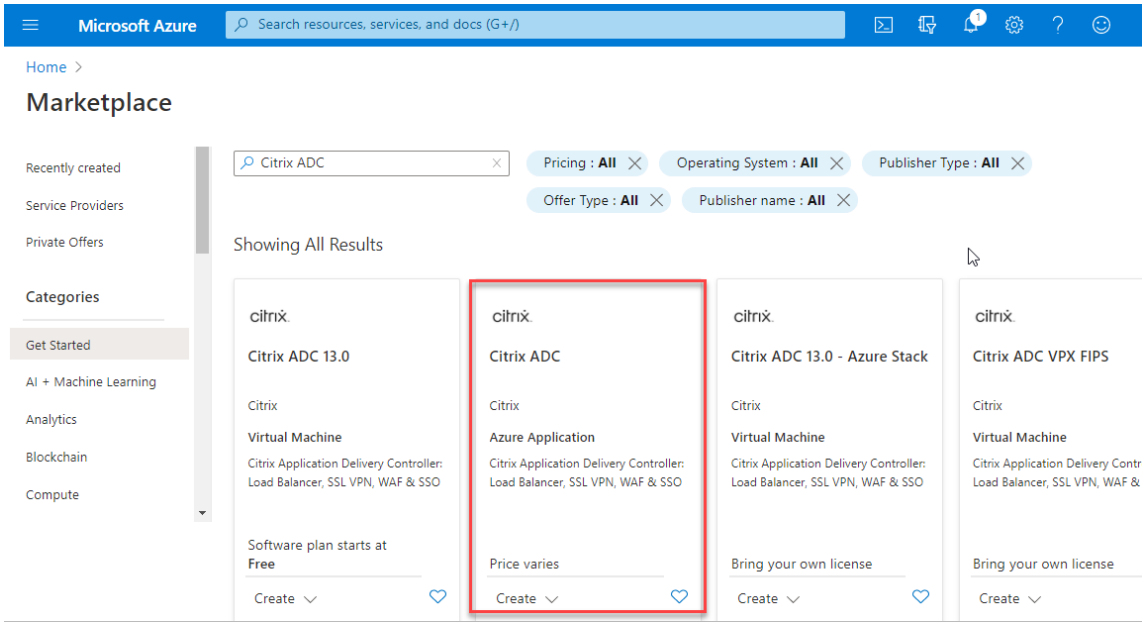
You can enable accelerated networking on a specific interface using the Azure console or the Azure PowerShell.

Do the following steps to enable accelerated networking by using Azure availability sets or availability zones.

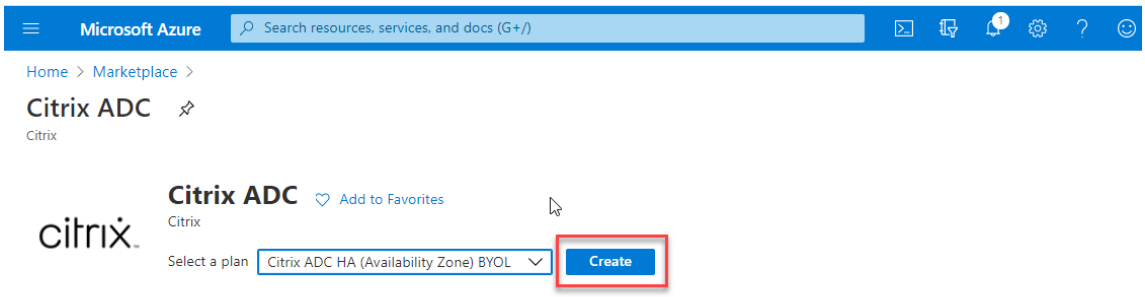
1. Log in to Azure portal, and navigate to **Azure Marketplace**.



2. From the **Azure Marketplace**, search **Citrix ADC**.

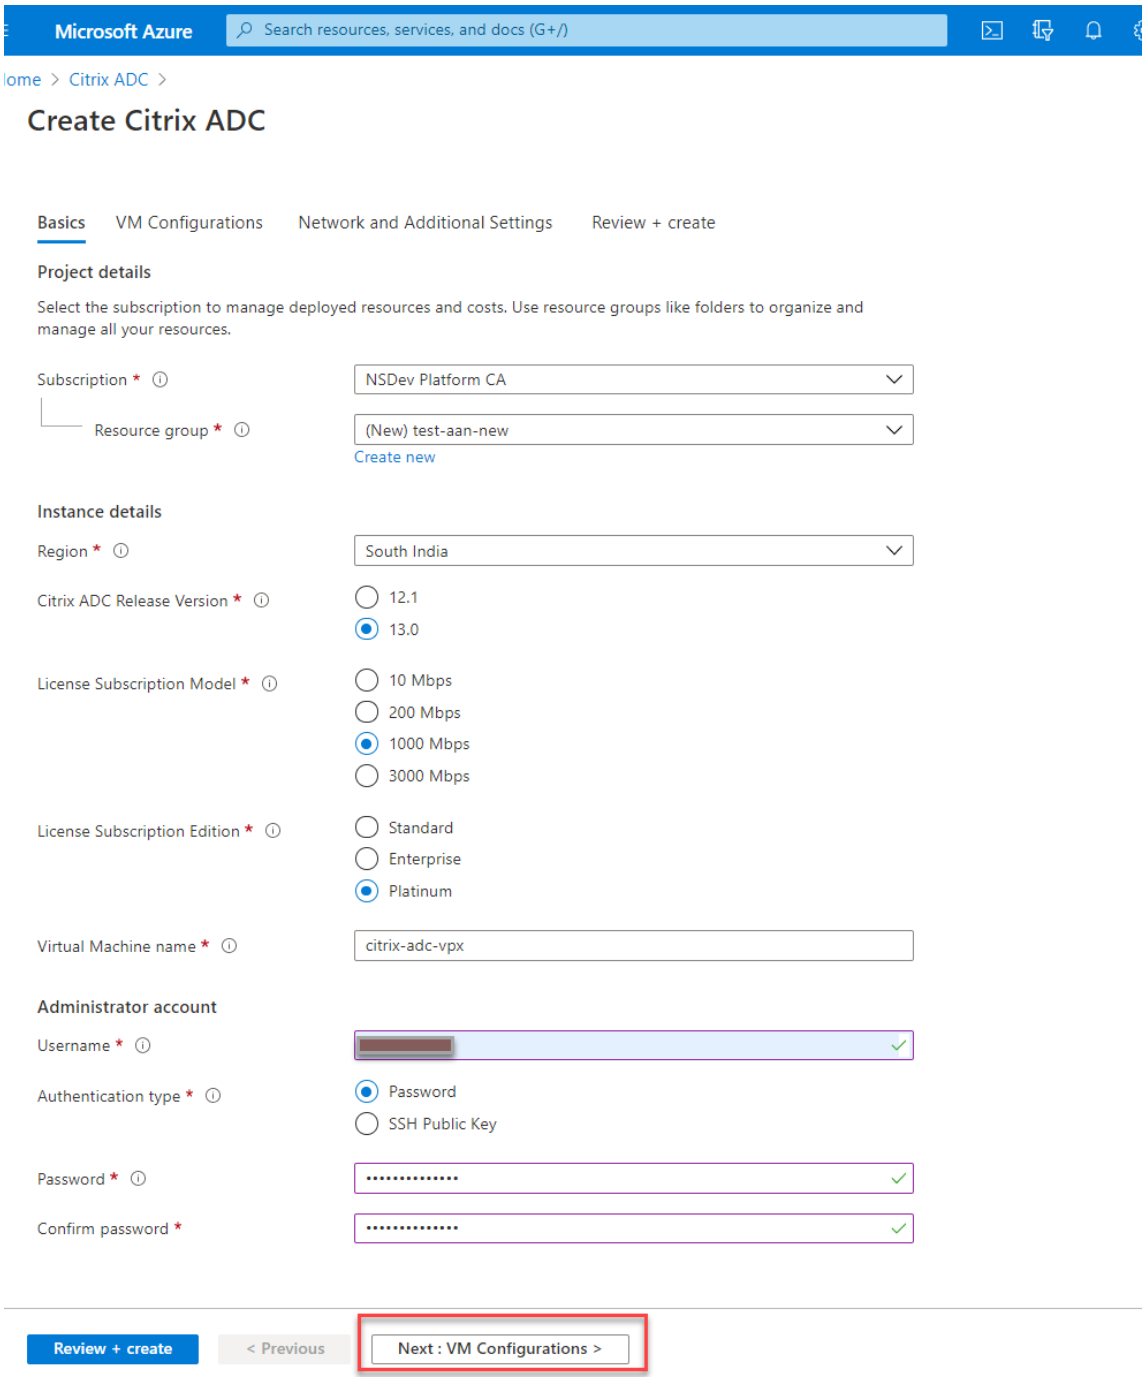


3. Select a non-FIPS Citrix ADC plan along with license, and click **Create**.



The **Create Citrix ADC** page appears.

4. In the **Basics** tab, create a Resource Group. Under the **Parameters** tab, enter details for the Region, Admin user name, Admin Password, license type (VM SKU), and other fields.



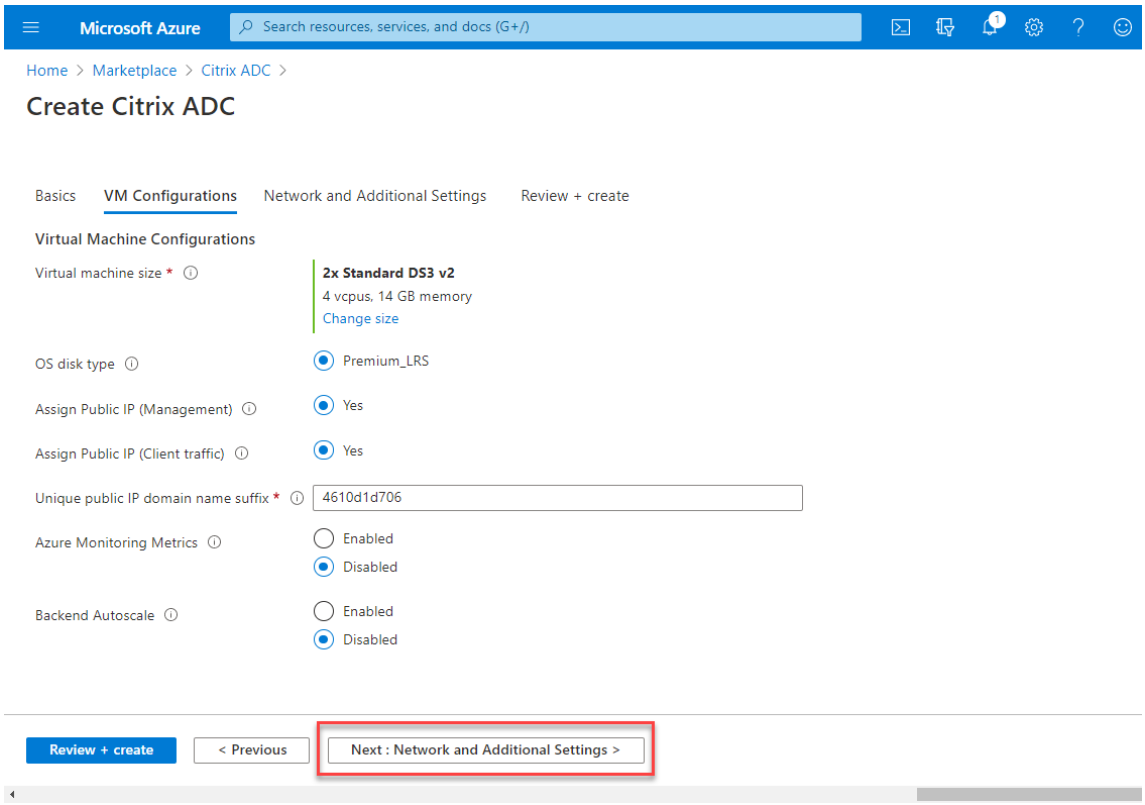
5. Click **Next : VM Configurations >**.

   On the **VM Configurations** page, perform the following:

   a) Configure public IP domain name suffix.

b) Enable or disable **Azure Monitoring Metrics**.

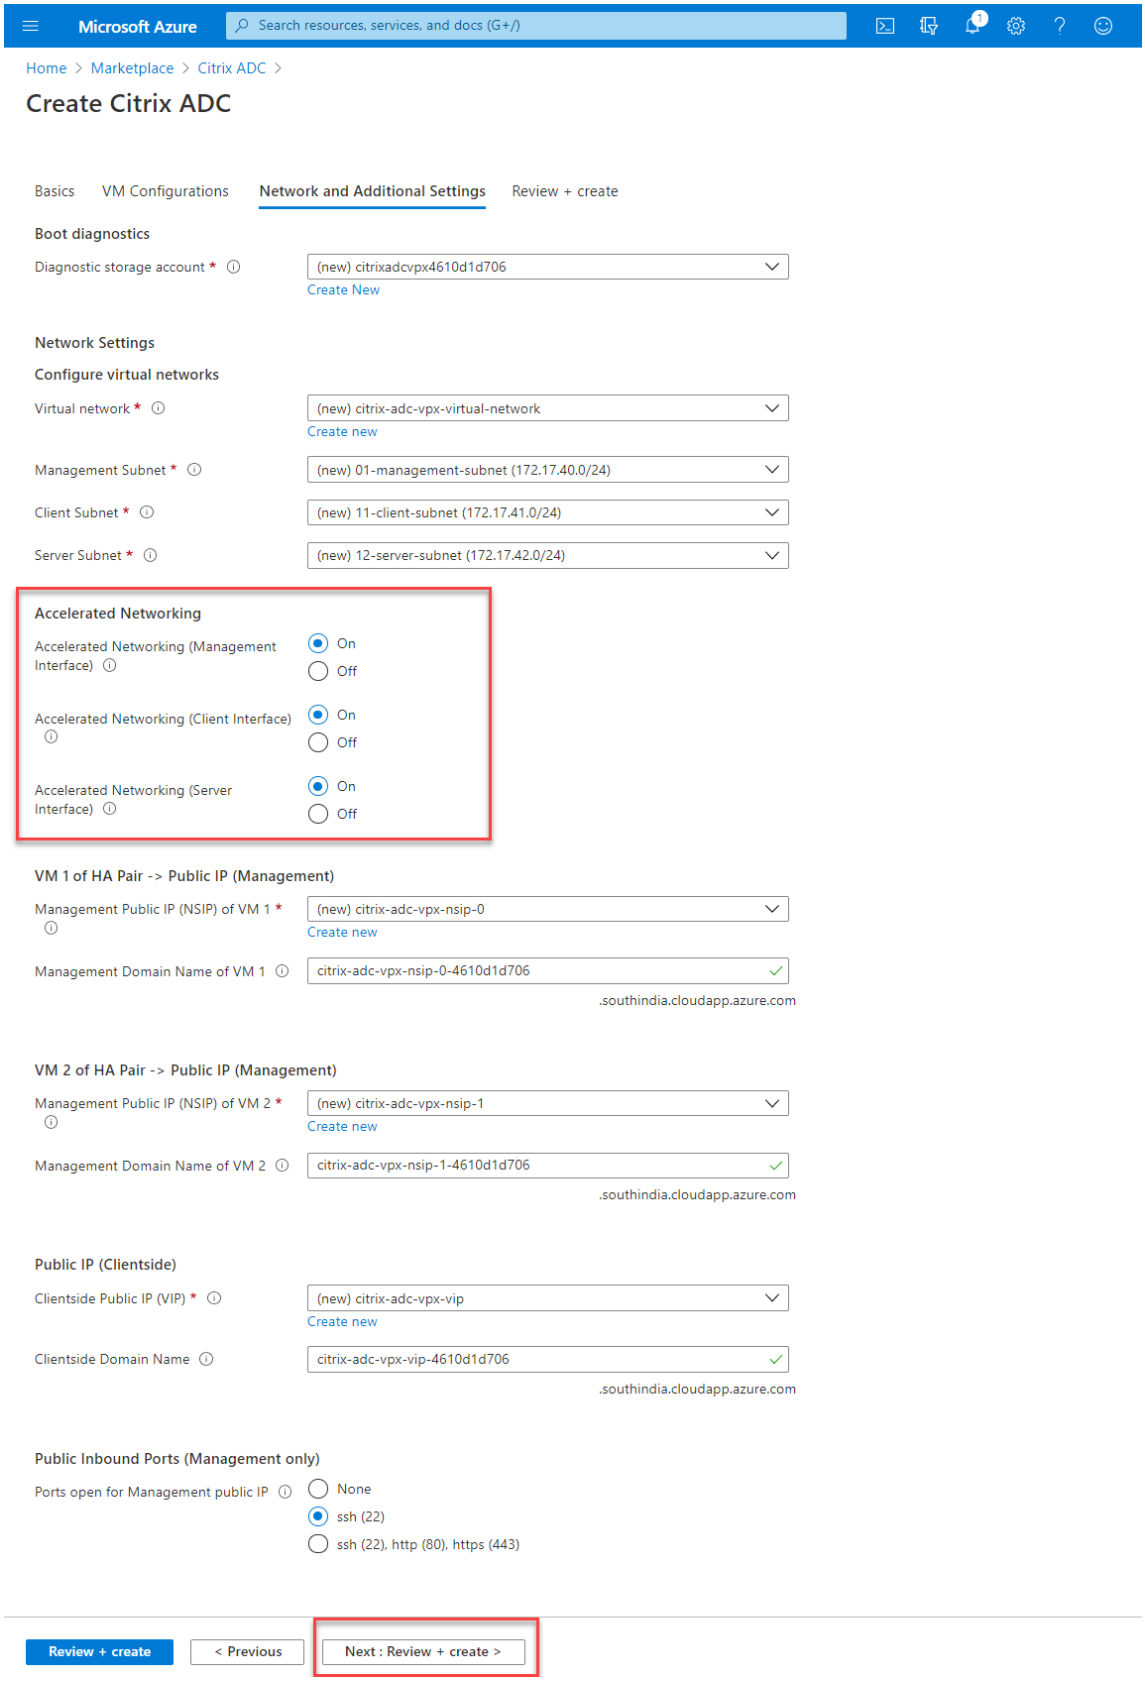
c) Enable or disable **Backend Autoscale**.



6. Click **Next: Network and Additional settings >**.

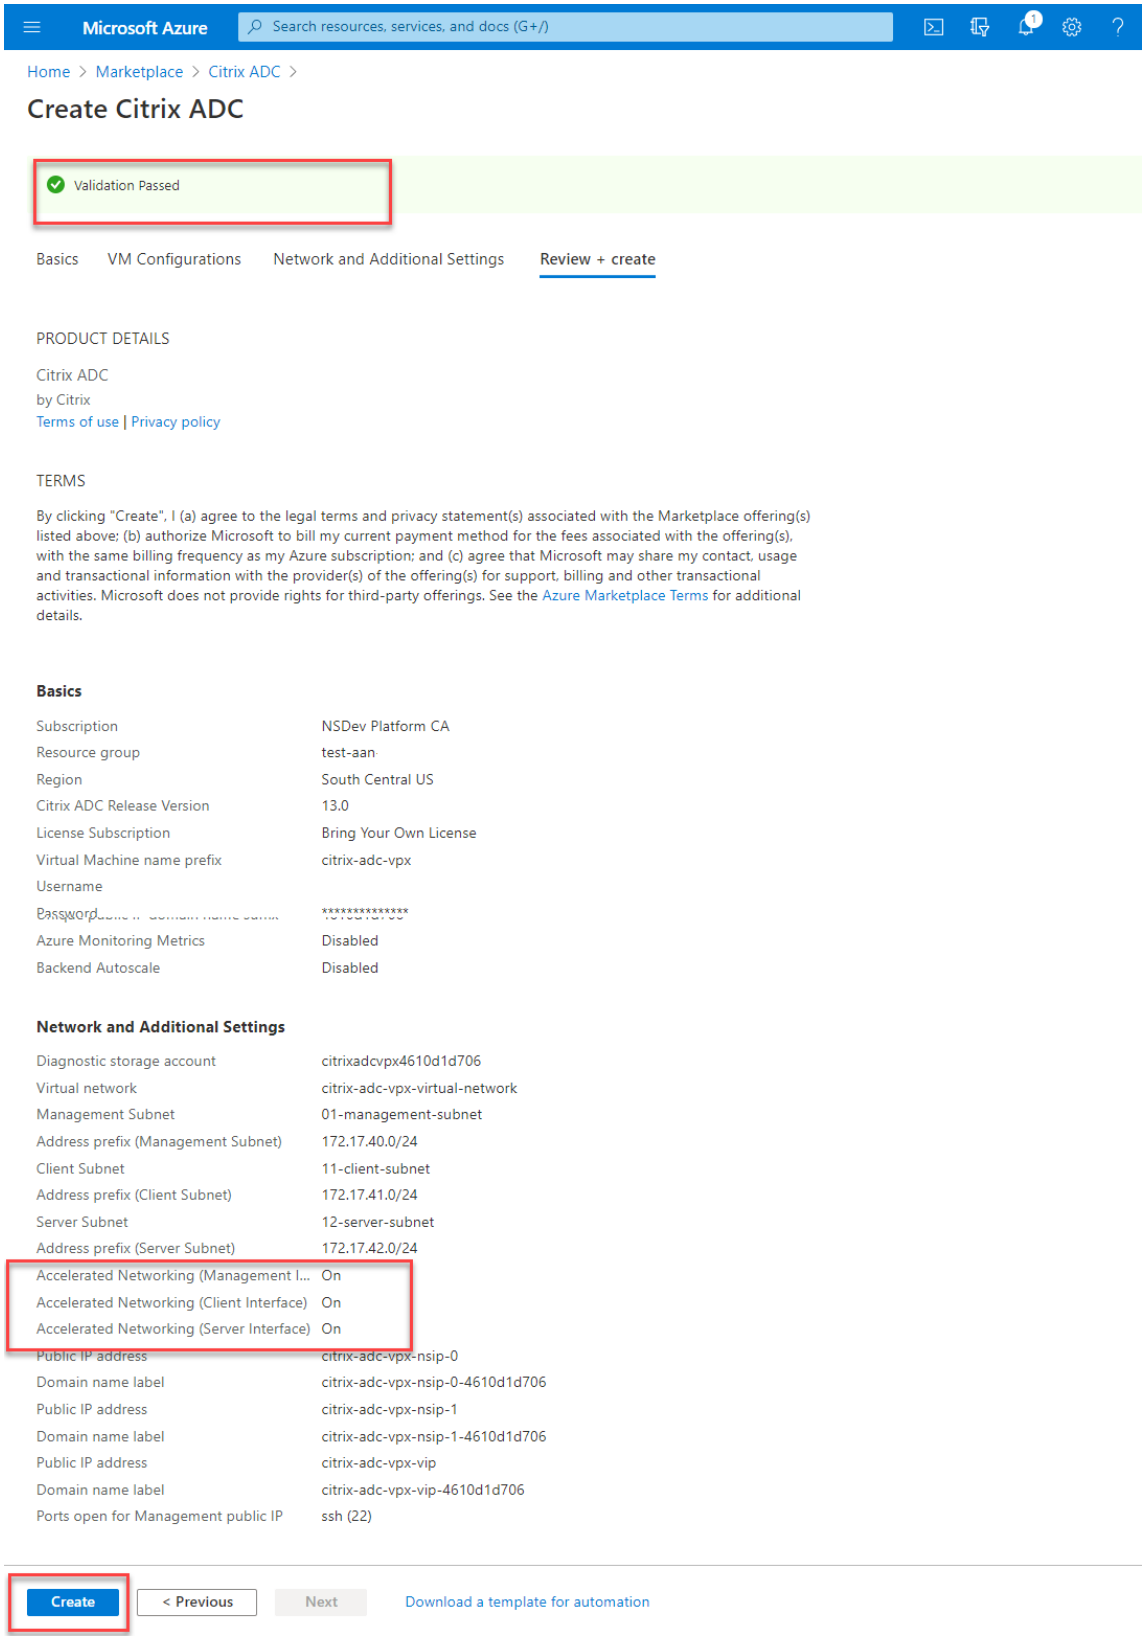
   On the **Network and Additional Settings** page, create a Boot diagnostics account and configure the network settings.

   Under the **Accelerated Networking** section, you have the option to enable or disable the accelerated networking separately for the Management interface, Client interface, and Server interface.

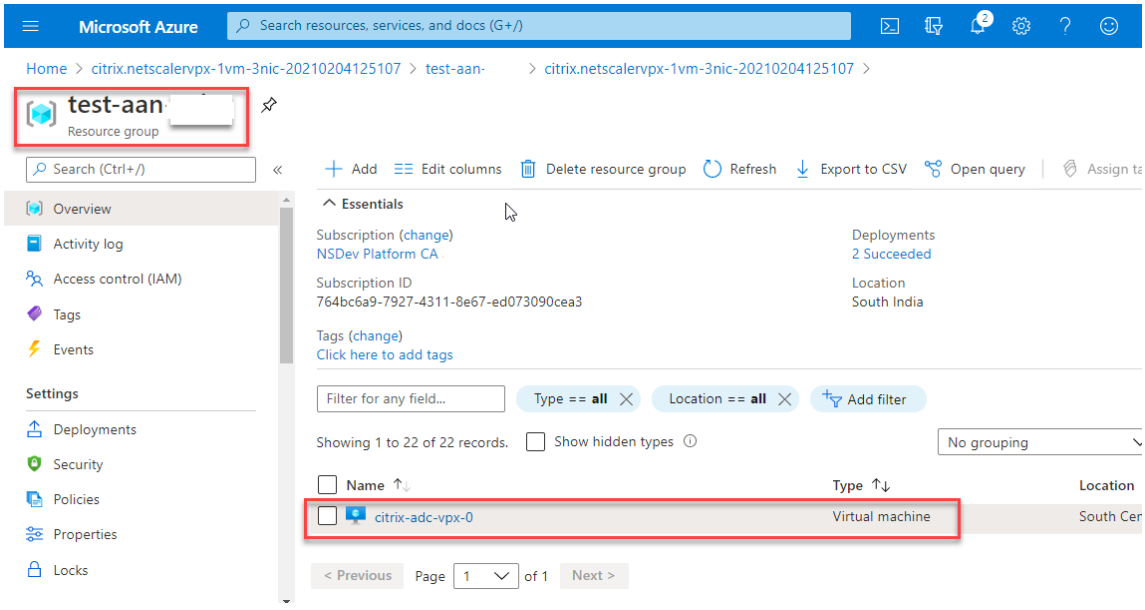


7. Click **Next: Review + create >**.

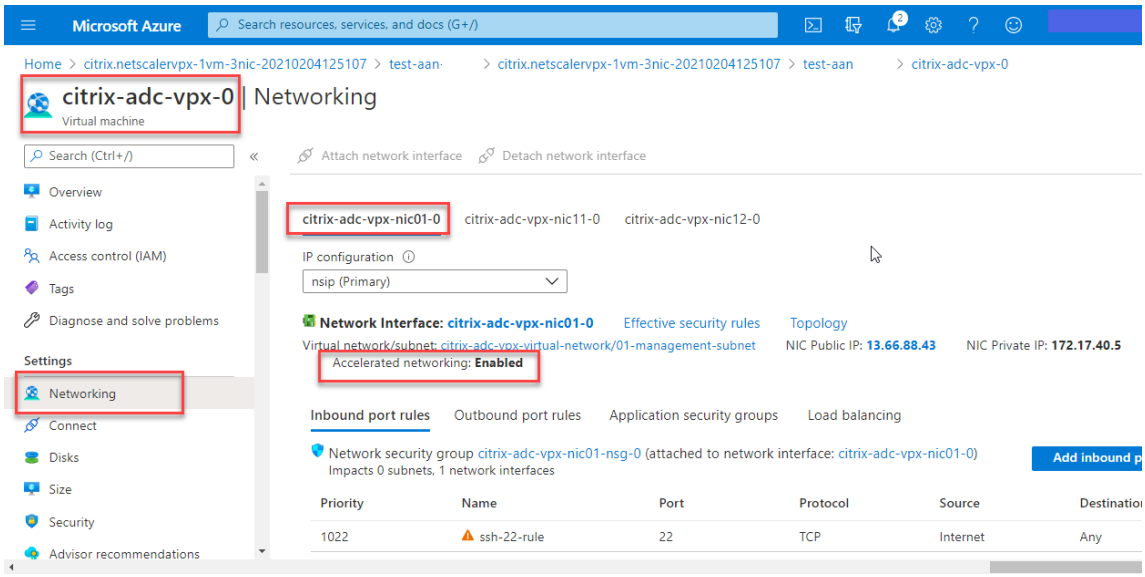
   After the validation is successful, review the basic settings, VM configurations, network and additional settings, and click **Create**. It might take some time for the Azure Resource Group to be created with the required configurations.



8. After the deployment is complete, select the **Resource Group** to see the configuration details.



9. To verify the Accelerated Networking configurations, select **Virtual machine > Networking**. The Accelerated Networking status is displayed as **Enabled** or **Disabled** for each NIC.



Enable accelerated networking using Azure PowerShell

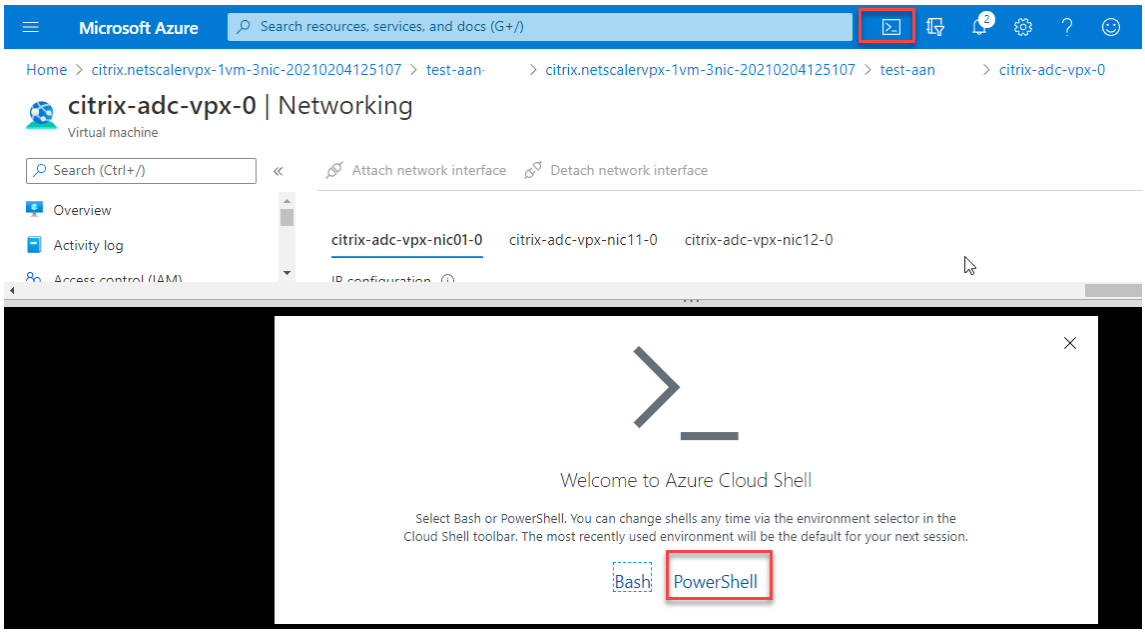
If you need to enable accelerated networking after the VM creation, you can do so using Azure PowerShell.

> Note:
>
> Ensure to stop the VM before you enable Accelerated Networking using Azure PowerShell.

Perform the following steps to enable accelerated networking by using Azure PowerShell.

1. Navigate to **Azure portal**, click the **PowerShell** icon on the right-hand top corner.

   > Note:
   >
   > If you are in the Bash mode, change to the PowerShell mode.



2. At the command prompt, run the following command:

```
az network nic update --name <nic-name> --accelerated-networking [true | false] --resource-group <resourcegroup-name>
<!--NeedCopy-->
```

The accelerated networking parameter accepts either of the following values:

- **True:** Enables accelerated networking on the specified NIC.
- **False:** Disables accelerated networking on the specified NIC.

To enable accelerated networking on a specific NIC:

```
az network nic update --name citrix-adc-vpx-nic01-0 --accelerated-networking true --resource-group rsgp1-aan
<!--NeedCopy-->
```

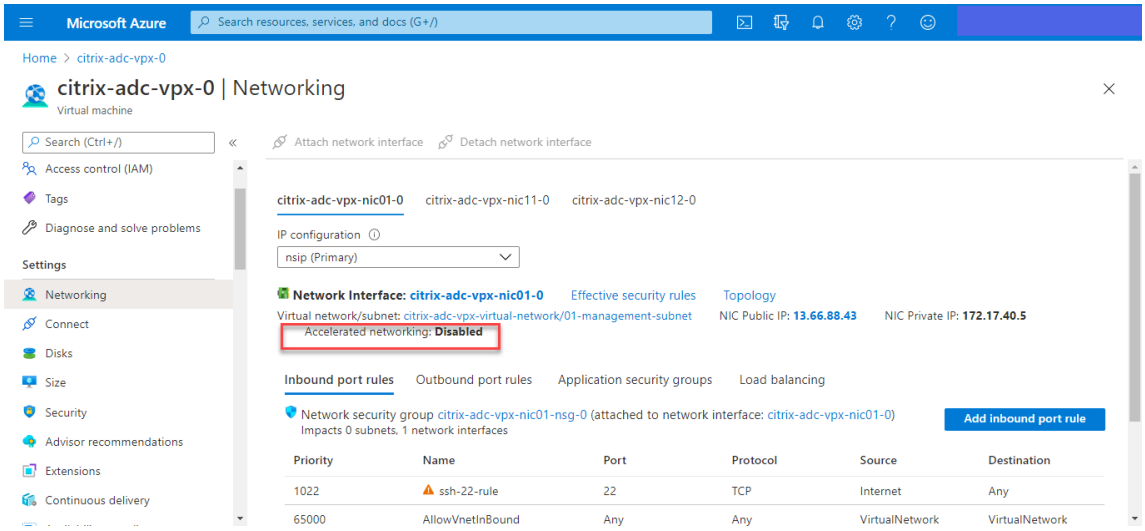
To disable accelerated networking on a specific NIC:

```
az network nic update --name citrix-adc-vpx-nic01-0 --accelerated-networking false --resource-group rsgp1-aan
<!--NeedCopy-->
```

3. To verify the Accelerated Networking status after the deployment is completed, Navigate to **VM > Networking**.

   In the following example, you can see that Accelerated Networking is **Enabled**.

   In the following example, you can see that Accelerated Networking is **Disabled**.



To verify accelerated networking on an interface by using FreeBSD Shell of Citrix ADC

You can log in to FreeBSD shell of Citrix ADC, and run the following commands to verify the accelerated networking status.

Example for ConnectX3 NIC:

The following example shows the “ifconfig” command output of the Mellanox ConnectX3 NIC. The “50/n” indicates the VF interfaces of the Mellanox ConnectX3 NICs. 0/1 and 1/1 indicates the PV inter-

faces of the Citrix ADC VPX instance. You can observe that both PV interface (1/1) and CX3 VF interface (50/1) have the same MAC addresses (00:22:48:1c:99:3e). This indicates that the two interfaces are bundled together.

```
root@nvr-us-cx3# ifconfig
lo0: flags=8049<UP,LOOPBACK,RUNNING,MULTICAST> metric 0 mtu 1500
        options=3<RXCSUM,TXCSUM>
        inet 127.0.0.1 netmask 0xff000000
        inet6 ::1 prefixlen 128
        inet6 fe80::1%lo0 prefixlen 64 scopeid 0x1
        nd6 options=3<PERFORMNUD,ACCEPT_RTADV>
0/1: flags=8843<UP,BROADCAST,RUNNING,SIMPLEX,MULTICAST> metric 0 mtu 1500
        options=80019<RXCSUM,VLAN_MTU,VLAN_HWTAGGING,LINKSTATE>
        ether 00:0d:3a:98:71:be
        inet 172.16.27.11 netmask 0xffffff00 broadcast 172.16.27.255
        inet6 fe80::20d:3aff:fe98:71be%0/1 prefixlen 64 autoconf scopeid 0x2
        nd6 options=3<PERFORMNUD,ACCEPT_RTADV>
        media: Ethernet autoselect (10Gbase-T <full-duplex>)
        status: active
1/1: flags=8802<BROADCAST,SIMPLEX,MULTICAST> metric 0 mtu 1500
        options=80019<RXCSUM,VLAN_MTU,VLAN_HWTAGGING,LINKSTATE>
        ether 00:22:48:1c:99:3e
        media: Ethernet autoselect (10Gbase-T <full-duplex>)
        status: active
50/1: flags=8842<BROADCAST,RUNNING,SIMPLEX,MULTICAST> metric 0 mtu 1500

options=900b8<VLAN_MTU,VLAN_HWTAGGING,JUMBO_MTU,VLAN_HWCSUM,VLAN_HWFILTER,LINKSTATE>
        ether 00:22:48:1c:99:3e
        media: Ethernet autoselect (<unknown subtype>)
        status: active
```

Example for ConnectX4 NIC:

The following example shows the “ifconfig” command output of the Mellanox ConnectX4 NIC. The “100/n” indicates the VF interfaces of the Mellanox ConnectX4 NICs. 0/1, 1/1, and 1/2 indicates the PV interfaces of Citrix ADC VPX instance.

You can observe that both PV interface (1/1) and CX4 VF interface (100/1) have the same MAC addresses (00:0d:3a:9b:f2:1d). This indicates that the two interfaces are bundled together. Similarly, the PV interface (1/2) and CX4 VF interface (100/2) have the same MAC addresses (00:0d:3a:1e:d2:23).

```
root@SmartNIC-CX4-NS-DUT-NEW1# ifconfig
lo0: flags=8049<UP,LOOPBACK,RUNNING,MULTICAST> metric 0 mtu 1500
        options=3<RXCSUM,TXCSUM>

        inet6 ::1 prefixlen 128
        inet6 fe80::1%lo0 prefixlen 64 scopeid 0x1
        nd6 options=3<PERFORMNUD,ACCEPT_RTADV>
1/1: flags=8843<UP,BROADCAST,RUNNING,SIMPLEX,MULTICAST> metric 0 mtu 1500
        options=80019<RXCSUM,VLAN_MTU,VLAN_HWTAGGING,LINKSTATE>

        ether 00:0d:3a:9b:f2:1d

        inet 10.0.1.29 netmask 0xffffff00 broadcast 10.0.1.255
        inet6 fe80::20d:3aff:fe9b:f21d%0/1 prefixlen 64 autoconf scopeid 0x2
        nd6 options=3<PERFORMNUD,ACCEPT_RTADV>
        media: Ethernet autoselect (10Gbase-T <full-duplex>)
        status: active

1/2: flags=8802<BROADCAST,SIMPLEX,MULTICAST> metric 0 mtu 1500
        options=80019<RXCSUM,VLAN_MTU,VLAN_HWTAGGING,LINKSTATE>

        ether 00:0d:3a:1e:d2:23

        media: Ethernet autoselect (10Gbase-T <full-duplex>)
        status: active

100/1: flags=8a03<UP,BROADCAST,ALLMULTI,SIMPLEX,MULTICAST> metric 0 mtu 1500

        ether 00:0d:3a:9b:f2:1d

        media: Ethernet autoselect <full-duplex,rxpause,txpause> (autoselect
<full-duplex,rxpause>)
        status: active

100/2: flags=8a03<UP,BROADCAST,ALLMULTI,SIMPLEX,MULTICAST> metric 0 mtu 1500

        ether 00:0d:3a:1e:d2:23

        media: Ethernet autoselect <full-duplex,rxpause,txpause> (autoselect
<full-duplex,rxpause>)
        status: active
```

To verify accelerated networking on an interface by using ADC CLI

Example for ConnectX3 NIC:

The following show interface command output indicates that the PV interface 1/1 is bundled with virtual function 50/1, which is an SR-IOV VF NIC. The MAC addresses of both 1/1 and 50/1 NICs are the same. After accelerated networking is enabled, the data of the 1/1 interface is sent through datapath of the 50/1 interface, which is a ConnectX3 interface. You can see that the “show interface” output of PV interface (1/1) points to the VF (50/1). Similarly, the “show interface” output of VF interface (50/1) points to the PV interface (1/1).

```
> show interface 1/1

        Interface 1/1 (NetScaler Virtual Interface, SmartNIC, VF 50/1 Datapath 50/1) #1
        flags=0xe060 <ENABLED, UP, UP, HEARTBEAT, 802.1q>
        MTU=1500, native vlan=1, MAC=00:22:48:1c:99:3e, uptime 0h00m07s
        LLDP Mode: NONE,                LR Priority: 1024

        RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.

Done

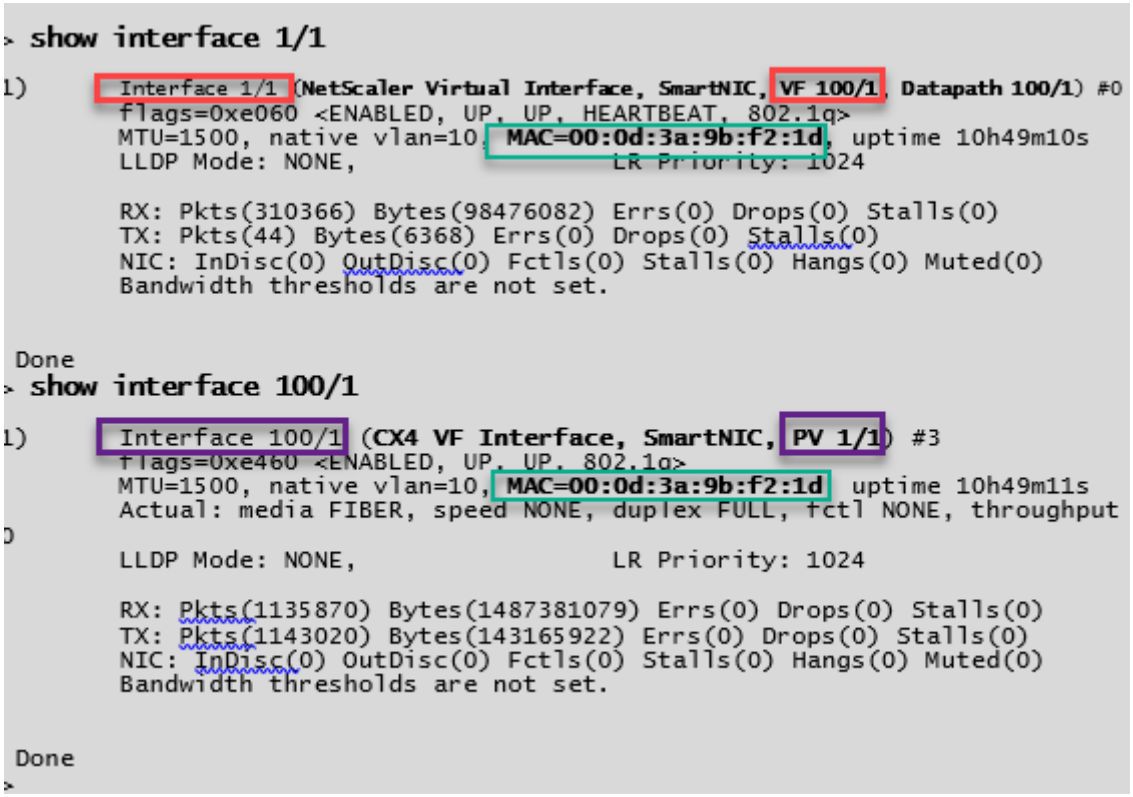
> show interface 50/1

      Interface 50/1 (CX3 VF Interface, SmartNIC, PV 1/1) #2
        flags=0xe460 <ENABLED, UP, UP, 802.1q>
        MTU=1500, native vlan=1, MAC=00:22:48:1c:99:3e, uptime 0h00m08s
        Actual: media NONE, speed 50000, duplex FULL, fctl NONE, throughput 50000
        LLDP Mode: NONE,                LR Priority: 1024

        RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
```

Example for ConnectX4 NIC:

The following show interface command output indicates that the PV interface 1/1 is bundled with virtual function 100/1, which is an SR-IOV VF NIC. The MAC addresses of both 1/1 and 100/1 NICs are the same. After accelerated networking is enabled, the data of 1/1 interface is sent through the data path of 100/1 interface, which is a ConnectX4 interface. You can see that the “show interface” output of PV interface (1/1) points to the VF (100/1). Similarly, the “show interface” output of VF interface (100/1) points to the PV interface (1/1).



Points to note in Citrix ADC

- PV interface is considered as the primary or main interface for all the necessary operations. Configurations must be performed on PV interfaces only.
- All the 'set' operations on a VF interface are blocked except the following:
  - enable interface
  - disable interface
  - reset interface
  - clear stats

  > Note:
  >
  > Citrix recommends that you do not perform any operations on the VF interface.

- You can verify the binding of PV interface with VF interface using the `show interface` command.

Configure a VLAN to a PV interface

When a PV interface is bound to a VLAN, the associated accelerated VF interface is also bound to the same VLAN as the PV interface. In this example, the PV interface (1/1) is bound to VLAN (20). The VF interface (100/1) that is bundled with the PV interface (1/1) is also bound to VLAN 20.

Example:

1. Create a VLAN.

```
add vlan 20
<!--NeedCopy-->
```

2. Bind a VLAN to the PV interface.

```
bind vlan 20  - ifnum 1/1

show vlan

1)  VLAN ID: 1
    Link-local IPv6 addr: fe80::20d:3aff:fe9b:f21d/64
    Interfaces : LO/1

2)  VLAN ID: 10     VLAN Alias Name:
    Interfaces : 0/1 100/1
    IPs : 10.0.1.29  Mask: 255.255.255.0

3)  VLAN ID: 20     VLAN Alias Name:
    Interfaces :  1/1 100/2

<!--NeedCopy-->
```

> Note
>
> VLAN binding operation is not permitted on an accelerated VF interface.

```
bind vlan 1 -ifnum 100/1
ERROR: Operation not permitted
<!--NeedCopy-->
```

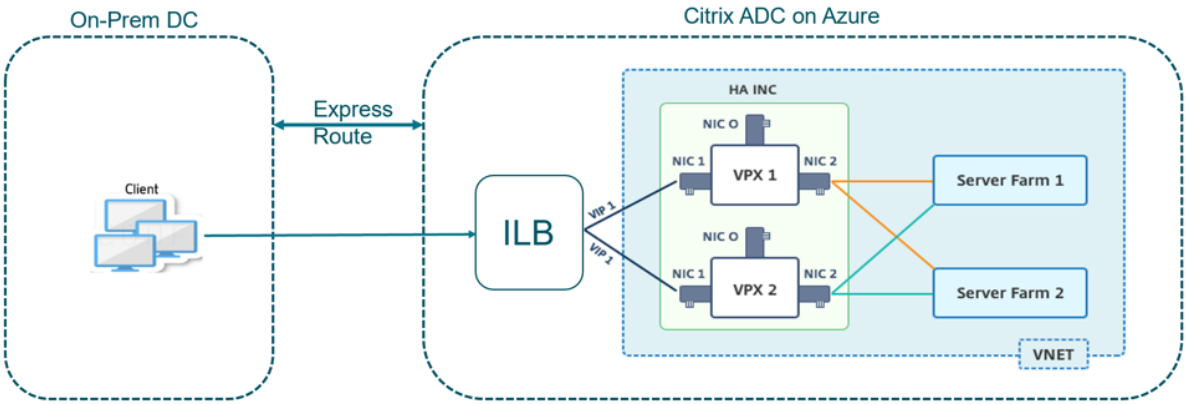
Configure HA-INC nodes by using the Citrix high availability template with Azure ILB

November 10, 2021

You can quickly and efficiently deploy a pair of VPX instances in HA-INC mode by using the standard template for intranet applications. The Azure internal load balancer (ILB) uses an internal or private IP address for the front end as shown in Figure 1. The template creates two nodes, with three sub-

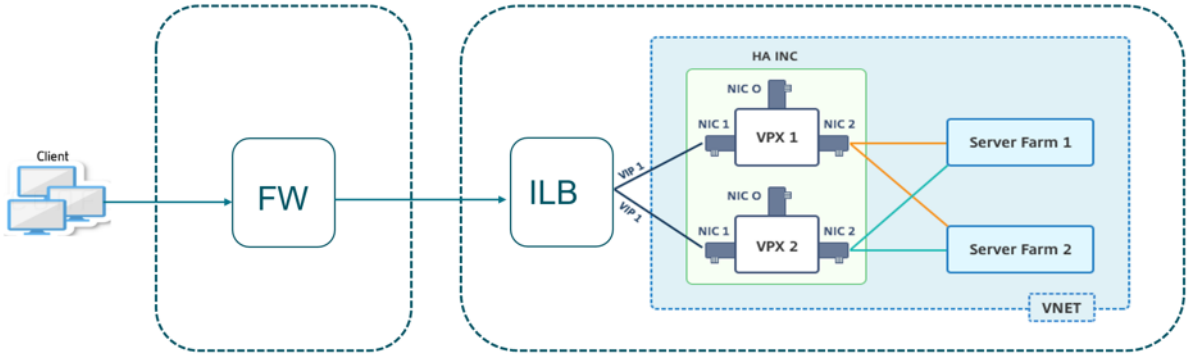
nets and six NICs. The subnets are for management, client, and server-side traffic with each subnet belonging to a different NIC on each device.

Figure 1: Citrix ADC HA pair for clients in an internal network



You can also use this deployment when the Citrix ADC HA pair is behind a firewall as shown in Figure 2. The public IP address belongs to the firewall and is NAT'd to the front-end IP address of the ILB.

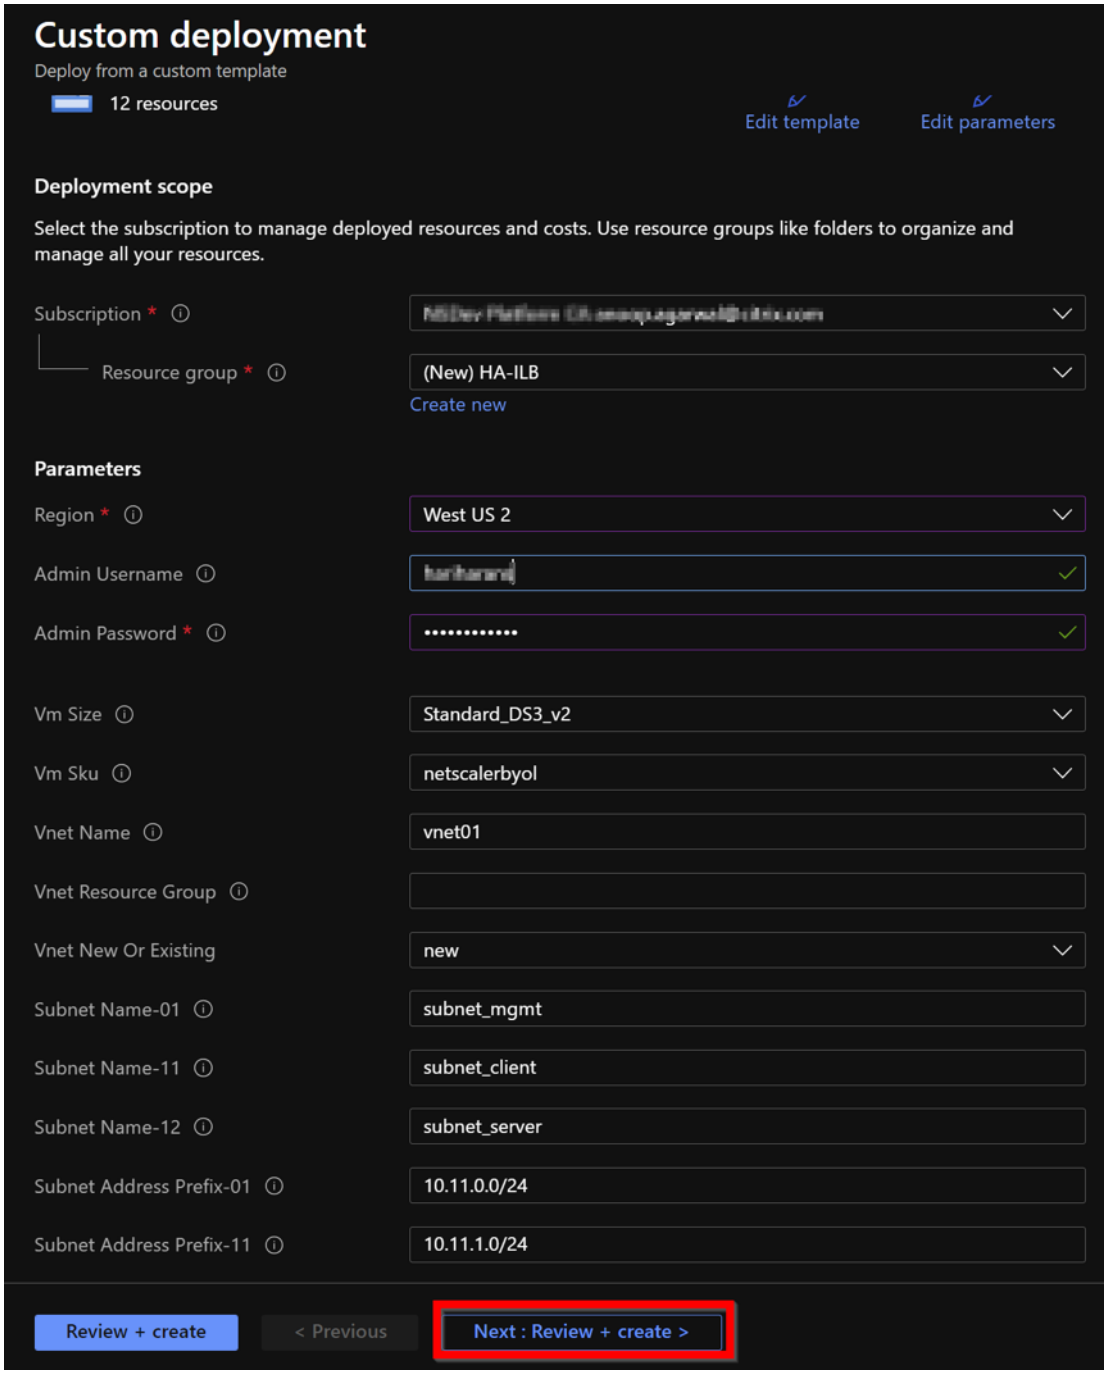
Figure 2: Citrix ADC HA pair with firewall having public IP address



You can get the Citrix ADC HA pair template for intranet applications at the Azure portal.

Complete the following steps to launch the template and deploy a high availability VPX pair by using Azure Availability Sets.

1. From the Azure portal, navigate to the **Custom deployment** page.
2. The **Basics** page appears. Create a Resource Group. Under the **Parameters** tab, enter details for the Region, Admin user name, Admin Password, license type (`VM sku`), and other fields.

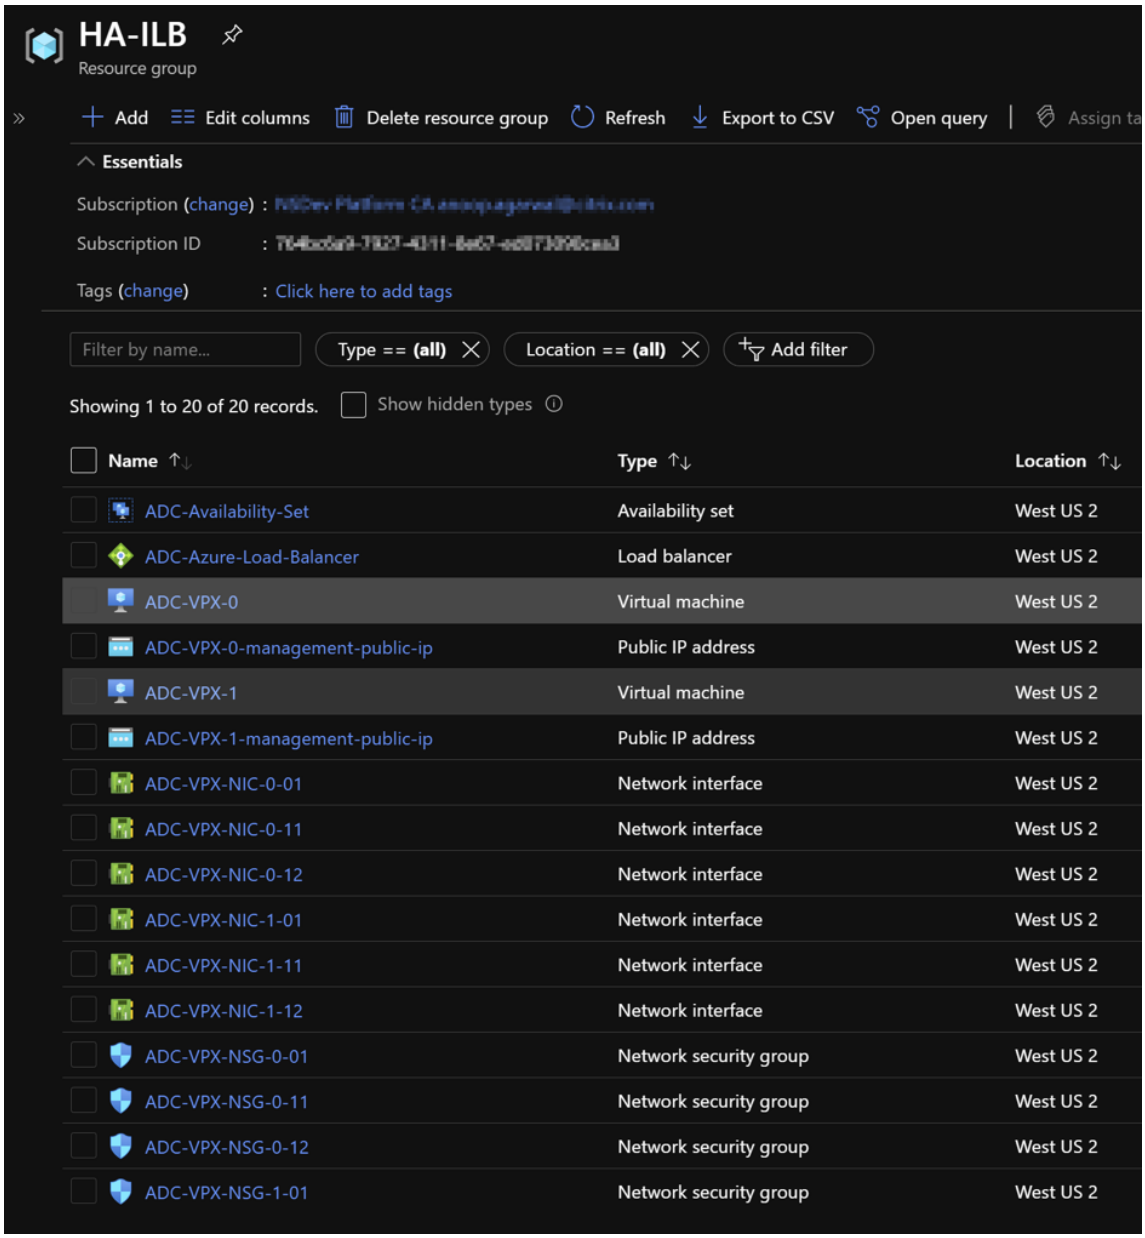


3. Click **Next : Review + create >**.

   It might take a moment for the Azure Resource Group to be created with the required configurations. After completion, select the Resource Group in the Azure portal to see the configuration details, such as LB rules, back-end pools, health probes. The high availability pair appears as ADC-VPX-0 and ADC-VPX-1.

   If further modifications are required for your HA setup, such as creating more security rules and ports, you can do that from the Azure portal.

Once the required configuration is complete, the following resources are created.



4. You must log on to **ADC-VPX-0** and **ADC-VPX-1** nodes to validate the following configuration:

   - NSIP addresses for both nodes must be in the management subnet.
   - On the primary (ADC-VPX-0) and secondary (ADC-VPX-1) nodes, you must see two SNIP addresses. One SNIP (client subnet) is used for responding to ILB probes and the other SNIP (server subnet) is used for back-end server communication.

   > Note
   >
   > In the HA-INC mode, the SNIP address of the ADC-VPX-0 and ADC-VPX-1 VMs are different while in the same subnet, unlike with the classic on-premises ADC HA deployment where

> both are the same.
> To support deployments when the VPX pair SNIP is in different subnets, or anytime the VIP is not in the same subnet as a SNIP, you must either enable Mac-Based Forwarding (MBF), or add a static host route for each VIP to each VPX node.

On the primary node (ADC-VPX-0)

```
> sh ip
        Ipaddress        Traffic Domain  Type             Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----             ----     ---      ----     -------  ------
1)      10.11.0.5        0               NetScaler IP     Active   Enabled  Enabled  NA       Enabled
2)      10.11.1.5        0               SNIP             Active   Enabled  Enabled  NA       Enabled
3)      10.11.3.4        0               SNIP             Active   Enabled  Enabled  NA       Enabled
 Done
>
>
```

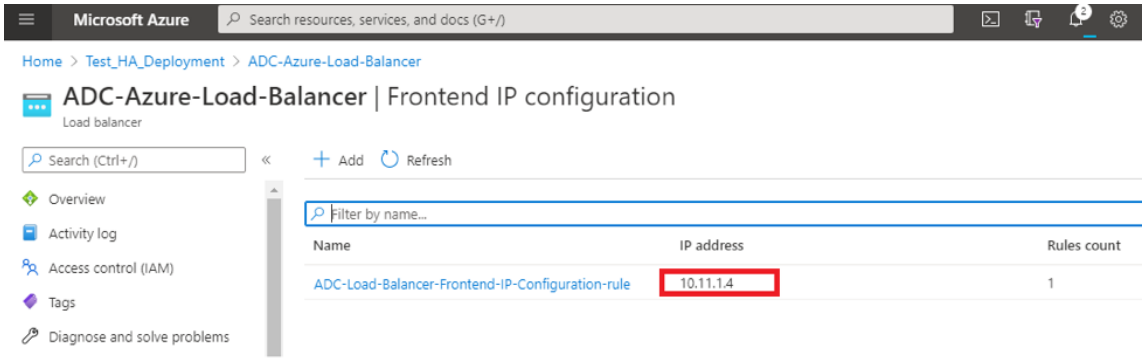
```
> sh ha node
1)      Node ID:      0
        IP:       10.11.0.5 (ADC-VPX-0)
        Node State: UP
        Master State: Primary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: ENABLED
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
        Sync Status Strict Mode: DISABLED
        Hello Interval: 200 msecs
        Dead Interval: 3 secs
        Node in this Master State for: 0:0:20:26 (days:hrs:min:sec)
2)      Node ID:      1
        IP:       10.11.0.4
        Node State: UP
        Master State: Secondary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: SUCCESS
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
 Done
>
```

On the secondary node (ADC-VPX-1)

```
> sh ip
        Ipaddress        Traffic Domain  Type            Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----            ----     ---      ----     -------  ------
1)      10.11.0.4        0               NetScaler IP    Active   Enabled  Enabled  NA       Enabled
2)      10.11.1.6        0               SNIP            Active   Enabled  Enabled  NA       Enabled
3)      10.11.3.5        0               SNIP            Active   Enabled  Enabled  NA       Enabled
 Done
>
>
```

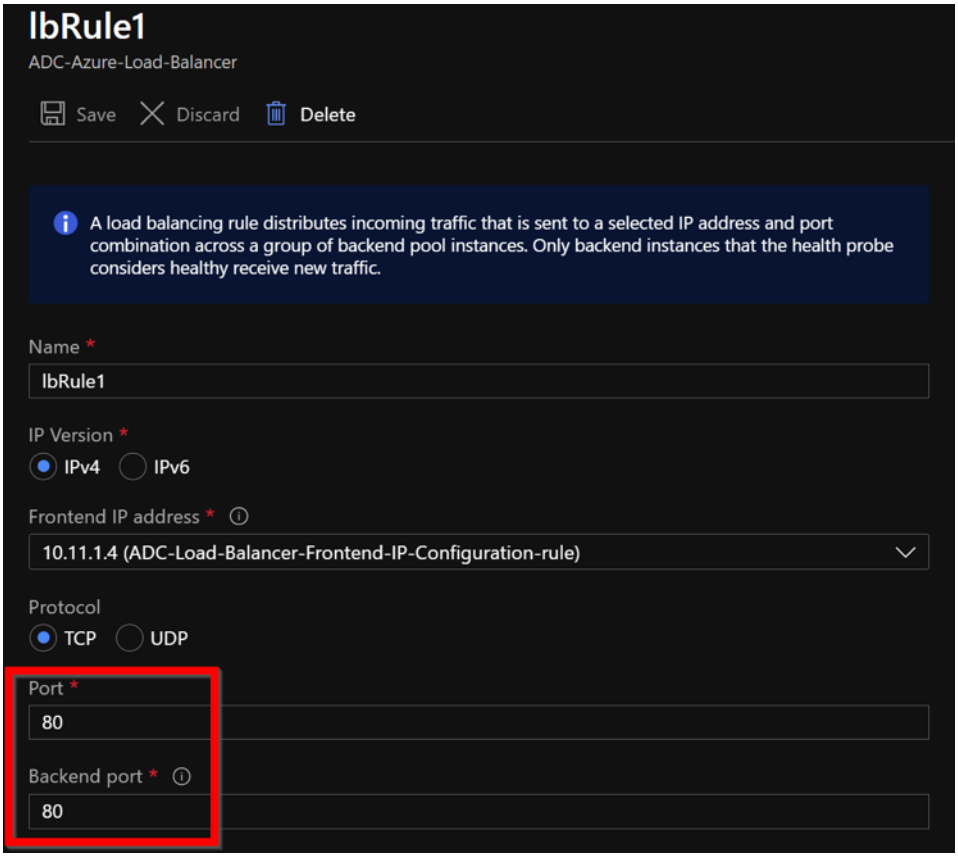
```
> sh ha node
1)      Node ID:      0
        IP:       10.11.0.4 (ADC-VPX-1)
        Node State: UP
        Master State: Secondary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: SUCCESS
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
        Sync Status Strict Mode: DISABLED
        Hello Interval: 200 msecs
        Dead Interval: 3 secs
        Node in this Master State for: 0:0:24:18 (days:hrs:min:sec)
2)      Node ID:      1
        IP:       10.11.0.5
        Node State: UP
        Master State: Primary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: ENABLED
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
 Done
>
```

5. After the primary and secondary nodes are UP and the Synchronization status is **SUCCESS**, you must configure the load balancing virtual server or the gateway virtual server on the primary node (ADC-VPX-0) with the private floating IP (FIP) address of the ADC Azure load balancer. For more information, see the Sample configuration section.
6. To find the private IP address of ADC Azure load balancer, navigate to **Azure portal > ADC Azure Load Balancer > Frontend IP configuration**.



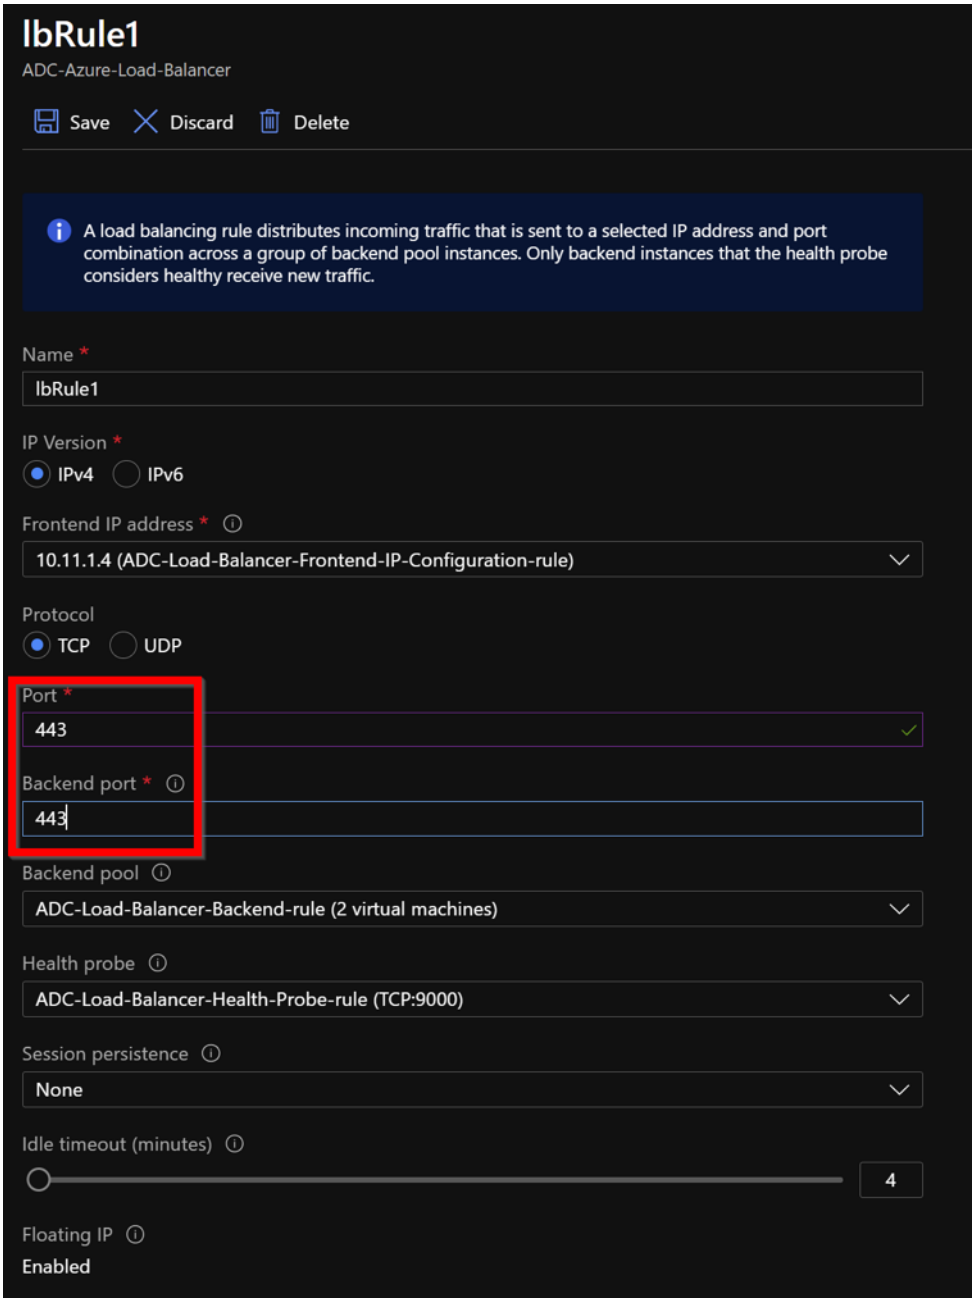
7. In the **Azure Load Balancer** configuration page, the ARM template deployment helps create the LB rule, back-end pools, and health probes.

   - The LB Rule (LbRule1) uses port 80, by default.



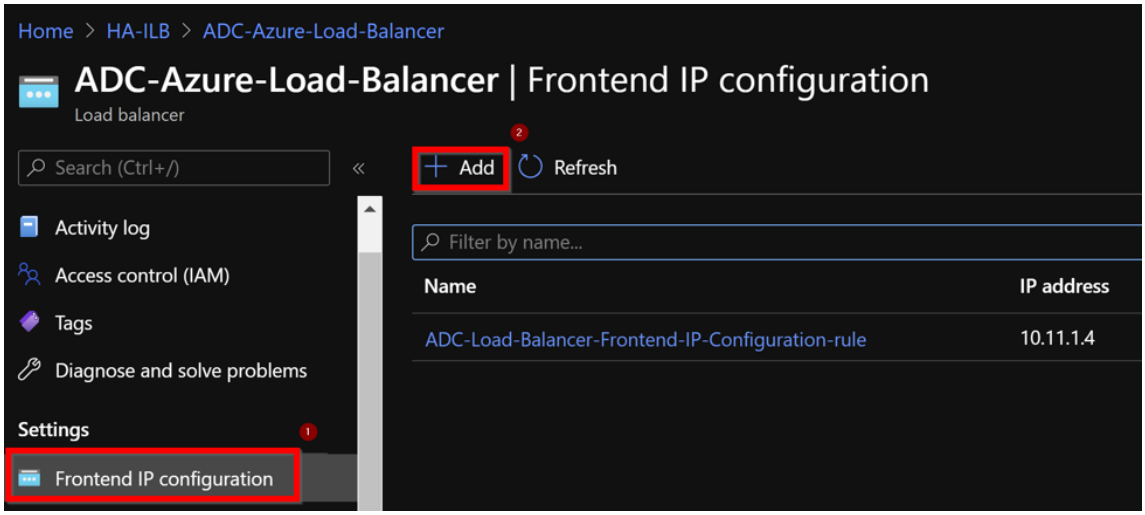
- Edit the rule to use port 443, and save the changes.

> Note
>
> For enhanced security, Citrix recommends you to use SSL port 443 for LB virtual server or Gateway virtual server.

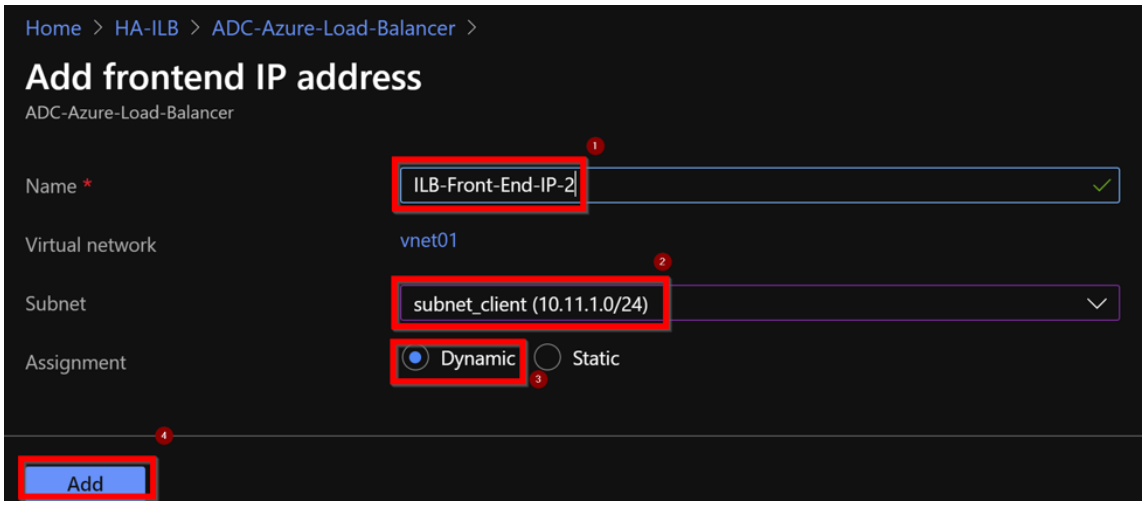


To add more VIP addresses on the ADC, perform the following steps:

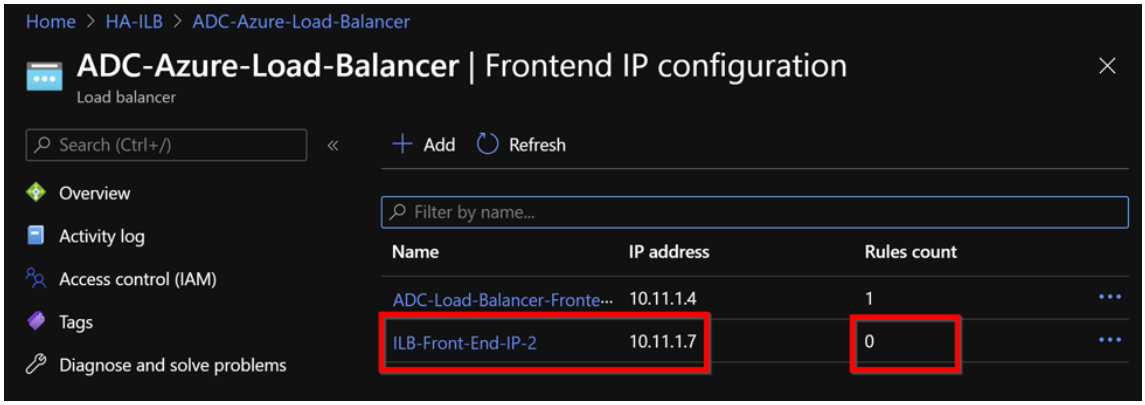
1. Navigate to **Azure Load Balancer > Frontend IP configuration**, and click **Add** to create a new internal load balancer IP address.



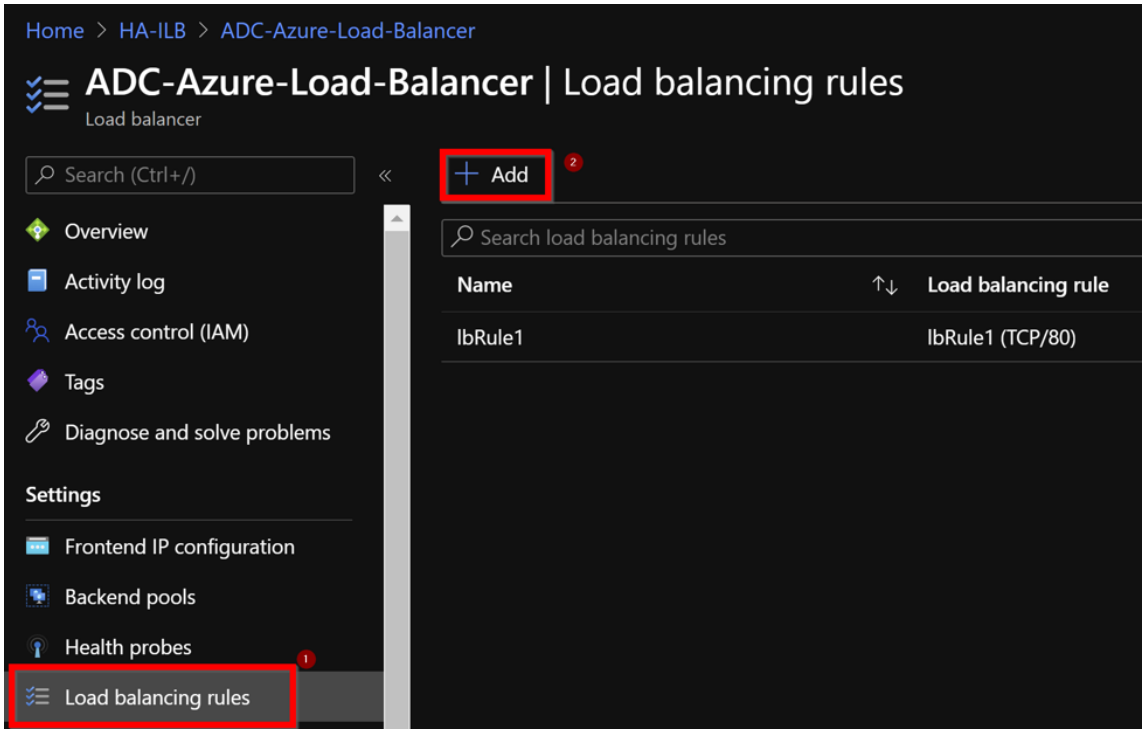
2. In the **Add frontend IP address** page, enter a name, choose the client subnet, assign either dynamic or static IP address, and click **Add**.



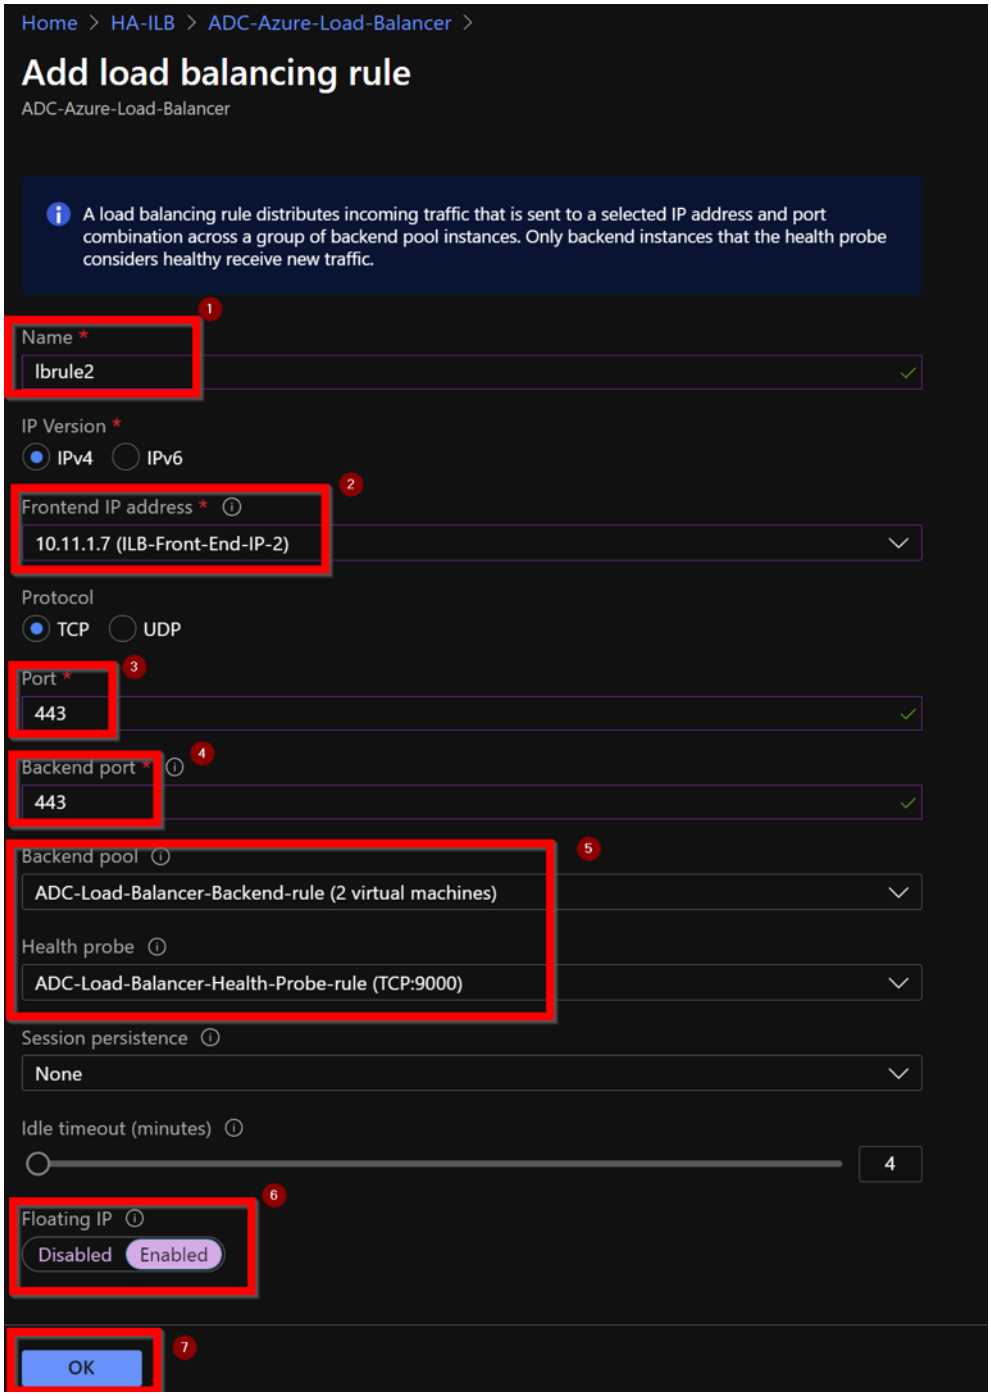
3. The front-end IP address is created but an LB Rule is not associated. Create a new load balancing rule, and associate it with the front-end IP address.



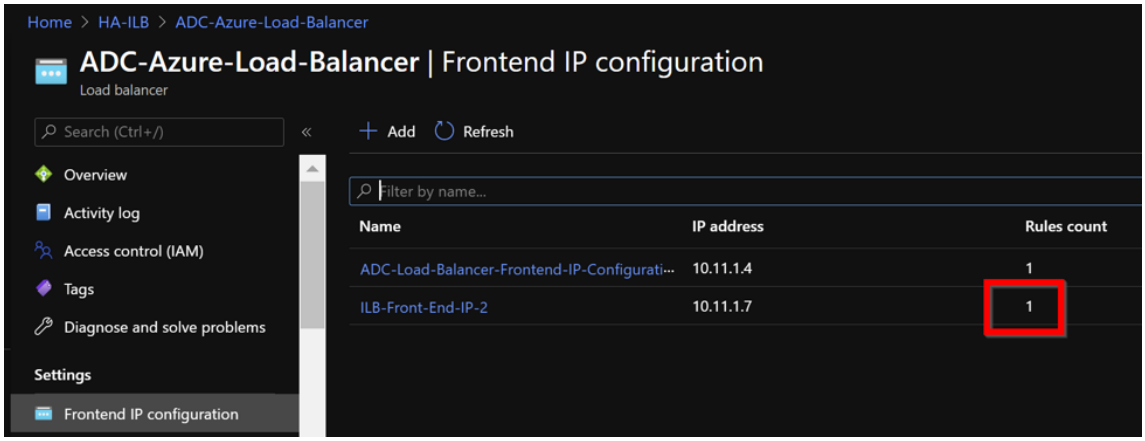
4. In the **Azure Load Balancer** page, select **Load balancing rules**, and then click **Add**.



5. Create a new LB Rule by choosing the new front-end IP address and the port. **Floating IP** field must be set to **Enabled**.



6. Now the **Frontend IP configuration** shows the LB rule that is applied.



Sample configuration

To configure a gateway VPN virtual server and load balancing virtual server, run the following commands on the primary node (ADC-VPX-0). The configuration auto synchronizes to the secondary node (ADC-VPX-1).

Gateway sample configuration

```
enable feature aaa LB SSL SSLVPN
enable ns mode MBF
add vpn vserver vpn_ssl SSL 10.11.1.4 443
add ssl certKey ckp -cert wild-cgwsanity.cer -key wild-cgwsanity.key
bind ssl vserver vpn_ssl -certkeyName ckp
<!--NeedCopy-->
```

Load balancing sample configuration

```
enable feature LB SSL
enable ns mode MBF
add lb vserver lb_vs1 SSL 10.11.1.7 443
bind ssl vserver lb_vs1 -certkeyName ckp
<!--NeedCopy-->
```

You can now access the load balancing or VPN virtual server using the fully qualified domain name (FQDN) associated with the internal IP address of ILB.

See the **Resources** section for more information about how to configure the load-balancing virtual server.

Configure HA-INC nodes by using the Citrix high availability template for internet-facing applications

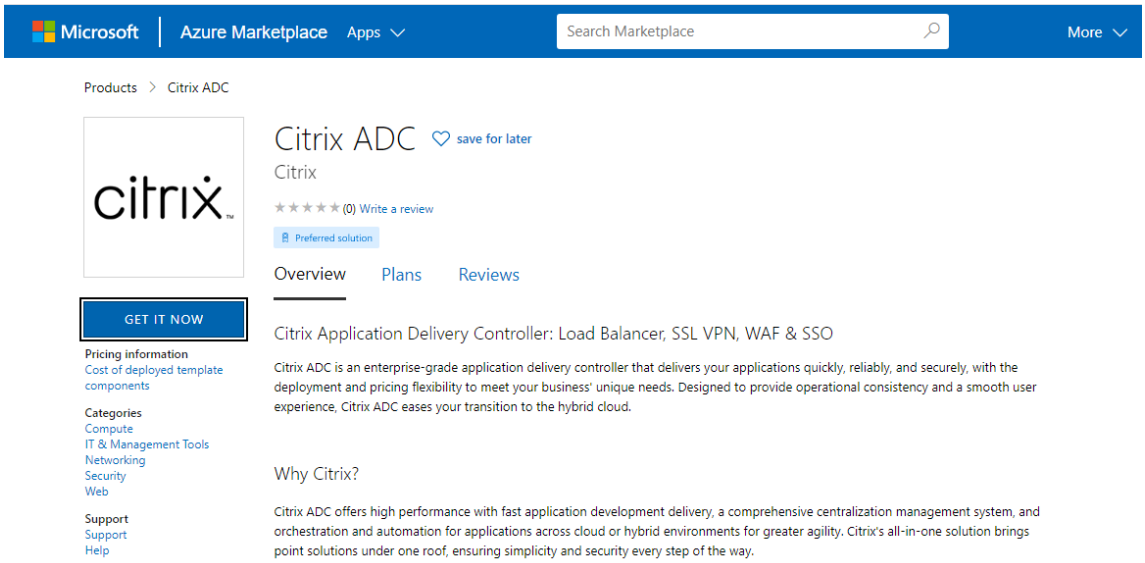
September 14, 2021

You can quickly and efficiently deploy a pair of VPX instances in HA-INC mode by using the standard template for internet-facing applications. The Azure load balancer (ALB) uses a public IP address for the front end. The template creates two nodes, with three subnets and six NICs. The subnets are for management, client, and server-side traffic. Each subnet has two NICs for both the VPX instances.

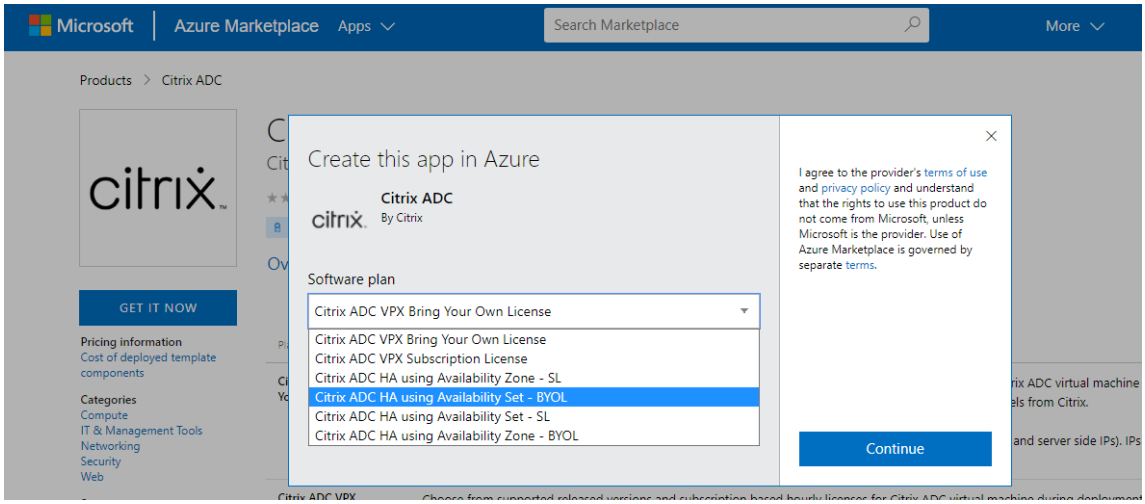
You can get the Citrix ADC HA pair template for internet-facing applications at the Azure Marketplace.

Complete the following steps to launch the template and deploy a high availability VPX pair by using Azure availability sets or availability zone.

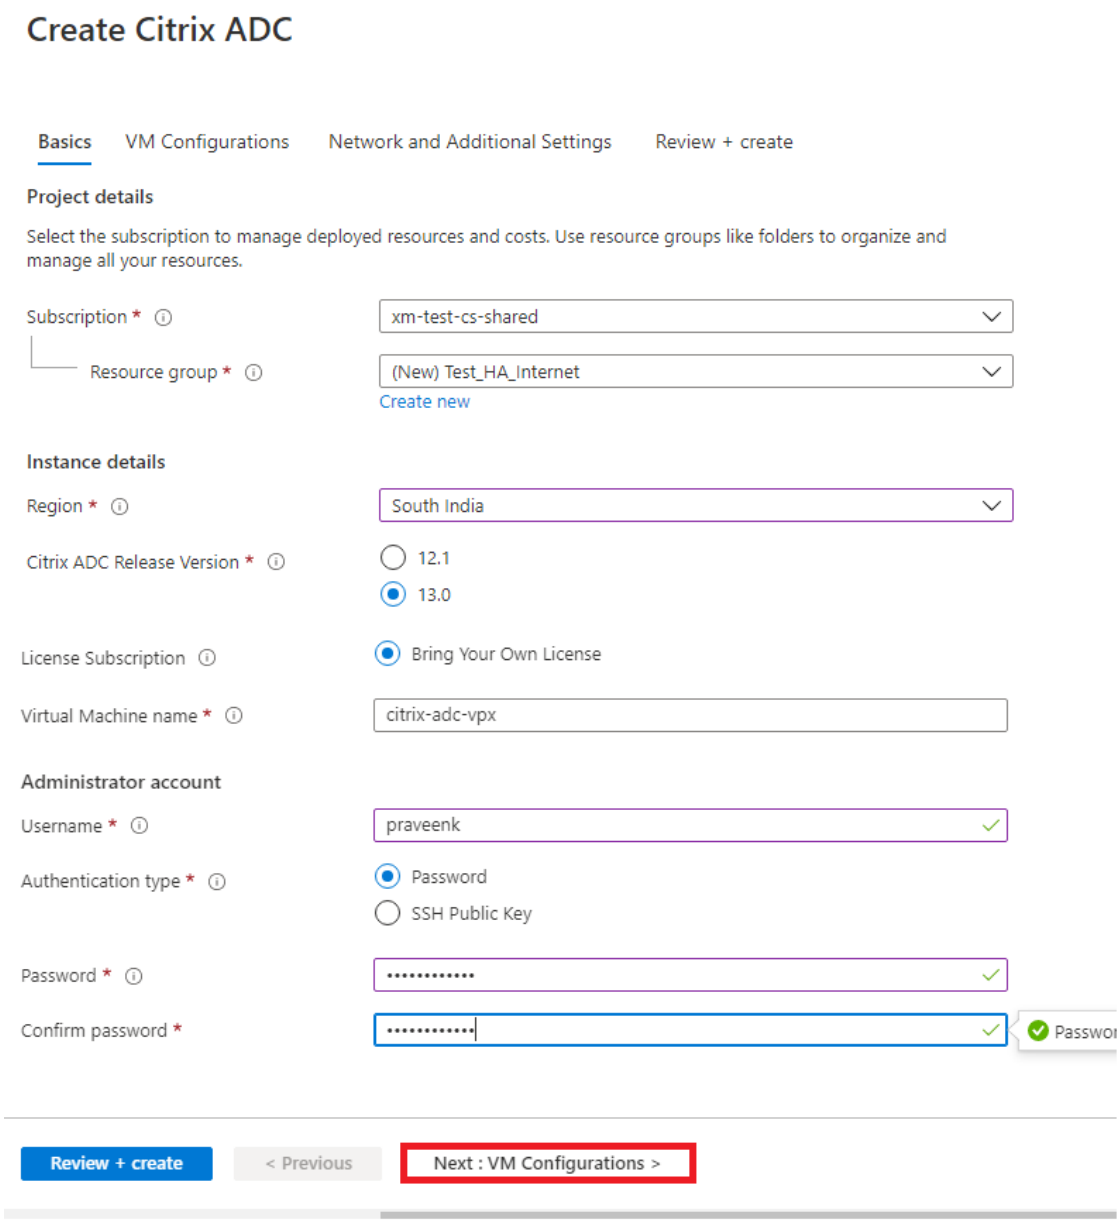
1. From the Azure Marketplace, search **Citrix ADC**.
2. Click **GET IT NOW**.



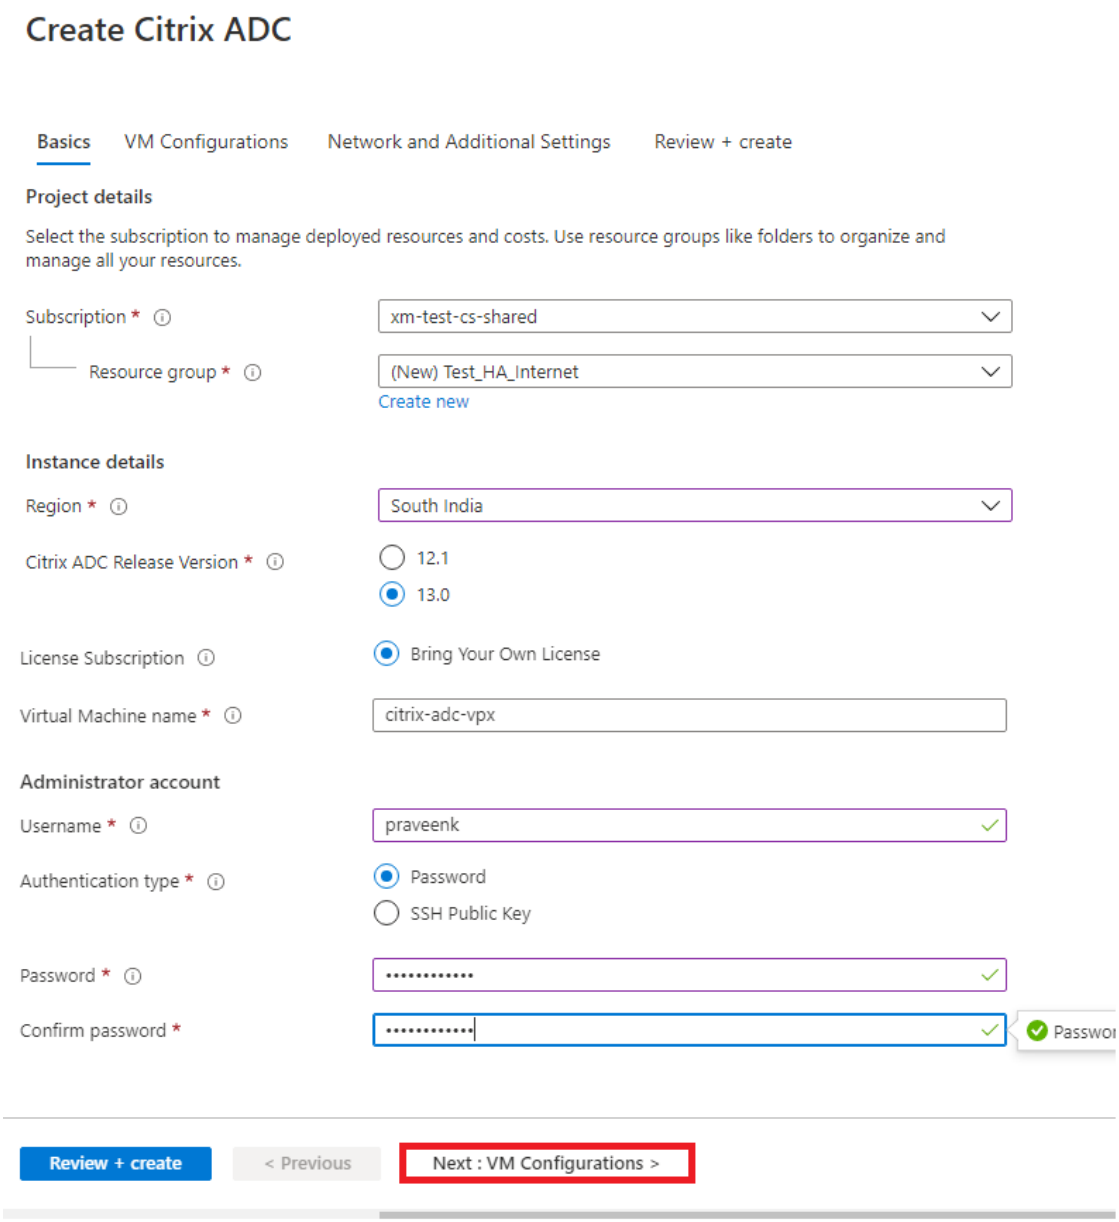
3. Select the required HA deployment along with license, and click **Continue**.



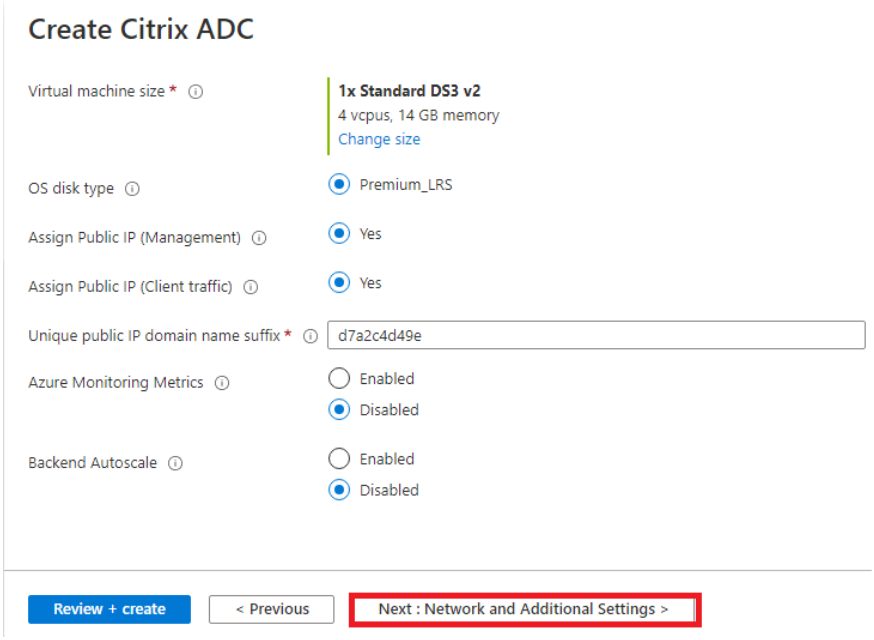
4. The **Basics** page appears. Create a Resource Group. Under the **Parameters** tab, enter details for the Region, Admin user name, Admin Password, license type (VM SKU), and other fields.



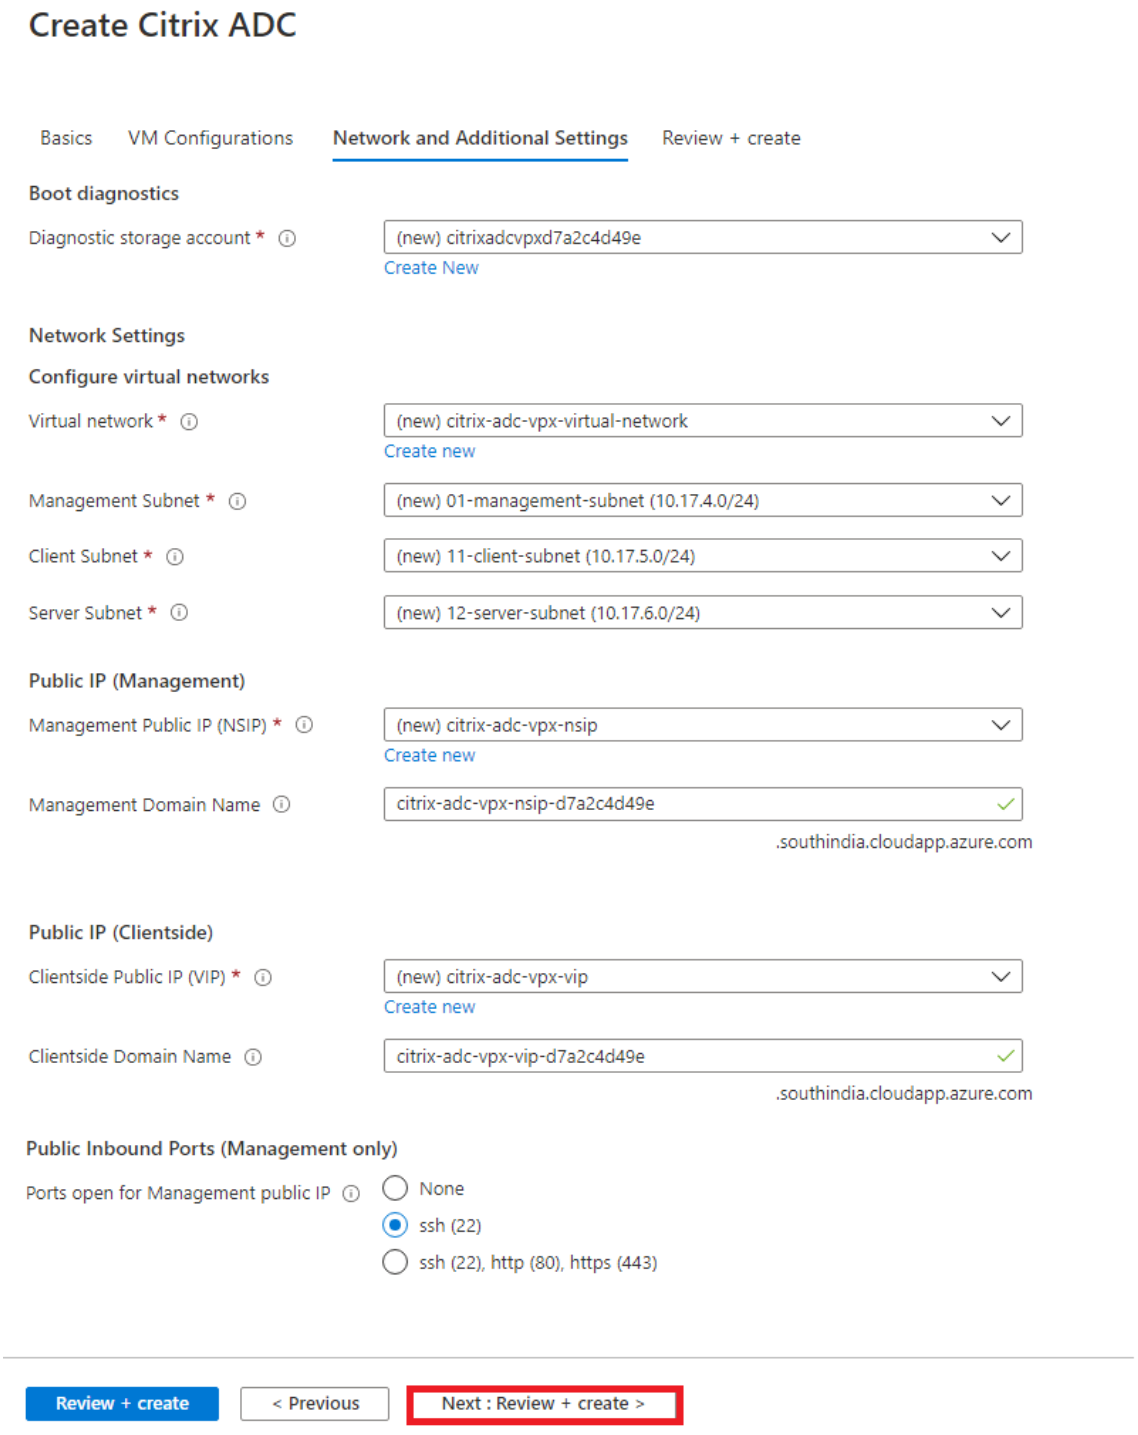
5. Click **Next : VM Configurations >**.



6. On the **VM Configurations** page, perform the following:
    - Configure public IP domain name suffix
    - Enable or disable **Azure Monitoring Metrics**
    - Enable or disable **Backend Autoscale**
7. Click **Next: Network and Additional settings >**



8. On **Network and Additional Settings** page, create Boot diagnostics account and configure the network settings.



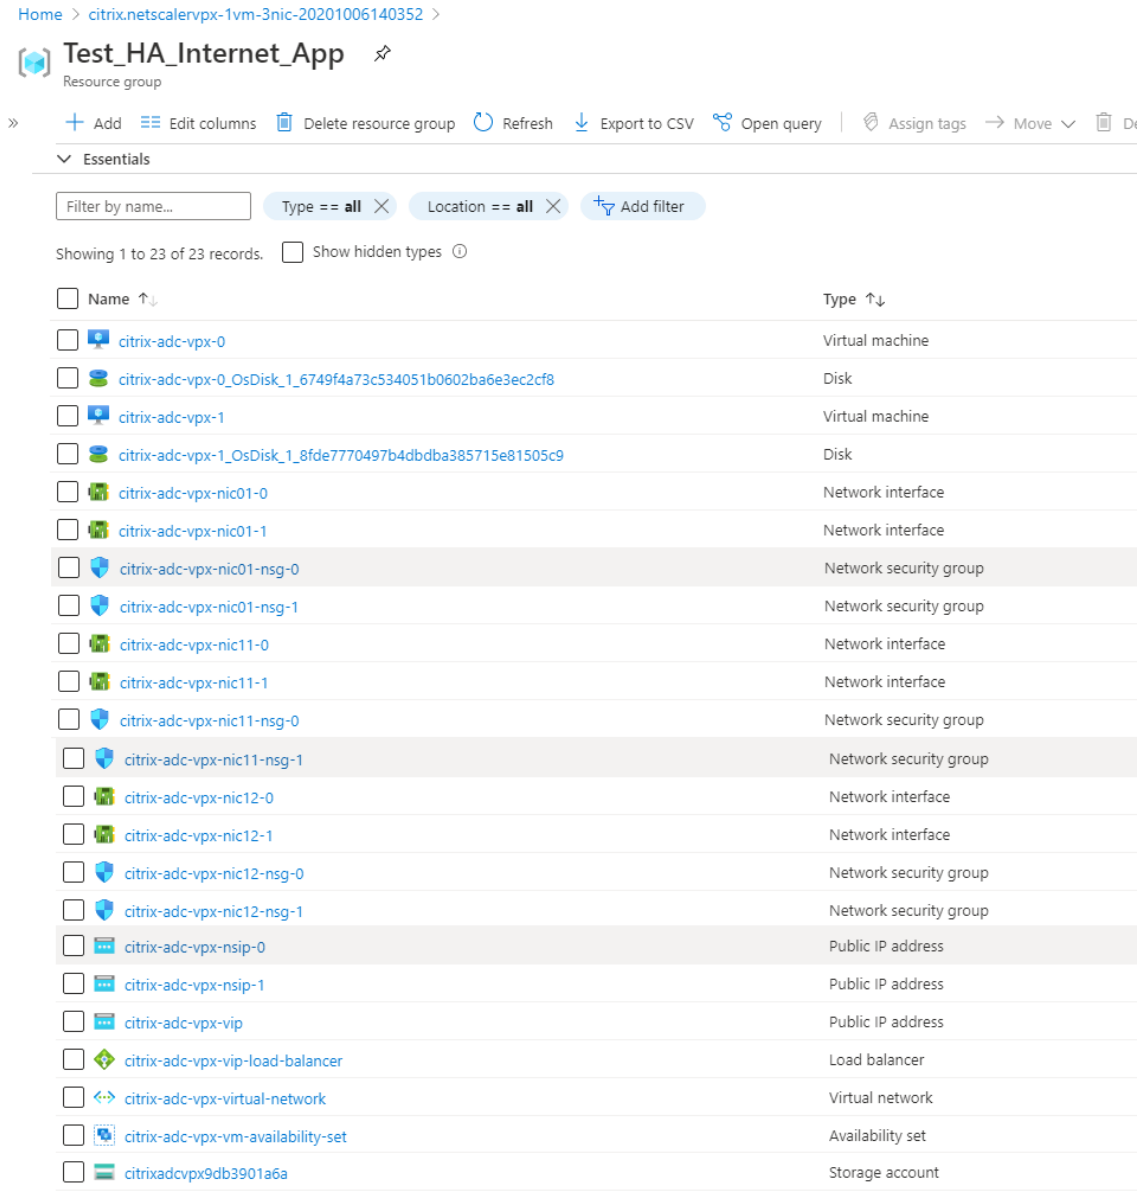
9. Click **Next: Review + create >**.
10. Review the basic settings, VM configuration, network and additional settings, and click **Create**.

    It might take a moment for the Azure Resource Group to be created with the required configura-

tions. After completion, select the Resource Group in the Azure portal to see the configuration details, such as LB rules, back-end pools, and health probes. The high availability pair appears as **citrix-adc-vpx-0** and **citrix-adc-vpx-1**.

If further modifications are required for your HA setup, such as creating more security rules and ports, you can do that from the Azure portal.

Once the required configuration is complete, the following resources are created.



11. You must log on to **citrix-adc-vpx-0** and **citrix-adc-vpx-1** nodes to validate the following configuration:

    - NSIP addresses for both nodes must be in the management subnet.
    - On the primary (citrix-adc-vpx-0) and secondary (citrix-adc-vpx-1) nodes, you must see

two SNIP addresses. One SNIP (client subnet) is used for responding to the ALB probes and the other SNIP (server subnet) is used for back-end server communication.

> Note
>
> In the HA-INC mode, the SNIP addresses of the citrix-adc-vpx-0 and citrix-adc-vpx-1 VMs are different, unlike with the classic on-premises ADC high availability deployment where both are the same.

On the primary node (citrix-adc-vpx-0)

```
> sh ip
        Ipaddress        Traffic Domain  Type            Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----            ----     ---      ----     -------  ------
1)      10.18.0.4        0               NetScaler IP    Active   Enabled  Enabled  NA       Enabled
2)      10.18.1.5        0               SNIP            Active   Enabled  Enabled  NA       Enabled
3)      10.18.2.4        0               SNIP            Active   Enabled  Enabled  NA       Enabled
 Done
```

```
> sh ha node
1)      Node ID:      0
        IP:       10.18.0.4 (ns-vpx0)
        Node State: UP
        Master State: Primary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: ENABLED
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
        Sync Status Strict Mode: DISABLED
        Hello Interval: 200 msecs
        Dead Interval: 3 secs
        Node in this Master State for: 0:3:34:21 (days:hrs:min:sec)
2)      Node ID:      1
        IP:       10.18.0.5
        Node State: UP
        Master State: Secondary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: SUCCESS
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
 Done
```

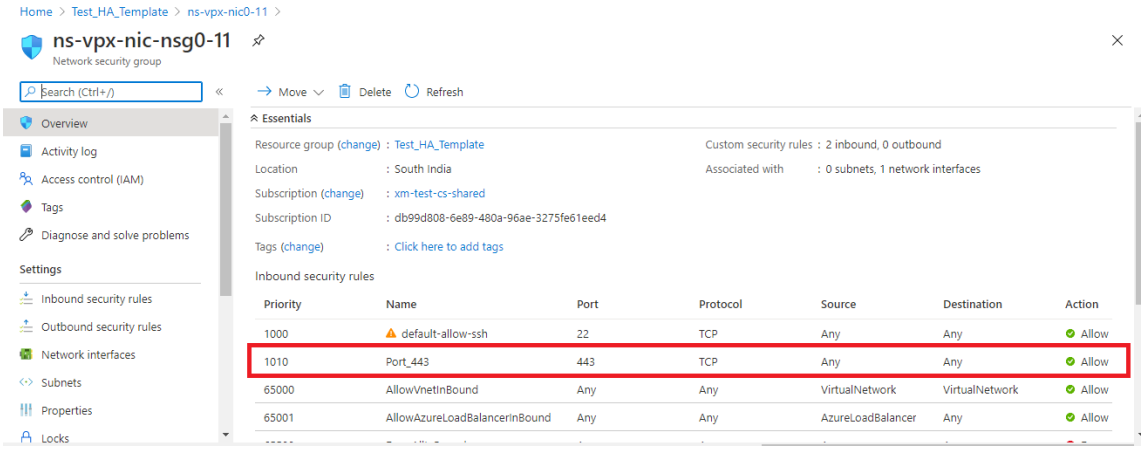
On the secondary node (citrix-adc-vpx-1)

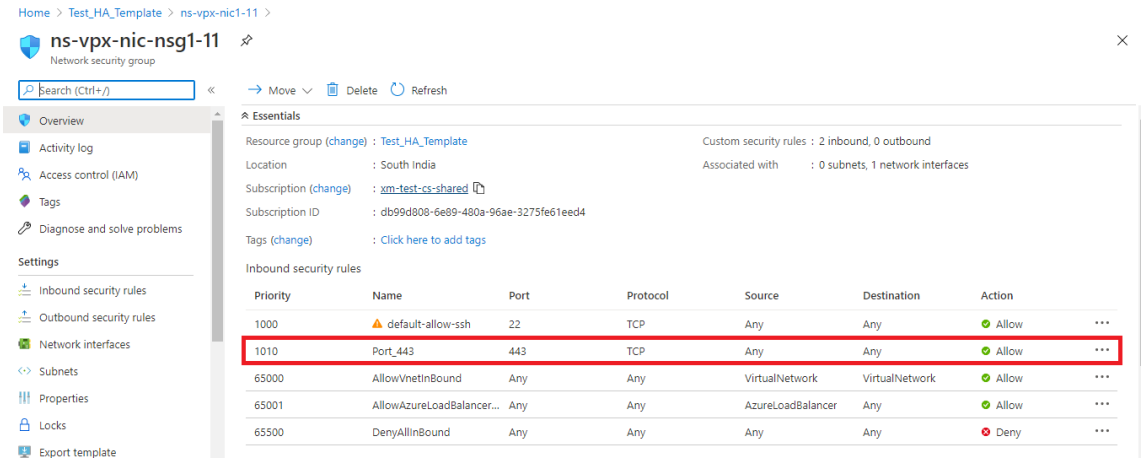
```
> show ip
        Ipaddress        Traffic Domain  Type            Mode     Arp      Icmp     Vserver  State
        ---------        --------------  ----            ----     ---      ----     -------  ------
1)      10.18.0.5        0               NetScaler IP    Active   Enabled  Enabled  NA       Enabled
2)      10.18.1.4        0               SNIP            Active   Enabled  Enabled  NA       Enabled
3)      10.18.2.5        0               SNIP            Active   Enabled  Enabled  NA       Enabled
 Done
>
```

```
> sh ha node
1)      Node ID:      0
        IP:       10.18.0.5 (ns-vpx1)
        Node State: UP
        Master State: Secondary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: SUCCESS
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
        Sync Status Strict Mode: DISABLED
        Hello Interval: 200 msecs
        Dead Interval: 3 secs
        Node in this Master State for: 0:3:23:51 (days:hrs:min:sec)
2)      Node ID:      1
        IP:       10.18.0.4
        Node State: UP
        Master State: Primary
        Fail-Safe Mode: OFF
        INC State: ENABLED
        Sync State: ENABLED
        Propagation: ENABLED
        Enabled Interfaces : 0/1 1/1 1/2
        Disabled Interfaces : None
        HA MON ON Interfaces : None
        HA HEARTBEAT OFF Interfaces : None
        Interfaces on which heartbeats are not seen : 1/1 1/2
        Interfaces causing Partial Failure: None
        SSL Card Status: NOT PRESENT
 Done
>
```

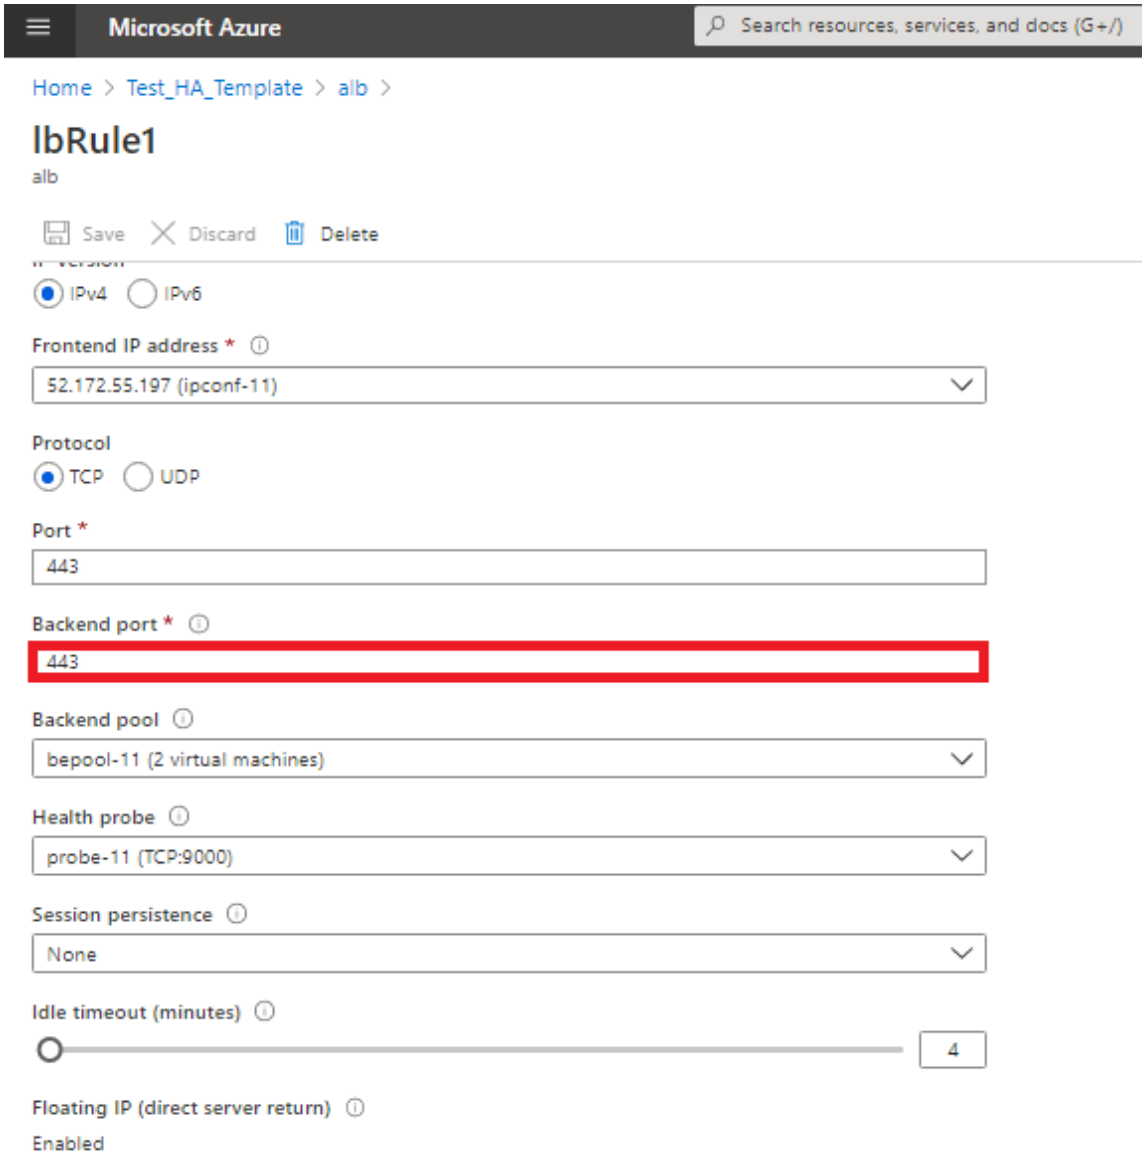
12. After the primary and secondary nodes are UP and the Synchronization status is **SUCCESS**, you must configure the load balancing virtual server or the gateway virtual server on the primary node (citrix-adc-vpx-0) with the public IP address of the ALB virtual server. For more information, see the Sample configuration section.
13. To find the public IP address of ALB virtual server, navigate to **Azure portal > Azure Load Balancer > Frontend IP configuration**.

14. Add the inbound security rule for virtual server port 443 on the network security group of both the client interfaces.

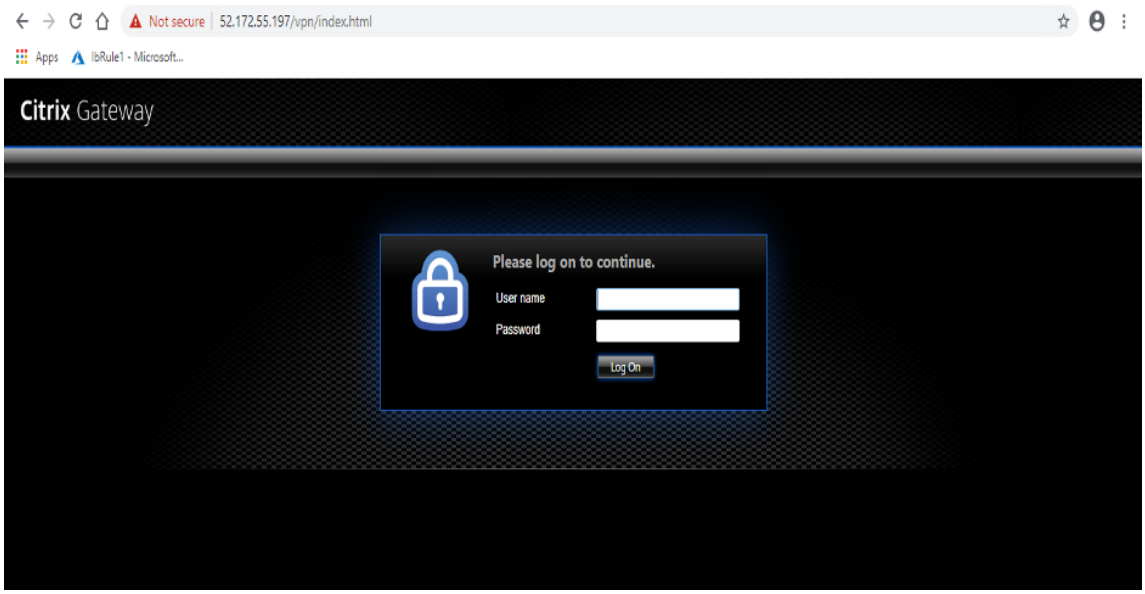




15. Configure the ALB port that you want to access, and create inbound security rule for the specified port. The Backend port is your load balancing virtual server port or the VPN virtual server port.



16. Now, you can access the load balancing virtual server or the VPN virtual server using FQDN associated with the ALB public IP address.



Sample configuration

To configure a gateway VPN virtual server and load balancing virtual server, run the following commands on the primary node (ADC-VPX-0). The configuration auto synchronizes to the secondary node (ADC-VPX-1).

Gateway sample configuration

```
enable feature aaa LB SSL SSLVPN
add ip 52.172.55.197 255.255.255.0 -type VIP
add vpn vserver vpn_ssl SSL 52.172.55.197 443
add ssl certKey ckp -cert cgwsanity.cer -key cgwsanity.key
bind ssl vserver vpn_ssl -certkeyName ckp
<!--NeedCopy-->
```

Load balancing sample configuration

```
enable feature LB SSL
enable ns mode MBF
add lb vserver lb_vs1 SSL 52.172.55.197 443
bind ssl vserver lb_vs1 -certkeyName ckp
<!--NeedCopy-->
```

You can now access the load balancing or VPN virtual server using the fully qualified domain name (FQDN) associated with the internal IP address of ILB.

See the **Resources** section for more information about how to configure the load balancing virtual server.

Resources:

The following links provide additional information related to HA deployment and virtual server configuration:

- Create virtual servers
- Set up basic load balancing

Configure a high-availability setup with Azure external and internal load balancers simultaneously

September 14, 2021

The high availability pair on Azure supports both external and internal load balancers simultaneously.

You have the following two options to configure a high availability pair using both Azure external and internal load balancers:

- Using two LB virtual servers on the Citrix ADC appliance.
- Using one LB virtual server and an IP set. The single LB virtual server serves traffic to multiple IPs, which are defined by the IPset.

Perform the following steps to configure a high availability pair on Azure using both the external and internal load balancers simultaneously:

For Steps 1 and 2, use the Azure portal. For Steps 3 and 4, use the Citrix ADC VPX GUI or the CLI.

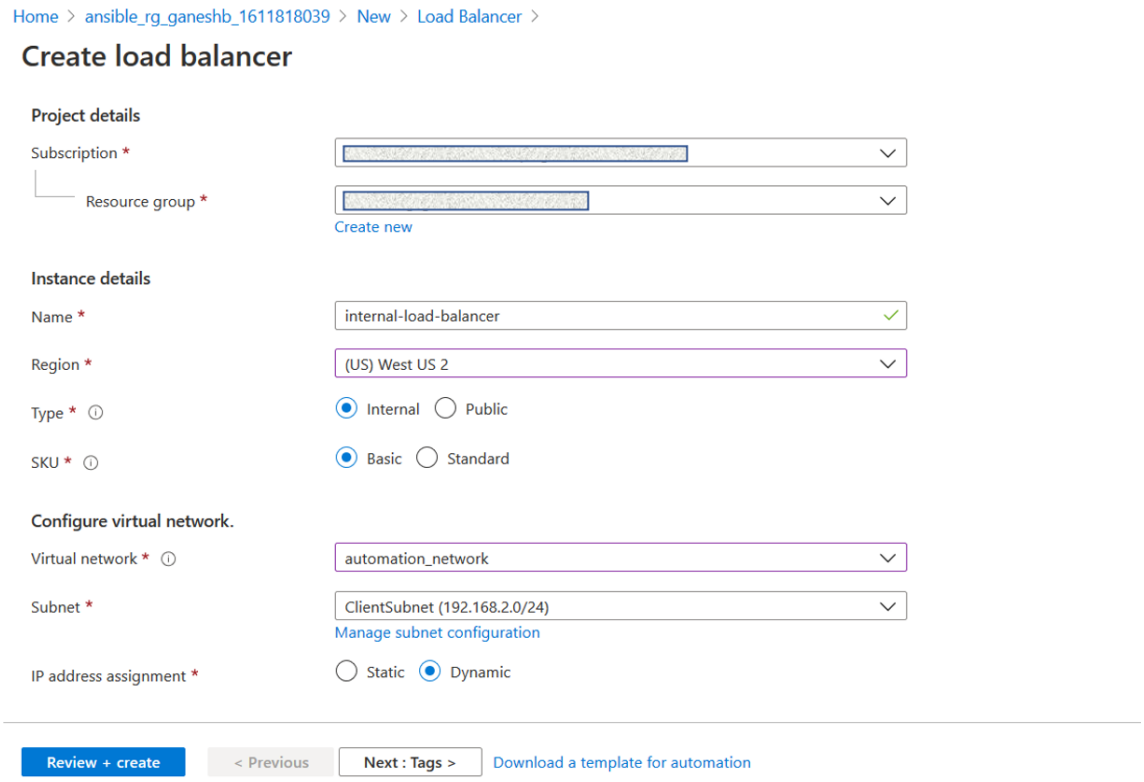
Step 1. Configure an Azure load balancer, either an external load balancer or an internal load balancer.

For more information on configuring high-availability setup with Azure external load balancers, see Configure a high-availability setup with multiple IP addresses and NIC.

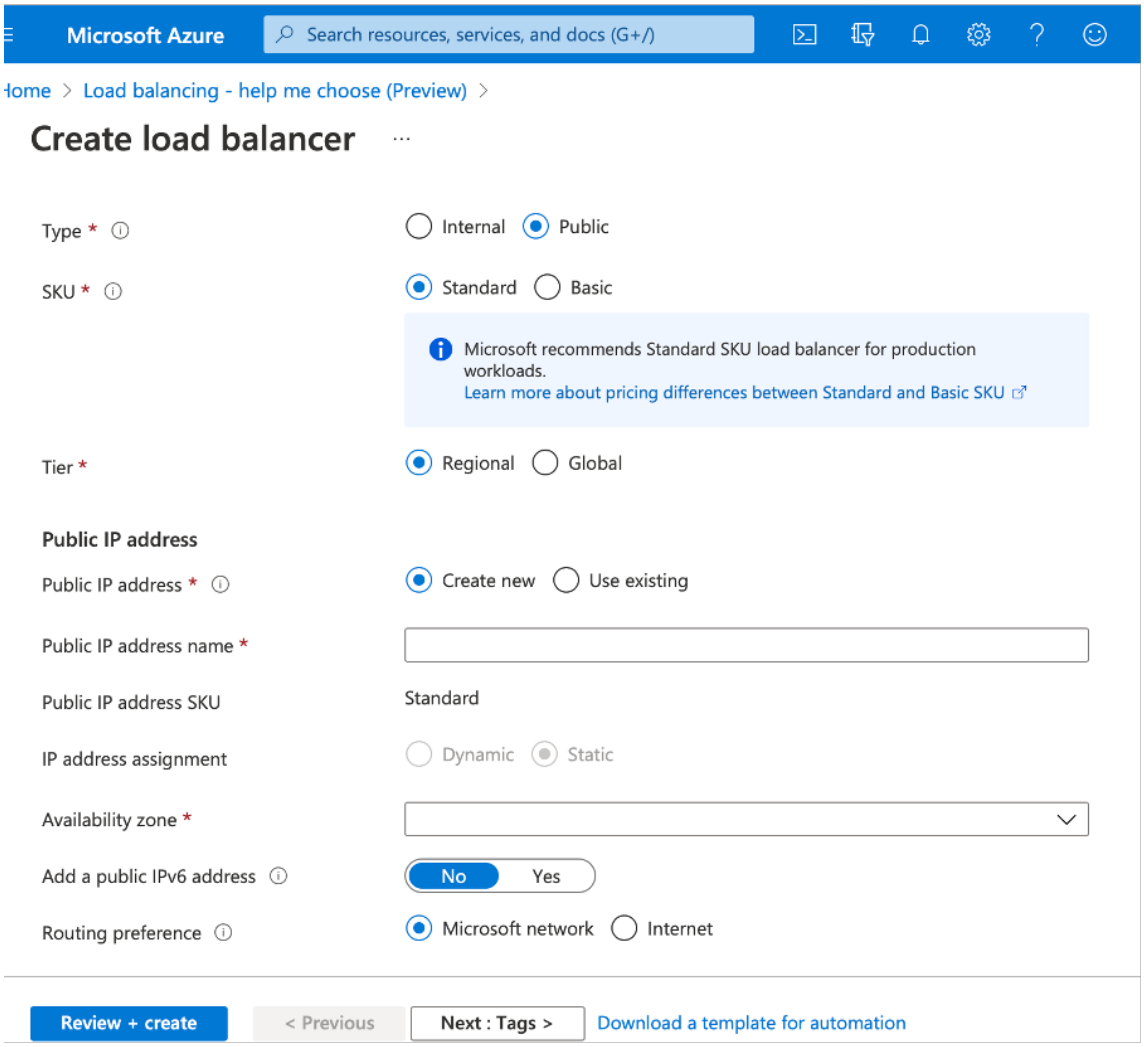
For more information on configuring high-availability setup with Azure internal load balancers, see Configure HA-INC nodes by using the Citrix high availability template with Azure ILB.

Step 2. Create an extra load balancer (ILB) in your resource group. In Step 1, if you have created an external load balancer, you now create an internal load balancer and conversely.

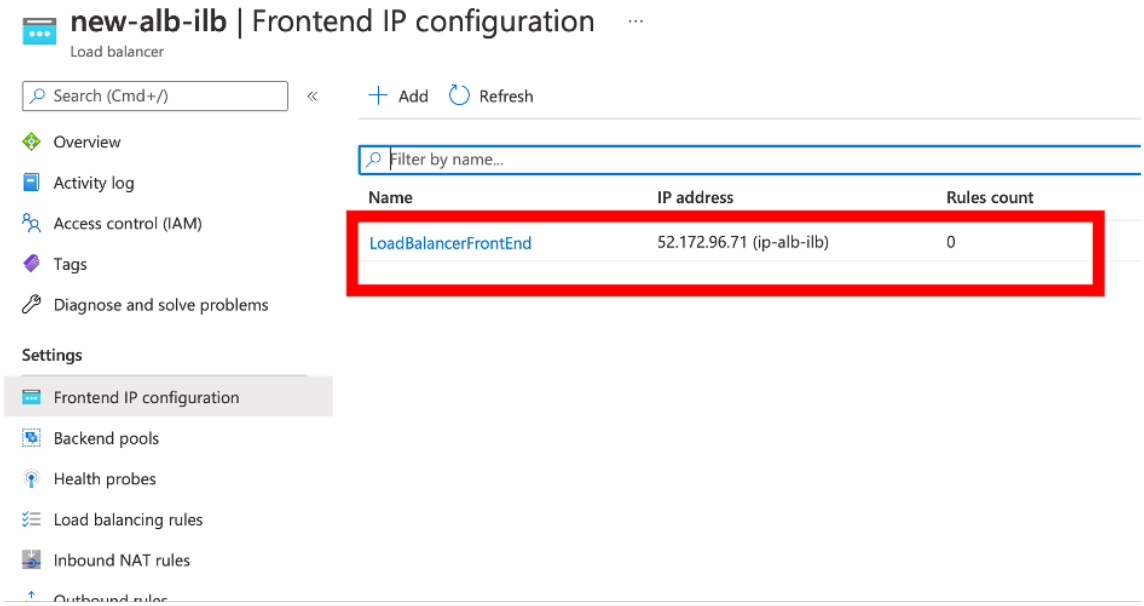
- To create an internal load balancer, choose the load balancer type as **Internal**. For the **Subnet** field, you must choose your Citrix ADC client subnet. You can choose to provide a static IP address in that subnet, provided there are no conflicts. Otherwise, choose the dynamic IP address.



- To create an external load balancer, choose the load balancer type as **Public** and create the public IP address here.



1. After you have created the Azure Load Balancer, navigate to **Frontend IP configuration** and note down the IP address shown here. You must use this IP address while creating the ADC load balancing virtual server as in Step 3.



2. In the **Azure Load Balancer configuration** page, the ARM template deployment helps create the LB rule, back-end pools, and health probes.
3. Add the high availability pair client NICs to the backend pool for the ILB.
4. Create a health probe (TCP, 9000 port)
5. Create two load balancing rules:
    - One LB rule for HTTP traffic (webapp use case) on port 80. The rule must also use the backend port 80. Select the created backend pool and the health probe. Floating IP must be enabled.
    - Another LB rule for HTTPS or CVAD traffic on port 443. The process is the same as the HTTP traffic.

Step 3. On the primary node of Citrix ADC appliance, create a load balancing virtual server for ILB.

1. Add a load balancing virtual server.

```
add lb vserver <name> <serviceType> [<ILB Frontend IP address>] [<
    port>]
<!--NeedCopy-->
```

Example:

```
add lb vserver vserver_name HTTP 52.172.96.71 80
<!--NeedCopy-->
```

> Note:
>
> Use the load balancer frontend IP address, which is associated with the additional Load balancer that you create in Step 2.

2. Bind a service to a load balancing virtual server.

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

For more information, see Set up basic load balancing

Step 4: As an alternative to Step 3, you can create a load balancing virtual server for ILB using IPsets.

1. Add an IP address of type virtual server IP (VIP).

```
add nsip <ILB Frontend IP address> -type <type>
<!--NeedCopy-->
```

Example:

```
add nsip 52.172.96.71 -type vip
<!--NeedCopy-->
```

2. Add an IPset on both primary and secondary nodes.

```
add ipset <name>
<!--NeedCopy-->
```

Example:

```
add ipset ipset1
<!--NeedCopy-->
```

3. Bind IP addresses to the IP set.

```
bind ipset <name> <ILB Frontend IP address>
<!--NeedCopy-->
```

Example:

```
bind ipset ipset1 52.172.96.71
<!--NeedCopy-->
```

4. Set the existing LB virtual server to use the IPset.

```
set lb vserver <vserver name> -ipset <ipset name>
<!--NeedCopy-->
```

Example:

```
set lb vserver vserver_name -ipset ipset1
<!--NeedCopy-->
```

For more information, see Configure a multi-IP virtual server.

Install a Citrix ADC VPX instance on Azure VMware Solution

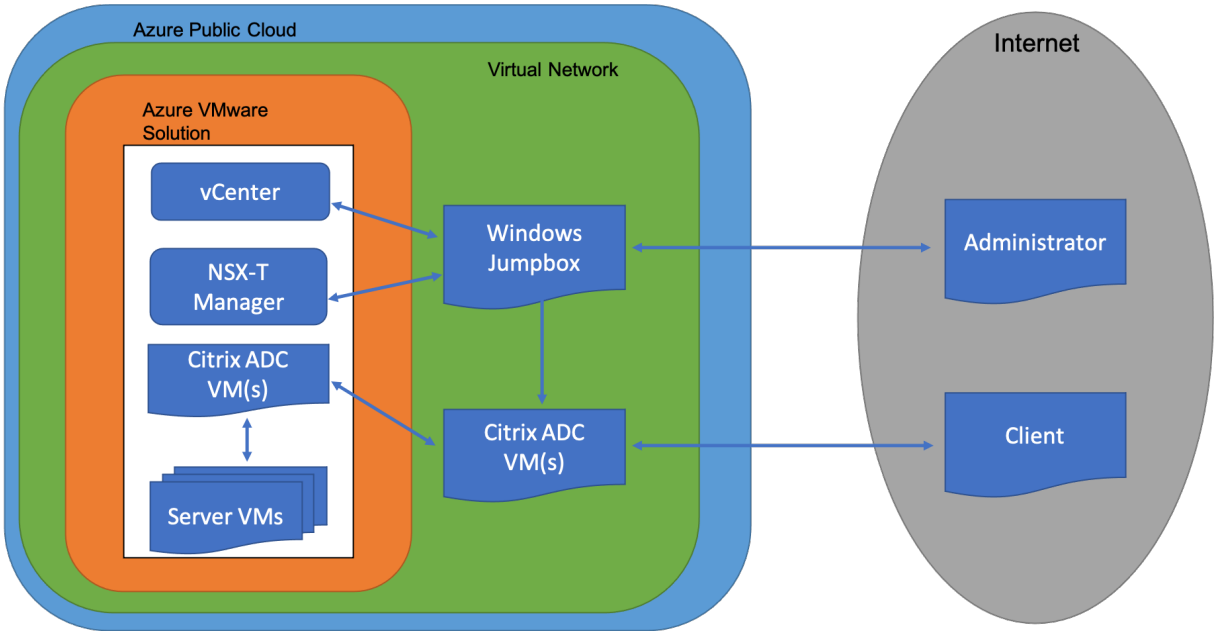
September 14, 2021

Azure VMware Solution (AVS) provides you with private clouds that contain vSphere clusters, built from dedicated bare-metal Azure infrastructure. The minimum initial deployment is three hosts, but additional hosts can be added one at a time, up to a maximum of 16 hosts per cluster. All provisioned private clouds have vCenter Server, vSAN, vSphere, and NSX-T.

The VMware Cloud (VMC) on Azure enables you to create cloud software-defined data centers (SDDC) on Azure with the number of ESX hosts that you want. The VMC on Azure supports Citrix ADC VPX deployments. VMC provides a user interface same as on-prem vCenter. It functions similar to the ESX-based Citrix ADC VPX deployments.

The following diagram shows the Azure VMware solution on the Azure public cloud that an administrator or a client can access over the internet. An administrator can create, manage, and configure workload or server VMs using Azure VMware solution. The admin can access the AVS's web-based vCenter and NSX-T Manager from a Windows Jumpbox. You can create the Citrix ADC VPX instances (standalone or high availability pair) and server VMs within Azure VMware Solution using vCenter, and manage the corresponding networking using NSX-T manager. The Citrix ADC VPX instance on AVS works similar to the on-prem VMware cluster of hosts. AVS is managed from a Windows Jumpbox that is created in the same virtual network.

A client can only access the AVS service by connecting to the VIP of ADC. Another Citrix ADC VPX instance outside Azure VMware Solution but in the same Azure virtual network helps add the VIP of the Citrix ADC VPX instance within Azure VMware Solution as a service. As per requirement, you can configure the Citrix ADC VPX instance to provide service over the internet.



Prerequisites

Before you begin installing a virtual appliance, do the following:

- For more information on Azure VMware solution and its prerequisites, see Azure VMware Solution documentation.
- For more information on deploying Azure VMware solution, see Deploy an Azure VMware Solution private cloud.
- For more information on creating a Windows Jump box VM to access and manage Azure VMware Solution, see Access an Azure VMware Solution private cloud
- In Windows Jump box VM, download the Citrix ADC VPX appliance setup files.
- Create appropriate NSX-T network segments on VMware SDDC to which the virtual machines connect. For more information, see Add a network segment in Azure VMware Solution
- Obtain VPX license files.
- Virtual machines (VMs) created or migrated to the Azure VMware Solution private cloud must be attached to a network segment.

VMware cloud hardware requirements

The following table lists the virtual computing resources that the VMware SDDC must provide for each VPX nCore virtual appliance.

Table 1. Minimum virtual computing resources required for running a Citrix ADC VPX instance

Component	Requirement
Memory	2 GB
Virtual CPU (vCPU)	2
Virtual network interfaces	In VMware SDDC, you can install a maximum of 10 virtual network interfaces if the VPX hardware is upgraded to version 7 or higher.
Disk space	20 GB

> Note
>
> This is in addition to any disk requirements for the hypervisor.

For production use of the VPX virtual appliance, the full memory allocation must be reserved.

OVF Tool 1.0 system requirements

OVF Tool is a client application that can run on Windows and Linux systems. The following table describes the system requirements for installing OVF tool.

Table 2. System requirements for OVF tool installation

Component	Requirement
Operating system	For detailed requirements from VMware, search for the “OVF Tool User Guide” PDF file at http://kb.vmware.com/.
CPU	750 MHz minimum, 1 GHz or faster recommended
RAM	1 GB Minimum, 2 GB recommended
NIC	100 Mbps or faster NIC

For information about installing OVF, search for the “OVF Tool User Guide” PDF file at http://kb.vmware.com/.

Downloading the Citrix ADC VPX setup files

The Citrix ADC VPX instance setup package for VMware ESX follows the Open Virtual Machine (OVF) format standard. You can download the files from the Citrix website. You need a Citrix account to log

on. If you do not have a Citrix account, access the home page at http://www.citrix.com. Click the **New Users link**, and follow the instructions to create a new Citrix account.

Once logged on, navigate the following path from the Citrix home page:

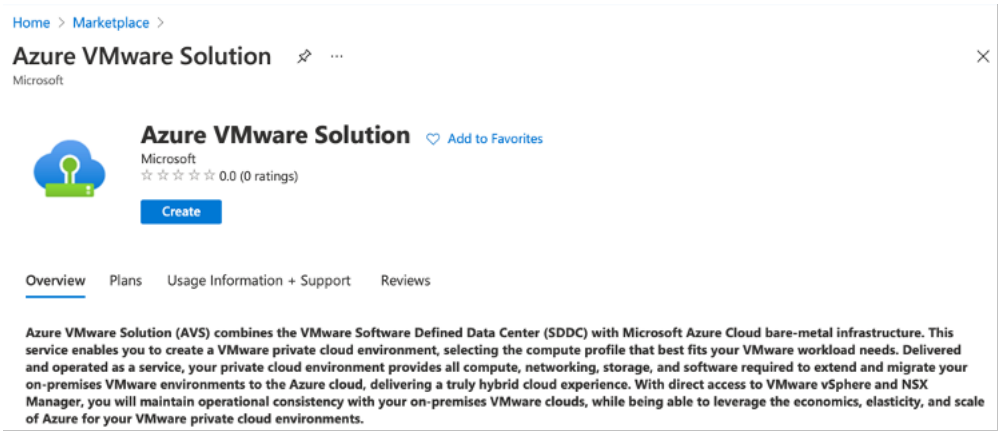
Citrix.com > **Downloads > Citrix ADC > Virtual Appliances**.

Copy the following files to a workstation on the same network as the ESX server. Copy all three files into the same folder.

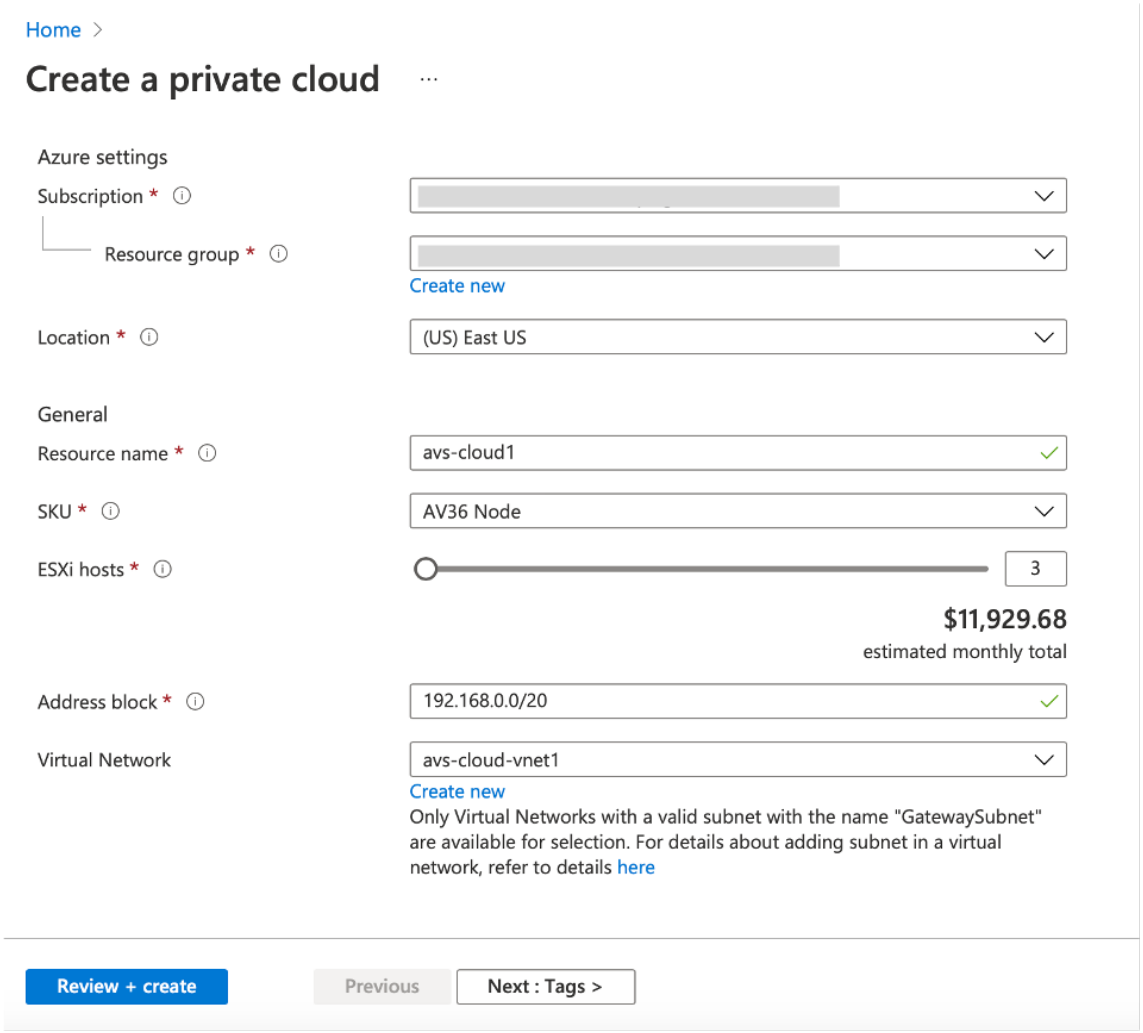
- NSVPX-ESX-<release number>-<build number>-disk1.vmdk (for example, NSVPX-ESX-13.0-79.64-disk1.vmdk)
- NSVPX-ESX-<release number>-<build number>.ovf (for example, NSVPX-ESX-13.0-79.64.ovf)
- NSVPX-ESX-<release number>-<build number>.mf (for example, NSVPX-ESX-13.0-79.64.mf)

Deploy Azure VMware solution

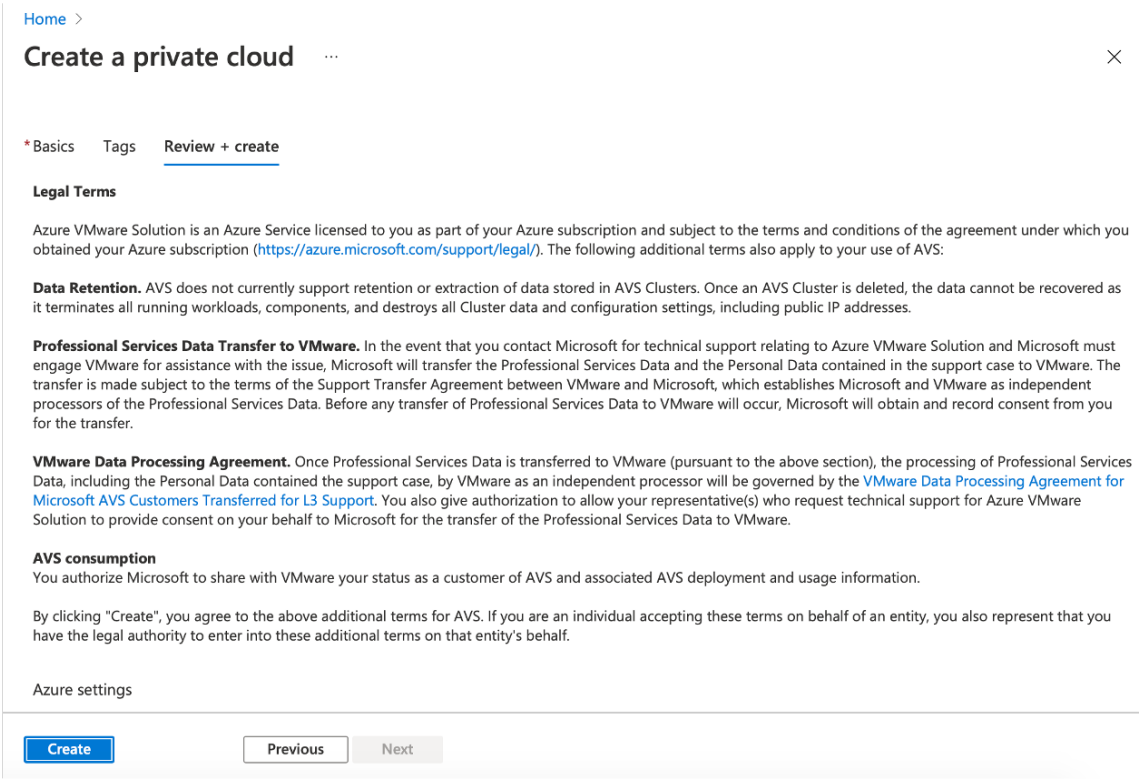
1. Log in to your Microsoft Azure portal, and navigate to **Azure Marketplace**.
2. From the **Azure Marketplace**, search **Azure VMware Solution** and click **Create**.



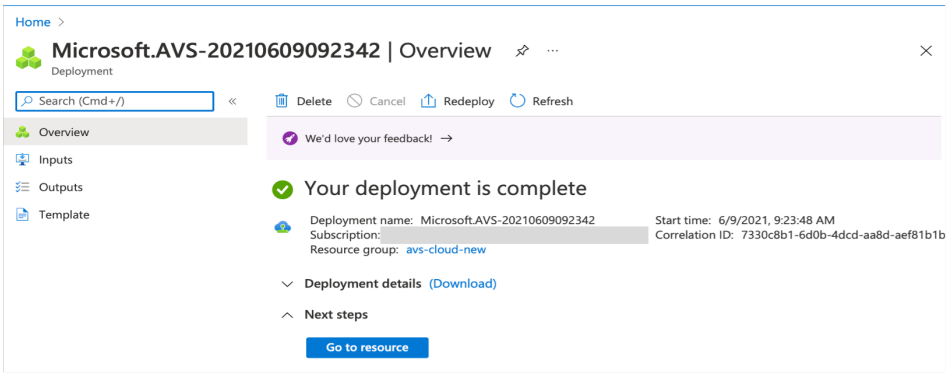
3. In the **Create a private cloud** page, enter the following details:
    - Select a minimum of 3 ESXi hosts to create the default cluster of your private cloud.
    - For the **Address block** field, use **/22** address space.
    - For the **Virtual Network**, make sure that the CIDR range doesn't overlap with any of your on-premises or other Azure subnets (virtual networks) or with the gateway subnet.
    - Gateway subnet is used to express route the connection with private cloud.



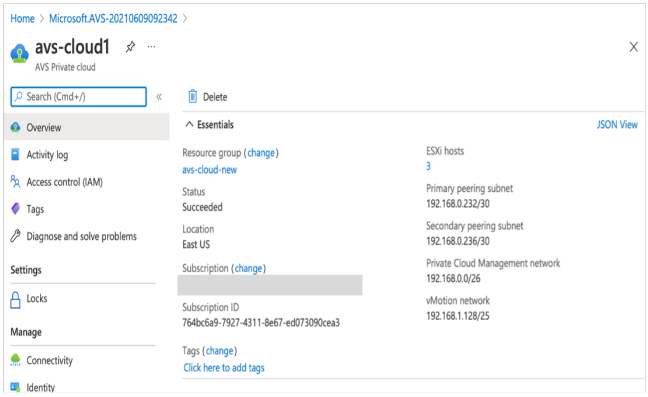
4. Click **Review + Create**.
5. Review the settings. If you must change any settings, click **Previous**.



6. Click **Create**. Private cloud provisioning process starts. It can take up to two hours for the private cloud to be provisioned.



7. Click **Go to resource**, to verify the private cloud that is created.



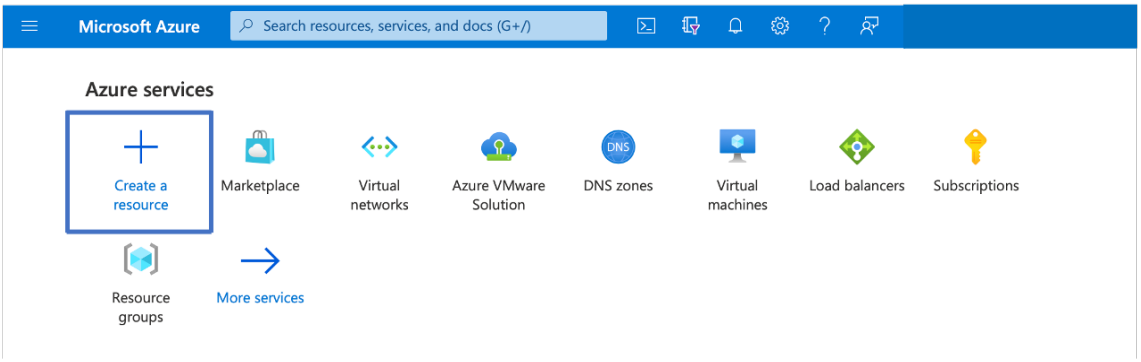
> Note
>
> To access this resource, you need a VM in Windows that acts as a Jump box.

Connect to an Azure virtual machine running Windows

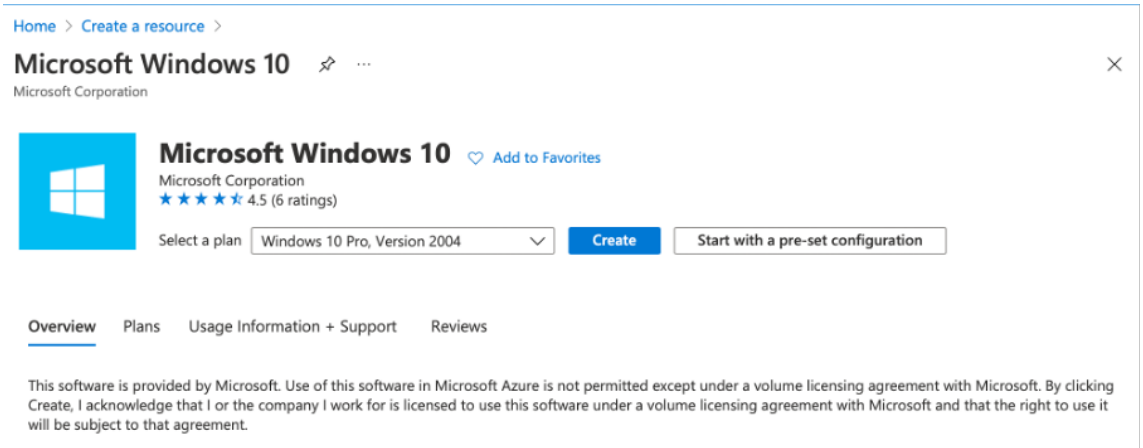
This procedure shows you how to use the Azure portal to deploy a virtual machine (VM) in Azure that runs Windows Server 2019. To see your VM in action, you then RDP to the VM and install the IIS web server.

To access the private cloud that you have created, you need to create a Windows Jump box within the same virtual network.

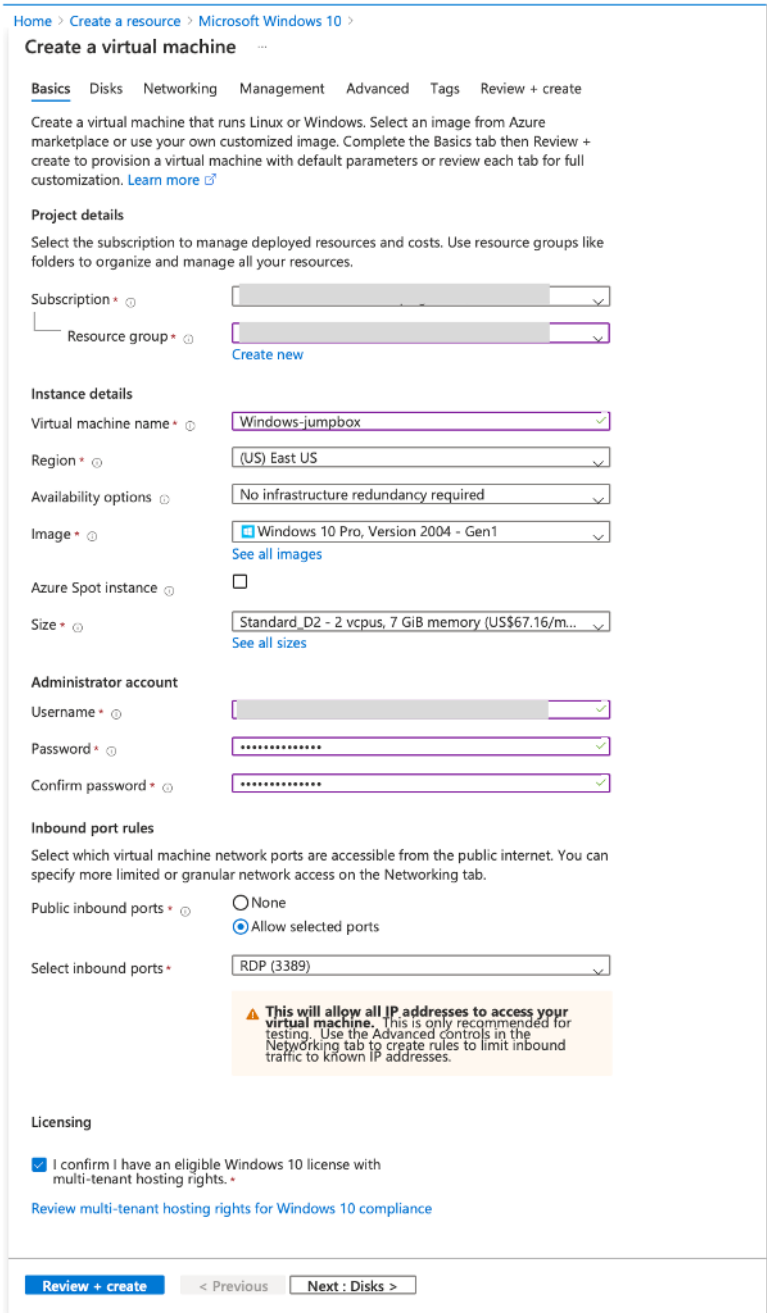
1. Go to the **Azure portal**, and click **Create a Resource**.



2. Search for **Microsoft Windows 10**, and click **Create**.



3. Create a virtual machine (VM) that runs Windows Server 2019. The **Create a virtual machine** page appears. Enter all the details in **Basics** tab, and select the **Licensing** check box. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.



4. After validation runs, select the **Create** button at the bottom of the page.
5. After the deployment is complete, select **Go to resource**.
6. Go to the Windows VM that you have created. Use the public IP address of the Windows VM and connect using RDP.

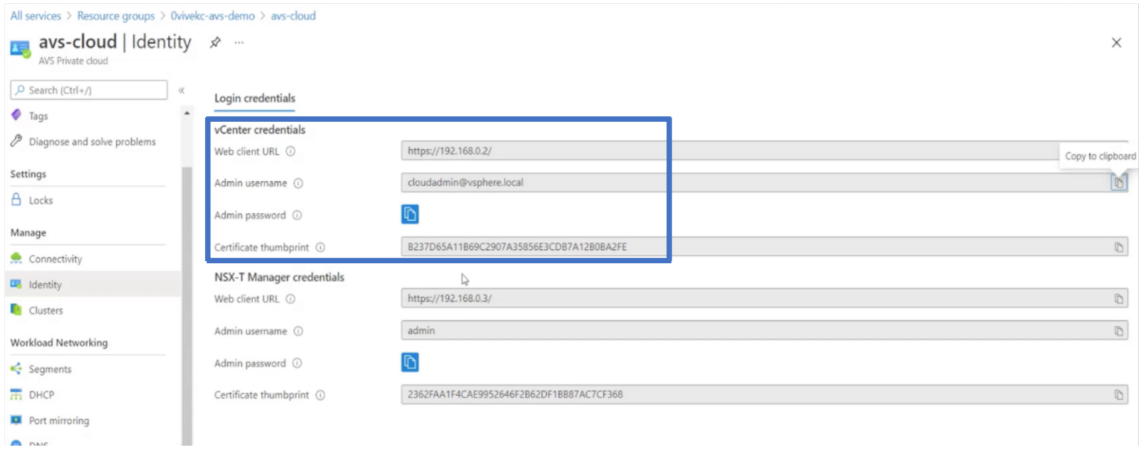
   Use the **Connect** button in the Azure portal to start a Remote Desktop (RDP) session from a Windows desktop. First you connect to the virtual machine, and then you sign on.

   To connect to a Windows VM from a Mac, you must install an RDP client for Mac such as Microsoft

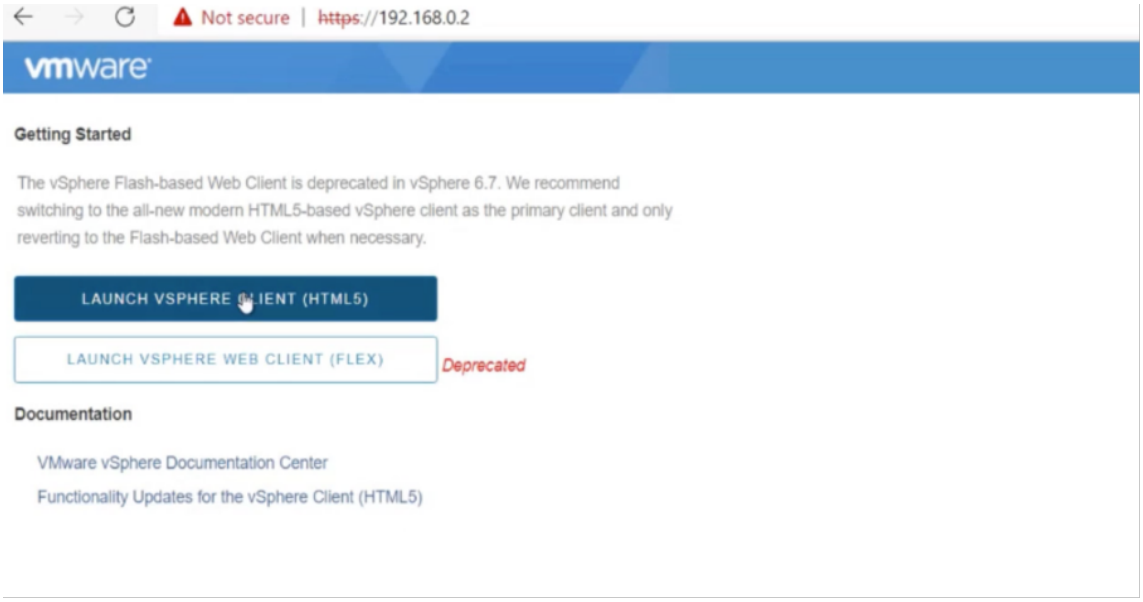
Remote Desktop. For more information, see How to connect and sign on to an Azure virtual machine running Windows.

Access your Private Cloud vCenter portal

1. In your Azure VMware Solution private cloud, under **Manage**, select **Identity**. Make note of the vCenter credentials.

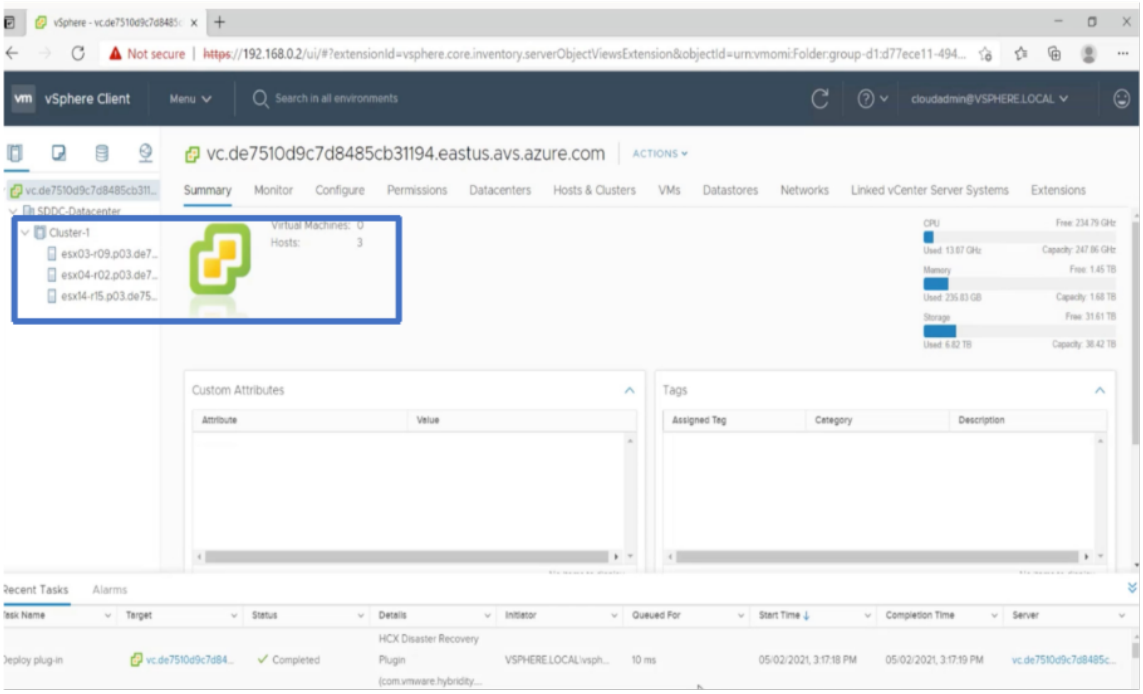


2. Launch the vSphere client by typing the vCenter web client URL.



3. Log in to VMware vSphere using the vCenter credentials of your Azure VMware Solution private cloud.

4. In the vSphere client, you can verify the ESXi hosts that you created in Azure portal.



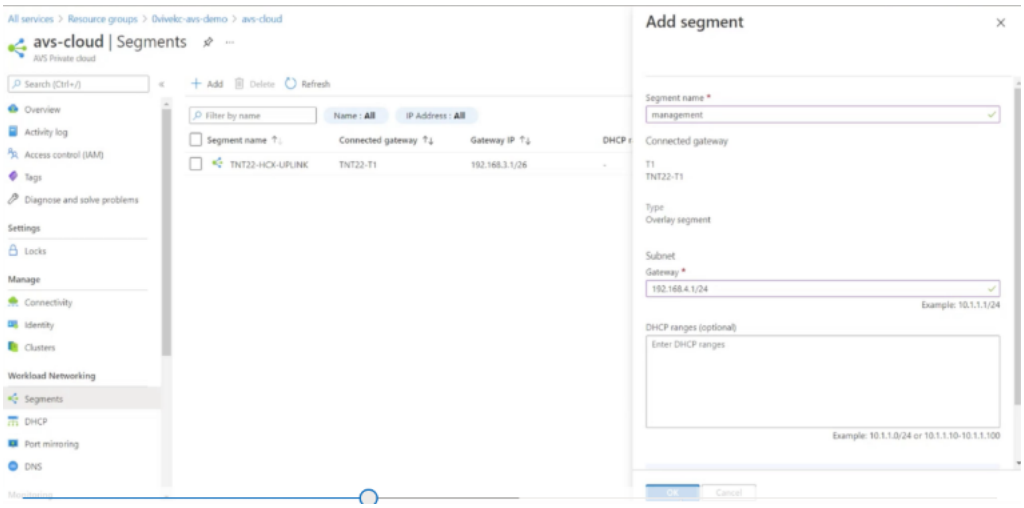
For more information, see Access your Private Cloud vCenter portal.

Create an NSX-T segment in the Azure portal

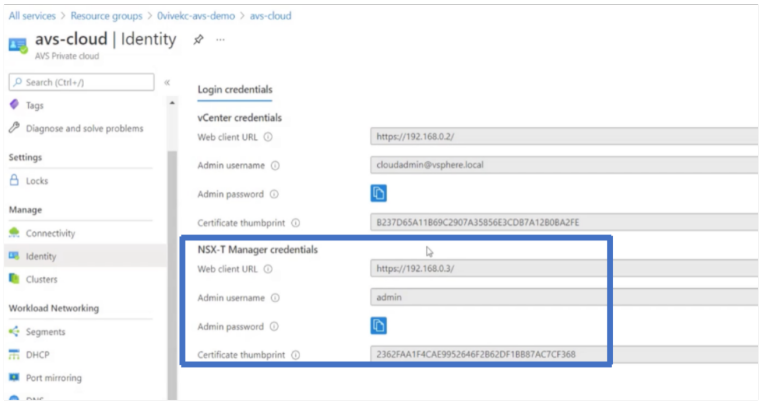
You can create and configure an NSX-T segment from the Azure VMware Solution console in the Azure portal. These segments are connected to the default Tier-1 gateway, and the workloads on these segments get East-West and North-South connectivity. Once you create the segment, it displays in NSX-T

Manager and vCenter.

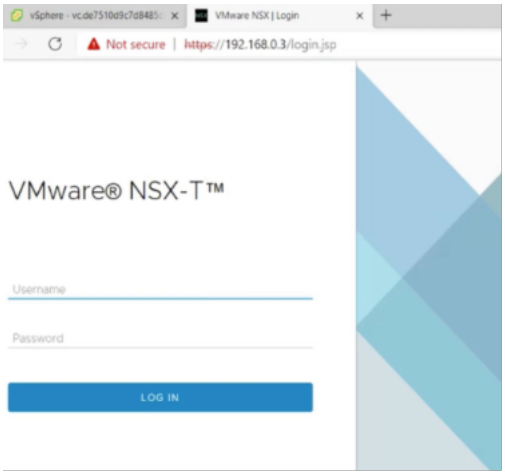
1. In your Azure VMware Solution private cloud, under **Workload Networking**, select **Segments > Add**. Provide the details for the new logical segment and select **OK**. You can create three separate segments for Client, Management, and Server interfaces.



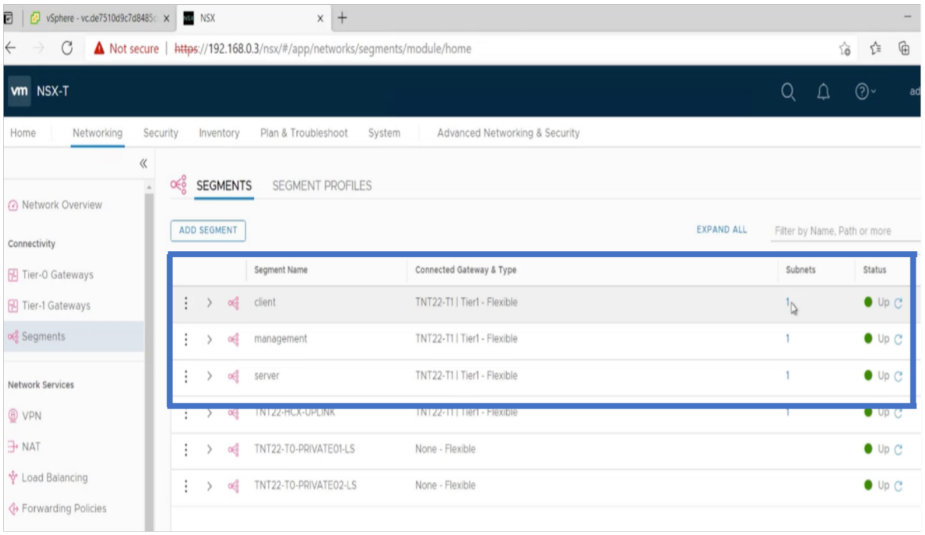
2. In your Azure VMware Solution private cloud, under **Manage**, select **Identity**. Make note of the NSX-T Manager credentials.



3. Launch the VMware NSX-T Manager by typing the NSX-T web client URL.



4. In the NSX-T manager, under **Networking > Segments**, you can see all the segments that you have created. You can also verify the subnets.



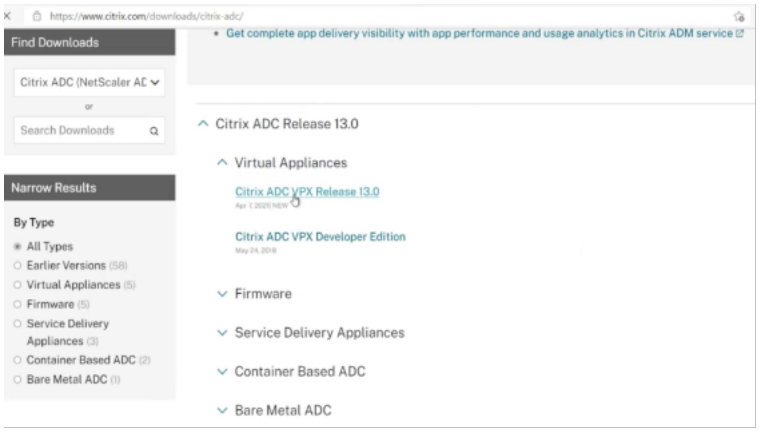
For more information, see Create an NSX-T segment in the Azure portal.

Install a Citrix ADC VPX instance on VMware cloud

After you have installed and configured VMware Software-Defined Data Center (SDDC), you can use the SDDC to install virtual appliances on the VMware cloud. The number of virtual appliances that you can install depends on the amount of memory available on the SDDC.

To install Citrix ADC VPX instances on VMware cloud, perform these steps in Windows Jumpbox VM:

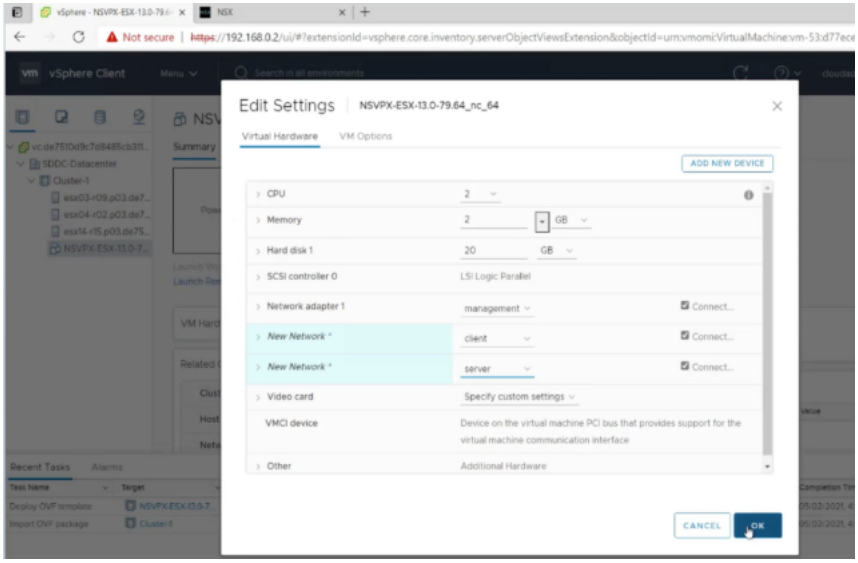
1. Download the Citrix ADC VPX instance setup files for ESXi host from the Citrix Downloads site.



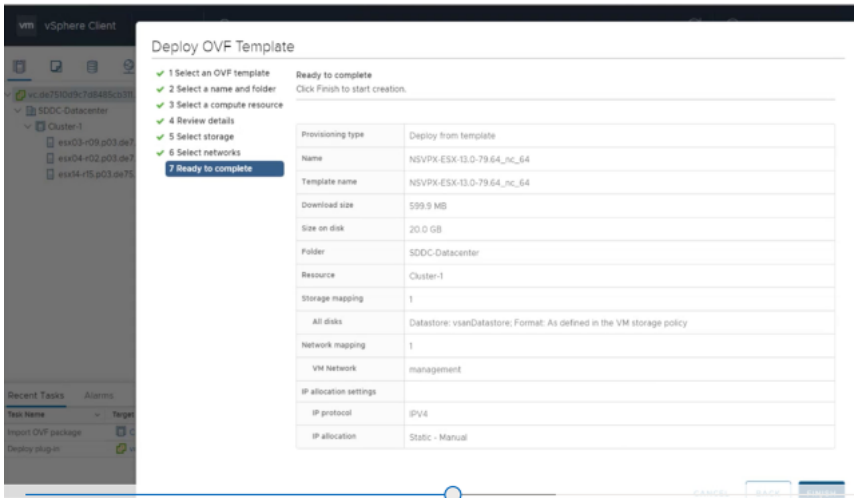
2. Open VMware SDDC in the Windows Jumpbox.
3. In the **User Name** and **Password** fields, type the administrator credentials, and then click **Login**.
4. On the **File** menu, click **Deploy OVF Template**.
5. In the **Deploy OVF Template** dialog box, in **Deploy from file** field, browse to the location at which you saved the Citrix ADC VPX instance setup files, select the .ovf file, and click **Next**.

   > NOTE
   >
   > By default, the Citrix ADC VPX instance uses E1000 network interfaces. To deploy ADC with the VMXNET3 interface, modify the OVF to use VMXNET3 interface instead of E1000. Availability of VMXNET3 interface is limited by Azure infrastructure and might not be available in Azure VMware Solution.

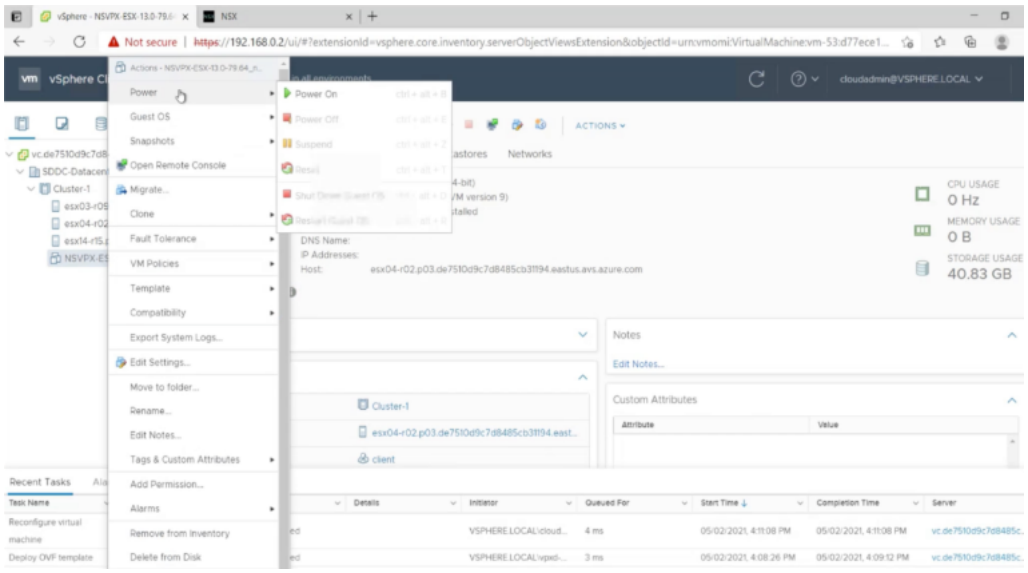
6. Map the networks shown in the virtual appliance OVF template to the networks that you configured on the VMware SDDC. Click **OK**.



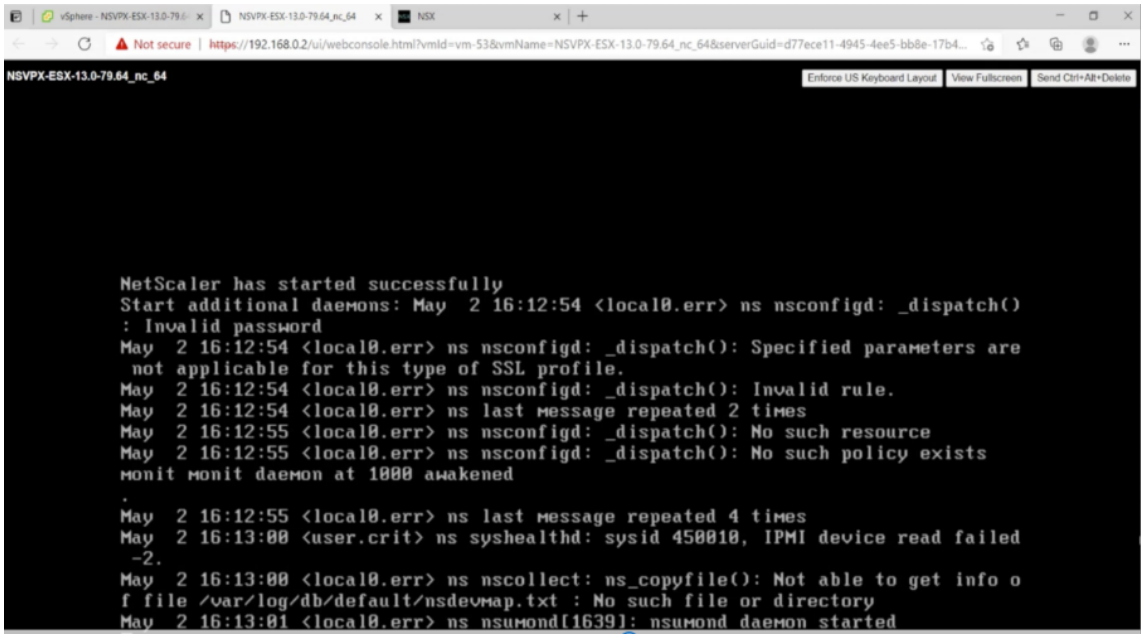
7. Click **Finish** to start installing a virtual appliance on VMware SDDC.



8. You are now ready to start the Citrix ADC VPX instance. In the navigation pane, select the Citrix ADC VPX instance that you have installed and, from the right-click menu, select **Power On**. Click the **Console** tab to emulate a console port.



9. You are now connected to the Citrix ADC VM from the vSphere client.



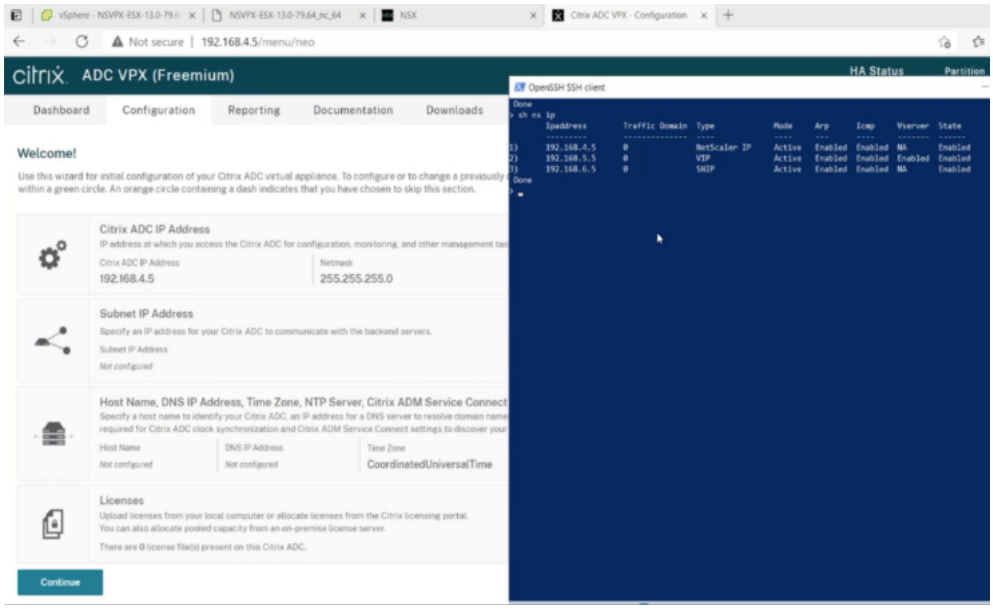
10. To access the Citrix ADC appliance by using the SSH keys, type the following command in the CLI:

```
ssh nsroot@<management IP address>
<!--NeedCopy-->
```

Example:

```
ssh nsroot@192.168.4.5
<!--NeedCopy-->
```

11. You can verify the ADC configuration by using the `show ns ip` command.



Add Azure Autoscale settings

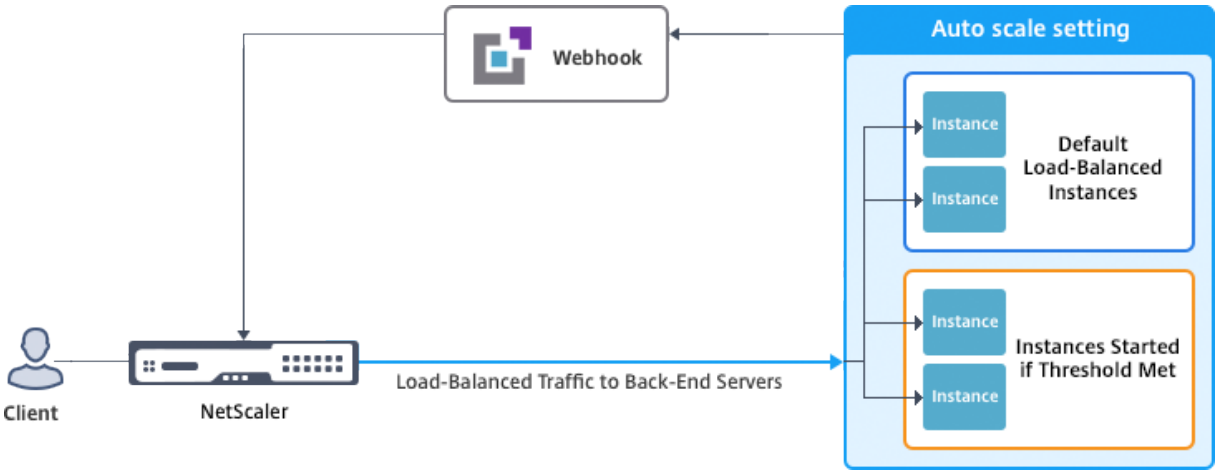
September 14, 2021

Efficient hosting of applications in a cloud involves easy and cost-effective management of resources depending on the application demand. To meet increasing demand, you have to scale network resources upward. Whether demand subsides, you must scale down to avoid the unnecessary cost of idle resources. To minimize the cost of running the application, you have to constantly monitor traffic, memory and CPU use, and so on. However, monitoring traffic manually is cumbersome. For the application environment to scale up or down dynamically, you must automate the processes of monitoring traffic and of scaling resources up and down whenever necessary.

You can use Autoscale with Azure virtual machine scale sets (VMSS) for VPX multi-IP standalone and high availability deployment on Azure.

Integrated with the Azure virtual machine scale sets (VMSS) and Autoscale feature, the Citrix ADC VPX instance provides the following advantages:

- Load balance and management: Auto configures servers to scale up and scale down, depending on demand. The VPX instance auto detects the VMSS Autoscale setting in the back-end subnet in the same resource group as the VPX instance and allows the user to select the VMSS Autoscale setting to balance the load. All of this is done by auto configuring Citrix ADC virtual and subnet IP addresses on the VPX instance.
- High availability: Detects Autoscale groups in the same resource group and load-balance servers.
- Better network availability: The VPX instance supports back-end servers on different virtual networks (VNets).



For more information, see the following Azure topic

- Virtual Machine Scale Sets Documentation
- Overview of Autoscale in Microsoft Azure Virtual Machines, Cloud Services, and Web Apps

Before you begin

1. Read Azure-related usage guidelines. For more information, see Deploy a Citrix ADC VPX instance on Microsoft Azure.
2. Create one or more Citrix ADC VPX instances with three network interfaces on Azure according to your requirement (standalone or high availability deployment).
3. Open the TCP 9001 port on the network security group of the 0/1 interface of the VPX instance. The VPX instance uses this port to receive the scale-out and scale-in notification.
4. Create an Azure virtual machine scale set (VMSS) in the same resource group. If you don't have an existing VMSS configuration, complete the following tasks:

   a) Create a VMSS

   b) Enable Autoscale on VMSS

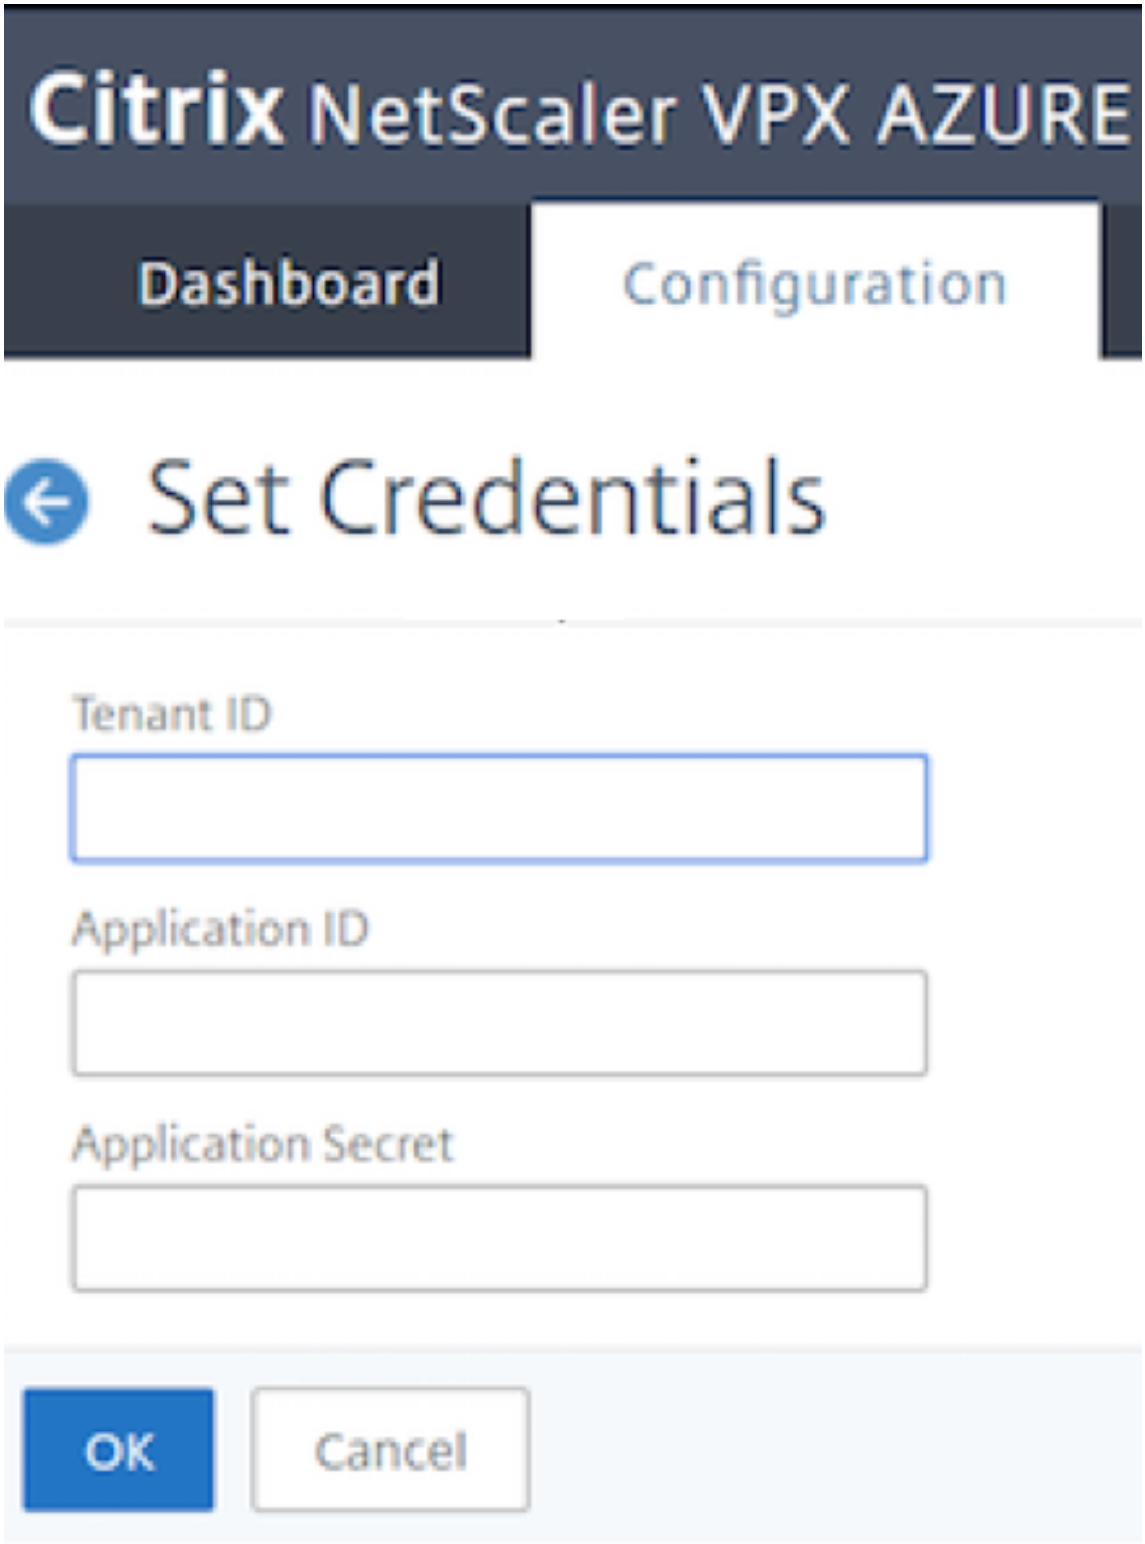
   c) Create scale-in and scale-out policy in VMSS Autoscale setting

   For more information, see Overview of Autoscale with Azure virtual machine scale sets.
5. Create an Azure Active Directory (ADD) application and service principal that can access resources. Assign contributor role to the newly created AAD application. For more information, see Use portal to create an Azure Active Directory application and service principal that can access resources.

Add VMSS to a Citrix ADC VPX instance

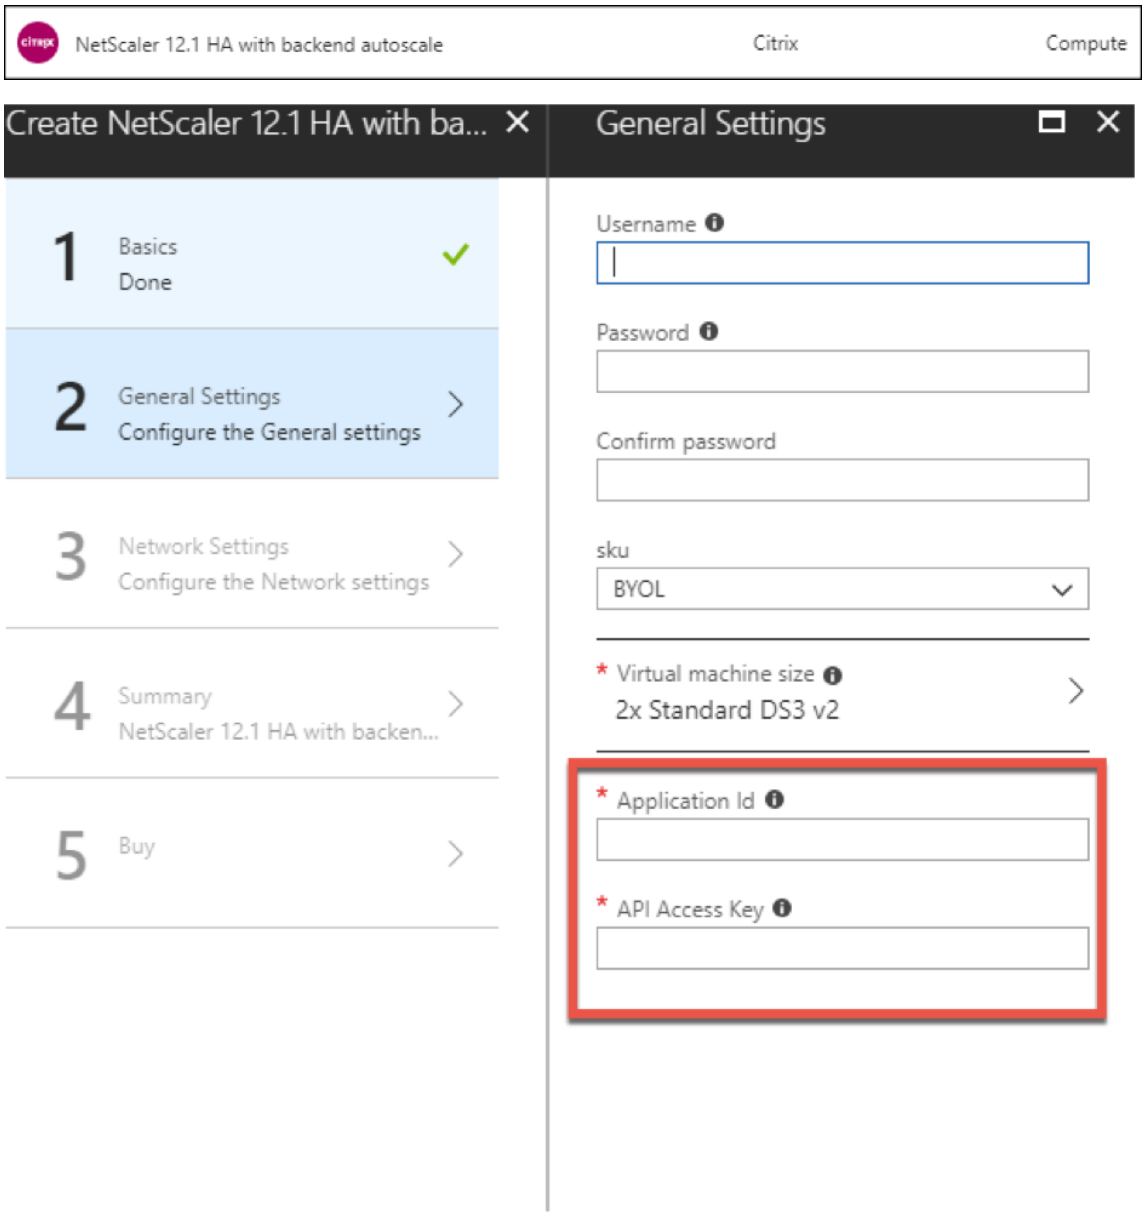
You can add the Autoscale setting to a VPX instance with a single click by using the GUI. Complete these steps to add the Autoscale setting to the VPX instance:

1. Log on to the VPX instance.
2. When you log on to the Citrix ADC VPX instance for the first time, you see the Set Credentials page. Add the required Azure credentials for the Autoscale feature to work.



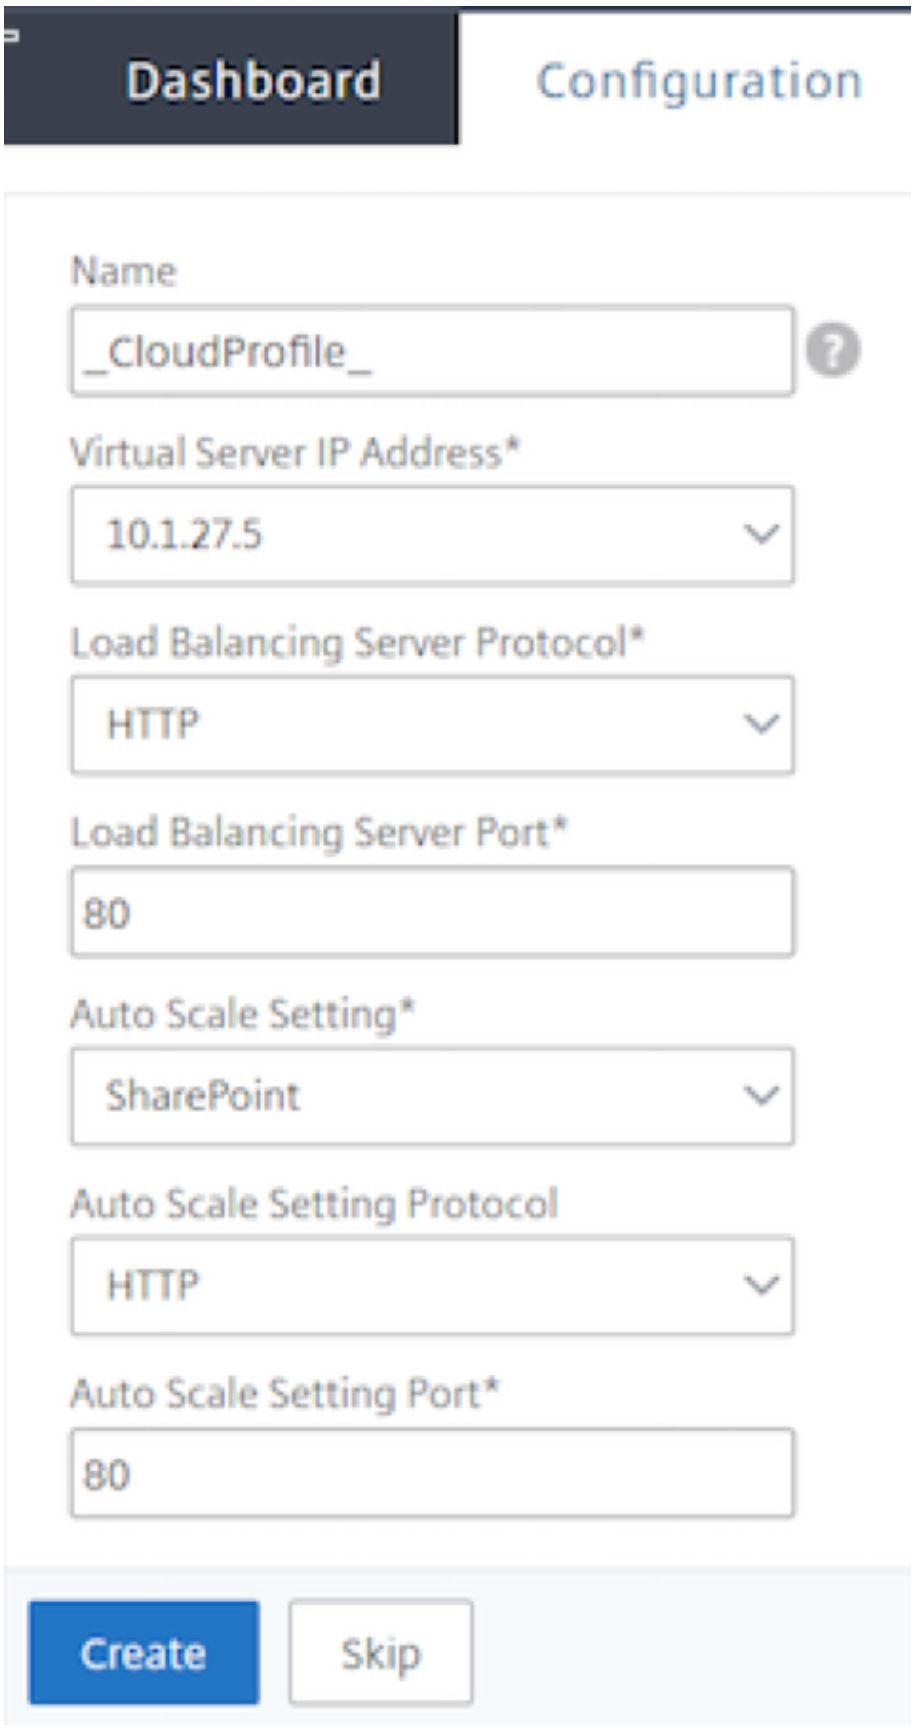
The Set Credential page appears only when the application ID and API access key are not set or the correct application ID and API access keys (same as application secret) is not set in the Azure portal.

When you deploy the “NetScaler 12.1 HA with back end Autoscale” offer from the Azure Marketplace, the Azure portal prompts for Azure service principal credentials (application ID and API access key).



For information about how to create an application ID see Adding an application and to create an access key or application secret see Configure a client application to access web APIs.

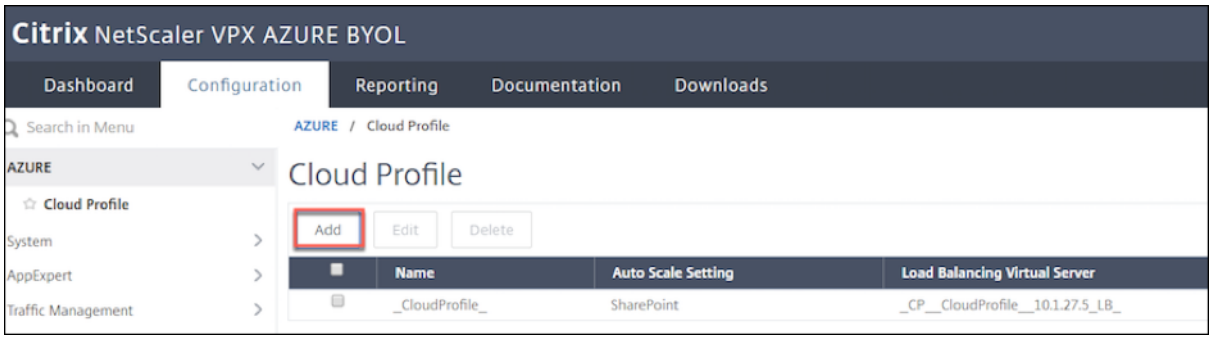
3. In the default cloud profile page, enter the details, as shown in the following example, and click Create.



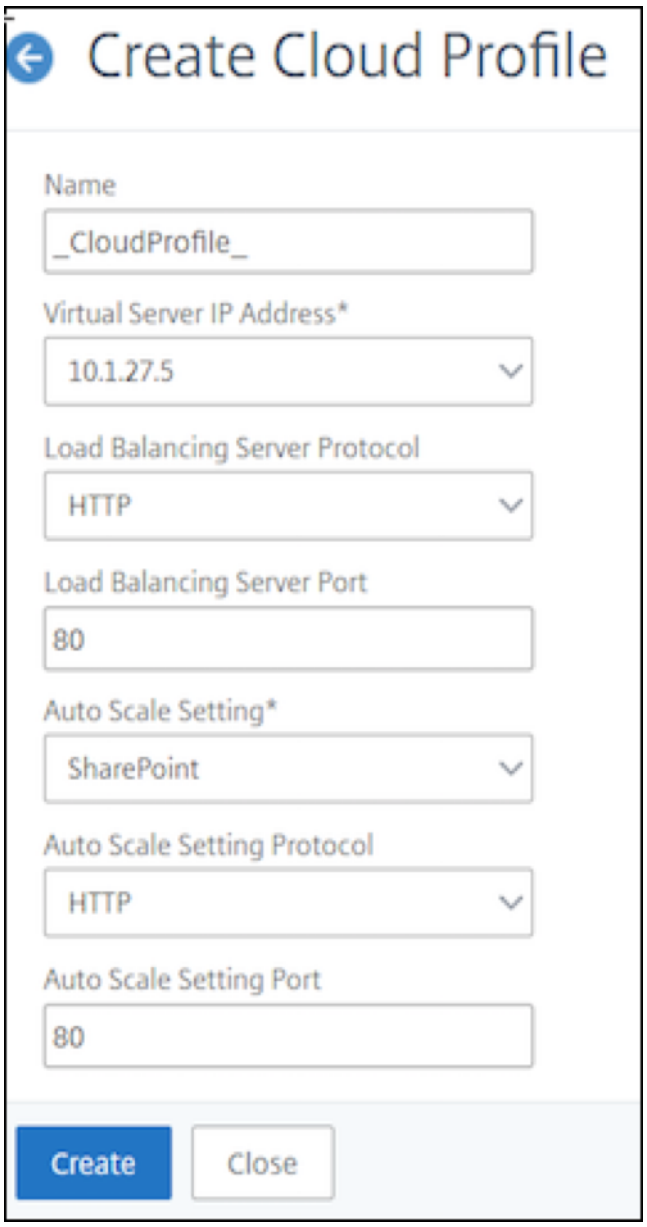
Points to keep in mind while creating a cloud profile

- The virtual server IP address is auto-populated from the free IP address available to the VPX instance. For more information, see Assign multiple IP addresses to virtual machines using the Azure portal.
- Autoscale setting is prepopulated from the VMSS Autoscale setting configured in the current resource group on your Azure account. For more information, see Overview of Autoscale with Azure virtual machine scale sets.
- While selecting the Auto Scaling Group protocol and port, ensure your servers listen on those protocol and ports and you bind the correct monitor in the service group. By default, the TCP monitor is used.
- For SSL Protocol type Autos Scaling, after you create the Cloud Profile the load balance virtual server or service group will be down because of a missing certificate. You can bind the certificate to the virtual server or service group manually.

After the first time logon, if you want to create a cloud profile, on the GUI go to System > Azure > Cloud Profile and click Add.



The Create Cloud Profile configuration page appears.



Cloud Profile creates a Citrix ADC load-balancing (LB) virtual server (virtual server) and a service group with members (servers) as the servers of the Auto Scaling Group. Your back-end servers must be reachable through the SNIP configured on the VPX instance.

To view autoscale-related information in the Azure portal, go to All service > Virtual machine scale set > Select Virtual machine scale set > Scaling.

Azure tags for Citrix ADC VPX deployment

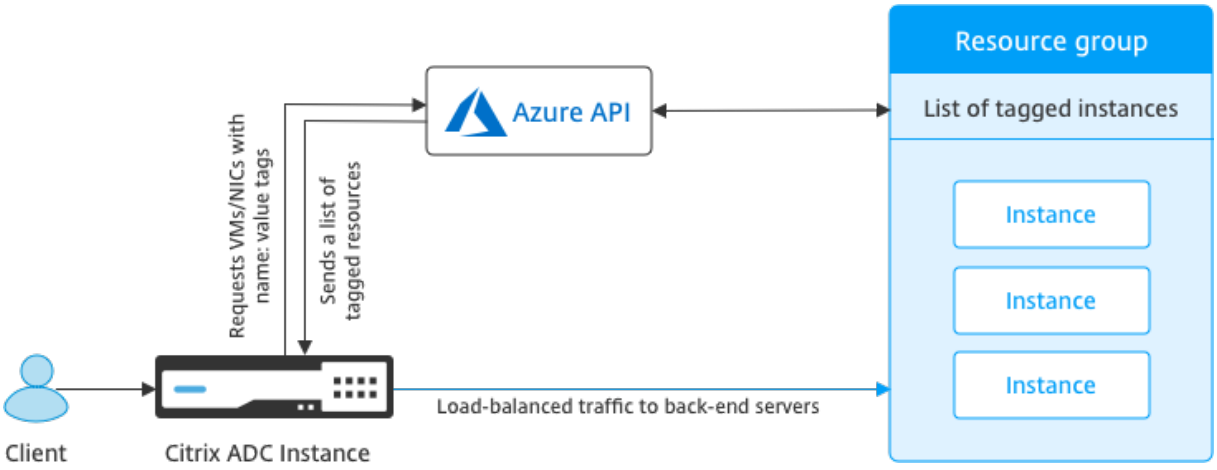
September 14, 2021

In the Azure cloud portal, you can tag resources with a name: value pair (such as Dept: Finance) to categorize and view resources across resource groups and, within the portal, across subscriptions. Tagging is helpful when you need to organize resources for billing or management or automation.

How Azure tag works for VPX deployment

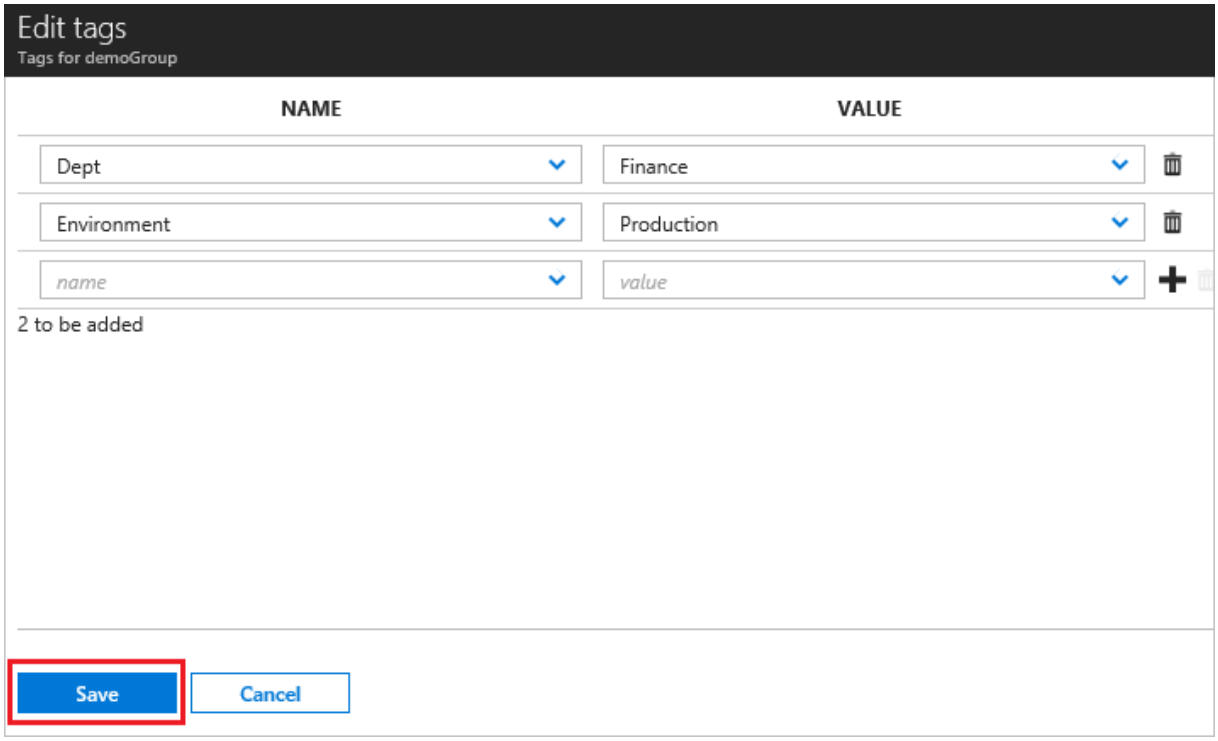
For Citrix ADC VPX standalone and high-availability instances deployed on Azure Cloud, now you can create load balancing service groups associated with an Azure tag. The VPX instance constantly monitors Azure virtual machines (back-end servers) and network interfaces (NICs), or both, with the respective tag and updates the service group accordingly.

The VPX instance creates the service group that load balances the back-end servers using tags. The instance queries the Azure API for all resources that are tagged with a particular tag name and tag value. Depending on the assigned poll period (by default 60 seconds), the VPX instance periodically polls the Azure API and retrieves the resources available with the tag name and tag values assigned in the VPX GUI. Whenever a VM or NIC with the appropriate tag is added or deleted, the ADC detects the respective change and adds or deletes the VM or NIC IP address from the service group automatically.



Before you begin

Before creating Citrix ADC load balancing service groups, add a tag to the servers in Azure. You can assign the tag to either the virtual machine or to NIC.



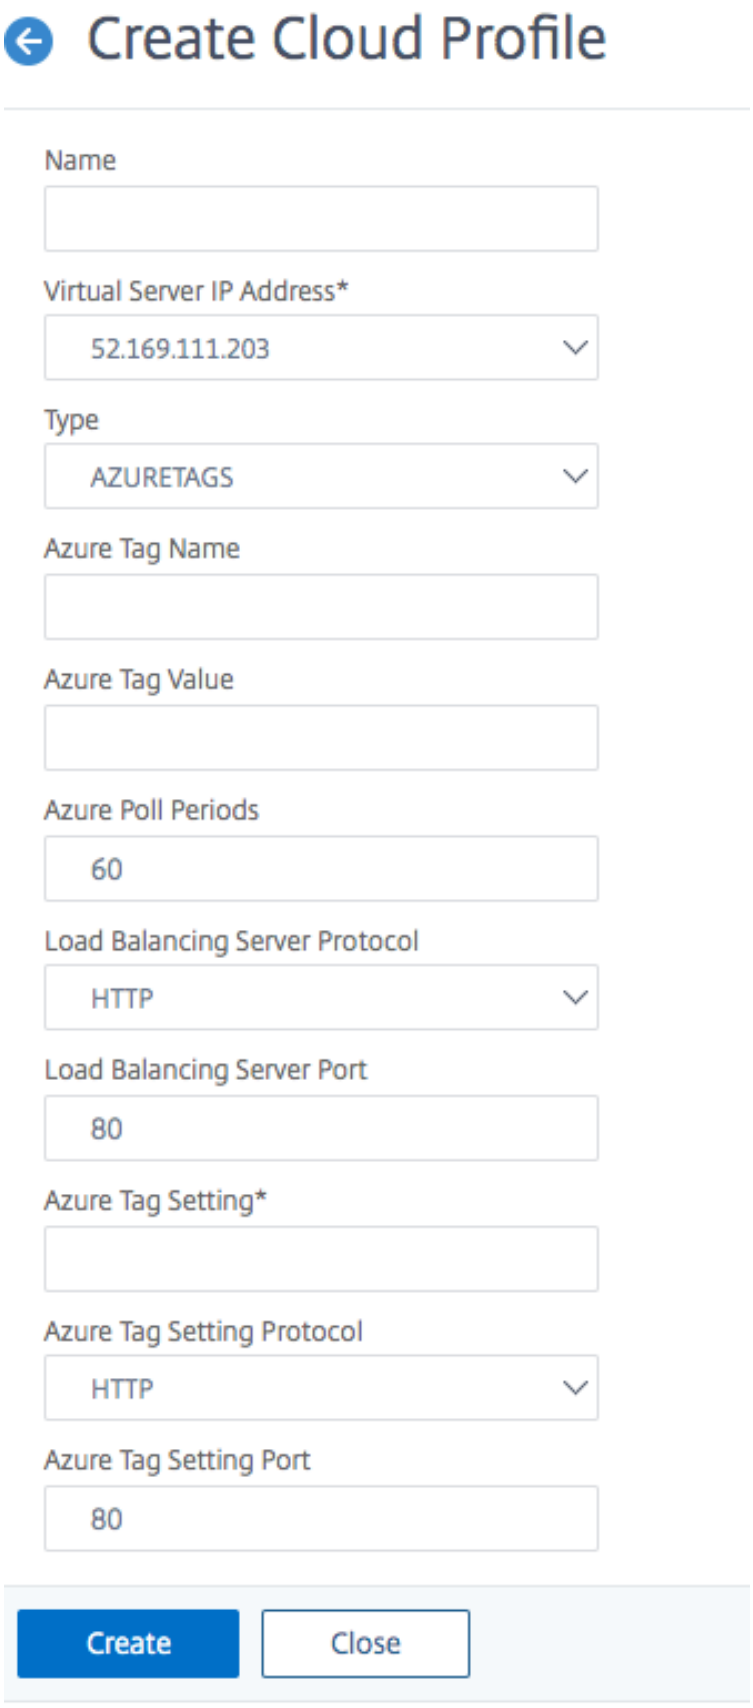
For more information about adding Azure tags, see Microsoft document Use tags to organize your Azure resources.

> Note
> ADC CLI commands to add Azure tag settings support tag names and tag values that start only with numerals or alphabets and not other keyboard characters.

How to add Azure tag settings by using VPX GUI

You can add the Azure tag cloud profile to a VPX instance by using the VPX GUI so that the instance can load balance the back-end servers using the specified tag. Follow these steps:

1. From the VPX GUI, go to **Configuration > Azure > Cloud Profile**.
2. Click Add to create a cloud profile. The cloud profile window opens.



1. Enter values for the following fields:
   - Name: Add a name for your profile
   - Virtual Server IP Address: The virtual server IP address is auto-populated from the free IP address available to the VPX instance. For more information, see Assign multiple IP addresses to virtual machines using the Azure portal.
   - Type: From the menu, select AZURETAGS.
   - Azure Tag Name: Enter the name that you have assigned to the VMs or NICs in the Azure portal.
   - Azure Tag Value: Enter the value that you have assigned to the VMs or NICs in Azure portal.
   - Azure Poll Periods: By default the poll period is 60 seconds, which is the minimum value. You can change it according to your requirement.
   - Load Balancing Server Protocol: Select the protocol that your load balancer listens on.
   - Load Balancing Server Port: Select the port that your load balancer listens on.
   - Azure tag setting: The name of the service group that will be created for this cloud profile.
   - Azure Tag Setting Protocol: Select the protocol that your back-end servers listen on.
   - Azure Tag Setting Port: Select the port that your back-end servers listen on.
2. Click **Create**.

A load-balancer virtual server and a service group are created for the tagged VMs or NICs. To see the load balancer virtual server, from the VPX GUI, navigate to **Traffic Management > Load Balancing > Virtual Servers**.

How to add Azure tag settings by using VPX CLI

Type the following command on Citrix ADC CLI to create a cloud profile for Azure tags.

```
add cloud profile `<profile name>` -type azuretags -vServerName `<
    vserver name>` -serviceType HTTP -IPAddress `<vserver IP address>` -
    port 80 -serviceGroupName `<service group name>` -
    boundServiceGroupSvcType HTTP -vsvrbindsvcport 80 -azureTagName `<
    Azure tag specified on Azure portal>` -azureTagValue `<Azure value
    specified on the Azure portal>` -azurePollPeriod 60

<!--NeedCopy-->
```

> Important
> You must save all configurations; otherwise, the configurations are lost after you restart the instance. Type `save config`.

Example 1: Here's a sample command for a cloud profile for HTTP traffic of all Azure VMs/NICs tagged with the "myTagName/myTagValue" pair:

```
add cloud profile MyTagCloudProfile -type azuretags -vServerName
    MyTagVServer -serviceType HTTP -IPAddress 40.115.116.57 -port 80 -
    serviceGroupName MyTagsServiceGroup -boundServiceGroupSvcType HTTP -
    vsvrbindsvcport 80 -azureTagName myTagName -azureTagValue myTagValue
     -azurePollPeriod 60
Done
<!--NeedCopy-->
```

To display the cloud profile, type `show cloudprofile`.

Example 2: The following CLI command prints information about the newly added cloud profile in example 1.

```
show cloudprofile
1)    Name:  MyTagCloudProfile Type:  azuretags         VServerName:
    MyTagVServer ServiceType:  HTTP       IPAddress:  52.178.209.133
    Port:  80               ServiceGroupName:  MyTagsServiceGroup
    BoundServiceGroupSvcType:  HTTP
       Vsvrbindsvcport:  80     AzureTagName:  myTagName AzureTagValue:
           myTagValue AzurePollPeriod:  60     GraceFul:  NO
          Delay:  60
<!--NeedCopy-->
```

To remove a cloud profile, type rm cloud profile <cloud profile name>

Example 3: The following command removes the cloud profile created in example 1.

```
> rm cloudprofile MyTagCloudProfile
  Done
<!--NeedCopy-->
```

Troubleshooting

Issue: In very rare cases, the “rm cloud profile” CLI command might fail to remove service group and servers associated with the deleted cloud profile. This happens when the command is issued seconds before the poll period of the cloud profile being deleted elapses.

Solution: Manually delete the remaining service groups by entering the following CLI command for each of the remaining service groups:

```
#> rm servicegroup <serviceGroupName>

<!--NeedCopy-->
```

Also remove each of the remain servers by entering the following CLI command for each of the remaining servers:

```
#> rm server <name>
<!--NeedCopy-->
```

Issue: If you add an Azure tag setting to a VPX instance by using CLI, the rain_tags process continues to run on an HA pair node after a warm reboot.

Solution: Manually terminate the process on the secondary node after a warm reboot. From the CLI of the secondary HA node exit to the shell prompt:

```
#> shell

<!--NeedCopy-->
```

Use the following command to kill the rain_tags process:

```
# PID=`ps -aux | grep rain_tags | awk '{
 print $2 }
 '`; kill -9 $PID

<!--NeedCopy-->
```

Issue: Back-end servers might not be reachable and reported as DOWN by the VPX instance, in spite of being healthy.
Solution: Make sure that the VPX instance can reach the tagged IP address corresponding to the back-end server. For a tagged NIC, this is the NIC IP address; whereas for a tagged VM, this is the VM's primary IP address. If the VM/NIC resides on a different Azure VNet, make sure that VNet peering is enabled.

Configure GSLB on Citrix ADC VPX instances

September 14, 2021

Citrix ADC appliances configured for global server load balancing (GSLB) provide disaster recovery and continuous availability of applications by protecting against points of failure in a WAN. GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers if there is an outage.

This section describes how to enable GSLB on VPX instances on two sites in a Microsoft Azure environment, by using Windows PowerShell commands.

> **Note**
>
> For more information about GSLB, see Global Server Load Balancing.

You can configure GSLB on a Citrix ADC VPX instance on Azure, in two steps:

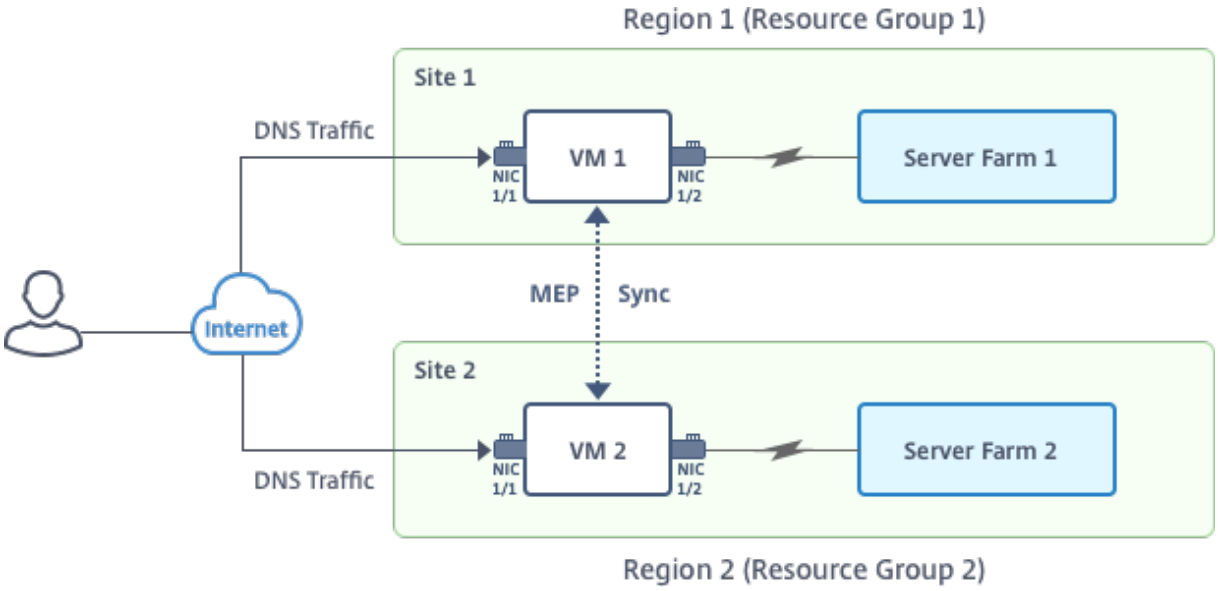
1. Create a VPX instance with multiple NICs and multiple IP addresses, on each site.
2. Enable GSLB on the VPX instances.

> **Note**
>
> For more information about configuring multiple NICs and IP addresses see: Configure multiple IP addresses for a Citrix ADC VPX instance in standalone mode by using PowerShell commands

Scenario

This scenario includes two sites - Site 1 and Site 2. Each site has a VM (VM1 and VM2) configured with multiple NICs, multiple IP addresses, and GSLB.

Figure. GSLB setup implemented across two sites - Site 1 and Site 2.



In this scenario, each VM has three NICs - NIC 0/1, 1/1, and 1/2. Each NIC can have multiple private and public IP addresses. The NICs are configured for the following purposes.

- NIC 0/1: to serve management traffic
- NIC 1/1: to serve client-side traffic
- NIC 1/2: to communicate with back-end servers

For information about the IP addresses configured on each NIC in this scenario, see the IP configuration details section.

Parameters

Following are sample parameters settings for this scenario in this document. You can use different settings if you want.

```
$location="West Central US"

$vnetName="NSVPX-vnet"

$RGName="multiIP-RG"

$prmStorageAccountName="multiipstorageaccnt"

$avSetName="MultiIP-avset"

$vmSize="Standard\_DS3\_V2"
<!--NeedCopy-->
```

Note: The minimum requirement for a VPX instance is 2 vCPUs and 2 GB RAM.

```
$publisher="citrix"

$offer="netscalervpx111"

$sku="netscalerbyol"

$version="latest"

$vmNamePrefix="MultiIPVPX"

$nicNamePrefix="MultiipVPX"

$osDiskSuffix="osdiskdb"

$numberOfVMs=1

$ipAddressPrefix="10.0.0."

$ipAddressPrefix1="10.0.1."

$ipAddressPrefix2="10.0.2."

$pubIPName1="MultiIP-pip1"

$pubIPName2="MultiIP-pip2"
```

```
26
27 $IpConfigName1="IPConfig1"
28

Create a VM

Follow steps 1–10 to create VM1 with multiple NICs and multiple IP addresses, by using PowerShell commands:

1. Create resource group
2. Create storage account
3. Create availability set
4. Create virtual network
5. Create public IP address
6. Create NICs
7. Create VM config object
8. Get credentials and set OS properties for the VM
9. Add NICs
10. Specify OS disk and create VM

After you complete all the steps and commands to create VM1, repeat these steps to create VM2 with parameters specific to it.

Create resource group

```
New-AzureRMResourceGroup -Name $RGName -Location $location
<!--NeedCopy-->
```

Create storage account

```
$prmStorageAccount=New-AzureRMStorageAccount -Name
    $prmStorageAccountName -ResourceGroupName $RGName -Type Standard_LRS
     -Location $location
<!--NeedCopy-->
```

Create availability set

```
$avSet=New-AzureRMAvailabilitySet -Name $avSetName -ResourceGroupName
    $RGName -Location $location
<!--NeedCopy-->
```

Create virtual network

1. Add subnets.

```
$subnet1=New-AzureRmVirtualNetworkSubnetConfig -Name
    $frontendSubnetName -AddressPrefix "10.0.0.0/24"
$subnet2=New-AzureRmVirtualNetworkSubnetConfig -Name
    $backendSubnetName1 -AddressPrefix "10.0.1.0/24"
$subnet3=New-AzureRmVirtualNetworkSubnetConfig -Name
    $backendSubnetName2 -AddressPrefix "10.0.2.0/24"
<!--NeedCopy-->
```

2. Add virtual network object.

```
$vnet=New-AzureRmVirtualNetwork -Name $vnetName -ResourceGroupName
     $RGName -Location $location -AddressPrefix 10.0.0.0/16 -Subnet
     $subnet1, $subnet2, $subnet3
<!--NeedCopy-->
```

3. Retrieve subnets.

```
$frontendSubnet=$vnet.Subnets|?{
 $_.Name -eq $frontendSubnetName }

$backendSubnet1=$vnet.Subnets|?{
```

```
 $_.Name -eq $backendSubnetName1 }

$backendSubnet2=$vnet.Subnets|?{
 $_.Name -eq $backendSubnetName2 }

<!--NeedCopy-->
```

Create public IP address

```
$pip1=New-AzureRmPublicIpAddress -Name $pubIPName1 -ResourceGroupName
    $RGName -Location $location -AllocationMethod Dynamic
$pip2=New-AzureRmPublicIpAddress -Name $pubIPName2 -ResourceGroupName
    $RGName -Location $location -AllocationMethod Dynamic
<!--NeedCopy-->
```

Create NICs

Create NIC 0/1

```
$nic1Name=$nicNamePrefix + $suffixNumber + "-Mgmnt"
$ipAddress1=$ipAddressPrefix + $suffixNumber
$IPConfig1=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName1 -
    SubnetId $frontendSubnet.Id -PublicIpAddress $pip1 -PrivateIpAddress
     $ipAddress1 -Primary
$nic1=New-AzureRMNetworkInterface -Name $nic1Name -ResourceGroupName
    $RGName -Location $location -IpConfiguration $IpConfig1
<!--NeedCopy-->
```

Create NIC 1/1

```
$nic2Name $nicNamePrefix + $suffixNumber + "-frontend"
$ipAddress2=$ipAddressPrefix1 + ($suffixNumber)
$ipAddress3=$ipAddressPrefix1 + ($suffixNumber + 1)
$IPConfig2=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName2 -
    PublicIpAddress $pip2 -SubnetId $backendSubnet1.Id  -
    PrivateIpAddress $ipAddress2  -Primary
$IPConfig3=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName3 -
    SubnetId $backendSubnet1.Id  -PrivateIpAddress $ipAddress3
nic2=New-AzureRMNetworkInterface -Name $nic2Name -ResourceGroupName
    $RGName -Location $location -IpConfiguration $IpConfig2, $IpConfig3
<!--NeedCopy-->
```

Create NIC 1/2

```
$nic3Name=$nicNamePrefix + $suffixNumber + "-backend"
$ipAddress4=$ipAddressPrefix2 + ($suffixNumber)
$IPConfig4=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName4 -
    SubnetId $backendSubnet2.Id -PrivateIpAddress $ipAddress4 -Primary
$nic3=New-AzureRMNetworkInterface -Name $nic3Name -ResourceGroupName
    $RGName -Location $location -IpConfiguration $IpConfig4
<!--NeedCopy-->
```

Create VM config object

```
$vmName=$vmNamePrefix
$vmConfig=New-AzureRMVMConfig -VMName $vmName -VMSize $vmSize -
    AvailabilitySetId $avSet.Id
<!--NeedCopy-->
```

Get credentials and set OS properties

```
$cred=Get-Credential -Message "Type the name and password for VPX login
    ."
$vmConfig=Set-AzureRMVMOperatingSystem -VM $vmConfig -Linux -
    ComputerName $vmName -Credential $cred
$vmConfig=Set-AzureRMVMSourceImage -VM $vmConfig -PublisherName
    $publisher -Offer $offer -Skus $sku -Version $version
<!--NeedCopy-->
```

Add NICs

```
$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic1.Id -
    Primary
$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic2.Id
$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic3.Id
<!--NeedCopy-->
```

Specify OS disk and create VM

```
$osDiskName=$vmName + "-" + $osDiskSuffix
$osVhdUri=$prmStorageAccount.PrimaryEndpoints.Blob.ToString() + "vhds/"
     +$osDiskName + ".vhd"
```

```
3 $vmConfig=Set-AzureRMVMOSDisk -VM $vmConfig -Name $osDiskName -VhdUri
    $osVhdUri -CreateOption fromImage
4 Set-AzureRmVMPlan -VM $vmConfig -Publisher $publisher -Product $offer -
    Name $sku
5 New-AzureRMVM -VM $vmConfig -ResourceGroupName $RGName -Location
    $location
6 <!--NeedCopy-->
```

> **Note**
>
> Repeat steps 1–10 listed in "Create Multi-NIC VMs by Using PowerShell Commands" to create VM2 with parameters specific to VM2.

IP configuration details

The following IP addresses are used.

Table 1. IP addresses used in VM1

NIC	Private IP	Public IP (PIP)	Description
0/1	10.0.0.10	PIP1	Configured as NSIP (management IP)
1/1	10.0.1.10	PIP2	Configured as SNIP/GSLB Site IP
-	10.0.1.11	-	Configured as LB server IP. Public IP is not mandatory
1/2	10.0.2.10	-	Configured as SNIP for sending monitor probes to services; public IP is not mandatory

Table 2. IP addresses used in VM2

NIC	Internal IP	Public IP (PIP)	Description
0/1	20.0.0.10	PIP4	Configured as NSIP (management IP)

NIC	Internal IP	Public IP (PIP)	Description
1/1	20.0.1.10	PIP5	Configured as SNIP/GSLB Site IP
-	20.0.1.11	-	Configured as LB server IP. Public IP is not mandatory
1/2	20.0.2.10	-	Configured as SNIP for sending monitor probes to services; public IP is not mandatory

Here are sample configurations for this scenario, showing the IP addresses and initial LB configurations as created through the Citrix ADC VPX CLI for VM1 and VM2.

Here's an example configuration on VM1.

```
add ns ip 10.0.1.10 255.255.255.0 -mgmtAccess ENABLED
Add nsip 10.0.2.10 255.255.255.0
add service svc1 10.0.1.10 ADNS 53
add lb vserver v1 HTTP 10.0.1.11 80
add service s1 10.0.2.120 http 80
Add service s2 10.0.2.121 http 80
Bind lb vs v1 s[1-2]
<!--NeedCopy-->
```

Here's an example configuration on VM2.

```
add ns ip 20.0.1.10 255.255.255.0  -mgmtAccess ENABLED
Add nsip 20.0.2.10 255.255.255.0
add service svc1 20.0.1.10 ADNS 53
add lb vserver v1 HTTP 20.0.1.11 80
Add service s1 20.0.2.90 http 80
Add service s2 20.0.2.91 http 80
Bind lb vs v1 s[1-2]
<!--NeedCopy-->
```

Configure GSLB sites and other settings

Perform the tasks described in the following topic to configure the two GSLB sites and other necessary settings:

Global Server Load Balancing

For more information, see this support article: https://support.citrix.com/article/CTX110348

Here's an example GSLB configuration on VM1 and VM2.

```
enable ns feature LB GSLB
add gslb site site1 10.0.1.10 -publicIP PIP2
add gslb site site2 20.0.1.10 -publicIP PIP5
add gslb service site1_gslb_http_svc1 10.0.1.11 HTTP 80 -publicIP PIP3
   -publicPort 80 -siteName site1
add gslb service site2_gslb_http_svc1 20.0.1.11 HTTP 80 -publicIP PIP6
   -publicPort 80 -siteName site2
add gslb vserver gslb_http_vip1 HTTP
bind gslb vserver gslb_http_vip1 -serviceName site2_gslb_http_svc1
bind gslb vserver gslb_http_vip1 -serviceName site1_gslb_http_svc1
bind gslb vserver gslb_http_vip1 -domainName www.gslbindia.com -TTL 5
<!--NeedCopy-->
```

You've configured GSLB on Citrix ADC VPX instances running on Azure.

For additional information about how to configure GSLB on Citrix ADC VPX instances, click the following image to watch the video about Configuring Citrix ADC GSLB in Microsoft Azure.

Configure GSLB on an active-standby high-availability setup

September 14, 2021

You can configure global server load balancing (GSLB) on active-standby HA deployment on Azure in three steps:

1. Create a VPX HA pair on each GSLB site. See Configure a high-availability setup with multiple IP addresses and NICs for information about how to create an HA pair.
2. Configure the Azure Load Balancer (ALB) with the front-end IP address and rules to allow GSLB and DNS traffic.

   This step involves the following substeps. See the scenario in this section for the PowerShell commands used to complete these substeps.

a. Create a front-end `IPconfig` for GSLB site.

b. Create a back-end address pool with IP address of NIC 1/1 of nodes in HA.

c. Create load-balancing rules for following:

```
TCP/3011  -  gslb communication
TCP/3010 - gslb communication
UDP/53 - DNS communication
```

d. Associate back-end address pool with the LB rules created in step c.

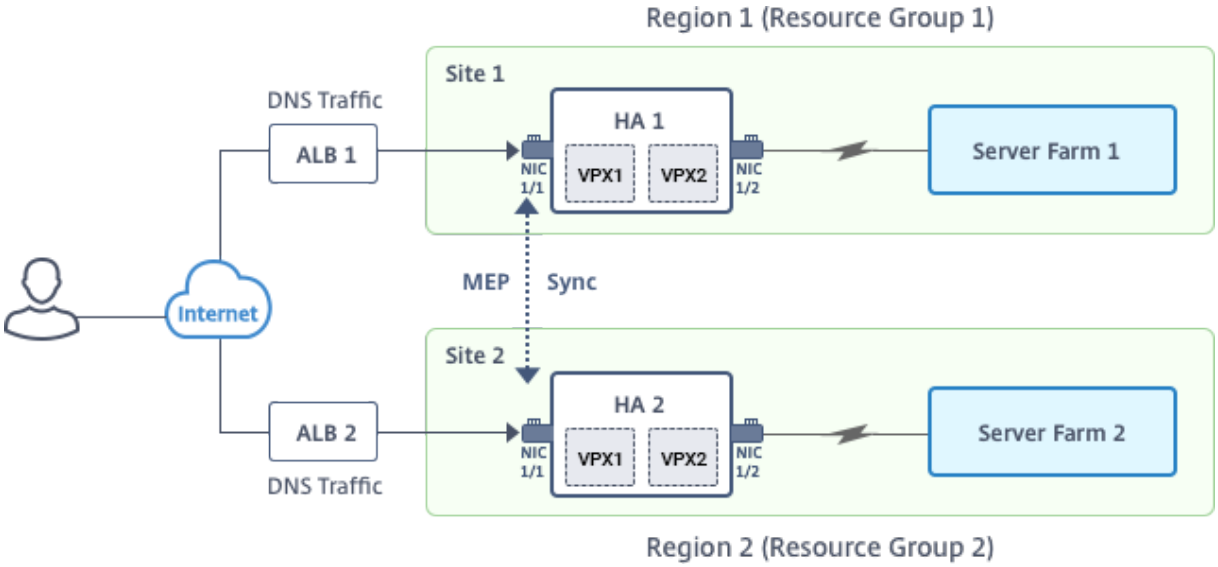
e. Update the network security group of NIC 1/1 of nodes in both the HA pair to allow the traffic for TCP 3010, TCP 3011 and UDP 53 ports.

3. Enable GSLB on each HA pair.

Scenario

This scenario includes two sites - Site 1 and Site 2. Each site has an HA pair (HA1 and HA2) configured with multiple NICs, multiple IP addresses, and GSLB.

Figure: GLSB on Active-Standy HA Deployment on Azure



In this scenario, each VM has three NICs - NIC 0/1, 1/1, and 1/2. The NICs are configured for the following purposes.

NIC 0/1: to serve management traffic

NIC 1/1: to serve client-side traffic

NIC 1/2: to communicate with back-end servers

Parameter Settings

Following are sample parameters settings for the ALB. You can use different settings if you want.

```
$locName="South east Asia"

$rgName="MulitIP-MultiNIC-RG"

$pubIPName4="PIPFORGSLB1"

$domName4="vpxgslbdns"

$lbName="MultiIPALB"

$frontEndConfigName2="FrontEndIP2"

$backendPoolName1="BackendPoolHttp"

$lbRuleName2="LBRuleGSLB1"

$lbRuleName3="LBRuleGSLB2"

$lbRuleName4="LBRuleDNS"

$healthProbeName="HealthProbe"
```

Configure ALB with the front-end IP address and rules to allow GSLB and DNS traffic

Step 1. **Create a public IP for GSLB site IP**

```
$pip4=New-AzureRmPublicIpAddress -Name $pubIPName4 -ResourceGroupName
    $rgName -DomainNameLabel $domName4 -Location $locName -
    AllocationMethod Dynamic

Get-AzureRmLoadBalancer -Name $lbName -ResourceGroupName $rgName | Add-
    AzureRmLoadBalancerFrontendIpConfig -Name $frontEndConfigName2 -
    PublicIpAddress $pip4 | Set-AzureRmLoadBalancer
```

Step 2. **Create LB rules and update the existing ALB**.

```
$alb = get-AzureRmLoadBalancer -Name $lbName -ResourceGroupName $rgName

```

```
$frontendipconfig2=Get-AzureRmLoadBalancerFrontendIpConfig -
    LoadBalancer $alb -Name $frontEndConfigName2

$backendPool=Get-AzureRmLoadBalancerBackendAddressPoolConfig -
    LoadBalancer $alb -Name $backendPoolName1

$healthprobe=Get-AzureRmLoadBalancerProbeConfig -LoadBalancer $alb -
    Name $healthProbeName

$alb | Add-AzureRmLoadBalancerRuleConfig -Name $lbRuleName2 -
    BackendAddressPool $backendPool -FrontendIPConfiguration
    $frontendipconfig2 -Protocol "Tcp" -FrontendPort 3011 -BackendPort
    3011 -Probe $healthprobe -EnableFloatingIP  | Set-
    AzureRmLoadBalancer

$alb | Add-AzureRmLoadBalancerRuleConfig -Name $lbRuleName3 -
    BackendAddressPool $backendPool -FrontendIPConfiguration
    $frontendipconfig2 -Protocol "Tcp" -FrontendPort 3010 -BackendPort
    3010 -Probe $healthprobe -EnableFloatingIP  | Set-
    AzureRmLoadBalancer

$alb | Add-AzureRmLoadBalancerRuleConfig -Name $lbRuleName4 -
    BackendAddressPool $backendPool -FrontendIPConfiguration
    $frontendipconfig2 -Protocol "Udp" -FrontendPort 53 -BackendPort 53
    -Probe $healthprobe -EnableFloatingIP  | Set-AzureRmLoadBalancer
```

Enable GSLB on each high availability pair

Now you've two front-end IP addresses for each ALB: ALB 1 and ALB 2. One IP address is for the LB virtual server and the other for the GSLB site IP.

HA 1 has the following front-end IP addresses:

- FrontEndIPofALB1 (for LB virtual server)
- PIPFORGSLB1 (GSLB IP)

HA 2 has the following front-end IP addresses:

- FrontEndIPofALB2 (for LB virtual server)
- PIPFORGSLB2 (GSLB IP)

The following commands are used for this scenario.

```
enable ns feature LB GSLB

add service dnssvc PIPFORGSLB1 ADNS 53

add gslb site site1 PIPFORGSLB1 -publicIP PIPFORGSLB1

add gslb site site2 PIPFORGSLB2 -publicIP PIPFORGSLB2

add gslb service site1_gslb_http_svc1 FrontEndIPofALB1 HTTP 80 -
   publicIP FrontEndIPofALB1 -publicPort 80 -siteName site1

add gslb service site2_gslb_http_svc1 FrontEndIPofALB2 HTTP 80 -
   publicIP FrontEndIPofALB2 -publicPort 80 -siteName site2

add gslb vserver gslb_http_vip1 HTTP

bind gslb vserver gslb_http_vip1 -serviceName site2_gslb_http_svc1

bind gslb vserver gslb_http_vip1 -serviceName site1_gslb_http_svc1

bind gslb vserver gslb_http_vip1 -domainName www.gslbindia.com -TTL 5
```

Configure GSLB on Citrix ADC VPX instances

Global Server Load Balancing

Configure address pools intranet IP for a Citrix Gateway appliance

September 14, 2021

In some situations, users who connect with the Citrix Gateway Plug-in need a unique IP address for a Citrix ADC Gateway appliance. When you enable address pools (also known as IP pooling) for a group, the Citrix Gateway appliance can assign a unique IP address alias to each user. You configure address pools by using intranet IP (IIP) addresses.

You can configure address pools on a Citrix Gateway appliance deployed on Azure by following this 2-step procedure:

- Registering the private IP addresses that are used in the address pool, in Azure
- Configuring address pools in the Citrix Gateway appliance

Register a private IP address in the Azure portal

In Azure, you can deploy a Citrix ADC VPX instance with multiple IP addresses. You can add IP addresses to a VPX instance in two ways:

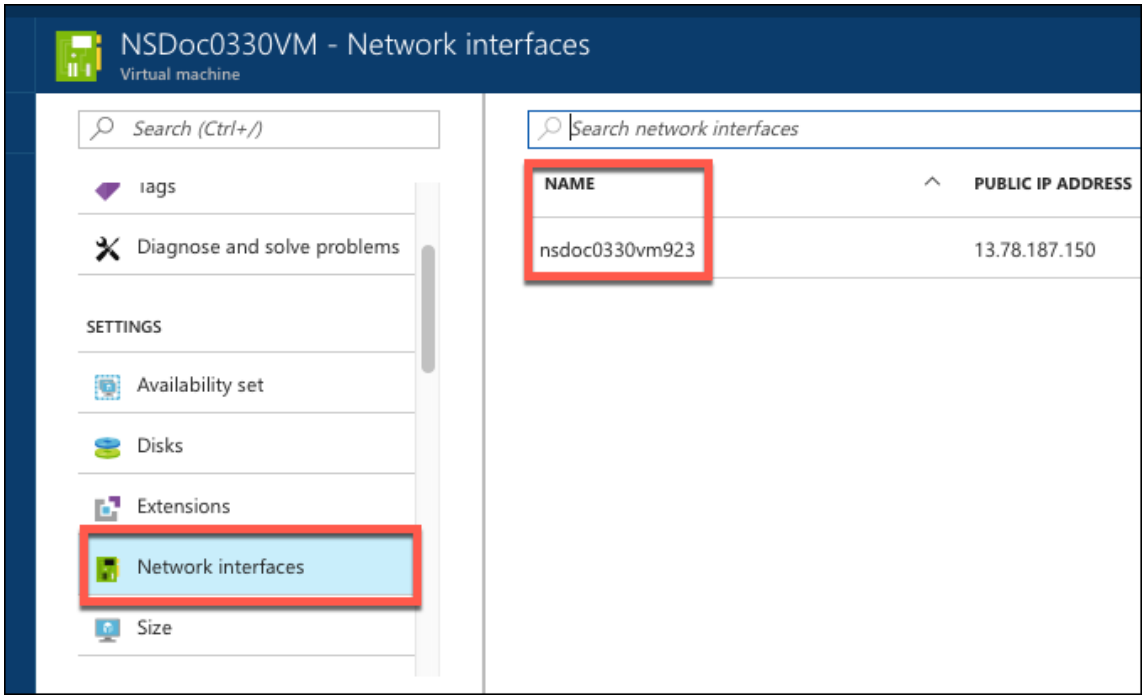
a. While provisioning a VPX instance

For more information about how to add multiple IP addresses while provisioning a VPX instance, see Configure multiple IP addresses for a Citrix ADC standalone instance. To add IP addresses by using PowerShell commands while provisioning a VPX instance, see Configure multiple IP addresses for a Citrix ADC VPX instance in standalone mode by using PowerShell commands.

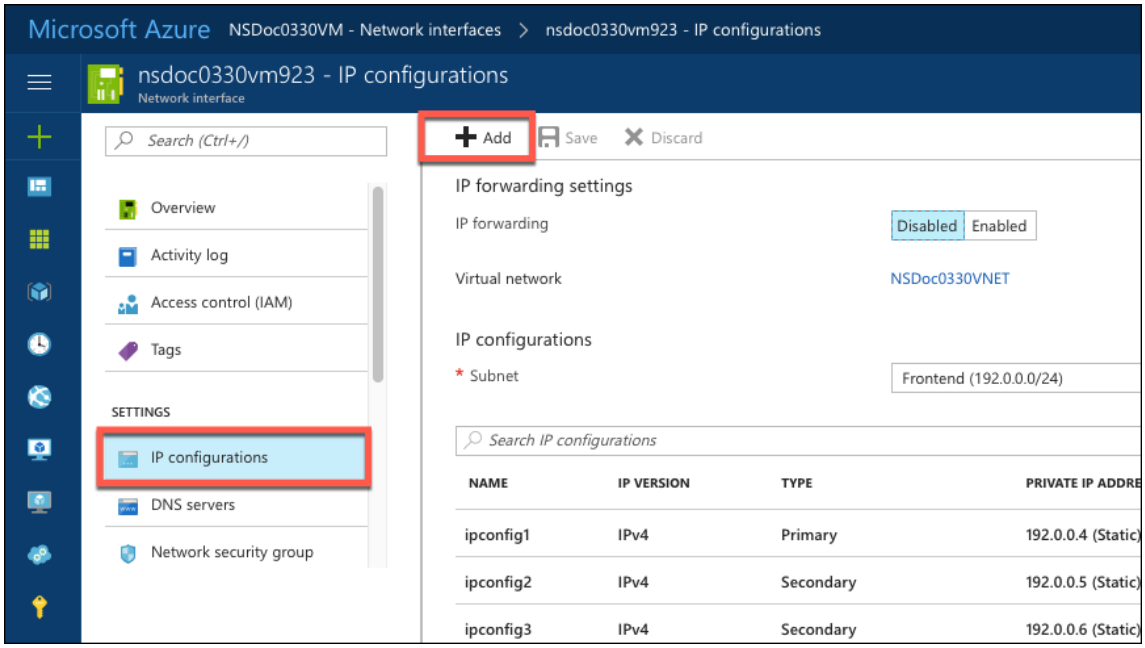
b. After provisioning a VPX instance

After you've provisioned a VPX instance, follow these steps to register a private IP address in the Azure portal, which you configure as an address pool in the Citrix Gateway appliance.

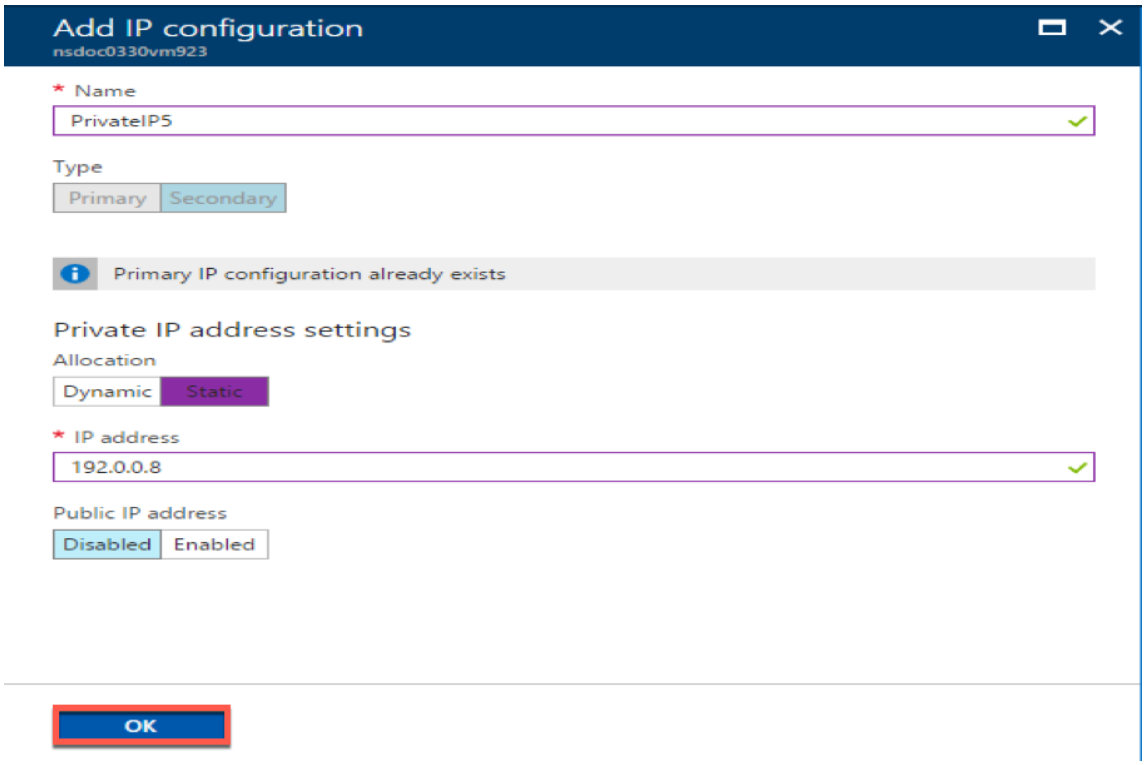
1. From Azure Resource Manager (ARM), go to the already created Citrix ADC VPX instance > **Network interfaces**. Choose the network interface which is bound to a subnet to which the IIP that you want to register belongs.



2. Click **IP Configurations**, and then click **Add**.



3. Provide the required details as shown in the example below and click **OK**.



Configure address pools in the Citrix Gateway appliance

For more information about how to configure address pools on the Citrix Gateway, see this Configuring Address Pools.

Limitation: You cannot bind a range of IIP addresses to users. Every IIP address that is used in an address pool must be registered.

Configure multiple IP addresses for a Citrix ADC VPX standalone instance by using PowerShell commands

September 14, 2021

In an Azure environment, a Citrix ADC VPX virtual appliance can be deployed with multiple NICs. Each NIC can have multiple IP addresses. This section describes how to deploy a Citrix ADC VPX instance with a single NIC and multiple IP addresses, by using PowerShell commands. You can use the same script for multi-NIC and multi-IP deployment.

> **Note**
>
> In this document, IP-Config refers to a pair of IP addresses, public IP, and private IP, that is associated with an individual NIC. For more information, see the Azure terminology section.

Use case

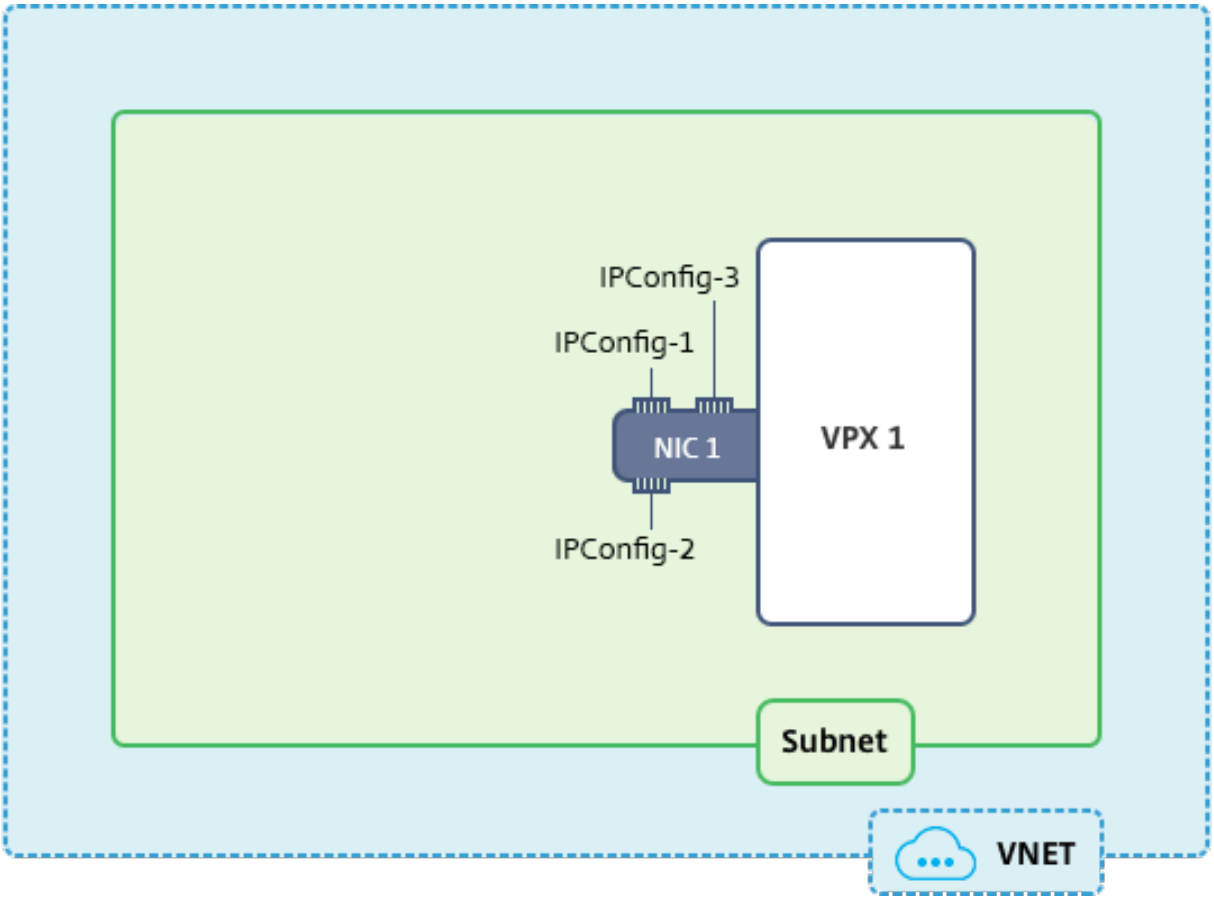
In this use case, a single NIC is connected to a virtual network (VNET). The NIC is associated with three IP configurations, as shown in the following table.

IP Config	Associated with
IPConfig-1	Static public IP address; static private IP address
IPConfig-2	Static public IP address; static private address
IPConfig-3	Static private IP address

> **Note**
>
> IPConfig-3 is not associated with any public IP address.

Diagram: Topology

Here is the visual representation of the use case.



> **Note**
>
> In a multi-NIC, multi-IP Azure Citrix ADC VPX deployment, the private IP address associated with the primary (first) `IPConfig` of the primary (first) NIC is automatically added as the management NSIP address of the appliance. The remaining private IP addresses associated with `IPConfigs` must be added in the VPX instance as VIPs or SNIPs by using the `add ns ip` command, as determined by your requirements.

Here is the summary of the steps required for configuring multiple IP addresses for a Citrix ADC VPX virtual appliance in standalone mode:

1. Create Resource Group
2. Create Storage Account
3. Create Availability Set
4. Create Network service group
5. Create Virtual Network
6. Create Public IP Address
7. Assign IP Configuration
8. Create NIC
9. Create Citrix ADC VPX Instance

10. Check NIC Configurations
11. Check VPX-side Configurations

Script

Parameters

Following are sample parameters settings for the use case in this document. You can use different settings if you want.

$locName=”westcentralus”

$rgName=”Azure-MultiIP”

$nicName1=”VM1-NIC1”

$vNetName=”Azure-MultiIP-vnet”

$vNetAddressRange=”11.6.0.0/16”

$frontEndSubnetName=”frontEndSubnet”

$frontEndSubnetRange=”11.6.1.0/24”

$prmStorageAccountName=”multiipstorage”

$avSetName=”multiip-avSet”

$vmSize=”Standard_DS4_V2” (This parameter creates a VM with up to four NICs.)

Note: The minimum requirement for a VPX instance is 2 vCPUs and 2 GB RAM.

$publisher=”Citrix”

$offer=”netscalervpx110-6531” (You can use different offers.)

$sku=”netscalerbyol” (According to your offer, the SKU can be different.)

$version=”latest”

$pubIPName1=”PIP1”

$pubIPName2=”PIP2”

$domName1=”multiipvpx1”

$domName2=”multiipvpx2”

$vmNamePrefix=”VPXMultiIP”

$osDiskSuffix=”osmultiipalbdiskdb1”

Network Security Group (NSG)-related information:

$nsgName=”NSG-MultiIP”

$rule1Name=”Inbound-HTTP”

$rule2Name=”Inbound-HTTPS”

$rule3Name=”Inbound-SSH”

$IpConfigName1=”IPConfig1”

$IPConfigName2=”IPConfig-2”

$IPConfigName3=”IPConfig-3”

1. Create Resource Group

```
New-AzureRmResourceGroup -Name $rgName -Location $locName
```

2. Create Storage Account

```
$prmStorageAccount = New-AzureRMStorageAccount -Name $prmStorageAccountName
 -ResourceGroupName $rgName -Type Standard_LRS -Location $locName
```

3. Create Availability Set

```
$avSet = New-AzureRMAvailabilitySet -Name $avSetName -ResourceGroupName
$rgName -Location $locName
```

4. Create Network Security Group

1. Add rules. You must add a rule to the network security group for any port that serves traffic.

```
$rule1=New-AzureRmNetworkSecurityRuleConfig -Name $rule1Name -Description
 "Allow HTTP"-Access Allow -Protocol Tcp -Direction Inbound -Priority
101 -SourceAddressPrefix Internet -SourcePortRange * -DestinationAddressPrefix
 * -DestinationPortRange 80
$rule2=New-AzureRmNetworkSecurityRuleConfig -Name $rule2Name -Description
 "Allow HTTPS"-Access Allow -Protocol Tcp -Direction Inbound -Priority
110 -SourceAddressPrefix Internet -SourcePortRange * -DestinationAddressPrefix
 * -DestinationPortRange 443
$rule3=New-AzureRmNetworkSecurityRuleConfig -Name $rule3Name -Description
 "Allow SSH"-Access Allow -Protocol Tcp -Direction Inbound -Priority
120 -SourceAddressPrefix Internet -SourcePortRange * -DestinationAddressPrefix
 * -DestinationPortRange 22
```

2. Create network security group object.

```
$nsg=New-AzureRmNetworkSecurityGroup -ResourceGroupName $rgName -
Location $locName -Name $nsgName -SecurityRules $rule1,$rule2,$rule3
```

5. Create Virtual Network

1. Add subnets.

```
$frontendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name $frontEndSubnetName
 -AddressPrefix $frontEndSubnetRange
```

2. Add virtual network object.

```
$vnet=New-AzureRmVirtualNetwork -Name $vNetName -ResourceGroupName
$rgName -Location $locName -AddressPrefix $vNetAddressRange -Subnet
$frontendSubnet
```

3. Retrieve subnets.

```
$subnetName="frontEndSubnet"
$subnet1=$vnet.Subnets|?{ $_.Name -eq $subnetName }
```

6. Create Public IP Address

```
$pip1=New-AzureRmPublicIpAddress -Name $pubIPName1 -ResourceGroupName
$rgName -DomainNameLabel $domName1 -Location $locName -AllocationMethod
Static
$pip2=New-AzureRmPublicIpAddress -Name $pubIPName2 -ResourceGroupName
$rgName -DomainNameLabel $domName2 -Location $locName -AllocationMethod
Static
```

> **Note**
>
> Check availability of domain names before using.
>
> Allocation method for IP addresses can be dynamic or static.

7. Assign IP Configuration

In this use case, consider the following points before assigning IP addresses:

- IPConfig-1 belongs to subnet1 of VPX1.
- IPConfig-2 belongs to subnet 1 of VPX1.
- IPConfig-3 belongs to subnet 1 of VPX1.

> **Note**
>
> When you assign multiple IP configurations to a NIC, one configuration must be assigned as primary.

```
$IPAddress1="11.6.1.27"
$IPConfig1=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName1 -Subnet $subnet1 -PrivateIpAddress $IPAddress1 -PublicIpAddress $pip1 -Primary
$IPAddress2="11.6.1.28"
$IPConfig2=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName2 -Subnet $subnet1 -PrivateIpAddress $IPAddress2 -PublicIpAddress $pip2
$IPAddress3="11.6.1.29"
$IPConfig3=New-AzureRmNetworkInterfaceIpConfig -Name $IPConfigName3 -Subnet $subnet1 -PrivateIpAddress $IPAddress3 -Primary
```

Use a valid IP address that meets your subnet requirements and check its availability.

8. Create NIC

```
$nic1=New-AzureRmNetworkInterface -Name $nicName1 -ResourceGroupName $rgName -Location $locName -IpConfiguration $IpConfig1,$IpConfig2,$IPConfig3 -NetworkSecurityGroupId $nsg.Id
```

9. Create Citrix ADC VPX Instance

1. Initialize variables.

   ```
   $suffixNumber = 1
   $vmName = $vmNamePrefix + $suffixNumber
   ```

2. Create VM config object.

   ```
   $vmConfig=New-AzureRMVMConfig -VMName $vmName -VMSize $vmSize -AvailabilitySetId $avSet.Id
   ```

3. Set credentials, OS, and image.

   ```
   $cred=Get-Credential -Message "Type the name and password for VPX login."
   $vmConfig=Set-AzureRMVMOperatingSystem -VM $vmConfig -Linux -ComputerName $vmName -Credential $cred
   $vmConfig=Set-AzureRMVMSourceImage -VM $vmConfig -PublisherName $publisher -Offer $offer -Skus $sku -Version $version
   ```

4. Add NIC.

```
$vmConfig=Add-AzureRMVMNetworkInterface -VM $vmConfig -Id $nic1.Id -
Primary
```

> **Note**
>
> In a multi-NIC VPX deployment, one NIC must be primary. So, "-Primary" must be appended while adding that NIC to the VPX instance.

5. Specify OS disk and create VM.

```
$osDiskName=$vmName + "-"+ $osDiskSuffix1
$osVhdUri=$prmStorageAccount.PrimaryEndpoints.Blob.ToString()+ "vhds/"+
 $osDiskName + ".vhd"
$vmConfig=Set-AzureRMVMOSDisk -VM $vmConfig -Name $osDiskName -VhdUri
$osVhdUri -CreateOption fromImage
Set-AzureRmVMPlan -VM $vmConfig -Publisher $publisher -Product $offer -
Name $sku
New-AzureRMVM -VM $vmConfig -ResourceGroupName $rgName -Location
$locName
```

10. Check NIC Configurations

After the VPX instance starts, you can check the IP addresses allocated to `IPConfigs` of the VPX NIC by using the following command.

```
$nic.IPConfig
```

11. Check VPX-side Configurations

When the Citrix ADC VPX instance starts, a private IP address associated with primary `IPconfig` of the primary NIC is added as the NSIP address. The remaining private IP addresses must be added as VIP or SNIP addresses, as determined by your requirements. Use the following command.

```
add nsip <Private IPAddress><netmask> -type VIP/SNIP
```

You've now configured multiple IP addresses for a Citrix ADC VPX instance in standalone mode.

Additional PowerShell scripts for Azure deployment

September 14, 2021

This section provides the PowerShell cmdlets with which you can perform the following configurations in Azure PowerShell:

- Provision a Citrix ADC VPX standalone instance
- Provision a Citrix ADC VPX pair in a high availability setup with an Azure external load balancer
- Provision a Citrix ADC VPX pair in a high availability setup with Azure internal load balancer

Also see the following topics for configurations that you can perform by using PowerShell commands:

- Configure a high-availability setup with multiple IP addresses and NICs by using PowerShell commands
- Configure GSLB on Citrix ADC VPX instances
- Configure GSLB on a NetScaler active-standby high-availability setup
- Configure multiple IP addresses for a Citrix ADC VPX instance in standalone mode by using PowerShell commands
- Configure multiple Azure VIPs for a standalone VPX instance

Provision a Citrix ADC VPX standalone instance

1. **Create a resource group**

   The resource group can include all the resources for the solution, or only those resources that you want to manage as a group. The location specified here is the default location for resources in that resource group. Make sure all commands to create a load balancer use the same resource group.

   ```
   $rgName="<resource group name>"
   $locName="<location name, such as West US>
   New-AzureRmResourceGroup -Name $rgName -Location $locName
   ```

   For example:

   ```
   $rgName = "ARM-VPX"
   $locName = "West US"
   New-AzureRmResourceGroup -Name $rgName -Location $locName
   <!--NeedCopy-->
   ```

2. **Create a storage account**

   Choose a unique name for your storage account that contains only lowercase letters and numbers.

   `$saName="<storage account name>"`
   `$saType="<storage account type>"`, specify one: `Standard_LRS`, `Standard_GRS`, `Standard_RAGRS`, or `Premium_LRS`

```
New-AzureRmStorageAccount -Name $saName -ResourceGroupName $rgName -
Type $saType -Location $locName
```

For example:

```
$saName="vpxstorage"
$saType="Standard\_LRS"
New-AzureRmStorageAccount -Name $saName -ResourceGroupName $rgName
    -Type $saType -Location $locName
<!--NeedCopy-->
```

3. **Create an availability set**

   Availability set helps to keep your virtual machines available during downtime, such as during maintenance. A load balancer configured with an availability set ensures that your application is always available.

   ```
   $avName="<availability set name>"
   ```

   ```
   New-AzureRmAvailabilitySet -Name $avName -ResourceGroupName $rgName -
   Location $locName
   ```

4. **Create a virtual network**

   Add a new virtual network with at least one subnet, if the subnet was not created previously.

   ```
   $FrontendAddressPrefix="10.0.1.0/24"
   $BackendAddressPrefix="10.0.2.0/24"
   $vnetAddressPrefix="10.0.0.0/16"
   $frontendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name frontendSubnet
    -AddressPrefix $FrontendAddressPrefix
   $backendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name backendSubnet
    -AddressPrefix $BackendAddressPrefix
   New-AzureRmVirtualNetwork -Name TestNet -ResourceGroupName $rgName -
   Location $locName -AddressPrefix $vnetAddressPrefix -Subnet $frontendSubnet
   ,$backendSubnet
   ```

   For example:

   ```
   $frontendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
       frontendSubnet -AddressPrefix $FrontendAddressPrefix

   $backendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
       backendSubnet -AddressPrefix $BackendAddressPrefix

   New-AzureRmVirtualNetwork -Name TestNet -ResourceGroupName $rgName
        -Location $locName -AddressPrefix $vnetAddressPrefix -Subnet
       $frontendSubnet,$backendSubnet
   ```

```
<!--NeedCopy-->
```

5. **Create a NIC**

   Create a NIC and associate the NIC with the Citrix ADC VPX instance. The front end Subnet created in the above procedure is indexed at 0 and the back end Subnet is indexed at 1. Now create NIC in one of the three following ways:

   a) *NIC with Public IP address*

   ```
   $nicName="<name of the NIC of the VM>"

   $pip = New-AzureRmPublicIpAddress -Name $nicName -ResourceGroupName
   $rgName -Location $locName -AllocationMethod Dynamic

   $nic = New-AzureRmNetworkInterface -Name $nicName -ResourceGroupName
   $rgName -Location $locName -SubnetId $vnet.Subnets[$subnetIndex].Id -
   PublicIpAddressId $pip.Id
   ```

   b) *NIC with Public IP and DNS label*

   ```
   $nicName="<name of the NIC of the VM>"

   $domName="<domain name label>"

   $pip = New-AzureRmPublicIpAddress -Name $nicName -ResourceGroupName
   $rgName -DomainNameLabel $domName -Location $locName -AllocationMethod
   Dynamic
   ```

   Before assigning $domName, check it is available or not by using command:

   ```
   Test-AzureRmDnsAvailability -DomainQualifiedName $domName -Location
   $locName

   $nic = New-AzureRmNetworkInterface -Name $nicName -ResourceGroupName
   $rgName -Location $locName -SubnetId $vnet.Subnets[$subnetIndex].Id -
   PublicIpAddressId $pip.Id
   ```

   For example:

   ```
   $nicName="frontendNIC"

   $domName="vpxazure"

   $pip = New-AzureRmPublicIpAddress -Name $nicName -
       ResourceGroupName $rgName -DomainNameLabel $domName -Location
       $locName -AllocationMethod Dynamic

   ```

```
$nic = New-AzureRmNetworkInterface -Name $nicName -
    ResourceGroupName $rgName -Location $locName -SubnetId $vnet.
    Subnets\[0\].Id -PublicIpAddressId $pip.Id
<!--NeedCopy-->
```

c) *NIC with Dynamic Public Address and Static Private IP address*

Make sure that the private (static) IP address you add to the VM must be the same range as that of the subnet specified.

```
$nicName="<name of the NIC of the VM>"

$staticIP="<available static IP address on the subnet>"

$pip = New-AzureRmPublicIpAddress -Name $nicName -ResourceGroupName
$rgName -Location $locName -AllocationMethod Dynamic

$nic = New-AzureRmNetworkInterface -Name $nicName -ResourceGroupName
$rgName -Location $locName -SubnetId $vnet.Subnets[$subnetIndex].Id -
PublicIpAddressId $pip.Id -PrivateIpAddress $staticIP
```

6. **Create a virtual object**

```
$vmName="<VM name>"

$vmSize="<VM size string>"

$avSet=Get-AzureRmAvailabilitySet -Name $avName -ResourceGroupName
$rgName

$vm=New-AzureRmVMConfig -VMName $vmName -VMSize $vmSize -AvailabilitySetId
 $avset.Id
```

7. **Get the Citrix ADC VPX image**

```
$pubName="<Image publisher name>"

$offerName="<Image offer name>"

$skuName="<Image SKU name>"

$cred=Get-Credential -Message "Type the name and password of the local
administrator account."
```

Provide your credentials that is used to log in into VPX

```
$vm=Set-AzureRmVMOperatingSystem -VM $vm -Linux -ComputerName $vmName -
Credential $cred -Verbose

$vm=Set-AzureRmVMSourceImage -VM $vm -PublisherName $pubName -Offer
$offerName -Skus $skuName -Version "latest"
```

```
$vm=Add-AzureRmVMNetworkInterface -VM $vm -Id $nic.Id
```

For example:

```
$pubName="citrix"
```

The following command is used for displaying all offers from Citrix:

```
1 Get-AzureRMVMImageOffer -Location $locName -Publisher $pubName |
     Select Offer
2
3 $offerName="netscalervpx110-6531"
4 <!--NeedCopy-->
```

The following command is used to know SKU offered by publisher for specific offer name:

```
Get-AzureRMVMImageSku -Location $locName -Publisher $pubName -Offer
$offerName | Select Skus
```

8. **Create a virtual machine**

```
$diskName="<name identifier for the disk in Azure storage, such as
OSDisk>"
```

For example:

```
1 $diskName="dynamic"
2
3 $pubName="citrix"
4
5 $offerName="netscalervpx110-6531"
6
7 $skuName="netscalerbyol"
8
9 $storageAcc=Get-AzureRmStorageAccount -ResourceGroupName $rgName -
     Name $saName
10
11 $osDiskUri=$storageAcc.PrimaryEndpoints.Blob.ToString() + "vhds/"
     + $diskName  + ".vhd"
12
13 $vm=Set-AzureRmVMOSDisk -VM $vm -Name $diskName -VhdUri $osDiskUri
      -CreateOption fromImage
14 <!--NeedCopy-->
```

When you create VM from Images present in marketplace, use the following command to specify the VM plan:

```
Set-AzureRmVMPlan -VM $vm -Publisher $pubName -Product $offerName -Name
 $skuName
```

```
New-AzureRmVM -ResourceGroupName $rgName -Location $locName -VM $vm
```

Provision a Citrix ADC VPX pair in a high availability setup with an Azure external load balancer

Log on to AzureRmAccount using your Azure user credentials.

1. **Create a resource group**

   The location specified here is the default location for resources in that resource group. Make sure that all commands used to create a load balancer use the same resource group.

   ```
   $rgName="<resource group name>"
   ```

   ```
   $locName="<location name, such as West US>"
   ```

   ```
   New-AzureRmResourceGroup -Name $rgName -Location $locName
   ```

   For example:

   ```
   $rgName = "ARM-LB-NS"

   $locName = "West US"

   New-AzureRmResourceGroup -Name $rgName -Location $locName
   <!--NeedCopy-->
   ```

2. **Create a storage account**

   Choose a unique name for your storage account that contains only lowercase letters and numbers.

   ```
   $saName="<storage account name>"
   ```

   ```
   $saType="<storage account type>"
   ```

   , specify one: `Standard_LRS`, `Standard_GRS`, `Standard_RAGRS`, or `Premium_LRS`

   ```
   New-AzureRmStorageAccount -Name $saName -ResourceGroupName $rgName -
   Type $saType -Location $locName
   ```

   For example:

   ```
   $saName="vpxstorage"

   $saType="Standard_LRS"

   New-AzureRmStorageAccount -Name $saName -ResourceGroupName $rgName
       -Type $saType -Location $locName
   <!--NeedCopy-->
   ```

3. **Create an availability set**

   A load balancer configured with an availability set ensures that your application is always available.

   ```
   $avName="<availability set name>"

   New-AzureRmAvailabilitySet -Name $avName -ResourceGroupName $rgName -
   Location $locName
   ```

4. **Create a virtual network**

   Add a new virtual network with at least one subnet, if the subnet was not created previously.

   ```
   1  $vnetName = "LBVnet"
   2
   3  $FrontendAddressPrefix="10.0.1.0/24"
   4
   5  $BackendAddressPrefix="10.0.2.0/24"
   6
   7  $vnetAddressPrefix="10.0.0.0/16"
   8
   9  $frontendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
          frontendSubnet -AddressPrefix $FrontendAddressPrefix
   10
   11 $backendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
          backendSubnet -AddressPrefix $BackendAddressPrefix
   12
   13 $vnet=New-AzureRmVirtualNetwork -Name $vnetName -ResourceGroupName
           $rgName -Location $locName -AddressPrefix $vnetAddressPrefix -
          Subnet $frontendSubnet,$backendSubnet
   14 <!--NeedCopy-->
   ```

   Note: Choose the AddressPrefix parameter value as per your requirement.

   Assign front end and back end subnet to the virtual network that you created earlier in this step.

   If the front end subnet is the first element of array VNet, subnetId must be $vnet.Subnets[0].Id.

   If the front end subnet is the second element in the array, the subnetId must be $vnet.Subnets[1].Id, and so on.

5. **Configure front end IP address and create back end address pool**

   Configure a front end IP address for the incoming load balancer network traffic and create a back end address pool to receive the load balanced traffic.

   ```
   1  $pubName="PublicIp1"
   2
   ```

```
$publicIP1 = New-AzureRmPublicIpAddress -Name $pubName -
    ResourceGroupName $rgName -Location $locName -AllocationMethod
    Static -DomainNameLabel nsvpx
<!--NeedCopy-->
```

Note: Check for the availability of the value for DomainNameLabel.

```
$FIPName = "ELBFIP"

$frontendIP1 = New-AzureRmLoadBalancerFrontendIpConfig -Name
    $FIPName -PublicIpAddress $publicIP1

$BEPool = "LB-backend-Pool"

$beaddresspool1= New-AzureRmLoadBalancerBackendAddressPoolConfig -
    Name $BEPool
<!--NeedCopy-->
```

6. **Create a health probe**

   Create a TCP health probe with port 9000 and interval 5 seconds.

```
$healthProbe = New-AzureRmLoadBalancerProbeConfig -Name
    HealthProbe -Protocol Tcp -Port 9000 -IntervalInSeconds 5 -
    ProbeCount 2
<!--NeedCopy-->
```

7. **Create a load balancing rule**

   Create an LB rule for each service that you are load balancing.

   For example:

   You can use the following example to load balance HTTP service.

```
$lbrule1 = New-AzureRmLoadBalancerRuleConfig -Name "HTTP-LB" -
    FrontendIpConfiguration $frontendIP1 -BackendAddressPool
    $beAddressPool1 -Probe $healthProbe -Protocol Tcp -FrontendPort
     80 -BackendPort 80
<!--NeedCopy-->
```

8. **Create inbound NAT rules**

   Create NAT rules for services that you are not load balancing.

   For example, when creating an SSH access to a Citrix ADC VPX instance.

   Note: Protocol-FrontEndPort-BackendPort triplet must not be the same for two NAT rules.

```
$inboundNATRule1= New-AzureRmLoadBalancerInboundNatRuleConfig -
    Name SSH1     -FrontendIpConfiguration $frontendIP1 -Protocol
    TCP -FrontendPort 22 -BackendPort 22

$inboundNATRule2= New-AzureRmLoadBalancerInboundNatRuleConfig -
    Name SSH2 -FrontendIpConfiguration $frontendIP1 -Protocol TCP -
    FrontendPort 10022 -BackendPort 22
<!--NeedCopy-->
```

9. **Create a load balancer entity**

   Create the load balancer adding all objects (NAT rules, load balancer rules, probe configurations) together.

```
$lbName="ELB"

$NRPLB = New-AzureRmLoadBalancer -ResourceGroupName $rgName -Name
    $lbName -Location $locName -InboundNatRule $inboundNATRule1,
    $inboundNATRule2 -FrontendIpConfiguration $frontendIP1 -
    LoadBalancingRule $lbrule1 -BackendAddressPool $beAddressPool1
    -Probe $healthProbe
<!--NeedCopy-->
```

10. **Create a NIC**

    Create two NICs and associate each NIC with each VPX instance

    a) NIC1 with VPX1

    For example:

```
$nicName="NIC1"

$lbName="ELB"

$bePoolIndex=0

\* Rule indexes starts from 0.

$natRuleIndex=0

$subnetIndex=0

\* Frontend subnet index

```

```
15 $lb=Get-AzureRmLoadBalancer -Name $lbName -ResourceGroupName
      $rgName
16
17 $nic1=New-AzureRmNetworkInterface -Name $nicName -
      ResourceGroupName $rgName -Location $locName -Subnet $vnet.
      Subnets\[$subnetIndex\] -LoadBalancerBackendAddressPool $lb.
      BackendAddressPools\[$bePoolIndex\] -LoadBalancerInboundNatRule
       $lb.InboundNatRules\[$natRuleIndex\]
18 <!--NeedCopy-->
```

b) NIC2 with VPX2

For example:

```
1  $nicName="NIC2"
2
3  $lbName="ELB"
4
5  $bePoolIndex=0
6
7  $natRuleIndex=1
8
9  \* Second Inbound NAT (SSH) rule we need to use
10
11 `$subnetIndex=0
12
13 \* Frontend subnet index
14
15 $lb=Get-AzureRmLoadBalancer -Name $lbName -ResourceGroupName
      $rgName
16
17 $nic2=New-AzureRmNetworkInterface -Name $nicName -
      ResourceGroupName $rgName -Location $locName -Subnet $vnet.
      Subnets\[$subnetIndex\] -LoadBalancerBackendAddressPool $lb.
      BackendAddressPools\[$bePoolIndex\] -LoadBalancerInboundNatRule
        $lb.InboundNatRules\[$natRuleIndex\]
18 <!--NeedCopy-->
```

11. **Create Citrix ADC VPX instances**

    Create two Citrix ADC VPX instances as part of the same resource group and availability set, and attach it to the external load balancer.

    a) Citrix ADC VPX instance 1

    For example:

```
$vmName="VPX1"

$vmSize="Standard\_A3"

$pubName="citrix"

$offerName="netscalervpx110-6531"

$skuName="netscalerbyol"

$avSet=Get-AzureRmAvailabilitySet -Name $avName -ResourceGroupName
    $rgName

$vm1=New-AzureRmVMConfig -VMName $vmName -VMSize $vmSize -
   AvailabilitySetId $avset.Id

$cred=Get-Credential -Message "Type Credentials which will be used
    to login to VPX instance"

$vm1=Set-AzureRmVMOperatingSystem -VM $vm1 -Linux -ComputerName
   $vmName -Credential $cred -Verbose

$vm1=Set-AzureRmVMSourceImage -VM $vm1 -PublisherName $pubName -
   Offer $offerName -Skus $skuName -Version "latest"

$vm1=Add-AzureRmVMNetworkInterface -VM $vm1 -Id $nic1.Id

$diskName="dynamic"

$storageAcc=Get-AzureRmStorageAccount -ResourceGroupName $rgName -
   Name $saName

$osDiskUri1=$storageAcc.PrimaryEndpoints.Blob.ToString() + "vhds1/
   " + $diskName  + ".vhd"

$vm1=Set-AzureRmVMOSDisk -VM $vm1 -Name $diskName -VhdUri
   $osDiskUri1 -CreateOption fromImage

Set-AzureRmVMPlan -VM $vm1 -Publisher $pubName -Product $offerName
    -Name $skuName

New-AzureRmVM -ResourceGroupName $rgName -Location $locName -VM
   $vm1
<!--NeedCopy-->
```

b) Citrix ADC VPX instance 2

For example:

```
$vmName="VPX2"

$vmSize="Standard\_A3"

$avSet=Get-AzureRmAvailabilitySet -Name $avName -ResourceGroupName
    $rgName

$vm2=New-AzureRmVMConfig -VMName $vmName -VMSize $vmSize -
   AvailabilitySetId $avset.Id

$cred=Get-Credential -Message " Type Credentials which will be
   used to login to VPX instance "

$vm2=Set-AzureRmVMOperatingSystem -VM $vm2 -Linux -ComputerName
   $vmName -Credential $cred -Verbose

$vm2=Set-AzureRmVMSourceImage -VM $vm2 -PublisherName $pubName -
   Offer $offerName -Skus $skuName -Version "latest"

$vm2=Add-AzureRmVMNetworkInterface -VM $vm2 -Id $nic2.Id

$diskName="dynamic"

$storageAcc=Get-AzureRmStorageAccount -ResourceGroupName $rgName -
   Name $saName

$osDiskUri1=$storageAcc.PrimaryEndpoints.Blob.ToString() + "vhds2/
   " + $diskName  + ".vhd"

$vm2=Set-AzureRmVMOSDisk -VM $vm2 -Name $diskName -VhdUri
   $osDiskUri1 -CreateOption fromImage

Set-AzureRmVMPlan -VM $vm2 -Publisher $pubName -Product $offerName
    -Name $skuName

New-AzureRmVM -ResourceGroupName $rgName -Location $locName -VM
   $vm2
<!--NeedCopy-->
```

12. **Configure the virtual machines**

    When both the Citrix ADC VPX instances start, then connect to both Citrix ADC VPX instances

using the SSH protocol to configure the virtual machines.

a) Active-Active: Run the same set of configuration commands on the command line of both the Citrix ADC VPX instances.

b) Active-Passive: Run this command on the command line of both the Citrix ADC VPX instances.

```
add ha node ##nodeID <nsip of other Citrix ADC VPX>
```

In Active-Passive mode, run configuration commands on the primary node only.

Provision a Citrix ADC VPX pair in a high availability setup with Azure internal load balancer

Log on to AzureRmAccount using your Azure user credentials.

1. **Create a resource group**

   The location specified here is the default location for resources in that resource group. Make sure all commands to create a load balancer use the same resource group.

   ```
   $rgName="\<resource group name\>"
   ```

   ```
   $locName="\<location name, such as West US\>"
   ```

   ```
   New-AzureRmResourceGroup -Name $rgName -Location $locName
   ```

   For example:

   ```
   $rgName = "ARM-LB-NS"

   $locName = "West US"

   New-AzureRmResourceGroup -Name $rgName -Location $locName
   <!--NeedCopy-->
   ```

2. **Create a storage account**

   Choose a unique name for your storage account that contains only lowercase letters and numbers.

   ```
   $saName="<storage account name>"
   ```

   ```
   $saType="<storage account type>"
   ```

   , specify one: `Standard_LRS`, `Standard_GRS`, `Standard_RAGRS`, or `Premium_LRS`

   ```
   New-AzureRmStorageAccount -Name $saName -ResourceGroupName $rgName -
   Type $saType -Location $locName
   ```

   For example:

```
$saName="vpxstorage"

$saType="Standard_LRS"

New-AzureRmStorageAccount -Name $saName -ResourceGroupName $rgName
    -Type $saType -Location $locName
<!--NeedCopy-->
```

3. **Create an availability set**

   A load balancer configured with an availability set ensures that your application is always available.

   ```
   $avName="<availability set name>"
   ```

   ```
   New-AzureRmAvailabilitySet -Name $avName -ResourceGroupName $rgName -
   Location $locName
   ```

4. **Create a virtual network**

   Add a new virtual network with at least one subnet, if the subnet was not created previously.

   ```
   $vnetName = "LBVnet"

   $vnetAddressPrefix="10.0.0.0/16"

   $FrontendAddressPrefix="10.0.1.0/24"

   $BackendAddressPrefix="10.0.2.0/24"

   $vnet=New-AzureRmVirtualNetwork -Name $vnetName -ResourceGroupName
       $rgName -Location $locName -AddressPrefix $vnetAddressPrefix -
      Subnet $frontendSubnet,$backendSubnet\`

   $frontendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
      frontendSubnet -AddressPrefix $FrontendAddressPrefix

   $backendSubnet=New-AzureRmVirtualNetworkSubnetConfig -Name
      backendSubnet -AddressPrefix $BackendAddressPrefix
   <!--NeedCopy-->
   ```

   Note: Choose the AddressPrefix parameter value as per your requirement.

   Assign front end and back end subnet to the virtual network that you created earlier in this step.

   If the front end subnet is the first element of array VNet, subnetId must be $vnet.Subnets[0].Id.

If the front end subnet is the second element in the array, the subnetId must be $vnet.Subnets[1].Id, and so on.

5. **Create a backend address pool**

```
$beaddresspool= New-AzureRmLoadBalancerBackendAddressPoolConfig -Name "
LB-backend"
```

6. **Create NAT rules**

Create NAT rules for services that you are not load balancing.

```
1 $inboundNATRule1= New-AzureRmLoadBalancerInboundNatRuleConfig -
     Name "Inboundnatrule1" -FrontendIpConfiguration $frontendIP -
     Protocol TCP -FrontendPort 3441 -BackendPort 3389
2
3 $inboundNATRule2= New-AzureRmLoadBalancerInboundNatRuleConfig -
     Name "RDP2" -FrontendIpConfiguration $frontendIP -Protocol TCP
     -FrontendPort 3442 -BackendPort 3389
4 <!--NeedCopy-->
```

Use front end and back end ports as per your requirement.

7. **Create a health probe**

Create a TCP health probe with port 9000 and interval 5 seconds.

```
1 $healthProbe = New-AzureRmLoadBalancerProbeConfig -Name "
     HealthProbe"  " -Protocol tcp -Port 9000 -IntervalInSeconds 5 -
     ProbeCount 2
2 <!--NeedCopy-->
```

8. **Create a load balancing rule**

Create an LB rule for each service that you are load balancing.

For example:

You can use the following example to load balance HTTP service.

```
1 $lbrule = New-AzureRmLoadBalancerRuleConfig -Name "lbrule1" -
     FrontendIpConfiguration $frontendIP -BackendAddressPool
     $beAddressPool -Probe $healthProbe -Protocol Tcp -FrontendPort
     80 -BackendPort 80
2 <!--NeedCopy-->
```

Use front end and back end ports as per your requirement.

9. **Create a load balancer entity**

Create the load balancer adding all objects (NAT rules, load balancer rules, probe configurations) together.

```
$NRPLB = New-AzureRmLoadBalancer -ResourceGroupName $rgname -Name
    "InternalLB" -Location $locName -FrontendIpConfiguration
    $frontendIP -InboundNatRule $inboundNATRule1,$inboundNatRule2 -
    LoadBalancingRule $lbrule -BackendAddressPool $beAddressPool -
    Probe $healthProbe
<!--NeedCopy-->
```

10. **Create a NIC**

    Create two NICs and associate each NIC with each Citrix ADC VPX instance

```
$backendnic1= New-AzureRmNetworkInterface -ResourceGroupName
    $rgName -Name lb-nic1-be -Location $locName -PrivateIpAddress
    10.0.2.6 -Subnet $backendSubnet -LoadBalancerBackendAddressPool
     $nrplb.BackendAddressPools\[0\] -LoadBalancerInboundNatRule
    $nrplb.InboundNatRules\[0\]
<!--NeedCopy-->
```

    This NIC is for Citrix ADC VPX 1. The Private IP must be in same subnet as that of subnet added.

```
$backendnic2= New-AzureRmNetworkInterface -ResourceGroupName
    $rgName -Name lb-nic2-be -Location $locName -PrivateIpAddress
    10.0.2.7 -Subnet $backendSubnet -LoadBalancerBackendAddressPool
     $nrplb.BackendAddressPools\[0\] -LoadBalancerInboundNatRule
    $nrplb.InboundNatRules\[1\].
<!--NeedCopy-->
```

    This NIC is for Citrix ADC VPX 2.The parameter `Private IPAddress` can have any private IP as per your requirement.

11. **Create Citrix ADC VPX instances**

    Create two VPX instances part of the same resource group and availability set, and attach it to the internal load balancer.

    a) Citrix ADC VPX instance 1

    For example:

```
$vmName="VPX1"

$vmSize="Standard\_A3"

$avSet=Get-AzureRmAvailabilitySet -Name $avName -ResourceGroupName
     $rgName
```

```
6
7  $vm1=New-AzureRmVMConfig -VMName $vmName -VMSize $vmSize -
       AvailabilitySetId $avset.Id
8
9  $cred=Get-Credential -Message "Type Credentials which will be used
       to login to VPX instance"
10
11 $vm1=Set-AzureRmVMOperatingSystem -VM $vm1 -Linux -ComputerName
       $vmName -Credential $cred -Verbose
12
13 $vm1=Set-AzureRmVMSourceImage -VM $vm1 -PublisherName $pubName -
       Offer $offerName -Skus $skuName -Version "latest"
14
15 $vm1=Add-AzureRmVMNetworkInterface -VM $vm1 -Id $backendnic1.Id
16
17 $diskName="dynamic"
18
19 $storageAcc=Get-AzureRmStorageAccount -ResourceGroupName $rgName -
       Name $saName
20
21 $osDiskUri1=$storageAcc.PrimaryEndpoints.Blob.ToString() + "vhds1/
       " + $diskName  + ".vhd"
22
23 $vm1=Set-AzureRmVMOSDisk -VM $vm1 -Name $diskName -VhdUri
       $osDiskUri1 -CreateOption fromImage
24
25 Set-AzureRmVMPlan -VM $vm1 -Publisher $pubName -Product $offerName
       -Name $skuName
26
27 New-AzureRmVM -ResourceGroupName $rgName -Location $locName -VM
       $vm1
28 <!--NeedCopy-->
```

b) Citrix ADC VPX instance 2

For example:

```
1  $vmName="VPX2"
2
3  $vmSize="Standard\_A3"
4
5  $avSet=Get-AzureRmAvailabilitySet -Name $avName -ResourceGroupName
       $rgName
6
7  $vm2=New-AzureRmVMConfig -VMName $vmName -VMSize $vmSize -
```

```
    AvailabilitySetId $avset.Id
8
9  $cred=Get-Credential -Message " Type Credentials which will be
    used to login to VPX instance "
10
11 $vm2=Set-AzureRmVMOperatingSystem -VM $vm2 -Linux -ComputerName
    $vmName -Credential $cred -Verbose
12
13 $vm2=Set-AzureRmVMSourceImage -VM $vm2 -PublisherName $pubName -
    Offer $offerName -Skus $skuName -Version "latest"
14
15 $vm2=Add-AzureRmVMNetworkInterface -VM $vm2 -Id $backendnic2.Id
16
17 $diskName="dynamic"
18
19 $storageAcc=Get-AzureRmStorageAccount -ResourceGroupName $rgName -
    Name $saName
20
21 $osDiskUri1=$storageAcc.PrimaryEndpoints.Blob.ToString() + "vhds2/
    " + $diskName  + ".vhd"
22
23 $vm2=Set-AzureRmVMOSDisk -VM $vm2 -Name $diskName -VhdUri
    $osDiskUri1 -CreateOption fromImage
24
25 Set-AzureRmVMPlan -VM $vm2 -Publisher $pubName -Product $offerName
     -Name $skuName
26
27 New-AzureRmVM -ResourceGroupName $rgName -Location $locName -VM
    $vm2
28 <!--NeedCopy-->
```

12. **Configure the virtual machines**

    When both the Citrix ADC VPX instances start, then connect to both Citrix ADC VPX instances using the SSH protocol to configure the virtual machines.

    a) Active-Active: Run the same set of configuration commands on the command line of both the Citrix ADC VPX instances.

    b) Active-Passive: Run this command on the command line of both the Citrix ADC VPX instances.

    ```
    add ha node ##nodeID <nsip of other Citrix ADC VPX>
    ```

    In Active-Passive mode, run configuration commands on the primary node only.

Azure FAQs

September 14, 2021

- **Is the upgrade procedure of Citrix ADC VPX instance installed from Azure Marketplace different from the on-premises upgrade procedure?**

  No. You can upgrade your Citrix ADC VPX instance in the Microsoft Azure cloud to Citrix ADC VPX release 11.1 or later, using standard Citrix ADC VPX upgrade procedures. You can upgrade either using GUI or CLI procedures. For any new installations, use the Citrix ADC VPX image for Microsoft Azure cloud.

  To download the Citrix ADC VPX upgrade builds, go to **Citrix Downloads** > **Citrix ADC Firmware**.

- **How to correct MAC moves and interface mutes observed on Citrix ADC VPX instances hosted on Azure?**

  In Azure Multi-NIC environment, by default, all data interfaces might show MAC moves and interface mutes. To avoid MAC moves and interface mutes on Azure environments, Citrix recommends you to create a VLAN per data interface (without tag) of the ADC VPX instance and bind the primary IP of the NIC in Azure.

  For more information, see CTX224626 article.

Deploy a Citrix ADC VPX instance on the Google Cloud Platform

September 14, 2021

You can deploy a Citrix ADC VPX instance on the Google Cloud Platform (GCP). A VPX instance in GCP enables you to take advantage of GCP cloud computing capabilities and use Citrix load balancing and traffic management features for your business needs. You can deploy VPX instances in GCP as standalone instances. Both single NIC and multi NIC configurations are supported.

Supported features

A VPX instance running in GCP supports the following features:

- Load Balancing
- ICA Proxy
- Content Switching
- Authentication, authorization, and auditing
- Rewrite

- Responder
- RDP Proxy
- nFactor
- LDAP
- VPN (CVPN/Full)
- GSLB

Limitation

- IPv6 isn't supported.

Hardware requirements

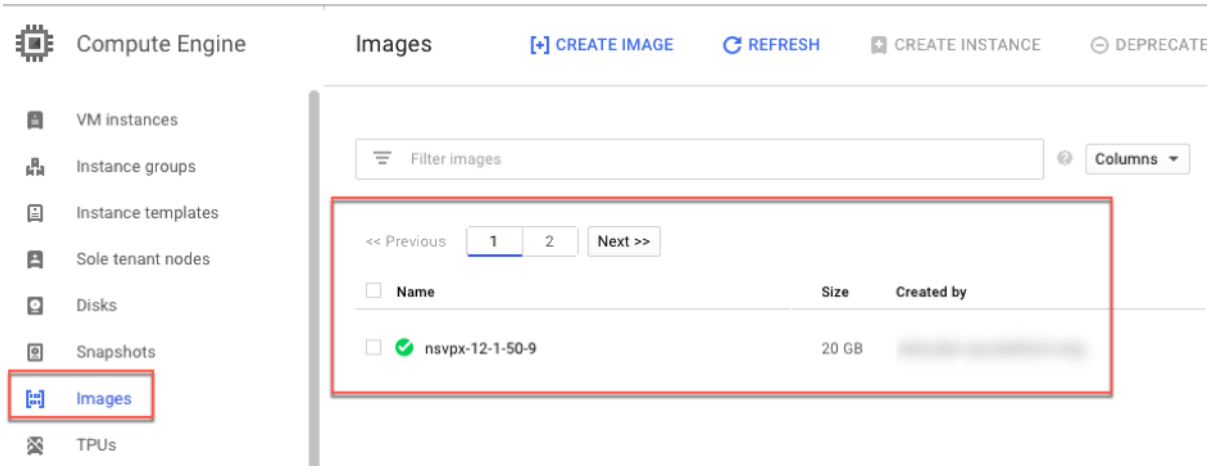
VPX instance in GCP must have minimum of 2 vCPUs and 4 GB RAM.

Prerequisites

1. Install the "gcloud" utility on your device. You can find the utility at this link: https://cloud.google.com/sdk/install
2. Download the NSVPX-GCP image from the Citrix download site.
3. Upload the file(for example, NSVPX-GCP-12.1-50.9_nc_64.tar.gz) to a storage bucket on Google by following the steps given at https://cloud.google.com/storage/docs/uploading-objects.
4. Run the following command on the gcloud utility to create an image.

```
gcloud compute images create <IMAGE_NAME> --source-uri=gs://<
    STORAGE_BUCKET_NAME>/<FILE_NAME>.tar.gz --guest-os-features=
    MULTI_IP_SUBNET
<!--NeedCopy-->
```

It might take a moment for the image to be created. After the image is created, it appears under **Compute** > **Compute Engine** in the GCP console.



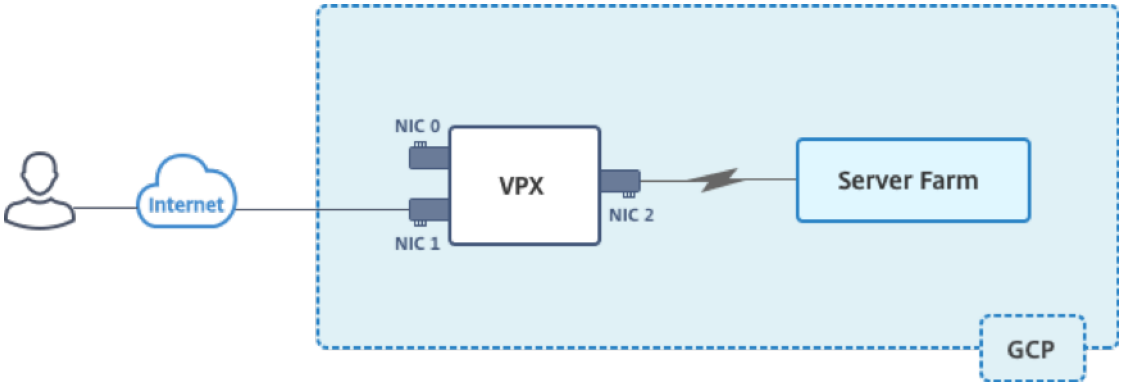
Points to note

Consider the following GCP-specific points before you begin your deployment.

- After creating the instance, you cannot add or remove any network interfaces.
- For a multi-NIC deployment, create separate VPC networks for each NIC. One NIC can be associated with only one network.
- For a single-NIC instance, the GCP console creates a network by default.
- Minimum 4 vCPUs are required for an instance with more than two network interfaces.
- If IP forwarding is required, you must enable IP forwarding while creating the instance and configuring the NIC.

Scenario: Deploy a multi-NIC, multi-IP standalone VPX instance

This scenario illustrates how to deploy a Citrix VPX standalone instance in GCP. In this scenario, you create a standalone VPX instance with multiple NICs. The instance communicates with back-end servers (the server farm).



Create three NICs to serve the following purposes.

NIC	Purpose	Associated with VPC network
NIC 0	Serves management traffic (Citrix ADC IP)	Management network
NIC 1	Serves client-side traffic (VIP)	Client network
NIC 2	Communicates with back-end servers (SNIP)	Back-end server network

Also, set up the required communication routes between the instance and the back-end servers, and between the instance and the external hosts on the public internet.

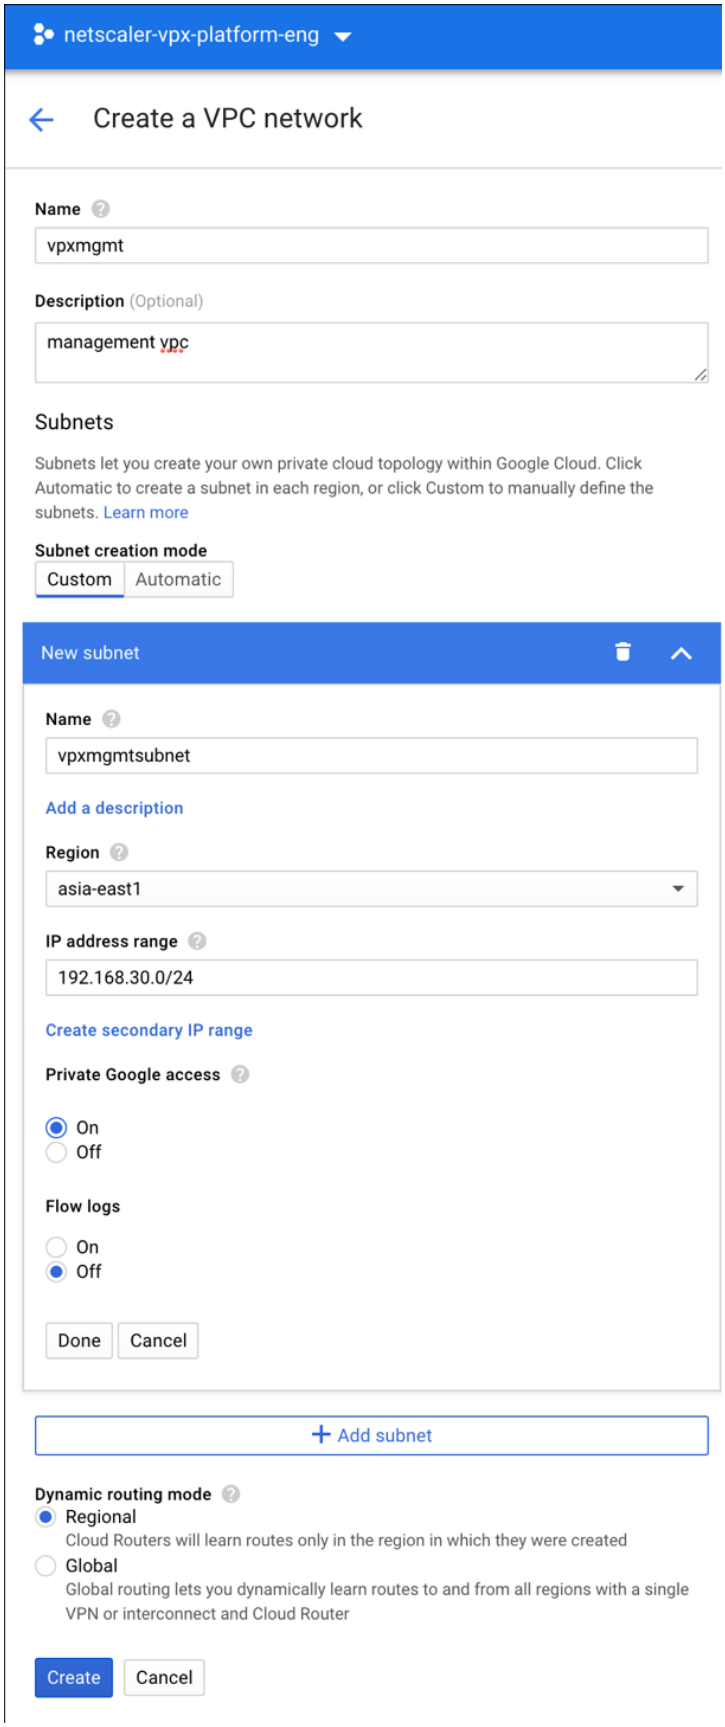
Summary of deployment steps

1. Create three VPC networks for three different NICs.
2. Create firewall rules for ports 22, 80, and 443
3. Create an instance with three NICs

Note: Create an instance in the same region where you've created the VPC networks.

Step 1. Create VPC networks.

Create three VPC networks that is associated with management NIC, client NIC, and server NIC. To create a VPC network, log on to **Google console > Networking > VPC network > Create VPC Network**. Complete the required fields, as shown in the screen capture, and click **Create**.

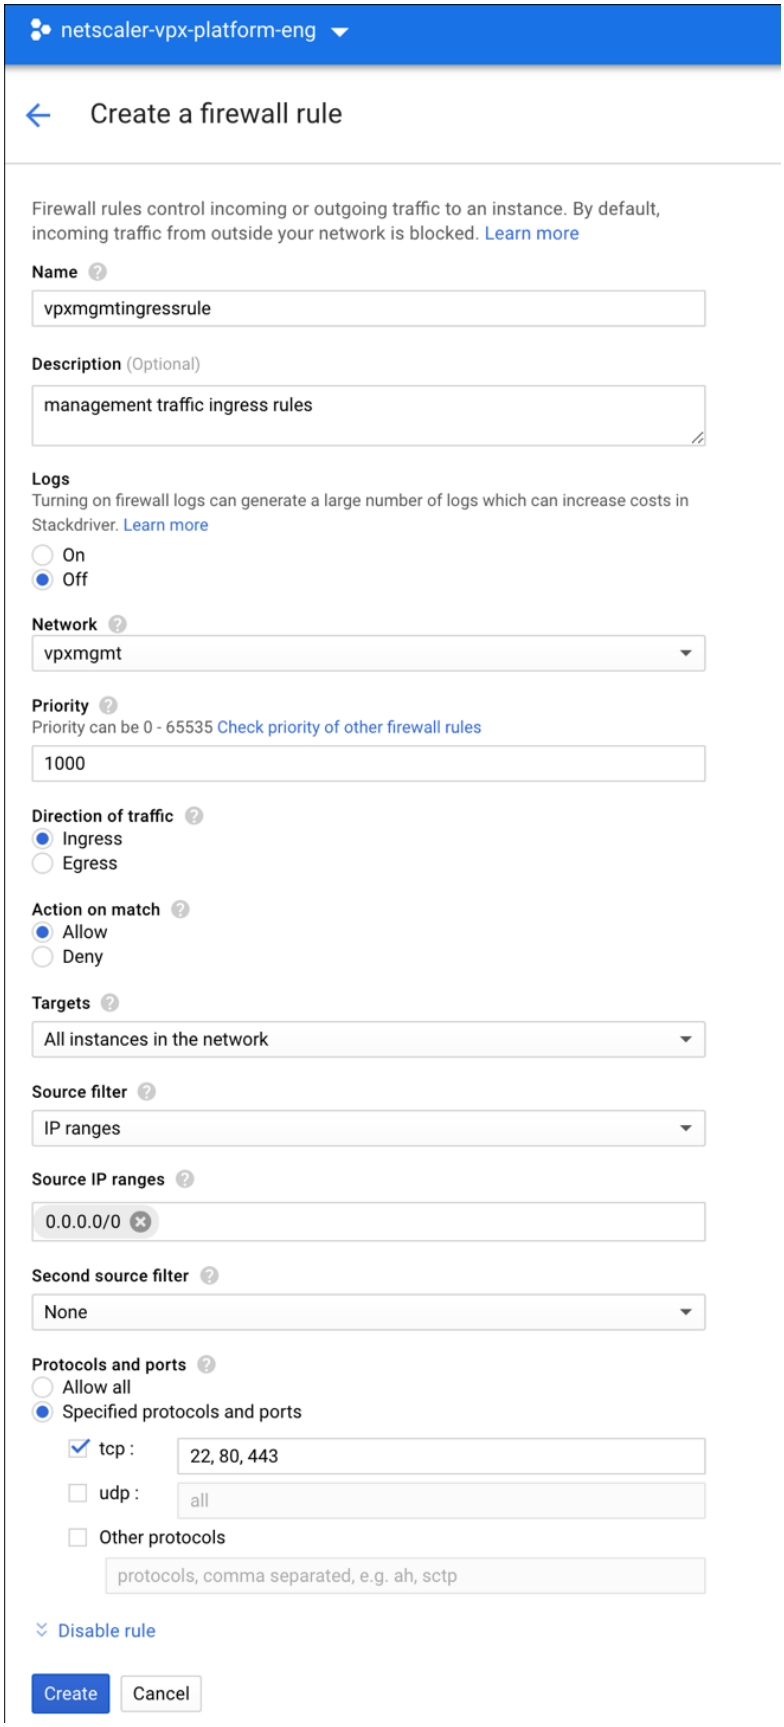


Similarly, create VPC networks for client and server-side NICs.

Note: All three VPC networks must be in the same region, which is asia-east1 in this scenario.

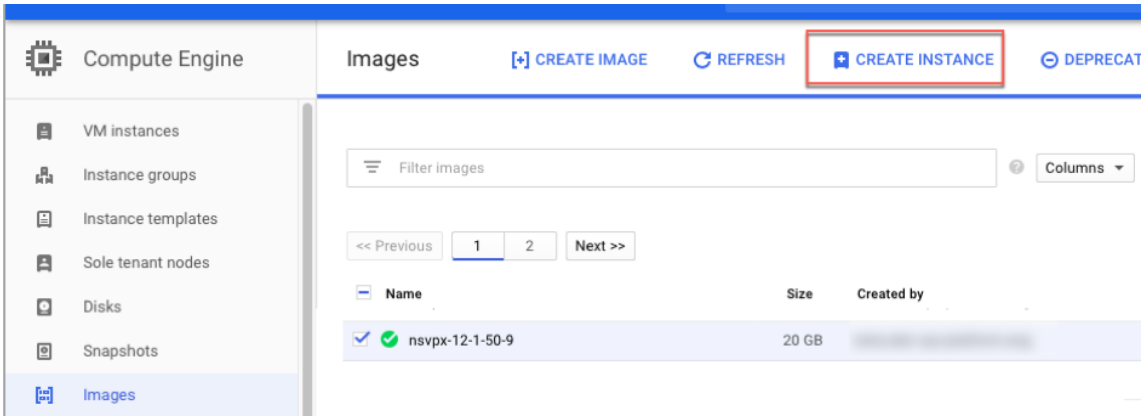
Step 2. Create firewall rules for ports 22, 80, and 443.

Create rules for SSH (port 22), HTTP (port 80), and HTTPS (port 443) for each VPC networks. For more information about firewall rules, see Firewall Rules Overview.



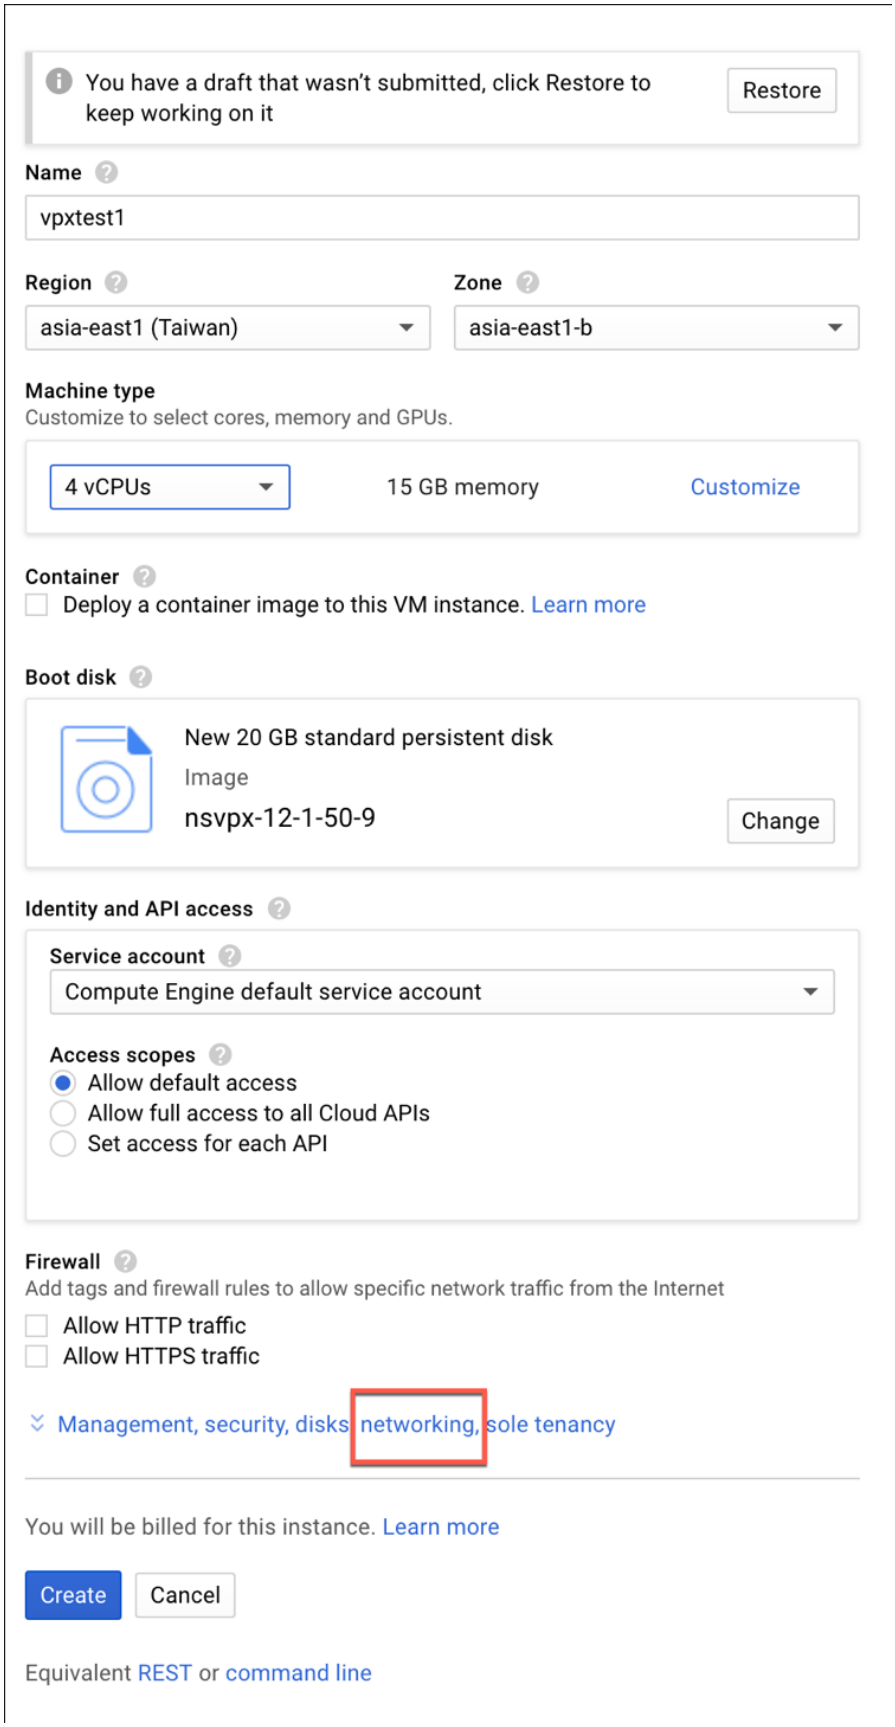
Step 3. Create the VPX instance.

1. Log on to the GCP console.
2. Under **Compute**, hover over Compute Engine, and select **Images**.
3. Select the image, and click **Create Instance**.

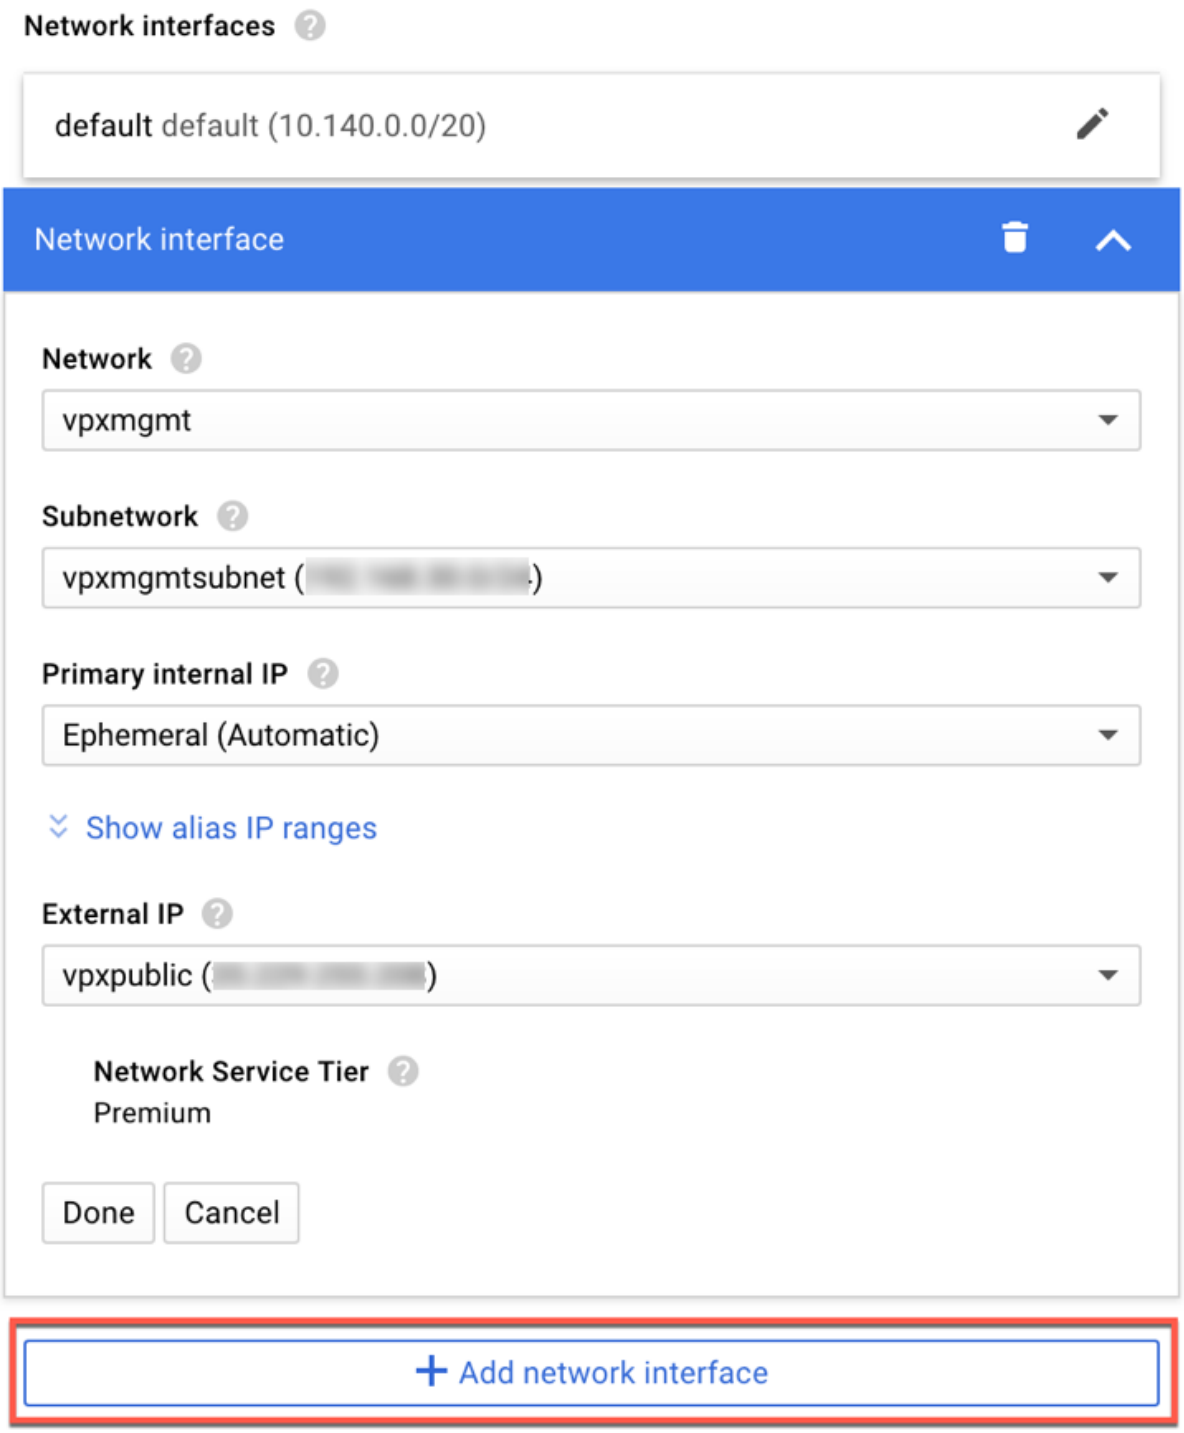


4. Select an instance with 4 vCPUs, to support multiple NICs.
5. Click the networking option from Management, security, disks, networking, sole tenancy to add the additional NICs.

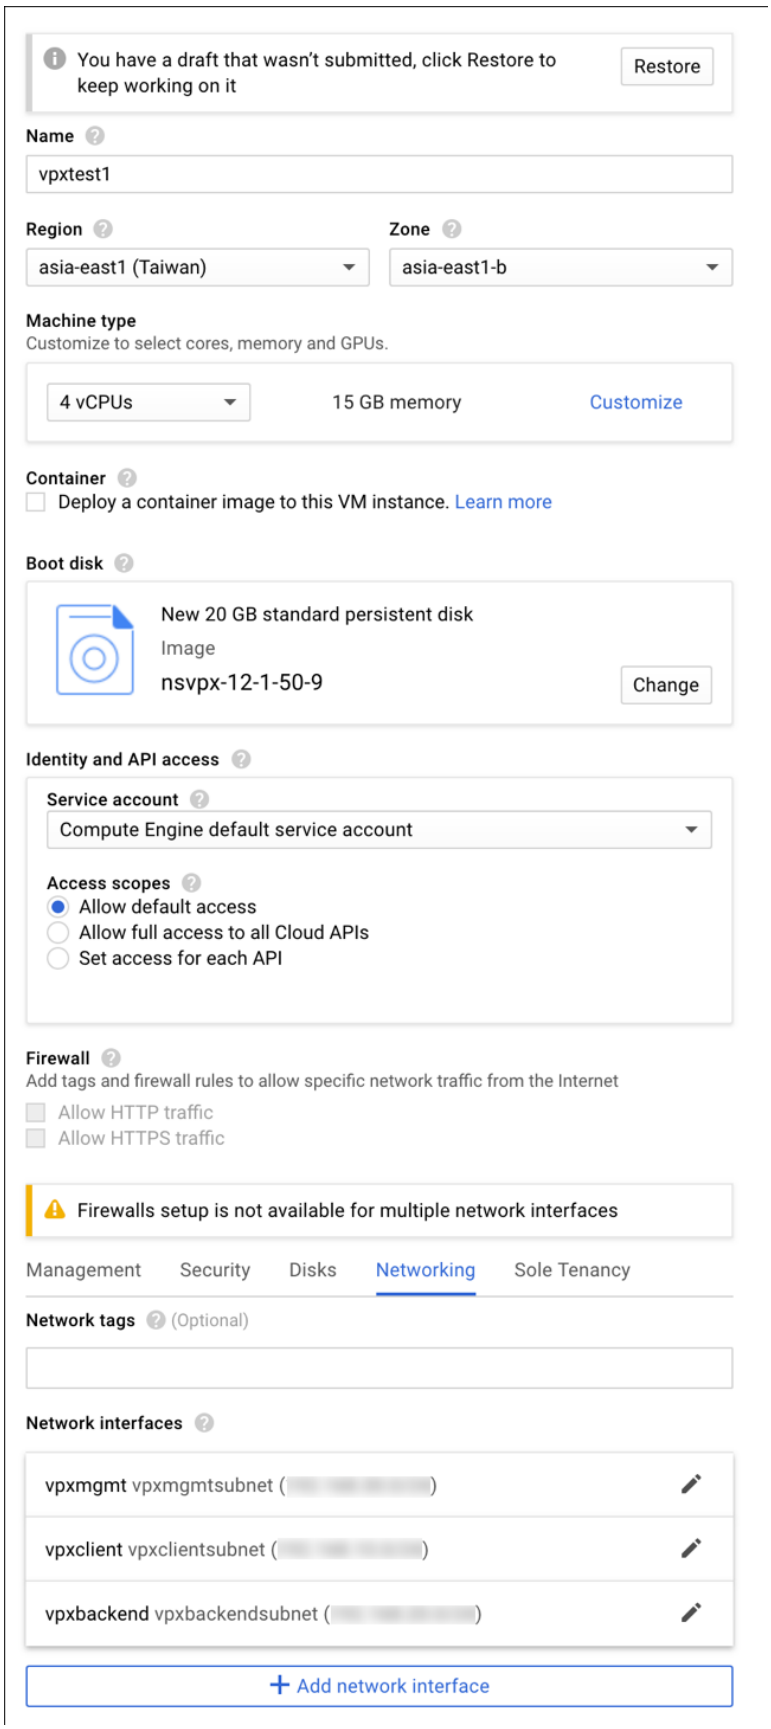
   Note: Container image is not supported on VPX instances on GCP.



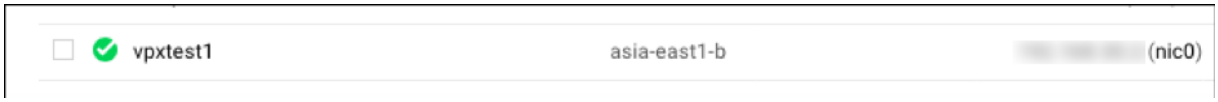
6. Under **Networking interfaces**, click the edit icon to edit the default NIC. This NIC is the management NIC.
7. In the **Network interfaces** window, under **Network**, select the VPC network you created for the management NIC.
8. For the management NIC, create a static external IP address. Under the External IP list, click **Create IP address**.
9. In the **Reserve a new static IP address** window, add a name and description and click **Reserve**.
10. Click **Add network interface** to create NICs for a client and server-side traffic.



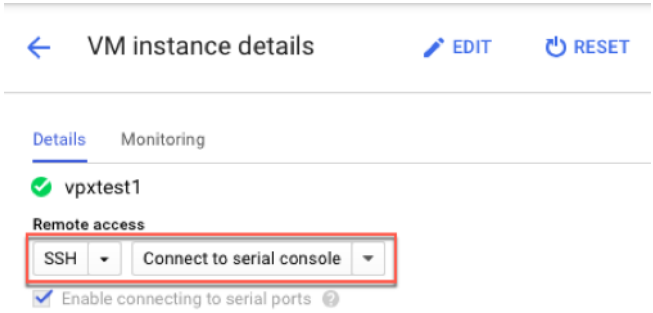
After you've created all the NICs, click **Create** to create the VPX instance.



The instance appears under **VM instances**.

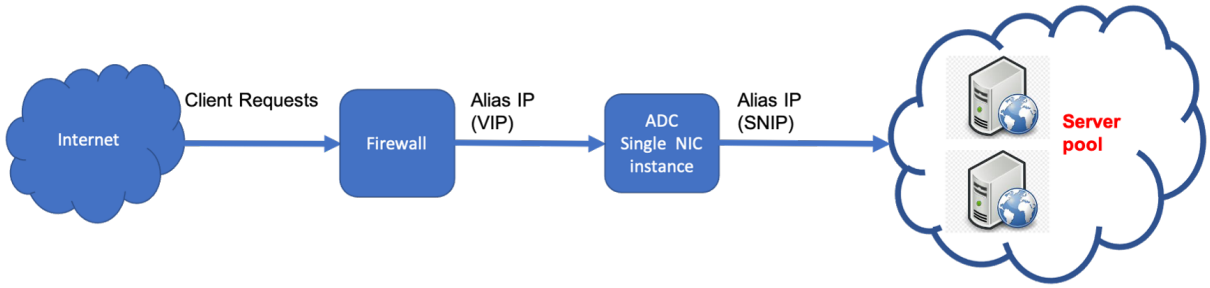


Use the GCP SSH or the serial console to configure and manage the VPX instance.



Scenario: Deploy a single-NIC, standalone VPX instance

This scenario illustrates how to deploy a Citrix VPX standalone instance with a single NIC in GCP. The alias IP addresses are used to achieve this deployment.



Create a single NIC (NIC0) to serve the following purposes:

- Handle management traffic (Citrix ADC IP) in the management network.
- Handle client-side traffic (VIP) in the client network.
- Communicate with back-end servers (SNIP) in the back-end server network.

Set up the required communication routes between the following:

- Instance and the back-end servers.
- Instance and the external hosts on the public internet.

Summary of deployment steps

1. Create a VPC network for NIC0.
2. Create firewall rules for ports 22, 80, and 443.

3. Create an instance with a single NIC.
4. Add Alias IP addresses to VPX.
5. Add VIP and SNIP on VPX.
6. Add a load balancing virtual server.
7. Add a service or service group on the instance.
8. Bind the service or service group to the load balancing virtual server on the instance.

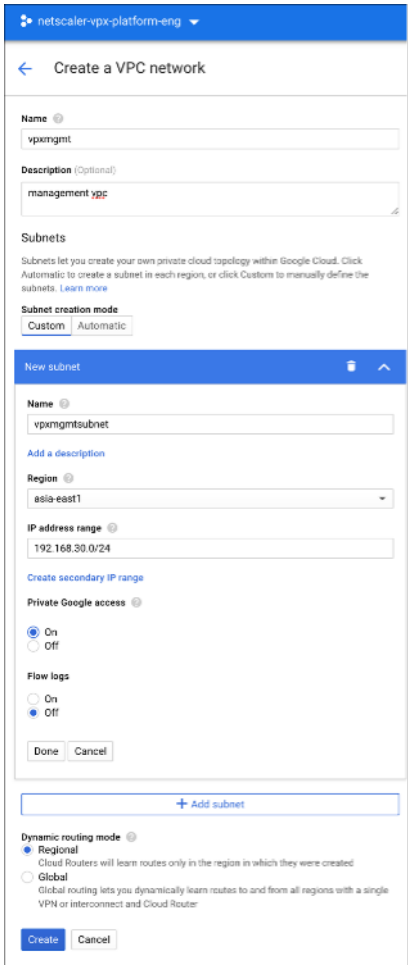
> **Note**:
>
> Create an instance in the same region where you've created the VPC networks.

Step 1. Create one VPC network.

Create one VPC network to associate with NIC0.

To create a VPC network, do these steps:

1. Log on to **GCP console > Networking > VPC network > Create VPC Network**
2. Complete the required fields, and click **Create**.



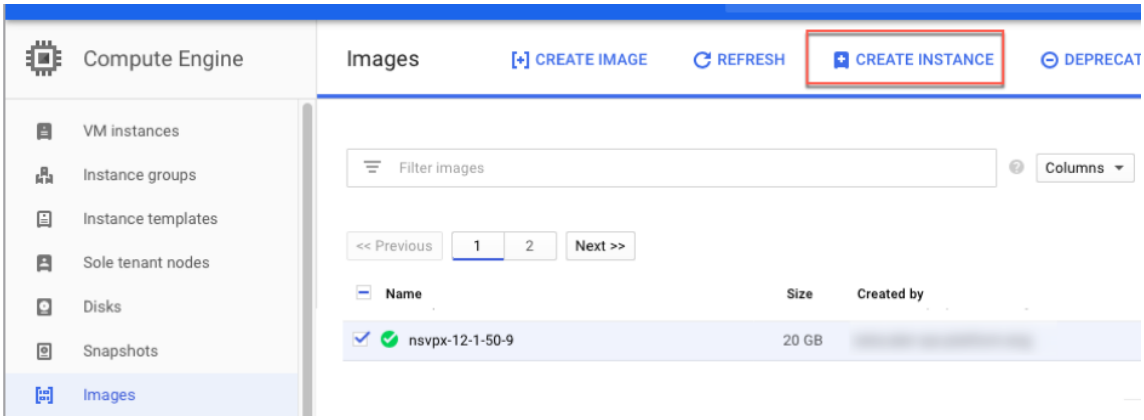
Step 2. Create firewall rules for ports 22, 80, and 443.

Create rules for SSH (port 22), HTTP (port 80), and HTTPS (port 443) for the VPC network. For more information about firewall rules, see Firewall Rules Overview.

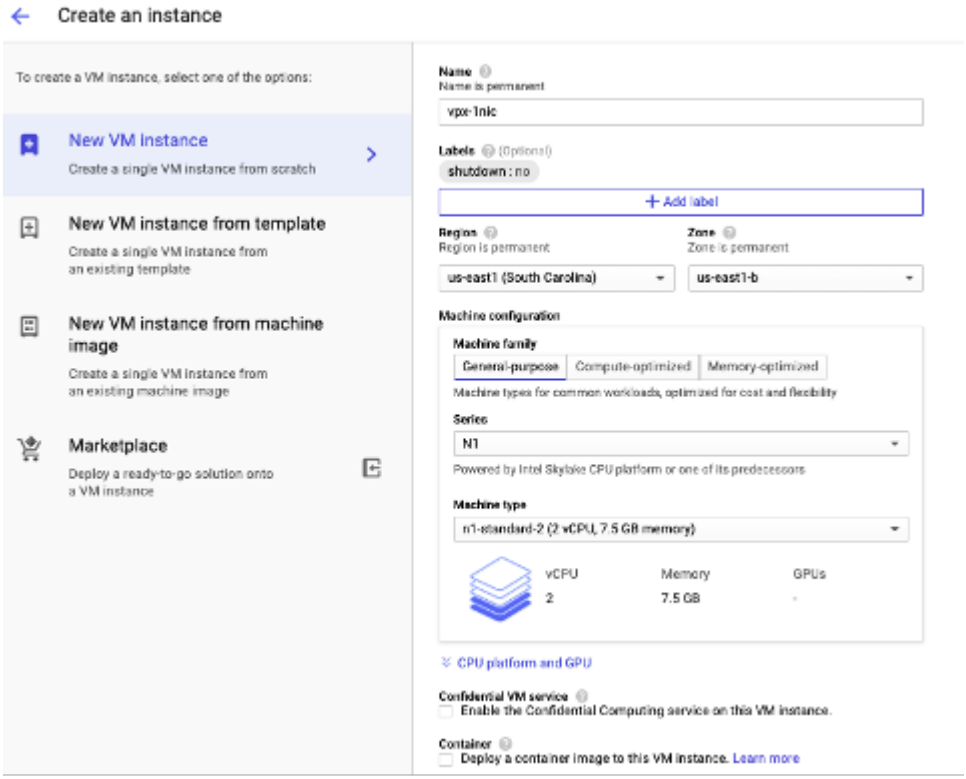
Step 3. Create an instance with single NIC.

To create an instance with single NIC, do these steps:

1. Log on to the **GCP console**.
2. Under **Compute**, hover over **Compute Engine**, and select **Images**.
3. Select the image, and click **Create Instance**.



4. Select an instance type with two vCPUs (minimum requirement for ADC).



5. Click the **Networking** tab from the **Management, security, disks, networking** window.
6. Under **Network interfaces**, click the **Edit** icon to edit the default NIC.
7. In the **Network interfaces** window, under **Network**, select the VPC network that you created.
8. You can create a static external IP address. Under the **External IP addresses**, click **Create IP address**.
9. In the **Reserve a static address** window, add a name and description and click **Reserve**.
10. Click **Create** to create the VPX instance.
    The new instance appears under VM instances.

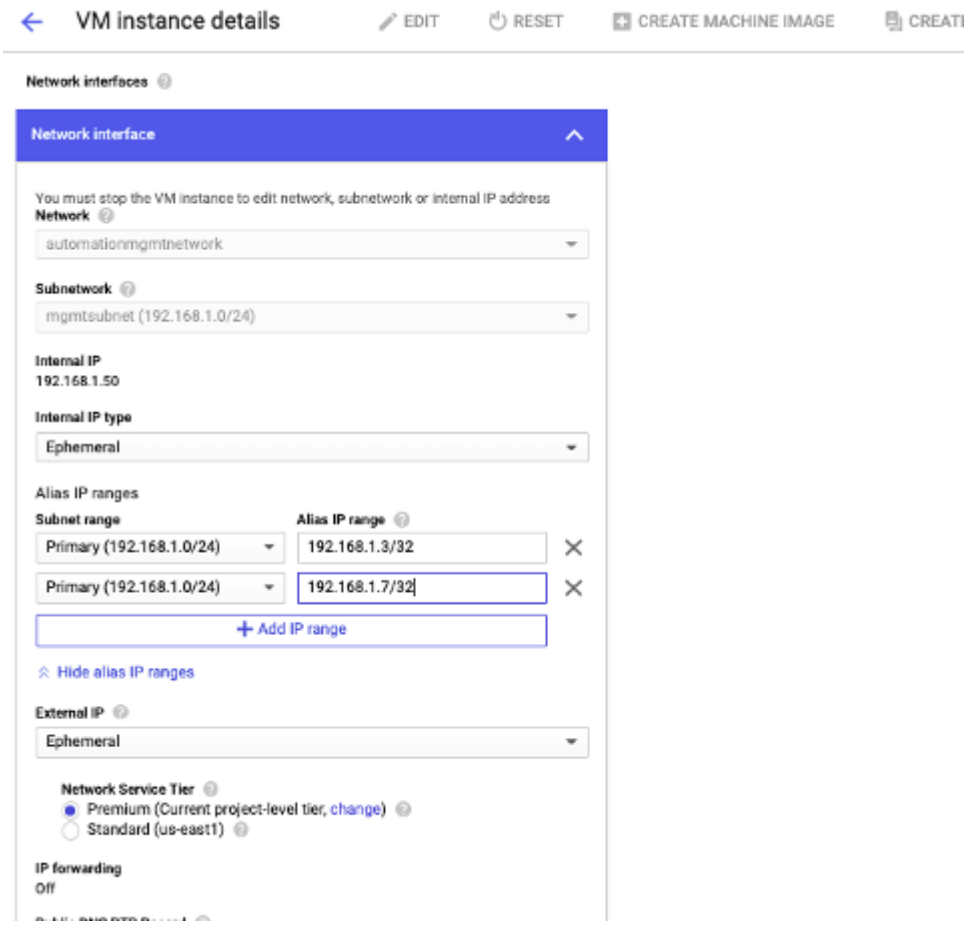
Step 4. Add alias IP addresses to the VPX instance.

Assign two alias IP addresses to the VPX instance to use as VIP and SNIP addresses.

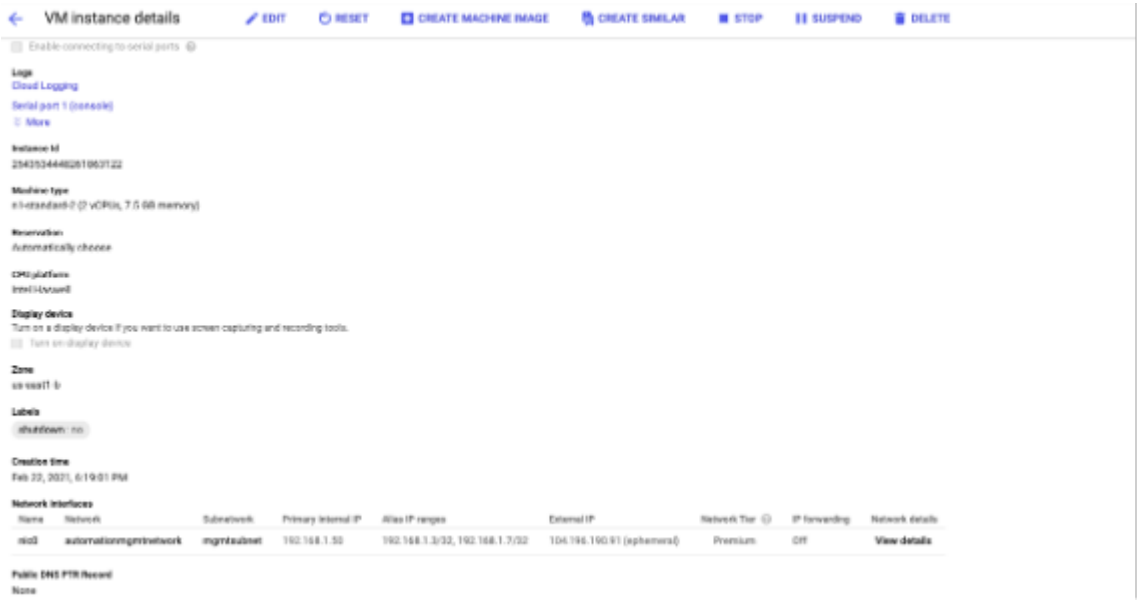
> **Note:**
>
> Do not use the primary internal IP address of the VPX instance to configure the VIP or SNIP.

To create an alias IP address, perform these steps:

1. Navigate to the VM instance and click **Edit**.
2. In the **Network interface** window, edit the NIC0 interface.
3. In the **Alias IP range** field, enter the alias IP addresses.



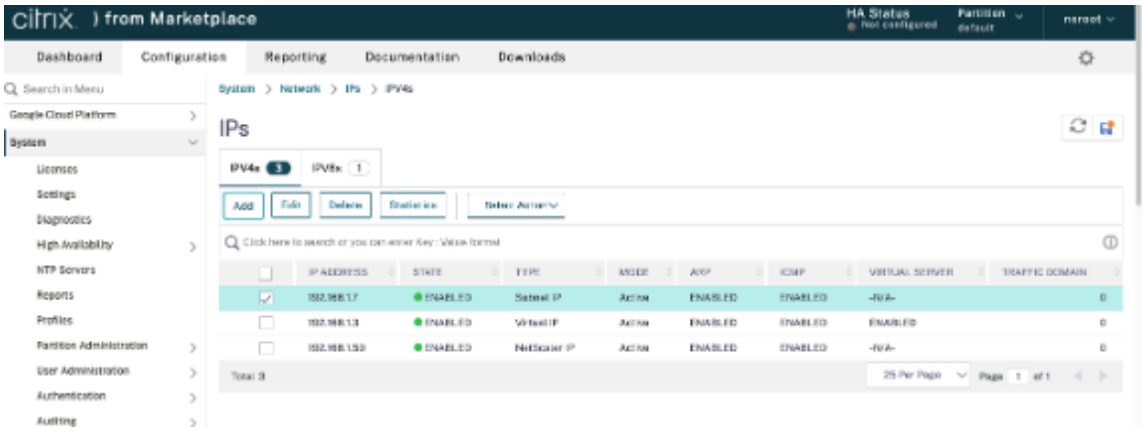
4. Click **Done**, and then **Save**.
5. Verify the alias IP addresses in the **VM instance details** page.



Step 5. Add VIP and SNIP on the VPX instance.

On the VPX instance, add client alias IP address and server alias IP address.

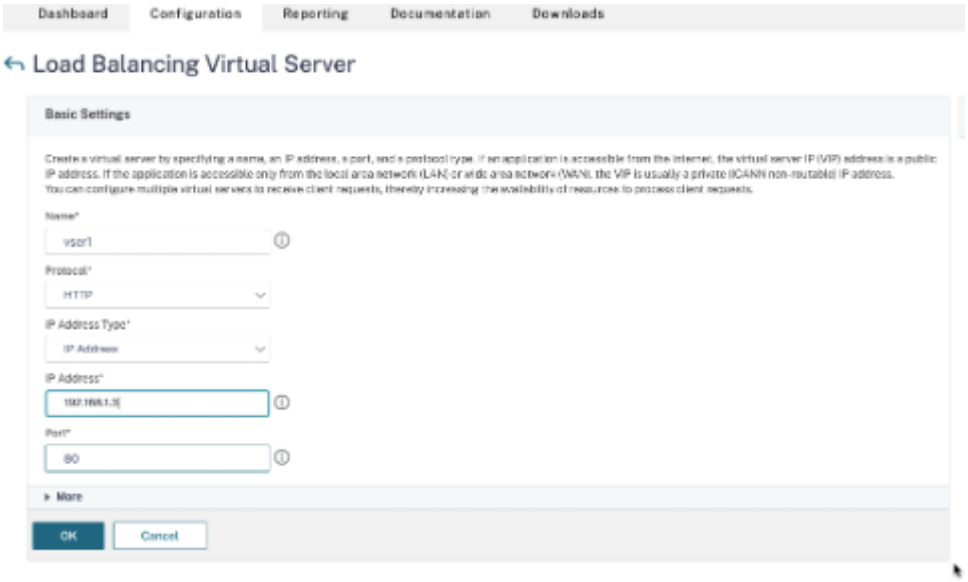
1. On the Citrix ADC GUI, navigate to **System > Network > IPs > IPv4s**, and click **Add**.



2. To create a client alias IP (VIP) address:
   - Enter the client-alias IP address and netmask configured for the VPC subnet in the VM instance.
   - In the **IP Type** field, select **Virtual IP** from the drop-down menu.
   - Click **Create**.
3. To create a server alias IP (SNIP) address:
   - Enter the server-alias IP address and netmask configured for the VPC subnet in the VM instance.
   - In the **IP Type** field, select **Subnet IP** from the drop-down menu.
   - Click **Create**.

Step 6. Add load balancing virtual server.

1. On the Citrix ADC GUI, navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**, and click **Add**.
2. Add the required values for Name, Protocol, IP Address Type (IP Address), IP Address (client alias IP), and Port.
3. Click **OK** to create the load balancing virtual server.



Step 7. Add a service or service group on the VPX instance.

1. From the Citrix ADC GUI, navigate to **Configuration > Traffic Management > Load Balancing > Services**, and click **Add**.
2. Add the required values for Service Name, IP Address, Protocol, and Port, and click **OK**.

Step 8. Bind the service/service group to the Load Balancing Virtual Server on the instance.

1. From the GUI, navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**.
2. Select the load balancing virtual server configured in **Step 6**, and click **Edit**.
3. In the **Service and Service Groups** window, click **No Load Balancing Virtual Server Service Binding**.
4. Select the service configured in **Step 7**, and click **Bind**.

Points to note after you've deployed the VPX instance on GCP

- Log on to the VPX with user name `nsroot` and instance ID as password. At the prompt, change the password and save the configuration.
- For collecting a technical support bundle, run the command `shell /netscaler/showtech_cloud.pl` instead of the customary `show techsupport`.

- After deleting a Citrix ADC VM from GCP console, delete the associated Citrix ADC internal target instance also. To do so, go to gcloud CLI and type the following command:

```
gcloud compute -q  target-instances delete <instance-name>-
   adcinternal --zone <zone>
<!--NeedCopy-->
```

> Note: `<instance-name>-adcinternal` is the name of the target instance that must be deleted.

Citrix ADC VPX licensing

A Citrix ADC VPX instance on GCP requires a license. The following licensing options are available for Citrix ADC VPX instances running on GCP.

- **Subscription-based licensing**: Citrix ADC VPX appliances are available as paid instances on the GCP marketplace. Subscription-based licensing is a pay-as-you-go option. Users are charged hourly. The following VPX models and license editions are available on the GCP marketplace.

VPX model	License editions
VPX10	Standard, Advanced, Premium

- **Bring your own license (BYOL)**: If you bring your own license (BYOL), see the VPX Licensing Guide at http://support.citrix.com/article/CTX122426. You have to:
  - Use the licensing portal within the Citrix website to generate a valid license.
  - Upload the license to the instance.
- **Citrix ADC VPX Check-In/Check-Out licensing**: For more information, see Citrix ADC VPX Check-In/Check-Out Licensing.

VPX Express for on-premises and cloud deployments does not require a license file. For more information on Citrix ADC VPX Express see the "Citrix ADC VPX Express license" section in Citrix ADC licensing overview.

GDM templates to deploy a Citrix ADC VPX instance

You can use a Citrix ADC VPX Google Deployment Manager (GDM) template to deploy a VPX instance on GCP. For details, see Citrix ADC GDM Templates.

Citrix ADC marketplace images

You can use the images in GDM templates to bring up the Citrix ADC appliance.

The following table lists the images that are available on GCP marketplace.

Release	Image name	Image location
13.0	citrix-adc-vpx-1000-advanced-13-0-61-48	projects/citrix-master-project/global/images/citrix-adc-vpx-1000-advanced-13-0-61-48

- Deploy a VPX high-availability pair on Google Cloud Platform

Deploy a VPX high-availability pair on Google Cloud Platform

September 14, 2021

You can configure two Citrix ADC VPX instances on Google Cloud Platform (GCP) as a high availability (HA) active-passive pair. When you configure one instance as the primary node and the other as the secondary node, the primary node accepts connections and manages servers. The secondary node monitors the primary. If for any reason, if the primary node is unable to accept connections, the secondary node takes over.

For more information on HA, see High Availability.

The nodes must be in the same region; however, they can be either in the same zone or different zones. For more information, see Regions and Zones.

Each VPX instance requires at least three IP subnets (Google VPC networks):

- A management subnet
- A client-facing subnet (VIP)
- A back-end facing subnet (SNIP, MIP, and so on)

Citrix recommends three network interfaces for a standard VPX instance.

You can deploy a VPX high-availability pair in the following methods:

- Using external static IP address
- Using private IP address

GDM templates to deploy a VPX high-availability pair on GCP

You can use a Citrix ADC Google Deployment Manager (GDM) template to deploy a VPX high-availability pair on GCP. For details, see Citrix ADC GDM Templates.

Forwarding rules support for VPX high-availability pair on GCP

You can deploy a VPX high-availability pair on the GCP using forwarding rules.

For more information on forwarding rules, see Forwarding rules overview.

Prerequisites

- Forwarding rules must be in the same region as the VPX instances.
- Target instances must be in the same zone as the VPX instance.
- Number of target instances for both primary and secondary nodes must match.

Example:

You have a high-availability pair in the `us-east1` region with primary VPX in `us-east1-b` zone and secondary VPX in `us-east1-c` zone. A forwarding rule is configured for the primary VPX with the target instance in `us-east1-b` zone. Configure a target instance for secondary VPX in `us-east1-c` zone to update the forwarding rule on failover.

Limitations

Only forwarding rules that are configured with target instances at the back end are supported in VPX high-availability deployment.

Deploy a VPX high-availability pair with external static IP address on the Google Cloud Platform

September 14, 2021

You can deploy a VPX high-availability pair on GCP using an external static IP address. The client IP address of the primary node must be bound to an external static IP address. Upon failover, the external static IP address is moved to the secondary node for traffic to resume.

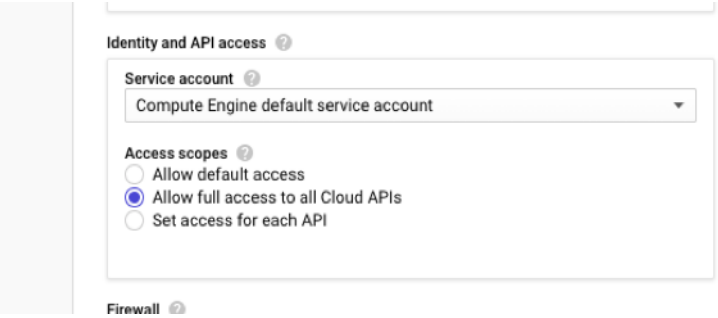
A static external IP address is an external IP address that is reserved for your project until you decide to release it. If you use an IP address to access a service, you can reserve that IP address so that only your project can use it. For more information, see Reserving a Static External IP Address.

For more information on HA, see High Availability.

Before you start

- Read the Limitation, Hardware requirements, Points to note mentioned in Deploy a Citrix ADC VPX instance on Google Cloud Platform. This information applies to HA deployments also.
- Enable **Cloud Resource Manager API** for your GCP project.

- Allow full access to all Cloud APIs while creating the instances.



- Ensure that the IAM role associated with your GCP service account has the following IAM permissions:

```
REQUIRED_INSTANCE_IAM_PERMS = [

"compute.addresses.use",
 “compute.forwardingRules.list” ,
 “compute.forwardingRules.setTarget” ,
 “compute.instances.setMetadata”
"compute.instances.addAccessConfig",
"compute.instances.deleteAccessConfig",
"compute.instances.get",
"Compute.instances.list",
"compute.networks.useExternalIp",
"compute.subnetworks.useExternalIp",
 “compute.targetInstances.list” ,
 “compute.targetInstances.use” ,
"compute.zones.list",
]
<!--NeedCopy-->
```

- If you have configured alias IP addresses on an interface other than the management interface, ensure that your GCP service account has the following extra IAM permissions:

```
"compute.instances.updateNetworkInterface"
<!--NeedCopy-->
```

- If you have configured GCP forwarding rules on the primary node, read the limitations and requirements mentioned in Forwarding rules support for VPX high-availability pair on GCP to update them to new primary on failover.

How to deploy a VPX HA pair on Google Cloud Platform

Here’s a summary of the HA deployment steps:

1. Create VPC networks in the same region. For example, Asia-east.
2. Create two VPX instances (primary and secondary nodes) on the same region. They can be in the same zone or different zones. For example Asia east-1a and Asia east-Ib.
3. Configure HA settings on both instances by using the Citrix ADC GUI or ADC CLI commands.

Step 1. Create VPC networks

Create VPC networks based on your requirements. Citrix recommends you to create three VPC networks for associating with management NIC, client NIC, and server NIC.

To create a VPC network, perform these steps:

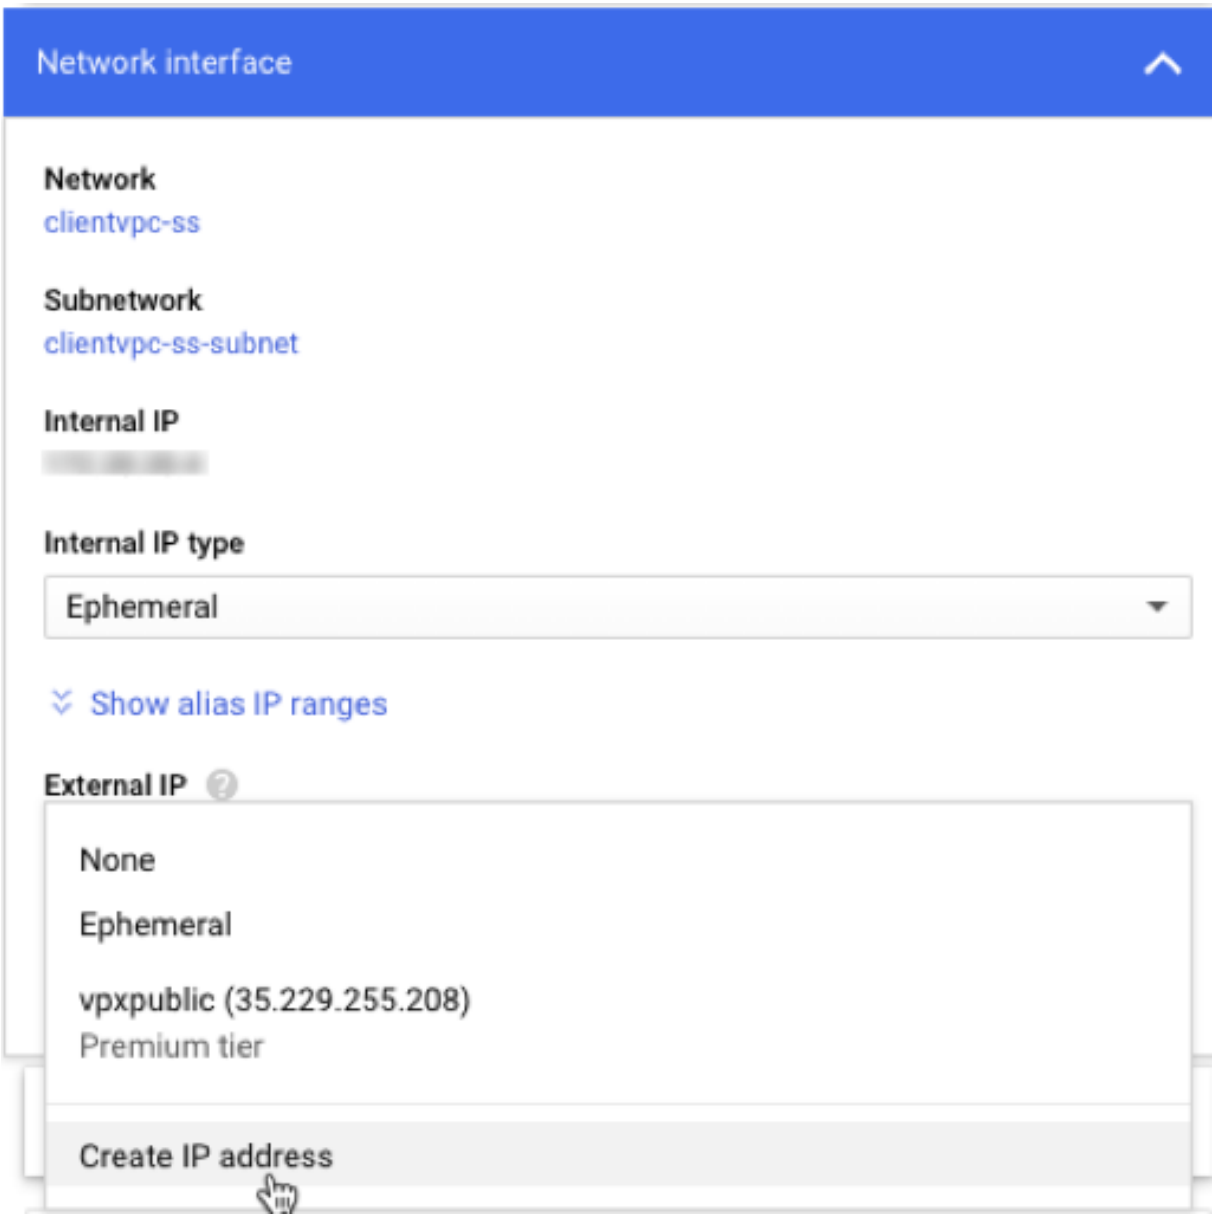
1. Log on the **Google console > Networking > VPC network > Create VPC Network**.
2. Complete the required fields, and click **Create**.

For more information, see the **Create VPC Networks** section in Deploy a Citrix ADC VPX instance on Google Cloud Platform.

Step 2. Create two VPX instances

Create two VPX instances by following the steps given in Scenario: deploy a multi-NIC, multi-IP standalone VPX instance.

> **Important**
>
> Assign a static external IP address to client IP address (VIP) of the primary node. You can use an existing reserved IP address or create a new one. To create a static external IP address, navigate to **Network interface > External IP**, click **Create IP address**.



After the failover, when the old primary becomes the new secondary, the static external IP address moves from the old primary and is attached to the new primary. For more information, see the Google cloud document Reserving a Static External IP Address.

After you've configured the VPX instances, you can configure the VIP and SNIP addresses. For more information, see Configuring Citrix ADC-owned IP addresses.

Step 3. Configure high availability

After you've created the instances on Google Cloud Platform, you can configure HA by using the Citrix ADC GUI for CLI.

Configure HA by using the GUI

Step 1. Set up high availability in INC mode on both the instances.

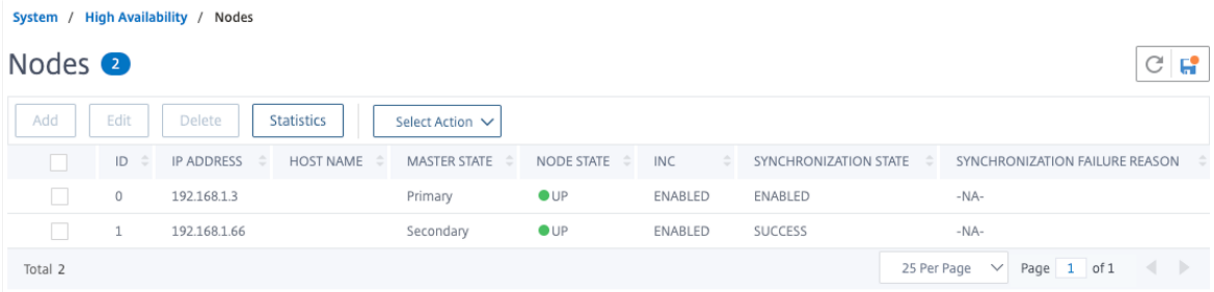
On the **primary node**, perform the following steps:

1. Log on to the instance with user name `nsroot` and instance ID of the node from GCP console as the password.
2. Navigate to **Configuration > System > High Availability > Nodes**, and click **Add**.
3. In the **Remote Node IP address** field, enter the private IP address of the management NIC of the secondary node.
4. Select the **Turn on INC (Independent Network Configuration) mode on self node** check box.
5. Click **Create**.

On the **secondary node**, perform the following steps:

1. Log on to the instance with user name `nsroot` and instance ID of the node from GCP console as the password.
2. Navigate to **Configuration > System > High Availability > Nodes**, and click **Add**.
3. In the **Remote Node IP address** field, enter the private IP address of the management NIC of the primary node.
4. Select the **Turn on INC (Independent Network Configuration) mode on self node** check box.
5. Click **Create**.

Before you proceed further, ensure that the Synchronization state of the secondary node is shown as **SUCCESS** in the **Nodes** page.



> **Note**
>
> Now, the secondary node has the same log-on credentials as the primary node.

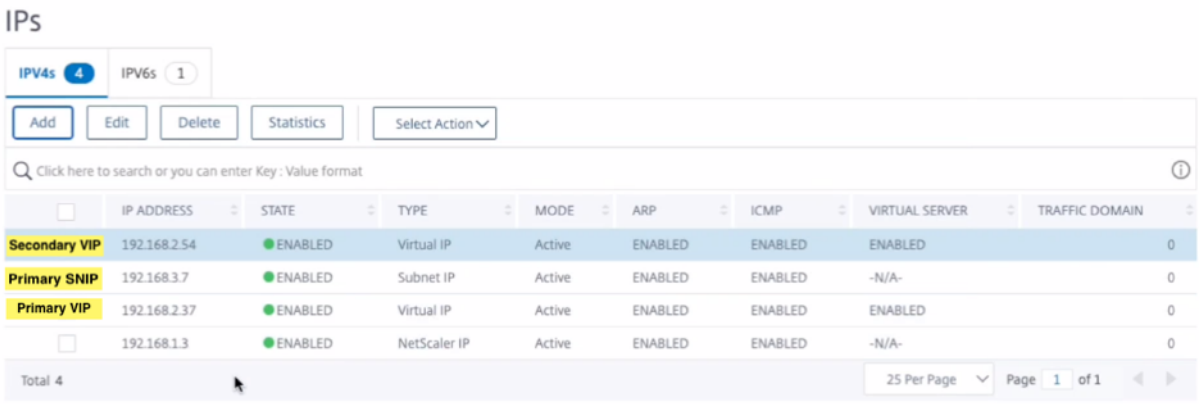
Step 2. Add Virtual IP address and Subnet IP address on both the nodes.

On the **primary node**, perform the following steps:

1. Navigate to **System > Network > IPs > IPv4s**, and click **Add**.
2. Add a primary VIP address by following these steps:
   a) Enter the internal IP address of the client-facing interface of the primary instance and netmask configured for the client subnet in the VM instance.

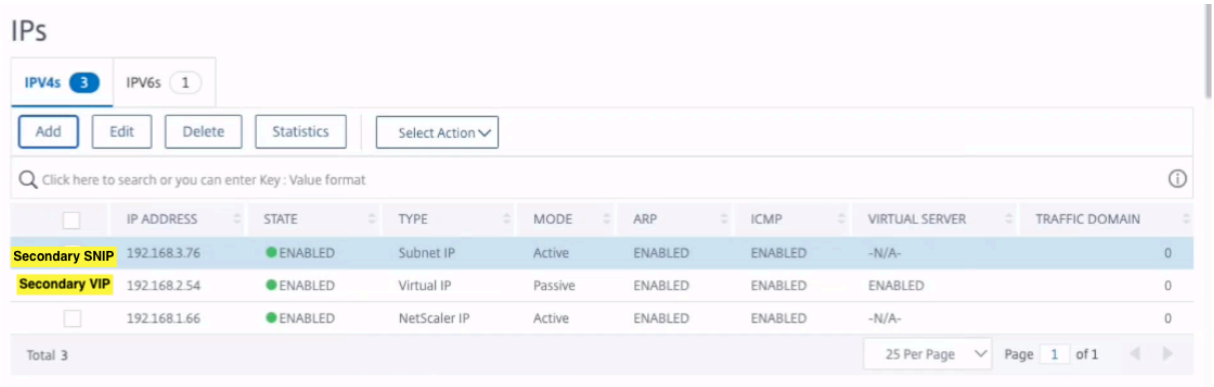
b) In the **IP Type** field, select **Virtual IP** from the drop-down menu.
c) Click **Create**.

3. Add a primary SNIP address by following these steps:
   a) Enter the internal IP address of the server-facing interface of the primary instance and netmask configured for the server subnet in the primary instance.
   b) In the **IP Type** field, select **Subnet IP** from the drop-down menu.
   c) Click **Create**.
4. Add a secondary VIP address by following these steps:
   a) Enter the internal IP address of the client-facing interface of the secondary instance and netmask configured for the client subnet in the VM instance.
   b) In the **IP Type** field, select **Virtual IP** from the drop-down menu.
   c) Click **Create**.



On the **secondary node**, perform the following steps:

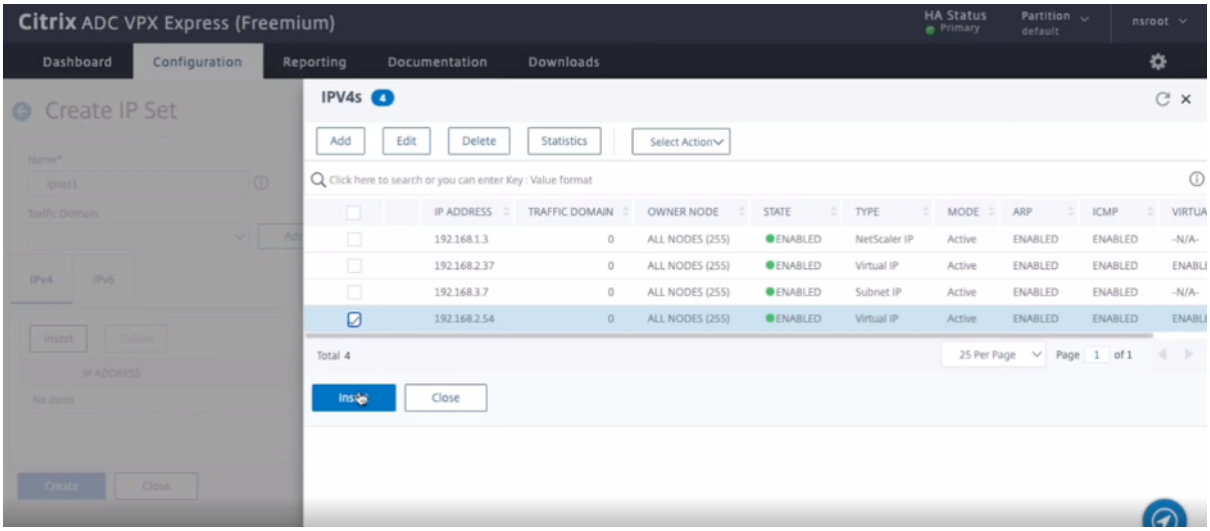
1. Navigate to **System > Network > IPs > IPv4s**, and click **Add**.
2. Add a secondary VIP address by following these steps:
   a) Enter the internal IP address of the client-facing interface of the secondary instance and netmask configured for the client subnet in the VM instance.
   b) In the **IP Type** field, select **Virtual IP** from the drop-down menu.
3. Add a secondary SNIP address by following these steps:
   a) Enter the internal IP address of the server-facing interface of the secondary instance and netmask configured for the server subnet in the secondary instance.
   b) In the **IP Type** field, select **Subnet IP** from the drop-down menu.
   c) Click **Create**.



Step 3. Add IP set and bind IP set to the secondary VIP on both the instances.

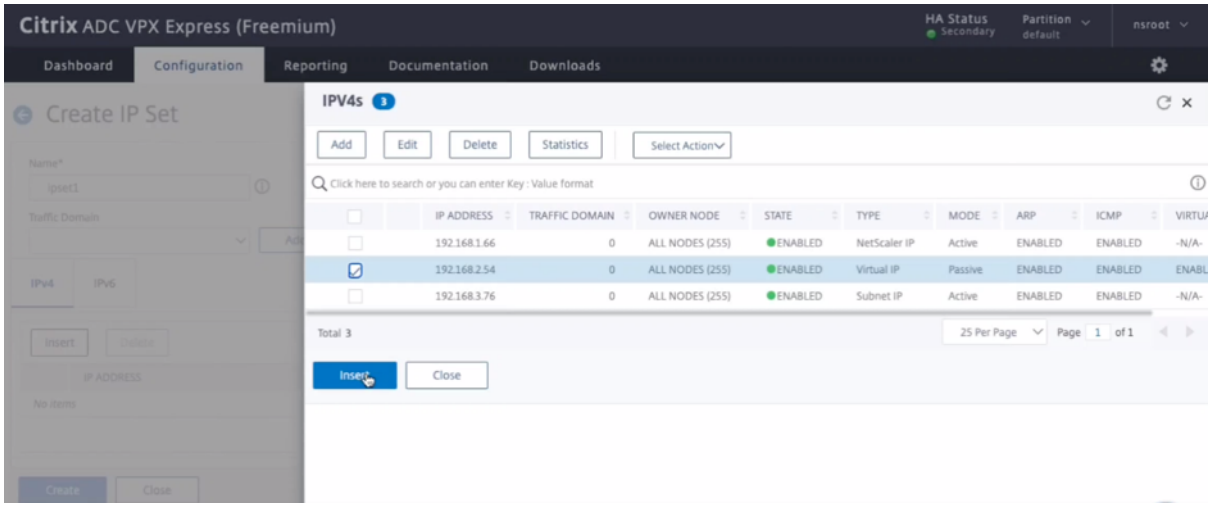
On the **primary node**, perform the following steps:

1. Navigate to **System > Network > IP Sets > Add**.
2. Add an IP set name and click **Insert**.
3. From the **IPV4s** page, select the virtual IP (secondary VIP) and click **Insert**.
4. Click **Create** to create the IP set.



On the **secondary node**, perform the following steps:

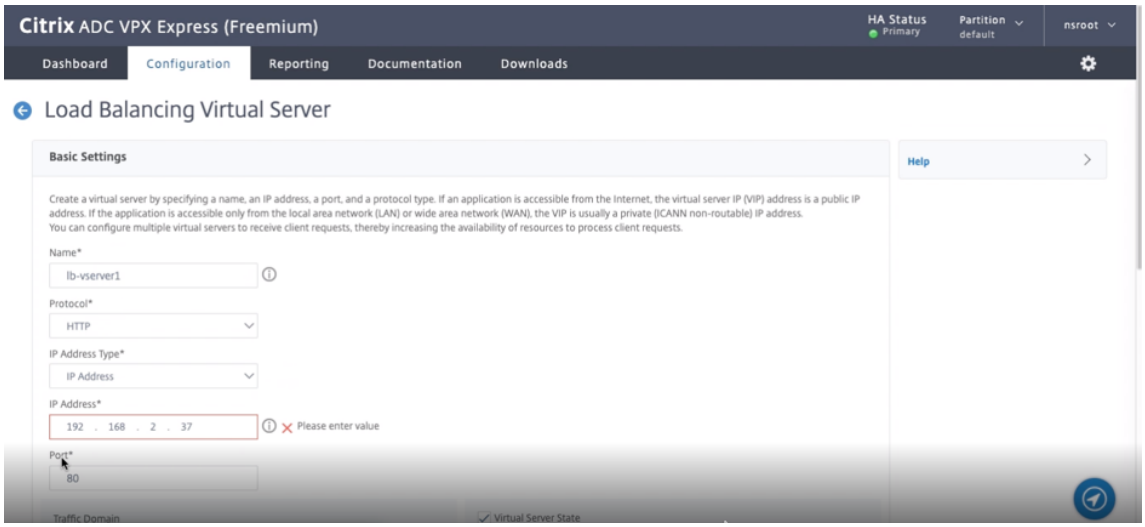
1. Navigate to **System > Network > IP Sets > Add**.
2. Add an IP set name and click **Insert**.
3. From the **IPV4s** page, select the virtual IP (secondary VIP) and click **Insert**.
4. Click **Create** to create the IP set.



> **Note**
>
> IP set name must be same on both the instances.

Step 4. Add a load balancing virtual server on the primary instance.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers > Add**.
2. Add the required values for Name, Protocol, IP Address Type (IP Address), IP address (primary VIP), and Port.



3. Click **More**. Navigate to **IP Range IP Set Settings**, select **IPset** from the drop-down menu, and provide the IPset created in **Step 3**.
4. Click **OK** to create the load balancing virtual server.

Step 5. Add a service or service group on the primary node.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Services > Add**.
2. Add the required values for Service Name, IP Address, Protocol and Port, and click **OK**.

Step 6. Bind the service or service group to the load balancing virtual server on the primary node.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**.
2. Select the load balancing virtual server configured in **Step 4**, and click **Edit**.
3. In the **Service and Service Groups** tab, click **No Load Balancing Virtual Server Service Binding**.
4. Select the service configured in the **Step 5**, and click **Bind**.

Save the configuration. After a forced failover, the secondary becomes the new primary. The external static IP of the old primary VIP moves to the new secondary VIP.

Configure high availability using CLI

Step 1. Set up high availability in INC mode in both the instances.

On the primary node, type the following command.

```
1 add ha node 1 <sec_ip> -inc ENABLED
2 <!--NeedCopy-->
```

On the secondary node, type the following command.

```
1 add ha node 1 <prim_ip> -inc ENABLED
2 <!--NeedCopy-->
```

`sec_ip` refers to the internal IP address of the management NIC of the secondary node.

`prim_ip` refers to the internal IP address of the management NIC of the primary node.

Step 2. Add Virtual and Subnet IPs on both the nodes.

On the primary node, type the following command.

```
1 add ns ip <primary_vip> <subnet> -type VIP
2
3 add ns ip <secondary_vip> <subnet> -type VIP
4
5 add ns ip <primary_snip> <subnet> -type SNIP
6 <!--NeedCopy-->
```

`primary_vip` refers to the internal IP address of the client-facing interface of the primary instance.

`secondary_vip` refers to the internal IP address of the client-facing interface of the secondary instance.

`primary_snip` refers to the internal IP address of the server-facing interface of the primary instance.

On the secondary node, type the following command.

```
1 add ns ip <secondary_vip> <subnet> -type VIP
2
3 add ns ip <secondary_snip> <subnet> -type SNIP
4 <!--NeedCopy-->
```

`secondary_vip` refers to the internal IP address of the client-facing interface of the secondary instance.

`secondary_snip` refers to the internal IP address of the server-facing interface of the secondary instance.

Step 3. Add IP set and bind IP set to secondary VIP on both the instances.

On the primary node, type the following command:

```
1 add ipset <ipsetname>
2 bind ipset <ipsetname> <secondary VIP>
3 <!--NeedCopy-->
```

On the secondary node, type the following command:

```
1 add ipset <ipsetname>
2 bind ipset <ipsetname> <secondary VIP>
3 <!--NeedCopy-->
```

> **Note**
>
> IP set name must be same on both the instances.

Step 4. Add a virtual server on the primary instance.

Type the following command:

```
1 add <server_type> vserver <vserver_name> <protocol> <primary_vip> <port
     > -ipset <ipset_name>
2 <!--NeedCopy-->
```

Step 5. Add a service or service group on the primary instance.

Type the following command:

```
1 add service <service_name> <service_ip_address> <protocol> <port>
2 <!--NeedCopy-->
```

Step 6. Bind the service/service group to the load balancing virtual server on the primary instance.

Type the following command:

```
bind <server_type> vserver <vserver_name> <service_name>
<!--NeedCopy-->
```

> *Note*:
>
> To save your configuration, type the command `save config`. Otherwise, the configurations are lost after you restart the instances.

Step 7. Verify the configuration.

Ensure that the external IP address attached to the primary client NIC moves to the secondary on a failover.

1. Make a cURL request to the external IP address and make sure that it is reachable.
2. On the primary instance, perform failover:

   From GUI, navigate to **Configuration > System > High Availability > Action > Force Failover**.

   From CLI, type the following command:

   ```
   force ha failover -f
   <!--NeedCopy-->
   ```

   On the GCP console, goto the Secondary instance. The external IP address must have moved to the client NIC of secondary after failover.
3. Issue a cURL request to the external IP and ensure it is reachable again.

Deploy a VPX high-availability pair with private IP address on Google Cloud Platform

September 14, 2021

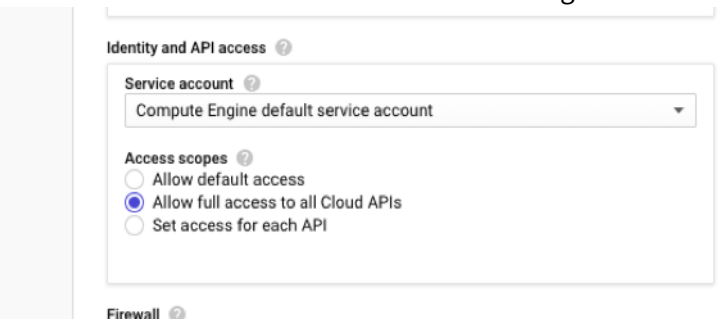
You can deploy a VPX high-availability pair on GCP using private IP address. The client IP (VIP) must be configured as alias IP address on the primary node. Upon failover, the Client IP address is moved to the secondary node, for the traffic to resume.

For more information on high availability, see High Availability.

Before you start

- Read the Limitation, Hardware requirements, Points to note mentioned in Deploy a Citrix ADC VPX instance on Google Cloud Platform. This information applies to high availability deployments also.

- Enable **Cloud Resource Manager API** for your GCP project.
- Allow full access to all Cloud APIs while creating the instances.



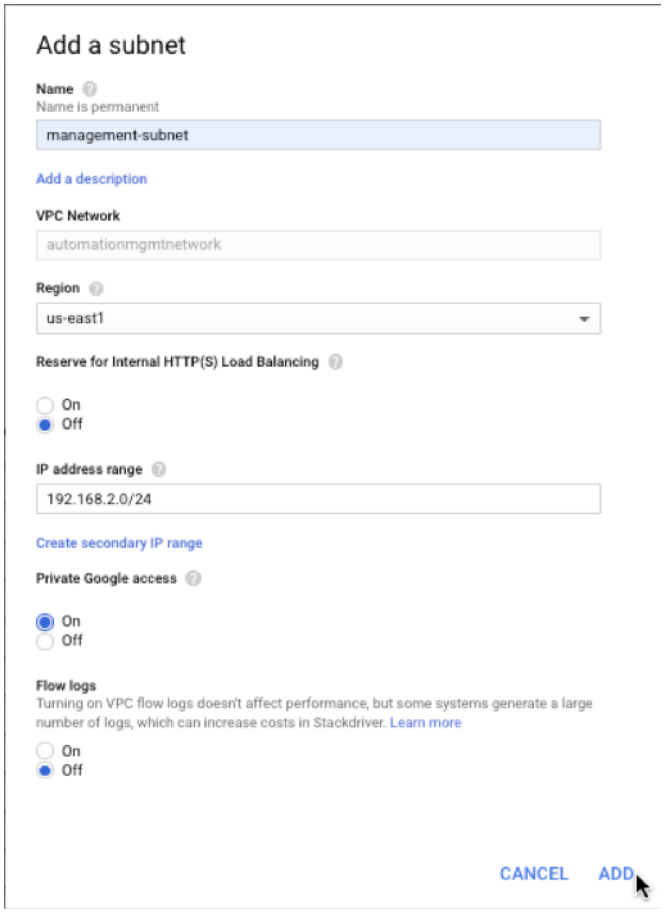
- Ensure that your GCP service account has the following IAM permissions:

```
REQUIRED_INSTANCE_IAM_PERMS = [
 “compute.forwardingRules.list” ,
 “compute.forwardingRules.setTarget” ,
 “compute.instances.setMetadata” ,
"compute.instances.get",
"compute.instances.list",
"compute.instances.updateNetworkInterface",
 “compute.targetInstances.list” ,
 “compute.targetInstances.use” ,
"compute.zones.list",
]
<!--NeedCopy-->
```

- If you have configured external IP addresses on an interface other than the management interface, ensure that your GCP service account has the following additional IAM permissions:

```
REQUIRED_INSTANCE_IAM_PERMS = [
"compute.addresses.use"
"compute.instances.addAccessConfig",
"compute.instances.deleteAccessConfig",
"compute.networks.useExternalIp",
"compute.subnetworks.useExternalIp",
]
<!--NeedCopy-->
```

- If your VMs do not have internet access, you must enable **Private Google Access** on the management subnet.



- If you have configured GCP forwarding rules on the primary node, read the limitations and requirements mentioned in Forwarding rules support for VPX high-availability pair on GCP to update them to new primary on failover.

How to deploy a VPX high availability pair on Google Cloud Platform

Here is a summary of the high availability deployment steps:

1. Create VPC networks in the same region. For example, Asia-east.
2. Create two VPX instances (primary and secondary nodes) on the same region. They can be in the same zone or different zones. For example Asia east-1a and Asia east-Ib.
3. Configure high availability settings on both instances by using the Citrix ADC GUI or ADC CLI commands.

Step 1. Create VPC networks

Create VPC networks based on your requirements. Citrix recommends you to create three VPC networks for associating with management NIC, client NIC, and server NIC.

To create a VPC network, perform these steps:

1. Log on the **Google console > Networking > VPC network > Create VPC Network**.
2. Complete the required fields, and click **Create**.

For more information, see the **Create VPC Networks** section in Deploy a Citrix ADC VPX instance on Google Cloud Platform.

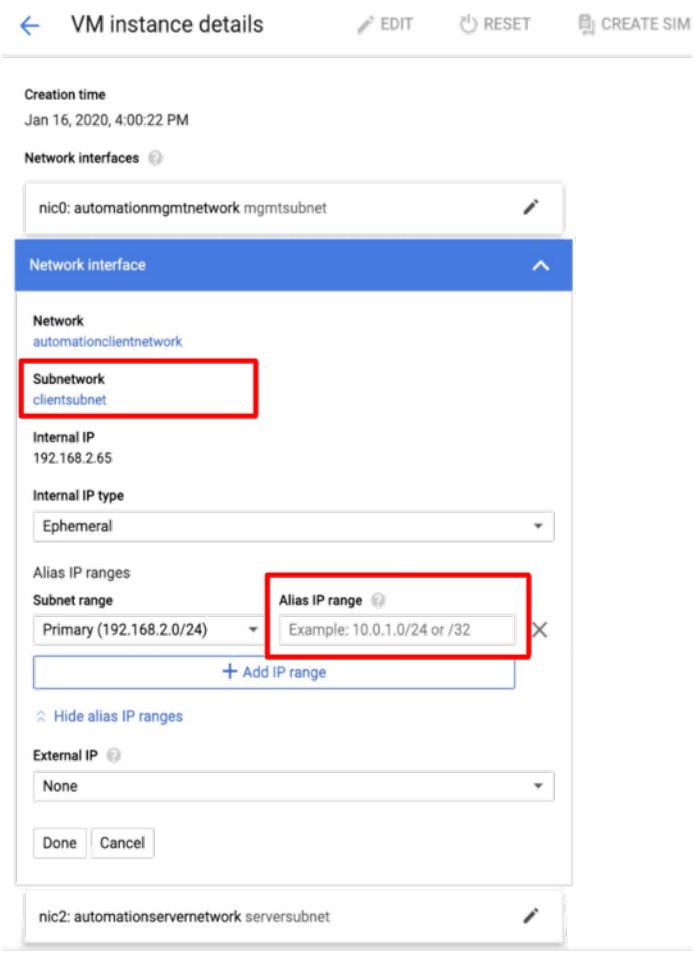
Step 2. Create two VPX instances

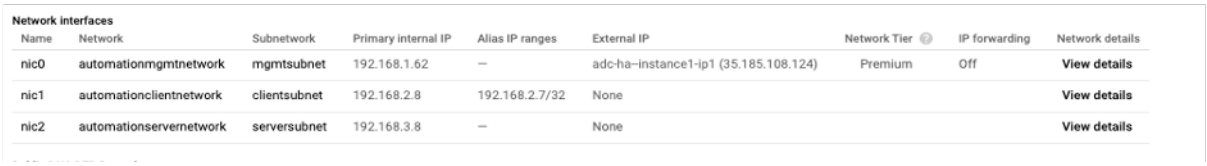
Create two VPX instances by following the steps given in Scenario: deploy a multi-NIC, multi-IP standalone VPX instance.

> **Important:**
>
> Assign a client alias IP address to the primary node. Do not use the internal IP address of the VPX instance to configure the VIP.

To create a client alias IP address, perform these steps:

1. Navigate to the VM instance and click **Edit**.
2. In the **Network Interface** window, edit the client interface.
3. In the **Alias IP range** field, enter the client alias IP address.





After the failover, when the old primary becomes the new secondary, the alias IP addresses move from the old primary and is attached to the new primary.

After you have configured the VPX instances, you can configure the Virtual (VIP) and Subnet IP (SNIP) addresses. For more information, see Configuring Citrix ADC-owned IP addresses.

Step 3. Configure high availability

After you've created the instances on Google Cloud Platform, you can configure high availability by using the Citrix ADC GUI or CLI.

Configure high availability by using the GUI

Step 1. Set up high availability in INC Enabled mode on both the nodes.

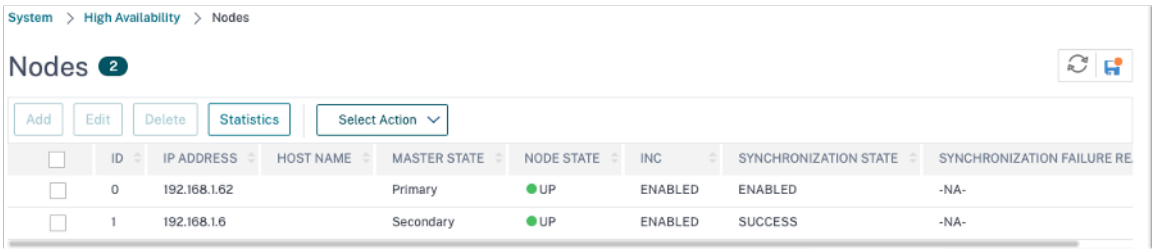
On the **primary node**, perform the following steps:

1. Log on to the instance with user name `nsroot` and instance ID of the node from GCP console as the password.
2. Navigate to **Configuration > System > High Availability > Nodes**, and click **Add**.
3. In the **Remote Node IP address** field, enter the private IP address of the management NIC of the secondary node.
4. Select the **Turn on INC (Independent Network Configuration) mode on self node** check box.
5. Click **Create**.

On the **secondary node**, perform the following steps:

1. Log on to the instance with user name `nsroot` and instance ID of the node from GCP console as the password.
2. Navigate to **Configuration > System > High Availability > Nodes**, and click **Add**.
3. In the **Remote Node IP address** field, enter the private IP address of the management NIC of the primary node.
4. Select the **Turn on INC (Independent Network Configuration) mode on self node** check box.
5. Click **Create**.

Before you proceed further, ensure that the Synchronization state of the secondary node is shown as **SUCCESS** in the **Nodes** page.



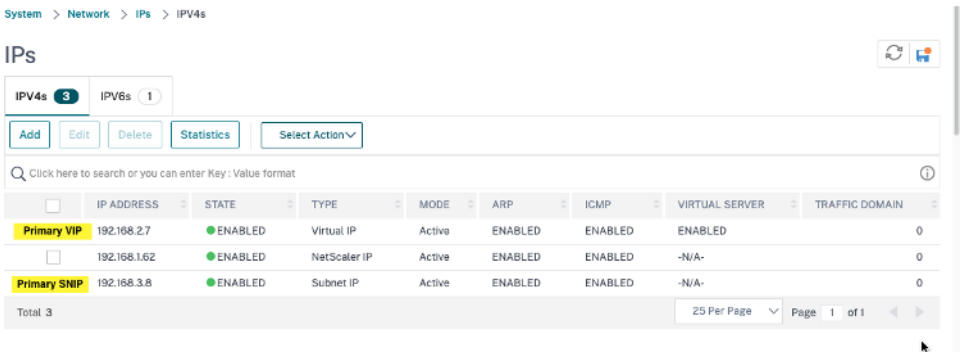
> **Note**
>
> Now, the secondary node has the same log-on credentials as the primary node.

Step 2. Add Virtual IP address and Subnet IP address on both the nodes.

On the primary node, perform the following steps:

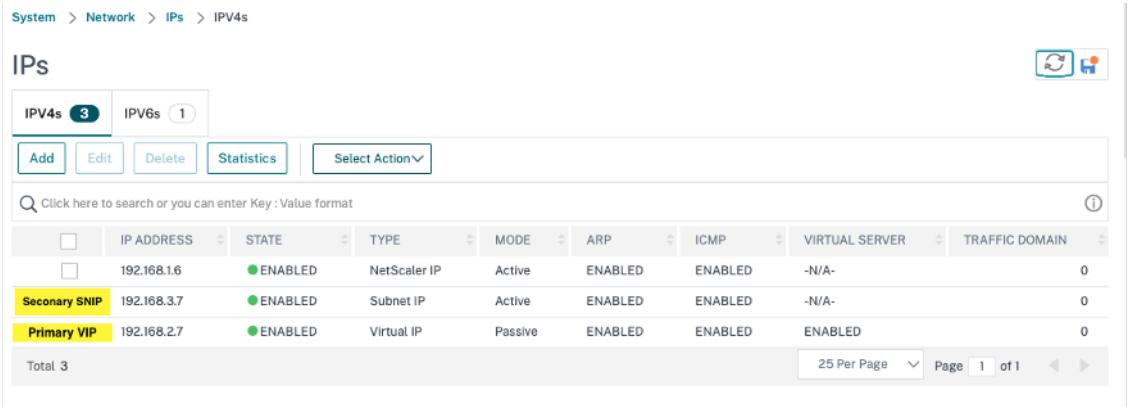
1. Navigate to **System > Network > IPs > IPv4s**, and click **Add**.
2. To create a client alias IP (VIP) address:
   a) Enter the Alias IP address and netmask configured for the client subnet in the VM instance.
   b) In the **IP Type** field, select **Virtual IP** from the drop-down menu.
   c) Click **Create**.
3. To create a server IP (SNIP) address:

a) Enter the internal IP address of the server-facing interface of the primary instance and netmask configured for the server subnet.
b) In the **IP Type** field, select **Subnet IP** from the drop-down menu.
c) Click **Create**.



On the secondary node, perform the following steps:

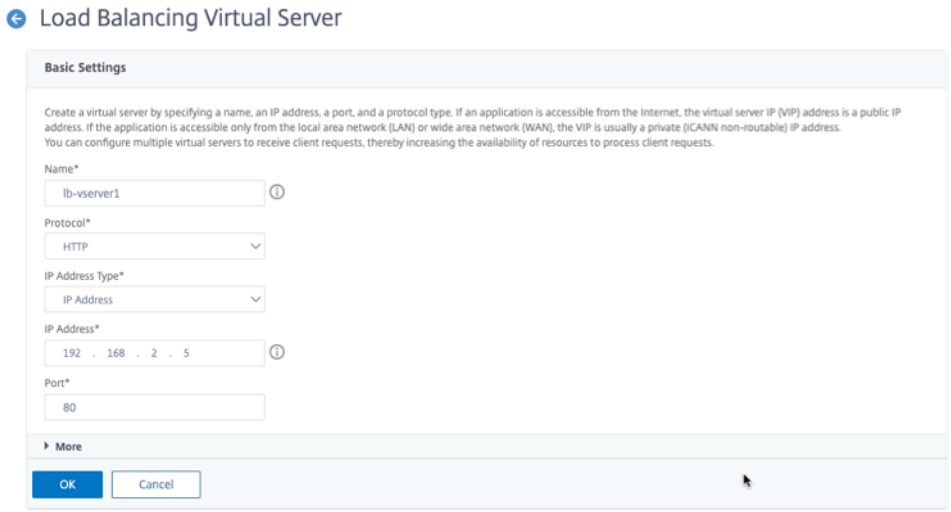
1. Navigate to **System > Network > IPs > IPv4s**, and click **Add**.
2. To create a client alias IP (VIP) address:
   a) Enter the Alias IP address and netmask configured for the client subnet on the primary VM instance.
   b) In the **IP Type** field, select **Subnet IP** from the drop-down menu.
   c) Click **Create**.
3. To create a server IP (SNIP) address:
   a) Enter the internal IP address of the server-facing interface of the secondary instance and netmask configured for the server subnet.
   b) In the **IP Type** field, select **Subnet IP** from the drop-down menu.
   c) Click **Create**.



Step 3. Add a load balancing virtual server on the primary node.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers > Add**.

2. Add the required values for Name, Protocol, IP Address Type (IP Address), IP Address (primary client alias IP address) and Port, and click **OK**.



Step 4. Add a service or service group on the primary node.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Services > Add**.
2. Add the required values for Service Name, IP Address, Protocol and Port, and click **OK**.

Step 5. Bind the service or service group to the load balancing virtual server on the primary node.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**.
2. Select the load balancing virtual server configured in **Step 3**, and click **Edit**.
3. In the **Service and Service Groups** tab, click **No Load Balancing Virtual Server Service Binding**.
4. Select the service configured in the **Step 4**, and click **Bind**.

Step 5. Save the configuration.

After a forced failover, the secondary becomes the new primary. The client alias IP (VIP) and the server alias IP (SNIP) from the old primary moves to the new primary.

Configure high availability by using the CLI

Step 1. Set up high availability in **INC Disabled** mode in both the instances by using the Citrix ADC CLI.

On the primary node, type the following command.

```
1 add ha node 1 <sec_ip> -inc ENABLED
2 <!--NeedCopy-->
```

On the secondary node, type the following command.

```
add ha node 1 <prim_ip> -inc ENABLED
<!--NeedCopy-->
```

The `sec_ip` refers to the internal IP address of the management NIC of the secondary node.

The `prim_ip` refers to the internal IP address of the management NIC of the primary node.

Step 2. Add VIP and SNIP on both nodes.

Type the following commands on the primary node:

```
add ns ip <primary_client_alias_ip> <subnet> -type VIP

<!--NeedCopy-->
```

> **Note:**
>
> Enter the Alias IP address and netmask configured for the client subnet in the VM instance.

```
add ns ip <primary_snip> <subnet> -type SNIP
<!--NeedCopy-->
```

The `primary_snip` refers to the internal IP address of the server-facing interface of the primary instance.

Type the following commands on the secondary node:

```
add ns ip <primary_client_alias_ip> <subnet> -type VIP
<!--NeedCopy-->
```

> Note
>
> Enter the Alias IP address and netmask configured for the client subnet on the primary VM instance.

```
add ns ip <secondary_snip> <subnet> -type SNIP
<!--NeedCopy-->
```

The `secondary_snip` refers to the internal IP address of the server-facing interface of the secondary instance.

> **Note:**
>
> Enter the IP address and netmask configured for the server subnet in the VM instance.

Step 3. Add a virtual server on the primary node.

Type the following command:

```
add <server_type> vserver <vserver_name> <protocol> <
    primary_client_alias_ip> <port>
<!--NeedCopy-->
```

Step 4. Add a service or service group on the primary node.

Type the following command:

```
add service <service_name> <service_ip_address> <protocol> <port>
<!--NeedCopy-->
```

Step 5. Bind the service or service group to the load balancing virtual server on the primary node.

Type the following command:

```
bind <server_type> vserver <vserver_name> <service_name>
<!--NeedCopy-->
```

> **Note:**
>
> To save your configuration, type the command `save config`. Otherwise, the configurations are lost after you restart the instances.

Add back-end GCP Autoscaling service

September 14, 2021

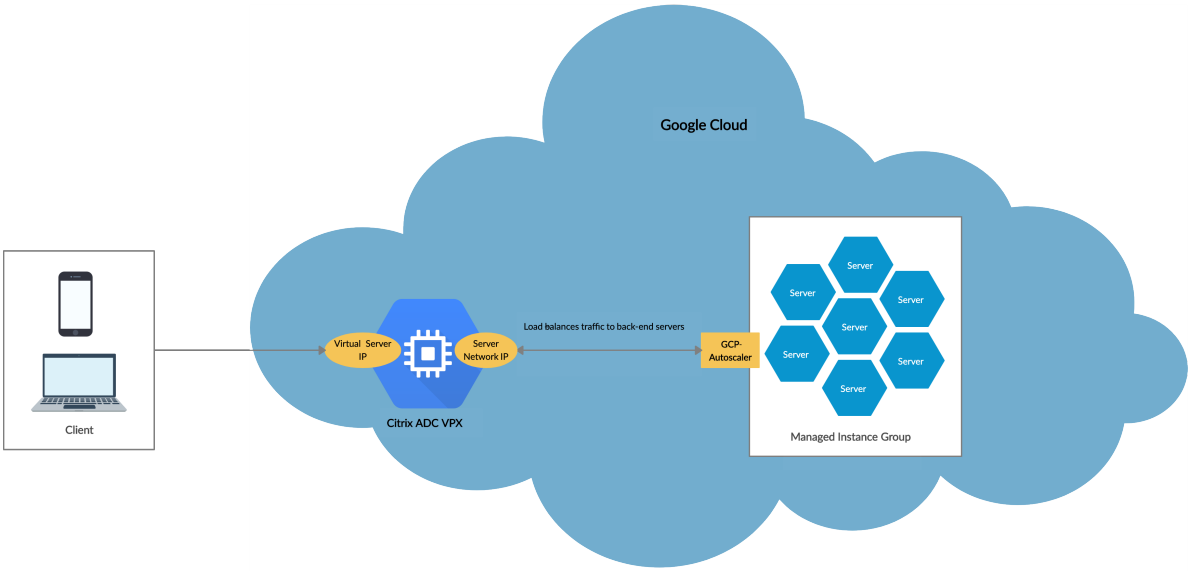
Efficient hosting of applications in a cloud requires easy and cost-effective management of resources, depending on the application demand. To meet the increasing demand, you have to scale network resources upward. When demand subsides, you need to scale down to avoid the unnecessary cost of underutilized resources. To minimize the cost of running the application, you have to constantly monitor traffic, memory and CPU use, and so on. However, monitoring traffic manually is cumbersome. For the application environment to scale up or down dynamically, you must automate the processes of monitoring traffic and of scaling resources up and down whenever necessary.

Integrated with the GCP Autoscaling service, the Citrix ADC VPX instance provides the following advantages:

- **Load balance and management**: Auto configures servers to scale up and scale down, depending on demand. The VPX instance auto detects managed instance groups in the back-end subnet and allows you to select the managed instance groups to balance the load. The virtual and subnet IP addresses are auto configured on the VPX instance.

- **High availability**: Detects managed instance groups that span multiple zones and load-balance servers.
- **Better network availability**: The VPX instance supports:
  - Back-end servers on same placement groups
  - Back-end servers on different zones

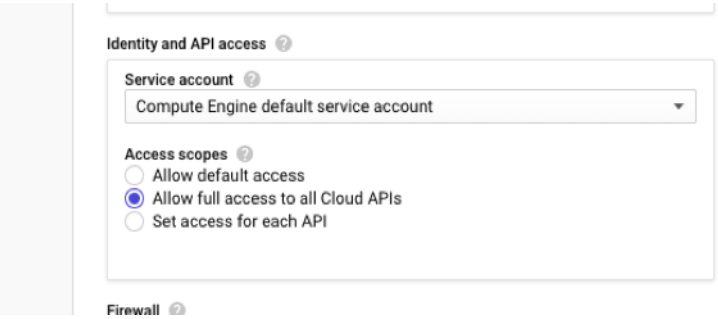
This diagram illustrates how the GCP Autoscaling service works in a Citrix ADC VPX instance acting as the load balancing virtual server.



Before you begin

Before you start using Autoscaling with your Citrix ADC VPX instance, you must complete the following tasks.

- Create a Citrix ADC VPX instance on GCP according to your requirement.
  - For more information about how to create a Citrix ADC VPX instance, see Deploy a Citrix ADC VPX instance on the Google Cloud Platform.
  - For more information about how to deploy VPX instances in HA mode, see Deploy a VPX high-availability pair on the Google Cloud Platform.
- Enable **Cloud Resource Manager API** for your GCP project.
- Allow full access to all Cloud APIs while creating the instances.



- Ensure your GCP service account has the following IAM permissions:

```
REQUIRED_INSTANCE_IAM_PERMS = [

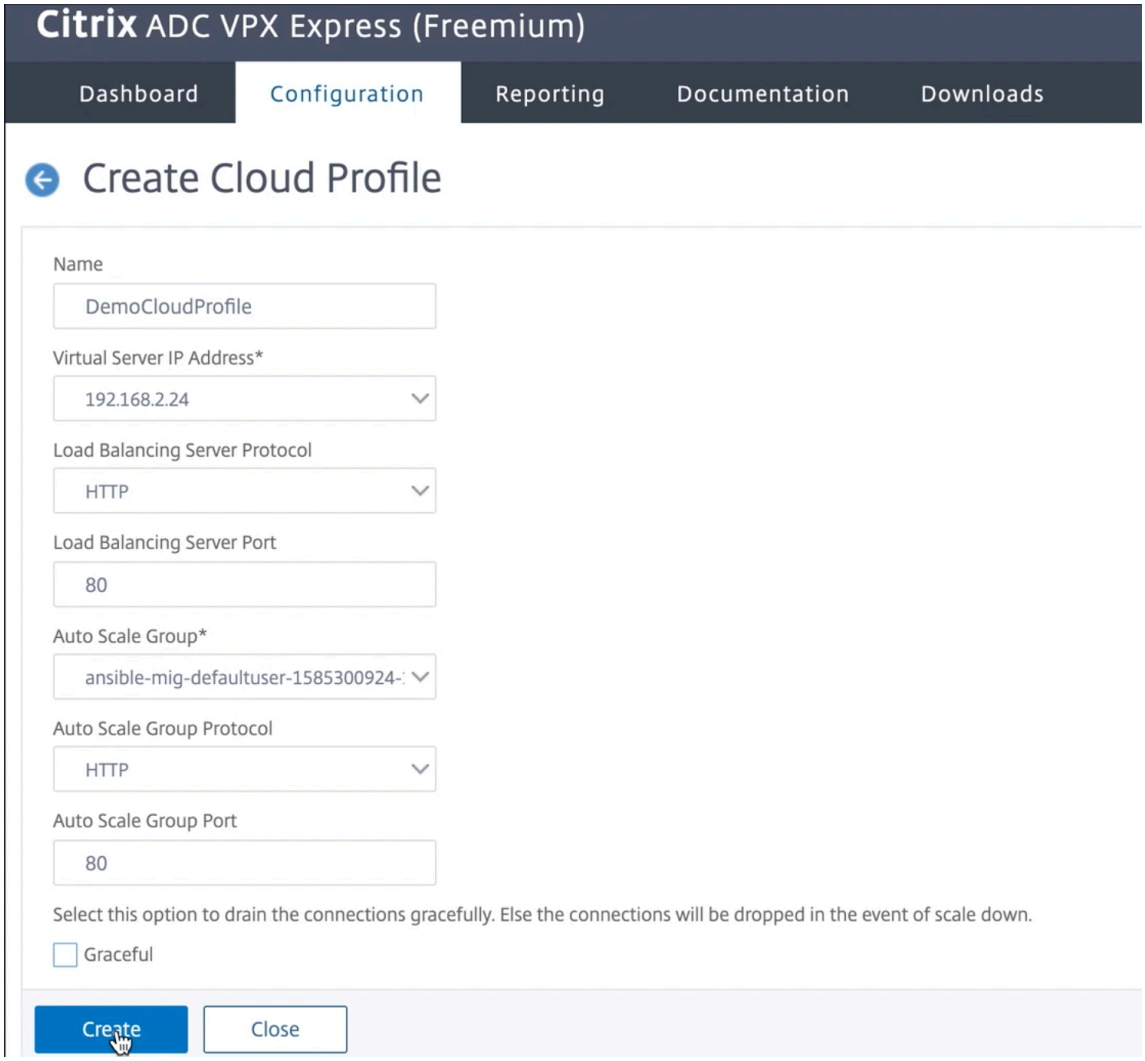
"compute.instances.get",
"compute.zones.list",
"compute.instanceGroupManagers.list",
"compute.instanceGroupManagers.get"
]
<!--NeedCopy-->
```

- To set up Autoscaling, ensure the following are configured:
  - Instance template
  - Managed Instance group
  - Autoscaling policy

Add the GCP Autoscaling service to a Citrix ADC VPX instance

You can add the Autoscaling service to a VPX instance with a single click by using the GUI. Complete these steps to add the Autoscaling service to the VPX instance:

1. Log on to the VPX instance by using your credentials for `nsroot`.
2. When you log on to the Citrix ADC VPX instance for the first time, you see the default Cloud Profile page. Select the GCP managed instance group from the drop-down menu and click **Create** to create a cloud profile.

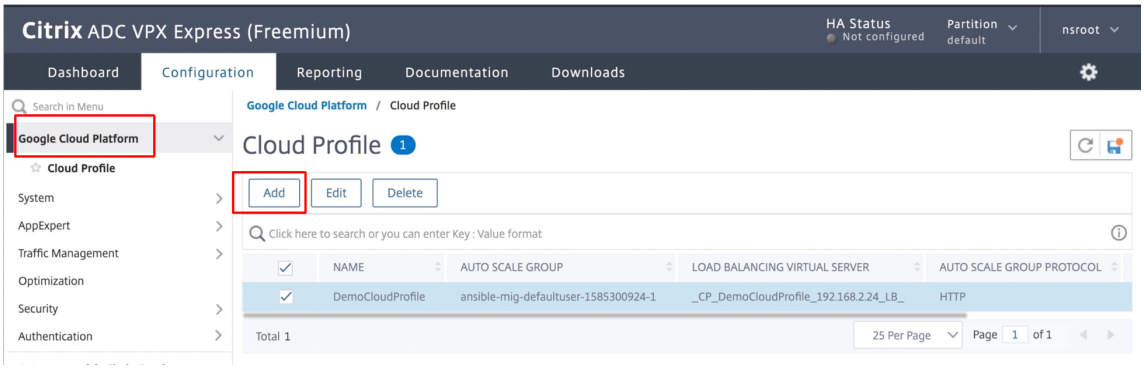


- The **Virtual Server IP Address** field is auto-populated from all the IP addresses associated with the instances.
- The **Autoscale Group** is prepopulated from the managed instance group configured on your GCP account.
- When selecting the **Autoscale Group Protocol** and **Autoscale Group Port**, ensure that your servers listen on the configured protocol and ports. Bind the correct monitor in the service group. By default, the TCP monitor is used.
- Clear the **Graceful** check box because it is not supported.

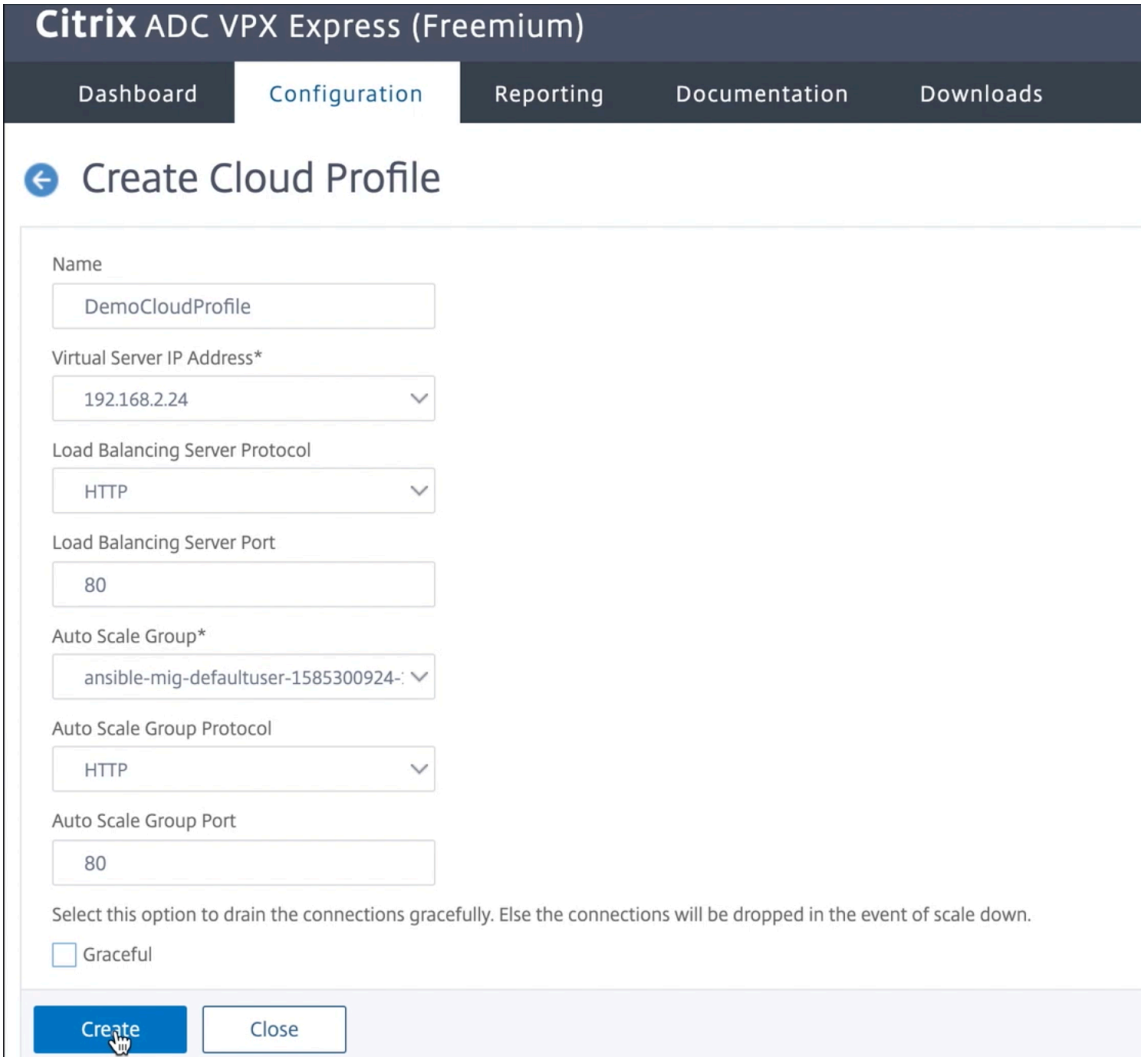
> Note:
>
> For SSL Protocol type Autoscaling, after you create the Cloud Profile, the load balance virtual server or service group is down because of a missing certificate. You can bind the certificate to the virtual server or service group manually.

3. After the first time logon if you want to create Cloud Profile, on the GUI go to **System > Google**

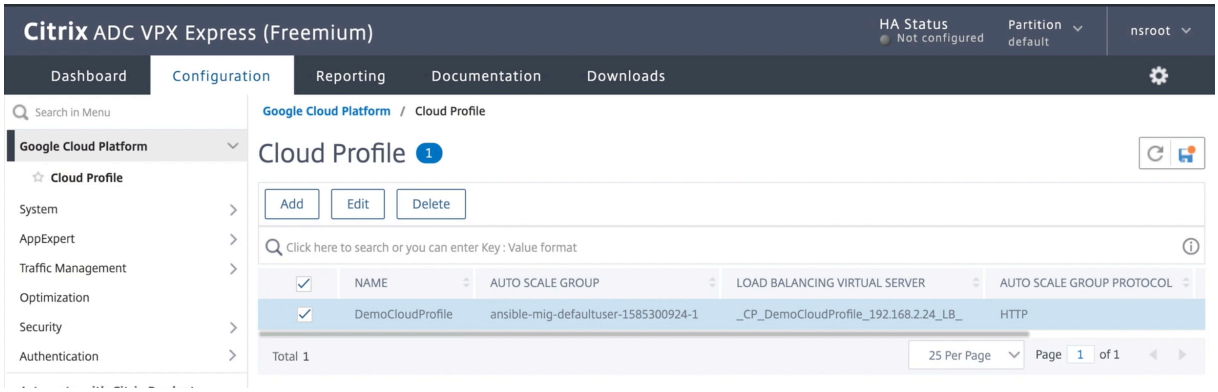
Cloud Platform > Cloud Profile and click **Add**.



The **Create Cloud Profile** configuration page appears.



Cloud Profile creates a Citrix ADC load-balancing virtual server and a service group with members as the servers of the managed instance group. Your back-end servers must be reachable through the SNIP configured on the VPX instance.



VIP scaling support for Citrix ADC VPX instance on GCP

September 14, 2021

A Citrix ADC appliance resides between the clients and the servers, so that client requests and server responses pass through it. In a typical installation, virtual servers configured on the appliance provide connection points that clients use to access the applications behind the appliance. The number of public virtual IP (VIP) addresses needed for a deployment varies on a case-by-case basis.

The GCP architecture restricts each interface on the instance to be connected to a different VPC. A VPC on GCP is a collection of subnets, and each subnet can span across zones of a region. In addition, GCP imposes the following limitation:

- There is a 1:1 mapping of number of public IP addresses to number of NICs. Only one public IP address can be assigned to a NIC.
- A maximum of only 8 NICs can be attached on a higher capacity instance type.

For example, an n1-standard-2 instance can have only 2 NICs, and the Public VIPs that can be added is limited to 2. For more information, see VPC resource quotas.

To achieve higher scales of public virtual IP addresses on a Citrix ADC VPX instance, you can configure the VIP addresses as part of the metadata of the instance. The ADC VPX instance internally uses forwarding rules provided by the GCP to achieve VIP scaling. The ADC VPX instance also provides high availability to the VIPs configured.
After you configure VIP addresses as part of the metadata, you can configure an LB virtual server using the same IP that is used to create the forwarding rules. Thus, we can use forwarding rules to mitigate the limitations we have w.r.t scale in using public VIP addresses on an ADC VPX instance on GCP.

For more information on forwarding rules, see Forwarding rules overview.

For more information on HA, see High Availability.

Points to note

- Google charges some additional cost for each virtual IP forwarding rule. The actual cost depends on the number of entries created. The associated cost can be found from the Google pricing documents.
- Forwarding rules are applicable only for public VIPs. You can use alias IP addresses when the deployment needs private IP addresses as VIPs.
- You can create forwarding rules only for the protocols, which need the LB virtual server. VIPs can be created, updated, or deleted on the fly. You can also add a new load balancing virtual server with the same VIP address but with a different protocol.

Before you start

- Citrix ADC VPX instance must be deployed on GCP.
- External IP address must be reserved. For more information, see Reserving a static external IP address.
- Ensure that your GCP service account has the following IAM permissions:

```
REQUIRED_IAM_PERMS = [
"compute.addresses.list",
"compute.addresses.get",
"compute.addresses.use",
"compute.forwardingRules.create",
"compute.forwardingRules.delete",
"compute.forwardingRules.get",
"compute.forwardingRules.list",
"compute.instances.use",
"compute.subnetworks.use",
"compute.targetInstances.create"
"compute.targetInstances.get"
"compute.targetInstances.use",
]

<!--NeedCopy-->
```

Configure external IP addresses for VIP scaling on Citrix ADC VPX instance

1. In the Google Cloud Console, navigate to the **VM Instances** page.
2. Create a new VM instance or use an existing instance.
3. Click the instance name. On the **VM instance details** page, click **Edit**.

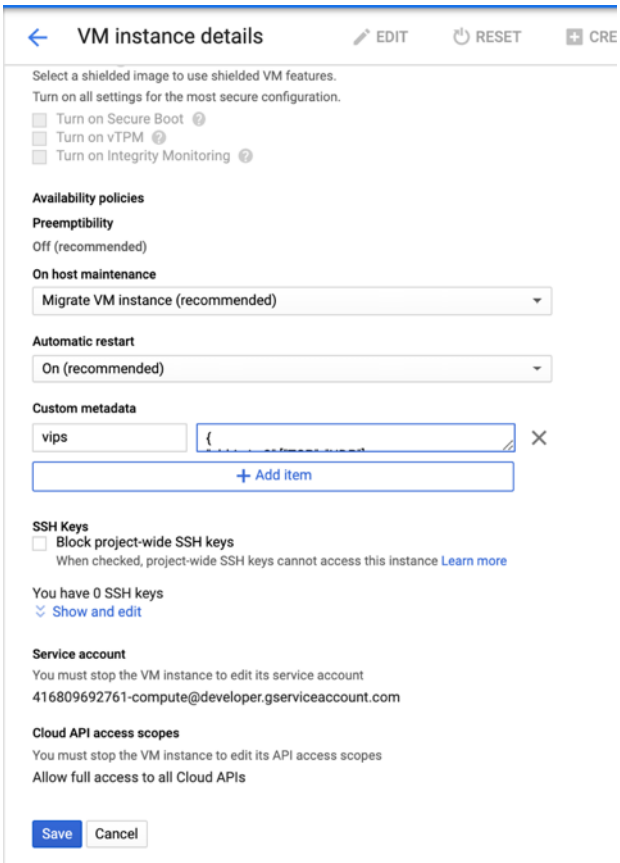
4. Update the **Custom metadata** by entering the following:

   - Key = vips
   - Value = Provide a value in the following JSON format:

     {
     “Name of external reserved IP”: [list of protocols],
     }

   GCP supports the following protocols:

   - AH
   - ESP
   - ICMP
   - SCT
   - TCP
   - UDP



For more information, see Custom metadata.

Example for Custom metadata:

{
“external-ip1-name”:[“TCP”, “UDP”],

“external-ip2-name”:[“ICMP”, “AH”]
}

In this example, the ADC VPX instance internally creates one forwarding rule for each IP, protocol pair. The metadata entries are mapped to the forwarding rules. This example helps you understand how many forwarding rules are created for a metadata entry.

Four forwarding rules are created as follows:

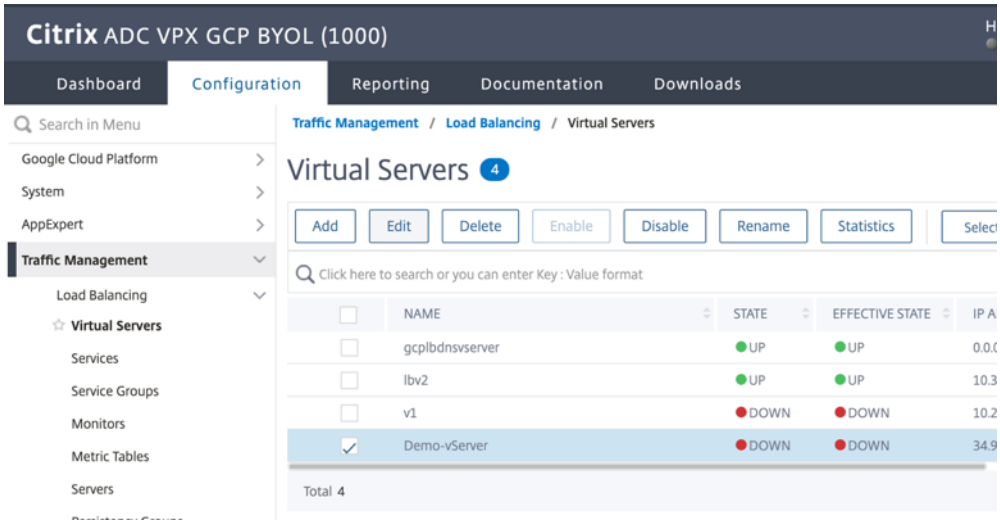
a) external-ip1-name and TCP
b) external-ip1-name and UDP
c) external-ip2-name and ICMP
d) external-ip2-name and AH

5. Click **Save**.

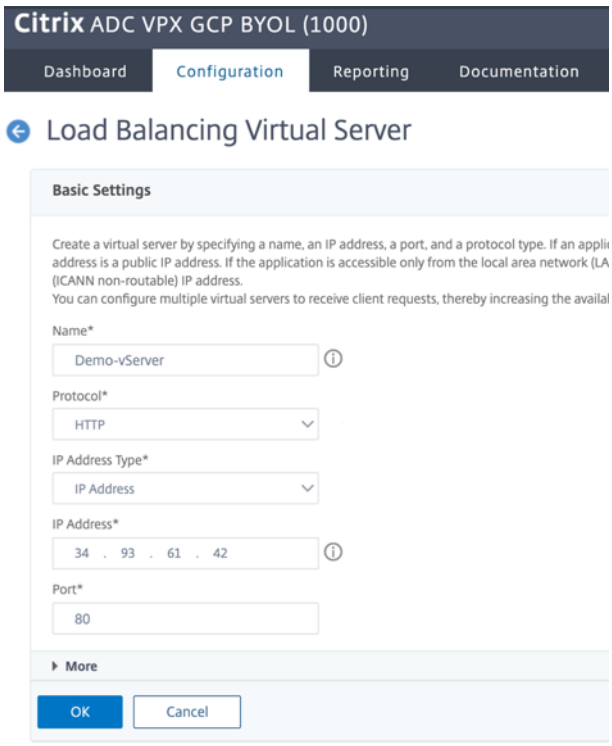
Setting up a load balancing virtual server with external IP address on a Citrix ADC VPX instance

Step 1. Add a load balancing virtual server.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers > Add**.

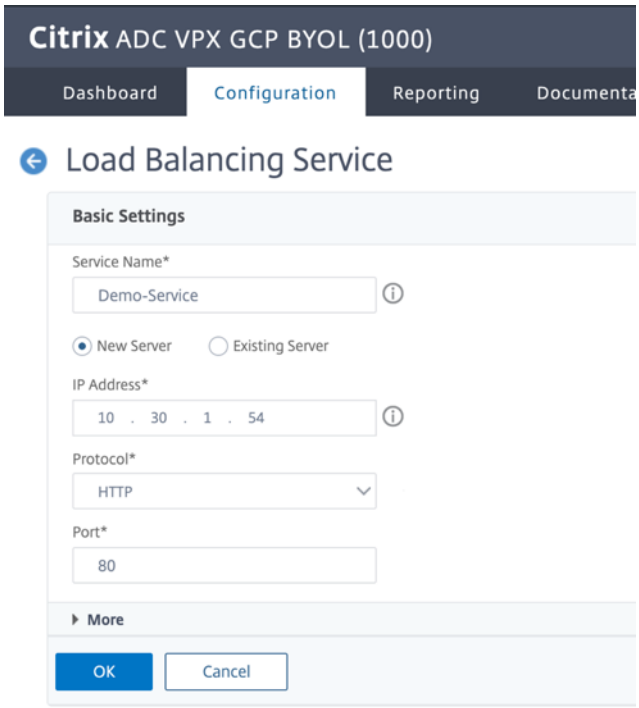


2. Add the required values for Name, Protocol, IP Address Type (IP Address), IP Address (External IP address of the forwarding rule that is added as VIP on ADC) and Port, and click **OK**.



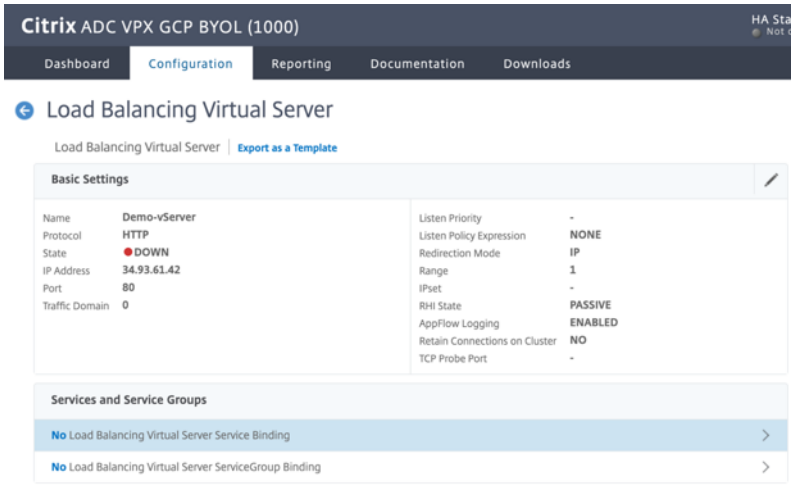
Step 2. Add a service or service group.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Services > Add**.
2. Add the required values for Service Name, IP Address, Protocol and Port, and click **OK**.

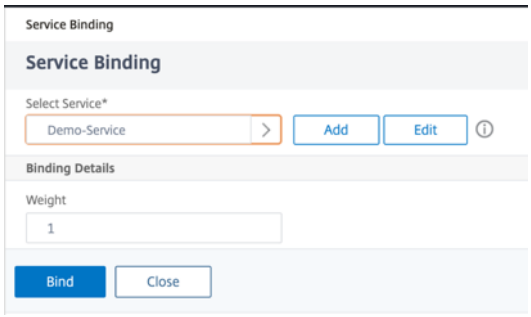


Step 3. Bind the service or service group to the load balancing virtual server.

1. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**.
2. Select the load balancing virtual server configured in **Step 1**, and click **Edit**.
3. In the **Service and Service Groups** page, click **No Load Balancing Virtual Server Service Binding**.



4. Select the service configured in the **Step 3**, and click **Bind**.



5. Save the configuration.

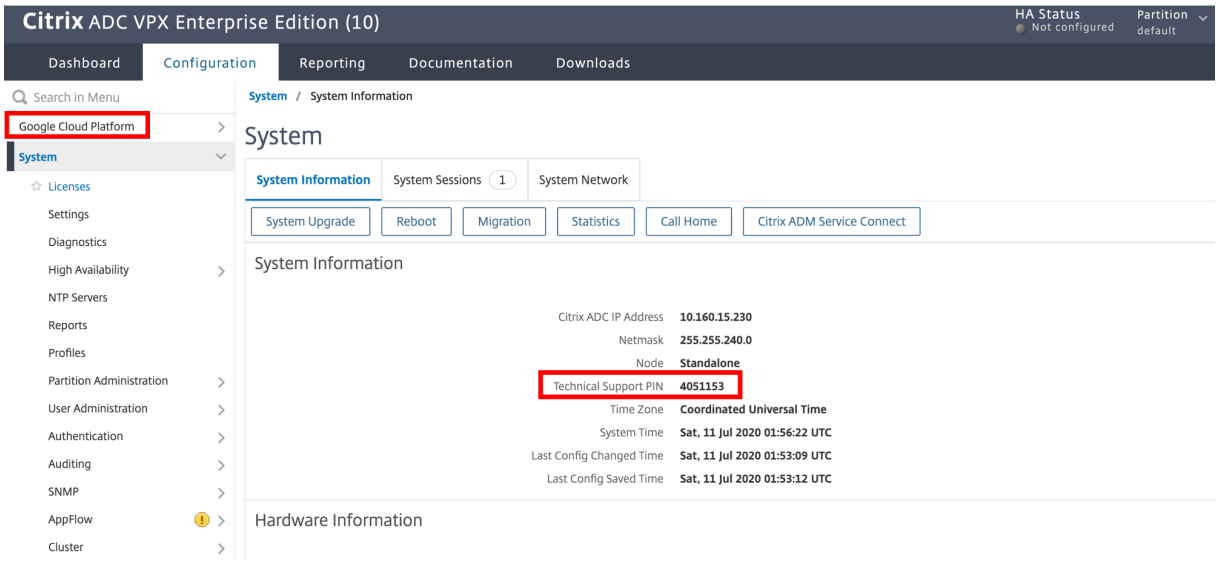
Troubleshoot a VPX instance on GCP

September 14, 2021

Google Cloud Platform (GCP) provides console access to a Citrix ADC VPX instance. You can debug only if the network is connected. To view an instance's System Log, access the console and check **System Log files**.

Citrix supports fee based Citrix ADC VPX instances (utility license with hourly fee) on GCP. To file a support case, find your GCP account number and support PIN code, and call Citrix support. You are asked to provide your name and email address. To find the support PIN, log on to the VPX GUI and navigate to the **System** page.

Here is an example of a system page showing the support PIN.



Jumbo frames on Citrix ADC VPX instances

September 14, 2021

Citrix ADC VPX appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A Citrix ADC appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

For more information, seeConfiguring Jumbo Frames Support on a Citrix ADC Appliance.

Jumbo frames support is available on Citrix ADC VPX appliances running on the following virtualization platforms:

- VMware ESX
- Linux-KVM Platform
- Citrix XenServer
- Amazon Web Services (AWS)

Jumbo frames on VPX appliances work similar to jumbo frames on MPX appliances. For more information on Jumbo Frames and its use cases, see Configuring Jumbo Frames on MPX appliances. The use cases of jumbo frames on MPX appliances also apply to VPX appliances.

Configure jumbo frames for a VPX instance running on VMware ESX

Perform the following tasks to configure jumbo frames on a Citrix ADC VPX appliance running on the VMware ESX server:

1. Set the MTU of the interface or channel of the VPX appliance to a value in the range 1501–9000. Use the CLI or GUI to set the MTU size. The Citrix ADC VPX appliances running on VMware ESX support receiving and transmitting jumbo frames containing up to only 9000 bytes of IP data.
2. Set the same MTU size on the corresponding physical interfaces of the VMware ESX server by using its management applications. For more information about setting the MTU size on the physical interfaces of VMware ESX, see http://vmware.com/.

Configure jumbo frames for a VPX instance running on Linux-KVM server

Perform the following tasks to configure jumbo frames on a Citrix ADC VPX appliance running on a Linux-KVM Server:

1. Set the MTU of the interface or channel of the VPX appliance to a value in the range 1501–9216. Use the Citrix ADC VPX CLI or GUI to set the MTU size.
2. Set the same MTU size on the corresponding physical interfaces of a Linux-KVM Server by using its management applications. For more information about setting the MTU size on the physical interfaces of Linux-KVM, see http://www.linux-kvm.org/.

Configure jumbo frames for a VPX instance running on Citrix XenServer

Perform the following tasks to configure jumbo frames on a Citrix ADC VPX appliance running on Citrix XenServer:

1. Connect to the XenServer using XenCenter.
2. Shut down all the VPX instances that use the Networks for which the MTU must be changed.
3. On the **Networking** tab, select the network - network 0/1/2.
4. Select **Properties** and edit MTU.

After configuring the jumbo frames on the XenServer, you can configure the jumbo frames on the ADC appliance. For more information, see Configuring Jumbo Frames Support on a Citrix ADC Appliance.

Configure jumbo frames for a VPX instance running on AWS

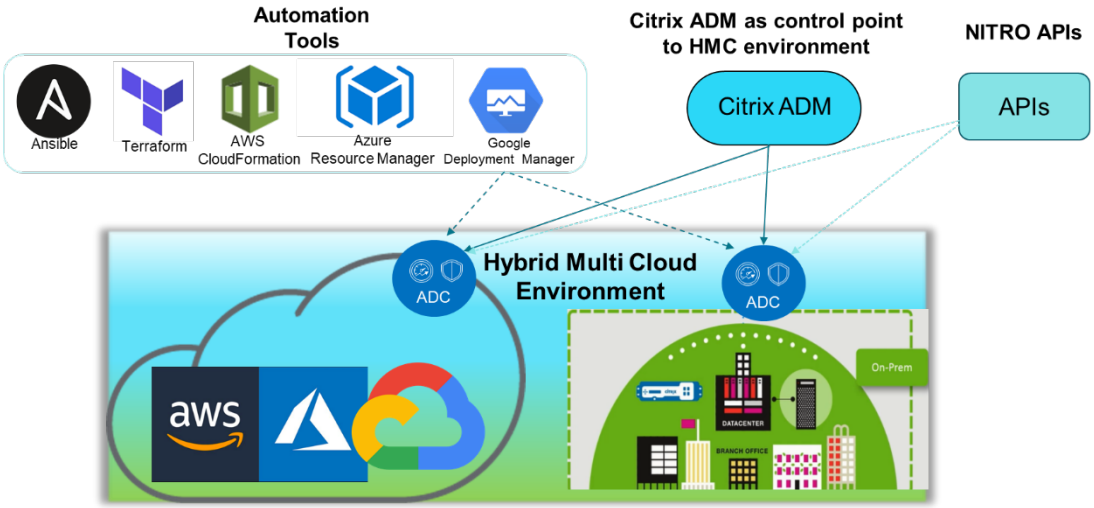
Host-level configuration is not required for VPX on Azure. To configure Jumbo Frames on VPX, follow the steps given in Configuring Jumbo Frames Support on a Citrix ADC Appliance.

Automate deployment and configurations of Citrix ADC

September 14, 2021

Citrix ADC provides multiple tools to automate your ADC deployments and configurations. This document provides a brief summary of various automation tools and references to various automation resources that you can use to manage ADC configurations.

The following illustration provides an overview of Citrix ADC automation in a hybrid multi cloud (HMC) environment.



Automate Citrix ADC using Citrix ADM

Citrix ADM acts as automation control point to your distributed ADC infrastructure. The Citrix ADM provides comprehensive set of automation capabilities from provisioning ADC appliances to upgrading it. The following are the key automation features of ADM:

- Provisioning Citrix ADC VPX instances on AWS
- Provisioning Citrix ADC VPX instances on Azure
- StyleBooks
- Configuration jobs
- Configuration audit
- ADC upgrades

- SSL certificate management
- Integrations - GitHub, ServiceNow, Event notifications integrations

Citrix ADM blogs and videos on automation

- Application migrations using StyleBooks
- Integrate ADC configurations with CI/CD using ADM StyleBooks
- Simplifying public cloud Citrix ADC deployments through ADM
- 10 ways Citrix ADM service supports easier Citrix ADC upgrades

Citrix ADM also provides APIs for its various capabilities that integrate Citrix ADM and Citrix ADC as part of the overall IT automation. For more information, see Citrix ADM Service APIs.

Automate Citrix ADC using Terraform

Terraform is a tool that takes infrastructure as code approach to provision and manage cloud, infrastructure, or service. Citrix ADC terraform resources are available in GitHub for use. Refer GitHub for detailed documentation and usage.

- Citrix ADC Terraform modules to configure ADC for various use cases such as Load Balancing and GSLB
- Terraform cloud scripts to deploy ADC in AWS
- Terraform cloud scripts to deploy ADC in Azure

Videos on Terraform for ADC automation

- Automate your Citrix ADC deployments with Terraform
- Provision and configure ADC in HA setup in AWS using Terraform

Automate Citrix ADC using Ansible

Ansible is an open-source software provisioning, configuration management, and application-deployment tool enabling infrastructure as code. Citrix ADC Ansible modules and sample playbooks can be found in GitHub for use. Refer GitHub for detailed documentation and usage.

- Ansible modules to configure ADC
- Automate ADC with Ansible-whitepaper
- Ansible modules for ADM

Citrix is a certified Ansible Automation Partner. Users having Red Hat Ansible Automation Platform subscription can access Citrix ADC Collections from Red Hat Automation Hub.

Terraform and Ansible automation blogs

- Terraform and Ansible Automation for app delivery and security

Public cloud templates for ADC deployments

Public cloud templates simplify provisioning of your deployments in public clouds. Different Citrix ADC templates are available for various environments. For usage details, refer to respective GitHub repositories.

AWS CFTs:

- CFTs to provision Citrix ADC VPX on AWS

Azure Resource Manager (ARM) Templates:

- ARM templates to provision Citrix ADC VPX on Azure

Google Cloud Deployment Manager (GDM) Templates:

- GDM templates to provision Citrix ADC VPX on Google

Videos on Templates

- Deploy Citrix ADC HA in AWS using CloudFormation Template
- Deploy Citrix ADC HA across Availability Zones using AWS QuickStart
- Citrix ADC HA deployment in GCP using GDM templates

AWS Quick Starts

- Citrix WAF Quick Start
- AWS Quick Start for Citrix ADC VPX for Web Applications on AWS

NITRO APIs

The Citrix ADC NITRO protocol allows you to programmatically configure and monitor the Citrix ADC appliance by using Representational State Transfer (REST) interfaces. Therefore, NITRO applications can be developed in any programming language. For applications that must be developed in Java or .NET or Python, NITRO APIs are exposed through relevant libraries that are packaged as separate Software Development Kits (SDKs).

- NITRO API documentation
- Citrix ADC API reference
- Sample ADC use case configuration using NITRO API

FAQs

September 14, 2021

The following section helps you to categorize the FAQs based on Citrix Application Delivery Controller (ADC) VPX.

- Feature and functionality
- Encryption
- Pricing and packaging
- Citrix ADC VPX Express
- Hypervisor
- Capacity planning or sizing
- System requirements
- Other technical FAQs

Feature and functionality

What is Citrix ADC VPX?

Citrix ADC VPX is a virtual ADC appliance that can be hosted on a Hypervisor installed on industry standard servers.

Does Citrix ADC VPX include all the web application optimization functionality as ADC appliances?

Yes. Citrix ADC VPX includes all load balancing, traffic management, application acceleration, application security (including Citrix ADC Gateway and Citrix Application Firewall), and offload functionality. For a complete overview of the Citrix ADC feature and functionality, see Application delivery your way.

Are there any limitations with Citrix Application Firewall when using it on Citrix ADC VPX?

Citrix Application Firewall on Citrix ADC VPX provides the same security protections as it does on Citrix ADC appliances. Performance or throughput of Citrix Application Firewall varies by platform.

Are there any differences between Citrix ADC Gateway on Citrix ADC VPX and Citrix ADC Gateway on Citrix ADC appliances?

Functionally, they are identical. Citrix ADC Gateway on Citrix ADC VPX supports all the Citrix ADC Gateway features available in Citrix ADC software release 9.1. However, because Citrix ADC appliances provide dedicated SSL acceleration hardware, it offers greater SSL VPN scalability than a Citrix ADC VPX instance.

Other than the obvious difference of being able to run on a Hypervisor, how does Citrix ADC VPX differ from Citrix ADC physical appliances?

There are two main areas where customers see differences in behavior. The first is Citrix ADC VPX cannot offer the same performance as many Citrix ADC appliances. The second is that while Citrix ADC appliances incorporate its own L2 networking functionality, Citrix ADC VPX relies upon the Hypervisor for its L2 networking services. Generally, it does not limit how the Citrix ADC VPX can be deployed. There can be certain L2 functionality that is configured on a physical Citrix ADC appliance must be configured on the underlying Hypervisor.

How does Citrix ADC VPX play a role in the Application Delivery market?

Citrix ADC VPX changes the game in the application delivery market in the following ways:

- By making a Citrix ADC appliance even more affordable, Citrix ADC VPX enables any IT organization to deploy a Citrix ADC appliance. It is not just for their most mission-critical web applications, but for all of their Web applications.
- Citrix ADC VPX allows customers to further converge networking and virtualization within their data centers. Citrix ADC VPX cannot only be used to optimize web applications hosted on virtualized servers. It also enables web application delivery itself to become a virtualized service that can be easily and rapidly deployed anywhere. IT organizations use the standard data center processes for tasks such as provisioning, automation, and charge-back for the web application delivery infrastructure.
- Citrix ADC VPX opens up new deployment architectures that are not practical if only physical appliances are used. Citrix ADC VPX and Citrix ADC MPX appliances can be used basis, tailored to the individual needs of each respective application to handle processor-intensive actions such as compression and application firewall inspection. At the data center edge, Citrix ADC MPX appliances handle high-volume network-wide tasks such as initial traffic distribution, SSL encryption or decryption, denial of service (DoS) attack prevention, and global load balancing. Pairing high-performance Citrix ADC MPX appliances with easy-to-deploy Citrix ADC VPX virtual appliance brings unparalleled flexibility and customization capabilities to modern, large-scale, data center environments while also reducing overall data center costs.

How does Citrix ADC VPX fit into our Citrix delivery center strategy?

With the availability of Citrix ADC VPX, the entire Citrix delivery center offering is available as a virtualized offering. The entire Citrix delivery center benefits from the powerful management, provisioning, monitoring, and reporting capabilities available in Citrix XenCenter. This can be deployed rapidly into almost any environment, and managed centrally from anywhere. With one integrated, virtualized application delivery infrastructure, organizations can deliver desktops, client-server applications, and Web applications.

Encryption

Does Citrix ADC VPX support SSL offload?

Yes. However, Citrix ADC VPX does all SSL processing in software, so Citrix ADC VPX does not offer the same SSL performance as Citrix ADC appliances. Citrix ADC VPX can support up to 750 new SSL transactions per second.

Does third-party SSL cards installed on the server hosting Citrix ADC VPX accelerate SSL encryption or decryption?

No. Supporting third-party SSL cards cannot associate the Citrix ADC VPX to specific hardware implementations. It greatly diminishes an organizations ability to flexibly host Citrix ADC VPX anywhere within the data center. Citrix ADC MPX appliances must be used when more SSL throughput than Citrix ADC VPX provides is required.

Does Citrix ADC VPX support the same encryption ciphers as physical Citrix ADC appliances?

VPX supports all encryption ciphers as physical Citrix ADC appliances, except the ECDSA.

What is the SSL transactions throughput of Citrix ADC VPX?

See Citrix ADC VPX data sheet for information on SSL transactions throughput.

Pricing and packaging

How is Citrix ADC VPX packaged?

Citrix ADC VPX selection is similar to the selection of Citrix ADC appliances. First, the customer selects the Citrix ADC edition based on its functionality requirements. Then, the customer selects the specific Citrix ADC VPX bandwidth tier based on their throughput requirements. Citrix ADC VPX is available in Standard, Advanced, and Premium Editions. Citrix ADC VPX offers from 10 Mbps (VPX 10) to 100 Gbps (VPX 100G). More details can be found in the Citrix ADC VPX data sheet.

Is Citrix ADC VPX priced the same for all Hypervisors?

Yes.

Are the same Citrix ADC SKUs used for VPX on all Hypervisors?

Yes.

Can a Citrix ADC VPX license be moved from one Hypervisor to another (For example from VMware to Hyper-V)?

Yes. Citrix ADC VPX licenses are independent of the underlying Hypervisor. If you decide to move the Citrix ADC VPX virtual machine from one Hypervisor to another, you do not have to get a new license. However, you might need to rehost the existing Citrix ADC VPX license.

Can Citrix ADC VPX instances be upgraded?

Yes. Both the throughput limits and Citrix ADC family edition can be upgraded. Upgrade SKUs for both types of upgrade are available.

If I want to deploy Citrix ADC VPX in a high availability pair, how many licenses do I need?

As with Citrix ADC physical appliances, a Citrix ADC high availability configuration requires two active instances. Therefore, the customer must purchase two licenses.

Citrix ADC VPX Express and 90-day fee trial

Does Citrix ADC VPX Express include all Citrix ADC standard functionality? Does it include Citrix ADC Gateway and load balancing for Citrix Virtual Apps (formerly XenApp) Web Interface and XML broker?

Yes. Citrix ADC VPX Express includes full Citrix ADC Standard functionality. Starting from Citrix ADC release 12.0–56.20, Citrix modified the VPX express behavior.

Does Citrix ADC VPX Express include all Citrix ADC standard functionality? Does it include Citrix ADC Gateway and load balancing for Citrix Virtual Apps Web Interface and XML broker?

Starting from Citrix ADC release 12.0–56.20, VPX Express offers the Citrix ADC Standard Edition feature set, except Gateway functionality. Earlier to the 12.0–56.20 release, VPX expresses includes all features in the standard edition.

Does Citrix ADC VPX Express require a license?

With the new Citrix ADC VPX Express release (12.0–56.20 and onwards), VPX Express is free and requires no license files to install and comes with no commitment. If you have a VPX Express license already, then the prior VPX Express behavior is preserved. If the VPX Express *license file* is removed and the 12.0–56.20 and onwards release is used, the new VPX express behavior takes effect.

Does the Citrix ADC VPX Express license expire?

With the new VPX express, no. There is no license and no expiry date. If you have a VPX express license already, the license expires one year after download.

Does Citrix ADC VPX Express include the five free Citrix ADC Gateway concurrent licenses?

Yes, if you own a VPX express license.

Is there a limit to how many Citrix ADC VPX Expresses a customer can download?

Five.

Does Citrix ADC VPX Express support the same encryption ciphers as Citrix ADC MPX appliances?

For general availability, all the same strong encryption ciphers supported on Citrix ADC appliances are available on Citrix ADC VPX and Citrix ADC VPX Express. It is subjected to the same import or export regulations.

Can I file technical support cases for Citrix ADC VPX Express?

No. A retail Citrix ADC VPX license such as, VPX-10, VPX-200, VPX-1000, VPX- 3000 is required to file technical support cases. However, Citrix ADC VPX Express users are free to use both the Citrix ADC VPX Knowledge Center, and request help from the community using the Z discussion forums.

Can Citrix ADC VPX Express be upgraded to a retail version?

Yes. Simply purchase the retail Citrix ADC VPX license you need, and then apply the corresponding license to the Citrix ADC VPX Express instance.

Hypervisor

What VMware versions does Citrix ADC VPX support?

Citrix ADC VPX supports both VMware ESX and ESXi for versions 3.5 or later. For more information, see Support matrix and usage guidelines

For VMware, how many virtual network interfaces can you allocate to a VPX?

You can allocate up to 10 virtual network interfaces to a Citrix ADC VPX.

From vSphere, how can we access the Citrix ADC VPX command line?

The VMware vSphere client provides built-in access to the Citrix ADC VPX command line through a console tab. Also, you can use any SSH or Telnet client to access the command line. You can use the NSIP address of the Citrix ADC VPX in the SSH or Telnet client.

How can you access the Citrix ADC VPX GUI?

To access the Citrix ADC VPX GUI, type the NSIP of the Citrix ADC VPX, for example, `http://NSIP address` in the address field of any browser.

Can two Citrix ADC VPX instances installed on the same VMware ESX be configured in a high availability setup?

Yes, but it is not recommended. A hardware failure would affect both Citrix ADC VPX instances.

Can two Citrix ADC VPX instances running on two different VMware ESX systems be configured in a high availability setup?

Yes. It is recommended in a high availability setup.

For the VMware, are interface related events supported on Citrix ADC VPX?

No. Interface related events are not supported.

For the VMware, are tagged VLANs supported on Citrix ADC VPX?

Yes. Citrix ADC tagged VLANs are supported on Citrix ADC VPX from release 11.0 and higher. For more information, see Citrix documentation.

For VMware, are link aggregation and LACP supported on Citrix ADC VPX?

No. Link Aggregation and LACP are not supported for Citrix ADC VPX. Link aggregation must be configured at the VMware level.

How do we access Citrix ADC VPX documentation?

The documentation is available from the Citrix ADC VPX GUI. After logging in, select the **Documentation** tab.

Capacity planning or sizing

What performance can I expect with Citrix ADC VPX?

Citrix ADC VPX offers good performance. See Citrix ADC VPX data sheet for a specific performance level achievable using Citrix ADC VPX.

Given that server CPU power varies, how can we estimate the maximum performance of a Citrix ADC instance?

Using a faster CPU can result in higher performance (up to the maximum allowed by the license), while using a slower CPU can certainly limit the performance.

Are Citrix ADC VPX bandwidth or throughput limits for inbound only traffic, or both inbound and outbound traffic?

Citrix ADC VPX bandwidth limits are enforced for traffic inbound to the Citrix ADC only, regardless of whether the request traffic or response traffic. It indicates that a Citrix ADC VPX-1000 (for example) can process both 1 Gbps of inbound traffic and 1 Gbps of outbound traffic simultaneously. Inbound and outbound traffic is not the same as request and response traffic. To the Citrix ADC, both traffic coming from endpoints (request traffic) and traffic coming from origin servers (response traffic) is “inbound” (that is, coming into the Citrix ADC).

Can multiple instances of Citrix ADC VPX be run on the same server?

Yes. However, ensure that the physical server has enough CPU and I/O capacity to support the total workload running on the host, or Citrix ADC VPX performance can be impacted.

If more than one instance of Citrix ADC VPX is running on a physical server, what is the minimum hardware requirement per Citrix ADC VPX instance?

Each Citrix ADC VPX instance must be allocated 2 GB of physical RAM, 20 GB of hard disk space, and 2 vCPUs.

Can I host Citrix ADC VPX and other applications on the same server?

Yes. For example, Citrix ADC VPX, Citrix Virtual Apps Web Interface and Citrix Virtual Apps XML Broker can all be virtualized and can run on the same server. For best performance, ensure that the physical host has enough CPU and I/O capacity to support all the running workloads.

Will adding CPU cores to a single Citrix ADC VPX instance increase the performance of that instance?

Depending on the license, a Citrix ADC VPX instance can use up to 4 vCPU today. Adding an extra CPU to a Citrix ADC VPX instance that can use more CPUs increases the performance.

Why Citrix ADC VPX looks like consuming more than 90% of the CPU even though it is idle?

It is normal behavior and Citrix ADC appliances exhibit the same behavior. To see the true extent of Citrix ADC VPX CPU utilization, use the stat CPU command in the Citrix ADC CLI, or view Citrix ADC VPX CPU utilization from the Citrix ADC GUI. The Citrix ADC packet processing engine is always "looking for work," even when there is no work to be done. Therefore, it does everything to take control of the CPU and not release it. On a server installed with Citrix ADC VPX and nothing else, results in looking like (from the Hypervisor perspective) that Citrix ADC VPX is consuming the entire CPU. Looking at the CPU utilization from "inside Citrix ADC" (by using the CLI or the GUI) provides a picture of Citrix ADC VPX CPU capacity being used.

System requirements

What is the minimum hardware requirement for Citrix ADC VPX?

See Citrix ADC VPX data sheet for its system requirements.

Citrix ADC VPX requires:

- Processor requirements: Dual core server with Intel VT-x.
- Memory available: 2 GB RAM(4 GB if there is VPX running on 13.0 firmware), 20 GB hard drive.
- Hypervisor: Citrix Hypervisor 5.6 or later; VMware ESX/ESXi 3.5 or later, Windows Server 2008 R2 with Hyper-V.
- Connectivity: 100 Mbps minimum. 1 Gbps recommended.

- A NIC compatible with the Hypervisor.

> **Note**
>
> AMD processors are not supported.

What is Intel VT-x?

These features, sometimes referred to as “hardware assist” or “virtualization assist,” trap sensitive or privileged CPU instructions run by the guest OS out to the Hypervisor. This simplifies hosting guest OSs (BSD for a Citrix ADC VPX) on the Hypervisor.

How common are VT-x?

Virtually, all servers shipped within the last two years might support VT-x. Many servers ship with virtualization assist disabled in the BIOS. Before assuming you cannot run Citrix ADC VPX, check if you need to change this setting on the server.

Is there a hardware compatibility list (HCL) for Citrix ADC VPX?

As long as the server supports Intel VT-x, Citrix ADC VPX must run on any server compatible with the underlying Hypervisor. See the Hypervisor HCL for a comprehensive list of supported platforms.

What version of Citrix ADC OS is Citrix ADC VPX based on?

Citrix ADC VPX is based on Citrix ADC 9.1 or later releases.

Since Citrix ADC VPX runs on BSD, can it be run natively on a server with BSD Unix installed?

No. Citrix ADC VPX requires the Hypervisor to run. Detailed Hypervisor supports can be found in Citrix ADC VPX data sheet.

Other technical FAQs

Does link aggregation on a physical server with multiple NIC’s work?

LACP is not supported. For the Citrix Hypervisor, Static link aggregation is supported and has limits of four channels and seven virtual interfaces. For VMware, static link aggregation is not supported within Citrix ADC VPX, but can be configured at the VMware level.

Is MAC based forwarding (MBF) supported on VPX? Is there any change from the Citrix ADC appliance implementation?

MBF is supported and it behaves the same way as with the Citrix ADC appliance. The Hypervisor basically switches all the packets received from Citrix ADC VPX to the outside and conversely.

How is the Citrix ADC VPX upgrade process carried out?

Upgrades are performed the same way as for Citrix ADC appliances: download a kernel file and use install ns or the upgrade utility in the GUI.

What is the size of the `/var` partition when using the default image for VPX? How to increase the disk space?

The size of the root disk is limited to 20 GB to keep the disk image small.

If you want to increase the `/var/core/` or the `/var/crash/` directory space, attach an extra disk. To increase the `/var` size, currently, you must attach an extra disk and create a symbolic link to `/var`, after copying the critical contents to the new disk.

What can we expect to regard the NetScaler VPX build numbering and interoperability with other builds?

Citrix ADC VPX has similar build numbering as the 9.1. Cl (classic) and 9.1. Nc (nCore) release, for instance 9.1_97.3.vpx, 9.1_97.3.nc, and 9.1_97.3.cl.

Can the Citrix ADC VPX be a part of a high availability setup with a Citrix ADC appliance?

Not a supported configuration.

Are all the interfaces visible in Citrix ADC VPX directly related to the number of interfaces on the Hypervisor?

No. You can add up to seven interfaces (10 for VMware) through the Citrix ADC VPX configuration utility with only one physical NIC on the Hypervisor.

Can Citrix Hypervisor XenMotion or VMware VMotion or Hyper-V live migration be used to move active instances of Citrix ADC VPX?

Citrix ADC VPX does not support XenMotion or Hyper-V live migration. VMotion is supported from Citrix ADC 12.1 release onwards. For more information, see Release Notes.

Licensing overview

September 14, 2021

Citrix offers a wide range of product editions and licensing models for MPX and VPX appliances, to meet your organization's need.

For proper operation of a Citrix ADC appliance, it must have one of the Citrix ADC family edition licenses. The ADC product line has three family editions:

- Standard Edition
- Advanced Edition
- Premium Edition

For more information, see the Citrix ADC data sheet.

After you've selected the Citrix ADC edition, you can select one of the MPX and VPX licensing offerings. Based on the criteria such as perpetual and subscription (yearly and hourly subscription), vCPU and bandwidth, on-premises and cloud, and so on.

Citrix ADC VPX licenses

The following are VPX-specific licenses.

Citrix ADC VPX Express license

Starting with Citrix ADC release 12.0 56.20, VPX Express for on-premises and cloud deployments does not require a license file and it comes with the following features:

- 20 Mbps bandwidth
- All ADC standard license features, except Citrix Gateway and L4 and L7 defenses
- Maximum 250 SSL sessions
- 20 Mbps SSL throughput

You can upgrade the VPX Express License to the following two options:

1. A standalone Citrix ADC VPX license
2. Citrix ADC Pooled Capacity license for VPX instances. For more information, see Citrix ADC Pooled Capacity.

> **Important**
>
> Clustering is available in Standard edition for VPX public cloud, and in VPX Express license.

Citrix ADC VPX pooled capacity license

You can use Citrix Application Delivery Management (ADM) to create a licensing framework that comprises a common bandwidth and instance pool. For complete information, see Citrix ADC pooled capacity.

Related resources

The Citrix Licensing System

How to Allocate Citrix ADC VPX Licenses

VPX licensing on cloud

VPX deployment is supported on public cloud providers such as Azure, AWS, and Google. For more information, see the following documents:

- VPX-Azure license
- VPX-AWS license
- VPX-GCP license

Allocate and apply a license

September 14, 2021

In the Citrix MPX and VPX ADC GUI, you can use your hardware serial number (HSN) or your license access code to allocate your licenses. Alternatively, if a license is already present on your local computer, you can upload it to the appliance.

For all other functionality, such as returning or reallocating your license, you must use the licensing portal. Optionally, you can still use the licensing portal for license allocation. For more information, see Use Manage Licenses in My Account on citrix.com.

Citrix Licensing guide

Citrix Licensing guide also covers information about installing licenses in a Citrix ADC appliance and installing licenses in other Citrix products. For more information, see Citrix Licensing Guide.

Prerequisites

> **Note:**
>
> Purchase separate licenses for each appliance in a high availability pair. Ensure that the same types of licenses are installed on both the appliances. For example, if you purchase a Premium license for one appliance, you must purchase another Premium license for the other appliance.

To use the hardware serial number or license access code to allocate your licenses:

- You must be able to access public domains through the appliance. For example, the appliance should be able to access www.citrix.com. The license allocation software internally accesses the Citrix licensing portal for your license. To access a public domain:
  - Use a proxy server or set up a DNS server.
  - Configure a Citrix ADC IP (NSIP) address or a subnet IP (SNIP) address on your Citrix ADC appliance.
- Your license must be linked to your hardware, or you must have a valid license access code. Citrix sends your license access code by email when you purchase a license.

Allocate a license by using the GUI

If your license is already linked to your hardware, the license allocation process can use the hardware serial number. Otherwise, you must type the license access code.

You can partially allocate licenses as required for your deployment. For example, if your license file contains 10 licenses, but your current requirement is for only six licenses, you can allocate six licenses now, and allocate more licenses later. You cannot allocate more than the total number of licenses present in your license file.

To allocate your license

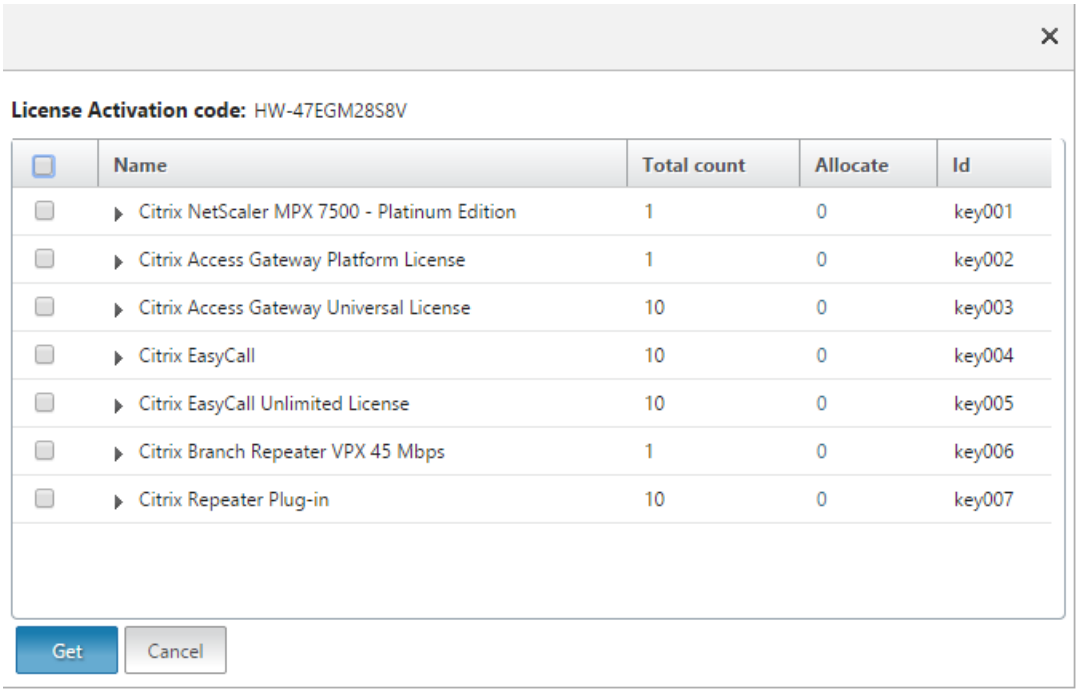
1. In a web browser, type the IP address of the Citrix ADC appliance (for example, `http://192.168.100.1`).
2. In User Name and Password, type the administrator credentials.
3. On the **Configuration** tab, navigate to **System > Licenses**.
4. In the details pane, click **Manage Licenses**, click **Add New License**, and then select one of the following options:
   - **Use Serial Number**: The software internally fetches the serial number of your appliance and uses this number to display your licenses.
   - **Use license access code**: Citrix emails the license access code for the license that you purchased. Enter the license access code in the text box.

If you do not want to configure internet connectivity on the Citrix ADC appliance, you can use a proxy server. Select the **Connect through Proxy Server** check box and specify the IP address and port of your proxy server.

5. Click **Get Licenses**. Depending on the option that you selected, one of the following dialog boxes appears.

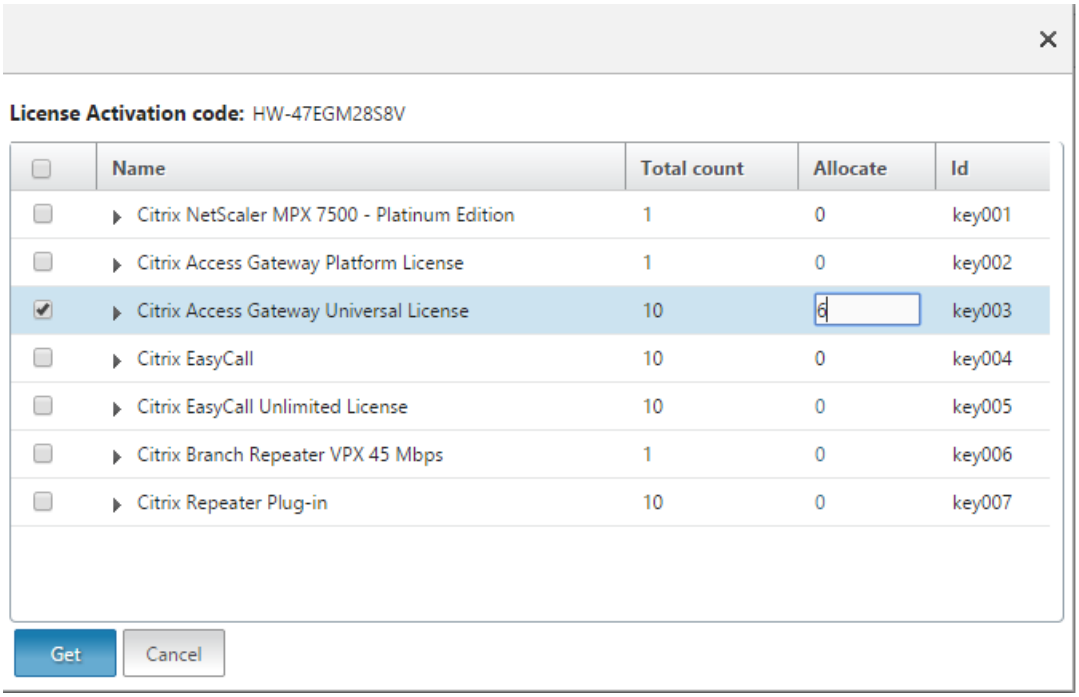
   - The following dialog box appears if you selected Hardware Serial Number.

   - The following dialog box appears if you selected license access code.

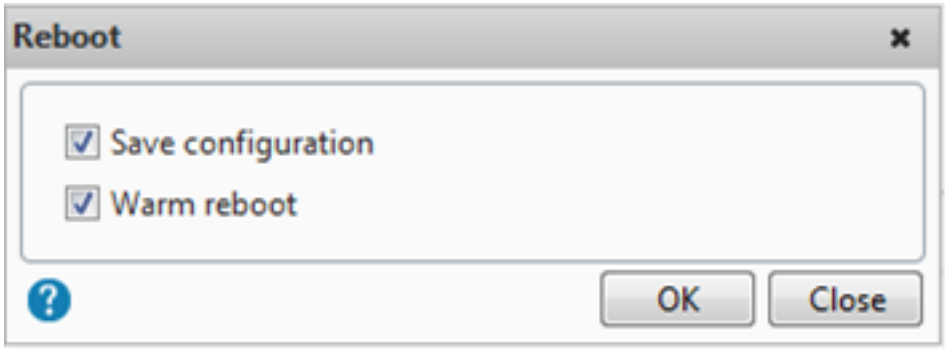


6. Select the license file that you want to use to allocate your licenses.
7. In the **Allocate** column, enter the number of licenses to be allocated. Then click **Get**.
   - If you selected **Hardware Serial Number**, enter the number of licenses, as shown in the following screenshot.

   - If you selected **license access code**, enter the number of licenses, as shown in the following screenshot.



8. Click restart for the license to take effect.
9. In the restart dialog box, click **OK** to proceed with the changes, or click **Close** to cancel the changes.



Install a license

If you downloaded your license file to your local computer by accessing the licensing portal, you must upload the license to the appliance.

To install a license file by using the GUI

1. In a web browser, type the IP address of the Citrix ADC appliance (for example, `http://192.168.100.1`).
2. In User Name and Password, type the administrator credentials.

3. On the **Configuration** tab, navigate to System Licenses.
4. In the details pane, click **Manage Licenses**.
5. Click **Add New License**, then select **Upload license files from a local computer**.
6. Click **Browse**. Navigate to the location of the license files, select the license file, and then click **Open**.
7. Click restart to apply the license.
8. In the restart dialog box, click **OK** to proceed with the changes, or click **Close** to cancel the changes.

To install the licenses by using the CLI

1. Open an **SSH connection** to the ADC appliance by using an SSH client, such as PuTTY.
2. Log on to the ADC appliance by using the administrator credentials.
3. Switch to the shell prompt, create a license subdirectory in the `nsconfig` directory, if it does not exist, and copy one or more new license files to this directory.

   Example

   ```
   login: nsroot
   Password: nsroot
   Last login: Mon Aug  4 03:37:27 2008 from 10.102.29.9
   Done
   > shell
   Last login: Mon Aug  4 03:51:42 from 10.103.25.64
   root@ns# mkdir /nsconfig/license
   root@ns# cd /nsconfig/license
   <!--NeedCopy-->
   ```

   Copy one or more new license files to this directory.

   Note: The Citrix ADC appliance does not prompt for a reboot option when you use the command line interface to install the licenses. Run the reboot -w command to warm restart the system, or run the restart command to restart the system normally.

Verify licensed features

Before using a feature, ensure that your license supports the feature.

To verify the licensed features by using the CLI

1. Open an **SSH connection** to the ADC appliance by using an SSH client, such as PuTTY.
2. Log on to the ADC appliance by using the administrator credentials.

3. At the command prompt, enter the sh ns license command to display the features supported by the license.

   Example

```
sh ns license
        License status:
                              Web Logging: YES
                        Surge Protection: YES
                          .......

                          HTML Injection: YES
 Done
<!--NeedCopy-->
```

To verify the licensed features by using the GUI

1. In a web browser, type the IP address of the ADC appliance, such as `http://192.168.100.1`.
2. In User Name and Password, type the administrator credentials.
3. Provide the User name and Password and click **Login**.
4. In the navigation pane, expand **System**, and then click **Licenses**. You see a green check mark next to the licensed features.

Enable or disable a feature

When you use the Citrix ADC appliance for the first time, you must enable a feature before you can use its functionality. If you configure a feature before it is enabled, a warning message appears. The configuration is saved but it applies only after the feature is enabled.

To enable a feature by using the CLI

At the command prompt, type the following commands to enable a feature and verify the configuration:

- enable feature <FeatureName>
- show feature

  Example

```
 enable feature lb cs
 done
  >show feature

```

```
5           Feature                         Acronym
               Status
6           -------                         -------
               ------
7    1)     Web Logging                     WL                    OFF
8    2)     Surge Protection                SP                    ON
9    3)     Load Balancing                  LB                    ON
10   4)     Content Switching               CS                    ON
11   5)     Cache Redirection               CR                    ON
12   .
13   .
14   .
15   24)    NetScaler Push                  push                  OFF
16   Done
17  <!--NeedCopy-->
```

The example shows how to enable load balancing (lb) and content switching (cs).

If the license key is not available for a particular feature, the following error message appears for that feature:

ERROR: feature(s) not licensed

Note: To enable an optional feature, you must have a feature-specific license. For example, you have purchased and installed the Citrix NetScaler Advanced Edition license. However, to enable the Integrated Caching feature, you must purchase and install the AppCache license.

To disable a feature by using the CLI

At the command prompt, type the following commands to disable a feature and verify the configuration:

- disable feature <FeatureName>
- show feature

Example

The following example shows how to disable load balancing (LB).

```
1   > disable feature lb
2    Done
3   > show feature
4
5           Feature                         Acronym
               Status
```

```
6           -------                         -------
                ------
7    1)     Web Logging                     WL                  OFF
8    2)     Surge Protection                SP                  ON
9    3)     Load Balancing                  LB                  OFF
10   4)     Content Switching               CS                  ON
11   .
12   .
13   .
14   24)    NetScaler Push                  push                OFF
15   Done
16  >
17  <!--NeedCopy-->
```

Check license expiry information

You can check Citrix ADC license expiry information through GUI or CLI.

To check Citrix ADC license expiry information through GUI:

Go to **Configuration > System > Licenses**.

A GUI alert appears when the ADC license expiry date is less than or equal to 30 days.

To check the license expiry information through CLI:

Type the command “show ns license”.

```
> sh license
    License status:

    Web Logging: YES
    Surge Protection: YES

    Web Logging: YES
    Surge Protection: YES

    …

Days to expiry: 204

Done
>
<!--NeedCopy-->
```

After the license expires, the Citrix ADC appliance generates an SNMP alarm “NS_LICENSE_EXPIRY,” and an expiry event is logged to console.

Upon license expiry, the Citrix ADC appliance automatically restarts to revoke the license. If Citrix ADC appliance uses Citrix service provider (CSP) licenses, the appliance does not restart automatically to revoke the license. However, if the user restarts the appliance, it restarts as unlicensed.

Upgrade a license

You can upgrade a Citrix ADC appliance from one family edition to another and from one capacity range to another by purchasing a higher capacity license.

Upgrades are of two types:

- Edition upgrades: Standard to Advanced, Standard to Premium, and Advanced to Premium. Edition upgrades must be within the same bandwidth.
- Capacity upgrades: You can upgrade from lower to higher capacity, for both vCPU and bandwidth. Capacity upgrades can only be performed on the same Edition (Standard, Advanced, or Premium).

If you want to upgrade both capacity and edition, first upgrade capacity, restart the appliance, and then upgrade the edition.

Example: To upgrade a VPX 10 Mbps Standard Edition license to the VPX 200 Mbps Premium Edition, the upgrade must be done in two steps.

- VPX upgrade from 10 Mbps Standard Edition to 200 Mbps Standard Edition.
- VPX upgrade from 200 Mbps Standard Edition to 200 Mbps Premium Edition.

> Note
>
> You can use Citrix Application Delivery Management (ADM) to create a licensing framework that comprises a common bandwidth and instance pool. For complete information, see Citrix ADC pooled capacity.

What is Citrix ADM service connect?

Citrix Application Delivery Management (ADM) service connect is a feature to enable seamless on-boarding of Citrix ADC MPX, SDX, and VPX instances, and Citrix Gateway appliances onto Citrix ADM service. This feature lets the Citrix ADC instance or Citrix Gateway appliance automatically, securely connect with Citrix ADM service, and send system, usage, and telemetry data to it. Based on this data, you get insights and recommendations for your Citrix ADC infrastructure on Citrix ADM service.

By using the Citrix ADM service connect feature and onboarding your Citrix ADC instances or Citrix Gateway appliances to Citrix ADM service. You can also manage all your Citrix ADC and Citrix Gateway assets whether on-premises or in the cloud. Also, you benefit from access to a rich set of visibility features that help in quick identification of performance issues, high resource usage, critical errors, and so on. Citrix ADM service provides a wide range of capabilities for your Citrix ADC instances and applications. For more information on Citrix ADM service, see Citrix Application Delivery Management Service

> **Important**
>
> - Citrix Gateway appliance also supports the Citrix ADM service connect feature. For better ease, the Citrix Gateway appliance isn't called explicitly in the consecutive sections.

What is Citrix ADM service?

Citrix ADM service is a cloud-based solution that helps you manage, monitor, orchestrate, automate, and troubleshoot your Citrix ADC instances. It also provides you analytical insights and curated ma-

chine learning based recommendations about Citrix ADC instances and about application health, performance, and security. For more information, see Citrix ADM service Overview

How the Citrix ADM service connect is enabled?

Citrix ADM service connect is enabled by default, after you install or upgrade Citrix ADC or Gateway to release 13.0 build 61.xx and above.

What data is captured using Citrix ADM service connect?

The following details are captured using Citrix ADM service connect:

- **Citrix ADC details**
  - Serial ID
  - Encoded Serial ID
  - Host ID
  - UUID
  - Management IP address
  - Host name
  - Version
  - Build type
  - Build
  - License type
  - Hypervisor
  - Deployment type(standalone/HA)
  - Platform type
  - Platform description
  - System ID
  - Modes enabled on ADC
  - Features enabled on ADC
- **License Information**
  - Features licensed on Citrix ADC
  - License number
- **Key usage metrics**
  - System date time
  - CPU usage percentage
  - Management CPU percentage
  - Throughput
  - SSL new sessions

  - SSL encryption throughput
  - SSL decryption throughput
  - System Uptime

- **Configuration**

  - ns.conf file

    > **Note**
    >
    > Before the Citrix ADM service connect sends the `ns.conf` file from Citrix ADC appliance to the Citrix ADM service, it anonymizes the encrypted or hashed passwords. The Citrix ADM service connect checks for "-encrypted" or "-passcrypt" parameters and replaces the associated encrypted or hashed value with 'XXXX'. The Citrix ADM service connect then encodes and compresses the `ns.conf` file, and sends it to the Citrix ADM service endpoint.

- **Critical error details**

  - Hard disk failures
  - SSL card failures
  - Power Supply Unit (PSU) failures
  - Flash drive failure
  - Warm reboot
  - Sustained memory usage above 90% or a memory leak
  - Sustained rate limit drops

How the data is used?

By collecting the data, Citrix can provide you with timely and in-depth insights about your Citrix ADC installations, which include the following:

- **Key metrics**. Details of key metrics about CPU, memory, throughput, SSL throughput, and highlight anomalous behavior on Citrix ADC instances.
- **Critical errors**. Any critical errors that might have occurred on your Citrix ADC instances.
- **Deployment advisory**. Identify Citrix ADC instances that are deployed in standalone mode but have high throughput and are vulnerable to a single point of failure.

How long the collected data is kept?

Any data collected is kept for no longer than 13 months.

If you decide to terminate the use of the service by disabling the Citrix ADM service connect feature from the Citrix ADC, any previously collected data is deleted after a period of 30 days.

Where the data is stored and how secure is it?

All data collected by Citrix ADM service connect is stored in one of the three regions–United States, European Union, and Australia and New Zealand (ANZ). For more information, see Geographical Considerations.

The data is stored securely with strict tenant isolation at the database layer.

How to disable Citrix ADM service connect?

If you want to disable data collection through Citrix ADM service connect, see How to enable and disable Citrix ADM service connect.

Introduction to Citrix ADM service connect for Citrix ADC appliances

September 14, 2021

Citrix ADM service is a cloud-based solution that helps you manage, monitor, orchestrate, automate, and troubleshoot your Citrix ADC instances. It also provides analytical insights and curated machine learning based recommendations for your applications health, performance, and security. For more information, see Citrix Application Delivery Management Service.

Citrix Application Delivery Management (ADM) service connect is a feature to enable seamless onboarding of Citrix ADC instances onto Citrix ADM service. This feature helps Citrix ADC instances and Citrix ADM service to function as a holistic solution, which offers customers multi fold benefits.

Citrix ADM service connect feature lets the Citrix ADC instance automatically connect with the Citrix ADM service and send system, usage, and telemetry data to it. Based on this data, the Citrix ADM service gives you some insights and recommendations on your Citrix ADC and Gateway infrastructure like the following:

- Security advisory insight highlighting your vulnerable ADC appliances.
- Upgrade advisory insight highlighting ADC appliances that have reached or about to reach end of maintenance and end of life.
- Quick identification of performance issues, high resource usage, and critical errors.

To harness the power of Citrix ADM service, you can choose to onboard your Citrix ADC instances to Citrix ADM service. The onboarding process uses ADM service connect, and makes the experience smooth and faster for you.

> **Points to note**
>
> - Citrix ADM service connect is now available on Citrix ADC MPX, SDX, and VPX instances and

> Citrix Gateway appliances.
>
> - The initiative in Citrix ADM service that uses this Citrix ADM service connect feature is ADM service connect based low-touch onboarding. For more information, see Low-touch on-boarding of Citrix ADC instances using Citrix ADM service connect.

For more information, see Data governance.

> **Important**
>
> Citrix ADM service connect fails to collect the probe data and cannot help in on-boarding the ADC appliance to ADM service if the following conditions are met:
>
> - `NSinternal` user account is disabled.
> - SSH public key is not set up.
>
> To overcome the preceding scenario, Citrix recommends you follow any one of the following:
>
> - Enable `internaluser` user account by using the `set ns param -internaluserlogin ENABLED`.
> - Configure the public key authentication. For more information, see Access a Citrix ADC appliance by using SSH keys and no password.

How does Citrix ADM service connect support with Citrix ADM service?

Here is a high-level workflow of how the Citrix ADM service connect feature on Citrix ADC interacts with Citrix ADM service.

1. Citrix ADM service connect feature on Citrix ADC appliance auto connects with Citrix ADM service using a periodic probe request.
2. This request has system, usage and telemetry data, using which the Citrix ADM service gives you some insights and recommendations on your Citrix ADC infrastructure. Like; quick identification of performance issues, high resource usage, and critical errors.
3. You can view the insights and recommendations and decide to onboard your ADC instances to the Citrix ADM service to start managing your Citrix ADC instances.
4. When you decide to onboard, the Citrix ADM service connect feature helps complete the on-boarding seamlessly.

What versions of Citrix ADC is Citrix ADM service connect supported on?

Citrix ADM service connect is supported on all Citrix ADC platforms and all appliance models (MPX, VPX, and SDX). Starting from Citrix ADC release 13.0 build 61.xx, Citrix ADM service connect is enabled by default for Citrix ADC appliances.

How to enable Citrix ADM service connect?

If you are an existing Citrix ADC customer, and upgrade to Citrix ADC release 13.0 build 61.xx, Citrix ADM service connect is enabled by default as part of the upgrade process.

If you are a new Citrix ADC customer, installing Citrix ADC release 13.0 build 61.xx, Citrix ADM service connect is enabled by default as part of the install process.

> **Note**
>
> Unlike the new Citrix ADC appliances, existing Citrix ADC appliances find the route through Citrix Insight Service (CIS) or Call Home.

How to enable and disable Citrix ADM service connect?

You can enable and disable Citrix ADM service connect from CLI, GUI, or NITRO API methods.

Using CLI

To enable the Citrix ADM service connect by using the CLI

At the command prompt, type:

```
set adm parameter -admserviceconnect ENABLED
```

To disable the Citrix ADM service connect by using the CLI

At the command prompt, type:

```
set adm parameter -admserviceconnect DISABLED
```

> **Important**
>
> If your Citrix ADC is on release 13.0 build 61.xx, the parameter name to enable or disable Citrix ADC service connect is “autoconnect.” For example, to enable service connect, use the `set adm parameter -autoconnect ENABLED` command.

Using the GUI

To disable the Citrix ADM service connect by using the Citrix ADC GUI

1. In a web browser, type the IP address of the Citrix ADC appliance (for example, http://192.0.2.10).
2. In **User Name** and **Password**, enter the administrator credentials.
3. Navigate to **System > Settings > Configure ADM Parameters**.

4. On the **Configure ADM Parameters** page, clear the **Enable Citrix ADM service connect** dialog box, and click **OK**.

Using the NITRO API

You can disable Citrix ADM service connect by using the **NITRO** command.

- In Citrix ADC release 13.0 build 61.xx, you can enable or disable the Citrix ADM service connect by using the following command:

  - `curl -X PUT -H "Content-Type:application/json"http://192.0.2.10/nitro/v1/config/admparameter> -d '{ "admparameter":{ "autoconnect":"enabled" } } ' -u nsroot:Test@1`

- From Citrix ADC release 13.0 build 64.xx, the “autoconnect” parameter name is renamed to `admserviceconnect`. You can disable the Citrix ADM service connect by using the following command:

  - `curl -X PUT -H “Content-Type:application/json” http://192.0.2.10/nitro/v1/config/admparameter -d '{ "admparameter":{ "admserviceconnect":"disabled" } } ' -u nsroot:Test@1`

> **Note**
>
> While onboarding the Citrix ADC instances onto Citrix ADM service, you might come across issues. You can troubleshoot the issues using the diagnostic tool. For more information, see Troubleshoot issues using the diagnostic tool.

Citrix ADM built-in agent behavior

From Citrix ADC release 13.0 build 61.xx and higher, the Citrix ADM built-in agent available on Citrix ADC instances communicates with ADM service. It communicates without the need for manual initialization on the respective ADC instance. After communication with ADM service is established, the built-in agent stays evergreen by auto-upgrading itself to the latest software version regularly.

Previously, you had to initialize the built-in agent on the ADC instances, using `mastools` commands, to establish communication with ADM service and for regular auto-upgrades.
For more information, see Configure the ADC built-in agent to manage instances.

- Data governance: Data governance.
- Citrix ADM service: Citrix Application Delivery Management Service.

Upgrade and downgrade a Citrix ADC appliance

September 14, 2021

> **Note**
>
> Citrix ADM service connect is enabled by default, after you install or upgrade Citrix ADC or Citrix Gateway to release 13.0 build 61.xx and above. For more information see, Data governance and Citrix ADM service connect.

Citrix ADC 13.0 offers new and updated features with increased functionality. A comprehensive list of enhancements is listed in the release notes accompanying the release announcement. Read the release notes document before you upgrade your software.

This section provides information about **upgrading and downgrading a Citrix ADC appliance** (MPX and VPX) firmware **by using the Citrix ADC GUI or CLI**.

You can also **use Citrix ADM to upgrade a Citrix ADC appliance**. For more information, see:

- 10 ways Citrix ADM service supports easier Citrix ADC upgrades
- Use Citrix ADM service to upgrade Citrix ADC instances
- Use Citrix ADM software to upgrade Citrix ADC instances

For information about **upgrading a Citrix ADC SDX appliance**, see Single Bundle Upgrade.

Before you begin

November 22, 2021

Before you start the upgrade or downgrade process, make sure you check the following:

- Time allocated for upgrading Citrix ADC appliances. Follow your organization's change control procedure. Allocate twice as much time to perform the upgrades. Allocate enough time to upgrade each of the Citrix ADC appliance.
- Evaluate your organization's support agreement. Document appliance serial number, support agreement, and contacts details for support from Citrix Technical Support or the Citrix Authorized Partner.
- The licensing framework and types of licenses. A software edition upgrade might require new licenses, such as:
  - upgrading from the standard edition to the advanced edition, or
  - the standard edition to the Premium edition, or

  - the advanced edition to the Premium edition.

  Existing Citrix ADC licenses continue to work when you upgrade to version 13.0. For more information, see Licensing

- Check for New and deprecated commands, parameters, and SNMP OIDs.
- Check for Citrix ADC MPX Hardware and Software Compatibility Matrix.
- If the Citrix ADC Gateway logon page is customized, then make sure that the UI theme is set to default.
- If you are upgrading LOM, review the LOM Firmware Upgrade page.
- Download the Citrix ADC firmware from the Citrix ADC Downloads. For the detailed steps to download the Citrix ADC firmware, see the Download a Citrix ADC release package.
- Back up files. Perform a backup of the configuration file, customization file, certificates, monitor scripts, license files, and so on either manually or refer to the following documentation for backup using Citrix ADC CLI or GUI - Backup and restore.
  - Refer to the following list for additional common customized files for back up.
    * `/nsconfig/monitors/*.pl`
    * `/nsconfig/htmlinjection/*`
    * `/nsconfig/rc.netscaler`
  - Back up the customization folder. This is usually under `/var/customizations`. An example of customization is a logon page with a logo. After you have copied the customizations folder, you have to delete it from the Citrix ADC appliance, before you upgrade the appliance. Upgrading with customization in place might cause some issues.

  > **Important:**
  > Citrix highly recommends reviewing the above backup procedures. Have an action plan in the event the update does not complete on the Citrix ADC appliance.

- Verify that there is adequate space in the /var and /flash directory for the Citrix ADC appliance before performing an upgrade. The /var requires 5 GB of free space (1 GB for the upgrade bundle + 4 GB for the upgrade process)
  The /flash requires enough space to copy over the new kernel, which differs between 140MB to 160MB approximately, ensure that there is atleast 250 MB free space available.
  For more information on clearing out the disk space in /var see, How to free space on /var directory for logging issues with a Citrix ADC appliance.
  For more information on clearing out the disk spaces in /flash see, https://support.citrix.com/article/CTX133587.
- Validate the integrity of the Citrix ADC appliance. If you have a Citrix ADC hardware appliance, Citrix highly recommends running `fsck` for running a disk check and validating the integrity of the Citrix ADC hard drive. In the event of an error, reset the hard disk drive and repeating the disk

check command. If the error message reappears, contact Citrix Support to further investigate the issue.

  - Validate the disk integrity of the hard drive using fsck command. For more information, see CTX122845.
  - Validate the integrity of Citrix ADC appliance using the diagnostic bundles files and uploading the logs to Citrix Insight Service for analysis. For more information, see How to collect a technical support bundle.

- Check the Citrix ADC VPX Support matrix and usage guidelines.
- Check the FAQ section.
- It is a best practice to upgrade to one major release at a time. Do not upgrade directly to the latest version.

  For example, if the Citrix ADC appliance is on release 12.0, and you want to upgrade to release 13.0, you must upgrade the appliance to release 12.1 first, and then to release 13.0.
- Verify the upgrading procedures with a test environment.

For more information about prerequisites for upgrading or downgrading the Citrix ADC appliance, see these support articles:

- CTX220371: Must Read Articles Before and After Upgrading Citrix ADC

Upgrade considerations - SNMP configuration

September 14, 2021

The timeout parameter for an SNMP alarm is an internal option that has no impact on the alarm configuration.

Timeout parameter might appear in the SNMP alarm configurations in the running configuration (sh running) and the saved configuration (ns.conf) even if you have not made any changes to these SNMP alarm configurations.

On upgrading to a release build with the fix for the timeout setting issue, the SNMP configurations are erroneously reset to default values.

The following SNMP alarms (if configured) are impacted during an upgrade:

- APPFW-BUFFER-OVERFLOW
- APPFW-COOKIE
- APPFW-CSRF-TAG
- APPFW-DENY-URL

- APPFW-FIELD-CONSISTENCY
- APPFW-FIELD-FORMAT
- APPFW-POLICY-HIT
- APPFW-REFERER-HEADER
- APPFW-SAFE-COMMERCE
- APPFW-SAFE-OBJECT
- APPFW-SQL
- APPFW-START-URL
- APPFW-VIOLATIONS-TYPE
- APPFW-XML-ATTACHMENT
- APPFW-XML-DOS
- APPFW-XML-SCHEMA-COMPILE
- APPFW-XML-SOAP-FAULT
- APPFW-XML-SQL
- APPFW-XML-VALIDATION
- APPFW-XML-WSI
- APPFW-XML-XSS
- APPFW-XSS
- CLUSTER-BACKPLANE-HB-MISSING
- CLUSTER-NODE-HEALTH
- CLUSTER-NODE-QUORUM
- CLUSTER-VERSION-MISMATCH
- COMPACT-FLASH-ERRORS
- CONFIG-CHANGE
- CONFIG-SAVE
- HA-BAD-SECONDARY-STATE
- HA-NO-HEARTBEATS
- HA-SYNC-FAILURE
- HA-VERSION-MISMATCH
- HARD-DISK-DRIVE-ERRORS
- HA-STATE-CHANGE
- HA-STICKY-PRIMARY
- PORT-ALLOC-FAILED
- SYNFLOOD

These SNMP alarms configurations are impacted when you upgrade the Citrix ADC to the following release builds:

- Release 11.1 build 61.2 or later
- Release 12.0 build 61.0 or later
- Release 12.1 build 30.1 or later

- Release 13.0 build 51.4 or later

Example

Let's consider an example of CLUSTER-NODE-HEALTH SNMP alarm.

```
CLUSTER-NODE-HEALTH SNMP alarm is set up by using the Citrix ADC
    command line:

> set snmp alarm CLUSTER-NODE-HEALTH -time 111 -state DISABLED -
    severity Major

> save config
<!--NeedCopy-->
```

This SNMP alarm configuration appears in the saved configuration file (`ns.conf`) as:

```
set snmp alarm CLUSTER-NODE-HEALTH -time 111 -state DISABLED -severity
    Major -timeout 86400

<!--NeedCopy-->
```

During an upgrade to any of the release builds mentioned above, the following error appears in ns.log file:

```
May 23 09:14:46 <local0.err> ns nsconfigd: __init_config_filter(): (
    null) line 0: No such argument [-timeout]>> set snmp alarm CLUSTER-
    NODE-HEALTH -time 111 -state DISABLED -severity Major -timeout
    86400.
<!--NeedCopy-->
```

After the upgrade, the SNMP alarm configurations are reset to the default values.

Workaround

Use one of the following workarounds:

- Before the upgrade, remove the timeout setting from the SNMP configurations in the saved configuration file (ns.conf).
- After the upgrade, reconfigure the SNMP alarms without the timeout parameter.

Download a Citrix ADC release package

September 14, 2021

Complete the following steps to download a Citrix ADC release package:

1. Open Citrix ADC Downloads page in a Web browser.
2. On the Citrix ADC Downloads page, expand the **Citrix ADC release** that you want to update to.
3. Expand one of the appropriate categories, and click the Citrix ADC build link. For example, for downloading a version of Citrix ADC firmware, expand **Firmware**, and click the Citrix ADC build that you want to download.
4. On the selected Citrix ADC build page, expand the **Build** section, click **Download File** to download the Citrix ADC build package.

> **Note:**
> The checksum is provided to ensure that you match the downloaded build package with the actual package which is hosted on the website. Checksum is an important check to ensure that you have the correct bits.

Upgrade a Citrix ADC standalone appliance

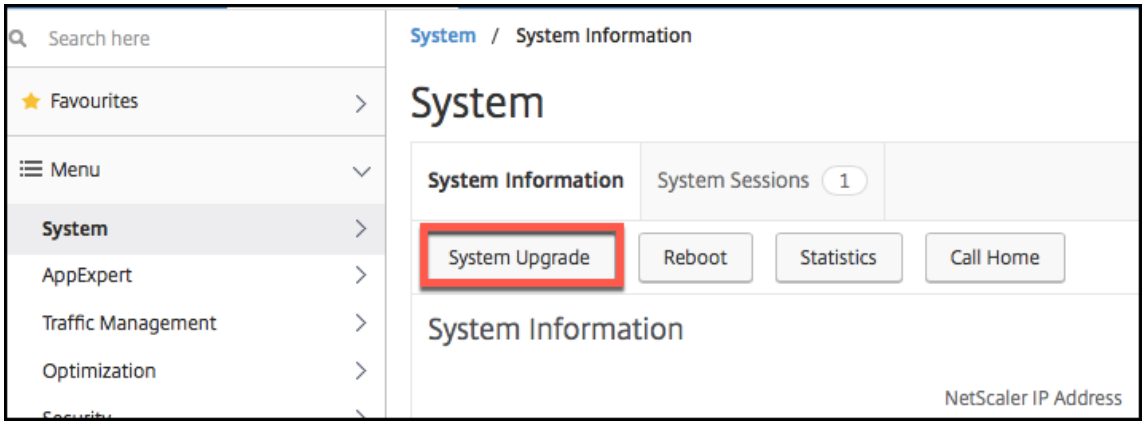
September 14, 2021

Before upgrading the system software, make sure that you read the Before you begin section and complete the prerequisites such as backing up the necessary files and downloading the Citrix ADC firmware.

Upgrade a Citrix ADC standalone appliance by using the GUI

Follow these steps to upgrade a standalone Citrix ADC to release 13.0 by using the GUI.

1. In a web browser, type the IP address of the Citrix ADC, for example `http://10.102.29.50`.
2. In User Name and Password, type the administrator credentials (nsroot/nsroot) and then click **Log On**.
3. From the GUI, click **System Upgrade**.



4. From the **Choose File** menu choose the appropriate option: **Local** or **Appliance**. If you want to use the Appliance option, the firmware needs to be uploaded to the Citrix ADC first. You can use any file transfer method such as WinSCP to upload the Citrix ADC firmware to the appliance.
5. Select the correct file and click **Upgrade**.
6. Follow the instructions to upgrade the software.
7. When prompted, select **Reboot**.

After the upgrade, close all browser instances and clear your computer's cache before accessing the appliance.

Upgrade a Citrix ADC standalone appliance by using the CLI

Follow these steps to upgrade a standalone Citrix ADC to release 13.0 by using the CLI:

In the following procedure, `<release>` and `<releasenumber>` represent the release version you are upgrading to, and `<targetbuildnumber>` represents the build number that you are upgrading to. The procedure includes optional steps to avoid losing any updates that are pushed to the /etc directory during the upgrade.

1. Use an SSH client, such as PuTTy, to open an SSH connection to the appliance.
2. Log on to the appliance by using the administrator credentials. Save the running configuration. At the prompt, type:

   ```
   save config
   ```

3. Switch to the shell prompt by running the following command:

   ```
   shell
   ```

4. Create a copy of the ns.conf file. At the shell prompt, type:

   - `cd /nsconfig`
   - `cp ns.conf ns.conf.NS<currentreleasenumber><currentbuildnumber>`

You should backup the configuration file to another computer.

5. (Optional) If you have modified some of the following files in the /etc directory, and copied them to /nsconfig to maintain persistency, any updates that are pushed to the /etc directory during the upgrade might be lost:

   - ttys
   - resolv.conf
   - sshd_config
   - host.conf
   - newsyslog.conf
   - host.conf
   - httpd.conf
   - rc.conf
   - syslog.conf
   - crontab
   - monitrc

   To avoid losing these updates, create a `/var/nsconfig_backup` directory, and move the customized files to this directory. That is, move any files that you modified in /etc directory and copied to /nsconfig by running the following command:

   ```
   cp /nsconfig/<filename> /var/nsconfig_backup
   ```

   Example:

   ```
   cp /nsconfig/syslog.conf /var/nsconfig_backup
   ```

6. Create a location for the installation package. At the shell prompt type:

   - `cd /var/nsinstall`
   - `cd <releasenumber>`

     > **Note:**
     >
     > If the desired release number directory is not present, create one using the following command:
     >
     > `mkdir <releasenumber>`
     >
     > **Example:**
     >
     > `mkdir 13.0`

   - `mkdir build_<targetbuildnumber>`
   - `cd build_<targetbuildnumber>`

7. Copy the already downloaded Citrix ADC firmware to the build directory that you have created in the above step, by using any file transferring method such as WinSCP. See the Before You

Begin section for more information about downloading the Citrix ADC firmware.

8. Extract the contents of the installation package. Example:

   ```
   tar -xvzf build-13.0-37.2_nc_64.tgz
   ```

9. Run the installns script to install the new version of the system software.

   ```
   ./installns
   ```

10. When prompted, restart the Citrix ADC.
11. (Optionally) If you've created a copy of the ns.conf file in the Before You Begin section, do the following:

    a) Manually compare the files in /var/nsconfig_backup and /etc and make appropriate changes in /etc.
    b) To maintain persistency, move the updated files in /etc to /nsconfig.
    c) Restart the appliance to put the changes into effect.

Below is an example of Citrix ADC firmware upgrade.

```
login: nsroot

Password: nsroot

Last login: Mon Apr 17 15:05:05 2018 from 10.252.243.134

Upgrade a Citrix ADC standalone appliance by using NITRO API

To use NITRO API to upgrade or downgrade a Citrix ADC, see Automate Citrix ADC Upgrade and Downgrade with a Single API.

Verify entities status on the Citrix ADC appliance after upgrading

After the Citrix ADC appliance is upgraded, verify the status of the following entities:

- Virtual servers are in UP state
- Monitors are in UP state
- GSLB sites synchronise without any issues
- All certificates are present on the appliance
- All the licenses are present on the appliance

Check and install Citrix ADC 13.0 software update

Update the Citrix ADC software when an update is available, for better performance. A Citrix ADC update can include feature improvements, performance fixes, or enhancements. Make sure you read the release notes to see what fixes and enhancements are available in the update. To check and install a software update, do the following.

1. In the Citrix ADC home page, click **Check for Update** from the **nsroot** menu at the top right corner.

2. In the **Latest System Software Updates Available** page, check the available software update that you can install.
3. Click **Download** to download the installation package from the Citrix download website.
4. After you have downloaded the software package, install the update through either CLI or GUI procedure.

> **Note**
>
> The **Check for Update** link is accessible only if you log into the GUI through HTTP protocol and not through HTTPS protocol.

The following resources provide related information about upgrading or downgrading a Citrix ADC appliance:

- Video tutorial - How to upgrade your Citrix ADC using CLI

Downgrade a Citrix ADC standalone appliance

September 14, 2021

You can downgrade to any earlier release on a standalone Citrix ADC by using the CLI or GUI.

> **Note:**
>
> Loss in configuration might occur when downgrading. Compare the configurations before and after the downgrade, and then manually reenter any missing entries.

Downgrade a Citrix ADC appliance by using the CLI

Follow the steps given below to downgrade a Citrix ADC standalone appliance running release 13.0 to an earlier release.

In this procedure, `<release>` and `<releasenumber>` represent the release version you are downgrading to, and `<targetbuildnumber>` represents the build number that you are downgrading to.

1. Open an SSH connection to the Citrix ADC by using an SSH client, such as PuTTY.
2. Log on to the Citrix ADC by using the administrator credentials. Save the running configuration. At the prompt, type:

   save config

3. Create a copy of the ns.conf file. At the shell prompt, type:

a) `cd /nsconfig`
b) `cp ns.conf ns.conf.NS<currentbuildnumber>`

You should backup a copy of the configuration file on another computer.

4. Copy the <releasenumber> configuration file (ns.conf.NS<releasenumber>) to ns.conf. At the shell prompt, type:

```
cp ns.conf.NS<releasenumber> ns.conf
<!--NeedCopy-->
```

> **Note:**
>
> `ns.conf.NS<releasenumber>` is the backup configuration file that is automatically created when the system software is upgraded from release version `<releasenumber>` to the current release version.
>
> There may be some loss in configuration when downgrading. After the appliance restarts, compare the configuration saved in step 3 with the running configuration, and make any adjustments for features and entities configured before the downgrade. Save the running configuration after making the changes.
>
> **Important:**
>
> If routing is enabled, perform step 5. Otherwise, skip to step 6.

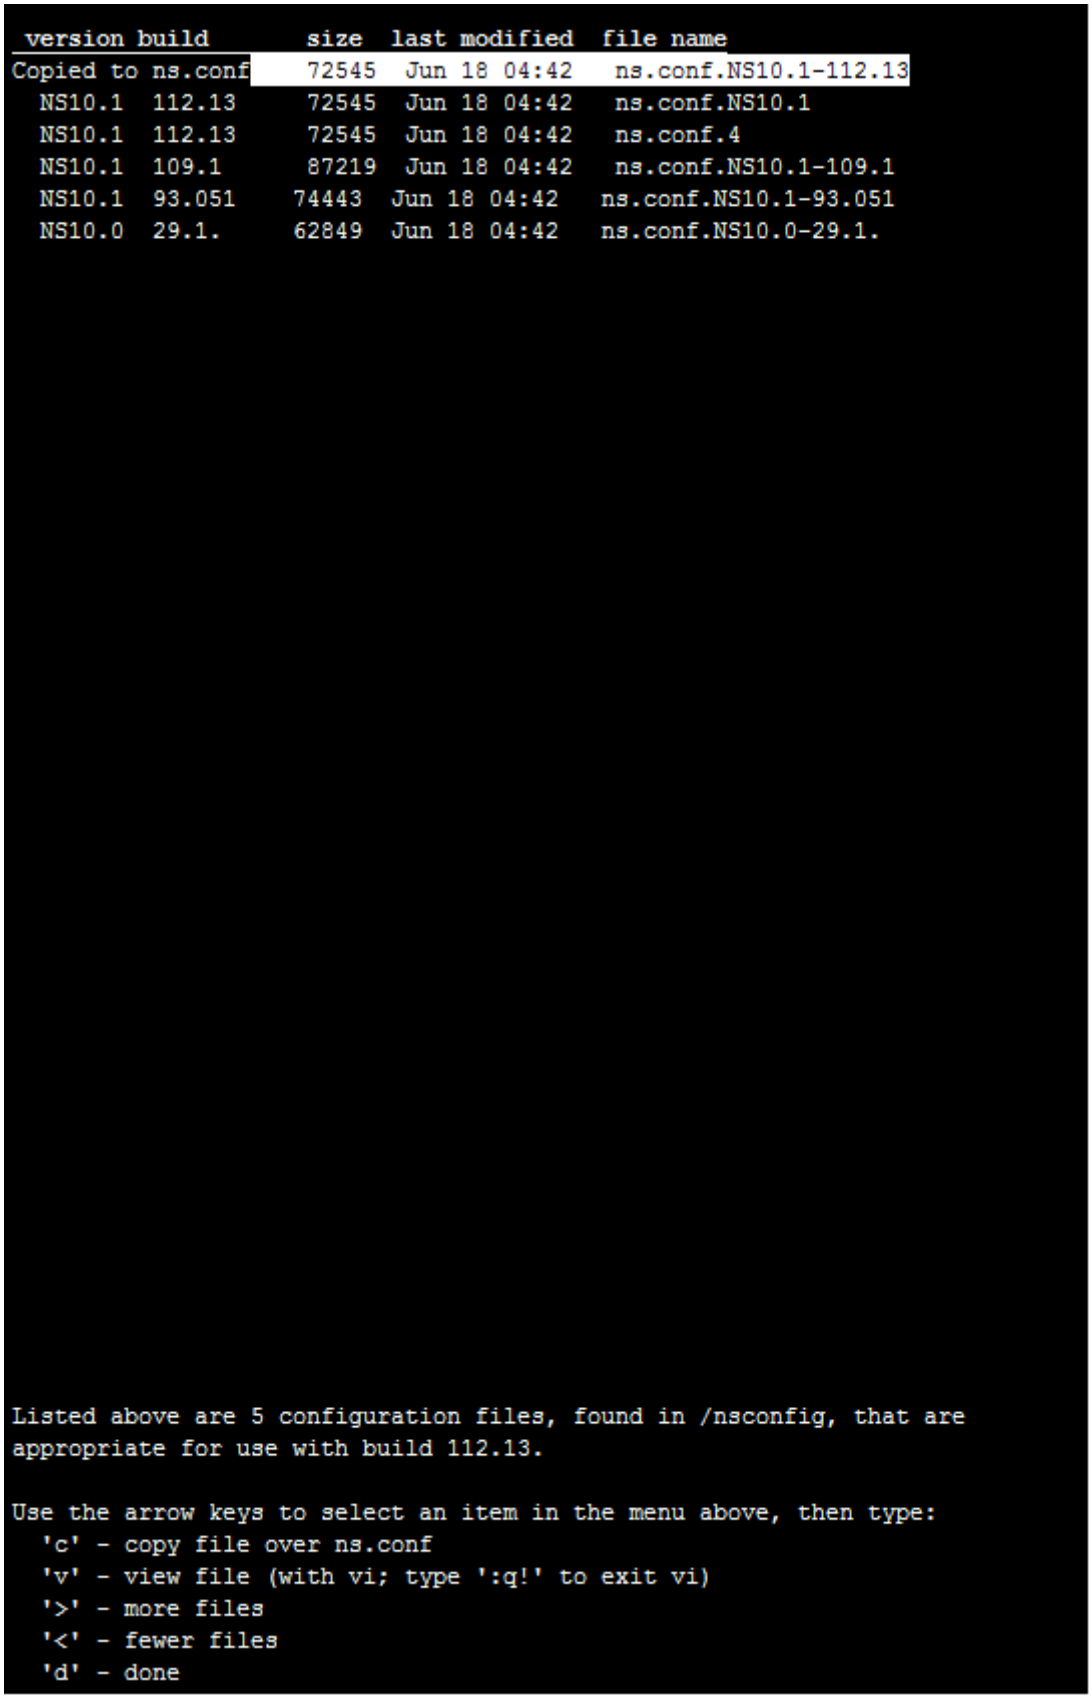
5. If routing is enabled, the ZebOS.conf file contains the configuration. At the shell prompt, type:

```
cd /nsconfig
cp ZebOS.conf ZebOS.conf.NS
cp ZebOS.conf.NS<targetreleasenumber> ZebOS.conf
<!--NeedCopy-->
```

6. Change directory to `/var/nsinstall/<releasenumber>nsinstall`, or create one if it does not exist.
7. Change directory to `build_<targetbuildnumber>`, or create one if it does not exist.
8. Download or copy the installation package (`build-<release>-<targetbuildnumber>.tgz`) to this directory and extract the contents of the installation package.
9. Run the `installns` script to install the new version of the system software. The script updates the `/etc` directory.

   If the configuration file for the build that you are downgrading to, exists on the appliance, you are prompted to load that configuration:

   Figure 1. Downgrade menu if configuration file exists



If the free space available on the flash drive is insufficient to install the new build, the Citrix ADC aborts the installation. Manually clean up the flash drive and restart the installation.

Example:

```
login: nsroot

Password: nsroot

Last login: Mon Apr 24 02:06:52 2017 from 10.102.29.9

Done

> save config

> shell

root@NSnnn# cp ns.conf.NS10.5 ns.conf

root@NSnnn# cd /var/nsinstall

root@NSnnn# mkdir 10.5nsinstall

root@NSnnn# cd 10.5nsinstall

root@NSnnn# mkdir build_57

root@NSnnn# cd build_57

root@NSnnn# ftp 10.102.1.1

ftp> mget build-10.5-57_nc.tgz

ftp> bye

root@NSnnn# tar -xzvf build-10.1-125_nc.tgz

root@NSnnn# ./installns

installns version (10.5-57) kernel (ns-10.5-57.gz)

...

...

```

```
...

Copying ns-10.5-57.gz to /flash/ns-10.5-57_nc.gz ...

Changing /flash/boot/loader.conf for ns-10.5-57 ...

Installation has completed.

Reboot NOW? [Y/N] Y
<!--NeedCopy-->
```

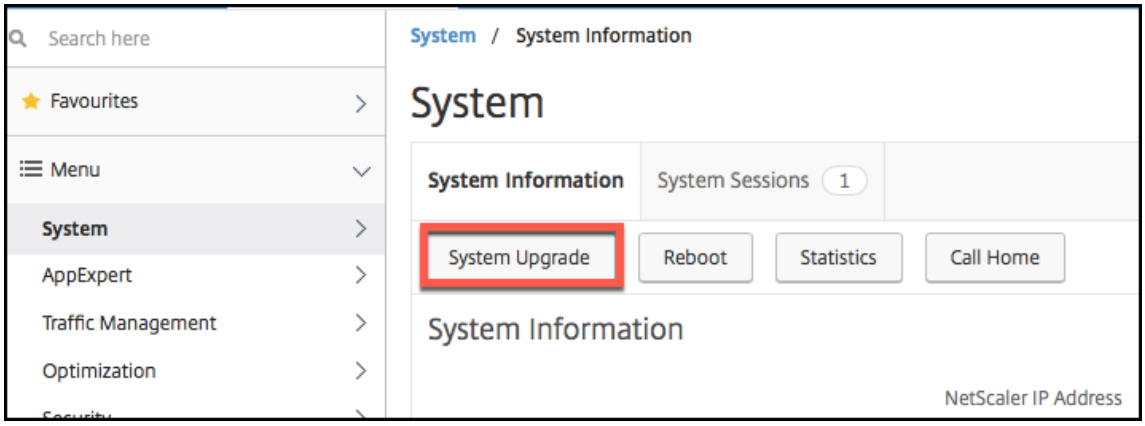
Downgrade a Citrix ADC appliance by using the GUI

You can use the upgrade wizard of the GUI to downgrade a Citrix ADC appliance running release 13.0 to an earlier release.

> **Notes:**
>
> You cannot downgrade a Citrix ADC appliance running release 13.0 directly to release 10.5 or earlier by using the GUI. Citrix recommends using the CLI for downgrading.
>
> Visit the Product Matrix site for more information on the Citrix ADC release lifecycle.
>
> It is a best practice to downgrade to one major release at a time.
>
> For example, if the Citrix ADC appliance is on release 13.0, and you want to downgrade to release 12.0, you must downgrade the appliance to release 12.1 first, and then to release 12.0.

Follow the steps given below to downgrade a Citrix ADC appliance running release 13.0 to an earlier release by using GUI.

1. In a web browser, type the IP address of the Citrix ADC, for example `http://10.102.29.50`.
2. In User Name and Password, type the administrator credentials and then click **Log On**.
3. From the GUI, click **System Upgrade**.



4. From the **Choose File** menu choose the appropriate option: **Local** or **Appliance**. If you want to use the Appliance option, the firmware must be uploaded to the Citrix ADC first. You can use any file transfer method such as WinSCP to upload the Citrix ADC firmware to the appliance.
5. Select the correct file and click **Upgrade**.
6. Follow the instructions to downgrade the software.
7. When prompted, select **Reboot**.

After the downgrade, close all browser instances and clear your computer's cache before accessing the appliance.

Upgrade a high availability pair

September 14, 2021

One of the requirements of Citrix ADC appliances in a high availability setup is to install the same Citrix ADC software release on both appliances of the setup. Therefore, when software on one appliance is upgraded, ensure that the software is upgraded on both the appliances.

You can follow the same procedure to upgrade a standalone appliance or each appliance in a high availability pair, although additional considerations apply to upgrading a high availability pair.

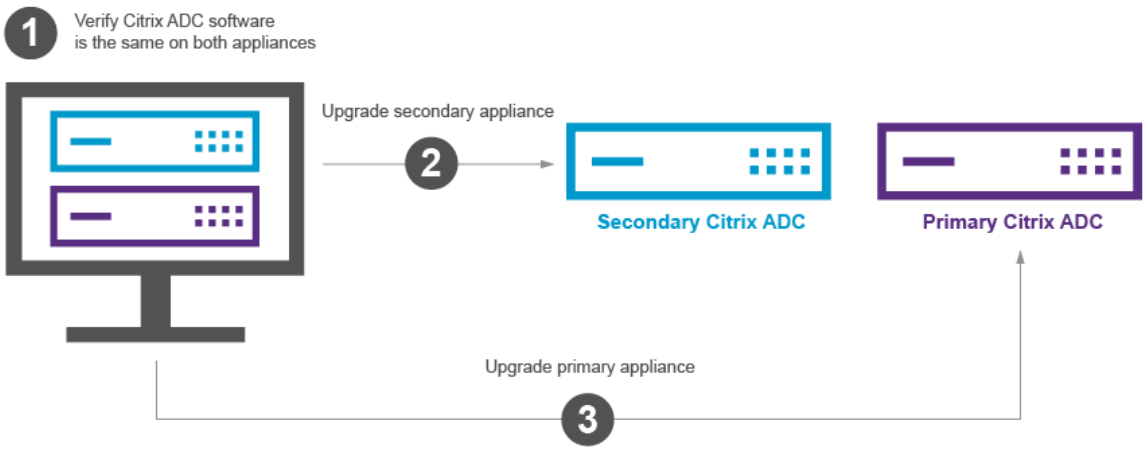
Before you start a Citrix ADC firmware upgrade on an HA pair, read the prerequisites mentioned in the Before you begin section. Also, you need to consider a few HA-specific points.

Points to note

- First upgrade the secondary node, and then the primary node. Upgrading software on the secondary appliance before the primary appliance ensures that the upgrade process is completed without any issues.
- If both the nodes in a high availability (HA) setup are running different Citrix ADC software releases, the following functionalities are disabled:
  - HA config synchronization
  - HA command propagation
  - HA synchronization of states services information
  - Connection mirroring (connection failover) of sessions
  - HA synchronization of persistence sessions information
- The above mentioned functionalities are disabled, if both the nodes in a high availability (HA) setup are running different builds of the same release but both the builds have different internal HA versions. The above mentioned functionalities works fine if both the nodes in a high availability (HA) setup are running different builds of the same release but both the builds have the same internal HA versions.

  Refer to the Points to note section of the release notes to check if the internal HA version has changed in Citrix ADC build.
- Synchronization of the files in the All mode of the Sync HA files command works successfully if the two nodes in an HA configuration are running different Citrix ADC software releases, or the two nodes are running different builds of the same release. For more information, see Synchronising Configuration Files in High Availability Setup.

Figure. Upgrade a high availability pair



You can upgrade using the Citrix ADC CLI or GUI.

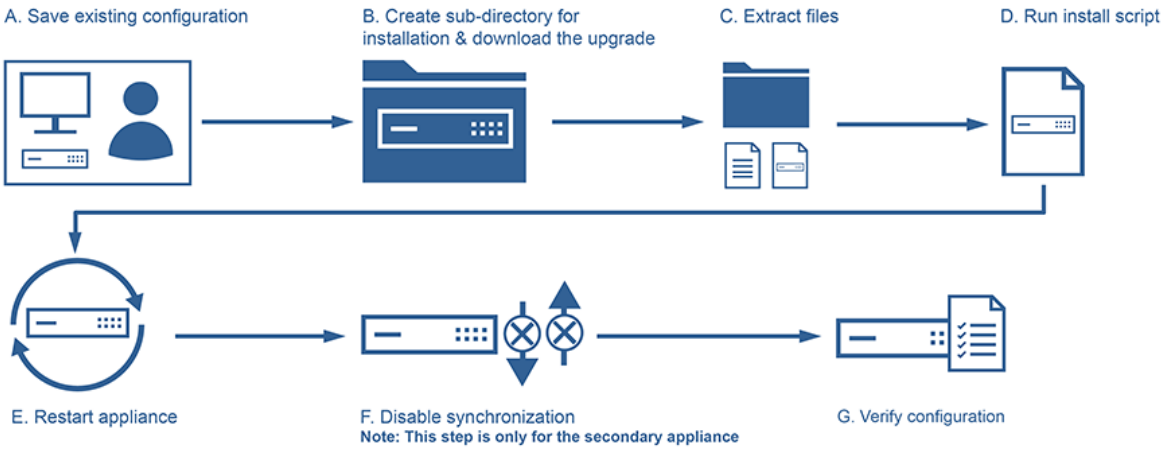
Upgrade a high availability pair by using the CLI

The upgrade process includes the following steps:

1. Upgrade software on the secondary appliance
2. Upgrade software on the primary appliance
3. Synchronize secondary appliance

Upgrade software on the secondary appliance

The following illustration depicts the procedure to upgrade software on the secondary appliance:



1. Log on to the secondary NetScaler appliance using an SSH utility, such as PuTTY and specifying the NetScaler IP (NSIP). Use the nsroot credentials to log on to the appliance.
2. From the command line interface of the appliance, type the following command to save the existing configuration: save config
3. Switch to the shell prompt.

```
login as: username
Using keyboard-interactive authentication.
Password:
Last login: Wed Jun 24 14:59:16 2015 from 10.252.252.65
Done
> shell
Copyright (c) 1992-20

<!--NeedCopy-->
```

4. Run the following command to change to the default installation directory: # cd /var/nsinstall
5. Run the following command to create a temporary subdirectory of the nsinstall directory: **# mkdir x_xnsinstall**

> Note: The text x_x is used to name the NetScaler version for future configurations. For example, the directory for the installation files of NetScaler 9.3 us called 9_3nsinstall. Do not use a period (.) in the folder name, it can cause failed upgrades.

6. Change to the **x_xnsinstall** directory.
7. Download the required installation package and documentation bundle, such as "ns-x.0-xx.x-doc.tgz," to the temporary directory created in Step 4.

   > **Note:**
   >
   > Some builds do not have a documentation bundle as it does not have to be installed.
   >
   > Click the **Documentation** tab from the GUI to access the documentation.

8. Before you run the install script, the files must be extracted and placed on the appliance. Use the following command to uncompress the bundle downloaded from Citrix website: **tar -zxvf ns-x.0-xx.x-doc.tgz**. The following is a quick explanation of the parameters used.

   x: Extract files

   v: Print the file names as they are extracted one by one

   z: The file is a "gzipped" file

   f: Use the following tar archive for the operation

9. Run the following command to install the downloaded software: # ./installns

   > Note: If the appliance does not have sufficient disk space to install the new kernel files, the installation process performs an automatic cleanup of the flash drive.

10. After the installation process is complete, the process prompts to restart the appliance. Press y to restart the appliance.
11. Log on to the appliance Command Line Interface using the nsroot credentials.
12. Run the following command from to display the state of the NetScaler appliance: **show ha node** The output of the preceding command should indicate that the appliance is a secondary node and synchronization is disabled.
13. Run the following command to perform a force failover and takeover as primary appliance: **force failover**

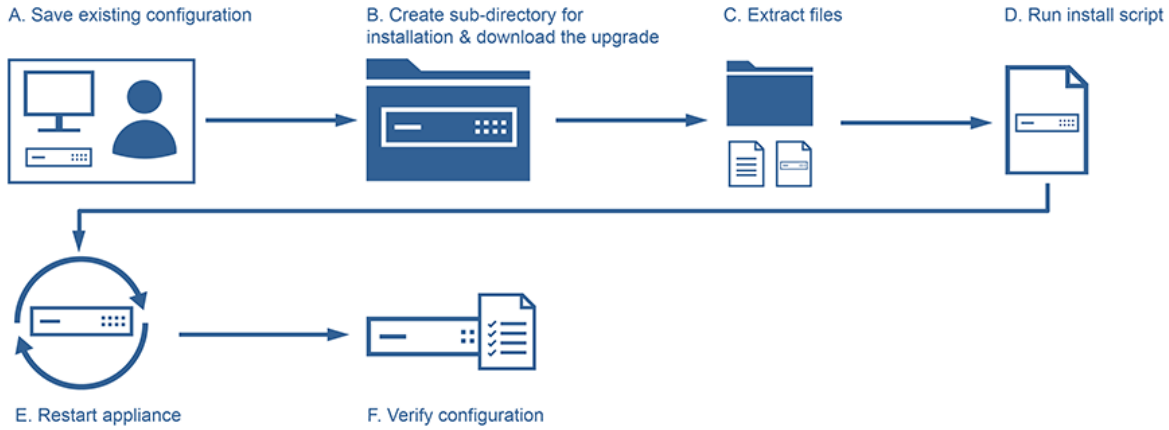
Here's a sample configuration in the new primary node.

```
login: nsroot
Password: nsroot
Last login: Monday Apr  17 08:37:26 2017 from 10.102.29.9
Done
show ha node
```

```
        2 nodes:
1)      Node ID:      0
        IP:        10.0.4.2
        Node State: UP
        Master State: Primary
        ...
        Sync State: AUTO DISABLED
        Propagation: AUTO DISABLED
        ...
Done
<!--NeedCopy-->
```

Upgrade software on the primary appliance

The following illustration depicts the procedure to upgrade software on the primary appliance:



> Note: After completing the “Upgrade software on the secondary appliance” procedure, the original primary appliance is now a secondary appliance.

1. Log on to the secondary NetScaler appliance using an SSH utility, such as PuTTY. Use the nsroot credentials to log on to the appliance. Follow the same steps as mentioned in the above section to complete the installation process. We have to follow the same steps as mentioned in step 2 to step 9 in the previous section(Upgrade software of the secondary appliance)
2. After the installation process is complete, the process prompts to restart the appliance. Press y to restart the appliance.
3. Log on to the appliance Command Line Interface using the nsroot credentials.
4. Run the following command to display the state of the NetScaler appliance: **show ha node**. The output of the preceding command should indicate that the appliance is a secondary node and the status of the node state is marked as UP.

5. Run the following command to perform a force failover to ensure that the appliance is a primary appliance: **force failover**
6. Verify that the appliance is a primary appliance.

   Here's an example configuration of the new primary node and the new secondary node.

```
show ha node
    Node ID:      0
    IP:   10.0.4.11
    Node State: UP
    Master State: Primary
    ...
    ...
    INC State: DISABLED
    Sync State: ENABLED
    Propagation: ENABLED
    Enabled Interfaces : 1/1
    Disabled Interfaces : None
    HA MON ON Interfaces : 1/1
    ...
    ...
    Local node information
    Critical Interfaces: 1/1
Done

Show ha node
    Node ID:      0
    IP:   10.0.4.2
    Node State: UP
    Master State: Secondary
    ..
    ..
    INC State: DISABLED
    Sync State: SUCCESS
    Propagation: ENABLED
    Enabled Interfaces : 1/1
    Disabled Interfaces : None
    HA MON ON Interfaces : 1/1
    . .
    . .
    Local node information:
    Critical Interfaces: 1/1
Done
<!--NeedCopy-->
```

Upgrade a high availability pair by using the GUI

Follow these steps to upgrade a Citrix ADC pair in a high availability setup, by using the ADC GUI. Consider an example of a high availability setup of Citrix ADC appliances CITRIX-ADC-A (primary) and CITRIX-ADC-B (secondary).

1. **Upgrade the secondary node**. Log on to the secondary node GUI using administrator credentials, and perform the upgrade as described in Upgrade a Citrix ADC standalone appliance by using the GUI.
2. **Force failover**. Perform a force failover on the secondary node using GUI as described in Forcing a node to fail over.

   After failover operation, the secondary node takes over as primary and the primary node becomes the new secondary node. After the failover operation in the example HA setup:

   - CITRIX-ADC-B becomes the new primary
   - CITRIX-ADC-A becomes the new secondary
3. **Upgrade the original primary node (new secondary node)**. Log on to the new secondary node GUI (CITRIX-ADC-A) and perform the upgrade as described in Upgrade a Citrix ADC standalone appliance by using the GUI.
4. **Force failover**. Perform a force failover on the new secondary node (CITRIX-ADC-A) using GUI as described in Forcing a node to fail over.

   After this second failover operation, the state of both the nodes return to the same state as before starting the HA upgrade operation. After the failover operation in the example HA setup:

   - CITRIX-ADC-A becomes primary
   - CITRIX-ADC-B becomes secondary
5. **Verify the upgrade process**. Log on to the GUI of both the nodes. Navigate to **System > High Availability**, on the details page, verify the HA state of both the nodes. Also, verify the upgraded release details displayed on the top pane of the GUI.

The following resources provide related information about upgrading a Citrix ADC high availability setup:

- Video tutorial - How to upgrade your Citrix ADC HA pair using the GUI

In Service Software Upgrade support for high availability for performing zero downtime upgrade

September 14, 2021

During a regular upgrade process in a high availability setup, at some point, both nodes run different software builds. These two builds can have the same or different internal high availability version numbers.

If both the builds have different high availability version numbers, connection failover (even if it is enabled) for existing data connections is not supported. In other words, all existing data connections are lost, which leads to downtime.

To address this issue, in Service Software Upgrade (ISSU) can be used for high availability set-ups. ISSU introduces a migration functionality, which replaces the force failover operation step in the upgrade process. The migration functionality takes care of honoring the existing connections and includes the force failover operation.

After migration operation is performed, the new primary node always receives traffic (request and response) related to the existing connections but steers them to the old primary node. The old primary node processes the data traffic and then sends them directly to the destination.

How the enhanced ISSU works

The regular upgrade process in a high availability setup consist of the following sequential steps:

1. **Upgrade the secondary node**. This step includes software upgrade of the secondary node and restart of the node.
2. **Force Failover**. Running the force failover makes the upgraded secondary node to primary, and the primary node to secondary.
3. **Upgrade the new secondary node**. This step includes software upgrade of the new secondary node and restart of the node.

During the time frame between step 1 and step 3, both nodes run different software builds. These two builds can have the same or different internal high availability versions.

If both the builds have different high availability version numbers, connection failover (even if it is enabled) for existing data connections is not supported. In other words, all existing data connections are lost, which leads to downtime.

The ISSU upgrade process in a high availability setup consists of the following steps:

1. **Upgrade the secondary node**. This step includes software upgrade of the secondary node and restart of the node.

2. **ISSU migration operation**. The step includes the force failover operation and takes care of the existing connections. After you perform the migration operation, the new primary node always receives traffic (request and response) related to the existing connections but steers them to the old primary node through the configured SYNC VLAN in GRE tunnel. The old primary node processes the data traffic and then sends them directly to the destination. The ISSU migration operation is completed when all the existing connections are closed.
3. **Upgrade the new secondary node**. This step includes software upgrade of the new secondary node and restart of the node.

Before you begin

Before you start performing the ISSU process in a high availability setup, go through the following pre-requisites and limitations:

- Make sure the SYNC VLAN is configured on both the nodes of the high availability setup. For more information, see Restricting high availability synchronization traffic to a VLAN.
- ISSU is not supported in Microsoft Azure cloud because Microsoft Azure does not support GRE tunneling.
- High availability config propagation and synchronization do not work during ISSU.
- ISSU is not supported for IPv6 high availability setup.
- ISSU is not supported for following sessions:
  - Jumbo frames
  - IPv6 sessions
  - Large scale NAT (LSN)

Configuration steps

ISSU includes a migration feature, which replaces the force failover operation in the regular upgrade process of a high availability setup. The migration functionality takes care of honoring the existing connections and includes the force failover operation.

During the ISSU process of a high availability setup, you run the migration operation just after you upgraded the secondary node. You can perform the migration operation from either of the two nodes.

CLI Procedure

To perform the high availability migration operation by using the CLI:

At the command prompt type:

```
start ns migration
<!--NeedCopy-->
```

GUI Procedure

To perform the high availability migration operation by using the GUI:

Navigate to **System**, click **System Information** tab, click **Migration tab**, and then click **Start Migration**.

Display ISSU statistics

You can view the ISSU statistics for monitoring the current ISSU process in a high availability setup. The ISSU statistics displays the following information:

- Current status of ISSU migration operation
- Start time of the ISSU migration operation
- End time of the ISSU migration operation
- Start time of the ISSU rollback operation

You can view the ISSU statistics on either of HA nodes by using CLI or GUI.

CLI Procedure

To display the ISSU statistics by using the CLI:

At the command prompt type:

```
show ns migration
<!--NeedCopy-->
```

GUI Procedure

To display the ISSU statistics by using the GUI:

Navigate to **System**, click **System Information** tab, click **Migration tab**, and then click **Show Migration**.

Rollback of the ISSU process

High availability (HA) setups now support rollback of the In Service Software Upgrade (ISSU) process. The ISSU rollback feature is helpful if you observe that the HA setup during the ISSU migration operation is not stable, or is not performing at an optimum level as expected.

The ISSU rollback is applicable when the ISSU migration operation is in progress. The ISSU rollback does not work if ISSU migration operation is already completed. In other words, you must run the ISSU rollback operation when ISSU migration operation is in progress.

The ISSU rollback functions differently based on the state of the ISSU migration operation when the ISSU rollback operation is triggered:

- **Force failover has not yet happened during ISSU migration operation**. The ISSU rollback stops the ISSU migration operation, and removes any internal data related to the ISSU migration stored in both the nodes. The current primary node remains as primary node and continues to process data traffic related to existing and new connections.
- **Force failover has happened during ISSU migration operation**. If the high availability failover has happened during the ISSU migration operation, then the new primary node (say it is N1) processes traffic related to the new connections. The old primary node (new secondary node, say it is N2) processes traffic related to the old connections (existing connections before the ISSU migration operation).

  The ISSU rollback stops the ISSU migration operation and triggers a force failover. The new primary node (N2) now starts processing traffic related to the new connections. The new primary node (N2) also continues to processes traffic related to old connections (existing connections established before the ISSU migration operation). In other words, the existing connections established before the ISSU migration operation are not lost.

  The new secondary node (N1) removes all the existing connections (new connections created during the ISSU migration operation) and does not process any traffic. In other words, any existing connections that were established after the force failover of ISSU migration operation are lost forever.

Configuration steps

You can use Citrix ADC CLI or GUI to perform the ISSU rollback operation.

CLI Procedure

To perform the ISSU rollback operation by using the CLI:

At the command prompt type:

```
1 stop ns migration
2 <!--NeedCopy-->
```

GUI Procedure

To perform the ISSU rollback operation by using the GUI:

Navigate to **System**, click **System Information** tab, click **Migration tab**, and then click **Stop Migration**.

SNMP traps for In Service Software Upgrade process

The In Service Software Upgrade (ISSU) process for a high availability setup supports the following SNMP trap messages at the start and end of the ISSU migration operation.

SNMP Trap	Description
migrationStarted	This SNMP trap is generated and sent to the configured SNMP trap listeners when the ISSU migration operation starts.
migrationComplete	This SNMP trap is generated and sent to the configured SNMP trap listeners when the ISSU migration operation completes.

The primary node (before the start of the ISSU process) always generates these two SNMP traps and sends them to the configured SNMP trap listeners.

There are no SNMP alarms associated with the ISSU SNMP traps. In other words, these traps are generated irrespective of the any SNMP alarm. You only have to configure the trap SNMP listeners.

For more information on configuring SNMP trap listeners, see SNMP traps on Citrix ADC.

Downgrade a high availability pair

September 14, 2021

You can downgrade to any release on a high availability pair by using the command line interface. The GUI does not support the downgrade process.

To downgrade the system software on a Citrix ADC pair in a high availability pair, you need to downgrade the software first on the secondary node and then on the primary node. For instructions on downgrading each node separately, see Downgrade a Citrix ADC standalone appliance.

> **Important**
>
> Loss in configuration might occur when downgrading. You should compare the configurations before and after the downgrade, and then manually re-enter any missing entries.

Troubleshooting issues related to the installation, upgrade, and downgrade processes

September 14, 2021

If the appliance does not work as expected after you complete the installation, upgrade, or downgrade process, the first thing to do is to check for the most common causes of the problem.

Resources for troubleshooting

For best results, use the following resources to troubleshoot an issue related to installing, upgrading, or downgrading a Citrix ADC:

- The configuration files from the appliance. In case of a High Availability pair, the configuration files from both appliances.
- The following files from the appliance(s):
  - The relevant newnslog files.
  - The ns.log file.
  - The messages file.
- A network topology diagram.

Issues and resolutions

Following are the most common installation, upgrade, and downgrade issues, and tips for resolving them:

1. **Issue**

   Upgrading a Citrix ADC MPX appliance fails due to hardware and software incompatibility.

   Resolution

   See the Citrix ADC MPX hardware-software compatibility matrix and check whether the software release is supported on the Citrix ADC MPX hardware.

2. **Issue**

   Upgrading a Citrix ADC VPX appliance fails due to Citrix ADC VPX appliance and hypervisor incompatibility.

Resolution

See the Citrix ADC VPX appliance and hypervisor compatibility matrix and check whether the Citrix ADC VPX appliance model is supported on the hypervisor.

3. **Issue**

   Upgrading a Citrix ADC appliance fails due to hardware errors.

   Resolution

   Validate the integrity of the Citrix ADC appliance. If you have a Citrix ADC hardware appliance, Citrix recommends running `fsck` for running a disk check and validating the integrity of the Citrix ADC hard drive.

   For more information, see How to Verify the File System Integrity of a Citrix ADC appliance.

4. **Issue**

   Upgrading a Citrix ADC appliance by using the GUI stalls.

   Resolution

   Refresh the browser to check whether the upgrade is progressing or not.

5. **Issue**

   Upgrading a Citrix ADC appliance fails due to low Space in /var Directory

   Resolution

   Free up space on the /var directory. For more information, see
   Refer to How to free space on /var directory.

6. **Issue**

   The Citrix ADC is not accessible after the software downgrade

   Cause

   During the software downgrade process, if the configuration file of the existing release and build does not match the configuration file of the earlier release and build, the appliance cannot load the configuration, and the default IP address is assigned to the appliance.

   Resolution

   - Verify that the appliance is accessible from the console.
   - Verify the NSIP address and the routes on the appliance.
     - If the IP address has changed to the default 192.168.100.1 IP address, change the IP address as required.
     - Verify that the appliance is accessible.

7. **Issue**

   During an upgrade, if I run the command for synchronizing, the following message appears:

   Command failed on the secondary node but succeeded on the primary node.

   Resolution

   Do not run any dependent commands (set /unset /bind /unbind) when High Availability (HA) synchronization is in progress.

8. **Issue**

   During an upgrade process, traffic does not pass through the new primary node when you run the force failover command.

   Resolution

   - Check for problems with the network topology and the switch configurations.
   - Run the set L2param -garpreply ENABLED command to enable the GARP reply.
   - Try using virtual MAC if not already used.
   - Run the sendarp –a command from the primary node.

9. **Issue**

   After upgrading or downgrading a Citrix ADC appliance, connecting to the appliance fails through SSH.

   Resolution

   Perform the following operations in the Citrix ADC appliance:

   - Remove old or insecure host keys at `/nsconfig/ssh/ssh_host_*`.
   - Review the custom SSHD configuration at `/nsconfig/sshd_config` and check if it is still relevant and compatible. Rename or remove the custom SSHD configuration accordingly.
   - Cold reboot the Citrix ADC appliance

10. **Issue**

    In an HA pair, after you run the force HA failover command the devices keep rebooting. The secondary device does not come up after an upgrade.

    Resolution

    Check to see if the /var directory is full. If so, remove the old installation files. Run the df –h command to show the available disk space.

11. **Issue**

    After upgrading an HA pair, one of the nodes is listed as state UNKNOWN.

    Resolution

- Check to see if both nodes are running the same build. If the builds are not same and HA nodes have a version mismatch, some of the fields are shown as UNKNOWN when you run the show ha node command.
- Check to see if the secondary appliance is reachable.

12. **Issue**

    After you upgrade the Citrix ADC, the interface shows most of the load balancing virtual servers and services are DOWN.

    Resolution

    Verify that the SNIP address is active on the secondary appliance. Also, type the show service command to see if the service is running.

13. **Issue**

    After performing an upgrade, all virtual servers are down on the secondary appliance.

    Resolution

    Enable the HA state and HA synchronization by running the following commands:

    - set node hastate enable
    - set node hasync enable

    Disabling HA is not recommended.

14. **Issue**

    After performing a downgrade, the Citrix ADC does not boot up properly.

    Resolution

    Check to see if the correct license has been installed.

15. **Issue**

    In an HA pair, some features do not get synchronized after an upgrade is performed.

    Resolution

    Run the sync ha file misc command to synchronize the configurations files from the primary node to secondary node.

16. **Issue**

    During reboot, the following error message appears:

    One or more commands in ns.conf failedWhat should I do?

    Resolution

Make sure that no command in the ns.conf file exceeds the 255 byte limit. In commands that create policies that are too long for the 255-byte limit, you can use pattern sets to shorten the policies.

Example:

```
add cs policy p11 -rule 'HTTP.REQ.URL.ENDSWITH_ANY("
    ctx_file_extensions")'
Done
<!--NeedCopy-->
```

ctx_file_extensions is a default patset that covers a large number of extensions. In addition to the default pattern sets, you can create user-defined pattern sets. Add a patset by running the following command:

```
add patset <name>
<!--NeedCopy-->
```

Note: Patsets are supported only in release 9.3 or later.

17. **Issue**

    When upgrading a Citrix ADC VPX appliance, I am told to free up space in /var. What files do I remove?

    Resolution

    Remove the old installation files from /var/tmp/ directory. Also remove unwanted files from /flash.

18. **Issue**

    There is no connectivity to the graphical user interface (GUI) when you run the force HA failover command on the secondary appliance.

    Resolution

    Log on to the secondary appliance using the command line interface and enable the access to GUI by running the set ns ip <IP> -gui enabled command.

19. **Issue**

    After performing an upgrade, and when I click on any link on the GUI that has to load a java applet (Upgrade Wizard or license Wizard), the following error message appears: **GUI version does not match with the kernel version. Please close this instance, clear java plug-in cache and reopen**.

    Resolution

    - Log on to the Citrix ADC using the GUI.

- Navigate to Citrix ADC Gateway > Global Settings.
- Click Change Global Settings under Settings.
- In the details pane, under Client Experience, select Default from the UI theme list.
- Click OK.

20. **Issue**

    If upgrading a Citrix ADC appliance failed because of any reason, how to restore the appliance using the backed-up files?

    Resolution

    If the upgrade is unsuccessful then restore the appliance to the previous version of the Citrix ADC appliance using the backed-up files. For more information, see Backup and restore a Citrix ADC appliance.

    For more information on backup and restore of a Citrix ADC cluster setup, see Backup and restore of a cluster setup.

21. **Issue**

    If licenses are missing after a failed upgrade of a Citrix ADC appliance, how to resolve the issue?

    Resolution

    If any license goes missing or if you want to reallocate the licenses, refer to the following topic Licensing overview.

> **Note**
>
> These troubleshooting steps also apply to issues with configuration loss when downgrading the software across multiple releases.
>
> For any other issue, see the release notes, Knowledge Center articles, and FAQs.

FAQs

September 14, 2021

For answers to the questions that you might have about upgrading the Citrix ADC firmware, see the Installing, Upgrading, and Downgrading FAQs.

New and deprecated commands, parameters, and SNMP OIDs

September 14, 2021

This section lists the new and deprecated commands, parameters, and SNMP OIDs.

New commands

The following table lists the new commands in release 13.0.

Command group	Command
Authentication, authorization, and auditing	add aaa ssoprofile; rm aaa ssoprofile; show aaa ssoprofile; set aaa ssoprofile; add authentication citrixAuthAction; rm authentication citrixAuthAction; set authentication citrixAuthAction; unset authentication citrixAuthAction; show authentication citrixAuthAction; lock aaa user; set aaa otpparameter; show aaa otpparameter; add authentication emailAction; rm authentication emailAction; set authentication emailAction; show authentication emailAction; add authentication noAuthAction; rm authentication noAuthAction; set authentication noAuthAction; show authentication noAuthAction; add authentication captchaAction; rm authentication captchaAction; set authentication captchaAction; show authentication captchaAction; add authentication adfsProxyProfile; rm authentication adfsProxyProfile; set authentication adfsProxyProfile; show authentication adfsProxyProfile
AppFlow	bind appflow action; unbind appflow action
Application Firewall	stat rnat6 and stat MapBmr

Command group	Command
Content Inspection	add contentInspection profile; rm contentInspection profile; set contentInspection profile; show contentInspection profile; add contentInspection callout; rm contentInspection callout; set contentInspection callout; show contentInspection callout; count contentInspection callout; set contentInspection parameter; unset contentInspection parameter; show contentInspection parameter
LSN	add lsn appsattributes; rm lsn appsattributes; set lsn appsattributes; show lsn appsattributes
Network	add rnat; rename rnat; bind rnat; unbind rnat; rm rnat
SSL	add ssl caCertGroup; bind ssl caCertGroup; rm ssl caCertGroup; unbind ssl caCertGroup; show ssl caCertGroup
System	enable system autorestorefeature ; rm system restorepoint; show system restorepoint; migrate ns; show ns timezone; disable system autorestorefeature; create system restorepoint
URL Filtering	add urlfiltering Categorization; clear urlfiltering Categorization; show urlfiltering Categorization
VPN	add vpn urlPolicy; rm vpn urlPolicy; set vpn urlPolicy; show vpn urlPolicy; stat vpn urlPolicy; rename vpn urlPolicy; add vpn urlAction; rm vpn urlAction; set vpn urlAction; show vpn urlAction; rename vpn urlAction

New parameters

Command group: Authentication, authorization, and auditing

Command:

- set aaa parameter [-maxKBQuestions]
- unset aaa parameter [-maxKBQuestions]
- show aaa parameter [-maxKBQuestions]

Command group: Admin Partition

Command:

- add ns ip6 [-advertiseOnDefaultPartition]
- set ns ip6 [-advertiseOnDefaultPartition]
- show ns ip6 [-advertiseOnDefaultPartition]
- add ns ip [-advertiseOnDefaultPartition]
- set ns ip [-advertiseOnDefaultPartition]
- show ns ip [-advertiseOnDefaultPartition]

Command group: AppFlow

Command:

- bind appflow action [-analyticsProfile]
- unbind appflow action [-analyticsProfile]
- show appflow action [-analyticsProfile]
- set appflow param [-gxSessionReporting] [-usageRecordInterval] [-metrics] [-events [-auditlogs] [-observationPointId] [-distributedTracing] [-distTracingSamplingRate] [-tcpAttackCounterInterval]
- show appflow param [-observationPointId] [-subscriberIdObfuscationAlgo] [-gxSessionReporting] [-usageRecordInterval] [-metrics] [-events] [-auditlogs [-distributedTracing] [-distTracingSamplingRate] [-tcpAttackCounterInterval]

Command group: Application Firewall

Command:

- add appfw profile [-postBodyLimitSignature]
- add appfw profile [-rfcprofile]
- set appfw profile [-postBodyLimitSignature] [-rfcprofile]
- show appfw profile [-postBodyLimitSignature] [-rfcprofile]
- set appfw settings [-malformedReqAction]
- show appfw settings [-malformedReqAction]
- import appfw signatures [-preservedefactions]

Command group: Audit

Command:

- add audit syslogAction [-ContentInspectionLog]

- set audit syslogAction [-ContentInspectionLog]
- unset audit syslogAction [-ContentInspectionLog]
- show audit syslogAction [-ContentInspectionLog]
- add audit nslogAction [-ContentInspectionLog]
- set audit nslogAction [-ContentInspectionLog]
- unset audit nslogAction [-ContentInspectionLog]
- show audit nslogAction [-ContentInspectionLog]
- set audit syslogParams [-ContentInspectionLog]
- unset audit syslogParams [-ContentInspectionLog]
- show audit syslogParams [-ContentInspectionLog]
- set audit nslogParams [-ContentInspectionLog]
- unset audit nslogParams [-ContentInspectionLog]
- show audit nslogParams [-ContentInspectionLog]

Command group: Authentication

Command:

- add authentication ldapAction [-KBAttribute] [-alternateEmailAttr]
- set authentication ldapAction [-KBAttribute] [-alternateEmailAttr]
- show authentication ldapAction [-KBAttribute] [-alternateEmailAttr]
- add authentication tacacsAction [-Attributes]
- set authentication tacacsAction [-Attributes]
- show authentication tacacsAction [-Attributes]
- add authentication samlAction [-Attributes] [-storeSAMLResponse]
- set authentication samlAction [-Attributes] [-storeSAMLResponse]
- show authentication samlAction [-Attributes] [-storeSAMLResponse]
- add authentication vserver [-certkeyNames]
- set authentication vserver [-certkeyNames]
- show authentication vserver [-certkeyNames]- show authentication loginSchema [-feature]- - add authentication OAuthIDPProfile [-configservice] [-signatureAlg] [-Attributes][-sendPassword]
- set authentication OAuthIDPProfile [-configservice] [-signatureAlg] [-Attributes] [-sendPassword]
- show authentication OAuthIDPProfile [-configservice] [-signatureAlg] [-Attributes] [-sendPassword]
- add authentication pushService [-CertEndpoint] [-signingKeyName] [-signingKey] [-clientID] [-clientSecret] [-CustomerID] [-refreshInterval] [-trustService]
- set authentication pushService [-CertEndpoint] [-signingKeyName] [-signingKey] [-clientID] [-clientSecret] [-CustomerID] [-refreshInterval] [-trustService]
- show authentication pushService [-clientID] [-clientSecret] [-CustomerID] [-CertEndpoint] [-refreshInterval] [-pushServiceStatus] [-trustService] [-pushCloudServerStatus] [-signingKeyName] [-signingKey]
- show authentication adfsProxyProfile [-adfsTrustStatus]

Command group: Basic

Command:

- add server [-queryType]
- show server [-queryType] [-serviceGroupEntName2] [-svcitmPriority] [-svcitmActSvcs] [-svcitmBoundSvcs] [-weight]
- add service [-contentInspectionProfileName]
- set service[-contentInspectionProfileName]
- unset service [-contentInspectionProfileName]- show service [-contentInspectionProfileName]- bind serviceGroup [-nameServer] [-dbsTTL]
- show serviceGroup [-numOfCurConnections] [-numOfLastConnections] [-nameServer] [-dbsTTL] [-svcitmActSvcs] [-svcitmPriority] [-svcitmBoundSvcs]

Command group: Cache Redirection

Command:

- add cr vserver [-UseOriginIpPortForCache]
- set cr vserver [-UseOriginIpPortForCache]
- show cr vserver [-UseOriginIpPortForCache]

Command group: Clustering

Command:

- show cluster instance [-heterogeneousFlag]

Command group: Content Switching

Command:

- add cs vserver [-persistenceType] [-persistMask] [-v6persistmasklen] [-timeout] [-cookieName] [-persistenceBackup] [-backupPersistenceTimeout]
- set cs vserver [-persistenceType] [-persistMask] [-v6persistmasklen] [-timeout] [-cookieName] [-persistenceBackup] [-backupPersistenceTimeout]
- show cs vserver [-persistenceType] [-persistMask] [-v6persistmasklen] [-timeout] [-cookieName] [-persistenceBackup] [-backupPersistenceTimeout]

Command group: DNS

Command:

- set dns nameServer [-type]
- rm dns nameServer [-type]
- enable dns nameServer [-type]
- disable dns nameServer [-type]
- show dns action64
- set dns parameter [-maxUDPPacketSize]

- show dns parameter [-maxUDPPacketSize]

Command group: GSLB

Command:

- show gslb service [-gslbsvcHealth] [-glsbsvcHealthdescr]
- show gslb parameter [-builtin]

Command group: High Availability

Command:

- show HA node [-haSyncFailureReason]

Command group: ICA

Command:

- set ica parameter [-HDXInsightNonNSAP]
- show ica parameter [-HDXInsightNonNSAP]

Command group: Load Balancing

Command:

- add lb vserver [-adfsProxyProfile]
- set lb vserver [-adfsProxyProfile]
- unset lb vserver [-adfsProxyProfile]
- show lb vserver [-adfsProxyProfile]
- set lb parameter [-dbsTTL]
- show lb parameter [-dbsTTL]

Command group: LSN

Command:

- add lsn logprofile [-analyticsProfile] [-logSessDeletion]
- set lsn logprofile [-analyticsProfile] [-logSessDeletion]
- show lsn logprofile [-analyticsProfile] [-logSessDeletion]
- bind lsn appsprofile [-appsattributesname]
- unbind lsn appsprofile [-appsattributesname]
- show lsn appsprofile [-appsattributesname]

Command group: Network

Command:

- add route [-vlan]
- rm route [-vlan]
- add netProfile [-proxyProtocol] [-proxyProtocoltxversion]

- set netProfile [-proxyProtocol] [-proxyProtocoltxversion]
- show netProfile [-proxyProtocol] [-proxyProtocoltxversion]
- set rnat [-name]
- unset rnat [-name]
- add rnat [-name]
- rename rnat [-name] [-newName]
- bind rnat [-name] [-natIP]
- unbind rnat [-name] [-natIP]
- rm rnat [-name]
- show rnat [-name] [-stateflag]

Command group: Policy

Command:

- show policy expression
- show policy patset
- show policy urlset [-imported]
- import policy urlset [-subdomainExactMatch]

Command group: RDP

Command:

- add rdp clientprofile [-randomizeRDPFilename] [-rdpLinkAttribute]
- set rdp clientprofile [-randomizeRDPFilename] [-rdpLinkAttribute]
- show rdp clientprofile [-randomizeRDPFilename] [-rdpLinkAttribute]
- add rdp serverprofile [-rdpRedirection]
- set rdp serverprofile [-rdpRedirection]
- show rdp serverprofile [-rdpRedirection]

Command group: SSL

Command:

- create ssl ecdsaKey [-pkcs8]
- ssl certKey [-deletefromdevice]
- clear ssl certKey [-ocspstaplingCache]
- add ssl action [-caCertGrpName]
- show ssl action [-clientCertVerification] [-caCertGrpName]
- show ssl ocspResponder [-port]
- create ssl rsakey [-pkcs8]
- set ssl parameter [-ndcppComplianceCertCheck]
- show ssl parameter [-ndcppComplianceCertCheck]
- set ssl vserver [-preload] [-preload]

- show ssl dtlsProfile
- add ssl profile [-preload]
- set ssl profile [-preload]
- show ssl profile [-preload]

Command group: System

Command:

- create system backup [-useLocalTimezone] [-includekernel]
- show system backup [-useLocalTimezone]
- add ns tcpProfile [-taillossprobe]
- set ns tcpProfile [-taillossprobe]
- show ns tcpProfile [-taillossprobe]
- add ns icapProfile [-insertHTTPRequest]
- set ns icapProfile [-insertHTTPRequest]
- show ns icapProfile [-insertHTTPRequest]
- add ns httpProfile [-markTraceReqInval]
- set ns httpProfile [-markTraceReqInval]
- unset ns httpProfile [-markTraceReqInval]
- show ns httpProfile[- markTraceReqInval]
- save ns config all
- set ns param [-mgmthttpport] [-mgmthttpsport] [-proxyProtocol]
- show ns param [-mgmthttpport] [-mgmthttpsport] [-proxyProtocol]
- set ns httpParam [-ignoreConnectCodingScheme]
- show ns httpParam [-ignoreConnectCodingScheme]
- add ns icapProfile [-logAction]
- set ns icapProfile [-logAction]
- show ns icapProfile [-logAction]

Command group: Subscriber

Command:

- set subscriber gxInterface [-healthCheck] [-healthCheckTTL] [-cerRequestTimeout] [-negativeTTLLimitedSuccess] [-purgeSDBonGxFailure] [-gxReportingAvp1] [-gxReportingAvp1VendorId] [-gxReportingAvp1Type] [-gxReportingAvp2] [-gxReportingAvp2VendorId] [-gxReportingAvp2Type] [-gxReportingAvp3] [-gxReportingAvp3VendorId] [-gxReportingAvp3Type] [-gxReportingAvp4] [-gxReportingAvp4VendorId] [-gxReportingAvp4Type] [-gxReportingAvp5] [-gxReportingAvp5VendorId] [-gxReportingAvp5Type]
- show subscriber gxInterface [-healthCheck] [-healthCheckTTL] [-cerRequestTimeout] [-negativeTTLLimitedSuccess] [-purgeSDBonGxFailure] [-gxReportingAvp1] [-gxReportingAvp1VendorId] [-gxReportingAvp1Type] [-gxReportingAvp2] [-gxReportingAvp2VendorId] [-gxReportingAvp2Type] [-gxReportingAvp3] [-gxReportingAvp3VendorId] [-gxReportingAvp3Type] [-gxReportingAvp4]

[-gxReportingAvp4VendorId] [-gxReportingAvp4Type] [-gxReportingAvp5] [-gxReportingAvp5VendorId] [-gxReportingAvp5Type]

Command group: Traffic Management

Command:

- show tm sessionPolicy
- show tm sessionAction
- show tm global
- show tm sessionParameter [-tmsessionpolicyBindtype] [-tmsessionpolicyCount]

Command group: URL Filtering

Command:

- set urlfiltering parameter [-CloudHost] [-SeedDBPath]
- show urlfiltering parameter [-CloudHost] [-SeedDBPath]

Command group: VPN

Command:

- show vpn sessionPolicy
- add vpn sessionAction [-fqdnSpoofedIP]
- set vpn sessionAction [-fqdnSpoofedIP]
- show vpn sessionAction [-feature] [-fqdnSpoofedIP]
- show vpn clientlessAccessPolicy
- bind vpn global [-userDataEncryptionKey]
- unbind vpn global [-userDataEncryptionKey]
- show vpn global [-userDataEncryptionKey]
- set vpn parameter [-fqdnSpoofedIP] [-netmask]
- unset vpn parameter [-fqdnSpoofedIP]
- show vpn parameter [-fqdnSpoofedIP]

Deprecated parameters

Command group: AppFlow

Command:

- add appflow action [-MetricsLog]
- show appflow action [-MetricsLog]

Command group: LSN

Command:

- add lsn transportprofile [-stuntimeout]
- set lsn transportprofile [-stuntimeout]
- show lsn transportprofile [-stuntimeout]

Command group: Network

Command:

- clear rnat

Solutions for Telecom Service Providers

September 14, 2021

Information and Communication Technology (ICT) is about bringing the Internet user closer to the apps and data. The latest datacenter technologies have enabled the user, apps and data to be located anywhere. A user can access apps and data from the office or from home, or from a location such as an airport. The apps and data can be located either on the enterprise's premises, in a public or private cloud, or on a hybrid host. The result has been on only increased productivity, but also reduced costs of ownership and maintenance.

Service provides offer the core infrastructure needed for carrying the user's apps and data over the network. Because the core infrastructure serves millions of subscribers and a wide variety of apps and data, requirements for scale and protocol support are very high. The core infrastructure handles two major types of traffic: data plane and control plane. Each of these planes has its own scale and protocol-support requirements.

The data plane is the part of the core infrastructure that carries user apps and data from end to end, that is, between end-user equipment and the application server. The number of users accessing apps and data is in the thousands of millions, so throughput and IP-addressing requirements are very high. Every user in the network must be uniquely identifiable. Only then can the service provider control the traffic, monitor network usage, deliver user-specific services, and log information correctly. Many of the today's client devices and application servers support IPv6 natively. The core infrastructure must not only support a mix of IPv4 and IPv6 clients and servers, but also provide the technologies for cross-communication between IPv4 and IPv6. Finally, a service provider is measured by the quality of service (directly related to end-user experience) and the availability of service without disruptions. The data plane should be resilient enough to provide both quality and availability at the same time.

The control-plane infrastructure manages user traffic and maintains the business and network operations services. The most important of the many protocols that run in this plane are Diameter, Radius, and SMPP. Diameter is a base protocol over which several other function-specific protocols have been developed. For example:

- Gx interface between the Policy and Charging Enforcement Function (PCEF) and the Policy and Charging Rules Function (PCRF)
- Gy interface between the Online Charging System (OCS) and the Cisco Packet Data Network Gateway (PGW)/Policy and Charging Enforcement Function (PCEF)

The volume of control plane traffic is in direct proportion to user activity. To manage the control plane traffic, service providers use several ADC functionalities, such as load balancing and content switching. They need fine-grain control of control plane traffic, which equals data-plane traffic in complexity.

Service providers must meet demanding service-level agreements (SLAs), and are scrutinized thoroughly by regulators for compliance. Adhering to requirements while managing the data and control plane traffic requires a service provider to keep its infrastructure nimble, within budget, easily upgradable, and flexible. As the most powerful and advanced ADCs in the market today, Citrix ADC products are a natural fit for the service-provider environment.

Large Scale NAT

September 14, 2021

> **Note**
>
> This feature is available with a Citrix ADC Advanced or Premium edition license.

The Internet's phenomenal growth has resulted in a shortage of public IPv4 addresses. Large Scale NAT (LSN/CGNAT) provides a solution to this issue, maximizing the use of available public IPv4 addresses by sharing a few public IPv4 addresses among a large pool of Internet users.

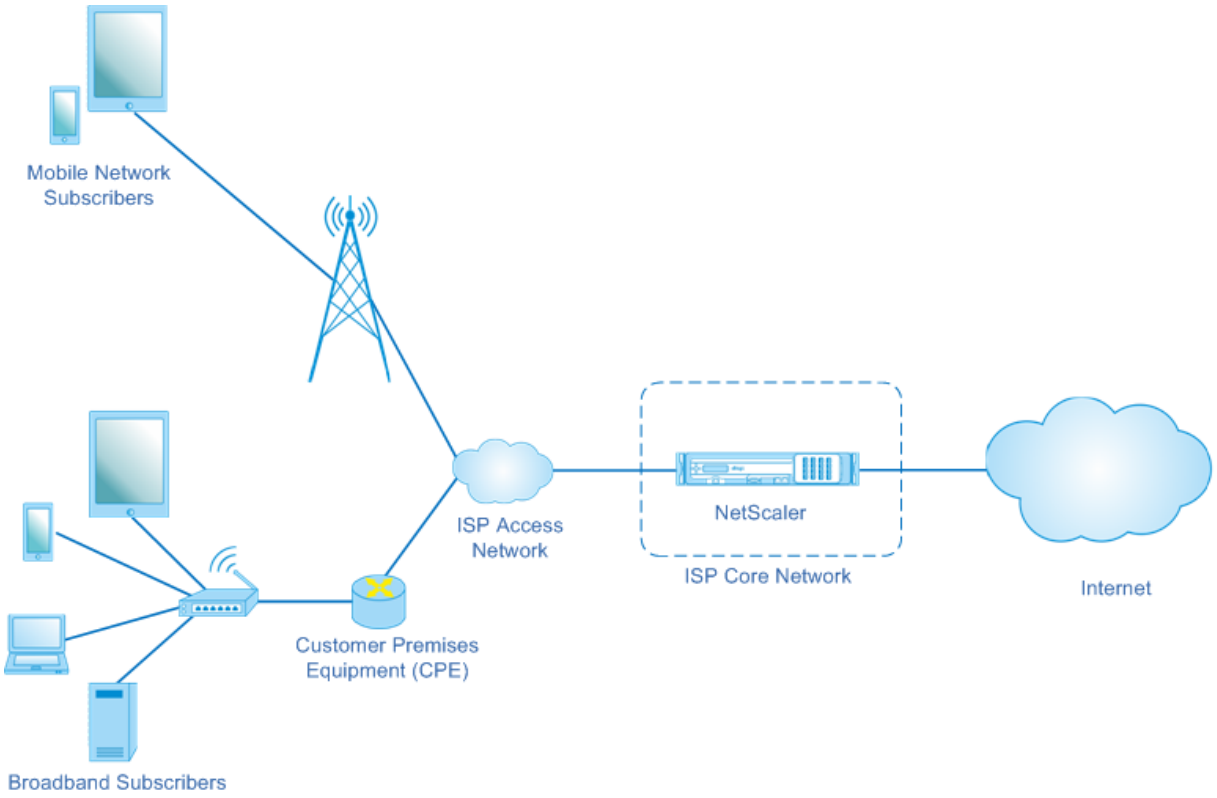
LSN translates private IPv4 addresses into public IPv4 addresses. It includes network address and port translation methods to aggregate many private IP addresses into fewer public IPv4 addresses. LSN is designed to handle NAT on a large scale. The Citrix ADC LSN feature is very useful for Internet Service Providers (ISPs) and carriers providing millions of translations to support a large number of users (subscribers) and at very high throughput.

LSN Architecture

The LSN architecture of an ISP using Citrix products consists of subscribers (Internet users) in private address spaces accessing the Internet through a Citrix ADC appliance deployed in ISP's core network. Subscribers are connected to the ISP through the ISP's access network. Usually, subscribers for commercial use of the Internet are directly connected to the ISP's access network. Serving those subscribers requires only one level of NAT (NAT44).

Noncommercial subscribers, however, are typically behind customer-premises equipment (CPE), such as routers and modems, that also implements NAT. These two levels of NAT create the NAT444

model. Deploying a Citrix ADC appliance in an ISP's core network for LSN functionality is transparent to the subscribers and requires no configuration changes to subscribers or the CPEs.



Large Scale NAT

The Citrix ADC appliance receives all subscriber packets destined to the Internet. The appliance is configured with a pool of pre-defined NAT IP addresses to use for LSN. The Citrix ADC appliance uses its LSN feature to translate the source IP address (private) and port of the packet to the NAT IP address (public) and NAT port, and then sends the packet to its destination on the Internet. The appliance maintains a record of all active sessions that use the LSN feature. These sessions are called LSN sessions. The Citrix ADC appliance also maintains the mappings between subscriber IP address and port, and NAT IP address and port, for each session. These mappings are called LSN mappings. From LSN sessions and LSN mappings, the Citrix ADC appliance recognizes a response packet (received from the Internet) belonging to a particular session. The appliance translates the destination IP address and port of the response packet from NAT IP address:port to the subscriber IP address:port, and sends the translated packet to the subscriber.

LSN Features Supported on Citrix ADC appliance

The following describes some of the LSN features supported on Citrix ADC appliance:

NAT Resource Allocation

The Citrix ADC appliance allocates NAT IP addresses and ports, from its pre-defined NAT resource pool, to subscribers to translate their packets for transmission to external hosts (Internet). The Citrix ADC appliance supports the following types of NAT IP address and port allocation for subscribers:

- **Deterministic.** The Citrix ADC appliance allocates a NAT IP address and a block of ports to each subscriber. The appliance sequentially allocates NAT resources to these subscribers. It assigns the first block of ports on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT address is assigned to the subscriber, and so on.

  The Citrix ADC appliance logs the allocated NAT IP address and the port block for a subscriber. For a connection, a subscriber can be identified just by its mapped NAT IP address and port block. Because of this reason, the Citrix ADC appliance does not log any LSN session created or deleted. If the entire block of ports is being used, the Citrix ADC appliance drops any new connection from the subscriber.

- **Dynamic.** The Citrix ADC appliance allocates a random NAT IP address and a port from the LSN NAT pool for a subscriber's connection. When port block allocation is enabled in the configuration, the appliance allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The Citrix ADC appliance then allocates this NAT IP address and one of the ports from the allocated block to each subsequent connection from this subscriber. If the entire block of ports is being used, the appliance allocates a new random port block to the subscriber when it initiates a new connection. One of the port in the new port block is allocated for the new connection.

IP Pooling

The following NAT resource allocation options are available for subsequent sessions of a subscriber who was allocated a random NAT IP address and port for an existing session.

- **Paired.** The Citrix ADC appliance allocates the same NAT IP address for all sessions associated with the same subscriber. When no more ports are available for that address, the appliance drops any new connections from the subscriber. This option is needed for proper functioning of certain applications that require creation of multiple sessions on the same source IP address (for example in peer-to-peer applications that use RTP or RTCP protocol.
- **Random.** The Citrix ADC appliance allocates random NAT IP addresses, from the pool, for different sessions associated with the same subscriber.

Reusing LSN Mappings

The Citrix ADC appliance can reuse an existing LSN map for new connections originating from the same subscriber IP address and port. The Citrix ADC LSN feature supports the following types of LSN mapping reuse:

1. **Endpoint Independent.** The Citrix ADC appliance reuses the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to any external IP address and port. This type of LSN map reuse is useful for proper functioning of VOIP and peer-to-peer applications.
2. **Address dependent.** The Citrix ADC appliance reuses the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to the same external IP address (Y), regardless of the external port.
3. **Address port dependent.** The Citrix ADC appliance reuses the LSN mapping for subsequent packets sent from the same internal IP address and port (X:x) to the same external IP address and port (Y:y) while the mapping is still active.

LSN Filtering

The Citrix ADC appliance can filter packets from external hosts based on the active LSN sessions and LSN mappings. Consider an example of an LSN mapping that includes the mapping of subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y). The Citrix ADC LSN feature supports the following types of filtering:

1. **Endpoint Independent.** The Citrix ADC appliance filters out only those packets that are not destined to NAT IP:port (N:n), which represents subscriber IP:port (X:x), regardless of the external host IP address and port source (Z:z). The Citrix ADC appliance forwards any packets destined to X:x. In other words, sending packets from the subscriber to any external IP address is sufficient to allow packets from any external host to the subscriber. This type of filtering is useful for proper functioning of VOIP and peer-to-peer applications.
2. **Address dependent.** The Citrix ADC appliance filters out packets not destined to NAT IP:port (N:n), which represents subscriber IP:port (X:x). In addition, the appliance filters out packets from external host IP address and port (Y:y) destined for N:n if the subscriber has not previously sent packets to Y:anyport (external port independent). In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external host's IP address.
3. **Address port dependent.** The Citrix ADC appliance filters out packets not destined to NAT IP:port (N:n), which represents subscriber IP:port (X:x). In addition, the appliance filters out packets from external host IP address and port (Y:y) destined for N:n if the subscriber has not previously sent packets to Y:y. In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external IP address and port.

Quotas

The Citrix ADC appliance can limit the number of NAT ports and sessions for each subscriber to ensure fair distribution of resources among subscribers. The Citrix ADC appliance can also limit the number of session for a subscriber group to ensure fair distribution of resources among different subscriber groups.

- **Port quota.** The Citrix ADC appliance can limit the LSN NAT ports to be used at a time by each subscriber for a specified protocol. For example, you could limit each subscriber to a maximum of 500 TCP NAT ports. When the LSN NAT mappings for a subscriber reach the limit, the Citrix ADC appliance does not allocate additional NAT ports of the specified protocol to that subscriber.
- **Subscriber Session Limit.** The number of concurrent session for a subscriber can be more than it port quota. The Citrix ADC appliance can limit the LSN sessions allowed for each subscriber for a specified protocol. When the number of LSN sessions reaches the limit for a subscriber, the Citrix ADC appliance does not allow the subscriber to open additional sessions of the specified protocol.
- **Group Session Limit.** The Citrix ADC appliance can limit the total number of LSN sessions allowed for a subscriber group for a specified protocol. When the total number of LSN sessions reaches the limit for a group for a specified protocol, the Citrix ADC appliance does not allow any subscriber of the group to open additional sessions of the specified protocol. For example, You limit a group to a maximum of 10000 UDP sessions. When the total number of UDP sessions for this group reaches 10000, the Citrix ADC appliance does not allow any subscriber of the group to open additional UDP sessions.

Application Layer Gateways

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway for a protocol parses the packet's payload and does necessary changes to ensure that the protocol continues to work over LSN.

The Citrix ADC appliance supports ALG for the following protocols:

- FTP
- ICMP
- TFTP
- PPTP
- SIP
- RTSP

Hairpin Support

The Citrix ADC appliance supports communication between subscribers or internal hosts using NAT IP addresses. This type of communication between two subscribers using NAT IP addresses is called hairpin flow. Hairpin flow is enabled by default, and you cannot disable it.

Points to Consider before Configuring LSN

September 14, 2021

Consider the following points before configuring LSN on a Citrix ADC appliance:

- Make sure that you understand the different components of Large Scale NAT, described in RFCs 6888, 5382, 5508, and 4787.
- Endpoint independent mapping (EIM) and endpoint independent filtering (EIF) are disabled by default. These options must be enabled for proper functioning of VoIP and peer-to-peer (P2P) applications.
- **Logging LSN**: Following are the consideration points for logging LSN information:
  - Citrix recommends logging the LSN information on external log servers instead of on the Citrix ADC appliance. Logging on external servers facilitates optimal performance when the appliance creates large numbers of LSN log entries (in order of millions).
  - Citrix recomends using SYSLOG over TCP, or NSLOG. By default SYSLOG uses UDP, and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data.
  - The following limitations apply to SYSLOG over TCP:
    * The Syslog over TCP solution does not provide authentication, integrity check, and privacy.
    * The Citrix ADC appliance relies on the TCP protocol to provide confirmation of SYSLOG message delivery to external log servers.
- **High Availability**: Following are the consideration points for high availability of Citrix ADC appliances for LSN:
  - Citrix recommends configuring the LSN feature in a high availability deployment of two Citrix ADC appliances for uninterrupted and seamless operation of all LSN sessions.
  - In a high availability deployment, Citrix recommends:
    * Setting the SYNC VLAN parameter for dedicating a VLAN for all HA related communication.
    * Synchronizing the symmetric RSS key of the primary node to the secondary node for stateful synchronization of a large number of LSN mappings and sessions.
    * Binding the subnet of LSN IP addresses to a VLAN to avoid flooding of GARP broadcasts on all VLANs after a failover.

  - In a high availability deployment of Citrix ADC appliances, ALG-related sessions are not mirrored to the secondary appliance.
- **Application Layer Gateways (ALGs)**: Following are the consideration points related for ALGs on a Citrix ADC appliance:
  - The following are not supported for SIP ALG:
    - Multicast IP addresses
    - Encrypted SDP
    - SIP messages over TLS
    - FQDN translation in SIP messages
    - Authentication of SIP messages
    - Traffic domains, admin partitions, andCitrix ADC clusters.
    - SIP messages with multipart bodies.
  - The following are not supported for RTSP ALG:
    - Multicast RTSP sessions
    - RTSP session over UDP
    - Citrix ADC traffic domains, admin partitions, andCitrix ADC clusters
  - The Citrix ADC appliance does not support ALG for the IPSec protocol.
- If you disable the LSN feature when some LSN sessions exist on the Citrix ADC appliance, these sessions continue to exist for the duration of the configured timeout interval.
- LSN takes precedence over RNAT. If a packet from a specified LSN subscriber also matches a RNAT rule, the packet is translated according to the LSN configuration.
- Forwarding of packets related only to the LSN sessions is based on the Citrix ADC appliance's routing table.
- Unlike with subnet IP addresses, selection of an LSN NAT IP address for a subscriber's connection is not based on the routing entry for the destination IP address.
- For inbound packets, static LSN mappings take precedence over dynamic LSN mappings.
- For outbound packets, LSN application profiles take precedence over static mapping.
- When a large number of LSN sessions (> 1 million) exist on the Citrix ADC appliance, Citrix recommends displaying selected LSN sessions instead of all of them. In the command line interface or the configuration utility, use the selection parameters for showing LSN session operation.
- To reduce the amount of active memory allocated to the LSN feature, you must warm restart the Citrix ADC appliance after changing the configured-memory setting. Without a warm restart, you can only increase the amount of active memory.

Configuration Steps for LSN

September 14, 2021

Configuring LSN on a Citrix ADC appliance consists of the following tasks:

1. **Set the global LSN parameters.** Global parameters include the amount of Citrix ADC memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
2. **Create an LSN client entity and bind subscribers to it.** An LSN client entity is a set of subscribers on whose traffic you want the Citrix ADC appliance to perform LSN. The client entity includes IPv4 addresses and extended ACL rules for identifying subscribers. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an LSN client entity and binding a subscriber to the LSN client entity. The configuration utility combines these two operations on a single screen.
3. **Create an LSN pool and bind NAT IP addresses to it.** An LSN pool defines a pool of NAT IP addresses to be used by the Citrix ADC appliance to perform LSN. The pool is assigned parameters, such as port block allocation and NAT type (Deterministic or Dynamic). An LSN pool bound to an LSN group applies to all subscribers of an LSN client entity bound to the same group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiple LSN pools can be bound to an LSN group. For Dynamic NAT, an LSN pool can be bound to multiple LSN groups. For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The configuration utility combines these two operations on a single screen.
4. **(Optional) Create an LSN Transport Profile for a specified protocol.** An LSN transport profile defines various timeouts and limits, such as maximum LSN sessions and maximum ports usage, that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
5. **(Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it.** An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The configuration

utility combines these two operations on a single screen.

6. **Create an LSN Group and bind LSN pools, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group.** An LSN group is an entity consisting of an LSN client, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. For Dynamic NAT, an LSN pool can be bound to multiple LSN groups. For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN group and binding LSN pools, LSN transport profiles, LSN application profiles to the LSN group. The configuration utility combines these two operations in a single screen.

The following table lists the maximum numbers of different LSN entities and bindings that can be created on a Citrix ADC appliance. These limits are also subject to memory available on the Citrix ADC appliance.

LSN entities and bindings	Limit
LSN clients	1024
LSN pools	128
LSN groups	1024
Subscriber networks that can be bound to an LSN client	64
Extended ACLs that can be bound to an LSN client	1024
NAT IP addresses in a Pool	4096
LSN pools that can be bound to an LSN group	8
LSN groups that can use the same LSN pool	16
LSN transport profiles that can be bound to an LSN group	3 (one each for TCP, UDP, and ICMP protocols)
LSN groups that can use same LSN transport profile	8
LSN application profiles that can be bound to an LSN group	64
LSN groups that can use same LSN application profile	8

LSN entities and bindings	Limit
Port ranges that can be bound to an LSN application profile	8

Configuration Using the Command Line Interface

To create an LSN client by using the command line interface

At the command prompt, type:

```
add lsn client <clientname>

show lsn client
<!--NeedCopy-->
```

To bind a network address or an ACL rule to an LSN client by using the command line interface

At the command prompt, type:

```
bind lsn client <clientname> ((-network <ip_addr> [-netmask <netmask>]
    [-td<positive_integer>]) | -aclname <string>)

show lsn client
<!--NeedCopy-->
```

To create an LSN pool by using the command line interface

At the command prompt, type:

```
add lsn pool <poolname> [-nattype ( DYNAMIC | DETERMINISTIC )] [-
    portblockallocation ( ENABLED | DISABLED )] [-portrealloctimeout <
    secs>] [-maxPortReallocTmq <positive_integer>]

show lsn pool
<!--NeedCopy-->
```

To bind an IP address range to an LSN pool by using the command line interface

At the command prompt, type:

```
bind lsn pool <poolname> <lsnip>

show lsn pool
<!--NeedCopy-->
```

Note: For removing LSN IP addresses from an LSN pool, use the unbind lsn pool command.

To create an LSN transport profile by using the command line interface

At the command prompt, type:

```
add lsn transportprofile <transportprofilename> <transportprotocol> [-
    sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota <
    positive_integer>] [-sessionquota <positive_integer>] [-
    portpreserveparity ( ENABLED | DISABLED )] [-portpreserverange (
    ENABLED | DISABLED )] [-syncheck ( ENABLED | DISABLED )]

show lsn transportprofile
<!--NeedCopy-->
```

To create an LSN application profile by using the command line interface

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> <transportprotocol> [-ippooling (
    PAIRED | RANDOM )] [-mapping <mapping>] [-filtering <filtering>][-
    tcpproxy ( ENABLED | DISABLED )] [-td <positive_integer>]

show lsn appsprofile
<!--NeedCopy-->
```

To bind an application protocol port range to an LSN application profile by using the command line interface

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
<!--NeedCopy-->
```

To create an LSN group by using the command line interface

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-nattype ( DYNAMIC |
    DETERMINISTIC )] [-portblocksize <positive_integer>] [-logging (
    ENABLED | DISABLED )] [-sessionLogging ( ENABLED | DISABLED )][-
    sessionSync (ENABLED | DISABLED )] [-snmptraplimit <positive_integer
    >] [-ftp ( ENABLED | DISABLED )]

show lsn group
<!--NeedCopy-->
```

To bind LSN profiles and LSN pools to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> (-poolname <string> | -transportprofilename
    <string> | -appsprofilename <string>)

show lsn group
<!--NeedCopy-->
```

Configuration Using the Configuration Utility

To configure an LSN client and bind an IPv4 network address or an ACL rule by using the configuration utility

Navigate to **System** > **Large Scale NAT** > **Clients**, and add a client and then bind an IPv4 network address or an ACL rule to the client.

To configure an LSN pool and bind NAT IP addresses by using the configuration utility

Navigate to **System > Large Scale NAT** > **Pools**, and add a pool and then bind an NAT IP address or a range of NAT IP addresses to the pool.

To configure an LSN transport profile by using the configuration utility

1. Navigate to **System > Large Scale NAT > Profiles**.
2. On the details pane, click **Transport** tab, and then add a transport profile.

To configure an LSN application profile by using the configuration utility

1. Navigate to **System > Large Scale NAT > Profiles**.
2. On the details pane, click **Application** tab, and then add an application profile.

To configure an LSN group and bind an LSN client, pools, transport profiles, and application profiles by using the configuration utility

Navigate to **System > Large Scale NAT > Groups**, and add a group and then bind an LSN client, pools, transport profiles, and application profiles to the group.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn client
  - clientname

    Name for the LSN client entity. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN client is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn client1” or ‘lsn client1’).

    This is a mandatory argument. Maximum Length: 127

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn client
  - clientname

    Name for the LSN client entity. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN client is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn client1” or ‘lsn client1’).

    This is a mandatory argument. Maximum Length: 127

  - network

    IPv4 address(es) of the LSN subscriber(s) or subscriber network(s) on whose traffic you want the Citrix ADC appliance to perform Large Scale NAT.

  - netmask

    Subnet mask for the IPv4 address specified in the Network parameter.

    Default value: 255.255.255.255

- td

  ID of the traffic domain on which this subscriber or the subscriber network (as specified by the network parameter) belongs.

  If you do not specify an ID, the subscriber or the subscriber network becomes part of the default traffic domain.

  Default value: 0

  Minimum value: 0

  Maximum value: 4094

- aclname

  Name(s) of any configured extended ACL(s) whose action is ALLOW. The condition specified in the extended ACL rule identifies the traffic from an LSN subscriber for which the Citrix ADC appliance is to perform large scale NAT. Maximum Length: 127

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn pool
  - poolname

    Name for the LSN pool. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN pool is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn pool1" or 'lsn pool1').

    This is a mandatory argument. Maximum Length: 127

  - nattype

    Type of NAT IP address and port allocation (from the LSN pools bound to an LSN group) for subscribers (of the LSN client entity bound to the LSN group):

    Available options function as follows:

    * **Deterministic**—Allocate a NAT IP address and a block of ports to each subscriber (of the LSN client bound to the LSN group). The Citrix ADC appliance sequentially allocates NAT resources to these subscribers. The Citrix ADC appliance assigns the first block of ports (block size determined by the port block size parameter of the LSN group) on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. In this case, the first port block on

the next NAT address is used for the subscriber, and so on. Because each subscriber now receives a deterministic NAT IP address and a block of ports, a subscriber can be identified without any need for logging. For a connection, a subscriber can be identified based only on the NAT IP address and port, and the destination IP address and port.

* **Dynamic**—Allocate a random NAT IP address and a port from the LSN NAT pool for a subscribers connection. If port block allocation is enabled (in LSN pool) and a port block size is specified (in the LSN group), the Citrix ADC appliance allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The appliance allocates this NAT IP address and a port (from the allocated block of ports) for different connections from this subscriber. If all the ports are allocated (for different subscribers connections) from the subscribers allocated port block, the appliance allocates a new random port block for the subscriber. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group.

  Possible values: DYNAMIC, DETERMINISTIC

  Default value: DYNAMIC

– portblockallocation

  Allocate a random NAT port block, from the available NAT port pool of an NAT IP address, for each subscriber when the NAT allocation is set as Dynamic NAT. For any connection initiated from a subscriber, the Citrix ADC appliance allocates a NAT port from the subscribers allocated NAT port block to create the LSN session.

  You must set the port block size in the bound LSN group. For a subscriber, if all the ports are allocated from the subscribers allocated port block, the Citrix ADC appliance allocates a new random port block for the subscriber.

  For Deterministic NAT, this parameter is enabled by default, and you cannot disable it.

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

– portrealloctimeout

  The waiting time, in seconds, between deallocating LSN NAT ports (when an LSN mapping is removed) and reallocating them for a new LSN session. This parameter is necessary in order to prevent collisions between old and new mappings and sessions. It ensures that all established sessions are broken instead of redirected to a different subscriber. This is not applicable for ports used in:

  * Deterministic NAT

    * Address-Dependent filtering and Address-Port-Dependent filtering
    * Dynamic NAT with port block allocation

  In these cases, ports are immediately reallocated.

  Default value: 0

  Maximum value: 600

- maxPortReallocTmq

  Maximum number of ports for which the port reallocation timeout applies for each NAT IP address. In other words, the maximum deallocated-port queue size for which the reallocation timeout applies for each NAT IP address.

  When the queue size is full, the next port deallocated is reallocated immediately for a new LSN session.

  Default value: 65536

  Maximum value: 65536

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn pool
  - poolname

    Name for the LSN pool. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN pool is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn pool1” or ‘lsn pool1’).

    This is a mandatory argument. Maximum Length: 127

  - lsnip

    IPv4 address or a range of IPv4 addresses to be used as NAT IP address(es) for LSN.

    After the pool is created, these IPv4 addresses are added to the Citrix ADC appliance as Citrix ADC owned IP address of type LSN. An LSN IP address associated with an LSN pool cannot be shared with other LSN pools. IP addresses specified for this parameter must not already exist on the Citrix ADC appliance as any Citrix ADC owned IP addresses. In the command line interface, separate the range with a hyphen. For example: 10.102.29.30-10.102.29.189. You can later remove some or all the LSN IP addresses from the pool, and add IP addresses to the LSN pool.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn transportprofile
  - transportprofilename

    Name for the LSN transport profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN transport profile is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn transport profile1” or ‘lsn transport profile1’).

    This is a mandatory argument. Maximum Length: 127
  - transportprotocol

    Protocol for which to set the LSN transport profile parameters.

    This is a mandatory argument.

    Possible values: TCP, UDP, ICMP
  - sessiontimeout

    Timeout, in seconds, for an idle LSN session. If an LSN session is idle for a time that exceeds this value, the Citrix ADC appliance removes the session.

    This timeout does not apply for a TCP LSN session when a FIN or RST message is received from either of the endpoints.

    Default value: 120

    Minimum value: 60
  - finrsttimeout

    Timeout, in seconds, for a TCP LSN session after a FIN or RST message is received from one of the endpoints.

    f a TCP LSN session is idle (after the Citrix ADC appliance receives a FIN or RST message) for a time that exceeds this value, the Citrix ADC appliance removes the session.

    Since the LSN feature of the Citrix ADC appliance does not maintain state information of any TCP LSN sessions, this timeout accommodates the transmission of the FIN or RST, and ACK messages from the other endpoint so that both endpoints can properly close the connection.

    Default value: 30
  - portquota

Maximum number of LSN NAT ports to be used at a time by each subscriber for the specified protocol. For example, each subscriber can be limited to a maximum of 500 TCP NAT ports. When the LSN NAT mappings for a subscriber reach the limit, the Citrix ADC appliance does not allocate additional NAT ports for that subscriber.

Default value: 0

Minimum value: 0

Maximum value: 65535

- sessionquota

  Maximum number of concurrent LSN sessions allowed for each subscriber for the specified protocol. When the number of LSN sessions reaches the limit for a subscriber, the Citrix ADC appliance does not allow the subscriber to open additional sessions.

  Default value: 0

  Minimum value: 0

  Maximum value: 65535

- portpreserveparity

  Enable port parity between a subscriber port and its mapped LSN NAT port. For example, if a subscriber initiates a connection from an odd numbered port, the Citrix ADC appliance allocates an odd numbered LSN NAT port for this connection. You must set this parameter for proper functioning of protocols that require the source port to be even or odd numbered, for example, in peer-to-peer applications that use RTP or RTCP protocol.

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

- portpreserverange

  If a subscriber initiates a connection from a well-known port (0-1023), allocate a NAT port from the well-known port range (0-1023) for this connection. For example, if a subscriber initiates a connection from port 80, the Citrix ADC appliance can allocate port 100 as the NAT port for this connection.

  This parameter applies to dynamic NAT without port block allocation. It also applies to Deterministic NAT if the range of ports allocated includes well-known ports.

  When all the well-known ports of all the available NAT IP addresses are used in different subscribers connections (LSN sessions), and a subscriber initiates a connection from a well- known port, the Citrix ADC appliance drops this connection.

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

- syncheck

  Silently drop any non-SYN packets for connections for which there is no LSN-NAT session present on the Citrix ADC appliance.

  If you disable this parameter, the Citrix ADC appliance accepts any non-SYN packets and creates a new LSN session entry for this connection.

  Following are some reasons for the Citrix ADC appliance to receive such packets:

  * LSN session for a connection existed but the Citrix ADC appliance removed this session because the LSN session was idle for a time that exceeded the configured session timeout.
  * Such packets can be a part of a DoS attack.

  Possible values: ENABLED, DISABLED

  Default value: ENABLED

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn appsprofile
  - appsprofilename

    Name for the LSN application profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN application profile is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn application profile1” or ‘lsn application profile1’).

    This is a mandatory argument. Maximum Length: 127

  - transportprotocol

    Name of the protocol for which the parameters of this LSN application profile applies.

    This is a mandatory argument.

    Possible values: TCP, UDP, ICMP

  - ippooling

    NAT IP address allocation options for sessions associated with the same subscriber.

    Available options function as follows:

    * **Paired**—The Citrix ADC appliance allocates the same NAT IP address for all sessions associated with the same subscriber. When all the ports of a NAT IP address are used

in LSN sessions (for same or multiple subscribers), the Citrix ADC appliance drops any new connection from the subscriber.

* **Random**—The Citrix ADC appliance allocates random NAT IP addresses, from the pool, for different sessions associated with the same subscriber.

This parameter is applicable to dynamic NAT allocation only.

Possible values: PAIRED, RANDOM

Default value: RANDOM

– mapping

Type of LSN mapping to apply to subsequent packets originating from the same subscriber IP address and port.

Consider an example of an LSN mapping that includes the mapping of the subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y).

Available options function as follows:

* **ENDPOINT-INDEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to any external IP address and port.
* **ADDRESS-DEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to the same external IP address (Y), regardless of the external port.
* **ADDRESS-PORT-DEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same internal IP address and port (X:x) to the same external IP address and port (Y:y) while the mapping is still active.

Possible values: ENDPOINT-INDEPENDENT, ADDRESS-DEPENDENT, ADDRESS-PORT-DEPENDENT

Default value: ADDRESS-PORT-DEPENDENT

– filtering

Type of filter to apply to packets originating from external hosts.

Consider an example of an LSN mapping that includes the mapping of subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y).

Available options function as follows:

* **ENDPOINT INDEPENDENT**—Filters out only packets not destined to the subscriber IP address and port X:x, regardless of the external host IP address and port source (Z:z). The Citrix ADC appliance forwards any packets destined to X:x. In other words, sending packets from the subscriber to any external IP address is sufficient to allow packets from any external hosts to the subscriber.

* **ADDRESS DEPENDENT**—Filters out packets not destined to subscriber IP address and port X:x. In addition, the appliance filters out packets from Y:y destined for the subscriber (X:x) if the client has not previously sent packets to Y:anyport (external port independent). In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external host's IP address.
* **ADDRESS PORT DEPENDENT** (the default)—Filters out packets not destined to subscriber IP address and port (X:x). In addition, the Citrix ADC appliance filters out packets from Y:y destined for the subscriber (X:x) if the subscriber has not previously sent packets to Y:y. In other words, receiving packets from a specific external host requires that the subscriber first send packets first to that external IP address and port.

Possible values: ENDPOINT-INDEPENDENT, ADDRESS-DEPENDENT, ADDRESS-PORT-DEPENDENT

Default value: ADDRESS-PORT-DEPENDENT

– tcpproxy

Enable TCP proxy, which enables the Citrix ADC appliance to optimize the TCP traffic by using Layer 4 features.

Possible values: ENABLED, DISABLED

Default value: DISABLED

– td

ID of the traffic domain through which the Citrix ADC appliance sends the outbound traffic after performing LSN.

If you do not specify an ID, the appliance sends the outbound traffic through the default traffic domain, which has an ID of 0.

Default value: 65535

Maximum value: 65535

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn appsprofile
  - appsprofilename

    Name for the LSN application profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN application profile is created. The following requirement applies only to the

CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn application profile1” or ‘lsn application profile1’).

This is a mandatory argument. Maximum Length: 127

- lsnport

  Port numbers or range of port numbers to match against the destination port of the incoming packet from a subscriber. When the destination port is matched, the LSN application profile is applied for the LSN session. Separate a range of ports with a hyphen. For example, 40-90.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn group
  - groupname

    Name for the LSN group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn group1” or ‘lsn group1’).

    This is a mandatory argument. Maximum Length: 127

  - clientname

    Name of the LSN client entity to be associated with the LSN group. You can associate only one LSN client entity with an LSN group. You cannot remove this association or replace with another LSN client entity once the LSN group is created.

    This is a mandatory argument. Maximum Length: 127

  - nattype

    Type of NAT IP address and port allocation (from the bound LSN pools) for subscribers:

    Available options function as follows:

    * **Deterministic**—Allocate a NAT IP address and a block of ports to each subscriber (of the LSN client bound to the LSN group). The Citrix ADC appliance sequentially allocates NAT resources to these subscribers. The Citrix ADC appliance assigns the first block of ports (block size determined by the port block size parameter of the LSN group) on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. In this case, the first port block on

the next NAT address is used for the subscriber, and so on. Because each subscriber now receives a deterministic NAT IP address and a block of ports, a subscriber can be identified without any need for logging. For a connection, a subscriber can be identified based only on the NAT IP address and port, and the destination IP address and port.

* **Dynamic**—Allocate a random NAT IP address and a port from the LSN NAT pool for a subscriber's connection. If port block allocation is enabled (in LSN pool) and a port block size is specified (in the LSN group), the Citrix ADC appliance allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The appliance allocates this NAT IP address and a port (from the allocated block of ports) for different connections from this subscriber. If all the ports are allocated (for different subscribers connections) from the subscribers allocated port block, the appliance allocates a new random port block for the subscriber.

Possible values: DYNAMIC, DETERMINISTIC

Default value: DYNAMIC

– portblocksize

Size of the NAT port block to be allocated for each subscriber.

To set this parameter for Dynamic NAT, you must enable the port block allocation parameter in the bound LSN pool. For Deterministic NAT, the port block allocation parameter is always enabled, and you cannot disable it.

In Dynamic NAT, the Citrix ADC appliance allocates a random NAT port block, from the available NAT port pool of an NAT IP address, for each subscriber. For a subscriber, if all the ports are allocated from the subscribers allocated port block, the appliance allocates a new random port block for the subscriber.

– logging

Log mapping entries and sessions created or deleted for this LSN group. The Citrix ADC appliance logs LSN sessions for this LSN group only when both logging and session logging parameters are enabled.

The appliance uses its existing syslog and audit log framework to log LSN information. You must enable global level LSN logging by enabling the LSN parameter in the related NSLOG action and SYLOG action entities. When the Logging parameter is enabled, the Citrix ADC appliance generates log messages related to LSN mappings and LSN sessions of this LSN group. The appliance then sends these log messages to servers associated with the NSLOG action and SYSLOG actions entities.

A log message for an LSN mapping entry consists of the following information:

* NSIP address of the Citrix ADC appliance

    * Time stamp
    * Entry type (MAPPING or SESSION)
    * Whether the LSN mapping entry is created or deleted
    * Subscriber's IP address, port, and traffic domain ID
    * NAT IP address and port
    * Protocol name
    * Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
        - Destination IP address and port are not logged for Endpoint-Independent mapping
        - Only Destination IP address (and not port) is logged for Address-Dependent mapping
        - Destination IP address and port are logged for Address-Port-Dependent mapping

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

- sessionLogging

  Log sessions created or deleted for the LSN group. The Citrix ADC appliance logs LSN sessions for this LSN group only when both logging and session logging parameters are enabled.

  A log message for an LSN session consists of the following information:

    * NSIP address of the Citrix ADC appliance
    * Time stamp
    * Entry type (MAPPING or SESSION)
    * Whether the LSN session is created or removed
    * Subscriber's IP address, port, and traffic domain ID
    * NAT IP address and port
    * Protocol name
    * Destination IP address, port, and traffic domain ID

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

- sessionSync

  In a high availability (HA) deployment, synchronize information of all LSN sessions related to this LSN group with the secondary node. After a failover, established TCP connections and UDP packet flows are kept active and resumed on the secondary node (new primary).

  For this setting to work, you must enable the global session synchronization parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

- snmptraplimit

  Maximum number of SNMP Trap messages that can be generated for the LSN group in one minute.

  Default value: 100

  Minimum value: 0

  Maximum value: 10000

- ftp

  Enable Application Layer Gateway (ALG) for the FTP protocol. For some application-layer protocols, the IP addresses and protocol port numbers are usually communicated in the packets payload. When acting as an ALG, the appliance changes the packets payload to ensure that the protocol continues to work over LSN.

  Note: The Citrix ADC appliance also includes ALG for ICMP and TFTP protocols. ALG for the ICMP protocol is enabled by default, and there is no provision to disable it. ALG for the TFTP protocol is disabled by default. ALG is enabled automatically for an LSN group when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

  Possible values: ENABLED, DISABLED

  Default value: ENABLED

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn group
  - groupname

    Name for the LSN group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn group1” or ‘lsn group1’).

    This is a mandatory argument. Maximum Length: 127

  - poolname

Name of the LSN pool to bind to the specified LSN group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group.

For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. For Dynamic NAT, pools bound to an LSN group can be bound to multiple LSN groups. Maximum Length: 127

- transportprofilename

  Name of the LSN transport profile to bind to the specified LSN group. Bind a profile for each protocol for which you want to specify settings.

  By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called a default transport.

  An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol. Maximum Length: 127

- appsprofilename

  Name of the LSN application profile to bind to the specified LSN group. For each set of destination ports, bind a profile for each protocol for which you want to specify settings.

  By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile.

  When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. Maximum Length: 127

Sample LSN Configurations

September 14, 2021

The following are examples of configuring LSN through command line interface.

Create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, and default settings:

```
1 add lsn client LSN-CLIENT-1
2
3 Done
4
5 bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0
```

```
6
7  Done
8
9  add lsn pool LSN-POOL-1
10
11 Done
12
13 bind lsn pool LSN-POOL-1 203.0.113.3
14
15 Done
16
17 add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1
18
19 Done
20
21 bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1
22
23 Done
24 <!--NeedCopy-->
```

Create an LSN configuration with an extended ACL for identifying LSN subscribers:

```
1  add ns acl LSN-ACL-2 ALLOW -srcIP 192.0.2.10-192.0.2.20
2
3  Done
4
5  apply acls
6
7  Done
8
9  add lsn client LSN-CLIENT-2
10
11 Done
12
13 bind lsn client LSN-CLIENT-2  - aclname LSN-ACL-2
14
15 Done
16
17 add lsn pool LSN-POOL-2
18
19 Done
20
21 bind lsn pool LSN-POOL-2 203.0.113.5-203.0.113.10
22
23 Done
```

```
24
25 add lsn group LSN-GROUP-2 -clientname LSN-CLIENT-2
26
27 Done
28
29 bind lsn group LSN-GROUP-2 -poolname LSN-POOL-2
30
31 Done
32 <!--NeedCopy-->
```

Create an LSN configuration with endpoint-independent mapping for HTTP protocol (port 80) and address-port dependent mapping for SSH protocol (port 22). Also, restrict each subscriber to use a maximum of 1000 NAT ports for TCP protocol and 100 NAT ports for UDP protocol. Restrict each subscriber to have a maximum of 2000 concurrent sessions for TCP protocol. Restrict the group to have a maximum of 30000 concurrent sessions for TCP protocol:

```
1  add lsn client LSN-CLIENT-3
2
3  Done
4
5  bind lsn client LSN-CLIENT-3 -network 192.0.3.0 -netmask 255.255.255.0
6
7  Done
8
9  add lsn pool LSN-POOL-3
10
11 Done
12
13 bind lsn pool LSN-POOL-3 203.0.113.11
14
15 Done
16
17 add lsn group LSN-GROUP-3 -clientname LSN-CLIENT-3
18
19 Done
20
21 bind lsn group LSN-GROUP-3 -poolname LSN-POOL-3
22
23 Done
24
25 add lsn appsprofile LSN-APPS-HTTPPROFILE-3 TCP -mapping ENDPOINT-
      INDEPENDENT
26
27 Done
```

```
28
29 bind lsn appsprofile LSN-APPS-HTTPPROFILE-3 80
30
31 Done
32
33 bind lsn group LSN-GROUP-3 -applicationprofilename LSN-APPS-HTTPPROFILE
       -3
34
35 Done
36
37 add lsn appsprofile LSN-APPS-SSHPROFILE-3 TCP -mapping ADDRESS-PORT-
       DEPENDENT
38
39 Done
40
41 bind lsn appsprofile LSN-APPS-SSHPROFILE-3 22
42
43 Done
44
45 bind lsn group LSN-GROUP-3 -applicationprofilename LSN-APPS-SSHPROFILE
       -3
46
47 Done
48
49 add lsn transportprofile LSN-TRANS-PROFILE-TCP-3 TCP -portquota 1000 -
       sessionquota 2000 -groupSessionLimit 30000
50
51 Done
52
53 bind lsn group LSN-GROUP-3 -transportprofilename LSN-TRANS-PROFILE-TCP
       -3
54
55 Done
56
57 add lsn transportprofile LSN-TRANS-PROFILE-UDP-3 UDP -portquota 100
58
59 Done
60
61 bind lsn group LSN-GROUP-3 -transportprofilename LSN-TRANS-PROFILE-UDP
       -3
62
63 Done
64 <!--NeedCopy-->
```

Create an LSN configuration for a large set of subscribers:

```
add lsn client LSN-CLIENT-4

Done

bind lsn client LSN-CLIENT-4 -network 192.0.4.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.5.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.6.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.7.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.8.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-4

Done

bind lsn pool LSN-POOL-4 203.0.113.30-203.0.113.40

Done

bind lsn pool LSN-POOL-4 203.0.113.45-203.0.113.50

Done

bind lsn pool LSN-POOL-4 203.0.113.55-203.0.113.60

Done

add lsn group LSN-GROUP-4 -clientname LSN-CLIENT-4

Done

```

```
bind lsn group LSN-GROUP-4 -poolname LSN-POOL-4

Done

add lsn appsprofile LSN-APPS-WELLKNOWNPROFILE-4 TCP -mapping ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile LSN-APPS-WELLKNOWN-PORTS-PROFILE-4 1- 1023

Done

bind lsn group LSN-GROUP-4 -applicationprofilename LSN-APPS-WELLKNOWN-PORTS-PROFILE-4

Done
<!--NeedCopy-->
```

Create an LSN configuration with sharing of NAT resources among multiple LSN groups. In this example, LSN pool LSN-POOL-5 is shared with LSN groups LSN-GROUP-5 and LSN-GROUP-6:

```
add lsn client LSN-CLIENT-5

Done

bind lsn client LSN-CLIENT-5 -network 192.0.15.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-5

Done

bind lsn pool LSN-POOL-5 203.0.113.12-203.0.113.14

Done

add lsn group LSN-GROUP-5 -clientname LSN-CLIENT-5

Done

bind lsn group LSN-GROUP-5 -poolname LSN-POOL-5

Done
```

```
24
25 add lsn client LSN-CLIENT-6
26
27 Done
28
29 bind lsn client LSN-CLIENT-6 -network 192.0.16.0 -netmask 255.255.255.0
30
31 Done
32
33 add lsn pool LSN-POOL-6
34
35 Done
36
37 bind lsn pool LSN-POOL-6 203.0.113.15-203.0.113.18
38
39 Done
40
41 add lsn group LSN-GROUP-6 -clientname LSN-CLIENT-6
42
43 Done
44
45 bind lsn group LSN-GROUP-6 -poolname LSN-POOL-6
46
47 Done
48
49 bind lsn group LSN-GROUP-6 -poolname LSN-POOL-5
50
51 Done
52 <!--NeedCopy-->
```

Create an LSN configuration with deterministic NAT resource allocation:

```
1  add lsn client LSN-CLIENT-7
2
3  Done
4
5  bind lsn client LSN-CLIENT-7 -network 192.0.17.0 -netmask 255.255.255.0
6
7  Done
8
9  add lsn pool LSN-POOL-7 -nattype DETERMINISTIC
10
11 Done
12
13 bind lsn pool LSN-POOL-7 203.0.113.19-203.0.113.23
```

```
14
15 Done
16
17 add lsn group LSN-GROUP-7 -clientname LSN-CLIENT-7 -nattype
      DETERMINISTIC -portblocksize 1024
18
19 Done
20
21 bind lsn group LSN-GROUP-7 -poolname LSN-POOL-7
22
23 Done
24 <!--NeedCopy-->
```

Create an LSN configuration with multiple subscriber networks having the same network address but each network belonging to a different traffic domain. Also, restrict the outbound traffic related to HTTP protocol (port 80), sending it through a particular traffic domain (td 5):

```
1  add lsn client LSN-CLIENT-8
2
3  Done
4
5  bind lsn client LSN-CLIENT-8 -network 192.0.18.0 -netmask 255.255.255.0
       -td 1
6
7  Done
8
9  bind lsn client LSN-CLIENT-8 -network 192.0.18.0 -netmask 255.255.255.0
       -td 2
10
11 Done
12
13 bind lsn client LSN-CLIENT-8 -network 192.0.18.0 -netmask 255.255.255.0
       -td 3
14
15 Done
16
17 add lsn pool LSN-POOL-8
18
19 Done
20
21 bind lsn pool LSN-POOL-8 203.0.113.80-203.0.113.86
22
23 Done
24
25 add lsn group LSN-GROUP-8 -clientname LSN-CLIENT-8
```

```
26
27 Done
28
29 bind lsn group LSN-GROUP-8 -poolname LSN-POOL-8
30
31 Done
32
33 add lsn appsprofile LSN-APPS-HTTP-PROFILE-8 TCP -td 5
34
35 Done
36
37 bind lsn appsprofile LSN-APPS-HTTP-PROFILE-8 80
38
39 Done
40
41 bind lsn group LSN-GROUP-8 -applicationprofilename LSN-APPS-HTTP-
      PROFILE-8
42
43 Done
44 <!--NeedCopy-->
```

Create an LSN configuration that restricts the outbound traffic of a specific protocol (TCP), sending it through a particular traffic domain (td 5). With endpoint-independent filtering, receive inbound traffic related to this protocol (TCP) on any traffic domain:

```
1  add lsn client LSN-CLIENT-9
2
3  Done
4
5  bind lsn client LSN-CLIENT-9 -network 192.0.9.0 -netmask 255.255.255.0
       -td 1
6
7  Done
8
9  add lsn pool LSN-POOL-9
10
11 Done
12
13 bind lsn pool LSN-POOL-9 203.0.113.90
14
15 Done
16
17 add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9
18
19 Done
```

```
20
21 bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9
22
23 Done
24
25 add lsn appsprofile LSN-APPS-PROFILE-9 TCP -filtering ENDPOINT-
      INDEPENDENT -td 5
26
27 Done
28
29 bind lsn group LSN-GROUP-9 -approfile LSN-APPS-PROFILE-9
30
31 Done
32 <!--NeedCopy-->
```

Create an LSN configuration that restricts outbound HTTP (port 80) traffic, sending it through a particular traffic domain (td 10). With address-dependent filtering, receive inbound traffic related to this protocol (HTTP) on the specified traffic domain (td 10):

```
1  add lsn client LSN-CLIENT-10
2
3  Done
4
5  bind lsn client LSN-CLIENT-10 -network 192.0.10.0 -netmask
      255.255.255.0 -td 1
6
7  Done
8
9  add lsn pool LSN-POOL-10
10
11 Done
12
13 bind lsn pool LSN-POOL-10 203.0.113.100
14
15 Done
16
17 add lsn group LSN-GROUP-10 -clientname LSN-CLIENT-10
18
19 Done
20
21 bind lsn group LSN-GROUP-10 -poolname LSN-POOL-10
22
23 Done
24
25 add lsn appsprofile LSN-APPS-PROFILE-10 TCP -mapping ENDPOINT -
```

```
      INDEPENDENT -filtering ADDRESS-DEPENDENT -td 10
26
27 Done
28
29 bind lsn appsprofile LSN-APPS-PROFILE-10 80
30
31 Done
32
33 bind lsn group LSN-GROUP-10 -approfile LSN-APPS-PROFILE-10
34
35 Done
36 <!--NeedCopy-->
```

Configuring Static LSN Maps

September 14, 2021

The Citrix ADC appliance supports manual creation of a one-to-one LSN mapping between a subscriber IP address:port and a NAT IP address:port. Static LSN mappings are useful in cases where you want to ensure that the connections initiated to a NAT IP:Port maps to the subscriber IP address:Port. For example, Web servers located in the internal network.

To create a static LSN mapping by using the command line interface

At the command prompt, type:

```
1 add lsn static <name> <transportprotocol> <subscrIP> <subscrPort> [-td
     <positive_integer>] [<natIP> [<natPort>]] [-destIP <ip_addr> [-dsttd
      <positive_integer>]]
2 -  show lsn static
3 <!--NeedCopy-->
```

To create a static LSN mapping by using the configuration utility

Navigate to System > Large Scale NAT > Static, and add a new static mapping.

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn static name

Name for the LSN static mapping entry. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “lsn static1” or ‘lsn static1’). This is a mandatory argument. Maximum Length: 127

transportprotocol

Protocol for the LSN mapping entry. This is a mandatory argument. Possible values: TCP, UDP, ICMP

subscrIP

IPv4 address of an LSN subscriber for the LSN mapping entry. This is a mandatory argument.

subscrPort

Port of the LSN subscriber for the LSN mapping entry. This is a mandatory argument. Maximum value: 65535

td

ID of the traffic domain to which the subscriber belongs. If you do not specify an ID, the subscriber is assumed to be a part of the default traffic domain. Default value: 0, Minimum value: 0, Maximum value: 4094

natIP

IPv4 address, already existing on the Citrix ADC appliance as type LSN, to be used as NAT IP address for this mapping entry.

natPort

NAT port for this LSN mapping entry.

destIP

Destination IP address for the LSN mapping entry.

dsttd

ID of the traffic domain through which the destination IP address for this LSN mapping entry is reachable from the Citrix ADC appliance. If you do not specify an ID, the destination IP address is assumed to be reachable through the default traffic domain, which has an ID of 0. Default value: 0, Minimum value: 0, Maximum value: 4094

Wildcard Port Static Maps

A static mapping entry is usually a one-to-one LSN mapping between a subscriber IP address:port and a NAT IP address:port. A one-to-one static LSN mapping entry exposes only one port of the subscriber to the Internet.

Some situations might require exposing all ports (64K) of a subscriber to the Internet (for example, a server hosted on an internal network and running a different service on each port). To make these internal services accessible through the Internet, you have to expose all the ports of the server to the Internet.

One way to meet this requirement is to add 64K one-to-one static mapping entries, one mapping entry for each port. Creating 64K entries is very cumbersome and a big task. Also, this large number of configuration entries might lead to performance issues in the Citrix ADC appliance.

Another simple method is to use wildcard ports in a static mapping entry. You just need to create one static mapping entry with NAT-port and subscriber-port parameters set to the wildcard character (*), and the protocol parameter set to ALL, to expose all the ports of a subscriber to the Internet. For a subscriber's inbound or outbound connections matching a wildcard static mapping entry, the subscriber's port does not change after the NAT operation.

When a subscriber-initiated connection to the Internet matches a wildcard static mapping entry, the Citrix ADC appliance assigns a NAT port that has the same number as the subscriber port from which the connection is initiated. Similarly, an Internet host gets connected to a subscriber's port by connecting to the NAT port that has the same number as the subscriber's port.

Configuring the Citrix ADC appliance to Provide Access to All Ports of an IPv4 Subscriber

To configure the Citrix ADC appliance to provide access to all ports of an IPv4 subscriber, create a wildcard static map with the following mandatory parameter settings:

- Protocol=ALL
- Subscriber port = *
- NAT port = *

In a wildcard static map, unlike in a one-to-one static map, setting the NAT IP parameter is mandatory. Also, the NAT IP address assigned to a wildcard static map cannot be used for any other subscribers.

To create a wildcard static map by using the command line interface

At the command prompt, type:

```
add lsn static <name> ALL <subscrIP> *  <natIP> * [-td <
   positive_integer>] [-destIP <ip_addr> [-dsttd <positive_integer>]]

show lsn static
<!--NeedCopy-->
```

Sample Configuration

In the following sample configuration of a wildcard static map, all ports of a subscriber whose IP address is 192.0.2.10 are made accessible through NAT IP 203.0.11.33.

Sample configuration:

```
add lsn static NAT44-WILDCARD-STATIC-1 ALL  192.0.2.10 * 203.0.113.33 *

Done
<!--NeedCopy-->
```

Configuring Application Layer Gateways

September 14, 2021

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway for a protocol parses the packet's payload and does necessary changes to ensure that the protocol continues to work over LSN.

The Citrix ADC appliance supports ALG for the following protocols:

- FTP
- ICMP
- TFTP
- PPTP
- SIP
- RTSP

Application Layer Gateway for FTP, ICMP, and TFTP Protocols

September 14, 2021

You can enable or disable ALG for the FTP protocol for an LSN configuration by enabling or disabling the FTP option of the LSN group of the LSN configuration.

ALG for the ICMP protocol is enabled by default, and there is no provision to disable it.

ALG for the TFTP protocol is disabled by default. TFTP ALG is enabled automatically for an LSN configuration when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Sample LSN Configuration for FTP ALG:
In the following sample LSN configuration, FTP ALG is enabled for subscribers that have IP address in the range 192.0.2.30-192.0.2.100.

```
add ns acl LSN-ACL-1 ALLOW -srcIP 192.0.2.30-192.0.2.100

Done

apply acls

Done

add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1  -aclname LSN-ACL

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.10

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1  -FTP ENABLED

Done

```

```
bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done
<!--NeedCopy-->
```

Sample LSN Configuration for TFTP ALG:

In the following sample LSN configuration, endpoint-independent mapping and endpoint-independent filtering are enabled for TFTP protocol (UDP port 69). The Citrix ADC appliance automatically enables TFTP ALG for this LSN configuration.

```
add lsn client LSN-CLIENT-2

Done

bind lsn client LSN-CLIENT-2 -network 198.51.100.0 -netmask
   255.255.255.0

Done

add lsn pool LSN-POOL-2

Done

bind lsn pool LSN-POOL-2 203.0.113.10-203.0.113.11

Done

add lsn group LSN-GROUP-2 -clientname LSN-CLIENT-2

Done

bind lsn group LSN-GROUP-2 -poolname pool1 LSN-POOL-2

Done

add lsn appsprofile LSNAPPSPROFILE-TFTP-2 UDP -mapping ENDPOINT-
   INDEPENDENT - filtering ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile LSNAPPSPROFILE-TFTP-2 69

Done

```

```
33 bind lsn group LSN-GROUP-1 -applicationprofilename LSNAPPSPROFILE-TFTP
       -2
34
35 Done
36 <!--NeedCopy-->
```

Application Layer Gateway for PPTP Protocol

September 14, 2021

The Citrix ADC appliance supports Application Layer Gateways (ALGs) for the Point-to-Point Tunneling Protocol (PPTP).

PPTP is a network protocol that enables secure transfer of data from a remote client to an enterprise server by creating a tunnel across TCP/IP-based data networks. PPTP encapsulates PPP packets into IP packets for transmission over the Internet. PPTP establishes a tunnel for each communicating PPTP network server (PNS)-PPTP Access Concentrator (PAC) pair. After the tunnel is set up, enhanced generic routing encapsulation (GRE) is used to exchange PPP packets. A call ID in the GRE header indicates the session to which a particular PPP packet belongs.

The Citrix ADC appliance recognizes PPTP packets that arrive on the default TCP port, 1723. The appliance parses PPTP control packets, translates the call ID, and assigns a NAT IP address. For two-way data communication between the client and server, the Citrix ADC appliance creates an LSN session entry based on the server call ID, and an LSN session based on the client call ID. The appliance then parses the GRE data packets and translates call IDs on the basis of the two LSN session entries.

For PPTP protocol, the Citrix ADC appliance also includes timeout setting for any idle PPTP LSN sessions. If a PPTP LSN session is idle for a time that exceeds the timeout setting, the Citrix ADC appliance removes the session.

Limitations:

The following are the limitations of PPTP ALG on a Citrix ADC appliance:

- PPTP ALG is not supported for hairpin LSN flow.
- PPTP ALG is not supported to work with any RNAT configuration.
- PPTP ALG is not supported in Citrix ADC clusters.

Configuring PPTP ALG

Configuring PPTP ALG on the Citrix ADC appliance consist of the following tasks:

- Create an LSN configuration and enable PPTP ALG on it. In an LSN configuration, the LSN group includes the PPTP ALG setting. For instructions on creating an LSN configuration, see Configuration Steps for LSN.
- (Optional) Set the global timeout for idle PPTP LSN sessions.

To enable PPTP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-pptp ( ENABLED |
   DISABLED )]

show lsn group
<!--NeedCopy-->
```

To set the global timeout for idle PPTP LSN sessions by using the CLI

At the command prompt, type:

```
set appAlgParam -pptpGreIdleTimeout <positive_integer>

show appAlgParam
<!--NeedCopy-->
```

Example:

In the following sample LSN configuration, PPTP ALG is enabled for subscribers in the 192.0.2.0/24 network.

Also idle PPTP LSN session timeout is set to 200 secs.

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3
```

```
14
15 Done
16
17 add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1  -pptp ENABLED
18
19 Done
20
21 bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1
22
23 Done
24
25 set appAlgParam -pptpGreIdleTimeout 200
26
27 Done
28 <!--NeedCopy-->
```

Application Layer Gateway for SIP Protocol

September 14, 2021

Using Large Scale NAT (LSN) with Session Initiation Protocol (SIP) is complicated, because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When LSN is used with SIP, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media.

SIP ALG adheres to the following RFCs:

- RFC 3261
- RFC 3581
- RFC 4566
- RFC 4475

> **Note**
>
> SIP ALG is supported in a Citrix ADC standalone appliance, in a Citrix ADC high availability setup, as well as in a Citrix ADC cluster setup.

How SIP ALG Works

How IP address translation is performed depends on the type and direction of the message. A message can be any of the following:

- Inbound request
- Outbound response
- Outbound request
- Inbound response

For an outgoing message, the private IP address and port number of the SIP client are replaced with the Citrix ADC owned public IP address and port number, called the *LSN pool IP address and port number*, specified during LSN configuration. For an incoming message, the LSN pool IP address and the port number are replaced with the private address of the client. If the message contains any public IP addresses, the Citrix ADC SIP ALG retains them. Also, a pinhole is created on the:

- LSN pool IP address and port on behalf of the private client, so that the messages that arrive at this IP address and port from the public network are treated as SIP messages.
- Public IP address and port on behalf of the public clients, so that the messages that arrive at this IP address and port from the private network are treated as SIP messages.

When a SIP message is sent out across the network, the SIP Application Layer Gateway (ALG) collects information from the message and translates the IP addresses in the following headers into LSN pool IP addresses:

- Via
- Contact
- Route
- Record-Route

In the following sample SIP request message, LSN replaces the IP addresses in the header fields to hide them from the outside network.

```
1 INVITE adam@10.102.185.156 SIP/2.0 Via: SIP/2.0/UDP 192.170.1.161:62914
      From: eve@10.120.210.3 To: adam@10.102.185.156 Call-ID: a12abcde@10
     .120.210.3 Contact: adam@10.102.185.156 Route: <sip:netscreen@10
     .150.20.3:5060> Record-Route: <sip:netscreen@10.150.20.3:5060>
2 <!--NeedCopy-->
```

When a message containing SDP information arrives, the SIP ALG collects information from the message and translates the IP addresses in the following fields into LSN pool IP addresses and port numbers:

- c= (connection information)

  This field can appear at the session or media level. It appears in the following format:

  c=<network-type><address-type><connection-address>

  If the destination IP address is a unicast IP address, the SIP ALG creates pinholes by using the IP address and port numbers specified in the m= field.

- m= (media announcement)

  This field appears at the media level and contains the description of the media. It appears in the following format:

  m=<media><port><transport><fmt list>

- a= (information about the media field)

  This field can appear at the session or media level, in the following format:

  a=<attribute>

  a=<attribute>:<value>

The following excerpt from a sample SDP section shows the fields that are translated for resource allocation.

o=user 2344234 55234434 IN IP4 10.150.20.3

c=IN IP4 10.150.20.3

m=audio 43249 RTP/AVP 0

The following table shows how SIP payload is translated.

Inbound Request (from public to private)	To:	None
	From:	None
	Call-ID:	None
	Via:	None
	Request-URI:	Replace LSN pool IP address with private IP address
	Contact:	None
	Record-Route	None
	Route:	None
Outbound Response (from private to public)	To:	None
	From:	None
	Call-ID:	None
	Via:	None

	Request-URI:	Replace private IP address with LSN pool IP address
	Contact:	Replace private IP address with LSN pool IP address
	Record-Route	None
	Route:	None
Outbound Request (from private to public)	To:	None
	From:	None
	Call-ID:	None
	Via:	Replace private IP address with LSN pool IP address
	Request-URI:	None
	Contact:	Replace private IP address with LSN pool IP address
	Record-Route	None
	Route:	None
Inbound Response (from public to private)	To:	None
	From:	None
	Call-ID:	None
	Via:	Replace LSN pool IP address with private IP address
	Request-URI:	None
	Contact:	Retain public IP address, if present
	Record-Route	None
	Route:	None

Limitations of SIP ALG

A SIP ALG has the following limitations:

- Only SDP payload is supported.
- The following are not supported:
  - Multicast IP addresses
  - Encrypted SDP
  - SIP TLS
  - FQDN translation
  - SIP layer authentication
  - TD/partitioning
  - Multipart body
  - SIP messages over IPv6 network
  - Line folding

Tested SIP Clients and Proxy Servers

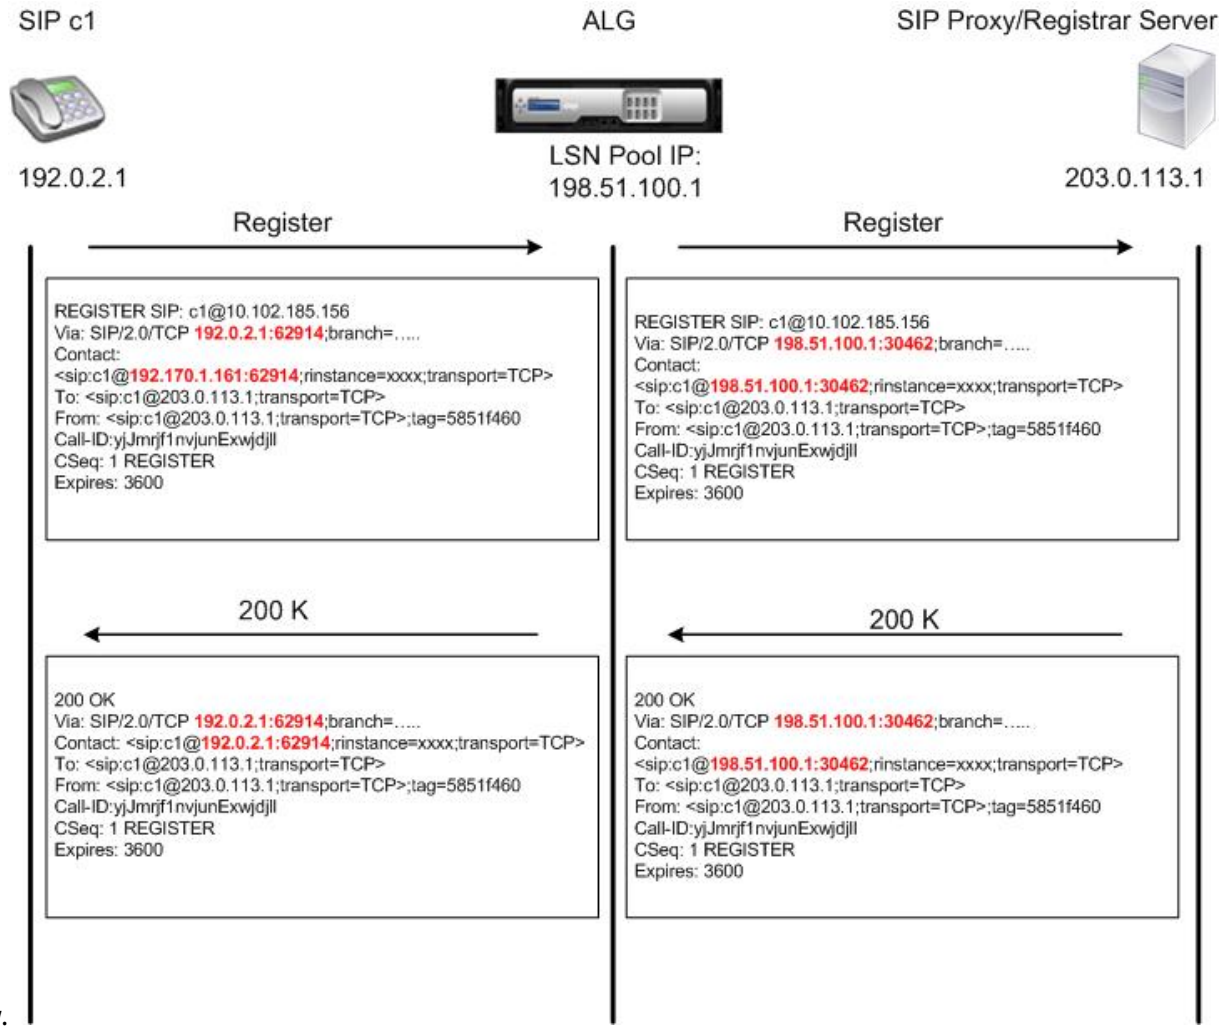
The following SIP clients and proxy server have been tested with SIP ALG:

- **SIP Clients:** X-Lite, Zoiper, Ekiga. Avaya
- **Proxy Server:** openSIPS

LSN SIP Scenario: SIP Proxy Outside the Private Network (Public Network)

SIP Client Registration

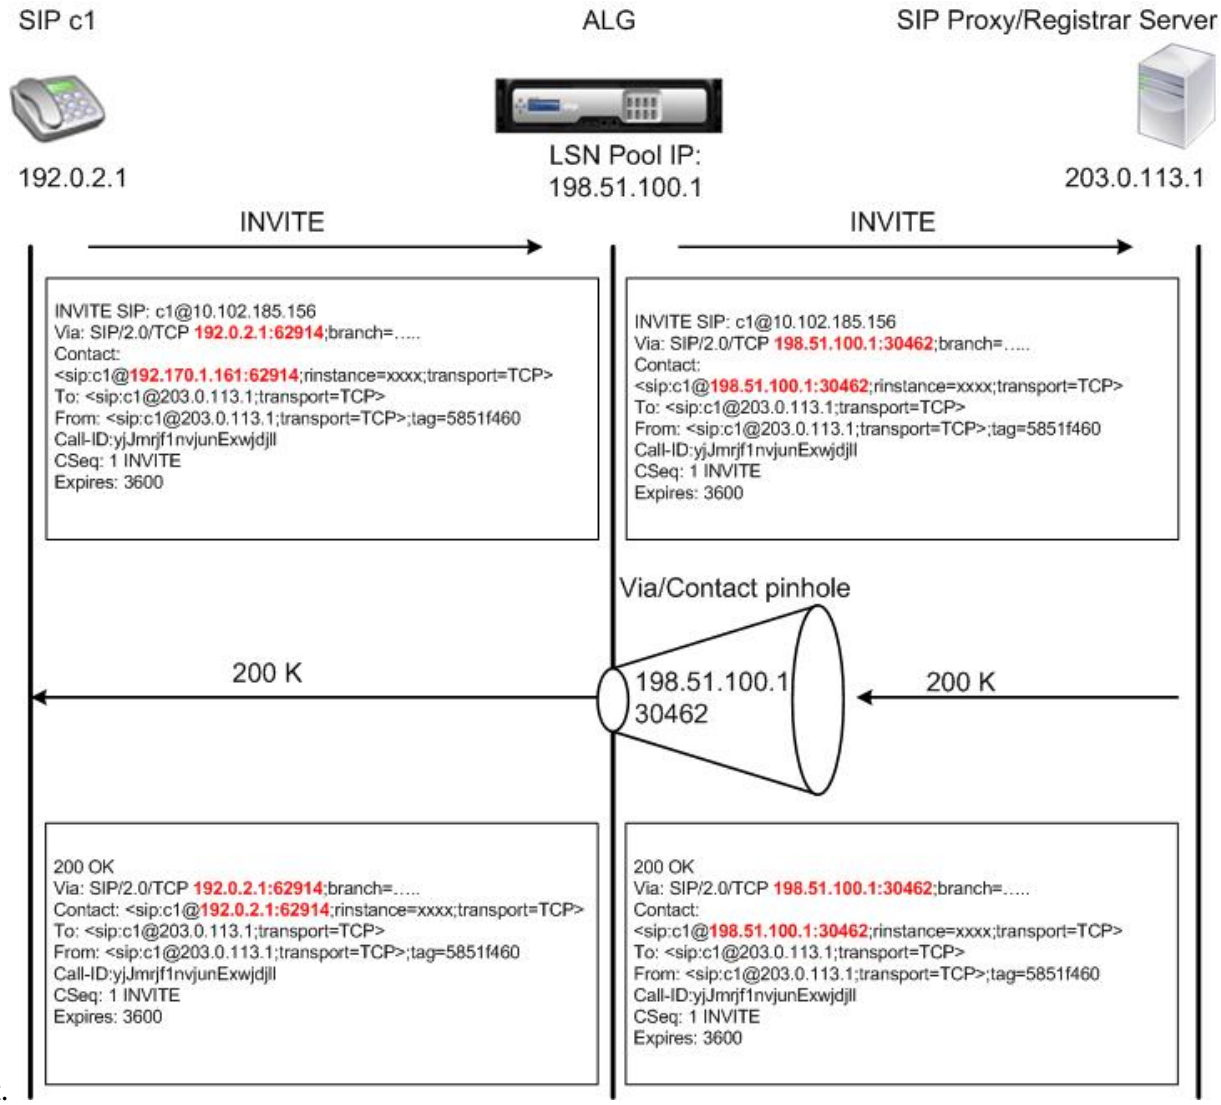
For a typical SIP call, SIP client must register with the SIP registrar by composing a REGISTER request and sending it to the SIP registrar. The Citrix ADC appliance's SIP ALG intercepts the request, replaces the IP address and port number in the request with the LSN pool IP address and port number provided in the LSN configuration, and forwards the request to the SIP registrar. The SIP ALG then opens a pinhole in the Citrix ADC configuration to allow further SIP communication between the SIP client and the SIP registrar. The SIP registrar sends a 200 OK response to the SIP client over the LSN pool IP address and port number. The Citrix ADC appliance captures this response in the pinhole, and the SIP ALG replaces the SIP header, putting the original Contact, Via, Route, and Record-Route SIP fields back into the message. The SIP ALG then forwards the message to the SIP client. The following figure shows how SIP ALG uses LSN in a SIP call registration



flow.

Outgoing Calls

A SIP call is initiated with a SIP INVITE message sent from the internal to the external network. The SIP ALG performs NAT on the IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, replacing them with the LSN pool IP address and port number. LSN stores these mappings for subsequent SIP messages in the SIP call. The SIP ALG then opens separate pinholes in the Citrix ADC configuration to allow SIP and media through the Citrix ADC appliance on the dynamically assigned ports specified in the SDP and SIP headers. When a 200 OK message arrives at the Citrix ADC, it is captured by one of the created pinholes. The SIP ALG replaces the SIP header, restoring the original Contact, Via, Route, and Record-Route SIP fields, and then forwards the message to the internal SIP

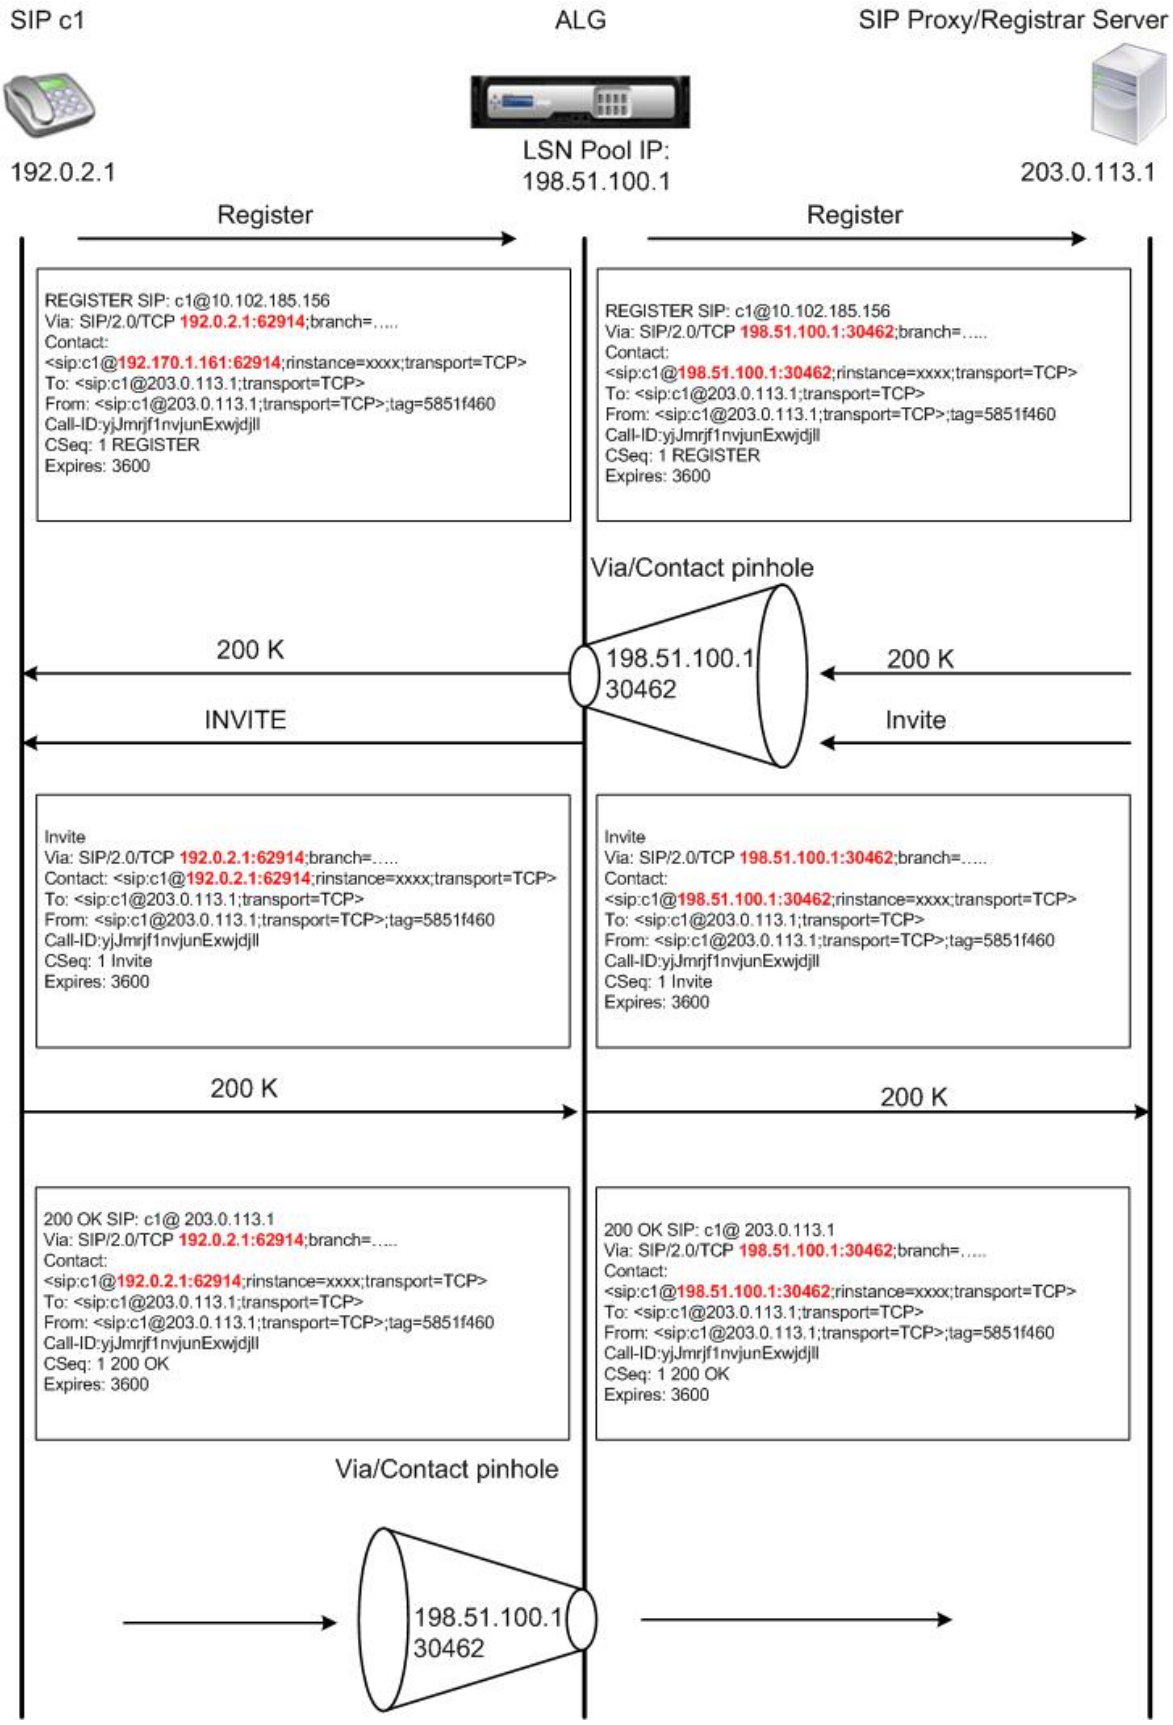


client.

Incoming Calls

A SIP incoming call is initiated with a SIP INVITE message from the external client to the internal network. The SIP registrar forwards the INVITE message to the SIP client in the internal network, using the pinhole that was created when the Internal SIP client registered with the SIP registrar.

The SIP ALG performs NAT on the LSN IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, translating them to the IP address and port number of the internal SIP client, and forwards the request to the SIP client. When the 200 OK response message sent by the internal SIP client arrives at the Citrix ADC appliance, the SIP ALG performs NAT on the IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, translating them to the LSN pool IP address and port number, forwards the response message to the SIP registrar, and then opens a pinhole in the outbound direction for further SIP communica-



tion.

Call Termination

The BYE message terminates a call. When the device receives a BYE message, it translates the header fields in the message just as it does for any other message. But because a BYE message must be acknowledged by the receiver with a 200 OK, the ALG delays call teardown for 15 seconds to allow time for transmission of the 200 OK.

Call Between Clients in the Same Network

When both client A and client B in the same network initiate a call, the SIP messages are routed through the SIP proxy in the outside network. The SIP ALG processes the INVITE from client A as a normal outgoing call. Since client B is in the same network, the SIP proxy sends the INIVITE back to the Citrix ADC appliance. The SIP ALG examines the INIVITE message, determines that it contains the NAT IP address of client A, and replaces that address with the private IP address of client A before sending the message to client B. Once the call is established between the clients, the Citrix ADC is not involved in the media transmission between the clients.

More LSN SIP Scenarios: SIP Proxy Inside the Private Network

If you want to host the SIP Proxy server inside the private network, Citrix recommends that you do one of the following:

- Configure a static LSN Mapping for the private SIP proxy. For more information, see Configuring Static LSN Maps. Make sure that the NAT port is the same as the port configured in the SIP ALG profile.
- Configure the SIP Proxy server inside a demilitarized zone (DMZ).

Figure 1. SIP Call Registration

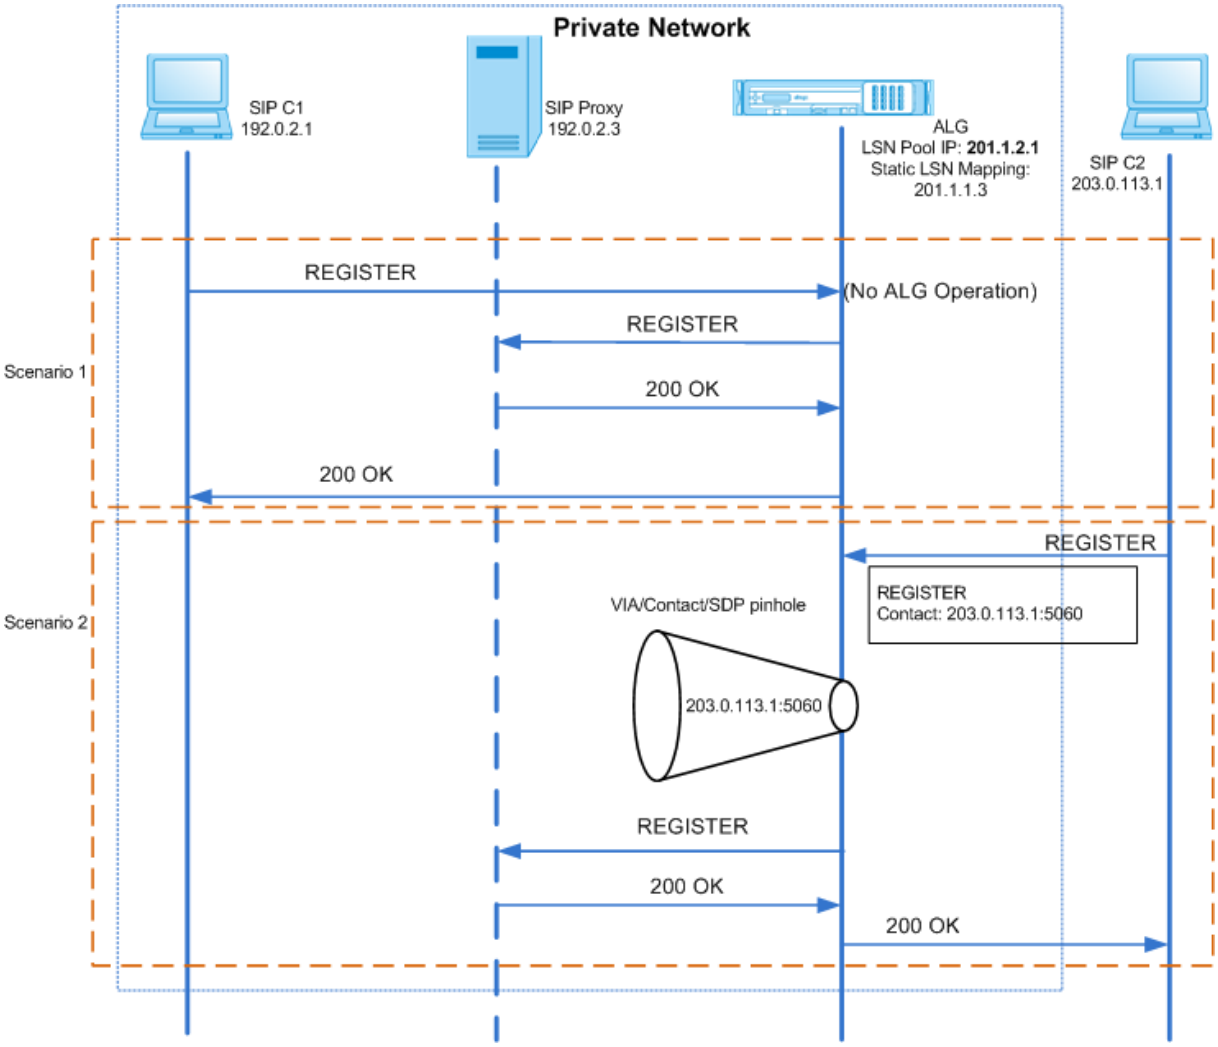


Figure 2. SIP Incoming Call Flow

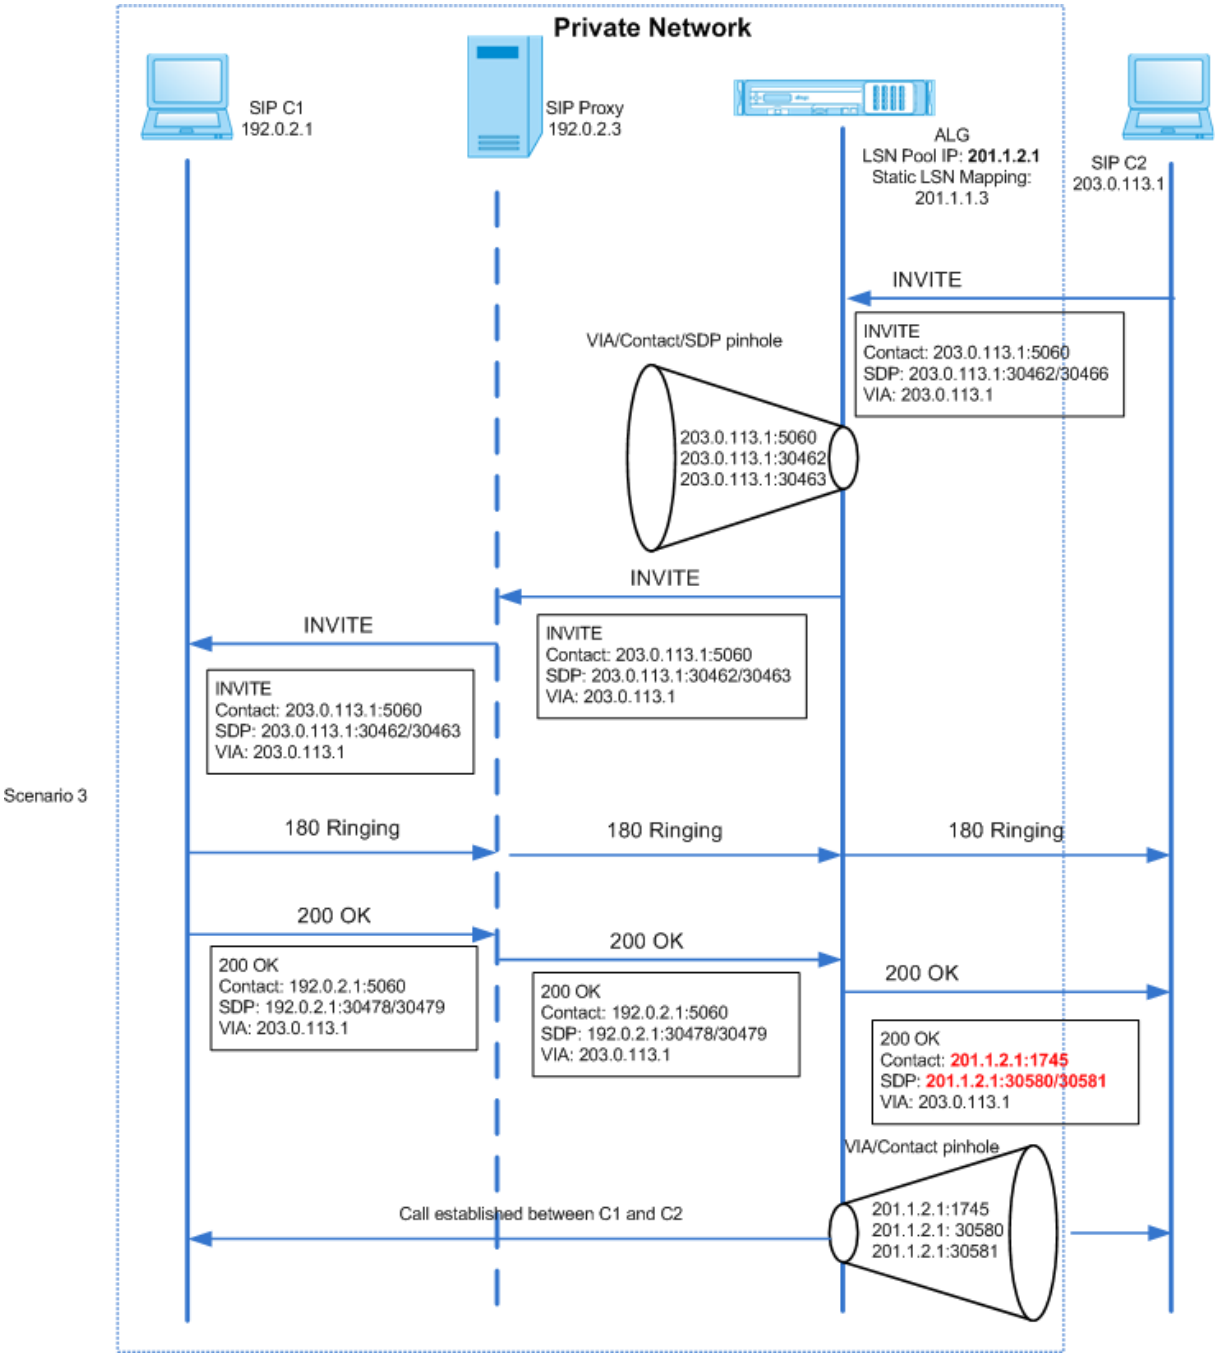

Figures 1 and 2 show the following scenarios:

- Scenario 1—SIP client in the private network registers with the SIP proxy server in the same network. ALG operations are not performed, because the SIP client and SIP proxy server are in the same network.
- Scenario 2—SIP client in the public network registers with the SIP proxy server in the private network. The REGISTER message from the public SIP client is sent to the Citrix ADC appliance by using the static LSN mapping configured on the appliance, and the appliance creates a pinhole

for further SIP operations.

- Scenario 3— SIP Incoming call flow. A SIP incoming call is initiated with a SIP INVITE message from the external to the internal network. The Citrix ADC appliance receives the INVITE message from SIP client C2, which is in the external network, through the static LSN maps configured on the Citrix ADC appliance.
  The appliance creates a pinhole and forwards the INVITE message to the SIP proxy. The SIP proxy then forwards the INVITE message to SIP client C1 in the internal network. SIP client C1 then sends 180 and 200 OK messages to the SIP proxy, which in turn forwards the message to SIP client C2 through the Citrix ADC appliance.
  When the 200 OK response message sent by internal SIP client C1 arrives at the Citrix ADC, the SIP ALG performs NAT on the IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, and in the SDP fields, replacing them with the LSN pool IP address and port number. The SIP ALG then forwards the response message to SIP client C2 and opens a pinhole in the outbound direction for further SIP communication.

Support for Audit Logs

You can log ALG information as part of LSN logging by enabling ALG in the LSN audit logging configuration. For more information on LSN logging, see Logging and Monitoring LSN. A log message for an ALG entry in the LSN log consists of the following information:

- Time stamp
- Type of SIP message (for example, SIP request)
- Source IP address and port of the SIP client
- Destination IP address and port of the SIP proxy
- NAT IP address and port
- SIP method
- Sequence number
- Whether or not the SIP client is registered
- Caller's user name and domain
- Receiver's user name and domain

Sample audit log:

Request:

```

Configuring SIP ALG

You need to configure the SIP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuration Steps for LSN. While configuring LSN, make sure that you:

- Set the following parameters while adding the LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT

Important: For the SIP ALG to work, a full cone NAT configuration is mandatory.

Example:

```
add lsn appsprofile app_tcp TCP -ippooling PAIRED -mapping ENDPOINT-
    INDEPENDENT -filtering ENDPOINT-INDEPENDENT
<!--NeedCopy-->
```

- Create a SIP ALG profile and make sure that you define either the source port range or destination port range.

Example:

```
add lsn sipalgprofile sipalgprofile_tcp -sipsrcportrange 1-65535 -
    sipdstportrange 5060 -openViaPinhole ENABLED -openRecordRoutePinhole
     ENABLED  - sipTransportProtocol TCP
<!--NeedCopy-->
```

- Set SIP ALG = ENABLED, while creating the LSN group.

Example:

```
add lsn group g1 -clientname c1 -sipalg ENABLED
<!--NeedCopy-->
```

- Bind the SIP ALG profile to the LSN group.

Sample SIP ALG Configuration:

The following sample configuration shows how to create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, SIP ALG specific setting, and configure SIP ALG:

```
add lsn pool p1

Done

bind lsn pool p1 10.102.185.190

Done

add lsn client c1

Done

bind lsn client c1 -network 192.170.1.0 -netmask 255.255.255.0

Done

add lsn appsprofile app_tcp TCP -ippooling PAIRED -mapping ENDPOINT-
    INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn appsprofile app_udp UDP -ippooling PAIRED -mapping ENDPOINT-
    INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile app_tcp 1-65535

Done

bind lsn appsprofile app_udp 1-65535

Done
```

```
32
33 add lsn sipalgprofile sipalgprofile_tcp -sipdstportrange 5060 -
      openViaPinhole ENABLED -openRecordRoutePinhole ENABLED  -
      sipTransportProtocol TCP
34
35 Done
36
37 add lsn sipalgprofile sipalgprofile_udp -sipdstportrange 5060 -
      openViaPinhole ENABLED -openRecordRoutePinhole ENABLED -
      sipTransportProtocol UDP
38
39 Done
40
41 add lsn group g1 -clientname c1 -sipalg ENABLED
42
43 Done
44
45 bind lsn group g1 -poolname p1
46
47 Done
48
49 bind lsn group g1 -appsprofilename app_tcp
50
51 Done
52
53 bind lsn group g1 -appsprofilename app_udp
54
55 Done
56
57 bind lsn group g1 -sipalgprofilename sipalgprofile_tcp
58
59 Done
60
61 bind lsn group g1 -sipalgprofilename sipalgprofile_udp
62
63 Done
64 <!--NeedCopy-->
```

Application Layer Gateway for RTSP Protocol

September 14, 2021

Real Time Streaming Protocol (RTSP) is an application-level protocol for the transfer of real-time media data. Used for establishing and controlling media sessions between end points, RTSP is a control channel protocol between the media client and the media server. The typical communication is between a client and a streaming media server.

Streaming media from a private network to a public network requires translating IP addresses and port numbers over the network. Citrix ADC functionality includes an Application Layer Gateway (ALG) for RTSP, which can be used with Large Scale NAT (LSN) to parse the media stream and make any necessary changes to ensure that the protocol continues to work over the network.

How IP address translation is performed depends on the type and direction of the message, and the type of media supported by the client-server deployment. Messages are translated as follows:

- Outbound request—Private IP address to Citrix ADC owned public IP address called an LSN pool IP address.
- Inbound response—LSN pool IP address to private IP address.
- Inbound request—No translation.
- Outbound response—Private IP address to LSN pool IP address.

> **Note**
>
> RTSP ALG is supported in a Citrix ADC standalone appliance, in a Citrix ADC high availability setup, as well as in a Citrix ADC cluster setup.

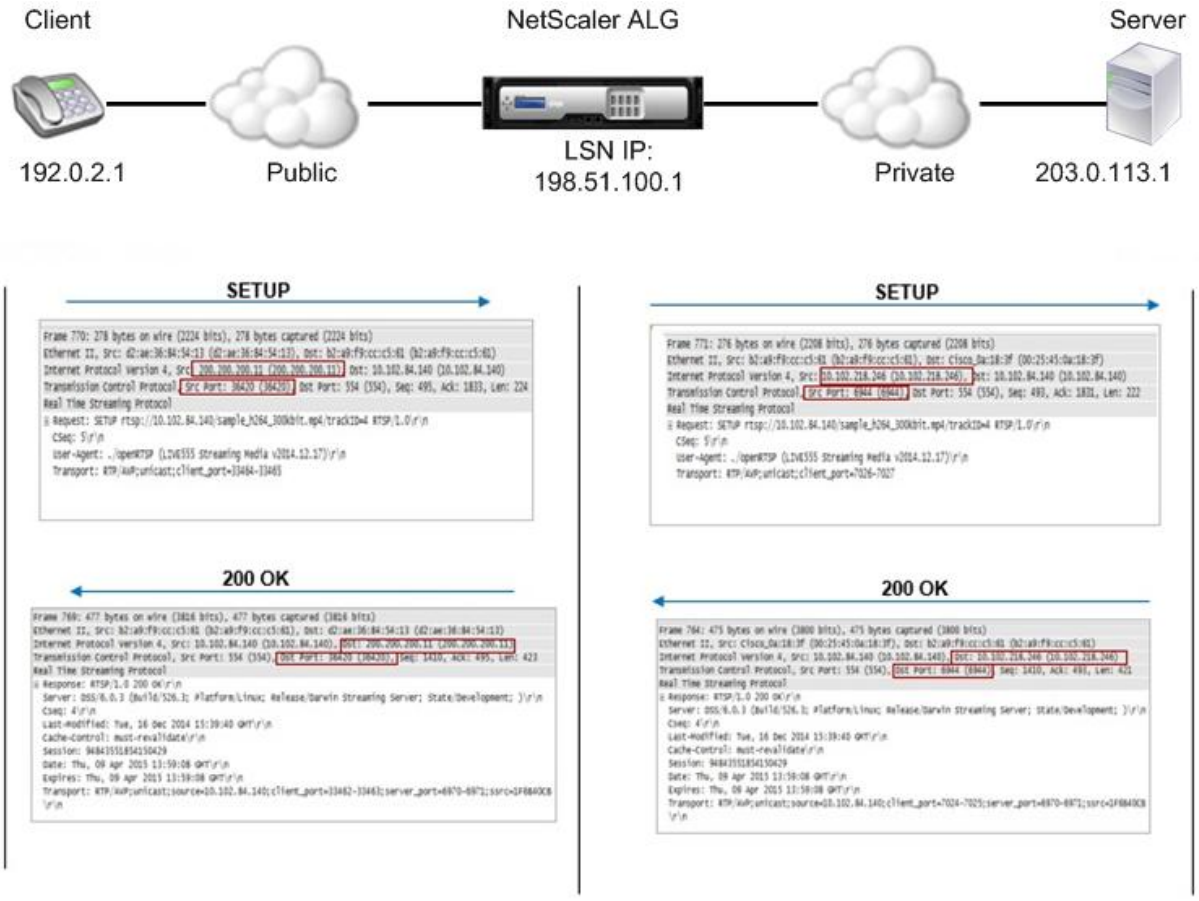
Limitations of RTSP ALG

The RTSP ALG does not support the following:

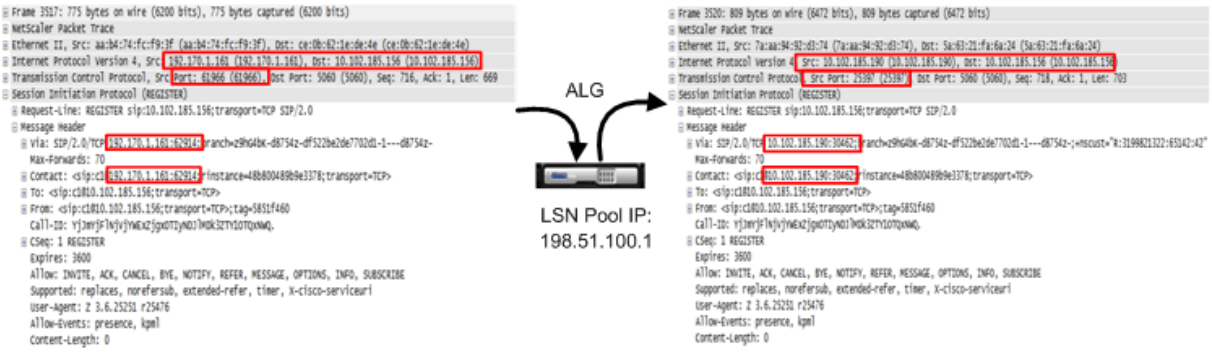
- Multicast RTSP sessions
- RTSP session over UDP
- TD/admin partitioning
- RSTP Authentication
- HTTP tunneling

RTSP and LSN scenario

The following figure shows an RTSP SETUP request flow. Typically, a SETUP request specifies how a single media stream must be transported. The request contains the media stream URL and a transport specifier. This specifier typically includes one local port for receiving RTP data (audio or video), and another for receiving RTCP data (meta information). The server reply usually confirms the chosen parameters and fills in the missing parts, such as the server's chosen ports. Each media stream must be configured by using the SETUP command before an aggregate play request can be sent.

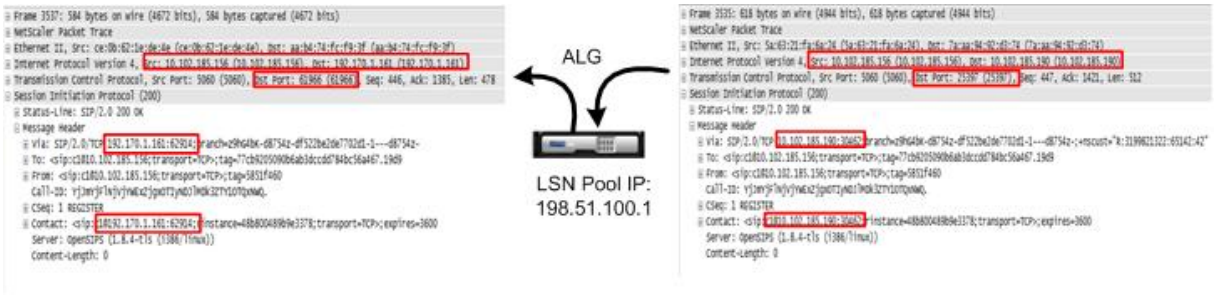


In a typical RTSP communication, the media client in the public network sends a SETUP request to the media server in the private network. RSTP ALG intercepts the request and, in the media stream, replaces the public IP address and port number with the LSN pool IP address and LSN port number. The following figure shows the translation performed by a Citrix ADC appliance in the media stream for an outbound request:



The media server in the private network uses the LSN pool IP address and LSN port number to send a 200 OK response to the media client in the public network. The Citrix ADC RTSP ALG intercepts the response and replaces the LSN pool IP address and LSN port number with the public IP address and port number of the media client. The following figure shows the translation performed by a Citrix ADC

appliance in the media stream for an inbound response:



Configuring RTSP ALG

Configure RTSP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuration Steps for LSN. While configuring LSN, make sure that you:

- Set the **NAT Type** as DETERMINSTIC or DYNAMIC while adding the LSN pool.
- Set the following parameters while adding the LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Create a RTSP ALG profile and bind the RTSP ALG profile to the LSN group

Sample RTSP ALG Configuration:

The following sample configuration shows how to create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, and RTSP ALG settings:

```
1  enable ns feature WL SP LB CS LSN
2
3  Done
4
5  add lsn pool pool1 -nattype DETERMINISTIC
6
7  Done
8
9  bind lsn pool pool1 10.102.218.246
10
11 Done
12
13 add lsn client client1
14
15 Done
16
17 bind lsn client client1 -network 200.200.200.11 -netmask 255.255.255.0
18
```

```
Done

add lsn appsprofile app1 TCP -ippooling PAIRED -mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn appsprofile app2 UDP -ippooling PAIRED -mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile app1 1-65535

Done

bind lsn appsprofile app2 1-65535

Done

add lsn rtspalgprofile rtspalgprofiledefault -rtspIdleTimeout 1000 -rtspportrange 554

Done

add lsn group group1 -clientname client1 -nattype DETERMINISTIC -portblocksize 512 -rtspalg ENABLED

Done

bind lsn group group1 -poolname pool1

Done

bind lsn group group1 -appsprofilename app1

Done

bind lsn group group1 -appsprofilename app2

Application Layer Gateway for IPSec Protocol

September 14, 2021

If communication between two network devices (for example, client and server) uses the IPSec protocol, IKE traffic (which is over UDP) uses port fields, but Encapsulating Security Payload (ESP) traffic does not. If a NAT device on the path assigns the same NAT IP address (but different ports) to two or more clients at the same destination, the NAT device is unable to distinguish and properly route the return ESP traffic does not contain port information. Therefore, IPSec ESP traffic fails at the NAT device.

NAT-Traversal (NAT-T) capable IPSec endpoints detect the presence of an intermediate NAT device during IKE phase 1 and switch to UDP port 4500 for all subsequent IKE and ESP traffic (encapsulating ESP in UDP). Without NAT-T support on the peer IPSec endpoints, IPSec protected ESP traffic is transmitted without any UDP encapsulation. Therefore, IPSec ESP traffic fails at the NAT device.

The Citrix ADC appliance supports IPSec application layer gateway (ALG) functionality for large scale NAT configurations. The IPSec ALG processes IPSec ESP traffic and maintains session information so that the traffic does not fail when the IPSec endpoints do no support NAT-T (UDP encapsulation of ESP traffic).

How IPSec ALG Works

An IPSec ALG monitors IKE traffic between a client and the server, and permits only one IKE phase 2 message exchange between the client and the server at any given time.

Once the two-way ESP packets are received for a particular flow, the IPSec ALG creates a NAT session for this particular flow so that subsequent ESP traffic can flow smoothly. The ESP traffic is identified by Security Parameters Indexes (SPIs), which are unique for a flow and for each direction. An IPSec ALG uses ESP SPIs in place of source and destination ports for performing large scale NAT.

If a gate receives no traffic, it times out. After both gates time out, another IKE phase 2 exchange is permitted.

IPSec ALG Timeouts

IPsec ALG on a Citrix ADC appliance has three timeout parameters:

- **ESP Gate Timeout**. Maximum time that the Citrix ADC appliance blocks an IPSec ALG gate for a particular client on a specific NAT IP address for a given server if no two-way ESP traffic is exchanged between the client and the server.
- **IKE Session Timeout**. Maximum time that the Citrix ADC appliance keeps the IKE session information before removing it if there is no IKE traffic for that session.
- **ESP Session Timeout**. Maximum time that Citrix ADC appliance keeps the ESP session information before removing it if there is no ESP traffic for that session.

Points to Consider before Configuring IPSec ALG

Before you start configuring IPSec ALG, consider the following points:

- You must understand the different components of IPSec protocol.
- IPSec ALG is not supported for DS-Lite and Large scale NAT64 configurations.
- IPSec ALG is not supported for hairpin LSN flow.
- IPSec ALG does not work with RNAT configurations.
- IPSec ALG is not supported in Citrix ADC clusters.

Configuration Steps

Configuring IPSec ALG for large scale NAT44 on a Citrix ADC appliance consists of the following tasks:

- **Create an LSN application profile and bind it to the LSN configuration.** Set the following parameters while configuring an application profile:
  - Protocol=UDP
  - IP Pooling = PAIRED
  - Port=500

Bind the application profile to the LSN group of an LSN configuration. For instructions on creating an LSN configuration, see Configuration Steps for LSN.

- **Create an IPSec ALG profile**. An IPSec profile includes various IPSec timeouts, such as IKE session timeout, ESP session timeout, and ESP gate timeout. You bind an IPSec ALG profile to an LSN group. An IPSec ALG profile has the following default settings:
  - IKE session timeout = 60 minutes
  - ESP session timeout = 60 minutes
  - ESP gate timeout = 30 seconds
- **Bind the IPSec ALG profile to the LSN configuration**. IPSec ALG is enabled for an LSN configuration when you bind an IPSec ALG profile to the LSN configuration. Bind the IPSec ALG profile to the LSN configuration by setting the IPSec ALG profile parameter to the name of the created profile in the LSN group. An IPSec ALG profile can be bound to multiple LSN groups, but an LSN group can have only one IPSec ALG profile.

To create an LSN application profile by using the command line interface

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> UDP -ippooling PAIRED

show lsn appsprofile
<!--NeedCopy-->
```

To bind destination port to the LSN application profile by using the command line interface

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
<!--NeedCopy-->
```

To bind an LSN application profile to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -appsprofilename <string>

show lsn group
<!--NeedCopy-->
```

To create an IPSec ALG profile by using the CLI

At the command prompt, type:

```
add ipsecalg profile <name> [-ikeSessionTimeout <positive_integer>] [-
    espSessionTimeout <positive_integer>] [-espGateTimeout <
    positive_integer>] [-connfailover ( ENABLED | DISABLED)

show ipsecalg profile <name>
<!--NeedCopy-->
```

To bind an IPSec ALG profile to an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname> -poolname <string> - ipsecAlgProfile <string
    >

show lsn group <name>
<!--NeedCopy-->
```

To create an LSN application profile and bind it to an LSN configuration by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Application** tab, add an LSN application profile and bind it to an LSN group.

To create an IPSec ALG profile by using the GUI**

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **IPSEC ALG** tab, and then add an IPSec ALG profile.

To bind an IPSec ALG profile to an LSN configuration by using the GUI**

1. Navigate to **System** > **Large Scale NAT** > **LSN Group**, open the LSN group.
2. In **Advanced Settings**, click **+ IPSEC ALG Profile** to bind the created IPSec ALG profile to the LSN group.

Sample Configuration

In the following sample large scale NAT44 configuration, IPSec ALG is enabled for subscribers in the 192.0.2.0/24 network. IPSec ALG profile IPSECALGPROFILE-1 with various IPSec timeout settings is created and is bound to LSN group LSN Group -1.

Sample configuration:

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

```

```
bind lsn pool LSN-POOL-1 203.0.113.3-203.0.113.9

Done

add lsn appsprofile LSN-APPSPROFILE-1 UDP -ippooling PAIRED

Done

bind lsn appsprofile LSN-APPSPROFILE-1 500

Done

add ipsecalg profile  IPSECALGPROFILE-1 -ikeSessionTimeout 45  -
   espSessionTimeout 40  - espGateTimeout 20 -connfailover ENABLED

Done

bind lsn group LSN-GROUP-1 -appsprofilename LSN-APPSPROFILE-1

Done

bind lsn group LSN-GROUP-1 -poolname LSN-POOL-1

Done

bind lsn group LSN-GROUP-1 - ipsecAlgProfile IPSECALGPROFILE-1

Done
<!--NeedCopy-->
```

Logging and Monitoring LSN

September 14, 2021

You can log LSN information to diagnose, troubleshoot problems, and to meet legal requirements. You can monitor the performance of the LSN feature by using LSN statistical counters and displaying current LSN sessions.

Logging LSN

Logging LSN information is one of the important functions required by the ISPs to meet legal requirements and for identifying the source of traffic at any given time.

A Citrix ADC appliance logs LSN mapping entries and the LSN sessions created or deleted for each LSN group. You can control logging of LSN information for an LSN group by using the logging and session logging parameters of the LSN group. These are group level parameters and are disabled by default. The Citrix ADC appliance logs LSN sessions for an LSN group only when both logging and session logging parameters are enabled.

The following table displays the logging behavior for an LSN group for various settings of logging and session logging parameters.

Logging	Session Logging	Logging Behavior
Enabled	Enabled	Logs LSN mapping entries as well as LSN sessions.
Enabled	Disabled	Logs LSN mapping entries but not LSN sessions.
Disabled	Enabled	Logs neither mapping entries nor LSN sessions.

A log message for an LSN mapping entry consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced.
- Time stamp
- Entry type (MAPPING)
- Whether the LSN mapping entry was created or deleted
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for an LSN session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced.
- Time stamp
- Entry type (SESSION)
- Whether the LSN session is created or removed

- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The appliance uses its existing syslog and audit log framework to log LSN information. You must enable global level LSN logging by enabling the LSN parameter in the related NSLOG action and SYLOG action entities. When the Logging parameter is enabled, the Citrix ADC appliance generates log messages related to LSN mappings and LSN sessions of this LSN group. The appliance then sends these log messages to servers associated with the NSLOG action and SYSLOG action entities.

For logging LSN information, Citrix recommends:

- Logging the LSN information on external log servers instead of on the Citrix ADC appliance. Logging on external servers facilitates optimal performance when the appliance creates large amounts of LSN log entries (in order of millions).
- Using SYSLOG over TCP, or NSLOG. By default SYSLOG uses UDP, and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data.

  Note:

  - The SYSLOG generated on Citrix ADC appliance are dynamically sent to the external log servers.
  - When using SYSLOG over TCP, if the TCP connection is down or the SYSLOG server is busy, then the Citrix ADC appliances stores the logs in buffer and send the data once the connection is active.

For more information about configuring logging, see Audit Logging.

Configuring LSN logging consists of the following tasks:

- **Configuring the Citrix ADC appliance for logging.** This task involves creating and setting various entities and parameters of the Citrix ADC appliance:
  - **Create a SYSLOG or NSLOG audit logging configuration**. Creating an audit logging configuration involves the following tasks:
    * Create a NSLOG or SYSLOG audit action and enable the LSN parameter. Audit actions specify the IP addresses of log servers.
    * Create a SYSLOG or NSLOG audit policy and bind the audit action to the audit policy. Audit actions specify the IP addresses of log servers. Optionally, you can set the transport method for log messages that are sent to the external log servers. By default UDP is selected, you can set the transport method as TCP for a reliable transport mechanism.Bind the audit policy to system global.
    * Create a SYSLOG or NSLOG audit policy and bind the audit action to the audit policy.

    * Bind the audit policy to system global.
      Note: For an existing audit logging configuration, just enable the LSN parameter for logging LSN information in the server specified by the audit action.
  - **Enable logging and session logging parameters.** Enable logging and session logging parameters either as you add LSN groups or after you have created the groups. The Citrix ADC appliance generates log messages related to these LSN groups and sends them to the server of those audit actions that have the LSN parameter enabled.
- **Configuring log servers.** This task involves installing SYSLOG or NSLOG packages on the desired servers. This task also involves specifying the NSIP address of the Citrix ADC appliance in the configuration file of SYSLOG or NSLOG. Specifying the NSIP address enables the server to identify the log information sent by the Citrix ADC appliance for storing them in a log file.

For more information about configuring logging, see Audit Logging.

SYSLOG Configuration Using the Command Line Interface

To create a SYSLOG server action for LSN logging by using the command line interface

At the command prompt, type:

```
add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel
    <logLevel>... [-transport (TCP)] [-lsn ( ENABLED | DISABLED )]
<!--NeedCopy-->
```

To create a SYSLOG server policy for LSN logging by using the command line interface

At the command prompt, type:

```
add audit syslogPolicy <name> <rule> <action>
<!--NeedCopy-->
```

To bind a SYSLOG server policy to system global for LSN logging by using the command line interface

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>]]
<!--NeedCopy-->
```

SYSLOG Configuration Using the Configuration Utility

To configure a SYSLOG server action for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Syslog** and, on the Servers tab, add a new auditing server or edit an existing server.
2. To enable LSN logging, select the **Large Scale NAT Logging** option.
3. (Optional) To enable SYSLOG over TCP, select the **TCP Logging** option.

To configure a SYSLOG server policy for LSN logging by using the configuration utility

Navigate to **Systems** > **Auditing** > **Syslog** and, on the **Policies** tab, add a new policy or edit an existing policy.

To bind a SYSLOG server policy to system global for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Syslog**.
2. On the **Policies** tab, in the **Action** list, click **Global Bindings** to bind the audit global policies.

NSLOG Configuration Using the Command Line Interface

To create a NSLOG server action for LSN logging by using the command line interface

At the command prompt, type:

```
add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel
    <logLevel> ... [-lsn ( ENABLED | DISABLED )]
<!--NeedCopy-->
```

To create a NSLOG server policy for LSN logging by using the command line interface

At the command prompt, type:

```
add audit nslogPolicy <name> <rule> <action>
<!--NeedCopy-->
```

To bind a NSLOG server policy to system global for LSN logging by using the command line interface

At the command prompt, type:

```
bind system global [<policyName>]
<!--NeedCopy-->
```

NSLOG Configuration Using the Configuration Utility

To configure a NSLOG server action for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Nslog** and, on the **Servers** tab, add a new auditing server or, edit an existing server.
2. To enable LSN logging, select the **Large Scale NAT Logging** option.

To configure a NSLOG server policy for LSN logging by using the configuration utility

Navigate to **Systems** > **Auditing** > **Nslog** and, on the **Policies** tab, add a new policy or edit an existing policy.

To bind a NSLOG server policy to system global for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Nslog**.
2. On the **Policies** tab, in the **Action** list, click **Global Bindings** to bind the audit global policies.

Example

The following configuration specifies two SYSLOG and two NSLOG servers for storing log entries including LSN logs. LSN Logging is configured for LSN groups LSN-GROUP-2 and LSN-GROUP-3.

The Citrix ADC appliance generates log messages related to LSN mappings and LSN sessions of these LSN groups, and sends them to the specified log servers.

```
add audit syslogAction SYS-ACTION-1 198.51.101.10 -logLevel ALL -lsn
    ENABLED
Done
add audit syslogPolicy SYSLOG-POLICY-1 ns_true SYS-ACTION-1
Done
bind system global SYSLOG-POLICY-1
Done

add audit syslogAction SYS-ACTION-2 198.51.101.20 -logLevel ALL -lsn
    ENABLED
Done
add audit syslogPolicy SYSLOG-POLICY-2 ns_true SYS-ACTION-2
Done
bind system global SYSLOG-POLICY-2
Done

add audit nslogAction NSLOG-ACTION-1 198.51.101.30 -logLevel ALL -lsn
    ENABLED
```

```
Done
add audit nslogPolicy NSLOG-POLICY-1 ns_true NSLOG-ACTION-1
Done
bind system global NSLOG-POLICY-1
Done
add audit nslogAction NSLOG-ACTION-2 198.51.101.40 -logLevel ALL -lsn
    ENABLED
Done
add audit nslogPolicy NSLOG-POLICY-2 ns_true NSLOG-ACTION-2
Done
bind system global NSLOG-POLICY-2
Done

add lsn group LSN-GROUP-3 -clientname LSN-CLIENT-2  - logging ENABLED  -
    sessionLogging ENABLED
Done
set lsn group LSN-GROUP-2   - logging ENABLED  - sessionLogging ENABLED
Done
<!--NeedCopy-->
```

The following configuration specifies SYSLOG configuration for sending log messages to the external SYSLOG server 192.0.2.10 using TCP.

```
add audit syslogAction SYS-ACTION-1 192.0.2.10 -logLevel ALL -transport
    TCP
Done

add audit syslogPolicy SYSLOG-POLICY-1 ns_true SYS-ACTION-1
Done

bind system global SYSLOG-POLICY-1
Done
<!--NeedCopy-->
```

The following table displays sample LSN log entries of each type stored on the configured log servers. These LSN log entries are generated by a Citrix ADC appliance whose NSIP address is 10.102.37.115.

LSN Log Entry Type	Sample Log Entry
LSN session creation	Local4.Informational 10.102.37.115 08/05/2014:09:59:48 GMT 0-PPE-0 : LSN LSN_SESSION 2581750 : SESSION CREATED Client IP:Port:TD 192.0.2.10: 15136:0, NatIP:NatPort 203.0.113.6: 6234, Destination IP:Port:TD 198.51.100.9: 80:0, Protocol: TCP
LSN session deletion	Local4.Informational 10.102.37.115 08/05/2014:10:05:12 GMT 0-PPE-0 : LSN LSN_SESSION 3871790 : SESSION DELETED Client IP:Port:TD 192.0.2.11: 15130:0, NatIP:NatPort 203.0.113.6: 7887, Destination IP:Port:TD 198.51.101.2:80:0, Protocol: TCP
LSN mapping creation	Local4.Informational 10.102.37.115 08/05/2014:09:59:47 GMT 0-PPE-0 : LSN LSN_MAPPING 2581580 : EIM CREATED Client IP:Port 192.0.2.15: 14567, NatIP:NatPort 203.0.113.5: 8214, Protocol: TCP
LSN mapping deletion	Local4.Informational 10.102.37.115 08/05/2014:10:05:12 GMT 0-PPE-0 : LSN LSN_MAPPING 3871700 : EIM DELETED Client IP:Port 192.0.3.15: 14565, NatIP:NatPort 203.0.113.11: 8217, Protocol: TCP

Minimal Logging

Deterministic LSN configurations and Dynamic LSN configurations with port block significantly reduces the LSN log volume. For these two types of configuration, the Citrix ADC appliance allocates a NAT IP address and a block of ports to a subscriber. The Citrix ADC appliance generates a log message for a port block at the time of allocation to a subscriber. The Citrix ADC appliance also generates a log message when a NAT IP address and port block is freed. For a connection, a subscriber can be identified just by its mapped NAT IP address and port block. Because of this reason, the Citrix ADC appliance does not log any LSN session created or deleted. The appliance also neither logs any mapping entry created for a session nor when the mapping entry gets removed.

The minimal logging feature for deterministic LSN configurations and dynamic LSN configurations with port block is enabled by default and there is no provision to disable it. In other words, the Citrix ADC appliance automatically do minimal logging for deterministic LSN configurations and dynamic

LSN configurations with port block. There is no option available for disabling this feature. The appliance sends the log messages to all the configured log servers.

A log message for each port block consists of the following information:

- NSIP address of the Citrix ADC appliance
- Time stamp
- Entry type as DETERMINISTIC or PORTBLOCK
- Whether a port block is allocated or is freed
- Subscriber's IP address and the assigned NAT IP address and port block
- Protocol name

Minimal Logging for Deterministic LSN Configuration

Consider an example of a simple deterministic LSN configuration for four subscribers having the IP address 192.0.17.1, 192.0.17.2, 192.0.17.3, and 192.0.17.4.

In this LSN configuration, the port block size is set to 32768 and LSN NAT IP address pool has IP addresses in the range 203.0.113.19-203.0.113.23.

```
1  add lsn client LSN-CLIENT-7
2  Done
3  bind lsn client LSN-CLIENT-7 -network 192.0.17.0 -netmask
       255.255.255.253
4  Done
5  add lsn pool LSN-POOL-7 -nattype DETERMINISTIC
6  Done
7  bind lsn pool LSN-POOL-7 203.0.113.19-203.0.113.23
8  Done
9  add lsn group LSN-GROUP-7 -clientname LSN-CLIENT-7 -nattype
       DETERMINISTIC -portblocksize 32768
10 Done
11 bind lsn group LSN-GROUP-7 -poolname LSN-POOL-7
12 Done
13 <!--NeedCopy-->
```

The Citrix ADC appliance sequentially preallocates, from the LSN NAT IP pool and on the basis of the set port block size, an LSN NAT IP address and a block of ports to each subscriber. It assigns the first block of ports (1024-33791) on the beginning NAT IP address (203.0.113.19) to the beginning subscriber IP address (192.0.17.1). The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT IP address is assigned to the subscriber, and so on. The appliance logs the NAT IP address and the block of ports allocated for each subscriber.

The Citrix ADC appliance does not log any LSN session created or deleted for these subscribers. The appliance generates the following log messages for the LSN configuration.

```
1) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201453 0 :  Dtrstc ALLOC Client 12.0.0.241,
   NatInfo 50.0.0.2:59904 to 60415
2) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201454 0 :  Dtrstc ALLOC Client 12.0.0.242,
   NatInfo 50.0.0.2:60416 to 60927
3) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201455 0 :  Dtrstc ALLOC Client 12.0.0.243,
   NatInfo 50.0.0.2:60928 to 61439
4) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201455 0 :  Dtrstc ALLOC Client 12.0.0.243,
   NatInfo 50.0.0.2:60928 to 61439
<!--NeedCopy-->
```

When you remove the LSN configuration, the allocated NAT IP address and block of ports is freed from each subscriber. The appliance logs NAT IP address and block of ports freed from each subscriber. The appliance generates the following log messages for each subscriber when you remove the LSN configuration.

```
1) 03/23/2015:00:33:57 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201706 0 :  Dtrstc FREE Client 12.0.0.238,
   NatInfo 50.0.0.2:58368 to 58879
2) 03/23/2015:00:33:57 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201707 0 :  Dtrstc FREE Client 12.0.0.239,
   NatInfo 50.0.0.2:58880 to 59391
3) 03/23/2015:00:33:57 GMT  Informational 0-PPE-0 : default LSN
   LSN_DETERMINISTIC 79201708 0 :  Dtrstc FREE Client 12.0.0.240,
   NatInfo 50.0.0.2:59392 to 59903
<!--NeedCopy-->
```

Minimal Logging for Dynamic LSN Configuration with Port Block

Consider an example of a simple dynamic LSN configuration with port block for any subscriber in the network 192.0.2.0/24. In this LSN configuration, the port block size is set to 1024 and LSN NAT IP address pool has IP addresses in the range 203.0.113.3-203.0.113.4.

```
set lsn parameter -memLimit 4000
Done
add lsn client LSN-CLIENT-1
Done
bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0
```

```
6  Done
7  add lsn pool LSN-POOL-1
8  Done
9  bind lsn pool LSN-POOL-1 203.0.113.3-203.0.113.4
10 Done
11 add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1 -portblocksize 1024
12 Done
13 bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1
14 Done
15 <!--NeedCopy-->
```

The Citrix ADC appliance allocates a random NAT IP address and a block of ports, from the LSN NAT IP pool and on the basis of the set port block size, for a subscriber when it initiates a session for the first time. The Citrix ADC logs the NAT IP address and block of ports allocated to this subscriber. The appliance does not log any LSN session created or deleted for this subscriber. If all the ports are allocated (for different subscriber's sessions) from the subscriber's allocated port block, the appliance allocates a new random NAT IP address and port block for the subscriber for additional sessions. The Citrix ADC logs every NAT IP address and port block allocated to a subscriber.

The appliance generates the following log message when the subscriber, having the IP address 192.0.2.1, initiates a session. The log message shows that the appliance has allocated NAT IP address 203.0.113.3 and port block 1024-2047 to the subscriber.

```
1 03/23/2015:00:07:12 GMT  Informational 0-PPE-3 : default LSN
     LSN_PORTBLOCK 106725793 0 :  Portblock ALLOC Client 12.0.2.72,
     NatInfo 203.0.113.3:1024 to 2047, Proto:TCP
2 <!--NeedCopy-->
```

Once there are no more sessions left that is using the allocated NAT IP address and one of the ports in the allocated port block, the allocated NAT IP address and block of ports is freed from the subscriber. The Citrix ADC logs that the NAT IP address and the block of ports is freed from the subscriber. The appliance generates the following log messages for the subscriber, having the IP address 192.0.2.1 , when no more sessions are left that is using the allocated NAT IP address (203.0.113.3) and a port from the allocated port block (1024-2047). The log message shows that the NAT IP address and port block are freed from the subscriber.

```
1 03/23/2015:00:11:09 GMT Informational 0-PPE-3 : default LSN
     LSN_PORTBLOCK 106814342 0 :  Portblock FREE Client 12.0.3.122,
     NatInfo 203.0.113.3: 1024 to 2047, Proto:TC
2 <!--NeedCopy-->
```

Load Balancing SYSLOG Servers

The Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

```
add service <name>(<IP> | <serverName>) <serviceType (SYSLOGTCP |
    SYSLOGUDP)> <port>
<!--NeedCopy-->
```

Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

```
add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod
    <AUDITLOGHASH>]
<!--NeedCopy-->
```

Bing the service to the load balancing virtual server.

```
Bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

```
add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel
     <logLevel>]
<!--NeedCopy-->
```

Add a SYSLOG policy by specifying the rule and action.

```
add syslogpolicy <name> <rule> <action>
<!--NeedCopy-->
```

Bind the SYSLOG policy to the system global for the policy to take effect.

```
bind system global <policyName>
<!--NeedCopy-->
```

Load balancing of SYSLOG servers using the configuration utility

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

   Navigate to Traffic Management > Services, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

   Navigate to Traffic Management > Virtual Servers, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

3. Bing the service to the load balancing virtual server to the service.

   Bing the service to the load balancing virtual server.

   Navigate to Traffic Management > Virtual Servers, select a virtual server and then selectAUDITLOGHASH in the Load Balancing Method.

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   Navigate to System > Auditing, click Servers and add a server by selecting LB Vserver option inServers.

5. Add a SYSLOG policy by specifying the rule and action.

   Navigate to System > Syslog, click Policies and add a SYSLOG policy.

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   Navigate to System > Syslog, select a SYSLOG policy and click Action, and then click Global Bindings and bind the policy to system global.

Example:

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. The Citrix ADC appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
add service service1 192.0.2.10 SYSLOGUDP 514
Done

add service service2 192.0.2.11 SYSLOGUDP 514
Done

add service service3 192.0.2.11 SYSLOGUDP 514
Done

```

```
add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH
Done

bind lb vserver lbvserver1 service1
Done

bind lb vserver lbvserver1 service2
Done

bind lb vserver lbvserver1 service3
Done

add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All
Done

add syslogpolicy syspol1 ns_true sysaction1
Done

bind system global syspol1
Done
<!--NeedCopy-->
```

Logging HTTP Header Information

The Citrix ADC appliance can now log request header information of an HTTP connection that is using the LSN fucntionality of the Citrix ADC. The following header information of an HTTP request packet can be logged:

- URL that the HTTP request is destined to.
- HTTP Method specified in the HTTP request.
- HTTP version used in the HTTP request.
- IP address of the subscriber that sent the HTTP request.

The HTTP header logs can be used by ISPs to see the trends related to the HTTP protocol among a set a subscribers. For example, an ISP can use this feature to find out the most popular websites among a set of subscribers.

An HTTP header log profile is a collection of HTTP header attributes (for example, URL and HTTP method) that can be enabled or disabled for logging. The HTTP header log profile is then bound to an LSN group. The Citrix ADC appliance then logs HTTP header attributes, which are enabled in the bound HTTP header log profile for logging, of any HTTP requests related to the LSN group. The appliance then sends the log messages to the configured log servers.

An HTTP header log profile can be bound to multiple LSN groups but an LSN group can have only one

HTTP header log profile.

To create an HTTP header log profile by using the the command line interface

At the command prompt, type:

```
add lsn httphdrlogprofile <httphdrlogprofilename> [-logURL ( ENABLED | DISABLED )] [-logMethod ( ENABLED | DISABLED )] [-logVersion ( ENABLED | DISABLED )] [-logHost ( ENABLED | DISABLED )]

show lsn httphdrlogprofile
<!--NeedCopy-->
```

To bind an HTTP header log profile to an LSN group by using the the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -httphdrlogprofilename <string>

show lsn group <groupname>
<!--NeedCopy-->
```

Example

In the following example of an LSN configuration, HTTP header log profile HTTP-Header-LOG-1 is bound to LSN group LSN-GROUP-1. The log profile has all the HTTP attributes (URL, HTTP method, HTTP version, and HOST IP address) enabled for logging so that all these attributes are logged for any HTTP requests from subscribers (in the network 192.0.2.0/24) related to the LSN group.

```
add lsn httphdrlogprofile HTTP-HEADER-LOG-1
Done

set lsn parameter -memLimit 4000
Done

add lsn client LSN-CLIENT-1
Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0
Done

add lsn pool LSN-POOL-1
Done
```

```
15
16 bind lsn pool LSN-POOL-1 203.0.113.3-203.0.113.4
17 Done
18
19 add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1 -portblocksize 1024
20 Done
21
22 bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1
23 Done
24
25 bind lsn group  LSN-GROUP-1  -httphdrlogprofilename HTTP-HEADER-LOG-1
26 Done
27 <!--NeedCopy-->
```

The Citrix ADC generates the following HTTP header log message when one of the subscriber belonging to the LSN configuration example sends an HTTP request.

The log message tells us that a client having the IP address 192.0.2.33 sends an HTTP request to URL example.com using HTTP method GET and HTTP version 1.1.

```
1 03/19/2015:16:24:04 GMT  Informational 0-PPE-1 : default LSN Message 59
      0 :  "LSN Client IP:TD 10.102.37.118:0 URL: example.com Host:
     192.0.2.33 Version: HTTP1.1 Method: GET"
2 <!--NeedCopy-->
```

Logging MSISDN Information

A Mobile Station Integrated Subscriber Directory Number (MSISDN) is a telephone number uniquely identifying a subscriber across multiple mobile networks. The MSISDN is associated with a country code and a national destination code identifying the subscriber's operator.

You can configure a Citrix ADC appliance to include MSISDNs in LSN log entries for subscribers in mobile networks. The presence of MSISDNs in the LSN logs helps the administrator in faster and accurate back tracing of a mobile subscriber who has violated a policy or law, or whose information is required by lawful interception agencies.

The following sample LSN log entries include MSISDN information for a connection from a mobile subscriber in an LSN configuration. The log entries show that a mobile subscriber whose MSISDN is E164:5556543210 was connected to destination IP:port 23.0.0.1:80 through the NAT IP:port 203.0.113.3:45195.

Log Entry Type	Sample Log Entry
LSN session creation	Oct 14 15:37:30 10.102.37.77 10/14/2015:10:08:14 GMT 0-PPE-6 : default LSN LSN_SESSION 25012 0 : SESSION CREATED E164:5556543210 Client IP:Port:TD 192.0.2.50:4649:0, NatIP:NatPort 203.0.113.3:45195, Destination IP:Port:TD 23.0.0.1:0:0, Protocol: TCP
LSN mapping creation	Oct 14 15:37:30 10.102.37.77 10/14/2015:10:08:14 GMT 0-PPE-6 : default LSN LSN_ADDR_MAPPING 25013 0 : ADM CREATED E164:5556543210 Client IP:Port:TD 192.0.2.50:4649:0, NatIP:NatPort 203.0.113.3:45195, Destination IP:Port:TD 23.0.0.1:0:0, Protocol: TCP
LSN session deletion	Oct 14 15:40:30 10.102.37.77 10/14/2015:10:11:14 GMT 0-PPE-6 : default LSN LSN_SESSION 25012 0 : SESSION CREATED E164:5556543210 Client IP:Port:TD 192.0.2.50:4649:0, NatIP:NatPort 203.0.113.3:45195, Destination IP:Port:TD 23.0.0.1:0:0, Protocol: TCP
LSN mapping	Oct 14 15:40:30 10.102.37.77 10/14/2015:10:11:14 GMT 0-PPE-6 : default LSN LSN_ADDR_MAPPING 25013 0 : ADM CREATED E164:5556543210 Client IP:Port:TD 192.0.2.50:4649:0, NatIP:NatPort 203.0.113.3:45195, Destination IP:Port:TD 23.0.0.1:0:0, Protocol: TCP

Perform the following tasks for including MSISDN information in LSN logs

- **Create an LSN log profile**. An LSN log profile includes the log subscriber ID parameter, which specifies whether to or not to include the MSISDN information in the LSN logs of an LSN configuration. Enable the log subscriber ID parameter when creating the LSN log profile.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the created LSN log profile to an LSN group of an LSN configuration by setting the log profile name parameter to the

created LSN log profile name. For instructions on configuring Large Scale NAT, see Configuration Steps for LSN.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename -logSubscriberID ( ENABLED |
   DISABLED )

show lsn logprofile
<!--NeedCopy-->
```

To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
<!--NeedCopy-->
```

Sample Configuration:

In this example of LSN configuration, the LSN log profile has the log subscriber ID parameter enabled. The profile is bound to LSN group LSN-GROUP-9. MSISDN information is included in the LSN session and LSN mapping logs for connections from mobile subscribers (in the network 192.0.2.0/24).

```
add lsn logprofile  LOG-PROFILE-MSISDN-9   -logSubscriberID ENABLED

Done
add lsn client LSN-CLIENT-9

Done
bind lsn client LSN-CLIENT-9 -network 192.0.2.0 -netmask 255.255.255.0

Done
add lsn pool LSN-POOL-9

Done
bind lsn pool LSN-POOL-9 203.0.113.3-203.0.113.4

Done
add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9
```

```
17
18 Done
19 bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9
20
21 Done
22 bind lsn group  LSN-GROUP-9  -logprofilename LOG-PROFILE-MSISDN-9
23
24 Done
25 <!--NeedCopy-->
```

Displaying Current LSN Sessions

You can display the current LSN sessions for detecting any unwanted or inefficient LSN sessions on the Citrix ADC appliance. You can display all or some LSN sessions on the basis of selection parameters.

Note: When more than a million LSN sessions exist on the Citrix ADC appliance, Citrix recommends displaying selected LSN sessions instead of all by using the selection parameters.

Configuration Using the Command Line Interface

To display all LSN sessions by using the command line interface

At the command prompt, type:

```
1 show lsn session
2 <!--NeedCopy-->
```

To display selective LSN sessions by using the command line interface

At the command prompt, type:

```
1 show lsn session [-clientname <string>] [-network <ip_addr> [-netmask <
     netmask>] [-td <positive_integer>]] [-natIP <ip_addr> [-natPort <
     port>]]
2 <!--NeedCopy-->
```

Example

To display all LSN sessions existing on a Citrix ADC

```
> show lsn session
          SubscrIP             SubscrPort      SubscrTD              DstIP                      DstPort DstTD     NatIP NatPort Proto   Dir

4.      192.0.2.19              19876           0              198.51.103.8            80              0       203.0.113.5     1567            TCP     OUT
Done
```

Configuration Using the Configuration Utility

To display all or selected LSN sessions by using the configuration utility

1. Navigate to System > Large Scale NAT > Sessions, and click the NAT44 tab.
2. For displaying LSN sessions on the basis of selection parameters, click Search.

Parameter Descriptions (of commands listed in the CLI procedure)

- show lsn session
  - clientname

    Name of the LSN Client entity. Maximum Length: 127
  - network

    IP address or network address of subscriber(s).

- netmask

  Subnet mask for the IP address specified by the network parameter.

  Default value: 255.255.255.255

- td

  Traffic domain ID of the LSN client entity.

  Default value: 0

  Minimum value: 0

  Maximum value: 4094

- natIP

  Mapped NAT IP address used in LSN sessions.

Displaying LSN Statistics

You can display statistics related to the LSN feature for evaluating the performance of the LSN feature or to troubleshoot problems. You can display a summary of statistics of the LSN feature or of a particular LSN group. The statistical counters reflect events since the Citrix ADC appliance was last restarted. All these counters are reset to 0 when the Citrix ADC appliance is restarted.

To display all LSN statistics by using the command line interface

At the command prompt, type:

```
stat lsn
<!--NeedCopy-->
```

To display statistics for a specified LSN group by using the command line interface

At the command prompt, type:

```
stat lsn group [<groupname>]
<!--NeedCopy-->
```

Example

```
> stat lsn

Large Scale NAT statistics
```

```
4                                                    Rate(/s)
                                                        Total
5  LSN TCP Received Packets                            0
       40
6  LSN TCP Received Bytes                              0
       3026
7  LSN TCP Transmitted Packets                         0
       40
8  LSN TCP Transmitted Bytes                           0
       3026
9  LSN TCP Dropped Packets                             0
                            0
10 LSN TCP Current Sessions                            0
                            0
11 LSN UDP Received Packets                            0
                            0
12 LSN UDP Received Bytes                              0
                            0
13 LSN UDP Transmitted Packets                         0
                            0
14 LSN UDP Transmitted Bytes                           0
                            0
15 LSN UDP Dropped Packets                             0
                            0
16 LSN UDP Current Sessions                            0
                            0
17 LSN ICMP Received Packets                           0
       982
18 LSN ICMP Received Bytes                             0
       96236
19 LSN ICMP Transmitted Packets                        0
                            0
20 LSN ICMP Transmitted Bytes                          0
                            0
21 LSN ICMP Dropped Packets                            0
       982
22 LSN ICMP Current Sessions                           0
                            0
23 LSN Subscribers                                     0
                            1
24
25 Done
26
27 > stat lsn group LSN-GROUP-1
28
```

```
29 LSN Group Statistics
30                                                    Rate (/s)
                                                         Total
31 TCP Translated Pkts                                  0
      40
32 TCP Translated Bytes                                 0
      3026
33 TCP Dropped Pkts                                     0
                          0
34 TCP Current Sessions                                 0
                          0
35 UDP Translated Pkts                                  0
                          0

                          0
42 ICMP Current Sessions                                0
                          0
43 Current Subscribers                                  0
                          1
44
45 Done
46 <!--NeedCopy-->
```

Parameter Descriptions (of commands listed in the CLI procedure)

- stat lsn group
  - groupname

    Name of the LSN Group. Maximum Length: 127
  - detail

    Specifies detailed output (including more statistics). The output can be quite voluminous. Without this argument, the output will show only a summary.

- fullValues

  Specifies that numbers and strings should be displayed in their full form. Without this option, long strings are shortened and large numbers are abbreviated.

- ntimes

  The number of times, in intervals of seven seconds, the statistics should be displayed.

  Default value: 1

- logFile

  The name of the log file to be used as input.

- clearstats

  Clear the statsistics / counters

  Possible values: basic, full

Compact Logging

Logging LSN information is one of the important functions needed by ISPs to meet legal requirements and be able to identify the source of traffic at any given time. This eventually results in a huge volume of log data, requiring the ISPs to make large investments to maintain the logging infrastructure.

Compact logging is a technique for reducing the log size by using a notational change involving short codes for event and protocol names. For example, C for client, SC for session created, and T for TCP. Compact logging results in an average of 40 percent reduction in log size.

The following examples of NAT44 mapping creation log entries show the advantage of compact logging.

Default logging format	02/02/2016:01:13:01 GMT Informational 0-PPE-2 : default LSN LSN_ADDRPORT_MAPPING 85 0 : A&PDM CREATED ClientIP:Port:TD1.1.1.1:6500:0,NatIP:NatPort8.8.8.8:47902, DestinationIP:Port:TD2.2.2.2:80:0, Protocol: TCP
Compact logging format	02/02/2016:01:14:57 GMT Info 0-PE2:default LSN 87 0:A&PDMC|C-1.1.1.1:6500:0|N-8.8.8.9:51066|D-2.2.2.2:80:0|T

Configuration Steps

Perform the following tasks for logging LSN information in compact format:

- **Create an LSN log profile.** An LSN log profile includes the Log Compact parameter, which specifies whether to or not to log information in compact format for an LSN configuration.
- **Bind the LSN log profile to an LSN group of an LSN configuration.** Bind the created LSN log profile to an LSN group of an LSN configuration by setting the Log Profile Name parameter to the created LSN log profile name. All sessions and mappings for this LSN group are logged in compact format.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename> -logCompact (ENABLED|DISABLED)

show lsn logprofile
<!--NeedCopy-->
```

To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname> -logProfileName <lsnlogprofilename>

show lsn group
<!--NeedCopy-->
```

Sample configuration:

```
add lsn logprofile  LOG-PROFILE-COMPACT-9 -logCompact ENABLED

Done
add lsn client LSN-CLIENT-9
Done
bind lsn client LSN-CLIENT-9 -network 192.0.2.0 -netmask 255.255.255.0
Done
add lsn pool LSN-POOL-9
Done
bind lsn pool LSN-POOL-9 203.0.113.3-203.0.113.4
Done
add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9
Done
```

```
bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9
Done
bind lsn group  LSN-GROUP-9  - logProfileName LOG-PROFILE-COMPACT-9
Done
<!--NeedCopy-->
```

IPFIX Logging

The Citrix ADC appliance supports sending information about LSN events in Internet Protocol Flow Information Export (IPFIX) format to the configured set of IPFIX collector(s). The appliance uses the existing AppFlow feature to send LSN events in IPFIX format to the IPFIX collectors.

IPFIX based logging is available for the following large scale NAT44 related events:

- Creation or deletion of an LSN session.
- Creation or deletion of an LSN mapping entry.
- Allocation or de-allocation of port blocks in the context of deterministic NAT.
- Allocation or de-allocation of port blocks in the context of dynamic NAT.
- Whenever subscriber session quota is exceeded.

Points to Consider before you Configure IPFIX logging

Before you start configuring IPSec ALG, consider the following points:

- You must configure the AppFlow feature and IPFIX collector(s) on the Citrix ADC appliance. For instructions, see Configuring the AppFlow feature topic.

Configuration Steps

Perform the following tasks for logging LSN information in IPFIX format:

- **Enable LSN logging in the AppFlow configuration**. Enable the LSN logging parameter as part of AppFlow configuration.
- **Create an LSN log profile**. An LSN log profile includes the IPFIX parameter that enables or disables the log information in IPFIX format.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the LSN log profile to one or multiple LSN group(s). Events related to the bound LSN group will be logged in IPFIX format.

To enable LSN logging in the AppFlow configuration by using the CLI

At the command prompt, type:

```
set appflow param -lsnLogging ( ENABLED | DISABLED )

show appflow param
<!--NeedCopy-->
```

To create an LSN log profile by using the CLIAt the command prompt

At the command prompt, type:

```
set lsn logprofile <logProfileName>  -logipfix ( ENABLED | DISABLED )

show lsn logprofile
<!--NeedCopy-->
```

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
<!--NeedCopy-->
```

To create an LSN log profile by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Log** tab, and then add a log profile.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI

1. Navigate to **System** > **Large Scale NAT** > **LSN Group,** open the **LSN** group.
2. In **Advanced Settings,** click **+ Log Profile** to bind the created Log profile to the LSN group.

TCP SYN Idle Timeout

September 14, 2021

SYN idle timeout is the timeout for establishing TCP connections that use LSN on the Citrix ADC appliance. If a TCP session is not established within the configured timeout period, the Citrix ADC removes

the session. SYN idle timeout is useful in providing protection against SYN flood attacks. In an LSN configuration, the LSN group entity includes the SYN idle timeout setting.

Example:

In the following sample LSN configuration, SYN idle timeout is set to 30 secs for TCP connections related to subscribers from the 192.0.2.0/24 network.

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1  - synidletimeout 30

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done
<!--NeedCopy-->
```

Overriding LSN configuration with Load Balancing Configuration

September 14, 2021

An LSN configuration takes precedence over any load balancing configuration by default. For overriding the large scale networking (LSN) configuration with the load balancing configuration for traffic matching both configurations, create a net profile with Override LSN parameter enabled and bind this profile to the virtual server of the load balancing configuration. USNIP or USIP settings of the load balancing configuration are applied to the traffic, instead of applying the LSN IP address of the LSN configuration.

This option is useful in an LSN deployment that includes Citrix ADC appliances and value added services, such as firewall and optimization devices. In this type of deployment, the ingress traffic on the Citrix ADC appliance is required to pass through these value-added services before an LSN configuration on the appliance is applied to the traffic. For the Citrix ADC appliance to send the ingress traffic to a value added service, a load balancing configuration is created and override LSN is enabled on the appliance. The load balancing configuration includes value added services, represented as load balancing services, bound to a virtual server of type ANY. The virtual server is configured with listen policies for identifying the traffic to be sent to the value added service.

To enable override lsn in a net profile by using the CLI

To enable override lsn while adding a net profile, at the command prompt, type

```
add netProfile <name> -overrideLsn ( ENABLED | DISABLED )

show netprofile <name>
<!--NeedCopy-->
```

To enable override lsn while adding a net profile, at the command prompt, type

```
set netProfile <name> -overrideLsn ( ENABLED | DISABLED )

show netprofile <name>
<!--NeedCopy-->
```

To enable override lsn in a net profile by using GUI

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Set the **Override LSN** parameter while adding or modifying net profiles.

In the following sample configuration, net profile NETPROFILE-OVERRIDELSN-1 has override LSN option enabled and is bound to load balancing virtual server LBVS-1.

Sample configuration:

```
add netprofile NETPROFILE-OVERRIDELSN-1 -overrideLsn ENABLED

Done

set lb vserver LBVS-1 -netprofile NETPROFILE-OVERRIDELSN-1

Done
```

```
<!--NeedCopy-->
```

Clearing LSN Sessions

September 14, 2021

You can remove any unwanted or inefficient LSN sessions from the Citrix ADC appliance. The appliance immediately releases resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected LSN sessions from the Citrix ADC appliance.

To clear all LSN sessions by using the command line interface

At the command prompt, type:

```
flush lsn session

show lsn session
<!--NeedCopy-->
```

To clear selective LSN sessions by using the command line interface

At the command prompt, type:

```
flush lsn session [-clientname <string>] [-network <ip_addr> [-netmask
   <netmask>] [-td <positive_integer>]] [-natIP <ip_addr> [-natPort <
   port>]]

show lsn session
<!--NeedCopy-->
```

Example

Clear all LSN sessions existing on a Citrix ADC

```
flush lsn session

Done
<!--NeedCopy-->
```

Clear all LSN sessions related to LSN client entity LSN-CLIENT-1

```
flush lsn session -clientname LSN-CLIENT-1

Done
<!--NeedCopy-->
```

Clear all LSN sessions related to a subscriber network (192.0.2.0) of LSN client entity LSN-CLIENT-2 belonging to traffic domain 100

```
flush lsn session -clientname LSN-CLIENT-2 -network 192.0.2.0 -
   netmask 255.255.255.0 -td 100

Done
<!--NeedCopy-->
```

To clear all LSN sessions by using the configuration utility

Navigate to System > Large Scale NAT > Sessions, and click Flush Sessions.

Parameter Descriptions (of commands listed in the CLI procedure)

- flush lsn session
  - clientname

    Name of the LSN Client entity. Maximum Length: 127
  - network

    IP address or network address of subscriber(s).
  - netmask

    Subnet mask for the IP address specified by the network parameter.

    Default value: 255.255.255.255
  - td

    Traffic domain ID of the LSN client entity.

    Default value: 0

    Minimum value: 0

    Maximum value: 4094
  - natIP

    Mapped NAT IP address used in LSN sessions.

- natPort

  Mapped NAT port used in the LSN sessions.

Load Balancing SYSLOG Servers

September 14, 2021

The Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

At the command prompt, type:

Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

```
add service <name>(<IP> | <serverName>) <serviceType (SYSLOGTCP |
    SYSLOGUDP)> <port>
<!--NeedCopy-->
```

Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

```
add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod
    <AUDITLOGHASH>]
<!--NeedCopy-->
```

Bind the service to the load balancing virtual server.

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

1. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

```
add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel
    <logLevel>]
<!--NeedCopy-->
```

Add a SYSLOG policy by specifying the rule and action.

```
add syslogpolicy <name> <rule> <action>
<!--NeedCopy-->
```

Bind the SYSLOG policy to the system global for the policy to take effect.

```
bind system global <policyName>
<!--NeedCopy-->
```

Load balancing of SYSLOG servers using the configuration utility

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

   Navigate to Traffic Management > Services, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

   Navigate to Traffic Management > Virtual Servers, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

3. Bing the service to the load balancing virtual server to the service.

   Bing the service to the load balancing virtual server.

   Navigate to Traffic Management > Virtual Servers, select a virtual server and then selectAUDITLOGHASH in the Load Balancing Method.

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   Navigate to System > Auditing, click Servers and add a server by selecting LB Vserver option inServers.

5. Add a SYSLOG policy by specifying the rule and action.

   Navigate to System > Syslog, click Policies and add a SYSLOG policy.

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   Navigate to System > Syslog, select a SYSLOG policy and click Action, and then click Global Bindings and bind the policy to system global.

Example:

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. The Citrix ADC appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
add service service1 192.0.2.10 SYSLOGUDP 514

add service service2 192.0.2.11 SYSLOGUDP 514

add service service3 192.0.2.11 SYSLOGUDP 514

add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH

bind lb vserver lbvserver1 service1

bind lb vserver lbvserver1 service2

bind lb vserver lbvserver1 service3

add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All

add syslogpolicy syspol1 ns_true sysaction1

bind system global syspol1
<!--NeedCopy-->
```

Limitations:

The Citrix ADC appliance does not support an external load balancing virtual server load balancing the SYSLOG messages among the log servers.

Port Control Protocol

September 14, 2021

Citrix ADC appliances now support Port Control Protocol (PCP) for large scale NAT (LSN). Many of an ISP's subscriber applications must be accessible from Internet (for example, Internet of Things (IOT) devices, such as an IP camera that provides surveillance over the Internet). One way to meet this requirement is to create static large scale NAT (LSN) maps. But for a very large number of subscribers, creating static LSN NAT maps is not a feasible solution.

Port Control Protocol (PCP) enables a subscriber to request specific LSN NAT mappings for itself and/or for other 3rd party devices. The large scale NAT device creates an LSN map and sends it to the subscriber. The subscriber sends the remote devices on the Internet the NAT IP address:NAT port at which they can connect to the subscriber.

Applications usually send frequent keep-alive messages to the large scale NAT device so that their LSN mappings do not time out. PCP helps reduce the frequency of such keep-alive messages by enabling

the applications to learn the timeout settings of the LSN mappings. This helps reduce bandwidth consumption on the ISP's access network and battery consumption on mobile devices.

PCP is a client-server model and runs over the UDP transport protocol. A Citrix ADC appliance implements the PCP server component and is compliant with RFC 6887.

Configuration Steps

Perform the following tasks for configuring PCP:

- (Optional) Create a PCP profile. A PCP profile includes settings for PCP related parameters (for example, to listen for mapping and peer PCP requests). A PCP profile can be bound to a PCP server. A PCP profile bound to a PCP server applies all its settings to the PCP server. A PCP profile can be bound to multiple PCP servers. By default, one PCP profile with default parameters settings is bound to all PCP servers. A PCP profile that you bind to a PCP server overrides the default PCP profile settings for that server. A default PCP profile has the following parameter settings:
  - Mapping: Enabled
  - Peer: Enabled
  - Minimum map life: 120 seconds
  - Maximum max life: 86400 seconds
  - Announce count: 10
  - Third Party: Disabled
- Create a PCP server and bind a PCP profile to it. Create a PCP server on the Citrix ADC appliance to listen for PCP related requests and messages from the subscribers. A Subnet IP (SNIP) address must be assigned to a PCP server to access it. By default, a PCP server listens on port 5351.
- Bind the PCP server to an LSN group of an LSN configuration. Bind the created PCP server to an LSN group of an LSN configuration by setting the PCP Server parameter to specify the created PCP server. The created PCP server can be accessed only by the subscribers of this LSN group.

> **Note**
>
> A PCP server for a large scale NAT configuration does not serve requests from subscribers that are identified from ACL rules.

To create a PCP profile by using the CLI

At the command prompt, type:

```
add pcp profile <name> [-mapping ( ENABLED | DISABLED )] [-peer (
    ENABLED | DISABLED )] [-minMapLife <secs>]  [-maxMapLife <secs>] [-
    announceMultiCount <positive_integer>][-thirdParty ( ENABLED |
    DISABLED )]
```

```
2
3 show pcp profile <name>
4 <!--NeedCopy-->
```

To create a PCP server by using the CLI

At the command prompt, type:

```
1 add pcp server <name> <IPAddress> [-port <portNum|*>] [-pcpProfile <
     string>]
2
3 show pcp server <name>
4 <!--NeedCopy-->
```

Sample Configuration for NAT44

In the following sample configuration, PCP server PCP-SERVER-9, with default PCP settings, is bound to LSN group LSN-GROUP-9. PCP-SERVER-9 serves PCP requests from subscribers in network 192.0.2.0/24.

Sample configuration:

```
1 add pcp server PCP-SERVER-9 192.0.3.9
2
3 Done
4
5 add lsn client LSN-CLIENT-9
6
7 Done
8
9 bind lsn client LSN-CLIENT-9 -network 192.0.2.0 -netmask 255.255.255.0
10
11 Done
12
13 add lsn pool LSN-POOL-9
14
15 Done
16
17 bind lsn pool LSN-POOL-9 203.0.113.3-203.0.113.4
18
19 Done
20
21 add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9
```

```
22
23 Done
24
25 bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9
26
27 Done
28
29 bind lsn group  LSN-GROUP-9  -pcpServer PCP-SERVER-9
30
31 Done
32 <!--NeedCopy-->
```

LSN44 in a cluster setup

September 14, 2021

Large scale NAT44 configurations are supported on a Citrix ADC cluster setup.

A Citrix ADC cluster is a group of Citrix ADC appliances that are configured and managed as a single system. A Citrix ADC cluster provides scalability and availability. Each Citrix ADC appliance in a cluster setup acts as an independent LSN entity and is managed as a single system.

The LSN configuration in a cluster setup is same as in a standalone appliance except a specific pool of LSN IP addresses are owned by only one node at a time. In other words, an LSN IP pool entity is configured as a spotted entity in a particular node. All the nodes of a cluster setup can have a specific LSN IP pool entity. To make sure that the packets related to an LSN session are received on the same cluster node that performed the NAT operation, policy based backplane (PBS) steering is configured. PBS steers the received related packets of an LSN session to the same cluster node.

Sample configuration:

```
1  add lsn client LSN-CLIENT-1
2
3  Done
4
5  bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0
6
7  Done
8
9  add lsn pool LSN-POOL-1
10
11 Done
12
```

```
bind lsn pool LSN-POOL-1 -ownerNode 1 203.0.113.3

Done

bind lsn pool LSN-POOL-1 -ownerNode 2 203.0.113.3

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done

add ns acl b1 ALLOW -srcIP = 192.0.2.0-192.0.2.255 -type DFD -dfdhash
   SIP

Done

apply ns acls -type DFD

Done
<!--NeedCopy-->
```

Dual-Stack Lite

September 14, 2021

Because of the shortage of IPv4 addresses, and the advantages of IPv6 over IPv4, many ISPs have started transitioning to IPv6 infrastructure. But during the transition, ISPs must continue to support IPv4 along with IPv6, because most of the public Internet still uses only IPv4, and many subscribers do not support IPv6.

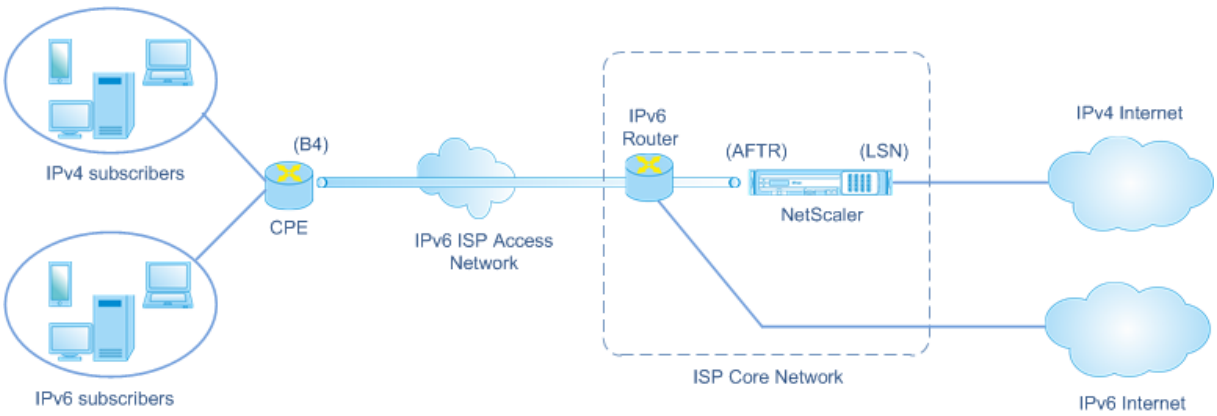
Dual Stack Lite (DS-Lite) is an IPv6 transition solution for ISPs with IPv6 infrastructure to connect their IPv4 subscribers to the Internet. DS-Lite uses IPv4-in-IPv6 tunneling to send a subscriber's IPv4 packet through a tunnel on the IPv6 access network to the ISP. The IPv6 packet is decapsulated to recover the subscriber's IPv4 packet and is then sent to the Internet after NAT address and port translation and other LSN related processing. The response packets traverse through the same path to the subscriber.

The Citrix ADC appliance implements the AFTR component of a DS-Lite deployment and is compliant with RFC 6333.

Architecture

The Dual-Stack Lite architecture for an ISP consists of the following components:

- **Basic Bridging Broadband (B4).** Basic Bridging broadband, or B4, is a device or component that resides in the subscriber premises. Typically, B4 is a component in the CPE devices in the subscriber premises. IPv4 subscribers are connected to the IPv6-only ISP access network through the CPE device containing the B4 component. The main function of the B4 is to initiate an IPv6 tunnel between B4 and an address family transition router (AFTR) in order to send or receive subscriber IPv4 request or response packets over the tunnel. B4 includes an IPv6 address known as the B4 tunnel endpoint address. B4 uses this address to source IPv6 packets to AFTR and receive packets from AFTR.
- **Address family transition router (AFTR).** AFTR is a device or component residing in the ISP's core network. AFTR terminates the IPv6 tunnel from the B4 device. In other words, the IPv6 tunnel is formed between B4 in the subscriber premise and AFTR in ISP core network. AFTR decapsulates IPv6 packets received from B4 to recover the subscribers' original IPv4 packets. AFTR sends the IPv4 packets to the LSN device or component. LSN routes the IPv4 packets to their destination after performing NAT address and port translation (NAT 44) and other LSN related processing. AFTR includes an IPv6 address known as the AFTR tunnel endpoint address. AFTR uses this address to source IPv6 packets to B4 and receive IPv6 packets from B4. The Citrix ADC appliance implements the AFTR component.
- **Softwire.** The IPv6 tunnel created between B4 and AFTR is called a softwire.



The DS-Lite architecture of an ISP using a Citrix ADC appliance consists of subscribers in private address spaces accessing the Internet through a Citrix ADC appliance deployed in ISP's core network. IPv4 subscribers are connected to a CPE device that includes the DS-Lite B4 functionality. The CPE device is connected to the ISP core network through ISP's IPv6-only access network. The Citrix ADC appliance contains the DS-Lite AFTR and LSN functionality.

IPv4 subscribers connected to the CPE device are assigned private IPv4 addresses either manually or through DHCP server running on the CPE device. On the CPE device, the AFTR tunnel endpoint address is specified manually or through DHCPv6. Configuration of CPE devices is vendor specific and therefore outside the scope of this documentation.

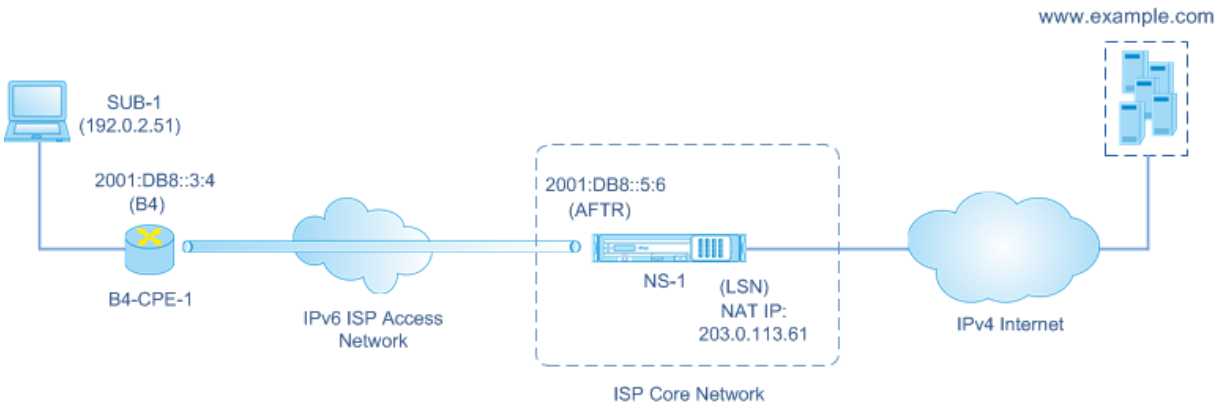
Upon receiving a request packet that is from an IPv4 subscriber and destined to a location on the Internet, the B4 component of the CPE device encapsulates the IPv4 packet in an IPv6 packet and sends it to the Citrix ADC appliance in the ISP core network. The Citrix ADC appliance's AFTR functionality decapsulates the IPv6 packet to recover the subscriber's original IPv4 packet. The LSN functionality of the Citrix ADC appliance translates the source IP address and port of the IPv4 packet to an NAT IP address and NAT port selected from the configured NAT pool, and then sends the packet to its destination on the Internet.

The appliance maintains a record of all active sessions that use the AFTR and LSN functionalities. These sessions are called DS-Lite sessions. The Citrix ADC appliance also maintains the mappings between B4 IPv6 address, subscriber IPv4 address and port, and NAT IPv4 address and port, for each DS-Lite session. These mappings are called DS-Lite LSN mappings. From DS-Lite session entries and DS-Lite LSN mapping entries, the Citrix ADC appliance recognizes a response packet (received from the Internet) as belonging to a particular DS-Lite session.

When the Citrix ADC appliance receives a response packet belonging to a particular DS-Lite session, the appliance's LSN functionality translates the destination IP address and port of the response packet from NAT IP address and port to the subscriber IP address and port, the AFTR functionality encapsulates the resulting packet in an IPv6 packet and sends it to the CPE device. The B4 functionality of the CPE device decapsulates the IPv6 packet to recover the IPv4 response packet, and then sends the IPv4 packet to the subscriber.

Example

Consider an example of a DS-Lite deployment consisting of Citrix ADC NS-1 in an ISP's core network, CPE device B4-CPE-1 in a subscriber premise, and a single IPv4 subscriber SUB-1. B4-CPE-1 supports the B4 functionality of DS-Lite feature.



The following table lists the settings used in this example.

Entity	Name	Details
IPv4 address of subscriber SUB-1		192.0.2.51
IPv6 address of softwire endpoint on the B4 device (B4-CPE-1)		2001:DB8::3:4
IPv6 address of the softwire endpoint on the AFTR device (NS-1)		2001:DB8::5:6

Settings on Citrix ADC appliance NS-1:

Entity	Name	Details
LSN client	LSN-DSLITE-CLIENT-1	Network6 (Identifying traffic from B4 devices) = 2001:DB8::3:0/100
LSN pool	LSN-DSLITE-POOL-1	LSN IPs (NAT IP) = 203.0.113.61 - 203.0.113.70
IPv6 Profile	LSN-DSLITE-PROFILE-1	Type = DS-LITE; IPv6 address (AFTR IPv6 address) = One of the Citrix ADC owned IPv6 address of type SNIP6 = 2001:DB8::5:6
LSN group	LSN-DSLITE-GROUP-1	LSN client = LSN-DSLITE-CLIENT-1; LSN pool = LSN-DSLITE-POOL-1;IPv6 profile = LSN-DSLITE-PROFILE-1

Following is the traffic flow in this example:

1. IPv4 subscriber SUB-1 sends a request to (`http://www.example.com/`). The IPv4 packet has:
    - Source IP address = 192.0.2.51

- Source port = 2552
- Destination IP address = 198.51.100.250
- Destination port = 80

2. Upon receiving the IPv4 request packet, B4-CPE-1 encapsulates it in the payload of an IPv6 packet and then sends the IPv6 packet to NS-1. The IPv6 packet has:
   - Source IP address = 2001:DB8::3:4
   - Destination IP address = 2001:DB8::5:6
3. When NS-1 receives the IPv6 packet, the AFTR module decapsulates the packet by removing the IPv6 headers. The resulting packet is SUB-1's original IPv4 request packet.
4. The LSN module of NS-1 translates the source IP address and port of the packet to an NAT IP address and NAT port selected from the configured NAT pool. The translated IPv4 packet has:
   - Source IP address = 203.0.113.61
   - Source port = 3002
   - Destination IP address = 198.51.100.250
   - Destination port = 80
5. The LSN module also creates an LSN mapping and session entry for this DS Lite session. The mapping includes the following information:
   - Source IP address of the IPv6 packet (B4-CPE-1's IPv6 address) = 2001:DB8::3:4
   - Source IP address of the IPv4 packet (SUB-1's IPv4 address) = 192.0.2.51
   - Source port of the IPv4 packet = 2552
   - NAT IP address = 203.0.113.61
   - NAT port = 3002
6. NS-1 sends the resulting IPv4 packet to its destination on the Internet.
7. The server for www.example.com processes the request packet and sends a response packet. The IPv4 response packet has:
   - Source IP address = 198.51.100.250
   - Source port = 80
   - Destination IP address = 203.0.113.61
   - Destination port = 3002
8. Upon receiving the IPv4 packet, NS-1 examines the LSN mapping and session entries and finds that the IPv4 response packet belongs to a DS Lite session. The LSN module of NS-1 translates the destination IP address and port. The IPv4 packet now has:
   - Source IP address = 198.51.100.250
   - Source port = 80
   - Destination IP address = 192.0.2.51

- Destination port = 2552

9. The AFTR module of NS-1 encapsulates the IPv4 packet in an IPv6 packet and then sends the IPv6 packet to B4-CPE-1. The IPv6 packet has:
   - Source IP address = 2001:DB8::5:6
   - Destination IP address = 2001:DB8::3:4
10. Upon receiving the packet, B4-CPE-1 decapsualtes the IPv6 packet by removing the IPv6 headers, and then sends the resulting IPv4 packet to CL-1.

Points to Consider before Configuring DS-Lite

September 14, 2021

Consider the following points before configuring DS-Lite on a Citrix ADC appliance:

1. You must understand the different components of DS-Lite, described in RFC 6333.
2. A DS-lite configuration on a Citrix ADC appliance uses the LSN commands sets. In a DS-Lite configuration, the LSN client entity specifies the IPv6 address or IPv6 network address or ACL6 rules for identifying the traffic from the B4 device. A DS-Lite configuration also includes an IPv6 profile, which specifies the IPv6 address AFTR component on a Citrix ADC appliance. For more information on Citrix ADC LSN feature, see Large Scale NAT.
3. For a DS-Lite configuration, the Citrix ADC appliance supports LSN for IPv4 packets that belong to one of the following protocols only. The Citrix ADC appliance drops IPv4 packets belonging to other protocols:
   - TCP
   - UDP
   - ICMP
4. The Citrix ADC appliance supports the following ALGs DS-Lite:
   - ICMP
   - FTP
   - TFTP
   - Session Initiation Protocol (SIP)
   - Real Time Streaming Protocol (RTSP)

Configuring DS-Lite

September 14, 2021

A DS-lite configuration on a Citrix ADC appliance uses the LSN commands sets. In a DS-Lite configuration, the LSN client entity specifies the IPv6 address or IPv6 network address or ACL6 rules for identifying the traffic from the B4 device. For more information on the Citrix ADC LSN feature, see Large Scale NAT. A DS-Lite configuration also includes an IPv6 profile, which specifies the IPv6 address (of type SNIP6) of the DS-Lite AFTR component on a Citrix ADC appliance.

Configuring DS-Lite on a Citrix ADC appliance consists of the following tasks:

- **Set the global LSN parameters**. Global parameters include the amount of Citrix ADC memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
- **Create an LSN client entity for identifying traffic from B4 CPE devices**. The LSN client entity refers to a set of DS-Lite B4 devices. The client entity includes IPv6 addresses or IPv6 network address or ACL6 rules for identifying the traffic from these B4 devices. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an LSN client entity and binding a subscriber to the LSN client entity. The configuration utility combines these two operations on a single screen.
- **Create an LSN pool and bind NAT IP addresses to it**. An LSN pool defines a pool of NAT IP addresses to be used by the Citrix ADC appliance to perform LSN. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The configuration utility combines these two operations on a single screen.
- **Create an LSN IP6 profile.** An LSN IP6 profile defines the IPv6 address of the DS-Lite AFTR component on the Citrix ADC appliance. The IPv6 address must be one of the Citrix ADC owned IPv6 address of type SNIP6.
- **(Optional) Create an LSN Transport Profile for a specified protocol**. An LSN transport profile defines various timeouts and limits, such as maximum LSN sessions and maximum ports usage that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called the default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
- **(Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it**. An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination

ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The configuration utility combines these two operations on a single screen.

- **Create an LSN Group and bind LSN pools, LSN IPv6 profile, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group**. An LSN group is an entity consisting of an LSN client, an LSN IPv6 profile, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only one LSN IPv6 profile can be bound to an LSN group, and an LSN IPv6 profile bound to an LSN group cannot be bound to other LSN groups. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN group and binding LSN pools, LSN transport profiles, and LSN application profiles to the LSN group. The configuration utility combines these two operations in a single screen.

Configuration by Using the Command Line

To create an LSN client by using the command line interface:

At the command prompt, type:

```
add lsn client <clientname>

show lsn client
<!--NeedCopy-->
```

To bind an IPv6 network or an ACL6 rule to an LSN client by using the command line interface:

At the command prompt, type:

```
bind lsn client <clientname> (-network6 <ipv6_addr|*>| -acl6name <
    string>)

```

```
3 show lsn client
4 <!--NeedCopy-->
```

To create an LSN pool by using the command line interface:

At the command prompt, type:

```
1 add lsn pool <poolname> [-nattype ( DYNAMIC )] [-portblockallocation (
     ENABLED | DISABLED )] [-portrealloctimeout <secs>] [-
     maxPortReallocTmq <positive_integer>]
2
3 show lsn pool
4 <!--NeedCopy-->
```

To bind an IP address range to an LSN pool by using the command line interface:

At the command prompt, type:

```
1 bind lsn pool <poolname> <lsnip>
2
3 show lsn pool
4 <!--NeedCopy-->
```

Note: For removing LSN IP addresses from an LSN pool, use the unbind lsn pool command.

To configure an LSN IPv6 profile by using the command line interface:

At the command prompt, type:

```
1 add lsn ip6profile <name>  -type DS-Lite  -network6 < ipv6_addr|*s >
2
3 show lsn ip6profile
4 <!--NeedCopy-->
```

To create an LSN transport profile by using the command line interface:

At the command prompt, type:

```
1 add lsn transportprofile <transportprofilename> <transportprotocol> [-
     sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota <
     positive_integer>] [-sessionquota <positive_integer>] [-
     portpreserveparity ( ENABLED | DISABLED )] [-portpreserverange (
     ENABLED | DISABLED )] [-syncheck ( ENABLED | DISABLED )]
2
3 show lsn transportprofile
4 <!--NeedCopy-->
```

To create an LSN application profile by using the command line interface:

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> <transportprotocol> [-ippooling (
    PAIRED | RANDOM )] [-mapping <mapping>] [-filtering <filtering>][-
    tcpproxy ( ENABLED | DISABLED )] [-td <positive_integer>]

show lsn appsprofile
<!--NeedCopy-->
```

To bind an application protocol port range to an LSN application profile by using the command line interface:

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
<!--NeedCopy-->
```

To create an LSN group by using the command line interface:

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-nattype ( DYNAMIC )]
    [-portblocksize <positive_integer>] [-logging (ENABLED | DISABLED )]
     [-sessionLogging ( ENABLED | DISABLED )][-sessionSync ( ENABLED |
    DISABLED )] [-snmptraplimit<positive_integer>] [-ftp ( ENABLED |
    DISABLED )] [-pptp ( ENABLED |DISABLED )] [-sipalg ( ENABLED |
    DISABLED )] [-rtspalg ( ENABLED |DISABLED )] [-ip6profile <string>]

show lsn group
<!--NeedCopy-->
```

To bind LSN protocol profiles and LSN pools to an LSN group by using the command line interface:

At the command prompt, type:

```
bind lsn group <groupname> (-poolname <string> | -transportprofilename
    <string> | -httphdrlogprofilename <string> | -appsprofilename <
    string> | -sipalgprofilename <string> | rtspalgprofilename <string>)

show lsn group
<!--NeedCopy-->
```

Configuration by Using the Configuration Utility

To configure an LSN client and bind an IPv6 network address or an ACL6 rule by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Clients**, and add a client and then bind an IPv6 network address or an ACL6 rule to the client.

To configure an LSN pool and bind NAT IP addresses by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Pools**, and add a pool and then bind an NAT IP address or a range of NAT IP addresses to the pool.

To configure an LSN IPv6 profile by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Profiles**, click the **IPv6** tab, and assign an IPv6 address for DS-Lite AFTR.

To configure an LSN transport profile by using the configuration utility:

1. Navigate to **System** > **Large Scale NAT** > **Profiles**.
2. On the details pane, click **Transport**, and then add a transport profile.

To configure an LSN application profile by using the configuration utility:

1. Navigate to **System** > **Large Scale NAT** > **Profiles**.
2. On the details pane, click **Application**, and then add an application profile.

To configure an LSN group and bind an LSN client, an LSN IPv6 profile, pools, transport profiles, and application profiles by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Groups**, and add a group and then bind an LSN client, an LSN IPv6 profile, pools, transport profiles, and application profiles to the group.

```
1  > add lsn client LSN-DSLITE-CLIENT-1
2  Done
3  > bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/100
4  Done
5  > add lsn pool LSN-DSLITE-POOL-1
6  Done
7  > bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70
8  Done
9  > add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6 2001:
       DB8::5:6
10 Done
11 > add lsn group LSN-DSLITE-GROUP-1 -clientname LSN-DSLITE-CLIENT-1 -
       portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-1
12 Done
13 > add lsn group LSN-DSLITE-GROUP-1 -poolname LSN-DSLITE-POOL-1
```

```
14 Done
```

Logging and Monitoring DS-Lite

You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The Citrix ADC appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a Citrix ADC appliance whose NSIP address is 10.102.37.115.You can

log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The Citrix ADC appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a Citrix ADC appliance whose NSIP address is 10.102.37.115.

LSN Log Entry Type	Sample Log Entry

DS-Lite session creation	Local4.Informational 10.102.37.115 08/14/2015:13:35:38 GMT 0-PPE-1 : default LSN LSN_SESSION 37647607 0 : SESSION CREATED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 203.0.113.61:3002, Destination IP:Port:TD 198.51.100.250:80:0, Protocol:TCP
DS-Lite session deletion	Local4.Informational 10.102.37.115 08/14/2015:13:38:22 GMT 0-PPE-1 : default LSN LSN_SESSION 37647617 0 : SESSION DELETED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 203.0.113.61:3002, Destination IP:Port:TD 198.51.100.250:80:0, Protocol: TCP
DS-Lite LSN mapping creation	Local4.Informational 10.102.37.115 08/14/2015:13:35:39 GMT 0-PPE-1 : default LSN LSN_EIM_MAPPING 37647610 0 : EIM CREATED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 198.51.100.250:80, Protocol: TCP
DS-Lite LSN mapping deletion	Local4.Informational 10.102.37.115 08/14/2015:13:38:25 GMT 0-PPE-1 : default LSN LSN_EIM_MAPPING 37647618 0 : EIM DELETED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 198.51.100.250:80, Protocol: TCP

Displaying Current DS-Lite Sessions

You can display the current DS-Lite sessions for detecting any unwanted or inefficient sessions on the Citrix ADC appliance. You can display all or some DS-Lite sessions, on the basis of selection parameters.

Configuration by Using the Command Line Interface

To display all DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
show lsn session  -nattype DS-Lite
<!--NeedCopy-->
```

To display selected DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
show lsn session  -nattype DS-Lite [-clientname <string>] [-network <
   ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <
   ip_addr> [-natPort <port>]]
<!--NeedCopy-->
```

Example:

The following sample ouput displays all DS-Lite sessions existing on a Citrix ADC appliance:

```
show lsn session  -nattype DS-Lite
  B4-Address SubscrIP SubscrPort SubscrTD DstIP DstPort DstTD NatIP
     NatPort Proto Dir

1.  2001:DB8::3:4 192.0.2.51 2552 0 198.51.100.250 80 0 203.0.113.61
   3002 TCP OUT

2.  2001:DB8::3:4 192.0.2.51 3551 0 198.51.100.300 80 0 203.0.113.61
   52862 TCP OUT

3.  2001:DB8::3:4 192.0.2.100 4556 0 198.51.100.250 0 0 203.0.113.61
   48116 ICMP OUT

4.  2001: DB8::190 192.0.2.150 3881 0 198.51.100.199 80 0 203.0.113.69
   48305 TCP OUT

Done
<!--NeedCopy-->
```

Configuration Using the Configuration Utility

To display all or selected DS-Lite sessions by using the configuration utility

1. **Navigate to System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. For displaying DS-Lite sessions on the basis of selection parameters, click **Search**.

Clearing DS-Lite Sessions

You can remove any unwanted or inefficient DS-Lite sessions from the Citrix ADC appliance. The appliance immediately releases the resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected DS-Lite sessions from the Citrix ADC appliance.

To clear all DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
flush lsn session -nattype DS-Lite
show lsn session -nattype DS-Lite
```

To clear selected DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
1 flush lsn session  - nattype DS-Lite [-clientname <string>] [-network <
     ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <
     ip_addr> [-natPort <port>]]
2
3 show lsn session  - nattype DS-Lite
4 <!--NeedCopy-->
```

To clear all or selected DS-Lite sessions by using the configuration utility:

1. Navigate to **System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. Click **Flush Sessions**.

Configuring DS-Lite Static Maps

September 14, 2021

The Citrix ADC appliance supports manual creation of DS-Lite LSN mappings, which contain the mapping between the following information:

- Subscriber's IP address and port, and IPv6 address of B4 device or component
- NAT IP address and port

Static DS-Lite LSN mappings are useful in cases where you want to ensure that the connections initiated to a NAT IP address and port map to the subscriber IP address and port through the specified B4 device (for example, web servers located in the internal network).

Note: This feature is supported in release 11.0 build 64.x and later.

To create a DS-Lite static LSN mapping by using the command line

At the command prompt, type:

```
add lsn static <name> <transportprotocol> <subscrIP> <subscrPort> [-td
    <positive_integer>] [-network6 <B4_ADDR>] [<natIP> [<natPort>]] [-
    destIP<ip_addr> [-dsttd <positive_integer>]]

show lsn static
<!--NeedCopy-->
```

Parameter Descriptions

add lsn static

- name

Name for the LSN static mapping entry. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “ds-lite lsn static1” or ‘ds-lite lsn static1’). This is a mandatory argument. Maximum Length: 127

- transportprotocol

Protocol for the DS-Lite LSN mapping entry.

- subscrIP

IPv4 address of a subscriber for the DS-Lite LSN mapping entry.

- subscrPort

Port of the subscriber for the DS-Lite LSN mapping entry.

- Network6

IPv6 address of the B4 device or component.

- td

ID of the traffic domain to which the B4 device belongs. The IPv6 address of the B4 device is specified in the network6 paramter. If you do not specify an ID, the B4 device is assumed to be a part of the default traffic domain.

- natIP

IPv4 address, already existing on the Citrix ADC appliance as type LSN, to be used as NAT IP address for this mapping entry.

- natPort

NAT port for this DS-Lite LSN mapping entry.

- destIP

Destination IP address for the DS-Lite LSN mapping entry.

- dsttd

ID of the traffic domain through which the destination IP address for this DS-Lite LSN mapping entry is reachable from the Citrix ADC appliance. If you do not specify an ID, the destination IP address is assumed to be reachable through the default traffic domain, which has an ID of 0.

To create a DS-Lite static LSN mapping by using the configuration utility

Navigate to System > Large Scale NAT > Static, and add a new DS-Lite static LSN mapping.

Configuring Deterministic NAT Allocation for DS-Lite

September 14, 2021

Deterministic NAT allocation for DS-Lite LSN deployments is a type of NAT resource allocation in which the Citrix ADC appliance pre-allocates, from the LSN NAT IP pool and on the basis of the specified port block size, an LSN NAT IP address and a block of ports to each subscriber (subscriber behind B4 device).

Note: This feature is supported in release 11.0 build 64.x and later.

The appliance sequentially allocates NAT resources to these subscribers. It assigns the first block of ports on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT address is assigned to the subscriber, and so on.

The Citrix ADC appliance logs the allocated NAT IP address and the port block for a subscriber. For a connection, a subscriber can be identified by just its mapped NAT IP address and port block. For this reason, the Citrix ADC appliance does not log the creation or deletion of an LSN session.

A DS-Lite subscriber can have only one deterministic port block. If the entire block of ports is being used, the Citrix ADC appliance drops any new connection from the subscriber.

Example: Deterministic DS-Lite

In this example, a deterministic DS-Lite configuration includes four subscribers with IP addresses 192.0.17.5, 192.0.17.6, 192.0.17.7, and 192.0.17.8. These ipv4 subscribers are behind a B4 device having the IPv6 address 2001:DB8::3:4. In this configuration, the port block size is set to 20480 and LSN NAT IP address pool has IP addresses in the range 203.0.113.41-203.0.113.42.

The Citrix ADC appliance sequentially pre-allocates, from the LSN NAT IP pool and on the basis of the set port block size, an LSN NAT IP address and a block of ports to each subscriber. It assigns the first block of ports (1024-21503) on the beginning NAT IP address (203.0.113.41) to the beginning subscriber IP address (192.0.17.5). The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT IP address is assigned to the subscriber, and so on. The Citrix ADC logs the NAT IP address and the block of ports allocated for each subscriber.

The Citrix ADC appliance does not log any LSN session created or deleted for these subscribers.

The following table lists the NAT IP address and blocks of ports allocated to each subscriber in this example:

Subscriber IP address	Allocated NAT IP address	Allocated Block of Ports	IPv6 address of B4
192.0.17.5	203.0.113.41	1024 - 21503	2001:DB8::3:4
192.0.17.6	203.0.113.41	21504 - 41983	2001:DB8::3:4
192.0.17.7	203.0.113.41	41984 - 62463	2001:DB8::3:4
192.0.17.8	203.0.113.42	1024 - 21503	2001:DB8::3:4

Configuration Steps

You need to configure deterministic NAT as part of the DS-Lite configuration. For instructions on configuring DS-Lite, see Configuring DS-Lite.

While configuring DS-Lite, make sure that you:

- Set the NAT Type parameter to Deterministic when adding the LSN pool and the LSN group.
- Set the desired port block size parameter when adding the LSN group, unless you can accept the default value.

Points to Consider before Configuring Deterministic DS-Lite

Consider the following points before configuring deterministic DS-Lite:

- The complete IP address of each subscriber must be specified in a separate add lsn client command, by setting the Network and Netmask parameters. (Set Netmask to 255.255.255.255.) Also the IPv4 address of the B4 device specified in Network6 parameter must be complete (/128 prefix). In other words, Network and Network6 parameter do not accept addresses other than /32 bit mask and /128 prefix, respectively.
- The Citrix ADC appliance drops connections from subscribers that are not specified in any deterministic DS-Lite configuration but are behind B4 devices specified in a deterministic DS-lite configuration.
- The Citrix ADC appliance recognizes subscribers having the same IPv4 address as different subscribers if they are behind different B4 devices. A combination of subscriber IPv4 address and B4 device defines a unique subscriber in the LSN client entity of a DS-Lite configuration.

Sample Deterministic DS-Lite Configuration:

The following configuration uses the settings listed in section Example: Deterministic DS-Lite.

```
1  add lsn client LSN-DSLITE-CLIENT-10
2
3  Done
4  bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.5 -netmask
       255.255.255.255 -network6 2001:DB8::3:4/128
5
6  Done
7  bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.6 -netmask
       255.255.255.255 -network6 2001:DB8::3:4/128
8
9  Done
10 bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.7 -netmask
       255.255.255.255 -network6 2001:DB8::3:4/128
11
12 Done
13 bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.8 -netmask
       255.255.255.255 -network6 2001:DB8::3:4/128
14
15 Done
16 add lsn pool LSN-DSLITE-POOL-10 -nattype DETERMINISTIC
17
18 Done
19 bind lsn pool LSN-DSLITE-POOL-10  203.0.113.41-203.0.113.42
20
21 Done
```

```
22 add lsn ip6profile LSN-DSLITE-PROFILE-10 -type DS-Lite -network6 2001:
      DB8::5:6
23
24 Done
25 add lsn group LSN-DSLITE-GROUP-10 -clientname LSN-DSLITE-CLIENT-10 -
      nattype DETERMINISTIC -portblocksize 20480 -ip6profile LSN-DSLITE-
      PROFILE-10
26
27 Done
28 bind lsn group LSN-DSLITE-GROUP-10 -poolname LSN-DSLITE-POOL-10
29
30 Done
31 <!--NeedCopy-->
```

Configuring Application Layer Gateways for DS-Lite

September 14, 2021

For some application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway (AGL) for a protocol parses the packet payload and does necessary changes to ensure that the protocol continues to work over DS-Lite.

The Citrix ADC appliance supports ALG for the following protocols for DS-Lite:

- FTP
- ICMP
- TFTP
- SIP
- RTSP

Application Layer Gateway for FTP, ICMP, and TFTP Protocols

September 14, 2021

You can enable or disable ALG for the FTP protocol for a DS-Lite configuration by enabling or disabling the FTP ALG option of the LSN group of the configuration.

ALG for the ICMP protocol is enabled by default, and there is no provision to disable it.

ALG for the TFTP protocol is disabled by default. TFTP ALG is enabled automatically for a DS-Lite configuration when you bind a UDP LSN application profile, with endpoint-independent-mapping,

endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Application Layer Gateway for SIP Protocol

September 14, 2021

Using DS-Lite with Session Initiation Protocol (SIP) is complicated, because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When LSN is used with SIP, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media. SIP ALG for DS-Lite is compliant with RFC 3261, RFC 3581, RFC 4566, and RFC 4475.

> **Note**
>
> SIP ALG is supported in a Citrix ADC standalone appliance, in a Citrix ADC high availability setup, as well as in a Citrix ADC cluster setup.

Limitations of SIP ALG

SIP ALG for DS-Lite has the following limitations:

- Only SDP payload is supported.
- The following are not supported:
  - Multicast IP addresses
  - Encrypted SDP
  - SIP TLS
  - FQDN translation
  - SIP layer authentication
  - Admin partitions
  - Multipart body
  - Line folding

Configuring SIP ALG

You need to configure the SIP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuring DS-Lite. While configuring LSN, make sure that you:

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED

  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT

- Create a SIP ALG profile and make sure that you define either the source port range or destination port range. Bind the SIP ALG profile to the LSN group
- Enable SIP ALG in the LSN group

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string>[-sipalg ( ENABLED |
    DISABLED )]

show lsn group<groupname>
<!--NeedCopy-->
```

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn sipalgprofile<sipalgprofilename>[-dataSessionIdleTimeout<
    positive_integer>][-sipSessionTimeout<positive_integer>][-
    registrationTimeout<positive_integer>][-sipsrcportrange<port[-port
    ]>][-sipdstportrange<port[-port]>][-openRegisterPinhole ( ENABLED |
    DISABLED )][-openContactPinhole ( ENABLED | DISABLED )][-
    openViaPinhole ( ENABLED | DISABLED )][-openRecordRoutePinhole (
    ENABLED | DISABLED )]-sipTransportProtocol ( TCP | UDP )[-
    openRoutePinhole ( ENABLED | DISABLED )][-rport ( ENABLED | DISABLED
     )]

show lsn sipalgprofile<sipalgprofilename>
<!--NeedCopy-->
```

Sample Configuration

The following sample DS-Lite configuration, SIP ALG is enabled for TCP traffic from B4 devices in the network 2001:DB8::3:0/96.

```
add lsn client LSN-DSLITE-CLIENT-1
Done
bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/96
Done
```

```
add lsn pool LSN-DSLITE-POOL-1
Done
bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70
Done
add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6 2001:DB8::5:6
Done
add lsn appsprofile LSN-DSLITE-APPS-PROFILE-1 TCP -ippooling PAIRED -mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT
Done
add lsn sipalgprofile SIPALGPROFILE-1  -sipdstportrange 5060 -sipTransportProtocol TCP
Done
add lsn group LSN-DSLITE-GROUP-1 -clientname LSN-DSLITE-CLIENT-1 -portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-1 -sipalg ENABLED
Done
bind lsn group LSN-DSLITE-GROUP-1 -poolname LSN-DSLITE-POOL-1
Done
bind lsn group LSN-DSLITE-GROUP-1 -appsprofilename LSN-DSLITE-APPS-PROFILE-1
Done
bind lsn group LSN-DSLITE-GROUP-1 -sipalgprofilename SIPALGPROFILE-1
Done
<!--NeedCopy-->
```

Application Layer Gateway for RTSP Protocol

September 14, 2021

Real Time Streaming Protocol (RTSP) is an application-level protocol for the transfer of real-time media data. Used for establishing and controlling media sessions between end points, RTSP is a control channel protocol between the media client and the media server. The typical communication is between a client and a streaming media server.

Streaming media from a private network to a public network requires translating IP addresses and port numbers over the network. Citrix ADC functionality includes an Application Layer Gateway (ALG) for RTSP, which can be used with Large Scale NAT (LSN) to parse the media stream and make any necessary changes to ensure that the protocol continues to work over the network.

How IP address translation is performed depends on the type and direction of the message, and the type of media supported by the client-server deployment. Messages are translated as follows:

- Outbound request—Private IP address to Citrix ADC owned public IP address called LSN IP address.
- Inbound response—LSN IP address to private IP address.
- Inbound request—No translation.
- Outbound response—Private IP address to LSN pool IP address.

> **Note**
>
> RTSP ALG is supported in a Citrix ADC standalone appliance, in a Citrix ADC high availability setup, as well as in a Citrix ADC cluster setup.

Limitations of RTSP ALG

The RTSP ALG does not support the following:

- Multicast RTSP sessions
- RTSP session over UDP
- Admin partitions
- RTSP Authentication
- HTTP tunneling

Configuring RTSP ALG

Configure RTSP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuring DS-Lite. While configuring LSN, make sure that you:

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Enable RTSP ALG in the LSN group
- Create a RTSP ALG profile and bind the RTSP ALG profile to the LSN group

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-rtspalg ( ENABLED |
    DISABLED )]

show lsn group <groupname>
<!--NeedCopy-->
```

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn rtspalgprofile <rtspalgprofilename> [-rtspIdleTimeout <
    positive_integer>] -rtspportrange <port[-port]> [-
    rtspTransportProtocol (TCP|UDP)]

show lsn rtspalgprofile <rtspalgprofilename>
<!--NeedCopy-->
```

Sample RTSP ALG Configuration

The following sample DS-Lite configuration, RTSP ALG is enabled for TCP traffic from B4 devices in the network 2001:DB8::4:0/96.

Sample RTSP ALG Configuration:

```
add lsn client LSN-DSLITE-CLIENT-5
Done
bind lsn client LSN-DSLITE-CLIENT-5 -network6 2001:DB8::4:0/96
Done
add lsn pool LSN-DSLITE-POOL-5
Done
bind lsn pool LSN-DSLITE-POOL-5 203.0.113.61 - 203.0.113.70
Done
add lsn ip6profile LSN-DSLITE-PROFILE-5 -type DS-Lite -network6 2001:
    DB8::5:6
Done
add lsn appsprofile LSN-DSLITE-APPS-PROFILE-5 TCP -ippooling PAIRED -
    mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT
Done
add lsn rtspalgprofile RTSPALGPROFILE-5 -rtspIdleTimeout 1000 -
    rtspportrange 554
Done
add lsn group LSN-DSLITE-GROUP-5 -clientname LSN-DSLITE-CLIENT-5 -
    portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-5 -rtspalg ENABLED
Done
bind lsn group LSN-DSLITE-GROUP-5 -poolname LSN-DSLITE-POOL-5
Done
bind lsn group LSN-DSLITE-GROUP-5 -appsprofilename LSN-DSLITE-APPS-
    PROFILE-5
Done
bind lsn group LSN-DSLITE-GROUP-5 -rtspalgprofilename RTSPALGPROFILE-5
Done
```

```

```

Logging and Monitoring DS-Lite

September 14, 2021

You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The Citrix ADC appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a Citrix ADC appliance whose NSIP address is 10.102.37.115.You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The Citrix ADC appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a Citrix ADC appliance whose NSIP address is 10.102.37.115.

LSN Log Entry Type	Sample Log Entry
DS-Lite session creation	Local4.Informational 10.102.37.115 08/14/2015:13:35:38 GMT 0-PPE-1 : default LSN LSN_SESSION 37647607 0 : SESSION CREATED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 203.0.113.61:3002, Destination IP:Port:TD 198.51.100.250:80:0, Protocol:TCP
DS-Lite session deletion	Local4.Informational 10.102.37.115 08/14/2015:13:38:22 GMT 0-PPE-1 : default LSN LSN_SESSION 37647617 0 : SESSION DELETED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 203.0.113.61:3002, Destination IP:Port:TD 198.51.100.250:80:0, Protocol: TCP
DS-Lite LSN mapping creation	Local4.Informational 10.102.37.115 08/14/2015:13:35:39 GMT 0-PPE-1 : default LSN LSN_EIM_MAPPING 37647610 0 : EIM CREATED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 198.51.100.250:80, Protocol: TCP
DS-Lite LSN mapping deletion	Local4.Informational 10.102.37.115 08/14/2015:13:38:25 GMT 0-PPE-1 : default LSN LSN_EIM_MAPPING 37647618 0 : EIM DELETED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 198.51.100.250:80, Protocol: TCP

Displaying Current DS-Lite Sessions

You can display the current DS-Lite sessions for detecting any unwanted or inefficient sessions on the Citrix ADC appliance. You can display all or some DS-Lite sessions, on the basis of selection parameters.

To display all DS-Lite sessions by using the command line interface

At the command prompt, type:

```
show lsn session  -nattype DS-Lite
<!--NeedCopy-->
```

To display selected DS-Lite sessions by using the command line interface

At the command prompt, type:

```
show lsn session  -nattype DS-Lite [-clientname <string>] [-network <
    ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <
    ip_addr> [-natPort <port>]]
<!--NeedCopy-->
```

The following sample ouput displays all DS-Lite sessions existing on a Citrix ADC appliance:

> show lsn session –nattype DS-Lite

```
  B4-Address SubscrIP SubscrPort SubscrTD DstIP DstPort DstTD NatIP
     NatPort Proto Dir

1. 2001:DB8::3:4 192.0.2.51 2552 0 198.51.100.250 80 0 203.0.113.61
    3002 TCP OUT

2. 2001:DB8::3:4 192.0.2.51 3551 0 198.51.100.300 80 0 203.0.113.61
    52862 TCP OUT

3. 2001:DB8::3:4 192.0.2.100 4556 0 198.51.100.250 0 0 203.0.113.61
    48116 ICMP OUT

4. 2001: DB8::190 192.0.2.150 3881 0 198.51.100.199 80 0 203.0.113.69
    48305 TCP OUT
Done
<!--NeedCopy-->
```

Configuration Using the Configuration Utility

To display all or selected DS-Lite sessions by using the configuration utility

1. **Navigate to System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. For displaying DS-Lite sessions on the basis of selection parameters, click **Search**.

Clearing DS-Lite Sessions

You can remove any unwanted or inefficient DS-Lite sessions from the Citrix ADC appliance. The appliance immediately releases the resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected DS-Lite sessions from the Citrix ADC appliance.

To clear all DS-Lite sessions by using the command line interface

At the command prompt, type:

```
flush lsn session -nattype DS-Lite

show lsn session -nattype DS-Lite
<!--NeedCopy-->
```

To clear selected DS-Lite sessions by using the command line interface

At the command prompt, type:

```
flush lsn session -nattype DS-Lite [-clientname <string>] [-network <
    ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <
    ip_addr> [-natPort <port>]]

show lsn session -nattype DS-Lite
<!--NeedCopy-->
```

To clear all or selected DS-Lite sessions by using the configuration utility

1. Navigate to **System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. Click **Flush Sessions**.

Logging HTTP Header Information

The Citrix ADC appliance can log request header information of an HTTP connection that is using the DS-Lite functionality. The following header information of an HTTP request packet can be logged:

- URL that the HTTP request is destined to
- HTTP Method specified in the HTTP request
- HTTP version used in the HTTP request
- IPv4 address of the subscriber that sent the HTTP request

The HTTP header logs can be used by ISPs to see the trends related to the HTTP protocol among a set of subscribers. For example, an ISP can use this feature to find out the most popular website among a set of subscribers.

Configuration Steps

Perform the following tasks for configuring the Citrix ADC appliance to log HTTP header information:

- **Create an HTTP header log profile**. An HTTP header log profile is a collection of HTTP header attributes (for example, URL and HTTP method) that can be enabled or disabled for logging.
- **Bind the HTTP header to an LSN group of a DS-Lite LSN configuration**. Bind the HTTP header log profile to an LSN group of an LSN configuration by setting the HTTP header log profile name parameter to the name of the created HTTP header log profile. The Citrix ADC appliance then logs HTTP header information of any HTTP requests related to the LSN group. An HTTP header log profile can be bound to multiple LSN groups, but an LSN group can have only one HTTP header log profile.

To create an HTTP header log profile by using the command line interface

At the command prompt, type:

```
add lsn httphdrlogprofile <httphdrlogprofilename> [-logURL ( ENABLED |
    DISABLED )] [-logMethod ( ENABLED | DISABLED )] [-logVersion (
    ENABLED | DISABLED )] [-logHost ( ENABLED | DISABLED )]

show lsn httphdrlogprofile
<!--NeedCopy-->
```

To bind an HTTP header log profile to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -httphdrlogprofilename <string>

show lsn group <groupname>
<!--NeedCopy-->
```

Sample Configuration

In the following DS-Lite LSN configuration, HTTP header log profile HTTP-Header-LOG-1 is bound to LSN group LSN-DSLITE-GROUP-1. The log profile has all the HTTP attributes (URL, HTTP method,

HTTP version, and HOST IP address) enabled for logging, so that all these attributes are logged for any HTTP requests from B4 devices (in the network 2001:DB8:5001::/96).

Sample Configuration:

```
add lsn httphdrlogprofile HTTP-HEADER-LOG-1

Done

add lsn client LSN-DSLITE-CLIENT-1

Done

bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/100

Done

add lsn pool LSN-DSLITE-POOL-1

Done

bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6 2001:
   DB8::5:6

Done

add lsn group LSN-DSLITE-GROUP-1 -clientname LSN-DSLITE-CLIENT-1 -
   portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -poolname LSN-DSLITE-POOL-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -httphdrlogprofilename HTTP-HEADER-
   LOG-1

Done
<!--NeedCopy-->
```

IPFIX Logging

The Citrix ADC appliance supports sending information about LSN events in Internet Protocol Flow Information Export (IPFIX) format to the configured set of IPFIX collector(s). The appliance uses the existing AppFlow feature to send LSN events in IPFIX format to the IPFIX collectors.

IPFIX based logging is available for the following DS_Lite related events:

- Creation or deletion of an LSN session.
- Creation or deletion of an LSN mapping entry.
- Allocation or de-allocation of port blocks in the context of deterministic NAT.
- Allocation or de-allocation of port blocks in the context of dynamic NAT.
- Whenever subscriber session quota is exceeded.

Points to Consider before you Configure IPFIX logging

Before you start configuring IPSec ALG, consider the following points:

- You must configure the AppFlow feature and IPFIX collector(s) on the Citrix ADC appliance. For instructions, see Configuring the AppFlow feature.

Configuration Steps

Perform the following tasks for logging LSN information in IPFIX format:

- **Enable LSN logging in the AppFlow configuration**. Enable the LSN logging parameter as part of AppFlow configuration.
- **Create an LSN log profile**. An LSN log profile includes the IPFIX parameter that enables or disables the log information in IPFIX format.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the LSN log profile to one or multiple LSN group(s). Events related to the bound LSN group will be logged in IPFIX format.

To enable LSN logging in the AppFlow configuration by using the CLI

At the command prompt, type:

```
set appflow param -lsnLogging (ENABLED |DISABLED )

show appflow param
<!--NeedCopy-->
```

To create an LSN log profile by using the CLIAt the command prompt, type

At the command prompt, type:

```
set lsn logprofile <logProfileName>  -logipfix ( ENABLED | DISABLED )

show lsn logprofile
<!--NeedCopy-->
```

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
<!--NeedCopy-->
```

To create an LSN log profile by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Log** tab, and then add a log profile.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI

1. Navigate to **System** > **Large Scale NAT** > **LSN Group,** open the **LSN** group.
2. In **Advanced Settings,** click **+ Log Profile** to bind the created Log profile to the LSN group.

Port Control Protocol for DS-Lite

September 14, 2021

Citrix ADC appliances now support Port Control Protocol (PCP) for large scale NAT (LSN). Many of an ISP's subscriber applications must be accessible from Internet (for example, Internet of Things (IOT) devices, such as an IP camera that provides surveillance over the Internet). One way to meet this requirement is to create static large scale NAT (LSN) maps. But for a very large number of subscribers, creating static LSN NAT maps is not a feasible solution.

Port Control Protocol (PCP) enables a subscriber to request specific LSN NAT mappings for itself and/or for other 3rd party devices. The large scale NAT device creates an LSN map and sends it to the subscriber. The subscriber sends the remote devices on the Internet the NAT IP address:NAT port at which they can connect to the subscriber.

Applications usually send frequent keep-alive messages to the large scale NAT device so that their LSN mappings do not time out. PCP helps reduce the frequency of such keep-alive messages by enabling the applications to learn the timeout settings of the LSN mappings. This helps reduce bandwidth consumption on the ISP's access network and battery consumption on mobile devices.

PCP is a client-server model and runs over the UDP transport protocol. A Citrix ADC appliance implements the PCP server component and is compliant with RFC 6887.

Configuration Steps

Perform the following tasks for configuring PCP:

- (Optional) Create a PCP profile. A PCP profile includes settings for PCP related parameters (for example, to listen for mapping and peer PCP requests). A PCP profile can be bound to a PCP server. A PCP profile bound to a PCP server applies all its settings to the PCP server. A PCP profile can be bound to multiple PCP servers. By default, one PCP profile with default parameters settings is bound to all PCP servers. A PCP profile that you bind to a PCP server overrides the default PCP profile settings for that server. A default PCP profile has the following parameter settings:
  - Mapping: Enabled
  - Peer: Enabled
  - Minimum map life: 120 seconds
  - Maximum max life: 86400 seconds
  - Announce count: 10
  - Third Party: Disabled
- Create a PCP server and bind a PCP profile to it. Create a PCP server on the Citrix ADC appliance to listen for PCP related requests and messages from the subscribers. A Subnet IP (SNIP) address must be assigned to a PCP server to access it. By default, a PCP server listens on port 5351.
- Bind the PCP server to an LSN group of an LSN configuration. Bind the created PCP server to an LSN group of an LSN configuration by setting the PCP Server parameter to specify the created PCP server. The created PCP server can be accessed only by the subscribers of this LSN group. Note: A PCP server for a large scale NAT configuration does not serve requests from subscribers that are identified from ACL rules.

To create a PCP profile by using the CLI

At the command prompt, type:

```
1 add pcp profile <name> [-mapping ( ENABLED | DISABLED )] [-peer (
    ENABLED | DISABLED )] [-minMapLife <secs>]  [-maxMapLife <secs>] [-
    announceMultiCount <positive_integer>][-thirdParty ( ENABLED |
    DISABLED )]
```

```
2
3 show pcp profile <name>
4 <!--NeedCopy-->
```

To create a PCP server by using the CLI

At the command prompt, type:

```
1 add pcp server <name> <IPAddress> [-port <portNum|*>] [-pcpProfile <
     string>]
2
3 show pcp server <name>
4 <!--NeedCopy-->
```

Sample Configuration for DS-LITE

In the following sample configuration, PCP server PCP-SERVER-1, with PCP settings from PCP-DSLITE-PROFILE-1, is bound to LSN group LSN-DSLITE-GROUP-1. PCP-SERVER-9 serves PCP requests from IPv4 subscribers behind B4 devices from network 2001:DB8::3:0/100.

Sample configuration:

```
1 add pcp profile PCP-DSLITE-PROFILE-1 -minMapLife 300
2 Done
3 add pcp server PCP-DSLITE-SERVER-1 192.0.3.10  -pcpProfile PCP-DSLITE-
     PROFILE-1
4 Done
5 add lsn client LSN-DSLITE-CLIENT-1
6 Done
7 bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/100
8 Done
9 add lsn pool LSN-DSLITE-POOL-1
10 Done
11 bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70
12 Done
13 add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6 2001:
     DB8::5:6
14 Done
15 add lsn group LSN-DSLITE-PROFILE-1 -clientname LSN-NAT64-CLIENT-1  -
     ip6profile LSN-NAT64-PROFILE-1
16 Done
17 bind lsn group LSN-DSLITE-GROUP-1 -poolname LSN-NAT64-POOL-1
18 Done
```

```
bind lsn group LSN-DSLITE-GROUP-1 -poolname  PCP-NAT64-SERVER-1
Done
<!--NeedCopy-->
```

Large Scale NAT64

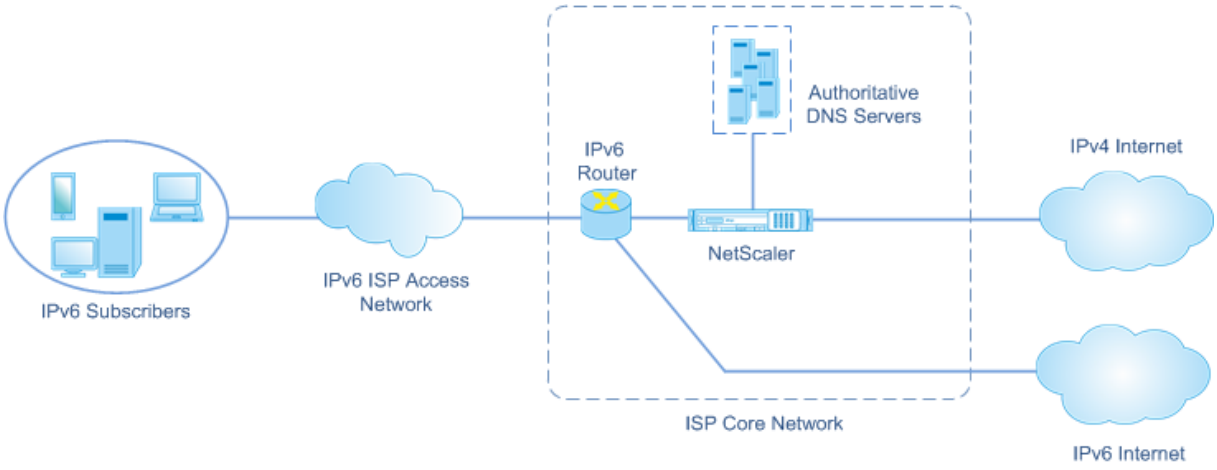
September 14, 2021

Because of the imminent exhaustion of IPv4 addresses, ISPs have started transitioning to IPv6 infrastructure. But during the transition, ISPs must continue to support IPv4 along with IPv6, because most of the public Internet still uses IPv4. Large scale NAT64 is an IPv6 transition solution for ISPs with IPv6 infrastructure to connect their IPv6-only subscribers to the IPv4 Internet. DNS64 is a solution for enabling discovery of IPv4-only domains by IPv6-only clients. DNS64 is used with large scale NAT64 to enable seamless communication between IPv6-only clients and IPv4-only servers.

A Citrix ADC appliance implements large scale NAT64 and DNS64 and is compliant with RFCs 6145, 6146, 6147, 6052, 3022, 2373, 2765, and 2464.

Architecture

The NAT64 architecture of an ISP using a Citrix ADC appliance consists of IPv6 subscribers accessing the IPv4 Internet through a Citrix ADC appliance deployed in the ISP's core network. IPv6 subscribers are connected to the ISP core network through the ISP's IPv6-only access network.



The large scale NAT64 functionality of a Citrix ADC appliance enables communication between IPv6 clients and IPv4 servers through IPv6-to-IPv4 packet translation, and vice versa, while maintaining session information on the Citrix ADC appliance.Citrix ADC DNS64 functionality represents IPv4-only domains to IPv6-subscribers by synthesizing DNS AAAA records for IPv4-only domains and sending them to the subscribers.

Large scale NAT64 has two main components: NAT64 prefix and NAT IPv4 pool. DNS64 has one main component, DNS64 prefix, which has the same value as NAT64 prefix.

Upon receiving an AAAA request from an IPv6-only subscriber for a domain name that is hosted on an IPv4-only web server on the Internet, the Citrix ADC DNS64 functionality synthesizes an AAAA record for the domain name and sends it to the subscriber. The AAAA record is synthesized by concatenating the DNS64 prefix (which is set to the NAT64 prefix) and the actual IPv4 address of the domain name.

The subscriber now has an IPv6 destination address that corresponds to the desired domain name. The subscriber sends the request to the synthesized IPv6 address. Upon receiving the IPv6 request, the large scale Citrix ADC NAT64 functionality translates the IPv6 request packet to an IPv4 request packet. Large scale NAT64 sets the IPv4 request's destination address to the IPv4 address, which is extracted from the IPv6 request's destination address by stripping the NAT64 prefix from the IPv6 address. The destination port is retained from the IPv6 request. Large Scale NAT64 also sets the source IP address:source port of the IPv4 packet to the NAT IP address:NAT port selected from the configured NAT pool.

The appliance maintains a record of all active sessions that use the large scale NAT64 functionality. These sessions are called large scale NAT64 sessions. The appliance also maintains the mappings between subscriber IPv6 address and port, and NAT IPv4 address and port, for each large scale NAT64 session. These mappings are called large scale NAT64 mappings. From large scale NAT64 session entries and large scale NAT64 mapping entries, the Citrix ADC appliance recognizes a response packet (received from the Internet) as belonging to a particular NAT64 session.

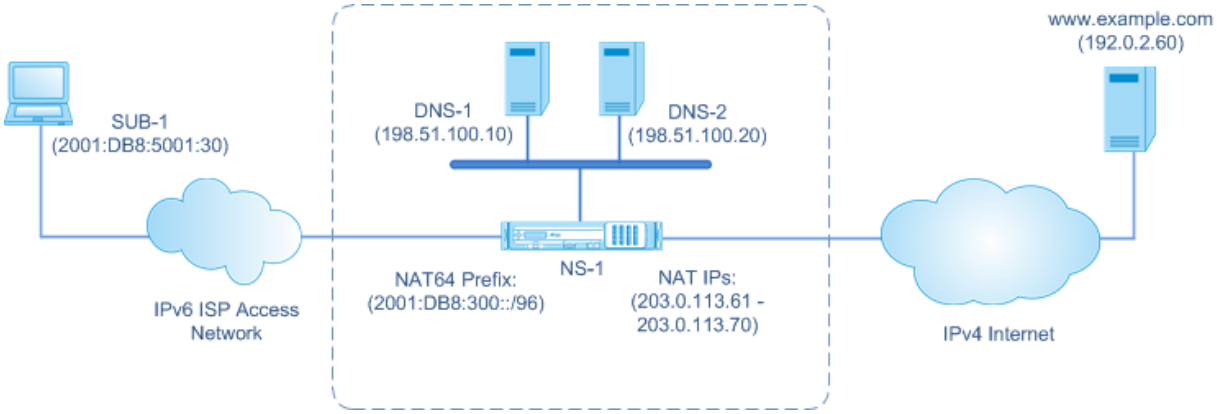
When the appliance receives an IPv4 response packet belonging to a particular NAT64 session, it uses the information stored in the NAT64 session to translate the IPv4 packet into an IPv6 packet, and then sends the IPv6 response packet to the subscriber.

Example: Traffic Flow of NAT64 and DNS64 Deployment

Consider an example of a large scale NAT64 and DNS64 deployment consisting of Citrix ADC appliance NS-1 and two local DNS servers, DNS-1 and DNS-2, in an ISP's core network, and IPv6 subscriber SUB-1. SUB-1 is connected to NS-1 through the ISP's IPv6 access network. NS-1 includes large scale NAT64 and DNS64 configurations for enabling the communication between IPv6 subscriber SUB-1 and IPv4 hosts (internal and external).

Large scale NAT64 configuration includes a NAT64 prefix (2001:DB8:300::/96) and NAT IPv4 pool for translation of IPv6 requests to IPv4 requests and IPv4 responses to IPv6 responses.

DNS64 configuration includes a DNS load balancing virtual server LBVS-DNS64-1 (2001:DB8:9999::99) and a DNS64 prefix (2001:DB8:300::/96). LBVS-DNS64-1 represents local DNS server DNS-1 and DNS-2 to ISP's subscribers. The DNS64 prefix, which has the same value as the NAT64 prefix, is used for synthesizing DNS AAAA records from DNS A records received from DNS servers DNS-1 and DNS-2. NS-1 responds with a synthesized AAAA record to SUB-1 for a DNS request to resolve an IPv4 host.



DNS64 Traffic Flow

Traffic flows between IPv6 subscriber SUB-1 and site `www.example.com`, which resides on an IPv4-only web server on the Internet, as follows:

1. IPv6 subscriber SUB-1 sends a DNS AAAA request for `www.example.com` to its designated DNS server (2001:DB8:9999::99).
2. DNS load balancing virtual server LBVS-DNS64-1 (2001:DB8:9999::99) on Citrix ADC appliance NS1 receives the AAAA request. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
3. DNS-1 returns an empty record or an error message, because there is no AAAA record available for `www.example.com`.
4. Because the DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of `www.example.com`.
5. DNS-1 responds with the A record of 192.0.2.60 for `www.example.com`.
6. DNS64 module on NS1 synthesizes an AAAA record for `www.example.com` by concatenating the DNS64 Prefix (2001:DB8:300::/96) associated with LBVS-DNS64-1, and IPv4 address (192.0.2.60) for `www.example.com` = 2001:DB8:300::192.0.2.60
7. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

NAT64 Traffic Flow

1. IPv6 subscriber SUB-1 sends a request to 2001:DB8:5001:30 `www.example.com`. The IPv6 packet has:
   - Source IP address = 2001:DB8:5001:30
   - Source port = 2552

- Destination IP address = 2001:DB8:300::192.0.2.60
- Destination port = 80

2. IPv6 subscriber SUB-1 sends a request to 2001:DB8:5001:30 www.example.com. The IPv6 packet has:
   - Source IP address = 2001:DB8:5001:30
   - Source port = 2552
   - Destination IP address = 2001:DB8:300::192.0.2.60
   - Destination port = 80
3. When NS-1 receives the IPv6 packet, the large scale NAT64 module creates a translated IPv4 request packet with:
   - Source IP address = One of the IPv4 addresses available in the configured NAT pool (203.0.113.61)
   - Source port = One of ports available with the allocated NAT IPv4 address (3002)
   - Destination IP address = IPv4 address extracted from the IPv6 request's destination address by stripping the NAT64 prefix (2001:DB8:300::/96) from the IPv6 address (192.0.2.60)
   - Destination port = IPv6 request's destination port (80)
4. The large scale NAT64 module also creates mapping and session entries for this large scale NAT64 flow. The session and mapping entries include the following information:
   - Source IP address of the IPv6 packet = 2001:DB8:5001:30
   - Source port of the IPv6 packet = 2552
   - NAT IP address = 203.0.113.61
   - NAT port = 3002
   - NS-1 sends the resulting IPv4 packet to its destination on the Internet.
5. Upon receiving the request packet, the server for www.example.com processes the packet and sends a response packet to NS-1. The IPv4 response packet has:
   - Source IP address = 192.0.2.60
   - Source port = 80
   - Destination IP address = 203.0.113.61
   - Destination port = 3002
6. Upon receiving the IPv4 response packet, NS-1 examines the large scale NAT64 mapping and session entries and finds that the IPv4 response packet belongs to a large scale NAT64 session. The large scale NAT64 module creates a translated IPv6 response packet:
   - Source IP address = 2001:DB8:300::192.0.2.60
   - Source port = 80
   - Destination IP address = 2001:DB8:5001:30
   - Destination port = 2552

7. NS-1 sends the translated IPv6 response to client SUB-1.

Large Scale NAT64 features Supported on Citrix ADC appliances

Large scale NAT64 on a Citrix ADC appliance supports the standard LSN feature set. For more information on these LSN features, see LSN Architecture.

Following are some of the large scale NAT64 features supported on Citrix ADC appliances:

- ALGs. Support of application Layer Gateway (ALG) for SIP, RTSP, FTP, ICMP, and TFTP protocols.
- Deterministic/Fixed NAT. Support for pre-allocation of blocks of ports to subscribers to minimize logging.
- Mapping. Support of Endpoint-independent mapping (EIM), Address-dependent mapping (ADM), and Address-Port dependent mapping (APDM).
- Filtering. Support of Endpoint-Independent Filtering (EIF), Address-Dependent Filtering (ADF), and Address-Port-Dependent Filtering (APDF).
- Quotas. Configurable limits on number of ports, sessions per subscriber, and sessions per LSN group.
- Static Mapping. Support for manually defining a large scale NAT64 mapping.
- Hairpin Flow. Support for communication between subscribers or internal hosts using NAT IP addresses.
- 464XLAT connections. Support for communication between IPv4-only applications on IPv6 subscriber hosts and IPv4 hosts on the Internet through IPv6 network.
- Variable length NAT64 and DNS64 prefixes. The Citrix ADC appliance supports defining NAT64 and DNS64 prefixes of lengths of 32, 40, 48, 56, 64, and 96.
- Multiple NAT64 and DNS64 prefix. The Citrix ADC appliance supports multiple NAT64 and DNS64 prefixes.
- LSN Clients. Support for specifying or identifying subscribers for large scale NAT64 by using IPv6 prefixes and extended ACL6 rules.
- Logging. Support for logging NAT64 sessions for law enforcement. In addition, the following are also supported for logging.
  - **Reliable SYSLOG**. Support for sending SYSLOG messages over TCP to external log servers for a more reliable transport mechanism.
  - **Load balancing of log servers**. Support for load balancing of external log servers for preventing storage of redundant log messages.
  - **Minimal Logging**. Deterministic LSN configurations or Dynamic LSN configurations with port block significantly reduce the large scale NAT64 log volume.
  - **Logging MSISDN information**. Support for including subscribers' MSISDN information in large scale NAT64 logs to identify and track subscriber activity over the Internet.

Points to Consider for Configuring Large Scale NAT64

September 14, 2021

Before you start configuring large scale NAT64 and DNS64, consider these points:

1. Make sure you understand the different components of large scale NAT64, described in RFCs.
2. The Citrix ADC appliance supports only the following ALGs for large Scale NAT64:
   - FTP
   - TFTP
   - ICMP
   - SIP
   - RTSP
3. In a high availability setup of two Citrix ADC appliances, large NAT64 session synchronization (connection mirroring) is not supported.

Configuring DNS64

September 14, 2021

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

- Add DNS services. DNS services are logical representations of DNS servers for which the Citrix ADC appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see Load Balancing.
- Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy. A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude-rule and mapped-rule settings.
- Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it. The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see Load Balancing.

> **Note**
>
> The command line interface has separate commands for these two tasks, but the GUI combines them in a single dialog box.

- Enable caching of DNS records. Enable the global parameter for the Citrix ADC appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see Enabling Caching of DNS Records.

To create a service of type DNS by using the command line interface

At the command prompt, type:

```
add service <name> <IP> <serviceType> <port> …
<!--NeedCopy-->
```

To create a DNS64 action by using the command line interface

At the command prompt, type:

```
add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule <
    expression>] [-excludeRule <expression>]
<!--NeedCopy-->
```

To create a DNS64 policy by using the command line interface

At the command prompt, type:

```
add dns policy64 <name> -rule <expression> -action <string>
<!--NeedCopy-->
```

To create a DNS load balancing virtual server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> DNS <IPAddress> <port> -dns64 (ENABLED | DISABLED
    ) [-bypassAAAA ( YES | NO)] …
<!--NeedCopy-->
```

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName> ...

```

```
bind lb vserver <name> -policyName <string> -priority <positive_integer
    > ...
<!--NeedCopy-->
```

Sample configuration:

```
add service SVC-DNS-1 203.0.113.50 DNS 53
Done
add service SVC-DNS-2 203.0.113.60 DNS 53
Done
add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
Done
add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET(2001:
    DB8:5001::/64)" -action DNS64-Action-1
Done
add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
Done
bind lb vserver LBVS-DNS64-1 SVC-DNS-1
Done
bind lb vserver LBVS-DNS64-1 SVC-DNS-2
Done
bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
Done
<!--NeedCopy-->
```

Configuring Large Scaler NAT64

September 14, 2021

A large scale NAT64 configuration on a Citrix ADC appliance uses the LSN commands sets. In a large scale NAT64 configuration, the LSN client entity specifies the IPv6 address or IPv6 network address, or ACL6 rules, for identifying IPv6 subscribers. A NAT64 configuration also includes an IPv6 profile, which specifies a NAT64 prefix.

Configuring NAT64 on a Citrix ADC appliance consists of the following tasks:

- Set the global LSN parameters. Global parameters include the amount of Citrix ADC memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
- Create an LSN client entity for identifying traffic from IPv6 subscribers. The LSN client entity refers to a set of IPv6 subscribers. The client entity includes IPv6 addresses or IPv6 network prefixes, or ACL6 rules, for identifying the traffic from these subscribers. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an

LSN client entity and binding a subscriber to the LSN client entity. The GUI combines these two operations on a single screen.

- Create an LSN pool and bind NAT IP addresses to it. An LSN pool defines a pool of NAT IP addresses to be used by the Citrix ADC appliance to perform large scale NAT64. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The GUI combines these two operations on a single screen.
- Create an LSN IP6 profile. An LSN IP6 profile defines the NAT64 prefix for a large scale NAT64 configuration.
- (Optional) Create an LSN Transport Profile for a specified protocol. An LSN transport profile defines various timeouts and limits, such as maximum large scale NAT64 sessions and maximum ports usage that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called the default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
- (Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it. An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The GUI combines these two operations on a single screen.
- Create an LSN Group and bind LSN pools, LSN IPv6 profile, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group. An LSN group is an entity consisting of an LSN client, an LSN IPv6 profile, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only one LSN IPv6 profile can be bound to an LSN group, and an LSN IPv6 profile bound to an LSN group cannot be bound to other LSN groups. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN

group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN group and binding LSN pools, LSN transport profiles, and LSN application profiles to the LSN group. The GUI combines these two operations in a single screen.

Configuration Using the Command Line

You can create different configurations using the command line interface. Follow the steps given below.

To create an LSN client by using the command line interface

At the command prompt, type:

```
add lsn client <clientname
<!--NeedCopy-->
```

To bind an IPv6 network or an ACL6 rule to an LSN client by using the command line interface

At the command prompt, type:

```
bind lsn client <clientname> (-network6 <ipv6_addr|*>| -acl6name <
   string>)

show lsn client
<!--NeedCopy-->
```

To create an LAN pool by using the command line interface

At the command prompt, type:

```
add lsn pool <poolname>

show lsn pool <poolname>
<!--NeedCopy-->
```

To bind NAT IP addresses to an LSN pool by using the command line interface

At the command prompt, type:

```
bind lsn pool <poolname> <lsnip>

show lsn pool
<!--NeedCopy-->
```

> **Note**
>
> For removing NAT IP (LSN IP addresses) addresses from an LSN pool, use the unbind lsn pool command.

To configure an LSN IPv6 profile by using the command line interface

At the command prompt, type:

```
add lsn ip6profile <name>  -type NAT64 -natprefix <ipv6_addr|*>

show lsn ip6profile
<!--NeedCopy-->
```

To create an LSN transport profile by using the command line interface

At the command prompt, type:

```
add lsn transportprofile <transportprofilename> <transportprotocol> [-
    sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota <
    positive_integer>] [-sessionquota <positive_integer>] [-
    portpreserveparity ( ENABLED | DISABLED )] [-portpreserverange (
    ENABLED | DISABLED )] [-syncheck ( ENABLED | DISABLED )]

show lsn transportprofile
<!--NeedCopy-->
```

To create an LSN application profile by using the command line interface

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> <transportprotocol> [-ippooling (
    PAIRED | RANDOM )] [-mapping <mapping>] [-filtering <filtering>][-
    tcpproxy ( ENABLED | DISABLED )]

show lsn appsprofile
<!--NeedCopy-->
```

To bind an application protocol port range to an LSN application profile by using the command line interface

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
<!--NeedCopy-->
```

To create an LSN group by using the command line interface

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-nattype ( DYNAMIC |
    DETERMINISTIC )] [-portblocksize <positive_integer>] [-logging(
    ENABLED | DISABLED )] [-sessionLogging ( ENABLED | DISABLED )][-
    sessionSync ( ENABLED | DISABLED )] [-snmptraplimit<positive_integer
    >] [-ftp ( ENABLED | DISABLED )] [-sipalg ( ENABLED | DISABLED )] [-
    rtspalg ( ENABLED |DISABLED )] [-ip6profile <string>]

show lsn group
<!--NeedCopy-->
```

To bind LSN protocol profiles and LSN pools to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> (-poolname <string> | -transportprofilename
    <string> | -httphdrlogprofilename <string> | -appsprofilename <
    string> | -sipalgprofilename <string> | rtspalgprofilename <string>)

show lsn group
<!--NeedCopy-->
```

Sample Large Scale NAT64 Configurations

Here are some sample configurations of large scale NAT64:

Simple large scale NAT64 configuration with default settings:

```
add lsn client LSN-NAT64-CLIENT-1
```

```
2
3 bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96
4
5 add lsn pool LSN-NAT64-POOL-1
6
7 bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70
8
9 add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
    :300::/96
10
11 add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
    ip6profile LSN-NAT64-PROFILE-1
12
13 bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
14
15 <!--NeedCopy-->
```

Simple large scale NAT64 configuration with an extended ACL6 rule for identifying subscribers:

```
1 add ns acl6 LSN-NAT64-ACL-2 ALLOW  - srcIPv6 = 2001:DB8:5002::20 - 2001:
    DB8:5002::200
2
3 apply acl6s
4
5 add lsn client LSN-NAT64-CLIENT-2
6
7 bind lsn client LSN-NAT64-CLIENT-2  - acl6name LSN-NAT64-ACL-2
8
9 add lsn pool LSN-NAT64-POOL-2
10
11 bind lsn pool LSN-NAT64-POOL-2 203.0.113.5-203.0.113.10
12
13 add lsn ip6profile LSN-NAT64-PROFILE-2 -type NAT64 -natprefix 2001:DB8
    :302::/96
14
15 add lsn group LSN-NAT64-GROUP-2 -clientname LSN-NAT64-CLIENT-2 -
    ip6profile LSN-NAT64-PROFILE-2
16
17 bind lsn group LSN-NAT64-GROUP-2 -poolname LSN-NAT64-POOL-2
18
19 <!--NeedCopy-->
```

Large scale NAT64 configuration with deterministic NAT resource allocation:

```
1 add lsn client LSN-NAT64-CLIENT-7
```

```
2
3 bind lsn client LSN-NAT64-CLIENT-7 -network6 2001:DB8:1002::7/128
4
5 add lsn pool LSN-NAT64-POOL-7 -nattype DETERMINISTIC
6
7 bind lsn pool LSN-NAT64-POOL-7 203.0.113.24-203.0.113.27
8
9 add lsn ip6profile LSN-NAT64-PROFILE-7 -type NAT64 -natprefix 2001:DB8
     :307::/96
10
11 add lsn group LSN-NAT64-GROUP-7 -clientname LSN-NAT64-CLIENT-7 -
     ip6profile LSN-NAT64-PROFILE-7 -nattype DETERMINISTIC -portblocksize
      256
12
13 bind lsn group LSN-NAT64-GROUP-7 -poolname LSN-POOL-7
14
15 <!--NeedCopy-->
```

Configuring Application Layer Gateways for Large Scale NAT64

September 14, 2021

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet payload. Application Layer Gateway for a protocol parses the packet's payload and does necessary changes to ensure that the protocol continues to work over large scale NAT64.

The Citrix ADC appliance supports ALG for the following protocols for large scale NAT64:

- FTP
- ICMP
- TFTP
- SIP
- RTSP

Application Layer Gateway for FTP, ICMP, and TFTP Protocols

September 14, 2021

You can enable or disable ALG for the FTP protocol for an large scale NAT64 configuration by enabling or disabling the FTP ALG option of the LSN group of the configuration.

ALG for the ICMP protocol is enabled by default, and there is no provision to disable it.

ALG for the TFTP protocol is disabled by default. TFTP ALG is enabled automatically for an large scale NAT64 configuration when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Application Layer Gateway for SIP Protocol

September 14, 2021

Using Large Scale NAT64 with Session Initiation Protocol (SIP) is complicated, because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When LSN is used with SIP, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media. SIP ALG for large scale NAT64 is compliant with RFC 3261, RFC 3581, RFC 4566, and RFC 4475.

> **Note**
>
> SIP ALG is supported in a Citrix ADC standalone appliance, in a Citrix ADC high availability setup, as well as in a Citrix ADC cluster setup.

Limitations of SIP ALG

SIP ALG for large scale NAT64 has the following limitations:

- Only SDP payload is supported.
- The following are not supported:
  - Multicast IP addresses
  - Encrypted SDP
  - SIP TLS
  - FQDN translation
  - SIP layer authentication
  - Traffic Domains
  - Admin partitions
  - Multipart body
  - Line folding

Configuring SIP ALG

You need to configure the SIP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuration Large Scale NAT64. While configuring LSN, make sure that you:

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Create a SIP ALG profile and make sure that you define either the source port range or destination port range. Bind the SIP ALG profile to the LSN group.
- Enable SIP ALG in the LSN group.

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-sipalg ( ENABLED |
    DISABLED )]

show lsn group <groupname>
<!--NeedCopy-->
```

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn sipalgprofile <sipalgprofilename>[-dataSessionIdleTimeout <
    positive_integer>][-sipSessionTimeout <positive_integer>] [-
    registrationTimeout <positive_integer>] [-sipsrcportrange <port[-
    port]>] [-sipdstportrange <port[-port]>] [-openRegisterPinhole (
    ENABLED | DISABLED )] [-openContactPinhole ( ENABLED | DISABLED )]
    [-openViaPinhole ( ENABLED | DISABLED )] [-openRecordRoutePinhole (
    ENABLED | DISABLED )]-sipTransportProtocol ( TCP | UDP ) [-
    openRoutePinhole ( ENABLED | DISABLED )] [-rport ( ENABLED |
    DISABLED )]

show lsn sipalgprofile <sipalgprofilename
<!--NeedCopy-->
```

Sample Configuration

The following sample large scale NAT64 configuration, SIP ALG is enabled for TCP traffic from subscriber devices in the network 2001:DB8:1003::/96.

```
add lsn client LSN-NAT64-CLIENT-9

Done
bind lsn client LSN-NAT64-CLIENT-9 -network6 2001:DB8:1002::/96

Done
add lsn pool LSN-NAT64-POOL-9

Done
bind lsn pool LSN-NAT64-POOL-9 203.0.113.90

Done
add lsn ip6profile LSN-NAT64-PROFILE-9 -type NAT64 -natprefix 2001:DB8
   :309::/96

Done
add lsn appsprofile LSN-NAT64-APPS-PROFILE-9 TCP -ippooling PAIRED -
   mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done
add lsn sipalgprofile SIPALGPROFILE-9  -sipdstportrange 5060  -
   sipTransportProtocol TCP

Done
add lsn group LSN-NAT64-GROUP-9 -clientnameLSN-NAT64-CLIENT-9 -
   ip6profile LSN-NAT64-PROFILE-7 -sipalg ENABLED

Done
bind lsn group LSN-NAT64-GROUP-9 -poolnameLSN-NAT64-POOL-9
Done
bind lsn group LSN-NAT64-GROUP-9 -appsprofilename LSN-NAT64-APPS-
   PROFILE-9
Done
bind lsn group LSN-NAT64-GROUP-9 -sipalgprofilename SIPALGPROFILE-9
Done
<!--NeedCopy-->
```

Application Layer Gateway for RTSP Protocol

September 14, 2021

Real Time Streaming Protocol (RTSP) is an application-level protocol for the transfer of real-time media data. Used for establishing and controlling media sessions between end points, RTSP is a control channel protocol between the media client and the media server. The typical communication is between a client and a streaming media server.

Streaming media from a private network to a public network requires translating IP addresses and port numbers over the network. Citrix ADC functionality includes an Application Layer Gateway (ALG) for RTSP, which can be used with Large Scale NAT (LSN) to parse the media stream and make any necessary changes to ensure that the protocol continues to work over the network.

How IP address translation is performed depends on the type and direction of the message, and the type of media supported by the client-server deployment. Messages are translated as follows:

- Outbound request—Private IP address to Citrix ADC owned public IP address called LSN IP address.
- Inbound response—LSN IP address to private IP address.
- Inbound request—No translation.
- Outbound response—Private IP address to LSN pool IP address.

> **Note**
>
> RTSP ALG is supported in a Citrix ADC standalone appliance, in a Citrix ADC high availability setup, as well as in a Citrix ADC cluster setup.

Limitations of RTSP ALG

The RTSP ALG does not support the following:

- Multicast RTSP sessions
- RTSP session over UDP
- Admin partitions
- RTSP Authentication
- HTTP tunneling

Configuring RTSP ALG

Configure RTSP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuring Large Scale NAT64. While configuring, make sure that you:

- Set the following parameters while adding an LSN application profile:

  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Enable RTSP ALG in the LSN group
- Create a RTSP ALG profile and bind the RTSP ALG profile to the LSN group

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-rtspalg ( ENABLED |
    DISABLED )]

show lsn group <groupname>
<!--NeedCopy-->
```

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn rtspalgprofile <rtspalgprofilename> [-rtspIdleTimeout <
    positive_integer>] -rtspportrange <port[-port]> [-
    rtspTransportProtocol (TCP|UDP)]

show lsn rtspalgprofile <rtspalgprofilename>
<!--NeedCopy-->
```

Sample RTSP ALG Configuration

The following sample large scale NAT64 configuration, RTSP ALG is enabled for TCP traffic from subscriber devices in the network 2001:DB8:1002::/96.

```
add lsn client LSN-NAT64-CLIENT-9
Done
bind lsn client LSN-NAT64-CLIENT-9 -network6 2001:DB8:1002::/96
Done
add lsn pool LSN-NAT64-POOL-9
Done
bind lsn pool LSN-NAT64-POOL-9 203.0.113.90
Done
add lsn ip6profile LSN-NAT64-PROFILE-9 -type NAT64 -natprefix 2001:DB8
    :309::/96
```

```
Done
add lsn appsprofile LSN-NAT64-APPS-PROFILE-9 TCP -ippooling PAIRED -
    mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT
Done
add lsn rtspalgprofile RTSPALGPROFILE-9 -rtspIdleTimeout 1000 -
    rtspportrange 554
Done
add lsn group LSN-NAT64-GROUP-9 -clientname LSN-NAT64-CLIENT-9 -
    ip6profile LSN-NAT64-PROFILE-7 -rtspalg ENABLED
Done
bind lsn group LSN-NAT64-GROUP-9 -poolname LSN-NAT64-POOL-9
Done
bind lsn group LSN-NAT64-GROUP-9 -appsprofilename LSN-NAT64-APPS-
    PROFILE-9
Done
bind lsn group LSN-NAT64-GROUP-9  -rtspalgprofilename RTSPALGPROFILE-9
Done
<!--NeedCopy-->
```

Configuring Static Large Scale NAT64 Maps

September 14, 2021

The Citrix ADC appliance supports manual creation of NAT64 mappings, which contain the mapping between the following information:

- Subscriber's IP address and port
- NAT IP address and port

Static Large Scale NAT64 mappings are useful in cases where you want to ensure that the IPv4 connections initiated to a NAT IP address:port are IPv6 translated and mapped to the subscriber IP address:port (for example, web servers located in the internal network).

To create a Large Scale NAT64 mapping by using the command line

At the command prompt, type:

```
add lsn static <name> <transportprotocol> <subscrIP> <subscrPort>  [<
    natIP> [<natPort>]] [-destIP <ip_addr> [-dsttd <positive_integer>]]

show lsn static
<!--NeedCopy-->
```

Wildcard Port Static Large Scale NAT64 Maps

A static large scale NAT64 mapping entry is usually a one-to-one mapping between a subscriber IPv6 address:port and a NAT IPv4 address:port. A one-to-one static large scale NAT64 mapping entry exposes only one port of the subscriber IP address to the Internet.

Some situations might require exposing all ports (64K - limited to the maximum number of ports of a NAT IPv4 address) of a subscriber IP address to the Internet (for example, a server hosted on an internal network and running a different service on each port). To make these internal services accessible through the Internet, you have to expose all the ports of the server to the Internet.

One way to meet this requirement is to add 64 thousand one-to-one static mapping entries, one mapping entry for each port. Creating those entries is very cumbersome and a big task. Also, this large number of configuration entries might lead to performance issues in the Citrix ADC appliance.

A simpler method is to use wildcard ports in a static mapping entry. You just need to create one static mapping entry with NAT-port and subscriber-port parameters set to the wildcard character (*), and the protocol parameter set to ALL, to expose all the ports of a subscriber IP address for all protocols to the Internet.

For a subscriber's inbound or outbound connections matching a wildcard static mapping entry, the subscriber's port does not change after the NAT operation. When a subscriber-initiated connection to the Internet matches a wildcard static mapping entry, the Citrix ADC appliance assigns a NAT port that has the same number as the subscriber port from which the connection is initiated. Similarly, an Internet host gets connected to a subscriber's port by connecting to the NAT port that has the same number as the subscriber's port.

To configure the Citrix ADC appliance to provide access to all ports of a subscriber IPv6 address, create a wildcard static map with the following mandatory parameter settings:

- Protocol=ALL
- Subscriber port = *
- NAT port = *

In a wildcard static map, unlike in a one-to-one static map, setting the NAT IP parameter is mandatory. Also, the NAT IP address assigned to a wildcard static map cannot be used for any other subscribers.

To create a wildcard static map by using the command line interface

At the command prompt, type:

```
1 add lsn static <name> ALL <subscrIP> *  <natIP> * [-td <
     positive_integer>] [-destIP <ip_addr>
2
3 show lsn static
4 <!--NeedCopy-->
```

In the following sample configuration of a wildcard static map, all ports of a subscriber whose IP address is 2001:DB8:5001::3 are made accessible through NAT IP 203.0.11.33.

```
1 add lsn static NAT64-WILDCARD-STATIC-1 ALL 2001:DB8:5001::3 *
     203.0.113.33 *
2 Done
3 <!--NeedCopy-->
```

Logging and Monitoring Large Scale NAT64

September 14, 2021

You can log large scale NAT64 information to diagnose and troubleshoot problems, and to meet legal requirements. You can monitor the performance of the large scale NAT64 deployment by using statistical counters and displaying the related current sessions.

Logging Large Scale NAT64

Logging large scale NAT64 information is required for ISPs to meet legal requirements and identify the source of traffic at any given time.

A log message for a large scale NAT64 mapping entry consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced.
- Time stamp.
- Entry type (MAPPING).
- Whether the mapping entry was created or deleted.
- Subscriber's IP address, port, and traffic domain ID.
- NAT IP address and port.
- Protocol name.
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for endpoint-independent mapping.
  - Only the destination IP address is logged for address-dependent mapping. The port is not logged.
  - Destination IP address and port are logged for address-port-dependent mapping.

A log message for a large scale NAT64 session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced

- Time stamp
- Entry type (SESSION)
- Whether the session is created or removed
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table displays sample large scale NAT64 log entries of each type stored on the configured log servers. The log entries show that a subscriber whose IPv6 address is 2001:db8:5001::9 was connected to destination IP:port 23.0.0.1:80 through NAT IP:port 203.0.113.63:45195 on April 7, 2016, from 14:07:57 GMT to 14:10:59 GMT.

Log Entry Type	Sample Log Entry
Session Creation	04/07/2016:14:07:57 GMT Informational 0-PPE-10 : default LSN LSN_SESSION 5532 0 : SESSION CREATED Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP
Mapping Creation	04/07/2016:14:07:57 GMT Informational 0-PPE-10 : default LSN LSN_ADDR_MAPPING 5533 0 : ADM CREATED Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:TD 23.0.0.1:80, Protocol: TCP
Session Deletion	04/07/2016:14:10:59 GMT 0-PPE-10 : default LSN LSN_SESSION 25012 0 : SESSION DELETED Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP
Mapping Deletion	04/07/2016:14:10:59 GMT 0-PPE-10 : default LSN LSN_ADDR_MAPPING 25013 0 : ADM DELETED Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP

Configuration Steps

You can configure logging of large scale NAT64 information for a large scale NAT64 configuration by setting the LSN groups's logging and session logging parameters. These are group level parameters and are disabled by default. The Citrix ADC appliance logs large scale NAT64 sessions for an LSN group only when both logging and session logging parameters are enabled.

The following table displays the logging behavior for an LSN group for various settings of logging and session logging parameters.

Logging	Session Logging	Logging Behavior
Enabled	Enabled	Logs LSN mapping entries as well as LSN sessions
Enabled	Disabled	Logs LSN mapping entries but not LSN sessions
Disabled	Enabled	Logs neither mapping entries nor LSN sessions

To log large scale NAT64 information by using the CLI

To set the logging and session logging parameters while adding an LSN group, at the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-logging (ENABLED|
    DISABLED)] [-sessionLogging (ENABLED|DISABLED)]

show lsn group
<!--NeedCopy-->
```

To set the logging and session logging parameters for an existing LSN group, at the command prompt, type:

```
set lsn group <groupname> [-logging (ENABLED|DISABLED)] [-
    sessionLogging (ENABLED|DISABLED)]

show lsn group
<!--NeedCopy-->
```

Sample Configuration

In this example of large scale NAT64 configuration, logging and session logging paramters are enabled for LSN group LSN-NAT64-GROUP-1.

The Citrix ADC appliance logs large scale NAT64 session and mapping information for connections from subscribers (in the network 2001:DB8:5001::/96).

Sample configuration:

```
add lsn client LSN-NAT64-CLIENT-1 Done
Done
bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96
Done
add lsn pool LSN-NAT64-POOL-1
Done
bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70
Done
add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
    :300::/96
Done
add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
    ip6profile LSN-NAT64-PROFILE-1  -logging ENABLED -sessionLogging
    ENABLED
Done
bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
Done
<!--NeedCopy-->
```

Logging MSISDN Information for Large Scale NAT64

A Mobile Station Integrated Subscriber Directory Number (MSISDN) is a telephone number uniquely identifying a subscriber across multiple mobile networks. The MSISDN is associated with a country code and a national destination code identifying the subscriber's operator.

You can configure a Citrix ADC appliance to include MSISDNs in large scale NAT64 LSN log entries for subscribers in mobile networks. The presence of MSISDNs in the LSN logs facilitates faster and accurate back tracing of a mobile subscriber who has violated a policy or law, or whose information is required by lawful interception agencies.

The following sample LSN log entries include MSISDN information for a connection from a mobile subscriber in an LSN configuration. The log entries show that a mobile subscriber whose MSISDN is E164:5556543210 and IPv6 address is 2001:db8:5001::9 was connected to destination IP:port 23.0.0.1:80 through the NAT IP:port 203.0.113.63:45195 on April 7, 2016, from 14:07:57 GMT to 14:10:59 GMT.

Log Entry Type	Sample Log Entry
Session Creation	04/07/2016:14:07:57 GMT Informational 0-PPE-10 : default LSN LSN_SESSION 5532 0 : SESSION CREATED **E164:5556543210** Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP
Mapping Creation	04/07/2016:14:07:57 GMT Informational 0-PPE-10 : default LSN LSN_ADDR_MAPPING 5533 0 : ADM CREATED **E164:5556543210** Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:TD 23.0.0.1:80, Protocol: TCP
Session Deletion	04/07/2016:14:10:59 GMT 0-PPE-10 : default LSN LSN_SESSION 25012 0 : SESSION DELETED **E164:5556543210** Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP
Mapping Deletion	04/07/2016:14:10:59 GMT 0-PPE-10 : default LSN LSN_ADDR_MAPPING 25013 0 : ADM DELETED **E164:5556543210** Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP

Configuration Steps

Perform the following tasks for including MSISDN information in LSN logs:

- **Create an LSN log profile**. An LSN log profile includes the log subscriber ID parameter, which specifies whether to or not to include the MSISDN information in the LSN logs of an LSN configuration.
- Bind the LSN log profile to an LSN group of an LSN configuration.Bind the created LSN log profile to an LSN group of an LSN configuration by setting the log profile name parameter to the created LSN log profile name. MSISDN information is included in all LSN logs related to mobile subscribers of this LSN group.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename> -logSubscriberID ( ENABLED |
   DISABLED )

show lsn logprofile
<!--NeedCopy-->
```

To bind an LSN log profile to an LSN group of an NAT64 LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
<!--NeedCopy-->
```

Sample Configuration

In this example of NAT64 LSN configuration, the LSN log profile LOG-PROFILE-MSISDN-1 has the log subscriber ID parameter enabled. LOG-PROFILE-MSISDN-1 is bound to LSN group LSN-NAT64-GROUP-1. MSISDN information is included in the LSN session and LSN mapping logs for connections from mobile subscribers (in network 2001:DB8:5001::/96).

```
add lsn logprofile  LOG-PROFILE-MSISDN-1  -logSubscriberID ENABLED
Done
add lsn client LSN-NAT64-CLIENT-1
Done
bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96
Done
add lsn pool LSN-NAT64-POOL-1
Done
bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70
Done
add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
   :300::/96
Done
add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
   ip6profile LSN-NAT64-PROFILE-1
Done
bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
Done
```

```
bind lsn group LSN-NAT64-GROUP-1 -logprofilename  LOG-PROFILE-MSISDN-1
Done
<!--NeedCopy-->
```

Compact Logging for Large Scale NAT

Logging LSN information is one of the important functions needed by ISPs to meet legal requirements and be able to identify the source of traffic at any given time. This eventually results in a huge volume of log data, requiring the ISPs to make large investments to maintain the logging infrastructure.

Compact logging is a technique for reducing the log size by using a notational change involving short codes for event and protocol names. For example, C for client, SC for session created, and T for TCP. Compact logging results in an average of 40 percent reduction in log size.

Configuration Steps

Perform the following tasks for logging LSN information in compact format:

1. Create an LSN log profile. An LSN log profile includes the Log Compact parameter, which specifies whether to or not to log information in compact format for an LSN configuration.
2. Bind the LSN log profile to an LSN group of an LSN configuration. Bind the created LSN log profile to an LSN group of an LSN configuration by setting the Log Profile Name parameter to the created LSN log profile name. All sessions and mappings for this LSN group are logged in compact format.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename> -logCompact (ENABLED|DISABLED)

show lsn logprofile
<!--NeedCopy-->
```

To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname> -logProfileName <lsnlogprofilename>

show lsn group
<!--NeedCopy-->
```

Sample Configuration for NAT64:

```
add lsn logprofile  LOG-PROFILE-COMPACT-1 -logCompact ENABLED
Done
add lsn client LSN-NAT64-CLIENT-1
Done
bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96
Done
add lsn pool LSN-NAT64-POOL-1
Done
bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70
Done
add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
    :300::/96
Done
add lsn group LSN-NAT64-PROFILE-1 -clientname LSN-NAT64-CLIENT-1  -
    ip6profile LSN-NAT64-PROFILE-1
Done
bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
Done
bind lsn group LSN-NAT64-GROUP-1  - logProfileName LOG-PROFILE-COMPACT-1
Done
<!--NeedCopy-->
```

Logging HTTP Header Information

The Citrix ADC appliance can log request header information of an HTTP connection that is using the Citrix ADC large scale NAT64 functionality. The following header information of an HTTP request packet can be logged:

- URL that the HTTP request is destined to
- HTTP Method specified in the HTTP request
- HTTP version used in the HTTP request
- IPv6 address of the subscriber that sent the HTTP request

The HTTP header logs can be used by ISPs to see the trends related to the HTTP protocol among a set of subscribers. For example, an ISP can use this feature to find out the most popular website among a set of subscribers.

Configuration Steps

Perform the following tasks for configuring the Citrix ADC appliance to log HTTP header information:

- Create an HTTP header log profile. An HTTP header log profile is a collection of HTTP header attributes (for example, URL and HTTP method) that can be enabled or disabled for logging.
- Bind the HTTP header to an LSN group of a large scale NAT64 configuration. Bind the HTTP header log profile to an LSN group of an LSN configuration by setting the HTTP header log profile name parameter to the name of the created HTTP header log profile. The Citrix ADC appliance then logs HTTP header information of any HTTP requests related to the LSN group. An HTTP header log profile can be bound to multiple LSN groups, but an LSN group can have only one HTTP header log profile.

To create an HTTP header log profile by using the the command line interface

At the command prompt, type:

```
add lsn httphdrlogprofile <httphdrlogprofilename> [-logURL ( ENABLED |
    DISABLED )] [-logMethod ( ENABLED | DISABLED )] [-logVersion (
    ENABLED | DISABLED )] [-logHost ( ENABLED | DISABLED )]

show lsn httphdrlogprofile
<!--NeedCopy-->
```

To bind an HTTP header log profile to an LSN group by using the the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -httphdrlogprofilename <string>

show lsn group <groupname>
<!--NeedCopy-->
```

Sample Configuration

```
add lsn httphdrlogprofile HTTP-HEADER-LOG-1
Done
add lsn client LSN-NAT64-CLIENT-1 Done
Done
bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96
Done
add lsn pool LSN-NAT64-POOL-1
Done
bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70
Done
```

```
11 add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
      :300::/96
12 Done
13 add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
      ip6profile LSN-NAT64-PROFILE-1
14 Done
15 bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
16 Done
17 bind lsn group LSN-NAT64-GROUP-1 -httphdrlogprofilename HTTP-HEADER-LOG
      -1
18 Done
19 <!--NeedCopy-->
```

Displaying Current Large Scale NAT64 Sessions

You can display the current large scale NAT64 sessions in order to detect any unwanted or inefficient sessions on the Citrix ADC appliance. You can display all or some large scale NAT64 sessions on the basis of selection parameters.

> **Note**
>
> When more than a million large scale NAT64 sessions exist on the Citrix ADC appliance, Citrix recommends using the selection parameters to display selected large scale NAT64 sessions instead of displaying all of them.

To display all large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
1 show lsn session  - nattype NAT64
2 <!--NeedCopy-->
```

To display selective large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
1 show lsn session  - nattype NAT64 [-network6 <ipv6_addr|*>] [-clientname
      <string>] [-natIP <ip_addr> [-natPort <port>]]
2 <!--NeedCopy-->
```

Displaying Large Scale NAT64 Statistics

You can display statistics related to large scale NAT64 module, and evaluate its performance or troubleshoot problems. You can display a summary of statistics of all large scale NAT64 configurations or of a particular large scale NAT64 configuration. The statistical counters reflect events since the Citrix ADC appliance was last restarted. All these counters are reset to 0 when the Citrix ADC appliance is restarted.

To display total statistics of large scale NAT64 by using the command line interface

At the command prompt, type:

```
stat lsn nat64
<!--NeedCopy-->
```

To display statistics for a specified large scale NAT64 configuration by using the command line interface

At the command prompt, type:

```
stat lsn group <groupname>
<!--NeedCopy-->
```

Clearing Large Scale NAT64 Sessions

You can remove any unwanted or inefficient large scale NAT64 sessions from the Citrix ADC appliance. The appliance immediately releases resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected large scale NAT64 sessions from the Citrix ADC appliance.

To clear all large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
flush lsn session -nattype NAT64

show lsn session -nattype NAT64
<!--NeedCopy-->
```

To clear selective large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
flush lsn session -nattype NAT64 [-network6 <ipv6_addr|*>] [-clientname <string>] [-natIP <ip_addr> [-natPort <port>]]

show lsn session -nattype NAT64 [-network6 <ipv6_addr|*>] [-clientname <string>] [-natIP <ip_addr> [-natPort <port>]]
<!--NeedCopy-->
```

Sample configuration:

Clear all large scale NAT64 sessions existing on a Citrix ADC appliance

```
flush lsn session -nattype NAT64
Done
<!--NeedCopy-->
```

Clear all large scale NAT64 sessions related to client entity LSN-NAT64-CLIENT-1

```
flush lsn session -nattype NAT64 -clientname LSN-NAT64-CLIENT-1
Done
<!--NeedCopy-->
```

Clear all large scale NAT64 sessions related to a subscriber network (2001:DB8:5001::/96) of LSN client entity LSN-NAT64-CLIENT-2

```
flush lsn session -nattype NAT64 -network6 2001:DB8:5001::/96 -clientname LSN-NAT64-CLIENT-2
Done
<!--NeedCopy-->
```

IPFIX Logging

The Citrix ADC appliance supports sending information about LSN events in Internet Protocol Flow Information Export (IPFIX) format to the configured set of IPFIX collector(s). The appliance uses the existing AppFlow feature to send LSN events in IPFIX format to the IPFIX collectors.

IPFIX based logging is available for the following NAT64 related events:

- Creation or deletion of an LSN session.
- Creation or deletion of an LSN mapping entry.
- Allocation or de-allocation of port blocks in the context of deterministic NAT.
- Allocation or de-allocation of port blocks in the context of dynamic NAT.
- Whenever subscriber session quota is exceeded.

Points to Consider before you Configure IPFIX logging

Before you start configuring IPSec ALG, consider the following points:

- You must configure the AppFlow feature and IPFIX collector(s) on the Citrix ADC appliance. For instructions, see Configuring the AppFlow feature.

Configuration Steps

Perform the following tasks for logging LSN information in IPFIX format:

- **Enable LSN logging in the AppFlow configuration**. Enable the LSN logging parameter as part of AppFlow configuration.
- **Create an LSN log profile**. An LSN log profile includes the IPFIX parameter that enables or disables the log information in IPFIX format.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the LSN log profile to one or multiple LSN group(s). Events related to the bound LSN group will be logged in IPFIX format.

To enable LSN logging in the AppFlow configuration by using the CLI

At the command prompt, type:

```
set appflow param -lsnLogging ( ENABLED | DISABLED )

show appflow param
<!--NeedCopy-->
```

To create an LSN log profile by using the CLIAt the command prompt, type

At the command prompt, type:

```
set lsn logprofile <logProfileName>  -logipfix ( ENABLED | DISABLED )

show lsn logprofile
<!--NeedCopy-->
```

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

```

```
show lsn group
<!--NeedCopy-->
```

To create an LSN log profile by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Log** tab, and then add a log profile.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI

1. Navigate to **System** > **Large Scale NAT** > **LSN Group,** open the **LSN** group.
2. In **Advanced Settings,** click **+ Log Profile** to bind the created Log profile to the LSN group.

Port Control Protocol for Large Scale NAT64

September 14, 2021

Citrix ADC appliances now support Port Control Protocol (PCP) for large scale NAT (LSN). Many of an ISP's subscriber applications must be accessible from Internet (for example, Internet of Things (IOT) devices, such as an IP camera that provides surveillance over the Internet). One way to meet this requirement is to create static large scale NAT (LSN) maps. But for a very large number of subscribers, creating static LSN NAT maps is not a feasible solution.

Port Control Protocol (PCP) enables a subscriber to request specific LSN NAT mappings for itself and/or for other 3rd party devices. The large scale NAT device creates an LSN map and sends it to the subscriber. The subscriber sends the remote devices on the Internet the NAT IP address:NAT port at which they can connect to the subscriber.

Applications usually send frequent keep-alive messages to the large scale NAT device so that their LSN mappings do not time out. PCP helps reduce the frequency of such keep-alive messages by enabling the applications to learn the timeout settings of the LSN mappings. This helps reduce bandwidth consumption on the ISP's access network and battery consumption on mobile devices.

PCP is a client-server model and runs over the UDP transport protocol. A Citrix ADC appliance implements the PCP server component and is compliant with RFC 6887.

Configuration Steps

Perform the following tasks for configuring PCP:

- **(Optional) Create a PCP profile**. A PCP profile includes settings for PCP related parameters (for example, to listen for mapping and peer PCP requests). A PCP profile can be bound to a

PCP server. A PCP profile bound to a PCP server applies all its settings to the PCP server. A PCP profile can be bound to multiple PCP servers. By default, one PCP profile with default parameters settings is bound to all PCP servers. A PCP profile that you bind to a PCP server overrides the default PCP profile settings for that server. A default PCP profile has the following parameter settings:

- Mapping: Enabled
- Peer: Enabled
- Minimum map life: 120 seconds
- Maximum max life: 86400 seconds
- Announce count: 10
- Third Party: Disabled

- **Create a PCP server and bind a PCP profile to it**. Create a PCP server on the Citrix ADC appliance to listen for PCP related requests and messages from the subscribers. A Subnet IP (SNIP) or (SNIP6) address must be assigned to a PCP server to access it. By default, a PCP server listens on port 5351.
- **Bind the PCP server to an LSN group of an LSN configuration**. Bind the created PCP server to an LSN group of an LSN configuration by setting the PCP Server parameter to specify the created PCP server. The created PCP server can be accessed only by the subscribers of this LSN group.

> **Note**
>
> A PCP server for a large scale NAT configuration does not serve requests from subscribers that are identified from ACL rules.

To create a PCP profile by using the CLI

At the command prompt, type:

```
add pcp profile <name> [-mapping ( ENABLED | DISABLED )] [-peer (
    ENABLED | DISABLED )] [-minMapLife <secs>]  [-maxMapLife <secs>] [-
    announceMultiCount <positive_integer>][-thirdParty ( ENABLED |
    DISABLED )]

show pcp profile <name>
<!--NeedCopy-->
```

To create a PCP server by using the CLI

At the command prompt, type:

```
add pcp server <name> <IPAddress> [-port <portNum|*>] [-pcpProfile <
    string>]
```

```
2
3 show pcp server <name>
4 <!--NeedCopy-->
```

Sample Configuration for NAT64

In the following sample configuration, PCP server PCP-SERVER-1, with PCP settings from PCP-PROFILE-1,is bound to LSN group LSN-NAT64-GROUP-1. PCP-SERVER-1 serves PCP requests from IPv6 subscribers in network 2001:DB8:5001::/96.

Sample configuration:

```
1 add pcp profile PCP-PROFILE-1 -minMapLife 400
2 Done
3 add pcp server PCP-SERVER-1 2001:DB8:6001::90  -pcpProfile PCP-PROFILE
     -1
4 Done
5 add lsn client LSN-NAT64-CLIENT-1
6 Done
7 bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96
8 Done
9 add lsn pool LSN-NAT64-POOL-1
10 Done
11 bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70
12 Done
13 add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
     :300::/96
14 Done
15 add lsn group LSN-NAT64-PROFILE-1 -clientname LSN-NAT64-CLIENT-1  -
     ip6profile LSN-NAT64-PROFILE-1
16 Done
17 bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
18 Done
19 bind lsn group LSN-NAT64-GROUP-1  - pcpServer PCP-NAT64-SERVER-1
20 Done
21 <!--NeedCopy-->
```

LSN64 in a cluster setup

September 14, 2021

Large scale NAT64 configurations are supported on a Citrix ADC cluster setup.

A Citrix ADC cluster is a group of Citrix ADC appliances that are configured and managed as a single system. A Citrix ADC cluster provides scalability and availability. Each Citrix ADC appliance in a cluster setup acts as an independent LSN entity and is managed as a single system.

The LSN configuration in a cluster setup is same as in a standalone appliance except for a specific pool of LSN IP addresses are owned by only one node at a time. In other words, an LSN IP pool entity is configured as a spotted entity in a particular node. All the nodes of a cluster setup can have a specific LSN IP pool entity. To make sure that the packets related to an LSN session are received on the same cluster node that performed the NAT operation, policy based backplane (PBS) steering is configured. PBS steers the received related packets of an LSN session to the same cluster node.

Sample configuration:

```
add lsn client LSN-NAT64-CLIENT-1

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1

Done

bind lsn pool LSN-NAT64-POOL-1 -ownerNode 1  203.0.113.61 -
    203.0.113.70

Done

bind lsn pool LSN-NAT64-POOL-1 -ownerNode 2  203.0.113.101 -
    203.0.113.110

Done

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix 2001:DB8
    :300::/96

Done

add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
    ip6profile LSN-NAT64-PROFILE-1

Done

```

```
29 bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1

Mapping Address and Port using Translation

September 14, 2021

Mapping Address and Port using Translation (MAP-T) is an IPv6 transition solution for ISPs with IPv6 infrastructure to connect their IPv4 subscribers to the IPv4 internet_.MAP-T is built on stateless IPv4 and IPv6 address translation technologies. MAP-T is a mechanism that performs double translation (IPv4 to IPv6 and vice versa) on customer edge (CE) devices and border routers (in ISP core network).

In a MAP-T deployment, the CE device implements a combination of stateful NAPT44 translation and stateless NAT46 translation. The CE device obtains NAT-IP and the port-block to be used for translation through DHCPv6 or any other method.

When an IPv4 packet from a subscriber device arrives at the CE device, the CE device performs NAPT44 and stores the NAPT44 binding information. After NAT44 translation, the packet is subjected to NAT46 translation and then forwarded to the border router (BR) device located in the ISP's core network. The BR device receives the IPv6 packets from the CE device, extracts and validates the NAT-IP and port-block embedded in the IPv6 header, and forwards the IPv4 packet to the IPv4 Internet. When the BR receives the IPv4 packet from the Internet, it translates the IPv4 packet to an IPv6 packet and send the IPv6 packet to the CE device.

MAP-T is stateless on a BR device, so it does not require the BR device to perform NAT on the traffic. Instead, NAT functionality is delegated to the CE devices. This delegation and stateless functionality in BR devices allows the BR deployment to scale in proportion to the volume of traffic.

The Citrix ADC appliance implements the BR functionality of a MAP-T solution as described by RFC 7599.

Configuring MAP-T

Configuring MAP-T on a Citrix ADC appliance consists of the following tasks:

- Add a default mapping rule
- Add a basic mapping rule
- Bind an IPv4 NAT address range of CE devices to a basic mapping rule
- Add a map domain and bind a basic mapping rule and default mapping rule to the domain

To add a default mapping rule by using the CLI

At the command prompt, type:

```
add MapDmr <name> -BRIpv6Prefix ( <ipv6_addr> | <*> )

show MapDmr <name>
<!--NeedCopy-->
```

To add a basic mapping rule by using the CLI

At the command prompt, type:

```
add MapBmr <name> -RuleIpv6Prefix <ipv6_addr> | <*>  [-psidoffset <
    positive_integer>] [-EAbitLength <positive_integer>]  [-psidlength <
    positive_integer>]

show MapBmr <name>
<!--NeedCopy-->
```

To bind IPv4 NAT address range of CE devices to a basic mapping rule by using the CLI

At the command prompt, type:

```
bind MapBmr <name> (-network <ip_addr>  [-netmask <netmask>])

show MapBmr <name>
<!--NeedCopy-->
```

To add a map domain by using the CLI

At the command prompt, type:

```
add MapDomain <name> -MapDmrName <string>

show MapDomain <name>
<!--NeedCopy-->
```

To bind a basic mapping rule to a map domain by using the CLI

At the command prompt, type:

```
bind MapDomain <name> -MapBmrName <string>

show MapDomain <name>
<!--NeedCopy-->
```

Sample configuration

```
add mapdmr DMR-1 -BRIpv6Prefix 2002:db8::/64

Done

add mapbmr BMR-1 -ruleIpv6Prefix 2002:db8:89ab::/48 -eAbitLength 16 -
    psidlength 8 -psidoffset 6

Done

bind mapbmr BMR-1 -network 192.0.1.0 -netmask 255.255.255.0

Done

add MapDomain MAP-DOMAIN-1 -mapdmrname DMR-1

Done

bind MapDomain MAP-DOMAIN-1 -mapbmrname BMR-1
Done
<!--NeedCopy-->
```

Telco subscriber management

September 14, 2021

The number of subscribers in a telco network is increasing at an unprecedented rate, and managing them is becoming a challenge for service providers. Newer, faster, and smarter devices are placing high demand on the network and the subscriber management systems. It is no longer feasible to provide each subscriber the same standard of service, and the need for traffic processing on a per-subscriber basis is imperative.

The Citrix ADC appliance provides the intelligence to profile subscribers based on their information stored in the Policy and Charging Rules Function (PCRF). When a mobile subscriber connects to the Internet, the packet gateway associates an IP address with the subscriber and forwards the data packet to the appliance. The appliance receives the subscriber information dynamically, or you can configure static subscribers. This information enables the appliance to apply its rich traffic management capabilities, such as content switching, integrated caching, rewrite, and responder, on a per-subscriber basis to manage the traffic.

Before you configure the Citrix ADC appliance to manage subscribers, you must allocate memory to the module that stores subscriber sessions. For dynamic subscribers, you must configure an interface through which the appliance receives session information. Static subscribers must be assigned IDs, and you can associate them with policies.

You can also do the following:

- Subscriber policy enforcement and management.
- Configure the appliance to uniquely identify a subscriber by using only the IPv6 prefix instead of the complete IPv6 address.
- Use policies to optimize TCP traffic for both dynamic and static subscribers. These policies associate different TCP profiles with different types of users.
- Manage idle sessions on a Citrix ADC appliance.
- Enable logging to a log server.
- Remove LSN sessions for deleted subscriber sessions.

Allocating memory for the subscriber session store module

Each subscriber session entry consumes 1 KB of memory. Storing 500,000 subscriber sessions at any point in time requires 500 MB of memory. This value must be added to the minimum memory requirement, which is shown as part of the output of the “show extendedmemoryparam” command. In the following example, the output is for a Citrix ADC VPX instance with 3 packet engines and 8 GB memory.

To store 500,000 subscriber sessions on this appliance, the configured memory must be 2058+500 MB (500,000 x 1 KB = 500 MB.)

> **Note**

> The configured memory must be in multiples of 2 MB and must not exceed the maximum memory usage limit. The appliance must be restarted for the changes to take effect.

Example

```
show extendedmemoryparam
       Extended Memory Global Configuration. This memory is utilized by
           LSN and Subscriber Session Store Modules:
        Active Memory Usage: 0 MBytes
        Configured Memory Limit: 0 MBytes
        Minimum Memory Required: 2058 MBytes
        Maximum Memory Usage Limit: 2606 MBytes
    Done
    set extendedmemoryparam -memLimit 2558
    Done
    show extendedmemoryparam
            Extended Memory Global Configuration. This memory is
               utilized by LSN and Subscriber Session Store Modules:

            Active Memory Usage: 2558 MBytes
            Configured Memory Limit: 2558 MBytes
            Minimum Memory Required: 2058 MBytes
            Maximum Memory Usage Limit: 2606 MBytes
    Done
<!--NeedCopy-->
```

Configure an interface for dynamic subscribers

The Citrix ADC appliance dynamically receives the subscriber information through any of the following types of interface:

- Gx Interface
- RADIUS Interface
- RADIUS and Gx Interface

> **Note**
>
> - Starting with NetScaler release 12.0 build 57.19, Gx interface is supported for a cluster deployment. For more information see Gx interface in a cluster topology.
> - In an HA setup, the subscriber sessions are continually synchronized on the secondary node. In the event of a failover, the subscriber information is still available on the secondary node.

Gx interface

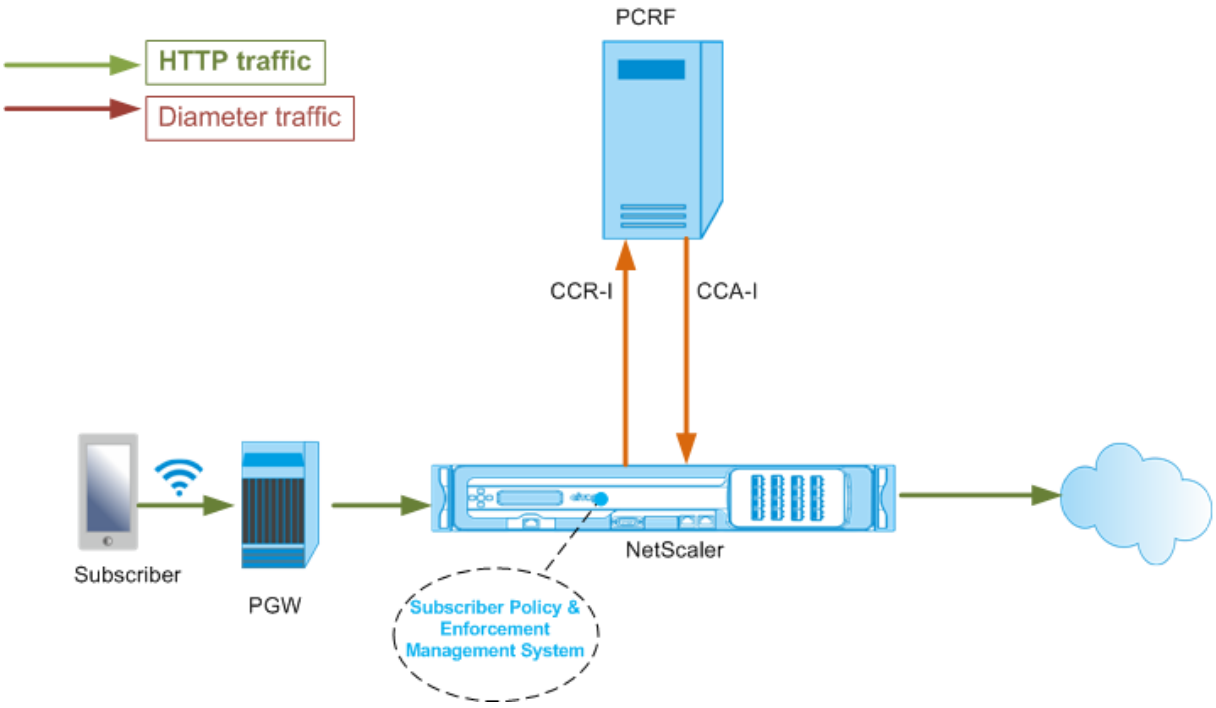
A Gx interface (as specified in 3GPP 29.212) is a standard interface based on the Diameter protocol that allows exchange of policy control and charging rules between a PCRF and a Policy and Charging Enforcement Function (PCEF) entity in a Telco network.

When an IP-CAN session is established, the packet gateway forwards the subscriber ID, such as the MSISDN, and Framed-IP address information about the subscriber to the PCRF as a Diameter message. When the data packet arrives at the appliance from packet gateway (PGW), the appliance uses the subscriber IP address to query the PCRF to get the subscriber information. This is also known as secondary PCEF functionality.

The Policy and Charging Control (PCC) rules received by the appliance over the Gx interface are stored on the appliance during the subscriber session, that is, until the PCRF sends a Re-Auth-Request (RAR) message with a Session-Release-Cause AVP or the subscriber session is terminated from the CLI or the configuration utility. If there are any updates to an existing subscriber, the PCRF sends the updates in an RAR message. A subscriber session is initiated when a subscriber logs on to the network, and terminated when the subscriber logs off.

> **Note**: If the PCRF server is down, the Citrix ADC appliance creates negative sessions for the pending or incoming Gx subscriber requests. When the PCRF server is back up again, the Citrix ADC appliance prevents a storm of requests by waiting for the negative sessions to expire before performing the specific subscriber requests.

The following illustration shows the high-level traffic flow. It assumes that the data plane traffic is HTTP. The appliance sends a Credit Control Request (CCR) over a Gx interface to the PCRF server and, in the credit control answer (CCA), receives the PCC rules and, optionally, other information, such as the Radio Access Technology (RAT) type, that applies to the particular subscriber. PCC rules include one or more policy (rule) names and other parameters. The appliance uses this information to retrieve the predefined rules stored on the appliance, and to direct the flow of traffic. It also stores this information in the subscriber policy and enforcement management system during the subscriber session. After a subscriber session is terminated, the appliance discards all the information about the subscriber.



The following example shows the commands for configuring a Gx interface. The commands are in boldface.

To set up a Gx interface, perform the following tasks

Add a DIAMETER service for each Gx interface. For example:

```
add service pcrf-svc1 203.0.113.1 DIAMETER 3868

add service pcrf-svc2 203.0.113.2 DIAMETER 3868
<!--NeedCopy-->
```

Add a non-addressable DIAMETER load balancing virtual server and bind the services created in step 1 to this virtual server. For more than one service, specify a persistenceType and the persistAVPno so that specific sessions are handled by the same PCRF server. For example:

```
add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER -
    persistAVPno 263

bind lb vserver vdiam pcrf-svc1

bind lb vserver vdiam pcrf-svc2
<!--NeedCopy-->
```

Configure Citrix ADC diameter identity and realm. Identity and realm are used as Origin-Host and Origin-Realm AVPs in diameter messages sent by the Gx client. For example:

```
set ns diameter  - identity netscaler.com  - realm com
<!--NeedCopy-->
```

Configure the Gx interface to use the virtual server created in step 2 as the PCRF virtual server. Specify the PCRF realm to use as Destination-Realm AVP in diameters messages sent by the Gx client. For example:

```
set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf.com
<!--NeedCopy-->
```

Set the subscriber interface type to GxOnly. For example:

```
set subscriber param -interfaceType GxOnly
<!--NeedCopy-->
```

To see the Gx interface configuration and status, type:

```
show subscriber gxinterface
<!--NeedCopy-->
```

Example

```
show subscriber gxinterface
    Gx Interface parameters:
        PCRF Vserver: vdiam (DOWN)
        Gx Client Identity...:  netscaler1.com
        Gx Client Realm ..........:  com
        PCRF Realm: epc.mnc030.mcc234.3gppnetwork.org
        Hold Packets On Subscriber Absence: YES
        CCR Request Timeout: 4 Seconds
        CCR Request Retry Attempts: 1
        Gx HealthCheck enabled: NO
        Gx HealthCheck TTL : 30 Seconds
        CER Request Timeout: 10 Seconds
        RevalidationTimeout: 30 Seconds
        NegativeTTL: 60 Seconds
        NegativeTTL Limited Success: NO
        Purge SDB on Gx Failure: YES
        ServicePath AVP code: 262099    ServicePath AVP VendorID: 3845
        PCRF Connection State: PCRF is not ready
    Done

<!--NeedCopy-->
```

ARGUMENTS

vServer

Name of the load balancing or content switching virtual server to which the Gx connections are established. The service type of the virtual server must be DIAMETER or SSL_DIAMETER. This parameter is mutually exclusive with the service parameter. Therefore, you cannot set both service and the virtual server in the Gx interface.

Service

Name of DIAMETER or SSL_DIAMETER service corresponding to PCRF to which the Gx connection is established. This parameter is mutually exclusive with the vserver parameter. Therefore, you cannot set both service and the virtual server in the Gx Interface.

pcrfRealm

The realm of PCRF to which the message is to be routed. This is the realm used in Destination-Realm AVP by Citrix ADC Gx client (as a Diameter node).

holdOnSubscriberAbsence

Set to Yes to hold packets until the subscriber session information is fetched from the PCRF server. If set to No, the default subscriber profile is applied until the subscriber session information is fetched from the PCRF server. If a default subscriber profile is not configured, an UNDEF is raised for expressions that use subscriber attributes.

requestTimeout

Time, in seconds, within which the Gx CCR request must complete. If the request does not complete within this time, the request is retransmitted for the number of times specified in the requestRetryAttempts parameter. If request is not complete even after retransmitting, then the default subscriber profile is applied to this subscriber. If a default subscriber profile is not configured, an UNDEF is raised for expressions that use subscriber attributes. Zero disables the timeout. Default value: 10

requestRetryAttempts

Specify the number of times a request must be retransmitted if the request does not complete within the value specified in the requestTimeout parameter. Default value: 3.

healthCheck

Set to Yes to enable inline health check of Gx peer. When enabled, Citrix ADC sends DWR packets to the PCRF server. When the Gx session is idle, the healthCheck timer expires and DWR packets are initiated to check if the PCRF server is active. Default value: No.
Note: This parameter is supported in Citrix ADC 12.1 build 51.xx and later.

healthCheckTTL

Time in seconds defined for watchdog supervision. After the health check TTL time expires, DWR is sent to check the status of the PCRF server. Any CCR, CCA, RAR, or RAA message resets the timer.
Minimum value: 6 seconds. Default value: 30 seconds.
Note: This parameter is supported in Citrix ADC 12.1 build 51.xx and later.

cerRequestTimeout

Time in seconds defined for retransmission of the capabilities exchange request. Citrix ADC initiates a new CER message if it does not receive a CEA from the PCRF within this configured time.
If no response is received from the PCRF server, the appliance tries to send the CER message 5 times. If there is no response even after 5 CER messages, the appliance closes the TCP connection and reports a failure. If the timeout value is set to 0, the application health check feature is disabled.
Minimum value: 0 seconds. Default value: 0 seconds.
Note: This parameter is supported in Citrix ADC 12.1 build 51.xx and later.

revalidationTimeout

Time, in seconds, after which the Gx CCR-U request is sent after any PCRF activity on a session. Any RAR or CCA message resets the timer. Zero value disables the idle timeout.

negativeTTL

Time, in seconds, after which the Gx CCR-I request is resent for sessions that have not been resolved by PCRF because the server is down or there is no response or a failed response is received. Instead of polling the PCRF server constantly, a negative-TTL makes the appliance hold on to an unresolved session. For negative sessions, the appliance inherits the attributes from the default subscriber profile, if one is configured and from the RADIUS accounting message, if one is received. Zero value disables the negative sessions. The appliance does not install negative sessions even if a subscriber session could not be fetched. Default value: 600

negativeTTLLimitedSuccess

Set to Yes to create negative session for partial success response code (2002). If set to No, regular session is created. Default value: No.

This parameter is supported in Citrix ADC 12.1 build 49.xx and later.

purgeSDBonGxFailure

Set to Yes to flush subscriber database when the Gx interface fails. Gx interface failure includes both DWR monitoring (if enabled) and network healthCheck (if enabled). When set to Yes, all subscriber sessions are cleared.
Default value: No.
Note: This parameter is supported in Citrix ADC 12.1 build 51.xx and later.

servicePathAVP

The AVP code in which PCRF sends the service path applicable to a subscriber.

servicePathVendorid

The vendor id of the AVP in which PCRF sends the service path applicable to a subscriber.

To configure Gx interface by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In Interface Type, select **GxOnly**.
4. Specify the values for the all required parameters.
5. Click **OK**.

Detect transport failures over established Gx connections

Note: This feature is supported in Citrix ADC 12.1 build 51.xx and later.

A Citrix ADC appliance can be configured to detect transport failures over established Gx connections by using device watchdog request (DWR) and device watchdog answer (DWA) messages.

After a Gx session is established, a predefined timer is triggered to detect if a session is idle. A DWR message is sent after the idle time timer expires. The idle time timer is reset each time the Citrix ADC appliance receives a message over an established Gx session. The peer's availability is confirmed based on the DWA message after a DWR message is sent.

- If the DWA is received, a peer's availability is confirmed and the watchdog timer is reset.

- If the DWA is not received and the watchdog timer expires twice consecutively, the session is considered as down and peer unavailable. The appliance closes the session and tries to establish a new session with the Gx peer.

When the watchdog timer expires twice without a response, the Citrix ADC appliance considers the Gx connection as faulty and initiates a connection closure. Once the connection is closed, no other watchdog request is sent towards the Gx peer. Citrix ADC appliance uses the next available Gx session for any PCRF requests.

To detect transport failures over established Gx connections by using the CLI

At the command prompt, type:

```
set subscriber gxInterface [-vServer <string>] [-service <string>] [-
    healthCheck ( YES | NO )] [-healthCheckTTL<positive_integer>][-
    cerRequestTimeout <positive_integer>] [-purgeSDBonGxFailure ( YES |
    NO )]
<!--NeedCopy-->
```

Example:

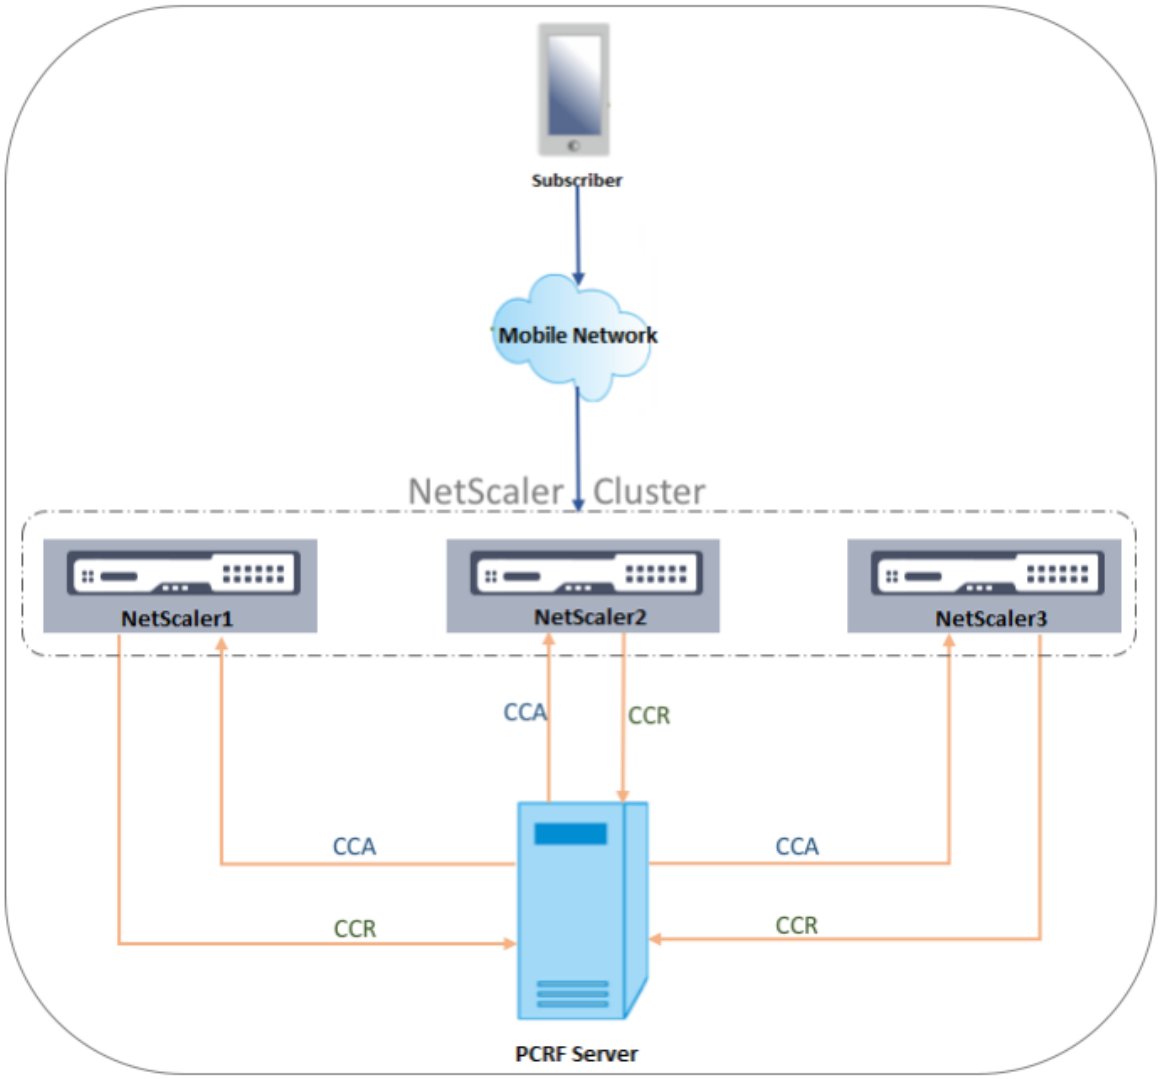
```
set subscriber gxInterface set subscriber gxInterface -vServer vdiam -
    healthCheck YES -healthCheckTTL 31 -cerRequestTimeout 15
    purgeSDBonGxFailure  YES
<!--NeedCopy-->
```

To detect transport failures over established Gx connections by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In **Interface Type**, select **GxOnly**.
4. Specify the values for all required parameters.
5. Select **Health Check** and specify values for **Health Check TTL** and **CER Request Timeout**.
6. Click **OK**.

Gx interface in a cluster topology

The Citrix ADC appliance supports Gx interface in a cluster topology.



The Citrix ADC nodes in the cluster communicate with an external PCRF server through the Gx interface. When a node receives client traffic, the appliance performs the following:

- Sends a CCR-I request to the PCRF server to fetch subscriber information.
- The PCRF server responds with a CCR-A.
- The Citrix ADC node then stores the received subscriber information in its subscriber store and applies the rules to the client traffic.

Each node maintains an independent subscriber store and subscriber sessions are not synchronized to other nodes.

As per the Diameter Base Protocol RFC 6733, each peer must be configured with a unique diameter identity to communicate with other peers over the diameter protocol. Hence, in a cluster deployment, configuration of diameter identity is spotted. The diameter parameters (identity, realm, server close propagation) for each node can be configured individually by using the GUI or the CLI.

When a node is added to a cluster, it assumes the default diameter parameters (identity=netscaler.com, realm=com, serverClosePropogation=NO). After the nodes are added, the diameter parameters for each node must be configured.

To configure the diameter parameters by using the GUI

1. Navigate to **System** > **Settings**.
2. In the details pane, click **Change Diameter Parameters**.
3. In the Diameter Parameters page, select the Citrix ADC node for which you want to configure the diameter parameters and then click **Configure**.
4. In the Configure Diameter Parameters page, configure the diameter Identity, diameter Realm, and server Close Propagation for the selected node.
5. Click **OK**.

To configure the diameter parameters by using the CLI

At the command prompt, type:

```
set ns diameter [-identity <string>] [-ownerNode <positive_integer>]
<!--NeedCopy-->
```

ARGUMENTS

Identity

Diameter Identity is used to identify a Diameter node uniquely. Before setting up diameter configuration, the Citrix ADC appliance (as a Diameter node) must be assigned a unique diameter identity.

For example, set ns diameter -identity netscaler.com -ownerNode 1. So, whenever Citrix ADC system needs to use identity in diameter messages, it uses ‘netscaler.com’ as Origin-Host AVP as defined in RFC3588.

Maximum Length: 255

OwnerNode

OwnerNode represents the ID of the cluster node for which the diameter ID is set. OwnerNode can be configured only through CLIP.

Minimum value: 0

Maximum value: 31

Example:

set ns diameter -identity netscaler1.com -ownerNode 1

Note:

The OwnerNode option is also added to the show ns diameter command.

Example:

```
show diameter -ownerNode <0-31>
<!--NeedCopy-->
```

When the show ns diameter command is executed, it displays the diameter parameters for a given node.

To configure a Gx interface for cluster deployment

To set up a Gx interface, perform the following tasks:

Add a DIAMETER service for each Gx interface.

Example:

```
add service pcrf-svc1 203.0.113.1 DIAMETER 3868
add service pcrf-svc2 203.0.113.2 DIAMETER 3868
<!--NeedCopy-->
```

Add a DIAMETER load balancing virtual server and bind the services created in step 1 to this virtual server.

Example:

```
add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER -
    persistAVPno 263

bind lb vserver vdiam pcrf-svc1

bind lb vserver vdiam pcrf-svc2
<!--NeedCopy-->
```

Configure Citrix ADC diameter identity and realm on all the cluster nodes. Identity and realm are used as Origin-Host and Origin-Realm AVPs in diameter messages sent by the Gx client.

Example:

```
set ns diameter -identity node0.netscaler.com -realm netscaler.com -
    ownerNode 0
```

```
2
3 set ns diameter -identity node1.netscaler.com -realm netscaler.com -
     ownerNode 1
4 <!--NeedCopy-->
```

Configure the Gx interface to use the virtual server created in step 2 as the PCRF virtual server and set the PCRF realm as well.

Example:

```
1 set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf.com
2
3 Set the subscriber interface type to GxOnly.
4 <!--NeedCopy-->
```

Example:

```
1 set subscriber param -interfaceType GxOnly
2 <!--NeedCopy-->
```

To see the Gx interface configuration and status, type:

```
1 show subscriber gxinterface
2 <!--NeedCopy-->
```

RADIUS interface

With a RADIUS interface, the packet gateway forwards the subscriber information in a RADIUS Accounting Start message to the appliance through the RADIUS interface when an IP-CAN session is established. A service of type RADIUSListener processes RADIUS Accounting messages. Add a shared secret for the RADIUS client. If a shared secret is not configured, the RADIUS message is silently dropped. The following example shows the commands for configuring a RADIUS interface. The commands are in boldface.

To set up a RADIUS interface, perform the following tasks:

Create a RADIUS listener service at the SNIP address where the RADIUS messages are received. For example:

```
1 add service srad1 192.0.0.206 RADIUSLISTENER 1813
2 <!--NeedCopy-->
```

Configure the subscriber RADIUS interface to use this service. For example:

```
set subscriber radiusInterface -listeningService srad1
<!--NeedCopy-->
```

Set the subscriber interface type to RadiusOnly. For example:

```
set subscriber param -interfaceType RadiusOnly
<!--NeedCopy-->
```

Add a RADIUS client specifying a subnet and shared secret. For example:

```
add radius client 192.0.2.0/24 -radkey client123
<!--NeedCopy-->
```

A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients. To see the RADIUS interface configuration and status, type:

```
show subscriber radiusInterface
<!--NeedCopy-->
```

RADIUS Interface parameters:

Radius Listener Service: srad1(UP)

Done

Example:

```
add service pcrf-svc1 203.0.113.1 DIAMETER 3868

add service pcrf-svc2 203.0.113.2 DIAMETER 3868
<!--NeedCopy-->
```

ARGUMENTS

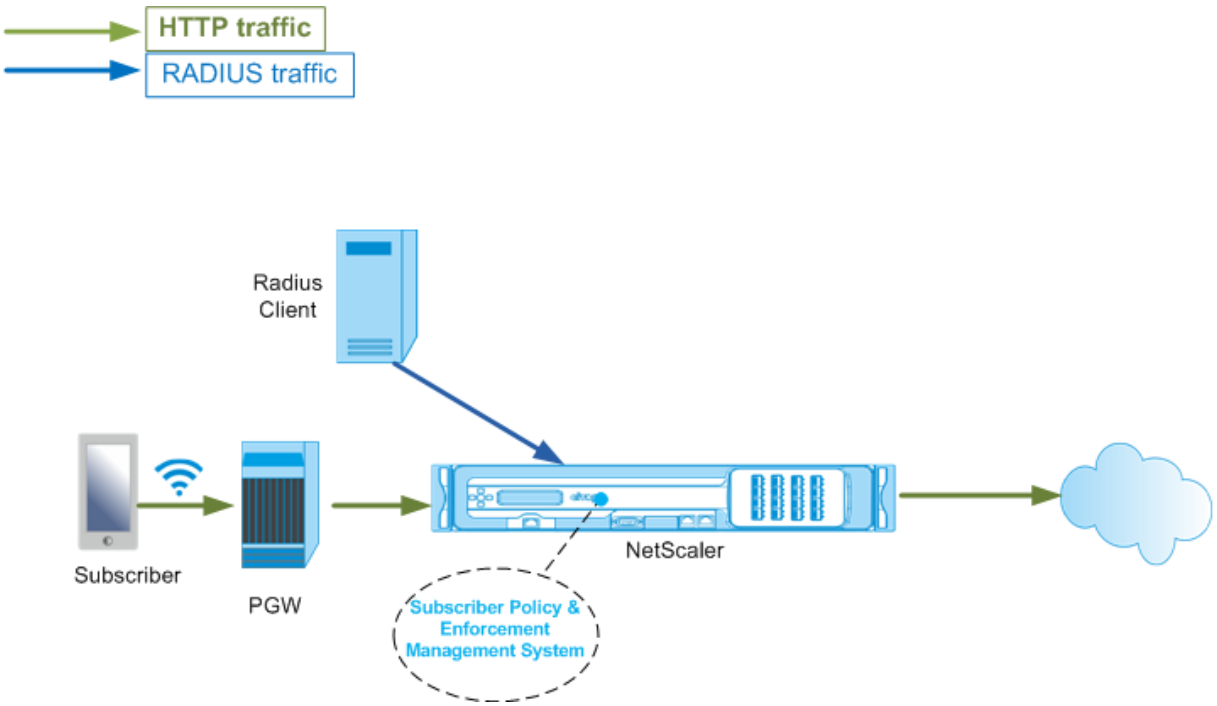
ListeningService

Name of the RADIUS listening service that processes the RADIUS accounting requests.

svrState

The state of the RADIUS listening service.

The following illustration shows the high-level traffic flow.



To configure RadiusOnly interface by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In Interface Type, select **RadiusOnly**.
4. Specify the values for the all required parameters.
5. Click **OK**.

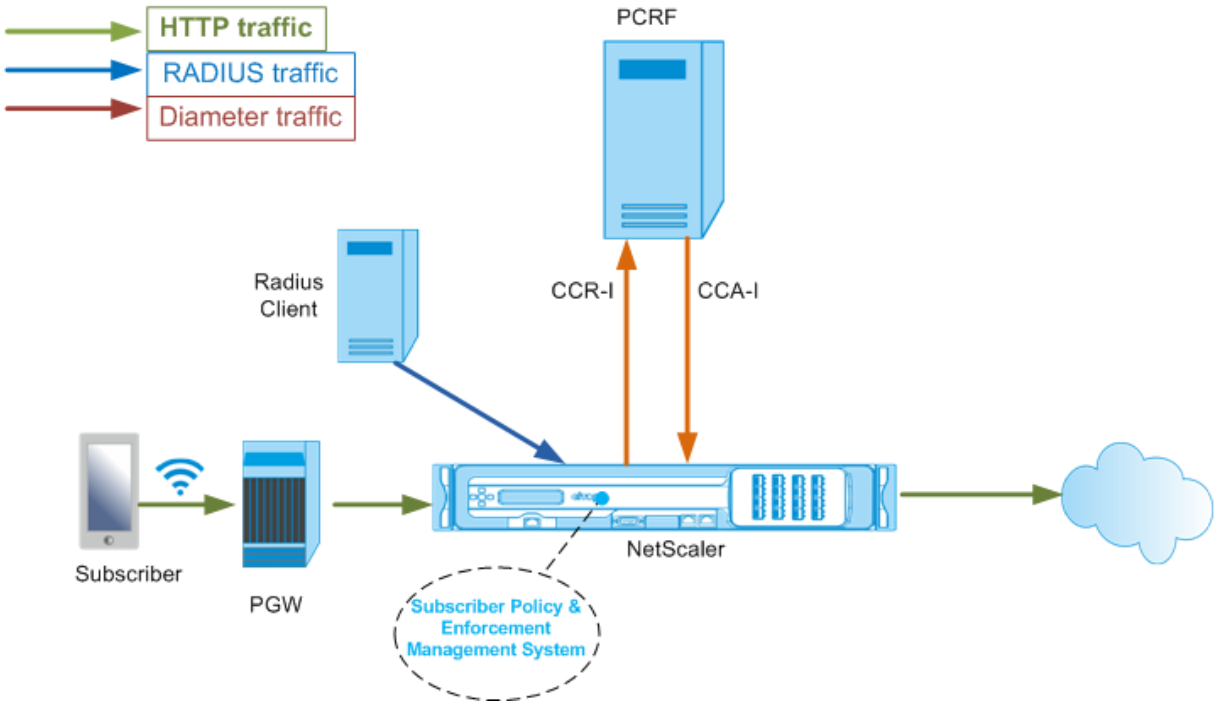
RADIUS and Gx interface

With a RADIUS and Gx interface, when an IP-CAN session is established, the packet gateway forwards the subscriber ID, such as the MSISDN, and Framed-IP address information about the subscriber to the appliance through the RADIUS interface. The appliance uses this subscriber ID to query the PCRF on the Gx interface to get the subscriber information. This is known as primary PCEF functionality. The following example shows the commands for configuring a RADIUS and Gx interface.

```
set subscriber param -interfaceType RadiusandGx
add service pcrf-svc 203.0.113.1 DIAMETER 3868
add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER -
    persistAVPno 263
bind lb vserver vdiam pcrf-svc
set subscriber gxInterface -vServer vdiam -pcrfRealm testrealm1.net -
    holdOnSubscriberAbsence YES -revalidationTimeout 60 -negativeTTL 120
```

```
6 add service srad1 192.0.0.206 RADIUSLISTENER 1813    set subscriber
     radiusInterface -listeningService srad1
7 <!--NeedCopy-->
```

The following illustration shows the high-level traffic flow.



To configure RadiusAndGx interface by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In Interface Type, select **RadiusAndGx**.
4. Specify the values for the all required parameters.
5. Click **OK**.

Configure static subscribers

You can configure the subscribers manually on the Citrix ADC appliance by using the command line or the configuration utility. You create static subscribers by assigning a unique subscriber ID and optionally associating a policy with each subscriber. The following examples show the commands for configuring a static subscriber.

In the following examples, **subscriptionIdvalue** specifies the international telephone number, and **subscriptionIdType** (E164 in this example) specifies the general format for international telephone numbers.

```
1     add subscriber profile 203.0.113.6 -subscriberRules policy1 policy2
          -subscriptionIdType E164 -subscriptionIdvalue 98767543211
2     add subscriber profile 2002::a66:e8d3/64 -subscriberRules policy1
         policy3 -subscriptionIdtype E164 -subscriptionIdvalue
         98767543212
3     add subscriber profile 203.0.24.2 10 -subscriberRules policy2
         policy3 -subscriptionIdtype E164 -subscriptionIdvalue
         98767543213
4 <!--NeedCopy-->
```

To view the configured subscriber profiles, type:

> show subscriber profile

```
1     > show subscriber profile
2
3     1)  Subscriber IP: 203.0.24.2 VLAN:10
4         Profile Attributes:
5                 Active Rules: policy2, policy3
6                 Subscriber Id Type: E164
7                 Subscriber Id Value: 98767543213
8     2)  Subscriber IP: 2002::/64
9         Profile Attributes:
10                Active Rules: policy1, policy3
11                Subscriber Id Type: E164
12                Subscriber Id Value: 98767543212
13    3)  Subscriber IP: 203.0.113.6
14        Profile Attributes:
15                Active Rules: policy1, policy2
16                Subscriber Id Type: E164

18
19     Done
20 <!--NeedCopy-->
```

Default subscriber profile

A default subscriber profile is used if the subscriber IP address is not found in the subscriber session store on the appliance. In the following example, a default subscriber profile is added with the subscriber rule policy1.

```
1     > add subscriber profile * -subscriberRules policy1
2 <!--NeedCopy-->
```

View and clear subscriber sessions

Use the following command to display all the static and dynamic subscriber sessions.

> show subscriber sessions

```
    > show subscriber sessions
    1)  Subscriber IP: 2002::/64
        Session Attributes:
                Active Rules: policy1, policy3
                Subscriber Id Type: E164
                Subscriber Id Value: 98767543212
    2)  Subscriber IP: *
        Session Attributes:
                Active Rules: policy1
    3)  Subscriber IP: 203.0.24.2 VLAN:10
        Session Attributes:
                Active Rules: policy2, policy3
                Subscriber Id Type: E164
                Subscriber Id Value: 98767543213
    4)  Subscriber IP: 203.0.113.6
        Session Attributes:
                Active Rules: policy1, policy2
                Subscriber Id Type: E164
                Subscriber Id Value: 98767543211
    5)  Subscriber IP: 192.168.0.11
        Session Attributes:
                Idle TTL remaining: 361 Seconds
                Active Rules: policy1
                Subscriber Id Type: E164
                Subscriber Id Value: 1234567811
                Service Path: policy1
                AVP(44): 34 44 32 42 42 38 41 43  2D 30 30 30 30 30 30
                   31 31
                AVP(257): 00 01 C0 A8 0A 02
                PCRF-Host: host.pcrf.com
                AVP(280): 74 65 73 74 2E 63 6F 6D

    Done
<!--NeedCopy-->
```

Use the following command to clear a single session or the complete session store. If you do not specify an IP address, the complete subscriber session store is cleared.

```
clear subscriber sessions <ip>
<!--NeedCopy-->
```

Subscriber policy enforcement & management system

The Citrix ADC appliance uses the subscriber's IP address as the key to the subscriber policy enforcement and management system.

You can add subscriber expressions to read the subscriber information available in the Subscriber Policy Enforcement & Management System. These expressions can be used with policy rules and actions that are configured for Citrix ADC features, such as integrated caching, rewrite, responder, and content switching.

The following commands are an example of adding a subscriber-based responder action and policy. The policy evaluates to true if the subscriber rule value is"pol1."

```
1     add responder action error_msg respondwith '"HTTP/1.1 403 OKrnrn" +
          " You are  not authorized to access Internet"'
2     add responder policy no_internet_access "SUBSCRIBER.RULE_ACTIVE("
         pol1")" error_msg
3 <!--NeedCopy-->
```

The following example shows the commands to add a subscriber-based rewrite action and policy. The action inserts an HTTP header "X-Nokia-MSISDN" by using the value of AVP(45) in the subscriber session.

```
1     > add rewrite action AddHDR-act insert_http_header X-Nokia-MSISDN "
         SUBSCRIBER.AVP(45).VALUE"
2     > add rewrite policy AddHDR-pol "HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.
         URL).EQUALS_ANY("patset-test")" AddHDR-act
3 <!--NeedCopy-->
```

In the following example, two policies are configured on the appliance. When the appliance checks the subscriber information and the subscriber rule is cache_enable, it performs caching. If the subscriber rule is cache_disable, the appliance does not perform caching.

```
1     > add cache policy nocachepol -rule "SUBSCRIBER.RULE_ACTIVE("
         cache_disable")" - action NOCACHE
2     > add cache policy cachepol -rule "SUBSCRIBER.RULE_ACTIVE("
         cache_enable")" - action CACHE -storeInGroup cg1
3 <!--NeedCopy-->
```

For a complete list of expressions starting with "SUBSCRIBER." see the Policy Configuration Guide.

> **Important**
>
> Citrix ADC software release 12.1 supports IPANDVLAN key lookup method when the subscriber interface is set to GxOnly. For details, see IP address and VLAN ID key lookup method.

IPv6 prefix based subscriber sessions

A telco user is identified by the IPv6 prefix rather than the complete IPv6 address. The Citrix ADC appliance now uses the prefix instead of the complete IPv6 address (/128) to identify a subscriber in the database (subscriber store). For communicating with the PCRF server (for example, in a CCR-I message), the appliance now uses the framed-IPv6-Prefix AVP instead of the complete IPv6 address. The default prefix length is /64, but you can configure the appliance to use a different value.

To configure the IPv6 prefix by using the command line

```
set subscriber param [-ipv6PrefixLookupList <positive_integer> ...]
```

The first example command below sets a single prefix and the second example command sets multiple prefixes.

```
1     set subscriber param -ipv6PrefixLookupList 64
2     set subscriber param -ipv6PrefixLookupList 64 72 96
3 <!--NeedCopy-->
```

To configure the IPv6 prefix by using the configuration utility

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. In the details pane, under **Settings**, click **Configure Subscriber Parameters** and in **IPv6 Prefix Lookup List**, specify one or more prefixes.

IP address and VLAN ID key lookup method

The Citrix ADC appliance uses the subscriber's IP address as the key lookup method to the subscriber policy enforcement and management system. This method is not effective if the IP addresses are overlapping. In such cases, you can use the VLAN ID as an additional subscriber lookup type. IPANDVLAN key lookup method is supported only when the subscriber interface is set to GxOnly. When IPANDVLAN is configured as the lookup method, the Citrix ADC appliance performs the following:

- Includes the originating VLAN ID in the Gx query for IPv4 subscribers.
- Includes the Gx VLAN AVP in all Gx responses. However, if there is a VLAN ID mismatch, the appliance ignores the responses.

For example, if the appliance sends a CCR-I with GxSessionId-a:IPv4-b:VLAN-c and the response contains GxSessionId-a:IPv4-b:VLAN-d, the response is dropped and a default subscriber entry is created.

> **Note**
>
> - Interface type RadiusAndGx and RadiusOnly cannot be configured together with key type

IPANDVLAN.

- If the traffic is from an IPv6 address, the Citrix ADC appliance uses the IP lookup method.

To configure IP or IPANDVLAN as the key lookup method by using the CLI

At the command prompt, type:

```
set subscriber param [-keytype ( IP | IPANDVLAN )] [-interfaceType <
   interfaceType>]
<!--NeedCopy-->
```

Example:

```
set subscriber param -keytype IPANDVLAN -interfaceType GxOnly

set subscriber param -keytype IP -interfaceType GxOnly
<!--NeedCopy-->
```

Note

Changing the keytype parameter from IP to IPANDVLAN and conversely clears all subscriber data.

VLAN parameter

The VLAN parameter is also added for the following commands.

```
add subscriber profile <ip>@ [-vlan]

set subscriber profile <ip>@ [-vlan] [-subscriptionIdType  <
   subscriptionIdType>]

show subscriber profile [<ip>@] [-vlan]

rm subscriber profile <ip>@ [-vlan <positive_integer>]
<!--NeedCopy-->
```

Arguments

ip

Represents the subscriber IP address. This is a mandatory argument and cannot be changed after the subscriber profile is added.

vlan

Represents the VLAN number on which the subscriber is located. The VLAN number cannot be changed after the subscriber profile is added.

Minimum value: 1

Maximum value: 4096

```
add subscriber profile 192.0.2.23 10

set subscriber profile 192.0.2.23 10 -subscriptionIdtype E164

show subscriber profile 192.0.2.23 10

rm subscriber profile 192.0.2.23 10

<!--NeedCopy-->
```

To configure IP or IPANDVLAN as the key lookup method by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters.**
2. Click **Configure Subscriber Parameters.**
3. In **Key Type**, select **IP** or **IPANDVLAN** as per your requirement.
4. Complete the configuration and click **OK**.

Idle session management of subscriber sessions in a Telco network

Subscriber session cleanup on a Citrix ADC appliance is based on control plane events, such as a RADIUS Accounting Stop message, a Diameter RAR (session release) message, or a “clear subscriber session” command. In some deployments, the messages from a RADIUS client or a PCRF server might not reach the appliance. Also, during heavy traffic, the messages might be lost. A subscriber session that is idle for a long time continues to consume memory and IP resources on the Citrix ADC appliance. The idle session management feature provides configurable timers to identify idle sessions, and cleans up these sessions based on the specified action.

A session is considered idle if no traffic from this subscriber is received on the data plane or the control plane. You can specify an update, terminate (inform PCRF and then delete the session), or delete (without informing PCRF) action. The action is taken only after the session is idle for the time specified in the idle timeout parameter.

To configure the idle session timeout and the associated action by using the command line

```
set subscriber param [-idleTTL <positive_integer>] [-idleAction <
    idleAction>]
<!--NeedCopy-->
```

Examples:

```
set subscriber param -idleTTL 3600 -idleAction ccrTerminate

set subscriber param -idleTTL 3600 -idleAction ccrUpdate

set subscriber param -idleTTL 3600 -idleAction delete
<!--NeedCopy-->
```

To disable the idle session timeout, set the idle timeout to zero.

set subscriber param –idleTTL 0

To configure the idle session timeout and the associated action by using the configuration utility

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. In the details pane, under **Settings**, click **Configure Subscriber Parameters** and specify an **Idle Time** and **Idle Action**.

Subscriber session event logging

If you enable subscriber logging, you can track the RADIUS and Gx control plane messages specific to a subscriber, and use the historical data to analyze subscriber activities. Some of the key attributes are MSISDN and time stamp. The following attributes are also logged:

- Session Event (Install, Update, Delete, Error)
- Gx Message Type (CCR-I, CCR-U, CCR-T, RAR)
- Radius Message Type (Start, Stop)
- Subscriber IP
- SubscriberID Type (MSISDN(E164), IMSI)
- SubscriberID value

By using these logs, you can track users by IP address and, if available, MSISDN.

You can enable subscriber session logging to a local or remote syslog or nslog server. The following example shows how to enable subscriber logging to a remote syslog server.

```
1      > add syslogAction sysact1 192.0.2.0 -loglevel EMERGENCY ALERT
          CRITICAL ERROR WARNING NOTICE INFORMATIONAL -subscriberlog
          enabled
2  <!--NeedCopy-->
```

From these logs, you can learn about any activity related to a user, such as the time when a session was updated, deleted, or created (installed). Additionally, error messages are also logged.

Examples:

1. The following log entries are examples of RADIUSandGx session creation, session update, and session deletion.

   > 09/30/2015:16:29:18 GMT Informational 0-PPE-0 : default SUBSCRIBER SESSION_EVENT 147 0 : Session Install, GX MsgType: CCR-I, RADIUS MsgType: Start, IP: 100.10.1.1, ID: E164 - 30000000001
   >
   > 09/30/2015:16:30:18 GMT Informational 0-PPE-0 : default SUBSCRIBER SESSION_EVENT 148 0 : Session Update, GX MsgType: CCR-U, IP: 100.10.1.1, ID: E164 - 30000000001
   >
   > 09/30/2015:17:27:56 GMT Informational 0-PPE-0 : default SUBSCRIBER SESSION_EVENT 185 0 : Session Delete, GX MsgType: CCR-T, RADIUS MsgType: Stop, IP: 100.10.1.1, ID: E164 - 30000000001

2. The following log entries are examples of failure messages, such as when a subscriber is not found on the PCRF server and when the appliance cannot connect to the PCRF server.

   > 09/30/2015:16:44:15 GMT Error 0-PPE-0 : default SUBSCRIBER SESSION_FAILURE 169 0 : Failure Reason: PCRF failure response, GX MsgType: CCR-I, IP: 100.10.1.1
   >
   > Sep 30 13:03:01 09/30/2015:16:49:08 GMT 0-PPE-0 : default SUBSCRIBER SESSION_FAILURE 176 0 : Failure Reason: Unable to connect to PCRF, GX MsgType: CCR-I, RADIUS MsgType: Start, IP: 100.10.1.1, ID: E164 - 30000000001#000#000#000#000#000#000#000#000#000#000#000#000#00

Subscriber aware LSN session termination

In earlier releases, if a subscriber session is deleted when a RADIUS Accounting STOP or a PCRF-RAR message is received, or as a result of any other event, such as TTL expiry or flush, the corresponding LSN sessions of the subscriber are removed only after the configured LSN timeout period. LSN sessions that are kept open until this timeout expires continue to consume resources on the appliance.

From release 11.1, a new parameter (subscrSessionRemoval) is added. If this parameter is enabled, and the subscriber information is deleted from the subscriber database, LSN sessions corresponding to that subscriber are also removed. If this parameter is disabled, the subscriber sessions are timed out as specified by the LSN timeout settings.

To configure subscriber aware LSN session termination by using the CLI

At the command prompt, type:

```
set lsn parameter -subscrSessionRemoval (          DISABLED )
ENABLED
```

```
1      > set lsn parameter -subscrSessionRemoval ENABLED
2      Done
3      > sh lsn parameter
4                   LSN Global Configuration:
5
6                   Active Memory Usage: 0 MBytes
7                   Configured Memory Limit: 0 MBytes
8                   Maximum Memory Usage Limit: 912 MBytes
9                   Session synchronization: ENABLED
10                  Subscriber aware session removal: ENABLED
11 <!--NeedCopy-->
```

To configure subscriber aware LSN session termination by using the GUI

1. Navigate to **System** > **Large Scale NAT**.
2. In **Getting started**, click **Set LSN Parameter**.
3. Set the **Subscriber Aware Session Removal parameter**.

Troubleshooting

If your deployment is not working as expected, use the following commands to troubleshoot:

- show subscriber gxinterface
  This command's output can include the following error messages (shown here with suggested responses):
  - Gx Interface Not Configured-Use set subscriber param command to configure the correct interface type.
  - PCRF not configured-Configure a Diameter vServer or Service on GxInterface-Use the set subscriber gx interface command to assign a Diameter virtual server or service to this interface.
  - PCRF is not ready-Check corresponding vserver/service for more details-Use the show LB vserver or show service command to check the state of the service.
  - Citrix ADC is waiting for CEA from PCRF-Capability negotiation between the PCRF and Citrix ADC might be failing. This could be an intermittent state. If it persists, check the DIAMETER

settings on your PCRF server.
  - Memory is not configured to store subscriber sessions. Please use ‘set extendedmemoryparam -memlimit <>’-Use the set extendedmemoryparam command to configure extended memory.
- show subscriber radiusinterface
  If “Not Configured” is the output of this command, use the set subscriber radiusinterface command to specify a RADIUSListener service.

If subscriber logging is enabled, you can get more detailed information from the log files.

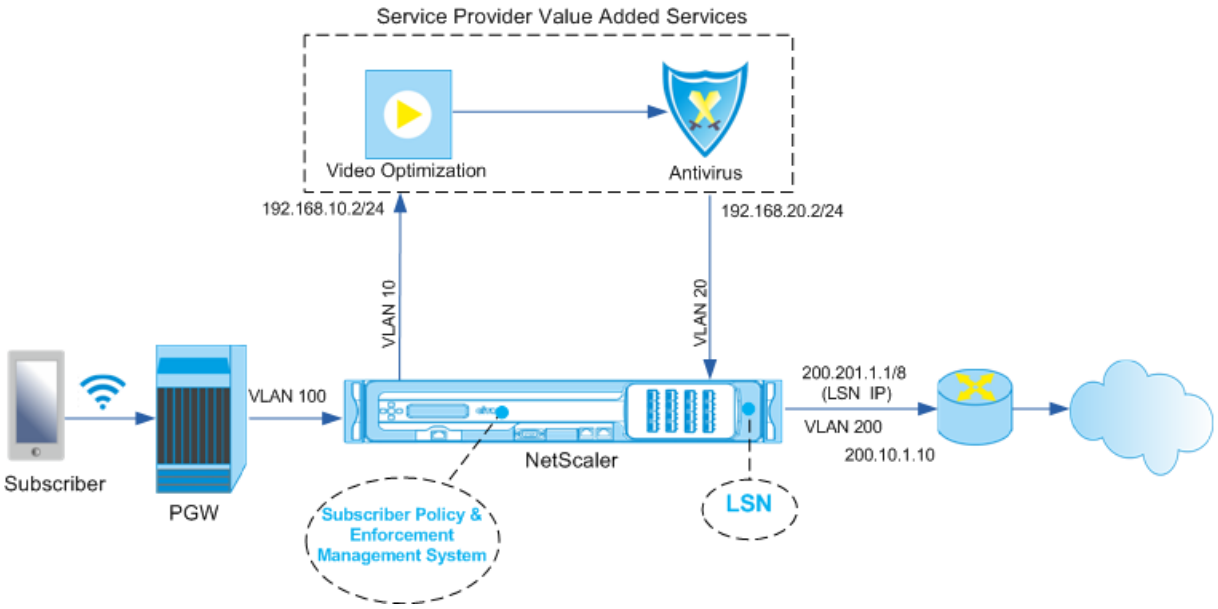
Subscriber aware traffic steering

September 14, 2021

Traffic steering directs subscriber traffic from one point to another. When a subscriber connects to the network, the packet gateway associates an IP address with the subscriber and forwards the data packet to the Citrix ADC appliance. The appliance communicates with the PCRF server over the Gx interface to get the policy information. Depending on the policy information, the appliance performs one of the following actions:

- Forward the data packet to another set of services (as shown in the following illustration).
- Drop the packet.
- Perform only Large Scale NAT (LSN), if LSN is configured on the appliance.

The values shown in the following figure are configured in the CLI procedure that follows the figure. A content switching virtual server on the Citrix ADC appliance directs requests to the value added services or skips them, depending on the defined rule, and then sends the packet out to the Internet after performing LSN.



To configure traffic steering for the above deployment by using the CLI

Add the appliance's subnet IP (SNIP) addresses.

Example:

```
add ns ip 192.168.10.1 255.255.255.0 -type snip

add ns ip 192.168.20.1 255.255.255.0 -type snip

add ns ip 100.100.100.1 255.0.0.0 -type snip

add ns ip 200.200.200.1 255.0.0.0 -type snip

add ns ip 100.1.1.1 255.0.0.0 -type snip

add ns ip 200.201.1.1 255.0.0.0 -type snip
<!--NeedCopy-->
```

Add the VLANs. VLANs help the appliance identify the source of the traffic. Bind the VLANs to the interfaces and subnet IP addresses.

Example:

```
add vlan 10

add vlan 20

add vlan 100
```

```
6
7  add vlan 200
8
9  bind vlan 10 -ifnum 1/4 -tagged -IPAddress 192.168.10.1 255.255.255.0
10
11 bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.20.1 255.255.255.0
12
13 bind vlan 100 -ifnum 1/2 -tagged -IPAddress 100.1.1.1 255.0.0.0
14
15 bind vlan 200 -ifnum 1/3 -tagged -IPAddress 200.1.1.1 255.0.0.0
16 <!--NeedCopy-->
```

Specify the VLAN on which the subscriber traffic arrives on the appliance. Specify the service path AVP that tells the appliance where to look for the service path name within the subscriber session. For primary PCEF functionality, specify the interfaceType as RadiusAndGx.

Example:

```
1 set ns param -servicePathIngressVLAN 100
2
3 set subscriber gxinterface -servicepathAVP 1001 1005 -
     servicepathVendorid 10415
4
5 set subscriber param -interfaceType RadiusAndGx
6 <!--NeedCopy-->
```

Configure a service and virtual server of type Diameter, and bind the service to the virtual server. Then, specify the PCRF realm and subscriber Gx interface parameters. For primary PCEF functionality, configure a RADIUS listener service and RADIUS interface.

Example:

```
1  add service sd1 10.102.232.200 DIAMETER 3868
2
3  add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER -
      persistAVPno 263
4
5  bind lb vserver vdiam sd1
6
7  set ns diameter -identity netscaler.sc1.net -realm pcrf1.net
8
9  set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf1.net -
      holdOnSubscriberAbsence YES -idleTTL 1200 -negativeTTL 120
10
11 add service srad1 10.102.232.236 RADIUSListener 1813
```

```
12
13 set subscriber radiusInterface -listeningService srad1
14 <!--NeedCopy-->
```

Add service functions to associate a VAS with an ingress VLAN. Add a service path to define the chain, that is, specify the VAS that the packet must be sent to and the order in which it must go to that VAS. The service path name is usually sent by the PCRF. However, the service path of the default subscriber profile (*) applies if any of the following is true:

- PCRF does not have the subscriber information.
- The subscriber information does not include this AVP.
- The appliance is unable to query the PCRF. For example, the service representing the PCRF is DOWN.

The service path AVP that contains this name must already be configured as part of the global configuration. Bind the service function to the service path. The service index specifies the order in which the VAS is added to the chain. The highest number (255) indicates the beginning of the chain.

Example:

```
1 add ns servicefunction SF1 -ingressVLAN 20
2
3 add ns servicepath pol1
4
5 bind ns servicepath pol1 -servicefunction SF1 -index 255
6
7 add subscriber profile * -subscriberrules default_path
8 <!--NeedCopy-->
```

Add the LSN configuration. That is, define the NAT pool and identify the clients for which the appliance must perform LSN.

```
1 add lsn pool pool1
2
3 bind lsn pool pool1 200.201.1.1
4
5 add lsn client client1
6
7 bind lsn client client1 -network 100.0.0.0 -netmask 255.0.0.0
8
9 add lsn group group1 -clientname client1
10
11 bind lsn group group1 -poolname pool1
12 <!--NeedCopy-->
```

The appliance performs LSN by default. To override LSN, you must create a net profile with the overrideLsn parameter enabled, and bind this profile to all the load balancing virtual servers that are configured for value added services (VASs).

Example:

```
add netprofile np1

set netprofile np1 -overrideLsn ENABLED

set lb vserver vs1 -netprofile np1
<!--NeedCopy-->
```

Configure the VAS on the appliance. This includes creating the services and virtual servers and then binding the services to the virtual servers.

```
add service vas1 192.168.10.2 ANY 80 -usip YES

add service sint 200.10.1.10 ANY 80 -usip YES

add lb vserver vs1 ANY -m MAC -l2Conn ON

add lb vserver vint ANY -m MAC -l2Conn ON

bind lb vserver vs1 vas1

bind lb vserver vint sint
<!--NeedCopy-->
```

Add the content switching (CS) configuration. This includes virtual servers, policies, and their associated actions. The traffic arrives at the CS virtual server and is then redirected to the appropriate load balancing virtual server. Define expressions that associate a virtual server with a service function.

Example:

```
add cs vserver cs1 ANY * 80 -l2Conn ON

add cs action csact1 -targetLBVserver vs1

add cs action csactint -targetLBVserver vint

add cs policy cspol1 -rule  SUBSCRIBER.SERVICEPATH.IS_NEXT("SF1") &&
    SYS.VSERVER("vs1").STATE.EQ(UP)" -action csact1

bind cs vserver cs1 -policyName cspol1 -priority 110

```

```
bind cs vserver cs1 -lbvserver vint
<!--NeedCopy-->
```

To configure traffic steering on the appliance by using the GUI

1. Navigate to **System** > **Network** > **IPs** and add the subnet IP addresses.
2. Navigate to System > Network > **VLANs** and add VLANs, Bind the VLANs to the interfaces and subnet IP addresses.
3. Navigate to **Traffic Management** > **Service Chaining** > **Configure Service Path Ingress VLAN** and specify an ingress VLAN.
4. Navigate to **Traffic Management** > **Subscriber** > **Parameters** > **Configure Subscriber Parameters** and specify the following:
   - Interface Type: Specify **RadiusAndGx**.
   - Configure a diameter virtual server, PCRF realm, and the subscriber GX interface parameters.
   - Specify the RADIUS interface parameters.
5. Navigate to **Traffic Management** > **Service Chaining** > **Service Function** and add service functions to associate a value-added service with an ingress VLAN.
6. Navigate to **System** > **Network** > **Large Scale NAT**. Click **Pools** and add a pool. Click **Clients** and add a client. Click **Groups** and add a group and specify the client. Edit the group and bind the pool to this group.
7. Navigate to **System** > **Network** > **Net Profiles** and add a net profile. Select **Override LSN**. Optionally, navigate to **System** > **Network** > **Settings** > **Configure Layer 3 Parameters** and verify that **Override LSN** is not selected.
8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and configure the virtual servers and value-added services on the appliance. Bind the services and the net profile to the virtual server.
9. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and configure a virtual server, policy, and action. Specify the target load balancing virtual server.

To configure service chaining on the appliance by using the GUI

1. Navigate to **System** > **Network** > **IPs** and add the subnet IP addresses.
2. Navigate to System > Network > **VLANs** and add VLANs, Bind the VLANs to the interfaces and subnet IP addresses.
3. Navigate to **Traffic Management** > **Service Chaining** > **Configure Service Path Ingress VLAN** and specify an ingress VLAN.
4. Navigate to **Traffic Management** > **Subscriber** > **Parameters** > **Configure Subscriber Parameters** and specify the following:

- Interface Type: Specify **RadiusAndGx**.
- Configure a diameter virtual server, PCRF realm, and the subscriber GX interface parameters.
- Specify the RADIUS interface parameters.

5. Navigate to **Traffic Management** > **Service Chaining** > **Service Function** and add service functions to associate a value-added service with an ingress VLAN.
6. Navigate to **System** > **Network** > **Large Scale NAT**. Click **Pools** and add a pool. Click **Clients** and add a client. Click **Groups** and add a group and specify the client. Edit the group and bind the pool to this group.
7. Navigate to **System** > **Network** > **Net Profiles** and add a net profile. Select **Override LSN**. Optionally, navigate to **System** > **Network** > **Settings** > **Configure Layer 3 Parameters** and verify that **Override LSN** is not selected.
8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and configure the virtual servers and value-added services on the appliance. Bind the services and the net profile to the virtual server.
9. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and configure a virtual server, policy, and action. Specify the target load balancing virtual server.

Subscriber aware service chaining

September 14, 2021

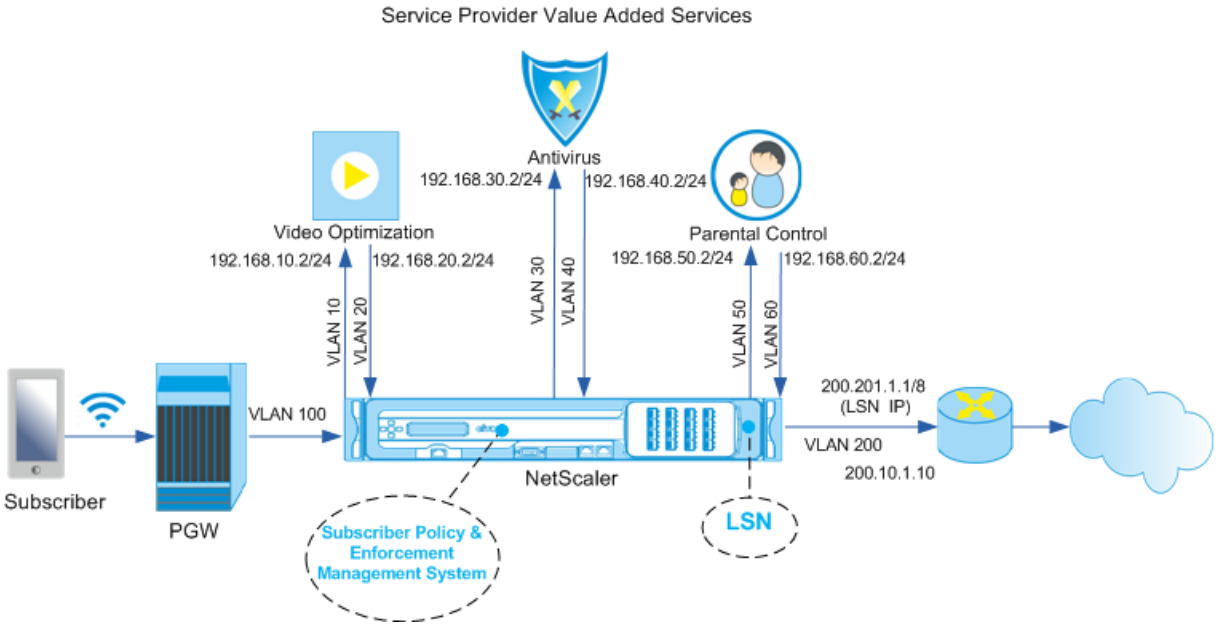
With the huge increase in the data traffic passing through telco networks, it is no longer feasible for service providers to steer all the traffic through all the value added services (VAS). A service provider should be able to optimize usage of VAS and intelligently steer traffic to improve the user experience. For example, video optimization is not required for traffic that does not include a video. Moreover, if a subscriber is connected to a 4G network, content can be streamed in high definition (HD), and video optimization might not be needed. However, video optimization improves the experience for a user in a 3G network. Similarly, caching provides a faster and better user experience and can be enabled depending on the subscriber plan. Another example of VAS is parental control. If parents provide a mobile handset to a minor child, they would like some kind of control over the websites that their child visits.

To do the above and more, service providers must be able to provide value-added services on a per-subscriber basis. In other words, entities in the service provider network must be capable of extracting the subscriber information and intelligently steering the packet on the basis of this information.

Service chaining determines the set of services through which the traffic from a subscriber must pass before going to the Internet. Instead of sending all the traffic to all the services, the Citrix ADC intelligently routes all requests from a subscriber to a specific set of services on the basis of the policy

defined for that subscriber.

The following figure shows the entities involved in service chaining. The values shown are configured in the procedure that follows the figure. A content switching virtual server on the Citrix ADC appliance directs requests to the value added services or skips them, depending on the defined rule, and then sends the packet out to the Internet after performing LSN.



To configure service chaining for the above deployment by using the CLI

Add the appliance's subnet IP (SNIP) addresses.

Example:

```
add ns ip 192.168.10.1 255.255.255.0 -type snip

add ns ip 192.168.20.1 255.255.255.0 -type snip

add ns ip 192.168.30.1 255.255.255.0 -type snip

add ns ip 192.168.40.1 255.255.255.0 -type snip

add ns ip 192.168.50.1 255.255.255.0 -type snip

add ns ip 192.168.60.1 255.255.255.0 -type snip

add ns ip 100.1.1.1 255.0.0.0 -type snip

add ns ip 200.201.1.1 255.0.0.0 -type snip
```

```
<!--NeedCopy-->
```

Add the VLANs. VLANs help the appliance identify the source of the traffic. Bind the VLANs to the interfaces and subnet IP addresses. Add an ingress and an egress VLAN for each VAS.

Example:

```
add vlan 10

add vlan 20

add vlan 30

add vlan 40

add vlan 50

add vlan 60

add vlan 100

add vlan 200

bind vlan 10 -ifnum 1/4 -tagged -IPAddress 192.168.10.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.20.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.30.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.40.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.50.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.60.1 255.255.255.0

bind vlan 100 -ifnum 1/2 -tagged -IPAddress 100.1.1.1 255.0.0.0

bind vlan 200 -ifnum 1/3 -tagged -IPAddress 200.201.1.1 255.0.0.0
<!--NeedCopy-->
```

Specify the VLAN on which the subscriber traffic arrives on the appliance. Specify the service path AVP that tells the appliance where to look for the service path name within the subscriber session. For primary PCEF functionality, specify the interfaceType as RadiusAndGx.

Example:

```
set ns param -servicePathIngressVLAN 100

set subscriber gxinterface -servicepathAVP 1001 1005 -
    servicepathVendorid 10415

set subscriber param -interfaceType RadiusAndGx
<!--NeedCopy-->
```

Configure a service and virtual server of type Diameter, and bind the service to the virtual server. Then, specify the PCRF realm and subscriber Gx interface parameters. For primary PCEF functionality, configure a RADIUS listener service and RADIUS interface.

Example:

```
add service sd1 10.102.232.200 DIAMETER 3868

add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER -
    persistAVPno 263

bind lb vserver vdiam sd1

set ns diameter -identity netscaler.sc1.net -realm pcrf1.net

set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf1.net -
    holdOnSubscriberAbsence YES -idleTTL 1200 -negativeTTL 120

add service srad1 10.102.232.236 RADIUSListener 1813

set subscriber radiusInterface -listeningService srad1
<!--NeedCopy-->
```

Add service functions to associate a VAS with an ingress VLAN. Add a service path to define the chain, that is, specify the VAS that the packet must be sent to and the order in which it must go to that VAS. The service path name is usually sent by the PCRF. However, the service path of the default subscriber profile (*) applies if any of the following is true:

- PCRF does not have the subscriber information.
- The subscriber information does not include this AVP.
- The appliance is unable to query the PCRF. For example, the service representing the PCRF is DOWN.

The service path AVP that contains this name must be configured as part of the global configuration earlier. Bind the service function to the service path. The service index specifies the order in which the VAS is added to the chain. The highest number (255) indicates the beginning of the chain.

Example:

```
add ns servicefunction SF1 -ingressVLAN 20

add ns servicefunction SF2 -ingressVLAN 40

add ns servicefunction SF3 -ingressVLAN 60

add ns servicepath pol1

bind ns servicepath pol1 -servicefunction SF1 -index 255

bind ns servicepath pol1 -servicefunction SF2 -index 254

bind ns servicepath pol1 -servicefunction SF3 -index 253

add ns servicepath pol2

bind ns servicepath pol2 -servicefunction SF2 -index 255

add ns servicepath pol3

bind ns servicepath pol3 -servicefunction SF1 -index 255

add subscriber profile * -subscriberrules default_path
<!--NeedCopy-->
```

Add the LSN configuration. That is, define the NAT pool and identify the clients for which the appliance must perform LSN.

Example:

```
add lsn pool pool1

bind lsn pool pool1 200.201.1.1

add lsn client client1

bind lsn client client1 -network 100.0.0.0 -netmask 255.0.0.0

add lsn group group1 -clientname client1

bind lsn group group1 -poolname pool1
<!--NeedCopy-->
```

The appliance performs LSN by default. To override LSN, you must create a net profile with over-

rideLsn parameter enabled and bind this profile to all the load balancing virtual servers that are configured for value added services (VASs).

Example:

```
add netprofile np1

set netprofile np1 -overrideLsn ENABLED

set lb vserver vs1 -netprofile np1
<!--NeedCopy-->
```

Configure the VAS on the appliance. This includes creating the services and virtual servers and then binding the services to the virtual servers.

Example:

```
add service vas1 192.168.10.2 ANY 80 -usip YES

add service vas2 192.168.30.2 ANY 80 -usip YES

add service vas3 192.168.50.2 ANY 80 -usip YES

add service sint 200.10.1.10 ANY 80 -usip YES

add lb vserver vs1 ANY -m MAC -l2Conn ON

add lb vserver vs2 ANY -m MAC -l2Conn ON

add lb vserver vs3 ANY -m MAC -l2Conn ON

add lb vserver vint ANY -m MAC -l2Conn ON

bind lb vserver vs1 vas1

bind lb vserver vs2 vas2

bind lb vserver vs3 vas3

bind lb vserver vint sint
<!--NeedCopy-->
```

Add the content switching (CS) configuration. This includes virtual servers, policies, and their associated actions. The traffic arrives at the CS virtual server and is then redirected to the appropriate load balancing virtual server. Define expressions that associate a virtual server with a service function.

Example:

```
add cs vserver cs1 ANY * 80 -l2Conn ON

add cs action csact1 -targetLBVserver vs1

add cs action csact2 -targetLBVserver vs2

add cs action csact3 -targetLBVserver vs3

add cs action csactint -targetLBVserver vint

add cs policy cspol1 -rule "SUBSCRIBER.SERVICEPATH.IS_NEXT("SF1") &&
   SYS.VSERVER("vs1").STATE.EQ(UP)" -action csact1

add cs policy cspol2 -rule "SUBSCRIBER.SERVICEPATH.IS_NEXT("SF2") &&
   SYS.VSERVER("vs2").STATE.EQ(UP)" -action csact2

add cs policy cspol3 -rule "SUBSCRIBER.SERVICEPATH.IS_NEXT("SF3") &&
   SYS.VSERVER("vs3").STATE.EQ(UP)" -action csact3

bind cs vserver cs1 -policyName cspol1 -priority 110

bind cs vserver cs1 -policyName cspol2 -priority 120

bind cs vserver cs1 -policyName cspol3 -priority 130

bind cs vserver cs1 -lbvserver vint
<!--NeedCopy-->
```

To configure service chaining on the appliance by using the GUI

1. Navigate to **System** > **Network** > **IPs** and add the subnet IP addresses.
2. Navigate to **System** > **Network** > **VLANs** and add VLANs, Bind the VLANs to the interfaces and subnet IP addresses.
3. Navigate to **Traffic Management** > **Service Chaining** > **Configure Service Path Ingress VLAN** and specify an ingress VLAN.
4. Navigate to **Traffic Management** > **Subscriber** > **Parameters** > **Configure Subscriber Parameters** and specify the following:
   - Interface Type: Specify **RadiusAndGx**.
   - Configure a diameter virtual server, PCRF realm, and the subscriber GX interface parameters.
   - Specify the RADIUS interface parameters.

5. Navigate to **Traffic Management** > **Service Chaining** > **Service Function** and add service functions to associate a value-added service with an ingress VLAN.
6. Navigate to **System** > **Network** > **Large Scale NAT**. Click **Pools** and add a pool. Click **Clients** and add a client. Click **Groups** and add a group and specify the client. Edit the group and bind the pool to this group.
7. Navigate to **System** > **Network** > **Net Profiles** and add a net profile. Select **Override LSN**. Optionally, navigate to **System** > **Network** > **Settings** > **Configure Layer 3 Parameters** and verify that **Override LSN** is not selected.
8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and configure the virtual servers and value-added services on the appliance. Bind the services and the net profile to the virtual server.
9. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and configure a virtual server, policy, and action. Specify the target load balancing virtual server.

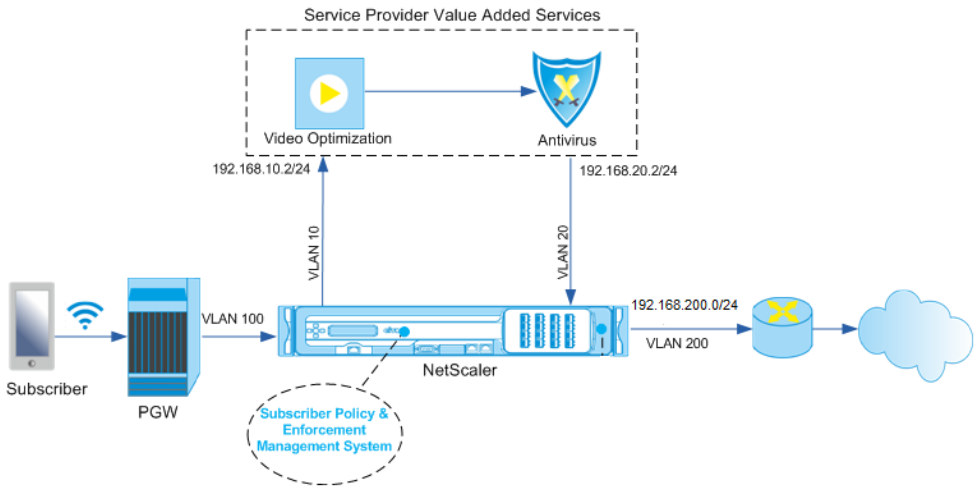
Subscriber aware traffic steering with TCP optimization

September 14, 2021

Traffic steering directs subscriber traffic from one point to another. When a subscriber connects to the network, the packet gateway associates an IP address with the subscriber and forwards the data packet to the Citrix ADC appliance. The appliance communicates with the PCRF server over the Gx interface to get the subscriber policy information. Depending on the policy information, the appliance performs one of the following actions:

- Forward the data packet to another set of services (as shown in the following illustration).
- Perform only TCP optimization.

The values shown in the following figure are configured in the CLI procedure that follows the figure. A content switching virtual server on the Citrix ADC appliance directs requests to the value added services or skips them and performs TCP optimization, depending on the defined rule, and then sends the packet out to the Internet.



> **Note**
>
> Support for the configuration shown below was introduced in release 11.1 build 50.10.

To configure traffic steering for the above deployment by using the CLI:

1. Add the appliance's subnet IP (SNIP) addresses.

```
add ns ip 192.168.10.1 255.255.255.0 -type snip

add ns ip 192.168.20.1 255.255.255.0 -type snip

add ns ip 192.168.100.1 255.255.255.0 -type snip

add ns ip 192.168.200.1 255.255.255.0 -type snip

add ns ip 10.102.232.236 255.255.255.0  - type snip
<!--NeedCopy-->
```

2. Add the VLANs. VLANs help the appliance identify the source of the traffic. Bind the VLANs to the interfaces and subnet IP addresses.

```
add vlan 10

add vlan 20

add vlan 100

add vlan 200

add vlan 102
```

```
10
11 bind vlan 10 -ifnum 1/4 -tagged -IPAddress 192.168.10.1
      255.255.255.0
12
13 bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.20.1
      255.255.255.0
14
15 bind vlan 100 -ifnum 1/2 -tagged -IPAddress 192.168.100.1
      255.255.255.0
16
17 bind vlan 200 -ifnum 1/2 -tagged -IPAddress 192.168.200.1
      255.255.255.0
18
19 bind vlan 102  - ifnum 1/1  - tagged  - IPAddress 10.102.232.236
      255.255.255.0
20 <!--NeedCopy-->
```

3. Configure a service and virtual server of type Diameter, and bind the service to the virtual server. Specify the PCRF realm and values for the subscriber Gx interface parameters. Also specify the service path AVP that indicates where the appliance can find the service path name within the subscriber session. For primary PCEF functionality, configure a RADIUS listener service and RADIUS interface, and specify the interface type as “RadiusAndGx”.

```
1  add service sd1 10.102.232.200 DIAMETER 3868
2
3  add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
      -persistAVPno 263
4
5  bind lb vserver vdiam sd1
6
7  set ns diameter -identity netscaler.sc1.net -realm pcrf1.net
8
9  set extendedmemoryparam -memLimit 2558
10
11 set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf1.net
12
13 set subscriber gxinterface -servicepathAVP 1001 1005 -
      servicepathVendorid 10415
14
15 add service srad1 10.102.232.236 RADIUSListener 1813
16
17 set subscriber radiusInterface -listeningService srad1
18
19 set subscriber param -interfaceType RadiusAndGx
```

```
20 <!--NeedCopy-->
```

4. Specify a default subscriber profile (*) to be applied if any of the following is true:

   - PCRF does not have the subscriber information.
   - The subscriber information does not include the service path AVP.
   - The appliance is unable to query the PCRF. For example, the service representing the PCRF is DOWN.

```
1 add subscriber profile * -subscriberrules default_path
2 <!--NeedCopy-->
```

5. Create TCP profiles for the VAS and TCP optimization path, respectively. Traffic steered to VAS will not undergo any TCP optimization before or after leaving the VAS. Therefore, the TCP mode of the VAS profile should be set to TRANSPARENT while the TCP mode of the TCPOpt profile should be set to ENDPOINT.

   add ns tcpProfile VAS –tcpMode TRANSPARENT

   add ns tcpProfile TCPOpt -WS ENABLED -SACK ENABLED -WSVal 8 -mss 1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -bufferSize 4000000 -flavor BIC -dynamicReceiveBuffering ENABLED -KA ENABLED -sendBuffsize 4000000 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED -ecn ENABLED -frto ENABLED -maxcwnd 1000000 -fack ENABLED -rstMaxAck enABLED -tcpmode ENDPOINT

6. Configure load balancing for the VAS servers. Create a non-addressable virtual server of type TCP. Create TCP services with the IP addresses of the VAS servers, and bind the services to the virtual server. The virtual server and services will use the transparent TCP profile created for the VAS path:

```
1  add service vas1 192.168.10.2 TCP * -usip YES -useproxyport NO -
       TCPB NO -tcpProfileName VAS
2
3  add service vas2 192.168.10.3 TCP * -usip YES -useproxyport NO -
       TCPB NO -tcpProfileName VAS
4
5  add lb vserver vs1 TCP -m MAC -l2Conn ON  - tcpProfileName VAS
6
7  bind lb vserver vs1 vas1
8
9  bind lb vserver vs1 vas2
10 <!--NeedCopy-->
```

7. Add a load balancing virtual server to capture VAS egress traffic. This vserver will monitor the VAS egress VLAN and will use the transparent TCP profile:

```
add lb vserver vsint TCP * * -Listenpolicy "CLIENT.VLAN.ID.EQ(20)"
    -Listenpriority 30 -l2Conn ON -tcpProfileName VAS
<!--NeedCopy-->
```

8. Add a TCP optimization virtual server that listens for any traffic in the wireless-side VLAN and uses the endpoint TCP profile created for the TCP optimization path:

```
add lb vserver vs-TcpOpt TCP * * -Listenpolicy "client.vlan.id.eq
    (100)" -Listenpriority 20 -l2Conn ON -tcpProfileName TCPOpt
<!--NeedCopy-->
```

9. Add the content switching (CS) configuration. This includes virtual servers, policies, and their associated actions. The CS virtual server receives the traffic and redirects it to the appropriate load balancing virtual server according to defined CS policies. Create a CS TCP virtual server that listens for any traffic in the wireless-side VLAN with highest priority and uses the endpoint TCP profile. Create a CS policy that evaluates to TRUE when “vas” is the subscriber rule, and specify a CS action that steers traffic to VAS. Make the TCP optimization virtual server the default LB vserver. Any subscriber traffic with a rule other than “vas” will go through the default LB vserver.

```
add cs vserver cs1 TCP * * -Listenpolicy "client.vlan.id.eq(100)"
    -Listenpriority 10 -l2Conn ON -tcpProfileName TCPOpt

add cs action csact1 -targetLBVserver vs1

add cs policy cspol1 -rule SUBSCRIBER.RULE_ACTIVE(\"vas\") && SYS
    .VSERVER(\"vs1\").STATE.EQ(UP)" -action csact1

bind cs vserver cs1 -policyName cspol1

bind cs vserver cs1 -lbvserver vs-TcpOpt
<!--NeedCopy-->
```

10. Add static or policy based routes to the internet. Dynamic routing is also supported in this configuration. The following example uses policy based routes:

```
add ns pbr pbr-vlan100-to-vlan200 ALLOW -nextHop 192.168.200.10 -
    vlan 100 -priority 10

add ns pbr pbr-vlan20-to-vlan200 ALLOW -nextHop 192.168.200.10 -
    vlan 20 -priority 11

apply ns pbrs
<!--NeedCopy-->
```

Note

The CS policies can contain IP addresses and port numbers in addition to the subscriber expressions—for example, SUB-SCRIBER.RULE_ACTIVE(”vas”) && && (CLIENT.TCP.DSTPORT.EQ(80)	CLIENT.TCP.DSTPORT.EQ(443). They can also contain HTTP based expressions—for example, HTTP.REQ.HOSTNAME.DOMAIN.EQ(”somedor In this case, replace TCP entities (vserver, service, etc.) with HTTP. The TCP profile configuration remains the same.

-
- Add IPv6 configuration (addresses, routes, PBRs) to support IPv6 subscribers. Happy Eyeballs client applications will work smoothly for both VAS and TCP optimization paths.
- Add VLANs, IP addresses, PBRs and LB virtual servers in front of VAS (vs1, vs2, etc.) to support multiple subscriber flows. Modify the listen policies of CS vserver “cs1” and LB vserver “vsint” to include the additional VLANs.

Policy based TCP profile selection

September 14, 2021

You can configure the Citrix ADC appliance to perform TCP optimization based on subscriber attributes. For example, the appliance can select different TCP profiles at run time, based on the network to which the user equipment (UE) is connected. As a result, you can improve a mobile user’s experience by setting some parameters in the TCP profiles and then using policies to select the appropriate profile.

Create separate TCP profiles for subscribers connecting through a 4G network and for users connecting through any other network. Define a policy rule that is selected on the basis of a subscriber parameter, such as RAT-type. In the following examples, if RAT-Type is EUTRAN, a TCP profile that supports a faster connection is selected (Example 1). For all other RAT-Type values, a different TCP profile is selected (Example 2).

Note

> The RAT-Type AVP (AVP code 1032) is of type Enumerated and is used to identify the radio access technology that is serving the UE.
>
> The value “1004” indicates that the RAT is EUTRAN. (RFC 29.212).

Example1:

```
add ns tcpProfile tcp2 -WS ENABLED -SACK ENABLED -WSVal 8 -initialCwnd
    16 - oooQSize 15000 -slowStartIncr 1 -bufferSize 1000000 -flavor BIC
     - dynamicReceiveBuffering DISABLED -sendBuffsize 1000000 -dsack
    DISABLED -maxcwnd 4000000 -fack ENABLED -minRTO 500 -maxburst 15

add appqoe action appact2 -priority HIGH -tcpprofile tcp2

add appqoe policy apppol2 -rule "SUBSCRIBER.AVP(1032).VALUE.
    GET_UNSIGNED32(0, BIG_ENDIAN).EQ(1004)" -action appact2

bind cs vserver <name>  -policyname apppol2 -priority 20 -type request
<!--NeedCopy-->
```

Example2:

```
add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -initialCwnd
    16 - oooQSize 15000 -slowStartIncr 1 -bufferSize 150000 -flavor BIC
    - dynamicReceiveBuffering DISABLED -sendBuffsize 150000 -dsack
    DISABLED -maxcwnd 4000000 -fack ENABLED -minRTO 200 -maxburst 15

add appqoe action appact1 -priority HIGH -tcpprofile tcp1

add appqoe policy apppol1 -rule "SUBSCRIBER.AVP(1032).VALUE.
    GET_UNSIGNED32(0, BIG_ENDIAN).NE(1004)" -action appact1

bind cs vserver <name>  -policyname apppol1 -priority 10 -type request
<!--NeedCopy-->
```

Load Balance Control-Plane Traffic that is based on Diameter, SIP, and SMPP Protocols

September 14, 2021

With the increase in control-plane traffic, the servers can become a bottleneck because the traffic is not optimally distributed among the servers. Therefore, messages must be load balanced. The Citrix ADC appliance supports Diameter, SIP, and SMPP load balancing.

SIP

Citrix ADC enables you to load balance SIP messages over UDP or over TCP (including TLS) to a group of proxy servers. Citrix ADC also provides Call-ID based persistence and Call-ID hash load balancing method using which you direct packets for a particular SIP session to the same load balanced SIP server.
The Citrix ADC default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions are intended to be used in policies for SIP protocol that operates on a request/response basis. These expressions can be used in content switching, rate limiting, responder, and rewrite policies.

For more information, see Load Balancing a Group of SIP Servers.

SMPP

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers.
The Citrix ADC appliance provides optimal distribution of messages across your servers, preventing poor performance and outages. The Citrix ADC appliance:

- Load balances messages originating from the server and from the client
- Monitors the health of the message centers
- Provides content switching support for the message centers
- Handles concatenated messages

Limitation: Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the Citrix ADC appliance responds with an error message.

For more information, see SMPP Load Balancing

Diameter

Diameter is a base protocol with more than 50 protocols (also called applications) built over it. Therefore, the diameter traffic generated in a Telco network is high. To optimally maintain this diameter traffic, the Citrix ADC appliance performs load balancing, content switching, and acts as a relay agent. Additionally, the appliance offers rewrite and responder functionality. The appliance supports rate limiting of Diameter messages.

For more information, see Configuring Diameter Load Balancing.

Provide DNS Infrastructure/Traffic Services, such as, Load Balancing, Caching, and Logging for Telecom Service Providers

September 14, 2021

Telecom service providers can configure the Citrix ADC appliance to function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the Citrix ADC appliance. This enables the Citrix ADC appliance to provide quick responses for repeated translations and hence enhances the customer experience and also saves the bandwidth. The caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the Citrix ADC appliance returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the Citrix ADC appliance. The Citrix ADC appliance then returns the address to the client.

For requests for a domain that has been cached earlier, the Citrix ADC appliance serves the Address record of the domain from the cache without querying the configured DNS server and hence saves the bandwidth.

From 11.0 release onwards, Citrix ADC also logs the DNS requests that it receives and also the responses that it sends to the client. Telecom service providers can use this log to:

- Audit the DNS responses to the client
- Audit DNS clients
- Detect and prevent DNS attacks
- Troubleshooting

For more information, see Domain Name System.

Provide Subscriber Load Distribution Using GSLB Across Core-Networks of a Telecom Service Provider

September 14, 2021

Scalability, high availability and performance are critical to service provider deployments. While many service providers deploy there infrastructure at a single location or multiple location, these deployments are subject to a number of inherent limitations, such as:

- If the site loses connectivity to all or part of the public Internet, it will be inaccessible to users and customers, which can have significant impact on the business.

- Users accessing the site from geographically distant locations may experience large and highly variable delays, which are exacerbated by the large number of round trips that HTTP requires to transfer content.

Citrix ADC appliance's Global Server Load Balancing (GSLB) overcomes these problems by distributing traffic among sites deployed in multiple geographic locations. By serving content from many different points in the Internet, GSLB alleviates the impact of network bandwidth bottlenecks and provides robustness in case of network failures at a particular site. Users can be automatically directed to the nearest or least loaded site at the time of the request, minimizing the likelihood of long download delays and/or service disruptions.

You can use Citrix ADC appliance's global server load balancing for:

- Disaster recovery or high availability by configuring an Active-standby data center setup that consists of an active and a standby data center. When a failover occurs as a result of a disaster event, the standby data center becomes operational.
- High availability and speed by configuring an active-active data center setup that consists of multiple active data centers. Client requests are load balanced across active data centers.
- Directing client requests to the data center that is closest in geographical distance or network distance by configuring a proximity setup.
- Full-DNS resolutions, GSLB processes DNS queries of the A, AAAA and CNAME types, and the DNS function option can process DNS queries of all other types, such as MX and PTR. Also, if the recursive resolution is enabled, the appliance will forward DNS queries for domain names that are not configured on the Citrix ADC appliance.

For more information, see Global Server Load Balancing.

Bandwidth Utilization Using Cache Redirection Functionality

September 14, 2021

The volume of web traffic on the Internet is enormous and a large percentage of that traffic is redundant. Multiple clients ask web servers for the same content repeatedly leading to inefficient use of bandwidth. To relieve the origin web server of processing each request, Internet Service Providers (ISPs) can use the cache redirection feature of Citrix ADC appliance and serve the content from a cache server instead of from the origin server. The Citrix ADC appliance analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers. Cache redirection feature of Citrix ADC is policy-based, and by default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

For more information, see Cache Redirection.

Citrix ADC TCP Optimization

September 14, 2021

The Citrix ADC appliance provides advanced TCP tuning and optimization techniques and capabilities that are well suited to modern 3.5 and 4G networks, improving user experience and perceived download speeds significantly.

This section focuses on detailed instructions relevant to:

- Choosing and inserting an appropriate Citrix ADC T1000 Series model in a mobile network for TCP optimization
- Full configuration instructions related to not only TCP optimization but also for appropriate Layer-2 and Layer-3 configuration of the T1 device

The section includes the following topics:

- Getting Started
- Managment Network
- Licensing
- High Availability
- Gi-LAN Integration
- TCP Optimization Configuration
- Optimizing TCP Performance Using TCP NILE
- Analytics and Reporting
- Real-time Statistics
- SNMP
- Technical Recipes
- Troubleshooting Guidelines
- Frequently Asked Questions

Getting Started

September 14, 2021

Hardware

Citrix provides a wide breath of Citrix ADC models that might be loosely based on two factors:

- Capacity, currently ranging from hundreds of Mbps for the low-end VPX appliance to 160Gbps for the high-end 25000 MPX series appliance
- Telco grade, with the availability of the T1000 series for Telco datacenters.

Your Citrix Sales or Support representative can help you select the appropriate hardware for your demo, trial, or production needs.

The remainder of this section uses a Citrix ADC T1200 as a reference hardware. Note that putting aside superficial differences related to number and notation of available interfaces (see * in note) or well-documented limitations of Citrix ADC VPX (see * in note) the instructions should apply mostly verbatim regardless of the Citrix ADC model selected.

> **Note**
>
> * For instance a the T1010 model only has 12x1GbE typically marked as 1/1-1/12 rather than the 10/x notation used in this document.
>
> ** A Citrix ADC VPX instance typically doesn't support LACP aggregation; it might also not support VLAN tagging.

Initial Setup

Through Serial Console

After a serial cable is connected, you can log on to the Citrix ADC appliance with the following credentials:

- Username: nsroot
- Password: nsroot

Once logged in, configure the basic details of the Citrix ADC appliance as shown in the screen capture below.

Example:

```
set ns config  - IPAddress <ip_addr> -netmask <netmask>

saveconfig

reboot -warm
<!--NeedCopy-->
```

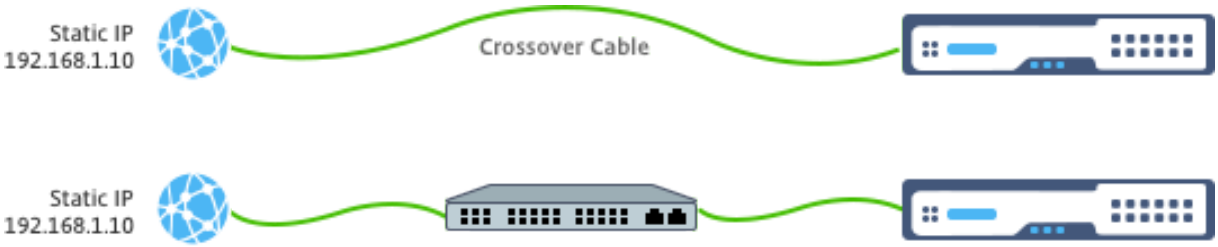
After you restart the appliance, you might use SSH for further configuration of the T1100 nodes.

Through LOM

Lights out Management (LOM) port on the front panel of the Citrix ADC appliance allows operator to remotely monitor and manage the appliance independently of the operating system. Operator can change the IP address, power cycle, and perform a code dump by connecting to the Citrix ADC appliance through the LOM port.

Default IP Address of LOM port is 192.168.1.3

Figure. Intial Configuration of LOM Module



Set a static IP on your laptop and plug it directly into the LOM interface with a crossover cable or into a switch in the same broadcast domain as the LOM interface.

For initial configuration, type the port's default address: http://192.168.1.3 in a web browser and change the LOM port's default IP address.

Refer to Configuration Guides for further details.

Software

The Citrix ADC TCP optimization for mobile networks is constantly evolving. The capabilities and tunings outlined in this document require a Citrix ADC Telco build. Here is an example showing the Citrix ADC Telco build.

Example:

```
1 show ver
2
3 NetScaler NS11.0: Build 64.957.nc, Date: Aug 26 2016, 02:00:23
4 <!--NeedCopy-->
```

If the T1000 has not shipped with the appropriate build revision, contact the Citrix ADC Customer Support.

> **Important**
>
> Both the appliances should have the same software image.

SSH Client

A Citrix ADC appliance can be configured by using either the CLI or the HTML5 GUI. However, this section provides only CLI-based instructions.

While the CLI is accessible through the Citrix ADC serial console, an SSH client is normally recommended to allow for remote Citrix ADC configuration.

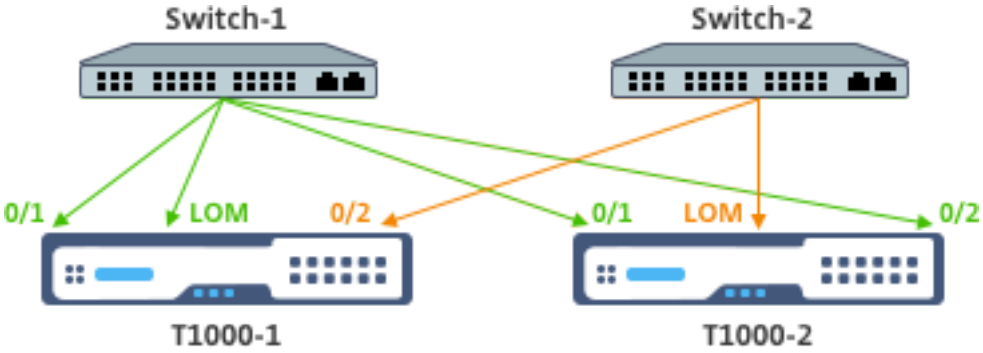
Management Network

September 14, 2021

Connectivity

Most Citrix ADC devices offer redundant 1GbE OAM ports, notated as 0/1 and 0/2. To provide for redundancy in case of a switch failure, you should connect the relevant ports to different upstream switches.

A high-level overview of the recommended connectivity is outlined in the following diagram:



After the Citrix ADC appliance is connected to the management network, subsequent configuration steps can be performed remotely using SSH or web connectivity to the CLI and GUI respectively.

Routing

The add route command may be used to configure any routes appropriate to the management network. The relevant gateway should be reachable on the NSIP subnet, as shown below.

Example:

```
add route <network>  <netmask>  <gateway>
<!--NeedCopy-->
```

Licensing

September 14, 2021

A valid license file should be installed on the Citrix ADC appliance. The license should support at least as many Gbps as the expected maximum Gi-LAN throughput.

License files should be copied through an SCP client to the /nsconfig/license of the appliance, as shown in the screen capture below.

EXample:

```
shell ls /nsconfig/license/

CNS_V3000_SERVER_PLT_Retail.lic ssl
<!--NeedCopy-->
```

Do a warm restart to apply the new license, as shown in the screen capture below.

EXample:

```
reboot -warm

Are you sure you want to restart NetScaler (Y/N)? [N]:y

Done
<!--NeedCopy-->
```

After the restart completes, verify that the license has been properly applied, by using the show license CLI.

In the example below a 3Gbps Premium license has been successfully installed.

Example:

```
> show license

            License status:

                                  Web Logging: YES

                                          ...

                               Model Number ID: 3000

                                  License Type: Premium License

```

```
Done

<!--NeedCopy-->
```

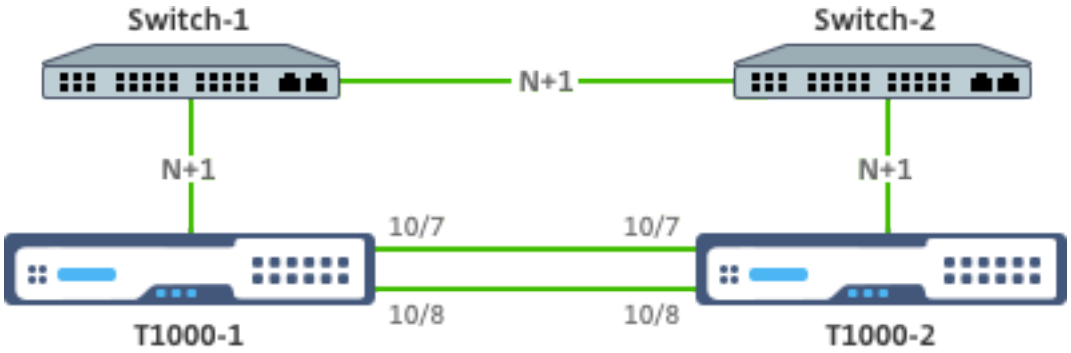
High Availability

September 14, 2021

High availability (HA) refers to an active-standby operational mode of a Citrix ADC device pair. Each device has its own dedicated management IP address. All other IP addresses are owned by the active device in the pair.

Connectivity

While there are multiple connectivity options for a Citrix ADC HA pair, the most recommended one is depicted in the following diagram:



In the above diagram, the N+1 red links between each T1000 and the respective switch imply N+1 redundancy - as explained in Connectivity. For instance, considering a 45 Gbps Gi-LAN N=5 is an appropriate value, with 6x10GbE LACP channels between each switch and the respective T1000 as well as between the two switches.

An extra pair of links is recommended between the Citrix ADC pair, to provide for HA communication isolation from the OAM network.

Gi-LAN Integration

November 22, 2021

Typically, a Citrix ADC appliance is inserted as a separate L3 inline node in the Gi-LAN, similarly to an L3 router.

Figure: A simple depiction of a Gi-LAN

Connectivity

A physical Citrix ADC connectivity to upstream switches is recommended to provide for sufficient redundancy. For example, assuming that a Citrix ADC appliance is inserted in a Gi-LAN that is handling a total (uplink+downlink) of 24Gbps, connectivity with 4x10GbE or more interfaces is recommended. This effectively provides for N+1 redundancy in case of a link failure.

The relevant ports on the upstream switch should be configured for LACP port aggregation. The relevant configuration on Citrix ADC is outlined below:

Connectivity Configuration:

```
set interface 10/1 -tagall ON -lacpMode ACTIVE -lacpKey 1

set interface 10/2 -tagall ON -lacpMode ACTIVE -lacpKey 1

set interface 10/3 -tagall ON -lacpMode ACTIVE -lacpKey 1

set interface 10/4 -tagall ON -lacpMode ACTIVE -lacpKey 1
<!--NeedCopy-->
```

You can verify the appropriate functionality of LACP using the “show interface” command:

show interface:

```
sh interface LA/1

    1)      Interface LA/1 (802.3ad Link Aggregate) #39

             flags=0x4100c020 <ENABLED, UP, AGGREGATE, UP, HAMON, 802.1
                q>

             MTU=1500, native vlan=1, MAC=02:e0:ed:33:88:b0, uptime 340
                h11m56s

             Requested: media NONE, speed AUTO, duplex NONE, fctl NONE,
```

```
                throughput 0

                Actual: throughput 4000

                LLDP Mode: NONE,

                RX: Pkts(918446) Bytes(110087414) Errs(0) Drops(795989)
                    Stalls(0)

                TX: Pkts(124113) Bytes(15255532) Errs(0) Drops(0) Stalls
                    (0)

                NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0)
                    Muted(0)

                Bandwidth thresholds are not set.

Disable the remaining unused interfaces and turn off the monitor.

set interface 10/5  -haMonitor OFF
<!--NeedCopy-->
```

Command:

```
set interface 10/24  -haMonitor OFF

disable interface 10/5

disable interface 10/24
<!--NeedCopy-->
```

Configuration of physical interfaces is not shared across the two Citrix ADC units. Hence, the above commands must be run across both Citrix ADC nodes in case of an HA pair deployment.

HA Configuration

All other configuration parameters are shared between the Citrix ADC nodes of an HA pair. Hence, HA sync should be enabled prior to any other configuration commands being run. Basic HA configuration involves the following steps:

1. Using the exact same Citrix ADC hardware, software, and license: HA pairs are not supported between different models (i.e. a T1100 and an MPX21550) or same models with different firmware levels. Refer to the appropriate instructions on upgrading an existing HA pair - Upgrading to Release 11.1.

2. Establishing the HA pair.

Example:

```
netscaler-1> add HA node 1 <netscaler-2-NSIP>

netscaler-2> add HA node 1 <netscaler-1-NSIP>
<!--NeedCopy-->
```

3. Verify the HA pair establishment running the following command in either node; both nodes should be visible, one of them as Primary (active), the other as a Secondary (standby).

Example:

```
show HA node
<!--NeedCopy-->
```

4. Enable failsafe mode and maxFlips. This ensures that in case of a route monitor failure on both nodes at least one node remains active without active/standby status constantly switching.

Example:

```
set HA node  - failsafe ON

set HA node -maxFlips 3 -maxFlipTime 1200
<!--NeedCopy-->
```

5. Finally, enable HA sync to occur over the dedicated intra-Citrix ADC ports rather than the OAM network.

Example:

```
add vlan 4080 -aliasName syncVlan

set HA node -syncvlan 4080
<!--NeedCopy-->
```

> **Note**
>
> The VLAN 4080 in the commands in the above example shouldn't be taken literally. Any unused VLAN-ID might be reserved.

VLAN Configuration

After the physical interfaces have been appropriately configured, you might configure the appropriate Gi-LAN VLANs. For instance, consider a rather simple Gi-LAN environment with an ingress/egress VLAN pair with 100/101 VLAN-identifier respectively.

The following commands configure the relevant VLANs on top of the LACP channel created in the prior step.

```
add vlan 100
add vlan 101
bind vlan 100 -ifnum LA/1 -tagged
bind vlan 101 -ifnum LA/1 -tagged
<!--NeedCopy-->
```

IPv4 Configuration

Typically, a Citrix ADC appliance requires one SNIP per VLAN. The example below assumes that the networks outlined in the Gi-LAN integration diagram, given in the begining of this page, have a /24 subnet mask:

```
add ns ip 192.168.1.254 255.255.255.0 -vserver DISABLED -mgmtAccess
    DISABLED
add ns ip 192.168.2.254 255.255.255.0 -vserver DISABLED -mgmtAccess
    DISABLED
<!--NeedCopy-->
```

After the SNIPs have been configured they should be associated with the appropriate VLAN:

```
bind vlan 100 -IPAddress 192.168.1.254 255.255.255.0
bind vlan 101 -IPAddress 192.168.2.254 255.255.255.0
<!--NeedCopy-->
```

IPv4 Static Routing

The example outlined in the Management Network section calls for only a couple of static routing rules:

- A 10.0.0.0/8 static route to the clients through the ingress router
- A default route to the internet through the egress router

Example:

```
add route 0.0.0.0 0.0.0.0 192.168.2.1
add route 10.0.0.0 255.0.0.0 192.168.1.1
<!--NeedCopy-->
```

IPv4 Policy-Based (VLAN - VLAN) routing

A Citrix ADC appliance allows for policy-based routing instead of static routing, with routing decisions usually keyed against the incoming interface and/or VLAN rather than destination IP. Policy-based routing is either a convenient alternative, in case the client source IP address range is subject to periodic changes, or a mandatory consideration, in case a packet's destination IP address is not sufficient by itself to reach a routing decision (i.e. in case of overlapping client IP addresses across multiple VLANs).

Example:

```
add ns pbr fromWirelessToInternet ALLOW -nextHop 192.168.2.1 -vlan
    100 -priority 10

Done

 add ns pbr fromInternetToWireless ALLOW -nextHop 192.168.1.1 -vlan
     200 -priority 20

Done

apply ns pbrs
<!--NeedCopy-->
```

IPv6 Configuration

The following commands assign IPv6 SNIP per vlan. The example below assumes that the networks outlined in the Figure: A simple depiction of a Gi-LAN in this page have a /64 subnet mask:

Command:

```
add ns ip6 fd00:192:168:1::254/64 -vServer DISABLED -mgmtAccess
    DISABLED
add ns ip6 fd00:192:168:2::254/64 -vServer DISABLED -mgmtAccess
    DISABLED
bind vlan 100 -IPAddress fd00:192:168:1::254/64
bind vlan 200 -IPAddress fd00:192:168:2::254/64
<!--NeedCopy-->
```

IPv6 Routing

After IPv6 addressing is complete, IPv6 static routing might be configured:

- A fd00:10::/64 static route to the clients via the ingress router

- A default route to the internet via the egress router

Example:

```
add route6 fd00:10::/64 fd00:192:168:1::1
add route6 ::/0 fd00:192:168:2::1
<!--NeedCopy-->
```

Or using policy-based routing:

Example:

```
add ns pbr6 fromWirelessToInternetv6 ALLOW -vlan 100 -priority 10 -
    nextHop fd00:192:168:2::1

add ns pbr6 fromInternetToWirelessv6 ALLOW -vlan 200 -priority 20 -
    nextHop fd00:192:168:1::1

apply ns pbr6
<!--NeedCopy-->
```

LACP Redundancy and Failover

In case of an HA configuration, it's recommended to leverage the throughput option to configure a low threshold for the LACP channel. For instance, consider a 25Gbps Gi-LAN and a 4x10GbE channel between each Citrix ADC appliance in the HA pair and the upstream switch to provide N+1 link redundancy:

Example:

```
set interface LA/1 -haMonitor ON -throughput 29000
<!--NeedCopy-->
```

In case of a double-link failure between the primary appliance and the upstream switch the maximum Gi-LAN throughput that can be supported would fall to 20Gbps. A 29Gbps low threshold per the example above would result in a redundancy switchover event to the secondary appliance (which has not suffered similar link failures) so that Gi-LAN traffic is not affected.

Route Monitors

In addition to LACP redundancy, route monitor checks might be configured and associated with the HA pair configuration. Route monitor checks can be useful to detect failures between the Citrix ADC appliance and the next-hop routers, especially if said routers are not directly connected but through an upstream switch.

A typical HA route monitor configuration per the sample Gi-LAN in section 2.5.1 is outlined below:

```
add route 192.168.1.0 255.255.255.0 192.168.1.1 -msr ENABLED -monitor
    arp
add route 192.168.2.0 255.255.255.0 192.168.2.1 -msr ENABLED -monitor
    arp
bind HA node -routeMonitor 192.168.1.0 255.255.255.0
bind HA node -routeMonitor 192.168.2.0 255.255.255.0
<!--NeedCopy-->
```

TCP optimization configuration

September 14, 2021

Before configuring TCP optimization, apply the following basic configuration settings on the Citrix ADC appliance:

Initial configuration:

```
enable ns feature LB IPv6PT
enable ns mode FR L3 USIP MBF Edge USNIP PMTUD
disable ns feature SP
disable ns mode TCPB
set lb parameter -preferDirectRoute NO
set lb parameter -vServerSpecificMac ENABLED
set l4param -l2ConnMethod Vlan
set rsskeytype -rsstype SYMMETRIC
set ns param -useproxyport DISABLED
<!--NeedCopy-->
```

> **Note**
>
> Restart the Citrix ADC appliance if you change the rsskeytype system parameter.

TCP termination

For Citrix ADC T1 to apply TCP optimization it needs to first terminate incoming TCP traffic. Towards this end, a wildcard TCP vserver should be created and configured to intercept ingress traffic and then forward it to the Internet router.

Static or dynamic routing environment

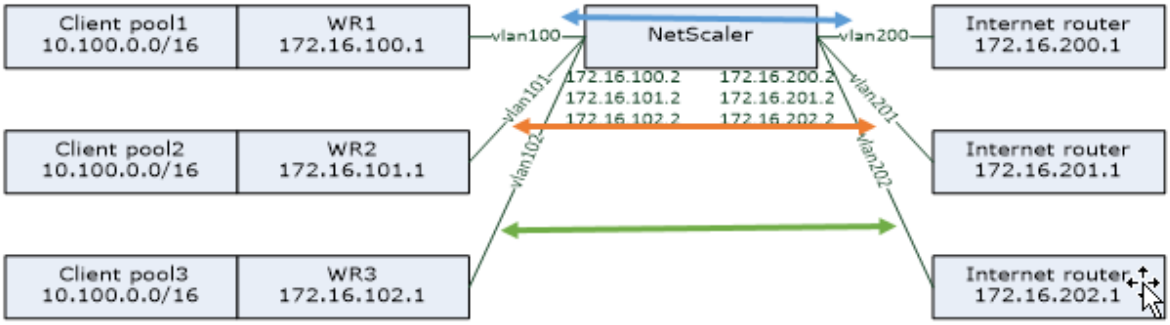
For environments with static or dynamic routing in place, vserver can rely on routing table info to forward packets towards internet router. Default route must point to the internet router and also routing entries for client subnets towards wireless router should be in place:

Example:

```
add lb vserver vsrv-wireless TCP * * -persistenceType NONE -
    Listenpolicy "CLIENT.VLAN.ID.EQ(100) && SYS.VSERVER(\"vsrv-wireless
    \").STATE.EQ(UP)" -m IP -cltTimeout 9000
add route 0.0.0.0 0.0.0.0 192.168.2.1
add route 10.0.0.0 255.0.0.0 192.168.1.1
<!--NeedCopy-->
```

VLAN-to-VLAN (PBR) environment

There are customer environments where subscriber traffic is segmented to multiple flows and needs to be forwarded to different routers based on incoming traffic parameters. Policy Based Routing (PBR) can be used to route packets based on incoming packet parameters, such as VLAN, MAC address, Interface, source IP, source port, destination IP address, and destination port.



Example:

```
add lb vserver vsrv-wireless TCP * * -m IP -l2Conn ON -listenpolicy "
    CLIENT.VLAN.ID.EQ(100) || CLIENT.VLAN.ID.EQ(101) || CLIENT.VLAN.ID.
    EQ(102)"

add ns pbr pbr-vlan100-to-vlan200 ALLOW -vlan 100 -nexthop 172.16.200.1

add ns pbr pbr-vlan101-to-vlan201 ALLOW -vlan 101 -nexthop 172.16.201.1

add ns pbr pbr-vlan102-to-vlan202 ALLOW -vlan 102 -nexthop 172.16.202.1
<!--NeedCopy-->
```

Using Policy Based Routing to route TCP optimized traffic is a new feature added in release 11.1 50.10. For previous releases, having multiple "mode MAC" vserver entities per VLAN is an alternative solution for multi-VLAN environments. Each vserver has a bound service representing the internet router for the particular flow.

Example:

```
add server internet_router_1 172.16.200.1

add server internet_router_2 172.16.201.1

add server internet_router_3 172.16.202.1

add service svc-internet-1 internet_router_1 TCP * -usip YES -
   useproxyport NO

add service svc-internet-2 internet_router_2 TCP * -usip YES -
   useproxyport NO

add service svc-internet-3 internet_router_3 TCP * -usip YES -
   useproxyport NO

bind service svc-internet-1 -monitorName arp

bind service svc-internet-2 -monitorName arp

bind service svc-internet-3 -monitorName arp

add lb vserver vsrv-wireless-1 TCP * * -Listenpolicy "CLIENT.VLAN.ID.EQ
   (100) && SYS.VSERVER(\"vsrv-wireless-1\").STATE.EQ(UP)" -m MAC -
   l2Conn ON

add lb vserver vsrv-wireless-2 TCP * * -Listenpolicy "CLIENT.VLAN.ID.EQ
   (101) && SYS.VSERVER(\"vsrv-wireless-2\").STATE.EQ(UP)" -m MAC -
   l2Conn ON

add lb vserver vsrv-wireless-3 TCP * * -Listenpolicy "CLIENT.VLAN.ID.EQ
   (102) && SYS.VSERVER(\"vsrv-wireless-3\").STATE.EQ(UP)" -m MAC -
   l2Conn ON

bind lb vserver vsrv-wireless-1 svc-internet-1

bind lb vserver vsrv-wireless-2 svc-internet-2

bind lb vserver vsrv-wireless-3 svc-internet-3
```

```
<!--NeedCopy-->
```

> **Note:**
>
> The vserver mode is MAC in contrast to previous examples where it is mode IP. This is required to retain the destination IP information when we have service(s) bound to vserver. Also, the additional PBR configuration need to route non-optimized traffic.

TCP optimization

Out-of-the-box Citrix ADC TCP termination is configured for TCP pass-through functionality. TCP pass-through essentially means that Citrix ADC T1 may transparently intercept a client-server TCP stream but does not retain separate client/server buffers or otherwise apply any optimization techniques.

To enable TCP optimization a TCP profile, named as nstcpprofile, is used to specify TCP configurations that is used if no TCP configurations are provided at the service or virtual server level and it should be modified as follows:

Command:

```
add ns tcpProfile nstcpprofile -WS ENABLED -SACK ENABLED -WSVal 8 -mss
    1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -
    bufferSize 4000000 -flavor BIC -dynamicReceiveBuffering ENABLED -KA
    ENABLED -sendBuffsize 4000000 -rstWindowAttenuate ENABLED -
    spoofSynDrop ENABLED -ecn ENABLED -frto ENABLED -maxcwnd 1000000 -
    fack ENABLED -rstMaxAck enABLED -tcpmode ENDPOINT
<!--NeedCopy-->
```

> **Note:**
>
> If there is not any profile explicitly created and bound to vserver and service, the profile nstcp_default_profile is bound by default.
>
> In case of multiple TCP profiles requirement, extra TCP profiles can be created and associated with the appropriate virtual server

Command:

```
add ns tcpProfile custom_profile -WS ENABLED -SACK ENABLED -WSVal 8 -
    mss 1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -
    bufferSize 4000000 -flavor BIC -dynamicReceiveBuffering ENABLED -KA
    ENABLED -sendBuffsize 4000000 -rstWindowAttenuate ENABLED -
    spoofSynDrop ENABLED -ecn ENABLED -frto ENABLED -maxcwnd 1000000 -
    fack ENABLED -rstMaxAck enABLED -tcpmode ENDPOINT

set lb vserver vsrv-wireless -tcpProfileName custom_profile
```

```
<!--NeedCopy-->
```

> **Note:**
>
> For deployments with vserver -m MAC and service, same profile should be associated with service.

```
set service svc-internet -tcpProfileName custom_profile
<!--NeedCopy-->
```

TCP optimization capabilities

Most of the relevant TCP optimization capabilities of a Citrix ADC appliance are exposed through a corresponding TCP profile. Typical CLI parameters that should be considered when creating a TCP profile are the following:

1. **Window Scaling (WS)**: TCP Window scaling allows increasing the TCP receive window size beyond 65535 bytes. It helps improving TCP performance overall and specially in high bandwidth and long delay networks. It helps with reducing latency and improving response time over TCP.
2. **Selective acknowledgment (SACK)**: TCP SACK addresses the problem of multiple packet loss which reduces the overall throughput capacity. With selective acknowledgement the receiver can inform the sender about all the segments which are received successfully, enabling sender to only retransmit the segments which were lost. This technique helps T1 improve overall throughput and reduce the connection latency.
3. **Window Scaling Factor (WSVal)**: Factor used to calculate the new window size. It must be configured with a high value in order to allow the advertised window by NS to be at least equal to the buffer size.
4. **Maximum Segment Size (MSS)**: MSS of a single TCP segment. This value depends on the MTU setting on intermediate routers and end clients. A value of 1460 corresponds to an MTU of 1500.
5. **maxBurst**: Maximum number of TCP segments allowed in a burst.
6. **Initial Congestion Window size(initialCwnd)**: TCP initial congestion window size determines the number of bytes which can be outstanding in beginning of the transaction. It enables T1 to send those many bytes without bothering for congestion on the wire.
7. **Maximum OOO packet queue size(oooQSize)**: TCP maintains Out Of Order queue to keep the OOO packets in the TCP communication. This setting impacts system memory if the queue size is long as the packets need to be kept in runtime memory. Thus this needs to be kept at optimized level based on the kind of network and application characteristics.
8. **Minimum RTO(minRTO)**: The TCP retransmission timeout is calculated on each received ACK based on internal implementation logic. The default retransmission timeout happens at 1 second to start with and this can be tweaked with this setting. For second retransmission of these packets RTO will be calculated by N*2 and then N*4 … N*8… goes on till last retransmission

attempt.

9. **bufferSize/sendBuffsize**: these refer to the maximum amount of data that the T1 may receive from the server and buffer internally without sending to the client. They should be set to a value larger (at least double) than the Bandwidth Delay Product of the underlying transmission channel.
10. **flavor**: this refers to the TCP congestion control algorithm. Valid values are Default, BIC, CUBIC, Westwood and Nile.
11. **Dynamic receive buffering**: allows the receive buffer to be adjusted dynamically based on memory and network conditions. It will fill up the buffer as much as it's required to keep the client's download pipe full instead of filling up, by reading ahead from server, a fixed size buffer, as latter is specified in TCP profile and typically based on criteria such as 2*BDP, for a connection. Citrix ADC T1 monitors the network conditions to the client and estimates how much it should read ahead from the server.
12. **Keep-Alive (KA)**: Send periodic TCP keep-alive (KA) probes to check if peer is still up.
13. rstWindowAttenuate: Defending TCP against spoofing attacks. It will reply with corrective ACK when a sequence number is invalid.
14. **rstMaxAck**: Enable or disable acceptance of RST that is out of window yet echoes highest ACK sequence number.
15. **spoofSynDrop**: Drop of invalid SYN packets to protect against spoofing.
16. **Explicit Congestion Notification(ecn)**: It sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption.
17. **Forward RTO-Recovery**: In case of spurious retransmissions, the congestion control configurations are reverted to their original state.
18. **TCP maximum congestion window (maxcwnd)**: TCP maximum congestion window size that is user configurable.
19. **Forward acknowledgment (FACK)**: To avoid TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either T1 or a client) control the amount of data injected into the network during retransmission timeouts.
20. **tcpmode**: TCP optimization modes for specific profile. There are two TCP optimization modes - Transparent and Endpoint.

- Endpoint. In this mode, the appliance manages the client and server connections seperately.
- Transparent. In the transparent mode the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them. In the example shown in the following figure, a NetScaler appliance is placed between the client and the server, so the traffic must pass through the appliance.

Silently dropping idle connections

In a telco network, almost 50 percent of a Citrix ADC appliance's TCP connections become idle, and the appliance sends RST packets to close them. The packets sent over radio channels activate those channels unnecessarily, causing a flood of messages that in turn cause the appliance to generate a flood of service-reject messages. The default TCP profile now includes DropHalfClosedConnOnTimeout and DropEstConnOnTimeout parameters, which by default are disabled. If you enable both of them, neither a half closed connection nor an established connection causes a RST packet to be sent to the client when the connection times out. The appliance just drops the connection.

```
set ns tcpProfile nstcpprofile  -DropHalfClosedConnOnTimeout ENABLED
set ns tcpProfile nstcpprofile  -DropEstConnOnTimeout ENABLED
<!--NeedCopy-->
```

Analytics and Reporting

September 14, 2021

The TCP Speed Reporting is a Citrix ADC feature which extracts TCP connection statistics, as a measure of TCP download and upload performance, and is utilized in TCP Insight reports of the Citrix Application Delivery Management (ADM). To achieve this, Citrix ADC monitors each TCP connection, locates packet bursts on an idle time-out basis and reports key metrics (such as byte count, retransmitted byte count and duration) for the identified maximum burst. TCP Speed Reporting feature is enabled by default, support both TCP and HTTP vServers and depends on the Appflow/ULFD reporting infrastructure.

Real-time Statistics

September 14, 2021

The stat command might be used to verify that TCP optimization is properly applied:

Command:

```
> stat lb vserver vsrv-wireless
Virtual Server Summary
                      vsvrIP  port     Protocol        State   Health
                         actSvcs
vsrv...eless              *     0          TCP           UP      100
           1
```

The Total counters should constantly increase for an operational system. In addition, the Rate counters should be non-zero.

> **Note**
>
> The preceding output is from an operational yet idle lab system, explaining the zero rate.

SNMP

September 14, 2021

SNMP agent can be queried for system specific information from a remote device (SNMP Manager). Based on the query, the agent searches for the equal object identifier (OID) in the management information base (MIB) for the data requested and sends the information to the SNMP Manager. The following are the most useful SNMP OIDs for Telco deployments:

Memory

- **resMemUsage (1.3.6.1.4.1.5951.4.1.1.41.2)**

Percentage of memory utilization on Citrix ADC.

Packet Engine CPU

- **resCpuUsage (1.3.6.1.4.1.5951.4.1.1.41.1)**

CPU utilization percentage.

- **nsCPUTable (1.3.6.1.4.1.5951.4.1.1.41.6)**

This table contains information about each CPU in Citrix ADC.

Indexed on: nsCPUname

- **nsCPUname (1.3.6.1.4.1.5951.4.1.1.41.6.1.1)**

The name of the CPU.

- **nsCPUusage (1.3.6.1.4.1.5951.4.1.1.41.6.1.2)**

CPU utilization percentage.

Throughput

- **allNicTotRxMbits (1.3.6.1.4.1.5951.4.1.1.71.1)**

Number of megabits received by the Citrix ADC appliance.

- **allNicTotTxMbits (1.3.6.1.4.1.5951.4.1.1.71.2)**

Number of megabits transmitted by the Citrix ADC appliance.

- **ipTotRxPkts (1.3.6.1.4.1.5951.4.1.1.43.25)**

IP packets received.

- **ipTotRxMbits (1.3.6.1.4.1.5951.4.1.1.43.27)**

Megabits of IP data received.

- **ipTotTxPkts (1.3.6.1.4.1.5951.4.1.1.43.28)**

IP packets transmitted.

- **ipTotTxMbits (1.3.6.1.4.1.5951.4.1.1.43.30)**

Megabits of IP data transmitted.

Connections

Active connections:

- **tcpActiveServerConn (1.3.6.1.4.1.5951.4.1.1.46.8)**

Connections to a server currently responding to requests.

Total connections:

- **tcpCurServerConn (1.3.6.1.4.1.5951.4.1.1.46.1)**

Server connections, including connections in the Opening, Established, and Closing state.

- **tcpCurClientConn (1.3.6.1.4.1.5951.4.1.1.46.2)**

Client connections, including connections in the Opening, Established, and Closing state.

Note: Because of SYN-Cookie, this doesn't include Client in Opening state

- **tcpTotZombieCltConnFlushed (1.3.6.1.4.1.5951.4.1.1.46.26)**

Client connections that are flushed because the client has been idle for some time.

- **tcpTotZombieSvrConnFlushed (1.3.6.1.4.1.5951.4.1.1.46.27)**

Server connections that are flushed because there have been no client requests in the queue for some time.

Errors

- **tcpErrSynGiveUp (1.3.6.1.4.1.5951.4.1.1.46.37)**

Attempts to establish a connection on the Citrix ADC that timed out.

- **tcpErrRetransmitGiveUp (1.3.6.1.4.1.5951.4.1.1.46.60)**

Number of times Citrix ADC terminates a connection after retransmitting the packet seven times on that connection. Retransmission happens when recieving end doesn't acknowledges the packet.

- **ifInDiscards (1.3.6.1.2.1.2.2.1.13)**

The number of inbound packets which were chosen to be discarded even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space.

- **ifOutDiscards (1.3.6.1.2.1.2.2.1.19)**

The number of outbound packets which were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space.

- **ifErrTxOverflow (1.3.6.1.4.1.5951.4.1.1.54.1.36)**

Number of packets that have passed through the overflow queues, during transmission on the specified interface, since the Citrix ADC appliance was started or the interface statistics were cleared. This gets incremented only on congested ports.

Optimized/Bypass connections

- **tcpOptimizationEnabled (1.3.6.1.4.1.5951.4.1.1.46.131)**

Total number of connections enabled with TCP optimization.

- **tcpOptimizationBypassed (1.3.6.1.4.1.5951.4.1.1.46.132)**

Total number of connections bypassed TCP Optimization.

Technical Recipes

September 14, 2021

The Citrix ADC T1 models provide advanced features and a powerful policy configuration language that allow for evaluation of complex decision in runtime.

While it is not possible to evaluate all capabilities that are potentially unlocked by the T1000 features and policy configuration guide, technical receipes consider implementation of various requirements brought in by Telco operators. Feel free to re-use the "recipes" as is or adapt to your environment.

Per-user Connection Limit

The Citrix ADC T1 model can be configured to limit the number of connections per unique subscriber IP. With the below configuration, N concurrent TCP connections per IP (CLIENT.IP.SRC) is allowed. For every attempt for connection beyond the configured threshold, T1 sends an RST. For maximum 2 concurrent connections per user:

Command:

```
add stream selector streamSel_usrlimit CLIENT.IP.SRC
add ns limitIdentifier limitId_usrlimit -threshold 2 -mode CONNECTION -
    selectorName streamSel_usrlimit
add responder policy respPol_usrlimit "SYS.CHECK_LIMIT(\"
    limitId_usrlimit\")" RESET
bind lb vserver vsrv-wireless -policyName respPol_usrlimit -priority 1
    -gotoPriorityExpression END
<!--NeedCopy-->
```

Smooth Insertion/Deletion of Vserver

Many operators concern about TCP connections disruption when the Citrix ADC T1 model is activated inline for TCP optimization or when it is disabled for maintenance purposes. To avoid breaking existing connections when vserver is introduced, the following configuration needs to be applied before configuring or activating vserver for TCP optimization:

Command:

```
add ns acl acl-ingress ALLOW  - vlan 100
add forwardingSession fwd-ingress  - aclname acl-ingress
apply ns acls
<!--NeedCopy-->
```

Forwarding sessions are effective on top of routing (either static or dynamic or PBR) and create session entries for traffic that is routed (L3 mode). Any existing connection is handled by forwarding session due to corresponding sessions, and upon vserver introduction it starts capturing only new TCP connections.

ACLs can be configured to capture only specific ports like vserver, in order to avoid creating sessions for unnecessary traffic, which is memory consuming. Another option is to remove specific configuration after vserver activation.

For maintenance purposes, vserver should be disabled and its state appears as OUT OF SERVICE. When this happens, the vserver terminates all connections immediately by default. To make vserver to still serve the existing connections and not accept new, the following configuration should be applied:

Command:

```
set lb vserver vsrv-wireless  -downStateFlush DISABLED
<!--NeedCopy-->
```

New connections go through the routing table, and corresponding session entries are created due to forwarding sessions.

Policy-Based TCP Profiling

Policy-based TCP Profile selection allows operators to configure TCP profile dynamically for clients coming from different traffic domains (i.e. 3G or 4G). Some of the QoS metrics are different for these traffic domains, and in order to achieve better performance, you need to change some of the TCP parameter dynamically. Consider a case where clients coming from 3G and 4G hit same vserver and use same TCP profile, which have negative impact on some client's performance. AppQoE functionality can classify these clients and dynamically change TCP profile on vserver.

Example:

```
enable feature AppQoE

add ns tcpProfile nstcpprofile1 -WS ENABLED -SACK ENABLED -WSVal 8 -mss
     1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -
    slowStartIncr 1 -bufferSize 4000000 -flavor BIC -KA ENABLED -
    sendBuffsize 4000000 -rstWindowAttenuate ENABLED -spoofSynDrop
    ENABLED -frto ENABLED -maxcwnd 1000000 -fack ENABLED -tcpmode
    ENDPOINT

add ns tcpProfile nstcpprofile2 -WS ENABLED -SACK ENABLED -WSVal 8 -mss
     1460 -maxBurst 15 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -
    slowStartIncr 1 -bufferSize 128000 -flavor BIC -KA ENABLED -
```

```
    sendBuffsize 6000000 -rstWindowAttenuate ENABLED -spoofSynDrop
    ENABLED -frto ENABLED -maxcwnd 64000 -fack ENABLED -tcpmode ENDPOINT
6
7 add appqoe action action_1 -priority HIGH -tcpprofile nstcpprofile1
8
9 add appqoe action action_2 -priority HIGH -tcpprofile nstcpprofile2
10
11 add appqoe policy appqoe_4G -rule "CLIENT.VLAN.ID.EQ(100)" -action
    action_1
12
13 add appqoe policy appqoe_3G -rule "CLIENT.VLAN.ID.EQ(200)" -action
    action_2
14
15 bind lb vserver vsrv-wireless -policyName appqoe_4G -priority 100
16
17 bind lb vserver vsrv-wireless -policyName appqoe_3G -priority 110
18 <!--NeedCopy-->
```

The Citrix ADC T1 model is capable to receive the subscriber information dynamically through Gx or Radius or Radius and Gx interface and apply different TCP profile on a per-subscriber basis.

Command:

```
1 add appqoe action action_1 -priority HIGH -tcpprofile nstcpprofile1
2
3 add appqoe action action_2 -priority HIGH -tcpprofile nstcpprofile2
4
5 add appqoe policy appqoe_4G -rule "SUBSCRIBER.RULE_ACTIVE(\"3G\")" -
    action action_1
6
7 add appqoe policy appqoe_3G -rule "SUBSCRIBER.RULE_ACTIVE(\"4G\")" -
    action action_2
8 <!--NeedCopy-->
```

For integration of the Citrix ADC T1 model with operator control-plane network, see Telco Subscriber Management.

Scalability

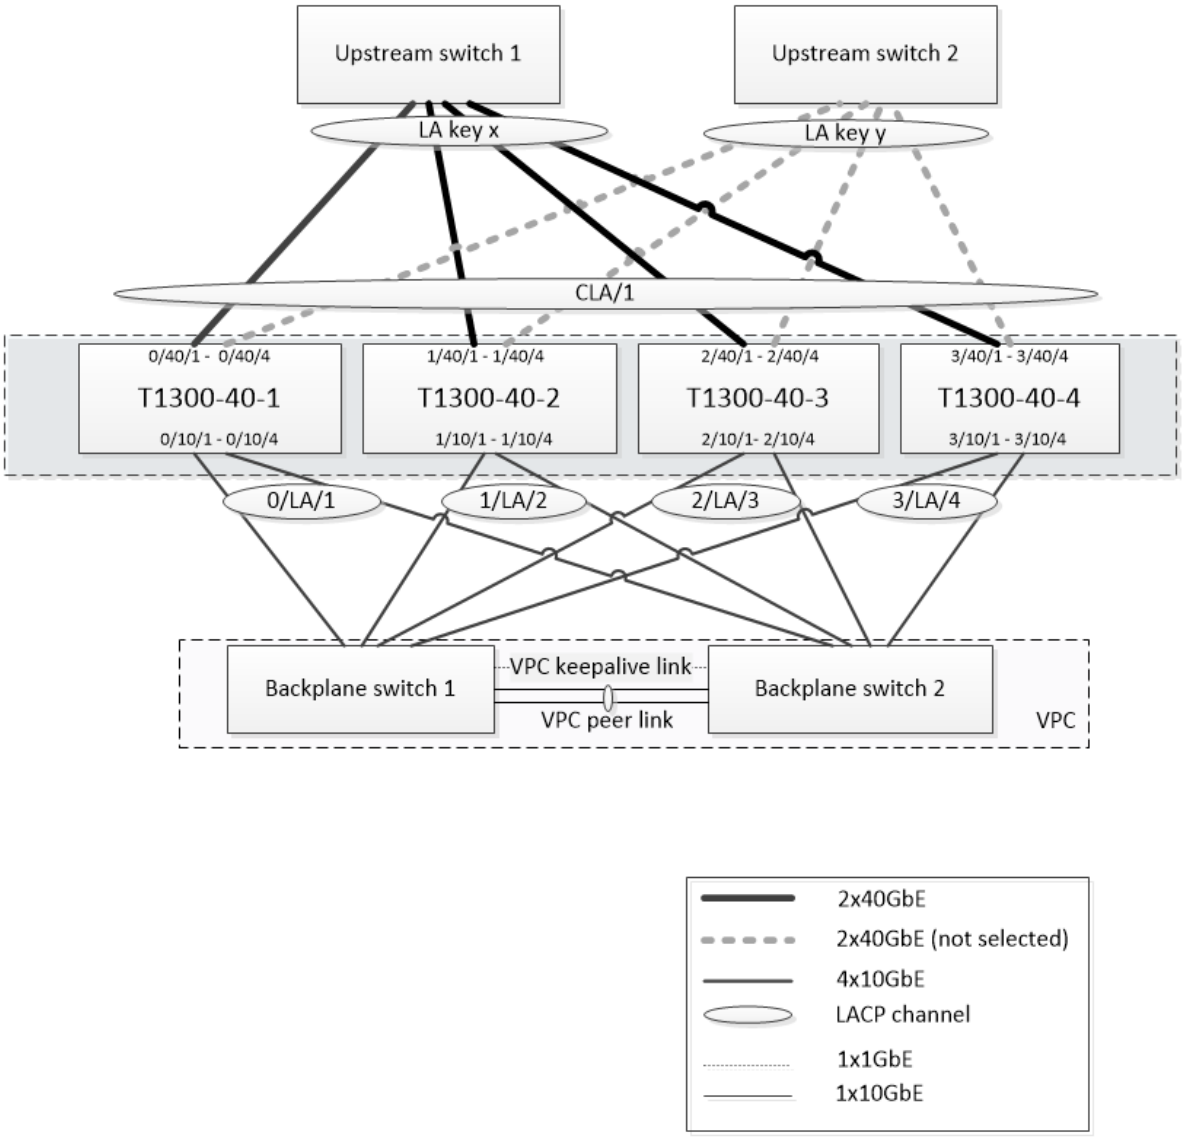
September 14, 2021

Because TCP optimization is resource intensive, a single Citrix ADC appliance, even a high end –appliance, might not be able to sustain high Gi-LAN throughputs. To expand the capacity of your

network, you can deploy Citrix ADC appliances in an N+1 cluster formation. In a cluster deployment, the Citrix ADC appliances work together as a single system image. The client traffic is distributed across the cluster nodes with the help of external switch device.

Topology

Figure 1 is an example of a cluster consisting of four T1300-40G nodes.



The setup shown in Figure 1 has the following properties:

1. All cluster nodes belong to the same network (also known as an L2 cluster).
2. Data plane and backplane traffic are handled by different switches.
3. Assuming Gi-LAN throughput is 200 Gbps and that a T1300-40G appliance can sustain 80Gbps of throughput, we need three T1300-40G appliances. To provide redundancy in case of single

cluster node failure, we deploy four appliances in total.

4. Each node will receive up to 67Gbps of traffic (50Gbps in normal operating conditions and 67Gbps in case of single cluster node failure), so it needs 2x40Gbps connections to the upstream switch. To provide redundancy in case of switch failure, we deploy a couple of upstream switches and double the number of connections.
5. Cluster Link Aggregation (CLAG) is used to distribute traffic across cluster nodes. A single CLAG handles both client and server traffic. Link Redundancy is enabled on the CLAG, so only one "subchannel" is selected at any given time and handles the traffic. If some link fails or throughput falls below specified threshold, the other subchannel is selected.
6. The upstream switch performs symmetric port-channel load balancing (for example, source-dest-ip-only algorithm of Cisco IOS 7.0(8) N1(1)) so that forward and reverse traffic flows are handled by the same cluster node. This property is desirable because it eliminates packet reordering, which would degrade TCP performance.
7. Fifty percent of data traffic is expected to be steered to backplane, which means each node will steer up to 34Gbps to other cluster nodes (25Gbps in normal operating conditions and 34Gbps in case of single cluster node failure). Thus, each node needs at least 4x10G connections to the backplane switch. To provide redundancy in case of switch failure, we deploy a couple of backplane switches and double the number of connections. Link redundancy is not currently supported for backplane, so Cisco VPC or equivalent technology is desired to achieve switch-level redundancy.
8. MTU size of steered packets is 1578 bytes, so backplane switches must support an MTU more than 1500 bytes.

Note: The design depicted in Figure 1 is also applicable to T1120 and T1310 appliances. For T1310 we would use 40GbE interfaces for the backplane connections, since it lacks 10GbE ports.

Note: While this document uses Cisco VPC as an example, if working with non-Cisco switches alternate equivalent solutions could be used, such as Juniper's MLAG.

Note: While other topologies such as ECMP instead of CLAG are possible, they are not currently supported for this particular use case.

Configuring TCP Optimization in a Citrix ADC T1000 Cluster

After physical installation, physical connectivity, software installation, and licensing are completed, you can proceed with the actual cluster configuration. The configurations described below apply to the cluster depicted in Figure 1.

Note: For more information about cluster configuration, see Setting up a Citrix ADC cluster.

Assume that the four T1300 nodes in Figure 1 have the following NSIP addresses:

Four T1300 nodes with NSIP address:

```
T1300-40-1: 10.102.29.60
T1300-40-2: 10.102.29.70
T1300-40-3: 10.102.29.80
T1300-40-4: 10.102.29.90
```

The cluster will be managed through the cluster IP (CLIP) address, which is assumed to be 10.78.16.61.

Setting Up the Cluster

To begin configuring the cluster shown in Figure 1, log on to the first appliance that you want to add to the cluster (for example, T1300-40-1) and do the following.

1. At the command prompt, enter the following commands:

   Command:

   ```
   > add cluster instance 1
   > add cluster node 0 10.102.29.60 -state ACTIVE
   > add ns ip 10.102.29.61 255.255.255.255 -type clip
   > enable cluster instance 1
   > save ns config
   > reboot  - warm
   ```

2. After the appliance restarts, connect to the Cluster IP (CLIP) address and add the rest of the nodes to the cluster:

   Command:

   ```
   > add cluster node 1 10.102.29.70 -state ACTIVE
   > add cluster node 2 10.102.29.80 -state ACTIVE
   > add cluster node 3 10.102.29.90  - state ACTIVE
   > save ns config
   ```

3. Connect to the NSIP address of each of the newly added nodes and join the cluster:

   Command:

   ```
   > join cluster -clip 10.102.29.61 -password nsroot
   > save ns config
   > reboot  - warm
   ```

4. After the nodes restart, proceed with backplane configuration. On the cluster IP address, enter the following commands to create an LACP channel for the backplane link of each cluster node:

   Command:

```
> set interface 0/10/[1-8] -lacpkey 1 -lacpmode ACTIVE
> set interface 1/10/[1-8] -lacpkey 2 -lacpmode ACTIVE
> set interface 2/10/[1-8] -lacpkey 3 -lacpmode ACTIVE
> set interface 3/10/[1-8] -lacpkey 4 -lacpmode ACTIVE
```

5. Similarly, configure dynamic LA and VPC on the backplane switches. Make sure the MTU of the backplane switch interfaces is at least 1578 bytes.
6. Verify the channels are operational:

   Command:

```
> show channel 0/LA/1
> show channel 1/LA/2
> show channel 2/LA/3
> show channel 3/LA/4
```

7. Configure the cluster node backplane interfaces.

   Command:

```
> set cluster node 0 -backplane 0/LA/1
> set cluster node 1 -backplane 1/LA/2
> set cluster node 2 -backplane 2/LA/3
> set cluster node 3 -backplane 3/LA/4
```

8. Check the cluster status and verify that the cluster is operational:

```
> show cluster instance
> show cluster node
```

For more information on cluster setup, see Setting up a Citrix ADC cluster

Distributing Traffic Across Cluster Nodes

After you have formed theCitrix ADC cluster, deploy Cluster Link Aggregation (CLAG) to distribute traffic across cluster nodes. A single CLAG link will handle both client and server traffic.

On the cluster IP address, execute the following commands to create the Cluster Link Aggregation (CLAG) group shown in Figure 1:

Command:

```
> set interface 0/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster
> set interface 1/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster
> set interface 2/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster
```

```
4 > set interface 3/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster
```

Configure dynamic link aggregation on the external switches.

Then, enable Link Redundancy as follows:

Code:

```
1 > set channel CLA/1 -linkRedundancy ON -lrMinThroughput 240000
```

Finally, check the channel status by entering:

Command:

```
1 > show channel CLA/1
```

The channel should be UP and the actual throughput should be 320000.

For more information about cluster link aggregation, see the following topics:

- Dynamic Cluster Link Aggregation
- Link Redundancy in a Cluster with LACP.

Because we will be using MAC-based forwarding (MBF), configure a linkset and bind it to the CLAG group as follows:

Command:

```
1 > add linkset LS/1
2 > bind linkset LS/1 -ifnum CLA/1
```

More information about linksets, see the following topics:

- Configuring Linksets
- Using Cluster LA Channel with Linksets

Configuring VLAN and IP Addresses

We will be using striped IP configuration, which means that IP addresses are active on all nodes (default setting). See Striped, Partially Striped, and Spotted Configurations for more information about this topic.

1. Add the ingress and egress SNIPs:

   Command:

   ```
   1 > add ns ip 172.16.30.254 255.255.255.0 -type SNIP
   2 > add ns ip 172.16.31.254 255.255.255.0 -type SNIP
   3 > add ns ip6 fd00:172:16:30::254/112 -type SNIP
   ```

```
4 > add ns ip6 fd00:172:16:31::254/112 -type SNIP
```

2. Add the corresponding ingress and egress VLANs:

   Command:

```
1 > add vlan 30 -aliasName wireless
2 > add vlan 31 -aliasName internet
```

3. Bind VLANs with IPs and linkset:

   Command:

```
1 > bind vlan 31 -ifnum LS/1 -tagged
2 > bind vlan 30 -ifnum LS/1 -tagged
3 > bind vlan 30 -IPAddress 172.16.30.254 255.255.255.0
4 > bind vlan 31 -IPAddress 172.16.31.254 255.255.255.0
5 > bind vlan 30 -IPAddress fd00:172:16:30::254/112
6 > bind vlan 31 -IPAddress fd00:172:16:31::254/112
```

More ingress and egress VLANs can be added if needed.

Configuring TCP Optimization

At this point, we have applied all cluster specific commands. To complete the configuration, follow the steps described in TCP optimization configuration.

Configuring Dynamic Routing

A Citrix ADC cluster can be integrated into the dynamic routing environment of the customer's network. Following is an example of dynamic routing configuration using BGP routing protocol (OSPF is also supported).

1. From the CLIP address, enable BGP and dynamic routing on ingress and egress IP addresses:

   Command:

```
1 > enable ns feature bgp
2 > set ns ip 172.16.30.254 -dynamicRouting ENABLED
3 > set ns ip 172.16.31.254 -dynamicRouting ENABLED
```

2. Open vtysh and configure BGP for the egress side:

   Code:

```
> shell
root@ns# vtysh
ns# configure terminal
ns(config)# router bgp 65531
ns(config-router)# network 10.0.0.0/24
ns(config-router)# neighbor 172.16.31.100 remote-as 65530
ns(config-router)# neighbor 172.16.31.100 update-source
    172.16.31.254
ns(config-router)# exit
ns(config)# ns route-install propagate
ns(config)# ns route-install default
ns(config)# ns route-install bgp
ns(config)# exit
```

3. Configure the egress-side BGP peer to advertise the default route to the Citrix ADC cluster. For example:

   Command:

```
router bgp 65530
 bgp router-id 172.16.31.100
 network 0.0.0.0/0
 neighbor 172.16.31.254 remote-as 65531
```

4. Follow similar steps to configure the ingress side.
5. From vtysh verify that configuration is propagated to all cluster nodes, by entering:

   Command:

```
ns# show running-config
```

6. Finally, log on to NSIP address of each cluster node and verify routes advertised from BGP peer:

   Command:

```
> show route | grep BGP
```

Optimizing TCP Performance using TCP Nile

September 14, 2021

TCP uses the following optimization techniques and congestion control strategies (or algorithms) to avoid network congestion in data transmission.

Congestion Control Strategies

The Transmission Control Protocol (TCP) has long been used to establish and manage Internet connections, handle transmission errors, and smoothly connect web applications with client devices. But network traffic has become more difficult to control, because packet loss does not depend only on the congestion in the network, and congestion does not necessarily cause packet loss. Therefore, to measure congestion, a TCP algorithm should focus on both packet loss and bandwidth.

NILE Algorithm

Citrix Systems has developed a new congestion-control algorithm, NILE, a TCP optimization algorithm designed for high-speed networks such as LTE, LTE advanced and 3G. Nile addresses unique challenges caused by fading, random or congestive losses, link layer retransmissions and carrier aggregation.

The NILE algorithm:

- Bases queue-latency estimates on round-trip time measurements.
- Uses a congestion-window-increase function that is inversely proportional to the measured queue latency. This method results in approaching the network congestion point more slowly than does the standard TCP method, and reduces the packet losses during congestion.
- Can distinguish between random loss and congestion based loss on the network by using the estimated queue latency.

The telecom service providers can use the NILE algorithm in their TCP infrastructure to:

- Optimize mobile and long-distance networks— The NILE algorithm achieves higher throughput compared to standard TCP. This feature is especially important for mobile and long-distance networks.
- Decrease application perceived latency and enhance subscriber experience— The Nile algorithm uses packet loss information to determine whether the transmission-window size should be increased or decreased, and uses queuing delay information to determine the size of the increment or decrement. This dynamic setting of transmission-window size decreases the application latency on the network.

To configure NILE support using the command line interface

At the command prompt, type the following:

```
set ns tcpProfile <name> [-flavor NILE]
<!--NeedCopy-->
```

Configuring NILE support using the configuration utility

1. Navigate to **System** > **Profiles** > **TCP Profiles** and click **TCP profiles**.
2. From the **TCP Flavor** drop-down list, select **NILE**.

Example:

```
set ns tcpProfile tcpprofile1 -flavor NILE
<!--NeedCopy-->
```

Proportional Rate Recovery (PRR) Algorithm

TCP Fast Recovery mechanisms reduce web latency caused by packet losses. The new Proportional Rate Recovery (PRR) algorithm is a fast recovery algorithm that evaluates TCP data during a loss recovery. It is patterned after Rate-Halving, by using the fraction that is appropriate for the target window chosen by the congestion control algorithm. It minimizes window adjustment, and the actual window size at the end of recovery is close to the Slow-Start threshold (ssthresh).

TCP Fast Open (TFO)

TCP Fast Open (TFO) is a TCP mechanism that enables speedy and safe data exchange between a client and a server during TCP's initial handshake. This feature is available as a TCP option in the TCP profile bound to a virtual server of a Citrix ADC appliance. TFO uses a TCP Fast Open Cookie (a security cookie) that the Citrix ADC appliance generates to validate and authenticate the client initiating a TFO connection to the virtual server. By using the TFO mechanism, you can reduce an application's network latency by the time required for one full round trip, which significantly reduces the delay experienced in short TCP transfers.

How TFO works

When a client tries to establish a TFO connection, it includes a TCP Fast Open Cookie with the initial SYN segment to authenticate itself. If authentication is successful, the virtual server on the Citrix ADC appliance can include data in the SYN-ACK segment even though it has not received the final ACK segment of the three-way handshake. This saves up to one full round-trip compared to a normal TCP connection, which requires a three-way handshake before any data can be exchanged.

A client and a backend server perform the following steps to establish a TFO connection and exchange data securely during the initial TCP handshake.

1. If the client does not have a TCP Fast Open Cookie to authenticate itself, it sends a Fast Open Cookie request in the SYN packet to the virtual server on the Citrix ADC appliance.

2. If the TFO option is enabled in the TCP profile bound to the virtual server, the appliance generates a cookie (by encrypting the client's IP address under a secret key) and responds to the client with a SYN-ACK that includes the generated Fast Open Cookie in a TCP option field.
3. The client caches the cookie for future TFO connections to the same virtual server on the appliance.
4. When the client tries to establish a TFO connection to the same virtual server, it sends SYN that includes the cached Fast Open Cookie (as a TCP option) along with HTTP data.
5. The Citrix ADC appliance validates the cookie, and if the authentication is successful, the server accepts the data in the SYN packet and acknowledges the event with a SYN-ACK, TFO Cookie, and HTTP Response.

Note: If the client authentication fails, the server drops the data and acknowledges the event only with a SYN indicating a session timeout.

1. On the server side, if the TFO option is enabled in a TCP profile bound to a service, the Citrix ADC appliance determines whether the TCP Fast Open Cookie is present in the service to which it is trying to connect.
2. If the TCP Fast Open Cookie is not present, the appliance sends a cookie request in the SYN packet.
3. When the backend server sends the Cookie, the appliance stores the cookie in the server information cache.
4. If the appliance already has a cookie for the given destination IP pair, it replaces the old cookie with the new one.
5. If the cookie is available in the server information cache when the virtual server tries to reconnect to the same backend server by using the same SNIP address, the appliance combines the data in SYN packet with the cookie and sends it to the backend server.
6. The backend server acknowledges the event with both data and a SYN.

Note: If the server acknowledges the event with only a SYN segment, the Citrix ADC appliance immediately resends the data packet after removing the SYN segment and the TCP options from the original packet.

Configuring TCP Fast Open

To use the TCP Fast Open (TFO) feature, enable the TCP Fast Open option in the relevant TCP profile and set the TFO Cookie Timeout parameter to a value that suits the security requirement for that profile.

To enable or disable TFO by using the command line

At the command prompt, type one of the following commands to enable or disable TFO in a new or existing profile.

Note: The default value is DISABLED.

```
add tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED
set tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED
unset tcpprofile <TCP Profile Name> - tcpFastOpen
<!--NeedCopy-->
```

Examples:

add tcpprofile Profile1 – tcpFastOpen
Set tcpprofile Profile1 – tcpFastOpen Enabled
unset tcpprofile Profile1 – tcpFastOpen

To set TCP Fast Open cookie timeout value by using the command line interface

At the command prompt, type:

```
set tcpparam  - tcpfastOpenCookieTimeout <Timeout Value>
<!--NeedCopy-->
```

Example:

```
set tcpprofile  - tcpfastOpenCookieTimeout 30secs
<!--NeedCopy-->
```

To configure the TCP Fast Open by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **TCP Fast Open** checkbox.
3. Click **OK** and then **Done**.

To Configure the TCP Fast Cookie timeout value by using the GUI

Navigate to **Configuration** > **System** > **Settings** > **Change TCP Parameters** and then **Configure TCP Parameters** page to set the TCP Fast Open Cookie timeout value.

TCP Hystart

A new TCP profile parameter, hystart, enables the Hystart algorithm, which is a slow-start algorithm that dynamically determines a safe point at which to terminate (ssthresh). It enables a transition to congestion avoidance without heavy packet losses. This new parameter is disabled by default.

If congestion is detected, Hystart enters a congestion avoidance phase. Enabling it gives you better throughput in high-speed networks with high packet loss. This algorithm helps maintain close to maximum bandwidth while processing transactions. It can therefore improve throughput.

Configuring TCP Hystart

To use the Hystart feature, enable the Cubic Hystart option in the relevant TCP profile.

To configure Hystart by using the command line interface (CLI)

At the command prompt, type one of the following commands to enable or disable Hystart in a new or existing TCP profile.

```
add tcpprofile <profileName> -hystart ENABLED
set tcpprofile <profileName> -hystart ENABLED
unset tcprofile <profileName> -hystart
<!--NeedCopy-->
```

Examples:

```
add tcpprofile Profile1 - tcpFastOpen
Set tcpprofile Profile1 - tcpFastOpen Enabled
unset tcpprofile Profile1 - tcpFastOpen
<!--NeedCopy-->
```

To configure Hystart support by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **Cubic Hystart** check box.
3. Click **OK** and then **Done**.

Optimization Techniques

TCP uses the following optimization techniques and methods for optimized flow controls.

Policy based TCP Profile Selection

Network traffic today is more diverse and bandwidth-intensive than ever before. With the increased traffic, the effect that Quality of Service (QoS) has on TCP performance is significant. To enhance QoS, you can now configure AppQoE policies with different TCP profiles for different classes of network traffic. The AppQoE policy classifies a virtual server's traffic to associate a TCP profile optimized for a particular type of traffic, such as 3G, 4G, LAN, or WAN.

To use this feature, create a policy action for each TCP profile, associate an action with AppQoE policies, and bind the policies to the load balancing virtual servers.

Configuring Policy Based TCP Profile Selection

Configuring policy based TCP profile selection consists of the following tasks:

- Enabling AppQoE. Before configuring the TCP profile feature, you must enable the AppQoE feature.
- Adding AppQoE Action. After enabling the AppQoE feature, configure an AppQoE action with a TCP profile.
- Configuring AppQoE based TCP Profile Selection. To implement TCP profile selection for different classes of traffic, you must configure AppQoE policies with which your Citrix ADC appliance can distinguish the connections and bind the correct AppQoE action to each policy.
- Binding AppQoE Policy to Virtual Server. Once you have configured the AppQoE policies, you must bind them to one or more load balancing, content switching, or cache redirection virtual servers.

Configuring using the command line interface

To enable AppQoE by using the command line interface:

At the command prompt, type the following commands to enable the feature and verify that it is enabled:

```
enable ns feature appqoe

show ns feature
<!--NeedCopy-->
```

To bind a TCP profile while creating an AppQoE action using the command line interface

At the command prompt, type the following AppQoE action command with tcpprofiletobind option.

Binding a TCP Profile:

```
add appqoe action <name> [-priority <priority>] [-respondWith ( ACS |
    NS ) [<CustomFile>] [-altContentSvcName <string>] [-altContentPath <
    string>] [-maxConn <positive_integer>] [-delay <usecs>]] [-polqDepth
     <positive_integer>] [-priqDepth <positive_integer>] [-
    dosTrigExpression <expression>] [-dosAction ( SimpleResponse |
    HICResponse )] [-tcpprofiletobind <string>]

show appqoe action
```

```
<!--NeedCopy-->
```

To configure an AppQoE policy by using the command line interface

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
<!--NeedCopy-->
```

To bind an AppQoE policy to load balancing, cache redirection or content switching virtual servers by using the command line interface

At the command prompt, type:

```
bind cs vserver cs1 -policyName <appqoe_policy_name> -priority <
    priority>
bind lb vserver <name> - policyName <appqoe_policy_name> -priority <
    priority>
bind cr vserver <name> -policyName <appqoe_policy_name> -priority <
    priority>
<!--NeedCopy-->
```

Example:

```
add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -nagle
    ENABLED -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 500 -
    slowStartIncr 1 -bufferSize 4194304 -flavor BIC -KA ENABLED -
    sendBuffsize 4194304 -rstWindowAttenuate ENABLED -spoofSynDrop
    ENABLED -dsack enabled -frto ENABLED -maxcwnd 4000000 -fack ENABLED
    -tcpmode ENDPOINT

add appqoe action appact1 -priority HIGH -tcpprofile tcp1

add appqoe policy apppol1 -rule "client.ip.src.eq(10.102.71.31)" -
    action appact1

bind lb vserver lb2 -policyName apppol1 -priority 1 -
    gotoPriorityExpression END -type REQUEST

bind cs vserver cs1 -policyName apppol1 -priority 1 -
    gotoPriorityExpression END -type REQUEST
<!--NeedCopy-->
```

Configuring Policy based TCP Profiling using the GUI

To enable AppQoE by using the GUI

1. Navigate to **System** > **Settings**.
2. In the details pane, click **Configure Advanced Features**.
3. In the **Configure Advanced Features** dialog box, select the **AppQoE** check box.
4. Click **OK**.

To configure AppQoE policy by using the GUI

1. Navigate to **App-Expert** > **AppQoE** > **Actions**.
2. In the details pane, do one of the following:
3. To create a new action, click **Add**.
4. To modify an existing action, select the action, and then click **Edit**.
5. In the **Create AppQoE Action** or the **Configure AppQoE Action** screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Action" as follows (asterisk indicates a required parameter):
    a) Name—name
    b) Action type—respondWith
    c) Priority—priority
    d) Policy Queue Depth—polqDepth
    e) Queue Depth—priqDepth
    f) DOS Action—dosAction
6. Click **Create**.

To bind AppQoE policy by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select a server and then click **Edit**.
2. In the **Policies** section and click (+) to bind an AppQoE policy.
3. In the **Policies** slider, do the following:
    a) Select a policy type as AppQoE from the drop-down list.
    b) Select a traffic type from the drop-down list.
4. In the **Policy Binding** section, do the following:
    a) Click **New** to create a new AppQoE policy.
    b) Click **Existing Policy** to select an AppQoE policy from the drop-down list.
5. Set the binding priority and click **Bind** to the policy to the virtual server.

6. Click **Done**.

SACK Block Generation

TCP performance slows down when multiple packets are lost in one window of data. In such a scenario, a Selective Acknowledgement (SACK) mechanism combined with a selective repeat retransmission policy overcomes this limitation. For every incoming out-of-order packet, you must generate a SACK block.

If the out-of-order packet fits in the reassembly queue block, insert packet info in the block, and set the complete block info as SACK-0. If an out-of-order packet does not fit into reassembly block, send the packet as SACK-0 and repeat the earlier SACK blocks. If an out-of-order packet is a duplicate and packet info is set as SACK-0 then D-SACK the block.

Note: A packet is considered as D-SACK if it is an acknowledged packet, or an out of order packet which is already received.

Client Reneging

A Citrix ADC appliance can handle client reneging during SACK based recovery.

Memory checks for marking end_point on PCB is not considering total available memory

In a Citrix ADC appliance, if the memory usage threshold is set to 75 percent instead of using the total available memory, it causes new TCP connections to bypass TCP optimization.

Unnecessary retransmissions due to missing SACK blocks

In a non-endpoint mode, when you send DUPACKS, if SACK blocks are missing for few out of order packets, triggers additional retransmissions from the server.

SNMP for number of connections bypassed optimization because of overload

The following SNMP ids have been added to a Citrix ADC appliance to track number of connections bypassed TCP optimization due to overload.

1. 1.3.6.1.4.1.5951.4.1.1.46.13 (tcpOptimizationEnabled). To track the total number of connections enabled with TCP optimization.
2. 1.3.6.1.4.1.5951.4.1.1.46.132 (tcpOptimizationBypassed). To track the total number of connections bypassed TCP Optimization.

Dynamic Receive Buffer

To maximize TCP performance, a Citrix ADC appliance can now dynamically adjust the TCP receive buffer size.

Troubleshooting Guidelines

September 14, 2021

Technical Support

All troubleshooting and escalation queries require a recent Citrix ADC techsupport bundle, which captures current configuration, firmware version installed, log files, outstanding cores, and others.

Example:

```
show techsupport

showtechsupport data collector tool - $Revision: #5 $!
...
<!--NeedCopy-->
```

All the data will be collected under

```
...
Archiving all the data into "/var/tmp/support/collector_P_192
   .168.121.117_18Jun2015_09_53.tar.gz" ....
Created a symbolic link for the archive with /var/tmp/support/support.
   tgz
/var/tmp/support/support.tgz  ---- points to ---> /var/tmp/support/
   collector_P_192.168.121.117_18Jun2015_09_53.tar.gz
<!--NeedCopy-->
```

After a techsupport bundle has been generated, it might be copied using SCP.

Traces

Citrix ADC TCP optimization issues normally require Citrix ADC traces to troubleshoot properly. Note that one should try to capture traces under similar conditions, i.e. on the same cell, during the same time of day, using the same user equipment and application, and others.

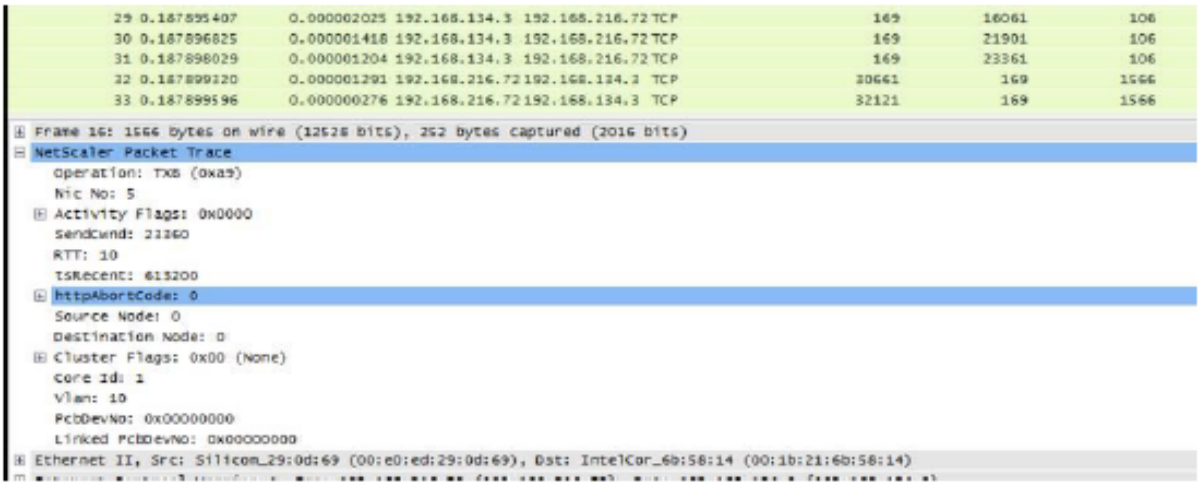
The start nstrace and stop nstrace commands might be used to capture traces:

- It's strongly recommended that the appropriate filter is used to avoid capturing extraneous, unnecessary packets on the trace. For instance use start nstrace -filter 'IP == 10.20.30.40' to only capture packets being sent to or received from IP address 10.20.30.40, which is the user equipment IP address.
- Do not use the -tcpdump option, since it strips the nstrace headers which are required for debugging.

Trace Analysis

After a Citrix ADC trace has been captured, it might be viewed with Wireshark 1.12 or later. Verify that the captured traces include the appropriate Citrix ADC Packet Trace headers, as shown in the screen capture below:

The additional debug headers are also visible per the illustration below:



Connection Table

When the issue is related to TCP optimization and it can be reproduced or it's on-going, it is best to get also the connection table when the issue occurs from the primary T1 node.

To get the table you shall need to switch to the BSD shell and run the following command:

```
shell
...

nscli -U 127.0.0.1:nsroot:nsroot show connectiontable -detail full link
    > /var/tmp/contable.log
<!--NeedCopy-->
```

> **Note**
>
> The command might be executed for a longer time and management CPU might be stressed at that time (depends on the number of connection table entries), but it's not service affecting.

Frequently Asked Questions

September 14, 2021

Timeouts

> **Important**
>
> Before using *any nsapimgr* knob, consult with Citrix Customer Support.

The following is a list of different idle connection timeouts that can be set on Citrix ADC T1 virtual servers and services. Idle timeout set for client or server connections at the vserver or service level are applicable only for the connections in TCP ESTABLISHED state and are idle.

- Load Balancing virtual server cltTimeout parameter specifies the time in seconds that a connection from a client to a Load Balancing virtual server must be idle, before the appliance closes the connection.
- Service svrTimeout parameter specifies the time in seconds that a connection from the appliance to a service or server must be idle, before the appliance closes the connection.
- Service cltTimeout parameter specifies the time in seconds that a connection from a client to a service must be idle, before the appliance closes the connection.

When a service is bound to a Load Balancing virtual server, then the cltTimeout for the Load Balancing virtual server takes precedence, and the service cltTimeout for service is ignored.

In case of there is not service bound to Load Balancing virtual server, global idle timeout, namely tcpServer, is used for server side connections. It can be configured as follows:

Command:

```
set ns timeout  - tcpServer 9000
```

```
<!--NeedCopy-->
```

Connections in other state have different timeout values:

- Half open connections idle timeout: 120 seconds (hardcoded value)
- TIME_WAIT connections idle timeout: 40 seconds (hardcoded value)
- Half close connections idle timeout. By default it is 10s and can be configured between 1s and 600s using the snippet

Command:

```
 set ns timeout -halfclose 10
<!--NeedCopy-->
```

When half-close timeout is triggered, connection is moved to zombie state. When zombie timeout expires, zombie cleanup kicks in and T1 sends RST on both client and server side for given connection by default.

- Zombie timeout: Interval at which the zombie cleanup process must run to clean up inactive TCP connections. Default timeout value is 120s and can be configured between 1s and 600s.

Command:

```
set ns timeout -zombie 120
<!--NeedCopy-->
```

Maximum Segment Size Table

A Citrix ADC T1 appliance defends against SYN flood attacks by using SYN cookies instead of maintaining half-open connections on the system memory stack. The appliance sends a cookie to each client that requests a TCP connection, but it does not maintain the states of half-open connections. Instead, the appliance allocates system memory for a connection only upon receiving the final ACK packet, or, for HTTP traffic, upon receiving an HTTP request. This prevents SYN attacks and allows normal TCP communications with legitimate clients to continue uninterrupted. Specific function is enabled by default without option to disable.

However, there is caveat as standard SYN cookies limit connections to the use of only eight Maximum Segment Size (MSS) values. If connection MMS does not match with any predefined value, it will pick up the next available lower value towards both client and server side.

The predefined TCP Maximum Segment Size (MSS) values are the following and can be configured through a new nsapimgr knob.

1460	1440	1330	1220	956	536	384	128

The new MSS table:

- Need not contain Jumbo-Frame support. Even though by default 8 values are reserved in the MSS table for jumbo frames, the table settings can be modified to include standard Ethernet-sized frames only.
- Should have 16 values
- Should have values in descending order
- Should include 128 as the last value

If the new MSS table is valid, the table is stored and the old values are switched out at the SYN-cookie rotation time. Otherwise the new table returns an error. Changes are applied to new connections while existing connections preserve the old MSS table until the connections expire or are terminated.

To display the current MSS table in a Citrix ADC appliance, type the following command.

Command:

```
>shell

#nsapimgr -d mss_table
```

Example:

```
#nsapimgr -d mss_table

MSS table

{
 9176,9156,8192,7168,6144,4196,3072,2048,1460,1440,1330,1212,956,536,384,128
     }

Done.
```

To change the mss table, type the following command:

Command:

```
>shell

#nsapimgr -s mss_table=<16 comma seperated values>
```

Example:

```
#nsapimgr -ys mss_table
   =9176,9156,8192,7168,6144,4196,3072,2048,1460,1400,1330,1212,956,536,384,128

# nsapimgr -d mss_table

MSS table

{
 9176,9156,8192,7168,6144,4196,3072,2048,1460,1400,1330,1212,956,536,384,128
     }

Done.
```

An example using standard Ethernet-sized values is depicted below:

Example:

```
#nsapimgr -ys mss_table
   =1460,1440,1420,1400,1380,1360,1340,1320,1300,1280,1260,1212,956,536,384,128

# nsapimgr -d mss_table

MSS table

{
 1460,1440,1420,1400,1380,1360,1340,1320,1300,1280,1260,1212,956,536,384,128
     }

Done.
```

To make this change permanent even after the Citrix ADC appliance restarts, include the command `##nsapimgr -ys mss_table=<16 comma seperated values>` in the "/nsconfig/rc.netscaler" file. If the "rc.netscaler" file doesn't exist, create it under the "/nsconfig" folder, and then append the command.

Memory Overload Protection

A Citrix ADC Packet Processing Engine (PPE) starts bypassing connections from TCP optimization if the memory in use by that one PPE is more than a specified high watermark value. If a PPE memory

utilization goes above ~2.6GB, then it starts bypassing *any new* connections from optimization. The existing connections (ones admitted for optimization previously) continues getting optimization. This watermark value has been purposefully selected and is not recommended for tuning.

> **Note**
>
> If you believe that there is a good reason to change that watermark value, contact Customer Support.

Support for Happy Eyeballs Clients

If the Citrix ADC appliance receives a SYN for a destination for which the state is unknown, the appliance first checks the reachability of the server and then acknowledges the client. This probing mechanism enables clients with dual IP stacks to discover the reachability of dual-stack internet servers. If the client discovers that both IPv6 and IPv4 access are available, it establishes a connection to the server that responds more quickly, and resets the other. For the connection for the Citrix ADC appliance receives a reset, it will reset the corresponding server side connection.

Note: This feature has no user configurable TCP settings to be disabled/enabled on the Citrix ADC appliance.

For more information on Happy Eyeballs support, see RFC 6555.

Citrix ADC Video Optimization

September 14, 2021

The Citrix ADC appliance provides optimization techniques and capabilities to optimization ABR video traffic for video traffic over mobile networks. This improves user experience and reduces the overall network bandwidth consumption.

The section includes the following topics:

- Getting Started
- Licensing
- Configuring Video Optimization over TCP
- Configuring Video Optimization over UDP

Getting Started

September 14, 2021

Media files have been driving an increasing amount of traffic over mobile networks, and migration to faster networking technologies has dramatically increased the volume of encrypted video traffic. The traditional media delivery technology (Progressive Download) is failing to deliver acceptable quality of experience (QoE) at a high transmission rate. This has led to the introduction of the Adaptive Bit Rate (ABR) protocol. It can adapt the streaming bit rate to the available network bandwidth and restrict streaming quality to match the capability of the handset receiving the video. However, the ABR protocol does not work as well in mobile networks as it does over the internet. Mobile operators must, therefore, optimize ABR traffic.

A Citrix ADC appliance has unique capabilities to detect incoming video traffic and selectively optimize ABR videos.

How Citrix ADC Video Optimization Works

A Citrix ADC appliance can identify and optimize encrypted ABR traffic (including Facebook video traffic) over TCP, and YouTube ABR traffic over QUIC. The appliance has the following capabilities:

1. Detect Progressive Download (PD) videos over HTTP.
2. Detect and optimize ABR videos over HTTP.
3. Detect and optimize ABR videos over HTTPS.
4. Detect and optimize YouTube ABR videos over QUIC.

Also, the appliance uses the following support domains for detecting video traffic over TCP and QUIC protocols.

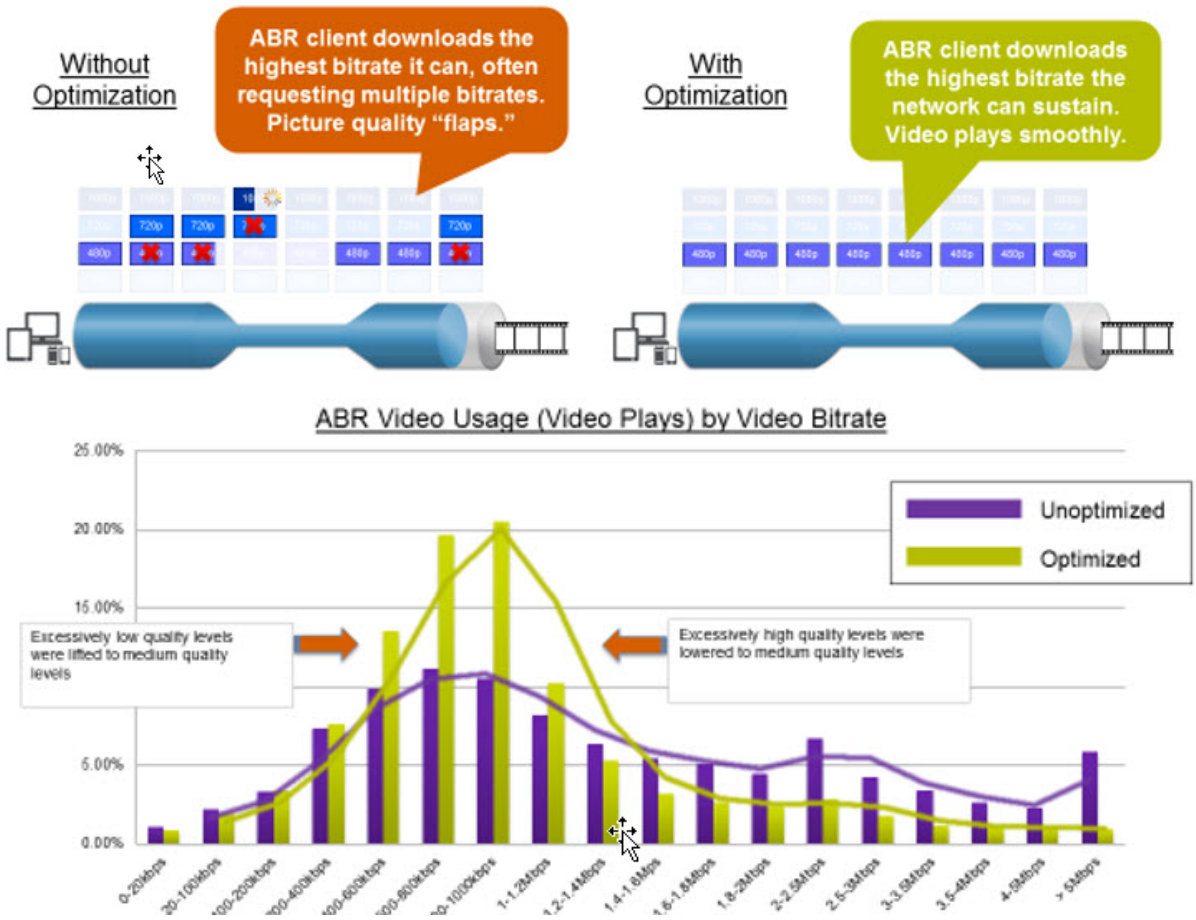
- Unencrypted ABR videos over TCP. Appliance detects all standard compliant video streaming web sites. The appliance detects ABR sessions by inspecting the response video payload header, URL, and HTTP headers.
- Encrypted ABR video over TCP. Appliance detects ABR sessions using a generic and heuristic algorithm based on domain, SSL header and traffic patterns. Using this, the appliance has a built-in support to detect top video web sites, with 95 percent accuracy and we continue to add support for new video types. Citrix ADC also has a program to provide additional verification for top encrypted ABR sites for a region or country to ensure network coverage.
- Encrypted ABR videos over QUIC. The appliance detects ABR sessions for QUIC based video provider, such as YouTube. The detection algorithm is on the basis of a heuristic leveraging the QUIC headers and domain. Citrix ADC will continue to add support for newer video sites using QUIC.

Benefits

Optimizing the ABR video traffic can provide the following benefits:

- Manage the network during congestion in peak hours.

- Improve video play consistency and reduce video stalling.
- Enable new video service offerings (for example, Binge-on video services).
- Enable customers to select the best sustainable video quality.
- Provide a consistent user experience for the subscriber.



Video Optimization over TCP

Citrix ADC optimization of ABR traffic over TCP works as follows:

1. HTTP or HTTPS traffic that the appliance receives over TCP is sent to the corresponding load balancing virtual server.
2. The built-in detection policies bound to the virtual server combined with other proprietary detection algorithms evaluate the traffic.
3. The policies use a set of built-in video detection signatures to detect the video type. The policy that matches traffic applies an action that categorizes the video type as one of the following:
   a) Clear-text PD
   b) Clear-text ABR
   c) Encrypted ABR

d) Other

4. The optimization policies bound to the same virtual server evaluate the traffic and determine the optimization bit rate to apply to the traffic.
5. The optimization bit rate is applied if the traffic is either clear-text ABR or encrypted ABR.

A mobile service provider can improve the quality of experience (QoE) by setting the download speed for 2G, 3G, and 4G mobile traffic. This reduces the video start times or buffering events. Optimization can also reduce the amount of network bandwidth consumed by video sessions.

The optimization techniques include dynamic burst control and random sampling.

Dynamic Burst Control

Citrix ADC ABR optimization adapts dynamically to changing network conditions. It allows an initial burst rate of 1.3 times the configured pacing rate for 15 seconds. The initial burst rate applies to the beginning of every optimized ABR video session, even when multiple sessions use the same TCP connection or group of TCP connections.

The appliance also supports recovery bursts in the event that the bit rate supported by the network drops below the configured pacing rate. For example, if the effective bit rate drops at the 7th second and recovers at 15th second of the initial burst, the appliance recovers the loss during the next burst cycle. By doing so, the appliance dynamically optimizes the network bandwidth for all subscribers so that the quality of video remains consistent per pixel.

Note: When a recovery burst happens during an initial burst, the pacing bit rate must not exceed the maximum recovery-burst and initial-burst rates (you must not add the Recovery Burst factor on top of the Initial Burst factor). Otherwise, it might be so fast that the media player shifts to a higher quality mode. However, if necessary, you can extend the duration of the Initial Burst to compensate the unused bandwidth.

Random Sampling

To estimate the savings from video optimization, the Citrix ADC appliance implements random sampling. With this technique, the appliance randomly selects a configurable percentage of the detected video traffic (the random sampling parameter is an integer number ranging from 0 to 100, so less than 1 percent is not possible). These randomly selected and non-optimized transactions (and sessions) become a reference group, and they are identified in the transaction logs (along with other characteristics, such as byte size and timer fields. The characteristics of the optimized sessions are also logged, and the reporting engine compares statistics of the optimized and reference groups to estimate the savings from optimization (including the savings from ABR Optimization).

Video Optimization over UDP

Google has introduced a new transport protocol called QUIC. Google's QUIC protocol is very similar to TCP+TLS+HTTP/2 and is implemented on top of UDP. Citrix ADC can detect YouTube ABR videos streamed over the QUIC protocol, and apply ABR video optimization in a similar way as ABR over TCP.

Licensing

September 14, 2021

The Video Optimization feature works on Telco platforms with the purchase of a basic CBM license and CBM Premium license and for other Citrix ADC platforms, the feature works with the purchase of a CNS Premium license. Before you configure the video optimization feature, your appliance must have a suitable license.

License support for Telco platforms:

- **CBM_TXXX_SERVER_Retail.lic**
- **CBM_TPRE_SERVER_Retail.lic**
- **CNS_WEBF_SSERVER_Retail.lic**

Where XXX is the throughput, for example, Citrix ADC T1000.

License support for other Citrix ADC platforms:

- **CNS_XXX_SERVER_PLT_Retail.lic**

Where XXX is the throughput.

To upload a Premium license file, follow the steps given below:

1. A valid license file should be installed on the Citrix ADC appliance. The license should support at least as many Gbps as the expected maximum Gi-LAN throughput.

   License files should be copied through an SCP client to the /nsconfig/license of the appliance, as shown in the screen capture below.

   ```
   > shell ls /nsconfig/license/
   CNS_V3000_SERVER_PLT_Retail.lic ssl
   <!--NeedCopy-->
   ```

2. Do a warm restart to apply for the new license, as shown in the screen capture below.

   ```
   > reboot -warm
   Are you sure you want to restart NetScaler (Y/N)? [N]:y
    Done
   <!--NeedCopy-->
   ```

3. After the restart completes, verify that the license has been properly applied, by using the show license CLI.

In the example below a Premium license with Premium edition has been successfully installed.

```
    > show license

                License status:

                                        Video Optimization: YES

                                                    ...

                                    Model Number ID: 110050

                                       License Type: Premium License
<!--NeedCopy-->
```

Configuring Video Optimization over TCP

September 21, 2021

> **Warning:**
>
> As part of video optimization, the video pacing functionality is deprecated and will be removed from the Citrix ADC appliance in forthcoming releases.

To optimize video traffic over TCP, begin by enabling the video optimization feature. The appliance then activates the built-in detection policies to detect the incoming video traffic and identify the type of video. User configurable optimization policies for each video type specify the optimization bit rate needed for optimizing the traffic.

Configuring Video Optimization over TCP by using the CLI

To configure video optimization on a Citrix ADC appliance, you perform the following tasks:

1. Enable the video optimization feature.
2. Add virtual servers for HTTP and HTTPS traffic.
3. Bind all the built-in detection policies to a load balancing virtual server for HTTP traffic.
4. Bind all the built-in detection policies to an SSL-bridge load balancing virtual server for HTTPS traffic.
5. Add the desired optimization policies for HTTP and HTTPS traffic.

6. Bind optimization policies to a load balancing virtual server for HTTP Traffic.
7. Bind optimization policies to an SSL-bridge load balancing virtual server for HTTPS traffic.

Enabling Video Optimization

If you want the Citrix ADC appliance to detect, optimize, and report video traffic, you must enable the Video Optimization feature and set optimization to ON. After enabling the feature you can use built-in detection policies to identify the incoming video traffic, and you can configure optimization policies to optimize encrypted ABR traffic. To optimize ABR video traffic, you must configure the download bit rate (also called the *pacing rate*).

You must also enable the load balancing feature, and if you want to use video optimization for HTTPS traffic you must enable the SSL feature.

To enable the video optimization feature

At the command prompt, type the following command:

```
enable ns feature VideoOptimization
<!--NeedCopy-->
```

> **Note**
>
> If you want to monitor the video optimization performance and video insight reports you must enable the AppFlow feature and then access the Video Analytics feature on Citrix Application Delivery Management (ADM). For more information, see Video Insight documentation.

Creating Virtual Servers for HTTP and HTTPS Video Traffic

A Citrix ADC appliance uses different virtual servers for detecting and optimizing the different types of incoming video traffic. The appliance supports the following types of virtual servers for TCP traffic.

- **HTTP Load Balancing virtual server**. For detecting HTTP video traffic, the appliance uses an HTTP load balancing virtual server. It manages HTTP video requests that the appliance receives from clients.
- **SSL-Bridge Load Balancing virtual server**. To detect encrypted video traffic, you must configure an SSL bridge virtual server on the appliance.

To add an HTTP Load Balancing virtual server for detecting HTTP video traffic

At the command prompt, type the following:

```
add lb vserver <name> HTTP * 80 -persistenceType NONE
<!--NeedCopy-->
```

Example:

```
add lb vserver ProxyVserver-HTTP HTTP * 80 -persistenceType NONE -
    cltTimeout 120
<!--NeedCopy-->
```

To add an SSL Bridge virtual server for detecting HTTPS video traffic

At the command prompt, type the following:

```
add lb vserver <name> SSL_BRIDGE * 443 -persistenceType NONE
<!--NeedCopy-->
```

Example:

```
add lb vserver ProxyVserver-SSL SSL_BRIDGE * 443 -persistenceType NONE
    -cltTimeout 180
<!--NeedCopy-->
```

Binding Built-In Detection Policies to an HTTP Load Balancing Virtual Server

To detect video traffic over an HTTP connection, you must bind all the built-in detection policies to a load balancing virtual server. You must bind the policies to either request-time or response-time processing, depending on the policy type.

> **Note:**
>
> The `ns_videoopt_http_body_detection` video optimization policy does not support the `CONNECT` HTTP request method.

To bind detection policies for different video types to an HTTP load balancing virtual server

At the command prompt, type the appropriate command for each type. The available commands are:

```
bind lb vserver <name> -policyName ns_videoopt_http_abr_netflix -
    priority <integer> -type (REQUEST | RESPONSE)

bind lb vserver <name>   -policyName ns_videoopt_http_abr_netflix2 -
    priority <integer> -type (REQUEST | RESPONSE)

```

```
bind lb vserver <name>   -policyName ns_videoopt_http_abr_youtube -priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver <name>    -policyName ns_videoopt_http_pd_youtube -priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver <name>    -policyName ns_videoopt_http_pd_youtube2  -priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver  <name>   -policyName ns_videoopt_http_pd_youtube3 -priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver  <name>  -policyName ns_videoopt_http_abr_generic -priority <integer> -type (REQUEST | RESPONSE)
<!--NeedCopy-->
```

Example:

```
bind lb vserver ProxyVserver-HTTP    -policyName ns_videoopt_http_abr_netflix -priority 400  type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName ns_videoopt_http_abr_netflix2 -priority 500 -type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName ns_videoopt_http_abr_youtube -priority 600  -type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName ns_videoopt_http_pd_youtube -priority 800  -type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName ns_videoopt_http_pd_youtube2 -priority 900 -type RESPONSE

bind lb vserver  ProxyVserver-HTTP   -policyName ns_videoopt_http_pd_youtube3 -priority 1000 -type REQUEST

bind lb vserver  ProxyVserver-HTTP   -policyName ns_videoopt_http_abr_generic -priority 1100 -type RESPONSE
<!--NeedCopy-->
```

Binding the HTTP Body Content Detection Policy to Load Balancing Virtual Server

To detect video traffic over HTTP, you must bind the body content detection policy to the load balancing virtual server. You can use the following command:

```
bind lb vserver <name> -policyName ns_videoopt_http_body_detection -
    priority <integer> -type (REQUEST | RESPONSE)
<!--NeedCopy-->
```

Example:

```
bind lb vserver ProxyVserver-HTTP -policyName
    ns_videoopt_http_body_detection -priority 1500 -type REQUEST
<!--NeedCopy-->
```

Binding Built-In Detection Policies to an SSL-Bridge Load Balancing Virtual Server

To detect video traffic over an HTTPS connection, you must bind built-in detection policies to an SSL Bridge load balancing virtual server.

To bind a detection policy to an SSL bridge load balancing virtual server

At the command prompt, type the appropriate command for each type. The available commands are:

```
bind lb vserver <name> -policyName ns_videoopt_https_abr_netflix -
    priority <positive_integer> -type (REQUEST | RESPONSE)

bind lb vserver <name> -policyName ns_videoopt_https_abr_youtube -
    priority <positive_integer> -type (REQUEST | RESPONSE)

bind lb vserver <name> -policyName ns_videoopt_https_abr_generic -
    priority <positive_integer> -type (REQUEST | RESPONSE)
<!--NeedCopy-->
```

Example:

```
bind lb vserver ProxyVserver-SSL -policyName
    ns_videoopt_https_abr_netflix -priority 120 -type REQUEST

bind lb vserver ProxyVserver-SSL -policyName
    ns_videoopt_https_abr_youtube -priority 140 -type REQUEST

bind lb vserver ProxyVserver-SSL -policyName
    ns_videoopt_https_abr_generic -priority 150 -type REQUEST
<!--NeedCopy-->
```

Adding Optimization Policies for Pacing ABR traffic

To optimize ABR traffic, you have to configure optimization policies and the associated actions. You then bind the policies to the same load balancing virtual servers to which you bound the detection policies. For each policy, create the action first, so that you can include it when you create the policy.

To add an optimization action

At the command prompt, type:

```
add videooptimization pacingaction <action Name> -rate <integer> [-
   comment <string>]
<!--NeedCopy-->
```

Where the **rate** parameter specifies the rate in Kbps at which to send the traffic (the pacing rate).

Example:

```
add videooptimization pacingaction MyOptAct2000 -rate 2000
<!--NeedCopy-->
```

To add an optimization policy

At the command prompt, type:

```
add videooptimization pacingpolicy <name> -rule <expression> -action <
   string>
<!--NeedCopy-->
```

Example:

```
add videooptimization pacingpolicy myOptPolicy2000 -rule TRUE -action
   MyOptAct2000
<!--NeedCopy-->
```

Binding Optimization Policies to an HTTP Load Balancing Virtual Server

To optimize ABR video traffic over an HTTP connection, you must bind the optimization policies to a load balancing virtual server to which the detection policies are bound.

To bind an optimization policy to a Load Balancing virtual server

At the command prompt, type the following command:

```
bind lb vserver <name> -policyName <policy_name> -priority <
    positive_integer> -type  (REQUEST | RESPONSE)
<!--NeedCopy-->
```

Example:

```
bind lb vserver ProxyVserver-HTTP -policyName myOptPolicy2000 -priority
     3400 -type  REQUEST
<!--NeedCopy-->
```

Binding Optimization Policies to SSL-bridge Virtual Servers

To optimize ABR video traffic over an HTTPS connection, you must bind the optimization policies to the SSL Bridge virtual server to which the built-in detection policies are bound.

To bind an optimization policy to SSL Bridge virtual server for pacing encrypted traffic

At the command prompt, type the following command:

```
bind lb vserver <name> -policyName <policy_name> -priority <
    positive_integer> -type  (REQUEST |RESPONSE)
<!--NeedCopy-->
```

Example:

```
bind lb vserver ProxyVserver-SSL -policyName myOptPolicy2000 -priority
    3400 -type  REQUEST
<!--NeedCopy-->
```

Setting video optimization pacing parameters

The CLI enables you to set the video optimization pacing parameters, such as random sampling percentage.

To set the random sampling percentage

At the command prompt, type the following command:

```
set videooptimization parameter  - RandomSamplingPercentage <realNumber>
<!--NeedCopy-->
```

Where, a realNumber is a value from 0.0 to 100.0.

Example:

```
set videooptimization parameter -RandomSamplingPercentage 50
<!--NeedCopy-->
```

Configuring Video Optimization over TCP by using the GUI

The GUI enables you to:

- Enable video optimization feature.
- Create HTTP load balancing virtual server.
- Create SSL-bridge load balancing virtual server.
- Bind built-in detection policies to HTTP load balancing virtual server.
- Bind built-in detection policies to SSL-bridge load balancing virtual server.
- Create an optimization policy.
- Create an optimization action.
- Configuring optimization pacing parameter.
- Bind optimization policy to load balancing virtual server for HTTP traffic.
- Bind optimization policy to SSL-bridge load balancing virtual server for HTTPS traffic.

To enable video optimization feature

1. In the navigation pane, expand **System**, and then click **Settings**.
2. On the **Settings** page, click the **Configure Advanced Features** link.
3. On the **Configure Advanced Features** page, select the **Video Optimization** check box.
4. Click **OK**, and then click **Close**.

To create load balancing virtual server for HTTP traffic

1. Sign in to the Citrix ADC appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the Load Balancing Virtual Server screen, set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. Select protocol type as HTTP
   c) **IP Address Type**. IP address type: IPv4 or IPv6.
   d) **IP Address**. IPv4 or IPv6 address assigned to the virtual server.
   e) **Port**. Port number of the virtual server.

4. Click **OK** to continue with configuration of other, optional, parameters. For more information, see Creating a Virtual Server.
5. Click **Create** and **Close**.

To create load balancing virtual server for HTTPS traffic

1. Sign in to the Citrix ADC appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** screen, set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. Select protocol type as SSL-bridge.
   c) **IP Address Type**. IP address type: IPv4 or IPv6.
   d) **IP Address**. IPv4 or IPv6 address assigned to the virtual server.
   e) **Port**. Port number of the virtual server.
4. Click **OK** to continue with the configuration of other, optional, parameters. For more information, see Creating a Virtual Server.
5. Click **Create** and then **Close**.

To bind a built-in detection policy to a load balancing virtual server

1. Sign in to the Citrix ADC appliance and navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the load balancing virtual server and click **Edit**.
   a) In the **Advanced Setting** section, click **Policies**.
   b) In the **Policies** section, click the **+** icon to access the **Policies** slider.
   c) In the **Policies** section, set the following parameters.
   d) Choose Policy. Select a video optimization detection policy from the drop-down list.
   e) Choose Type. Select the policy type as Request.
   f) Click **Continue**.
3. Select the video detection policy from the list and click **Close**.

To bind a built-in detection policy to a SSL-bridge load balancing virtual server

1. Log on to the Citrix ADC appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the SSL-bridge load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. In the **Policies** section, set the following parameters.

a) Choose Policy. Select video optimization detection policy from the drop-down list.
b) Choose Type. Select the policy type as Request.

6. Click **Continue**.
7. Select the video detection policy from the list and click **Close**.

To create a video optimization action

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Actions**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Action** page, set the following parameters.
   a) **Name**. Name of the optimization action.
   b) **ABR Optimization Rate (Kbps).** Pacing rate at which to send the ABR video traffic. The default rate for ABR optimization is 1000 Kbps. The minimum value is 1, and the maximum value is 2147483647.
   c) **Comment**. A short description of the action.
4. Click **Create** and **Close**.

To create a video optimization policy

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Policies**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Policy** page, set the following parameters.
   a) **Name**. Name of the optimization policy
   b) **Expression**. Custom regex expressions that implement the policy.
   c) **Action**. Optimization action associated with the policy to handle the incoming video traffic.
   d) **UNDEF Action.** Undefined event if the incoming request does not match the optimization policy.
   e) **Comment**. A short description of the policy.
   f) **Log Action.** Select the audit log action that creates the desired log messages.
4. Click **Create**, and then click **Close.**

To set video optimization pacing parameters

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization.**
2. In the **Video Optimization** page, click **Change Video Optimization Settings** link.
3. In the **Video Optimization Settings** page, set the following parameter.

a) **Random Sampling Percentage (%)**. Percentage of packets selected for random sampling.

4. Click **OK** and **Close**.

To bind a video optimization policy to an HTTP load balancing virtual server

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization**.
2. On the **Video Optimization** page, click the **Video Optimization Pacing Policy Manager** link.
3. Set the following parameters.
   a) **Bind Point**. The point at which to apply the optimization policy during request or response processing.
   b) **Connection Type**. Connection type as Request or Response.
   c) **Virtual Server**. The load balancing virtual server to which to bind the policy.
   d) Click **Continue**.
4. In the **Bind Point** section, do one of the following:
   a) Select a policy from the list.
   b) Click **Add Binding** to access the **Policies Binding** slider.
      i. Select an existing policy or add a new policy.
      ii. Enter binding details and click **Bind**.
5. Click **Close**.

To bind a video optimization policy to an SSL-bridge load balancing virtual server

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization**.
2. On the **Video Optimization** page, click the **Video Optimization Pacing Policy Manager** link.
3. On the **Video Optimization Policy Manager** page, set the following parameters.
   a) Bind Point. The point at which to apply the optimization policy during request/response processing.
   b) Connection Type. Connection type as Request or Response.
   c) Virtual Server. The SSL-bridge load balancing virtual server to which to bind the policy.
4. Click **Continue**.
5. In the **Bind Point** section, do one of the following:
   a) Select a policy binding from the list.
   b) Click **Add Binding** to access the **Policies Binding** slider.
      i. Select an existing policy or add a new policy.
      ii. Enter binding details and click **Bind**.
6. Click **Close**.

Configuring Video Optimization over UDP

September 14, 2021

To optimize QUIC ABR video traffic over UDP, begin by enabling the video optimization feature. After you complete the configuration, the appliance detects QUIC based ABR video traffic and applies the optimization bit rate that is configured on the appliance.

Configuring video optimization for QUIC by using the CLI

To configure video optimization for QUIC video traffic over UDP, you must perform the following tasks:

1. Enable Video Optimization.
2. Create a QUIC service.
3. Create a QUIC load balancing virtual server.
4. Bind QUIC web service to the loading balancing virtual server.
5. Create video optimization policy for pacing QUIC based UDP traffic.
6. Bind optimization policy to a QUIC based load balancing virtual server.

Enabling video optimization for QUIC traffic

If you want the Citrix ADC appliance to detect, optimize, and report video traffic, you must enable the Video Optimization feature and set optimization ON.

> **Note**
>
> If you want to use video optimization for QUIC traffic, you must enable the load balancing and AppFlow features.

To enable the video optimization

At the command prompt, type the following command:

```
enable ns feature VideoOptimization
<!--NeedCopy-->
```

Creating a service for QUIC traffic

A Citrix ADC appliance uses a QUIC service for the load balancing virtual server to connect to the egress router in the static routing mode.

> **Note**
>
> Currently, dynamic routing is not supported.

To create a load balancing web service for QUIC video traffic

At the command prompt, type:

```
add service <name> <router-IP> <serviceType> <port> -usip yes -
   useproxyport  [yes | no]
<!--NeedCopy-->
```

Example:

```
add service svc-quic 10.102.29.200 QUIC 443  - usip yes  - useproxyport
   no

where IP address is the internet router address.
<!--NeedCopy-->
```

Creating a load balancing virtual server for QUIC traffic

A Citrix ADC appliance uses a load balancing virtual server for detecting and optimizing QUIC video traffic over UDP.

To create a load balancing virtual server for QUIC video traffic

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port> -m MAC
<!--NeedCopy-->
```

Example:

```
add lb vserver vs-quic QUIC * 443 -persistenceType NONE -m MAC -
   cltTimeout 120
<!--NeedCopy-->
```

Binding a QUIC web service to the load balancing virtual server

After you have created the web services and load balancing virtual server for QUIC traffic, you must bind the services to the virtual server.

To bind a web service to load balancing virtual server for QUIC video traffic

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver vs-quic svc-quic
<!--NeedCopy-->
```

Creating Video Optimization Policy for QUIC based UDP traffic

To optimize QUIC based UDP traffic, you have to configure optimization pacing policies and its actions. You must then, bind the policies to QUIC based load balancing virtual servers. For each policy, create an action first so that you can associate it to the policy.

To add an optimization action

At the command prompt, type:

```
add videooptimization pacingaction <action Name> -rate <integer> [-
   comment <string>]
<!--NeedCopy-->
```

Where, the **rate** parameter specifies the rate in Kbps at which to send the traffic (the pacing rate).

Example:

```
set videooptimization parameter -QUICPacingRate 1000
<!--NeedCopy-->
```

where 1000 represents the desired pacing rate in Kbits/sec.

To add an optimization policy

At the command prompt, type:

```
add videooptimization pacingpolicy <name> -rule <expression> -action <
   string>
<!--NeedCopy-->
```

Example:

```
add videooptimization pacingpolicy myOptPolicy2000 -rule TRUE -action
   MyOptAct2000
<!--NeedCopy-->
```

Binding Optimization Policies to a QUIC Load Balancing Virtual Server

To optimize QUIC video traffic over a UDP connection, you must bind the optimization policies to a QUIC load balancing virtual server.

To bind an optimization policy to a QUIC Load Balancing virtual server

At the command prompt, type the following command:

```
bind lb vserver <name> -policyName <policy_name> -priority <
   positive_integer> -type (REQUEST)
<!--NeedCopy-->
```

> **Note**
>
> The pacing policies must be bound to a QUIC load balancing virtual server only at request time.

Example:

```
bind lb vserver vs-quic -policyName myOptPolicy2000 -priority 3400 -
   type  REQUEST
<!--NeedCopy-->
```

Configuring video optimization for QUIC by using the GUI

To configure the feature on the appliance through the GUI, you must perform the following tasks:

1. Enable video optimization
2. Configure a QUIC servers
3. Configure QUIC service
4. Configure a QUIC load balancing virtual server
5. Bind the QUIC web service to the load balancing virtual server
6. Create optimization policy.
7. Create optimization action.
8. Configuring optimization pacing parameter.
9. Bind optimization policy to load balancing virtual server for QUIC traffic.

To enable video optimization

1. Log on to the Citrix ADC appliance and navigate to **System** > **Settings.**
2. On the details page, select **Configure Advanced Features** link.
3. On the **Configure Advanced Features** page, select the **Video Optimization** check box.

To create a QUIC servers

1. Log on to the Citrix ADC appliance and navigate to the **Traffic Management** > **Load Balancing** > **Servers** screen.
2. In the details pane, click **Add**.
3. On the **Create Server** page, set the following parameters:
   a) Name. Name of the QUIC server.
   b) IP address. IP address of the QUIC server
   c) Traffic Domain. Domain name of the server.
   d) Enabling after creating. Initial state of the server.
   e) Comments. Brief information about the server.
4. Click **Create.**

To create a QUIC service

1. Log on to the Citrix ADC appliance and navigate to the **Traffic Management** > **Load Balancing** > **Services screen**.
2. In the details pane, click **Add**.
3. On the **Load Balancing Service** page, set the following parameters:
   a) **Service Name**. Name of the QUIC service.
   b) **IP address**. IP address assigned to the QUIC service.
   c) **Protocol**. Select protocol as QUIC.
   d) **Port**. Port number of the web service.
4. Click **OK** to continue. You can then configure other, optional, parameters. For more, see Configuring Services.
5. Once you configure the optional parameters, click **OK** and **Close**.

To create a load balancing virtual server

1. Log on to the Citrix ADC appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** page, set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. The protocol used by the service to send QUIC requests.

c) IP Address Type. IP address type: IPv4 or IPv6.
d) **IP Address**. IP 4 or IP6 IP address assigned to the virtual server.
e) **Port**. Port number of the virtual server.

4. Click OK to continue with the configuration of other, optional, parameters. For more information, see Creating a Virtual Server.

To bind a load balancing virtual server to a QUIC service

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and select a virtual server.
2. Click **Services and Service Groups** to access the **Load Balancing Virtual Server Service Binding** screen.
3. Select a QUIC based web service and click **Bind**.
4. Click **Done**.

To bind a load balancing virtual server to a QUIC service

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and select a virtual server.
2. Click **Services and Service Groups** to access the **Load Balancing Virtual Server Service Binding** screen.
3. Select a QUIC based web service and click **Bind**.
4. Click **Done**.

To create a video optimization action for QUIC traffic

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Actions**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Action** page, set the following parameters.
   a) **Name**. Name of the optimization action.
   b) **ABR Optimization Rate (Kbps).** Pacing rate at which to send the ABR video traffic. The default rate for ABR optimization is 1000 Kbps. The minimum value is 1, and the maximum value is 2147483647.
   c) **Comment**. A short description of the action.
4. Click **Create** and **Close**.

To create a video optimization policy for QUIC traffic

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Policies**.

2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Policy** page, set the following parameters.
   a) Name. Name of the optimization policy
   b) Expression. Custom regrex expressions that implement the policy.
   c) Action. Optimization action associated with the policy to handle the incoming video traffic.
   d) UNDEF Action. Undefined event if the incoming request does not match the optimization policy.
   e) Comment. A short description of the policy.
   f) Log Action. Select the audit log action that creates the desired log messages.
4. Click **Create**, and then click **Close**.

To bind a video optimization policy to an QUIC load balancing virtual server

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization**.
2. On the **Video Optimization** page, click the **Video Optimization Pacing Policy Manager** link.
3. On the **Video Optimization Policy Manager** page, set the following parameters.
   a) Bind Point. The point at which to apply the optimization policy during request processing. **Note**: The pacing policies must be bound to a QUIC load balancing virtual server only at request time.
   b) Connection Type. Connection type as Request or Response.
   c) Virtual Server. The load balancing virtual server to which to bind the policy.
4. Click **Continue**.
5. In the **Bind Point** section, do one of the following:
   a) Select a policy from the list.
   b) Click **Add Binding** to access the **Policies Binding** slider.
      i. Select an existing policy or add a new policy.
      ii. Enter binding details and click **Bind**.
6. Click **Close**.

Citrix ADC URL Filtering

September 14, 2021

URL Filtering provides policy-based control of websites by using the information contained in URLs. This feature helps network administrators monitor and control user access to malicious websites on mobile networks.

As an administrator, you can configure a URL filtering policy by using either the URL Categorization feature or the URL List feature.

URL List. Controls access to blacklisted websites and web pages by blocking access to URLs that are in a URL set imported into the appliance.

URL Categorization. Controls access to websites and web pages by filtering traffic on the basis of a predefined list of categories.

URL List

September 14, 2021

The URL List feature enables you to control access to customized URL lists (up to one million entries). The feature filters websites by applying a URL filtering policy bound to a virtual server.

As an administrator, you must import the URL List into the Citrix ADC appliance. This imported list is internally stored as a Policy data set called a *URL Set*. The appliance then applies a unique fast URL matching algorithm to the incoming URL requests. If the incoming URL request matches an entry in the set, the appliance applies the associated policy action to control access.

URL List Types

Each entry in a URL set can include a URL and, optionally, its metadata (URL category, category groups, or any other related data). For URLs with a metadata, the appliance uses a policy expression that evaluates the metadata. For more information, see URL Sets.

Custom URL List. You can create a customized URL set of up to 1,000,000 URL entries and import it as a text file into your appliance. The list can contain URLs with or without metadata (which could be like a URL category). TheCitrix ADC platform automatically detects whether metadata is present. It also supports storing the imported lists securely. For more information, see URL Set.

You can host the URL list and configure the Citrix ADC appliance to periodically update the list without requiring manual intervention. Once the URL list is updated, the appliance can automatically detect the metadata and the categories by using policy expressions to evaluate each incoming URL and then apply actions such as allow, block, redirect, or notify the user.

URL List Policy Expressions

The following table describes the basic expressions you can use to evaluate incoming traffic. After you import an URL List to the appliance, it is called a *URL Set*.

Expression	Operation
<URL expression>.URLSET_MATCHES_ANY (<URLSET>)	Evaluates to TRUE if the URL exactly matches any entry in the URL set.
<URL expression>. GET_URLSET_METADATA(<URLSET>)	The GET_URLSET_METADATA() expression returns the associated metadata if the URL exactly matches any pattern within the URL set. An empty string is returned if there is no match.
<URL expression>.GET_ URLSET_METADATA(<URLSET>).EQ(< METADATA>)	Evaluates to TRUE if the matched metadata is equal to <METADATA>.
<URLexpression>.GET_URLSET_METADATA (<URLSET>).TYPECAST_LIST_T(‘,’).GET (0).EQ(<CATEGORY>)	Evaluates to TRUE if the matched metadata is at the beginning of the category. This pattern can be used to encode separate fields within metadata, but match only the 1st field.
HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL)	Joins the host and URL parameters, which can then be used as a <URL expression> for matching.

URL List Policy Actions

The most common enforcement action for URLs that match a URL list is to restrict access. Create a URL list policy with a desired URL list matching expression and enforcement action. The policy group usage depends upon the incoming traffic type (HTTP or HTTPS) and the virtual server configured on the appliance. You can use a Responder policy for HTTP traffic or a Video Optimization policy for HTTPS traffic. Specify actions to apply to the URLs that match the expressions in the policies. The following table lists the available actions.

Action Type	Policy	Description
ALLOW	Responder	Allow the request to access the target URL.
REDIRECT	Responder	Redirect the request to the URL specified as the target.
DENY	Responder	Deny the request.
RESET	Responder, VideoOptimization	Reset the connection.

Action Type	Policy	Description
DROP	Responder, VideoOptimization	Drop the connection.

Prerequisites

To configure URL List feature, make sure you have configured the following server.

DNS Server for DNS Requests

You must configure a DNS server if you import a URL Set from a hostname URL.

At the command prompt, type:

```
add dns nameServer ((<IP> [-local]) | <dnsVserverName>) [-state (
   ENABLED | DISABLED )] [-type <type>] [-dnsProfileName <string>]
<!--NeedCopy-->
```

Example:

```
add dns nameServer 10.140.50.5
<!--NeedCopy-->
```

Importing a custom URL list

To import a URL set, see URL Set topic.

Configuring a URL List for HTTP traffic

The Citrix ADC appliance supports HTTP and HTTPS traffic. To configure a load balancing virtual server for HTTP traffic and bind URL list policies to the server, do the following:

- Add URL List actions.
- Add URL List policies.
- Add an HTTP load balancing virtual server for HTTP traffic
- Bind the URL List policies to the HTTP load balancing virtual server for HTTP traffic

To add a URL list action

At the command prompt, type the following:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment <
    string>] [-responseStatusCode <positive_integer>] [-reasonPhrase <
    string>]
<!--NeedCopy-->
```

To add a HTTP load balancing virtual server for HTTP traffic

At the command prompt, type the following:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-cltT
    imeout <secs>]
<!--NeedCopy-->
```

Example:

```
add lb vserver vsrv-HTTP HTTP * 80 -persistenceType NONE -cltTimeout
    120
<!--NeedCopy-->
```

To bind URL list policy to HTTP load balancing virtual server

At the command prompt, type the following:

```
bind lb vserver <vServerName> -policyName <string> [-priority <
    positive_integer>]
<!--NeedCopy-->
```

Configuring URL List for HTTPS traffic

The Citrix ADC appliance supports HTTP and HTTPS traffic. To configure a SSL-bridge load balancing virtual server for HTTPS traffic and bind URL list policies to the server, do the following:

- Add URL List actions.
- Add URL List policies.
- Add a SSL-bridge load balancing virtual server for HTTP traffic
- Bind the URL List policies to the SSL-bridge load balancing virtual server for HTTP traffic

To add a URL List policy for HTTPS traffic

At the command prompt, type:

```
add videooptimization detectionpolicy <name> -rule <expression> -action
     <string> [-undefAction <string>] [-comment <string>] [-logAction <
    string>]
<!--NeedCopy-->
```

To add a SSL-bridge load balancing virtual server

At the command prompt type:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-cltT
    imeout <secs>]
<!--NeedCopy-->
```

Example:

```
add lb vserver vsrv-HTTPS SSL_BRIDGE * 443 -persistenceType NONE -
    cltTimeout 180
<!--NeedCopy-->
```

To bind URL List policy with SSL-bridge load balancing by using the CLI

At the command prompt type:

```
bind lb vserver <vServerName> -policyName <string> [-priority <
    positive_integer>]
<!--NeedCopy-->
```

Configuring a URL List by using the GUI

The GUI enables you to:

- Import a URL list.
- Add a URL list.
- Configure URL list actions.
- Configure URL list policies for HTTP traffic.
- Add an HTTP load balancing virtual server for HTTP traffic.
- Add an SSL-bridge load balancing virtual server for HTTPS traffic.
- Bind URL list policies to the HTTP load balancing virtual server.
- Bind a URL list policies to the SSL-bridge load balancing virtual server.

To import a URL list

1. In the navigation pane, expand **AppExpert** > **URL Sets**.
2. In the details pane, click **Import**.
3. On the **Configure URL Set** page, set the following parameters.
   a) **Name**. Name of the URL set.
   b) **URL**. Web address of the location at which to access the URL Set.
   c) **Overwrite**. Overwrite a previously imported URL set.
   d) **Delimiter**. Character sequence that delimits a CSV file record.
   e) **Row Separator**. Row separator used in the CSV file. A single character value is permitted for example "/n".
   f) **Interval**. Interval in seconds, rounded off to the nearest 15 minutes, at which the URL set is updated.
   g) **Private Set.** Option to prevent exporting the URL set
   h) **Canary URL**. Internal URL for testing whether the content of the URL set is to be kept confidential. The maximum length of the URL is 2047 characters
4. Click **Create**, and then **Close**.

To add a URL list

1. In the navigation pane, expand **AppExpert** > **URL Sets**.
2. In the details pane, click **Add**.
3. On the **Create URL Set** page, set the following parameters.
   a) **Name**. The name of the URL set that was given when it was imported.
   b) **Comments**. A short description about the URL set.
4. Click **Create**.

To configure a URL list action

1. Log on to the Citrix ADC appliance and navigate to **Configuration** tab page.
2. In the menu pane, navigate to **AppExpert** > **Responder** > **Actions**.
3. In the details pane, click **Add**.
4. On the **Create Responder Action** page, set the following parameters.
   a) **Name**. Name of the URL List policy action.
   b) **Type**. Select an action type.
   c) **Expression**. Use the expression editor to create the policy expression.
   d) **Comments**. A short description about the policy action.
5. Click **Create** and **Close**.

To configure a URL list policy

1. In the navigation pane, expand **AppExpert** > **Responder** > **Policies**.
2. In the details pane, click **Add**.
3. On the **Create Responder Policy** page, set the following parameters.
   a) **Name**. Name of the URL List policy action.
   b) **Action**. Select the URL List action that you prefer to associate with the policy.
   c) **Log Action**. Select the log action.
   d) **AppFlow**. Select an AppFlow action.
   e) **Expression**. Use the expression editor to create the policy expression.
   f) **Comments**. A short description about the policy.
4. Click **Create** and **Close**.

To add an HTTP load balancing virtual server

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** screen, set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. Choose protocol type as HTTP.
   c) **IP Address Type**. IP addressable type.
   d) **IP Address**. IP 4 or IP6 IP address assigned to the virtual server.
   e) **Port**. Port number of the virtual server.
4. Click **OK** to continue with the configuration of other, optional, parameters. For more information, see Creating a Virtual Server.

To bind a URL List policy to the HTTP load balancing virtual server

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. In the **Policies** section, set the following parameters.
   a) Choose Policy. Select a URL categorization policy from the drop-down list.
   b) Choose Type. Select the policy type as Request.
6. Click **Continue**.
7. In the Policies page, select the URL List policy from the list and click **Select**.
8. In the **Policies** slider, click **Bind** and **Close**.

To add URL List policy for HTTPS traffic

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Detection**.
2. On the **Detection** page, click the **Video Optimization Detection Policies** link.
3. On the **Video Optimization Detection Policies** page, click **Add**.
4. On the **Create Video Optimization Detection Policy** page, set the following parameters.
   a) **Name**. Name of the optimization policy
   b) **Expression**. Configure policy using custom expressions.
   c) **Action**. Optimization action associated with the policy to handle the incoming video traffic.
   d) **UNDEF Action**. Undefined event if the incoming request does not match the optimization policy.
   e) **Comment**. A short description of the policy.
   f) **Log Action**. Select an audit log action that specifies the action to be performed for the log messages.
5. Click **Create** and **Close**.

To add a SSL-bridge load balancing virtual server for HTTPS traffic

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** screen, set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. Select protocol type as SSL-bridge.
   c) **IP Address Type**. IP address type: IPv4 or IPv6.
   d) **IP Address**. IPv4 or IP6vIP address assigned to the virtual server.
   e) **Port**. Port number of the virtual server.
4. Click **OK** to continue with the configuration of other, optional, parameters. For more information, see “Creating a Virtual Server” topic.

To bind a URL List Policy to the SSL-bridge load balancing virtual server

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the SSL-bridge load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. Set the following parameters.
   a) **Choose Policy.** Select video detection policy from the drop-down list.
   b) **Choose Type**. Select the policy type as Request.

6. Click **Continue**.
7. Select the video detection policy from the list and click **Close**.

Configuring Audit Log Messaging

Audit logging enables you to review a condition or a situation in any phase of URL List process. When a Citrix ADC appliance receives an incoming URL, if the responder policy has an URL Set advanced policy expression, the audit log feature collects URL Set information in the URL and stores the details as a log message for any target allowed by audit logging.

The log message contains the following information:

1. Timestamp.
2. Log message type.
3. The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency).
4. Log message information, such as URL set name, policy action, URL.

To configure audit logging for URL List feature, you must complete the following tasks:

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging.

URL List Semantics

The following table lists the URL Match patterns and describes how the URLs within a URL list are matched against the incoming-request URLs. For example, the pattern www.example.com/bar matches only with one page at www.example.com/bar. To match all the pages whose URL starts with ‘ www.example.com/bar’, you would add an asterisk (*) to the end of the URL.

Semantics	URL Pattern	Matched	Unmatched
Subdomain matching	domain.com	domain.com; www.domain.com; sub.one.domain.com	yourdomain.com; wwwdomain.com
URL matching, exact path	domain.com/example/bar/index.html	domain.com/example/bar/index.html; www.domain.com/example/bar/index.html; sub.domain.com/example/bar/index.html	www.domain.com/example/bar/index.html/example/bar/index.html/c

Semantics	URL Pattern	Matched	Unmatched
URL matching, exact path	domain.com/example/I	domain.com/example/I www.domain.com/exar s.domain.com/example	wwwdomaincom/examp do- main.com/example/bar/index.html/
URL matching, subpath matching	domain.com/example/bar/	domain.com/example/bar/ www.domain.com/ example/bar/ index.html; do- main.com/example/bar/index.html/one.jpg	www.domain.com/example/bar/index

URL Categorization

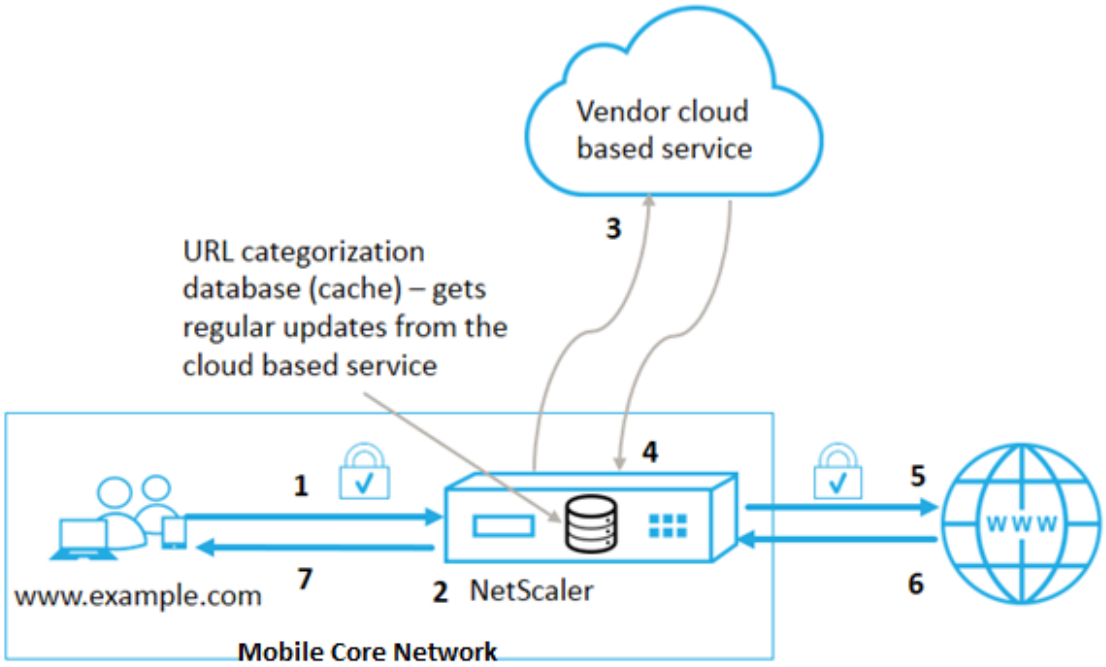
September 14, 2021

URL Categorization restricts user access to specific websites and website categories. As a subscribed service in collaboration with NetSTAR, the feature enables enterprise customers to filter web traffic using a commercial categorization database. The NetSTAR database has a vast number (billions) of URLs classified into different categories, such as social networking, gambling, adult content, new media, and shopping. In addition to categorization, each URL has a reputation score kept up to date based on the site's historical risk profile. We can use NetSTAR data to filter the traffic by configuring advanced policies based on categories, category groups (such as Terrorism, Illegal drugs), or site-reputation scores.

For example, you might block access to dangerous sites, such as sites infected with malware, or selectively restrict access to adult content or entertainment streaming media.

How URL Categorization Works

The following figure shows how the Citrix ADC URL Filtering service is integrated with a commercial URL Categorization database and cloud services for frequent updates.



The components interact as follows:

1. Client sends internet bound URL request.
2. A Citrix ADC policy attempts to evaluate the request in terms of categorization details (such as category, category group, and site-reputation score) retrieved from the URL categorization database. If the database returns the category details, the process jumps to step 5.
3. If the database does not return categorization details, the request is sent to a cloud-based lookup service maintained by a URL categorization vendor. However, the appliance does not wait for a response. Instead, it marks the URL as Uncategorized and jumps to step 5. However, it continues to monitor the cloud query feedback and uses it to update the cache so that future requests can benefit from the cloud lookup.
4. The Citrix ADC appliance receives the URL category details (category, category group, and reputation score) from the cloud-based service and stores it in the cloud cache.
5. If the policy allows the URL, the request is sent to the origin server. Otherwise, the appliance drops or redirects the request, or responds with a custom HTML page.
6. The origin server responds with the requested data to the Citrix ADC appliance.
7. The appliance sends the response to the client.

You can use the URL filtering feature to detect sites that violate safe internet usage mandates issued by the government and implement policies to block these sites. Sites that host adult content, streaming media, or social networking identified as unsafe for children or banned as illegal.

Prerequisites

The feature works on Telco platforms with the purchase of a basic CBM license and CBM Premium license and for other Citrix ADC platforms, the feature works with the purchase of a CNS Premium license.

Note: In addition to a Basic CBM license and a CBM Premium license, the appliance must have a URL Threat Intelligence license with a subscription service for 1 year or 3 years. Before enabling and configuring the feature, you must install the following licenses:

License support for Telco platforms:

- **CBM_TXXX_SERVER_Retail.lic**
- **CBM_TPRE_SERVER_Retail.lic**
- **CNS_WEBF_SSERVER_Retail.lic**

Where XXX is the throughput, for example, Citrix ADC T1000.

License support for other Citrix ADC platforms:

- **CNS_XXX_SERVER_PLT_Retail.lic**

Where XXX is the throughput.

URL Categorization Policy Expressions

The following table lists the different URL categorization policy expressions for identifying incoming URLs and applies a configured action.

Expression	Operation
<text>. URL_CATEGORIZE (< min_reputation>, <max_reputation>)	Returns a URL_CATEGORY object. Reputation score is a number from 1 to 4. To get objects all reputation scores use 0.0 as <min reputation> and . If is greater than 0, the returned object does not contain a category with reputation lower than . If is greater than 0, the returned object does not contain a category with reputation higher than . If the category fails to resolve in a timely manner, the undef value is returned.
<url_category>. CATEGORY	Returns the category string for this object. If the URL does not have a category, or if the URL is malformed, the returned value is “Uncategorized”.

Expression	Operation
<url_category>. GROUP	Returns a string identifying the object's category group. This is a higher level grouping of categories, which is useful in operations that require less detailed information about the URL category. If the URL does not have a category, or if the URL is malformed, the returned value is "Uncategorized".
<url_category>. REPUTATION	Returns the reputation score as a number from 1 to 4, where 4 indicates the riskiest reputation. If the category is "Uncategorized," the reputation value is 2.

Sample Policy Expressions

Policy	Policy Expressions
Policy to select requests for URLs that are in the Search Engine category	add responder policy p1 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGO CATEGORY.EQ("Search Engine")
Policy to select requests for URLs that are in the Adult category group	add responder policy p1 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGO GROUP.EQ("Adult")'
Policy to select requests for Search Engine URLs with a reputation score equal to 4.	add responder policy p2 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGO CATEGORY.EQ("Search Engine")'
Policy to select requests for Search Engine and Shopping URLs	add policy patset good_categories; bind policy good_categories "Search Engine"; bind policy good_categories "Shopping"; add responder policy p3 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGO CATEGORY .EQUALS_ANY("good_categories")
Policy to select requests for Search Engine URLs with a reputation score equal to 4.	add responder policy p5 'CLIENT.SSL.DETECTED_DOMAIN.URL_CATEGORIZE(4,0). CATEGORY.EQ("Search Engine")

URL Categorization Policy Actions

A URL filtering policy evaluates the traffic to identify requests belonging to a particular category. The following table lists the actions that you can assign to a URL filtering policy.

Policy Action	Policy Group	Description
ALLOW	Responder	Allow the incoming request to access the target URL
REDIRECT	Responder	Redirect the incoming request to the URL specified as the target.
DENY	Responder	Deny incoming request.
RESET	Responder, VideoOptimization	Reset connection.
DROP	Responder, VideoOptimization	Drop connection.

> **Note**
>
> For encrypted traffic, the VideoOptimization policy includes actions that implement the URL Filtering actions.

Configuring URL Categorization

To configure URL categorization, begin by enabling the URL Filtering feature. You must then configure the cache memory limits, categorization policy, and virtual servers for HTTP and HTTPS traffic. Configuring URL Categorization by using the CLI.

To use the CLI configure URL categorization on a Citrix ADC appliance, do the following:

- Set up URL Categorization.
  - Enable the URL Filtering feature.
  - Configure shared memory to limit cache memory.
  - Configure URL categorization parameters.
- Configure URL categorization for HTTP traffic.
  - Add URL categorization actions.
  - Add URL categorization policies.
  - Add a load balancing virtual server for HTTP traffic.
  - Bind URL categorization policies to the load balancing virtual server.
- Configure URL categorization for HTTPS traffic.

- Add URL categorization policies.
- Add a SSL-Bridge load balancing virtual server.
- Bind URL categorization policies to the load balancing virtual server.

Setting up URL Categorization

To set up the feature, you must enable the URL Categorization feature, configure the filtering parameters and set the shared memory limit.

To enable URL Filtering feature

At the command prompt, type:

```
enable ns feature URLFiltering VideoOptimization Responder IC SSL AppFlow
```

To configure shared memory limit

At the command prompt, type:

```
1 set cache parameter [-memLimit <megaBytes>]
2 <!--NeedCopy-->
```

Where memLimit is the memory limit for caching.

Example:

```
set cache parameter -memLimit 10
```

To configure URL categorization parameters

At the command prompt, type:

```
1 set urlfiltering parameter [-HoursBetweenDBUpdates <positive_integer>]
     [-TimeOfDayToUpdateDB <HH:MM>]
2 <!--NeedCopy-->
```

***Example:**

```
set urlfiltering parameter -HoursBetweenDBUpdates 3 -TimeOfDayToUpdateDB
03:00
```

Configuring URL categorization for HTTP traffic

To configure the URL categorization feature for HTTP traffic, you must configure a loading balancing virtual server, add URL categorization policies and bind the policies to the virtual server. By doing so, the virtual server receives the HTTP traffic and based on policy evaluation, the system assigns a filtering action.

To add URL categorization action for HTTP traffic

At the command prompt, type:

```
add responder action <name> <type> (<target> | <htmlpage>)[-comment <string
>] [-responseStatusCode <positive_integer>] [-reasonPhrase <string>]
```

Example:

```
add responder action act_url_categorize respondwith "\"HTTP/1.1 200 OK\r\n\
r\n\" + HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY
 + \"\n\""
```

To add URL categorization policy for HTTP traffic

At the command prompt, type:

```
add responder policy <name> <rule> <action> [<undefAction>] [-comment <
string>] [-logAction <string>] [-appflowAction <string>]
```

Example:

```
add responder policy pol_url_categorize_http "HTTP.REQ.HOSTNAME.APPEND(
HTTP.REQ.URL).URL_CATEGORIZE(0,0).GROUP.EQ(\"Adult\")|| HTTP.REQ.HOSTNAME.
APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).GROUP.EQ(\"Gambling\")"RESET
```

To add an HTTP load balancing virtual server

If a virtual server for HTTP traffic is not already configured, at the command prompt, type:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-clt Timeout
<secs>]
```

Example:

```
add lb vserver vsrv-HTTP HTTP * 80 -persistenceType NONE -cltTimeout 120
```

To bind URL categorization policy with load balancing virtual server

At the command prompt, type:

```
bind lb vserver <name> -policyName <string> [-priority <positive_integer>]
```

Example:

```
bind lb vserver vsrv-HTTP -policyName pol_url_categorize_http -priority 10
-gotoPriorityExpression END -type REQUEST
```

Configuring URL categorization for HTTPS traffic

To configure the URL categorization feature for HTTPS traffic, you must configure a SSL-bridge loading balancing virtual server, add URL categorization policies and bind the policies to the SSL-bridge virtual server. By doing so, the server receives the HTTPS traffic and based on policy evaluation, the system assigns a filtering action.

To add URL categorization policy for HTTPS traffic

At the command prompt, type:

```
add videooptimization detectionpolicy <name> -rule <expression> -action <
string> [-undefAction <string>] [-comment <string>] [-logAction <string>]
```

Example:

```
add videooptimization detectionpolicy pol_url_categorize_https_block_adult -
rule "CLIENT.SSL.DETECTED_DOMAIN.URL_CATEGORIZE(0,0).CATEGORY.EQ("Adult")' -
action RESET
```

To add SSL-Bridge load balancing virtual server

At the command prompt, type:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-cltT imeout
<secs>]
```

Example:

```
add lb vserver vsrv-HTTPS SSL_BRIDGE * 443 -persistenceType NONE -cltTimeout
 180
```

To bind categorization policy with SSL-Bridge virtual server

At the command prompt, type:

```
bind lb vserver <name> -policyName <string> [-priority <positive_integer>]
```

Example:

```
bind lb vserver vsrv-HTTPS -policyName pol_url_categorize_https_block_adult
 -priority 20 -type REQUEST
```

Configuring URL Categorization by using the GUI

The GUI enables you to:

- Enable the URL Categorization feature.
- Add URL Categorization actions for HTTP traffic.
- Add URL Categorization policies for HTTP traffic.
- Add URL Categorization policies for HTTPS traffic.
- Add a load balancing virtual server for HTTP traffic.
- Add an SSL bridge load balancing virtual server for HTTPS traffic.
- Bind URL Categorization policies to the load balancing virtual server.
- Bind URL Categorization policies to the SSL-Bridge load balancing virtual server.
- Configure shared memory limit.
- Configure URL categorization parameters.

To enable URL categorization

1. In the navigation pane, expand **System** and then click **Settings**.
2. On the **Settings** page, click **Configure Advanced Features** link.
3. On the **Configure Advanced Features** page, select **URL Filtering** check box.
4. Click **OK** and **Close**.

To add a URL categorization action

1. In the navigation pane, expand **AppExpert** > **Responder** > **Action**.
2. In the details pane, click **Add**.
3. On the **Create Responder Action** page, set the following parameters.
   a) **Name**. Name of the URL categorization policy action.
   b) **Type**. Select an action type.
   c) **Expression**. Use the expression editor to create the policy expression.
   d) **Comments**. A short description of the policy action.
4. Click **Create** and **Close**.

To add a URL categorization policy for HTTP traffic

1. In the navigation pane, expand **AppExpert** > **Responder** > **Policies**.
2. On the details pane, click **Add**.
3. On the **Create Responder Policy** page, set the following parameters.
   a) **Name**. Name of the URL categorization policy action.
   b) **Action**. Select the URL Categorization action that you prefer to associate with the policy.
   c) **Log Action**. Select the log action.
   d) **AppFlow**. Select an AppFlow action.
   e) **Expression**. Use the expression editor to create the policy expression.
   f) **Comments**. A short description about the policy action.
4. Click **Create** and **Close**.

To add a categorization policy for HTTPS traffic

1. Log on to the Citrix ADC appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Detection**.
2. On the **Detection** page, click the **Video Optimization Detection Policies** link.
3. On the Video Optimization Detection Policies page, click **Add**.
4. On the **Create Video Optimization Detection Policy** page, set the following parameters.
   a) **Name**. Name of the optimization policy
   b) **Expression**. Configure policy using custom expressions.
   c) **Action**. Optimization action associated with the policy to handle the incoming video traffic.
   d) **UNDEF Action**. Undefined event if the incoming request does not match the optimization policy.
   e) **Comment**. A short description about the policy.
   f) **Log Action.** Select an audit log action that specifies the action to be performed for the log messages.
5. Click **Create** and **Close**.

To add a load balancing virtual server for HTTP traffic

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** page set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. Choose protocol type as HTTP.
   c) **IP Address Type.** IPv4 or IPv6.
   d) **IP Address.** IPv4 or IPv6, VIP address assigned to the virtual server.

e) **Port**. Port number of the virtual server.

4. Click **OK** to continue with the configuration of other, optional, parameters.
5. Click **Create** and **Close**.

To add an SSL-bridge load balancing virtual server

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. On the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** page, set the following parameters:
   a) **Name**. Name of the load balancing virtual server.
   b) **Protocol**. Select protocol type as SSL-bridge.
   c) **IP Address Type**. IP addressable type.
   d) **IP Address**. IP 4 or IP6 IP address assigned to the virtual server.
   e) **Port**. Port number of the virtual server.
4. Choose **OK** to continue configuration other optional parameters.
5. Click **Create** and then **Close**.

To bind a URL categorization policy to the HTTP load balancing virtual server

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. On the details pane, select the load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. Set the following parameters.
   a) **Choose Policy**. Select URL categorization policy from the drop-down list.
   b) **Choose Type**. Select the policy type as Request.
6. Click **Continue**.
7. Select the URL categorization policy from the list and click **Close**.

To bind a categorization policy to the SSL-bridge load balancing virtual server

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the SSL-bridge load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click **+** icon to access the **Policies** slider.
5. In the **Policies** section, set the following parameters.
   a) **Choose Policy**. Select video detection policy from the drop-down list.
   b) **Choose Type**. Select the policy type as Request.
6. Click **Continue**.
7. Select the video detection policy from the list and click **Close**.

To configure the shared memory limit

1. Sign on to the appliance and navigate to **Optimization** > **Integrated Caching**.
2. In the details pane, click **Change cache settings** link.
3. On the **Cache Global Settings** page, set the following parameters.
    a) **Memory Usage Limit (MB).**
    b) **Active memory Usage Limit**.
    c) **Via Header**.
    d) **Maximum Post Body Length to be Cached**
    e) **Global Undefined-Result Action**
    f) **Enable HA Object Persist**
    g) **Verify Cached Object Persist**
    h) **Prefetches**
4. Click **OK** and **Close**.

To configure URL categorization parameters

1. Sign to the appliance and navigate to **Security**.
2. On the details pane, click **Change URL filtering settings** link.
3. In the **Configuring URL Filtering Params** page, set the following parameters.
    a) Hours Between DB Updates. URL Filtering hours between database updates. Minimum value: 0 and Maximum value: 720.
    b) Time of Day to Update DB. URL Filtering time of day to update the database.
4. Click **OK** and **Close.**

Configuring Audit Log Messaging

When a Citrix ADC appliance receives an incoming URL, if the responder policy has a URL Filtering expression, the audit log feature collects categorization information and displays it as log messages to any target audit log server that is configured. The info is logged.

- Source IP address (the IP address of the client that made the request).
- Destination IP address (the IP address of the requested server).
- Requested URL containing the schema, the host, and the domain name (`http://www.example.com`).
- URL category that the URL filtering framework returns.
- URL category group that the URL filtering framework returned.
- URL reputation number that the URL filtering framework returned.
- Audit log action taken by URL Categorization policy.

To configure audit logging for the URL List feature, you must complete the following tasks:

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging topic.

Storing Failure Errors Using SYSLOG Messaging

At any stage of the URL Filtering process, if there is a system-level failure, the Citrix ADC appliance uses the audit log mechanism to store logs in the ns.log file. The errors are stored as text messages in SYSLOG format so that, an administrator can view it later in a chronological order of event occurrence. These logs are also sent to an external SYSLOG server for archival. For more information, see article CTX229399.

For example, if a failure occurs when you initialize the URL Filtering SDK, the error message is stored in the following messaging format.

Oct 3 15:43:40 <local0.err> ns URLFiltering[1349]: Error initializing NetStar SDK (SDK error=-1). (status=1).

The Citrix ADC appliance stores the error messages under four different failure categories:

- Download failure. If an error occurs when you try to download the categorization database.
- Integration failure. If an error occurs when you integrate an update into the existing categorization database.
- Initialization failure. If an error occurs when you initialize the URL Categorization feature, set categorization parameters, or end a categorization service.
- Retrieval failure. If an error occurs when the appliance retrieves the categorization details of the request.

URL Reputation Score

The URL Categorization feature provides policy-based control to restrict blacklisted URLs. You can control access to websites based on URL category, reputation score, or URL category and reputation score. If a network administrator monitors a user accessing highly risky websites, he or she can use a responder policy bound to the URL reputation score to block such risky websites.

Upon receiving an incoming URL request, the appliance retrieves the category and reputation score from the URL categorization database. Based on the reputation score returned by the database, the appliance assigns a reputation rating for websites. The value can range from 1 to 4, where 4 is the riskiest type of websites, as shown in the following table.

URL Reputation Rating	Reputation Comment
1	Clean site.
2	Unknown site.
3	Potentially dangerous or affiliated to dangerous site.
4	Malicious site.

FAQs

September 14, 2021

This section provides the FAQ on the following Citrix ADC features

- Admin Partition
- AppFlow
- Call Home
- Clustering
- Connection Management
- Content Switching
- Debugging
- Hardware
- High Availability
- Integrated Caching
- Installing, Upgrading, and Downgrading
- Load Balancing
- NetScaler GUI
- SSL

Admin Partition

September 14, 2021

Where can I get the Citrix ADC configuration file for a partition?

The configuration file (*ns.conf*) for the default partition is available in the */nsconfig* directory. For admin partitions, the file is available in the */nsconfig/partitions/<partitionName>* directory.

How can I configure integrated caching in a partitioned Citrix ADC appliance?

> **Note**
>
> Integrated caching in admin partitions is supported from NetScaler 11.0 onwards.

To configure integrated caching (IC) on a partitioned Citrix ADC, after defining the IC memory on the default partition, the superuser can configure the IC memory on each admin partition such that the total IC memory allocated to all admin partitions does not exceed the IC memory defined on the default partition. The memory that is not configured for the admin partitions remains available for the default partition.

For example, if a Citrix ADC appliance with two admin partitions has 10 GB of IC memory allocated to the default partition, and the IC memory allocation for the two admin partitions is as follows:

- Partition1: 4 GB
- Partition2: 3 GB

Then, the default partition has 10 - (4 + 3) = 3 GB of IC memory available for use.

> **Note**
>
> If all IC memory is used by the admin partitions, no IC memory is available for the default partition.

What is the scope for L2 and L3 parameters in admin partitions?

> **Note**
>
> - Applicable from NetScaler 11.0 onwards.
> - For ARP to work in non-default partition, you must enable the “proxyArp” parameter in the “set l2param” command.

On a partitioned Citrix ADC appliance, the scope of updating the L2 and L3 parameters is as follows:

- For L2 parameters that are set by using the “set L2Param” command, the following parameters can be updated only from the default partition, and their values are applicable to all the admin partitions:

  maxBridgeCollision, bdgSetting, garpOnVridIntf, garpReply, proxyArp, resetInterfaceOnHAfailover, and skip_proxying_bsd_traffic.

The other L2 parameters can be updated in specific admin partitions, and their values are local to those partitions.

- For L3 parameters that are set by using the “set L3Param” command, all parameters can be updated in specific admin partitions, and their values are local to those partitions. Similarly, the values that are updated in the default partition are applicable only to the default partition.

How to enable dynamic routing in an admin partition?

> **Note**
>
> Dynamic routing in admin partitions is supported from NetScaler 11.0 onwards.

While dynamic routing (OSPF, RIP, BGP, ISIS, BGP+) is by default enabled on the default partition, in an admin partition, it must be enabled by using the following command:

```
> set L3Param -dynamicRouting ENABLED
```

> **Note**
>
> A maximum of 63 partitions can run dynamic routing (62 admin partitions and 1 default partition).

On enabling dynamic routing on an admin partition, a virtual router (VR) is created.

- Each VR maintains its own vlan0 which will be displayed as vlan0_<partition-name>.
- All unbound IP addresses that are exposed to ZebOS are bound to vlan0.
- The default VR (of the default partition) shows all the VRs that are configured.
- The default VR shows the VLANs that are bound to these VRs (except default VLANs).

Where can I find the logs for a partition?

Citrix ADC logs are not partition-specific. Log entries for all partitions must be stored in the */var/log/* directory.

How can I get audit logs for an admin partition?

In a partitioned Citrix ADC, you cannot have specific log servers for a specific partition. The servers that are defined at the default partition are applicable across all admin partitions. Therefore, to view the audit logs for a specific partition, you have to use the “show audit messages” command.

> **Note**
>
> The users of an admin partition do not have access to the shell and therefore are not able to access the log files.

How can I get web logs for an admin partition?

You can get the web logs for an admin partition as follows:

- **For NetScaler 11.0 and later versions**

  The web logging feature must be enabled on each of the partitions that require web logging. Using the Citrix ADC Web Logging (NSWL) client, the Citrix ADC retrieves the web logs for all the partitions with which the user is associated.

- **For versions prior to NetScaler 11.0**

  Web logs can be obtained only by `nsroot` and other superusers. Also, even though web logging is enabled on the default partition, the Citrix ADC Web Logging (NSWL) client fetches web logs for all the partitions.

To view the partition for each log entry, customize the log format to include the %P option. You can then filter the logs to view the logs for a specific partition.

How can I get the trace for an admin partition?

You can get the trace for an admin partition as follows:

- **For NetScaler 11.0 and later versions**

  In a partitioned Citrix ADC appliance, the `nstrace` operation can be performed on individual admin partitions. The trace files are stored in the */var/partitions/<partitionName>/nstrace/*directory.

  Note: You cannot get the trace of an admin partition by using the GUI. You must use the CLI.

- **For versions prior to NetScaler 11.0**

  The `nstrace` operation can only be performed on the default partition. Therefore, packet captures are available for the entire Citrix ADC system. To get partition-specific packet captures, use VLAN-ID based filters.

How can I get the technical support bundle specific to an admin partition?

To get the tech support bundle for a specific partition, you must run the following command from the default partition:

```
> show techsupport -scope partition -partitionname <string>
```

Note: This command also gives system-specific information.

AppFlow

September 14, 2021

- **Which build of Citrix ADC supports AppFlow?**

  AppFlow is supported on Citrix ADC appliances running version 9.3 and above with nCore build.

- **What is the format used by AppFlow to transmit data?**

  AppFlow transmits information in the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information.

- **What do AppFlow records contain?**

  AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response-status codes, server response time, and latency). IPFIX flow records are based on templates that must be sent before sending flow records.

- **After an upgrade to NetScaler Version 9.3 Build 48.6 Cl, why does an attempt to open a virtual server from the GUI result in the error message "The AppFlow feature is only available on Citrix ADC Ncore"?**

  AppFlow is supported only on nCore appliances. When you open the virtual server configuration tab, clear the **AppFlow** check box.

- **What does the transaction ID in an AppFlow records contain?**

  A transaction ID is an unsigned 32-bit number identifying an application-level transaction. For HTTP, a transaction corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. A typical transaction has four flow records. If the Citrix ADC generates the response by itself (served from the integrated cache or by a security policy), there might be only two flow records for the transaction.

- **What is an AppFlow action ?**

  An AppFlow action is a set of collectors to which the flow records are sent if the associated AppFlow policy matches.

- **What commands can I run on the Citrix ADC appliance to verify that the AppFlow action is a hit?**

  The show AppFlow action. For example:

```
1   > show appflow action
```

```
1) Name: aFL-act-collector-1
  Collectors: collector-1
  Hits: 0
  Action Reference Count: 2
 2) Name: apfl-act-collector-2-and-3
  Collectors: collector-2, collecter-3
  Hits: 0
  Action Reference Count: 1
 3) Name: apfl-act-collector-1-and-3
  Collectors: collector-1, collecter-3
  Hits: 0
  Action Reference Count: 1
<!--NeedCopy-->
```

- **What is an AppFlow collector?**

A collector receives flow records generated by the Citrix ADC appliance. To be able to send flow records, you must specify at least one collector. You can specify up to four. You can remove unused collectors.

- **What Citrix ADC verison is required for using AppFlow?**

  Use NetScaler version 9.3.49.5 or higher, and remember that AppFlow is available in only the nCore builds.

- **What transport protocol does AppFlow use?**

  AppFlow uses UDP as the transport protocol.

- **What ports needs to be opened if I have a firewall in the network?**

  Port 4739. It is the default UDP port the AppFlow collector uses for listening on IPFIX messages. If the user changes the default port, that port must be opened on the firewall.

- **How can I change the default port AppFlow uses?**

  When you add an AppFlow collector by using the add appflowCollector command, you can specify the port to be used.

```
> add appflowCollector coll1 -IPAddress 10.102.29.251 -port 8000
 Done
<!--NeedCopy-->
```

- **What does setting clientTrafficOnly do?**

  Citrix ADC generates AppFlow records only for client-side traffic.

- **How many collectors can be configured at a time?**

You can configure up to four AppFlow collectors at a time on the Citrix ADC appliance. Note that the maximum number of collectors that can be configured on a Citrix ADC appliance is four.

Call Home

September 14, 2021

- **What is Call Home on a Citrix ADC appliance?**

  Call Home monitors, and notifies critical events on a Citrix ADC appliance. By enabling Call Home, you can automate the error notification process. You not only avoid calling Citrix support, raise a service request, and upload system data before Citrix support can troubleshoot the issue, but also identify and resolve issues before it occurs.

- **Is Call Home enabled by default on a Citrix ADC appliance?**

  Yes, Call Home is enabled by default on the appliance. If you upgrade to the latest software from an older version where Call Home was disabled by default, the upgrade process automatically enables the feature. If you later choose to disable it, the updated setting is remembered for all further upgrades. For information, see Call Home.

- **What are the pre-requisites for Call Home to work?**

  Access to an Internet connection.

  Note: If your Citrix ADC appliance does not have an Internet connectivity, you can configure a proxy server through which Citrix ADC can generate System Logs and upload it to the Citrix Technical Support server (CIS).

- **What are the benefits of using Call Home?**

  - Monitor hardware and software error conditions.
  - Notify about the occurrence of critical events that impact your network.
  - Send performance data and System Logs to Citrix to:
    * Analyze and improve product quality.
    * Provide real-time troubleshooting information for proactive issue identification, and faster issue resolution.

- **Which release of Citrix ADC software supports Call Home?**

  Citrix ADC release 10.0 and later.

- **What Citrix ADC platform models support Call Home?**

  Call Home feature is enabled by default on all Citrix ADC platforms and all appliance models (MPX, VPX, and SDX).

  - Citrix ADC MPX: All MPX models.
  - Citrix ADC VPX: All VPX models. In addition, it is supported on VPX appliances that obtain their licenses from external or central licensing pools. However, the feature remains the same as for a standard VPX appliance.
  - Citrix ADC SDX: Monitors the disk drive and assigned SSL chips for any errors or failures. The VPX instances, however, do not have access to the Power Supply Unit (PSU) and therefore their status is not monitored. In an SDX platform, you can configure Call Home either directly on an individual instance or through the SVM.

- **Should I configure SNMP alarm for Call Home to notify error conditions?**

  No, you need not configure SNMP for Call Home to monitor error conditions, because SNMP and Call Home uploads are independent of each other. If you want to be notified each time an error condition occurs, you can configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever a Call Home upload happens. The SNMP alert notifies the local administrator about the occurrences of critical events.

- **How do I contact a technical support?**

  For all critical hardware-related events, Call Home automatically creates a service request to Citrix. For other errors, after you review the System Logs, you can contact the Citrix Technical Support team to open a service request for further investigation. For more information, see http://support.citrix.com/article/CTX200021.

- **What error conditions does Call Home monitor in a Citrix ADC appliance?**

  Call Home supports monitoring of the following events in a Citrix ADC appliance:

  - Compact flash drive errors
  - Hard disk drive errors
  - Power supply unit failure
  - SSL card failure
  - Warm restart
  - Memory anomalies
  - Rate limit drops

- **Do you need a separate license for Call Home?**

  No, Call Home does not require a separate license. You can enable it in all Citrix ADC platform licenses.

- **What data does Call Home send to Citrix Support server and how frequently is it sent?**

  Call Home collects and sends two types of data to the CIS. They are:

  - Basic System information (running Citrix ADC version, deployment mode (standalone, HA, cluster), hardware details and so on). It is sent at the time of Call Home registration and

as part of periodic heartbeats. The heartbeat is sent once every 30 days, but you can configure this interval anywhere from 1 to 30 days. However, a value of less than 5 days is not recommended, because frequent uploads are usually not very useful.

- An abbreviated version of the `show tech support bundle` when there is an error condition. It is sent upon the first occurrence of a particular error condition since the appliance was last started. That is, a reoccurrence of the same error condition does not trigger another upload unless the appliance was rebooted after the previous occurrence.

- **Can Call Home generate and upload system logs through a proxy server?**

  Yes. If your Citrix ADC appliance does not have direct Internet connectivity, you can configure a proxy server and upload System Logs to the Citrix Technical Support server (CIS).

- **Can I review Call Home data before it is sent to CIS?**

  Unfortunately, you cannot review Call Home data before it is sent to CIS. Call Home does not collect any other data in addition to the data that you will provide when contacting the Citrix support team.

- **How secure and private are the Call Home uploads?**

  Call Home provides data security and privacy in the following ways:

  - Uses a secure SSL/TLS channel to transfer data to Citrix servers.
  - Uploaded data is reviewed only by authorized personnel and is not shared with any third party.

Clustering

September 14, 2021

Click here for FAQs on clustering.

Connection Management

September 14, 2021

- **What is an admin connection?**

  An admin connection establishes a connection to the NSIP address and allows administrators to configure and monitor the Citrix ADC appliance.

- **What are the types of admin connections?**

  There are two types of admin connections:

  - SSH connection – Admin users use an SSH client to log on through the NSIP address.
  - NITRO API connection – Admin users use NITRO APIs to automate the logon process to the Citrix ADC appliance.

> **Note**
>
> Admin users can also log on through the GUI to log on, by using a browser to connect to the NSIP address. The GUI internally opens a NITRO API connection. Therefore, a GUI session is equivalent to a NITRO API connection, and FAQs related to the NITRO API apply to GUI.

- **How many concurrent admin connections are allowed on a Citrix ADC appliance?**

  The appliance allows up to 20 concurrent admin connections.

- **Which login credentials are required for an admin logon?**

  Admin logon requires a user name and a password.

  Note: An authentication key can be used instead of a password.

- **Which external authentication methods does a Citrix ADC appliance support?**

  The appliance supports the following external authentication methods:

  - RADIUS
  - LDAP
  - TACACS

- **What is a client?**

  A client is a device (laptop or desktop), used by the admin user to open an admin connection.

- **What is a session token?**

  A session token is a unique identifier that the Citrix ADC appliance issues to a client that sends a NITRO API logon request.

  - API clients can reuse the session token, if it has not expired, for subsequent API requests on new TCP connections
  - GUI clients internally open NITRO API connections and keep the session token active during the GUI session.

- **What is an active session on a Citrix ADC appliance?**

  A CLI session is considered active if the session has not expired and has an open SSH connection with a Citrix ADC appliance.

  A NITRO API session is considered active if the session token timeout has not expired on the Citrix ADC appliance.

- **How does Citrix ADC enforce the concurrent connection limit?**

Every time the Citrix ADC appliance receives an admin connection request (SSH or NITRO API), it checks the number of admin connections it has open. If the number is lower than 20, a new connection is opened.

- **Which counter reflects the number of admin connections on a Citrix ADC appliance?**

  The connection counter (nsconfigd_cur_clients) reflects the number of active connections. This counter is incremented when a client opens new connection to the appliance, and is decremented when a connection is closed.

- **Which counter reflects the number of active tokens on the Citrix ADC appliance?**

  The *configd_cur_tokens* counter reflects the number of active tokens on the Citrix ADC appliance.

- **How does Citrix ADC appliance handle errors on a connection?**

  The Citrix ADC appliance immediately closes the client (CLI, API, and GUI) connection if it encounters errors on a connection.

- **Does a CLI or GUI session on a connection to the management address count against the admin connection limit?**

  Yes, all CLI and GUI connections are TCP based connections, and every TCP connection to the management address counts against the admin connection limit.

- **Does a NITRO session count against the admin connection limit?**

  A NITRO session counts against the admin connection limit if there is an open TCP connection using the session token issued by the Citrix ADC appliance.

- **What is the default timeout period for API, GUI, and CLI sessions on Citrix ADC appliance?**

  The following table lists the default timeout period for API, GUI, and CLI sessions on the Citrix ADC appliance:

Citrix ADC Releases	CLI default timeout period (min)	API default timeout period (min)	GUI default timeout period (min)
NetScaler 9.3	None	30 Minutes	30 Minutes
NetScaler 10.1	None	30 Minutes	30 Minutes
NetScaler 10.5 Onwards	15 Minutes	30 Minutes	15 Minutes

- **How can you set the CLI sessions time out on a Citrix ADC appliance?**

  The CLI session timeout can be configured by running the following command at the CLI prompt:

```
set cli mode -timeout \<xx seconds>
```

- **How do you override the default timeout period when using the NITRO API?**

  You can override the default timeout period for a NITRO API by setting the timeout duration in the “timeout” field of the login object. If the session timeout is set to zero, the session token has an infinite timeout.

  Note: An infinite timeout is not advisable, because sessions that do not time out continue to count against the admin connection count.

- **What happens if a user account is deleted from the Citrix ADC appliance after an admin session is created?**

  For internal system users, the Citrix ADC appliance closes the existing CLI or NITRO API session.

  For external system users, the session remains active until it expires.

- **Can NITRO API clients use a single session token to open multiple admin connections on the Citrix ADC appliance?**

  Yes. Each such connection counts against the admin connection limit.

- **If management access is enabled for a SNIP address, do admin connections to that address count against the limit for the number of admin connections?**

  Yes, admin connections to management address (SNIP) count against the admin connection limit on Citrix ADC.

- **Can a Citrix ADC admin log on to the Citrix ADC appliance after the maximum connections limit is reached?**

  Yes. One more admin connection is allowed after the maximum connection limit is reached.

- **Can NITRO API endpoints open multiple admin connections on Citrix ADC the appliance?**

  Yes, NITRO API endpoints can open multiple admin connections and exhaust the concurrent admin connection limit on a Citrix ADC appliance. In such situations, an extra SSH/CLI connection is allowed and the admin can force closure of old API sessions, or reduce the session timeout duration for the existing API sessions.

- **Can same client open multiple API sessions on a Citrix ADC appliance?**

  Yes, a client can open multiple API sessions by repeatedly logging on. For example, the client might log back on after a reboot.
  Note: Repeated client logons count against the admin connection limit on Citrix ADC appliance.

- **Can API clients use the entire API session token limit?**

  Yes, API clients can use the entire API session token limit, provided by repeatedly logging on without using a previously issued token.

Note: If a client's session timeout is zero, the token is valid forever. Repeated logons using new session tokens can count against the limit for API session tokens.

- **Do CLI sessions count against the API session token limit?**

  No, CLI sessions are not counted against the API session token limit.

- **Can admin users use telnet to open a CLI session?**

  No. Only an SSH client can open a CLI session.

- **What is connection limit and API session limit applicable for various Citrix ADC releases?**

  The following table lists the maximum concurrent admin connection and active API session limits applicable for various Citrix ADC releases:

Citrix ADC Releases	9.3	10.1 (Before 130.x)	10.1 (Before 130.10)	10.1 (From 130.10)
Maximum number of concurrent admin connections	20	20	20	20
Maximum number of active API sessions*	1000	20	1000	1000

Note:

- API sessions are considered active if they have not timed out. For example, if 500 API sessions were created but 100 have expired, 400 API sessions are active.
- An API session need not open a TCP connection to the Citrix ADC appliance.

Content Switching

September 14, 2021

- **I have installed a non-Citrix ADC load balancing appliance on the network. However, I would like to use the content switching feature of the Citrix ADC appliance to direct the client requests to the load balancing appliance. Is it possible to use the Content switching feature of the Citrix ADC appliance with a non-Citrix ADC load balancing appliance?**

Yes. You can use the Content switching feature of the Citrix ADC appliance with the load balancing feature of the Citrix ADC appliance or a non-Citrix ADC load balancing appliance. However, when using the non-Citrix ADC load balancing appliance, make sure that you create a load balancing virtual server on the Citrix ADC appliance and bind it to the non-Citrix ADC load balancing appliance as a service.

- **How is a Content switching virtual server different from a load balancing virtual server?**

  A Content switching virtual server is capable only of sending the client requests to other virtual servers. It does not communicate with the servers.

  A Load balancing virtual server balances the client load among servers and communicates with the servers. It monitors server availability and can be used to apply different load balancing algorithms to distribute the traffic load.

  Content switching is a method used to direct client requests for specific types of content to targeted servers by way of load balancing virtual servers. You can direct the client requests to the servers best suited to handle them. This result in reduced overheads to process the client requests on the servers.

- **I want to implement the Content switching feature of the Citrix ADC appliance to direct the client requests. What types of client request can I direct by using the Content switching feature?**

  You can direct only HTTP, HTTPS, FTP, TCP, Secure TCP, and RTSP client requests by using the Content switching feature. To direct HTTPS client requests, you must configure the SSL offload feature on the appliance.

- **I want to create Content switching rules on the Citrix ADC appliance. What are the various elements of the client request on which I can create a content switching rule?**

  You can create the content switching rules based on the following elements and their values in the client request:

  - URL
  - URL tokens
  - HTTP version
  - HTTP Headers
  - Source IP address of the client
  - Client version
  - Destination TCP port

- **I understand that the content switching feature of the Citrix ADC appliance helps enhance the performance of the network. Is this correct?**

  Yes. You can direct the client requests you the servers best suited to handle them. The result is reduced overhead for processing the client requests on the servers.

- **Which feature of the Citrix ADC appliance should I configure on the Citrix ADC appliance to enhance the site manageability and response time to the client requests?**

  You can configure the content switching feature of the Citrix ADC appliance to enhance the site manageability and response time to the client request. This feature enables you to create content groups within the same domain name and IP address. This approach is flexible, unlike the common approach of explicitly partitioning the content into different domain names and IP addresses, which are visible to the user.

  Multiple partitions dividing a website into various domain names and IP addresses force the browser to create a separate connection for each domain it finds when rendering and fetching the content of a webpage. These additional WAN connections degrade the response time for the webpage.

- **I have hosted a web site on a web server farm. What advantages does the Citrix ADC content switching feature offer for this type of setup?**

  The content switching feature provides the following advantages on a Citrix ADC appliance in a site that is based in a web server farm:

  - Manage the site content by creating a content group within the same domain and IP address.
  - Enhance the response time to client requests by using the content group within the same domain and IP address.
  - Avoid the need for full content replication across domains.
  - Enable application-specific content partitioning. For example, you can direct client requests to a server that handles only dynamic content or only static content, as appropriate for the request.
  - Support multi-homing of multiple domains on the same server and use the same IP address.
  - Reuse connections to the servers.

- **I want to implement the content switching feature on the Citrix ADC appliance. I want to direct the client requests to the various servers after evaluating the various parameters of each request. What approach should I follow to implement this setup when configuring the content switching feature?**

  You can use policy expressions to create policies for the content switching feature. An expression is a condition evaluated by comparing the qualifiers of the client request to an operand by using an operator. You can use the following parameters of the client request to create an expression:

  - **Method**- HTTP request method.
  - **URL**- URL in the HTTP header.
  - **URL TOKENS**- Special tokens in the URL.

- **VERSION**- HTTP request version.
- **URL QUERY**- Contains the URL Query LEN, URL LEN, and HTTP header.
- **SOURCEIP**- IP address of the client.

Following is a complete list of the operators that you can use to create an expression:

- == (equals)
- != (not equals)
- EXISTS
- NOT EXISTS
- CONTAINS
- NOT CONTAINS
- GT (greater than)
- LT (less than)

You can also create various rules, which are logical aggregations of a set of expressions. You can combine multiple expressions to create rules. To combine expressions, you can use the && (AND) and	(OR) operators. You can also use parenthesis to create nested and complex rules.

- **I want to configure a rule based policy along with a URL based policy for the same content switching virtual server. Is it possible to create both types of policies for the same content switching virtual server?**

  Yes. You can create both type of policies for the same content switching virtual server. However, be sure to assign priorities to set an appropriate precedence for the policies.

- **I want to create content switching policies that evaluate the domain name, along with a prefix and suffix of a URL, and direct the client requests accordingly. Which type of content switching policy should I create?**

  You can create a Domain and Exact URL policy. When this type of policy is evaluated, the Citrix ADC appliance selects a content group if the complete domain name and the URL in the client request match the ones configured. The client request must match the configured domain name and exactly match the prefix and suffix of the URL if they are configured.

- **I want to create content switching policies that evaluate the domain name, along with a partial prefix and suffix of URL, and direct the client requests accordingly. Which type of content switching policy should I create?**

You can create a Domain and Wildcard URL policy for the content switching virtual server. When this type of policy is evaluated, the Citrix ADC appliance selects a content group if the request matches the complete domain name and partially matches the URL prefix.

- **What is a Wildcard URL policy?**

  You can use wildcards to evaluate partial URLs in client requests to the URL you have configured on the Citrix ADC appliance. You can use wildcards in the following types of URL-based policies:

  - Prefix only. For example, the /sports/* expression matches all URLs available under the /sports URL. Similarly, the /sports* expression matches all URLs whose prefix is /sports.
  - Suffix only. For example the /*.jsp expression matches all URLs with a file name extension of jsp.
  - Prefix and Suffix. For example, the /sports/*.jsp expression matches all URLs under the /sports/ URL that also have the jsp file name extension. Similarly, the /sports*.jsp expression matches all URLs with a prefix of /sports* and a file name extension of jsp.

- **What is a Domain and Rule policy?**

  When you create a Domain and Rule policy, the client request must match the complete domain and the rule configured on the Citrix ADC appliance.

- **What is the default precedence set for evaluating policies?**

  By default, the rule based policies are evaluated first.

- **If some of the content is the same for all client requests, what type of precedence should I use for evaluating policies?**

  If some of the content is the same for all the users and different content must be served on the basis of client attributes, you can use URL-based precedence for policy evaluation.

- **What policy expression syntaxes are supported in content switching?**

  Content switching supports two types of policy expressions:

  - **Classic Syntax-** Classic syntax in content switching starts with the keyword REQ and is more advanced than the default syntax. Classic policies cannot be bound to an action. Therefore, the target load balancing virtual server can be added only after binding the content switching virtual server.
  - **Default Syntax:** Default syntax generally starts with the key word HTTP and is easier to configure. A target load balancing virtual server action can be bound to a Default Syntax policy, and the policy can be used on multiple content switching virtual servers.

- **Can I bind a single content switching policy to multiple virtual servers?**

  Yes. You can bind a single content switching policy to multiple virtual servers by using policies with defined actions. Content switching policies that use an action can be bound to multiple content switching virtual servers because the target load balancing virtual server is no longer

specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of the content switching configuration.

For more information, see the following Knowledge Center articles and Citrix documentation topics:

- See CTX122918 - How to Bind the Same Content Switching Policy to Two Content Switching virtual server on a Citrix ADC Appliance.
- See CTX122736 - How to Bind the Same Advanced Policy to Multiple Content Switching Virtual Servers using Policy Labels.
- Configuring Basic Content Switching.

- **Can I create an action based policy using classic expressions?**

  No. As of now Citrix ADC does not support policies using classic syntax expressions with actions. The target load balancing virtual server must be added when binding the policy instead of defining it in an action.

Debugging

September 14, 2021

- **How can I determine the interface (CLI, GUI, or API) through which an operation was performed?**

  The Citrix ADC keeps track of the interfaces through which operations are performed. You can view this information in syslogs (in the GUI, navigate to Configuration > System > Auditing > Audit Messages > Syslog messages) or in the ns.log (located at the /var/log/ directory) file.

  For example, operations that are performed through the API are flagged as "API CMD_EXECUTED."

Hardware

September 14, 2021

Click here for FAQs about MPX hardware.

High Availability

September 14, 2021

- **What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?**

  In an HA configuration, both nodes use the following ports to exchange HA related information:

  - UDP Port 3003, to exchange heartbeat packets
  - Port 3010, for synchronization and command propagation

- **What configurations are not synced or propagated in an HA configuration in either INC or non-INC mode?**

  Configurations implemented with the following commands are neither propagated nor synced to the secondary node:

  - All node specific HA configuration commands. For example, `add ha node`, `set ha node`, and `bind ha node`.
  - All Interface related configuration commands. For example, set interface and unset interface.
  - All channel related configuration commands. For example, add channel, set channel, and bind channel.

  For more information about HA Configuration in INC mode, see Configuring High Availability Nodes in Different Subnets.

- **What configurations are not synced or propagated in an HA configuration in INC mode?**

  The following configurations are neither synced nor propagated. Each node has its own.

  - MIPs
  - SNIPs
  - VLANs
  - Routes (except LLB routes)
  - Route monitors
  - RNAT rules (except any RNAT rule with VIP as the NAT IP)
  - Dynamic routing configurations.

- **What are the conditions that trigger synchronization?**

  Synchronization is triggered by any of the following conditions:

  - The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.
    Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:
    * All HA configuration related commands. For example, `add ha node`, `set ha node`, and `bind ha node`.

        * All Interface related commands. For example, set interface and unset interface.
        * All channel-related commands. For example, add channel, set channel, and bind channel.
    - The secondary node comes up after a restart.
    - The primary node becomes secondary after a failover.

- **Does a configuration added to the secondary node get synchronized on the primary?**

  No, a configuration added to the secondary node is not synchronized to the primary.

- **What could be the reason for both nodes claiming to be the primary in an HA configuration?**

  The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem can be with the network between the nodes.

- **Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?**

  Different system-clock settings on the two nodes can cause the following issues:

    - The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
    - After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
    - Similar considerations apply to any time related decisions on the nodes.

- **What are the conditions for failure of the *force HA sync* command?**

  Forced synchronization fails in any of the following circumstances:

    - You force synchronization when synchronization is already in progress.
    - The secondary node is disabled.
    - HA synchronization is disabled on the current secondary node.
    - HA propagation is disabled on the current primary node and you force synchronization from the primary.

- **What are the conditions for failure of the *sync HA files* command?**

  Synchronizing configuration files fail if the secondary node is disabled.

- **In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?**

  No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the *force failover* command.

- **What are the conditions for failure of the *force failover* command?**

  A forced failover fails in any of the following circumstances:

  - The secondary node is disabled.
  - The secondary node is configured to remain secondary.
  - The primary node is configured to remain primary.
  - The state of the peer node is unknown.

Integrated Caching

September 14, 2021

Content Groups

- **How is a DEFAULT content group different from other content groups?**

  The behavior of the DEFAULT content group is the same as any other group. The only attribute that makes the DEFAULT content group special is that if an object is being cached and no content group has been created. The object is cached in the DEFAULT group.

- **What is the 'cache-Control' option of the content group level?**

  You can send any cache-control header the browser. There is a content group level option, -cacheControl, which enables you to specify the cache-control header that you want to be inserted in the response to the browser.

- **What is the 'Minhit' option in content group level?**

  `Minhit` is an integer value specifying the minimum number of select to a cache policy before the object is cached. This value is configurable at the content group level. Following is the syntax to configure this value from the CLI.

  ```
  add/set cache contentGroup \<Content_Group_Name> [-minHits \<Integer>]
  ```

- **What is the use of the expireAtLastByte option?**

  The expireAtLastByte option enables the integrated cache to expire the object when it is downloaded. Only requests that are outstanding requests then are served from the cache. any new requests are sent to the server. This setting is useful when the object is frequently modified, as in the case of stock quotes. This expiry mechanism works along with the Flash Cache feature. To configure a expireAtLastByte option, run the following command from the CLI:

  ```
  add cache contentGroup \<Group_Name> -expireAtLastByte YES
  ```

Cache policy

- **What is a caching policy?**

  Policies determine which transactions are cacheable and which are not. Also, policies add or override the standard HTTP caching behavior. Policies determine an action, such as CACHE or NOCACHE, depending on the specific characteristics of the request or response. If a response matches the policy rules, the object in the response is added to the content group configured in the policy. If you have not configured a content group, the object is added to the DEFAULT content group.

- **What is a policy hit?**

  A select occurs when a request or response matches a cache policy.

- **What is a miss?**

  A miss occurs when a request or response does not match any cache policy. A miss can also occur if the request or response matches a cache policy but some override of RFC behavior prevents the object from being stored in the cache.

- **I have configured Integrated Caching feature of the Citrix ADC appliance. When adding the following policy, an error message appears. Is there any error in the command?**

  ```
  add cache policy image_caching -rule exp1 | ns_ext_not_jpeg -action
  cache
  ```

  ```
  \> ERROR: No such command
  ```

  In the preceding command, the expression must be within the quotation marks. Without quotation marks, the operator is considered to be the pipe operator.

Memory Requirements

- **What are the commands that I can run on the Citrix ADC appliance to check the memory allocated to cache?**

  To display the memory allocated for cache in the Citrix ADC appliance, run any of the following commands from the CLI:

  - `show cache parameter`

    In the output, check the value of the Memory usage limit parameter. This is the maximum memory allocated for cache.

  - `show cache \<Content_Group_Name>`

    In the output, check the values of the Memory usage and Memory usage limit parameters indicating the memory used and allocated for the individual content group.

- **My Citrix ADC appliance has 2 GB of memory. Is there any recommended memory limit for cache?**

  For any model of the Citrix ADC appliance, you can allocate half of the memory to the cache. However, Citrix recommends allocating a little less than half of the memory, because of internal memory dependency. You can run the following command to allocate 1 GB of memory to the cache:

  ```
  set cache parameter -memLimit 1024
  ```

- **Is it possible to allocate memory for individual content groups?**

  Yes. Even though you allocate memory for the integrated cache globally by running the set cache parameter –memlimit<Integer>, you can allocate memory to individual content groups by running the set cache <Content_Group_Name> –memLimit <Integer> command. The maximum memory you can allocate to content groups (combined) cannot exceed the memory you have allocated to the integrated cache.

- **What is the dependency of memory between integrated cache and TCP buffer?**

  If the Citrix ADC appliance has 2 GB memory, then the appliance reserves approximately 800 MB to 900 MB of memory and the remaining is allocated to the FreeBSD operating system. Therefore, you can allocate up to 512 MB of memory to the integrated cache and the rest is allocated to the TCP buffer.

- **Does it affect the caching process if I do not allocate global memory to the integrated cache?**

  If you do not allocate memory to the integrated cache, all requests are sent to the server. To make sure that you have allocated memory to the integrated cache, run the show cache parameter command. Actually no objects are cached if the global memory is 0, so it must be set first.

Verification commands

- **What are the options for displaying cache statistics?**

  You can use either of the following options to display the statistics for cache:

  - `stat cache`

    To display the summary of the cache statistics.

  - `stat cache -detail`

    To display the full details of the cache statistics.

- **What are the options for displaying the cached content?**

  To display the cached content, you can run the `show cache object` command.

- **What is the command that I can run to display the characteristics of an object stored in cache?**

  If the object stored in the cache is, for example, GET //10.102.12.16:80/index.html, you can display the details about the object by running the following command from the CLI of the appliance:

  ```
  show cache object -url '/index.html'-host 10.102.3.96 -port 80
  ```

- **Is it mandatory to specify the group name as a parameter to display the parameterized objects in cache?**

  Yes. It is mandatory to specify the group name as a parameter to display the parameterized objects in the cache. For example, consider that you have added the following policies with the same rule:

  ```
  1 add cache policy p2 -rule ns_url_path_cgibin -action CACHE -
      storeInGroup g1
  2 add cache policy p1 -rule ns_url_path_cgibin -action CACHE -
      storeInGroup g2
  3 <!--NeedCopy-->
  ```

  In this case, for the multiple requests, if policy p1 is evaluated, its select counter is incremented and the policy stores the object in the g1 group, which has select parameters. Therefore, you have to run the following command to display the objects from the cache:

  ```
  show cache object -url "/cgi-bin/setCookie.pl"-host 10.102.18.152
  groupName g1
  ```

  Similarly, for another set of multiple requests, if policy p2 is evaluated, its select counter is incremented and the policy stores the object in the g2 group, which does not have select parameters. Therefore, you have to run the following command to display the objects from the cache:

  ```
  show cache object -url "/cgi-bin/setCookie2.pl"-host 10.102.18.152
  ```

- **I notice that there are some blank entries in the output of the nscachemgr command. What are those entries?**

  Consider the following sample output of the `nscachemgr` command. The blank entries in this output are highlighted in bold face for your reference:

  ```
  1 root@ns# /netscaler/nscachemgr -a
  2 //10.102.3.89:80/image8.png
  3 //10.102.3.97:80/staticdynamic.html
  4 //10.102.3.97:80/
  5 //10.102.3.89:80/image1.png
  6 //10.102.3.89:80/file5.html
  7 //10.102.3.96:80/
  ```

```
 8   //10.102.3.97:80/bg_logo_segue.png
 9   //10.102.3.89:80/file500.html
10   //10.102.3.92:80/
11   //10.102.3.96:80/cgi-bin/rfc/ccProxyReval.pl
12   Total URLs in IC = 10
13   <!--NeedCopy-->
```

The blank entries in the output are due to the default caching properties for GET / HTTP/1.1.

Flushing Objects

- **How can I flush a selective object from the cache?**

  You can identify an object uniquely by its complete URL. To flush such an object, you can perform any of the following tasks:

  - Flush cache
  - Flush content group
  - Flush the specific object

  To flush the specific object, you have to specify the query parameters. You specify the invalParam parameter to flush the object. This parameter applies only to a query.

- **Does any change in the cache configuration trigger flushing of cache?**

  Yes. When you change to the cache configuration, all the SET cache commands inherently flush the appropriate content groups.

- **I have updated the objects on the server. Do I need to flush the cached objects?**

  Yes. When you update objects on the server, you must flush the cached objects, or at least the relevant objects and content groups. The integrated cache is not affected by an update to the server. It continues to serve the cached objects until they expire.

Flash Cache

- **What is Flash Cache feature of the Citrix ADC appliance?**

  The phenomenon of Flash crowds occurs when many clients access the same content. The result is a sudden surge in traffic toward the server. The Flash Cache feature enables the Citrix ADC appliance to improve performance in such a situation by sending only one request to the server. All other requests are queued on the appliance and the single response is served to the requests. You can use either of the following commands to enable the Fast Cache feature:

  - `add cache contentGroup \<Group_Name> -flashCache YES`
  - `set cache contentGroup \<Group_Name> -flashCache YES`

- **What is the limit for Flash Cache clients?**

  The number of Flash Cache clients depends on the availability of resources on the Citrix ADC appliance.

Default Behavior

- **Does the Citrix ADC appliance proactively receive objects upon expiry?**

  The Citrix ADC appliance never proactively receives objects on expiry. This is true even for the negative objects. The first access after expiry triggers a request to the server.

- **Does the integrated cache add clients to the queue for serving even before it starts receiving the response?**

  Yes. The integrated cache adds clients to the queue for serving even before it starts receiving the response.

- **What is the default value for the Verify cached object using parameter of the cache configuration?**

  HOSTNAME_AND_IP is the default value.

- **Does the Citrix ADC appliance create log entries in the log files?**

  Yes. The Citrix ADC appliance creates log entries in the log files.

- **Are compressed objects stored in the cache?**

  Yes. Compressed objects are stored in the cache.

Interoperability with other features

- **What happens to objects that are currently stored in cache and are being accessed through SSL VPN?**

  Objects stored in the cache and accessed regularly are served as cache, select when accessed through the SSL VPN.

- **What happens to objects stored in the cache when accessed through SSL VPN and later accessed through a regular connection?**

  The objects stored through the SSL VPN access are served as a select when accessed through the regular connection.

- **When using web logging, how do I differentiate entries that indicate response served from cache from those served by the server?**

For responses served from the integrated cache, the server log field contains the value IC. For responses served from a server, the server log field contains the value sent by the server. Following is a sample log entry for an integrated caching transaction:

```
"10.102.1.52 - "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 4.0; .NET
 CLR 1.0.3705)""GET /"200 0 "IC"10.102.1.45"
```

Along with a client request, the response logged is the one sent to the client and not necessarily the one sent by the server.

> **Note**
>
> When using the web logging, the responses from the integrated cache contains the value IC in the server log field. The server log field is present in the NSWL client with "%o1" format specifier.

Miscellaneous

- **What do you mean by configuring relexpiry and absexpiry?**

  By configuring `relexpiry` and `absexpiry`, it means that you are overriding the header irrespective of what appears in the header. You can configure a different expiry setting and the content group level. With `relexpiry`, the expiration of the header is based on the time at which the object is received by the Citrix ADC. With `absexpiry`, expiration is based on the time configured on the Citrix ADC. `Relexpiry` is configured in terms of seconds. `Absexpiry` is a time of day.

- **What do you mean by configuring weakpos and heuristic?**

  The `weakpos` and heuristic are like fallback values. If there is an expiry header, it is considered only if the last-modified header is present. The Citrix ADC appliance sets expiry based on the last-modified header and the heuristic parameter. The heuristic expiry calculation determines the time to expiry by checking the last-modified header. Some percentage of the duration since the object was last modified is used as time to expiry. The heuristic of an object that remains unmodified for longer periods of time and is likely to have longer expiry periods. The –heurExpiryParam specifies what percentage value to use in this calculation. Otherwise, the appliance uses the `weakpos` value.

- **What should I consider before configuring dynamic caching?**

  If there is some parameter that is in name-value form and does not have the full URL query, or the appliance receives the parameter in a cookie header or POST body, consider configuring dynamic caching. To configure dynamic caching, you have to configure the hitParams parameter.

- **How is hexadecimal encoding supported in the parameter names?**

  On the Citrix ADC appliance, the %HEXHEX encoding is supported in the parameter names. In the names that you specify for hitParams or invalParams, you can specify a name that contains

%HEXHEX encoding in the names. For example, name, name%65, and n %61m%65 are equivalent.

- **What is the process for selecting a hitParam parameter?**

  Consider the following excerpt of an HTTP header for a POST request:

```
POST /data2html.asp?param1=value1&param2=&param3&param4=value4
HTTP/1.1
Accept: image/gif, image/x-xbitmap, image/jpeg, image/pjpeg,
application/vnd.ms-powerpoint, application/vnd.ms-excel,
application/msword, application/x-shockwave-flash, */*
Referer: http://10.102.3.97/forms.html
Accept-Language: en-us
Content-Type: application/x-www-form-urlencoded
Accept-Encoding: gzip, deflate
User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1)
Host: 10.102.3.97
Content-Length: 153
Connection: Keep-Alive
Cache-Control: no-cache
Cookie: ASPSESSIONIDQGQGGRNY=NNLLKDADEENOAFLCCDGFGDMO
S1=This+text+is+only+text%2C+not+more+and+not+less%2C+%0D%0Ajust+
   text+to+be+itself%2C+namely+%22Text%22+to+be+posted+as+text
   +%28what+else...%29&B1=Submit
<!--NeedCopy-->
```

  In the preceding request, you can use S1 and B1, highlighted in bold face for your reference, as hitParams depending on your requirements. Also, if you use -matchCookies YES in the ASPSESSIONIDQGQGGRNY content group, then you can also use these parameters as hitParams.

- **What happens to the queued clients if the response is not cacheable?**

  If the response is not cacheable, all the clients in the queue receive the same response that the first client receives.

- **Can I enable the Poll every time (PET) and Flash Cache features on the same content group?**

  No. You cannot enable PET and Flash Cache on the same content group. The integrated cache does not perform the AutoPET function on Flash Cache content groups. The PET feature ensures that the integrated cache does not serve a stored object without consulting the server. You can configure PET explicitly for a content group.

- **When are the log entries created for the queued clients?**

  The log entries are created for the queued clients soon after the appliance receives the response

header. The log entries are created only if the response header does not make the object non-cacheable.

- **What is the meaning of the DNS, HOSTNAME, and HOSTNAME_AND_IP values of the Verify cached object using parameter of the cache configuration?**

  The meanings are as follows:

  - `set cache parameter -verifyUsing HOSTNAME`

    The command ignores the destination IP address.

  - `set cache parameter -verifyUsing HOSTNAME_AND_IP`

    The command matches the destination IP address.

  - `set cache parameter -verifyUsing DNS`

    The command uses the DNS server.

- **I have set weakNegRelExpiry to 600, which is 10 minutes. I noticed that 404 responses are not getting cached. What is the reason?**

  This completely depends on your configuration. By default, 404 responses are cached for 10 minutes. If you want all 404 responses to be fetched from the server, specify–weakNegRelExpiry 0. You can fine-tune the –weakNegRelExpiry to a desired value, such as higher or lower to get the 404 responses cached appropriately. If you have configured –absExpiry for positive responses, then it might not yield the desired results.

- **When the user accesses the site by using the Mozilla Firefox browser, the updated content is served. However, when the user accesses the site by using the Microsoft Internet Explorer browser, stale content is served. What could be the reason?**

  The Microsoft Internet Explorer browser might be taking the content from its local cache instead of the Citrix ADC integrated cache. The reason can be that the Microsoft Internet Explorer browser is not respecting the expiry related header in the response.

  To resolve this issue, you can disable the local cache of the Internet Explorer and clear the offline content. After clearing the offline content, the browser must display the updated content.

- **What if Hits are zero?**

  Check to see if the server time and NS time are in sync. And the weakPosrelexpiry limit set must bear the time difference between NS and server as following:

```
1  root@ns180\# date
2  Tue May 15 18:53:52 IST 2012
3  <!--NeedCopy-->
```

- **Why are policies getting hits but nothing is being cached?**

  Verify that memory is allocated to the integrated cache and that the allocation is greater than zero.

- **Is it possible to zero the cache counters?**

  There is no command line or GUI option for setting the cache counters to zero, and flushing the cache does not do so either. Rebooting the box automatically sets these counters to zero.

Install, upgrade, and downgrade

September 14, 2021

Install and upgrade

How to download a specific Citrix ADC release build package?

For information on downloading a specific Citrix ADC release build package, see Download a Citrix ADC release package.

How to upgrade the system software of a Citrix ADC appliance?

For information on upgrading the system software of a Citrix ADC appliance, see Upgrade a Citrix ADC standalone appliance.

Where do I find the release notes for a Citrix ADC release build?

The release notes document for a Citrix ADC release build lists the following for the release build:

- Enhancements
- Fixed issues
- Known issues

The release notes document for a Citrix ADC release build is found at the following locations:

- Citrix ADC firmware or virtual appliance downloads page of a specific release build.
- Citrix ADC release notes page in Citrix docs site

Where do I find security updates for Citrix ADC appliances?

Citrix security team regularly releases security bulletins on Common Vulnerabilities and Exposures (CVE) for all related Citrix products. This information can be found at Citrix security bulletin. Alternatively, you can search for a specific CVE at Citrix Support site.

What is the use of the zebos.conf file available in a Citrix ADC release?

A Citrix ADC appliance uses ZebOS as the routing suite. The zebos.conf file available in a Citrix ADC release is the configuration file for ZebOS.

I want to change the SSH port (22) on the Citrix ADC appliance to some other port. Is it possible to change the SSH port on the appliance?

Yes. You can change the SSH port on the Citrix ADC appliance by editing the sshd_config file in the /nsconfig directory. If the file does not exist in the /nsconfig directory, copy it from the /etc directory.

In the sshd_config file, edit the entry for Port 22 to Port <Number>, where <Number> is the target port number. If you do not want to restart the appliance and make the changes effective, terminate the `sshd` process by using the kill command, and then restart the process.

The flash directory is missing from the Citrix ADC appliance. What procedure must I follow to mount the flash directory?

To mount the flash directory, do the following:

1. Start the Citrix ADC appliance in single-user mode.

   When the appliance starts, the following message appears:

   Select [Enter] to boot immediately, or any other key for the command prompt. Booting [kernel] in 10 seconds…" Select space and you must see the following prompt:

   Type '?' for a list of commands, 'help' for more detailed help.

2. Enter the following command to start FreeBSD in single-user mode:

   boot –s

   After the appliance starts, the following message appears:

   Enter full pathname of shell or RETURN for /bin/sh:

3. Press Enter to display the # prompt.
4. Run the following command to mount the flash directory:

```
mount /dev/ad0s1a /flash

Note: If the preceding command displays an error message about
   permissions, run the following command to check the disk for
   consistency:

fsck /dev/ad0s1a

Run the mount command again to mount the flash directory.
```

5. Restart the appliance.
6. From the shell prompt, run the following command to verify that the flash directory is mounted:

```
df -kh
```

I want to log on to the Citrix ADC appliance without entering the password. Is it possible to configure SSH on the appliance to allow that?

Yes. You can configure SSH on the Citrix ADC appliance to log on without a password. However, you must provide your user name. To configure SSH for logging in without a password, do the following:

1. Run the following command to generate the public and private keys:

```
\# ssh-keygen -t rsa
```

2. Run the following command to copy the id_rsa.pub file to the .ssh directory of the remote host that you want to log on to:

```
\# scp id_dsa.pub \<user>@\<remote_host>/.ssh/id_dsa.pub
```

3. Log on to the remote host.
4. Change to the .ssh directory.
5. Run the following commands to add the public key of the client to the known public keys:

```
\# cat id_dsa.pub >> authorized_keys2

\# chmod 640 authorized_keys2

\# rm id_dsa.pub
```

What is the procedure to reset the Citrix ADC appliance BIOS? Under what circumstances must I reset the BIOS?

To reset the BIOS of the Citrix ADC appliance, complete the following procedure:

1. Connect to the appliance through the serial port.
2. Start the appliance and press Delete when the boot-up process starts.

   Pressing Delete during the POST process displays the appliance's BIOS settings.
3. Activate the Exit page of the BIOS settings.
4. Select the Load Optimal Defaults option. The Load Optimal Settings message box appears.
5. Select OK.
6. Make the following changes to the BIOS settings on the various tabs:

   Tab
7. Activate the Exit page of the BIOS settings.
8. Select Save changes and Exit.
9. Select OK to confirm.
10. Verify that the appliance starts cleanly and the serial console displays output after the appliance starts.

    You must reset BIOS when the serial console does not respond. This usually happens after you upgrade the appliance and the serial console is disabled. However, you can still access the appliance by using the telnet or SSH utility.

I need to reset the Citrix ADC appliance to the factory defaults. What procedure must I follow?

To reset the Citrix ADC appliance to the factory defaults, you need to reset two environments: the Citrix ADC application environment and the base FreeBSD environment.
To reset the Citrix ADC application environment of the appliance to the factory defaults, do the following:

1. Make a backup of the appliance's /nsconfig/ns.conf.
2. Delete the /nsconfig/ns.conf file.
3. Restart the appliance. To reset the FreeBSD environment of the appliance to the factory defaults, do the following:
   a) Install a fresh Citrix ADC code image on the appliance. This overwrites several FreeBSD-level configuration files with default values.
   b) Delete any users and groups that are added to the appliance, that is, all except the default users.

c) Delete the /etc/resolv.conf file.
d) Delete the entries that you have added to the /etc/hosts file.
e) If the /etc/rc.netscaler file exists, delete it.
f) Open the /etc/nsperm_group_suser file and make sure that all IOCTL entries are comment entries.
g) Open the /etc/rc.conf file and make sure that the syslogd_enable=NO entry is not changed to syslogd_enable=YES.
h) Open the /etc/syslog.conf file and make sure that there are no additional entries in the file.
i) Delete the contents of the /var/nslog, /var/nstrace, and /var/crash files.
j) If the syslog process is enabled on the appliance and the appliance creates log files locally, delete the contents of the log files listed in the /etc/syslog.conf file. The files are created in the /var/log directory. For example, if the syslog process writes system events to the /var/log/events file, and `sslvpn` access events to the /var/log/sslvpnevents file, delete these files.

The appliance displays a message similar to the "Jun 21 12:20:18 ns /flash/ns-10.0-47.15: [1/2]dc0: NIC hangs condition #663: TX 10000/10000, RX 0, HF 0" message on the console. What is the meaning of this message?

The message consists of the following components (shown here as examples):

- #663: Number of times this condition has occurred on the appliance.
- TX 10000/10000: Number of packets that the appliance attempted to transmit, and number of packets transmitted. If both numbers are the same, as in this example, the NIC transmitted all the packets that the appliance attempted to transmit.
- RX 0: Number of packets received. In this example, no packet was received.
- HF0: Number of hardware issues reported by the NIC. In this example, the NIC did not report any hardware issue.

If the appliance does not receive any packets, it reports a hang condition, because on a network it is unlikely not to receive any packets. However, if the appliance is plugged into quite the interface, you can ignore this error message.

After I upgraded the Citrix ADC release on the appliance, the appliance still displays the earlier release/build. What can be the reason?

The appliance displays the software version number from the /flash/boot/loader.conf file. If the kernel entry for the current Citrix ADC release is missing from that file, the appliance displays the last Citrix ADC release version for which the entry was available.
To resolve this issue, do the following:

1. Verify that the kernel file exists in the /nsconfig directory.

2. Check the /flash/boot/loader.conf file for an entry for the kernel.

   (You can expect the entry for the kernel of the release/build that you installed to be missing from the file.)

3. Open the loader.conf file in a text editor, such as the vi editor, and update the kernel entry for the new release/build.
4. Save and close the file.
5. Repeat step 2 through step 4 for the /flash/boot/loader.conf.local file.
6. Update the release/build entry in the ns.conf file.
7. Restart the appliance.

Since I upgraded the Citrix ADC release on the appliance, the LCD display on the front panel of the appliance displays the out of service message or does not display anything. How can I resolve this issue?

Run the following command from the appliance's shell prompt:

```
1 /netscaler/nslcd -k
```

I have upgraded the Citrix ADC release/build. However, after the upgrade process, the appliance fails to start. Can I downgrade the appliance's software to the previous release/build?

Yes. You can start the appliance with the kernel.old kernel file. When you restart the appliance, press the F1 key when the appliance console displays the Press F1 message. Type kernel.old and press **Enter**.

After upgrading the Citrix ADC release on the appliance, I accidentally deleted the kernel file from the /flash directory. As a result, I am not able to start the appliance. Is there a method for starting the appliance in this situation?

Yes. You can start the appliance by using the `kernel.GENERIC` kernel file, as follows:

1. When you restart the appliance, press the F1 key when the appliance console displays the Press F1 message.
2. Type kernel. GENERIC and press Enter.
3. Log in as the root user.
4. Reinstall the Citrix ADC release.
5. Restart the appliance.

After upgrading the appliance software, I am not able to log on to the appliance, and the following message appears. I tried to resolve this issue by using the password recovery procedure, but I was not successful. Have I done something incorrectly?

```
```
login: nsroot
Password:
connect: No such file or directory
nsnet_connect: No such file or directory
Login incorrect
<!--NeedCopy--> ```
```

You cannot resolve this issue by using the password recovery procedure. Citrix ADC release 12.1 or later use the new licensing system, based on the `Imgrd` daemon, which runs during the startup procedure. For this daemon to work properly, the host name of Citrix ADC appliance, which is set in the /nsconfig/rc.conf file, must be resolved by a name server to the NSIP address. Alternately, you can create a hosts file in the /nsconfig directory and add the 127.0.0.1 <Host_Name> entry in file.

Also, make sure that you have copied the license files to the /nsconfig/license/ directory.

**During an upgrade of a high availability pair, the following message appears repeatedly. What can be the reason?**

<auth.err> ns sshd[5035]: error: Invalid user name or password

This error message appears when the appliances involved in the high availability pairing have either a different Citrix ADC release or a different build of the same release installed. The appliances can have different version installed if you have upgraded or downgraded one appliance but not the other.

**I want to change the netmask of the NSIP address on a Citrix ADC appliance. Can I do so without causing an outage?**

Changing the netmask of the Citrix ADC IP might result in a short outage. Make sure that you change the netmask on the secondary appliance, and then break the high availability pairing. Check the functionality of the appliance. If everything works as expected, rebuild the high availability pairing.

To change the netmask on the appliance, run the `config ns` command from the CLI prompt, and then choose the second option in the menu.

 
```

I have configured a High Availability pair of Citrix ADC appliances. After upgrading the software release from a preview release to a final release, I noticed that some of the appliance configurations are missing. Can I retrieve the lost configurations?

You can use the following procedure to restore the configuration:

1. Log on to the Citrix ADC command line of the primary appliance.
2. Run the following commands:

```
save config

shell

\#cp /nsconfig/ns.conf /nsconfig/ns.conf.bkup

The ns.conf.bkup file is a backup for the running configuration.
```

3. Upgrade software of both the appliances to the final release.
4. Log on to the Citrix ADC command line of the primary appliance.

Can the primary appliance and secondary appliance have separate builds?

Recommended practice is to use the same version and build number on both the primary and the secondary appliance.

Can both the appliances in a High Availability (HA) pair be upgraded at the same time?

No. In an HA pair, first upgrade the secondary node and then upgrade the primary node.

For details, refer Upgrading a High Availability Pair.

Does Citrix support firmware upgrades in the Amazon Web Services cloud?

Yes.

Can I upgrade the Citrix ADC instance independently of the SDX version?

It is not required to upgrade the SDX version when the Citrix ADC appliance is upgraded. However, some features might not work.

Can I use the FTP server to upgrade the Citrix ADC appliance?

No. You must first download the firmware from the Citrix download site, save it on your local computer and then upgrade the appliance.

Is the procedure for upgrading the Citrix ADC appliance with GSLB configurations different from an upgrade of an appliance that is not involved in GSLB?

No. The upgrade procedure is similar to the basic upgrade procedure. The only difference is that you can upgrade the standalone or HA appliances on different sites in a phased manner.

Downgrade

I have received a Citrix ADC appliance with the latest Citrix ADC release installed on it. However, I want to downgrade the software release. Can I do so?

No. If you attempt to downgrade the software release, the appliance might not work as expected, because the ns.conf file of the later release might not be compatible with the earlier release, and the appliance might restore to the factory settings.

When downgrading the Citrix ADC release, I followed the instructions. However, the appliance displays the following message. How is the rollback procedure performed on a Citrix ADC appliance?

```
root@LBCOL03B# ./installns
installns version (10.0-47.7) kernel (ns-10.0-47.7.gz)
Note:
Installation may pause for up to 3 minutes while data is written to the
    flash.
Caution:
Do not interrupt the installation process.
Doing so may cause the system to become unusable.
Installation will proceed in 5 seconds, CTRL-C to abort
No Valid Citrix ADC Version Detected
root@LBCOL03B#
```

The rollback procedure is similar to the basic upgrade procedure. Select the target build that you want to roll back to and perform the downgrade. Before rolling back to a different release, Citrix recommends that you create a copy of your current configuration files. To downgrade from a release, see Downgrading a Citrix ADC Standalone Appliance.

Load Balancing

September 14, 2021

- **What are the various load balancing policies I can create on the Citrix ADC appliance?**

  You can create the following types of load balancing policies on the Citrix ADC appliance:

  - Least Connections
  - Round Robin
  - Least response time
  - Least bandwidth
  - Least packets
  - URL hashing
  - Domain name hashing
  - Source IP address hashing
  - Destination IP address hashing
  - Source IP - Destination IP hashing
  - Token
  - LRTM

- **Can I achieve the Web farm security by implementing load balancing using the Citrix ADC appliance?**

  Yes. You can achieve Web farm security by implementing load balancing using the Citrix ADC appliance. Citrix ADC appliance enables you to implement the following options of the load balancing feature:

  - IP Address hiding: Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the Citrix ADC appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
  - Port Mapping: Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the Citrix ADC appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

- **What are various devices that I can use to load balance with a Citrix ADC appliance?**

  You can load balance the following devices with a Citrix ADC appliance:

  - Server farms
  - Caches or Reverse Proxies

  - Firewall devices
  - Intrusion detection systems
  - SSL offload devices
  - Compression devices
  - Content Inspection servers

- **Why should I implement the load balancing feature for the website?**

  You can implement the Load balancing feature for the website to take the following advantages:

  - Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.
  - Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the back-end server that is not available.

- **Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?**

  - If you enable the MBF option, the Citrix ADC appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires that the best path be chosen for the return traffic.
  - Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

- **What are the various persistence types available on the Citrix ADC appliance?**

  The Citrix ADC appliance supports the following persistence types:

  - Source IP
  - Cookie insert
  - SSL session ID
  - URL passive
  - Custom Server ID
  - Rule
  - DESTIP

GUI

September 14, 2021

- **When I use Firefox to compare two Citrix ADC configurations, the browser seems to freeze?**

  Firefox will eventually display the differences in the configurations, but the process takes a considerable amount of time if there are more than 1000 differences. Use Chrome for a faster response.

- **I am using a MAC Safari browser to upgrade a Citrix ADC. On the upgrade wizard, when I click the Browse button to choose the build file from the appliance, the dialog box does not show any files or folders. Also, when I navigate back to the root folder, the dialog box displays the top level folder, but I cannot browse it. What should I do?**

  On the Safari browser, click the Settings icon and navigate to Preferences > Security > Manage Website Settings > Java, and then change the value of the When visiting other websites setting to Run in unsafe mode.

- **What should I do before accessing the GUI?**

  Before accessing a new version of the Citrix ADC software:

  - Clear browser cache including cookies.
  - Access GUI in browser incognito mode.
  - Access GUI in some other browser.
  - Clear 'Use software acceleration' option in setting and restart the browser.
  - Access chrome: extensions, clear the 'Enable' box and restart the Chrome browser.

- **Which port should I open to access GUI using HTTP or HTTPS?**

  The following lists the default port numbers for HTTP and HTTPS management services (GUI) in the Citrix ADC MPX, VPX and CPX appliances:

  - Citrix ADC MPX and VPX appliances: 80 (HTTP) and 443 (HTTPS)
  - Citrix ADC CPX appliances: 9080 (HTTP) and 9443 (HTTPS)

  Also, you can configure ports for HTTP and HTTPS management services (GUI) other than port 80 and 443. For more information, see Configure HTTP and HTTPS management ports.

- **With which browsers is the GUI compatible for different operating systems?**

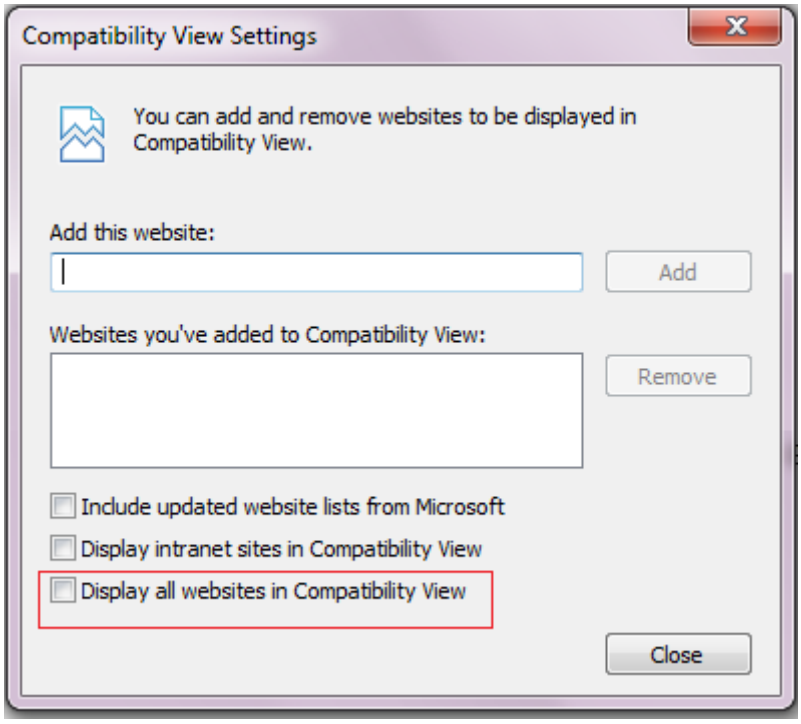
  The following table lists the compatible browsers for NetScaler GUI version 12.0, 12.1, and 13.0:

Operating System	Browser	Versions
Windows 7 & later	Internet Explorer	11, Edge, & later

Operating System	Browser	Versions
Windows 7 & later	Mozilla Firefox	45 & later
Windows 7 & later	Chrome	60 & later
MAC	Mozilla Firefox	45 & later
MAC	Safari	10.1.1 & later

- **When I access the GUI by using Internet Explorer version 8 or 9, the browser displays only a grey bar at the top of the screen. What should I do?**

  The browser might be set in compatibility mode. To disable compatibility mode, go to **Tools** > **Compatibility View Settings** and clear the **Display all websites in Compatibility View** check box.



- **Even after I disable compatibility mode in Internet Explorer version 8 or 9, the GUI does not appear. What should I do?**

  Make sure that the browser mode and document mode in the browser are set to the same version. To view the configuration, press F12. Set the values to either Internet Explorer 8 or Internet Explorer 9.

- **After logging into the Citrix ADC appliance, the page appears blank. What should I do?**

  Make sure you have disabled the Protected mode in your browser settings. If this is enabled, the Java Script is causing the Citrix ADC user interface screen to appear blank.

To disable this option:

1. In your Internet Explorer browser settings, go to **Internet Options**.
2. Go to **Security** tab settings, click **Restricted sites** zone to disable **Enable Protected Mode** check box.
3. Click **Apply** and **OK**.

- **When I access the GUI by using Internet Explorer version 9, the utility displays the following error message: "You are not logged in. Please login." What should I do?**

  Make sure that the cookies are not blocked in your Internet Explorer settings. Go to **Tools** > **Internet Options**. Click the **Privacy** tab, and then under **Settings**, make sure that the slider is set to **Medium** or any lower value.

SSL

Click here for FAQs about SSL.

Authentication, authorization, and auditing application traffic

September 14, 2021

Many companies restrict website access to valid users only, and control the level of access permitted to each user. The authentication, authorization, and auditing feature allows a site administrator to manage access controls with the Citrix ADC appliance instead of managing these controls separately for each application. Doing authentication on the appliance also permits sharing this information across all websites within the same domain that are protected by the appliance.

To use authentication, authorization, and auditing, you must configure authentication virtual servers to handle the authentication process and traffic management virtual servers to handle the traffic to web applications that require authentication. You also configure your DNS to assign FQDNs to each virtual server. After configuring the virtual servers, you configure a user account for each user that will authenticate via the Citrix ADC appliance, and optionally you create groups and assign user accounts to groups. After creating user accounts and groups, you configure policies that tell the appliance how to authenticate users, which resources to allow users to access, and how to log user sessions. To put the policies into effect, you bind each policy globally, to a specific virtual server, or to the appropriate user accounts or groups. After configuring your policies, you customize user sessions by configuring

session settings and binding your session policies to the traffic management virtual server. Finally, if your intranet uses client certs, you set up the client certificate configuration.

To understand how authentication, authorization, and auditing works in a distributed environment, consider an organization with an intranet that its employees access in the office, at home, and when traveling. The content on the intranet is confidential and requires secure access. Any user who wants to access the intranet must have a valid user name and password. To meet these requirements, the ADC does the following:

- Redirects the user to the login page if the user accesses the intranet without having logged in.
- Collects the user's credentials, delivers them to the authentication server, and caches them in a directory that is accessible through the Lightweight Directory Access Protocol (LDAP). For more information, see Determining Attributes in Your LDAP Directory.
- Verifies that the user is authorized to access specific intranet content before delivering the user's request to the application server.
- Maintains a session timeout after which users must authenticate again to regain access to the intranet. (You can configure the timeout.)
- Logs the user accesses, including invalid login attempts, in an audit log.

Supported authentication types

- Local
- LDAP
- RADIUS
- SAML
- TACACS+
- Client certificate authentication (including smart card authentication)
- Web
- Advanced authentication
- Forms based authentication
- 401 based authentication
- Native OTP
- Push notification
- Email OTP
- reCaptcha

Citrix Gateway also supports RSA SecurID, Gemalto Protiva, and SafeWord. You use a RADIUS server to configure these types of authentication.

Before configuring authentication, authorization, and auditing, you must be familiar with and understand how to configure load balancing, content switching, and SSL on the Citrix ADC appliance.

Authentication without authorization

Authorization specifies the network resources to which users have access when they log on to the appliance. The default setting for authorization is to deny access to all network resources. Citrix recommends using the default global setting and then creating authorization policies to define the network resources users can access.

You configure authorization on the appliance by using an authorization policy and expressions. After you create an authorization policy, you can bind it to the users or groups that you configured on the appliance.

You can configure the appliance to use authentication only, without authorization. When you configure authentication without authorization, the appliance does not perform a group authorization check. The policies that you configure for the user or group are assigned to the user.

Enabling authentication, authorization, and auditing

To use the authentication, authorization, and auditing feature, you must enable it. You can configure authentication, authorization, and auditing entities—such as the authentication and traffic management virtual servers—before you enable the authentication, authorization, and auditing feature, but the entities do not function until the feature is enabled.

To enable authentication, authorization, and auditing by using the CLI

At the command prompt, type the following commands to enable authentication, authorization, and auditing and verify the configuration:

```
enable ns feature AAA
<!--NeedCopy-->
```

To enable authentication, authorization, and auditing by using the GUI

1. Navigate to **System > Settings**.
2. In the details pane, under **Modes and Features**, click **Change Basic Features**.
3. In the **Configure Basic Features** dialog box, select the **Authentication, Authorization and Auditing** check box.
4. Click **OK**.

Disabling Authentication

If your deployment does not require authentication, you can disable it. You can disable authentication for each virtual server that does not require authentication.

> **Important:**
>
> **Important:** Citrix recommends disabling authentication with caution. If you are not using an external authentication server, create local users and groups to allow the appliance to authenticate users. Disabling authentication stops the use of authentication, authorization, and accounting features that control and monitor connections to the appliance. When users type a web address to connect to the appliance, the logon page does not appear.

To disable authentication

1. Navigate to **Configuration > Citrix Gateway > Virtual Servers**.
2. In the details pane, click a virtual server, and then click **Open**.
3. In the **Basic Settings** page, clear the **Enable Authentication** check box.

How authentication, authorization, and auditing works

September 14, 2021

Authentication, authorization, and auditing provides security for a distributed internet environment by allowing any client with the proper credentials to connect securely to protected application servers from anywhere on the Internet. This feature incorporates the three security features of authentication, authorization, and auditing. Authentication enables the Citrix ADC to verify the client's credentials, either locally or with a third-party authentication server, and allow only approved users to access protected servers. Authorization enables the ADC to verify which content on a protected server it allows each user to access. Auditing enables the ADC to keep a record of each user's activity on a protected server.

To understand how authentication, authorization, and auditing works in a distributed environment, consider an organization with an intranet that its employees access in the office, at home, and when traveling. The content on the intranet is confidential and requires secure access. Any user who wants to access the intranet must have a valid user name and password. To meet these requirements, the ADC does the following:

- Redirects the user to the login page if the user accesses the intranet without having logged in.
- Collects the user's credentials, delivers them to the authentication server, and caches them in a directory that is accessible through LDAP. For more information, see Determining Attributes in Your LDAP Directory.
- Verifies that the user is authorized to access specific intranet content before delivering the user's request to the application server.

- Maintains a session timeout after which users must authenticate again to regain access to the intranet. (You can configure the timeout.)
- Logs the user accesses, including invalid login attempts, in an audit log.

Configure authentication authorization and auditing policies

After you set up your users and groups, you next configure authentication policies, authorization policies, and audit policies to define which users are allowed to access your intranet, which resources each user or group is allowed to access, and what level of detail authentication, authorization, and auditing will preserve in the audit logs. An authentication policy defines the type of authentication to apply when a user attempts to log on. If external authentication is used, the policy also specifies the external authentication server. Authorization policies specify the network resources that users and groups can access after they log on. Auditing policies define the audit log type and location.

You must bind each policy to put it into effect. You bind authentication policies to authentication virtual servers, authorization policies to one or more user accounts or groups, and auditing policies both globally and to one or more user accounts or groups.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the Citrix ADC operating system, policy priorities work in reverse order: the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The authentication, authorization, and auditing feature implements only the first of each type of policy that a request matches, not any additional policies of that type that a request might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind the policies. You can then add additional policies at any time without having to reassign the priority of an existing policy.

For additional information about binding policies on the Citrix ADC appliance, see the Citrix ADC product documentation.

Configure the No_Auth policy to bypass certain traffic

You can now configure No_Auth policy to bypass certain traffic from authentication when 401-based authentication is enabled on traffic management virtual server. For such traffic, you must bind a “No_Auth” policy.

To configure the No_Auth policy to bypass certain traffic by using the CLI

At the command prompt, type:

```
add authentication policy <name> -rule <expression> -action <string>
<!--NeedCopy-->
```

Example:

```
add authentication policy ldap -rule ldapAct1 -action No_Auth
<!--NeedCopy-->
```

Basic components of authentication, authorization, and auditing configuration

September 14, 2021

The basic components of the authentication, authorization, and auditing configuration are as follows:

- **Authentication virtual server** - All authentication requests are redirected by the traffic management virtual server (load balancing or content switching) to the authentication virtual sever. This virtual server processes the associated authentication policies and accordingly provides access to the application. For details, see Authentication virtual server.
- **Authentication profiles** - An authentication profile specifies the authentication virtual server, the authentication host, the authentication domain, and an authentication level.

You can create one or more authentication profiles to specify different authentication settings and bind these authentication profiles to relevant traffic management servers based on your requirements. For details, see Authentication profiles.

- **Authentication policies** - When users log on to the Citrix ADC or Citrix Gateway appliance, they are authenticated according to a policy that you create. An authentication policy comprises of an expression and an action. Authentication policies use Citrix ADC expressions. For details, see Authentication policies.
- **Authorization policies** - When you configure an authorization policy, you can set it to allow or deny access to network resources in the internal network. For details, see Authorization policies.
- **Users and groups:** - After configuring the authentication, authorization, and auditing basic setup, you create users and groups. You first create a user account for each person who will authenticate via the Citrix ADC appliance. If you are using local authentication controlled by

the Citrix ADC appliance itself, you create local user accounts and assign passwords to each of those accounts. For details, see Users and groups.

Authentication virtual server

September 14, 2021

The traffic management virtual server (load balancing or content switching) redirects all authentication requests to the authentication virtual server. This virtual server processes the associated authentication policies and accordingly provides access to the application.

Note: You cannot bind traffic management policies to authentication, authorization, and auditing virtual servers.

Set up authentication virtual server

The steps involved in setting up an authentication virtual server are;

1. Enable the authentication, authorization, and auditing feature.

```
enable ns feature AAA
<!--NeedCopy-->
```

2. Configure an authentication virtual server. It must be of type SSL and make sure to bind the SSL certificate-key pair to the virtual server.

```
add authentication vserver <name> SSL <ipaddress> <port>

bind ssl certkey <auth-vserver-name> <certkey>
<!--NeedCopy-->
```

3. Specify the FQDN of the domain for the authentication virtual server.

```
set authentication vserver <name> -authenticationDomain <FQDN>
<!--NeedCopy-->
```

4. Associate the authentication virtual server to the relevant traffic management virtual server.

   Points to Note:

   - The FQDN of the traffic management virtual server must be in the same domain as the FQDN of the authentication virtual server for the domain session cookie to function correctly. On the traffic management virtual server:
     - Enable authentication.

- Specify the FQDN of the authentication virtual server as the authentication host of the traffic management virtual server.
- [Optional] Specify the authentication domain on the traffic management virtual server.
- If you do not configure the authentication domain, the appliance assigns an FQDN that consists of the FQDN of the authentication virtual server without the host name portion. For example, if the domain name of the authentication virtual server is **tm.xyz.bar.com**, the appliance assigns **xyz.bar.com** as the authentication domain.
  * For load balancing:

```
set lb vserver <name> -authentication ON -
   authenticationhost <FQDN> [-authenticationdomain <
   authdomain>]
<!--NeedCopy-->
```

  * For content switching:

```
set cs vserver <name> <protocol> <IPAddress> <port>
<!--NeedCopy-->
```

- If you have to set a domain wide cookie for an authentication domain, you must enable authentication profile on a load balancing virtual server.

5. Verify that both the virtual servers are UP and configured correctly.

```
show authentication vserver <name>
<!--NeedCopy-->
```

To set up an authentication virtual server by using the GUI

1. Enable the authentication, authorization, and auditing feature.

   Navigate to **System > Settings**, click **Configure Basic features**, and enable **Authentication, Authorization and Auditing**.

2. Configure the authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and configure as required.

3. Configure the traffic management virtual server for authentication.

   - **For load balancing:**

     Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and configure the virtual server as required.

   - **For content switching:**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, and configure the virtual server as required.

4. • Verify the authentication setup.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and check the details of the relevant authentication virtual server.

Configure the authentication virtual server

To configure authentication, authorization, and auditing, first configure an authentication virtual server to handle authentication traffic. Next, bind an SSL certificate-key pair to the virtual server to enable it to handle SSL connections.
For additional information about configuring SSL and creating a certificate-key pair, see SSL certificates.

Configure an authentication virtual server by using the CLI

To configure an authentication virtual server and verify the configuration, at the command prompt type the following commands in the same order:

```
add authentication vserver <name> ssl <ipaddress>

show authentication vserver <name>

bind ssl certkey <certkeyName>

show authentication vserver <name>

set authentication vserver <name>

show authentication vserver <name>
<!--NeedCopy-->
```

Example:

```
add authentication vserver Auth-Vserver-2 SSL 10.102.29.77 443 Done

show authentication vserver Auth-Vserver-2 Auth-Vserver-2
    (10.102.29.77:443) - SSL Type: CONTENT State: DOWN[Certkey not bound
    ] Client Idle Timeout: 180 sec Down state flush: DISABLED Disable
    Primary Vserver On Down : DISABLED Authentication : ON Current AAA
    Users: 0 Done

```

```
bind ssl certkey Auth-Vserver-2 Auth-Cert-1 Done

show authentication vserver Auth-Vserver-2 Auth-Vserver-2
    (10.102.29.77:443) - SSL Type: CONTENT State: UP Client Idle Timeout
    : 180 sec Down state flush: DISABLED Disable Primary Vserver On Down
     : DISABLED Authentication : ON Current AAA Users: 0 Done

set authentication vserver Auth-Vserver-2

show authentication vserver Auth-Vserver-2 Auth-Vserver-2
    (10.102.29.77:443) - SSL Type: CONTENT State: DOWN[Certkey not bound
    ] Client Idle Timeout: 180 sec Down state flush: DISABLED Disable
    Primary Vserver On Down : DISABLED Authentication : ON Current AAA
    Users: 0 Done
<!--NeedCopy-->
```

> **Note**
>
> The Authentication Domain parameter is deprecated. Use Authentication Profile for setting domain wide cookies.

Configure an authentication virtual server by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Virtual Servers**.
2. In the details pane, do one of the following:
   - To create a new authentication virtual server, click **Add**.
   - To modify an existing authentication virtual server, select the virtual server, and then click **Edit**. The Configuration dialog opens with the Basic Settings area expanded.
3. Specify values for the parameters as follows (asterisk indicates a required parameter):
   - Name*—name (Cannot be changed for a previously created virtual server)
   - IP Address Type*—IP address type of the authentication virtual server
   - IP Address*—IP address of the authentication virtual server
   - Port*—TCP port on which the virtual server accepts connections.
   - Failed login timeout—failedLoginTimeout (Seconds allowed before login fails, and user must start login process again.)
   - Max login attempts—maxLoginAttempts (Number of login attempts allowed before user is locked out)

   > **Note:**
   >
   > The authentication virtual server uses only the SSL protocol and port 443, so those options

> are grayed out. Any options that are not mentioned can be ignored.

4. Click **Continue** to display the Certificates area.
5. In the **Certificates** area, configure any SSL certificates you want to use with this virtual server.
   - To configure a CA certificate, click the arrow on the right of CA Certificate to display the CA Cert Key dialog box, select the certificate you want to bind to this virtual server, and click **Save**.
   - To configure a server certificate, click the arrow on the right of Server Certificate, and follow the same process as for the CA certificate.
6. Click **Continue** to display the **Advanced Authentication Policies** area.
7. If you want to bind an advanced authentication policy to the virtual server, click the arrow on the right side of the line to display the **Authentication Policy** dialog box, choose the policy that you want to bind to the server, set the priority, and then click **OK**.
8. Click **Continue** to display the **Basic Authentication Policies** area.
9. If you want to create a basic authentication policy and bind it to the virtual server, click the plus sign to display the **Policies** dialog box, and follow the prompts to configure the policy and bind it to this virtual server.
10. Click **Continue** to display the 401-Based Virtual Servers area.
11. In the 401-Based Virtual Servers area, configure any load balancing or content switching virtual servers that you want to bind to this virtual server.
    - To bind a load balancing virtual server, click the arrow to the right of load balancing virtual server to display the Load Balancing Virtual Servers dialog box, and follow the prompts.
    - To bind a content switching virtual server, click the arrow to the right of content switching virtual server to display the Content Switching Virtual Servers dialog box, and follow the same process as to bind an LB virtual server.
12. If you want to create or configure a group, in the Groups area click the arrow to display the Groups dialog box, and follow the prompts.
13. Review your settings, and when you are finished, click **Done**. The dialog box closes. If you created a new authentication virtual server, it now appears in the **Configuration** window list.

Traffic management virtual server

After you have created and configured your authentication virtual server, you next create or configure a traffic management virtual server and associate your authentication virtual server with it. You can use either a load balancing or content switching virtual server for a traffic management virtual server. For more information about creating and configuring either type of virtual server, see the *Citrix Traffic Management Guide* at Traffic Management.

> **Note:**
>
> The FQDN of the traffic management virtual server must be in the same domain as the FQDN of the authentication virtual server for the domain session cookie to function correctly.

You configure a traffic management virtual server for authentication, authorization, and auditing by enabling authentication and then assigning the FQDN of the authentication server to the traffic management virtual server. You can also configure the authentication domain on the traffic management virtual server currently. If you do not configure this option, the Citrix ADC appliance assigns the traffic management virtual server an FQDN that consists of the FQDN of the authentication virtual server without the host name portion. For example, if the domain name of the authentication virtual server is tm.xyz.bar.com, the appliance assigns xyz.bar.com. as the authentication domain.

To configure a traffic management virtual server by using the CLI

At the command prompt, type one of the following sets of commands:

```
set lb vserver <name>  -authentication ON -authenticationhost <FQDN> [-
    authenticationdomain <authdomain>]
show lb vserver <name>
set cs vserver <name>  -authentication ON -authenticationhost <FQDN> [-
    authenticationdomain <authdomain>]
show cs vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver vs-cont-sw -Authentication ON -AuthenticationHost mywiki
    .index.com Done

show lb vserver vs-cont-sw vs-cont-sw (0.0.0.0:0) - TCP Type: ADDRESS
    State: DOWN Last state change was at Wed Aug 19 10:03:15 2009 (+410
    ms) Time since last state change: 5 days, 20:00:40.290 Effective
    State: DOWN Client Idle Timeout: 9000 sec Down state flush: ENABLED
    Disable Primary Vserver On Down : DISABLED No. of Bound Services : 0
     (Total) 0 (Active) Configured Method: LEASTCONNECTION Mode: IP
    Persistence: NONE Connection Failover: DISABLED Authentication: ON
    Host: mywiki.index.com
Done
<!--NeedCopy-->
```

To configure a traffic management virtual server by using the GUI

1. In the navigation pane, do one of the following.

- Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
- Navigate to **Traffic Management > Content Switching > Virtual Servers**
- In the details pane, select the virtual server on which you want to enable authentication, and then click **Edit**.
- In the Domain text box, type the authentication domain.
- In the **Advanced** menu on the right, select **Authentication**.
- Choose either **Form Based Authentication** or **401 Based Authentication**, and fill in the Authentication information.
  - For Form Based Authentication, enter the Authentication FQDN (the fully qualified domain name of the authentication server), the Authentication virtual server (the IP address of the authentication virtual server), and the Authentication Profile (the profile to use for authentication).
  - For 401 Based Authentication, enter the Authentication virtual server and the Authentication Profile only.
- Click **OK**. A message appears in the status bar, stating that the virtual server has been configured successfully.

Simplified login protocol support for authentication, authorization, and auditing

The login protocol between authentication, authorization, and auditing traffic management virtual servers and authentication, authorization, and auditing virtual servers is simplified to use internal mechanisms as opposed to sending the encrypted data through query parameters. Using this feature, the replay of requests is prevented.

Configure DNS

For the domain session cookie used in the authentication process to function correctly, you must configure DNS to assign both the authentication and the traffic management virtual servers to FQDNs in the same domain. For information about how to the configure DNS address records, see Domain Name System.

Verify authentication virtual server

After you configure authentication and traffic management virtual servers and before you create user accounts, you must verify that both virtual servers are configured correctly and are in the UP state.

Configure a noAuth authentication by using the CLI

At the command prompt, type the following command:

```
show authentication vserver <name>
<!--NeedCopy-->
```

Example:

```
show authentication vserver Auth-Vserver-2
Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
State: UP
Client Idle Timeout: 180 sec
Down state flush: DISABLED
Disable Primary Vserver On Down : DISABLED
Authentication : ON
Current AAA Users: 0
Authentication Domain: myCompany.employee.com
Done
<!--NeedCopy-->
```

Configure a noAuth authentication by using the GUI

1. Navigate to **Security > Citrix ADC AAA - Application Traffic > Virtual Servers**.
   Note: From Citrix Gateway, navigate to **Citrix Gateway > Virtual Servers**.
2. Review the information in the **AAA Virtual Servers** pane to verify that your configuration is correct and your authentication virtual server is accepting traffic. You can select a specific virtual server to view detailed information in the details pane.

Authorization policies

September 14, 2021

When you configure an authorization policy, you can set it to allow or deny access to network resources in the internal network. For example, to allow users access to the 10.3.3.0 network, use the following expression:

CLIENT.IP.DST.IN_SUBNET(10.3.0.0/16)

Authorization policies are applied to users and groups. After a user is authenticated, Citrix Gateway performs a group authorization check by obtaining the user's group information from either an RADIUS, LDAP, or TACACS+ server. If group information is available for the user, Citrix Gateway checks the network resources allowed for the group.

To control which resources users can access, you must create authorization policies. If you do not need to create authorization policies, you can configure default global authorization.

If you create an expression within the authorization policy that denies access to a file path, you can only use the subdirectory path and not the root directory. For example, use fs.path contains "\\dir1\\dir2" instead of fs.path contains "\\rootdir\\dir1\\dir2". If you use the second version in this example, the policy fails.

After you configure the authorization policy, you then bind it to a user or group.

By default, authorization policies are validated first against policies that you bind to the virtual server and then against policies bound globally. If you bind a policy globally and want the global policy to take precedence over a policy that you bind to a user, group, or virtual server, you can change the priority number of the policy. Priority numbers start at zero. A lower priority number gives the policy higher precedence.

For example, if the global policy has a priority number of one and the user has a priority of two, the global authentication policy is applied first.

> **Important:**
>
> - Classic authorization policies are applied only on TCP traffic.
> - Advanced authorization policy can be applied on all types of traffic (TCP/UDP/ICMP/DNS).
>   - To apply policy on UDP/ICMP/DNS traffic, policies must be bound at type UDP_REQUEST, ICMP_REQUEST, and DNS_REQUEST respectively.
>   - While binding, if "type" is not explicitly mentioned or "type" is set to REQUEST, the behavior does not change from earlier builds, that is these policies are applied only to TCP traffic.
>   - The policies bound at UDP_REQUEST do not apply for DNS traffic. For DNS, policies must be explicitly bound to DNS_REQUEST TCP_DNS is similar to other TCP requests.

For more details on advanced authorization policies, see article https://support.citrix.com/article/CTX232237.

Configure and bind an authorization policy

Configure an authorization policy by using the GUI

1. Navigate to **Citrix Gateway > Policies > Authorization.**
2. In the details pane, click **Add**.
3. In **Name**, type a name for the policy.
4. In **Action**, select **Allow** or **Deny**.
5. In **Expression**, click **Expression Editor**.

6. To start to configure the expression, click **Select** and choose the necessary elements.
7. Click **Done** when your expression is complete.
8. Click **Create**.

Bind an authorization policy to a user by using the GUI

1. Navigate to **Citrix Gateway > User Administration.**
2. Click **AAA Users**.
3. In the details pane, select a user and then click **Edit**.
4. In **Advanced Settings**, click **Authorization Policies**.
5. In **Policy Binding** page, select a policy or create a policy.
6. In **Priority**, set the priority number.
7. In **Type**, select the request type and then click **OK**.

Bind an authorization policy to a group by using the GUI

1. Navigate to **Citrix Gateway > User Administration**.
2. Click **AAA Groups**.
3. In the details pane, select a group and then click **Edit**.
4. In **Advanced Settings**, click **Authorization Policies**.
5. In **Policy Binding** page, select a policy or create a policy.
6. In **Priority**, set the priority number.
7. In **Type**, select the request type and then click **OK**.

Authorization specifies the network resources to which users have access when they log on to Citrix Gateway. The default setting for authorization is to deny access to all network resources. Citrix recommends using the default global setting and then creating authorization policies to define the network resources users can access.

You configure authorization on Citrix Gateway by using an authorization policy and expressions. After you create an authorization policy, you can bind it to the users or groups that you configured on the appliance.

Default global authorization

To define the resources to which users have access on the internal network, you can configure default global authorization. You configure global authorization by allowing or denying access to network resources globally on the internal network.

Any global authorization action you create is applied to all users who do not already have an authorization policy associated with them, either directly or through a group. A user or group authorization policy always overrides the global authorization action. If the default authorization action is set to

Deny, you must apply authorization policies for all users or groups to make network resources accessible to those users or groups. This requirement helps to improve security.

To set default global authorization:

1. In the configuration utility, on the Configuration tab, in the navigation pane, expand Citrix Gateway and then click Global Settings.
2. In the details pane, under Settings, click Change global settings.
3. On the Security tab, next to Default Authorization Action, select Allow or Deny then and click OK.

Authentication profiles

September 14, 2021

When you want the same authentication settings to be used by multiple traffic management virtual servers, you can create an authentication profile which specifies the authentication virtual server, the authentication host, the authentication domain, and the authentication level.

This authentication profile can be associated with the relevant traffic management virtual servers.

Configure an authentication profile

Configure an authentication profile by using the CLI

- Create the authentication profile and set the required parameters.

  For example, to create a profile with an authentication virtual server named “authVS”.

```
1  add authentication authnProfile authProfile1 -authnVsName authVS
       -authenticationHost authnVS.example.com -authenticationDomain
       example.com -authenticationLevel
2  <!--NeedCopy-->
```

> **Note:**
>
> The authentication weight or level depends on the virtual server to which the traffic is bound. A session that is created by authenticating against the traffic management virtual server at a given level cannot be used to access the traffic management virtual server at a higher level.

- Bind the authentication profile to the relevant traffic management virtual servers.

  For example, to bind authProfile1 to a load balancing virtual server named “vserver1”.

```
set lb vserver vserver1 -authnProfile authProfile1
<!--NeedCopy-->
```

Configure an authentication profile by using the GUI

In the **Configuration** tab, navigate to **Security > AAA - Application Traffic > Authentication Profile**, and configure the authentication profile as required.

> **Note:**
>
> - You can create an authentication profile by using the Citrix Gateway wizard as well. The profile contains all the settings for the authentication policy. You configure the profile when you create the authentication policy.
> - With the Citrix Gateway wizard, you can use the chosen authentication type to configure authentication. If you want to configure other authentication policies after running the wizard, you can use the configuration utility. For more information about the Citrix Gateway wizard, see Configuring Settings by Using the Citrix Gateway Wizard].

Authentication policies

September 14, 2021

When users log on to the Citrix ADC or Citrix Gateway appliance, they are authenticated according to a policy that you create. An authentication policy comprises of an expression and an action. Authentication policies use Citrix ADC expressions.

After creating an authentication action and an authentication policy, bind it to an authentication virtual server and assign a priority to it. When binding it, also designate it as either a primary or a secondary policy. Primary policies are evaluated before secondary policies. In configurations that use both types of policy, primary policies are normally more specific policies while secondary policies are normally more general policies. It is intended to handle authentication for any user accounts that do not meet the more specific criteria. The policy defines the authentication type. A single authentication policy can be used for simple authentication needs and is typically bound at the global level. You can also use the default authentication type, which is local. If you configure local authentication, you must also configure users and groups on the appliance.

You can configure multiple authentication policies and bind them to create a detailed authentication procedure and virtual servers. For example, you can configure cascading and two-factor authentication by configuring multiple policies. You can also set the priority of the authentication policies to

determine which servers and the order in which the appliance checks user credentials. An authentication policy includes an expression and an action. For example, if you set the expression to True value, when users log on, the action evaluates user logon to true and then users have access to network resources.

After you create an authentication policy, you bind the policy at either the global level or to virtual servers. When you bind at least one authentication policy to a virtual server, any authentication policies that you bound to the global level are not used when users log on to the virtual server, unless the global authentication type has a higher precedence than the policy bound to the virtual server.

When a user logs on to the appliance, authentication is evaluated in the following order:

- The virtual server is checked for any bound authentication policies.
- If authentication policies are not bound to the virtual server, the appliance checks for global authentication policies.
- If an authentication policy is not bound to a virtual server or globally, the user is authenticated through the default authentication type.

If you configure LDAP and RADIUS authentication policies and want to bind the policies globally for two-factor authentication, you can select the policy in the configuration utility and then select if the policy is the primary or secondary authentication type. You can also configure a group extraction policy.

> **Note:**
>
> The Citrix ADC or the Citrix Gateway appliance encodes only UTF-8 characters for authentication, and it is not compatible with servers that use ISO-8859-1 characters.

Create an authentication policy

Create an authentication policy by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication**, and then select the type of policy that you want to create.
   For Citrix Gateway, navigate to **Citrix Gateway > Policies > Authentication**.
2. In the details pane, on the **Policies** tab, do one of the following:
   - To create a new policy, click **Add**.
   - To modify an existing policy, select the action, and then click **Edit**.
3. In the Create Authentication Policy or Configure Authentication Policy dialog, type or select the values for the parameters.
   - **Name** — policy name (Cannot be changed for a previously configured action)
   - **Authentication Type** — `authtype`

- **Server** — `authVsName`
- **Expression** — rule (You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open the Add Expression dialog box and using the drop-down lists in it to construct your expression.)

4. Click **Create** or **OK**. The policy that you created appears in the Policies page.
5. Click the **Servers** tab, and in the details pane do one of the following:
   - To use an existing server, select it, and then click.
   - To create a server, click Add, and follow the instructions.
6. If you want to designate this policy as a secondary authentication policy, on the Authentication tab, click Secondary. If you want to designate this policy as a primary authentication policy, skip this step.
7. Click **Insert Policy**.
8. Choose the policy you want to bind to the authentication virtual server from the drop-down list.
9. In the **Priority** column to the left, modify the default priority to ensure that the policy is evaluated in the proper order.
10. Click **OK**. A message appears in the status bar, stating that the policy has been configured successfully.

Modify an authentication policy by using the GUI

You can modify configured authentication policies and profiles, such as the IP address of the authentication server or the expression.

1. In the configuration utility, on the Configuration tab, expand **Citrix Gateway > Policies > Authentication**.
   Note: You can also configure the policy from **Security > AAA - Application Traffic > Policies > Authentication**, and then select the type of policy that you want to modify.
2. In the navigation pane, under Authentication, select an authentication type.
3. In the details pane, on the Servers tab, select a server and then click Open.

Remove an authentication policy by using the GUI

If you changed or removed an authentication server from your network, remove the corresponding authentication policy from Citrix Gateway.

1. In the configuration utility, on the Configuration tab, expand **Citrix Gateway > Policies \ > Authentication**.

Note: To configure from ADC, navigate **Security > AAA - Application Traffic > Policies > Authentication**, and then select the type of policy that you want to remove.

2. In the navigation pane, under Authentication, select an authentication type.
3. In the details pane, on the Policies tab, select a policy and then click Remove.

Create an authentication policy by using the CLI

At the command prompt, type the following commands:

```
add authentication negotiatePolicy <name> <rule> <reqAction>

show authentication localPolicy <name>

bind authentication vserver <name> -policy <policyname> [-priority <
    priority>][-secondary]]

show authentication vserver <name>
<!--NeedCopy-->
```

Example:

```
    > add authentication localPolicy Authn-Pol-1 ns_true
      Done
    > show authentication localPolicy
    1)      Name: Authn-Pol-1       Rule: ns_true          Request
        action: LOCAL   Done
    > bind authentication vserver Auth-Vserver-2 -policy Authn-Pol-1
    Done
    > show authentication vserver Auth-Vserver-2
        Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT State: UP
            Client Idle
        Timeout: 180 sec Down state flush: DISABLED
        Disable Primary Vserver On Down : DISABLED
        Authentication : ON
        Current AAA Users: 0
        Authentication Domain: myCompany.employee.com
    1)  Primary authentication policy name:  Authn-Pol-1 Priority: 0
        Done
<!--NeedCopy-->
```

Modify an existing authentication policy by using the CLI

At the command prompt, type the following commands to modify an existing authentication policy:

```
set authentication localPolicy <name> <rule> [-reqaction <action>]<!--
    NeedCopy-->
```

```
Example

<!--NeedCopy-->
```

set authentication localPolicy Authn-Pol-1 'ns_true'

```
### Remove an authentication policy by using the CLI

At the command prompt, type the following command to remove an
    authentication policy:

<!--NeedCopy-->
```

rm authentication localPolicy

```
Example

<!--NeedCopy-->
```

rm authentication localPolicy Authn-Pol-1

```
### Bind an authentication policy

After you configure the authentication policies, you bind the policy
    either globally or to a virtual server. You can use either the
    configuration utility to bind an authentication policy.

To bind an authentication policy globally by using the configuration
    utility:

1.  In the configuration utility, on the Configuration tab, expand **
    Citrix Gateway \> Policies \ > Authentication**.
     Note: To configure from ADC, navigate **Security > AAA -
        Application Traffic > Policies > Authentication**
1.  Click an authentication type.
1.  In the details pane, on the Policies, tab, click a server and then
    in Action, click Global Bindings.
1.  On the Primary or Secondary tab, under Details, click Insert Policy
    .
1.  Under Policy Name, select the policy and then click OK.

```

```
    **Note:** When you select the policy, Citrix Gateway sets the
       expression to True value automatically.

To unbind a global authentication policy by using the configuration
   utility:

1.  In the configuration utility, on the Configuration tab, expand **
   Citrix Gateway \> Policies \ > Authentication**.
    Note: To configure from ADC, navigate **Security > AAA -
       Application Traffic > Policies > Authentication**
1.  On the Policies tab, in Action, click Global Bindings.
1.  In the Bind/Unbind Authentication Policies to Global dialog box, on
    the Primary or Secondary tab, in Policy Name, select the policy,
   click Unbind Policy, and then click OK.

## Add an authentication action

### Add an authentication action by using the command line interface

If you do not use LOCAL authentication, you need to add an explicit
   authentication action. At the command prompt, type the following
   command:

<!--NeedCopy-->
```

add authentication tacacsAction -serverip [-serverPort][-authTimeout][...]

```
Example

<!--NeedCopy-->
```

add authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65 -serverport 1812 -authtimeout 15 -tacacsSecret “minotaur” -authorization OFF -accounting ON -auditFailedCmds OFF -defaultAuthenticationGroup “users”

```
### Configure an authentication action by using the command line
   interface

To configure an existing authentication action, at the command prompt,
   type the following command:

<!--NeedCopy-->
```

set authentication tacacsAction -serverip [-serverPort][-authTimeout][...]

```
Example

<!--NeedCopy-->
```

set authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65 -serverport 1812 -authtimeout 15 -tacacsSecret “minotaur” -authorization OFF -accounting ON -auditFailedCmds OFF -defaultAuthenticationGroup “users”

```
### Remove an authentication action by using the command line interface

To remove an existing RADIUS action, at the command prompt, type the following command:

<!--NeedCopy-->
```

rm authentication radiusAction

```
Example

<!--NeedCopy-->
```

rm authentication tacacsaction Authn-Act-1

```
## The noAuth authentication

Citrix ADC appliance supports noAuth authentication capability that enables the customer to configure a defaultAuthenticationGroup parameter in the `noAuthAction` command, when a user performs this policy. The administrator can check for the presence of this group in user's group to determine the user's navigation through the noAuth policy.

### To configure a noAuth authentication by using the command line interface

At the command prompt, type;

<!--NeedCopy-->
```

add authentication noAuthAction [-defaultAuthenticationGroup]

```
**Example:**

<!--NeedCopy-->
```

add authentication noAuthAction noauthact –defaultAuthenticationGroup mynoauthgroup

```
## Default global authentication types

When you installed Citrix Gateway and ran the Citrix Gateway wizard, you configured authentication within the wizard. This authentication policy is bound automatically to the Citrix Gateway global level. The authentication type you configure within the Citrix Gateway wizard is the default authentication type. You can change the default authorization type by running the Citrix Gateway wizard again or you can modify the global authentication settings in the configuration utility.

If you need to add other authentication types, you can configure authentication policies on Citrix Gateway and bind the policies to Citrix Gateway by using the configuration utility. When you configure authentication globally, you define the type of authentication, configure the settings, and set the maximum number of users that can be authenticated.

After configuring and binding the policy, you can set the priority to define which authentication type takes precedence. For example, you configure LDAP and RADIUS authentication policies. If the LDAP policy has a priority number of 10 and the RADIUS policy has a priority number of 15, the LDAP policy takes precedence, regardless of where you bind each policy. This is called cascading authentication.

You can select to deliver logon pages from the Citrix Gateway in-memory cache or from the HTTP server running on Citrix Gateway. If you choose to deliver the logon page from the in-memory cache, the delivery of the logon page from Citrix Gateway is faster than from the HTTP server. Choosing to deliver the logon page from the in-memory cache reduces the wait time when many users log on at the same time. You can only configure the delivery of logon pages from the cache as part of a global authentication policy.

You can also configure the network address translation (NAT) IP address that is a specific IP address for authentication. This IP address is unique for authentication and is not the Citrix Gateway subnet, mapped, or virtual IP addresses. This is an optional setting.

**Note:**
>
>You cannot use the Citrix Gateway wizard to configure SAML
```

```
    authentication.
16
17 You can use the Quick Configuration wizard to configure LDAP, RADIUS,
    and client certificate authentication. When you run the wizard, you
    can select from an existing LDAP or RADIUS server configured on
    Citrix Gateway. You can also configure the settings for LDAP or
    RADIUS. If you use two-factor authentication, Citrix recommends
    using LDAP as the primary authentication type.
18
19 ### Configure default global authentication types
20
21 1.  In the configuration utility, on the Configuration tab, in the
    navigation pane, expand Citrix Gateway and then click Global
    Settings.
22 1.  In the details pane, under Settings, click Change authentication
    settings.
23 1.  In Maximum Number of Users, type the number of users who can be
    authenticated by using this authentication type.
24 1.  In NAT IP address, type the unique IP address for authentication.
25 1.  Select Enable static caching to deliver logon pages faster.
26 1.  Select Enable Enhanced Authentication Feedback to provide a message
     to users if authentication fails. The message users receive include
     password errors, account disabled or locked, or the user is not
    found, to name a few.
27 1.  In Default Authentication Type, select the authentication type.
28 1.  Configure the settings for your authentication type and then click
    OK.
29 <!--NeedCopy-->
```

Users and groups

September 14, 2021

After configuring the authentication, authorization, and auditing basic setup, you create users and groups. You first create a user account for each person who authenticates via the Citrix ADC appliance. If you are using local authentication controlled by the Citrix ADC appliance itself, you create local user accounts and assign passwords to each of those accounts.

You also create user accounts on the Citrix ADC appliance if you are using an external authentication server. In this case, however, each user account must exactly match an account for that user on the external authentication server, and you do not assign passwords to the user accounts that you create on the Citrix ADC. The external authentication server manages the passwords for users that authenticate

with the external authentication server.

If you are using an external authentication server, you can still create local user accounts on the Citrix ADC appliance if, for example, you want to allow temporary users (such as visitors) to log in but do not want to create entries for those users on the authentication server. You assign a password to each local user account, just as you would if you were using local authentication for all user accounts.

Each user account must be bound to policies for authentication and authorization. To simplify this task, you can create one or more groups and assign user accounts to them. You can then bind policies to groups instead of individual user accounts.

Configure policies with groups

After you configure groups, you can use the **Group** dialog box to apply policies and settings that specify user access. If you are using local authentication, you create users and add them to groups that are configured on Citrix Gateway. The users then inherit the settings for that group.

You can configure the following policies or settings for a group of users in the **Group** dialog box:

- Users
- Authorization policies
- Auditing policies
- Session policies
- Traffic policies
- Bookmarks
- Intranet applications
- Intranet IP addresses

In your configuration, you might have users that belong to more than one group. In addition, each group might have one or more bound session policies, with different parameters configured. Users that belong to more than one group inherit the session policies assigned to all the groups to which the user belongs. To ensure which session policy evaluation takes precedence over the other, you must set the priority of the session policy.

For example, you have group1 that is bound with a session policy configured with the home page www.homepage1.com. Group2 is bound with a session policy configured with home page www.homepage2.com. When these policies are bound to respective groups without a priority number or with a same priority number, the home page that appears to users who belong to both the groups depends on which policy is processed first. By setting a lower priority number, which gives higher precedence, for the session policy with home page www.homepage1.com, you can ensure that users who belong to both the groups receive the home page www.homepage1.com.

If session policies do not have a priority number assigned or have the same priority number, precedence is evaluated in the following order:

- User
- Group
- Virtual server
- Global

If policies are bound to the same level, without a priority number or if the policies have the same priority number, the order of evaluation is per the policy bind order. Policies that are bound first to a level receive precedence over policies bound later.

If we have a user bound to multiple groups with each group having IIP bound, the user can get free IP from any of the bound groups.

Create users and groups

Configure authentication, authorization, and auditing local users by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Users**
   From Citrix Gateway, expand **Citrix Gateway > User Administration**, and then click **AAA Users**.
2. In the details pane, do one of the following:
   - To create a new user account, click **Add**.
   - To modify an existing user account, select the user account, and then click **Open**.
3. In the **Create AAA User** dialog box, in the **User Name** text box, type a name for the user.
4. If creating a locally authenticated user account, clear the **External Authentication** check box and provide a local password that the user uses to log on.
5. Click **Create** or **OK**, and then click **Close**. A message appears in the status bar, stating that the user has been configured successfully.

Configure authentication, authorization, and auditing local groups and add users to them by using the configuration utility

1. Navigate to **Security > AAA - Application Traffic > Groups**
   From Citrix Gateway, expand **Citrix Gateway > User Administration**, and then click **AAA Groups**.
2. In the details pane, do one of the following:
   - To create a new group, click **Add**.
   - To modify an existing group, select the group, and then click **Edit**.
3. If you are creating a new group, in the **Create AAA Group** dialog box, in the **Group Name** text box, type a name for the group.

4. In the **Advanced** area to the right, click **AAA Users**.
   - To add a user to the group, select the user, and then click **Add**.
   - To remove a user from the group, select the user, and then click **Remove**.
   - To create a new user account and add it to the group, click the **Plus** icon, and then follow the instructions in "To configure authentication, authorization, and auditing local users by using the configuration utility."
5. Click **Create** or **OK**. The group that you created appears in the **AAA Groups** page.

Delete a group by using the GUI

You can also delete user groups from Citrix Gateway.

1. Navigate to **Security > AAA - Application Traffic > Groups**
   From Citrix Gateway, expandCitrix **Gateway > User Administration,** and then click **AAA Groups**.
   In the details pane, select the group, and then click Remove.

Configure authentication, authorization, and auditing local users by using the CLI

At the command prompt, type the following commands:

```
add aaa group <groupname>

bind aaa group <groupname> -username <username>
<!--NeedCopy-->
```

Example:

```
add aaa group group-2

bind aaa group group-2 -username user-2
<!--NeedCopy-->
```

Remove users from an authentication, authorization, and auditing group by using the command line interface

At the command prompt, unbind users from the group by typing the following command once for each user account that is bound to the group:

```
unbind aaa group <groupname> -username <username><!--NeedCopy-->
```

```
**Example:**

<!--NeedCopy-->
```

unbind aaa group group-hr -username user-hr-1

```
### Remove an authentication, authorization, and auditing group by
    using the command line interface

First remove all users from the group. Then, at the command prompt,
    type the following command to remove a Citrix ADC AAA group and
    verify the configuration:

<!--NeedCopy-->
```

rm aaa group

```
**Example:**

<!--NeedCopy-->
```

rm aaa group group-hr

```
> **Note**
>
>You cannot add a user name with domain if the user name is already
    added without domain. If the user name with domain is added first
    followed by the same user name without domain, then the Citrix ADC
    appliance adds the user name to the user list.

The following example shows adding a user name with domain is not
    permitted if the same user name is added without domain.

<!--NeedCopy-->
```

> add aaa user u47985
> Done
> show aaa users
> 1) UserName: u47985
> Done
> add aaa user u47985@domain.com

> ERROR: User already exists
> ‘‘‘

The following example shows if the user name with domain is added first followed by the same user name without domain, then the Citrix ADC appliance adds the user name to the user list.

```
> add aaa user u47985@domain.com
Done
> add aaa user u47985
Done
> sh aaa user
1)   UserName: u47985@domain.com
2)   UserName: u47985
```

‘‘‘

Authentication methods

September 14, 2021

The Citrix ADC appliance can authenticate users with local user accounts or by using an external authentication server. The appliance supports the following authentication types:

- **LOCAL:** Authenticates to the Citrix ADC appliance by using a password, without reference to an external authentication server. User data is stored locally on the Citrix ADC appliance.
- **RADIUS:** Authenticate to an external RADIUS server.
- **LDAP:** Authenticates to an external LDAP authentication server.
- **TACACS:** Authenticates to an external Terminal Access Controller Access-Control System (TACACS) authentication server.
- **CERT:** Authenticates to the Citrix ADC appliance by using a client certificate, without reference to an external authentication server.
- **NEGOTIATE:** Authenticates to a Kerberos authentication server. If there is an error in Kerberos authentication, Citrix ADC uses NTLM authentication.
- **SAML:** Authenticates to a server that supports the Security Assertion Markup Language (SAML).
- **SAML IDP:** Configures the Citrix ADC to serve as a Security Assertion Markup Language (SAML) Identity Provider (IdP).
- **WEB:** Authenticates to a web server, providing the credentials that the web server requires in an HTTP request and analyzing the web server response to determine that the user authentication was successful.

- **Native OTP:** Citrix ADC appliance supports one-time passwords (OTPs) without having to use a third-party server.
- **Push notification:** Citrix Gateway supports push notifications for OTP. Users do not have to manually enter the OTP received on their registered devices to log in to Citrix Gateway. Admins can configure Citrix Gateway such that login notifications are sent to users' registered devices using push notification services.
- **Email OTP:** The Email OTP method enables you to authenticate using the one-time password (OTP) that is sent to the registered email address. When you try to authenticate on any service, the server sends an OTP to the registered email address of the user.
- **reCaptcha authentication** - Citrix Gateway supports a new first class action 'captchaAction' that simplifies reCaptcha configuration. As reCaptcha is a first class action, it can be a factor of its own. You can inject reCaptcha anywhere in the nFactor flow.
- **nFactor authentication:** Multifactor authentication enhances the security of an application by requiring users to provide multiple proofs of identify to gain access. The Citrix ADC appliance provides an extensible and flexible approach to configuring multifactor authentication. This approach is called nFactor authentication.
- **OAuth authentication:** OAuth authentication authorizes and authenticates users to services that are hosted on applications such as Google, Facebook, and Twitter.

nFactor authentication

September 14, 2021

> **Important**
>
> - nFactor authentication is supported from NetScaler 11.0 Build 62.x onwards.
> - For nFactor authentication to work with Citrix ADC, an Advanced license or a Premium license is required.
> - Starting from release 13.0 build 67.x, nFactor authentication is supported with Standard license only for Gateway/VPN virtual server. For more information about nFactor authentication with Citrix Gateway, see nFactor for Gateway Authentication.
> - nFactor authentication is not supported for Linux client.

Multifactor authentication enhances the security of an application by requiring users to provide multiple proofs of identify to gain access. The Citrix ADC appliance provides an extensible and flexible approach to configuring multifactor authentication. This approach is called *nFactor authentication*.

How nFactor authentication works

Each authentication factor performs the following tasks:

- Collects credentials from the user. Citrix ADC supported authentication mechanisms include LDAP, RADIUS, SAML assertion, Client Certificate, OAuth OpenID Connect, Kerberos, and so on.
- Evaluates the supplied credentials to decide whether the authentication succeeded, failed or the actions like Group extraction, Attribute extraction is to be performed.
- Based on the evaluation results, access is either granted, denied, or a next factor is selected.
- Repeat these steps, until there are no more next factors to evaluate.

With nFactor authentication you can:

- Configure any number of authentication factors.
- Base the selection of the next factor on the result of executing the previous factor.
- Customize the login interface. For example, you can customize the label names, error messages, and help text.
- Extract user group information without doing authentication.
- Configure pass-through for an authentication factor. This means that no explicit login interaction is required for that factor.
- Configure the order in which different types of authentication are applied. Any of the authentication mechanisms that are supported on the Citrix ADC appliance can be configured as any factor of the nFactor authentication setup. These factors are executed in the order in which they are configured.
- Configure the Citrix ADC to proceed to an authentication factor that must be executed when authentication fails. To do so, you configure another authentication policy with the exact same condition, but with the next highest priority and with the action set to “NO_AUTH”. You must configure the next factor, which must specify the alternative authentication mechanism to apply.

Encryption of Citrix Gateway login information for nFactor authentication

Citrix Gateway with nFactor authentication can encrypt the login request fields submitted by a client (browser or SSO apps) during authentication process. The encrypted login request fields provide an extra layer of security to protect the user’s sensitive data from being disclosed.

Compatible browsers

The following table lists the browsers along with version details that support login encryption.

Browsers	Version
Chrome	78 and above
Firefox	69 and above
Internet Explorer	11
Edge	42 and above
Safari	11.0 and above
Opera	66

Compatible clients

The following section lists the clients along with version details that support encryption of Citrix Gateway login information.

- Citrix Workspace app in Mac supports encryption only when OS version is 10.14.x and above.
- Citrix SSO app in Mac supports encryption only when OS version is 10.14.x and above.
- Windows SSO app does not have restrictions on the compatibility.
- Password encryption in Citrix Workspace app for Windows clients is supported only in Internet Explorer 11 version.

To enable the login encryption by using the CLI

At the command prompt, type:

```
set aaa parameter [-loginEncryption (ENABLED | DISABLED)]
```

> **Note**
>
> The loginEncryption parameter is DISABLED by default. You must ENABLE it.

To enable the login encryption by using the GUI

1. Navigate to **Security > AAA – Application Traffic**, click **Change authentication AAA settings** under **Authentication Settings** section.
2. On the **Configure AAA Parameter** page, scroll down to the **Login Encryption** option, and enable it.

nFactor concepts, entities, and terminology

September 14, 2021

This topic captures some of the major entities involved in nFactor authentication and their significance.

Login schema

nFactor decouples the 'view', the user interface, with the 'model' that is the runtime handling. nFactor's view is defined by login schema'. Login schema is an entity that defines what user sees and specifies how to extract the data from user.

For defining view, login schema points to a file on disk that defines the logon form. This file should be according to the specification of "Citrix Common Forms Protocol." This file is essentially an XML definition of the logon form.

In addition to the XML file, login schema contains advanced policy expressions to glean user name and password from the user's login request. These expressions are optional, and can be omitted if user name and password from user arrive with expected form variable names.

Login schema also defines, whether current set of credentials should be used as default SingleSignOn credentials.

Policy label

A policy label is a collection of policies. It is a construct not alien to Citrix ADC's policy infrastructure. Policy label defines an authentication factor. That is, it contains all the policies necessary to determine whether credentials from user are satisfied. All the policies in a policy label can be assumed as homogenous. Policy label for authentication cannot take policies of different type, say rewrite. To put in a different way, all the policies in a policy label validate same password/credential from user, mostly. The result of policies in a policyLabel follows logical OR condition. Hence, if the authentication specified by first policy succeeds, other policies following it are skipped.

Policy label can be created by executing the following CLI command:

```
1 add authentication policy label mylabel  - loginSchema <>
2 <!--NeedCopy-->
```

A policy label takes login schema as the property. Login schema defines the view for that policy label. If login schema is not specified, an implicit login schema, LSCHEMA_INT, is associated with that policy label. Login schema decides whether a policy label becomes a passthrough or not.

Virtual server label

In Citrix ADC's advanced policy infrastructure, a virtual server is also an implicit policy label. That's because virtual server can also be bound with more than one policy. However, a virtual server is special because it is the entry point for client traffic and can take policies of a different type. Each of the policies it put under its own label within the virtual server. Hence, virtual server is a conglomeration of labels.

Next factor

Whenever a policy is bound to a virtual server or a policy label, it can be specified with next factor. Next factor determines what should be done if a given authentication succeeds. If there is no next factor, that concludes authentication process for that user.

Each policy bound to a virtual server or policy label can have a different next factor. This allows for ultimate flexibility where in every policy's success can define a new path for user's authentication. Administrator can take advantage of this fact and craft clever fallback factors for users who do not meet certain policies.

No-Auth policy

nFactor introduces a special kind of built-in policy called NO_AUTHN. NO_AUTHN policy always returns success as authentication result. No-auth policy can be created by executing the following CLI command:

```
1 add authentication policy noauthpolicy  -rule <> -action NO_AUTHN
2 <!--NeedCopy-->
```

As per the command, no-authentication policy takes a rule that can be any advanced policy expression. Authentication result is always success from NO_AUTHN.

A no-auth policy in itself does not seem to add value. However, when used along with passthrough policy labels, it offers great flexibility to make logical decisions to drive user authentication flow. NO_AUTHN policy and passthrough factors offer a new dimension to nFactor's flexibility.

Note: Check the examples that depict the usage of no-auth and passthrough in subsequent sections.

Passthrough factor/label

Once the user has passed the authentication at virtual server (for first factor), subsequent authentications happen at policy labels or user defined (secondary) factors.
Every policy label/factor is associated with a login schema entity to display view for that factor. This allows for customizing views based on the path user would have taken to arrive at a given factor.

There are specialized kinds of policy labels which do not point explicitly to a login schema. Specialized policy labels point to a login schema that does not actually point to the XML file for the view. These policy labels/factors are called 'passthrough' factors.

Passthrough factors can be created by executing the following CLI commands:

Example 1:

```
1 add authentication policylabel example1
2 <!--NeedCopy-->
```

Example 2:

```
1 add loginschema passthrough_schema  -authenticationSchema noschema
2
3 add authentication policylabel example2  -loginschema
     passthrough_schema
4 <!--NeedCopy-->
```

Passthrough factor implies that authentication, authorization, and auditing subsystem should not go back to user to get credential set for that factor. Instead, it is a hint for authentication, authorization, and auditing to continue with already obtained credentials. This is useful in cases where user intervention is not desired. For example,

- When user is presented two password fields. After the first factor, second factor does not need user intervention
- When authentication of a type (say certificate) is done, and administrator needs to extract groups for that user.

Passthrough factor can be used with NO_AUTH policy to make conditional jumps.

nFactor authentication flow

Authentication always begins at virtual server in nFactor. Virtual server defines the first factor for the user. The first form that the user sees is served by the virtual server. The logon form that user sees can be customized at virtual server using login schema policies. If there are no login schema policies, a single user name and password field are displayed to the user.

If more than one password fields must be displayed to the user on customized form, login schema policies must be used. They allow for displaying different forms based on the configured rules (such as intranet user versus external user, service provider A versus service provider B).

Once user credentials are posted, authentication begins at authentication virtual server, the first factor. Because authentication virtual server can be configured with multiple policies, each of them is evaluated in a sequence. At any given point, if an authentication policy succeeds, the next factor

specified against it is taken. If there is no next factor, the authentication process ends. If next factor exists, it is checked if that factor is a passthrough factor or a regular factor. If that is passthrough, authentication policies on that factor are evaluated without user intervention. Otherwise, login schema associated with that factor is displayed to the user.

Example of using passthrough factor and no-auth policies to make logical decisions

Administrator would like to decide nextFactor based on groups.

- Add authentication policylabel group check
- Add authentication policy admin group –rule http.req.user.is_member_of(“Administrators”) –action NO_AUTHN
- Add authentication policy nonadmins –rule true –action NO_AUTHN
- Bind authentication policy label group check –policy admingroup –pri 1 –nextFactor factor-for-admin
- Bind authentication policy label groupcheck –policy nonadmins –pri 10 –nextfactor factor-for-others
- Add authentication policy first_factor_policy –rule <> -action <>
- Bind authentication vserver <> -policy first_factor_policy –priority 10 –nextFactor groupcheck

Configuring nFactor authentication

September 14, 2021

You can configure multiple authentication factors using nFactor configuration rather than just two factors. nFactor configuration is supported only in Citrix ADC Advanced and Premium editions.

Methods to configure nFactor

You can configure nFactor authentication by one of the following methods:

- **nFactor Visualizer:** nFactor visualizer enables you to easily link factors or policy labels together in a single pane and also change the linking of the factors in the same pane. You can create an nFactor flow using the visualizer and bind that flow to a Citrix ADC AAA virtual server. For details about nFactor Visualizer and an example nFactor configuration using visualizer, see nFactor Visualizer for simplified configuration.
- **Citrix ADC GUI:** For details, see section **Configuration elements involved in nFactor configuration**.

- **Citrix ADC CLI:** For a sample snippet on nFactor configuration using the Citrix ADC CLI, see Sample snippet on nFactor configuration by using the Citrix ADC CLI.

> **Important:** This topic contains details about configuring nFactor by using the Citrix ADC GUI.

Configuration elements involved in nFactor configuration

The following elements are involved in configuring nFactor. For detailed steps, refer to the appropriate sections in this topic.

Configuration element	Tasks to be performed
AAA virtual server	Create a AAA virtual server
	Bind portal theme to AAA virtual server
	Enable client certificate authentication
Login schema	Configure a login schema profile
	Create and bind a login schema policy
Advanced authentication policies	Create advanced authentication policies
	Bind first factor advanced authentication policy to Citrix ADC AAA virtual server
	Use extracted LDAP groups to select the next authentication Factor
Authentication policy label	Create authentication policy label
	Bind authentication policy label
nFactor for Citrix Gateway	Create authentication profile to link a Citrix ADC AAA virtual server with Citrix Gateway virtual server
	Configure SSL parameters and CA certificate for Citrix Gateway
	Configure Citrix Gateway traffic policy for nFactor single sign-on to StoreFront

How nFactor works

When a user connects to Citrix ADC AAA or Citrix Gateway virtual server, the sequence of events that occur are as follows:

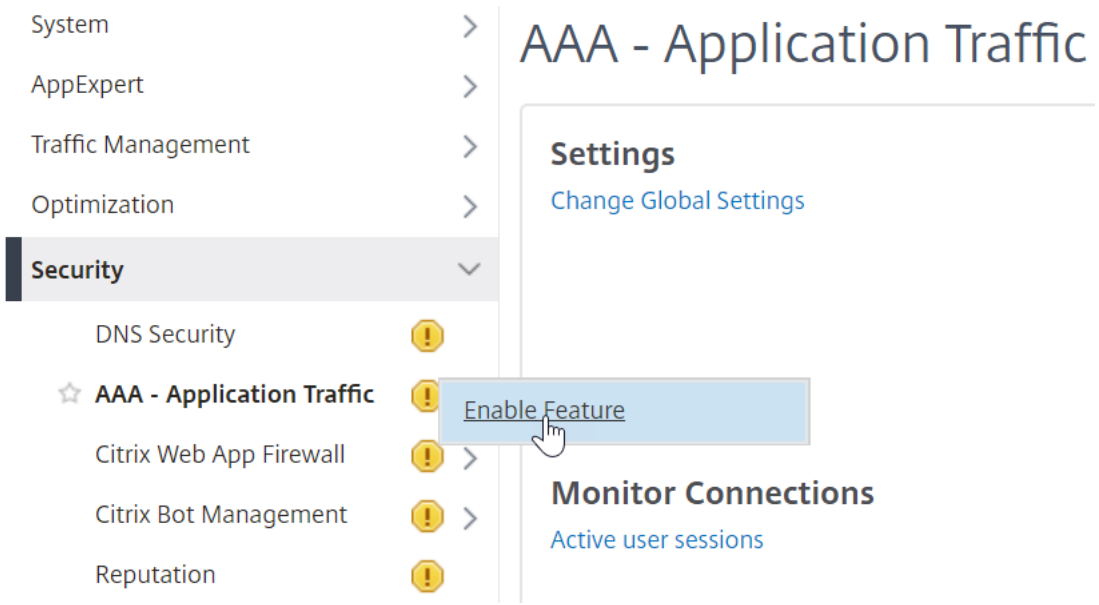
1. If forms-based authentication is used, the login schema bound to the Citrix ADC AAA virtual server is displayed.
2. Advanced authentication policies bound to the Citrix ADC AAA virtual server are evaluated.
    - If the advanced authentication policy succeeds, and if next factor (authentication policy label) is configured, next factor is evaluated. If Next Factor is not configured, then authentication is complete and successful.
    - If the advanced authentication policy fails, and if Goto Expression is set to Next, then next bound advanced authentication policy is evaluated. If none of the advanced authentication policies succeed, then authentication fails.
3. If the next factor authentication policy label has a Login Schema bound to it, it is displayed to the user.
4. The advanced authentication policies bound to the next factor authentication policy label is evaluated.
    - If the Advanced authentication policy succeeds, and if next factor (authentication policy label) is configured, next factor is evaluated.
    - If Next Factor is not configured, then authentication is complete and successful.
5. If the Advanced authentication policy fails, and if Goto Expression is Next, then the next bound advanced authentication policy is evaluated.
6. If none of the advanced authentication policies succeeds, then authentication fails.

AAA virtual server

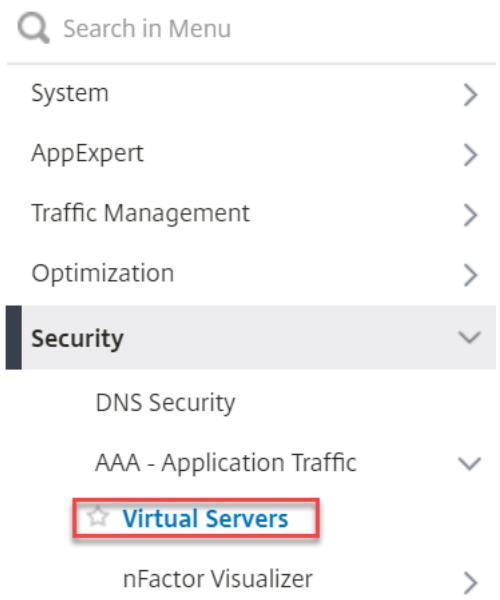
To use nFactor with Citrix Gateway, you first configure it on a AAA Virtual Server. Then you later link the AAA virtual server to the Citrix Gateway virtual server.

Create AAA Virtual Server

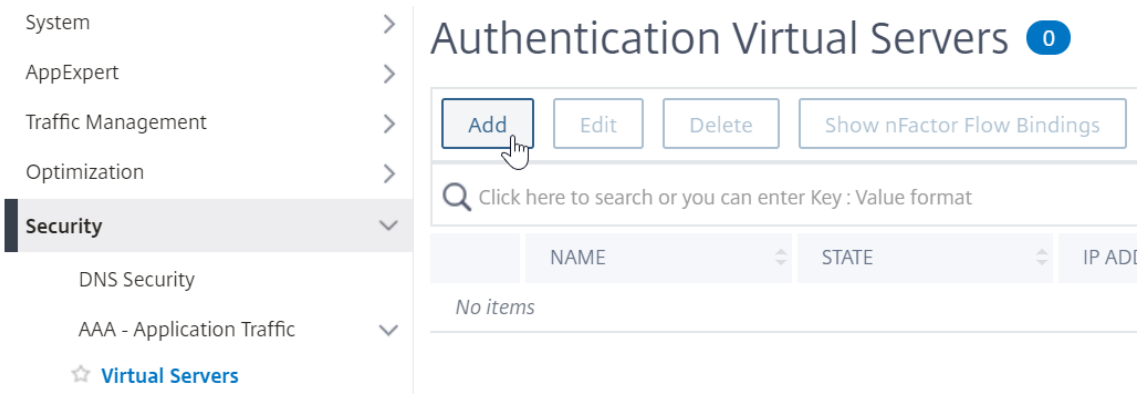
1. If AAA feature is not already enabled, navigate to, **Security > AAA – Application Traffic**, and right click to enable feature.



2. Navigate to **Configuration > Security > AAA - Application Traffic > Virtual Servers**.

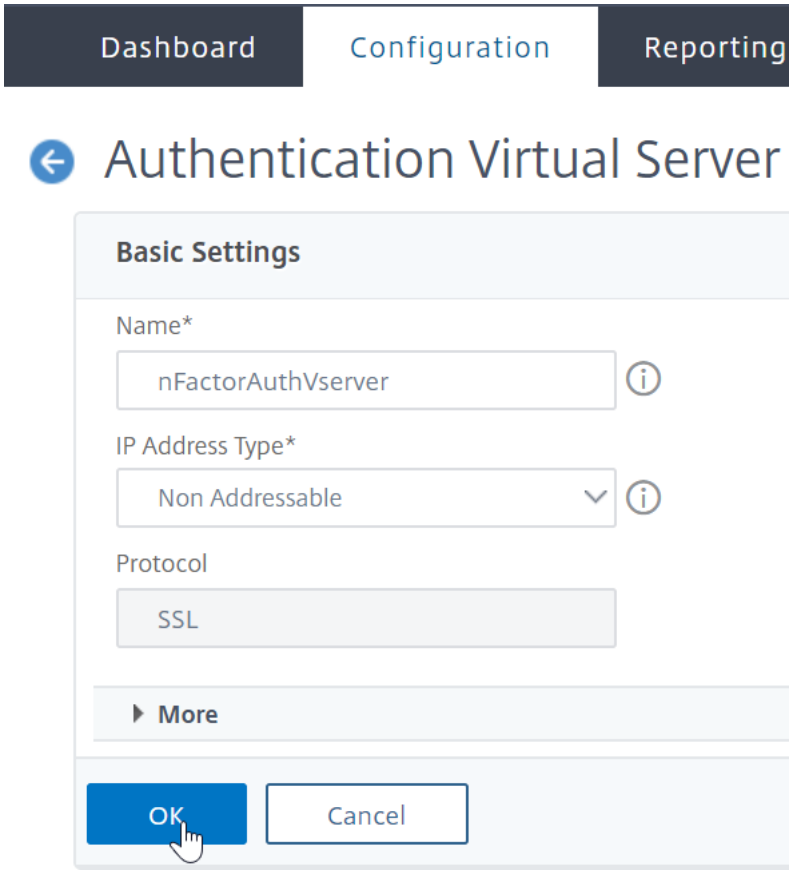


3. Click **Add** to create an authentication virtual server.

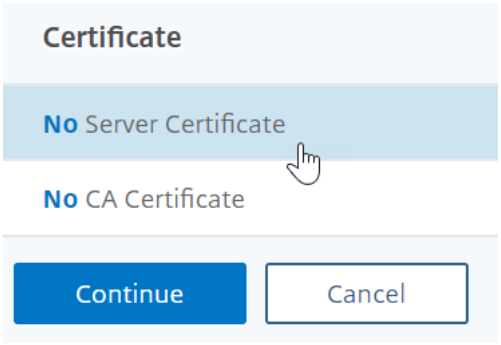


4. Enter the following information and click **OK**.

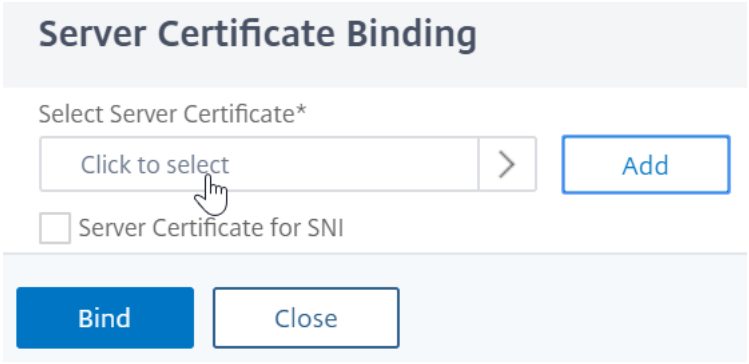
Parameter name	Parameter Description
Name	Name for the AAA virtual server.
IP address Type	Change the IP address Type to **Non Addressable** if this virtual server is used only for Citrix Gateway.



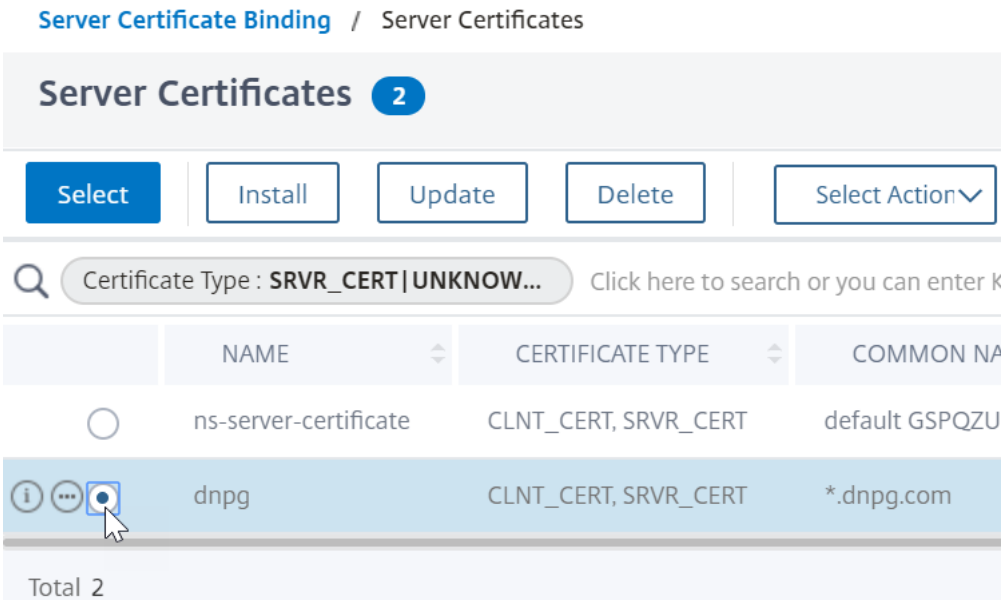
5. Under Certificate, select **No Server Certificate**.



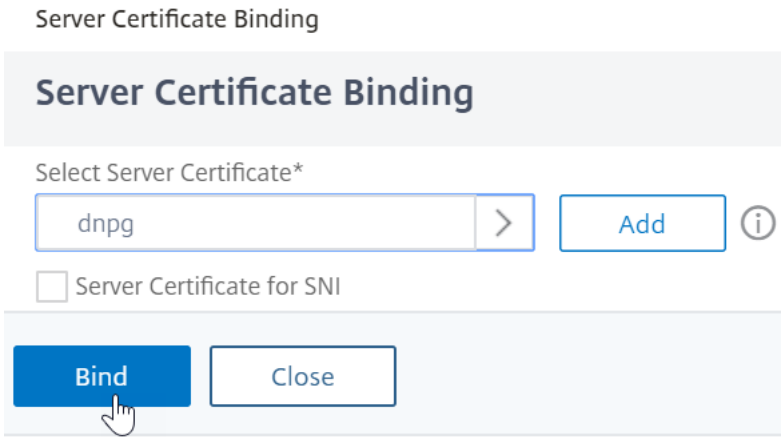
6. Click the text, **Click to select** to select the server certificate.



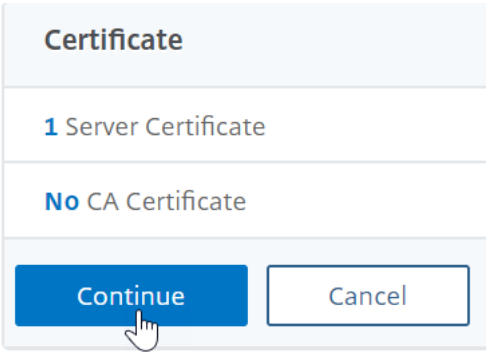
7. Click the radio button next to a certificate for the AAA Virtual Server, and click **Select**.The chosen certificate doesn't matter because this server is not directly accessible.



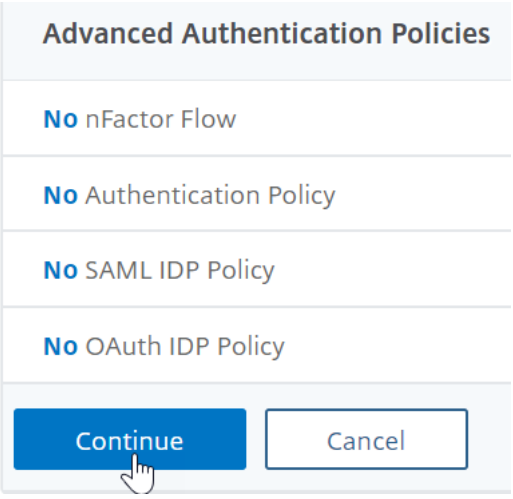
8. Click **Bind**.



9. Click **Continue** to close the **Certificate** section.

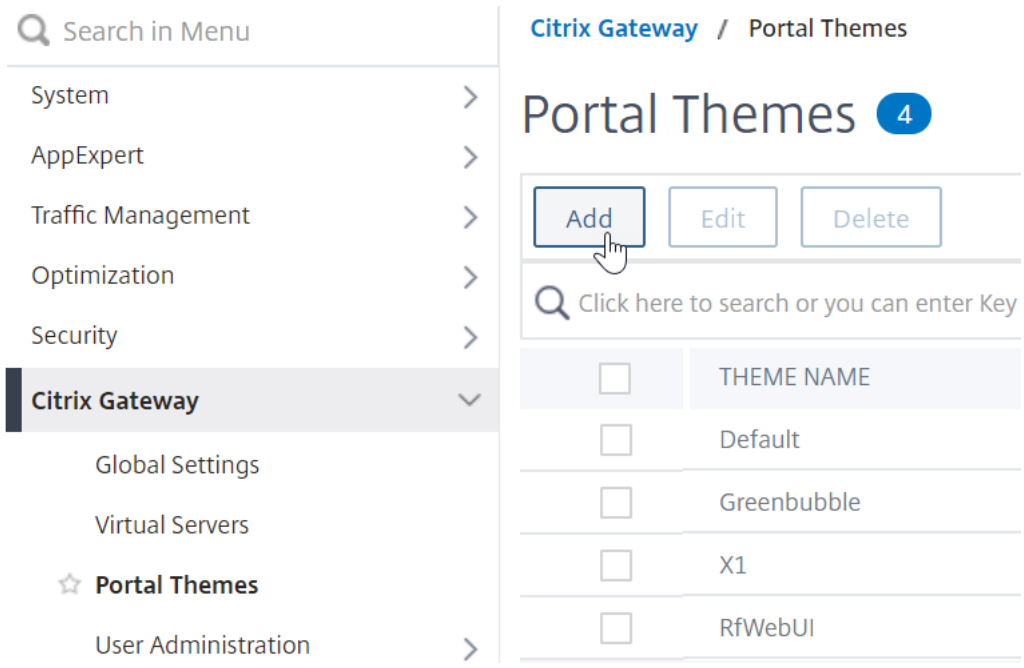


10. Click **Continue**.

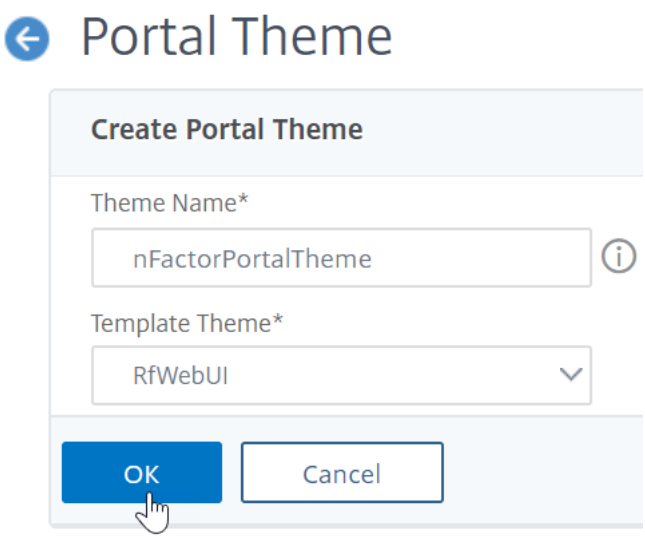


Bind portal theme to AAA virtual server

1. Navigate to **Citrix Gateway > Portal Themes**, and add a theme. You create the theme under Citrix Gateway, and then later bind it to the AAA virtual server.

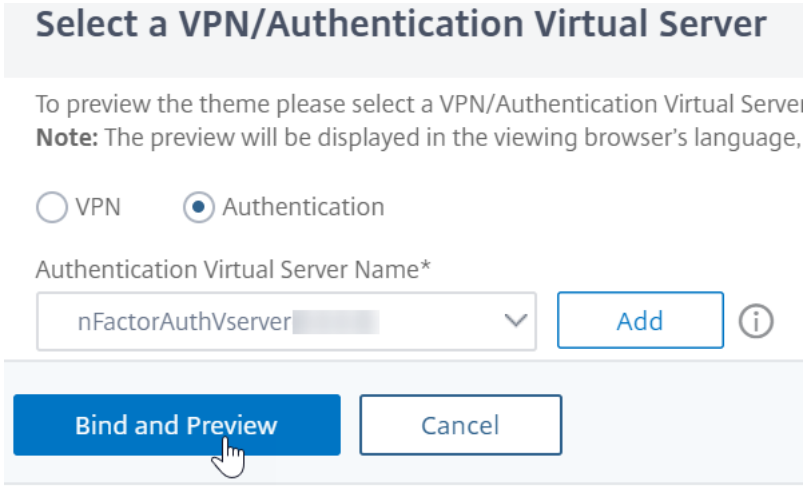


2. Create a theme based on the RfWebUI template theme.



3. After adjusting the theme as desired, at the top of the portal theme editing page, click **Click to Bind and View Configured Theme**.

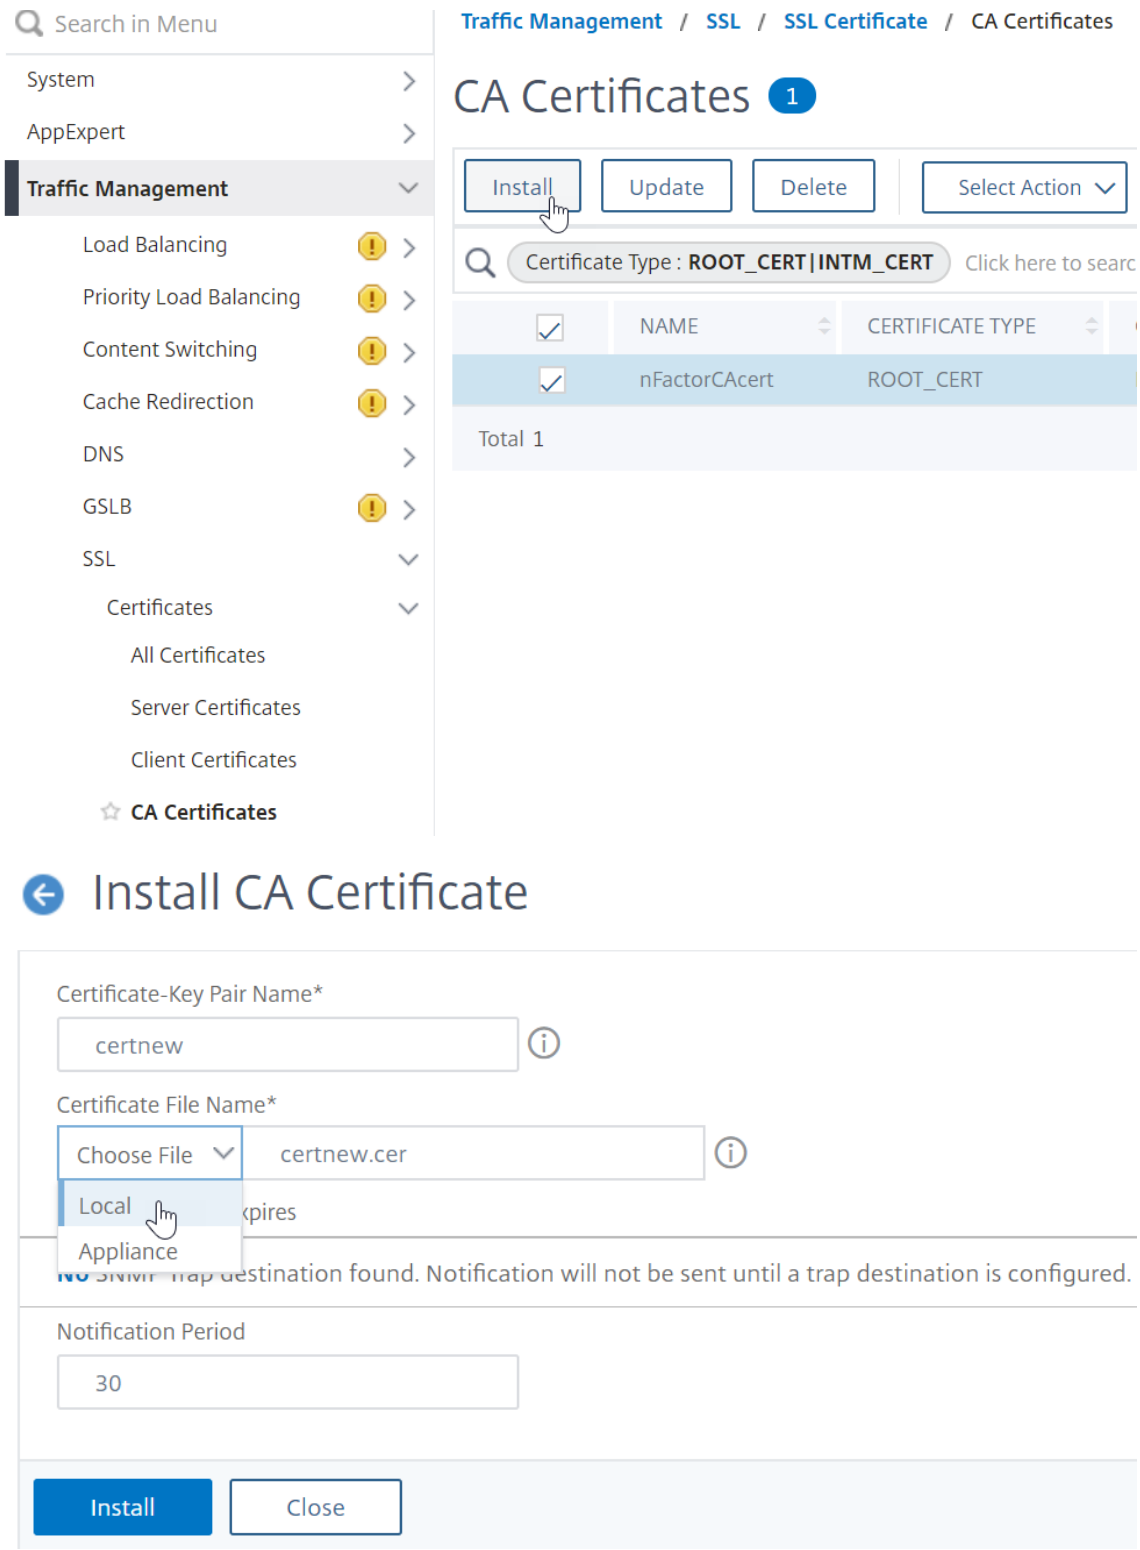
4. Change the selection to Authentication. From the **Authentication Virtual Server Name** drop-down menu, select the AAA Virtual Server, and click **Bind and Preview** and close the preview window.



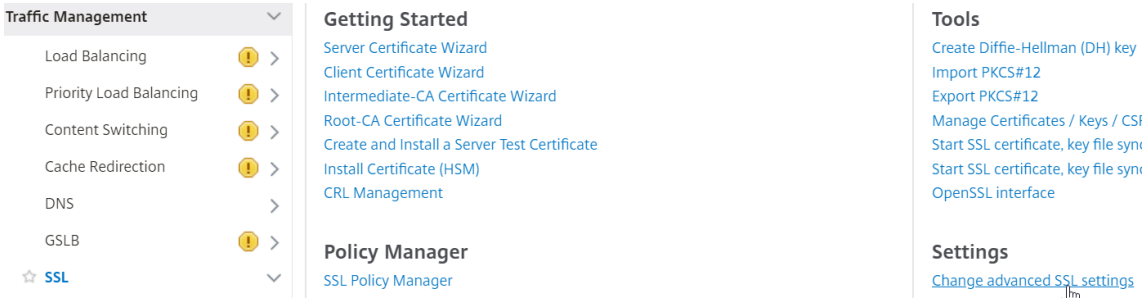
Enable client certificate authentication

If one of your authentication Factors is client certificate, then you must perform some SSL configuration on the AAA Virtual Server:

1. Navigate to **Traffic Management > SSL > Certificates > CA Certificates**, and install the root certificate for the issuer of the client certificates. Root certificates do not have a key file.



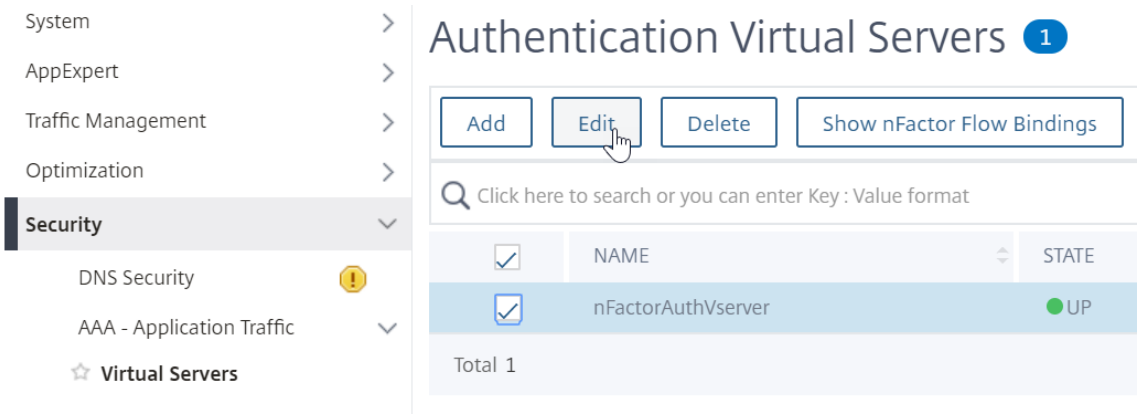
2. Navigate to **Traffic Management > SSL > Change advanced SSL settings**.



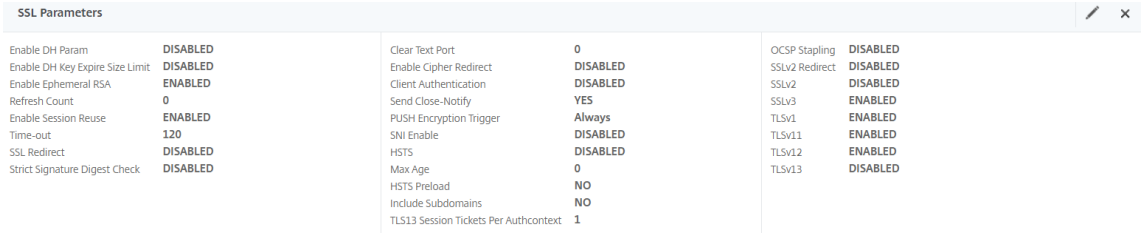
a. Scroll down to check whether **Default Profile** is **ENABLED**. If yes, then you must use an SSL Profile to enable Client Certificate Authentication. Otherwise, you can enable Client Certificate Authentication directly on the AAA Virtual Server in the SSL Parameters section.

3. If default SSL Profiles are not enabled:

a. Navigate to **Security > AAA - Application > Virtual Servers**, and edit an existing AAA virtual server.

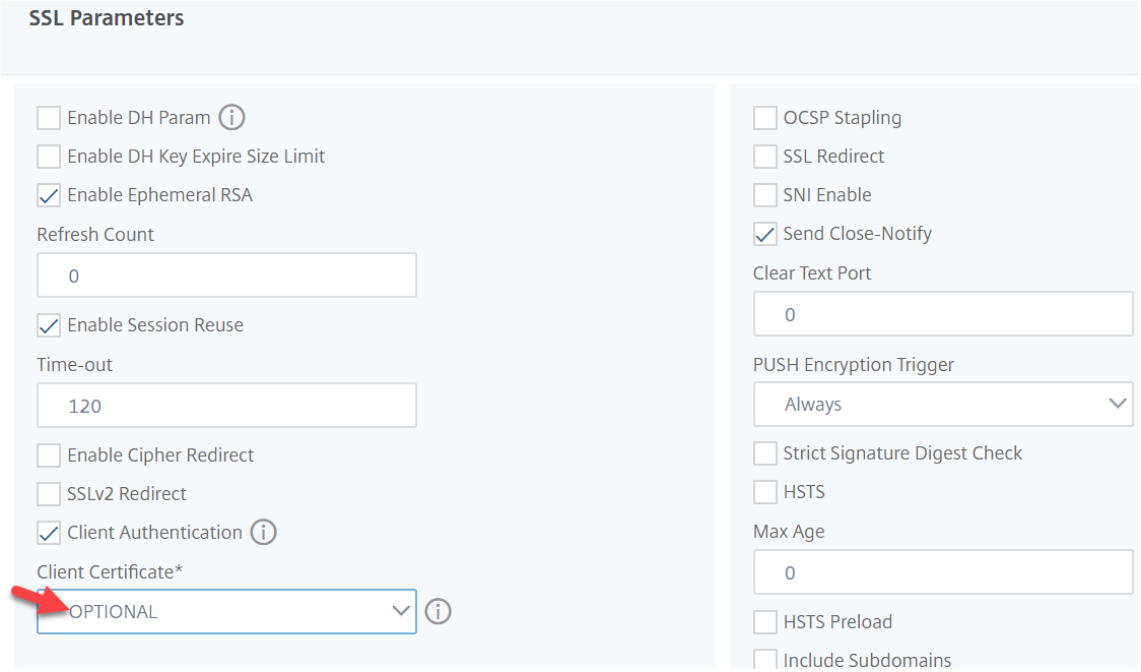


b. On the left, in the **SSL Parameters** section, click the pencil icon.



c. Check the box next to **Client Authentication**.

d. Make sure **Optional** is selected in the **Client Certificate** drop-down menu, and click **OK**.



4. If Default SSL Profiles are enabled, then create a new SSL Profile with Client Authentication enabled:

   a. On the left menu, expand System, and click Profiles.

   b. On the top right, switch to the SSL Profile tab.

   c. Right-click the ns_default_ssl_profile_frontend profile, and click Add. This copies settings from the default profile.

   d. Give the Profile a name. The purpose of this profile is to enable Client Certificates.

   e. Scroll down and find the Client Authentication checkbox. Check the box.

   f. Change the Client Certificate drop-down to OPTIONAL.

   g. Copying the default SSL Profile does not copy the SSL Ciphers so you'll have to redo them.

   h. Click Done when done creating the SSL Profile.

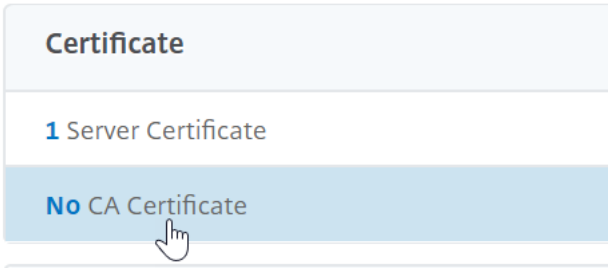
   i. Navigate to Security > AAA – Application Traffic > Virtual Servers, and edit a AAA vServer.

   j. Scroll down to the SSL Profile section and click the pencil.

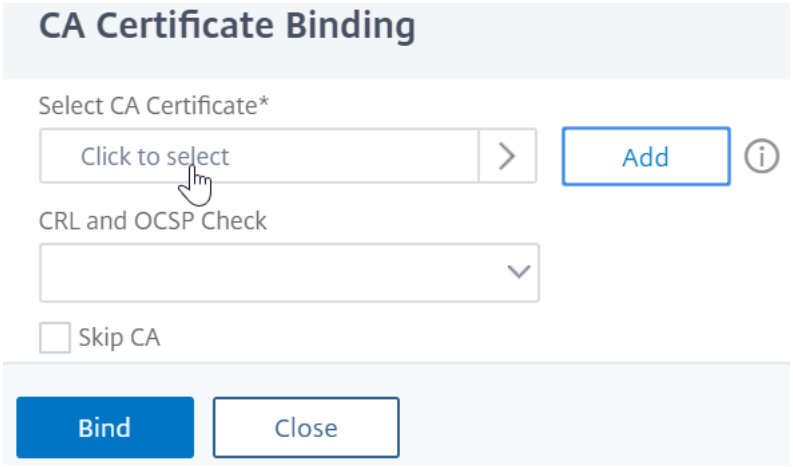
   k. Change the SSL Profile drop-down to the profile that has Client Certificates enabled. Click OK.

   l. Scroll down this article until you reach the instructions to bind the CA certificate.

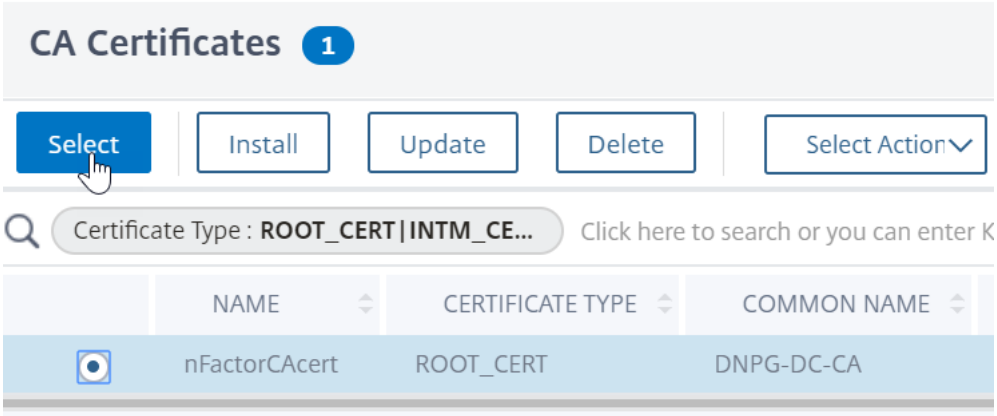
5. On the left, in the **Certificates** section, click where it says **No CA Certificate**.



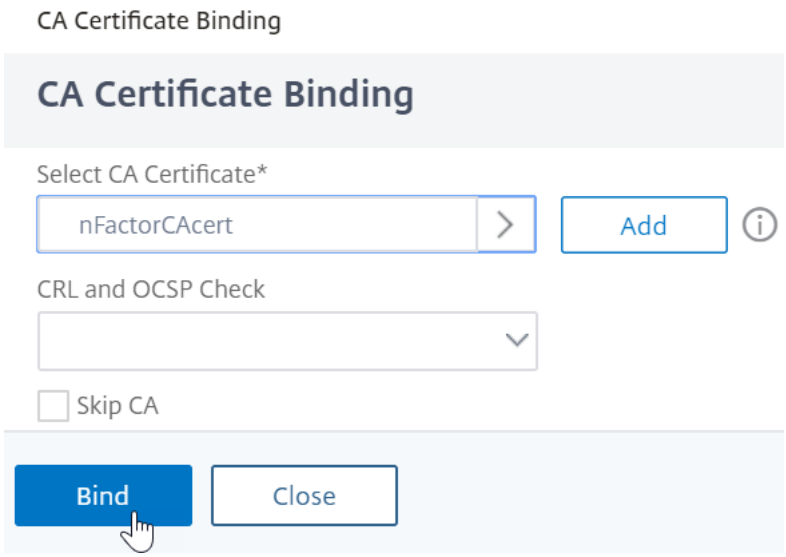
6. Click the text, **Click to select**.



7. Click the radio button next to the root certificate for the issuer of the client certificates, and click **Select**.



8. Click **Bind**.



Login schema XML file

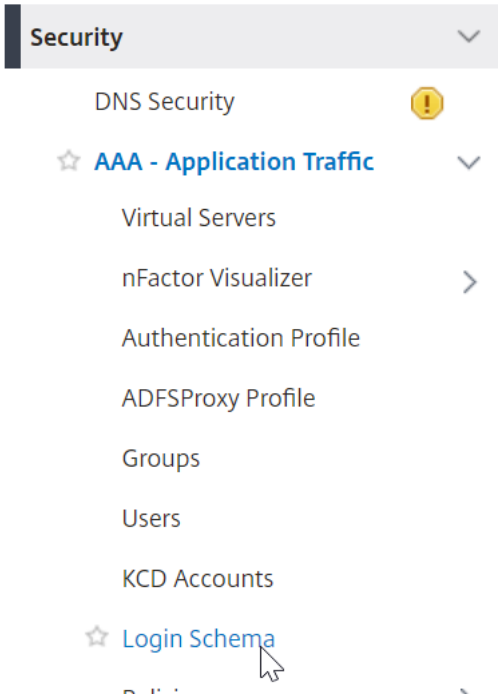
Login Schema is an XML file providing the structure of forms-based authentication logon pages.

nFactor implies multiple authentication Factors that are chained together. Each Factor can have different Login Schema pages/files. In some authentication scenarios, users could be presented with multiple logon screens.

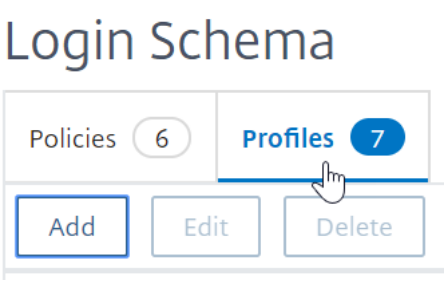
Configure a login schema profile

To configure a Login Schema Profile:

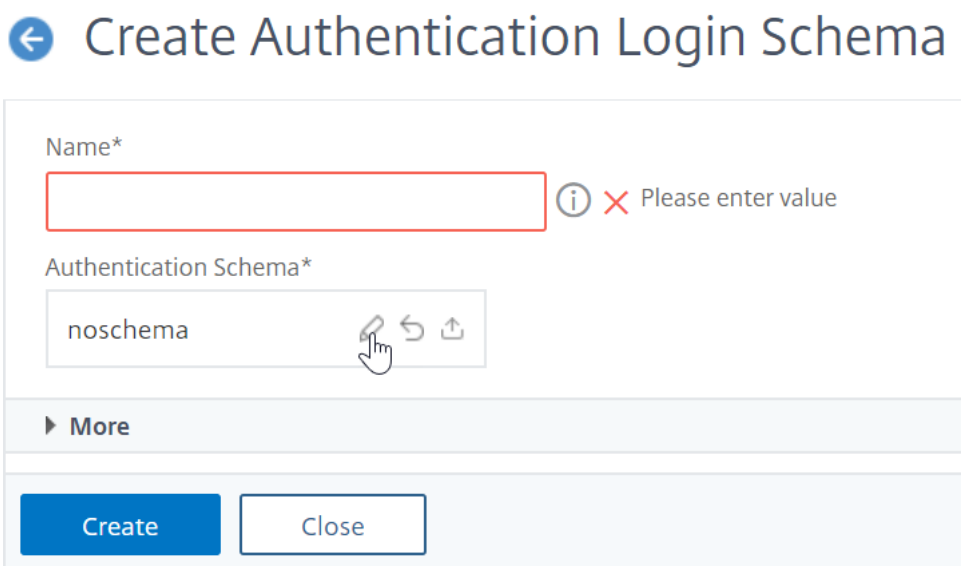
1. Create or Edit a Login Schema .XML file based on your nFactor design.
2. Navigate to **Security > AAA - Application Traffic > Login Schema**.



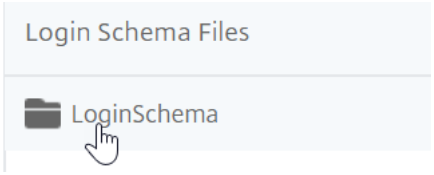
3. On the right, switch to the **Profiles** tab, and click **Add**.



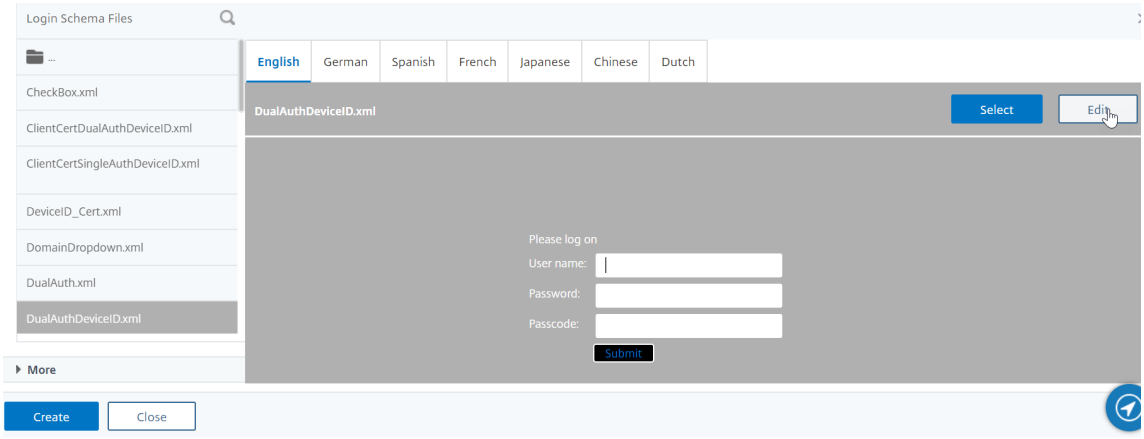
4. In the **Authentication Schema** field, click the pencil icon.



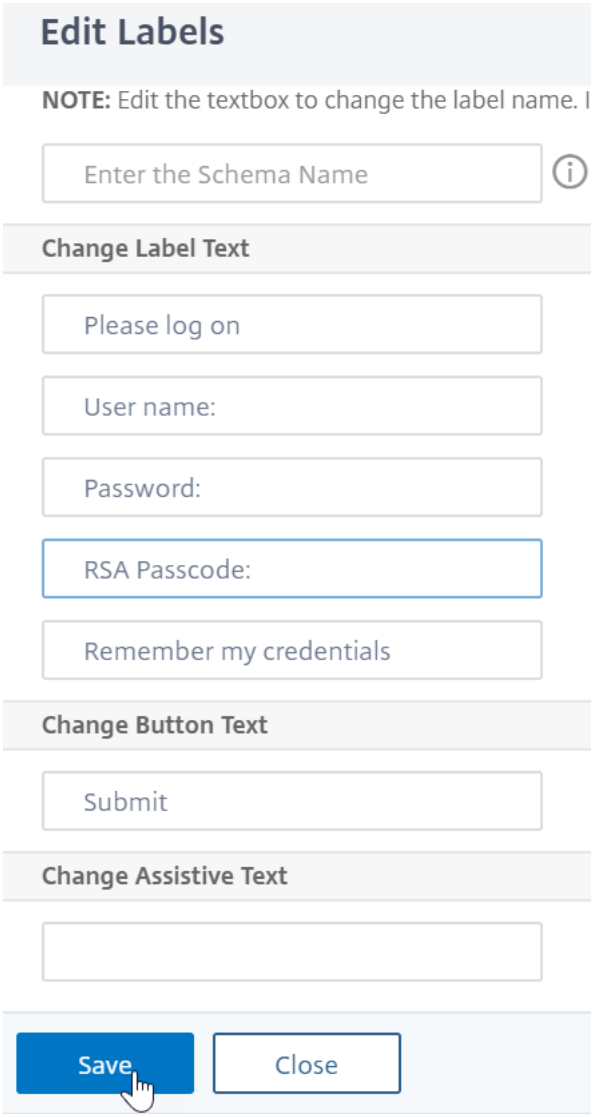
5. Click the LoginSchema folder to see the files in it.



6. Select one of the files. You can see a preview on the right. The labels can be changed by clicking the **Edit** button on the top right.

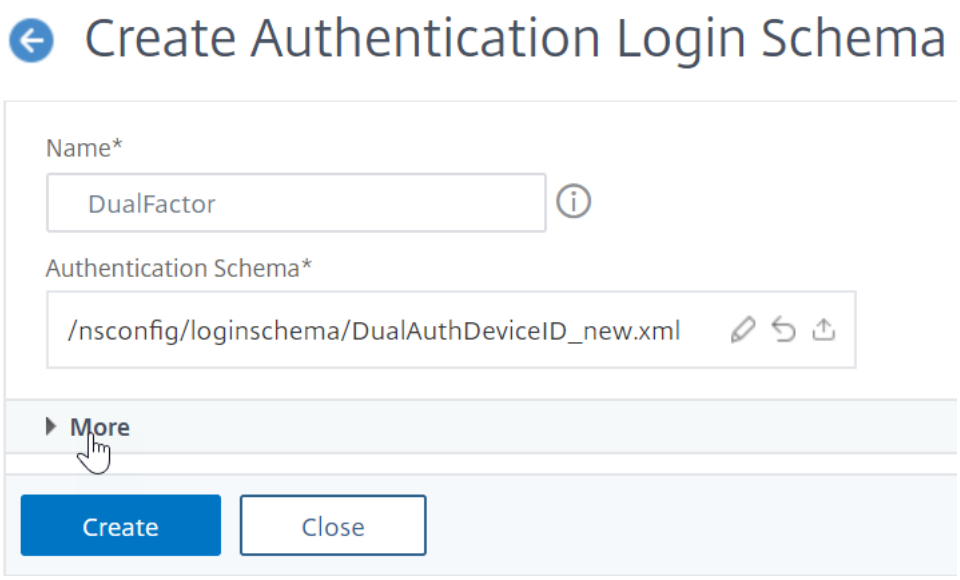


7. When you Save the changes, a new file is created under /nsconfig/LoginSchema.



8. On the top right, click **Select**.

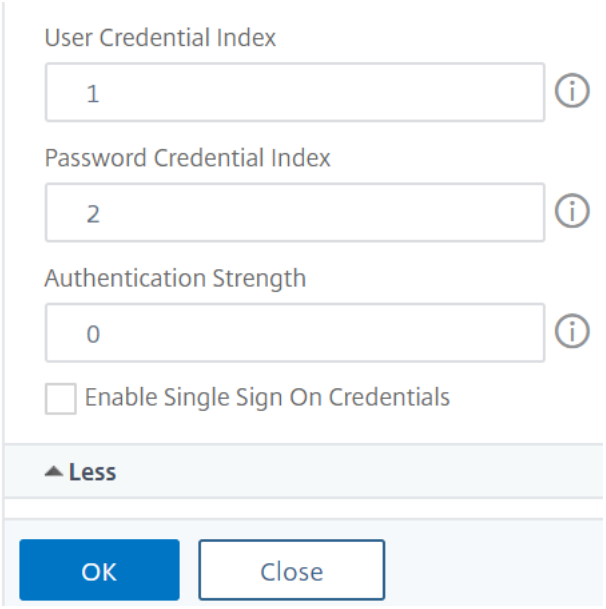
9. Give the Login Schema a name, and click **More**.



10. You might need to use the username and the password entered in the login schema for Single Sign-on (SSO) to a backend service, for example StoreFront.

    You can use the credentials entered in the login schema as your Single Sign-On credentials by using any of the following methods.

    - Click **More** at the bottom of the **Create Authentication Login Schema** page and select **Enable Single Sign On Credentials**.
    - Click **More** at the bottom of the **Create Authentication Login Schema** page and enter unique values for the user credential index and password credential index. These values can be between 1 and 16. Later you reference these index values in a traffic policy/profile by using the expression AAA.USER.ATTRIBUTE(#).



11. Click **OK** to create the login schema profile.

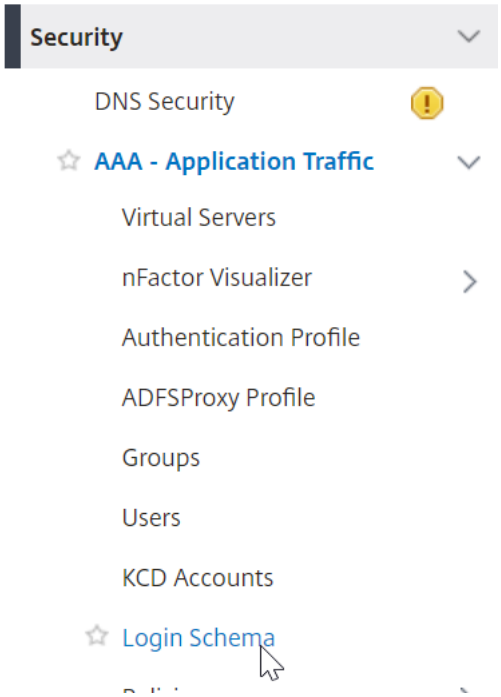
> **Note:** If you edit the login schema file (.xml) later, for changes to be reflected you need to edit the login schema profile and select the login schema (.xml) file again.

Create and bind a login schema policy

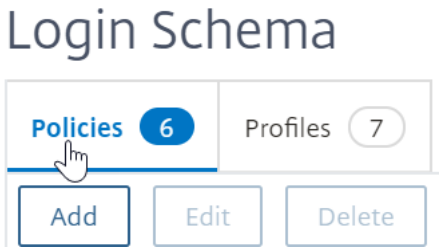
To bind a login schema profile to a AAA vServer, you must first create a login schema policy. Login schema policies are not required when binding the login schema profile to an authentication policy label, as detailed later.

To create and bind a login schema policy:

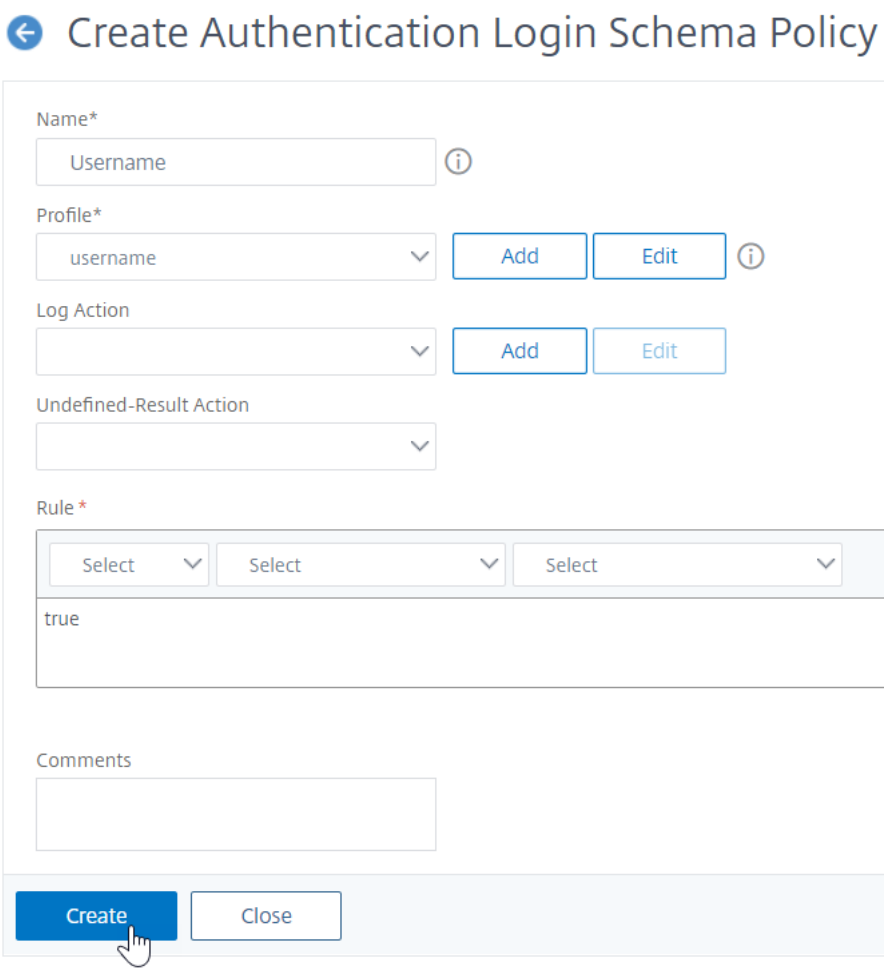
1. Navigate to **Security > AAA - Application Traffic > Login Schema**.



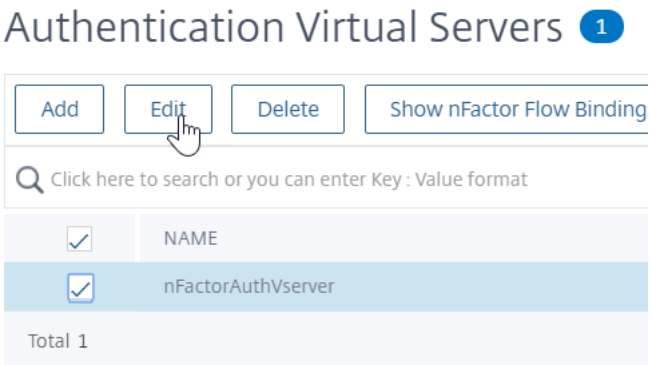
2. On the **Policies** tab, click **Add**.



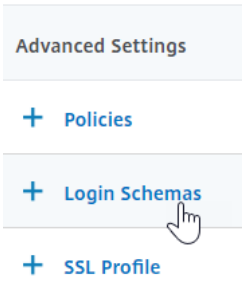
3. Use the **Profile** drop-down menu to select the Login Schema Profile you already created.
4. Enter a Default Syntax expression (e.g. true) in the **Rule** box, and click **Create**.



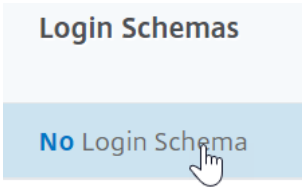
5. On the left, navigate to **Security > AAA - Application Traffic > Virtual Servers**, and edit an existing AAA Virtual Server.



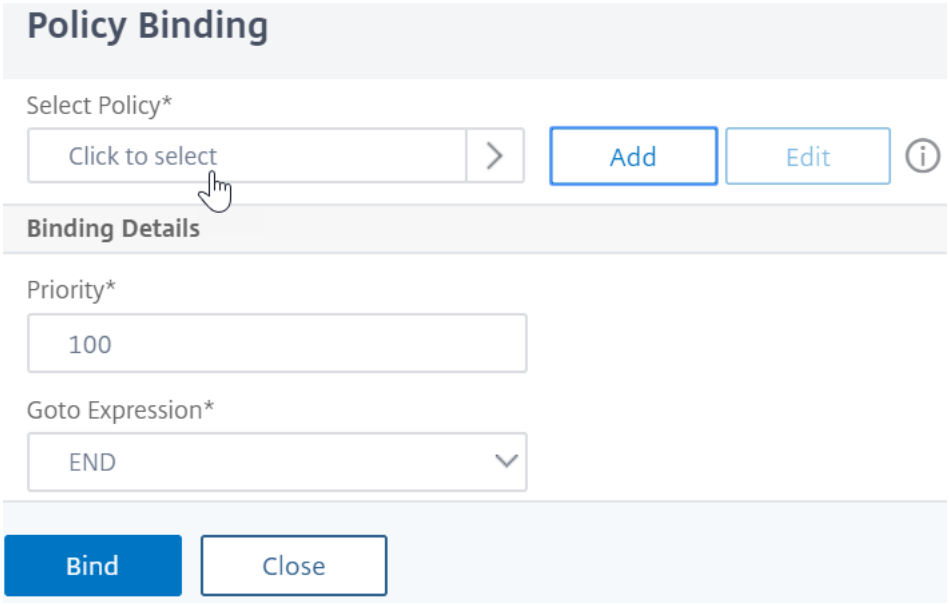
6. In the Advanced Settings column, click **Login Schemas**.



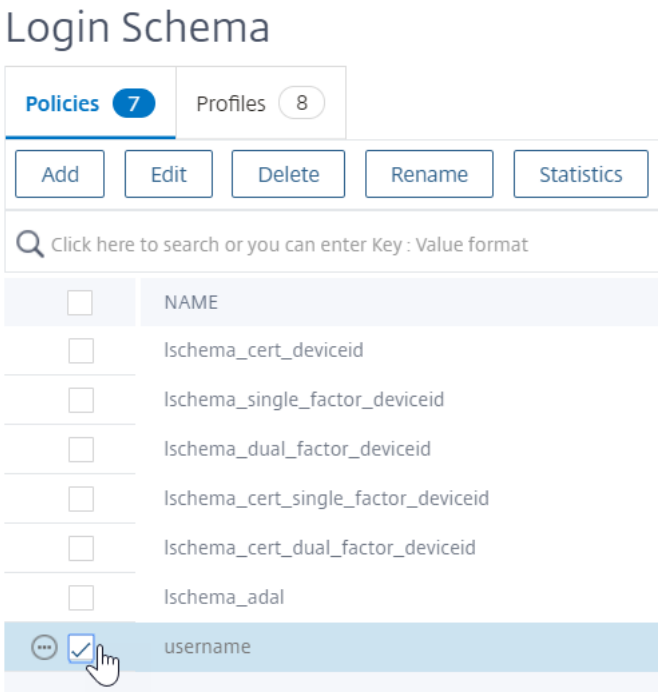
7. In the Login Schemas section, click the text **No Login Schema**.



8. Click the text, **Click to select**.



9. Click the radio button next to the login schema policy, and click **Select**. Only login schema policies appear in this list. Login schema profiles (without a policy) do not appear.



10. Click **Bind**.

Advanced authentication polices

Authentication policies are a combination of policy expression, and policy action. If the expression is true, then evaluate the authentication action.

Create advanced authentication policies

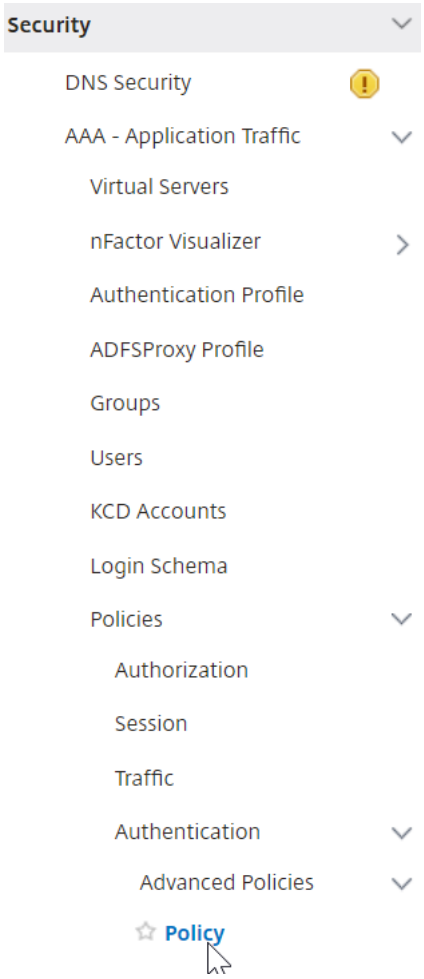
Authentication policies are a combination of policy expression and policy action. If the expression is true, then evaluate the authentication action.

You will need authentication actions/servers (e.g. LDAP, RADIUS, CERT, SAML, etc.)
When creating an advanced authentication policy, there's a plus (Add) icon that lets you create authentication actions/servers.

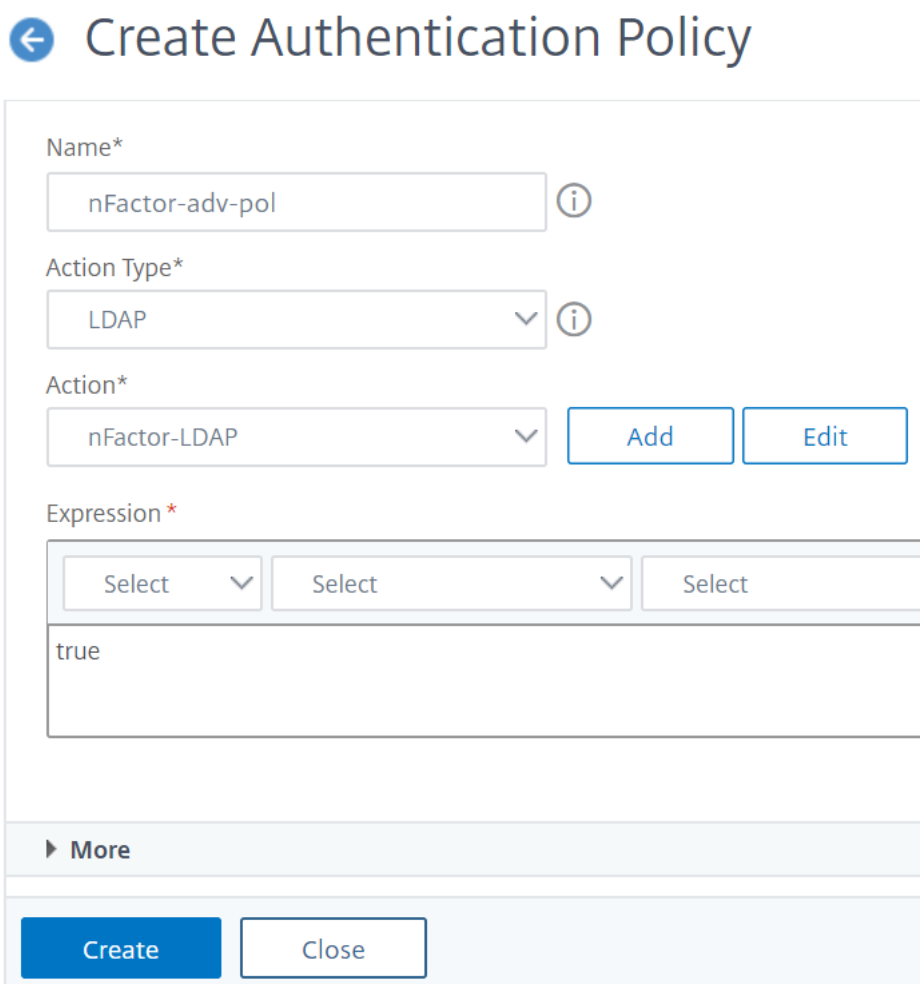
Or you can create authentication actions (aervers) prior to creating the advanced authentication policy. The authentication servers are located under **Authentication > Dashboard**. On the right, click Add and select a Server Type. The instructions for creating these Authentication Servers is not detailed here. See the Authentication – NetScaler 12 / Citrix ADC 12.1 procedures.

To create an Advanced Authentication Policy:

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy**



2. In the details pane do one of the following:
   - To create a policy, click **Add**.
   - To modify an existing policy, select the policy, and then click **Edit**.
3. In the **Create Authentication Policy** or **Configure Authentication Policy** dialog box, type or select values for the parameters.



- **Name** - The policy name. Cannot be changed for a previously configured policy.
- **Action Type** - The policy type: Cert, Negotiate, LDAP, RADIUS, SAML, SAMLIDP, TACACS, or WEBAUTH.
- **Action** - The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create an action of the proper type.
- **Log Action** - The audit action to associate with the policy. You can choose an existing audit action, or click the plus and create an action.
  You don't have any Actions configured, or to create an action, click **Add** and complete the steps.
- **Expression** - The rule that selects connections to which you want to apply the action that you specified. The rule can be simple ("true" selects all traffic) or complex. You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open Add Expression dialog box and using the drop-down lists in it to construct your expression.)
- **Comment** - You can type a comment that describes the type of traffic that this authentica-

tion policy applies to. Optional.

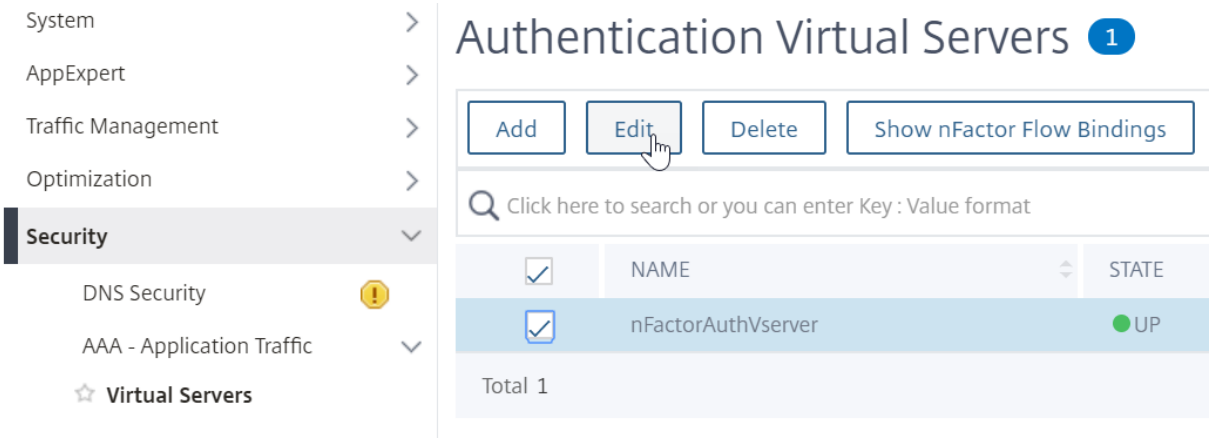
4. Click **Create** and then click **Close**. If you created a policy, that policy appears in the Authentication Policies and Servers page.

You must create additional advanced authentication policies as required based on your nFactor design.

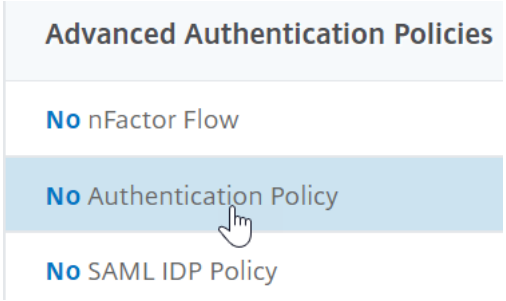
Bind first factor advanced authentication policy to Citrix ADC AAA

You can directly bind advanced authentication policies for the first Factor the Citrix ADC AAA virtual server. For the next factors, you must bind the advanced authentication policies to the authentication policy labels.

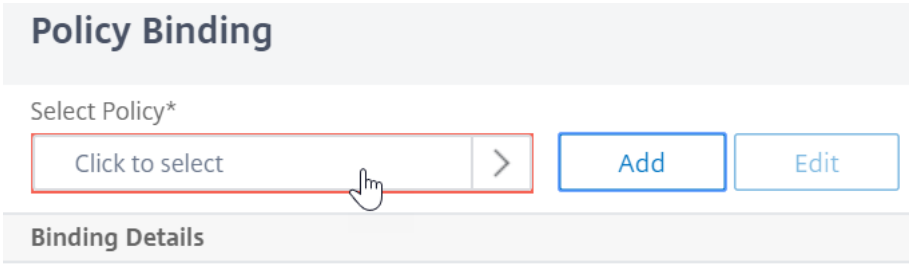
1. Navigate to **Security > AAA - Application Traffic > Virtual Servers**. Edit an existing virtual server.



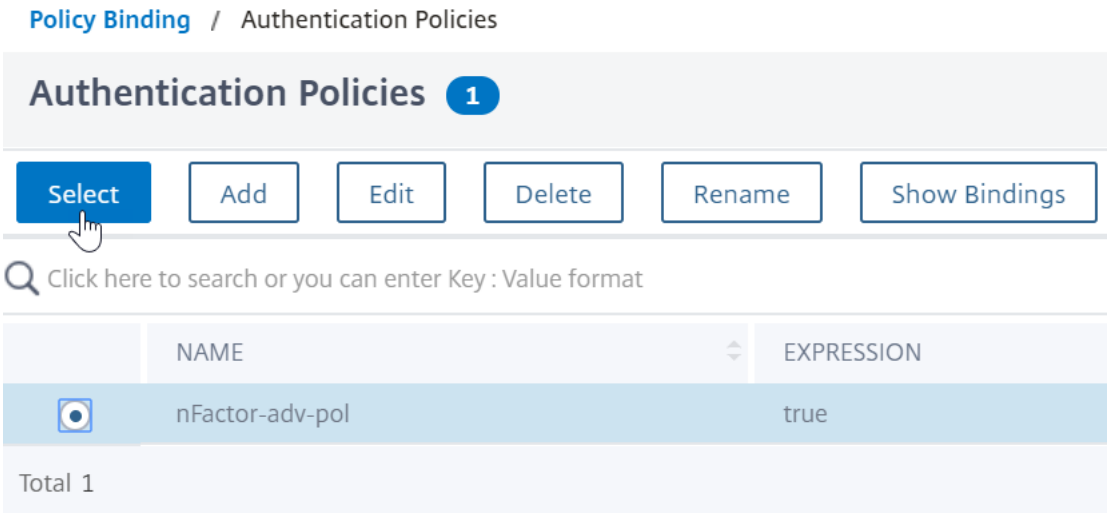
1. On the left, in the Advanced Authentication Policies section, click **No Authentication Policy**.



2. In **Select Policy**, click the text, **Click to select**.

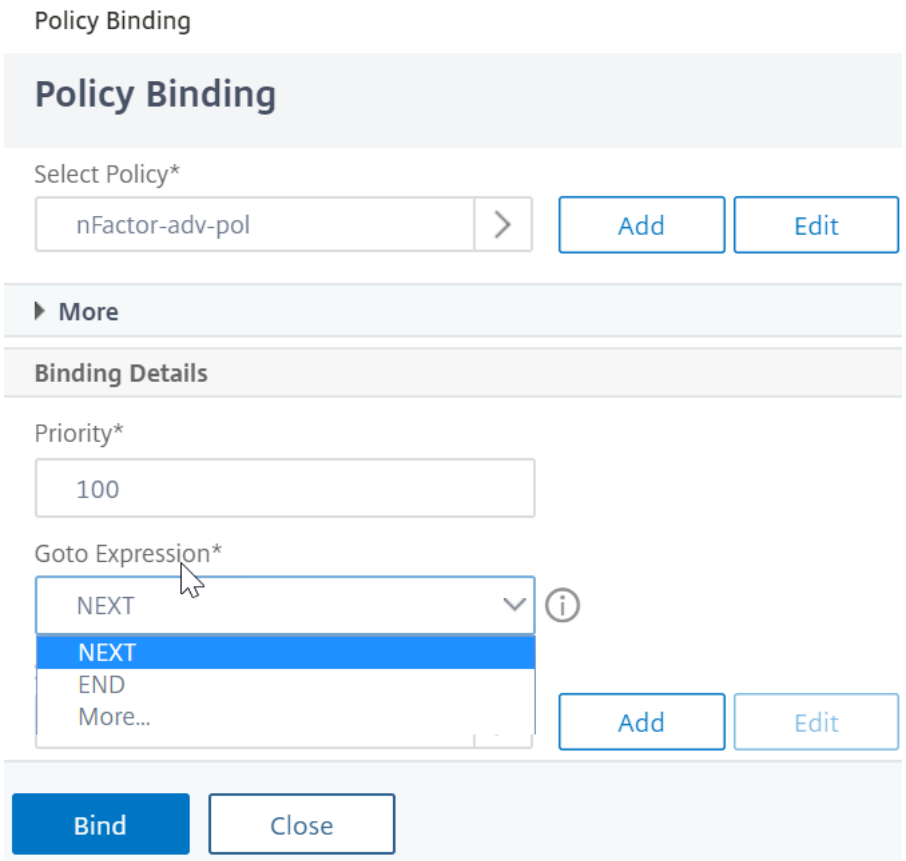


3. Click the radio button next to the **Advanced Authentication Policy**, and click **Select**.

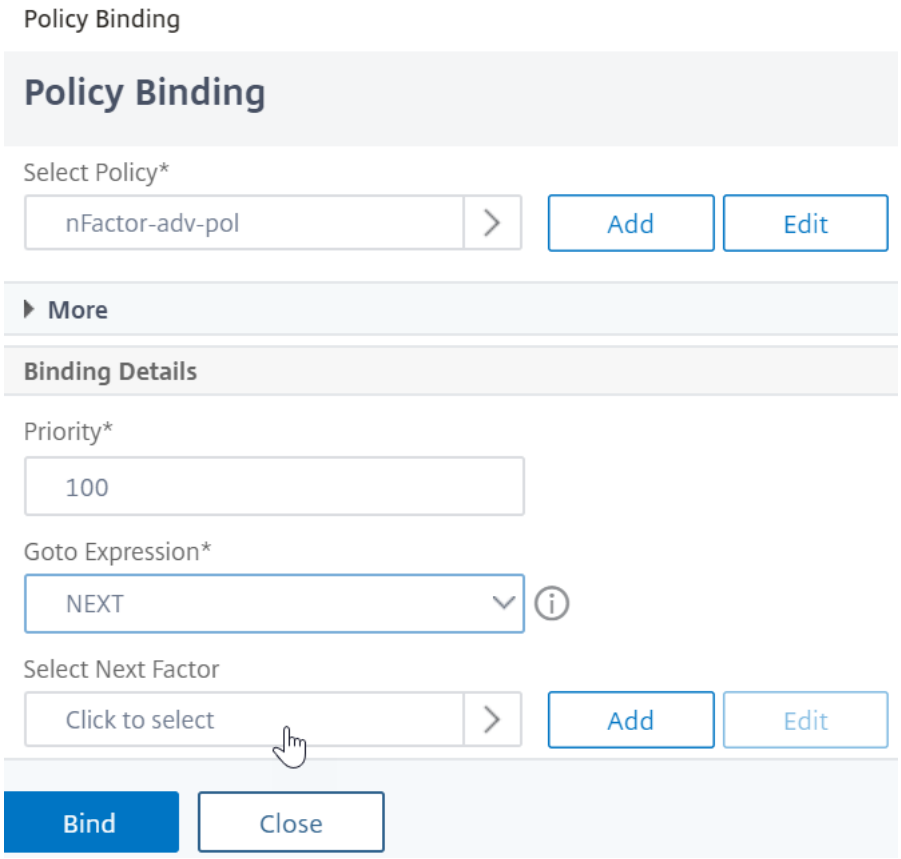


4. In the Binding Details section, the **Goto Expression** determines what happens next if this advanced authentication policy fails.

   - If **Goto Expression** is set to **NEXT**, then the next advanced authentication policy bound to this Citrix ADC AAA Virtual Server is evaluated.
   - If **Goto Expression** is set to **END**, or if there are no more advanced authentication policies bound to this Citrix ADC AAA Virtual Server, then authentication is completed and marked as failed.



5. In **Select Next Factor**, you can select can point to an authentication policy label. The next factor is evaluated only if the advanced authentication policy succeeds. Finally, click **Bind**.



Use extracted LDAP groups to select the next authentication Factor

You can use extracted LDAP groups to select the next authentication factor without actually authentication with LDAP.

1. When creating or editing an LDAP server or LDAP action, clear the **Authentication** check box.
2. In **Other Settings**, select appropriate values in **Group Attribute** and **Sub Attribute Name**.

Authenticate the policy label

When you bind an advanced authentication policy to the Citrix ADC AAA Virtual Server and have selected a next factor, the next factor is evaluated only if the advanced authentication policy. The next factor that is evaluated is an authentication policy label.

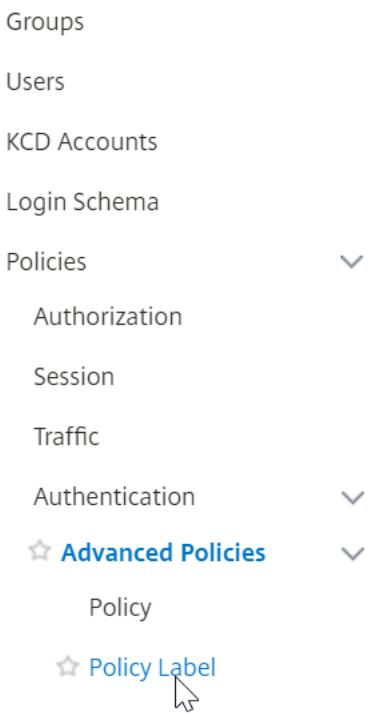
The authentication policy label specifies a collection of authentication policies for a particular factor. Each policy label corresponds to a single factor. It also specifies the login form that must be presented to the user. The authentication policy label must be bound as the next factor of an authentication policy or of another authentication policy label.

Note: Every factor does not need a login schema. Login schema profile is required only if you are binding a login schema to an Authentication Policy Label.

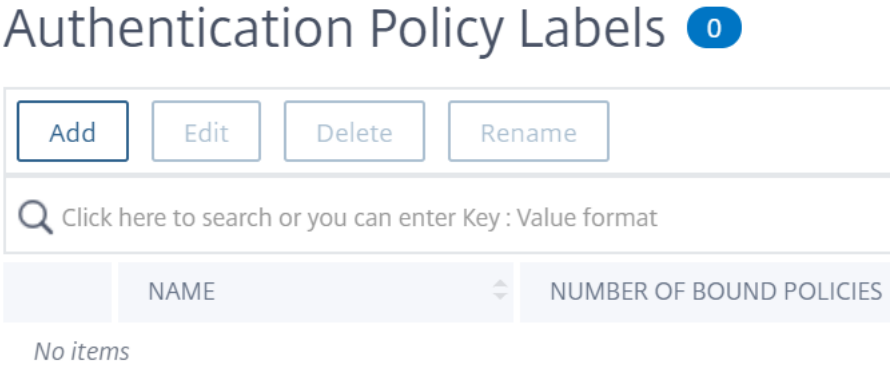
Create authentication policy label

A policy label specifies the authentication policies for a particular factor. Each policy label corresponds to a single factor. The policy label specifies the login form that must be presented to the user. The policy label must be bound as the next factor of an authentication policy or of another authentication policy label. Typically, a policy label includes authentication policies for a specific authentication mechanism. However, you can also have a policy label that has authentication policies for different authentication mechanisms.

1. Navigate to **Security > AAA – Application Traffic > Policies > Authentication > Advanced Policies > Policy Label**.



2. Click the **Add** button.

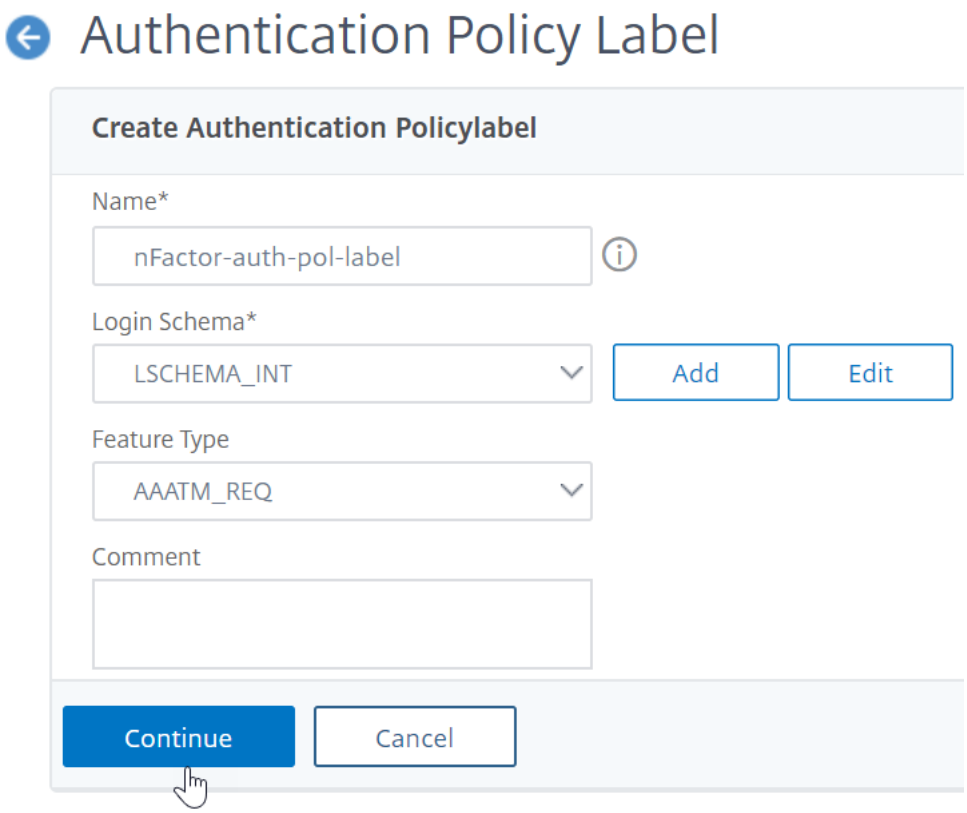


3. Complete the following fields to Create Authentication Policy Label:

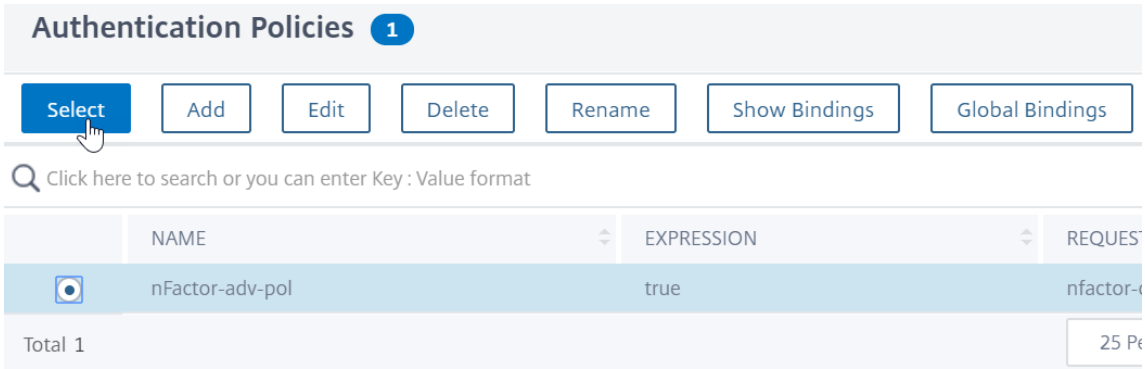
   a) Enter the **Name** for the new authentication policy label.

b) Select the **Login Schema** associated with authentication policy label. IF you do not want to display anything to the user, you can select a login schema profile that is set to noschema (LSCHEMA_INT).

c) Click **Continue**.



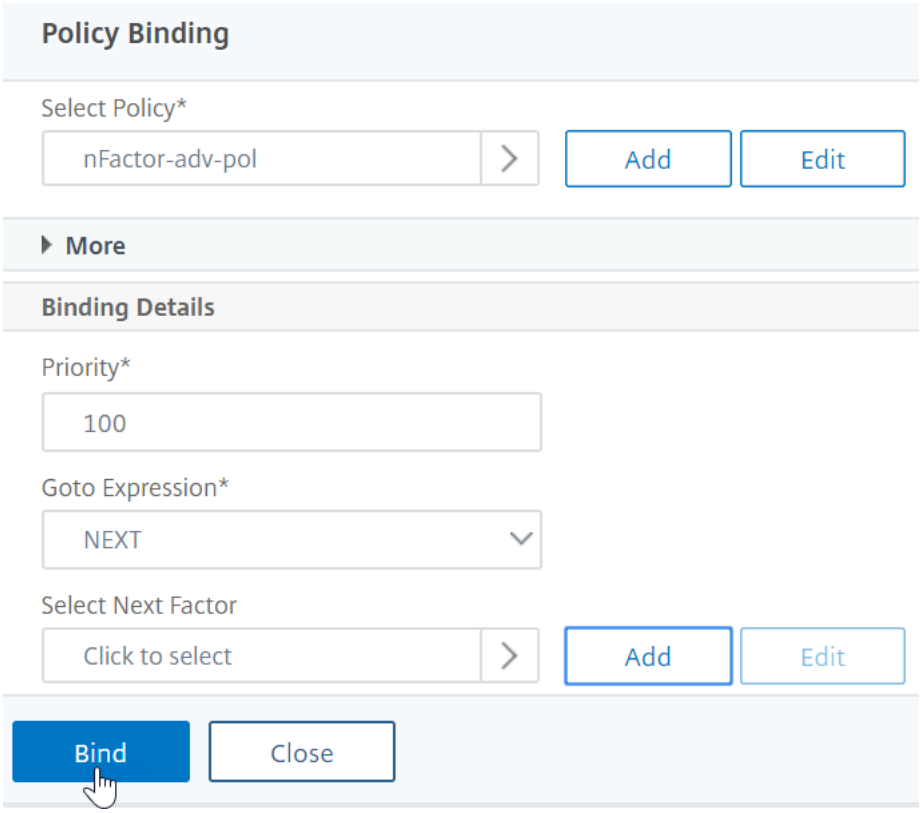
4. In **Policy Binding** section, click where it says **Click to select**.
5. Select the authentication policy that evaluates this factor.



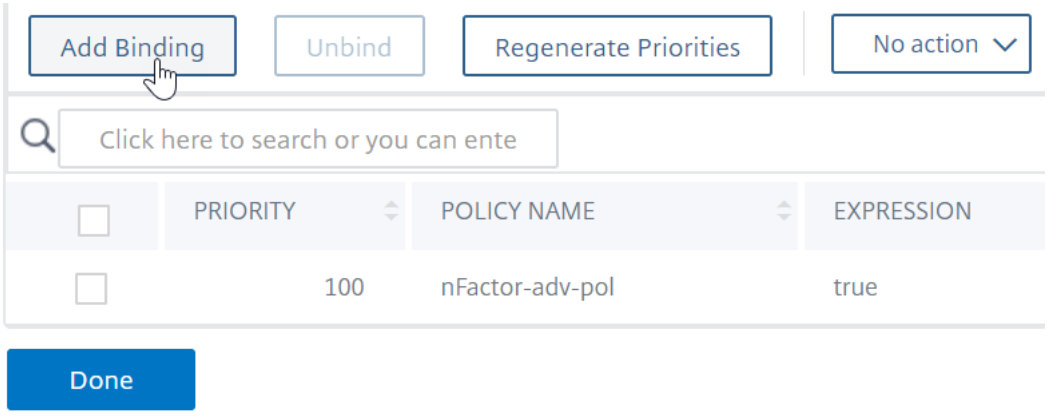
6. Complete the following fields:

   a) Enter the **Priority** of the policy binding.

   b) In **Goto Expression** select **NEXT** if you want to bind more advanced authentication policies to this factor or select **END**.



7. In **Select Next Factor**, if you want to add another factor, click to select and bind the next authentication policy label (next factor).
   If you do not select the next factor, and if this advanced authentication policy succeeds, then authentication is successful and complete.
8. Click **Bind**.
9. You can click **Add Binding** to add more advanced authentication policies to this policy label (factor). Click **Done** upon completion.



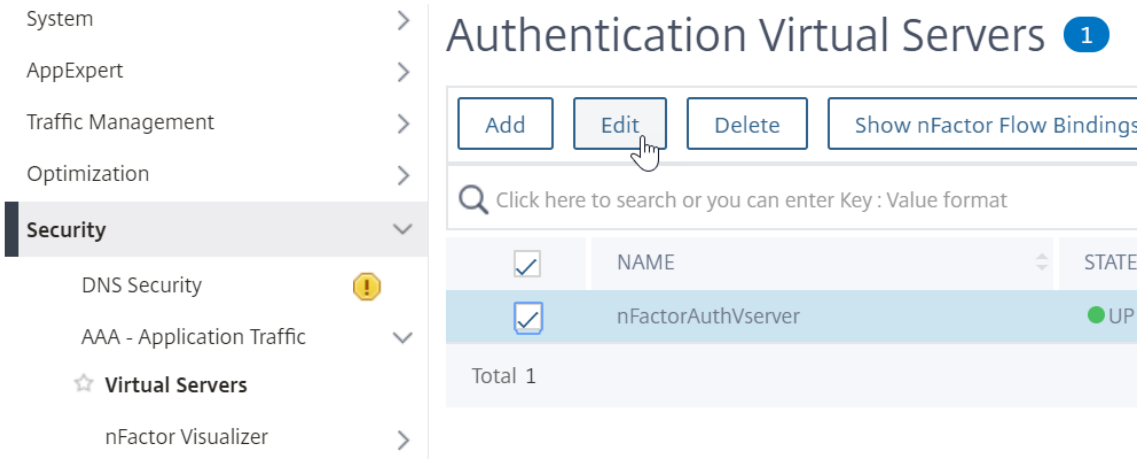
Bind authentication policy label

After you create the policy label, you bind it to an existing advanced authentication policy binding to chain factors together.

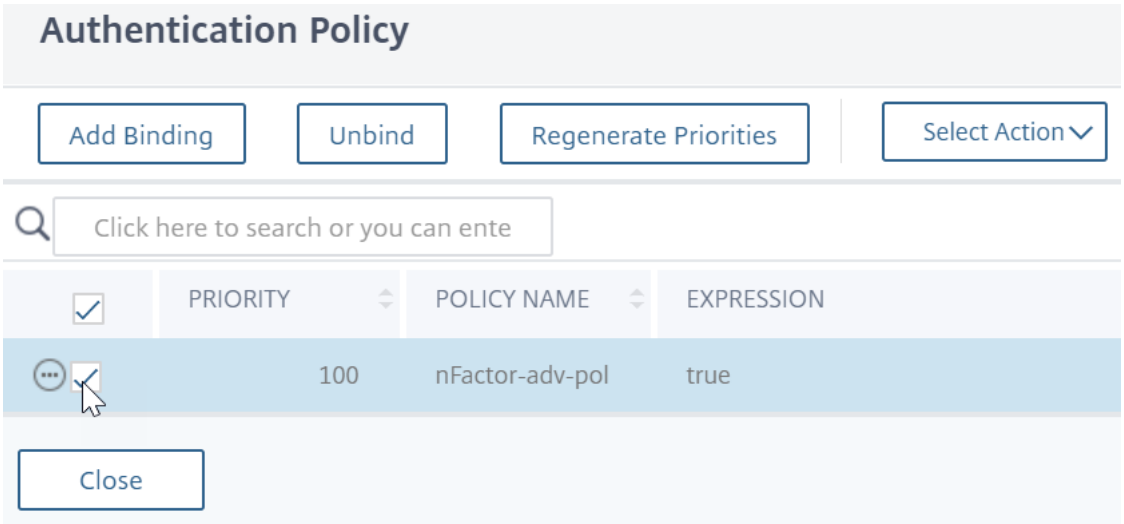
You can select the next factor when editing an existing Citrix ADC AAA virtual server that has an advanced authentication policy bound or when editing a different policy label to include next factor.

To edit an existing Citrix ADC AAA virtual server that has an advanced authentication policy already bound to it

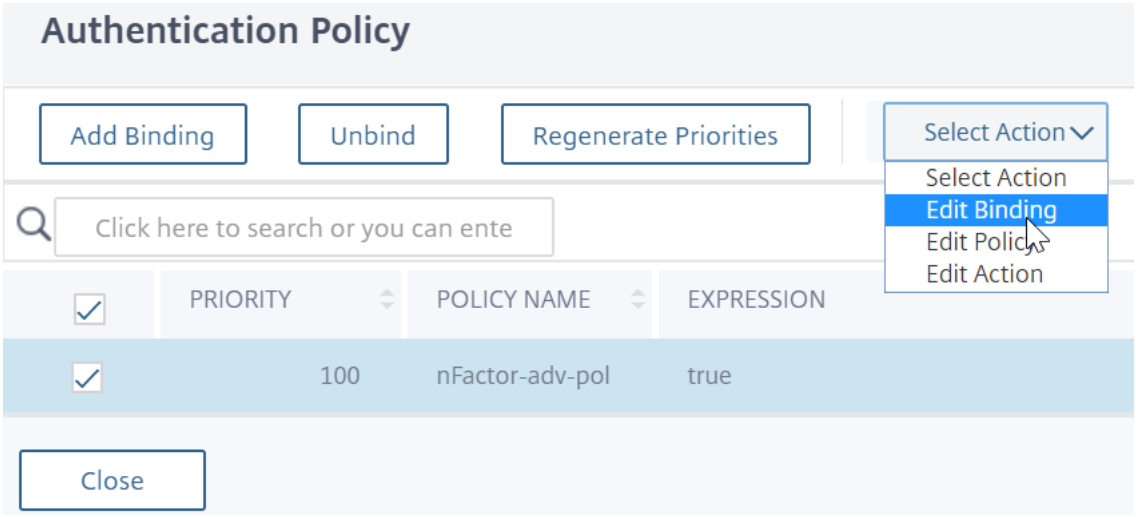
1. Navigate to **Security > AAA – Application Traffic > Virtual Servers.** Select the virtual server and click **Edit**.



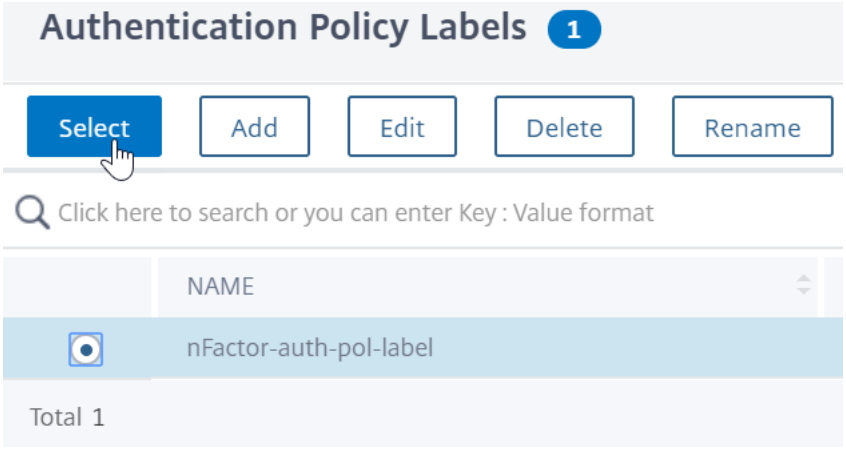
2. On the left, in the **Advanced Authentication Policies** section, click an existing authentication policy binding.



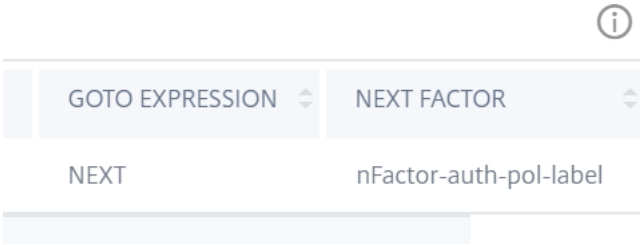
3. In **Select Action**, click **Edit Binding**.



4. In **Select Next Factor**, click, and select an existing authentication policy label (next factor).

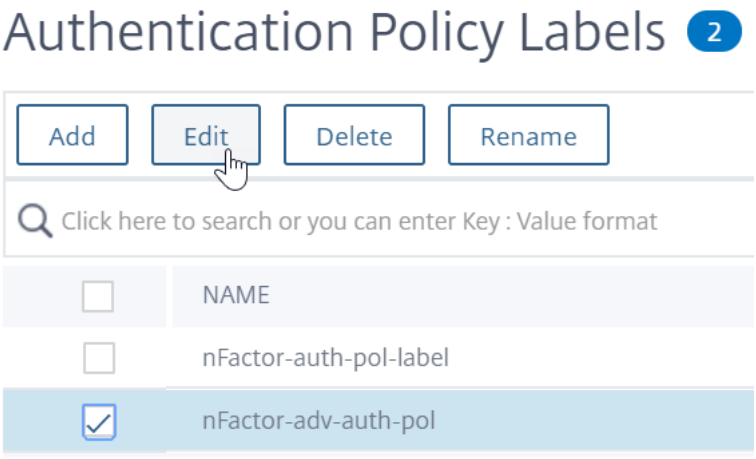


5. Click **Bind**. You can see the next factor on the extreme right.

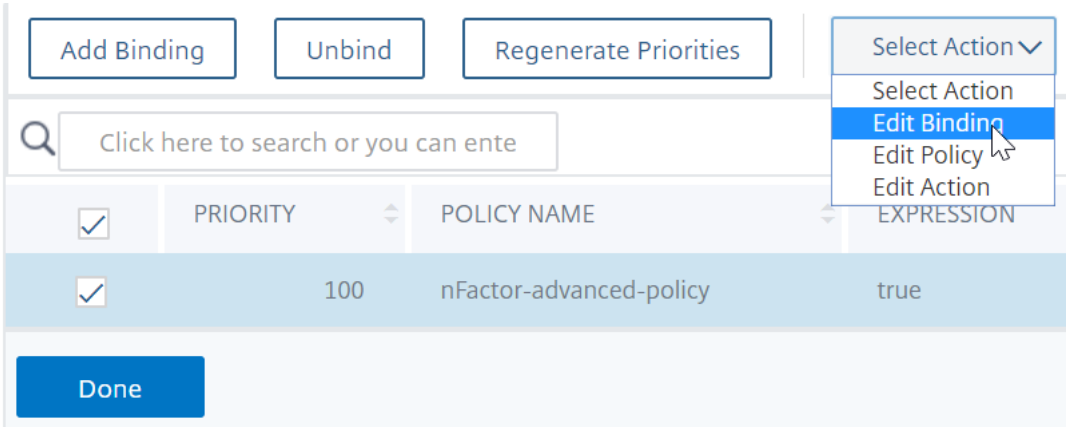


To add a policy label next factor to a different policy label

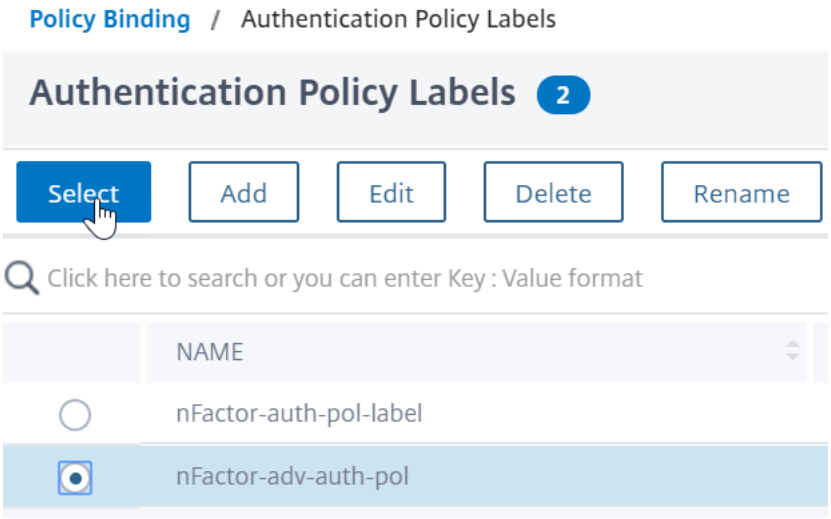
1. Navigate to **Security > AAA – Application Traffic > Policies > Authentication > Advanced Policies > PolicyLabel**. Select a different policy label and click **Edit.**



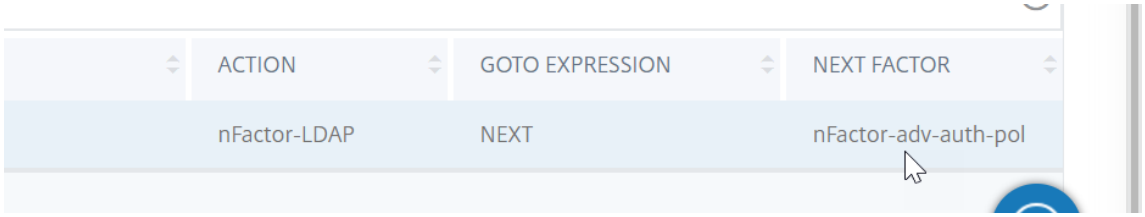
2. In **Select Action**, click **Edit Binding**.



3. In **Binding Details > Select Next Factor**, click to select the next factor.
4. Choose the policy label for the next factor and click the **Select** button.



5. Click **Bind.** You can see the next factor on the right.

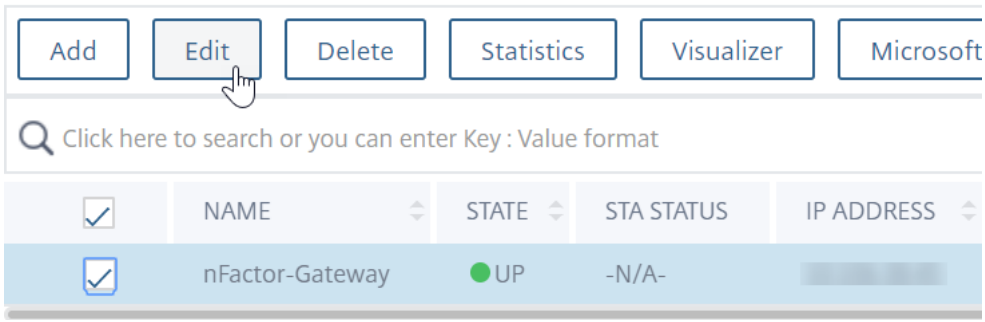


nFactor for Citrix Gateway

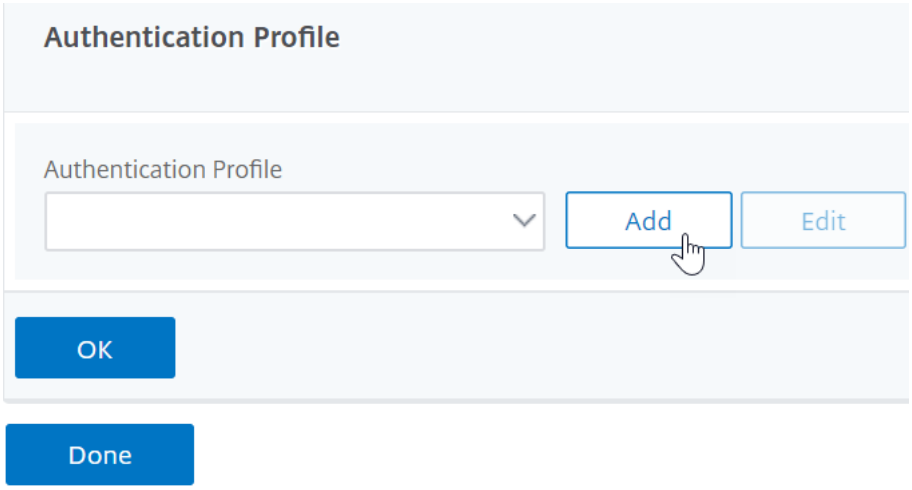
To enable nFactor on Citrix Gateway, an authentication profile must be linked to a Citrix ADC AAA virtual server.

Create authentication profile to link a Citrix ADC AAA virtual server with Citrix Gateway virtual server

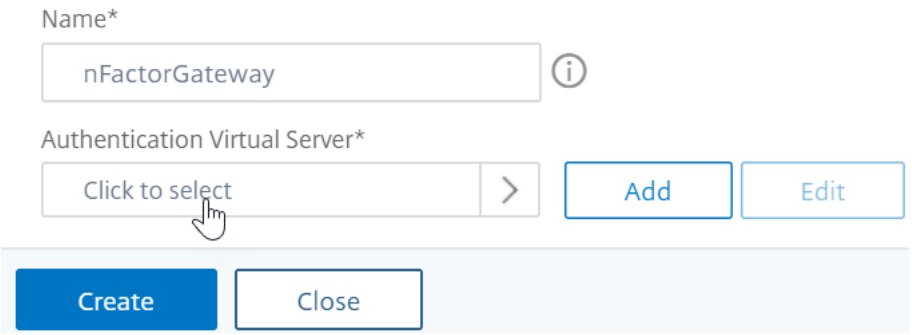
1. Navigate to **Citrix Gateway > Virtual Servers** and select and existing gateway virtual server to edit.



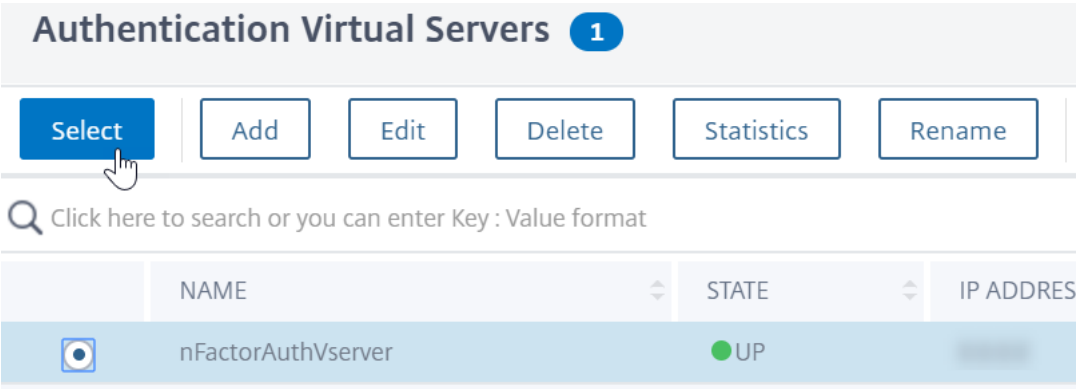
2. In **Advanced Settings**, click **Authentication Profile**.
3. Click **Add** under **Authentication Profile**



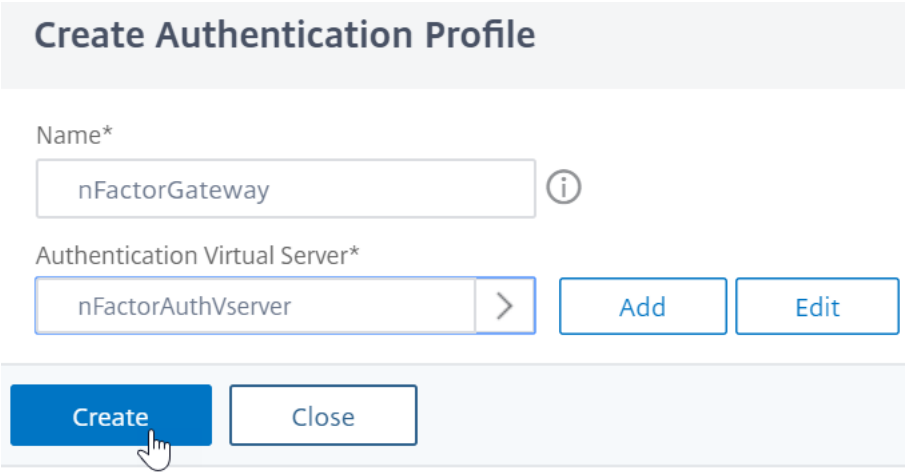
4. Enter the name for the authentication profile and click where it says **Click to select**.



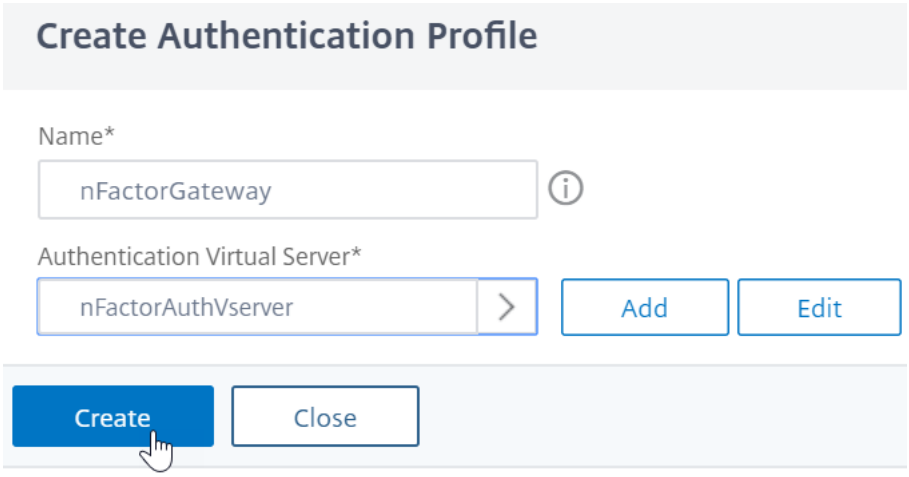
5. In **Authentication Virtual Server**, select an existing server that has login schema, advanced authentication policy, and authentication policy labels configured. You can also create an authentication virtual server. The Citrix ADC AAA virtual server does not need an IP address. Click **Select**.



6. Click **Create**.



7. Click **OK** to close the Authentication Profile section.



Note: If you have configured one of the factors as client certificates, then must configure SSL parameters and CA certificate.

After you have completed linking the authentication profile to a AAA virtual server, and when you browse to your Citrix Gateway, you can view the nFactor authentication screens.

Configure SSL parameters and CA certificate

If one of the authentication factors is a certificate, then you must perform some SSL configuration on the Citrix Gateway virtual server.

1. Navigate to **Traffic Management > SSL > Certificates > CA Certificates**, and install the root certificate for the issuer of the client certificates. Certificate Authority certificates do not need key files.

   If default SSL Profiles are enabled, then you should have already created an SSL Profile that has Client Authentication enabled.

2. Navigate to **Citrix Gateway > Virtual Servers**, and edit an existing Citrix Gateway virtual server that is enabled for nFactor.
   - If default SSL Profiles are enabled, click the edit icon.
   - In the SSL Profile list, select the SSL Profile that has Client Authentication enabled and set to OPTIONAL.
   - If default SSL Profiles are not enabled, click the edit icon.
   - Check the Client Authentication check box.
   - Ensure Client Certificate is set to Optional
3. Click OK.
4. In Certificates section, click **No CA Certificate.**

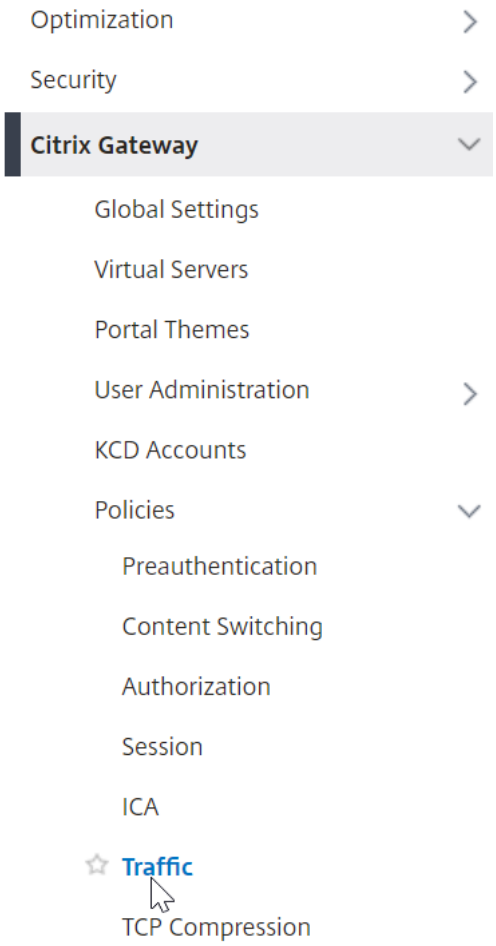
5. In Select CA Certificate, click to select and select the root certificate for the issuer of the client certificates.
6. Click Bind.

Note: You might have to also bind any Intermediate CA Certificates that issued the client certificates.

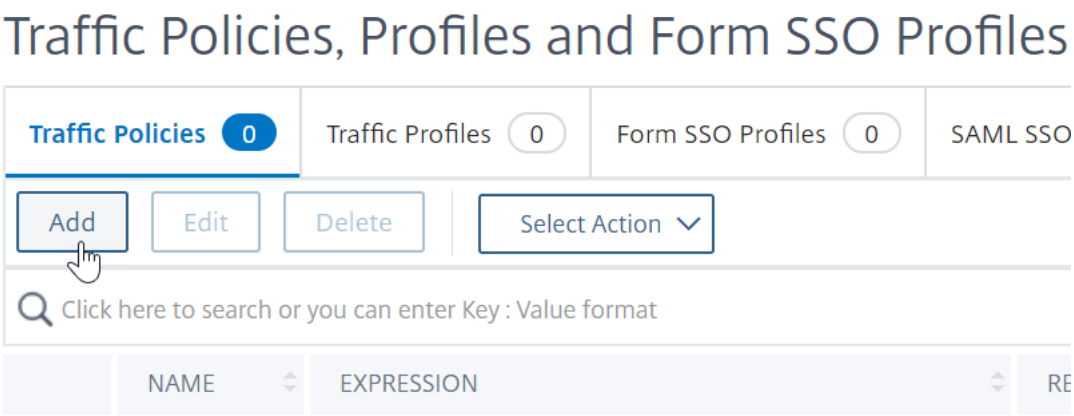
Configure Citrix Gateway traffic policy for nFactor single sign-on to StoreFront

For single sign-on to StoreFront, nFactor defaults to using the last entered password. If LDAP is not the last entered password, then you must create a traffic policy/profile to override the default nFactor behavior.

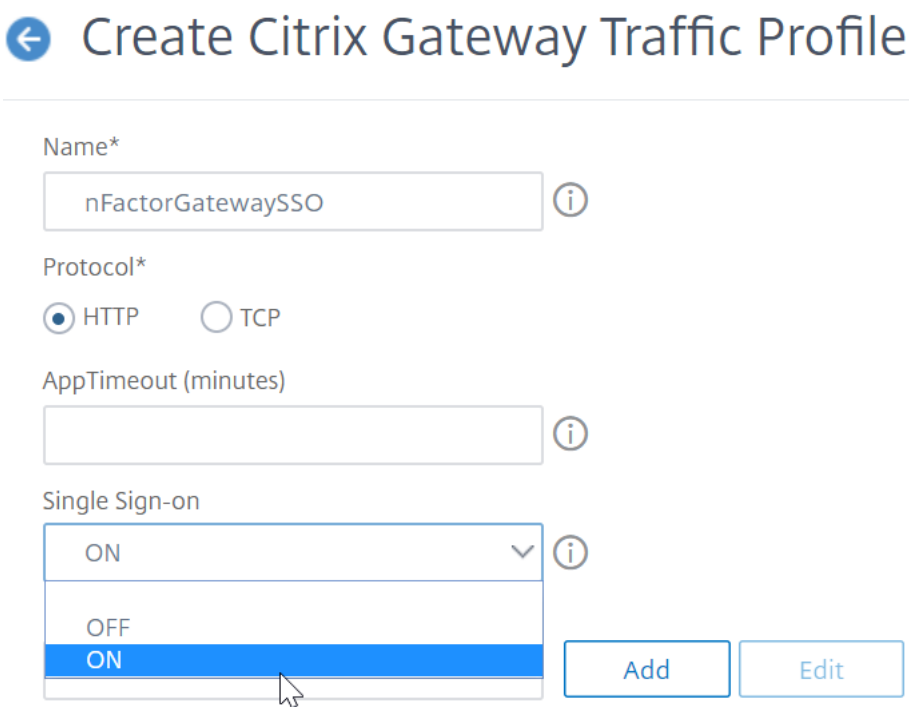
1. Navigate to **Citrix Gateway > Policies > Traffic**.



2. In **Traffic Profiles** tab, click **Add**.

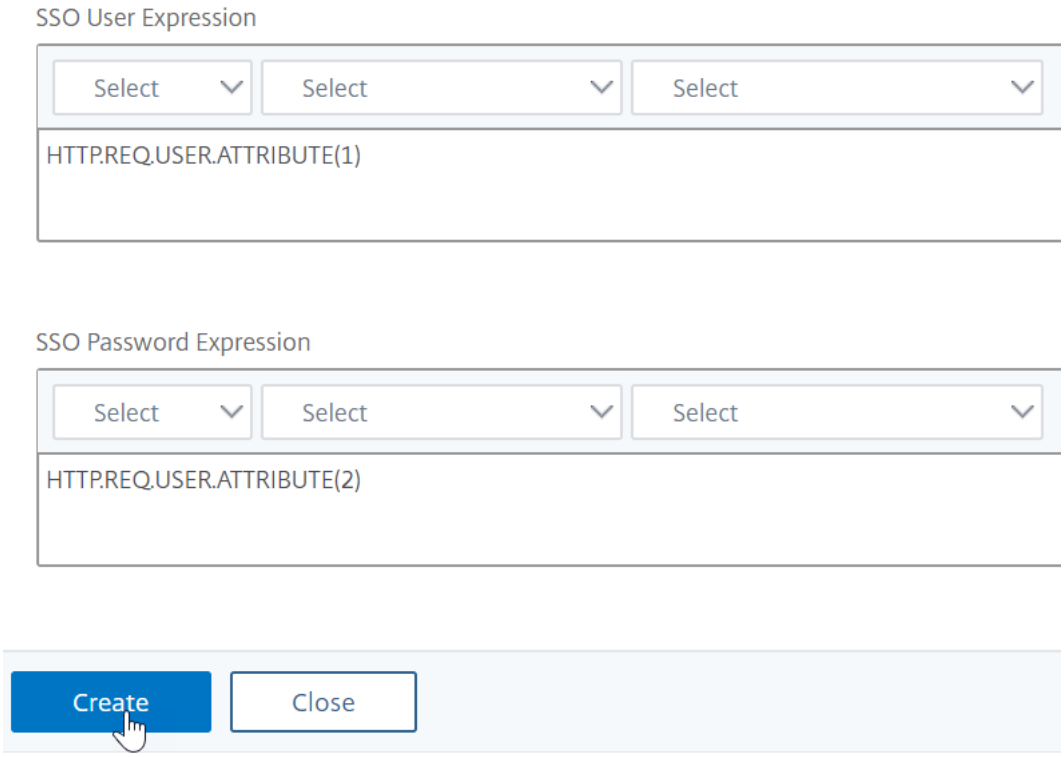


3. Enter a name for the traffic profile. Select the **HTTP** protocol.
   In **Single Sign-on**, select **ON**.



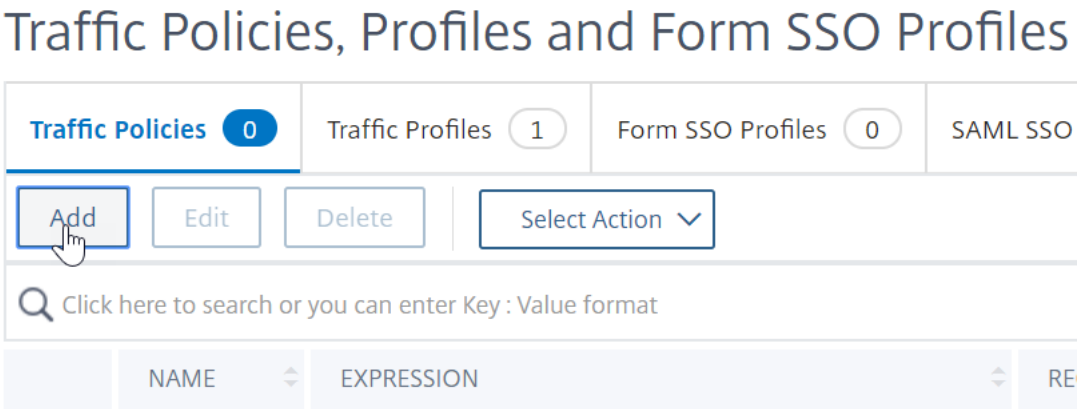
4. In the **SSO Expression**, enter a AAA.USER.ATTRIBUTE(#) expression that matches the indexes specified in the login schema and click **Create**.

> **Note**
> AAA.USER expression is now implemented to replace the deprecated HTTP.REQ.USER expressions.



5. Click **Traffic Policies** tab, and click **Add**.

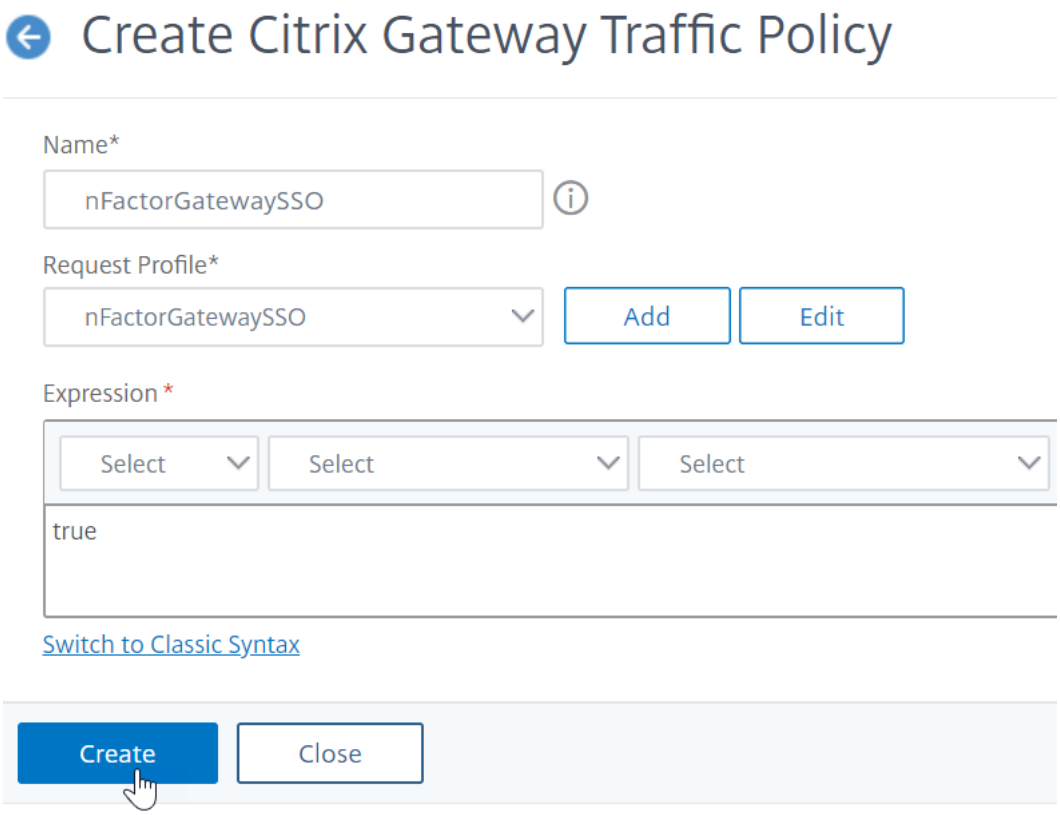
   Enter a name for the policy.
   Select the traffic profile created in the previous step.
   In **Expression**, enter an advanced expression, for example true.
   Click **Create**.



6. Navigate to **Citrix Gateway > Citrix Gateway Virtual Server**.

   - Select and existing virtual server and click **Edit**.
   - In the **Policies** section, click the **+** sign.
   - In **Choose Policy**, select **Traffic**.
   - In **Choose Type**, select **Request**.

- Select the traffic policy that you have created and then click **Bind**.



Sample snippet on nFactor configuration by using the Citrix ADC CLI

To understand the step-wise configurations for nFactor authentication, let us consider a two-factor authentication deployment where the first factor is LDAP authentication and the second factor is RADIUS authentication.

This sample deployment requires the user to log in to both factors using a single login form. Therefore, we define a single login form that accepts two passwords. The first password is used for LDAP authentication and the other for RADIUS authentication.
Here are the configurations that are performed:

1. Configure the load balancing virtual server for authentication

   add lb vserver lbvs89 HTTP 1.136.19.55 80 -AuthenticationHost auth56.aaatm.com -Authentication ON

2. Configure the authentication virtual server.

   add authentication vserver auth56 SSL 10.106.30.223 443 -AuthenticationDomain aaatm.com

3. Configure the login schema for the login form and bind it to a login schema policy.

add authentication loginSchema login1 -authenticationSchema login-2passwd.xml -userCredentialIndex 1 -passwordCredentialIndex 2

> **Note**
>
> You might need to use the username and one of the passwords entered in the login schema for Single Sign-on (SSO) to a backend service, for example StoreFront. You can reference these index values in the traffic action by using the expression AAA.USER.ATTRIBUTE(#). The values can be between 1 and 16.
>
> Alternatively, you can use the credentials entered in the login schema as your Single Sign-On credentials by using the following command.
>
> **add authentication loginSchema** login1 -authenticationSchema login-2passwd.xml -SSOCredentials YES

add authentication loginSchemaPolicy login1 -rule true -action login1

4. Configure a login schema for the pass-through and bind it to a policy label

   add authentication loginSchema login2 -authenticationSchema noschema

   add authentication policylabel label1 -loginSchema login2

5. Configure the LDAP and RADIUS policies.

   add authentication ldapAction ldapAct1 -serverIP 10.17.103.28 -ldapBase “dc=aaatm, dc=com” -ldapBindDn administrator@aaatm.com -ldapBindDnPassword 81qw1b99ui971mn1289op1abc125 -encrypted -encryptmethod ENCMTHD_3 -ldapLoginName samAccountName -groupAttrName memberOf -subAttributeName CN

   add authentication Policy ldap -rule true -action ldapAct1

   add authentication radiusAction radius -serverIP 10.101.14.3 -radKey n231d9a8cao8671or4a9ace940d8623 -encrypted -encryptmethod ENCMTHD_3 -radNASip ENABLED -radNASid NS28.50 -radAttributeType 11 -ipAttributeType 8

   add authentication Policy radius -rule true -action radius

6. Bind the login schema policy to the authentication virtual server

   bind authentication vserver auth56 -policy login1 -priority 1 -gotoPriorityExpression END

7. Bind the LDAP policy (first factor) to the authentication virtual server.

   bind authentication vserver auth56 -policy ldap -priority 1 -nextFactor label1 -gotoPriorityExpression next

8. Bind the RADIUS policy (second factor) to the authentication policy label.

   bind authentication policylabel label1 -policyName radius -priority 2 -gotoPriorityExpression end

nFactor Visualizer for simplified configuration

September 14, 2021

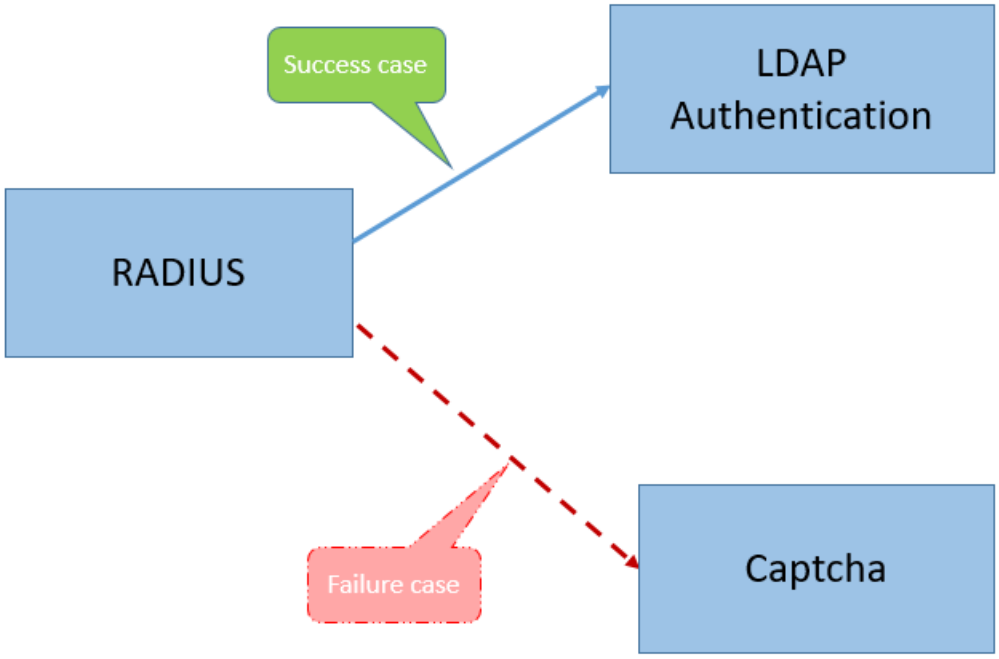
Starting from Citrix ADC release 13.0 build 36.27, nFactor configuration through the GUI is simplified by using the nFactor Visualizer. The nFactor Visualizer helps admins add multiple factors without losing track of each factor. The group of factors that are built in the flow are displayed in one place. Admins can add authentication success and failure paths separately. After creating the flow, admins have to bind the nFactor flow to an authentication virtual server.

> **Note**
>
> - All factors created by an admin in the nFactor flow are retained for any future use.
> - From Citrix ADC feature release 13.0 build 64.35 and above, using the nFactor visualizer, you can start the nFactor flow with a decision block.

Previously, nFactor configuration was cumbersome wherein the admins had to visit many pages to configure it. If a change was required, the admins had to revisit the configured sections each time. Also, there was no option to view the complete configuration in one place.

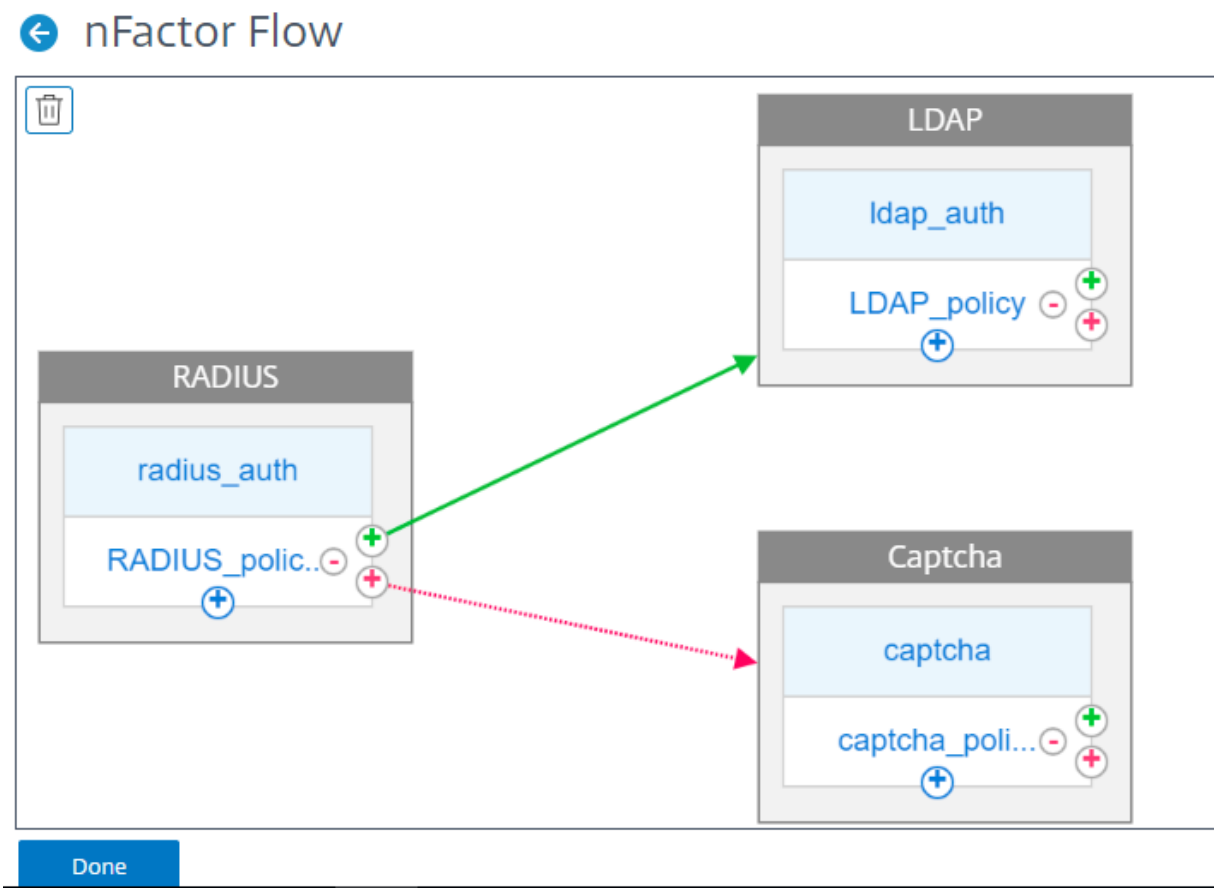
Use Case 1: RADIUS followed by LDAP authentication, else fallback to Captcha through nFactor Visualizer

Achieve RADIUS authentication as the first-level authentication followed by LDAP authentication. In case RADIUS fails, authentication must fall back to Captcha.



To achieve this use case, you can use the nFactor Visualizer. The Visualizer provides various controls that can be used to add this flow and the related items.

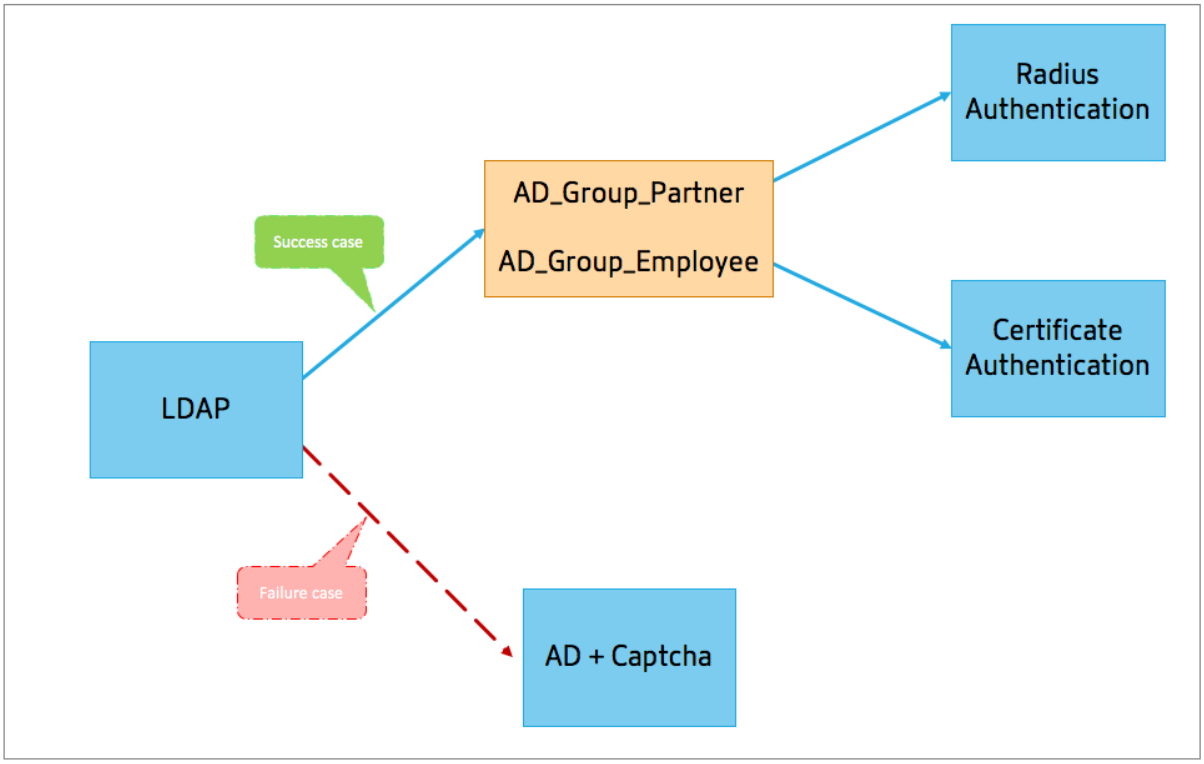
The following figure displays the nFactor flow created for the previous mentioned use case by using the visualizer.



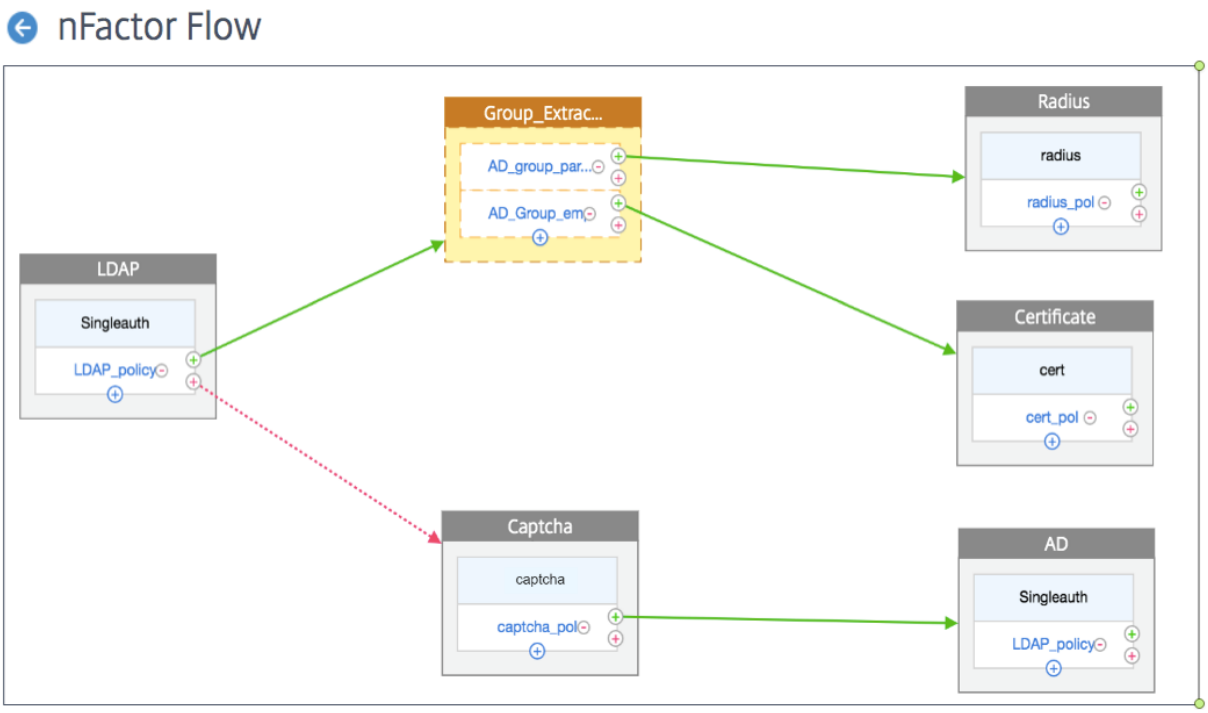
- **RADIUS.** You configure RADIUS as the first factor. You add a login schema and a policy. In this example, radius_auth and RADIUS_policy are the login schema and policy that is added. For the RADIUS_Policy, you can add another factor for the success case. In this example, an LDAP factor block is added for the success case. For the failure case, you can add a Captcha factor.
- **LDAP.** You configure LDAP authentication as the second factor. You add a login schema and a policy. In this example, ldap_auth and LDAP_policy are the login schema and policy that is added.
- **Captcha.** For the RADIUS policy failure case, you create a Captcha factor. In this example, captcha and captcha_policy are the login schema and policy that is added.

Use Case 2: LDAP followed by RADIUS/Certificate authentication with Captcha based on LDAP Group Membership through nFactor Visualizer

Achieve RADIUS authentication as the first-level authentication followed by LDAP authentication. In case RADIUS fails, authentication must fall back to Captcha.



The following figure displays the nFactor flow created for the previous mentioned use case by using the visualizer.



- **LDAP.** You configure LDAP as the first factor. You add a login schema and a policy. In this example SingleAuth and LDAP_Policy are the login schema and policy that is added. For the

LDAP_Policy, you can add another factor for the success case. In this example, a decision block is added for the success case. For the failure case, you can add Captcha followed by AD factor.

- **Group Extraction LDAP.** Is the decision block added for the LDAP success case. The decision block is used as a branch out factor to branch out the users based on the policy rules. Visualizer allows configuring only a NO_AUTHN policy for the decision block.

  In this example, Group_Extraction_LDAP is the decision block. You add two policies (`AD_Group_Partner and AD_Group_Employee`) to this decision block. As explained in the use cases, all requests routed through AD_Group_Partner policy use RADIUS authentication. Therefore, you connect the success case of this policy to the next factor that is RADIUS factor. Similarly, all requests routed through AD_Group_Employee policy use certification authentication. Therefore, you connect the success case of this policy to the next factor that is the certification authentication factor.

  - **RADIUS.** For the AD_Group_Partner policy success case, you create the RADIUS authentication factor.
  - **Certificate.** For the AD_Group_Employee policy success case, you create the certificate authentication factor.

- **Captcha.** For the LDAP policy failure case, you create two next factors, Captcha and AD factor.

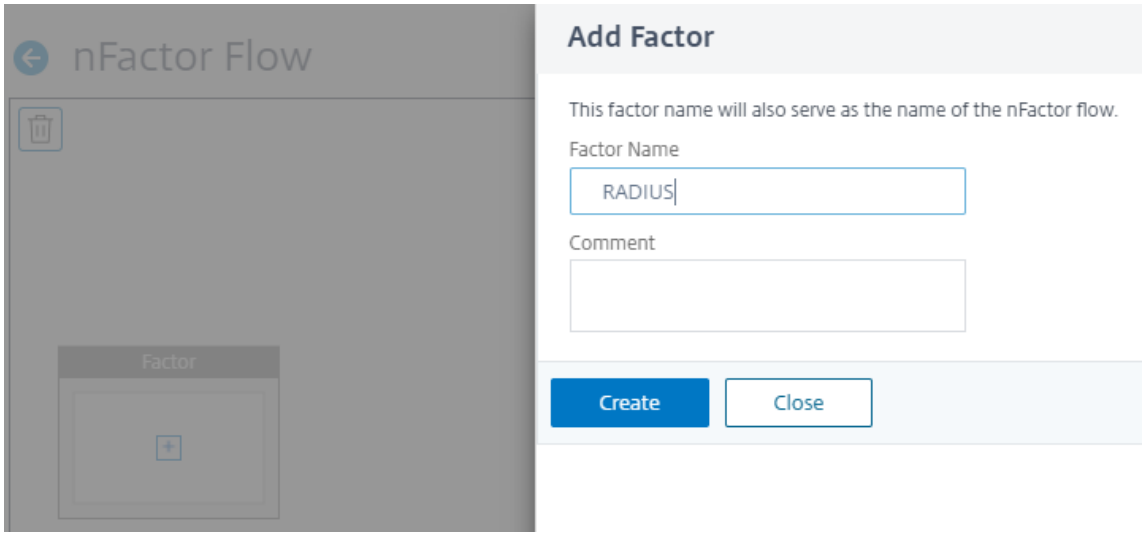
> **Note**
>
> - If you have a use case to branch out as a first thing, then you can either create two flows and bind separately or create one flow with the first one as branch out, and bind it to the virtual server.
> - If you have multiple blocks, and to view the entire flow in the nFactor Flow screen, click the visualizer and drag the flow to the extreme left.
> - Citrix recommends modifying the nFactor flows using the nFactor Flows page only.

To configure nFactor by using the nFactor Visualizer

> **Note**
>
> The following nFactor configuration is a simple example that helps you accomplish the Use Case 1 scenario configurations.

1. Navigate to **Security > AAA – Application Traffic > nFactor Visualizer > nFactor Flows**.
2. Click **Add**.
3. On the **nFactor Flows** page, click **+** to add a first factor for the flow. The first factor also serves as an identifier for this nFactor flow.

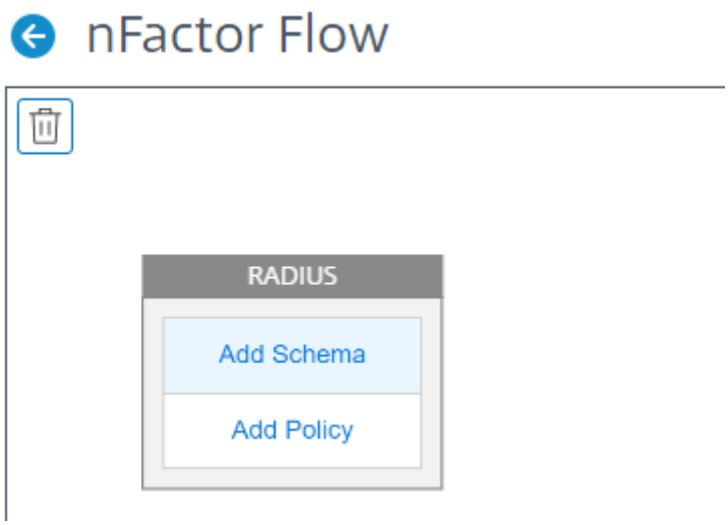
4. Enter the factor name and click **Create**.



The factor name appears on the factor block in the nFactor Flow page.

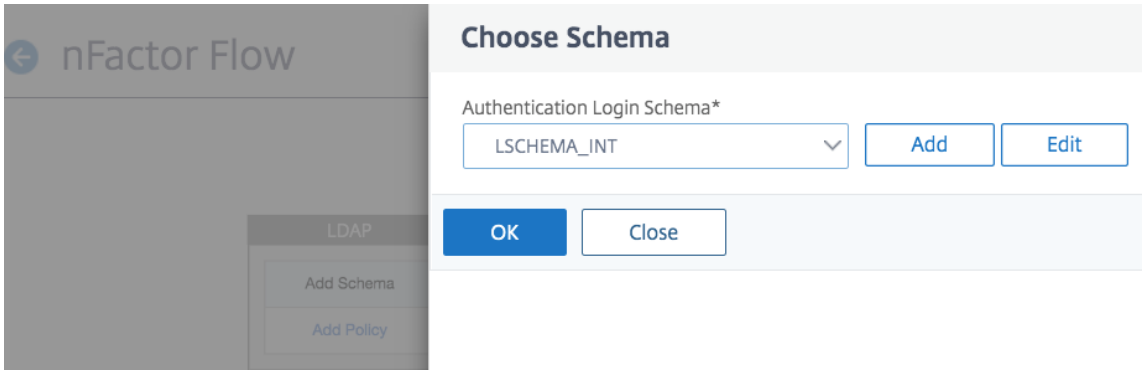
> **Note**
>
> Citrix recommends that you must not use policy label names such as, `__root` and `__<flow_name>` as suffix and `_db_` as prefix. It is used as the factor names that are created in the nFactor flow.

5. Once the RADIUS factor is created, the Add Schema and Add Policy must be created.

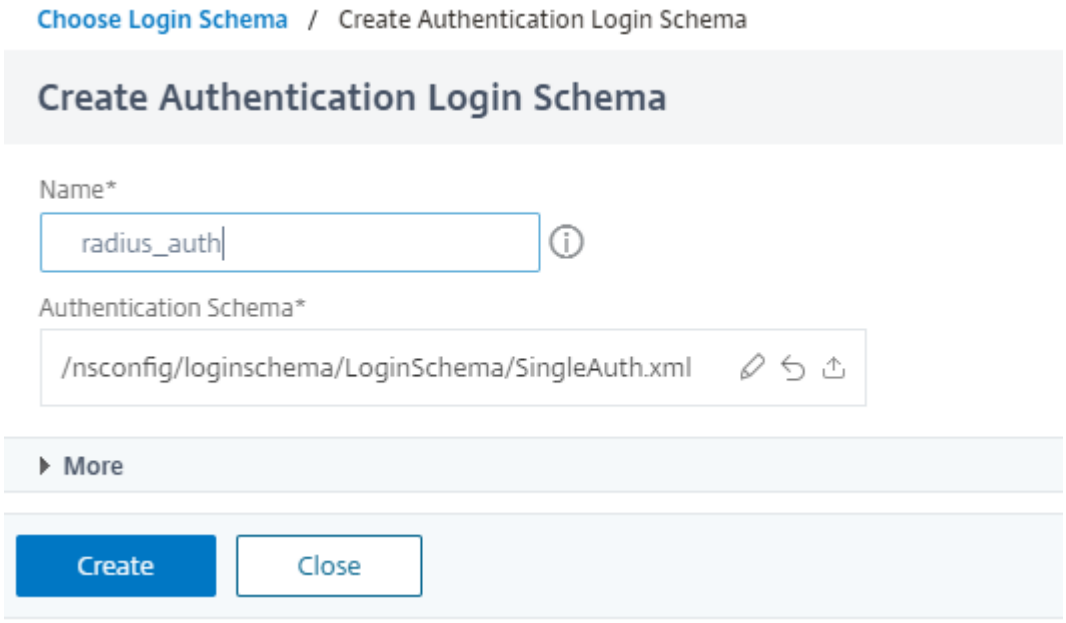


> **Note**
>
> For more information, see nFactor concepts, entities, and terminology

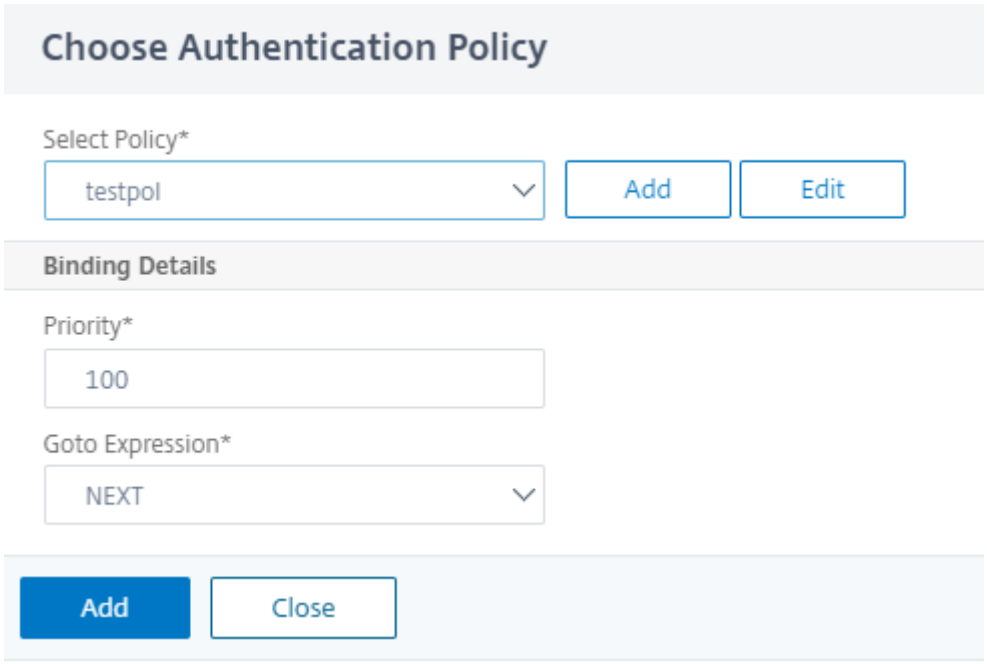
6. Click **Add Schema**. You can either add a new login schema or select an existing login schema from the **Authentication Login Schema** list.



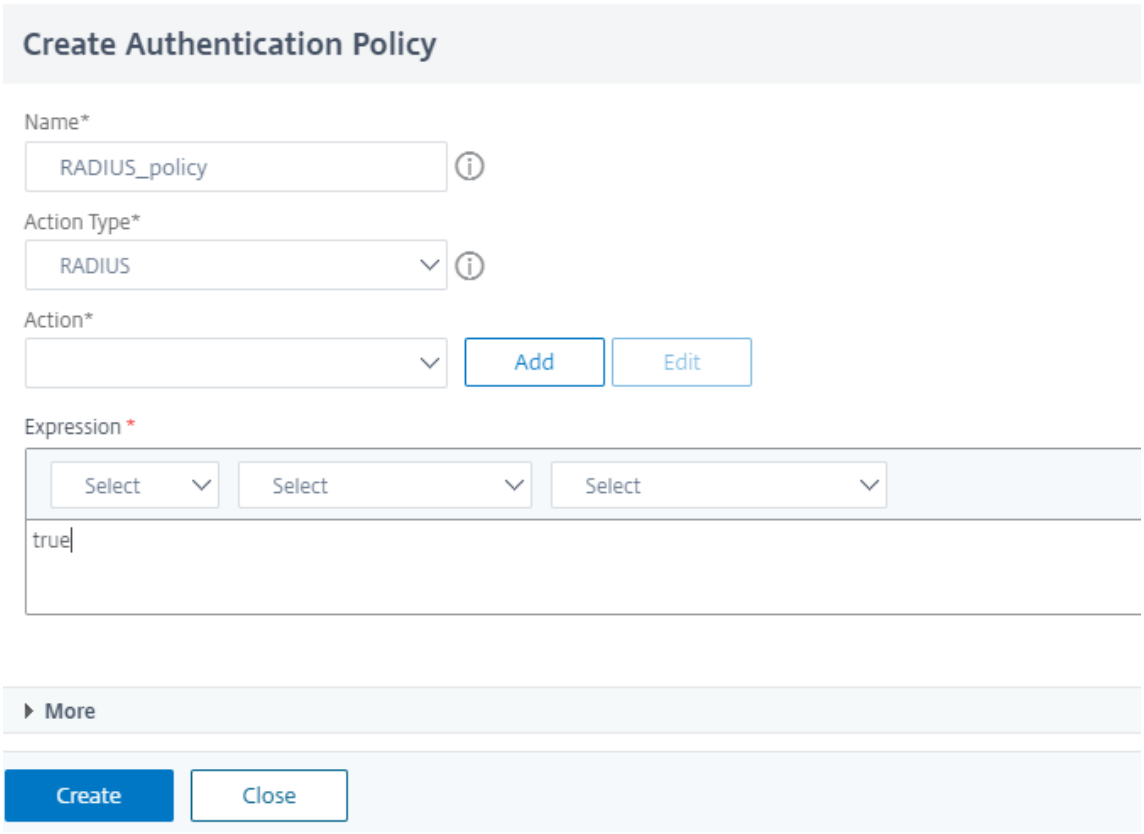
7. To create a login schema, click **Add** and in the **Create Authentication Login Schema** page, enter the name for the schema. Click **Edit** (pencil icon) to select the **Login Schema Files** from the list.



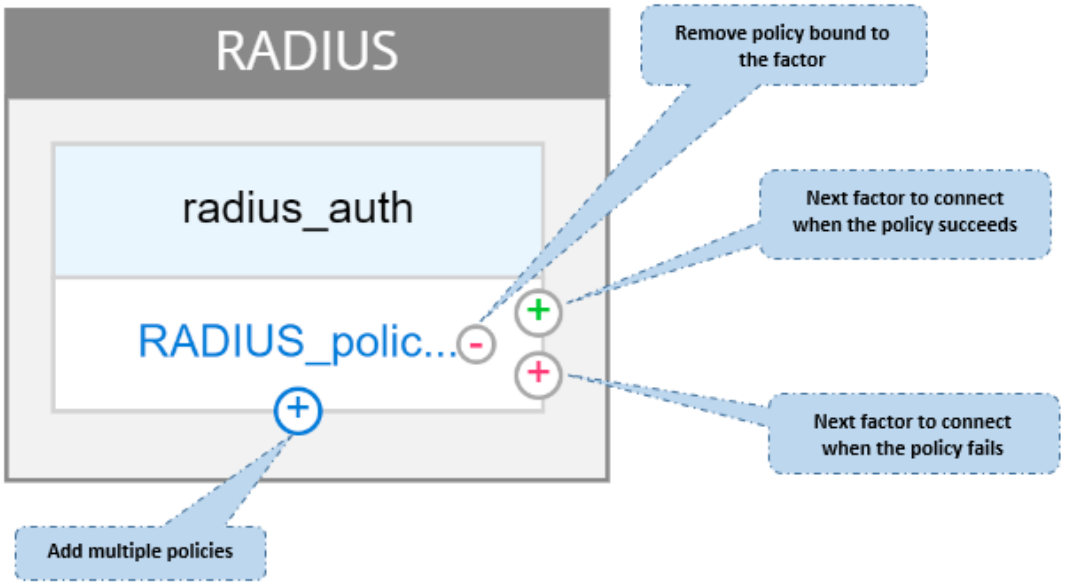
8. Click **Add Policy**. You can create an authentication policy or select an existing authentication policy.



9. To create a new policy, click **Add** and in the **Create Authentication Policy** page, enter the name for the policy and click **Create**.



10. After you add a login schema and policy to the factor, the login schema and policy appear on the factor in the Visualizer as displayed in the following figure. For any given factor, you can add multiple policies and define the next factor for the success and failure of each policy. You can also remove the policies that are part of the factor.



11. After you create the flow, you can then bind the nFactor flow to an authentication virtual server.

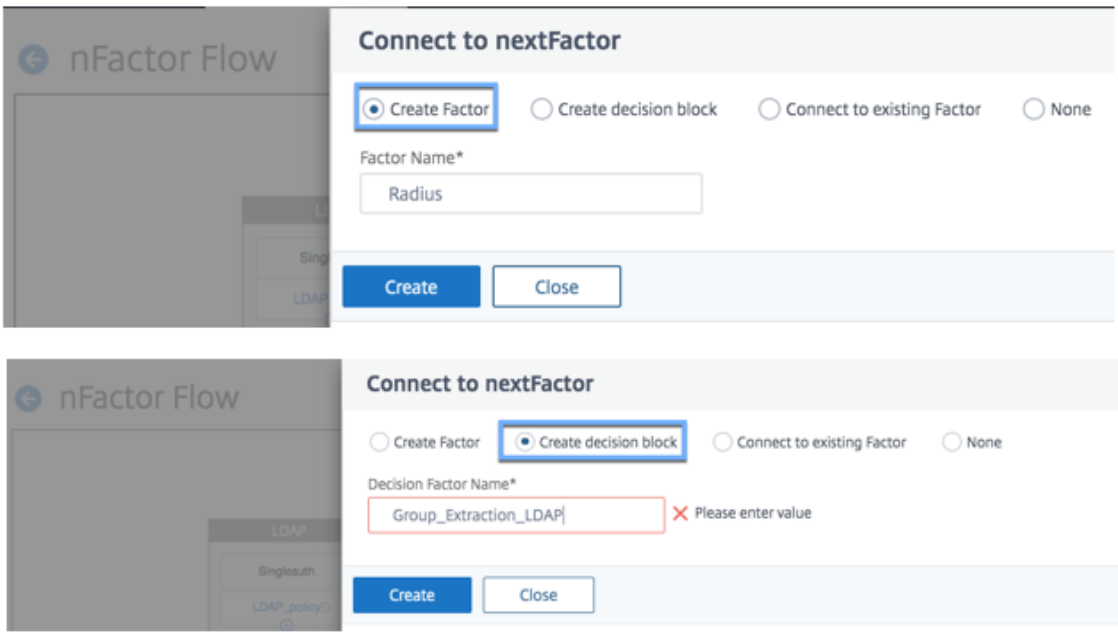
Adding the next factor

To add the next factor, you can select one of the following options as per your requirement:

- **Create Factor**. Create a factor. Each factor that is created in a flow is exclusive to that flow.
- **Create a decision block.** Create a decision block to serve as a branch-out factor. You cannot add a login schema to the decision block. Visualizer allows configuring only a NO_AUTHN policy for the decision block.

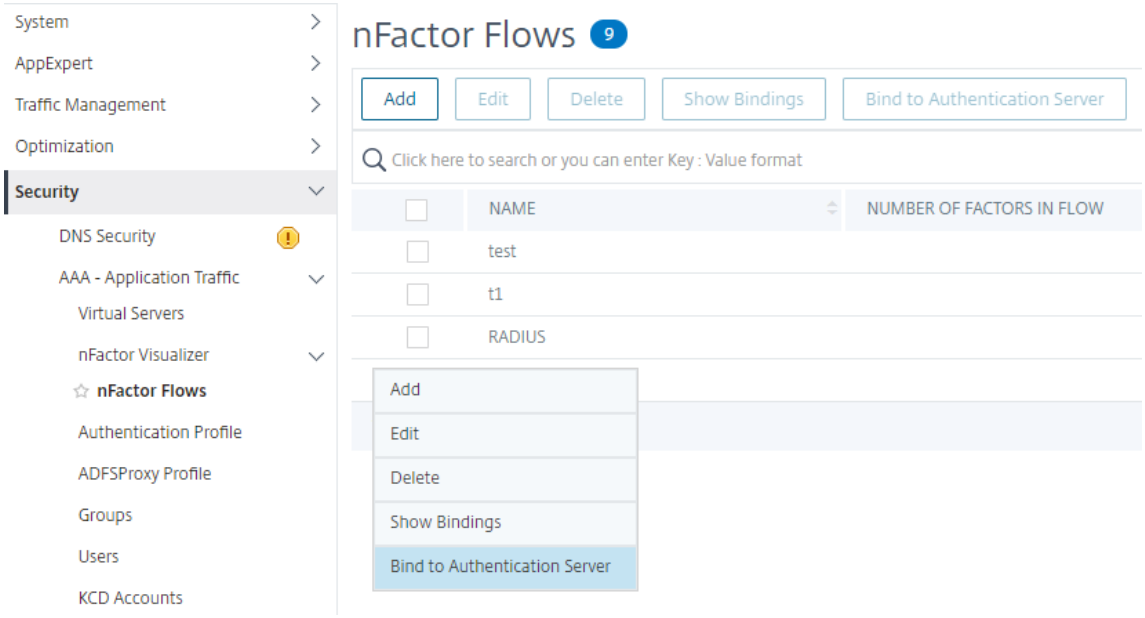
  > **Note**
  >
  > You can only add or edit the decision block through the Citrix ADC GUI. There is no option to configure the decision block from the CLI command.

- **Connect to an existing Factor**. Select an existing factor as your next factor. All the factors that appear in the existing list are created exclusively for that flow.
- **None.** Remove an existing connection.

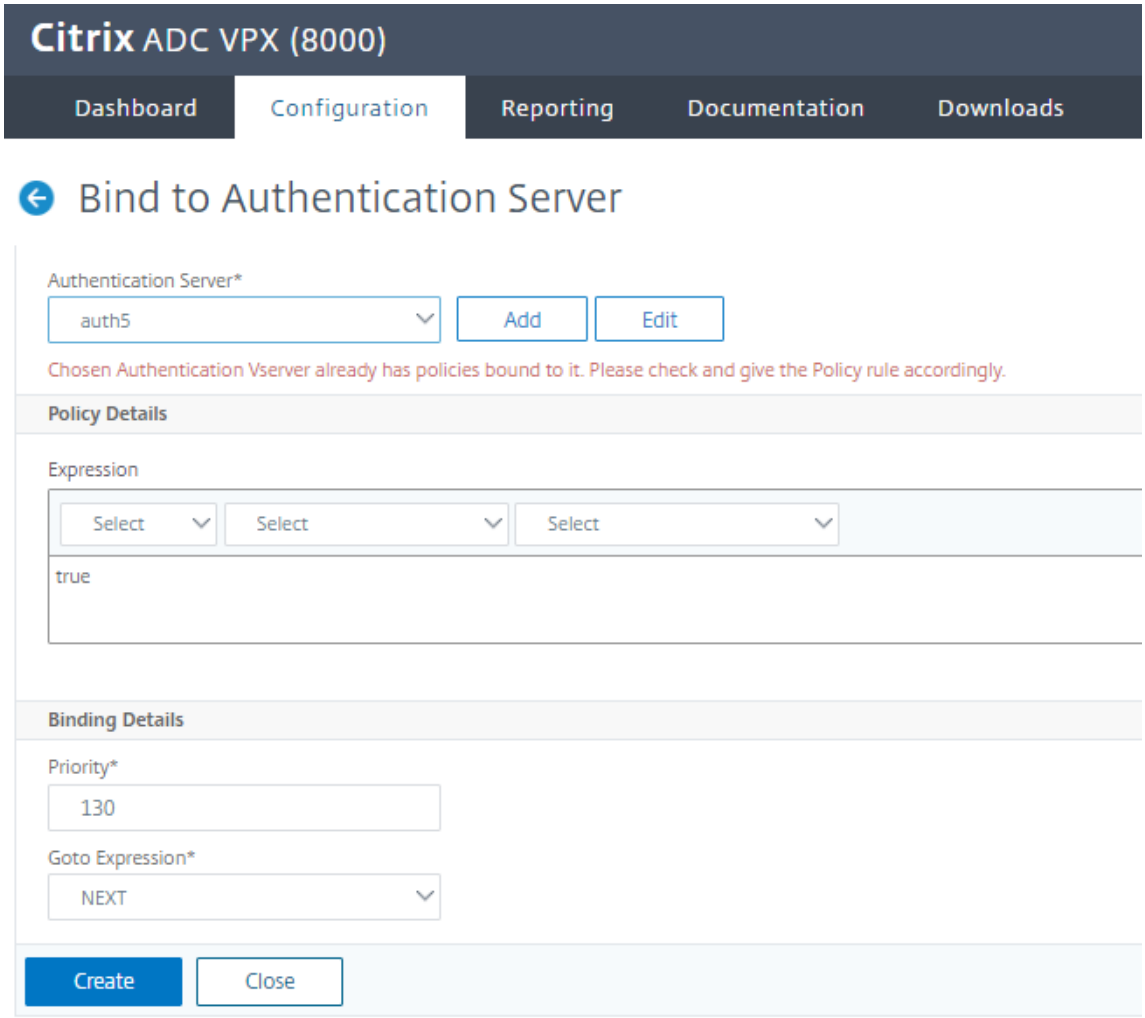


To bind the nFactor flow to authentication server

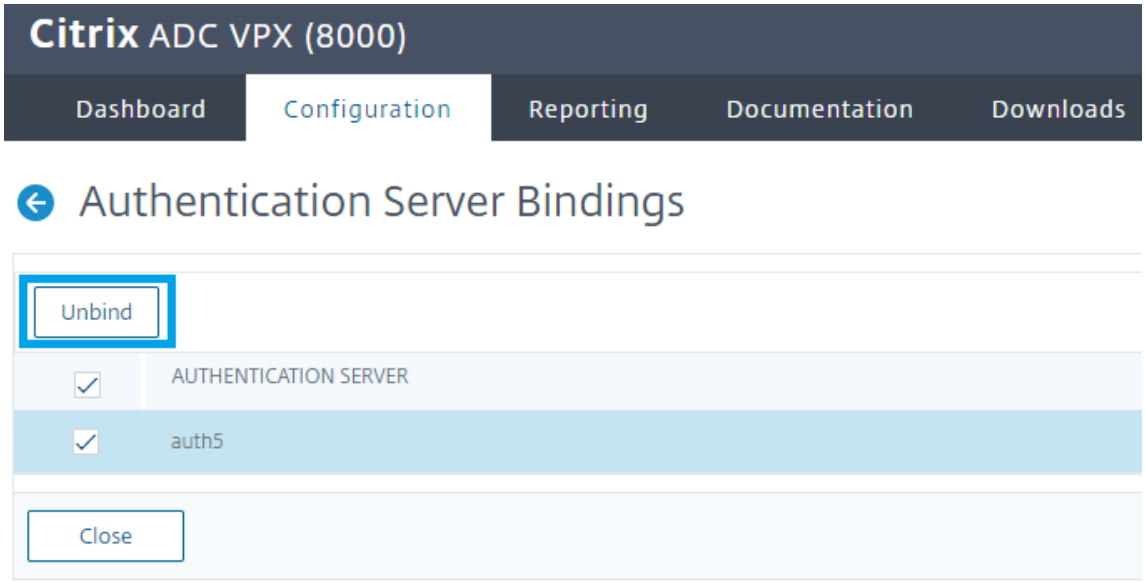
1. On the **nFactor Flows** page, select an nFactor flow that you prefer to bind to an authentication virtual server.
2. Click the hamburger icon to select **Bind to Authentication Server** option or in the details pane, click **Bind to Authentication Server**.



3. On the **Bind to Authentication Server** page, you can perform the following actions:
   - To add a **Authentication Virtual Server**, click **Add**.
   - To select an existing authentication server from the list, click **Authentication Server** field.



4. Click **Show Bindings** from the hamburger icon to view the bindings.
5. To unbind the authentication server from the specific nFactor flow, perform the following steps:
   - On the **nFactor Flows** page, click **Show Bindings** from the hamburger icon.
   - On the **Authentication Server Bindings** page, select the authentication server to unbind and click **Unbind**. Click **Close**.



For more information on nFactor authentication, see the following topics:

- Concept: Multi-Factor (nFactor) authentication.
- Workflow: How nFactor authentication works.
- Configuration: Configuring nFactor authentication.

Enhancements to the nFactor Visualizer

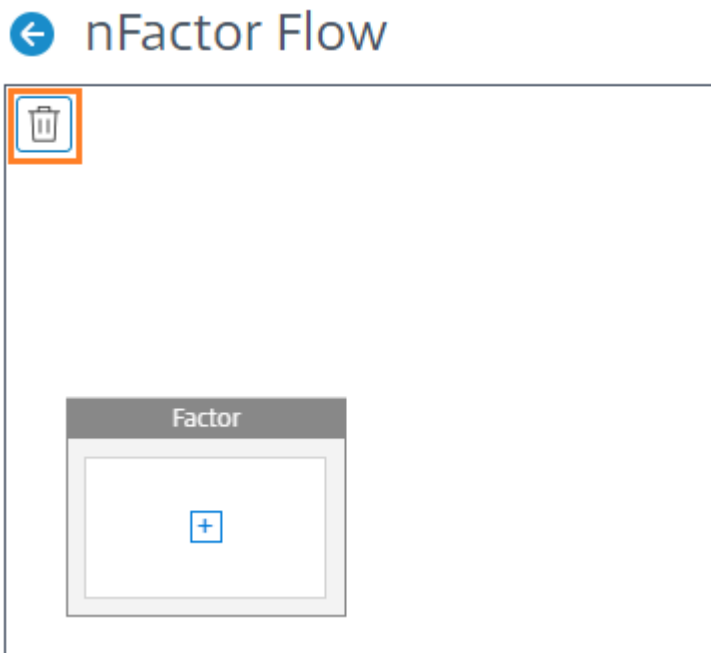
Starting from Citrix ADC release 13.0 build 41.20, the following enhancements are made in the nFactor Visualizer.

- Admins can move the created factors to the trash icon.
- View the nFactor flows in the Authentication Virtual server page.

Trash icon. Admins can only delete the nodes that have no connections. However, the underlying policies or the schemas that are created for the factor are not deleted if the factor is moved to trash.

To view the trash icon,

1. Navigate to **Security > AAA – Application Traffic > nFactor Visualizer > nFactor Flows**.

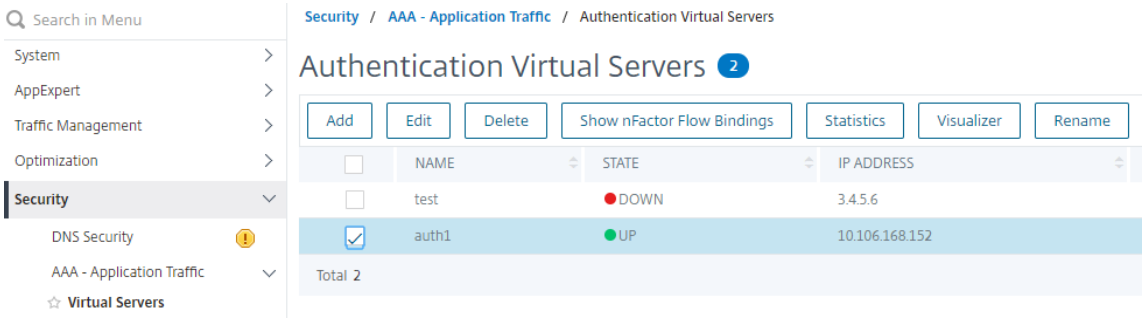


2. To delete the factor, click the factor block and drag it to trash.

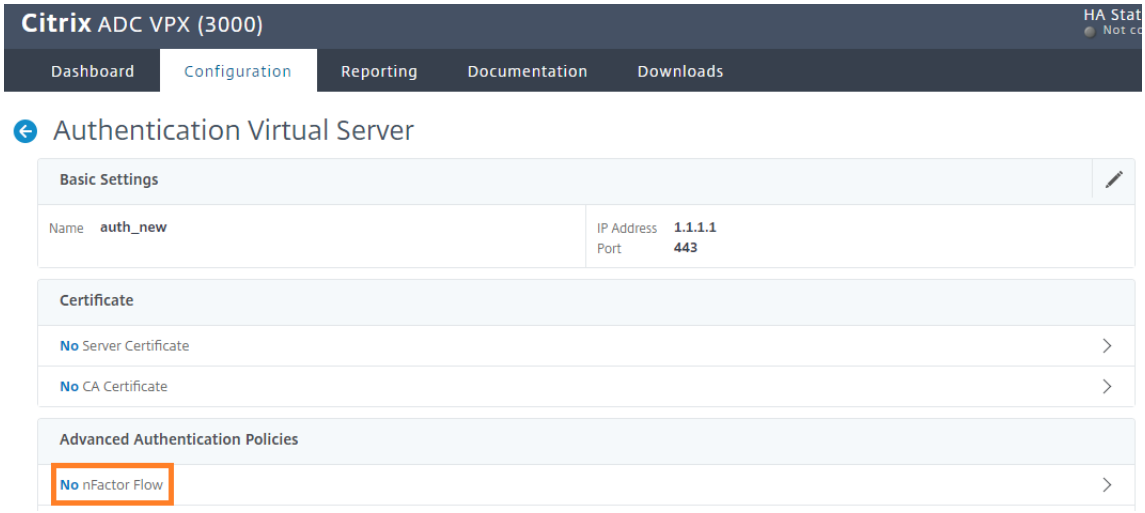
View nFactor flow from Authentication Virtual Server. Admins can also view the created nFactor flows from theAuthentication Virtual Server page.

To view the nFactor flow from Authentication Virtual Server page,

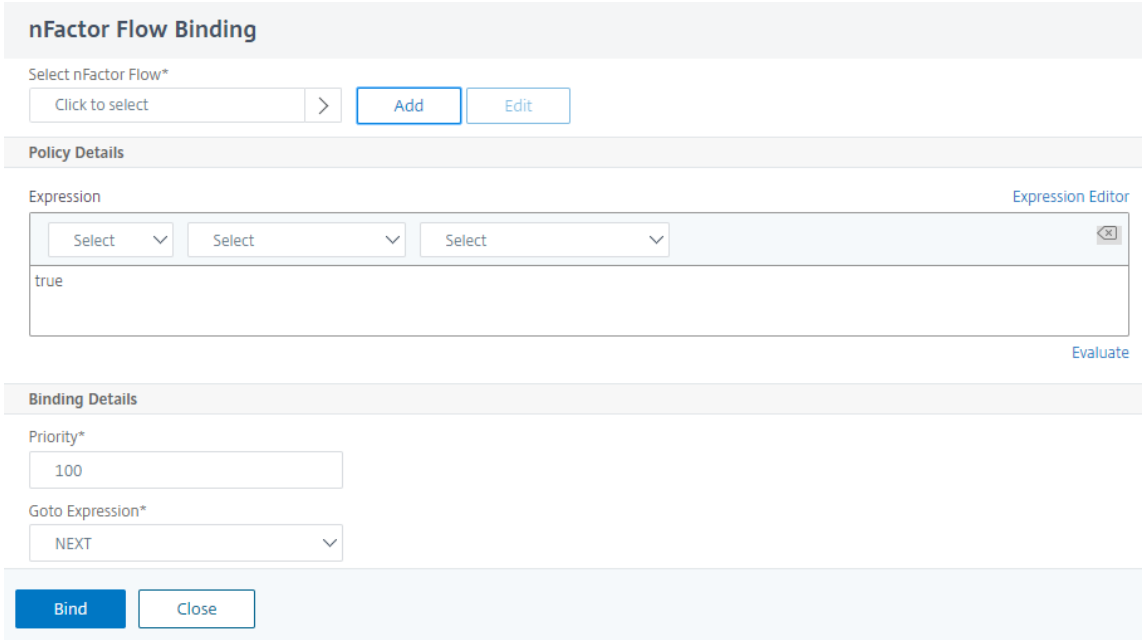
1. Navigate to **Security > AAA – Application Traffic > Virtual Servers**. On the **Authentication Virtual Servers** page, you can perform the following steps:
   - To add an authentication virtual server, click **Add**.
   - To edit an existing authentication virtual server, click **Edit** option from the details pane.



2. On the **Authentication Virtual Server** page, you can view the **nFactor Flow** option under **Advanced Authentication Policies**.



3. If there is no nFactor flow bound to the virtual server, you can click **No nFactor Flow** option under **Advanced Authentication Policies** section to either add a new nFactor flow or select the existing nFactor flow from the list.



nFactor Extensibility

September 14, 2021

nFactor authentication framework provides the flexibility of adding customizations to make the logon interface more intuitive for rich user experience. You can add custom login labels, custom login credentials, customizing UI displays and so on.

With nFactor, each factor can have its own logon screen. In each logon screen you can present any information from any of the previous factors or more information that is invisible in other factors. For example, your last factor can be an informative page where the user reads instructions and click continue.

Before nFactor, custom login pages were limited and customizations and needed support. It was possible to replace the tmindex.html or apply rewrite rules to change some of its behavior. However, it was not possible to achieve the underlying functionality.

The following nFactor related customizations are captured in detail in this topic.

- Customize login labels
- Customize UI to display images
- Customize Citrix ADC nFactor logon form

Assumptions

You are familiar with nFactor, Shell commands, XML, and text editors.

Prerequisites

- Customization described in this topic is possible only when RfWeb UI theme (or theme based) is configured on Citrix ADC.
- Authentication policy must be bound to the authentication, authorization, and auditing virtual server, else the flow does not work as intended. For details, see CTX224241.
- You have the following items related to nFactor
  - XML schema
  - JavaScript
  - Authentication actions
  - Authentication virtual server
  - Citrix ADC version 11.1 and later

Customize logon labels

To customize logon labels, you need the following:

- The XML schema that describes how the logon page looks.
- The script.js file that contains the JavaScript that is used to change the rendering process.

How it works

The JavaScript parses the XML file, rendering each item inside the `<Requirements>` tag. Each element corresponds to a line in the HTML form. For example, a login field is a line, the password field

is another line, and so is the logon button. To introduce new lines, you must specify them in the XML schema file using the StoreFront SDK. The StoreFront SDK allows the logon page with an XML schema to use the <Requirement> tag and define elements on it. These elements allow to use JavaScript to introduce in that space whatever HTML elements are required. In this case, a line is created with some text in the form of HTML.

The XML that can be used is as follows:

```
<Requirement>
<Credential>
<Type>nsg-custom-cred</Type>
<ID>passwd</ID>
</Credential>
<Label>
<Type>nsg-custom-label</Type>
</Label>
</Requirement>
<!--NeedCopy-->
```

<Requirement>: Space provided in the logon page. The credential fills the space, and the other parts route the engine into the correct information. In this case, type nsg-custom-cred. This is defined as plain text and the label is defined for its body.
The requirement XML is paired with the JavaScript code to achieve the required results.

```
// Custom Label Handler for Self Service Links
CTXS.ExtensionAPI.addCustomAuthLabelHandler({

getLabelTypeName: function () {
  return "nsg-custom-label";  }
 ,
getLabelTypeMarkup: function (requirements) {

return $("< Your HTML Code Here>");
 }
 ,
// Instruction to parse the label as if it was a standard type
parseAsType: function () {

return "plain";
 }

 }
 );
//Custom Credential Handler for Self Service Links
CTXS.ExtensionAPI.addCustomCredentialHandler({
```

```
22
23 getCredentialTypeName: function () {
24   return "nsg-custom-cred";  }
25  ,
26 getCredentialTypeMarkup: function (requirements) {
27
28 return $("<div/>");
29  }
30  ,
31  }
32  );
33 <!--NeedCopy-->
```

The XML portion indicates the logon page what to display, and the JavaScript code provides the actual text. The credential handler opens up the space and the label fills the space. Because all authentication traffic is now invisible to rewrite and responder, you can change the look and feel of the page. Configuration to customize login labels

1. Create and bind a theme based on RfWeb.

   ```
   1 add vpn portaltheme RfWebUI_MOD -basetheme RfWebUI
   2
   3 bind vpn vserver TESTAAA  - portaltheme RfWebUI_MOD
   4 <!--NeedCopy-->
   ```

   The path for the files based on the theme is available in the directory; /var/netscaler/logon/themes/RfWebUI_MOD

2. Add the following snippet to the end of script.js file:

   Note: Failing to include the preceding lines inside the correct file or missing to include any JavaScript functions prevent the XML from being loaded. The error can only be seen in the Developer Console of the browser with the following text: “Undefined Type nsg-custom-cred.”

   ```
   1 // Custom Label Handler for Self Service Links
   2 CTXS.ExtensionAPI.addCustomAuthLabelHandler({
   3
   4 getLabelTypeName: function () {
   5   return "nsg-custom-label";  }
   6  ,
   7 getLabelTypeMarkup: function (requirements) {
   8
   9 return $("<a href=\"https://identity.test.com/identity/faces/
       register\" style=\"font-size: 16px;\" style=\"text-align:
       center;\">Self Registration</a><br><a href=\"https://identity.
       test.com/identity/faces/forgotpassword\" style=\"font-size: 16
   ```

```
      px;\" style=\"text-align: center;\">Forgot Password</a><br><a
      href=\"https://identity.test.com/identity/faces/forgotuserlogin
      \" style=\"font-size: 16px;\" style=\"text-align: center;\">
      Forgot User Login</a>");
 }
 ,
// Instruction to parse the label as if it was a standard type
parseAsType: function () {

return "plain";
 }

 }
 );
//Custom Credential Handler for Self Service Links
CTXS.ExtensionAPI.addCustomCredentialHandler({

getCredentialTypeName: function () {
  return "nsg-custom-cred";  }
 ,
getCredentialTypeMarkup: function (requirements) {

return $("<div/>");
 }
 ,
 }
 );
<!--NeedCopy-->
```

Loginschema used in this example

```
<?xml version="1.0" encoding="utf-8"?>
<AuthenticateResponse xmlns="http://citrix.com/authentication/response
   /1">
<Status>success</Status>
<Result>more-info</Result>
<StateContext/>
<AuthenticationRequirements>
<PostBack>/nf/auth/doAuthentication.do</PostBack>
<CancelPostBack>/Citrix/Authentication/ExplicitForms/CancelAuthenticate
   </CancelPostBack>
<CancelButtonText>Cancel</CancelButtonText>
<Requirements>
<Requirement>
```

```
<Credential>
<ID>login</ID>
<SaveID>Username</SaveID>
<Type>username</Type>
</Credential>
<Label>
<Text>User name</Text>
<Type>plain</Type>
</Label>
<Input>
<AssistiveText>Please supply either domain\username or user@fully.
   qualified.domain</AssistiveText>
<Text>
<Secret>false</Secret>
<ReadOnly>false</ReadOnly>
<InitialValue></InitialValue>
<Constraint>.+</Constraint>
</Text>
</Input>
</Requirement>
<Requirement>
<Credential>
<ID>passwd</ID>
<SaveID>Password</SaveID>
<Type>password</Type>
</Credential>
<Label>
<Text>Password:</Text>
<Type>plain</Type>
</Label>
<Input>
<Text>
<Secret>true</Secret>
<ReadOnly>false</ReadOnly>
<InitialValue/>
<Constraint>.+</Constraint>
</Text>
</Input>
</Requirement>
<Requirement>
<Credential>
<Type>nsg-custom-cred</Type>
<ID>passwd</ID>
</Credential>
<Label>
```

```
<Type>nsg-custom-label</Type>
</Label>
</Requirement>
<Requirement>
<Credential>
<ID>loginBtn</ID>
<Type>none</Type>
</Credential>
<Label>
<Type>none</Type>
</Label>
<Input>
<Button>Please Log On</Button>
</Input>
</Requirement>
</Requirements>
</AuthenticationRequirements>
</AuthenticateResponse>
<!--NeedCopy-->
```

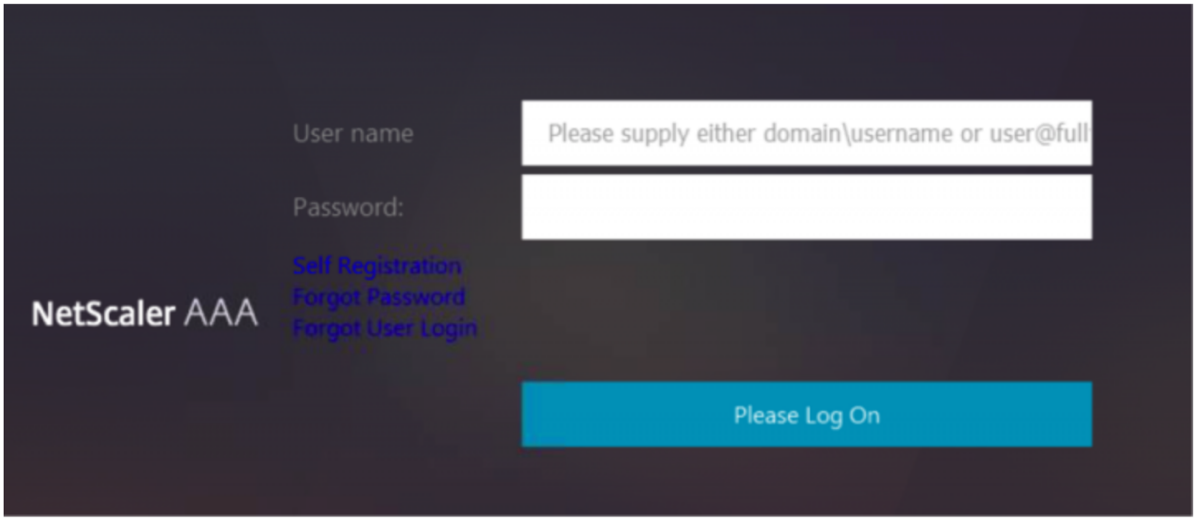
Execute the following commands to load custom schema to config.

```
add authentication loginSchema custom -authenticationSchema custom.xml

add authentication loginSchemaPolicy custom -rule true -action custom

bind authentication vserver AAATEST -policy custom -priority 100 -
   gotoPriorityExpression END
<!--NeedCopy-->
```

The following figure displays the login page that is rendered with this configuration.



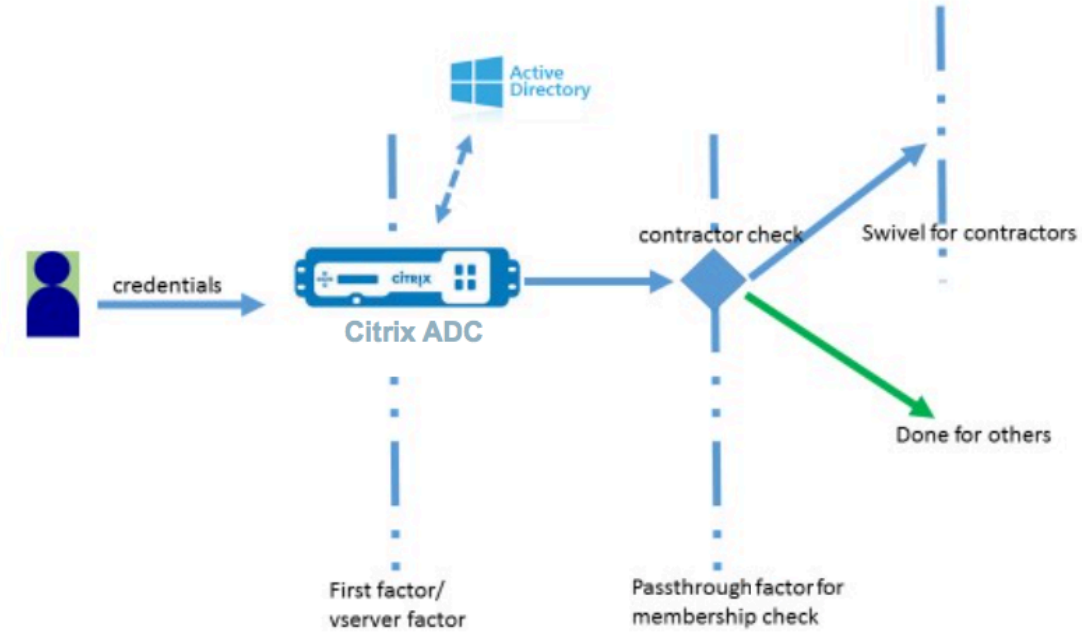
Customize UI to display images

nFactor allows for customized display with the use of loginschema files. There might be a requirement for further customizations other than those offered by the built-in loginschema files. For example, displaying a hyperlink or writing custom logic in the UI. These can be achieved using 'custom credentials' that comprise of loginschema extension and corresponding javascript file.

For UI customization to display images, a deployment flow in "Citrix ADC-Swivel" integration is used as an example.

There are two factors in this flow.

- First factor: Checks user's AD credentials.
- Second factor: Prompts for user logon based on group membership.



In this flow, all users go through first factor. Before second factor, there is a pseudo factor to check if some users can be omitted from “swivel” factor. If user requires “swivel” factor, an image and a text box are displayed to enter code.

Solution

The solution for customizing UI to display images contains two parts;

- Loginschema extension.
- Custom script to process the loginschema extension.

Loginschema extension

To control form rendering, a custom ‘id’/’credential’ is injected into the loginschema. This can be done by reusing existing schema and modifying as per the requirement.

In the example, a loginschema that has only one text field (such as /nsconfig/loginschema/LoginSchema/OnlyPassword.xml) is considered.
The following snippet is added to the loginschema.

```
<Requirement><Credential><ID>swivel_cred</ID><Type>swivel_cred</Type><
   Input><Text><Hidden>true</Hidden><InitialValue>${
 http.req.user.name }
 </InitialValue></Text></Input></Credential></Requirement>
<!--NeedCopy-->
```

In the snippet, “swivel_cred” is specified as “Type” of the credential. Because this is not recognized as a built-in ‘credential,’ UI looks for a handler for this type, and calls it if it exists.
An initial value is sent for this credential which is an expression that Citrix ADC dynamically fills. In the example, it is the user’s name used to notify swivel server of the user name. It might not be needed all the time or it can be augmented with some other data. Those details must be added as required.

Javascript to handle custom credential

When the UI finds a custom credential, it looks for a handler. All custom handlers are written in /var/netscaler/logon/LogonPoint/custom/script.js for default portal theme.
For custom portal themes, script.js can be found in the directory /var/netscaler/logon/themes/<custom_theme>/.

The following script is added to render mark-up for custom credentials.

```
CTXS.ExtensionAPI.addCustomCredentialHandler({

    // The name of the credential, must match the type returned by the server
    getCredentialTypeName: function () {
  return "swivel_cred";  }
 ,
    // Generate HTML for the custom credential
    getCredentialTypeMarkup: function (requirements) {

        var div = $("<div></div>");
        var image = $("<img/>");
        var username = requirements.input.text.initialValue; //Get the secret from the response
        image.attr({

            "style" : "width:200px;height:200px;",
            "id" : "qrcodeimg",
            "src" : "https://myswivelserver.citrix.com:8443/pinsafe/SCImage?username=" + username
         }
 );
        div.append(image);
        return div;
     }

 }
 );
<!--NeedCopy-->
```

This snippet is for handling the mark-up for ‘swivel_cred’. Credential name highlighted must match the ‘type’ specified earlier in the loginschema extension.
To generate mark-up, an image whose source points to swivel server needs to be added. Once this is done, UI loads image from specified location. Because this loginschema also has a textbox, UI renders that text box.

Note: Administrator can modify “style” of image element to resize the image. Currently it configured for 200x200 pixels.

Configuration for customizing UI to display images

nFactor configuration is better constructed bottom-up, that is the last factor first because when you try to specify ‘nextFactor’ for the previous factors, you require the subsequent factor’s name.

Swivel factor configuration:

```
add loginschema swivel_image -authenticationSchema /nsconfig/
    loginschema/SwivelImage.xml

add authentication policylabel SwivelFactor -loginSchema swivel_image

bind authentication policylabel SwivelFactor -policy <policy-to-check-
    swivel-image> -priority 10
<!--NeedCopy-->
```

Note: Download SwivelImage.xml from the loginschema used in the example.

Pseudo factor for group check configuration:

```
add authentication policylabel GroupCheckFactor

add authentication policy contractors_auth_policy -rule 'http.req.
    user.is_member_of( "contractors" )' -action NO_AUTHN

add authentication policy not_contractors _auth_policy -rule true -
    action NO_AUTHN

bind authentication policylabel GroupCheckFactor -policy
    contractors_auth_policy -pri 10 -nextFactor SwivelFactor

bind authentication policylabel GroupCheckFactor -policy
    not_contractors_auth_policy -pri 20
<!--NeedCopy-->
```

First factor for Active Directory login:

```
add ldapAction <>

add authentication policy user_login_auth_policy -rule true -action <>

bind authentication vserver <> -policy user_login_auth_policy -pri 10 -nextFactor GroupCheckFactor
<!--NeedCopy-->
```

In the configuration, three factors are specified of which one is implicit/pseudo.

Loginschema used in this example

The following is an example schema with swivel credential and a text box.

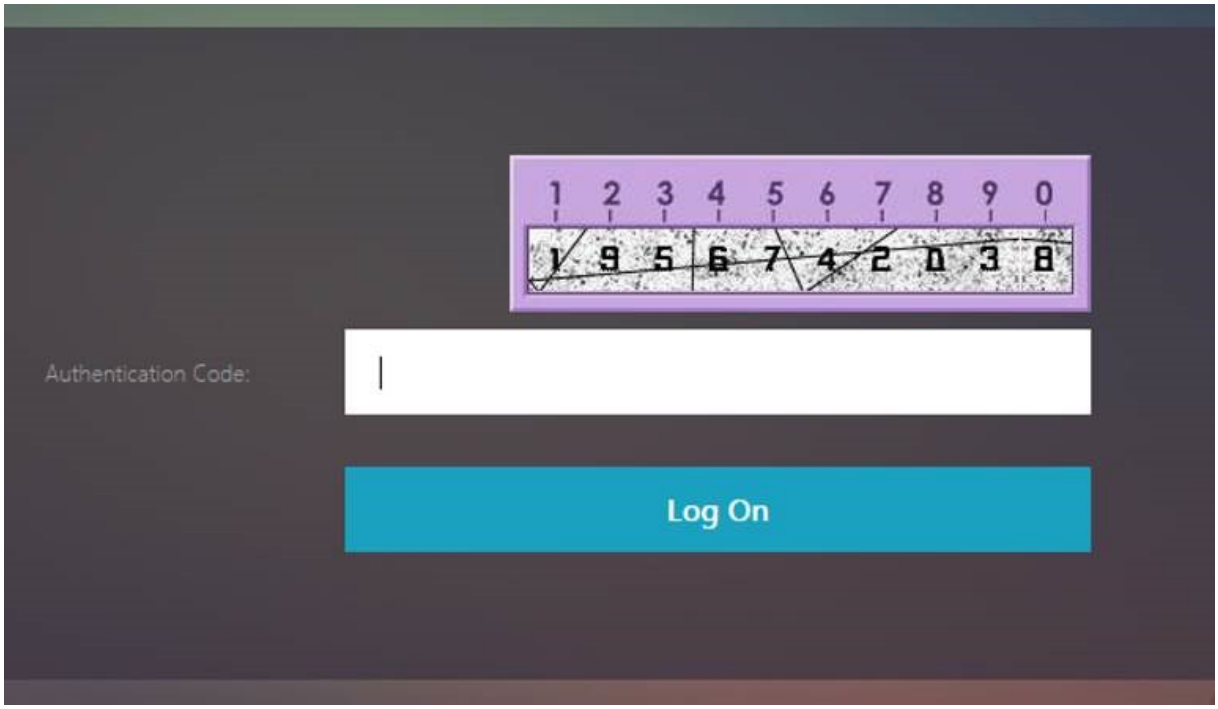
Note: When copying data for web browser, quotes might be displayed differently. Copy data in editors like notepad before saving them to files.

```
<?xml version="1.0" encoding="UTF-8"?>
<AuthenticateResponse xmlns="http://citrix.com/authentication/response/1">
<Status>success</Status>
<Result>more-info</Result>
<StateContext></StateContext>
<AuthenticationRequirements>
<PostBack>/nf/auth/doAuthentication.do</PostBack>
<CancelPostBack>/nf/auth/doLogoff.do</CancelPostBack>
<CancelButtonText>Cancel</CancelButtonText>
<Requirements>
<Requirement><Credential><ID>swivel_cred</ID><Type>swivel_cred</Type><Input><Text><Hidden>true</Hidden><InitialValue>${
 http.req.user.name }
 </InitialValue></Text></Input></Credential></Requirement>
<Requirement><Credential><ID>passwd</ID><SaveID>ExplicitForms-Password</SaveID><Type>password</Type></Credential><Label><Text>Password:</Text><Type>plain</Type></Label><Input><Text><Secret>true</Secret><ReadOnly>false</ReadOnly><InitialValue></InitialValue><Constraint>.+</Constraint></Text></Input></Requirement>
<Requirement><Credential><Type>none</Type></Credential><Label><Text>Hello ${
 http.req.user.name }
 , Please enter passcode from above image.</Text><Type>confirmation</Type></Label><Input /></Requirement>
```

```
<Requirement><Credential><ID>saveCredentials</ID><Type>savecredentials
    </Type></Credential><Label><Text>Remember my password</Text><Type>
    plain</Type></Label><Input><CheckBox><InitialValue>false</
    InitialValue></CheckBox></Input></Requirement>
<Requirement><Credential><ID>loginBtn</ID><Type>none</Type></Credential
    ><Label><Type>none</Type></Label><Input><Button>Log On</Button></
    Input></Requirement>
</Requirements>
</AuthenticationRequirements>
</AuthenticateResponse>
<!--NeedCopy-->
```

Output

Once the configuration is performed, the following image is displayed.



Note: Image height and placement can be altered in the JavaScript.

Customize Citrix ADC nFactor logon form to show or hide fields

Citrix Gateway's RfWeb UI allows for wide variety of customizations. This capability when combined with nFactor authentication framework lets customers configure complex flows without compromising existing workflows.

In this example, two authentication options, OAuth and LDAP are available from the Logon Type list. When the form is first loaded, user name and password fields (LDAP is shown first) are displayed. If OAuth is selected, all the fields are hidden because OAuth implies offload of authentication to a third party server. This way, administrator can configure intuitive workflows as per user convenience.

Note:

- The values in the Logon Type list can be modified with simple modifications to the script file.
- This section describes only the UI part of the flow. The run time handling of the authentication is outside the scope of this article. Users are recommended to refer to nFactor documentation for authentication configuration.

How to customize nFactor logon form

Customizing nFactor logon form can be classified into two parts

- Sending right loginschema to the UI
- Writing a handler to interpret loginschema and user selections

Send right loginschema to the UI

In this example, a simple claim/requirement is sent in the loginschema.

For this, SingleAuth.xml file is modified. SingleAuth.xml is shipped with Citrix ADC firmware and can be found in /nsconfig/loginschema/LoginSchema directory.

Steps to send loginschema:

1. Log in via SSH and drop to shell (type 'shell').
2. Copy SingleAuth.xml to a different file for modification.

   Note: The destination folder is different from the default Citrix ADC loginschemas folder.

   cp /nsconfig/loginschema/LoginSchema/SingleAuth.xml /nsconfig/loginschema/SingleAuth-Dynamic.xml
3. Add the following claim to SingleAuthDynamic.xml.

```
<Requirement><Credential><ID>nsg_dropdown</ID><Type>nsg_dropdown</Type></Credential><Label><Text>Logon Type:</Text><Type>plain</Type></Label></Requirement>
<!--NeedCopy-->
```

4. Configure Citrix ADC to send this loginschema to load the first form.

```
add loginschema single_auth_dynamic -authenticationSchema SingleAuthDynamic.xml
```

```
2
3 add loginschemaPolicy single_auth_dynamic -rule true -action
     single_auth_dynamic
4
5 bind authentication vserver aaa_nfactor -policy
     single_auth_dynamic -pri 10
6 <!--NeedCopy-->
```

Script changes to load form and handle user events

You can modify the JavaScript that enables administrator to customize display for logon form. In this example, user name and password field are displayed if LDAP is chosen and are hidden if OAuth is chosen. Administrator can also hide only the password.
Admins must append the following snippet to “script.js” that is at “/var/netscaler/logon/LogonPoint/-custom” directory.

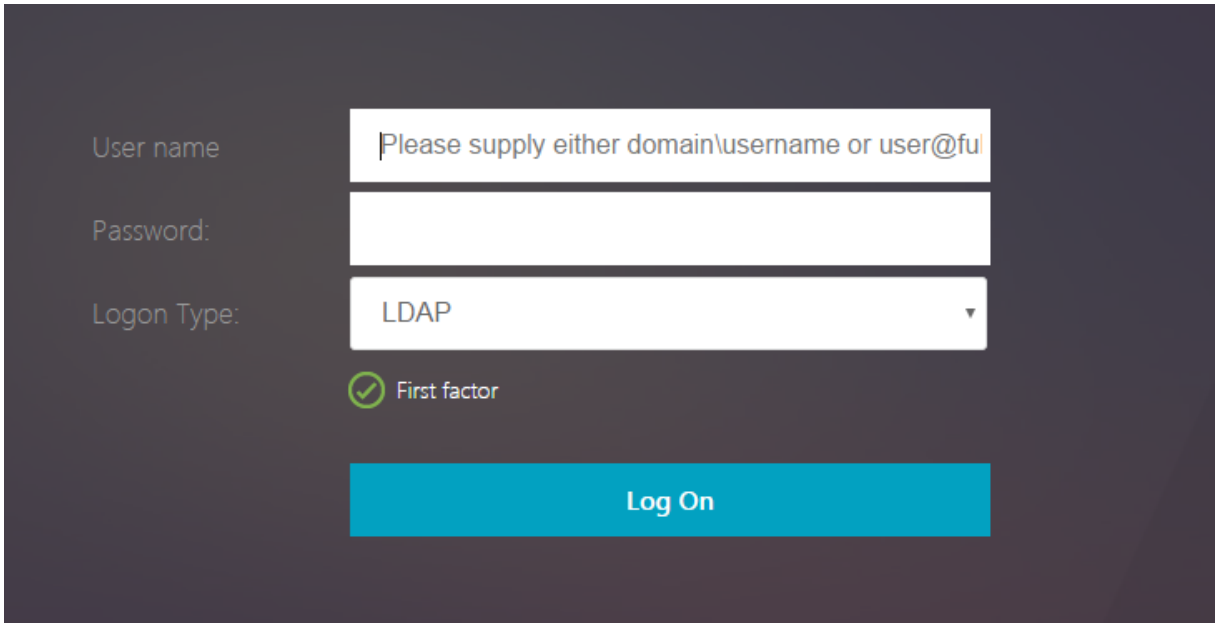
Note: Because this directory is a global directory, create a portal theme and edit the “script.js” file within that folder, at "/var/netscaler/logon/themes/<THEME_NAME>".

```
1 CTXS.ExtensionAPI.addCustomCredentialHandler({
2
3     // The name of the credential, must match the type returned by the
        server
4     getCredentialTypeName: function () {
5  return "nsg_dropdown";  }
6 ,
7     // Generate HTML for the custom credential
8     getCredentialTypeMarkup: function (requirements) {
9
10         var div = $("<div></div>");
11         var select = $("<select name='nsg_dropdown'></select>").attr("
              id", "nsg_dropdown");
12
13         var rsa = $("<option></option>").attr("selected", "selected").
              text("LDAP").val("LDAP");
14         var OAuthID = $("<option></option>").text("OAuth").val("OAuth")
              ;
15         select.append(rsa, OAuthID);
16
17         select.change(function(e) {
18
19             var value = $(this).val();
20             var ldapPwd = $($(".credentialform").find(".
                  CredentialTypepassword")[0]);
```

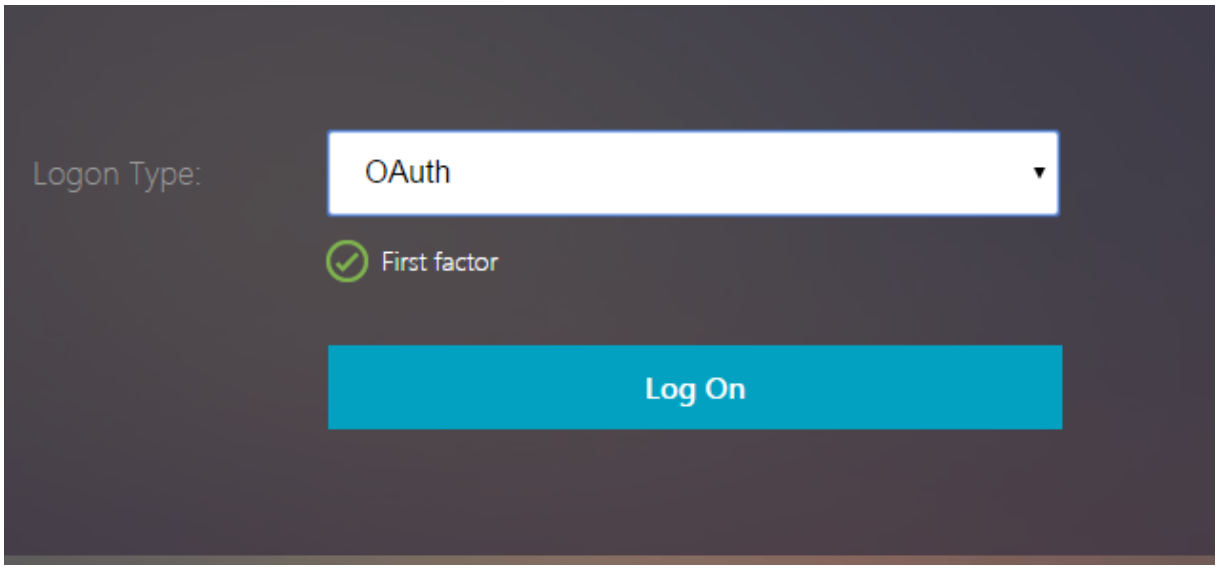
```
21              var ldapUname = $($(".credentialform").find(".
                   CredentialTypeusername"));
22              if(value == "OAuth") {
23
24                  if (ldapPwd.length)
25                          ldapPwd.hide();
26                  if (ldapUname.length)
27                          ldapUname.hide();
28               }
29    else if(value == "LDAP") {
30
31                  if (ldapPwd.length)
32                          ldapPwd.show();
33                  if (ldapUname.length)
34                          ldapUname.show();
35               }
36
37           }
38  );
39        div.append(select);
40         return div;
41      }
42
43  }
44  );
45 <!--NeedCopy-->
```

End-user experience

When an end user loads the logon page first time, the following screen appears.



If **OAuth** is selected in **Logon Type**, user name and password fields are hidden.



If **LDAP** is selected, user name and password are displayed. This way, the logon page can be dynamically loaded based on user selection.

Loginschema used in this example

```
<?xml version="1.0" encoding="UTF-8"?>
<AuthenticateResponse xmlns="http://citrix.com/authentication/response/1">
<Status>success</Status>
<Result>more-info</Result>
```

Set a cookie using nFactor

September 14, 2021

You can apply the nFactor custom labels and set a cookie as a factor of the authentication flow.

Through custom labels, you can use JavaScript to manipulate the login schema.

To set a cookie as a factor, you do not need to display any information to the user, which is performed with a no schema login. Instead, you must interact with the user's browser to instruct the login schema to store the desired data. A login schema is required to set the cookie when the page is loaded. The cookie is set with a custom label and JavaScript code.

To implement a factor that sets a cookie, create an XML file called cookie.xml to store the schema in the /nsconfig/loginschema/ directory with the following content:

```
<?xml version="1.0" encoding="UTF-8"?>
<AuthenticateResponse xmlns="http://citrix.com/authentication/response
   /1">
<Status>success</Status>
<Result>more-info</Result>
<StateContext></StateContext>
<AuthenticationRequirements>
<PostBack>/nf/auth/doAuthentication.do</PostBack>
<CancelPostBack>/nf/auth/doLogoff.do</CancelPostBack>
<CancelButtonText>Cancel</CancelButtonText>
<Requirements>

<Requirement>
<Credential><ID>nsg_cookie</ID><Type>nsg_cookie</Type></Credential>
<Label><Text>Logon Type:</Text><Type>Plain</Type></Label>
</Requirement>

<Requirement>
<Credential><ID>loginBtn</ID><Type>none</Type></Credential>
<Label><Type>none</Type></Label><Input><Button>Log On</Button></Input>
</Requirement>

</Requirements>
</AuthenticationRequirements>
</AuthenticateResponse>
<!--NeedCopy-->
```

In this XML;

- The custom label nsg_cookie is used to create the cookie and submit the form, and the form button.
- The RfWebUI_custom is the new Portal theme based on the RfWebUI theme.

Steps to set a cookie using nFactor

1. Create a portal theme based on the RfWebUI theme.

```
add vpn portaltheme RfWebUI_custom -basetheme RfWebUI
<!--NeedCopy-->
```

   This command creates a folder for this theme at /var/netscaler/logon/themes/RfWebUI_custom

2. Edit the file /var/netscaler/logon/themes/RfWebUI_custom/script.js and add the following script:

```
CTXS.ExtensionAPI.addCustomCredentialHandler({

    // The name of the credential, must match the type returned by
        the server
    getCredentialTypeName: function () {
  return "nsg_cookie";  }
 ,
    // Generate HTML for the custom credential
    getCredentialTypeMarkup: function (requirements) {

        var div = $("<div></div>");
        $(document).ready(function() {

        //Set cookie valid for 1000 days
        var exdays = 1000;
        var d = new Date();
        d.setTime(d.getTime() + (exdays*24*60*60*1000));
        var expires = "expires="+ d.toUTCString();
        document.cookie = "NSC_COOKIE_NAME=CookieValeu;" + expires
            + ";path=/";

        //Submit form
        document.getElementById('loginBtn').click();
         }
 );
        return div;
     }

 }
 );
<!--NeedCopy-->
```

   This code performs the following:

- Waits for the browser to finish loading the page
- Sets a cookie called NSC_COOKIE_NAME with the value CookieValue, valid for 1000 days
- Auto-submits the form.

The cookie is created and the user does not need to interact with the page.

3. Create a login schema to bind to the policy label that represents the set cookie factor.

```
1 add authentication loginSchema Cookie_LS -authenticationSchema "/
     nsconfig/loginschema/cookie.xml"
2 <!--NeedCopy-->
```

4. Create a NO_AUTHN authentication policy to bind to the policy label that represents the set cookie factor.

```
1 add authentication Policy NO_AUTHN_POL -rule TRUE -action NO_AUTHN
2 <!--NeedCopy-->
```

This policy always evaluates as true, moving the user to the next factor or completing the authentication flow.

5. Bind the portal theme RfWebUI_custom to the Citrix Gateway virtual server or Citrix ADC AAA virtual server.

Sample deployments using nFactor authentication

September 14, 2021

The following are the sample deployments using nFactor authentication:

- Getting two passwords up-front, pass-through in next factor. Read
- Group extraction followed by certificate or LDAP authentication, based on group membership. Read
- SAML followed by LDAP or certificate authentication, based on attributes extracted during SAML. Read
- SAML in first factor, followed by group extraction, and then LDAP or certificate authentication, based on groups extracted. Read
- Prefilling user name from certificate. Read
- Certificate authentication followed by group extraction for 401 enabled traffic management virtual servers. Read
- Username and two passwords with group extraction in third factor. Read
- Certificate fallback to LDAP in same cascade; one virtual server for both certificate and LDAP authentication. Read

- LDAP in first factor and WebAuth in second factor. Read
- Domain drop down in first factor, then different policy evaluations based on group. Read

How to articles

September 14, 2021

The Authentication, authorization, and auditing "How to articles" are simple, relevant, and easy to implement articles. These articles contain information about some of the popular Authentication, authorization, and auditing features such LDAP authentication and multifactor authentication. For some of the popular articles on configuring and troubleshooting authentication through Citrix ADC, see Citrix ADC Authentication: How do I?

Endpoint Analysis

Configure pre-authentication Endpoint Analysis scan as a factor in nFactor authentication

Configure post-authentication Endpoint Analysis scan as a factor in Citrix ADC nFactor authentication

Configure pre-authentication and post-authentication EPA scan as a factor in nFactor authentication

Configure periodic Endpoint Analysis scan as a factor in nFactor authentication

Configure Citrix Gateway preauthentication EPA scan for the domain check

First factor and second factor configuration combinations

Configure nFactor for Citrix Gateway with WebAuth in first factor and LDAP with password change in second factor

Configure SAML followed by LDAP or certificate authentication based on SAML attribute extraction in nFactor authentication

Configure certificate authentication as first factor and LDAP as second factor in Citrix ADC nFactor authentication

Configure two-factor authentication with one login schema and one passthrough schema in Citrix ADC nFactor authentication

Configure user name and two passwords with group extraction in third factor by nFactor authentication

Configure domain drop-down, username, and password field in the first factor and policy evaluation based on groups in the next factor

Configure email ID (or user name) input based group extraction at first factor to decide the next factor authentication flow

Configure a domain drop-down list for user input in the first factor to decide the next factor authentication flow

EULA as an authentication factor

Configure EULA as an authentication factor in Citrix ADC nFactor system

Prefill user name from certificate

Configure prefill user name from certificate in Citrix ADC nFactor authentication

Step-up authentication

Configure nFactor for applications with different login site requirements including step-up authentication

SAML authentication

September 14, 2021

Security Assertion Markup Language (SAML) is an XML-based authentication mechanism that provides single sign-on capability and is defined by the OASIS Security Services Technical Committee.

> Note
>
> Starting from NetScaler 12.0 Build 51.x, Citrix ADC appliance used as a SAML Service Provider (SP) with Multi-Factor (nFactor) authentication now prepopulates the user-name field on the login page. The appliance sends a NameID attribute as part of a SAML authorization request, retrieves the NameID attribute value from the Citrix ADC SAML Identity Provider (IdP), and prepopulates the user-name field.

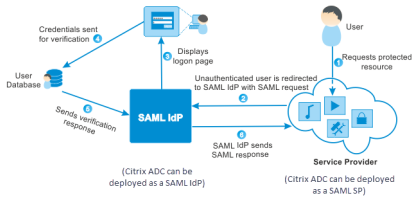
Why use SAML authentication

Consider a scenario in which a service provider (LargeProvider) hosts a number of applications for a customer (BigCompany). BigCompany has users that must seamlessly access these applications. In a traditional setup, LargeProvider would need to maintain a database of users of BigCompany. This raises some concerns for each of the following stakeholders:

- LargeProvider must ensure security of user data.

- BigCompany must validate the users and keep the user data up-to-date, not just in its own database, but also in the user database maintained by LargeProvider. For example, a user removed from the BigCompany database must also be removed from the LargeProvider database.
- A user has to log on individually to each of the hosted applications.

The SAML authentication mechanism provides an alternative approach. The following deployment diagram shows how SAML works (SP initiated flow).



The concerns raised by traditional authentication mechanisms are resolved as follows:

- LargeProvider does not have to maintain a database for BigCompany users. Freed from identity management, LargeProvider can concentrate on providing better services.
- BigCompany does not bear the burden of making sure the LargeProvider user database is kept in sync with its own user database.
- A user can log on once, to one application hosted on LargeProvider, and be automatically logged on to the other applications that are hosted there.

The Citrix ADC appliance can be deployed as a SAML Service Provider (SP) and a SAML Identity Provider (IdP). Read through the relevant topics to understand the configurations that must be performed on the Citrix ADC appliance.

A Citrix ADC appliance configured as a SAML service provider can now enforce an audience restriction check. The audience restriction condition evaluates to “Valid” only if the SAML replying party is a member of at least one of the specified audiences.

You can configure a Citrix ADC appliance to parse attributes in SAML assertions as group attributes. Parsing them as group attributes enables the appliance to bind policies to the groups.

Citrix ADC as a SAML SP

September 14, 2021

The SAML Service Provider (SP) is a SAML entity deployed by the service provider. When a user tries to access a protected application, the SP evaluates the client request. If the client is unauthenticated (does not have a valid NSC_TMAA or NSC_TMAS cookie), the SP redirects the request to the SAML Identity Provider (IdP).

The SP also validates SAML assertions that are received from the IdP.

When the Citrix ADC appliance is configured as an SP, all user requests are received by a traffic management virtual server (load balancing or content switching) that is associated with the relevant SAML action.

The Citrix ADC appliance also supports POST and Redirect bindings during logout.

> **Note**
>
> A Citrix ADC appliance can be used as a SAML SP in a deployment where the SAML IdP is configured either on the appliance or on any external SAML IdP.

When used as a SAML SP, a Citrix ADC appliance:

- Can extract the user information (attributes) from the SAML token. This information can then be used in the policies that are configured on the Citrix ADC appliance. For example, if you want to extract the GroupMember and emailaddress attributes, in the SAMLAction, specify the **Attribute2** parameter as GroupMember and the **Attribute3** parameter as emailaddress.

  > **Note**
  >
  > Default attributes such as username, password, and logout URL must not be extracted in attributes 1–16, because they as are implicitly parsed and stored in the session.

- Can extract attribute names of up to 127 bytes from an incoming SAML assertion. The previous limit was 63 bytes.
- Supports post, redirect, and artifact bindings.

  > **Note**
  >
  > Redirect binding should not be used for large amount of data, when the assertion after inflate or decoding is greater than 10K.

- Can decrypt assertions.
- Can extract multi-valued attributes from a SAML assertion. These attributes are sent is nested XML tags such as:

  <AttributeValue> <AttributeValue>Value1</AttributeValue>
  <AttributeValue>Value2</AttributeValue>
  </AttributeValue>

  > **Note**
  >
  > From Citrix ADC 13.0 Build 63.x and above, the individual maximum length for SAML attributes has been increased to allow a maximum of 40k bytes. The size of all the attributes must not exceed 40k bytes.

When presented with previous XML, the Citrix ADC appliance can extract both Value1 and Value2 as values of a given attribute, as opposed to the old firmware that extracts only Value1.

- Can specify the validity of a SAML assertion.

  If the system time on Citrix ADC SAML IdP and the peer SAML SP is not in sync, the messages might get invalidated by either party. To avoid such cases, you can now configure the time duration for which the assertions are valid.

  This duration, called the "skew time," specifies the number of minutes for which the message should be accepted. The skew time can be configured on the SAML SP and the SAML IdP.

- Can send extra attribute called 'ForceAuth' in the authentication request to external IdP (Identity Provider). By default, the ForceAuthn is set to 'False'. It can be set to 'True' to suggest IdP to force authentication despite existing authentication context. Also, Citrix ADC SP does authentication request in query parameter when configured with artifact binding.

To configure the Citrix ADC appliance as a SAML SP by using the command line interface

1. Configure a SAML SP action.

   Example

   The following command adds a SAML action that redirects unauthenticated user requests.

   ```
   add authentication samlAction SamlSPAct1 -samlIdPCertName nssp -samlSigningCertNa
    nssp -samlRedirectUrl https://auth1.example.com -relaystateRule "AAA.
   LOGIN.RELAYSTATE.EQ(\"https://lb.example1.com/\")"
   ```

   Points to note

   - Certificate provided for `-samlIdPCertName` in the samlAction command must match the corresponding certificate from IdP for the signature verification to succeed.
   - SAML supports only RSA certificate. Other certificates like HSM, FIPS, and so on are not supported.
   - Citrix recommends to have a full domain name with trailing '/' in the expression.
   - Administrators must configure an expression for **relaysStateRule** in the samlAction command. The expression must contain the list of published domains that the user connects to before being redirected to the authentication virtual server. For example, the expression must contain the domains of the front-end virtual server (VPN, LB, or CS) that use this SAML action for authentication.

   For more details on the command, see https://developer-docs.citrix.com/projects/citrix-adc-command-reference/en/latest/authentication/authentication-samlAction and https://support.citrix.com/article/CTX316577.

2. Configure the SAML policy.

   Example

   The following command defines a SAML policy that applies the previously defined SAML action to all traffic.

   ```
   add authentication policy SamlSPPol1 -rule true -action SamlSPAct1
   ```

3. Bind the SAML policy to the authentication virtual server.

   Example

   The following command binds the SAML policy to an authentication virtual server named "av_saml".

   ```
   bind authentication vserver av_saml -policy SamlSPPol1
   ```

4. Bind the authentication virtual server to the appropriate traffic management virtual server.

   Example

   The following command adds a load balancing virtual server named "lb1_ssl" and associates the authentication virtual server named "av_saml" to the load balancing virtual server.

   ```
   add lb vserver lb1_ssl SSL 10.217.28.224 443 -persistenceType NONE -
   cltTimeout 180 -AuthenticationHost auth1.example.com -Authentication ON
    -authnVsName av_saml
   ```

   For more details on the command, see https://developer-docs.citrix.com/projects/citrix-adc-command-reference/en/latest/authentication/authentication-samlAction

To configure a Citrix ADC appliance as a SAML SP by using the GUI

1. Navigate to **Security>AAA-Policies>Authentication>Basic Policies>SAML**.
2. Select **Servers** tab, click **Add**, enter values for the following parameters, and click **Create**.

   Parameter description:

   Name - Name of the server

   Redirect URL - URL that users will authenticate against. Some IdP's have special URLs that are not reachable unless under SAML setup.

   Single Logout URL - URL specified so that the Citrix ADC can recognize when to send the client back to the IdP to complete the Sign out process. We will not use it in this simple deployment.

   SAML Binding - Method that is be used to move the client from the SP to the IdP. This needs to be the same on the IdP so that it understands how the client will connect to it.
   When the Citrix ADC acts as an SP, it supports POST, REDIRECT and ARTIFACT bindings.

Logout Binding - REDIRECT

IDP Certificate Name - IdPCert Certificate (Base64) present under SAML Signing Certificate.

User Field - Section of the IdP's SAML authentication form that contains the username for SP to extract if required.

Signing Certificate Name - Select the SAML SP certificate (with private key) that Citrix ADC uses to sign authentication requests to the IdP. The same certificate (without private key) must be imported to the IdP, so that the IdP can verify the authentication request signature. This field is not needed by most IdPs.

IssuerName - Identifier. Unique ID that is specified on both the SP and IdP to help identify the Service Provider to each other.

Reject unsigned assertion - Option that you can specify if you require the Assertions from the IdP to be signed. You can ensure that only the Assertion needs to be signed (ON) or both the Assertion and Response from the IdP need to be signed (STRICT).

Audience - Audience for which assertion sent by IdP is applicable. This is typically entity name or URL that represents ServiceProvider.

Signature Algorithm - RSA-SHA256

Digest Method - SHA256

Default Authentication Group - The default group that is chosen when the authentication succeeds in addition to extracted groups.

Group Name Field - Name of the tag in assertion that contains user groups.

Skew Time (mins) - This option specifies the allowed clock skew in number of minutes that Citrix ADC ServiceProvider allows on an incoming assertion.

3. Similarily, create a corresponding SAML policy and bind it to the authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and associate the SAML policy with the authentication virtual server.

4. Associate the authentication server with the appropriate traffic management virtual server.

   Navigate to **Traffic Management > Load Balancing** (or **Content Switching**) > **Virtual Servers**, select the virtual server, and associate the authentication virtual server with it.

Citrix ADC as a SAML IdP

September 14, 2021

The SAML IdP (Identity Provider) is a SAML entity that is deployed on the customer network. The IdP receives requests from the SAML SP and redirects users to a logon page, where they must enter their credentials. The IdP authenticates these credentials with the active directory (external authentication server, such as LDAP) and then generates a SAML assertion that is sent to the SP.

The SP validates the token, and the user is then granted access to the requested protected application.

When the Citrix ADC appliance is configured as an IdP, all requests are received by an authentication virtual server that is associated with the relevant SAML IdP profile.

> **Note**
>
> A Citrix ADC appliance can be used as a IdP in a deployment where the SAML SP is configured either on the appliance or on any external SAML SP.

When used as a SAML IdP, a Citrix ADC appliance:

- Supports all authentication methods that it supports for traditional logons.
- Digitally signs assertions.
- Supports single-factor and two-factor authentication. SAML must not be configured as the secondary authentication mechanism.
- Can encrypt assertions by using the public key of the SAML SP. This is recommended when the assertion includes sensitive information.
- Can be configured to accept only digitally signed requests from the SAML SP.
- Can log on to the SAML IdP by using the following 401-based authentication mechanisms: Negotiate, NTLM, and Certificate.
- Can be configured to send 16 attributes in addition to the NameId attribute. The attributes must be extracted from the appropriate authentication server. For each of them, you can specify the name, the expression, the format, and a friendly name in the SAML IdP profile.
- If the Citrix ADC appliance is configured as a SAML IdP for multiple SAML SP, a user can gain access to applications on the different SPs without explicitly authenticating every time. The Citrix ADC appliance creates a session cookie for the first authentication, and every subsequent request uses this cookie for authentication.
- Can send multi-valued attributes in a SAML assertion.
- Supports post and redirect bindings. Support for artifact binding is introduced in Citrix ADC release 13.0 Build 36.27.
- Can specify the validity of a SAML assertion.

  If the system time on Citrix ADC SAML IdP and the peer SAML SP is not in sync, the messages might get invalidated by either party. To avoid such cases, you can now configure the time duration for which the assertions are valid.

This duration, called the “skew time,” specifies the number of minutes for which the message must be accepted. The skew time can be configured on the SAML SP and the SAML IdP.

- Can be configured to serve assertions only to SAML SPs that are pre-configured on or trusted by the IdP. For this configuration, the SAML IdP must have the service provider ID (or issuer name) of the relevant SAML SPs.

> **Note**
>
> Before proceeding, make sure that you have an authentication virtual server that is linked to an LDAP authentication server.

To configure a Citrix ADC appliance as a SAML IdP by using the command line interface

1. Configure a SAML IdP profile.

   Example

   Adding Citrix ADC appliance as an IdP with SiteMinder as the SP.

```
add authentication samlIdPProfile samlIDPProf1 -samlSPCertName siteminder
-cert -encryptAssertion ON -samlIdPCertName ns-cert -assertionConsumerServiceURL
 http://sm-proxy.nsi-test.com:8080/affwebservices/public/saml2assertionconsumer
 -rejectUnsignedRequests ON -signatureAlg RSA-SHA256 -digestMethod
SHA256 -acsUrlRule AAA.LOGIN.SAML_REQ_ACS_URL.REGEX_MATCH(re##^https://
example2\.com/cgi/samlauth$##)
```

   Points to note

   - In SAML IdP profile, configure **acsURLRule** that takes an expression of the list of applicable service provider URLs for this IdP. This expression depends on the SP being used. If Citrix ADC is configured as SP, ACS URL will be `https://<SP-domain_name>/cgi/samlauth`. Citrix recommends having a full URL in the expression for matching.
   - SAML supports only RSA certificate. Other certificates like HSM, FIPS, and so on are not supported.
   - You must specify the starting of the domain with “^” sign (example: ^https) along with the dollar sign “$” at the end of the string (example: samlauth$).

   For more details on the command, see https://developer-docs.citrix.com/projects/citrix-adc-command-reference/en/latest/authentication/authentication-samlAction and https://support.citrix.com/article/CTX316577.

2. Configure the SAML authentication policy and associate the SAML IdP profile as the action of the policy.

```
add authentication samlIdPPolicy samlIDPPol1 -rule true -action samlIDPProf1
```

3. Bind the policy to the authentication virtual server.

   ```
   bind authentication vserver saml-auth-vserver -policy samlIDPPol1 -
   priority 100
   ```

   For more details on the command, see https://developer-docs.citrix.com/projects/citrix-adc-command-reference/en/latest/authentication/authentication-samlIdPProfile.

To configure a Citrix ADC appliance as a SAML IdP by using the GUI

1. Navigate to **Security>AAA-Policies>Authentication>Advanced Policies>SAML IdP**.
2. Select **Servers** tab, click **Add**, enter values for the following parameters, and click **Create**.

   Parameter description:

   Assertion Consumer Service URL - URL that the authenticated user will be redirected to.

   IdP Certificate Name - Certificate-Key pair used for the authentication page.

   SP Certificate Name - Certificate of the Service Provider in this scenario, the key is not required for this.

   Sign Assertion - The option to sign the assertion and the response when redirecting the client back to the Service Provider.

   Issuer Name - Identifier. Unique ID that is specified on both the SP and IdP to help identify the Service Provider to each other.

   Service Provider ID - Unique ID that will be specified on both the SP and IdP to help identify the Service Provider to each other. This can be anything and does not need to be the URL as specified below, but needs to be the same on both the SP and IdP profiles.

   Reject Unsigned Requests - Option you can specify to ensure only assertions signed with the SP Certificate are accepted.

   Signature Algorithm - Algorithm used to sign and verify the assertions between the IdP and SP, this needs to be the same on both the IdP and SP profiles.

   Digest Method - Algorithm used to verify the integrity of the Assertions between the IdP and SP, this needs to be the same on both the IdP and SP profiles.

   SAML Binding - Same as described in the SP profile, it needs to be the same on both the SP and IdP.

3. Associate the SAML IdP policy with an authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and associate the SAML IdP policy with the authentication virtual server.

Configure SAML single sign-on

November 8, 2021

To provide single sign-on capabilities across applications that are hosted on the service provider, you can configure SAML single sign-on on the SAML SP.

Configuring SAML single sign-on by using the command line interface

1. Configure the SAML SSO profile.

   Example

   In the following command, Example is the load balancing virtual server that has a web link from the SharePoint portal. Nssp.example.com is the Traffic Management virtual server that is load balancing the SharePoint server.

   ```
   add tm samlSSOProfile tm-saml-sso -samlSigningCertName nssp -
       assertionConsumerServiceURL "https://nssp2.example.com/cgi/
       samlauth" -relaystateRule "\\"https://nssp2.example.com/
       samlsso.html\\"" -sendPassword ON -samlIssuerName nssp.example
       .com
   <!--NeedCopy-->
   ```

2. Associate the SAML SSO profile with the traffic action.

   Example

   The following command enables SSO and binds the SAML SSO profile created above to a traffic action.

   ```
   add tm trafficAction html_act -SSO ON -samlSSOProfile tm-saml-sso
   <!--NeedCopy-->
   ```

3. Configure the traffic policy that specifies when the action must be executed.

   Example

   The following command associates the traffic action with a traffic policy.

   ```
   add tm trafficPolicy html_pol "HTTP.REQ.URL.CONTAINS(\\"abc.html\\
       ")" html_act
   <!--NeedCopy-->
   ```

4. Bind the traffic policy created previously to a traffic management virtual server (load balancing or content switching). Alternatively, the traffic policy can be associated globally.

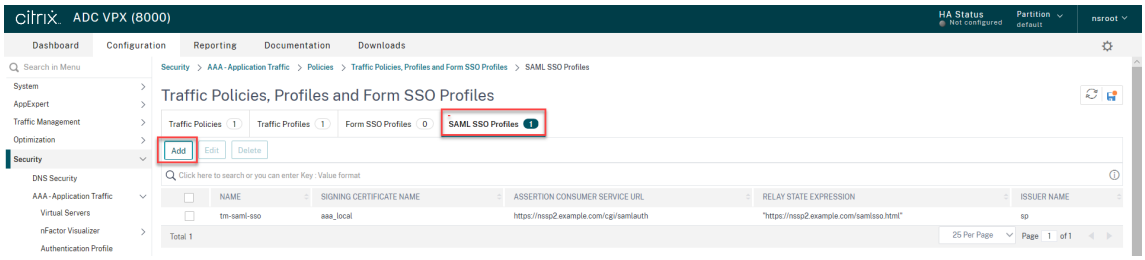
> **Note**
>
> This traffic management virtual server must be associated with the relevant authentication virtual server that is associated with the SAML action.

```
bind lb vserver lb1_ssl -policyName html_pol -priority 100 -
    gotoPriorityExpression END -type REQUEST
<!--NeedCopy-->
```

Configuring SAML single sign-on by using the GUI

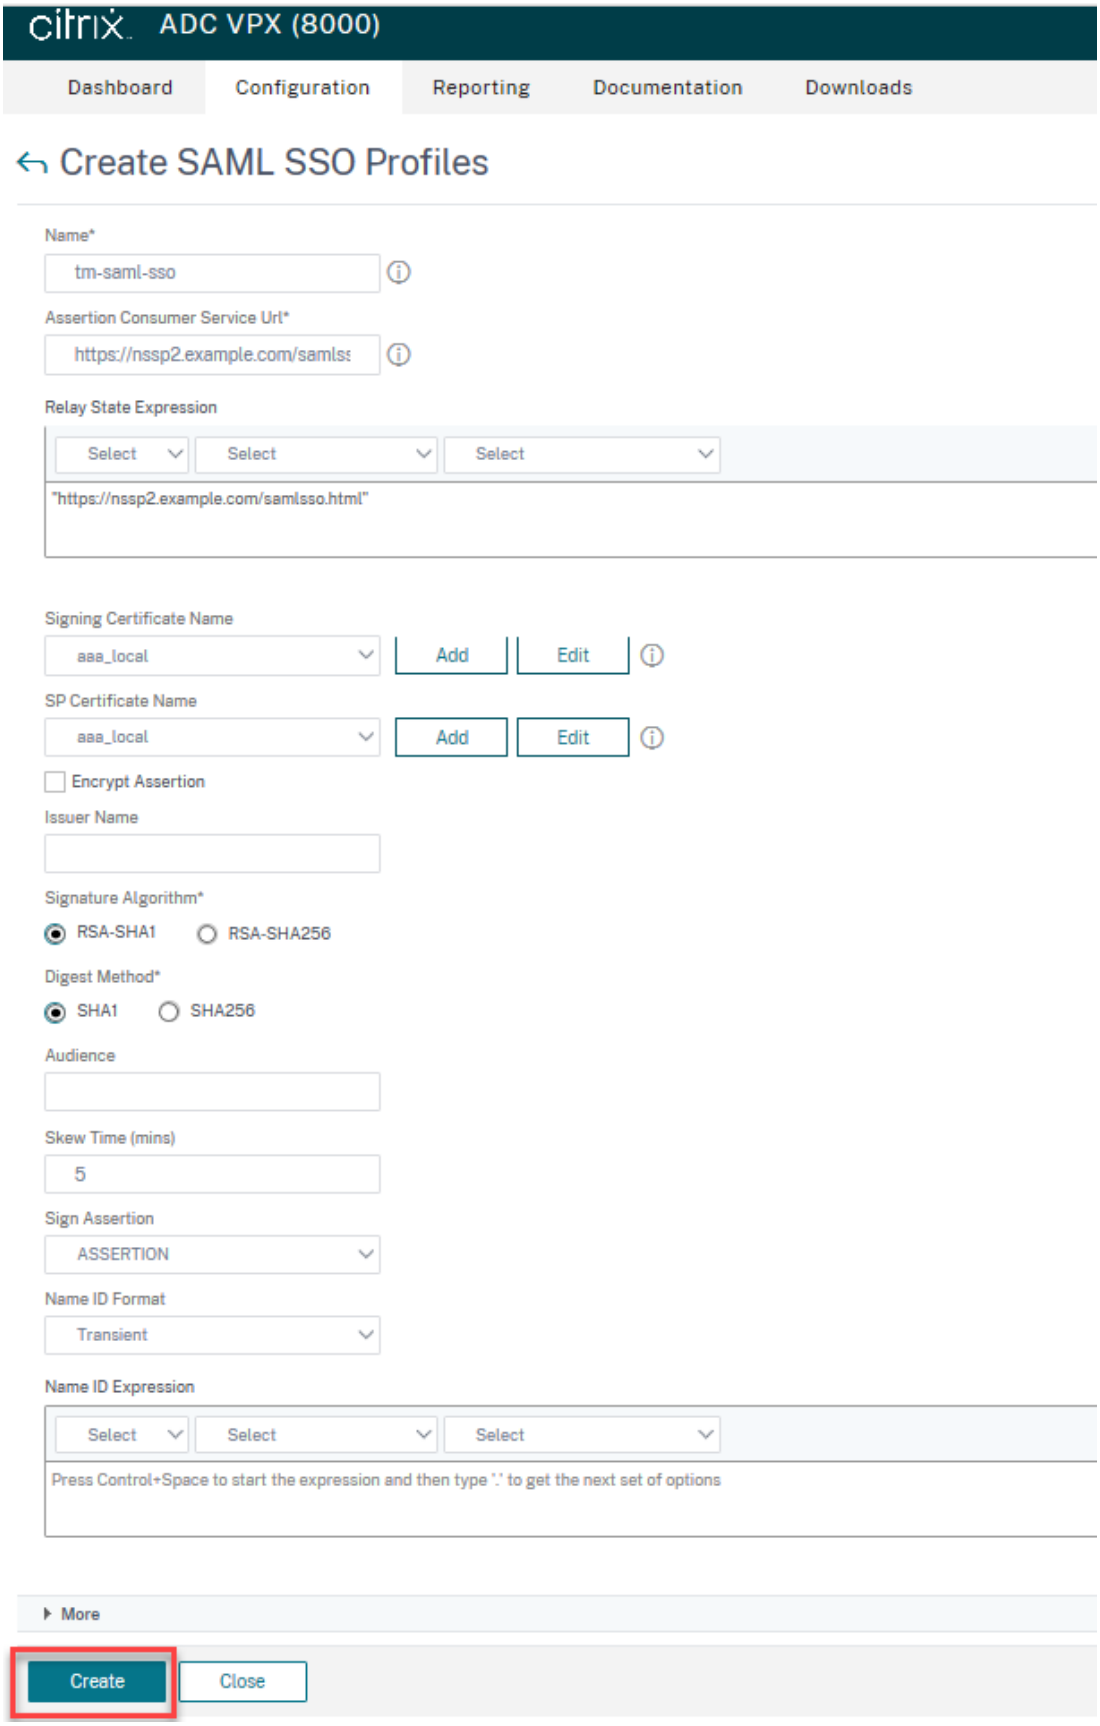
To configure SAML single sign-on you need to define the SAML SSO profile, the traffic profile, and the traffic policy and bind the traffic policy to a traffic management virtual server or globally to the Citrix ADC appliance.

1. Navigate to **Security > AAA-Application Traffic > Policies > Traffic > SAML SSO Profiles** and click **Add**.

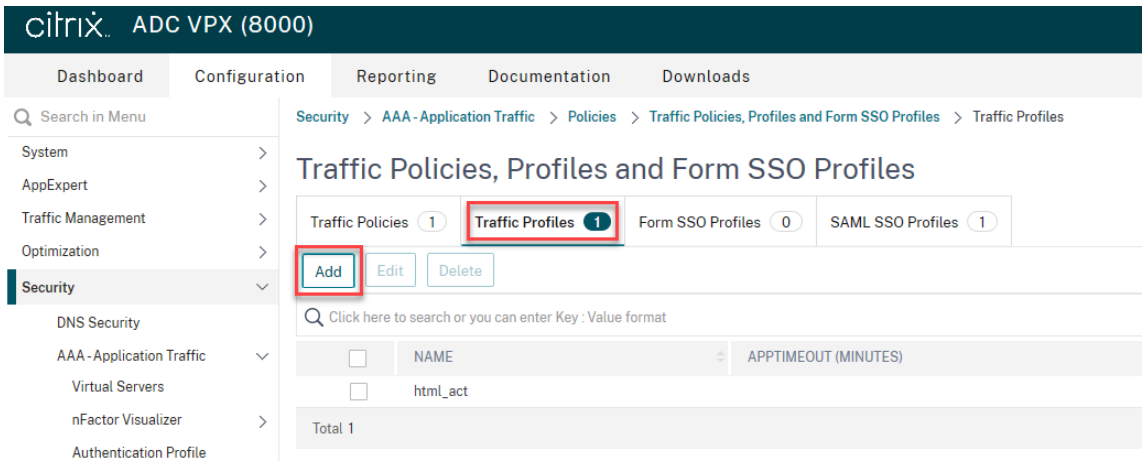


2. On the **Create SAML SSO Profiles** page, enter values for the following fields and click **Create**.
   - Name - Name for the SAML SSO Profile
   - Assertion Consumer Service Url - URL to which the assertion is to be sent
   - Signing Certificate Name - Name of the SSL certificate that is used to Sign Assertion
   - SP Certificate Name - Name of the SSL certificate of a peer/receiving party using which Assertion is encrypted
   - Issuer Name - The name to be used in requests sent from Citrix ADC to IdP to uniquely identify Citrix ADC
   - Signature Algorithm - Algorithm to be used to sign/verify SAML transactions
   - Digest Method - Audience for which assertion sent by IdP is applicable. This is typically entity name or url that represents a ServiceProvider
   - Audience - Audience for which an assertion sent by IdP is applicable. This is typically an entity name or url that represents a ServiceProvider
   - Skew Time (mins) - The number of minutes on either side of current time that the assertion would be valid
   - Sign Assertion - Option to sign portions of assertion when Citrix ADC IDP sends one. Based on the user selection, either Assertion or Response or Both or none can be signed.

- Name ID Format - Format of Name Identifier sent in Assertion
- Name ID Expression - Expression that will be evaluated to obtain NameIdentifier to be sent in assertion

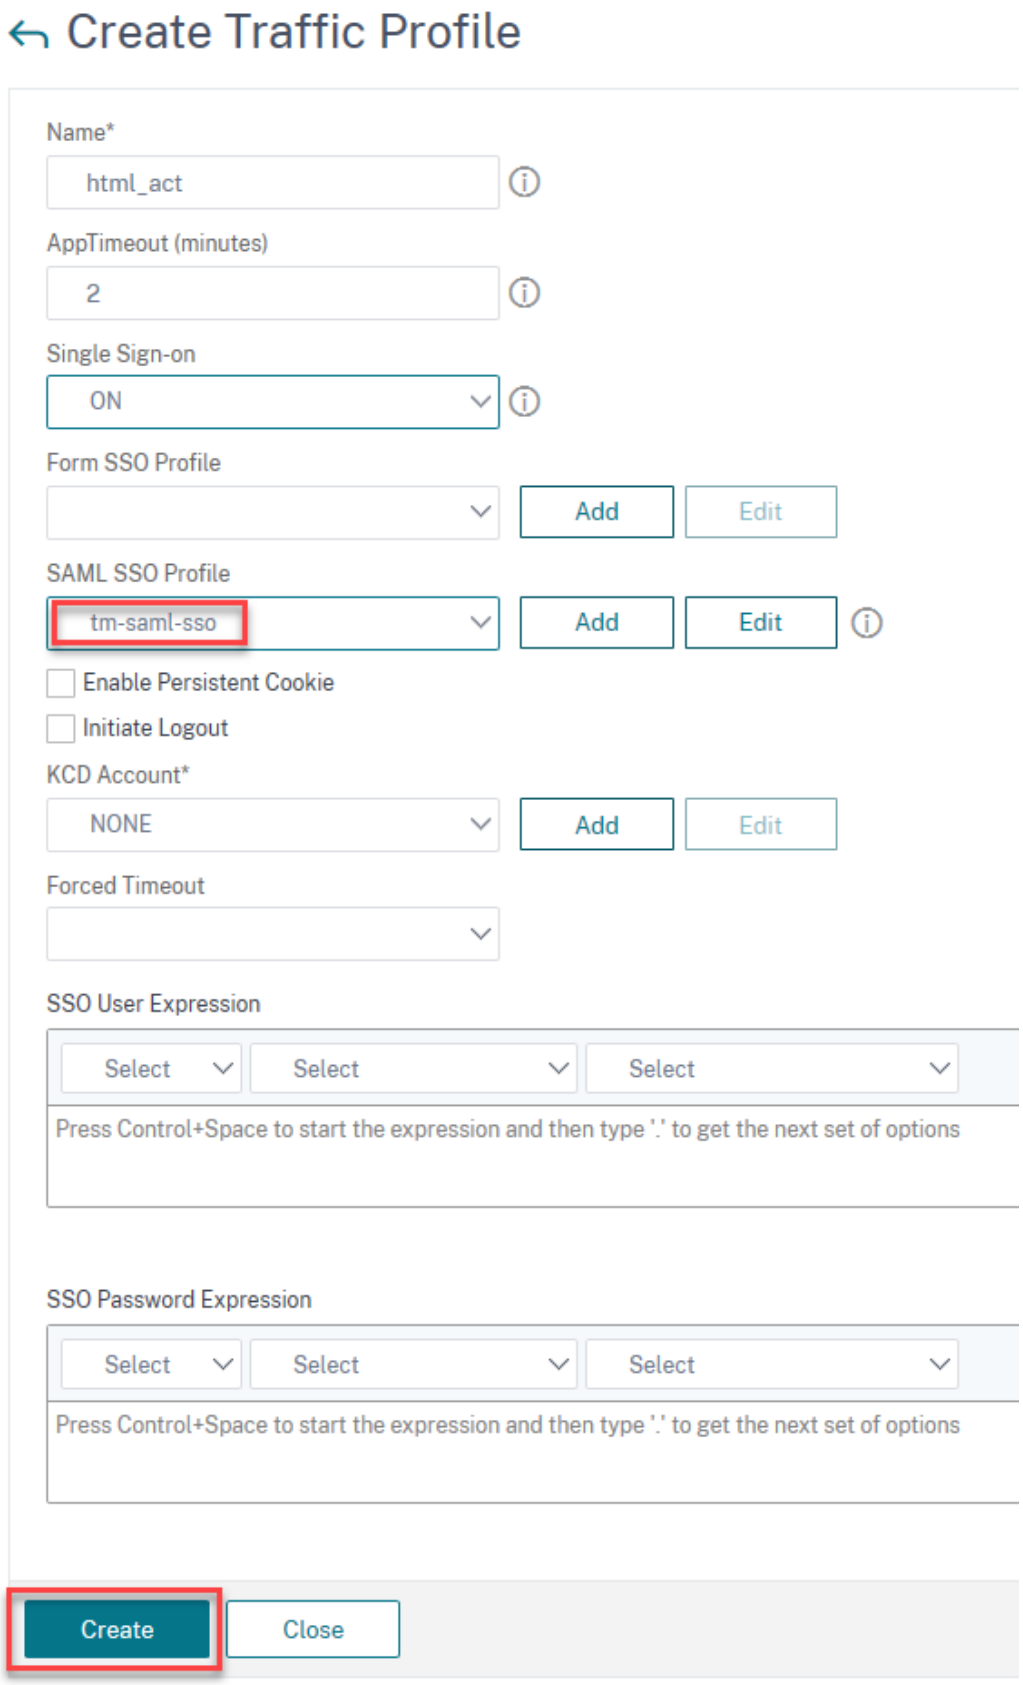


3. Navigate to **Security > AAA-Application Traffic > Policies>Traffic > Traffic Profiles** and click **Add**.

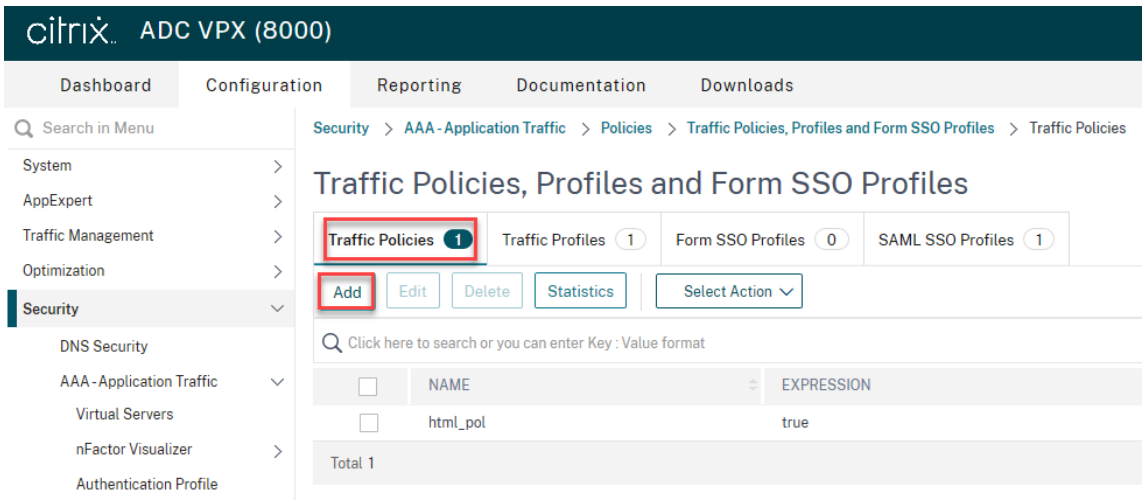


4. On the **Create Traffic Profile** page, enter values for the following fields, and click **Create**.

   - Name - Name for the traffic action.
   - AppTimeout (minutes) - Time interval, in minutes, of user inactivity after which the connection is closed.
   - Single Sign-on - Select ON
   - SAML SSO Profile - Select the created SAML SSSO Profile
   - KCD Account - Kerberos constrained delegation account name
   - SSO User Expression - Expression that will be evaluated to obtain user name for Single-SignOn
   - SSO Password Expression - Expression that will be evaluated to obtain password for SingleSignOn

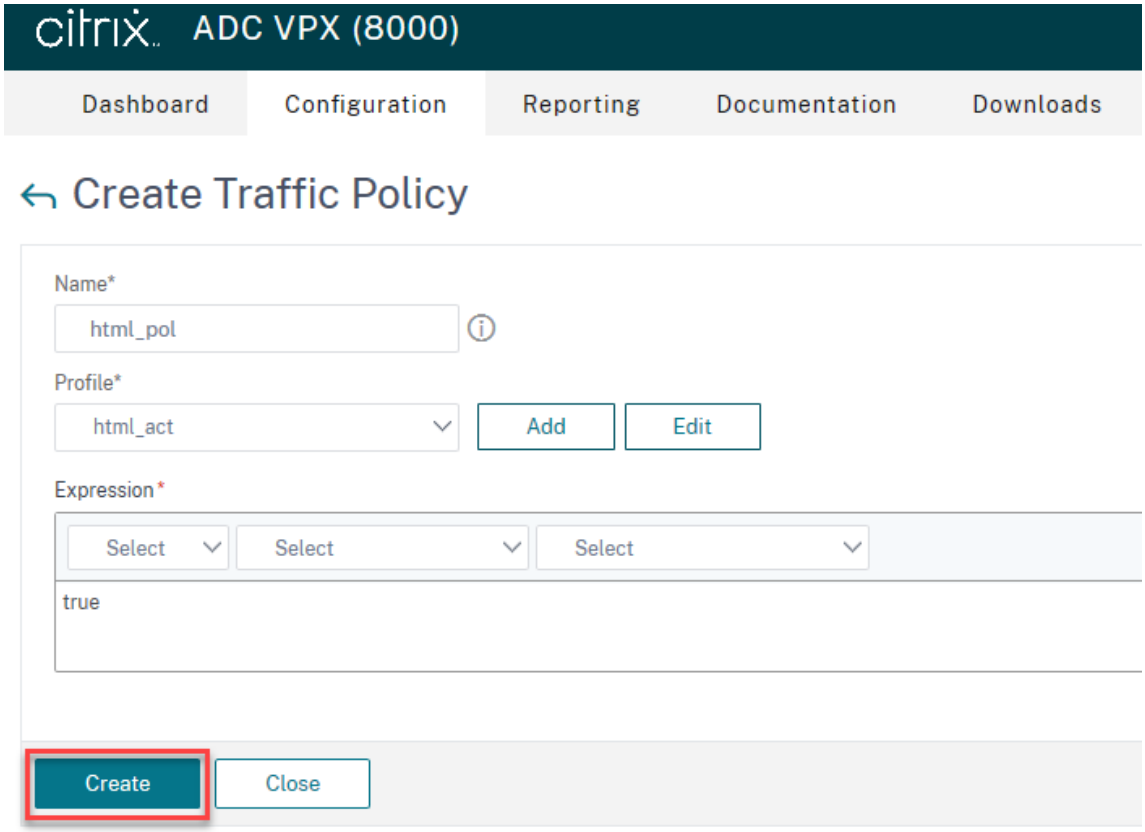


5. Navigate to **Security > AAA-Application Traffic > Policies > Traffic > Traffic Policies** and click **Add**.

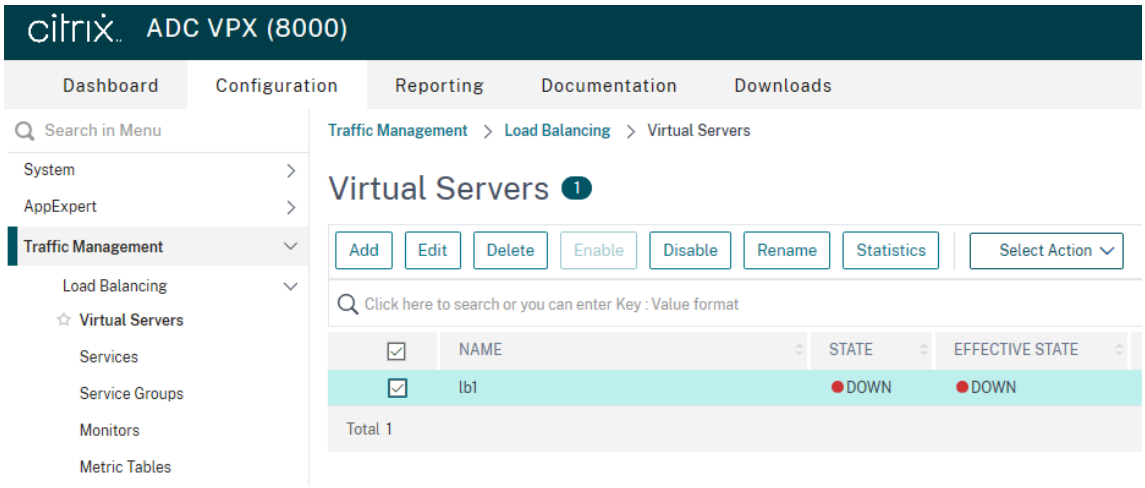


6. On the **Create Traffic policy** page, enter values for the following, and click **Create**.

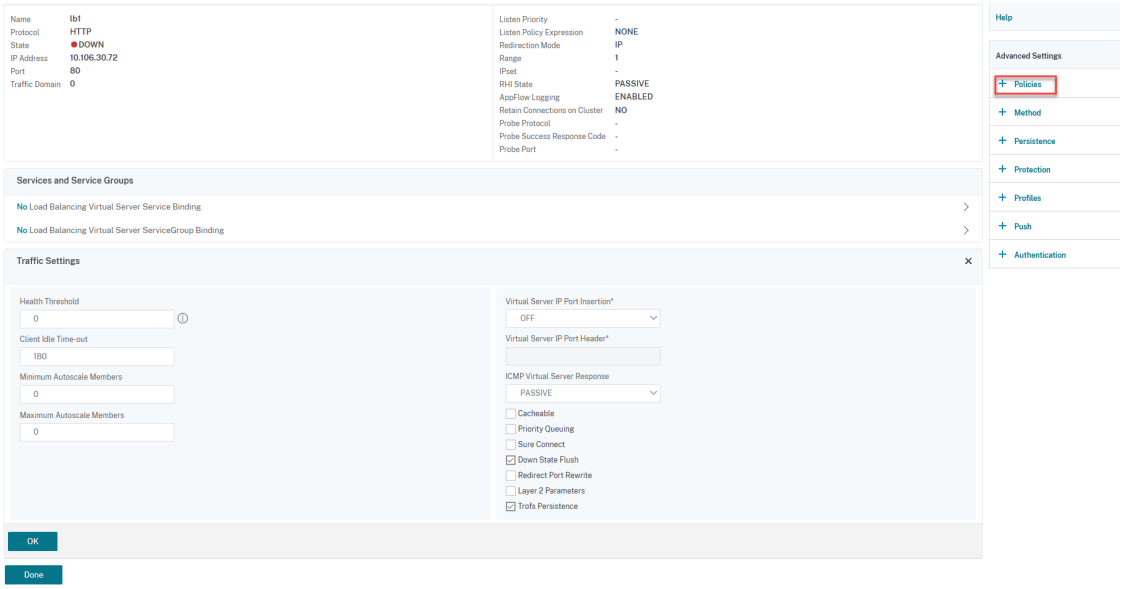
   - Name – Name of the traffic policy to be created
   - Profile – Select the created Traffic profile
   - Expression – Default syntax expression that the policy uses to respond to specific request. For example, true.



7. To bind the traffic policy to a traffic management virtual server, select a virtual server.



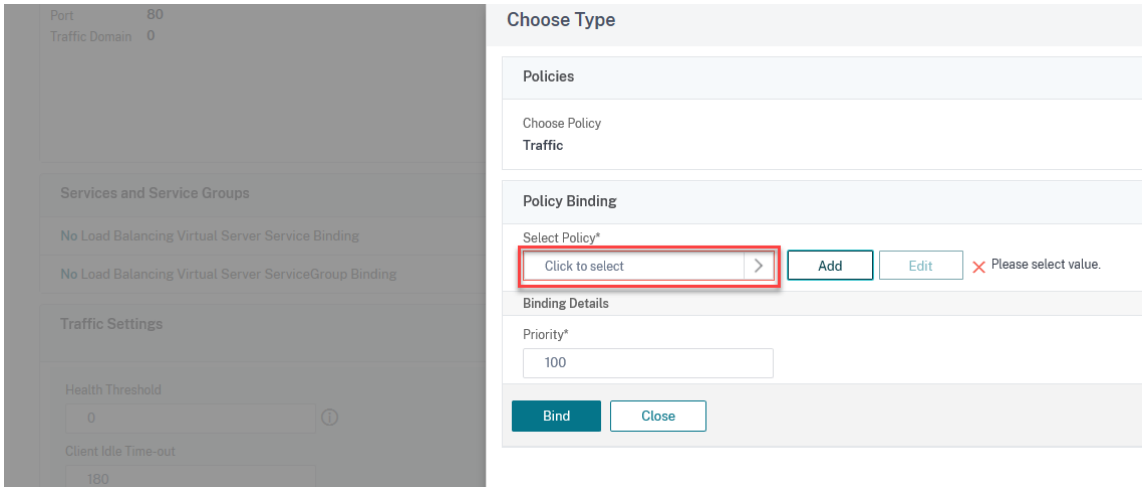
8. Click **Policies**.



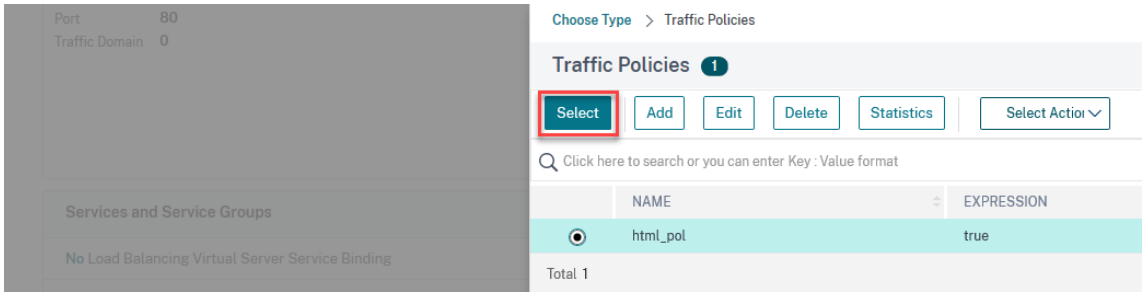
9. Select **Traffic** in the **Choose Policy** field and select **Request** in the **Choose Type** field, and click **Continue**.

   ![Click to add policy(/en-us/citrix-adc/media/saml-9.png)

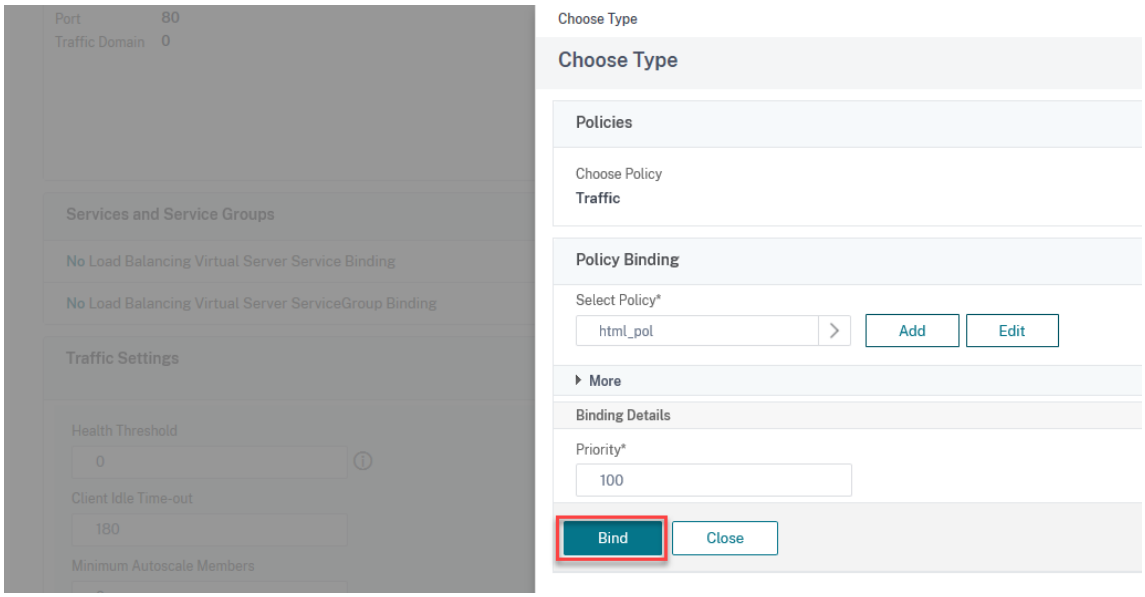
10. Under **Select Policy** field, click to select the created traffic .



11. Click **Select**.



12. Click **Bind** to bind the traffic policy to the virtual server.



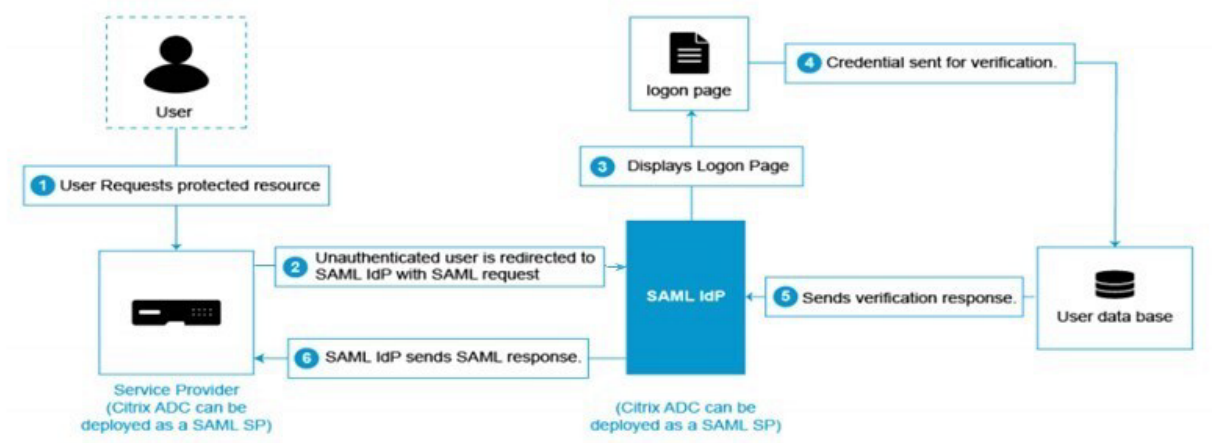
Configure Azure AD as SAML IdP and Citrix ADC as SAML SP

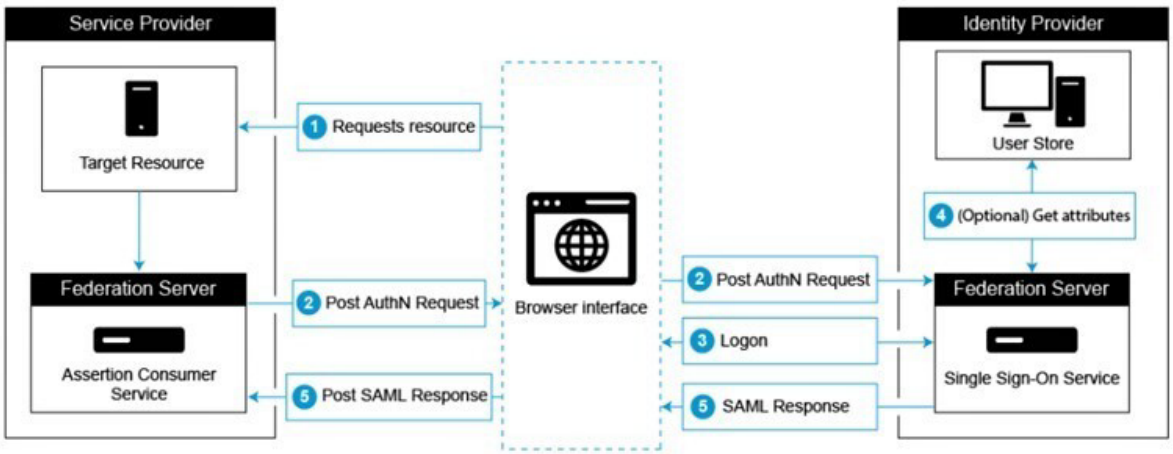
September 14, 2021

The SAML Service Provider (SP) is a SAML entity that is deployed by the service provider. When a user tries to access a protected application, the SP evaluates the client request. If the client is unauthenticated (does not have a valid NSC_TMAA or NSC_TMAS cookie), the SP redirects the request to the SAML Identity Provider (IdP). The SP also validates SAML assertions that are received from the IdP.

The SAML IdP (Identity Provider) is a SAML entity that is deployed on the customer network. The IdP receives requests from the SAML SP and redirects users to a logon page, where they must enter their credentials. The IdP authenticates these credentials with the user directory (external authentication server, such as LDAP) and then generates a SAML assertion that is sent to the SP. The SP validates the token, and the user is then granted access to the requested protected application.

The following diagram depicts the SAML authentication mechanism.

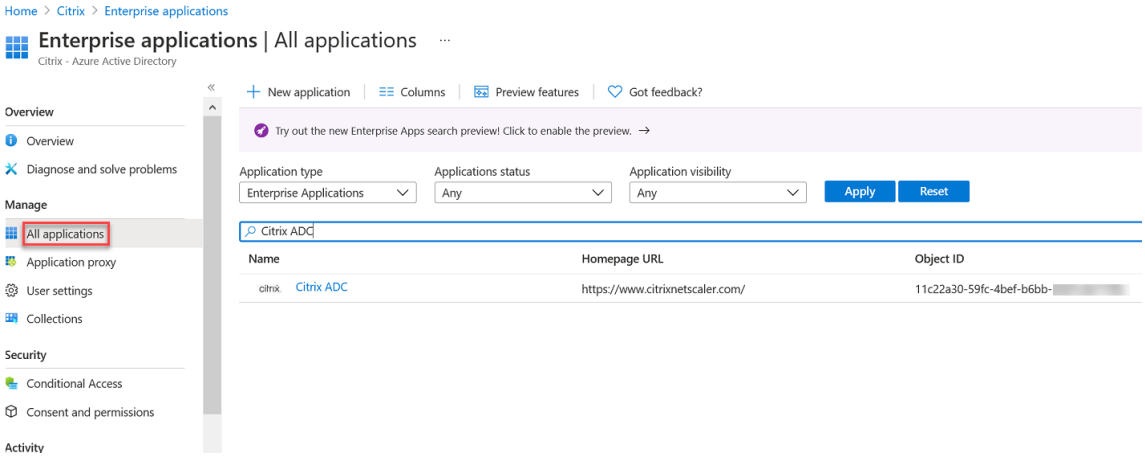




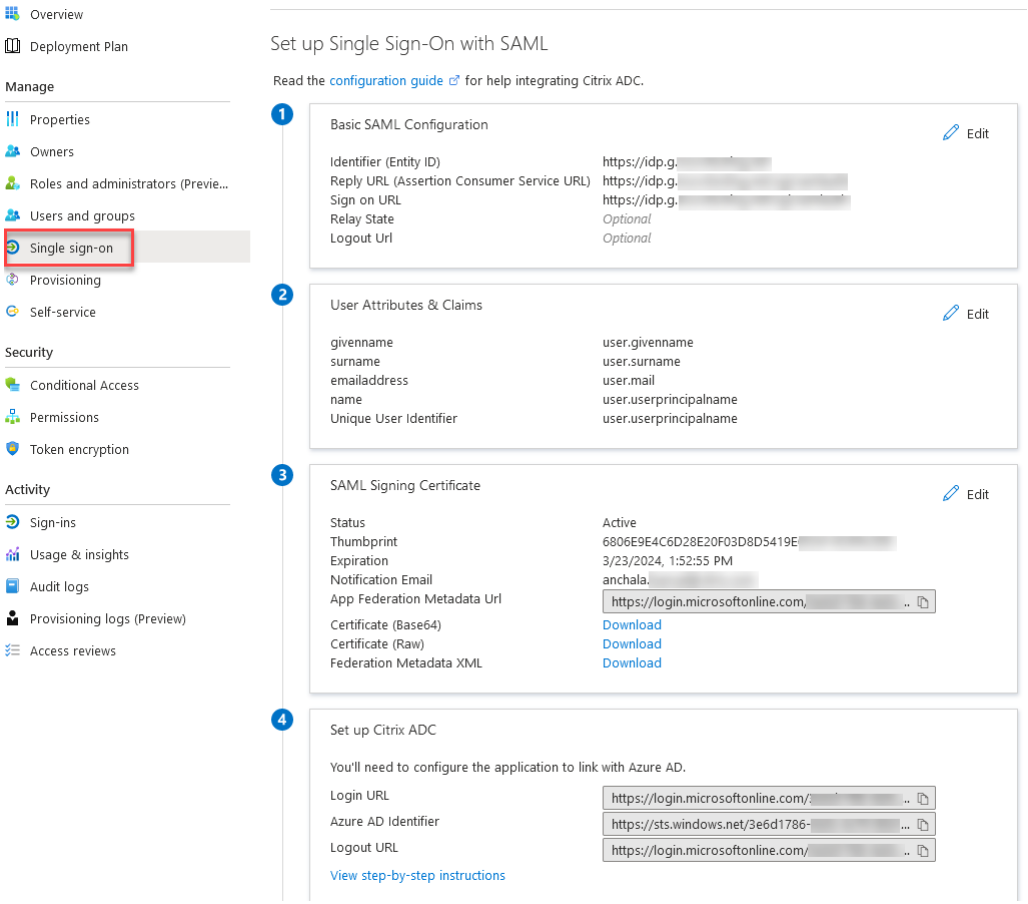
Azure AD side configurations

Configure single sign-on settings:

1. On the Azure portal, click **Azure Active Directory**.
2. Under **Manage** section in the navigation pane, click **Enterprise Applications**. A random sample of the applications in your Azure AD tenant appears.
3. In the search bar, enter Citrix ADC.



4. Under the **Manage** section, select **Single sign-on**.
5. Select **SAML** to configure single sign-on. The **Set up Single Sign-On with SAML - Preview** page appears. Here, Azure is acting as a SAML IdP.
6. Download certificate (Base64) present under **SAML Signing Certificate** to be used as samlidPCertName while configuring Citrix ADC as SAML SP.



7. **Configure basic SAML options:**

   Identifier (Entity ID) - Required for some apps. Uniquely identifies the application for which single sign-on is being configured. Azure AD sends the identifier to the application as the audience parameter of the SAML token. The application is expected to validate it. This value also appears as the Entity ID in any SAML metadata provided by the application.

   Reply URL - Mandatory. Specifies where the application expects to receive the SAML token. The reply URL is also referred as the Assertion Consumer Service (ACS) URL.

   Sign-on URL - When a user opens this URL, the service provider redirects to Azure AD to authenticate and sign on the user.

   Relay State - Specifies to the application where to redirect the user after the authentication is complete.

Citrix ADC side configurations

1. Navigate to **Security>AAA-Policies>Authentication>Basic Policies>SAML**.
2. Select **Servers** tab, click **Add**, enter values for the following parameters, and click **Create**.

Parameter description:

The value for parameters in bold needs to be taken from the Azure side configurations.

Name - Name of the server

Redirect URL - Enter the login URL used previously in the Azure AD “Setup Citrix ADC” section. `https://login.microsoftonline.com/3e6d1786-4e0c-4c70-86d2-ae7811f97f79/saml2`

Single Logout URL - `https://login.microsoftonline.com/3e6d1786-4e0c-4c70-86d2-ae7811f97f79/saml2`

SAML Binding - POST

Logout Binding - REDIRECT

IDP Certificate Name - IdPCert Certificate (Base64) present under SAML Signing Certificate.

User Field - userprincipalName. Taken from “User Attributes and Claims” section of Azure IdP.

Signing Certificate Name - Not needed for Azure AD. Select the SAML SP certificate (with private key) that Citrix ADC uses to sign authentication requests to the IdP. The same certificate (without private key) must be imported to the IdP, so that the IdP can verify the authentication request signature. This field is not needed by most IdPs.

IssuerName - Identifier. `https://idp.g.nssvctesting.net`

Reject unsigned assertion - ON

Audience - Audience for which assertion sent by IdP is applicable. This is typically entity name or URL that represents ServiceProvider.

Signature Algorithm - RSA-SHA256

Digest Method - SHA256

Default Authentication Group - The default group that is chosen when the authentication succeeds in addition to extracted groups.

Group Name Field - Name of the tag in assertion that contains user groups.

Skew Time (mins) - This option specifies the allowed clock skew in number of minutes that Citrix ADC ServiceProvider allows on an incoming assertion.

Two factor - OFF

Requested Authentication Context - exact

Authentication Class Type - None

Send Thumbprint - OFF

Enforce Username - ON

Force Authentication - OFF

Store SAML Response - OFF

Similarily, create a corresponding SAML policy and bind it to the authentication virtual server.

Note: Azure AD does not expect the Subject ID field in the SAML request. For Citrix ADC to not send the Subject ID field, type the following command on the Citrix ADC command prompt.

```
nsapimgr_wr.sh -ys call="ns_saml_dont_send_subject"
```

Additional features supported for SAML

September 14, 2021

The following features are suported for SAML.

Metadata reading and generation support for SAML SP and IdP configuration

Citrix ADC appliance now supports metadata files as means of configuration entities for both SAML Service Provider (SP) and Identity Provider (IdP). The metadata file is a structured XML file that describes the configuration of an entity. The metadata files for SP and IdP are separate. Based on deployment, and at times, one SP or IdP entity can have multiple metadata files.
As an administrator, you can export and import (SAML SP and IdP) metadata files on Citrix ADC.
The functionality of metadata export and import for SAML SP and IdP are explained in the following sections.

Metadata export for SAML SP

Consider an example where Citrix ADC is configured as SAML SP and an SAML IdP would like to import metadata that contains Citrix ADC SP configuration. Assume that Citrix ADC appliance is already configured with a “samlAction” attribute that specifies SAML SP configuration.

To export metadata from users or administrator, query Citrix Gateway or authentication virtual server as shown below:

```
1 https://vserver.company.com/metadata/samlsp/<action-name>
```

Metadata import for SAML SP

Currently, SAML Action configuration on Citrix ADC appliance takes various parameters. Administrator manually specifies these. However, administrators are often unaware of nomenclature if it comes

to interop with different SAML systems. If metadata of IdP is available, then bulk of the configuration in the 'samlAction' entity can be avoided. In fact, the entire IdP specific configuration might be omitted if IdP metadata file is given. The 'samlAction' entity now takes an additional parameter to read configuration from metadata file.

When you import a metadata in a Citrix ADC appliance, the metadata does not contain any signature algorithms to be used, it contains the endpoint details. A metadata can be signed with certain algorithms which can be used to verify the metadata itself. The algorithms are not stored in the 'samlAction' entity.

Therefore, what you specify in the 'samlAction' entity are the ones used when sending the data out. An incoming data can contain a different algorithm for a Citrix ADC appliance to process.

To fetch the metadata files by using command line interface.

```
set samlAction <name> [-metadataUrl <url> [-metadataRefreshInterval <
    int>] https://idp.citrix.com/samlidp/metadata.xml
```

> **Note**
>
> The metadataRefreshInterval parameter is the interval in minutes for fetching metadata information from the specified metadata URL. Default value 36000.

Metadata import for SAML IdP

The "samlIdPProfile" parameter takes a new argument to read the entire configuration that is specific to SP. SAML IdP configuration can be simplified by replacing SP specific properties with an SP metadata file. This file is queried through HTTP.

To read from metadata file using command line interface:

```
set samlIdPProfile <name> [-metadataUrl <url>] [-
    metadataRefreshInterval <int>]
```

Name-value attribute support for SAML authentication

You can now configure SAML authentication attributes with a unique name along with values. The names are configured in the SAML action parameter and the values are obtained by querying for the names. By specifying the name attribute value, admins can easily search for the attribute value associated with the attribute name. Also, admins no longer have to remember the attribute by its value alone.

> **Important**
>
> - In samlAction command, you can configure a maximum of 64 attributes separated by comma with total size less than 2048 bytes.
> - Citrix recommends that you use the attributes list. Use of “attribute 1 to attribute 16” will cause session failure if the extracted attribute size is large.

To configure the name-value attributes by using the CLI

At the command prompt, type:

```
add authentication samlAction <name> [-Attributes <string>]
```

Example:

```
add authentication samlAction samlAct1 -attributes  “mail,sn,
   userprincipalName”
```

Assertion Consumer Service URL support for SAML IdP

A Citrix ADC appliance configured as a SAML Identity Provider (IdP) now supports Assertion Consumer Service (ACS) indexing to process SAML Service Provider (SP) request. The SAML IdP imports ACS indexing configuration from SP metadata or allows for entering ACS indexes information manually. The following table lists some articles that are specific to deployments where the Citrix ADC appliance is used as a SAML SP or a SAML IdP.

The following table lists some articles that are specific to deployments where the Citrix ADC appliance is used as a SAML SP or a SAML IdP.

SAML SP	SAML IdP	Information Link
Citrix ADC	Microsoft Azure AD	Citrix Support
Okta	Citrix ADC	Citrix Support
AWS	Citrix ADC	Citrix Support

Some information on other specific deployments:

- NetScaler as SAML SP on FIPS Device
- Configuring Office365 for Single Sign-on with NetScaler as SAML IdP

WebView credential type support for authentication mechanisms

The authentication of a Citrix ADC appliance can now support AUTHv3 protocol. The WebView credential type in AUTHv3 protocol support all type of authentication mechanisms (including SAML and OAuth). The WebView credential type is a part of AUTHv3, which is implemented by Citrix Receiver and browser in web applications.

The following example explains the flow of WebView events through Citrix Gateway and Citrix Receiver:

1. The Citrix Receiver negotiates to Citrix Gateway for AUTHv3 protocol support.
2. Citrix ADC appliance responds positively and suggests a specific start URL.
3. Citrix Receiver then connects to the specific endpoint (URL).
4. The Citrix Gateway sends a response to the client to start the WebView.
5. Citrix Receiver starts WebView and sends initial request to Citrix ADC appliance.
6. Citrix ADC appliance redirects URI to browser login endpoint.
7. Once authentication is complete, Citrix ADC appliance sends completion response to WebView.
8. The WebView now exits and gives control back to Citrix Receiver to continue AUTHv3 protocol for session establishment.

Increase of SessionIndex size in SAML SP

The SessionIndex size of the SAML Service Provider (SP) is increased to 96 bytes. Previously, the default maximum size of SessionIndex was 63 bytes.

> **Note**
>
> Support introduced in NetScaler 13.0 Build 36.x

Custom authentication class reference support for SAML SP

You can configure custom authentication class reference attribute in the SAML action command. Using the custom authentication class reference attribute, you can customize the class names in the appropriate SAML tags. The custom authentication class reference attribute along with namespace is sent to the SAML IdP as part of SAML SP authentication request.

Previously, using SAML action command, you could configure only a set of predefined classes defined in authnCtxClassRef attribute.

> **Important**
>
> While configuring customAuthnCtxClassRef attribute, ensure the following:

- The names of the classes must include alphanumeric characters or a valid URL with proper XML tags.

- If you have to configure multiple custom classes, each class must be separated by commas

To configure the customAuthnCtxClassRef attributes by using the CLI

At the command prompt, type:

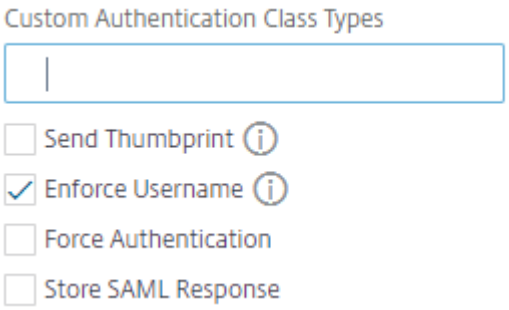
- add authentication samlAction <name> [-customAuthnCtxClassRef <string>]
- set authentication samlAction <name> [-customAuthnCtxClassRef <string>]

Example:

- `add authentication samlAction samlact1 -customAuthnCtxClassRef http://www.class1.com/LoA1,http://www.class2.com/LoA2`
- `set authentication samlAction samlact2 -customAuthnCtxClassRef http://www.class3.com/LoA1,http://www.class4.com/LoA2`

To configure the customAuthnCtxClassRef attributes by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > SAML**.
2. On the SAML page, select **Servers** tab and Click **Add**.
3. On the **Create Authentication SAML Server** page, enter the name for SAML action.
4. Scroll down to configure the class types in **Custom Authentication Class Types** section.



Support for artifact binding in SAML IdP

Citrix ADC appliance configured as SAML Identity Provider (IdP) supports artifact binding. The artifact binding enhances the security of SAML IdP and restricts the malicious users from inspecting the assertion.

Assertion Consumer Service URL support for SAML IdP

A Citrix ADC appliance configured as a SAML Identity Provider (IdP) now supports Assertion Consumer Service (ACS) indexing to process SAML Service Provider (SP) request. The SAML IdP imports ACS indexing configuration from SP metadata or allows for entering ACS indexes information manually.

FIPS offload support

A Citrix ADC MPX FIPS appliance used as a SAML service provider now supports encrypted assertions. Also, a Citrix ADC MPX FIPS appliance functioning as a SAML service provider or a SAML identity provider can now be configured to use the SHA2 algorithms on FIPS hardware.

> **Note**
>
> In FIPS mode, only RSA-V1_5 algorithm is supported as key transport algorithm.

Configuring FIPS offload support using the command line interface:

1. Add SSL FIPS

   add ssl fipsKey fips-key

2. Create a CSR and use it at CA server to generate a certificate. You can then copy the certificate in **/nsconfig/ssl**. Let's assume that the file is *fips3cert.cer*.

   ```
   add ssl certKey fips-cert -cert fips3cert.cer -fipsKey fips-key<!--
   NeedCopy-->
   ```

3. Specify this certificate in the SAML action for SAML SP module

   ```
   set samlAction <name> -samlSigningCertName fips-cert<!--NeedCopy-->
   ```

4. Use the certificate in samlIdpProfile for SAML IDP module

   ```
   set samlidpprofile fipstest -samlIdpCertName fips-cert<!--NeedCopy-->
   ```

Common SAML terminologies

The following are some common SAML terminologies:

- **Assertion:** A SAML assertion is an XML document returned by the Identity Provider to the Service Provider after authentication of the user. The assertion has a very specific structure, as defined by the SAML standard.
- **Types of Assertions:** The following are the types of assertion.
  - Authentication - the user is authenticated by a particular means at a particular time
  - Authorization - the user was granted or denied access to a specified resource
  - Attributes - the user is associated with the supplied attributes

- **Assertion Consumer Service (ACS):** The service provider's endpoint (URL) that is responsible for receiving and parsing a SAML assertion
- **Audience Restriction:** A value within the SAML assertion that specifies who (and only who) the assertion is intended for. The "audience" will be the service provider and is typically a URL but can technically be formatted as any string of data.
- **Identity Provider (IdP):** In terms of SAML, the Identity Provider is the entity that verifies the identity of the user, in response to a request by the Service Provider.

  The Identity Provider is responsible for maintaining and authenticating the user's identity
- **Service Provider (SP):** In terms of SAML, the Service Provider (SP) offers a service to the user and allows the user to sign in by using SAML. When the user attempts to sign in, the SP sends a SAML authentication request to the Identity Provider (IdP)
- **SAML Binding:** SAML requestors and responders communicate by exchanging messages. The mechanism to transport these messages is called a SAML binding.
- **HTTP Artifact:** One of the binding options supported by the SAML protocol. HTTP Artifact is useful in scenarios where the SAML requester and responder are using an HTTP User-Agent and do not want to transmit the entire message, either for technical or security reasons. Instead, a SAML Artifact is sent, which is a unique ID for the full information. The IdP can then use the Artifact to retrieve the full information. The artifact issuer must maintain state while the artifact is pending. An Artifact Resolution Service (ARS) must be set up.

  HTTP Artifact sends the artifact as a query parameter.
- **HTTP POST:** One of the binding options supported by the SAML protocol.

  HTTP POST sends the message content as a POST parameter, in the payload.
- **HTTP Redirect:** One of the binding options supported by the SAML protocol.

  When HTTP Redirect is used, the Service Provider redirects the user to the Identity Provider where the login happens, and the Identity Provider redirects the user back to the Service Provider. HTTP Redirect requires intervention by the User-Agent (the browser).

  HTTP Redirect sends the message content in the URL. Because of this, it cannot be used for the SAML response, because the size of the response will typically exceed the URL length allowed by most browsers.

  Note: The Citrix ADC appliance supports POST and Redirect bindings during logout.
- Metadata: Metadata is the configuration data in SP and IDP to know how to communicate to each other which will be in XML standards

Other useful Citrix articles related to SAML authentication

OAuth authentication

September 14, 2021

The authentication, authorization, and auditing traffic management feature supports OAuth and OpenID Connect (OIDC) authentication. It authorizes and authenticates users to services that are hosted on applications such as Google, Facebook, and Twitter.

Points to note

- Citrix ADC Advanced Edition and higher is required for the solution to work.
- A Citrix ADC appliance must be on version 12.1 or later for the appliance to work as an OAuth IdP using OIDC.
- OAuth on a Citrix ADC appliance is qualified for all SAML IdPs that are compliant with "OpenID connect 2.0".

A Citrix ADC appliance can be configured to behave as a Service Provider (SP) or an Identity Provider (IdP), using SAML and OIDC. Previously, a Citrix ADC appliance configured as IdP supported only SAML protocol. Starting from Citrix ADC 12.1 version, Citrix ADC supports the OIDC as well.

OIDC is an extension to OAuth authorization/delegation. A Citrix ADC appliance supports OAuth and OIDC protocols in the same class of other authentication mechanisms. OIDC is an add-on to OAuth as it provides a way for getting user information from the authorization server as opposed to OAuth that gets only a token which cannot be gleaned for user information.

The authentication mechanism facilitates the inline verification of OpenID tokens. A Citrix ADC appliance can be configured to obtain certificates and verify signatures on the token.

A major advantage of using the OAuth and OIDC mechanisms is that the user information is not sent to the hosted applications. Therefore, the risk of identity theft is considerably reduced.

The Citrix ADC appliance configured for authentication, authorization, and auditing now accepts incoming tokens that are signed using the HMAC HS256 algorithm. In addition, the public keys of the SAML Identity Provider (IdP) are read from a file, instead of learning from a URL endpoint.

In the Citrix ADC implementation, the application is accessed by the authentication, authorization, and auditing traffic management virtual server. So, to configure OAuth, you must configure an OAuth policy which must then be associated with an authentication, authorization, and auditing traffic management virtual server.

Configure the OpenID Connect protocol

A Citrix ADC appliance can now be configured as an identity provider by using OIDC protocol. OIDC protocol strengthens the identity providing capabilities of the Citrix ADC appliance. You can now access the enterprise wide hosted application with a single sign-on. The OIDC offers more security by not transferring user password but works with tokens with specific lifetime. OIDC also is designed to integrate with non-browser clients such as apps and services. Therefore, many implementations adopt OIDC widely.

Advantages of having the OpenID Connect support

- OIDC eliminates the overhead of maintaining multiple authentication passwords as the user has a single identity across the organization.
- OIDC provides a robust security for your password as the password is shared only with your identity provider and not with any application you access.
- OIDC has vast interoperability with various systems making it easier for the hosted applications to accept OpenID.
- OIDC is a simple protocol that enables native clients to easily integrate with servers.

To configure a Citrix ADC appliance as an IdP using the OpenID Connect protocol by using GUI

1. Navigate to **Configuration > Security > AAA-Application Traffic > Policies > Authentication > Advanced Policies > OAuth IdP**.
2. Click **Profile** and click **Add.**

   On the **Create Authentication OAuth IDP Profile** screen, set values for the following parameters and click **Create**.

   - **Name** – Name of the authentication profile.
   - **Client ID** – Unique string that identifies SP.
   - **Client Secret** – Unique secret that identifies SP.
   - **Redirect URL** – Endpoint on SP to which code/token has to be posted.
   - **Issuer Name** – String that identifies IdP.
   - **Audience** – Target recipient for the token being sent by IdP. This might be checked by the recipient.
   - **Skew Time** – The time for which the token remains valid.

- **Default Authentication Group** – A group added to the session for this profile to simplify policy evaluation and help in customizing policies.

3. Click **Policies** and click **Add.**
4. On the **Create Authentication OAuth IDP Policy** screen, set values for the following parameters and click **Create**.

   - **Name –** The name of the authentication policy.
   - **Action** – Name of profile created earlier.
   - **Log Action** –Name of message log action to use when a request matches this policy. Not a mandatory filed.
   - **Undefined-Result Action** – Action to perform if the result of policy evaluation is undefined(UNDEF). Not a mandatory field.
   - **Expression** – Default syntax expression that the policy uses to respond to specific request. For example, true.
   - **Comments** – Any comments about the policy.

Binding the OAuthIdP policy and LDAP policy to the authentication virtual server

1. Navigate to **Configuration > Security > AAA-Application Traffic > Policies >Authentication > Advanced Policies > Actions > LDAP**.
2. On **LDAP Actions** screen, click **Add**.
3. On **Create Authentication LDAP Server** screen, set the values for the following parameters, and click **Create**.

   - **Name –** The name of the LDAP action
   - **ServerName/ServerIP –** Provide FQDN or IP of the LDAP server
   - Choose appropriate values **for Security Type, Port, Server Type, Time-Out**
   - Make sure **Authentication** is checked
   - **Base DN –** Base from which to start LDAP search. For example, dc=aaa,dc=local.
   - **Administrator Bind DN:** User name of the bind to LDAP server. For example, admin@aaa.local.
   - **Administrator Password/Confirm Password: Password to bind LDAP**
   - Click **Test Connection** to test your settings.
   - **Server Logon Name Attribute:** Choose **"sAMAccountName"**
   - Other fields are not mandatory and hence can be configured as required.

4. Navigate to **Configuration > Security > AAA-Application Traffic > Policies >Authentication > Advanced Policies > Policy.**
5. On **Authentication Policies** screen, click **Add**.

6. On **Create Authentication Policy** page, set the values for the following parameters, and click **Create.**
    - **Name –** Name of the LDAP Authentication Policy.
    - **Action Type –** Choose **LDAP.**
    - **Action –** Choose the LDAP action.
    - **Expression –** Default syntax expression that the policy uses to respond to specific request. For example, true**.

To configure the Citrix ADC appliance as an IdP using the OpenID Connect protocol by using CLI

At the command prompt, type the following commands:

- `add authentication OAuthIDPProfile <name> [-clientID <string>][-clientSecret ][-redirectURL <URL>][-issuer <string>][-audience <string>][-skewTime <mins>] [-defaultAuthenticationGroup <string>]<!--NeedCopy-->`
- `add authentication OAuthIdPPolicy <name> -rule <expression> [-action <string> [-undefAction <string>] [-comment <string>][-logAction <string >]<!--NeedCopy-->`
- `add authentication ldapAction aaa-ldap-act -serverIP 10.0.0.10 -ldapBase "dc=aaa,dc=local"<!--NeedCopy-->`
- `ldapBindDn <administrator@aaa.local> -ldapBindDnPassword <password> -ldapLoginName sAMAccountName<!--NeedCopy-->`
- `add authentication policy aaa-ldap-adv-pol -rule true -action aaa-ldap-act<!--NeedCopy-->`
- `bind authentication vserver auth_vs -policy <ldap_policy_name> -priority 100 -gotoPriorityExpression NEXT<!--NeedCopy-->`
- `bind authentication vserver auth_vs -policy <OAuthIDPPolicyName> -priority 5 -gotoPriorityExpression END<!--NeedCopy-->`
- `bind vpn global -certkey <><!--NeedCopy-->`

> **Note**
>
> You can bind more than one key. Public parts of certificates bound are sent in response to `jwks \\_uri query (https://gw/oauth/idp/certs).`

Citrix ADC as an OAuth SP

September 14, 2021

The authentication, authorization, and auditing traffic management feature supports OAuth authentication for authenticating users to applications that are hosted on applications such as Google, Facebook, and Twitter.

Points to note

- Citrix ADC Advanced Edition and higher is required for the solution to work.
- OAuth on Citrix ADC appliance is qualified for all SAML IdPs that are compliant with “OpenID connect 2.0”.

To configure OAuth by using the configuration utility

1. Configure the OAuth action and policy.

   Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy**, and create a policy with OAuth as the action type, and associate the required OAuth action with the policy.

2. Associate the OAuth policy with an authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and associate the OAuth policy with the authentication virtual server.

> **Note**
>
> Attributes (1 to 16) can be extracted in the OAuth response. Currently these attributes are not evaluated. They are added for the future reference.

To configure OAuth by using the command line interface:**

1. Define an OAuth action.

```
1 add authentication OAuthAction <name> -authorizationEndpoint <URL>
      -tokenEndpoint <URL> [-idtokenDecryptEndpoint <URL>] -clientID
      <string> -clientSecret <string> [-defaultAuthenticationGroup <
     string>][-tenantID <string>][-GraphEndpoint <string>][-
     refreshInterval <positive_integer>] [-CertEndpoint <string>][-
     audience <string>][-userNameField <string>][-skewTime <mins>][-
     issuer <string>][-Attribute1 <string>][-Attribute2 <string>][-
     Attribute3 <string>]...
2 <!--NeedCopy-->
```

2. Associate the action with an advanced authentication policy.

```
1 add authentication Policy** <name> -rule <expression> -action <
     string>
2 <!--NeedCopy-->
```

Example:

```
add authentication oauthAction a -authorizationEndpoint https://example
.com/ -tokenEndpoint https://example.com/ -clientiD sadf -clientsecret
df
```

For more information on authentication OAuthAction parameters, see authentication OAuthAction.

> **Note**
>
> When a certEndpoint is specified, the Citrix ADC appliance polls that endpoint at the configured frequency to learn the keys.

To configure a Citrix ADC to read the local file and parse keys from that file, a new configuration option is introduced as follows:

```
1 set authentication OAuthAction <> -**CertFilePath** <path to local file
     with jwks>
2 <!--NeedCopy-->
```

OAuth feature now supports the following capabilities in the token API from the Relying Party (RP) side and from the IdP side of Citrix Gateway and Citrix ADC.

- PKCE (Proof Key for Code Exchange) support
- Support for client_assertion

Name-value attribute support for OAuth authentication

You can now configure OAuth authentication attributes with a unique name along with the values. The names are configured in the OAuth action parameter either as “Attributes” and the values are obtained by querying for the names. The extracted attributes are stored in authentication, authorization, and auditing session. Admins can query these attributes either using `http.req.user.attribute("attribute name")` or `http.req.user.attribute(1)`, based on the chosen method of specifying attribute names.

By specifying the name of the attribute, admins can easily search for the attribute value associated with that attribute name. Also, admins no longer have to remember the “attribute1 to attribute16” by its number alone.

> **Important**
>
> In a OAuth command, you can configure a maximum of 64 attributes separated by comma with a total size less than 1024 bytes.
>
> **Note**
>
> The session failure can be avoided if the total value size of “attribute 1 to attribute 16” and the values of attributes specified in “Attributes” are not more than 10 KB.

To configure the name-value attributes by using the CLI

At the command prompt, type:

- `add authentication OAuthAction <name> [-Attributes <string>]`
- `set authentication OAuthAction <name> [-Attributes <string>]`

Examples:

- `add authentication OAuthAction a1 -attributes "email,company"-attribute1 email`
- `set authentication OAuthAction oAuthAct1 -attributes "mail,sn,userprincipalName"`

Citrix ADC as an OAuth IdP

September 14, 2021

A Citrix ADC appliance can now be configured as an identity provider by using the OpenID-Connect (OIDC) protocol. OIDC protocol strengthens the identity providing capabilities of the Citrix ADC appliance. You can now access the enterprise wide hosted application with a single sign-on as OIDC offers more security by not transferring the user password but using tokens with specific lifetime. OpenID also is designed to integrate with non-browser clients such as apps and services. Therefore, the OIDC protocol is widely adopted by many implementations.

> **Note**
>
> Citrix ADC must be on version 12.1 or later for the appliance to work as an OAuth IdP using the OIDC protocol.

Advantages of having Citrix ADC as an OAuth IdP

- Eliminates the overhead of maintaining multiple authentication passwords as the user has a single identity across an organization.

- Provides a robust security for your password as the password is shared only with your identity provider and not with any application you access.
- Provided vast interoperability with various systems making it easier for the hosted applications to accept OpenID.

> **Note**
>
> Citrix ADC Advanced Edition and higher is required for the solution to work.

To configure the Citrix ADC appliance as an OAuth IdP using the GUI

1. Navigate to **Configuration > Security > AAA-Application Traffic > Policies > Authentication > Advanced Policies > OAuth IdP**.
2. Click **Profile** and click **Add.**

   On the **Create Authentication OAuth IDP Profile** screen, set values for the following parameters and click **Create**.

   - **Name** – Name of the authentication profile. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the profile is created.
   - **Client ID** – Unique string that identifies SP. Authorization server infers client configuration using this ID. Maximum Length: 127.
   - **Client Secret** – Secret string established by user and authorization server. Maximum Length: 239.
   - **Redirect URL** – Endpoint on SP to which code/token has to be posted.
   - **Issuer Name** – Identity of the server whose tokens are to be accepted. Maximum Length: 127.
   - **Audience** – Target recipient for the token being sent by IdP. This might be checked by the recipient.
   - **Skew Time** – This option specifies the allowed clock skew in number of minutes that Citrix ADC allows on an incoming token. For example, if skewTime is 10, then the token would be valid from (current time - 10) min to (current time + 10) min, that is 20 min in all. Default value: 5.
   - **Default Authentication Group** – A group added to session internal grouplist when this profile is chosen by IdP which can be used in nFactor flow. It can be used in expression (AAA.USER.IS_MEMBER_OF("xxx")) for authentication policies to identify relying party related nfactor flow. Maximum Length: 63

A group added to the session for this profile to simplify policy evaluation and help in customizing policies. This is the default group that is chosen when the authenticatiob succeeds in addition to the extracted groups. Maximum Length: 63.

3. Click **Policies** and click **Add.**
4. On the **Create Authentication OAuth IDP Policy** screen, set values for the following parameters and click **Create**.
    - **Name** – The name of the authentication policy.
    - **Action** – Name of profile created above.
    - **Log Action** – Name of messagelog action to use when a request matches this policy. Not a mandatory filed.
    - **Undefined-Result Action** – Action to perform if the result of policy evaluation is undenfined(UNDEF). Not a mandatory field.
    - **Expression** – Default syntax expression that the policy uses to respond to specific request. For example, true.
    - **Comments** – Any comments about the policy.

Binding the OAuthIDP policy and LDAP policy to the authentication virtual server

1. Navigate to **Configuration > Security > AAA-Application Traffic > Policies >Authentication > Advanced Policies > Actions > LDAP**.
2. On **LDAP Actions** screen, click **Add**.
3. On the **Create Authentication LDAP Server** screen, set the values for the following parameters, and click **Create**.
    - **Name –** The name of the ldap action
    - **ServerName/ServerIP –** Provide FQDN or IP of the LDAP server
    - Choose appropriate values **for Security Type, Port, Server Type, Time-Out**
    - Make sure **Authentication** is checked
    - **Base DN –** Base from which to start LDAP search. For example, dc=aaa,dc=local.
    - **Administrator Bind DN:** Username of the bind to LDAP server. For example, admin@aaa.local.
    - **Administrator Password/Confirm Password: Password to bind LDAP**
    - Click **Test Connection** to test your settings.
    - **Server Logon Name Attribute:** Choose **"sAMAccountName"**
    - Other fields are not mandatory and hence can be configured as required.
4. Navigate to **Configuration > Security > AAA-Application Traffic > Policies >Authentication > Advanced Policies > Policy.**
5. On the **Authentication Policies** screen, click **Add**.

6. On the **Create Authentication Policy** page, set the values for the following parameters, and click **Create.**

   - **Name –** Name of the LDAP Authentication Policy.
   - **Action Type –** Choose **LDAP.**
   - **Action –** Choose the LDAP action.
   - **Expression –** Default syntax expression that the policy uses to respond to specific request. For example, true**.

OAuth feature now supports the following capabilities in the token API from the Relying Party (RP) side and from the IdP side of Citrix Gateway and Citrix ADC.

- PKCE (Proof Key for Code Exchange) support
- Support for client_assertion

To configure the Citrix ADC appliance as an IdP using the OIDC protocol with the command line

At the command prompt, type the following commands:

```
add authentication OAuthIDPProfile <name> [-clientID <string>][-
    clientSecret ][-redirectURL <URL>][-issuer <string>][-audience <
    string>][-skewTime <mins>] [-defaultAuthenticationGroup <string>]

add authentication OAuthIdPPolicy <name> -rule <expression> [-action <
    string> [-undefAction <string>] [-comment <string>][-logAction <
    string>]

add authentication ldapAction aaa-ldap-act -serverIP 10.0.0.10 -
    ldapBase "dc=aaa,dc=local"

ldapBindDn <administrator@aaa.local> -ldapBindDnPassword <password> -
    ldapLoginName sAMAccountName

add authentication policy aaa-ldap-adv-pol -rule true -action aaa-ldap-
    act

bind authentication vserver auth_vs -policy <ldap_policy_name> -
    priority 100 -gotoPriorityExpression NEXT

bind authentication vserver auth_vs -policy <OAuthIDPPolicyName> -
    priority 5 -gotoPriorityExpression END

bind vpn global  - certkey <>
<!--NeedCopy-->
```

> **Note**
>
> You can bind more than one key. Public parts of certificates bound are sent in response to `jwks \\_uri query (https://gw/oauth/idp/certs).`

Encrypted tokens support on OIDC protocol

Citrix ADC appliance with the OIDC mechanism now supports the sending of encrypted tokens along with signed tokens. The Citrix ADC appliance uses JSON web encryption specifications to compute the encrypted tokens and supports only compact serialization of encrypted tokens. To encrypt an OpenID token, a Citrix ADC appliance needs the public key of the relying party (RP). The public key is obtained dynamically by polling the relying party's well-known configuration endpoint.

A new "relyingPartyMetadataURL" option is introduced in the "authentication OAuthIDPProfile." profile.

To configure the relying party's endpoint by using CLI

At the command prompt, type:

"'set authentication OAuthIDPProfile [-relyingPartyMetadataURL] [-refreshInterval] [-status < >]

```
- **relyingPartyMetadataURL** - Endpoint at which Citrix ADC IdP can
  get details about the relying party being configured. Metadata
  response must include endpoints for jwks_uri for RP public keys.

- **refreshInterval** - Defines the rate at which this endpoint must
  be polled to update the certificates in minutes.

- **status** - Reflects the status of the polling operation. The
  status is complete once the Citrix ADC appliance successfully
  obtains the public keys.

   **Example**

   ```
   set authentication OAuthIDPProfile sample_profile -
      relyingPartyMetadataURL https://rp.customer.com/metadata -
      refreshInterval 50 -status < >
   <!--NeedCopy-->
```

After the endpoint is configured, a Citrix ADC appliance first polls the relying party's well-known endpoint to read configuration. Currently, the Citrix ADC appliance processes only the 'jwks_uri' endpoint.

```

- If the 'jwks_uri' is absent in the response, the status of the profile is not complete.
- If the 'jwks_uri' is present in the response, Citrix ADC polls that endpoint also to read the public keys of the relying party.

> **Note:** Only RSAES-OAEP and AES GCM encryption type algorithms are supported for token encryption.

### Custom attributes support on OpenID Connect

OpenID relying parties may require more than a user name or a user principal name (UPN) in the token to create the user profile or make authorization decisions. Most commonly, the user groups are required to apply authorization policies for the user. Sometimes, more details, such as the first or the last name is required for provisioning a user account.

Citrix ADC appliance configured as an IdP can be used to send extra attributes in the OIDCid_token using expressions. Advanced policy expressions are used to send the custom attributes as per the requirement. The Citrix IdP evaluates the expressions corresponding to the attributes and then computes the final token.

Citrix ADC appliance automatically JSONify the output data. For example, numbers (such as SSN) or boolean values (true or false) are not surrounded by quotes. Multi-valued attributes, such as groups are placed within an array marker ("[" and "]"). The complex type attributes are not automatically computed, and you can configure the PI expression of those complex values as per your requirement.

#### To configure the relying party's endpoint by using CLI

At the command prompt, type:

```
set oauthidpprofile <name> -attributes <AAA-custom-attribute-pattern>
<!--NeedCopy-->
```

The <AAA-custom-attribute-pattern> can be described as:

Attribute1=PI-Expression@@@attribute2=PI-Expression@@@

'attribute1','attribute2' are literal strings that represent the name of the attribute to be inserted in the id_token.

> **Note:** You can configure up to 2,000 bytes of attributes.

Example: `set oauthidpprofile sample_1 -attributes q{ myname=http.req.user.name@@@ssn="123456789"@@@jit="false"@@@groups=http.req.user.groups }`

- Preceding PI expression is an advanced policy expression that represents the value to be used against the attribute. The PI expression can be used to send a string literal, such as "'hardcoded

string"'. The string literal is surrounded by double quotes around single quotes or double quotes around a start and pattern (as stated earlier, the start pattern is "q{"). If the value of the attribute is not a string literal, the expression is evaluated at runtime and its value is sent in token. If the value at runtime is empty, the corresponding attribute is not added to the ID token.

- As defined in the example, "false" is a literal string for the attribute "jit". Also, "ssn" has hard-coded value for reference. Groups and "myname" are PI expressions that yield strings.

Support for active-active GSLB deployments on Citrix Gateway

Citrix Gateway configured as an Identity Provider (IdP) using the OIDC protocol can support active-active GSLB deployments. The active-active GSLB deployment on Citrix Gateway IdP provides the capability to load balance an incoming user login request across multiple geographic locations.

> **Important**
>
> Citrix recommends you to bind CA certificates to the SSL service and enable certificate validation on the SSL service for enhanced security.

For more information on configuring GSLB setup, see Example of a GSLB setup and configuration.

API authentication with the Citrix ADC appliance

September 14, 2021

There is a paradigm shift in the way modern applications interact with their clients. Traditionally, browser clients were used to access services. Applications usually set session cookies to track user context. Modern and distributed applications make it hard to maintain user sessions across microservices. Due to this, most of the application accesses have become API based.
Clients that communicate with these distributed services have also evolved. Most clients obtain tokens from a trusted entity called Authorization Server to prove user identity and access. These clients then present the token to the application with each access request. Therefore, traditional proxy devices like Citrix ADC need to evolve to support these clients. A Citrix ADC appliance provides a way for administrators to handle such traffic. Citrix ADC can be deployed as an API Gateway to front-end all the traffic that destined to the published services. An API Gateway can be deployed for traditional (Hybrid Multi Cloud or HMC) or Cloud native environments. The API Gateway terminates all the inbound traffic to offer several services such as authentication, authorization, rate limiting, routing, caching, SSL offload, application firewall, and so on. Therefore, it becomes a critical component in the infrastructure.

Token types

Tokens exchanged during the API access mostly conform to the OAuth/OpenID Connect (OIDC) protocol. Access tokens that are used only for 'delegated access' conform to the OAuth protocol, whereas ID Tokens that comply with OIDC carry user information as well.
Access tokens are normally an opaque or random blob of data. However, they can sometimes be singed tokens conforming to JWT (Json Web Token) standards. ID Tokens are always signed JWTs.

API Access with OAuth

OAuth authentication type on a Citrix ADC appliance can be used to handle both OAuth and OIDC protocols. OIDC is an extension to the OAuth protocol.

OAuthAction on a Citrix ADC appliance can be used to handle interactive clients such as browsers and native clients such as client apps. Interactive clients are redirected to Identity Provider for login using the OIDC protocol. Native clients can obtain tokens out of band and can present those tokens at a Citrix ADC appliance for access.

> **Note:**
>
> The access token obtained from endpoints can be cached for subsequent requests, thereby enhancing the API performance.

To configure token caching support by using the command line interface, type the following command at the command prompt:

```
set aaaparameter  - apITokenCache <ENABLED>

<!--NeedCopy-->
```

The following sections describe the API access method performed by native clients.

Virtual server for API Access

To deploy a Citrix ADC appliance for an API access, a Traffic Management (TM) virtual server is deployed with 401 Authentication. It is associated with an authentication (authentication, authorization, and auditing) virtual server to hold the authentication and session policies. Following configuration snippet creates one such virtual server.

```
Add lb vserver lb-api-access SSL <IP> 443 -authn401 On -AuthnVsName
    auth-api-access

Bind ssl vserver lb-api-access -certkeyName <ssl-cert-entity>

Add authentication vserver auth-api-access SSL
```

```
<!--NeedCopy-->
```

> **Note:**
>
> You would need to bind a service to the TM vserver, and an authentication policy (with OAuthAction described as follows) to the authentication virtual server to complete the configuration.

After creating the virtual server, one needs to add an OAuthAction along with corresponding policy. There are several other options within an OAuth action depending on the token type, and other security mechanisms.

OAuth Configuration for ID Tokens

ID Tokens are always signed JWTs. That is, they carry header, payload and signature. Since these are self-contained tokens, a Citrix ADC appliance can validate these tokens locally. To validate these tokens, the appliance would need to know the public key of the corresponding private key used to sign these tokens.

Following is an example of OAuthAction with certain mandatory arguments along with “certEndpoint”.

```
Add authentication OAuthAction oauth-api-access -clientid <your-client-id> -clientsecret <your-client-secret> -authorizationEndpoint <URL to which users would be redirected for login> -tokenEndpoint <endpoint at which tokens could be obtained> -certEndpoint <uri at which public keys of IdP are published>
<!--NeedCopy-->
```

Where,

- **Client ID** – Unique string that identifies SP. Authorization server infers client configuration using this ID. Maximum Length: 127.
- **Client Secret** – Secret string established by user and authorization server. Maximum Length: 239.
- **authorizationEndpoint** - URL at which users would normally log in (when using interactive clients).
- **tokenEndpoint** - URL on Authorization Server at which tokens/code are obtained/exchanged
- **certEndpoint** - URL at which Authorization Server publishes public keys used to sign the tokens. Authorization Server can publish more than one key and choose one of them to sign tokens.

> **Note:** Client ID/Client Secret/authorizationEndpoint/TokenEndpoint are optional parameters for API Access. However, it is a good practice to provide values for these parameters as the action entity can be reused for different purposes.

In the preceding configuration 'certEndpointpoint' is essential for ID Token validation. This endpoint contains public keys of the certificate used to sign the tokens. These public keys must correspond to JWKs (Json Web Keys) specification.

Once the certEndpoint is configured at the Citrix ADC appliance, it polls the endpoint periodically (with the default interval of 1 day that can be customizable in the configuration) to keep the public keys up to date. After the public keys are available, ADC can perform local validation of the incoming ID Tokens.

OAuth Configuration for opaque access tokens

Opaque tokens cannot be verified locally on the Citrix ADC appliance. These need to be validated on the Authorization server. A Citrix ADC appliance uses 'introspection protocol' mentioned in OAuth specifications in order to verify these tokens. A new option, introspectURL, is provided in OAuth configuration for verifying opaque tokens.

```
1 set oauthAction oauth-api-acccess -introspectURL <uri of the
     Authorization Server for introspection>
2
3 <!--NeedCopy-->
```

The format of the introspection API conforms to the specification at https://tools.ietf.org/html/rfc7662##section-2.1 as follows:

```
1 POST /introspect HTTP/1.1
2 Host: server.example.com
3 Accept: application/json
4 Content-Type: application/x-www-form-urlencoded
5 Authorization: Basic czZCaGRSa3F0MzpnWDFmQmF0M2JW
6 token=mF_9.B5f-4.1JqM&token_type_hint=access_token
7
8 <!--NeedCopy-->
```

Binding policy to Authentication vserver

Once OAuthAction is created, corresponding policy needs to be created for invoking it.

```
1 add authentication policy oauth-api-access -rule <> -action <oauth-api-
     access><!--NeedCopy-->
```

bind authentication vserver auth-api-access -policy oauth-api-access -pri 100

```
## Additional security settings on a Citrix ADC appliance

Token validation includes token lifetime checks. Tokens outside of
    acceptable time are rejected. Following are the additional settings
    for extra security. Some of these are recommended to be configured
    always.

**Audience**: OAuth Action can be configured with an intended recipient
     of the token. All tokens are matched against this configured URL. A
     Citrix ADC appliance has an additional capability where the
    audience field actually points to a pattern set on the appliance.
    Using this pattern set, an administrator can configure more than one
     url for the audience.

<!--NeedCopy-->
```

add policy patset oauth_audiences

bind patset oauth_audiences https://app1.company.com

bind patset oauth_audiences https://app2.company.com

bind patset oauth_audiences httpsL//app1.company.com/path1

set oAuthAccess oauth-api-access -audience oauth_audiences

```
In the preceding example, more than one audience is specified in a
    pattern set. Therefore, an incoming token is allowed only if it
    contains any of the configured URLs in the pattern set.

**Issuer**: Identity of the server whose tokens are to be accepted.
    Maximum Length: 127. It is a good practice to configure the issuer
    of the tokens in OAuth action. This ensures that tokens issued by
    wrong Authorization Server are not allowed.

**SkewTime**: Specifies the allowed clock skew in number of minutes
    that a Citrix ADC appliance allows on an incoming token. For example
    , if skewTime is 10, then the token would be valid from (current
    time - 10) min to (current time + 10) min, that is 20 min in all.
    Default value: 5

**AllowedAlgorithms**: This option allows administrator to restrict
    certain algorithms in the incoming tokens. By default, all the
    supported methods are allowed. However, these can be controlled
    using this option.
```

```
8
9  The following configuration ensures only tokens that use RS256 and
       RS512 are allowed:
10
11 <!--NeedCopy-->
```

set oAuthAction oauth-api-access -allowedAlgorithms RS256 RS512

```
1  After above configuration, only tokens that use RS256 and RS512 are
       allowed.
2
3  ## Bypassing certain traffic from authentication
4
5  In many instances, there are some discovery APIs that are publicly
       accessible to the clients. These APIs typically reveal configuration
        and capabilities of the service itself. AN administrator can
       configure the Citrix ADC appliance to bypass authentication from
       these metadata URLs using 'No Authentication' policy described as
       follows:
6
7  <!--NeedCopy-->
```

add authentication policy auth-bypass-policy -rule <> -action NO_AUTHN

bind authentication vserver auth-api-access -policy auth-bypass-policy -pri 110

```
1  NO_AUTHN is an implicit action that results in authentication to be
       completed when the rule matches. There are other uses of NO_AUTHN
       action beyond the scope of API access.
2  <!--NeedCopy-->
```

LDAP authentication

September 14, 2021

As with other types of authentication policies, a Lightweight Directory Access Protocol (LDAP) authentication policy comprises an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. In addition to standard authentication functions, LDAP can search other active directory (AD) servers for user accounts for users that do not exist locally. This function is called referral support or referral chasing.

Normally you configure the Citrix ADC to use the IP address of the authentication server during authentication. With LDAP authentication servers, you can also configure the ADC to use the FQDN of the LDAP server instead of its IP address to authenticate users. Using an FQDN can simplify an otherwise much more complex authentication, authorization, and auditing configuration in environments where the authentication server might be at any of several IP addresses, but always uses a single FQDN. To configure authentication by using a server's FQDN instead of its IP address, you follow the normal configuration process except when creating the authentication action. When creating the action, you use the **serverName** parameter instead of the **serverIP** parameter, and substitute the server's FQDN for its IP address.

Before you decide whether to configure the ADC to use the IP or the FQDN of your LDAP server to authenticate users, consider that configuring authentication, authorization, and auditing to authenticate to an FQDN instead of an IP address adds an extra step to the authentication process. Each time the ADC authenticates a user, it must resolve the FQDN. If a great many users attempt to authenticate simultaneously, the resulting DNS lookups might slow the authentication process.

LDAP referral support is disabled by default and cannot be enabled globally. It must be explicitly enabled for each LDAP action. Make sure that the AD server accepts the same `binddn credentials` that are used with the referring (GC) server. To enable referral support, you configure an LDAP action to follow referrals, and specify the maximum number of referrals to follow.

If referral support is enabled, and the Citrix ADC receives an LDAP_REFERRAL response to a request, authentication, authorization, and auditing follows the referral to the active directory (AD) server contained in the referral and performs the update on that server. First, authentication, authorization, and auditing looks up the referral server in DNS, and connects to that server. If the referral policy requires SSL/TLS, it connects via SSL/TLS. It then binds to the new server with the `binddn credentials` that it used with the previous server, and performs the operation which generated the referral. This feature is transparent to the user.

The port numbers for LDAP connections are:

- 389 for unsecured LDAP connections (for plain text LDAP)
- 636 for secure LDAP connections (for SSL LDAP)
- 3268 for Microsoft unsecure LDAP connections (for plain text Global Catalog Server)
- 3269 for Microsoft secure LDAP connections (for SSL Global Catalog Server)

The following table contains examples of user attribute fields for LDAP servers:

LDAP server	User attribute	Case sensitive
Microsoft Active Directory Server	sAMAccountName	No
Novell eDirectory	ou	Yes

LDAP server	User attribute	Case sensitive
IBM Directory Server	uid	Yes
Lotus Domino	CN	Yes
Sun ONE directory (formerly iPlanet)	uid or cn	Yes

This table contains examples of the base DN:

LDAP server	Base DN
Microsoft Active Directory Server	DC=citrix,DC=local
Novell eDirectory	ou=users,ou=dev
IBM Directory Server	cn=users
Lotus Domino	OU=City,O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	ou=People,dc=citrix,dc=com

The following table contains examples of bind DN:

LDAP server	Bind DN
Microsoft Active Directory Server	CN=Administrator, CN=Users, DC=citrix, DC=local
Novell eDirectory	cn=admin, o=citrix
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	uid=admin,ou=Administrators, ou=TopologyManagement,o=NetscapeRoot

For more information about setting up authentication policies in general, see Authentication Policies. For more information about Citrix ADC expressions, which are used in the policy rule, see Policies and Expressions.

To create LDAP authentication server by using the command line interface

At the command prompt, type the following commands:

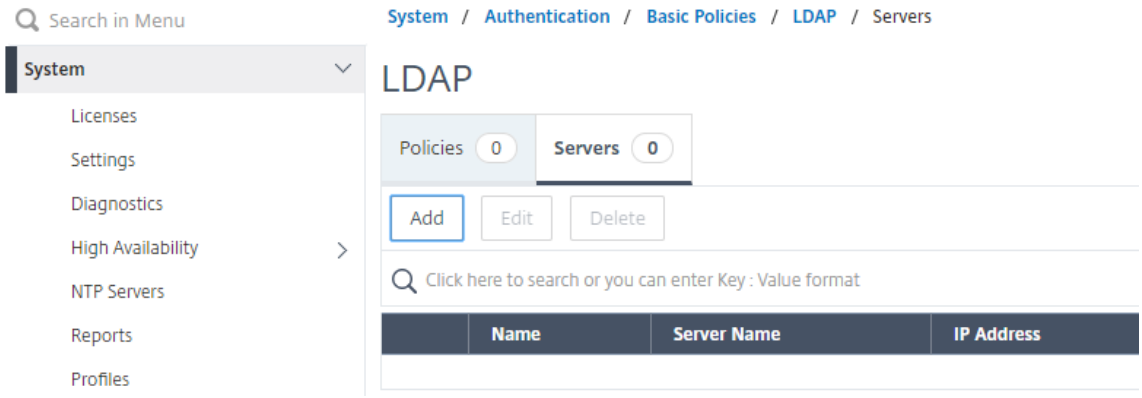
```
add authentication ldapAction <name> {
 -serverIP }
  <ip_addr|ipv6_addr|> | {
 -serverName <string> }
  }
```

Example

```
add authentication ldapAction ldap_server -serverip 1.1.1.1 -serverName
    ldap_test
```

To create LDAP authentication server by using the configuration utility

1. Navigate to **System > Authentication > Basic Policies > LDAP > Servers > Add**.



2. On the **Create Authentication LDAP Server** page, configure the parameters for the LDAP server.
3. Click **Create**.

To enable an authentication policy by using the command line interface

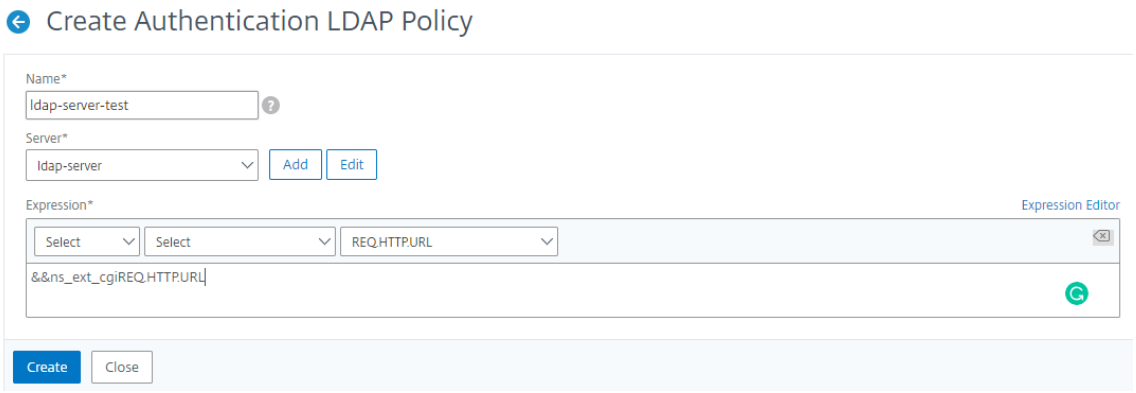
```
add authentication ldappolicy <name> <rule> [<reqAction>]
```

Example:

```
add authentication ldappolicy ldap-service-policy ns_true ldap_Server
```

To create LDAP authentication policy by using the configuration utility

1. Navigate to **System > Authentication > Basic Policies > LDAP > Policies > Add**
2. On the **Create Authentication LDAP Policy** page, configure the parameters for LDAP policy.



3. Click **Create**.

> **Note**
>
> You can configure LDAP servers/policies through **Security** tab. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Basic Policies > LDAP > Servers / Policies**.

To enable LDAP referral support by using the command line interface

At the command prompt, type the following commands:

- `set authentication ldapAction <name> -followReferrals ON<!--NeedCopy-->`
- `set authentication ldapAction <name> -maxLDAPReferrals <integer><!--NeedCopy-->`

Example

```
1 > set authentication ldapAction ldapAction-1 -followReferrals ON
2 > set authentication ldapAction ldapAction-1 -maxLDAPReferrals 2
```

Key-based authentication support for LDAP users

With key-based authentication, you can now fetch the list of public keys that are stored on the user object in LDAP server through SSH. The Citrix ADC appliance during the role-based authentication (RBA) process must extract public SSH keys from the LDAP server. The retrieved public key, which is compatible with SSH, must allow you to log in through RBA method.

A new attribute “sshPublicKey” is introduced in the “add authentication ldapAction” and “set authentication ldapAction” commands. By using this attribute, you can obtain the following benefits:

- Can store the retrieved public key, and the LDAP action uses this attribute to retrieve SSH key information from LDAP server.
- Can extract attribute names of up to 24 KB.

> Note
>
> The external authentication server, such as LDAP is used only to retrieve SSH key information. It is not used for authentication purpose.

Following is an example of the flow of events through SSH:

- SSH daemon sends an AAA_AUTHENTICATE request with password field empty to authentication, authorization, and auditing daemon port.
- If LDAP is configured to store the SSH public key, authentication, authorization, and auditing responds with “sshPublicKey” attribute along with other attributes.
- SSH daemon verifies these keys with the client keys.
- SSH daemon passes user name in the request payload, and authentication, authorization, and auditing returns the keys specific to this user along with generic keys.

To configure the sshPublicKey attribute, at the command prompt type the following commands:

- With add operation, you can add “sshPublicKey” attribute while configuring ldapAction command.

```
add authentication ldapAction <name> ( -serverIP <ip_addr|ipv6_addr
|*> | ( -serverName <string> ) ) [-serverPort <port>] … [-Attribute1 <
string>] … [-Attribute16 <string>][-sshPublicKey <string>][-authentication
 off]<!--NeedCopy-->
```

- With set operation, you can configure “sshPublicKey” attribute to an already added ldapAction command.

```
set authentication ldapAction <name> [-sshPublicKey <string>][-authentication
 off]<!--NeedCopy-->
```

Name-value attribute support for LDAP authentication

You can now configure the attributes of LDAP authentication with a unique name along with values. The names are configured in the LDAP action parameter and the values are obtained by querying for the name. By using this feature, a Citrix ADC appliance administrator can now achieve the following benefits:

- Minimizes the effort for administrators by remembering the attribute by name (not just by value)
- Enhances the search to query the attribute value associated with a name
- Provides an option to extract multiple attributes

To configure this feature at the Citrix ADC appliance command prompt, type:

"'add authentication ldapAction [-Attribute1]

```
Example

```add authentication ldapAction ldapAct1 attribute1 mail<!--NeedCopy
   -->
```

Support for validating end-to-end LDAP authentication

The Citrix ADC appliance can now validate end-to-end LDAP authentication through GUI. To validate this feature, a new "test" button is introduced in the GUI. A Citrix ADC appliance administrator can use this feature to achieve the following benefits:

- Consolidates the complete flow (packet engine – Citrix ADC AAA daemon – external server) to provide better analysis
- Reduces time on validating and troubleshooting issues related to individual scenarios

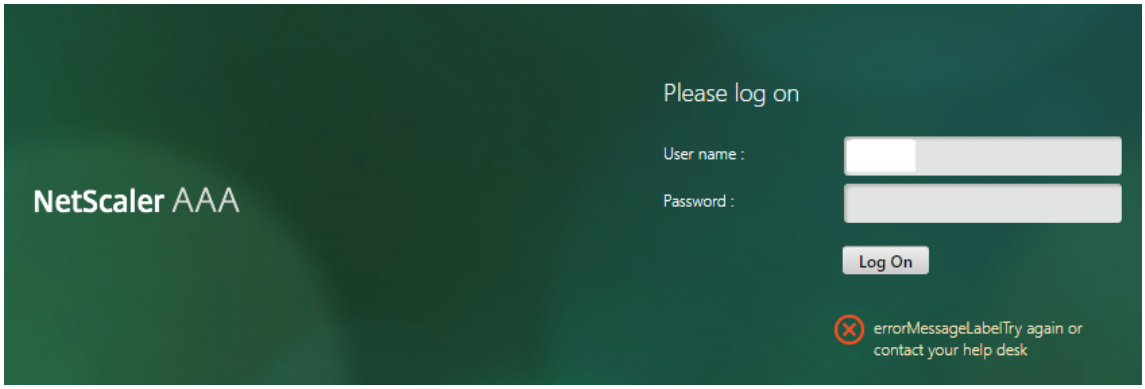
You have two options to configure and view the test results of LDAP end-to-end authentication by using the GUI.

From system option

1. Navigate to **System > Authentication > Basic Policies > LDAP,** click **Servers** tab.
2. Select the available **LDAP action** from the list.
3. On the **Configure Authentication LDAP Server** page, you have two options under **Connections Settings** section.
4. To check the LDAP server connection, click **Test LDAP Reachability** tab. You can view a pop-up message of successful connection to LDAP server with TCP port details and authenticity of valid credentials.
5. To view the end-to-end LDAP authentication, click **Test End User Connection** link.
6. On the **Test End User Connection** page, click **Test**.
    - On the authentication page, enter the valid credentials to log in. The success screen is displayed.

```

- If the authentication fails, the error screen is displayed.

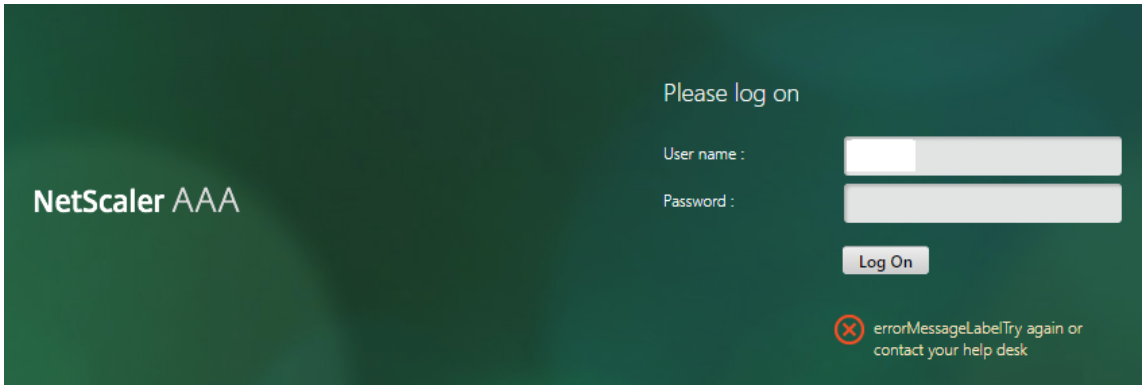


**From Authentication option**

1. Navigate to **Authentication > Dashboard**, select the available LDAP action from the list.
2. On the **Configure Authentication LDAP Server** page, you have two options under **Connections Settings** section.
3. To check the LDAP server connection, click **Test LDAP Reachability** tab. You can view a pop-up message of successful connection to LDAP server with TCP port details and authenticity of valid credentials.
4. To view the end-to-end LDAP authentication status, click **Test End User Connection** link.
5. On the **Test End User Connection** page, click **Test**.
    - On the authentication page, enter the valid credentials to log in. The success screen is displayed.

- If the authentication fails, the error screen is displayed.



### 14-day password expiry notification for LDAP authentication

The Citrix ADC appliance now supports 14-day password expiry notification for LDAP based authentication. By using this feature, administrators can notify the end users about the password expiry threshold time in days. The 14-day password expiry notification is a precursor to self-service password reset (SSPR).

> **Note**
>
> The maximum value or threshold time in days for password expiry notification is 255 days.

#### Advantages of password expiry notification

- Permit users to reset their passwords on their own and provide administrators a flexible way to notify end user about their password expiry in days.
- Eliminates end user dependence to track their password expiration days.
- Sends notifications to the VPN portal page to the users (based on the number of days) to change their password before expiry.

> **Note**
>
> This feature is applicable only for LDAP based authentication schemes, not for RADIUS or TACACS.

#### Understanding the 14-day password notification

The Citrix ADC appliance fetches two attributes (`Max-Pwd-Age and Pwd-Last-Set`) from LDAP authentication server.

- **Max-Pwd-Age.** This attribute denotes the maximum amount of time, in 100-nanosecond intervals, until the password is valid. The value is stored as a large integer that represents the number of 100-nanosecond intervals from the time the password was set before the password expires.

- **Pwd-Last-Set.** This attribute determines the date and time at which the password for an account was last changed.

By fetching the two attributes from the LDAP authentication server, Citrix ADC appliance determines the time left for the password to expire for a particular user. This information is collected when any user credentials are validated on the authentication server and a notification is sent back to the user.

A new parameter "pwdExpiryNotification" is introduced in `set aaa parameter`command. By using this parameter, an administrator can keep track the number of days left for password expiry. The Citrix ADC appliance can now start notifying the end user about their password expiry.

> **Note**
>
> Currently, this feature works only for authentication servers having Microsoft AD servers with LDAP implementation. Support for OpenLDAP based servers is targeted later.

Following is an example of the flow of events for setting a 14-day password expiry notification:

1. An administrator, by using Citrix ADC appliance, sets a time (14-days) for password expiration.
2. The user sends an HTTP or HTTPS request to access a resource on the back-end server.
3. Before providing access, the Citrix ADC appliance validates the user credentials with what is configured on the LDAP authentication server.
4. Along with this query to the authentication server, the Citrix ADC appliance carries the request to fetch the details of two attributes (`Max-Pwd-Age and Pwd-Last-Set`).
5. Based on the time left for the password to expire, an expiry notification is displayed.
6. The user then takes appropriate action to update the password.

#### To configure 14-day expiry notification by using the command line interface

> **Note**
>
> 14-day expiry notification can be configured for clientless VPN and Full VPN use cases and not for ICA Proxy.

At the command prompt, type the following commands:

- `set aaa parameter -pwdExpiryNotificationDays <positive_integer><!--NeedCopy-->`
- `show aaa parameter<!--NeedCopy-->`

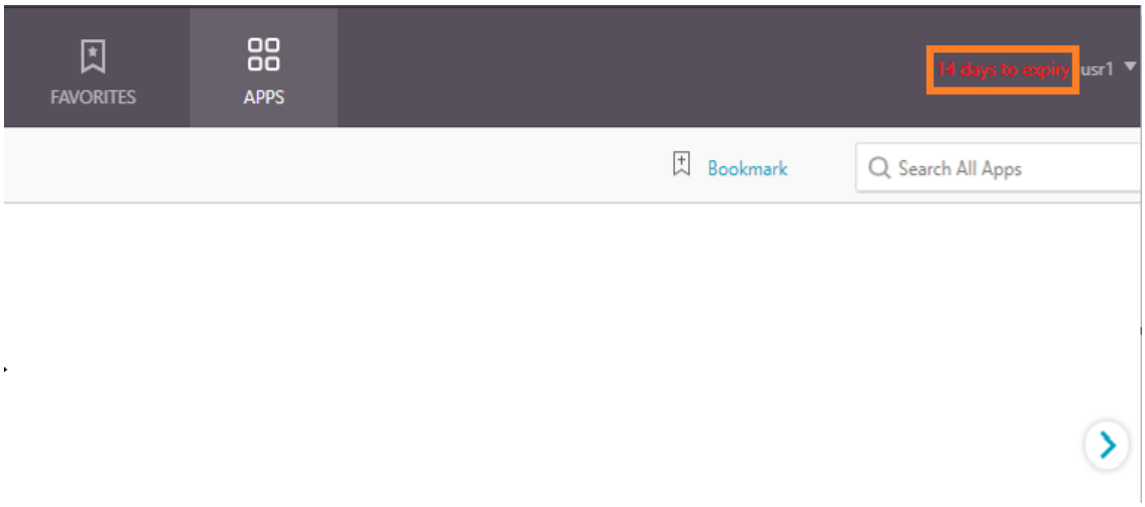
Example

```
1 > set aaa parameter -pwdExpiryNotificationDays 14
2 Done
3 > show aaa parameter   Configured AAA parameters
      EnableStaticPageCaching: YES EnableEnhancedAuthFeedback: NO
    DefaultAuthType: LOCAL MaxAAAUsers: Unlimited
```

```
                                                AAAD nat ip: None
      EnableSessionStickiness : NO  aaaSessionLoglevel : INFORMATIONAL
                    AAAD Log Level : INFORMATIONAL                 Dynamic
       address: OFF
4     GUI mode: ON
5     Max Saml Deflate Size: 1024              Password Expiry
         Notification Days: 14
```

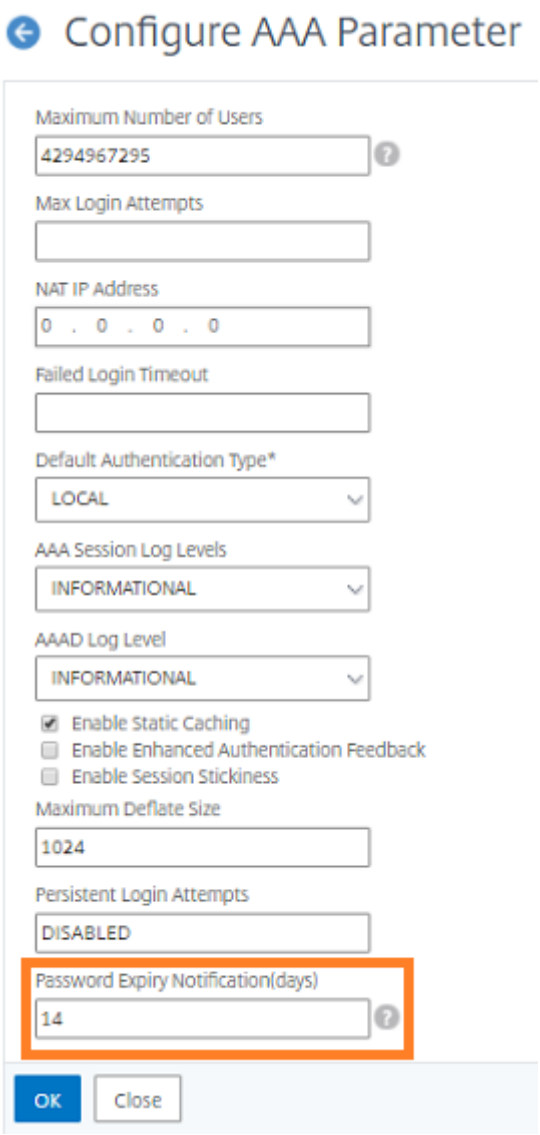
To configure 14-day expiry notification by using GUI

1. Navigate to **Security > AAA - Application Traffic > Authentication Settings**.
2. Click **Change authentication AAA settings**.
3. On the **Configure AAA Parameter** page, specify the days in the **Password Expiry Notification(days)** field.



4. Click **OK.**

   The notification appears on the top right corner of VPN portal page.



Configure LDAP authentication on the Citrix ADC appliance for management purposes

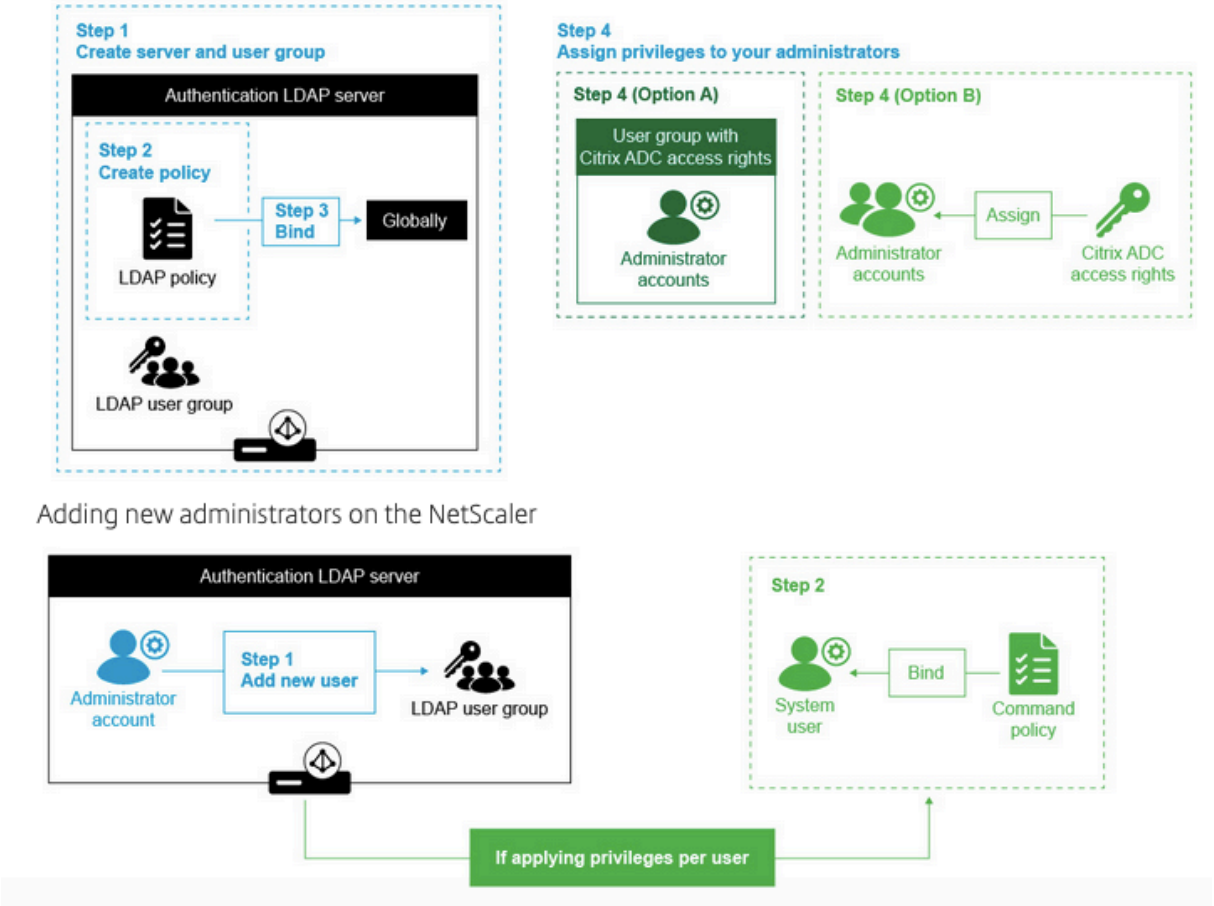
November 8, 2021

You can configure user logon to the Citrix ADC appliance using the active directory credentials (user name and password) for management purposes (superuser, read-only, network privileges and all others).

Prerequisites

- Windows Active Directory domain controller servers
- A dedicated domain group for NetScaler administrators
- Citrix Gateway 10.1 and later versions

The following figures illustrate the LDAP authentication on the Citrix ADC appliance.

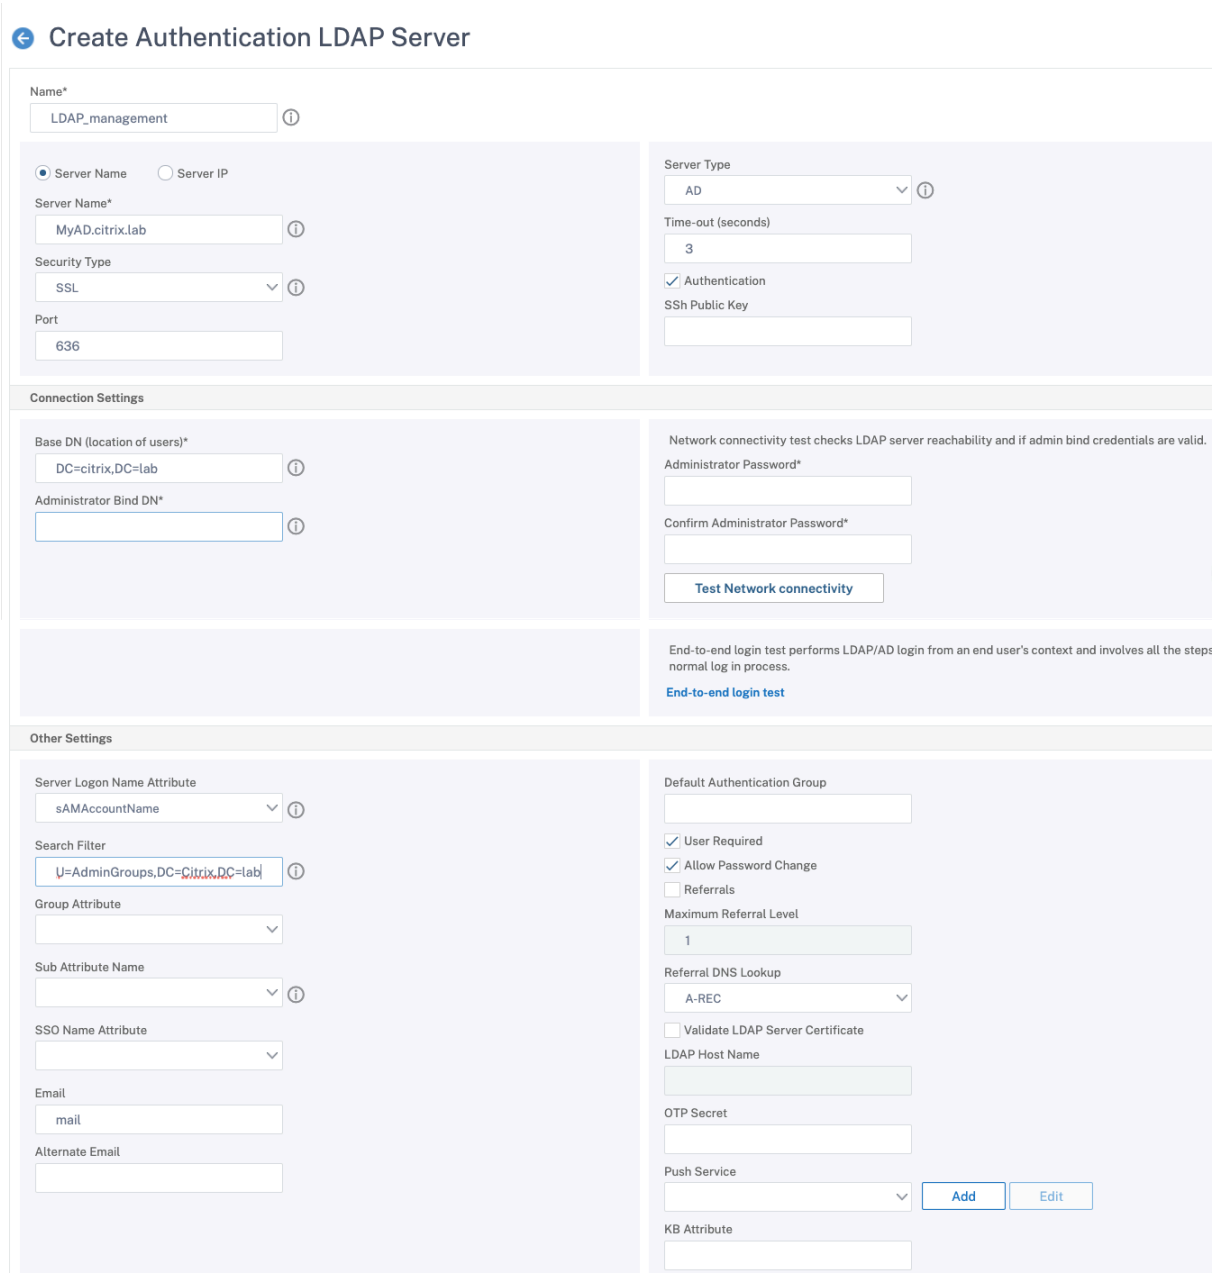


High level configuration steps

1. Create an LDAP server
2. Create an LDAP policy
3. Bind the LDAP policy
4. Assign privileges to your administrators by one of the following ways
    - Apply privileges on group
    - Apply privileges individually for each user

Create an authentication LDAP server

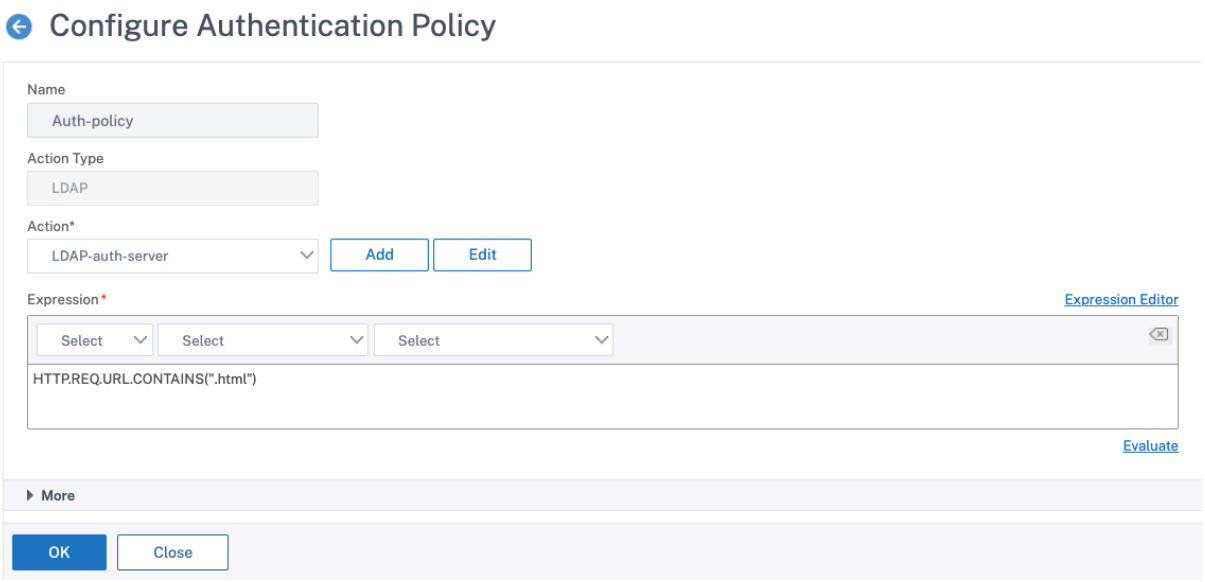
1. Navigate to **System > Authentication > LDAP**.
2. Click the **Server** tab and then click **Add**.
3. Complete the configuration, and then click **Create**.



> **Note:**
>
> In this example, the access is limited to the Citrix ADC appliance by filtering the authentication on the user group membership by setting Search Filter. The value used for this example is - &(memberof=CN=NSG_Admin,OU=AdminGroups,DC=Citrix,DC=lab)

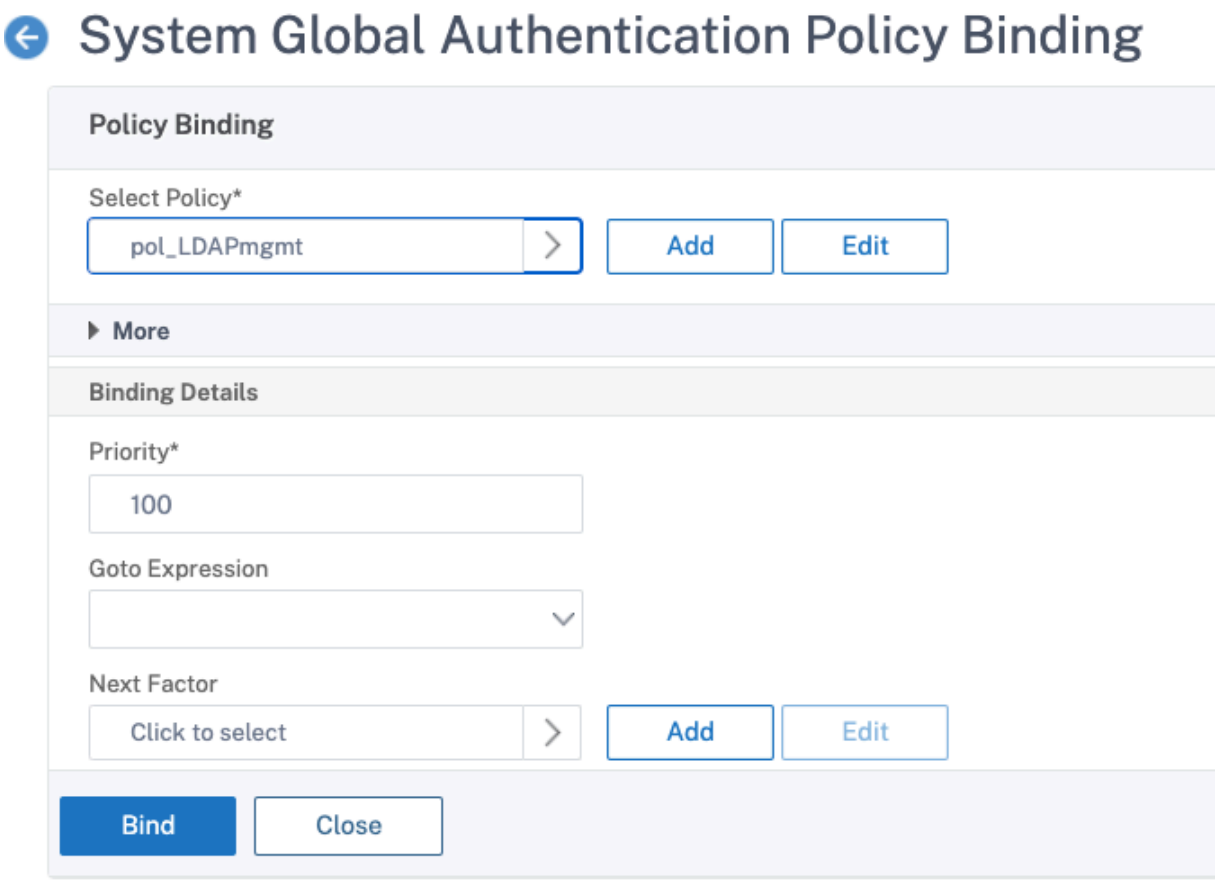
Create an LDAP Policy

1. Navigate to **System > Authentication > Advanced Policies > Policy**.
2. Click **Add**.
3. Enter a name for the policy, select the server that you created in the previous steps.
4. In the Expression text field, enter the appropriate expression, and then click **Create**.



Bind the LDAP policy globally

1. Navigate to **System > Authentication > Advanced Policies > Policy**.
2. In the Authentication Policies page, click **Global Bindings**.
3. Select the policy you created (in this example, pol_LDAPmgmt).
4. Choose a priority accordingly (the lower the number, the higher the priority)
5. Click **Bind,** and then **Done**. A green checkmark appears in the **Globally Bound** column.



Assign privileges to your administrators

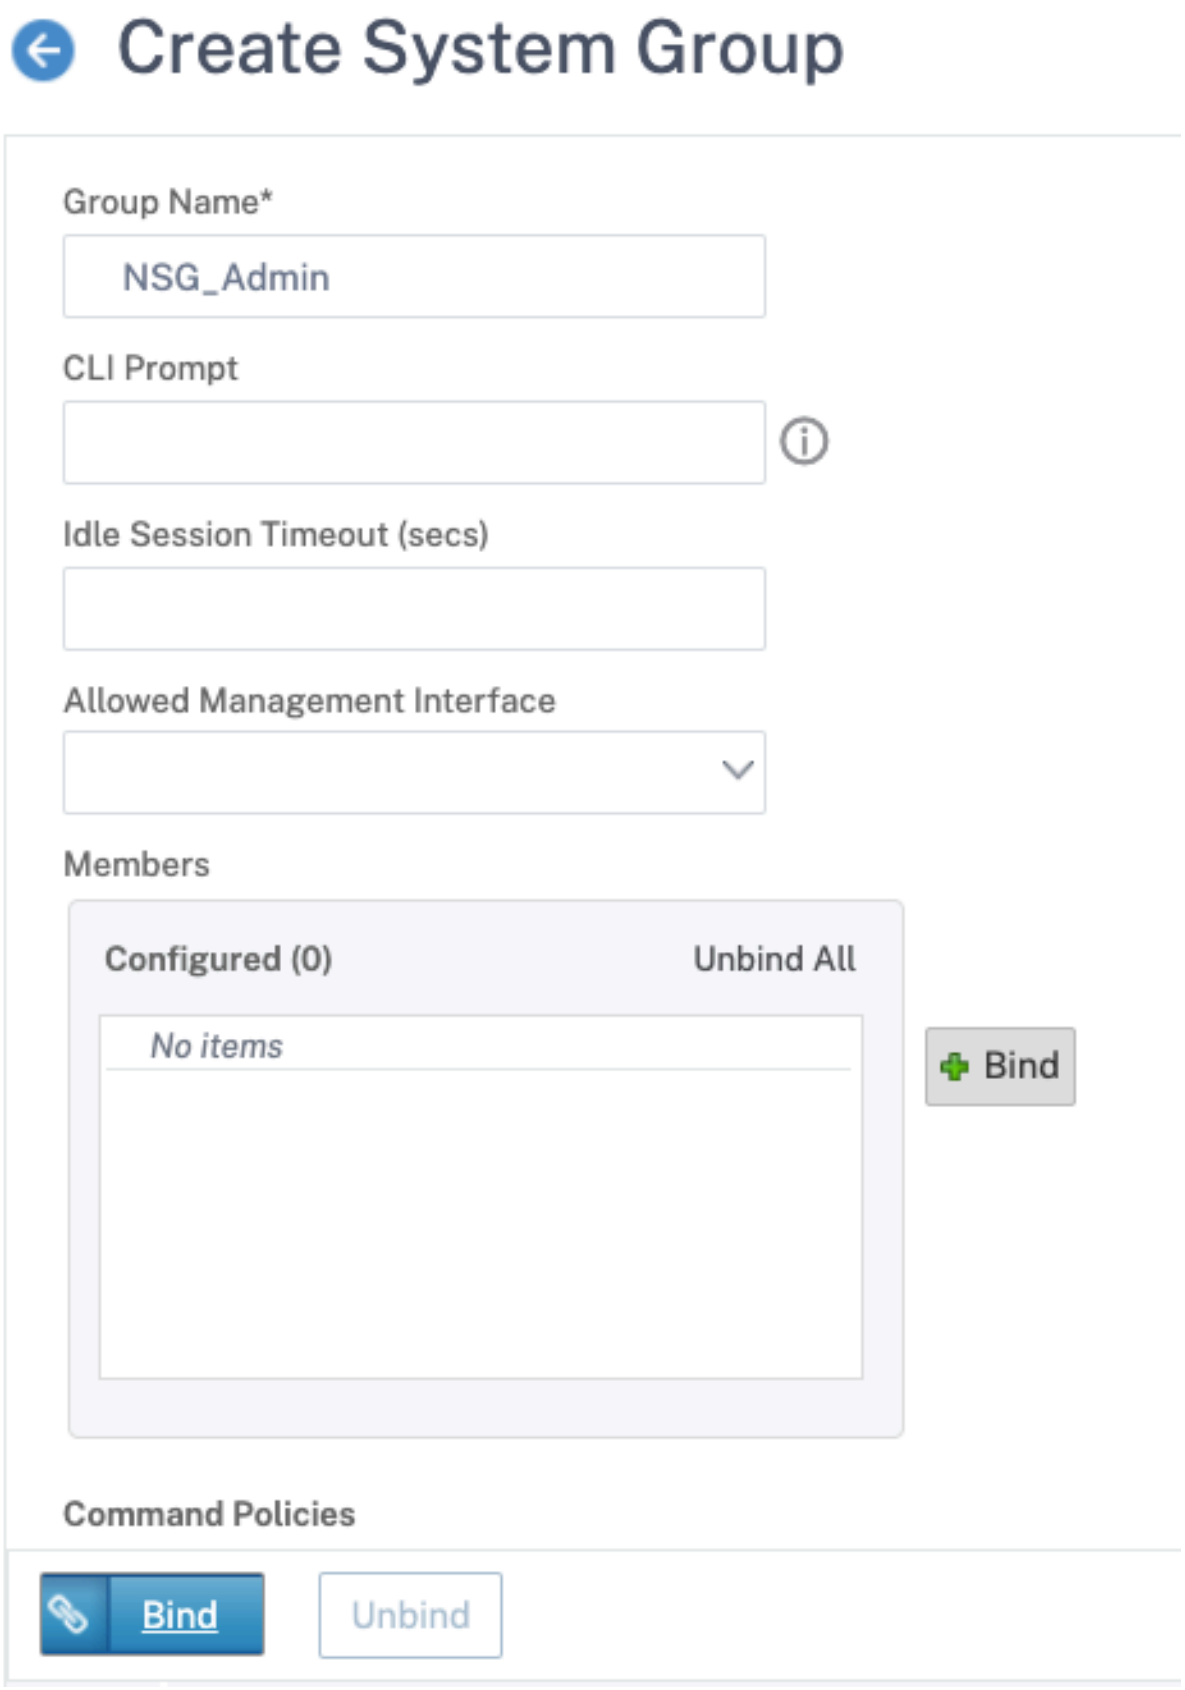
You can choose one of the following two options.

- **Apply privileges on a group:** Add a group in the Citrix ADC appliance and assign the same access rights for each user who is a member of this group.
- **Apply privileges individually for each user:** Create each user administrator account and assign rights for each of them.

Apply privileges on a group

When you apply privileges on a group, users who are member of the Active Directory group configured in the Search filter (in this example, NSG_Admin) can connect to the Citrix ADC Management interface and have superuser command policy.

1. Navigate to **System > User Administration > Groups**.
2. Enter the details as per the requirement, and then click **Create**.



You have defined the active directory group that the users belong to and also the command policy level that must be associated to the account when logging in. You can add new administrator users to the LDAP group you configured on the search filter.

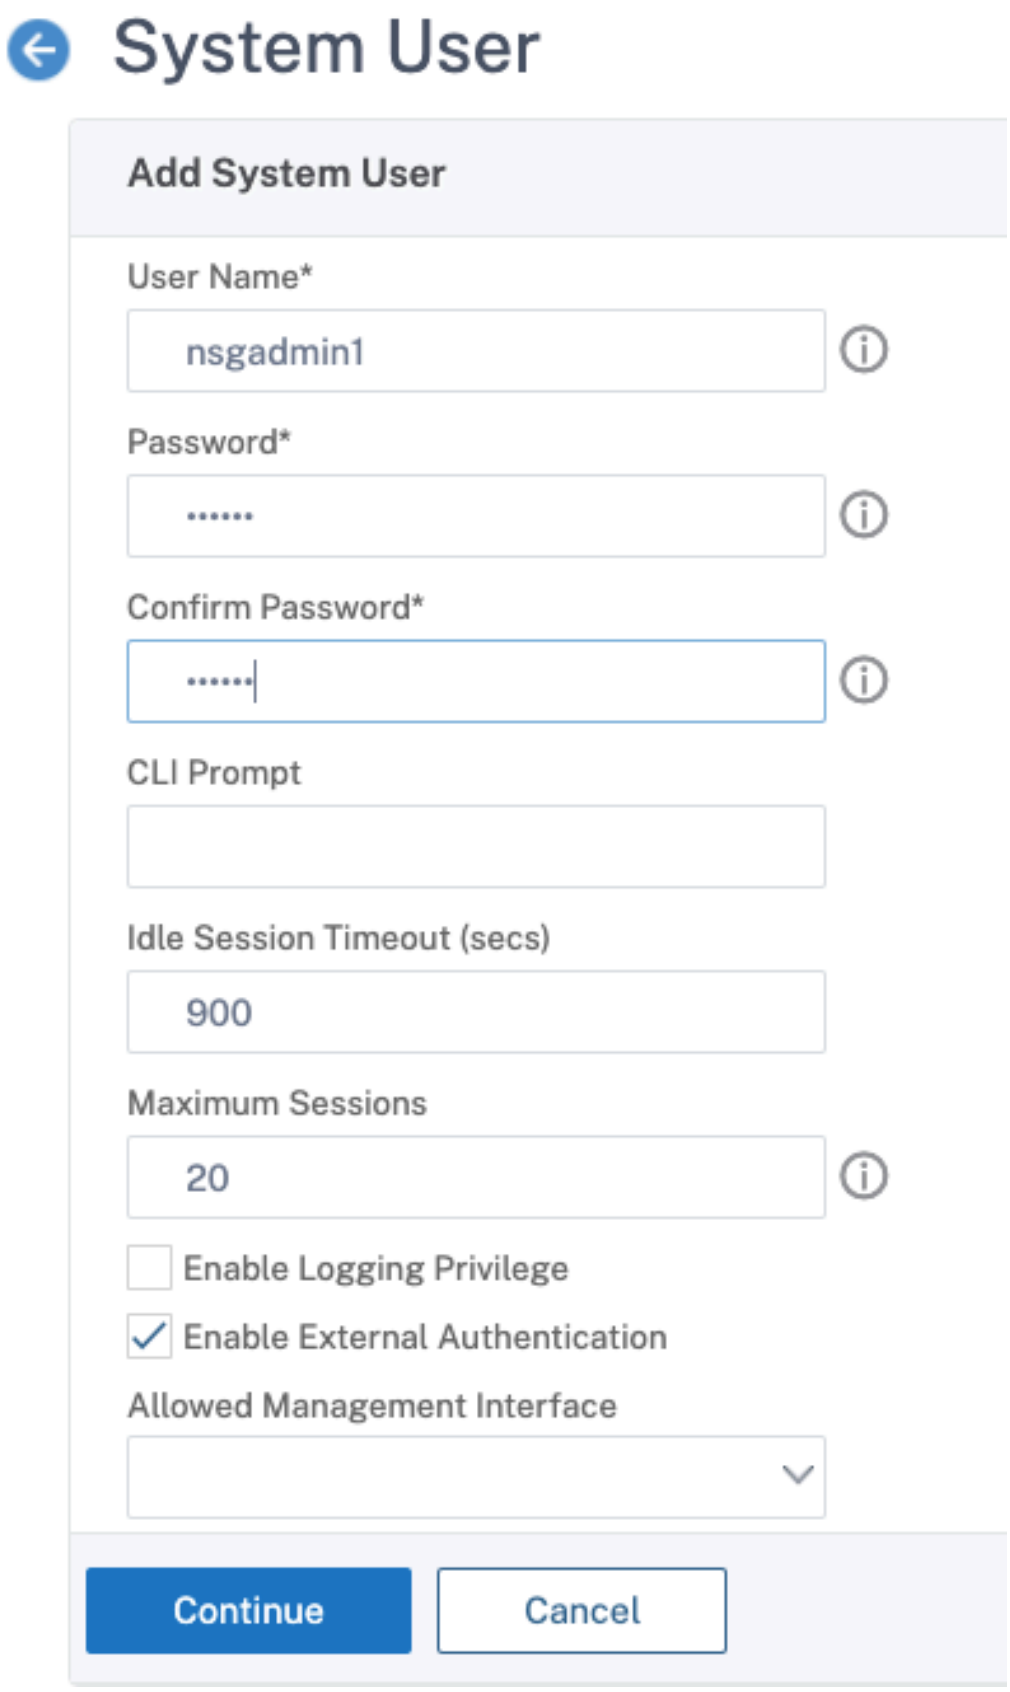
> **Note:**
>
> The group name must match the active directory record.

Apply privileges individually for each user

In this scenario, users who are member of your Active Directory group configured in the search filter (in this example, NSG_Admin) can connect to the Citrix ADC management interface but do not have any privileges until you create the specific user on the Citrix ADC appliance and bind the command policy to it.

1. Navigate to **System > User Administration > Users**.
2. Click **Add**.
3. Enter the details as per the requirement.

   Note: Make sure to select **Enable External Authentication**.



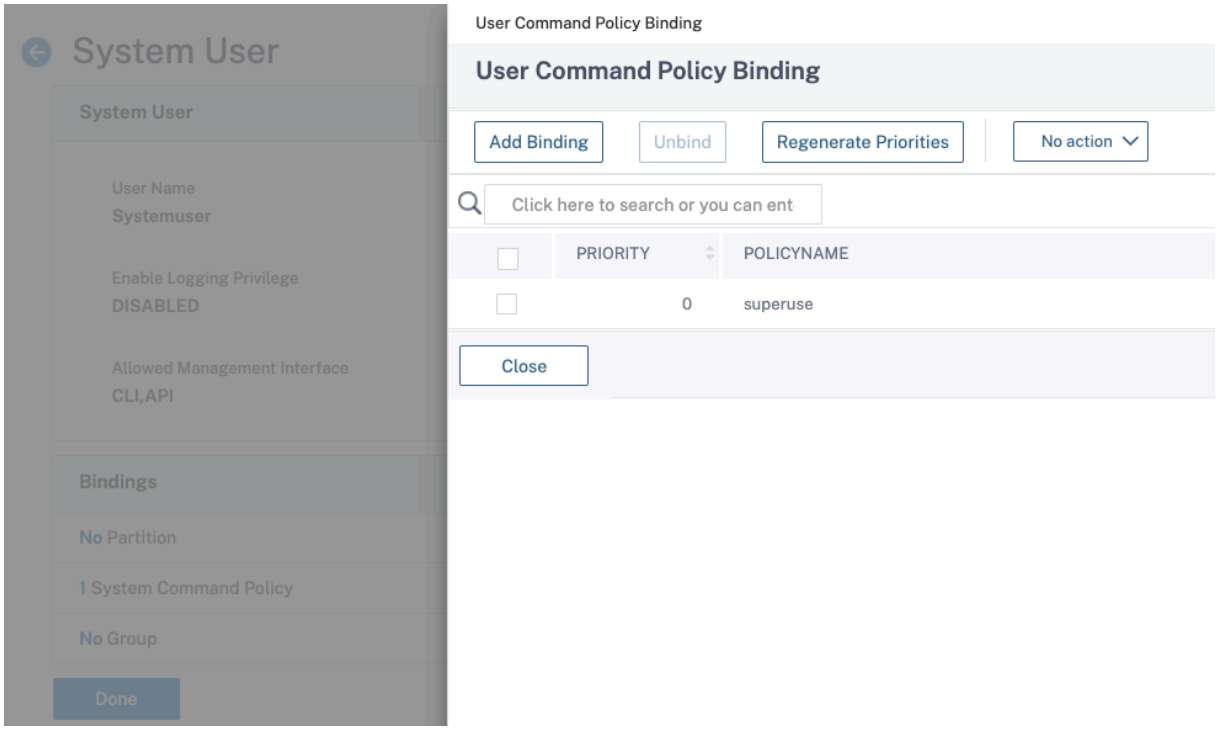
1. Click **Continue**.

You have defined the active directory user and the command policy level that must be associated to the account when logging in.

> **Note:**
>
> - The user name must match the existing user's active directory record.
> - When you add a user to the Citrix ADC for external authentication, you must provide a password, if the external authentication is not available. For the external authentication to work properly, the internal password must not be the same as the user account LDAP password.

Add command policy to the user

1. Navigate to **System > User Administration > Users**.
2. Select the user that you created, and then click **Edit.**
3. In Bindings, click **System Command Policy**.
4. Select the correct command policy to apply to your user.
5. Click **Bind**, then click **Close**.



To add more administrators;

- Add the administrator users to the LDAP group you configured on the search filter.
- Create the system user in Citrix ADC and assign the correct command policy.

To configure LDAP authentication on the Citrix ADC appliance for management purposes by using the CLI

Use the following commands as a reference to configure log on for a group with superuser privileges on the Citrix ADC appliance CLI.

1. Create an LDAP server

```
add authentication ldapAction LDAP_mgmt -serverIP myAD.citrix.lab
    -serverPort 636 -ldapBase "DC=citrix,DC=lab" -ldapBindDn
    readonly@citrix.lab -ldapBindDnPassword -ldapLoginName
    sAMAccountName -searchFilter "&(memberof=CN=NSG_Admin,OU=
    AdminGroups,DC=citrix,DC=lab)" -groupAttrName memberOf
<!--NeedCopy-->
```

2. Create and LDAP policy

```
add authentication policy pol_LDAPmgmt -rule true -action
    LDAP_mgmt
<!--NeedCopy-->
```

3. Binding the LDAP policy

```
bind system global pol_LDAPmgmt -priority 110
<!--NeedCopy-->
```

4. Assign privileges to your administrators

   - To apply privileges on the group

```
add system group NSG_Admin
bind system group NSG_Admin -policyName superuser 100
<!--NeedCopy-->
```

   - To apply privileges individually for each user

```
add system user admyoa
bind system user admyoa superuser 100
<!--NeedCopy-->
```

RADIUS authentication

September 14, 2021

As with other types of authentication policies, a Remote Authentication Dial In User Service (RADIUS) authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. However, setting up a RADIUS authentication policy has certain special requirements that are described below.

Normally you configure the Citrix ADC to use the IP address of the authentication server during authentication. With RADIUS authentication servers, you can now configure the ADC to use the FQDN of the RADIUS server instead of its IP address to authenticate users. Using an FQDN can simplify an otherwise much more complex authentication, authorization, and auditing configuration in environments where the authentication server might be at any of several IP addresses, but always uses a single FQDN. To configure authentication by using a server's FQDN instead of its IP address, you follow the normal configuration process except when creating the authentication action. When creating the action, you substitute the **serverName** parameter for the **serverIP** parameter.

Before you decide whether to configure the Citrix ADC to use the IP or the FQDN of your RADIUS server to authenticate users, consider that configuring authentication, authorization, and auditing to authenticate to an FQDN instead of an IP address adds an extra step to the authentication process. Each time the ADC authenticates a user, it must resolve the FQDN. If a great many users attempt to authenticate simultaneously, the resulting DNS lookups might slow the authentication process.

> **Note**
>
> These instructions assume that you are already familiar with the RADIUS protocol and have already configured your chosen RADIUS authentication server.

To add an authentication action for a RADIUS server by using the command line interface

If you authenticate to a RADIUS server, you need to add an explicit authentication action. To do this, at the command prompt, type the following command:

```
1 add authentication radiusAction <name> [-serverip <IP> | -serverName] <
     FQDN>][-serverPort <port>] [-authTimeout <positive_integer>] {
2  -radKey  }
3   [-radNASip ( ENABLED | DISABLED )][-radNASid <string>] [-radVendorID
       <positive_integer>][-radAttributeType <positive_integer>][-
       radGroupsPrefix <string>] [-radGroupSeparator <string>][-
       passEncoding <passEncoding>][-ipVendorID <positive_integer>] [-
       ipAttributeType <positive_integer>][-accounting ( ON | OFF )][-
       pwdVendorID <positive_integer> [-pwdAttributeType <
       positive_integer>]] [-defaultAuthenticationGroup <string>] [-
       callingstationid ( ENABLED | DISABLED )]
4
```

```
5 <!--NeedCopy-->
```

The following example adds a RADIUS authentication action named **Authn-Act-1**, with the server IP **10.218.24.65**, the server port **1812**, the authentication timeout **15** minutes, the radius key **WareTheLorax**, NAS IP disabled, and NAS ID **NAS1**.

```
1 add authentication radiusaction Authn-Act-1 -serverip 10.218.24.65 -
     serverport 1812 -authtimeout 15 -radkey WareTheLorax -radNASip
     DISABLED -radNASid NAS1
2 Done
3
4 <!--NeedCopy-->
```

The following example adds the same RADIUS authentication action, but using the server FQDN **rad01.example.com** instead of the IP.

```
1 add authentication radiusaction Authn-Act-1 -serverName rad01.example.
     com -serverport 1812 -authtimeout 15 -radkey WareTheLorax -radNASip
     DISABLED -radNASid NAS1
2 Done
3
4 <!--NeedCopy-->
```

To configure an authentication action for an external RADIUS server by using the command line

To configure an existing RADIUS action, at the command prompt, type the following command:

```
1 set authentication radiusAction <name> [-serverip <IP> | -serverName] <
     FQDN>][-serverPort <port>] [-authTimeout <positive_integer>] {
2  -radKey  }
3   [-radNASip ( ENABLED | DISABLED )][-radNASid <string>] [-radVendorID
       <positive_integer>][-radAttributeType <positive_integer>][-
       radGroupsPrefix <string>] [-radGroupSeparator <string>][-
       passEncoding <passEncoding>][-ipVendorID <positive_integer>] [-
       ipAttributeType <positive_integer>][-accounting ( ON | OFF )][-
       pwdVendorID <positive_integer> [-pwdAttributeType <
       positive_integer>]] [-defaultAuthenticationGroup <string>] [-
       callingstationid ( ENABLED | DISABLED )]
4
5 <!--NeedCopy-->
```

To remove an authentication action for an external RADIUS server by using the command line interface

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>

<!--NeedCopy-->
```

Example

```
rm authentication radiusaction Authn-Act-1
Done

<!--NeedCopy-->
```

To configure a RADIUS server by using the configuration utility

> **Note**
>
> In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Radius**
2. In the details pane, on the **Servers** tab, do one of the following:
   - To create a new RADIUS server, click **Add**.
   - To modify an existing RADIUS server, select the server, and then click **Edit**.
3. In the **Create Authentication RADIUS Server** or **Configure Authentication RADIUS Server** dialog, type or select values for the parameters. To fill out parameters that appear beneath **Send Calling Station ID**, expand **Details**.
   - Name*—radiusActionName (Cannot be changed for a previously configured action)
   - Authentication Type*—authtype (Set to RADIUS, cannot be changed)
   - Server Name / IP Address*—Choose either Server Name or Server IP
     - Server Name*—serverName <FQDN>
     - IP Address*—serverIp <IP> If the server is assigned an IPv6 IP address, select the IPv6 check box.
   - Port*—serverPort
   - Time-out (seconds)*—authTimeout
   - Secret Key*—radKey (RADIUS shared secret.)

- Confirm Secret Key*—Type the RADIUS shared secret a second time. (No command line equivalent.)
- Send Calling Station ID—callingstationid
- Group Vendor Identifier—radVendorID
- Group Attribute Type—radAttributeType
- IP Address Vendor Identifier—ipVendorID
- pwdVendorID—pwdVendorID
- Password Encoding—passEncoding
- Default Authentication Group—defaultAuthenticationGroup
- NAS ID—radNASid
- Enable NAS IP address extraction—radNASip
- Group Prefix—radGroupsPrefix
- Group Separator—radGroupSeparator
- IP Address Attribute Type—ipAttributeType
- Password Attribute Type—pwdAttributeType
- Accounting—accounting

4. Click **Create** or **OK**. The policy that you created appears in the Servers page.

Support to pass through RADIUS attribute 66 (Tunnel-Client-Endpoint)

The Citrix ADC appliance now allows the pass-through of RADIUS attribute 66 (Tunnel-Client-Endpoint) during RADIUS authentication. By applying this feature, the clients IP address is received by second-factor authentication from entrusting to make risk-based authentication decisions.

A new attribute “tunnelEndpointClientIP” is introduced in both “add authentication radiusAction” and “set radiusParams” command.

To use this feature, at the Citrix ADC appliance command prompt, type:

```
add authentication radiusAction <name> {
 -serverIP <ip_addr|ipv6_addr|*> | {
 -serverName <string> }
  }
  [-serverPort <port>] … [-tunnelEndpointClientIP (ENABLED|DISABLED)]

set radiusParams {
 -serverIP <ip_addr|ipv6_addr|*> |{
```

```
 -serverName <string> }
  }
  [-serverPort<port>] … [-tunnelEndpointClientIP(ENABLED|DISABLED)]

<!--NeedCopy-->
```

Example

```
add authentication radiusAction radius -severIP 1.217.22.20 -serverName
    FQDN -serverPort 1812 -tunnelEndpointClientIp ENABLED

set radiusParams -serverIp 1.217.22.20 -serverName FQDN1 -serverPort
   1812 -tunnelEndpointClientIP ENABLED

<!--NeedCopy-->
```

Support for validating end-to-end RADIUS authentication

The Citrix ADC appliance can now validate end-to-end RADIUS authentication through a GUI. To validate this feature, a new “test” button is introduced in GUI. A Citrix ADC appliance administrator can leverage this feature to achieve the following benefits:

- Consolidates the complete flow (packet engine – aaa daemon – external server) to provide better analysis
- Reduces time on validating and troubleshooting issues related to individual scenarios

You have two options to configure and view the test results of RADIUS end-to-end authentication by using the GUI.

From system option

1. Navigate to **System > Authentication > Basic Policies > RADIUS,** click **Servers** tab.
2. Select the available **RADIUS action** from the list.
3. On the **Configure Authentication RADIUS Server** page, you have two options under **Connections Settings** section.
4. To check the RADIUS server connection, click **Test RADIUS Reachability** tab.
5. To view the end-to-end RADIUS authentication, click **Test End User Connection** link.

From Authentication option

1. Navigate to **Authentication > Dashboard**, select the available RADIUS action from the list.
2. On the **Configure Authentication RADIUS Server** page, you have two options under **Connections Settings** section.

3. To check the RADIUS server connection, click **Test RADIUS Reachability** tab.
4. To view the end-to-end RADIUS authentication status, click **Test End User Connection** link.

TACACS authentication

September 14, 2021

TACACS authentication policy authenticates to an external Terminal Access Controller Access-Control System (TACACS) authentication server.
After a user authenticates to a TACACS server, the Citrix ADC connects to the same TACACS server for all subsequent authorizations. When a primary TACACS server is unavailable, this feature prevents any delay while the ADC waits for the first TACACS server to time out. It happens before resending the authorization request to the second TACACS server.

> **Note:**
>
> TACACS authorization server does not support commands whose string length exceeds 255 characters.
>
> **Workaround:** Use local authorization instead of a TACACS authorization server.

When authenticating through a TACACS server, authentication, authorization, and auditing traffic management logs only successfully runs TACACS commands. It prevents the logs from showing TACACS commands that are entered by the users who were not authorized to run them.

Starting from NetScaler 12.0 Build 57.x, the Terminal Access Controller Access-Control System (TACACS) is not blocking the authentication, authorization, and auditing daemon while sending the TACACS request. The allow LDAP, and RADIUS authentication to proceed with the request. The TACACS authentication request resumes once the TACACS server acknowledges the TACACS request.

> **Important:**
>
> - Citrix recommends you do not modify any TACACS related configurations when you run a “clear ns config” command.
> - TACACS related configuration related to advanced policies is cleared and reapplied when the “RBAconfig” parameter is set to NO in “clear ns config” command for advanced policy.

Name-value attribute support for TACACS authentication

You can now configure TACACS authentication attributes with a unique name along with values. The names are configured in the TACACS action parameter and the values are obtained by querying for the names. By specifying the name attribute value, admins can easily search for the attribute value

associated with the attribute name. Also, admins no longer have to remember the attribute by its value alone.

> **Important**
>
> - In the tacacsAction command, you can configure a maximum of 64 attributes separated by comma with total size less than 2048 bytes.

To configure the name-value attributes by using the CLI

At the command prompt, type:

```
add authentication tacacsAction <name> [-Attributes <string>]
<!--NeedCopy-->
```

Example:

```
add authentication tacacsAction tacacsAct1 -attributes  “mail,sn,
   userprincipalName”
<!--NeedCopy-->
```

To add an authentication action by using the command line interface

If you do not use LOCAL authentication, you need to add an explicit authentication action. At the command prompt, type the following command:

```
add authentication tacacsAction <name> -serverip <IP> [-serverPort <
   port>][-authTimeout <positive_integer>][ ... ]
<!--NeedCopy-->
```

Example

```
add authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65 -
   serverport 1812                  -authtimeout 15 -tacacsSecret "
   minotaur" -authorization OFF -accounting ON -auditFailedCmds OFF -
   defaultAuthenticationGroup "users"
<!--NeedCopy-->
```

To configure an authentication action by using the command line interface

To configure an existing authentication action, at the command prompt, type the following command:

```
set authentication tacacsAction <name> -serverip <IP> [-serverPort <
   port>][-authTimeout <positive_integer>][ ... ]
```

```
<!--NeedCopy-->
```

Example

```
    > set authentication tacacsaction Authn-Act-1 -serverip
       10.218.24.65 -serverport 1812                  -authtimeout 15
       -tacacsSecret "minotaur" -authorization OFF -accounting ON -
       auditFailedCmds OFF -defaultAuthenticationGroup "users"    Done
<!--NeedCopy-->
```

To remove an authentication action by using the command line interface

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>
<!--NeedCopy-->
```

Example

```
rm authentication tacacsaction Authn-Act-1
<!--NeedCopy-->
```

Client certificate authentication

September 14, 2021

Web sites that contain sensitive content, such as online banking websites or websites with employee personal information, sometimes require client certificates for authentication. To configure authentication, authorization, and auditing to authenticate users on the basis of client-side certificate attributes, you first enable client authentication on the traffic management virtual server and bind the root certificate to the authentication virtual server. Then, you implement one of two options. You can configure the default authentication type on the authentication virtual server as CERT, or you can create a certificate action that defines what the Citrix ADC must do to authenticate users on the basis of a client certificate. In either case, your authentication server must support CRLs. You configure the ADC to extract the user name from the SubjectCN field or another specified field in the client certificate.

When the user tries to log on to an authentication virtual server for which an authentication policy is not configured, and a global cascade is not configured, the user name information is extracted from the specified field of the certificate. If the required field is extracted, the authentication succeeds. If the user does not provide a valid certificate during the SSL handshake, or if the user name extraction

fails, authentication fails. After it validates the client certificate, the ADC presents a logon page to the user.

The following procedures assume that you have already created a functioning authentication, authorization, and auditing configuration, and therefore they explain only how to enable authentication by using client certificates. These procedures also assume that you have obtained your root certificate and client certificates and have placed them on the ADC in the /nsconfig/ssl directory.

Configure client certificate authentication

To configure the authentication, authorization, and auditing client certificate parameters by using the command line interface

At the command prompt, type the following commands, in the order shown, to configure the certificate and verify the configuration:

```
add ssl certKey <certkeyName> -cert <certFile> -key <keyFile> -password
    -inform <inform> -expiryMonitor <expiryMonitor> -notificationPeriod
    <notificationPeriod>

bind ssl certKey <certkeyName> -vServer <certkeyName> -CA -crlCheck
   Mandatory

show ssl certKey [<certkeyName>]

set aaa parameter -defaultAuthType CERT

show aaa parameter

set aaa certParams -userNameField "Subject:CN"

show aaa certParams
<!--NeedCopy-->
```

To configure the authentication, authorization, and auditing client certificate parameters by using the configuration utility

1. Navigate to **Security > AAA - Application Traffic > Virtual Servers.**
2. In the details pane, select the virtual server that you want to configure to handle client certificate authentication, and then click **Edit.**
3. On the **Configuration** page, under **Certificates**, click the right arrow (>) to open the CA Cert Key installation dialog.
4. In the **CA Cert Key** dialog box, click **Insert.**

5. In the **CA Cert Key - SSL Certificates** dialog box, click **Install.**
6. In the **Install Certificate** dialog box, set the following parameters, whose names correspond to the CLI parameter names as shown:
   - Certificate-Key Pair Name*—certkeyName
   - Certificate File Name—certFile
   - Key File Name—keyFile
   - Certificate Format—inform
   - Password—password
   - Certificate Bundle—bundle
   - Notify When Expires—expiryMonitor
   - Notification Period—notificationPeriod
7. Click **Install**, and then click **Close**.
8. In the **CA Cert Key** dialog box, in the **Certificate** list, select the root certificate.
9. Click **Save**.
10. Click **Back** to return to the main configuration screen.
11. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > CERT**.
12. In the details pane, select the policy you want to configure to handle client certificate authentication, and then click **Edit**.
13. In the **Configure Authentication CERT Policy** dialog, Server drop-down list, select the virtual server you just configured to handle client certificate authentication.
14. Click **OK**. A message appears in the status bar, stating that the configuration completed successfully.

Client certificate authentication using advanced policies

Following are the steps to configure client certificate authentication on Citrix ADC using advanced policies.

1. Navigate to **Security > AAA - Application Traffic > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure to handle client certificate authentication, and click **Edit**.

   > **Note:**
   >
   > If you have imported a valid CA certificate and server certificate for the virtual server you can skip **step 3 to step 10**.

3. On the **Configuration** page, under **Certificates**, click **>** to open the **CA Cert Key** installation dialog box.
4. In the **CA Cert Key** dialog box, click **Insert**.
5. In the **CA Cert Key - SSL Certificates** dialog box, click **Install**.

6. In the **Install Certificate** dialog box, set the following parameters, whose names correspond to the CLI parameter names as shown:
    - Certificate-Key Pair Name—certkeyName
    - Certificate File Name—certFile
    - Key File Name—keyFile
    - Certificate Format—inform
    - Password—password
    - Certificate Bundle—bundle
    - Notify When Expires—expiryMonitor
    - Notification Period—notificationPeriod
7. Click **Install**, and then click Close.
8. In the **CA Cert Key** dialog box, from the Certificate list, select the root certificate.
9. Click **Save**.
10. Click **Back** to return to the main configuration screen.
11. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies**, and then select **Policy**.
12. In the details pane do one of the following:
    - To create a new policy, click **Add**.
    - To modify an existing policy, select the policy, and then click **Edit**.
13. In the **Create Authentication Policy** or **Configure Authentication Policy** dialog box, type or select values for the parameters.
    - Name - The policy name. Cannot be changed for a previously configured policy.
    - Action Type - Select Cert
    - Action - The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create a new action of the proper type.
    - Log Action - The audit action to associate with the policy. You can choose an existing audit action, or click the plus and create a new action.
    - Expression - The rule that selects connections to which you want to apply the action that you specified. The rule can be simple (“true” selects all traffic) or complex. You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open Add Expression dialog box and using the drop-down lists in it to construct your expression.)
    - Comment - You can type a comment that describes the type of traffic that this authentication policy will apply to. Optional.

14. Click **Create** or **OK**, and then click **Close**. If you created a policy, that policy appears in the Authentication Policies and Servers page.

Client certificate pass-through

The Citrix ADC can now be configured to pass client certificates through to protected applications that require client certificates for user authentication. The ADC first authenticates the user, then inserts the client certificate into the request and sends it to the application. This feature is configured by adding appropriate SSL policies.

The exact behavior of this feature when a user presents a client certificate depends upon the configuration of the VPN virtual server.

- If the VPN virtual server is configured to accept client certificates but not require them, the ADC inserts the certificate into the request and then forwards the request to the protected application.
- If the VPN virtual server has client certificate authentication disabled, the ADC renegotiatiates the authentication protocol and reauthenticates the user before it inserts the client certificate in the header and forwards the request to the protected application.
- If the VPN virtual server is configured to require client certificate authentication, the ADC uses the client certificate to authenticate the user, then inserts the certificate in the header and forwards the request to the protected application.

In all of these cases, you configure client certificate pass-through as follows.

Create and configure client certificate pass-through by using the command line interface

At the command prompt, type the following commands:

```
1 add vpn vserver <name> SSL <IP> 443
2 <!--NeedCopy-->
```

For *name*, substitute a name for the virtual server. The name must contain from one to 127 ASCII characters, beginning with a letter or underscore (_), and containing only letters, numbers, and the underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. For <IP>, substitute the IP address assigned to the virtual server.

```
1 set ssl vserver <name> -clientAuth ENABLED -clientCert <clientcert>
2 <!--NeedCopy-->
```

For <name>, substitute the name of the virtual server that you just created. For <clientCert>, substitute one of the following values:

- disabled—disables client certificate authentication on the VPN virtual server.

- mandatory—configures the VPN virtual server to require client certificates to authenticate.
- optional—configures the VPN virtual server to allow client certificate authentication, but not to require it.

```
bind vpn vserver <name> -policy local
<!--NeedCopy-->
```

For <name>, substitute the name of the VPN virtual server that you created.

```
bind vpn vserver <name> -policy cert
<!--NeedCopy-->
```

For <name>, substitute the name of the VPN virtual server that you created.

```
bind ssl vserver <name> -certkeyName <certkeyname>
<!--NeedCopy-->
```

For <name>, substitute the name of the virtual server that you created. For <certkeyName>, substitute the client certificate key.

```
bind ssl vserver <name> -certkeyName <cacertkeyname> -CA -ocspCheck
   Optional
<!--NeedCopy-->
```

For <name>, substitute the name of the virtual server that you created. For <cacertkeyName>, substitute the CA certificate key.

```
add ssl action <actname> -clientCert ENABLED -certHeader CLIENT-CERT
<!--NeedCopy-->
```

For <actname>, substitute a name for the SSL action.

```
add ssl policy <polname> -rule true -action <actname>
<!--NeedCopy-->
```

For <polname>, substitute a name for your new SSL policy. For <actname>, substitute the name of the SSL action that you just created.

```
bind ssl vserver <name> -policyName <polname> -priority 10
<!--NeedCopy-->
```

For <name>, substitute the name of the VPN virtual server.

Example

```
add vpn vserver vs-certpassthru SSL 10.121.250.75 443
set ssl vserver vs-certpassthru -clientAuth ENABLED -clientCert
   optional
bind vpn vserver vs-certpassthru -policy local
bind vpn vserver vs-certpassthru -policy cert
bind ssl vserver vs-certpassthru -certkeyName mycertKey
bind ssl vserver vs-certpassthru -certkeyName mycertKey -CA -ocspCheck
   Optional
add ssl action act-certpassthru -clientCert ENABLED -certHeader CLIENT-
   CERT
add ssl policy pol-certpassthru -rule true -action act-certpassthru
bind ssl vserver vs-certpassthru -policyName pol-certpassthru -priority
    10
<!--NeedCopy-->
```

Negotiate authentication

September 14, 2021

As with other types of authentication policies, a Negotiate authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy.

In addition to standard authentication functions, the Negotiate Action command can now extract user information from a keytab file instead of requiring you to enter that information manually. If a keytab has more than one SPN, authentication, authorization, and auditing selects the correct SPN. You can configure this feature at the command line, or by using the configuration utility.

> **Note**
>
> These instructions assume that you are already familiar with the LDAP protocol and have already configured your chosen LDAP authentication server.

To configure authentication, authorization, and auditing to extract user information from a keytab file by using the command line interface

At the command prompt, type the appropriate command:

```
add authentication negotiateAction <name> {
 -domain <string> }
  {
```

```
 -domainUser <string> }
  {
 -domainUserPasswd  }
  [-defaultAuthenticationGroup <string>] [-keytab <string>] [-NTLMPath
     <string>]

set authentication negotiateAction <name> {
 -domain <string> }
  {
 -domainUser <string> }
  {
 -domainUserPasswd }
  [-defaultAuthenticationGroup <string>] [-keytab <string>] [-NTLMPath
     <string>]
<!--NeedCopy-->
```

Parameter description

- **name** - Name of the negotiate action to be used.
- **domain** - Domain name of the service principal that represnts Citrix ADC.
- **domainUser** - User name of the account that is mapped with Citrix ADC principal. This can be given along with domain and password when keytab file is not available. If username is given along with keytab file, then that keytab file will be searched for this user's credentials. Maximum Length: 127
- **domainUserPasswd** - Password of the account that is mapped to the Citrix ADC principal.
- **defaultAuthenticationGroup** - This is the default group that is chosen when the authentication succeeds in addition to extracted groups. Maximum Length: 63
- **keytab** - The path to the keytab file that is used to decrypt kerberos tickets presented to Citrix ADC. If keytab is not available, domain/username/password can be specified in the negotiate action configuration. Maximum Length: 127
- **NTLMPath** - The path to the site that is enabled for NTLM authentication, including FQDN of the server. This is used when clients fallback to NTLM. Maximum Length: 127

To configure authentication, authorization, and auditing to extract user information from a keytab file by using the configuration utility

> Note
>
> In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to **Security > AAA - Application Traffic > Authentication > Advanced Policies > Actions > NEGOTIATE Actions**.

2. In the details pane, on the **Servers** tab, do one of the following:
   - If you want to create a new **Negotiate** action, click **Add**.
   - If you want to modify an existing **Negotiate** action, in the data pane select the action, and then click **Edit**.
3. If you are creating a new **Negotiate** action, in the **Name** text box, type a name for your new action. The name can be from one to 127 characters in length and can consist of upper- and lowercase letters, numbers, and the hyphen (-) and underscore (_) characters. If you are modifying an existing Negotiate action, skip this step. The name is read-only; you cannot change it.
4. Under **Negotiate**, if the Use Keytab file check box is not already checked, check it.
5. In the Keytab file path text box, type the full path and filename of the keytab file that you want to use.
6. In the Default authentication group text box, type the authentication group that you want to set as default for this user.
7. Click **Create** or **OK** to save your changes.

Points to note when advanced encryptions is used for Kerberos authentication

> - **Sample configuration when keytab is used:** add authentication negotiateAction neg_act_aes256 -keytab "/nsconfig/krb/lbvs_aes256.keytab"
> - **Use the following command when keytab has multiple encryption types.** The command additionally captures domain user parameters: add authentication negotiateAction neg_act_keytab_all -keytab "/nsconfig/krb/lbvs_all.keytab" -domainUser "HTTP/lbvs.aaa.local"
> - **Use the following commands when user credential are used:** add authentication negotiateAction neg_act_user -domain AAA.LOCAL -domainUser "HTTP/lbvs.aaa.local" -domainUserPasswd <password>
> - Ensure that the correct **domainUser** information is provided. You can look for the user logon name in AD.

Web authentication

September 14, 2021

Authentication, authorization, and auditing is now able to authenticate a user to a web server, providing the credentials that the web server requires in an HTTP request and analyzing the web server response to determine that user authentication was successful. As with other types of authentication

policies, a Web authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy.

To set up web-based authentication with a specific web server, first you create a web authentication action. Since authentication to web servers does not use a rigid format, you must specify exactly which information the web server requires and in which format when creating the action. To do this, you create an expression in Citrix ADC appliance default syntax that contains the following items:

- **Server IP**—The IP address of the authentication Web server.
- **Server Port**—The port of the authentication Web server.
- **Authentication Rule**—An expression in Citrix ADC appliance default syntax that contains the user's credentials in the format that the Web server expects.
- **Scheme**—HTTP (for unencrypted web authentication) or HTTPS (for encrypted web authentication).
- **Success Rule**—An expression in Citrix ADC appliance default syntax that matches the web server response string that signifies that the user authenticated successfully.

For all other parameters, follow the normal rules for the add authentication action command.

Next you create a policy associated with that action. The policy is similar to an LDAP policy, and like LDAP policies uses Citrix ADC appliance syntax.

> **Note**
>
> These instructions assume that you are already familiar with the authentication requirements of the web server(s) to which you want to authenticate, and have already configured the web authentication server.

To configure a Web authentication action by using the command line interface

To create a web authentication action at the command line, at the command line type the following command:

```
1 add authentication webAuthAction <name> -serverIP <ip_addr|ipv6_addr|*>
      -serverPort <port|*> [-fullReqExpr <string>] -scheme ( http | https
      ) -successRule <expression> [-defaultAuthenticationGroup <string
     >][-Attribute1 <string>][-Attribute2 <string>] [-Attribute3 <string
     >][-Attribute4 <string>] [-Attribute5 <string>][-Attribute6 <string
     >] [-Attribute7 <string>][-Attribute8 <string>] [-Attribute9 <string
     >][-Attribute10 <string>] [-Attribute11 <string>][-Attribute12 <
     string>] [-Attribute13 <string>][-Attribute14 <string>] [-
     Attribute15 <string>][-Attribute16 <string>]
2 <!--NeedCopy-->
```

Example

```
add policy expression post_data "\"username=\" + http.REQ.BODY(1000).
    SET_TEXT_MODE(IGNORECASE).AFTER_STR(\"login=\").BEFORE_STR(\"&\") +
    \"&passwort=\" + http.REQ.BODY(1000).SET_TEXT_MODE(IGNORECASE).
    AFTER_STR(\"passwd=\")"

add policy expression length_post_data "(\"username= \" + http.REQ.BODY
    (1000).SET_TEXT_MODE(IGNORECASE).AFTER_STR(\"login=\").BEFORE_STR
    (\"&\") + \"passwort=\" + http.REQ.BODY(1000).SET_TEXT_MODE(
    IGNORECASE).AFTER_STR(\"passwd=\")).length"

add authentication webAuthAction webAuth_POST -serverIP 10.106.187.54 -
    serverPort 80 -fullReqExpr q{
 "POST /MyPHP/auth.php HTTP/" + http.req.version.major + "." + http.req
     .version.major + "\r\nAccept:*/*\r\nHost: 10.106.187.54\r\nReferer:
      http://10.106.187.54/MyPHP/auth.php\r\nAccept-Language: en-US\r\
     nUser-Agent: Mozilla/5.0 (compatible; MSIE 9.0; Windows NT 6.1;
     Trident/5.0)\r\nContent-Type: application/x-www-form-urlencoded\r\n
     " + "Content-Length: " + length_post_data + "\r\nConnection: Keep-
     Alive\r\n\r\n" + post_data }
  -scheme http -successRule "http.res.status.eq(200)"
<!--NeedCopy-->
```

To configure a Web authentication action by using the configuration utility

> **Note**
>
> In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to **Security > AAA - Application Traffic > Policies > LDAP**.
2. In the details pane, on the **Servers** tab, do one of the following:
   - If you want to create a new web authentication action, click **Add**.
   - If you want to modify an existing web authentication action, in the data pane select the action, and then click **Edit**.
3. If you are creating a new web authentication action, in the **Create Authentication Web** server dialog box, **Name** text box, type a name for the new web authentication action. The name can be from one to 127 characters in length, and can consist of upper- and lowercase letters, numbers, and the hyphen (-) and underscore (_) characters. If you are modifying an existing web authentication action, skip this step. The name is read-only; you cannot change it.
4. In the **Web Server IP Address** text box, type the IPv4 or IPv6 IP address of the authentication web server. If the address is an IPv6 IP address, select the IPv6 check box first.

5. In the Port text box, type the port number on which the web server accepts connections.
6. Select **HTTP** or **HTTPS** in the **Protocol** drop-down list.
7. In the HTTP Request Expression text area, type a PCRE-format regular expression that creates the web server request that contains the user's credentials in the exact format expected by the authentication web server.
8. In the Expression to validate the Authentication text area, type a Citrix ADC appliance default syntax expression that describes the information in the web server response that indicates that user authentication was successful.
9. Fill out the remaining fields as described in the general authentication action documentation.
10. Click **OK**.

SMS two factor authentication using Web authentication

September 14, 2021

Citrix ADC can now be integrated with a third party SMS provider to provide an extra layer of authentication.

Citrix ADC appliance can be configured to send an OTP on the user's mobile as a second factor of authentication. The appliance presents the user with a logon form to enter the OTP after successful AD login. It is only after the successful second factor authentication the user is presented with the requested resource.

Configure SMS two factor authentication with Citrix ADC

Before you configure the SMS two factor authentication feature, you must have an LDAP authentication configured on a Citrix ADC appliance as first factor with authentication enabled. For instructions to configure LDAP authentication, see To configure LDAP authentication by using the configuration utility.

> **Note**
>
> Mobile number can be extracted using AAA.USER.ATTRIBUTE(1) and can be included while sending it to a back-end server.

Assign NS variable

At the command prompt, type the following commands:

```
add ns variable <variable name> -type "map(text(65),text(6),100000)" -
    ifValueTooBig undef -ifNoValue undef -expires 5

add ns assignment<variable name> -variable "$test[AAA.USER.SESSIONID]"
    -set ("000000" + SYS.RANDOM.MUL(1000000).TYPECAST_UNSIGNED_LONG_AT.
    TYPECAST_TEXT_T).SUFFIX(6)
<!--NeedCopy-->
```

Sample NS Variable assignment

```
add ns variable test -type "map(text(65),text(6),100000)" -
    ifValueTooBig undef -ifNoValue undef -expires 5

add ns assignment test -variable "$test[AAA.USER.SESSIONID]" -set ("
    000000" + SYS.RANDOM.MUL(1000000).TYPECAST_UNSIGNED_LONG_AT.
    TYPECAST_TEXT_T).SUFFIX(6)
<!--NeedCopy-->
```

Configure Webauth action

At the command prompt, type the following commands:

```
add policy expression <expression name> "\"method=sendMessage&send_to=&
    msg=OTP i \" + $test[AAA.USER.SESSIONID] + \"for login into secure
    access  gateway. Valid till EXPIRE_TIME. Do not share the OTP with
    anyone for security reasons.&userid=#####&password=###=1.0\""

add authentication webAuthAction webAuth_Get -serverIP <SERVER_IP> -
    serverPort <SERVER_PORT> -fullReqExpr q{
 "GET /GatewayAPI/rest?" + <expression name> + "HTTP/" + http.req.
     version.major + "." + http.req.version.minor.sub(1) + "\r\nAccept
     :*/*\r\nHost: <FQDN>\r\n" }
  -successRule "http.res.status.eq(200)" -scheme -successRule true

set authentication webAuthAction <web auth action name> <server IP
    address> -serverPort 8080 -fullReqExpr q{
 "POST /MyPHP/auth.php HTTP/" + http.req.version.major + "." + http.req
     .version.major + "\r\nAccept:*/*\r\nHost: <server IP address> \r\
     nContent-Length: 10\r\n\r\n" + <name in the format expected by SMS
     server> }
  -scheme http -successRule true
<!--NeedCopy-->
```

Sample Webauth action configuration

```
add policy expression otp_exp "\"method=sendMessage&send_to=&msg=OTP i
    \" + $test[AAA.USER.SESSIONID] + \"for login into secure access
    gateway. Valid till EXPIRE_TIME. Do not share the OTP with anyone
    for security reasons.&userid=#####&password=###=1.0\""

add authentication webAuthAction webAuth_Get -serverIP -serverIP
    10.106.168.210 -serverPort 8080 -fullReqExpr q{
 "GET /GatewayAPI/rest?" + otp_exp + "HTTP/" + http.req.version.major +
     "." + http.req.version.minor.sub(1) + "\r\nAccept:*/*\r\nHost: <
    FQDN>\r\n" }
  -successRule "http.res.status.eq(200)" -scheme -successRule true

set authentication webAuthAction webAuth_POST -serverIP 10.106.168.210
    -serverPort 8080 -fullReqExpr q{
 "POST /MyPHP/auth.php HTTP/" + http.req.version.major + "." + http.req
    .version.major + "\r\nAccept:*/*\r\nHost: 10.106.168.210 \r\
    nContent-Length: 10\r\n\r\n" + otp_set }
  -scheme http -successRule true
<!--NeedCopy-->
```

Sample first factor configuration

```
add authentication ldapAction ldap_action -serverIP 1.1.1.1 -serverPort
    3268 -authTimeout 30 -ldapBase "dc=nsi-test,dc=com" -ldapBindDn
    Administrator@nsi-test.com -ldapBindDnPassword freebsd -
    ldapLoginName samaccountname -groupAttrName memberOf -
    ssoNameAttribute samaccountname  -Attribute1 mobile -email mail -
    CloudAttributes DISABLED

add authentication Policy ldap_policy -rule true -action ldap_action
<!--NeedCopy-->
```

Sample second factor configuration

```
add authentication policylabel set_otp -loginSchema LSCHEMA_INT
add authentication Policy set_otp -rule true -action test

bind authentication policylabel set_otp -policyName set_otp -priority 1
    -gotoPriorityExpression NEXT
bind authentication policylabel set_otp -policyName cascade_noauth -
    priority 2 -gotoPriorityExpression NEXT -nextFactor check_otp

```

```
add authentication Policy check_otp -rule "$test.valueExists(AAA.USER.SESSIONID)" -action NO_AUTHN
add authentication policylabel check_otp -loginSchema LSCHEMA_INT
bind authentication policylabel check_otp -policyName wpp -priority 1 -gotoPriorityExpression NEXT
bind authentication policylabel check_otp -policyName wpp_cascade_noauth -priority 2 -gotoPriorityExpression NEXT -nextFactor otp_verify

add authentication Policy wpp -rule true -action webAuth_POST
add authentication Policy wpp_cascade_noauth -rule true -action NO_AUTHN

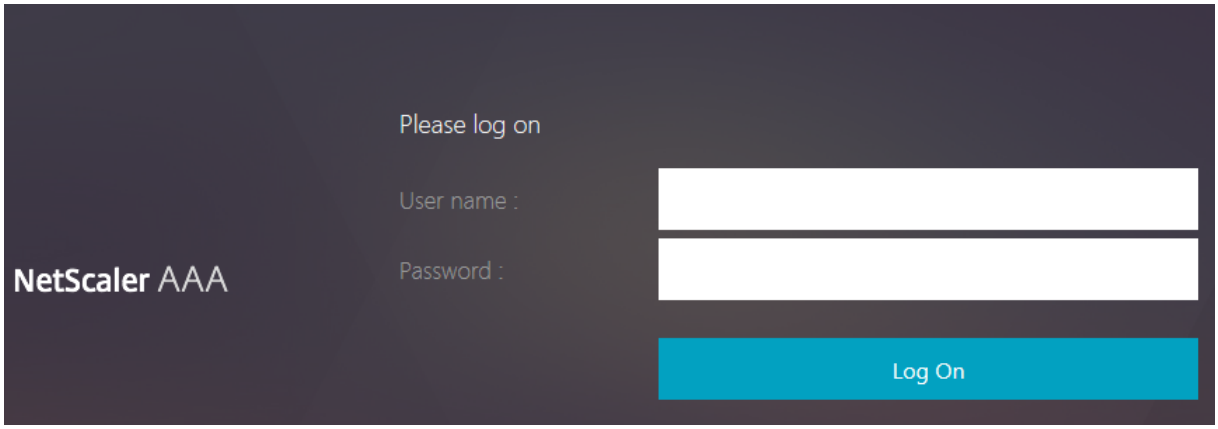
add authentication Policy otp_verify -rule "AAA.LOGIN.PASSWORD.EQ($test[AAA.USER.SESSIONID])" -action NO_AUTHN
add authentication policylabel otp_verify -loginSchema onlyPassword
bind authentication policylabel otp_verify -policyName otp_verify -priority 1 -gotoPriorityExpression NEXT

add authentication vserver avs SSL 10.106.40.121 443
bind authentication vserver avs -policy ldap_policy  -priority 1 -nextFactor set_otp -gotoPriorityExpression NEXT
<!--NeedCopy-->
```

Forms based authentication

September 14, 2021

With Forms based authentication, a logon form is presented to the end-user. This type of authentication form supports both multifactor (nFactor) authentication and Classic authentication.



Ensure the following for the Forms based authentication to work:

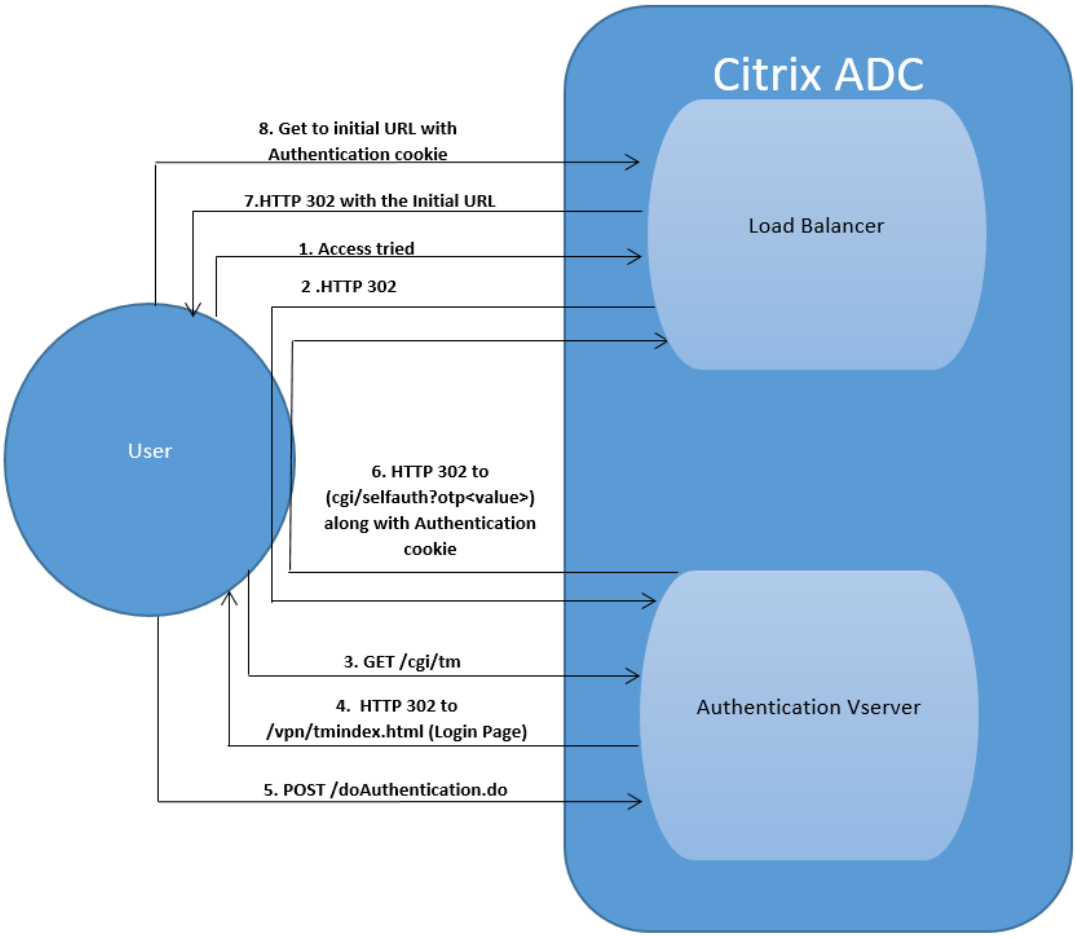
- The load balancing virtual server must have authentication turned **ON**.
- 'authenticationHost' parameter must be specified to which the user must be redirected for authentication. The command for configuring the same is as follows:

```
set lb vs lb1 -authentication on  - authenticationhost aaavs-ip/
   fqdn
```

- Form based authentication is compatible with browser that supports HTML

The following steps walk through how the Forms based authentication works:

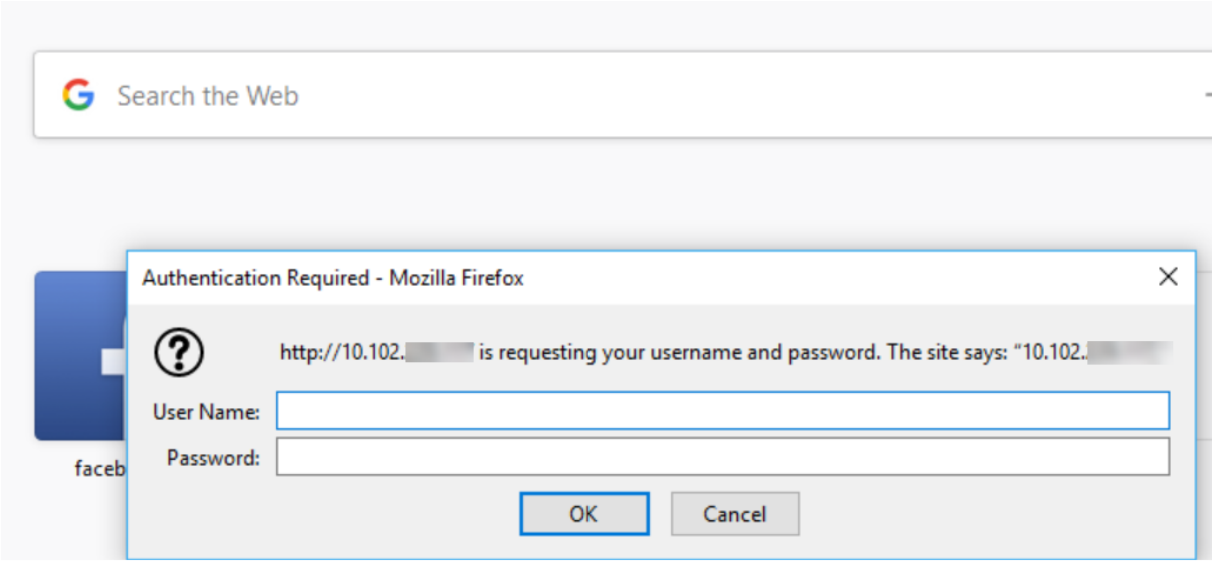
1. The client (browser) sends a GET request for a URL on the TM (load balancing/CS) virtual server.
2. The TM virtual server determines that the client has not been authenticated, and sends an HTTP 302 response to the client. The response contains a hidden script that causes the client to issue a GET request for /cgi/tm to the authentication virtual server.
3. The client sends GET /cgi/tm containing the target URL to the authentication virtual server.
4. The authentication virtual server sends out a redirect to the login page.
5. The user sends out its credentials to the authentication virtual server with a POST /doAuthentication.do. Authentication is done by the authentication virtual server.
6. If the credentials are correct, the authentication virtual server sends an HTTP 302 response to the cgi/selfauth url on the load balancing server with a one time token (OTP).
7. The load balancing server sends HTTP 302 to the client.
8. The client sends a GET request for their initial URL target URL along with a 32 byte cookie.



401 based authentication

September 14, 2021

With 401 based Authentication, the Citrix ADC appliance presents a pop-up dialog box to the end user.



Form based AAA-TM works on the redirect messages. However, some applications do not support redirects. In such applications, 401 authentication enabled AAA-TM is used.

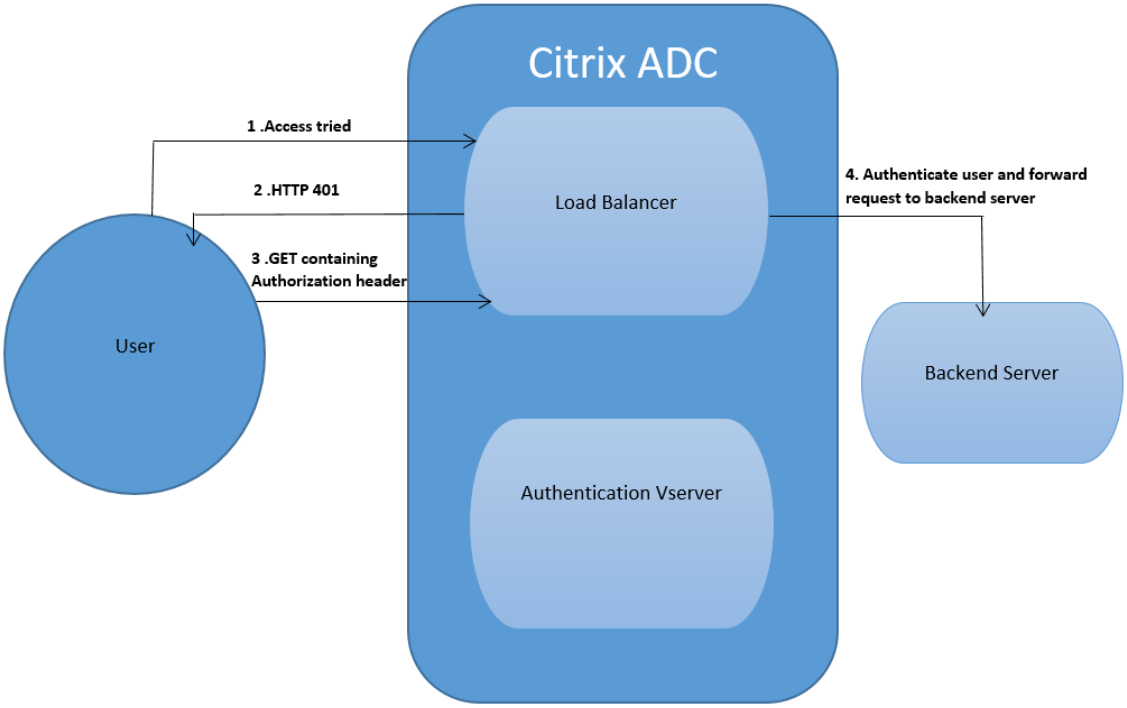
Ensure the following for 401 Authentication Enabled AAA-TM to work:

- 'authnVsName' parameter value for the load balancing virtual server must be the name of the authentication virtual server to be used to authenticate users.
- 'authn401' parameter must be enabled. The command for configuring the same is as follows:

```
1  set lb vs lb1 -authn401 on -authnvsName <aaavs-name>
```

The following steps walk through how the 401 Authentication works:

1. User tries to access a particular URL using the load balancing virtual server.
2. The load balancing virtual server sends a 401 HTTP response back to the user indicating that authentication is required for the access.
3. The user sends its credentials to the load balancing virtual server in the authorization header.
4. The load balancing virtual server authenticates the user and then connects the user to the back end servers.



reCaptcha configuration for nFactor authentication

September 14, 2021

Citrix Gateway supports a new first class action 'captchaAction' that simplifies reCaptcha configuration. As reCaptcha is a first class action, it can be a factor of its own. You can inject reCaptcha anywhere in the nFactor flow.

Previously, you had to write custom WebAuth policies with changes to RfWeb UI as well. With the introduction of captchaAction, you do not have to modify the JavaScript.

> **Important**
>
> If reCaptcha is used along with username or password fields in the schema, submit button is disabled until reCaptcha is met.

reCaptcha configuration

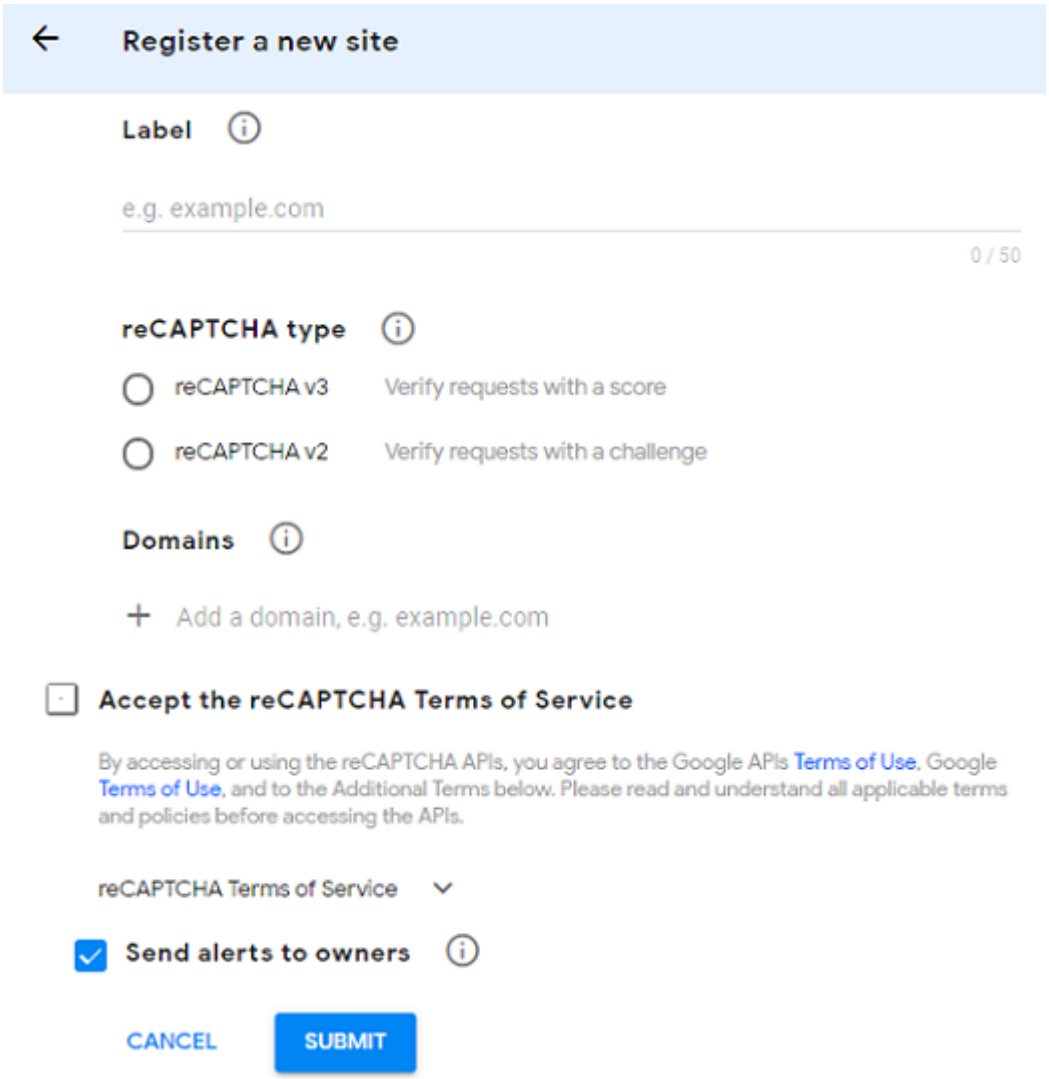
reCaptcha configuration involves two parts.

1. Configuration on Google for registering reCaptcha.
2. Configuration on Citrix ADC appliance to use reCaptcha as part of login flow.

reCaptcha configuration on Google

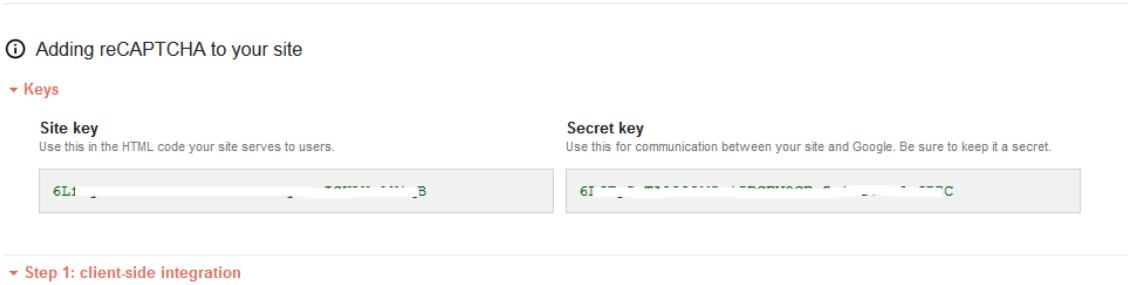
Register a domain for reCaptcha at https://www.google.com/recaptcha/admin.

1. When you navigate to this page, the following screen appears.



> **Note**
>
> Use reCAPTCHA v2 only. Invisible reCAPTCHA is still in Beta.

2. After a domain is registered, the “SiteKey” and “SecretKey” are displayed.



> **Note**
>
> The “SiteKey” and “SecretKey” are grayed out for security reasons. “SecretKey” must be kept safe.

reCaptcha configuration on Citrix ADC appliance

reCaptcha configuration on Citrix ADC appliance can be divided into three parts:

- Display reCaptcha screen
- Post the reCaptcha response to Google server
- LDAP configuration is second factor for user logon (optional)

Display reCaptcha screen

The login form customization is done through the SingleAuthCaptcha.xml loginschema. This customization is specified at authentication virtual server and is sent to UI for rendering the login form. The built-in loginschema, SingleAuthCaptcha.xml, is at /nsconfig/loginSchema/LoginSchema directory on the Citrix ADC appliance.

> **Important**
>
> - Based on your use case and different schemas, you can modify the existing schema. For instance if you need only reCaptcha factor (without username or password) or dual authentication with reCaptcha.
> - If any custom modifications are performed or the file is renamed, Citrix recommends copying all loginSchemas from /nsconfig/loginschema/LoginSchema directory to parent directory, /nsconfig/loginschema.

To configure display of reCaptcha using CLI

- `add authentication loginSchema singleauthcaptcha -authenticationSchema /nsconfig/loginschema/SingleAuthCaptcha.xml`
- `add authentication loginSchemaPolicy singleauthcaptcha -rule true -action singleauthcaptcha`

- add authentication vserver auth SSL <IP> <Port>
- add ssl certkey vserver-cert -cert <path-to-cert-file> -key <path-to-key-file>
- bind ssl vserver auth -certkey vserver-cert
- bind authentication vserver auth -policy singleauthcaptcha -priority 5 -gotoPriorityExpression END

Post the reCaptcha response to Google server

After you have configured the reCaptcha that must be displayed to the users, admins post add the configuration to the Google server to verify the reCaptcha response from browser.

To verify reCaptcha response from the browser

- add authentication captchaAction myrecaptcha -sitekey <sitekey-copied-from-google> -secretkey <secretkey-from-google>
- add authentication policy myrecaptcha -rule **true** -action myrecaptcha
- bind authentication vserver auth -policy myrecaptcha -priority 1

The following commands are required to configure if AD authentication is desired. Else, you can ignore this step.

- add authentication ldapAction ldap-**new** -serverIP x.x.x.x -serverPort 636 -ldapBase "cn=users,dc=aaatm,dc=com"-ldapBindDn adminuser@aaatm.com -ldapBindDnPassword <password> -encrypted -encryptmethod ENCMTHD_3 -ldapLoginName sAMAccountName -groupAttrName memberof -subAttributeName CN -secType SSL -passwdChange ENABLED -defaultAuthenticationGroup ldapGroup
- add authenticationpolicy ldap-**new** -rule **true** -action ldap-**new**

LDAP configuration is second factor for user logon (optional)

The LDAP authentication happens after reCaptcha, you add it to the second factor.

- add authentication policylabel second-factor
- bind authentication policylabel second-factor -policy ldap-**new** -priority 10
- bind authentication vserver auth -policy myrecaptcha -priority 1 -nextFactor second-factor

Administrator needs to add appropriate virtual servers depending on whether load balancing virtual server or Citrix Gateway appliance is used for access. Administrator must configure the following command if load balancing virtual server is required:

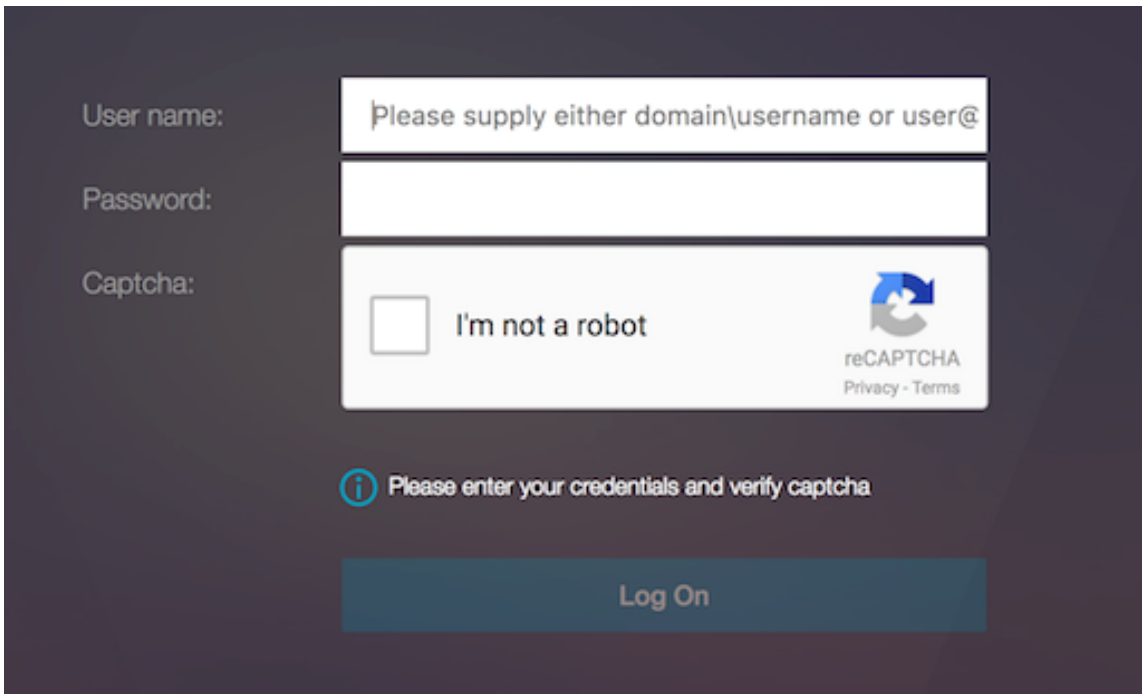
- `add lb vserver lbtest HTTP <IP> <Port> -authentication ON -authenticationHost nssp.aaatm.com`

  nssp.aaatm.com – Resolves to authentication virtual server.

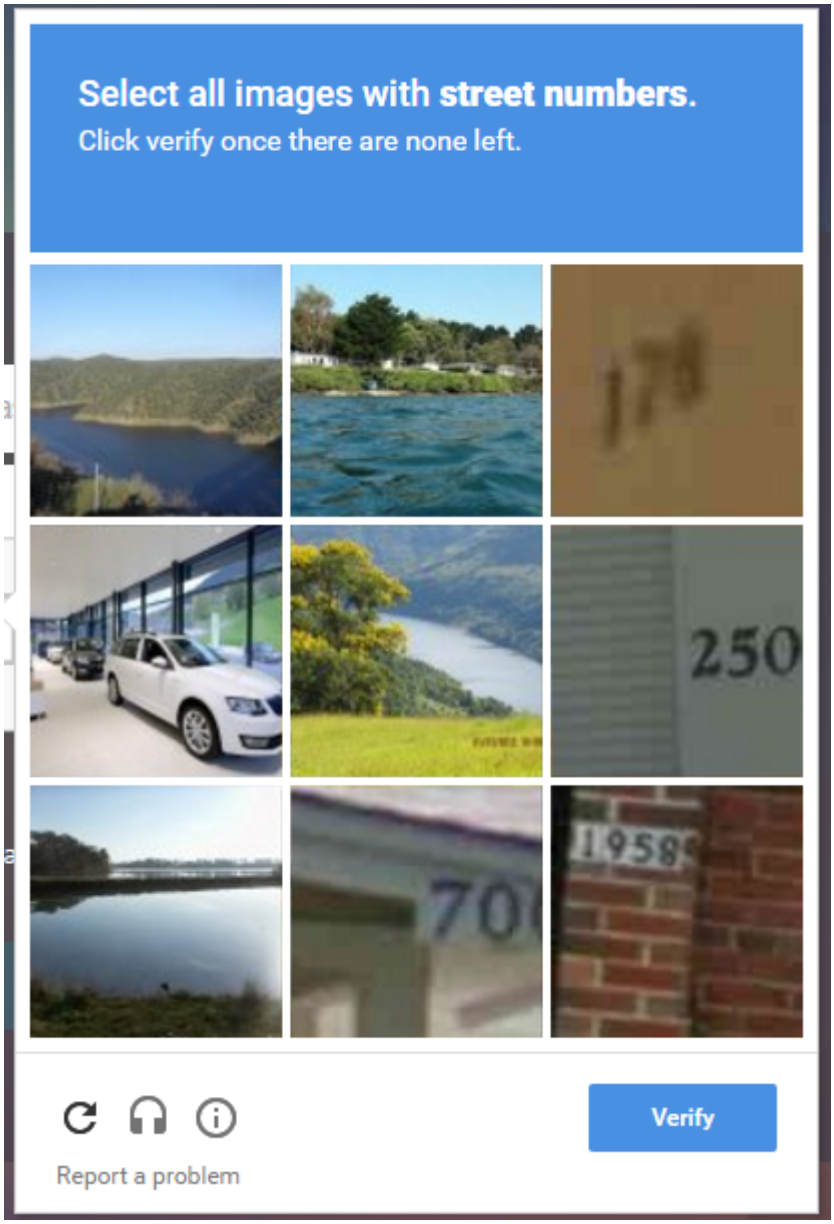
User validation of reCaptcha

Once you have configured all the steps mentioned in the previous sections, you must see the UI screenshots shown below.

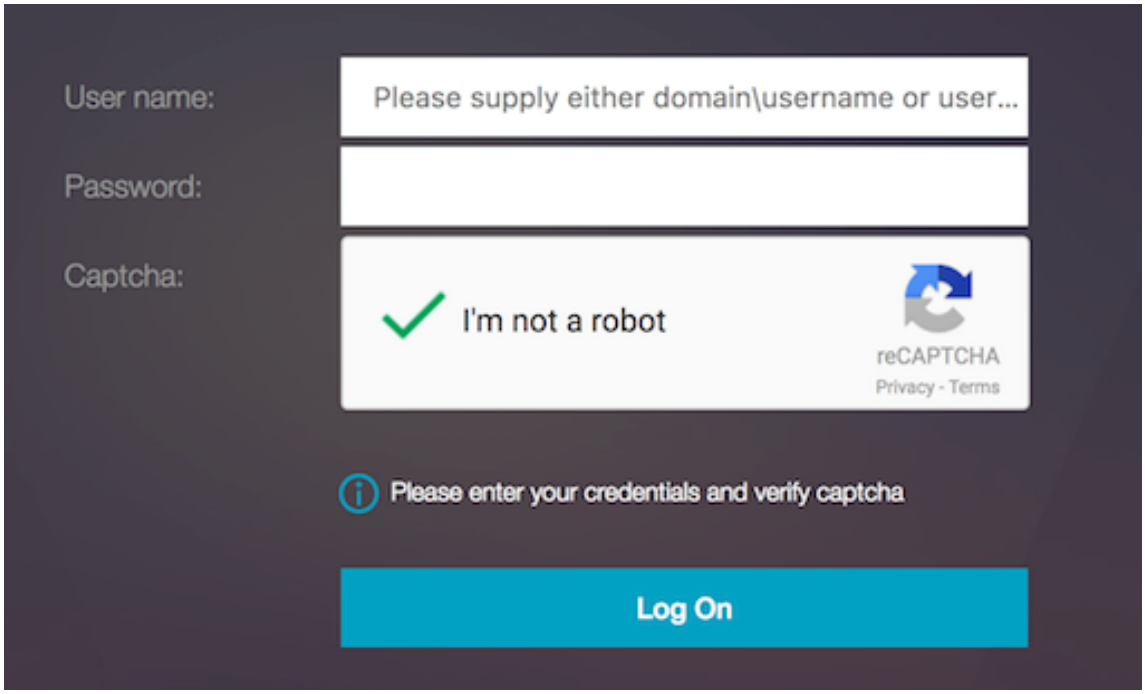
1. Once the authentication virtual server loads the login page, the logon screen is displayed. **Log On** is disabled until reCaptcha is complete.



2. Select I'm not a robot option. The reCaptcha widget is displayed.



3. You are navigated through series of reCaptcha images, before the completion page is displayed.
4. Enter the AD credentials, select the **I'm not a robot** check box and click **Log On**. If authentication succeeds, you are redirected to the desired resource.



Notes

- If reCaptcha is used with AD authentication, Submit button for credentials is disabled until reCaptcha is complete.
- The reCaptcha happens in a factor of its own. Therefore, any subsequent validations like AD must happen in the 'nextfactor' of reCaptcha.

Native OTP support for authentication

September 14, 2021

Citrix ADC supports one-time passwords (OTPs) without having to use a third-party server. One-time password is a highly secure option for authenticating to secure servers as the number or passcode generated is random. Previously, specialized firms, such as RSA with specific devices that generate random numbers offered the OTPs. This system must be in constant communication with the client to generate a number expected by the server.

In addition to reducing capital and operating expenses, this feature enhances the administrator's control by keeping the entire configuration on the Citrix ADC appliance.

Note

Because third-party servers are no longer needed, the Citrix ADC administrator has to configure an interface to manage and validate user devices.

User must be registered with a Citrix ADC virtual server to use the OTP solution. Registration is required only once per unique device, and can be restricted to certain environments. Configuring and validation of a registered user is similar to configuring an extra authentication policy.

Advantages of having Native OTP support

- Reduces operating cost by eliminating the need to have an extra infrastructure on an authenticating server in addition to the Active Directory.
- Consolidates configuration only to Citrix ADC appliance thus offering great control to administrators.
- Eliminates the client's dependence on an extra authentication server for generating a number expected by clients.

Native OTP workflow

The native OTP solution is a two-fold process and the workflow is classified as the following:

- Device registration
- End user login

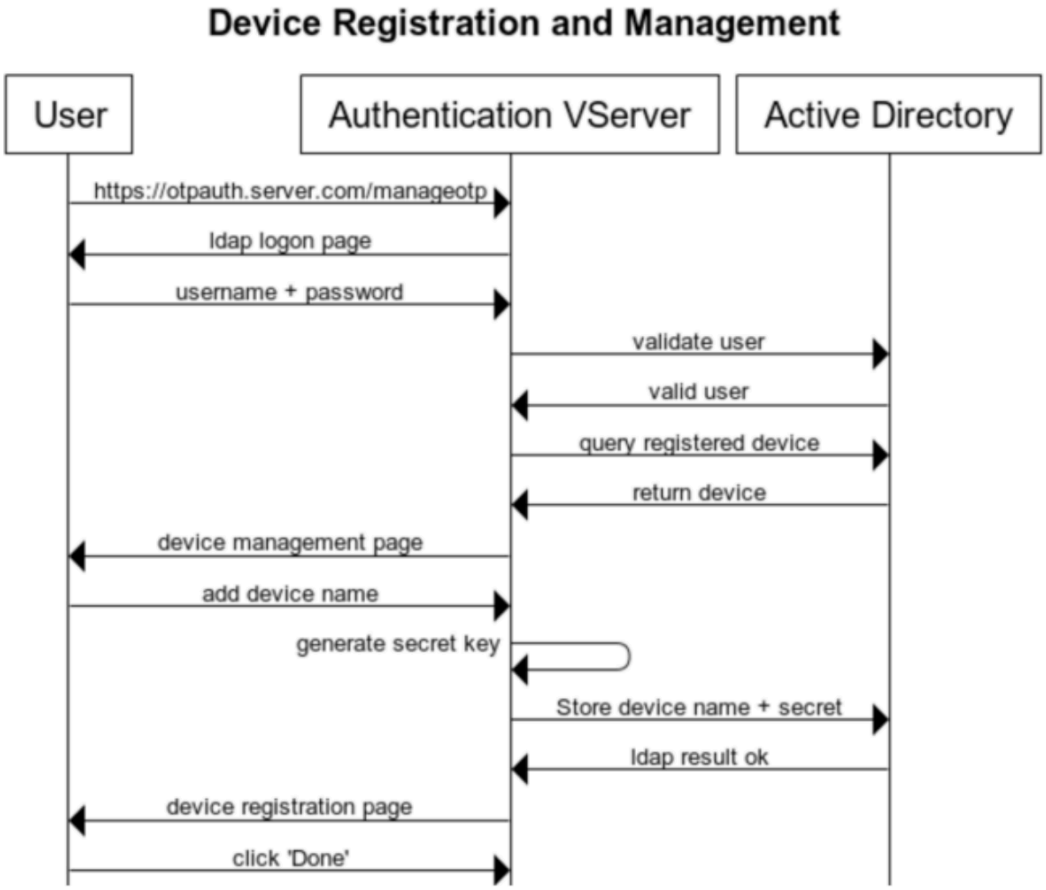
Important: You can skip the registration process if you are using third-party solutions or managing other devices apart from the Citrix ADC appliance. The final string that you add must be in the Citrix ADC specified format.

The following figure depicts the device registration flow to register a new device to receive OTP.

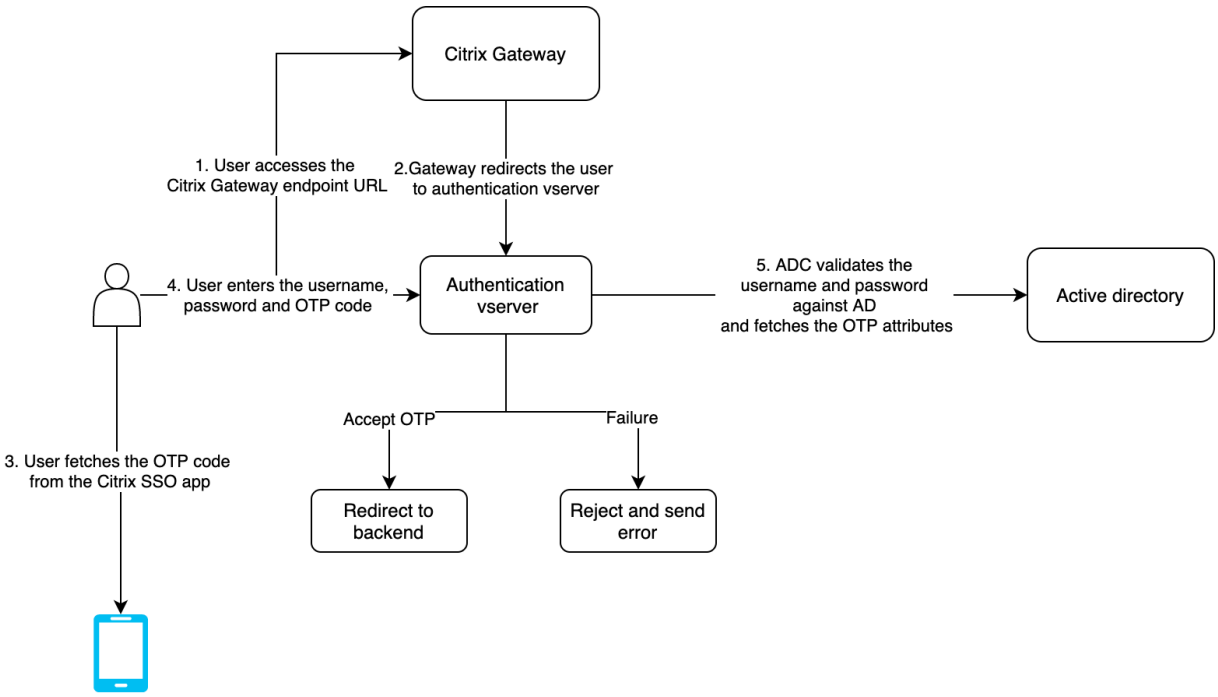
Note: The device registration can be done using any number of factors. The single factor (as specified in the previous figure) is used as an example to explain the device registration process.

The following figure depicts the verification of OTP through the registered device.

The following figure depicts the device registration and management flow.



The following figure depicts the end user flow for the Native OTP feature.



Prerequisites

To use the native OTP feature, make sure the following prerequisites are met.

- Citrix ADC feature release version is 12.0 build 51.24 and later.
- Advanced or Premium edition license is installed on Citrix Gateway.
- Citrix ADC is configured with management IP and the management console is accessible both using a browser and command line.
- Citrix ADC is configured with authentication, authorization, and auditing virtual server to authenticate users. For more information, see AAA
- Citrix ADC appliance is configured with Unified Gateway and the authentication, authorization, and auditing profile is assigned to the Gateway virtual server.
- Native OTP solution is restricted to nFactor authentication flow. Advanced policies are required to configure the solution. For more details, see Native OTP

Also ensure the following for Active Directory:

- A minimum attribute length of 256 characters.
- Attribute type must be 'DirectoryString' such as UserParameters. These attributes can hold string values.
- Attribute string type must be Unicode, if device name is in non-English characters.
- Citrix ADC LDAP administrator must have write access to the selected AD attribute.
- Citrix ADC appliance and client machine must be synced to a common Network Time Server.

Configure Native OTP using the GUI

The native OTP registration is not just a single factor authentication. The following sections help you to configure the single and second factor authentication.

Create Login Schema for first factor

1. Navigate to **Security AAA > Application Traffic > Login Schema**.
2. Go to **Profiles** and click **Add**.
3. On the **Create Authentication Login Schema** page, enter *lschema_single_auth_manage_otp* under the **Name** field and click **Edit** next to **noschema**.
4. Click the **LoginSchema** folder.
5. Scroll down to select **SingleAuth.xml** and click **Select**.
6. Click **Create**.
7. Click **Policies** and Click **Add**.
8. On the **Create Authentication Login Schema Policy** screen, enter the following values.

   Name: lpol_single_auth_manage_otp_by_url

   Profile: Select lschema_single_auth_manage_otp from the list.

   Rule: HTTP.REQ.COOKIE.VALUE(“NSC_TASS”).EQ(“`manageotp`”)

Configure authentication, authorization, and auditing virtual server

1. Navigate to **Security > AAA – Application Traffic > Authentication Virtual Servers**. Click to edit the existing virtual server. For more information, see AAA
2. Click the **+** icon next to **Login Schemas** under **Advanced Settings** in the right pane.
3. Select **No Login Schema**.
4. Click the arrow and select the **lpol_single_auth_manage_otp_by_url** Policy, click **Select**, and click **Bind**.
5. Scroll up and select **1 Authentication Policy** under **Advanced Authentication Policy**.
6. Right-click the **nFactor Policy** and select **Edit Binding**. Right-click the already configured nFactor Policy or refer to nFactor to create one and select Edit Binding.
7. Click the arrow under **Select Next Factor,** to select an existing configuration or click **Add** to create a new factor.

8. On the **Create Authentication PolicyLabel** screen, enter the following, and click **Continue**:

   Name: manage_otp_flow_label

   Login Schema: Lschema_Int

9. On the **Authentication PolicyLabel** screen, click **Add** to create a Policy.

   ```
   Create a policy for a normal LDAP server.
   ```

10. On the **Create Authentication Policy** screen, enter the following:

    Name: auth_pol_ldap_native_otp

11. Select the Action type as **LDAP** using the **Action Type** list.

12. In the **Action** field, click **Add** to create an action.

    ```
    Create the first LDAP action with authentication enabled to be used for
     single factor.
    ```

13. In the **Create Authentication LDAP server** page, select **Server IP** radio button, deselect the check box next to **Authentication**, enter the following values, and select **Test Connection**. The following is a sample configuration.

    Name: ldap_native_otp

    IP Address: 192.168.xx.xx

    Base DN: DC=training, DC=lab

    Administrator: Administrator@training.lab

    Password: `xxxxx`

    ```
    Create a policy for OTP .
    ```

14. On the **Create Authentication Policy** screen, enter the following:

    Name: auth_pol_ldap_otp_action

15. Select the Action type as **LDAP** using the **Action Type** list.

16. In the **Action** field, click **Add** to create an action.

    ```
    Create the second LDAP action to set OTP authenticator with OTP secret
    configuration and authentication unchecked.
    ```

17. In the **Create Authentication LDAP server** page, select **Server IP** radio button, deselect the check box next to **Authentication**, enter the following values, and select **Test Connection**. The following is a sample configuration.

    Name: ldap_otp_action

    IP Address: 192.168.xx.xx

Base DN: DC=training, DC=lab

Administrator: Administrator@training.lab

Password: xxxxx

18. Scroll down to the **Other Settings** section. Use the drop-down menu to select the following options.
Server Logon Name Attribute as **New** and type **userprincipalname**.
19. Use the drop-down menu to select **SSO Name Attribute** as **New** and type **userprincipalname**.
20. Enter “UserParameters” in the **OTP Secret** field and click **More**.
21. Enter the following Attributes.

Attribute 1 = mail
Attribute 2 = objectGUID
Attribute 3 = immutableID

22. Click **OK**.
23. On the **Create Authentication Policy** page, set the Expression to **true** and click **Create**.
24. On the **Create Authentication Policylabel** page, click **Bind**, and click **Done.**
25. On the **Policy Binding** page, click **Bind**.
26. On the **Authentication policy** page, click **Close** and click **Done**.

```
Create OTP for OTP verification.
```

27. On the **Create Authentication Policy** screen, enter the following:

Name: auth_pol_ldap_otp_verify

28. Select the Action type as **LDAP** using the **Action Type** list.
29. In the **Action** field, click **Add** to create an action.

```
Create the third LDAP action to verify OTP.
```

30. In the **Create Authentication LDAP server** page, select **Server IP** radio button, deselect the check box next to **Authentication**, enter the following values, and select **Test Connection**. The following is a sample configuration.

Name: ldap_verify_otp

IP Address: 192.168.xx.xx

Base DN: DC=training, DC=lab

Administrator: Administrator@training.lab

Password: xxxxx

31. Scroll down to the **Other Settings** section. Use the drop-down menu to select the following options.
    Server Logon Name Attribute as **New** and type **userprincipalname**.
32. Use the drop-down menu to select **SSO Name Attribute** as **New** and type **userprincipalname**.
33. Enter “UserParameters” in the **OTP Secret** field and click **More**.
34. Enter the following Attributes.

    Attribute 1 = mail
    Attribute 2 = objectGUID
    Attribute 3 = immutableID
35. Click **OK**.
36. On the **Create Authentication Policy** page, set the Expression to **true** and click **Create**.
37. On the **Create Authentication Policylabel** page, click **Bind**, and click **Done.**
38. On the **Policy Binding** page, click **Bind**.
39. On the **Authentication policy** page, click **Close** and click **Done**.

You probably don’t already have an Advanced Authentication Policy for your normal LDAP server.
Change the Action Type to LDAP.
Select your normal LDAP server, which is the one that has Authentication enabled.
Enter true as the expression. This uses Default Syntax instead of Classic Syntax.
Click Create.

> **Note**
>
> The authentication virtual server must be bound to the RFWebUI portal theme. Bind a server certificate to the server. The server IP ‘1.2.3.5’ must have a corresponding FQDN that is, otpauth.server.com, for later use.

Create login schema for second factor OTP

1. Navigate to **Security > AAA-Application Traffic > Virtual Servers**. Select the virtual server to be edited.
2. Scroll down and select **1 Login Schema**.
3. Click **Add Binding**.
4. Under the **Policy Binding** section, click **Add** to add a policy.
5. On the **Create Authentication Login Schema Policy** page, enter Name as OTP, and click **Add** to create a profile.
6. On the **Create Authentication Login Schema** page, enter Name as OTP, and click the pencil icon next to **noschema**.

7. Click the **LoginSchema** folder, select **DualAuthManageOTP.xml**, and then click **Select**.
8. Click **More** and scroll down.
9. In the **Password Credential Index** field, enter 1. This causes nFactor to save the user's password into AAA Attribute #1, which can be used later in a Traffic Policy to Single Sign-on to StoreFront. If you don't do this, then Citrix Gateway tries to use the Passcode to authenticate to StoreFront, which does not work.
10. Click **Create**.
11. In the **Rule** section, enter **True**. Click **Create**.
12. Click **Bind**.
13. Notice the two factors of authentication. Click **Close** and click **Done**.

Traffic Policy for Single Sign-on

1. Navigate to **Citrix Gateway > Policies > Traffic**
2. On the **Traffic Profiles** tab, click **Add**.
3. Enter a name for the traffic profile for OTP.
4. Scroll down, in the SSO Password Expression box, enter the following, and click **Create**. This is where we use the login schema password attribute specified for the second factor OTP.

   ```
   http.REQ.USER.ATTRIBUTE(1)
   ```

5. On **Traffic Policies** tab, click **Add**.
6. In the **Name** field, enter a name for the traffic policy.
7. In the **Request Profile** field, select the traffic profile you created.
8. In the Expression box, enter **True**. If your Citrix Gateway virtual server allows full VPN, change the expression to the following.

   ```
   http.req.method.eq(post)||http.req.method.eq(get)&& false
   ```

9. Click **Create**.

Configure content switching policy for manage OTP

The following configurations are required if you are using Unified Gateway.

1. Navigate to **Traffic Management > Content Switching > Policies**. Select the content switching policy, right click, and select **Edit**.
2. Edit the expression to evaluate the following OR statement and click **OK**:

is_vpn_url||HTTP.REQ.URL.CONTAINS("manageotp")

Configure Native OTP using the CLI

You must have the following information to configure the OTP device management page:

- IP assigned to authentication virtual server
- FQDN corresponding to the assigned IP
- Server certificate for authentication virtual server

> **Note:** Native OTP is a web-based solution only.

To configure the OTP device registration and management page

Create authentication virtual server

```
add authentication vserver authvs SSL 1.2.3.5 443
bind authentication vserver authvs -portaltheme RFWebUI
bind ssl vserver authvs -certkeyname otpauthcert
```

> **Note:** The authentication virtual server must be bound to the RFWebUI portal theme. Bind a server certificate to the server. The server IP '1.2.3.5' must have a corresponding FQDN that is, otpauth.server.com, for later use.

To create LDAP logon action

```
add authentication ldapAction <LDAP ACTION NAME> -serverIP <SERVER IP>
    -  serverPort <SERVER PORT> -ldapBase <BASE> -ldapBindDn <AD USER> -
    ldapBindDnPassword <PASSWO> -ldapLoginName <USER FORMAT>
```

Example:

```
add authentication ldapAction ldap_logon_action -serverIP 1.2.3.4 -
    serverPort 636 -ldapBase "OU=Users,DC=server,DC=com" -ldapBindDn
    administrator@ctxnsdev.com -ldapBindDnPassword PASSWORD -
    ldapLoginName userprincipalname
```

To add authentication policy for LDAP Logon

```
add authentication Policy auth_pol_ldap_logon -rule true -action
    ldap_logon_action
```

To present UI via LoginSchema

Show user name field and password field to users upon logon

```
add authentication loginSchema lschema_single_auth_manage_otp -
    authenticationSchema "/nsconfig/loginschema/LoginSchema/
    SingleAuthManageOTP.xml"
```

Display device registration and management page

Citrix recommends two ways of displaying the device registration and management screen: URL or host name.

- **Using URL**

  When the URL contains '/manageotp'

  - `add authentication loginSchemaPolicy lpol_single_auth_manage_otp_by_url -rule "http.req.cookie.value("NSC_TASS").contains("manageotp")"-action lschema_single_auth_manage_otp`
  - `bind authentication vserver authvs -policy lpol_single_auth_manage_otp_by_url -priority 10 -gotoPriorityExpression END`

- **Using hostname**

  When the host name is 'alt.server.com'

  - `add authentication loginSchemaPolicy lpol_single_auth_manage_otp_by_host -rule "http.req.header("host").eq("alt.server.com")"-action lschema_single_auth_manage_otp`
  - `bind authentication vserver authvs -policy lpol_single_auth_manage_otp_by_host -priority 20 -gotoPriorityExpression END`

To configure the user login page using the CLI

You must have the following information to configure the User Logon page:

- IP for a load balancing virtual server
- Corresponding FQDN for the load balancing virtual server
- Server certificate for the load balancing virtual server

  bind ssl vserver lbvs_https -certkeyname lbvs_server_cert

Back-end service in load balancing is represented as follows:

```
add service iis_backendsso_server_com 1.2.3.210 HTTP 80
bind lb vserver lbvs_https iis_backendsso_server_com
```

To create OTP passcode validation action

```
add authentication ldapAction <LDAP ACTION NAME> -serverIP <SERVER IP>
    -serverPort <SERVER PORT> -ldapBase <BASE> -ldapBindDn <AD USER> -
    ldapBindDnPassword <PASSWORD> -ldapLoginName <USER FORMAT> -
    authentication DISABLED -OTPSecret <LDAP ATTRIBUTE>`
```

Example:

```
add authentication ldapAction ldap_otp_action -serverIP 1.2.3.4 -
    serverPort 636 -ldapBase "OU=Users,DC=server,DC=com" -ldapBindDn
    administrator@ctxnsdev.com -ldapBindDnPassword PASSWORD -
    ldapLoginName userprincipalname -authentication DISABLED -OTPSecret
    userParameters
```

> **Important:** The difference between the LDAP logon and OTP action is the need to disable the authentication and introduce a new parameter `OTPSecret`. Do not use the AD attribute value.

To add authentication policy for OTP passcode validation

```
add authentication Policy auth_pol_otp_validation -rule true -action
    ldap_otp_action
```

To present the two-factor authentication through LoginSchema

Add the UI for two factor authentication.

```
add authentication loginSchema lscheme_dual_factor -
    authenticationSchema "/nsconfig/loginschema/LoginSchema/DualAuth.xml
    "
add authentication loginSchemaPolicy lpol_dual_factor -rule true -
    action lscheme_dual_factor
```

To create passcode validation factor via the policy label

Create a manage OTP flow policy label for the next factor (first factor is LDAP logon)

```
add authentication loginSchema lschema_noschema -authenticationSchema
    noschema
add authentication policylabel manage_otp_flow_label -loginSchema
    lschema_noschema
```

To bind the OTP policy to the policy label

```
bind authentication policylabel manage_otp_flow_label -policyName
    auth_pol_otp_validation -priority 10 -gotoPriorityExpression NEXT
```

To bind the UI flow

Bind the LDAP logon followed by the OTP validation with the authentication virtual server.

```
bind authentication vserver authvs -policy auth_pol_ldap_logon -
    priority 10 -nextFactor  manage_otp_flow_label -
    gotoPriorityExpression NEXT
bind authentication vserver authvs -policy lpol_dual_factor -priority
    30 -gotoPriorityExpression END
```

Register your device with Citrix ADC

1. Navigate to your Citrix ADC FQDN (first public facing IP), with a /manageotp suffix. For example, https://otpauth.server.com/manageotp Login with user credentials.
2. Click the **+** icon to add a device.
3. Enter a device name and press **Go**. A barcode appears on the screen.
4. Click **Begin Setup** and then click **Scan Barcode**.
5. Hover the device camera over the QR code. You can optionally enter the 16 digit code.

   > **Note**: The displayed QR code is valid for 3 minutes.

6. Upon successful scan, you are presented with a 6 digit time sensitive code that can be used to log in.
7. To test, click **Done** on the QR screen, then click the green check mark on the right.
8. Select your device from the drop-down menu and enter the code from Google Authenticator (must be blue, not red) and click **Go**.
9. Make sure to log out using the drop-down menu at the top right corner of the page.

Log in to Citrix ADC using the OTP

1. Navigate to your first public facing URL and enter your OTP from Google Authenticator to log on.
2. Authenticate to the Citrix ADC splash page.

Store OTP secret data in an encrypted format

September 14, 2021

Starting from Citrix ADC release 13.0 build 41.20, the OTP secret data can be stored in an encrypted format instead of plain text.

Previously, the Citrix ADC appliance stored OTP secret as a plain text in AD. Storing OTP secret in plain text poses a security threat as a malicious attacker or an admin might exploit the data by viewing the shared secret of other users.

The encryption parameter enables encryption of OTP secret in AD. When you register a new device with Citrix ADC version 13.0 build 41.20, and enable the encryption parameter, the OTP secret is stored in an encrypted format, by default. However, if the encryption parameter is disabled, the OTP secret is stored in plain text format.

For devices registered prior to 13.0 build 41.20, you must perform the following as a best practice:

1. Upgrade the 13.0 Citrix ADC appliance to 13.0 build 41.20.
2. Enable the encryption parameter on the appliance.
3. Use the OTP secret migration tool to migrate OTP secret data from plain text format to encrypted format.

For details about the OTP secret migration tool, see OTP encryption tool.

> **Important**
>
> Citrix recommends you as an admin to ensure the following criteria is met:
>
> - A new certificate must be configured to encrypt OTP secrets if you are not using KBA as part of self-service password reset feature.
>   - To bind the certificate to VPN global, you can use the following command:
>
>     ```
>     bind vpn global -userDataEncryptionKey <certificate name>
>     ```
>
> - If you are already using a certificate to encrypt KBA, you can use the same certificate to encrypt OTP secrets.

To enable OTP encryption data by using the CLI

At the command prompt, type:

```
set aaa otpparameter [-encryption ( ON | OFF )]
```

Example

```
set aaa otpparameter -encryption ON
```

To configure the OTP encryption by using the GUI

1. Navigate to **Security > AAA – Application Traffic** and click **Change authentication AAA OTP Parameter** under **Authentication Settings** section.
2. On the **Configure AAA OTP Parameter** page, select **OTP Secret encryption**.
3. Click OK.

Configuring the number of end-user devices for receiving OTP notifications

Administrators can now configure the number of devices that an end user can register to receive OTP notification or authentication.

To configure the number of devices in OTP by using the CLI

At the command prompt, type:

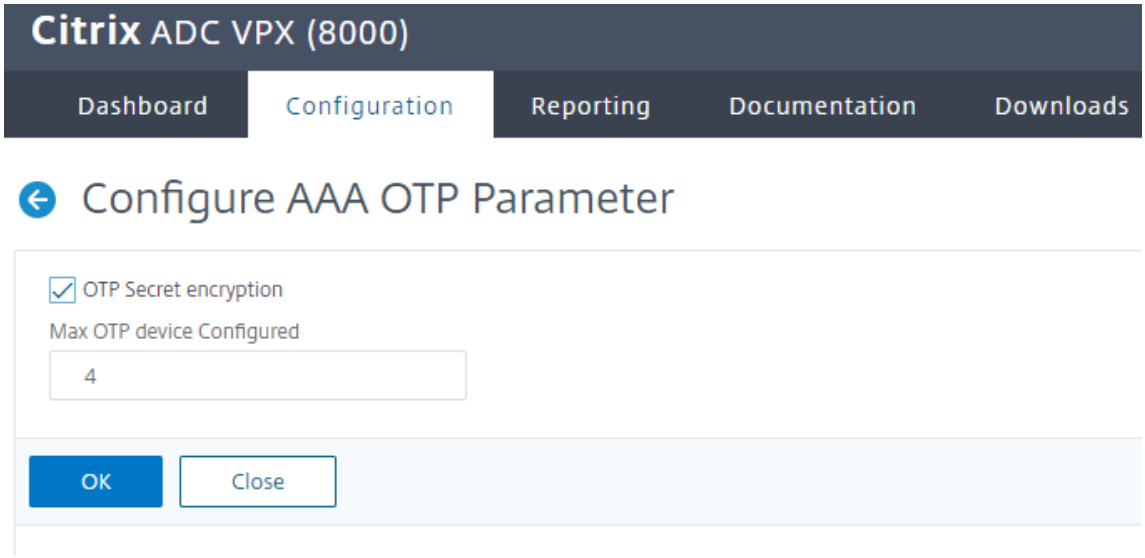
```
set aaa otpparameter [-maxOTPDevices <positive_integer>]
```

Example

```
set aaa otpparameter -maxOTPDevices 4
```

To configure the number of devices by using the GUI

1. Navigate to **Security > AAA – Application Traffic**, click **Change authentication AAA OTP Parameter** under **Authentication Settings** section.
2. On the **Configure AAA OTP Parameter** page, enter the value for **Max OTP device Configured**.
3. Click **OK**.



OTP encryption tool

September 14, 2021

Starting from Citrix ADC release 13.0 build 41.20, the OTP secret data is stored in an encrypted format instead of plain text for enhanced security. Storing of OTP secret in encrypted format is automatic and does not require manual intervention.

Previously, the Citrix ADC appliance stored OTP secret as a plain text in the active directory. Storing OTP secret in a plain text format posed a security threat as a malicious attacker or an admin could exploit the data by viewing the shared secret of other users.

The OTP encryption tool provides the following advantages:

- Does not result in any data loss even if you have old devices that are using old format (plain text).
- The backward compatibility support with old Citrix Gateway versions, helps to integrate and work with the existing devices, along with the new device.
- The OTP encryption tool helps admins migrate all the OTP secret data of all users at once.

> **Note**
>
> OTP encryption tool does not encrypt or decrypt KBA registration or Email registration data.

Uses of OTP encryption tool

The OTP encryption tool can be used for the following:

- **Encryption**. Store the OTP secret in encrypted format. The tool extracts the OTP data of the devices registered with Citrix ADC, and then converts the OTP data in plain text format to encrypted format.
- **Decryption**. Revert the OTP secret to the plain text format.
- **Update certificates**. Administrators can update the certificate to a new certificate at any time. Admins can use the tool to enter the new certificate and update all the entries with the new certificate data. The certificate path must either be an absolute path or a relative path.

> **Important**
>
> - You must enable the encryption parameter in the Citrix ADC appliance to use the OTP encryption tool.
> - For devices registered with Citrix ADC prior to build 41.20, you must perform the following:
>   - Upgrade the 13.0 Citrix ADC appliance to 13.0 build 41.20.
>   - Enable the encryption parameter on the appliance.
>   - Use the OTP Secret migration tool to migrate OTP secret data from plain text format to encrypted format.

OTP secret data in plain text format

Example:

```
##@devicename=<16 or more bytes>&tag=<64bytes>&,
```

As you can see, the starting pattern for old format is always “#@” and ending pattern is always “&”. All the data between “devicename=” and end pattern, constitutes user OTP data.

OTP secret data in encrypted format

The new encrypted format of OTP data is of the following format:

Example:

```
{

      "otpdata” : {

       “devices” : {

                        “device1” :  “value1” ,
                        “device2” :  “value2” , ⋯
                    }

          }

```

```
13       }
14
15 <!--NeedCopy-->
```

Where, value1 is base64 encoded value of kid + IV +cipher data

Cipher data is structured as following:

```
1     {
2
3       secret:<16-byte secret>,
4       tag : <64-byte tag value>
5       alg: <algorithm used> (not mandatory, default is sha1, specify
            the algorithm only if it is not default)
6       }
7
8  <!--NeedCopy-->
```

- In “devices”, you have value against each name. The value is base64encode(kid).base64encode(IV).base64en
- In standard AES algorithms, IV is always sent as first 16 or 32 bytes of cipher data. You can follow the same model.
- IV will differ for each device though key remains the same.

OTP encryption tool setup

The OTP encryption tool is located in the directory `\var\netscaler\otptool`. You must download the code from the Citrix ADC source and run the tool with the required AD credentials.

- Prerequisites for using the OTP encryption tool:
  - Install python 3.5 or higher version in the environment where this tool is run.
  - Install pip3 or later versions.
- Execute the following commands:
  - **pip install requirements.txt**. Automatically installs the requirements
  - **python main.py**. Invokes the OTP encryption tool. You must provide the required arguments as per your need for the migration of OTP secret data.
- The tool can be located at `\var\netscaler\otptool` from shell prompt.
- Run the tool with the required AD credentials.

OTP encryption tool interface

The following figure displays a sample OTP encryption tool interface. The interface contains all the arguments that must be defined for encryption/decryption/certificate upgrade. Also, a brief description of each argument is captured.

OPERATION argument

You must define the OPERATION argument to use the OTP encryption tool for encryption, decryption, or certificate upgrade.

The following table summarizes some of the scenarios in which you can use the OTP encryption tool and the corresponding OPERATION argument values.

Scenario	Operation argument value and other arguments
Convert plaintext OTP secret to encrypted format in the same attribute	Enter the OPERATION argument value as 0 and provide the same value for source and target attribute. **Example:** `python3 main.py -Host 192.0.2.1 -Port 636 -username ldapbind_user@aaa.local -search_base cn=users,dc=aaa,dc=local -source_attribute unixhomedirectory -target_attribute unixhomedirectory -operation 0 -cert_path aaatm_wild_all.cert`
Convert plaintext OTP secret to encrypted format in a different attribute	Enter the OPERATION argument value as 0 and provide the corresponding values for source and target attribute. **Example:** `python3 main.py -Host 192.0.2.1 -Port 636 -username ldapbind_user@aaa.local -search_base cn=users,dc=aaa,dc=local -source_attribute unixhomedirectory -target_attribute userparameters -operation 0 -cert_path aaatm_wild_all.cert`
Convert the encrypted entries back to plaintext	Enter the OPERATION argument value as 1 and provide the corresponding values for source and target attribute. **Example:** `python3 main.py -Host 192.0.2.1 -Port 636 -username ldapbind_user@aaa.local -search_base cn=users,dc=aaa,dc=local -source_attribute unixhomedirectory -target_attribute userparameters -operation 1 -cert_path aaatm_wild_all.cert`

Scenario	Operation argument value and other arguments
Update the certificate to a new certificate	Enter the OPERATION argument value as 2 and provide all the previous certificate and the new certificate details in the corresponding arguments. **Example:** `python3 main.py -Host 192.0.2.1 -Port 636 -username ldapbind_user@aaa.local -search_base cn=users,dc=aaa,dc=local -source_attribute unixhomedirectory -target_attribute userparameters -operation 2 -cert_path aaatm_wild_all.cert -new_cert_path aaatm_wild_all_new.cert`

CERT_PATH argument

The CERT_PATH argument specifies the certificate which is used in the Citrix ADC for encrypting the data. The user must provide this argument for all the three operations namely **Encryption**, **Decryption**, and **Update certificates**.

> **Points to note about the certificate**
>
> - The user must provide the same certificate which is bound globally in Citrix ADC for user data encryption.
> - The certificate must contain the Base64 encoded public certificate and its corresponding RSA private key in the same file.
> - The format of the certificate has to be either PEM or CERT. The certificate must adhere to X509 format.
> - Password protected certificate format and *.pfx* file are not accepted by this tool. The user must convert the PFX certificates to *.cert* before providing the certificates to the tool.

SEARCH_FILTER argument

The SEARCH_FILTER argument is used to filter the AD domains or users. The format of this search filter is same as the LDAP search filter format used in the LDAP action command in Citrix ADC.

Enabling encryption option in the Citrix ADC appliance

To encrypt the plain text format, you must enable the encryption option in the Citrix ADC appliance.

To enable OTP encryption data by using the CLI, at the command prompt, type:

```
set aaa otpparameter [-encryption ( ON | OFF )]
```

Example:

```
set aaa otpparameter -encryption ON
```

OTP encryption tool use cases

The OTP encryption tool can be used for the following use cases.

Register new devices with Citrix ADC appliance version 13.0 build 41.20

When you register your new device with Citrix ADC appliance version 13.0 build 41.x, and if the encryption option is enabled, then the OTP data is saved in an encrypted format. You can avoid manual intervention.

If the encryption option is not enabled, the OTP data is stored in the plain text format.

Migrate OTP data for the devices registered previous to 13.0 build 41.20

You must perform the following to encrypt the OTP secret data for the devices that are registered with Citrix ADC appliance prior to 13.0 build 41.20.

- Use the conversion tool to migrate OTP data from plain text format to encrypted format.
- Enable the “Encryption” parameter on Citrix ADC appliance.
  - To enable encryption option by using the CLI:
    - `set aaa otpparameter -encryption ON`
  - To enable encryption options by using the GUI:
    - Navigate to **Security > AAA – Application Traffic** and click **Change authentication AAA OTP Parameter** under **Authentication Settings** section.
    - On the **Configure AAA OTP Parameter** page, select **OTP Secret encryption**, and click **OK**.
  - Log in with the valid AD credentials.
  - If it is required, register additional devices (optional).

Migrate encrypted data from old certificate to new certificate

If admins want to update the certificate to a new certificate, the tool provides an option to update the new certificate data entries.

To update the certificate to a new certificate by using the CLI

At the command prompt, type:

Example:

```
python3 main.py -Host 192.0.2.1 -Port 636 -username ldapbind_user@aaa.local
-search_base cn=users,dc=aaa,dc=local -source_attribute unixhomedirectory -
target_attribute userparameters -operation 2 -cert_path aaatm_wild_all.cert
 -new_cert_path aaatm_wild_all_new.cert
```

> **Note**
>
> - The certificates must contain both private and public keys.
> - Currently, the functionality is provided only for OTP.

Re-encrypt or migrate to new certificate for devices registered after the appliance is upgraded to 13.0 build 41.20 with encryption

Admin can use the tool on the devices that are already encrypted with a certificate, and can update that certificate with a new certificate.

Convert encrypted data back to plain text format

Admin can decrypt the OTP secret and revert them to the original plain text format. The OTP encryption tool scans through all the users for OTP secret in encrypted format and converts them to decrypted format.

To update the certificate to a new certificate by using the CLI

At the command prompt, type:

Example:

```
1 python3 main.py -Host 192.0.2.1 - Port 636 -username  ldapbind_user@aaa
     .local -search_base cn=users,dc=aaa,dc=local -source_attribute
     unixhomedirectory -target_attribute userparameters -operation 1
2 <!--NeedCopy-->
```

Troubleshooting

The tool generates the following log files.

- **app.log**. Logs all the major steps of execution and information about errors, warnings, and failures.

- **unmodified_users.txt**. Contains a list of User DNs that was not upgraded from plain text to encrypted format. These logs are generated to an error in format or might be due to some other reason.

Push notification for OTP

September 14, 2021

Citrix Gateway supports push notifications for OTP. Users do not have to manually enter the OTP received on their registered devices to log in to Citrix Gateway. Admins can configure Citrix Gateway such that login notifications are sent to users' registered devices using push notification services. When users receive the notification, they have to simply tap Allow on the notification to log in to Citrix Gateway. When gateway receives acknowledgment from the user, it identifies source of the request, and sends response to that browser connection.

If the notification response is not received within the timeout period (30 seconds), users are redirected to the Citrix Gateway login page. The users can then enter the OTP manually or click **Resend Notification** to receive the notification again on the registered device.

Admins can make push notification authentication as the default authentication by using the login schemas created for push notification.

> **Important:**
>
> Push notification feature is available with a Citrix ADC Premium edition license.

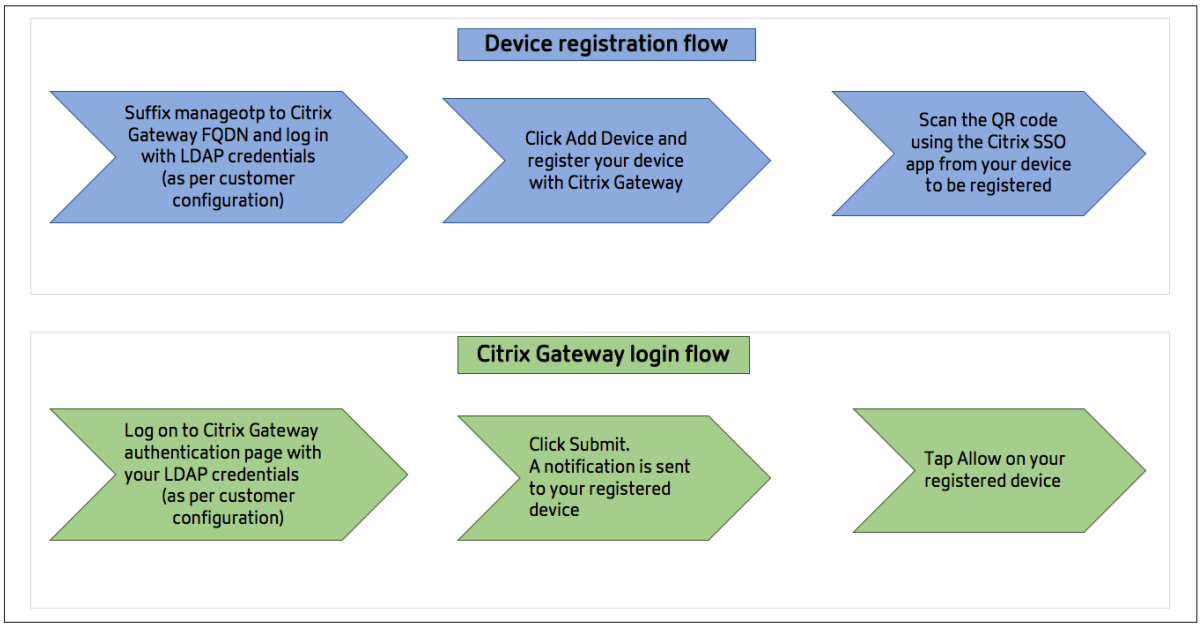
Advantages of push notifications

- Push notifications provide a more secure multifactor authentication mechanism. Authentication to Citrix Gateway is not successful until the user approves the login attempt.
- Push notification is easy to administer and use. Users have to download and install the Citrix SSO mobile app that does not require any administrator assistance.
- Users do not have to copy or remember the code. They have to simply tap on the device to get authenticated.
- Users can register multiple devices.

How push notifications work

The push notification workflow can be classified into two categories:

- Device registration
- End user login



Prerequisites for using push notification

- Complete the Citrix Cloud onboarding process.
  1. Create a Citrix Cloud company account or join an existing one. For detailed processes and instructions on how to proceed, see Signing Up for Citrix Cloud.
  2. Log in to https://citrix.cloud.com, and select the customer.
  3. From Menu, select **Identity and Access Management** and then navigate to **API Access** tab to create a client for the account.
  4. Copy the ID, secret, and customer ID. The ID and secret are required to configure push service in Citrix ADC as “ClientID” and “ClientSecret” respectively.

> **Important:**
>
> - Same API credentials can be used on multiple data centers.
> - On premises Citrix ADC appliances must be able to resolve server addresses mfa.cloud.com and trust.citrixworkspacesapi.net and are accessible from the appliance. This is to ensure that there are no firewalls or IP address blocks for these servers over port 443.

- Download the Citrix SSO mobile app from App Store and Play Store for iOS devices and Android devices respectively. Push notification is supported on iOS from build 1.1.13 on Android from 2.3.5.
- Ensure the following for the Active Directory.
  - Minimum attribute length must be at least 256 characters.

- Attribute type must be 'DirectoryString' such as UserParameters. These attributes can hold string values.
- Attribute string type must be Unicode, if device name is in non-English characters.
- Citrix ADC LDAP administrator must have write access to the selected AD attribute.
- Citrix ADC and the client machine must be synchronized to a common Network Time Server.

Push notification configuration

The following are the high-level steps that must be completed to use the push notification functionality.

- The Citrix Gateway administrator must configure the interface to manage and validate users.
  1. Configure a push service.
  2. Configure Citrix Gateway for OTP management and end user login.

     Users must register their devices with gateway for logging in to Citrix Gateway.
  3. Register your device with Citrix Gateway.
  4. Log in to Citrix Gateway.

Create a push service

1. Navigate to **Security** > **AAA-Application Traffic** > **Policies** > **Authentication** > **Advanced Policies** > **Actions** > **Push Service** and click **Add**.
2. In **Name**, enter the name of the push service.
3. In **Client ID**, enter the unique identity of the relying party for communicating with Citrix Push server in cloud.
4. In **Client Secret**, enter the unique secret of the relying party for communicating with Citrix Push server in cloud.
5. In **Customer ID**, enter the customer ID or name of the account in cloud that is used to create Client ID and Client Secret pair.

> **Important**
>
> The TLS 1.2 version is required for push service. For more information, see TLS 1.2 configuration details.

Configure Citrix Gateway for OTP management and end user login

Complete the following steps for OTP management and end user login.

- Create login schema for OTP management
- Configure authentication, authorization, and auditing virtual server
- Configure VPN or load balancing virtual servers
- Configure policy label
- Create login schema for end user login

For details on configuration, see Native OTP support.

Important: For push notification, admins must explicitly configure the following:

- Create a push service.
- While creating login schema for OTP management, select the SingleAuthManageOTP.xml login schema or equivalent as per the need.
- While creating login schema for end user login, select the DualAuthOrPush.xml login schema or equivalent as per the need.

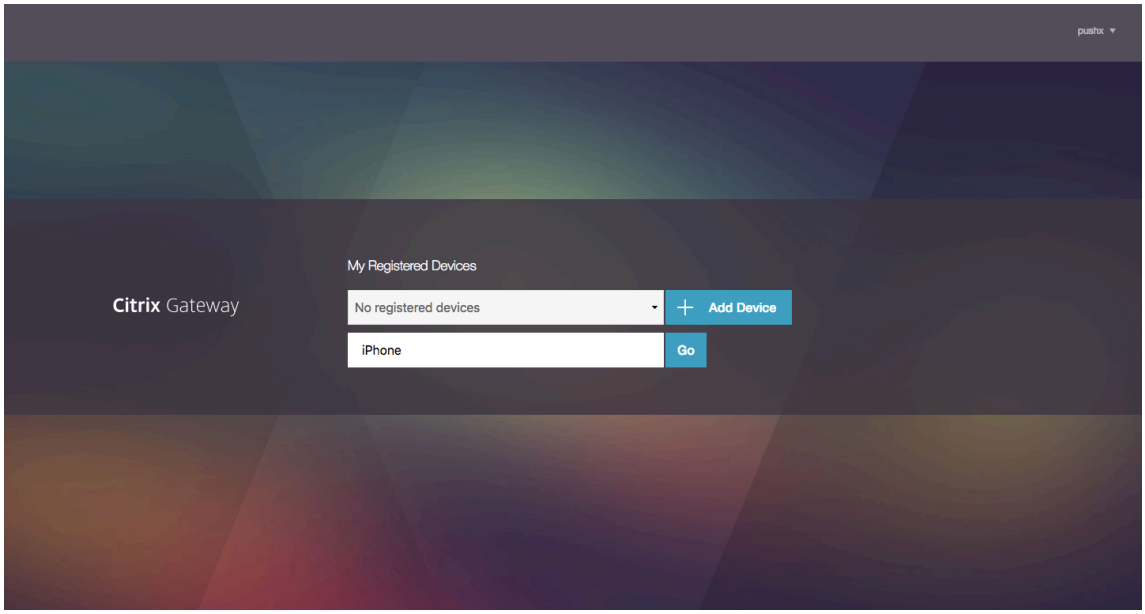
Register your device with Citrix Gateway

Users must register their devices with Citrix Gateway to use the push notification functionality.

1. In your web browser, browse to your Citrix Gateway FQDN, and suffix **/manageotp** to the FQDN.

   This loads the authentication page.
   Example: https://gateway.company.com/manageotp

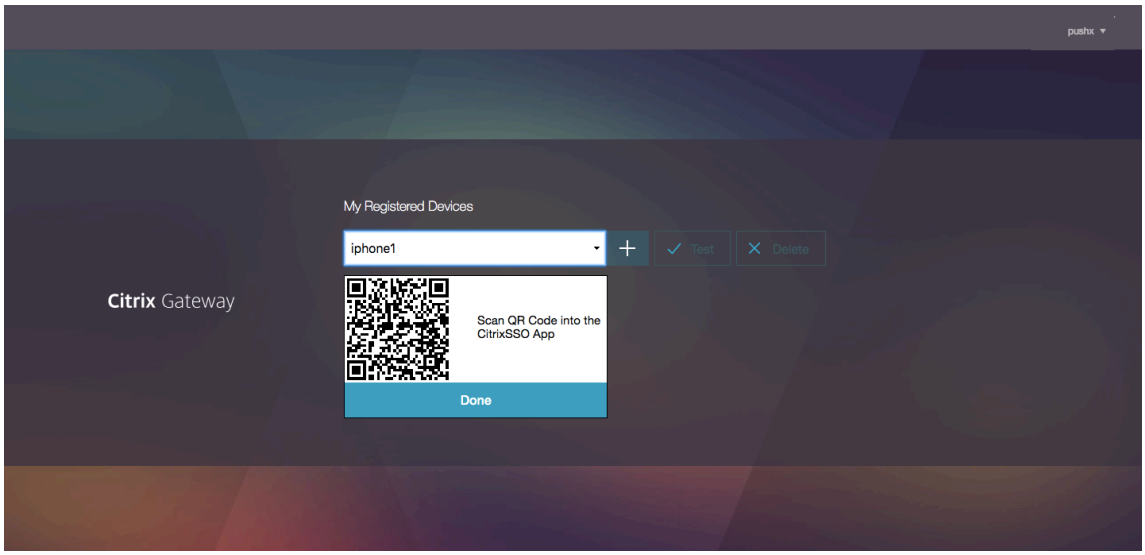
2. Log in using your LDAP credentials or appropriate two-factor authentication mechanisms, as required.



3. Click **Add Device**.

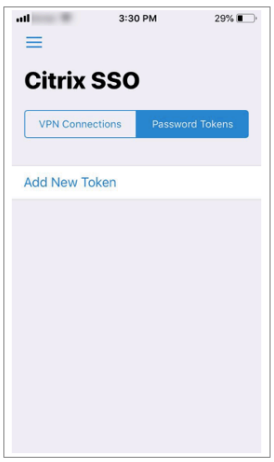
4. Enter a name for your device, then click **Go**.

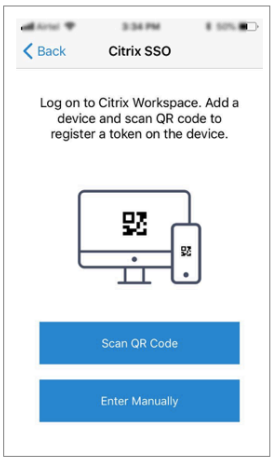
   A QR code is displayed on the Citrix Gateway browser page.

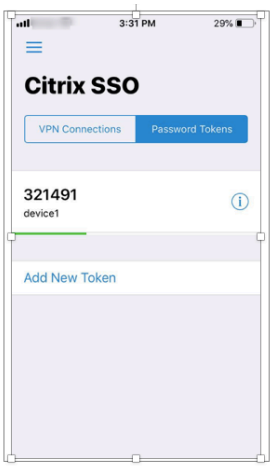


5. Scan this QR code using the Citrix SSO app from the device to be registered.

   Citrix SSO validates the QR code and then registers with gateway for push notifications. If there are no errors in the registration process, the token is successfully added to the password tokens page.







6. If there are no additional devices to add/manage log out using the list at the top right corner of the page.

Test one-time password authentication

1. To test the OTP, click your device from the list and then click **Test**.
2. Enter the OTP that you have received on your device and click **Go**.

   The OTP verification successful message appears.

3. Log out using the list at the top right corner of the page.

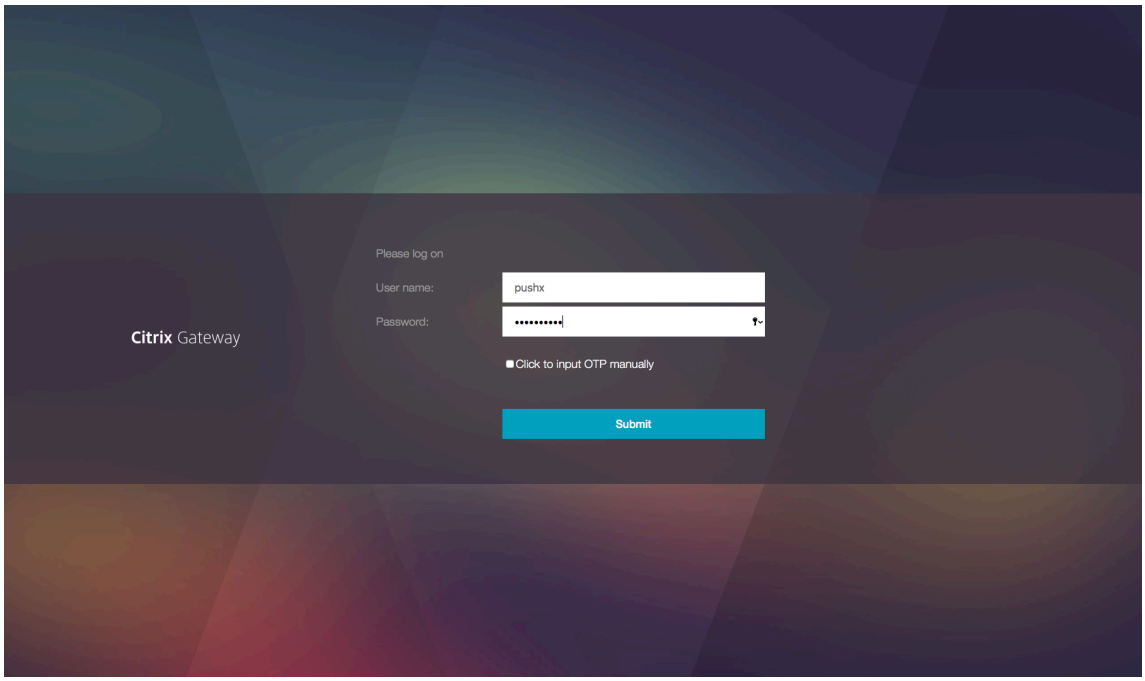
Note: You can use the OTP management portal anytime to test authentication, remove registered devices, or register more devices.

Log in to Citrix Gateway

After registering their devices with Citrix Gateway, users can use the push notification functionality for authentication.

1. Navigate to your Citrix Gateway authentication page (for example: https://gateway.company.com)

   You are prompted to enter only your LDAP credentials depending on the login schema configuration.

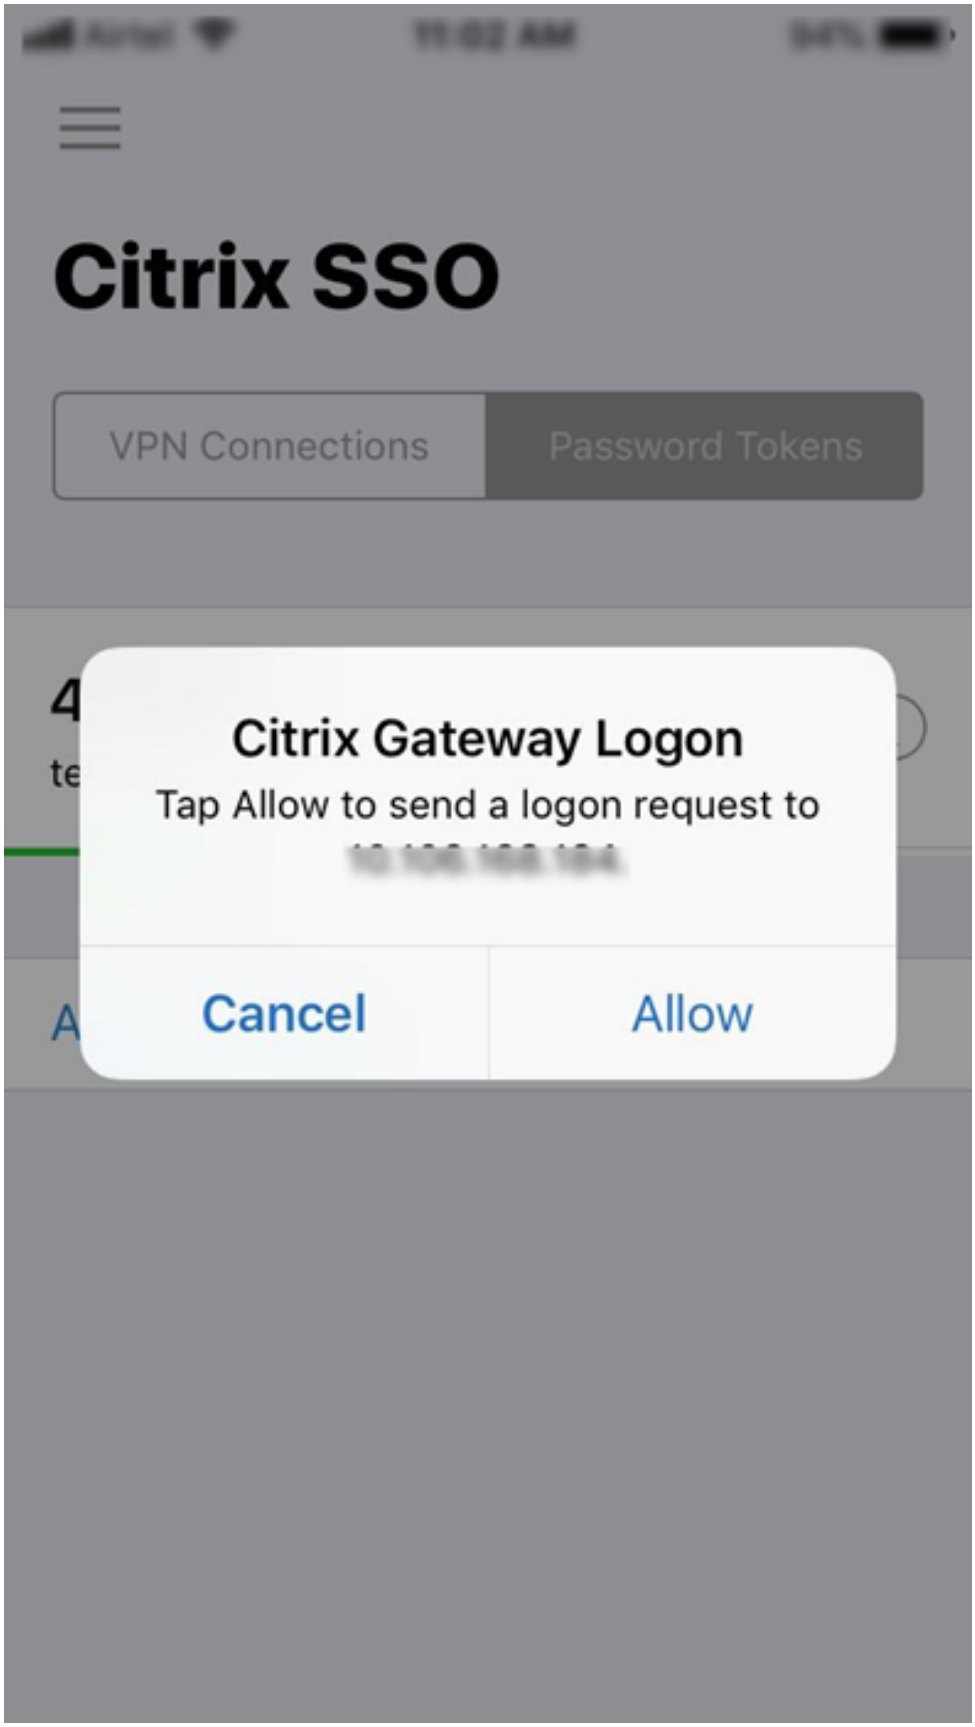


2. Enter your LDAP user name and password, then select **Submit**.

   A notification is sent to your registered device.

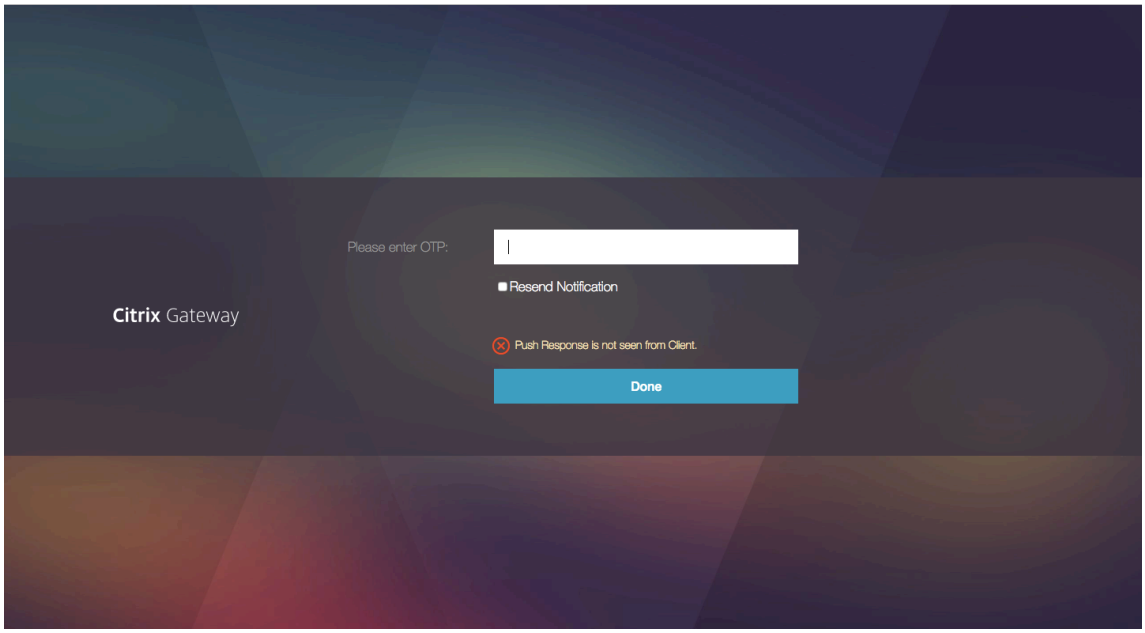
   Note: If you want to enter the OTP manually, you must select **Click** to input OTP manually and enter the OTP in the **TOTP** field.

3. Open the Citrix SSO app on your registered device and tap **Allow**.



Note:

- In case of an iOS device, you are prompted for Touch-ID/Face-ID/Passcode as an extra factor of authentication.
- The authentication server waits for push server notification response until the configured timeout period expires. After the timeout, Citrix Gateway displays the login page. The users can then enter the OTP manually or click **Resend Notification** to receive the notification again on the registered device. Based on your selected option, gateway validates the OTP that you have entered or resends the notification on your registered device.



- No notification is sent to your registered device regarding login failure.

Failure conditions

- The device registration might fail in the following cases.
