An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The Citrix ADC forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the Citrix ADC responds with an error message.

Configuring SMPP Load Balancing on the Citrix ADC

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.

4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.

To configure SMPP load balancing by using the command line

At the command prompt, type:

```
add smpp user <username> -password <password>
add service <name> <IP> SMPP <port>  - customserverID <customserverID>
add lb vserver <name> <IP> SMPP <port>
bind lb vserver <name> <service name>
set smpp param
<!--NeedCopy-->
```

Example

```
add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -
    encrypted -encryptmethod ENCMTHD_2
add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -
    encrypted -encryptmethod ENCMTHD_2
add service smmpsvc 10.102.84.140 SMPP 2775 -gslb NONE -maxClient 0 -
    maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
     180 -svrTimeout 360 -CustomServerID ab -CKA NO -TCPB NO -CMP NO
add service smmpsvc2 10.102.81.175 SMPP 2775 -gslb NONE -maxClient 0 -
    maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
     180 -svrTimeout 360 -CustomServerID xy -CKA NO -TCPB NO -CMP NO
add lb vserver smppvs SMPP 10.102.239.179 2775 -persistenceType NONE -
    cltTimeout 180
bind lb vserver smppvs smmpsvc2
bind lb vserver smppvs smmpsvc
set smpp param -addrrange "d*"
<!--NeedCopy-->
```

To configure SMPP load balancing by using the configuration utility

1. Navigate to **System > User Administration > SMPP Users**, and add an SMPP user.
2. Navigate to **Traffic Management > Load Balancing > Configure SMPP Parameters**, and set the parameters as required by your deployment.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and add a virtual server of type SMPP.

4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

Use case 2: Configure rule based persistence based on a name-value pair in a TCP byte stream

September 14, 2021

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called "FIX fields"). The field format is <tag>=<value><delimiter>. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. In the example;

- The tag 35 indicates the message type.
- The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. A value of A for the tag 35 indicates that the message is a logon message.
- The delimiter is the nonprinting "Start of Header" (SOH) ASCII character (0x01), which is the caret symbol (^).
- Each field is also assigned a name. The field with tag 35 is the msgType field.

Following is an example of a logon message.

8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another. This variation depends on the message type, the preceding fields, and the lengths of the preceding values. It also varies based on the implementation from one to another, depending on whether custom fields have been defined. Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application. You want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule "CLIENT.TCP.PAYLOAD(300).
TYPECAST_NVLIST_T('=','^').VALUE("\49\")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the Citrix ADC appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET_TEXT_MODE(IGNORECASE) function if you want the appliance to ignore the case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET_TEXT_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=','^').SET_TEXT_MODE(IGNORECASE
).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression CLIENT.TCP.PAYLOAD(300).BEFORE_STR("^").AFTER_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPE
  tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).TYPECAST_NVLIST_T('=','^').VALUE("<tag>",2).
  Note: If the second argument that is passed to the
  VALUE() function is
  n, the appliance extracts the value of the
  (n+1)
  th instance of the field because the count starts from zero (
  0).

Following are more examples of rules that you can use to configure persistence. Only the payload-

based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

Use case 3: Configure load balancing in direct server return mode

September 14, 2021

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the Citrix ADC appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the Citrix ADC appliance does not replace the load balancing virtual server's IP address with the destination server's IP address. Instead, it forwards packets to a service by using the server's MAC address. The VIP must be configured on the server and ARP must be disabled for the VIP which is configured on the server. Doing so prevents the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user must configure VIP in the loopback interface and disable the ARP for the same VIP.

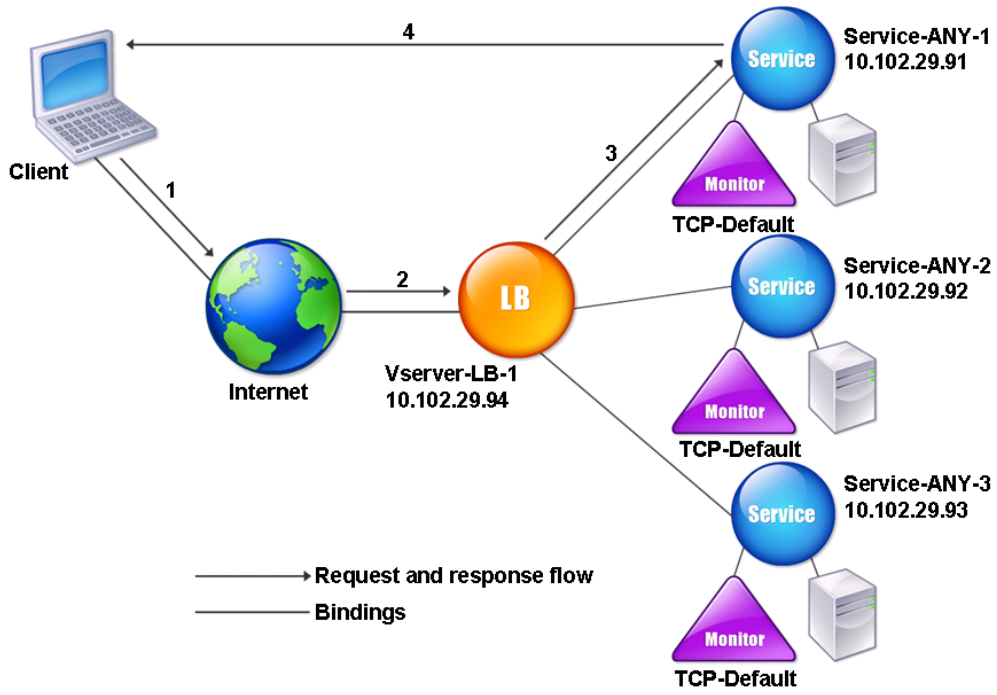
- The appliance obtains the server's MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the Citrix ADC appliance, do not learn a server's MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the Citrix ADC appliance, the ARP requests always resolve to the MAC address of the Citrix ADC interface. Therefore, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.
- The Citrix ADC appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the Citrix ADC appliance. The following table lists the names and values of the entities configured on the Citrix ADC appliance in DSR mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model



For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server.

Next, you configure a basic load balancing setup as described in Setting Up Basic Load Balancing, naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
   RedirectionMode> -sessionless <Value>
<!--NeedCopy-->
```

Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless
   enabled
<!--NeedCopy-->
```

> **Note**
>
> For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.
3. In Traffic Settings, select Sessionless Load Balancing.

To configure a service to use source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-ANY-1 -usip yes
<!--NeedCopy-->
```

To configure a service to use source IP address by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and in Traffic Settings, select **Use Source IP Address**.

Some additional steps are required in certain situations, which are described in the succeeding sections.

Use case 4: Configure LINUX servers in DSR mode

September 14, 2021

The LINUX operating system requires that you set up a loopback interface with the Citrix ADC appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the Citrix ADC appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
ifconfig dummy0 up

ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up

echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore

echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
<!--NeedCopy-->
```

Then, run the software that remaps the TOS id to VIP.

Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

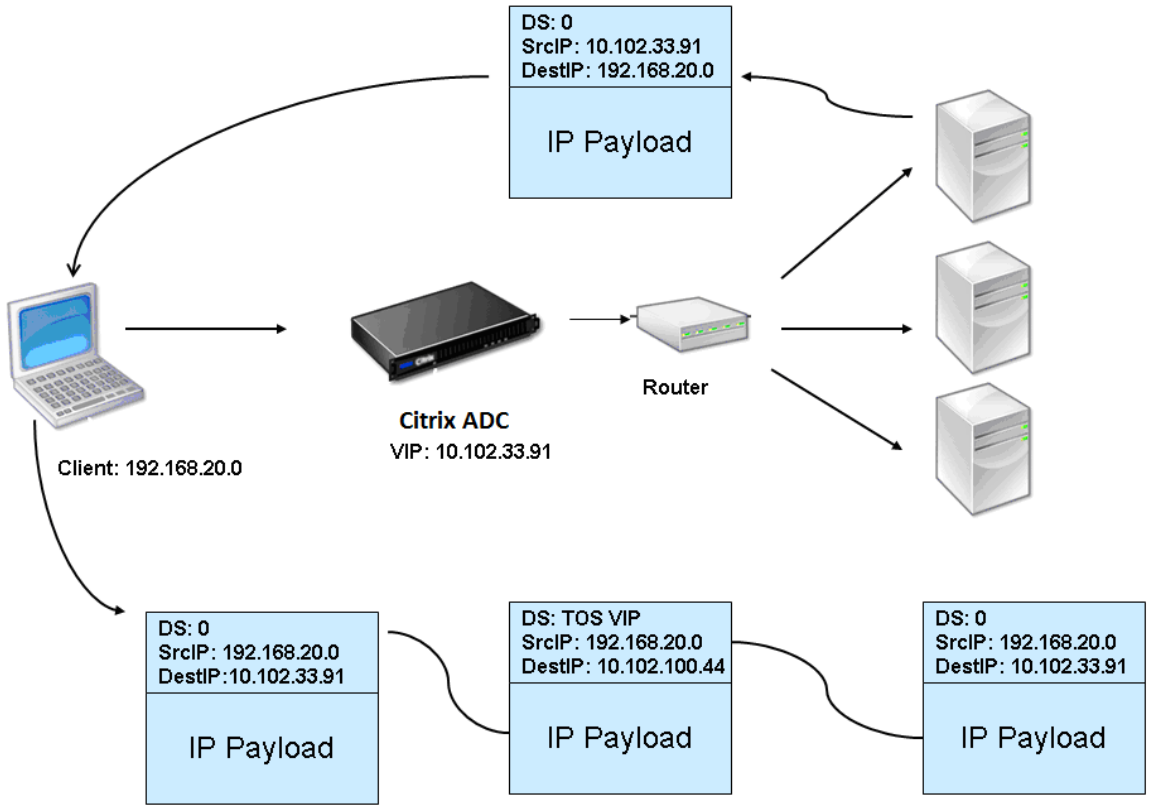
Use case 5: Configure DSR mode when using TOS

September 14, 2021

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the IPv4 packet header. The equivalent field in the IPv6 header is Traffic Class. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the Citrix ADC appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the **TOS** field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The Citrix ADC appliance in DSR mode with TOS



The TOS feature is customized for a controlled environment as follows:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client does not understand the message, as the source IP address is the IP address of the load balanced server and not the Citrix ADC VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

Entity Type	Name	IP Address	Protocol
Virtual server	Vserver-LB-1	10.102.33.91	ANY
Services	Service-ANY-1	10.102.100.44	ANY
Monitors	PING	None	None

DSR with TOS requires that load balancing is set up on layer 3. To configure a basic load balancing setup for Layer 3, see Setting Up Basic Load Balancing. Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -m <Value> -tosId <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -m TOS -tosId 3
<!--NeedCopy-->
```

To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and in Redirect Mode, select TOS ID.

To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

```
add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -
    tosId <Value>
<!--NeedCopy-->
```

Example:

```
add monitor mon1 PING -destip 10.102.33.91 -tos Yes  -tosId 3
<!--NeedCopy-->
```

To create the transparent monitor for TOS by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

Wildcard TOS Monitors

In a load balancing configuration in DSR mode using TOS field, monitoring its services requires a TOS monitor to be created and bound to these services. A separate TOS monitor is required for each load balancing configuration in DSR mode using the TOS field, because a TOS monitor requires the VIP address and the TOS ID to create an encoded value of the VIP address. The monitor creates probe packets in which the **TOS** field is set to the encoded value of the VIP address. It then sends the probe packets to the servers represented by the services of a load balancing configuration.

With many load balancing configurations, creating a separate custom TOS monitor for each configuration is a significant, cumbersome task. Managing these TOS monitors is also a significant task. Now, you can create wildcard TOS monitors. Create only one wildcard TOS monitor for all load balancing configurations that use the same protocol (for example, TCP or UDP).

A wildcard TOS monitor has the following mandatory settings:

- Type = <protocol>
- TOS = Yes

The following parameters can be set to a value or can be left blank:

- Destination IP
- Destination Port
- TOS ID

A wildcard TOS monitor (with destination IP, Destination port, and TOS ID not set) bound to a DSR service automatically learns the TOS ID and the VIP address of the load balancing virtual server. The monitor creates probe packets with the TOS field set to the encoded VIP address and then sends the probe packets to the server represented by the DSR service.

To create a wildcard TOS monitor by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <Type> -tos YES

show lb monitor <monitorName>
<!--NeedCopy-->
```

To bind a wildcard TOS monitor to a service by using the CLI

At the command prompt, type:

```
bind lb monitor <monitorName> <serviceName>

show lb monitor <monitorName>
<!--NeedCopy-->
```

To create a wildcard TOS monitor by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Add a monitor with the following parameter settings:
   - Type = <protocol>
   - TOS = YES

To bind a wildcard TOS monitor to a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Open a service and bind a wildcard TOS monitor to it.

In the following sample configuration, V1, V2, and V3 are load balancing virtual servers of type ANY and has TOS ID set to 1, 2, and 3 respectively. S1, S2, S3, S4, and S5 are services of type ANY. S1 and S2 are bound to both V1 and V2. S3, S4, and S5 and bound to both V1 and V3. WLCD-TOS-MON is a wildcard TOS monitor with type TCP and is bound to S1, S2, S3, S4, and S5.

WLCD-TOS-MON automatically learns the TOD ID and VIP address of virtual servers bound to S1, S2, S3, S4, and S5.

Because S1 is bound to V1 and V2, WLCD-TOS-MON creates two types of probe packets for S1, one with the **TOS** field set to the encoded VIP address (203.0.113.1) of V1 and the other with the VIP address (203.0.113.2) of V2. The Citrix ADC then sends these probe packets to the server represented by S1. Similarly, WLCD-TOS-MON creates probe packets for S2, S3, S4, and S5.

```
add lb monitor WLCD-TOS-MON  TCP -tos YES

Done

add lb vserver V1 ANY 203.0.113.1 * -m TOS  - tosID 1

Done

add lb vserver V2 ANY 203.0.113.2 * -m TOS  - tosID 2

Done

add lb vserver V3 ANY 203.0.113.3 * -m TOS  - tosID 3

Done

add service S1 198.51.100.1 ANY *

Done

add service S2 198.51.100.2 ANY *

Done

add service S3 198.51.100.3 ANY *

Done

add service S4 198.51.100.4 ANY *

Done

add service S5 198.51.100.5 ANY *

Done

bind lb monitor WLCD-TOS-MON S1

Done

bind lb monitor WLCD-TOS-MON S2

Done

```

```
bind lb monitor WLCD-TOS-MON S3

Done

bind lb monitor WLCD-TOS-MON S4

Done

bind lb monitor WLCD-TOS-MON S5

Done

bind lb vserver V1 S1, S2, S3, S4, S5

Done

bind lb vserver V2, S1, S2

Done

bind lb vserver V3 S3, S4, S5

Done
<!--NeedCopy-->
```

Use case 6: Configure load balancing in DSR mode for IPv6 networks by using the TOS field

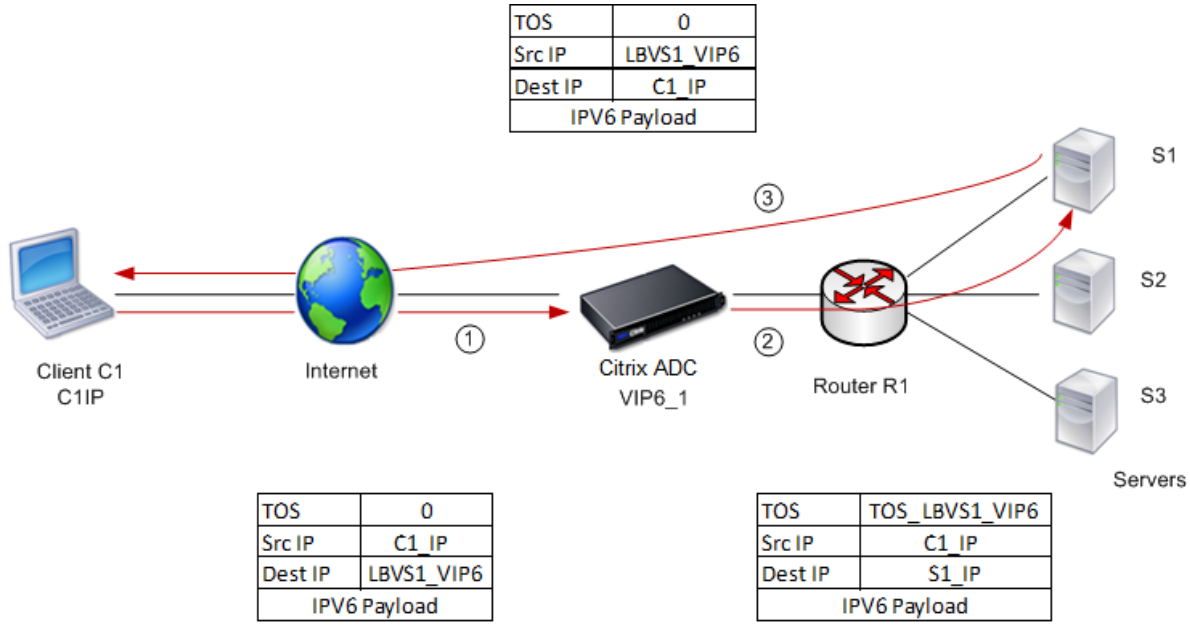
September 14, 2021

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the Citrix ADC appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a Citrix ADC appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the appliance.

Consider an example where a load balancing virtual server LBVS1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The Citrix ADC appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.



The following table lists the settings used in this example.

Entities	Name
IPv6 address of client C1	C1_IP (for reference purposes only)
Load balancing virtual server on NS1	LBVS1
IPv6 address of LBVS1	LBVS1_VIP6 (for references purpose only)
TOS value	TOS_LBVS1_VIP6 (for references purpose only)
Service for server S1 on NS1	SVC_S1
IPv6 address for server S1	S1_IP (for references purpose only)
Service for server S2 on NS1	SVC_S2
IPv6 address for server S1	S2_IP (for references purpose only)
Service for server S3 on NS1	SVC_S3
IPv6 address for server S1	S3_IP (for references purpose only)

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.

2. LBVS1's load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
   - TOS field set to TOS_LBVS1_VIP6.
   - Source IP address as C1_IP.
3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the appliance, with:
   - Source IP address set to the derivedLBVS1_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

To configure load balancing in DSR Mode using TOS by using the command line interface

At the command prompt, type:

```
enable ns mode USIP

add service <serviceName> <IP> <serviceType> <port>
<!--NeedCopy-->
```

Repeat the earlier command as many times as necessary to add each server as a service on the Citrix ADC appliance.

```
add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -
    tosId <positive_integer>

bind lb vserver <vserverName> <serviceName>
<!--NeedCopy-->
```

To enable USIP mode by using the configuration utility

Navigate to **System > Settings > Configure Modes**, and select **Use Source IP Address**.

To create services by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services**, and create a service.

To create a load balancing virtual server and bind services by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server.
2. Click in the Service section to bind a service to this virtual server.

Use case 7: Configure load balancing in DSR mode by using IP Over IP

October 26, 2021

You can configure a Citrix ADC appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the Citrix ADC appliance. This improves response time and throughput. As with standard DSR mode, the Citrix ADC appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the Citrix ADC appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the Citrix ADC appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client. This is often referred to as L3DSR.

To configure L3-DSR mode on your Citrix ADC appliance:

- Create a load balancing virtual server. Set the mode to IPTUNNEL and enable sessionless tracking.
- Create services. Create a service for each back-end application and bind the services to the virtual server.
- Configure for decapsulation. Configure either a Citrix ADC appliance or a back-end server to act as a decapsulator.

  > Note:
  >
  > When you use a Citrix ADC appliance, the decapsulation setup is an IP tunnel between the ADC appliances with the back end doing L2DSR to the real servers.

Configure a load balancing virtual server

Configure a virtual server to handle requests to your applications. Assign the service type that matches the service, or use a type of ANY for multiple services.
Set the forwarding method to IPTUNNEL and enable the virtual server to operate in sessionless mode. Configure any load balancing method that you want to use.

To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

```
1 add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <
     port> -lbMethod <method> -m <ipTunnelTag> -sessionless [ENABLED |
     DISABLED]
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

Example:

In the following example, we have selected the load balancing method as sourceIPhash and configured sessionless load balancing.

```
1 add lb vserver Vserver-LB-1 ANY 1.1.1.80 * -lbMethod SourceIPHash -m
     IPTUNNEL -sessionless ENABLED
2 <!--NeedCopy-->
```

To create and configure a load balancing virtual server for IP over IP DSR by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a virtual server, and specify Redirection Mode as **IP Tunnel Based**.

Configure services for IP over IP DSR

After creating your load-balanced server, configure one service for each of your applications. The service handles traffic from the Citrix ADC appliance to those applications, and allows the Citrix ADC appliance to monitor the health of each application.

Assign the services to use USIP mode and bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

```
add service <serviceName> <serverName> <serviceType> <port> -usip <usip
   >

add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <
   iptunnel>

bind service <serviceName> -monitorName <monitorName>
<!--NeedCopy-->
```

Example:

In the following example, a monitor of type IPTUNNEL is created.

```
add monitor mon_DSR PING -destip 1.1.1.80 -iptunnel yes
add service svc_DSR01 2.2.2.100 ANY * -usip yes
bind service svc_DSR01 -monitorName mon_DSR
<!--NeedCopy-->
```

An alternative approach to simplify the routing at both the server and the ADC appliance is to setup both the ADC and server to use an IP from the same subnet. Doing so ensures that any traffic with a destination of a tunnel endpoint is sent over the tunnel. In the example, 10.0.1.0/30 is used.

> **Note:**
>
> The purpose of the monitor is to ensure that the tunnel is active by reaching the loopback of each server through the IP tunnel. If the service is not up, verify whether the outer IP routing between ADC and server is good. Also verify whether the inner IP addresses are reachable through the IP tunnel. Routes might be required on the server, or PBR is added to ADC depending on the chosen implementation.

Example:

```
add ns ip 10.0.1.2 255.255.255.252 -vServer DISABLED
add netProfile netProfile_DSR -srcIP 10.0.1.2
add lb monitor mon_DSR PING -LRTM DISABLED -destIP 1.1.1.80 -ipTunnel
   YES -netProfile netProfile_DSR
<!--NeedCopy-->
```

To configure a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.

2. Create a monitor, and select **IP Tunnel**.

To create and configure a service for IP over IP DSR by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Create a service and, in **Settings** tab, select **Use Source IP Address**.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-DSR-1
<!--NeedCopy-->
```

To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section to bind a service to the virtual server.

Using the client IP address in the Outer header of tunnel packets

The Citrix ADC supports using the client-source IP address as the source IP address in the outer header of tunnel packets related to direct server return mode using IP tunneling. This feature is supported for DSR with IPv4 and DSR with IPv6 tunneling modes. For enabling this feature, enable the **use client source IP address** parameter for IPv4 or IPv6. This setting is applied globally to all the DSR configurations that use IP tunneling.

To use a client-source IP address as the source IP address by using the CLI

At the command prompt, type:

- `set iptunnelparam -useclientsourceip [YES | NO]`
- `show iptunnelparam`

To use client source IP address as the source IP address by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv4 Tunnel Global Settings**.
3. In the **Configure IPv4 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

To use client source IP address as the source IP address by using the CLI

At the command prompt, type:

- `set ip6tunnelparam -useclientsourceip [YES | NO]`
- `show ip6tunnelparam`

To use client source IP address as the source IP address by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv6 Tunnel Global Settings**.
3. In the **Configure IPv6 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

Decapsulation configuration

You can configure either a Citrix ADC appliance or a back-end server as a decapsulation.

Citrix ADC decapsulation

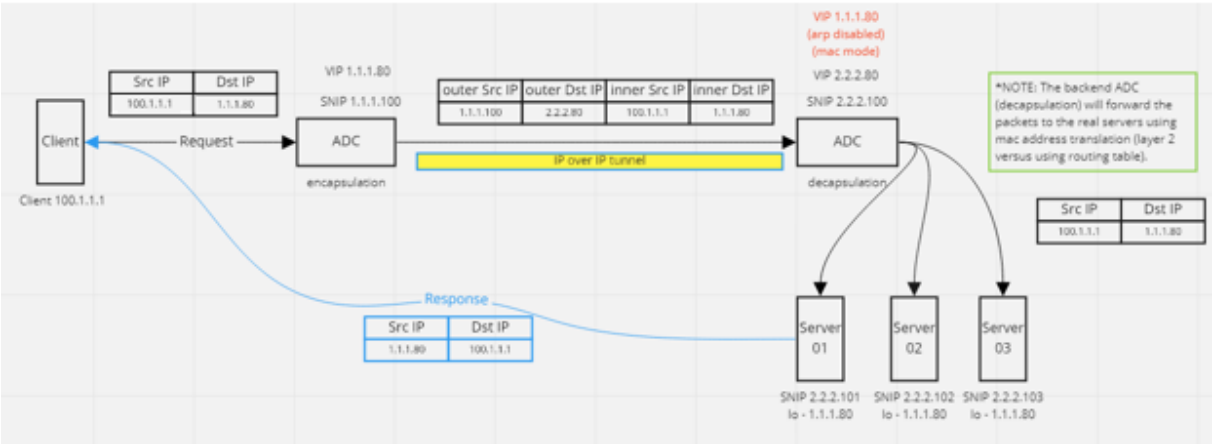
When a Citrix ADC appliance is used as a decapsulation, an IP tunnel must be created in the Citrix ADC appliance. For more details, see Configuring IP Tunnels.

The Citrix ADC decapsulation setup consists of the following two virtual servers:

- The first virtual server receives the encapsulated packet and removes the outer IP encapsulation.
- The second virtual server has the IP of the original service on the front-end ADC and uses MAC translation to forward the packet towards the back end by using the MAC address of the bound services. This setup is typically known as L2DSR. Ensure to disable ARP on this virtual server.

Example setup:

The following illustration shows a decapsulation setup using the ADC appliances.



The complete configuration required for the setup is as follows.

Front-end ADC configuration:

```
add service svc_DSR01 2.2.2.80 ANY * -usip YES -useproxyport NO
add lb vserver vip_DSR_ENCAP ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
    IPTUNNEL -sessionless ENABLED
bind lb vserver vip_DSR_ENCAP svc_DSR01
<!--NeedCopy-->
```

Back-end ADC configuration:

```
add ipTunnel DSR-IPIP 1.1.1.100 255.255.255.255 *

add service svc_DSR01_01 2.2.2.101 ANY * -usip YES -useproxyport NO
add service svc_DSR01_02 2.2.2.102 ANY * -usip YES -useproxyport NO
add service svc_DSR01_03 2.2.2.103 ANY * -usip YES -useproxyport NO

add lb vserver vs_DSR_DECAP ANY 2.2.2.80 * -lbMethod SOURCEIPHASH -m
    IPTUNNEL -sessionless ENABLED -netProfile netProf_DSR_MBF_noIP

add ns ip 1.1.1.80 255.255.255.255 -type VIP -arp DISABLED -snmp
    DISABLED
add lb vserver vs_DSR_Relay ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
    MAC -sessionless ENABLED

bind lb vserver vs_DSR_DECAP svc_DSR01_01
bind lb vserver vs_DSR_DECAP svc_DSR01_02
bind lb vserver vs_DSR_DECAP svc_DSR01_03

bind lb vserver vip_DSR_Relay svc_DSR01_01
bind lb vserver vip_DSR_Relay svc_DSR01_02
bind lb vserver vip_DSR_Relay svc_DSR01_03
```

```
19
20 add netProfile netProf_DSR_MBF_noIP -MBF ENABLED
21 add lb monitor mon_DSR_MAC PING -netProfile netProf_DSR_MBF_noIP
22 bind service svc_DSR01_01 -monitorName mon_DSR_MAC
23 bind service svc_DSR01_02 -monitorName mon_DSR_MAC
24 bind service svc_DSR01_03 -monitorName mon_DSR_MAC
25 <!--NeedCopy-->
```

The following example shows a testing setup using Ubuntu and Red Hat servers running apache2. These commands are set up on each back-end server.

```
1 sudo ip addr add 1.1.1.80 255.255.255.255 dev lo
2 sudo sysctl net.ipv4.conf.all.arp_ignore=1
3 sudo sysctl net.ipv4.conf.all.arp_announce=2
4 sudo sysctl net.ipv4.conf.eth4.rp_filter=2 (The interface has the
     external IP with route towards the ADC)
5 sudo sysctl net.ipv4.conf.all.forwarding=1
6 sudo ip link set dev lo arp on
7 <!--NeedCopy-->
```

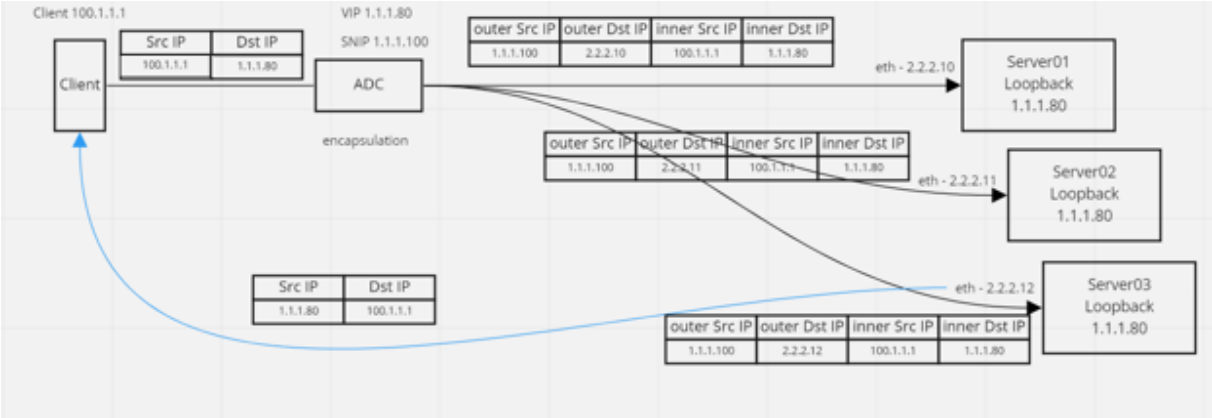
Back-end server decapsulation

When you use the back-end servers as a decapsulation, the back-end configuration varies depending upon the server OS type. You can configure a back-end server as a decapsulation by following these steps:

1. Configure a loop back interface with IP for service IP.
2. Create a tunnel interface.
3. Add a route through tunnel interface.
4. Configure interface settings as required for traffic.

> Note:
>
> Windows OS servers cannot do IP tunneling natively, so the commands are provided as examples for Linux based systems. Third-party plug-ins are available for Windows OS servers, however, that is outside the scope of this example.

The following illustration shows a decapsulation setup using the back-end servers.



Example configuration:

In this example, 1.1.1.80 is the Citrix ADC virtual IP (VIP) address and 2.2.2.10-2.2.2.12 are the back-end server IP addresses. The VIP address is configured in the loopback interface, and a route is added through the tunnel interface. The monitors use the server IP, and tunnel the monitor packets over the IP tunnel using the tunnel endpoints.

The complete configuration required for the setup is as follows.

Front-end ADC configuration:

The following configuration creates a monitor that uses the tunnel endpoint as source. Then, send pings over tunnel to service IP address.

```
add ns ip 10.0.1.2 255.255.255.252 -vServer DISABLED
add netProfile netProfile_DSR -srcIP 10.0.1.2
add lb monitor mon_DSR PING -LRTM DISABLED -destIP 1.1.1.80 -ipTunnel
    YES -netProfile netProfile_DSR
<!--NeedCopy-->
```

The following configuration creates a VIP for service that uses the original source IP address. Then, forwards traffic over IP tunnel to back-end servers.

```
add service svc_DSR01 2.2.2.10 ANY * -usip YES -useproxyport NO
bind service svc_DSR01 -monitorName mon_DSR

add service svc_DSR02 2.2.2.11 ANY * -usip YES -useproxyport NO
bind service svc_DSR02 -monitorName mon_DSR

add service svc_DSR03 2.2.2.12 ANY * -usip YES -useproxyport NO
bind service svc_DSR03 -monitorName mon_DSR

add lb vserver vip_DSR_ENCAP ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
    IPTUNNEL -sessionless ENABLED
bind lb vserver vip_DSR_ENCAP svc_DSR01
```

```
bind lb vserver vip_DSR_ENCAP svc_DSR02
bind lb vserver vip_DSR_ENCAP svc_DSR03
<!--NeedCopy-->
```

Back-end server configuration of each server:

The following commands are required for the back-end server to receive the IPIP packet, remove the outer encapsulation, then respond from the loopback to the original client IP. Doing so ensures the IP addresses in the packet received by the client match the IP addresses in the original request.

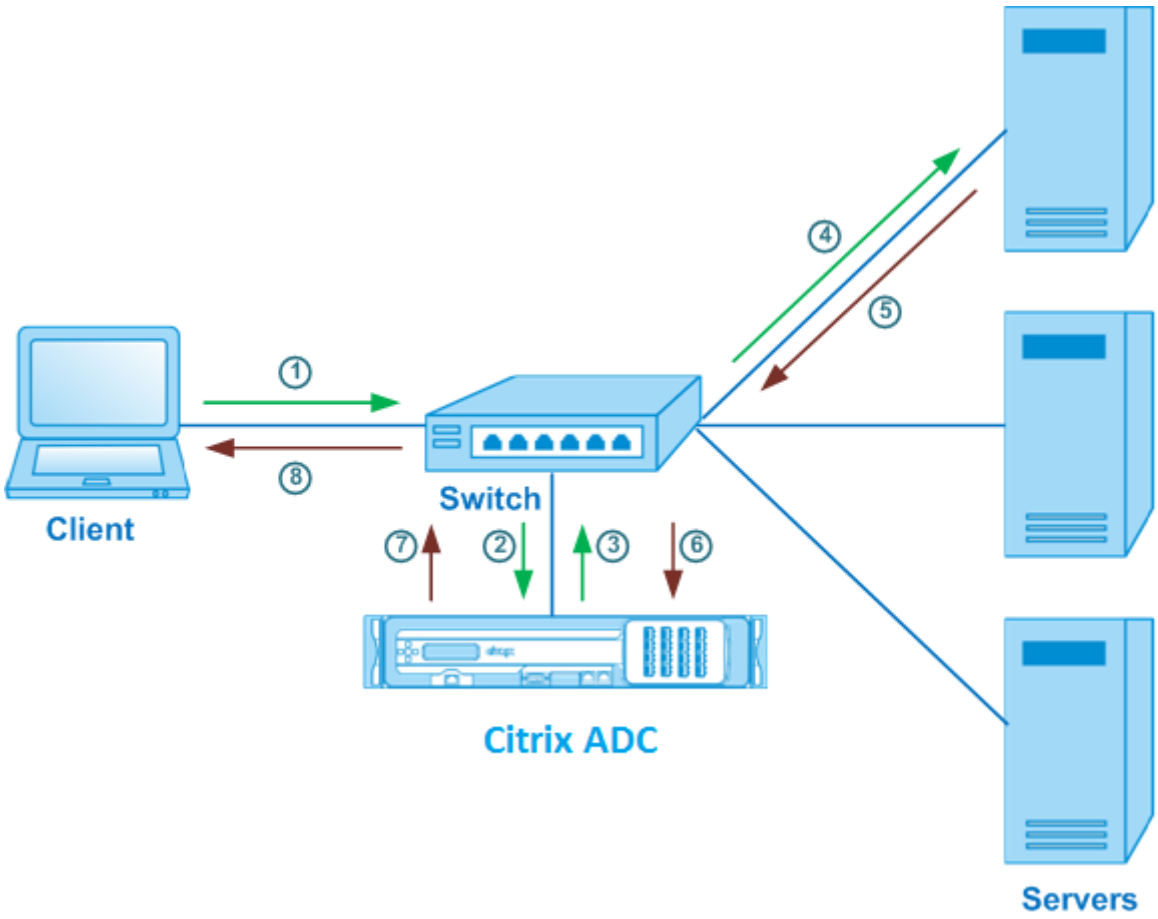
```
modprobe ipip
sudo ip addr add 1.1.1.80 255.255.255.255 dev lo
nmcli connection add type ip-tunnel ip-tunnel.mode ipip con-name tun0
ifname tun0 remote 198.51.100.5 local 203.0.113.10
nmcli connection modify tun0 ipv4.addresses '10.0.1.1/30'
nmcli connection up tun0
sudo sysctl net.ipv4.conf.all.arp_ignore=1
sudo sysctl net.ipv4.conf.all.arp_announce=2
sudo sysctl net.ipv4.conf.tun0.rp_filter=2
sudo sysctl net.ipv4.conf.all.forwarding=1
sudo ip link set dev lo arp off
<!--NeedCopy-->
```

Use case 8: Configure load balancing in one-arm mode

September 14, 2021

In a one-arm setup, you connect the Citrix ADC appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service.

Figure 1. Load balancing in one-arm mode



In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

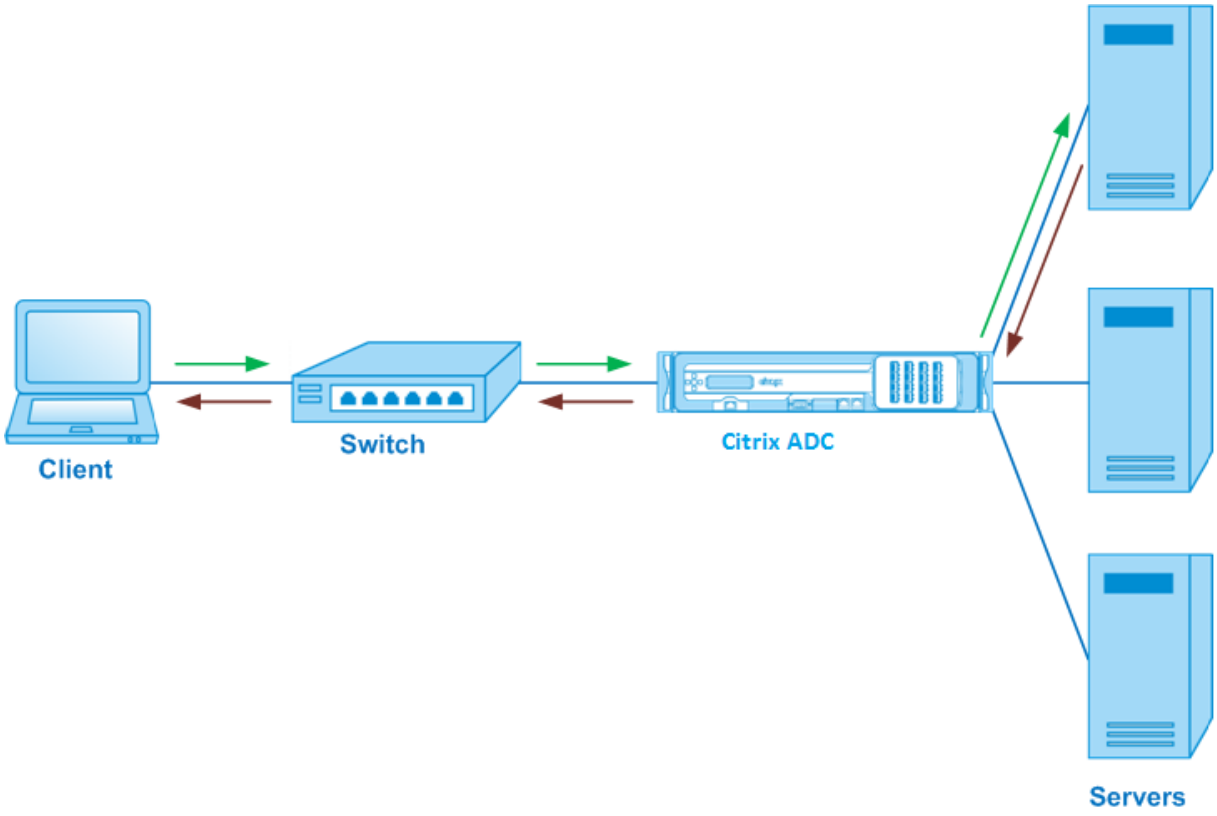
Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None

To configure a load balancing setup in one-arm mode, see Setting Up Basic Load Balancing.

Use case 9: Configure load balancing in the inline mode

September 14, 2021

In an inline mode (also called two-arm mode) setup, you connect the Citrix ADC appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service.



The configuration and the entity diagram for inline mode are the same as described in Configuring Load Balancing in One-arm Mode.

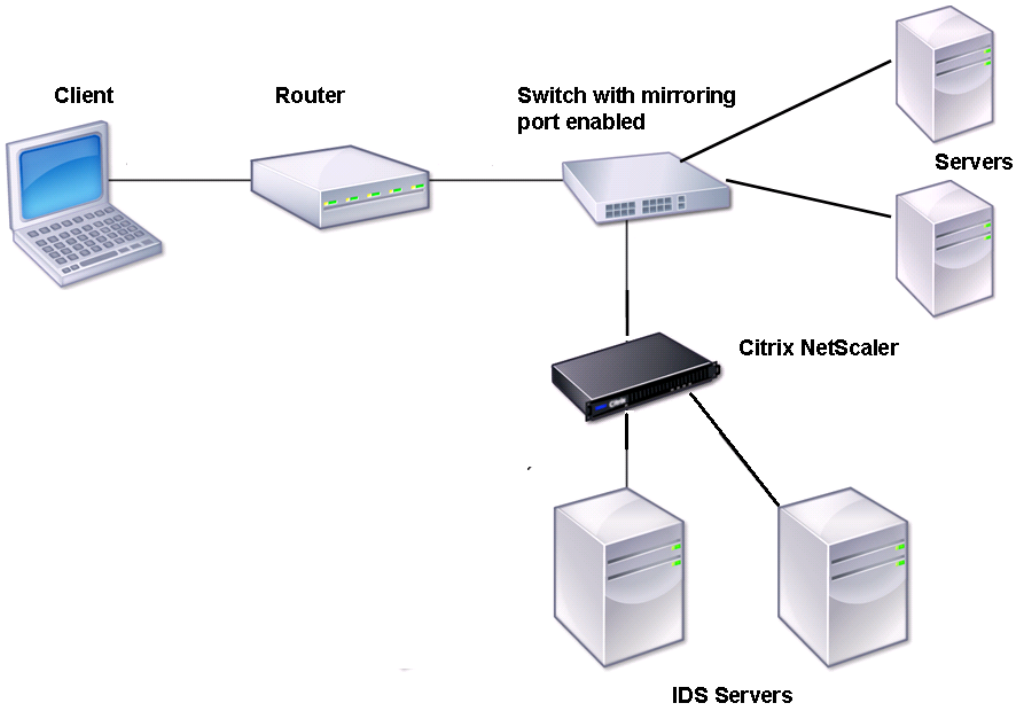
Use case 10: Load balancing of intrusion detection system servers

September 14, 2021

To enable the Citrix ADC appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch,

the request packets are copied or sent to the Citrix ADC appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers



Note: Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets

flowing from the client to a service on the appliance must be sent to a single IDS server.

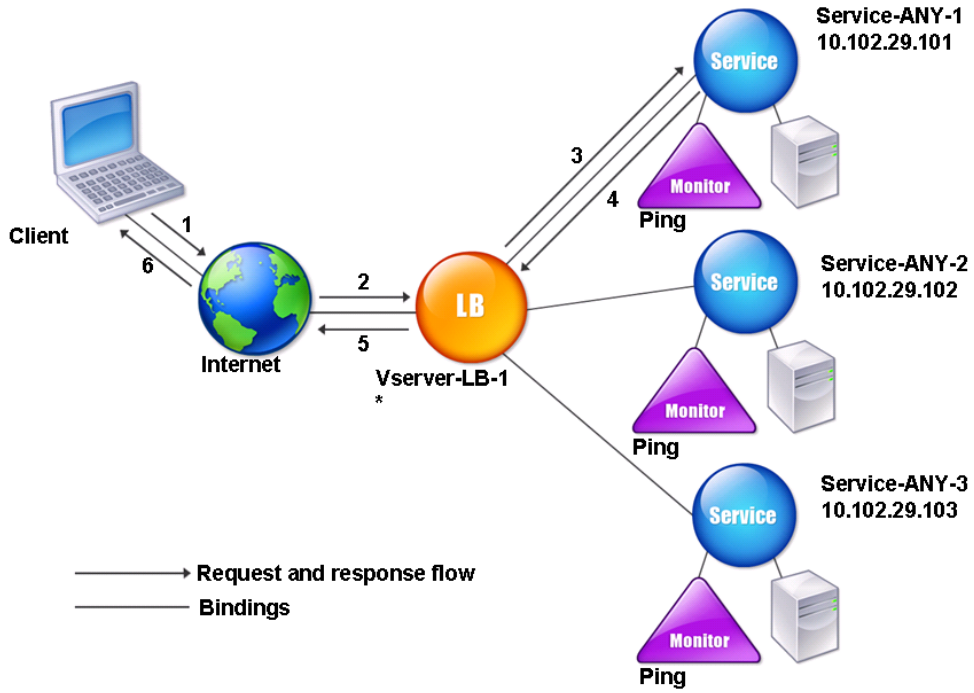
Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual server	Vserver-LB-1	*	*	ANY
Services	Service-ANY-1	10.102.29.101	*	ANY
	Service-ANY-2	10.102.29.102	*	ANY
	Service-ANY-3	10.102.29.103	*	ANY
Monitors	Ping	None	None	None

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers



To configure an IDS load balancing setup, you must first enable MAC-based forwarding. Also disable layer 2 and layer 3 modes on the appliance.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
enable ns mode <ConfigureMode>
<!--NeedCopy-->
```

Example:

```
enable ns mode MAC
<!--NeedCopy-->
```

To enable MAC-based forwarding by using the configuration utility

Navigate to **System > Settings > Configure Modes**, and select **MAC Based Forwarding**.

Next, see "Setting Up Basic Load Balancing", to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

To configure a load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
   RedirectionMode> -sessionless <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -
   sessionless enabled
<!--NeedCopy-->
```

> **Note**
>
> For a service that is bound to a virtual server on which the -m MAC option is enabled, you must bind a non-user monitor.

To configure a load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

To set a service to use the source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-ANY-1 -usip yes
<!--NeedCopy-->
```

To set a service to use the source IP address by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Open a service, and in Settings select **Use Source IP Address**.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see IP Addressing.

Use case 11: Isolating network traffic using listen policies

September 14, 2021

> **Note**
>
> The traffic isolation solution using shadow virtual servers to simulate multitenant isolation is no more recommended. Alternatively, Citrix recommends you to use the Citrix ADC Admin Partitioning feature for such deployments. For more information, see Admin Partitioning.

A common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IdP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multitenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a Citrix ADC appliance identifies the network domains and controls the traffic across the domains. The Citrix ADC solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on several client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

Category	Parameters
Ethernet protocol	Source MAC address, destination MAC address
Network interface	Network ID, receiving throughput, sending throughput, transmission throughput
IP protocol	Source IP address, destination IP address
IPv6 protocol	Source IPv6 address, destination IPv6 address
TCP protocol	Source port, destination port, maximum segment size, payload, and other options
UDP protocol	Source port, destination port
VLAN	ID

Table 1. Client Parameters Used to Define Listen Policies

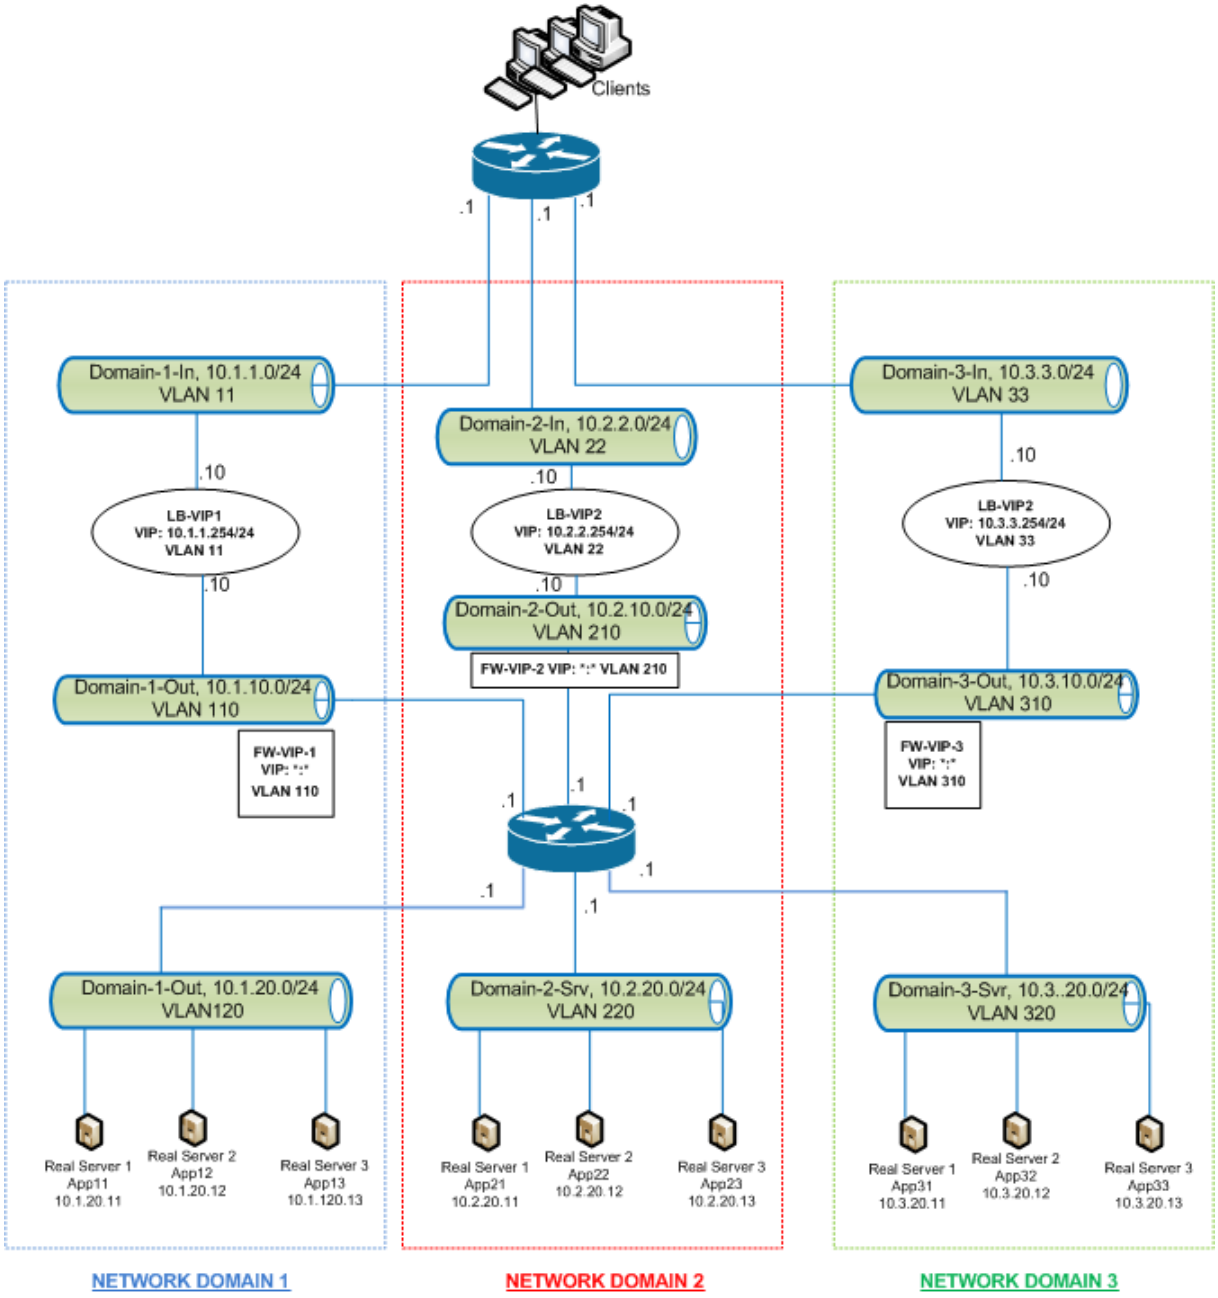
On the Citrix ADC appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (*) IP address and port, and its service type is set to ANY.

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

How network paths are isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path



Traffic within network domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.

- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the Citrix ADC for all the traffic that originates from a client.

Traffic between network domain 1 and network domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANS: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VALN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

Configuration Steps

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic.
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create an expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (*). Enable MAC-based forwarding on this virtual server.

  - Enable the L2 Connection option on both the virtual servers.
    Generally, to identify a connection, the Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.
- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all the firewall services to the shadow virtual server.

To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

```
add policy expression <expressionName> <listenPolicyExpression>

add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -
   listenPolicy <expressionName>
<!--NeedCopy-->
```

Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.

```
add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <
   expressionName>
<!--NeedCopy-->
```

Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

Example:

```
add policy expression e110 client.vlan.id==110
add policy expression e210 client.vlan.id==210
add policy expression e310 client.vlan.id==310
add policy expression e11 client.vlan.id==11
add policy expression e22 client.vlan.id==22
add policy expression e33 client.vlan.id==33

add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -
   listenPolicy e11
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE -
   listenPolicy e22
```

```
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE -
    listenPolicy e33
-cltTimeout 180 -l2Conn ON

add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod
    ROUNDROBIN - listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout
    120

add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod
    ROUNDROBIN - listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout
    120

add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod
    ROUNDROBIN - listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout
    120

add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
    DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
    NO -TCPB NO -CMP NO

add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
    DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
    NO -TCPB NO -CMP NO

add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
    DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
    NO -TCPB NO -CMP NO

bind lb vserver FW-VIP-1 RD-1

bind lb vserver FW-VIP-2 RD-2

bind lb vserver FW-VIP-3 RD-3
<!--NeedCopy-->
```

To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in Creating a Service.
2. Add each firewall as a service:
   a) Navigate to **Traffic Management > Load Balancing > Services**.
   b) Create a service, specifying the protocol as ANY, server as firewall's IP address, and port as 80.
3. Configure a load balancing virtual server.
4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

Use case 12: Configure XenDesktop for load balancing

September 14, 2021

For an improved performance in the delivery of virtual desktop applications, you can integrate the Citrix ADC appliance with Citrix XenDesktop and use the Citrix ADC load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or XenApp, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

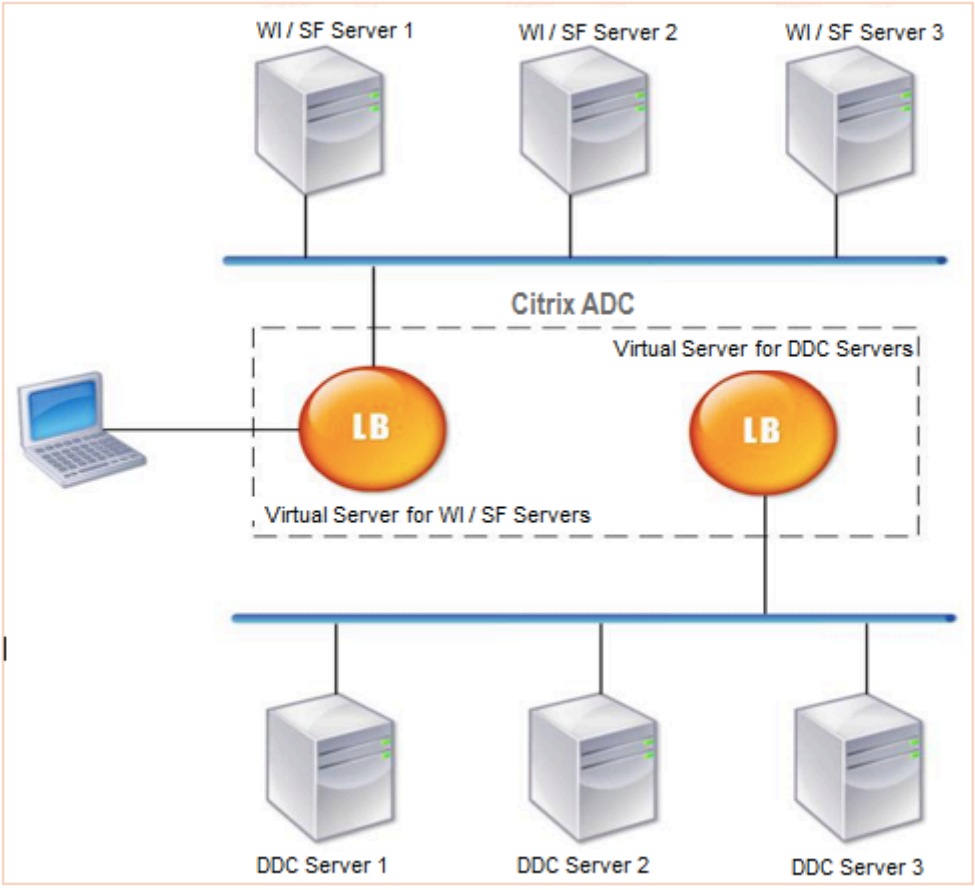
The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user's device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a Citrix ADC appliance working with XenDesktop.

Figure 1. Load Balancing of XenDesktop



> **Note**
>
> Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC appliance. You can use the HTTP protocol for communication between the Citrix ADC and the DDC servers even though you use the SSL protocol for communication with the client.

To configure load balancing for XenDesktop by using the GUI

1. Create a service.
   a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
   b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
   a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and click **Add**.
   b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and

then click **OK**.

3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and select a server.
   a) Click **Edit**.
   b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
   c) Select the service you want to bind and enter the weight value.
   d) Click **Bind**.

To configure load balancing for XenDesktop by using the command line interface

- To create a service, at the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 192.0.2.5 HTTP 80
<!--NeedCopy-->
```

- To create a virtual server, at the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
<!--NeedCopy-->
```

Example:

add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

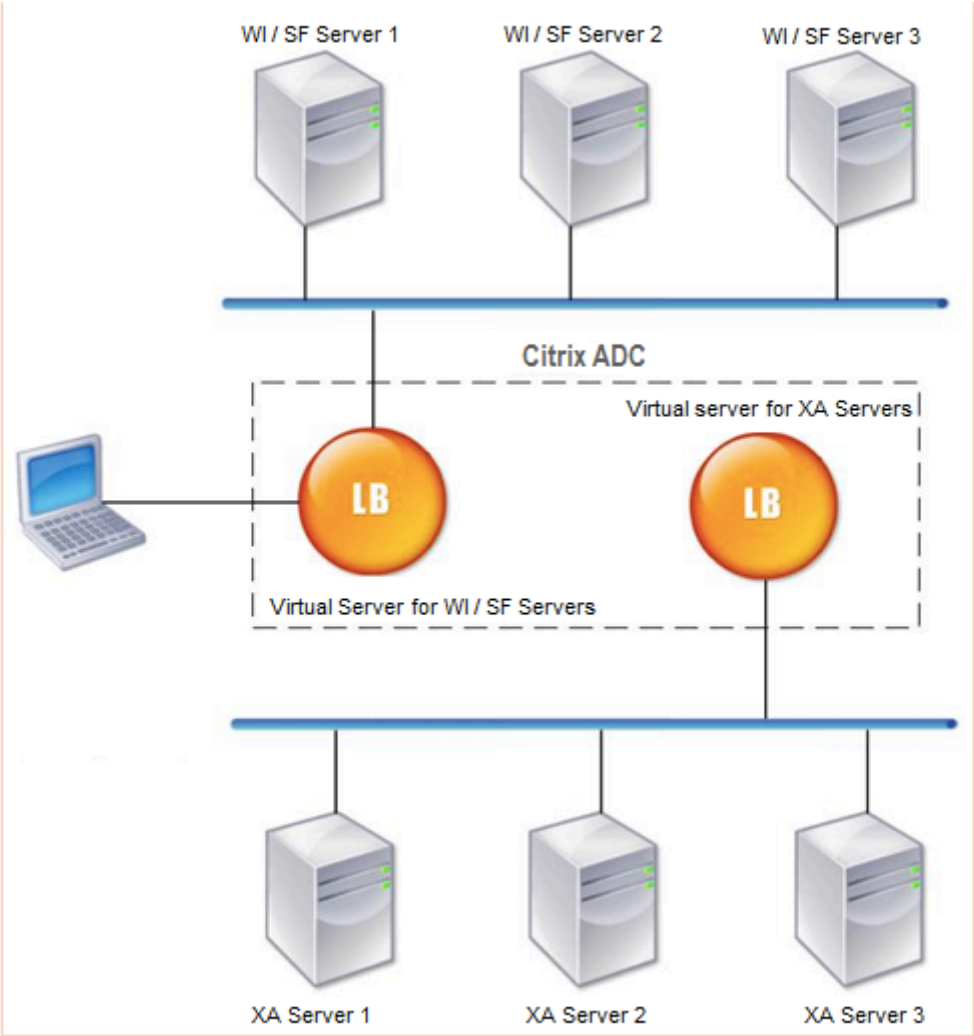
```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

Use case 13: Configure XenApp for load balancing

September 14, 2021

For efficient delivery of applications, you can integrate the Citrix ADC appliance with Citrix XenApp and use the Citrix ADC load balancing feature to distribute the load across the XenApp server farms. The following figure is a topology diagram of such a setup.

Figure 1. Load Balancing of XenApp



The Web Interface servers provide secure access to XenApp application resources through the user's Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the XenApp server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users

with access to applications, and the XML Broker evaluates the user's permissions to determine which applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. Based on the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using the Citrix ADC appliance. Configure one virtual server to load balance the Web Interface servers and another for the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

> **Note**
>
> Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC. You can use the HTTP protocol for communication between the Citrix ADC and the WI servers even though you use the SSL protocol for communication with the client.

To configure load balancing for XenApp by using the GUI

1. Create a service.
   a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
   b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
   a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and click **Add**.
   b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and select a server.
   a) Click **Edit**.
   b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
   c) Select the service you want to bind and enter the weight value.
   d) Click **Bind**.

To configure load balancing for XenApp by using the command line interface

- To create a service, at the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 192.0.2.5 HTTP 80
<!--NeedCopy-->
```

- To create a virtual server, at the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
<!--NeedCopy-->
```

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

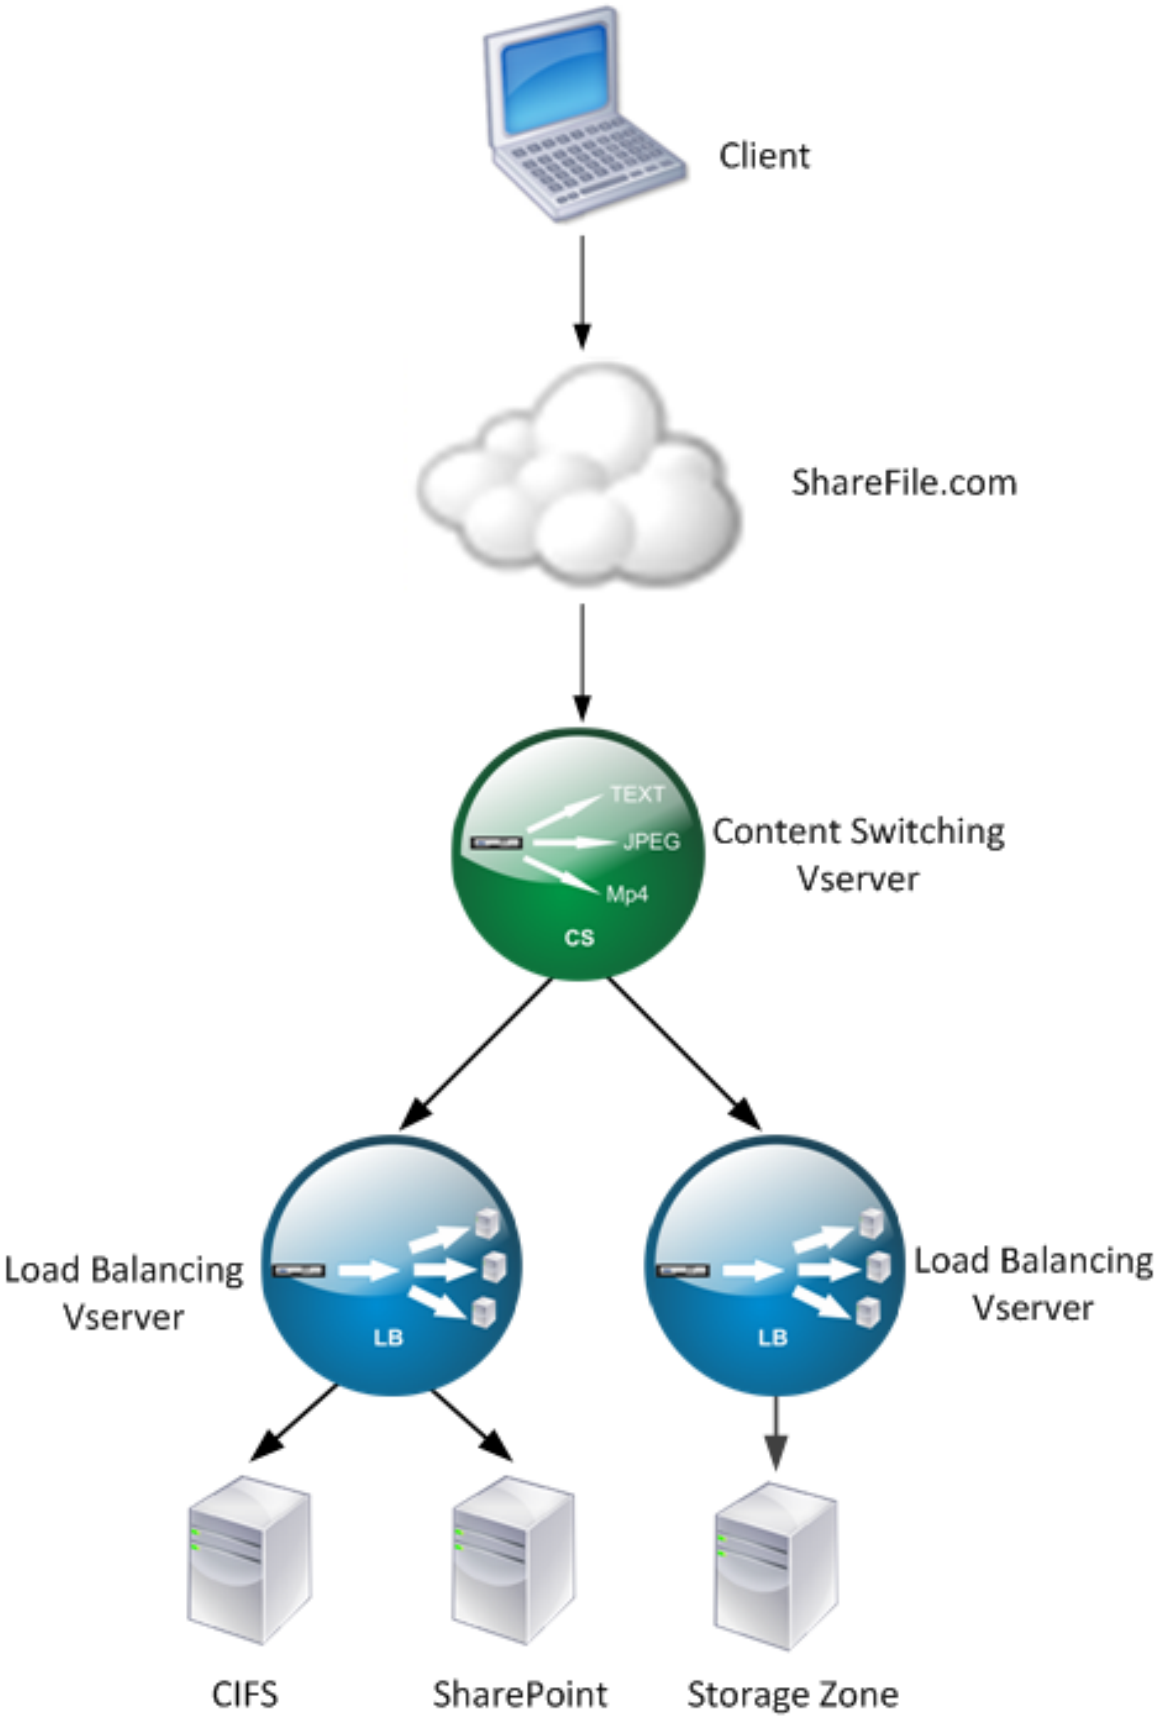
Use case 14: ShareFile wizard for load balancing Citrix ShareFile

September 14, 2021

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up the load balancing configuration for the ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS, or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS, or SharePoint. The content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the following diagram.

Figure 1. ShareFile Data Load Balancing

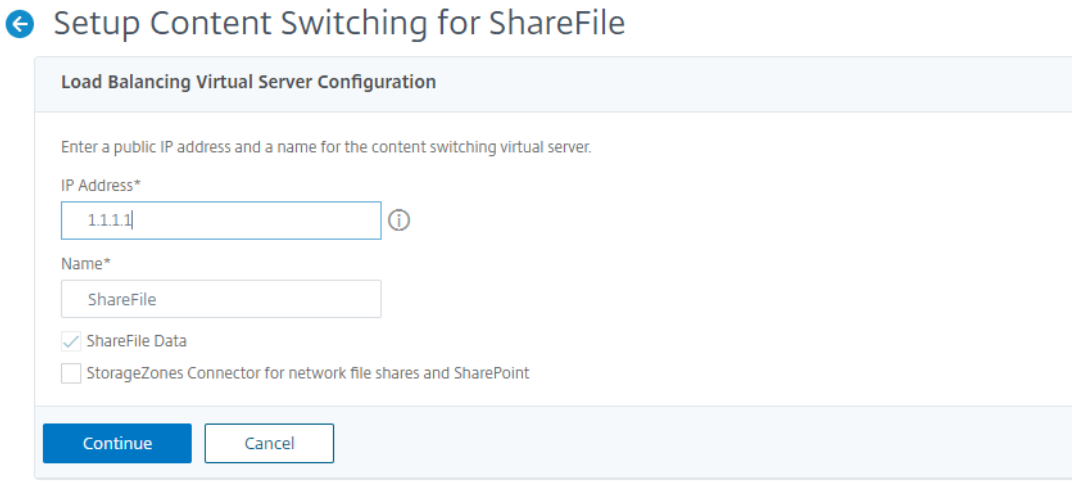


You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to **Traffic Management > Virtual Servers** and **Services > Virtual Servers**. You cannot manually remove the virtual servers created using the ShareFile wizard. Use the wizard to remove the virtual servers.

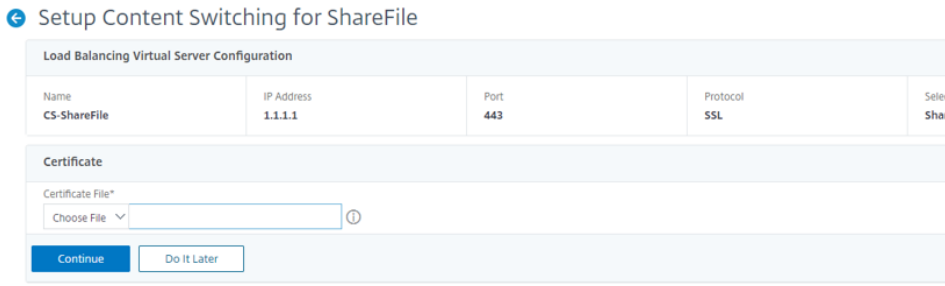
Citrix ADC uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

To configure a Citrix ADC appliance for load balancing Citrix ShareFile

1. In the navigation pane, click **Traffic Management**.
2. Under **Citrix ShareFile** section, click **Setup Citrix ADC for ShareFile**.
3. On the **Setup Content Switching for ShareFile** page, provide the following information:
   - IP Address: IP address of the content switching virtual server.
   - Name: Name of the content switching virtual server.
   - If you want to set up load balancing for CIFS or SharePoint, click the **StorageZone Connector for Network File Shares/SharePoint** check box and then click **Continue**. By default, the **ShareFile Data** check box is selected.



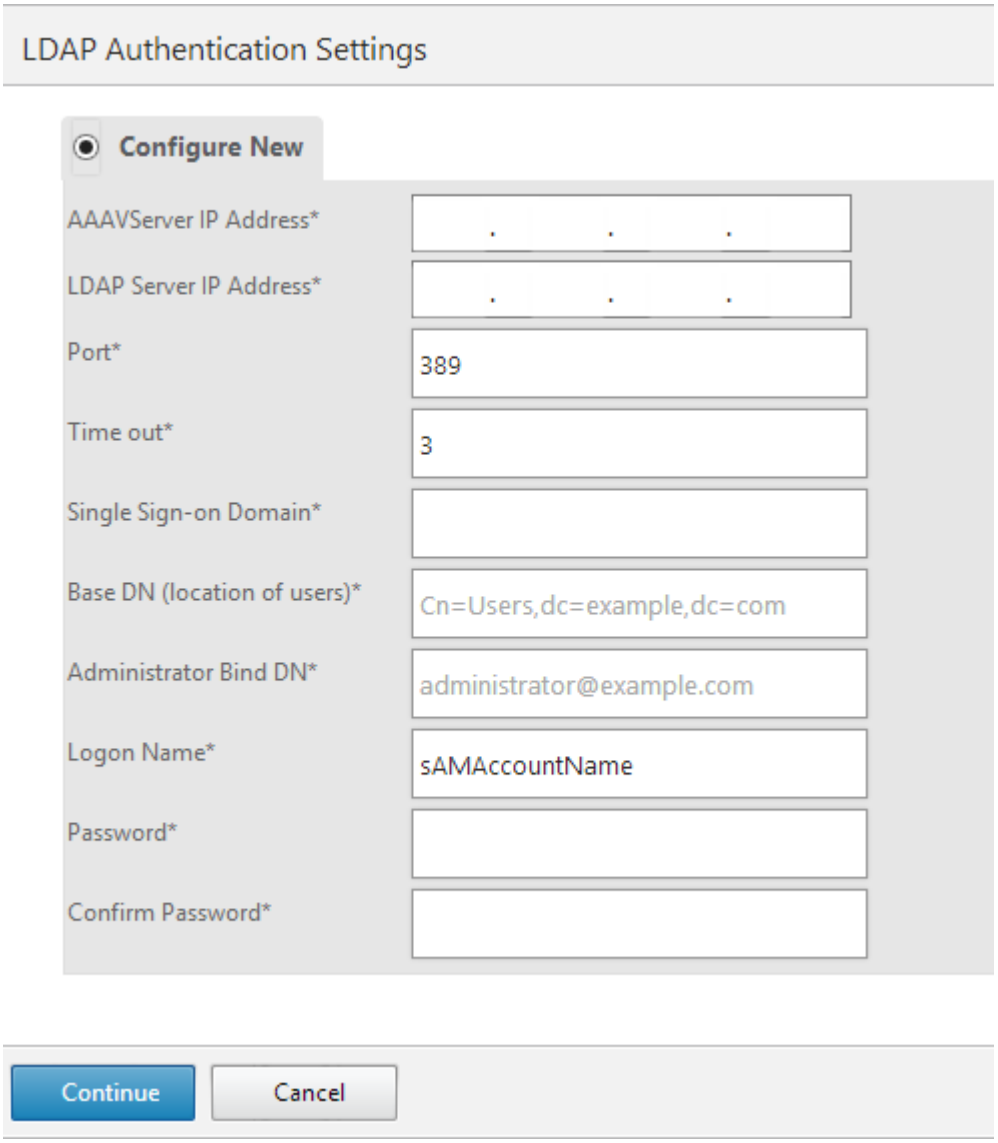
4. Provide a valid certificate. If you have a certificate, click **Choose Certificate** and from the drop-down list select the certificate. If you have to install a certificate, click **Install Certificate** and provide the Certificate-Key pair.



5. Click **Continue**.
6. In the **Add New StorageZone Controller** dialog box, specify the values of the following parameters:

- StorageZone Controller IP Address— IP address
- Port— Port number. The default value is 443.
- Protocol— Select from HTTPS or HTTP

7. Click **Create** and then click **Done**. The wizard automatically creates a service and autogenerates the name of the service.
8. If you chose load balancing for CIFS or SharePoint in step 4.c, then specify the values for LDAP Authentication Settings:
   - Citrix ADC AAA virtual server IP Address— IP address of Citrix ADC AAA virtual server
   - LDAP Server IP Address— IP Address of the LDAP server
   - Port— Port number. The default value is 389
   - Timeout— The time-out value in minutes
   - Single sign-on Domain— Single sign-on domain name
   - Base DN— Base domain name
   - Administrator Bind DN— LDAP account name with the domain name, for example, administrator@domainname.com
   - Logon Name— Logon name is the sAMAccountName
   - Password and Confirm Password— Enter the password and confirm the password



9. Click **Continue** and then click **Done**.

To remove load balancing configuration for ShareFile

1. In the navigation pane, click **Traffic Management**.
2. Under **Citrix ShareFile** section, click **Remove ShareFile Configuration**.

Use case 15: Configure layer 4 load balancing on the Citrix ADC appliance

September 14, 2021

The layer 4 load balancer (TCP and UDP ports) uses information provided in the networking transport layer for routing client requests across the server groups.

When a layer 4 connection is established between a client and a server, it has a packet view of traffic exchanged between them. The layer 4 load balancer makes its routing decisions based on the address information extracted from the first few packets in the TCP stream, and doesn't inspect the packet content. Therefore, the layer 4 load balancing is also called as connection-based load balancing.

The layer 4 load balancer monitors the health of a server. Traffic is not routed to the server if it is DOWN.

The layer 4 load balancing is useful for various applications that uses TCP or UDP payloads. Such protocols exchange data as TCP payload and don't have a specific structure to follow.

To configure layer 4 load balancing using the command line interface

At the command prompt, type:

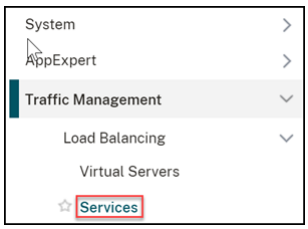
```
add service <name> <serverName> <serviceType> <port>
add lb vserver <name> <serviceType> <ip> <port>
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
add service TCPservice 192.0.2.3 TCP 1
add lb vserver TCPserver TCP 192.0.2.4 1
bind lb vserver TCPserver TCPservice
<!--NeedCopy-->
```

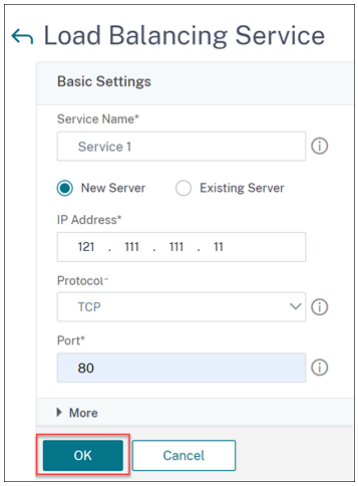
To configure layer 4 load balancing using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.



2. Click **Add** to a create a service.
3. Specify the required details in **Service Name** and **IP Address**.
4. Select either **TCP** or **UDP** in **Protocol**.

5. Click **OK**.



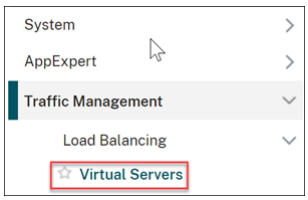
6. Click **Done**.

   A service is created.

   When you create a service using UDP as the transport layer protocol, a ping monitor (built-in monitor) is automatically bound to the service. When you create a service using TCP as the transport layer protocol, a **tcp_default** monitor is automatically bound to the service.

   For the load balancing setup, you can bind your service to a different type of monitor or multiple monitors. For advance monitoring requirements you can use the **tcp-ecv** monitor and configure the request and response messages.

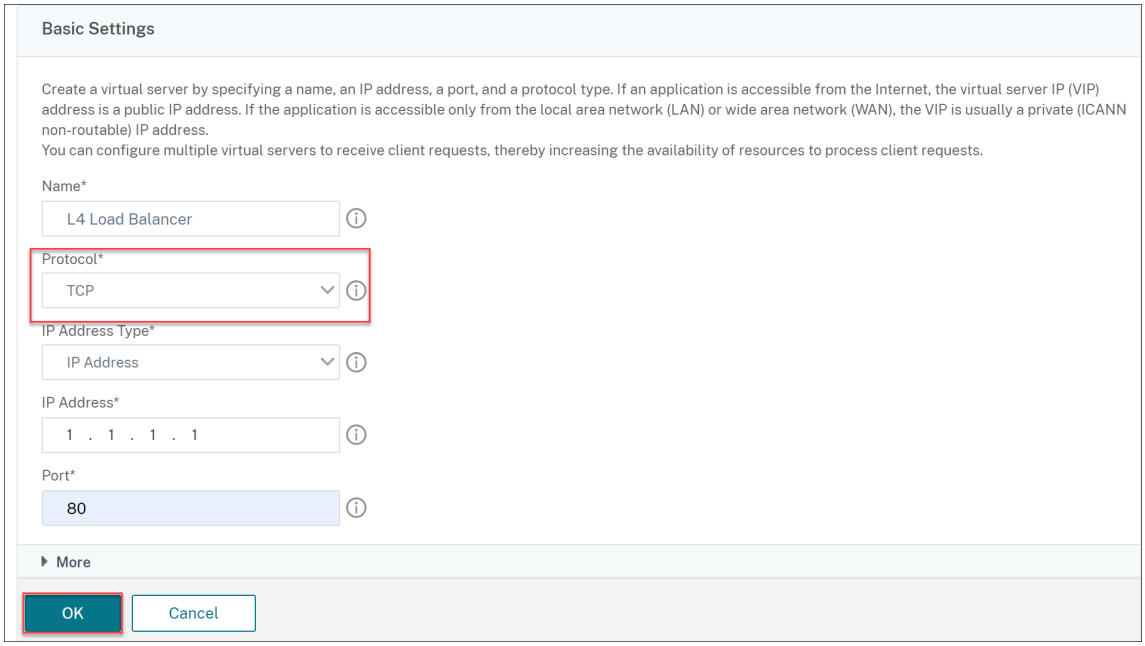
7. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.



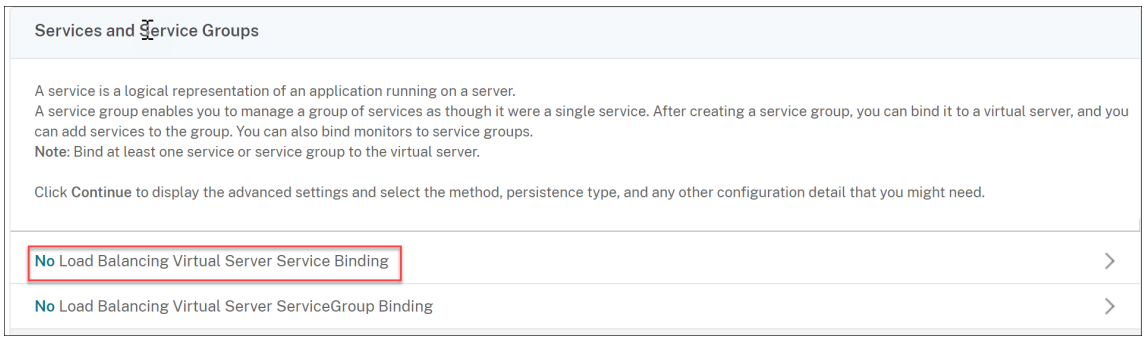
8. Click **Add** to create a new virtual server.

   When the load balancing is configured, you can connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.

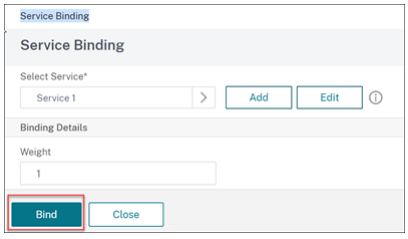
9. Specify the required details in **Name**, **IP Address Type**, and **IP Address**.
10. Select either **TCP** or **UDP** in **Protocol**.
11. Type a port number (0–1023 based on the type of service) in **Port**.
12. Click **OK**.



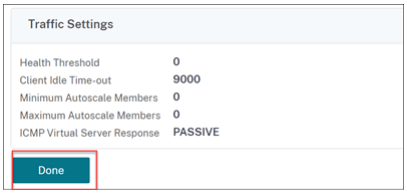
13. Click **No Load Balancing Virtual Server Service Binding** in **Services and Service Groups**.



14. In the **Service Binding** page, select **Click to Select** in **Select Service**.
15. Select the service to be bound and click **Select**.
16. Click **Bind** to bind the service to the virtual server.



17. Click **Continue**.
18. Click **Done**.



The layer 4 load balancing virtual server configuration is completed.

Troubleshooting

September 14, 2021

If the load balancing does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for Troubleshooting Load Balancing

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Latest ns.conf file
- Relevant `newnslog` files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistency related issues.
- The Wireshark application customized for the Citrix ADC trace files.

Troubleshooting Load Balancing Issues

- **Issue**

CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which the -m MAC option is enabled.

- **Resolution**

Bind a non-user monitor to the service.

- **Issue**

  I created a user script for monitoring, but it is not working.

Resolution

Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the CLI to debug the script.

- **Issue**

  I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to off the monitor probes?

  Resolution

  You can set off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

- **Issue**

  I have set up monitors for services, but connections are still directed to servers that are DOWN.

  Resolution

  You probably need to decrease the monitor probe intervals. The Citrix ADC appliance does not detect the DOWN state until the monitor sends a probe.

- **Issue**

  A metric bound to the monitor is present in the local and custom metric tables.

  Resolution

  Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don't need to add any prefix.

- **Issue**

  The monitor probes to a service are not reaching the service.

  Resolution

  Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the monitorSkipMaxClient parameter to ENABLED.

- **Issue**

  I am able to ping the servers, but the state of the services is always shown as DOWN.

  Resolution

  Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor must change the state of the service to UP.

- **Issue**

  Setting a weight for load monitors does not help in deciding the state of the service.

  Resolution

  Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- **Issue**

  A service is not stable.

  Resolution

  Consider troubleshooting the following components:

  - Verify that a correct server is bound to the service.
  - Verify the type of monitor bound to the service.
  - Verify the reasons for the monitor failures. You can open a service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
  - If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
  - You can record packet traces on the Citrix ADC appliance and verify the monitor probes and server response for further investigation.

- **Issue**

  The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

  Resolution

  Consider troubleshooting the following components:

  - Verify that the load balancing feature is licensed.
  - Verify that the feature is enabled.
  - Verify that an appropriate service is bound to the virtual server.
  - If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service must be Out-Of-Service. In such a case, you must enable the service and verify if the issue is resolved.
  - Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
  - If the VIP address is not stable, all the services bound to the virtual server must fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the Citrix ADC appliance and the servers.

- **Issue**

  The site is experiencing uneven load balancing.

  Resolution

  Consider troubleshooting the following components:

  - Verify the load balancing method configured on the appliance.
  - Verify weights associated with the services are as expected.
  - If the load balancing method is other than round robin, verify the number of connections to the server logged in the `newnslog` file. You can run the following command to verify the number on the `newnslog` file:

    ```
    ## nsconmsg -K <newnslog_file> -s ConLb=2 -d oldconmsg
    ```

    Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), number of requests, Persistent requests and persistent rate (P) to troubleshoot the issue further.
  - If the load balancing method is round robin, verify the persistent requests as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue
  - Verify if persistency is configured on the appliance.
  - Verify if any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

- **Issue**

  The service status is displayed as DOWN.

  Resolution

  Consider troubleshooting the following components:

  - Verify whether a SNIP address is configured.
  - Verify that appropriate monitors are bound to the service.
  - If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
  - Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this can be due to the MIP address being unable to communicate to the server.

- **Issue**

  There is an issue with the response time.

Resolution

Consider troubleshooting the following components:

- Verify the server response time from the service stats either by running the following command:

```
## nsconmsg -K <newnslog_file> -s ConLb=2 -d oldconmsg
```

- Check for service not stable and service status being displayed as DOWN issues.

- **Issue**

One of the servers is serving more requests than the other load balanced servers.

Resolution

Consider troubleshooting the following components:

- Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
- Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given server might be carrying a heavier load to maintain its session, especially If the persistence sessions are long.
- Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

- **Issue**

Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

Resolution

Consider troubleshooting the following components:

- Verify the load balance method. If it is round robin, consider changing the method to least connections.
- Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to the server which is functional.
- If the connections are stalled for a long period, a surge queue might build. Consider flushing the surge queue to avoid a sudden spike in load on the server.
- If the servers are working at their maximum level, consider adding a new server for better performance.

- **Issue**

A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.

Resolution

Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server's IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

- **Troubleshooting Tips**
  For other issues, consider the following tips to troubleshoot an issue not listed above:
  - If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.
  - If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
  - When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if the status of at least one of the custom load monitors is not UP.
  - All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
  - The CUSTOMLOAD load balancing method also follows the startup round robin.
  - If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
  - When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message "5xx - server busy error" is displayed.
  - A maximum of 10 metrics from a custom table can be bound to the monitor.
  - The OIDs must be scalar variables.
  - For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
  - A user cannot modify the local table.

Load balancing FAQs

September 14, 2021

What are the various load balancing policies I can create on the Citrix ADC appliance

You can create the following types of load balancing policies on the Citrix ADC appliance:

- Least Connections
- Round Robin
- Least response time
- Least bandwidth
- Least packets
- URL hashing
- Domain name hashing
- Source IP address hashing
- Destination IP address hashing
- Source IP - Destination IP hashing
- Token
- LRTM

Can I achieve the Web farm security by implementing load balancing using the Citrix ADC appliance?

Yes. You can achieve Web farm security by implementing load balancing using the Citrix ADC appliance. Citrix ADC appliance enables you to implement the following options of the load balancing feature:

- IP Address hiding: Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the Citrix ADC appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
- Port Mapping: Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the Citrix ADC appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

What are the various devices that I can use to load balance with a Citrix ADC appliance?

You can load balance the following devices with a Citrix ADC appliance:

- Server farms
- Caches or Reverse Proxies
- Firewall devices
- Intrusion detection systems

- SSL offload devices
- Compression devices
- Content Inspection servers

Why do I implement the load balancing feature for the website?

You can implement the Load balancing feature for the website to take the following advantages:

- Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.
- Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the back-end server that is not available.

Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?

- If you enable the MBF option, the Citrix ADC appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires the best path to be chosen for the return traffic.
- Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

Networking

September 14, 2021

The following topics provide a conceptual reference and instructions for configuring the various networking components on the Citrix ADC appliance.

IP Addressing	Learn the various types of Citrix ADC owned IP addresses and how to create, customize, and remove them.
Interfaces	Configure some of the basic network configurations that must be done to get started.
Access Control Lists (ACLs)	Configure the different types of Access Control Lists and how to create, customize, and remove them.
IP Routing	Learn and configure the routing functionality of the Citrix ADC appliance, both static and dynamic.
Internet Protocol version 6 (IPv6)	Learn how the Citrix ADC appliance supports IPv6.
Traffic Domains	Learn and configure traffic domains to segment network traffic for different applications.
VXLAN	Learn and configure VXLANs to meet the scalability needs in your datacenter.

IP Addressing

September 14, 2021

Before you can configure the Citrix ADC appliance, you must assign the NSIP address, also known as the Management IP address. You can also create other Citrix ADC-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

Configuring Citrix ADC-owned IP addresses

September 14, 2021

The Citrix ADC-owned IP addresses—NSIP address, Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the Citrix ADC appliance. The NSIP uniquely identifies the Citrix ADC on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The Citrix ADC terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP. You can configure some Citrix ADC-owned IP addresses to provide access for management applications.

Configuring the NSIP address

September 14, 2021

The NSIP address is the IP address at which you access the Citrix ADC appliance for management purposes. The appliance can have only one NSIP, which is also called the management IP address. You must add this IP address when you configure the Citrix ADC for the first time. You cannot remove an NSIP address. For security reasons, the NSIP should be a non-routable IP address on your organization's LAN.

If you modify this address, you must reboot the Citrix ADC appliance. If the subnet address of the new NSIP address is different from the previous one, you must add a default route for this subnet so that the new NSIP address becomes reachable from other networks on the LAN.

> **Important**
>
> Configuring the NSIP address is mandatory.

Changing the NSIP address of a Citrix ADC appliance consists of the following tasks:

- Change the NSIP address.
- Add a default route for the subnet address of the NSIP address, if one is not present.
- Save the configuration.
- Restart the appliance.

Command Line Procedures

To change the NSIP address by using the CLI:

At the command prompt, type:

- **set ns config -IPAddress** <ip_addr> **-netmask** <netmask>
- **show ns config**

To add a default route by using the CLI:

At the command prompt, type:

- **add route 0 0** <gateway IP address>
- **show route**

To save the configuration by using the CLI:

At the command prompt, type:

- **save config**

To restart the Citrix ADC appliance by using the CLI:

At the command prompt, type:

- **reboot**

GUI Procedures

To configure the NSIP address by using the GUI:

1. Click the gear icon in the top-right corner of the **Configuration** page.
2. Click the **NSIP address** pane.
3. On the **NSIP address** page, set the following parameters, and then click **Done**:
    - NSIP address
    - Netmask

To add a default route by using the GUI:

Navigate to **System** > **Network** > **Routes** and, on the **Basic** tab, add a default route with the following parameter settings, and then click **Create**.

- Network (set to zero)
- Netmask (set to zero)
- Gateway (IP address of the gateway)

To restart the Citrix ADC by using the GUI:

1. On the **System Information** tab page of the **System** node, click **Reboot**.
2. When prompted to reboot, select **Save Configuration** to make sure that you do not lose any configurations.

Sample configuration

In the following example, the NSIP address of a Citrix ADC appliance is changed to 192.0.2.90, which has a different subnet address (192.0.2.0/24) than the previous NSIP address. Therefore, a default route is added for this subnet, so that the new NSIP address becomes reachable from other networks.

```
> set nsconfig -ipAddress 192.0.2.90 -netmask 255.255.255.0

 Warning: The configuration must be saved and the system rebooted for
    these settings to take effect
> add route 0 0 192.0.2.1

 Warning: The configuration must be saved and the system rebooted for
    these settings to take effect
> save config

 Done
> reboot
```

Configuring and Managing Virtual IP (VIP) Addresses

September 14, 2021

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the Citrix ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see Load Balancing.

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple Citrix ADC appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the appliance sends, and then responds to, ARP requests. VIPs are the only Citrix ADC-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests. As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example:

```
> add ns ip 10.102.29.59 255.255.255.0 -type VIP
 Done
<!--NeedCopy-->
```

To create a range of VIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example:

```
> add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
ip "10.102.29.60" added
ip "10.102.29.61" added
ip "10.102.29.62" added
ip "10.102.29.63" added
ip "10.102.29.64" added
 Done
<!--NeedCopy-->
```

To enable or disable an IPv4 VIP address by using the CLI:

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

Example:

```
> enable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

        IP: 10.102.29.79
        Netmask: 255.255.255.255
        Type: VIP
        state: Enabled
        arp: Enabled
        icmp: Enabled
        vserver: Enabled
```

```
        management access: Disabled
          telnet: Disabled
          ftp: Disabled
          ssh: Disabled
          gui: Disabled
          snmp: Disabled
        Restrict access: Disabled
        dynamic routing: Disabled
        hostroute: Disabled
 Done
> disable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

        IP: 10.102.29.79
        Netmask: 255.255.255.255
        Type: VIP
        state: Disabled
        arp: Enabled
        icmp: Enabled
        vserver: Enabled
        management access: Disabled
          telnet: Disabled
          ftp: Disabled
          ssh: Disabled
          gui: Disabled
          snmp: Disabled
        Restrict access: Disabled
        dynamic routing: Disabled
        hostroute: Disabled

 Done
<!--NeedCopy-->
```

To configure a VIP address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPV4s**, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. In the **Action** list, select **Add Range**.

To enable or disable a VIP address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Do one of the following:

- Select a VIP address.
- Hold down the **Ctrl** key and select multiple server address entries.
- Hold down the **Shift** key and select a range of server address entries.
- Select all the addresses by selecting the checkbox on the left side of the header row.

3. From the **Action** list, select **Disable** or **Enable**.

Detecting a Citrix ADC Appliance in a UDP Load Balancing Setup through TTL Updates

The following table displays how a Citrix ADC appliance handles the TTL value of received packets in different functionalities.

Functionality	TTL value
Virtual Server	TTL is set to 255 when forwarding the request to the backend servers. TTL is decremented by 1 when forwarding the response to the client.
L2 Mode	TTL is not changed.
L3 Mode	TTL is set to 255.
INAT	TTL is set to 255 when forwarding the request to the backend server. TTL is decremented by 1 when forwarding the response to the client.

Some enterprises/scenarios running a monitoring application requires the Citrix ADC appliance of a load balancing setup to be detected as one of the hop in a traceroute. A Citrix ADC appliance of a load balancing setup is not detected in a traceroute because the appliance, by default, sets the TTL value to 255 instead of decrementing it when forwarding the request to a backend server.

To meet this requirement, **Decrement TTL** parameter of a VIP address can be used. This parameter applies to all UDP virtual servers using this VIP.

When you enable the **Decrement TTL** parameter of a VIP, the Citrix ADC appliance decrements the TTL value by 1 instead of setting it to 255 when forwarding requests, which are received on the UDP virtual servers that uses this VIP.

Monitoring applications using traceroute data can now detect the presence of a Citrix ADC appliance of a UDP load balancing setup.

Before You Begin

Before you begin configuring a Citrix ADC appliance to be detected in a traceroute of a load balancing setup, note the following points:

- Decrement TTL parameter is supported only for UDP load balancing virtual servers.
- Decrement TTL parameter is supported for IPv4 VIP as well as IPv6 VIP (VIP6) addresses.
- Decrement TTL parameter is supported for standalone Citrix ADC appliances as well as for high availability (HA) and cluster setups.

Configuration Steps

Configuring a Citrix ADC appliance to be detected in a traceroute of a UDP load balancing setup consists of the following tasks:

- Create a UDP load balancing configuration
- Enable the Decrement TTL parameter for the VIP address

CLI Procedures

To enable the decrement TTL option for a VIP address by using the CLI:

- To enable the decrement TTL option for a VIP address while adding the VIP address, at the command prompt, type:
  - **add ns ip** <ip> <mask> -**type VIP** -**decrementTTL ENABLED**
  - **show ns ip** <VIP address>
- To enable the decrement TTL option for an existing VIP address, at the command prompt, type:
  - **set ns ip** <ip> <mask> -**decrementTTL ENABLED**
  - **show ns ip** <VIP address>

To enable the decrement TTL option for a VIP6 address by using the CLI:

- To enable the decrement TTL option for a VIP6 address while adding the VIP6 address, at the command prompt, type:
  - **add ns ip6** <IP6/prefix> <mask> -**type VIP** -**decrementTTL ENABLED**
  - **show ns ip6** <VIP6/prefix>
- To enable the decrement TTL option for an existing VIP6 address, at the command prompt, type:
  - **set ns ip6** <ip6/prefix> <mask> -**decrementTTL ENABLED**
  - **show ns ip6** <VIP6 address>

```
1     > add ns ip 203.0.113.30 -type VIP -decrementTTL ENABLED
2      Done
3
4     > add ns ip6  2001:DB8:5001::30 -type VIP -decrementTTL ENABLED
5      Done
6 <!--NeedCopy-->
```

GUI Procedures

To enable the decrement TTL option for a VIP address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPv4s**, and enable the **Decrement TTL** parameter while adding a new VIP address or editing an existing address.

To enable the decrement TTL option for a VIP6 address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPv6s**, and enable the **Decrement TTL** parameter while adding a new VIP6 address or editing an existing address.

Configuring ARP response Suppression for Virtual IP addresses (VIPs)

September 14, 2021

You can configure the Citrix ADC appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a Citrix ADC appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE**. The Citrix ADC appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER**. The Citrix ADC appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER**. The Citrix ADC appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of Citrix ADC appliance for a VIP configured with two virtual servers:

Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
NONE				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN

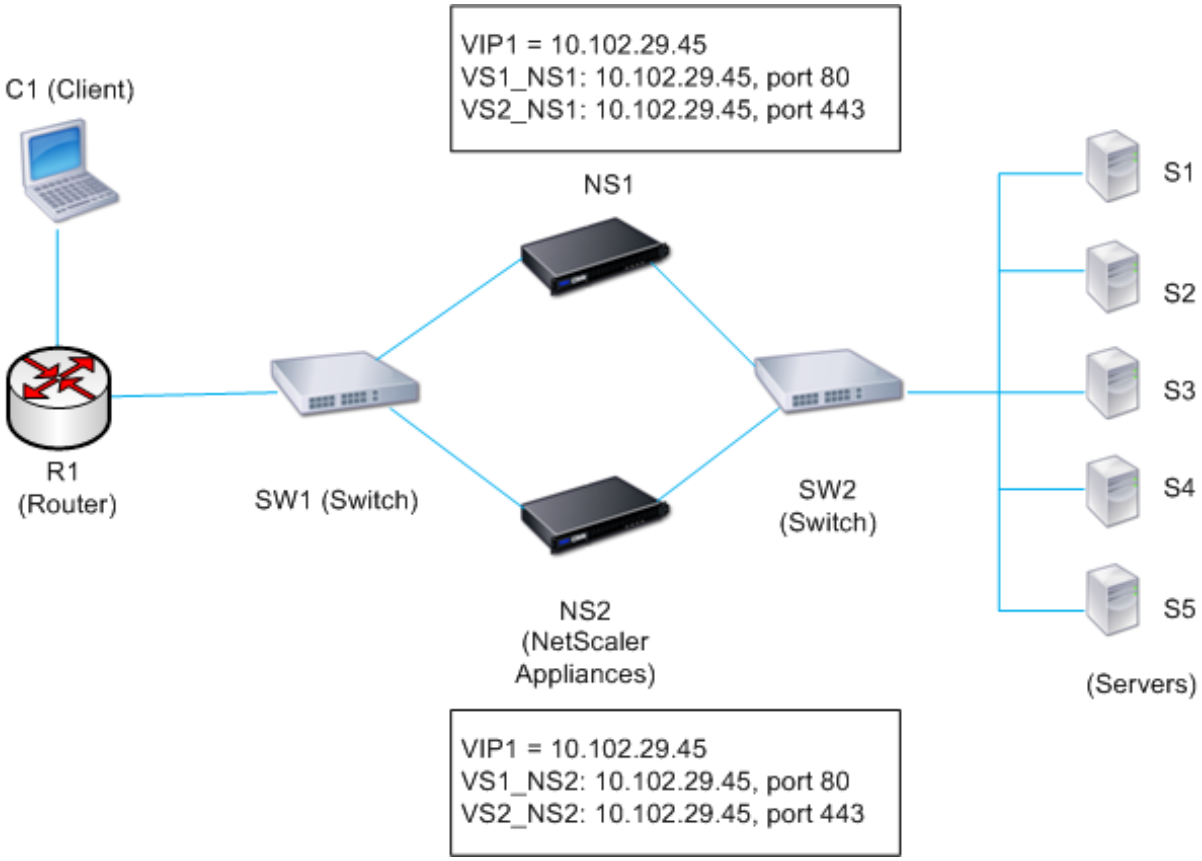
Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
Respond to an ARP request for this VIP?	Yes	Yes	Yes	Yes
ONE VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	No
ALL VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	No	No	No

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on Citrix ADC appliances NS1 and NS2. Let's call the shared VIP address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for VIP1.

Figure 1.



The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.
8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request

for VIP1.

10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the CLI:

At the command prompt, type:

- **set ns ip** -**arpResponse** <arpResponse>]
- **sh ns ip** <IPAddress>

Example:

```
> set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
 Done
<!--NeedCopy-->
```

To configure ARP response suppression by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Open an IP address entry and select the type of ARP Response.

Configuring Subnet IP Addresses (SNIPs)

September 14, 2021

A subnet IP address (SNIP) is a Citrix ADC owned IP address that is used by the Citrix ADC to communicate with the servers.

The Citrix ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers. Depending on your network topology, you might have to configure one or more SNIPs for different scenarios.

To configure a SNIP address on a Citrix ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode. As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example:

```
> add ns ip 10.102.29.203 255.255.255.0 -type SNIP
 Done
<!--NeedCopy-->
```

To create a range of SNIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example:

```
> add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
ip "10.102.29.205" added
ip "10.102.29.206" added
ip "10.102.29.207" added
ip "10.102.29.208" added
ip "10.102.29.209" added
 Done
<!--NeedCopy-->
```

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the GUI:

Navigate to System > Network > IPs > IPV4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns mode USNIP
- disable ns mode USNIP

To enable or disable USNIP mode by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

Using SNIPs for a Directly Connected Server Subnet

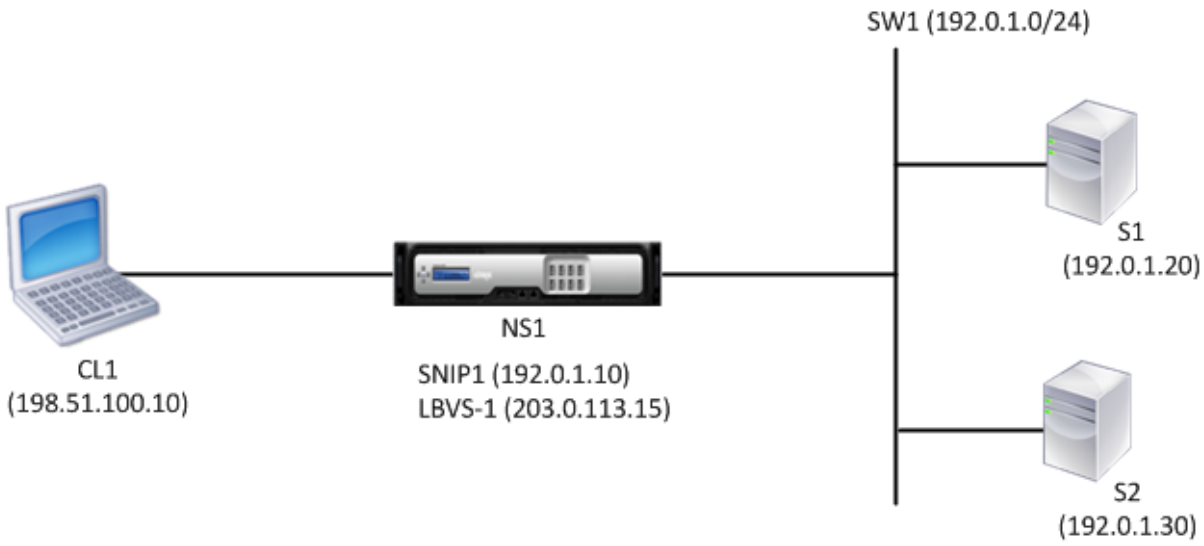
To enable communication between the Citrix ADC and a server that is either connected directly to the Citrix ADC or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a Citrix ADC, see Load Balancing.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.
5. NS1 sends the request packet to S2 from SNIP1. The request packet has:

- Source IP = SNIP1 (192.0.1.10)
- Destination IP = IP address of S2 (192.0.1.30)

6. S2's response returns by the same path.

Using SNIPs for Server Subnets Connected through a Router

To enable communication between the Citrix ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

Citrix ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

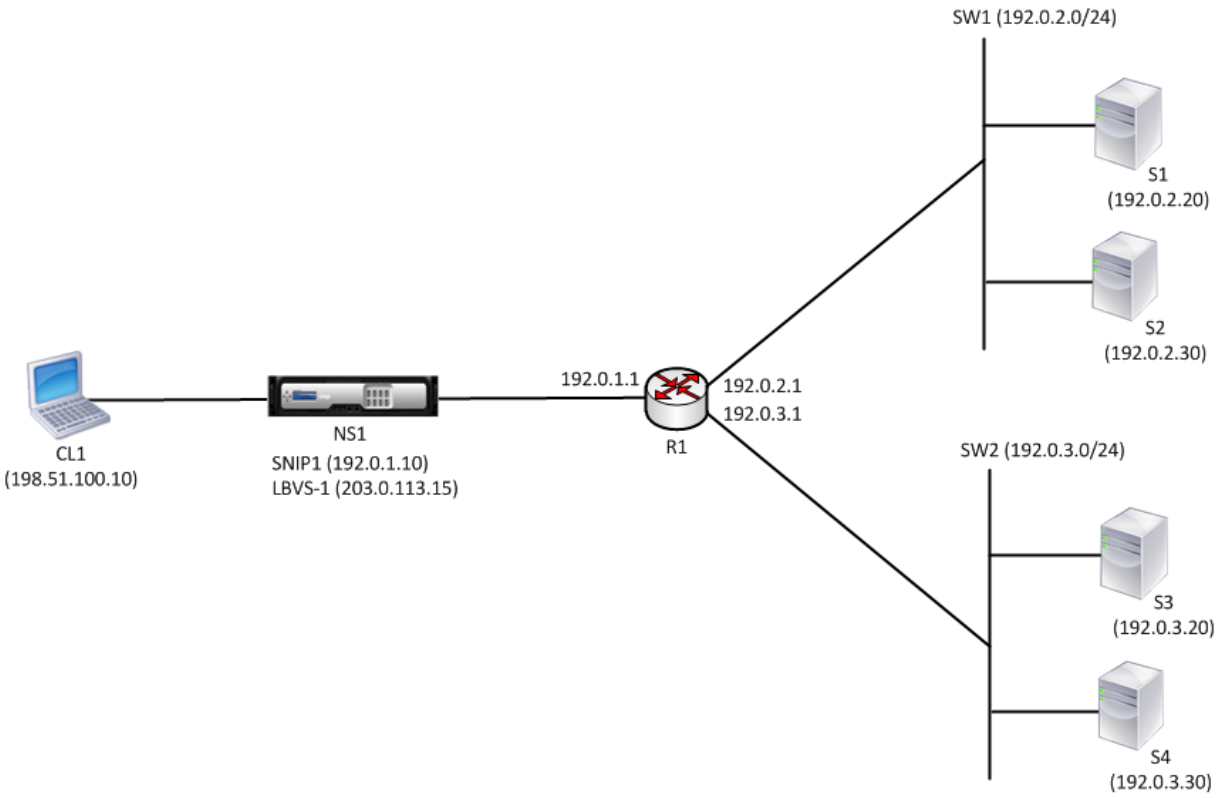
For more information about configuring load balancing on a Citrix ADC, see Load Balancing.

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables, that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a Citrix ADC, see IP Routing.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
   - Source IP address = SNIP1 (192.0.1.10)
   - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3's response returns by the same path.

Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a Citrix ADC, you must configure at least one SNIP address for each of the server subnets, so that the Citrix ADC can communicate with these server subnets.

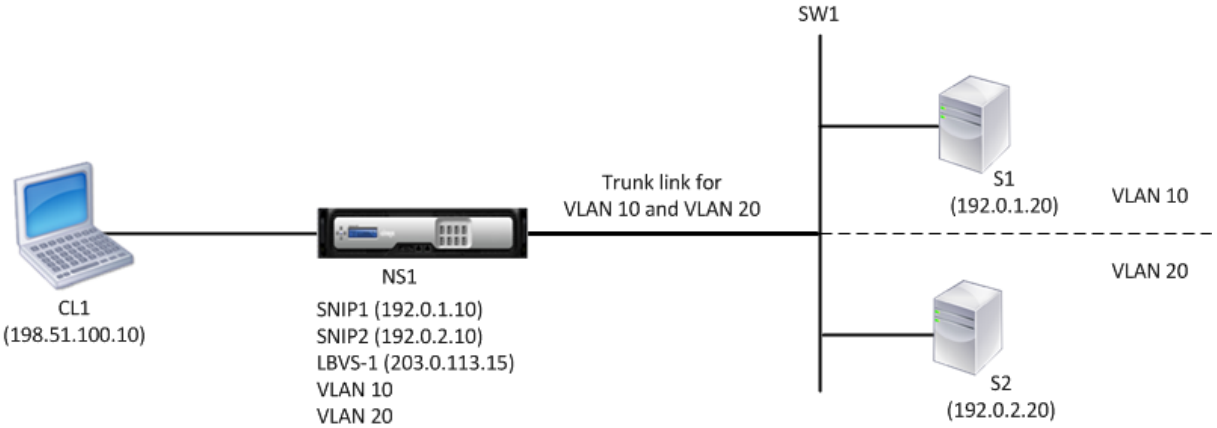
Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a Citrix ADC, see Load Balancing.

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a Citrix ADC, see Configuring a VLAN.

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.
   Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.
5. NS1 sends the request packet to S2 from SNIP2. The request packet has:
   - Source IP = SNIP1 (192.0.2.10)
   - Destination IP = IP address of S2 (192.0.2.20)
6. S2's response returns by the same path.

Configuring GSLB Site IP Addresses (GSLBIP)

September 14, 2021

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the Citrix ADC appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see Global Server Load Balancing.

Removing a Citrix ADC-owned IP address

September 14, 2021

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

IP address type	Implications
Subnet IP address (SNIP)	If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another Citrix ADC-owned IP address.
Virtual Server IP address (VIP)	Before removing a VIP, you must first remove the virtual server associated with it. For information about removing the virtual server, see Load Balancing.
GSLB-Site-IP address	Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see Global Server Load Balancing.

To remove an IP address by using the CLI:

At the command prompt, type:

rm ns ip <IPaddress>

Example:

```
> rm ns ip 10.102.29.54
Done
<!--NeedCopy-->
```

To remove an IP address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPV4s**, delete the IP address.

Configuring Application Access Controls

September 14, 2021

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see Access Control Lists (ACLs).

The Citrix ADC appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

Management Access	Telnet (State Configured on the Citrix ADC)	Telnet (Effective State at the IP Level)
Enable	Enable	Enable
Enable	Disable	Disable
Disable	Enable	Disable
Disable	Disable	Disable

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

Application/ IP	NSIP	SNIP	VIP
ARP	Yes	Yes	No
Server side traffic	No	Yes	No
RNAT	No	Yes	Yes
ICMP PING	Yes	Yes	No
Dynamic routing	Yes	Yes	Yes

The following table provides an overview of the applications available on these IP addresses.

Application/ IP	NSIP	SNIP	VIP
SNMP	Yes	Yes	Yes
System access	Yes	Yes	No

You can access and manage the Citrix ADC by using applications such as Telnet, SSH, GUI, and FTP.

Note: Telnet and FTP are disabled on the Citrix ADC for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the Citrix ADC to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the Citrix ADC appliance's attack prevention capabilities.

You can block access to these non-management applications on a SNIP or NSIP. When access is blocked, a user connecting to a Citrix ADC by using the SNIP or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the CLI:

At the command prompt, type:

set ns ip <IPAddress> -mgmtAccess <value> -**telnet** <value> -**ftp** <value> -**gui** <value> -**ssh** <value> -**snmp** <value> -**restrictAccess** (**ENABLED** | **DISABLED**)

Example:

```
1  > set ns ip 10.102.29.54 -mgmtAccess enabled -restrictAccess ENABLED
2   Done
```

```
<!--NeedCopy-->
```

To enable management access for an IP address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Open an IP address entry, and select the **Enable Management Access control** to support the listed applications option.

Enable secure access to Citrix ADC GUI using a subnet IP address(SNIP)

Secure access to Citrix ADC GUI is enabled by default for the Citrix ADC IP (NSIP). You can also enable secure access to the Citrix ADC appliance by using a subnet IP address of the appliance.

After configuring an SNIP address for secure access to a high availability pair, the secure access is available to the primary appliance, if you access the SNIP address.

Citrix ADC CLI procedure

To enable secure access to Citrix ADC GUI using a subnet IP address(SNIP) by using the CLI:

At the command prompt, type:

set ns ip <SNIP_Address> **-type SNIP -gui SECUREONLY -mgmtAccess ENABLED**

Example:

```
> set ns ip 203.0.113.99 -mgmtAccess enabled -restrictAccess ENABLED

 Done
<!--NeedCopy-->
```

How the Citrix ADC Proxies Connections

September 14, 2021

When a client initiates a connection, the Citrix ADC appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see Load Balancing.

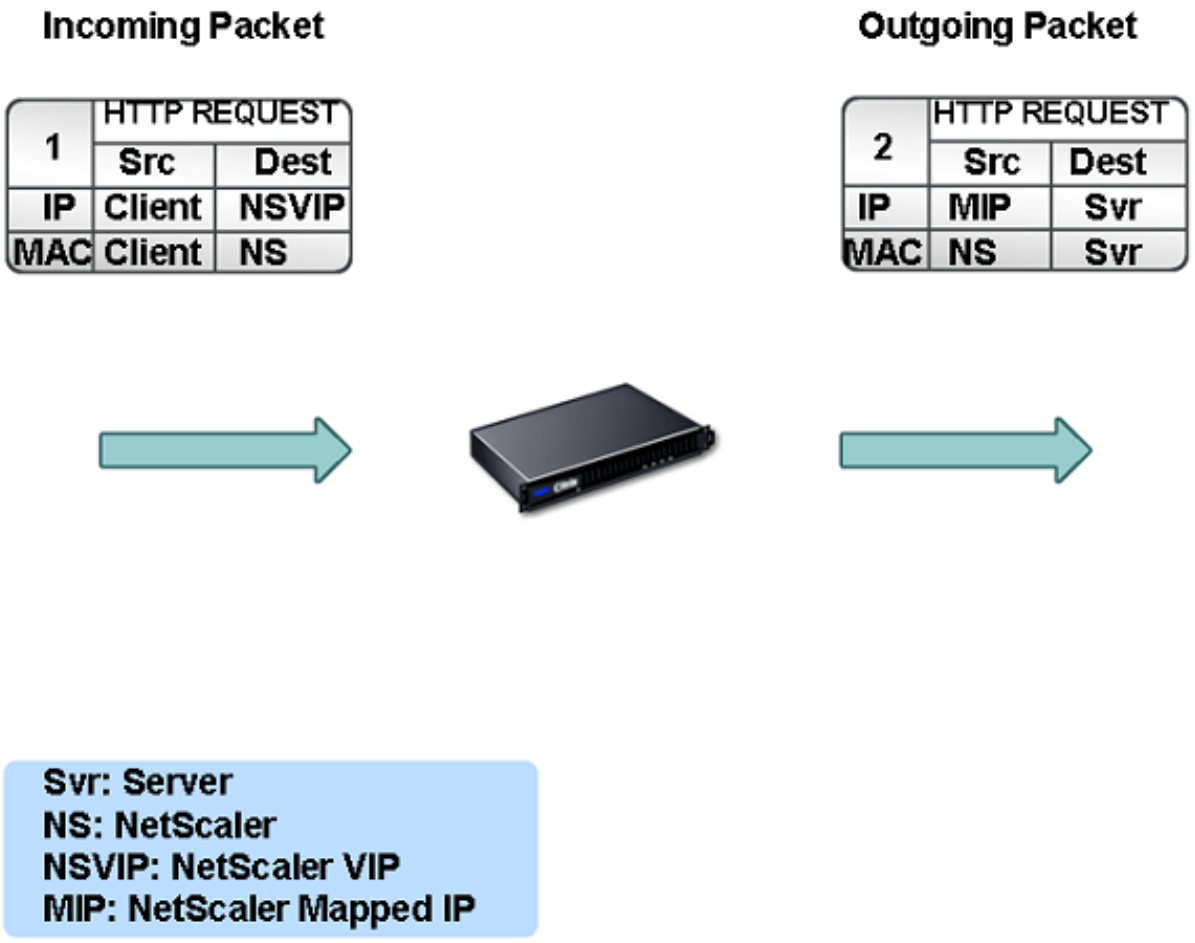
You can configure the Citrix ADC to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending

the packet to the server. You can configure the Citrix ADC to retain the source IP address of the packets by enabling Use Source IP mode.

How the Destination IP Address Is Selected

Traffic sent to the Citrix ADC appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The Citrix ADC terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

Figure 1. Proxying Connections to VIPs



Packets destined for a service are sent directly to the appropriate server, and the Citrix ADC does not modify the destination IP addresses. In this case, the Citrix ADC functions as a proxy.

How the Source IP Address Is Selected

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. Citrix ADC maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, Citrix ADC selects a specific SNIP address.

Note: If the Use Source IP (USIP) option is enabled, appliance uses the IP address of the client.

Enable Use Source IP Mode

September 14, 2021

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of selecting a SNIP address depends on the subnet in which the physical server resides.

If necessary, you can configure the Citrix ADC appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Google provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the Citrix ADC may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want the Citrix ADC to use the client's IP address for communication with the servers.

The following figure shows how the appliance uses IP addresses in USIP mode.

Before you begin

Before you enable USIP mode, note the following points:

- Enable USIP in the following situations:
  - Load balancing of Intrusion Detection System (IDS) servers
  - SMTP load balancing
  - Stateless connection failover
  - Sessionless load balancing
  - If you use the Direct Server Return (DSR) mode
- The USIP global setting applies only to services that are created after the USIP global setting is made. In other words, the USIP global setting does not apply to the existing services when the USIP global setting is made. For example, Disabling USIP globally does not disable USIP on the existing services. But it stops the subsequently created services from having USIP enabled automatically.

  To enable or disable USIP on a set of existing services, you need to enable or disable USIP on each of these services.
- When USIP is enabled, you must set server's gateway to one of the Citrix ADC owned IP addresses (of type Subnet IP (SNIP) so that server's response always go through the Citrix ADC appliance.
- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.
- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends

setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.

- As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.
- In earlier Citrix ADC releases, USIP mode had the following source-port options for server-side connections:
  - **Use the client's port**. With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.
  - **Use proxy port**. With this option, connection reuse is possible for all requests from the same client.

  In the later Citrix ADC releases, if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

  By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

  Note: If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

  For more information about the Use Proxy Port option, see Configure the source port for server-side connections.

Configuration Steps

Enable Use Source IP mode (USIP) mode if you want Citrix ADC to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the Citrix ADC or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

CLI procedures

To globally enable or disable USIP mode by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns mode USIP**
- **disable ns mode USIP**

To enable USIP mode for a service by using the CLI:

At the command prompt, type:

set service <name>@ -**usip** (**YES** | **NO**)

Example:

```
> set service Service-HTTP-1 -usip YES
Done
<!--NeedCopy-->
```

GUI procedures

To globally enable or disable USIP mode by using the GUI:

1. Navigate to **System** > **Settings**, in **Modes and Features** group, click **Change Modes**.
2. Select or clear the **Use Source IP** option.

To enable USIP mode for a service by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, and edit a service.
2. In **Advanced Settings**, select **Service Settings**, and select **Use Source IP Address**.

Configuring Network Address Translation

September 14, 2021

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the Citrix ADC appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the Citrix ADC. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The Citrix ADC supports the following types of network address translation:

- **Inbound NAT (INAT).** The Citrix ADC replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- **Reverse NAT (RNAT).** The Citrix ADC replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

Inbound Network Address Translation

September 14, 2021

When a client sends a packet to a Citrix ADC appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping**: A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance translates the packet's public destination IP address to the destination IP address of the server. Then the appliance forwards the packet to the server at that address.
- **IPv4-IPv6 Mapping**: A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.
- **IPv6-IPv4 Mapping**: A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping**: A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance translates the packet's public destination IP address to the destination IP address of the server. Then the appliance forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the appliance uses a subnet IP address (SNIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the appliance uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the Citrix ADC to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the Citrix ADC attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the Citrix ADC from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you can disable them.

Configure INAT rules

You can create, modify, or remove an INAT entry.

CLI procedures

To create an INAT entry by using the CLI:

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- **add inat** <name> <publicIP> <privateIP> [-**tcpproxy** (**ENABLED** | **DISABLED**)] [-**ftp** (**ENABLED** | **DISABLED**)] [-**usip** (**ON** | **OFF**)] [-**usnip** (**ON** | **OFF**)] [-**proxyIP** <**ip_addr > ipv6_addr>**]
- **show inat** [<name>]

Example:

```
> add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
 Done
<!--NeedCopy-->
```

To modify an INAT entry by using the CLI:

To modify an INAT entry, type the `set inat` command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the CLI:

At the command prompt, type:

- **rm inat** <name>

Example:

```
> rm inat ip4-ip4
 Done
<!--NeedCopy-->
```

GUI procedures

To configure an INAT entry by using the GUI:

Navigate to **System** > **Network** > **Routes** > **INAT**, and add an INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the GUI:

Navigate to **System** > **Network** > **Routes** > **INAT**, delete the INAT configuration.

Connection failover for INAT rules

Connection failover or connection mirroring enables the primary node to duplicate connection and persistence information to the secondary node in a high availability. The state information of the connection is shared with the secondary node regularly when connection mirroring is enabled.

Enabling connection failover provides more reliability but it comes at the cost of some system time being used up for sharing the state information. The connection data is synchronized to the standby unit with every packet or flow state update. Hence, it must be used only at places where connection level reliability is of prime importance.

Citrix ADC appliance high availability setups support connection failover for INAT connections. The primary node sends INAT mappings and other INAT related connection information to the secondary node at regular intervals. The secondary appliance uses the mapping and connection information only in the event of a failover.

When a failover occurs, the new primary node has information about the INAT connections established before the failover. Hence, it continues to serve those connections even after the failover.

From the client's perspective the failover is transparent. During the transition period, the client and server might experience a brief disruption and retransmissions. Connection failover can be enabled per INAT rule.

For enabling connection failover on an INAT rule, you enable the `connFailover` parameter of that specific RNAT rule by using CLI.

CLI procedure

To enable connection failover for an INAT rule by using the CLI:

To enable connection failover while adding an INAT rule, at the command prompt, type:

- **add inat** <name> <publicIP> <privateIP> [-**tcpproxy** (**ENABLED** | **DISABLED**)] [-**ftp** (**ENABLED** | **DISABLED**)] [-**usip** (**ON** | **OFF**)] [-**usnip** (**ON** | **OFF**)] [-**proxyIP** <ip_addr|ipv6_addr>] -**connfailover** (**ENABLED** | **DISABLED**)
- **show inat** <name>

To enable connection failover while modifying an existing INAT rule, at the command prompt, type:

set inat -connfailover (**ENABLED** **DISABLED**)

-
- **show inat** <name>

Coexistence of INAT and Virtual Servers

September 14, 2021

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the Citrix ADC device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

Case	Result
You have configured a virtual server and a service to send all data packets received on a specific Citrix ADC port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.	All packets received on the Citrix ADC, except those received on the specified port, pass through the TCP engine.
You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the Citrix ADC, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.	Only packets received on the specified port pass through the TCP engine.
You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.	The INAT configuration is not allowed.
You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.	The vserver configuration is not allowed.

Stateless NAT46

September 14, 2021

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the Citrix ADC appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

A stateless NAT46 configuration on the Citrix ADC appliance has the following components:

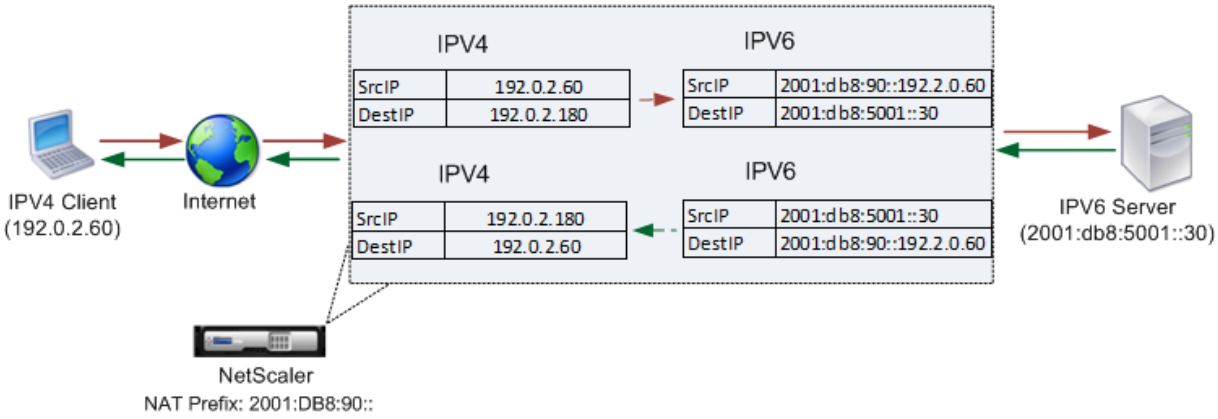
- **IPv4-IPv6 INAT entry.** An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.

  The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.

- **NAT46 IPv6 prefix.** A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.

  During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, Citrix ADC appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.



The following table lists the settings used in this example:

Entities	Name	Value
IP address of the client	Client_IPv4 (for reference purposes only)	192.0.2.60
IPv6 address of the server	Sevr_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address defined in the INAT entry for IPv6 server S1	Map-Sevr-IPv4 (for reference purposes only)	192.0.2.180
IPv6 prefix for NAT 46 translation	NAT46_Prefix (for reference purposes only)	2001:DB8:90::

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the Citrix ADC appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
   - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
   - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the Citrix ADC appliance with:
   - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60
   - Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30

6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30). It finds the Map-Sevr-IPv4 address (192.0.2.180).
7. The appliance creates an IPv4 response packet with:
   - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client_IPv4 (192.0.2.60)
   - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
8. The appliance sends the translated IPv4 response to client CL1.

Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

Configure Stateless NAT46

Creating the required entities for stateless NAT46 configuration on the Citrix ADC appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Create a NAT46 IPv6 prefix.

CLI procedures

To configure an INAT mapping entry by using the CLI:

At the command prompt, type:

- add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS
- show inat <name>

To create an NAT46 prefix by using the CLI:

At the command prompt, type:

```
set inatparam -nat46v6Prefix <ipv6_addr            *>
```

-
- show inatparam

Example:

```
 > add inat exmpl-com-stls-nat46 192.0.2.180
2001:DB8:5001::30 -mode stateless
Done

> set inatparam -nat46v6Prefix 2001:DB8:90::/96
Done
<!--NeedCopy-->
```

GUI procedures

To create an INAT mapping entry by using the GUI:

1. Navigate to System > Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
   - Name*
   - Public IP Address*
   - Private IP Address* (Select the IPv6 check box and enter the address in IPv6 format.)
   - Mode (Select Stateless from the drop down list.)

   * A required parameter

To create a NAT46 prefix by using the GUI:

Navigate to **System** > **Network**, in the **Settings** group, click **Configure INAT Parameters**, and set the **Prefix** parameter.

Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the CLI:

At the command prompt, type:

set inatparam [-**nat46IgnoreTOS** (**YES**	**NO**)] [-**nat46ZeroCheckSum** (**ENABLED**	**DISABLED**)] [-**nat46v6Mtu** <positive_integer>] [-**nat46FragHeader** (**ENABLED**	**DISABLED**)]

-
- **show inatparam**

Example:

```
> set inatparam -nat46IgnoreTOS YES -nat46ZeroCheckSum DISABLED -
    nat46v6Mtu 1400 -nat46FragHeader DISABLED
 Done
<!--NeedCopy-->
```

To set global parameters for stateless NAT46 by using the GUI:

Navigate to **System** > **Network**, in the **Settings** group, click **Configure INAT Parameters**.

DNS64

September 14, 2021

The Citrix ADC DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery of the IPv4domain by the IPV6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the Citrix ADC appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the Citrix ADC appliance. The Citrix ADC appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a Citrix ADC appliance with DNS64 and NAT64 configuration can deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the Citrix ADC appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the Citrix ADC appliance is deployed on the client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a Citrix ADC appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, andDNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

The global DNS parameter cacherecords is enabled on the Citrix ADC appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example: DNS64 example settings.

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site www.example.com.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on Citrix ADC appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site www.example.com does not exist in the DNS cache.
4. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site www.example.com is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site www.example.com.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.
7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of www.example.com.
8. DNS-1 responds by sending the DNS A record for www.example.com to LBVS-DNS64-1. The A record includes the IPv4 address for www.example.com.
9. NS1 synthesizes an AAAA record for the site www.example.com with:
    - IPv6 address for site www.example.com = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = 2001:DB8:300::192.0.2.60
10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

Points to Consider for a DNS64 Configuration

Before configuring DNS64 on a Citrix ADC appliance, consider the following points:

- The DNS64 feature of the Citrix ADC appliance is compliant with RFC 6174.
- The DNS64 feature of the Citrix ADC appliance does not support DNSSEC. The Citrix ADC appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.
- The Citrix ADC appliance supports DNS64 prefix of length of only 96 bits.
- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the Citrix ADC appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a Citrix ADC appliance, see Stateful NAT64.
- The following are the different cases of DN64 processing by the Citrix ADC appliance:
  - If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the Citrix ADC appliance for the particular DNS64 configuration. The Citrix ADC removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the Citrix ADC appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
  - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.
  - If the response from the DNS server includes RCODE=1 (format error), the Citrix ADC appliance forwards the same to the client. If there is no response before the timeout, the Citrix ADC appliance sends a response with RCODE=2 (server failure) to the client.
  - If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the Citrix ADC appliance fetches the DNS A record to be used for synthesizing AAAA record. The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.
- The DNS64 feature of the Citrix ADC appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping

the IP6-ARPA domain into the corresponding IN-ADDR. ARPA domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The Citrix ADC appliance uses the response from the DNS server to synthesize response for the initial PTR request.

Configuration Steps

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the Citrix ADC appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see Load Balancing.
- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.
- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see Load Balancing.

  Note: The CLI has separate commands for these two tasks, but the GUI combines them in a single dialog box.

  Enable caching of DNS records. Enable the global parameter for the Citrix ADC appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see Domain Name System.

CLI procedures

To create a service of type DNS by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> …

To create a DNS64 action by using the CLI:

At the command prompt, type:

- add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule <expression>] [-excludeRule <expression>]

To create a DNS64 policy by using the CLI:

At the command prompt, type:

- add dns policy64 <name> -rule <expression> -action <string>

To create a DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- add lb vserver <name> DNS <IPAddress> <port> -dns64 (ENABLED | DISABLED) [-bypassAAAA (YES | NO)] …

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- bind lb vserver <name> <serviceName> …
- bind lb vserver <name> -policyName <string> -priority <positive_integer> …

GUI procedures

To create a service of type DNS by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
    - Service Name*
    - Server*
    - Protocol* (Select DNS from the drop down list.)
    - Port*

To create a DNS64 action by using the GUI:

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the GUI:

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
    - Name*
    - IP Address*
    - Protocol* (Select DNS from the drop down list.)
    - Port*

3. Select the Enable DNS64 option.
4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

Sample Configuration

```
 > add service SVC-DNS-1 203.0.113.50 DNS 53
 Done

> add service SVC-DNS-2 203.0.113.60 DNS 53
 Done

> add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
 Done

> add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET
   (2001:DB8:5001::/64)"
-action DNS64-Action-1
 Done

> add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
 Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-1
 Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-2
 Done

> bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
 Done

<!--NeedCopy-->
```

Stateful NAT64 Translation

September 14, 2021

The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the Citrix ADC appliance.

A stateful NAT64 configuration on the Citrix ADC appliance has the following components:

- **NAT64 rule**— An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of Citrix ADC owned SNIP Addresses.
- **NAT64 IPv6 Prefix**— A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance.
  Note: Currently the Citrix ADC appliance supports only one prefix to be used commonly with all NAT 64 rules.

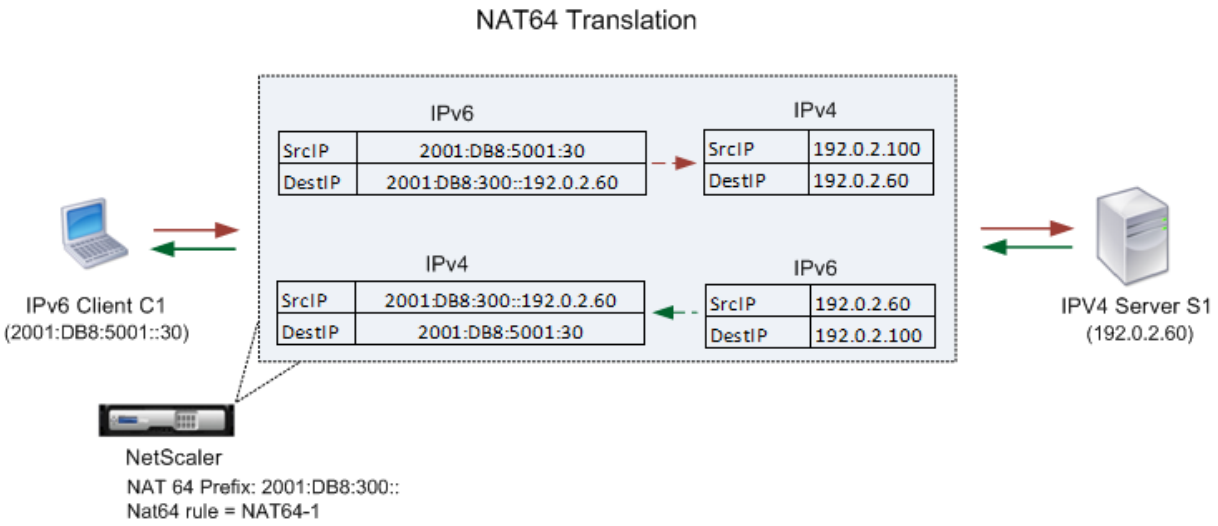
The Citrix ADC appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the Citrix ADC appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the Citrix ADC appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The Citrix ADC appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate withIPv4 server S1.



The following table lists the settings used in this example: Stateful NAT64 translation example settings.

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The Citrix ADC appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the Citrix ADC considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
   - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr_IPv4 = 192.0.2.60)
   - Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)
4. The Citrix ADC appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
5. IPv64 server S1 responds by sending an IPv4 packet to the Citrix ADC appliance with:
   - Destination IP address field containing 192.0.2.100
   - Source IP address field containing the address ofSevr_IPv4(192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.
7. The appliance creates a translated IPv6 response packet with:
   - Destination IP address field=Client_IPv6=2001:DB8:5001::30
   - Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr_IPv4 (last 32 bits) =2001:DB8:300::192.0.2.60

8. The appliance sends the translated IPv6 response to client CL1.

Limitations of Statelful NAT64

The following limitations apply to stateful NAT64:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

Configuring Stateful NAT64

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACl6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

CLI procedures

To add an ACL6 rule by using the CLI:

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> …

To add an IPset and bind multiple IPs to it by using the CLI:

At the command prompt, type:

- add ipset <name>
- bind ipset <name> <IPaddress …>

To add a netprofile by using the CLI:

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the CLI:

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the CLI:

At the command prompt, type:

```
set ipv6 -natprefix <ipv6_addr                    *>
```

-

Example:

```
 > add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
 Done

> apply acls6
 Done

> add ip 192.0.2.100 255.255.255.0  - type SNIP
 Done

> add ip 192.0.2.102 255.255.255.0   - type SNIP
 Done

> add ipset IPset-1
 Done

> bind ipset IPset-1 192.0.2.100 192.0.2.102
IPAddress "192.0.2.100" bound
IPAddress "192.0.2.102" bound
 Done

> add netprofile Netprofile-1 -srcIP IPset-1
 Done

> add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
 Done

> set ipv6 -natprefix 2001:DB8:300::/96
 Done
<!--NeedCopy-->
```

GUI procedures

To add a NAT64 rule by using the GUI:

Navigate to System > Network > Routes > NAT64, and a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

RNAT

September 14, 2021

In Reverse Network Address Translation (RNAT), the Citrix ADC appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a SNIP address as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

Note: The ephemeral port range for RNAT on the Citrix ADC appliance is 1024-65535.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the Citrix ADC appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:

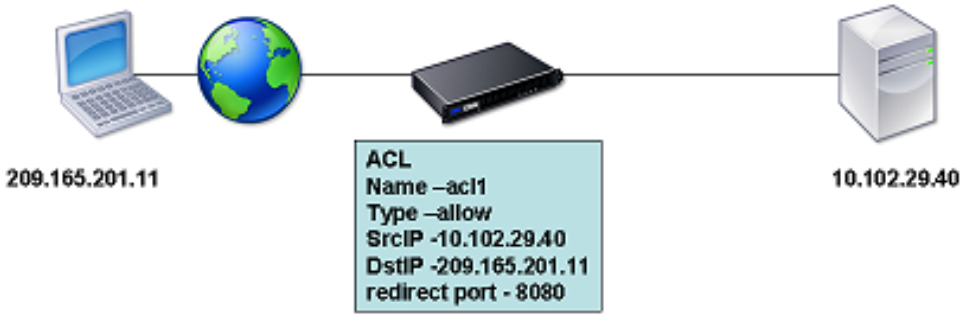
  1. Configure the ACL.
  2. Configure RNAT to change the source IP address and Destination Port.
  3. Apply the ACL.

  The following diagram illustrates RNAT configured with an ACL.

  Figure 1. RNAT with an ACL

Source IP Address	Destination IP Address	Destination Port
209.165.202.129	209.165.201.11	8080

Source IP Address	Destination IP Address
10.102.29.40	209.165.201.11

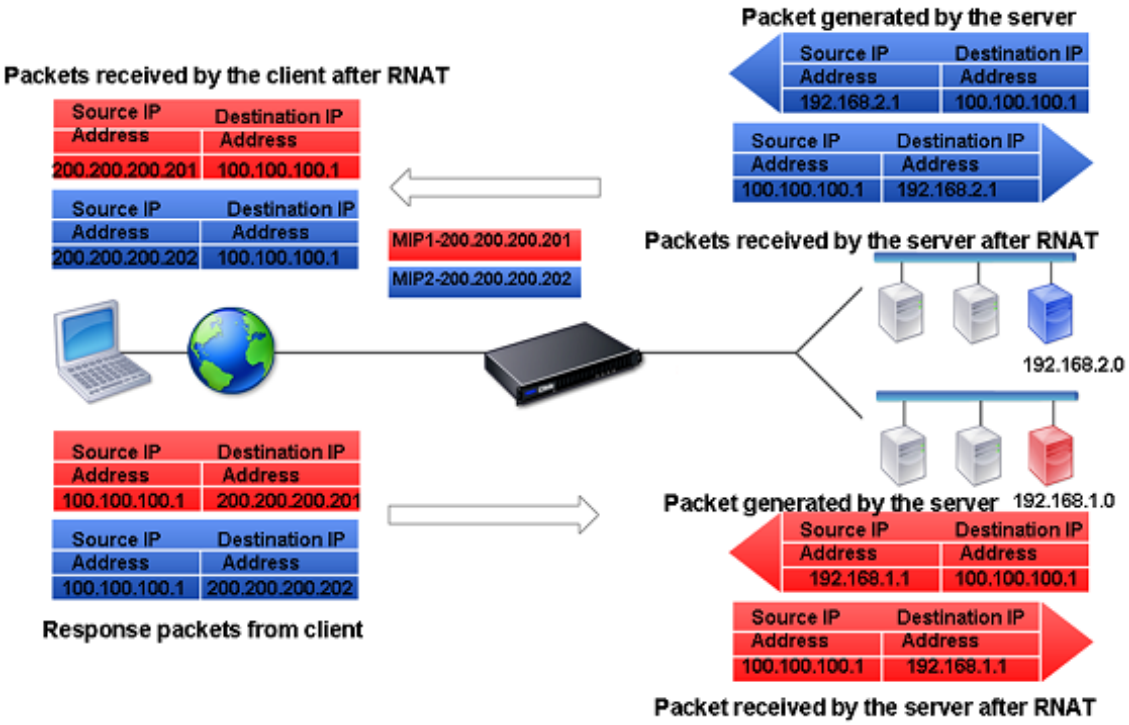


You have the following basic choices for the type of NAT IP address:

- **Using a SNIP as the NAT IP Address.** When using a SNIP as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the a SNIP. Therefore, the SNIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the Citrix ADC can use a subnet IP address (SNIP) as the NAT IP address.
- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public Citrix ADC-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

  This configuration is illustrated in the following diagram.

  Figure 2. Using a Unique IP Address as the NAT IP Address



Before you begin

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the Citrix ADC appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- In a topology where the Citrix ADC appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see Link Load Balancing.

Configure RNAT

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the GUI, all of the variations can be configured in the same dialog box, so there is only one procedure for GUI users.

CLI procedures

To create an RNAT rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- `add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))`
- `bind rnat <name> <natIP>@ …`
- `show rnat`

To modify or remove an RNAT rule by using the CLI:

- To modify an RNAT rule:

  `set rnat <name> (<aclname> [-redirectPort <port>])`

- To remove an RNAT rule, type the command.

  `rm rnat <name>`

Use the following command to verify the configuration:

- `show rnat`

Examples:

```
A network address as the condition and a SNIP address as the NAT IP
    address:

> add rnat RNAT-1 192.168.1.0 255.255.255.0
Done

A network address as the condition and a unique IP address as the NAT
    IP address:

> add rnat RNAT-2 192.168.1.0 255.255.255.0
Done

> bind rnat RNAT-2 -natip 10.102.29.50
Done

If instead of a single NAT IP address you specify a range, RNAT entries
     are created with all the Citrix ADC-owned IP addresses, except the
    NSIP, that fall within the range specified:

> add rnat RNAT-3 192.168.1.0 255.255.255.0
Done

> bind rnat RNAT-3 -natip 10.102.29.[50-110]
Done

An ACL as the condition and a SNIP address as the NAT IP address:

> add rnat RNAT-4 acl1
```

```
Done

An ACL as a condition and a unique IP address as the NAT IP address:

> add rnat RNAT-4 acl1
Done

> bind rnat RNAT-4 -natip 10.102.29.50
Done

If instead of a single NAT IP address you specify a range, RNAT entries
     are created with all the Citrix ADC-owned IP addresses, except the
    NSIP, that fall within the range specified:

> add rnat RNAT-5 acl1
Done

> bind rnat RNAT-5 -natip 10.102.29.[50-70]
Done

<!--NeedCopy-->
```

GUI procedures

To create an RNAT entry by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT** tab, and add a new RNAT rule, or edit an existing rule.

Monitor RNAT

You can display RNAT statistics to troubleshoot issues related to IP address translation.

The following table describes the statistics associated with RNAT and RNAT IP.

Statistic	Description
Bytes received	Bytes received during RNAT sessions
Bytes sent	Bytes sent during RNAT sessions
Packets received	Packets received during RNAT sessions
Packets sent	Packets sent during RNAT sessions

Statistic	Description
Syn sent	Requests for connections sent during RNAT sessions
Current sessions	Currently active RNAT sessions

To view RNAT statistics by using the CLI:

At the command prompt, type:

- **stat rnat**

Example:

```
> stat rnat

RNAT summary
                                Rate (/s)            Total
Bytes Received                    0                    0
Bytes Sent                        0                    0
Packets Received                  0                    0
Packets Sent                      0                    0
Syn Sent                          0                    0
Current RNAT sessions            --                    0
 Done
>
<!--NeedCopy-->
```

To monitor RNAT by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT** tab, and then click **Statistics**.

Configure RNAT6

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the Citrix ADC owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address**. When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s**. When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of Citrix ADC owned SNIP6 and VIP6 addresses for an RNAT6 rule. The Citrix ADC appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any Citrix ADC owned SNIP6 or VIP6 address for an RNAT6 rule. The Citrix ADC appliance uses any one of the Citrix ADC owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

CLI procedures

To create an RNAT6 rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- **add rnat6** <name> (<network> | (<acl6name> [-**redirectPort** <port>]))
- **bind rnat6** <name> <natIP6>@ …
- **show rnat6**

To modify or remove an RNAT6 rule by using the CLI:

- To modify an RNAT6 rule whose condition is an ACL6, type the **set rnat6** <name> command, followed by a new value for the **redirectPort** parameter.
- To remove an RNAT6 rule, type the **clear rnat6** <name> command.

GUI procedures

To configure an RNAT6 rule by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT6** tab, and add a new RNAT6 rule, or edit an existing rule.

Monitor RNAT6

You can display statistics related to the RNAT6 feature to monitor the performance or to troubleshoot problems related to RNAT6 feature. You can display a summary of statistics of the RNAT6 rules or of a particular RNAT6 rule. The statistical counters reflect events since the Citrix ADC appliance was last restarted. All these counters are reset to 0 when the Citrix ADC appliance is restarted.

The following lists some of the statistics counters associated with the RNAT6 feature:

- **Bytes received** - Total bytes received during RNAT6 sessions.
- **Bytes sent** - Total number of bytes sent during RNAT6 sessions.
- **Packets received** - Total number of packets received during RNAT6 sessions.

- **Packets sent** - Total number of packets sent during RNAT6 sessions.
- **Syn sent** - Total number of requests for connections sent during RNAT6 sessions
- **Current sessions** - Currently active RNAT6 sessions

To display a summarized statistics of all RNAT6 rules by using the CLI:

At the command prompt, type:

- **stat rnat6**

To display statistics for a specified RNAT6 rule by using the CLI:

At the command prompt, type:

- **stat rnat6** [<rnat6 rule name>]

To display RNAT6 statistics by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT6** tab, and then click **Statistics**.

```
> stat rnat6

RNAT6 summary

                          Rate (/s)               Total

Bytes Received             178                20644

Bytes Sent                 178                20644

Packets Received            5                  401

Packets Sent                5                  401

Syn Sent                    0                    2

Current RNAT6 sessions      --                   1

Done

<!--NeedCopy-->
```

Log Start Time and Connection Closure Reasons in RNAT Log Entries

For diagnosing or troubleshooting problems related to RNAT, the Citrix ADC appliance logs RNAT sessions whenever they are closed.

A log message for an RNAT session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp of log creation
- Protocol of the RNAT session
- Source IP address
- RNAT IP address
- Destination IP address
- Start time of the RNAT session
- Closing time of the RNAT session
- Total bytes sent by the Citrix ADC appliance for this RNAT session
- Total bytes received by the Citrix ADC appliance for this RNAT session
- Reason for closure of the RNAT session. The Citrix ADC appliance logs closure reason for TCP RNAT sessions that do not use the TCP proxy (TCP proxy disabled) of the appliance. The following are the type of closure reasons that are logged for TCP RNAT sessions:
  - **TCP FIN**. The RNAT session was closed because of a TCP FIN sent by either the source or destination device.
  - **TCP RST**. The RNAT session was closed because of a TCP Reset that was sent by either the source or destination device.
  - **TIMEOUT**. The RNAT session timed out.

The following table shows some sample log entries for RNAT sessions.

Type of Entry	Sample Log Entry
Sample log entry for UDP RNAT session	Dec 1 15:28:12 10.102.53.114 12/01/2015:15:28:12 GMT 0-PPE-0 : default UDP NAT_OTHERCONN_DELINK 154 0 : Source 1.2.2.5:23431 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:4045 - Destination 192.168.123.122:22 - Start Time 12/01/2015:15:26:58 GMT - Delink Time 12/01/2015:15:28:12 GMT - Total_bytes_send 2511 - Total_bytes_recv 3725

Type of Entry	Sample Log Entry
Sample log entry for TCP RNAT session. The log entry shows that the session closed because of TCP Reset	Dec 1 15:29:59 10.102.53.114 12/01/2015:15:27:59 GMT 0-PPE-0 : default TCP NAT_OTHERCONN_DELINK 152 0 : Source 1.2.2.5:33826 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:2384 - Destination 192.168.123.122:22 - Start Time 12/01/2015:15:27:40 GMT - Delink Time 12/01/2015:15:27:59 GMT - Total_bytes_send 2147 - Total_bytes_recv 3257 - Closure Reason TCP RST
Sample log entry for TCP RNAT session. The log entry shows that the session timed out	Dec 1 15:30:12 10.102.53.114 12/01/2015:15:30:12 GMT 0-PPE-0 : default TCP NAT_OTHERCONN_DELINK 155 0 : Source 1.2.2.5:64976 - Destination 192.168.123.115:22 - NatIP 192.168.123.1:19636 - Destination 192.168.123.115:22 - Start Time 12/01/2015:15:27:25 GMT - Delink Time 12/01/2015:15:30:12 GMT - Total_bytes_send 0 - Total_bytes_recv 0 - Closure Reason TIMEOUT

Stateful Connection Failover for RNAT

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. The Citrix ADC appliance now supports stateful connection failover for connections related to RNAT rules in a Citrix ADC High Availability (HA) setup. In an HA setup, connection failover (or connection mirroring) refers to the process of keeping an established TCP or UDP connection active when a failover occurs.

The primary appliance sends messages to the secondary appliance to synchronize current information about the RNAT connections. The secondary appliance uses this connection information only in the event of a failover. When a failover occurs, the new primary Citrix ADC appliance has information about the connections established before the failover and hence continues to serve those connections even after the failover. From the client's perspective this failover is transparent. During the transition period, the client and server may experience a brief disruption and retransmissions.

Connection failover can be enabled per RNAT rule. For enabling connection failover on an RNAT rule, you enable the connFailover (Connection Failover) parameter of that specific RNAT rule by using either CLI or GUI.

To enable connection failover for a RNAT rule by using the CLI:

At the command prompt, type:

- `set rnat <name> -connfailover (ENABLED | DISABLED)`
- `show rnat`

To enable connection failover for a RNAT rule by using the GUI:

1. Navigate to **System** > **Network** > **NATs**, and then click the **RNAT** tab.
2. Select **Connection Failover** while adding a new RNAT rule, or while editing an existing rule.

Reserving the source port for RNAT connections to servers

For a request hitting an RNAT configuration that has one or more RNAT IP addresses and Use Proxy port parameter disabled, the Citrix ADC appliance uses one of the RNAT IP address and the source port of the RNAT request for connecting to servers. Prior to the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the same source port is already been used in some other connections.

- **Source port less than 1024**. By default, the Citrix ADC appliance reserves the first 1024 ports of any Citrix ADC owned IP address (including RNAT IP addresses). Prior to 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the source port of the RNAT request is less than or equal to 1024. With the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server succeeds even if the source port of the RNAT request is less than or equal to 1024.
- **Source port greater than 1024**. Prior to the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the same source port is already been used in some other connections. With 13.0 47.x build, you can specify a range of RNAT client source ports in the `Retain Source Port range` (`retainsourceportrange`) parameter as part of an RNAT configuration. The Citrix ADC appliance reserves these RNAT client source ports on the RNAT IP address to be used only for RNAT connection to servers.

Removing RNAT Sessions

You can remove any unwanted or inefficient RNAT sessions from the Citrix ADC appliance. The appliance immediately releases resources (such as the port of the NAT IP address, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected RNAT sessions from the Citrix ADC appliance.

To clear all RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession**

To clear selective RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession** ((-**network** <ip_addr> -**netmask** <netmask>) | -**natIP** <ip_addr> | -**aclname** <string>)

To clear all or selective RNAT sessions by using the GUI:

1. Navigate to **System** > **Network** > **NATs**, and then click the **RNAT** tab.
2. In the **Actions** Menu, click **Flush RNAT Sessions** to remove all or selective RNAT sessions (for example, removing RNAT sessions with a specific RNAT IP, or belonging to a specific Network or ACL based RNAT rule).

Sample Configurations:

```
    Clear all RNAT sessions existing on a Citrix ADC appliance

    > flush rnatsession

    Done

    Clear all RNAT sessions belonging to network based RNAT rules that
       has 203.0.113.0/24 network as the matching condition.

    > flush rnatsession -network 203.0.113.0 -netmask 255.255.255.0

    Done

    Clear all RNAT sessions with RNAT IP 192.0.2.90.

    > flush rnatsession -natIP 192.0.2.90

    Done

    Clear all RNAT sessions belonging to ACL based RNAT rules that has
       ACL-RNAT-1 as the matching condition.

    > flush rnatsession -aclname ACL-RNAT-1

    Done
<!--NeedCopy-->
```

Configuring Prefix-Based IPv6-IPv4 Translation

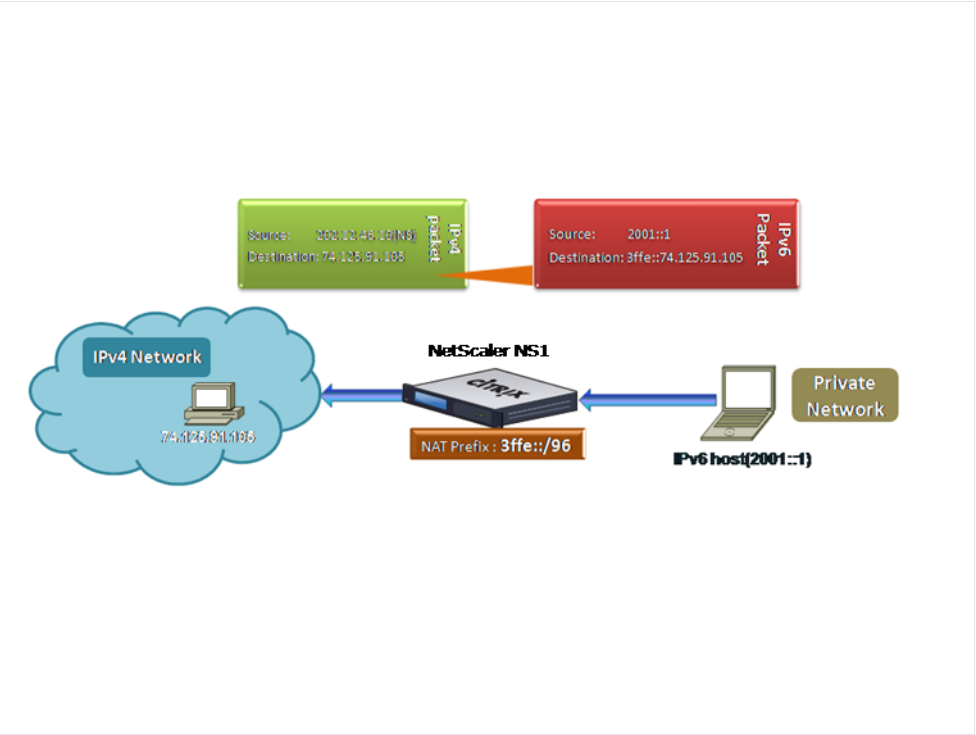
September 14, 2021

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the Citrix ADC appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The Citrix ADC appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the Citrix ADC appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the Citrix ADC so that the IPv6-IPv4 translation is done by the Citrix ADC.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on Citrix ADC NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation



To configure prefix-based IPv6-IPv4 translation by using the CLI:

At the command prompt, type:

```
set ipv6 [-natprefix <ipv6_addr                    *>]
```

-
- show ipv6

Example:

```
> set ipv6 -natprefix 3ffe::/96
 Done
<!--NeedCopy-->
```

To configure prefix-based IPv6-IPv4 translation by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

IP Prefix NAT

September 14, 2021

The Citrix ADC appliance supports translating a part of the source IP address instead of the complete address of packets received on the appliance. IP prefix NAT includes changing one or more octets or bits of the source IP address.

The Citrix ADC appliance supports IP prefix NAT for load balancing configurations of the following types: ANY, UDP, DNS, TCP, and HTTP.

Use Case: Zonification of Clients for a Deployment of a Citrix ADC appliance and an Optimization Device

IP prefix NAT is very useful in a deployment that includes a Citrix ADC appliance and an optimization device (for example, Citrix ByteMobile). This type of deployment has different geographically located client networks, which share the same network address. The Citrix ADC appliance must send the traffic received from each of the client networks to the optimization device before forwarding to the destination.

The device sends the optimized traffic back to the Citrix ADC appliance. Because the optimization requirement is different for traffic from each client network, the optimization device must recognize the client network of each packet that it receives. The solution is to segregate traffic from each client

network into a different zone by using VLANs. IP prefix NAT with a different setting is configured for each zone. The Citrix ADC appliance translates the last octet of the source IP address of every packet, and the translated octet value is different for each zone.

Consider an example of two zones, Z1 and Z2, sharing network address 192.0.2.0/24. On the Citrix ADC appliance, IP prefix NAT entities named natrule-1 and natrule-2 are configured for these two zones. Before the appliance forwards a packet from Z1, natrule-1 translates the last octet of the packet's source IP address to 100. Similarly, for packets from Z2, natrule-2 translates the last octet of the source IP address to 200. For two clients, CL1-Z1 in zone Z1 and CL1-Z2 in zone Z2, each with IP address 192.0.2.30, the Citrix ADC appliance translates the source IP address of CL1-Z1's packets to 100.0.2.30 and of CL1-Z2's packets to 200.0.2.30. The optimization device to which the Citrix ADC appliance sends the translated packets is configured to use a packet's source IP address to recognize the zone, so it applies the appropriate optimization configured for the zone from which the packet originated.

Configuration Steps

Configuring IP prefix NAT consists of the following steps:

- **Create a net profile and set the NAT Rule parameter of a net profile**. A NAT rule specifies two IP addresses and a net mask. The first IP address (specified by IP Address parameter) is the source IP address that is to be translated with the second one (specified by IP Rewrite parameter). The net mask specifies the part of the source IP address that is to be translated with the same part of the second IP address.
- **Bind the net profile to load balancing virtual servers or services**. A net profile with NAT rule setting can be bound to a virtual server or service of type ANY, UDP, DNS, TCP, and HTTP. After binding a net profile to a virtual server or service, the Citrix ADC appliance matches the source IP address of the incoming packets related to the virtual server or service with the NAT rule setting. The Citrix ADC then performs IP prefix NAT for packets that match the NAT rule.

To configure IP prefix NAT translation by using the command line:

At the command prompt, type:

- **bind netProfile** <name> (-**natRule** <ip_addr> <netmask> <rewriteIp>)
- **show netprofile** <name>

To configure IP prefix NAT by using the GUI:

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Set the following parameters under NAT Rules while adding or modifying NetProfiles.
    - IP Address
    - Netmask
    - Rewrite IP

Sample configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has IP prefix NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
> add netprofile PARTIAL-NAT-1
Done

> bind netprofile PARTIAL-NAT-1  - natrule 192.0.0.0 255.0.0.0 100.0.0.0
Done

> add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
Done
<!--NeedCopy-->
```

Static ARP

September 14, 2021

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip_addr> -**mac**<mac_addr> -**ifnum** <interface_name>
- **show arp** <IPAddress>

Example:

```
> add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
 Done
<!--NeedCopy-->
```

To remove a static ARP entry by using the CLI:

At the command prompt, type the **rm arp** command and the IP address.

To add a static ARP entry by using the GUI:

Navigate to **System** > **Network** > **ARP Table**, and add a static ARP entry.

Specify a VLAN in a Static ARP Entry

In a static ARP entry, you can specify the VLAN through which the destination device is accessible. This feature is useful when the interface specified in the static ARP entry is part of multiple tagged VLANs and the destination is accessible through one of the VLANs. The Citrix ADC appliance includes the specified VLAN ID in the outgoing packets matching the static ARP entry. If you don't specify a VLAN ID in an ARP entry, and the specified interface is part of multiple tagged VLANs, the appliance assigns the interface's native VLAN to the ARP entry.

For example, say Citrix ADC interface 1/2 is part of native VLAN 2 and of tagged VLANs 3 and 4, and you add a static ARP entry for network device A, which is part of VLAN 3 and is accessible through interface 1/2. You must specify VLAN 3 in the ARP entry for network device A. The Citrix ADC appliance then includes tagged VLAN 3 in all the packets destined to network device A, and sends them from interface 1/2.

If you don't specify a VLAN ID, the Citrix ADC appliance assigns native VLAN 2 for the ARP entry. Packets destined to device A are dropped in the network path, because they do not specify tagged VLAN 3, which is the VLAN for device A.

To specify a VLAN in a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip_addr> **-mac**<mac_addr> **-ifnum** <interface_name> [-**vlan** <positive_integer>]
- **show arp** <IPAddress>

Example:

```
1 > add arp -ip 198.51.100.91 -mac 36:db:4b:f6:12:15 -ifnum 1/2 -vlan 3
2 Done
3 <!--NeedCopy-->
```

Set the Timeout for Dynamic ARP Entries

September 14, 2021

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing

ARP entries expire after the previously configured aging time. You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the CLI:

At the command prompt, type:

- **set arpparam** -**timeout** <positive_integer>]
- **show arpparam**

Example:

```
> set arpparam -timeout 500
 Done
<!--NeedCopy-->
```

To set the time-out for dynamic ARP entries to its default value by using the CLI:

At the command prompt, type:

- **unset arpparam**
- **show arpparam**

Example:

```
> unset arpparam
 Done
<!--NeedCopy-->
```

To set the time-out for dynamic ARP entries by using the GUI:

Navigate to **System** > **Network**, in the **Settings** group, click **Configure ARP Global Parameters**, and set the **ARP Table Entry Timeout** parameter.

Neighbor Discovery

September 14, 2021

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

- **Router Discovery**: Enables a host to discover the local routers on an attached link and automatically configure a default router.
- **Prefix Discovery**: Enables the host to discover the network prefixes for local destinations.

  Note: The Citrix ADC appliance does not support Prefix Discovery.
- **Parameter Discovery**: Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.
- **Address Autoconfiguration**: Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The Citrix ADC does not support Address Autoconfiguration for Global IPv6 addresses.
- **Address Resolution**: Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.
- **Neighbor Unreachability Detection**: Enables a node to determine the reachability state of a neighbor.
- **Duplicate Address Detection**: Enables a node to determine whether an NSIP address is already in use by a neighboring node.
- **Redirect**: Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

Note: The Citrix ADC appliance does not support IPv6 Redirect.

Configuration Steps

Configuring neighbor discovery consists of the following tasks:

- Adding IPv6 neighbors
- (Optional) Removing IPv6 neighbors

CLI procedures

To add an IPv6 neighbor by using the CLI:

At the command prompt, type:

- **add nd6** <neighbor> <mac> <ifnum> [-**vlan** <integer>]
- **sh nd6**

Example:

```
> add nd6 2001::1 00:04:23:be:3c:06 1/1  - vlan 1
 Done

```

```
> show nd6
   Neighbor                 MAC-Address(Vlan, Interface)       State
             TIME
   --------                 ----------------------------       -----
            --------
1) ::1                      00:d0:68:0b:58:da(   1,  LO/1)   REACHABLE
        PERMANENT
2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da(   1,  LO/1)   REACHABLE
        PERMANENT
3) 2001::1                  00:04:23:be:3c:06(   1,   1/1)   REACHABLE
          STATIC
 Done
<!--NeedCopy-->
```

To remove a neighbor discovery entry by using the CLI:

At the command prompt, type:

- **rm nd6** <Neighbor> -**vlan** <VLANID>

Example:

```
 rm nd6 3ffe:100:100::1 -vlan 1
<!--NeedCopy-->
```

To remove all neighbor discovery entries by using the CLI:

At the command prompt, type:

- **clear nd6**

GUI procedures

To add an IPv6 neighbor by using the GUI:

Navigate to **System** > **Network** > **IPv6 Neighbors**, and add a new IPv6 neighbor.

To remove a neighbor discovery entry by using the GUI:

Navigate to **System** > **Network** > **IPv6 Neighbors**, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the GUI:

Navigate to **System** > **Network** > **IPv6 Neighbors**, and click **Clear**.

IP Tunnels

September 14, 2021

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The Citrix ADC appliance implements IP Tunneling in the following ways:

- **Citrix ADC as an Encapsulator (Load Balancing with DSR Mode)**: Consider an organization that has multiple data centers across different countries, where the Citrix ADC maybe at one location and the back-end servers are located in a different country. In essence, the Citrix ADC and the back-end servers are on different networks and are connected via a router.

  When you configure Direct Server Return (DSR) on this Citrix ADC, the packet sent from the source subnet is encapsulated by the Citrix ADC and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the Citrix ADC.

- **Citrix ADC as a Decapsulator:** Consider an organization having multiple data centers each having Citrix ADCs and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another Citrix ADC. The Citrix ADC processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the Citrix ADC must be able to decapsulate the packet before sending it to the back-end servers. To enable the Citrix ADC to function as a decapsulator, a tunnel is added between the router and the Citrix ADC. When the encapsulated packet, with additional header information, reaches the Citrix ADC, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

  The Citrix ADC can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

Configure IP Tunnels

Configuring IP tunnels on a Citrix ADC appliance consists of creating IP tunnel entities. An IP tunnel entity specifies the local and remote tunnel end-point IP addresses and the protocol to be used for the IP tunnel.

Note: While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP address.

CLI procedures

To create an IP tunnel by using the CLI:

At the command prompt type:

- **add iptunnel** <name> <remote> <remoteSubnetMask> <local> -**type** -**protocol** (**ipoverip** | **GRE**)
- **show iptunnel**

To remove an IP tunnel by using the CLI:

To remove an IP tunnel, type the **rm iptunnel** command and the name of the tunnel.

To create an IPv6 tunnel by using the CLI:

At the command prompt type:

- **add ip6tunnel** <name> <remoteIp> <local>
- **show ip6tunnel**

To remove an IPv6 tunnel by using the CLI:

To remove an IPv6 tunnel, type the **rm ip6tunnel** command and the name of the tunnel.

GUI procedures

To create an IP Tunnel by using the GUI:

Navigate to **System** > **Network** > **IP Tunnels**, add a new IP tunnel.

To create an IPv6 Tunnel by using the GUI:

Navigate to **System** > **Network** > **IP Tunnels** > **IPv6 Tunnels**, and add a new IPv6 tunnel.

Customizing IP Tunnels Globally

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the Citrix ADC appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

CLI procedures

To globally customize IP tunnels by using the CLI:

At the command prompt, type:

- **set ipTunnelParam** -**srcIP** <sourceIPAddress> -**srcIPRoundRobin** (**YES** | **NO**)-**dropFrag** [**YES** | **NO**] -**dropFragCpuThreshold** <Positive integer>
- **show ipTunnelParam**

Example:

```
> set iptunnelparam  - srcIP 12.12.12.22 -dropFrag Yes  -
    dropFragCpuThreshold 50
 Done

> set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes  -
    dropFragCpuThreshold 50
 Done
<!--NeedCopy-->
```

To globally customize IPv6 tunnels by using the CLI:

At the command prompt, type:

- **set ip6tunnelparam** -**srcIP** <IPv6Address> -**srcIPRoundRobin** (**YES** | NO)-**dropFrag** [**YES** | **NO**] -**dropFragCpuThreshold** <Positive integer>
- **show ip6tunnelparam**

GUI procedures

To globally customize IP tunnels by using the GUI:

Navigate to **System** > **Network**, in the Settings group, click **IPv4 Tunnel Global Settings**.

1. Navigate to **System** > **Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

To globally customize IPv6 tunnels by using the GUI:

1. Navigate to **System** > **Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

GRE Payload Options in a GRE IP Tunnel

For a configured GRE IP tunnel, the Citrix ADC appliance encapsulates the entire Layer 2 packet, including the Ethernet header and the VLAN header (dot1q VLAN tag). IP GRE tunnels between Citrix ADC appliances and some 3rd party devices might not be stable, because these 3rd party devices are not programmed to process some or the Layer 2 packet headers. To configure a stable IP GRE tunnel between a Citrix ADC appliance and a 3rd party device, you can use the GRE payload parameter of the GRE IP tunnel command set. GRE payload setting can also be applied to a GRE with IPSec tunnel.

You can set the GRE payload parameter to do one of the following before the packet is sent through the GRE tunnel:

- **Ethernet with DOT1Q**. Carry the Ethernet header as well the VLAN header. This is the default setting. For a tunnel bound to a netbridge, inner Ethernet header and VLAN header contains

information from the ARP and bridge table of the Citrix ADC appliance. For a tunnel set as a next hop to a PBR rule, Inner Ethernet destination MAC address is set to zero and the VLAN header specifies the default VLAN. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

Outer Ethernet Header	Outer IP Header	GRE Header	Inner Ethernet	Inner VLAN header	Inner IP/IPv6/ARP header	Inner TCP/UDP Header	Payload

- **Ethernet**. Carry the Ethernet header but drop the VLAN header. Because the packets do not carry any VLAN information in the tunnel, for a tunnel with this setting and bound to a netbridge, you must bind an appropriate VLAN to the netbridge so that on receiving any packets on the tunnel, the Citrix ADC can forward these packet to the specified VLAN. If the tunnel is set as a next hop in a PBR rule, the Citrix ADC routes the packets that are received on the tunnel. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

Outer Ethernet header	Outer IP header	GRE Header	Inner Ethernet header	Inner IP/IPv6/ARP header	Inner TCP/UDP header	Payload

- **IP**. Drop the Ethernet header as well as the VLAN header. Because tunnels with this setting do not carry Layer 2 headers, these tunnels cannot be bound to a netbridge but can be set as a next hop in a PBR rule. The peer tunnel endpoint device on receiving the packet either consumes or routes it. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

Outer Ethernet header	Outer IP header	GRE header	Inner IP/IPv6 header	Inner TCP/UDP header	Payload

To drop Layer 2 headers of packets in a GRE IP tunnel by using the CLI:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> [-**protocol** <GRE> [-**vlan** <positive_integer>]] [-**grepayload** <grepayload>] [-**ipsecProfileName** <string>]
- **show iptunnel** <tunnelname>

Example:

```
> add iptunnel IPTUNNEL-1 203.0.113.133 255.255.255.0 198.51.100.15 -
    protocol GRE  - grepayload Ethernet -ipsecProfileName IPTUNNEL-IPSEC
    -1
Done
<!--NeedCopy-->
```

IPv6 Traffic through GRE IPV4 Tunnels

The Citrix ADC appliance supports transferring IPv6 traffic through an IPV4 GRE tunnel. This feature can be used for enabling communication between Isolated IPv6 networks without upgrading the IPv4 infrastructure between them.

For configuring this feature, you associate a PBR6 rule with the configured IPv4 GRE tunnel through which you want the Citrix ADC to send and receive IPv6 traffic. The source IPv6 address and destination IPv6 address parameters of the PBR6 rule specify the IPv6 networks whose traffic is to traverse the IPv4 GRE tunnel.

Note: IPSec protocol is not supported on GRE IPv4 tunnels that are configured to transfer IPv6 packets.

To create a GRE IPv4 tunnel by using the CLI:

At the command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -**protocol GRE**
- **show ipTunnel** <name>

To associate a PBR6 rule with a GRE IPv4 tunnel by using the CLI:

- **add ns pbr6** <pbrName> **ALLOW** -**srcIPv6** <network-range> -**dstIPv6** <network-range> -**ipTunnel** <tunnelName>
- **show pbr**

Sample configuration

In the following sample configuration, GRE IP tunnel TUNNEL-V6onV4 is created with remote tunnel endpoint IP address 10.10.6.30 and local tunnel endpoint IP address 10.10.5.30. The tunnel is then bound to pbr6 PBR6-V6onV4. The srcIPv6 specifies the IPv6 network connected to the local endpoint and destIPv6 specifies the IPv6 network connected to the remote endpoint. The traffic from these Ipv6 networks are allowed to traverse through the GRE IPv4 tunnel.

```
1 > add ipTunnel TUNNEL-V6onV4 10.10.6.30 255.255.255.255 10.10.5.30 -
     protocol GRE
2 -ipsecProfileName None
3 Done
4 > add ns pbr6 PBR6-V6onV4 ALLOW -srcIPv6 = 2001:0db8:1::1-2001:0db8
     :1::255 -destIPv6 =
5 1-2001:0db8:4::255 -ipTunnel TUNNEL-V6onV4
6 <!--NeedCopy-->
```

Send Response Traffic Through an IP-IP Tunnel

You can configure a Citrix ADC appliance to send response traffic through an IP-IP tunnel instead of routing it back to the source. By default, when the appliance receives a request from another Citrix ADC or a third-party device through an IP-IP tunnel, it routes the response traffic instead of sending it through the tunnel. You can use policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) to send the response through the tunnel.

In a PBR rule, specify the subnets at both end points whose traffic is to traverse the tunnel. Also set the next hop as the tunnel name. When response traffic matches the PBR rule, the Citrix ADC appliance sends the traffic through the tunnel.

Alternatively, you can enable MBF to meet this requirement, but the functionality is limited to traffic for which the Citrix ADC appliance stores session information (for example, traffic related to load balancing or RNAT configurations). The appliance uses the session information to send the response traffic through the tunnel.

CLI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the CLI:

At the command prompt, type:

- **add ns pbr** <pbr_name> **ALLOW** -**srcIP** = <local_subnet_range> -**destIP** = <remote_subnet_range> -**ipTunnel** <tunnel_name>
- **apply ns pbrs**
- **show ns pbr** <pbr_name>

To enable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **show ns mode**

GUI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the GUI:

1. Navigate to **System** > **Network** > **PBRs**. On the **PBRs** tab, create a **PBR** rule.
2. While creating the PBR, set the **Next Hop Type** to **IP tunnel** and **IP Tunnel Name** to the configured IP-IP tunnel name.

To enable MAC-based forwarding by using the GUI:

1. Navigate to **System** > **Settings**, in **Modes and Features**, click **Configure Modes**.
2. On the **Configure Modes** page, select **MAC-based forwarding**.

Sample configuation

Consider an example of an IPIP tunnel, NS1-NS2-IPIP, which is set up between two Citrix ADC appliances NS1 and NS2.

By default, for any request that NS2 receives through the tunnel, its routes the response traffic to the source instead of sending it (to NS1) through the tunnel.

You can configure policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) on NS2 for enabling it to send the response through the tunnel.

In the following sample configuration on NS2, NS1-NS2-IPIP is an IPIP tunnel and NS1-NS2-IPIP-PBR is a PBR rule. For requests (with inner source IP address in the range 10.102.147.0-10.102.147.255 and inner destination IP address in the range 10.102.147.0-10.102.147.255) received by NS2 through the tunnel, NS2 sends the corresponding response through the tunnel (to NS1) instead of routing it to the source. The functionality is limited to the traffic that matches the PBR rule.

```
1 > add iptunnel NS1-NS2-IPIP 192.0.2.99 255.255.255.255 203.0.113.99 -
     protocol IPIP
2
3 Done
4 > add pbr NS1-NS2-IPIP-PBR -srcIP 10.102.147.0-10.102.147.255  - destIP
     10.20.1.0-10.20.1.255  - ipTunnel NS1-NS2-IPIP
5
6 Done
7 > apply pbrs
8
9 Done
```

Alternatively, MBF can be enabled on NS2. The functionality is limited to traffic for which NS2 stores session information (for example, traffic related to load balancing or RNAT configurations).

```
1 > enable ns mode MBF
2
3 Done
```

Class E IPv4 packets

September 14, 2021

By default, the Citrix ADC appliance drops any packets if they contain any class E IPv4 address in the source IP or the destination IP fields. If your setup is using class E IPv4 addresses, you can configure the Citrix ADC appliance to process class E IPv4 packets.

Before you begin

Before you begin configuring a Citrix ADC appliance to process class E IPv4 packets, note the following points:

- Citrix ADC appliances do not support configuring any Citrix ADC owned IPv4 address (for example, SNIP and VIP) in the class E range. Citrix ADC appliances only support processing of class E IPv4 packets.
- A Citrix ADC appliance internally uses class E IPv4 addresses for the IPv6 feature. The Citrix ADC appliance does not support both features (processing class E IPv4 packets and IPv6 support) working at the same time. The Citrix ADC appliance imposes a restriction to not enable the IPv6 feature when processing of class E IPv4 packets is enabled, and vice versa.

Configuration steps

Configuring a Citrix ADC appliance to process class E IPv4 packets consist of the task of enabling the **IPv4 Class E address clients** (**allowClassEIPv4**) Layer 3 parameter.

CLI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the CLI:

At the command prompt, type:

set l3param -allowClassEIPv4 (**ENABLED** **DISABLED**)

-
- **show l3param**

Sample Configuration:

```
> set l3param -allowClassEIPv4 ENABLED

Done

> sh l3param

    Network L3 related Configuration Parameters

    icmpgen_rate_threshold      : 100

    srcnat                      : ENABLED

```

```
13     override_rnat                 : DISABLED
14
15     drop_df_flag                  : DISABLED
16
17     .
18
19     .
20
21     .
22
23     IPv6DynamicRouting           : DISABLED
24
25     allowClassEIPv4              : ENABLED
26
27 Done
28 <!--NeedCopy-->
```

GUI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the GUI:

1. Navigate to **System** > **Network**, and then in the **Settings** section, click **Configure Layer 3 Parameters**.
2. Select **IPv4 Class E address clients** and click **OK**.

Interfaces

September 14, 2021

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix ADC appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. Citrix ADC appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. You can use the Network Visualizer tool to view the network configuration of a Citrix ADC deployment and configure interfaces, channels, VLANs, and bridge groups.

Configuring MAC-Based Forwarding

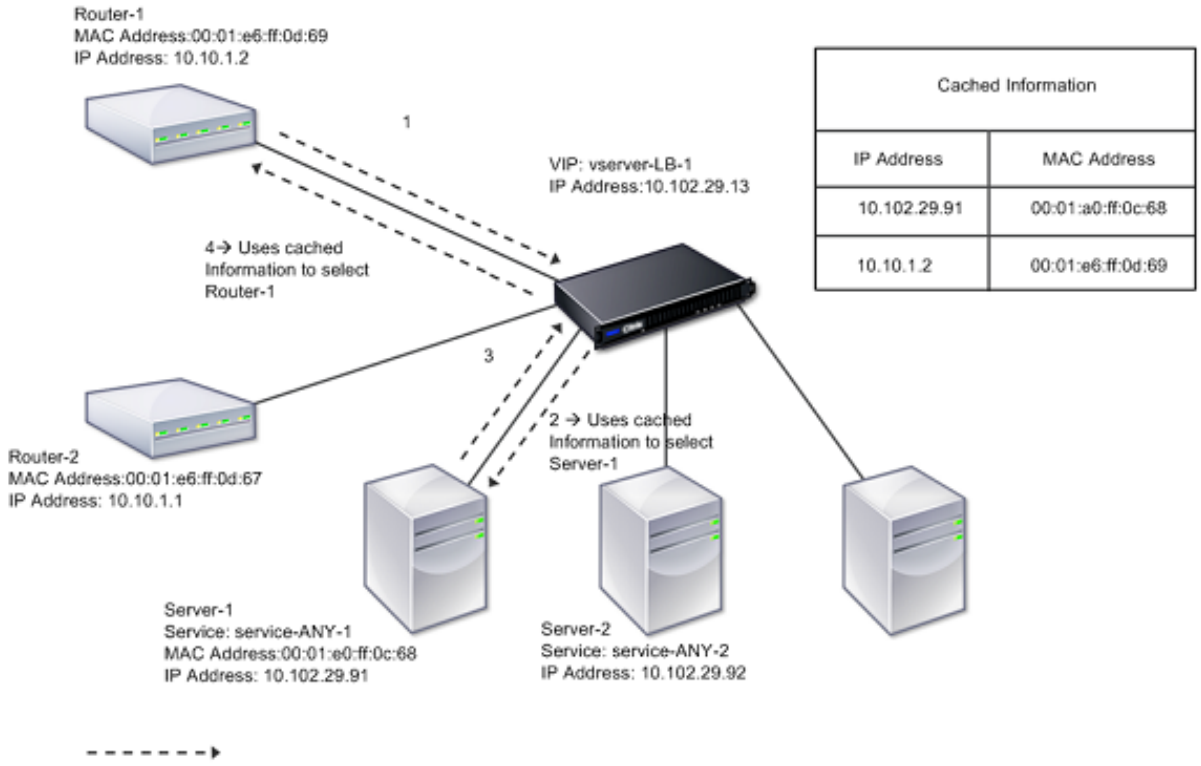
September 14, 2021

With MAC-based forwarding (MBF) enabled, when a request reaches the Citrix ADC appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the Citrix ADC is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode



When MAC-based forwarding (MBF) is enabled, the Citrix ADC caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the Citrix ADC appliance, the appliance sets the destination MAC ad-

dress of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the Citrix ADC initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see Load Balancing.

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the Citrix ADC and server.
  Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.
- **When firewall clustering is used**. Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the appliance uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the appliance uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the Citrix ADC looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the Citrix ADC requests the ARP entries.

To enable or disable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **disable ns mode MBF**

To enable or disable MAC-based forwarding by using the GUI:

1. Navigate to **System** > **Settings**, in the **Modes and Features** group, click **Configure modes**.
2. Select or clear the **MAC-based forwarding** option.

MAC based forwarding for a load balancing setup

Some load balancing setups require that the Citrix ADC appliance bypasses the global MBF (if enabled) for these setups and instead use the route/ARP lookups for sending packets to the destination.

The MBF parameter of a net profile is used to enable or disable MBF for a specific load balancing configuration. MBF can be set for the client side as well as the server side of a load balancing configuration by binding net profiles (MBF enabled or disabled) to the virtual server and the services.

For example, if a net profile with MBF disabled is bound to the virtual server of a load balancing configuration, the Citrix ADC appliance bypasses the global MBF (if enabled) and instead use the route/ARP lookups for sending response packets to clients.

Before you begin

Before you begin configuring MBF for a load balancing configuration, note the following points:

- In a load balancing configuration, the client side (virtual server) and the server side (service/service groups) can have different MBF settings.
- A load balancing configuration inherits global MBF setting if MBF is not set explicitly in the net profiles bound to the virtual server and the services.
- In a load balancing configuration, server side (service) inherits client side MBF setting of net profile bound to the virtual server if no net profile is bound to the service.
- In a load balancing configuration with direct server return mode, client side inherits the MBF setting in the net profile bound to the service.
- In a content switching configuration, client side takes the MBF setting in the net profile bound to the content switching virtual server instead of from the target load balancing virtual server.

Limitations

Before you begin configuring MBF for a load balancing configuration, note the following limitations:

- MBF setting for load balancing configurations is not supported in a cluster setup.
- For a load balancing virtual server with MAC mode or L2Conn settings, MBF is enabled irrespective of the MBF setting in the bound net profile to the virtual server.
- The Citrix ADC appliance does not support setting MBF for load balancing monitors using net profile. In other words, the MBF setting of a net profile is not applied to the monitors to which the net profile is bound. The global MBF setting is applied to monitors irrespective of the MBF setting of the bound net profile.

Configure MBF for load balancing configuration

Configuring MBF for a load balancing configuration consists of the following tasks:

- Enable MBF parameter in a net profile.
- Bind the net profile to a load balancing virtual server or services.

To enable MBF in a net profile by using the CLI:

- To enable MBF while adding a net profile, at the command prompt, type:
  - **add netProfile** <name> -**MBF** (**ENABLED** | **DISABLED**)
  - **show netprofile** <name>
- To enable MBF in an existing net profile, at the command prompt, type:
  - **set netProfile** <name> -**MBF** (**ENABLED** | **DISABLED**)
  - **show netprofile** <name>

To enable MBF in a net profile by using GUI**

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Enable the **MBF** parameter while adding or modifying a net profile.

In the following sample configuration, net profile NETPROFILE-MBF-LBVS has MBF enabled and is bound to load balancing virtual server LBVS-1. Also, net profile NETPROFILE-MBF-SVC has MBF enabled and is bound to a load balancing service SVC-1.

```
> add netprofile NETPROFILE-MBF-LBVS -MBF ENABLED

Done

> add netprofile NETPROFILE-MBF-SVC -MBF ENABLED

Done

> set lb vserver LBVS-1 -netprofile NETPROFILE-MBF-LBVS

Done

> set service SVC-1 -netprofile NETPROFILE-MBF-SVC

Done

<!--NeedCopy-->
```

Configure network interfaces

September 14, 2021

Network interfaces in the Citrix ADC appliance are numbered in <slot><port> notation. After configuring your interfaces, display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you can do the following;

- Enable some interfaces and disable others.
- Reset an interface to renegotiate its settings.
- Clear the accumulated statistics for an interface.

To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

Set the network interface parameters

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

To set the network interface parameters by using the CLI:

At the command prompt, type:

```
1 -  set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl
      <flowControl>] [-autoneg ( DISABLED | ENABLED )] [-haMonitor ( ON |
      OFF )] [ ( ON | OFF )] [-tagall ( ON | OFF )] [-lacpMode <lacpMode
     >] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>]
     [-lacpTimeout (LONG | SHORT )] [-ifAlias <string>] [-throughput <
     positive_integer>][-bandwidthHigh <positive_integer> [-
     bandwidthNormal <positive_integer>]]
2 -  show interface [<id>]
3 <!--NeedCopy-->
```

Example:

```
1 > set interface 1/8 -duplex full
2  Done
3 <!--NeedCopy-->
```

To set the network interface parameters by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface that you want to modify (for example, 1/8), click **Edit**, and then set the parameters.

Setting the receive ring size and ring type for an interface

You can increase the receive ring size and ring type for IX, F1X, F2X, or F4X interfaces on Citrix ADC MPX and SDX platforms.

An increased ring size provides more cushion to handle burst traffic, but might impact the performance. A ring size of up to 8192 is supported for IX interfaces. A ring size of up to 4096 is supported for F1X, F2X, and F4X interfaces. The default ring size remains 2048.

Interface ring types are elastic by default. They increase or decrease in size based on packet arrival rate. You can configure the ring type as “fixed” in which case the ring size does not change based on traffic rate.

Note: This feature is supported from release 13.0 build 41.x, and supported on platforms that have IX, F1X, F2X, or F4X interfaces.

Use the `show hardware` command to identify whether your appliance has IX, F1X, F2X, or F4X interfaces.

Examples:

The following model has 16 F1X (10G) interfaces and 4 F4X (40G) interfaces.

```
> sh hardware
        Platform: NSMPX-25000-40G 20*CPU+16*F1X+4*F4X+2*E1K+2*CVM N3
            250040
        Manufactured on: 12/16/2016
        CPU: 2800MHZ
        Host Id: 234913926
        Serial no: N43RJCRV3X
        Encoded serial no: N43RJCRV3X
        Netscaler UUID: 336a32d6-2cfa-11e8-bf01-00e0ed5dd23c
        BMC Revision: 4.08
 Done
<!--NeedCopy-->
```

The following model has 2 1X (10G) interfaces.

```
> sh hardware
        Platform: NSMPX-10500 8*CPU+2*E1K+8*E1K+2*IX+8*CVM 1620 760100
        Manufactured on: 12/27/2010
        CPU: 2832MHZ
        Host Id: 1707114630
        Serial no: 7VZZV1ZXJ4
        Encoded serial no: 7VZZV1ZXJ4
        Netscaler UUID: eb1bfd72-5176-11e7-ba18-00e0ed1b0d12
 Done
<!--NeedCopy-->
```

To configure ring size and ring type by using the CLI
At the command line, type:

```
set interface <id> -ringsize <positive_integer> -ringtype ( Elastic |
    Fixed )
<!--NeedCopy-->
```

Parameters:

ringsize:

The receive ring size of the interface. A higher number provides more buffers to handle incoming traffic.

Default value: 2048
Minimum value: 512
Maximum value: 16384

ringtype:

The receive ring type of the interface. A fixed ring type preallocates the configured number of buffers irrespective of traffic rate. In contrast, an elastic ring, expands and shrinks based on incoming traffic rate.

Possible values: Elastic, Fixed

Default value: Elastic

Example:

```
> set interface 40/2 -ringsize 4096 -ringtype Fixed
 Done
> show interface 40/2

1)      Interface 40/2 (40G Ethernet, CR4, 40 Gbit) #21  flags=0xc020 <
    ENABLED, UP, UP, autoneg, HAMON, HEARTBEAT, 802.1q> MTU=1500, native
     vlan=10, MAC=00:e0:ed:75:14:2a, uptime 119h26m32s
        Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,
            throughput 0
        Actual: media UTP, speed 40000, duplex FULL, fctl OFF,
            throughput 40000
        LLDP Mode: NONE, LR Priority: 1024
        RX: Pkts(1443972660032) Bytes(1457207315336105) Errs(0) Drops
            (53319) Stalls(0)
        TX: Pkts(1452311431262) Bytes(1458534011197761) Errs(0) Drops
            (788) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
        Rx Ring: Configured size=4096, Actual size=4096, Type: Fixed
 Done
```

```
<!--NeedCopy-->
```

The last line shows the configured and actual ring size, and the ring type.

To configure ring size and ring type by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select your interface and click **Edit**.
3. In **Ring Size**, specify one of the following:
   - **IX interfaces:** 512, 1024, 2048, 4096, or 8192.
   - **F1X, F2X, or F4X interfaces:** 512, 1024, 2048, or 4096.
4. In **Ring Type**, select Elastic or Fixed.
5. Click **OK**.

Enable and disable network interfaces

By default, the network interfaces are enabled. Disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause a failover.

For more information about high availability, see High Availability.

To enable or disable a network interface by using the CLI:

At the command prompt, type:

```
-  enable interface <interface_num>
-  show interface <interface_num>
-  disable interface <interface_num>
-  show interface <interface_num>
<!--NeedCopy-->
```

Example:

```
> enable interface 1/8
 Done
> show interface 1/8
        Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2
        flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg,
           802.1q>
        MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
        Requested: media UTP, speed AUTO, duplex FULL, fctl OFF,
           throughput 0
```

```
        RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
Done
<!--NeedCopy-->
```

To enable or disable a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select Enable or Disable.

Reset network interfaces

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the CLI:

At the command prompt, type:

```
-  reset interface <interface_num>
-  show interface <interface_num>
<!--NeedCopy-->
```

Example:

```
> reset interface 1/8
 Done
<!--NeedCopy-->
```

To reset a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select **Reset Interface**.

Monitor a network interface

You can display network interface statistics to monitor parameters and use the information to check the health of the network interface. You can monitor parameters, such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the CLI:

At the command prompt, type:

```
-  stat interface <interface_num>
<!--NeedCopy-->
```

Example:

```
> stat interface 1/8
 Done
<!--NeedCopy-->
```

To clear a network interface's statistics by using the CLI:

At the command prompt, type:

```
-  clear interface <interface_num>
<!--NeedCopy-->
```

Example:

```
> clear interface 1/8
 Done
<!--NeedCopy-->
```

To display the statistics of an Interface by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface, and click **Interface Statistics**.

To clear a network interface's statistics by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select **Clear Statistics**.

Configuring Forwarding Session Rules

September 14, 2021

By default, the Citrix ADC appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the Citrix ADC. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address**. When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule**. When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix**. When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule**. When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the CLI:

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- add forwardingSession <name> [<network> <netmask>] | [-aclname <string>] -connfailover (ENABLED | DISABLED)
- show forwardingSession

Example:

```
A network address as the condition:

> add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
 Done

An ACL as the condition:

> add forwardingSession fs-acl-1 acl1
 Done
<!--NeedCopy-->
```

To configure an IPv4 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the CLI:

- At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- add forwardingSession <name> [<IPv6 prefix>] | [-acl6name <string>]
- show forwardingSession

Example:

```
    An IPv6 prefix as the condition:

    > add forwardingSession fsv6-pfx-1 3ffe::/64
     Done

    An ACL6 rule as the condition:

    > add forwardingSession fsv6-acl6-1  -acl6name ACL6-FS
     Done
<!--NeedCopy-->
```

To configure an IPv6 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

Assigning an ACL rule to an Existing Forwarding Session Rule

You can assign an ACL rule to a Network-address/IPv6-prefix based forwarding session rule, in which case it becomes an ACL based forwarding session rule. You can also change an existing ACL rule to another ACL rule in an ACL based forwarding session rule. After the existing related forwarding session entries (if any) have timed out, the rules start using the newly assigned ACL to identify IPv4/IPv6 traffic for which to create a forwarding-session entry.

To assign an extended ACL rule to an existing IPv4 forwarding session rule by using the CLI:

At the command prompt, type

- `set forwardingSession <name> [-aclname <string>]`
- `show forwardingSession <name>`

To assign an ACL6 rule to an existing IPv6 forwarding session rule by using the CLI:

At the command prompt, type

- `set forwardingSession <name> [-acl6name <string>]`
- `show forwardingSession <name>`

Example:

```
> add forwardingSession FS-1 -aclname ACL-9
Done

```

```
> add forwardingSession FS6-1  -acl6name ACL6-9
Done
```

Disabling Steering for Forwarding Sessions on a Cluster Setup

The default behavior of a Citrix ADC cluster is for the node that receives traffic (flow receiver) to direct the traffic to another node (flow processor), which processes the traffic. Directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

Steering can be an overhead for real-time processing or when the setup includes high-latency links.

Steering for forwarding sessions can now be disabled so that the processing becomes local to the flow receiver. That is, the flow receiver becomes the flow processor.

Before you begin

Note the following points before configuring forwarding session rules in a cluster setup:

- You must configure linksets to be used for forwarding sessions.
- You must enable MAC Based Forwarding (MBF) on the cluster setup.

Configuring Forwarding Session Rules in a Cluster Setup

Disabling steering for forwarding session rules in a cluster setup can be done at the following two levels:

- **Specific forwarding session rule level**. Enable the Process Local parameter while adding a new forwarding session rule or editing an existing forwarding session rule.
- **Global level**. Enable the Process Local parameter while adding a new cluster instance or editing an existing cluster instance. The global setting takes precedence over the forwarding session rule setting.

CLI procedures

To disable steering for a forwarding session rule on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new forwarding session rule:
  - **add forwardingSession** <name> ((<network> [<netmask>]) | -**acl6name** <string> | -**aclname** <string>) -**processLocal ENABLED**
  - **show forwardingSession** <name>
- If reconfiguring an existing forwarding session rule:

- **set forwardingSession** <name> -**processLocal ENABLED**
- **show forwardingSession** <name>

To disable steering for all (global level) forwarding session rules on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new cluster instance:
  - **add cluster instance** <clid> -**processLocal Enabled**
  - **show cluster instance** <clid>
- If reconfiguring an existing cluster instance:
  - **set cluster instance** <clid> -**processLocal Enabled**
  - **show cluster instance** <clid>

Sample configuration:

Following are two examples of disabling steering at the forwarding session rule level, and an example of disabling steering at the global level.

```
An IPv4 forwarding session rule:

> add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV4-1 10.102.105.51
    255.255.255.255 -processLocal Enabled
Done

An IPv6 forwarding session rule:

> add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV6-1  -acl6name ACL6-
    FWD-SESSN-1 -processLocal Enabled
Done

A cluster setup, with an instance ID 10, has steering disabled at
    global level:

> set cluster instance 10 -processLocal Enabled
Done
<!--NeedCopy-->
```

GUI procedures

To disable steering for a forwarding session rule on a cluster setup by using the GUI:

Navigate to **System** > **Network** > **Forwarding Sessions**, select **Process Local** while adding a new forwarding session rule or editing an existing forwarding session rule.

To disable steering for all (global level) forwarding session rules on a cluster setup by using the GUI:

Navigate to **System** > **Cluster**, and select **Process Local** while adding a cluster configuration or modifying an existing cluster configuration.

Understanding VLANs

September 14, 2021

A Citrix ADC appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The Citrix ADC then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The Citrix ADC supports the following types of VLANs:

- **Port-Based VLANs.** The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the Citrix ADC are members of VLAN 1.

  If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

- **Default VLAN.** By default, the network interfaces on the Citrix ADC are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

  When you add a network interface to a to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

- **Tagged VLANs.** 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the Citrix ADC) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

  The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the

frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the Citrix ADC connects must be on the same VLAN as the Citrix ADC network interface.

Note: This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

- **Ingress rules.** Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:
  - If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
  - If frame has a tag value equal to FFF, the frame is dropped.
  - If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.
- **Egress Rules.** The following egress rules are applied:
  - If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
  - During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the Citrix ADC.
  - A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

VLANs and Packet Forwarding on the Citrix ADC

The forwarding process on the Citrix ADC appliance is similar to that on any standard switch. However, the Citrix ADC performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.

- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the Citrix ADC. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the Citrix ADC are processed at the upper layers.
- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the Citrix ADC supports prefix-based VLANs.

Configuring a VLAN

September 14, 2021

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the Citrix ADC. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the Citrix ADC to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a

VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other Citrix ADC appliances. The Citrix ADC forwards packets between configured IP subnets (VLANs).

When you configure the Citrix ADC, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the Citrix ADC appliance.

Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the Citrix ADC appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the Citrix ADC appliances. The result is identical actions on all the appliances. For example, adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other Citrix ADC appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

Creating or Modifying a VLAN

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

CLI procedures

To create a VLAN by using the CLI:

At the command prompt, type:

- `add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED|DISABLED)]`
- `sh vlan <id>`

Example:

```
  > add vlan 2  -aliasName "Network A"   Done
<!--NeedCopy-->
```

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -ifnum <slot/port>`
- `sh vlan <id>`

Example:

```
  > bind vlan 2 -ifnum 1/8   Done
<!--NeedCopy-->
```

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -IPAddress <IPAddress> <netMask>`
- `sh vlan <id>`

Example:

```
  > bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0   Done
<!--NeedCopy-->
```

To remove a VLAN by using the CLI:

At the command prompt, type:

- `rm vlan <id>`

GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

Monitoring VLANs

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the CLI:

At the command prompt, type:

- `stat vlan <vlanID>`

Example:

```
1   stat vlan 2
2 <!--NeedCopy-->
```

To view the statistics of a VLAN by using the GUI:

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.

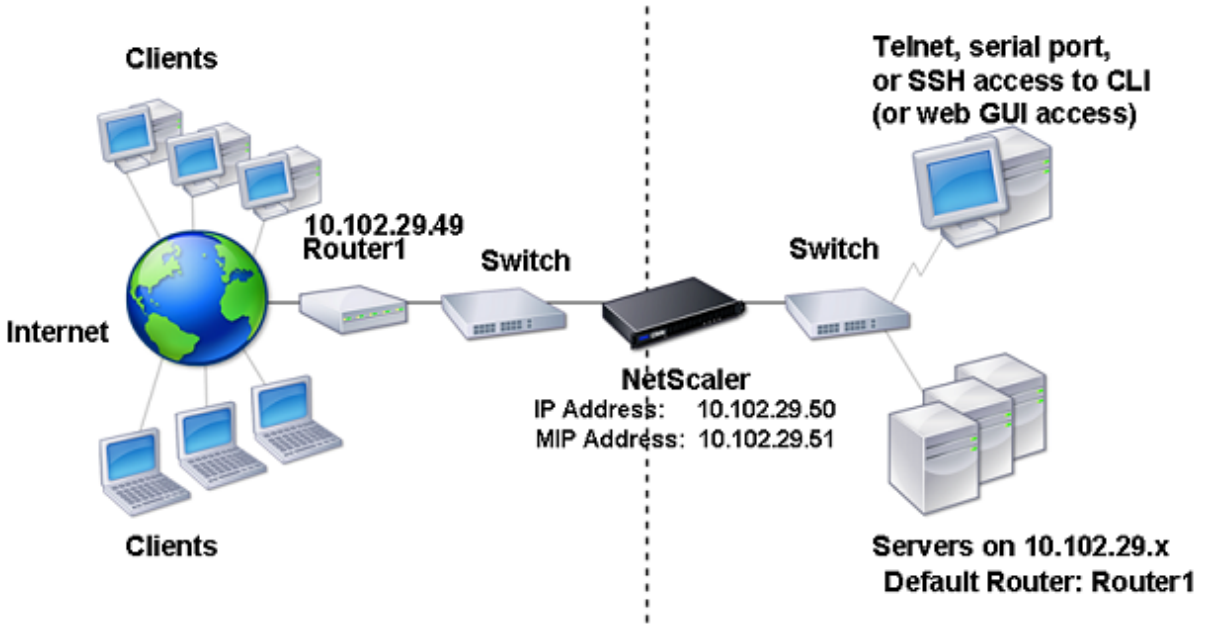
Configuring VLANs on a Single Subnet

September 14, 2021

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet



In the above figure:

1. The default router for the Citrix ADC and the servers is Router 1.
2. Layer 2 mode must be enabled on the Citrix ADC for the Citrix ADC to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the Citrix ADC appliance.

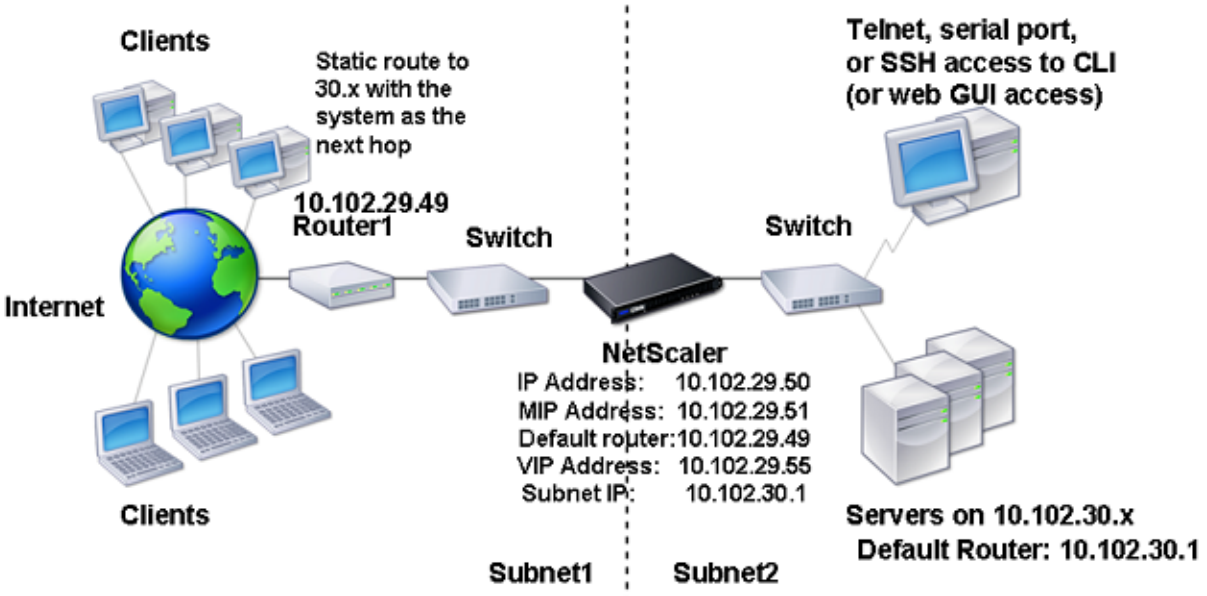
To configure a VLAN on a single subnet, follow the procedures described in Configuring a VLAN.

Configuring VLANs on Multiple Subnets

September 14, 2021

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN



To configure a single VLAN across multiple subnets, perform the following tasks:

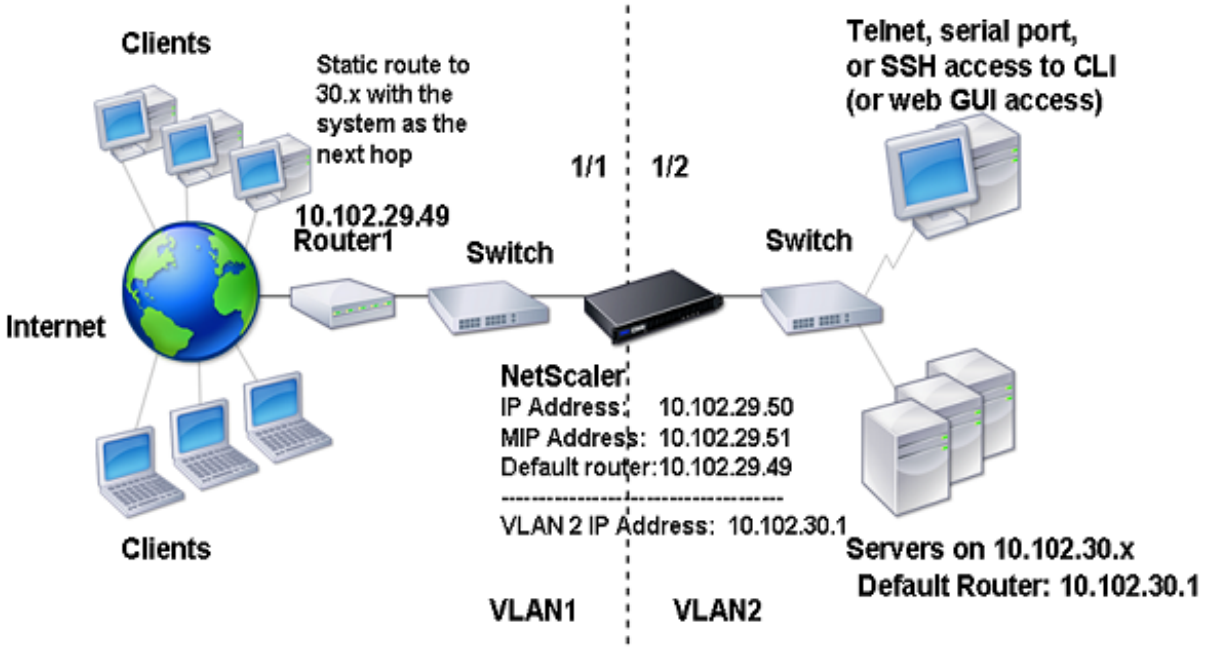
1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see Packet forwarding modes.
2. Add a VIP address. For the procedure to add a VIP address, see Configuring and Managing Virtual IP Addresses (VIPs).
3. Configure RNAT rule. For the procedure to configure the RNAT ID, see Configuring RNAT.

Configuring Multiple Untagged VLANs across Multiple Subnets

September 14, 2021

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

Figure 1. Multiple Subnets with VLANs - No Tagging



To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and subnet mask to VLAN 2.

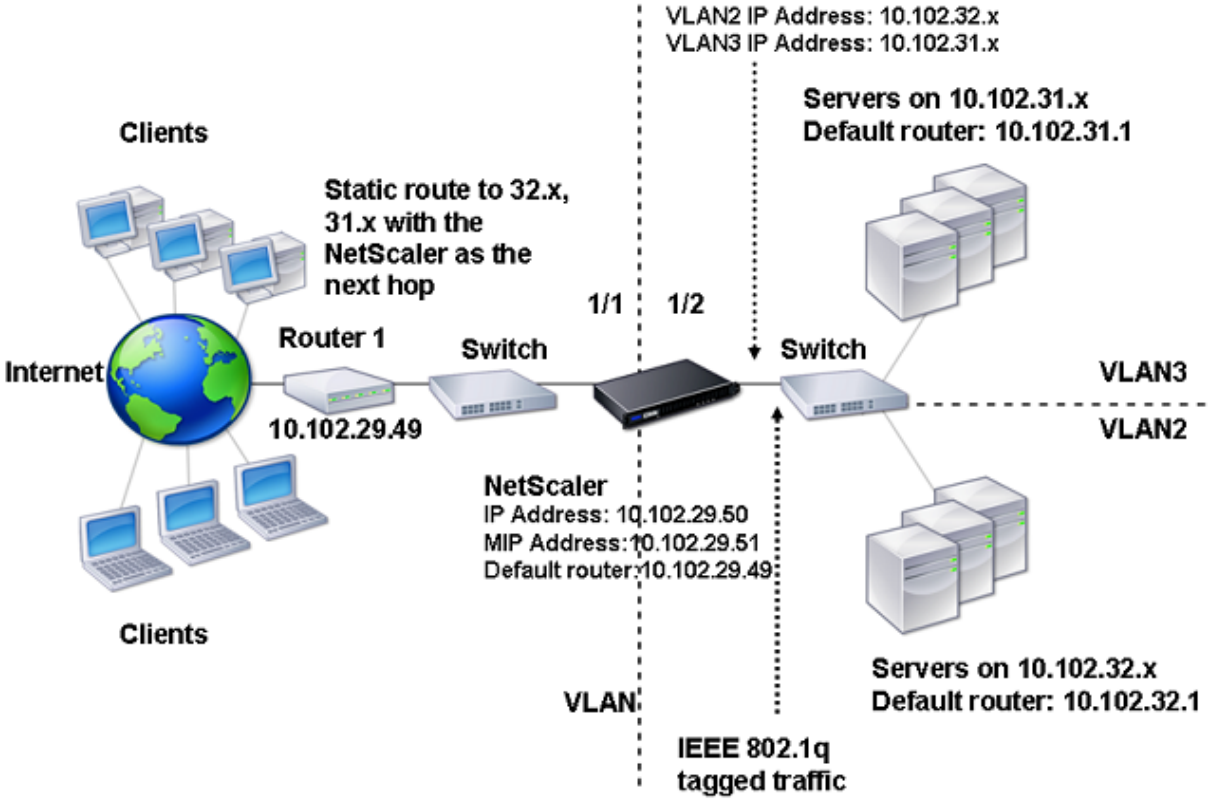
For procedures on these tasks, see Configuring a VLAN.

Configuring Multiple VLANs with 802.1q Tagging

September 14, 2021

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

Figure 1. Multiple VLANs with IEEE 802.1q Tagging



To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and netmask to VLAN 2.
4. Add VLAN 3.
5. Bind the 1/2 network interface of the Citrix ADC to VLAN 3 as a tagged network interface.
6. Bind the IP address and netmask to VLAN 3.

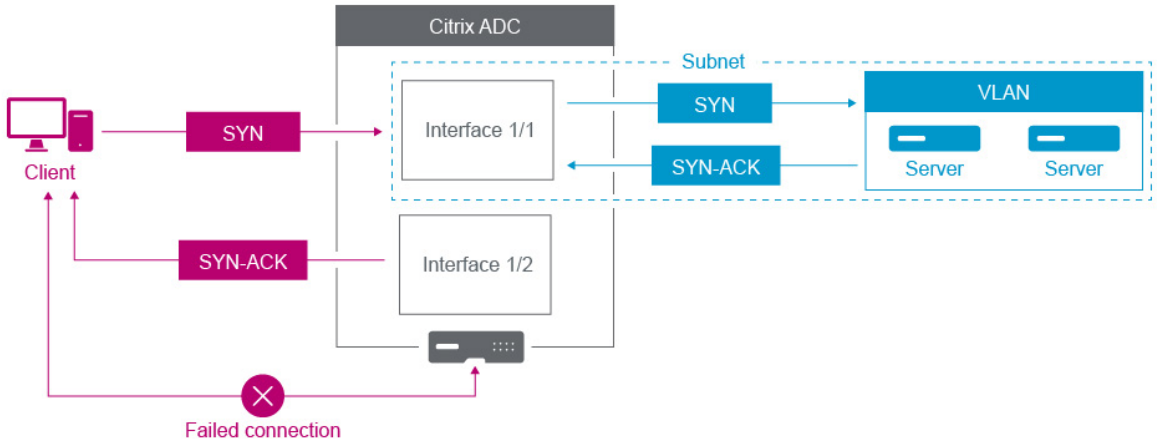
For procedures on these tasks, see Configuring a VLAN.

Associate an IP Subnet with a Citrix ADC Interface by Using VLANs

September 14, 2021

BY default, a Citrix ADC appliance does not provide any differentiation between network interfaces. The appliance functions more like a network hub than a switch. This can lead to Layer 3 network loops where duplicated traffic is transmitted on multiple interfaces.

In such scenarios, depending on network design, it is possible that a request could be transmitted on one interface and the corresponding response is received on a different interface.



For example, a SYN packet sent on one interface and the SYN-ACK response received on a different interface can result in a failed connection, as the appliance expects to receive the SYN-ACK on the same interface that sent the original SYN packet.

To resolve such issues, the appliance can use internal or external VLANs, to associate specific subnets with interfaces.

Before you begin

Before you begin associating an IP Subnet with a Citrix ADC interface by using VLANs, note the following points:

- The network connectivity might be accidentally lost when associating a VLAN to the subnet or interface that is currently being used to access the Citrix ADC GUI or command line interface. Therefore, in such scenarios, it is highly recommended that the change is made by accessing the command line interface through the serial console of a physical Citrix ADC appliance or through the virtual serial console of a Citrix ADC VPX.
- Citrix ADC management interfaces lack certain hardware optimization features which makes them less desirable for use with production data traffic. As such, it is recommended that the Citrix ADC be configured to only use the management interfaces for management (NSIP) traffic. In the default configuration, there is no logical differentiation between the management interfaces and data interfaces on a hardware NetScaler. In order to accomplish this goal, it is recommended that the NSIP be on a separate VLAN from data traffic, which allows management traffic to be on a separate interface.

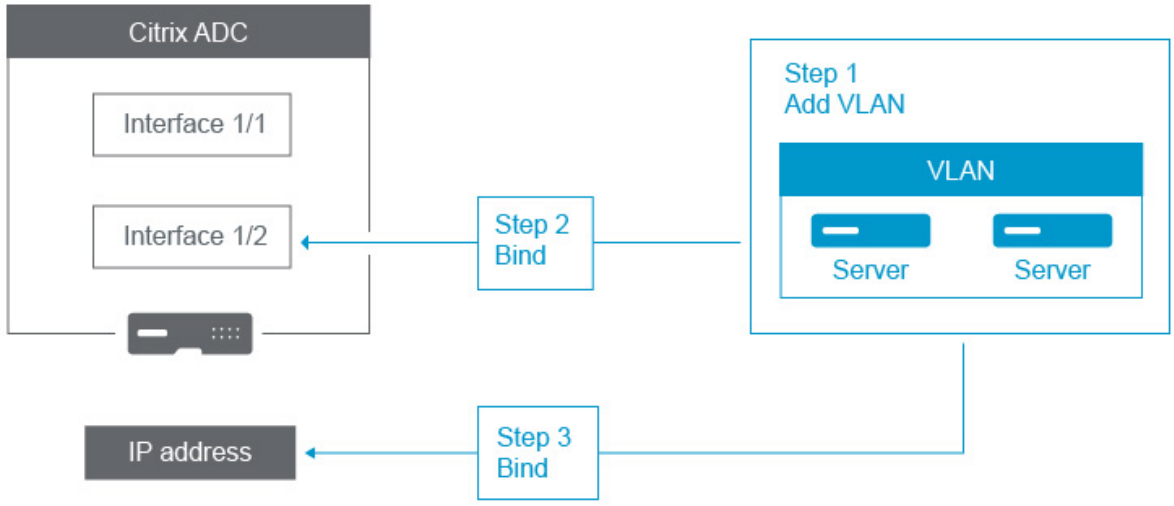
  Although the concept is the same, to change the VLAN associations of the subnet that contains the NSIP address, you must configure NSVLAN instead of the below instructions. Such changes

will also require a reboot of the Citrix ADC in order to take effect. For more information, see Configuring NSVLAN.

- On Citrix ADC SDX, it is highly recommended that the NSIP of each instance be on the same subnet and VLAN as the SDX's SVM (Management Service GUI) and XenServer. The SVM communicates with instances via the network. If the SVM, XenServer, and instances are not on the same VLAN and subnet, management traffic must flow outside of the SDX. In this situation, network issues can cause Instance state to show up as yellow or red and can prevent the management and configuration changes of the Citrix ADC instances.

Configuration Steps

Associate an IP subnet with a Citrix ADC Interface consists of the following tasks:



Add a VLAN. While adding a VLAN, if you are tagging the VLAN, then you must select a VLAN number that is defined in the network switch for the associated switch port. If the VLAN is untagged and is internal to the appliance, then it is recommended that you select the VLAN number that is available in the switch configuration for easy reference.

Bind an interface to the VLAN. While binding, if you are using Link Aggregation, associate the VLAN with the LA channel (for example, LA/1) instead of the physical interface. The VLAN must be associated with only one network interface.

If you want to tag the traffic on the interface, use the tagged (Tag) option. Else, the traffic leaves the appliance untagged and is associated with the native VLAN of the switch port.

Bind an IP address to the VLAN. While binding, if you bind more than one IP address from the same subnet, an error occurs. When an IP address is associated with a VLAN, all IP addresses in that subnet are automatically associated with the VLAN.

> **Note:**
>
> In a high availability (HA) setup, these VLAN configurations are added automatically from the primary node to the secondary node during HA synchronization. For more information about high availability setups, see High Availability.

CLI procedures

To add a VLAN by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **sh vlan** <id>

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> -**ifnum** <slot/port>
- **sh vlan** <id>

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> -**IPAddress** <IPAddress> <netMask>
- **sh vlan** <id>

Example:

```
> add vlan 100

> bind vlan 100 -ifnum 1/1

> bind vlan 100 -ipAddress 10.0.1.0 255.255.255.0
<!--NeedCopy-->
```

GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to **System** > **Network** > **VLANs**, add a new VLAN.
2. To bind a network interface to a VLAN, under **Interface Bindings**, select the **Active** option corresponding to the interface that you want to bind to the VLAN.

3. To bind an IP address to a VLAN, under **IP Bindings**, select the **Active** option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The **Type** column displays the IP address type for each IP address in the **IP Address** column.

Citrix ADC appliance networking and VLAN best practices

September 14, 2021

A Citrix ADC appliance uses VLANs to determine which interface must be used for which traffic. In addition, Citrix ADC appliance does not participate in Spanning Tree. Without the proper VLAN configuration, the Citrix ADC appliance is unable to determine which interface to use, and it can function more like a HUB than a switch or a router. In other words, the Citrix ADC appliance can use all interfaces for each conversation.

Symptoms of VLAN misconfiguration

VLAN misconfiguration issue can manifest itself in many forms, including performance issues, inability to establish connections, randomly disconnected sessions, and in severe situations, network disruptions seemingly unrelated to the Citrix ADC appliance itself. The Citrix ADC appliance may also report MAC moves, muted interfaces, and/or management interface transmit or receive buffer overflows, depending on the exact nature of the interaction with your network.

MAC Moves (counter nic_tot_bdg_mac_moved): This issue indicates that the Citrix ADC appliance is using more than one interface to communicate with the same device (MAC address), because it could not properly determine which interface to use.

Muted interfaces (counter nic_err_bdg_muted): This issue indicates that the Citrix ADC appliance has detected that it is creating a routing loop due to VLAN configuration issues, and as such, it has shut down one or more of the offending interfaces in order to prevent a network outage.

Interface buffer overflows, typically referring to management interfaces (counter nic_err_tx_overflow):This issue can be caused if too much traffic is being transmitted over a management interface. Management interfaces on the Citrix ADC appliance is not designed to handle large volumes of traffic, which may result from network and VLAN misconfigurations triggering the Citrix ADC appliance to use a management interface for production data traffic. This often occurs because the Citrix ADC appliance has no way to differentiate traffic on the VLAN / subnet of the NSIP (NSVLAN) from regular production traffic. It is highly recommended that the NSIP be on a separate VLAN and subnet from any production devices such as workstations and servers.

Orphan ACKs (counter tcp_err_orphan_ack): This issue indicates that the Citrix ADC appliance received an ACK packet that it was not expecting, typically on a different interface than the ACK'd traffic

originated from. This situation can be caused by VLAN misconfigurations where the Citrix ADC appliance transmits on a different interface than the target device would typically use to communicate with the Citrix ADC appliance (often seen in conjunction with MAC moves)

High rates of retransmissions or retransmit give ups (counters: tcp_err_retransmit_giveups, tcp_err_7th_retransmit, various other retransmit counters): The Citrix ADC appliance attempts to retransmit a TCP packet a total of 7 times before it gives up and terminates the connection. While this situation can be caused by network conditions, it often occurs as a result of VLAN and interface misconfiguration.

High Availability Split Brain: Split Brain is a condition where both high availability nodes believe they are Primary, leading to duplicate IP addresses and loss of Citrix ADC appliance functionality. This is caused when the two high availability nodes cannot communicate with each-other using high availability Heartbeats on UDP Port 3003 using the NSIP, across any interface. This is typically caused by VLAN misconfigurations where the native VLAN on the Citrix ADC appliance interfaces does not have connectivity between Citrix ADC appliances.

Best practices for VLAN and network configurations

1. Each subnet must be associated with a VLAN.
2. More than one subnet can be associated with the same VLAN (depending on your network design).
3. Each VLAN should be associated to only one interface (for purposes of this discussion, a LA channel counts as a single interface).
4. If you require more than one subnet to be associated with an interface, the subnets must be tagged.
5. Contrary to popular belief, the Mac-Based-Forwarding (MBF) feature on the Citrix ADC appliance is not designed to mitigate this type of issue. MBF is designed primarily for the DSR (Direct Server Return) mode of the Citrix ADC appliance, which is rarely used in most environments (it is designed to allow traffic to purposely bypass the Citrix ADC appliance on the return path from the back-end servers). MBF may hide VLAN issues in some instances, but it should not be relied-upon to resolve this type of problem.
6. Every interface on Citrix ADC appliance requires a native VLAN (unlike Cisco, where native VLANs are optional), although the TagAll setting on an interface can be used so that no untagged traffic leaves the interface in question.
7. The native VLAN can be tagged if necessary for your network design (this is the TagAll option for the interface).
8. The VLAN for the subnet of your Citrix ADC appliance's NSIP is a special case. This is called the NSVLAN. The concepts are the same but the commands to configure it are different and changes

to the NSVLAN require a reboot of the Citrix ADC appliance to take effect. If you attempt to bind a VLAN to a SNIP that shares he same subnet as the NSIP, you get "Operation not permitted." This is because you have to use the NSVLAN commands instead. Also, on some firmware versions, you cannot set an NSVLAN if that VLAN number exists using `add VLAN` command. Simply remove the VLAN and then set the NSVLAN again.

9. High availability Heartbeats always use the Native VLAN of the respective interface (optionally tagged if the TagAll option is set on the interface).

10. There must be communication between at least one set of Native VLAN(s) on the two nodes of an high availability pair (this can be direct or via a router). The native VLANs are used for high availability heartbeats. If the Citrix ADC appliances cannot communicate between native VLANs on any interface, this will lead to high availability failovers and possibly a split-brain situation where both Citrix ADC appliances think they are primary (leading to duplicate IP addresses, amongst other things).

11. The Citrix ADC appliance does not participate in spanning tree. As such, it is not possible to use spanning tree to provide for interface redundancy when using a Citrix ADC appliance. Instead, use a form of Link Aggregation (LACP or manual LAG) for this purpose.

    Note: If you want to have link aggregation between multiple physical switches, you must have the switches configured as a virtual switch, using a feature such as Cisco's Switch Stack.

12. The high availability synchronization and command Propagation, by default, use the NSIP/NSVLAN. To separate these out to a different VLAN, you can use the SyncVLAN option of the `set HA node` command.

13. There is nothing built-in to the Citrix ADC appliance default configuration that denotes that a management interface (0/1 or 0/2) is restricted to management traffic only. This restriction must be enforced by the end user through VLAN configuration. The management interfaces are not designed to handle data traffic, so your network design must take this point into account. Management interfaces, contained on the Citrix ADC appliance motherboard, lack various offloading features such as CRC offload, larger packet buffers, and other optimizations, making them much less efficient in handling large amounts of traffic. To separate production data and management traffic, the NSIP must not be on the same subnet/VLAN as your data traffic.

14. If it is desired to use a management interface to carry management traffic, it is best practice that the Default Route be on a subnet other than the subnet of the NSIP (NSVLAN).

    In many configurations, the default route is relied-upon for workstation commmunication (in an internet scenario). If the default route is on the same subnet as the NSIP, then the ADC appliance can use the management interface to send and receive data traffic. This use of data traffic can overload the management interface.

15. Also, an SDX-the SVM, XenServer, and all Citrix ADC instance NSIPs must be on the same VLAN and subnet. There is no **backplane** in the SDX appliance that allows for communication be-

tween SVM/Xen/Instances. If they are not on the same VLAN/subnet/interface, traffic between them must leave the physical hardware, be routed on your network, and return.

This configuration can lead to obvious connectivity issues between the instances and SVM and as such, is not recommended. A common symptom of this is a Yellow Instance State indicator in the SVM for the VPX instance in question, and the inability to use the SVM to reconfigure a VPX instance.

16. If some VLANs are bound to subnets and some are not, during a high availability failover, GARP packets are not be sent for any IP addresses on any of the subnets that are not bound to a VLAN. This configuration can cause dropped connections and connectivity issues during high availability failovers. This issue is caused because the Citrix ADC appliance cannot notify the network MAC ownership IP addresses change on non-VMAC-configured Citrix ADC appliances.

    Symptoms of this are that during/after a high availability failover, the ip_tot_floating_ip_err counter increments on the former primary Citrix ADC appliance for more than a few seconds, indicating that the network did not receive or process GARP packets and the network is continuing to transmit data to the new secondary Citrix ADC appliance.

Configuring NSVLAN

September 14, 2021

NSVLAN is a VLAN to which the Citrix ADC management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN 1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the Citrix ADC appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the Citrix ADC IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface. If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN 1, restoring the default NSVLAN.

To configure NSVLAN by using the CLI:

At the command prompt, type:

- set ns config -nsvlan <positive_integer> -ifnum <interface_name> … [-tagged (YES|NO)]
- show ns config

  Note: The configuration takes effect after the Citrix ADC appliance is rebooted.

Example:

```
> set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged NO
 Done

> save config
 Done
<!--NeedCopy-->
```

To restore the default NSVLAN configuration by using the CLI:

At the command prompt, type:

- unset ns config -nsvlan
- show ns config

Example:

```
> unset ns config -nsvlan
 Done
<!--NeedCopy-->
```

To configure NSVLAN by using the GUI:

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

Setting the MTU on the NSVLAN

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throughput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the CLI:

At the command prompt, type:

- **set vlan** <id> **-mtu** <positive_integer>
- **show vlan** <id>

To set the MTU of the NSVLAN by using the GUI:

Navigate to **System** > **Network** > **VLANs**, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

Sample configuration:

In the following sample configuration, VLAN 100 is the NSVLAN.

```
> set ns config -nsvlan 100 -ifnum 1/1 -tagged no

  Warning: The configuration must be saved and the system rebooted for
     these settings to take effect
```

```
4
5  > set vlan 100 -mtu 1600
6
7    Done
8
9  > sh vlan
10
11   1)  VLAN ID: 1
12
13       Link-local IPv6 addr:

Configuring Allowed VLAN List

September 14, 2021

Citrix ADC accepts and sends tagged packets of a VLAN on an interface if the VLAN is explicitly configured on the Citrix ADC appliance and the interface is bound to the VLAN. Some deployments (for example, Bump in the wire) require the Citrix ADC appliance to function as a transparent device to accept and forward tagged packets related to a large number of VLANs. For this requirement, configuring and managing a large number of VLANs is not a feasible solution.

Allowed VLAN list on an interface specifies a list of VLANs. The interface transparently accepts and

sends tagged packets related to the specified VLANs without the need for explicitly configuring these VLANs on the appliance.

Points to Consider before Configuring Allowed VLAN List

Consider the following points before configuring allowed VLAN list

- In a high availability setup, allowed VLAN list is not propagated or synchronized. Therefore, you have to configure allowed VLAN list on both the nodes.
- The traffic of a native VLAN might leak to the non-member interfaces that specifies the native VLAN in its allowed VLAN list.
- A Maximum of 60 VLAN ranges can be specified as part of allowed VLAN list for an interface.
- The Citrix ADC appliance does not support allowed VLAN list on interfaces that are part of link aggregation channels or redundant interface sets. For more information on redundant interface set, see Redundant Interface Set.
- Allowed VLAN list is not supported on a Citrix ADC cluster configuration.
- The Citrix ADC appliance does not support allowed VLAN list for Bridge groups.
- The Citrix ADC appliance does not support allowed VLAN list for VXLANs.

Configuring Allowed VLAN List

To configure allowed VLAN list by using the CLI:

At the command prompt, type:

- **set interface** <id> **-trunkmode** (ON|OFF) **-trunkAllowedVlan** <int[-int]> …
- **show interface** <id>

To configure allowed VLAN list by using the GUI:

Navigate to **System** > **Network** > **Interfaces**, select a network interface, click **Edit**, and then set the following parameters:

- Trunk Mode
- Trunk Allowed VLAN

Sample Configuration:

In the following sample configuration, VLANS in the ranges 100-120, 190-200, and 300-330 are specified as part of allowed VLAN list for interface 1/2.

```
1 > set int 1/2 -trunkmode on -trunkallowedVlan 100-120 190-200 300-330
2
3 Done
4
5 > sh int 1/2
```

```
6
7  1)      Interface 1/2 (Gig Ethernet 10/100/1000 MBits) #6
8          flags=0xc020
9
10         <ENABLED, UP, UP, AUTONEG OFF, HEARTBEAT, 802.1q, trunkmode>
11
12         Trunk Allowed Vlans:  100-120 190-200 300-330
13
14 Done
15
16 <!--NeedCopy-->
```

Configuring Bridge Groups

September 14, 2021

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANS can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the Citrix ADC appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The Citrix ADC accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

> **Note**
>
> Bridge Group feature and Bridge BPDU mode cannot work together.

Configuration steps

Perform the following steps to configure a bridge group:

- Enable Layer 2 mode
- Add a bridgegroup and bind VLANs to the bridgegroup

CLI procedures

To enable Layer 2 mode by using the CLI:
At the command prompt, type:

- **enable ns mode l2**
- **show ns mode**

To add a bridge group and bind VLANs by using the CLI:

At the command prompt, type:

- **add bridgegroup** <id> [-**ipv6DynamicRouting** (**ENABLED** | **DISABLED**)]
- **bind bridgegroup** <id> -**vlan** <positive_integer>
- **show bridgegroup** <id>

Example:

```
1 > add bridgegroup 12
2  Done
3 <!--NeedCopy-->
```

To remove a bridge group by using the CLI:

At the command prompt, type:

- **rm bridgegroup** <id>

Example:

```
1  rm bridgegroup 12
2 <!--NeedCopy-->
```

GUI Procedures

To configure a bridge group by using the GUI:

Navigate to **System** > **Network** > **Bridge Groups**, add a new bridge group and bind VLANs to the bridgegroup, or edit an existing bridge group.

Configuring virtual MACs

September 14, 2021

The primary and secondary nodes in a high availability (HA) setup share the virtual MAC address floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a virtual MAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a virtual MAC, see Configuring Virtual MAC Addresses.

Configuring Link Aggregation

September 14, 2021

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the Citrix ADC appliance and other connected devices. An aggregated link is also referred to as a "channel." You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

Configuring Link Aggregation Manually

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

CLI procedures

To create a link aggregation channel by using the CLI:

At the command prompt, type:

- add channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)][-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example:

```
> add channel LA/1 -ifnum 1/8
Done
<!--NeedCopy-->
```

To bind an interface to or unbind an interface from an existing link aggregation channel by using the CLI:

At the command prompt, type one of the following commands:

- bind channel <id> <interfaceName>
- unbind channel <id> <interfaceName>

Example:

```
bind channel LA/1 1/8
<!--NeedCopy-->
```

To modify a link aggregation channel by using the CLI:

At the command prompt, type the
set channel command, the channel ID, and the parameters to be changed, with their new values.

To remove a link aggregation channel by using the CLI:

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

- rm channel <id>

Example:

```
> rm channel LA/1
 Done
<!--NeedCopy-->
```

GUI procedures

To configure a link aggregation channel by using the GUI:

Navigate to System > Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the GUI:

> **Important:**
>
> When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Navigate to System > Network > Channels, select the channel that you want to remove and click Delete.

Configuring Link Aggregation by Using the Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

Note: In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

Configuring the LACP System Priority

The LACP system priority determines which peer device of an LACP LA channel can have control over the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the value, the higher the priority.

To configure the LACP system priority by using the CLI:

At the command prompt, type the following commands to set the priority for a standalone appliance and verify the configuration:

- set lacp -sysPriority <positive_integer>
- show lacp

Example:

```
set lacp -sysPriority 50
<!--NeedCopy-->
```

To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

- set lacp -sysPriority <positive_integer> -ownerNode <positive_integer>
- show lacp

Example:

```
set lacp -sysPriority 50 -ownerNode 2
<!--NeedCopy-->
```

To configure the LACP system priority by using the GUI:

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

Creating Link Aggregation Channels

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

Note:

- When enabling LACP on a network interface, you must specify the LACP Key.
- By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the CLI:

At the command prompt, type:

- set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)]
- show interface [<id>]

To create an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.

Modifying Link aggregation Channels

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel by using the CLI:

At the command prompt, type:

- set channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example:

```
> set channel LA/3 -state ENABLED -speed 10000
 Done
<!--NeedCopy-->
```

To modify an LACP channel by using the GUI:

Navigate to System > Network > Channels, and modify an existing LACP channel.

Removing a Link Aggregation Channel

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the CLI:

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

To remove an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

Link Redundancy using LACP channels

Link Redundancy using LACP channels enables the Citrix ADC to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.

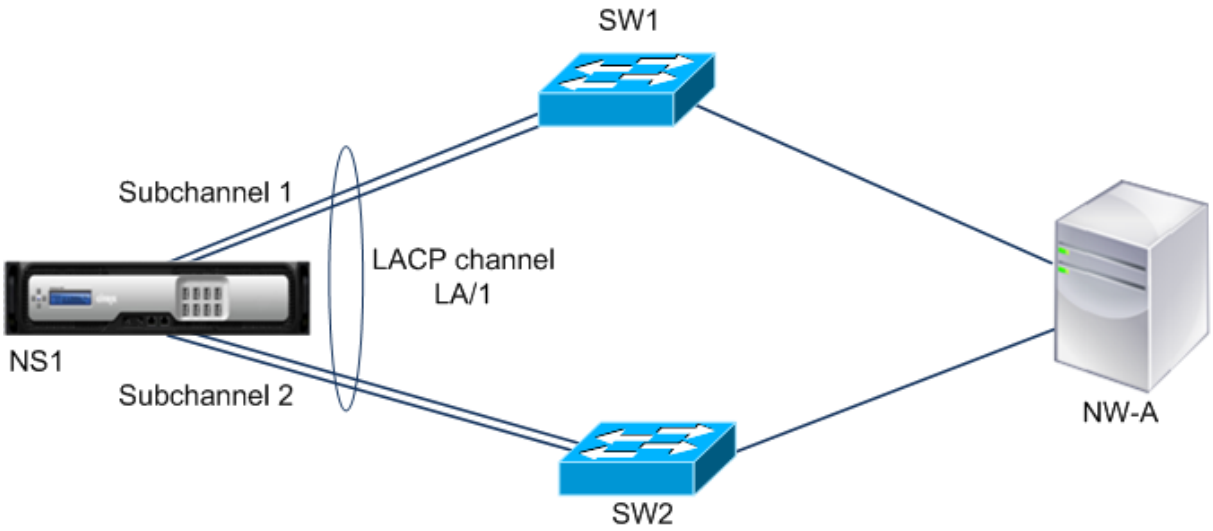
A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a Citrix ADC, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.

To configure link redundancy for an LACP channel, set the lrMinThroughput parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the lrMinThroughput value, link failover occurs and a standby subchannel becomes active.

If you unset the lrMinThroughput parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

Example

Consider an example of link redundancy configured between Citrix ADC NS1 and switches SW1 and SW2.



NS1 is connected to network device NW-A through SW1 and SW2.
On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.
When the lrMinThroughput parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on

standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

Link Redundancy using LACP channels in a High Availability setup

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (lrMinThroughput parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the lrMinThroughput parameter.

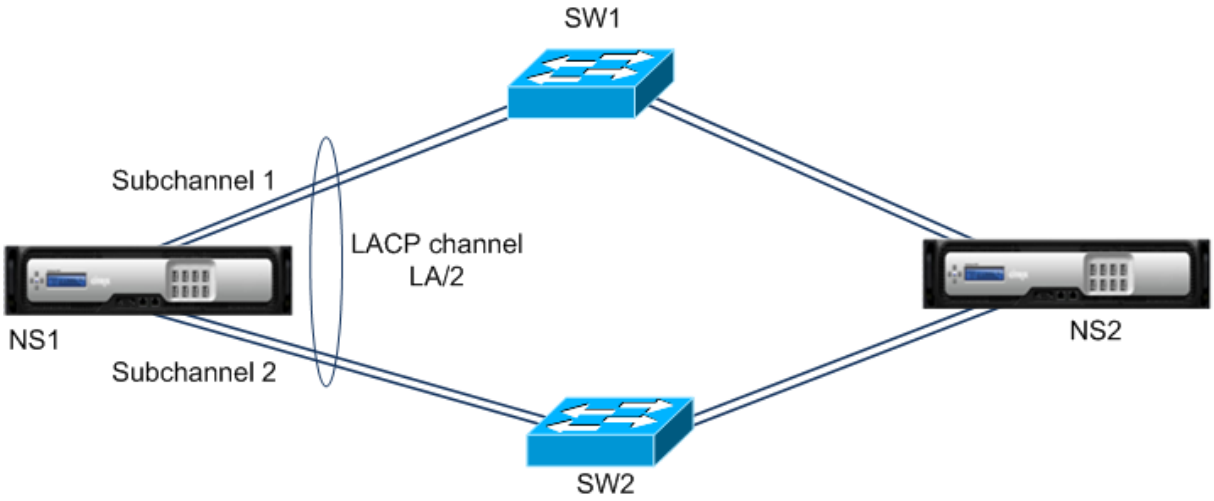
The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the lrminthroughput parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels' maximum supported throughput meet the lrMinThroughput parameter value.
- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has Citrix ADCs NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.



Following are the LACP-parameter settings in this example:

Parameter	Value
Throughput	2000
lrminthroughput	2000

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2's maximum supported throughput also falls below the lrminthroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:

Configure Link Redundancy using LACP channels

To configure link redundancy for a LACP channel by using the CLI:

At the command prompt, type the following commands to configure the channel and verify the configuration:

- **set channel** <id> -lrMinThroughput <positive_integer>
- **show channel**

Example:

```
1 > set channel la/1 - lrMinThroughput 2000
2 Done
3 > set channel la/2 - throughput 2000 - lrMinThroughput 2000
4 Done
5 <!--NeedCopy-->
```

To configure link redundancy for a LACP channel by using GUI

1. Navigate to System > Network > Channels.

2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.
3. In the Configure LACP channel dialog box, set the lrMinThroughput parameter.
4. Click Close.

Redundant Interface Set

September 14, 2021

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the Citrix ADC appliance and a peer device by providing back up links between them.
- Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, redundant interface set appear as individual interfaces and not as a set or collection.
- In an high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

> **Note**
>
> Redundant Interface Set was formerly known as 'NIC bundling' when first introduced in 10.5 release.

How Redundant Interface Set Works

For a redundant interface set, the Citrix ADC appliance derives a MAC address on the basis of an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contains the MAC address assigned to the redundant interface set and not the interface's own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority**. This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.
- **Binding order of the member interfaces**. If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.

Points to Consider for Configuring Redundant Interface Sets

Consider the following points before you configure a redundant interface set:

- In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.
- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- You can configure a maximum of four redundant interface sets on a Citrix ADC appliance.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a link aggregate (LA) channel.
- LA channels cannot be bound to a redundant interface set.
- Redundant interface sets cannot be bound to an LA channel.
- In a cluster setup:
  - Redundant interface sets cannot be bound to a cluster link aggregation.
  - A link redundant set is specified in N/LR/X notation (for example, 1/LR/3). Where:
    N is the ID of the cluster node on which the redundant interface set is to be created.
    X is a link-redundant set identifier on a cluster node. X can range from 1-4.
  - A cluster link aggregation cannot be bound to a redundant interface set.
  - A redundant interface set can include only the interfaces of the node to which the redundant interface set belongs.

- An Existing elink redundancy set configuration on a standalone appliance automatically changes to cluster notation (N/LR/X) after the appliance is added to a cluster setup.

Configuration Steps

Configuring redundant interface set on a Citrix ADC appliance consists of the following tasks:

- **Create a redundant interface set**. Use the channel command operation for creating a redundant interface set.

  In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

  In a cluster setup, a link redundant set is specified in N/LR/X (for example, 1/LR/3), where: N is the ID of the cluster node on which the redundant interface set is to be created, X is link redundant set identifier on a cluster node. X can range from 1-4.

- **Bind interfaces to the redundant interface set**. Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.

- **(Optional) Set a redundant interface priority on the member interface**. Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the CLI:

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the CLI:

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the CLI:

At the command prompt:

- set interface <ID> -lrsetpriority <positive_integer>
- show interface <ID>

Sample configuration 1:

In the following example, redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command displays that the interface 1/1 is the current active interface for the redundant interface set lr/1.

```
> add channel lr/1
 Done
> bind channel lr/1 1/1 1/2 1/3 1/4
 Done
> show channel
1)    Interface LR/1 (Link Redundant) #23
        flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
        MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
        Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
                 throughput 0
        Actual: throughput 1000
        LLDP Mode: NONE,
        RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
        TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
                1/1: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Active Member
                1/2: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
                1/3: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
                1/4: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
Done
<!--NeedCopy-->
```

Sample configuration 2:

In the following example, redundant interface priority of the member interface 1/4 is set to 100, which is lower than the set redundant interface priority of all the other member interfaces of LR/1.

Output of the show channel command displays that the interface 1/4 is the current active interface for the redundant interface set LR/1.

```
> set interface 1/4 -lrsetPriority 100
Done
> show channel
1)      Interface LR/1 (Link Redundant) #23
        flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
        MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
        Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
                 throughput 0
        Actual: throughput 1000
        LLDP Mode: NONE,
```

```
        RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
        TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
                1/1: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
                1/2: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
                1/3: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
                1/4: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Active Member
Done
<!--NeedCopy-->
```

Sample configuration 3:

Consider a cluster setup of four nodes N1, N2, N3, and N4. In this example, redundant interface set 1/LR/3 is created on node N1, and interfaces 1/1/1, 1/1/2, and 1/1/3 are bound to it. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command indicates that interface 1/1/1 is the current active interface for redundant interface set 1/LR/3.

```
    > add channel 1/LR/3

    Done
    > bind channel 1/LR/3 1/1/1 1/1/2 1/1/3

    Done
    > show channel
    1)    Interface 1/LR/3 (Link Redundant) #14
            flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON,
               802.1q>
            MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0
               h00m00s
            Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
            throughput 0
            Actual: throughput 1000
            LLDP Mode: NONE,
            RX: Pkts(66) Bytes(4406) Errs(0) Drops(82) Stalls(0)
            TX: Pkts(55) Bytes(2626) Errs(0) Drops(145) Stalls(0)
            NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted
               (0)
            Bandwidth thresholds are not set.

```

```

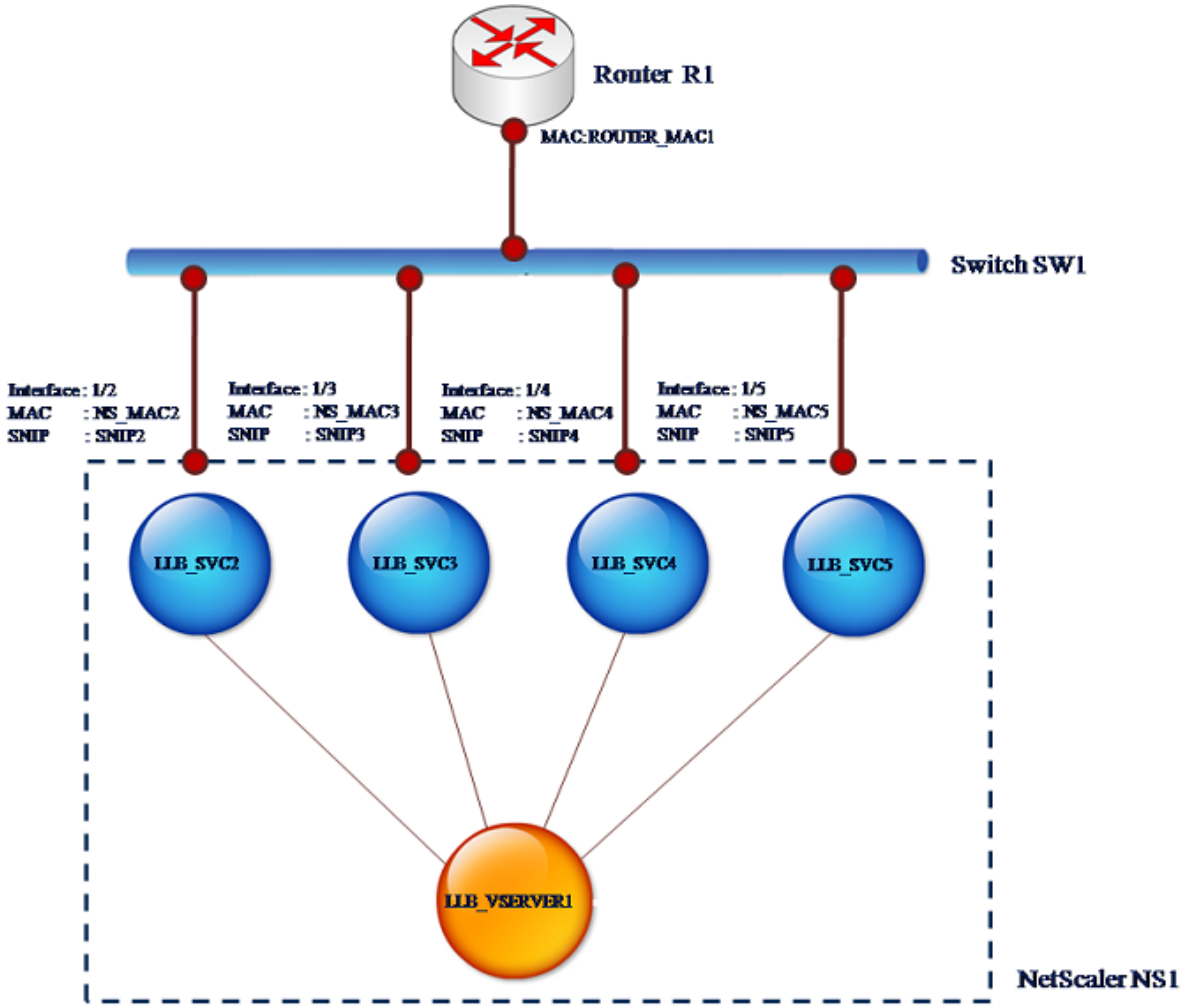
Binding an SNIP address to an Interface

September 14, 2021

You can now bind a Citrix ADC owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the Citrix ADC appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.



The following tables describe the example settings for the scenario:

Entity	Name	Value
SNIP addresses on NS1	SNIP2 (for reference purpose only)	10.10.10.2
	SNIP3 (for reference purpose only)	10.10.10.3
	SNIP4 (for reference purpose only)	10.10.10.4
	SNIP5 (for reference purpose only)	10.10.10.5
LLB virtual server on NS1	LLB_VSERVER1	-
Transparent monitor on NS1	TRANS_MON	-

Entity	Name	Value
LLB services on NS1	LLB_SVC2	10.10.10.240
	LLB_SVC3	10.10.10.120
	LLB_SVC4	10.10.10.60
	LLB_SVC5	10.10.10.30
MAC address of interface 1/2 on NS1	NS_MAC_2 (for reference purpose only)	00:e0:ed:0f:bc:e0
MAC address of interface 1/3 on NS1	NS_MAC_3 (for reference purpose only)	00:e0:ed:0f:bc:df
MAC address of interface 1/4 on NS1	NS_MAC_4 (for reference purpose only)	00:e0:ed:0f:bc:de
MAC address of interface 1/5 on NS1	NS_MAC_5 (for reference purpose only)	00:e0:ed:1c:89:53
IP address of Router R1	Router_IP (for reference purpose only)	10.10.10.1
MAC address of interface of R1	ROUTER_MAC1 (for reference purpose only)	00:21:a1:2d:db:cc

To configure the example settings:

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see Configuring Subnet IP Addresses (SNIPs).

   CLI example:

```
> add ns ip 10.10.10.2 255.255.255.0 -type SNIP
 Done
> add ns ip 10.10.10.3 255.255.255.128 -type SNIP
Done
> add ns ip 10.10.10.4 255.255.255.192 -type SNIP
Done
> add ns ip 10.10.10.5 255.255.255.224 -type SNIP
Done
<!--NeedCopy-->
```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see Set up basic load balancing.

CLI example:

```
> add service LLB_SVC2 10.10.10.240 any *
 Done
> add service LLB_SVC3 10.10.10.120 any *
 Done
> add service LLB_SVC4 10.10.10.60 any *
 Done
> add service LLB_SVC5 10.10.10.30 any *
 Done
<!--NeedCopy-->
```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see Configure monitors in a load balancing setup.

   CLI example:

```
> add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
 Done
> bind monitor TRANS_MON LLB_SVC2
 Done
> bind monitor TRANS_MON LLB_SVC3
 Done
> bind monitor TRANS_MON LLB_SVC4
 Done
> bind monitor TRANS_MON LLB_SVC5
 Done
<!--NeedCopy-->
```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see Configuring a Basic LLB Setup.

   CLI example:

```
> add lb vserver LLB_VSERVER1 any
 Done
> set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
```

```
 Done
<!--NeedCopy-->
```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see Configuring a Basic LLB Setup.

   CLI example:

```
> add lb route 0.0.0.0 0.0.0.0  LLB_VSERVER1
 Done
<!--NeedCopy-->
```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see Configuring Static ARP.

   CLI example:

```
> add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum
   1/2
 Done
> add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum
   1/3
 Done
> add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4
 Done
> add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5
 Done
<!--NeedCopy-->
```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see Configuring Static ARP.

   CLI example:

```
> add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
 Done
> add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
 Done
> add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
 Done
> add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
 Done
<!--NeedCopy-->
```

Monitor the Bridge Table and Changing the Aging time

September 14, 2021

Citrix ADC appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics. All the MAC entries in the bridge table are updated with the aging time.

To set the aging time of bridge table entries by using the CLI:

At the command prompt, type:

- **set l2param** -**bridgeagetimeout** <positive_integer>
- **show l2param**

Example:

```
> set l2param -bridgeagetimeout 90
 Done
<!--NeedCopy-->
```

To view the statistics of a bridge table by using the CLI:

At the command prompt, type:

- **stat bridge**

To set the aging time of bridge table entries by using the GUI:

Navigate to **System** > **Network**. On the **Network** page, in the **Settings** section, click **Configure Layer2 Parameters** and set the **Timeout Value For The Bridge Table Entries (seconds)** parameter.

To view the statistics of a bridge table by using the GUI:

Navigate to **System** > **Network** > **Bridge Table**, select the MAC address, and click **Statistics**.

Citrix ADC Appliances in Active-Active Mode Using VRRP

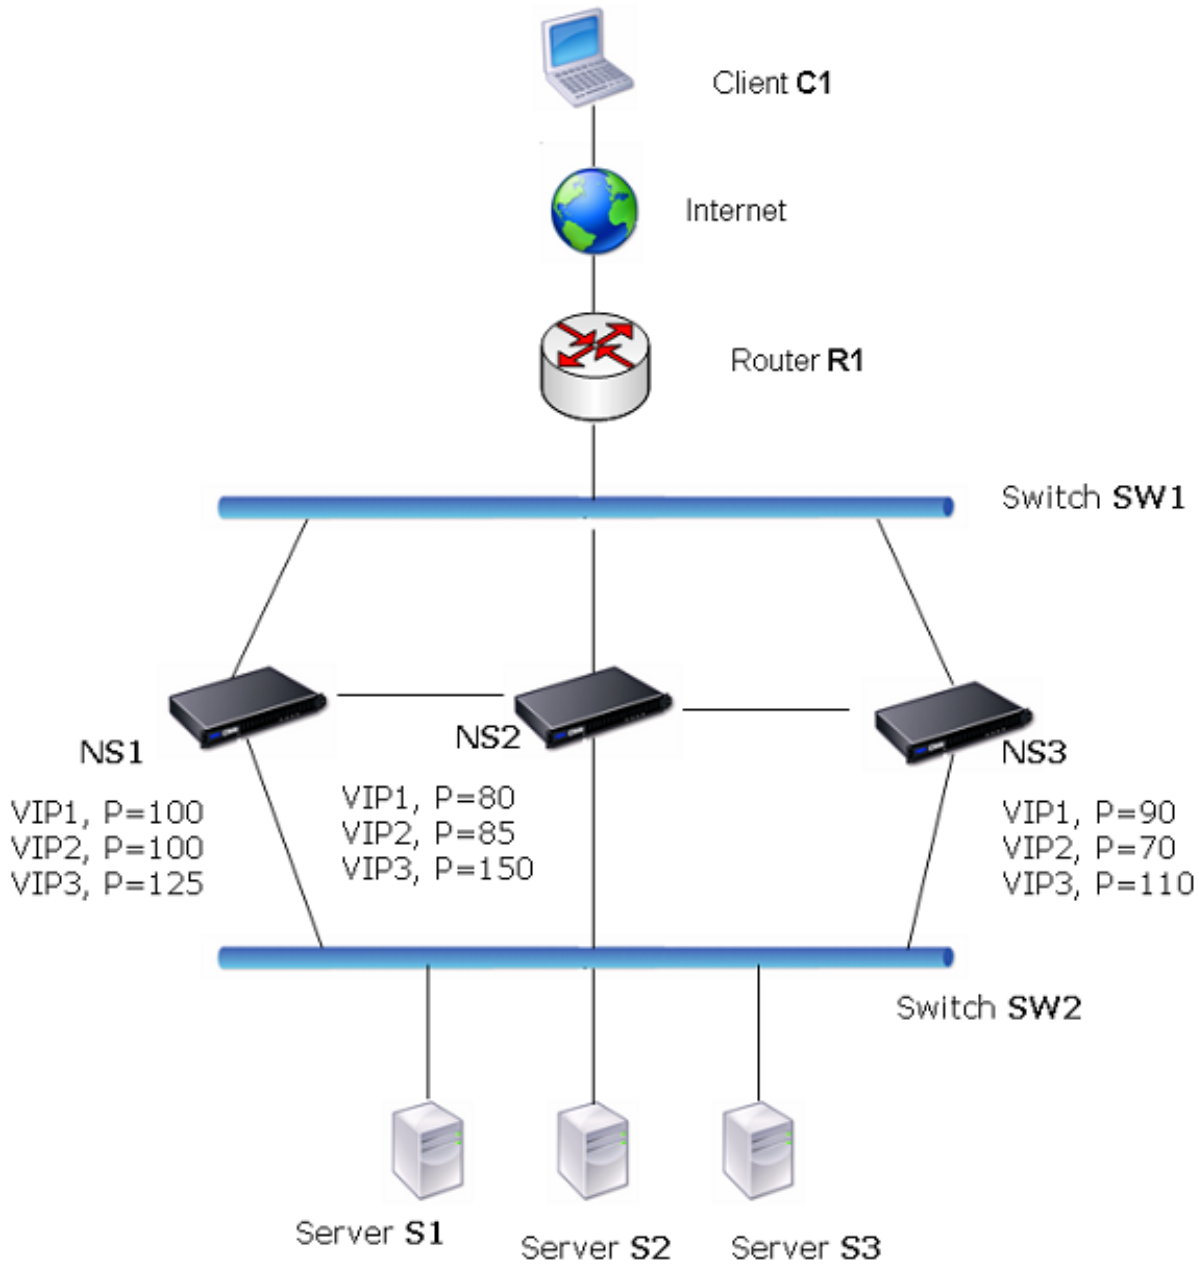
September 14, 2021

An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all Citrix ADC appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

The active VIP is called the master VIP, and the corresponding VIPs on the other Citrix ADC appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the Citrix ADC appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

Citrix ADC appliances in active-active mode can be configured so that no Citrix ADC is idle. In this configuration, different sets of VIPs are active on each Citrix ADC. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration



The Citrix ADC appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an ARP entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the virtual MAC (for example virtual MAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with virtual MAC1 and VIP1.

6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2.
8. S2 replies to the SNIP on the Citrix ADC.
9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the Citrix ADC appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, virtual MAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for virtual MAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

Health Tracking

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.
- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

Note: If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

Preemption

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

Sharing

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure **An Active-Active Configuration** VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

Configuring Active-Active Mode

September 14, 2021

On each Citrix ADC appliance that you want to deploy in active-active mode, you must add a virtual MAC and bind the virtual MAC to a VIP. The virtual MAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID (VRID) must be created on each Citrix ADC and bound to VIP 10.102.29.5 on each Citrix ADC. When you bind a virtual MAC to a VIP, the appliance sends VRRP advertisements to each VLAN that is bound to that VIP. The virtual MAC can be shared by different VIPs configured on the same Citrix ADC.

Configuring IPv4 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a virtual MAC address**. Add a virtual MAC address by adding a VRID. You can also specify a priority and enable or disable preemption and sharing on this VRID address.

- **Add a VIP address and associate the virtual MAC's VRID**. Add a VIP address and set the VRID parameter to the newly created VRID. The attributes of the VRID (for example, priority and preemption) are bound to this VIP address.
  Note: The same VIP address must be added to all the other Citrix ADC appliances.

To add a virtual MAC address by using the CLI

At the command prompt, type:

- **add vrID** <id> [-**priority** <positive_integer>] [-**preemption** (**ENABLED**|**DISABLED**)][-**sharing** (**ENABLED**|**DISABLED**)] [-**tracking** <tracking>]
- **show vrid**

To add a VIP address by using the CLI:

At the command prompt, type:

- **add ns ip** <IPv4Address> -type VIP -vrid <value>
- **show ns ip**

To configure a virtual MAC by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**, on the **VMAC** tab, add a new virtual MAC, or edit an existing virtual MAC.
2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Tracking
   - Preemption
   - Sharing

To configure a VIP address and associate the VRID to it by using the GUI:

1. Navigate to **System** > **Network** > **IPs**, on the **IPV4s** tab, add an IP address of type VIP.
2. While adding the IP address, select the virtual router ID from the **Virtual Router Id** drop down box.

Sample Configuration:

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv4 active-active mode. VIP address 203.0.113.10 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP address is bound to a virtual MAC address. 203.0.113.10 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100).

```
1     Settings on NS1
2
3     > add vrid 10 -Priority 100 -Preemption Enabled -sharing Enabled
4
```

```
5      Done
6
7      > add ns ip 203.0.113.10  -type VIP  -vrid 10
8
9      Done
10
11     Settings on NS2
12
13     > add vrid 10  -Priority 200  -Preemption Enabled  -sharing Enabled
14
15     Done
16
17     > add ns ip 203.0.113.10  -type VIP  -vrid 10
18
19     Done
20 <!--NeedCopy-->
```

Configuring IPv6 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a virtual MAC6 address**. Add a virtual MAC6 address by adding a VRID6. You can also specify a priority and enable or disable preemption and sharing on this VRID6 address.
- **Add a VIP6 address**. Add a VIP6 address. Set the VRID6 parameter to the VRID6 of the newly created virtual MAC6.The attributes of the virtual MAC6 (for example, priority and preemption) are bound to this VIP6 address.
  Note: The same VIP6 address must be added to all the other Citrix ADC appliances.

To add a virtual MAC6 address by using the CLI:

At the command prompt, type:

- **add vrID6** <id> [-**priority** <positive_integer>] [-**preemption** (**ENABLED** | **DISABLED**)] [-**sharing** (**ENABLED** | **DISABLED**)]
- **show vrID6**

To add a VIP6 address by using the CLI:

At the command prompt, type:

- **add ns ip6** <IPv6Address> -**type** VIP -**vrid** <value>
- **show ns ip6**

To configure a virtual MAC6 by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**, on the **VMAC6** tab, add a new virtual MAC6, or edit an existing **VMAC6**.
2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Preemption
   - Sharing

To configure a VIP6 address and associate the VRID to it by using the GUI:

1. Navigate to **System** > **Network** > **IPs**, on the **IPV6s** tab, add an IPv6 address of type VIP.
2. While adding the VIP6 address, select the VRID6 from the **Virtual Router Id** drop down box.

Sample Configuration:

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv6 active-active mode. VIP6 address 2001:db8::5001 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP6 address is bound to a virtual MAC6 address. 2001:db8::5001 is master on NS2, because it's priority (200) on NS2 is higher than on NS1 (100).

```
    Settings on NS1
    > add vrid6 10 -Priority 100 -Preemption Enable -sharing Enable

    Done
    > add ns ip6 2001:db8::5001 -type VIP -vrid6 10

    Done
    Settings on NS2
    > add vrid6 10 -Priority 200 -Preemption Enable -sharing Enable

    Done
    > add ns ip6 2001:db8::5001 -type VIP -vrid6 10

    Done
<!--NeedCopy-->
```

Configuring Send to Master

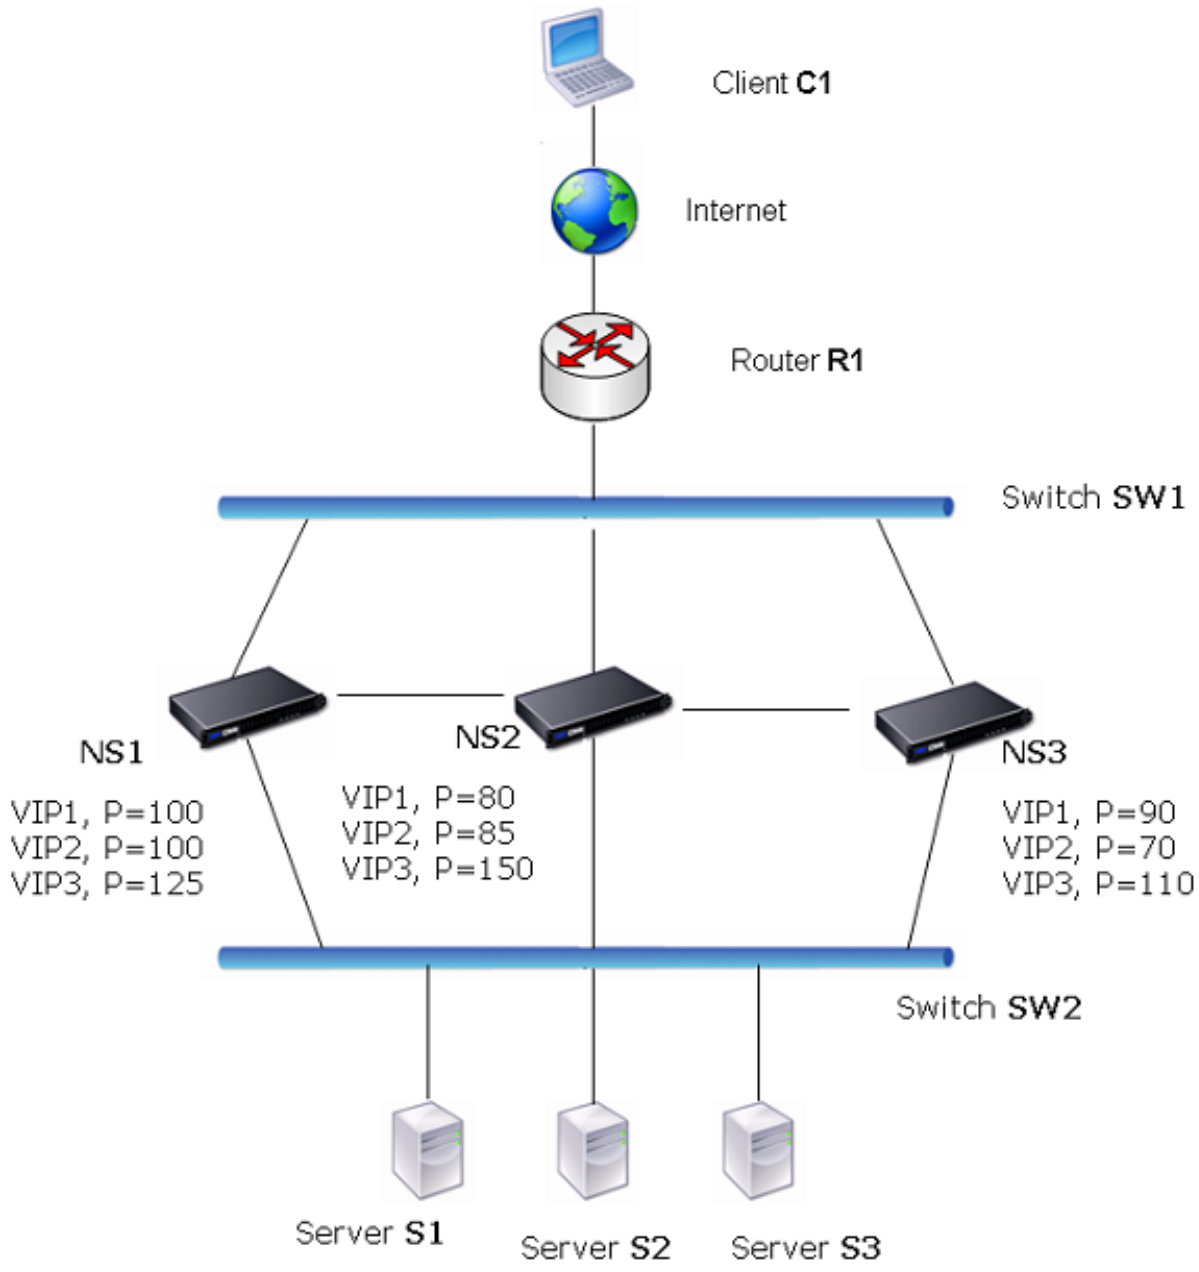
September 14, 2021

Usually, the traffic destined to a VIP reaches the Citrix ADC appliance on which the VIP is active, because an ARP request with the VIP and a virtual MAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet,

or a topology that blocks this route, the traffic can reach a Citrix ADC appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled



To enable send to master by using the CLI:

At the command prompt, type:

```
set vrIDParam -sendToMaster (ENABLED          DISABLED)
```

Example:

```
> set vrIDParam -sendToMaster ENABLED
 Done
<!--NeedCopy-->
```

To enable send to master by using the GUI:

1. Navigate to **System** > **Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. Select the **Send to Master** option.

Configuring VRRP Communication Intervals

September 14, 2021

In an active-active deployment, all Citrix ADC nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval**. Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.
- **Dead Interval**. Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

To configure VRRP communication intervals by using the CLI:

At the command prompt, type:

- **set vrIDParam** [-**helloInterval** <msecs>] [-**deadInterval** <secs>]
- **sh vrIDParam**

Example:

```
> set vrIDParam -helloInterval 500 -deadInterval 2
 Done
<!--NeedCopy-->
```

To configure VRRP communication intervals by using the GUI:

1. Navigate to **System** > **Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. In **Configure Virtual Router Parameter**, set the **Hello Interval** and **Dead Interval** parameters.

3. Click **OK**.

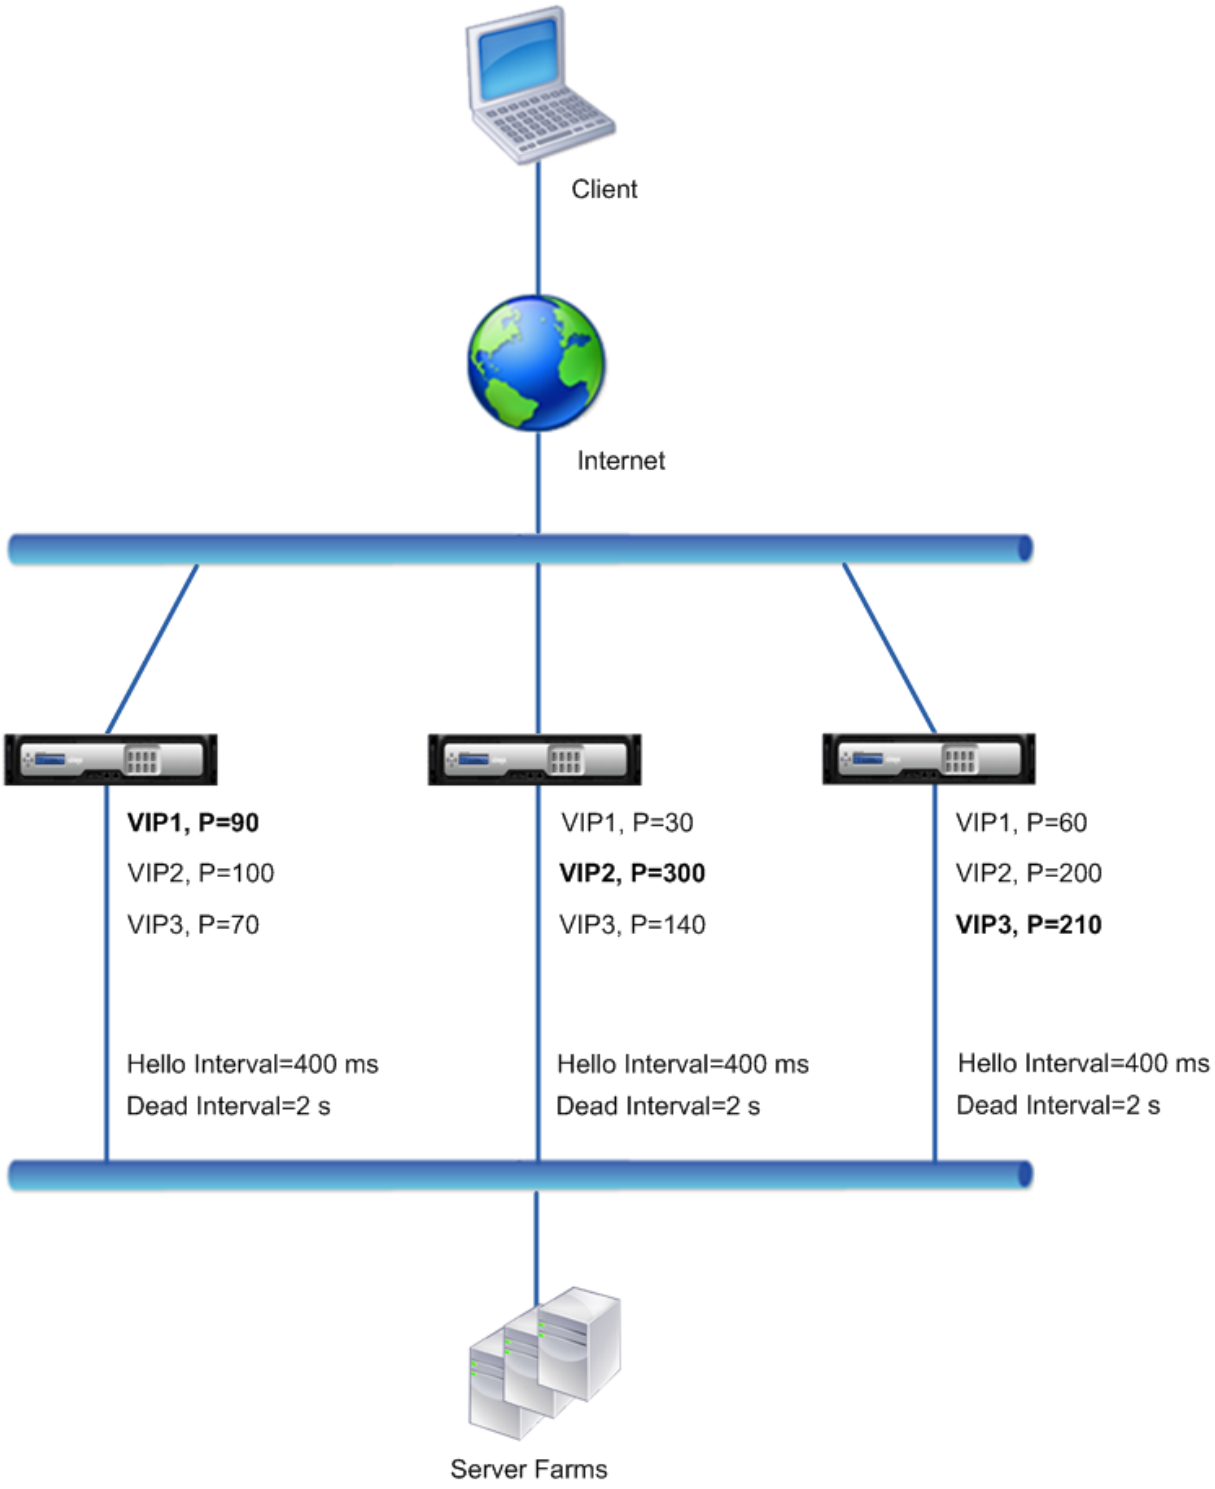
Example 1: Nodes with the Same VRRP Dead Intervals

Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes. The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn, apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node. Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: VRRP interval example 1 settings.



The execution flow is as follows:

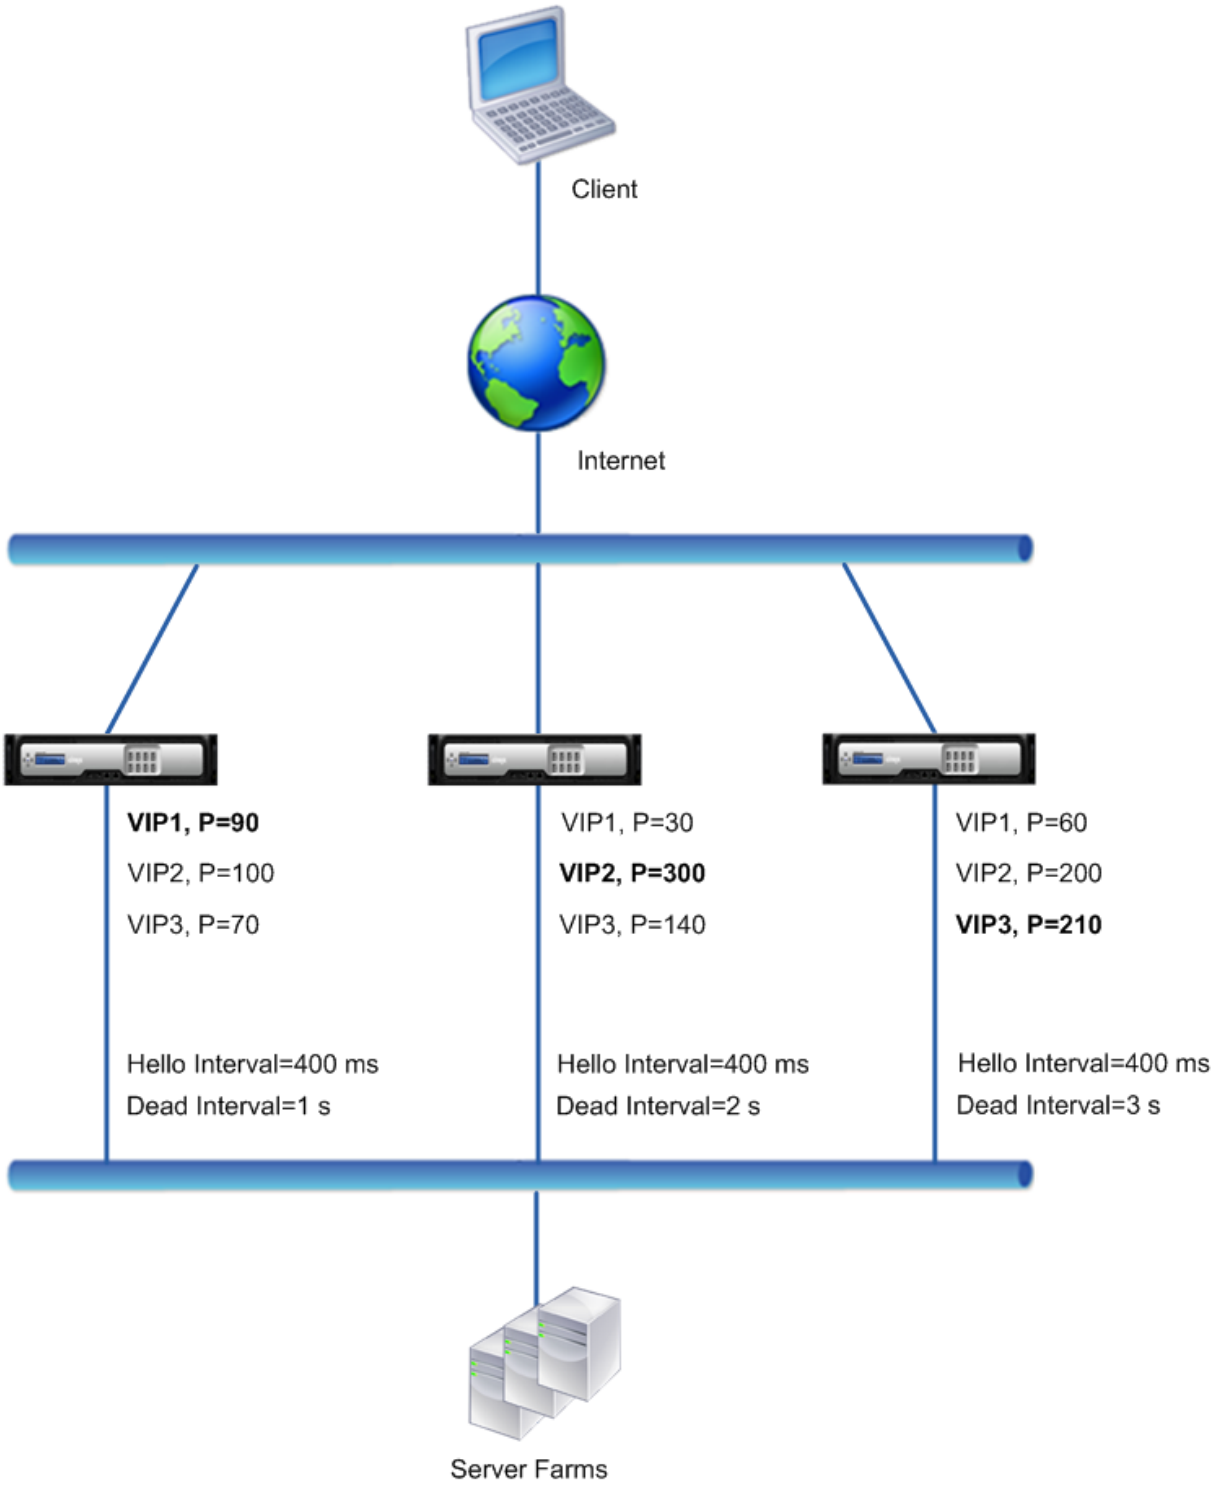
1. NS1 sends hello messages at a set hello interval of 400 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages for VIP2, and NS3 sends hello messages for VIP3.

2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master) because its VRID priority (60) is higher than that of VIP1 of NS2 (30).

Example 2: Nodes with Different VRRP Dead Intervals

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: VRRP interval example 2 settings.



The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages

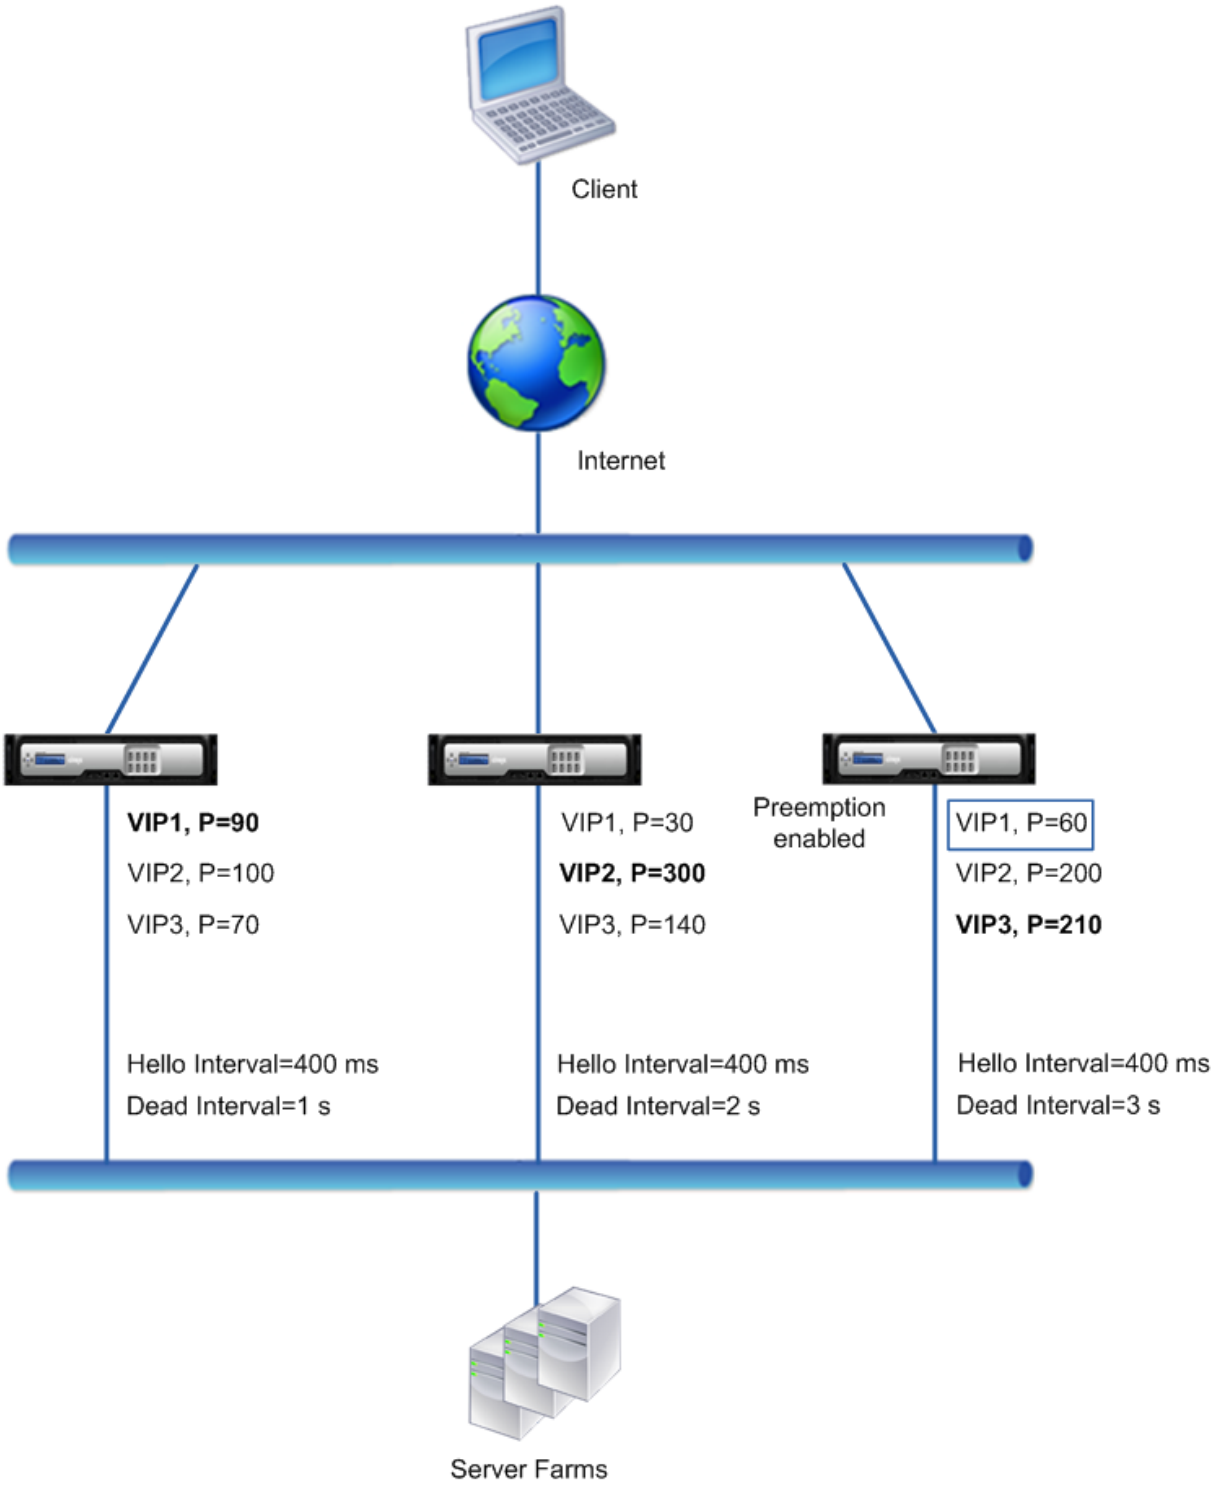
for VIP1.

Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3's larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

Example 3: Nodes with Different Dead Intervals and Preemption Enabled

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example: VRRP interval example 3 settings.



The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to down after not receiving any hello messages from NS1 for 2 seconds (NS2's set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.

2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

Configuring Health Tracking based on Interface State

September 14, 2021

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address when the state of an interface on the node changes. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP. This feature is a per node configuration for each VIP address.

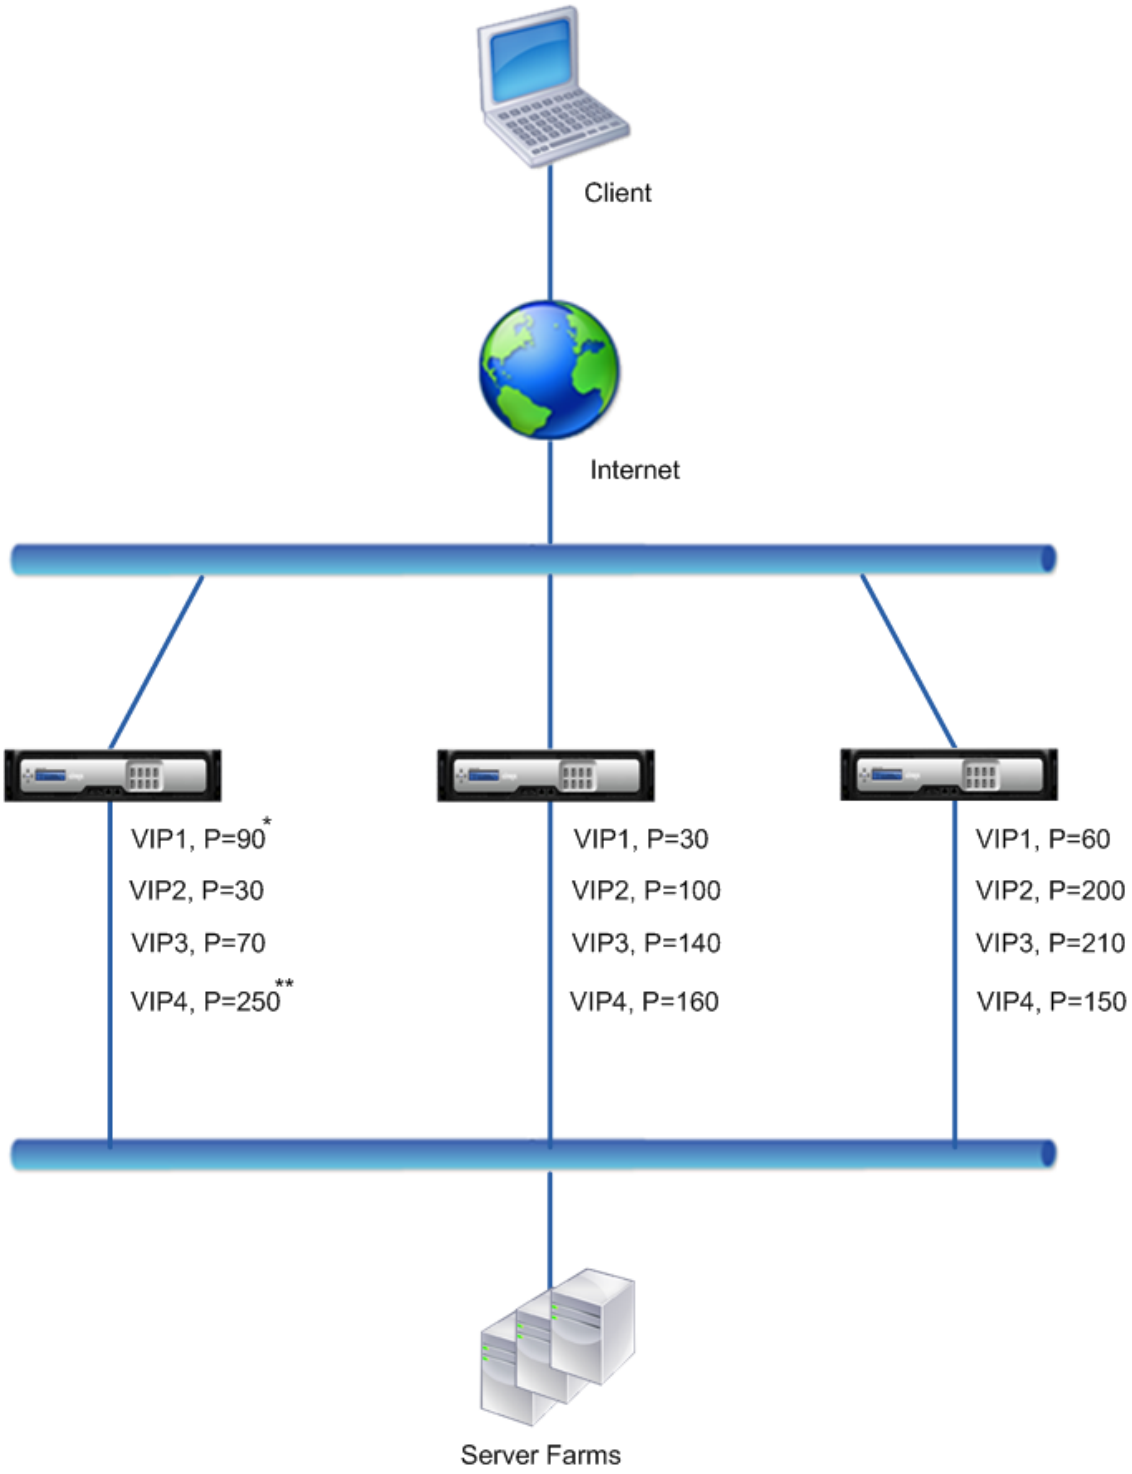
Example

Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (trackifNumPriority) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example: Health tracking example settings.



* Packet Interfaces = 1/2, 1/3, 1/5
Reduced Priority = 20

** Packet Interfaces = 1/5, 1/7
Reduced Priority = 55

The execution flow is as follows on NS1 when multiple interface on NS1 goes down:

1. If interface 1/3 goes down, the priority of address VIP1 is reduced by 20 (VIP1's reduced priority value), because interface 1/3 is associated with VIP1:
   - Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of address VIP1 is further reduced:
   - Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4's reduced priority value (55).
   - Effective priority of VIP4 = (250 - 55) = 195
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
   - Effective priority of VIP4 = (Current priority - reduced priority) = (195-55) = 145
6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

Configuration Steps for IPv4 Active-Active Mode

To configure this feature on a node for a VIP address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (trackifNumPriority) value.

To set reduced priority and bind interfaces to the virtual router ID by using the CLI:

At the command prompt, type:

- **set vrID** <id> [-**trackifNumPriority** <positive_integer>]
- **bind vrID** <id> -**trackifNum** <interface_name>
- **show vrID** <id>

Example:

```
    > set vrID 125 -trackifNumPriority 10
    Done

    > bind vrID 125 -trackifNum 1/4 1/5
    Done
<!--NeedCopy-->
```

To set reduced priority and bind interfaces to the virtual router ID by using the GUI:

1. Navigate to **System** > **Network** > **VMAC.**
2. On the **VMACs** tab, select a virtual router ID, and click **Edit**.
3. Under **Configure virtual MAC**, set the **Reduced Priority** parameter.
4. Select the **Interfaces tracked for the VRID** option and, under **Associate Interfaces**, add interfaces to the virtual router ID.

Configuration Steps for IPv6 Active-Active Mode

To configure this feature on a node for a VIP6 address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP6 address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP6 address by the configured Reduced Priority (trackifNumPriority) value.

To change the priority of a VIP address automatically by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new virtual MAC6:
  - **add vrID6** <id> [-**trackifNumPriority** <positive_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface_name>
  - **show vrID6** <id>
- If reconfiguring an existing virtual MAC6:
  - **set vrID6** <id> [-**trackifNumPriority** <positive_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface_name>
  - **show vrID6** <id>

Example:

```
    > set vrID6 130 -trackifNumPriority 10
    Done

    > bind vrID6 130 -trackifNum 1/4 1/5
    Done
<!--NeedCopy-->
```

Delaying Preemption

September 14, 2021

By default, a backup VIP address preempts the master VIP address immediately after its priority becomes higher than that of the master VIP. When configuring a backup VIP address, you can specify an amount of time by which to delay the preemption. Preemption delay time is a per-node setting for each backup VIP address.

The preemption delay setting for a backup VIP does not apply in the following conditions:

- The node of the master VIP goes down. In this case, the backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.
- The priority of the master VIP is set to zero. The backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.

Example: Delaying Preemption

Consider an active-active deployment consisting of Citrix ADC appliances NS1 and NS2. Virtual IP address VIP1 is configured on each of these appliances. Because of their priorities, VIP1 is master on NS2. Preemption is enabled and preemption delay time is set for VIP1 on these two nodes.

The following table lists the settings used in this example.

Entity and Parameters	Settings on NS1	Settings on NS2
VIP1 (for reference purposes only)	**IP address:** 192.0.1.10, **VRID:** 10, **Priority:** 100, **Preemption:** Enabled, **Preemption delay time:** 1000 seconds	**IP address:** 192.0.1.10, **VRID: 10**, **Priority:** 200, **Preemption:** Enabled, **Preemption delay time:** 2000 seconds
Dead Interval	1 Seconds	2 Seconds

Following are some examples of possible preemption behavior in this setup:

- If the priority of VIP1 on NS1 is set to a value (for example, 210) higher than that of VIP1 on NS2, VIP1 on NS1 takes over as master after its set preemption delay time (1000 secs).
- If a third node NS3 with the following VRRP settings is added to this deployment, VIP1 on NS3 becomes master after its set preemption delay time (3000 secs).
  - VIP1
    - VRID: 30
    - IP address:
    - Priority = 300
    - Preemption delay time = 3000 seconds
- If NS2 goes down, VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

- If NS2 goes down and NS1 restarts, VIP1 on NS1 becomes master 1 second (set dead interval on NS1) after NS1 comes up. Preemption delay time for VIP1 on NS1 does not apply in this case.
- If the priority of VIP1 on NS2 is set to zero, VIP1 goes to standby mode. VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

Configuring Delay Preemption for IPv4 Active-Active Mode

To configure preemption delay time for a VIP address, you set the preemption delay timer parameter of the associated virtual MAC address. You can the set this parameter when you add the address, or you can modify an existing virtual MAC address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a virtual MAC, at the command prompt, type:
  - **add vrID** <id> -**preemptiondelaytimer** <secs>
  - **show vrID**
- To set the preemption delay time while modifying a virtual MAC, at the command prompt, type:
  - **set vrID** <id> -**preemptiondelaytimer** <secs>
  - **show vrID**

To configure preemption delay time by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMAC** tab. While adding a new virtual MAC, or editing an existing virtual MAC, set the **Preemption Delay Timer** parameter.

Sample configuration:

The following configuration uses the settings listed in table in section Example: Delaying Preemption.

```
1     Settings on NS1
2
3     > set vrid param  -deadInterval 1
4
5     Done
6
7     > add ns ip 192.0.1.10 255.255.255.255  -type VIP
8
9     Done
10
11    > add vrid 10  -Priority 100  -Preemption Enable  -
         preemptiondelaytimer 1000
12
13    Done
14
```

```
15      > bind ns ip 192.0.1.10 255.255.255.255 -vrid 10
16
17      Done
18
19      Settings on NS2
20
21      > set vrid param -deadInterval 2
22
23      Done
24
25      > add ns ip 192.0.1.10 255.255.255.255 -type VIP
26
27      Done
28
29      > add vrid 20 -Priority 200 -Preemption Enable -
            preemptiondelaytimer 2000
30
31      Done
32
33      > set ns ip 192.0.1.10 255.255.255.255 -vrid 10
34
35      Done
36  <!--NeedCopy-->
```

Configuring Delay Preemption for IPv6 Active-Active Mode

To configure preemption delay time for a VIP6 address, you set the preemption delay timer parameter of the associated virtual MAC6 address. You can the set this parameter when you add the virtual MAC6 address, or you can modify an existing virtual MAC6 address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a virtual MAC6, at the command prompt, type:
  - **add vrID6** <id> -**preemptiondelaytimer** <secs>
  - **show vrID6**
- To set the preemption delay time while modifying a virtual MAC6, at the command prompt, type:
  - **set vrID6** <id> -**preemptiondelaytimer** <secs>
  - **show vrID6**

To configure preemption delay time by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**.

2. On the **VMAC6** tab. While adding a virtual MAC6 address, or editing an existing virtual MAC6 address, set the **Preemption Delay Timer** parameter.

Keeping a VIP Address in the Backup State

September 14, 2021

You can force a VIP address to always stay in backup state. This operation is helpful in maintenance or testing of a VRRP deployment.

When a VIP address is forced to stay in backup state, it does not participate in VRRP state transitions. Also, it cannot become master even if all other nodes go down.

To force a VIP address to stay in backup state, you set the priority of the associated virtual MAC address to zero. To ensure that none of the VIP addresses of a node handle traffic during a maintenance process on the node, set all the priorities to zero.

You can the set the priority of a virtual MAC address while adding or modifying the address.

To force a VIP address to stay in the backup state by using the CLI:

- To set the priority while adding a virtual MAC, at the command prompt, type:
  - **add vrID** <id> -**priority** 0
  - **show vrID**
- To set the priority while modifying a virtual MAC, at the command prompt, type:
  - **set vrID** <id> -**priority** 0
  - **show vrID**

To force a VIP address to stay in backup state by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMAC** tab, while adding a new virtual MAC or editing an existing virtual MAC, set the **Priority** parameter to zero.

Network Visualizer

September 14, 2021

The network visualizer shows a graphical view of all the interfaces, channels, VLANs, IP addresses, and bindings to VLANs on a Citrix ADC appliance. An enabled interface or channel has a black label. A disabled interface or channel has a red label.

This complete picture of the appliance's network connections can be useful for detecting flaws in the network design and for optimizing the network. It can also help a new administrator easily understand the appliance's network configuration.

To open the Network Visualizer:

Navigate to **System** > **Network**. In **Monitor Connections**, click **Network Visualizer**.

Configuring Link Layer Discovery Protocol

September 14, 2021

The Citrix ADC supports the industry standard (IEEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the Citrix ADC to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbour devices.

> **Note:**
> Link Layer Discovery Protocol (LLDP) is supported only in Citrix ADC MPX platforms.

Using LLDP, the Citrix ADC transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs). An LLDPU is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The Citrix ADC sends the following TLVs in each LLDPU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

Note: You cannot specify the TLVs to be sent in LLDP messages.

Citrix ADC interfaces support the following LLDP modes:

- **NONE**. The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER**. The interface transmits LLDP messages to the directly connected device but does not receive LLDP messages from the directly connected device.

- **RECEIVER**. The interface receives LLDP messages from the directly connected device but does not transmit LLDP messages to the directly connected device.
- **TRANSCEIVER**. The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings: Interface and global level LLDP modes.

Note the following points related to LLDP messages transmitted or received by the Citrix ADC:

- **Transmitting LLDP messages.** The Citrix ADC transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

  Following are the global LLDP transmitting parameters on the Citrix ADC:

  - **Timer**. Interval, in seconds, between LLDPUs that the Citrix ADC sends to a directly connected device.
  - **Holdtime Multiplier**. A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the **Holdtime Multiplier** parameter value multiplied by the Timer parameter value.

- **Receiving LLDP Messages.** The Citrix ADC stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The Citrix ADC retains this LLDP information for the duration specified in the received LLDPU.

  If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.

Configuration Steps

Configuring LLDP on a Citrix ADC appliance consists of the following tasks:

1. **Set global level LLDP parameters.** In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.
2. **Set the interface level LLDP parameters.** In this task, you set the LLDP mode for an interface.
3. **(Optional) Display neighbor-device information.** You can display the neighbor-device LLDP information collected on all of the Citrix ADC's interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a Citrix ADC:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).
2. Verify that you have configured LLDP on the desired directly connected devices.

CLI procedures

To set global level LLDP parameters by using the CLI:

At the command prompt, type:

- set lldp param [-[-holdtimeTxMult <positive_integer>][-timer <positive_integer>] [-Mode <Mode>]
- show lldp param

To configure an interface for LLDP by using the CLI:

At the command prompt, type:

- set interface <id> -lldpmode <lldpmode>
- show interface <id>

To display neighbor device information by using the CLI:

At the command prompt, type one of the following commands:

- show lldp neighbors
- show lldp neighbors <ifnum>

GUI procedures

To set the global level LLDP parameters by using the GUI:

1. Navigate to System > Network, and click Configure LLDP Parameters.
2. Set the following parameters:
    - Hold Timer Multiplier
    - Timer
    - Mode

To configure an interface for LLDP by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the GUI:

Navigate to System > Network > Interfaces and, in the Action list, select View LLDP Neighbors.

LLDP Support in a Cluster Setup

In a cluster setup, the GUI and CLI display the LLDP neighbour configuration of all or specific cluster nodes when the GUI or CLI is accessed through the Cluster IP address (CLIP). Any change made to the global level LLDP mode is applied to the global level LLDP mode on each of the cluster nodes.

Consider an example of a cluster setup of three nodes, NS1, NS2, and NS3. Each of these nodes are connected to both routers Router-1 and Router-2. The following output is displayed when the **show lldp neighbor -summary** operation is performed on the Cluster CLI that is accessed through the Cluster IP address (CLIP) of the cluster setup. The output shows the LLDP neighbour information of all these nodes.

```
> show lldp neighbor -summary

Node Id: 1
------------------------------------------------------------
    Interface    ChassisId           PortId     System name
------------------------------------------------------------
1     1/1/1      fe:c7:3b:13:bd:11    1/1         Router-1

2     1/1/2      12:68:7b:9e:4c:11    1/1         Router-2

Node Id: 2
------------------------------------------------------------
    Interface    ChassisId           PortId     System name
------------------------------------------------------------
1     2/1/1      fe:c7:3b:13:bd:12    1/2        Router-1

2     2/1/2      12:68:7b:9e:4c:12    1/2        Router-2

Node Id: 3
------------------------------------------------------------
    Interface    ChassisId            PortId     System name
------------------------------------------------------------

1     3/1/1       fe:c7:3b:13:bd:13    1/3        Router-1

2     3/1/2       12:68:7b:9e:4c:13    1/3        Router-2

Done
<!--NeedCopy-->
```

Jumbo Frames

September 14, 2021

Citrix ADC appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A Citrix ADC appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The Citrix ADC appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS

Configuring Jumbo Frames Support on a Citrix ADC Appliance

September 14, 2021

To enable the Citrix ADC appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the Citrix ADC appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a Citrix ADC appliance

1. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
2. The MTU for a channel is propagated to all the bound interfaces.
3. When an interface is bound to the channel whose MTU is different from the interface's MTU, the interface goes onto the inactive list.
4. When you change the MTU of a member interface, the interface goes onto the inactive list.

5. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
6. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
7. You cannot set the MTU on the default VLAN. The Citrix ADC appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
8. For TCP based traffic on a load balancing configuration on a Citrix ADC appliance, MSSs are set accordingly at each end point for supporting jumbo frames:
    - For a connection between a client and a load balancing virtual server on the Citrix ADC appliance, the MSS on the Citrix ADC appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
    - For a connection between the Citrix ADC appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the Citrix ADC appliance.
    - By default, a TCP profile nstcp_default_profile is bound to all TCP based load balancing servers and services on the Citrix ADC appliance.
    - For supporting jumbo frames, you can either change the MSS value of the TCP profile nstcp_default_profile, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.
    - The default MSS value of any TCP profile is 1460.

CLI procedures

To set the MTU of an interface by using the CLI:

At the command prompt, type:

- set interface <id> -mtu <positive_integer>
- show interface <id>

Example:

```
> set interface 10/1  - mtu 9000
Done
<!--NeedCopy-->
```

To set the MTU of a channel by using the CLI:

At the command prompt, type:

- set channel <id> -mtu <positive_integer>
- show channel <id>

Example:

```
> set channel LA/1  - mtu 9000
Done
<!--NeedCopy-->
```

To set the MTU of a VLAN by using the CLI:

At the command prompt, type:

- add vlan <id> -mtu <positive_integer>
- show vlan <id>

Example:

```
> set vlan 20  - mtu 9000
Done
<!--NeedCopy-->
```

GUI procedures

To set the MTU of an interface by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the GUI:

Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the GUI:

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

Use Case 1 – Jumbo to Jumbo Setup

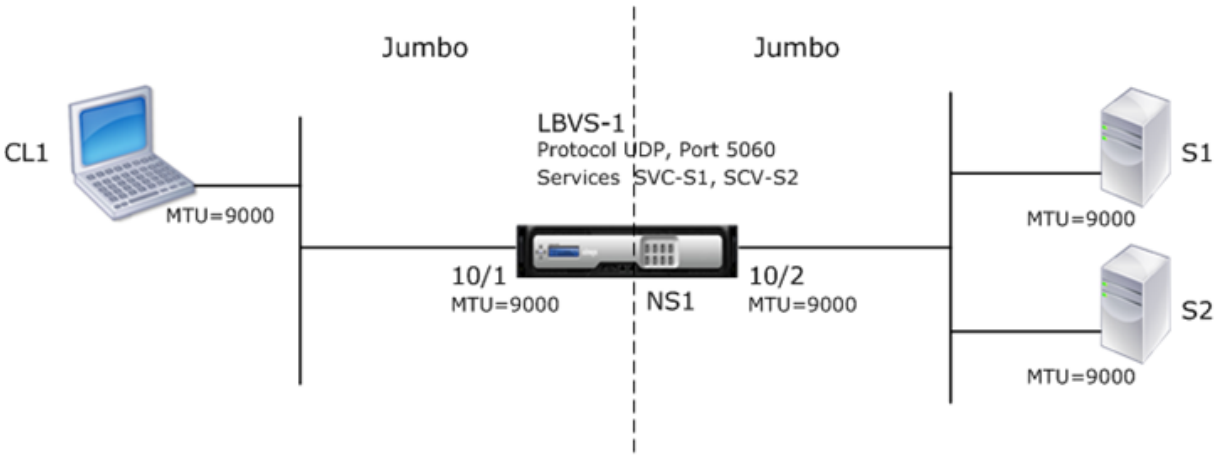
September 14, 2021

Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on Citrix ADC appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.



The following table lists the settings used in the example.

Entity	Name	Details
IP address of client CL1	-	192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	9000
	10/2	9000
	VLAN 10	9000
	VLAN 20	9000
Services on NS1 representing servers	SVC-S1	**IP address:** 198.51.100.19, **Protocol:** SIP, **Port:** 5060
	SVC-S2	**IP address:** 198.51.100.20, **Protocol:** SIP, **Port:** 5060

Entity	Name	Details
Load balancing virtual server on VLAN 10	LBVS-1	**IP address:** 203.0.113.15, **Protocol:** SIP, **Port:** 5060, **Bound services:** SVC-S1, SVC-S2

Following is the traffic flow of CL1's request to NS1:

1. CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
2. CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 2048] = 2068
3. NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
4. NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
5. LBVS-1's load balancing algorithm selects server S1.
6. NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 2048] = 2068

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.
2. S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000

- Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
- Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.
4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.
5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1's IP address.
   - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
   - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
   - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

Configuration Tasks

The following table list the tasks, Citrix ADC commands, and examples for creating the required configuration on the Citrix ADC appliance.

Task	Citrix ADC Command Syntax	Example
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer>, show interface <id>	set int 10/1 -mtu 9000 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer>, show vlan <id>	add vlan 10 -mtu 9000 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan <id> -ifnum <interface_name>, show vlan <id>	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP, show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP

Task	Citrix ADC Command Syntax	Example
Create services representing SIP servers	add service <serviceName> <ip> SIP_UDP <port>, show service <name>	add service SVC-S1 198.51.100.19 SIP_UDP 5060 add service SVC-S2 198.51.100.20 SIP_UDP 5060
Create SIP load balancing virtual servers and bind the services to it	add lb vserver <name> SIP_UDP <ip> <port> bind lb vserver <vserverName> <serviceName>, show lb vserver <name>	add lb vserver LBVS-1 SIP_UDP 203.0.113.15 5060 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Save the configuration	save ns config, show ns config	

Use Case 2 – Non-Jumbo to Jumbo Setup

September 14, 2021

Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.

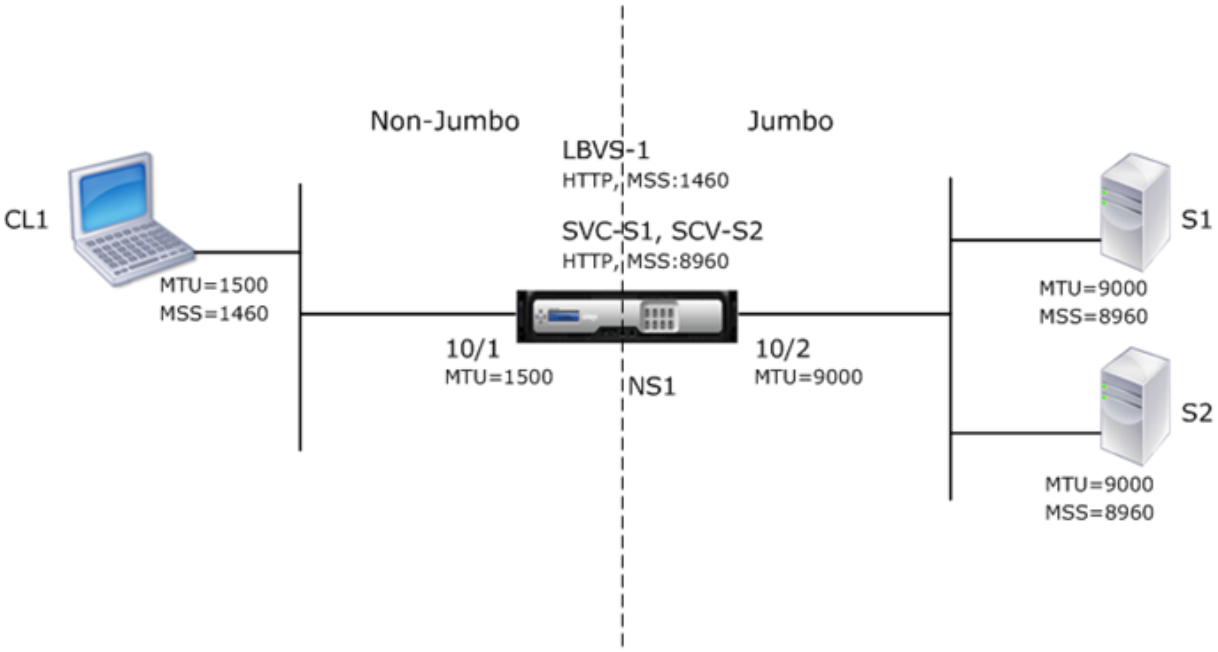
Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S1) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp_default_profile is used that is by default bound to LBVS-1 and

has the MSS set to the default value of 1460.



The following table lists the settings used in this example.

Entity	Name	Details
IP address of client CL1		192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	1500
	10/2	9000
	VLAN 10	1500
	VLAN 20	9000
Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	NS1-SERVERS-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	IP address: 198.51.100.19, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)

Entity	Name	Details
	SVC-S2	IP address: 198.51.100.20, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
Load balancing virtual server on VLAN 10	LBVS-1	IP address = 203.0.113.15, Protocol: HTTP, Port:80, Bound services: SVC-S1, SVC-S2, TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1's MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.

   Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240
4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
6. Because S1's MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.

   Size of the request packet = [IP Header + TCP Header + [TCP Request] = [20 + 20 + 200] = 240

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
   - Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000

- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

3. NS1 receives the response packets at interface 10/2.
4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
   - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

Configuration Tasks

The following table list the tasks, Citrix ADC commands, and examples for creating the required configuration on the Citrix ADC appliance.

Tasks	CLI Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer>, show interface <id>	set int 10/1 -mtu 1500 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer>, show vlan <id>	add vlan 10 -mtu 1500 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan <id> -ifnum <interface_name>, show vlan <id>	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP, show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing HTTP servers	add service <serviceName> <ip> HTTP <port>, show service <name>	add service SVC-S1 198.51.100.19 http 80, add service SVC-S2 198.51.100.20 http 80

Tasks	CLI Syntax	Examples
Create HTTP load balancing virtual servers and bind the services to it	add lb vserver <name> HTTP <ip> <port>, bind lb vserver <vserverName> <serviceName>, show lb vserver <name>	add lb vserver LBVS-1 http 203.0.113.15 80, bind lb vserver LBVS-1 SVC-S1, bind lb vserver LBVS-1 SVC-S2
Create a custom TCP profile and set its MSS for supporting jumbo frames	add tcpProfile <name> -mss <positive_integer>, show tcpProfile <name>	add tcpprofile NS1-SERVERS-JUMBO -mss 8960
Bind the custom TCP profile to the desired services	set service <Name> -tcpProfileName <string>, show service <name>	set service SVC-S1 -tcpProfileName NS1-SERVERS-JUMBO, set service SVC-S2 -tcpProfileName NS1-SERVERS-JUMBO
Save the configuration	save ns config, show ns config	

Use Case 3 – Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

September 14, 2021

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on Citrix ADC appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.

CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

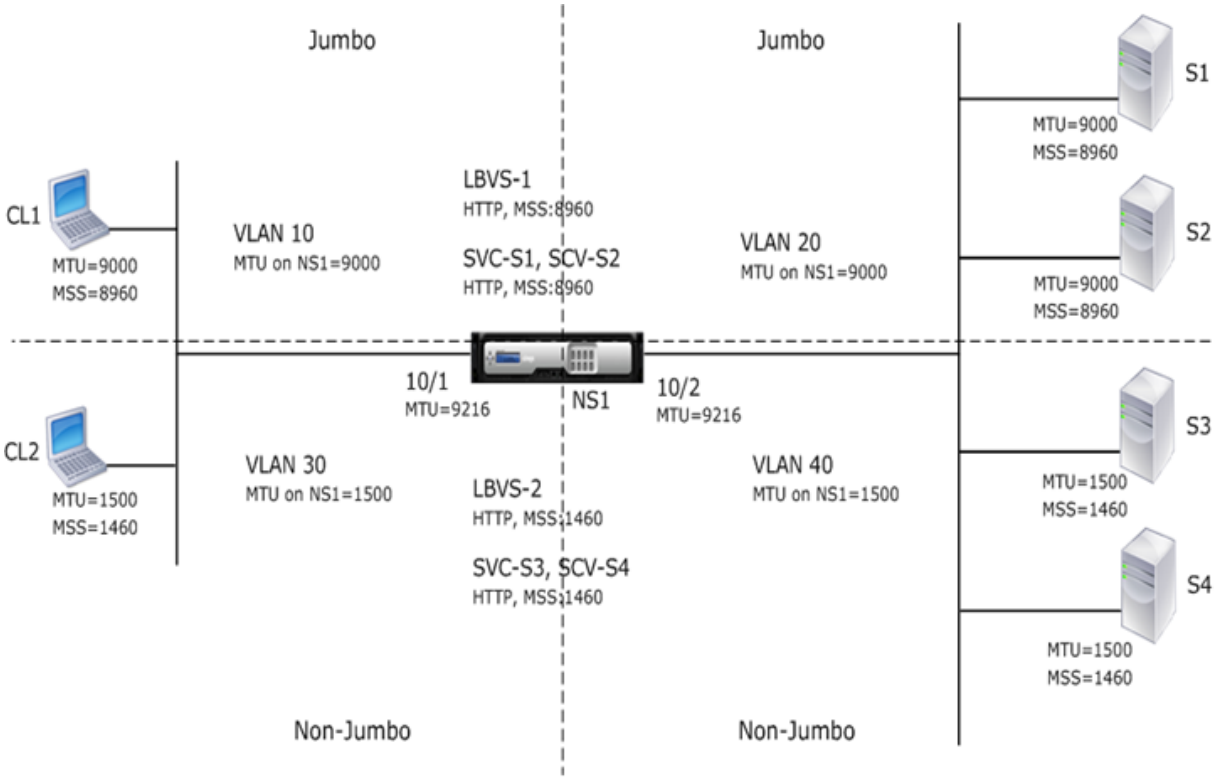
The effective MTU on a Citrix ADC interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.



The following table lists the settings used in this example: Jumbo frames use case 3 example settings.

Following is the traffic flow of CL1's request to S1:

1. Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.
3. Because NS1's MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 10 to NS1.
   - Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
4. NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
5. From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
6. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
7. NS1 segments the request data into multiples of S1's MSS and sends these segments in IP pack-

ets tagged as VLAN 20 to S1.

- Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1's response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
   - Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS's IP address and destined to CL1's IP address.
   - Size of first three packet = [IP Header + TCP Header + [(TCP payload=CL1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

Configuration Tasks

Following table lists tasks, commands, and examples for creating the required configuration on the Citrix ADC appliance: Jumbo frames use case 3 configuration tasks.

Citrix ADC Support for Microsoft Direct Access Deployment

September 14, 2021

Microsoft Direct Access is a technology that enables remote users to seamlessly and securely connect to the enterprise's internal networks, without the need to establish a separate VPN connection. Un-

like VPN connections, which require user intervention to open and close connections, a Direct Access-enabled client connects automatically to the enterprise's internal networks whenever the client connects to the Internet.

Manage-Out is a Microsoft Direct Access feature that allows administrators inside the enterprise network to connect to Direct Access clients outside the network and manage them (for example, performing administration tasks, such as scheduling service updates, and providing remote support.

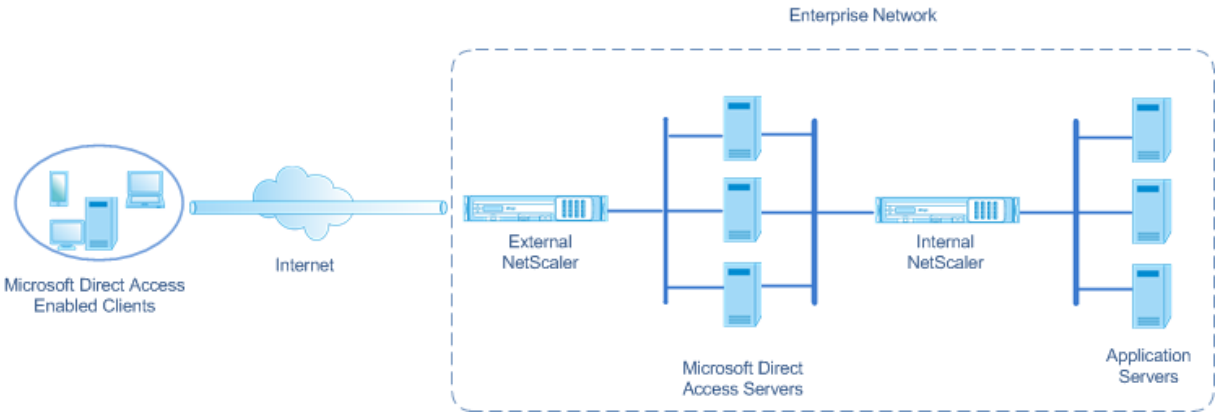
In a Direct Access deployment, Citrix ADC appliances provide high availability, scalability, high performance, and security. Citrix ADC load balancing functionality sends client traffic through the most appropriate server. The appliances can also forward Manage-Out traffic through the right path to reach the client.

Architecture

The architecture of a Microsoft Direct Access deployment consists of Direct Access enabled clients, Direct Access servers, application servers, and internal and external Citrix ADC appliances. Clients connect to an application server through a Direct Access server. An external Citrix ADC appliance load balance the client traffic to a Direct Access server, and an Internal Citrix ADC appliance forwards the client traffic from the Direct Access server to the destination application server. Direct Access is used for tunneling the client's IPv6 traffic over the IPv4 network. An IPv4 load balancing virtual server on the external Citrix ADC appliance load balances the client's tunneled traffic to one of the Direct Access servers. The Direct Access server extracts the IPv6 packets from the received client's IPv4 packets and sends them to the destination application server through the internal Citrix ADC appliance. The Internal Citrix ADC appliance has forwarding session rules with the source route cache option enabled for storing Layer 2 and Layer 3 connection information about the client's traffic from the Direct Access Server. The Citrix ADC appliance stores the following Layer 2 and Layer 3 information in a table called the source route cache table:

- Source IP address of the received packet
- MAC address of the Direct Access server that sent the packet
- VLAN ID of the Citrix ADC appliance that received the packet
- Interface ID of the Citrix ADC appliance that received the packet

The Citrix ADC appliance uses the information in the source route cache table for forwarding a response to the same Direct Access server because it has the tunneling information to reach the client. Also, the Internal appliance uses the source route cache table to forward application server's Manage-out traffic to the appropriate Direct Access server to reach a particular client.



Configuring the Internal Citrix ADC Appliance in a Microsoft Direct Access Deployment

To configure the Internal Citrix ADC appliance for forwarding an application server's response and manage-out traffic to the appropriate Direct Access Gateway, configure forwarding session rules. In each rule, set the sourceroutecache parameter to ENABLED.

To create a forwarding session rule by using the CLI:

At the command prompt, type:

- **add forwardingSession** <name> ((<network> [<netmask>]) | **-acl6name** <string> | **-aclname** <string>) **-sourceroutecache** (**ENABLED** | **DISABLED**]
- **show forwardingsession** <name>

Sample configuration:

In the following example, forwarding-session rule MS-DA-FW-1 is created on the internal Citrix ADC appliance. The forwarding session stores Layer 2 and Layer 3 information for any incoming IPv6 packets from a Direct Access server that matches source IPv6 prefix 2001:DB8::/96.

```
1 > add forwardingSession MS-DA-FW-1 2001:DB8::/96 -sourceroutecache -
    ENABLED
2  Done
```

Displaying the Source Route Cache Table

You can display the source route cache table for monitoring or detecting any unwanted connections between direct access servers and application servers.

To display the source route cache table by using the CLI:

At the command prompt, type:

- **show sourceroutecachetable**

Example:

```
> show sourceroutecachetable
SOURCEIP            MAC                 VLAN    INTERFACE
2001:DB8:5001:10    56:53:24:3d:02:eb    30        1/2
2001:DB8:5003:30    60:54:35:3e:04:bd    60        1/3
Done
```

Clearing the Source Route Cache Table

You can clear all the entries from the source route cache table on a Citrix ADC appliance.

To clear the source route cache table by using the CLI:

At the command prompt, type:

- **flush ns sourceroutecachetable**

Access Control Lists

September 14, 2021

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the Citrix ADC evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the Citrix ADC receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- ALLOW—Process the packet.
- BRIDGE—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- DENY—Drop the packet.

ACL rules are the first level of defense on the Citrix ADC.

Citrix ADC supports the following types of ACLs:

- **Simple ACLs** filter packets based on their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.

- **Extended ACLs** filter data packets based on various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the Citrix ADC to process the packet, bridge the packet, or drop the packet.

Nomenclature

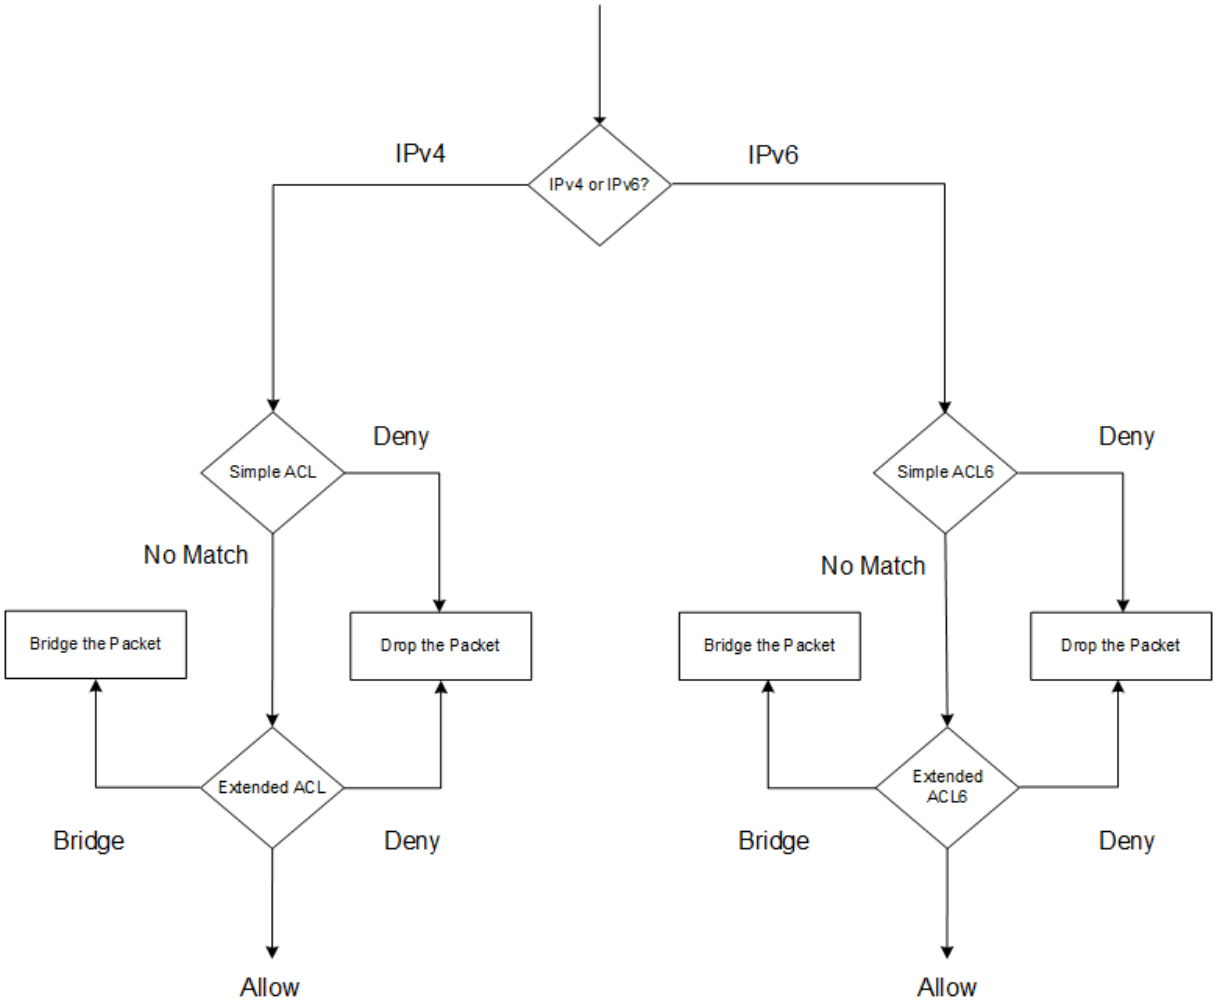
In the Citrix ADC user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.

ACL Precedence

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The Citrix ADC first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s. If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence



Simple ACLs and Simple ACL6s

September 14, 2021

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped based on their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

Configuring Simple ACLs and Simple ACL6s

Configuring a simple ACL or simple ACL6 on a Citrix ADC can include the following tasks.

- **Create simple ACLs or simple ACL6s**. Creating simple ACLs or simple ACL6s to drop (deny) packets based on their source IP address and, optionally, their protocol, destination port, or traffic domain.
- **Remove simple ACLs or simple ACL6s**. These ACLs cannot be modified once created. If you must modify a simple ACL or simple ACL6, you must remove it and create a one.

CLI procedures

To create a simple ACL by using the CLI:

At the command prompt, type:

```
1 - ns simpleacl <aclname> DENY -srcIP <ip_addr> [-destPort <port> -
    protocol ( TCP | UDP )] [-TTL \<positive_integer>]
2 - show ns simpleacl [\<aclname>]
3 <!--NeedCopy-->
```

Example:

```
1 > add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
2 Done
3 <!--NeedCopy-->
```

To create a simple ACL6 by using the CLI:

At the command prompt, type:

```
1 - add ns simpleacl6 <aclname> DENY - srcIPv6 <ipv6_addr|null> [-
    destPort <port> -protocol ( TCP | UDP )] [-TTL <positive_integer>]
2 - show ns simpleacl6 [<aclname>]
3 <!--NeedCopy-->
```

Example:

```
1 > add ns simpleacl6 rule1 DENY - srcIPv6 3ffe:192:168:215::82 -
    destPort 80 -Protocol TCP -TTL 9000
2  Done
3 <!--NeedCopy-->
```

To remove a single simple ACL by using the CLI:

At the command prompt, type:

- **rm ns simpleacl** <aclname>
- **show ns simpleacl**

To remove a single simple ACL6 by using the CLI:

At the command prompt, type:

- **rm ns simpleacl6**<aclname>
- **show ns simpleacl6**

To remove all simple ACLs by using the CLI:

At the command prompt, type:

- **clear ns simpleacl**
- **show ns simpleacl**

To remove all simple ACL6s by using the CLI:

At the command prompt, type:

- **clear ns simpleacl6**
- **show ns simpleacl6**

GUI procedures

To create a simple ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, add a new simple ACL.

To create a simple ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, add a new simple ACL6.

To remove a single simple ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, delete the simple ACL.

To remove a single simple ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, delete the simple ACL6.

To remove all simple ACLs by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACLs** tab, in the **Action** list, click **Clear**.

To remove all simple ACL6s by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Clear**.

Displaying Simple ACL and Simple ACL6 Statistics

You can display the simple ACL (or simple ACL6) statistics, which include the number of matches, the number of misses, and the number of simple ACLs configured.

The following table describes the statistics you can display for simple ACLs and simple ACL6s.

Statistics	Indicates
ACL match	Packets matching an ACL
ACL misses	Packets not matching any ACL
ACL count	Number of ACLs configured

CLI procedures

To display simple ACL statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl**

Example:

```
> stat ns simpleacl

SimpleACL Statistics

                                          Rate (/s)
                                             Total
SimpleACL hits                                  0
                        0
SimpleACL misses                                0
    51872

```

To display simple ACL6 statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl6**

GUI procedures

To display simple ACL statistics by using the GUI:

Navigate to **System** > **Network** > **ACLs** and, on the **Simple ACLs** tab, select the ACL and click **Statistics**.

To display simple ACL6 statistics by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, select the simple ACL6 and click **Statistics**.

Terminating Established Connections

For a simple ACL or simple ACL6, the Citrix ADC blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the CLI or the GUI.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the Citrix ADC. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate many connections from a particular network without taking the time to terminate them one by one.

Before you begin

- When you run flush, the Citrix ADC searches through all of its established connections and terminates the connections that match the conditions specified in any of the simple ACLs configured on the ADC.
- If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all simple ACLs and then running flush only once.

CLI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the CLI:

At the command prompt, type:

- **flush simpleacl -estSessions**

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the CLI:

At the command prompt, type:

- **flush simpleacl6 -estSessions**

GUI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.

Extended ACLs and Extended ACL6s

September 14, 2021

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data based on parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

Note: If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.

The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the Citrix ADC to log details for packets that match an extended ACL.

Applying Extended ACLs and Extended ACL6s: Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the Citrix ADC do not work until they are applied. Also, if you make any changes to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must reapply the extended ACLs or ACL6s. You must reapply them after enabling logging. The procedure to

apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the Citrix ADC starts comparing incoming packets against them. However, if you disable them, they are not used until you reenable them, even if they are reapplied.

Renumbering the priorities of Extended ACLs and Extended ACL6s: Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the Citrix ADC automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

Configuring Extended ACLs and Extended ACL6s

Configuring an extended ACL or ACL6 on a Citrix ADC consists of the following tasks.

- **Create an extended ACL or ACL6.** Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.
- (Optional) **Modify an extended ACL or ACL6**. You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenable it.
- **Apply extended ACLs or ACL6s**. After you create, modify, disable or reenable, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.
- (Optional) **Renumber the priorities of extended ACLs or ACL6s**. If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

CLI procedures

To create an extended ACL by using the CLI:

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>]

[-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)] [-**logstate** (ENABLED | DISABLED) [-**ratelimit** <positive_integer>]]

- **show ns acl** [<aclName>]

To create an extended ACL6 by using the CLI:

At the command prompt, type:

- **add ns acl6** <acl6name> <acl6action> [-**srcIPv6** [<operator>] <srcIPv6Val>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIPv6** [<operator>] <destIPv6Val>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)]
- **show ns acl6** [<aclName>]

To modify an extended ACL by using the CLI:

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

To modify an extended ACL6 by using the CLI:

To modify an extended ACL6, type the **set ns acl6** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

To disable or enable an extended ACL by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl** <aclname>
- **enable ns acl** <aclname>

To disable or enable an extended ACL6 by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl6** <aclname>
- **enable ns acl6** <aclname>

To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply ns acls**

To apply extended ACL6s by using the CLI:

At the command prompt, type:

- **apply ns acls6**

To renumber the priorities of extended ACLs by using the CLI:

At the command prompt, type:

- **renumber ns acls**

To renumber the priorities of extended ACL6s by using the CLI:

At the command prompt, type:

- **renumber ns acls6**

GUI procedures

To configure an extended ACL by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

To configure an extended ACL6s by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL6 or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

To apply extended ACLs by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

To apply extended ACL6s by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Apply**.

To renumber the priorities of extended ACLs by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

To renumber the priorities of extended ACL6s by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Renumber Priority (s)**.

Sample Configurations

The following table shows examples of configuring extended ACL rules through the command line interface: ACLs sample configurations.

Logging extended ACLs

You can configure the Citrix ADC to log details for packets that match extended ACLs.

In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the `nslog` file, depending on the type of global logging (`syslog or nslog`) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence.

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the Citrix ADC performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

Note: You must apply ACLs after you enable logging.

CLI procedures

To configure extended ACL Logging by using the CLI:

At the command prompt, type the following commands to configure logging and verify the configuration:

- **set ns acl** <aclName> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]
- **apply acls**
- **show ns acl** [<aclName>]

GUI procedures

To configure extended ACL Logging by using the GUI:

1. Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
   - **Log State**—Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured `syslog or auditlog` server.
   - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

Sample configuration

```
> set ns acl restrict -logstate ENABLED -ratelimit 120
Warning: ACL modified, apply ACLs to activate change

> apply ns acls
Done
<!--NeedCopy-->
```

Logging extended ACL6s

You can configure the Citrix ADC appliance to log details for packets that match an extended ACL6 rule. In addition to the ACL6 name, the logged details include packet-specific information, such as the source and destination IP addresses. The information is stored either in a syslog or `nslog` file, depending on the type of logging (`syslog or nslog`) that you have configured in the Citrix ADC appliance.

To optimize logging, when multiple packets from the same flow match an ACL6, only the first packet's details are logged. The counter is incremented for every other packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the following parameters:

- Source IP
- Destination IP
- Source port
- Destination port
- Protocol (TCP or UDP)

If an incoming packet is not from the same flow, a new flow is created. The total number of different flows that can be logged at any given time is limited to 10,000.

CLI procedures

To configure logging for an extended ACl6 rule by using the CLI:

- To configure logging while adding the extended ACL6 rule, at the command prompt, type:
  - **add acl6** <acl6Name> <acl6action> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]
  - **apply acls6**
  - **show acl6** [<acl6Name>]
- To configure logging for an existing extended ACL6 rule, at the command prompt, type:
  - **set acl6** <acl6Name> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]
  - **show acl6** [<acl6Name>]
  - **apply acls6**

GUI procedures

To configure extended ACL6 Logging by using the GUI:

1. Navigate to **System** > **Network** > **ACLs** and, then click the **Extended ACL6s** tab.
2. Set the following parameters while adding, or modifying an existing extended ACL6 rule.
   - **Log State** — Enable or disable logging of events related to the extended ACL6s rule. The log messages are stored in the configured syslog or `auditlog` server.
   - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the **Log State** parameter.

Sample configuration

```
> set acl6 ACL6-1 -logstate ENABLED -ratelimit 120
Done

> apply acls6
Done
<!--NeedCopy-->
```

Displaying extended ACLs and extended ACL6s statistics

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

Statistic	Specifies
Allow ACL matches	Packets matching ACLs with processing mode set to ALLOW. The Citrix ADC processes these packets.
NAT ACL matches	Packets matching a NAT ACL, resulting in a NAT session.
Deny ACL matches	Packets dropped because they match ACLs with processing mode set to DENY.
Bridge ACL matches	Packets matching a bridge ACL, which in transparent mode bypasses service processing.
ACL matches	Packets matching an ACL.
ACL misses	Packets not matching any ACL.
ACL Count	Total number of ACL rules configured by users.

Statistic	Specifies
Effective ACL Count	Total number of effective ACL configured internally. For an extended ACL with a range of IP addresses, the Citrix ADC appliance internally creates an extended ACL for each IP address. For example, for an extended ACL with 1000 IPv4 addresses (range or dataset), the Citrix ADC internally created 1000 extended ACLs.

CLI procedures

To display the statistics of all extended ACLs by using the CLI:

At the command prompt, type:

- **stat ns acl**

To display the statistics of all extended ACL6s by using the CLI:

At the command prompt, type:

- **stat ns acl6**

GUI procedures

To display the statistics of an extended ACL by using the GUI:

- Navigate to **System > Network > ACLs**, on the **Extended ACLs** tab, select the extended ACL, and click **Statistics**.

To display the statistics of an extended ACL6 by using the GUI:

- Navigate to **System > Network > ACLs**, on the **Extended ACL6s** tab, select the extended ACL, and click **Statistics**.

Stateful ACLs

A stateful ACL rule creates a session when a request matches the rule and allows the resulting responses even if these responses match a deny ACL rule in the Citrix ADC appliance. A stateful ACL offloads the work of creating more ACL rules/forwarding session rules for allowing these specific responses.

Stateful ACLs can be best used in an edge firewall deployment of a Citrix ADC appliance having the following requirements:

- The Citrix ADC appliance must allow requests initiated from internal clients and the related responses from the Internet.
- The appliance must drop the packets from the Internet that are not related to any client connections.

Before you begin

Before you configure stateful ACL rules, note the following points:

- The Citrix ADC appliance supports stateful ACL rules and stateful ACL6 rules.
- In a high availability setup, the sessions for a stateful ACL rule are not synchronized to the secondary node.
- You cannot configure an ACL rule as stateful if the rule is bound to any Citrix ADC NAT configuration. Some examples of Citrix ADC NAT configurations are:
  - RNAT
  - Large Scale NAT (large scale NAT44, DS-Lite, large scale NAT64)
  - NAT64
  - Forwarding session
- You cannot configure an ACL rule as stateful if TTL and Established parameters are set for this ACL rule.
- The sessions created for a stateful ACL rule continue to exist until time out irrespective of the following ACL operations:
  - Remove ACL
  - Disable ACL
  - Clear ACL
- Stateful ACLs are not supported for the following protocols:
  - Active FTP
  - TFTP

Configure stateful IPv4 ACL rules

Configuring a stateful ACL rule consists of enabling the stateful parameter of an ACL rule.

To enable the stateful parameter of an ACL rule by using the CLI:

- To enable the stateful parameter while adding an ACL rule, at the command prompt, type:
  - **add acl** <lname> ALLOW -**stateful** (ENABLED | DISABLED)
  - **apply acls**
  - **show acl** <name>
- To enable the stateful parameter of an existing ACL rule, at the command prompt, type:
  - **set acl** <name> -**stateful** (ENABLED | DISABLED)

- **apply acls**
- **show acl** <name>

To enable the stateful parameter of an ACL rule by using the GUI:

1. Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL rule.

Sample configuration

```
> add acl ACL-1 allow -srciP 1.1.1.1 -stateful Yes

Done

> apply acls

Done

> show acl

1)         Name: ACL-1

    Action: ALLOW                          Hits: 0

    srcIP = 1.1.1.1

    destIP

    srcMac:

    Protocol:

    Vlan:                                 Interface:

    Active Status: ENABLED                 Applied Status: NOTAPPLIED

    Priority: 10                           NAT: NO

    TTL:

    Log Status: DISABLED

    Forward Session: NO

    Stateful: YES
```

```
<!--NeedCopy-->
```

Configure stateful ACL6 rules

Configuring a stateful ACL6 rule consists of enabling the stateful parameter of an ACL6 rule.

To enable the stateful parameter of an ACL6 rule by using the CLI:

- To enable the stateful parameter while adding an ACL6 rule, at the command prompt, type:
  - **add acl6** <name> ALLOW -stateful (ENABLED | DISABLD)
  - **apply acls6**
  - **show acl6** <name>
- To enable the stateful parameter of an existing ACL6 rule, at the command prompt, type:
  - **set acl6** <name> -**stateful** (ENABLED | DISABLED)
  - **apply acls6**
  - **show acl6** <name>

To enable the stateful parameter of an ACL6 rule by using the GUI:

1. Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL6 rule.

Sample configuration

```
>  add acl6 ACL6-1 allow -srcipv6 1000::1  - stateful Yes

Done

>  apply acls6

Done

> show acl6

1)    Name: ACL6-1

    Action: ALLOW                          Hits: 0

    srcIPv6 = 1000::1

    destIPv6

    srcMac:
```

```
20
21     Protocol:
22
23     Vlan:                                  Interface:
24
25     Active Status: ENABLED                  Applied Status: NOTAPPLIED
26
27     Priority: 10                            NAT: NO
28
29     TTL:
30
31     Forward Session: NO
32
33     Stateful: YES
34 <!--NeedCopy-->
```

Dataset based extended ACLs

Many ACLs are required in an enterprise. Configuring and managing many ACLs is difficult and cumbersome when they require frequent changes.

A Citrix ADC appliance supports datasets in extended ACLs. Dataset is an existing feature of a Citrix ADC appliance. A dataset is an array of indexed patterns of types: number (integer), IPv4 address, or IPv6 address.

Dataset support in extended ACLs is useful for creating multiple ACL rules, which require common ACL parameters.

While creating an ACL rule, instead of specifying the common parameters, you can specify a dataset, which includes these common parameters.

Any changes made in the dataset are automatically reflected in the ACL rules that are using this dataset. ACLs with datasets are easier to configure and manage. They are also smaller and easier to read than the conventional ACLs.

Currently, the Citrix ADC appliance supports only the IPv4 address type dataset for extended ACLs.

Before you begin

Before configuring dataset based extended ACL rules, note the following points:

- Make sure that you are familiar with the dataset feature of a Citrix ADC appliance. For more information about datasets, see Pattern sets and data sets.
- The Citrix ADC appliance supports datasets only for IPv4 extended ACLs.

- The Citrix ADC appliance supports only the IPv4 type datasets for extended ACLs.
- The Citrix ADC appliance supports Dataset based extended ACLs for all set ups: standalone, high availability, and cluster.
- For an extended ACL with a range of IP addresses, the Citrix ADC appliance internally creates an extended ACL for each IP address. For example, for an IPv4 dataset based extended ACL with 1000 IPv4 addresses bound to the dataset, the Citrix ADC appliance internally created 1000 extended ACLs.
  - The Citrix ADC appliance supports a maximum of 10K extended ACLs. For an IPv4 dataset based extended ACL with a range of IP addresses bound to the dataset, the Citrix ADC appliance stops creating internal ACLs once the total number of extended ACLs reaches the maximum limit.
  - The following counters are present as part of the extended ACL statistics:
    * **ACL count**. Total number of ACL rules configured by users.
    * **Effective ACL count**. Total number of effective ACL rules that the Citrix ADC appliance configures internally.

    For more information, see Displaying extended ACL and extended ACL6s Statistics.
- The Citrix ADC appliance does not support `set` and `unset` operations for associating/dissociating datasets with the parameters of an extended ACL. You can set the ACL parameters to a dataset only during the `add` operation.

Configure dataset based extended ACLs

Configuring a dataset based extended ACL rule consists of the following tasks:

- **Add a dataset**. A dataset is an array of indexed patterns of types: number (integer), IPv4 address, or IPv6 address. In this task, you create a type of dataset, for example, a dataset of type IPv4.
- **Bind values to the dataset**. Specify a value or a range of values to the dataset. The specified values must be of the same type as the dataset type. For example, you can specify an IPv4 address or a range of IPv4 addresses to the dataset of type IPv4.
- **Add an extended ACL and set ACL paramters to the dataset**. Add an extended ACL and set the required ACL parameters to the dataset. This setting results in the parameters set to the values specified in the dataset.
- **Apply extended ACLs**. Apply the ACLs to activate any new or modified extended ACLs.

To add a policy dataset by using the CLI:

At the command prompt, type:

- **add policy dataset** <name> <type>
- **show policy dataset**

To bind a pattern to the data set by using the CLI:

At the command prompt, type:

- **bind policy dataset** <name> <value> [-endRange <string>]
- **show policy dataset**

To add an extended ACL and set the ACL paramters to the dataset by using the CLI:

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] …
- **show acls**

To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply acls**

Sample configuration

In the following sample configuration of a dataset based extended ACL, an IPv4 dataset DATASET-ACL-1 is created. Two IPv4 addresses: 192.0.2.30 and 192.0.2.60, and two IPv4 address ranges: (198.51.100.15 - 45) and (203.0.113.60-90) are bound to DATASET-ACL-1. DATASET-ACL-1 is then specified to the srcIP and destIP parameters of the extended ACL ACL-1.

```
add policy dataset DATASET-ACL-1 IPV4

bind dataset DATASET-ACL-1 192.0.2.30

bind dataset DATASET-ACL-1 192.0.2.60

bind dataset DATASET-ACL-1 198.51.100.15 -endrange 198.51.100.45

bind dataset DATASET-ACL-1 203.0.113.60 -endrange 203.0.113.90

add ns acl ACL-1 ALLOW -srcIP DATASET-ACL-1 -destIP DATASET-ACL-1

apply acls
<!--NeedCopy-->
```

MAC Address Wildcard Mask for ACLs

September 14, 2021

A wildcard mask parameter has been introduced for extended ACLs and ACL6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of incoming packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask must meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an ACL, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the incoming packets.

To specify a range of source MAC addresses in an ACL rule by using the CLI:

At the command prompt, type:

```
1 -  add ns acl <name> <action> -srcMac <mac_addr> -srcMacMask <string>
2 -  show ns acl <aclname>
3 <!--NeedCopy-->
```

Example:

```
1 add ns acl ACL-1 ALLOW  - protocol TCP  - srcport 2000-3000 -srcMac 96:fa
     :95:1d:67:4a
```

```
  - srcMacMask 000000111111
Done
<!--NeedCopy-->
```

To specify a range of source MAC addresses in an ACL6 rule by using the CLI:

At the command prompt, type:

```
-  add ns acl6 <name> <action> -srcMac <mac_addr> -srcMacMask <string>
-  show ns acl6 <acl6name>
<!--NeedCopy-->
```

Example:

```
> add ns acl6 ACL6-1 ALLOW -destIPv6 2001::45 -srcMac 96:fa:90:1d:67:4a
 - srcMacMask 000000001111
Done
<!--NeedCopy-->
```

Blocking Traffic on Internal Ports

September 14, 2021

By default, a Citrix ADC appliance does not block some type of internal traffic even using ACL rules.

The following table lists the internal traffic types that a Citrix ADC appliance does not block even using ACL rules:

Citrix ADC Setup	Protocol	Destination Port	Destination IP address
All	TCP	3008–3011	NSIP or SNIP
All	TCP	179	NSIP or SNIP
All	UDP	520	NSIP or SNIP
High availability	UDP	3003	NSIP
High availability	TCP	4001	NSIP
High availability	TCP	22	NSIP
Cluster	UDP	7000	NSIP

This feature of not blocking the earlier mentioned types of traffic is specified by the default setting of

the global Layer-3 `Implicit ACL Allow` (`implicitACLAllow`) parameter.

You can disable this parameter if you want to block the earlier mentioned traffic types using the ACL rules. An appliance in a high availability setup makes an exception for its partner (primary or secondary) node. It does not block traffic from that node.

To disable or enable this parameter by using the CLI:

At the command prompt, type:

set l3param -implicitACLAllow [ENABLED DISABLED]

-
- **sh l3param**

Note: The parameter implicitACLAllow is enabled by default.

Example:

```
1 > set l3param -implicitACLAllow DISABLED
2 Done
3 <!--NeedCopy-->
```

IP Routing

September 14, 2021

Citrix ADC appliances support both dynamic and static routing. Because simple routing is not the primary role of a Citrix ADC, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most Citrix ADC implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

Configuring Dynamic Routes

September 14, 2021

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone Citrix ADC appliances. Dynamic routing on a Citrix ADC appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see Dynamic Routing Protocol Command Reference Guides and Unsupported Commands.

The Citrix ADC supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

Routing Tables in Citrix ADC

In a Citrix ADC appliance, the Citrix ADC kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

NS Kernel Routing Table

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the add ns ip command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the CLI (CLI). The entries in this table are used by the Citrix ADC in packet forwarding. From the CLI, they can be inspected with the show route command.

FreeBSD Routing Table

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a Citrix ADC appliance, these applications are tightly coupled to FreeBSD,

and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the Citrix ADC establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the route command. The FreeBSD routing table can be inspected by using the netstat command from any UNIX shell.

Network Services Module (NSM) FIB

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

- **Connected routes**. IP subnets that are directly reachable from the Citrix ADC. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.
- **Kernel routes**. All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the CLI that have the - advertise option enabled. Alternatively, if the Citrix ADC is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.
- **Static routes**. Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.
- **Learned routes**. If the Citrix ADC is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTYSH.

Dynamic Routing in a High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node

is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the GUI or a command-line interface. The Citrix ADC supports two independent command-line interfaces: the CLI and the Virtual Teletype Shell (VTYSH). The CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The Citrix ADC routing suite is based on ZebOS, the commercial version of GNU Zebra.

> **Note:**
>
> Citrix recommends that you use VTYSH for all commands except those that can be configured only on the CLI. Use of the CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

Dynamic Routing Protocol Command Reference Guides and Unsupported Commands

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the Citrix ADC appliance: Dynamic routing protocol reference guides and unsupported commands.

Configuring RIP

September 14, 2021

Routing Information Protocol (RIP) is a Distance Vector protocol. The Citrix ADC supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

Enabling and Disabling RIP

Use either of the following procedures to enable or disable RIP. After you enable RIP, the Citrix ADC appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the CLI:

At the command prompt, enter one of the following commands to enable or disable RIP:

- **enable ns feature RIP**
- **disable ns feature RIP**

To enable or disable RIP routing by using the GUI:

1. Navigate to **System** > **Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **RIP Routing** option.

Advertising Routes

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

To configure RIP to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

```
<!--NeedCopy-->
```

Limiting RIP Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# passive-interface VLAN0
<!--NeedCopy-->
```

Verifying the RIP Configuration

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line:

At the command prompt, type the following commands in the following order:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh rip	Display updated RIP routing table.

Command	Specifies
sh rip interface <vlan_name>	Displays RIP information for the specified VLAN.

Example:

```
NS# VTYSH
NS# sh rip
NS# sh rip interface VLAN0
<!--NeedCopy-->
```

Configuring OSPF

October 28, 2021

The Citrix ADC supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the Citrix ADC are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the Citrix ADC.
- The Citrix ADC can advertise Type-1 or Type-2 external metrics for all routes.
- The Citrix ADC can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the Citrix ADC.
- The Citrix ADC supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

Enabling and Disabling OSPF

To enable or disable OSPF, you must use either the CLI or the GUI. When OSPF is enabled, the Citrix ADC starts the OSPF process. When OSPF is disabled, the Citrix ADC stops the OSPF routing process.

To enable or disable OSPF routing by using the CLI:

At the command prompt, type one of the following commands:

1. **enable ns feature OSPF**
2. **disable ns feature OSPF**

To enable or disable OSPF routing by using the GUI:

1. Navigate to **System** > **Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **OSPF Routing** option.

Advertising OSPF Routes

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure OSPF to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enters global configuration mode.
router OSPF	Start OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	Enable routing on an IP network.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
```

```
NS(config-router)# network 10.102.29.0/24 area 0
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
<!--NeedCopy-->
```

Limiting OSPF Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router OSPF	Start OSPF routing process and enters configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# passive-interface VLAN0
<!--NeedCopy-->
```

Verifying the OSPF Configuration

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.

Command	Specifies
sh OSPF neighbor	Displays current neighbors.
sh OSPF route	Displays OSPF routes.

Example:

```
>VTYSH
NS# sh ip OSPF neighbor
NS# sh ip OSPF route
<!--NeedCopy-->
```

Configuring Graceful Restart for OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

> **Note:**
>
> Graceful restart is not supported for high availability setups in INC mode.

To configure graceful restart for OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.

Command	Example	Command Description
router-id <id>	NS(config)# router-id 1.1.1.1	Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA setup.
ospf restart grace-period <1-1800>	NS(config)# ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.
ospf restart helper max-grace-period <1-1800>	NS(config)# ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode.
router ospf	NS(config)# router ospf	Starts OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	NS(config-router)# network 192.0.2.0/24 area 0	Enables routing on an IP network.
capability restart graceful	NS(config-router)# capability restart graceful	Enables graceful restart on the OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring BGP

October 28, 2021

The Citrix ADC appliance supports BGP (RFC 4271). The features of BGP on the Citrix ADC are:

- The Citrix ADC advertises routes to BGP peers.
- The Citrix ADC injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The Citrix ADC generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.
- As-Override Support in Border Gateway Protocol

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Enable the IPv6 feature.

Enabling and Disabling BGP

To enable or disable BGP, you must use either the CLI or the GUI. When BGP is enabled, the Citrix ADC appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the CLI:

At the command prompt, type one of the following commands:

- enable ns feature BGP
- disable ns feature BGP

To enable or disable BGP routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

You can configure the Citrix ADC appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
Address-family ipv4	Enter address family configuration mode.
Neighbor < IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor 10.102.29.170 remote-as 100
NS(config-router)# Address-family ipv4
NS(config-router-af)# Neighbor 10.102.29.170 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
<!--NeedCopy-->
```

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Enable the IPv6 feature.

Advertising IPv6 BGP Routes

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure BGP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
<!--NeedCopy-->
```

Verifying the BGP Configuration

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
VTYSH
You are now in the VTYSH command prompt. An output similar to the
   following appears:
NS170#
At the VTYSH command prompt, type:
NS170# sh ip BGP
NS170# sh BGP
NS170# sh ip BGP neighbors
NS170# sh ip BGP summary
NS170# sh ip BGP route-map <map-tag>
<!--NeedCopy-->
```

As-Override Support in Border Gateway Protocol

As a part of BGP loop prevention functionality, if a router receives a BGP packet containing the router's Autonomous System Number (ASN) in the Autonomous Systems (AS) path, the router drops the packet. The assumption is that the packet originated from the router and has reached the place from where it originated.

If an enterprise has several sites with a same ASN, BGP loop prevention causes the sites with an identical ASN to not get linked by another ASN. Routing updates (BGP packets) are dropped when another site receives them.

To solve this issue, BGP AS-Override functionality has been added to the ZebOS BGP routing module of the Citrix ADC.

With AS-Override enabled for a peer device, when the Citrix ADC appliance receives a BGP packet for forwarding to the peer, and the ASN of the packet matches that of the peer, the appliance replaces the ASN of the BGP packet with its own ASN number before forwarding the packet.

You can enable AS-Override for a specific neighbor or a group of neighbors (peer group) by using the VTYSH command line.

To configure BGP AS-Override for a IPv4 neighbor by using the VTYSH command line:

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <IPv4 address> as-override	Enable BGP as-override for the specified neighbor.

```
1      > VTYSH NS# configure terminal
2      NS(config)# router BGP 200
3      NS(config-router)# Neighbor 192.0.2.100 remote-as 100
4      NS(config-router)# Neighbor 10.102.29.100 as-override
5  <!--NeedCopy-->
```

To configure BGP AS-Override for a IPv4 BGP peer group by using the VTYSH command line:

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor <peer group name> **peer-group**	Create a BGP peer group.
Neighbot <IPv4 address> **peer-group** <peer group name>	Associate neighbors to the specified peer group.
Neighbor <peer group name> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <peer group name> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```
1      > VTYSH NS# configure terminal
2      NS(config)# router BGP 200
3      NS(config-router)# neighbor external-peers-1 peer-group
```

```
4     NS(config-router)# neighbor 192.0.2.101 peer-group external-peers-1
5     NS(config-router)# neighbor 192.0.2.102 peer-group external-peers-1
6     NS(config-router)# neighbor 192.0.2.103 peer-group external-peers-1
7     NS(config-router)# Neighbor external-peers-1 remote-as 100
8     NS(config-router)# Neighbor external-peers-1 as-override
9  <!--NeedCopy-->
```

To configure BGP AS-Override for an IPv6 neighbor by using the VTYSH command line:

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <IPv6 address> as-override	Enable BGP as-override for the specified neighbor.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the specified neighbor and the Citrix ADC by using the link local address.
Neighbor <IPv6 address> as-override	Enable BGP as-override for the specified neighbor.

```
1     > VTYSH NS# configure terminal
2     NS(config)# router BGP 200
3     NS(config-router)# Neighbor a1bc::102 remote-as 100
4     NS(config-router)# Neighbor a1bc::102 as-override
5     NS(config-router)# Address-family ipv6
6     NS(config-router-af)# Neighbor a1bc::102 activate
7     NS(config-router)# Neighbor a1bc::102 as-override
8  <!--NeedCopy-->
```

To configure BGP AS-Override for IPv6 peer group by using the VTYSH command line:

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor <peer group name> **peer-group**	Create a BGP peer group.
Neighbor <IPv6 address> **peer-group** <peer group name>	Associate a neighbor with the specified peer group.
Neighbor <peer group name> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <peer group name> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.
Address-family ipv6	Enter address family configuration mode.
Neighbor <peer group name> activate	Exchange prefixes for the IPv6 router family between the neighbors of the specified peer group and the Citrix ADC by using the link local address.
Neighbor <peer group name> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```
1      > VTYSH NS# configure terminal
2      NS(config)# router BGP 200
3      NS(config-router)# neighbor external-peers-2 peer-group
4      NS(config-router)# neighbor 2001::1 peer-group external-peers-2
5      NS(config-router)# neighbor 2001::2 peer-group external-peers-2
6      NS(config-router)# Neighbor external-peers-2 remote-as 100
7      NS(config-router)# Neighbor external-peers-2 as-override
8      NS(config-router)# Address-family ipv6
9      NS(config-router-af)# Neighbor external-peers-2 activate
10     NS(config-router)# Neighbor external-peers-2 as-override
11 <!--NeedCopy-->
```

Graceful Restart

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

> **Note:**
>
> Graceful restart is not supported for high availability setups in INC mode.

Configuring Graceful Restart for BGP

To configure graceful restart for BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id <ID>	NS(config)# router-id 1.1.1.1	A router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same identifier must be specified on the other node in a high availability setup for graceful restart to work properly.
router bgp <AS-number>	NS(config)# router bgp 5	Enters BGP configuration mode.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.

Command	Example	Command Description
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes.
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the Citrix ADC appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
neighbor <IPv4 address of the peer router> remote-as <AS-number>	NS(config-router)# neighbor 192.0.2.30 remote-as 2	Establishes BGP peering with the specified neighbor router device.
neighbor <IPv4 address of the peer router> capability graceful-restart	NS(config-router)# neighbor 192.0.2.30 capability graceful-restart	Enables graceful restart with the specified neighbor.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring Graceful Restart for IPv6 BGP

To configure graceful restart for IPv6 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.

Command	Example	Command Description
router-id <id>	NS(config)# router-id 1.1.1.1	Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability setup for graceful restart to work properly.
router bgp <AS-number>	NS(config)# router bgp 5	Enters configuration mode for BGP protocol.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes. The default value is 360 seconds.
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the Citrix ADC appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
neighbor <IPv6 address> remote-as <AS-number>	NS(config-router)# neighbor 2001:db8::10 remote-as 2	Establishes BGP peering with the specified neighbor router device.
address-family ipv6	NS(config-router)#address-family ipv6	Enters address family configuration mode.

Command	Example	Command Description
neighbor <IPv6 address of the neighbor> activate	NS(config-router-af)#neighbor 2001:db8::10 activate	Enables the exchange of address family routes with the specified neighbor router device.
neighbor <IPv6 address of the neighbor> capability graceful-restart	NS(config-router-af)#neighbor 2001:db8::10 capability graceful-restart	Enables graceful restart with the specified neighbor router device.
redistribute kernel	NS(config-router-af)#redistribute kernel	Redistributes kernel routes.
exit-address-family	NS(config-router-af)#exit-address-family	Exits address family configuration mode.

Configuring MD5 Authentication for IPv4 BGP

The Citrix ADC appliance supports MD5 authentication for Border Gateway Protocol (BGP). When authentication is enabled, any TCP segment belonging to BGP exchanged between the Citrix ADC appliance and its peer device is verified and accepted only if authentication is successful. For authentication to be successful, both the peers must be configured with the same MD5 password. If authentication fails, the BGP neighbor relationship is not being established. MD5 authentication support for BGP in the Citrix ADC appliance is compliant with RFC 2385.

Before you Begin

Before you start configuring BGP MD5 authentication, consider the following points:

- Make sure that you understand the different components of BGP MD5 authentication, described in RFC 2385.
- BGP MD5 authentication is not supported for Citrix ADC admin partitions.
- BGP MD5 authentication is not supported for IPv6 BGP configurations.
- BGP MD5 authentication is supported for Citrix ADC cluster configurations as well as for high availability configurations.
- Because of the following issue in FreeBSD, Citrix recommends to set a low keep-live and hold-time values (for example, 5 and 15) and configure graceful restart for a BGP session in a Layer 2 high availability configuration. Otherwise, with MD5 authentication enabled, BGP might take a longer time to re-establish a connection with the neighbour after a failover.
  - Last ACK from FreeBSD does not contain md5 digest:
    * https://forums.freebsd.org/threads/11170/

* http://support.pfsense.narkive.com/povrH5HI/bgp-md5-weird-behavior-when-connection-closes

Configuring MD5 Authentication for IPv4 BGP

To configure MD5 authentication for IPv4 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Displays VTYSH command prompt.
configure terminal	Enters global configuration mode.
router bgp <AS-number>	Enters configuration mode for BGP protocol. <AS-number> is a BGP autonomous system number and is a required parameter.
neighbor <neighbour IPv4 address> remote-as < AS-number >	Updates the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
neighbor < neighbour IPv4 address > password < password in double quotes>	Configures MD5 authentication for the specified neighbour with the specified MD5 password. For MD5 authentication to be successful, you must configure the same MD5 password on the Citrix ADC appliance and the neighbour appliance.

```
> vtysh

ns# configure terminal

ns(config)#router bgp 5

ns(config-router)#neighbor 20.20.20.138 remote-as 1

ns(config-router)#neighbor 20.20.20.138 password  “secret”

ns(config-router)#redistribute kernel

ns(config-router)#exit

<!--NeedCopy-->
```

Configuring IPv6 RIP

September 14, 2021

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

Advertising IPv6 RIP Routes

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 rip
```

```
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->
```

Limiting IPv6 RIP Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 rip
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->
```

Verifying the IPv6 RIP Configuration

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.

Commands	Specifies
sh ipv6 rip	Display updated IPv6 RIP routing table.
sh ipv6 rip interface <vlan_name>	Display IPv6 RIP information for the specified VLAN.

Example:

```
NS# VTYSH
NS# sh ipv6 rip
NS# sh ipv6 rip interface VLAN0
<!--NeedCopy-->
```

Configuring IPv6 OSPF

October 28, 2021

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

Advertising IPv6 Routes

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
<!--NeedCopy-->
```

Limiting IPv6 OSPF Propagations

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
passive-interface < vlan_name >	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
```

```
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# passive-interface VLAN0
<!--NeedCopy-->
```

Verifying the IPv6 OSPF Configuration

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 OSPF neighbor	Display current neighbors.
sh ipv6 OSPF route	Display IPv6 OSPF routes.

Example:

```
>VTYSH
NS# sh ipv6 OSPF neighbor
NS# sh ipv6 OSPF route
<!--NeedCopy-->
```

OSPFv3 Authentication

To ensure the integrity, data origin authentication, and data confidentiality of OSPFv3 packets, OSPFv3 authentication must be configured on OSPFv3 peers.

The Citrix ADC appliance supports OSPFv3 authentication and is partially compliant with RFC 4552. OSPFv3 authentication is based on the two IPSec protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP). The Citrix ADC appliance supports only the AH protocol for OSPFv3 authentication.

OSPFv3 authentication uses manually defined IPSec Security Associations (SAs) between the OSPFv3 peers and does not rely on IKE protocol for forming dynamic SAs. Manual SAs define the security parameter Index (SPI) values, algorithms, and keys to be used between the peers. Manual SAs require no negotiation between the peers; therefore, the same SA must be defined on both the peers.

You can configure OSPFv3 authentication on a VLAN or for an OSPFv3 area. When you configure for a

VLAN, the settings are applied to all the interfaces that are members of the VLAN. When you configure OSPFv3 authentication for an OSPF area, the settings are applied to all the VLANs in that area. The settings are in turn applied to all the interfaces that are members of these VLANs. These settings do not apply to member VLANs on which you have configured OSPFv3 authentication directly.

Consider the following points and limitations before configuring OSPFv3 authentication on a Citrix ADC appliance:

- Make sure that you understand the different components of OSPFv3 authentication, described in RFC 4552.
- Only Authentication Header protocol is supported for OSPFv3 authentication. Encapsulating Security Payload (ESP) is not supported.
- You must define an SA with the same setting on the peer interface.
- Rekeying of manual keys is not supported.

To configure OSPFv3 authentication on a VLAN by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: OSPFv3 authentication VLAN commands.

Example:

```
1 > VTYSH NS# configure terminal
2 NS(config)# interface vlan2
3 NS(config-if)# ipv6 ospf authentication ipsec spi 256 md5 123456789
     ABCDEF0123456789ABCDEF0
4 <!--NeedCopy-->
```

To configure OSPFv3 authentication on an OSPF area by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: OSPFv3 authentication OSPF area commands.

Example:

```
1 > VTYSH NS# configure terminal
2 ns(config)#router ipv6 ospf 30
3 ns(config-router)# area 1 authentication ipsec spi 256
     md5123456789ABCDEF0123456789ABCDEF0
4 <!--NeedCopy-->
```

Configuring Graceful Restart for IPv6 OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neigh-

bor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

> **Note:**
>
> Graceful restart is not supported for high availability setups in INC mode.

To configure graceful restart for IPv6 OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	> VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id id>	NS(config)#router-id 1.1.1.1	Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA set up.
IPv6ospf restart grace-period <1-1800>	NS(config)# IPv6ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.

Command	Example	Command Description
IPv6 ospf restart helper max-grace-period <1-1800>	NS(config)# IPv6 ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode.
interface <VLANID>	NS(config)#interface vlan3	Enters VLAN configuration mode.
ipv6 router ospf area <area_id> tag <tag_id>	NS(config-if)#ipv6 router ospf area 0 tag 1	Starts IPv6 OSPF routing process on a VLAN.
exit	NS(config-if)#exit	Exits VLAN configuration mode.
router ipv6 ospf	NS(config)# router ipv6 ospf 1	Starts IPv6 OSPF routing process and enters configuration mode for the routing process.
capability restart graceful	NS(config-router)#capability restart graceful	Enables graceful restart on the IPv6 OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring ISIS

September 14, 2021

The Citrix ADC appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP)

networks.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

Enabling ISIS

Use either of the following procedures to enable the ISIS routing feature on the Citrix ADC appliance.

To enable ISIS routing by using the CLI:

At the command prompt, type:

enable ns feature ISIS

To enable ISIS routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

Creating an ISIS Routing Process and Starting It on a VLAN

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.
net XX….XXXX.YYYY.YYYY.YYYY.00	Specifies a NET value for the routing process, where: ·**XX. .. .XXXX** is the Area Address (can be 1-13 bytes), ·**YYYY.YYYY.YYYY** is the System ID (6 bytes), ·**00** is the N-selector (1 byte).
is-type (level-1|level-1-2|level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.

Command	Description
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface <vlan_name>	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

Example:

```
> VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# net 15.aabb.ccdd.0097.00
NS(config-router)# is-type level-1
NS(config-router)# exit
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)#  ip router isis 11
NS(config-if)# ipv6 router isis 11
<!--NeedCopy-->
```

Advertising Routes

Route advertisement enables an upstream router to track network entities located behind the Citrix ADC appliance.

To configure ISIS to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Starts the ISIS routing instance and enter configuration mode for the routing process.

Command	Description
redistribute connected (level-1 or level-1-2 or level-2)	Redistributes connected routes, where: **level-1**: Redistribute connected routes into Level-1, **level-1-2**: Redistribute connected routes into Level-1 and Level-2, **level-2**: Redistribute connected routes into Level-2.
redistribute kernel (level-1 or level-1-2 or level-2)	Redistributes kernel routes, where: **level-1**: Redistribute kernel routes into Level-1, **level-1-2**: Redistribute kernel routes into Level-1 and Level-2, **level-2**: Redistribute kernel routes into Level-2.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# redistribute connected level-1
NS(config-router)# redistribute kernel level-1
<!--NeedCopy-->
```

Limiting ISIS Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface <vlan_name>	Suppresses routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# passive-interface VLAN0
<!--NeedCopy-->
```

Verifying the ISIS Configuration

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface <vlan_name>	Displays IPv6 ISIS information for the specified VLAN.

Example:

```
NS# VTYSH
NS#  show ip isis route
NS#  show ipv6 isis route
NS# sh isis interface VLAN0
<!--NeedCopy-->
```

Install Routes to the Citrix ADC Routing Table

September 14, 2021

The Citrix ADC appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line:

At the CLI, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns route-install Default	Install IPv4 default routes to the internal routing table.
ns route-install RIP	Install IPv4 RIP specific routes to the internal routing table.
ns route-install BGP	Install IPv4 BGP specific routes to the internal routing table.
ns route-install OSPF	Install IPv4 OSPF specific routes to the internal routing table.
ns route-install IPv6 Default	Install IPv6 default routes to the internal routing table.
ns route-install IPv6 RIP	Install IPv6 RIP specific routes to the internal routing table.
ns route-install IPv6 BGP	Install IPv6 BGP specific routes to the internal routing table.
ns route-install IPv6 OSPF	Install IPv6 OSPF specific routes to the internal routing table.

Example:

```
>VTYSH
NS# configure terminal
NS# ns route-install Default
NS(config)# ns route-install RIP
NS(config)# ns route-install BGP
NS(config)# ns route-install OSPF
NS# ns route-install IPv6 Default
NS(config)# ns route-install IPv6 RIP
NS(config)# ns route-install IPv6 BGP
NS(config)# ns route-install IPv6 OSPF
<!--NeedCopy-->
```

Advertisement of SNIP and VIP Routes to Selective Areas

September 14, 2021

To advertise some SNIP addresses to selective areas, enabling DRADV mode or redistribute connect ZebOS operations cannot be used. This is because these operations send all the connected routes to ZebOS. Also, adding dummy static routes in ZebOS for the required subnets, or adding ACLs in ZebOS to filter unwanted connected routes, is a cumbersome and tedious task.

The Network Route and the Tag options address this issue. You can enable the Network Route option for only one SNIP address per subnet. The connected route for that SNIP address is sent as a kernel route to ZebOS.

For VIP and SNIP addresses, Tag, can be assigned an integer from 1 to 4294967295. This parameter can be set only when Host Route or Network Route is enabled for VIP or SNIP addresses. The tag value associated with VIP and SNIP addresses are also sent along with their routes to ZebOS. Tags with different values can be set for VIP and SNIP routes. These tag values can then be matched in route maps in ZebOS and advertised to selective areas.

Advertise SNIP Routes to Selective Areas

To configure the network route and tag parameters of a SNIP address by using the CLI:

At the command prompt, type:

- If adding a new SNIP address:
  - **add ns ip** <IPAddress>@ <netmask> -**type SNIP** -**networkroute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing SNIP address:
  - **set ns ip** <IPAddress>@ <netmask> -**type SNIP** - **networkroute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a SNIP address by using GUI:

1. Navigate to **System**> **Network** > **IPs** > **IPV4s**.
2. Set the **Network Route** and **Tag** parameters while adding a Subnet IP (SNIP) address or modifying an existing Subnet IP address.

Advertise VIP Routes to Selective Areas

To configure the host route and tag parameters of a VIP address by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new VIP address:
  - **add ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing VIP address:
  - **set ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a VIP address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Set the **Host Route** and **Tag** parameters while adding a VIP address or modifying an existing VIP address.

Configuring Bidirectional Forwarding Detection

September 14, 2021

Bidirectional Forwarding Detection (BFD) protocol is a mechanism for fast detection of failures of forwarding paths. BFD detects path failures in the order of milliseconds. BFD is used with dynamic routing protocols.

In BFD operation, routing peers exchange BFD packets at a negotiated interval. If a packet is not received from a peer within the negotiated interval plus grace interval, the peer is considered to be dead and a notification will be sent to the set of registered routing protocols. In turn, the routing protocols recalculate the best path and reprogram the routing table. BFD supports smaller time interval, when compared to the timers provided by the routing protocols, thus resulting in faster detection of failures.

The Citrix ADC appliance supports BFD for the following routing protocols: BGP (IPv4 and IPv6), OSPFv2 (IPv4), and OSPFv3 (IPv6). BFD support in the Citrix ADC appliance is compliant with RFCs 5880, 5881, and 5883.

Points to Consider for Configuring Bidirectional Forwarding Detection

Before you start configuring BFD, consider the following points:

- Make sure that you understand the different components of BFD, described in RFCs 5880, 5881, and 5883.
- BFD on a Citrix ADC appliance is supported for the following routing protocols:

  - BGP (IPv4 and IPv6)
  - OSPFv2 (IPv4)
  - OSPFv3 (IPv6)
- BFD on a Citrix ADC appliance is not supported for the following routing protocols:
  - ISIS
  - RIP (IPv4)
  - RIPng (IPv6)
- The following BFD features are not supported on a Citrix ADC appliance:
  - BFD Echo mode
  - BFD Authentication
  - BFD Demand asynchronous mode
- The minimum values for BFD interval and BFD Rx timers are 100 milliseconds.
- When BFD is used in a topology with shared IP addresses (for example, Layer 2 high availability setup with SNIP addresses or a cluster setup with striped IP addresses), BFD brings down the active sessions during a failover because the BFD failure detection time (order of milliseconds) is lesser than the HA failover detection interval (3–4 seconds). Therefore, Citrix recommends usage of Graceful restart in layer-2 HA topologies as the routes are retained during the failover process.

Configuration Steps

Configuring BFD on a Citrix ADC appliance consists of the following tasks:

- Configure BFD Parameters
- Configure BFD Support for Dynamic Routing Protocols

Configure BFD Parameters

The Citrix ADC appliance provides separate BFD session parameters for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. If you do not configure BFD parameters for a type of session, the default values are applied for that session.

The default value of each BFD parameter is same for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. The following table displays the default value of each BFD parameter.

BFD Parameter Name	Default Value
Interval	750 milliseconds
Minimum Rx	500 milliseconds
Multiplier	3

> **IMPORTANT:**
>
> Mellanox NICs in a Citrix appliance take around 1500 ms to initialize. You must set the BFD timers to more than 1500 ms for a Citrix ADC appliance with Mellanox NICs. Citrix recommends setting the BFD timers to 3000 ms:
>
> - Interval Tx = 600 ms
> - Minimum Rx = 600 ms
> - Multipler = 5

Configuring BFD Parameters for a Single Hop Session

To configure BFD parameters for a single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`interface vlan ID>`	Enter the interface configuration mode.
`bfd singlehop-peer interval <num> minrx <num> multiplier <num>`	Configure the BFD parameters on the specified interface.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)# interface vlan3

ns(config-if)# bfd singlehop-peer interval 200 minrx 200 multiplier 5

ns(config-if)# exit
<!--NeedCopy-->
```

Configuring BFD Parameters for IPv4 Multiple Hop Sessions

To configure BFD parameters for IPv4 multiple hop sessions by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`bfd multihop-peer <ipv4addr> interval <num> minrx <num> multiplier <num>`	Configure the BFD parameters for IPv4 multiple hops sessions.

Sample configuration:

```
1      > vtysh
2
3      ns# configure terminal
4
5      ns(config)# bfd multihop-peer 20.20.20.138 interval 300 minrx 300
           multiplier 5
6
7      ns(config)# exit
8  <!--NeedCopy-->
```

Configuring BFD Parameters for IPv6 Multiple Hop Sessions

To configure BFD parameters for IPv6 multiple hop sessions by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`bfd multihop-peer ipv6 <ipv6addr> interval <num> minrx <num> multiplier <num>`	Configure the BFD parameters for IPv6 multiple hops sessions.

Sample configuration:

```
1      > vtysh
2
3      ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx
           500 multiplier 5
```

```
4
5     ns(config)# exit
6  <!--NeedCopy-->
```

Configure BFD Support for Dynamic Routing Protocols

You can enable BFD for a dynamic routing protocol for a type of session with a peer. For example, single hop and multiple hops. The Citrix ADC appliance applies the relevant BFD parameter settings to the session.

Configuring BFD for an IPv4 BGP Single Hop Session

To configure BFD for an IPv4 BGP single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router bgp <asnumber>	BGP autonomous system. asnumber is a required parameter.
neighbor <ipv4addr> remote-as <num>	Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
neighbor <ipv4addr> fall-over bfd	Enable BFD for the specified neighbor.

Sample configuration:

```
1     > vtysh
2
3     ns# configure terminal
4
5     ns(config)#router bgp 1
6
7     ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9     ns(config-router)#neighbor 20.20.20.138 fall-over bfd
10
11    ns(config-router)#redistribute kernel
12
```

```
13      ns(config-router)#exit
14  <!--NeedCopy-->
```

Configuring BFD for an IPv4 BGP Multiple Hop Session

To configure BFD for an IPv4 BGP multiple hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router bgp <asnumber>	BGP autonomous system. asnumber is a required parameter.
neighbor <ipv4addr> remote-as <num>	Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
neighbor <ipv4addr> fall-over bfd multihop	Enable BFD for the specified neighbor.

Sample configuration:

```
1       > vtysh
2
3       ns# configure terminal
4
5       ns(config)#router bgp 1
6
7       ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9       ns(config-router)#neighbor 20.20.20.138 fall-over bfd multihop
10
11      ns(config-router)#redistribute kernel
12
13      ns(config-router)#exit
14  <!--NeedCopy-->
```

Configuring BFD for an IPv6 BGP Single Hop Session

To configure BFD for an IPv6 BGP single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router bgp <asnumber>	BGP autonomous system. asnumber is a required parameter.
neighbor <ipv6addr> remote-as <num>	Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
neighbor <ipv6addr> fall-over bfd	Enable BFD for the specified neighbor.
address-family ipv6	Enter address family configuration mode.
neighbor <ipv6addr> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.

Sample configuration:

```
> vtysh

ns# configure terminal ns(config)#router bgp 1

ns(config-router)#neighbor 30fe:123::124 remote-as 1

ns(config-router)#neighbor 30fe:123::124 fall-over bfd

ns(config-router)#address-family ipv6

ns(config-router-af)#neighbor 30fe:123::124 activate

ns(config-router-af)#redistribute kernel

ns(config-router-af)#exit

<!--NeedCopy-->
```

Configuring BFD for an IPv6 BGP Multiple Hop Session

To configure BFD for an IPv6 BGP multiple hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router bgp <asnumber>	BGP autonomous system. asnumber is a required parameter.
neighbor <ipv6addr> remote-as <num>	Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
neighbor <ipv6addr> fall-over bfd multihop	Enable BFD for the specified neighbor.
address-family ipv6	Enter address family configuration mode.
neighbor <ipv6addr> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link-local address.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx 500
    multiplier 5

ns(config)#router bgp 1

ns(config-router)#neighbor 20fe:125::138 remote-as 1

ns(config-router)#neighbor 20fe:125::138 fall-over bfd multihop

ns(config-router)#address-family ipv6

ns(config-router-af)#neighbor 20fe:125::138 activate

ns(config-router-af)#redistribute kernel
```

```
18
19 ns(config-router-af)#end
20
21 <!--NeedCopy-->
```

Configuring BFD for OSPFv2 (IPv4) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv2 protocol.

To configure BFD for OSPFv2 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ospf <process tag>	Enter OSPFv2 configuration mode.
bfd all-interfaces	Enable BFD on all interfaces that use OSPFv2.

Sample configuration:

```
1      > vtysh
2
3      ns# configure terminal
4
5      ns(config)#router ospf 1
6
7      ns(config-router)#bfd all-interfaces
8
9      ns(config-router)#redistribute kernel
10
11     ns(config-router)#exit
12 <!--NeedCopy-->
```

To configure BFD for OSPFv2 on a specific interface by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.

Command	Specifies
`configure terminal`	Enter global configuration mode.
`interface` <vlan ID>	Enter the interface configuration mode.
`ip ospf bfd`	Enable BFD on the specified interface that uses OSPFv2.

Sample configuration:

```
1      > vtysh
2
3      ns# configure terminal
4
5      ns(config)# interface vlan5
6
7      ns(config-if)# ip ospf bfd
8
9      ns(config-if)# exit
10 <!--NeedCopy-->
```

Configuring BFD for OSPFv3 (IPv6) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv3 protocol.

To configure BFD for OSPFv3 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router ipv6 ospf <process tag>`	Enter OSPFv3 configuration mode.
`bfd all-interfaces`	Enable BFD on all interfaces that use OSPFv3.

Sample configuration:

```
1      > vtysh
2
3      ns# configure terminal
```

```
4
5     ns(config)#router ipv6 ospf 10
6
7     ns(config-router)#bfd all-interfaces
8
9     ns(config-router)#redistribute kernel
10
11    ns(config-router)#exit
12 <!--NeedCopy-->
```

To configure BFD for OSPFv3 on a specific interface by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`interface` <vlan ID>	Enter the interface configuration mode.
`ipv6 ospf bfd`	Enable BFD on the specified interface that uses OSPFv3.

Sample configuration:

```
1     > vtysh
2
3     ns# configure terminal
4
5     ns(config)# interface vlan15
6
7     ns(config-if)# ipv6 ospf bfd
8
9     ns(config-if)# exit
10 <!--NeedCopy-->
```

Configuring Static Routes

September 14, 2021

Static routes are manually created to improve the performance of your network. You can monitor

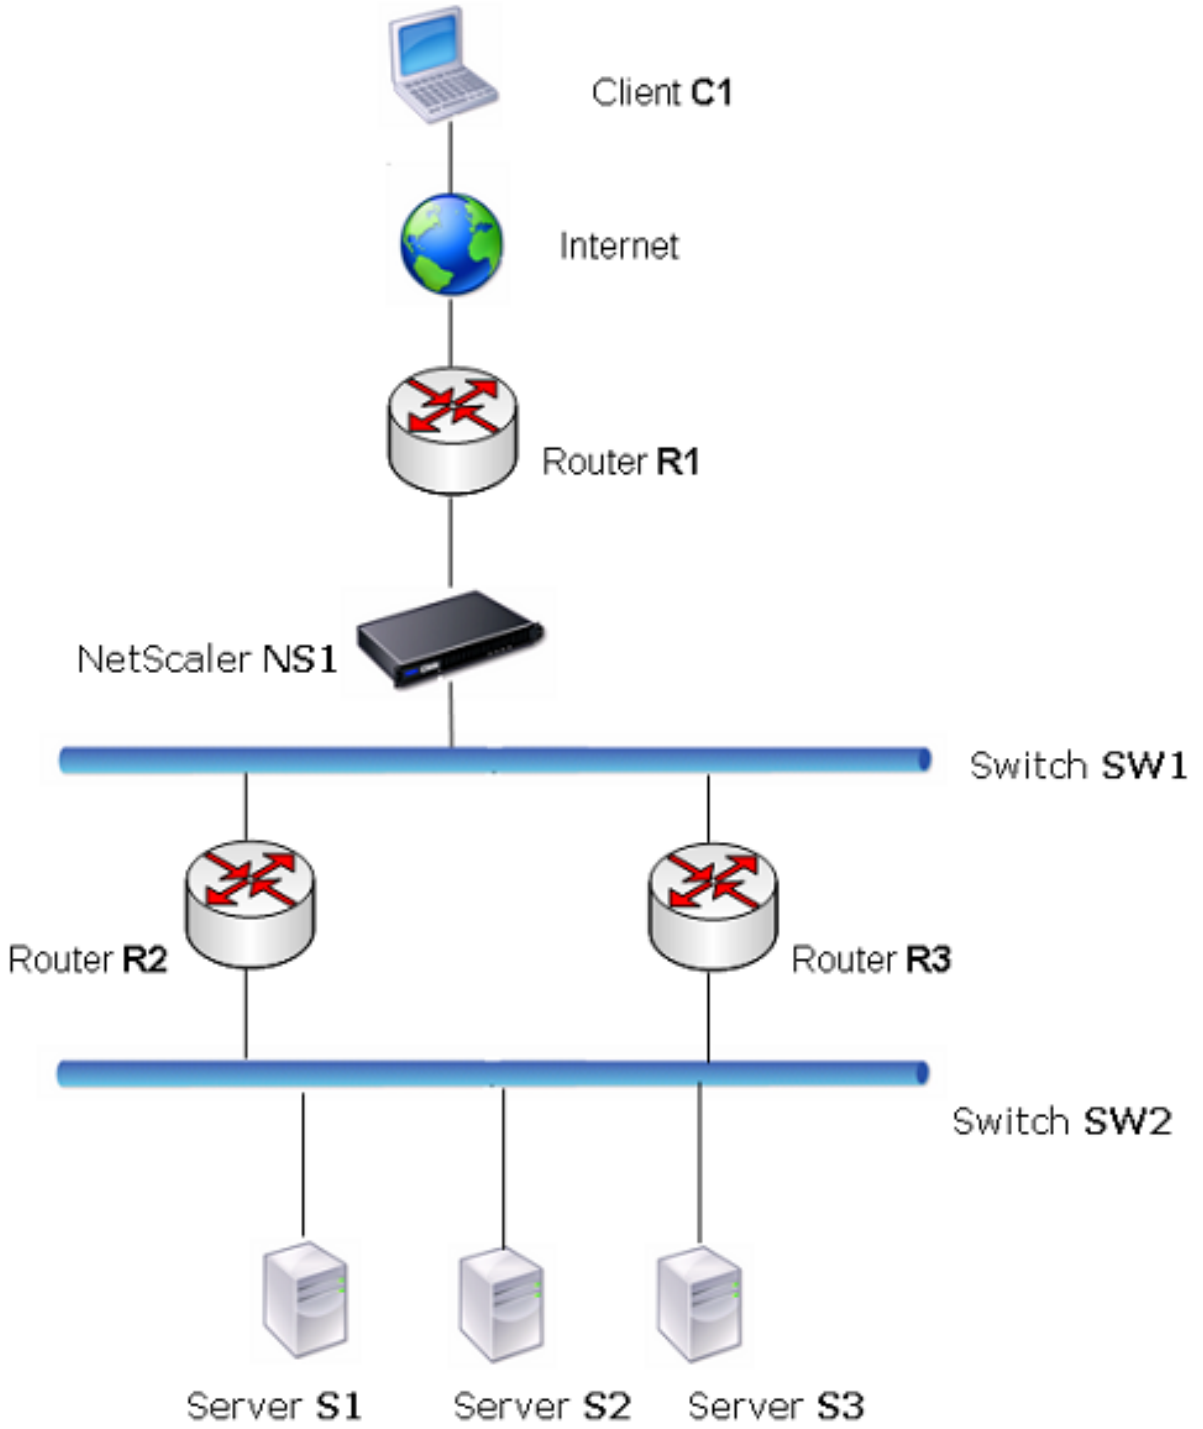
static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

Monitored Static Routes. If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the Citrix ADC appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the Citrix ADC. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

Note: In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.

Consider the following simple topology, in which a Citrix ADC is load balancing traffic to a site across multiple servers.



Router R1 moves traffic between the client and the Citrix ADC appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers'

subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the Citrix ADC points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the Citrix ADC marks it as DOWN. The Citrix ADC now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The Citrix ADC supports monitoring of IPv4 and IPv6 static routes. You can configure the Citrix ADC to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the Citrix ADC to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

Weighted Static Routes. When the Citrix ADC appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The Citrix ADC then uses both the weight and the hashed value for balancing the load.

Null Routes. If the route chosen in a routing decision is inactive, the Citrix ADC appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

Configuring IPv4 Static Routes

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

CLI procedures

To create a static route by using the CLI:

At the command prompt, type:

- add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise (DISABLED | ENABLED)]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example:

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise
   ENABLED
 Done
<!--NeedCopy-->
```

To create a monitored static route by using the CLI:

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive_integer>] [-weight <positive_integer>][-msr (ENABLED | DISABLED) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example:

```
> add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6
    -msr ENBLED -monitor PING
 Done
<!--NeedCopy-->
```

To create a null route by using the CLI:

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

Example:

```
> add route 10.102.29.0 255.255.255.0 null
 Done
<!--NeedCopy-->
```

To remove a static route by using the CLI:

At the command prompt, type:

rm route <network> <netmask> <gateway>

Example:

```
> rm route 10.102.29.0 255.255.255.0 10.102.29.3
 Done
<!--NeedCopy-->
```

GUI procedures

To configure a static route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

Configuring IPv6 Static Routes

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

CLI procedures

To create an IPv6 route by using the CLI:

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- add route6 <network> <gateway> [-vlan <positive_integer>]
- show route6 [<network> [<gateway>]

Example:

```
1 > add route6 ::/0 FE80::67 -vlan 5
2  Done
3 <!--NeedCopy-->
```

To create a monitored IPv6 static route by using the CLI:

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the configuration:

- add route6 <network> <gateway> [-msr (ENABLED | DISABLED) [-monitor <string>]
- show route6 [<network> [<gateway>]

Example:

```
1 > add route6 ::/0 2004::1 -msr ENABLED -monitor PING
2  Done
3 <!--NeedCopy-->
```

To remove an IPv6 route by using the CLI:

At the command prompt, type:

rm route6 <network> <gateway>

Example:

```
> rm route6 ::/0 FE80::67
 Done
<!--NeedCopy-->
```

GUI procedures

To configure an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

Route Health Injection Based on Virtual Server Settings

September 14, 2021

The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the Citrix ADC appliance for advertising the route of a VIP address.

- **VSVR_CNTRLD**. It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.
- **RHI STATE**. It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the Citrix ADC always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.

- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The Citrix ADC appliance has two virtual servers V1 and V2 associated with the VIP address:

Associated virtual servers for a VIP	State 1	State 2	State 3	State 4
RHI State set to PASSIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	Yes
RHI State set to ACTIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	No
RHI State set to ACTIVE on one virtual server and PASSIVE on the other				
V1 (RHI State = ACTIVE)	UP	UP	DOWN	DOWN
V2 (RHI State = PASSIVE)	UP	DOWN	UP	DOWN

Associated virtual servers for a VIP	State 1	State 2	State 3	State 4
Advertise the route for this VIP address?	Yes	Yes	No	No

To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to VSVR_CNTRLD for the VIP address.
- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using the CLI:

At the command prompt, type:

- **set ns ip** <IPAddress> [-**vserverRHILevel** <vserverRHILevel>]

To set the RHI State parameter of a virtual server by using the CLI:

At the command prompt, type:

- **set lb vserver** <name> [-**RHIstate** (**PASSIVE** | **ACTIVE**)]

To set the vServer RHI Level for a VIP address by using GUI

1. Navigate to **System** > **Network** > **IPs**.
2. Select a VIP address, and then click **Edit**.
3. Set the **Vserver RHI Level** parameter to **VSVR_CNTRLD**, and then click **OK**.

To set the RHI State parameter of a virtual server by using GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Select a load balancing virtual server, and then click **Edit**.
3. Set the **RHI State** parameter, and then click **OK**.

Configuring Policy-Based Routes

September 14, 2021

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the Citrix ADC appliance to route outgoing packets from a specific

IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the Citrix ADC applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the Citrix ADC to route the packet. These actions are known as "processing modes." The processing modes are:

- **ALLOW.** The appliance sends the packet to the designated next-hop router.
- **DENY.** The Citrix ADC applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

Policy-Based Routes (PBR) for IPv4 Traffic

September 14, 2021

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBRs. When you create a PBR without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR, the Citrix ADC compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the Citrix ADC and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

CLI procedures

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr

Example:

```
> add ns pbr pbr1  allow -srcip 10.102.37.252 -destip 10.10.10.2 -
   nexthop 10.102.29.77
 Done
<!--NeedCopy-->
```

To modify the priority of a PBR by using the CLI:

At the command prompt, type the following commands to modify the priority and verify the configuration:

- set ns pbr <name> [-action (ALLOW | DENY)] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr [<name>]

Example:

```
> set ns pbr pbr1 -priority 23
 Done
```

```
<!--NeedCopy-->
```

To remove one or all PBRs by using the CLI:

At the command prompt, type one of the following commands:

- rm ns pbr <name>
- clear ns pbrs

Example:

```
> rm ns pbr pbr1
 Done

> clear ns PBRs
 Done
<!--NeedCopy-->
```

GUI procedures

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

Applying a PBR

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

Note: PBRs created on the Citrix ADC appliance do not work until they are applied.

To apply a PBR by using the CLI:

At the command prompt, type:

apply ns PBRs

To apply a PBR by using the GUI:

1. Navigate to System > Network > PBRs.

2. On the PBRs tab, select the PBR, in the Action list, select Apply.

Enabling or Disabling PBRs

By default, the PBRs are enabled. This means that when PBRs are applied, the Citrix ADC appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the Citrix ADC does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the CLI:

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

Example:

```
> enable ns PBR pbr1
 Done
> show ns PBR pbr1
1)      Name: pbr1
        Action: ALLOW                           Hits: 0
        srcIP = 10.102.37.252
        destIP = 10.10.10.2
        srcMac:                                 Protocol:
        Vlan:                                   Interface:
        Active Status: ENABLED                  Applied Status: APPLIED
        Priority: 10
        NextHop: 10.102.29.77

 Done

> disable ns PBR pbr1
Warning: PBR modified, use 'apply pbrs' to commit this operation

> apply pbrs
 Done

> show ns PBR pbr1
1)      Name: pbr1
        Action: ALLOW                           Hits: 0
        srcIP = 10.102.37.252
        destIP = 10.10.10.2
        srcMac:                                 Protocol:
```

```
28          Vlan:                                   Interface:
29          Active Status: DISABLED                 Applied Status:
               NOTAPPLIED
30          Priority: 10
31          NextHop: 10.102.29.77
32  Done
33  <!--NeedCopy-->
```

To enable or disable a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

Renumbering PBRs

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the CLI:

At the command prompt, type:

- renumber ns pbrs

To renumber PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

Use Case - PBR with Multiple Hops

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on Citrix ADC appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The Citrix ADC appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.

- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - ROUNDROBIN
  - DESTINATIONIPHASH
  - SOURCEIPHASH
  - SRCIPDESTIPHASH
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - LTRM
  - CALLIDHASH
  - CUSTOM LOAD
- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP

The following table lists the names and values of the entities configured on the Citrix ADC appliance:

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

Table 1. Sample Values for Creating Entities

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example:

```
> add service Router1 1.1.1.254 ANY *
 Done
> add service Router2 2.2.2.254 ANY *
 Done
> add service Router3 3.3.3.254 ANY *
 Done
<!--NeedCopy-->
```

To create a service by using the GUI:

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

Example:

```
> add lb vserver LLB1 ANY
 Done
> bind lb vserver LLB1 Router1 Router2 Router3
 Done
<!--NeedCopy-->
```

To create a link load balancing virtual server and bind a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
   Note: Make sure that
   Directly Addressable is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

Example:

```
> add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
 Done
> add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
 Done
<!--NeedCopy-->
```

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

Policy-Based Routes (PBR6) for IPv6 Traffic

September 14, 2021

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

Creating or Modifying a PBR6

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR6, the Citrix ADC compares the packet against the PBR6 with the next highest priority.

CLI procedures

To create a PBR6 by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>]

[-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]

- show ns pbr

To modify or remove a PBR6 by using the CLI:

To modify a PBR6, type the **set pbr6** <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the CLI:

At the command prompt, type one of the following commands:

- **rm ns pbr6** <name>
- **clear ns pbr6**

GUI procedures

To create or modify a PBR6 by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

Applying PBR6s

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

Note: PBR6s created on the Citrix ADC appliance do not work until they are applied.

To apply PBR6s by using the CLI:

At the command prompt, type:

- **apply ns PBR6**

To apply PBR6s by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

Enabling or Disabling a PBR6

By default, the PBR6s are enabled. This means that when PBR6s are applied, the Citrix ADC appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the Citrix ADC does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns pbr** <name>
- **disable ns pbr** <name>

To enable or disable a PBR6 by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

Renumbering PBR6s

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the CLI:

At the command prompt, type:

- **renumber ns pbr6**

To renumber PBR6s by using the GUI:

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

MAC Address Wildcard Mask for PBRs

September 14, 2021

A wildcard mask parameter has been introduced for extended PBRs and PBR6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of outgoing packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an PBR rule, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the outgoing packets.

To specify a range of source MAC addresses in a PBR rule by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> <action> -**srcMac** <mac_addr> -**srcMacMask** <string>
- **show ns pbr** <pbrname>

Example:

```
1 > add ns pbr PBR-1 ALLOW -srcip 192.0.2.34 -srcMac 96:fa:95:1d:67:4a
      - srcMacMask 000000111111 -nexthop 198.51.100.1
2
3  Done
```

To specify a range of source MAC addresses in an PBR6 rule by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> -**srcMac** <mac_addr> -**srcMacMask** <string>
- **show pbr6** <pbr6name>

Example:

```
> add ns pbr6 PBR6-1 ALLOW  -srcipv6 2001:db8:0::7 -srcMac 96:fa:95:1d
   :67:4a   -srcMacMask 000000001111 -nexthop 2001:db8:0::1
 Done
```

Using NULL Policy Based Routes to Drop Outgoing Packets

September 14, 2021

Some situations might demand that the Citrix ADC appliance drops specific outgoing packets instead of routing them, for example, in testing cases and during deployment migration.

NULL policy based routes can be used to drop specific outgoing packets. A NULL PBR is a type of PBR that has the nexthop parameter set to NULL. The Citrix ADC appliance drops outgoing packets that match a NULL PBR.

Configuring NULL PBRs for IPv4 Packets

To create a NULL PBR by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> ALLOW [**-td** <positive_integer>] [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] (-**nextHop NULL**) [**srcMac** <mac_addr> [-**srcMacMask** <string>]] [-**protocol** <protocol> | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer> | -**vxlan** <positive_integer>] [-**interface** <interface_name>] [-**priority** <positive_integer>] [-**msr** (**ENABLED** | **DISABLED**) [-**monitor** <string>]] [-**state** (**ENABLED** | **DISABLED**)[-**ownerGroup** <string>]
- **apply ns pbrs**
- **show ns pbr**<id>

To configure a NULL PBR by using the GUI:

Navigate to **System** > **Network**> **PBRs**, on the **PBRs** tab, add a **new NULL PBR**, or edit an existing NULL PBR.

Sample configuration

In the following sample configuration, NULL PBR6 PBR6-NULL-EXAMPLE-1 is configured for dropping any outgoing IPv6 packets from interface 1/5.

```
> add ns pbr PBR6-NULL-EXAMPLE-1 ALLOW  -nextHop NULL -interface 1/5
 Done

> apply ns pbr6
 Done
```

Traffic distribution in multiple routes based on five tuples information

September 14, 2021

In a load balancing setup, a Citrix ADC appliance can have multiple routes to send a packet to its destination. For example: to a server, and to a client.

A Citrix ADC appliance uses a hashing algorithm to select a route for sending the packet to its destination.

The hashing algorithm uses the following two tuples of a packet to calculate a hash, based on which the Citrix ADC appliance selects a route for the packet.

- Source IP address
- Destination IP address

The selection of routes based on two tuples information can cause an uneven distribution of traffic on the available routes. This uneven distribution of traffic leads to overloading of traffic in some routes.

To resolve this issue, from build 13.0 71.x, the Citrix ADC appliance uses the following five tuples information of a packet in the hashing algorithm to select a route for the packet:

- Source IP address (Client IP)
- Source Port (Client Port)
- Destination IP address(Service IP)
- Destination Port (Service Port)
- Protocol number

The selection of routes based on five tuples information ensures even distribution of traffic on the available routes. This even distribution of traffic prevents overloading of traffic in a route.

Consider an example of a load balancing setup where a client sends a request to the VIP address. The Citrix ADC appliance uses the following five tuples information to select a route to send the request packet to the load balanced server:

- Source IP address (Client IP address)
- Source Port (Client port)
- Destination IP address (Service IP address)

- Destination Port (Service port number)
- Protocol Number

Precedence regarding other route selection based Citrix ADC features

This section talks about the precedence of the route selection based on five tuples feature and other route selection related features in a Citrix ADC appliance.

- **Policy Based Routes (PBR)**. PBR rules always take precedence over route selection based on five tuples.
- **Mac Based Forwarding (MBF)**. In a load balancing configuration, MBF or route selection based on five tuples takes precedence in the following cases:
  - For a client initiated traffic to the VIP address of the load balancing configuration in the Citrix ADC appliance:
    * Request traffic destined to a load balanced server. Route selection based on five tuples takes preference over MBF.
    * Response Traffic destined to the client. MBF takes preference over route selection based on five tuples.
  - For a server initiated traffic to the SNIP address in the Citrix ADC appliance:
    * Response Traffic destined to the client. Route selection based on five tuples takes preference over MBF.
    * Request traffic destined to a load balanced server. MBF takes preference over route selection based on five tuples.

Troubleshooting Routing Issues

September 14, 2021

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the Citrix ADC appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.

- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

Generic Routing FAQs

September 14, 2021

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

  The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from CLI to save both ns.conf and ZebOS.conf files.

- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

  The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

- How do I block the advertisement of default routes?

  The default route is not injected into ZebOS.

- How do I view the debug output of networking daemons?

  You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

  ```
  ns(config)# log file /var/ZebOS.log
  <!--NeedCopy-->
  ```

  You can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

  ```
  ns# terminal monitor
  ```

```
<!--NeedCopy-->
```

- How do I collect cores of running daemons?

  You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

```
gcore [-s] [-c core] [executable] pid
<!--NeedCopy-->
```

  The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

```
root@ns#gcore -s -c nsm.core /netscaler/nsm 342
<!--NeedCopy-->
```

- How do I run a batch of ZebOS commands?

  You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

```
!
router bgp 234
network 1.1.1.1 255.255.255.0
!
route-map bgp-out2 permit 10
 set metric 9900
 set community 8602:300
!
<!--NeedCopy-->
```

Troubleshooting OSPF-Specific Issues

September 14, 2021

Before you start debugging any OSPF specific issue, you must collect information from the Citrix ADC appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
    - If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
    - If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

    ```
    gcore -s -c xyz.core /netscaler/ospfd <pid>
    ```

    Note: The gcore command is non-disruptive.

Collect additional information from the Citrix ADC as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

    ```
    ns(config)# log file /var/ospf.log
    <!--NeedCopy-->
    ```

2. Enable debugging ospf events and log them by using the following command:

    ```
    ns(config) #log file /var/ospf.log
    <!--NeedCopy-->
    ```

    Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

Internet Protocol version 6 (IPv6)

September 14, 2021

A Citrix ADC appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services.

The following table lists some of the IPv6 features that the Citrix ADC appliance supports.

Table 1. Some Supported IPv6 Features

IPv6 features
IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)
Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)
Management Applications (ping6, telnet6, ssh6)
Static Routing and Dynamic routing (OSPF, BGP, RIPng, and ISIS)
Port Based VLANs
Access Control Lists for IPv6 addresses (ACL6)
IPv6 Protocols (TCP6, UDP6, ICMP6)
Server Side Support (IPv6 addresses for vservers, services)
USIP (Use source IP) and DSR (Direct Server Return) for IPv6
SNMP and CVPN for IPv6
HA with native IPv6 node address
IPv6 addresses for MIPs
Path-MTU discovery for IPv6

Implementing IPv6 Support

You must enable IPv6 feature on a Citrix ADC appliance before you can use or configure it. If IPv6 is disabled, the Citrix ADC does not process IPv6 packets. It displays the following warning when you run an unsupported command:

```
"Warning: Feature(s) not enabled [IPv6PT]"
<!--NeedCopy-->
```

Use either of the following procedures to enable or disable IPv6.

CLI procedures

To enable or disable IPv6 by using the CLI:

At the command prompt, type one of the following commands:

- enable ns feature ipv6pt
- disable ns feature ipv6pt

GUI procedures

To enable or disable IPv6 by using the GUI:

1. Navigate to **System** > **Settings**, in the **Modes and Features** group, click **Configure Advanced Features**.
2. Select or clear the **IPv6 Protocol Translation** option.

VLAN Support

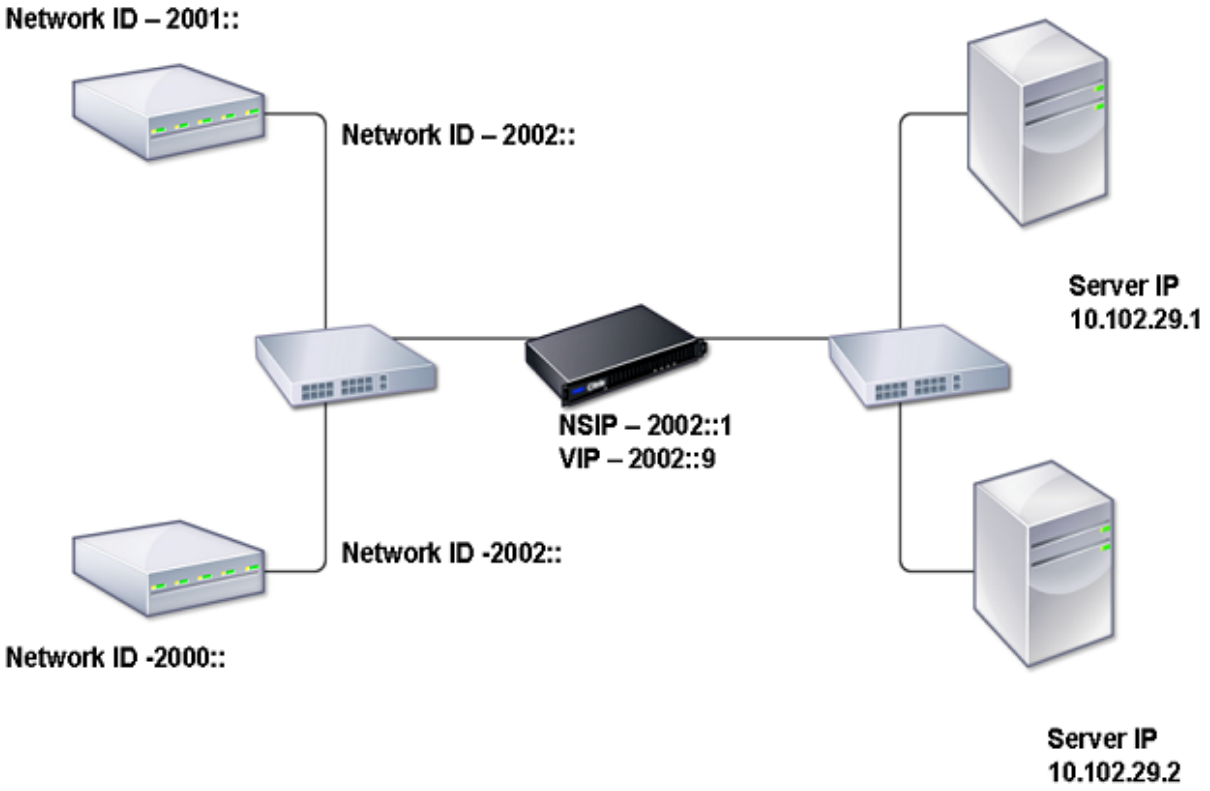
If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the Citrix ADC appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN. For more information about ND6 and VLANs, see Configuring Neighbor Discovery.

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

Simple Deployment Scenario

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology



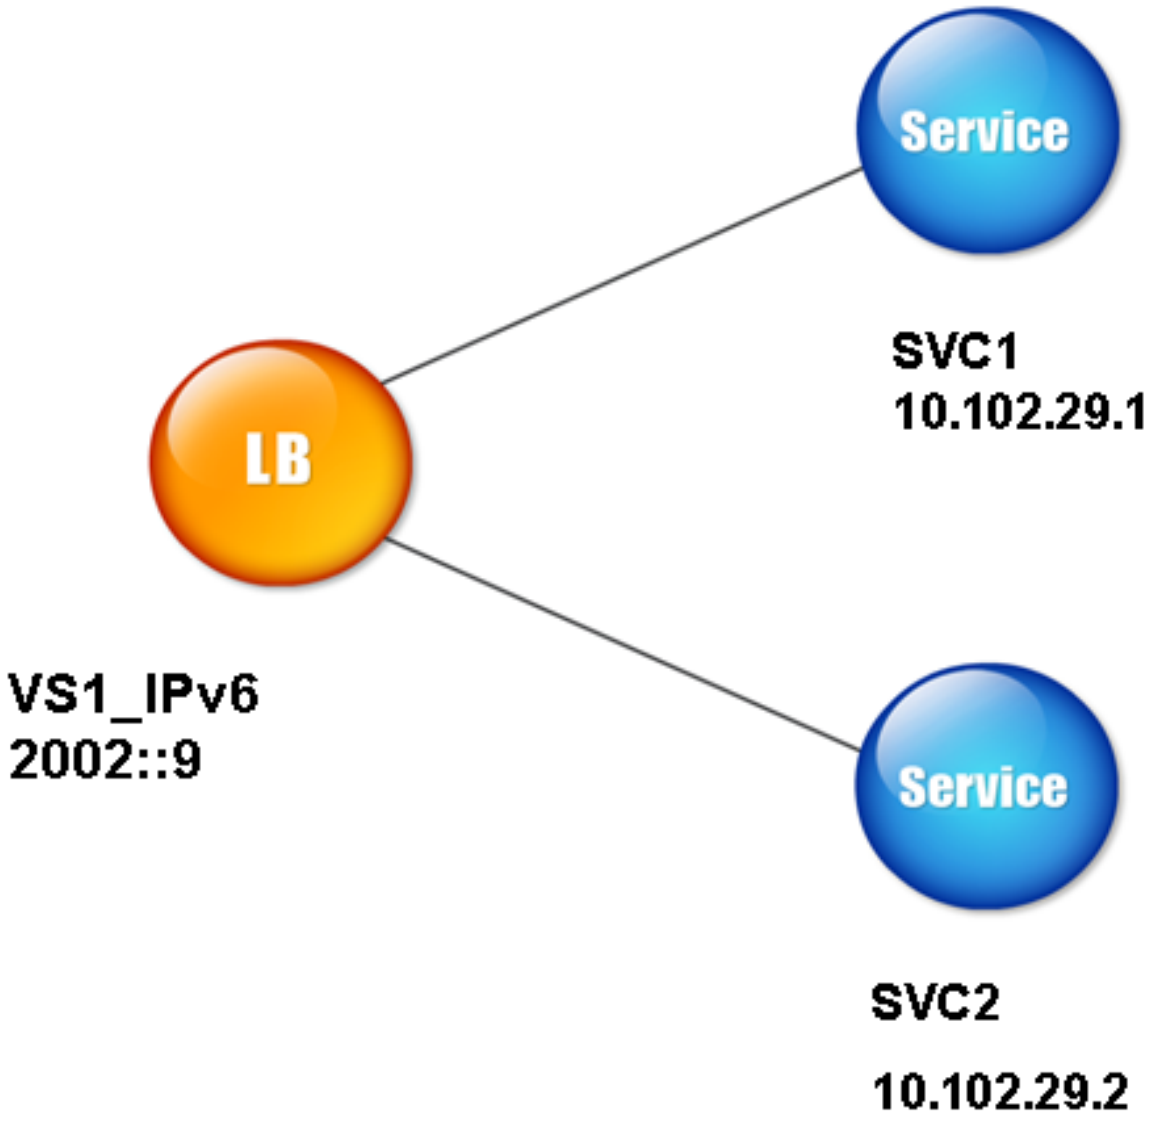
The following table summarizes the names and values of the entities that must be configured on the Citrix ADC.

Table 2. Sample Values for Creating Entities

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1
	SVC2	10.102.29.2

The following figure shows the entities and values of the parameters to be configured on the Citrix ADC.

Figure 2. IPv6 Entity Diagram



To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

CLI procedures

To create IPv4 services by using the CLI:

At the command prompt, type:

- **add service** <Name> <IPAddress> <Protocol> <Port>
- **sh service** <Name>

Example:

```
> add service SVC1 10.102.29.1 HTTP 80
Done

>add service SVC2 10.102.29.2 HTTP 80
Done
<!--NeedCopy-->
```

To create IPv6 vserver by using the CLI:

At the command prompt, type:

- **add lb vserver** <Name> <IPAddress> <Protocol> <Port>
- **sh lb vserver** <Name>

Example:

```
> add lb vserver VS1_IPv6 2002::9 HTTP 80
Done
<!--NeedCopy-->
```

To bind a service to an LB vserver by using the CLI:

At the command prompt, type:

- **bind lb vserver** <name> <service>
- **sh lb vserver** <name>

Example:

```
> bind lb vserver VS1_IPv6 SVC1
Done
<!--NeedCopy-->
```

GUI procedures

To create IPv4 services by using the GUI:

Navigate to **Traffic Management** > **Load Balancing** > **Services**, click **Add**, and then set the following parameters:

- Service Name
- IP Address
- Protocol

- Port

To create IPv6 vserver by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, click **Add**, and select the **IPv6** check box.
2. Set the following parameters:
   - Name
   - Protocol
   - IP Address Type
   - IP Address
   - Port

To bind a service to an LB vserver by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. In the **Load Balancing Virtual Servers** page, select the vserver for which you want to bind the service (for example, VS1_IPv6).
3. Click **Open**.
4. In the **Configure Virtual Server (Load Balancing)** dialog box, on the **Services** tab, select the **Active** check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click **OK**.
6. Repeat steps 1-4 to bind the service (for example, SVC2 to the vserver).

Host Header Modification

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

CLI procedures

To change the IPv6 address in the host header to an IPv4 address by using the CLI:

At the command prompt, type:

- **set ns ip6** <IPv6Address> -**map** <IPAddress>
- **sh ns ip6** <IPv6Address>

Example:

```
> set ns ip6 2002::9 -map 200.200.200.200
Done
<!--NeedCopy-->
```

GUI procedures

To change the IPv6 address in the host header to an IPv4 address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** and, on the **IPV6s** tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Edit.
2. In the **Mapped IP** text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

VIP Insertion

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP. Then, you can enable VIP insertion to enable insertion of the IPv4 VIP address and port number in the HTTP requests sent to the servers.

CLI procedures

To configure a map IPv6 address by using the CLI:

At the command prompt, type:

set ns ip6 <IPv6Address> -**map** <IPAddress>

Example:

```
> set ns ip6 2002::9 -map 200.200.200.200
 Done
<!--NeedCopy-->
```

To enable VIP insertion by using the CLI:

At the command prompt, type:

- **set lb vserver** <name> -**insertVserverIPPort** <Value>
- **sh lb vserver** <name>

Example:

```
> set lb vserver VS1_IPv6 -insertVserverIPPort ON
 Done

<!--NeedCopy-->
```

GUI procedures

To configure a map IPv6 address by using the GUI:

1. Navigate to **System** > **Network** > **IPs**, on the **IPV6s** tab, select the IP address for which you want to configure a map IP address, for example, 2002:0:0:0:0:0:0:9, and click **Edit**.
2. In the **Mapped IP** text box, type the map IP address that you want to configure, for example, 200.200.200.200.

To enable VIP insertion by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select the virtual server that you want to enable port insertion, and click **Edit**.
2. In the **Advanced** tab, under **Traffic Settings**, in the **Vserver IP Port Insertion** drop-down list box, select **VIPADDR**.
3. In the **Vserver IP Port Insertion** text box, type the vip header.

Traffic Domains

September 14, 2021

> **Warning**
>
> Citrix recommends you to use Admin Partitions instead of using Traffic Domains. For more information, see Admin Partitioning page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a Citrix ADC appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a Citrix ADC appliance are the following:

- **Use of duplicate IP addresses in a Network**. Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a Citrix ADC appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the Citrix ADC appliance**. Traffic domains also allow you to use duplicate Citrix ADC feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.
  Note: Duplicate entities with same name are not supported.

- **Multitenancy**. Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

A Citrix ADC appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the Citrix ADC appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see Supported Citrix ADC Features in Traffic Domains.

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1.

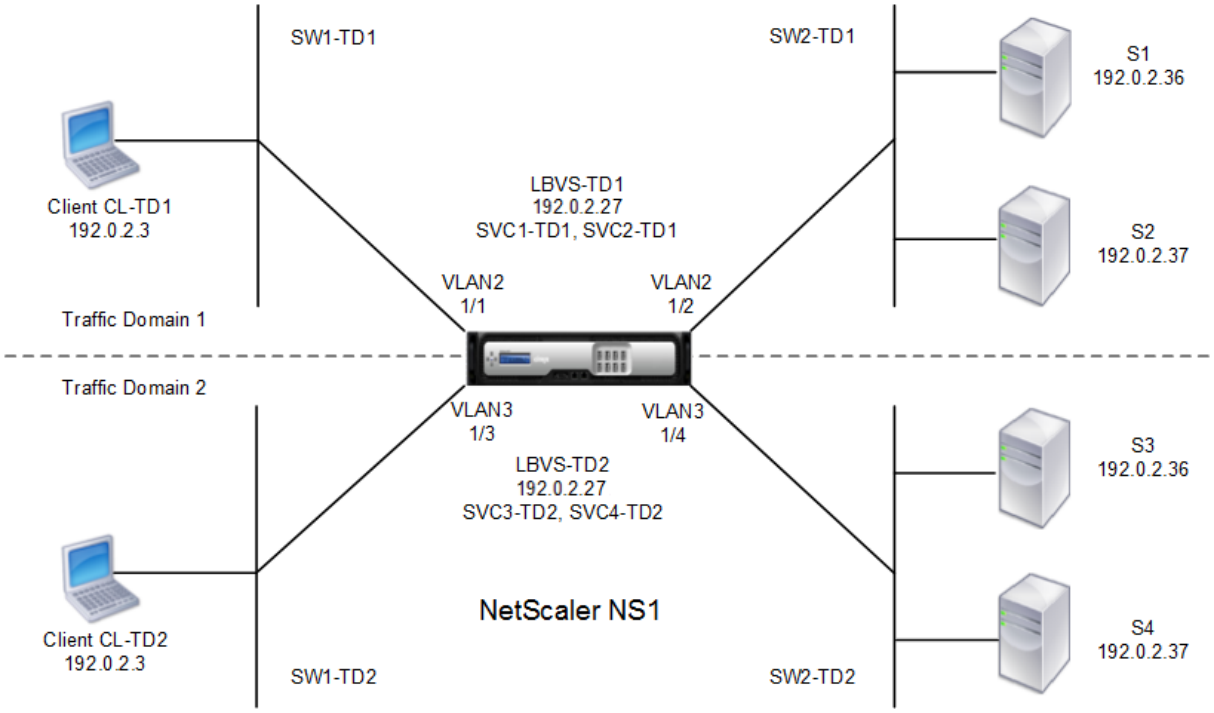
In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the Citrix ADC appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work



The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.27
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
Service bound to virtual server LBVS-TD1	SVC2-TD1	IP address: 192.0.2.37

Entity	Name	Details
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
Settings in traffic domain 2		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4
Client connected to TD2	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.27
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
Service bound to virtual server LBVS-TD2	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD1.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.27. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.27.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.27. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD2.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.27. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.27. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.27. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

Supported Citrix ADC Features in Traffic Domains

The Citrix ADC features in the following list are supported in all traffic domains.

> **Important**
>
> Any Citrix ADC feature not listed below is supported only in the default traffic domain.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6
- MSR
- MSR6
- Net profiles

- SNMP MIBs
- Fragmentation
- Monitors (Scriptable monitors are not supported)
- Content Switching
- Cache Redirection
- Persistency (Persistency groups are not supported)
- Service (Domain based services are not supported)
- Service group (Domain based service groups are not supported)
- Policies (*)
- PING
- TRACEROUTE
- PMTU
- High Availability (connection mirroring is not supported)
- Cluster (Supported on L2 clusters. Not supported on L3 clusters)
- Cookie Persistency
- MSS
- Logging (Syslog is not supported)
- Priority Queuing
- Surge Protection
- HTTP DOSP (**)
- Load balancing (The following types are not supported:)
  - TFTP
  - RTSP
  - Diameter
  - SIP
  - SMPP
- NAT46
- NAT64
- DNS64
- Forwarding Session Rules
- SNMP

> **Note**
>
> - * Policies do not have global binding points for traffic domains. However, policies can be bound to a specific load balancing virtual server of a traffic domain.
> - ** HTTP DOSP policies do not have global binding points for traffic domains. However, HTTP DOSP policies can be bound to a specific load balancing service of a traffic domain.
> - Global Server Loading Balancing (GSLB) and ADNS features in Citrix ADC are not aware of

> Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see http://support.citrix.com/article/CTX202277.

Configuring Traffic Domains

Configuring a traffic domain on the Citrix ADC appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain**. Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled How Traffic Domains Work.

The CLI has two commands for these two tasks, but the GUI combines them in a single dialog box.

CLI procedures

To create a VLAN and bind interfaces to it by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **bind vlan** <id> -**ifnum** <slot/port>
- **show vlan** <id>

To create a traffic domain entity and bind VLANs to it by using the CLI:

At the command prompt, type:

- **add ns trafficdomain** <td>
- **bind ns trafficdomain** <td> -**vlan** <id>
- **show ns trafficdomain** <td>

To create a service by using the CLI:

At the command prompt, type:

- **add service** <name> <IP> <serviceType> <port> -**td** <id>
- **show service** <name>

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- **add lb vserver** <name> <serviceType> <IPAddress> <port> -**td** <id>
- **bind lb vserver** <name> <serviceName>
- **show lb vserver** <name>

GUI procedures

To create a VLAN by using the GUI:

Navigate to **System** > **Network** > **VLANs**, click **Add**, and set the parameters.

To create a traffic domain entity by using the GUI:

Navigate to **System** > **Network** > **Traffic Domains**, click **Add**, and in the **Create Traffic Domain** dialog box, set the parameters.

To create a service by using the GUI:

Navigate to **Traffic Management** > **Load Balancing** > **Services**, click **Add**, and set the parameters.

To create a load balancing virtual server by using the GUI:

Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, click **Add**, and set the parameters.

Inter Traffic Domain Entity Bindings

September 14, 2021

You can bind services in one traffic domain to a virtual server in another traffic domain. All the services to be bound to a virtual server in a different traffic domain must reside in the same traffic domain.

You configure this support by using the existing bind lb vserver command or the related GUI procedure.

This capability can facilitate interaction between different traffic domains. In an enterprise, servers can be grouped in different traffic domains. Virtual servers are created in a traffic domain that faces the internet. A virtual server from this traffic domain can be configured to load balance servers in

another traffic domain. This virtual server receives connection requests from the Internet to be forwarded to the bound servers.

When a Citrix ADC is used in a cloud infrastructure, each tenant can be assigned a separate traffic domain, and all the resources (including servers) for a tenant can be grouped together in the tenant's traffic domain. For each tenant, a virtual server is created for load balancing servers in its traffic domain. All of these virtual servers are grouped together in a single traffic domain that faces the Internet.

Consider an example of in which cloud service provider Example-Cloud-A has three traffic domains, with IDs 10, 20, and 30, configured on Citrix ADC appliance NS1.

Example-Org-A and Example-Org-B are tenants of Example-Cloud-A. Tenant A is assigned traffic domain 20, and tenant B is assigned domain 30. Servers S1 and S2 reside in traffic domain 20 and servers S3 and S4 reside in traffic domain 30.

Traffic domain 10 faces the internet. Virtual servers LBVS-1 and LBVS-2 are created in traffic domain 10. LBVS-1, in traffic domain 10, is configured to load balance servers S1 and S2, which are in traffic domain 20. LBVS-2, in traffic domain 10, is configured to load balance servers S3 and S4, which are in traffic domain 30.

Therefore, these virtual servers accept Internet connection requests for servers that are in a different traffic domain than that of the virtual servers.

virtual MAC Based Traffic Domains

September 14, 2021

You can associate a traffic domain with a virtual MAC address instead of with VLANs. The Citrix ADC then sends the traffic domain's virtual MAC address in all responses to ARP queries for network entities in that domain. As a result, the ADC can segregate subsequent incoming traffic for different traffic domains on the basis of the destination MAC address, because the destination MAC address is the virtual MAC address of a traffic domain. After creating entities on a traffic domain, you can easily manage and monitor them by performing traffic domain level operations.

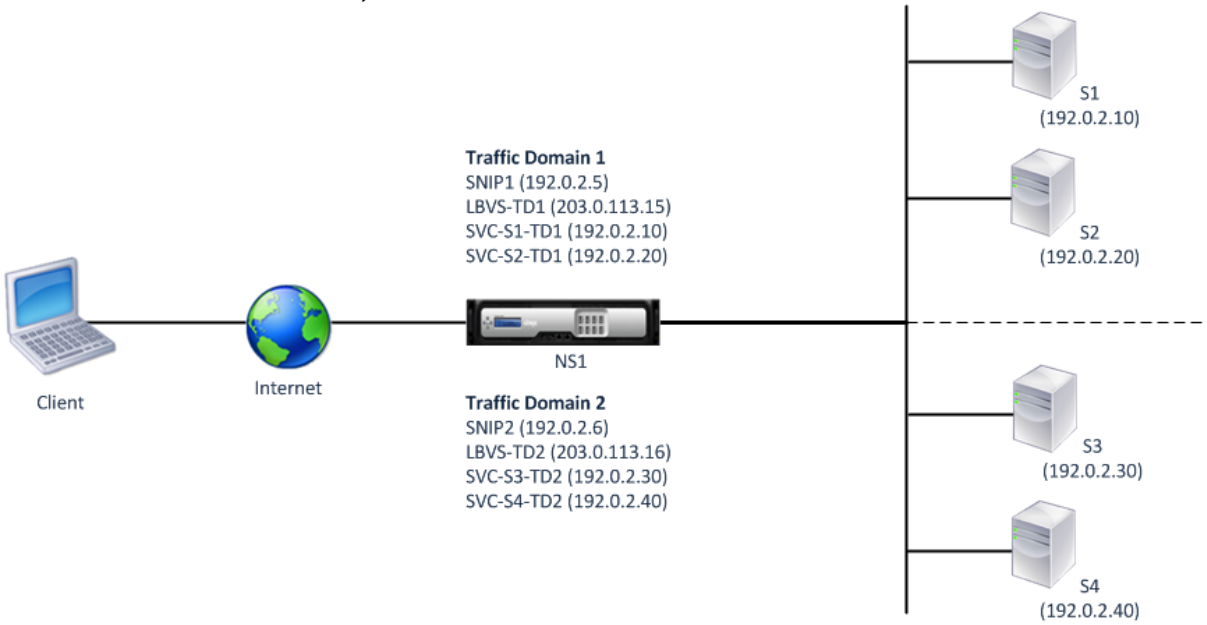
Consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1. The Citrix ADC creates a virtual MAC address virtual MAC1 and associates it with traffic domain 1. Similarly, the Citrix ADC created another virtual MAC address virtual MAC2 and associates with traffic domain 2.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. A subnet IP address (SNIP) SNIP1 is configured for enabling the Citrix ADC to communicate with S1 and S2. Because virtual MAC1 is associated with traffic domain 1, the

appliance sends virtual MAC1 as the MAC address in all ARP announcements and ARP responses for LBVS-TD1 and SNIP1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. A SNIP address SNIP2 is configured for enabling the Citrix ADC to communicate with S3 and S4. Because virtual MAC2 is associated with traffic domain 2, the appliance sends virtual MAC2 as the MAC address in all ARP announcements and ARP responses for LBVS-TD2 and SNIP2.

The Citrix ADC segregate subsequent incoming traffic for traffic domains 1 or 2 on the basis of the destination MAC address, if the destination MAC address is virtual MAC1 or virtual MAC2.



The following table lists the settings used in the example: Virtual MAC based traffic domain example settings.

Before you Begin

Following are points to consider before you configure virtual MAC based traffic domain:

1. virtual MAC based traffic domains are easiest way to achieve network traffic segregation.
2. Because virtual MAC based traffic domains segregate network traffic based on virtual MAC addresses and not VLANS, you cannot create duplicate IP addresses on different virtual MAC based traffic domains on a Citrix ADC.
3. virtual MAC based traffic domains do not work when the Citrix ADC is deployed only in L2 Mode.
4. Both VLAN and virtual MAC based traffic domains can coexist on a Citrix ADC. virtual MAC based traffic domains actually runs on all VLANs that are not bound to any VLAN based traffic domain.

Configuration Steps

Configuring a virtual MAC based traffic domain on a Citrix ADC appliance consists of the following tasks:

- Create a traffic domain entity and enable the virtual MAC option. Create a traffic domain entity uniquely identified by an ID, which is an integer value, and then enable the virtual MAC option. After creating the traffic domain entity, the Citrix ADC creates a virtual MAC address and then associates it to the traffic domain entity.
- Create feature entities on the traffic domain. Create the required feature entities in the traffic domain by specifying the traffic domain identifier (td) when configuring these feature entities. Citrix ADC owned network entities created in a virtual MAC based traffic domain are associated with the virtual MAC address, which is associated with the traffic domain. The Citrix ADC then sends the traffic domain's virtual MAC address in ARP announcements and ARP responses for these network entities.

CLI procedures

To create a virtual MAC based traffic domain by using the CLI:

At the command prompt, type:

```
add ns trafficDomain <td> [-vmac ( ENABLED        DISABLED )]
```

-
- show ns trafficdomain <td>

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP –td <id>
- show ns ip <IPAddress> -td <id>

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name> -td <id>

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>

- bind lb vserver <name> <serviceName>
- show lb vserver <name> -td <id>

Example:

```
> add ns trafficDomain 1 -vmac ENABLED
 Done
> add ns trafficDomain 2 -vmac ENABLED
 Done

> add ns ip 192.0.2.5 255.255.255.0 -type -SNIP -td 1
 Done
> add service  SVC-S1-TD1  192.0.2.10 HTTP 80 -td 1
 Done
> add service  SVC-S2-TD1  192.0.2.20 HTTP 80 -td 1
 Done
> add lb vserver  LBVS-TD1 HTTP   203.0.113.15 80 -td 1
 Done
> bind lb vserver  LBVS-TD1 SVC-S1-TD1
 Done
> bind lb vserver  LBVS-TD1 SVC-S2-TD1
 Done

> add ns ip 192.0.2.6 255.255.255.0 -type -SNIP -td 2
 Done
> add service  SVC-S3-TD2  192.0.2.30 HTTP 80 -td 2
 Done
> add service  SVC-S4-TD2  192.0.2.40 HTTP 80 -td 2
 Done
> add lb vserver  LBVS-TD1 HTTP   203.0.113.16 80 -td 1
 Done
> bind lb vserver  LBVS-TD2 SVC-S3-TD2
 Done
> bind lb vserver  LBVS-TD2 SVC-S3-TD2
 Done
<!--NeedCopy-->
```

GUI procedures

To create a virtual MAC based traffic domain by using the GUI:

1. Navigate to System > Network > Interfaces.
2. In the details pane, click Add.
3. On the Create Traffic Domain page, set the following parameters:

- Traffic Domain ID*
- Enable Mac

4. Click Create.

To configure a SNIP address by using the GUI:

1. Navigate to System > Network > IPs > IPv4
2. Navigate to Network > IPs > IPv4
3. In the details pane, click Add
4. In the Create IP page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - IP Address
   - Netmask
   - IP Type
   - Traffic Domain ID
5. Click Create.

To create a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Basic Settings Page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Service Name
   - Server
   - Protocol
   - Port
   - Traffic Domain ID
4. Click Continue, and click Done.
5. Repeat steps 2-4 to create another service.
6. Click Close.

To create a load balancing virtual server and bind services to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Name
   - IP Address
   - Protocol
   - Port
   - Traffic Domain ID
4. Click Continue, on the Service Pane, click >.

5. On the Service page, click Insert, and then select the check box for the services that you want to bind to the virtual server.
6. Click Continue, and click Done.
7. Repeat steps 2-5 to create another virtual server

VXLAN

September 14, 2021

Citrix ADC appliances support Virtual eXtensible Local Area Networks (VXLANs). A VXLAN overlays Layer 2 networks onto a layer 3 infrastructure by encapsulating Layer-2 frames in UDP packets. Each overlay network is known as a VXLAN Segment and is identified by a unique 24-bit identifier called the VXLAN Network Identifier (VNI). Only network devices within the same VXLAN can communicate with each other.

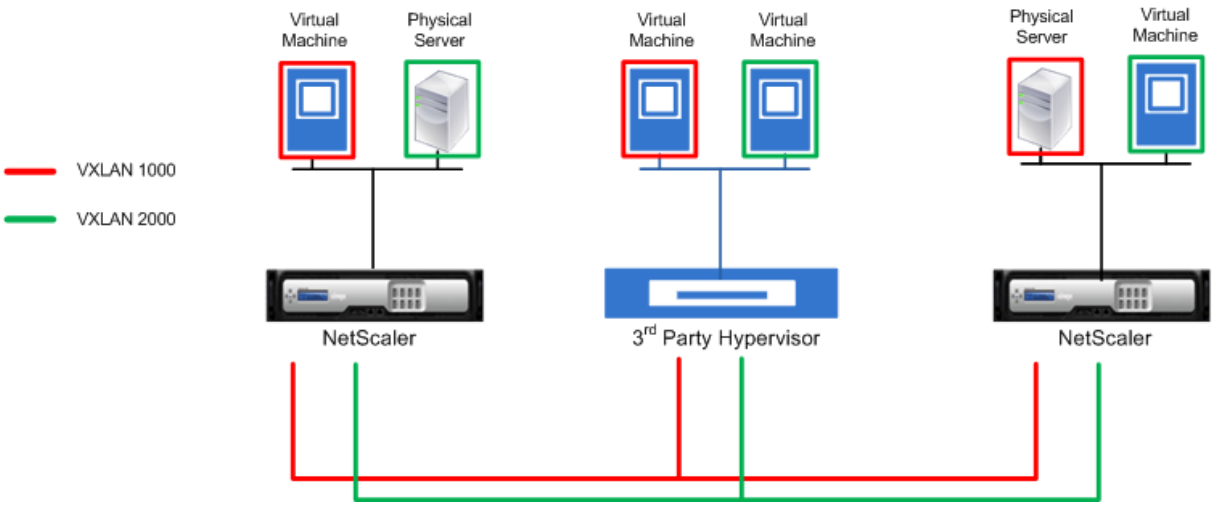
VXLANs provide the same Ethernet Layer 2 network services that VLANs do, but with greater extensibility and flexibility. The two main benefits of using VXLANs are the following:

- **Higher scalability.** Server virtualization and cloud computing architectures have dramatically increased the demand for isolated Layer 2 networks in a datacenter. The VLAN specification uses a 12-bit VLAN ID to identify a Layer 2 network, so you cannot scale beyond 4094 VLANs. That number can be inadequate when the requirement is for thousands of isolated Layer 2 networks. The 24-bit VNI accommodates up to 16 million VXLAN segments in the same administrative domain.
- **Higher flexibility.** Because VXLAN carries Layer 2 data frames over Layer 3 packets, VXLANs extend L2 networks across different parts of a datacenter and across geographically separated datacenters. Applications that are hosted in different parts of a datacenter and in different datacenters but are part of the same VXLAN appear as one contiguous network.

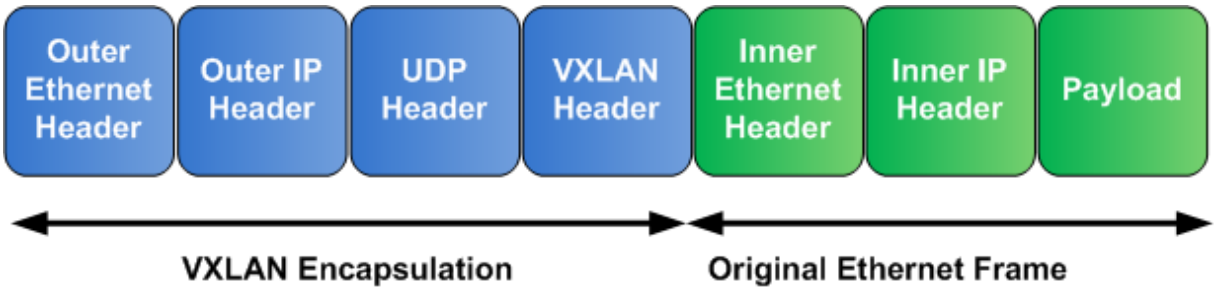
How VXLANs Work

VXLAN Segments are created between VXLAN Tunnel End Points (VTEPs). VTEPs support the VXLAN protocol and perform VXLAN encapsulation and decapsulation. You can think of a VXLAN segment as a tunnel between two VTEPs, where one VTEP encapsulates a Layer2 frame with a UDP header and an IP header and sends it through the tunnel. The other VTEP receives and decapsulates the packet to get the Layer 2 frame. A Citrix ADC is one example of a VTEP. Other examples are third-party hypervisors, VXLAN aware virtual machines, and VXLAN capable switches.

The following illustration displays virtual machines and physical servers connected through VXLAN tunnels.



The following illustration displays the format of a VXLAN packet.



VXLANs on a Citrix ADC use a Layer 2 mechanism for sending broadcast, multicast, and unknown unicast frames. A VXLAN supports the following modes for sending these L2 frames.

- **Unicast mode**: In this mode, you specify the IP addresses of VTEPs while configuring a VXLAN on a Citrix ADC. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to all VTEPs of this VXLAN.
- **Multicast mode**: In this mode, you specify a multicast group IP address while configuring a VXLAN on a Citrix ADC. Citrix ADCs do not support Internet Group Management Protocol (IGMP) protocol. Citrix ADCs rely on the upstream router to join a multicast group, which shares a common multicast group IP address. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN.

Similar to a Layer 2 bridge table, Citrix ADCs maintain VXLAN mapping tables based on the inner and outer header of the received VXLAN packets. This table maps of remote host MAC addresses to VTEP IP addresses for a particular VXLAN. The Citrix ADC uses the VXLAN mapping table to look up the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the Citrix ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

Because VXLANs function similarly to VLANs, most of the Citrix ADC features that support VLAN as a classification parameter support VXLAN. These features include an optional VXLAN parameter setting,

which specifies the VXLAN VNI.

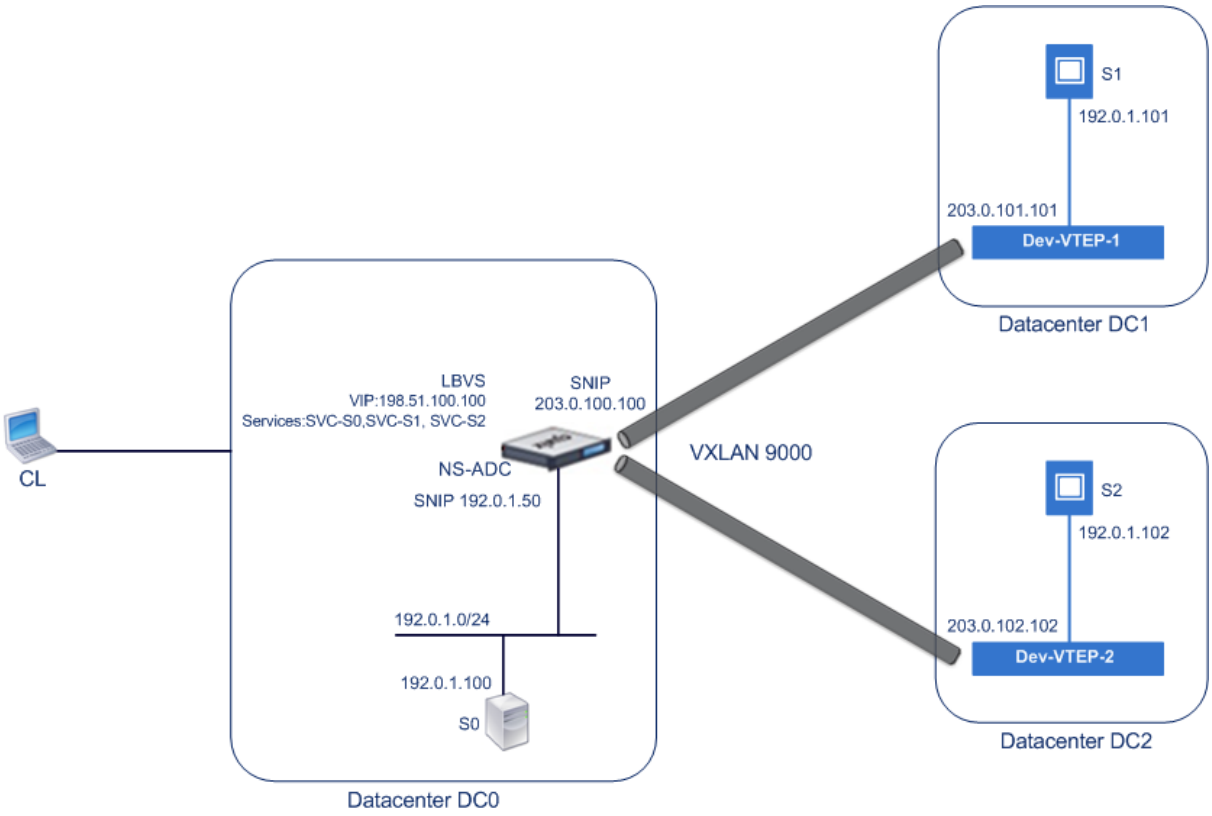
In a high availability (HA) configuration, the VXLAN configuration is propagated or synchronized to the secondary node.

VXLAN Use Case: Load Balancing across Datacenters

To understand the VXLAN functionality of a Citrix ADC, consider an example in which Example Corp hosts a site at www.example.com. To ensure application availability, the site is hosted on three servers, S0, S1, and S2. A load balancing virtual server, LBVS, on Citrix ADC NS-ADC is used to load balance these servers. S0, S1, and S2 reside in datacenters DC0, DC1, and DC2, respectively. In DC0, server S0 is connected to NS-ADC.

S0 is a physical server, and S1 and S2 are virtual machines (VMs). S1 runs on virtualization host device Dev-VTEP-1 in datacenter DC1, and S2 runs on host device Dev-VTEP-2 in DC2. NS-ADC, Dev-VTEP-1, and Dev-VTEP-2 support the VXLAN protocol.

S0, S1, and S2 are part of the same private subnet, 192.0.1.0/24. S0, S1, and S2 be part of a common broadcast domain, VXLAN 9000 is configured on NS-ADC, Dev-VTEP-1, and Dev-VTEP-2. Servers S1 and S2 are made part of VXLAN9000 on Dev-VTEP-1 and Dev-VTEP-2, respectively.



The following table lists the settings used in this example:
VXLAN settings.

Services SVC-S0, SVC-S1, and SVC-S2 on NS-ADC represent S0, S1, and S2. As soon as these services are configured, NS-ADC broadcasts ARP requests for S0, S1, and S2 to resolve IP-to-MAC mapping. These ARP requests are also sent over VXLAN 9000 to Dev-VTEP-1 and Dev-VTEP-2.

Following is the traffic flow for resolving the ARP request for S2:

1. NS-ADC broadcasts an ARP request for S2 to resolve IP-to-MAC mapping. This packet has:
    - Sourced IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
    - Source MAC address = MAC address of the NS-ADC's interface from which the packet is sent out = NS-MAC-1
2. NS-ADC prepares the ARP packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
    - VXLAN header with an ID (VNI) of 9000
    - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
3. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-1 and Dev-VTEP-2 on VXLAN-9000. The encapsulated packet has:
    - Source IP address = SNIP-VTEP-0 (203.0.100.100).
4. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the ARP request packet for S2, which is same as in step 1.
5. From the inner and outer header of the VXLAN packet, Dev-VTEP-2 makes an entry in its VXLAN mapping table that shows the mapping of MAC address (NS-MAC-1) and SNIP-VTEP-0 (203.0.100.100) for VXLAN9000.
6. Dev-VTEP-2 sends the ARP packet to S2. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000.
7. S2 responds with its MAC address (MAC-S2). The ARP response packet has:
    - Destination IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
    - Destination MAC address = NS-MAC-1
8. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000. Dev-VTEP-2 encapsulates the ARP response with VXLAN and UDP headers, and sends the resultant packet to SNIP-VTEP-0 (203.0.100.100) of NS-ADC.
9. NS-ADC on receiving the packet, decapsulates the packet by removing the VXLAN and UDP headers. The resultant packet is S2's ARP response. NS-ADC updates it VXLAN mapping table for S2's MAC address (MAC-S2) with Dev-VTEP-2's IP address (203.0.102.102) for VXLAN 9000. NS-ADC also updates it ARP table for S2's IP address (192.0.1.102) with S2's MAC address (MAC-S2).

Following is the traffic flow for load balancing virtual server LBVS in this example:

1. Client CL sends a request packet to LBVS of NS-ADC. The request packet has:
   - Source IP address = IP address of client CL (198.51.100.90)
   - Destination IP address = IP address (VIP) of LBVS = 198.51.110.100
2. LBVS of NS-ADC receives the request packet, and its load balancing algorithm selects server S2 of datacenter DC2.
3. NS-ADC processes the request packet, changing its destination IP address to the IP address of S2 and its source IP address to one of the Subnet IP (SNIP) addresses configured on NS-ADC. The request packet has:
   - Source IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
   - Destination IP address = IP address of S2 (192.0.1.102)
4. NS-ADC finds a VXLAN mapping entry for S2 in its bridge table. This entry indicates that S2 is reachable through Dev-VTEP-2 over VXLAN 9000.
5. NS-ADC prepares the packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
   - VXLAN header with an ID (VNI) of 9000
   - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
6. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-2. The request packet has:
   - Source IP address = SNIP address = SNIP-VTEP-0 (203.0.100.100)
   - Destination IP address = IP address of Dev-VTEP-2 (203.0.102.102)
7. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the same packet as in step 3.
8. Dev-VTEP-2 then forwards the packet to S2.
9. S2 processes the request packet and sends the response to the SNIP address of NS-ADC. The response packet has:
   - Source IP address = IP address of S2 (192.0.1.102)
   - Destination IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
10. Dev-VTEP-2 encapsulates the response packet in the same way that NS-ADC encapsulated the request packet in steps 4 and 5. Dev-VTEP-2 then sends the encapsulated UDP packet to SNIP address SNIP-for-Servers (192.0.1.50) of NS-ADC.
11. NS-ADC, upon receiving the encapsulated UDP packet, decapsulates the packet by removing the UDP and VXLAN headers in the same way that Dev-VTEP-2 decapsulated the packet in step 7. The resultant packet is the same response packet as in step 9.
12. NS-ADC then uses the session table for load balancing virtual server LBVS, and forwards the response packet to client CL. The response packet has:
    - Source IP address = IP address of client CL (198.51.100.90)
    - Destination IP address = IP address (VIP) of LBVS (198.51.110.100)

Points to Consider for Configuring VXLANs

Consider the following points before configuring VXLANs on a Citrix ADC:

- A maximum of 2048 VXLANs can be configured on a Citrix ADC.
- VXLANs are not supported in a cluster.
- Link-local IPv6 addresses cannot be configured for each VXLAN.
- Citrix ADCs do not support Internet Group Management Protocol (IGMP) protocol to form a multicast group. Citrix ADCs rely on the IGMP protocol of its upstream router to join a multicast group, which share a common multicast group IP address. You can specify a multicast group IP address while creating VXLAN bridge table entries but the multicast group must be configured on the upstream router. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN. The upstream router then forwards the packet to all the VTEPs that are part of the multicast group.
- VXLAN encapsulation adds an overhead of 50 bytes to each packet:

  Outer Ethernet Header (14) + UDP header (8) + IP header (20) + VXLAN header (8) = 50 bytes

  To avoid fragmentation and performance degradation, you must adjust the MTU settings of all network devices in a VXLAN pathway, including the VXLAN VTEP devices, to handle the 50 bytes of overhead in the VXLAN packets.

  Important: Jumbo frames are not supported on the Citrix ADC VPX virtual appliances, Citrix ADC SDX appliances, and Citrix ADC MPX 15000/17000 appliances. These appliances support an MTU size of only 1500 bytes and cannot be adjusted to handle the 50 bytes overhead of VXLAN packets. VXLAN traffic might be fragmented or suffer performance degradation, if one of these appliances is in the VXLAN pathway or acts as a VXLAN VTEP device.
- On Citrix ADC SDX appliances, VLAN filtering does not work for VXLAN packets.
- You cannot set a MTU value on a VXLAN.
- You cannot bind interfaces to a VXLAN.

Configuration Steps

Configuring a VXLAN on a Citrix ADC appliance consists of the following tasks.

- **Add a VXLAN entity**. Create a VXLAN entity uniquely identified by a positive integer, which is also called the VXLAN Network Identifier (VNI). In this step, you can also specify the destination UDP port of remote VTEP on which the VXLAN protocol is running. By default, the destination UDP port parameter is set to 4789 for the VXLAN entity. This UDP port setting must match the settings on all remote VTEPs for this VXLAN. You can also bind VLANs to this VXLAN. The traffic (which includes broadcasts, multicasts, unknown unicasts) of all bound VLANs are allowed over

this VXLAN. If no VLANs are bound to the VXLAN, the Citrix ADC allows traffic of all VLANs, on this VXLAN, that are not part of any other VXLANs.

- **Bind the local VTEP IP address and to the VXLAN entity**. Bind one of the configured SNIP address to the VXLAN to source outgoing VXLAN packets.
- **Add a bridgetable entry**. Add a bridgetable entry specifying the VXLAN ID and the remote VTEP IP address for the VXLAN to be created.
- **(Optional) Bind different feature entities to the configured VXLAN**. VXLANs function similarly to VLANs, most of the Citrix ADC features that support VLAN as a classification parameter also support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.
- **(Optional) Display the VXLAN mapping table**. Display the VXLAN mapping table, which includes mapping entries for remote host MAC address to VTEP IP address for a particular VXLAN. In other words, a VXLAN mapping states that a host is reachable through the VTEP on a particular VXLAN. The Citrix ADC learns VXLAN mappings and updates its mapping table from the VXLAN packets it receives. The Citrix ADC uses the VXLAN mapping table to lookup for the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the Citrix ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

CLI procedures

To add a VXLAN entity by using CLI:

At the command prompt, type

- **add vxlan** <id>
- **show vxlan**<id>

To bind the local VTEP IP address to the VXLAN by using CLI:

At the command prompt, type

- **bind vxlan** <id> -**SrcIP** <IPaddress>
- **show vxlan** <id>

To add a bridgetable by using CLI:

At the command prompt, type

- **add bridgetable** -**mac** <macaddress> -**vxlan** <ID> -**vtep** <IPaddress>
- **show bridgetable**

To display the VXLAN forwarding table by using the command line:

At the command prompt, type:

- **show bridgetable**

GUI procedures

To add a VXLAN entity and bind a local VTEP IP address by using the GUI:

Navigate to **System** > **Network** > **VXLANs**, and add a new VXLAN entity or modify an existing VXLAN entity.

To add a bridgetable by using the GUI:

Navigate to **System** > **Network** > **Bridge Table**, set the following paramters while adding or modifying a VXLAN bridge table entry:

- MAC
- VTEP
- VXLAN ID

To display the VXLAN forwarding table by using the GUI:

Navigate to **System** > **Network** > **Bridge Table**.

```
Example
> add vxlan 9000
Done
> bind vxlan 9000 -srcIP 203.0.100.100

Done
> add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
   203.0.101.101

Done
> add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
   203.0.102.102

Done
```

Support of IPv6 Dynamic Routing Protocols on VXLANs

The Citrix ADC appliance supports IPv6 dynamic routing protocols for VXLANs. You can configure various IPv6 Dynamic Routing protocols (for example, OSPFv3, RIPng, BGP) on VXLANs from the VTYSH command line. An option IPv6 Dynamic Routing Protocol has been added to VXLAN command set for enabling or disabling IPv6 dynamic routing protocols on a VXLAN. After enabling IPv6 dynamic routing protocols on a VXLAN, processes related to the IPv6 dynamic routing protocols are required to be started on the VXLAN by using the VTYSH command line.

To enable IPv6 Dynamic routing protocols on a VXLAN by using the CLI:

- **add vxlan** <ID> [-**ipv6DynamicRouting** (**ENABLED** | **DISABLED**)]

- **show vxlan**

```
In the following sample configuration, VXLAN-9000 is created and has
    IPv6 dynamic routing protocols enabled on it. Then, using the VTYSH
    command line, process for the IPv6 OSPF protocol is started on the
    VXLAN.

> add vxlan 9000 -ipv6DynamicRouting ENABLED

Done
> bind vxlan 9000 -srcIP 203.0.100.100

Done
> add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
    203.0.101.101

Done
> VTYSH
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface VXLAN-9000
NS(config-if)# ipv6 router OSPF area 3
```

Extending VLANs from Multiple Enterprises to a Cloud using VXLAN-VLAN Maps

CloudBridge Connector tunnels is used to extend an enterprise's VLAN to a cloud. VLANs extended from multiple enterprises can have overlapping VLAN IDs. You can isolate each enterprise's VLANs, by mapping them to a unique VXLAN in the cloud. On a Citrix ADC appliance, which is the CloudBridge connector endpoint in the cloud, you can configure a VXLAN-VLAN map that links an enterprise's VLANs to a unique VXLAN in the cloud. VXLANs support VLAN tagging for extending multiple VLANs of an enterprise from CloudBridge Connector to the same VXLAN.

Perform the following tasks for extending VLANs of multiple enterprises to a cloud:

1. Create a VXLAN-VLAN map.
2. Bind the VXLAN-VLAN map to a network bridge based or PBR based CloudBridge Connector tunnel configuration on the Citrix ADC appliance on cloud.
3. (Optional) Enable VLAN tagging in a VXLAN configuration.

CLI procedures

To add a VXLAN-VLAN map by using the CLI:

- **add vxlanVlanMap** <name>

- **show vxlanVlanMap** <name>

To bind a VXLAN and VLANS to a VXLAN-VLAN map by using the CLI:

- **bind vxlanVlanMap** <name> [-**vxlan** <positive_integer> -**vlan** <int[-int]> …]
- **show vxlanVlanMap** <name>

To bind a VXLAN-VLAN map to a network bridge based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new network bridge:

- **add netbridge** <name> [-**vxlanVlanMap** <string>]
- **show netbridge** <name>

if reconfiguring an existing network bridge:

- **set netbridge** <name> [-**vxlanVlanMap** <string>]
- **show netbridge** <name>

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new PBR:

- **add pbr** <name> **ALLOW** (-**ipTunnel** <ipTunnelName> [-**vxlanVlanMap** <name>])
- **show pbr** <name>

if reconfiguring an existing PBR:

- **set pbr** <name> **ALLOW** (-**ipTunnel** <ipTunnelName> [-**vxlanVlanMap** <name>])
- **show pbr** <name>

To include VLAN tags in packets related to a VXLAN by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new VXLAN:

- **add vxlan** <vnid> -**vlanTag** (**ENABLED** | **DISABLED**)
- **show vxlan** <vnid>

if reconfiguring an existing VXLAN:

- **set vxlan** <vnid> -**vlanTag** (**ENABLED** | **DISABLED**)
- **show vxlan** <vnid>

GUI procedures

To add a VXLAN-VLAN map by using the GUI:

Navigate to **System** > **Network** > **VXLAN VLAN Map**, add a VXLAN VLAN map.

To bind a VXLAN-VLAN map to a netbridge based CloudBridge Connector tunnel by using the GUI:

Navigate to **System** > **CloudBridge Connector** > **Network Bridge**, select a VXLAN-VLAN map from the **VXLAN VLAN** drop down list while adding a new network bridge, or reconfiguring an existing network bridge.

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by by using the GUI:

Navigate to **System** > **Network** > **PBRs**, on the Policy Based Routing (PBRs) tab, select a **VXLAN-VLAN** map from the **VXLAN VLAN** drop down list while adding a new PBR, or reconfiguring an existing PBR.

To include VLAN tags in packets related to a VXLAN by using the GUI:

Navigate to **System** > **Network** > **VXLANs**, enable **Inner VLAN Tagging** while adding a new VXLAN, or reconfiguring an existing VXLAN.

```
1  > add vxlanVlanMap VXLANVLAN-DC1
2
3  Done
4
5  > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3000 -vlan 3
6
7  Done
8
9  > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3500 -vlan 4
10
11 Done
12
13 >add vxlanVlanMap VXLANVLAN-DC2
14
15 Done
16
17 > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 8000 -vlan 3 4
18
19 Done
20
21 > set pbr PBR-CBC-DC-1-CLOUD ALLOW  -ipTunnel  CBC-DC-1-CLOUD -
      vxlanVlanMap VXLANVLAN-DC1
22
23 Done
24
25 > set pbr PBR-CBC-DC-2-CLOUD ALLOW  -ipTunnel  CBC-DC-2-CLOUD -
      vxlanVlanMap VXLANVLAN-DC2
26
27 Done
```

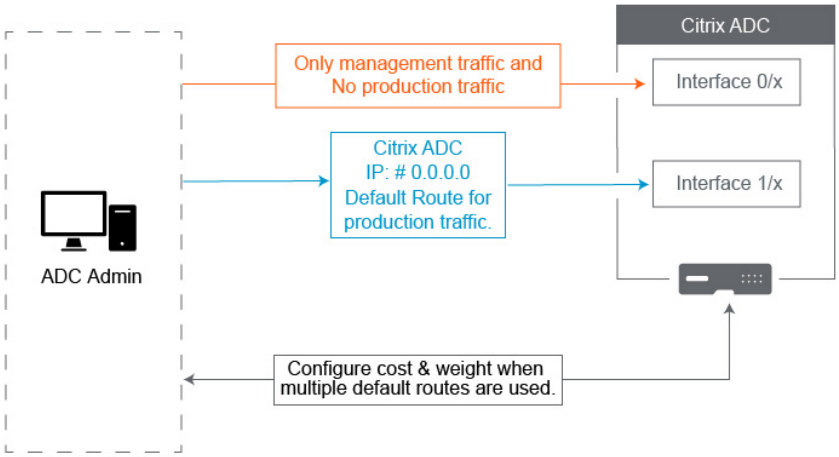
Best practices for network configurations

September 14, 2021

The following sections talk about some best practices for configuring networking features on a Citrix ADC appliance.

Routing and Default Routes

The following are some best practices for configuring Layer 3 features on a Citrix ADC appliance.



- **Interface `0/x` on a Citrix ADC appliance or Citrix SDX appliance must not be used for production traffic**. On an MPX or SDX, Interfaces named `0/x` are referred to the Management Interfaces. This does not mean you must use these interfaces for Management. What it means is that these interfaces are NOT designed for Production traffic. They do not have the hardware buffers and optimization necessary to achieve sustained 1 Gbps throughput. Therefore, If your Default Route is in the same Subnet as your NSIP, you must either change the default route or use a `1/x` interface for your Management network as the `1/x` interfaces are fully optimized for production 1 Gbps traffic.

  > **Note**:
  >
  > This does not apply to a Citrix ADC VPX appliance.

  - **Option 1**. Do not connect to Interfaces `0/x` – Disconnect the cable from interface `0/1`. NetScaler listens for the NSIP on the other interfaces. (NOTE: This is not an option for SDX, as the SVM and XenServer can only speak to `0/x` interfaces)
  - **Option 2**. change the default route to a different interface as detailed in the next section.

- **Default gateway (route 0.0.0.0) should be on a Production network, and not on any `0/x` interface**. When first setting up a NetScaler, it asks you for the NSIP, Subnet Mask, and Gateway address. The problem this creates for Administrators is that they just configured their default route to be on their Management Network using Interface 0/1.
  - To check what your routes are, run in CLI `show route` and your default gateway is the IP in the line where the Network and Netmask are 0.0.0.0. Here's an example where the Gateway is on Line 1:

```
1  > sh route
2          Network          Netmask          Gateway/OwnedIP
               State   Traffic Domain  Type
3          -------          -------          ---------------
               -----   --------------  ----
4  1)      0.0.0.0          0.0.0.0          10.25.213.65     UP
            0               STATIC
5  2)      127.0.0.0        255.0.0.0        127.0.0.1        UP
            0               PERMANENT
6  3)      10.25.213.64     255.255.255.192  10.25.213.68     UP
            0               DIRECT
7  4)      172.16.0.0       255.255.255.0    172.16.0.1       UP
            0               DIRECT
8
9  <!--NeedCopy-->
```

  - To check the Interface and VLAN used for your Default Gateway, check the ARP table using `sh arp` in CLI. You can also search for the specific IP using `show arp | grep 10.25.213.65`. Here's an example where you see the Gateway 10.25.213.65 is using Interface 1/1 and VLAN 1:

```
1  > sh arp
2          IP               MAC                Iface VLAN
               Origin     TTL     Traffic Domain
3          --               ---                ----- ----
               ------     ---     --------------
4  1)      127.0.0.1        02:00:18:a4:00:1e  LO/1  1
      PERMANENT  N/A    0
5  2)      10.25.213.70     02:00:0f:46:00:28  1/1   1
      DYNAMIC    967    0
6  3)      10.25.213.68     02:00:18:a4:00:1e  LO/1  1
      PERMANENT  N/A    0
7  4)      10.25.213.67     02:00:0f:46:00:28  1/1   1
      DYNAMIC    641    0
8  5)      10.25.213.65     00:08:e3:ff:fd:90  1/1   1
      DYNAMIC    483    0
```

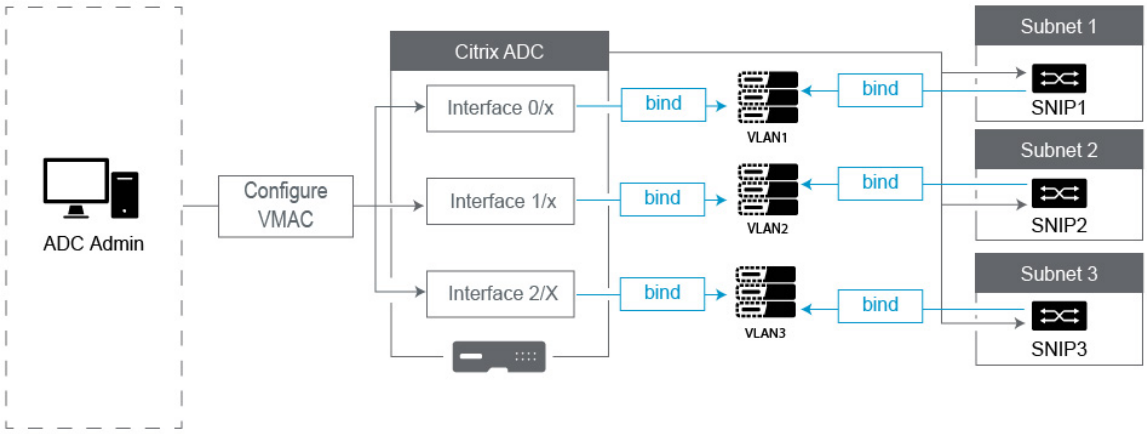
```
<!--NeedCopy-->
```

- Change the default route to use a Gateway on your Production Subnet and Interface. Assume your Management network is 10.0.0.0/24 with gateway 10.0.0.1, and Production network is 10.1.1.0/24 with gateway 10.1.1.1. Set up your config like this:
  - SNIP: (Management Access Disabled) 10.1.1.2
  - NSIP: (Management Access Enabled) 10.0.0.2
  - Default Route: 0.0.0.0 0.0.0.0 10.1.1.1 (System > Network > Routes). This uses a router on the SNIP network instead of the NSIP network.

    > **Note**:
    >
    > Changing the default gateway might break management traffic unless you configure static routes, a Policy Based Route, or enable MAC Based Forwarding.

Interfaces, channels, and VLANs

The following are some best practices for configuring Layer 2 features on a Citrix ADC appliance.



- **Do not connect multiple interfaces/channels to the same VLAN, including VLAN 1**:
  - If you do not properly configure your VLANs, it can cause some unexpected packet routing in your network and Layer 2 looping anytime there are more than one Active interface with the same VLAN (either Native or Tagged).
  - By Default, all Interfaces and Channels are on Native VLAN 1. This creates two possible problems:

        * The NetScaler thinks all traffic received is on the same network, so it uses any interface to send the traffic out on. If you have a different Native VLAN on the interface it sent data out on, then the traffic will not be routed as you expect.
        * If the NetScaler receives broadcast packets on one port, it may retransmit on another port. If both switchports are on the same VLAN, you just created a Layer 2 loop.
    - To remove an interface/channel from VLAN 1:
        * If you are not using Native VLANs on your switch interface/port channel. Change the Native VLAN on the NetScaler Interface/Channel to an unused VLAN number such as 999. You should not use the same unused VLAN number for multiple Channels or Interfaces, as it creates a layer 2 loop.
        * If you are using Native VLANs on your switch interface/port channel. Change the Native VLAN on the NetScaler Interface/Channel to match. However take care not to have multiple active Interfaces or Channels on the same VLAN as doing so creates Layer 2 loops.
        * You cannot remove the Native VLAN. Instead, you can change it or set TagAll for the interface or channel. If the switch port isn't configured with an untagged native VLAN, then enable tagall on the interface so High Availability heartbeat packets will be tagged.
    - To view the Native VLAN on an interface, run `sh interface` in CLI. This will also inform you if the interface is using the TAGALL option.

- **Bind an Interface to your VLAN** - The NetScaler, by default, does not attach a new VLAN to an interface. This means the VLAN is not going to be used until you bind it to an interface. When the new VLAN is not bound to an Interface and that VLAN is Tagged, the NetScaler drops all inbound traffic from that VLAN. Also, do not bind the same VLAN to more than one interface.
    - Bind Subnets to your VLANs. The NetScaler does not work like a typical Router. Most Routers attach IPs to Interfaces. On a NetScaler, the IPs float on any Interface unless configured otherwise. Therefore, any Subnet you want to ensure the NetScaler sends over a specific VLAN, especially when the NetScaler is Initiating that traffic, then you must bind a SNIP within that subnet to the VLAN.
    - A common argument we hear against this is that it used to work fine and now it doesn't without binding the Subnet to the VLAN. This often occurs because the NetScaler learns which VLAN to send traffic out, but this can take time as it builds its ARP tables. After a reboot or firmware upgrade, as it starts building the ARP tables again, it may initially learn and therefore be using a different path than you desire, such as your default route. It's best to instruct it which path to take by Binding the SNIP to the VLAN. Once a SNIP is bound to a VLAN, the entire subnet for that SNIP will be bound to the VLAN.

  - Ensure every SNIP is bound to a VLAN (except in cases where you have more than 1 SNIP in a subnet, then you only must bind one), and that the VLAN, in turn, is bound to only one Interface or channel. It is also often best to have a SNIP in every Subnet, but that is not required as the most specific Route will be used for any destination Subnet that does not have a SNIP.

- To identify the VLAN and Interface used by a Subnet:

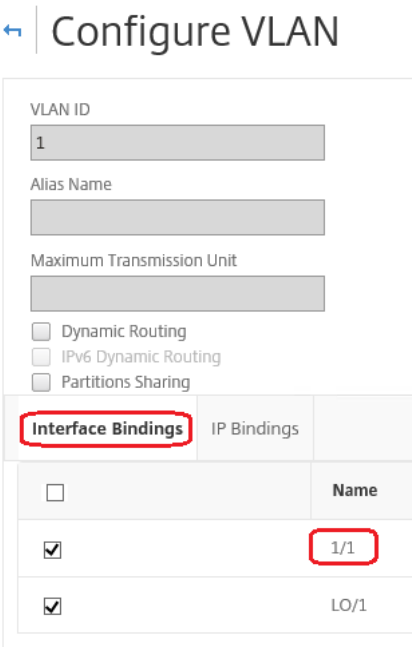
  1. Go to **System>Network > VLANs**.
  2. Edit each VLAN configured, in turn, until you find the correct IP address as explained in the next step.
  3. Click the IP Bindings tab to see which IP, and thus which Subnet is bound and thus is using this VLAN.
  4. Once you identify the VLAN that has an IP bound to it, where that IP is within the subnet of the Default Route, then click the Interface Bindings. Each Interface or Channel bound to this VLAN will be used.

Example

Assume the Default route is `0.0.0.0 0.0.0.0 10.1.1.1`.

Assume you have two SNIPs of 10.0.0.5 and 10.1.1.69. Since 10.1.1.69 is in the subnet of the default route, that is the one you want to look for. In the below screenshots, we are reviewing VLAN 1 and we see the IP 10.1.1.69 is bound to this VLAN, so we know we are looking at the correct VLAN.

Now Click Interface Bindings. In the VLAN Interface bindings we see that Interface `1/1` is used for this subnet, and therefore is used for the default route.



> **NOTE**:
>
> If you do not have any IPs bound to your VLANs, then by default it will be sent out VLAN 1, so in that case look at which Interfaces are bound to VLAN 1. This also means the NetScaler will not use your Configured VLANs for traffic it Initiates unless you bind an IP to the new VLAN.

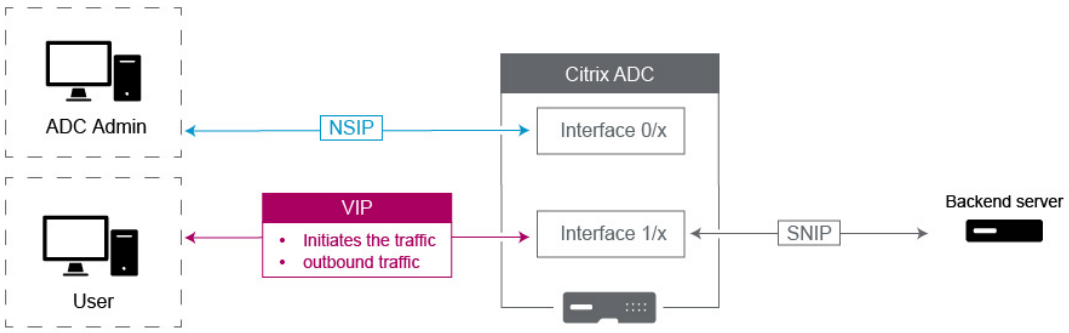
Gratuitous ARP

If GARP does not work, use VMAC - By default, the NetScaler uses GARP to advertise its IP to MAC address bindings to other network devices. This typically works without issue, however, as you create more services in the NetScaler, you may begin to experience issues when failing over on an HA pair. The most common issue is that services remain down in the NetScaler you failed over to due to some network devices not having updated their ARP tables with the new MAC address. You can easily verify this by checking their ARP tables to see if the MAC addresses match those on the now-Primary NetScaler. When this occurs, it is highly likely that some of your network devices are limiting the number of GARP advertisements they honor. In this case it is necessary to configure VMAC on all your active interfaces and/or channels. If you expect to have a large configuration on your NetScaler, it may be best to configure VMAC for all interfaces and channels during the initial deployment.

> **NOTE**:
>
> Do not forget to configure VMAC for the Interface or Channel used by your Default Route.

Citrix ADC owned IP Addresses

This section talks about the best practices for configuring Citrix ADC owned IP addresses:



- **Citrix ADC IP (NSIP)**: Generally this IP used for Management because it is the only IP unique to an individual NetScaler in an HA or Cluster environment. Also important to note is that LDAP, RADIUS, and User scripted Monitor traffic (such as the LDAP monitor and StoreFront monitor) will Source from the NSIP and thus route over the VLAN and Interface the NSIP is bound to (Default Native VLAN 1). If you need the LDAP and RADIUS traffic to source from the SNIP, then create an LB virtual server for your back end servers.
- **Subnet IP (SNIP)**: This IP address is used to initiate communication to back-end servers and is always going to initiate traffic. That said, it can be the destination for traffic in these cases:
  - It can be used as the Gateway address on other devices when doing Layer 3 routing on the NetScaler.
  - It can, when enabled, accept Management services, such as access to the GUI, SSH, and SNMP.
- **Virtual IP (VIP)**: The VIP is unique in that it will never be used to initiate outbound traffic. It is intended to receive Traffic only. Once it receives traffic, it replies and sends traffic outbound back to the client. In other words, the VIP address does not initiate the outbound traffic.

Note this also means it is notused as the source for communicating with back-end servers used in, for example, an LB virtual server.

Configure to source Citrix ADC FreeBSD data traffic from a SNIP address

September 14, 2021

Some Citrix ADC data features run on the underlying FreeBSD OS instead of on the Citrix ADC OS. Because of this reason, these features send traffic sourced from the Citrix ADC IP (NSIP) address instead

of sourced from a SNIP address. Sourcing the data traffic from the NSIP address is not desirable if your setup has configurations to separate all management and data traffic.

The following Citrix ADC data features run on the underlying FreeBSD OS and send traffic sourced from the Citrix ADC IP (NSIP) address:

- Load balancing scriptable monitors
- GSLB autosync

To resolve this issue, you can use the global Layer-2 parameter: `useNetprofileBSDtraffic`. When you enable this parameter, the Citrix ADC features send traffic sourced from one of the SNIP addresses in a net profile associated with the feature.

Before you begin

Before configuring the Citrix ADC appliance to source Citrix ADC features related traffic from a SNIP address, note the following points:

- Currently, the global Layer-2 parameter `useNetprofileBSDtraffic` is supported only for load balancing scriptable monitors.

  For configuring the Citrix ADC appliance to source GSLB autosync traffic from a SNIP address, you can use extended ACL rules and RNAT rules as a workaround.

- The `useNetprofileBSDtraffic` support for load balancing scriptable monitors is applicable only for net profiles bound to the related services. The `useNetprofileBSDtraffic` support is not applicable for net profiles bound to the related service groups.

  In other words, the Citrix ADC appliance does not use any SNIP address from the net profiles bound to the service groups for sourcing load balancing scriptable monitors traffic.

- The `useNetprofileBSDtraffic` support is not applicable for SSL services.

  In other words, the Citrix ADC appliance does not use any SNIP address from the net profiles bound to the SSL services for sourcing load balancing scriptable monitors traffic.

Configure the Citrix ADC appliance to source scriptable monitors traffic from a SNIP address

Configuring the Citrix ADC appliance to source scriptable monitors traffic from a SNIP address consists of the following tasks:

- Enable the global Layer-2 parameter `useNetprofileBSDtraffic`.
- Create a net profile and bind at least one SNIP address to it.
- Bind the net profile to the load balancing services that are using scriptable monitors.

To enable the Layer-2 parameter useNetprofileBSDtraffic by using the CLI:

At the command prompt, type:

- **set l2param** -**useNetprofileBSDtraffic** (**ENABLED** / **DISABLED**)
- **show l2param**

To Create a net profile and bind SNIP addresses to it by using the CLI:

At the command prompt, type:

- **add netProfile** <name> -**srcIP** <string>
- **show netProfile**

To bind a net profile to a load balancing service by using the CLI:

At the command prompt, type:

- **set service** <name> -**netProfile** <string>
- **show service** <name>

Sample configuration

The following sample configuration enables a Citrix ADC appliance to source scriptable monitors traffic from a SNIP address. A net profile NETPROFILE-1 is configured with SNIP address 198.51.100.20 bound to it. A user/scriptable monitor USER-MONITOR-1 is created and is bound to a load balancing service SERVICE-1. NETPROFILE-1 is bound to SERVICE-1. The Citrix ADC appliance sources all scriptable monitors packets of USER-MONITOR-1 from SNIP address 198.51.100.20.

```
1  set l2param -useNetprofileBSDtraffic ENABLED
2
3  set netprofile NETPROFILE-1 -srcip 198.51.100.20
4
5  add lb monitor USER-MONITOR-1 USER -scriptName nsftp.pl -scriptArgs "
       file=Index.png;user=nsroot;password=nsroot" -dispatcherIP 127.0.0.1
       -dispatcherPort 3013 -destIP 203.0.113.90 -destPort 21
6
7  bind service SERVICE-1 -monitorName USER-MONITOR-1
8
9  set service SERVICE-1 -netProfile NETPROFILE-1
10
11 <!--NeedCopy-->
```

Configure the Citrix ADC appliance to source GSLB autosync traffic from a SNIP address

Configuring the Citrix ADC appliance to source GSLB autosync traffic from a SNIP address consists of the following workaround tasks:

- **Create an extended ACL rule**. An extended ACL rule identifies the GSLB autosync packets. This identification is based on the source IP and destination IP addresses.
- **Apply ACLs**. Applying ACLs activates the newly created ACL rule.
- **Create an ACL based RNAT rule**. An RNAT rule changes the source IP address of these packets from the NSIP address to a SNIP address.

> **Note:**
>
> In a high availability or cluster setup, you must add ACL and RNAT rules for all the NSIP addresses of the setup.

To create an extended ACL by using the CLI:

At the command prompt, type:

- **add acl** <aclname> **ALLOW** -**srcIP** = <NSIP address> -**destIP** = <destination IP address of the packets>
- **show acl** <aclName>

To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply acls**

To create an ACL based RNAT rule by using the CLI:

At the command prompt, type:

- **add rnat** <name> <aclname>
- **bind rnat** <name> -**natIP** <SNIP address - source IP address for the packets>
- **show rnat** <name>

Sample configuration

The following sample configuration enables a Citrix ADC appliance to source GSLB autosync traffic from a SNIP address. ACL-2 identifies GSLB autosync packets, which are sourced from NSIP address 192.0.1.20 and destined to GSLB site IP address 203.0.113.20. RNAT-2 changes the source IP address to SNIP address 198.51.100.20 for these identified packets.

```
add acl ACL-2 ALLOW -srcIP = 192.0.1.20  -destIP = 203.0.113.20

apply acls
```

```
4
5 add rnat RNAT-2 ACL-2
6
7 bind rnat RNAT-2 -natIP 198.51.100.20
8 <!--NeedCopy-->
```

Priority Load Balancing

September 14, 2021

The priority load balancing feature enables you to assign a priority number for each of the services or service groups that are bound to a priority load balancing virtual server. A service or a service group with the lowest number has the highest priority. The application traffic is distributed only to this service or a service group as long as this service or the service group is UP. The service or the service group that is assigned the next priority number becomes operational only when all the services or members in the service group with the highest priority are DOWN. However, when any of the services or a member in the service group with the highest priority becomes available again, the traffic is redirected to that service or the service group.

For example, consider the service groups SVG1, SVG2, and SVG3 that is bound to a priority load balancing virtual server. The maximum number of priority groups is set to three. You assign the priority for each group as follows:

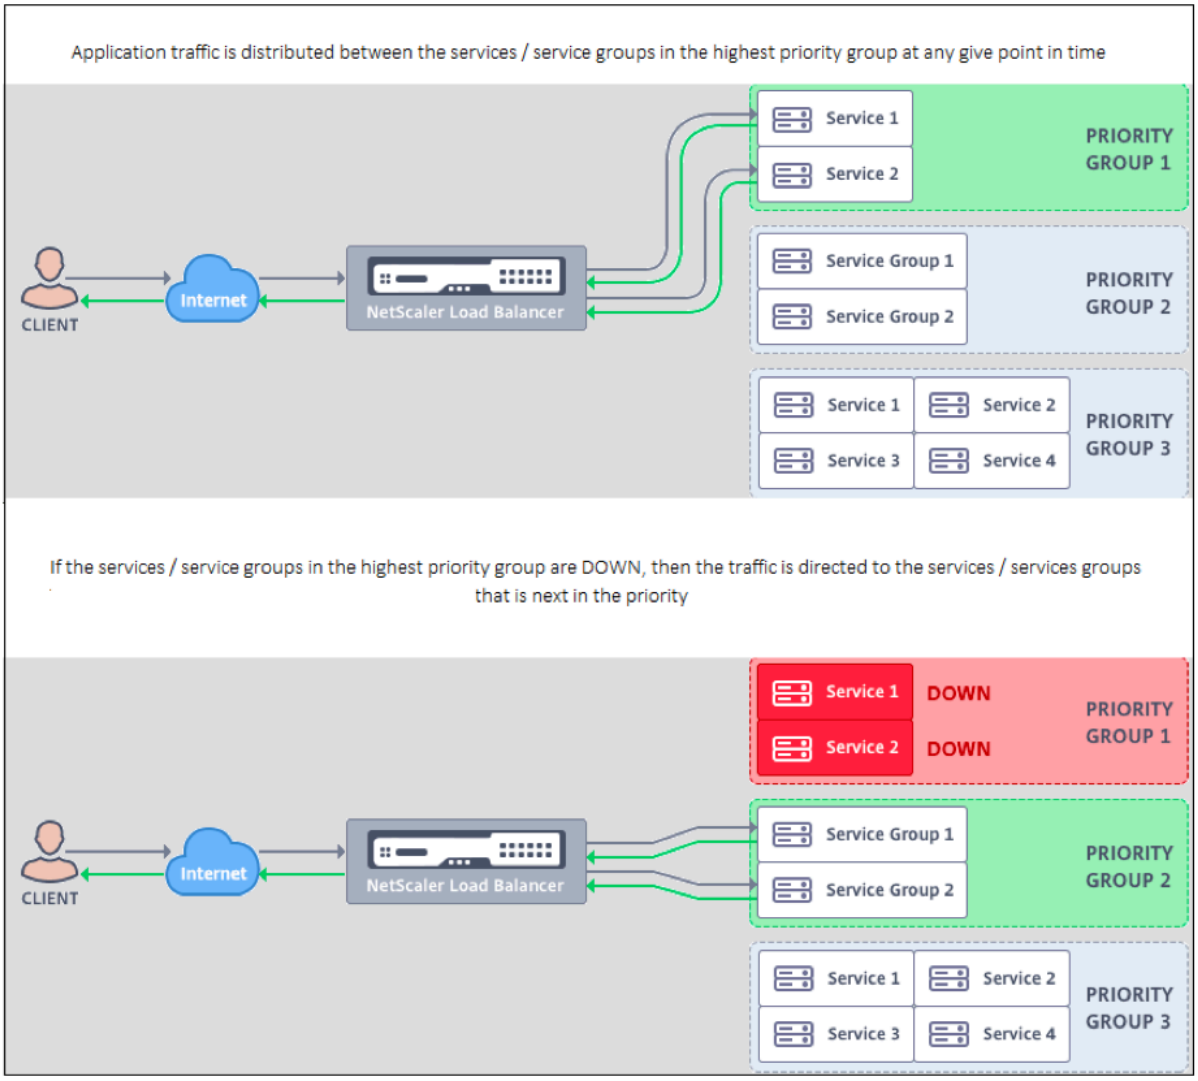
- SVG1 – priority 1
- SVG2 – priority 2
- SVG3 – priority 3

In this scenario, the application traffic is directed to service group SVG1 because this group is assigned the lowest priority number. If all the members in SVG1 are DOWN, the traffic is distributed to service group SVG2 as this group is assigned the next lower priority number. If all the members in SVG2 are also DOWN, the traffic is distributed to SVG3. However, when any of the members in SVG1 is UP, the traffic is redirected to SVG1 because SVG1 is assigned the lowest number and has the highest priority.

You can assign a priority to a service or a service group to upgrade the specific service or service group that has the highest priority, whenever required with minimal or no impact to the production traffic.

Also, if the upgrade is not successful, you can safely switch to the service or the service group that is next in the priority, with minimal or no impact to the production traffic.

The following figure illustrates the priority load balancing feature.



Configure priority load balancing

> **Note**
>
> The Citrix ADC priority load balancing configuration is supported only through the GUI. You cannot configure priority load balancing by using the CLI.

1. Navigate to **Traffic Management** > **Priority Load Balancing**> **Virtual *Servers** and specify the protocol for the virtual server, the IP address, and the port number of the virtual server.
2. In the **Maximum Priority Groups** box, enter the number of priority services or the service groups that can be bound to this virtual server. Default value is 2, and the maximum priority that can be set is 10. This parameter is noneditable after it is configured.

   Note:

   After you specify the maximum number of priority groups and click **OK**, a content switching vir-

tual server and “n” number of backup load balancing virtual servers are created. The alphabet “n” represents the maximum number of priority groups.

For example, if you have entered the virtual server name as vs1, and have set the maximum priority group as 5, then a content switching virtual server with the name `_Pri.LB##vs1##MaxPri=5` and the following 5 load balancing virtual servers are created.

- `_Pri.LB##vs1##MaxPri=5_LB1`
- `_Pri.LB##vs1##MaxPri=5_LB2`
- `_Pri.LB##vs1##MaxPri=5_LB3`
- `_Pri.LB##vs1##MaxPri=5_LB4`
- `_Pri.LB##vs1##MaxPri=5_LB5`

3. After you specify the maximum number of priority groups and click **OK**, you are prompted to choose the services or service groups that must be bound to this content switching virtual server.

   - To bind services to the virtual server, click **Insert** in the Services section. Next, either select an existing service or create a service and set the priority for this service. Also, set the priority number at which this service must be bound.
   - To bind service groups to the virtual server, click **Insert** in the Service Groups section. Next, either select an existing service group or create a service group and set the priority for this service group. Also, set the priority number at which this service group must be bound.

   Repeat step 3, depending on the maximum number of priority groups that you have entered.

   Note:

   - The service or the service group with the highest priority is bound to the load balancing virtual server that represents the highest priority.

   For example, if you have assigned priority 1 and 2 to service groups `SG_App1 and SG_App2` respectively, then `SG_App1` is bound to `virtual server _Pri.LB##vs1##MaxPri=5_LB1 and SG_App2` is bound to `virtual server _Pri.LB##vs1##MaxPri=5_LB2` created in step 2.

   - To change the priority of the service group or service, click the edit icon in the Priority Load Balancing Virtual Server page and change the priority as required.
   - You cannot set the load balancing methods and persistence for each virtual server explicitly, because the configuration of all load balancing virtual servers is identical.

4. From the Advanced Setting sections, complete the other configuration that meets your requirement.

> **Important:**
>
> The entities created during the priority load balancing configuration must not be modified from

> other tabs in the GUI and also from the CLI. It is recommended that you modify the priority load balancing entities from the Priority Load Balancing tab only.

Citrix ADC Extensions

September 14, 2021

Citrix ADC extensions can be used to customize a Citrix ADC appliance by writing extension code. Presently, policy extensions and protocol extensions are supported. Policy extensions can be used to extend the policy language. Protocol extensions can be used to add support for custom protocols on a Citrix ADC appliance.

Citrix ADC extensions are also supported on Citrix ADC CPX.

This document includes the following information:

- Citrix ADC Extensions - Language Overview
- Citrix ADC Extensions - Library Reference
- Citrix ADC Extensions API Reference
- Protocol Extensions
- Policy Extensions

Citrix ADC extensions - language overview

September 14, 2021

The extension language is based on the Lua 5.2 programming language. Lua provides a compact execution engine with good performance that is designed for embedding in C programs, like Citrix ADC software.

The extension language is dynamically typed, which means each object carries its own type information. Any variable can hold any type at any time during execution, so variable types are not declared.

The language is also free form, where white space between tokens is ignored. Statements may be separated by semicolons, but that is not required and usually not done. Blocks of statements are typically terminated by end. There are no brackets around blocks like the { and } in C or Java.

Identifiers are sequences of letters (a through z and A through Z), digits (0 through 9), and underscores (_), not starting in a digit. Identifiers are case-sensitive, so var, VAR, and Var are all different identifiers.

Comments are started by –. Everything after – is ignored to the end of the line. Example:

```
-- This is a comment.
```

Simple types

September 14, 2021

The language allows values of the following simple types:

- Numbers
- Strings
- Boolean
- Nil
- Other Types

Numbers

All numbers (even integers) are represented by IEEE 754 floating point values. Integers up to 2^54 have exact representations. Numeric values can be represented by:

- Signed and unsigned decimal integers (examples: 10, -5)
- Real numbers with decimal points (10.5, 3.14159)
- Real numbers with exponents (1.0e+10)
- Hexadecimals (0xffff0000)

Citrix ADC policy expressions have three numeric types:

- 32-bit integers (num_at)
- 64-bit integers (unsigned_long_at)
- 64-bit floating point (double_at)

All of these are converted into the number type when passed into an extension function, and numbers are converted to the expected policy numeric type when returned.

Strings

Strings are byte sequences of any length. They correspond to the policy **text_at** type. Strings can contain null (0x00) bytes. Arbitrary binary data can be held in strings, including any character code representation (e.g. UTF-8 and full Unicode). However, string functions **likestring.upper()** assume 8-bit ASCII.

Strings are automatically allocated when used. There is no need (or even way) to explicitly allocate buffers for strings. Strings are also automatically deallocated by garbage collection when no longer in use. There is no need (or even way) to explicitly free strings. This automatic allocation and deallocation avoids some common problems in languages like C, such as memory leaks and dangling pointers.

String literals are character strings enclosed in double or single quotes. There is no difference between the two types of quotes: “a string literal” is the same as ‘a string literal’. The usual backslash escaping is available: \s (bell), \b (backspace), \f (form feed), \n (newline/line feed), \t (horizontal tab), \\ (backslash), \“(double quote), and \’ (single quote). Decimal byte values can be entered by a backslash and one to three digits (\d, \dd, \ddd). Hexadecimal byte values can be entered by a backslash, an x, and two hex digits (\xhh)

A special syntax call the long bracket notation can be used for long, multi-line string literals. This notation encloses the string in double square brackets with zero or more equal signs between the brackets – the idea is to come up with a combination of brackets and equals that is not in the string. No escape sequences are honored in the string. Some examples:

[[This is a multi-line string using long bracket notation.]]

[=[This is a multi-line string using long notation with [[and]] and and an unescaped in it.]=]

Long bracket notation can be used to make a multi-line comment. Example:

–[[
This is a multi-line comment.
–]]

Boolean

The usual true and false boolean values are provided. Note that boolean values are different than number values, in contrast to C where zero is assumed to be false and any non-zero value is true.

Nil

nil is a special value that means “no value”. It is its own type and is not equivalent to any other value, in contrast to C where NULL is defined to be zero.

Other types

There are two other types, userdata and threads. These are advanced topics and are not covered here.

Variables

September 14, 2021

Variables hold values that may change during extension execution. Because of dynamic typing, any variable may hold values of any type. There are no type declarations for variables. Instead, a variable’s

type is determined at run time. In fact, the type of a variable's value may change during execution, although this is not a recommended practice. A variable initially has the value nil.

Variable names are identifiers, so are strings of letters, digits, and underscores not beginning in a digit. Examples: headers, combined_headers.

Global variables

In Lua, variables that are not otherwise declared are global within the program. However, global variables are not allowed in policy extension functions, because there are multiple Packet Engines in which a function can be executed, and each Packet Engine has its own memory.

If you use a global variable in your extension, you will get a runtime error: attempt to update or create a global reported in **/var/log/ns.log**.

Typos in variable names are a potential problem, because the variable with the typo will be interpreted as another, global variable, and will not cause a syntax error as in language like C or Java. As noted above, you will get a runtime error instead.

Local variables

A variable may be declared to be local to a block of statements, such as a function. This is done by local variable-name. The variable will be scoped to the block, that is, it will only exist within the block. The local declaration may optionally assign a value to the variable.

Examples:

local headers = {}
local combined_headers = {}

Expressions

September 14, 2021

Expressions compute values from variable and literal values.

- Arithmetic Operations
- Relational Operations
- Logical Operations
- Concatenation
- Length
- Precedence

Arithmetic operations

Arithmetic operations are performed on number values. If a string value is used in an arithmetic operation, it is converted to a number – if that fails, an error is returned.

a + b	add a and b
a - b	subtract b from a
a * b	multiply a and b
a / b	divide a by b
a % b	modulo = a - math.floor(a/b)*b
a ^ b	raise a to the b power; b can be any number
-a	negate a

Relational operations

Relational operations compare two values and return true if the relation is satisfied and false if it is not. Relational operations can be performed between values of any type. If the values are not the same type, false is returned. Numbers are compared in the usual way. Strings are compared using the collating sequence for the current locale.

a == b	a is equal to b
a ~= b	a is not equal to b
a < b	a is less than b
a > b	a is greater than b
a <= b	a is less than or equal to b
a >= b	a is greater than or equal to b

Logical operations

Logical operations are traditionally performed on Boolean values, but in this language they can be performed on any two values. nil and false is considered false and any other value is considered true. Logical operations use short-cut evaluation, where if the first value determines the result of the oper-

ation, the second value is not evaluated.

a and b	if a is false or nil then return a else return b
a or b	if a is not false and not nil then return a else return b
not a	if a is not false or nil return false else return true

The and and or operations can be used for conditional evaluation within an expression:

a or b	can be used to provide a default value b if a is uninitialized (nil). This is useful for optional parameters in functions.
a and b or c	can be used to chose non-nil b or c based on the condition a. If a is true, then a and b returns b, and b or c returns b. If a is false, then a and b returns false and false or c returns c. This is equivalent to a ? b : c in the C programming language.

Concatenation

String concatenation is s1 .. s2. This creates a new string large enough to hold the contents of s1 and s2 and copies the contents to the new string. An error results if s1 or s2 are not strings. Note that repeated concatenation may have considerable copying overhead. If you build a string of n bytes by concatenating one byte at a time, this will copy n*(n+1)/2 bytes. For better performance, you can put pieces of a string to be concatenated into a table (discussed later) and then use the table.concat()function. An example of this is shown in the COMBINE_HEADERS() example.

Length

The length of a string s is returned by #s. The # operator is also used with array tables, as discussed later.

Precedence

Operator precedence determines the order in which operations are performed in an expression, with higher precedence operations done before those with lower precedence. Precedence order can as usual be overridden by parentheses. For example, in `a + b \* c`, * has higher precedence than +, so the expression is evaluated as `a + (b \* c)`.

highest	^
-	not # - (unary)
-	* / %
-	..
-	= ~= < > <= >=
-	and
lowest	or

Operations with the same precedence are performed left to right (left associative), except ^ and .. that are performed right to left (right associative). So a^b^c is evaluated as a^(b^c).

Assignment

September 14, 2021

The assignment statement evaluates an expression and assigns the resulting value to a variable.

```
variable = expression
```

As noted earlier, values of any type can be assigned to any variable, so the following is allowed:

```
local v1 = "a string literal"
v1 = 10
```

An assignment statement can actually set multiple variables, using the form

variable1, variable2, … = expression1, expression2, …

If there are more variables than expressions, the extra variables are assigned nil. If there are more expressions than variables, the extra expression values are discarded. The expressions are all evaluated before the assignments, so this can be used to succinctly exchange the values of two variables:

v1, v2 = v2, v1

is equivalent to

tmp = v1
v2 = v1
v1 = tmp

Tables

September 14, 2021

Tables are collections of entries with keys and values. They are the only aggregate data structure provided. All other data structures (arrays, lists, sets, and so on) are built from tables. Table keys and values can be any type, including other tables. Keys and values within the same table can mix types.

- Table Constructors
- Table Usage
- Tables as Arrays
- Tables as Records

Table constructors

Table constructors allow you to specify a table with keys and associated values. The syntax is:

{[key1] = value1, [key2] = value2, …}

where the keys and values are expressions. If the keys are strings that are not reserved words, the brackets and quotes around the keys can be omitted. Example:

{key1 = “value1”, key2 = “value2”, key3 = “value3”}

An empty table is specified simply by {}.

A table constructor may be used in an assignment to set a variable to refer to a table. Examples:

local t1 = {} – set t1 to an empty table
local t2 = {key1 = “value1”, key2 = “value2”, key3 = “value3”}

Note that tables themselves are anonymous. More than one variable may refer to the same table. Continuing the above example:

local t3 = t2 – both t2 and t3 refer to the same table

Table usage

As you would expect, you can use keys to find values in a table. The syntax is table[key], where table is a table reference (typically a variable assigned a table), and key is an expression providing the key.

If this is used in an expression and the key exists in the table, this returns the value associated with the key. If the key is not in the table, this returns nil. If this is used as the variable in an assignment, and the key does not exist in the table, it creates a new entry for the key and value. If the key already exists in the table, it replaces the key's value with the new value. Examples:

local t = {} – sets t to an empty table
t["k1"] = "v1" – creates an entry for key "k1" and value "v1"
v1 = t["k1"] – sets v1 to the value for key "k1" = "v1"
t["k1"] = "new_v1" – sets the value for key "k1" to "new_v1"

Table as arrays

The traditional array can be implemented using a table with integer keys as indices. An array can have any indices, including negative ones, but the convention is to start arrays at index 1 (not 0 as is the case with languages like C and Java). There is a special purpose table constructor for such arrays:

{value1, value2, value3, … }

Array references are then array[index].

The length operator # returns the number of elements in an array with consecutive indices starting at 1. Example:

local a = {"value1", "value2", "value3"}
local length = #a – sets length to the length of array a = 3

Arrays can be sparse, where only the defined elements are allocated. But # cannot be used on a sparse array with non-consecutive indices. Example:

local sparse_array = {} – set up an empty array
sparse_array[1] = "value1" – add an element at index 1
sparse_array[99] = "value99" – add an element at index 99

Multidimensional arrays can be set up as tables of tables. For example, a 3x3 matrix could be set up by:

local m = {{1, 2, 3}, {4, 5, 6}, {7, 8, 9} }
local v22 = m[2][2] – sets v22 to 5

Tables as records

Records with fields can be implemented as tables with field name keys. The reference form table.field can be used for table["field"]. Examples:

local person = {name = "John Smith", phone = "777-777-7777"}
local name = person.name – sets name to "John Smith"

An array of tables can be used for a sequence of records. Example:

local people = {
{name = “John Smith”, phone = “777-777-7777”},
{name = “Jane Doe”, phone = “888-888-8888”}
…
}

name = people[2].name – sets name to “Jane Doe”

Control structures

September 14, 2021

The extension function language provides the usual statements to control program execution.

- If Then Else
- While Do and Repeat Until
- Numeric For
- Break
- Goto

If Then Else

If statements select blocks of statements to execute based on one or more conditions. There are three forms:

If then Form

```
if expression then
     statements to execute if expression is not false or nil
end
<!--NeedCopy-->
```

If then else Form

```
if expression then
     statements to execute if expression is not false or nil
else
     statements to execute if expression is false or nil
end
```

```
<!--NeedCopy-->
```

If then elseif else Form

```
if expression1 then
     statements to execute if expression1 is not false or nil
     elseif expression2 then
          statements to execute if expression2 is not false or nil
. . .
else
     statements to execute if all expressions are false or nil
end
<!--NeedCopy-->
```

Example:

```
if headers[name] then

     local next_value_index = #(headers[name]) + 1
     headers[name][next_value_index] = value

else

     headers[name] = {
 name .. ":" .. value }

end
<!--NeedCopy-->
```

Note:

- The expression is not enclosed in parentheses as is the case in C and Java.
- There is no equivalent to the C/Java switch statement. You have to use a series of if elseif statements to do the equivalent.

While Do and Repeat Until

The **while** and **repeat** statements provide loops controlled by an expression.

```
while expression do
     statements to execute while expression is not false or nil
end
```

```
4
5  repeat
6
7       statements to execute until expression is not false or nil
8
9  until expression
10 <!--NeedCopy-->
```

Example for while:

```
1 local a = {
2  1, 2, 3, 4 }
3
4 local sum, i = 0, 1 -- multiple assignment initializing sum and i
5 while i <= #a do -- check if at the end of the array
6      sum = sum + a[i] -- add array element with index i to sum
7      i = i + 1 -- move to the next element
8 end
9 <!--NeedCopy-->
```

Example for repeat:

```
1 sum, i = 0, 1 -- multiple assignment initializing sum and i
2 repeat
3      sum = sum + a[i] -- add array element with index i to sum
4      i = i + 1 -- move to the next element
5 until i > #a -- check if past the end of the array
6 <!--NeedCopy-->
```

Of course it is possible to write a loop that does not terminate, for example, if you omit the i = i + 1 statement in either of these examples. When such a function is executed, Citrix ADC will detect that the function did not complete in a reasonable time and will kill it with a runtime error:

```
Cpu limit reached. Terminating extension execution in [[string "function
extension function..."]]: line line-number.
```

will be reported in /var/log/ns.log.

Numeric For

There are two types of for loops. The first is the numeric for, which is similar to the usual use of the for statement in C and Java. The numeric for statement initializes a variable, tests if the variable has passed a final value, and if not executes a block of statements, increments the variable, and repeats. The syntax for the numerical for loop is:

```
for variable = initial, final, increment do

     statements in the loop body

end
<!--NeedCopy-->
```

where initial, final, and increment are all expressions that yield (or can be converted to) numbers. variable is considered to be local to the for loop statement block; it cannot be used outside of the loop. increment can be omitted; the default is 1. The expressions are evaluated once at the beginning of the loop. The terminating condition is variable > final if the increment is positive and variable < final if the increment is negative. The loop terminates immediately if the increment is 0.

Example (equivalent to the while and repeat loops in the preceding section):

```
sum = 0
for i = 1, #a do -- increment defaults to 1
     sum = sum + a[i]
end
<!--NeedCopy-->
```

The second type of for loop is the generic for, which can be used for more flexible types of loops. It involves the use of functions, so will be discussed later after functions have been introduced.

Break

The break statement is used inside a while, repeat, or for loop. It will terminate the loop and resume execution at the first statement after the loop. Example (also equivalent to the preceding while, repeat, and for loops):

```
sum, i = 0, 1
while true do
     if i > #a then
          break
     end
     sum = sum + a[i]
     i = i + 1
end
<!--NeedCopy-->
```

Goto

The goto statement can be used to jump forward or backward to a label. The label is an identifier, and its syntax is ::label::. The goto statement is goto label. Example (once again equivalent to the preceding loops):

```
sum, i = 0, 1
::start_loop::
     if i > #a then
          goto end_loop -- forward jump
     end
     sum = sum + a[i]
     i = i + 1
     goto start_loop -- backwards jump
::end_loop::
. . .
<!--NeedCopy-->
```

There has been a long running controversy over using gotos in programming. In general, you should try to use the other control structures to make your functions more readable and reliable. But occasional judicious use of gotos may lead to better programs. In particular, gotos may be useful in handling errors.

Functions

September 21, 2021

Functions are a basic building block of programming – they are a convenient and powerful way to group statements that perform a task. They are the interface between the Citrix ADC appliance and extension code. For policies, you define policy extension functions. For protocols, you implement callback functions for the protocol behaviors. Functions consist of function definitions that specify what values are passed into and out of the function and what statements are run for the function, and function calls, which run functions with specific input data and get results from the function.

Protocol behavior callback functions

The TCP client behavior consists of a callback function (on_data) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments. So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

Prototype of TCP client callback function:

```
1              Function                client on_data (ctxt, payload)
2
3                                              //.code
4
5              end
```

Where,

- ctxt - TCP client processing context
- payload – event payload
  - payload.data - TCP data received, available as a stream of bytes

Policy extension functions

Since the NetScaler policy expression language is typed, the definition of an extension function must specify the types of its inputs and its return value. The **Lua function** definition has been extended to include these types:

‘

function self-type: function-name(parameter1: parameter1-type, and so on): return-type
statements
end

Where,

The types are NSTEXT, NSNUM, NSBOOL, or NSDOUBLE.

‘

Self-type is the type of the implicit self-parameter that is passed into the function. When the extension function is used in a Citrix ADC policy expression, this is the value generated by the expression to the left of the function. Another way to view this is that the function extends that type in the Citrix ADC policy language.

The parameter-types are the types of each parameter specified in the extension function call in the policy expression. An extension function can have zero or more parameters.

Return-type is the type of the value returned by the extension function call. It is the input to the part of the policy expression, if any, to the right of the function, or else is the value of the expression result.

Example:

```
function NSTEXT:COMBINE_HEADERS(): NSTEXT
```

Use of the extension function in a policy expression:

```
HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n").COMBINE_HEADERS()
```

Here the self-parameter is the result of `HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n")`, which is a text value. The result of the COMBINE_HEADERS() call is text, and since there is nothing to the right of this call, the result of the entire expression is text.

Local function definition

Besides extension functions, no global functions can be defined in an extension file. But local functions can be defined within extension functions using the normal Lua function statement. This declares the name of the function and the names of its parameters (also known as arguments), and like all declarations in Lua, does not specify any types. The syntax for this is:

‘

Local function function-name(parameter1-name, parameter2-name, and so on)
statements
end
‘

The function and parameter names are all identifiers. (The function name is actually a variable and the function statement is shorthand for local function-name = function(parameter1, and so on), but you don’t have to understand this subtlety to use functions.)

Note that and so on is used here for continuation of the pattern of parameter names instead of the usual …. This is because … itself actually means a variable parameter list, which will not be discussed here.

Function body and return

The block of statements between the function and end statements is the function body. In the function body, the function parameters act like local variables, with values supplied by the function calls, as described previously.

The return statement supplies values to be returned to the caller of the function. It must appear at the end of a block (in a function, if then, for loop, and so on; It can be in its own block do return … end). It may specify no, one, or more than one return values:

‘

Return – returns nil
return expression – one return value
return expression1, expression2, … – multiple return values
‘

Examples:

‘

local function fsum(a)
local sum = 0
for i = 1, #a do
sum = sum + a[i]
end
return sum
end

Local function fsum_and_average(a)
local sum = 0
for i = 1, #a do
sum = sum + a[i]
end
return sum, sum/#a
end
‘

Function calls

A function call runs the body of a function, supplying values for its parameters, and receiving results. The syntax for a function call is function-name(expression1, expression2, and so on), where the function parameters are set to the corresponding expressions. The number of expressions and parameters need not be the same. If there are fewer expressions than parameters, the remaining parameters are set to nil. So you can make one or more parameters at the end of the call optional, and your function can check if they are specified by checking if they are not nil. A common way to do this is with the or operation:

‘

Function f(p1, p2) – p2 is optional
p2 = p2 or 0 – if p2 is nil, set to a default of 0
. . .
end
‘

If there are more expressions than parameters, the remaining expression values are ignored.

As noted previously, functions can return multiple values. These returns can be used in a multiple assignment statement. Example:

‘

```
Local my_array = {1, 2, 3, 4}
local my_sum, my_ave = sum_and_average(my_array)
```

‘

Iterator functions and generic for loops

Now that we have introduced functions, we can talk about generic for loops. The syntax for the generic for loop (with one variable) is:

‘

```
For variable in iterator(parameter1, parameter2, and so on) do
statements in the for loop body
end
```

‘

Where iterator() is a function with zero or more parameters that provide a value for variable on each iteration of the loop body. The iterator function keeps track of where it is in the iteration using a technique called closure, which you don’t have to worry about here. It signals the end of the iteration by returning nil. Iterator functions can return more than one value, for use in a multiple assignments.

Writing an iterator function is beyond the scope of this paper, but there are few useful built-in iterators that illustrate the concept. One is the pairs() iterator, which iterates through the entries in a table and returns two values, the key and the value of the next entry.

Example:

‘

```
Local t = {k1 = “v1”, k2 = “v2”, k3 = “v3”}
local a = {} – array to accumulate key-value pairs
local n = 0 – number of key-value pairs
for key, value in pairs(t) do
n = n + 1
a[n] = key.. “ = “.. Value – add key-value pair to the array
end
local s = table.concat(a, “;”) – concatenate all key-value pairs into one string
```

‘

Another useful iterator is the string.gmatch() function, which will be used in the following COMBINE_HEADERS() example.

Citrix ADC extensions - library reference

September 14, 2021

The list of libraries supported in policy extensions.

- Basic library
- String library
- Regular Expression Patterns - Character Classes
- Regular Expression Patterns - Pattern Items
- Table library
- Math library
- Bitwise library
- Operating System library
- Citrix ADC library

Basic library

assert(v[,message])	Issues an error, with an optional message, when v is false.
error(message)	Terminates a function and reports the error message.
ipairs(a)	Iterator for an array a. Returns an index and value for each iteration.
pairs(t)	Iterator for a table t. Returns a key and value for each iteration.
tonumber(e[,base])	Converts e to a number, with an optional base.
tostring(v)	Converts v to a string
type(v)	Returns the type of v: number, string, boolean, table, etc.

getmetatable (object)	Returns nil if the object does not have a metatable. Otherwise, if the object's metatable has a "__metatable" field, returns the associated value. Otherwise, returns the metatable of the given object.
setmetatable (table, metatable)	Sets the metatable for the given table. (You cannot change the metatable of other types from Lua, only from C.) If metatable is nil, removes the metatable of the given table. If the original metatable has a "__metatable" field, raises an error.
select (index, ···)	Returns all arguments after argument number index. If index is string "#", then it returns the total number of extra arguments it received.
pcall (f [, arg1, ···])	Calls function f with the given arguments in protected mode. It returns status code as first result which tells whether call succeeded or not. If call succeeded, then along with status code it also returns all results from the call, otherwise returns error message.
xpcall (f, msgh [, arg1, ···])	This function is similar to pcall, except that it also takes an argument for error handling.
_VERSION	Returns the current interpreter version.

String library

string.byte(s[,i[,j]])	Returns the byte values for s[i] to s[j]. Default i = 1 and j = i
string.char(…)	Returns a string constructed of the integer parameters.
string.find(s,pattern[,init[,plain])	Looks for the first match of a regular expression pattern in s. Return the first and last indices of match or nil. init is index to start, default 1. plain = true means pattern is not a regex.

string.format(form,…)	Returns a formatted version of the parameters.
string.gmatch(s,pattern)	Iterator for searching s with the regex pattern. Returns matching values.
string.gsub(s,pattern,repl[,n])	Returns a copy of s in which all (or n) occurences of the pattern have been replaced by repl.
string.len(s)	Returns the string length.
string.lower(s)	Returns a copy of the string converted to lowercase.
string.match(s,pattern[,init])	Looks for the first match of the regex pattern in s and returns the captures or the whole pattern. init is the index to start, default 1.
string.rep(s,n[,sep])	Returns a string that is n copies of s, with separator sep, default no separator
string.reverse(s)	Returns a string that is s reversed.
string.sub(s,i[,j])	Returns the substring of s from s[i] to s[j], default j is the end of the string.
string.upper(s)	Returns a copy of the string converted to uppercase.
string.dump (function)	Returns a string containing a binary representation of the given function.

Regular expression patterns - character classes

x	the character x, except for magic characters ^$()%.[]*+-?)
.	any character
%a	any letter
%c	any control character
%d	any digit
%g	any printable character except space

%l	any lowercase letter
%p	any punctuation character
%s	any white space character
%u	any uppercase letter
%w	any alphanumber letter
%x	an escaped magic character x (for example %%)
[set]	a set of characters: sequence of individual characters, ranges x-y, and % classes
[^set]	characters not in the set.

Regular expression patterns - pattern items

X	a character class
X*	0 or more longest repetitions of characters in X
X+	1 or more repetitions of characgers in X
X-	0 or more shortest repetitions of characters in X
X?	0 or 1 character in X
%n	n=1 to 9; matches nth captured string
%bxy	matches substring between two balanced characters x and y. Example %b() matches substring between two balanced parentheses.
%f[set]	matches an empty string at at any position such that the next character belongs to set and the previous character does not belong to set.

A pattern is a sequence of pattern items. ^pattern matches the beginning of a string and pattern$ matches the end of the string.

Matched substrings can be captured using (pattern). Parentheses with no pattern () capture the current string position (a number).

Table library

table.concat(list[,sep[,i[,j]]])	Returns a string list[i] .. sep .. list[i+1] .. sep . . . list[j]. Default sep is the empty string. Default i is 1, j is #list.
table.insert(list,[pos,]value)	Inserts value into list at index pos. Default for pos is #list (end of the list).
table.pack(…)	Returns an array containing the parameters starting at index 1, and a key n with the total number of parameters.
table.remove(list[,pos])	Removes from list the element at position pos, shifting elements to fill the position. Returns the removed element. Default for posis #list (end of the list.)
table.sort(list[,comp])	Sort the elements of list in place. comp is the comparison function to use. Default for comp is <.
table.unpack(list[,i[,j]])	Returns list[i] through list[j]. Default for i is 1 and j is #list<c/ode>.

Math library

Various trigonometric and logarithmic functions not shown.

math.abs(x)	Returns the absolute value of x.
math.ceil(x)	Returns the smallest integer >= x.
math.floor(x)	Returns the largest integer <= x.
math.fmod(x,y)	Returns the remainder of x/y rounding the quotient towards zero.
math.huge	A value >= any other number.
math.max(x,…)	Returns the maximum argument.
math.min(x,…)	Returns the minimum argument.
math.modf(x)	Returns the integral and fractional parts of x.

math.random()	Returns a pseudo-random number between 0 and 1.
math.random(m)	Returns a pseudo-random integer between 1 and m.
math.random(m, n)	Returns a pseudo-random integer betwen m and n.
math.randomseed(x)	Sets the pseudo-random number generator set to x.
math.sqrt(x)	Returns the square root of x (x^0.5)
math.acos(x)	Returns the arc cosine of x (in radians).
math.asin(x)	Returns the arc sine of x (in radians).
math.atan(x)	Returns the arc tangent of x (in radians).
math.atan2(y, x)	Returns the arc tangent of y/x (in radians).
math.cos(x)	Returns the cosine of x.
math.cosh(x)	Returns the hyperbolic cosine of x.
math.sin(x)	Returns the sine of x.
math.sinh(x)	Returns the hyperbolic sine of x.
math.tan(x)	Returns the tangent of x.
math.tanh(x)	Returns the hyperbolic tangent of x.
math.deg(x)	Returns the angle x (given in radians) in degrees.
math.exp(x)	Returns the value e^x.
math.frexp (x)	Returns m and e such that x = m2e, e is an integer and the absolute value of m is in the range [0.5, 1).
math.ldexp (m, e)	Returns m2e (e should be an integer).
math.log (x [, base])	Returns the logarithm of x in the given base. The default for base is e.
math.pow (x, y)	Returns x^y.
math.rad (x)	Returns the angle x (given in degrees) in radians.

math.pi	The value of π.

Bitwise library

Unless otherwise stated:

- All functions accept numeric arguments in the range (-2^51,+2^51).
- Each argument is normalized to the remainder of its division by 2^32 and truncated to an integer (in some unspecified way), so that its final value falls in the range [0,2^32 - 1].
- All results are in the range [0,2^32 - 1].

bit32.arshift(x,disp)	Returns x arithmetically shifted disp bits to the right (+disp) or left (-disp).
bit32.band(…)	Returns the bitwise and of the arguments.
bit32.bnot(x)	Returns the bitwise negation of x.
bit32.bor(…)	Returns the bitwise or of the arguments.
bit32.btest(…)	Returns true if the bitwise and of the arguments is not zero.
bit32.bxor(…)	Returns the bitwise exclusive or of the arguments.
bit32.extract(n,field[,width])	Returns the bits in n from field to field + width - 1 (bits number from most to least significant). Default for width is 1.
bit32.replace(n,v,field[,width])	Returns a copy of n with bits from field to field + width -1 replaced by v. Default width is 1.
bit32.lrotate(x,disp)	Returns x rotated disp bits to the left (+disp) or right (-disp).
bit32.lshift(x,disp)	Returns x shifted disp bits to the left (+disp) or right (-disp).
bit32.rrotate(x,disp)	Returns x rotated disp bits to the right (+disp) or left (-disp).
bit32.rshift(x,disp)	Returns x shifted disp bits to the right (+disp) or left (-disp).

Operating system library

os.clock ()	Returns an approximation of the amount in seconds of CPU time.
os.date ([format [, time]])	Returns a string or a table containing date and time, formatted according to the given string format.
os.time ([table])	Returns the current time when called without arguments, or a time representing the date and time specified by the given table.
os.difftime (t2, t1)	Returns the number of seconds from time t1 to time t2.

Citrix ADC library

ns.logger:level(message)	To log messages where level is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specifiers in the format string.

Citrix ADC extensions API reference

September 14, 2021

Behaviors are a formalization of common programmable patterns that are available on a Citrix ADC appliance. For example, a TCP virtual server supports a TCP client behavior and a TCP server behavior. A behavior is a pre-defined set of callback functions. You can implement behaviors by providing callback functions. For example, a TCP client behavior can consist of the on_data function, which processes the TCP data stream.

TCP client behavior

on_data - function callback for TCP client data events. The callback takes two arguments:

- **ctxt** - TCP client processing context
- **payload** – event payload
  - **payload.data** - TCP data received, available as a stream of bytes

TCP server behavior

on_data - function callback for TCP server data events, the callback takes two arguments:

- **ctxt** - TCP server processing context
- **payload** – event payload
  - **payload.data** - tcp data received, available as a stream of bytes

TCP client context

The context that is passed to the TCP client event callbacks:

- **ctxt.output** - The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message. The EOM event may or may not have TCP data with it. An EOM event with TCP data can be sent without a preceding DATA event to send a whole protocol message data and mark the end of message. The load balancing decision is made, downstream by the load balancing virtual server, on the first data received. A new load balancing decision is made after the receipt of the EOM message. So, to stream protocol message data, send multiple DATA events with the last event as EOM. All the contiguous DATA events and the following EOM events are sent to the same server connection selected by the load balancing decision on the first DATA event in the sequence.
- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.
- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
- **ctxt.vserver** - The virtual server context.
- **ctxt.client** – Client connection processing context. This processing context can be used to send data to the client, and to fetch some connection related information like IP address, source and destination ports.

- **ctxt:close()** – Close the client connection by sending FIN to the client. After calling this API, the client processing context is no longer usable and gives error on any usage.

TCP server context

The context that is passed to the TCP server event callbacks:

- **ctxt.output** – The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message.
- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.
- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
- **ctxt.vserver** - The virtual server context.
- **ctxt.server** - Server connection processing context. This processing context can be used to send data to the server, and to fetch some connection related information like IP address, source and destination ports.
- **ctxt:reuse_server_connection ()** - This API is used to allow the server connection to be reused for other client connections in the server context only. This API can be used only if an EOM event is used (in ns.send() API) to send the data in the client context. Otherwise, the ADC appliance throws an error.

  To allow a server connection to be reused by other clients, this API must be called at the end of each response message. After calling this API, if more data is received on this server connection, this is treated as an error and the server connection is closed. If this API is not used, then the server connection can be used only for that client for which it was opened. Also, if the same server is selected for another load balancing decision for that client, then the same server connection is used to send the client data. After using this API, server connection stops being tied to the client connection for which it was opened, and can be reused for a new load balancing decision for any other client connection. After calling this API, the server context is no longer usable and throws an error on any usage.

  Note: This API is available in Citrix ADC 12.1 build 49.xx and later.
- **ctxt:close()** – Close the server connection by sending FIN to the server. After calling this API, the client processing context is no longer usable and displays an error on any usage.

  Note: This API is available in Citrix ADC 12.1 build 50.xx and later.

Vserver context

The user virtual server context available through the contexts passed to callbacks:

- **vserver:counter_increment(counter_name)** - Increments the value of a virtual server counter passed as argument. Currently the following built-in counters are supported.
  - **- invalid_messages** – Number of invalid requests/responses on this virtual server.
  - **- invalid_messages_dropped** – Number of invalid requests/responses dropped by this virtual server.
- **vserver.params** - The configured parameters for the user virtual server. Parameters provide configurability of extensions. The extension code can access parameters that are specified in the CLI to add a user virtual server.

Client connection context

Client connection processing context to get connection related information.

- **client.ssl** – SSL context
- **client.tcp** – TCP context
- **client.is_ssl** – True if client connection is SSL-based

Server connection context

Server connection processing context to get connection related information.

- **server.ssl** – SSL context
- **server.tcp** – TCP context
- **server.is_ssl** – True if server connection is SSL-based

TCP context

TCP context operates on TCP protocol.

- **tcp.srcport** – Source port as a number
- **tcp.dstport** - Destination port as a number

IP context

IP context works on IP or IPv6 protocol data.

- **ip.src** - Source IP address context.
- **ip.dst** - Destination IP address context.

Note: This API is available in Citrix ADC 12.1 build 51.xx and later.

IP address context

IP address context works on IP or IPv6 address data.

- **<address>.to_s** - The address string in the appropriate ASCII notation.
- **<address>.to_n** - The address' numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 bytes for IPv6).
- **<address>.version** - Returns 4 for IPv4 and 6 for IPv6.
- **<address>:subnet(<prefix value>)** - Returns the subnet address string after applying the prefix number.
  - For IPv4 address, value must be between 0 and 32
  - For IPv6 address, value must be between 0 and 128.
- **<address>:apply_mask(<mask string>)** - Returns the address string after applying mask string. API validates the version of argument and does appropriate error checking.
- **address>:eq(<address string>)** - Returns true or false based on whether the argument is equivalent to the address object. API validates the version of the arguments.

Note: This API is available in Citrix ADC 12.1 build 51.xx and later.

SSL context

The SSL context provides information related to frontend SSL connection.

- **ssl.cert** – SSL certificate context. For the client connection, it provides client certificate context and for the server connection, it provides server certificate context.
- **ssl.version** - A number that represents the SSL protocol version of the current transaction, as follows:
  - - 0: The transaction is not SSL-based
  - - 0x002: The transaction is SSLv2
  - - 0x300: The transaction is SSLv3
  - - 0x301: The transaction is TLSv1
  - - 0x302: The transaction is TLSv1.1
  - - 0x303: The transaction is TLSv1.2
- **ssl.cipher_name** - SSL Cipher name as string if invoked from an SSL connection, otherwise gives NULL string.
- **ssl.cipher_bits** – Number of bits in cryptographic key.

SSL certificate context

- **Cert.version** – Version number of the certificate. If the connection is not SSL based, returns 0.

- **Cert.valid_not_before** – Date in string format before which certificate is not valid.
- **Cert.valid_not_after** – Date in string format after which certificate is no longer valid.
- **Cert.days_to_expire** – Number of days before which certificate is valid. Returns -1 for expired certificate.
- **Cert.to_pem** – Certificate in binary format.
- **cert.issuer** - Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (“=”) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

  Following is an example of the returned DN:
  /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@n
- **cert.auth_keyid** – Context of Authority Key Identifier extension of the X.509 V3 certificate.
  - **auth_keyid.exists** - TRUE if the certificate contains an Authority Key Identifier extension.
  - **auth_keyid.issuer_name** - Issuer Distinguished Name in the certificate as a name-value list.
    An equals sign (“=”) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

  Following is an example:
  /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@n
  - **auth_keyid.keyid** - KeyIdentifier field of the Authority Key Identifier as a blob
  - **auth_keyid.cert_serialnumber** - SerialNumber field of the Authority Key Identifier as a blob.
- **cert.pk_algorithm** - Name of the public key algorithm used by the certificate.
- **cert.pk_size** - Size of the public key used in the certificate.
- **cert.serialnumber** - Serial number of the client certificate. If this is a non-SSL transaction or there is an error in the certificate, this gives an empty string.
- **cert.signature_algorithm** - Name of the cryptographic algorithm used by the CA to sign this certificate.
- **cert.subject_keyid** - Subject KeyID of the client certificate. If there is no Subject KeyID, this gives a zero-length text object.
- **cert.subject** - Distinguished Name of the Subject as a name-value. An equals sign (“=”) separates names and values and a slash (“/”) delimits name-value pairs.

Following is an example:
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycom

Citrix ADC libraries

- **ns.tcp.stream** - String like library for handling TCP data as a stream of bytes. The maximum size of TCP stream data on which these APIs can work is 128 KB. The ns.tcp.stream library functions can also be called in the usual extension object oriented style of calling. For example, data:len() is the same as ns.tcp.stream.len(data)
  - **ns.tcp.stream.len(data)** - Returns length of data in bytes, similar to Lua's string.len
  - **ns.tcp.stream.find(data, pattern [, init])** - Function similar to Lua's string.find. In addition, it also does partial matching at the end of data. Upon partial match, the start index is returned and the end index becomes nil.
  - **ns.tcp.stream.split(data, length)** - Splits the data into two chunks, the first chunk is of the specified length. After a successful split the original data is no longer usable as a TCP data stream. Any attempt to use it that way causes an error.
  - **ns.tcp.stream.byte(data[, i [, j]])** - Function similar to Lua's string.byte. Returns the internal numerical codes of the characters data[i], data[i+1], …, data[j].
  - n**s.tcp.stream.sub(data, i [, j])** - Function similar to Lua's string.sub. Returns the substring of s that starts at i and continues until j.
  - **ns.tcp.stream.match(data, pattern, [, init])** - Function similar to Lua's string.match. Looks for the first *match* of pattern in string s.
- **ns.send(processing_ctxt, event_name, event_data)** - Generic function to send events to a processing context. Event data is a Lua table that can have any content. The contents depend on the event. After the ns.send() API is called, the data reference is no longer usable. Any attempt to use it causes an error.
- **ns.pipe(src_ctxt, dest_ctxt)** - Using a call to pipe() API, extension code can connect source context to a destination context. After a call to pipe, all the events that are sent from source context to the next module in the pipeline go directly to the destination context. This API is typically used by the module that makes the pipe() call, to remove itself from the pipeline.
- **ns.inet** – Library for internet addresses.
  - **ns.inet.apply_mask(address_str, mask_str)** - returns the address string after applying mask string.
  - **ns.inet.aton(address_str)** - Returns address' numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 for IPv6).
  - **ns.inet.ntoa(byte_str)** - Converts numeric byte value as a string of bytes to address string.
  - **ns.inet.ntohs(number)** - Convert the given network byte order to host byte order. If the input is greater than 2^16 - 1, then throws an error.
  - **ns.inet.htons(number)** - Converts the given host byte order to network byte order. If the input is greater than 2^16 - 1, then throws an error.
  - **ns.inet.ntohl(number)** - Converts the given network byte order to host byte order. If the

input is greater than 2^32 - 1, then throws an error.
- **ns.inet.htonl(number)** - Converts the given host byte order to network byte order. If the input is greater than 2^32 - 1, then throws an error.
- **ns.inet.subnet(address_str, subnet_value)** – Returns the subnet address string after applying given subnet.

Protocol extensions

September 14, 2021

The Citrix ADC appliances have native support for protocols such as HTTP. In addition to this, you can use protocol extensions to add support for custom protocols. Presently only TCP-based custom protocols are supported, for example, Message Queuing Telemetry Transport (MQTT) protocol. For secure transactions, TCP over SSL is also supported.

The protocol extensions on the Citrix ADC appliance are part of the high-level scripting infrastructure available on the Citrix ADC appliance. The scripting language is based on the Lua 5.2 programming language. To add a custom protocol to a Citrix ADC appliance, the user has to write extension code to implement the applicable behaviors. For example, the ns.tcp.client and ns.tcp.server behaviors are applicable to TCP based protocols. To implement a behavior, implement only the callbacks that you want to customize. If callback is not implemented, its default takes effect. For more information about the scripting language, see Citrix ADC Extensions - Language Overview. For details on behaviors, see Citrix ADC Extensions API Reference.

The Citrix ADC protocol extensions can be used for the following:

- Add new protocol support on the Citrix ADC appliance programmatically, using extensions.
- Parse protocol traffic and do protocol-specific message based load balancing (MBLB).
- Configure user defined load balancing persistence.

Protocol extensions - architecture

September 14, 2021

To achieve traffic-level extensibility, the traffic processing on a Citrix ADC appliance is exposed as a pipeline of separate processing modules. Traffic flows through them as it processes it from ingress to egress. These modules in the pipeline follow a shared nothing model. Message passing is used to send the traffic data from one module in the pipeline to the next module.

Certain points in the traffic processing pipeline are made extensible, so that you can add code to customize the Citrix ADC behavior.

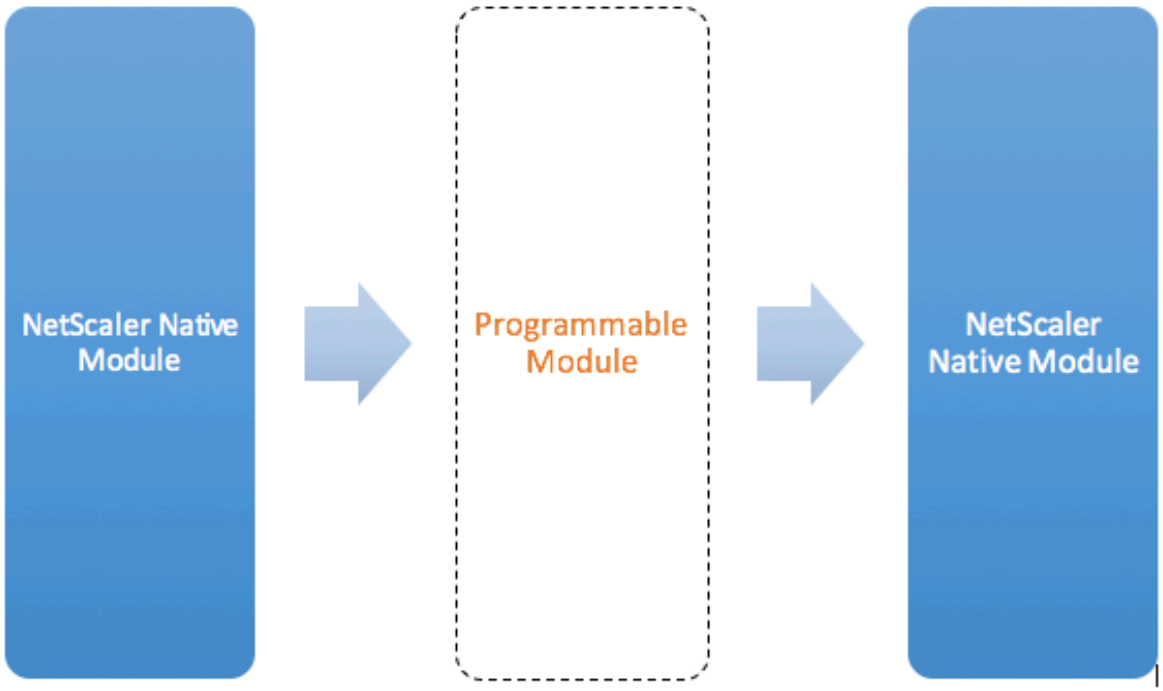


Figure: A Programmable Module In the Traffic Pipeline

By default, the traffic bypasses a programmable module to which you do not add any code.

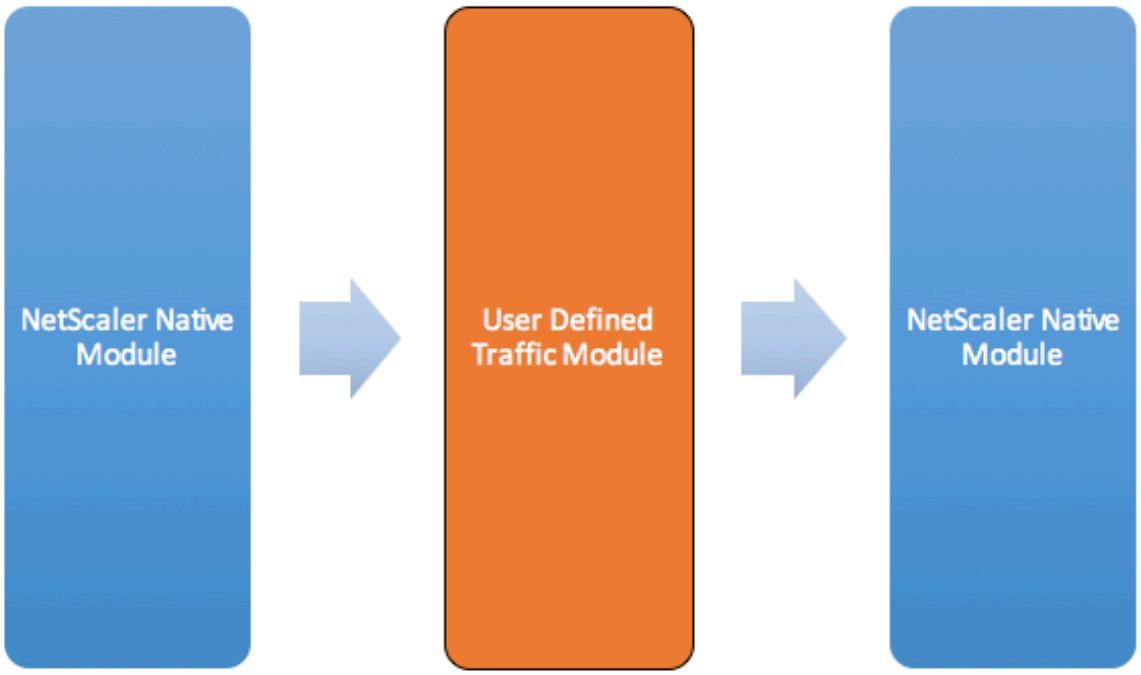

Figure: User Defined Traffic Module

Behaviors

The programmable interfaces for customizing the traffic handling are called behaviors. Behaviors are basically a formalization of common programmable patterns that are available on a Citrix ADC appliance. The behaviors consist of a pre-defined set of event callback functions. You can implement a behavior by providing callback functions conforming to the behavior.

For example, the TCP client behavior consists of a callback function (on_data) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

Context:

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

Payload:

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments.

So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

For Citrix ADC API extensions, see Citrix ADC extension API reference.

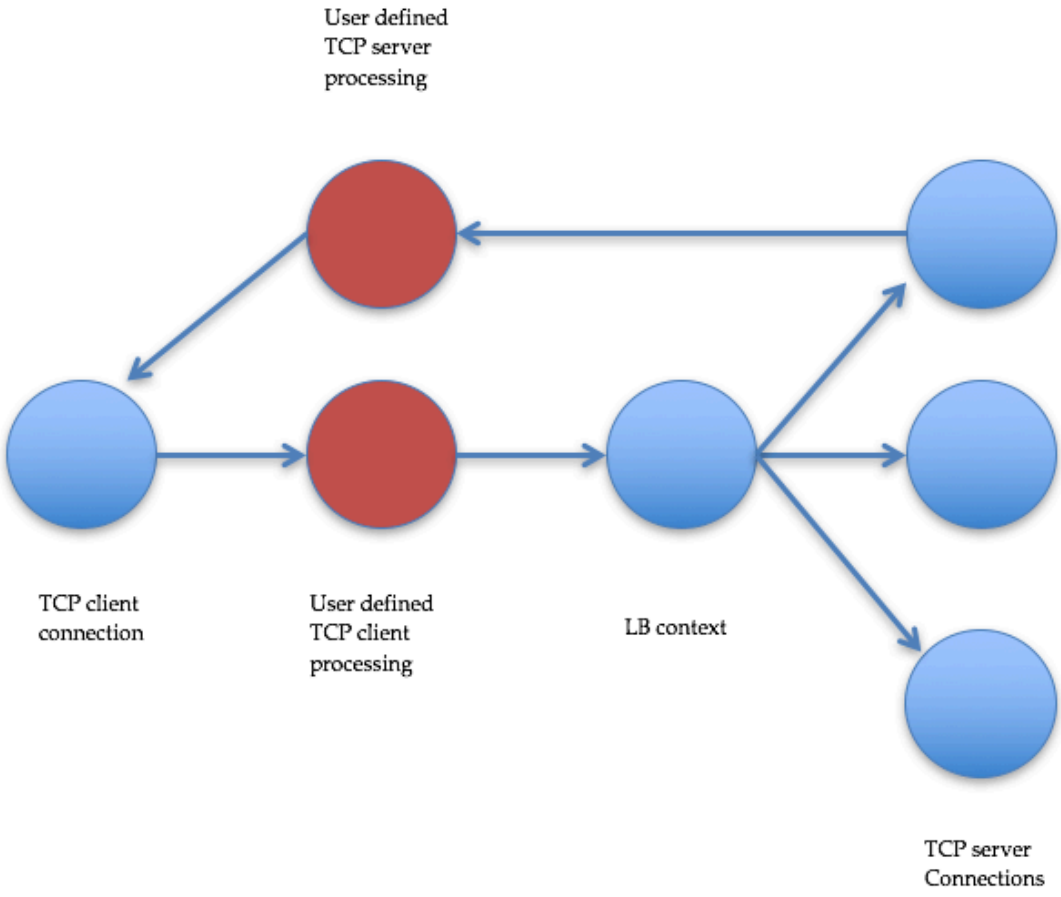
The following code snippet shows a user defined function to handle TCP client data stream events. The context and payload are passed to the function by Citrix ADC code. This code simply forwards the TCP data received in every call to the next processing module context in the pipeline. In this case, the next module is the load balancing (LB) context, which is a Citrix ADC native module.

```
function client.on_data(ctxt, payload)
    ns.send(ctxt.output, "DATA", {
 data = payload.data }
 )
end
<!--NeedCopy-->
```

Protocol extensions - traffic pipeline for user defined TCP client and server behaviors

September 14, 2021

The following figure illustrates the sample protocol extension - traffic pipeline for user defined TCP client and server behaviors



Traffic Pipeline For User Defined TCP Client And Server Behaviors

Add a custom protocol by using protocol extensions

The command line interface (CLI) commands for custom protocol use the keyword “user” to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

The following example illustrates the user flow for adding support for a new protocol. The example adds MQTT protocol support to the system. MQTT is a machine-to-machine "Internet of Things" connectivity protocol. It is a lightweight publish/subscribe messaging transport. Useful for connections with remote locations, this protocol uses client and broker tools to publish messages to subscribers.

1. Import the MQTT protocol extension implementation file to Citrix ADC system. The code listing for mqtt.lua is given below. The example below imports the MQTT extension file hosted on a webserver.

   ```
   import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
   ```

2. Add a new user TCP based protocol to the system using the extension.

   ```
   add user protocol MQTT -transport TCP -extension mqtt_code
   ```

3. Add a user load balancing vserver and bind backend services to it.

   ```
   1 add service mqtt_svr1 10.217.24.48 USER_TCP 1501
   2 add service mqtt_svr2 10.217.24.48 USER_TCP 1502
   3 add lb vserver mqtt_lb USER_TCP - lbmethod USER_TOKEN
   4 bind lb vserver mqtt_lb mqtt_svr1
   5 bind lb vserver mqtt_lb mqtt_svr2
   6 <!--NeedCopy-->
   ```

4. Add a user vserver for the newly added protocol. Set the defaultlb to the LB vserver configured above.

   ```
   add user vserver mqtt_vs MQTT 10.217.24.28 8765 -defaultLb mqtt_lb
   ```

5. Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

   ```
   set lb vserver mqtt_lb -persistenceType USERSESSION
   ```

Protocol extensions - use cases

September 14, 2021

Protocol extensions can be used for the following use cases.

- Message based load balancing (MBLB)
- Streaming
- Token based load balancing
- Load balancing persistence
- TCP connection based load balancing
- Content based load balancing

- SSL
- Modify traffic
- Originate traffic to client or server
- Process data on the connection establishment

Message based load balancing

Protocol extensions support Message Based Load Balancing (MBLB), which can parse any protocol on a Citrix ADC appliance and load balance the protocol messages arriving on one client connection, that is, distribute the messages over multiple server connections. MBLB is achieved by user code that parses the client TCP data stream.

The TCP data stream is passed to the on_data callbacks for client and server behaviors. The TCP data stream is available to the extension functions through a Lua string like interface. You can use an API similar to the Lua string API to parse the TCP data stream.

Useful APIs include:

```
data:len()
```

```
data:find()
```

```
data:byte()
```

```
data:sub()
```

```
data:split()
```

Once the TCP data stream has been parsed into a protocol message, the user code achieves load balancing by just sending the protocol message to the next context available from the context passed to the on_data callback for the client.

The ns.send() API is used to send messages to other processing modules. In addition to the destination context, the send API takes the event name and optional payload as arguments. There is one-to-one correspondence between the event name and the callback function names for the behaviors. The callbacks for events are called on_<event_name>. The callback names use only lowercase.

For example, the TCP client and server on_data callbacks are user-defined handlers for events named “DATA.” For sending the whole protocol message in one send call, the EOM event is used. EOM, which stands for end of message, signifies the end of protocol message to the LB context down stream, so a new load balancing decision is made for data that follows this message.

The extension code might sometimes not receive the whole protocol message in the on_data event. In such a case, the data can be held by using the ctxt:hold() API. The hold API is available for both TCP-client and server-callback contexts. When “hold with data” is called, the data is stored in the context. When more data is received in the same context, the newly received data is appended to the previously stored data and the on_data callback function is called again with the combined data.

Note: The load balancing method used depends on the configuration of the load balancing virtual server corresponding to the load balancing context.

The following code snippet shows the use of the send API to send the parsed protocol message.

Example:

```
    function client.on_data(ctxt, payload)
        --
        -- code to parse payload.data into protocol message comes here
        --
        -- sending the message to lb
        ns.send(ctxt.output, "EOM", {
 data = message }
 )
    end -- client.on_data

    function server.on_data(ctxt, payload)
        --
        -- code to parse payload.data into protocol message comes here
        --
        -- sending the message to client
        ns.send(ctxt.output, "EOM", {
 data = message }
 )

    end -- server.on_data
<!--NeedCopy-->
```

Streaming

In some scenarios, holding the TCP data stream until the whole protocol message is collected might not be necessary. In fact, it is not advised unless it is required. Holding the data increases memory usage on Citrix ADC appliance and can make the appliance susceptible to DDoS attacks by exhausting the memory on Citrix ADC appliance with incomplete protocol messages on many connections.

Users can achieve streaming of TCP data in the extension callback handlers by using the send API. Instead of holding the data until the whole message is collected, data can be sent in chunks. Sending data to ctxt.output by using the DATA event sends a partial protocol message. It can be followed by more DATA events. An EOM event must be sent to mark the end of the protocol message. The load balancing context downstream makes the load balancing decision on the first data received. A new load balancing decision is made after the receipt of the EOM message.

To stream protocol message data, send multiple DATA events followed by an EOM event. The contiguous DATA events and the following EOM event are sent to the same server connection selected by load

balancing decision for the first DATA event in the sequence.

For a send to client context, EOM and DATA events are effectively the same, because there is no special handling by the client context downstream for EOM events.

Token based load balancing

For natively supported protocols, a Citrix ADC appliance supports a token based load balancing method that uses PI expressions to create the token. For extensions, the protocol is not known in advance, so PI expressions cannot be used. For token based load balancing, you have to set the default load balancing virtual server to use the USER_TOKEN load balancing method, and provide the token value from the extension code by calling the send API with a user_token field. If the token value is sent from the send API and the USER_TOKEN load balancing method is configured on the default load balancing virtual server, the load balancing decision is made by calculating a hash based on the token value. The maximum length of token value is 64 bytes.

```
add lb vserver v\\_mqttlb USER\\_TCP -lbMethod USER\\_TOKEN
```

The code snippet in the following example uses a send API to send an LB token value.

Example:

```
        -- send the message to lb

        -- user_token is set to do LB based on clientID

        ns.send(ctxt.output, "EOM", {
 data = message,

                                user_token = token_info }
 )
<!--NeedCopy-->
```

Load balancing persistence

Load balancing persistence is closely related to token based load balancing. Users have to be able to programmatically calculate the persistence session value and use it for load balancing persistence. The send API is used to send persistence parameters. To use load balancing persistence, you have

to set the USERSESSION persistence type on the default load balancing virtual server and provide a persistence parameter from the extension code by calling the send API with a user_session field. The maximum length of the persistence parameter value is 64 bytes.

If you need multiple types of persistence for a custom protocol, you have to define user persistence types and configure them. The names of the parameters used to configure the virtual servers are decided by the protocol implementer. A parameter's configured value is also available to the extension code.

The following CLI and code snippet shows the use of a send API to support load balancing persistence. The code listing in the section Code Listing for mqtt.lua also illustrates the use of the user_session field.

For persistency, you have to specify the USERSESSION persistency type on the load balancing virtual server and pass the user_session value from the ns.send API.

```
add lb vserver v\\_mqttlb USER\\_TCP -persistencetype USERSESSION
```

Send the MQTT message to the load balancer, with the user_session field set to clientID in the payload.

Example:

```
1 -- send the data so far to lb
2
3 -- user_session is set to clientID as well (it will be used to persist
     session)
4
5 ns.send(ctxt.output,  "DATA" , {
6  data = data, user_session = clientID }
7  )
8 <!--NeedCopy-->
```

TCP connection based load balancing

For some protocols, MBLB might not be needed. Instead, you might need TCP connection based load balancing. For example, the MQTT protocol must parse the initial part of the TCP stream to determine the token for load balancing. And, all the MQTT messages on the same TCP connection must be sent to the same server connection.

TCP connection based load balancing can be achieved by using the send API with only DATA events and not sending any EOM. That way the downstream load balancing context bases the load balancing decision on the data received first, and sends all the subsequent data to the same server connection selected by the load balancing decision.

Also, some use cases might require the ability to bypass extension handling after the load balancing decision has been made. Bypassing the extension calls results in better performance, because the

traffic is processed purely by native code. Bypass can be done by using the ns.pipe() API. A call to the pipe() API extension code can connect input context to an output context. After the call to pipe(), all the events coming from input context directly go to the output context. Effectively, the module from which the pipe() call is made is removed from the pipeline.

The following code snippet shows streaming and the use of the pipe() API to bypass a module. The code listing in the section Code Listing for mqtt.lua also illustrates how to do streaming and the use of pipe() API to bypass the module for rest of the traffic on the connection.

Example:

```
        -- send the data so far to lb
        ns.send(ctxt.output, "DATA", {
 data = data,
                                      user_token = clientID }
 )
        -- pipe the subsequent traffic to the lb - to bypass the client
            on_data handler
        ns.pipe(ctxt.input, ctxt.output)
<!--NeedCopy-->
```

Content based load balancing

For native protocols, content switching like feature for protocol extensions is supported. With this feature, instead of sending the data to the default load balance, you can send the data to the selected load balancer.

Content switching feature for protocol extensions is achieved by using the ctxt:lb_connect(<lbname>) API. This API is available to the TCP client context. Using this API, the extension code can obtain a load balancing context corresponding to an already configured load balancing virtual server. You can then use the send API with the load balancing context thus obtained.

The lb context can be NULL sometimes:

- Virtual server does not exists
- Virtual server is not of user protocol type
- Virtual server's state is not UP
- Virtual server is user virtual server, not load balancing virtual server

If you remove the target load balancing virtual server when it is in use, then all connections associated with that load balancing virtual server is reset.

The following code snippet shows the use of lb_connect() API. The code maps the client ID to load balancing virtual server names (lbname) using the Lua table lb_map and then gets the LB context for lbname using lb_connect(). And finally sends to the LB context using send API.

```
    local lb_map = {

       ["client1*"] = "lb_1",
       ["client2*"] = "lb_2",
       ["client3*"] = "lb_3",
       ["client4*"] = "lb_4"
     }

    -- map the clientID to the corresponding LB vserver and connect to
       it
    for client_pattern, lbname in pairs(lb_map) do
       local match_idx = string.find(clientID, client_pattern)
       if (match_idx == 1) then
      lb_ctxt = ctxt:lb_connect(lbname)
      if (lb_ctxt == nil) then
         error("Failed to connect to LB vserver: " .. lbname)
      end
      break
       end
    end
    if (lb_ctxt == nil) then
    -- If lb context is NULL, the user can raise an error or send data
       to default LB
       error("Failed to map LB vserver for client: " .. clientID)
    end
-- send the data so far to lb
ns.send(lb_ctxt, "DATA", {
 data = data }

<!--NeedCopy-->
```

SSL

SSL for protocols using extensions is supported in ways similar to how SSL for native protocols is supported. Using the same parsing code for creating custom protocols, you can create a protocol instance over TCP or over SSL which can then be used to configure the virtual servers. Similarly, you can add user services over TCP or SSL.

For more information, see Configuring SSL Offloading for MQTT and Configuring SSL Offloading for MQTT With End-To-End Encryption.

Server connection multiplexing

Sometimes, the client sends one request at a time and sends the next request only after the response for the first request is received from the server. In such a case, server connection can be reused for other client connections, and for the next message on the same connection, after the response has been sent to the client. To allow reuse of server connection by other client connections, you must use the ctxt: reuse_server_connection() API on the server side context.

Note: This API is available in Citrix ADC 12.1 build 49.xx and later.

Modify traffic

To modify data in the request or response, you must use the native rewrite feature that uses an advanced policy PI expression. Because you cannot use PI expressions in extensions, you can use the following APIs to modify a TCP stream data.

```
data:replace(offset, length, new_string)
data:insert(offset, new_string)
data:delete(offset, length)
data:gsub(pattern, replace [,n]))
```

The following code snippet shows the use of replace() API.

```
-- Get the offset of the pattern, we want to replace
   local old_pattern =  “pattern to repalace”
local old_pattern_length = old_pattern:len()
   local pat_off, pat_end = data:find(old_pattern)
   -- pattern is not present
if (not pat_off) then
    goto send_data
   end
  -- If the data we want to modify is not completely present, then
  -- wait for more data
  if (not pat_end) then
        ctxt:hold(data)
        data = nil
     goto done
  end
data:replace(pat_off, old_pattern_length,  “new pattern” )
::send_data::
ns.send(ctxt.output,  “EOM” , {
 data = data }
 )
::done::
```

The following code snippet shows the use of insert() API.

```
data:insert(5,  “pattern to insert” )
```

The following code snippet shows the use of insert() API, when we want to insert after or before some pattern:

```
-- Get the offset of the pattern, after or before which we want to
    insert
   local pattern =  “pattern after/before which we need to insert”
local pattern_length = pattern:len()
   local pat_off, pat_end = data:find(pattern)
-- pattern is not present
   if (not pat_off) then
    goto send_data
   end
  -- If the pattern after which we want to insert is not
  -- completely present, then wait for more data
  if (not pat_end) then
        ctxt:hold(data)
        data = nil
     goto done
  end
-- Insert after the pattern
data:insert(pat_end + 1,  “pattern to insert” )
   -- Insert before the pattern
data:insert(pat_off,  “pattern to insert” )
::send_data::
    ns.send(ctxt.output,  “EOM” , {
 data = data }
 )
::done::
```

The following code snippet shows the use of delete() API.

```
-- Get the offset of the pattern, we want to delete
   local delete_pattern =  “pattern to delete”
local delete_pattern_length = delete_pattern:len()
   local pat_off, pat_end = data:find(old_pattern)
   -- pattern is not present
if (not pat_off) then
          goto send_data
   end
  -- If the data we want to delete is not completely present,
  -- then wait for more data
```

```
  if (not pat_end) then
        ctxt:hold(data)
        data = nil
    goto done
  end
data:delete(pat_off, delete_pattern_length)
::send_data::
ns.send(ctxt.output,  "EOM" , {
 data = data }
 )
::done::
```

The following code snippet shows the use of gsub() API.

```
    -- Replace all the instances of the pattern with the new string
data:gsub( "old pattern" ,  "new string" )
-- Replace only 2 instances of  "old pattern"
data:gsub( "old pattern" ,  "new string" , 2)
-- Insert new_string before all instances of  "http"
data:gsub( "input data" ,  "(http)" ,  "new_string%1" )
-- Insert new_string after all instances of  "http"
data:gsub( "input data" ,  "(http)" ,  "%1new_string" )
-- Insert new_string before only 2 instances of  "http"
data:gsub( "input data" ,  "(http)" ,  "new_string%1" , 2)
```

Note: This API is available in Citrix ADC 12.1 build 50.xx and later.

Originate traffic to client or server

You can use the ns.send() API to send data that originates from the extension code to a client and a back-end server. To send or receive response directly with a client, from client context, you must use ctxt.client as the target. To send or receive response directly with a back-end server from server context, you must use ctxt.server as the target. The data in the payload can be a TCP stream data or a Lua string.

To stop traffic processing on a connection, you can use ctxt:close() API from either the client or the server context. This API closes the client-side connection or any server connections linked to it.

When you call the ctxt:close() API, extension code sends TCP FIN packet to the client and server connections and if more data is received from the client or server on this connection, then the appliance resets the connection.

The following code snippet shows the use of ctxt.client and ctxt:close() APIs.

```
    -- If the input packet is not MQTT CONNECT type, then
```

```
-- send some error response to the client.
function client.on_data(ctxt, payload)
    local data = payload.data
    local offset = 1
    local msg_type = 0
    local error_response =  “Missing MQTT Connect packet.”
    byte = data:byte(offset)
msg_type = bit32.rshift(byte, 4)
if (msg_type ~= 1) then
-- Send the error response
   ns.send(ctxt.client,  “DATA” , {
 data = error_response }
 )
-- Since error response has been sent, so now close the connection
    ctxt:close()
end
```

The following code snippet shows the example when user can inject the data in the normal traffic flow.

```
-- After sending request, send some log message to the server.
function client.on_data(ctxt, payload)
local data = payload.data
local log_message =  “client id :  “..data:sub(3, 7)..”  user name :  “
    data:sub(9, 15)
-- Send the request we get from the client to backend server
ns.send(ctxt.output,  “DATA” , {
 data = data }
 )
After sending the request, also send the log message
ns.send(ctxt.output,  “DATA” , {
 data = log_message”  }
 )
end
```

The following code snippet shows the use of ctxt.to_server API.

```
-- If the HTTP response status message is  “Not Found” ,
-- then send another request to the server.
function server.on_data(ctxt, payload)
    local data = payload.data
    local request  “GET /default.html HTTP/1.1\r\n\r\n” ss
    local start, end = data:find( “Not Found” )
    if (start) then
    -- Send the another request to server
        ns.send(ctxt.server,  “DATA” , {
```

```
10   data = request }
11   )
12  end
```

Note: This API is available in Citrix ADC 12.1 build 50.xx and later.

Data processing on the connection establishment

There might be a use case where you want to send some data at the connection establishment (when the final ACK is received). For example, in proxy protocol, you might want to send client's source and destination IP addresses and ports to the back-end server at the connection establishment. In this case, you can use client.init() callback handler to send the data on connection establishment.

The following code snippet shows the use of client.init() callback:

```
1  -- Send a request to the next processing context
2  -- on the connection establishment.
3  function client.init(ctxt)
4     local request  "PROXY TCP4"  + ctxt.client.ip.src.to_s +  "  " +
          ctxt.client.ip.dst.to_s +  "  " + ctxt.client.tcp.srcport +  "  "
           +     ctxt.client.tcp.dstport
5  -- Send the another request to server
6     ns.send(ctxt.output,  "DATA" , {
7   data = request }
8   )
9    end
```

Note: This API is available in Citrix ADC 13.0 build xx.xx and later.

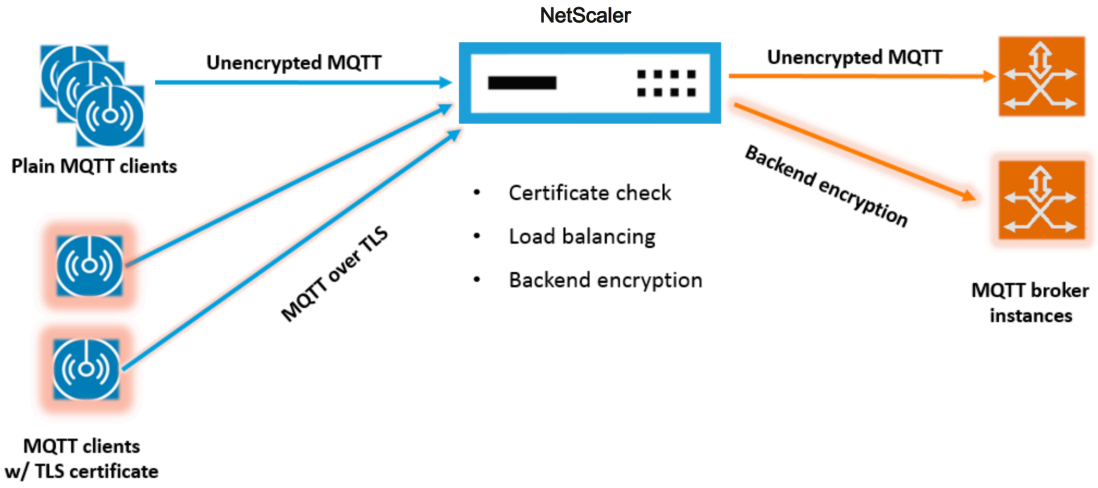
Tutorial – Add MQTT protocol to the Citrix ADC appliance by using protocol extensions

September 14, 2021

The command line interface (CLI) commands for custom protocol use the keyword "user" to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

MQTT protocol is used for illustration purposes.

The following diagram illustrates a Citrix ADC appliance and MQTT client and broker tools.



Code listing for mqtt.lua

September 14, 2021

The code listing below, mqtt.lua, gives the code to implement the MQTT protocol on Citrix ADC using protocol extensions. The code only has the TCP client data callback function defined - client.on_data(). For server data, it does not add a callback function and the server to client takes the fast native path. For client data, the code parses the CONNECT MQTT protocol message and extracts the ClientID. It then uses the ClientID for user_token value, which is used to load balance all the client traffic for the connection based on the ClientID by setting LB method for the LB vserver as USER_TOKEN. It uses the ClientID also for user_session value, which can be used for LB persistence by setting persistence type for the LB vserver as USERSESSION. The code uses the ns.send() to do LB and send the initial data. It uses the ns.pipe() API to send the rest of the client traffic directly to server connection, bypassing calls to extension callback handler.

```
--[[

  MQTT event handler for TCP client data

    ctxt - TCP client side App processing context.

    data - TCP Data stream received.

    - parse the client ID from the connect message - the first message
       should be connect

```

```
11      - send the data to LB with ClientID as user token and session
12
13      - pipe the subsequent data to LB directly. This way the subsequent
            MQTT traffic will
14
15        bypass the tcp client on_data handler
16
17      - if a parse error is seen, throw an error so the connection is
            reset
18
19  --]]
20

Configure MQTT by using protocol extensions

September 14, 2021

The following steps add a MQTT protocol to the Citrix ADC appliance.

Import the extension file to the Citrix ADC appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see Import extensions.

```
import ns extension local:mqtt_generic_fs.lua mqtt_code
```

Add a new user TCP based protocol to the system by using the extension.

```
add user protocol MQTT -transport TCP -extension mqtt_code
```

Add a service of type USER_TCP to indicate that this is a user-defined protocol.

```
add service s1 10.102.90.112 USER_TCP 80
```

Add a user load balancing vserver and bind backend services to it.

```
add lb vs mysv USER_TCP
```

```
bind lb vs mysv s1
```

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

```
add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv
```

Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

```
set lb vserver mqtt_lb -persistenceType USERSESSION
```

Configuring SSL offloading for MQTT

September 14, 2021

You can implement SSL offloading for user protocols by adding an SSL instance for the protocol. The example below shows how to do SSL offloading for a user protocol. The traffic to backend services is unencrypted with this configuration.

Note: This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see SSL certificates.

The following commands add the MQTT_SSL protocol by including mqtt.lua with transport value "SSL."

```
import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
add user protocol MQTT_SSL -transport SSL -extension mqtt_code
<!--NeedCopy-->
```

The following commands add a user load balancing virtual server and bind backend services to it.

```
add service mqtt_svr1 10.217.24.48 USER_TCP 1501
add service mqtt_svr2 10.217.24.48 USER_TCP 1502
add lb vserver mqtt_lb USER_TCP  - lbMethod ROUNDROBIN
bind lb vserver mqtt_lb mqtt_svr1
bind lb vserver mqtt_lb mqtt_svr2
<!--NeedCopy-->
```

The following command adds a user virtual server for the newly added protocol MQTT_SSL. Using MQTT_SSL means the Citrix ADC appliance will do SSL offloading, because MQTT_SSL was configured with SSL transport. The command also sets the defaultlb to the load balancing virtual server configured in the previous step.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb mqtt_lb
```

For SSL offloading, you also need to enable the SSL feature and bind a certkey to the user virtual server. For more information, see the following topics:

Add or update a certificate-key pair

Bind the certificate-key pair to the SSL virtual server

Example:

```
enable ns feature SSL

add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key

bind ssl vserver mqtt_vs  -certkeyName mqtt_svr_cert_key
<!--NeedCopy-->
```

Configuring SSL offloading with end-to-end encryption for MQTT

September 14, 2021

The following example shows how to do SSL offloading for MQTT with end-to-end encryption.

Note: This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see SSL certificates.

The following commands import the extension file and add the MQTT_SSL protocol with SSL transport.

```
import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
add user protocol MQTT_SSL -transport SSL -extension mqtt_code
<!--NeedCopy-->
```

The following commands add a user load balancing virtual server and bind backend services to it. Both the load balancing virtual server and the services are configured for the service type USER_SSL_TCP.

```
add service mqtt_svr1 10.217.24.48 USER_SSL_TCP 1501
add service mqtt_svr2 10.217.24.48 USER_SSL_TCP 1502
add lb vserver mqtt_lb USER_SSL_TCP  - lbmethod RR
bind lb vserver mqtt_lb mqtt_svr1
bind lb vserver mqtt_lb mqtt_svr2
<!--NeedCopy-->
```

The following command adds a user virtual server for the newly added protocol MQTT_SSL. Using MQTT_SSL means the Citrix ADC appliance will do SSL offloading, because MQTT_SSL was configured with SSL transport. The command also makes the load balancing virtual server, configured in previous step, the default load balancer.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb mqtt_lb
```

For end-to-end encryption, you also need to enable the SSL feature and bind a certkey to the user and default load balancing virtual servers. For more information, see the following topics:

Add or update a certificate-key pair

Bind the certificate-key pair to the SSL virtual server

```
enable ns feature SSL

add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key

bind ssl vserver mqtt_lb  -certkeyName mqtt_svr_cert_key

bind ssl vserver mqtt_vs  -certkeyName mqtt_svr_cert_key
<!--NeedCopy-->
```

Tutorial - load balancing syslog messages by using protocol extensions

September 14, 2021

Syslog protocol available on the Citrix ADC appliance works only for the messages generated on the Citrix ADC appliance. It does not load balance the messages coming from external nodes. To load balance such messages, you need to use the protocol extensions feature and write the syslog message parsing logic by using the Lua 5.2 programming language.

Code for parsing syslog message

The code only has the TCP client data callback function defined - client.on_data(). For server data, it does not add a callback function and the server to client takes the fast native path. The code identifies message boundary based on the trailing character. If the TCP packet contains more than one syslog messages, then we split the packet based on the trailing character and load balance each message.

```
--[[

  Syslog event handler for TCP client data

    ctxt - TCP client side App processing context.

    data - TCP Data stream received.

--]]

function client.on_data(ctxt, payload)

                  local message = nil

                  local data_len

                  local data = payload.data

                  local trailing_character = "\n"

                  ::split_message::

                                    -- Get the offset of trailing
                                       character

                                    local new_line_character_offset =
                                       data:find(trailing_character)
```

```
26
27                                  -- If trailing character is not
                                       found, then wait for more data.
28
29                                  if (not new_line_character_offset)
                                       then
30
31                                                  goto
                                                       need_more_data
32
33                                  end
34
35                                  -- Get the length of the current
                                       message
36
37                                  data_len = data:len()
38
39                                  -- Check whether we have more than
                                       one message
40
41                                  -- by comparing trailing character
                                       offset and
42
43                                  -- current data length
44
45                                  if (data_len >
                                       new_line_character_offset) then
46
47                                                  -- If we have
                                                       more than one
                                                       message, then
                                                       split
48
49                                                  -- the data into
                                                       two parts such
                                                        that first
                                                       part
50
51                                                  -- will contain
                                                       message upto
                                                       trailing
                                                       character
52
53                                                  -- offset and
                                                       second part
```

```
                                                                will contain
54
55                                                          -- remaining
                                                                message.
56
57                                                          message, data =
                                                                data:split(
                                                                new_line_character_offse
                                                                )
58
59                                      else
60
61                                                          message = data
62
63                                                          data = nil
64
65                                      end
66
67  -- Send the data to the backend server.
68
69                                      ns.send(ctxt.output, "EOM", {
70   data = message }
71   )
72
73                                      goto done
74
75                                      ::need_more_data::
76
77                                                          -- Wait for more
                                                                data
78
79                                                          ctxt:hold(data)
80
81                                                          data = nil
82
83                                                          goto done
84
85                                      ::done::
86
87                                                          -- If we have
                                                                more data to
                                                                parse,
88
89                                                          -- then do
                                                                parsing again.
```

```
90
91                                                  if (data) then
92
93                                                                  goto
                                                                      split_
94
95                                                  end
96
97  end
98  <!--NeedCopy-->
```

Configuring syslog protocol by using protocol extensions

September 14, 2021

The following steps add an user SYSLOG protocol to the Citrix ADC appliance.

Import the extension file to the Citrix ADC appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see Importing Extensions.

```
import ns extension local:syslog_parser.lua syslog_parser_code
```

Add a new user TCP-based protocol to the system by using the extension.

```
add user protocol USER_SYSLOG -transport TCP -extension syslog_parser_code
```

Add a service of type USER_TCP to indicate that this is a user-defined protocol.

```
add service s1 10.102.90.112 USER_TCP 80
```

Add a user load balancing vserver and bind backend services to it.

```
1  add lb vs mysv USER_TCP
2
3  bind lb vs mysv s1
4  <!--NeedCopy-->
```

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

```
add user vs v_syslog USER_SYSLOG 10.217.24.28 80 -defaultlb mysv
```

Protocol extensions command reference

September 14, 2021

The following table lists all the new commands added for custom protocols, and the existing commands that have been modified for custom protocols.

```
show lb persistentSessions [<vserv-name>]
```

- **CLI command:**

  ```
  add user protocol <name> -transport ( TCP | SSL )-extension <string> -comment <string>]>
  ```

- **Description:**

  Adds a new user protocol to the Citrix ADC appliance by using extensions. Currently only user protocols with transport value TCP or SSL are supported.

  > **Example:**
  >
  > add user protocol MQTT -transport TCP -extension mqtt_code

- **CLI command:**

  ```
  rm user protocol <name>
  ```

- **Description:**

  Removes a user protocol previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > rm user protocol mqtt

- **CLI command:**

  ```
  set user protocol <name> -comment <string>
  ```

- **Description:**

  Changes settings for a user protocol previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > set user protocol mqtt -comment “MQTT protocol implementation”

- **CLI command:**

  ```
  unset user protocol <name> -comment
  ```

- **Description:**

  Removes settings for a user protocol previously added to the Citrix ADC appliance.

> **Example:**
>
> unset user protocol mqtt -comment “MQTT protocol implementation”

- **CLI command:**

  ```
  update ns extension <extension name>
  ```

- **Description:**

  Updates the implementation for a previously added user protocol by using extensions.

  You can update the protocol implementation only if the protocol is not being used by any user virtual server.

  > **Example:**
  >
  > update ns extension my-extension

- **CLI command:**

  ```
  add lb vserver <name> [USER_TCP | USER_SSL_TCP] [-lbmethod USER_TOKEN]
  [-persistencetype USERSESSION] [-timeout <value>]
  ```

- **Description:**

  Adds a load balancing virtual server to the Citrix ADC appliance. This is an existing CLI command.

  For load balancing user virtual servers, the service type to use is USER_TCP or USER_SSL_TCP. The IP address and port are not allowed with user load balancing virtual servers.

  For user load balancing virtual servers, only the ROUNDROBIN load balancing method is allowed, and the token value is provided by the extension code. Similarly, only USERSESSION persistence is allowed, and the persistence setting is provided by the extension code.

  > **Example:**
  >
  > add lb vserver mysv USER_TCP –lbmethod ROUNDROBIN

- **CLI command:**

  ```
  add user vserver <name> <userProtocol> <IPAddress> <port> -defaultLB <
  string> [-params <string>] [-comment <string>]
  ```

- **Description:**

  Adds a virtual server for a user protocol by using extensions. The configured default user load balancing virtual server is available to the TCP client data extension handler as ctxt.output. For a virtual server, extension parameters can be set by using the -params option with a name and a value pair. The corresponding parameter value is available to the extension handlers as ctxt.vserver.params.<paramName>.

> **Example:**
>
> add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv

- **CLI command:**

```
rm user vserver <name>
```

- **Description:**

  Removes a user virtual server previously added to to the Citrix ADC appliance.

> **Example:**
>
> rm user vserver v_mqtt

- **CLI command:**

```
set user vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-defaultLB
<string>] [-params <string>] [-comment <string>]
```

- **Description:**

  Changes settings for a user virtual server previously added to to the Citrix ADC appliance. When an extension parameter is assigned a new value by the -params option, the old value is overwritten.

> **Example:**
>
> set user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment “MQTT protocol implementation”

- **CLI command:**

```
unset user vserver <name> [-params] [-comment]
```

- **Description:**

  Removes the settings for a user virtual server previously added to to the Citrix ADC appliance. If you use the –params option to unset an extension parameter, the corresponding parameter value available to extension handlers is changed to nil.

> **Example:**
>
> unset user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment “MQTT protocol implementation”

- **CLI command:**

```
show user protocol [<name>]
```

- **Description:**

  Displays information about a user protocol, such as extension and callbacks.

> **Example:**
>
> show user protocol mqtt

- **CLI command:**

  `show user vserver [<name>]`

- **Description:**

  Displays information about a user virtual server.

  > **Example:**
  >
  > show user vserver vs_mqtt

- **CLI command:**

  `stat user vserver [<name>]`

- **Description:**

  Displays statistics about a user virtual server.

  > **Example:**
  >
  > stat user vserver vs_mqtt

- **CLI command:**

  `show lb persistentSessions [<vserv-name>]`

- **Description:**

  Displays information about persistent sessions. This is an existing CLI. For user protocols, the persistence type is shown as USERSESSION.

- **CLI command:**

  `rm lb vserver <name>`

- **Description:**

  Removes a user LB vserver previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > rm lb vserver mysv

- **CLI command:**

  `add service <name> <IPAddr> (USER_TCP | USER_SSL_TCP)<Port>`

- **Description:**

  Adds a backend service to be used for a user protocol. This is an existing CLI command with new service types USER_TCP and USER_SSL_TCP.

> **Example:**
>
> add service mqtt_svr1 10.217.24.48 USER_TCP 1501
>
> **Note**: The existing “set service and unset service” commands can be used to remove or change the settings of a previously added service for a user protocol.

- **CLI command:**

  `bind lb vserver <name> <serviceName>`

- **Description:**

  Binds a service to a user LB vserver. The service type should be USER_TCP/USER_SSL_TCP for binding to an LB vserver with type of USER_TCP/USER_SSL_TCP.

  > **Example:**
  >
  > bind lb vserver mysv mqtt_svr1

- **CLI command:**

  `unbind lb vserver <name> <serviceName>`

- **Description:**

  Unbinds a previously bound service to a user LB vserver.

  > **Example:**
  >
  > unbind lb vserver mysv mqtt_svr1

- **CLI command:**

  `rm service <name>`

- **Description:**

  Removes a service that is previously added for a user protocol.

  > **Example:**
  >
  > rm service mqtt_svr1

Troubleshooting protocol extensions

September 14, 2021

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by

using the custom logging functionality, where you can define the log level to be captured on the Citrix ADC appliance.

Custom logging

You can also add your own logging to your extension function. To do so, use the built-in ns.logger:level() function, where level is emergency , alert , critical , error , warning , notice , info , or debug . The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specified in the format string. For example, you might add the following to the COMBINE_HEADERS function to log the result of a call:

```
local result\_str = table.concat(combined\_headers, "\\r\\n") .. "\\r\\
   n\\r\\n"

ns.logger:info("Result: %s", result\_str)

return result\_str
<!--NeedCopy-->
```

The above function would log the following message to/var/log/ns.log for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^M
 H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)libcurl
/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: \*/\*^M H2: h2val1, h2val2,
h2val3^M ^M"
```

Policy extensions

September 14, 2021

The policy extension feature enables you to write extension functions for built-in policy types. The extensions can be used in policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated. This feature is useful for:

- Adding customized functions to existing Policies.
- Implementing logical constructs for complex customer requirements.

The policy extension feature addresses these limitations by enabling users to write extension functions for built in Policy types. The extensions can then be used in the policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated.

The following table lists the policy types that can be used when writing an extension, and their associated mappings.

Policy Type	Mapped Policy Type	Output
TEXT_T	NSTEXT	String
BOOL_AT	NSBOOL	Boolean
NUM_AT	NSNUM	Number (double-precision floating point)
DOUBLE_AT	NSDOUBLE	Number (double-precision floating point)

Prerequisites for using policy extensions

The imported functions must conform to the existing policy standards. Therefore:

- The function name must start with a letter and may contain numbers or underscores.
- The function name is treated as case insensitive by Citrix ADC policies.
- The function must return a single value even if the extension language returns multiple values.
- Functions with a variable number of arguments are not supported.

How do policy extensions work?

The existing policies on a Citrix ADC appliance use an interpreter to evaluate the functions, which are imported in a policy extension file. When a user imports a new function in a policy extension file:

1. The extension file is validated for syntax and other conditions.
2. If the validation fails, the error is reported to the user.
3. If the validation succeeds, the extension file is imported to the Citrix ADC appliance and its contents can be used in policy expressions, just like any built-in policy function
    a) If the policy expression evaluation returns an error during runtime, it is reported as an undef event and the associated error counter is incremented.
    Note: If a policy undef event occurs and the policy rule contains one or more policy extension functions, the `show ns extension <name>` command displays the undef hits when applied to those policy extensions. If the extension function is aborted, the abort counter value is incremented.
    b) If the policy expression evaluation is successful, expression evaluation resumes until the entire expression is evaluated, or until it is aborted because of an error.

If the extension function takes too long to run, it is aborted, and the error counter pertaining to that extension function is incremented. The extension function is sandboxed, which prevents:

- Excessive CPU usage on the Citrix ADC appliance.
- Excessive memory usage on the Citrix ADC appliance.
- Usage of harmful built-in libraries or third-party libraries or binaries.
- Long-running scripts that could potentially cause the Citrix ADC appliance to reboot.

Configuring policy extensions

September 14, 2021

When your policy extension file is ready, import it to the Citrix ADC appliance. The import process copies the extension file into a directory on the Citrix ADC appliance and checks for syntax errors.

After the import, you have to make the extension file available for use in the policy expressions.

Note: The import command is used to download the file content from an external source \<src\>, or an internal source, onto the Citrix ADC file system. To load this file content into one or more packet engines for the first time, use the add command. If there is an update to the file content, the updated content can be downloaded to the Citrix ADC file system by issuing the import command with the overwrite argument. The command updates the contents in the file system. To load the updated content to one or more packet engines, use the update command.

Configure policy extensions by using the CLI

1. Import the policy extension file to the Citrix ADC Appliance, from either a web server (using HTTP) or your local workstation.

   a) HTTP Import

   If you have a web server available, you can store the extension file in the webserver directory and import it to the Citrix ADC appliance.

   ```
   import ns extension <src> <name> [-comment<string>] [-
      overwrite]
   <!--NeedCopy-->
   ```

   Example:

   ```
   import ns extension http://myhost/path/to/extension
      myextension -comment  “Custom crc calculation
   <!--NeedCopy-->
   ```

   b) Local Import

You can use the SSH client to copy the extension file from your workstation to the /var/tmp directory of the Citrix ADC appliance

```
scp extension-file-name <ns-userid@ns-ip-addr>:/var/tmp
<!--NeedCopy-->
```

where,

- extension-file-name is the name of the extension file on your client machine.
- ns-userid is the Citrix ADC appliance user with permission to write to /var/tmp.
- ns-ip-addr is the Citrix ADC IP address.

After copying the file to the Citrix ADC appliance, run the import command on the Citrix ADC appliance.

```
import ns extension local:\<extension-file-name extension-name
   \>
<!--NeedCopy-->
```

Note: The CLI must be used to import a local extension file, by running the **import** command.

2. Add the policy extension to the packet engine for evaluation.

```
add ns extension <name> [-comment <string>]
<!--NeedCopy-->
```

Example:

```
add ns extension myextension
<!--NeedCopy-->
```

After an extension file is imported, you can update it, if you included the -overwrite parameter in the import command, or remove it. You can also display the details of an imported extension file.

Update an extension file on the Citrix ADC appliance from the source

At the command prompt, type:

```
update ns extension <name>
<!--NeedCopy-->
```

Note: You can update the extension file only after importing the specified extension file to the Citrix ADC appliance with the -overwrite parameter.

Example:

```
update ns extension myextension
<!--NeedCopy-->
```

Remove an extension file from the Citrix ADC appliance

At the command prompt type:

```
rm ns extension <name>
<!--NeedCopy-->
```

Example:

```
rm ns extension myextension
<!--NeedCopy-->
```

Display the details of the specified extension function on the Citrix ADC appliance

At the command prompt, type:

```
show ns extension <name>
<!--NeedCopy-->
```

Example:

```
show ns extension myextension
<!--NeedCopy-->
```

Configure policy extensions by using the GUI

1. Import the policy extension file to the Citrix ADC Appliance, from either a web server (using HTTP) or your local workstation.
   a) Navigate to **AppExpert** > **Policy Extensions**, click **Policy Extension**, from the **Import From** drop-down list, select the URL for the location of the extension file that you want to import.
   b) Navigate to **AppExpert** > **Policy Extensions**, **Policy Extension** and import the extension file by selecting File in the **Import** From drop-down list.
2. Add the policy extension to the packet engine for evaluation.

   Navigate to **AppExpert** > **Policy Extensions** and, on the**Policy Extensions** tab, add the extension file.

Update an extension file on the Citrix ADC appliance from the source

Navigate to **AppExpert** > **Policy Extensions** and, on the **Policy Extensions** tab, update the extension file.

Remove an extension file from the Citrix ADC appliance

Navigate to **AppExpert** > **Policy Extensions** and, **Policy Extensions** tab, remove the extension file.

Display the details of the specified extension function on the Citrix ADC appliance

Navigate to **AppExpert** > **Policy Extensions** and, on the **Policy Extensions Functions** tab, click the click drop-down list arrow of the extension function that you want to see the details.

Policy extensions - use cases

September 14, 2021

Certain customer applications have requirements that cannot be addressed with existing policies and expressions. The policy extension feature enables customers to add customized functions to their applications to meet their requirement.

The following use cases illustrate the addition of new functions using the policy extension feature on the Citrix ADC appliance.

- Case 1: Custom hash
- Case 2: Collapse double slashes in URLs
- Case 3: Combine headers

Case 1: Custom hash

The CUSTOM_HASH function provides a mechanism to insert any type of hash value in the responses sent to the client. In this use case, the hash function is used to compute the hash of the query string for a rewrite HTTP request and insert an HTTP header named CUSTOM_HASH with the computed value. The CUSTOM_HASH function implements the DJB2 hash algorithm.

Sample Usage of CUSTOM_HASH:

```
1 > add rewrite action test_custom_hash insert_http_header "CUSTOM_HASH"
     "HTTP.REQ.URL.QUERY.CUSTOM_HASH"
2 <!--NeedCopy-->
```

Sample Definition of CUSTOM_HASH():

```
    -- Extension function to compute custom hash on the text

    -- Uses the djb2 string hash algorithm
    function NSTEXT:CUSTOM_HASH() : NSTEXT

        local hash = 5381

        local len = string.len(self)

        for i = 1, len do

             hash = bit32.bxor((hash * 33), string.byte(self, i))

        end

        return tostring(hash)

    end
<!--NeedCopy-->
```

Line-by-line description of the above sample:

```
function NSTEXT:CUSTOM_HASH() : NSTEXT

Defines the CUSTOM_HASH() function, with text input and a text return
   value.

local hash = 5381
local len = string.len(self)

Declares two local variables:

 - hash. Accumulates the compute hash value and is seeded with the
    number 5381

 - len. Sets to the length of the self input text string, using the
    built-in string.len() function.

for i = 1, len do
      hash = bit32.bxor((hash * 33), string.byte(self, i))
end

Iterates through each byte of the input string and adds the byte to the
```

```
        hash. It uses the built-in string.byte() function to get the byte
       and the built-in bit32.bxor() function to compute the XOR of the
       existing hash value (multiplied by 33) and the byte.
19
20 return tostring(hash)
21
22 Calls the built-in tostring() function to convert the numeric hash
       value to a string and returns the string as the value of the
       function.
23 <!--NeedCopy-->
```

Case 2: Collapse double slashes in URLs

Collapsing double slashes in URLs improves the website rendering time, because browsers parse the single slash URLs more efficiently. The single slash URLs also to maintain compatibility with applications that do not accept double slashes. The policy extension feature allows customers to add a function that replaces the double slashes with single slashes in the URLs. The following example illustrates the addition of a policy extension function that that collapses double slashes in URLs.

Sample Definition of COLLAPSE_DOUBLE_SLASHES():

```
1      -- Collapse double slashes in URL to a single slash and return the
          result
2      function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
3
4          local result = string.gsub(self, "//", "/")
5
6          return result
7
8      end
9  <!--NeedCopy-->
```

Line-by-line description of the above sample:

```
1  function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
2
3  Declares the COLLAPSE_DOUBLE_SLASHES() function with text input and
       return.
4
5  local result = string.gsub(self, "//", "/")
6
7  Declares a local variable named result and uses the built-in string.
       gsub() function to replace all double slashes with single slashes in
        the self input text.
```

```
8
9  The second parameter of string.gsub() is actually a regular expression
       pattern, although here a simple string is used for the pattern.
10
11 return result
12
13 Returns the resulting string.
14 <!--NeedCopy-->
```

Case 3: Combine headers

Certain customer applications cannot handle multiple headers in a request. Also, parsing of duplicate headers with same header values, or multiple headers with same name but different values in a request, consumes time and network resources. The policy extension feature allows customers to add a function to combine these headers into single headers with a value combining the original values. For example, combining the values of the headers H1 and H2.

Original request:

```
1  GET /combine_headers HTTP/1.1
2  User-Agent: amigo unit test
3  Host: myhost
4  H2: h2val1
5  H1: abcd
6  Accept: */*
7  H2: h2val2
8  Content-Length: 0
9  H2: h2val3
10 H1: 1234
11 <!--NeedCopy-->
```

Modified request:

```
1  GET /combine_headers HTTP/1.1
2  User-Agent: amigo unit test
3  Host: myhost
4  H2: h2val1, h2val2, h2val3
5  H1: abcd, 1234
6  Accept: */*
7  Content-Length: 0
8  <!--NeedCopy-->
```

In general, this type of request modification is done using the Rewrite feature, using policy expressions to delineate the part of the request to be modified (the target) and the modification to be performed

(the string builder expression). However, policy expressions do not have the ability to iterate over an arbitrary number of headers.

The solution to this problem requires an extension to the policy facility. To do this, we will define an extension function, called COMBINE_HEADERS. With this function, we can set up the following rewrite action:

```
> add rewrite action combine_headers_act replace 'HTTP.REQ.FULL_HEADER
.AFTER_STR("HTTP/1.1rn")''HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1rn").
COMBINE_HEADERS'
```

Here, the rewrite target is HTTP.REQ.FULL_HEADER.AFTER_STR(“HTTP/1.1rn”). The AFTER_STR(“HTTP/1.1rn”) is required because FULL_HEADER includes the first line of the HTTP request (e.g. GET /combine_headers HTTP/1.1).

The string builder expression is HTTP.REQ.FULL_HEADER.AFTER_STR(“HTTP/1.1rn”).COMBINE_HEADERS, where the headers (minus the first line) are fed into the COMBINE_HEADERS extension function, which combines and returns the values for headers.

Sample Definition of COMBINE_HEADERS():

```
1     -- Extension function to combine multiple headers of the same name
         into one header.
2
3
4
5     function NSTEXT:COMBINE_HEADERS(): NSTEXT
6
7         local headers = {
8   }
9   -- headers
10
11        local combined_headers = {
12  }
13  -- headers with final combined values
14        -- Iterate over each header (format "name:valuer\r\n")
15
16        -- and build a list of values for each unique header name.
17
18        for name, value in string.gmatch(self, "([^:]+):([^\r\n]*)\r\n"
             ) do
19
20            if headers[name] then
21
22                local next_value_index = #(headers[name]) + 1
23
```

```
                headers[name][next_value_index] = value

            else

                headers[name] = {
 name .. ":" .. value }

            end

        end

        -- iterate over the headers and concat the values with
           separator ","

        for name, values in pairs(headers) do

            local next_header_index = #combined_headers + 1

            combined_headers[next_header_index] = table.concat(values,
               ",")

        end

        -- Construct the result headers using table.concat()

        local result_str = table.concat(combined_headers, "\r\n") .. "\
           r\n\r\n"

        return result_str

    end
<!--NeedCopy-->
```

Line-by-line description of the above sample:

```
function NSTEXT:COMBINE_HEADERS(): NSTEXT

Defines the COMBINE_HEADERS extension function, with the text input
   into the function from the policy expression and a text return type
   to the policy expression.
```

```
4
5  local headers = {
6    }
7    -- headers
8  local combined_headers = {
9    }
10   -- headers with final combined values
11
12 Declares local variables headers and combined_headers and initialize
       these variables to empty tables. headers will be a table of arrays
       of strings, where each array holds one or more values for a header.
       combined_headers will be an array of strings, where each array
       element is a header with its combined values.
13
14 for name, value in string.gmatch(self, "([^:]+):([^\r\n\]*)\r\n") do
15 . . .
16 end
17 <!--NeedCopy-->
```

This generic for loop parses each header in the input. The iterator is the built-in string.gmatch() function. This function takes two parameters: a string to search, and a pattern to use to match pieces of the string. The string to search is supplied by the implicit self parameter, which is the text for the headers input into the function.

The pattern is expressed using a regular expression (regex for short). This regex matches the header name and value for each header, which the HTTP standard defines as `*name*:*value*\r\n`. The parentheses in the regex specify the matching parts to be extracted, so the regex schematic is (*match-name*):(*match-value*)\r\n. The *match-name* pattern needs to match all characters except the colon. This is written [^:]+([^:] is any character except : and + is one or more repetitions). Similarly, the *match-value* pattern has to match any characters except the \r\n, so it is written [^\r\n] ([^\r\n] matches any character except \r and \n and * is zero or more repetions). This makes the complete regex `([^:]+):([^\r\n]*)\r\n`.

The for statement uses a multiple assignment to set name and value to the two matches returned by the string.gmatch() iterator. These are implicitly declared as local variables within the body of the for loop.

```
1  if headers[name] then
2       local next_value_index = #(headers[name]) + 1
3       headers[name][next_value_index] = value
4  else
5       headers[name] = {
6   name .. ":" .. value }
7
```

```
8 end
9 <!--NeedCopy-->
```

These statements within the for loop put the header names and values into the headers table. The first time a header name is parsed (say H2: h2val1 in the example input), there is no headers entry for the name and headers[name] is nil.

Since nil is treated as false, the else clause is executed. This sets the headers entry for name to an array with one string value *name*:*value*.

Note: The array constructor in the else loop is equivalent to {[1] = name .. ":" .. value}, which sets the first element of the array.) For the first H2 header, it sets headers["H2"] = {"H2:h2val1"}.

On subsequent instances of a header, (say, H2: h2val2 in the example input). headers[name] is not nil, so the then clause is executed. This determines the next available index in the array value for headers[name], and puts the header value into that index. For the second H2 header, it sets headers["H2"] = {"H2:h2val1", "h2val2"}.

```
1 for name, values in pairs(headers) do
2     local next_header_index = #combined_headers + 1
3     combined_headers[next_header_index] = table.concat(values, ",")
4 end
5 <!--NeedCopy-->
```

After the original headers have been parsed and the headers table filled in, this loop builds the combined_headers array. It uses the pairs() function as the for loop iterator.

Each call to pairs() returns the name and value of the next entry in the headers table.

The next line determines the next available index in the combined_headers array, and the next line sets that array element to the combined header. It uses the built-in table.concat() function, which takes as its arguments an array of strings and a string to use as a separator, and returns a string that is the concatenation of the array strings, separated by the separator.

For example, for values = {"H2:h2val1", "h2val2"}, this produces "H2:h2val1, h2val2"

```
1 local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
2 <!--NeedCopy-->
```

After the combined_headers array are built, it concatenates the elements into one string, and adds a double \r\n that terminates the HTTP headers.

```
1 return result_str
2 <!--NeedCopy-->
```

Returns a string as the result of the COMBINE_HEADERS extension function.

Troubleshooting policy extensions

September 14, 2021

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the Citrix ADC appliance.

This topic provides information on:

- Extension tracing
- Custom logging

Extension tracing

To show what your extension function is doing, extension tracing functionality logs the execution of the function to the Citrix ADC system log (/var/log/ns.log). The trace logging uses the DEBUG log level, which normally is not enabled. Therefore, you have to enable ALL log levels. Then you can enable tracing by setting the -trace option of the set ns extension command. The available settings are:

- off turn off tracing (equivalent to unset ns extension -trace).
- calls trace function calls with arguments and function returns with the first return value.
- lines trace the above plus line numbers for executed lines.
- all trace the above plus local variables changed by executed lines.

Example:

```
set audit syslogParams -loglevel ALL

set ns extension combine_headers -trace all
<!--NeedCopy-->
```

Each trace message has the format

```
log-header : default NSEXTENSION Message message-number 0 : "TRACE function
-name CALL call-number: event"
```

Where,

- log-header supplies timestamps, the Citrix ADC IP address, and the Packet Engine ID.
- message-number is a sequential number identifying the log message.
- function-name is the extension function name.

- call-number is a sequential number for each extension function call. It can be used to group all the trace messages for an extension function call.
- event is one of the following:
  - CALL function-name ; parameter-values indicates that the function has been called with the specified parameters.
  - RETURN FROM function-name ; return = value indicates that a function has returned the specified (first) value. (Additional return values are not reported.)
  - LINE line-number ; variable-values indicates that a line has been executed and lists any variables with changed values.

Where,

- value or values is
  - a number, with or without a decimal point,
  - a string, enclosed in double quotes and with escaped characters as described earlier,
  - a boolean true or false,
  - nil,
  - a table constructor, of the format {[key1]=value1,[key2]=value2, …}.
- parameter-values is parameter1 = value1 ; parameter2 = value2 , …
- variable-values is variable1 = value1 ; variable2 = value2 , …

An example of abbreviated log messages:

```
>shell tail -f /var/log/ns.log | grep TRACE | more

... NSEXTENSION Message 3035 0 : "TRACE combine_headers CALL 30 : CALL
    COMBINE_HEADERS; self = "User-Agent: curl/7.24.0 (amd64-portbld-

34
35 ... NSEXTENSION Message 3118 0 : "TRACE combine_headers CALL 30 :
      RETURN FROM for iterator; return = nil"
36
37 ... NSEXTENSION Message 3119 0 : "TRACE combine_headers CALL 30 : LINE
      19"
38
39 ... NSEXTENSION Message 3120 0 : "TRACE combine_headers CALL 30 : CALL
      concat"
40
41 ... NSEXTENSION Message 3121 0 : "TRACE combine_headers CALL 30 :
      RETURN FROM concat; return = "User-Agent: curl/7.24.0 (amd64-portbld
      -freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r\nH1: abcd\r\
      nAccept: */*\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2, h2val3""
      ... NSEXTENSION Message 3122 0 : "TRACE combine_headers CALL 30 :
      LINE 25; result_str = "User-Agent: curl/7.24.0 (amd64-portbld-
```

```
      freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r\nH1: abcd\r\
      nAccept: */*\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2, h2val3\r\n\
      r\n""
42
43 ... NSEXTENSION Message 3123 0 : "TRACE combine_headers CALL 30 :
      RETURN FROM COMBINE_HEADERS; return = "User-Agent: curl/7.24.0 (
      amd64-portbld-freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r
      \nH1: abcd\r\nAccept: */*\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2
      , h2val3\r\n\r\n""
44 <!--NeedCopy-->
```

Custom logging

You can also add your own logging to your extension function. To do so, use the built-in ns.logger:*level*() function, where *level* is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specified in the format string. For example, you might add the following to the COMBINE_HEADERS function to log the result of a call:

```
1 local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
2
3 ns.logger:info("Result: %s", result_str)
4
5 return result_str
6 <!--NeedCopy-->
```

The above function would log the following message to/var/log/ns.log for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^M
 H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)libcurl
/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: */*^M H2: h2val1, h2val2,
h2val3^M ^M"
```

Optimization

September 14, 2021

The Citrix ADC optimization features reduce transaction times between the clients and the servers, and they reduce bandwidth consumption. They also enhance server performance by offloading some tasks and making others more efficient.

Feature	Description
Client Keep-Alive	Handles multiple requests on a single client connection. The client does not have to negotiate a new connection for each request to the server.
HTTP Compression	Compresses HTTP responses sent from the servers to compression-aware browsers. The smaller responses reduce download time and save bandwidth.
Integrated Caching	Stores responses to client requests. Subsequent requests for the same content are served from the Citrix ADC cache instead of being forwarded to the origin server.
Front End Optimization	Reduces the load and render time of web pages by simplifying and optimizing the content served to the client browser. **Note**: Supported from NetScaler 10.5 onwards.
Content Accelerator	Stores server responses on a Citrix ByteMobile T2100 appliance. **Note**: Supported from NetScaler 10.1 onwards.
SPDY (Speedy)	Acts as a SPDY gateway between clients and your servers, providing SPDY support without the need to configure/upgrade SPDY on the servers. **Note**: Supported from NetScaler 10.1 onwards.

Client keep-alive

September 14, 2021

The client keep-alive feature enables multiple clients requests to be sent on a single connection. This feature benefits transaction management. When the Client Keep-Alive mode is enabled on an appliance and the server response to the client request contains the Connection: close the HTTP header and performs the following tasks:

- Renames the existing Connection header name by shuffling the characters in the header name.

- Adds a new Connection: header with Keep-Alive as the value for the header.

The Client Keep-Alive mode enables the Citrix ADC appliance to process multiple requests and responses using the same socket connection. The feature keeps the connection between the client and the appliance (client-side connection) open even after the server closes the connection with the appliance. This allows multiple clients requests using a single connection and saves the round trips associated in opening and closing a connection. Client keep-alive is most beneficial in SSL sessions.

Client keep-alive is useful for the following scenarios:

- If the server does not support the client keep-alive.
- If the server supports but an application on the server does not support the client keep-alive.

> **Note:**
> Client keep-alive is applicable for HTTP and SSL traffic. Client-keep alive can be configured globally to handle all traffic. Also, you can activate it on specific services.

In the client keep-alive environment, the configured services intercept the client traffic and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a "Connection: Close" header is present in the server response, the appliance corrupts this header in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request. Instead, the connection to the server is reopened.

> **Note:**
> If a server sends back two "Connection: Close" headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is closed.

Configure client keep-alive

Client keep-alive, by default, is disabled on the Citrix ADC, both globally and at service level. Therefore, you must enable the feature at the required scope.

> **Note:**
> If you enable the client keep-alive globally, it is enabled for all services, regardless of whether you enable it at the service level. Also, you must configure some HTTP parameters to specify the following:
>
> - the maximum number of HTTP connections retained in the connection reuse pool.
> - enable connection multiplexing, and enable persistence `Etag`.
>
> **Note:**
> When Persistent `ETag` is enabled, the `ETag` header includes information about the server that

> served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server.

Configure client keep-alive by using Citrix ADC command interface

At the command prompt, do the following:

1. Enable client keep-alive on the Citrix ADC.
   - At global level - `enable ns mode cka`
   - At service level - `set service <name> -CKA YES`

   > **Note:**
   >
   > Client keep-alive can be enabled only for HTTP and SSL services.

2. Configure HTTP parameters on the HTTP profile that is bound to one or more services.

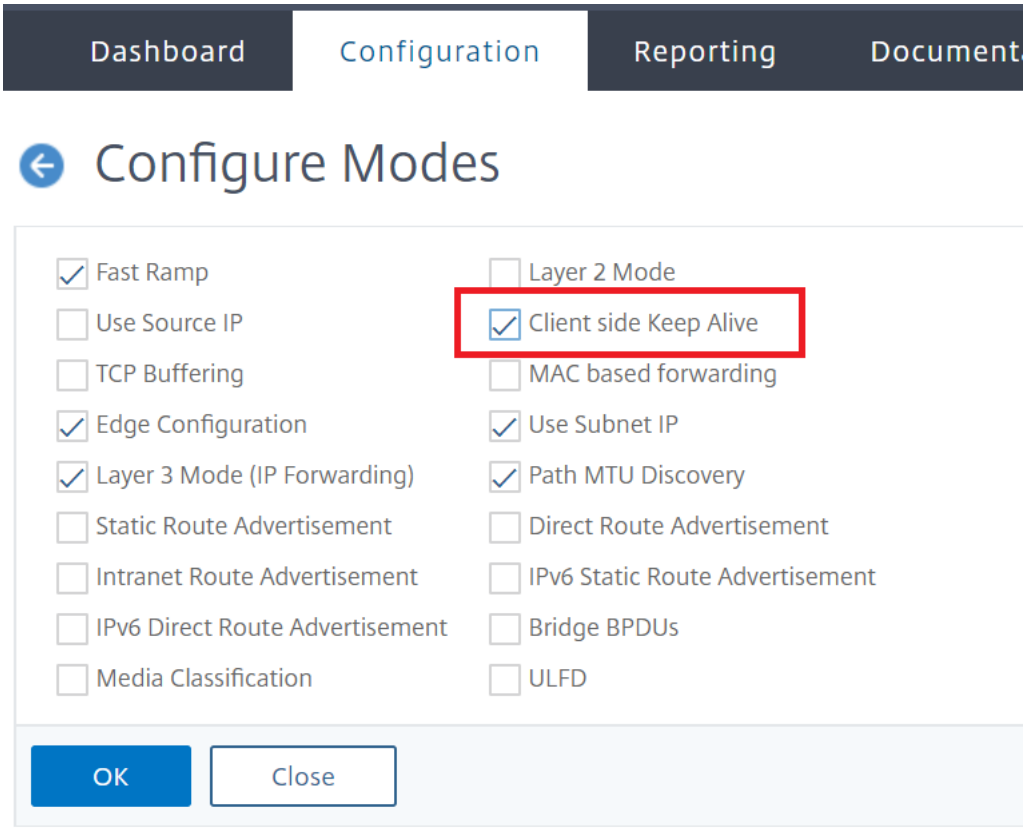
```
set ns httpProfile <name> -maxReusePool <value> -conMultiplex
    ENABLED -persistentETag ENABLED
<!--NeedCopy-->
```

> **Note:**
>
> Configure these parameters on the `nshttp_default _profile HTTP` profile, to make them available globally.

Configure client keep-alive by using Citrix ADC GUI

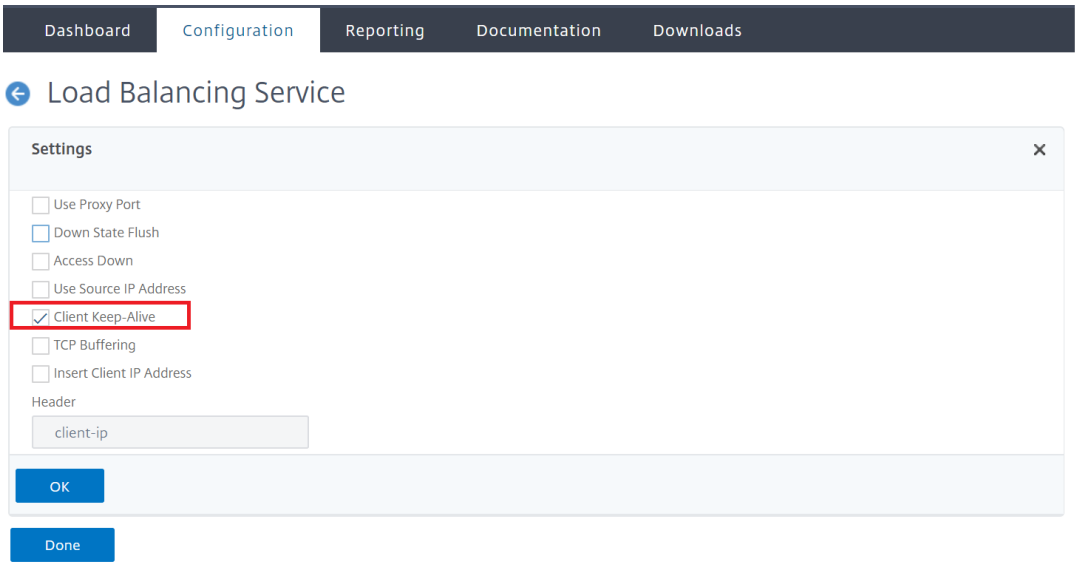
1. Enable client keep-alive on the Citrix ADC.
   - At global level

     Navigate to **System** > **Settings**, click **Configure Modes** and select **Client side Keep Alive**.



- At service level

  Navigate to **Traffic Management** > **Load Balancing** > **Services**, and select the required service. In the **Settings** section, select **Client Keep-Alive** check box.



2. Configure the required HTTP parameters on the HTTP profile that is bound to one or more ser-

vices.

3. Navigate to **System** > **Profiles**, and on **HTTP Profiles** tab, select the required profile and update the required HTTP parameters.

HTTP compression

September 14, 2021

For websites with compressible content, the HTTP compression feature implements lossless compression to alleviate latency, long download times, and other network-performance problems by compressing the HTTP responses sent from servers to compression-aware browsers. You can improve server performance by offloading the computationally intensive compression task from your servers to the Citrix ADC appliance.

The following table describes the capabilities of the HTTP compression feature:

Functionality	Description
Compression Ratio	Compression ratio depends on the types of files in the responses, but is always significant, noticeably reducing the amount of data transmitted over the network.
Browser Awareness	Citrix ADC serves compressed data to compression aware browsers only, reducing the transaction time between the client and the server. Most modern web browsers support HTTP compression.
Compression blocking	You can define content filters to selectively block compression by applying built-in actions.
Compression Caching	With the integrated caching feature enabled, subsequent requests for the same content are served from the local cache, reducing the number of round trips to the server and improving transaction times.
HTTPS Support	Compression is useful on SSL connections, because it reduces the amount of content that has to be encrypted, either on the server or by the Citrix ADC appliance, and decrypted by the client.

Functionality	Description
Intelligent Response Filtering	The Citrix ADC compression engine intelligently filters server responses based on defined compression parameters. For example, the compression engine detects zero-content-length responses and compressed responses and does not compress them. The detection of compressed responses enables origin sites to use server-based compression with the Citrix ADC compression feature.
Compression Switching	The Citrix ADC appliance transparently directs requests from compression aware clients to compression capable servers, so that responses to those clients are compressed, and responses to other clients are not delayed by compression processing.

How HTTP compression works

A Citrix ADC can compress both static and dynamically generated data. It applies the GZIP or the DEFLATE compression algorithm to remove extraneous and repetitive information from the server responses and represent the original information in a more compact and efficient format. This compressed data is sent to the client's browser and uncompressed as determined by the browser's supported algorithm or algorithms (GZIP or DEFLATE).

Citrix ADC compression treats static and dynamic content differently.

- Static files are compressed only once, and a compressed copy is stored in local memory. Subsequent client requests for cached files are serviced from that memory.
- Dynamic pages are dynamically created each time a client requests them.

When a client sends a request to the server:

1. The client request arrives at the Citrix ADC. The ADC examines the headers and stores information about what kind of compression, if any, the browser supports.
2. The ADC forwards the request to the server and receives the response.
3. The Citrix ADC compression engine examines the server response for compressibility by matching it against policies.
4. If the response matches a policy associated with a compression action, and the client browser

supports a compression algorithm specified by the action, the Citrix ADC applies the algorithm and sends the compressed response to the client browser.

5. The client applies the supported compression algorithm to decompress the response.

Configure HTTP compression

By default, compression is disabled on the Citrix ADC. You must enable the feature before configuring it. If the feature is enabled, the ADC compresses server requests specified by compression policies.

To enable HTTP compression by using the CLI

Compression can be enabled for HTTP and SSL services only. You can enable it globally, so that it applies to all HTTP and SSL services, or you can enable it just for specific services.

At the command prompt, enter one of the following commands to enable compression globally or for a specific service:

- `enable ns feature cmp`
  OR
- `set service \<name\> -CMP YES`

To configure compression by using the GUI

Do one of the following:

To enable compression globally, navigate to System > Settings, click **Configure Basic Features**, and select HTTP Compression.

To enable compression for a specific service, navigate to **Traffic Management > Load Balancing > Services**, select the service, and click Edit. In the Settings group, click the pencil icon and enable Compression.

Configuring a compression action

A compression action specifies the action to take when a request or response matches the rule (expression) in the policy with which the action is associated. For example, you can configure a compression policy that identifies requests that will be sent to a particular server, and associate the policy with an action that compresses the server's response.

There are four built-in compression actions:

- COMPRESS: Uses the GZIP algorithm to compress data from browsers that support either GZIP or both GZIP and DEFLATE. Uses the DEFLATE algorithm to compress data from browsers that support only the DEFLATE algorithm. If the browser does not support either algorithm, the browser's response is not compressed.
- NOCOMPRESS: Does not compress data.

- GZIP: Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm, the browser's response is not compressed.
- DEFLATE: Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support the DEFLATE algorithm, the browser's response is not compressed. After creating an action, you associate the action with one or more compression policies.

At the command prompt, enter the following command to create a compression action:

```
add cmp action <name> <cmpType> [-addVaryHeader <addVaryHeader> -varyHeaderValue
<string>]
```

To configure a compression policy by using the CLI

A compression policy contains a rule, which is a logical expression that enables the Citrix ADC appliance to identify the traffic that should be compressed.

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

At the command prompt, enter the following command to create a compression policy:

```
add cmp policy <name> -rule <expression> -resAction <string>
```

To create a compression action by using the GUI

Navigate to **Optimization** > **HTTP Compression** > **Actions** , click **Add** , and create a compression action to specify the type of compression to be performed on the HTTP response.

Configuring a compression policy

A compression policy contains a rule, which is a logical expression that enables the Citrix ADC appliance to identify the traffic that should be compressed.

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

The following table lists the built-in HTTP compression policies. These policies are activated globally when you enable compression.

Built-in Classic or Default Syntax Policy	Description
ns_nocmp_mozilla_47, ns_adv_nocmp_mozilla_	Prevents compression of CSS files when a request is sent from a Mozilla 4.7 browser.
ns_cmp_mscss, ns_adv_cmp_mscss	Compresses CSS files when the request is sent from a Microsoft Internet Explorer browser.
ns_cmp_msapp, ns_adv_cmp_msapp	Compresses files that are generated by the following applications: Microsoft Office Word, Microsoft Office Excel, Microsoft Office PowerPoint.
ns_cmp_content_type, ns_adv_cmp_content_type	Compresses data when the response containsContent-Type header and contains text.
ns_nocmp_xml_ie, ns_adv_nocmp_xml_ie	Prevents compression when a request is sent, from a Microsoft Internet Explorer browser and the response contains a Content-Type header and contains text or xml.

Binding a compression policy

To put a compression policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the Citrix ADC, or to a specific virtual server, so that the policy applies only to requests whose destination is the VIP address of that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

To bind a Compression Policy by using the CLI

At the command prompt, enter one of the following commands to bind a compression policy globally or to a specific virtual server:

- `bind cmp global <policyName> [-priority <positive_integer>] [-state ( ENABLED|DISABLED)]...`
- `bind lb vserver <vserverName> -policyName <policyName> -priority < positive_integer>.`

Repeat this command for each virtual server to which you want to bind the compression policy.

To bind a compression policy by using the GUI

Do one of the following:

At global level Navigate to **Optimization** > **HTTP Compression** > **Policies**, click **Policy Manager** and bind the required policies by specifying the relevant Bind Point and Connection Type (Request/Response).

At virtual server level

For load balancing virtual server, Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

For content switching virtual server, Navigate to **Traffic Management > Content Switching > Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

Set the Global Compression Parameters for Optimal Performance

Many users accept the default values for the global compression parameters, but you might be able to provide more effective compression by customizing these settings.

> **Note**
> After you configure the global compression parameters, you do not have to reboot your appliance. They get applied to the new flows immediately.

The following table describes the compression parameters that you can set on the Citrix ADC.

Compression Parameters	Description
Quantum size	Size, in KB, of the buffer maintained for accumulating server responses. The responses are compressed when the buffer size exceeds this value. For example, if you set the quantum size to 50 KB, the Citrix ADC compresses the buffer's contents when its size becomes larger than 50 KB. Minimum value: 1. Maximum value: 63488. Default: 57344.
Compression level	Level of compression to apply to server responses. Possible values: Best Speed, Best Compression, optimal.
Minimum HTTP response size	Minimum size, in bytes, of an HTTP response that is compressed. Responses smaller than the value specified by this parameter are sent without being compressed.
Bypass compression on CPU usage	Citrix ADC CPU usage, as a percentage, at or above which no compression is done. Default: 100.

Compression Parameters	Description
Policy Type*	Type of policies used for compression. Possible values: Classic, Default Syntax. Default: Classic.
Allow Server-side compression	Allow servers to send compressed data to the Citrix ADC.
Compress push packet	Upon receipt of a packet with a TCP PUSH flag, compress the accumulated packets immediately, without waiting for the quantum buffer to be filled.
External Cache	Issue a private response directive indicating that the response message is intended for a single user and must not be cached by a shared or proxy cache.

To configure HTTP compression by using the GUI

Do one of the following:

- To enable compression globally, navigate to **System** > **Settings**, click **Configure Basic Features**, and select **HTTP Compression**.
- To enable compression for a specific service, navigate to **Traffic Management** > **Load Balancing** > **Services**, select the service, and click **Edit**.
- In the **Settings** group, click the pencil icon and enable **Compression**.

To create a compression action by using the GUI

Navigate to **Optimization** > **HTTP Compression** > **Actions** , click **Add** , and create a compression action to specify the type of compression to be performed on the HTTP response

To create a compression policy by using the GUI

Navigate to **Optimization** > **HTTP Compression** > **Policies** , click **Add**, and create a compression policy by specifying the condition and the corresponding action to be run.

Evaluate compression configuration

You can view the compression statistics in the dashboard utility or in an SNMP monitor. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Optionally, you can also view statistics for a compression policy, including the number of requests that the policy counter increments during the policy based compression.

> **Note**
>
> - For more information about the statistics and charts, see the Dashboard help on the Citrix ADC appliance.
> - For more information about SNMP, see SNMP topic.

To view compression statistics by using the CLI

At the command prompt, enter the following commands to display the compression statistics:

1. To display compression statistics summary.

```
stat cmp
```

> **Note**
> The stat cmp policy command displays statistics for default syntax compression policies only.

2. To display compression policy hits and details

```
show cmp policy \<name\>
```

3. To display detailed compression statistics

```
stat cmp -detail
```

To view compression statistics by using the dashboard:

In the Dashboard utility, you can display the following types of compression statistics:

- Select Compression to display a summary of the compression statistics.
- To display detailed compression statistics by protocol type, click the Details
- To display the rate of requests processed by the compression feature, click the Graphical View tab.

To view compression statistics by using SNMP

You can view the following compression statistics by using the SNMP network management application.

- Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
- Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
- Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
- Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
- Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
- Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
- Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

To view more compression statistics by using the GUI

1. To display HTTP compression statistics:

Navigate to **Optimization** > **HTTP Compression** and click **Statistics**.

1. To display statistics of a compression policy.

Navigate to **Optimization** > **HTTP Compression** > **Policies** > select the policy, and click **Statistics**.

1. To display statistics of a compression policy label
2. Navigate to **Optimization** > **HTTP Compression** > **Policies** > select a policy label, and click **Statistics**.

Offloading HTTP compression

Performing compression on a server can affect the server's performance. A Citrix ADC placed in front of your web servers and configured for HTTP compression offloads compression of both static and dynamic content, saving server CPU cycles and resources.

You can offload compression from the Web servers in either of two ways:

Disable compression on the web servers, enable the Citrix ADC Compression feature at a global level, and configure services for compression.

Leave the compression feature enabled on the web servers and configure the Citrix ADC appliance to remove the "Accept Encoding" header from all HTTP client requests. The servers then send uncompressed responses. The Citrix ADC compresses the server responses before sending them to the clients.

> **Note**
> The second option does not work if the servers automatically compress all responses. The Citrix ADC does not attempt to compress a response that is already compressed.

The Servercmp parameter enables the Citrix ADC appliance to handle offload HTTP compression. By default, this parameter is set ON for the server to send compressed data to the Citrix ADC appliance. To offload HTTP compression, you need to set the servercmp parameter to OFF. At the command prompt, enter the following commands:

```
set service <service name> -CMP YES
```

Repeat this command for each service for which you want to enable compression.

```
show service <service name>
```

Repeat this command for each service, to verify that compression is enabled.

```
Save config
```

```
set cmp parameter -serverCmp OFF
```

> **Note:**
>
> When the `Servercmp` parameter is turned on and if the appliance receives compressed response from the server, the appliance does not further compress the data. Instead, it forwards the com-

> pressed response to the client.

Integrated caching

September 14, 2021

The integrated cache provides in-memory storage on the Citrix ADC appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of Citrix ADC appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple webpages and image files. You can also configure the integrated cache to store and serve dynamic content that is marked as non-cacheable by Web and application servers (for example, database records and stock quotes).

> **Note:**
>
> The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created. The Citrix ADC appliance performs the action associated with the policy. By default, all policies store cached objects in and retrieve them from the default content group. You can create your own content groups for different types of content.

To enable the appliance to find cached objects in a content group, you can configure selectors. The selectors match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors as recommended by Citrix, configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server. Or, you can bind a label that can be called from other policy banks.

Integrated caching can be improved using pre-loading cached object method before they are scheduled to expire. To manage the handling of cached data, you can configure caching-related headers inserted into the responses. The integrated cache can also act as a forward proxy for other cache servers.

> **Note:**
>
> Integrated caching requires some familiarity with HTTP requests and responses.

> For information about the structure of HTTP data, see *Live HTTP Headers* at "<http://livehttpheaders.mozdev.org/>."

How integration cache works

The integrated cache monitors HTTP and SQL requests that flow through the Citrix ADC appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, integrated caching serves as partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data is compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a request, and data served from the origin is a cache miss, as described in the following table.

Transaction Type	Specification
Cache Hit	Responses that the Citrix ADC appliance serves from the cache, including: Static objects, for example, image files and static webpages, 200 OK pages, 203 Non-Authoritative Response pages, 300 Multiple Choices pages, 301 Moved Permanently pages, 302 Found pages, 304 Not Modified pages, These responses are known as positive responses. The Citrix ADC appliance also caches the following negative responses: 307 Temporary Redirect pages, 403 Forbidden pages, 404 Not Found pages, 410 Gone pages. To further improve performance, you can configure the Citrix ADC appliance to cache more types of content.
Storable Cache Miss	For a storable cache miss, the Citrix ADC appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.

Transaction Type	Specification
Non-Storable Cache Miss	A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss: 201, 202, 204, 205, 206 status codes, All 4xx codes, except 403, 404 and 410, 5xx status codes

> **Note:**
> To integrate dynamic caching with your application infrastructure, use the NITRO API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated.

To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the Citrix ADC appliance receives a request that matches an expired response, it refreshes the response from the origin server.

> **Note:**
> Citrix recommends that you synchronize the times on the Citrix ADC appliance and one or more back-end servers.

How dynamic cache works

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```
1     GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&
         Template=view&TableId=1000
2
3     Host: mycompany.net
4
5     User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
          Gecko/2008052906 Firefox/3.0
6
7     Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q
         =0.8
8
9     Accept-Language: en-us,en;q=0.5
10 <!--NeedCopy-->
```

In this example, GET requests for this bug reporting application always contain the following parameters:

- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:

- You configure a caching policy that looks for the string mybugreportingsystem and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a `hit` selector that matches various parameter-value pairs, including IssuePage, RecordID, and so on.

> **Note**
>
> A browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID.

```
1     GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&
         Template=view&TableId=1000
2
3     GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=
         viewbtns&RecordId=31231&TableId=1000
4
5     GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=
         viewbody&RecordId=31231&tableid=1000
6 <!--NeedCopy-->
```

To fulfill these requests, multiple responses are sent to the user's browser, and the webpage that the user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache must be refreshed with data from the origin server. The bug reporting application issues HTTP POST requests when a user updates a bug report. In this example, you configure the following to ensure that POST requests trigger invalidation in the cache:

- A request-time invalidation policy that looks for the string mybugreportingsystem and the POST HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based on the RecordID parameter. This parameter appears in all the responses, so the invalidation selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report.

```
POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\
    r\n

User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0)
    Opera 7.23 [en]\r\n

Host: mybugreportingsystem\r\n

Cookie:ttSearch.134=%23options%3Afalse%23active%23owner%3Afalse%23
    unowned%3Afalse%23submitter%3Afalse%23incsub%3Atrue;

Cookie2: $Version=1\r\n

. . .

\r\n

ProjectId=2&RecordId=31231&TableId=1000&TransitionId=1&Action=
    Update&CopyProjectId=0&ReloadForm=0&State=&RecordLockId=49873+
    issues+in+HTTP&F43. . .
<!--NeedCopy-->
```

When the Citrix ADC appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the Citrix ADC appliance goes to the origin server for updated copies of all the responses that are associated with the report instance. It stores the responses in the content group, and serves them to the user's browser, which reassembles the report and displays it.

Configure integrated cache

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the Citrix ADC® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of Citrix ADC appliance memory allo-

cated to the integrated cache.

If you would like to observe cache operation before changing settings, see "Displaying Cached Objects and Cache Statistics."

> **Note:**
>
> The Citrix ADC cache is an in-memory store that is purged when you restart the appliance.

To install integrated cache license

- An integrated cache license is required.
- Obtain a license code from Citrix, go to the command line interface, and log in.

At the command line interface, copy the license file to the `/nsconfig/license` folder.

- Reboot the Citrix ADC appliance by using the following command:

```
reboot
```

To enable integrated caching:
When you enable integrated caching, the Citrix ADC appliance begins caching server responses. If you have not configured any policies or content groups, the built-in policies store cached objects in the Default content group.

At the command prompt, type one of the following commands to enable or disable integrated caching:

```
enable ns feature IC
```

Configure global attributes for caching

Global attributes apply to all cached data. You can specify the amount of Citrix ADC memory allocated to the integrated cache, Via header insertion. A criterion for verifying that a cached object must be served. The maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (central distribution hub of all incoming TCP requests) in the nCore Citrix ADC appliance is aware of objects cached by other packet engines in the nCore Citrix ADC appliance.

> **Note:**
>
> When the default global memory limit is set as 0 and the Integrated Caching (IC) feature is enabled, the appliance does not cache any objects. For caching, you must explicitly configure the global memory limit. However, if you enable "set authentication, authorization, and auditing parameter enableStaticPageCaching" option, there will be some default memory configured in the appliance. This memory is insufficient for caching large Objects and so it is necessary to assign a higher memory limit for IC. You can perform this by configuring the "set cache parameter

> –memLimit” command. The new setting is applied only after you save the configuration and reboot the appliance.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), the appliance continues to use the memory limit.

It means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the show cache parameter command indicates the configured value (memory Usage limit) and the actual value being used (memory usage limit (active value)).

At the command prompt, type:

```
1     set cache parameter [-memLimit <MBytes>] [-via <string>] [-
          verifyUsing <criterion>] [-maxPostLen <positiveInteger>] [-
          prefetchMaxPending <positiveInteger>] [-enableBypass(YES|NO)] [-
          undefAction (NOCACHE|RESET)]
2 <!--NeedCopy-->
```

Enable integrated caching by Citrix ADC GUI

Navigate to **System** > **Settings**, click **Configure Basic Features**, and select **Integrated Caching**.

Configure global settings for caching by using the Citrix ADC GUI

Navigate to **Optimization** > **Integrated Caching**, click **Change Cache Settings**, and configure the global settings for caching.

Set up built-in content group, pattern set, and policies for Integrated Cache

The Citrix ADC appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called ctx_cg_poc, a pattern set called ctx_file_extensions, and a set of integrated cache policies. In the content group ctx_cg_poc, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind the policies to a bind point if you want the Citrix ADC appliance to evaluate traffic against the policies. The policies cache objects in the ctx_cg_poc content group.

Integrated caching policy name	Policy rule
_cacheVPNStaticObjects	HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_IN
_cacheTCPVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(".css")
_cacheOCVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(".pdf")
_cacheWFStaticObjects	HTTP.REQ.URL.ENDSWITH(".js")
_mayNoCacheReq	HTTP.RES.HEADER("Content-Type").CONTAINS("application/x-javascript")
_noCacheRest	TRUE

Flush cache configuration

You can flush a cache group, cache groups, or cache object locator. Following are the commands to flush cache objects.

At the command prompt, type:

```
flush cache contentgroup all
```

Example

```
1          0x00000089bae000000004 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hello
2          0x00000089bae000000005 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hi
3
4          Flush cache contentGroup all
5          done
6
7  `flush cache contentgroup <content group name>`
8  <!--NeedCopy-->
```

Example:

```
1          0x00000089bae000000004 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hello
2          0x00000089bae000000005 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hi
3
4          Flush cache ob -| 0x00000089bae000000004
5          done
```

```
6
7 `flush cache object (-locator <positive_integer> | (-url <URL> (-host <
     string> [-port <port>] [-groupName <string>] [-httpMethod ( GET |
     POST )])))`
8 <!--NeedCopy-->
```

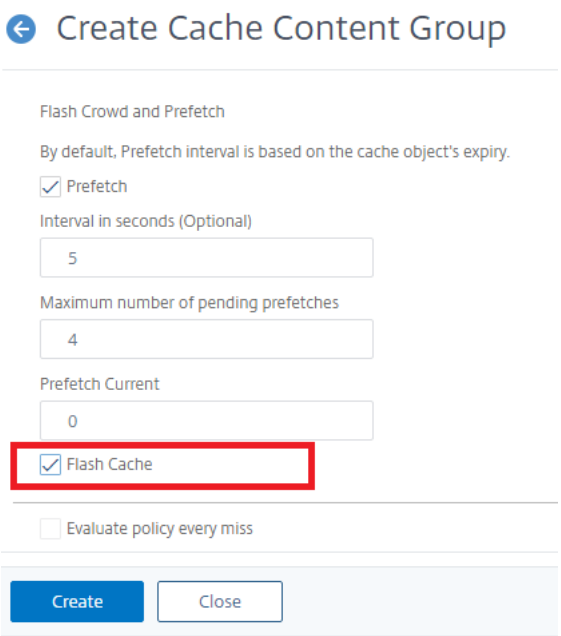
Example:

```
1         0x00000089bae000000006 DEFAULT GET //1.1.1.1:80/html/index.html
2
3         flush cache ob -URL /html/index.html -host 1.1.1.1 -groupName
             DEFAULT
4         done
5 <!--NeedCopy-->
```

Flush cache configuration by using the Citrix ADC GUI

Complete the steps to configure cache flushing using the Citrix ADC GUI

1. Navigate to **Optimization** > **Content Groups**.
2. In the **Content Groups** detailed pane, click **Add**.
3. In the **Create Cache Content Groups** page, set the following parameter under **Others** tab:
   a) Flush Cache. Select the check box to flush the cache object.
4. Click **Create** and **Close**.



Configure integrated caching for various scenarios

The following section describes the configuration of integrated caching on NetScaler appliance for various scenarios.

Starting from NetScaler 9.2 release, the integrated caching has more memory for caching. The integrated caching memory is only limited by the memory available on the hardware appliance. You can allocate up to 50 percent of the available memory to the integrated caching feature.

To set the memory allocation for the cache by using the CLI

At the command prompt, type:

```
set cache parameter -memlimit <value>
```

> **Note:**
>
> The default global memory limit for integrated caching is zero. Therefore, even if you enable the integrated caching feature, the NetScaler appliance does not cache any objects until the global memory limit is explicitly set.

The following section instructs you to configure integrated caching on different scenarios.

> **Note:**
>
> The memory limit of the NetScaler appliance is identified when the appliance starts. Therefore, any changes to the memory limit require you to restart the appliance to make the changes applicable across the packet engines.

Integrated caching is enabled and cache memory limit is set to non-zero

Consider a scenario, where you start the appliance, the integrated caching feature is enabled and the global memory limit is set to a positive number. The memory you had set earlier is allocated to the integrated caching feature during the boot process. You might want to change the memory limit to another value depending on the available memory on the appliance.

Configuring by using the CLI

1. Display the cache parameter

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 500 MBytes
4                  Memory usage limit (active value): 500 MBytes
5                  Maximum value for Memory usage limit: 843 MBytes
6                  Via header: NS-CACHE-9.3: 18
7                  Verify cached object using: HOSTNAME_AND_IP
```

```
                Max POST body size to accumulate: 0 bytes
                Current outstanding prefetches: 0
                Max outstanding prefetches: 4294967295
                Treat NOCACHE policies as BYPASS policies: YES
                Global Undef Action: NOCACHE
<!--NeedCopy-->
```

1. Set a non-zero memory limit

```
set cache parameter -memlimit 600
```

> **Note:**
>
> The preceding command displays the following warning message: **Warning: To use a new Integrated Cache memory limit, save the configuration and restart the NetScaler appliance.**

1. Save the configuration

```
save config
```

1. From the shell prompt, run the following command to verify in the configuration file.

```
root@ns## cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 600 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 0 -enableBypass YES -undefAction NOCACHE
```

1. Reboot the appliance

```
root@ns## reboot
```

1. Verify the new value for the memory limit

```
        > show cache parameter
                Integrated cache global configuration:
                Memory usage limit: 600 MBytes
                Memory usage limit (active value): 600 MBytes
                Maximum value for Memory usage limit: 843 MBytes
                Via header: NS-CACHE-9.3: 18
                Verify cached object using: HOSTNAME_AND_IP
                Max POST body size to accumulate: 0 bytes
                Current outstanding prefetches: 0
                Max outstanding prefetches: 4294967295
                Treat NOCACHE policies as BYPASS policies: YES
                Global Undef Action: NOCACHE
<!--NeedCopy-->
```

After all packet engines start successfully, the integrated caching feature negotiates the memory you had configured. If the appliance cannot use the configured memory, then the memory is allocated accordingly. If the available memory is less than the one you allocated, the appliance recommends a lesser number. The integrated caching feature uses same as the active value.

Integrated caching is disabled and cache memory limit is set to non-zero

In this scenario, when you start the appliance, the integrated caching feature is disabled and the global memory limit is set to a positive number. Therefore, no memory is allocated to the integrated caching during the boot process.

Configuring by using the CLI

1. Display the cache parameter

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 600 MBytes
4                  Maximum value for Memory usage limit: 843 MBytes
5                  Via header: NS-CACHE-9.3: 18
6                  Verify cached object using: HOSTNAME_AND_IP
7                  Max POST body size to accumulate: 0 bytes
8                  Current outstanding prefetches: 0
9                  Max outstanding prefetches: 4294967295
10                 Treat NOCACHE policies as BYPASS policies: YES

> **Note:**
>
> 500 MB of memory is allocated to the integrated caching feature.

1. Save the configuration to ensure that the memory is automatically allocated to the feature when the appliance is restarted.

Integrated caching is enabled and cache memory is set to zero

In this scenario, when you start the appliance, the integrated caching feature is enabled and the global memory limit is set to zero. Therefore, no memory is allocated to the integrated caching during the boot process.

Configuring by using the CLI

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns## cat ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 0 -via NS-CACHE-9.3: 18 -verifyUsing HOSTNAME_AND_IP
 -maxPostLen 4096 -enableBypass YES -undefAction NOCACHE
```

1. Verify the value for the memory limit

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 0 Mbytes
4                  Maximum value for Memory usage limit: 843 MBytes
5                  Via header: NS-CACHE-9.3: 18
6                  Verify cached object using: HOSTNAME_AND_IP

8                  Current outstanding prefetches: 0
9                  Max outstanding prefetches: 4294967295
10                 Treat NOCACHE policies as BYPASS policies: YES
11                 Global Undef Action: NOCACHE
12 <!--NeedCopy-->
```

> **Note:**
>
> The memory limit is set to 0 MB and no memory is allocated to the integrated caching feature.

1. Set the memory limits to ensure the integrated caching feature caches objects

```
set cache parameter -memLimit 600
```

Once you run the preceding command, the appliance negotiates memory for the integrated caching feature and the available memory is assigned to the feature. It results in appliance caching objects without restarting the appliance.

1. Verify the value for the memory limit

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 600 Mbytes
```

```
                Memory usage limit (active value): 600 Mbytes
                Maximum value for Memory usage limit: 843 MBytes
                Via header: NS-CACHE-9.3:
                Verify cached object using: HOSTNAME_AND_IP
                Max POST body size to accumulate: 0 bytes
                Current outstanding prefetches: 0
                Max outstanding prefetches: 4294967295
                Treat NOCACHE policies as BYPASS policies: YES
                Global Undef Action: NOCACHE
<!--NeedCopy-->
```

> **Note:**
>
> 600 MB of memory is allocated to the integrated caching feature.

1. Save the configuration. Ensure that the memory is automatically allocated to the feature when the appliance is restarted.
2. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns## cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 600 -via NS-CACHE-9.3: -verifyUsing HOSTNAME_AND_IP
 -maxPostLen 4096 -enableBypass YES -undefAction NOCACHE
```

Integrated caching is disabled and cache memory is set to zero

In this scenario, when you start the appliance, the integrated caching feature is disabled and the global memory limit is set to zero. Therefore, no memory is allocated to the integrated caching during the boot process.

Configuring by using the CLI

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns## cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 0 -via NS-CACHE-9.3: 18 -verifyUsing HOSTNAME_AND_IP
 -maxPostLen 4096 -enableBypass YES -undefAction NOCACHE
```

1. Verify the value for the memory limit

```
        > show cache parameter
                Integrated cache global configuration:
```

```
3                   Memory usage limit: 0 Mbytes

```

Configure selectors and basic content groups

September 14, 2021

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache requests or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use `hit` parameters and invalidation parameters. However, Citrix recommends that you configure selectors.

After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in Improving Cache Performance and Configuring Cookies, Headers, and Polling, but you might first want to configure caching policies.

> **Note**
>
> Content group parameters and selectors are used only at request time, and you typically asso-

> ciate them with policies that use MAY_CACHE or MAY_NOCACHE actions.

Advantages of selectors

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix® ADC appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for host1.domain.com\mypage.htm, host2.domain.com\mypage.htm, and host3.domain.com\mypage.htm. In contrast, a selector can match just the URL (mypage.html, using the expression http.req.url) and the domain (.com, using the expression http.req.hostname.domain), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example, a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see Policies and Expressions.

Use parameters Instead of selectors

Although Citrix recommends the use of selectors with a content group, you can instead configure `hit` parameters and invalidation parameters. For example, suppose that you configure three `hit` parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the Citrix ADC appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is an invalidation parameter and a user issues a POST request to update a bug report. An invalidation policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the Citrix ADC appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a `hit` parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body

- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

Configure a selector

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an *advanced expression*.

For more information about advanced expressions, see Policies and Expressions.

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

To configure a selector by using the CLI

At the command prompt, type:

```
add cache selector \<selectorName\> ( \<rule\> ... )
```

For information about configuring the expression or expressions, see To configure a selector expression by using the command line interface.

```
1 >add cache selector product_selector "http.req.url.query.value(\"
    ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url
    .query.value(\"depotLocation\")"
2
3 > add cache selector batch_selector "http.req.url.query.value(\"
    ProductId\")" "http.req.url.query.value(\"BatchId\")" "http.req.url.
    query.value(\"depotLocation\")"
4
5 > add cache selector product_id_selector "http.req.url.query.value(\"
    ProductId\")"
6
7 > add cache selector batchnum_selector "http.req.url.query.value(\"
    BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
8
```

```
> add cache selector batchid_selector "http.req.url.query.value(\"
    depotLocation\")" "http.req.url.query.value(\"BatchId\")"

<!--NeedCopy-->
```

To configure a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Selectors**, and add the cache selector.

Content groups

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups**. Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.
- **Dynamic content groups**. Looks for objects that contain particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

Serve a request from a content group

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the Citrix ADC appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, based on criteria that you configure in a selector.

For example, the content group can retrieve responses that match `NameField=username and BugID=ID`.

1. If it finds matching objects, the Citrix ADC appliance can serve them to the user's browser, where they are assembled into a complete response (for example, a bug report).

Invalidate an object in a content group

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).
2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.
3. The Citrix ADC appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.
4. If the request matches an invalidation policy, the Citrix ADC appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.

For example, an invalidation selector can find responses that match `NameField=username and BugID=ID`.

1. The next time the Citrix ADC appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user's browser, where they are assembled into a complete bug report.

Set up a basic content group

By default, all cached data is stored in the default content group. You can configure more content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

To set up a basic content group by using the command line interface

At the command prompt, type:

```
add cache contentgroup <name> (-hitSelector <hitSelectorName> -invalSelector
 <invalidationSelectorName> | -hitParams <hitParamName> -invalParams<
invalidationParamName>)-type <type> [-relExpiry <sec> | -relExpiryMilliSec
<msec>] [-heurExpiryParam <positiveInteger>]
```

```
add cache contentgroup Products_Details -hitSelector product_selector -
invalSelector id_selector
```

```
add cache contentgroup bugrep -hitParams IssuePage RecordID Template
TableId -invalParams RecordID -relExpiry 864000
```

To set up a basic content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and create the content group.

Expire or flush cached objects

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see Configuring Policies for Caching and Invalidation.
- Expire the content group or objects within it manually.

After a cached response expires, the Citrix ADC appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the Citrix ADC appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual**. Manually invalidate all responses in a content group or all responses in the cache.
- **Response-based**. Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry**. For responses that have a Last-Modified header, the heuristic expiry specifies the mount of time taken from when the response was modified (calculated as the current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses must be expired more often.
- **Absolute or relative**. Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time, or GMT. Local time may not work in all time zones.

Relative expiration specifies some seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.

Absolute and relative expiration overrides any expiration information in the response itself.

- **On download**. The option Expire After Complete Response Received expires a response when it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled.

Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the Citrix ADC appliance fetches only one response for a block of simultaneous requests.

- **Pinned**. By default, when the cache is full the Citrix ADC appliance replaces the least recently

used response first. The Citrix ADC appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are more options for expiring objects in the group:

- Configure a policy with an INVAL action that applies to the content group.
- Enter the names of content groups when configuring a policy that uses an INVAL action.

How expiration methods are applied

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive, and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

- You can control whether the Citrix ADC appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration causes the Citrix ADC appliance to ignore the response headers (they override any expiration information in the response).
- Heuristic expiration settings and "Weak Positive" and "Weak Negative" expiration (labeled as **Default** values in the configuration utility) cause the Citrix ADC appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the Citrix ADC appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, the Citrix ADC appliance uses the "weak positive" value.
  - For negative responses that lack an Expires or Cache-Control header, the Citrix ADC appliance uses the "weak negative" value.

The following table describes how these methods are applied.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	Any header	Expire Content After (relExpiry) with no other settings	Use the value of the **Expire Content After** setting.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	Any header	Expire Content At (absExpiry) with no other settings	Subtract current date from the value of the **Expire Content At** setting.
Positive	Any header	Expire Content After (relExpiry) and Expire content at (absExpiry)	Use the smaller of the two values for the content group settings. See the previous rows in this table.
Positive	Last-Modified (with any other headers)	Heuristic (heurExpiry Param) with any other setting	Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100.
Positive	Last-Modified (with any other headers)	Default (positive) (weakPosRel Expiry) and no other setting	Use the value of the Default (positive) expiry setting.
Positive	Expires or Cache-Control: Max-Age header is present	Last-Modified header is absent, Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both	Subtract the current date from the Expires or the `Cache-Control:Max-Age` date.
Positive	no caching headers	Default (positive) (weakPosRel Expiry) and any other expiration setting	Use the value of the Default (positive) setting.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	no caching headers	Heuristic (heurExpiry Param) is present, Default (positive) (weakPosRel Expiry) setting is absent.	If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status. If the Last-Modified header is present, use the heuristic expiry value.
Negative	Expires or `Cache-Control:Max-Age`	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.
Negative	Expires or Cache-Control headers are absent	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Response is not cached, or is cached with an Already Expired status.
Negative	Expires or `Cache-Control:Max-Age`	Any setting	Subtract the current date from the Expires or `Cache-Control:Max-Age` date.
Negative	Expires and Cache-Control:Max-Age headers are absent	Default (negative) (weakNegRel Expiry)	Use the value of the Default (negative) setting.
Negative	Expires and Cache-Control:Max-Age headers are absent	Any setting other than Default (negative) (weakNegRel Expiry)	Object is not cached or is cached with an Already Expired status.

Expire a content group by manual method

You can manually expire all of the entries in a content group.

To manually expire all responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache contentGroup <name>
```

To manually expire all responses in a content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, select the content group, and click Invalidate to expire all the responses in a content group.

To manually expire all responses in the cache by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and click Invalidate All to expire all the responses in cache.

Configure periodic expiration of a content group

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

To configure content group expiration by using the command line interface

At the command prompt, type:

```
set cache contentgroup \<name> (-relExpiry|-relExpiryMilliSec|-absExpiry
|-absExpiryGMT| -heurExpiryParam|-weakPosRelExpiry|-weakNegRelExpiry| -
expireAtLastBye)\<expirationValue>
```

To configure content group expiration by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, select the content group, and specify expiry method.

Expire individual responses

Expiring a response forces the Citrix ADC appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, `ETag` or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.

To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name and the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

To expire individual responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache object -url <URL> -host <hostName> [-port <port>] [-groupName<
contentGroupName>] [-httpMethod GET|POST]
```

To expire individual responses in a content group by using the CLI

At the command prompt, type the following command:

```
expire cache object -locator <positiveInteger>
```

To expire a cached response by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cached Objects**, select the cached response, and expire.

To expire a response by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cached Objects**, click **Search** and, set the search criteria to find the required cached response and expire.

Flushing responses in a content group

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing a cached response frees up memory for new cached responses.

> **Note:**
>
> To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

To flush responses from a content group by using the command line interface

At the command prompt, type:

```
flush cache contentGroup <name> [-query <queryString> | [-selectorValue <
selectorExpressionIDList> -host <hostName>]]
```

To flush responses from a content group by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**.
2. In the details pane, flush the responses as follows:
   - To flush all responses in all content groups, click Invalidate All, and flush all the responses.
   - To flush responses in a particular content group, select the content group, click **Invalidate**, and flush all the responses.

> **Note**:
> If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click **Flush and OK**.

> The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.

If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the **Query** field.

If the content group uses an invalidation parameter and Invalidate objects belonging to the target host is configured, enter strings in the **Query and Host** fields.

To flush a cached response by using the command line interface

At the command prompt, type:

```
flush cache object -locator <positiveInteger> | -url <URL> -host <hostName>
 [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET|POST]
```

To flush a cached response by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cached Objects**, select the cached object, and flush.

Deleting a content group

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltas group. The Default group stores cached responses that do not belong in any other content group.

To delete a content group by using the command line interface

At the command prompt, type:

```
rm cache contentgroup <name>
```

To delete a content group by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups,** select the content group, and delete.

Configure policies for caching and invalidation

September 14, 2021

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The NetScaler appliance provides built-in policies for integrated caching, and you can

configure more policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache's Policies node in the configuration utility. The built-in policy names begin with an underscore (_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions**. Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions**. Policies that you associate with the INVAL action immediately expire cached responses and refresh them from the origin server. For Web-based applications, invalidation policies often evaluate POST requests.
- **"Do not cache" actions**. Policies that you associate with a NOCACHE action never store objects in the cache.
- **Provisionally cache actions**. Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of more policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a `LOCK` request. For invalidation policies only, you can specify `LOCK` as a method by using the expression `http.req.method.eq( "lock" )`. Unlike policies for `GET` and `POST` requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you must understand how the bind points affect the order of processing before you create your policies.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks. In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

Actions to associate with integrated caching policies

The following table describes actions for integrated caching policies.

Action	Specification
CACHE	Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it. Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded. A CACHE action can be overridden by built-in policies.
NOCACHE	Always fetches the response from the origin server and marks the response as non-storable. You typically configure NOCACHE policies for data that is sensitive or personalized.

Action	Specification
MAY_CACHE	Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible: 1. If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy. 2. If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy. 3. If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied. 4. If a matching response-time policy has a NOCACHE action, perform a NOCACHE action. 5. If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.

Action	Specification
MAY_NOCACHE	For a request-time policy, this setting provisionally prevents caching the response. At response time, one of the following actions is taken: - If no response-time policy matches the request, the final action is NOCACHE. - If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy. - If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE. -If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.
INVAL	Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired. Note: You can specify INVAL actions in request-time policies only.

Bind points for a policy

You can bind the policy to one of the following bind points:

- **A global policy bank**. These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in "Order of Policy Evaluation."
- **A virtual server**. Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in "Order of Policy Evaluation." When binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label**. A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:
  - _reqBuiltinDefaults. This policy label, by default, is invoked from the request-time default policy bank.

  - _resBuiltinDefaults. This policy label, by default, is invoked from the response-time default policy bank.

You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points.

> **Important:**
> You must bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

Order of policy evaluation

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance's processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

- **Request-time override**. If a request matches a request-time override policy, by default the request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server**. If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance store the action that is associated with the matching policy.
- **Request-time content switching virtual server**. Policies that are bound to this bind point are evaluated after the request-time policies that are bound to load balancing virtual servers.
- **Request-time default**. If policy evaluation cannot be completed after all the request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes the request-time default policies. If the request matches a request-time default policy, by default the request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Response-time override**. Similar to request-time override policy evaluation.
- **Response-time load balancing virtual server**. Similar to request-time virtual server policy evaluation.
- **Response-time content switching virtual server**. Similar to request-time virtual server policy evaluation.
- **Response-time default**. Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

> **Note:**
> Request-time policies for POST data or cookie headers must be invoked during request-time override evaluation, because the built-in request-time policies in the integrated cache return a NOCACHE action for POST requests and a MAY_NOCACHE action for requests with cookies. You would associate MAY_CACHE or MAY_NOCACHE actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

Configure a policy for integrated caching

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

- Rule: A logical expression that evaluates an HTTP request or response.
- Action: You associate a policy with an action to determine what to do with a request or response that matches the policy rule.

Content groups: You associate the policy with one or more content groups to identify where the action is to be performed.

To configure a policy for caching by using the command line interface

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -actionCACHE|MAY_CACHE
|NOCACHE|MAY_NOCACHE [-storeInGroup <contentGroupName>] [-undefAction
NOCACHE|RESET]
> add cache policy image_cache -rule "http.req.url.contains(\"jpg\")|| http
.req.url.contains(\"jpeg\")"-action CACHE -storeingroup myImages_group -
undefaction NOCACHE

> add cache policy bugReportPolicy -rule "http.req.url.query.contains(\"
IssuePage\")"-action CACHE -storeInGroup bugReportGroup

> add cache policy my_form_policy -rule "http.req.header(\"Host\")contains
(\"my.company.com\")&& http.req.method.eq(\"GET\")&& http.req.url.query.
contains(\"v=7\")"-action CACHE -storeInGroup my_form_event

> add cache policy viewproducts_policy -rule "http.req.url.contains(\"
viewproducts.aspx\")"-action CACHE -storeInGroup Product_Details
```

To configure a policy for invalidation by using the command line interface

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -action INVAL [-
    invalObjects "\<contentGroupName1>[,<selectorName1>"]. . .]] | [-
    invalGroup \<contentGroupName1>[, <contentGroupName2>. . .]] [-
    undefAction NOCACHE|RESET]
<!--NeedCopy-->
```

```
> add cache policy invalidation_events_policy -rule "http.req.header("
    Host")contains("my.company.com") && http.req.method.eq("GET") &&
    http.req.url.query.contains("v=8") -action INVAL -invalObjects
    my_form_event -undefaction NOCACHE
<!--NeedCopy-->
```

```
> add cache policy inval_all -rule "http.req.method.eq("POST") && http.
    req.url.contains("jpeg")" -action INVAL -invalGroups myImages_group
    myApps_group PDF_group
<!--NeedCopy-->
```

```
> add cache policy bugReportInvalidationPolicy -rule "http.req.url.
    query.contains(\"TransitionForm\")" -action INVAL -invalObjects
    bugReport`
`> add cache policy editproducts_policy  - rule "http.req.url.contains
    (\"editproducts.aspx\")"  - action INVAL -invalObjects "
    Product_Details,batchnum_sel" "Products_In_Depots,batchid_sel"
<!--NeedCopy-->
```

To configure a policy for caching or invalidation by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Policies**, and create the new policy.

Globally binding an integrated caching policy

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

To bind an integrated caching policy globally by using the command line interface:

At the command prompt, type:

```
bind cache global <policy> -priority <positiveInteger> [-
    typeREQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] [-
    gotoPriorityExpression <expression>] [-invoke <labelType> <labelName
    >]
<!--NeedCopy-->
```

```
1 > bind cache global myCachePolicy -priority 100 -type req_default
2 <!--NeedCopy-->
```

> **Note:**
>
> The type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and response time parameters, it is bound to RES_DEFAULT. Following is an example of a binding that omits the type

Following is an example of a binding that omits the type.

```
> bind cache global myCache Policy 200
```

To bind an integrated caching policy globally by using the configuration utility

Navigate to **Optimization** > **Integrated Caching**, click **Cache Policy Manager** and bind policies by specifying the relevant bind point and connection type (Request/Response).

Bind an integrated caching policy to a virtual server

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the GUI, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all Citrix ADC modules that are bound to this virtual server. You can also use the **Policy Manager configuration** dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

To bind an integrated caching policy to a virtual server by using the command line interface:

At the command prompt, type:

```
1 bind lb vserver <name>@ -policyName <policyName> -priority <
     positiveInteger> -type(REQUEST|RESPONSE)
2 <!--NeedCopy-->
```

```
1 bind cs vserver <name>@ -policyName <policyName> -priority <
     positiveInteger> -type(REQUEST|RESPONSE)
2 <!--NeedCopy-->
```

To bind an integrated caching policy to a virtual server by using the configuration utility (virtual server method)

- CS Virtual Server - Navigate toTraffic **Management > Content Switching > Virtual Servers**, select the virtual server, and bind relevant cache policies.
- LB Virtual Server - Navigate toTraffic **Management > Load Balancing > Virtual Servers**, select the virtual server, and bind relevant cache policies.

To bind an integrated caching policy to a virtual server by using the GUI (Policy Manager method).

Navigate to **Optimization** > **Integrated Caching**, click **Cache Policy Manager**, and bind cache policies by specifying the relevant bind point and connection type.

> **Note:**
> You can bind cache policies to both load balancing virtual server and content switching virtual server by selecting the appropriate bind point.

How to cache compressed and uncompressed versions of a file

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an `Accept-Encoding:compression` format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For example, a `cached.gzip` file cannot be served in response to a request with an `Accept-Encoding:deflate` header.

A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot handle compression, and serving compressed versions of the same files to the client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.req.
header(\"Host\")"

add cache contentGroup uncompressed_group -hitSelector uncompressed_responst_selector
 -invalSelector uncomp_resp_sel

add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS(\"xyz\")&&
 !HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS"-action CACHE -storeInGroup
uncompressed_group

bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression
END -type REQ_OVERRIDE

add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.REQ.
HEADER(\"Host\")""HTTP.REQ.HEADER(\"Accept-Encoding\")"
```

```
add cache contentGroup compressed_group -hitSelector compressed_response_selector

add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS(\"xyz\")&&
 HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS"-action CACHE -storeInGroup
compressed_group

bind cache global cache_compressed -priority 200 -gotoPriorityExpression
END -type REQ_OVERRIDE
```

Configure a policy bank for caching

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling the order of policy evaluation by binding the policy and assigning a priority level, as described in "Binding Policies", you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed.

The following table summarizes the entries to control evaluation in a policy bank.

Attribute	Specifies
Name	The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.
Priority	An integer. The lower the integer, the higher the priority.

Attribute	Specifies
Goto Expression	Determines the next policy or policy bank to evaluate. You can provide one of the following values: 1. NEXT: Go to the policy with the next higher priority. 2. END: Stop evaluation. 3. USE_INVOCATION_RESULT: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT. 4. Positive number: Priority number of the next policy to be evaluated. 5. Numeric expression: Expression that produces the priority number of the next policy to be evaluated. The Goto can only proceed forward in a policy bank. Omitting the Goto expression is the same as specifying END.
Invocation Type	Designates a policy bank type. The value can be one of the following - 1. Request virtual server: Invokes request-time policies that are associated with a virtual server. 2. Response virtual server: Invokes response-time policies that are associated with a virtual server. 3. Policy label: Invokes another policy bank, as identified by the policy label for the bank.
Invocation Name	Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

The integrated cache has two built-in policy labels, and you can configure more policy labels:

`_reqBuiltInDefaults`: This policy label is invoked from the request-time default bind point.
`_resBuiltInDefaults`: This policy label is invoked from the response-time default bind point.

To invoke a policy label in a caching policy bank by using the command line interface

At the command prompt, type:

```
bind cache policylabel <labelName> -policname<policyName> -priority<
    priority> [-gotoPriorityExpression <gotopriorityExpression>] [-
```

```
    invoke <labelType> <labelName>]
<!--NeedCopy-->
```

To invoke a policy label in a caching policy bank by using the GUI:

1. Navigate to **Optimization** > **Integrated Caching**, click **Cache policy manager**, and specify the relevant bind point (Override Global or Default Global) and connection type to view the list of policies bound to this bind point.
2. If you want to invoke a policy label without evaluating a policy, click **NOPOLICY**.

> **Note:**
>
> To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

To invoke a caching policy label in a virtual server policy bank by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@ -policyName <policyName>|<NOPOLICY-CACHE> -
    priority<positiveInteger> -gotoPriorityExpression <expression> -type
     REQUEST|RESPONSE -invoke<labelType> <labelName>
<!--NeedCopy-->
```

```
bind cs vserver <name> -policyName <policyName>|<NOPOLICY-CACHE> -
    priority<positiveInteger> -gotoPriorityExpression <expression> -type
     REQUEST|RESPONSE -invoke<labelType> <labelName>
<!--NeedCopy-->
```

To invoke a caching policy label in a virtual server policy bank by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing/Content Switching** > **Virtual Servers**, select the virtual server, and click **Policies**.
2. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the “dummy” NOPOLICY entry, click **Add** and do one of the following:
   - To configure a new policy, click Cache and configure the new policy as described in Configuring a Policy in the Integrated Cache.
   - To invoke a policy bank without processing a policy a rule, select the `NOPOLICY-CACHE` option.

> **Note:**
>
> To invoke an external policy bank, click the field in the Invoke Type column, and select the type

> of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

Configure a policy label in an integrated cache

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the **Integrated Caching** details pane (request override, request default, response override, or response default) or the built-in policy labels `\\_reqBuiltinDefaults` and `\\_resBuiltinDefaults`. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The Citrix ADC GUI provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

> **Note**:
>
> You can use the `NOPOLICY` "dummy" policy to invoke any policy label from another policy bank. The `NOPOLICY` entry is a placeholder that does not process a rule.

To configure a policy label for caching by using the command line interface

At the command prompt, type the following command to create a policy label and verify the configuration:

- `add cache policylabel <labelName> -evaluates (REQ|RES)`
- `show cache policylabel <labelName>`

Invoke this policy label from a policy bank.

To configure a policy label for caching by using the GUI:

Navigate to **Optimization** > **Integrated Caching** > **Policy Labels**, add a policy label, and bind the cached policies.

> **Note:**
> To ensure that the Citrix ADC processes the policy label at the right time, configure an invocation of this label in one of the policy banks that are associated with the built-in bind points.

To rename a policy label by using the GUI:

Navigate to **Optimization** > **Integrated Caching** > **Policy Labels** select the policy label, and rename.

Unbind and delete an integrated caching policy and policy label

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy

label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).

To unbind a global caching policy by using the command line interface

At the command prompt, type:

```
unbind cache global <policy>
```

To unbind a virtual server-specific caching policy by using the command line interface

At the command prompt, type:

```
(unbind lb vserver|unbind cs vserver)<vserverName> -policyName <policyName>
 -type(REQUEST|RESPONSE)
```

To delete a caching policy by using the command line interface

At the command prompt, type:

```
rm cache policy <policyName>
```

To unbind a caching policy by using the GUI:

Navigate to **Optimization** > **Integrated Caching**, click **Cache Policy Manager**, and unbind policies by specifying the relevant bind point and connection type (Request/Response).

To delete a policy label invocation by using the GUI:

1. Navigate to **Optimization** > **Integrated Caching**, click **Cache policy manager**, and specify the relevant binding point (load balancing virtual server or content switching virtual server) and connection type to view the list of cache policies bound to this virtual server.
2. In the policy Invoke column, clear the entry.

Cache support for database protocols

September 14, 2021

The integrated cache feature monitors and caches database request as determined by the cache policies. Users must configure the cache policies for MYSQL and MSSQL protocols as the Citrix ADC appliance does not provide any default policies. When configuring the default protocols, remember the request-based policies support only CACHE and INVAL actions, while the response-based policies support only “NOCACHE” action. After configuring the policies, you must bind them to virtual servers. MYSQL and MSSQL policies, both request and response, are bound only to virtual servers.

Before creating a cache policy, you must create a cache content group of type MYSQL or MSSQL. When you create a cache content group, associate at least one select selector with it. See Setting Up a Basic Content Group for setting up a cache content group.

The following example explains how to configure and verify cache support for SQL protocols.

```
> enable feature IC
> set cache parameter -memlimit 100
> add cache selector sel1 mssql.req.query.text

> add cache contentgroup cg1  -type "MSSQL" -hitselector "sel1" -
   invalselector "inval_sel" -relExpiry "500" -maxResSize
 "100"
> add cache policy cp1  -rule "mssql.req.query.command.contains(\"
   select\")" -action "CACHE" -storeInGroup "cg1"
> add cache policy cp2  -invalObjects "cg1" -rule "mssql.req.query.text
   .contains(\"insert\")" -action "INVAL"
> add db user user1  -password "Pass1"
> add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -
   downstateflush "ENABLED"
> add lb vserver lb_mssql1 mssql 10.102.147.77 1433  -lbmethod "
   roundrobin"
> bind lb vserver lb_mssql1 svc_sql_1
> bind lb vserver lb_mssql1 -policyName cp1  -type "REQUEST" -priority
   "2"
> bind lb vserver lb_mssql1 -policyName cp2  -type "REQUEST" -priority
   "1"

> show cache selector sel1
     Name:sel1
                    Expressions:
                    1)mssql.req.query.text
> show cache policy cp1
                    Name:cp1
     Rule:mssql.req.query.command.contains("select")
                    CacheAction:CACHE
                    Stored in group: cg1
                    UndefAction:Use Global
                Hits:2

> The methods for reducing flash crowds, as explained in Reducing Flash Crowds, are not supported for MYSQL and MSSQL protocols.

Configure expressions for caching policies and selectors

September 14, 2021

A request-time expression examines data in the request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the Citrix ADC appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers `http://livehttpheaders.mozdev.org/)or HTTPFox https://addons.mozilla.org/en-US/firefox/addon/6647` can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```
GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi
    &selected=CTXS&random=0.00792039478975548 HTTP/1.1

Host: quotes.mystockquotes.com

User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
    Gecko/2008052906 Firefox/3.0

Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8

Accept-Language: en-us,en;q=0.5

Accept-Encoding: gzip,deflate,compress,pack200-gzip

Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7

Keep-Alive: 300
```

```
16
17 Connection: keep-alive
18
19 Referer: http://quotes.mystockquotes.com/quote.dll?mode=stock&symbol=
      CTXS&page=multi&selected=CTXS
20
21 Cookie: __qca=1210021679-72161677-10297606
22 <!--NeedCopy-->
```

When configuring an expression, note the following limitations:

Expression Type	Restrictions
Request	Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.
Response	Configure response-time expressions in caching policies only. Selectors can use only request-time expressions, Do not configure response-time expressions in a policy with an INVAL action. Note: Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action.

> **Note:**
> For a comprehensive discussion of advanced expressions, see Policies and Expression.

Expression syntax

Following are the basic components of the syntax:

- Separate keywords with periods (.), as follows:

```
http.req.url
```

- Enclose string values in parentheses and quotes, as follows:

```
http.req.url.query.contains("this")
```

- When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit the values in the expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as followings:

```
\"abc\"
```

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

Configure an expression in a caching policy or a selector

> **Note:**
> The syntax for a policy expression is different from a selector expression. For a comprehensive discussion of advanced expressions, see “Policies and Expressions.”

To configure a policy expression by using the command line interface

1. Start the policy definition as described in “Globally Binding an Integrated Caching Policy.”
2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

“http.req.url.contains(”jpg”)”

To add Boolean values, insert , or ! operators. &&,

1.

The following are examples:

```
"http.req.url.contains(\"jpg\")|| http.req.url.contains(\"jpeg\")"
```

```
"http.req.url.query.contains(\"IssuePage\")"
```

```
"http.req.header(\"Host\")contains(\"my.company.com\")&& http.req.method.eq
(\"GET\")&& http.req.url.query.contains(\"v=7\")"
```

1. To configure an order of evaluation for the constituent parts of a compound

```
"http.req.url.contains(\"jpg\")|| (http.req.url.contains(\"jpeg\")&& http.
req.method.eq(\"GET\"))"
```

To configure a selector expression by using the command line interface:

1. Start the selector definition as described in “About Content Groups.”
2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
"http.req.url.contains(\"jpg\")"
```

You cannot add Boolean values, insert &&,	, or ! operators. Enter each expression element delimited in quotes. Multiple expressions in the definition are treated as a compound expression joined by logical ANDs.

1.

The following are examples:

```
1 "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"
     BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
2 <!--NeedCopy-->
```

To configure a policy or selector expression by using the GUI

1. Start the policy or selector definition as described in “To configure a policy for caching or invalidation by using the configuration utility” or “To configure a selector by using the configuration utility.”
2. In the **Expression** field, you can either manually type the default syntax by clicking Switch to Classic Syntax or create new expression using **Expression Editor**.

To insert an operator between two parts of a compound expression, click the Operators button and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars,	):

3.
4. Click **Frequently Used Expressions** drop-down list to insert the commonly used expressions.
5. To test the expression, click the **Evaluate**. In the **Expression Evaluator** dialog box, select the

Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click **Evaluate**.

Display cached objects and cache statistics

You can view particular cached objects, and you can view summary statistics on cache requests, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

View cached objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

Properties	Description
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.

Properties	Description
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.
Contentgroup	The content group where the response is stored.
Complex match	If this object was cached based on parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.

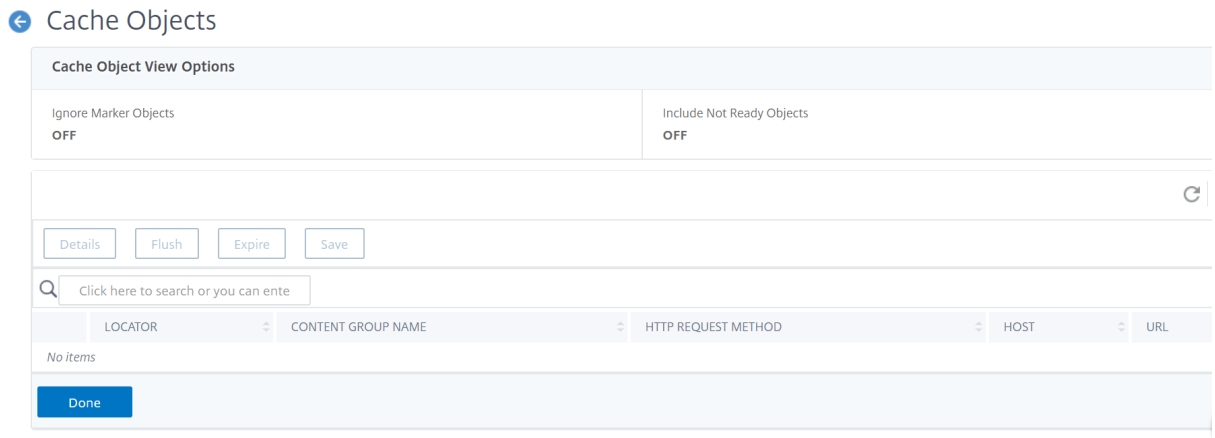
Properties	Description
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 “object not found” responses).
Current readers	Approximately the current number of requests being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.

Properties	Description
Weak etag present in response	Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a “W.”
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.
Reason marker created	The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
Citrix ADC Etag inserted in response	A variation of the ETag header generated by the Citrix ADC appliance. A value of YES appears if the Citrix ADC inserts an Etag in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin servers hit before caching a response.

Properties	Description
Minhit count	If this content group requires a minimum number of origin server requests before caching an object, this field displays a count of the number of requests received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

To view cached objects by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cache Objects**. You can view all the cached objects and sort them accordingly as per your requirement.



Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select **Copy**. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <
hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET
 | POST ]))| [-httpStatus <positive integer>] | -group <contentGroupName> |
 -ignoreMarkerObjects (ON | OFF)| -includeNotReadyObjects (ON | OFF)]
```

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects ( ON | OFF )| -
includeNotReadyObjects ( ON | OFF )| [-httpStatus<positive integer>]
```

To display cached responses in content groups that do not have a selector by using the configuration utility

Navigate to **Optimization > Integrated Caching > Cache Objects**, click Search, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

View cache statistics

The following table summarizes the detailed cache statistics that you can view.

Counter	Description
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action.
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache requests plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the Citrix ADC appliance served it, the Citrix ADC appliance serves a 304 response instead of the cached object.
This statistic indicates how many items the Citrix ADC appliance served from the cache, excluding 304 responses.	
304 hits	Number of 304 (object not modified) responses the Citrix ADC appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the Citrix ADC appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the Citrix ADC appliance served from the cache (cache requests) relative to responses that could not be served from the cache.

Counter	Description
Origin bandwidth saved (%)	An estimate of the processing capacity that the Citrix ADC appliance saved on the origin server due to serving responses from the cache.
Bytes served by the Citrix ADC	Total number of bytes that the Citrix ADC appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the Citrix ADC appliance served from the cache.
Byte hit ratio(%)	Percentage of data that the Citrix ADC appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the Citrix ADC appliance served in compressed form.
Storable misses	If the Citrix ADC appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user.
For more information, see “Inserting a Cache-Control Header.”	
Successful revalidations	Number of revalidations that have been performed.
For more information, see “Inserting a Cache-Control Header.”	
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server.

Counter	Description
For more information, see “Polling the Origin Server Every Time a Request Is Received.”	
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts.
For more information, see “Inserting a Cache-Control Header.”	
Expire at last byte	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table “Cache Hits and Misses.”
For more information, see “Example of Performance Optimization.”	
`Flashcache` misses	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses.
For more information, “Queuing Requests to the Cache.”	
Flashcache hits	Number of Flash Cache requests that were cache hits.
For more information, see “Queuing Requests to the Cache.”	
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.

Counter	Description
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.
Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the Citrix ADC appliance always consults the origin server before serving a stored object.
For more information, see “Polling the Origin Server Every Time a Request Is Received.”	
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method.
For more information, see “Polling the Origin Server Every Time a Request Is Received.”	

Counter	Description
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Maximum memory (KB)	Maximum amount of memory in the Citrix ADC appliance that is allocated to the cache. For more information, see “Configuring Global Attributes for Caching.”
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is allocated to the cache. For more information, see “How to Configure the Integrated Caching Feature of a Citrix ADC Appliance for various Scenarios.”
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.

Counter	Description
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface:

At the command prompt, type:

```
stat cache
```

To view specific cache statistics by using the command line interface:

At the command prompt, type:

```
stat cache -detail
```

```
> stat cache -detail

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the **Integrated Caching** section of the window.
3. To see detailed statistics, click the More… link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the **Reporting** tab at the top of the page.
2. Under Built-In Reports, expand **Integrated Cache**, and then click the report with the statistics you want to view.

3. To save the report as a template, click **Save As** and name the report. The saved report appears under **Custom** Reports.

Display cached objects and cache statistics

September 14, 2021

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

View cached objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

Properties	Specification
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.

Properties	Specification
Response status code	The status code sent with the response.
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.
Contentgroup	The content group where the response is stored.
Complex match	If this object was cached based on parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.

Properties	Specification
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 “object not found” responses).
Current readers	Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object.
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.

Properties	Specification
HTTP version in response	The version of HTTP that was used to send the response.
Weak `etag` present in response	Strong `etag` headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak `etag` headers change if the meaning of an entity changes. Weak `etag` values are based on semantic identity. Weak `etags` values start with a “W.”
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.
Reason marker created	The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the `ETag` response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
Citrix ADC Etag inserted in response	A variation of the `ETag` header generated by the Citrix ADC appliance. A value of YES appears if the Citrix ADC inserts an `Etag` in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.

Properties	Specification
Waiting for minhits	Indicates whether this content group requires a minimum number of origin servers hit before caching a response.
Minhit count	If this content group requires a minimum number of origin servers hit before caching an object, this field displays a count of the number of hits received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.

If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select Copy. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <
hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET
 | POST ]))| [-httpStatus<positive integer>] | -group <contentGroupName> |
-ignoreMarkerObjects (ON | OFF)| -includeNotReadyObjects (ON | OFF)]
```

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects ( ON | OFF )| -
includeNotReadyObjects ( ON | OFF )| [-httpStatus<positive integer>]
```

To display cached responses in content groups that do not have a selector by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cache Objects**, click **Search**, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

To display cached responses in content groups that have a selector by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cache Objects**, click **Search**, and set the selector search criteria to view the required cached response.

View cache statistics

The following table summarizes the cache statistics.

Counter

Specification

Viewing cache statistics

Updated: 2013-10-28

The following table summarizes the detailed cache statistics that you can view.

Counter	Specifies
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action..
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache hits plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the Citrix ADC appliance served it, the Citrix ADC appliance serves a 304 response instead of the cached object. This statistic indicates how many items the Citrix ADC appliance served from the cache, excluding 304 responses.
304 hits	Number of 304 (object not modified) responses the Citrix ADC appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the Citrix ADC appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the Citrix ADC appliance served from the cache (cache hits) relative to responses that could not be served from the cache.
Origin bandwidth saved (%)	An estimate of the processing capacity that the Citrix ADC appliance saved on the origin server due to serving responses from the cache.

Counter	Specifies
Bytes served by the Citrix ADC	Total number of bytes that the Citrix ADC appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the Citrix ADC appliance served from the cache.
Byte hit ratio(%)	Percentage of data that the Citrix ADC appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the Citrix ADC appliance served in compressed form.
Storable misses	If the Citrix ADC appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user. For more information, see “Inserting a Cache-Control Header.”
Successful revalidations	Number of revalidations that have been performed. For more information, see “Inserting a Cache-Control Header.”
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.

Counter	Specifies
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts. For more information, see “Inserting a Cache-Control Header.”
Expire at last byte	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table “Cache Hits and Misses.”For more information, see “Example of Performance Optimization.”
Flash cache misses	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses. For more information, “Queuing Requests to the Cache.”
`Flashcache` hits	Number of Flash Cache requests that were cache hits. For more information, see “Queuing Requests to the Cache.”
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.

Counter	Specifies
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.
Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the Citrix ADC appliance always consults the origin server before serving a stored object. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Maximum memory (KB)	Maximum amount of memory in the Citrix ADC appliance that is allocated to the cache. For more information, see “Configuring Global Attributes for Caching.”

Counter	Specifies
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see “How to Configure the Integrated Caching Feature of a Citrix ADC Appliance for various Scenarios.”
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface

At the command prompt, type:

```
stat cache
```

To view specific cache statistics by using the command line interface

At the command prompt, type:

```
stat cache -detail

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.

3. To see detailed statistics, click the More… link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears under Custom Reports.

Improve cache performance

September 14, 2021

You can improve the performance of the integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

Reduce flash crowds

Flash crowds occur when many users simultaneously request the same data. The requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

- **PREFETCH**: Refreshes a positive response before it expires to ensure that it never becomes stale or inactive. For more information, see “Refreshing a Response Prior to Expiration” section.
- **Cache buffering**: Starts serving a response to multiple clients when it receives the response header from the origin server, rather than waiting for the entire response to be downloaded. The only limit on the number of clients that can download a response simultaneously is the available system resources. The Citrix ADC appliance downloads and serves responses even if the client that initiated the download halts before the download is complete. If the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.
- **Flash Cache:** Flash Cache queues requests to the cache, and allows only one request to reach the server at a time.

For more information, see “Queuing Requests to the Cache” section.

Refresh a response before expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the first client request. From that point onward, the Citrix ADC appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

To configure prefetch for a content group by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds> | -
prefetchPeriodMilliSec <milliseconds>] [-prefetchMaxPending <positiveInteger
>]
```

*To configure prefetch for a content group by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the **content group**.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option, and specify the values in the Interval and Maximum number of pending prefetches text boxes.

Queue requests to the cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the Citrix ADC appliance stops serving the response from the cache and instead serves the origin server's response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

> **Note**:
> If Flash Cache is enabled, in some situations the Citrix ADC appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The Citrix ADC appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

To enable Flash Cache by using the command line interface

At the command prompt, type:

```
set cache contentgroup <contentGroupName> -flashcache yes
```

To enable Flash Cache by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option.

Cache a response after a client halts a download

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the Citrix ADC appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

To configure quick abort size by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -quickAbortSize <integerInKBytes>
```

To configure quick abort size by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in Quick Abort: Continue caching if more than text box.

Requiring a minimum number of server hits before caching

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You must consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -minhits <positiveInteger>
```

To configure the minimum number of hits that are required before caching by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in Do not cache, if hits are less than the text box.

Example for performance optimization

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to the clients, and the next request is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

Configure caching for a stock quote application

Create a content group for stock quotes

For more information, see “About Content Groups.”

Configure the following for this content group:

1. On the **Expiry Method** tab, select the Expire after complete response received check box.
2. On the **Others** tab, select the **Flash Cache** check box, and click **Create**.
3. Add a cache policy to cache the stock quotes.

For more information, see “Configuring a Policy in the Integrated Cache.”

Configure the following for the policy

1. In the **Action and Store in Group lists**, select **CACHE** and select the group that you defined in the previous step.
2. Click **Add**, and in the **Add Expression** dialog box configure an expression that identifies stock quote requests, for example: http.req.url.contains(“cgi-bin/stock-quote.pl”)
3. Activate the policy.

For more information, see “Globally Binding an Integrated Caching Policy.” In this example, you bind this policy to request-time override processing and set the priority to a low value.

Configure cookies, headers, and polling

October 27, 2021

This topic explains how to configure cache manages cookies, HTTP headers, and origin server polling. This includes modifying the default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring the cache to always poll the origin for updated content.

Divergence of cache behavior from the standards

By default, the integrated cache adheres to the following RFC standards:

- RFC 2616, “HTTP HTTP/1.1”
- The caching behaviors described in RFC 2617, “HTTP Authentication: Basic and Digest Access Authentication”
- The caching behavior described in RFC 2965, “HTTP State Management Mechanism”

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specification as follows:

- There is a limited support for the Vary header. By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains content-encoding: gzip, content-encoding: deflate, or content-encoding: pack200-gzip and is cacheable even if it contains the Vary: Accept-encoding header.
- The integrated cache ignores the values of the headers cache-control: no-cache and cache-control: private. For example, a response that contains cache-control: no-cache=”Set-Cookie” is treated as if the response contained Cache-Control: no-cache. By default, the response is not cached.
- An image (content-type = image/*) is always considered cacheable, even if an image response contains set-cookie or set-cookie2 headers, or if an image request contains a cookie header. The integrated cache removes set-cookie and set-cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

```
1 add cache policy rfc_compliant_images_policy -rule "http.res.header.set
     -cookie2.exists || http.res.header.set-cookie.exists" -action
     NOCACHE
2
3
4 bind cache global rfc_compliant_images_policy -priority 100 -type REQ\
     _OVERRIDE
5 <!--NeedCopy-->
```

- The following cache-control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

```
Cache-control: max-age=0
```

```
Cache-control: no-cache
```

To guard against denial-of-service attacks, this behavior is not the default.

- By default, the caching module considers a response to be cacheable unless a response header state otherwise. To make this behavior RFC 2616 compliant, set `-weakPosRelExpiry` and `-weakNegResExpiry` to 0 for all content groups.

Remove cookies from a response

Cookies are often personalized for a user, and typically should not be cached. The `Remove Response Cookies` parameter removes `Set-Cookie and Set-Cookie2` headers before caching a response. By default, the `Remove Response Cookies` option for a content group prevents caching of responses with `Set-Cookie` or `Set-Cookie2` headers.

> **Note:**
> When images are cached, the built-in behavior is to remove the `Set-Cookie` and `Set-Cookie2` headers before caching, no matter how the content group is configured.
>
> Citrix recommends that you accept the default `Remove Response Cookies` for every content group that stores embedded responses, for example, images.

To configure `Remove Response Cookies` for a content group by using the command line interface:

At the command prompt, type:

```
set cache contentgroup <name> -removeCookies YES
```

Configure Remove Response Cookies for a content group by using Citrix ADC GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On the **Others** tab, in the **Settings** group, select Remove response cookies option.

Inserting HTTP headers at response time

The integrated cache can insert HTTP headers in responses that result from cache requests. The Citrix ADC appliance does not alter headers in responses that result from cache misses.

The following table describes headers that you can insert in a response.

Header	Specification
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.

Header	Specification
via	Lists protocols and recipients between the start and end points for a request or a response. The Citrix ADC appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is `NS-CACHE-10.0`: last octet of the Citrix ADC IP address." For more information, see "Configuring Global Attributes for Caching."
`Tag`	The cache supports response validation using Last-Modified and `Tag` headers to determine if a response is stale. The cache inserts an `Tag` in a response only if it caches the response and the origin server has not inserted its own `Tag` header. The `Tag` value is an arbitrary unique number. The `Tag` value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With `Tag` header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an `Tag` header and replace the origin-provided Cache-Control header.

Header	Specification
Cache-Control	The Citrix ADC appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the Citrix ADC appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.

Header	Specification
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.
via	Lists protocols and recipients between the start and end points for a request or a response. The Citrix ADC appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is “NS-CACHE-9.2: last octet of the Citrix ADC IP address.” For more information, see “Configuring Global Attributes for Caching.”

Header	Specification
Tag	The cache supports response validation using the Last-Modified and Tag headers to determine if a response is stale. The cache inserts an Tag in a response only if it caches the response and the origin server has not inserted its own Tag header. The Tag value is an arbitrary unique number. The Tag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With Tag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an Tag header and replace the origin-provided Cache-Control header.
Cache-Control	The Citrix ADC appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the Citrix ADC appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.

Insert an age, via, or Tag header

The following procedures describe how to insert Age, Via, and ETag headers.

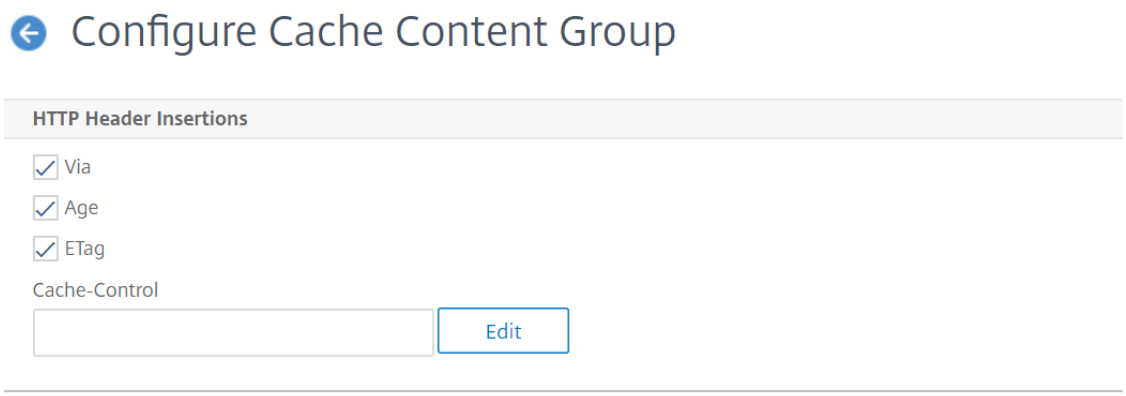
Insert an Age, Via, or Etag header by using the Citrix ADC command interface:

At the command prompt, type:

```
set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag YES
```

Configure the Age, Via, or Etag header by using the Citrix ADC GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups,** and select the **content group**.
2. On the **Others** tab, in the HTTP Header Insertions group, select the **Via**, **Age**, or **ETag** options, as appropriate.
3. The values for the other header types are calculated automatically. You configure the Via value in the main settings for the cache.



Insert a cache-control header

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

Insert a cache-control header by using the Citrix ADC command interface

At the command prompt, type:

```
set cache contentgroup <name> -cacheControl <value>
```

Insert a cache-control header by using the Citrix ADC GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and
   a) Click **Expiry Method** to clear the heuristic and default expiry settings and set the relevant value in the Expire content after text box.
   b) Click **Others** tab and type the header you want to insert in the Cache-Control text box. Alternatively, click Configure to set the Cache-Control directives in cached responses.

Ignore cache-control and pragma headers in requests

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in the Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore the Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header causes the Citrix ADC appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes Cache-Control and Pragma headers, the cached response is refreshed.

The following table summarizes the implications of various settings for these headers and the Ignore Browser's Reload Request setting.

Setting for Ignore Cache-Control and Pragma Headers	Setting for Ignore Browser's Reload Request	Outcome
Yes	Yes or No	Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.
No	Yes	The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed.

Setting for Ignore Cache-Control and Pragma Headers	Setting for Ignore Browser's Reload Request	Outcome
No	No	A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.

To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReqCachingHdrs YES
```

To ignore browser reload requests by using the command line interface

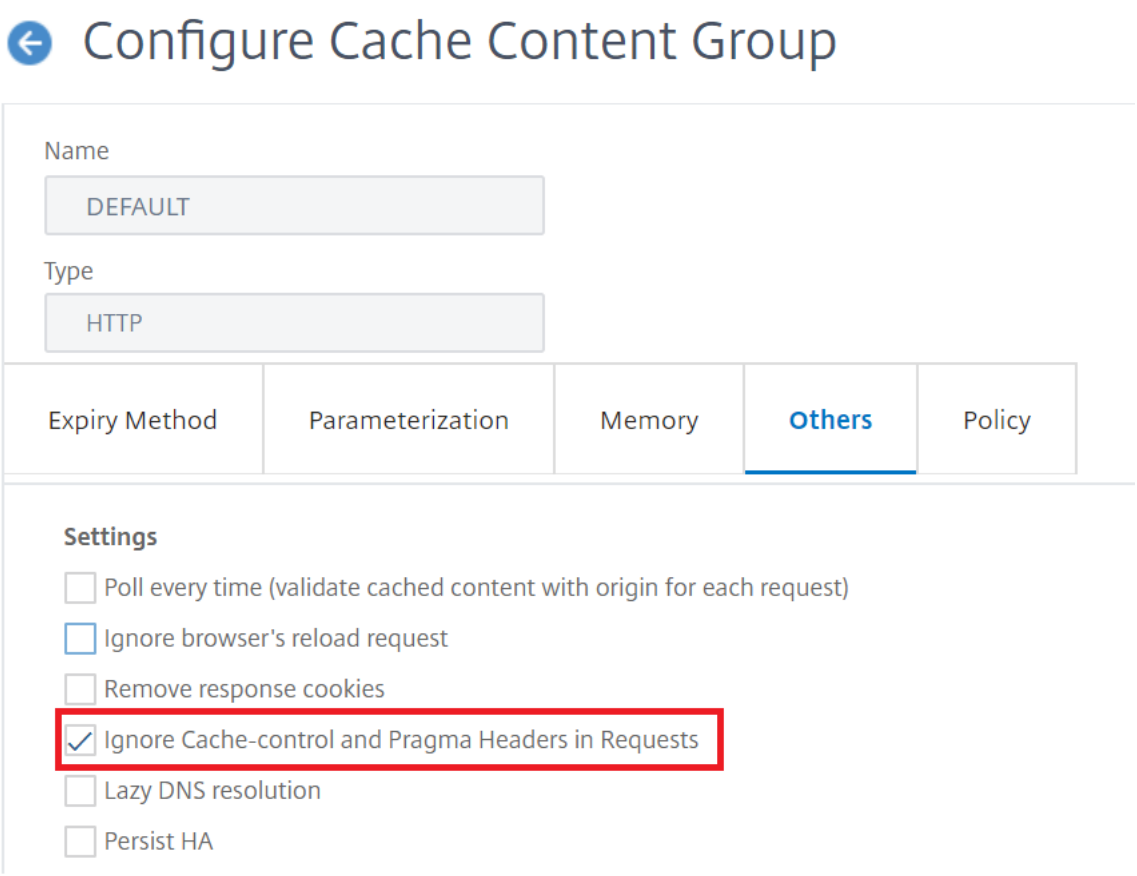
At the command prompt, type:

```
set cache contentgroup <name> -ignoreReloadReq NO
```

> **Note:**
> By default, the -ignoreReloadReq parameter is set to YES.

Ignore Cache-Control and Pragma headers in a request by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On the **Others** tab, in the **Settings** group, select **Ignore Cache-control and Pragma Headers** in **Requests** option.



Example of a policy to ignore Cache-Control headers:

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/* regardless of the Cache-Control header in the response.

To configure a request-time override policy to cache all responses with image/*

Flush the cache using the Invalidate All option.

Configure a new cache policy, and direct the policy to a particular content group. For more information, see "Configuring a Policy in the Integrated Cache."

Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in "Ignoring Cache-Control and Pragma Headers in Requests."

Bind the policy to the request-time override policy bank.

For more information, see Globally Binding an Integrated Caching Policy topic.

Poll origin server every time a request is received

You can configure the Citrix ADC appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the Citrix ADC appliance consults the origin

server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the Citrix ADC appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:

For a cached response that has validators in the form of a Tag or a Last-Modified header, if the response expires it is automatically marked PET and cached.

You can configure PET for a content group.

If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- Conditional Requests: A client issues a conditional request to ensure that the response that it has is the most recent copy. A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in If-Modified-Since or If-None-Match headers. The If-Modified-Since header contains the time from the Last-Modified header. An If-None-Match header contains the response's Tag header value. If the client's copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.
- Non-Conditional Requests: A non-conditional request can only generate a 200 OK that contains the entire response.

Origin Server Response	Action
Send the full response	The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.
304 Not Modified	The following header values in the 304 response are merged with the cached response and the cached response is served to the client: Date, Expires, Age, Cache-Control header Max-Age, and S-Maxage tokens
401 Unauthorized; 400 Bad Request; 405 Method Not Allowed; 406 Not Acceptable; 407 Proxy Authentication Required	The origin's response is served as-is to the client. The cached response is not changed.

Origin Server Response	Action
Any other error response, for example, 404 Not Found	The origin's response is served as-is to the client. The cached response is removed.

> **Note:**
> The Poll Every Time parameter treats the affected responses as non-storable.

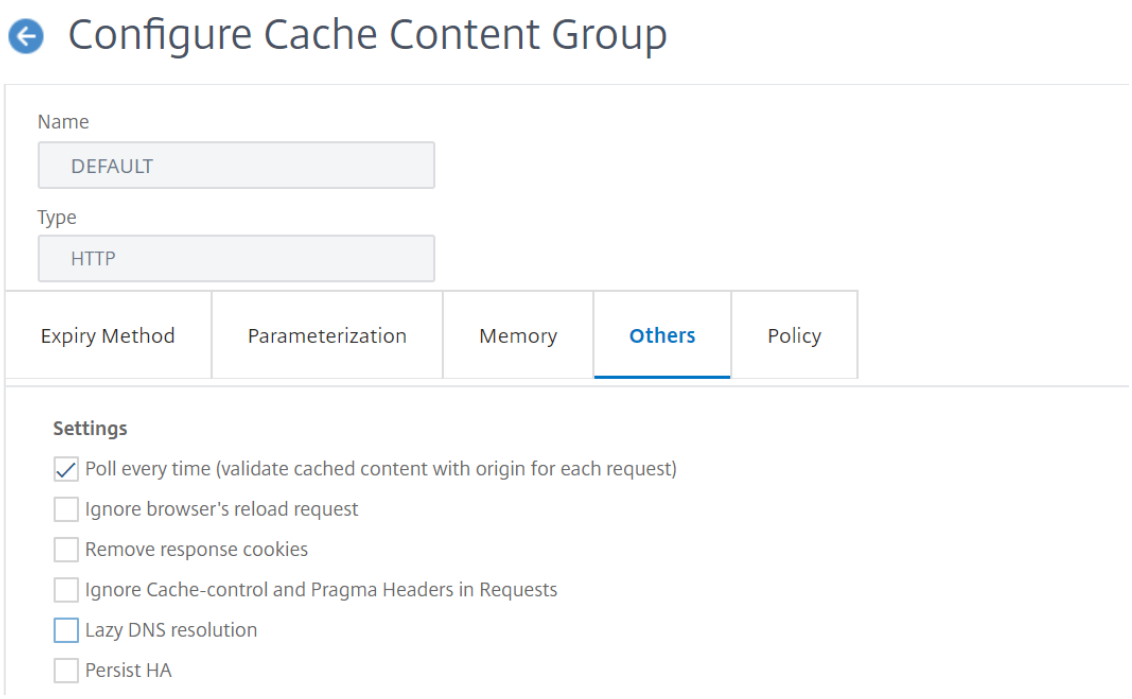
To configure poll every time by using the command line interface

At the command prompt, type:

```
add cache contentgroup <contentGroupName> -pollEveryTime YES
```

Poll by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On the **Others** tab, in the Settings group, select Poll every time (validate cached content with origin for every request) option.



PET and client-specific content

The PET function can ensure that content is customized for a client. For example, a website that serves content in multiple languages examines the Accept-Language request header to select the language

for the content that it is serving. For a multi-language website where English is the predominant language, all English language content can be cached in a PET content group. This ensures that every request goes to the origin server to determine the language for the response. If the response is English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

The following example shows commands to cache English responses in a PET content group, configure a named expression that identifies English responses in the cache, and configure a policy that uses this content group and named expression. Bold is used for emphasis:

```
add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
add expression containsENExpression  - rule "http.res.header(\\"Content-
    Language\\").contains(\\"en\\")"
add cache policy englishPolicy -rule containsENExpression -action CACHE
     -storeInGroup englishLanguageGroup
bind cache policy englishPolicy -priority 100 -precedeDefRules NO
<!--NeedCopy-->
```

PET and authentication, authorization, and auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from PET. All mail responses (*.EML objects) have an `ETag` validator that enables them to be stored as PET responses.

Every request for a mail response travels to the origin server, even if the response is cached. The origin server determines whether the requestor is authenticated and authorized. It also verifies that the response exists in the origin server. If all results are positive, the origin server sends a 304 Not Modified response.

Configure integrated cache as a forward proxy

September 14, 2021

The integrated cache can service as a forward proxy device that passes requests to other Citrix ADC appliances or to other types of cache servers. You configure the integrated cache as a forward proxy by identifying the IP addresses of the cache server or servers. After configuring the forward proxy, the Citrix ADC appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

To configure the Citrix ADC as a forward cache proxy by using the command line interface

At the command prompt, type:

```
add cache forwardProxy <IPAddress> <port>
```

To configure the Citrix ADC as a forward cache proxy by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Forward Proxy**, and add a forward proxy by specifying the IP address and port number.

Default settings for the integrated cache

September 14, 2021

The Citrix ADC integrated cache feature provides built-in policies with default settings and initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

Default caching policies

The integrated cache has built-in policies. The Citrix ADC appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

> **Note**
> If you configured policies prior to release 9.0 and specified the -precedeDefRules parameter when binding the policies, they are automatically assigned to override-time bind points during migration.

View default policies

The built-in policy names start with an underscore (_). You can view the built-in policies from the command line and the administrative console using the show cache policy command.

Default request policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the MAY_NOCACHE action stipulates that the transaction is cached only when there is a user-configured or built-in CACHE directive at response time.

The following policies are bound to the _reqBuiltinDefaults policy label. They are listed in priority order.

Do not cache a response for a request that uses any method other than GET.

The policy name is _nonGetReq. The following is the policy rule:

```
!HTTP.REQ.METHOD.eq(GET)
```

Set a NOCACHE action for a request with header value that contains If-Match or If-Unmodified-Since.

The policy name is _advancedConditionalReq. The following is the policy rule:

```
HTTP.REQ.HEADER("If-Match").EXISTS || HTTP.REQ.HEADER("If-Unmodified-Since"
).EXISTS
```

Set a MAY_NOCACHE action for a request with the following header values: Cookie, Authorization, Proxy-authorization, or a request which contains the NTLM or Negotiate header.

The policy name is _personalizedReq. The following is the policy rule:

```
HTTP.REQ.HEADER("Cookie").EXISTS || HTTP.REQ.HEADER("Authorization").EXISTS
 || HTTP.REQ.HEADER("Proxy-Authorization").EXISTS || HTTP.REQ.IS_NTLM_OR_NEGOTIATE
```

Default response policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the **_resBuiltinDefaults** policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.

   The policy name is **_uncacheableStatusRes**. The following is the policy rule:

   ```
   !((HTTP.RES.STATUS.EQ(200))|| (HTTP.RES.STATUS.EQ(304))|| (HTTP.RES.
   STATUS.BETWEEN(400,499))|| (HTTP.RES.STATUS.BETWEEN(300, 302))|| (HTTP.
   RES.STATUS.EQ(307))|| (HTTP.RES.STATUS.EQ(203)))
   ```

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.

   The compression module inserts the Vary: Accept_Encoding header. The name of this expression is **_uncacheableVaryRes**. The following is the policy rule:

   ```
   ((HTTP.RES.HEADER("Vary").EXISTS)&& ((HTTP.RES.HEADER("Vary").INSTANCE
   (1).LENGTH > 0)|| (!HTTP.RES.HEADER("Vary").STRIP_END\\_WS.SET_TEXT_MODE
   (IGNORECASE).eq("Accept-Encoding"))))
   ```

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.

The policy name is **_uncacheableCacheControlRes**. The following is the policy rule:

```
((HTTP.RES.CACHE\\_CONTROL.IS\\_PRIVATE)|| (HTTP.RES.CACHE\\_CONTROL.IS
\\_NO\\_CACHE)|| (HTTP.RES.CACHE\\_CONTROL.IS\\_NO\\_STORE)|| (HTTP.RES
.CACHE\\_CONTROL.IS\\_INVALID))
```

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.

   The policy name is **_cacheableCacheControlRes**. The following is the policy rule:

   ```
   ((HTTP.RES.CACHE_CONTROL.IS_PUBLIC)|| (HTTP.RES.CACHE_CONTROL.IS_MAX_AGE
   )|| (HTTP.RES.CACHE_CONTROL.IS_MUST_REVALIDATE)|| (HTTP.RES.CACHE_CONTROL
   .IS_PROXY_REVALIDATE)|| (HTTP.RES.CACHE_CONTROL.IS_S_MAXAGE))
   ```

5. Do not cache responses that contain a Pragma header.

   The name of the policy is **_uncacheablePragmaRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Pragma").EXISTS
   ```

6. Cache responses that contain an Expires header.

   The name of the policy is **_cacheableExpiryRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Expires").EXISTS
   ```

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.

   The name of the policy is **_imageRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWITH("
   image/")
   ```

   You can configure the following content group to work with this policy:

   ```
   add cache contentgroup nocookie -group -removeCookies YES
   ```

8. Do not cache a response that contains a Set-Cookie header.

   The name of the policy is **_ personalizedRes**. The following is the policy rule:

HTTP.RES.HEADER(“Set-Cookie”).EXISTS	HTTP.RES.HEADER(“Set-Cookie2”).EXISTS

Restrictions on default policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.
2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 byes.
3. Do not cache a response for a request that contains an If-Match header.
4. Do not cache a request that contains an If-Unmodified-Since header.

> **Note**
> This is different from the If-Modified-Since header.

1. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.
2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.
3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.
4. Do not cache the response if the caching module cannot parse its Cache-Control header.

Initial settings for the default content group

When you first enable integrated caching, the Citrix ADC appliance provides one predefined content group named the Default content group. For detailed information, see Default content group settings table.

Troubleshooting

September 14, 2021

If the integrated cache feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

For more information about the resources available for troubleshooting and sample configurations, see Resource for troubleshooting PDF file.

Front end optimization

September 14, 2021

> **Note:** Front end optimization is available if you have an Advanced or Premium Citrix ADC license and are running Citrix ADC release 10.5 or later.

The HTTP protocols that underlie web applications were originally developed to support the transmission and rendering of simple webpages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level.

The Citrix ADC front end optimization (FEO) feature addresses such issues and reduces the load time and render time of webpages by:

- Reducing the number of requests.
- Required for rendering each page.
- Reducing the number of bytes in page responses.

Simplifying and optimizing the content served to the client browser.

You can customize your FEO configuration to provide the best results for your users. Citrix ADCs support numerous web content optimizations for both desktop and mobile users. The following tables describe the front-end optimizations provided by the FEO feature, and the operations performed on different types of files.

Optimizations performed by the FEO feature

Web Optimization	Problem	What Citrix ADC FEO feature does	Benefits
Inlining	Client browsers often send multiple requests to servers for loading external CSS, images, and JavaScript associated with the webpage.	CSS inline, JavaScript inline, CSS combine	Loading the external CSS, images, and JavaScript inline with the HTML files improves page-rendering time. This optimization is beneficial for content that is viewed only once, and for mobile devices that have limited cache sizes.
Minification	Data fetched from servers includes inessential characters such as white spaces, comments, and newline characters. The time that browsers spend in processing such data creates website latency.	CSS minification, JavaScript minification, Removal of HTML comments	Minified files consume less bandwidth and avoid the latency caused by special processing.
Image optimization	Mobile browsers often have slow connection speeds and limited cache memory. Downloading the images on mobile clients consumes more bandwidth, processing time, and cache space, resulting in website latency.	JPEG optimization, CSS image inlining, **Image shrink-to** attributes, GIF to PNG conversion, HTML image inlining, WebP image conversion, JPEG, GIF, PNG to JPEG-XR image conversion	Reduces the image to the size indicated in the image tag by Citrix ADC, enabling client browsers to load images faster.

Web Optimization	Problem	What Citrix ADC FEO feature does	Benefits
Repositioning	Inefficient processing of external CSS, images, and JavaScript increases page-load time.	Image lazy loading, CSS move to Head, JavaScript move to end	Repositions HTML elements, to reduce rendering time for webpages and enable client browsers to load the objects faster.
Connection Management	Many browsers set limits on the number of simultaneous connections that can be established to a single domain. This can cause browsers to download webpage resources one at a time, resulting in higher browsers time.	Domain sharding	Overcomes the connection limitation, which improves page-rendering time by enabling client browsers to download more resources in parallel.

Web Optimizations on different file types:

Citrix ADC can perform web optimizations on CSS, images, Javascript, and HTML. For more information, see Web Optimizations PDF.

> **Note:**
> The front end optimization feature supports ASCII characters only. It does not support the Unicode character set.

How front end optimization works

After the Citrix ADC receives the response from the server:

1. Parses the contents of the page, creates an entry in the cache (wherever applicable), and applies the FEO policy.

   For example, a Citrix ADC can apply the following optimization rules:

   - Remove white spaces or comments present within a CSS or JavaScript.
   - Combine one or more CSS files to one file.

- Convert GIF image format to PNG format.

2. Rewrites the embedded objects and saves the optimized content in the cache, with a different signature than the one used for the initial cache entry.
3. For subsequent requests, fetches the optimized objects from the cache, not from the server, and forwards the responses to the client.

**

Remove extraneous information such as white spaces and comments.

The period during which the browser can use the cached resource without checking to see if fresh content is available on the server.

Configure front end optimization

Optionally, you can change the values of the front end optimization global settings. Otherwise, begin by creating actions that specify the optimization rules to be applied to the embedded objects.

After configuring actions, create policies, each with a rule specifying a type of request for which to optimize the response, and associate the actions with the policies.

> **Note:** The Citrix ADC evaluates front end optimization policies at request time only, not at response time.

To put the policies into effect, bind them to bind points. You can bind a policy globally, so that it applies to all traffic that flows through the Citrix ADC, or you can bind the policy to a load balancing or content switching virtual server of type HTTP or SSL. When you bind a policy, assign it a priority. A lower priority number indicates a higher value. The Citrix ADC applies the policies in the order of their priorities.

Prerequisites

Front end optimization requires the Citrix ADC integrated caching feature to be enabled. Also, you must perform the following integrated caching configurations:

- Allocate cache memory.
- Set the maximum response size and memory limit for a default cache content group.

For more information on configuring integrated caching, see Integrated Caching.

Note: The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

Configure front end optimization by using Citrix ADC command interface

At the command prompt, do the following:

1. Enable the front end optimization feature.

```
enable ns feature FEO
```

1. Create one or more front end optimization actions.

```
add feo action <name> [-imgShrinkToAttrib] [-imgGifToPng] ...
```

Example: To add a front end optimization action for converting images in GIF format to PNG format and to extend the cache expiry period:

```
add feo action allact -imgGifToPng -pageExtendCache
```

1. [Optional] Specify non-default values for front end optimization global settings.

```
set feo parameter [-cacheMaxage <integer>] [-JpegQualityPercent <integer>]
[-cssInlineThresSize <integer>] [-inlineJsThresSize <integer> [-inlineImgThresSize
 <integer>]
```

Example: To specify the cache maximum expiry period:

```
set feo parameter -cacheMaxage 10
```

1. Create one or more front end optimization policies.

```
add feo policy <name> <rule> <action>
```

Example: To add a front end optimization policy and associate it with the above specified allact action:

```
1 >add feo policy pol1 TRUE all act
2 >add feo policy pol1 "(HTTP.REQ.URL.CONTAINS(\"testsite\"))" allact1
3 <!--NeedCopy-->
```

1. Bind the policy to a load balancing or content switching virtual server, or bind it globally.

```
bind lb vserver <name> -policyName <string> -priority <num>
```

```
bind cs vserver <name> -policyName <string> -priority <num>
```

```
bind feo global <policyName> <priority> -type <type> <gotoPriorityExpression
>
```

Example: To apply the front end optimization policy to a virtual server named “abc”:

```
> bind lb vserver abc -policyName pol1 -priority 1 -type NONE
```

Example: To apply the front end optimization policy for all the traffic reaching the ADC:

```
> bind feo global pol1 100 -type REQ_DEFAULT
```

1. Save the configuration. save ns config

Configure front end optimization by using the GUI

1. Navigate to **Optimization** > **Front End Optimization** > **Actions**, and click **Add** and create a front end optimization action by specifying the relevant details.
2. [Optional] Specify the front end optimization global settings.
3. Navigate to **Optimization** > **Front End Optimization**, and on the right-pane, under Settings, click **Change Front End Optimization** settings and specify the front end optimization global settings.
4. Create a front end optimization policy.
5. Navigate to **Optimization** > **Front End Optimization** > **Policies**, click **Add** and create a front end optimization policy by specifying the relevant details.
6. Bind the policy to a load balancing or content switching virtual server.
   a) Navigate to **Optimization** > **Front End optimization** > **Policies**.
   b) Select a front end optimization policy and click **Policy Manager**.
   c) Under **Front End Optimization Policy Manager**, bind the front end optimization policy to a load balancing or content switching virtual server.

Verify front end optimization configuration

The dashboard utility displays summary and detailed statistics in tabular and graphic formats. You can view the FEO statistics to evaluate your FEO configuration.

Optionally, you can also display statistics for an FEO policy, including the number of select that the policy counter increments during the policy based FEO.

> **Note:**
> For more information about statistics and charts, see the Dashboard help on the Citrix ADC appliance.

View FEO statistics by using the CLI

At the command prompt, type the following commands to display a summary of FEO statistics, FEO policy select and details, and detailed FEO statistics, respectively:

- `stat feo` Note: The stat feo policy command displays statistics only for advanced FEO policies.
- `show feo policy name`
- `stat feo -detail`

View FEO statistics on Citrix ADC dashboard

In the dashboard GUI, you can:

- Select Front End Optimization to display a summary of `FEO` statistics.

- Click the **Graphical View** tab to display the rate of requests processed by the FEO feature.

Sample optimization:

Refer to the Sample PDF for some examples of content optimization actions that are applied on HTML content and the embedded objects within the HTML content.

Content accelerator

September 14, 2021

> **Important:**
>
> The content accelerator feature is no longer supported on the Citrix ADC appliance.

Content accelerator is a Citrix ADC feature that you can use in a Citrix ByteMobile T1100 deployment, to store data on a Citrix ByteMobile T2100 appliance.

Storing data on a T2100 appliance saves bandwidth and provides faster response times, because the Citrix ADC does not have to connect to the server for repeated requests of the same data.

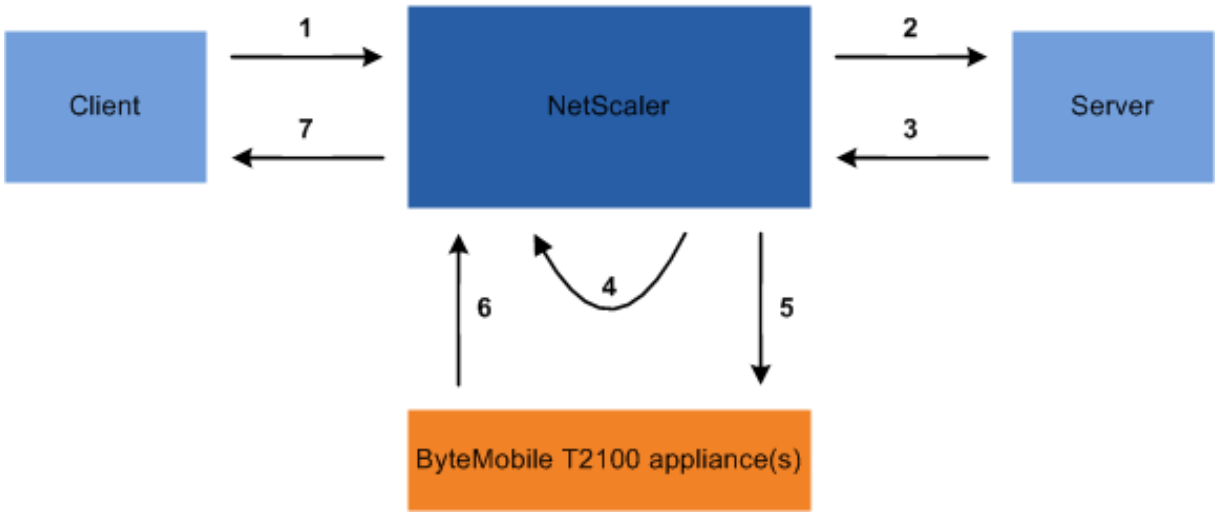
> **Note:** Content accelerator works with a Citrix ByteMobile Premium license. Contact customer support for more information and for obtaining the license.

How the content accelerator works

When a load balancing or content switching virtual server receives a client request, the Citrix ADC appliance evaluates a content accelerator policy that you have bound to the virtual server. The policy filters the requests to identify the ones to which to apply the content accelerator feature.

> **Note:**
>
> For HTTP requests, the content accelerator feature can serve partial content in response to single byte-range requests.

The following figure illustrates the operations that the appliance performs when a client request arrives at a virtual server configured to use the content accelerator feature:



The process flow is as follows:

1. Client sends request.
2. Citrix ADC forwards the request to the server.
3. Server responds with the predefined size of the response (specified by the accumResSize parameter of the add ca action command).
4. Citrix ADC computes a hash of the response sent by the server.
5. Citrix ADC looks up the hash on the T2100 appliance.
6. A successful lookup indicates that the data is available and the T2100 appliance sends the data to the Citrix ADC.

   > **Note:**
   > When the database lookup does not succeed, the appliance fetches the requested data from the server, and serves the data to the client and updates the data on the T2100 appliance.
   > The T2100 appliance can be configured to specify the number of requests for which to cache data.

7. Citrix ADC sends the response to the client.

Configure content accelerator

Before you configure the content accelerator feature, you must enable it on the Citrix ADC appliance.

You must configure the content accelerator feature to use one or more T2100 appliances. You must add each T2100 appliance as a service and bind these services to a load balancing virtual server that is dedicated for distributing the load between the configured T2100 appliances.

You must configure a content accelerator action to look up the data on the T2100 appliance. The action must specify the T2100 load balancing virtual server and the size of data (in KB) to be fetched from the server to calculate the hash.

The action must be bound to a content accelerator policy that defines the traffic on which to perform content acceleration. The content accelerator policy must be bound to a content switching or load balancing virtual server that receives client traffic. Alternatively, you can bind the policy globally to all applicable virtual servers.

To configure the content accelerator by using the command line interface

At the command prompt, do the following:

1. Enable the content accelerator feature.

   ```
   enable ns feature ca
   ```

2. Identify the T2100 appliances and add each as a service on the Citrix ADC appliance.

   ```
   add service <name> <IPAddress> <serviceType> <port>
   ```

   Example:

   ```
   > add service T2100-A 10.102.29.61 HTTP 30
   > add service T2100-B 10.102.29.62 HTTP 40
   > add service T2100-C 10.102.29.63 HTTP 50
   <!--NeedCopy-->
   ```

   > **Note:**
   > The services must be of type HTTP only.

3. Create a load balancing virtual server for the T2100 appliances. Specify the token load balancing method and the rule shown in the following syntax.

   ```
   add lb vserver <name> <serviceType> <IPAddress> <port> -lbMethod
      TOKEN -rule "http.req.url.after_str(\"/lookup/\") alt http.req.
      url.path.SKIP(1).PREFIX(64)"
   <!--NeedCopy-->
   ```

   Example:

   ```
   add lb vserver T2100-lbvserver HTTP 10.102.29.64 99 -lbMethod
      TOKEN -rule "http.req.url.after_str(\"/lookup/\") alt http.req.
      url.path.SKIP(1).PREFIX(64)"
   <!--NeedCopy-->
   ```

4. Bind the T2100 services to the load balancing virtual server that you created for them.

   ```
   bind lb vserver <name> <serviceName>
   ```

Example:

```
> bind lb vserver T2100-lbvserver T2100-A
> bind lb vserver T2100-lbvserver T2100-B
> bind lb vserver T2100-lbvserver T2100-C
<!--NeedCopy-->
```

5. Define a content accelerator action.

   ```
   add ca action <name> accumResSize <KBytes> -lbvserver <string> -type lookup
   ```

   Example:

   ```
   > add ca action ca_action1 -type lookup -lbvserver T2100-lbvserver -accumResSize 60
   ```

6. Define a content accelerator policy.

   ```
   add ca policy <name> -rule <expression> -action <name>
   ```

   Example:

   To create a content accelerator policy that caches all video formats.

   ```
   > add ca policy ca_mp4_pol -rule ns_video -action ca_action1
   ```

   where ns_video is a built-in expression.

7. Bind the content accelerator policy to either a virtual server that receives traffic or globally to the Citrix ADC system.

   ```
   bind lb vserver <name> -policyName <string>
   ```

   ```
   bind cs vserver <name> -policyName <string>
   ```

   ```
   bind ca global -policyName <string> -priority <num> -type <type>
   ```

   Example: To apply the content accelerator policy to a virtual server named “traf_rec”

   ```
   bind lb vserver traf_rec -policyName ca_mp4_pol
   ```

   Example: To apply the content accelerator policy for all traffic reaching the Citrix ADC.

   ```
   bind ca global -policyName ca_mp4_pol -priority 100 -type RES_DEFAULT
   ```

8. Save the configuration.

   ```
   save ns config
   ```

Configuring content accelerator by using the GUI

1. Navigate to **System** > **Settings** > **Configure Advanced Features** and select **Content Accelerator**.

2. Create a service for each of the T2100 appliances.
   a) Navigate to **Traffic Management** > **Load Balancing** > **Services**.
   b) Click **Add** and specify the relevant details. In the **Server** field, make sure you specify the IP address of the T2100 appliance. In the **Protocol** field select HTTP.
3. Create a virtual server and bind the T2100 services to it.
   a) Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
   b) Click **Add** and specify the relevant details.
   c) In the **Method and Persistence** tab, specify the Method as **Token**.
   d) In the **Policies** tab, specify the rule as http.req.url.after_str("/lookup/") alt http.req.url.path.SKIP(1).PRE
   e) In the **Services** tab, select the T2100 services that you want to bind to the virtual server.
4. Create a content accelerator action.
   a) Navigate to **Optimization** > **Content Accelerator** > **Actions**.
   b) Specify the relevant details.
5. Create a content accelerator policy.
   a) Navigate to **Optimization** > **Content Accelerator** > **Policies**.
   b) Click **Add**, specify the policy rule, and associate the content accelerator action.
6. Bind the content accelerator policy globally or to a virtual server.
   a) Navigate to **Optimization** > **Content Accelerator**.
   b) Under the **Content Accelerator Policy Manager** [REQUEST] or Content Accelerator Policy Manager [RESPONSE] sections, bind the content accelerator policy globally or to a virtual server.

Media classification

September 14, 2021

Understanding the type of traffic in the network helps network administrators to manage bandwidth consumption for optimal network performance. The media classification mode monitors and displays the statistics of media traffic going through the Citrix ADC appliance.

With this mode enabled, a network administrator can collect stats showing the amount of data accessed, and the types of devices from which the media files have been accessed. The Citrix ADC appliance also supports byte-range requests in this mode.

Currently the Citrix ADC appliance can monitor and display statistics for the following media file types:

Media	File type
Microsoft Smooth Streaming	Video
Apple Live Streaming	Video

Media	File type
Audio Data Transport Stream (ADTS)	Audio
Advanced Audio Coding (AAC)	Audio
Flash Video (FLV)	Audio and Video
3GP	Audio and Video

The appliance can display stats for the following devices:

Device Platform	Device Type
iOS	iPad and iPod
Android	Mobiles and tablets
Laptop or Desktop	Windows laptop and desktop computers
Others	Other mobile devices (mobiles and tablets)

The network administrators can check the following stats counters to know the amount of data accessed through the Citrix ADC appliance for various media traffic types.

Media File Name	Stats Counter
Microsoft Smooth Streaming	`mcmssmthstrmvid`—This counter records the total number of Microsoft Smooth Streaming videos served by the Citrix ADC appliance; `Mcmssmthstrvidpl`—This counter records the total number of Microsoft Smooth Streaming video playlists served by the Citrix ADC appliance; `Mcmssmthstrmvidbytes`—This counter records the total number of data bytes served for Microsoft Smooth Streaming media traffic on the Citrix ADC appliance; `Mcmssmthstrmplvidbytespl`—This counter records the total number of Microsoft Smooth Streaming playlist bytes served by the Citrix ADC appliance.

Media File Name	Stats Counter
Apple Live Streaming	mccaplelivestrmngvid—This counter records the total number of Apple Live Streaming videos served by the Citrix ADC appliance. Mccapplelivestrmngvidpl—This counter records the total number of Apple Live Streaming video playlists served by the Citrix ADC appliance. Mcapplelivestreamingvidbytes—This counter records the total number of data bytes served for Apple Live Streaming media traffic on the Citrix ADC appliance. Mcapplelivestreamingplaylistvidbytespl—This counter records the total number of Apple Live Playlist bytes served by the Citrix ADC appliance.
Audio Data Transport Stream (ADTS)	mcadtsaudio—This counter records the total number of ADTS audio clips served by the Citrix ADC appliance. Mcadtsaudiobytes—This counter records the total number of data bytes served for ADTS media traffic on the Citrix ADC appliance.
Advanced Audio Coding (AAC)	Mcaacaudio—This counter records the total number of AAC audio clips served by the Citrix ADC appliance. Mcaacaudiobytes—This counter records the total number of data bytes served for AAC media traffic on the Citrix ADC appliance.
Flash Video (FLV)	Mcflvvid—This counter records the total number of flash videos served by the Citrix ADC appliance. Mcflvvidbytes—This counter records the total number of data bytes served for flash videos on the Citrix ADC appliance.
3GP	mc3gpvidbytes—This counter records the total number of data bytes served for 3GP media traffic on the Citrix ADC appliance.

The Citrix ADC appliance detects media file types by their signatures in the *initial body bytes* of the responses. For example, the initial body bytes for an mp4 file have the following signature in the response:

```
**....ftypmp42** ....isommp42....moov...lmvhd.....c.\!.c.\!..
```

The Citrix ADC appliance detects the client device type by the *user agent string* that the client device includes in the HTTP GET request. For example, a window phone using a UC browser has the following user agent string in the HTTP GET request:

```
User-Agent: **UCWEB**/2.0 (**Windows**; U; wds 8.10; en-US; HTC; 8X by HTC)
U2/1.0.0
```

Enable media classification

By default, media classification is disabled on the Citrix ADC appliance. You have to enable the mode before using it.

To enable media classification by using the command line interface

At the command prompt, type:

```
enable ns mode Mediaclassification
```

To enable media classification by using the GUI

Enable media classification on Citrix ADC appliance

Navigate to **System** > **Settings** > **Configure Modes** and select **Media Classification**.

To view media traffic statistics on the Citrix ADC appliance

Navigate to **Optimization** and click **Media Classification** to view the media traffic statistics.

Verify media classification statistics

You can view the media traffic statistics in the dashboard utility or using the command line interface. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

> **Note**
> For more information about statistics and charts, see the Dashboard help on your Citrix ADC appliance.

To View media classification statistics by using the command line interface

At the command prompt, type one of the following commands to display a summary of media classification statistics, display detailed statistics, or clear the display:

```
stat Mediaclassification
```

```
stat Mediaclassification -detail

stat Mediaclassification -clearstats
```

To view Media Classification statistics on the Dashboard

In the **Dashboard** utility, you can display the following types of media classification statistics:

1. Select **Media Classification** to display a summary of the media traffic statistics.
2. To display detailed media traffic statistics, click the **Details**.
3. To clear the media traffic statistics, click **Clear**.

Reputation

September 14, 2021

Citrix offers reputation based security. Using reputation assessment to determine the risk of processing requests, you can take actions such as blocking or dropping certain requests to improve the performance of your application.

The Citrix ADC IP reputation feature uses IP reputation checks to prevent Zero day attacks and provide protection against malicious sources associated with web attacks, phishing activity, or web scanning.

For more details, see IP Reputation.

IP Reputation

October 25, 2021

IP reputation is a tool that identifies IP addresses that send unwanted requests. Using the IP reputation list you can reject requests that are coming from an IP address with a bad reputation. Optimize Web Application Firewall performance by filtering requests that you do not want to process. Reset, drop a request, or even configure a responder policy to take a specific responder action.

Following are some attacks that you can prevent by using IP Reputation:

- **Virus Infected personal computers**. (home PCs) are the single biggest source of Spam on the internet. IP Reputation can identify the IP address that is sending unwanted requests. IP reputation can be especially useful for blocking large scale DDoS, DoS, or anomalous SYN flood attacks from known infected sources.
- **Centrally managed and automated botnet**. Attackers have gained popularity for stealing passwords, because it doesn't take long when hundreds of computers work together to crack

your password. It is easy to launch botnet attacks to figure out passwords that use commonly used dictionary words.

- **Compromised web-server**. Attacks are not as common because awareness and server security have increased, so hackers and spammers look for easier targets. There are still web servers and online forms that hackers can compromise and use to send spam (such as viruses and porn). Such activity is easier to detect and quickly shut down, or block with a reputation list such as SpamRats.
- **Windows Exploits**. (such as Active IPs offering or distributing malware, shell code, rootkits, worms, or viruses).
- **Known spammers and hackers**.
- **Mass e-mail marketing campaigns**.
- **Phishing Proxies** (IP addresses hosting phishing sites, and other fraud such as ad click fraud or gaming fraud).
- **Anonymous proxies** (IPs providing proxy and anonymization services including The Onion Router aka TOR).

A Citrix ADC appliance uses **Webroot** as the service provider for a dynamically generated malicious IP database and the metadata for those IP addresses. Metadata might include geolocation details, threat category, threat count, and so on. The Webroot threat Intelligence engine receives real-time data from millions of sensors. It automatically and continuously captures, scans, analyses and scores the data, using advanced machine learning and behavioral analysis. Intelligence about a threat is continually updated.

The Citrix ADC appliance validates an incoming request for its bad reputation using the Webroot's uses IP reputation database. The database has a huge collection of IP address classified based IP threat categories. Following are the IP threat categories and its description.

- Spam Sources. Spam Sources includes Tunneling Spam messages through proxy, anomalous SMTP activities, Forum Spam activities.
- Windows Exploits. Windows exploit category includes active IP Address offering or distributing malware, shell code, rootkits, worms or viruses
- Web Attacks. Web attacks category includes cross site scripting, iFrame injection, SQL injection, cross domain injection, or domain password brute force attack
- Botnets. Botnet category includes Botnet C&C channels, and infected zombie machine controlled by Bot master
- Scanners. Scanners category includes all reconnaissance such as probes, host scan, domain scan and password brute force attack
- Denial of Service. Denial of Services category includes DOS, DDOS, anomalous sync flood, anomalous traffic detection
- Reputation. Deny access from IP addresses currently known to be infected with malware. This category also includes IPs with average low Webroot Reputation Index score. Enabling this category prevents access from sources identified to contact malware distribution points

- Phishing. Phishing category includes IP addresses hosting phishing sites, other kind of fraud activities such as Ad Click Fraud or Gaming fraud
- Proxy. Proxy category includes IP addresses providing proxy and def services.
- Mobile Threats. Mobile Threat category includes IP addresses of malicious and unwanted mobile applications. This category leverages data from the Webroot mobile threat research team.
- Tor Proxy. Tor proxy category includes IP addresses acting as exit nodes for the Tor Network. Exit nodes are the last point along the proxy chain and make a direct connection to the originator's intended destination.

When a threat is detected anywhere in the network, the IP address is flagged as malicious and all appliances connected to the network are immediately protected. The dynamic changes in the IP addresses are processed with high speed and accuracy by using advanced machine learning.

As stated in the data sheet from Webroot, the Webroot's sensor network identifies many key IP threat types, including spam sources, Windows exploits, botnets, scanners, and others. (See the flow diagram on the data sheet.)

The Citrix ADC appliance uses an `iprep` client process to get the database from Webroot. The `iprep` client uses the HTTP GET method to get the absolute IP list from Webroot for the first time. Later, it checks delta changes once every 5 minutes.

> **Important:**
>
> - Make sure that the Citrix ADC appliance has Internet access and DNS is configured before you use the IP Reputation feature.
> - To access the Webroot database, the Citrix ADC appliance must be able to connect to **api.bcti.brightcloud.com** on **port 443**. Each node in the HA or cluster deployment gets the database from Webroot and must be able to access this Fully Qualified Domain Name (FQDN).
> - Webroot hosts its reputation database in AWS currently. Therefore, Citrix ADC must be able to resolve AWS domains for downloading the reputation db. Also, the firewall must be open for AWS domains.
>
> **Note:**
>
> Each packet engine requires at least 4 GB to function properly when the IP Reputation feature is enabled.

Advanced policy Expressions. Configure the IP Reputation feature by using advanced policy expressions (default syntax expressions) in the policies bound to supported modules, such as Web Application Firewall and responder. Following are two examples showing expressions that can be used to detect whether the client IP address is malicious.

1. **CLIENT.IP.SRC.IPREP_IS_MALICIOUS**: This expression evaluates to TRUE if the client is included in the malicious IP list.

2. **CLIENT.IP.SRC.IPREP_THREAT_CATEGORY (CATEGORY)**: This expression evaluates to TRUE if the client IP is malicious IP and is in the specified threat category.

Following are the possible values for the threat category:

SPAM_SOURCES, WINDOWS_EXPLOITS, WEB_ATTACKS, BOTNETS, SCANNERS, DOS, REPUTATION, PHISHING, PROXY, NETWORK, CLOUD_PROVIDERS, MOBILE_THREATS, TOR_PROXY.

> **Note:**
>
> The IP reputation feature checks both source and destination IP addresses. It detects malicious IPs in the header. If the PI Expression in a policy can identify the IP address, the IP reputation check determines whether it is malicious.

IPRep log message. The `/var/log/iprep.log` file contains useful messages that capture information about communication with the Webroot database. The information can be about the credentials used during Webroot communication, failure to connect with Webroot, information included in an update (such as the number of IP addresses in the database).

Creating a blocklist or allowlist of IPs using a policy data set. You can maintain an allow list to allow access to specific IP addresses that are blocklisted in the Webroot database. You can also create a customized block list of IP addresses to supplement the Webroot reputation check. These lists can be created by using a policy **data set**. A data set is a specialized form of pattern set that is ideally suited for IPv4 address matching. To use data sets, first create the data set and bind IPv4 addresses to it. When configuring a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

To create an allow list of addresses to treat as exceptions during IP reputation evaluation:

- Configure the policy so that the PI expression evaluates to False even if an address in the allow list is listed as malicious by Webroot (or any service provider).

Enabling or disabling IP reputation. IP reputation is a part of the general reputation feature, which is license based. When you enable or disable the reputation feature, it enables or disables IP Reputation.

General procedure. Deploying IP reputation involves the following tasks

- Verify that the license installed on the Citrix ADC appliance has IP reputation support. Premium and standalone application firewall licenses support the IP reputation feature.
- Enable the IP reputation and application firewall features.
- Add an application firewall profile.
- Add an application firewall policy using the PI expressions to identify the malicious IP addresses in the IP Reputation database.
- Bind the application firewall policy to an appropriate bind point.
- Verify that any request received from a malicious address gets logged in the `ns.log` file to show that the request was processed as specified in the profile.

Configure the IP reputation feature using the CLI

At the command prompt, type:

- `enable feature reputation`
- `disable feature reputation`

The following examples show how you can add an application firewall policy using the PI expression to identify malicious addresses. You can use the built-in profiles, or add a profile, or configure an existing profile to invoke the desired action when a request matches a policy match.

Examples 3 and 4 show how to create a policy dataset to generate a block list or an allow list of IP addresses.

Example 1:

The following command creates a policy that identifies malicious IP addresses and block the request if a match is triggered:

```
add appfw policy pol1 CLIENT.IP.SRC.IPREP_IS_MALICIOUS APPFW_BLOCK
```

Example 2:

The following command creates a policy that uses the reputation service to check the client IP address in the `X-Forwarded-For` header and reset the connection if a match is triggered.

```
> add appfw policy pol1 "HTTP.REQ.HEADER(\"X-Forwarded-For\").TYPECAST_IP_ADDRESS_AT
.IPREP_IS_MALICIOUS"APPFW_RESET**
```

Example 3:

The following example shows how to add a list to add exceptions that allow specified IP addresses:

```
> add policy dataset Allow_list1 ipv4
> bind policy dataset Allow_list1 10.217.25.17 -index 1
> bind policy dataset Allow_list1 10.217.25.18 -index 2
```

Example 4:

The following example shows how to add the customized list to flag specified IP addresses as malicious:

```
> add policy dataset Block_list1 ipv4
> bind policy dataset Block_list1 10.217.31.48 -index 1
> bind policy dataset Block_list1 10.217.25.19 -index 2
```

Example 5:

The following example shows a policy expression to block the client IP in the following conditions:

- It matches an IP address configured in the customized Block_list1 (example 4)
- It matches an IP address listed in the Webroot database unless relaxed by inclusion in the Allow_list1 (example 3).

```
1 > add appfw policy "Ip_Rep_Policy" "((CLIENT.IP.SRC.IPREP_IS_MALICIOUS
     || CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Block_list1\")) && !
      (CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Allow_list1\")))"
     APPFW_BLOCK
2 <!--NeedCopy-->
```

Using Proxy server:

If the Citrix ADC appliance does not have direct access to the internet and is connected to a proxy, configure the IP Reputation client to send requests to the proxy.

At the command prompt, type:

```
set reputation settings -proxyServer <proxy server ip> -proxyPort <proxy server port>
```

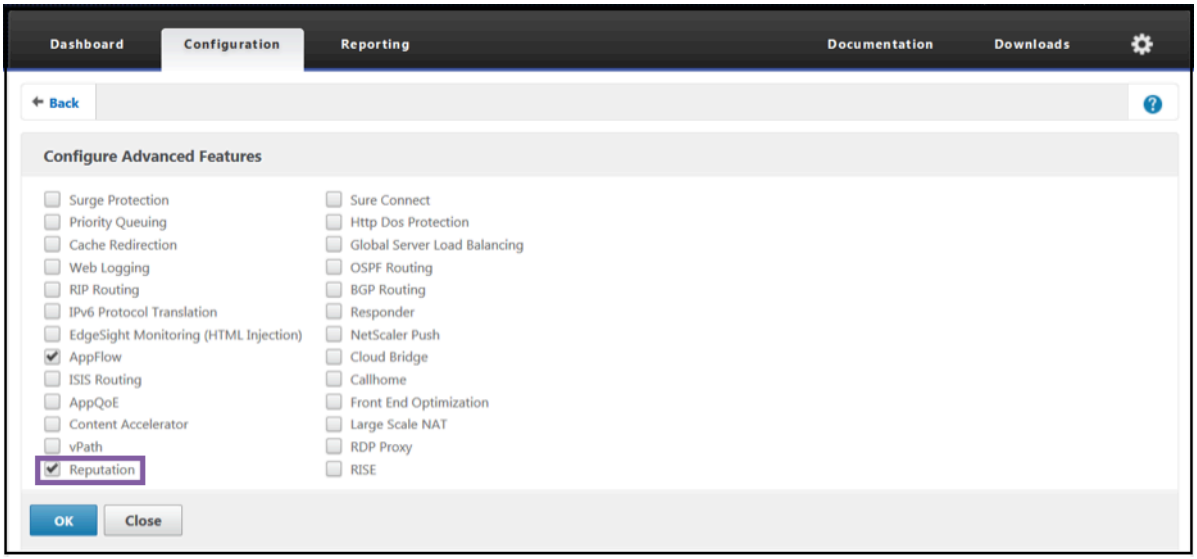
Example:

```
> set reputation settings proxyServer 10.102.30.112 proxyPort 3128
> set reputation settings -proxyServer testproxy.citrite.net -proxyPort 3128
> unset reputation settings -proxyserver -proxyport
> sh reputation settings
```

> **Note:**
>
> The Proxy Server IP can be an IP address or a fully qualified domain name (FQDN).

Configure IP reputation by using Citrix ADC GUI

1. Navigate to the **System > Settings**. In the **Modes and Features** section, click the link to access the **Configure Advanced Features** pane and enable the **Reputation** check box.
2. Click **OK**.

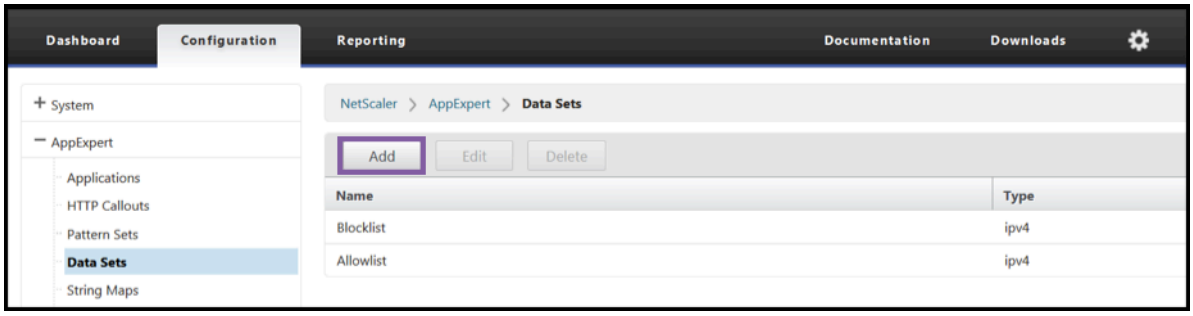


To configure a proxy server by using the Citrix ADC GUI

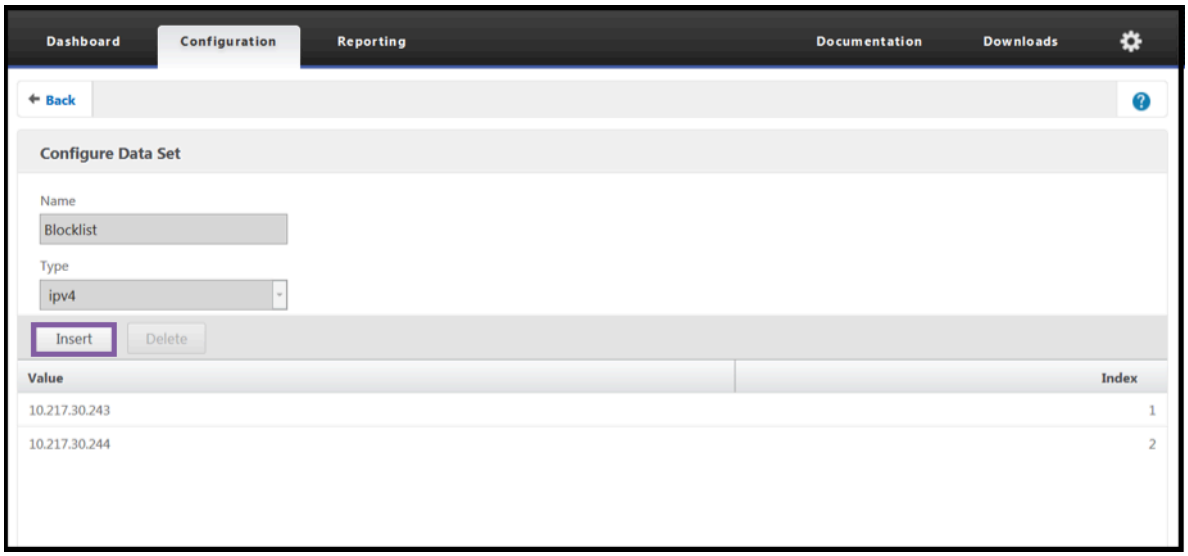
1. On the configuration tab, navigate to **Security > Reputation**. Under **Settings**, click **Change Reputation Settings** to configure a proxy server. You can also enable or disable the reputation feature. **Proxy Server** can be an IP address or a fully qualified domain name (FQDN). **Proxy port** accepts values between [1–65535].

Create an allow list and a block list of client IP addresses using the GUI

1. On the **Configuration** tab, navigate to **AppExpert > Data Sets**.
2. Click **Add**.



- In the **Create Data Set** (or **Configure Data set**) pane, provide a meaningful name for the list of the IP addresses. The name must reflect the purpose of the list.
- Select **Type** as **IPv4**.
- Click **Insert** to add an entry.



- In the **Configure Policy dataset binding** pane, add an IPv4 format IP address in the Value input box.
- Provide an index.
- Add a comment that explains the purpose of the list. This step is optional, but is recommended because a descriptive comment is helpful in managing the list.

Similarly, you can create a block list and add the IP addresses that are to be considered malicious.

Also see, Pattern sets and data sets for more details regarding using data sets and configuring default syntax policy expressions.

Configure an application firewall policy by using the Citrix ADC GUI

1. On the **Configuration** tab, navigate to **Security > Application Firewall > Policies > Firewall**. Click **Add** to add a policy using the PI expressions to use IP reputation.

You can also use the Expression editor to build your own policy expression. The list shows preconfigured options that are useful for configuring an expression using the threat categories.

Highlights

- Quickly and accurately stop bad traffic at the network's edge from known malicious IP addresses posing different types of threats. You can block the request without parsing the body.
- Dynamically configure IP reputation functionality for multiple applications.
- Secure your network against data breach without a performance penalty, and consolidate protections onto a single services fabric using fast and easy deployments.
- You can do IP Reputation checks on source and destination IPs.
- You can also inspect the headers to detect malicious IPs.
- IP reputation check is supported in both forward proxy and reverse proxy deployments.
- The IP Reputation process connects with Webroot and updates the database every 5 minutes.
- Each node in the High Availability (HA) or Cluster deployment gets the database from Webroot.
- The IP reputation data is shared across all partitions in admin-partition deployments.
- You can use an AppExpert data set to create lists of IP addresses to add exceptions for IPs blocklisted in the Webroot database. You can also create your own customized block list to designate specific IPs as malicious.
- The iprep.db file is created in the `/var/nslog/iprep` folder. Once created, it is not deleted even if the feature is disabled.
- When the reputation feature is enabled, the Citrix ADC Webroot database is downloaded. After that, it is updated every 5 minutes.
- The Webroot database version is 1.
- The minor version gets updated every day. The update version is incremented after every 5 minutes and is reset back to 1 when the minor version is incremented.
- PI expressions enable you to use IP reputation with other features, such as responder and rewrite.
- The IP addresses in the database are in decimal notation.

Debugging tips

- If you cannot see the reputation feature in the GUI, verify that you have the right license.
- Monitor the messages in `var/log/iprep.log` for debugging.
- **Webroot connectivity**: If you see the `ns iprep: Not able to connect/resolve WebRoot` message, make sure that the appliance has internet access and DNS is configured.
- **Proxy server**: If you see the `ns iprep: iprep_curl_download: 88 curl_easy_perform failed. Error code: 5 Err msg:couldnt resolve proxy name` message, make sure that the proxy server configuration is accurate.
- **IP Reputation feature not working**: The IP Reputation process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.
- **Database download**: If the IP DB data download is failing after enabling the IP Reputation fea-

ture, the following error is seen in the logs.

```
iprep: iprep_curl_download:86 curl_easy_perform failed. Error code:7 Err
msg:Couldn't connect to server
```

Solution: Allow the out-bound traffic to the following URLs or configure a proxy to resolve the issue.

```
1 localdb-ip-daily.brightcloud.com:443
2 localdb-ip-rtu.brightcloud.com:443
3 api.bcti.brightcloud.com:443
4 <!--NeedCopy-->
```

SSL offload and acceleration

September 14, 2021

A Citrix ADC appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client's perspective, the transaction seems to be directly with the server. A Citrix ADC configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS Citrix ADC appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM).

All Citrix ADC appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect and SafeNet external HSMs. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

Note: FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled Citrix ADC appliance.

SSL offloading configuration

September 14, 2021

To configure SSL offloading, you must enable SSL processing on the Citrix ADC appliance and configure an SSL based virtual server. The virtual server will intercept SSL traffic, decrypt the traffic, and forward it to a service that is bound to the virtual server. To secure time-sensitive traffic, such as media streaming, you can configure a DTLS virtual server. To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.

Enable SSL

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing. However, they do not work until SSL processing is enabled.

Enable SSL processing by using the CLI

At the command prompt, type:

```
enable ns feature ssl

show ns feature
<!--NeedCopy-->
```

Example:

```
enable ns feature SSL
 Done
show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  OFF
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 .
 .
 .
 9)     SSL Offloading                  SSL                 ON
 .
 .
 .
 24)    NetScaler Push                  push                OFF
 Done
<!--NeedCopy-->
```

Enable SSL processing by using the GUI

Navigate to **System > Settings** and, in the **Modes and Features** group, click **Configure Basic Features**, and click **SSL Offloading**.

Configure services

On the Citrix ADC appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

Add a service by using the CLI

At the command prompt, type the following commands to add a service and verify the configuration:

```
add service <name> (<IP> | <serverName>) <serviceType> <port>
show service <serviceName>
<!--NeedCopy-->
```

Example:

```
add service sslsvc 198.51.100.225 SSL 443

Done

sh ssl service sslsvc

            Advanced SSL configuration for Back-end SSL Service sslsvc:
            DH: DISABLED
            DH Private-Key Exponent Size Limit: DISABLED    Ephemeral
                RSA: DISABLED
            Session Reuse: ENABLED          Timeout: 300 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Server Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1:
                ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
            Send Close-Notify: YES
            Strict Sig-Digest Check: DISABLED
```

```
22              Zero RTT Early Data: ???
23              DHE Key Exchange With PSK: ???
24              Tickets Per Authentication Context: ???
25
26              ECC Curve: P_256, P_384, P_224, P_521
27
28      1)      Cipher Name: DEFAULT_BACKEND
29              Description: Default cipher list for Backend SSL session
30       Done
31  <!--NeedCopy-->
```

Modify or remove a service by using the CLI

To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.

To remove a service, use the rm service command, which accepts only the <name> argument.

```
1  rm service <servicename>
2  <!--NeedCopy-->
```

Example:

```
1  rm service sslsvc
2  <!--NeedCopy-->
```

To modify a service, use the set service command, select any parameter, and change it's setting.

```
1  set service <name> (<IP> | <serverName>) <serviceType> <port>
2  <!--NeedCopy-->
```

Example:

```
1  set service sslsvc 198.51.100.225 SSL 443
2  <!--NeedCopy-->
```

Configure a service by using the GUI

Navigate to **Traffic Management > Load Balancing > Services**, create a service, and specify the protocol as SSL.

SSL virtual server configuration

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the Citrix ADC appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

Note: The SSL virtual server is marked as down on the Citrix ADC appliance until a valid certificate / key pair and at least one service are bound to it. An SSL based virtual server is a load balancing virtual server of protocol type SSL or SSL_TCP. The load balancing feature must be enabled on the Citrix ADC appliance.

Add an SSL-based virtual server by using the CLI

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

```
add lb vserver <name> (serviceType) <IPAddress> <port>
show ssl vserver <name>
<!--NeedCopy-->
```

Example:

```
add lb vserver sslvs SSL 192.0.2.240 443
Done

sh ssl vserver sslvs

            Advanced SSL configuration for VServer sslvs:
            DH: DISABLED
            DH Private-Key Exponent Size Limit: DISABLED    Ephemeral
                RSA: ENABLED          Refresh Count: 0
            Session Reuse: ENABLED          Timeout: 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            HSTS: DISABLED
            HSTS IncludeSubDomains: NO
            HSTS Max-Age: 0
            SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1:
                ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
```

```
                Push Encryption Trigger: Always

Modify or remove an SSL-based virtual server by using the CLI

To modify the load balancing properties of an SSL virtual server, use the `set lb vserver` command. The set command is similar to the `add lb vserver` command, except that you enter the name of an existing virtual server. To modify the **SSL** properties of an SSL-based virtual server, use the `set ssl vserver` command. For more information, see the "SSL virtual server parameters" section later in this page.

To remove an SSL virtual server, use the `rm lb vserver` command, which accepts only the `<name>` argument.

Configure an SSL-based virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, create a virtual server, and specify the protocol as SSL.

Bind services to the SSL virtual server

The ADC appliance forwards decrypted SSL data to servers in the network. To forward data, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Typically, the link between the ADC appliance and the physical server is secure. Therefore, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to end-encryption by encrypting data transfer between the appliance and the server. For details, see Configure SSL offloading with end to end encryption.

Note: Enable the load balancing feature on the ADC appliance before you bind services to the SSL based virtual server.

Bind a service to a virtual server by using the CLI

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

```
bind lb vserver <name> <serviceName>
show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
bind lb vserver sslvs sslsvc
     Done

sh lb vserver sslvs

            sslvs (192.0.2.240:443) - SSL       Type: ADDRESS
            State: DOWN[Certkey not bound]
            Last state change was at Wed May  2 11:43:04 2018
            Time since last state change: 0 days, 00:13:21.150
            Effective State: DOWN

```

Unbind a service from a virtual server by using the CLI

At the command prompt, type the following command:

```
unbind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
unbind lb vserver sslvs sslsvc
     Done
<!--NeedCopy-->
```

Bind a service to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and click the **Load Balancing Virtual Server Service Bindings** tile under the **Services and Service Groups** section.
3. In the **Load Balancing Virtual Server Service Binding** page, click **Add Bindings** tab, click **Click to select** under **Select Service**, and select the check box next to the service to be bound.
4. Click **Select** and click **Bind**.

Configure a server name indication (SNI) virtual server for secure hosting of multiple sites

Virtual hosting is used by web servers to host more than one domain name with the same IP address. The appliance supports hosting of multiple secure domains by offloading SSL processing from the web servers using transparent SSL services or virtual server-based SSL offloading. However, when multiple websites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the appliance cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling SNI on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. The ADC appliance compares this host name to the common name

and, if it does not match, compares it to the subject alternative name (SAN). If the name matches, the appliance presents the corresponding certificate to the client.

A wildcard SSL certificate helps enable SSL encryption on multiple subdomains if the same organization controls these domains and the second-level domain name is the same. For example, a wildcard certificate issued to a sports network using the common name "*.sports.net" can be used to secure domains, such as "login.sports.net" and "help.sports.net". It cannot secure the "login.ftp.sports.net" domain.

Note:
On an ADC appliance, only domain name, URL, and email ID DNS entries in the **SAN** field are compared.

You can bind multiple server certificates to a single SSL virtual server or transparent service using the -SNICert option. The virtual server or service issues these certificates if SNI is enabled on the virtual server or service. You can enable SNI at any time.

Bind multiple server certificates to a single SSL virtual server by using the CLI

At the command prompt, type the following commands to configure SNI and verify the configuration:

```
set ssl vserver <vServerName>@ [-SNIEnable ( ENABLED | DISABLED )]

bind ssl vserver <vServerName>@ -certkeyName <string> -SNICert

show ssl vserver <vServerName>
<!--NeedCopy-->
```

To bind multiple server certificates to a transparent service by using the CLI, replace `vserver` with service and `vservername` with service name in the preceding commands.

Note: Create the SSL service with the `-clearTextPort 80` option.

Bind multiple server certificates to a single SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open an SSL virtual server and, in **Certificates**, select **Server Certificate**.
3. Add a certificate or select a certificate from the list, and click **Server Certificate for SNI**.
4. In **Advanced Settings**, select **SSL Parameters**.
5. Click **SNI Enable**.

Support for SNI on the back-end service

> **Note**: SNI is not supported on a DTLS back-end service.

The Citrix ADC appliance supports Server Name Indication (SNI) at the back end. That is, the common name is sent as the server name in the client hello to the back-end server for successful completion of the handshake. This support helps meet federal system integrator customer security requirements. Also, SNI provides the advantage of using only one port instead of opening hundreds of different IP addresses and ports on a firewall.

Federal system integrator customer security requirements include support for Active Directory Federation Services (ADFS) 3.0 in 2012R2 and WAP servers. To meet this requirement, support for SNI at the back end on a Citrix ADC appliance is required.

> **Note:**
>
> For SNI to work, the server name in the client hello must match the host name configured on the back-end service that is bound to an SSL virtual server. For example, if the host name of the back-end server is www.mail.example.com, the SNI-enabled back-end service must be configured with the server name as https://www.mail.example.com. And this host name must match the server name in the client hello.

Support for dynamic SNI on the back-end service

The Citrix ADC appliance supports dynamic SNI on the back-end TLS connections. That is, the appliance learns the SNI in the client connection and uses it in the server-side connection. You no longer need to specify a common name in the SSL service, service group, or profile. The common name received in the SNI extension of the Client Hello message is forwarded to the back-end SSL connection.

Earlier, you had to configure static SNI on SSL services, service groups, and SSL profiles. As a result, only the configured static SNI extension was sent to the server. If a client needed to access multiple domains at the same time, the ADC appliance was not able to send the SNI received from the client to the back-end service. Instead, it sent the static common name that was configured. Now, if the back-end server is configured for multiple domains, the server can respond with the correct certificate based on the SNI received in the Client Hello message from the appliance.

Point to Note:

- SNI must be enabled on the front end and the correct SNI certificate bound to the SSL virtual server. If you don't enable SNI on the front end, the SNI information is not passed to the back end.
- When server authentication is enabled, the server certificate is verified by the CA certificate and the common name/SAN entries in the server certificate are matched with the SNI. Therefore, the CA certificate must be bound to the service.
- Reuse of back-end connection and SSL session is based on SNI when dynamic SNI is enabled.

SSL monitors do not send SNI when dynamic SNI is enabled. For SNI based probing, attach a back-end profile on which static SNI is configured to the SSL monitors. The monitor must be configured with

the same custom header as SNI.

Configure SNI on the back-end service by using the CLI

At the command prompt, type:

```
add service <name>  <IP>  <serviceType>  <port>

add lb vserver <name>  <IPAddress> <serviceType>  <port>

bind lb vserver <name> <serviceName>

set ssl service <serviceName> -SNIEnable ENABLED -commonName <string>

set ssl profile <name> -SNIEnable ENABLED
<!--NeedCopy-->
```

Example:

```
    add service service_ssl 198.51.100.100 SSL 443

    add lb vserver ssl-vs 203.0.113.200 SSL 443

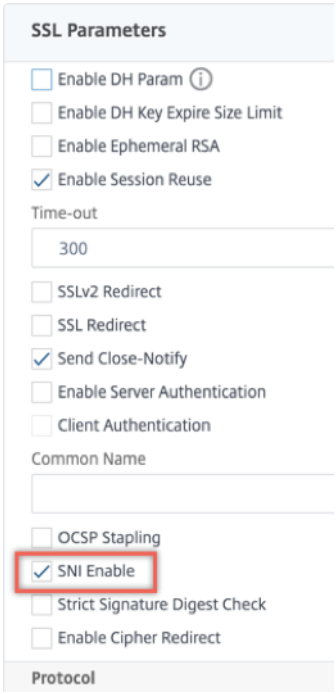
    bind lb vserver ssl-vs service_ssl

    set ssl service service_ssl -SNIEnable ENABLED  - commonName www.
       example.com

    set ssl profile sslprof -SNIEnable ENABLED
<!--NeedCopy-->
```

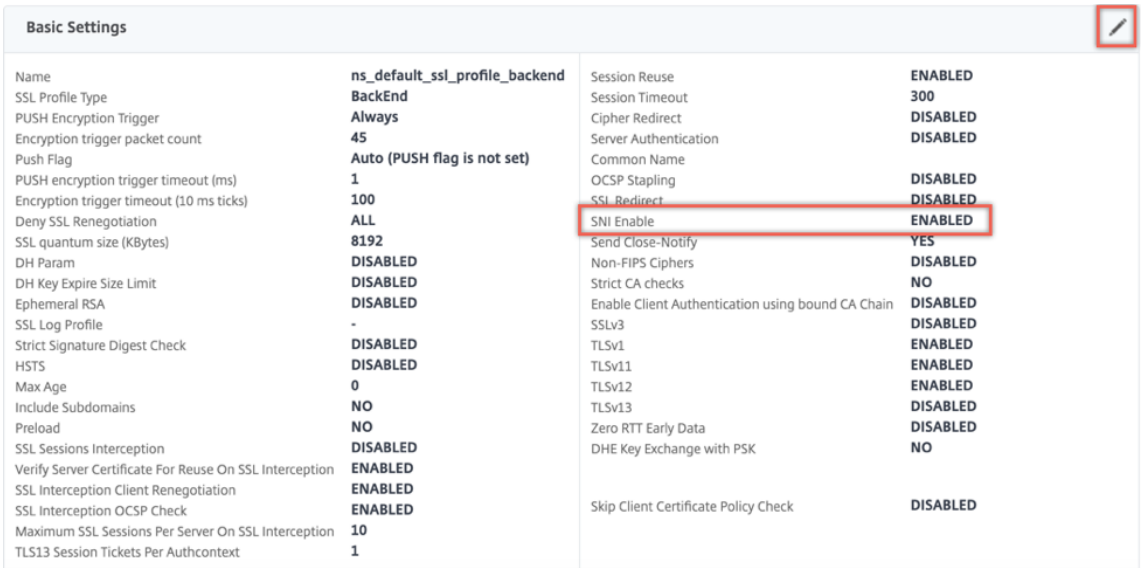
Configure SNI on the back-end service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Select an SSL service, and in **Advanced Settings**, click **SSL Parameters**.
3. Click **SNI Enable**.



Configure SNI on the SSL profile by using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Click **Add**.
3. In **Basic Settings**, select **SNI Enable**.



4. Click **OK**.

Bind a secure monitor to an SNI-enabled back-end service

You can bind secure monitors of type HTTP, HTTP-ECV, TCP, or TCP-ECV to the back-end services and service groups that support SNI. However, the monitor probes do not send the SNI extension if dynamic SNI is enabled. To send SNI probes, enable static SNI in the back-end SSL profile and bind the profile to the monitor. Set the custom header in the monitor to the server name that is sent as the SNI extension in the client hello of the monitor probe.

Configure and bind a secure monitor to an SNI-enabled back-end service by using the CLI

At the command prompt, type:

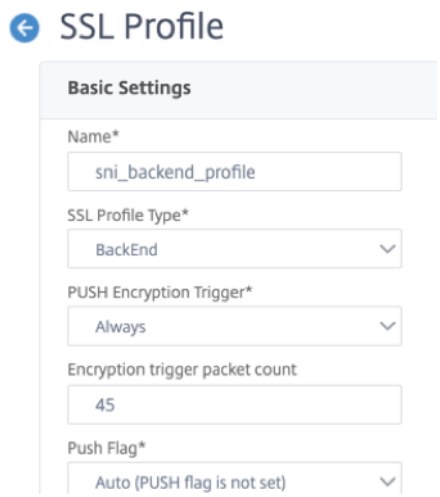
```
add lb monitor <monitorName> <type> -secure YES
add ssl profile <name> -sslProfileType BackEnd
set lb monitor <monitorName> <type> -customHeaders <string> -sslprofile
    <backend ssl profile>
set ssl profile <name> -sniEnable ENABLED -commonName <string>
bind service <name> -monitorName <string>
<!--NeedCopy-->
```

Example:

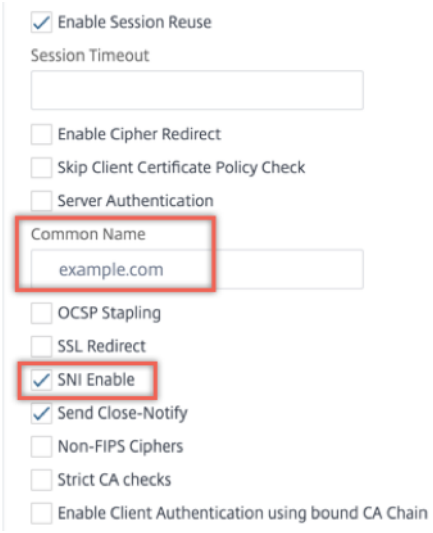
```
add ssl profile sni_backend_profile -sslProfileType BackEnd
set ssl profile sni_backend_profile -sniEnable ENABLED -commonName
   example.com
add lb monitor http-ecv-mon HTTP-ECV -secure YES
set monitor http-ecv-mon HTTP-ECV -customHeaders "Host: example.com\r\n
   " -sslprofile sni_backend_profile
bind service ssl_service  - monitorName http-ecv-mon
<!--NeedCopy-->
```

Configure and bind a secure monitor to an SNI enabled back-end service by using the GUI

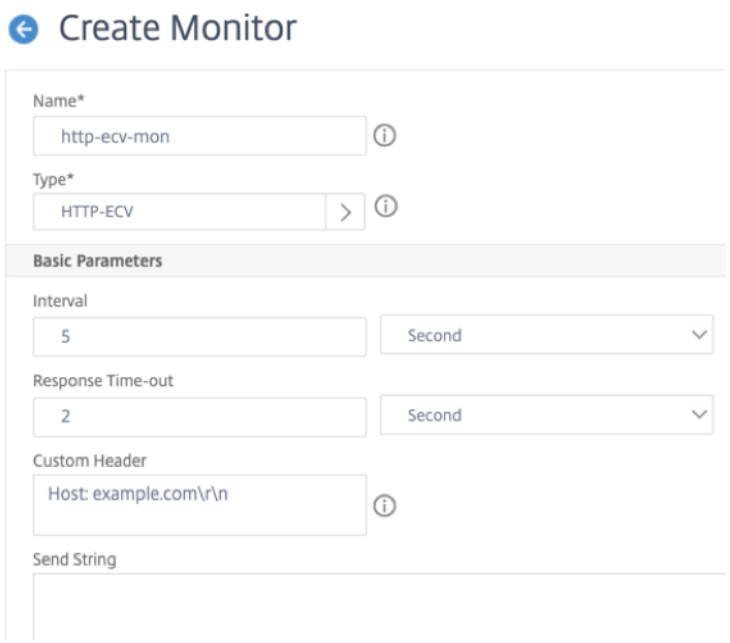
1. Navigate to **System > Profiles > SSL Profiles**.
2. Click **Add**.
3. Specify a name for the profile and in **SSL Profile Type**, select **Backend**.



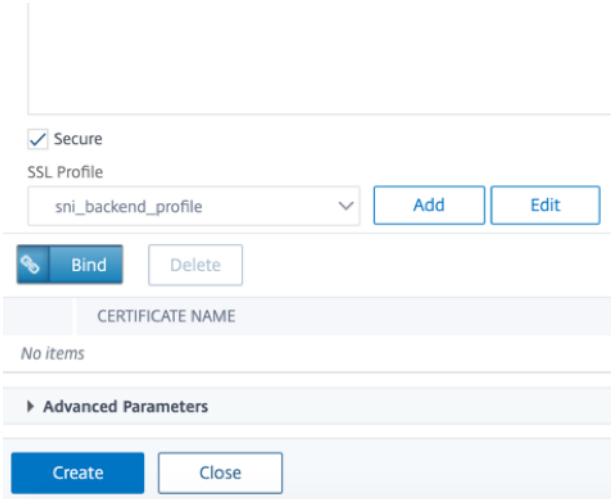
4. Specify the common name (same as host header) and select **SNI Enable**.



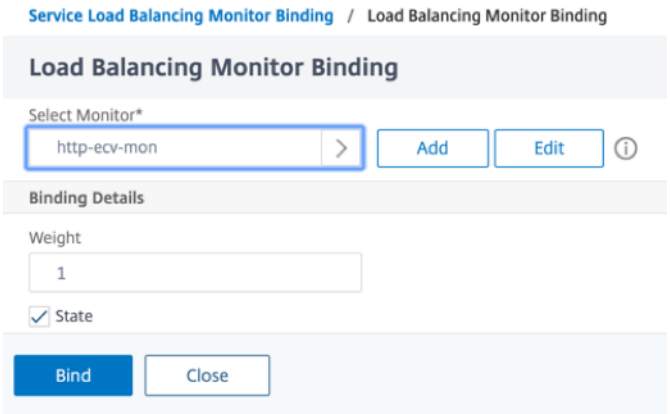
5. Click **OK**.
6. Navigate to **Traffic Management > Load Balancing > Monitor**.
7. Click **Add**.
8. Specify a name for the monitor. In **Type**, select HTTP, HTTP-ECV, TCP, or TCP-ECV.
9. Specify a **Custom Header**.



10. Select **Secure**.
11. In **SSL Profile**, select the back-end SSL profile created in the preceding steps.
12. Click **Create**.



13. Navigate to **Traffic Management > Load Balancing > Services**.
14. Select an SSL service and click **Edit**.
15. In **Monitors**, click **Add Binding**, select the monitor created in the preceding steps, and click **Bind**.



Configure and bind a secure monitor to an SNI-enabled back-end service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitor**.
2. Add a monitor of type **HTTP-ECV** or **TCP-ECV**, and specify a **Custom Header**.
3. Select **Create**.
4. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
5. Select an SSL service and click **Edit**.
6. In **Monitors**, click **Add Binding**, select the monitor created in step 3, and click **Bind**.

Add or update a certificate-key pair

> **Notes:**
>
> If you don't have an existing certificate and key, see Create a certificate.
>
> To create an ECDSA certificate-key pair, click Create an ECDSA certificate-key pair.
>
> From build 41.x, certificate names of up to 63 characters are supported.
>
> From release 13.0 build 79.x, password protected certificate-key pairs are always added successfully. Earlier, if strong password option was enabled on a Citrix ADC appliance, sometimes the password protected certificate-key pairs were not added. However, the certificate-key configuration is lost if you downgrade to an earlier build. Also, in the NITRO API response for certificate-key pairs, the `passplain` variable is sent instead of the `passcrypt` variable.

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server's public key, which is available through the server's certificate. Decryption requires the corresponding private key. The password of the private key used while adding an SSL certificate-key pair is saved using a unique encryption key for each Citrix ADC appliance.

The ADC appliance offloads SSL transactions from the server. Therefore, the server's certificate and private key must be present on the appliance, and the certificate must be paired with its correspond-

ing private key. This certificate-key pair must be bound to the virtual server that processes the SSL transactions.

Note: The default certificate on a Citrix ADC appliance is 2048 bits. In earlier builds, the default certificate was 512 bits or 1024 bits. After upgrading to release 11.0, you must delete all your old certificate-key pairs starting with `"ns-"`, and then restart the appliance to automatically generate a 2048-bit default certificate.

Both the certificate and the key must be in local storage on the Citrix ADC appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.

Important: Certificates and keys are stored in the /nsconfig/ssl directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the Citrix ADC appliance. The Citrix ADC FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.

Only RSA keys are supported on Citrix ADC appliances.

Set the notification period and enable the expiry monitor to issue a prompt before the certificate expires.

The Citrix ADC appliance supports the following input formats of the certificate and the private-key files:

- PEM - Privacy Enhanced Mail
- DER - Distinguished Encoding Rule
- PFX - Personal Information Exchange

The software automatically detects the format. Therefore, you are no longer required to specify the format in the inform parameter. If you do specify the format (correct or incorrect), the software ignores it. The format of the certificate and the key file must be the same.

Note: A certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384 (supported only on the front end)
- SHA-512 (supported only on the front end)

An MPX appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service

- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A VPX virtual appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

> **Note**
>
> A Citrix ADC SDX appliance supports certificates of 512 or more bits. Each Citrix ADC VPX instance hosted on the appliance supports the preceding certificate sizes for a VPX virtual appliance. However, if an SSL chip is assigned to an instance, that instance supports the certificate sizes supported by an MPX appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

```
add ssl certKey <certkeyName> -cert <string>[(-key <string> [-password
    ]) | -fipsKey <string>] [-inform ( DER | PEM )] [<passplain>] [-
    expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <
    positive_integer>]]

show ssl certKey [<certkeyName>]
<!--NeedCopy-->
```

Example:

```
add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -
    password ssl -expiryMonitor ENABLED -notificationPeriod 30
 Done
Note: For FIPS appliances, replace -key with -fipskey

show ssl certKey sslckey
        Name: sslckey           Status: Valid,   Days to expiration
            :8418
        Version: 3
        Serial Number: 01
        Signature Algorithm: md5WithRSAEncryption
```

```
        Issuer:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
        Validity
                Not Before: Jul 15 02:25:01 2005 GMT
                Not After : Nov 30 02:25:01 2032 GMT
        Subject:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.server.com
        Public Key Algorithm: rsaEncryption
        Public Key size: 2048
 Done
<!--NeedCopy-->
```

Update or remove a certificate-key pair by using the CLI

To modify the expiry monitor or notification period in a certificate-key pair, use the `set ssl certkey` command. To replace the certificate or key in a certificate-key pair, use the `update ssl certkey` command. The `update ssl certkey` command has an extra parameter for overriding the domain check. For both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the `rm ssl certkey` command, which accepts only the `<certkeyName>` argument.

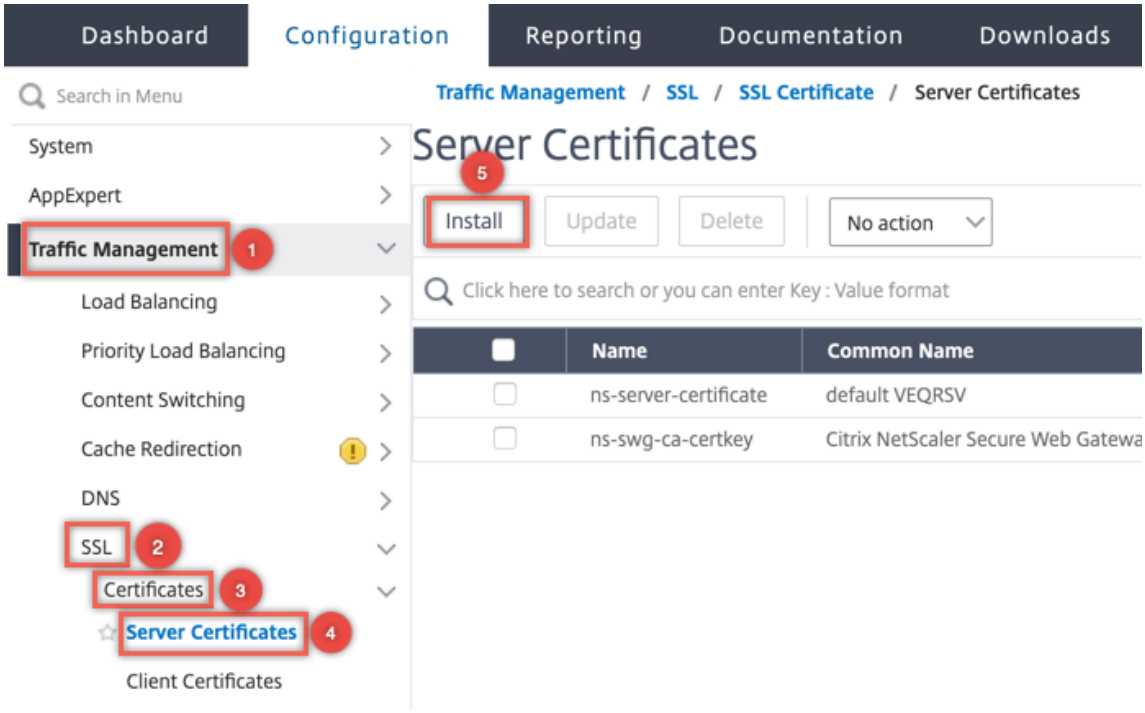
Example:

```
set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED )
       [-notificationPeriod <positive_integer>]]

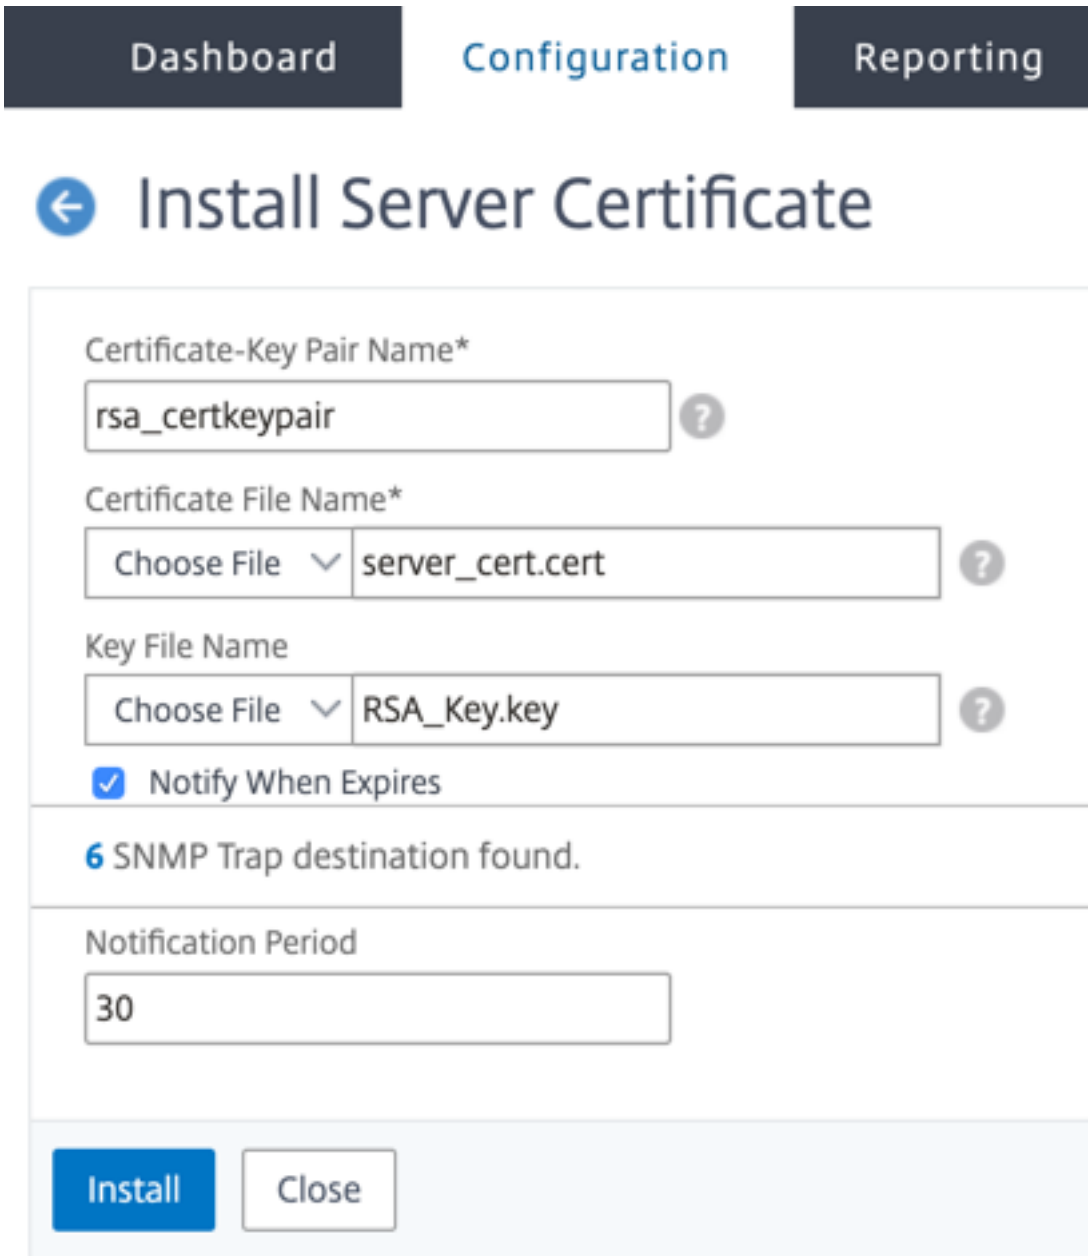
update ssl certKey <certkeyName> [-cert <string> [-password]] [-key
       <string> | -fipsKey <string>] [-inform <inform>] [-noDomainCheck
          ]
<!--NeedCopy-->
```

Add or update a certificate-key pair by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates > Server**.



2. Enter the values for the following parameters and click **Install**.
   - Certificate-Key Pair Name - Name for the certificate and private-key pair.
   - Certificate File Name - Signed certificate received from the certificate authority.
   - Key File Name - Name of and, optionally, path to the private-key file that is used to form the certificate-key pair.



Bind the certificate-key pair to the SSL virtual server

Important: Link any intermediate certificates to this certificate before binding the certificate to an SSL virtual server. For information about linking certificates, see Create a chain of certificates.

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

Use a valid, existing SSL certificate that you have uploaded to the Citrix ADC appliance. As an alternative for testing purposes, create your own SSL certificate on the appliance. Intermediate certificates

created by using a FIPS key on the appliance cannot be bound to an SSL virtual server.

During the SSL handshake, in the certificate request message during client authentication, the server lists the distinguished names (DN) of all the certificate authorities (CA) bound to the server. The server accepts a client certificate only from this list. If you do not want the DN name of a specific CA certificate to be sent to the SSL client, set the `skipCA` flag. This setting indicates that the particular CA certificate's distinguished name must not be sent to the SSL client.

For details on how to create your own certificate, see Managing Certificates.

Note: Citrix recommends that you use only valid SSL certificates issued by a trusted certificate authority.

Bind an SSL certificate-key pair to a virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

```
1 -  bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName
     > -CA -skipCAName
2 -  show ssl vserver <vServerName>
3 <!--NeedCopy-->
```

Example:

```
1 bind ssl vs vs1 -certkeyName cert2 -CA -skipCAName
2  Done
3 sh ssl vs vs1
4
5  Advanced SSL configuration for VServer vs1:
6
7  DH: DISABLED
8
9  Ephemeral RSA: ENABLED Refresh Count: 0
10
11  Session Reuse: ENABLED Timeout: 120 seconds
12
13  Cipher Redirect: DISABLED
14
15  SSLv2 Redirect: DISABLED
16
17  ClearText Port: 0
18
19  Client Auth: DISABLED
20
```

```
 SSL Redirect: DISABLED

```

Unbind an SSL certificate-key pair from a virtual server by using the CLI

If you try to unbind a certificate-key pair from a virtual server by using the `unbind ssl certKey <certkeyName>` command, an error message appears. The error appears because the syntax of the command has changed. At the command prompt, type the following command:

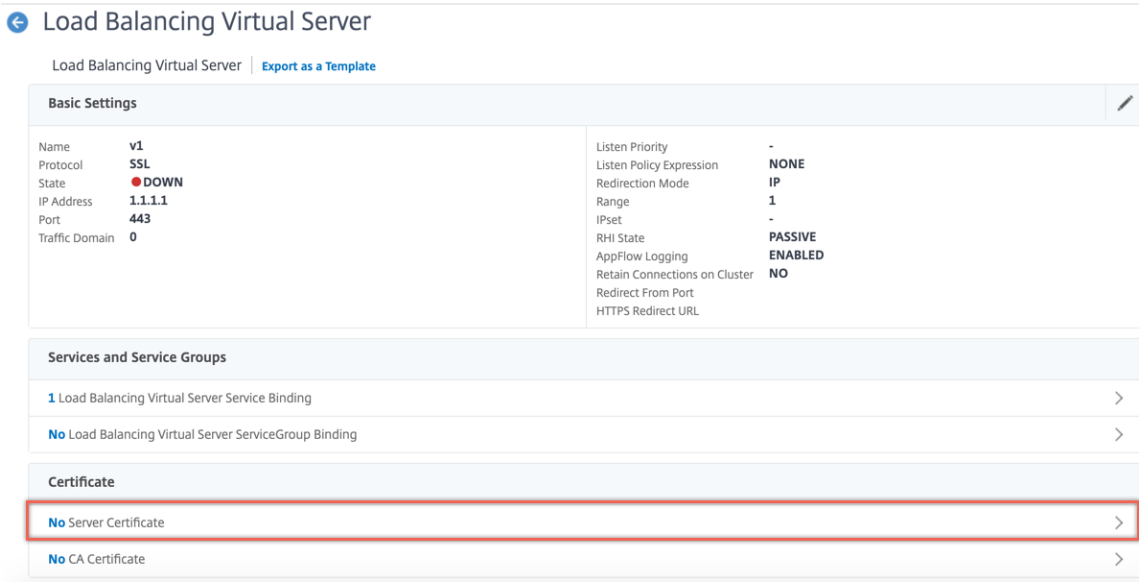
```
unbind ssl vserver <vServerName> -certkeyName <string>
<!--NeedCopy-->
```

Example:

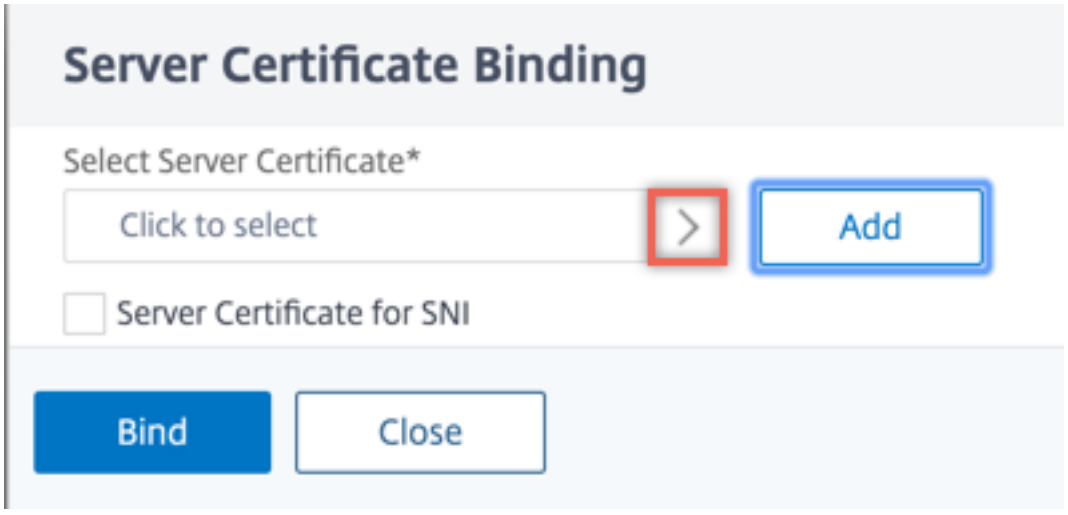
```
unbind ssl vserver vssl -certkeyName sslckey
<!--NeedCopy-->
```

Bind an SSL certificate-key pair to a virtual server by using the GUI

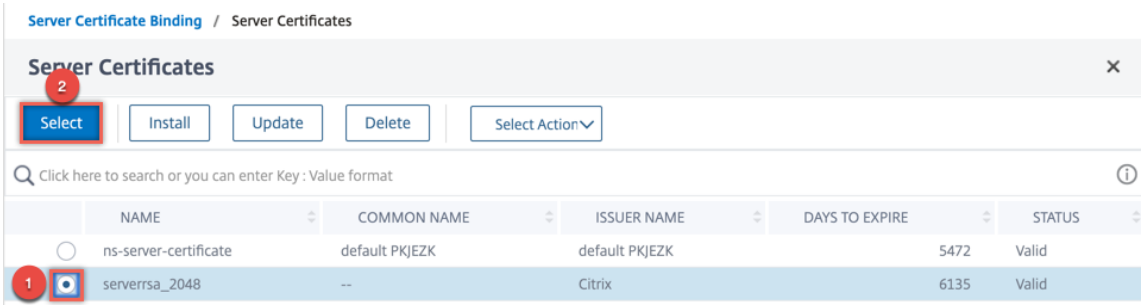
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and open an SSL virtual server. Click inside the **Certificate** section.



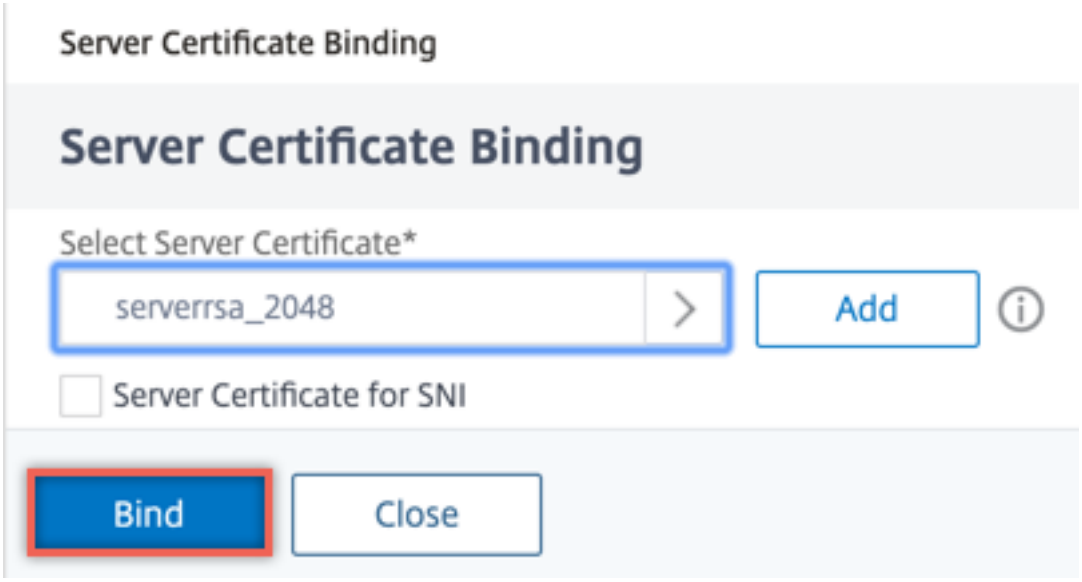
2. Click the arrow to select the certificate-key pair.



3. Select the certificate-key pair from the list.



4. Bind the certificate-key pair to the virtual server. To add a server certificate as an SNI certificate, select **Server Certificate for SNI**.



SSL virtual server parameters

Set the advanced SSL configuration for an SSL virtual server. You can also set many of these parameters in an SSL profile. For information about the parameters that can be set in an SSL profile, see SSL profile parameters.

Set SSL virtual server parameters by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName>@ [-clearTextPort <port>] [-dh ( ENABLED |
    DISABLED ) -dhFile <string>] [-dhCount <positive_integer>][-
    dhKeyExpSizeLimit ( ENABLED | DISABLED )] [-eRSA ( ENABLED |
    DISABLED) [-eRSACount <positive_integer>]] [-sessReuse ( ENABLED |
    DISABLED )[-sessTimeout <positive_integer>]] [-cipherRedirect (
    ENABLED | DISABLED ) [-cipherURL <URL>]] [-sslv2Redirect ( ENABLED |
     DISABLED )[-sslv2URL <URL>]] [-clientAuth ( ENABLED | DISABLED ) [-
```

```
    clientCert ( Mandatory | Optional )]] [-sslRedirect ( ENABLED |
    DISABLED )][-redirectPortRewrite ( ENABLED | DISABLED )] [-ssl2 (
    ENABLED | DISABLED )] [-ssl3 ( ENABLED | DISABLED )] [-tls1 (
    ENABLED | DISABLED )] [-tls11 ( ENABLED | DISABLED )] [-tls12 (
    ENABLED | DISABLED )][-tls13 ( ENABLED | DISABLED )] [-SNIEnable (
    ENABLED | DISABLED )][-ocspStapling ( ENABLED | DISABLED )] [-
    pushEncTrigger <pushEncTrigger>] [-sendCloseNotify ( YES | NO )] [-
    dtlsProfileName <string>] [-sslProfile <string>] [-HSTS ( ENABLED |
    DISABLED )][-maxage <positive_integer>] [-IncludeSubdomains ( YES |
    NO )][-strictSigDigestCheck ( ENABLED | DISABLED )] [-
    zeroRttEarlyData (ENABLED | DISABLED )] [-
    tls13SessionTicketsPerAuthContext <positive_integer>] [-
    dheKeyExchangeWithPsk ( YES | NO )]
<!--NeedCopy-->
```

Diffie-Hellman (DH) parameters

To use ciphers on the appliance that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the appliance. Configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the CLI, type: sh cipher DH.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to **Traffic Management > SSL > Cipher Groups**, and double-click **DH**.

For details on how to enable DH key exchange, see Generate a Diffie-Hellman (DH) key.

Configure DH parameters by using the CLI

At the command prompt, type the following commands to configure DH parameters and verify the configuration:

```
- `set ssl vserver <vserverName> -dh <Option> -dhCount <
    RefreshCountValue> -filepath <string>
- show ssl vserver <vServerName>`
<!--NeedCopy-->
```

Example:

```
set ssl vserver vs-server -dh ENABLED  -dhFile /nsconfig/ssl/ns-server.
    cert -dhCount 1000
Done

show ssl vserver vs-server

```

```
6               Advanced SSL configuration for VServer vs-server:
7               DH: ENABLED
8               Ephemeral RSA: ENABLED          Refresh Count: 1000
9               Session Reuse: ENABLED          Timeout: 120 seconds
10              Cipher Redirect: DISABLED
11              SSLv2 Redirect: DISABLED
12              ClearText Port: 0
13              Client Auth: DISABLED
14              SSL Redirect: DISABLED
15              Non FIPS Ciphers: DISABLED
16              SNI: DISABLED
17              OCSP Stapling: DISABLED
18              HSTS: DISABLED
19              HSTS IncludeSubDomains: NO
20              HSTS Max-Age: 0
21              SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2:
                    ENABLED  TLSv1.2: ENABLED
22
23      1)      Cipher Name: DEFAULT
24              Description: Predefined Cipher Alias
25  Done
26  <!--NeedCopy-->
```

Configure DH parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable DH Param**, and specify a refresh count and file path.

Ephemeral RSA

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object or resource, you need to disable ephemeral RSA key exchange.

By default, this feature is enabled on the Citrix ADC appliance, with the refresh count set to zero (infinite use).

Note:

The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted. It is reused later when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

Configure ephemeral RSA by using the CLI

At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

```
set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <
   positive_integer>
show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
 Done

show ssl vserver vs-server

        Advanced SSL configuration for VServer vs-server:
        DH: DISABLED
        Ephemeral RSA: ENABLED          Refresh Count: 1000
        Session Reuse: ENABLED          Timeout: 120 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        OCSP Stapling: DISABLED
        HSTS: DISABLED
        HSTS IncludeSubDomains: NO
        HSTS Max-Age: 0
        SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2:
           ENABLED  TLSv1.2: ENABLED

1)      Cipher Name: DEFAULT
        Description: Predefined Cipher Alias
 Done
<!--NeedCopy-->
```

Configure ephemeral RSA by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Ephemeral RSA**, and specify a refresh count.

Session reuse

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the Citrix ADC appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that the server can support.

Configure session reuse by using the CLI

At the command prompt, type the following commands to configure session reuse and verify the configuration:

```
set ssl vserver <vServerName> -sessReuse ( ENABLED | DISABLED ) -
   sessTimeout <positive_integer>
show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
 Done

show ssl vserver vs-ssl

        Advanced SSL configuration for VServer vs-ssl:
        DH: DISABLED
        Ephemeral RSA: ENABLED          Refresh Count: 1000
        Session Reuse: ENABLED          Timeout: 600 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        OCSP Stapling: DISABLED
        HSTS: DISABLED
        HSTS IncludeSubDomains: NO
        HSTS Max-Age: 0
```

```
21          SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2:
                ENABLED  TLSv1.2: ENABLED
22
23  1)      CertKey Name: Auth-Cert-1       Server Certificate
24
25  1)      Cipher Name: DEFAULT
26          Description: Predefined Cipher Alias
27   Done
28  <!--NeedCopy-->
```

Configure session reuse by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Session Reuse**, and specify a time for which to keep the session active.

SSL protocol settings

The Citrix ADC appliance supports the SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols. Each of these protocols can be set on the appliance as required by your deployment and the type of clients that connect to the appliance.

TLS protocol versions 1.0, 1.1, and 1.2 are more secure than older versions of the TLS/SSL protocol. However, to support legacy systems, many TLS implementations maintain backward compatibility with the SSLv3 protocol. In an SSL handshake, the highest protocol version common to the client and the SSL virtual server configured on the Citrix ADC appliance is used.

In the first handshake attempt, a TLS client offers the highest protocol version that it supports. If the handshake fails, the client offers a lower protocol version. For example, if a handshake with TLS version 1.1 is not successful, the client attempts to renegotiate by offering the TLSv1.0 protocol. If that attempt is unsuccessful, the client reattempts with the SSLv3 protocol. A “man in the middle” (MITM) attacker can break the initial handshake and trigger renegotiation with the SSLv3 protocol, and then exploit a vulnerability in SSLv3. To mitigate such attacks, you can disable SSLv3 or not allow renegotiation using a downgraded protocol. However, this approach might not be practical if your deployment includes legacy systems. An alternative is to recognize a signaling cipher suite value (TLS_FALLBACK_SCSV) in the client request.

A TLS_FALLBACK_SCSV value in a client hello message indicates to the virtual server that the client has previously attempted to connect with a higher protocol version and that the current request is a fallback. If the virtual server detects this value, and it supports a version higher than the one indicated by the client, it rejects the connection with a fatal alert. The handshake succeeds if one of the following conditions is met:

- TLS_FALLBACK_SCSV value is not included in the client hello message.
- The protocol version in the client hello is the highest protocol version supported by the virtual server.

Configure SSL protocol support by using the CLI

At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

```
set ssl vserver <vServerName> -ssl2 ( ENABLED | DISABLED ) -ssl3 (
    ENABLED | DISABLED ) -tls1 ( ENABLED | DISABLED ) -tls11 ( ENABLED |
     DISABLED ) -tls12 ( ENABLED | DISABLED )

show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
Done

sh ssl vs vs-ssl

        Advanced SSL configuration for VServer vs-ssl:
            DH: DISABLED
            Ephemeral RSA: ENABLED                              Refresh
               Count: 0
            Session Reuse: ENABLED                                Timeout
               : 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            SSLv2: DISABLED        SSLv3: ENABLED    TLSv1.0: ENABLED
               TLSv1.1: ENABLED  TLSv1.2: ENABLED
            Push Encryption Trigger: Always
            Send Close-Notify: YES
            1 bound certificate:

     1)     CertKey Name: mycert  Server Certificate
            1 configured cipher:

```

```
25      1)      Cipher Name: DEFAULT
26              Description: Predefined Cipher Alias
27
28  Done
29  <!--NeedCopy-->
```

Configure SSL protocol support by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select a protocol to enable.

Close-notify

A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see the "Global SSL parameters" section later in this page.

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unsetting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

Configure close-notify at the entity level by using the CLI

At the command prompt, type any of the following commands to configure the close-notify feature and verify the configuration:

1. To configure at the virtual server level, type:

```
1  set ssl vserver <vServerName> -sendCloseNotify ( YES | NO )
2  show ssl vserver <vServerName>
3  <!--NeedCopy-->
```

1. To configure at the service level, type:

```
1  set ssl service <serviceName> -sendCloseNotify ( YES | NO )
2  show ssl service <serviceName>
3  <!--NeedCopy-->
```

1. To configure at the service group level, type:

```
set ssl serviceGroup <serviceGroupName> -sendCloseNotify ( YES | NO )
show ssl serviceGroup <serviceGroupName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver sslvsvr -sendCloseNotify YES

Done
<!--NeedCopy-->
```

Configure the close-notify feature at the entity level by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Send Close-Notify**.

Global SSL parameters

Advanced customization of your SSL configuration addresses specific issues. You can use the `set ssl parameter` command or the configuration utility to specify the following:

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.
  Note: The time that you specify applies only if you use the `set ssl vserver` command or the configuration utility to set timer-based encryption.
- NDCPP compliance certificate check – Applies when the appliance acts a client (back-end connection). During certificate verification, ignore the common name if SAN is present in the SSL certificate.
- Enable a heterogeneous cluster of Cavium chip based appliances, such as MPX 14000, and Intel Coleto chip based appliances, such as MPX 15000 appliances with a different number of packet engines. (Support added in release 13.0 build 47.x).
- Enable secure renegotiation at the back end (Support added from release 1.0 build 58.x).
- Adaptive SSL traffic control (Support added in release 13.0 build 58.x).

Configure global SSL parameters by using the CLI

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:

```
set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <
    positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout
    <positive_integer>] [-sendCloseNotify (YES | NO)] [-
    encryptTriggerPktCount <positive_integer>] [-denySSLReneg <
    denySSLReneg>] [-insertionEncoding (Unicode|UTF-8)] [-ocspCacheSize
    <positive_integer>][- pushFlag <positive_integer>] [-
    dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <
    positive_integer>] [-ndcppComplianceCertCheck ( YES | NO)] [-
    heterogeneousSSLHW (ENABLED | DISABLED )]
show ssl parameter
<!--NeedCopy-->
```

Example:

```
set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks
    no -ssltriggerTimeout 100 -sendClosenotify no -
    encryptTriggerPktCount 45 -denySSLReneg NONSECURE -insertionEncoding
     unicode -ocspCacheSize 10 -pushFlag 3 -dropReqWithNoHostHeader YES
     -pushEncTriggerTimeout 100 ms -ndcppComplianceCertCheck YES
Done

show ssl parameter
Advanced SSL Parameters
-----------------------
    SSL quantum size                                    : 8 KB
    Max CRL memory size                                 : 256 MB
    Strict CA checks                                    : NO
    Encryption trigger timeout                          : 100 ms
    Send Close-Notify                                   : NO
    Encryption trigger packet count                     : 45
    Deny SSL Renegotiation                              : NONSECURE
    Subject/Issuer Name Insertion Format                : Unicode
    OCSP cache size                                     : 10 MB

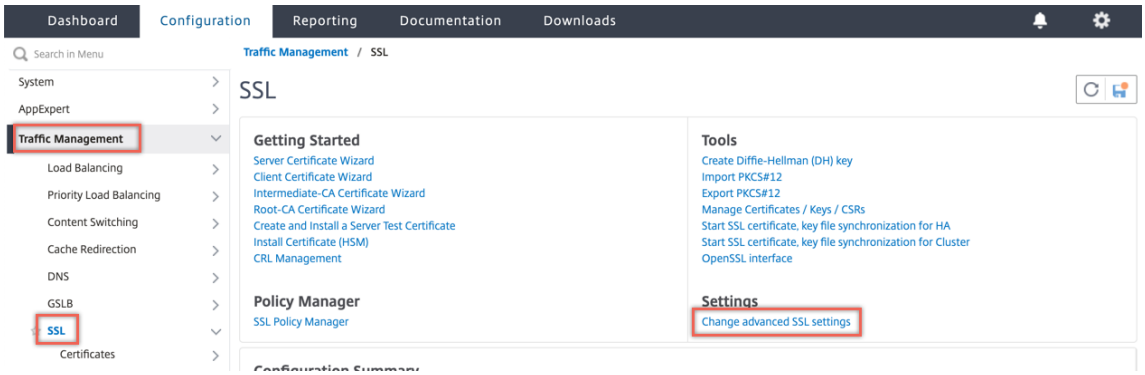
        every decrypted and encrypted record)
    Strict Host Header check for SNI enabled SSL sessions : YES
    PUSH encryption trigger timeout                     : 100 ms
    Crypto Device Disable Limit                         : 0
    Global undef action for control policies            : CLIENTAUTH
    Global undef action for data policies               : NOOP
```

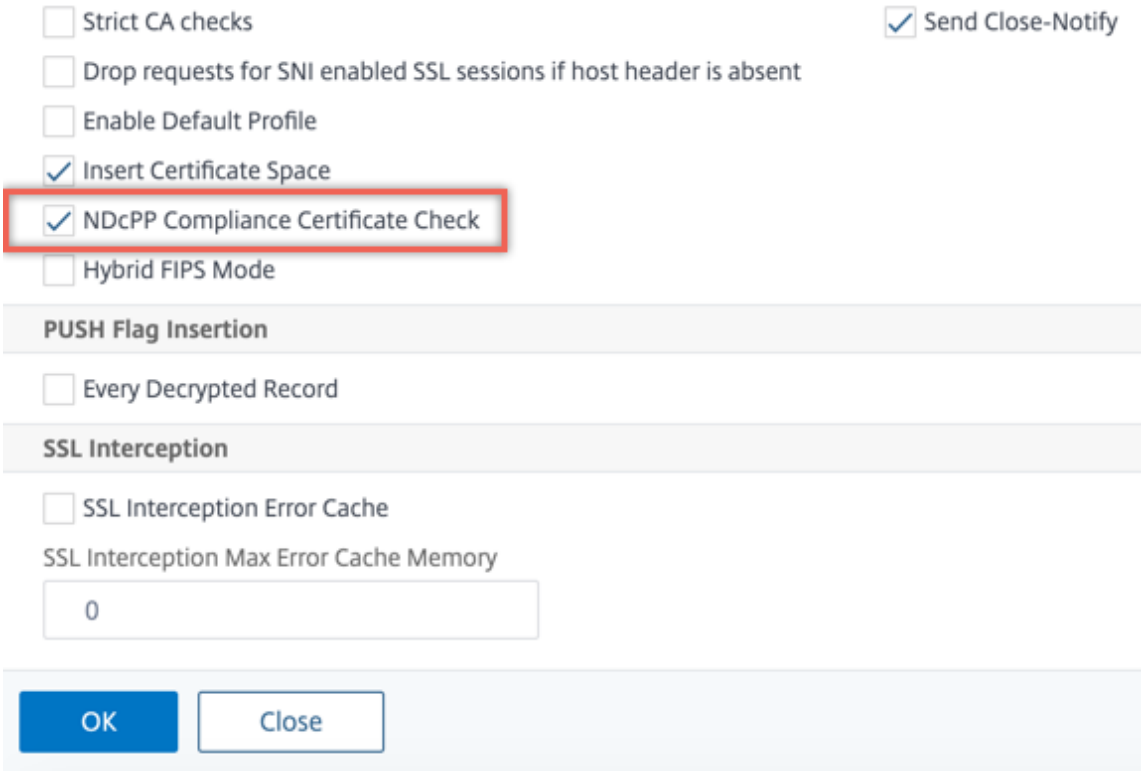
```
    Default profile                                          : DISABLED
    SSL Insert Space in Certificate Header                   : YES
    Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors       : NO
    Disable TLS 1.1/1.2 for dynamic and VPN services         : NO
    Software Crypto acceleration CPU Threshold               : 0
    Hybrid FIPS Mode                                         : DISABLED
    Signature and Hash Algorithms supported by TLS1.2        : ALL
    SSL Interception Error Learning and Caching              : DISABLED
    SSL Interception Maximum Error Cache Memory              : 0 Bytes
    NDCPP Compliance Certificate Check                       : YES
    Heterogeneous SSL HW (Cavium and Intel Based)            : ENABLED
 Done
<!--NeedCopy-->
```

Configure NDcPP compliance certificate check by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **Settings** group, select **Change advanced SSL settings**.



2. Select **NDCPP Compliance Certificate Check**. Click **OK**.



Support for secure renegotiation at the back end of a Citrix ADC appliance

Note: This feature is supported in release 13.0 build 58.x and later. In earlier releases and builds, only non-secure renegotiation was supported on the back end.

The feature is supported on the following platforms:
• VPX
• MPX platforms containing N2 or N3 chips
• Intel Coleto SSL chip based platforms

The feature is not yet supported on the FIPS platform.

Secure renegotiation is denied by default on the back end of an ADC appliance. That is, the denySSLReneg parameter is set to ALL (default).

To allow secure renegotiation on the back end, select from one of the following settings for the denySSLReneg parameter:

- NO
- FRONTEND_CLIENT
- FRONTEND_CLIENTSERVER
- NONSECURE

Enable secure renegotiation by using the CLI

At the command prompt, type:

```
set ssl parameter -denySSLReneg <denySSLReneg>
```

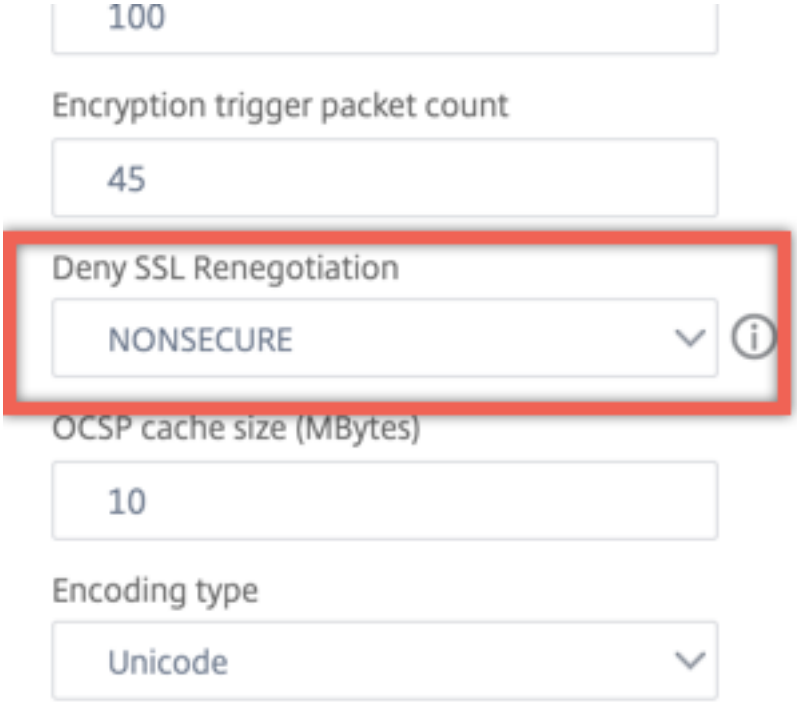
Example:

```
set ssl parameter -denySSLReneg NONSECURE
 Done

sh ssl parameter
Advanced SSL Parameters
-----------------------
    SSL quantum size                                  : 8 KB
    Max CRL memory size                               : 256 MB
    Strict CA checks                                  : NO
    Encryption trigger timeout                        : 100 ms
    Send Close-Notify                                 : YES
    Encryption trigger packet count                   : 45
    Deny SSL Renegotiation                            : NONSECURE
    Subject/Issuer Name Insertion Format              : Unicode
    OCSP cache size                                   : 10 MB
    Push flag                                         : 0x0 (Auto)
    Strict Host Header check for SNI enabled SSL sessions : NO
    Match HTTP Host header with SNI                   : CERT
    PUSH encryption trigger timeout                   : 1 ms
    Crypto Device Disable Limit                       : 0
    Global undef action for control policies          : CLIENTAUTH
    Global undef action for data policies             : NOOP
    Default profile                                   : ENABLED
    SSL Insert Space in Certificate Header            : YES
    Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors    : NO
    Disable TLS 1.1/1.2 for dynamic and VPN services      : NO
    Software Crypto acceleration CPU Threshold        : 0
    Hybrid FIPS Mode                                  : DISABLED
    Signature and Hash Algorithms supported by TLS1.2     : ALL
    SSL Interception Error Learning and Caching       : DISABLED
    SSL Interception Maximum Error Cache Memory       : 0 Bytes
    NDCPP Compliance Certificate Check                : NO
    Heterogeneous SSL HW (Cavium and Intel Based)         : DISABLED
    Crypto Operation Queue Limit                      : 150%
 Done
<!--NeedCopy-->
```

Enable secure renegotiation by using the GUI

1. Navigate to **Traffic Management > SSL > Change advanced SSL settings**.
2. Set **Deny SSL Renegotiation** to any value other than ALL.



Adaptive SSL traffic control

Note: This feature is supported in release 13.0 build 58.x and later.

When high traffic is received on the appliance and the crypto acceleration capacity is full, the appliance starts queuing connections to process later. Currently, the size of this queue is fixed at 64 K and the appliance starts dropping connections if this value is exceeded.

From release 13.0 build 58.x, the user can configure a value that is a percentage of the actual capacity. With this enhancement, the appliance drops new connections if the number of elements in the queue is greater than the limit that is adaptively and dynamically calculated. This approach controls incoming SSL connections and prevents excessive resource consumption and other failures, such as load balancing monitoring failure or slow response to secure applications, on the appliance.

If the queue is empty, the appliance can continue to accept connections. If the queue is not empty, the crypto system has reached its capacity and the appliance starts queuing connections.

The limit is calculated based on:

- The actual capacity of the appliance.
- Value configured by the user as a percentage of the actual capacity. Default value is set to 150%.

For example, if the actual capacity of an appliance is 1000 operations/second at a given time and the default percentage is configured, the limit after which the appliance drops connections is 1500 (150% of 1000).

To configure the operation queue limit by using the CLI

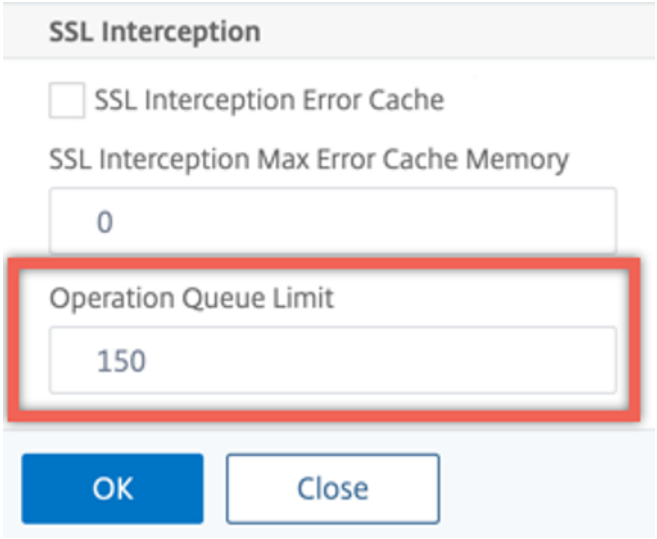
At the command prompt, type:

```
set ssl parameter -operationQueueLimit <positive_integer>
```

Operation Queue Limit - Limit in percentage of capacity of the crypto operations queue beyond which new SSL connections are not accepted until the queue is reduced. Default value: 150. Minimum value: 0. Maximum value: 10000.

To configure the operation queue limit by using the GUI

1. Navigate to **Traffic Management > SSL**.
2. In **Settings**, click **Change advanced SSL settings**.
3. Type a value in **Operation Queue Limit**. Default is 150.
4. Click **OK**.



Heterogeneous cluster deployments

From release 13.0 build 47.x, you can form a heterogeneous cluster deployment of Citrix ADC MPX appliances with a different number of packet engines by setting the SSL parameter “Heterogeneous SSL HW” to ENABLED. For example, to form a cluster of Cavium chip based appliances (MPX 14000 or similar) and Intel Coleto chip based appliances (MPX 15000 or similar), enable the SSL parameter

“Heterogeneous SSL HW.” To form a cluster of platforms using the same chip, keep the default value (DISABLED) for this parameter.

> **Notes:**
>
> The following features are not supported in a heterogeneous cluster:
>
> - VPX instances hosted on Citrix ADC SDX appliances.
> - SSLv3 protocol on SSL entities, such as virtual server, services, service group, and internal services.
> - Software crypto acceleration CPU threshold (using hardware and software to improve ECDSA and ECDHE cipher performance).

For more information about the platforms supported in a heterogeneous cluster, see https://docs.citrix.com/en-us/citrix-adc/13/clustering/support-for-heterogeneous-cluster.html.

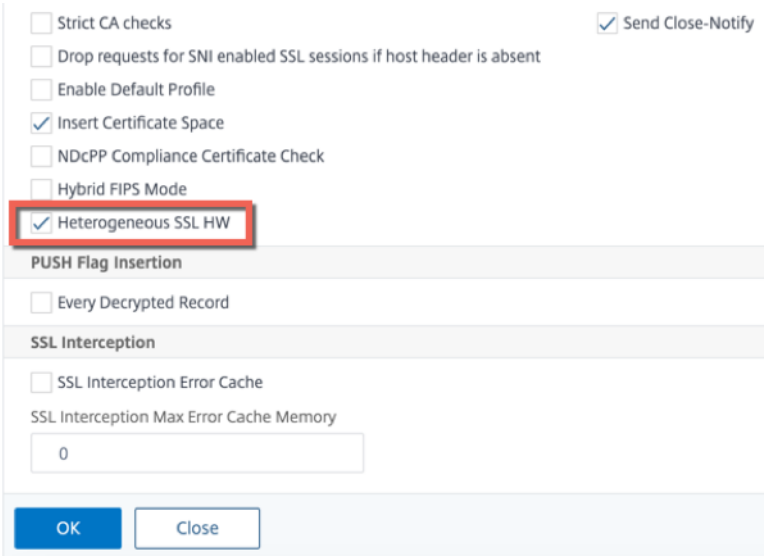
Enable a heterogeneous cluster using the CLI

At the command prompt, type:

```
set ssl parameter -heterogeneousSSLHW ENABLED
```

Enable a heterogeneous cluster using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **Settings** group, select **Change advanced SSL settings**.
2. Select **Heterogeneous SSL HW**. Click **OK**.



PUSH flag based encryption trigger mechanism

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:

- Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.
- Perform timer-based encryption, in which the time-out value is set globally by using the `set ssl parameter -pushEncTriggerTimeout <positive_integer>` command.

Configure PUSH flag-based encryption by using the CLI

At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

```
set ssl vserver <vServerName> [-pushEncTrigger <pushEncTrigger>]

show ssl vserver
<!--NeedCopy-->
```

Example:

```
set ssl vserver vserver1 -pushEncTrigger always

Done

sh ssl vserver vserver1

            Advanced SSL configuration for VServer vserver1:
            DH: DISABLED
            DH Private-Key Exponent Size Limit: DISABLED    Ephemeral
                RSA: ENABLED

                Refresh Count: 0
            Session Reuse: ENABLED          Timeout: 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            HSTS: DISABLED
            HSTS IncludeSubDomains: NO
```

```
21              HSTS Max-Age: 0
22              SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1:
                    ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
23              Push Encryption Trigger: Always
24              Send Close-Notify: YES
25              Strict Sig-Digest Check: DISABLED
26              Zero RTT Early Data: DISABLED
27              DHE Key Exchange With PSK: NO
28              Tickets Per Authentication Context: 1
29              ECC Curve: P_256, P_384, P_224, P_521
30
31      1)      Cipher Name: DEFAULT
32              Description: Default cipher list with encryption strength
                   >= 128bit
33  Done
34  <!--NeedCopy-->
```

Configure PUSH flag-based encryption by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers** and open an SSL virtual server.
2. In the **SSL Parameters** section, from the **PUSH Encryption Trigger** list, select a value.

Support for TLS1.2 signature hash algorithm

The Citrix ADC appliance is completely TLS1.2 signature hash extension compliant.

In an SSL handshake, a client sends a list of supported signature hash algorithms. The client indicate to the server which signature hash algorithm pairs might be used in the SSL handshake messages (SKE and CCV) by using the “signature_algorithms” extension. The “extension_data” field of this extension contains a “supported_signature_algorithms” value in the Client Hello message. The SSL handshake proceeds if the server supports one of these signature hash algorithms. If the server does not support any of these algorithms, the connection is dropped.

Similarly, if the server requests a client certificate for client authentication, the Certificate Request message contains a “supported_signature_algorithms” value. The client certificate is selected based on this signature hash algorithm.

> **Note:**
>
> The Citrix ADC appliance acts as a server to a client and as a client to the back-end server.

The appliance supports only RSA-SHA1 and RSA-SHA256 on the front end, and RSA-MD5, RSA-SHA1, and RSA-SHA256 on the back end.

The MPX/SDX/VPX appliance supports the following signature hash combinations. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

- On a VPX instance and on an MPX/SDX appliance without N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
- On an MPX/SDX appliance with N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
  - ECDSA-SHA1
  - ECDSA-SHA224
  - ECDSA-SHA256
  - ECDSA-SHA384
  - ECDSA-SHA512

By default, all the signature hash algorithms are enabled. However, you can enable only a few signature hash algorithms by using the following command:

```
set ssl parameter -sigDigestType <sigDigestType>

Parameters

sigDigestType

Signature digest algorithms supported by the appliance. The platform
   determines the list of algorithms supported by default.

             On VPX: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-SHA256 RSA-SHA384
                 RSA-

             SHA512

             On MPX with N3 cards: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-

```

```
15                SHA256 RSA-SHA384 RSA-SHA512 ECDSA-SHA1 ECDSA-SHA224
                      ECDSA-
16
17                SHA256 ECDSA-SHA384 ECDSA-SHA512
18
19                Other MPX Platforms: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-
                      SHA256 RSA-SHA384 RSA-
20
21                SHA512.
22
23      set ssl parameter -sigDigestType RSA-SHA224 RSA-SHA256 RSA-SHA384
            RSA-SHA512
24  <!--NeedCopy-->
```

Validate the peer certificate

According to RFC 5246, the peer certificate must be signed using one of the signature hash algorithms included in the Client Hello extension. You can use the `strictSigDigestCheck` parameter. Depending on the signature hash list sent by the client, if you enable `strictSigDigestCheck`, the appliance returns a certificate signed by one of the signature hash algorithms mentioned in the Client Hello extension. If the peer does not have a proper certificate, the connection is dropped. If this parameter is disabled, the signature hash is not checked in the peer certificate.

You can configure a strict signature digest check on an SSL virtual server and service. If you enable this parameter on an SSL virtual server, the server certificate sent by the server must be signed by one of the signature hash algorithms listed in the Client Hello extension. If client authentication is enabled, then the client certificate received by the server must be signed using one of the signature hash algorithms listed in the certificate request sent by the server.

If you enable this parameter on an SSL service, the server certificate received by the client must be signed by one of the signature hash algorithms listed in the Client Hello extension. The client certificate must be signed using one of the signature hash algorithms listed in the certificate request message.

If the default profile is enabled, you can use it to configure a strict signature digest check on an SSL virtual server, SSL service, and SSL profile.

Configure strict signature digest check on an SSL virtual server, service, or profile by using the CLI

At the command prompt, type:

```
1  set ssl vserver <vServerName> -strictSigDigestCheck ( ENABLED |
       DISABLED )
```

```
2
3 set ssl service <serviceName> -strictSigDigestCheck ( ENABLED |
     DISABLED )
4
5 set ssl profile <name>-strictSigDigestCheck ( ENABLED | DISABLED )
6
7 Parameters
8
9 strictSigDigestCheck
10
11              Check whether peer entity certificate is signed using one
                    of the signature-hash algorithms supported by the
                   Citrix ADC appliance.
12
13              Possible values: ENABLED, DISABLED
14
15              Default: DISABLED
16 <!--NeedCopy-->
```

Example:

```
1 set ssl vserver v1  -strictSigDigestCheck Enabled
2 set ssl service s1  -strictSigDigestCheck Enabled
3 set ssl profile p1  -strictSigDigestCheck Enabled
4 <!--NeedCopy-->
```

> **Important:**
>
> If DH, ECDHE, or ECDSA ciphers are configured on the appliance, the SKE message must be signed using one of the signature-hashes common to the client list and the list configured on the appliance. If there is no common signature hash, the connection is dropped.

TLSv1.3 protocol support as defined in RFC 8446

September 14, 2021

The Citrix ADC VPX and Citrix ADC MPX appliances now support the TLSv1.3 protocol, specified in RFC 8446.

> **Notes:**
>
> - From release 13.0 build 71.x and later, TLS1.3 hardware acceleration is supported on the following platforms:

  - MPX 5900
  - MPX/SDX 8900
  - MPX/SDX 15000
  - MPX/SDX 15000-50G
  - MPX/SDX 26000
  - MPX/SDX 26000-50S
  - MPX/SDX 26000-100G
  - Software-only support for the TLSv1.3 protocol is available on all other Citrix ADC MPX and SDX appliances except Citrix ADC FIPS appliances.
- TLSv1.3 is only supported with the enhanced profile. To enable the enhanced profile, see Enable the enhanced profile.
- To use TLS1.3, you must use a client that conforms to the RFC 8446 specification.

Supported Citrix ADC features

The following SSL features are supported:

1. TLSv1.3 cipher suites:
   - TLS1.3-AES256-GCM-SHA384 (0x1302)
   - TLS1.3_CHACHA20_POLY1305_SHA256 (0x1303)
   - TLS1.3-AES128_GCM-SHA256 (0x1301)
2. ECC curves for ephemeral Diffie-Hellman key exchange:
   - P_256
   - P_384
   - P_521
3. Abbreviated handshakes when ticket-based session resumption is enabled
4. 0-RTT early application data
5. Optional or mandatory certificate-based client authentication, with support for OCSP and CRL validation of client certificates
6. Server name extension: server certificate selection by using SNI
7. Application protocol negotiation (ALPN) by using the application_level_protocol_negotiation extension.
8. OCSP stapling
9. Log messages and AppFlow records are produced for TLSv1.3 handshakes.

10. Optional logging of TLS 1.3 traffic secrets by the `nstrace` packet capture utility.
11. Interoperability with TLS clients implementing RFC 8446. For example, Mozilla Firefox, Google Chrome, and OpenSSL.

Supported browsers

The following browser versions are supported and compatible with the Citrix ADC implementation oF TLS 1.3 protocol:

- Google Chrome - Version 72.0.3626.121 (Official Build) (64-bit)
- Mozilla Firefox - 65.0.2 (64-bit)
- Opera - Version:58.0.3135.79

Configuration

TLSv1.3 is disabled by default on an SSL profile.

Add an SSL profile by using the CLI

At the command prompt, type:

```
add ssl profile <tls13-profile-name>
<!--NeedCopy-->
```

Example:

```
add ssl profile tls13profile

sh ssl profile tls13profile
1)  Name: tls13profile           (Front-End)
    SSLv3: DISABLED              TLSv1.0: ENABLED  TLSv1.1: ENABLED
       TLSv1.2: ENABLED  TLSv1.3: DISABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks:   NO
    Session Reuse: ENABLED                      Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED   Ephemeral RSA:
       ENABLED                            Refresh Count: 0
    Deny SSL Renegotiation                                ALL
    Non FIPS Ciphers: DISABLED
    Cipher Redirect: DISABLED
    SSL Redirect: DISABLED
```

```
    Send Close-Notify: YES
    Strict Sig-Digest Check: DISABLED
    Zero RTT Early Data: DISABLED
    DHE Key Exchange With PSK: NO
    Tickets Per Authentication Context: 1
    Push Encryption Trigger: Always
    PUSH encryption trigger timeout:             1 ms
    SNI: DISABLED
    OCSP Stapling: DISABLED
    Strict Host Header check for SNI enabled SSL sessions: NO
    Push flag:            0x0 (Auto)
    SSL quantum size:                            8 kB
    Encryption trigger timeout           100 mS
    Encryption trigger packet count:               45
    Subject/Issuer Name Insertion Format: Unicode

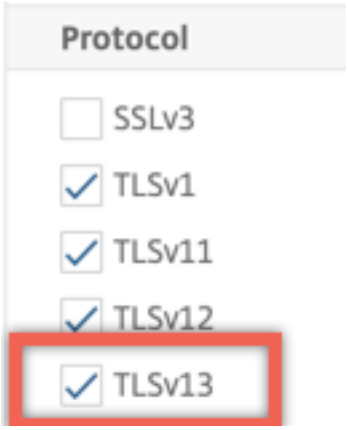
    SSL Interception: DISABLED
    SSL Interception OCSP Check: ENABLED
    SSL Interception End to End Renegotiation: ENABLED
    SSL Interception Maximum Reuse Sessions per Server:  10
    Session Ticket: DISABLED
    HSTS: DISABLED
    HSTS IncludeSubDomains: NO
    HSTS Max-Age: 0

    ECC Curve: P_256, P_384, P_224, P_521

1)  Cipher Name: DEFAULT Priority :1
    Description: Predefined Cipher Alias
Done
<!--NeedCopy-->
```

Add an SSL profile by using the GUI

1. Navigate to **System > Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. In **Protocol**, select **TLSv13**.



4. Click **OK**.

Bind an SSL profile to an SSL virtual server by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> -sslProfile <tls13-profile-name>
<!--NeedCopy-->
```

Example:

```
set ssl vserver ssl-vs -sslProfile tls13profile
```

Bind an SSL profile to an SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select an SSL virtual server.
2. In **Advanced Settings**, click **SSL Profile**.
3. Select the TLSv1.3 profile created earlier.
4. Click **OK**.
5. Click **Done**.

SSL profile parameters for TLSv1.3 protocol

1. Enable or disable TLS1.3 parameters in an SSL profile.

   tls13: State of TLSv1.3 protocol support for the SSL profile.

   Possible values: ENABLED, DISABLED

   Default value: DISABLED

```
set ssl profile tls13profile -tls13 enable
<!--NeedCopy-->
```

```
set ssl profile tls13profile -tls13 disable
<!--NeedCopy-->
```

2. Set number of session tickets issued.

   tls13SessionTicketsPerAuthContext: Number of tickets the SSL virtual server issues when TLS1.3 is negotiated, ticket-based resumption is enabled, and either (1) a handshake completes or (2) client authentication completes after the handshake.

   This value can be increased to enable clients to open multiple parallel connections using a fresh ticket for each connection.

   No tickets are sent if resumption is disabled.

   Default value: 1

   Minimum value: 1

   Maximum value: 10

```
set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 1

set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 10
<!--NeedCopy-->
```

3. Set DH key exchange

   dheKeyExchangeWithPsk: Specifies whether an SSL virtual server requires a DHE key exchange to occur when a preshared key is accepted during a TLS 1.3 session resumption handshake. A DHE key exchange ensures forward secrecy, even if ticket keys are compromised, at the expense of extra resources required to carry out the **DHE** key exchange.

   Available settings work as follows, if session ticket is enabled:

   YES: DHE key exchange is required when a pre-shared key is accepted, regardless of whether the client supports the key exchange. The handshake is aborted with a fatal alert, if the client does not support DHE key exchange when offering a pre-shared key.

   NO: DHE key exchange is performed when a pre-shared key is accepted, only if requested by the client.

   Possible values: YES, NO

   Default value: NO

```
set ssl profile tls13profile dheKeyExchangeWithPsk yes

set ssl profile tls13profile dheKeyExchangeWithPsk no
<!--NeedCopy-->
```

4. Enable or disable 0-RTT early data acceptance

   zeroRttEarlyData: State of TLS 1.3 early application data. Applicable settings work as follows:

   ENABLED: Early application data might be processed before the handshake is complete.
   DISABLED: Early application data is ignored.

   Possible values: ENABLED, DISABLED

   Default value: DISABLED

```
set ssl profile tls13profile -zeroRttEarlyData ENABLED

set ssl profile tls13profile -zeroRttEarlyData DISABLED
<!--NeedCopy-->
```

Default cipher group

The default cipher group includes TLS1.3 ciphers.

```
sh cipher DEFAULT
1) Cipher Name: TLS1-AES-256-CBC-SHA    Priority : 1
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(256)  Mac=SHA1
       HexCode=0x0035

2)  Cipher Name: TLS1-AES-128-CBC-SHA    Priority : 2
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(128)  Mac=SHA1
       HexCode=0x002f
...
...
27) Cipher Name: TLS1.3-AES256-GCM-SHA384         Priority : 27
    Description: TLSv1.3 Kx=any      Au=any  Enc=AES-GCM(256) Mac=AEAD
         HexCode=0x1302

28) Cipher Name: TLS1.3_CHACHA20_POLY1305_SHA256     Priority : 28
    Description: TLSv1.3 Kx=any      Au=any  Enc=CHACHA20/POLY1305(256)
        Mac=AEAD   HexCode=0x1303

29) Cipher Name: TLS1.3-AES128_GCM-SHA256        Priority : 29
```

```
16     Description: TLSv1.3 Kx=any      Au=any  Enc=AES-GCM(128) Mac=AEAD
           HexCode=0x1301
17 Done
18 <!--NeedCopy-->
```

Limitations

- On the Citrix ADC MPX platform, TLSv1.3 processing is not offloaded to crypto hardware.
- TLSv1.3 is not supported on the back end.
- TLSv1.3 is not supported on a Citrix Secure Web Gateway appliance and on a Citrix ADC FIPS appliance.

Operational considerations

TLS 1.3 draft version compatibility note: A Citrix ADC appliance implements the RFC 8446 variant of the TLS 1.3 protocol (as opposed to earlier draft versions of the protocol). Use a TLS 1.3 client that supports RFC 8446 (or an interoperable draft # - 26, 27 or 28) to complete a TLS 1.3 handshake with a Citrix ADC appliance. Clients and servers that implement different draft versions of the TLS 1.3 protocol might not interoperate with each other.

Security restrictions

TLSv1.3 server operators must keep in mind the following security restrictions for backward compatibility outlined in RFC 8446. The default configuration on a NetScaler appliance is compliant with these restrictions. However, a NetScaler appliance does not enforce that these rules are adhered to.

- The security of RC4 cipher suites is considered insufficient as described in RFC7465. Implementations must not offer or negotiate RC4 cipher suites for any version of TLS.
- Old versions of TLS allowed the use of low strength ciphers. Ciphers with a strength less than 112 bits must not be offered or negotiated for any version of TLS.
- The security of SSL 3.0 [SSLv3] is considered insufficient as described in RFC7568, and must not be negotiated. Disable SSLv3 when TLSv1.3 is enabled (SSLv3 is disabled by default.)
- The security of SSL 2.0 [SSLv2] is considered insufficient as described in RFC6176, and must not be negotiated. Disable SSLv2 when TLS 1.3 is enabled (SSLv2 is disabled by default.)

> **Note:**
>
> For information about troubleshooting protocols that run over TLS1.3, see Decrypting TLS1.3 traffic from packet trace.

How-to articles

September 14, 2021

How-to articles are simple and easy to use articles with configuration steps for common deployments. Click a link to view the article.

Create a certificate signing request and use SSL certificates on a Citrix ADC appliance

Configure SSL action to forward client traffic

Configure SSL action to forward client traffic if a cipher is not supported on the ADC

Configure per directory client authentication

Configure support for Outlook web access

Configure SSL based header insertion

Configure SSL offloading with end-to-end encryption

Configure transparent SSL acceleration

Configure SSL acceleration with HTTP on the front end and SSL on the back end

Configure SSL offloading with other TCP protocols

Configure SSL bridging

Configure SSL monitoring when client authentication is enabled on the back-end service

Configure a secure content switching server

Configure an HTTPS virtual server to accept HTTP traffic

Configure graceful cleanup of SSL sessions

Configure support for HTTP strict transport security (HSTS)

Configure SSLv2 redirection

Configure synchronization of files in a high availability setup

Disable TLS 1.0 and TLS 1.1 on NSIP

Export certificates used on the Citrix ADC appliance as PFX file

SSL certificates

September 14, 2021

An SSL certificate, which is a part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the Citrix ADC appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as Verisign
- By generating a new SSL certificate and key on the Citrix ADC appliance

Alternately, you can use an existing SSL certificate on the appliance.

Certificates are categorized into four types by the Citrix ADC appliance:

- **Server certificates:** A server certificate authenticates the server's identity to the client. On the front-end, the ADC appliance acts as a server. You bind a server certificate and a private key to an SSL virtual server on the ADC appliance.
- **Client certificates:** A client certificate authenticates the client's identity to the server. On the back-end, the ADC appliance acts as a client. You bind a client certificate and private key to the SSL service or service group on the ADC appliance.
- **CA certificates:** CA certificates issue the end-user certificates (client and server certificates). A CA certificate can be a trusted root CA (self-signed by the certificate authority) or an intermediate CA (signed by a trusted root CA). Typically, CA certificates do not need private keys.
- **Unknown certificates:** All other certificates fall in this category.

Important: Citrix recommends that you use certificates obtained from authorized CAs, such as Verisign, for all your SSL transactions. Use certificates generated on the Citrix ADC appliance for testing purposes only, not in any live deployment.

- If while adding a certificate-key pair, you add a certificate file with the same name as an existing certificate file, the original certificate file is overwritten with no warning. This action might cause issues after the appliance is restarted because the original certificate file is no longer available in the `/nsconfig/ssl` directory.
- Removing any certificate or key files in a cluster environment restricts further configuration on the ADC appliance. Add the files back at the same location to make any configuration changes.

Note: You can use the ADM SSL dashboard for ease of SSL certificate management and set notifications for certificates that are unused or soon to expire. For more information, see SSL certificate management.

Create a certificate

September 14, 2021

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Applications, such as web browsers, that conduct SSL transactions trust certificates issued or signed by a Certificate Authority. These applications maintain a list of the CAs that they trust. If any of the trusted CAs sign the certificate being used for the secure transaction, the application proceeds with the transaction.

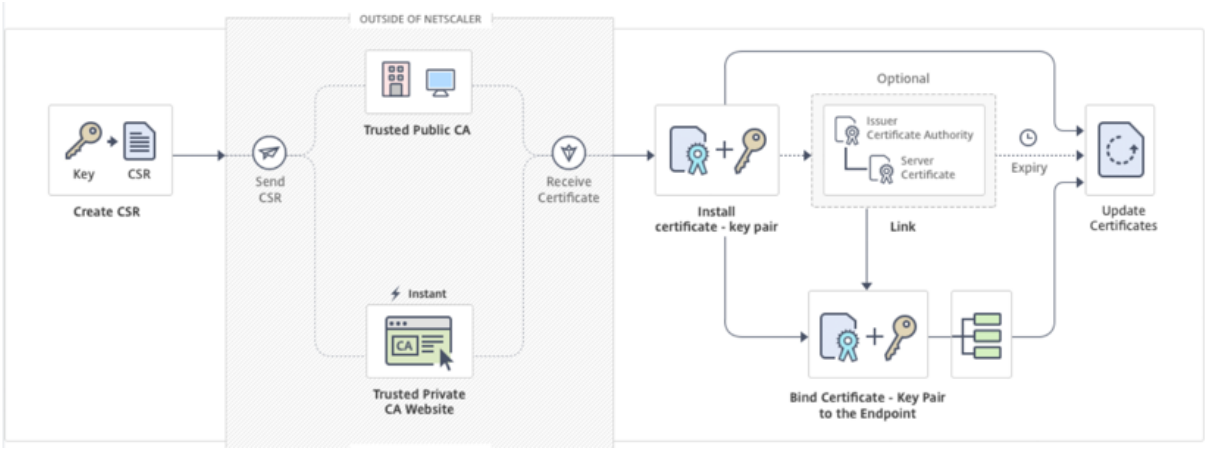
Caution: Citrix recommends that you use certificates obtained from authorized CAs, such as Verisign, for all your SSL transactions. Use certificates generated on the Citrix ADC appliance for testing purposes only, not in any live deployment.

To import an existing certificate and key, see Import a Certificate.

Perform the following steps to create a certificate and bind it to an SSL virtual server. The only special characters allowed in the file names are underscore and dot.

- Create a private key.
- Create a certificate signing request (CSR).
- Submit the CSR to a certificate authority.
- Create a certificate-key pair.
- Bind the certificate-key pair to an SSL virtual server

The following diagram illustrates the workflow.



Video link to How do I create and install a new certificate.

Create a private key

> **Notes:**
>
> - From release 12.1 build 49.x, you can use the AES256 algorithm with PEM key format to encrypt a private key on the appliance. AES with 256-bit key is more mathematically efficient and secure compared to the 56-bit key of the Data Encryption Standard (DES).
> - From release 12.1 build 50.x, you can create an RSA key in PKCS#8 format.

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and must be kept securely on the Citrix ADC appliance. Any data encrypted with the public key can be decrypted only by using the private key.

The certificate that you receive from the CA is valid only with the private key that was used to create the CSR. The key is required for adding the certificate to the Citrix ADC appliance.

The appliance supports only the RSA encryption algorithms for creating private keys. You can submit either type of private key to the certificate authority (CA). The certificate that you receive from the CA is valid only with the private key that was used to create the CSR. The key is required for adding the certificate to the Citrix ADC appliance.

Important:

> - Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data.
> - The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

All SSL certificates and keys are stored in the `/nsconfig/ssl` folder on the appliance. For added security, you can use the DES or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.

Create an RSA private key by using the CLI

At the command prompt, type:

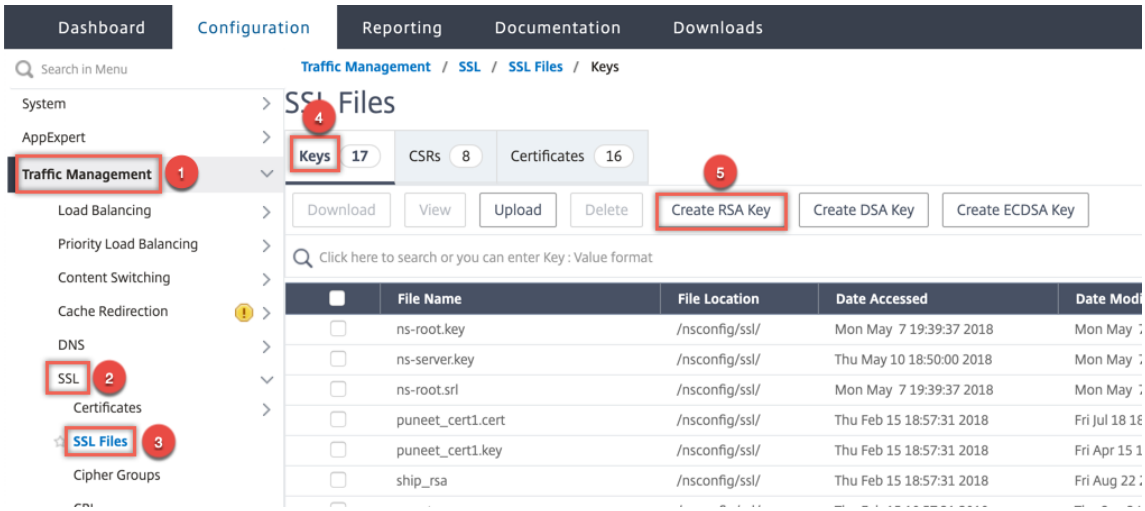
```
create ssl rsakey <keyFile> <bits> [-exponent ( 3 | F4 )] [-keyform (
    DER | PEM )] [-des | -des3 | -aes256] {
 -password  }
  [-pkcs8]
<!--NeedCopy-->
```

Example:

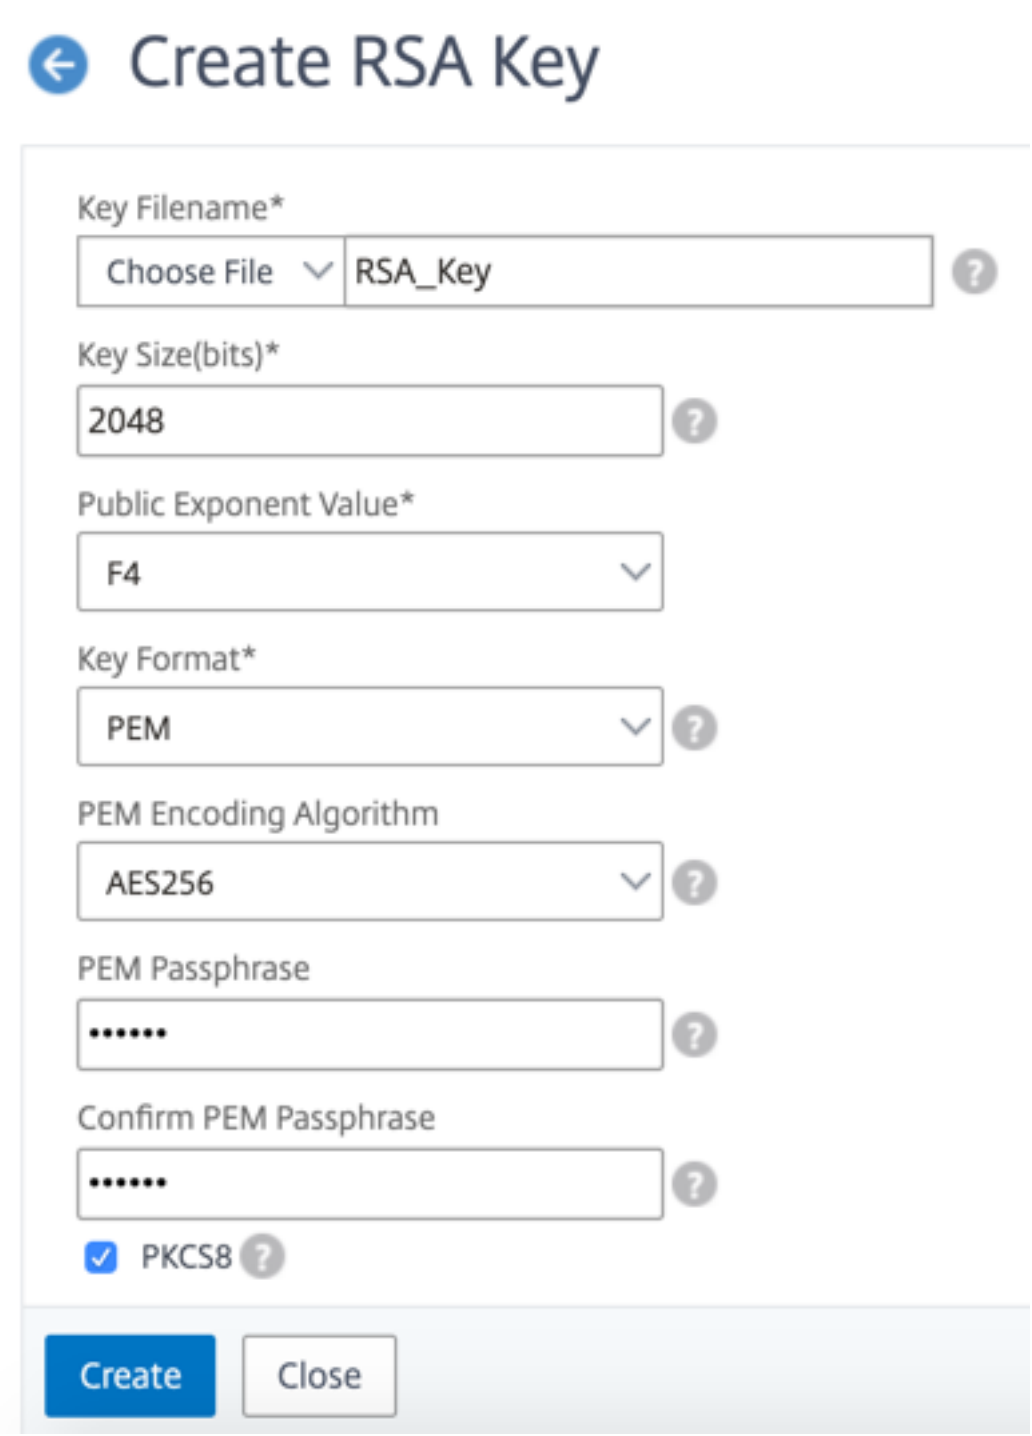
```
create rsakey testkey 2048 -aes256 -password 123456 -pkcs8
<!--NeedCopy-->
```

Create an RSA private key by using the GUI

1. Navigate to **Traffic Management > SSL > SSL Files**.
2. In the **Keys** tab, select **Create RSA Key**.



3. Enter values for the following parameters and click **Create**.
   - **Key Filename** - Name for and, optionally, path to the RSA key file. /nsconfig/ssl/ is the default path.
   - **Key Size** - Size, in bits, of the RSA key. Can range from 512 bits to 4096 bits.
   - **Public Exponent Value** - Public exponent for the RSA key. The exponent is part of the cipher algorithm and is required for creating the RSA key.
   - **Key Format** - The format in which the RSA key file is stored on the appliance.
   - **PEM Encoding Algorithm** - Encrypt the generated RSA key by using the AES 256, DES, or Triple-DES (DES3) algorithm. By default, private keys are unencrypted.
   - **PEM Passphrase** - If the private key is encrypted, enter a pass phrase for the key.



Select an AES256 encoding algorithm in an RSA key by using the GUI

1. Navigate to **Traffic Management > SSL > SSL Files > Create RSA Key**.
2. In **Key Format**, select **PEM**.

3. In **PEM Encoding Algorithm**, select **AES256**.
4. Select **PKCS8**.

Create a certificate signing request by using the CLI

At the command prompt, type:

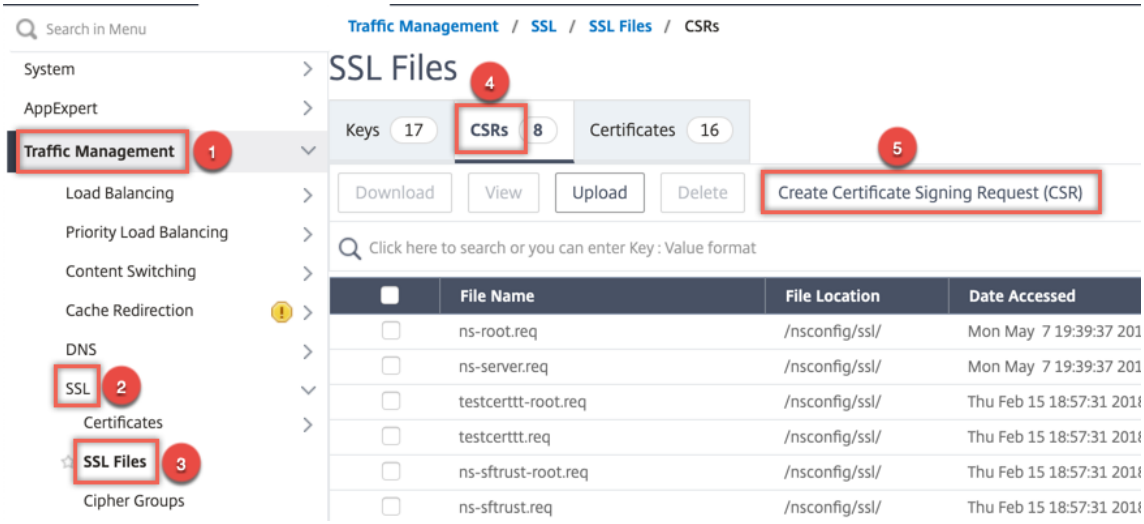
```
create ssl certreq <reqFile> -keyFile <input_filename> | -fipsKeyName <string>) [-keyForm (DER | PEM) {
 -PEMPassPhrase  }
 ] -countryName <string> -stateName <string> -organizationName <string> -organizationUnitName <string> -localityName <string> -commonName <string> -emailAddress <string> {
 -challengePassword  }
  -companyName <string> -digestMethod ( SHA1 | SHA256 )
<!--NeedCopy-->
```

Example:

```
create ssl certreq priv_csr_sha256 -keyfile priv_2048_2 -keyform PEM -countryName IN -stateName Karnataka -localityName Bangalore -organizationName Citrix -organizationUnitName NS -digestMethod SHA256
<!--NeedCopy-->
```

Create a certificate signing request by using the GUI

1. Navigate to **Traffic Management > SSL**.
2. In **SSL** Certificate, click **Create Certificate Signing Request (CSR)**.



3. In **Digest** Method, select **SHA256**.

See Create a CSR for more information.

Support for subject alternative name in a certificate signing request

The subject alternative name (SAN) field in a certificate allows you to associate multiple values, such as domain names and IP addresses, with a single certificate. In other words, you can secure multiple domains, such as www.example.com, www.example1.com, www.example2.com, with a single certificate.

Some browsers, such as Google Chrome, no longer support a common name in a certificate signing request (CSR). They enforce SAN in all publicly trusted certificates.

The Citrix ADC appliance supports adding SAN values when creating a CSR. You can send a CSR with a SAN entry to a certificate authority to obtain a signed certificate with that SAN entry. When the appliance receives a request, it checks for a matching domain name in the SAN entries in the server certificate. If a match is found, it sends the certificate to the client and completes the SSL handshake. You can use the CLI or the GUI to create a CSR with SAN values.

> **Note:** The Citrix ADC appliance processes only DNS based SAN values.

Create a CSR with the subject alternative name by using the CLI

```
create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName
    <string>) [-subjectAltName <string>] [-keyform ( DER | PEM )  {
 -PEMPassPhrase  }
 ] -countryName <string> -stateName <string> -organizationName <string>
     [-organizationUnitName <string>] [-localityName <string>] [-
    commonName <string>] [-emailAddress <string>] {
 -challengePassword  }
  [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]
<!--NeedCopy-->
```

Parameters:

subjectAltName: The subject alternative name (SAN) is an extension to X.509 that allows various values to be associated with a security certificate using a subjectAltName field. These values are called “Subject Alternative Names” (SAN). Names include:

1. IP addresses (Prefix with “IP:” Example: IP:198.51.10.5 IP:192.0.2.100)
2. DNS names (Prefix with “DNS:” Example: DNS:www.example.com DNS:www.example.org DNS:www.example.net)

On the command line, enter values within quotation marks. Separate two values with a space. Quotation marks are not required in the GUI.
Maximum Length: 127

Example:

```
create certReq test1.csr -keyFile test1.ky -countryName IN -stateName
    Kar -organizationName citrix -commonName ctx.com -subjectAltName "
    DNS:*.example.com DNS:www.example.org DNS:www.example.net"
<!--NeedCopy-->
```

> **Note:**
>
> On a FIPS appliance, you must replace the key file name with the FIPS key name if you create the FIPS key directly on the appliance.
>
> ```
> create certReq <csrname> -fipsKeyName fipskey.ky -countryName IN -
>     stateName Kar -organizationName citrix -commonName ctx.com -
>     subjectAltName "DNS:www.example.com DNS:www.example.org DNS:www.
>     example.net"
> <!--NeedCopy-->
> ```

Create a CSR by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **SSL Files**.
2. In the **CSR** tab, click **Create Certificate Signing Request (CSR)**.
3. Enter the values and click **Create**.

Limitations

To use SAN when creating an SSL certificate, you must explicitly specify the SAN values. The values are not read automatically from the CSR file.

Submit the CSR to the Certificate Authority

Most certificate authorities (CA) accept certificate submissions by email. The CA returns a valid certificate to the email address from which you submit the CSR.

The CSR is stored in the `/nsconfig/ssl` folder.

Generate a test certificate

> **Note:**
>
> To generate a server test certificate, see Generating a Server Test Certificate.

The Citrix ADC appliance has a built-in CA tools suite that you can use to create self-signed certificates for testing purposes.

Caution: Because the Citrix ADC appliance signs these certificates, and not an actual CA, you must not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users receive a "certificate invalid" warning each time the virtual server is accessed.

The appliance supports creation of the following types of certificates

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the Citrix ADC CA Tools to generate a certificate.

Create a certificate by using a wizard

1. Navigate to **Traffic Management > SSL**.
2. In the details pane, under **Getting Started**, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.

Create a root-CA certificate by using the CLI

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
   input_filename>] [-keyform ( DER | PEM )] [-days <positive_integer>]
<!--NeedCopy-->
```

In the following example, csreq1 is the CSR and rsa1 is the private key that was created earlier.

Example:

```
create ssl cert cert1 csreq1 ROOT_CERT -keyFile rsa1 -keyForm PEM -days
    365

  Done
```

```
4 <!--NeedCopy-->
```

Create an intermediate-CA certificate by using the CLI

```
1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <
     input_filename>] [-keyform ( DER | PEM )] [-days <positive_integer>]
      [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CAcertForm (
      DER | PEM )] [-CAkey <input_filename>] [-CAkeyForm ( DER | PEM )]
     [-CAserial <output_filename>]
2 <!--NeedCopy-->
```

In the following example, csr1 is the CSR created earlier. Cert1 and rsakey1 are the certificate and corresponding key of the self-signed (root-CA) certificate, and pvtkey1 is the private key of the intermediate-CA certificate.

Example:

```
1 create ssl cert certsy csr1 INTM_CERT -CAcert cert1 -CAkey rsakey1 -
     CAserial 23
2 Done
3
4 create ssl rsakey pvtkey1 2048 -exponent F4 -keyform PEM
5 Done
6 <!--NeedCopy-->
```

Create a root-CA certificate by using the GUI

Navigate to **Traffic Management > SSL** and, in the Getting Started group, select **Root-CA Certificate Wizard**, and configure a root CA certificate.

Create an intermediate-CA certificate by using the GUI

Navigate to **Traffic Management > SSL** and, in the Getting Started group, select **Intermediate-CA Certificate Wizard**, and configure an intermediate CA certificate.

Create an end-user certificate

An end-user certificate can be a client certificate or a server certificate. To create a test end-user certificate, specify the Intermediate CA certificate or the self-signed root-CA certificate.

> **Note:** To create an end-user certificate for production use, specify a trusted CA certificate and send the CSR to a certificate authority (CA).

Create a test end-user certificate by using the command line interface

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
    input_filename>] [-keyform ( DER | PEM )] [-days<positive_integer>]
    [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CAcertForm (
    DER | PEM )] [-CAkey<input_filename>] [-CAkeyForm ( DER | PEM )] [-
    CAserial <output_filename>]
<!--NeedCopy-->
```

If there is no intermediate certificate, use the certificate (cert1) and private key (rsakey1) values of the root-CA certificate in `CAcert` and `CAkey`.

Example:

```
create ssl cert cert12 csr1 SRVR_CERT -CAcert cert1 -CAkey rsakey1 -
    CAserial 23

Done
<!--NeedCopy-->
```

If there is an intermediate certificate, use the certificate (`certsy`) and private key (pvtkey1) values of the intermediate certificate in `CAcert` and `CAkey`.

Example:

```
create ssl cert cert12 csr1 SRVR_CERT -CAcert certsy -CAkey pvtkey1 -
    CAserial 23

Done
<!--NeedCopy-->
```

Create a self-signed SAN Certificate using OpenSSL

To create a self-signed SAN certificate with multiple subject alternate names, perform the following steps:

1. Create an OpenSSL configuration file on your local computer by editing the fields related as per the company requirements.

   Note: In the following example, the configuration file is “req.conf”.

```
[req]
distinguished_name = req_distinguished_name
x509_extensions = v3_req
prompt = no
[req_distinguished_name]
C = US
ST = VA
L = SomeCity
O = MyCompany
OU = MyDivision
CN = www.company.com
[v3_req]
keyUsage = keyEncipherment, dataEncipherment
extendedKeyUsage = serverAuth
subjectAltName = @alt_names
[alt_names]
DNS.1 = www.company.net
DNS.2 = company.com
DNS.3 = company.net
<!--NeedCopy-->
```

2. Upload the file to the /nsconfig/ssl directory on the Citrix ADC appliance.
3. Log on to Citrix ADC CLI as `nsroot` user and switch to the shell prompt.
4. Run the following command to create the certificate:

```
cd /nsconfig/ssl
openssl req -x509 -nodes -days 730 -newkey rsa:2048 -keyout cert.
   pem -out cert.pem -config req.conf -extensions 'v3_req'
<!--NeedCopy-->
```

5. Run the following command to verify the certificate:

```
openssl x509 -in cert.pem -noout  - text
Certificate:
Data:
Version: 3 (0x2)
Serial Number:
ed:90:c5:f0:61:78:25:ab
Signature Algorithm: md5WithRSAEncryption
Issuer: C=US, ST=VA, L=SomeCity, O=MyCompany, OU=MyDivision, CN=
   www.company.com
Validity
Not Before: Nov 6 22:21:38 2012 GMT
```

```
Not After : Nov 6 22:21:38 2014 GMT
Subject: C=US, ST=VA, L=SomeCity, O=MyCompany, OU=MyDivision, CN=
    www.company.com
Subject Public Key Info:
Public Key Algorithm: rsaEncryption
RSA Public Key: (2048 bit)
Modulus (2048 bit):
…
Exponent: 65537 (0x10001)
X509v3 extensions:
X509v3 Key Usage:
Key Encipherment, Data Encipherment
X509v3 Extended Key Usage:
TLS Web Server Authentication
X509v3 Subject Alternative Name:
DNS:www.company.net, DNS:company.com, DNS:company.net
Signature Algorithm: md5WithRSAEncryption …
<!--NeedCopy-->
```

Install, link, and update certificates

September 14, 2021

To install a certificate, see Add or update a certificate-key pair.

Link certificates

Many server certificates are signed by multiple hierarchical Certificate Authorities (CA), which means that the certificates form a chain like the following:

```
Root CA
|
+----------- Intermediate CA
|
+----------------------- End-Entity (Server) Certificate
```

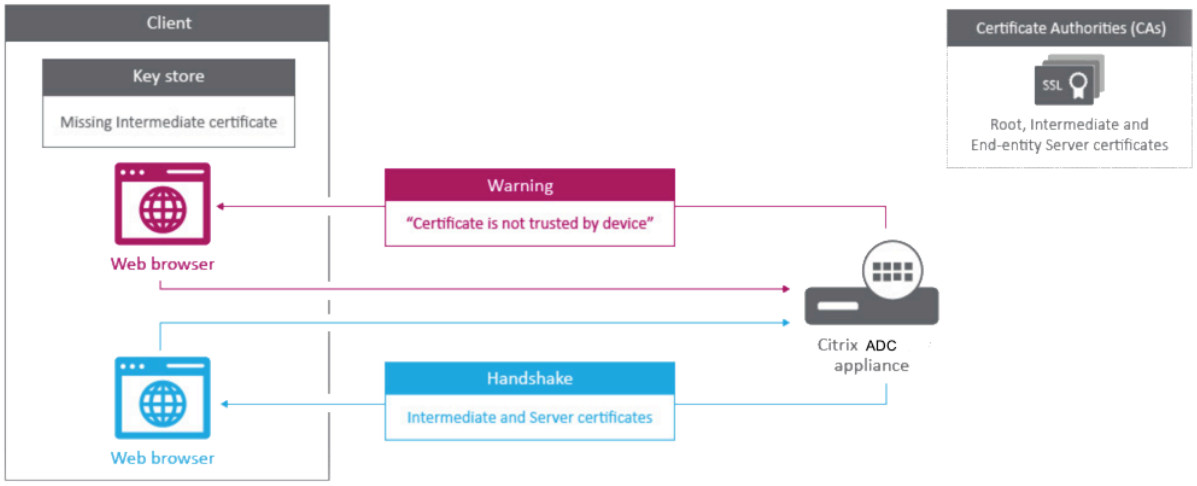
Sometimes, the Intermediate CA is split into a primary and secondary intermediate CA certificate. Then the certificates form a chain like the following:

```
Root CA
|
+------ Primary Intermediate CA
|+-------------- Secondary Intermediate CA
|
+----------------------- End-Entity (Server) Certificate
```

Client machines usually contain the root CA certificate in their local certificate store, but not one or more intermediate CA certificates. The ADC appliance must send one or more intermediate CA certificates to the clients.

Note: The appliance must not send the root CA certificate to the client. The Public Key Infrastructure (PKI) trust relationship model requires root CA certificates to be installed on clients through an out-of-band method. For example, the certificates are included with the operating system or web browser. The client ignores a root CA certificate sent by the appliance.

Sometimes, an intermediate CA that standard web browsers do not recognize as a trusted CA, issues the server certificate. In this case, one or more CA certificates must be sent to the client with the server's own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.



Video link to How do I link an intermediate authority certificate.

Refer to the following sections to add the server and intermediate certificates:

- Manual certificate linking
- Automated certificate linking
- Create a chain of certificates

Manual certificate linking

Note: This feature is not supported on the Citrix ADC FIPS platform and in a cluster setup.

Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file. You can specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (must be the first certificate in the file)

  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on
    Note: Intermediate certificate files are created for each intermediate certificate with the name "<certificatebundlename>.pem_ic<
    n>" where n is between 1 and 9. For example, bundle.pem_ic1, where **bundle** is the name of the certificate set and ic1 is the first intermediate certificate in the set.
- Bundle option is selected.
- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates exists on the appliance.
- The key is placed before the server certificate in the file.
- An intermediate certificate is placed before the server certificate.
- Intermediate certificates are not in placed in the file in the same order as they are created.
- No certificates are present in the file.
- A certificate is not in the proper PEM format.
- The number of intermediate certificates in the file exceeds nine.

Add a certificate set by using the CLI

At the command prompt, type the following commands to create a certificate set and verify the configuration:

```
1 add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES
      | NO)
2
3 show ssl
4
5 show ssl certlink
6 <!--NeedCopy-->
```

In the following example, the certificate set (bundle.pem) contains the following files:

Server certificate (bundle) linked to bundle_ic1

First intermediate certificate (bundle_ic1) linked to bundle_ic2

Second intermediate certificate (bundle_ic2) linked to bundle_ic3

Third intermediate certificate (bundle_ic3)

```
add ssl certKey bundletest -cert bundle9.pem -key bundle9.pem -bundle
   yes

sh ssl certkey

1)      Name: ns-server-certificate

```

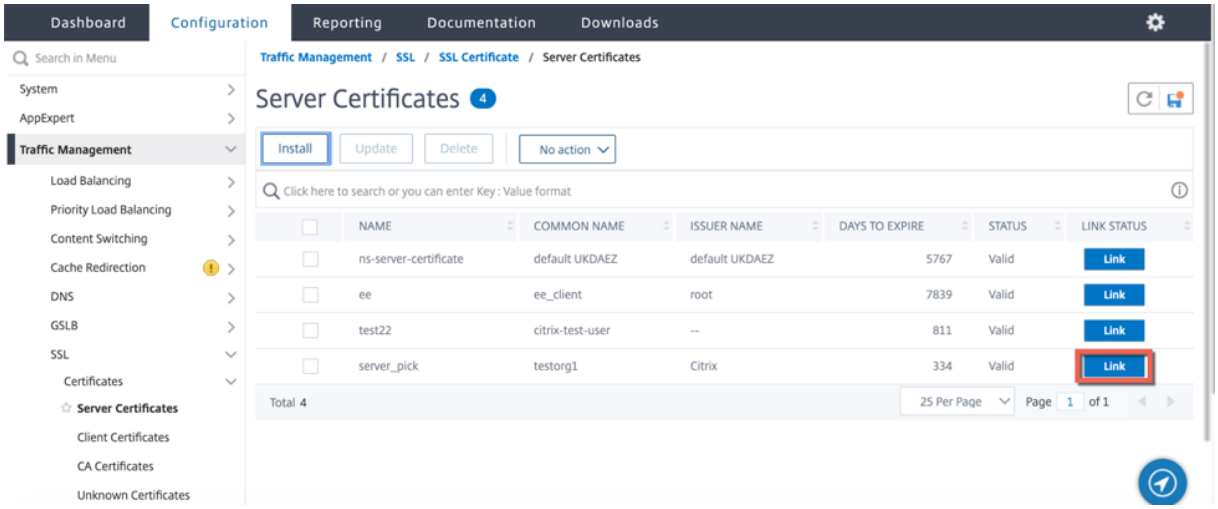
Add a certificate set by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Certificates** > **CA Certificates**.
2. In the details pane, click **Install**.
3. In the **Install Certificate** dialog box, type the details, such as the certificate and key file name, and then select **Certificate Bundle**.
4. Click **Install**, and then click **Close**.

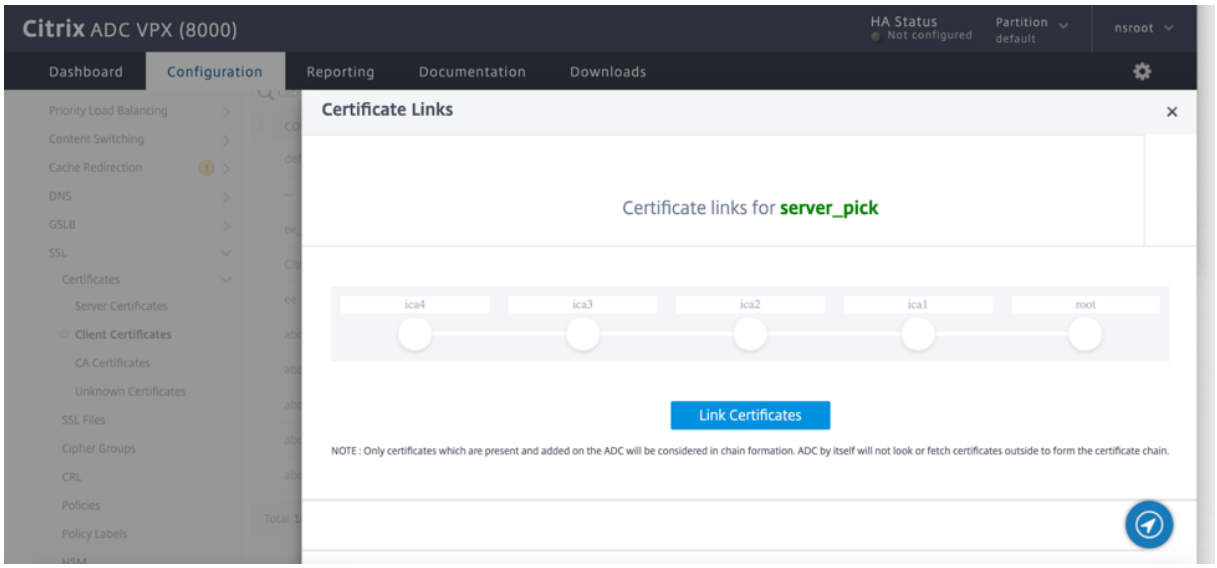
Automated certificate linking

Note: This feature is available from release 13.0 build 47.x.

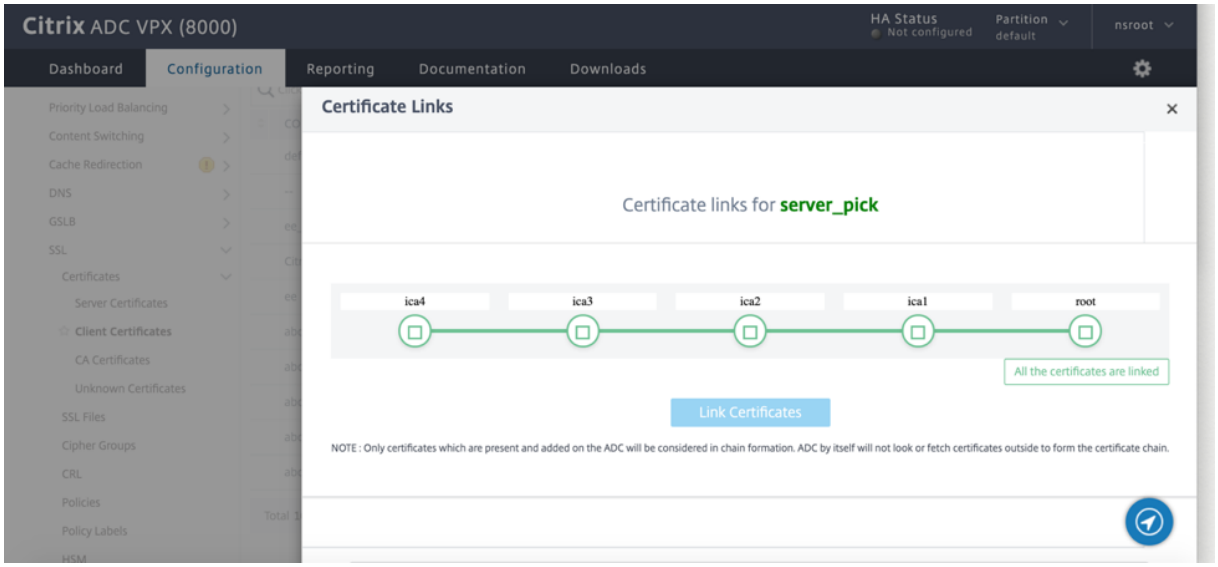
You no longer have to manually link a certificate to its issuer all the way to the root certificate. If the intermediate CA certificates and the root certificate are present on the appliance, you can click the **Link** button in the end user certificate.



The potential chain appears.



Click **Link Certificate** to link all the certificates.



Create a chain of certificates

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). This approach requires that the intermediate CA certificate file is installed on the ADC appliance, and the client application must trust one of the certificates in the chain. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.

Note: The appliance supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

Create a certificate chain by using the CLI

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

```
link ssl certkey <certKeyName> <linkCertKeyName>
show ssl certlink
<!--NeedCopy-->
```

Example:

```
link ssl certkey siteAcertkey CAcertkey
Done

show ssl certlink

linked certificate:
```

```
        1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
Done
<!--NeedCopy-->
```

Create a certificate chain by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Certificates**.
2. Select a server certificate, and in the **Action** list, select **Link**, and specify a CA certificate name.

Update an existing server certificate

To change an existing server certificate manually, you must perform the following steps:

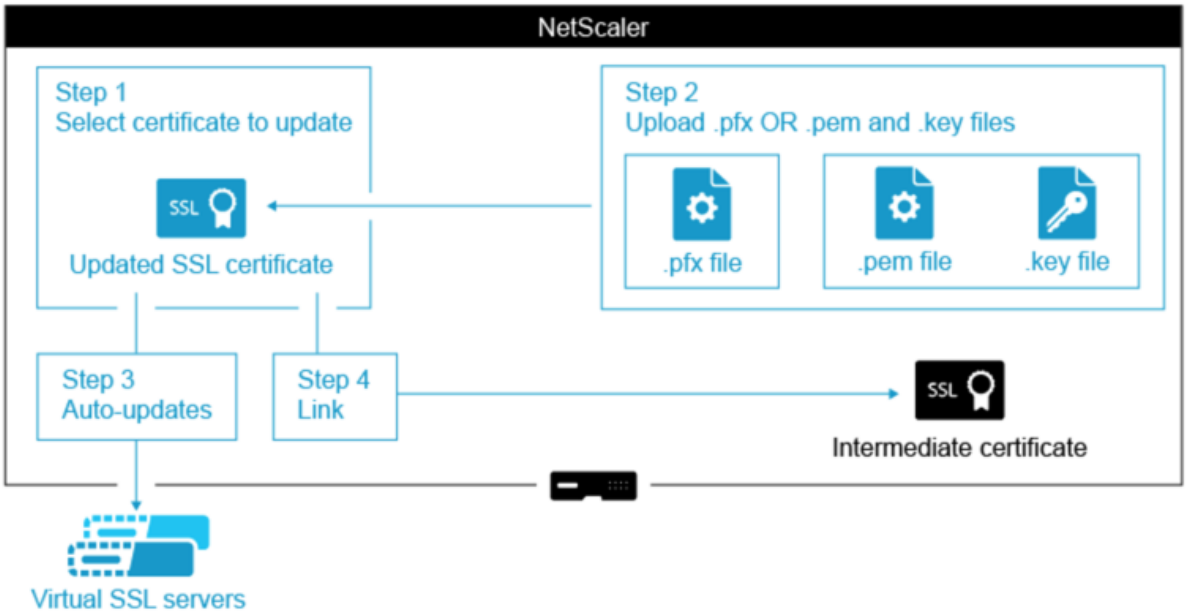
1. Unbind the old certificate from the virtual server.
2. Remove the certificate from the appliance.
3. Add the new certificate to the appliance.
4. Bind the new certificate to the virtual server.

To reduce downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

When you remove or unbind a certificate from a configured SSL virtual server or service, the virtual server or service becomes inactive. They are active after a new valid certificate is bound to them. To reduce downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service.

Overview diagram of how to update an SSL certificate on the Citrix ADC appliance.



Video link to How do I update an existing certificate.

Update an existing certificate-key pair by using the CLI

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

```
update ssl certkey <certkeyName> -cert <string> -key <string>

show ssl certKey <certkeyName>
<!--NeedCopy-->
```

Example:

```
update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /
   nsconfig/ssl/pkey.pem

Done

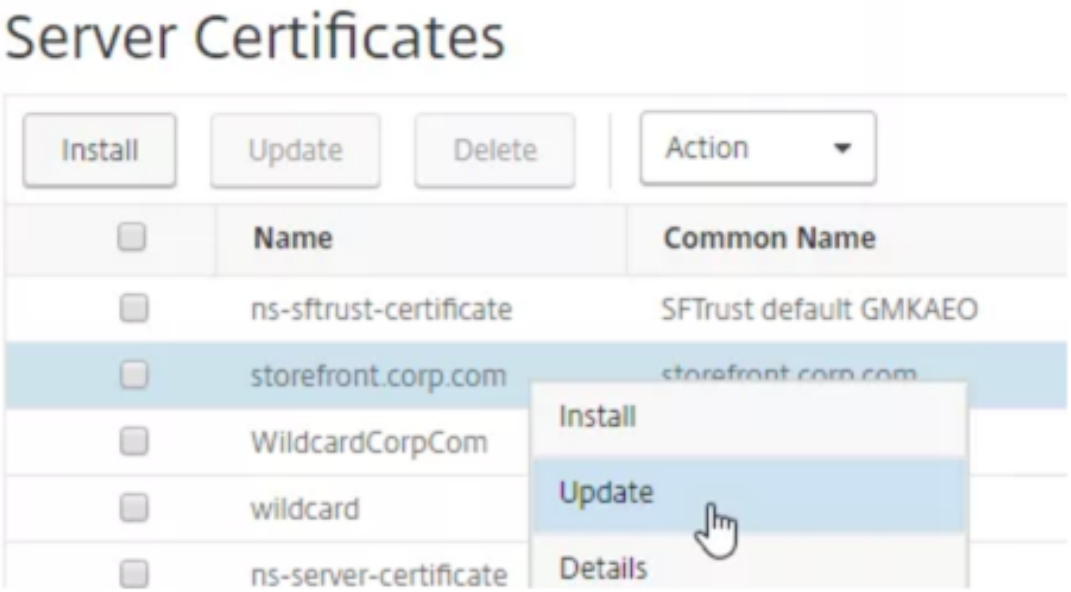
show ssl certkey siteAcertkey

Name: siteAcertkey       Status: Valid
          Version: 3
          Serial Number: 02
          Signature Algorithm: md5WithRSAEncryption
          Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
          Validity
               Not Before: Nov 11 14:58:18 2001 GMT
```

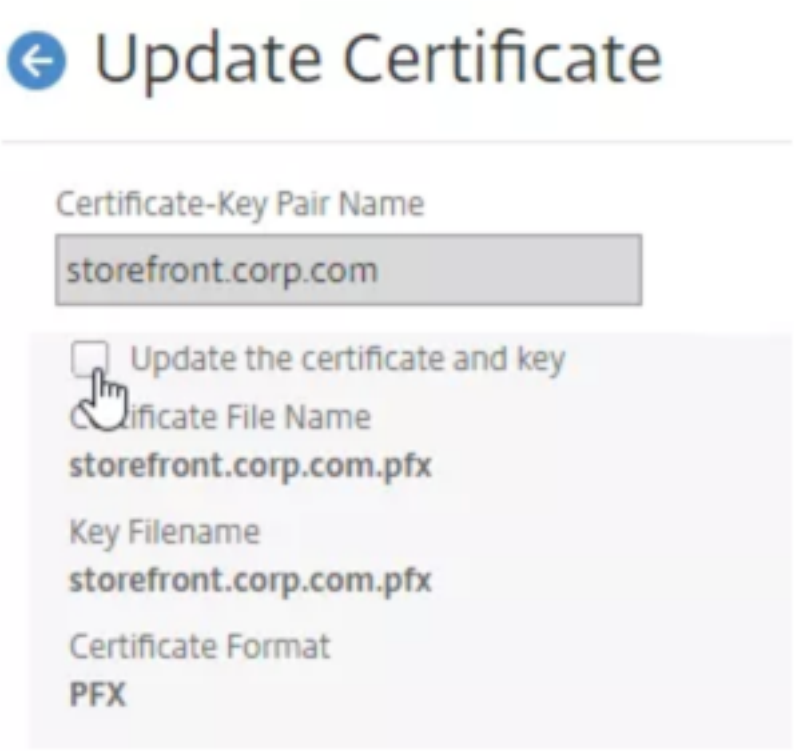
```
                Not After: Aug 7 14:58:18 2004 GMT
            Subject: /C=US/ST-CA/L=San Jose/O=CA/OU=Security
            Public Key Algorithm: rsaEncryption
            Public Key size: 2048
Done
<!--NeedCopy-->
```

Update an existing certificate-key pair by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Certificates** > **Server Certificates**.
2. Select the certificate that you want to update, and click **Update**.



3. Select **Update the certificate and key**.



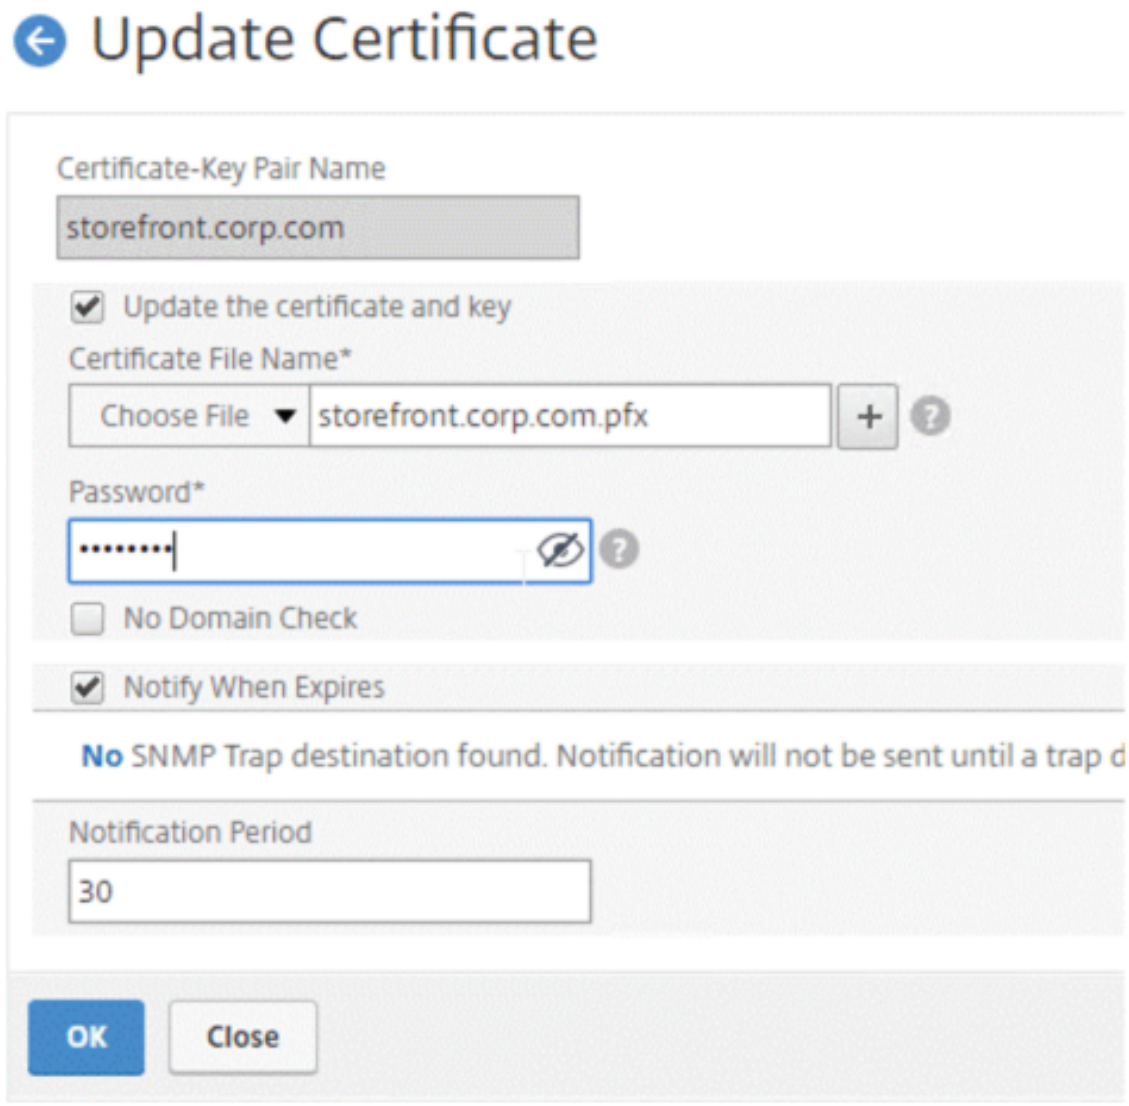
4. In **Certificate File Name**, click **Choose File** > **Local**, and browse to the updated .pfx file or certificate PEM file.

   - If you upload a .pfx file, you are prompted to specify the .pfx file password.
   - If you upload a certificate pem file, you must also upload a certificate key file. If the key is encrypted, you must specify the encryption password.

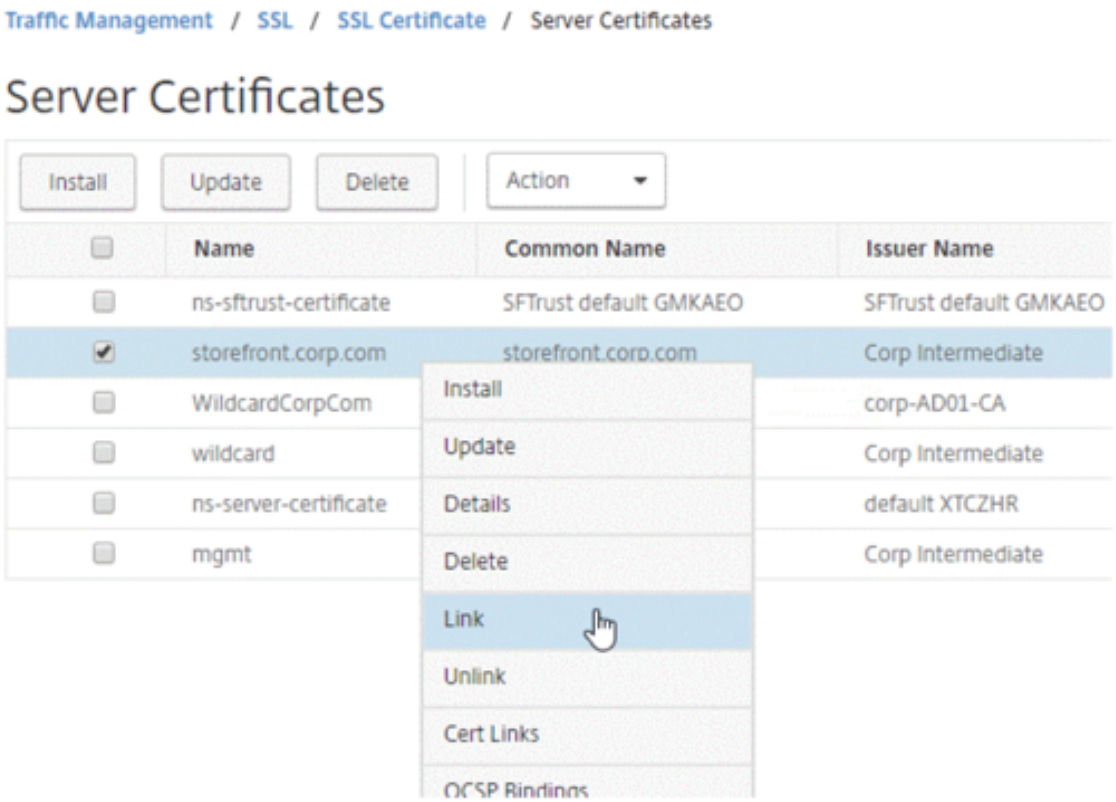
5. If the common name of the new certificate does not match the old certificate, then select **No**

Domain Check.

6. Click **OK**. All the SSL virtual servers to which this certificate is bound are automatically updated.

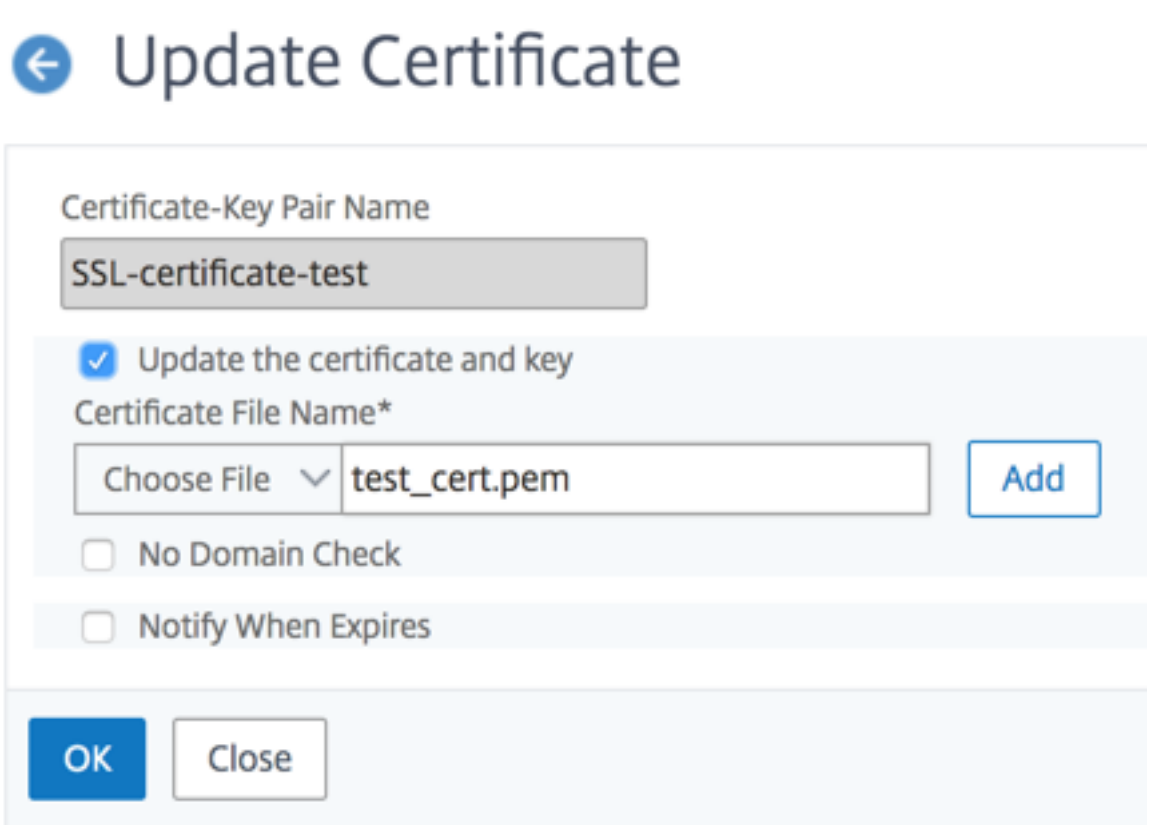


7. After replacing the certificate, you might have to update the certificate link to a new intermediate certificate. For more information about updating an intermediate certificate without breaking the links, see Update an intermediate certificate without breaking the links.
   - Right-click the updated certificate, and click **Cert Links**, to see if it is linked to an intermediate certificate.
   - If the certificate is not linked, then right-click the updated certificate, and click **Link** to link it to an intermediate certificate. If you don't see an option to link, then you must first have to install a new intermediate certificate on the appliance under the **CA Certificates** node.



Update an existing CA certificate

The steps to update an existing CA certificate are the same as updating an existing server certificate. The only difference is that you do not need a key in the case of CA certificates.



Disable domain checks

When an SSL certificate is replaced on the appliance, the domain name mentioned on the new certificate must match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to host a new domain, disable the domain check before updating its certificate.

Disable the domain check for a certificate by using the CLI

At the command prompt, type the following commands to disable the domain check and verify the configuration:

```
update ssl certKey <certkeyName> -noDomainCheck

show ssl certKey <certkeyName>
<!--NeedCopy-->
```

Example:

```
update ssl certKey sv -noDomainCheck

Done

show ssl certkey sv

Name: sv
Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
Format: PEM
Status: Valid,   Days to expiration:9349
Certificate Expiry Monitor: DISABLED
Done
<!--NeedCopy-->
```

Disable the domain check for a certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**, select a certificate, and click **Update**.
2. Select **No Domain Check**.

Replace the default certificate of an ADC appliance with a trusted CA certificate that matches the host name of the appliance

The following procedure assumes that the default certificate (`ns-server-certificate`) is bound to the internal services.

1. Navigate to **Traffic Management > SSL > SSL Certificates > Create Certificate Request**.
2. In common name, type `test.citrixadc.com`.
3. Submit the CSR to a trusted certificate authority.
4. After receiving the certificate from the trusted CA, copy the file to the `/nsconfig/ssl` directory.
5. Navigate to **Traffic Management > SSL > Certificates > Server Certificates**.
6. Select the default server certificate (`ns-server-certificate`) and click **Update**.
7. In the **Update Certificate** dialog box, in **Certificate File Name**, browse to the certificate received from the CA after signing.
8. In the **Key File Name** field, specify the default private key file name (`ns-server.key`).
9. Select **No Domain Check**.
10. Click **OK**.

Enable the expiry monitor

An SSL certificate is valid for a specific period. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the appliance creates entries in the appliance's syslog and ns audit logs when a certificate configured is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

Enable an expiry monitor for a certificate by using the CLI

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

```
set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED ) [-
    notificationPeriod <positive_integer>]]

show ssl certKey <certkeyName>
<!--NeedCopy-->
```

Example:

```
set ssl certKey sv -expiryMonitor ENABLED  - notificationPeriod 60
Done
<!--NeedCopy-->
```

Enable an expiry monitor for a certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**, select a certificate, and click **Update**.
2. Select **Notify When Expires**, and optionally specify a notification period.

Update an intermediate certificate without breaking the links

You can now update an intermediate certificate without breaking any existing links. The 'AuthorityKeyIdentifier' extension, in the linked certificate issued by the certificate to be replaced, must not contain an authority certificate serial number ('authorityCertSerialNumber') field. If the 'AuthorityKeyIdentifier' extension contains a serial number field, then the certificate serial numbers of the old and new certificate must be the same. You can update any number of certificates in the link, one at a time, if the preceding condition is met. Previously, the links broke if an intermediate certificate was updated.

For example, there are four certificates: `CertA`, `CertB`, `CertC`, and `CertD`. Certificate `CertA` is the issuer for `CertB`, `CertB` is the issuer for `CertC`, and so on. If you want to replace an intermediate

certificate CertB with CertB_new, without breaking the link, the following condition must be met:

The certificate serial number of CertB must match the certificate serial number of CertB_new if both of the following conditions are met:

- The AuthorityKeyIdentifier extension is present in CertC.
- This extension contains a serial number field.

If the common name in a certificate changes, while updating the certificate specify nodomaincheck.

In the preceding example, to change “www.example.com” in CertD to “*.example.com,” select the ‘No Domain Check” parameter.

Update the certificate by using the CLI

At the command prompt, type:

```
update ssl certKey <certkeyName> -cert <string> [-password] -key <
   string>  [-noDomainCheck]
<!--NeedCopy-->
```

Example:

```
update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /
   nsconfig/ssl/pkey.pem -noDomainCheck
<!--NeedCopy-->
```

Display a certificate chain

A certificate contains the name of the issuing authority and the subject to whom the certificate is issued. To validate a certificate, you must look at the issuer of that certificate and confirm if you trust the issuer. If you do not trust the issuer, you must see who issued the issuer certificate. Go up the chain until you reach the root CA certificate or an issuer that you trust.

As part of the SSL handshake, when a client requests a certificate, the appliance presents a certificate and the chain of issuer certificates present on the appliance. An administrator can view the certificate chain for the certificates present on the appliance and install any missing certificates.

View the certificate chain for the certificates present on the appliance by using the CLI

At the command prompt, type:

```
show ssl certchain <cert_name>
<!--NeedCopy-->
```

Examples

There are 3 certificates: c1, c2, and c3. Certificate c3 is the root CA certificate and signs c2, and c2 signs c1. The following examples illustrate the output of the `show ssl certchain c1` command in different scenarios.

Scenario 1:

Certificate c2 is linked to c1, and c3 is linked to c2.

Certificate c3 is a root CA certificate.

If you run the following command, the certificate links up to the root CA certificate are displayed.

```
show ssl certchain c1

Certificate chain details of certificate name c1 are:
    1) Certificate name: c2              linked; not a root
       certificate
    2) Certificate name: c3              linked; root certificate
Done
<!--NeedCopy-->
```

Scenario 2:

Certificate c2 is linked to c1.

Certificate c2 is not a root CA certificate.

If you run the following command, the information that certificate c3 is a root CA certificate but is not linked to c2 is displayed.

```
show ssl certchain c1

Certificate chain  details of certificate name c1 are:
    1) Certificate Name: c2              linked; not a root
       certificate
    2) Certificate Name: c3              not linked; root certificate
    Done
<!--NeedCopy-->
```

Scenario 3:

Certificate c1, c2, and c3 are not linked but are present on the appliance.

If you run the following command, information about all the certificates starting with the issuer of certificate c1 is displayed. It is also specified that the certificates are not linked.

```
show ssl certchain c1
```

```
2
3 Certificate chain details of certificate name c1 are:
4     1) Certificate Name: c2               not linked; not a root
         certificate
5     2) Certificate Name: c3               not linked; root certificate
6     Done
7 <!--NeedCopy-->
```

Scenario 4:

Certificate c2 is linked to c1.

Certificate c3 is not present on the appliance.

If you run the following command, information about the certificate linked to c1 is displayed. You are prompted to add a certificate with the subject name specified in c2. In this case, the user is asked to add the root CA certificate c3.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4     1) Certificate Name: c2               linked; not a root
         certificate
5     2) Certificate Name: /C=IN/ST=ka/O=netscaler/CN=test
6        Action: Add a certificate with this subject name.
7 Done
8 <!--NeedCopy-->
```

Scenario 5:

A certificate is not linked to certificate c1 and the issuer certificate of c1 is not present on the appliance.

If you run the following command, you are prompted to add a certificate with the subject name in certificate c1.

```
1 sh ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4     1) Certificate Name: /ST=KA/C=IN
5        Action: Add a certificate with this subject name.
6 <!--NeedCopy-->
```

Generate a server test certificate

September 14, 2021

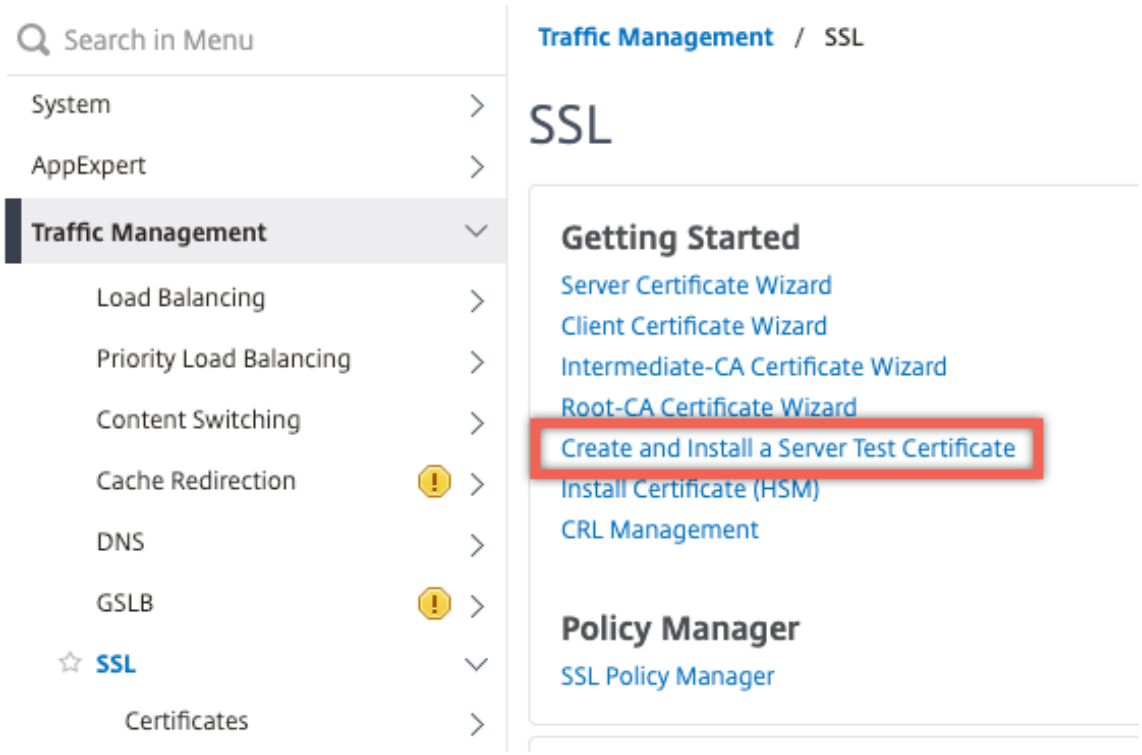
The Citrix ADC appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. Typically, a trusted CA issues a server certificate. The server sends the certificate to a client who uses it to authenticate the server.

For issuing a server test certificate, the appliance operates as a certificate authority. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. Do not use in a production environment.

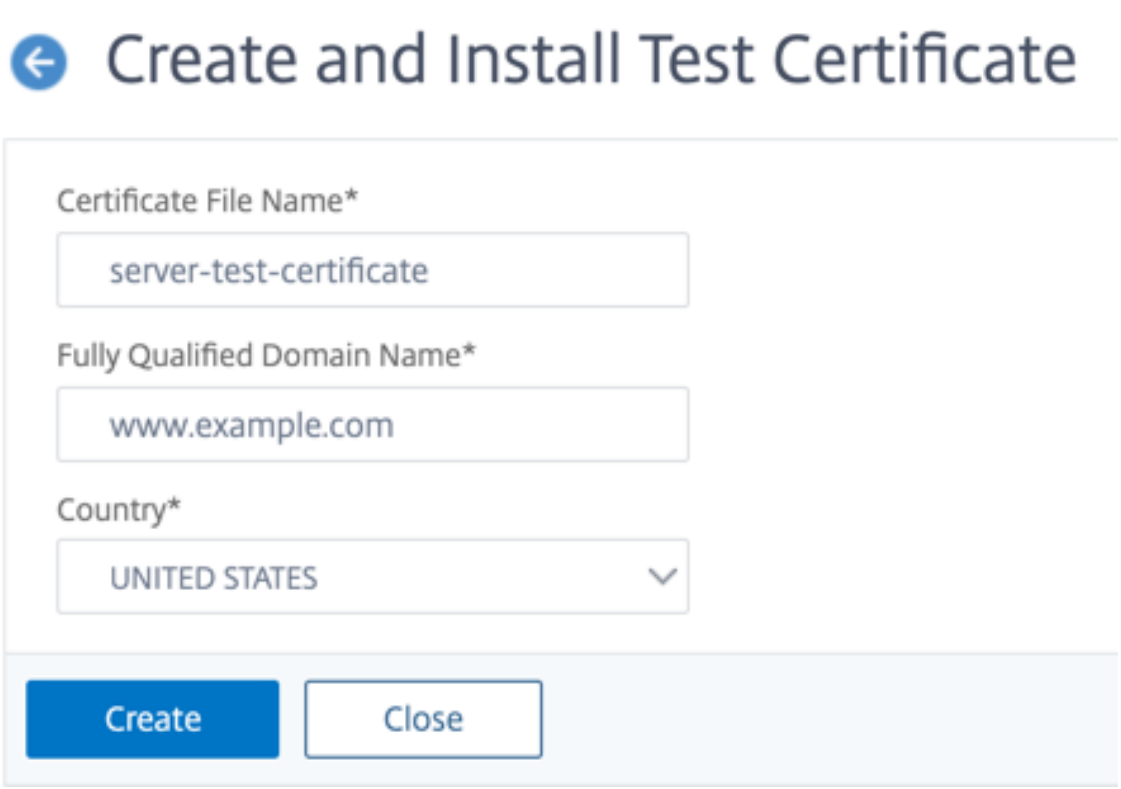
You can install the server test certificate on any virtual server that uses the SSL or the SSL_TCP protocol.

Generate a server test certificate by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **SSL Certificates group**, select **Create and Install a Server Test Certificate**.



2. Enter details for the parameters and click **Create**.



Import and convert SSL files

September 14, 2021

You can now import SSL resources, such as certificates, private keys, CRLs, and DH keys, from remote hosts even if FTP access to these hosts is not available. This feature is especially helpful in environments where shell access to the remote host is restricted. Default folders are created in /nsconfig/ssl as follows:

- For certificate files: /nsconfig/ssl/certfile
- For private keys: the /nsconfig/ssl/keyfile
- For CRLs: /var/netscaler/ssl/crlfile
- For DH keys: /nsconfig/ssl/dhfile

Imports from both HTTP and HTTPS servers are supported. However, the import fails if the file is on an HTTPS server that requires client certificate authentication for access.

> **Note:**
>
> The import command is not stored in the configuration (ns.conf) file, because reimporting the

> file after a restart might cause an error.

Import a certificate file

You can use the CLI and GUI to import a file (resource) from a remote host.

Import a certificate file from a remote host by using the CLI

At the command prompt, type:

```
import ssl certFile [<name>] [<src>]
<!--NeedCopy-->
```

Example:

```
import ssl certfile my-certfile http://www.example.com/file_1
<!--NeedCopy-->
```

```
show ssl certfile
     Name : my-certfile
     URL : http://www.example.com/file_1
<!--NeedCopy-->
```

To remove a certificate file, use the `rm ssl certFile` command, which accepts only the 'name' argument.

Import a key file from a remote host by using the CLI

At the command prompt, type:

```
import ssl keyFile [<name>] [<src>]
<!--NeedCopy-->
```

Example:

```
import ssl keyfile my-keyfile http://www.example.com/key_file
<!--NeedCopy-->
```

```
show ssl keyfile
     Name : my-keyfile
     URL : http://www.example.com/key_file
<!--NeedCopy-->
```

To remove a key file, use the `rm ssl keyFile` command, which accepts only the 'name' argument.

Import a CRL file from a remote host by using the CLI

At the command prompt, type:

```
import ssl crlFile [<name>] [<src>]
<!--NeedCopy-->
```

To remove a CRL file, use the `rm ssl crlFile` command, which accepts only the <name> argument.

Example:

```
import ssl crlfile my-crlfile http://www.example.com/crl_file

show ssl crlfile

    Name : my-crlfile
    URL : http://www.example.com/crl_file
<!--NeedCopy-->
```

Import a DH file from a remote host by using the CLI

At the command prompt, type:

```
import ssl dhFile [<name>] [<src>]
<!--NeedCopy-->
```

Example:

```
import ssl dhfile my-dhfile http://www.example.com/dh_file
show ssl dhfile
     Name : my-dhfile
     URL : http://www.example.com/dh_file
<!--NeedCopy-->
```

To remove a DH file, use the `rm ssl dhFile` command, which accepts only the <name> argument.

Import an SSL resource by using the GUI

Navigate to **Traffic Management > SSL > Imports**, and then select the appropriate tab.

Import PKCS#8 and PKCS#12 certificates

If you want to use certificates and keys that you already have on other secure servers or applications in your network, you can export them, and then import them to the Citrix ADC appliance. You might have to convert exported certificates and keys before you can import them to the Citrix ADC appliance.

For the details of how to export certificates from secure servers or applications in your network, see the documentation of the server or application from which you want to export.

> **Note:**
>
> For installation on the Citrix ADC appliance, key and certificate names cannot contain spaces or special characters other than those characters supported by the UNIX file system. Follow the appropriate naming convention when you save the exported key and certificate.

A certificate and private key pair is commonly sent in the PKCS#12 format. The appliance supports PEM and DER formats for certificates and keys. To convert PKCS#12 to PEM or DER, or PEM or DER to PKCS#12, see the "Convert SSL certificates for import or export" section later in this page.

The Citrix ADC appliance does not support PEM keys in PKCS#8 format. However, you can convert these keys to a supported format by using the OpenSSL interface, which you can access from the CLI or the configuration utility. Before you convert the key, you need to verify that the private key is in PKCS#8 format. Keys in PKCS#8 format typically start with the following text:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----

leuSSZQZKgrgUQ==

-----END ENCRYPTED PRIVATE KEY-----
<!--NeedCopy-->
```

Open the OpenSSL interface from the CLI

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance by using the administrator credentials.
3. At the command prompt, type shell.
4. At the shell prompt type `openssl`.

Open the OpenSSL interface from the GUI

Navigate to **Traffic Management > SSL** and, in the Tools group, select **OpenSSL interface**.

Convert a non-supported PKCS#8 key format to an encrypted supported key format by using the OpenSSL interface

At the OpenSSL prompt, type one of the following commands, depending on whether the non-supported key format is of type RSA or ECDSA:

```
1 OpenSSL>rsa- in <PKCS#8 Key Filename> -des3 -out <encrypted Key
     Filename>
2
3 OpenSSL>ec -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename
     >
4 <!--NeedCopy-->
```

Parameters for converting an unsupported key format to a supported key format

- **PKCS#8 Key Filename:** The input file name of the incompatible PKCS#8 private key.
- **encrypted Key Filename:** The output file name of the compatible encrypted private key in PEM format.
- **unencrypted Key Filename:** The output file name of the compatible unencrypted private key in PEM format.

Convert SSL certificates for import or export

A Citrix ADC appliance supports the PEM and DER formats for SSL certificates. Other applications, such as client browsers and some external secure servers, require various public key cryptography standard (PKCS) formats. The appliance can convert the PKCS#12 format to PEM or DER format for importing a certificate to the appliance, and can convert PEM or DER to PKCS#12 for exporting a certificate. For more security, conversion of a file for import can include encryption of the private key with the DES or DES3 algorithm.

> **Note:**
>
> If you use the GUI to import a PKCS#12 certificate, and the password contains a dollar sign ($), back quote (‘), or escape () character, the import might fail. If it does, the ERROR: Invalid password message appears. If you must use a special character in the password, be sure to prefix it with an escape character () unless all imports are performed by using the CLI.

Convert the format of a certificate by using the CLI

At the command prompt, type the following command:

```
convert ssl pkcs12 <outfile> [-import [-pkcs12File <inputFilename>] [-
    des | -des3] [-export [-certFile <inputFilename>] [-keyFile <
    inputFilename>]]
<!--NeedCopy-->
```

During the operation, you are prompted to enter an import password or an export password. For an encrypted file, you are also prompted to enter a passphrase.

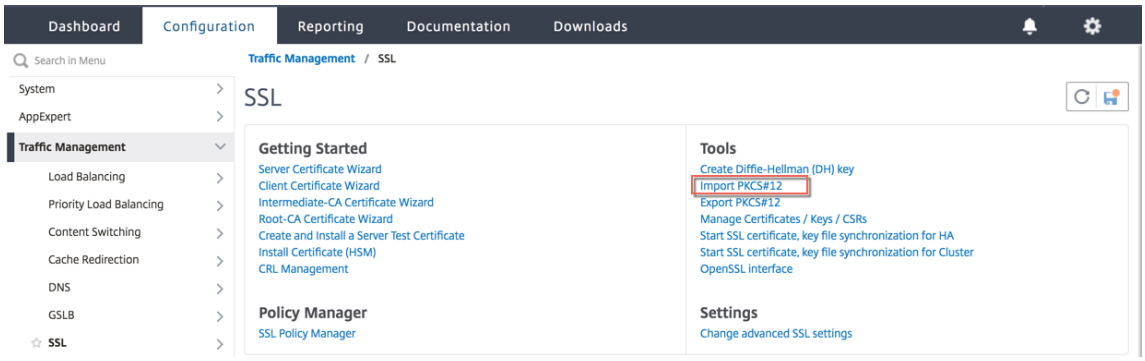
Example:

```
convert ssl pkcs12 Cert-Import-1.pem -import -pkcs12File Cert-Import-1.
    pfx -des

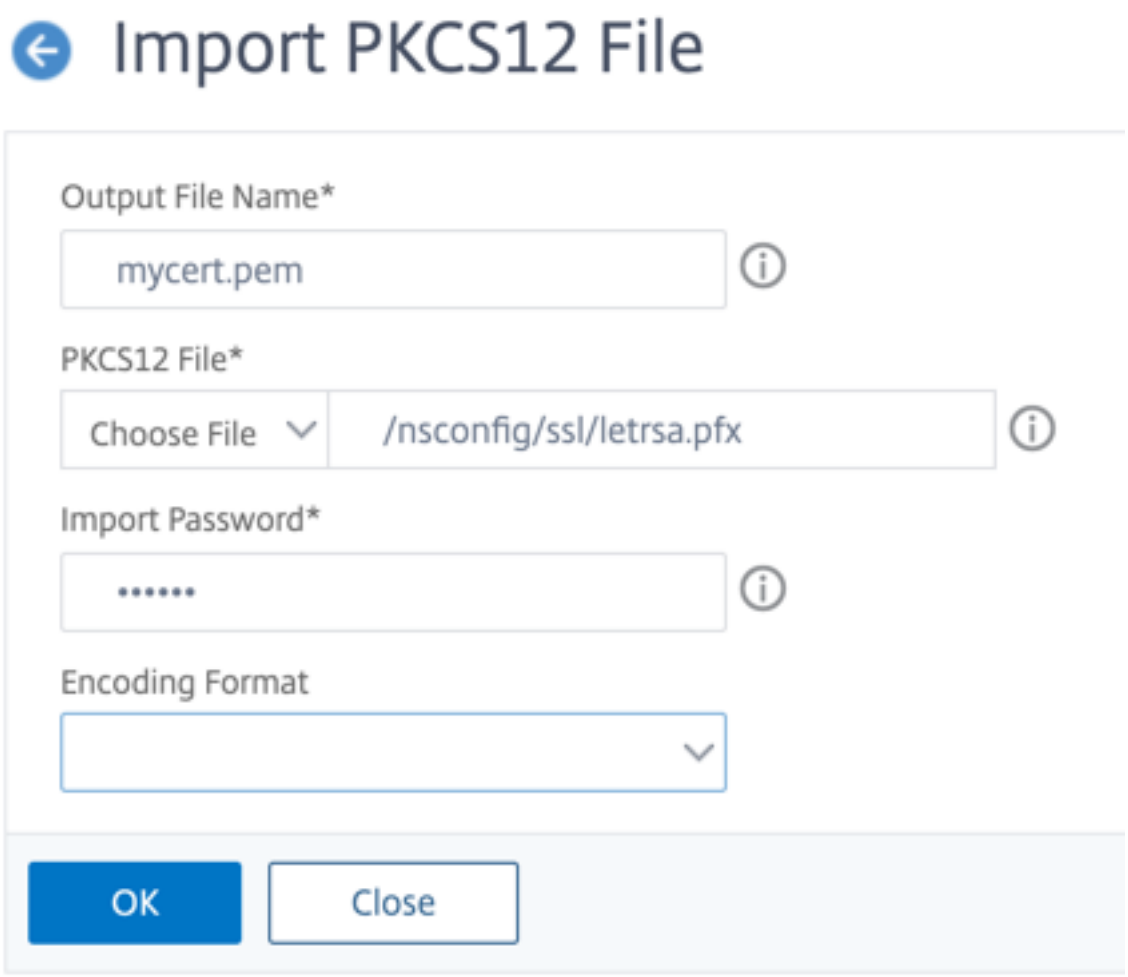
convert ssl pkcs12 Cert-Client-1.pfx -export -certFile Cert-Client-1 -
    keyFile Key-Client-1
<!--NeedCopy-->
```

Convert the format of a certificate by using the GUI

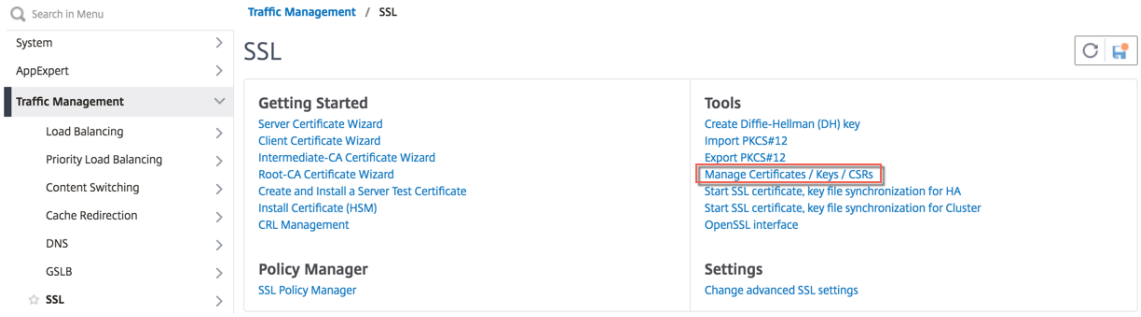
1. Navigate to **Traffic Management > SSL** and, in the **Tools** group, select **Import PKCS#12**.



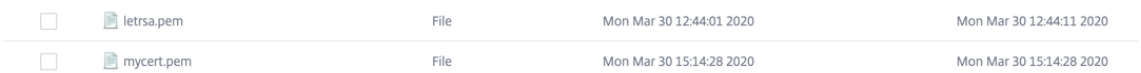
2. Specify the PEM certificate name in the **Output File Name** field.
3. Browse to the location of the PFX certificate on your local computer or the appliance.



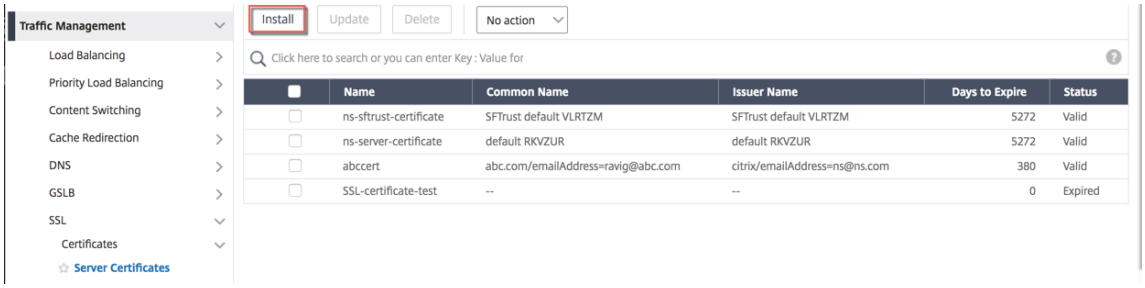
4. Click **OK**.
5. Click **Manage Certificates / Keys / CSRs** to view the converted PEM file.



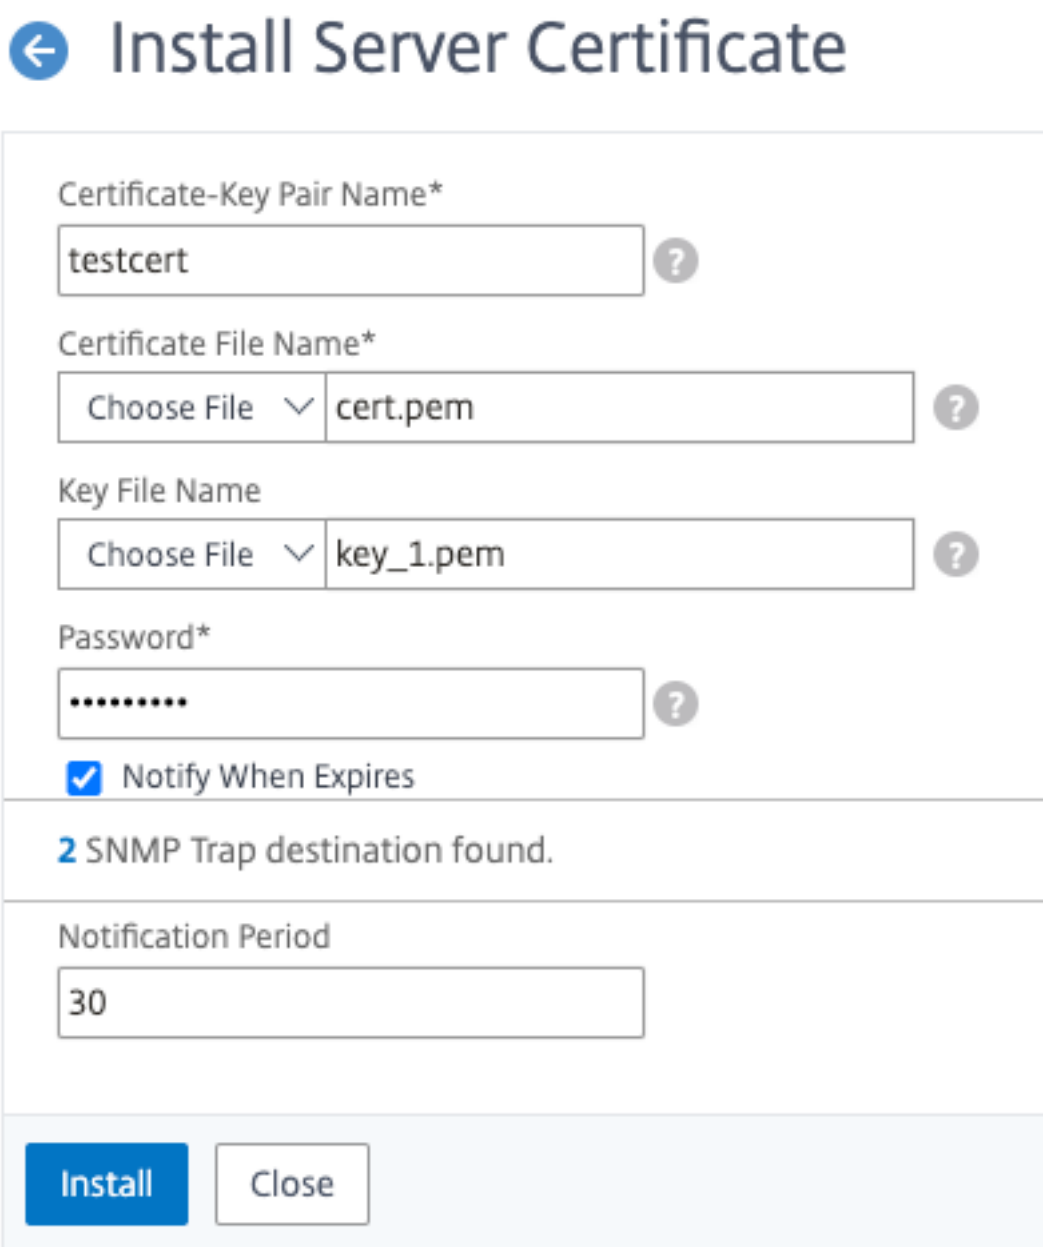
6. You can view the uploaded PFX file and the converted PEM file.



7. Navigate to **SSL** > **Certificates** > **Server Certificates** and click **Install**.



8. Specify a **Certificate-Key Pair Name**.
9. Browse to the location of the PEM file.
10. Specify the password when prompted.
11. Click **Install**.



12. Bind the certificate-key pair to an SSL virtual server.

Bind an SSL certificate to a virtual server on the Citrix ADC appliance

September 17, 2021

An SSL certificate is an essential part of SSL encryption and decryption processes. The certificate is used during an SSL handshake to establish the identity of the SSL server, which is the Citrix ADC appliance as it acts as the SSL termination point for the clients.

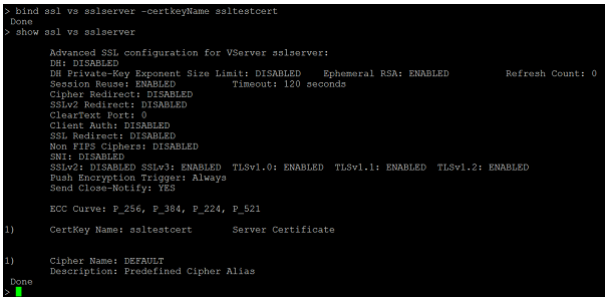
The certificate used for processing the SSL transactions must be bound to the virtual server (SSL) that receives the SSL data.

To bind an SSL certificate to an SSL virtual server using the command line interface

At the command prompt, type:

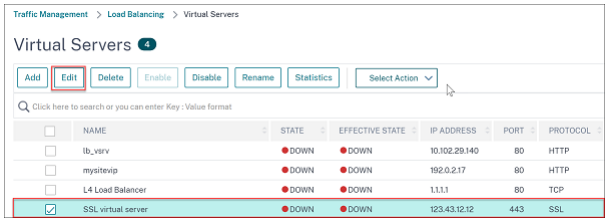
```
bind ssl vs <vServerName> -certkeyName <certificate-KeyPairName>
show ssl vs <vServerName>
<!--NeedCopy-->
```

Example:



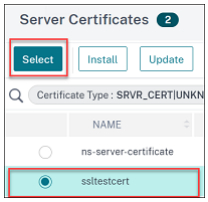
To bind an SSL certificate to an SSL virtual server using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server of type SSL and click **Edit**.



3. In the **Load Balancing Virtual Server** page, under the **Certificates** section, click **No Server Certificate**.

4. In the **Server Certificate Binding** page, click **Click to select**.
5. Select the SSL certificate and click **Select**.



6. Click **Bind** to bind the SSL certificate to the virtual server.
7. Click **Done**.

   You have completed binding the SSL certificate to the virtual server.

SSL profiles

September 14, 2021

An SSL profile is a collection of settings for SSL entities. It offers ease of configuration and flexibility. Instead of configuring the settings on each entity, you can configure them in a profile and bind the profile to all the entities that the settings apply to.

The SSL profile infrastructure has been enhanced to use the latest ciphers and protocols. Differences between the legacy profile (old profile) and the enhanced SSL profile (new profile) are highlighted.

Differences between the old and the new SSL profile infrastructure

Differences	Old Profile	New Profile
Ciphers and ECC Curves included in the profile	No	Yes
Inserting a cipher or cipher group in the middle of an existing list	Unbind all the ciphers and bind again in the order of the required priority.	Add a cipher and assign it a priority. If a priority is not specified, the cipher is assigned the lowest priority in the list.

Differences	Old Profile	New Profile
Unbinding all the ciphers	`unbind ssl vserver \< name\> ciphername -ALL`	`unbind ssl profile -cipherName FlushAllCiphers` (Release 11.0 build 64.x or later includes the FlushAllCiphers parameter for unbinding all the ciphers or cipher groups from a profile, because ALL is treated like a cipher group.)
State of SSLv3	n/a	Disabled on the default front-end profile (ns_default_ssl_profile_frontend). Note: Before you enable this profile, SSLv3 is enabled globally. After enabling the profile, SSLv3 is disabled on the front-end default profile.

SSL profile infrastructure

September 14, 2021

Vulnerabilities in SSLv3 and RC4 implementation have emphasized the need to use the latest ciphers and protocols to negotiate the security settings for a network connection. Implementing any changes to the configuration, such as disabling SSLv3 across thousands of SSL end points, is a cumbersome process. Therefore, settings that were part of the SSL end points configuration have been moved to the SSL profiles, along with the default ciphers. To implement changes in the configuration, including cipher support, you need only modify the profile that is bound to the entities.

The default front-end and default back-end SSL profiles contain all the default ciphers and ECC curves, in addition to the settings that were part of the old profiles. Sample outputs for the default profiles are provided in the appendix. The Enable Default Profile operation automatically binds the default front-end profile to all front-end entities, and the default back-end profile to all back-end entities. You can modify a default profile to suit your deployment. You can also create custom profiles and bind them to SSL entities.

The front-end profile contains parameters applicable to a front-end entity. That is, they apply to the entity that receives requests from a client. Typically, this entity is an SSL virtual server or transpar-

ent SSL service on the Citrix ADC appliance. The back-end profile contains parameters applicable to a back-end entity. That is, they apply to the entity on the ADC appliance that sends client requests to a back-end server. Typically, this entity is an SSL service on the Citrix ADC appliance. If you try to configure an unsupported parameter, the error `ERROR: Specified parameters are not applicable for this type of SSL profile` appears.

> **Important:**
>
> - An SSL profile takes precedence over SSL parameters. That is, if you configure SSL parameters using the `set ssl parameter` command, and later bind a profile to an SSL entity, the settings in the profile take precedence.
> - After the upgrade, if you enable the default profiles, you cannot undo the changes. That is, the profiles cannot be disabled. Save the configuration and create a copy of the configuration file (ns.conf) before enabling the profiles. However, if you do not want to use the features in the default profile, you can continue to use the old SSL profiles. For more information about these profiles, see Legacy SSL profile.
> - From release 11.1 51.x, in the GUI and CLI, a confirmation prompt is added when you enable the default profile to prevent enabling it by mistake.

Command:

```
1 set ssl parameter -defaultProfile ENABLED
2     Save your configuration before enabling the Default profile. You
         cannot undo the changes. Are you sure you want to enable the
         Default profile? [Y/N]Y
3 Done
4 <!--NeedCopy-->
```

By default, some SSL parameters, called *global parameters*, apply to all the SSL end points. However, if a profile is bound to an SSL end point, the global parameters do not apply. The settings specified in the profile apply instead.

Points to note

1. A profile can be bound to multiple virtual servers, but a virtual server can have only one profile bound to it.
2. To delete a profile that is bound to a virtual server, first unbind the profile.
3. A cipher or cipher group can be bound to multiple profiles at different priorities.
4. A profile can have multiple ciphers and cipher groups bound at different priorities.
5. Changes to a cipher group are immediately reflected in all the profiles and in all the virtual servers that one of the profiles is bound to.

6. If a cipher suite is part of a cipher group, edit the cipher group to remove that cipher suite before removing the cipher suite from the profile.
7. If you do not assign a priority to a cipher suite or cipher group attached to a profile, it is assigned the lowest priority within the profile.
8. You can create a custom cipher group (also called a user-defined cipher group) from existing cipher groups and cipher suites. If you create cipher group A and add existing cipher groups X and Y to it, in that order, Y is assigned at a lower priority than X. That is, the group that is added first has a higher priority.
9. If a cipher suite is part of two cipher groups attached to the same profile, the cipher suite is not added as part of the second cipher group. The cipher suite at the higher priority is in effect when traffic is processed.
10. Cipher groups are not expanded in the profile. As a result, the number of lines in the configuration file (ns.conf) is greatly reduced. For example, if two cipher groups containing 15 ciphers each are bound to a thousand SSL virtual servers, expansion adds 30*1000 cipher-related entries in the configuration file. With the new profile, it would have only two entries: one for each cipher group that is bound to a profile.
11. Creating a user defined cipher group from existing ciphers and cipher groups is a copy-paste operation. Any changes in the original group are not reflected in the new group.
12. A user-defined cipher group lists all the profiles that it is a part of.
13. A profile lists all the SSL virtual server, services, and service groups that it is bound to.
14. If the default SSL profile feature is enabled, use the profile to set or change any of the attributes of an SSL entity. For example, virtual server, service, service group, or an internal service.

Save the configuration by using the CLI

At the command prompt, type:

```
save config

shell

root@ns# cd /nsconfig

root@ns# cp ns.conf ns.conf.NS<currentreleasenumber><currentbuildnumber
   >
<!--NeedCopy-->
```

Example:

```
save config
shell
root@ns# cd /nsconfig
```

```
root@ns# cp ns.conf ns.conf.NS.11.0.jun.16
<!--NeedCopy-->
```

Enable the default profile

> **Important:**
>
> Save your configuration before you upgrade the software and enable the default profiles.
>
> From release 11.1 build 51.x, in the GUI and CLI, a confirmation prompt appears when you enable the default profile to avoid enabling it by mistake.

Command: The following command enables the default profile and binds this profile to the SSL entities to which a profile is already bound. That is, if a profile (for example P1) is already bound to an SSL entity, the default front-end profile or the default back-end profile replaces P1. The older profile (P1) is not deleted. It is now an enhanced SSL profile and contains the earlier settings, and the ciphers and ECC curves. If you do not want the default profile, you can explicitly bind P1 to the SSL entity.

```
set ssl parameter -defaultProfile ENABLED
    Save your configuration before enabling the Default profile. You
       cannot undo the changes. Are you sure you want to enable the
       Default profile? [Y/N]Y
Done
<!--NeedCopy-->
```

Upgrade the software to a build that supports the enhanced profile infrastructure, and then enable the default profiles.

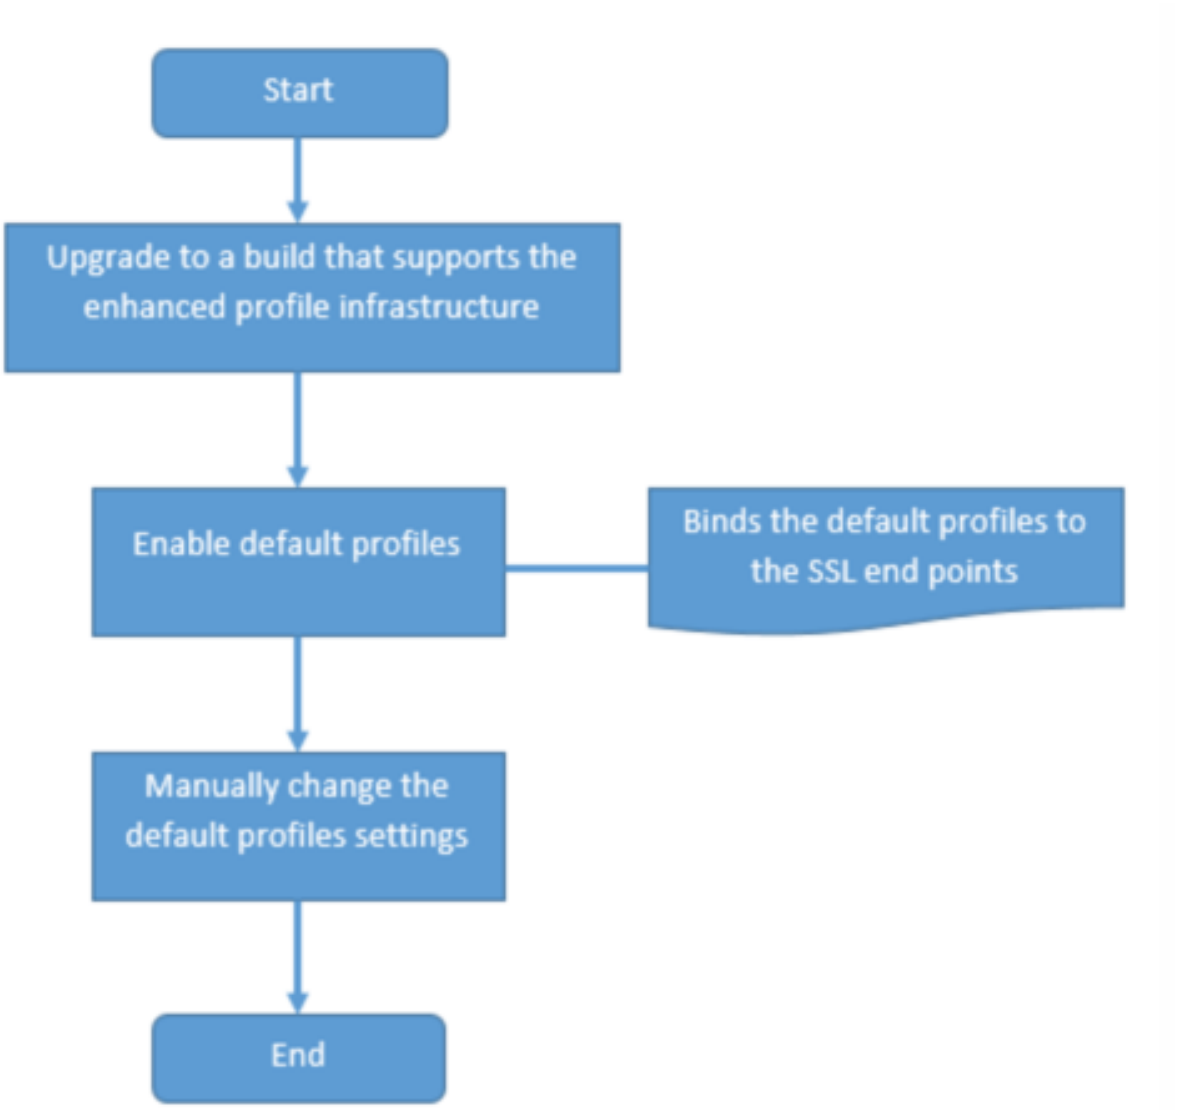
> **Notes:**
>
> - If a legacy profile (P1) is already bound to an SSL entity, and you enable the default profile, the default profile overrides the earlier binding. That is, the default profile is bound to the SSL entities. If you do not want the default profile to be bound, you must bind P1 to the SSL entity again.
> - A single operation (Enable Default Profile or `set ssl parameter -defaultProfile ENABLED`) enables (binds) both the default front-end profile and the default back-end profile.

Use case

After you enable the default profiles, they are bound to all the SSL end points. The default profiles are editable. If your deployment uses most of the default settings and changes only a few parameters, you can edit the default profiles. The changes are immediately reflected across all the end points.

You can also create custom SSL profiles with some custom and some default parameters and bind it to the SSL entities.

The following flowchart explains the steps that you must perform:



1. For information about upgrading the software, see Upgrading the System Software.
2. Enable the default profiles by using the CLI or GUI.

- At the command line, type: `set ssl parameter -defaultProfile ENABLED`
- If you prefer to use the GUI, navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**, scroll down, and select **Enable Default Profile**.

If a profile was not bound to an end point before the upgrade, a default profile is bound to the SSL end point. If a profile was bound to an end point before the upgrade, the same profile is bound after the upgrade, and default ciphers are added to the profile.

1. (Optional) Manually change any settings in the default profile.

- At the command line, type: `set ssl profile <name>` followed by the parameters to modify.
- If you prefer to use the GUI, navigate to **System** > **Profiles**. In **SSL Profiles**, select a profile and click **Edit**.

SSL profile parameters

You can set the following SSL parameters in an SSL profile. You can set some of these parameters in an SSL virtual server. For more information about SSL virtual server parameters, see SSL virtual server parameters.

Support for secure renegotiation at the back end of a Citrix ADC appliance

Note: This parameter is introduced in release 13.0 build 58.x and later. In earlier releases and builds, only non-secure renegotiation was supported on the back end.

The feature is supported on the following platforms:

- VPX
- MPX platforms containing N2 or N3 chips
- Intel Coleto SSL chip based platforms

The feature is not yet supported on the FIPS platform.

Secure renegotiation is denied by default on the back end of an ADC appliance. That is, the `denySSLReneg` parameter is set to ALL (default).

To allow secure renegotiation on the back end, select from one of the following settings for the `denySSLReneg` parameter:

- NO
- FRONTEND_CLIENT
- FRONTEND_CLIENTSERVER
- NONSECURE

Enable secure renegotiation by using the CLI

At the command prompt, type:

```
set ssl profile <name> -denySSLReneg <denySSLReneg>
```

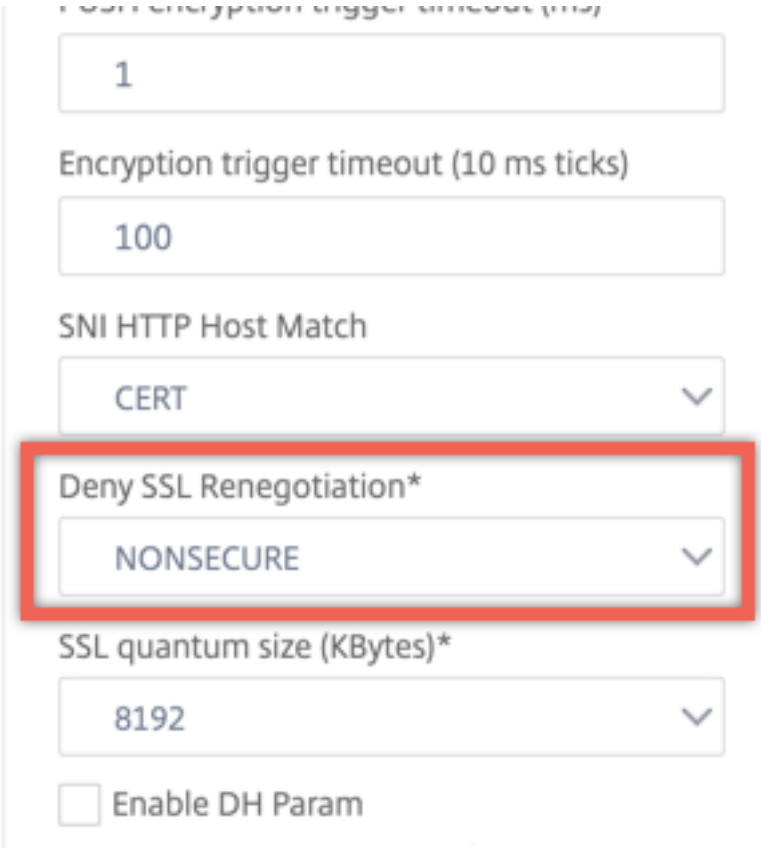
Example:

```
1 set ssl profile ns_default_ssl_profile_backend -denySSLReneg NONSECURE
2  Done
```

```
3
4  sh ssl profile ns_default_ssl_profile_backend
5  1)  Name: ns_default_ssl_profile_backend    (Back-End)
6      SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
          ENABLED  TLSv1.3: DISABLED
7      Server Auth: DISABLED
8      Use only bound CA certificates: DISABLED
9      Strict CA checks:       NO
10     Session Reuse: ENABLED      Timeout: 300 seconds
11     DH: DISABLED
12     Ephemeral RSA: DISABLED
13     Deny SSL Renegotiation      NONSECURE
14     Non FIPS Ciphers: DISABLED
15     Cipher Redirect: DISABLED
16     SSL Redirect: DISABLED
17     Send Close-Notify: YES
18     Strict Sig-Digest Check: DISABLED
19     Push Encryption Trigger: Always
20     PUSH encryption trigger timeout:    1 ms
21     SNI: DISABLED
22     OCSP Stapling: DISABLED
23     Strict Host Header check for SNI enabled SSL sessions:      NO
24     Push flag:  0x0 (Auto)
25     SSL quantum size:       8 kB
26     Encryption trigger timeout  100 mS
27     Encryption trigger packet count:    45
28
29     ECC Curve: P_256, P_384, P_224, P_521
30
31 1)  Cipher Name: DEFAULT_BACKEND        Priority :2
32     Description: Predefined Cipher Alias
33
34 1)  Service Name: s187
35  Done
36 <!--NeedCopy-->
```

Enable secure renegotiation by using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Add or edit a profile.
3. Set **Deny SSL Renegotiation** to any value other than ALL.



Host header validation

Note: This parameter is introduced in release 13.0 build 52.x.

With HTTP/1.1, clients had to use multiple connections to process multiple requests. With HTTP/2, clients can reuse connections across domains that are covered by the same certificate. For an SNI enabled session, the ADC appliance must be able to control how the HTTP host header is validated to accommodate this change. In earlier builds, the request was dropped if the parameter was enabled (set to “Yes”) and the request did not contain the host header for an SNI enabled session. If the parameter was disabled (set to “No”), the appliance did not perform the validation. A new parameter `SNIHTTPHostMatch` is added to an SSL profile and SSL global parameters to have better control on this validation. This parameter can take three values; CERT, STRICT, and NONE. These values work as follows for SNI enabled sessions only. SNI must be enabled on the SSL virtual server or the profile bound to the virtual server, and the HTTP request must contain the host header.

- CERT - Connection is forwarded if the host header value in the request is covered by the certificate used to establish this SSL session.
- STRICT - Connection is forwarded only if the host header value in the request matches the server name value passed in the Client Hello message of the SSL connection.
- NO - The host header value is not validated.

Possible values: NO, CERT, STRICT
Default value: CERT

With the introduction of the new parameter `SNIHTTPHostMatch` there is a change in the behavior of the `dropReqWithNoHostHeader` parameter. The setting of the `dropReqWithNoHostHeader` parameter no longer affects how the host header is validated against the SNI certificate.

Set SSL profile parameters by using the CLI

At the command prompt, type:

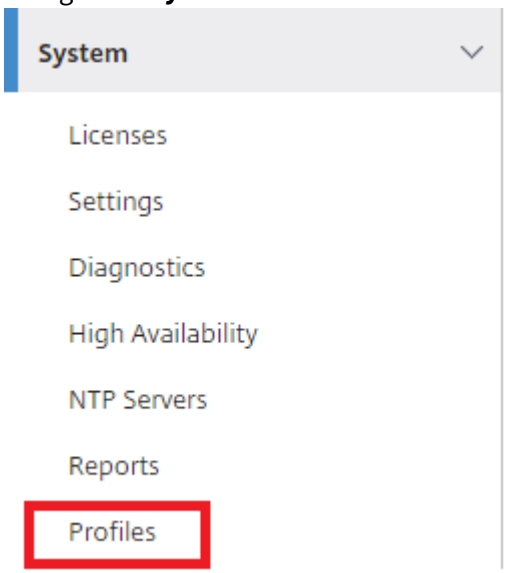
```
set ssl profile <name> [-ssllogProfile <string>] [-dh ( ENABLED |
    DISABLED ) -dhFile <string>] [-dhCount <positive_integer>][-
    dhKeyExpSizeLimit ( ENABLED | DISABLED )] [-eRSA ( ENABLED |
    DISABLED) [-eRSACount <positive_integer>]] [-sessReuse ( ENABLED |
    DISABLED )
[-sessTimeout <positive_integer>]] [-cipherRedirect ( ENABLED |
    DISABLED ) [-cipherURL <URL>]] [-clientAuth ( ENABLED | DISABLED )[-
    clientCert ( Mandatory | Optional )]] [-sslRedirect ( ENABLED |
DISABLED )] [-redirectPortRewrite ( ENABLED | DISABLED )] [-ssl3 (
    ENABLED | DISABLED )] [-tls1 ( ENABLED | DISABLED )] [-tls11 (
    ENABLED| DISABLED )] [-tls12 ( ENABLED | DISABLED )] [-tls13 (
    ENABLED |DISABLED )] [-SNIEnable ( ENABLED | DISABLED )] [-
    ocspStapling (ENABLED | DISABLED )] [-serverAuth ( ENABLED |
    DISABLED )] [-commonName <string>] [-pushEncTrigger <pushEncTrigger
    >] [-sendCloseNotify ( YES |
NO )] [-clearTextPort <port|*>] [-insertionEncoding ( Unicode | UTF-8)]
     [-denySSLReneg <denySSLReneg>] [-quantumSize <quantumSize>]
[-strictCAChecks ( YES | NO )] [-encryptTriggerPktCount <
    positive_integer>] [-pushFlag <positive_integer>][-
    dropReqWithNoHostHeader ( YES | NO )] [-SNIHTTPHostMatch <
    SNIHTTPHostMatch>] [-pushEncTriggerTimeout <positive_integer>]
[-sslTriggerTimeout <positive_integer>] [-clientAuthUseBoundCAChain (
    ENABLED | DISABLED )] [-sslInterception ( ENABLED | DISABLED )][-
    ssliReneg ( ENABLED | DISABLED )] [-ssliOCSPCheck ( ENABLED |
    DISABLED )] [-ssliMaxSessPerServer <positive_integer>] [-HSTS (
    ENABLED| DISABLED )] [-maxage <positive_integer>] [-
    IncludeSubdomains ( YES | NO )] [-preload ( YES | NO )] [-
    sessionTicket ( ENABLED | DISABLED )][-sessionTicketLifeTime <
    positive_integer>] [-sessionTicketKeyRefresh (ENABLED | DISABLED )]
    {
 -sessionTicketKeyData  }
  [-sessionKeyLifeTime <positive_integer>] [-prevSessionKeyLifeTime <
     positive_integer>]
```

```
[-cipherName <string> -cipherPriority <positive_integer>][-
   strictSigDigestCheck ( ENABLED | DISABLED )]
[-skipClientCertPolicyCheck ( ENABLED | DISABLED )] [-zeroRttEarlyData
   ( ENABLED | DISABLED )] [-tls13SessionTicketsPerAuthContext
<positive_integer>] [-dheKeyExchangeWithPsk ( YES | NO )]
<!--NeedCopy-->
```

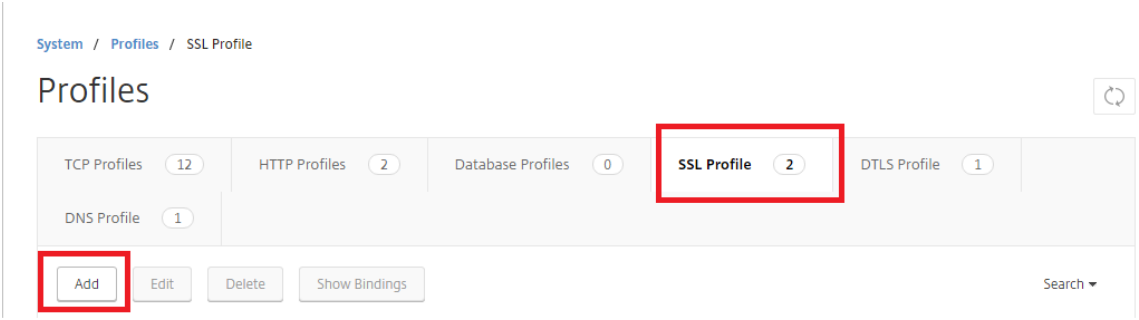
Set SSL profile parameters by using the GUI

To add a profile:

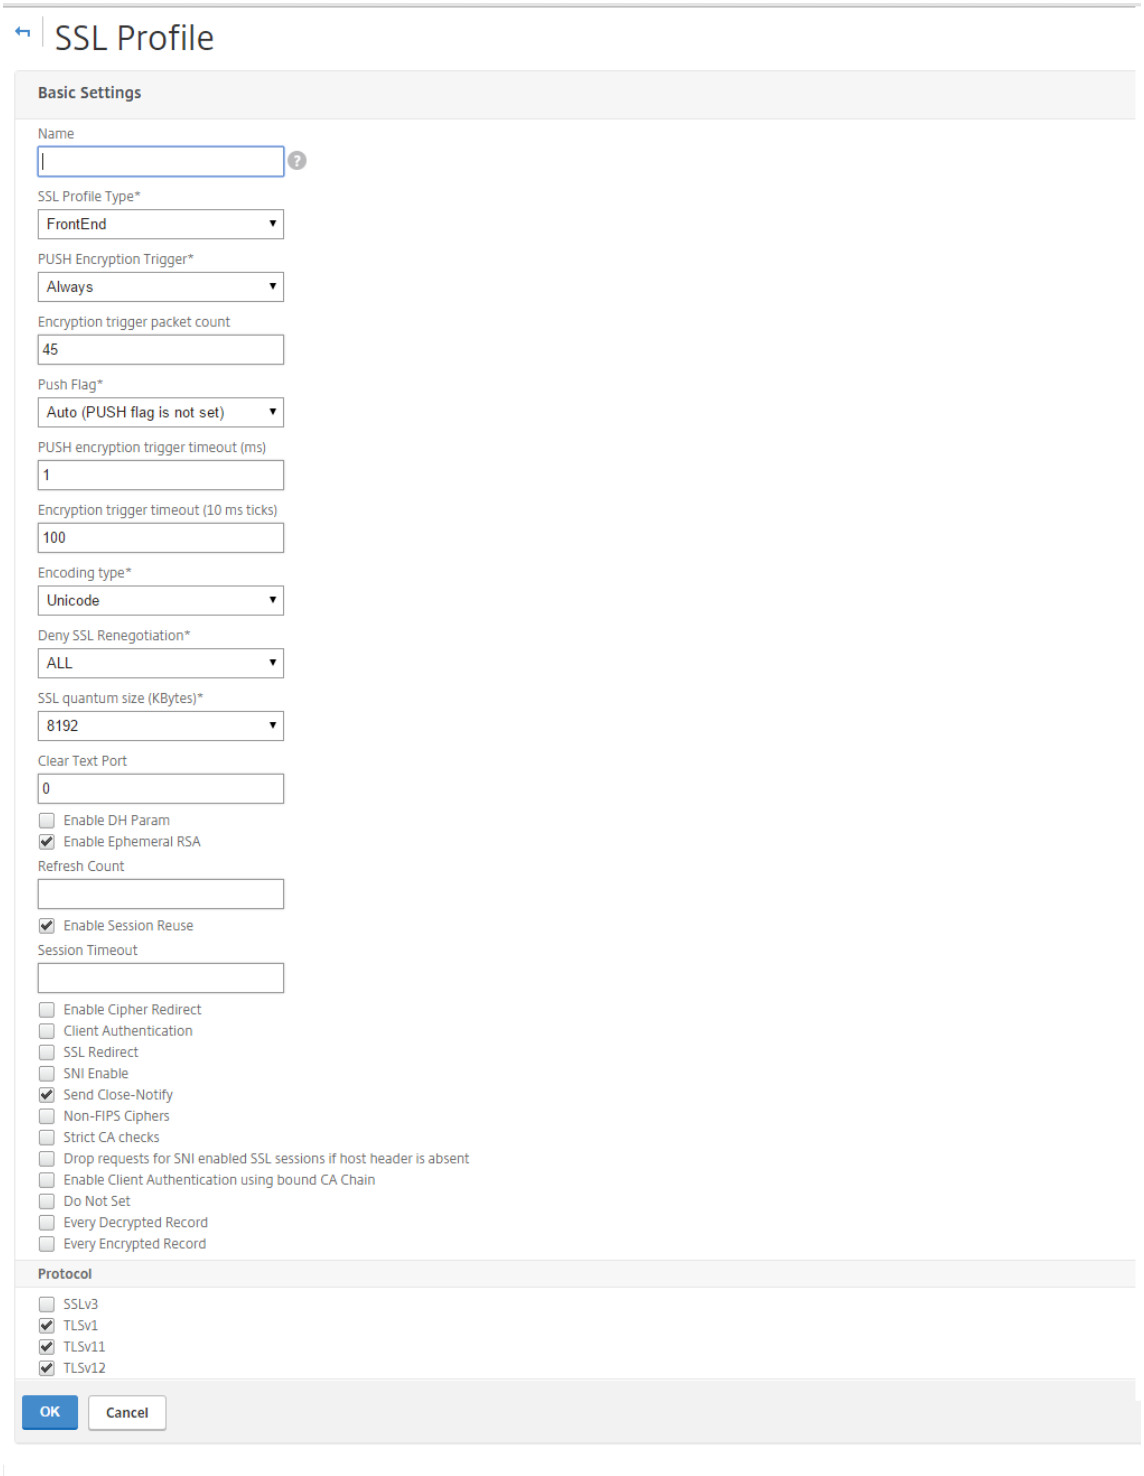
1. Navigate to **System > Profiles**.



2. Select **SSL Profiles**. Click **Add**.



3. Specify values for the different parameters.



4. Click **OK**.
5. Click **Done**.

To reuse an existing SSL profile:

1. Navigate to **System > Profiles**.
2. Select an existing profile and click **Add**.

3. Specify a different name, change any parameters, and click **OK**.
4. Click **Done**.

TLS session ticket extension

An SSL handshake is a CPU-intensive operation. If session reuse is enabled, the server/client key exchange operation is skipped for existing clients. They are allowed to resume their sessions. This action improves the response time and increases the number of SSL transactions per second that a server can support. However, the server must store details of each session state, which consumes memory and is difficult to share among multiple servers if requests are load balanced across servers.

Citrix ADC appliances support the SessionTicket TLS extension. Use of this extension indicates that the session details are stored on the client instead of on the server. The client must indicate that it supports this mechanism by including the session ticket TLS extension in the client Hello message. For new clients, this extension is empty. The server sends a new session ticket in the NewSessionTicket handshake message. The session ticket is encrypted by using a key-pair known only to the server. If a server cannot issue a new ticket now, it completes a regular handshake.

This feature is available only in front-end SSL profiles, and only at the front end of communication in which the appliance acts as a server and generates session tickets.

Limitations

- This feature is not supported on a FIPS platform.
- This feature is supported only with TLS versions 1.1 and 1.2.
- SSL session ID persistency is not supported with session tickets.

Enable TLS session ticket extension by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket (ENABLED | DISABLED ) [-
    sessionTicketLifeTime <positive_integer>
<!--NeedCopy-->
```

Arguments:

sessionTicket: State of TLS session ticket extension. Use of this extension indicates that the session details are stored on the client instead of on the server, as defined in RFC 5077.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sessionTicketLifeTime: Specify a time, in seconds, after which the session ticket expires and a new SSL handshake must be initiated.

Default value: 300

Minimum value: 0

Maximum value: 172800

Example:

```
add ssl profile profile1 -sessionTicket ENABLED -sessionTicketlifeTime
    300
Done
<!--NeedCopy-->
```

Enable TLS session ticket extension by using the GUI

1. Navigate to **System** > **Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. Select **Session ticket**.
4. Optionally, specify **Session Ticket Lifetime (secs)**.

Secure implementation of session tickets

By using TLS session tickets, clients can use abbreviated handshakes for faster reconnection to servers. However, if session tickets aren't encrypted or changed for long periods of time, they can pose a security risk. You can secure session tickets by encrypting them with a symmetric key. To achieve forward secrecy, you can specify a time interval at which the session-ticket key is refreshed.

The appliance generates the session ticket keys by default. However, if multiple appliances in a deployment need to decrypt each other's session tickets, they must all use the same session-ticket key. Therefore, you must set (add or load) the same session-ticket key data manually on all the appliances. Session-ticket key data includes the following information:

- Session ticket name.
- Session AES key used to encrypt or decrypt the ticket.
- Session HMAC key used to compute the digest of the ticket.

You can now configure session ticket key data of length 64 bytes to support 256-bit HMAC keys as recommended in RFC 5077. Key lengths of 48 bytes are also supported for backward compatibility.

> **Note:**
>
> While typing the session-ticket key data manually, ensure that the configuration across all the

> Citrix ADC appliances in an HA setup or in a cluster setup is the same.

The `sessionTicketKeyLifeTime` parameter specifies how often a session-ticket key is refreshed. You can set the `prevSessionTicketKeyLifeTime` parameter to specify how long the previous session-ticket key will be maintained for decrypting tickets using that key, after a new key is generated. The `prevSessionTicketKeyLifeTime` setting extends the time for which a client can use an abbreviated handshake to reconnect. For example, if `sessionTicketKeyLifeTime` is set to 10 minutes and `prevSessionTicketKeyLifeTime` to 5 minutes, a new key is generated after 10 minutes and used for all new sessions. However, previously connected clients have another 5 minutes for which previously issued tickets are honored for an abbreviated handshake.

Configure SSL session-ticket data by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket ENABLED -sessionTicketLifeTime <
    positive_integer> -sessionTicketKeyRefresh ( ENABLED | DISABLED )] -
    sessionTicketKeyLifeTime <positive_integer> [-
    prevSessionTicketKeyLifeTime <positive_integer>]
<!--NeedCopy-->
```

Arguments:

sessionTicket: Use session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the **ENABLED** setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

sessionTicketLifeTime: Lifetime, in seconds, of the session ticket. After this time expires, clients cannot use this ticket to resume their sessions.

Maximum value: 172800. Minimum value: 0. Default: 300.

sessionTicketKeyRefresh: When the time specified by the session-ticket key lifetime parameter expires, regenerate the session-ticket key used to encrypt or decrypt the session tickets. Automatically enabled if sessionTicket is enabled. Disabled if an administrator enters the session-ticket data.

Possible values: ENABLED, DISABLED. Default: ENABLED

sessionKeyLifeTime: Lifetime, in seconds, of a symmetric key used to encrypt the session tickets issued by a Citrix ADC appliance.

Maximum value: 86400. Minimum value: 600. Default: 3000

prevSessionKeyLifeTime: Time, in seconds, for which the previous symmetric key used to encrypt session tickets remains valid for existing clients after the session-ticket key lifetime expires. Within

this time, existing clients can resume their sessions by using the previous session ticket key. Session tickets for new clients are encrypted by using the new key.

Maximum value: 172800. Minimum value: 0. Default: 0

Example:

```
set ssl profile ns_default_ssl_profile_frontend -sessionTicket ENABLED
    -sessionTicketlifeTime 120 -sessionTicketKeyRefresh ENABLED -
    sessionTicketKeyLifeTime 100 -prevSessionTicketKeyLifeTime 60

Done

show ssl profile ns_default_ssl_profile_frontend

    Session Ticket: ENABLED
    Session Ticket Lifetime: 120 (secs)
    Session Key Auto Refresh: ENABLED
    Session Key Lifetime: 100 (secs)
    Previous Session Key Lifetime: 60 (secs)
<!--NeedCopy-->
```

Configure SSL session-ticket data by using the GUI

1. Navigate to **System** > **Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **Basic Settings** section, click the pencil icon and set the following parameters:
   - Session Ticket
   - Session Ticket Lifetime (secs)
   - Session Ticket Key Auto Refresh
   - Session Ticket Key Lifetime (secs)
   - Previous Session Ticket Key Lifetime (secs)
4. Click **OK**.

Type SSL session ticket data manually by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket ENABLED

set ssl profile <name> -sessionTicketKeyData

```

```
show ssl profile ns_default_ssl_profile_frontend
<!--NeedCopy-->
```

Arguments:

sessionTicket: Use of session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the **ENABLED** setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

sessionTicketKeyData: Contains the session ticket name (0-15 bytes), the session AES key used to encrypt or decrypt the session ticket (16-31 bytes), and the session HMAC key used to compute the digest of the ticket (32-63 bytes). Externally generated by an administrator and added to a Citrix ADC appliance.

Maximum length: 64 bytes

Example:

```
set ssl profile ns_default_ssl_profile_frontend -sessionTicket ENABLED

Done

set ssl profile ns_default_ssl_profile_frontend -sessionTicketKeyData
    1111111111111111111111111111111111111111111111111

Done

show ssl profile ns_default_ssl_profile_frontend

    1) Name: ns_default_ssl_profile_frontend (Front-End)
    SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2: ENABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks: NO
    Session Reuse: ENABLED Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA: ENABLED
        Refresh Count: 0
    Deny SSL Renegotiation ALL
    Non FIPS Ciphers: DISABLED
    Cipher Redirect: DISABLED
    SSL Redirect: DISABLED
    Send Close-Notify: YES
```

```
    Push Encryption Trigger: Always
    PUSH encryption trigger timeout: 1 ms
    SNI: DISABLED
    OCSP Stapling: DISABLED
    Strict Host Header check for SNI enabled SSL sessions: NO
    Push flag: 0x0 (Auto)
    SSL quantum size: 8 kB
    Encryption trigger timeout 100 mS
    Encryption trigger packet count: 45
    Subject/Issuer Name Insertion Format: Unicode
    Session Ticket: ENABLED
    Session Ticket Lifetime: 300 (secs)
    Session Key Auto Refresh: DISABLED
    Session Key Lifetime: 3000 (secs)
    Previous Session Key Lifetime: 0 (secs)
    Session Key Data: 84
       dad1afc6d56b0deeb0a7fd7f299a207e8d8c15cdd087a5684a11a329fd732e87a0535d9088

    7) Vserver Name: v1

Done
<!--NeedCopy-->
```

Type SSL session ticket data manually by using the GUI

1. Navigate to **System > Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **Basic Settings** section, click the pencil icon and set the following parameters:

- Session Ticket
- Session Ticket Key Data
- Confirm Session Ticket Key Data

4. Click **OK**.

Support for Extended Master Secret in SSL handshake on Citrix ADC non-FIPS platforms

Note: This parameter is introduced in release 13.0 build 61.x.

Extended Master Secret (EMS) is an optional extension to the Transport Layer Security (TLS) protocol. A new parameter is added that applies to both front-end and back-end SSL profiles to support EMS on the Citrix ADC appliance. If the parameter is enabled and the peer supports EMS, the ADC appliance uses the EMS calculation. If the peer does not support EMS, then the EMS calculation is not used for the connection even though the parameter is enabled on the appliance. For more information about EMS, see RFC 7627.

Note: EMS is only applicable for handshakes that use TLS protocol version 1.0, 1.1, or 1.2.

Platform support for EMS

- MPX and SDX platforms containing either Cavium N3 chips or Intel Coleto Creek crypto cards. The following platforms ship with Intel Coleto chips:
- MPX 5900
- MPX/SDX 8900
- MPX/SDX 26000
- MPX/SDX 26000-50S
- MPS/SDX 26000-100G
- MPX/SDX 15000-50G

You can also use the “show hardware’ command to identify whether your appliance has Coleto (COL) or N3 chips.

- MPX and SDX platforms without crypto cards (software-only).
- Software-only platforms: VPX, CPX, and BLX.

EMS cannot be enabled on the following platforms:

- MPX 9700 FIPS and MPX 14000 FIPS platforms.
- MPX and SDX platforms containing Cavium N2 crypto chips.

If the parameter is enabled, the ADC appliance attempts to use EMS in TLS 1.2, TLS 1.1, and TLS 1.0 connections. The setting does not affect TLS 1.3 or SSLv3 connections.

To allow EMS to be negotiated with the peer, enable the setting on the SSL profile bound to the virtual server (front end) or service (back end).

Enable EMS using the CLI

At the command prompt, type:

```
set ssl profile <profile name> [-allowExtendedMasterSecret (YES | NO)]
```

Examples

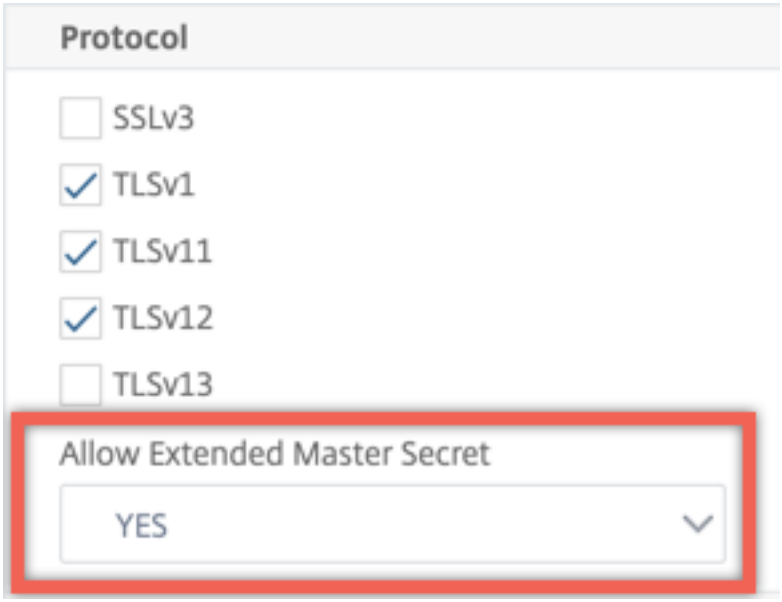
```
1 set ssl profile ns_default_ssl_profile_frontend  -
     allowExtendedMasterSecret YES
2
3 set ssl profile ns_default_ssl_profile_backend  -
     allowExtendedMasterSecret YES
4 <!--NeedCopy-->
```

The following table shows the default value of the `allowExtendedMasterSecret` parameter on different default and user defined profiles.

Profile	Default setting
Default front-end profile	NO
Default front-end secure profile	YES
Default back-end profile	NO
User-defined profile	NO

Enable EMS using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Add a profile or edit a profile.
3. Set **Allow Extended Master Secret** to YES.



Support for processing of ALPN extension in the client hello message

Note: This feature is supported in release 13.0 build 61.x and later.

A parameter `alpnProtocol` is added to the front-end SSL profiles to negotiate the application protocol in the ALPN extension for the connections handled by the SSL_TCP virtual server. Only the protocol specified in the SSL profile is negotiated, if the same protocol is received in the ALPN extension of the client hello message.

Note: The `alpnProtocol` parameter is supported only on front end SSL profiles and is applicable to the SSL connections handled by SSL_TCP type virtual servers.

Set the protocol in the front-end SSL profile using the CLI

At the command prompt, type:

```
set ssl profile ns_default_ssl_profile_frontend -alpnProtocol <protocol_name
>
```

The `alpnProtocol` parameter can take three values. Maximum length: 4096 bytes.

- **NONE:** Application protocol negotiation does not take place. This setting is the default.
- **HTTP1:** HTTP1 can be negotiated as the application protocol.
- **HTTP2:** HTTP2 can be negotiated as the application protocol.

Example:

```
1 set ssl profile ns_default_ssl_profile_frontend -ALPNProtocol HTTP2
2 > sh ssl profile ns_default_ssl_profile_frontend
```

```
1)  Name: ns_default_ssl_profile_frontend   (Front-End)
    SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
       ENABLED  TLSv1.3: DISABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks:   NO
    Session Reuse: ENABLED  Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA:
       ENABLED  Refresh Count: 0
    Deny SSL Renegotiation  ALL
    Non FIPS Ciphers: DISABLED
    Cipher Redirect: DISABLED
    SSL Redirect: DISABLED
    Send Close-Notify: YES
    Strict Sig-Digest Check: DISABLED
    Zero RTT Early Data: DISABLED
    DHE Key Exchange With PSK: NO
    Tickets Per Authentication Context: 1
    Push Encryption Trigger: Always
    PUSH encryption trigger timeout:    1 ms
    SNI: DISABLED
    OCSP Stapling: DISABLED
    Strict Host Header check for SNI enabled SSL sessions:  NO
    Match HTTP Host header with SNI:    CERT
    Push flag:  0x0 (Auto)
    SSL quantum size:   8 kB
    Encryption trigger timeout  100 mS
    Encryption trigger packet count:    45
    Subject/Issuer Name Insertion Format:   Unicode

    SSL Interception: DISABLED
    SSL Interception OCSP Check: ENABLED
    SSL Interception End to End Renegotiation: ENABLED
    SSL Interception Maximum Reuse Sessions per Server: 10

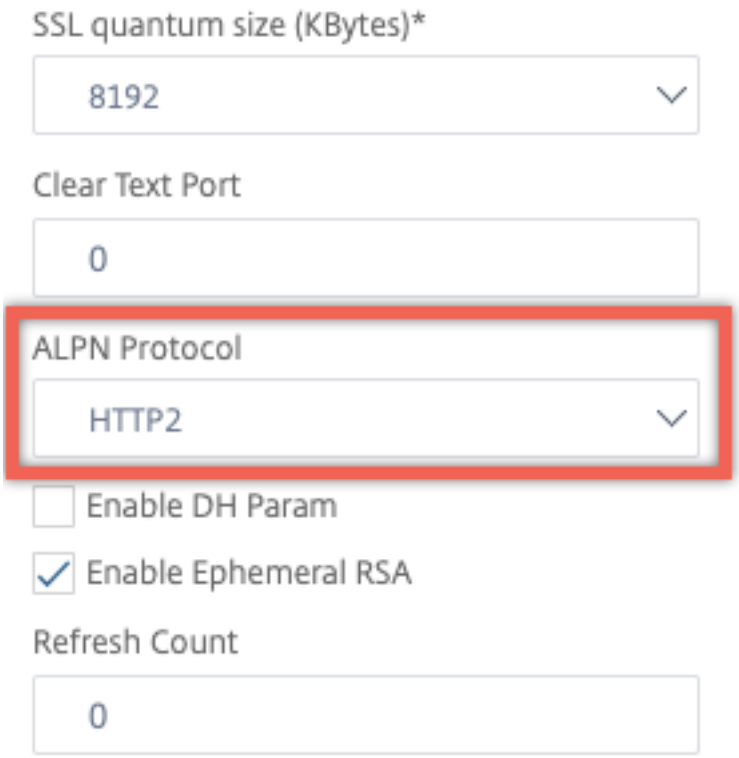
    HSTS: DISABLED
    HSTS IncludeSubDomains: NO
    HSTS Max-Age: 0
    HSTS Preload: NO
    Allow Extended Master Secret: NO
    Send ALPN Protocol: HTTP2

 Done
 <!--NeedCopy-->
```

Set the protocol in the front-end SSL profile using the GUI

1. Navigate to **System > Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **ALPN Protocol** list, select **HTTP2**.



Load an old configuration

Enabling the default profiles is not reversible. However, if you decide that your deployment does not require the default profiles, you can load an older configuration that you saved before you enabled the default profiles. The changes are effective after you restart the appliance.

Load an old configuration by using the CLI

At the command prompt, type:

```
shell

root@ns# clear config
```

```
4
5  root@ns# cd /nsconfig
6
7  root@ns# cp ns.conf.NS.11.0.jun.16 ns.conf
8
9  root@ns# reboot
10 <!--NeedCopy-->
```

Secure front-end profile

September 14, 2021

In addition to a default front-end and a default back-end profile, a new default secure front-end profile is available from release 12.1. The settings required for an A+ rating (as of May 2018) from Qualys SSL Labs are preloaded into this profile. Earlier, you had to explicitly set each of the parameters required for an A+ rating on an SSL front-end profile or an SSL virtual server. Now you can bind the ns_default_ssl_profile_secure_frontend profile to your SSL virtual server and the required parameters are automatically set on your SSL virtual server.

> **Note:**
>
> The secure front-end profile is not editable.

When you enable the default profile, the default front-end profile is automatically bound to all the SSL virtual servers. To get an A+ rating, you must explicitly bind the ns_default_ssl_profile_secure_frontend profile and also bind an SHA2/SHA256 server certificate to your SSL virtual server.

Secure front-end profile parameters

The parameters with their default settings are listed here:

```
1  SSLv3: DISABLED  TLSv1.0: DISABLED  TLSv1.1: DISABLED  TLSv1.2: ENABLED
       TLSv1.3: DISABLED
2
3  Deny SSL Renegotiation: NONSECURE
4
5  HSTS: ENABLED
6
7  HSTS IncludeSubDomains: YES
8
9  HSTS Max-Age: 15552000
10
```

```
Cipher Name: SECURE    Priority :1
<!--NeedCopy-->
```

Secure cipher alias

A new secure cipher alias is added and bound to the secure front-end profile. To list the ciphers that are part of this alias, at the command prompt type: show cipher SECURE

```
show cipher SECURE

    1) Cipher Name: TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 Priority : 1
           Description: TLSv1.2 Kx=ECC-DHE  Au=RSA  Enc=AES-GCM(256)
              Mac=AEAD   HexCode=0xc030
    2) Cipher Name: TLS1.2-ECDHE-RSA-AES128-GCM-SHA256 Priority : 2
           Description: TLSv1.2 Kx=ECC-DHE  Au=RSA  Enc=AES-GCM(128)
              Mac=AEAD   HexCode=0xc02f
    3) Cipher Name: TLS1.2-ECDHE-ECDSA-AES256-GCM-SHA384
       Priority : 3
           Description: TLSv1.2 Kx=ECC-DHE  Au=ECDSA Enc=AES-GCM(256)
              Mac=AEAD   HexCode=0xc02c
    4) Cipher Name: TLS1.2-ECDHE-ECDSA-AES128-GCM-SHA256
       Priority : 4
           Description: TLSv1.2 Kx=ECC-DHE  Au=ECDSA Enc=AES-GCM(128)
              Mac=AEAD   HexCode=0xc02b
Done
<!--NeedCopy-->
```

Configuration

Perform the following steps:

1. Add a load balancing virtual server of type SSL.
2. Bind a SHA2/SHA256 certificate.
3. Enable the default profile.
4. Bind the secure front-end profile to the SSL virtual server.

Get an A+ rating for an SSL virtual server by using the CLI

At the command prompt, type:

```
add lb vserver <name> <serviceType> <IPAddress> <port>
bind ssl vserver <vServerName> -certkeyName <string>
set ssl parameter -defaultProfile ENABLED
```

```
set ssl vserver <vServerName> -sslProfile
   ns_default_ssl_profile_secure_frontend
show ssl vserver [<vServerName>]
<!--NeedCopy-->
```

Example:

```
add lb vserver ssl-vsvr SSL 192.0.2.240 443

bind ssl vserver ssl-vsvr -certkeyName letrsa

set ssl parameter -defaultProfile ENABLED

Save your configuration before enabling the Default profile. You cannot
    undo the changes. Are you sure you want to enable the Default
   profile? [Y/N]y

set ssl vserver ssl-vsvr -sslProfile
   ns_default_ssl_profile_secure_frontend
<!--NeedCopy-->
```

```
sh ssl vserver ssl-vsvr

    Advanced SSL configuration for VServer ssl-vsvr:
    Profile Name :ns_default_ssl_profile_secure_frontend
    1) CertKey Name: letrsa     Server Certificate
Done
<!--NeedCopy-->
```

```
sh ssl profile ns_default_ssl_profile_secure_frontend

    1) Name: ns_default_ssl_profile_secure_frontend (Front-End)
    SSLv3: DISABLED  TLSv1.0: DISABLED  TLSv1.1: DISABLED  TLSv1.2:
       ENABLED  TLSv1.3: DISABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks:                   NO
    Session Reuse: ENABLED   Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA:
       ENABLED     Refresh Count: 0
    Deny SSL Renegotiation                NONSECURE
    Non FIPS Ciphers: DISABLED
    Cipher Redirect: DISABLED
```

```
    SSL Redirect: DISABLED
    Send Close-Notify: YES
    Strict Sig-Digest Check: DISABLED
    Zero RTT Early Data: DISABLED
    DHE Key Exchange With PSK: NO
    Tickets Per Authentication Context: 1
    Push Encryption Trigger: Always
    PUSH encryption trigger timeout:  1 ms
    SNI: DISABLED
    OCSP Stapling: DISABLED
    Strict Host Header check for SNI enabled SSL sessions:
                            NO
    Push flag:              0x0 (Auto)
    SSL quantum size:                8 kB
    Encryption trigger timeout       100 mS
    Encryption trigger packet count: 45
    Subject/Issuer Name Insertion Format:  Unicode
    SSL Interception: DISABLED
    SSL Interception OCSP Check: ENABLED
    SSL Interception End to End Renegotiation: ENABLED
    SSL Interception Maximum Reuse Sessions per Server:   10
    Session Ticket: DISABLED
    HSTS: ENABLED
    HSTS IncludeSubDomains: YES
    HSTS Max-Age: 15552000
    ECC Curve: P_256, P_384, P_224, P_521
    1) Cipher Name: SECURE    Priority :1
    Description: Predefined Cipher Alias
    1) Vserver Name: v2
Done
<!--NeedCopy-->
```

Get an A+ rating for an SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select an SSL virtual server.
2. In Advanced Settings, click SSL Profile.
3. Select ns_default_ssl_profile_secure_frontend.
4. Click OK.
5. Click Done.

Appendix A: Sample migration of the SSL configuration after upgrade

September 14, 2021

Note: This content has been removed because the SSL migration script for the new default profile is no longer supported.

Appendix B: Default front-end and back-end SSL profile settings

September 14, 2021

A default front-end profile has the following settings:

```
sh ssl profile ns_default_ssl_profile_frontend

1)Name: ns_default_ssl_profile_frontend

     Configuration for Front-End SSL profile
     DH: DISABLED
     Ephemeral RSA: ENABLED          Refresh Count: 0
     Session Reuse: ENABLED          Timeout: 120 seconds
     Non FIPS Ciphers: DISABLED
     Cipher Redirect: ENABLED   Redirect URL: http://10.102.28.212/
        redirect.html
     Client Auth: DISABLED
     SSL Redirect: DISABLED
     SNI: DISABLED
     SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
        ENABLED
     Push Encryption Trigger: Always
     PUSH encryption trigger timeout:     1 ms
     Send Close-Notify: YES
     Push flag: 0x0 (Auto)
     Deny SSL Renegotiation          NO
     SSL quantum size:          8 kB
     Strict CA checks:          NO
     Encryption trigger timeout 100 mS
     Encryption trigger packet count:     45
     Use only bound CA certificates: DISABLED
     Subject/Issuer Name Insertion Format: Unicode
     Strict Host Header check for SNI enabled SSL sessions:          NO

```

```
28       ECC Curve: P_256, P_384, P_521
29
30  1)   Cipher Name: AES     Priority :2
31       Description: Predefined Cipher Alias
32
33  1)   Vserver Name: v1
34  2)   Vserver Name: nshttps-::1l-443
35  3)   Vserver Name: nsrpcs-::1l-3008
36  4)   Vserver Name: nskrpcs-127.0.0.1-3009
37  5)   Vserver Name: nshttps-127.0.0.1-443
38  6)   Vserver Name: nsrpcs-127.0.0.1-3008
39  Done
40  <!--NeedCopy-->
```

A default back-end profile has the following settings:

```
1   sh ssl profile ns_default_ssl_profile_backend
2
3   1)Name: ns_default_ssl_profile_backend
4
5        Configuration for Back-End SSL profile
6        Session Reuse: ENABLED          Timeout: 300 seconds
7        Non FIPS Ciphers: DISABLED
8        Server Auth: DISABLED
9        SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: DISABLED  TLSv1.2:
             DISABLED
10       Push Encryption Trigger: Always
11       PUSH encryption trigger timeout:     1 ms
12       Send Close-Notify: YES
13       Push flag: 0x0 (Auto)
14       Deny SSL Renegotiation          ALL
15       SSL quantum size:          8 kB
16       Strict CA checks:          NO
17       Encryption trigger timeout 100 mS
18       Encryption trigger packet count:     45
19       Use only bound CA certificates: DISABLED
20
21       ECC Curve: P_256, P_224, P_521
22
23  1)   Cipher Name: AES     Priority :1
24       Description: Predefined Cipher Alias
25
26  2)   Cipher Name: RC4     Priority :2
27       Description: Predefined Cipher Alias

```

Legacy SSL profile

September 14, 2021

> **Note:**
>
> Citrix recommends using the enhanced profiles instead of legacy profiles. For information about the enhanced profile infrastructure, see SSL profile infrastructure.

Important:

> Bind an SSL profile to an SSL virtual server. Do not bind a DTLS profile to an SSL virtual server. For information about DTLS profiles, see DTLS Profiles.

You can use an SSL profile to specify how a Citrix ADC processes SSL traffic. The profile is a collection of SSL parameter settings for SSL entities, such as virtual servers, services, and service groups, and offers ease of configuration and flexibility. You are not limited to configuring only one set of global parameters. You can create multiple sets (profiles) of global parameters and assign different sets to different SSL entities. SSL profiles are classified into two categories:

- Front end profiles, containing parameters applicable to the front-end entity. That is, they apply to the entity that receives requests from a client.
- Back-end profiles, containing parameters applicable to the back-end entity. That is, they apply to the entity that sends client requests to a server.

Unlike a TCP or HTTP profile, an SSL profile is optional. Therefore, there is no default SSL profile. The same profile can be reused across multiples entities. If an entity does not have a profile attached, the values set at the global level apply. For dynamically learned services, current global values apply.

The following table lists the parameters that are part of each profile.

Front end profile	Back-end profile
cipherRedirect, cipherURL	denySSLReneg
clearTextPort*	encryptTriggerPktCount
clientAuth, clientCert	nonFipsCiphers
denySSLReneg	pushEncTrigger

Front end profile	Back-end profile
dh, dhFile, dhCount	pushEncTriggerTimeout
dropReqWithNoHostHeader	pushFlag
encryptTriggerPktCount	quantumSize
eRSA, eRSACount	serverAuth
insertionEncoding	commonName
nonFipsCiphers	sessReuse, sessTimeout
pushEncTrigger	SNIEnable
pushEncTriggerTimeout	ssl3
pushFlag	sslTriggerTimeout
quantumSize	strictCAChecks
redirectPortRewrite	tls1
sendCloseNotify	-
sessReuse, sessTimeout	-
SNIEnable	-
ssl3	-
sslRedirect	-
sslTriggerTimeout	-
strictCAChecks	-
tls1, tls11, tls12	-

* The clearTextPort parameter applies only to an SSL virtual server.

An error message appears if you try to set a parameter that is not part of the profile. For example, if you try to set the clientAuth parameter in a back-end profile.

Some SSL parameters, such as CRL memory size, OCSP cache size, UndefAction Control, and UndefAction Data, are not part of any of the preceding profiles, because these parameters are independent of entities.

An SSL profile supports the following operations:

- Add—Creates an SSL profile on the Citrix ADC. Specify whether the profile is front end or back end. Front end is the default.
- Set—Modifies the settings of an existing profile.

- Unset—Sets the specified parameters to their default values. If you do not specify any parameters, an error message appears. If you unset a profile on an entity, the profile is unbound from the entity.
- Remove—Deletes a profile. A profile that is being used by any entity cannot be deleted. Clearing the configuration deletes all the entities. As a result, the profiles are also deleted.
- Show—Displays all the profiles that are available on the Citrix ADC. If a profile name is specified, the details of that profile are displayed. If an entity is specified, the profiles associated with that entity are displayed.

Create an SSL profile by using the CLI

- To add an SSL profile, type:

```
add ssl profile <name> [-sslProfileType ( BackEnd | FrontEnd )]
<!--NeedCopy-->
```

- To modify an existing profile, type:

```
set ssl profile <name>
<!--NeedCopy-->
```

- To unset an existing profile, type:

```
unset ssl profile <name> [-dh] [-dhFile] [-dhCount] [-eRSA] ...
<!--NeedCopy-->
```

- To unset an existing profile from an entity, type:

```
unset ssl vserver <vServerName>  -sslProfile
<!--NeedCopy-->
```

- To remove an existing profile, type:

```
rm ssl profile <name>
<!--NeedCopy-->
```

- To display an existing profile, type:

```
sh ssl profile <name>
<!--NeedCopy-->
```

Create an SSL profile by using the GUI

Navigate to **System** > **Profiles**, select the SSL Profiles tab, and create an SSL profile.

Enable stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if a single Root-CA has issued them. That is, if only the Root-CA certificate is bound to the virtual server, and that Root-CA validates any of the intermediate certificates sent with the client certificate, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, the intermediate certificates can be validated by using a CRL or OCSP responder only if that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that one of the CA certificates bound to that virtual server has signed. To do so, you must enable the `ClientAuthUseBoundCAChain` setting in the SSL profile bound to the virtual server. The handshake fails if one of the CA certificates bound to the virtual server has not signed the client certificate.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, the Citrix ADC appliance only accepts clientcert1.

Enable stricter control on client certificate validation by using the CLI

At the command prompt, type: `set ssl profile <name> -ClientAuthUseBoundCAChain Enabled`

Enable stricter control on client certificate validation by using the GUI

1. Navigate to **System** > **Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.
2. Select **Enable Client Authentication using bound CA Chain**.

Certificate revocation lists

September 14, 2021

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA might revoke the issued certificate before the expiration date. For example, when an owner's private key is compromised, a company's or individual's name changes, or the association between the subject and the CA changes.

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.

Certificate authorities issue CRLs regularly. You can configure the Citrix ADC appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the Citrix ADC appliance. You can configure refresh options. You can also configure the Citrix ADC to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The appliance supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the Citrix ADC appliance.

If you have used the ADC as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the Citrix ADC are not used either in a production environment or beyond a particular date.

Note:

By default, CRLs are stored in the /var/netscaler/ssl directory on the Citrix ADC appliance.

Create a CRL on the ADC appliance

Since you can use the ADC appliance to act as a CA and create self-signed certificates, you can also revoke the following certificates:

- Certificates that you have created.
- Certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

Revoke a certificate or create a CRL by using the CLI

At the command prompt, type the following command:

```
1 create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <
     input_filename> | -genCRL <output_filename>)
2 <!--NeedCopy-->
```

Example:

```
1 create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1
2
3 create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
4 <!--NeedCopy-->
```

Revoke a certificate or create a CRL by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the Getting Started group, select CRL Management.
2. Enter the certificate details and, in the **Choose Operation** list, select **Revoke Certificate**, or **Generate CRL**.

Add an existing CRL to the ADC

Before you configure the CRL on the Citrix ADC appliance, make sure that the CRL file is stored locally on the Citrix ADC appliance. In an HA setup, the CRL file must be present on both ADC appliances, and the directory path to the file must be the same on both appliances.

Add a CRL on the Citrix ADC by using the CLI

At the command prompt, type the following commands to add a CRL on the Citrix ADC and verify the configuration:

```
add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]

show ssl crl [<crlName>]
<!--NeedCopy-->
```

Example:

```
> add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM

Done

> show ssl crl crl-one

            Name: crl-one   Status: Valid,  Days to expiration: 29
            CRL Path: /var/netscaler/ssl/CRL-one
            Format: PEM     CAcert: samplecertkey
            Refresh: DISABLED
            Version: 1
            Signature Algorithm: sha1WithRSAEncryption
            Issuer:  C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,
               OU=SSL Acceleration,CN=www.ns.com/emailAddress=
               support@Citrix ADC appliance.com
            Last_update:Jun 15 10:53:53 2010 GMT
            Next_update:Jul 15 10:53:53 2010 GMT

    1)      Serial Number: 00
```

```
            Revocation Date:Jun 15 10:51:16 2010 GMT
      Done
<!--NeedCopy-->
```

Add a CRL on the Citrix ADC by using the GUI

Navigate to **Traffic Management** > **SSL** > **CRL**, and add a CRL.

Configure CRL refresh parameters

A CRL is generated and published by a Certificate Authority periodically or, sometimes, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the Citrix ADC appliance regularly, for protection against clients trying to connect with certificates that are not valid.

The Citrix ADC appliance can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you run the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is /var/netscaler/ssl.

Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. Specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

Configure CRL autorefresh by using the CLI

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration:

```
set ssl crl <crlName> [-refresh ( ENABLED | DISABLED )] [-CAcert <
    string>] [-server <ip_addr|ipv6_addr|*> | -url <URL>] [-method (
    HTTP | LDAP )] [-port <port>] [-baseDN <string>] [-scope ( Base |
    One )] [-interval <interval>] [-day <positive_integer>] [-time <HH:
    MM>][-bindDN <string>] {
 -password  }
  [-binary ( YES | NO )]

show ssl crl [<crlName>]
<!--NeedCopy-->
```

Example:

```
1     set CRL crl1  -refresh enabled -method ldap -inform DER -CAcert ca1
          -server 10.102.192.192 -port 389 -scope base -baseDN "cn=
         clnt_rsa4_multicert_der,ou=eng,o=ns,c=in" -time 00:01
2
3     set ssl crl crl1 -refresh enabled -method http -cacert ca1 -port 80
          -time 00:10 -url http://10.102.192.192/crl/ca1.crl
4
5
6     > sh crl
7
8     1)         Name: crl1        Status: Valid,     Days to expiration:
          355
9                  CRL Path: /var/netscaler/ssl/crl1
10                 Format: PEM      CAcert: ca1
11                 Refresh: ENABLED          Method: HTTP
12                 URL: http://10.102.192.192/crl/ca1.crl
                      Port:80
13                 Refresh Time: 00:10
14                 Last Update: Successful, Date:Tue Jul  6 14:38:13 2010
15    Done
16 <!--NeedCopy-->
```

Configure CRL autorefresh using LDAP or HTTP by using the GUI

1. Navigate to **Traffic Management > SSL > CRL**.
2. Open a CRL, and select **Enable CRL Auto Refresh**.

> **Note**
>
> If the new CRL has been refreshed in the external repository before its actual update time as specified by the **Last Update time** field of the CRL, you must do the following:
>
> Immediately refresh the CRL on the Citrix ADC appliance.

To view the last update time, select the CRL, and click **Details**.

Synchronize CRLs

The Citrix ADC appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the Citrix ADC appliance needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the appliance to update CRLs automatically at a specified refresh interval.

The appliance maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated. It then connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.

> **Note:**
>
> If the CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, the following action is taken for connections:
>
> All client-authentication connections with the same issuer as the CRL are rejected as REVOKED until the CRL is successfully refreshed.

You can specify the interval at which the CRL refresh must be carried out. You can also specify the exact time.

Synchronize CRL autorefresh by using the CLI

At the command prompt, type the following command:

```
set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <
   HH:MM>]
<!--NeedCopy-->
```

Example:

```
set ssl crl CRL-1 -refresh ENABLE -interval MONTHLY -days 10 -time
   12:00
<!--NeedCopy-->
```

Synchronize CRL refresh by using the GUI

1. Navigate to **Traffic Management > SSL > CRL**.
2. Open a CRL, select **enable CRL Auto Refresh**, and specify the interval.

Perform client authentication by using a certificate revocation list

If a certificate revocation list (CRL) is present on a Citrix ADC appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional.

The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check
- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

Table 1. Result of a Handshake with a Client Using a Revoked Certificate

Rule for CRL Check	Rule for Client Certificate Check	State of the CRL Configured for the CA certificate	Result of a Handshake with a Revoked Certificate
Optional	Optional	Missing	Success
Optional	Mandatory	Missing	Success
Optional	Mandatory	Present	Failure
Mandatory	Optional	Missing	Success
Mandatory	Mandatory	Missing	Failure
Mandatory	Optional	Present	Success
Mandatory	Mandatory	Present	Failure
Optional/Mandatory	Optional	Expired	Success
Optional/Mandatory	Mandatory	Expired	Failure

Note:

- The CRL check is optional by default. To change from optional to mandatory or conversely, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.
- In the output of the `sh ssl vserver` command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the `sh ssl vserver` command only if the CRL check is set to mandatory. If the CRL check is set to optional, the CRL check details do not appear.

To configure CRL check by using the CLI

At the command prompt, type the following command:

```
bind ssl vserver <vServerName> -certkeyName <string> [(-CA -crlCheck (
    Mandatory | Optional ))]
sh ssl vserver
<!--NeedCopy-->
```

Example:

```
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory
> sh ssl vs v1

Advanced SSL configuration for VServer v1:

DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED

Optional	Optional	Undefined	Success	Success

Monitor certificate status with OCSP

September 14, 2021

Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. Citrix ADC appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. Citrix ADC implementation of OCSP includes request batching and response caching.

OCSP implementation

OCSP validation on a Citrix ADC appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the appliance creates an OCSP request and forwards it to the OCSP responder. To do so, the appliance uses a locally configured URL. The transaction is in a suspended state until the appliance evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the appliance allows the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.

The appliance supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.

OCSP request batching

Each time the appliance receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the appliance can query the status of more than one client certificate in the same request. For this feature to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.

OCSP response caching

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the appliance caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the appliance first checks its local cache for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the appliance sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.

> **Note**: From release 12.1 build 49.x, the cache timeout limit is now increased to a maximum of 43200 minutes (30 days). Earlier the limit was 1440 minutes (one day). The increased limit helps reduce the lookups on the OCSP server and avoid any SSL/TLS connection failures in case the OCSP server is not reachable due to network or other problems.

OCSP responder configuration

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

Add an OCSP responder by using the CLI

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```
add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED )
    [-cacheTimeout <positive_integer>]] [ -batchingDepth <
    positive_integer>][-batchingDelay <positive_integer>] [-resptimeout
    <positive_integer>] [-responderCert <string> | -trustResponder] [-
    producedAtTimeSkew <positive_integer>][-signingCert <string>][-
    useNonce ( YES | NO )][ -insertClientCert( YES | NO )]
<!--NeedCopy-->
```

```
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
    positive_integer>]
<!--NeedCopy-->
```

```
bind ssl vserver <vServerName>@ (-certkeyName <string> ( CA [-ocspCheck
     ( Mandatory | Optional )]))
<!--NeedCopy-->
```

```
show ssl ocspResponder [<name>]
<!--NeedCopy-->
```

Example:

```
add ssl ocspResponder ocsp_responder1 -url "http:// www.myCA.org:80/
    ocsp/" -cache ENABLED -cacheTimeout 30 -batchingDepth 8 -
    batchingDelay 100 -resptimeout 100 -responderCert responder_cert -
    producedAtTimeSkew 300 -signingCert sign_cert  -insertClientCert YES
<!--NeedCopy-->
```

```
bind ssl certKey ca_cert -ocspResponder ocsp_responder1 -priority 1
<!--NeedCopy-->
```

```
bind ssl vserver vs1 -certkeyName ca_cert -CA -ocspCheck Mandatory
<!--NeedCopy-->
```

```
sh ocspResponder ocsp_responder1

    1)Name: ocsp_responder1
    URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22
    Caching: Enabled        Timeout: 30 minutes
```

```
    Batching: 8 Timeout: 100 mS
    HTTP Request Timeout: 100mS
    Request Signing Certificate: sign_cert
    Response Verification: Full, Certificate: responder_cert
    ProducedAt Time Skew: 300 s
    Nonce Extension: Enabled
     Client Cert Insertion: Enabled
    Done
<!--NeedCopy-->
```

```
show certkey ca_cert

    Name: ca_cert     Status: Valid,   Days to expiration:8907
    Version: 3
    …

    1)  VServer name: vs1      CA Certificate
    1)  OCSP Responder name: ocsp_responder1     Priority: 1
Done
<!--NeedCopy-->
```

```
sh ssl vs vs1

    Advanced SSL configuration for VServer vs1:
    DH: DISABLED
    …

    1) CertKey Name: ca_cert CA Certificate OCSPCheck: Mandatory
    1) Cipher Name: DEFAULT
      Description: Predefined Cipher Alias
    Done
<!--NeedCopy-->
```

Modify an OCSP responder by using the CLI

You cannot modify the responder name. All other parameters can be changed using the `set ssl ocspResponder` command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED)
    ] [-cacheTimeout <positive_integer>] [-batchingDepth <
    positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout
```

```
      <positive_integer>] [ -responderCert <string> | -trustResponder][-
      producedAtTimeSkew <positive_integer>][-signingCert <string>] [-
      useNonce ( YES | NO )]
2
3 unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
4
5 bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
     positive_integer>]
6
7 show ssl ocspResponder [<name>]
8 <!--NeedCopy-->
```

Configure an OCSP responder by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **OCSP Responder**, and configure an OCSP responder.
2. Navigate to **Traffic Management** > **SSL** > **Certificates**, select a certificate, and in the **Action** list, select **OCSP Bindings**. Bind an OCSP responder.
3. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select **select OCSP Mandatory**.

OCSP stapling

September 14, 2021

The Citrix ADC implementation of CRL and OCSP reports the revocation status of client certificates only. To check the revocation status of a server certificate received during an SSL handshake, a client must send a request to a certificate authority.

For websites with heavy traffic, many clients receive the same server certificate. If each client sent a query for the revocation status of the server certificate, the certificate authority would be inundated with OCSP requests to check the validity of the certificate.

OCSP stapling solution

To avoid unnecessary congestion, the Citrix ADC appliance now supports OCSP stapling. That is, the appliance can now send the revocation status of a server certificate to a client, at the time of the SSL handshake, after validating the certificate status from an OCSP responder. The revocation status of a server certificate is “stapled” to the response the appliance sends to the client as part of the SSL

handshake. To use the OCSP stapling feature, you must enable it on an SSL virtual server and add an OCSP responder on the appliance.

Note:

- Citrix ADC appliances support OCSP stapling as defined in RFC 6066.
- OCSP stapling is supported only on the front-end of Citrix ADC appliances.

> **Important:**
>
> Citrix ADC support for OCSP stapling is limited to handshakes using TLS protocol version 1.0 or higher.

OCSP response caching of server certificates

During the SSL handshake, when a client requests the revocation status of the server certificate, the appliance first checks its local cache for an entry for this certificate. If a valid entry is found, it is evaluated and the server certificate and its status are presented to the client. If a revocation status entry is not found, the appliance sends a request for the revocation status of the server certificate to the OCSP responder. If it receives a response, it sends the certificate and the revocation status to the client. If the next update field is present in the OCSP response, the response is cached for the configured length of time (value specified in the timeout field.)

> **Note**: From release 12.1 build 49.x, you can clear the cached response, of the server certificate, from the OCSP responder even before the timeout expires. Earlier, it was not possible to discard the cached status in the certificate-key pair until the configured timeout was over.

To clear the cached status by using the CLI, at the command prompt, type:

```
clear ssl certKey <certkey name> -ocspstaplingCache
<!--NeedCopy-->
```

Example:

```
clear ssl certKey s1 -ocspstaplingCache
<!--NeedCopy-->
```

To clear the cached status by using the GUI

1. In the GUI, navigate to **Traffic Management** > **SSL** > **Certificates** > **CA Certificates**.
2. In the details pane, select a certificate.
3. In the **Select Action** list, select **Clear**. When prompted to confirm, click **Yes**.

OCSP stapling configuration

Configuring OCSP stapling involves enabling the feature and configuring OCSP. To configure OCSP, you must add an OCSP responder, bind the OCSP responder to a CA certificate, and bind the certificate to an SSL virtual server.

> **Note:**
>
> OCSP responders with only HTTP based URL are supported.

Enable OCSP stapling by using the CLI

At the command prompt, type:

```
set ssl vserver <name> -ocspstapling [ENABLED | DISABLED]
<!--NeedCopy-->
```

Example:

```
set ssl vserver vip1 -ocspStapling ENABLED
Done

sh ssl vserver vip1

     Advanced SSL configuration for VServer vip1:
     DH: DISABLED
     DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA:
        ENABLED Refresh Count: 0
     Session Reuse: ENABLED Timeout: 120 seconds
     Cipher Redirect: DISABLED
     SSLv2 Redirect: DISABLED
     ClearText Port: 0
     Client Auth: DISABLED
     SSL Redirect: DISABLED
     Non FIPS Ciphers: DISABLED
     SNI: ENABLED
     OCSP Stapling: ENABLED
     SSLv2: DISABLED SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED
          TLSv1.2: ENABLED
     Push Encryption Trigger: Always
     Send Close-Notify: YES

     ECC Curve: P_256, P_384, P_224, P_521

    1) CertKey Name: server_certificate1 Server Certificate

```

```
26      1) Cipher Name: DEFAULT
27       Description: Default cipher list with encryption strength >= 128
            bit
28  Done
29  <!--NeedCopy-->
```

Note: If the default (enhanced) profile is enabled, use the `set ssl profile <profile name> -ocspStapling [ENABLED | DISABLED]` command to enable or disable OCSP.

Enable OCSP stapling by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Virtual Server**.
2. Open a virtual server and, in **SSL Parameters**, select **OCSP Stapling**.

OCSP configuration

An OCSP responder is added dynamically or manually to send OCSP stapling requests. An internal responder is dynamically added when you add a server certificate and its issuer certificate based on the OCSP URL in the server certificate. A manual OCSP responder is added from the CLI or GUI. To send an OCSP request for a server certificate, the Citrix ADC appliance selects an OCSP responder based on the priority assigned to it when binding it to an issuer certificate. If a responder fails to send an OCSP stapling request, the responder with the next highest priority is selected for sending the request. For example, if only one responder is manually configured and it fails and a dynamically bound responder exists, it is selected for sending the OCSP request.

If the OCSP URL is other than HTTP, an internal OCSP responder is not created.

> **Note**
>
> A manually added OCSP responder takes precedence over a dynamically added responder.

Difference between a manually created OCSP responder and an internally created OCSP responder

Manually created OCSP responder	Internally (dynamically) created OCSP responder
Created manually and explicitly bound to the issuer certificate with a priority.	Created and bound by default, while adding a server certificate and its issuer certificate (CA certificate). Name starts with “ns_internal_”.

Priority between 1 and 127 is reserved for a configured responder.	Priority is automatically assigned from 128 onwards.
URL and batching depth can be changed.	URL and batching depth cannot be changed.
Deleted directly.	Deleted only when you delete the server certificate or the CA certificate.
Can be bound to any CA certificate.	Bound by default to one CA certificate. Cannot be bound to any other CA certificate.
Saved in the configuration (ns.conf).	Add commands are not saved in the configuration. Only set commands are saved.
If you bind three OCSP responders to the same issuer certificate with priorities 1, 2, and 3 respectively, and later unbind priority 2, the other priorities are not affected.	Three OCSP responders are automatically bound to an issuer certificate with priorities 128, 129, and 130 respectively. If you remove the server certificate that was used to create a responder bound with priority 129, then that responder is deleted. Also, the priority for the next responder (priority 130) is automatically changed to 129.

> **Example of request handling**:

1. Add a virtual server (VIP1).
2. Add issuer certificate (CA1) and bind it to VIP1.
3. Add three certificates S1, S2, and S3. Internal responders resp1, resp2, and resp3 respectively are created by default.
4. Bind S3 to VIP1.
5. A request comes to VIP1. Responder resp3 is selected.

To create an internal OCSP responder dynamically, the appliance needs the following:

- Certificate of the issuer of the server certificate (usually the CA certificate).
- Certificate-key pair of the server certificate. This certificate must contain the OCSP URL provided by the certificate authority. The URL is used as the name of the dynamically added internal responder.

An internal OCSP responder has the same default values as a manually configured responder.

> **Note:**
>
> Caching is disabled by default on an internal responder. Use the `set ssl ocspResponder`

> command to enable caching.

Configure OCSP by using the CLI

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <
    string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>]
    [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <
    positive_integer>]] [-bundle ( YES | NO )]

add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED )
    [-cacheTimeout <positive_integer>]] [-resptimeout <positive_integer
    >] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew
    <positive_integer>][-signingCert <string>][-useNonce ( YES | NO )][
    -insertClientCert ( YES | NO )]

bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
    positive_integer>]

show ssl ocspResponder [<name>]
<!--NeedCopy-->
```

Parameters:

httpMethod:

HTTP method used to send OCSP requests. For requests, less than 255 bytes long, you can configure the HTTP GET method for queries to an OCSP server. If you specify the GET method but the length is greater than 255 bytes, the appliance uses the default method (POST).

Possible values: GET, POST

Default value: POST

ocspUrlResolveTimeout:

Time, in milliseconds, to wait for an OCSP URL resolution. After this time elapses, the responder with the next higher priority is selected. If all the responders fail, an error message appears or the connection is dropped, depending on the settings on the virtual server.

Minimum value: 100

Maximum value: 2000

Example:

```
add ssl certkey root_ca1  - cert root_cacert.pem
add ssl ocspResponder ocsp_responder1 -url "http:// www.myCA.org:80/
    ocsp/" -cache ENABLED -cacheTimeout 30  -resptimeout 100 -
    responderCert responder_cert -producedAtTimeSkew 300 -signingCert
    sign_cert  -insertClientCert YES
bind ssl certKey root_ca1 -ocspResponder ocsp_responder1 -priority 1
sh ocspResponder ocsp_responder1
    1)Name: ocsp_responder1
    URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22
    Caching: Enabled        Timeout: 30 minutes
    Batching: 8 Timeout: 100 mS
    HTTP Request Timeout: 100mS
    Request Signing Certificate: sign_cert
    Response Verification: Full, Certificate: responder_cert
    ProducedAt Time Skew: 300 s
    Nonce Extension: Enabled
     Client Cert Insertion: Enabled
    Done

show certkey root_ca1
    Name: root_ca1     Status: Valid,   Days to expiration:8907
    Version: 3
    …
    1)  OCSP Responder name: ocsp_responder1     Priority: 1
    Done
<!--NeedCopy-->
```

Modify OCSP by using the CLI

You cannot modify the name of an OCSP responder, but you can use the `set ssl ocspResponder` command to change any of the other parameters.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED)
    ] [-cacheTimeout <positive_integer>]  [-resptimeout <
    positive_integer>] [ -responderCert <string> | -trustResponder][-
    producedAtTimeSkew <positive_integer>][-signingCert <string>] [-
    useNonce ( YES | NO )]

unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]

```

```
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
    positive_integer>]

show ssl ocspResponder [<name>]
<!--NeedCopy-->
```

Configure OCSP by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **OCSP Responder**, and configure an OCSP responder.
2. Navigate to **Traffic Management** > **SSL** > **Certificates**, select a certificate, and in the **Action** list, select **OCSP Bindings**. **Bind an OCSP responder**.
3. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select **OCSP Mandatory**.

> **Note:**
>
> The insert client certificate parameter in the `add ssl ocspResponder` and the `set ssl ocspResponder` commands is no longer valid. That is, the parameter is ignored during configuration.

Ciphers available on the Citrix ADC appliances

September 14, 2021

Your Citrix ADC appliance ships with a predefined set of cipher groups. To use ciphers that are not part of the DEFAULT cipher group, you have to explicitly bind them to an SSL virtual server. You can also create a user-defined cipher group to bind to the SSL virtual server. For more information about creating a user-defined cipher group, see Configure user-defined cipher groups on the ADC appliance.

> **Notes**
>
> RC4 cipher is not included in the default cipher group on the Citrix ADC appliance. However, it is supported in the software on the N3-based appliances. RC4 encryption, including the handshake, is done in software.
>
> Citrix recommends that you do not use this cipher because it is considered insecure and deprecated by RFC 7465.
>
> Use the 'show hardware' command to identify whether your appliance has N3 chips.

```
sh hardware

```

```
Platform: NSMPX-22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100

Manufactured on: 8/19/2013

CPU: 2900MHZ

Host Id: 1006665862

Serial no: ENUK6298FT

Encoded serial no: ENUK6298FT
<!--NeedCopy-->
```

- To display information about the cipher suites bound by default at the front end (to a virtual server), type: `sh cipher DEFAULT`
- To display information about the cipher suites bound by default at the back end (to a service), type: `sh cipher DEFAULT_BACKEND`
- To display information about all the cipher groups (aliases) defined on the appliance, type: `sh cipher`
- To display information about all the cipher suites that are part of a specific cipher group, type: `sh cipher <alias name>`. For example, sh cipher ECDHE.

The following links list the cipher suites supported on different Citrix ADC platforms and on external hardware security modules (HSMs):

- **Citrix ADC MPX/SDX (N3) appliance**: Cipher support on a Citrix ADC MPX/SDX (N3) appliance
- **Citrix ADC MPX/SDX Intel Coleto appliance**: Cipher support on a Citrix ADC MPX/SDX Intel Coleto SSL chip based appliance
- **Citrix ADC VPX appliance**: Cipher support on a Citrix ADC VPX appliance
- **Citrix ADC MPX/SDX 14000 FIPS appliance**: Cipher support on a Citrix ADC MPX/SDX 14000 FIPS appliance
- **External HSM (Thales/Safenet)**: Cipher supported on an External HSM (Thales/Safenet)
- **Citrix ADC MPX/SDX (N2) appliance**: Cipher support on a Citrix ADC MPX/SDX (N2) appliance
- **Citrix ADC MPX 9700 FIPS appliance**: Cipher support on a Citrix ADC MPX 9700 FIPS with firmware 2.2
- **Citrix ADC VPX FIPS and MPX FIPS appliances**: Cipher support on Citrix ADC VPX FIPS and MPX FIPS certified appliances

> **Note:**
>
> For DTLS cipher support, see DTLS cipher support on Citrix ADC VPX, MPX, and SDX appliances.

Table1 - Support on virtual server/frontend service/internal service:

Protocol/Platform	MPX/SDX (N2)	MPX/SDX (N3)	VPX	MPX 9700* FIPS with firmware 2.2	MPX/SDX 14000** FIPS	MPX 5900/8900 MPX 15000-50G MPX 26000-100G
TLS 1.3	13.0 all builds	13.0 all builds	13.0 all builds	Not supported	Not supported	13.0 all builds
	12.1–50.x	12.1–50.x	12.1–50.x	Not supported	Not supported	12.1–50.x
TLS 1.1/1.2	13.0 all builds	13.0 all builds	13.0 all builds	13.0 all builds	13.0 all builds	13.0 all builds
	12.1 all builds	12.1 all builds	12.1 all builds	12.1 all builds	12.1 all builds	12.1 all builds for MPX 5900/8900, 12.1-50.x for MPX 15000-50G and MPX 26000-100G
	12.0 all builds	12.0 all builds	12.0 all builds	12.0 all builds	12.0 all builds	12.0 all builds for MPX 5900/8900, 12.0-57.x for MPX 15000-50G, 12.0-60.x for MPX 26000-100G

Protocol/Platform	MPX/SDX (N2)	MPX/SDX (N3)	VPX	MPX 9700* FIPS with firmware 2.2	MPX/SDX 14000** FIPS	MPX 5900/8900 MPX 15000-50G MPX 26000-100G
	11.1 all builds	11.1 all builds	11.1 all builds	11.1 all builds	11.1 all builds	11.1–56.x for MPX 5900/8900 and MPX 15000-50G, 11.1-60.x for MPX 26000-100G
	11.0 all builds	11.0 all builds	11.0 all builds	11.0 all builds	11.0 all builds	11.0–70.x (only on MPX 5900/8900)
	10.5 all builds	10.5 all builds	10.5–57.x	10.5 58.1108.e	10.5–59.1359.e	10.5–67.x, 10.5-63.47 (only on MPX 5900/8900)
ECDHE/DHE (Example TLS1-ECDHE-RSA-AES128-SHA)	13.0 all builds	13.0 all builds	13.0 all builds	13.0 all builds	13.0 all builds	13.0 all builds

Protocol/Platform	MPX/SDX (N2)	MPX/SDX (N3)	VPX	MPX 9700* FIPS with firmware 2.2	MPX/SDX 14000** FIPS	MPX 5900/8900 MPX 15000-50G MPX 26000-100G

	Not supported	Not supported	12.0–56.x	Not supported	Not supported	Not supported

For the detailed list of ECDSA ciphers supported, see ECDSA Cipher Suites support.

> Note
>
> - TLS-Fallback_SCSV cipher suite is supported on all appliances from release 10.5 build 57.x
> - HTTP Strict Transport Security (HSTS) support is policy-based.

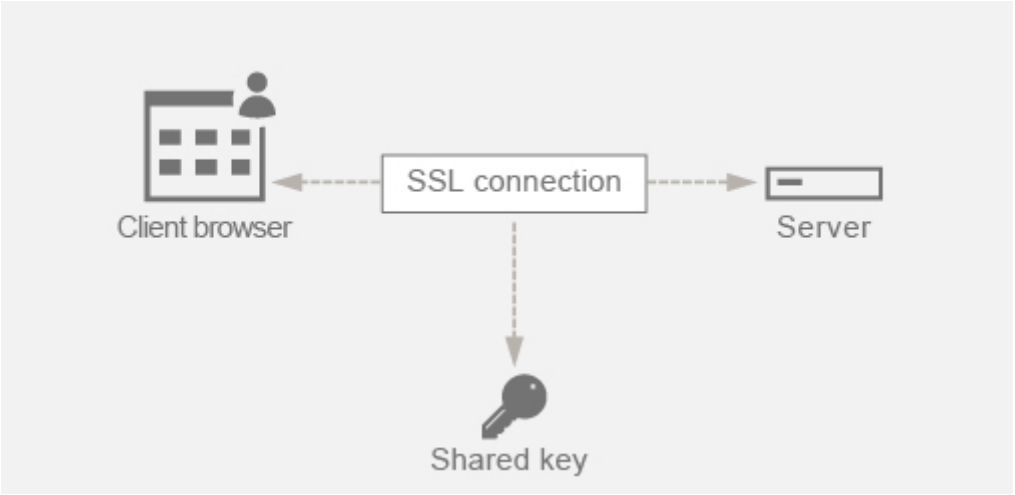
- All SHA-2 signed-certificates (SHA256, SHA384, SHA512) are supported on the front end of all appliances. In release 11.1 build 54.x and later, these certificates are also supported on the back-end of all appliances. In release 11.0 and earlier, only SHA256 signed-certificates are supported on the back end of all appliances.
- In release 11.1 build 52.x and earlier, the following ciphers are supported only on the front end of the MPX 9700 and MPX/SDX 14000 FIPS appliances:
  - TLS1.2-ECDHE-RSA-AES-256-SHA384
  - TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 From release 11.1 build 53.x, and in release 12.0, these ciphers are also supported on the back end.
- All ChaCha20-Poly1035 ciphers use a TLS pseudo random function (PSF) with the SHA-256 hash function.

Perfect Forward Secrecy (PFS)

Perfect Forward Secrecy ensures protection of current SSL communications even if the session key of a web server is compromised at a later point in time.

Why do you need Perfect Forward Secrecy (PFS)?

An SSL connection is used to secure the data being passed between a client and a server. This connection begins with the SSL handshake that takes place between a client's browser and the contacted web server. It is during this handshake that the browser and the server exchange certain information to arrive upon a session key which serves as a means to encrypt the data throughout the rest of the communication.



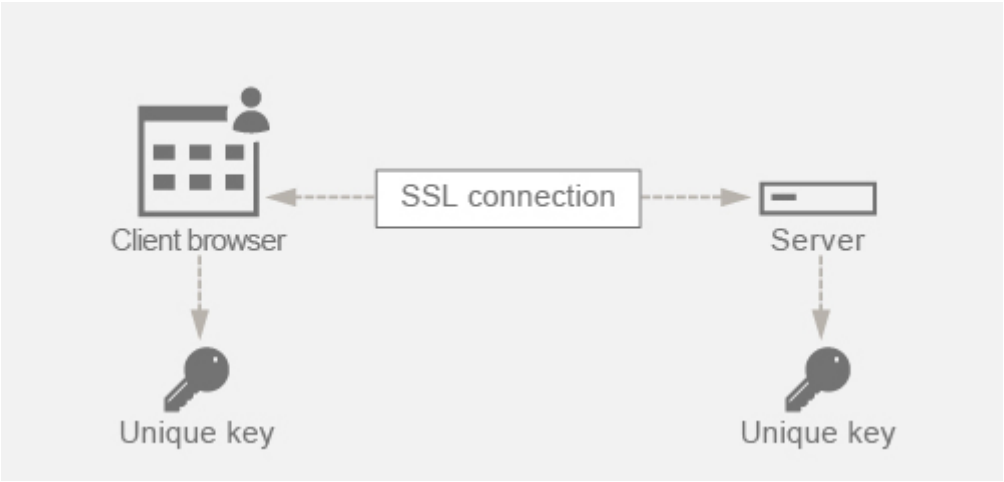
RSA is the most commonly used algorithm for key exchange. The browser uses the server's public key to encrypt and send across the pre-master secret to a server. This pre-master secret is used to arrive at the session key. The problem in the RSA key exchange approach is that if an attacker manages to

get hold of the server's private key at any point in time in the future, then the attacker gets hold of the pre-master secret using which the session key can be obtained. This session key can now be used by the attacker to decrypt all the SSL conversations. This means that your historical SSL communication was secure earlier but they are no longer secure as the server's stolen private key can be used to arrive at the session key and thus decrypt any saved historical conversation as well.

The need is to be able to protect the past SSL communication even if the server's private key has been compromised. This is where configuring Perfect Forward Secrecy (PFS) comes to the rescue.

How does PFS help?

Perfect Forward Secrecy (PFS) protects the past SSL communication by having the client and server agree upon a new key for each session and keeping the computation of this session key a secret. It works on the basis that compromise of a server key must not result in compromise of the session key. Session key is derived separately at both ends and is never transferred over the wire. The session keys are also destroyed once the communication is complete. These facts ensure that even if someone gets access to the server's private key, they would not be able to arrive at the session key and hence would not be able to decrypt the past data.



Explanation with example

Assume that we are using DHE for attaining PFS. The DH algorithm ensures that even though a hacker gets hold of the server's private key, the hacker will not be able to arrive at the session key because the session key and the random numbers (used to arrive at the session key) are kept secret at both ends and never exchanged over the wire.
PFS can be achieved by using the Ephemeral Diffie-Hellman key exchange which creates new temporary keys for each SSL session.

The flip side of creating a key for each session is that it requires extra computation but this can be overcome by using the Elliptic Curve which has smaller key sizes.

Configure PFS on Citrix ADC appliance

PFS can be configured on a Citrix ADC by configuring DHE or ECDHE ciphers. These ciphers ensure that the secret session key created is not shared on the wire (DH algorithm) and that the session key remains alive only for a short time (Ephemeral). Both the configurations are explained in the following sections.

Note: Using ECDHE ciphers instead of DHE makes the communication more secure with smaller key sizes.

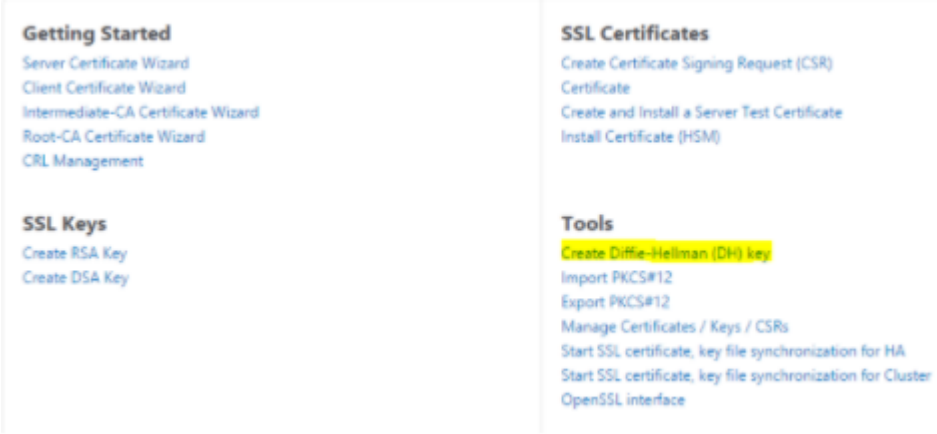
Configure DHE by using the GUI

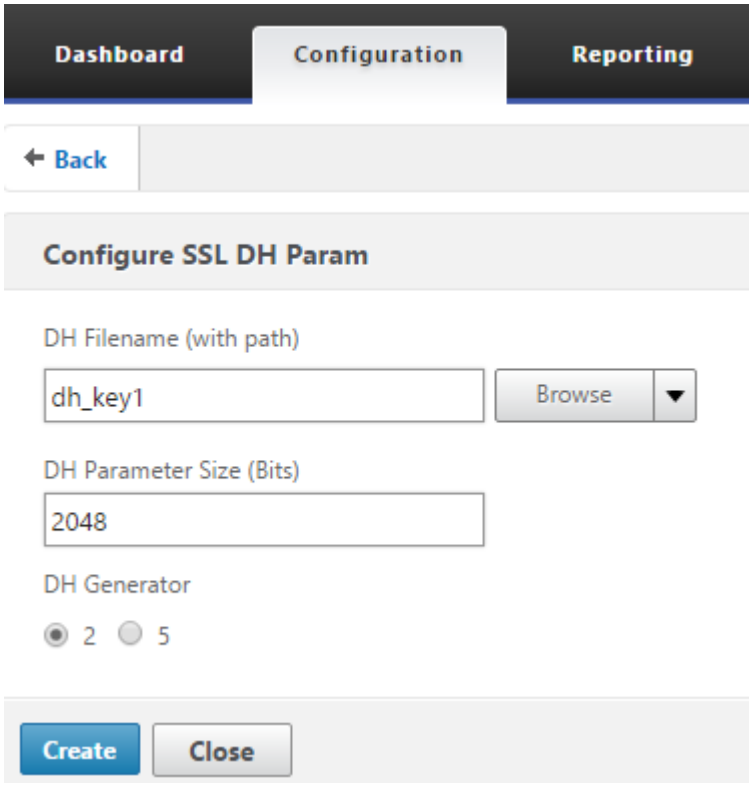
1. Generate a DH key.

   a. Navigate to **Traffic Management > SSL > Tools**.

   b. Click **Create Diffie Helman (DH) Key**.

   Note: Generating a 2048-bit DH key can take up to 30 minutes.



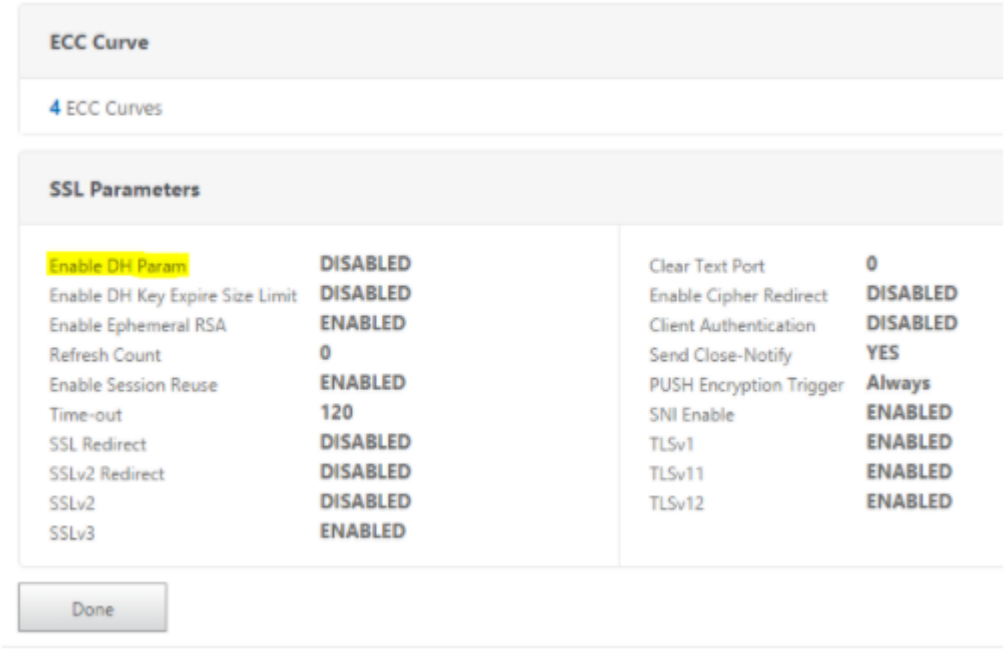


2. Enable DH Param for the SSL virtual server and attach the DH key to the SSL virtual server.

   a. Navigate to **Configuration > Traffic Management > Virtual Servers**.

   b. Select the virtual server on which you want to enable DH.

   c. Click **Edit**, click **SSL Parameters**, and click **Enable DH Param**.



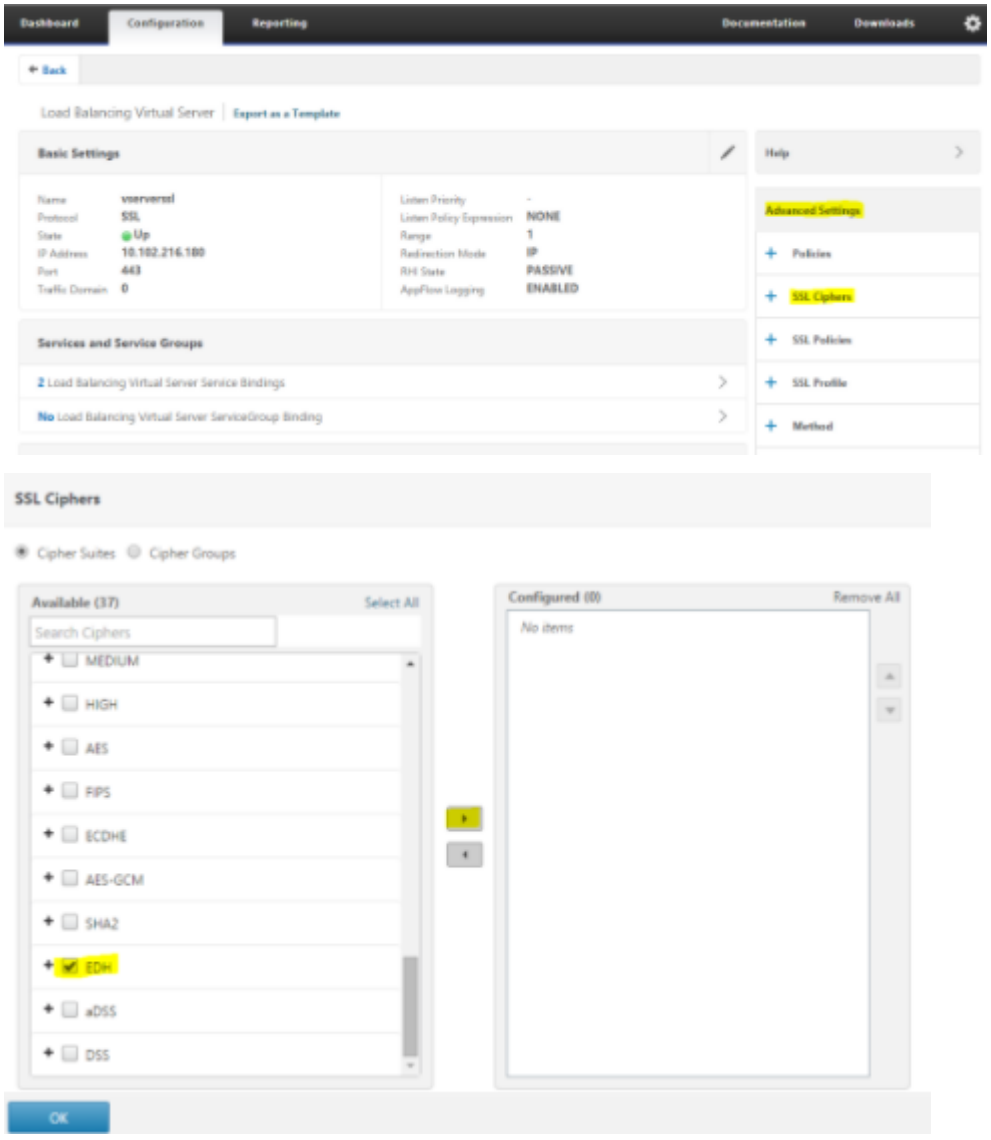
3. Bind the DHE ciphers to the virtual server.

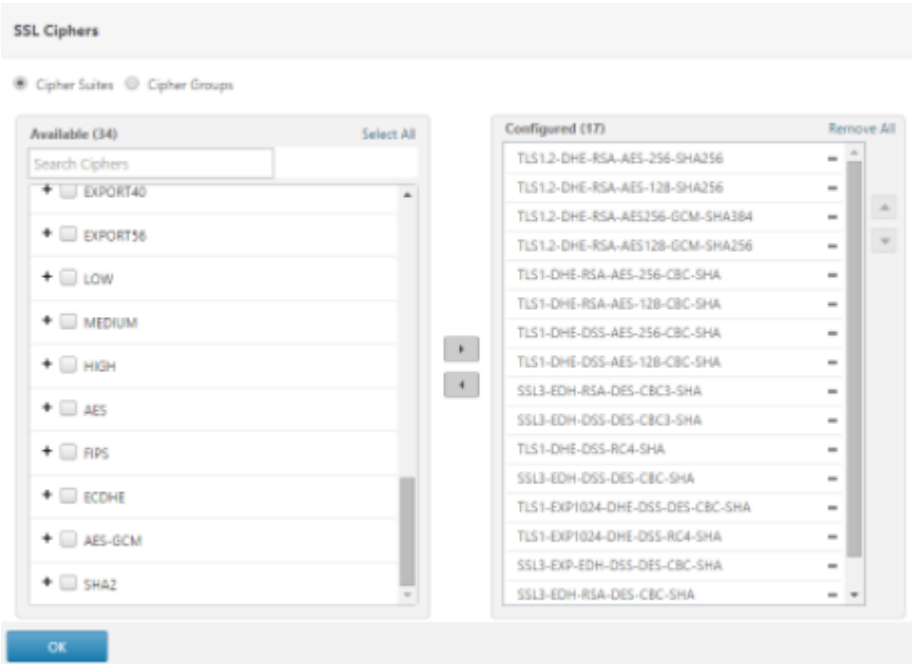
   a. Navigate to **Configuration > Traffic Management > Virtual Servers**.

   b. Select the virtual server on which you want to enable DH and click the pencil icon to edit.

   c. Under **Advanced Settings**, click plus icon next to **SSL Ciphers** and select the DHE cipher groups and click **OK** to bind.

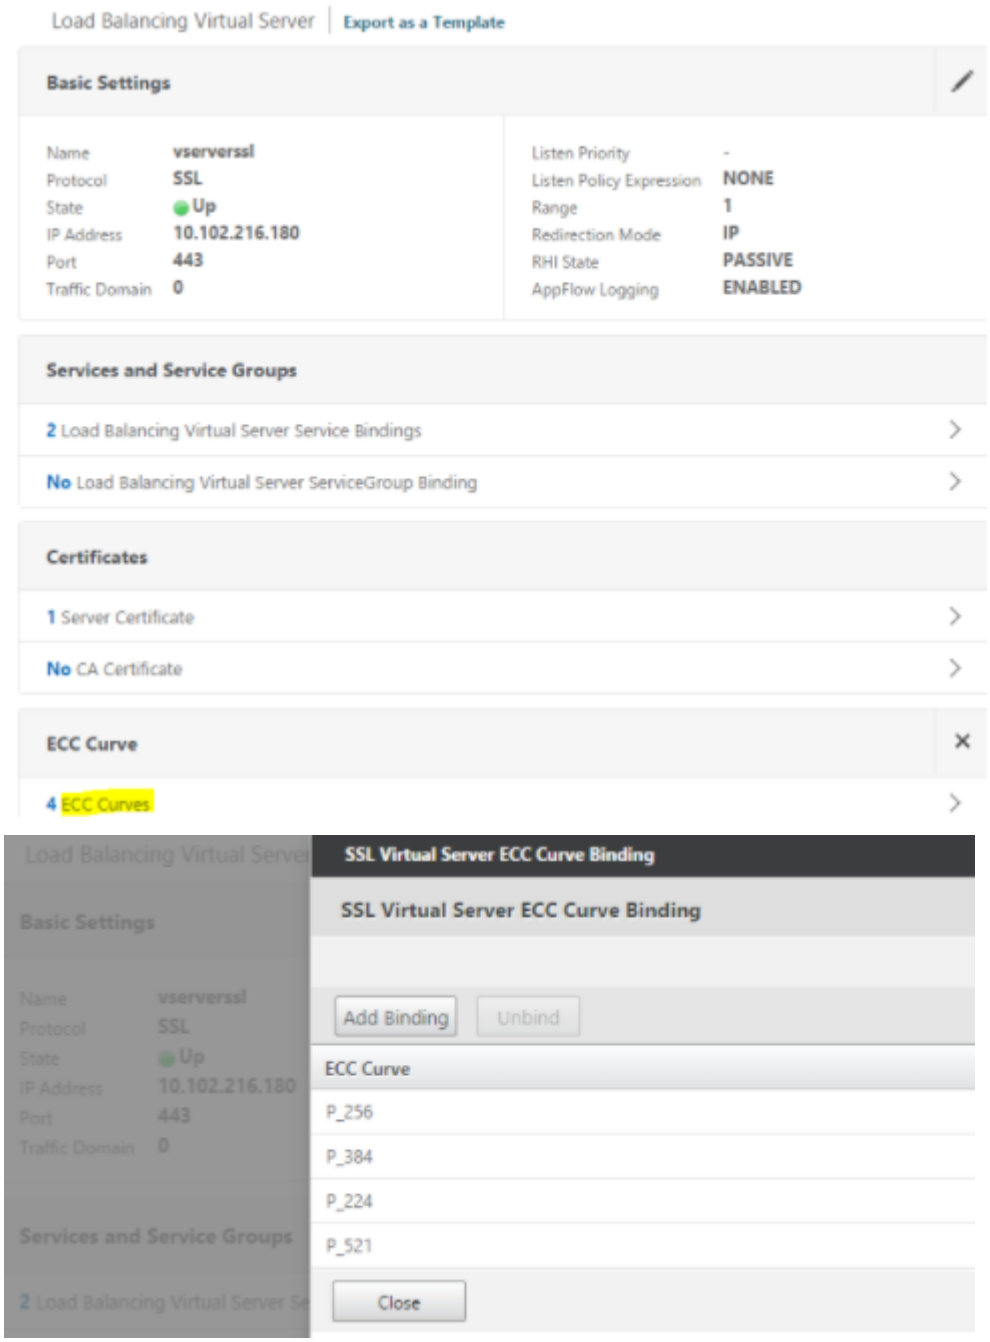
   Note: Ensure that the DHE ciphers are at the top of the cipher list bound to the virtual server.





Configure ECDHE by using the GUI

1. Bind the ECC curves to the SSL virtual server.
   a. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**.
   b. Select the SSL virtual server which you want to edit, click **ECC Curve** and click **Add Binding**.
   c. Bind the required ECC curve to the virtual server.

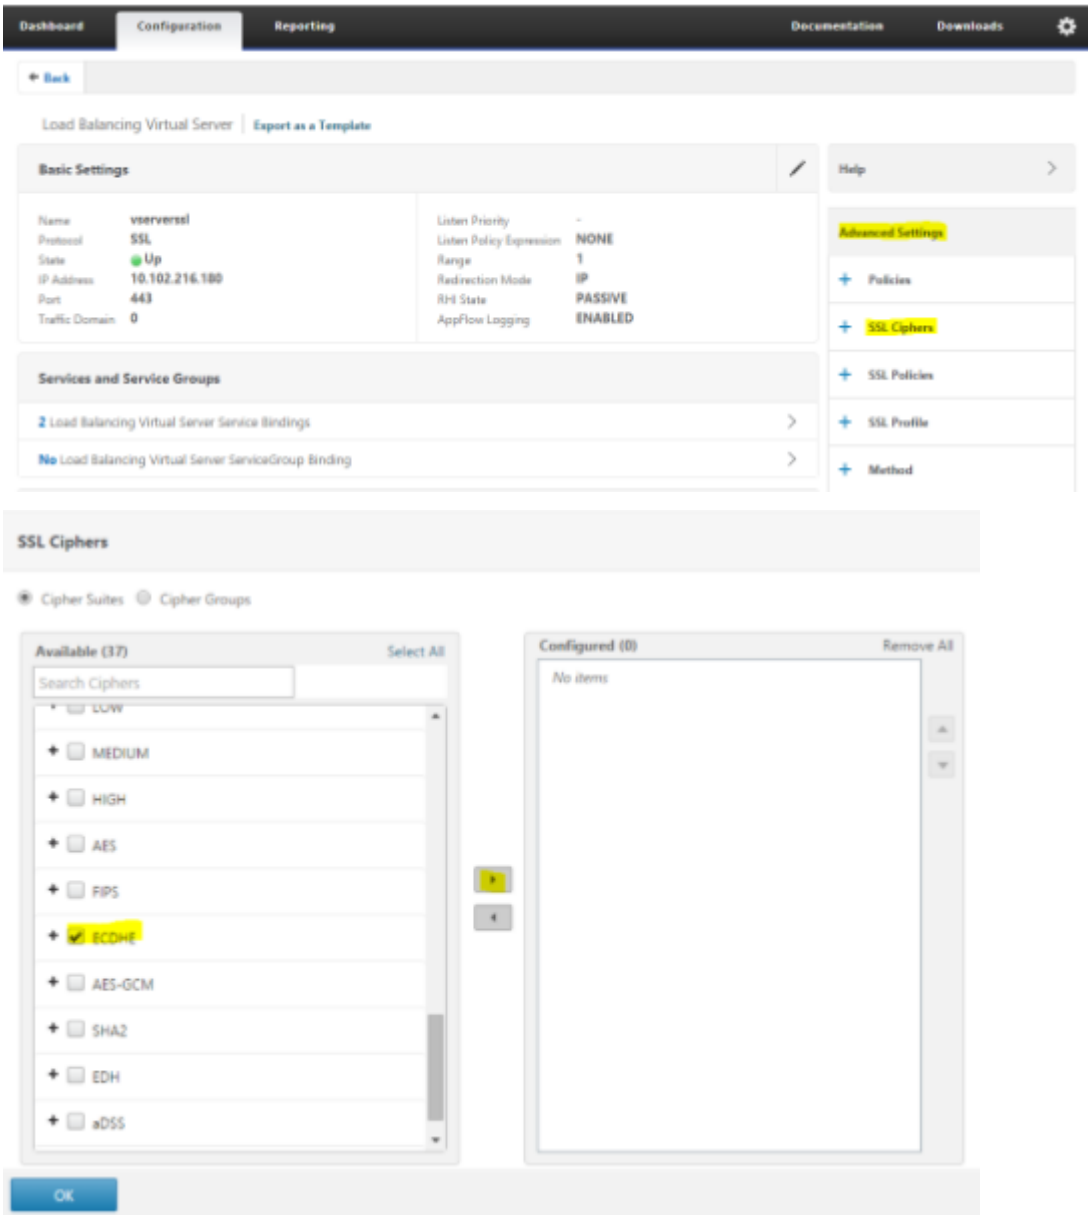


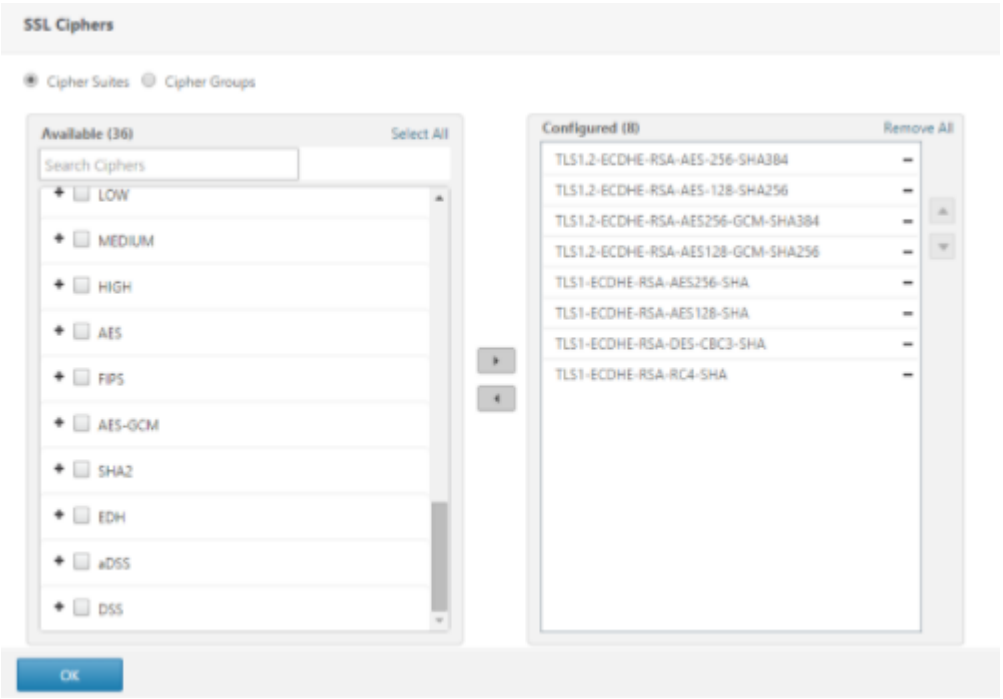
2. Bind the ECDHE ciphers to the virtual server.

   a. Navigate to **Configuration > Traffic Management > Virtual Servers** and select the virtual server on which you want to enable DH.

   b. Click **Edit > SSL Ciphers** and select the ECDHE cipher groups and click **Bind**.

   Note: Ensure that the ECDHE ciphers are at the top of the cipher list bound to the virtual server.





Note: For each case verify that the Citrix ADC appliance supports the ciphers you would like to use for the communication.

Configure PFS using an SSL profile

Note: Option to configure PFS (cipher or ECC) using an SSL profile is introduced from 11.0 64.x release onwards. Ignore the following section if on older versions.

To enable PFS using an SSL profile, a similar configuration (as explained in earlier configuration sections) needs to be done but on the SSL profile instead of directly configuring on a virtual server.

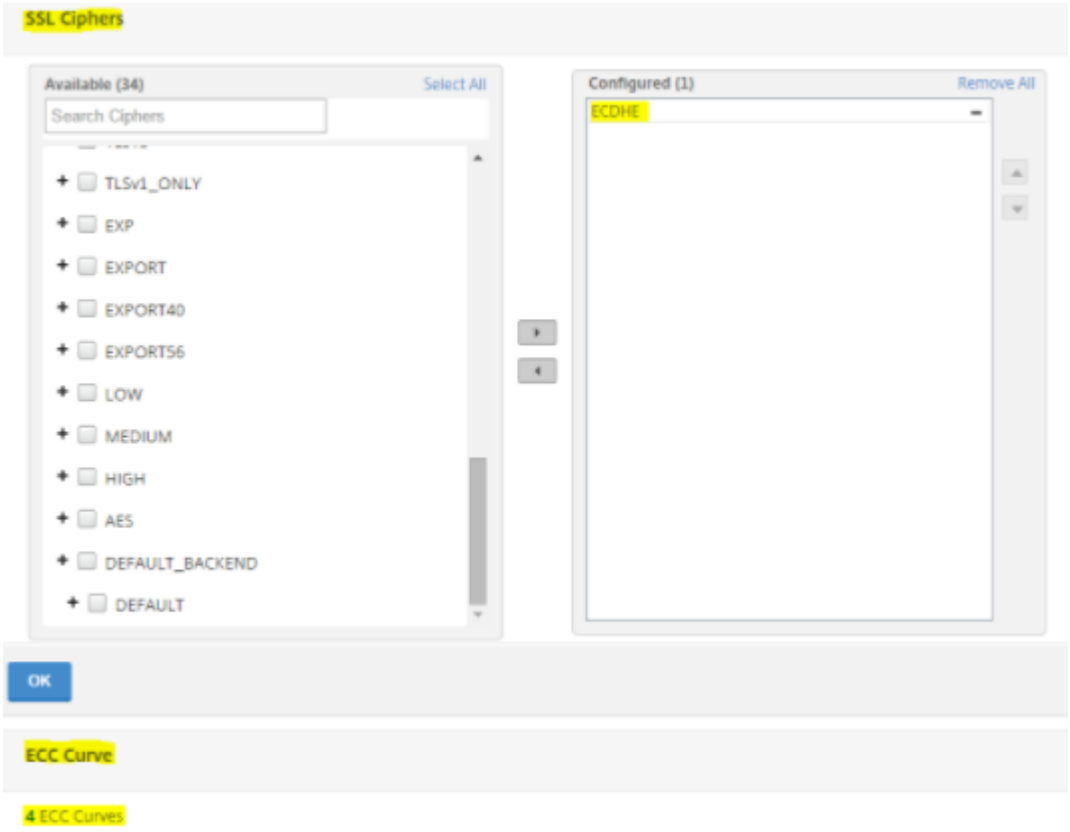
Configure PFS using an SSL profile by using the GUI

1. Bind the ECC curves and the ECDHE ciphers on the SSL profile.

   Note: ECC curves are already bound by default to all the SSL profiles.

   a. Navigate to **System > Profiles > SSL Profiles** and choose the profile you want to enable PFS on.

   b. Bind the ECDHE ciphers.



2. Bind the SSL profile to the virtual server.

   a. Go to **Configuration > Traffic Management > Virtual Servers** and select the virtual server.

   b. Click the pencil icon to edit the SSL profile.

   c. Click **OK** and click **Done**.

Configure PFS using SSL using the CLI

At the command prompt, type:

1. Bind ECC curves to the SSL profile.

```
bind sslprofile <SSLProfileName> -eccCurveName <Name_of_curve>
<!--NeedCopy-->
```

2. Bind the ECDHE cipher group.

```
bind sslprofile <SSLProfileName> cipherName <ciphergroupName>
<!--NeedCopy-->
```

3. Set the priority of the ECDHE cipher as 1.

```
set sslprofile <SSLProfileName> cipherName <ciphergroupName>
   cipherPriority <positive_integer>
<!--NeedCopy-->
```

4. Bind the SSL profile to the virtual server.

```
set SSL vserver <vservername> sslProfile <SSLProfileName>
<!--NeedCopy-->
```

ECDHE ciphers

September 14, 2021

All Citrix ADC appliances support the ECDHE cipher group on the front end and the back end. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

For more information about the builds and platforms that support these ciphers, see Ciphers available on the Citrix ADC appliances.

ECDHE cipher suites use elliptical curve cryptography (ECC). Because of its smaller key size, ECC is especially useful in a mobile (wireless) environment or an interactive voice response environment, where every millisecond is important. Smaller key sizes save power, memory, bandwidth, and computational cost.

A Citrix ADC appliance supports the following ECC curves:

- P_256
- P_384
- P_224
- P_521

Note: If you upgrade from a build earlier than release 10.1 build 121.10, you must explicitly bind ECC curves to your existing SSL virtual servers and services. The curves are bound by default to any virtual servers and services that you create after the upgrade.

You can bind an ECC curve to SSL front end and back end entities. By default all four curves are bound, in the following order: P_256, P_384,P_224,P_521. To change the order, you must first unbind all the curves, and then bind them in the desired order.

Bind ECC curves to an SSL virtual server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName > -eccCurveName <eccCurveName >
```

Example:

```
bind ssl vserver  v1 -eccCurveName P_224

sh ssl vserver v1

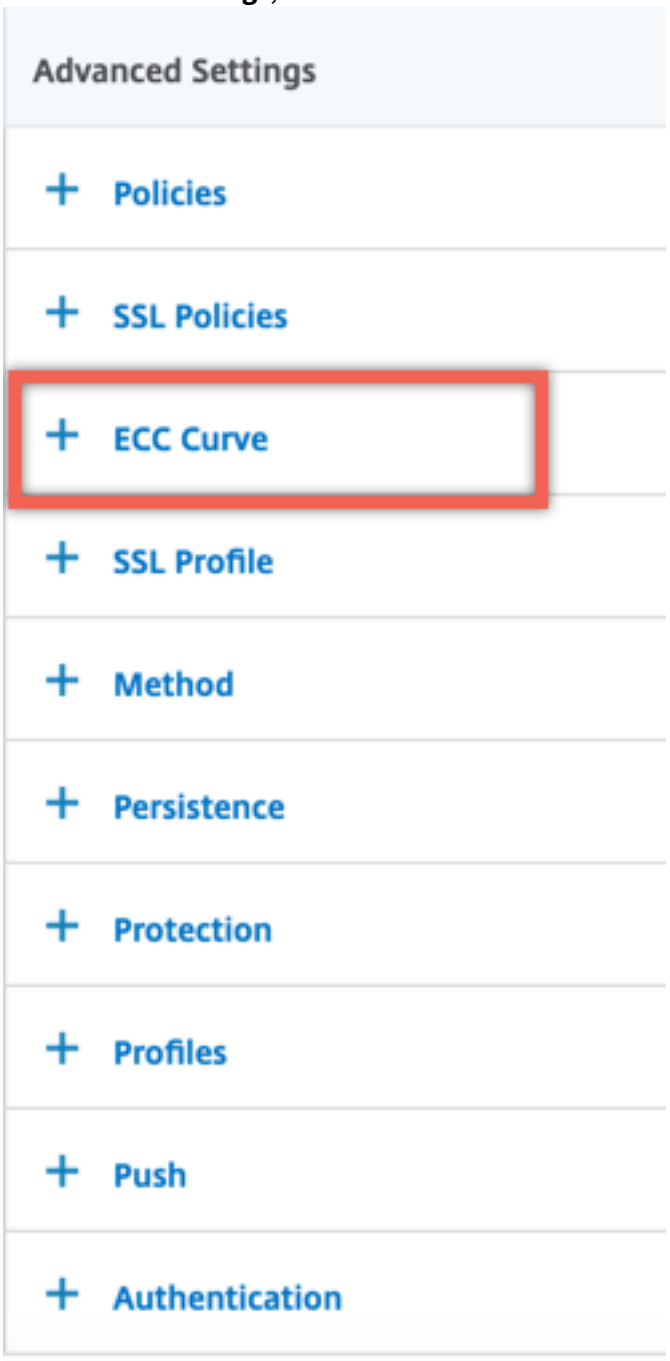
Advanced SSL configuration for VServer v1:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED  TLSv1.1: DISABLED
   TLSv1.2: DISABLED
Push Encryption Trigger: Always
Send Close-Notify: YES
ECC Curve: P_224

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done
<!--NeedCopy-->
```

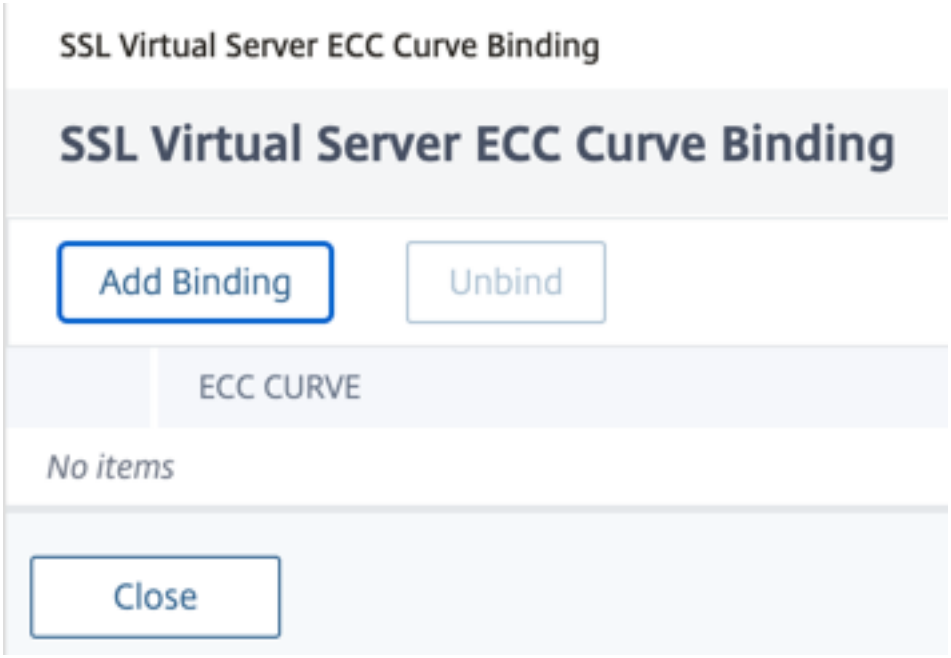
Bind ECC curves to an SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select an SSL virtual server and click **Edit**.

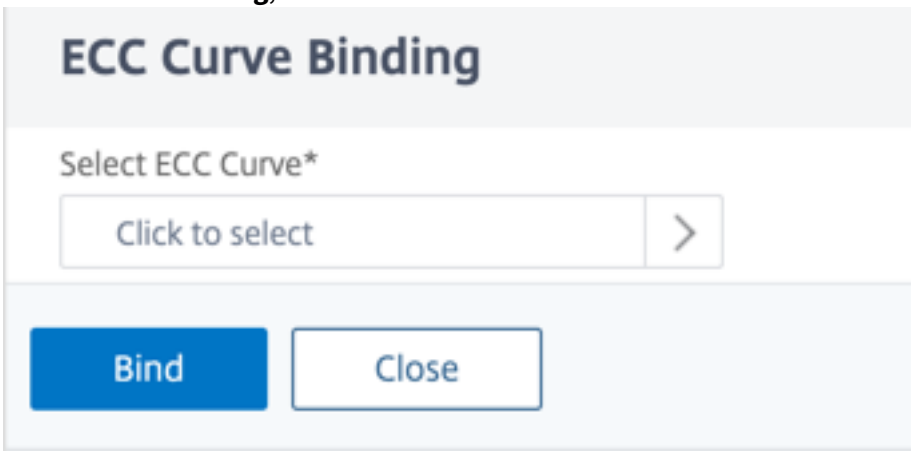
3. In **Advanced Settings**, click **ECC Curve**.



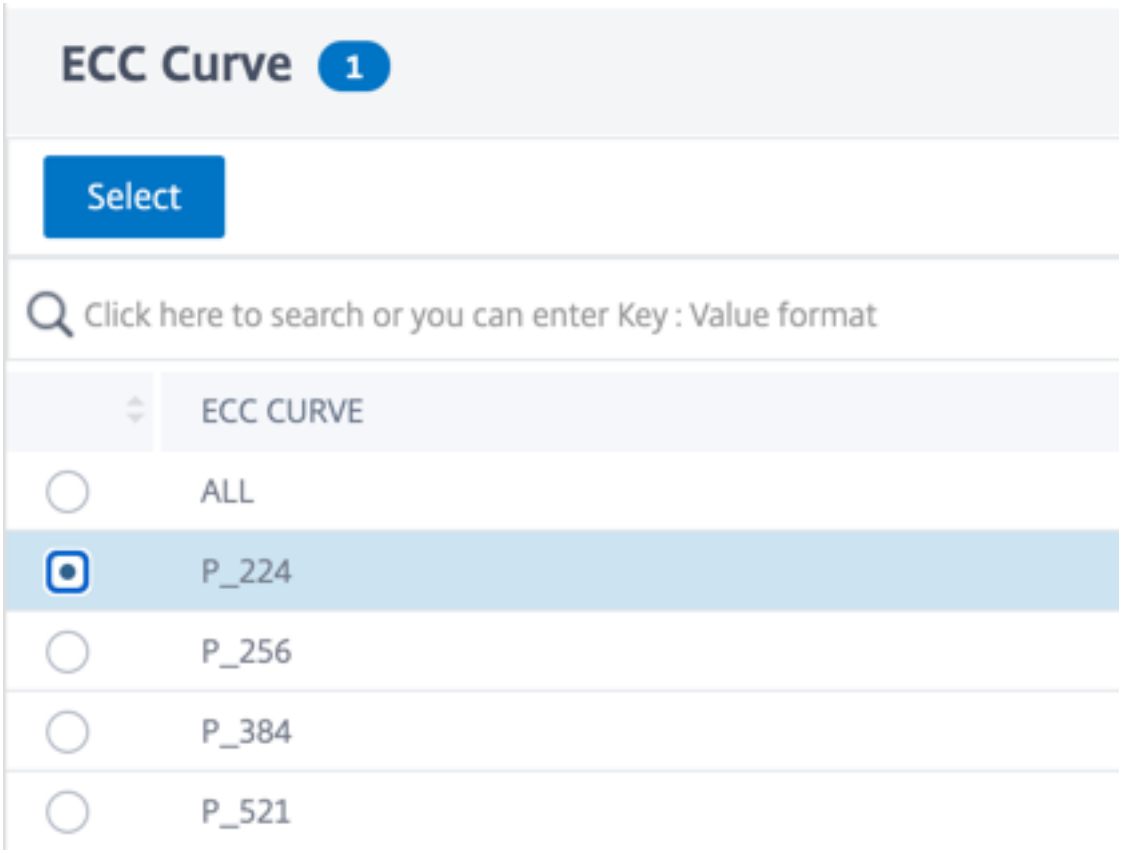
4. Click inside the ECC curve section.
5. In the **SSL Virtual Server ECC Curve Binding** page, click **Add Binding**.



6. In **ECC Curve Binding**, click **Select ECC Curve**.



7. Select a value, and then click **Select**.



8. Click **Bind**.
9. Click **Close**.
10. Click **Done**.

Bind ECC curves to an SSL service by using the CLI

At the command prompt, type:

```
bind ssl service <vServerName > -eccCurveName <eccCurveName >
```

Example:

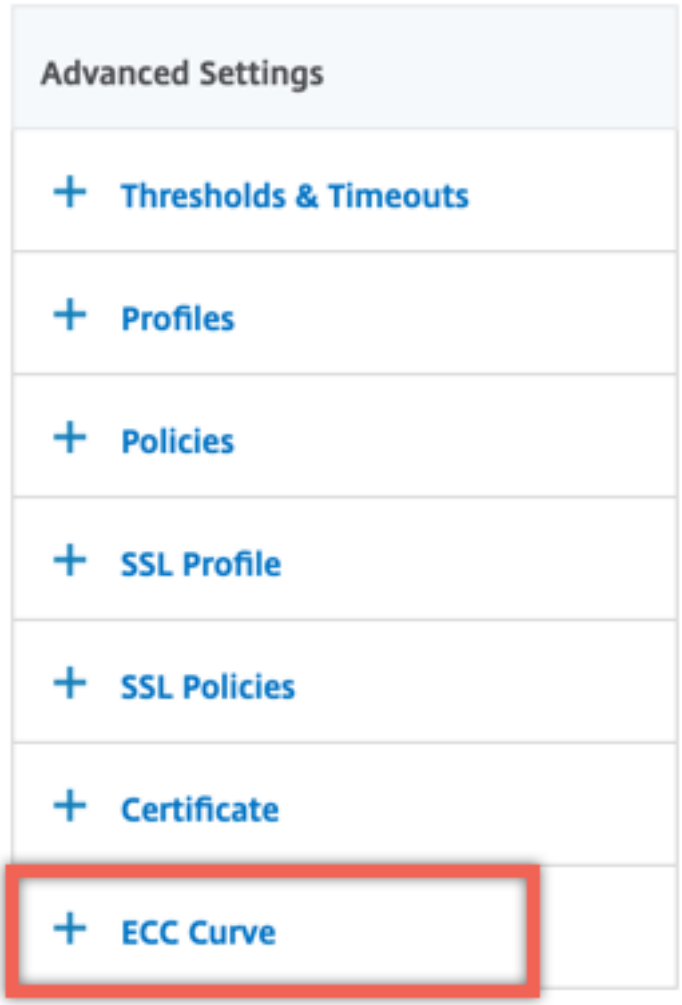
```
> bind ssl service sslsvc -eccCurveName P_224
 Done
> sh ssl service sslsvc

    Advanced SSL configuration for Back-end SSL Service sslsvc:
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA:
       DISABLED
    Session Reuse: ENABLED      Timeout: 300 seconds
    Cipher Redirect: DISABLED
    ClearText Port: 0
```

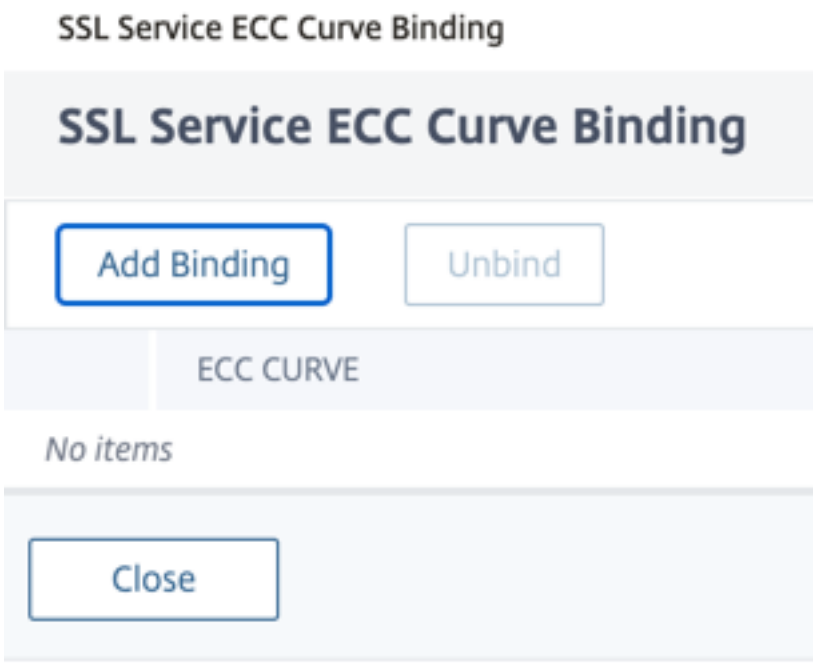
```
11      Server Auth: DISABLED
12      SSL Redirect: DISABLED
13      Non FIPS Ciphers: DISABLED
14      SNI: DISABLED
15      OCSP Stapling: DISABLED
16      SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
            ENABLED  TLSv1.3: DISABLED
17      Send Close-Notify: YES
18      Strict Sig-Digest Check: DISABLED
19      Zero RTT Early Data: ???
20      DHE Key Exchange With PSK: ???
21      Tickets Per Authentication Context: ???
22
23      ECC Curve: P_224
24
25
26  1)  Cipher Name: DEFAULT_BACKEND
27      Description: Default cipher list for Backend SSL session
28   Done
29  <!--NeedCopy-->
```

Bind ECC curves to an SSL service by using the GUI

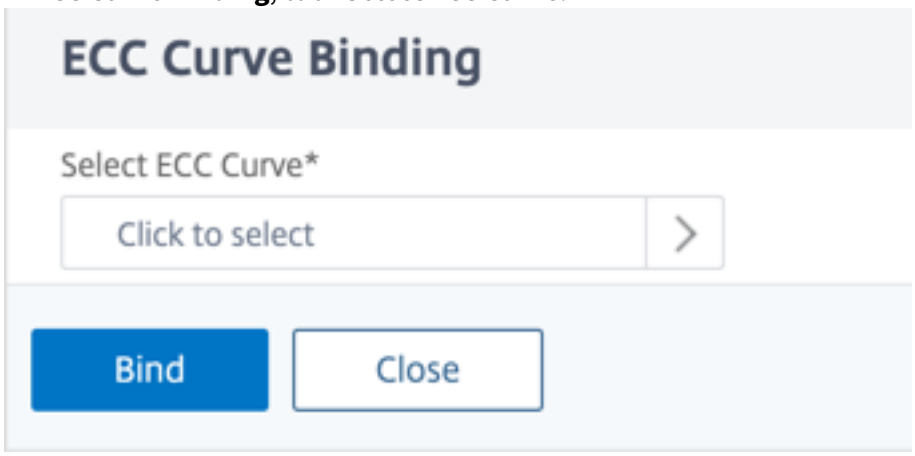
1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Select an SSL service and click **Edit**.
3. In **Advanced Settings**, click **ECC Curve**.



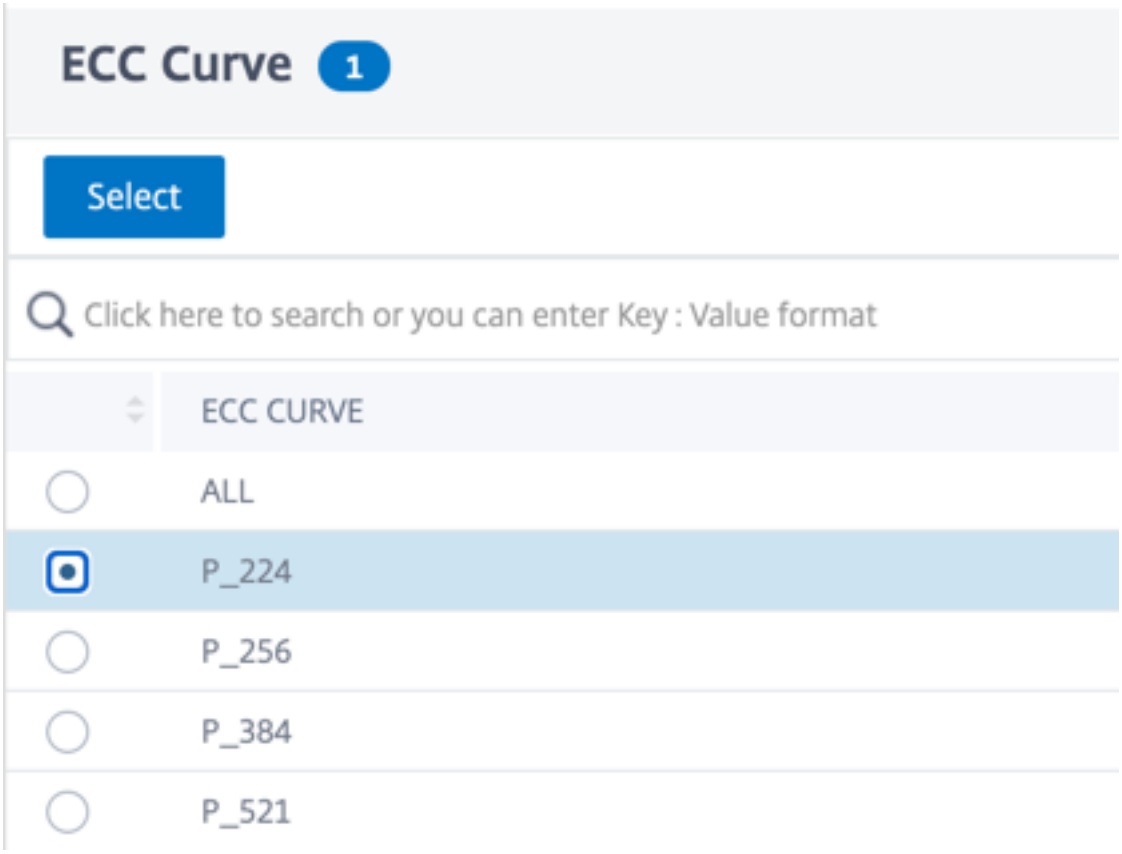
4. Click inside the ECC curve section.
5. In the **SSL Service ECC Curve Binding** page, click **Add Binding**.



6. In **ECC Curve Binding**, click **Select ECC Curve**.



7. Select a value, and then click **Select**.



8. Click **Bind**.
9. Click **Close**.
10. Click **Done**.

Diffie-Hellman parameters generation and achieving PFS with DHE

September 14, 2021

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction to agree upon a shared secret over an insecure channel. These parties have no prior knowledge about each other. This secret can be converted into cryptographic keying material for symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default. Configured the feature to support ciphers that use DH as the key exchange algorithm.

> **Note**:
>
> Generating 2048-bit DH parameters might take a long time (up to 30 minutes).

Generate DH parameters by using the CLI

At the command prompt, type the following command:

```
create ssl dhparam <dhFile> [<bits>] [-gen (2 | 5)]
<!--NeedCopy-->
```

Example:

```
create ssl dhparam Key-DH-1 512 -gen 2
<!--NeedCopy-->
```

Generate DH parameters by using the GUI

Navigate to **Traffic Management** > **SSL** and, in the **Tools** group, select **Create Diffie-Hellman (DH) key**, and **Configure SSL DH Param**.

> **Note:**
>
> For information about DH parameters, see Diffie-Hellman parameters.

Achieve perfect forward secrecy with DHE

Generating DH parameters is a CPU-intensive operation. In earlier releases, parameter generation, on a VPX appliance, took a long time because it was done in the software. Parameter generation is optimized by setting the `dhKeyExpSizeLimit` parameter. You can set this parameter for an SSL virtual server or an SSL profile and then bind the profile to a virtual server.

You can maintain perfect forward secrecy (PFS) on Citrix ADC MPX appliances by setting the DH count equal to zero. As a result, DH parameters are generated for each transaction (minimum `DHcount` is 0) on Citrix ADC MPX appliances. Thee parameters are generated without a significant drop in performance, because the operation is optimized. Earlier, the minimum DH count allowed was 500. That is, you cannot regenerate the key for up to 500 transactions.

On a Citrix ADC VPX appliance, you can generate DH parameters for every 500 transaction at the minimum (`DHcount` = 500). If you set `DHcount` equal to 0, then the DH parameters are not regenerated.

> **Limitation:**
>
> You cannot achieve PFS in VPX today with DH ciphers.

Optimize DH parameters generation by using the CLI

At the command prompt, type commands 1 and 2, or type command 3:

```
1. add ssl profile <name> [-sslProfileType ( BackEnd | FrontEnd )] [-
   dhCount <positive_integer>] [-dh ( ENABLED | DISABLED) -dhFile <
   string>] [-dhKeyExpSizeLimit ( ENABLED | DISABLED)]
2. set ssl vserver <vServerName> [-sslProfile <string>]
<!--NeedCopy-->
```

```
3. set ssl vserver <vServerName> [-dh ( ENABLED | DISABLED) -dhFile <
   string>] [-dhCount <positive_integer>] [-dhKeyExpSizeLimit ( ENABLED
    | DISABLED )]
<!--NeedCopy-->
```

Optimize DH parameters generation by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable DH Key Expire Size Limit**.

Cipher redirection

September 14, 2021

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

If the ciphers announced by the client does not match the ciphers configured on the SSL server, the SSL handshake fails. The failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When an SSL handshake fails, the ADC appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.

Configure cipher redirection by using the CLI

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

```
- set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED>
  -cipherURL < URL>
```

```
-  show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://
   redirectURl

Done

show ssl vserver vs-ssl

Advanced SSL configuration for VServer vs-ssl:
DH: DISABLED
Ephemeral RSA: ENABLED          Refresh Count: 1000
Session Reuse: ENABLED          Timeout: 600 seconds
Cipher Redirect: ENABLED        Redirect URL: http://redirectURl
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2: ENABLED
   TLSv1.2: ENABLED
    1)      CertKey Name: Auth-Cert-1       Server Certificate
    1)      Cipher Name: DEFAULT
            Description: Predefined Cipher Alias
Done
<!--NeedCopy-->
```

Configure cipher redirection by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Cipher Redirect**, and specify a redirect URL.

Use hardware and software to improve ECDHE and ECDSA cipher performance

September 14, 2021

> **Note:**
>
> This enhancement is applicable only to the following platforms:
>
> - MPX/SDX 11000
> - MPX/SDX 14000
> - MPX 22000, MPX 24000, and MPX 25000
> - MPX/SDX 14000 FIPS

Previously, ECDHE and ECDSA computation on a Citrix ADC appliance was performed only on the hardware (Cavium chips), which limited the number of SSL sessions at any given time. With this enhancement, some operations are also performed in the software. That is, processing is done both on the Cavium chips and on the CPU cores to improve ECDHE and ECDSA cipher performance.

The processing is first performed in software, up to the configured software crypto threshold. After this threshold is reached, the operations are offloaded to the hardware. Therefore, this hybrid model uses both hardware and software to improve SSL performance. You can enable the hybrid model by setting the “softwareCryptoThreshold” parameter to suit your requirement. To disable the hybrid model, set this parameter to 0.

Benefits are greatest if the current CPU utilization is not too high, because the CPU threshold is not exclusive to ECDHE and ECDSA computation. For example, if the current workload on the appliance consumes 50% of the CPU cycles, and the threshold is set to 80%, ECDHE and ECDSA computation can only use 30%. After the configured software crypto threshold of 80% is reached, further ECDHE and ECDSA computation is offloaded to the hardware. In that case, actual CPU utilization might exceed 80%, because performing ECDHE and ECDSA computations in hardware consumes some CPU cycles.

Enable the hybrid model by using the CLI

At the command prompt, type:

```
set ssl parameter -softwareCryptoThreshold <positive_integer>

Synopsis:

softwareCryptoThreshold:

Citrix ADC CPU utilization threshold (as a percentage) beyond which
    crypto operations are not done in software. A value of zero implies
```

```
      that CPU is not utilized for doing crypto in software.

Default = 0

Min = 0

Max = 100
<!--NeedCopy-->
```

Example:

```
set ssl parameter - softwareCryptoThreshold 80
Done

show ssl parameter
Advanced SSL Parameters

SSL quantum size                    : 8 KB
Max CRL memory size                 : 256 MB
Strict CA checks                    : NO
Encryption trigger timeout          : 100 ms
Send Close-Notify                   : YES
Encryption trigger packet c         : 45
Deny SSL Renegotiation              : ALL
Subject/Issuer Name Insertion Format : Unicode
OCSP cache size                     : 10 MB
Push flag                           : 0x0 (Auto)
Strict Host Header check for SNI enabled SSL sessions : NO
PUSH encryption trigger timeout     : 1 ms
Crypto Device Disable Limit         : 0
Global undef action for control policies : CLIENTAUTH
Global undef action for data policies : NOOP
Default profile                     : DISABLED
Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors    : NO
Disable TLS 1.1/1.2 for dynamic and VPN services : NO
Software Crypto acceleration CPU Threshold : 80
Signature and Hash Algorithms supported by TLS1.2 : ALL
<!--NeedCopy-->
```

Enable the hybrid model by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**.
2. Enter a value for **Software Crypto Threshold (%)**.

Set an SNMP alarm for ECDHE exchange rate

ECDHE-based key exchange can cause the transactions per second on the appliance to drop. From release 13.0 build 52.x, you can configure an SNMP alarm for ECDHE-based transactions. In this alarm, you can set the threshold and normal limits for the ECDHE exchange rate. A new counter `nsssl_tot_sslInfo_ECDHE_Tx` is added. This counter is the sum of all the ECDHE-based transaction counters on the front-end and back-end of the appliance. When the ECDHE-based key exchange crosses the configured limits an SNMP trap is sent. Another trap is sent when the value is back to the configured normal value.

Set an SNMP alarm for ECDHE exchange rate using the CLI

At the command prompt, type:

```
set snmp alarm ECDHE-EXCHANGE-RATE -logging ( ENABLED | DISABLED ) -
    severity <severity>
 -state ( ENABLED | DISABLED ) -thresholdValue <positive_integer>  [-
     normalValue <positive_integer>] -time <secs>
<!--NeedCopy-->
```

Example:

```
set snmp alarm ECDHE-EXCHANGE-RATE -logging eNABLED -severity critical
    -state eNABLED -thresholdValue 100 -normalValue 50
<!--NeedCopy-->
```

ECDSA cipher suites support

September 14, 2021

ECDSA cipher suites use elliptical curve cryptography (ECC). Because of its smaller size, it is helpful in environments where processing power, storage space, bandwidth, and power consumption are constrained.

When the ECDHE_ECDSA cipher group is used, the server's certificate must contain an ECDSA-capable public key.

The following table lists the ECDSA ciphers that are supported on the Citrix ADC MPX and SDX appliances with N3 chips, Citrix ADC VPX appliances, MPX 5900/26000, and MPX/SDX 8900/15000 appliances.

Cipher Name	Priority	Description	Key Exchange Algorithm	Authentication Algorithm	Encryption Algorithm (Key Size)	Message Authentication Code (MAC) Algorithm	HexCode
TLS1-ECDHE-ECDSA-AES128-SHA	1	SSLv3	ECC-DHE	ECDSA	AES(128)	SHA1	0xc009
TLS1-ECDHE-ECDSA-AES256-SHA	2	SSLv3	ECC-DHE	ECDSA	AES(256)	SHA1	0xc00a
TLS1.2-ECDHE-ECDSA-AES128-SHA256	3	TLSv1.2	ECC-DHE	ECDSA	AES(128)	SHA-256	0xc023
TLS1.2-ECDHE-ECDSA-AES256-SHA384	4	TLSv1.2	ECC-DHE	ECDSA	AES(256)	SHA-384	0xc024
TLS1.2-ECDHE-ECDSA-AES128-GCM-SHA256	5	TLSv1.2	ECC-DHE	ECDSA	AES-GCM(128)	SHA-256	0xc02b
TLS1.2-ECDHE-ECDSA-AES256-GCM-SHA384	6	TLSv1.2	ECC-DHE	ECDSA	AES-GCM(256)	SHA-384	0xc02c

Cipher Name	Priority	Description	Key Exchange Algorithm	Authentication Algorithm	Encryption Algorithm (Key Size)	Message Authentication Code (MAC) Algorithm	HexCode
TLS1-ECDHE-ECDSA-RC4-SHA	7	SSLv3	ECC-DHE	ECDSA	RC4(128)	SHA1	0xc007
TLS1-ECDHE-ECDSA-DES-CBC3-SHA	8	SSLv3	ECC-DHE	ECDSA	3DES(168)	SHA1	0xc008
TLS1.2-ECDHE-ECDSA-CHACHA20-POLY1305	9	TLSv1.2	ECC-DHE	ECDSA	CHACHA20/	AEAD	0xcca9

ECDSA/RSA cipher and certificate selection

You can bind both ECDSA and RSA server certificates at the same time to an SSL virtual server. When both ECDSA and RSA certificates are bound to the virtual server, it automatically selects the appropriate server certificate to present to the client. If the client cipher list includes RSA ciphers, but does not include ECDSA ciphers, the virtual server presents the RSA server certificate. If both ciphers are present in the client's list, then the server certificate presented depends on the cipher priority set on the virtual server. That is, if RSA has a higher priority, the RSA certificate is presented. If ECDSA has a higher priority, the ECDSA certificate is presented to the client.

Client authentication by using an ECDSA or an RSA certificate

For client authentication, the CA certificate bound to the virtual server can be ECDSA or RSA signed. The appliance supports a mixed certificate chain. For example, the following certificate chain is supported.

Client certificate (ECDSA) <-> CA certificate (RSA) <-> Intermediate certificate (RSA) <-> Root certificate (RSA)

The following table shows the elliptical curves supported on the different Citrix ADC appliances with ECDSA cipher groups and ECDSA certificates:

Elliptical curves	Platforms supported
prime256v1	All platforms, including FIPS.
secp384r1	All platforms, including FIPS.
secp521r1	MPX 5900, MPX/SDX 8900, MPX/SDX 15000, MPX/SDX 26000, VPX
secp224r1	MPX 5900, MPX/SDX 8900. MPX/SDX 15000, MPX/SDX 26000, VPX

Create an ECDSA certificate-key pair

You can create an ECDSA certificate-key pair directly on a Citrix ADC appliance by using the CLI or the GUI. Earlier, you were able to install and bind an ECC certificate-key pair on the appliance, but you had to use OpenSSL to create a certificate-key pair.

Only P_256 and P_384 curves are supported.

> **Note**
>
> This support is available on all platforms except MPX 9700/1050/12500/15500.

To create an ECDSA certificate-key pair by using the CLI:

At the command prompt, type:

```
create ssl ecdsaKey <keyFile> -curve ( P_256 | P_384 ) [-keyform ( DER | PEM )] [-des | -des3] {
 -password  }
  [-pkcs8]
<!--NeedCopy-->
```

Example:

```
create ecdsaKey ec_p256.ky -curve P_256 -pkcs8
Done
create ecdsaKey ec_p384.ky -curve P_384
Done
<!--NeedCopy-->
```

To create an ECDSA certificate-key pair by using the GUI:

1. Navigate to **Traffic Management > SSL > SSL Files > Keys** and click **Create ECDSA Key**.
2. To create a key in PKCS#8 format, select **PKCS8**.

Configure user-defined cipher groups on the ADC appliance

September 14, 2021

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the Citrix ADC appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create an SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

Note: If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

Binding a cipher group to an SSL virtual server, service, or service group, appends the ciphers to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity. Then bind the specific cipher group to the entity. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.

```
unbind ssl service <service name> -cipherName ALL
<!--NeedCopy-->
```

2. Bind the AES cipher group to the service

```
bind ssl service <Service name> -cipherName AE
<!--NeedCopy-->
```

If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

```
bind ssl service <service name> -cipherName DES
<!--NeedCopy-->
```

Note: The free Citrix ADC virtual appliance supports only the DH cipher group.

Configure a user-defined cipher group by using the CLI

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

```
add ssl cipher <cipherGroupName>
bind ssl cipher <cipherGroupName> -cipherName <cipherGroup/cipherName>
show ssl cipher <cipherGroupName>
<!--NeedCopy-->
```

Example:

```
add ssl cipher test

Done

bind ssl cipher test -cipherName ECDHE

Done

sh ssl cipher test

1)      Cipher Name: TLS1-ECDHE-RSA-AES256-SHA  Priority : 1
Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=AES(256)  Mac=SHA1   HexCode
   =0xc014
2)      Cipher Name: TLS1-ECDHE-RSA-AES128-SHA  Priority : 2

Done

bind ssl cipher test -cipherName TLS1-ECDHE-RSA-DES-CBC3-SHA
<!--NeedCopy-->
```

Unbind ciphers from a cipher group by using the CLI

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:

```
show ssl cipher <cipherGroupName>

unbind ssl cipher <cipherGroupName> -cipherName <string>

show ssl cipher <cipherGroupName>
<!--NeedCopy-->
```

Remove a cipher group by using the CLI

Note: You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.

At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

```
rm ssl cipher <userDefCipherGroupName> [<cipherName> ...]
show ssl cipher <cipherGroupName>

<!--NeedCopy-->
```

Example:

```
rm ssl cipher test Done

sh ssl cipher test ERROR: No such resource [cipherGroupName, test]
<!--NeedCopy-->
```

Configure a user-defined cipher group by using the GUI

1. Navigate to **Traffic Management > SSL > Cipher Groups**.
2. Click **Add**.
3. Specify a name for the cipher group.
4. Click **Add** to view the available ciphers and cipher groups.
5. Select a cipher or cipher group, and click the arrow button to add them.
6. Click **Create**.

7. Click **Close**.

To bind a cipher group to an SSL virtual server, service, or service group by using the CLI:

At the command prompt, type one of the following:

```
bind ssl vserver <vServerName> -cipherName <string>

bind ssl service <serviceName> -cipherName <string>

bind ssl serviceGroup <serviceGroupName> -cipherName <string>

<!--NeedCopy-->
```

Example:

```
bind ssl vserver ssl_vserver_test -cipherName test
Done

bind ssl service  nshttps -cipherName test
Done

bind ssl servicegroup  ssl_svc  -cipherName test
Done
<!--NeedCopy-->
```

To bind a cipher group to an SSL virtual server, service, or service group by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

   For service, replace virtual servers with services. For service groups, replace virtual servers with service groups.

   Open the virtual server, service, or service group.

2. In **Advanced Settings**, select **SSL Ciphers**.
3. Bind a cipher group to the virtual server, service, or service group.

Binding individual ciphers to an SSL virtual server or service

You can also bind individual ciphers, instead of a cipher group, to a virtual server or service.

To bind a cipher by using the CLI:

At the command prompt, type:

```
bind ssl vserver <vServerName> -cipherName <string>
bind ssl service <serviceName> -cipherName <string>
<!--NeedCopy-->
```

Example:

```
bind ssl vserver v1 -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
Done

bind ssl service sslsvc -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
Done
<!--NeedCopy-->
```

To bind a cipher to an SSL virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select an SSL virtual server and click **Edit**.
3. In **Advanced Settings**, select **SSL Ciphers**.
4. In **Cipher Suites**, select **Add**.
5. Search for the cipher in the available list and click the arrow to add it to the configured list.
6. Click **OK**.
7. Click **Done**.

To bind a cipher to an SSL service, repeat the preceding steps after replacing virtual server with service.

Server certificate support matrix on the ADC appliance

September 14, 2021

From release 13.0 build 41.x, the Citrix ADC appliance supports server certificate messages that are fragmented into more than one record so long as the total size is within 32 KB. Earlier, the maximum supported size was 16 KB and fragmentation was not supported.

The Citrix ADC appliance supports the following server certificates.

Table 1: Support on front-end (FE) and back-end (BE) service

Server certificate/-Platform	MPX/SDX (N2 CHIPS) FE	MPX/SDX (N2 CHIPS) BE	MPX/SDX (N3 CHIPS) FE	MPX/SDX (N3 CHIPS) BE	VPX FE	VPX BE
MD5	Y	Y	Y	Y	Y	Y
SHA1	Y	Y	Y	Y	Y	Y
SHA224	Y	Y	Y	Y	Y	Y
SHA256	Y	Y	Y	Y	Y	Y
SHA384	Y	Y	Y	Y	Y	Y

Server certificate/-Platform	MPX/SDX (N2 CHIPS) FE	MPX/SDX (N2 CHIPS) BE	MPX/SDX (N3 CHIPS) FE	MPX/SDX (N3 CHIPS) BE	VPX FE	VPX BE
SHA512	Y	Y	Y	Y	Y	Y
RSA Key	1024, 2048, 3072, and 4096 bits	1024, 2048, 3072, and 4096 bits	1024, 2048, 3072, and 4096 bits	1024, 2048, 3072, and 4096 bits	1024, 2048, 3072, and 4096 bits	1024, 2048, 3072, and 4096 bits
DH Key	1024 bits and 2048 bits	1024 bits and 2048 bits	1024 bits and 2048 bits	1024 bits and 2048 bits	1024, 2048, 3072, and 4096 bits	1024, 2048, 3072, and 4096 bits

Server certificate/Platform	MPX 9700/10500/12500/15500/ FIPS with FW 2.2 FE	MPX 9700/10500/12500/15500/ FIPS with FW 2.2 BE	MPX/SDX 14030/14060/14080 FIPS FE	MPX/SDX 14030/14060/14080 FIPS BE
MD5	Y	Y	Y	Y
SHA1	Y	Y	Y	Y
SHA224	Y	Y	Y	Y
SHA256	Y	Y	Y	Y
SHA384	Y	Y	Y	Y
SHA512	Y	Y	Y	Y
RSA Key	2048 bits	2048 bits	2048 bits and 3072 bits	2048 bits and 3072 bits
DH Key	N	N	N	N

Note:

- In release 11.1 and earlier, a Citrix ADC appliance supports the following “signature algorithms” extensions in the back end client hello message: RSA-MD5, RSA-SHA1, and RSA-SHA256.
  Because the Citrix ADC appliance does not support SHA 384 and SHA 512 signature algorithms extensions, some servers, such as Windows IIS servers, reset the connection.
- Starting release 12.0, a Citrix ADC appliance supports all the signature_algorithms extensions.

Client authentication

September 14, 2021

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server. To do so, it checks the server's certificate before initiating the SSL transaction. Sometimes, however, you might want to configure the server to authenticate the client that is connecting to it.

Note: From release 13.0 build 41.x, the Citrix ADC appliance supports certificate request messages that are fragmented into more than one record provided the total size is within 32 KB. Earlier, the maximum supported size was 16 KB and fragmentation was not supported.

With client authentication enabled on an SSL virtual server, the Citrix ADC appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

Note: For the appliance to verify issuer signatures, the certificate of the CA that issued the client certificate must be installed on the appliance and bound to the virtual server that the client is transacting with.

If the certificate is valid, the appliance allows the client to access all secure resources. But if the certificate is invalid, the appliance drops the client request during the SSL handshake.

The appliance verifies the client certificate by first forming a chain of certificates, starting with the client certificate, and ending with the root CA certificate for the client (for example, Verisign). The root CA certificate might contain one or more intermediate CA certificates (if the root CA does not directly issue the client certificate).

Before you enable client authentication on the Citrix ADC appliance, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that handles the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the appliance.

Note: A Citrix ADC MPX appliance supports a certificate-key pair size from 512 bits to 4096 bits. The certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

On an SDX appliance, if an SSL chip is assigned to a VPX instance, the certificate-key pair size support

of an MPX appliance applies. Otherwise, the normal certificate-key pair size support of a VPX instance applies.

A Citrix ADC virtual appliance (VPX instance) supports certificates of at least 512 bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
- 4096-bit certificate on the physical server

Note: From release 13.0 build 79.x, client authentication with 4096-bit RSA client certificate is supported during an SSL handshake on VPX platform.

Notes:

- For MPX FIPS limitations, see MPX FIPS limitations.
- For SDX FIPS limitations, see SDX FIPS limitations.

Provide the client certificate

Before you configure client authentication, a valid client certificate must be installed on the client. A client certificate includes details about the specific client system that creates secure sessions with the Citrix ADC appliance. Each client certificate is unique and must be used by only one client system.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the Citrix ADC appliance, you must convert the certificate to the correct format. On the Citrix ADC appliance, certificates are stored in either the PEM or DER format and must be converted to PKCS#12 format before they are installed on the client system. After converting the certificate and transferring it to the client system, ensure that it is installed on that system and configured for the client application. The application, such as a web browser, must be part of the SSL transactions.

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see Import and convert SSL files.

For instructions on how to generate a client certificate, see Create a certificate.

Enable client-certificate based authentication

By default, client authentication is disabled on the Citrix ADC appliance, and all SSL transactions proceed without authenticating the client. You can configure client authentication to be either optional or mandatory as part of the SSL handshake.

If client authentication is optional, the appliance requests the client certificate but proceeds with the SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory, the appliance terminates the SSL handshake if the SSL client does not provide a valid certificate.

Caution: Citrix recommends that you define proper access control policies before changing the client-certificate-based authentication check to optional.

Note: Client authentication is configured for individual SSL virtual servers, not globally.

Enable client-certificate based authentication by using the CLI

At the command prompt, type the following commands to enable the client-certificate-based authentication and verify the configuration:

```
set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-
    clientCert (MANDATORY | OPTIONAL)]
show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
Done
show ssl vserver vssl

Advanced SSL configuration for VServer vssl:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        OCSP Stapling: DISABLED
        HSTS: DISABLED
        HSTS IncludeSubDomains: NO
        HSTS Max-Age: 0
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2: ENABLED TLSv1
    .2: ENABLED

1) CertKey Name: sslckey Server Certificate

1) Policy Name: client_cert_policy Priority: 0

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
```

```
28 Done
29 <!--NeedCopy-->
```

Enable client-certificate based authentication by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the SSL Parameters section, select Client Authentication, and in the Client Certificate list, select Mandatory.

> **Note:**
>
> If client authentication is set to mandatory and if the client certificate contains policy extensions, certificate validation fails. From release 12.0-56.x, you can set a parameter in the front-end SSL profile to skip this check. The parameter is disabled by default. That is, the check is performed by default.

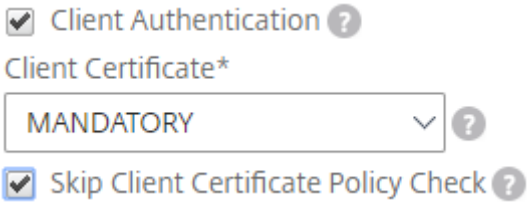
Skip the policy extension check during client authentication by using the CLI

At the command prompt, type:

```
1  set ssl profile ns_default_ssl_profile_frontend -clientauth ENABLED -
       skipClientCertPolicyCheck ENABLED
2
3  Parameter
4
5  skipClientCertPolicyCheck
6
7                Control policy extension check, if present inside the
                     X509 certificate chain. Applicable only if client
                     authentication is enabled and client certificate is
                     set to mandatory. Possible values functions as follows
                     :
8
9  - ENABLED: Skip the policy check during client authentication.
10
11 - DISABLED: Perform policy check during client authentication.
12
13 Possible values: ENABLED, DISABLED
14
15 Default: DISABLED
16 <!--NeedCopy-->
```

Skip the policy extension check during client authentication by using the GUI

1. Navigate to **System** > **Profiles** > **SSL Profiles**.
2. Create a new front-end profile or edit an existing front-end profile.
3. Verify that client authentication is enabled and client certificate is set to mandatory.
4. Select **Skip Client Certificate Policy Check**.



Bind CA certificates to the virtual server

A CA whose certificate is present on the Citrix ADC appliance must issue the client certificate used for client authentication. Bind this certificate to the Citrix ADC virtual server that carries out client authentication.

Bind the CA certificate to the SSL virtual server in such a way that the appliance can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The appliance forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by **CA_A**, where **CA_A** is an intermediate CA whose certificate is issued by **CA_B**, whose certificate is in turn issued by a trusted root CA, **Root_CA**, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the Citrix ADC appliance.

For instructions on binding one or more certificates to the virtual server, see Bind the certificate-key pair to the SSL virtual server.

For instructions on creating a chain of certificates, see Create a chain of certificates.

Stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if a single Root-CA issues them. That is, if only the Root-CA certificate is bound to the virtual server, and that Root-CA valiadates any intermediate certificate sent with the client certificate, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL

virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the **ClientAuthUseBoundCAChain** setting in the SSL profile bound to the virtual server. The handshake fails if one of the CA certificates bound to the virtual server has not signed the client certificate.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, the Citrix ADC appliance only accepts clientcert1.

Enable stricter control on client certificate validation by using the CLI

At the command prompt, type:

```
set ssl profile <name> -ClientAuthUseBoundCAChain Enabled
<!--NeedCopy-->
```

Enable stricter control on client certificate validation by using the GUI

1. Navigate to **System** > **Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.
2. Select **Enable Client Authentication using bound CA Chain**.

Server authentication

September 14, 2021

Since the Citrix ADC appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server's certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the appliance becomes the SSL client and carries out a secure transaction with the SSL server. It verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.

To authenticate the server, enable server authentication and bind the certificate of the CA that signed the server's certificate to the SSL service on the ADC appliance. When binding the certificate, you must specify the bind as a CA option.

Enable (or disable) server certificate authentication

You can use the CLI and the GUI to enable and disable server certificate authentication.

Enable (or disable) server certificate authentication using the CLI

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

```
set ssl service <serviceName> -serverAuth ( ENABLED | DISABLED )
show ssl service <serviceName>
<!--NeedCopy-->
```

Example:

```
set ssl service ssl-service-1 -serverAuth ENABLED
<!--NeedCopy-->
```

```
show ssl service ssl-service-1

            Advanced SSL configuration for Back-end SSL Service ssl-
               service-1:`
            DH: DISABLED
            Ephemeral RSA: DISABLED
            Session Reuse: ENABLED          Timeout: 300 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            Server Auth: ENABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED
    1)      Cipher Name: ALL
            Description: Predefined Cipher Alias
Done
<!--NeedCopy-->
```

Enable (or disable) server certificate authentication by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open an SSL service.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a Common Name.
3. In Advanced Settings, select Certificates, and bind a CA certificate to the service.

Bind the CA certificate to the service by using the CLI

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

```
bind ssl service <serviceName> -certkeyName <string> -CA

show ssl service <serviceName>
<!--NeedCopy-->
```

Example:

```
bind ssl service ssl-service-1 -certkeyName samplecertkey -CA
<!--NeedCopy-->
```

```
show ssl service ssl-service-1

            Advanced SSL configuration for Back-end SSL Service ssl-
               service-1:
            DH: DISABLED
            Ephemeral RSA: DISABLED
            Session Reuse: ENABLED          Timeout: 300 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            Server Auth: ENABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED
    1)      CertKey Name: samplecertkey     CA Certificate
       CRLCheck: Optional
    1)      Cipher Name: ALL
            Description: Predefined Cipher Alias
Done
<!--NeedCopy-->
```

Configure a common name for server certificate authentication

In end-to-end encryption with server authentication enabled, you can include a common name in the configuration of an SSL service or service group. The name that you specify is compared to the common name in the server certificate during an SSL handshake. If the two names match, the handshake is successful.

If the common names do not match, the common name specified for the service or service group is compared to the values in the subject alternative name (SAN) field in the certificate. If it matches one

of those values, the handshake is successful. This configuration is especially useful if there are, for example, two servers behind a firewall and one of the servers spoofs the identity of the other. If the common name is not checked, a certificate presented by either server is accepted if the IP address matches.

Note: Only domain name, URL, and email ID DNS entries in the SAN field are compared.

Configure common-name verification for an SSL service or service group by using the CLI

At the command prompt, type the following commands to specify server authentication with common-name verification and verify the configuration:

1. To configure a common name in a service, type:

```
set ssl service <serviceName> -commonName <string> -serverAuth
   ENABLED
show ssl service <serviceName>
<!--NeedCopy-->
```

2. To configure a common name in a service group, type:

```
set ssl serviceGroup <serviceGroupName> -commonName <string> -
   serverAuth ENABLED
show ssl serviceGroup <serviceGroupName>
<!--NeedCopy-->
```

Example:

```
> set ssl service svc1 -commonName xyz.com -serverAuth ENABLED
<!--NeedCopy-->
```

```
show ssl service svc

     Advanced SSL configuration for Back-end SSL Service svc1:
     DH: DISABLED
     Ephemeral RSA: DISABLED
     Session Reuse: ENABLED Timeout: 300 seconds
     Cipher Redirect: DISABLED
     SSLv2 Redirect: DISABLED
     Server Auth: ENABLED Common Name: www.xyz.com
     SSL Redirect: DISABLED
     Non FIPS Ciphers: DISABLED
     SNI: DISABLED
     SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
    1) CertKey Name: cacert CA Certificate OCSPCheck: Optional
```

```
    1) Cipher Name: ALL
     Description: Predefined Cipher Alias
Done
<!--NeedCopy-->
```

Configure common-name verification for an SSL service or service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services** or Navigate to **Traffic Management > Load Balancing > Service Groups**, and open a service or service group.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a common name.

SSL actions and policies

September 14, 2021

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). Configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, do one of the following:

- Bind the policy to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server.
- Bind the policy globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL.

Note: Users who are not experienced in configuring policies at the CLI usually find using the configuration utility to be considerably easier.

You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.

Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the Citrix ADC appliance.

SSL policies

September 14, 2021

Policies on the Citrix ADC appliance help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must do one of the following:

- Bind the policy to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server.
- Bind the policy globally, so that it applies to all traffic flowing through any virtual server configured on the Citrix ADC appliance.

The Citrix ADC appliance SSL feature supports default syntax (advanced) policies. For a complete description of default syntax expressions, how they work, and how to configure them manually, see Policies and Expressions.

> **Note:**
>
> Users who are not experienced in configuring policies at the CLI usually find using the configuration utility considerably easier.

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies.
In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see SSL built-in actions and user-defined actions.

SSL default syntax policies

An SSL default syntax policy, also known as an advanced policy, defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy**. A control policy uses a control action, such as forcing client authentication. Note: In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL. However, control policies, such as CLIENTAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReneg to NO.
- **Data policy**. A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed.

You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an extra action, called an UNDEF action, to be performed when applying the expression to a request has an undefined result.

SSL policy configuration

You can configure an SSL default syntax policy by using the CLI and the GUI.

Configure an SSL policy by using the CLI

At the command prompt, type:

```
1 add ssl policy <name> -rule <expression> -Action <string> [-undefAction
      <string>] [-comment <string>]
2 <!--NeedCopy-->
```

Configure an SSL policy by using the GUI

Navigate to **Traffic Management > SSL > Policies** and, on the **Polices** tab, click *Add*.

Support for SSL policies with TLS1.3 protocol

From release 13.0 build 71.x and later, support is added for SSL policies with the TLS1.3 protocol. When the TLSv1.3 protocol is negotiated for a connection, policy rules that inspect TLS data received from the client now trigger the configured action.

For example, if the following policy rule returns true, the traffic is forwarded to the virtual server defined in the action.

```
1 add ssl action action1 -forward vserver2
2 add ssl policy pol1 -rule client.ssl.client_hello.sni.contains( “xyz” )
      -action action1
3 <!--NeedCopy-->
```

Limitations

- Control policies are not supported.
- The following actions are not supported:
  - DOCLIENTAUTH
  - NOCLIENTAUTH
  - caCertGrpName
  - clientCertVerification
  - ssllogProfile

SSL built-in actions and user-defined actions

September 14, 2021

Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies. Then, you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- DOCLIENTAUTH—Perform client certificate authentication. (Not supported for TLS1.3)
- NOCLIENTAUTH—Do not perform client certificate authentication. (Not supported for TLS1.3)

The built-in data actions are:

- RESET—Close the connection by sending an RST packet to the client.
- DROP—Drop all packets from the client. The connection remains open until the client closes it.
- NOOP—Forward the packet without performing any operation on it.

Note: Any dependent actions to client authentication, such as clientCertVerification and ssllogProfile, are not supported with the TLS 1.3 protocol.

You can create user-defined data actions. If you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server.

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying DOCLIENTAUTH or NOCLIENTAUTH.

Examples of built-in actions in a policy

In the following example, if the client sends a cipher other than an EXPORT category cipher, the Citrix ADC appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

```
1 add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction
     DOCLIENTAUTH
2 <!--NeedCopy-->
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:

```
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -
     reqAction NOOP
2 <!--NeedCopy-->
```

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

```
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -
     reqAction DROP
2 <!--NeedCopy-->
```

If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

```
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -
     reqAction RESET
2 <!--NeedCopy-->
```

Client certificate verification with policy based client authentication

You can set client certificate verification to mandatory or option when you have configured policy based client authentication. Default is mandatory.

Set client certificate verification to optional using the CLI

At the command prompt, type:

```
1 add ssl action <name> ((-clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH ) [-
     clientCertVerification ( Mandatory | Optional )]
2 <!--NeedCopy-->
```

Example:

```
1 add ssl action sslact -clientauth DOCLIENTAUTH -clientcertverification
     OPTIONAL
2 <!--NeedCopy-->
```

Set client certificate verification to optional using the GUI

1. Navigate to **Traffic Management > SSL > Policies**.
2. On the **SSL Actions** tab, click **Add**.

3. Specify a name and in the **Client Certificate Verification** list, select **Optional**.

User-defined SSL actions

In addition to built-in actions, you can also configure other SSL actions depending on your deployment. These actions are called user-defined actions.

Configure a user-defined SSL action by using the CLI

At the command prompt, type the following commands to configure an action and verify the configuration:

```
add SSL action <name> -clientAuth(DOCLIENTAUTH | NOCLIENTAUTH) -
    clientCert (ENABLED | DISABLED) certHeader <string> -clientHeader <
    string> -clientCertSerialNumber (ENABLED | DISABLED) -
    certSerialHeader <string> -clientCertSubject (ENABLED | DISABLED) -
    certSubjectHeader <string> -clientCertHash (ENABLED | DISABLED) -
    certHashHeader <string> -clientCertIssuer (ENABLED | DISABLED) -
    certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -
    sessionIDheader <string> -cipher (ENABLED | DISABLED) -cipherHeader
    <string> -clientCertNotBefore (ENABLED | DISABLED) -
    certNotBeforeHeader <string> -clientCertNotAfter (ENABLED | DISABLED
    ) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)
<!--NeedCopy-->
```

```
show ssl action [<name>]
<!--NeedCopy-->
```

Example:

```
add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X
    -Client-Cert"
<!--NeedCopy-->
```

```
show ssl action Action-SSL-ClientCert

1)      Name: Action-SSL-ClientCert
        Data Insertion Action:
        Cert Header: ENABLED            Cert Tag: X-Client-Cert
Done
<!--NeedCopy-->
```

Configure a user-defined SSL action by using the GUI

Navigate to **Traffic Management > SSL > Policies** and, on the **Actions** tab, click **Add**.

Configure an SSL action to forward client traffic to another virtual server

Admins can configure an SSL action to forward the client traffic received on an SSL virtual server to another virtual server to avoid SSL offloading. Or for terminating the connection on the ADC appliance. This virtual server can be of the type: SSL, TCP, or SSL_BRIDGE. For example, admins can choose to forward the request to another virtual server for further action instead of terminating the connection if any of the following cases:

- The appliance does not have a certificate.
- The appliance does not support a specific cipher.

To achieve the above, a new bind point 'CLIENTHELLO_REQ' is added to evaluate client traffic when a client hello is received. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, the traffic is forwarded to another virtual server. If this virtual server is of type SSL, it performs the handshake. If this virtual server is of type TCP or SSL_BRIDGE, the back-end server performs the handshake.

In release 12.1-49.x, only the forward and reset actions are supported for the CLIENTHELLO_REQ bind point. The following expression prefixes are available:

- CLIENT.SSL.CLIENT_HELLO.CIPHERS.HAS_HEXCODE
- CLIENT.SSL.CLIENT_HELLO.CLIENT_VERSION
- CLIENT.SSL.CLIENT_HELLO.IS_RENEGOTIATE
- CLIENT.SSL.CLIENT_HELLO.IS_REUSE
- CLIENT.SSL.CLIENT_HELLO.IS_SCSV
- CLIENT.SSL.CLIENT_HELLO.IS_SESSION_TICKET
- CLIENT.SSL.CLIENT_HELLO.LENGTH
- CLIENT.SSL.CLIENT_HELLO.SNI
- CLIENT.SSL.CLIENT_HELLO.ALPN.HAS_NEXTPROTOCOL (from release 13.0 build 61.x)

For a description of these prefixes, see Advanced policy expressions: parsing SSL.

A parameter `forward` is added to the `add SSL action` command and a new bind point `CLIENTHELLO_REQ` is added to the `bind ssl vserver` command.

Configuration using the CLI

At the command prompt, type:

```
add ssl action <name> -forward <virtual server name>
```

```
3 add ssl policy <name> -rule <expression> -action <string>
4
5 bind ssl vserver <vServerName> -policyName <string> -priority <
     positive_integer> -type <type>
6 <!--NeedCopy-->
```

EXAMPLE:

```
1 add ssl action act1 -forward v2
2
3 add ssl policy pol1 -rule client.ssl.client_hello.ciphers.has_hexcode(0
     x002f) -action act1
4
5 bind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
6 <!--NeedCopy-->
```

Configuration using the GUI

Navigate to **Traffic Management > SSL > Policies**.

Create SSL action:

1. In **SSL Actions**, click **Add**.
2. In **Create SSL Action**, specify a name for the action.
3. In **Forward Action Virtual Server**, select an existing virtual server or add a new virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click **Create**.

Create SSL policy:

1. In **SSL Policies**, click **Add**.
2. In **Create SSL Policy**, specify a name for the policy.
3. In **Action**, select the action that you created earlier.
4. In **Expression Editor**, enter the rule to evaluate.
5. Click **Create**.

Create or add a virtual server and bind policy:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Add or select a virtual server.
3. In **Advanced Settings**, click **SSL Policies**.
4. Click in the SSL Policy section.
5. In **Select Policy**, select the policy that you created earlier.
6. In **Policy Binding**, specify a priority for the policy.

7. In **Type**, select **CLIENTHELLO_REQ**.
8. Click **Bind**.
9. Click **Done**.

For the end-to-end configuration for the most popular use cases, see the following topics:

- Configure SSL action to forward client traffic if the appliance does not have a domain specific (SNI) certificate.
- Configure an SSL action to forward client traffic based on the protocol in the ALPN extension of the client hello message.
- Configure SSL action to forward client traffic if a cipher is not supported on the ADC.

SSL action to selectively pick CAs based on SNI for client authentication

You can send only the list of CAs based on SNI (domain) in the client certificate request rather than the list of all the CAs bound to an SSL virtual server. For example, when a client hello is received, only the CA certificates based on the SSL policy expression (for example, SNI) are sent. To send a specific set of certificates, you must create a CA certificates group. Then, bind this group to an SSL action, and bind the action to an SSL policy. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, only a specific CA certificates group is sent in the client request certificate.

Earlier, you had to bind CA certificates to an SSL virtual server. With this enhancement, you can simply add CA certificate groups and associate them to an SSL action.

Note: Enable client authentication and SNI on the SSL virtual server. Bind the correct SNI certificates to the virtual server.

Perform the following steps:

1. Add a CA certificate group.
2. Add certificate-key pairs.
3. Bind the certificate-key pairs to this group.
4. Add an SSL action.
5. Add an SSL policy. Specify the action in the policy.
6. Bind the policy to an SSL virtual server. Specify the bind point as CLIENTHELLO_REQ.

Configuration using the CLI

At the command prompt, type the following commands in a sequence:

```
add ssl caCertGroup <caCertGroupName>
add ssl certkey <certkey_name> -cert <cert> -key <key>
bind ssl caCertGroup <caCertGroupName> <certkey_name>
add ssl action <name> -caCertGrpName <string>
add ssl policy <name> -rule <expression> -action <string>
bind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type CLIENTHELLO_REQ
<!--NeedCopy-->
```

Example:

```
add ssl cacertGroup ca_cert_group

add ssl certkey ca_certkey1 -cert cacert1 -key cakey1
add ssl certkey ca_certkey2 -cert cacert2 -key cakey2
add ssl certkey snicert -cert snicert -key snikey

bind ssl cacertGroup ca_cert_group ca_certkey1
bind ssl caCertGroup ca_cert_group ca_certkey2
<!--NeedCopy-->
```

```
sh ssl caCertGroup ca_cert_group

CA GROUP NAME:     ca_cert_group
ACTIONS REFERRING: 1

1) CertKey Name: ca_certkey1   CA Certificate   CRLCheck: Optional
   CA_Name Sent
2) CertKey Name: ca_certkey2   CA Certificate   CRLCheck: Optional
   CA_Name Sent
<!--NeedCopy-->
```

```
add ssl action pick_ca_group -cacertGrpName ca_cert_group
<!--NeedCopy-->
```

```
sh ssl action pick_ca_group
1) Name: pick_ca_group
   Type: Data Insertion
   PickCaCertGroup: ca_cert_group
   Hits: 0
   Undef Hits: 0
   Action Reference Count: 1
<!--NeedCopy-->
```

```
add ssl policy snipolicy -rule client.ssl.client_hello.sni.contains("
    abc") -action pick_ca_group
bind ssl vserver v_SSL -policyName snipolicy -type CLIENTHELLO_REQ -
    priority 10
<!--NeedCopy-->
```

```
sh ssl policy snipolicy
    Name: snipolicy
    Rule: client.ssl.client_hello.sni.contains("abc")
    Action: pick_ca_group
    UndefAction: Use Global
    Hits: 0
    Undef Hits: 0

    Policy is bound to following entities
1)  Bound to: CLIENTHELLO_REQ VSERVER v_SSL
    Priority: 10
<!--NeedCopy-->
```

```
set ssl vserver v_SSL -clientauth ENABLED -SNIEnable ENABLED
bind ssl vserver v_SSL -certkeyName snicert -sniCert
<!--NeedCopy-->
```

```
sh ssl vserver v_SSL

38  <!--NeedCopy-->
```

Configuration using the GUI

Create CA certificates group and bind certificates to the group:

1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Click **Add** and specify a name for the group.
3. Click **Create**.
4. Select the **CA certificate group** and then click **Show Bindings**.
5. Click **Bind**.
6. In the **CA Certificate Binding** page, select an existing certificate or click Add to add a new certificate.
7. Click **Select** and then click **Bind**.
8. To bind another certificate, repeat steps 5 through 7.
9. Click **Close**.

Navigate to **Traffic Management > SSL > Policies**.

Create SSL action:

1. In **SSL Actions**, click **Add**.
2. In **Create SSL Action**, specify a name for the action.

3. In **Forward Action Virtual Server**, select an existing virtual server or add a virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click **Create**.

Create SSL policy:

1. In **SSL Policies**, click **Add**.
2. In **Create SSL Policy**, specify a name for the policy.
3. In **Action**, select the action created earlier.
4. In **Expression Editor**, enter the rule to evaluate.
5. Click **Create**.

Create or add a virtual server and bind policy:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Add or select a virtual server.
3. In **Advanced Settings**, click **SSL Policies**.
4. Click in the SSL Policy section.
5. In **Select Policy**, select the policy that you created earlier.
6. In **Policy Binding**, specify a priority for the policy.
7. In **Type**, select **CLIENTHELLO_REQ**.
8. Click **Bind**.
9. Click **Done**.

Unbind a CA certificate group by using the GUI

1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Select a certificate group and click **Show Bindings**.
3. Select the certificate to remove from the group and click **Unbind**.
4. If prompted for confirmation, click **Yes••.
5. Click **Close**.

Remove a CA certificate group by using the GUI

1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Select a certificate group and click **Delete**.
3. If prompted for confirmation, click **Yes**.

SSL policy binding

September 14, 2021

You can bind SSL policies globally or to an SSL type virtual server only. Globally bound policies are evaluated after all policies bound to services, virtual servers, or other Citrix ADC bind points are evaluated. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered, and the action associated with it is carried out.

When binding an SSL policy to a virtual server, you must select from one of the following bind points:

- REQUEST (Default bind point. Policy evaluation is done in the HTTP layer after the SSL handshake is completed.)
- INTERCEPT_REQ (This option applies to a Citrix Secure Web Gateway setup. For more information, see SSL policy infrastructure for SSL interception).
- CLIENTHELLO_REQ

Similarly, when unbinding a policy from a virtual server, you must specify the bind point.

If you specify CLIENTHELLO_REQ as the bind point, the policy is evaluated when a client hello message is received. The allowed actions are RESET, FORWARD, and `caCertGrpName`. The reset action terminates the connection. The forward action forwards the request to a load balancing virtual server for processing. The `caCertGrpName` action selectively picks CAs based on SNI for client authentication. For more information about SSL actions, see SSL built-in actions and user-defined actions.

Note: The action caCertGrpName is not supported with the TLS 1.3 protocol.

Bind an SSL policy globally by using the CLI

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

```
bind ssl global - policyName <string> [- priority <positive_integer>]
show ssl global
<!--NeedCopy-->
```

Example:

```
bind ssl global -policyName Policy-SSL-2 -priority 90
Done

sh ssl global

      1) Name: Policy-SSL-2 Priority: 90
```

```
      2) Name: Policy-SSL-1 Priority: 100
      Done
<!--NeedCopy-->
```

Bind an SSL policy globally by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Policies**.
2. In the details pane, click **Global Bindings**.
3. In the **Bind/Unbind SSL Policies to Global** dialog box, click **Insert Policy**.
4. In the **Policy Name** list, select a policy.
5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.
6. Click **OK**. A message appears in the status bar, stating that the policy has been bound successfully.

Bind or unbind an SSL policy to a virtual server by using the CLI

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

```
bind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type <type>

unbind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type <type>

<!--NeedCopy-->
```

Example:

```
bind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
<!--NeedCopy-->
```

```
unbind ssl vserver v1 -policyName pol1 -priority 1 -type
   CLIENTHELLO_REQ
<!--NeedCopy-->
```

```
show ssl vserver vs-server

Advanced SSL configuration for VServer vs-server:

DH: DISABLED
```

```
6
7  Ephemeral RSA: ENABLED          Refresh Count: 1000
8
9  Session Reuse: ENABLED          Timeout: 120 seconds
10
11 Cipher Redirect: DISABLED
12
13 SSLv2 Redirect: DISABLED
14
15 ClearText Port: 80
16
17 Client Auth: DISABLED
18
19 SSL Redirect: ENABLED
20
21 SSL-REDIRECT Port Rewrite: ENABLED
22
23 Non FIPS Ciphers: DISABLED
24
25 SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED
26
27 1)      Policy Name: ssl-policy-1        Priority: 10
28
29 1)      Cipher Name: DEFAULT
30
31             Description: Predefined Cipher Alias
32
33 Done
34 <!--NeedCopy-->
```

Bind an SSL policy to a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open an SSL virtual server.
2. In **Advanced Settings**, select **SSL Policy**. Click in the **SSL policy** section to bind a policy to the virtual server.
3. In the **Policy Binding** page, select an existing policy or add a new policy.
4. Specify priority and type (bind point) for the policy.
5. Select **Bind**.
6. Select **Done**.

SSL policy labels

September 14, 2021

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy bank, bind policies to the label and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. At the CLI, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box.

Note: Policy labels of type control are not supported with the TLS 1.3 protocol.

Create an SSL policy label and bind policies to the label by using the CLI

At the command prompt, type:

```
add ssl policylabel <labelName> -type ( CONTROL | DATA )

bind ssl policylabel <labelName> <policyName> <priority> [<
    gotoPriorityExpression>] [-invoke (<labelType> <labelName>) ]
<!--NeedCopy-->
```

Example:

```
add ssl policylabel cpl1 -type CONTROL

add ssl policylabel dpl1 -type DATA

bind ssl policylabel cpl1 -policyName ctrlpol -priority 1

bind ssl policylabel dpl1 -policyName datapol -priority 1
<!--NeedCopy-->
```

Configure an SSL policy label and bind policies to the label by using the GUI

Navigate to **Traffic Management > SSL > Policy Labels**, and configure an SSL policy label.

Selective SSL logging

September 14, 2021

In a large deployment comprising thousands of virtual servers, all SSL-related information is logged. Earlier, filtering the client authentication and SSL handshake successes and failures for a few critical virtual servers was not easy. Perusing through the entire log to get this information was a time-consuming and tedious task because the infrastructure did not offer the control to filter the logs. Now, you can log SSL-related information in `ns.log`, for a specific virtual server or for a group of virtual servers. This information is especially helpful in debugging failures. To log this information, you must add an SSL log profile.

See sample ns.log output for successful client authentication at the end of this page.

Important: Set the syslog log level to DEBUG. At the command prompt, type:

```
set audit syslogParams -logLevel DEBUG
```

SSL log profile

An SSL log profile provides control over logging the following events for a virtual server or a group of virtual servers:

- Client authentication success and failures, or only failures.
- SSL handshake success and failures, or only failures.

By default, all the parameters are disabled.

An SSL log profile can be set on an SSL profile, or on an SSL action. If set to an SSL profile, you can log both client authentication and SSL handshake success and failure information. If set to an SSL action, you can only log client authentication success and failure information because the handshake is complete before the policy is evaluated.

Client authentication and SSL handshake success and failures are logged even if you do not configure an SSL log profile. However, selective logging is possible only if an SSL log profile is used.

> **Note:**
>
> SSL log profile is supported in high availability and cluster setups.

Add an SSL log profile by using the CLI

At the command prompt, type:

```
add ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )] [-
    ssllogClAuthFailures ( ENABLED | DISABLED )] [-sslLogHS ( ENABLED |
    DISABLED )] [-sslLogHSfailures ( ENABLED | DISABLED )]
<!--NeedCopy-->
```

Parameters:

Name:

Name for the SSL log profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the profile is created.

Name is a mandatory argument. Maximum Length: 127

sslLogClAuth:

Log all client authentication events. Includes both success and failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssllogClAuthFailures:

Log all client authentication failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sslLogHS:

Log all SSL handshake related events. Includes both success and failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sslLogHSfailures:

Log all SSL handshake related failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example:

```
> add ssl logprofile ssllog10 -sslLogClAuth ENABLED -sslLogHS ENABLED

 Done

sh ssllogprofile ssllog10
```

```
6
7  1)      Name: ssllog10
8
9          SSL log ClientAuth [Success/Failures] : ENABLED
10
11         SSL log ClientAuth [Failures] : DISABLED
12
13         SSL log Handshake [Success/Failures] : ENABLED
14
15         SSL log Handshake [Failures] : DISABLED
16
17  Done
18 <!--NeedCopy-->
```

Add an SSL log profile by using the GUI

Navigate to **System > Profiles > SSL Log Profile** and add a profile.

Modify an SSL log profile by using the CLI

At the command prompt type:

```
1 set ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )][-
     ssllogClAuthFailures ( ENABLED | DISABLED )] [-sslLogHS ( ENABLED |
     DISABLED )] [-sslLogHSfailures ( ENABLED | DISABLED )]
2 <!--NeedCopy-->
```

Example:

```
1 set ssllogprofile ssllog10 -ssllogClAuth en -ssllogClAuthFailures en -
     ssllogHS en -ssllogHSfailures en
2
3 Done
4
5 sh ssllogprofile ssllog10
6
7     1)            Name: ssllog10
8
9                     SSL log ClientAuth [Success/Failures] : ENABLED
10                    SSL log ClientAuth [Failures] : ENABLED
11                    SSL log Handshake [Success/Failures] : ENABLED
12                    SSL log Handshake [Failures] : ENABLED
13      Done
14 <!--NeedCopy-->
```

Modify an SSL log profile by using the GUI

1. Navigate to **System > Profiles > SSL Log Profile**, select a profile, and click **Edit**.
2. Make changes and click **OK**.

View all the SSL log profiles by using the CLI

At the command prompt, type:

```
sh ssl logprofile
<!--NeedCopy-->
```

Example:

```
sh ssl logprofile

    1)            Name: ssllogp1
                    SSL log ClientAuth [Success/Failures] : ENABLED
                    SSL log ClientAuth [Failures] : ENABLED
                    SSL log Handshake [Success/Failures] : DISABLED
                    SSL log Handshake [Failures] : ENABLED

    2)            Name: ssllogp2
                    SSL log ClientAuth [Success/Failures] : DISABLED
                    SSL log ClientAuth [Failures] : DISABLED
                    SSL log Handshake [Success/Failures] : DISABLED
                    SSL log Handshake [Failures] : DISABLED

    3)            Name: ssllogp3
                    SSL log ClientAuth [Success/Failures] : DISABLED
                    SSL log ClientAuth [Failures] : DISABLED
                    SSL log Handshake [Success/Failures] : DISABLED
                    SSL log Handshake [Failures] : DISABLED

    4)            Name: ssllog10
                    SSL log ClientAuth [Success/Failures] : ENABLED
                    SSL log ClientAuth [Failures] : ENABLED
                    SSL log Handshake [Success/Failures] : ENABLED
                    SSL log Handshake [Failures] : ENABLED
Done
<!--NeedCopy-->
```

View all the SSL log profiles by using the GUI

Navigate to **System > Profiles > SSL Log Profile**. All the profiles are listed.

Attach an SSL log profile to an SSL profile

You can attach (set) an SSL log profile on an SSL profile when you are creating an SSL profile, or later by editing the SSL profile. You can log both client authentication and handshake successes and failures.

> **Important:**
>
> The default SSL profile must be enabled before you can attach an SSL log profile.

Attach an SSL log profile on an SSL profile by using the CLI

At the command prompt, type:

```
set ssl profile <name> [-ssllogProfile <string>]
<!--NeedCopy-->
```

Example:

```
set ssl profile fron_1 -ssllogProfile ssllog10
<!--NeedCopy-->
```

Attach an SSL log profile to an SSL profile by using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Click **Edit** and in **SSL Log Profile**, specify a profile.

Attach an SSL log profile to an SSL action

You can set an SSL log profile only while creating an SSL action. You cannot modify an SSL action to set the log profile. Associate the action to a policy. You can only log client authentication successes and failures.

Attach an SSL log profile to an SSL action by using the CLI

At the command prompt, type:

```
add ssl action <name> -clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH ) -
    ssllogProfile <string>
<!--NeedCopy-->
```

Example:

```
> add ssl action act1 -clientAuth DoCLIENTAUTH -ssllogProfile ssllog10

Done

> sh ssl action act1

    1)            Name: act1
                    Type: Client Authentication (DOCLIENTAUTH)
                    Hits: 0
                    Undef Hits: 0
                    Action Reference Count: 0
                    SSLlogProfile: ssllog10
Done
<!--NeedCopy-->
```

Attach an SSL log profile to an SSL action by using the GUI

1. Navigate to **Traffic Management > SSL > Policies** and click **SSL Actions**.
2. Click **Add**.
3. In Client Authentication, select **ENABLED**.
4. In SSL Log Profile, select a profile from the list, or click “+” to create a profile.
5. Click **Create**.

Sample output from the log file

The following is a sample log output from `ns.log` for successful client authentication.

```

Support for DTLS protocol

September 14, 2021

Notes:

- DTLSv1.0 protocol is supported on Citrix ADC MPX/SDX (N2 and N3 based), VPX, and MPX 14000 FIPS appliances. It is not supported on external HSMs.
- DTLS 1.0 protocol is supported on Citrix ADC appliances containing Intel Coleto SSL chips (from release 12.1 build 50.x).
- DTLSv1.2 protocol is supported on the front-end of Citrix ADC VPX appliances (from release 13.0 build 47.x).
- DTLS 1.2 protocol is supported on the front-end of Citrix ADC appliances containing Intel Coleto SSL chips (from release 13.0 build 52.x). For more information about the platforms containing Intel Coleto SSL chips, see Support for Intel Coleto SSL chip based platforms.
- Service groups of type DTLS are not supported.
- DTLSv1.2 protocol is supported on the front-end of Citrix ADC MPX (N3 based) appliances (from release 13.0 build 58.x).
- For information about Enlightened Data Transport (EDT) support for Citrix Gateway, see HDX enlightened data transport support.
- There are changes made to the DTLS profile from release 13.0 build 79.x. For more information, see DTLS profile.
- From release 13.0 build 82.x, a new parameter “maxBadmacIgnorecount “ is introduced in the DTLS profile to ignore bad MAC records received in a DTLS session. For more informa-

> tion, see DTLS profile.

The SSL and TLS protocols have traditionally been used to secure streaming traffic. Both of these protocols are based on TCP, which is slow. Also, TLS cannot handle lost or reordered packets.

UDP is the preferred protocol for audio and video applications, such as Lync, Skype, iTunes, YouTube, training videos, and flash. However, UDP is not secure or reliable. The DTLS protocol is designed to secure data over UDP and is used for applications such as media streaming, VOIP, and online gaming for communication. In DTLS, each handshake message is assigned a specific sequence number within that handshake. When a peer receives a handshake message, it can quickly determine whether that message is the next one expected. If it is, the peer processes the message. If not, the message is queued for handling after all the previous messages have been received.

Create a DTLS virtual server and a service of type UDP. By default, a DTLS profile (nsdtls_default_profile) is bound to the virtual server. Optionally, you can create and bind a user-defined DTLS profile to the virtual server.

Note: RC4 ciphers are not supported on a DTLS virtual server.

DTLS configuration

You can use the command line (CLI) or the configuration utility (GUI) to configure DTLS on your ADC appliance.

Note: From release 13.0 build 47.x, the DTLS 1.2 protocol is supported on the front end of a Citrix ADC VPX appliance. While configuring a DTLSv1.2 virtual server, specify DTLS12. Default is DTLS1.

At the command prompt, type:

```
set ssl vserver DTLS [-dtls1 ( ENABLED | DISABLED )] [-dtls12 ( ENABLED | DISABLED )]
```

Create a DTLS configuration by using the CLI

At the command prompt, type:

```
add lb vserver <vserver_name> DTLS <IPAddress>  <port>
add service  <service_name>  <IPAddress> UDP 443
bind lb vserver  <vserver_name>  <udp_service_name>
<!--NeedCopy-->
```

The following steps are optional:

```
add dtlsProfile dtls-profile -maxretryTime <positive_integer>
set ssl vserver <vserver_name> -dtlsProfileName <dtls_profile_name>
<!--NeedCopy-->
```

Create a DTLS configuration by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a virtual server of type DTLS, and bind a UDP service to the virtual server.
3. A default DTLS profile is bound to the DTLS virtual server. To bind a different profile, in SSL Parameters, select a different DTLS profile. To create a profile, click the plus (+) next to DTLS Profile.

Support for SNI on a DTLS virtual server

For information about SNI, see Configure an SNI virtual server for secure hosting of multiple sites.

Configure SNI on a DTLS virtual server by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> -SNIEnable ENABLED
bind ssl vserver <vServerName> -certkeyName <string> -SNICert
show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set ssl vserver v1 -sniEnable ENABLED
bind ssl vserver  v1 -certkeyName san2 -sniCert
bind ssl vserver  v1 -certkeyName san13  - sniCert
bind ssl vserver  v1 -certkeyName san17  - sniCert
<!--NeedCopy-->
```

```
sh ssl vserver v1

Advanced SSL configuration for VServer v1:
DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED
Ephemeral RSA: ENABLED
Refresh Count: 0
Session Reuse: ENABLED
Timeout: 1800 seconds
Cipher Redirect: DISABLED

ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
```

```
SNI: ENABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
DTLSv1: ENABLED
Send Close-Notify: YES
Strict Sig-Digest Check: DISABLED
Zero RTT Early Data: DISABLED
DHE Key Exchange With PSK: NO
Tickets Per Authentication Context: 1

DTLS profile name: nsdtls_default_profile

ECC Curve: P_256, P_384, P_224, P_521

1) CertKey Name: ca
CA Certificate  OCSPCheck: OptionalCA_Name Sent
2) CertKey Name: san2 Server Certificate for SNI
3) CertKey Name: san17 Server Certificate for SNI
4) CertKey Name: san13 Server Certificate for SNI

1) Cipher Name: DEFAULT
Description: Default cipher list with encryption strength >= 128bit
Done
<!--NeedCopy-->
```

Configure SNI on a DTLS virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a DTLS virtual server and, in Certificates, click **Server Certificate**.
3. Add a certificate or select a certificate from the list and select **Server Certificate for SNI**.
4. In **Advanced Settings**, click **SSL Parameters**.
5. Select **SNI Enable**.

Features not supported by a DTLS virtual server

The following options cannot be enabled on a DTLS virtual server:

- SSLv2
- SSLv3
- TLSv1

- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL

Parameters not used by a DTLS virtual server

A DTLS virtual server ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

Configure renegotiation on a DTLS service

Non-secure renegotiation is supported on a DTLS service. You can use the CLI or the GUI to configure this setting.

Configure renegotiation on a DTLS service by using the CLI

At the command prompt, type:

```
set ssl parameter -denysslreneg NONSECURE
<!--NeedCopy-->
```

Example:

```
set ssl parameter -denysslreneg NONSECURE

sh ssl parameter
Advanced SSL Parameters
-----------------------
SSL quantum size                                  : 8 KB
Max CRL memory size                               : 256 MB
Strict CA checks                                  : NO
Encryption trigger timeout                        : 100 ms
Send Close-Notify                                 : YES
Encryption trigger packet count                   : 45
Deny SSL Renegotiation                            : NONSECURE
```

```
Subject/Issuer Name Insertion Format                  : Unicode
OCSP cache size                                       : 10 MB
Push flag                                             : 0x0 (Auto)
Strict Host Header check for SNI enabled SSL sessions : NO
PUSH encryption trigger timeout                       : 1 ms
Crypto Device Disable Limit                           : 0
Global undef action for control policies              : CLIENTAUTH
Global undef action for data policies                 : NOOP
Default profile                                       : DISABLED
SSL Insert Space in Certificate Header                : YES
Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors    : NO
Disable TLS 1.1/1.2 for dynamic and VPN services      : NO
Software Crypto acceleration CPU Threshold            : 0
Hybrid FIPS Mode                                      : DISABLED
Signature and Hash Algorithms supported by TLS1.2     : ALL
SSL Interception Error Learning and Caching           : DISABLED
SSL Interception Maximum Error Cache Memory           : 0 Bytes
Done
<!--NeedCopy-->
```

Configure renegotiation on a DTLS service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Select a DTLS service and click **Edit**.
3. Navigate to **SSL** > **Advanced Settings**.
4. Select **Deny SSL Renegotiation**.

Features not supported by a DTLS service

The following options cannot be enabled on a DTLS service:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- SNI
- Secure renegotiation

Parameters not used by a DTLS service

A DTLS service ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

> **Note:**
>
> SSL session reuse handshake fails on a DTLS service because session reuse is not currently supported on DTLS services.
>
> **Workaround:** Manually disable session reuse on a DTLS service. At the CLI, type:
>
> `set ssl service <dtls-service-name> -sessReuse DISABLED`

DTLS profile

A DTLS profile with the default settings is automatically bound to a DTLS virtual server. However, you can create a DTLS profile with specific settings to suit your requirement.

Use a DTLS profile with a DTLS virtual server or a VPN DTLS virtual server. You cannot use an SSL profile with a DTLS virtual server.

> **Note:**
>
> Change the maximum record size setting in the DTLS profile based on the changes in MTU and packet size. For example, the default max record size of 1459 bytes is calculated based on an IPv4 address header size. With IPv6 records, the header size is larger and therefore the maximum record size must be reduced to meet the following criteria.

`max record size + UDP header(8bytes)+ IP header size < MTU`

Example:

```
Default DTLS profile
    1) Name: nsdtls_default_profile
    PMTU Discovery: DISABLED
    Max Record Size: 1459 bytes
    Max Retry Time: 3 sec
    Hello Verify Request: ENABLED
    Terminate Session: DISABLED
    Max Packet Count: 120 bytes

Custom DTLS profile
```

```
    1) Name: ns_dtls_profile_ipv6_1
    PMTU Discovery: DISABLED
    Max Record Size: 1450 bytes
    Max Retry Time: 3 sec
    Hello Verify Request: ENABLED
    Terminate Session: DISABLED
    Max Packet Count: 120 bytes
<!--NeedCopy-->
```

Create a DTLS profile by using the CLI

Notes:

From release 13.0 build 79.x, the changes to the DTLS profile are as follows:

- The `helloverifyrequest` parameter is enabled by default. Enabling this parameter helps mitigate the risk of an attacker or bots overwhelming the network throughput, potentially leading to outbound bandwidth exhaustion. That is, it helps mitigate the DTLS DDoS amplification attack.
- The `maxHoldQlen` parameter is added. This parameter defines the number of datagrams that can be queued at the DTLS layer for processing. A high value of the `maxHoldQlen` parameter can cause memory buildup at the DTLS layer if UDP multiplexing is transmitting high UDP traffic. Therefore, configuring a lower value is recommended. Minimum value is 32, maximum value is 65535, and default value is 32.

From release 13.0 build 82.x, a new parameter `maxBadmacIgnorecount` is introduced in the DTLS profile to ignore bad MAC records received in a DTLS session. Using this parameter, bad records up to the value set in the parameter are ignored. The appliance terminates the session only after the limit is reached and sends an alert.

This parameter setting is effective only when the “terminateSession” parameter is enabled.

```
ssl dtlsProfile <name> -maxRetryTime <positive_integer> -
    helloVerifyRequest ( ENABLED | DISABLED ) -terminateSession (ENABLED
     | DISABLED ) -maxHoldQLen <positive_integer> -maxBadmacIgnorecount
    <positive_integer>

helloVerifyRequest
              Send a Hello Verify request to validate the client.
              Possible values: ENABLED, DISABLED
              Default value: ENABLED

terminateSession
              Terminate the session if the message authentication code
                  (MAC)
```

```
                of the client and server do not match.
                Possible values: ENABLED, DISABLED
                Default value: DISABLED

maxHoldQLen
                Maximum number of datagrams that can be queued at DTLS
                    layer for
                processing
                Default value: 32
                Minimum value: 32
                Maximum value: 65535

maxBadmacIgnorecount
                Maximum number of bad MAC errors to ignore for a
                    connection prior disconnect. Disabling parameter
                    terminateSession
terminates session immediately when bad MAC is detected in the
    connection.
                Default value: 100
                Minimum value: 1
                Maximum value: 65535
<!--NeedCopy-->
```

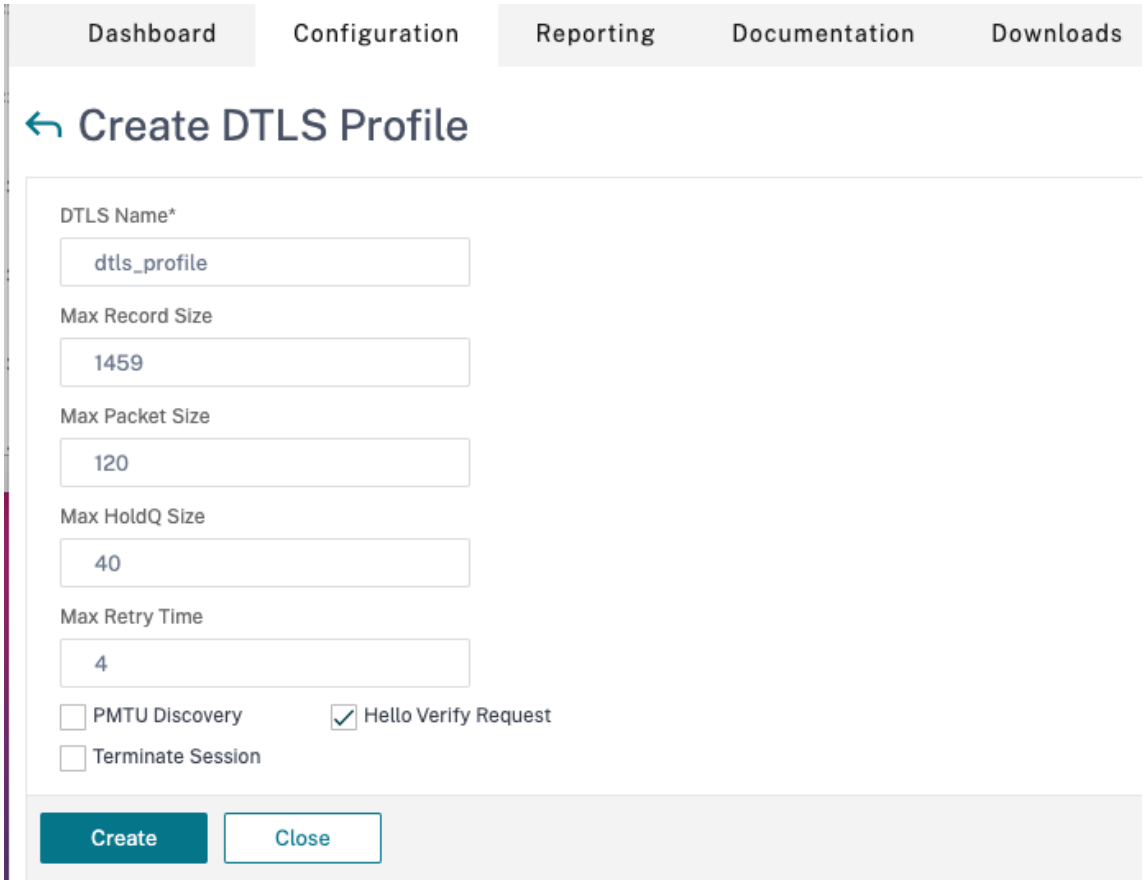
Example:

```
> add ssl dtlsprofile dtls_profile -maxRetryTime 4 -helloVerifyRequest
    ENABLED -terminateSession ENABLED -maxHoldQLen 40 -
    maxBadmacIgnorecount 150
 Done
> sh dtlsprofile dtls_profile
1)  Name: dtls_profile
    PMTU Discovery: DISABLED
    Max Record Size: 1459 bytes
    Max Retry Time: 4 sec
    Hello Verify Request: ENABLED
    Terminate Session: ENABLED
    Max Packet Count: 120 bytes
    Max HoldQ Size: 40 datagrams
    Max bad-MAC Ignore Count: 150

 Done
<!--NeedCopy-->
```

Create a DTLS profile by using the GUI

1. Navigate to **System > Profiles > DTLS Profiles** and click **Add**.
2. In the **Create DTLS Profile** page, type values for the different parameters.



3. Click **Create**.

Example for an end-to-end DTLS configuration

```
enable ns feature SSL LB

add server s1 198.51.100.2

en ns mode usnip

add service svc_dtls s1 DTLS 443

add lb vserver v1 DTLS 10.102.59.244 443

bind ssl vserver v1 -ciphername ALL

```

```
13 add ssl certkey servercert -cert servercert_aia_valid.pem -key
      serverkey_aia.pem
14
15 bind ssl vserver v1 -certkeyname servercert
16
17 bind lb vserver lb1 svc_dtls
18
19 sh lb vserver v1
20
21                     v1 (10.102.59.244:4433) - DTLS     Type: ADDRESS
22                     State: UP
23                     Last state change was at Fri Apr 27 07:00:27 2018
24                     Time since last state change: 0 days, 00:00:04.810
25                     Effective State: UP
26                     Client Idle Timeout: 120 sec
27                     Down state flush: ENABLED

DTLS support for IPv6 address

DTLS is supported with IPv6 addresses also. However, to use DTLS with IPv6 addresses the maximum record size must be adjusted in the DTLS profile.

If the default value is used for the maximum record size, the initial DTLS connection might fail. Adjust the maximum record size using a DTLS profile.

DTLS cipher support

By default, a DTLS cipher group is bound when you create a DTLS virtual server or service. DEFAULT_DTLS contains the ciphers that a front-end DTLS entity supports. This group is bound by default when you create a DTLS virtual server. DEFAULT_DTLS_BACKEND contains the ciphers that

are supported to a back-end DTLS entity. This group is bound by default to a DTLS back-end service. DTLS_FIPS contains the ciphers that are supported on the Citrix ADC FIPS platform. This group is bound by default to a DTLS virtual server or service created on a FIPS platform.

DTLS cipher support on Citrix ADC VPX, MPX/SDX (N2 and N3 based) appliances

How to read the tables:

Unless a build number is specified, a cipher suite is supported for all builds in a release.

Example:

- **10.5, 11.0, 11.1, 12.0, 12.1, 13.0**: All builds of 10.5, 11.0, 11.1, 12.0, 12.1, 13.0 releases.
- **-NA-**: not applicable.

DTLS cipher support on the Citrix ADC MPX 14000 FIPS platform

Note: Enlightened Data Support (EDT) is supported on the FIPS platform if the following conditions are met:

- UDT MSS value set on StoreFront is 900.
- Windows client version is 4.12 or later.
- DTLS enabled VDA version is 7.17 or later.
- Non-DTLS VDA version is 7.15 LTSR CU3 or later.

How to read the tables:

Unless a build number is specified, a cipher suite is supported for all builds in a release.

Example:

- **10.5, 11.0, 11.1, 12.0, 12.1, 13.0**: All builds of 10.5, 11.0, 11.1, 12.0, 12.1, 13.0 releases.

- **-NA-**: not applicable.

Cipher suite Name	Hex Code	Wireshark Cipher suite Name	Builds Supported (front end)	Builds Supported (back end)

TLS1-ECDHE-RSA-DES-CBC3-SHA	0xc012	TLS_ECDHE_RSA_	12.1–49.x, 13.0	-NA-
TLS1-DHE-RSA-AES-128-CBC-SHA	0x0033	TLS_DHE_RSA_WITH_AES_128_CBC_SHA	12.1–49.x, 13.0	12.1–49.x, 13.0
TLS1-DHE-RSA-AES-256-CBC-SHA	0x0039	TLS_DHE_RSA_WI	12.1–49.x, 13.0	12.1–49.x, 13.0

To view the list of default ciphers supported on a Citrix ADC FIPS appliance, at the command prompt, type:

```
1 show ssl cipher DTLS_FIPS
```

```
1)    Cipher Name: TLS1-AES-256-CBC-SHA    Priority : 1
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(256)  Mac=SHA1
       HexCode=0x0035
2)    Cipher Name: TLS1-AES-128-CBC-SHA    Priority : 2
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(128)  Mac=SHA1
       HexCode=0x002f
3)    Cipher Name: TLS1-ECDHE-RSA-AES256-SHA    Priority : 3
    Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=AES(256)  Mac=SHA1
       HexCode=0xc014
4)    Cipher Name: TLS1-ECDHE-RSA-AES128-SHA    Priority : 4
    Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=AES(128)  Mac=SHA1
       HexCode=0xc013
5)    Cipher Name: TLS1-ECDHE-RSA-DES-CBC3-SHA  Priority : 5
    Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=3DES(168) Mac=SHA1
       HexCode=0xc012
6)    Cipher Name: SSL3-DES-CBC3-SHA    Priority : 6
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=3DES(168) Mac=SHA1
       HexCode=0x000a
<!--NeedCopy-->

DTLSv1.2 cipher support on the front-end VPX appliances, MPX/SDX (Coleto and N3 based) appliances

The following table lists the additional ciphers supported for the DTLSv1.2 protocol.

Cipher suite Name	Hex Code	Wireshark Cipher suite Name	Builds Supported (VPX front end)	Builds Supported (Coleto based)	Builds Supported (N3 based)
TLS1.2-AES256-GCM-SHA384	0x009d	TLS_RSA_WITH	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-AES128-GCM-SHA256	0x009c	TLS_RSA_WITH_AES_128_GCM_SHA256	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES256-GCM-SHA384	0xc030	TLS_ECDHE_RS	13.0–47.x	13.0–52.x	13.0–58.x

Cipher suite Name	Hex Code	Wireshark Cipher suite Name	Builds Supported (VPX front end)	Builds Supported (Coleto based)	Builds Supported (N3 based)
TLS1.2-ECDHE-RSA-AES128-GCM-SHA256	0xc02f	TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES256-GCM-SHA384	0x009f	TLS_DHE_RSA_	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES128-GCM-SHA256	0x009e	TLS_DHE_RSA_WITH_AES_128_GCM_SHA256	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-AES-256-SHA256	0x003d	TLS_RSA_WITH	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-AES-128-SHA256	0x003c	TLS_RSA_WITH_AES_128_CBC_SHA256	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES-256-SHA384	0xc028	TLS_ECDHE_RS	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES-128-SHA256	0xc027	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES-256-SHA256	0x006b	TLS_DHE_RSA_	13.0–47.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES-128-SHA256	0x0067	TLS_DHE_RSA_WITH_AES_128_CBC_SHA256	13.0–47.x	13.0–52.x	13.0–58.x

Support for Intel Coleto SSL chip based platforms

September 14, 2021

The following appliances ship with Intel Coleto chips:

- MPX 5900
- MPX/SDX 8900
- MPX/SDX 15000
- MPX/SDX 15000-50G
- MPX/SDX 26000
- MPX/SDX 26000-50S
- MPX/SDX 26000-100G

Use the 'show hardware' command to identify whether your appliance has Coleto (COL) chips.

```
> sh hardware

    Platform: NSMPX-8900 8*CPU+4*F1X+6*E1K+1*E1K+1*COL 8955 30010
    Manufactured on: 10/18/2016
    CPU: 2100MHZ
    Host Id: 0
    Serial no: CRAC5CR8UA
    Encoded serial no: CRAC5CR8UA
 Done
<!--NeedCopy-->
```

Note: Secure renegotiation is supported on the back end for these platforms.

Limitations:

- DH 512 cipher is not supported.
- SSLv3 protocol is not supported.
- Hardware security module (HSM) is not supported.
- GnuTLS is not supported.
- ECDSA certificates with ECC curves P_224 and P521 are not supported (Not supported on platforms with Cavium chips also.)
- DNSSEC offload is not supported. (DNSSEC is supported in software but offload to hardware is not supported.)

View the SSL chip utilization on Citrix ADC MPX platforms

From release 13.0 build 47.x, you can view the SSL chip utilization on MPX platforms that ship with Intel Coleto chips. This feature is not supported on the SDX platform and on an MPX cluster.

At the command prompt, type:

```
> stat ssl

SSL Summary

# SSL cards present                              4

# SSL cards UP                                   4

SSL engine status                                1

SSL sessions (Rate)                            0

MPX 9700/10500/12500/15500 FIPS appliances

September 14, 2021

Important! The MPX 9700/10500/12500/15500 FIPS platform has reached end of life.

The Federal Information Processing Standard (FIPS), issued by the US National Institute of Standards and Technologies, specifies the security requirements for a cryptographic module used in a security system. The Citrix ADC FIPS appliance complies with the second version of this standard, FIPS-140-2.

Note: Henceforth, all references to FIPS imply FIPS-140-2.

The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—and a Cavium CN1620-NFBE3-2.0-G on the MPX 9700/10500/12500/15500 FIPS appliances—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser can perform operations on the keys stored inside the HSM.

The following table summarizes the differences between standard Citrix ADC and Citrix ADC FIPS appliances.

Setting	Citrix ADC appliance	Citrix ADC FIPS appliance
Key storage	On the hard disk	On the FIPS card
Cipher support	All ciphers	FIPS approved ciphers
Accessing keys	From the hard disk	Not accessible

Configuring a FIPS appliance involves configuring the HSM immediately after completing the generic configuration process. You then create or import a FIPS key. After creating a FIPS key, you must export it for backup. You might also need to export a FIPS key so that you can import it to another appliance. For example, configuring FIPS appliances in a high availability setup requires transferring the FIPS key from the primary node to the secondary node immediately after completing the standard high availability setup.

You can upgrade the firmware version on the FIPS card from version 4.6.0 to 4.6.1. You can also reset an HSM that has been locked to prevent unauthorized logon. Only FIPS approved ciphers are supported on a Citrix ADC FIPS appliance.

HSM configuration

Before you can configure the HSM of your Citrix ADC FIPS appliance, you must complete the initial hardware configuration. For more information about MPX appliances, see Initial Configuration. For information about SDX appliances, click here.

Configuring the HSM of your Citrix ADC FIPS appliance erases all existing data on the HSM. To configure the HSM, you must be logged on to the appliance as the superuser. The HSM is preconfigured with default values for the Security Officer (SO) password and User password, which you use to configure the HSM or reset a locked HSM. The maximum length allowed for the password is 14 alphanumeric characters. Symbols are not allowed.

Important: Run the `set ssl fips` command only after first resetting the FIPS card and restarting the MPX FIPS appliance.

Although the FIPS appliance can be used with the default password values, you must modify them before using it. The HSM can be configured only when you log on to the appliance as the superuser and specify the SO and User passwords.

Important: Due to security constraints, the appliance does not provide a means for retrieving the SO password. Store a copy of the password safely. If you need to reinitialize the HSM, you need to specify this password as the old SO password.

Before initializing the HSM, you can upgrade to the latest build of the software. To upgrade to the latest build, see Upgrading or Downgrading the System Software.

After upgrading, verify that the /nsconfig/fips directory has been successfully created on the appliance.

Configure the HSM on the MPX 9700/10500/12500/15500 FIPS platform by using the CLI

After logging on to the appliance as the superuser and completing the initial configuration, at the command prompt, type the following commands to configure the HSM and verify the configuration:

```
show ssl fips

reset ssl fips

reboot

set ssl fips -initHSM Level-2 <newSOpassword> <oldSOpassword> <
   userPassword> [-hsmLabel <string>]

save ns config

reboot

show ssl fips
<!--NeedCopy-->
```

Example:

```
show fips

    FIPS Card is not configured
    Done
    reset fips
    reboot
    Are you sure you want to restart NetScaler (Y/N)? [N]:y

    set ssl fips -initHSM Level-2 sopin12345 so12345 user123 -hsmLabel
       cavium

    This command will erase all data on the FIPS card. You must save
       the configuration

    (saveconfig) after executing this command.

    Do you want to continue?(Y/N)y
    Done
```

```
18
19      save ns config
20
21      reboot
22
23      Are you sure you want to restart NetScaler (Y/N)? [N]:y
24
25      show fips
26
27              FIPS HSM Info:
28      HSM Label               : Citrix ADC FIPS

66  <!--NeedCopy-->
```

Configure the HSM on the MPX 9700/10500/12500/15500 FIPS platform by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the **FIPS Infotab**, click **Reset FIPS**.
3. In the navigation pane, click **System**.
4. In the details pane, click **Reboot**.
5. In the details pane, on the FIPS Info tab, click **Initialize HSM**.
6. In the Initialize HSM dialog box, specify values for the following parameters:
   - Security Officer (SO) Password*—new SO password
   - Old SO Password*—old SO password
   - User Password*—user password
   - Level—initHSM (Currently set to Level2 and cannot be changed)
   - HSM Label—hsmLabel

   *A required parameter
7. Click **OK**.
8. In the details pane, click **Save**.
9. In the navigation pane, click **System**.
10. In the details pane, click **Reboot**.
11. Under FIPS HSM Info, verify that the information displayed is correct for the FIPS HSM that you configured.

Create and transfer FIPS keys

After configuring the HSM of your FIPS appliance, you are ready to create a FIPS key. The FIPS key is created in the appliance's HSM. You can then export the FIPS key to the appliance's CompactFlash card as a secured backup. Exporting the key also enables you to transfer it by copying it to the /flash of another appliance and then importing it into the HSM of that appliance. Enable SIM between two standalone nodes before you export and transfer the keys. In a high availability setup, if one of the nodes is replaced with a new one, you must perform the following steps:

1. Enable SIM between this new appliance and the existing appliance of the high availability setup.
2. Export or import FIPS keys.

Instead of creating a FIPS key, you can import an existing FIPS key or import an external key as a FIPS key. If you are adding a certificate-key pair of 2048 bits on the MPX 9700/10500/12500/15500 FIPS appliances, make sure that you have the correct certificate and key pair.

Note: If you are planning a high availability setup, make sure that the FIPS appliances are configured in a high availability setup before creating a FIPS key.

Create FIPS keys

Before creating a FIPS key, make sure that the HSM is configured.

Specify the key type (RSA or ECDSA) and specify the curve for ECDSA keys.

Create a FIPS key by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the FIPS Keys tab, click **Add**.
3. In the Create FIPS Key dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - Modulus*—modulus
   - Exponent*—exponent

   *A required parameter
4. Click **Create**, and then click **Close**.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you created are correct.

Create a FIPS key by using the CLI

At the command prompt, type the following commands to create a FIPS key and verify the settings:

```
create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent
    ( 3 | F4 )]

show ssl fipsKey [<fipsKeyName>]
<!--NeedCopy-->
```

Example:

```
    create fipskey Key-FIPS-1 -keytype RSA -modulus 2048 -exponent 3

    show ssl fipsKey Key-FIPS-1

                FIPS Key Name: Key-FIPS-1 Key Type: RSA Modulus: 2048
                     Public Exponent: F4 (Hex: 0x10001)
<!--NeedCopy-->
```

Export FIPS keys

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, there is no way to create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the `/nsconfig/ssl` folder on the appliance's CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

Export a FIPS key by using the CLI

At the command prompt, type:

```
export ssl fipsKey <fipsKeyName> -key <string>
<!--NeedCopy-->
```

Example:

```
export fipskey Key-FIPS-1 -key Key-FIPS-1.key
<!--NeedCopy-->
```

Export a FIPS key by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the FIPS Keys tab, click **Export**.
3. In the Export FIPS key to a file dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - File Name*—key (To put the file in a location other than the default, you can either specify the complete path or click the Browse button and navigate to a location.)

*A required parameter

4. Click **Export**, and then click **Close**.

Import an existing FIPS key

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard disk of the appliance into its HSM.

Note: To avoid errors when importing a FIPS key, make sure that the name of the key imported is the same as the original key name when it was created.

Import a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the CLI

At the command prompt, type the following commands to import a FIPS key and verify the settings:

```
1 -  import ssl fipsKey <fipsKeyName> -key <string> -inform SIM -exponent
     (F4 | 3)
2 -  show ssl fipskey <fipsKeyName>
3 <!--NeedCopy-->
```

Example:

```
1 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
2 show ssl fipskey key-FIPS-2
3 FIPS Key Name: Key-FIPS-2 Modulus: 2048   Public Exponent: F4 (Hex
     value 0x10001)
4 <!--NeedCopy-->
```

Import a FIPS key by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the FIPS Keys tab, click **Import**.
3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.
   - Exponent*

   *A required parameter
4. Click **Import**, and then click **Close**.

5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you imported are correct.

Import an external key

You can transfer FIPS keys that are created within the Citrix ADC appliance's HSM. You can also transfer external private keys (such as keys created on a standard Citrix ADC, Apache, or IIS) to a Citrix ADC FIPS appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance's flash drive under `/nsconfig/ssl`.

On the MPX 9700/10500/12500/15500 FIPS appliances, the -exponent parameter in the **`import`** `ssl fipskey` command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the -exponent parameter is ignored.

The Citrix ADC FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 9700/10500/12500/15500 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 9700/10500/12500/15500 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

```
1 openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>
2 <!--NeedCopy-->
```

Note: If you import an RSA key as a FIPS key, Citrix recommends that you delete the RSA key from the appliance for security purposes.

Import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the CLI

1. Copy the external key to the appliance's flash drive.
2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:

```
1 convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx
     file name> -password <password>
2 <!--NeedCopy-->
```

3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:

```
import ssl fipsKey <fipsKeyName> -key <string> -informPEM
show ssl fipskey<fipsKeyName>
<!--NeedCopy-->
```

Example:

```
convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx

import fipskey Key-FIPS-2 -key iis.pem -inform PEM

show ssl fipskey key-FIPS-2

FIPS Key Name: Key-FIPS-2 Modulus: 0   Public Exponent: F4 (Hex value 0
   x10001)
<!--NeedCopy-->
```

Import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the GUI

1. If the key is in .pfx format, you must first convert it to PEM format.
   a) Navigate to **Traffic Management > SSL**.
   b) In the details pane, under Tools, click **Import PKCS#12**.
   c) In the Import PKCS12 File dialog box, set the following parameters:
      - Output File Name*
      - PKCS12 File Name*—Specify the .pfx file name.
      - Import Password*
      - Encoding Format

      *A required parameter
2. Navigate to **Traffic Management > SSL > FIPS**.
3. In the details pane, on the FIPS Keys tab, click **Import**.
4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.

   *A required parameter
5. Click **Import**, and then click **Close**.

6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you imported are correct.

Configure FIPS on appliances in a high availability setup

September 14, 2021

Important! The MPX 9700/10500/12500/15500 FIPS platform has reached end of life.

You can configure two appliances in a high availability (HA) pair as FIPS appliances.

Prerequisites

- The Hardware Security Module (HSM) must be configured on both the appliances. For more information, see Configure the HSM.
- When using the GUI, ensure that the appliances are already in an HA setup. For more information about configuring an HA setup, see High availability.

Note: Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause an inconsistency that requires an appliance restart. In addition, if you use the CLI, the `create ssl fipskey` command is not propagated to the secondary node. When you run the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not the same. Create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).

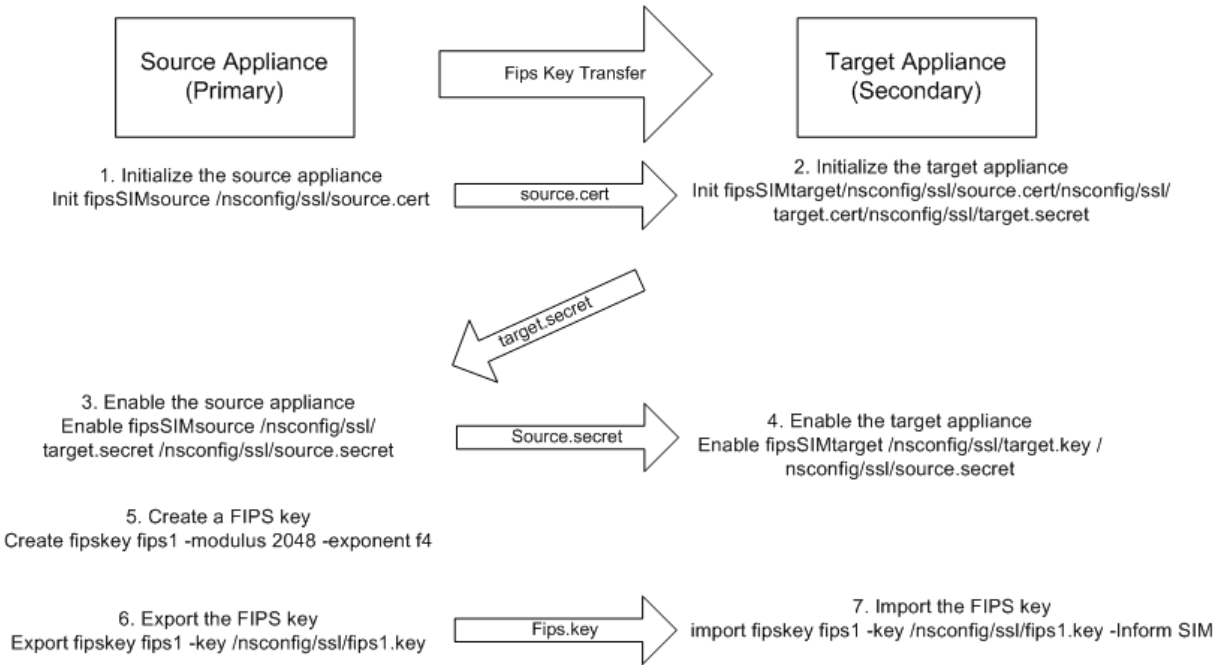
> **Important:** The HA setup must be completed within six minutes. If the procedure fails at any step, do the following:
>
> 1. Restart the appliance or wait for 10 minutes.
> 2. Remove all the files created by the procedure.
> 3. Repeat the HA setup procedure.
>
> Do not reuse existing file names.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.

Configure FIPS on appliances in a high availability setup by using the CLI

The following diagram summarizes the transfer process on the CLI.

Figure 1. Transfer the FIPS key-summary



1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance, using the administrator credentials.
3. Initialize appliance A as the source appliance. At the command prompt, type:

```
1 init ssl fipsSIMsource <certFile>
2 <!--NeedCopy-->
```

Example:

```
init fipsSIMsource /nsconfig/ssl/nodeA.cert
```

4. Copy this <certFile> file to appliance B, in the /nconfig/ssl folder.

Example:

```
scp /nsconfig/ssl/nodeA.cert nsroot@198.51.100.10:/nsconfig/ssl
```

5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
6. Log on to the appliance, using the administrator credentials.
7. Initialize appliance B as the target appliance. At the command prompt, type:

```
1 init ssl fipsSIMtarget <certFile> <keyVector> <targetSecret>
2 <!--NeedCopy-->
```

Example:

```
init fipsSIMtarget /nsconfig/ssl/nodeA.cert /nsconfig/ssl/nodeB.key /
nsconfig/ssl/nodeB.secret
```

8. Copy this <targetSecret> file to appliance A.

   Example:

   ```
   scp /nsconfig/ssl/fipslbdal0801b.secret nsroot@198.51.100.20:/nsconfig/
   ssl
   ```

9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:

   ```
   enable ssl fipsSIMSource <targetSecret> <sourceSecret>
   <!--NeedCopy-->
   ```

   Example:

   ```
   enable fipsSIMsource /nsconfig/ssl/nodeB.secret /nsconfig/ssl/nodeA.
   secret
   ```

10. Copy this <sourceSecret> file to appliance B.

    Example:

    ```
    scp /nsconfig/ssl/fipslbdal0801b.secret nsroot@198.51.100.10:/nsconfig/
    ssl
    ```

11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:

    ```
    enable ssl fipsSIMtarget <keyVector> <sourceSecret>
    <!--NeedCopy-->
    ```

    Example:

    ```
    enable fipsSIMtarget /nsconfig/ssl/nodeB.key /nsconfig/ssl/nodeA.secret
    ```

12. **On appliance A**, create a FIPS key, as described in Create a FIPS key.
13. Export the FIPS key to the appliance's hard disk, as described in Export a FIPS key.
14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.
15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in Import an existing FIPS key.

Configure FIPS on appliances in a high availability setup by using the GUI

1. On the appliance to be configured as the source (primary) appliance, navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the FIPS Info tab, click **Enable SIM**.

3. In the **Enable SIM for HA Pair** dialog box, in the **Certificate File Name** text box, type the file name. The file name must contain the path to the location at which the FIPS certificate must be stored on the source appliance.
4. In the **Key Vector File Name** text box, type the file name. The file name must contain the path to the location at which the FIPS key vector must be stored on the source appliance.
5. In the **Target Secret File Name** text box, type the location for storing the secret data on the target appliance.
6. In the **Source Secret File Name** text box, type the location for storing the secret data on the source appliance.
7. Under **Secondary System Login Credential**, enter the values for **User Name** and **Password**.
8. Click **OK**. The FIPS appliances are now configured in HA mode.

Note: After configuring the appliances in HA, create a FIPS key, as described in Create a FIPS key. The FIPS key is automatically transferred from the primary to the secondary appliance.

Update the firmware to version 2.2 on a FIPS card

September 14, 2021

Important! The MPX 9700/10500/12500/15500 FIPS platform has reached end of life.

FIPS firmware version 2.2 supports TLS protocol versions 1.1 and 1.2. From the command line, you can update the firmware version of the FIPS card of a Citrix ADC MPX 9700/10500/12500/15500 FIPS appliance from version 1.1 to version 2.2.

For successful SIM key propagation from primary to secondary in a high availability (HA) pair, the Cavium firmware version on each appliance must be identical. Perform the firmware update on the secondary appliance first. If performed on the primary appliance first, the long-running update process causes a failover.

Limitations

- Secure renegotiation is supported only on SSL virtual servers and front-end SSL services.
- Creating a certificate signing request by using a key that was created on firmware version 1.1 and updated to firmware version 2.2 fails.
- You cannot create a 1024-bit RSA key on firmware version 2.2. However, if you have imported or created a 1024-bit FIPS key on firmware version 1.1 and you then update to firmware version 2.2, you can use that FIPS key on firmware version 2.2.
- Only 2048-bit RSA keys are supported.

- 4096-bit client certificate is not supported (if client authentication is enabled on the back-end server).
- Secure renegotiation using the SSLv3 protocol is not supported.
- After you upgrade the firmware, TLSv1.1 and TLSv1.2 are disabled by default on the existing virtual server, internal, front end, and back-end services. To use TLS 1.1/1.2, you must explicitly enable these protocols, on the SSL entities, after the upgrade.
- FIPS keys that are created in firmware version 2.2 are not available if you downgrade the firmware to version 1.1.

Prerequisites

Download the following files from the download page on www.citrix.com. The files must be stored in the /var/nsinstall directory on the appliance.

- FW 2.2 File: FW-2.2-130013
- FW 2.2 Signature File: FW-2.2-130013.sign

FW-2.2-130013 is the recommended firmware version. It includes fixes to improve DRBG.

Update the FIPS firmware to version 2.2 on a standalone appliance

1. Log on to the appliance by using the administrator credentials.
2. At the prompt, type the following command to confirm that the FIPS card is initialized.

```
show fips

FIPS HSM Info:
HSM Label       : Citrix ADC FIPS
Initialization      : FIPS-140-2 Level-2
HSM Serial Number   : 3.0G1235-ICM000264
HSM State       : 2
HSM Model       : NITROX XL CN1620-NFBE

Hardware Version    : 2.0-G
Firmware Version    : 1.1
Firmware Release Date   : Jun04,2010

Max FIPS Key Memory : 3996
Free FIPS Key Memory    : 3992
Total SRAM Memory   : 467348
Free SRAM Memory    : 62512
Total Crypto Cores  : 3
```

```
Enabled Crypto Cores    : 1
Done
<!--NeedCopy-->
```

3. Save the configuration. At the prompt, type:

```
save config
<!--NeedCopy-->
```

4. Perform the update. At the prompt, type:

```
update ssl fips -fipsFW <path to the extracted contents>/CN16XX-
   NFBE-FW-2.2-1300013
<!--NeedCopy-->
```

   Press Y when the following prompt appears:

```
This command will update compatible version of the FIPS firmware.
     You must save the current configuration (saveconfig) before
   executing this command. You must reboot the system after
   execution of this command, for the firmware update to take
   effect. Do you want to continue?(Y/N)Y

Done
<!--NeedCopy-->
```

Note: You only need to specify the firmware file, because the firmware signature file is placed in the same location.

The update takes up to 10 seconds. The update command is blocking, which means that no other actions are performed until the command finishes. The command prompt reappears when execution of the command is completed.

1. Restart the appliance. At the prompt, type:

```
reboot

Are you sure you want to restart NetScaler (Y/N)? [N]:Y
<!--NeedCopy-->
```

2. Verify that the update is successful. At the prompt, type:

```
show fips
<!--NeedCopy-->
```

   The firmware version displayed in the output must be 2.2. For example:

```
sh fips
    FIPS HSM Info:
        HSM Label       : Citrix ADC FIPS
        Initialization      : FIPS-140-2 Level-2
        HSM Serial Number   : 2.1G1207-IC002429
        HSM State       : 2
        HSM Model       : NITROX XL CN1620-NFBE

        Hardware Version    : 2.0-G
        Firmware Version    : 2.2
        Firmware Build          : NFBE-FW-2.2-130013
        Max FIPS Key Memory : 3996
        Free FIPS Key Memory    : 3982
        Total SRAM Memory   : 467348
        Free SRAM Memory    : 50472
        Total Crypto Cores  : 3
        Enabled Crypto Cores    : 1
Done
<!--NeedCopy-->
```

Update the FIPS firmware to version 2.2 on appliances in a high availability pair

1. Log on to the secondary node and perform the update as described in “Update the FIPS firmware to version 2.2 on a standalone appliance”.

   Force the secondary node to become primary. At the prompt, type:

   ```
   force failover
   <!--NeedCopy-->
   ```

   Press **Y** at the confirmation prompt.

2. Log on to the new secondary node (old primary) and perform the update as described in “Update the FIPS firmware to version 2.2 on a standalone appliance”.

3. Force the new secondary node to become primary again. At the prompt, type:

   ```
   force failover
   <!--NeedCopy-->
   ```

   Press **Y** at the confirmation prompt.

Update the FIPS firmware to version 1.1 on a standalone appliance

1. Download the nfb_firmware-r1235_100604 and nfb_firmware-r1235_100604.sign files, to the same directory on the appliance, from the download page on www.citrix.com.
2. Log on to the appliance by using the administrator credentials.
3. At the prompt, type:

```
update ssl fips -fipsFW /<full path to the file>/nfb_firmware-
   r1235_100604
<!--NeedCopy-->
```

Reset a locked HSM

September 14, 2021

Important! The MPX 9700/10500/12500/15500 FIPS platform has reached end of life.

The HSM becomes locked (no longer operational) if you change the SO password, restart the appliance without saving the configuration, and make three unsuccessful attempts to change the password. The locking is a security measure for preventing unauthorized access attempts and changes to the HSM settings.

Important: To avoid this situation, save the configuration after initializing the HSM.
If the HSM is locked, you must reset the HSM and restart the appliance to restore the default passwords. You can then use the default passwords to access the HSM and configure it with new passwords. When finished, you must save the configuration and restart the appliance.

Caution: Reset the HSM only if it is locked.

Reset a locked HSM by using the CLI

At the command prompt, type the following commands to reset and reinitialize a locked HSM:

```
reset ssl fips
reboot -warm
set ssl fips -initHSM Level-2 <new SO password> <old SO password> <user
    password> [-hsmLabel <string>]
save ns config
reboot -warm
<!--NeedCopy-->
```

Example:

```
reset fips

reboot -warm

set fips -initHSM Level-2 newsopin123 sopin123 userpin123 -hsmLabel
   NSFIPS

saveconfig

reboot -warm

Note: By default the HSM passwords are preconfigured. The <
   Old_SO_Password> = so12345, <User_Password> = user123, <
   New_SO_Password> = sopin12345, <New_User_Password> = userpin123.
<!--NeedCopy-->
```

Reset a locked HSM by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**
2. In the details pane, on the FIPS Info tab, click Reset FIPS.
3. Configure the HSM, as described in Configuring the HSM.
4. In the details pane, click Save.

MPX 14000 FIPS appliances

October 14, 2021

> **Important:**
>
> - The MPX 9700/10500/12500/15500 FIPS platform has reached end of life.
> - Configuration steps for NetScaler MPX 14000 FIPS and NetScaler MPX 9700/10500/12500/15500 FIPS appliances are different. MPX 14000 FIPS appliances do not use firmware v2.2. A FIPS key created on the Hardware Security Module (HSM) of the MPX 9700 platform cannot be transferred to the HSM of the MPX 14000 platform. The other way round is also not supported. However, if you have imported an RSA key as a FIPS key, you can copy the RSA key to the MPX 14000 platform. Then import it as a FIPS key. Only 2048-bit and 3072-bit keys are supported.

A FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 12.0

build 56.x). The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the HSM. The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (`nsroot`) can perform operations on the keys stored inside the HSM.

Before configuring a FIPS appliance, you must check the state of the FIPS card and then initialize the card. Create a FIPS key and server certificate, and add any additional SSL configuration.

For information about the FIPS ciphers supported, see FIPS Approved Algorithms and Ciphers.

For information about configuring FIPS appliances in an HA setup, see Configure FIPS on appliances in an HA setup.

Limitations

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an MPX FIPS appliance.
2. 1024-bit and 4096-bit keys and exponent value of 3 aren't supported.
3. 4096-bit server certificate isn't supported.
4. 4096-bit client certificate isn't supported (if client authentication is enabled on the back-end server).

Configure the HSM

Before configuring the HSM on an MPX 14000 FIPS appliance, check the state of your FIPS card to verify that the driver loaded correctly. Then initialize the card.

At the command prompt, type:

```
1 show fips
2
3 FIPS Card is not configured
4
5 <!--NeedCopy-->
```

The message "ERROR: Operation not permitted - no FIPS card present in the system" appears if the driver is not loaded correctly.

Initialize the FIPS card

The appliance must be restarted three times for proper initialization of the FIPS card.

> **Important**
>
> - Verify that the /nsconfig/fips directory has been successfully created on the appliance.
> - Do not save the configuration before you restart the appliance for the third time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card (reset fips).
2. Restart the appliance (reboot).
3. Set the security officer password for partitions 0 and 1, and the user password for partition (set fips -initHSM Level-2 <soPassword> <oldsoPassword> <userPassword> -hsmLabel NSFIPS
).)

   Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration (saveconfig).
5. Verify that the password encrypted key for the main partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance (reboot).
7. Verify that the password encrypted key for the default partition (default_pek.key) has been created in the /nsconfig/fips/ directory.
8. Restart the appliance (reboot).
9. Verify that the FIPS card is UP (show fips).

Initialize the FIPS card by using the CLI

The set fips command initializes the Hardware Security Module (HSM) on the FIPS card and sets a new security officer password and user password.

Caution: This command erases all data on the FIPS card. You are prompted before proceeding with the command execution. A restart is required before and after running this command for the changes to apply. Save the configuration after running this command and before restarting the appliance.

At the command prompt, type the following commands:

```
reset fips

reboot

set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS

```

```
This command will erase all data on the FIPS card. You must save the
    configuration (saveconfig) after executing this command. Do you want
     to continue?(Y/N)y

<!--NeedCopy-->
```

Note: The following message appears when you run the `set fips` command:

```
This command will erase all data on the FIPS card. You must save the
    configuration (saveconfig) after executing this command. [Note: On
    MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by
    default, and the -initHSM Level-2 option is internally converted to
    Level-3]  Do you want to continue?(Y/N)y

saveconfig

reboot

reboot

show fips

        FIPS HSM Info:
                HSM Label               : NetScaler FIPS
                Initialization          : FIPS-140-2 Level-3
                HSM Serial Number       : 3.1G1836-ICM000136
                HSM State               : 2
                HSM Model               : NITROX-III CNN35XX-NFBE
                Hardware Version        : 0.0-G
                Firmware Version        : 1.0
                Firmware Build          : NFBE-FW-1.0-48
                Max FIPS Key Memory     : 102235
                Free FIPS Key Memory    : 102231
                Total SRAM Memory       : 557396
                Free SRAM Memory        : 262780
                Total Crypto Cores      : 63
                Enabled Crypto Cores    : 63

<!--NeedCopy-->
```

Create a FIPS key

You can create a FIPS key on your MPX 14000 FIPS appliance or import an existing FIPS key to the appliance. The MPX 14000 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent

value of F4 (whose value is 65537). For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your appliance.

Specify the key type (RSA or ECDSA). For ECDSA keys, specify only the curve. ECDSA key creation with curve P_256 and P_384 are supported.

> **Note:**
>
> 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

Create a FIPS key by using the CLI

At the command prompt, type:

```
create ssl fipsKey <fipsKeyName> -keytype ( RSA | ECDSA ) [-exponent ( 3 | F4 )] [-modulus <positive_integer>] [-curve ( P_256 | P_384 )]
<!--NeedCopy-->
```

Example1:

```
create fipsKey f1 -keytype RSA -modulus 2048 -exponent F4

show ssl fipskey f1

FIPS Key Name: f1  Key Type: RSA Modulus: 2048   Public Exponent: F4 (Hex: 0x10001)

<!--NeedCopy-->
```

Example2:

```
> create fipskey f2 -keytype ECDSA -curve P_256

> sh fipskey f2
    FIPS Key Name: f2   Key Type: ECDSA Curve: P_256

<!--NeedCopy-->
```

Create a FIPS key by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the FIPS Keys tab, click **Add**.
3. In the Create FIPS Key dialog box, specify values for the following parameters:

- FIPS Key Name*—fipsKeyName
- Modulus*—modulus
- Exponent*—exponent

*A required parameter

4. Click **Create**, and then click **Close**.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you created are correct.

Import a FIPS key

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard disk of the appliance into its HSM.

Note: To avoid errors when importing a FIPS key, ensure that the name of the key imported is the same as the original key name when it was created.

Import a FIPS key by using the CLI

At the command prompt, type:

```
import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-
   wrapKeyName <string>] [-iv<string>] -exponent  F4 ]
<!--NeedCopy-->
```

Example:

```
import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4

import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM

<!--NeedCopy-->
```

Verify that the FIPS key is created or imported correctly by running the `show fipskey` command.

```
show fipskey
1)      FIPS Key Name: Key-FIPS-2

<!--NeedCopy-->
```

Import a FIPS key by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.

2. In the details pane, on the FIPS Keys tab, click **Import**.
3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name* — To put the file in a location other than the default, specify the complete path or click **Browse** and navigate to a location.
   - Exponent*

   *A required parameter
4. Click **Import**, and then click **Close**.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you imported are correct.

Export a FIPS key

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, you cannot create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the `/nsconfig/ssl` folder on the appliance's CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

Export a FIPS key by using the CLI

At the command prompt, type:

```
export ssl fipsKey <fipsKeyName> -key <string>
<!--NeedCopy-->
```

Example:

```
export fipskey Key-FIPS-1 -key Key-FIPS-1.key
<!--NeedCopy-->
```

Export a FIPS key by using the GUI

1. Navigate to **Traffic Management > SSL > FIPS**.

2. In the details pane, on the FIPS Keys tab, click **Export**.
3. In the Export FIPS key to a file dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - File Name*—key (To put the file in a location other than the default, you can either specify the complete path or click the Browse button and navigate to a location.)

   *A required parameter
4. Click **Export**, and then click **Close**.

Import an external key

You can transfer FIPS keys that are created within the Citrix ADC appliance's HSM. You can also transfer external private keys (such as keys created on a standard Citrix ADC, Apache, or IIS) to a Citrix ADC FIPS appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance's flash drive under `/nsconfig/ssl`.

On the MPX 14000 FIPS appliances, the -exponent parameter in the **`import`** `ssl fipskey` command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the -exponent parameter is ignored.

The Citrix ADC FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 14000 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 14000 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

```
openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>
<!--NeedCopy-->
```

Note: If you import an RSA key as a FIPS key, Citrix recommends that you delete the RSA key from the appliance for security purposes.

Import an external key as a FIPS key by using the CLI

1. Copy the external key to the appliance's flash drive.
2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:

```
convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx
    file name> -password <password>
```

```
<!--NeedCopy-->
```

3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:

```
import ssl fipsKey <fipsKeyName> -key <string> -informPEM
show ssl fipskey<fipsKeyName>
<!--NeedCopy-->
```

Example:

```
convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx

import fipskey Key-FIPS-2 -key iis.pem -inform PEM

show ssl fipskey key-FIPS-2

FIPS Key Name: Key-FIPS-2 Modulus: 0   Public Exponent: F4 (Hex value 0
   x10001)
<!--NeedCopy-->
```

Import an external key as a FIPS key by using the GUI

1. If the key is in .pfx format, you must first convert it to PEM format.
   a) Navigate to **Traffic Management > SSL**.
   b) In the details pane, under Tools, click **Import PKCS#12**.
   c) In the Import PKCS12 File dialog box, set the following parameters:
      - Output File Name*
      - PKCS12 File Name*—Specify the .pfx file name.
      - Import Password*
      - Encoding Format

      *A required parameter
2. Navigate to **Traffic Management > SSL > FIPS**.
3. In the details pane, on the FIPS Keys tab, click **Import**.
4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.

   *A required parameter

5. Click **Import**, and then click **Close**.
6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you imported are correct.

Configure FIPS on appliances in an HA setup

You can configure two appliances in an HA pair as FIPS appliances.

Prerequisites

- The Hardware Security Module (HSM) must be configured on both the appliances. For more information, see Configure the HSM.
- When using the GUI, ensure that the appliances are already in an HA setup. For more information about configuring an HA setup, see High availability.

> **Note:**
>
> Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause an inconsistency that requires an appliance restart. In addition, if you use the CLI, the `create ssl fipskey` command is not propagated to the secondary node. When you run the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not the same. Create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).

Important: The HA setup must be completed within six minutes. If the procedure fails at any step, do the following:

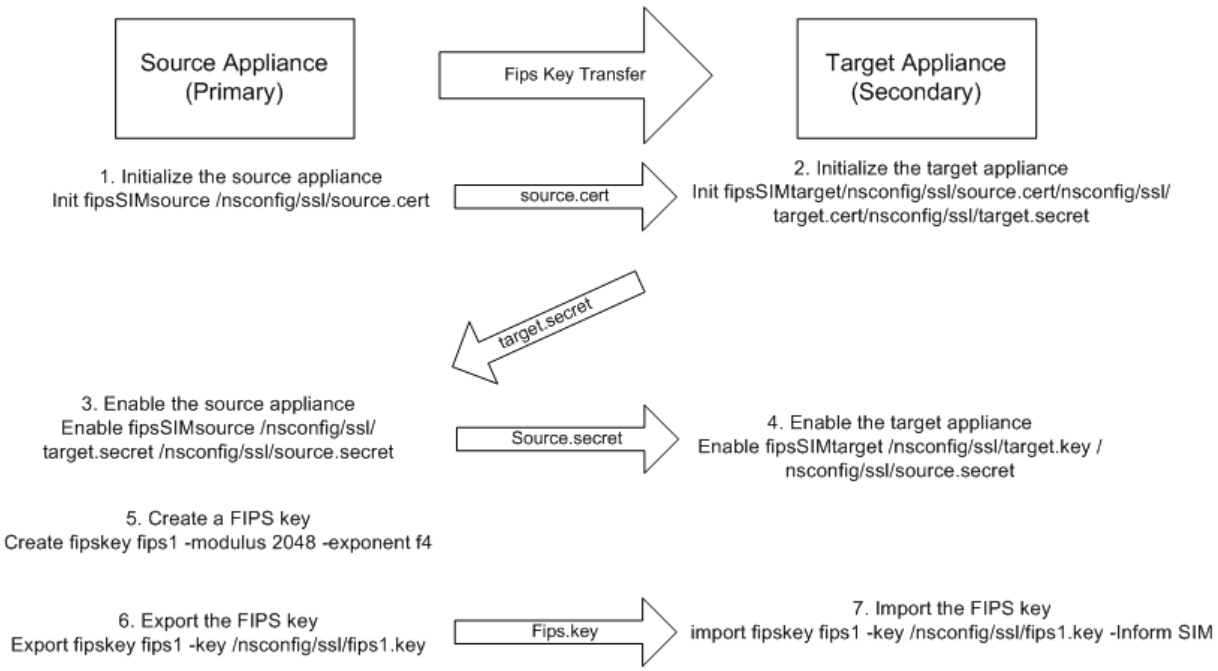
> 1. Restart the appliance or wait for 10 minutes.
> 2. Remove all the files created by the procedure.
> 3. Repeat the HA setup procedure.
>
> Do not reuse existing file names.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.

Configure FIPS on appliances in an HA setup by using the CLI

The following diagram summarizes the transfer process on the CLI.

Figure 1. Transfer the FIPS key-summary



1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance, using the administrator credentials.
3. Initialize appliance A as the source appliance. At the command prompt, type:

```
1 init ssl fipsSIMsource <certFile>
2 <!--NeedCopy-->
```

Example:

```
init fipsSIMsource /nsconfig/ssl/nodeA.cert
```

4. Copy this <certFile> file to appliance B, in the /nconfig/ssl folder.

Example:

```
scp /nsconfig/ssl/nodeA.cert nsroot@198.51.100.10:/nsconfig/ssl
```

5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
6. Log on to the appliance, using the administrator credentials.
7. Initialize appliance B as the target appliance. At the command prompt, type:

```
1 init ssl fipsSIMtarget <certFile> <keyVector> <targetSecret>
2 <!--NeedCopy-->
```

Example:

```
init fipsSIMtarget /nsconfig/ssl/nodeA.cert /nsconfig/ssl/nodeB.key /
nsconfig/ssl/nodeB.secret
```

8. Copy this <targetSecret> file to appliance A.

   Example:

   ```
   scp /nsconfig/ssl/fipslbdal0801b.secret nsroot@198.51.100.20:/nsconfig/
   ssl
   ```

9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:

   ```
   1 enable ssl fipsSIMSource <targetSecret> <sourceSecret>
   2 <!--NeedCopy-->
   ```

   Example:

   ```
   enable fipsSIMsource /nsconfig/ssl/nodeB.secret /nsconfig/ssl/nodeA.
   secret
   ```

10. Copy this <sourceSecret> file to appliance B.

    Example:

    ```
    scp /nsconfig/ssl/fipslbdal0801b.secret nsroot@198.51.100.10:/nsconfig/
    ssl
    ```

11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:

    ```
    1 enable ssl fipsSIMtarget <keyVector> <sourceSecret>
    2 <!--NeedCopy-->
    ```

    Example:

    ```
    enable fipsSIMtarget /nsconfig/ssl/nodeB.key /nsconfig/ssl/nodeA.secret
    ```

12. **On appliance A**, create a FIPS key, as described in Create a FIPS key.
13. Export the FIPS key to the appliance's hard disk, as described in Export a FIPS key.
14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.
15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in Import a FIPS key.

Configure FIPS on appliances in an HA setup by using the GUI

1. On the appliance to be configured as the source (primary) appliance, navigate to **Traffic Management > SSL > FIPS**.
2. In the details pane, on the FIPS Info tab, click **Enable SIM**.
3. In the **Enable SIM for HA Pair** dialog box, in the **Certificate File Name** text box, type the file name. The file name must contain the path to the location at which the FIPS certificate must be stored on the source appliance.

4. In the **Key Vector File Name** text box, type the file name. The file name must contain the path to the location at which the FIPS key vector must be stored on the source appliance.
5. In the **Target Secret File Name** text box, type the location for storing the secret data on the target appliance.
6. In the **Source Secret File Name** text box, type the location for storing the secret data on the source appliance.
7. Under **Secondary System Login Credential**, enter the values for **User Name** and **Password**.
8. Click **OK**. The FIPS appliances are now configured in HA mode.

Note: After configuring the appliances in HA, create a FIPS key, as described in Create a FIPS key. The FIPS key is automatically transferred from the primary to the secondary appliance.

Create a certificate signing request by using the CLI

At the command prompt, type:

```
create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName
    <string>) [-keyform ( DER | PEM )  {
 -PEMPassPhrase  }
 ] -countryName <string> -stateName <string> -organizationName<string>
     [-organizationUnitName <string>] [-localityName <string>] [-
     commonName <string>] [-emailAddress <string>] {
 -challengePassword  }
  [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]
<!--NeedCopy-->
```

Example:

```
>create certreq f1.req  - fipsKeyName  f1 -countryName US  -stateName CA
     -organizationName Citrix -companyName Citrix -commonName ctx -
    emailAddress test@example.com

<!--NeedCopy-->
```

Create a server certificate by using the CLI

At the command prompt, type:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
    input_filename>] [-keyform ( DER | PEM ) {
 -PEMPassPhrase  }
 ] [-days <positive_integer>] [-certForm ( DER | PEM )] [-CAcert <
     input_filename>] [-CAcertForm ( DER | PEM )] [-CAkey <
```

```
        input_filename>][-CAkeyForm ( DER | PEM )] [-CAserial <
        output_filename>]
4 <!--NeedCopy-->
```

Example:

```
1 create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-
     root.key -CAserial ns-root.srl -days 1000
2
3 <!--NeedCopy-->
```

The preceding example creates a server certificate using a local root CA on the appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type:

```
1 add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <
     string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>][-
     expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <
     positive_integer>]] [-bundle ( YES | NO )]
2 <!--NeedCopy-->
```

Example:

```
1 add certkey cert1 -cert f1.cert -fipsKey f1
2
3 <!--NeedCopy-->
```

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server. Save the configuration.

```
1  enable ns feature SSL LB
2
3  add server s1 10.217.2.5
4
5  add service sr1 s1 HTTP 80
6
7  add lb vserver v1 SSL 10.217.2.172 443
8
9  bind ssl vserver v1  - certkeyName cert1
10
11 bind lb vserver v1 sr1
```

```
12
13 saveconfig
14 <!--NeedCopy-->
```

The basic configuration of your MPX 14000 FIPS appliance is now complete.

For information about configuring secure HTTPS, click Configure FIPS.

For information about configuring secure RPC, click Configure FIPS for the first time.

Update the license on an MPX 14000 FIPS appliance

Any update to the license on this platform requires two reboots.

1. Update the license in the `/nsconfig/license` folder.
2. Restart the appliance.
3. Log on to the appliance.
4. Restart the appliance again.
   Note: Do not add new commands, save the config, or check the system state before the second reboot.
5. Log on to the appliance and ensure that FIPS is initialized by running the `show ssl fips` command.

Support for hybrid FIPS mode on the MPX 14000 FIPS and SDX 14000 FIPS platforms

> **Note:**
>
> This feature is supported only on the new MPX/SDX 14000 FIPS platform containing one primary FIPS card and one or more secondary cards. It is not supported on a VPX platform or a platform containing only one type of hardware card.

On a FIPS platform, the asymmetric and symmetric encryption and decryption are performed on the FIPS card for security reasons. However, you can perform part of this activity (asymmetric) on a FIPS card and offload the bulk encryption and decryption (symmetric) to another card without compromising the security of your keys.

The new MPX/SDX 14000 FIPS platform contains one primary card and one or more secondary cards. If you enable the hybrid FIPS mode, the pre-master secret decryption commands are run on the primary card because the private key is stored on this card. However, the bulk encryption and decryption is offloaded to the secondary card. This offload significantly increases the bulk encryption throughput on an MPX/SDX 14000 FIPS platform as compared to non-hybrid FIPS mode and the existing MPX 9700/10500/12500/15000 FIPS platform. Enabling the hybrid FIPS mode also improves the SSL transaction per second on this platform.

> **Notes:**
>
> - The hybrid FIPS mode is disabled by default to meet the strict certification requirements where all the crypto computation must be done inside a FIPS certified module. Enable the hybrid mode to offload the bulk encryption and decryption to the secondary card.
> - On an SDX 14000 FIPS platform, you must first assign an SSL chip to the VPX instance before you enable the hybrid mode.

Enable hybrid FIPS mode by using the CLI

At the command prompt, type:

```
set SSL parameter -hybridFIPSMode {
 ENABLED|DISABLED }

Arguments

hybridFIPSMode

When this mode is enabled, system will use additional crypto hardware
   to accelerate symmetric crypto operations.

Possible values: ENABLED, DISABLED

Default value: DISABLED
<!--NeedCopy-->
```

Example:

```
    set SSL parameter -hybridFIPSMode ENABLED
    show SSL parameter
    Advanced SSL Parameters
    -----------------------
    . . . . . .
    Hybrid FIPS Mode    : ENABLED
    . . . . . .

<!--NeedCopy-->
```

Enable hybrid FIPS mode by using the GUI

1. Navigate to **Traffic Management > SSL**.

2. In the details pane, under **Settings**, click **Change advanced SSL settings**.
3. In the **Change Advanced SSL Settings** dialog box, select **Hybrid FIPS Mode**.

Limitations:

1. Renegotiation is not supported.
2. The `stat ssl parameter` command on an SDX 14000 platform does not display the correct secondary card utilization percentage. It always displays 0.00% utilization.

```
stat ssl

SSL Summary
# SSL cards present 1
# SSL cards UP  1
# Secondary SSL cards present   4
# Secondary SSL cards UP    4
SSL engine status      1
SSL sessions (Rate)     963
Secondary card utilization (%)     0.00
<!--NeedCopy-->
```

SDX 14000 FIPS appliances

September 14, 2021

A Citrix ADC SDX appliance is a multitenant platform on which you can provision and manage multiple virtual Citrix ADC instances. The SDX appliance addresses cloud computing and multitenancy requirements by allowing a single administrator to configure and manage the appliance and delegate the administration of each hosted instance to tenants.

A Citrix ADC SDX 14030/14060/14080 FIPS appliance provides the capabilities of an SDX appliance with FIPS functionality. It is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 12.0 build 56.x). The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module. This module is also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (`nsroot`) can perform operations on the keys stored inside the HSM.

A Citrix ADC SDX 14030/14060/14080 FIPS appliance contains one FIPS HSM module with 63 cores. The FIPS HSM module can be partitioned up to a maximum of 32 partitions. The SDX administrator can assign dedicated key storage, cryptographic resources, and number of crypto SSL FIPS cores to

each partition. Keys and resources allocated to a partition are dedicated and secure and any other partition cannot access or share them.

The FIPS HSM partition that you create can be assigned or attached to a VPX instance at the time of provisioning the instance, or later by editing the instance. The FIPS partition created and attached to an instance acts like a virtual HSM module for that instance.

The VPX instances on an SDX 14030/14060/14080 FIPS appliance are assigned a FIPS virtual function (VF) partition, which is treated as an isolated FIPS virtual card or HSM. Therefore, the steps to configure a FIPS partition inside a VPX instance are similar to the steps to configure an MPX FIPS appliance. For compliance details, see the security policy details on the U.S. National Institute of Standards and Technology (NIST) website.

For information about configuring FIPS appliances in a high availability setup, see FIPS appliances in a high availability setup.

> **Important**
>
> Each key includes a private and a public key. As a result, it occupies two key spaces. Therefore, the maximum number of keys is limited to one less than half the key store size.

The SDX 14000 FIPS platform supports a hybrid FIPS mode. This mode allows you to offload part of the encryption and decryption activity to a non-FIPS card. For more information, see Hybrid FIPS mode.

Limitations

September 14, 2021

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an SDX FIPS appliance.
2. 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.
3. Backup and restore are not supported.
4. Cluster and administrative domains are not supported.
5. You can attach only one FIPS partition to an instance.
6. An instance with a FIPS partition can be assigned only one CPU core.
7. You can assign either a FIPS partition or an SSL core to an instance, but not both.
8. 4096-bit server certificate is not supported.
9. 4096-bit client certificate is not supported (if client authentication is enabled on the back-end server).

Terminology

September 14, 2021

Zeroize: Reset the HSM. All the data on the HSM is deleted. This step is mandatory before the HSM is initialized.

Initialize: Set the HSM capabilities. The Citrix ADC SDX FIPS appliance complies with FIPS-140-2 level 2. You can create partitions after you initialize the chip.

Key store size: Number of keys that can be stored on a partition. A maximum of 102235 keys can be specified. The maximum number of keys that can be stored is one less than half the number specified. For example, if you specify 100, you can create only 49 keys because one of the keys is the RSA key pair that consumes 2 key stores.

Crypto Core Capacity: Number of crypto cores assigned to a partition. A maximum of 63 cores are available.

SSL Context: Number of concurrent SSL connections that can be created on a partition.

Initialize the HSM

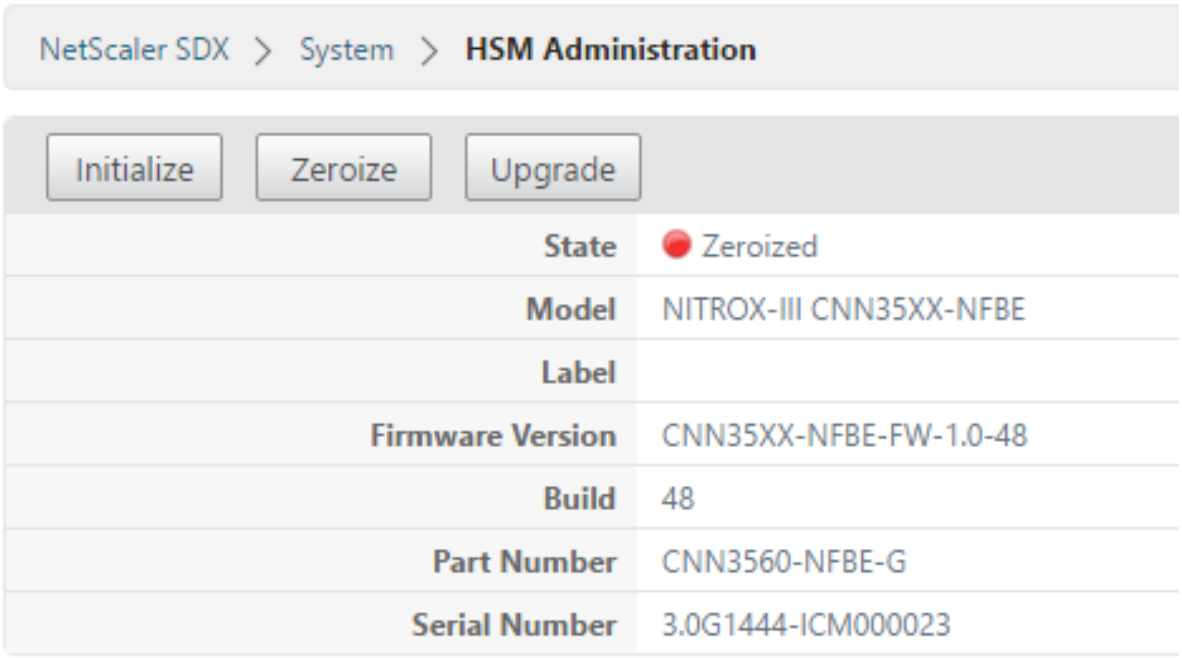
September 14, 2021

Before initializing the HSM, you must first zeroize it.

Zeroize the HSM by using the Management Service

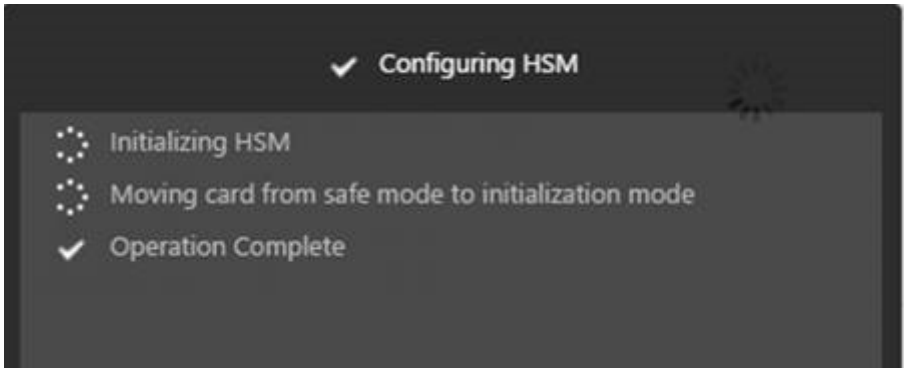
1. Open a browser and log on to the appliance.
2. On the **Configuration** tab, navigate to **System > HSM Administration**, and in the details plane, click **Zeroize**.

All data is wiped from the FIPS chip, and the state appears as “Zeroized.” Any HSM partitions created earlier are deleted.

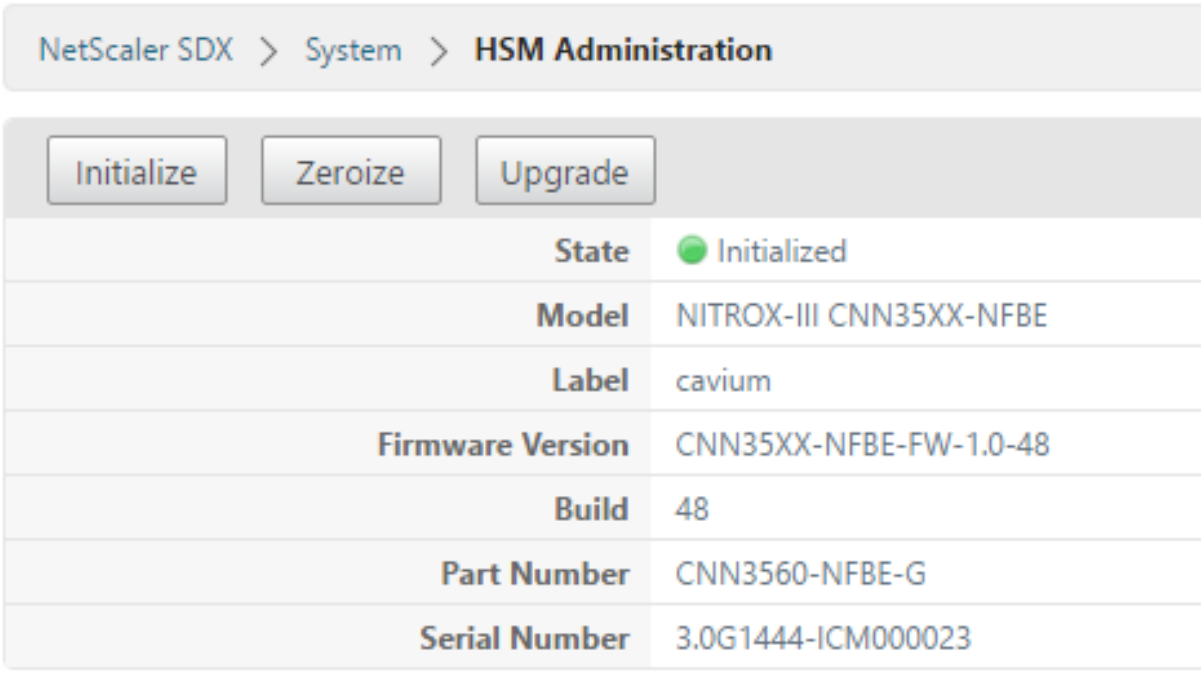


Initialize the HSM by using the Management Service

1. On the **Configuration** tab, navigate to **System > HSM Administration**, and in the details plane, click **Initialize**.
2. Type a new user name, specify a password, and click **OK**.



The card state appears as “Initialized.”



Create partitions

September 14, 2021

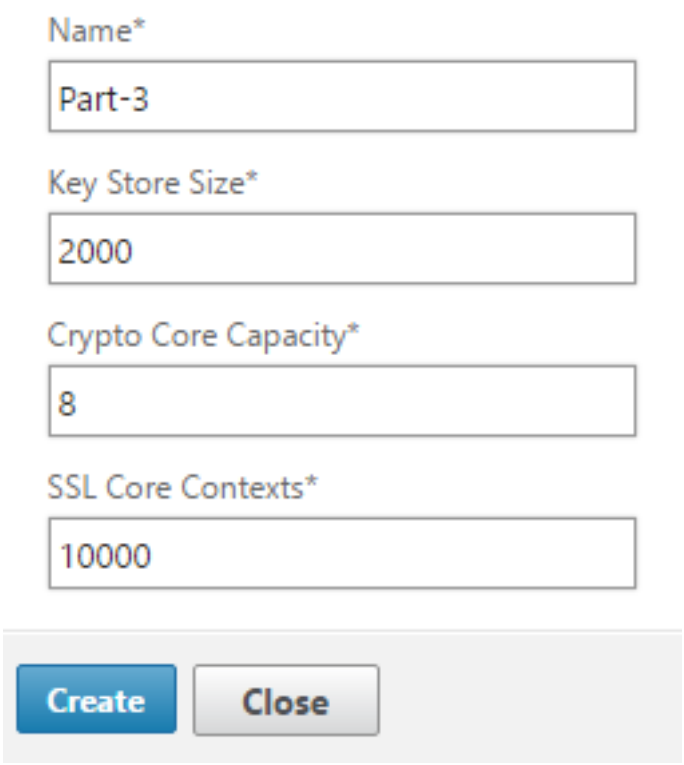
Create partitions for different tenants and specify the cryptographic resources for each partition. Each instance is assigned one partition, and a partition can be assigned to only one instance. Deleting an instance deletes the partition assigned to the instance. As a result, the partition data is also deleted and not left unsecured or accessible later. Number of keys and SSL context assignment depends on your application. For information about the number of cores to assign, see the Citrix ADC data sheet.

> **Important**
>
> After you assign a key store size and cores to an HSM partition, you cannot change them at run time. First detach the partition from the instance.

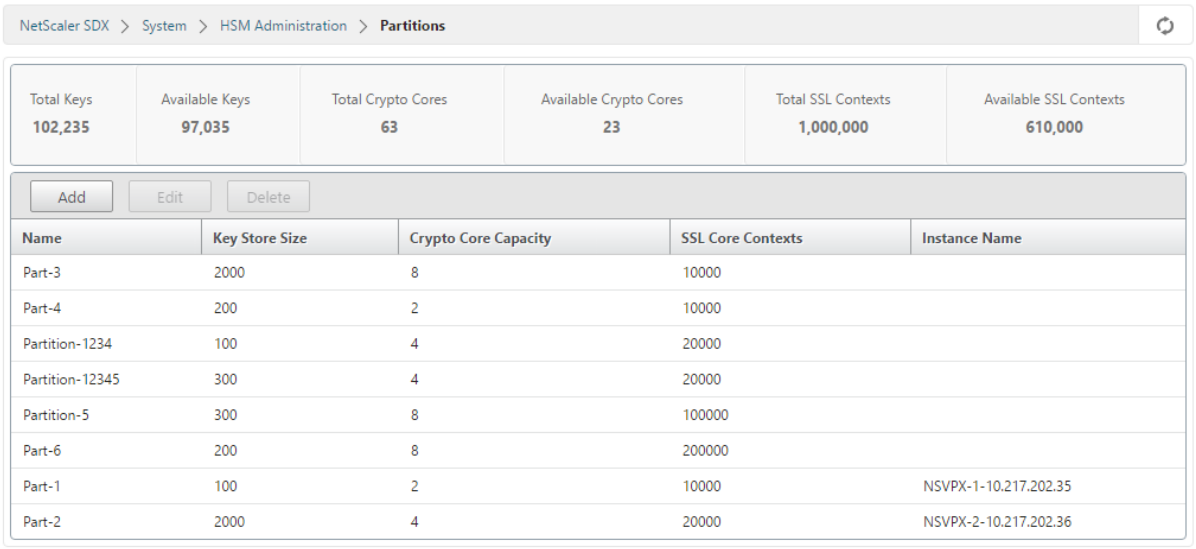
Create a partition by using the Management Service

1. On the Configuration tab, navigate to **System** > **HSM Administration** > **Partitions**, and in the details plane, click **Add**.
2. Specify a name for the partition, and the resources to be assigned to this partition.

3. Click **OK**.



The summary page displays all the partitions that were created. Some partitions are assigned an instance while some are free partitions.



Name	Key Store Size	Crypto Core Capacity	SSL Core Contexts	Instance Name
Part-3	2000	8	10000	
Part-4	200	2	10000	
Partition-1234	100	4	20000	
Partition-12345	300	4	20000	
Partition-5	300	8	100000	
Part-6	200	8	200000	
Part-1	100	2	10000	NSVPX-1-10.217.202.35
Part-2	2000	4	20000	NSVPX-2-10.217.202.36

Provision a new instance or modify an existing instance and assign a partition

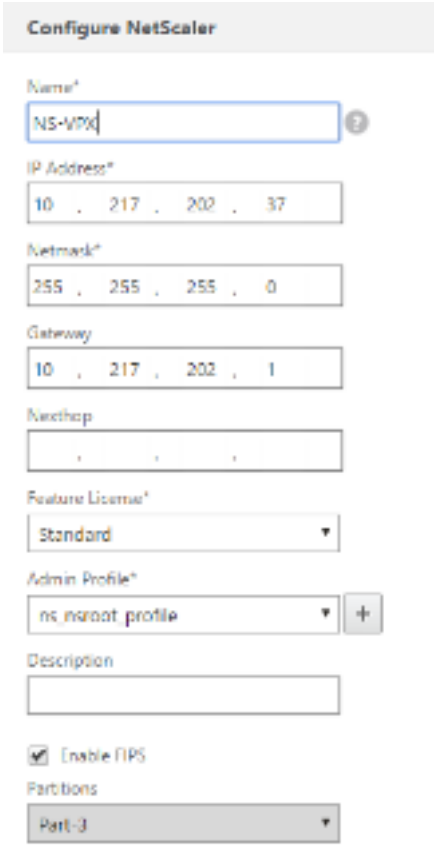
September 14, 2021

After creating the partitions, you must assign them to instances.

> **Important:**
>
> - You can attach only one FIPS partition to an instance.
> - An instance with a FIPS partition can be assigned only one CPU core.

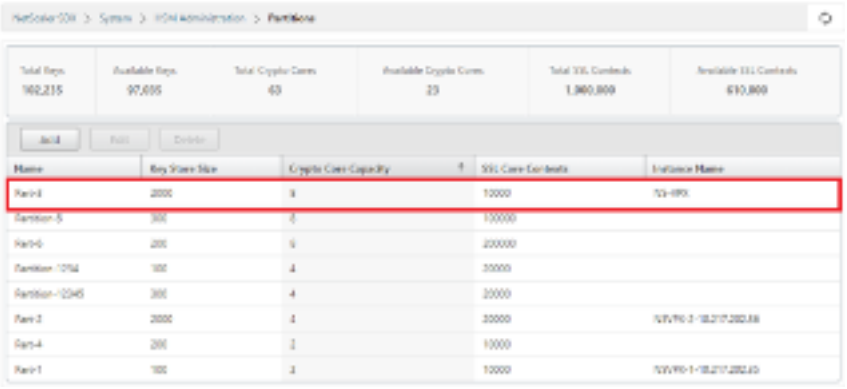
Provision a new instance or modify an existing instance

1. On the Configuration tab, navigate to **NetScaler** > **Instances**, and add or modify an instance.
2. Select **Enable FIPS**, and from the **Partitions** list, select a partition to attach to this instance.



You can verify that the partition is attached to an instance by using either the GUI or the CLI.

In the GUI, navigate to **System** > **HSM Administration** > **Partitions**. The instance name attached to the partition is displayed.



To unassign a FIPS partition , navigate to **NetScaler** > **Instances**. Edit the instance and clear the **Enable FIPS** check box.

In the CLI, at the command prompt, type the following commands:

```
show fips

FIPS Card is not configured
 Done
<!--NeedCopy-->
```

If you see the following output, see the troubleshooting section for debugging.

ERROR: Operation not permitted - no FIPS card present in the system

Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance

October 22, 2021

First check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

```
show fips

FIPS Card is not configured

Done
<!--NeedCopy-->
```

If the driver is not loaded correctly, the message “ERROR: Operation not permitted - no FIPS card present in the system” appears.

Initialize the FIPS card

> **Important:**
>
> Verify that the `/nsconfig/fips` directory has successfully been created on the appliance.

Do not save the configuration before you restart the appliance for the third time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card (`reset fips`).
2. Restart the appliance (`reboot`).
3. Set the security officer password for partitions 0 and 1, and the user password for partition (`set fips -initHSM Level-2 <soPassword> <oldsoPassword> <userPassword> -hsmLabel NSFIPS`).

   Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration (`saveconfig`).
5. Verify that the password encrypted key for the main partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance (`reboot`).
7. Verify that the FIPS card is UP (`show fips`).

Initialize the FIPS card by using the CLI

At the command prompt, type the following commands:

```
reset fips

reboot

set fips -initHSM Level-2 <soPassword> <oldsoPassword> <userPassword> -
    hsmLabel <string>
<!--NeedCopy-->
```

> **Note**: The following message appears when you run the **set fips** command:

```
This command will erase all data on the FIPS card. You must save the
    configuration (saveconfig) after executing this command. [Note: On
    MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by
    default, and the -initHSM Level-2 option is internally converted to
    Level-3]  Do you want to continue?(Y/N)y

saveconfig

reboot

show fips
<!--NeedCopy-->
```

Example:

```
reset fips

Done

reboot

set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS

This command will erase all data on the FIPS card. You must save the
    configuration (saveconfig) after executing this command. [Note: On
    MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by
    default, and the -initHSM Level-2 option is internally converted to
    Level-3]  Do you want to continue?(Y/N)y

Done

saveconfig

Done

reboot

show fips

    FIPS HSM Info:
    HSM Label : NSFIPS
    Initialization : FIPS-140-2 Level-2
    HSM Serial Number : 3.0G1532-ICM000228
    HSM State : 2
```

```

```

Create a FIPS key for an instance on an SDX 14030/14060/14080 FIPS appliance

September 14, 2021

You can create a FIPS key on your instance or import an existing FIPS key into the instance. An SDX 14030/14060/14080 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your instance.

> **Note:**
>
> 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

Create a FIPS key by using the CLI

At the command prompt, type:

```
1  create ssl fipsKey <fipsKeyName> -keytype ( RSA | ECDSA ) [-exponent (3
       | F4 )] [-modulus <positive_integer>] [-curve ( P_256 | P_384 )]
2  <!--NeedCopy-->
```

Example:

```
1  create fipsKey f1 -keytype RSA -modulus 2048 -exponent F4
2
3  Done
4
5  show ssl fipskey ddvws
```

```
6
7 FIPS Key Name: f1  Key Type: RSA Modulus: 2048   Public Exponent: F4 (
     Hex: 0x10001)
8
9 Done
10 <!--NeedCopy-->
```

Import a FIPS key by using the CLI

At the command prompt, type:

```
1 import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-
     wrapKeyName <string>] [-iv<string>] [-exponent F4 ]
2 <!--NeedCopy-->
```

Example:

```
1 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
2 Done
3 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM
4 Done
5 <!--NeedCopy-->
```

Verify that the FIPS key is created or imported correctly by running the **show fipskey** command.

```
1 show fipskey
2 1)      FIPS Key Name: Key-FIPS-2
3 Done
4 <!--NeedCopy-->
```

Create a certificate signing request by using the CLI

At the command prompt, type:

```
1 create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName
     <string>) [-keyform ( DER | PEM )  {
2  -PEMPassPhrase  }
3  ] -countryName <string> -stateName <string> -organizationName<string>
      [-organizationUnitName <string>] [-localityName <string>] [-
      commonName <string>] [-emailAddress <string>] {
4  -challengePassword  }
5   [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]
6 <!--NeedCopy-->
```

Example:

```
create certreq f1.req  - fipsKeyName f1 -countryName US -stateName CA -
    organizationName Citrix -companyName Citrix -commonName ctx -
    emailAddress test@example.com`
`Done
<!--NeedCopy-->
```

Create a server certificate by using the CLI

At the command prompt, type:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
    input_filename>] [-keyform ( DER | PEM ) {
 -PEMPassPhrase  }
 ] [-days <positive_integer>] [-certForm ( DER | PEM )] [-CAcert <
     input_filename>] [-CAcertForm ( DER | PEM )] [-CAkey <
     input_filename>] [-CAkeyForm ( DER | PEM )] [-CAserial <
     output_filename>]
<!--NeedCopy-->
```

Example:

```
create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-
    root.key -CAserial ns-root.srl -days 1000
Done
<!--NeedCopy-->
```

The preceding example creates a server certificate using a local root CA on the appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <
    string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>]
    [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod   <
    positive_integer>]] [-bundle ( YES | NO )]
<!--NeedCopy-->
```

Example:

```
add certkey cert1 -cert f1.cert -fipsKey f1
Done
```

```
<!--NeedCopy-->
```

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server, and save the configuration.

```
enable ns feature SSL LB
Done
add server s1 10.217.2.5
Done
add service sr1 s1 HTTP 80
Done
add lb vserver v1 SSL 10.217.2.172 443
Done
bind ssl vserver v1  -certkeyName cert1
Done
bind lb vserver v1 sr1
Done
saveconfig
Done
<!--NeedCopy-->
```

For information about configuring secure HTTPS and secure RPC, click here.

Upgrade the FIPS firmware on a VPX instance

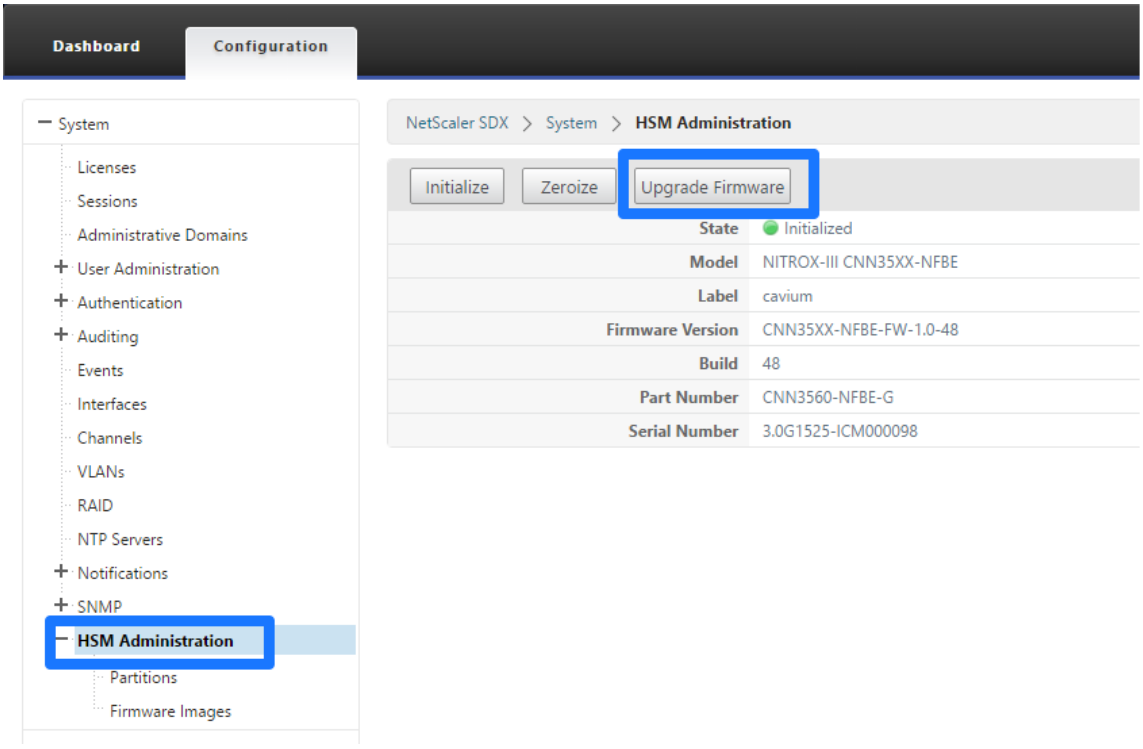
September 14, 2021

FIPS firmware updates are released from time to time. Download the latest firmware from the Citrix download page and upload it to the appliance. The upgrade process might take up to 10 minutes to complete. The instance is restarted after the upgrade.

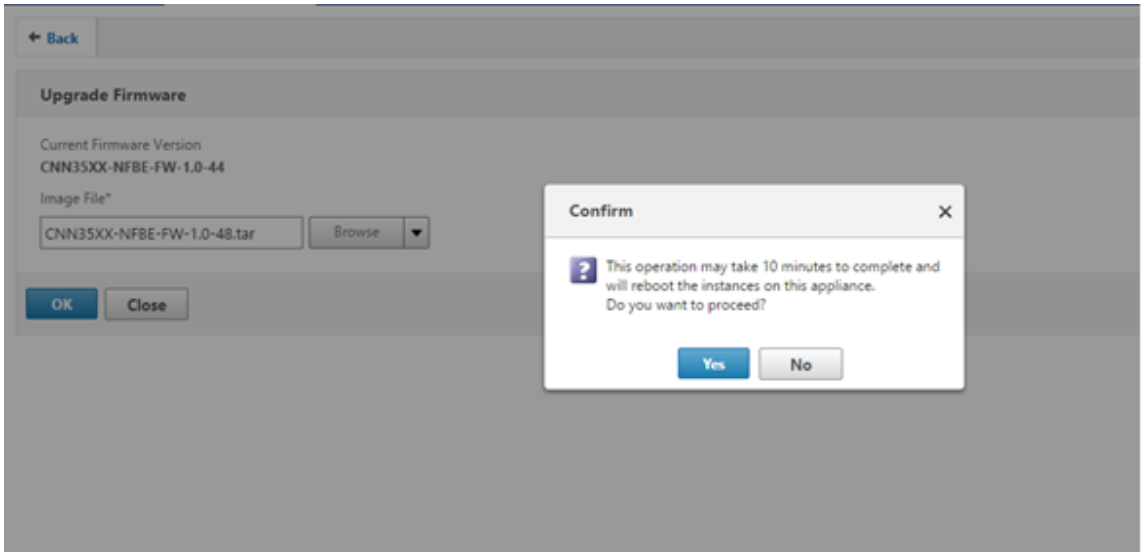
Upgrade the FIPS firmware

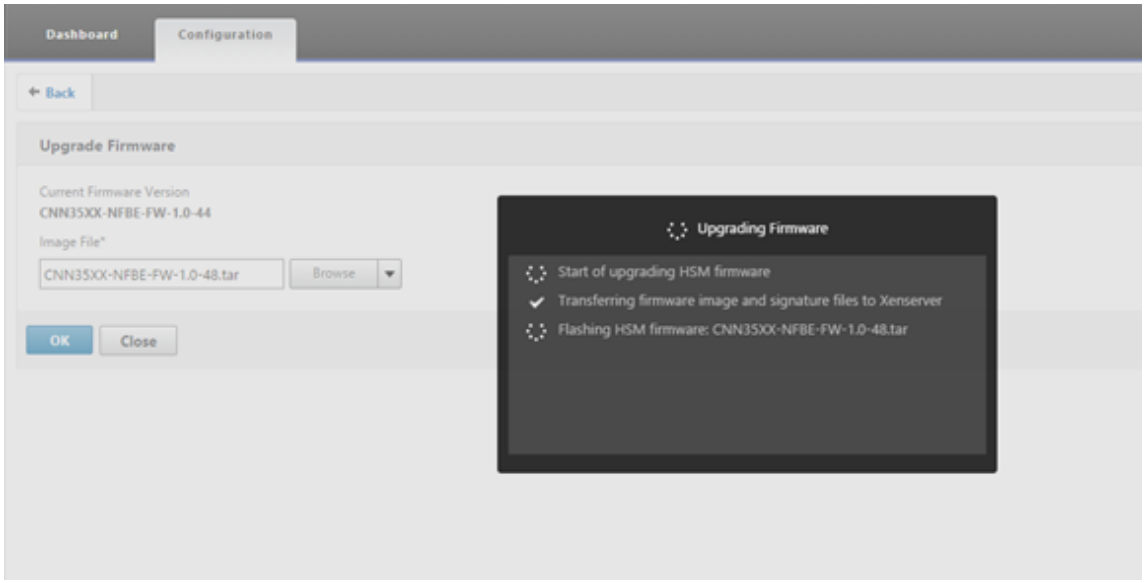
1. Navigate to **System > HSM Administration > Firmware Images**.
2. Select **Upload**.

3. Navigate to the folder that contains the firmware image and select the file.
4. Navigate to **System > HSM Administration**, and select **Upgrade Firmware**.



5. Select the firmware image to upgrade to, and click **OK**.





Support for nShield Connect hardware security module (HSM)

September 14, 2021

A non-FIPS Citrix ADC appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as the HSM. Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted by using special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX appliances, or on the SDX and VPX appliances. This limitation is addressed by supporting a nShield Connect external HSM on all Citrix ADC MPX, SDX, and VPX appliances

except the MPX 9700/10500/12500/15500 FIPS appliances.

nShield® Connect is an external FIPS-certified network-attached HSM. With an nShield HSM, the keys are securely stored as application key tokens on a remote file server (RFS) and can be reconstituted inside the nShield HSM only.

If you are already using a nShield HSM, you can now use a Citrix ADC to optimize, secure, and control the delivery of all enterprise and cloud services.

Note:

- nShield HSMs comply with FIPS 140-2 Level 3 specifications, while the MPX FIPS appliances comply with level 2 specifications.
- You cannot decrypt the trace while using the nShield HSM. Only the `hardserver` can read the response from the HSM to the Citrix ADC appliance, because it is encrypted.

Supported versions matrix

Citrix ADC Version	nShield Client Version	`Hardserver` Version	nShield Firmware Version
10.5e, 11.0, 11.1, 12.0, 12.1	11.70, 11.72	2.71.2	2.50.16, 2.51.10

Architecture overview

September 14, 2021

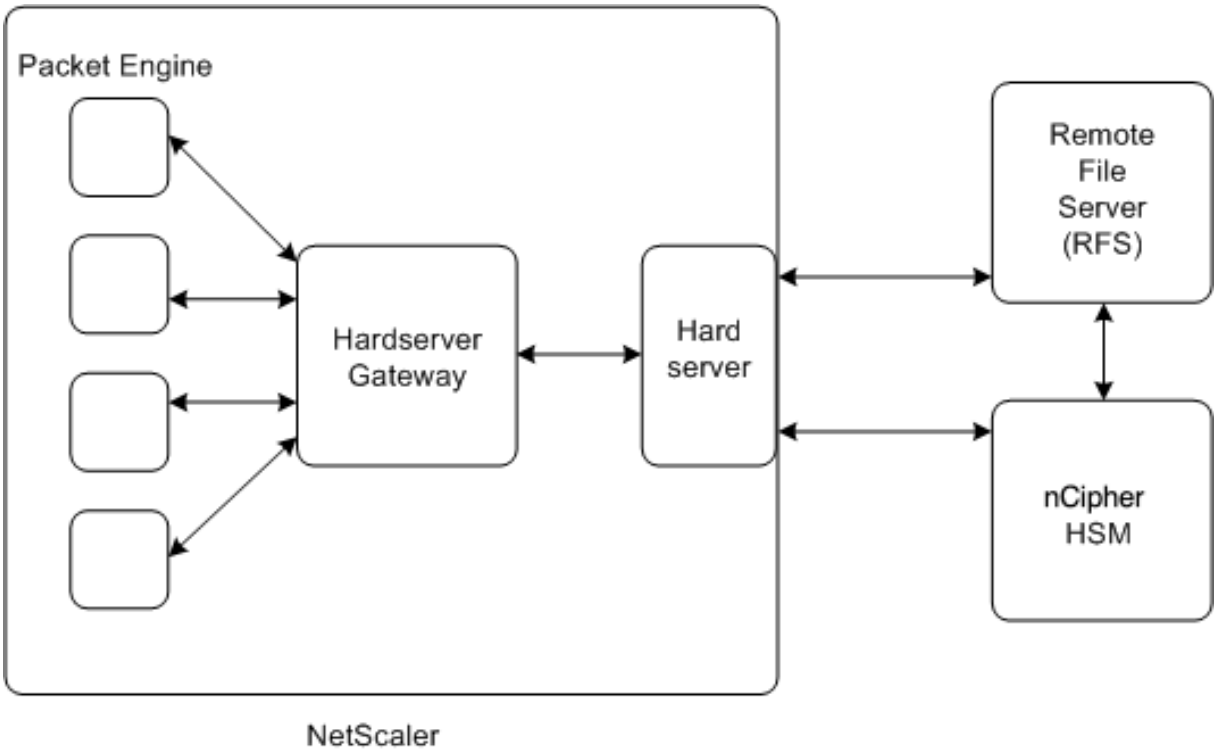
The three entities that are part of a Citrix ADC-Entrust deployment are an Entrust nShield Connect module, a remote file server (RFS), and a Citrix ADC.

The Entrust nShield Connect is a network-attached hardware security module. The RFS is used to configure the HSM and to store the encrypted key files.

`Hardserver`, a proprietary daemon provided by Entrust, is used for communication between the client (ADC), the Entrust HSM, and the RFS. It uses the IMPATH secure communication protocol. A gateway daemon, called the `Hardserver Gateway`, is used to communicate between the Citrix ADC packet engine and the `Hardserver`.

Note: The terms Entrust nShield Connect, Entrust HSM, and HSM are used interchangeably in this documentation.

The following figure illustrates the interaction between the different components.

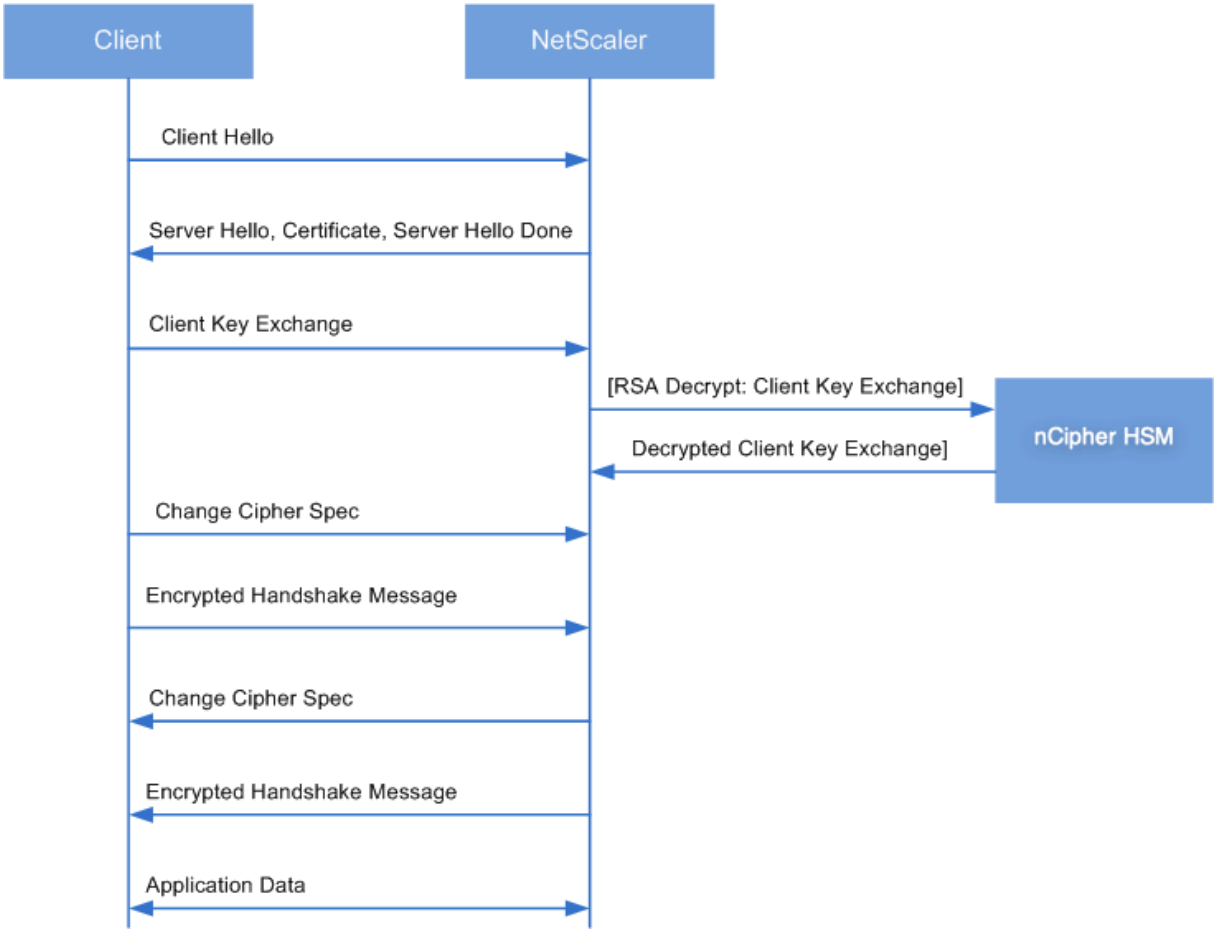


In a typical deployment, the RFS is used to securely store keys generated by the HSM. After the keys are generated, you can securely transfer them to the ADC and then use the GUI or command line to load the keys to the HSM. A virtual server on the ADC uses Entrust to decrypt the client key exchange to complete the SSL handshake. Thereafter, all the SSL operations are performed on the ADC.

Note: The terms keys and application key tokens are used interchangeably in this documentation.

The following figure illustrates the packet flow in the SSL handshake with the Entrust HSM.

Figure 1. SSL Handshake Packets Flow Diagram with Citrix ADC Using Entrust HSM



Note: The communication between the ADC and the HSM uses an Entrust proprietary communication protocol, called IMPATH.

Prerequisites

September 14, 2021

Before you can use an Entrust nShield Connect with a Citrix ADC, make sure that the following prerequisites are met:

- A Entrust nShield Connect device is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address is added as an authorized client on the HSM.
- A usable Security World exists. Security World is a unique key management architecture used by the Entrust nShield line of HSMs. It protects and manages keys as application key tokens, enabling unlimited key capacity, and automatic key backup and recovery. For more information about creating a Security World, see the nShield Connect Quick Start Guide from Entrust. You can also find the guide in the CD provided with the Entrust HSM module at CipherTools-linux-

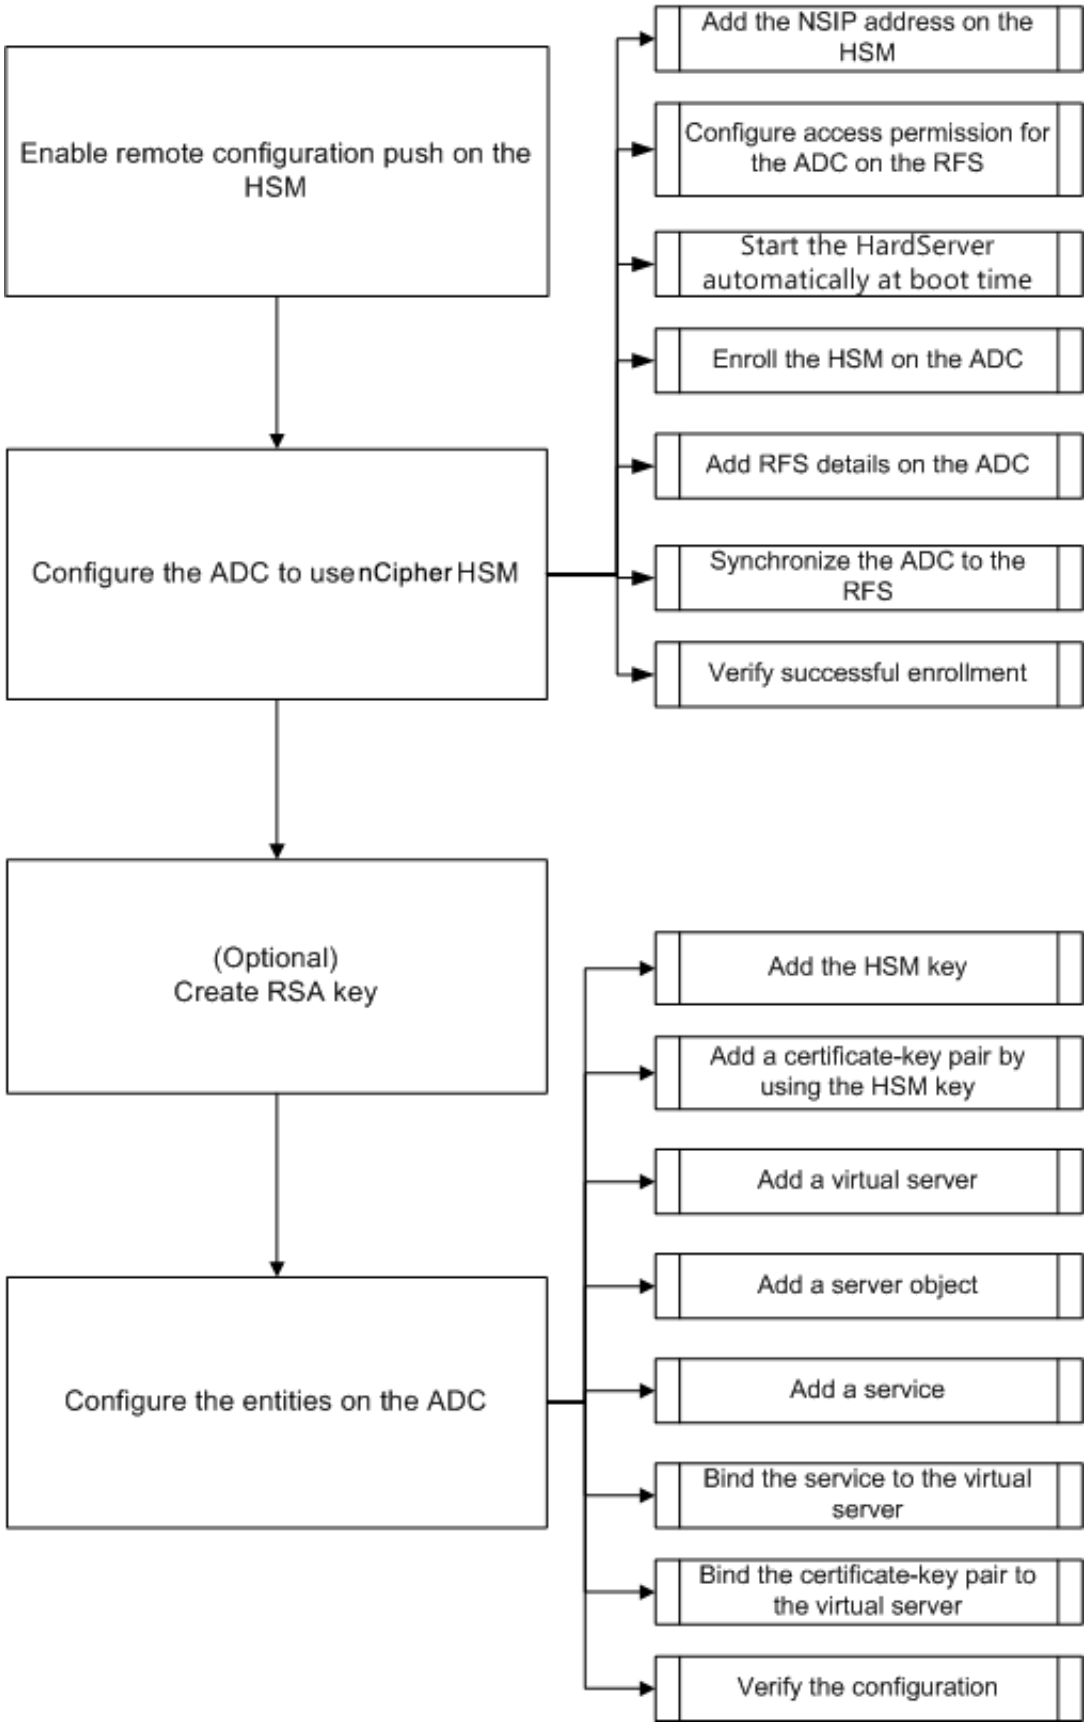
dev-xx.xx.xx/document/nShield_Connect_Quick_Start_Guide.pdf.
Note: `Softcard` or token/OCS protected keys are currently not supported on the Citrix ADC.

- Licenses are available to support the number of clients that are connected to the Entrust HSM. The ADC and remote file server (RFS) are clients of the HSM.
- An RFS is installed in the network and is accessible to the Citrix ADC.
- The Entrust nShield Connect device, the RFS, and the Citrix ADC can initiate connections with each other through port 9004.
- You are using NetScaler release 10.5 build 52.1115.e or later.
- The Citrix ADC appliance does not contain a FIPS Cavium card.
  Important: Entrust HSM is not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

Configure the ADC-Entrust integration

September 14, 2021

The following flowchart depicts the tasks that you need to perform to use Entrust HSM with a Citrix ADC:



As shown in the preceding flowchart, you perform the following tasks:

1. Enable remote configuration push, on the HSM.
2. Configure the ADC to use the Entrust HSM.
    - Add the NSIP address on the HSM.
    - Configure access permission for the ADC on the RFS.
    - Configure automatic start of the `Hardserver` at boot time.
    - Enroll the HSM on the ADC.
    - Add RFS details on the ADC.
    - Synchronize the ADC to the RFS.
    - Verify that Entrust HSM is successfully enrolled on the ADC.
3. (Optional) Create an HSM RSA key.
4. Configure the entities on the Citrix ADC.
    - Add the HSM key.
    - Add a certificate-key pair by using the HSM key.
    - Add a virtual server.
    - Add a server object.
    - Add a service.
    - Bind the service to the virtual server.
    - Bind the certificate-key pair to the virtual server.
    - Verify the configuration.

Configure the Entrust HSM

Specify the IP address of the RFS on the Entrust HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Entrust HSM to perform the following procedure.

Specify the IP address of a remote computer on the Entrust HSM

1. Navigate to **System Configuration > Config file options > Allow auto push**.
2. Select **ON**, and specify the IP address of the computer (RFS) from which to accept the configuration.

Enable pushing the remote configuration on the HSM

Specify the IP address of the RFS on the Entrust HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Entrust HSM to perform the following procedure.

Specify the IP address of a remote computer on the Entrust HSM

1. Navigate to **System Configuration > Config file options > Allow auto push**.
2. Select **ON**, and specify the IP address of the computer (RFS) from which to accept the configuration.

Configure the ADC to use the Entrust HSM

Sample values used in this documentation:

NSIP address=10.217.2.43

Entrust HSM IP address=10.217.2.112

RFS IP address=10.217.2.6

Add the NSIP address on the HSM

Typically you use the nShield Connect front panel to add clients to the HSM. For more information, see the nShield Connect Quick Start Guide.

Alternately, use the RFS to add the ADC as a client to the HSM. To add the ADC, you must add the NSIP address in the HSM configuration on the RFS, and then push the configuration to the HSM. Before you can push the configuration, you must know the electronic serial number (ESN) of the HSM.

To get the ESN of your HSM, run the following command on the RFS:

```
root@ns# /opt/nfast/bin/anonkneti <Entrust HSM IP address>
<!--NeedCopy-->
```

Example:

```
root@ns# /opt/nfast/bin/anonkneti 10.217.2.112
BD17-C807-58D9 5e30a698f7bab3b2068ca90a9488dc4e6c78d822
<!--NeedCopy-->
```

The ESN number is BD17-C807-58D9.

After you have the ESN number, use an editor, such as vi, to edit the HSM configuration file on the RFS.

```
vi /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
<!--NeedCopy-->
```

In the `hs_clients` section, add the following entries:

```
# Amount of data in bytes to encrypt with a session key before session
    key# renegotiation, or 0 for unlimitied. (default=1024*1024*8b=8Mb).
```

```
#  datalimit=INT
addr=10.217.2.43
clientperm=unpriv
keyhash=0000000000000000000000000000000000000000
esn=
timelimit=86400
datalimit=8388608
-----
<!--NeedCopy-->
```

Note: Include one or more hyphens as delimiters to add multiple entries in the same section.

To push the configuration to the HSM, run the following command on the RFS:

```
/opt/nfast/bin/cfg-pushnethsm --address=<Entrust HSM IP address> --
   force /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
<!--NeedCopy-->
```

Example:

```
/opt/nfast/bin/cfg-pushnethsm --address=10.217.2.112 --force
                /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
<!--NeedCopy-->
```

Configure access permission for the ADC on the RFS

To configure access permission for the ADC on the RFS, run the following command on the RFS:

```
/opt/nfast/bin/rfs-setup --force -g --write-noauth <NetScaler IP
   address>
<!--NeedCopy-->
```

Example:

```
[root@localhost bin]# /opt/nfast/bin/rfs-setup --force -g --write-
   noauth 10.217.2.43
Adding read-only remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local exists
Adding new writable remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local/sync-store exists
Saving the new config file and configuring the hardserver
Done
<!--NeedCopy-->
```

Verify that the ADC can reach both the RFS and Entrust HSM by using port 9004.

Configure automatic start of the hardserver at boot time

Create a file and then restart the appliance. Now, whenever you restart the appliance, and if this file is found, the Hardserver is automatically started.

At the shell prompt, type:

```
touch /var/opt/nfast/bin/thales_hsm_is_enrolled
<!--NeedCopy-->
```

At the command prompt, type:

```
reboot
<!--NeedCopy-->
```

Enroll the HSM on the ADC

Change directory to /var/opt/nfast/bin.

To add HSM details into the ADC configuration, run the following command on the ADC:

```
nethsmenroll --force <Thales_nShield_Connect_ip_address> $(anonkneti <Thales_nShield_Connect_ip_address>)
```

Example:

```
root@ns# ./nethsmenroll --force 10.217.2.112 $(anonkneti 10.217.2.112)
OK configuring hardserver's nethsm imports
<!--NeedCopy-->
```

This step adds the following entries after the line # ntoken_esn=ESN in the nethsm_imports section of the /var/opt/nfast/kmdata/config/config file.

```
...
local_module=0
remote_ip=10.217.2.112
remote_port=9004
remote_esn=BD17-C807-58D9
keyhash=5e30a698f7bab3b2068ca90a9488dc4e6c78d822
timelimit=86400
datalimit=8388608
privileged=0
privileged_use_high_port=0
ntoken_esn=
<!--NeedCopy-->
```

Change the directory to /var/opt/nfast/bin and run the following command on the ADC:

```
touch "thales_hsm_is_enrolled"
<!--NeedCopy-->
```

Note: To remove an HSM that is enrolled on the ADC, type:

```
./nethsmenroll - -remove <NETHSM-IP>
<!--NeedCopy-->
```

Add RFS details on the ADC

To add RFS details, change the directory to /var/opt/nfast/bin/ and then run the following command:

```
./rfs-sync --no-authenticate --setup <rfs_ip_address>
<!--NeedCopy-->
```

Example:

```
./rfs-sync --no-authenticate --setup 10.217.2.6
No current RFS synchronization configuration.
Configuration successfully written; new config details:
Using RFS at 10.217.2.6:9004: not authenticating.
<!--NeedCopy-->
```

This step adds the following entries after the # local_esn=ESN line in the `rfs_sync_client` section of the /var/opt/nfast/kmdata/config/config file.

```
... ...
remote_ip=10.217.2.6
remote_port=9004
use_kneti=no
local_esn=
<!--NeedCopy-->
```

Note: To remove an RFS that is enrolled on the ADC, type:

```
./rfs_sync - remove
<!--NeedCopy-->
```

Synchronize the ADC to the RFS

To synchronize all the files, change the directory to /var/opt/nfast/bin and then run the following command on the ADC:

```
./rfs-sync - -update
<!--NeedCopy-->
```

This command fetches all the World files, module files, and key files from the /opt/nfast/kmdata/local directory on the RFS and puts them into the /var/opt/nfast/kmdata/local directory on the ADC. Citrix recommends that you manually copy the World files, the module_XXXX_XXXX_XXXX files, where XXXX_XXXX_XXXX is the ESN of the enrolled HSM, and only the required RSA key and certificate files.

Verify the Entrust HSM is successfully enrolled on the ADC

After you synchronize the ADC to the RFS, do the following:

- Verify that the local `Hardserver` is UP and running. (Entrust server running).
- Get the state of the configured HSMs, and verify that the values for the n_modules (number of modules) field and the km info fields are non-zero.
- Verify that the HSM is enrolled correctly and is usable (state 0x2 Usable) by the ADC.
- Load tests using `sigtest` run properly.

Change the directory to /var/opt/nfast/bin, and at the shell prompt, run the following commands:

```
root@ns# ./chkserv root@ns# ./nfkminfo root@ns# ./sigtest
<!--NeedCopy-->
```

See Appendix for an example.

Create an HSM RSA Key

Only RSA keys are supported as HSM keys.

Note: Skip this step if keys are already present in the `/opt/nfast/kmdata/local` folder on the RFS.

Create an RSA key, a self-signed certificate, and a Certificate Signing Request (CSR). Send the CSR to a certificate authority to get a server certificate.

The following files are created in the following example:

- Embed RSA key: key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78
- Self-Signed Certificate: example_selfcert
- Certificate Signing Request: example_req

Note: The `generatekey` command is supported in strict FIPS 140-2 Level 3 Security World. An administrator card set (ACS) or an operator card set (OCS) is needed to control many operations, including the creation of keys and OCSs. When you run the `generatekey` command, you are prompted to insert an ACS or OCS card. For more information about strict FIPS 140-2 Level 3 Security World, see the nShield Connect User Guide.

The following example uses Level-2 Security World. In the example, the commands are in boldface type.

Example:

```
[root@localhost bin]# ./generatekey embed
size: Key size? (bits, minimum 1024) [1024] > 2048
OPTIONAL: pubexp: Public exponent for RSA key (hex)? []
>
embedsavefile: Filename to write key to? []
> example
plainname: Key name? [] > example
x509country: Country code? [] > US
x509province: State or province? [] > CA
x509locality: City or locality? [] > Santa Clara
x509org: Organisation? [] > Citrix
x509orgunit: Organisation unit? [] > NS
x509dnscommon: Domain name? [] > www.citrix.com
x509email: Email address? [] > example@citrix.com
nvram: Blob in NVRAM (needs ACS)? (yes/no) [no] >
digest: Digest to sign cert req with? (md5, sha1, sha256, sha384,
    sha512)
  [default sha1] > sha512
key generation parameters:
 operation      Operation to perform              generate
 application    Application                       embed
 verify         Verify security of key            yes
 type           Key type                          RSA
 size           Key size                          2048
 pubexp         Public exponent for RSA key (hex)
 embedsavefile  Filename to write key to          example
 plainname      Key name                          example
 x509country    Country code                      US
 x509province   State or province                 CA
 x509locality   City or locality                  Santa Clara
 x509org        Organisation                      Citrix
 x509orgunit    Organisation unit                 NS
 x509dnscommon  Domain name                       www.citrix.com
 x509email      Email address                     example@citrix.com
 nvram          Blob in NVRAM (needs ACS)         no
 digest         Digest to sign cert req with      sha512
Key successfully generated.
Path to key: /opt/nfast/kmdata/local/
    key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78
You have new mail in /var/spool/mail/root
```

```
<!--NeedCopy-->
```

Result:

You have created a CSR (example_req), a self-signed certificate (example_selfcert), and an application key token file in embed format (/opt/nfast/kmdata/local/key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2

Because the ADC supports keys in simple format only, you must convert the embed key to a simple key.

To convert the embed key to a simple key, run the following command on the RFS:

```
[root@localhost bin]# ./generatekey -r simple
from-application: Source application? (embed, simple) [embed] > embed
from-ident: Source key identifier? (
   c6410ca00af7e394157518cb53b2db46ff18ce29,
                                    2
                                       ed5428aaeae1e159bdbd63f25292c7113ec2c78
                                       )
  [default c6410ca00af7e394157518cb53b2db46ff18ce29]
> 2ed5428aaeae1e159bdbd63f25292c7113ec2c78
ident: Key identifier? [] > examplersa2048key
plainname: Key name? [] > examplersa2048key
key generation parameters:
 operation         Operation to perform    retarget
 application       Application             simple
 verify            Verify security of key  yes
 from-application  Source application      embed
 from-ident        Source key identifier   2
    ed5428aaeae1e159bdbd63f25292c7113ec2c78
 ident             Key identifier          examplersa2048key
 plainname         Key name                examplersa2048key
Key successfully retargetted.
Path to key: /opt/nfast/kmdata/local/key_simple_examplersa2048key
<!--NeedCopy-->
```

> **Important:**
>
> When prompted for the source key identifier, enter **2ed5428aaeae1e159bdbd63f25292c7113ec2c78** as the embed key.

Result:

A key with the prefix key_simple (for example key_simple_examplersa2048key) is created.

Note: examplersa2048key is the key identifier (ident) and is referred to as the HSM key name on the ADC. A key identifier is unique. All the simple files have the prefix key_simple.

Configure the entities on the ADC

Before the ADC can process traffic, you must do the following:

1. Enable features.
2. Add a subnet IP (SNIP) address.
3. Add the HSM key to the ADC.
4. Add a certificate-key pair by using the HSM key.
5. Add a virtual server.
6. Add a server object.
7. Add a service.
8. Bind the service to the virtual server.
9. Bind the certificate-key pair to the virtual server.
10. Verify the configuration.

Enable features on the ADC

Licenses must be present on the ADC before you can enable a feature.

Enable a feature by using the CLI

At the command prompt, run the following commands:

```
enable feature lb
enable feature ssl
<!--NeedCopy-->
```

Enable a feature by using the GUI

Navigate to **System** > **Settings** and, in the **Modes and Features** group, select **Configure basic features**, and then select **SSL Offloading**.

Add a subnet IP address

For more information about subnet IP addresses, see Configuring Subnet IP Addresses.

Add a SNIP address and verify the configuration by using the CLI

At the command prompt, run the following commands:

```
add ns ip <IPAddress> <netmask> -type SNIP
show ns ip
<!--NeedCopy-->
```

Example:

```
add ns ip 192.168.17.253 255.255.248.0 -type SNIP
Done
show ns ip
        Ipaddress        Traffic Domain  Type             Mode     Arp
                 Icmp     Vserver  State
        ---------        --------------  ----             ----     ---
                 ----     -------  ------
1)      192.168.17.251   0               NetScaler IP     Active
   Enabled  Enabled  NA       Enabled
2)      192.168.17.252   0               VIP              Active
   Enabled  Enabled  Enabled  Enabled
3)      192.168.17.253   0               SNIP              Active
   Enabled  Enabled  NA       Enabled
 Done
<!--NeedCopy-->
```

Add a SNIP address and verify the configuration by using the GUI

Navigate to **System > Network > IPs**, add an IP address, and select the **IP Type as Subnet IP**.

Copy the HSM key and certificate to the ADC

Use a secure file transfer utility to securely copy the key (key_simple_examplersa2048key) to the `/var/opt/nfast/kmdata/local` folder, and the certificate (example_selfcert) to the `/nsconfig/ssl` folder on the ADC.

Add the key on the ADC

All the keys have a key-simple prefix. When adding the key to the ADC, use the ident as the HSM key name. For example, if the key that you added is key_simple_XXXX, the HSM key name is XXXX.

Important:

- The HSM key name must be the same as the ident that you specified when you converted an embed key to a simple key format.
- The keys must be present in the `/var/opt/nfast/kmdata/local/` directory on the ADC.

Add an HSM key by using the CLI

At the shell prompt, run the following command:

```
add ssl hsmKey <hsmKeyName> -key <string>
<!--NeedCopy-->
```

Example:

```
add ssl hsmKey examplersa2048key  - key key_simple_examplersa2048key
Done
<!--NeedCopy-->
```

Add an HSM key by using the GUI

Navigate to **Traffic Management > SSL > HSM**, and add an HSM key.

Add a certificate-key pair on the ADC

For information about certificate-key pairs, see Add or update a certificate-key pair.

Add a certificate-key pair by using the CLI

At the command prompt, run the following command:

```
add ssl certKey <certkeyName> -cert <string> -hsmKey <string>
<!--NeedCopy-->
```

Example:

```
add ssl certKey key22 -cert example_selfcert -hsmKey examplersa2048key
Done
<!--NeedCopy-->
```

Add a certificate-key pair by using the GUI

Navigate to **Traffic Management > SSL > Certificates**, and add a certificate-key pair.

Add a virtual server

For information about a virtual server, see SSL virtual server configuration.

Configure an SSL-based virtual server by using the CLI

At the command prompt, run the following command:

```
add lb vserver <name> <serviceType> <IPAddress> <port>
<!--NeedCopy-->
```

Example:

```
add lb vserver v1 SSL 192.168.17.252 443
<!--NeedCopy-->
```

Configure an SSL-based virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, create a virtual server, and specify the protocol as SSL.

Add a server object

Before you can add a server object on the ADC, make sure that you have created a back-end server. The following example uses the built-in python HTTP Server module on a Linux system.

Example:

```
%python  -m SimpleHTTPServer 80
<!--NeedCopy-->
```

Add a server object by using the CLI

At the command prompt, run the following command:

```
add server <name> <IPAddress>
<!--NeedCopy-->
```

Example:

```
add server s1 192.168.17.246
<!--NeedCopy-->
```

Add a server object by using the GUI

Navigate to **Traffic Management > Load Balancing > Servers**, and add a server.

Add a service

For more information, see Configuring services.

Configure a service by using the CLI

At the command prompt, run the following command:

```
add service <name> <serverName> <serviceType> <port>
<!--NeedCopy-->
```

Example:

```
add service sr1 s1 HTTP 80
<!--NeedCopy-->
```

Configure a service by using the GUI

Navigate to **Traffic Management > Load Balancing > Services**, and create a service.

Bind the service to the virtual server

For more information, see Bind services to the SSL virtual server.

Bind a service to a virtual server by using the CLI

At the command prompt, run the following command:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver v1 sr1
<!--NeedCopy-->
```

Bind a service to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the Services pane to bind a service to the virtual server.

Bind the certificate-key pair to the virtual server on the ADC

For more information, see Bind the certificate-key pair to the SSL virtual server.

Bind a certificate-key pair to a virtual server by using the CLI

At the command prompt, run the following command:

```
bind ssl vserver <vServerName> -certkeyName <string>
<!--NeedCopy-->
```

Example:

```
bind ssl vserver v1 -certkeyName key22
Warning: Current certificate replaces the previous binding
<!--NeedCopy-->
```

Bind a certificate-key pair to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open an SSL virtual server and, in **Advanced Settings**, click **SSL Certificate**.
3. Bind a server certificate to the virtual server.

Verify the configuration

To view the configuration by using the CLI:

At the command prompt, run the following commands:

```
show lb vserver <name>
show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
show lb vserver v1
        v1 (192.168.17.252:443) - SSL   Type: ADDRESS
        State: UP
        Last state change was at Wed Oct 29 03:11:11 2014
        Time since last state change: 0 days, 00:01:25.220
        Effective State: UP
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
```

```
        Appflow logging: ENABLED
        No. of Bound Services :  1 (Total)       1 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: Bound service's state
           changed to UP
        Mode: IP

        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        SSLv2: DISABLED  SSLv3: DISABLED  TLSv1.0: ENABLED  TLSv1.1:
           DISABLED  TLSv1.2: DISABLED
        Push Encryption Trigger: Always
        Send Close-Notify: YES

        ECC Curve: P_256, P_384, P_224, P_521
```

```
18
19 1)      CertKey Name: key22       Server Certificate
20
21 1)      Cipher Name: DEFAULT
22         Description: Predefined Cipher Alias
23  Done
24 <!--NeedCopy-->
```

To view the configuration by using the GUI:

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and double-click an SSL virtual server to open it and view the configuration.

Limitations

September 14, 2021

- SSL version 3 (SSLv3) is not supported on an MPX appliance but is supported on a VPX virtual appliance. A VPX instance provisioned on an SDX appliance supports SSLv3 only if an SSL chip is not assigned to the instance.
- Export ciphers are not supported.
- SSL server key exchange using HSM keys is not supported.
- If you have added or removed keys after you last saved the configuration, you must save the configuration before you perform a warm restart. If you do not save the configuration, there is a key mismatch between the ADC and the HSM.
- You cannot bind an HSM key to a DTLS virtual server.
- You cannot bind a certificate-key pair that is created by using an HSM key to an SSL service.
- You cannot use the GUI to enroll the ADC as a client of the HSM or check the status of the HSM from the configuration utility.
- From release 11 build 62.x, SSL renegotiation is supported.
- You cannot sign OCSP requests by using a certificate-key pair that is created by using an HSM key.
- A certificate bundle with HSM keys is not supported.
- An error does not appear if the HSM key and certificate do not match. Therefore, while adding a certificate-key pair, you must make sure that the HSM key and certificate match.
- Clustering and admin partitions are not supported.

Support for Thales Luna Network hardware security module

September 14, 2021

A non-FIPS Citrix ADC appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted with special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances and the MPX/SDX 14000 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX/SDX appliances, or on the Citrix ADC VPX appliances. This limitation is addressed by supporting a Thales Luna network HSM on all Citrix ADC MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS and the MPX/SDX 14000 FIPS appliances.

A Thales Luna network HSM is designed to protect critical cryptographic keys and to accelerate sensitive cryptographic operations across a wide range of security applications.

Supported versions matrix

Citrix ADC Version	Software Appliance Version	Firmware Version	Client Version
11.1, 12.0, 12.1, 13.0	5.2.3-1	6.2.1	6.0.0
11.1, 12.0, 12.1, 13.0	6.2.2-5	6.10.9	6.2.2

Citrix ADC Version	Software Appliance Version	Firmware Version	Client Version
13.0	7.2.0-220	7.0.3	7.2.2 (7.2.0-220)

Prerequisites

September 14, 2021

Before you can use a Thales Luna network HSM with a Citrix ADC, make sure that the following prerequisites are met:

- A Thales Luna network HSM is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address or the SNIP address is added as an authorized client on the HSM.
- Licenses are available to support the required number of partitions on the HSM.
- The Thales Luna network HSM and the Citrix ADC can initiate connections with each other through port 1792.
- You are using NetScaler release 11.1 or later.
- The Citrix ADC appliance does not contain a FIPS Cavium card.

> **Important**
>
> Thales Luna network HSMs are not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

Configure a Thales Luna client on the ADC

September 14, 2021

After you have configured the Thales Luna HSM and created the required partitions, you must create clients and assign them to partitions. Begin by configuring the Thales Luna clients on the Citrix ADC and setting up the network trust links (NTLs) between the Thales Luna clients and the Thales Luna HSM. A sample configuration is given in the Appendix.

1. Change the directory to /var/safenet and install the Thales Luna client. At the shell prompt, type:

   ```
   cd /var/safenet
   <!--NeedCopy-->
   ```

   To install Thales Luna client version 6.0.0, type:

```
install_client.sh -v 600
<!--NeedCopy-->
```

To install Thales Luna client version 6.2.2, type:

```
install_client.sh -v 622
<!--NeedCopy-->
```

To install Thales Luna client version 7.2.2, type:

```
install_client.sh -v 722
<!--NeedCopy-->
```

2. Configure the NTLs between Thales Luna client (ADC) and HSM.

   After the '/var/safenet/' directory is created, perform the following tasks on the ADC.

   a) Change the directory to '/var/safenet/config/' and run the 'safenet_config' script. At the shell prompt, type:

```
cd /var/safenet/config

sh safenet_config
<!--NeedCopy-->
```

   This script copies the "Chrystoki.conf" file into the /etc/ directory. It also generates a symbolic link 'libCryptoki2_64.so' in the '/usr/lib/' directory.

   b) Create and transfer a certificate and key between the ADC and the Thales Luna HSM.

   To communicate securely, the ADC and the HSM must exchange certificates. Create a certificate and key on the ADC and then transfer it to the HSM. Copy the HSM certificate to the ADC.

   i) Change directory to /var/safenet/safenet/lunaclient/bin.

   ii) Create a certificate on the ADC. At the shell prompt, type:

```
./vtl createCert -n <ip address of Citrix ADC>
<!--NeedCopy-->
```

   This command also adds the certificate and key path to the "/etc/Chrystoki.conf" file.

   iii) Copy this certificate to the HSM. At the shell prompt, type:

```
scp /var/safenet/safenet/lunaclient/cert/client/<ip address of NS
   >.pem <LunaSA_HSM account>@<IP address of Luna SA>
<!--NeedCopy-->
```

iv) Copy the HSM certificate to the Citrix ADC. At the shell prompt, type:

```
scp <HSM account>@<HSM IP>:server.pem  /var/safenet/safenet/
   lunaclient/server_<HSM ip>.pem
<!--NeedCopy-->
```

3. Register the Citrix ADC as a client and assign it a partition on the Thales Luna HSM.

   Log on to the HSM and create a client. Enter the NSIP as the client IP. This address must be the IP address of the ADC from which you transferred the certificate to the HSM. After the client is successfully registered, assign a partition to it. Run the following commands on the HSM.

   a) Use SSH to connect to the Thales Luna HSM and enter the password.

   b) Register the Citrix ADC on the Thales Luna HSM. The client is created on the HSM. The IP address is the client's IP address. That is, the NSIP address.

   At the prompt, type:

   ```
   client register  -client <client name> -ip <Citrix ADC ip>
   <!--NeedCopy-->
   ```

   c) Assign the client a partition from the partition list. To view the available partitions, type:

   ```
   <luna_sh> partition list
   <!--NeedCopy-->
   ```

   Assign a partition from this list. Type:

   ```
   <lunash:> client assignPartition -client <Client Name> -par <
      Partition Name>
   <!--NeedCopy-->
   ```

4. Register the HSM with its certificate on the Citrix ADC.

   On the ADC, change the directory to "/var/safenet/safenet/lunaclient/bin" and, at the shell prompt, type:

   ```
   ./vtl addserver -n <IP addr of HSM> -c /var/safenet/safenet/
      lunaclient/server_<HSM_IP>.pem
   <!--NeedCopy-->
   ```

   To remove the HSM that is enrolled on the ADC, type:

   ```
   ./vtl deleteServer -n <HSM IP> -c <cert path>
   <!--NeedCopy-->
   ```

   To list the HSM servers configured on the ADC, type:

```
./vtl listServer
<!--NeedCopy-->
```

> **Note:**
>
> Before removing the HSM by using `vtl`, make sure all the keys for that HSM are manually removed from the appliance. HSM keys cannot be deleted after the HSM server is removed.

5. Verify the network trust links (NTLs) connectivity between the ADC and HSM. At the shell prompt, type:

```
./vtl verify
<!--NeedCopy-->
```

   If verification fails, review all the steps. Errors are due to an incorrect IP address in the client certificates.

6. Save the configuration.

   The preceding steps update the "/etc/Chrystoki.conf" configuration file. This file is deleted when the ADC is started. Copy the configuration to the default configuration file, which is used when an ADC is restarted.

   At the shell prompt, type:

```
root@ns# cp /etc/Chrystoki.conf /var/safenet/config/
<!--NeedCopy-->
```

   Recommended practice is to run this command every time there is a change to the Thales Luna related configuration.

7. Start the Thales Luna gateway process.

   At the shell prompt, type:

```
sh /var/safenet/gateway/start_safenet_gw
<!--NeedCopy-->
```

8. Configure automatic start of the gateway daemon at boot time.

   Create the "safenet_is_enrolled" file, which indicates that Thales Luna HSM is configured on this ADC. Whenever the ADC restarts and this file is found, the gateway is automatically started.

   At the shell prompt, type:

```
touch /var/safenet/safenet_is_enrolled
<!--NeedCopy-->
```

Configure Thales Luna HSMs in a high availability setup on the ADC

September 14, 2021

Configuring Thales Luna HSMs in a high availability (HA) ensures uninterrupted service even if all, but one of the devices, are unavailable. In an HA setup, each HSM joins an HA group in active-active mode. Thales Luna HSMs in an HA setup provide load balancing of all the group members to increase performance and response time while providing the assurance of high availability service. For more information, contact Thales Luna Sales and Support.

Prerequisites:

- Minimum two Thales Luna HSM devices. All the devices in an HA group must have either PED (trusted path) authentication or password authentication. A combination of trusted path authentication and password authentication in an HA group is not supported.
- Partitions on each HSM device must have the same password even if the label (name) is different.
- All partitions in HA must be assigned to the client (Citrix ADC appliance).

After configuring a Thales Luna client on the ADC as described in Configure a Thales Luna client on the ADC, perform the following steps to configure Thales Luna HSMs in HA:

1. On the Citrix ADC shell prompt, launch `lunacm` (/usr/safenet/lunaclient/bin)

   Example:

   ```
   root@ns# cd /var/safenet/safenet/lunaclient/bin/

   root@ns# ./lunacm
   <!--NeedCopy-->
   ```

2. Identify the slot IDs of the partitions. To list the available slots (partitions), type:

   ```
   lunacm:> slot list
   <!--NeedCopy-->
   ```

   Example:

   ```
       Slot Id ->              0
       HSM Label ->            trinity-p1
       HSM Serial Number ->    481681014
       HSM Model ->            LunaSA 6.2.1
       HSM Firmware Version -> 6.10.9
       HSM Configuration ->    Luna SA Slot (PED) Signing With
           Cloning Mode
       HSM Status ->           OK
   ```

```
8
9       Slot Id ->              1
10      HSM Label ->            trinity-p2
11      HSM Serial Number ->    481681018
12      HSM Model ->            LunaSA 6.2.1
13      HSM Firmware Version -> 6.10.9
14      HSM Configuration ->    Luna SA Slot (PED) Signing With
           Cloning Mode
15      HSM Status ->           OK
16
17       Slot Id ->              2
18       HSM Label ->            neo-p1
19       HSM Serial Number ->    487298014
20       HSM Model ->            LunaSA 6.2.1
21       HSM Firmware Version -> 6.10.9
22       HSM Configuration ->    Luna SA Slot (PED) Signing With
            Cloning Mode
23      HSM Status ->           OK
24
25      Slot Id ->              3
26      HSM Label ->            neo-p2
27      HSM Serial Number ->    487298018
28      HSM Model ->            LunaSA 6.2.1
29      HSM Firmware Version -> 6.10.9
30      HSM Configuration ->    Luna SA Slot (PED) Signing With
           Cloning Mode
31      HSM Status ->           OK
32
33      Slot Id ->              7
34      HSM Label ->            hsmha
35      HSM Serial Number ->    1481681014
36      HSM Model ->            LunaVirtual
37      HSM Firmware Version -> 6.10.9
38      HSM Configuration ->    Luna Virtual HSM (PED) Signing With
           Cloning Mode
39      HSM Status ->           N/A - HA Group
40
41      Slot Id ->              8
42      HSM Label ->            newha
43      HSM Serial Number ->    1481681018
44      HSM Model ->            LunaVirtual
45      HSM Firmware Version -> 6.10.9
46      HSM Configuration ->    Luna Virtual HSM (PED) Signing With
           Cloning Mode
47      HSM Status ->           N/A - HA Group
```

```
48
49      Current Slot Id: 0
50  <!--NeedCopy-->
```

3. Create the HA group. The first partition is called the primary partition. You can add more than one secondary partitions.

```
1  lunacm:> hagroup createGroup -slot <slot number of primary
       partition> -label <group name> -password <partition password >
2
3  lunacm:> hagroup createGroup -slot 1 -label gp12 -password ******
4  <!--NeedCopy-->
```

4. Add the secondary members (HSM partitions). Repeat this step for all partitions to be added to the HA group.

```
1  lunacm:> hagroup addMember -slot <slot number of secondary
       partition to be added> -group <group name> -password <partition
        password>
2  <!--NeedCopy-->
```

Code:

```
1  lunacm:> hagroup addMember -slot 2 -group gp12 -password ******
2  <!--NeedCopy-->
```

5. Enable HA only mode.

```
1  lunacm:> hagroup HAOnly  - enable
2  <!--NeedCopy-->
```

6. Enable active recovery mode.

```
1  lunacm:.>hagroup recoveryMode  - mode active
2  <!--NeedCopy-->
```

7. Set auto recovery interval time (in seconds). Default is 60 seconds.

```
1  lunacm:.>hagroup interval  - interval <value in seconds>
2  <!--NeedCopy-->
```

Example:

```
1  lunacm:.>hagroup interval  - interval 120
2  <!--NeedCopy-->
```

8. Set recovery retry count. A value of -1 allows an infinite number of retries.

```
lunacm:> hagroup retry -count <xxx>
<!--NeedCopy-->
```

Example:

```
lunacm:> hagroup retry -count 2
<!--NeedCopy-->
```

9. Copy the configuration from `Chrystoki.conf` to the SafeNet configuration directory.

```
cp /etc/Chrystoki.conf /var/safenet/config/
<!--NeedCopy-->
```

10. Restart the ADC appliance.

```
reboot
<!--NeedCopy-->
```

After configuring Thales Luna HSM in HA, see Other ADC configuration for further configuration on the ADC.

Other ADC configuration

September 14, 2021

1. Generate a key on the HSM.

   Use third party tools to create keys on the HSM.

2. Add an HSM key on the ADC.

   Important! The # character is not supported in a key name. If the key name includes this character, the load key operation fails.

   To add a Thales Luna HSM key by using the CLI:

   At the command prompt, type:

```
add ssl hsmkey <KeyName> -hsmType SAFENET -serialNum <serial #> -
    password
<!--NeedCopy-->
```

   where:

-keyName is the key created on the HSM by using third party tools.

-serialNum is the serial number of the partition on the HSM on which the keys are generated.

Note: For HSM in a high availability setup, use the serial number of the high availability group.

-password is the password of the partition on which the keys are present.

To add a Thales Luna HSM key by using the GUI:

Navigate to **Traffic Management** > **SSL** > **HSM** and add an HSM key. You must specify the HSM Type as **SAFENET**.

3. Add a certificate-key pair on the ADC. First use a third party tool to generate a certificate associated with the key. Then, copy the certificate to the /nsconfig/ssl/ directory on the ADC.

   Note: The key must be an HSM key.

   To add a certkey pair on the ADC by using the CLI:

   At the command prompt, type:

   ```
   add ssl certkey <CertkeyName> -cert <cert name> -hsmkey <KeyName>
   <!--NeedCopy-->
   ```

   To add a certkey pair on the ADC by using the GUI:

   a) Navigate to **Traffic Management** > **SSL**.
   b) In **Getting Started**, select **Install Certificate (HSM)** and create a certificate-key pair using an HSM key.

4. Create a virtual server and bind the certificate-key pair to this virtual server.

For information about creating a virtual server, click SSL virtual server configuration.

For information about adding a certificate-key pair, click Add or update a certificate-key pair.

For information about binding a certificate-key pair to an SSL virtual server, click Bind the certificate-key pair to the SSL virtual server.

Citrix ADC appliances in a high availability setup

September 14, 2021

You can configure a high availability (HA) setup on the Citrix ADC appliances with a Thales Luna HSM configuration in either of the following two ways:

- First, configure a Thales Luna HSM on the two nodes, using the same HSM and partition. Then create an HA pair. Finally, add the Citrix ADC configuration, such as keys, certificate-key pairs, and virtual servers, on the primary node.

- If a Thales Luna HSM is already configured on one node with the Citrix ADC configuration, add a similar configuration on the other node. Copy "/var/safenet/sfgw_ident_file" from the first node to the other and restart the safenet_gw binary. After the gateway is up and running, add the nodes in an HA setup.

Limitations

September 24, 2021

1. For any changes to the HSM-related configuration in an existing setup, such as adding or removing an HSM, or creating a high availability setup, copy '/etc/Chrystoki.conf' to '/var/safenet/config'.
2. After adding, removing, or restarting an HSM, you must restart the '/var/safenet/gateway/safenet_gw' binary. If you don't restart the gateway binary, the HSM will not serve any traffic after it is added back or after it restarts.
3. To reboot or stop the current '/var/safenet/gateway/safenet_gw' binary, use

   ```
   kill -SIGTERM <PID>
   kill -SIGINT <PID>
   <!--NeedCopy-->
   ```

   Important! Do not use `kill -9 <PID>` or `kill -6 <PID>`
4. Before removing an existing HSM from the ADC, remove, from the ADC, all the keys and certificate-key pairs that are associated with that HSM. You can't delete these files from the ADC after you remove the HSM.
5. On a standalone Citrix ADC appliance, Thales Luna HSMs in HA are supported for Luna version 6.2 and later.
6. EXPORT ciphers are not supported.
7. Update certificate-key pair operation is not supported.
8. When you generate an HSM key on a third-party tool, the private and public key names must be the same. When you add the HSM key on the appliance, provide this name as the key name.
9. The ## character is not supported in a key name and partition password.
10. Cluster and admin partitions are not supported.

Appendix

September 14, 2021

Sample commands with their outputs:

Run the script

```
1      root@ns# pwd
2     /var/safenet/config
3     root@ns# sh safenet_config
4 <!--NeedCopy-->
```

Create a certificate

```
1     root@ns# cd /var/safenet/safenet/lunaclient/bin
2     root@ns# ./vtl createcert -n 10.102.59.175
3     Private Key created and written to: /var/safenet/safenet/lunaclient
         /cert/client/10.102.59.175Key.pem
4     Certificate created and written to: /var/safenet/safenet/lunaclient
         /cert/client/10.102.59.175.pem
5 <!--NeedCopy-->
```

Copy the certificate to the HSM

```
1     root@ns# scp /var/safenet/safenet/lunaclient/cert/client
         /10.102.59.175.pem admin@10.217.2.7:
2     admin@10.217.2.7's password:
3
4     10.102.59.175.pem          100%  818     0.8KB/s   00:00
5 <!--NeedCopy-->
```

Copy the certificate and key from the HSM to the Citrix ADC appliance

```
1     root@ns# scp admin@10.217.2.7:server.pem /var/Thales Luna/safenet/
         lunaclient/server.2.7.pem
2     admin@10.217.2.7's password:
3
4     server.pem            100% 1164     1.1KB/s   00:01
5 <!--NeedCopy-->
```

Use SSH to connect to the Thales Luna HSM

```
    ssh admin@10.217.2.7
    Connecting to 10.217.2.7:22...
    Connection established.
    To escape to local shell, press 'Ctrl+Alt+]'.

    Last login: Thu Jun 23 02:20:29 2016 from 10.252.243.11

    Luna SA 5.2.3-1 Command Line Shell - Copyright (c) 2001-2014

```

FAQ

September 14, 2021

- **How do I check that the Thales Luna process is running?**

  At the Citrix ADC shell prompt, type:

```
ps - aux | grep safenet_gw
<!--NeedCopy-->
```

- **How do I verify the network trust links (NTLs) connectivity between the ADC and HSM?**

  After configuring Thales Luna, change the directory to "/var/safenet/safenet/lunaclient/bin" and type:

```
./vtl verify
<!--NeedCopy-->
```

Support for Azure Key Vault

November 12, 2021

The Citrix ADC appliance integrates with external HSMs (SafeNet and Thales) for on-premises deployments. For cloud deployments, the ADC appliance integrates with Azure Key Vault. The appliance stores its private keys in the Key Vault for ease of management and security of the private key in the public cloud domain. You no longer have to store and manage keys in different locations for ADC appliances deployed across multiple data centers and cloud providers.

Using ADC with the Azure Key Vault Premium pricing tier, which provided HSM backed keys, provides FIPS 140-2 level 2 compliance.

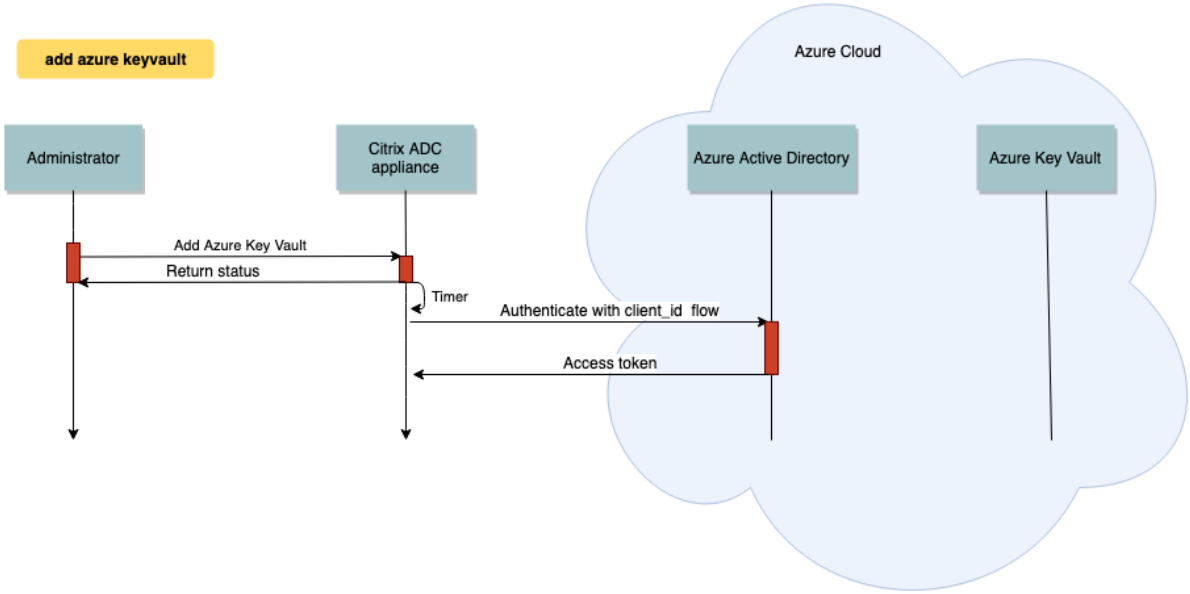
Azure Key Vault is a standard offering from Microsoft. For more information about Azure Key Vault, see the Microsoft Azure documentation.

Note: The Citrix ADC integration with Azure Key Vault is supported with the TLS 1.3 protocol.

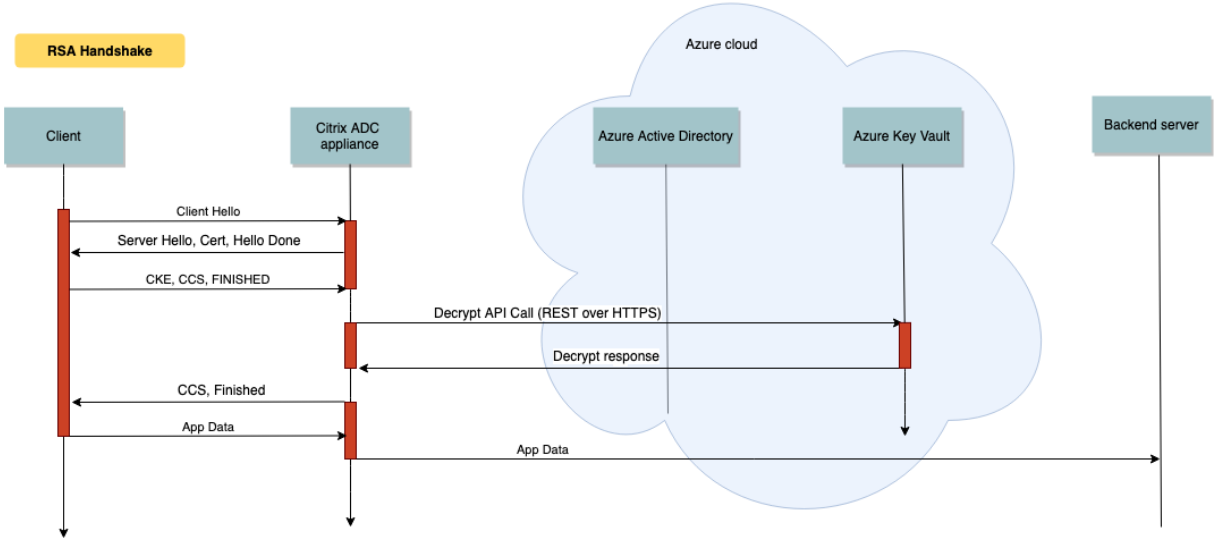
Architecture overview

Azure Key Vault is a service for storing secrets securely in the Azure cloud. By storing your keys in the Azure Key Vault, you reduce the chances of keys being stolen. Once the Key Vault is set up, you can store your keys in it. Configure virtual servers on the ADC appliance to perform private key operations in the Key Vault. The ADC appliance accesses the key for each SSL handshake.

The following diagram illustrates the process to get an access token from the Azure Active Directory after authentication. This token is used with REST API calls for crypto operations using private keys.



The following diagram shows a typical RSA handshake. The client key exchange (CKE) message that is encrypted using the public key is decrypted using the private key stored in the Key Vault.



In an ECDHE handshake, the server key exchange (SKE) message sent by the Citrix ADC appliance is signed by using the private key stored in the Key Vault.

Prerequisites

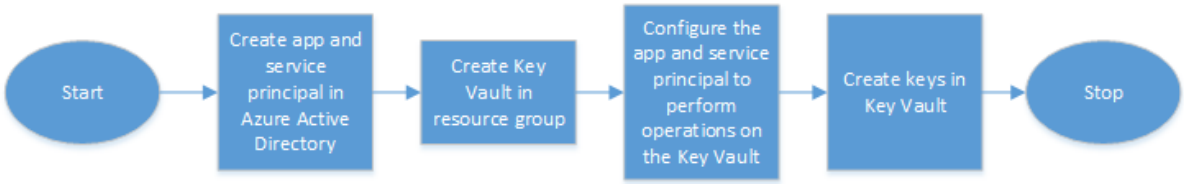
1. You must have an Azure subscription.
2. (Optional) Install Azure CLI on a Linux machine. For instructions, see the Azure documentation https://docs.microsoft.com/en-us/cli/azure/install-azure-cli-apt?view=azure-cli-latest.
3. Complete the configuration on the Azure portal before configuring entities on the ADC appliance.

Configure the ADC Azure Key Vault integration

First perform the configuration on the Azure portal followed by the configuration on the ADC appliance.

Perform the following steps on the Azure portal

The following flowchart shows the high-level flow for configuration required on the Azure portal.

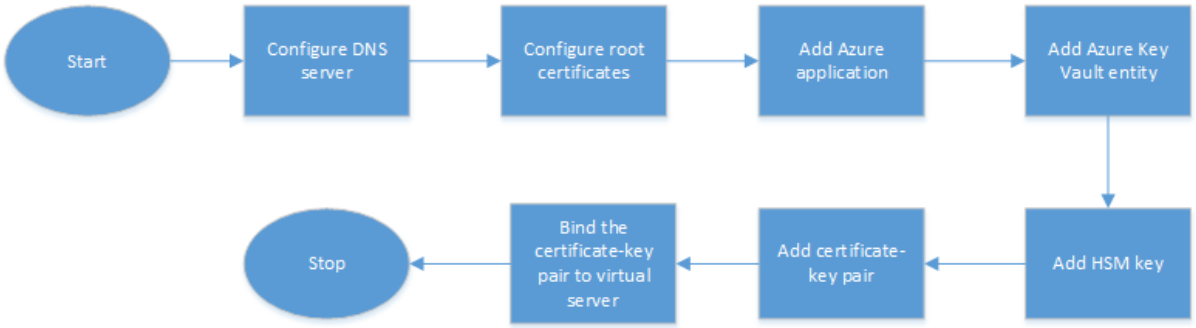


1. Create app and service principal in Azure Active Directory.
2. Create Key Vault in a resource group.
3. Configure the app and service principal to perform sign and decrypt operations on the Key Vault.
4. Create keys in the Key Vault using one of the following ways:
    a) By importing a key file.
    b) By generating a certificate.

For information about the commands to configure the preceding steps, see the Azure documentation at https://docs.microsoft.com/en-us/azure/active-directory/develop/app-objects-and-service-principals.

Perform the following steps on the ADC appliance

The following flowchart shows the high-level flow for configuration required on the ADC appliance.



1. Configure a DNS server.
2. Configure root certificates to verify the certificates presented by Azure.
3. Create an Azure application.
4. Create an Azure Key Vault entity.
5. Create an HSM key.
6. Create a certificate-key pair.
7. Bind the certificate-key pair to a virtual server.

Configure a DNS server

A DNS server is required for the name resolution of Key Vault host and Azure Active Directory end point.

To configure a DNS server by using the CLI

At the command prompt, type:

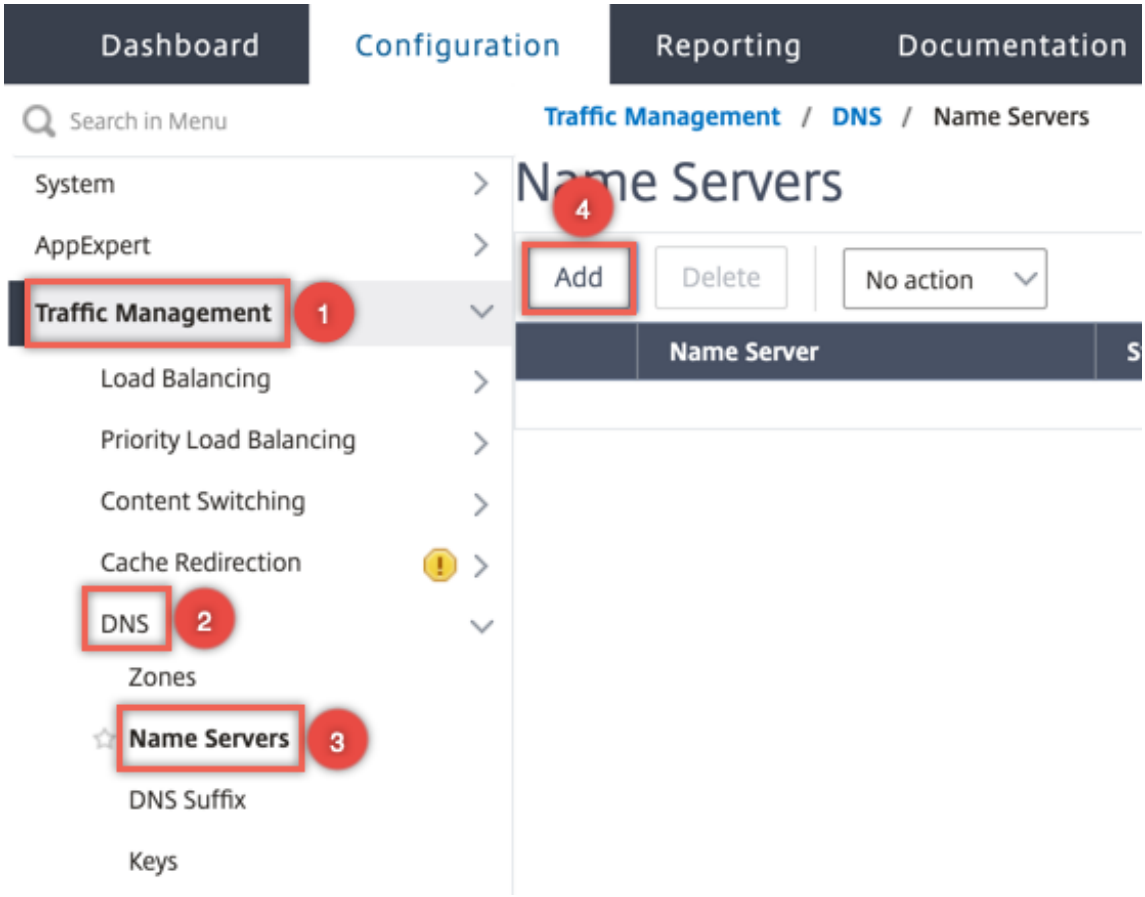
```
add dns nameserver <IP address>
<!--NeedCopy-->
```

Example:

```
add dns nameserver 192.0.2.150
<!--NeedCopy-->
```

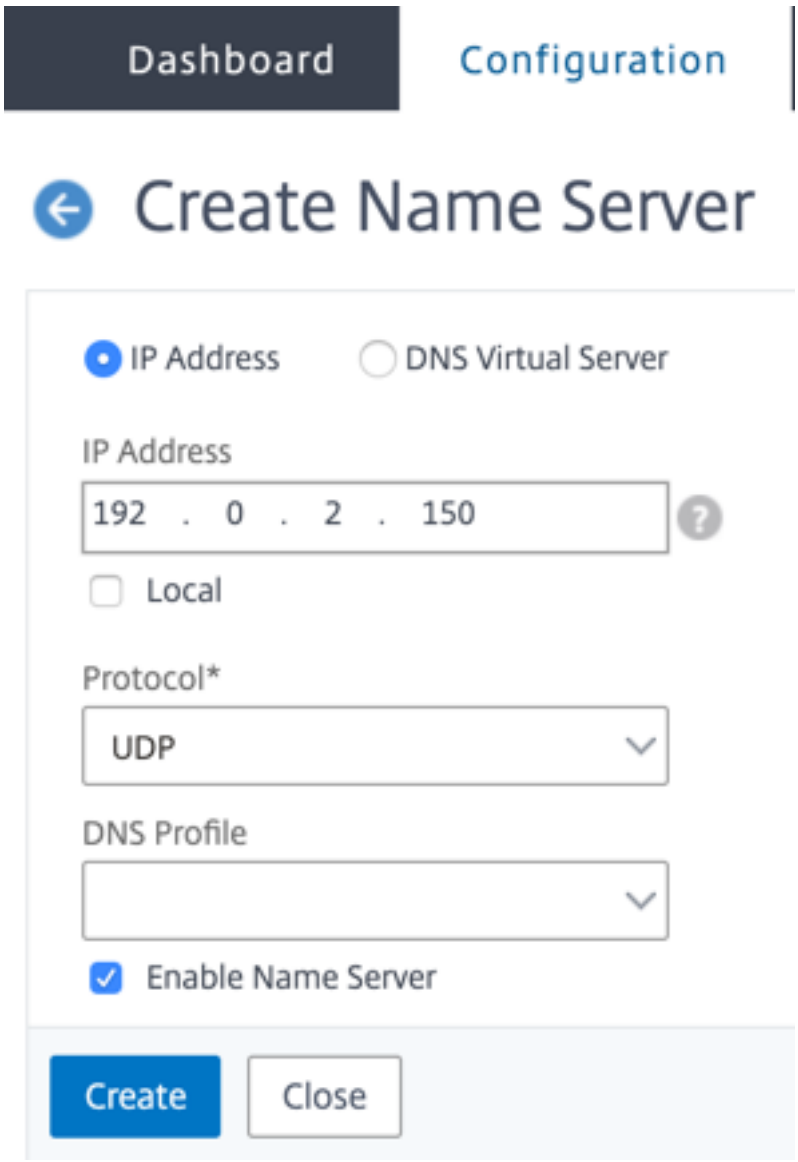
To configure a DNS server by using the GUI

1. Navigate to **Traffic Management > DNS > Name Servers**. Click **Add**.



2. Enter values for the following parameters:

   - IP Address - IP address of an external name server or, if the Local parameter is set, IP address of a local DNS server (LDNS).
   - Protocol - Protocol used by the name server. UDP_TCP is not valid if the name server is a DNS virtual server configured on the appliance.



3. Click **Create**.

Add and bind a root certificate

Download the root certificates of the certificate presented by Azure Key Vault `https://<vault_name>.vault.azure.net` and Azure Active Directory (AAD) https://login.microsoftonline.com and load it on the ADC appliance. These certificates are required to validate the certificate presented by Azure Key Vault and AAD. Bind one or more certificates to the CA certificate group `ns_callout_certs`.

To add a root certificate by using the CLI

At the command prompt, type:

```
add ssl certkey <certkeyname> -cert <certname>
bind ssl caCertGroup <caCertGroupName> <certkeyName>
<!--NeedCopy-->
```

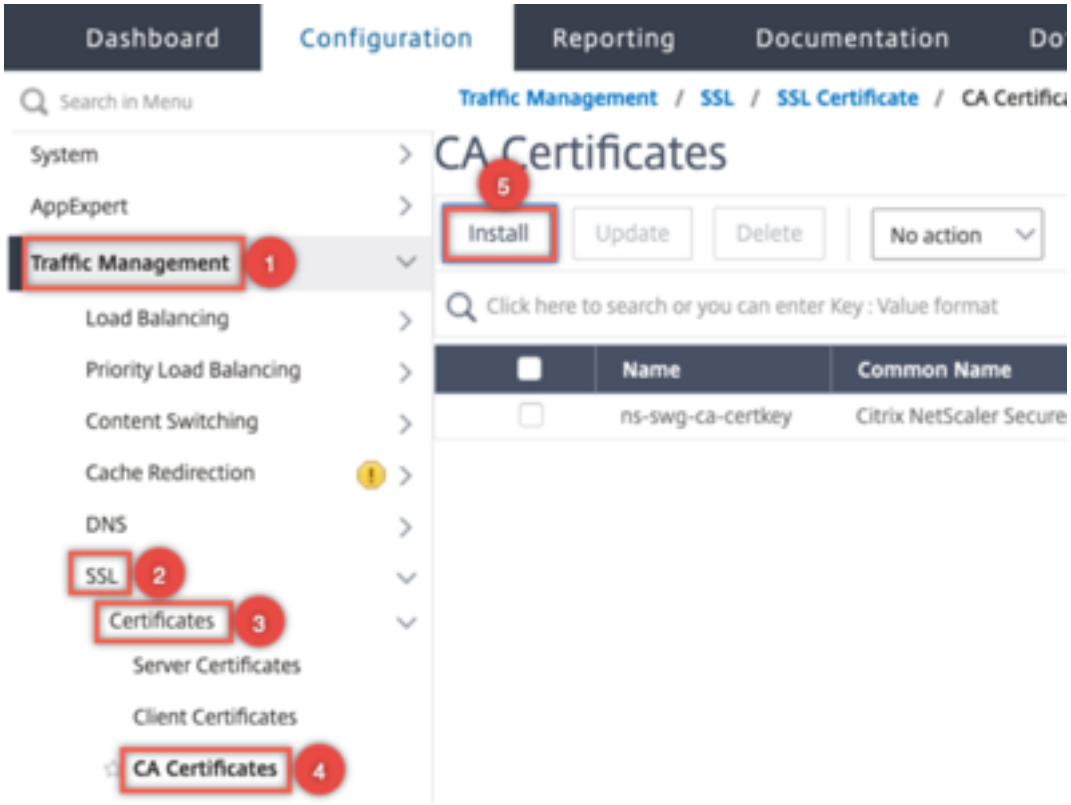
Example:

In the following example, the root certificate presented by Azure Key Vault and AAD is the same.

```
add ssl certKey rootcert -cert RootCyberTrustRoot.crt
bind ssl cacertGroup ns_callout_certs  rootcert
<!--NeedCopy-->
```

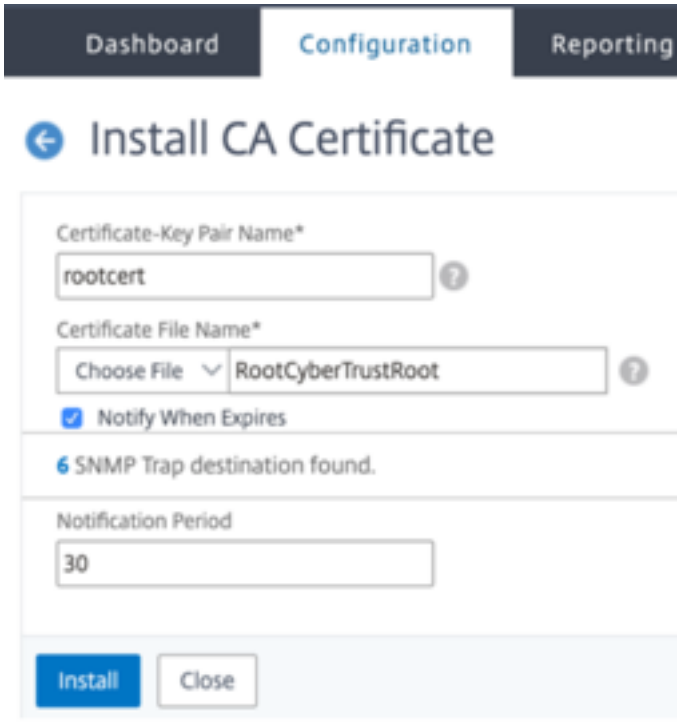
To add a root certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates > CA Certificates**.

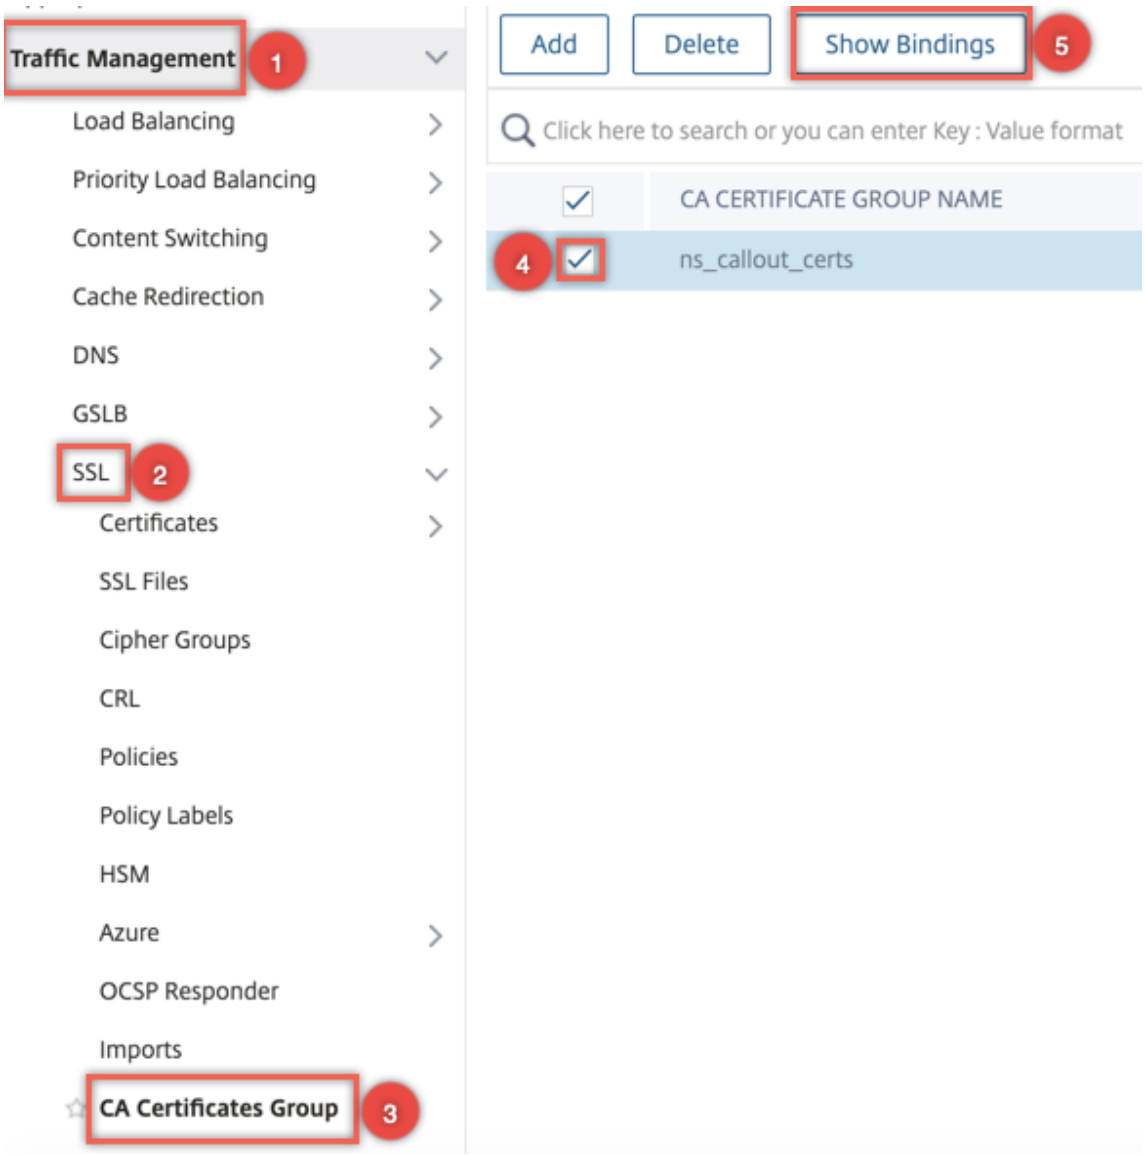


2. Enter values for the following parameters:

   - Certificate-key pair name
   - Certificate file name



3. Click **Install**.
4. Navigate to **Traffic Management > SSL > CA Certificates Group**.
5. Select **ns_callout_certs** and click **Show Bindings**.



6. Click **Bind**.
7. Select the CA certificate created earlier and click **Select**.
8. Click **Bind**, and then click **Close**.

Configure an Azure application

The Azure application entity contains the credentials required to authenticate to Azure Active Directory and obtain the access token. That is, to get authorization access to Key Vault resources and APIs, add the Azure Application ID, secret (password) and tenant ID on the ADC appliance.
When configuring the Azure Application entity using the CLI, you must enter the password. If you use the GUI, the Azure application entity contains the credentials required to authenticate to Azure Active Directory and obtain the access token.

To configure an Azure application by using the CLI

From release 13.0-61.x, a parameter, vaultResource, is added to the `add azure application` command to get the domain of the resource group before the access token is granted to the application. This parameter is added because the domain name might be different for different regions. For example, the domain might be `vault.azure.net` or `vault.usgov.net`.

At the command prompt, type:

```
add azure application <name> -clientID <string> -clientSecret -tenantID
    <string> -vaultResource <string> [-tokenEndpoint <URL>]
show azure application
<!--NeedCopy-->
```

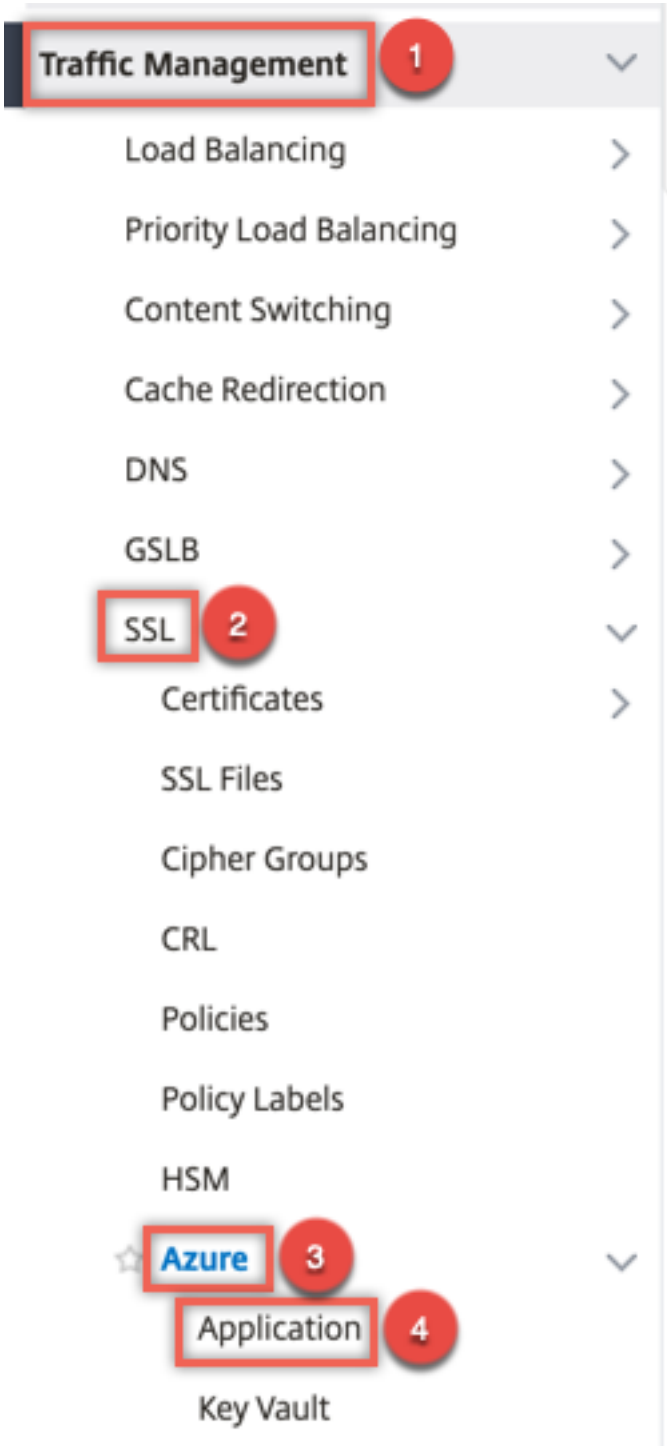
Example:

```
add azure application app10 -clientiD 12345t23aaa5 -clientsecret
   csHzOoEzmuY= -vaultResource example.vault.azure.net -tenantID 33583
   ee9ca5b
 Done
> sh azure application app10
1)  Name:  app10            ClientID:  12345t23aaa5
    TokenEndpoint:  "https://login.microsoftonline.com/33583ee9ca5b/"
    TenantID:  33583ee9ca5b  VaultResource:  example.vault.azure.net
 Done

<!--NeedCopy-->
```

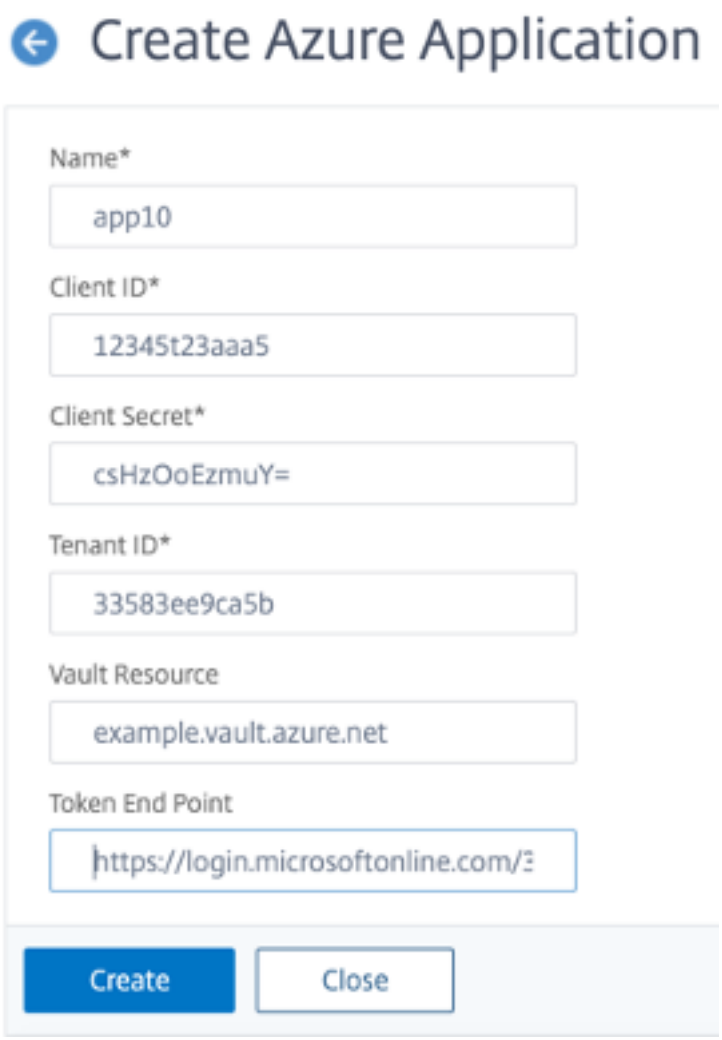
To configure an Azure application by using the GUI

1. Navigate to **Traffic Management > SSL > Azure > Application**.



2. In the details pane, click **Add**.
3. Enter values for the following parameters:
   - Name – Name for the application object on the Citrix ADC appliance.
   - Client ID – Application ID that is generated when an application is created in Azure Active Directory using either the Azure CLI or the Azure portal (GUI).

- Client Secret – Password for the application configured in Azure Active Directory. The password is specified in the Azure CLI or generated in the Azure portal (GUI).
- Tenant ID – ID of the directory inside Azure Active Directory in which the application was created.
- Vault Resource - Vault resource for which access token is granted. Example `vault.azure.net`.
- Token End point – URL from where the access token can be obtained. If the token end point is not specified, the default value is `https://login.microsoftonline.com/<tenant id>`.



Configure Azure Key Vault

Create an Azure Key Vault object on the ADC appliance.

To configure Azure Key Vault by using the CLI

At the command prompt, type:

```
add azure keyVault <name> -azureVaultName <string> -azureApplication
       <string>
show azure keyvault
<!--NeedCopy-->
```

Example:

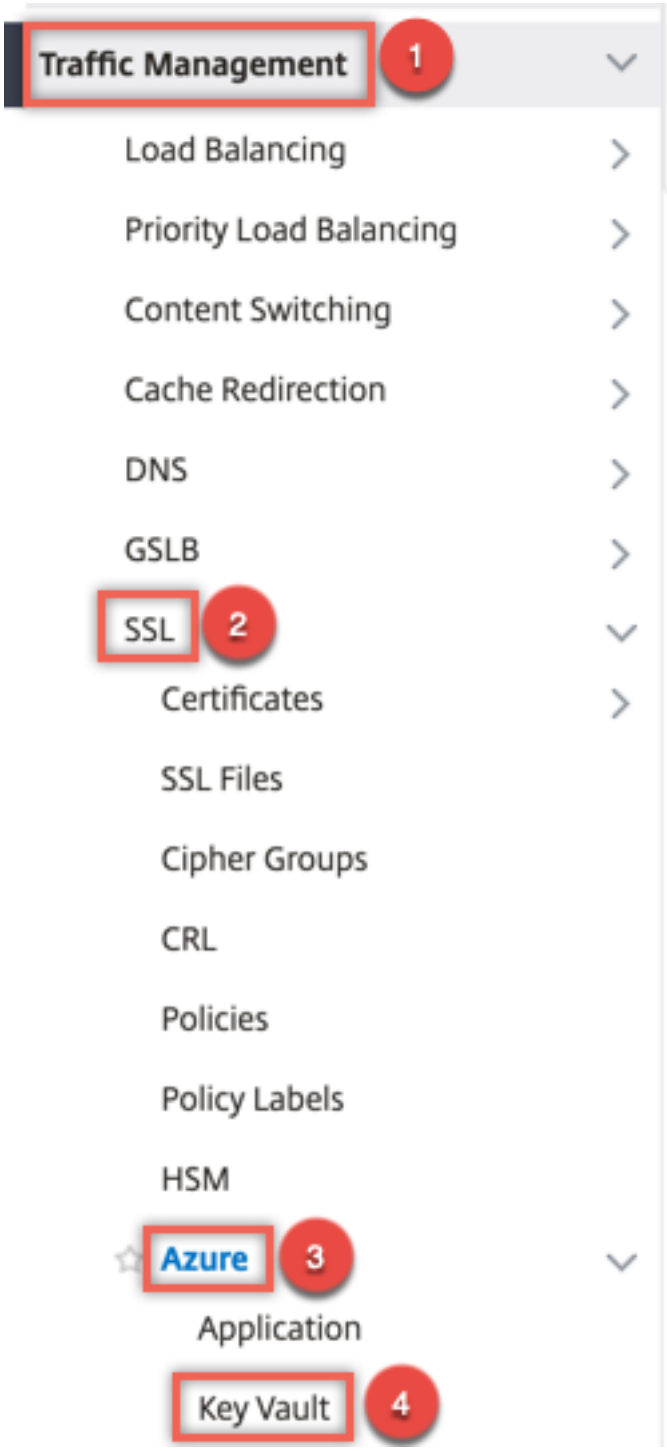
```
add azure keyvault kv1 -azureapplication app10 -azurevaultName pctest.
   vault.azure.net
> sh azure keyVault
1)  Name:  kv1               AzureVaultName:  pctest.vault.azure.net
  AzureApplication:  app10  State:  "Access token obtained"
 Done
<!--NeedCopy-->
```

The following table lists the different values that the state of the Azure Key Vault can take along with a brief description about each state.

State	Description
Created	Initial state of the Key Vault object. Authentication has not been attempted.
Could not reach token end point	Indicates one of the following: DNS server not configured, issuer certificate not bound to a CA certificate group, or network issues.
Authorization failed	Incorrect application credentials.
Token parse error	Response from Azure Active Directory is not in the expected format.
Access token obtained	Successfully authenticated by Azure Active Directory.

To configure the Azure Key Vault by using the GUI

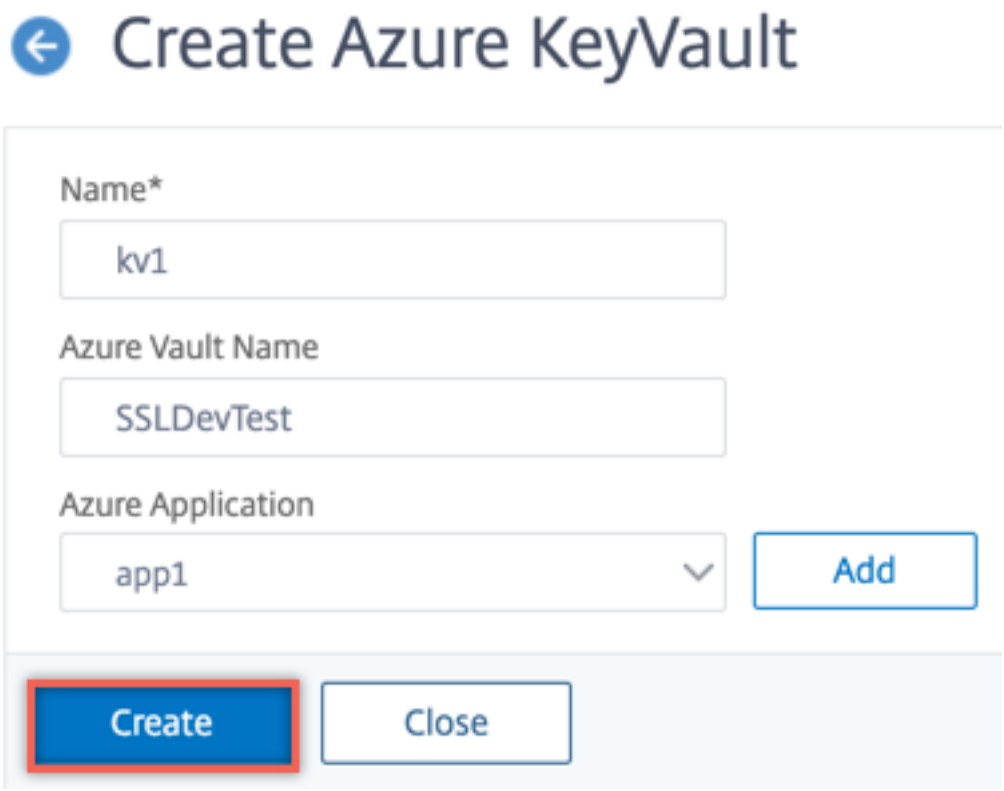
1. Navigate to **Traffic Management > SSL > Azure > Key Vault**.



2. Enter values for the following parameters:

   - Name - Name for the Key Vault.
   - Azure Key Vault Name - Name of the Key Vault configured in Azure cloud using either the Azure CLI or the Azure portal (GUI) with domain name.
   - Azure Application Name - Name of the Azure Application object created on the ADC appli-

ance. The Azure Application object with this name is used for authentication with Azure Active Directory.



Add HSM key

Storing your private key in the HSM provides FIPS 140-2 level 2 compliance.

To add an HSM key by using the CLI

At the command prompt, type:

```
add ssl hsmKey <hsmKeyName> [-hsmType <hsmType>] [-key <string> |
       -serialNum <string>] {
 -password  }
  [-keystore <string>]
<!--NeedCopy-->
```

Example:

```
add ssl hsmKey h1 -keystore kv1 -key san15key -hsmType KEYVAULT

> sh ssl hsmKey h1
```

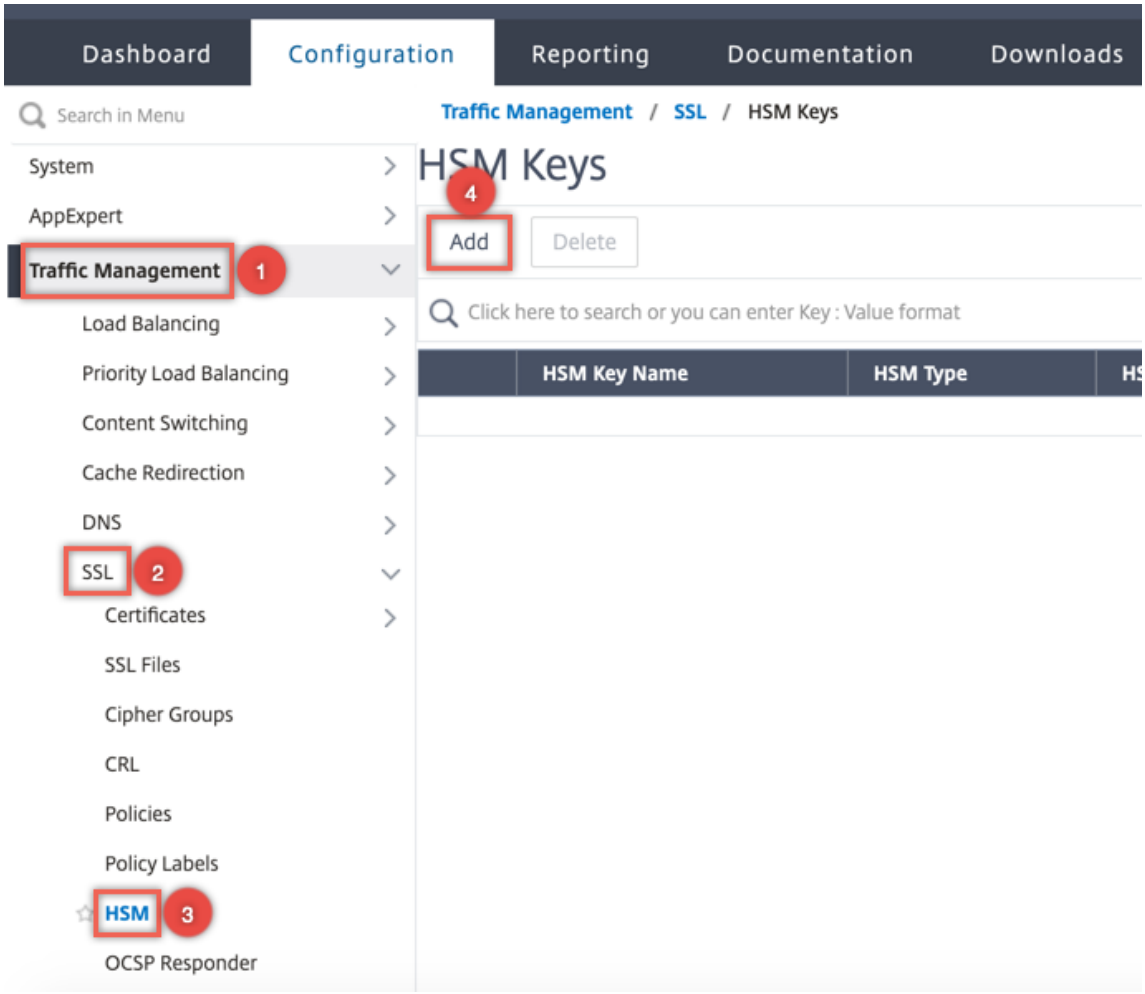
```
5      HSM Key Name: h1        Type: KEYVAULT
6      Key: san15key
7      Key store: kv1
8      State:  “Created”
9   Done
10 <!--NeedCopy-->
```

The following table lists the different values that the state of an HSM key can take along with a brief description about each state.

State	Description
Created	The HSM key is added on the ADC appliance. A key operation is not yet attempted.
Access token unavailable	Access token not available when key operation was attempted.
Unauthorized	Configured Azure application does not have permission to perform the key operation.
Does not exist	The key does not exist in the Azure Key Vault.
Unreachable	The Key Vault host is not reachable on the network.
Marked down	The HSM key is marked DOWN on the ADC appliance due to threshold errors during key operation.
Key operations successful	Success response received from the Key Vault for key operation.
Key operations failed	Failure response received from Key Vault for key operation.
Key operation throttled	The key operation request is throttled by the Key Vault.

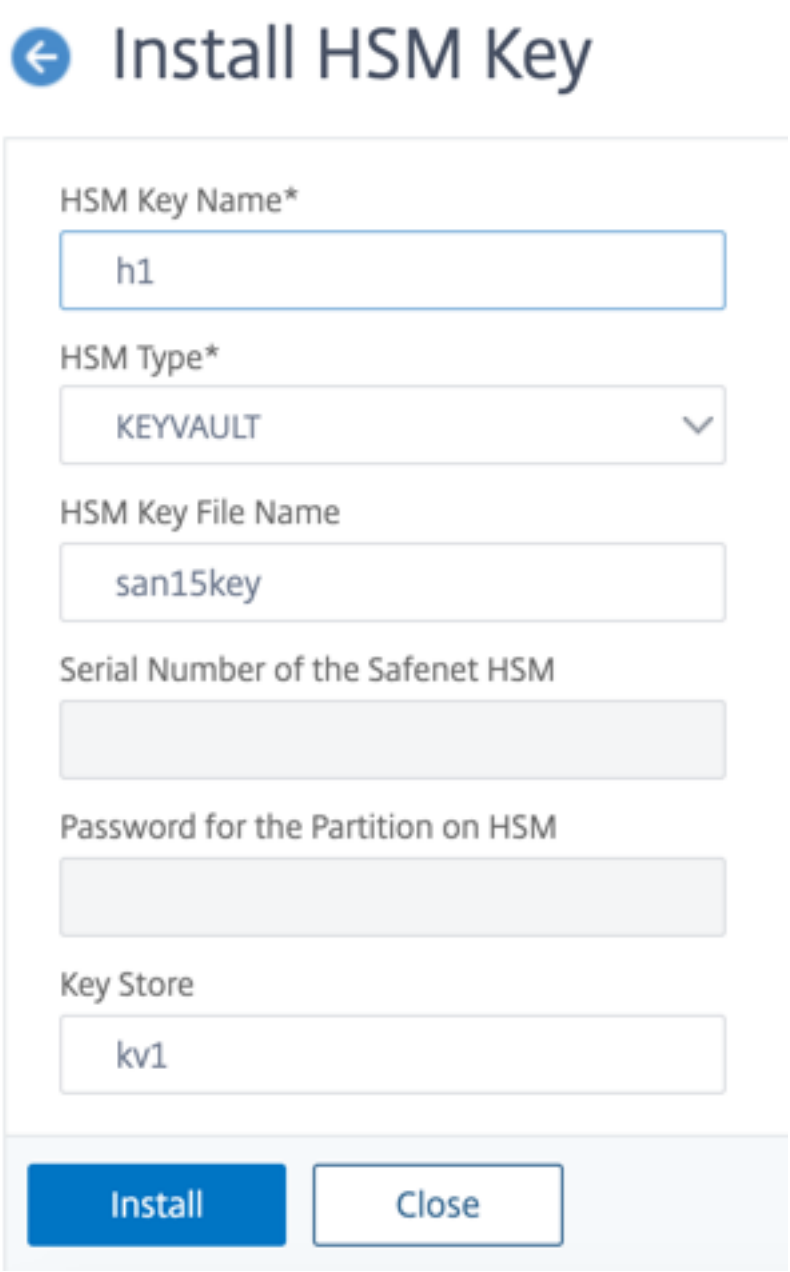
To add an HSM key by using the GUI

1. Navigate to **Traffic Management > SSL > HSM**.



2. Enter values for the following parameters.

   - HSM key name - Name of the key.
   - HSM type - Type of HSM.
   - Key store - Name of key store object representing HSM where the key is stored. For example, name of Key Vault object or Azure Key Vault authentication object. Applies only to KEYVAULT type HSM.



3. Click **Add**

Add a certificate-key pair

Add a certificate-key pair using the HSM key created earlier.

To add a certificate-key pair by using the CLI

At the command prompt, type:

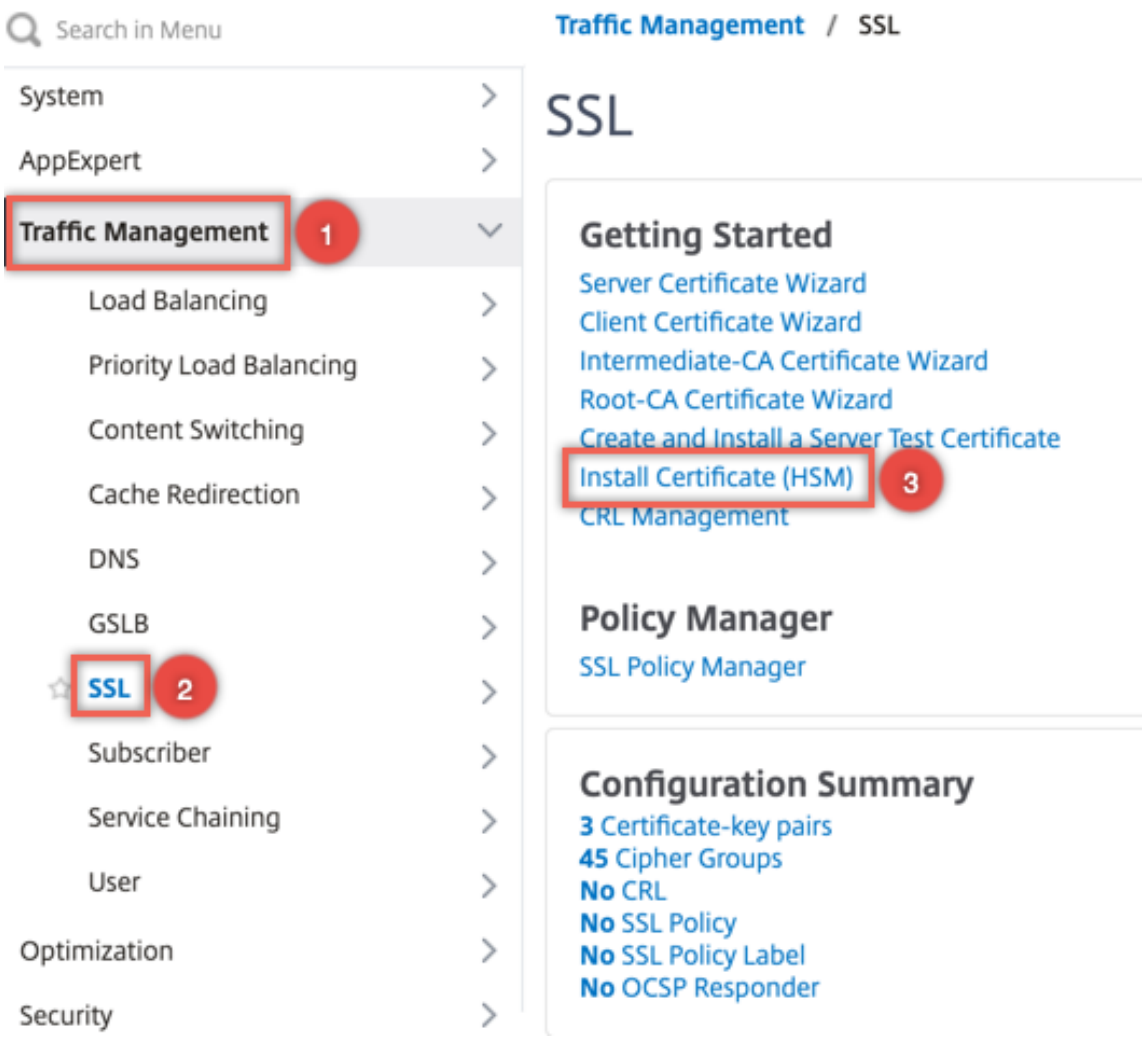
```
add ssl certKey <certkeyName> (-cert <string> [-password]) -hsmKey <
    string>]
show ssl certkey
<!--NeedCopy-->
```

Example:

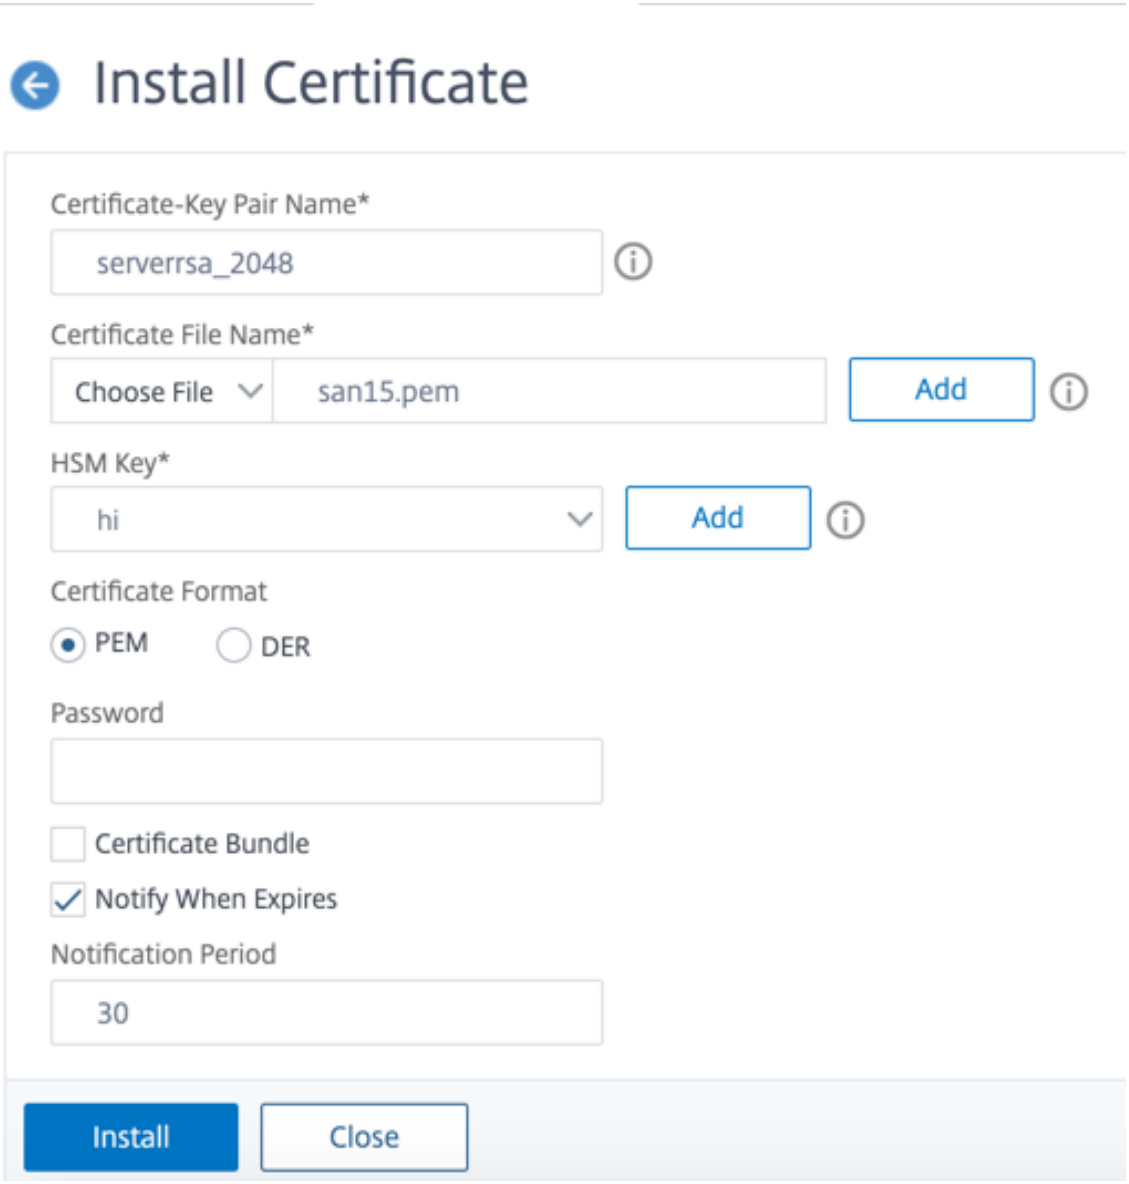
```
add ssl certKey serverrsa_2048 -cert /nsconfig/ssl/san_certs/san15.pem
    -hsmKey h1
> sh ssl certkey serverrsa_2048
    Name: serverrsa_2048        Status: Valid,   Days to expiration
        :9483
    Version: 3
    Serial Number: F5CFF9EF1E246022
    Signature Algorithm: sha256WithRSAEncryption
    Issuer:  C=in,O=citrix,CN=ca
    Validity
        Not Before: Mar 20 05:42:57 2015 GMT
        Not After : Mar 12 05:42:57 2045 GMT
    Certificate Type:   "Server Certificate"
    Subject:  C=in,O=citrix
    Public Key Algorithm: rsaEncryption
    Public Key size: 2048
    Ocsp Response Status: NONE
 Done
<!--NeedCopy-->
```

To add a certificate-key pair by using the GUI

1. Navigate to **Traffic Management > SSL > Install Certificate (HSM)**.



2. Enter values for the following parameters:
   - Certificate-Key Pair Name
   - Certificate File Name
   - HSM Key



3. Click **Install**.

Bind the certificate-key pair to a virtual server

The certificate used for processing SSL transactions must be bound to the virtual server that receives the SSL data.

To bind the SSL certificate-key pair to a virtual server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>
show ssl vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
bind ssl vserver v1 -certkeyName serverrsa_2048

sh ssl vserver v1

    Advanced SSL configuration for VServer v1:
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA:
       ENABLED      Refresh Count: 0
    Session Reuse: ENABLED      Timeout: 120 seconds
    Cipher Redirect: DISABLED
    ClearText Port: 0
    Client Auth: DISABLED
    SSL Redirect: DISABLED
    Non FIPS Ciphers: DISABLED
    SNI: DISABLED
    OCSP Stapling: DISABLED
    HSTS: DISABLED
    HSTS IncludeSubDomains: NO
    HSTS Max-Age: 0
    HSTS Preload: NO
    SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
       ENABLED  TLSv1.3: DISABLED
    Push Encryption Trigger: Always
    Send Close-Notify: YES
    Strict Sig-Digest Check: DISABLED
    Zero RTT Early Data: DISABLED
    DHE Key Exchange With PSK: NO
    Tickets Per Authentication Context: 1

    ECC Curve: P_256, P_384, P_224, P_521

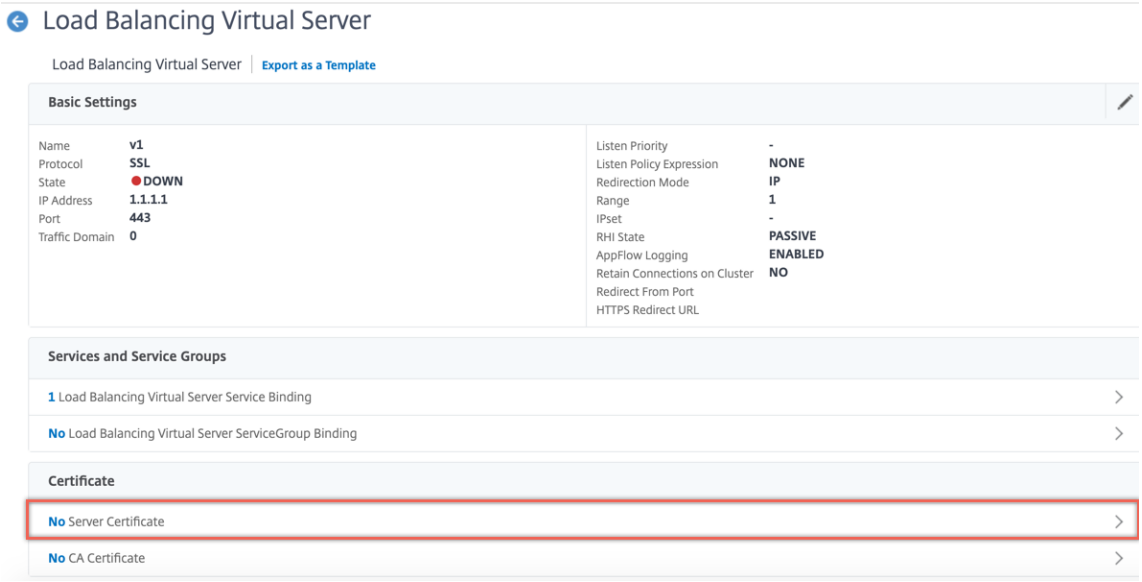
1)  CertKey Name: serverrsa_2048    Server Certificate

1)  Cipher Name: DEFAULT
    Description: Default cipher list with encryption strength >= 128bit
 Done
<!--NeedCopy-->
```

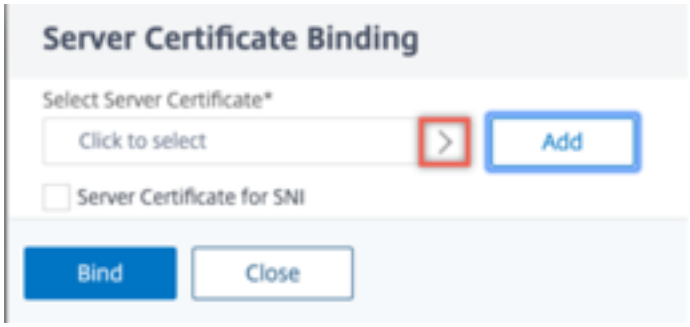
To bind an SSL certificate-key pair to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and open an SSL virtual

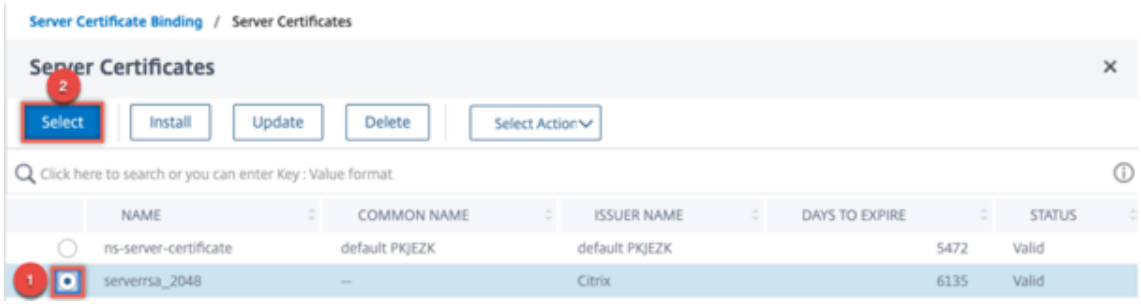
server. Click inside the Certificate section.



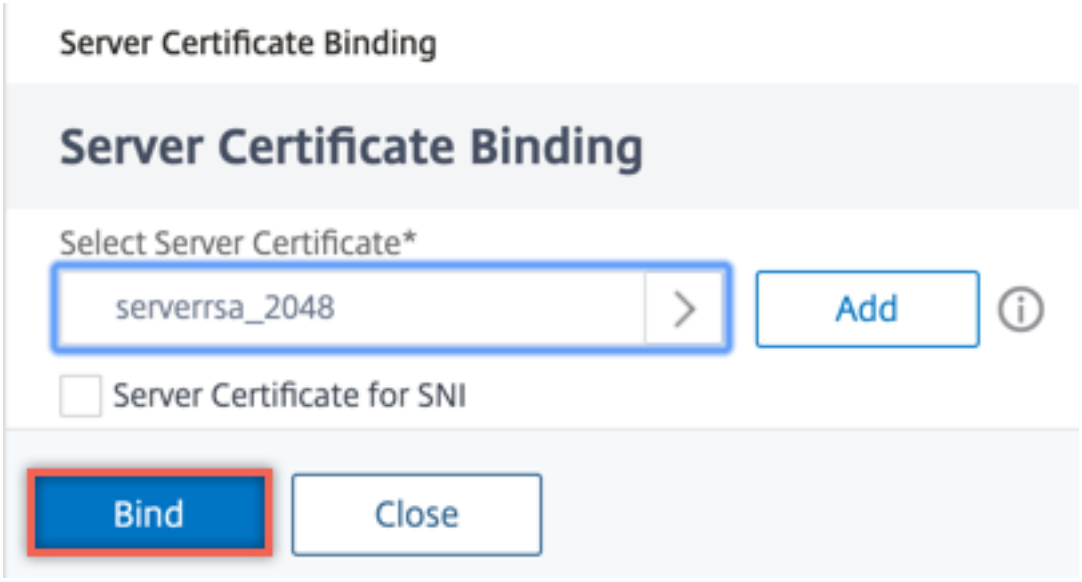
2. Click the arrow to select the certificate-key pair.



3. Select the certificate-key pair from the list.



4. Bind the certificate-key pair to the virtual server.



Limitations

- The number of concurrent calls to the Azure Key Vault for key operations is limited. Performance of the ADC appliance depends on the Key Vault limits. For more information see, Microsoft Azure Key Vault documentation.
- EC keys are not supported.
- EDT and DTLS protocols are not supported.
- ADC appliances with Intel Coleto SSL chips are not supported.
- Clustering and admin partitions are not supported.
- You cannot update the Azure Application entity, the Azure Key Vault object, and the HSM certificate-key pair after you have added them to the ADC appliance.
- A certificate bundle with HSM keys is not supported.
- An error does not appear if the HSM key and certificate do not match. While adding a certificate-key pair, ensure that the HSM key and certificate match.
- You cannot bind an HSM key to a DTLS virtual server.
- You cannot sign OCSP requests using a certificate-key pair that is created using an HSM key.
- You cannot bind a certificate-key pair to an SSL service if the certificate-key pair is created using an HSM key.

FAQ

When integrated with Azure Key Vault, are private keys stored in the ADC appliance memory?

No, private keys are not be stored in ADC appliance memory. For each SSL transaction, the appliance sends a request to Key Vault.

Is the integration FIPS 140-2 level 2 compliant?

Yes, the integrated solution provides FIPS 140-2 Level 2 support.

Which key types are supported?

Only RSA key types are supported.

What key sizes are supported?

1024-bit, 2048-bit, and 4096-bit RSA keys are supported.

Which ciphers are supported?

All ciphers supported on the ADC appliance, including TLSv1.3 ciphers with ECDHE and SHA256 are supported.

Are transactions logged?

The ADC appliance logs each transaction it makes with the Key Vault. Details such as, time, vault IP address, port, success or failure of connection, and errors are logged.
The following is a sample SSL log output.

```
1 Apr  9 16:35:30 <local0.debug> 10.102.57.30 04/09/2019:16:35:30 GMT

Troubleshooting

September 14, 2021

If the SSL feature does not work as expected after configuration, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

For best results, use the following resources to troubleshoot an SSL issue on a Citrix ADC appliance:

- The relevant ns.log file
- The latest ns.conf file
- The messages file
- The relevant `newnslog` file
- Trace files
- A copy of the certificate files, if possible
- A copy of the key file, if possible
- The error message, if any

In addition to these resources, you can use the Wireshark application customized for the Citrix ADC trace files to expedite troubleshooting.

Troubleshooting SSL issues

To troubleshoot an SSL issue, proceed as follows:

- Verify that the Citrix ADC appliance is licensed for SSL Offloading and load balancing.
- Verify that SSL Offloading and load balancing features are enabled on the appliance.
- Verify that the status of the SSL virtual server is not displayed as DOWN.
- Verify that the status of the service bound to the virtual server is not displayed as DOWN.
- Verify that a valid certificate is bound to the virtual server.
- Verify that the service is using an appropriate port, preferably port 443.

Decrypting TLS1.3 traffic from packet trace

To troubleshoot protocols that run over TLS1.3, you must first decrypt the TLS1.3 traffic. To decrypt TLS 1.3 in Wireshark, the secrets must be exported in the `NSS` key log format. For more information about the key log format, see NSS Key Log Format.

For information about how to capture a packet trace, see Capturing SSL Session Keys During a Trace.

Note: Citrix ADC automatically logs each connection's secrets in the appropriate format for the TLS/SSL protocol version in use.

CRL refresh does not happen on the secondary node in an HA setup

The refresh does not happen because the CRL server is accessible only to the primary node through a private network.

Workaround: Add a service on the primary node with the IP address of the CRL server. This service acts as a proxy for the CRL server. When the configuration is synchronized between the nodes, CRL refresh works for both primary and secondary nodes through the service configured on the primary node.

SSL FAQs

September 14, 2021

Basic questions

HTTPS access to the GUI fails on a VPX instance. How do I gain access?

A certificate-key pair is required for HTTPS access to the GUI. On a Citrix ADC appliance, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Citrix recommends that you install a certificate-key pair of at least 1024 bytes and bind it to the internal service for HTTPS access to the configuration utility. Alternately, update the `ns-server-certificate` to 1024 bytes. You can use HTTP access to the configuration utility or the CLI to install the certificate.

If I add a license to an MPX appliance, the certificate-key pair binding is lost. How do I resolve this problem?

If a license is not present on an MPX appliance when it starts, and you add a license later and restart the appliance, you might lose the certificate binding. Reinstall the certificate and bind it to the internal service

Citrix recommends that you install an appropriate license before starting the appliance.

What are the various steps involved in setting up a secure channel for an SSL transaction?

Setting up a secure channel for an SSL transaction involves the following steps:

1. The client sends an HTTPS request for a secure channel to the server.
2. After selecting the protocol and cipher, the server sends its certificate to the client.
3. The client checks the authenticity of the server certificate.
4. If any of the checks fail, the client displays the corresponding feedback.
5. If the checks pass or the client decides to continue even if a check fails, the client creates a temporary, disposable key. This key is called the *pre-master secret* and the client encrypts this key by using the public key of the server certificate.
6. The server, upon receiving the pre-master secret, decrypts it by using the server's private key and generates the session keys. The client also generates the session keys from the pre-master secret. Thus both client and server now have a common session key, which is used for encryption and decryption of application data.

I understand that SSL is a CPU-intensive process. What is the CPU cost associated with the SSL process?

The following two stages are associated with the SSL process:

- The initial handshake and secure channel setup by using the public and private key technology.
- Bulk data encryption by using the symmetric key technology.

Both of the preceding stages can affect server performance, and they require intensive CPU processing for of the following reasons:

1. The initial handshake involves public-private key cryptography, which is very CPU intensive because of large key sizes (1024 bit, 2048 bit, 4096 bit).
2. Encryption/decryption of data is also computationally expensive, depending on the amount of data that must be encrypted or decrypted.

What are the various entities of an SSL configuration?

An SSL configuration has the following entities:

- Server certificate
- Certificate Authority (CA) certificate
- Cipher suite that specifies the protocols for the following tasks:
  - Initial key exchange
  - Server and client authentication

    - Bulk encryption algorithm
    - Message authentication
- Client authentication
- CRL
- SSL Certificate Key Generation Tool that enables you to create the following files:
    - Certificate request
    - Self-signed certificate
    - RSA keys
    - DH parameters

I want to use the SSL offloading feature of the Citrix ADC appliance. What are the various options for receiving an SSL certificate?

You must receive an SSL certificate before you can configure the SSL setup on the Citrix ADC appliance. You can use any of the following methods to receive an SSL certificate:

- Request a certificate from an authorized certificate authority (CA).
- Use the existing server certificate.
- Create a certificate-key pair on the Citrix ADC appliance.

Note: This certificate is a test certificate signed by the test Root-CA generated by the Citrix ADC appliance. Test certificates signed by the test Root-CA are not accepted by browsers. The browser throws a warning message stating that the server's certificate cannot be authenticated.

- For anything other than test purposes, you must provide a valid CA certificate and CA key to sign the server certificate.

What are the minimum requirements for an SSL setup?

The minimum requirements for configuring an SSL setup are as follows:

- Obtain the certificates and keys.
- Create a load balancing SSL virtual server.
- Bind HTTP or SSL services to the SSL virtual server.
- Bind a certificate-key pair to the SSL virtual server.

What are the limits for the various components of SSL?

SSL components have the following limits:

- Bit size of SSL certificates: 4096.
- Number of SSL certificates: Depends on the available memory on the appliance.

- Maximum linked intermediate CA SSL certificates: 9 per chain.
- CRL revocations: Depends on the available memory on the appliance.

What are the various steps involved in the end-to-end data encryption on a Citrix ADC appliance?

The steps involved in the server-side encryption process on a Citrix ADC appliance are as follows:

1. The client connects to the SSL VIP configured on the Citrix ADC appliance at the secure site.
2. After receiving the secure request, the appliance decrypts the request and applies layer 4–7 content switching techniques and load balancing policies. Then, it selects the best available back-end web server for the request.
3. The Citrix ADC appliance creates an SSL session with the selected server.
4. After establishing the SSL session, the appliance encrypts the client request and sends it to the Web server by using the secure SSL session.
5. When the appliance receives the encrypted response from the server, it decrypts and re-encrypts the data. Then, it sends the data to the client by using the client side SSL session.

The multiplexing technique of the Citrix ADC appliance enables the appliance to reuse SSL sessions that have been established with the Web servers. Therefore, the appliance avoids the CPU intensive key exchange, known as *full handshake*. This process reduces the overall number of SSL sessions on the server and maintains end-to-end security.

Certificates and Keys

Can I place the certificate and key files at any location? Is there any recommended location to store these files?

You can store the certificate and key files on the Citrix ADC appliance or a local computer. However, Citrix recommends that you store the certificate and key files in the `/nsconfig/ssl` directory of the Citrix ADC appliance. The `/etc` directory exists in the flash memory of the Citrix ADC appliance. This action provides portability and facilitates backup and restoration of the certificate files on the appliance.

Note: Make sure that the certificate and the key files are stored in the same directory.

What is the maximum size of the certificate key supported on the Citrix ADC appliance?

A Citrix ADC appliance running a software release earlier than release 9.0 supports a maximum certificate key size of 2048 bits. Release 9.0 and later support a maximum certificate key size of 4096 bits. This limit is applicable to RSA certificates.

An MPX appliance supports certificates from 512 bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A virtual appliance supports certificates from 512 bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server from release 12.0-56.x. Older releases support 2048-bit certificates.
- 2048-bit client certificate (if client authentication is enabled on the virtual server) from release 12.0-56.x.

What is the maximum size of the DH parameter supported on the Citrix ADC appliance?

The Citrix ADC appliance supports a DH parameter of maximum 2048 bits.

What is the maximum certificate-chain length, that is, the maximum number of certificates in a chain, supported on a Citrix ADC appliance?

A Citrix ADC appliance can send a maximum of 10 certificates in a chain when sending a server certificate message. A chain of the maximum length includes the server certificate and nine intermediate CA certificates.

What are the various certificate and key formats supported on the Citrix ADC appliance?

The Citrix ADC appliance supports the following certificate and key formats:

- Privacy Enhanced Mail (PEM)
- Distinguished Encoding Rule (DER)

Is there a limit for the number of certificates and keys that I can install on the Citrix ADC appliance?

No. The number of certificates and keys that can be installed is limited only by the available memory on the Citrix ADC appliance.

I have saved the certificate and key files on the local computer. I want to transfer these files to the Citrix ADC appliance by using the FTP protocol. Is there any preferred mode for transferring these files to the Citrix ADC appliance?

Yes. If using the FTP protocol, you must use binary mode to transfer the certificate and key files to the Citrix ADC appliance.

Note: By default, FTP is disabled. Citrix recommends using the SCP protocol for transferring certificate and key files. The configuration utility implicitly uses SCP to connect to the appliance.

What is the default directory path for the certificate and key?

The default directory path for the certificate and key is '/nsconfig/ssl'.

When adding a certificate and key pair, what happens if I do not specify an absolute path to the certificate and key files?

When adding a certificate-key pair, specify an absolute path to the certificate and key files. If you do not specify, the ADC appliance searches the default directory for these files and attempts to load them to the kernel. The default directory is `/nsconfig/ssl`. For example, if the cert1024.pem and rsa1024.pem files are available in the `/nsconfig/ssl` directory of the appliance, both of the following commands are successful:

```
1 add ssl certKey cert1 -cert cert1204.pem -key rsa1024.pem
2 <!--NeedCopy-->
```

```
1 add ssl certKey cert1 -cert /nsconfig/ssl/cert1204.pem -key /nsconfig/
     ssl/rsa1024.pem
2 <!--NeedCopy-->
```

I have configured a high availability setup. I want to implement the SSL feature on the setup. How must I handle the certificate and key files in a high availability setup?

In a high availability setup, you must store the certificate and key files on both the primary and the secondary Citrix ADC appliance. The directory path for the certificate and key files must be the same on both appliances before you add an SSL certificate-key pair on the primary appliance.

nCipher nShield® HSM

When integrating with nCipher nShield® HSM, do we have to keep in mind any specific configuration when adding the Citrix ADC appliance to HA?

Configure the same nCipher devices on both the nodes in HA. nCipher configuration commands don't synchronize in HA. For information about the prerequisites for nCipher nShield® HSM, see Prerequisites.

Do we have to individually integrate both the appliances with nCipher nShield® HSM and RFS? Do we need to complete this action before or after the HA setup?

You can complete the integration before or after the HA setup. If the integration is done after the HA setup, the keys imported on the primary node before configuring the secondary node are not synced to the secondary node. Therefore, Citrix recommends nCipher integration before the HA setup.

Do we need to import the key into both the primary and secondary Citrix ADC appliances, or are the keys synchronized from the primary node to the secondary node?

If nCipher is integrated on both devices before forming the HA, the keys are automatically synchronized from RFS in the process of integration.

Given that the HSM is not on the Citrix ADC appliance, but on nCipher, what happens to the keys and certificates when a node fails and is replaced?

If a node fails, you can synchronize the keys and certificates to the new node, by integrating nCipher on the new node. Then, run the following commands:

```
1 sync ha files ssl
2 force ha sync
3 <!--NeedCopy-->
```

The certificates are synchronized and added if the keys are synchronized in the process of integrating nCipher.

Ciphers

What is a NULL-Cipher?

Ciphers with no encryption are known as NULL-Ciphers. For example, NULL-MD5 is a NULL-Cipher.

Are the NULL-Ciphers enabled by default for an SSL VIP or an SSL service?

No. NULL-Ciphers are not enabled by default for an SSL VIP or an SSL service.

What is the procedure to remove NULL-Ciphers?

To remove the NULL-Ciphers from an SSL VIP, run the following command:

```
bind ssl cipher <SSL_VIP> REM NULL
<!--NeedCopy-->
```

To remove the NULL-Ciphers from an SSL Service, run the following command:

```
bind ssl cipher <SSL_Service> REM NULL -service
<!--NeedCopy-->
```

What are the various cipher aliases supported on the Citrix ADC appliance?

To list the cipher aliases supported on the appliance, at the command prompt, type:

```
sh cipher
<!--NeedCopy-->
```

What is the command to display all the predefined ciphers of the Citrix ADC appliance?

To display all the predefined ciphers of the Citrix ADC appliance, at the CLI, type:

```
show ssl cipher
<!--NeedCopy-->
```

What is the command to display the details of an individual cipher of the Citrix ADC appliance?

To display the details of an individual cipher of the Citrix ADC appliance, at the CLI, type:

```
show ssl cipher <Cipher_Name/Cipher_Alias_Name/Cipher_Group_Name>
<!--NeedCopy-->
```

Example:

```
show cipher SSL3-RC4-SHA
     1) Cipher Name: SSL3-RC4-SHA
     Description: SSLv3 Kx=RSA Au=RSA Enc=RC4(128)
    Mac=SHA1
```

```
5        Done
6  <!--NeedCopy-->
```

What is the significance of adding the predefined ciphers of the Citrix ADC appliance?

Adding the predefined ciphers of the Citrix ADC appliance causes the NULL-Ciphers to get added to an SSL VIP or an SSL service.

Is it possible to change the cipher's order without unbinding them from a cipher group on a Citrix ADC appliance?

Yes. It is possible to change the cipher's order without unbinding the ciphers from a custom cipher group. However, you cannot change the priority in inbuilt cipher groups. To change the priority of a cipher bound to an SSL entity, first unbind the cipher from the virtual server, service, or service group.

Note: If the cipher group bound to an SSL entity is empty, the SSL handshake fails because there is no negotiated cipher. The cipher group must contain at least one cipher.

Is ECDSA supported on the Citrix ADC appliance?

ECDSA is supported on the following Citrix ADC platforms. For details of supported builds, see Table 1 and Table 2 in Ciphers available on the Citrix ADC appliances.

- Citrix ADC MPX and SDX appliances with N3 chips
- Citrix ADC MPX 5900/8900/15000/26000
- Citrix ADC SDX 8900/15000
- Citrix ADC VPX appliances

Does the Citrix ADC VPX appliance support AES-GCM/SHA2 ciphers on the front-end?

Yes, AES-GCM/SHA2 ciphers are supported on the Citrix ADC VPX appliance. For details about the supported builds, see Ciphers available on the Citrix ADC appliances.

Certificates

Is the distinguished name in a client certificate available for the length of the user session?

Yes. You can access the distinguished name of the client certificate in subsequent requests during the length of the user session. That is, even after the SSL handshake is complete and the certificate is not sent again by the browser. Use a variable and an assignment as detailed in the following sample configuration:

Example:

```
add ns variable v2 -type "text(100)"

add ns assignment a1 -variable "$v2" -set       "CLIENT.SSL.CLIENT_CERT
   .SUBJECT.TYPECAST_NVLIST_T('=','/').VALUE("CN")"

add rewrite action act1 insert_http_header subject "$v2"  // example:
   to insert the distinguished name in the header

add rewrite policy pol1 true a1

add rewrite policy pol2 true act1

bind rewrite global pol1 1 next -type RES_DEFAULT

bind rewrite global pol2 2 next -type RES_DEFAULT

set rewrite param -undefAction RESET
<!--NeedCopy-->
```

Why do I need to bind the server certificate?

Binding the server certificates is the basic requirement for enabling the SSL configuration to process SSL transactions.

To bind the server certificate to an SSL VIP, at the CLI, type:

```
bind ssl vserver <vServerName> -certkeyName <cert_name>
<!--NeedCopy-->
```

To bind the server certificate to an SSL service, at the CLI, type:

```
bind ssl service <serviceName> -certkeyName <cert_name>
<!--NeedCopy-->
```

How many certificates can I bind to an SSL VIP or an SSL service?

On a Citrix ADC VPX, MPX/SDX (N3), and MPX/SDX 14000 FIPS appliance, you can bind two certificates to an SSL virtual server or an SSL service if SNI is disabled. The certificates must be one each of type RSA and ECDSA. If SNI is enabled, you can bind multiple server certificates of type RSA or ECDSA. On a Citrix ADC MPX (N2) or MPX 9700 FIPS appliance, if SNI is disabled, you can bind only one certificate of type RSA. If SNI is enabled, you can bind multiple server certificates of type RSA only.

What happens if I unbind or overwrite a server certificate?

When you unbind or overwrite a server certificate, all the connections and SSL sessions created by using the existing certificate are terminated. When you overwrite an existing certificate, the following message appears:

```
ERROR:

Warning: Current certificate replaces the previous binding.
<!--NeedCopy-->
```

How do I install an intermediate certificate on a Citrix ADC appliance and link to a server certificate?

See the article at http://support.citrix.com/article/ctx114146 for information about installing an intermediate certificate.

Why am I getting a "resource already exists" error when I try to install a certificate on the Citrix ADC?

See the article at http://support.citrix.com/article/CTX117284 for instructions for resolving the "resource already exists" error.

I want to create a server certificate on a Citrix ADC appliance to test and evaluate the product. What is the procedure to create a server certificate?

Perform the following procedure to create a test certificate.

Note: A certificate created with this procedure cannot be used to authenticate all the users and browsers. After using the certificate for testing, you must obtain a server certificate signed by an authorized Root certificate authority.

To create a self-signed server certificate:

1. To create a Root CA certificate, at the CLI, type:

```
create ssl rsakey /nsconfig/ssl/test-ca.key 1024

create ssl certreq /nsconfig/ssl/test-ca.csr -keyfile /nsconfig/
   ssl/test-ca.key

Enter the required information when prompted, and then type the
   following command:

```

```
create ssl cert /nsconfig/ssl/test-ca.cer /nsconfig/ssl/test-ca.
    csr ROOT_CERT -keyfile /nsconfig/ssl/test-ca.key
<!--NeedCopy-->
```

2. Perform the following procedure to create a server certificate and sign it with the root CA certificate that you just created

   a) To create the request and the key, at the CLI, type:

```
create ssl rsakey /nsconfig/ssl/test-server.key 1024

    create ssl certreq /nsconfig/ssl/test-server.csr -keyfile
       /nsconfig/ssl/test-server.key
<!--NeedCopy-->
```

   b) Enter the required information when prompted.

   c) To create a serial-number file, at the CLI, type:

```
shell
 # echo '01' >
/nsconfig/ssl/serial.txt
 # exit
<!--NeedCopy-->
```

   d) To create a server certificate signed by the root CA certificate created in step 1, at the CLI, type:

```
create ssl cert /nsconfig/ssl/test-server.cer /nsconfig/ssl/
    test-server.csr SRVR_CERT -CAcert /nsconfig/ssl/test-ca.cer
     -CAkey /nsconfig/ssl/test-ca.key -CAserial /nsconfig/ssl/
    serial.txt
<!--NeedCopy-->
```

   e) To create a Citrix ADC cert-key pair, which is the in-memory object that holds the server certificate information for SSL handshakes and bulk encryption, at the CLI, type:

```
add ssl certkey test-certkey -cert /nsconfig/ssl/test-server.
    cer -key /nsconfig/ssl/test-server.key
<!--NeedCopy-->
```

   f) To bind the cert-key pair to the SSL virtual server, at the CLI, type:

```
bind ssl vserver <vServerName> -certkeyName <cert_name>
<!--NeedCopy-->
```

I have received a Citrix ADC appliance on which NetScaler software release 9.0 is installed. I have noticed an extra license file on the appliance. Is there any change in the licensing policy starting with NetScaler software release 9.0?

Yes. Starting with Citrix NetScaler software release 9.0, the appliance might not have a single license file. The number of license files depends on the Citrix ADC software release edition. For example, if you have installed the Advanced edition, you might need extra license files for the full functionality of the various features. However, if you have installed the Premium edition, the appliance has only one license file.

How do I export the certificate from the Internet Information Service (IIS)?

There are many ways, but by using the following method the appropriate certificate and private key for the website are exported. This procedure must be performed on the actual IIS server.

1. Open the Internet Information Services (IIS) Manager administration tool.
2. Expand the websites node and locate the SSL-enabled website that you want to serve through the Citrix ADC appliance.
3. Right-click this website and click Properties.
4. Click the Directory Security tab and, in the Secure Communications section of the window, select the View Certificate box.
5. Click the Details tab, and then click Copy to File.
6. On the Welcome to the Certificate Export Wizard page, click Next.
7. Select Yes, export the private key, and click Next.

   Note: The private key MUST be exported for SSL Offload to work on the Citrix ADC.
8. Make sure that the Personal Information Exchange -PKCS #12 radio button is selected, and select *only* the Include all certificates in the certification path if possible check box. Click Next.
9. Enter a password and click Next.
10. Enter a file name and location, and then click Next. Give the file an extension of .PFX.
11. Click Finish.

How do I convert the PKCS#12 certificate and install it on the Citrix ADC?

1. Move the exported .PFX certificate file to a location from where it can be copied to the Citrix ADC appliance. That is, to a machine that permits SSH access to the management interface of a Citrix ADC appliance. Copy the certificate to the appliance by using a secure copy utility such as SCP.

2. Access the BSD shell and convert the certificate (for example, cert.PFX) to .PEM format:

```
root@ns# openssl pkcs12 -in cert.PFX -out cert.PEM
<!--NeedCopy-->
```

3. To make sure that the converted certificate is in the correct x509 format, verify that the following command produces no error:

```
root@ns# openssl x509 -in cert.PEM -text
<!--NeedCopy-->
```

4. Verify that the certificate file contains a private key. Begin by issuing the following command:

```
root@ns# cat cert.PEM

Verify that the output file includes an RSA PRIVATE KEY section.

-----BEGIN RSA PRIVATE KEY-----
Mkm^s9KMs9023pz/s...
-----END RSA PRIVATE KEY-----
<!--NeedCopy-->
```

The following is another example of an RSA PRIVATE KEY section:

```
    Bag Attributes

... (more random characters) 5
   pLDWYVHhLkA1pSxvFjNJHRSIydWHc5ltGyKqIUcBezVaXyel94pNSUYx07NpPV
   /

MY2ovQyQZM8gGe3+lGFum0VHbv/y/gB9HhFesog=
-----END CERTIFICATE-----
<!--NeedCopy-->
```

The following is an INTERMEDIATE CA CERTIFICATE section:

```
Bag Attributes: <Empty Attributes>
subject=/DC=lan/DC=food/CN=hotdog
issuer=/DC=lan/DC=food/CN=hotdog
-----BEGIN CERTIFICATE-----
MIIESDCCAzCgAwIBAgIQah20fCRYTY9LRXYMIRaKGjANBgkqhkiG9w0BAQUFADA8

... (more random characters)
   Nt0nksawDnbKo86rQcNnY5xUs7c7pj2zxj/IOsgNHUp5W6dDI9pQoqFFaDk
   =

-----END CERTIFICATE-----
<!--NeedCopy-->
```

Further Intermediate CA certificates might follow, depending on the certification path of the exported certificate.

5. Open the .PEM file in a text editor

6. Locate the first line of the .PEM file and the first instance of the following line, and copy those two lines and all the lines between them:

```
-----END CERTIFICATE-----

Note: Make sure that last copied line is the first
-----END CERTIFICATE----- line in the .PEM file.

<!--NeedCopy-->
```

7. Paste the copied lines into a new file. Call the new file something intuitive, such as cert-key.pem. This certificate-key pair is for the server hosting the HTTPS service. This file must contain both the section labeled RSA PRIVATE KEY and the section labeled SERVER CERTIFICATE in the preceding example.

   Note: The certificate-key pair file contains the private key and must be kept secure.

8. Locate any subsequent sections beginning with —-BEGIN CERTIFICATE—- and ending with —END CERTIFICATE—-, and copy each such section to a separate new file.

   These sections correspond to certificates of trusted CAs that have been included in the certification path. These sections must be copied and pasted into new individual files for these certificates. For example, the INTERMEDIATE CA CERTIFICATE section of the preceding example must be copied and pasted into a new file).

   For multiple intermediate CA certificates in the original file, create files for each intermediate CA certificate in the order in which they appear in the file. Keep track (using appropriate file names) of the order in which the certificates appear, as they must be linked together in the correct order in a later step.

9. Copy the certificate-key file (cert-key.pem) and any additional CA certificate files into the /nsconfig/ssl directory on the Citrix ADC appliance.
10. Exit the BSD shell and access the Citrix ADC prompt.
11. Follow the steps in “Install the certificate-key files on the appliance” to install the key/certificate once uploaded on the device.

How do I convert the PKCS#7 certificate and install it on the Citrix ADC appliance?

You can use OpenSSL to convert a PKCS #7 Certificate to a format recognizable by the Citrix ADC appliance. The procedure is identical to the procedure for PKCS #12 certificates, except that you invoke OpenSSL with different parameters. The steps for converting PKCS #7 certificates are as follows:

1. Copy the certificate to the appliance by using a secure copy utility, such as SCP.
2. Convert the certificate (for example, cert.P7B) to PEM format:

```
openssl pkcs7 -inform DER -in cert.p7b -print_certs -text -out
    cert.pem
<!--NeedCopy-->
```

3. Follow steps 3 through 7 as described in the answer for PKCS #12 certificates.
   Note: Before loading the converted PKCS #7 certificate to the appliance, verify that it contains a private key, exactly as described in step 3 for the PKCS #12 procedure. PKCS #7 certificates, particularly the certificates exported from IIS, do not typically contain a private key.

When I bind a cipher to a virtual server or service by using the bind cipher command, I see the error message "Command deprecated."?

The command for binding a cipher to a virtual server or service has changed.

Use the `bind ssl vserver <vsername> -ciphername <ciphername>` command to bind an SSL cipher to an SSL virtual server.

Use the `bind ssl service <serviceName> -ciphername <ciphername>` command to bind an SSL cipher to an SSL service.

Note: New ciphers and cipher groups are added to the existing list and not replaced.

Why can't I create a cipher group and bind ciphers to it by using the add cipher command?

The add cipher command functionality has changed in release 10. The command only creates a cipher group. To add ciphers to the group, use the bind cipher command.

OpenSSL

How do I use OpenSSL to convert certificates between PEM and DER?

To use OpenSSL, you must have a working installation of the OpenSSL software and be able to run OpenSSL from the command line.

x509 certificates and RSA keys can be stored in several different formats.

Two common formats are:

- DER (a binary format used primarily by Java and Macintosh platforms)
- PEM (a base64 representation of DER with header and footer information, which is used primarily by UNIX and Linux platforms).

A key and the corresponding certificate, in addition to the root and any intermediate certificates, can also be stored in a single PKCS#12 (.P12, .PFX) file.

Procedure

Use the **OpenSSL** command to convert between formats as follows:

1. To convert a certificate from PEM to DER:

```
x509 -in input.crt -inform PEM -out output.crt -outform DER
<!--NeedCopy-->
```

2. To convert a certificate from DER to PEM:

```
x509 -in input.crt -inform DER -out output.crt -outform PEM
<!--NeedCopy-->
```

3. To convert a key from PEM to DER:

```
rsa -in input.key -inform PEM -out output.key -outform DER
<!--NeedCopy-->
```

4. To convert a key from DER to PEM:

```
rsa -in input.key -inform DER -out output.key -outform PEM
<!--NeedCopy-->
```

Note: If the key you are importing is encrypted with a supported symmetric cipher, you are prompted to enter the pass-phrase.

Note: To convert a key to or from the obsolete NET (Netscape server) format, substitute NET for PEM or DER as appropriate. The stored key is encrypted in a weak unsalted RC4 symmetric cipher, so a pass-phrase is requested. A blank pass-phrase is acceptable.

System Limits

What are the important numbers to remember?

1. Create Certificate Request:
   - Request File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - PEM Passphrase (For Encrypted Key): Maximum 31 characters
   - Common Name: Maximum 63 characters
   - City: Maximum 127 characters
   - Organization Name: Maximum 63 characters
   - State/Province Name: Maximum 63 characters
   - Email Address: Maximum 39 Characters

- Organization Unit: Maximum 63 characters
- Challenge Password: Maximum 20 characters
- Company Name: Maximum 127 characters

2. Create Certificate:

   - Certificate File Name: Maximum 63 characters
   - Certificate Request File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - PEM Passphrase: Maximum 31 characters
   - Validity Period: Maximum 3650 days
   - CA Certificate File Name: Maximum 63 characters
   - CA Key File Name: Maximum 63 characters
   - PEM Passphrase: Maximum 31 characters
   - CA Serial Number File: Maximum 63 characters

3. Create and Install a Server Test Certificate:

   - Certificate File Name: Maximum 31 characters
   - Fully Qualified Domain Name: Maximum 63 characters

4. Create Diffie-Hellman (DH) key:

   - DH File Name (with path): Maximum 63 characters
   - DH Parameter Size: Maximum 2048 bits

5. Import PKCS12 key:

   - Output File Name: Maximum 63 characters
   - PKCS12 File Name: Maximum 63 characters
   - Import Password: Maximum 31 characters
   - PEM Passphrase: Maximum 31 characters
   - Verify PEM Passphrase: Maximum 31 characters

6. Export PKCS12

   - PKCS12 File Name: Maximum 63 characters
   - Certificate File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - Export Password: Maximum 31 characters
   - PEM Passphrase: Maximum 31 characters

7. CRL Management:

   - CA Certificate File Name: Maximum 63 characters
   - CA Key File Name: Maximum 63 characters
   - CA Key File Password: Maximum 31 characters

- Index File Name: Maximum 63 characters
- Certificate File Name: Maximum 63 characters

8. Create RSA Key:
    - Key File Name: Maximum 63 characters
    - Key Size: Maximum 4096 bits
    - PEM Passphrase: Maximum 31 characters
    - Verify Passphrase: Maximum 31 characters
9. Change advanced SSL settings:
    - Maximum CRL memory size: Maximum 1024 Mbytes
    - Encryption trigger timeout (10 mS ticks): Maximum 200
    - Encryption trigger packet count: Maximum 50
    - OCSP cache size: Maximum 512 Mbytes
10. Install Certificate:
    - Certificate-Key pair Name: Maximum 31 characters
    - Certificate File Name: Maximum 63 characters
    - Private Key File Name: Maximum 63 characters
    - Password: Maximum 31 characters
    - Notification Period: Maximum 100
11. Create Cipher Group:
    - Cipher Group Name: Maximum 39 characters
12. Create CRL:
    - CRL Name: Maximum 31 characters
    - CRL File: Maximum 63 characters
    - URL: Maximum 127 characters
    - Base DN: Maximum 127 characters
    - Bind DN: Maximum 127 characters
    - Password: Maximum 31 characters
    - Days: Maximum 31
13. Create SSL Policy:
    - Name: Maximum 127 characters
14. Create SSL Action:
    - Name: Maximum 127 characters
15. Create OCSP Responder:
    - Name: Maximum 32 characters

- URL: Maximum 128 characters
- Batching Depth: Maximum 8
- Batching Delay: Maximum 10000
- Produced At Time Skew: Maximum 86400
- Request Time-out: Maximum120000

16. Create Virtual Server:
    - Name: Maximum 127 characters
    - Redirect URL: Maximum 127 characters
    - Client Time-out: Maximum 31536000 secs
17. Create Service:
    - Name: Maximum 127 characters
    - Idle Time-out (secs):
      Client: Maximum 31536000
      Server: Maximum 31536000
18. Create Service Group:
    - Service Group Name: Maximum 127 characters
    - Server ID: Maximum 4294967295
    - Idle Time-out (secs):
      Client: Maximum value 31536000
      Server: Maximum 31536000
19. Create Monitor:
    - Name: Maximum 31 characters
20. Create Server:
    - Server Name: Maximum 127 characters
    - Domain Name: Maximum 255 characters
    - Resolve Retry: Maximum 20939 secs

Content inspection

September 14, 2021

In recent times, there is an expansion of device types to display various multimedia content. The device types can be of mobile handsets to tablets, and to desktops. Intermediate infrastructure providers need to transform the original content from a web server to a format suitable for the device that asks for the content. The external devices inspect the content that transcodes and send it back

to the client. Commonly used protocol to achieve this is ICAP. ICAP enables the Citrix ADC appliance to be put in various deployments. ICAP uses the content inspection technique that inspects data for malware and security issues.

> **Note**
>
> HTTP/2 is not compatible with content inspection. The applications using the HTTP/2 might not function properly if the traffic is sent through the content inspection.

ICAP for remote content inspection

September 14, 2021

The Internet Content Adaptation Protocol (ICAP) is a simple lightweight protocol for running the value-added transformation service on HTTP messages. In a typical scenario, an ICAP client forwards HTTP requests and responses to one or more ICAP servers for processing. The ICAP servers perform content transformation on the requests and send back responses with appropriate action to take on the request or response.

ICAP on a Citrix ADC appliance

In a Citrix ADC setup, the appliance acts as an ICAP client interoperating with third-party ICAP servers (such as antimalware and Data Loss Protection (DLP)). When the appliance receives an incoming web traffic, the appliance intercepts the traffic and uses a Content Inspection policy to evaluate if the HTTP request needs an ICAP processing. If yes, the appliance decrypts and sends the message as a plain text to the ICAP servers. The ICAP servers run the content transformation service on the request message and send back a response to the appliance. The adapted messages can either be an HTTP request or an HTTP response. If the appliance interoperates with multiple ICAP servers, the appliance performs load balancing of ICAP servers. This scenario happens when one ICAP server is not sufficient to handle all the traffic load. Once the ICAP servers return a modified message, the appliance forwards the modified message to the back-end origin server.

The Citrix ADC appliance also provides a secured ICAP service if the incoming traffic is an HTTPS type. The appliance uses an SSL based TCP service to establish a secured connection between the appliance and ICAP servers.

How ICAP request modification (REQMOD) works

In the request modification (REQMOD) mode, the Citrix ADC appliance forwards the HTTP request received from the client to the ICAP server. The ICAP server then performs one of the following:

1. Sends back a modified version of the request and the appliance in turn sends the modified request to the back-end origin server or it pipelines the modified request to another ICAP server.
2. Responds with a message indicating no adaptation is required.
3. Returns an error and the appliance in turn sends the error message back to the user.

How ICAP response modification (RESPMOD) works

In the response modification (RESPMOD) mode, the Citrix ADC appliance sends an HTTP response to the ICAP server (the response sent by the appliance is typically the response sent by the origin server). The ICAP server then performs one of the following:

1. Sends a modified version of the response and the appliance in turn sends the response to the user or pipelines the response to another ICAP server.
2. Responds with a message indicating no adaptation is required.
3. Returns an error and the appliance in turn sends the error message to the user.

ICAP license

The ICAP feature works on a Citrix ADC standalone or high availability setup with Citrix ADC Premium or Advanced license edition.

Configure ICAP for content transformation service

To use ICAP for content transformation service, you must begin by enabling the Content inspection and load balancing features. Once you enable the features, you can complete the following tasks

To enable content inspection

If you want the Citrix ADC appliance to act as an ICAP client, you must first enable the Content Inspection and load balancing features.

At the command prompt, type:

```
enable ns feature contentInspection LoadBalancing
<!--NeedCopy-->
```

Add ICAP profile

ICAP configurations for a Citrix ADC appliance are specified in an entity called the ICAP profile. The profile has a collection of the ICAP settings. The settings include parameters to dynamically generate an ICAP request, receive the ICAP response, and log content inspection data.

To dynamically generate an ICAP request to the ICAP server, a new parameter, “insertHTTPRequest” is added to the ICAP profile. If this parameter is configured, the appliance takes the configured value as a policy expression and evaluates the expression and includes the result as an encapsulated HTTP request or response and then sent it to the ICAP server. Also, a new parameter “insertICAPHeaders” is configurable to dynamically evaluate and include the ICAP headers.

When the appliance sends an ICAP request and does not receive a response the ICAP server, the connection becomes unresponsive. It occurs until the ICAP server sends a response or a session gets freed. The behavior can be handled by configuring the ICAP response time-out option. You can set a request time-out parameter for action if there is delayed ICAP response. If the Citrix ADC appliance does not receive a response within the configured request time-out, the request timeout action is performed.

ReqTimeoutAction: Possible values are BYPASS, RESET, DROP.
BYPASS: This Ignores the remote ICAP server’s response and sends the request/response to Client/Server.
RESET (default): Reset the client connection by closing it.
DROP: Drop the request without sending a response to the user

To evaluate an ICAP response, a new policy expression `ICAP.RES` is used in the content inspection callout return expression. This expression evaluates the ICAP response similar to the `HTTP.RES` expression in a `HTTP_CALLOUT`.

For example, when a Citrix ADC appliance receives an HTTP request for a service hosted behind the Citrix ADC virtual IP address, the appliance might have to check the client’s authentication with an external server and take an action.

At the command prompt, type:

```
add ns icapProfile <name> [-preview ( ENABLED | DISABLED )][-previewLength
 <positive_integer>] -uri <string> [-hostHeader <string>] [-userAgent <
string>] -Mode ( REQMOD | RESPMOD )[-queryParams <string>] [-connectionKeepAlive
 ( ENABLED | DISABLED )][-allow204 ( ENABLED | DISABLED )] [-insertICAPHeaders
 <string>][-insertHTTPRequest <string>] [-reqTimeout <positive_integer>][-
reqTimeoutAction <reqTimeoutAction>] [-logAction <string>]
```

Example:

```
add icapprofile reqmod-profile -mode RESPMOD -uri  “/req_scan”  -hostHeader
 “Webroot.reqsca”  -useragent  “NS_SWG-Proxy”
```

```
add ns icapProfile icap_prof1 -uri "/example"-Mode REQMOD -reqtimeout 4 -
reqtimeoutaction BYPASS
```

```
> add icapProfile reqmode-profile -uri '/example'-mode REQMOD -insertHTTPRequest
 q{ HTTP.REQ.METHOD + ""+ HTTP.REQ.URL + "HTTP/1.1\r\n"+ "Host: "+ HTTP.REQ
```

```
.HOSTNAME + "\r\n\r\n"}
```

Log ICAP content inspection action

To dynamically generate content inspection log stream records or SYSLOG logs, you can use the ICAP.RES based policy expression on the ICAP response. This parameter is configurable in the ICAP profile to configure the policy expression to generate the dynamic log records.

At the command prompt, type:

```
add audit messageaction icap_log_expr INFORMATIONAL icap.res.full_header
```

```
set icapProfile reqmode-profile -logAction messageaction
```

Add ICAP service as a TCP or SSL_TCP service

After you enable the Content Inspection feature, you must add an ICAP service for the ICAP servers that will be part of the load balancing setup. The service that you add provides the ICAP connection between the Citrix ADC appliance and load balancing virtual servers.

Note: As an administrator, you can add an ICAP service and directly configure the ICAP server IP address in the Content Inspection action.

At the command prompt, type the following:

```
1 add service <name> <IP> <serviceType> <port>
2 <!--NeedCopy-->
```

Example:

```
add service icapsv1 10.10.10.10 SSL_TCP 1345
```

```
add service icapsv2 10.10.10.11 SSL_TCP 1345
```

Add a TCP or SSL_TCP based load balancing virtual server

After creating an ICAP service, you must create a virtual server to accept ICAP traffic and load balance the ICAP servers.

> **Note:**
>
> You can also use an SSL based TCP service over a secured channel. You use a SSL_TCP service and bind to the Content Inspection action.

At the command prompt, type the following:

```
1 add lb vserver <name> <serviceType> <port>
2 <!--NeedCopy-->
```

Example:

```
add lb vserver vicap TCP 0.0.0.0.0 - persistenceType NONE -cltTimeout
    9000

add lb vserver vicap SSL_TCP 0.0.0.0 0 - persistenceType NONE -
    cltTimeout 9000
<!--NeedCopy-->
```

Bind ICAP service to the load balancing virtual server

After you create an ICAP service and virtual server, you must bind the ICAP service to the virtual server.

At the command prompt, type the following:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver vicap icapsv1
<!--NeedCopy-->
```

Add content inspection action

After you enable the Content Inspection feature, you must add an ICAP action for handling the ICAP request information. The ICAP profile and services, or load balancing virtual server that are created are bound to the ICAP action. If the ICAP server is down, you can configure the `ifserverdown` parameter for the appliance to perform any one of the following actions.

CONTINUE: If the User wants to bypass the content inspection when the remote server is down, you can choose the “CONTINUE” action, as default.
RESET (default): This action responds to the client by closing the connection with RST.
DROP: This action silently drops the packets without sending a response to the user.

At the command prompt, type the following:

```
add contentInspection action <name> -type ICAP -serverName <string> -
    icapProfileName <string>

add ContentInspection action <name> -type ICAP -serverip <ip> -
    serverport <port> -icapProfileName <string>
<!--NeedCopy-->
```

> **Note:**
>
> If you can configure the ICAP service instead of a load balancing virtual server, you can mention the service name in the \<-serverip> option. When adding the Content Inspection action, the TCP service is automatically created for the given IP address with port 1344 and it is used for ICAP communication.

Example:

```
add ContentInspection action ci_act_lb -type ICAP -serverName vicap -
    icapProfileName icap_reqmod

add ContentInspection action ci_act_svc -type ICAP -serverName icapsv1
    -icapProfileName icap_reqmod

add ContentInspection action ci_act_svc -type ICAP -serverip 1.1.1.1 -
    serverport 1344 -icapProfileName icap_reqmod
<!--NeedCopy-->
```

Add content inspection policies

After you create a Content Inspection action, you must create content inspection policies to evaluate requests for ICAP processing and audit logging. The policy is based on a rule which consists of one or more expressions. The rule is associated to the content inspection action that is associated if a request matches the rule.

At the command prompt, type the following:

```
add contentInspection policy <name> -rule <expression> -action <string>
<!--NeedCopy-->
```

Example:

```
add ContentInspection policy ci_pol_basic - rule true - action
    ci_act_svc

add ContentInspection policy ci_pol_HTTP - rule HTTP.REQ.URL.CONTAINS(
    "html") - action ci_act_svc
<!--NeedCopy-->
```

Bind content inspection policies to the content switching or load balancing virtual server

To put an ICAP policy into effect, you must bind it globally or bind it to a Content Switching or load balancing virtual server, which front end the application. When you bind the policy, you must assign

a priority to it. The priority determines the order in which the policies you define are evaluated.

> **Note:**
>
> The application virtual server must be of type - HTTP/SSL/CS-PROXY.

For information about configuring a load balancing setup for forwarding the traffic to the back-end origin server after content transformation, see Load Balancing.

Configure secured ICAP service

To establish a secured connection between the Citrix ADC appliance and the ICAP web servers, the appliance uses an SSL-based TCP service or load balancing virtual server bound to an ICAP action.

To establish a secured ICAP connection, complete the following tasks:

1. Add SSL-based TCP service.
2. Bind SSL-based TCP service to load balancing virtual server of type TCP or SSL_TCP.
3. Bind SSL-based TCP service or load balancing virtual server to Content Inspection action.

Add SSL-based TCP service to load balancing virtual server

To establish a secured connection between the Citrix ADC appliance and the ICAP web servers, the appliance uses an SSL-based TCP service or load balancing virtual server bound to an ICAP action.

To establish a secured ICAP connection, complete the following tasks:

1. Add SSL-based TCP service.
2. Bind SSL-based TCP service to load balancing virtual server of type TCP or SSL_TCP.

Bind SSL-based TCP service or load balancing virtual server to Content Inspection action

Add SSL-based TCP service to load balancing virtual server

After you enable the Content Inspection feature, you must add a secured ICAP service that will be part of the load balancing setup. The service that you add provides a secured ICAP connection between the Citrix ADC appliance and load balancing virtual servers.

At the command prompt, type the following:

```
add service <name> <IP> <serviceType> <port>
<!--NeedCopy-->
```

Example:

```
add service icapsv2 10.102.29.200 SSL_TCP 1344 -gslb NONE -maxclient
    0 -maxReq 0 -cip DISABLED -usip NO -useproxport YES -sp ON -
    cltTimeout 9000 -svrTimeout 9000 -CKA NO -TCPB NO -CMP NO
<!--NeedCopy-->
```

Bind SSL-based TCP service to SSL_TCP or TCP load balancing virtual server

After you create a secured ICAP service, you must bind the service to the load balancing virtual server. It is required if you are using a load balancing virtual server to load balance the ICAP servers.

At the command prompt, type the following:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver vicap icapsv2
<!--NeedCopy-->
```

Bind SSL-based TCP service or load balancing virtual server to the Content Inspection action

You add an ICAP action for handling the ICAP request information and also bind the SSL-based TCP service to the action.

At the command prompt, type the following:

```
add contentInspection action <name> -type ICAP -serverName <string> -
    icapProfileName <string>
<!--NeedCopy-->
```

Example:

```
add ContentInspection action ci_act_svc -type ICAP -serverName icapsv2
    -icapProfileName icap_reqmod

add ContentInspection action ci_act_svc -type ICAP -serverName vicap -
    icapProfileName icap_reqmod
<!--NeedCopy-->
```

Configure ICAP protocol by using the GUI

1. Navigate to **Load Balancing** > **Services** and click **Add**.

2. In the **Services** page, enter the service details.
3. Navigate to **Load Balancing** > **Virtual Servers**. Add a load balancing virtual server of type HTTP/SSL. Or, you can select a virtual server and click **Edit**.
4. After entering the server basic details, click **Continue**.
5. In the **Advanced Settings** section, click **Policies**.
6. Go the **Policies** section and click the **Pencil** icon to configure the Content Inspection policy.
7. On the **Choose Policy** page, select **Content Inspection**. Click **Continue**.
8. In the **Policy Binding** section, click **+** to add a Content Inspection policy.
9. In the **Create ICAP Policy** page, enter a name for the policy.
10. In the **Action** field, click the "+" sign to add an ICAP action.
11. In the **Create ICAP Action** page, enter a name for the action.
12. Enter a name for the action.
13. In the **Server Name** field, enter the name of the TCP service already created.
14. In **ICAP Profile** field, click the "+" sign to add an ICAP profile.
15. In the **Create ICAP Profile** page, enter a profile name, URI, and MODE.
16. Click **Create**.
17. In the **Create ICAP Action** page, click **Create**.
18. In the **Create ICAP Policy** page, enter "true" in the **Expression Editor** and then click **Create**.
19. Click **Bind**.
20. When prompted to enable the Content Inspection feature, click **Yes**.
21. Click **Done**.

For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to the back-end origin server after content transformation, see Load Balancing.

Configure secured ICAP protocol by using the GUI

1. Navigate to **Load Balancing** > **Services** and click **Add**.
2. In the **Services** page, enter the service details.
3. Navigate to **Load Balancing** > **Virtual Servers**. Add a virtual server of type HTTP/SSL. Or, you can select a virtual server and click **Edit**.
4. After entering the server basic details, click **Continue**.
5. In the **Advanced Settings** section, click **Policies**.
6. Go the **Policies** section and click the **Pencil** icon to configure the Content Inspection policy.
7. On the **Choose Policy** page, select **Content Inspection**. Click **Continue**.
8. In the **Policy Binding** section, click **+** to add a Content Inspection policy.
9. In the **Create ICAP Policy** page, enter a name for the policy.
10. In the **Action** field, click the "+" sign to add an ICAP action.
11. In the **Create ICAP Action** page, enter a name for the action.
12. Enter a name for the action.

13. In the **Server Name** field, enter the name of the TCP_SSL service already created.
14. In **ICAP Profile** field, click the "+" sign to add an ICAP profile.
15. In the **Create ICAP Profile** page, enter a profile name, URI, and MODE.
16. Click **Create**.
17. In the **Create ICAP Action** page, click **Create**.
18. In the **Create ICAP Policy** page, enter "true" in the **Expression Editor** and then click **Create**.
19. Click **Bind**.
20. When prompted to enable the Content Inspection feature, click **Yes**.
21. Click **Done**.

Audit log support for remote content inspection

If an incoming request or outgoing response is content inspected, the Citrix ADC appliance logs the ICAP details. The appliance stores the details as a log message in the ns.log file.

Each log message typically contains the following details:

```
<Source IP> <Destination IP> <Domain> <ICAP server IP><ICAP Mode> <
    Service URI> <ICAP response> <Policy action>
<!--NeedCopy-->
```

Example for content inspected request log message:

```
Apr 18 14:45:41 <local0.info> 10.106.97.104 04/18/2018:14:45:41 GMT 0-
    PPE-0 : default CI ICAP_LOG 788 0 : Source 10.102.1.98:39048 -
    Destination 10.106.97.89:8011 - Domain 10.106.97.89 - Content-Type
    application/x-www-form-urlencoded - ICAP Server 10.106.97.99:1344 -
    Mode REQMOD - Service /example - Response 204 - Action FORWARD
<!--NeedCopy-->
```

Example for content inspected response log message:

```
Apr 18 12:34:08 <local0.info> 10.106.97.104 04/18/2018:12:34:08 GMT 0-
    PPE-0 : default CI ICAP_LOG 71 0 : Source 10.106.97.105:18552 -
    Destination 10.106.97.99:80 - Domain NA - Content-Type NA - ICAP
    Server 10.106.97.99:1344 - Mode RESPMOD - Service /example -
    Response 400 - Action Internal Error
<!--NeedCopy-->
```

Inline device integration with Citrix ADC

September 14, 2021

Security devices such as Intrusion Prevention System (IPS) and Next Generation Firewall (NGFW) protect servers from network attacks. These devices are deployed in layer 2 inline mode and their primary function is to protect servers from network attacks and report security threats on the network.

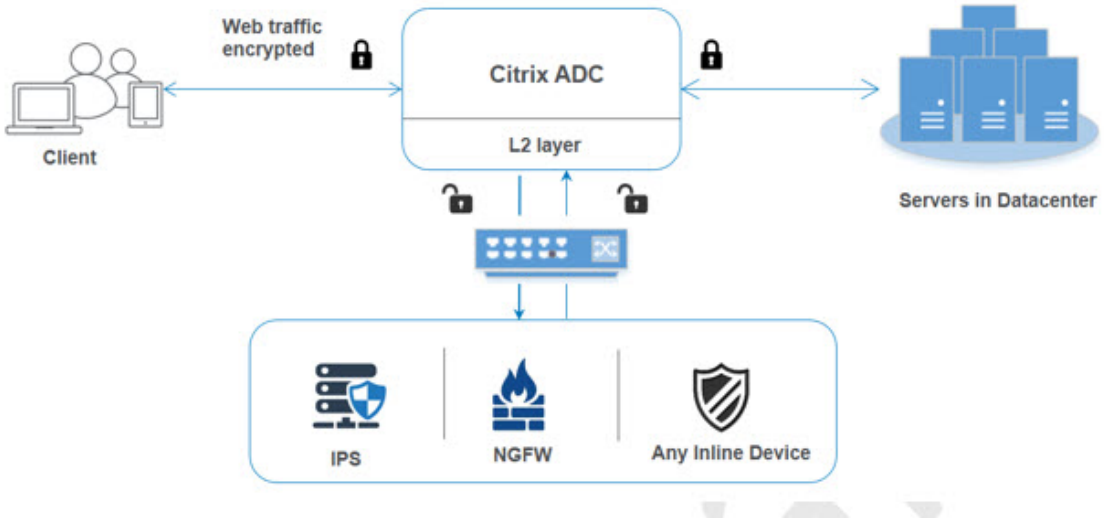
To prevent vulnerable threats and provide advanced security protection, a Citrix ADC appliance is integrated with one or more inline devices. The inline devices can be any security device such as IPS, NGFW.

Following are some of the use cases that benefit in using the inline device integration with the Citrix ADC appliance:

- **Inspecting encrypted traffic**. Most IPS and NGFW appliances bypass encrypted traffic, thereby leaving servers vulnerable to attacks. A Citrix ADC appliance can decrypt traffic and send it to inline devices for inspection. It enhances the customer's network security.
- **Offloading inline devices from TLS/SSL processing**. TLS/SSL processing is expensive and the issue can result in high system CPU in IPS or NGFW appliances if they decrypt the traffic. As encrypted traffic is growing at a fast pace, these systems fail to decrypt and inspect encrypted traffic. Citrix ADC helps in offloading inline devices from TLS/SSL processing. It results in the inline device supporting a high volume of traffic inspection.
- **Loading balancing inline devices**. The Citrix ADC appliance load balances multiple inline devices when there is a high volume of traffic.
- **Smart selection of traffic**. Every packet flowing into the appliance might be content inspected, for example download of text files. User can configure the Citrix ADC appliance to select specific traffic (for example .exe files) for inspection and send the traffic to inline devices for processing the data

How the Citrix ADC is integrated with inline devices

The following diagram shows how a Citrix ADC is integrated with inline security devices.



When you integrate inline devices with the Citrix ADC appliance, the component interacts as per the following:

1. A client sends a request to Citrix ADC appliance.
2. The appliance receives the request and sends it to an inline device based on policy evaluation.
   Note: If there are two or more inline devices, the appliance load balances the devices and sends the traffic.
   If the incoming traffic is an encrypted one, the appliance decrypts the data and sends it as a plain text to the inline device for content inspection.
3. The inline device inspects the data for threats and decides whether to drop, reset, or send the data back to the appliance.
4. If there are security threats, the device modifies the data and sends it to the appliance.
5. The Citrix ADC in turn re-encrypts the data and forwards the request to the back-end server.
6. The back-end server sends the response to the Citrix ADC appliance.
7. The appliance again decrypts the data and sends it to the inline device for inspection.
8. Appliance re-encrypts the data and sends the response to the client

Software licensing

To deploy the inline device integration, your Citrix ADC appliance must be provisioned with one of the following licenses:

1. ADC Premium
2. ADC Advanced
3. Telco Advanced

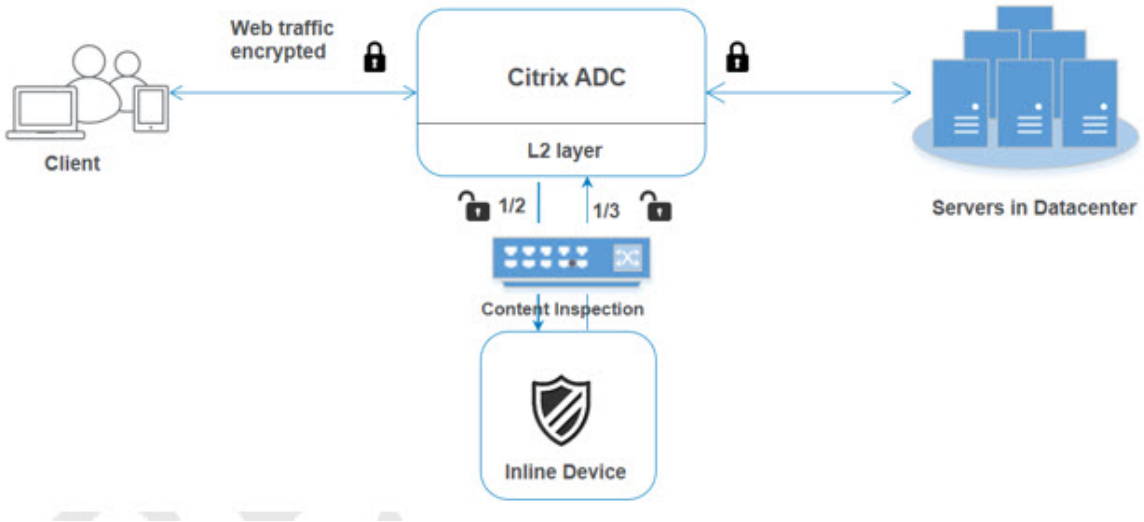
4. Telco Premium
5. SWG license

Configuring inline device integration

You can configure a Citrix ADC appliance with an inline device in three different ways. The configuration scenarios are as follows.

Scenario 1 for using a single inline device

If you want to integrate a security device (IPS or NGFW) in inline mode, you must begin by first enabling the Content Inspection feature and enabling the Citrix ADC in MBF (MAC-based forwarding) in global mode. Once you have enabled the features, you must add the Content Inspection profile, add the Content Inspection action for inline devices to reset, block, or drop the traffic based on inspection. Then, add the Content Inspection policy for the appliance to decide what subset of traffic to send to the inline devices. Then, configure the load balancing virtual server with layer 2 connection enabled on the server. Finally, bind the content inspection policy to the load balancing virtual server.



Enable MBF (MAC-based forwarding) mode

If you want the Citrix ADC appliance to be integrated to inline devices such as IPS, or firewalls, you must enable this mode. For more information about MBF, see Configure MAC-based Forwarding topic.

At the command prompt, type:

```
enable ns mode mbf
```

Enable Content Inspection

If you want the Citrix ADC appliance to decrypt and then send the content for inspection to the inline devices, you must enable the Content Inspection and load balancing features.

```
enable ns feature contentInspection LoadBalancing
```

Add Layer 2 connection method

To handle response generated by inline devices, the appliance uses the VLAN channel as a layer 2 method (L2ConnMethod) of communication with inline devices.

At the command prompt, type:

```
set l4param -l2ConnMethod <l2ConnMethod>
```

Example

```
set l4param -l2ConnMethod VlanChannel
```

Add Content Inspection profile for service

Inline device configuration for a Citrix ADC appliance can be specified in an entity called the Content Inspection profile. The profile has a collection of settings that explains how to integrate with an inline device.

At the command prompt, type:

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile Inline_profile1 -type InlineInspection -
ingressinterface "1/2" -egressInterface "1/3"
```

Add IPS-TCP monitor

If you want to configure monitors, you add a user defined monitor.
Note: If you want to configure monitors, you must use a custom monitor. When adding a monitor, you must enable the transparent parameter.

At the command prompt, type:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr>] [-destPort
 <port>] [-transparent ( YES | NO )]
```

Example:

```
add lb monitor ips_tcp TCP -destIP 192.168.10.2 -destPort 80 -transparent
YES
```

Add a service

Add a service. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address` (USIP) to YES. Set `useproxyport` to NO. By default, health monitoring is ON, bind the service to a health monitor, and also set the TRANSPARENT option in the monitor ON. At the command prompt, type:

```
add service <Service_name> <IP> TCP * - contentinspectionProfileName <Name>
 -healthMonitor YES -usip ON -useproxyport OFF
```

Example:

```
add service ips_service 192.168.10.2 TCP * -healthMonitor YES -usip YES -
useproxyport NO -contentInspectionProfileName ipsprof
```

Add a health monitor

By default the health monitor is turned on and you also have the option to disable it, if necessary. At the command prompt, type:

```
add lb monitor <name> TCP -destIP <ip address> -destPort 80 -transparent <
YES, NO>
```

Example:

```
add lb monitor ips_tcp TCP -destIP 192.168.10.2 -destPort 80 -transparent
YES
```

Bind the service to the health monitor

After configuring the health monitor, you must bind the service to the health monitor. At the command prompt, type:

```
bind service <name> -monitorName <name>
```

Example:

```
bind service ips_svc -monitorName ips_tcp
```

Add content inspection action for service

After you enable the Content Inspection feature and then after you add the inline profile and service, you must add the Content Inspection action for handling the request. Based on the content inspection action, the inline device can drop, reset, or block action after it has inspected the data.

If the Inline server or service is down, you can configure the `ifserverdown` parameter in the appliance to perform any one of the following actions.

CONTINUE: If the User wants to bypass the content inspection when the remote server is down, you can choose the “CONTINUE” action, as default.
RESET (default): This action responds to the client by closing the connection with RST.
DROP: This action silently drops the packets without sending a response to the user.

At the command prompt, type:

```
add contentInspection action <name> -type <type> (-serverName <string> [-
ifserverdown <ifserverdown>] [-reqTimeout <positive_integer>] [-reqTimeoutAction
 <reqTimeoutAction>]

add ContentInspection action <action_name> -type InlineINSPECTION -serverName
 Service_name/Vserver_name>
```

Example:

```
add ContentInspection action <Inline_action> -type InlineSPECTION -serverName
 Inline_service1
```

Add content inspection policy for inspection

After you create a Content Inspection action, you must add Content Inspection policies to evaluate requests for inspection. The policy is based on a rule which consists of one or more expressions. The policy evaluates and selects the traffic for inspection based on the rule.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name
>
```

Example

```
add contentInspection policy Inline_pol1 -rule true -action Inline_action
```

Add content switching or load balancing virtual server of type HTTP/SSL

To receive the web traffic, you must add a load balancing virtual server. Also you must enable the layer2 connection on the virtual server.

At the command prompt, type:

```
add lb vserver <name> <vserver name> -l2Conn ON
```

Example:

```
add lb vserver HTTP_vserver HTTP 10.102.29.200 8080 -l2Conn ON
```

Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL

You bind the load balancing virtual server or content switching virtual server of type HTTP/SSL to the Content Inspection policy.
At the command prompt, type the following:

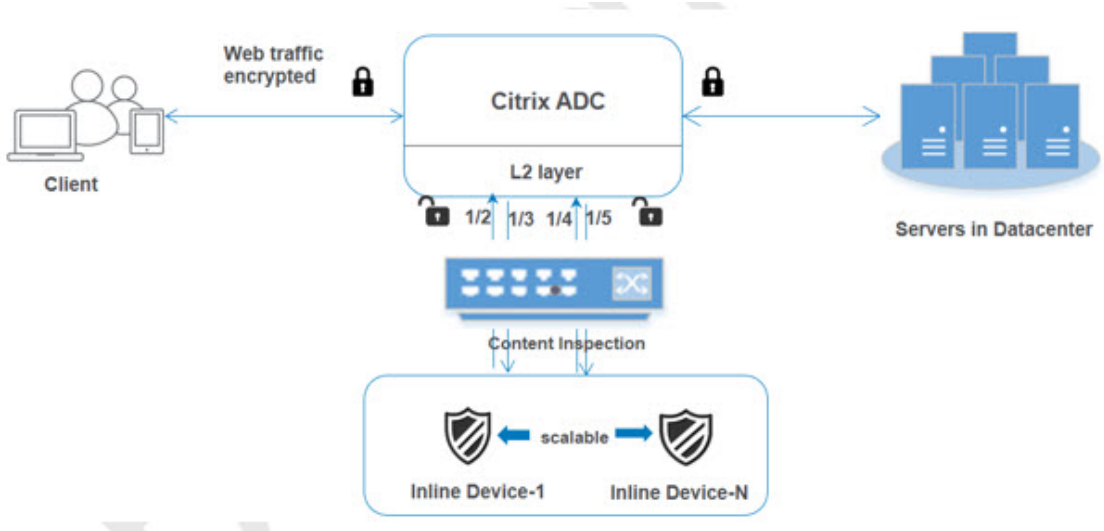
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <
priority > -type <REQUEST>
```

Example:

```
bind lb vserver HTTP_vserver -policyName Inline_pol1 -priority 100 -type
REQUEST
```

Scenario 2: Load balancing multiple inline devices using dedicated interfaces

If you are using two or more inline devices, you must load balance the devices using different content inspection services in a dedicated VLAN setup. In this case, the Citrix ADC appliance load balances the devices on top of sending a subset of traffic to each device through a dedicated interface.
For basic configuration steps, refer to scenario 1.



Add content inspection profile1 for service1

Inline configurations for a Citrix ADC appliance can be specified in an entity called the Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile1 is created for inline service 1 and the communication is through 1/2 and 1/3 dedicated interfaces.

At the command prompt, type:

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile Inline_profile1 -type InlineInspection -
ingressinterface "1/2" -egressInterface "1/3"
```

Add content inspection profile2 for service2

The Content Inspection profile2 is added for service2 and the inline device communicates with the appliance through 1/4 and 1/5 dedicated interfaces.
At the command prompt, type:

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile Inline_profile2 -type InlineInspection -
ingressinterface "1/4" -egressInterface "1/5"
```

Add service 1 for inline device 1

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 1 for inline device 1 to be part of the load balancing setup. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> TCP * -contentInspectionProfileName
<Inline_Profile_1> -healthmonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service Inline_service1 10.102.29.200 TCP 80 -contentInspectionProfileName
 Inline_profile1 -healthmonitor OFF -usip ON -useproxyport OFF
```

Add service 2 for inline device 2

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 2 for inline device 2. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> TCP * -contentInspectionProfileName
<Inline_Profile_2> -healthmonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service Inline_service1 10.29.20.205 TCP 80 -contentInspectionProfileName
 Inline_profile2 -healthmonitor OFF -usip ON -useproxyport OFF
```

Add load balancing virtual server

After you have added the inline profile and the services, you must add a load balancing virtual server for load balancing the services.

At the command prompt, type:

```
add lb vserver <vserver_name> TCP <Pvt_IP3> <port>
```

Example:

```
add lb vserver lb-Inline_vserver TCP *
```

Bind service 1 to the load balancing virtual server

After you add the load balancing virtual server, now bind the load balancing virtual server to the first service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:

```
bind lb vserver lb-Inline_vserver Inline_service1
```

Bind service 2 to the load balancing virtual server

After you add the load balancing virtual server, now bind the server to the second service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:

```
bind lb vserver lb-Inline_vserver Inline_service2
```

Add content inspection action for the service

After you enable the Content Inspection feature, you must add the Content Inspection action for handling the inline request information. Based on the action selected, the inline device drops, resets, or blocks after it has examined the given subset of traffic.

At the command prompt, type:

```
add contentInspection action <name> -type <type> (-serverName <string> [-
ifserverdown <ifserverdown>] [-reqTimeout <positive_integer>] [-reqTimeoutAction
 <reqTimeoutAction>]
```

```
add ContentInspection action < action_name > -type InlineINSPECTION -
serverName Service_name/Vserver_name>
```

Example:

```
add ContentInspection action Inline_action -type InlineINSPECTION -serverName
 lb-Inline_vserver
```

Add content inspection policy for inspection

After you create a Content Inspection action, you must add the Content Inspection policy to evaluate requests for service. The policy is based on a rule which consists of one or more expressions. The rule is associated to the Content Inspection action that is associated if a request matches the rule.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name
>
```

Example:

```
add contentInspection policy Inline_pol1 -rule true -action Inline_action
```

Add content switching or load balancing virtual server of type HTTP/SSL

Add a content switching or load balancing virtual server to accept web traffic. Also you must enable the layer2 connection on the virtual server.
For more information about load balancing, see How load balancing works topic.

At the command prompt, type:

```
add lb vserver <name> <vserver name> -l2Conn ON
```

Example:

```
add lb vserver http_vserver HTTP 10.102.29.200 8080 -l2Conn ON
```

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL

You must bind the content switching or load balancing virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

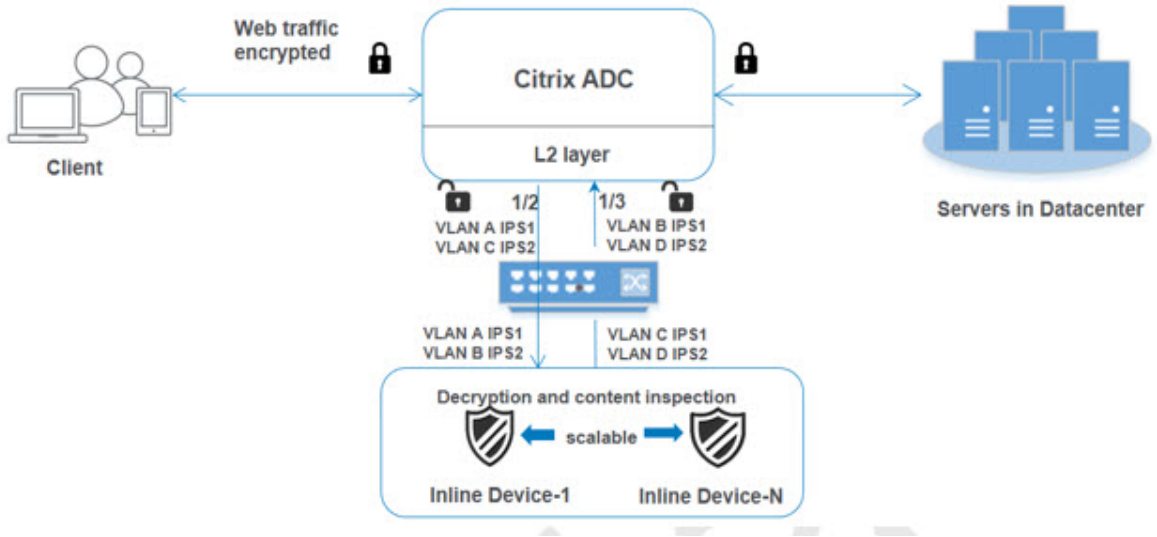
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <> -
type <L7InlineREQUEST | L4Inline-REQUEST>
```

Example:

```
bind lb vserver http_vserver -policyName Inline_pol1 -priority 100 -type
REQUEST
```

Scenario 3: Load balancing multiple inline devices using shared interfaces

You can refer to this configuration, if you are using multiple inline devices and if you want to load balance the devices using different services in a shared VLAN interface. This configuration using shared VLAN interfaces is similar to use case 2. For basic configuration, refer to scenario 2.



Bind VLAN A with sharing option enabled

At the command prompt, type the following:

```
bind vlan <id> -ifnum <interface> -tagged
```

Example:

```
bind vlan 100 -ifnum 1/2 tagged
```

Bind VLAN B with sharing option enabled

At the command prompt, type the following:

```
bind vlan <id> -ifnum <interface> -tagged
```

Example:

```
bind vlan 200 -ifnum 1/3 tagged
```

Bind VLAN C with sharing option enabled

At the command prompt, type the following:

```
bind vlan <id> -ifnum <interface> -tagged
```

Example:

```
bind vlan 300 -ifnum 1/2 tagged
```

Bind VLAN D with sharing option enabled

At the command prompt, type the following:

```
bind vlan <id> -ifnum <interface> -tagged
```

Example:

```
bind vlan 400 -ifnum 1/3 tagged
```

Add content inspection profile1 for service1

Inline configurations for a Citrix ADC appliance can be specified in an entity called the Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile is created for inline service 1 and the communication is through 1/2 and 1/3 dedicated interfaces.

At the command prompt, type:

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile Inline_profile1 -type InlineInspection -
ingressinterface “1/2” -egressInterface “1/3” -egressVlan 100 -ingressVlan
 300
```

Add content inspection profile2 for service2

The Content Inspection profile2 is added for service2 and the inline device communicates with the appliance through 1/2 and 1/3 dedicated interfaces.

At the command prompt, type:

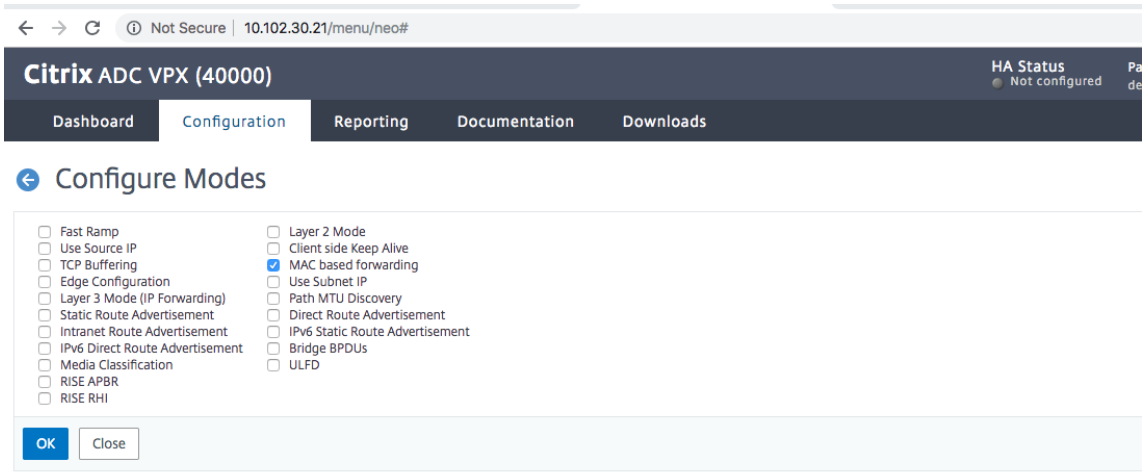
```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

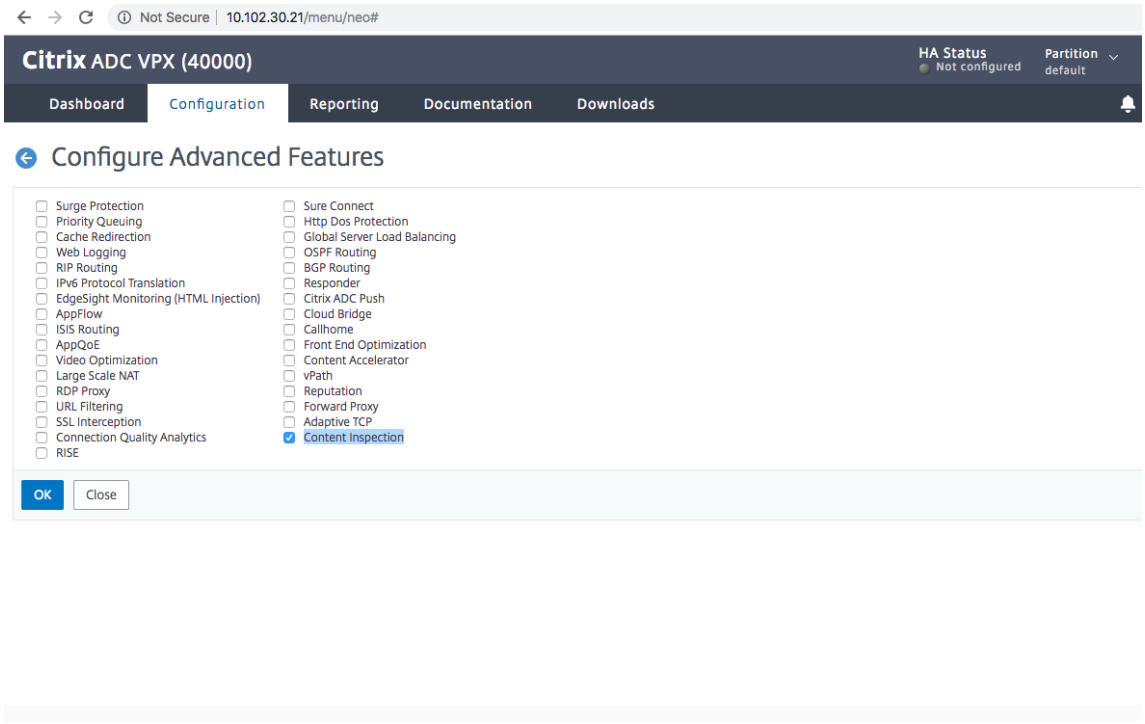
```
add contentInspection profile Inline_profile2 -type InlineInspection -
ingressinterface “1/2” -egressInterface “1/3” -egressVlan 200 -ingressVlan
 400
```

Configure inline service integration using the Citrix ADC GUI

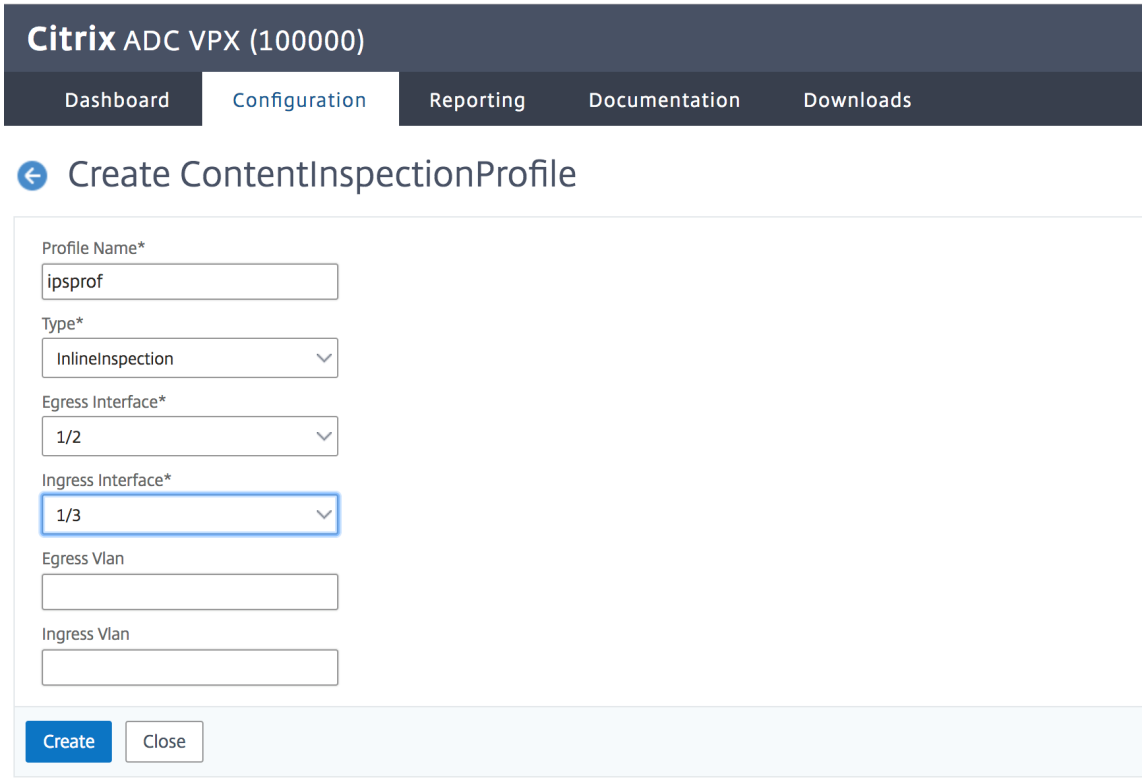
1. Log on to the Citrix ADC appliance and navigate to **Configuration** tab page.
2. Navigate to **System** > **Settings** > **Configure Modes**.
3. In the **Configure Modes** page, select **Mac Based Forwarding**.
4. Click **OK** and **Close**.



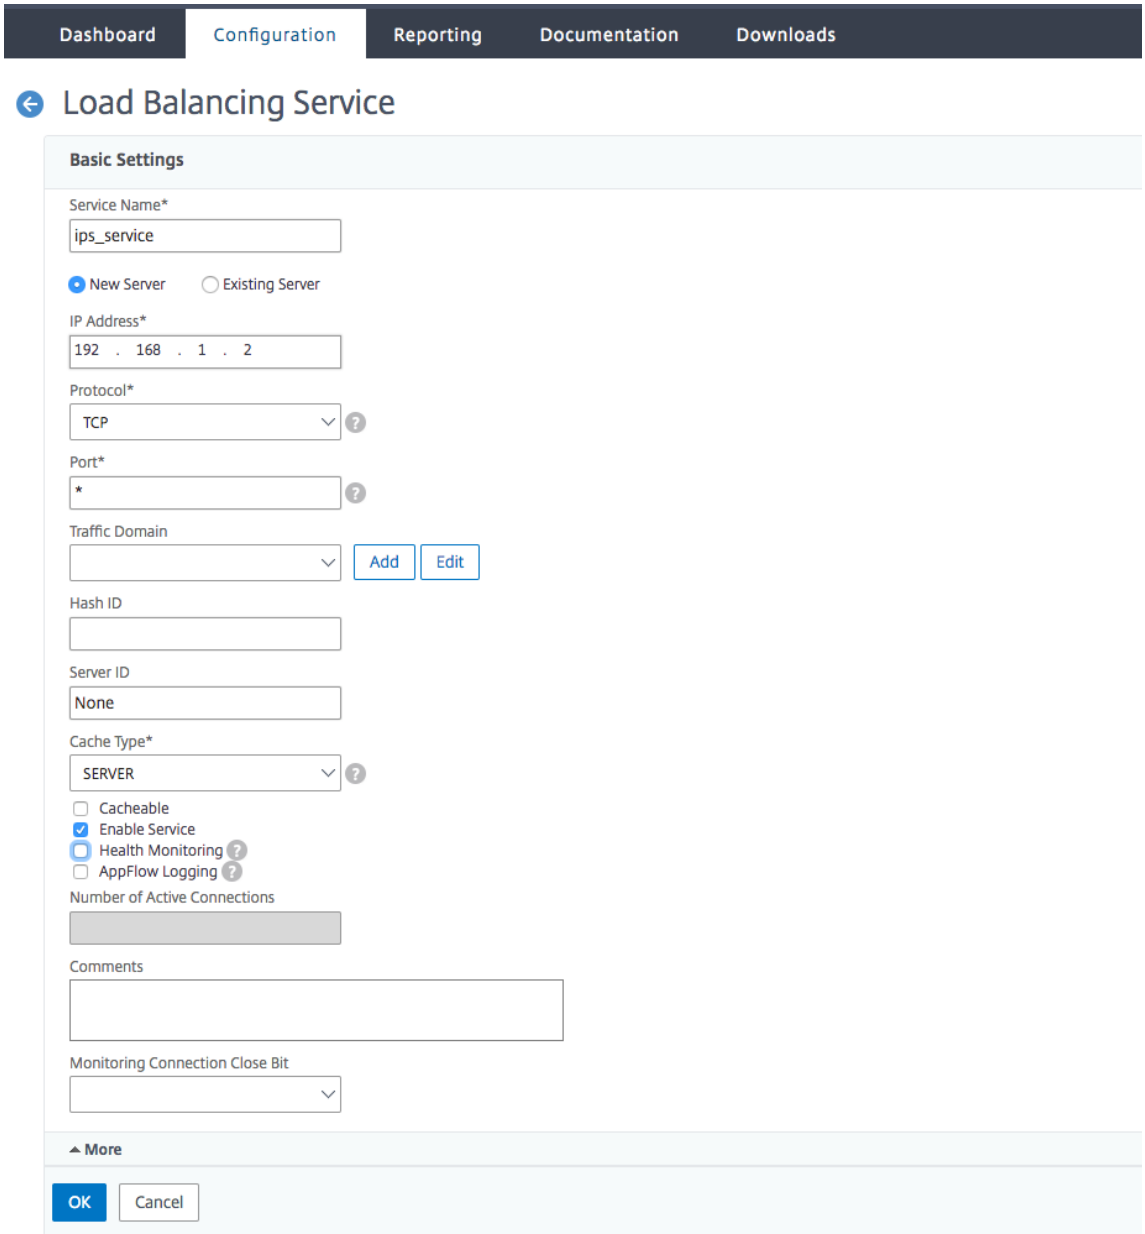
5. Navigate to **System** > **Settings** > **Configure Advanced Features**.
6. In the **Configure Advanced Feature** page, select **Content Inspection**.
7. Click **OK** and **Close**.



8. Navigate to **Security** > **Content Inspection** > **ContentInspection Profiles**.
9. In the **ContentInspection Profiles** page, click **Add**.
10. In the **Create ContentInspection Profiles** page, set the following parameters.
    a) Profile Name. Name of the content inspection profile.
    b) Type. Select the profile type as inlineInspection.
    c) Egress Interface. Interface through which the appliance sends traffic from the Citrix ADC to the Inline device.
    d) Ingress Interface. Interface through which the appliance receives traffic from the Inline device to the Citrix ADC.
    e) Egress VLAN. Interface VLAN ID through which the traffic is sent to the Inline device.
    f) Ingress VLAN. Interface VLAN ID through which the appliance receives traffic from Inline to Citrix ADC (if it is configured).

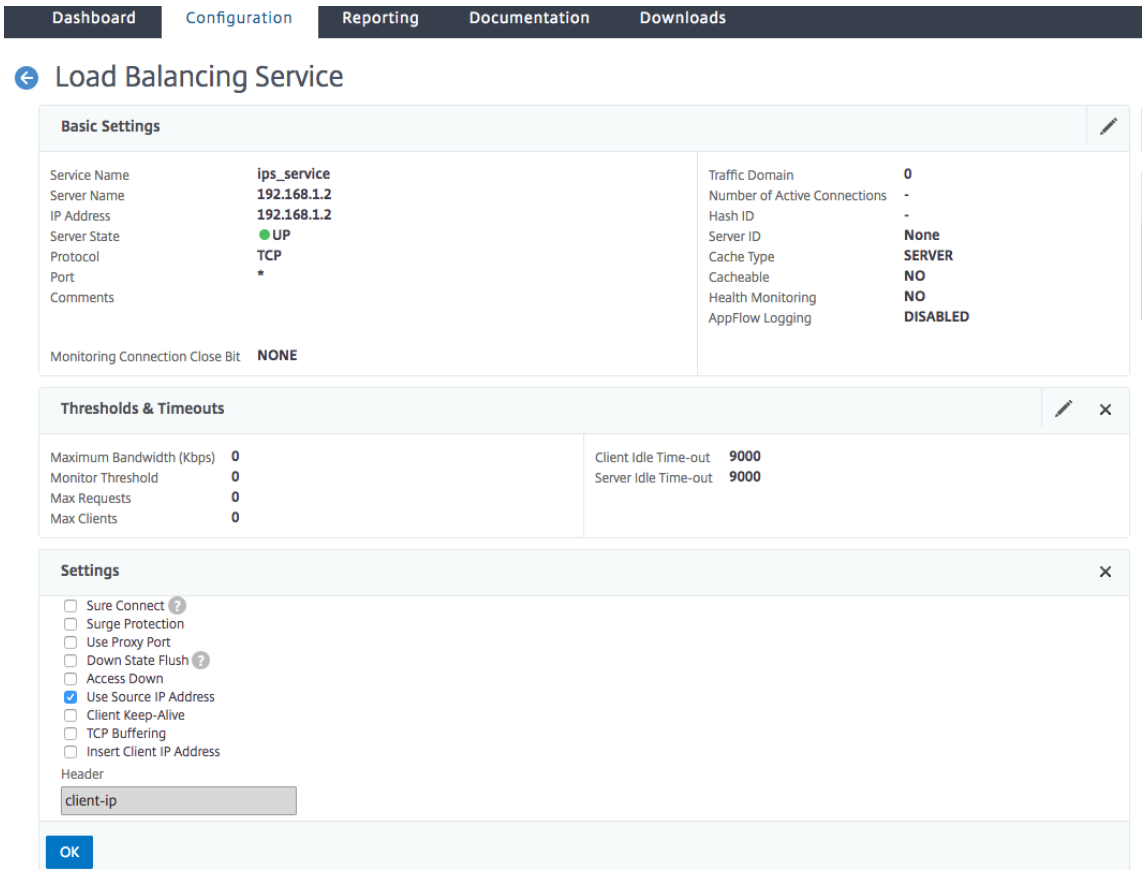


11. Click **Create** and **Close**.
12. Navigate to **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
13. In the **Services** page, set the following parameters:
    a) Service name. Name of the load balancing service.
    b) IP address. Use a dummy IP address. Note: No device must own the IP address.
    c) Protocol. Select protocol type as TCP.
    d) Port. Enter *
    e) Health Monitoring. Clear this option and enable it only if you want to bind the service to the TCP type monitor. If you want to bind a monitor to service then the TRANSPARENT option in the monitor must be ON. See step 14 on how to add monitor and how to bind it to service.
    f) Click **OK**.

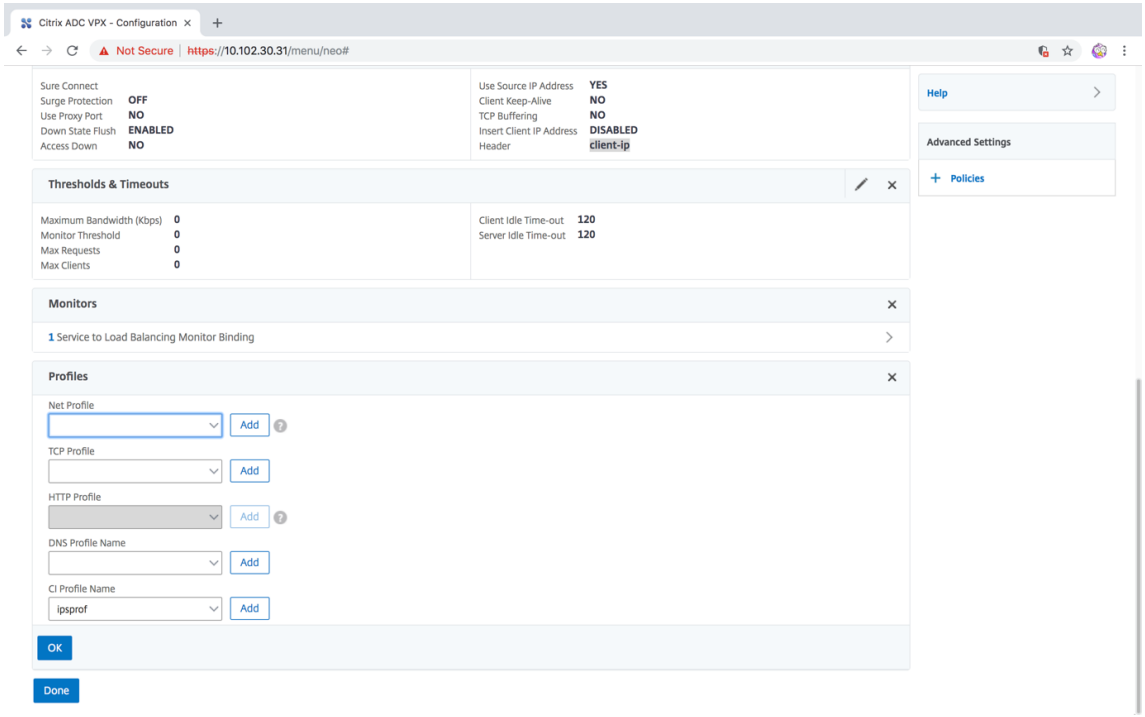


14. In the **Settings** section, edit the following and click **OK**.

    a) Use Proxy Port: Turn it OFF
    b) Use Source IP Address: Turn it ON



15. In the **Advanced Settings** section, click **Profiles**.
16. Go to **Profiles** section, and add the inline content inspection profile and click **OK**.

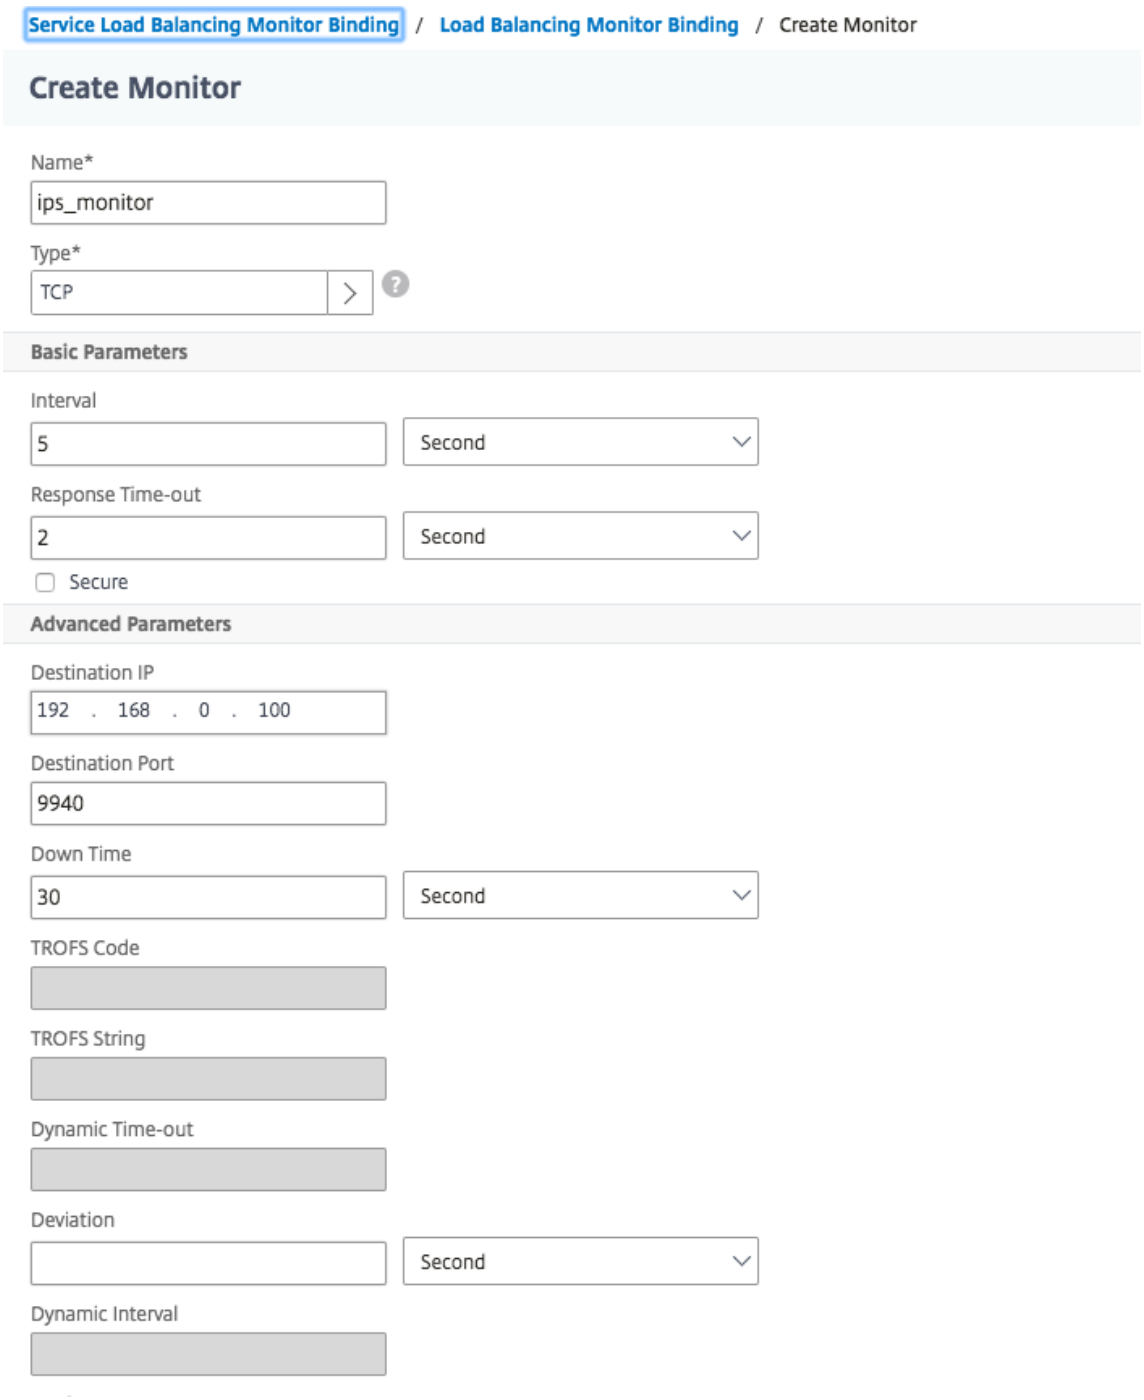


17. Go to **Monitors** section, **Add Bindings** > **Select Monitor** > **Add**.

    a) Name: Name of monitor
    b) Type: Select TCP type
    c) Destination IP, PORT: Destination IP address and Port.
    d) Transparent: Turn ON

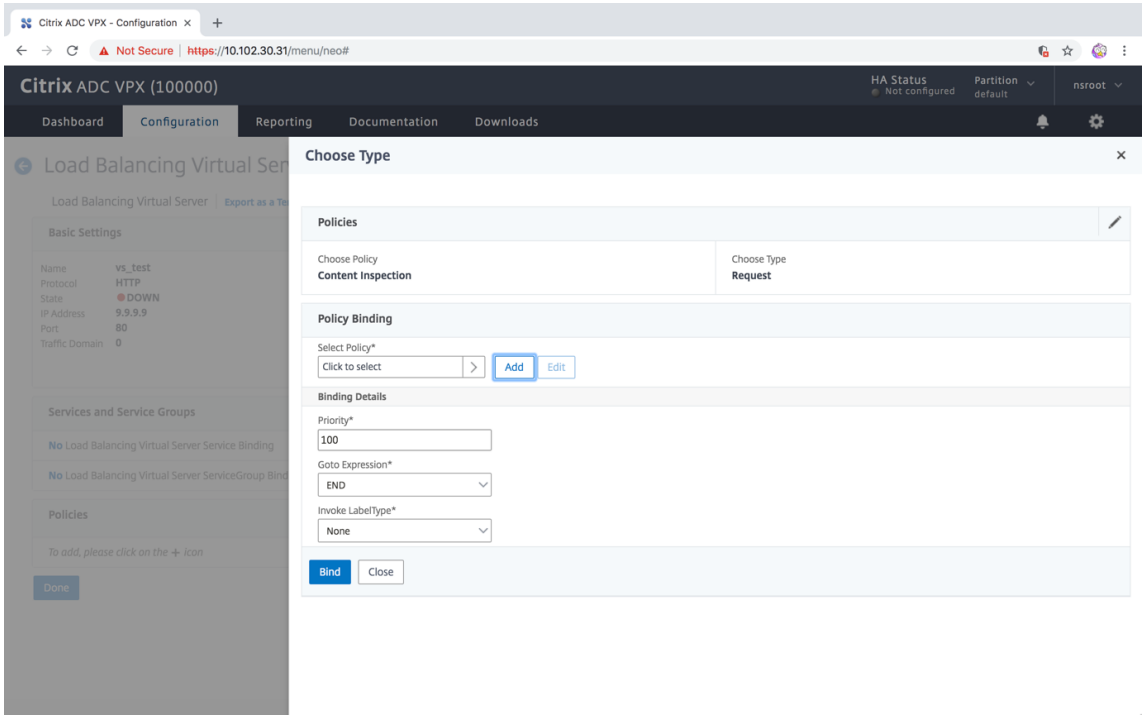
    Note: Monitor packets must flow through the inline device to monitor inline device status.

18. Click **Create**.

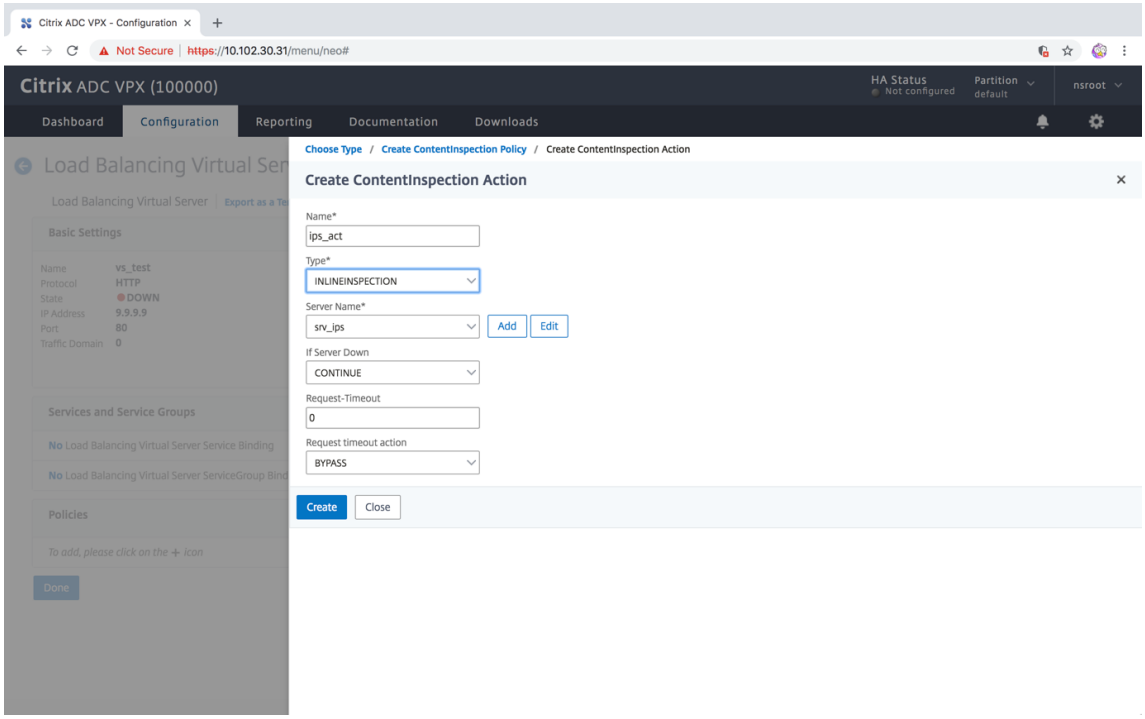


19. Click **Done**.
20. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**. Add a virtual server of type HTTP or SSL.
21. After entering the server details, click **OK** and again **OK**.
22. In the **Traffic Settings** section of Load Balancing Virtual Server, turn Layer 2 Parameters ON.
23. In the **Advanced Settings** section, click **Policies**.

24. Go the **Policies** section and click the “+” icon to configure the content inspection policy.
25. On the **Choose Policy** page, select Content Inspection. Click **Continue**.
26. In the **Policy Binding** section, click **Add** to add a Content Inspection policy.



27. In the **Create ContentInspection Policy** page, enter a name for the Inline content inspection policy.
28. In the **Action** field, click **Add** to create an Inline content inspection action.
29. In the **Create CI Action** page, set the following parameters:
    a) Name. Name of the content inspection Inline policy.
    b) Type. Select the type as inlineInspection.
    c) Server. Select the server/service as Inline devices.
    d) If Server Down. Select an operation if the server goes down.
    e) Request Time-out. Select a time-out value. You can use default values.
    f) Request Time-out Action. Select a time-out action. You can use default values.
30. Click **Create**.



31. Click **Create**.
32. In the **Create CI Policy** page, enter other details:
33. Click **OK** and **Close**.

Integration with IPS or NGFW as inline devices using SSL forward proxy

September 14, 2021

Security devices such as Intrusion Prevention System (IPS) and Next Generation Firewall (NGFW) protect servers from network attacks. These devices can inspect live traffic and are typically deployed in layer 2 inline mode. The SSL forward proxy appliance provides security of users and the enterprise network when accessing resources on the internet.

An SSL forward proxy appliance can be integrated with one or more inline devices to prevent threats and provide advanced security protection. The inline devices can be any security device, such as IPS and NGFW.

Some use cases where you can benefit by using the SSL forward proxy appliance and inline device integration are:

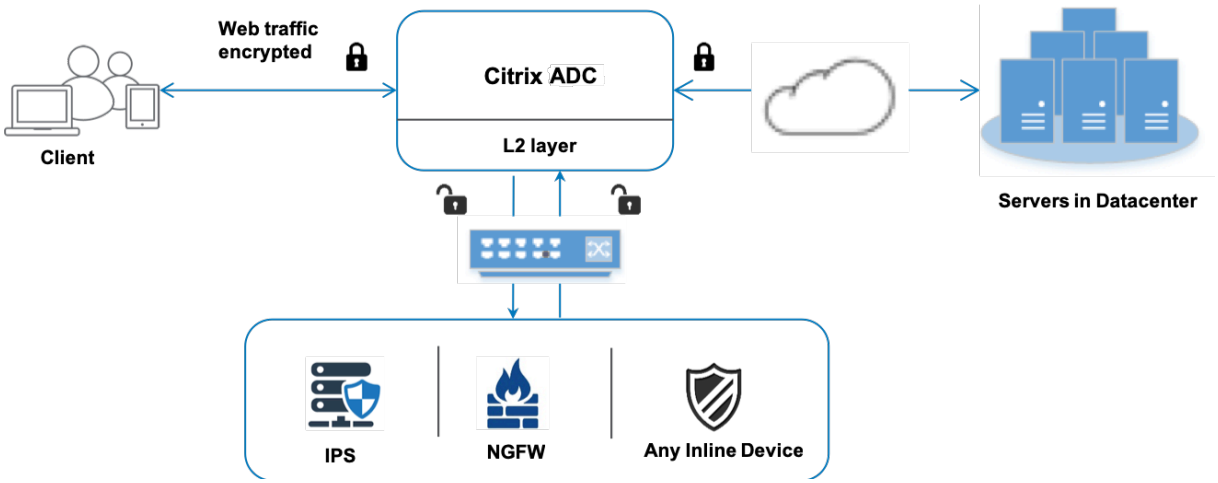
- **Inspecting encrypted traffic:** Most IPS and NGFW appliances bypass encrypted traffic, which can leave servers vulnerable to attacks. An SSL forward proxy appliance can decrypt traffic and

send it to the inline devices for inspection. This integration enhances the customer's network security.

- **Offloading inline devices from TLS/SSL processing:** TLS/SSL processing is expensive, which can result in high CPU utilization in IPS or NGFW appliances if they also decrypt the traffic. An SSL forward proxy appliance helps in offloading TLS/SSL processing from inline devices. As a result, inline devices can inspect a higher volume of traffic.
- **Loading balancing inline devices:** If you have configured multiple inline devices to manage heavy traffic, an SSL forward proxy appliance can load balance and distribute traffic evenly to these devices.
- **Smart selection of traffic:** Instead of sending all the traffic to the inline device for inspection, the appliance does a smart selection of traffic. For example, it skips sending text files for inspection to the inline devices.

SSL forward proxy integration with inline devices

The following diagram shows how an SSL forward proxy is integrated with inline security devices.



When you integrate inline devices with the SSL forward proxy appliance, the components interact as follows:

1. A client sends a request to an SSL forward proxy appliance.
2. The appliance sends the data to the inline device for content inspection based on the policy evaluation. For HTTPS traffic, the appliance decrypts the data and sends it in plain text to the inline device for content inspection.

> **Note**
>
> If there are two or more inline devices, the appliance load balances the devices and sends the traffic.

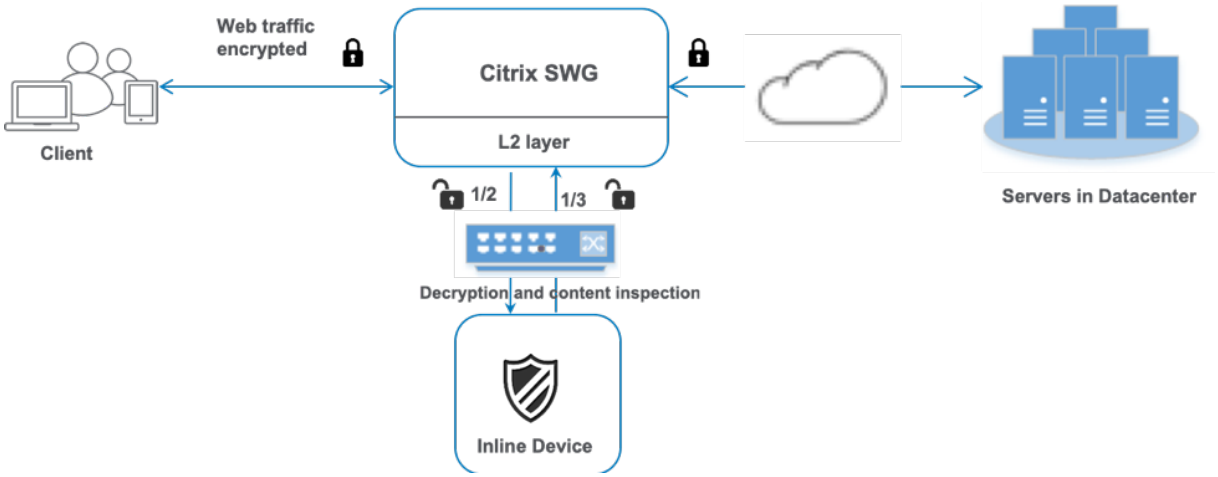
3. Add a content switching or an HTTP/HTTPS load balancing virtual server.
4. The inline device inspects the data for threats and decides whether to drop, reset, or send the data back to the appliance.
5. If there are security threats, the device modifies the data and sends it to the appliance.
6. For HTTPS traffic, the appliance re-encrypts the data and forwards the request to the back-end server.
7. The back-end server sends the response to the appliance.
8. The appliance again decrypts the data and sends it to the inline device for inspection.
9. The inline device inspects the data. If there are security threats, the device modifies the data and sends it to the appliance.
10. The appliance re-encrypts the data and sends the response to the client.

Configuring inline device integration

You can configure an SSL forward proxy appliance with an inline device in three different ways as follows:

Scenario 1: Using a single inline device

To integrate a security device (IPS or NGFW) in inline mode, you must enable content inspection and MAC-based forwarding (MBF) in global mode on the SSL forward proxy appliance. Then, add a content inspection profile, a TCP service, a content inspection action for inline devices to reset, block, or drop the traffic based on inspection. Also add a content inspection policy that the appliance uses to decide the subset of traffic to send to the inline devices. Finally, configure the proxy virtual server with layer 2 connection enabled on the server and bind the content inspection policy to this proxy virtual server.



Perform the following steps:

1. Enable MAC-based forwarding (MPF) mode.
2. Enable the content inspection feature.
3. Add a content inspection profile for the service. The content inspection profile contains the inline device settings that integrate the SSL forward proxy appliance with an inline device.
4. (Optional) Add a TCP monitor.

   > **Note:**
   >
   > Transparent devices do not have an IP address. Therefore, to perform health checks, you must explicitly bind a monitor.

5. Add a service. A service represents an inline device.
6. (Optional) Bind the service to the TCP monitor.
7. Add a content inspection action for the service.
8. Add a content inspection policy and specify the action.
9. Add an HTTP or HTTPS proxy (content switching) virtual server.
10. Bind the content inspection policy to the virtual server.

Configure using the CLI

Type the following commands at the command prompt. Examples are given after most commands.

1. Enable MBF.

```
enable ns mode mbf
```

1. Enable the feature.

```
enable ns feature contentInspection
```

1. Add a content inspection profile.

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile ipsprof -type InlineInspection -ingressinterface
 "1/2" -egressInterface "1/3"
```

1. Add a service. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address` (USIP) to YES. Set `useproxyport` to NO. By default, health monitoring is ON, bind the service to a health monitor, and also set the TRANSPARENT option in the monitor ON.

```
add service <service_name> <IP> TCP * - contentinspectionProfileName <Name>
 -healthMonitor YES -usip YES -useproxyport NO
```

Example:

```
add service ips_service 198.51.100.2 TCP * -healthMonitor YES -usip YES -
useproxyport NO -contentInspectionProfileName ipsprof
```

1. Add a health monitor. By default the health monitor is turned on and you also have the option to disable it, if necessary. At the command prompt, type:

   ```
   add lb monitor <name> TCP -destIP <ip address> -destPort 80 -transparent
    <YES, NO>
   ```

Example:

```
add lb monitor ips_tcp TCP -destIP 192.168.10.2 -destPort 80 -transparent
YES
```

1. Bind the service to the health monitor

After configuring the health monitor, you must bind the service to the health monitor. At the command prompt, type:

```
bind service <name> -monitorName <name>
```

Example:

```
bind service ips_svc -monitorName ips_tcp
```

1. Add a content inspection action.

```
add contentInspection action <name> -type INLINEINSPECTION -serverName <
string>
```

Example:

```
add contentInspection action ips_action -type INLINEINSPECTION -serverName
ips_service
```

1. Add a content inspection policy.

```
add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

```
add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE(\"CONNECT\")
"-action ips_action
```

1. Add a proxy virtual server.

```
add cs vserver <name> PROXY <IPAddress> <port> -cltTimeout <secs> -Listenpolicy
 <expression> -authn401 ( ON | OFF )-authnVsName <string> -l2Conn ON
```

> **Note:**
>
> Load balancing virtual servers of type HTTP/SSL are also supported.

Example:

```
add cs vserver transparentcs PROXY * * -cltTimeout 180 -Listenpolicy exp1 -
authn401 on -authnVsName swg-auth-vs-trans-http -l2Conn ON
```

1. Bind the policy to the virtual server.

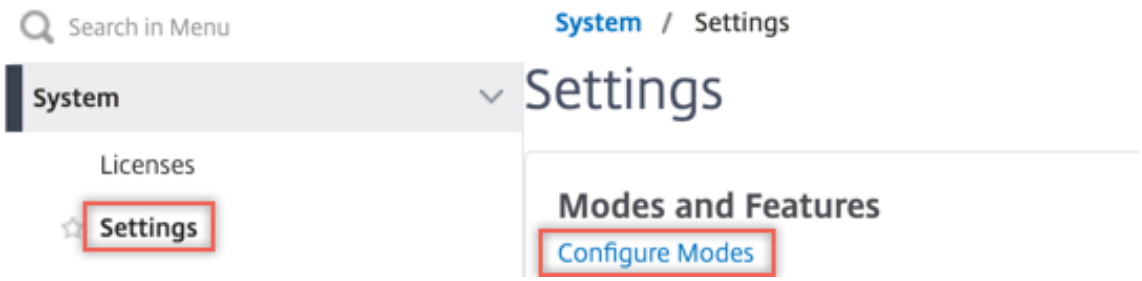
```
bind cs vserver <name> -policyName <string> -priority <positive_integer> -
gotoPriorityExpression <expression> -type REQUEST
```

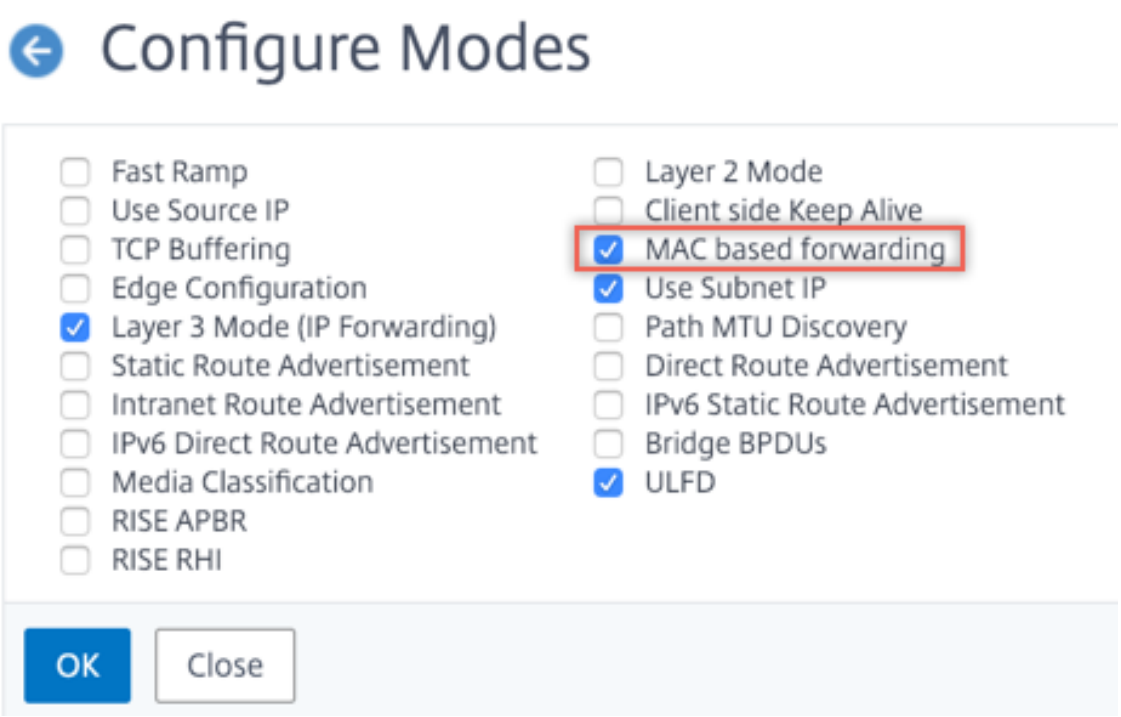
Example:

```
bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression
 END -type REQUEST
```

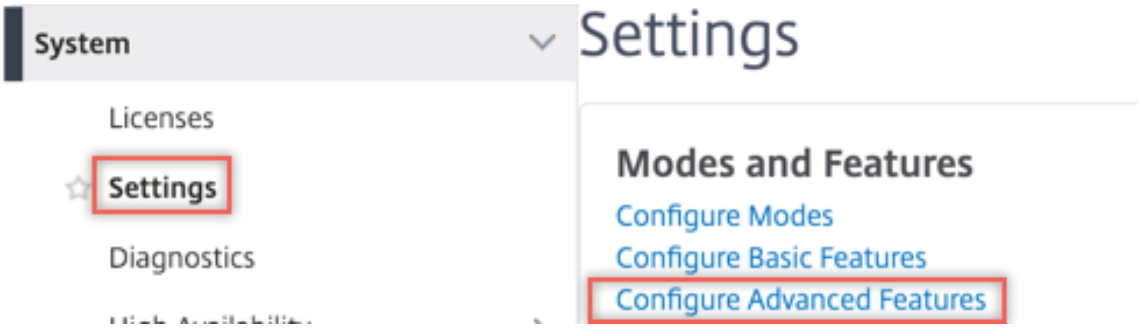
Configure using the GUI

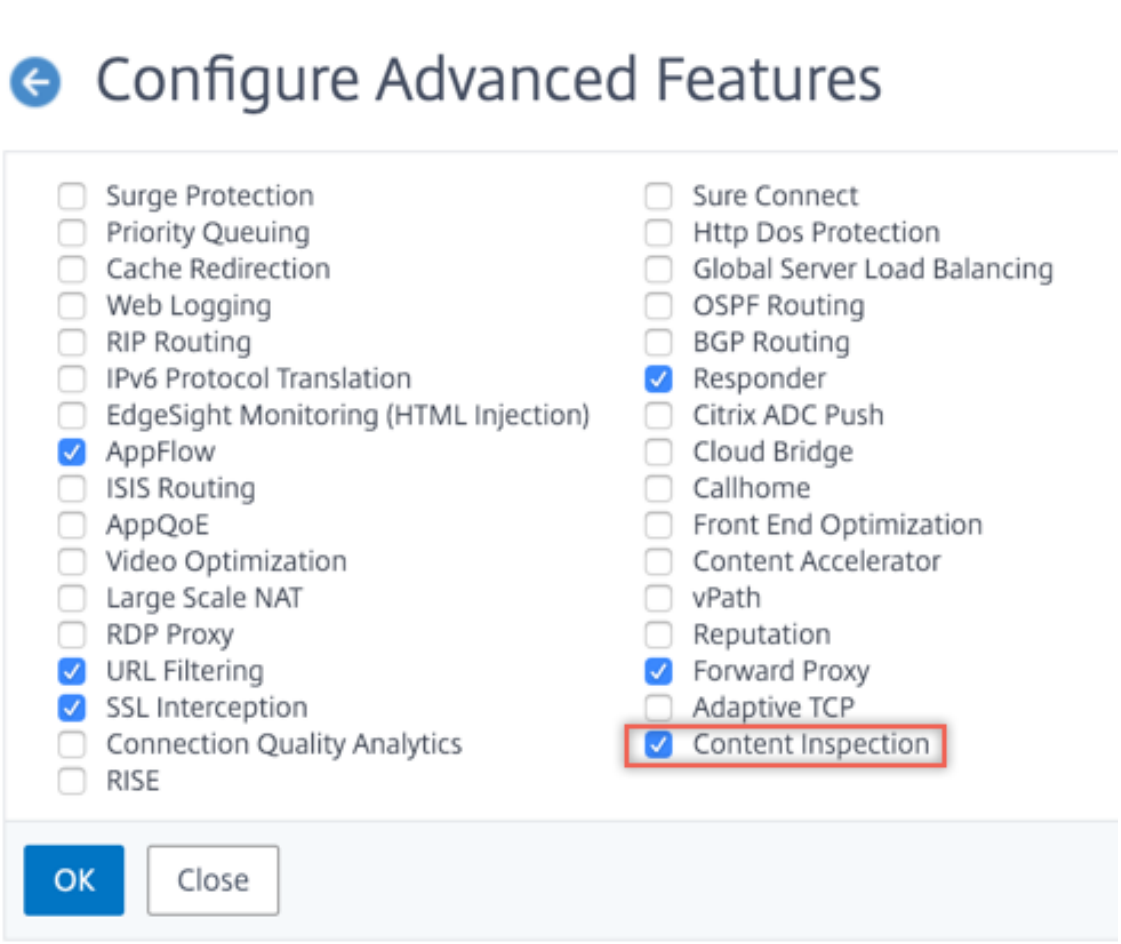
1. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Modes**.



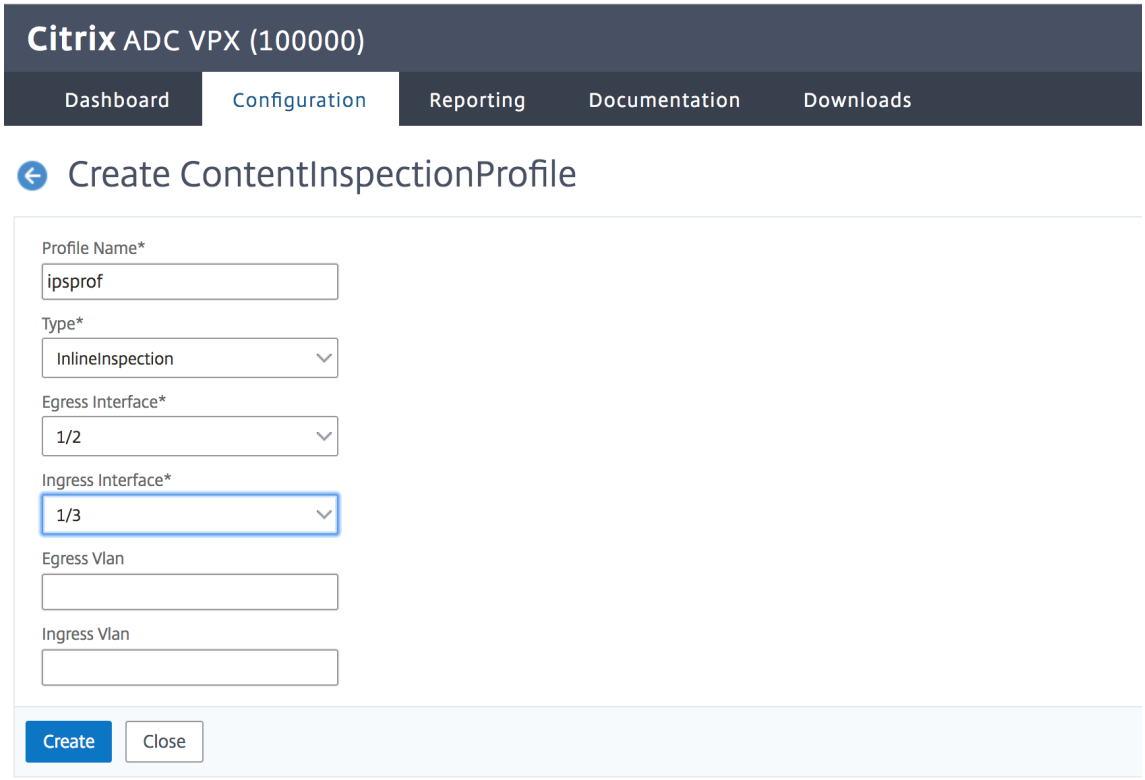


2. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Advanced Features**.

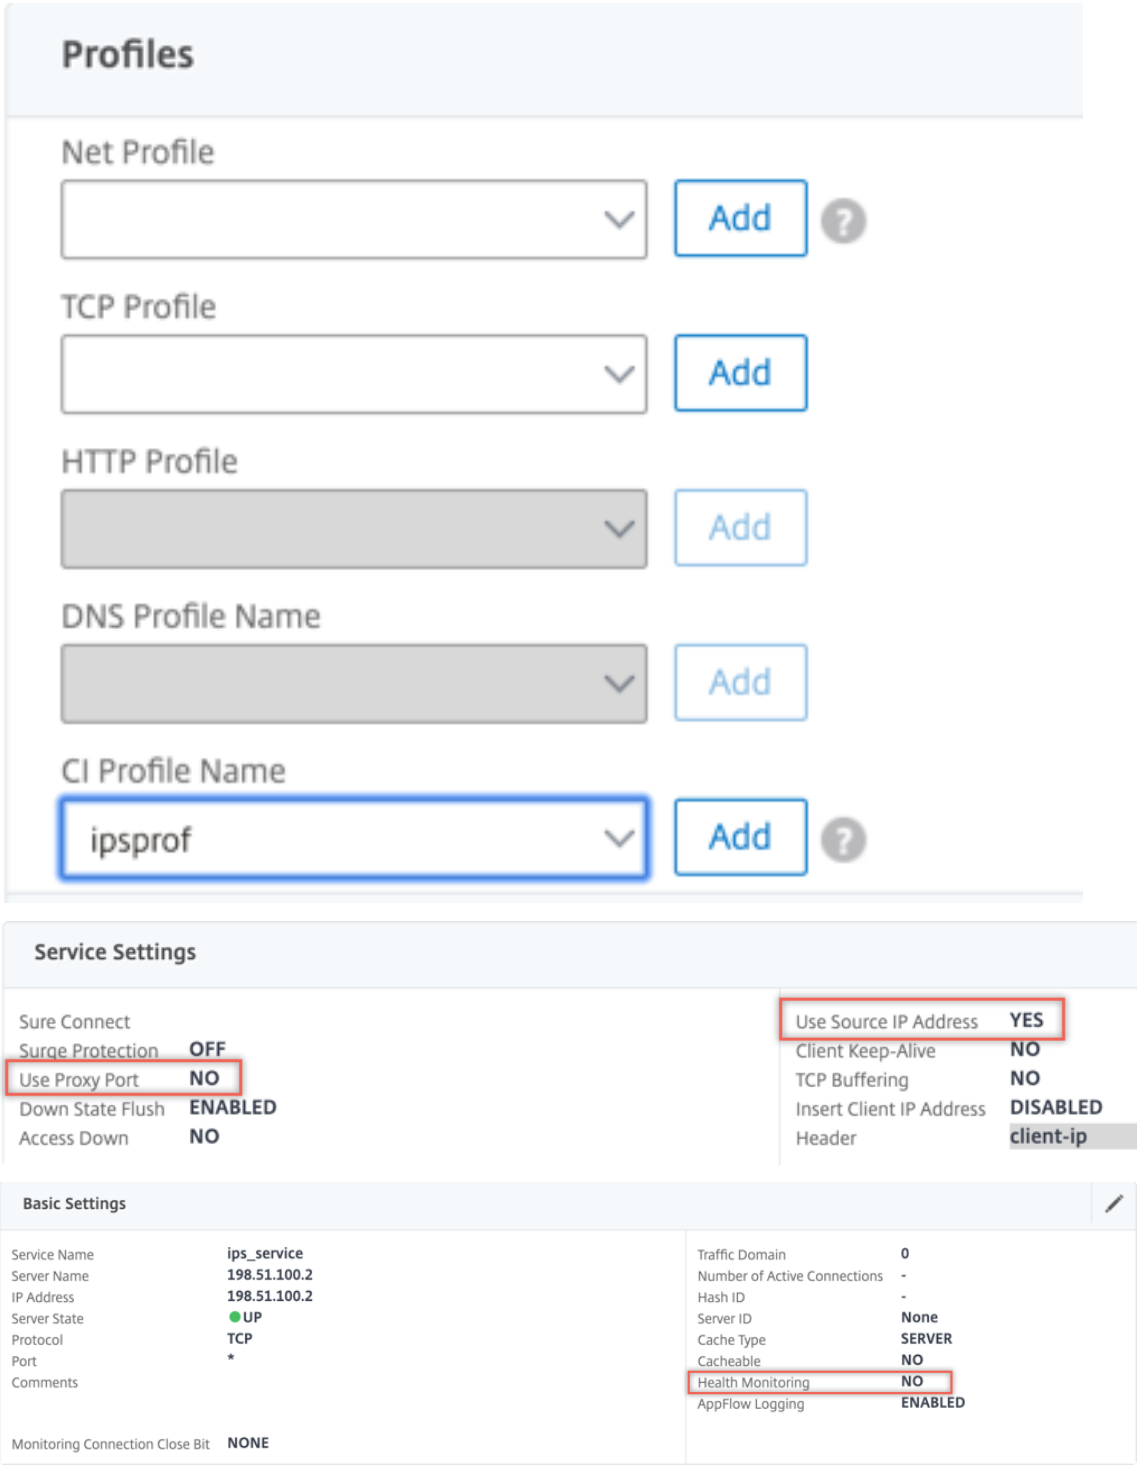




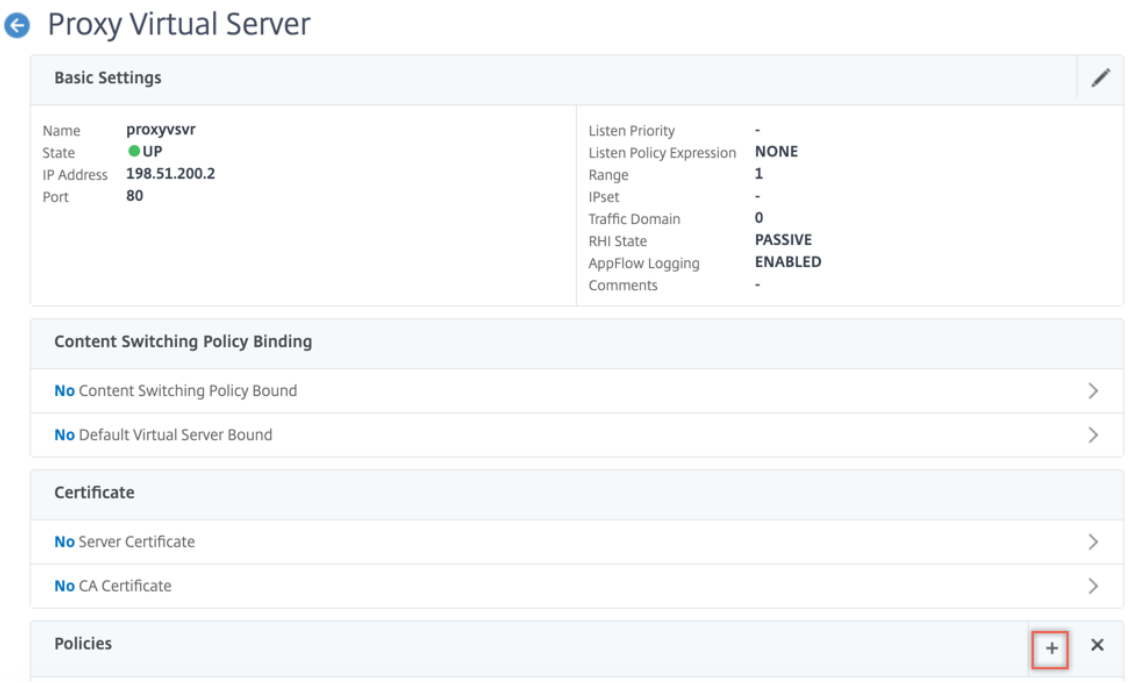
3. Navigate to **Secure Web Gateway > Content Inspection > Content Inspection Profiles**. Click **Add**.



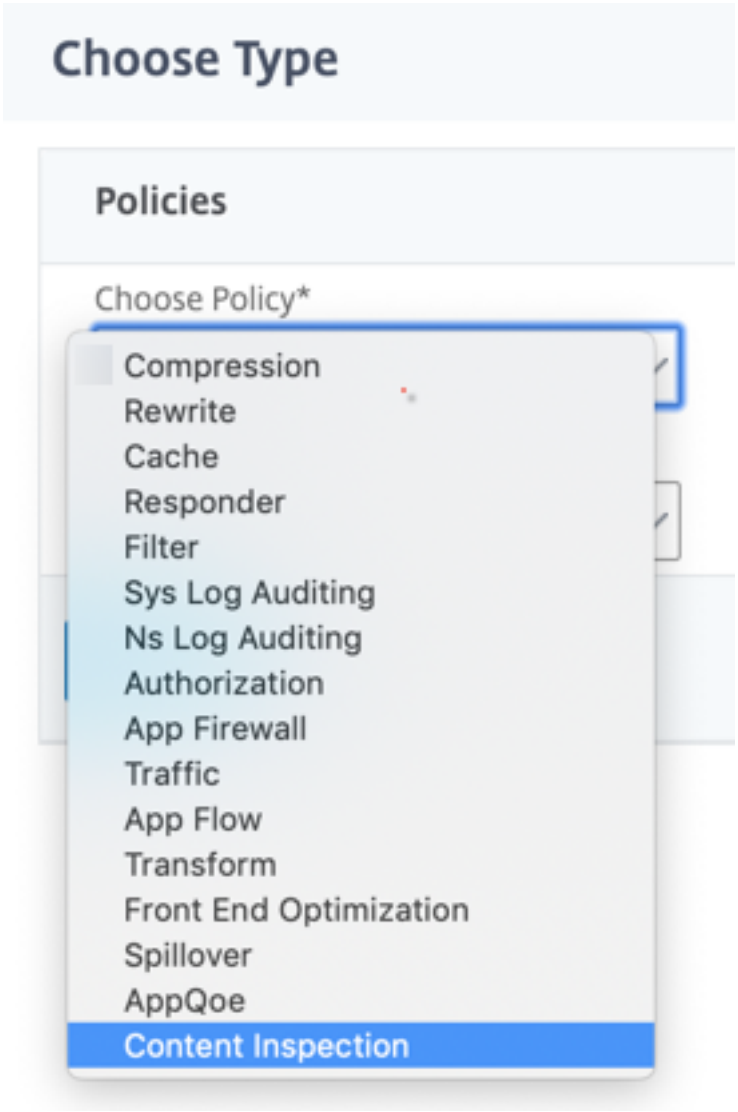
4. Navigate to **Load Balancing > Services > Add** and add a service. In **Advanced Settings**, click **Profiles**. In the **CI Profile Name** list, select the content inspection profile created earlier. In **Service Settings**, set **Use Source IP Address** to YES and **Use Proxy Port** to No. In **Basic Settings**, set **Health Monitoring** to NO. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in the monitor to ON.



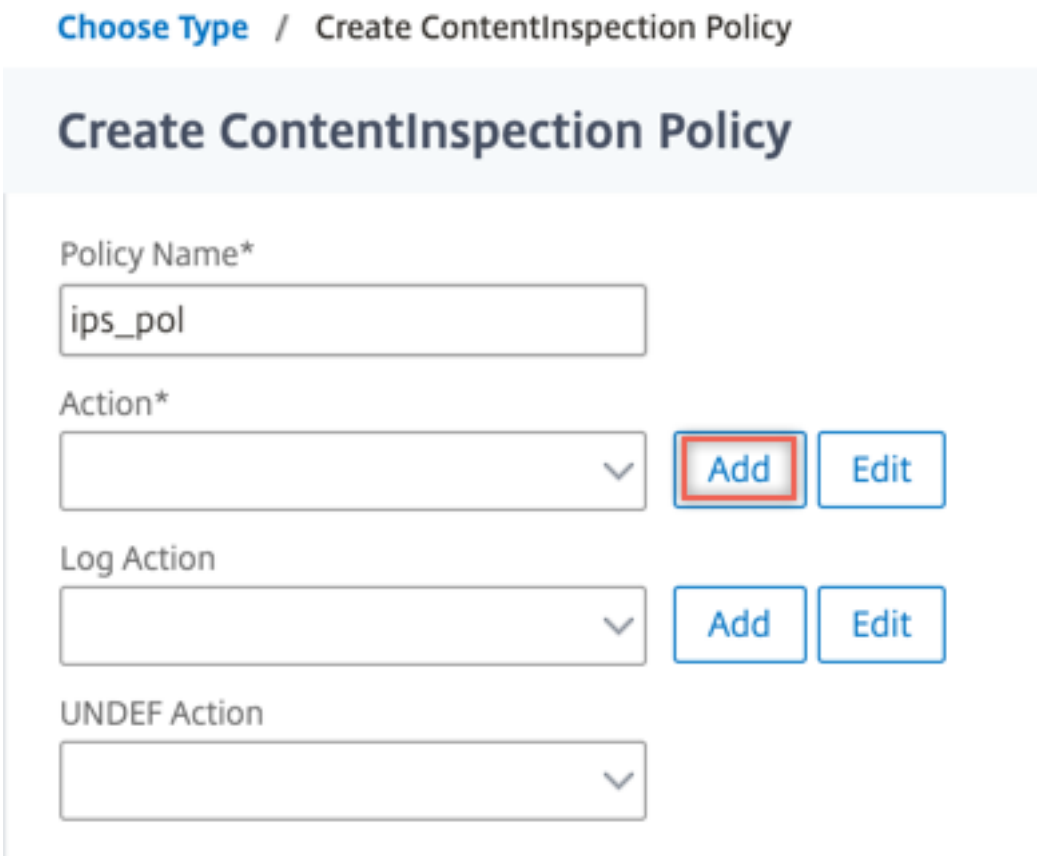
5. Navigate to **Secure Web Gateway > Proxy Virtual Servers> Add**. Specify a name, IP address, and port. In **Advanced Settings**, select **Policies**. Click the “+” sign.



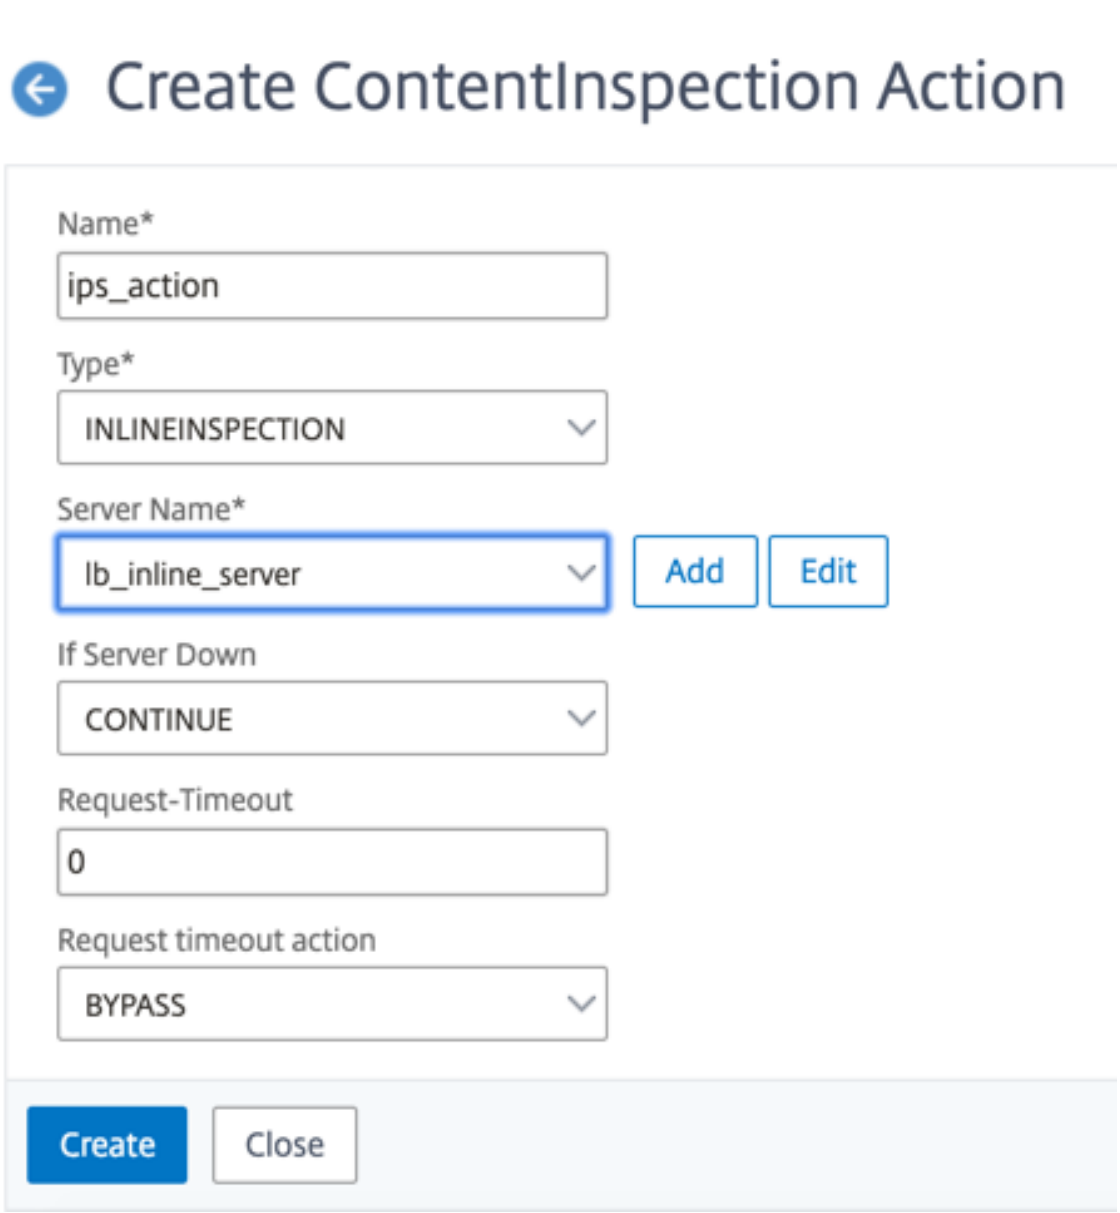
6. In **Choose Policy** select **Content Inspection**. Click **Continue**.



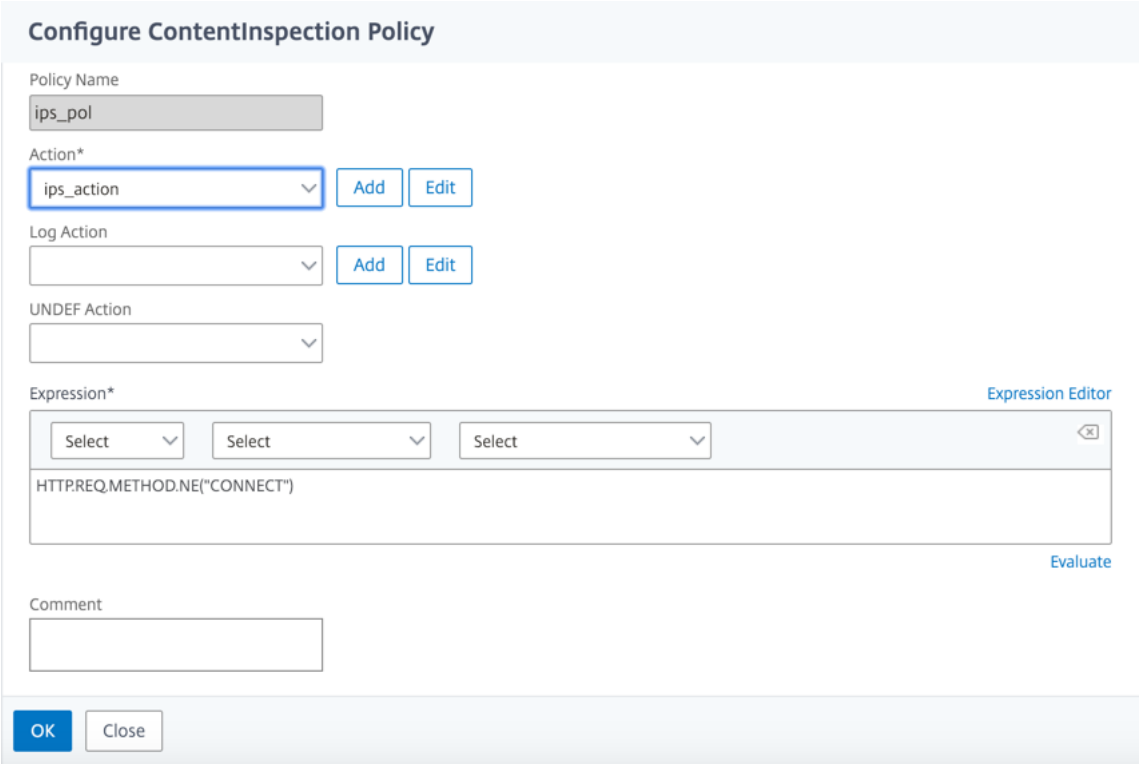
7. Click **Add**. Specify a name. In **Action**, click **Add**.



8. Specify a name. In **Type**, select **INLINEINSPECTION**. In **Server Name**, select the TCP service created earlier.



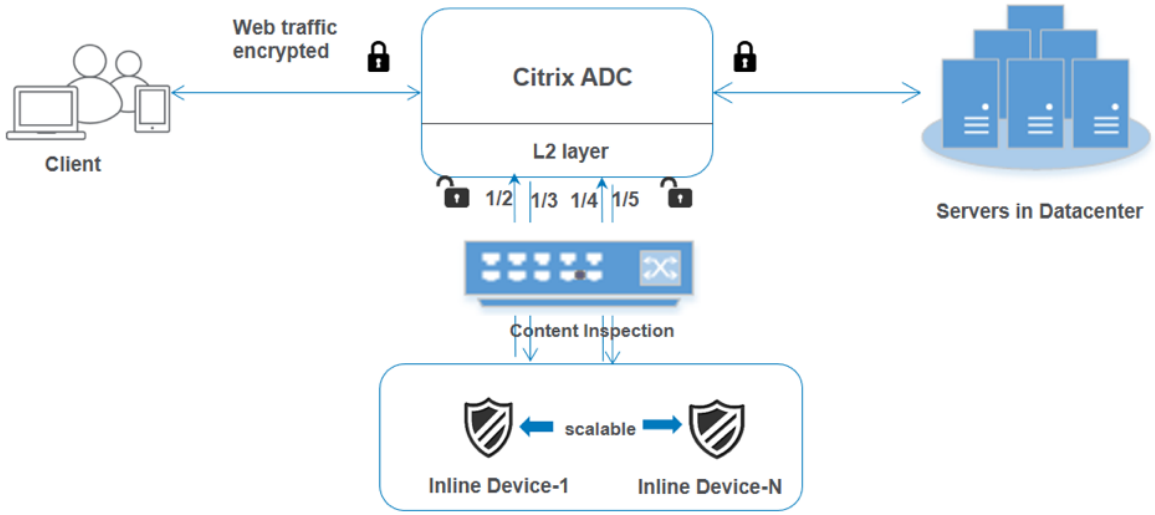
9. Click **Create**. Specify the rule and click **Create**.



10. Click **Bind**.
11. Click **Done**.

Scenario 2: Load balance multiple inline devices with dedicated interfaces

If you are using two or more inline devices, you can load balance the devices using different content inspection services with dedicated interfaces. In this case, the SSL forward proxy appliance load balances the subset of traffic sent to each device through a dedicated interface. The subset is decided based on the policies configured. For example, TXT or image files might not be sent for inspection to the inline devices.



The basic configuration remains the same as in scenario 1. However, you must create a content inspection profile for each inline device and specify the ingress and egress interface in each profile. Add a service for each inline device. Add a load balancing virtual server and specify it in the content inspection action. Perform the following extra steps:

1. Add content inspection profiles for each service.
2. Add a service for each device.
3. Add a load balancing virtual server.
4. Specify the load balancing virtual server in the content inspection action.

Configure using the CLI

Type the following commands at the command prompt. Examples are given after each command.

1. Enable MBF.

```
enable ns mode mbf
```

1. Enable the feature.

```
enable ns feature contentInspection
```

1. Add profile 1 for service 1.

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile ipsprof1 -type InlineInspection -ingressInterface
 "1/2"-egressInterface "1/3"
```

1. Add profile 2 for service 2.

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile ipsprof2 -type InlineInspection -ingressInterface
 "1/4"-egressInterface "1/5"
```

1. Add service 1. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address` (USIP) to YES. Set `useproxyport` to NO. Turn on health monitoring with TCP monitor with TRANSPARENT option set ON.

```
add service <service_name> <IP> TCP * - contentinspectionProfileName <Name>
 -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```
add service ips_service1 192.168.10.2 TCP * -healthMonitor NO -usip YES -
useproxyport NO -contentInspectionProfileName ipsprof1
```

1. Add service 2. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address` (USIP) to YES. Set `useproxyport` to NO. Turn on health monitoring with TRANSPARENT option set ON.

```
add service <service_name> <IP> TCP * - contentinspectionProfileName <Name>
 -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```
add service ips_service2 192.168.10.3 TCP * -healthMonitor NO -usip YES -
useproxyport NO -contentInspectionProfileName ipsprof2
```

1. Add a load balancing virtual server.

```
add lb vserver <LB_VSERVER_NAME> TCP <IP> <port>
```

Example:

```
add lb vserver lb_inline_vserver TCP 192.0.2.100 *
```

1. Bind the services to the load balancing virtual server.

```
bind lb vserver <LB_VSERVER_NAME> <service_name>
bind lb vserver <LB_VSERVER_NAME> <service_name>
```

Example:

```
bind lb vserver lb_inline_vserver ips_service1
bind lb vserver lb_inline_vserver ips_service2
```

1. Specify the load balancing virtual server in the content inspection action.

```
add contentInspection action <name> -type INLINEINSPECTION -serverName <
string>
```

Example:

```
add contentInspection action ips_action -type INLINEINSPECTION -serverName
lb_inline_vserver
```

1. Add a content inspection policy. Specify the content inspection action in the policy.

```
add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

```
add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE(\"CONNECT\")
"-action ips_action
```

1. Add a proxy virtual server.

```
add cs vserver <name> PROXY <IPAddress> <port> -l2Conn ON
```

Example:

```
add cs vserver transparentcs PROXY * * -l2Conn ON
```

1. Bind the content inspection policy to the virtual server.

```
bind cs vserver <name> -policyName <string> -priority <positive_integer> -
gotoPriorityExpression <expression> -type REQUEST
```

Example:

```
bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression
 END -type REQUEST
```

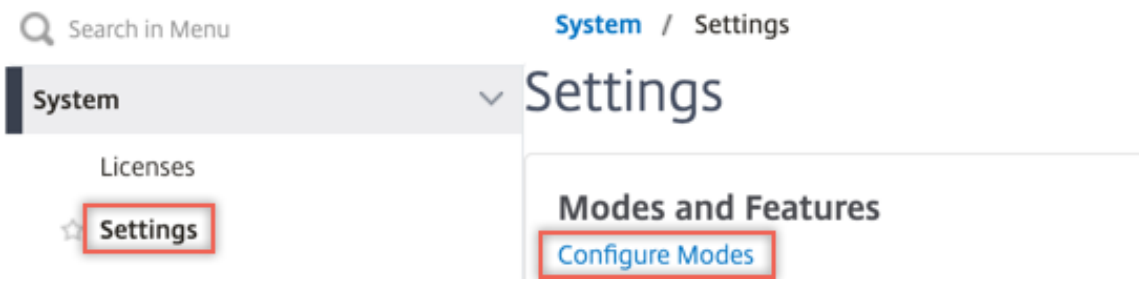
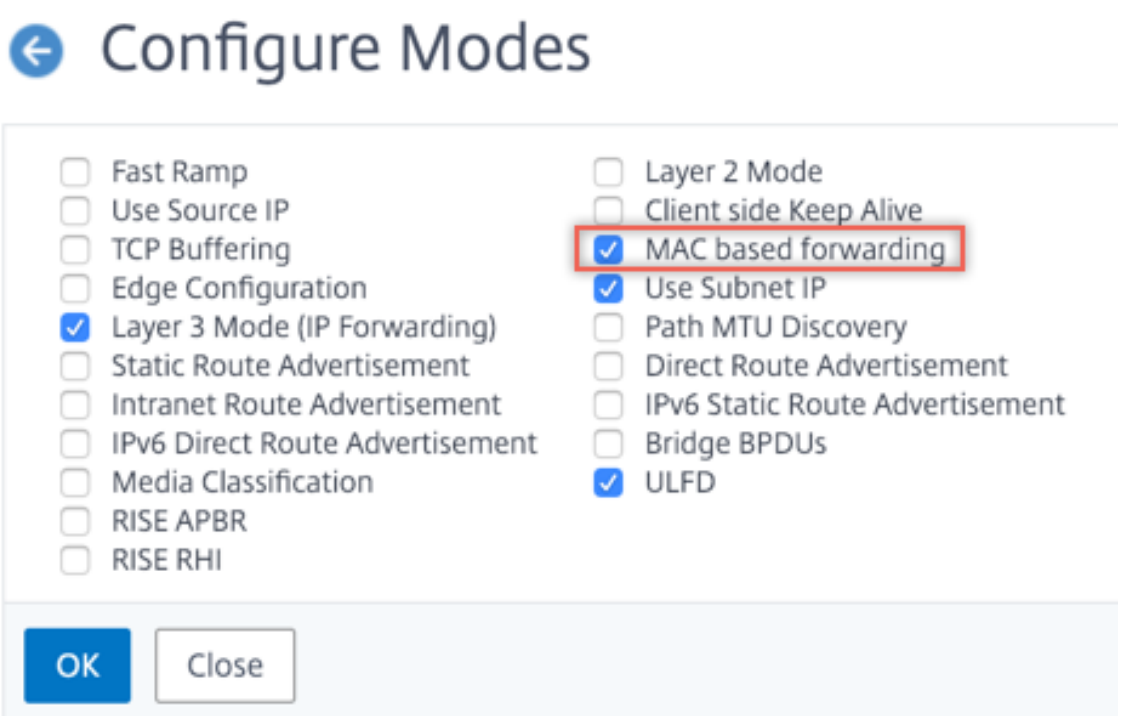
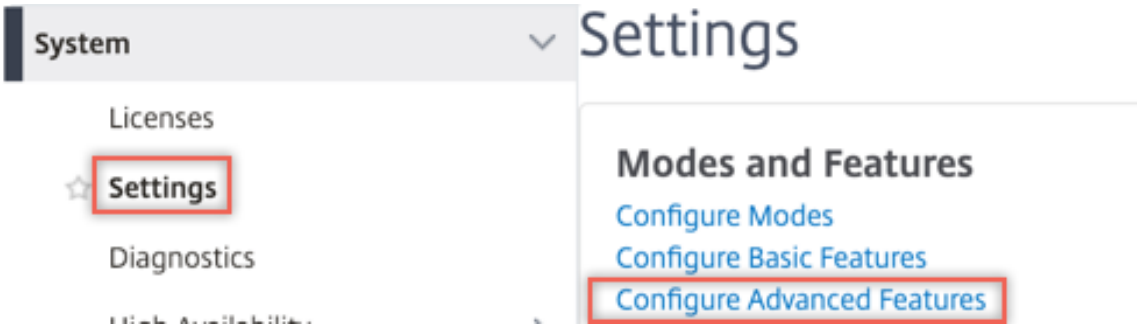
Configuration using the GUI

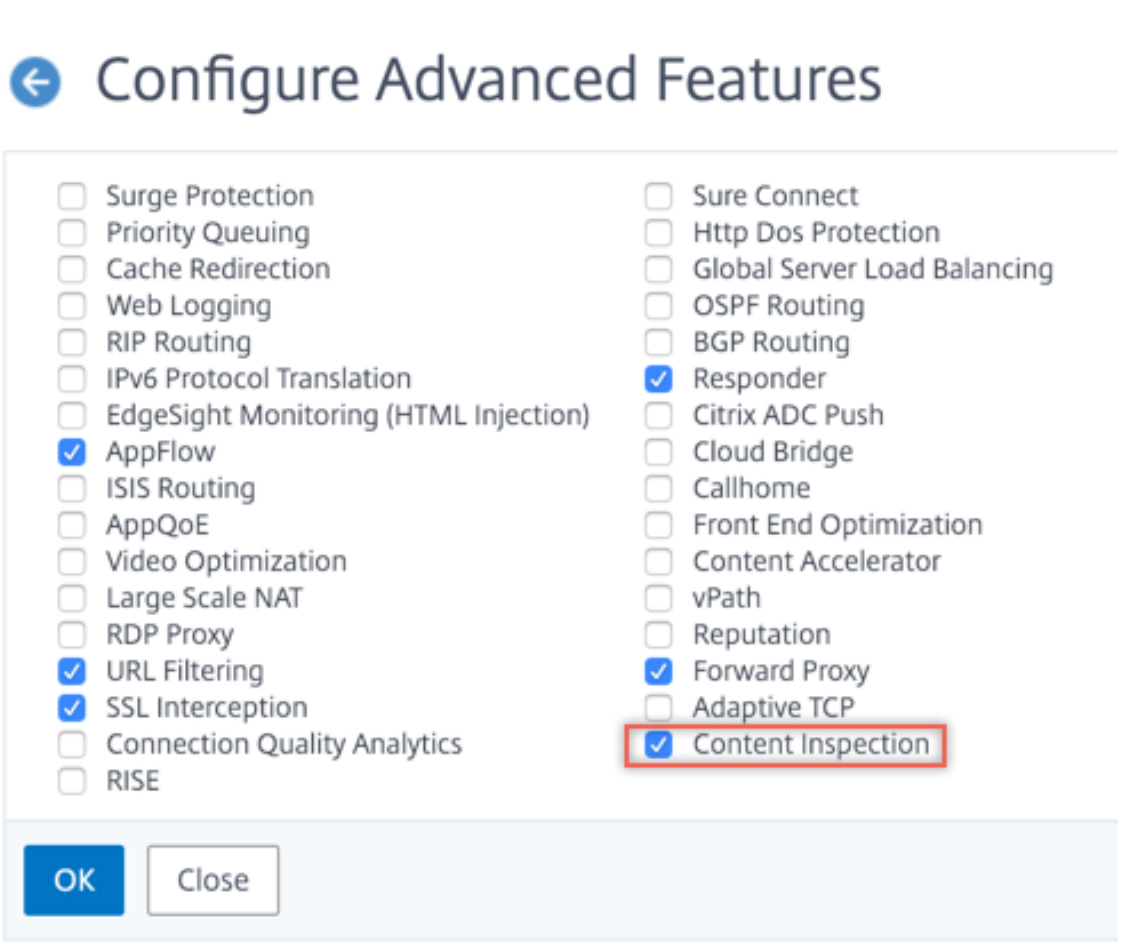
1. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Modes**.



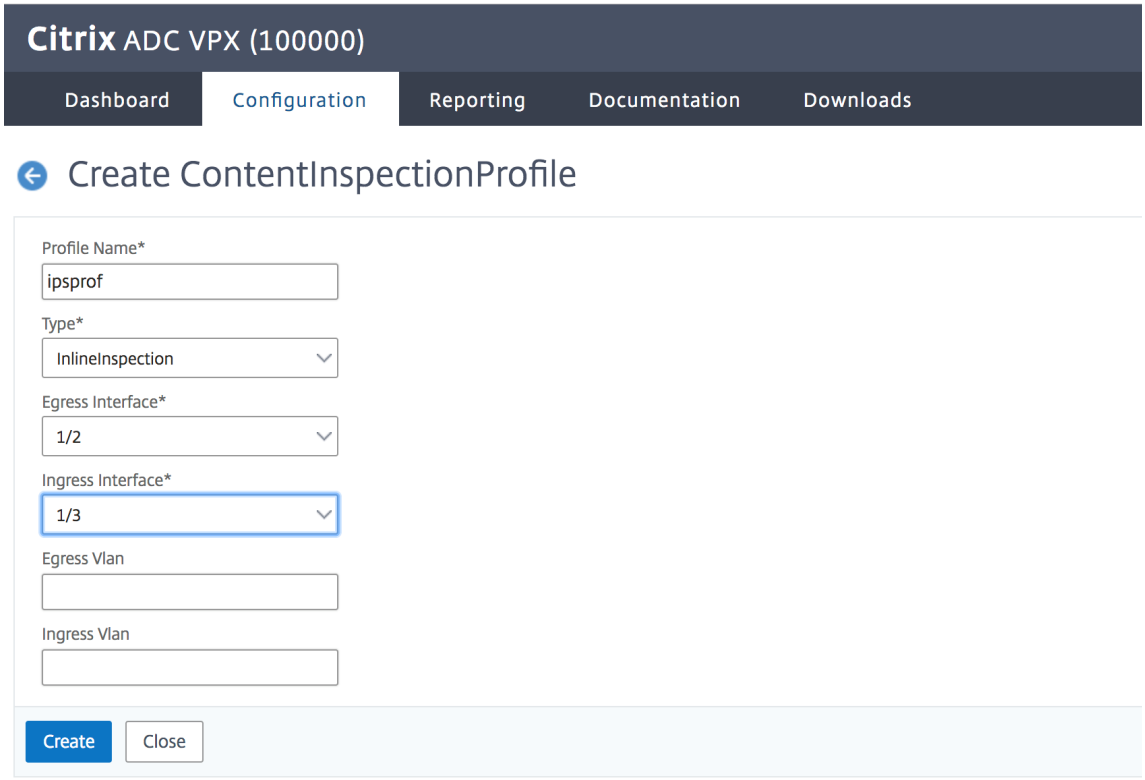


2. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Advanced Features**.

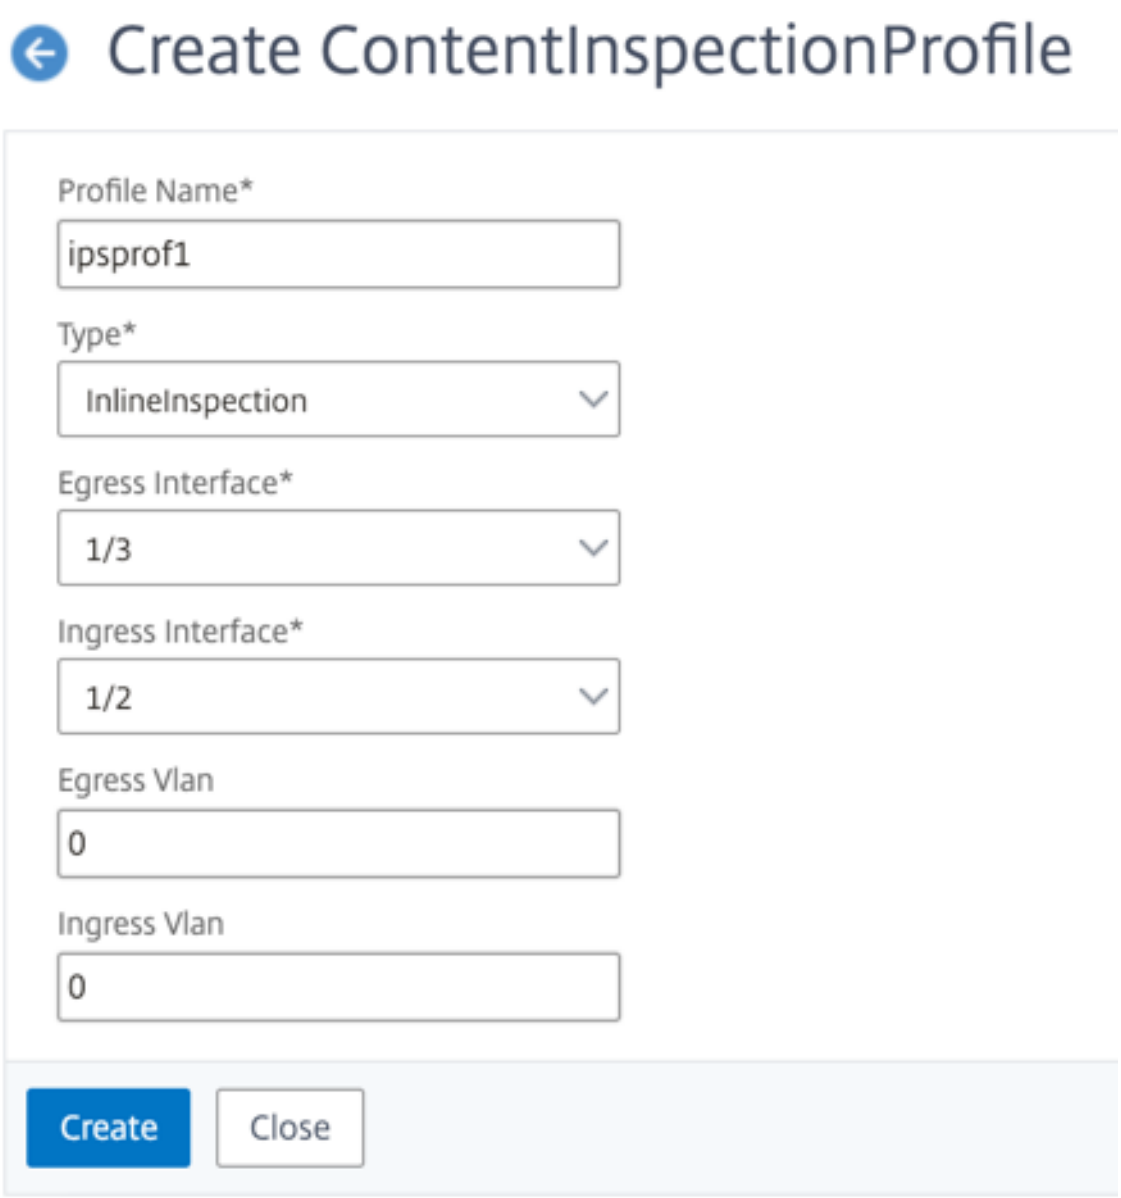




3. Navigate to **Secure Web Gateway > Content Inspection > Content Inspection Profiles**. Click **Add**.

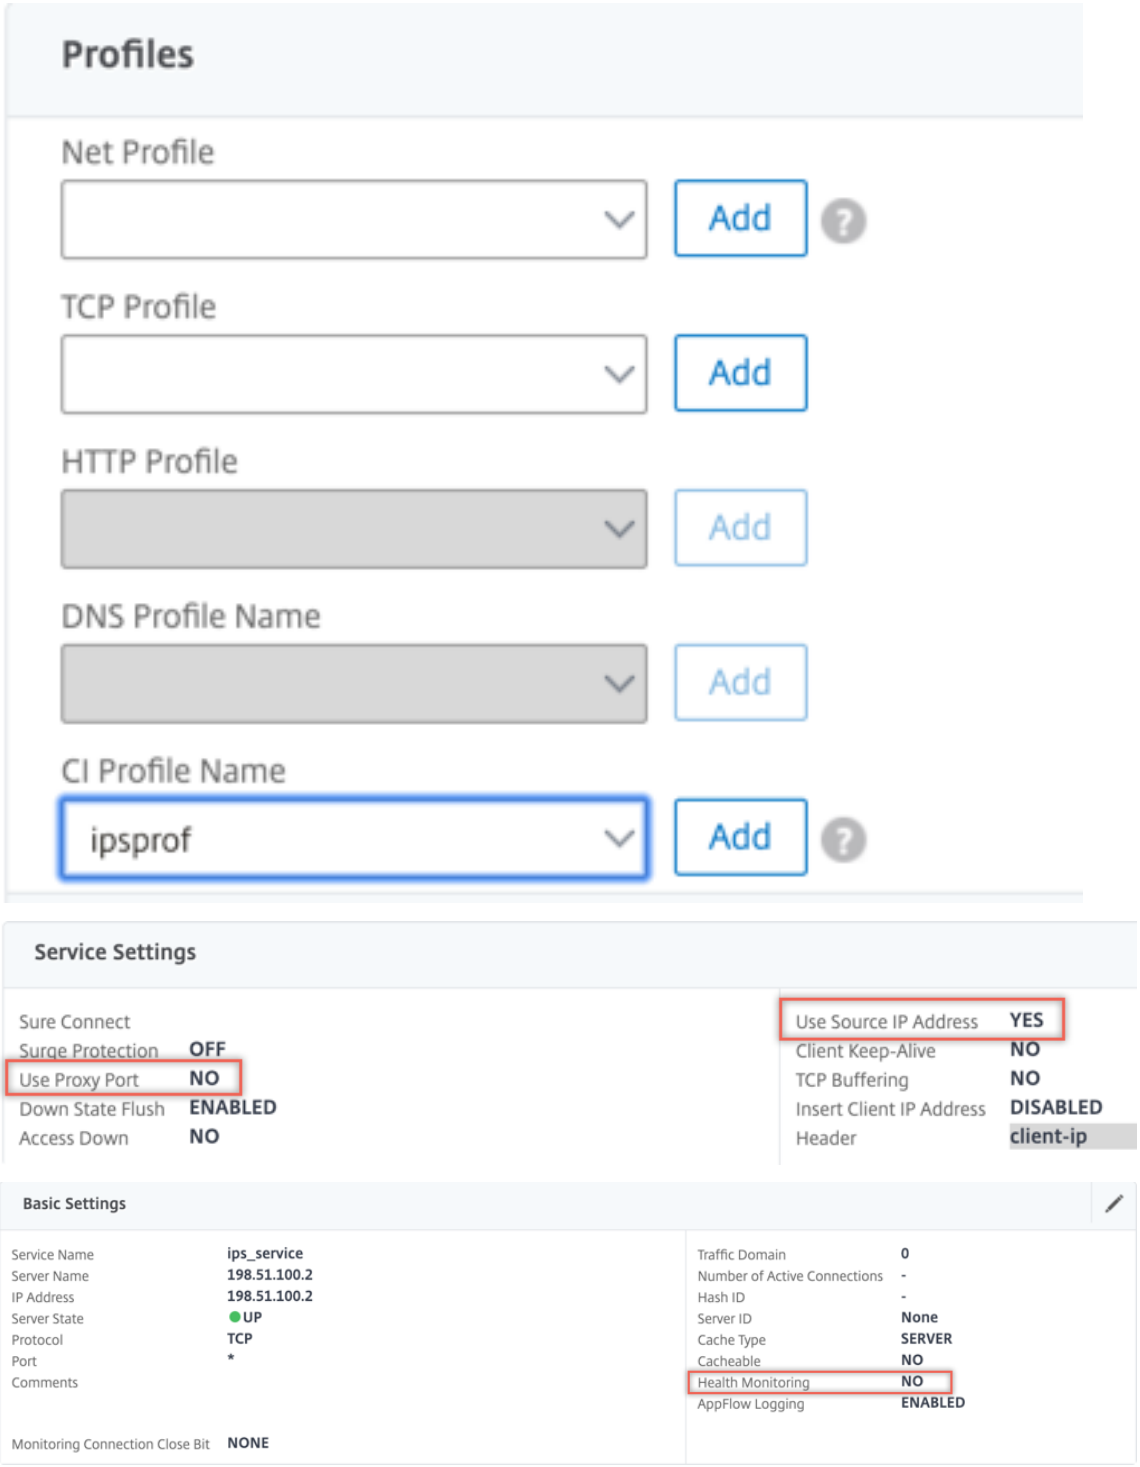


Specify the ingress and egress interfaces.



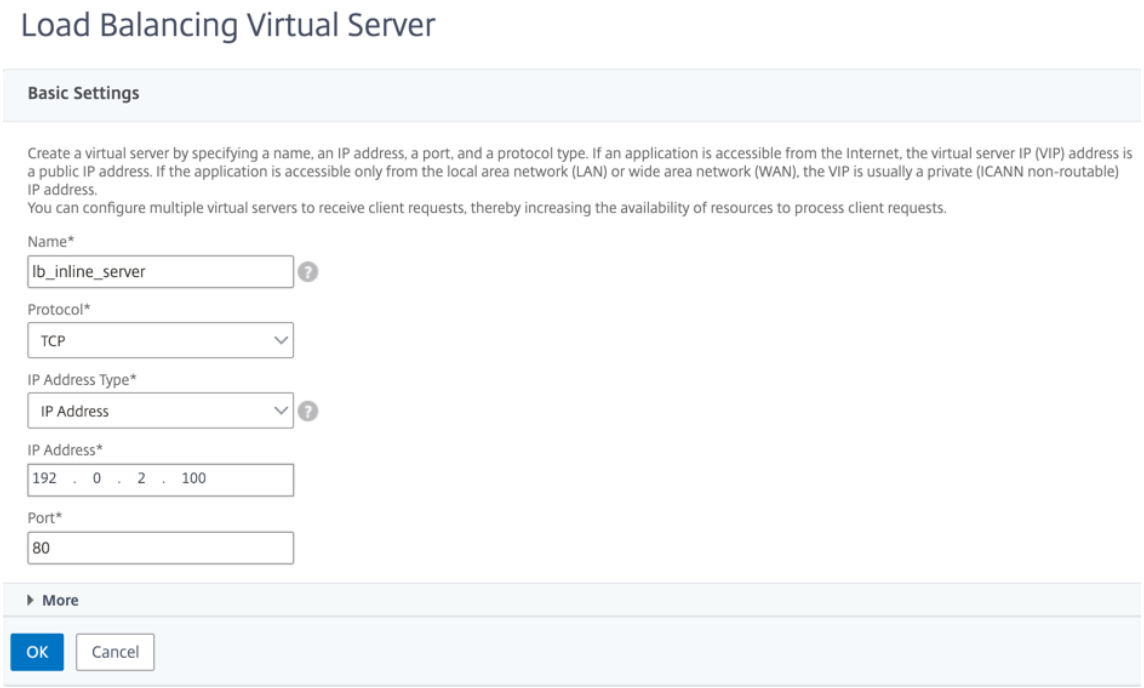
Create two profiles. Specify a different ingress and egress interface in the second profile.

4. Navigate to **Load Balancing > Services > Add** and add a service. In **Advanced Settings**, click **Profiles**. In the **CI Profile Name** list, select the content inspection profile created earlier. In **Service Settings**, set **Use Source IP Address** to YES and **Use Proxy Port** to No. In **Basic Settings**, set **Health Monitoring** to NO. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in the monitor to ON.



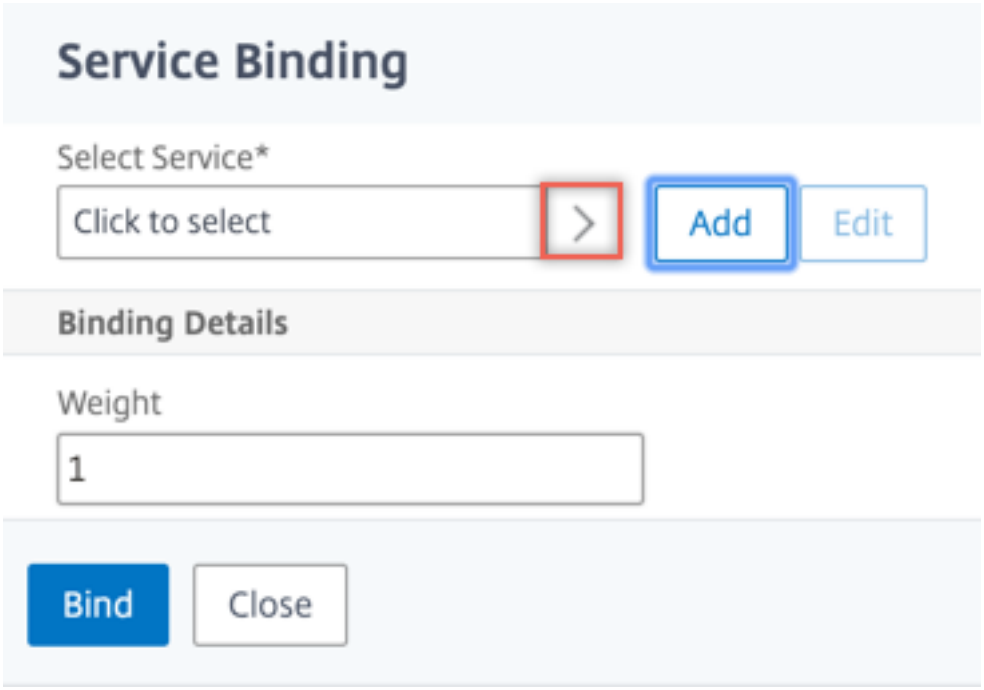
Create two services. Specify dummy IP addresses that are not owned by any of the devices, including the inline devices.

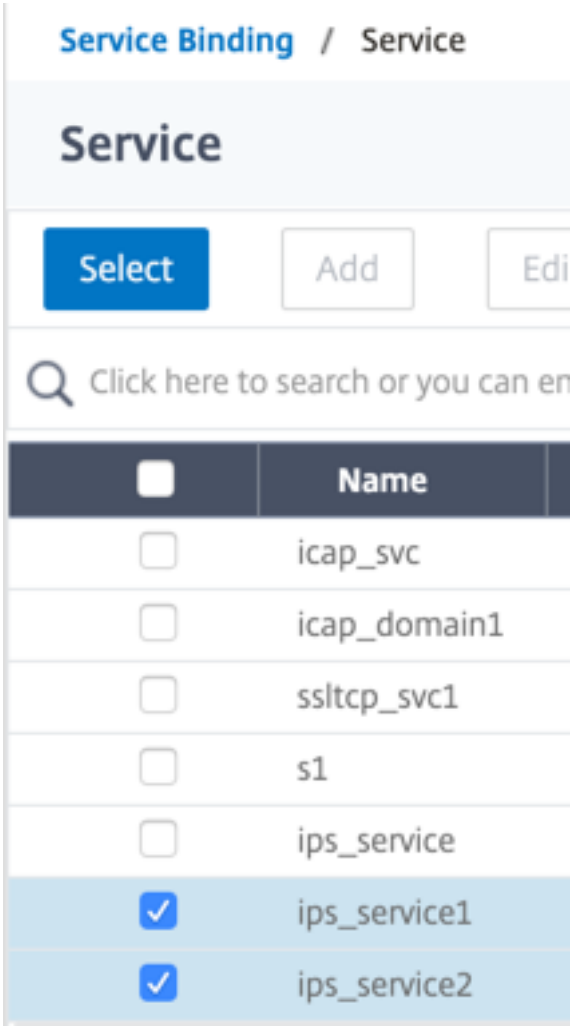
5. Navigate to **Load Balancing > Virtual Servers > Add**. Create a TCP load balancing virtual server.

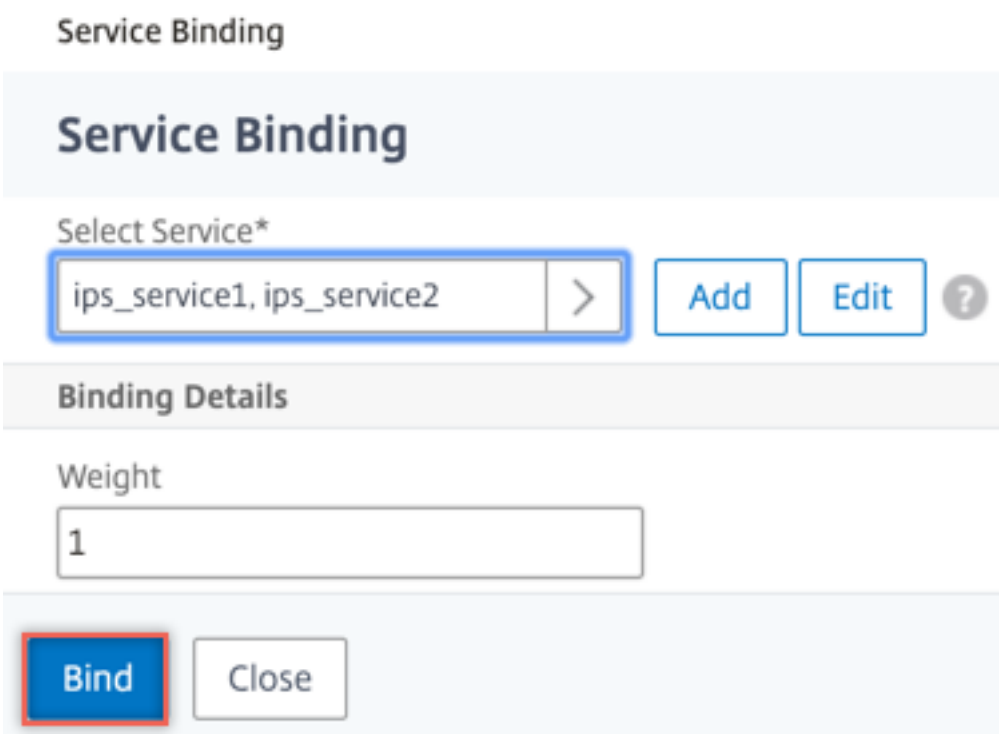


Click **OK**.

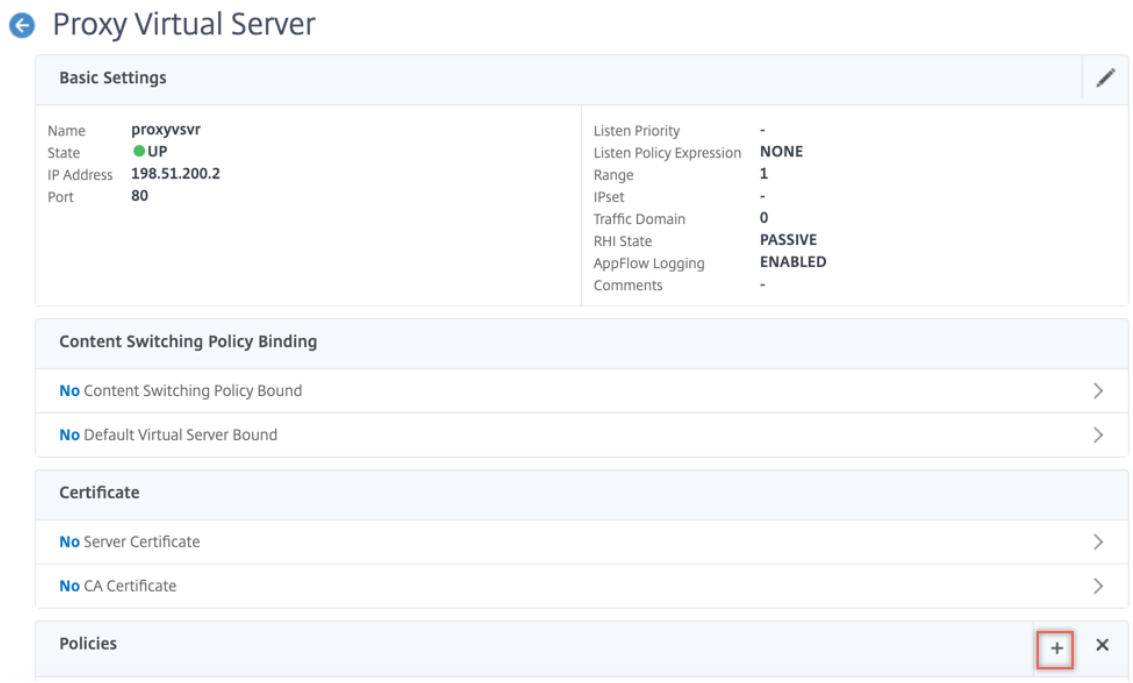
6. Click inside the **Load Balancing Virtual Server Service Binding** section. In **Service Binding**, click the arrow in **Select Service**. Select the two services created earlier, and click **Select**. Click **Bind**.



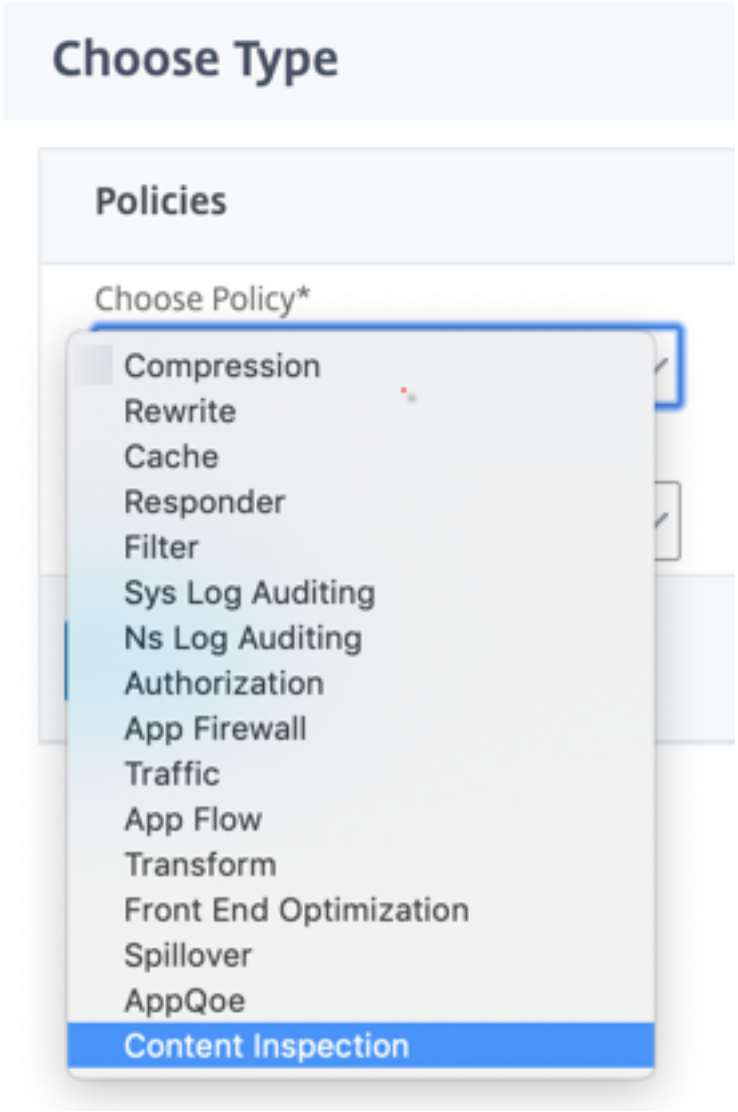




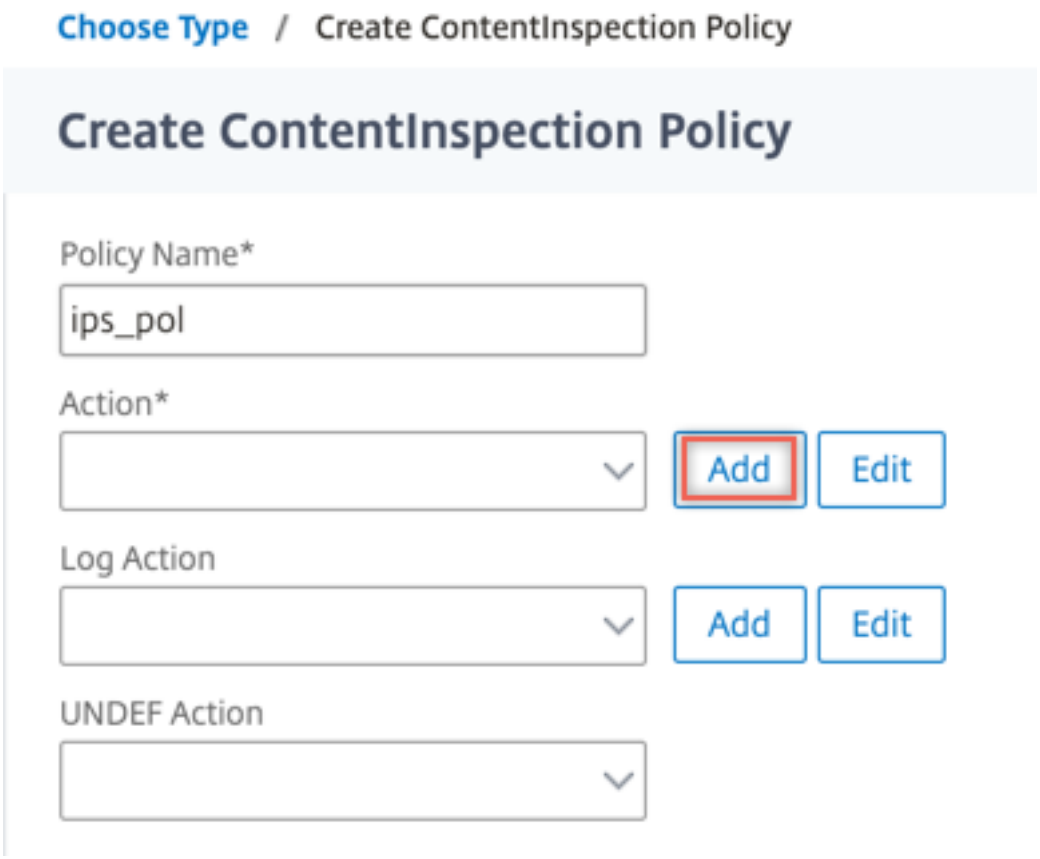
7. Navigate to **Secure Web Gateway > Proxy Virtual Servers> Add**. Specify a name, IP address, and port. In **Advanced Settings**, select **Policies**. Click the “+” sign.



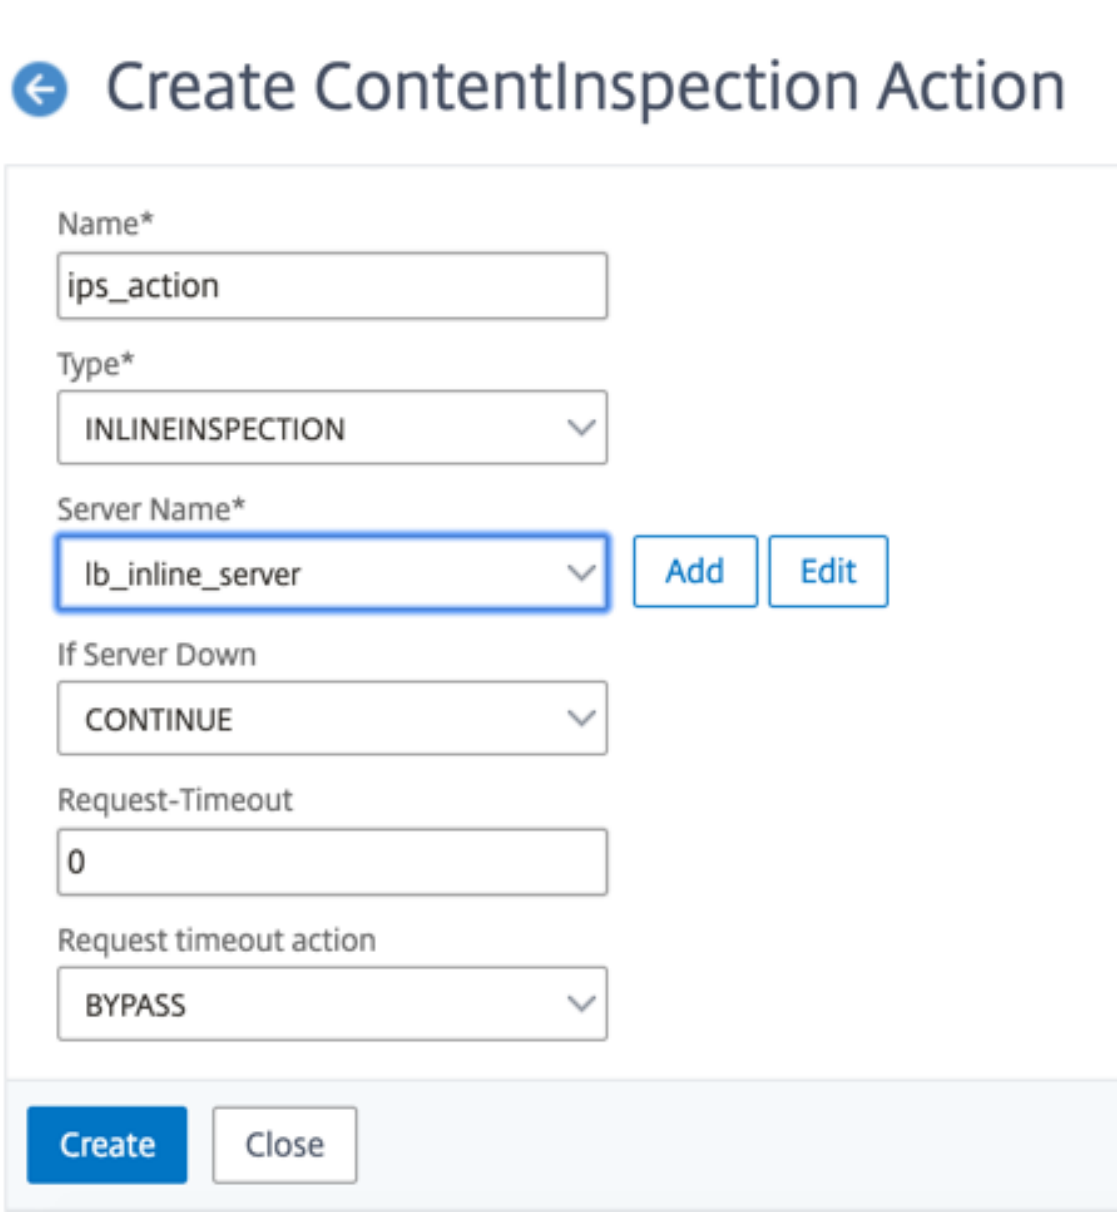
8. In **Choose Policy** select **Content Inspection**. Click **Continue**.



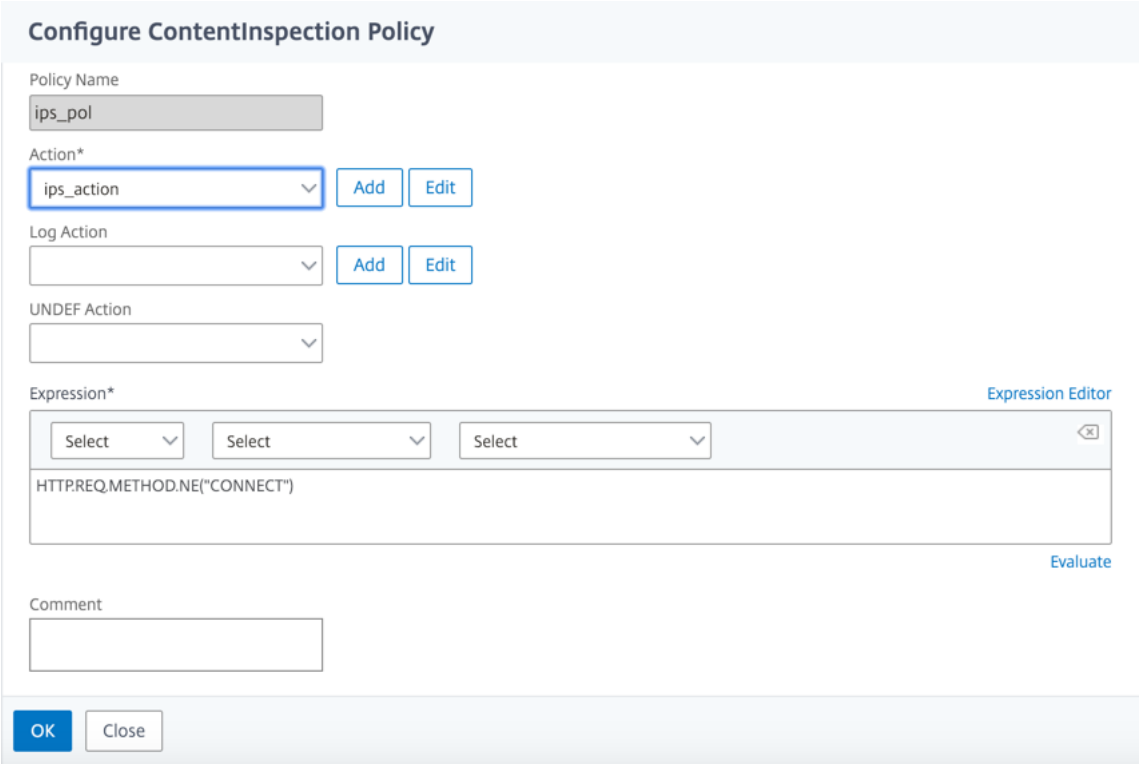
9. Click **Add**. Specify a name. In **Action**, click **Add**.



10. Specify a name. In **Type**, select **INLINEINSPECTION**. In **Server Name**, select the load balancing virtual server created earlier.



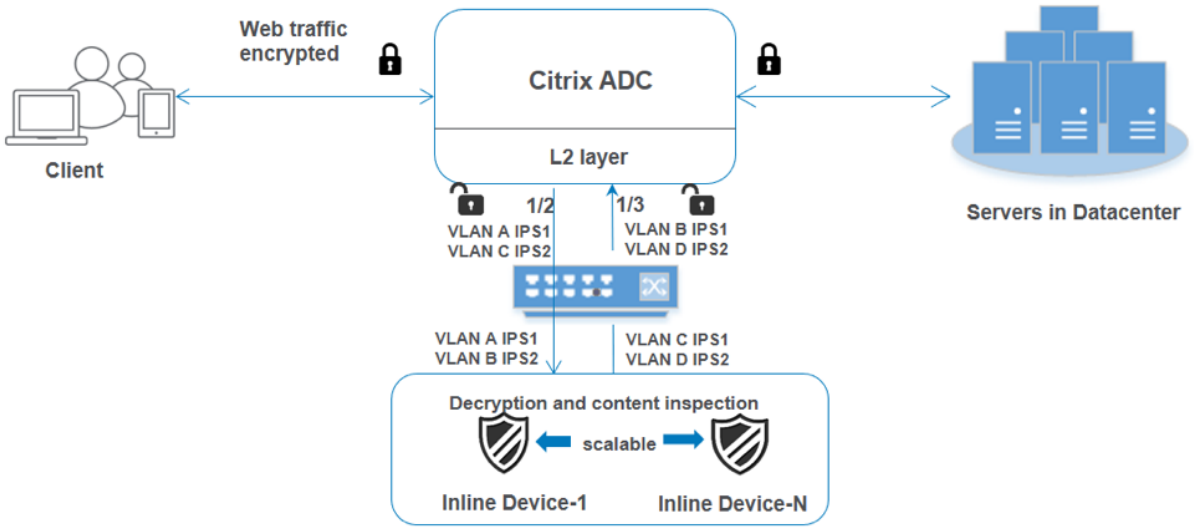
11. Click **Create**. Specify the rule and click **Create**.



12. Click **Bind**.
13. Click **Done**.

Scenario 3: Load balance multiple inline devices with shared interfaces

If you are using two or more inline devices, you can load balance the devices using different content inspection services with shared interfaces. In this case, the SSL forward proxy appliance load balances the subset of traffic sent to each device through a shared interface. The subset is decided based on the policies configured. For example, TXT or image files might not be sent for inspection to the inline devices.



The basic configuration remains the same as in scenario 2. For this scenario, bind the interfaces to different VLANs to segregate the traffic for each inline device. Specify the VLANs in the content inspection profiles. Perform the following extra steps:

1. Bind the shared interfaces to different VLANs.
2. Specify the ingress and egress VLANs in the content inspection profiles.

Configuration using the CLI

Type the following commands at the command prompt. Examples are given after each command.

1. Enable MBF.

```
enable ns mode mbf
```

1. Enable the feature.

```
enable ns feature contentInspection
```

1. Bind the shared interfaces to different VLANs.

```
bind vlan <id> -ifnum <interface> -tagged
```

Example:

```
bind vlan 100  - ifnum 1/2 tagged
bind vlan 200  - ifnum 1/3 tagged
bind vlan 300  - ifnum 1/2 tagged
bind vlan 400  - ifnum 1/3 tagged
<!--NeedCopy-->
```

1. Add profile 1 for service 1. Specify the ingress and egress VLANs in the profile.

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile ipsprof1 -type InlineInspection -egressInterface
 "1/3" -ingressinterface "1/2" -egressVlan 100 -ingressVlan 300
```

1. Add profile 2 for service 2. Specify the ingress and egress VLANs in the profile.

```
add contentInspection profile <name> -type InlineInspection -egressInterface
 <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer
>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile ipsprof2 -type InlineInspection -egressInterface
 "1/3" -ingressinterface "1/2" -egressVlan 200 -ingressVlan 400
```

1. Add service 1.

```
add service <service_name> <IP> TCP * - contentinspectionProfileName <Name>
 -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```
add service ips_service1 192.168.10.2 TCP * -healthMonitor NO -usip YES -
useproxyport NO -contentInspectionProfileName ipsprof1
```

1. Add service 2.

```
add service <service_name> <IP> TCP * - contentinspectionProfileName <Name>
 -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```
add service ips_service2 192.168.10.3 TCP * -healthMonitor NO -usip YES -
useproxyport NO -contentInspectionProfileName ipsprof2
```

1. Add a load balancing virtual server.

```
add lb vserver <LB_VSERVER_NAME> TCP <IP> <port>
```

Example:

```
add lb vserver lb_inline_vserver TCP 192.0.2.100 *
```

1. Bind the services to the load balancing virtual server.

```
bind lb vserver <LB_VSERVER_NAME> <service_name>
bind lb vserver <LB_VSERVER_NAME> <service_name>
```

Example:

```
bind lb vserver lb_inline_vserver ips_service1
bind lb vserver lb_inline_vserver ips_service2
```

1. Specify the load balancing virtual server in the content inspection action.

```
add contentInspection action <name> -type INLINEINSPECTION -serverName <
string>
```

Example:

```
add contentInspection action ips_action -type INLINEINSPECTION -serverName
lb_inline_vserver
```

1. Add a content inspection policy. Specify the content inspection action in the policy.

```
add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

```
add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE(\"CONNECT\")
"-action ips_action
```

1. Add a proxy virtual server.

```
add cs vserver <name> PROXY <IPAddress> <port> -l2Conn ON
```

Example:

```
add cs vserver transparentcs PROXY * * -l2Conn ON
```

1. Bind the content inspection policy to the virtual server.

```
bind cs vserver <name> -policyName <string> -priority <positive_integer> -
gotoPriorityExpression <expression> -type REQUEST
```

Example:

```
bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression
 END -type REQUEST
```

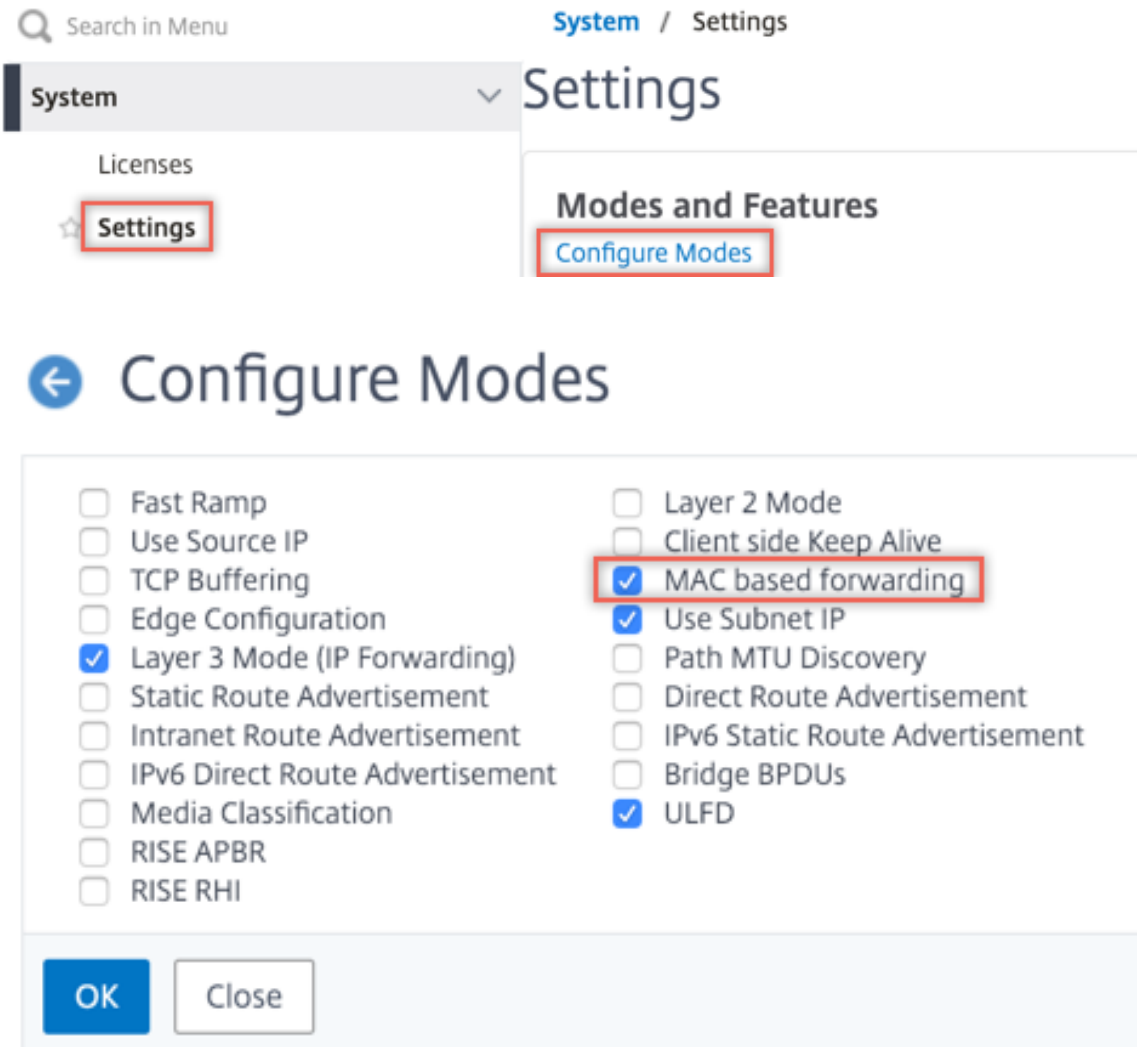
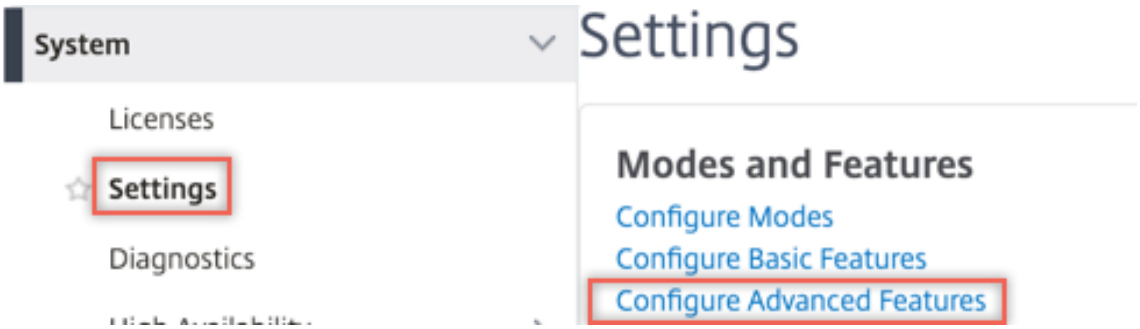
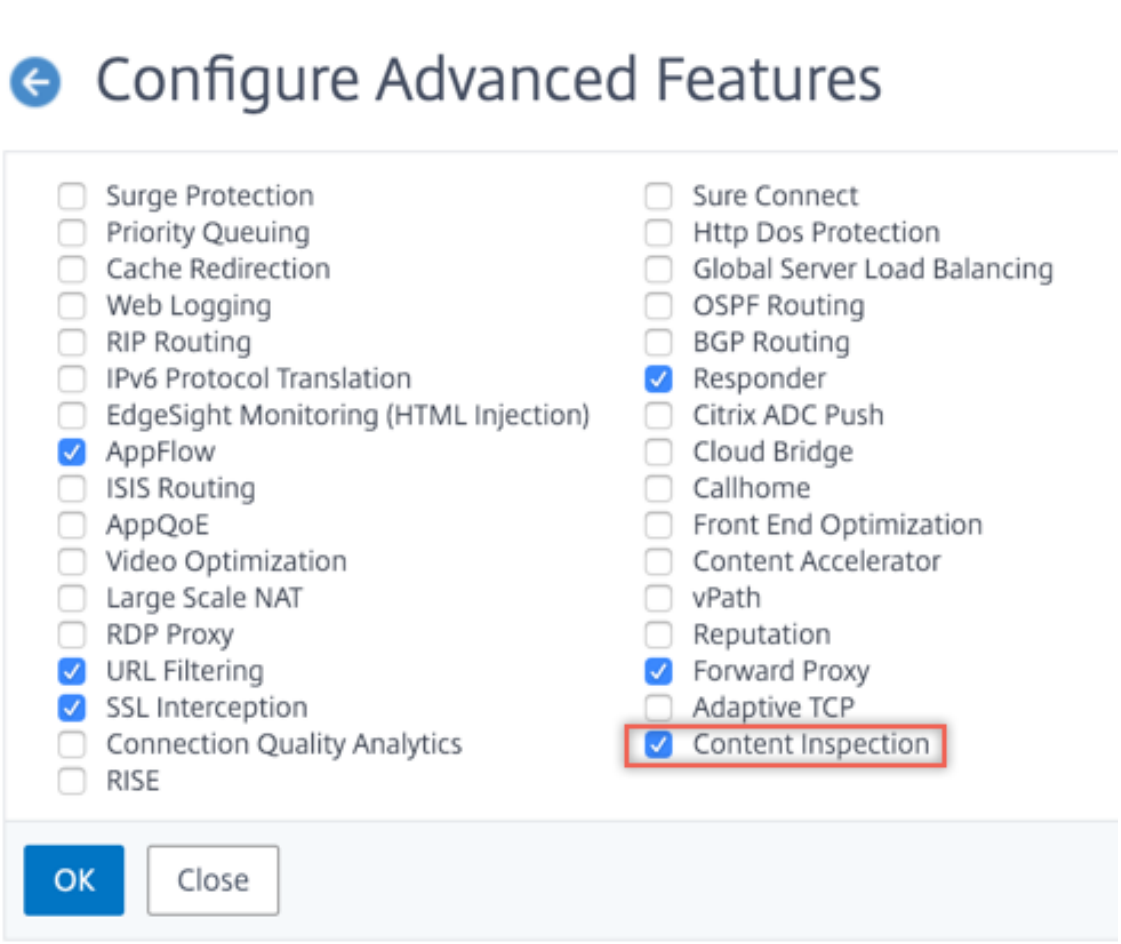
Configuration using the GUI

1. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Modes**.

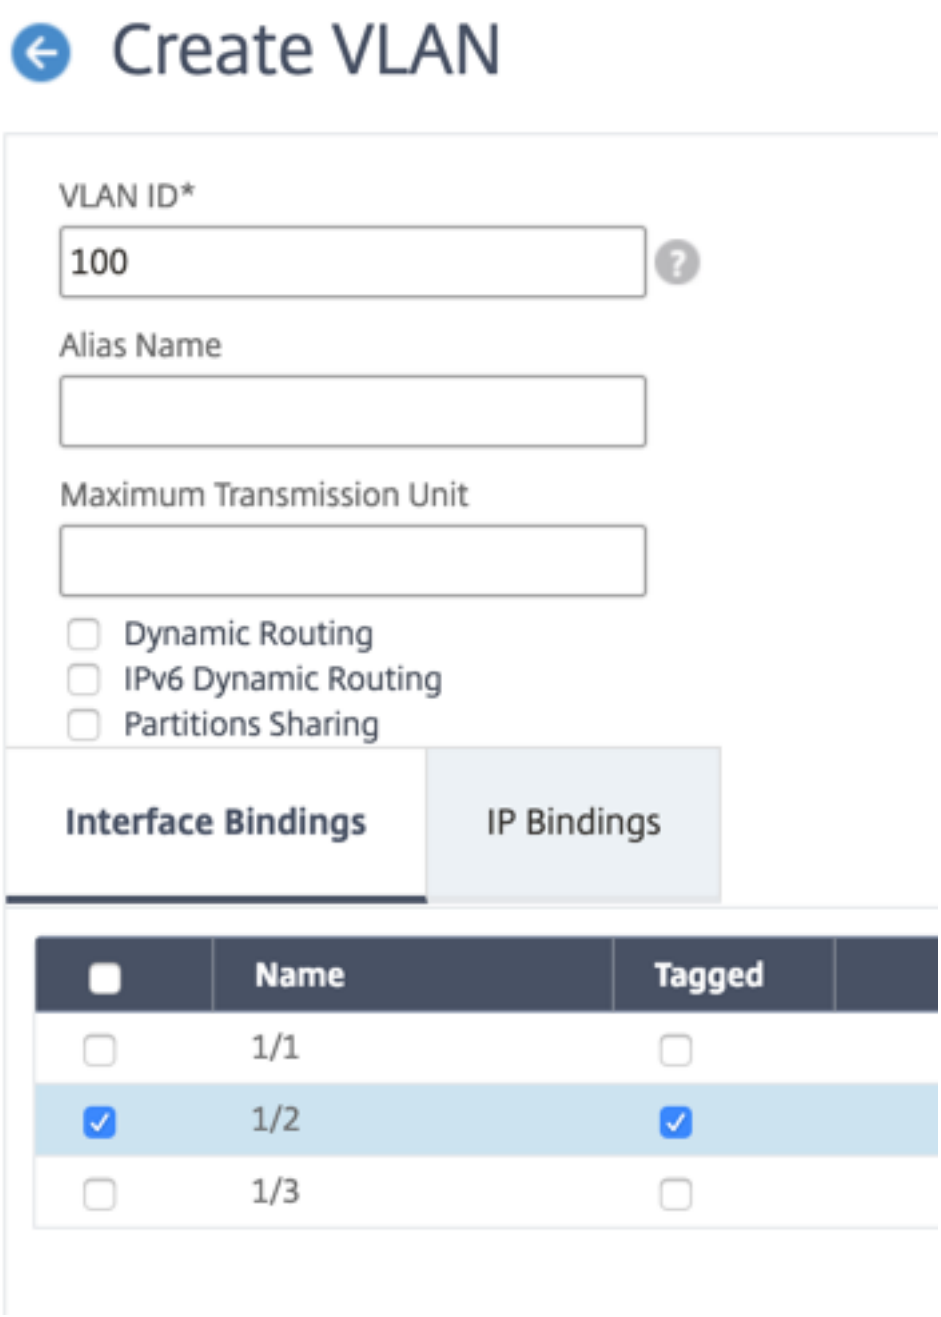


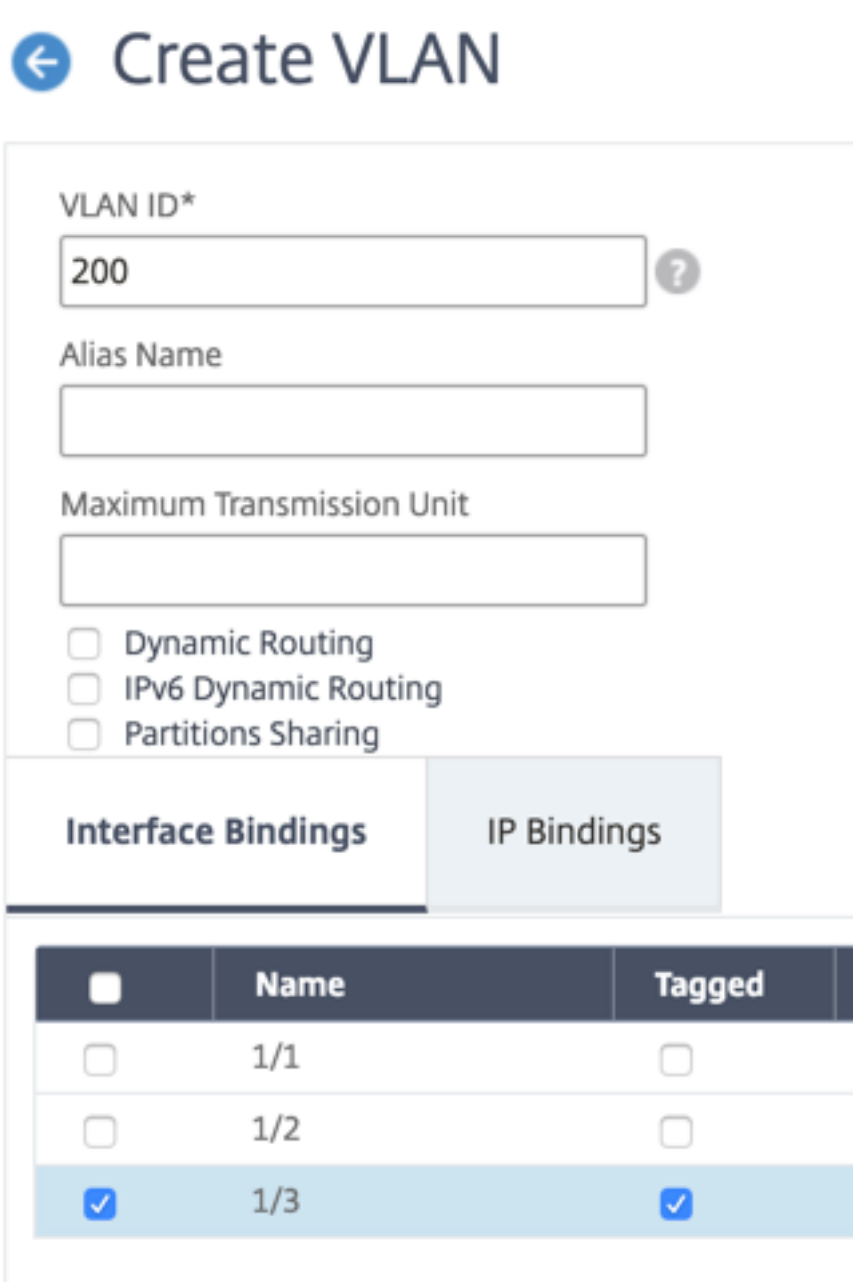
2. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Advanced Features**.

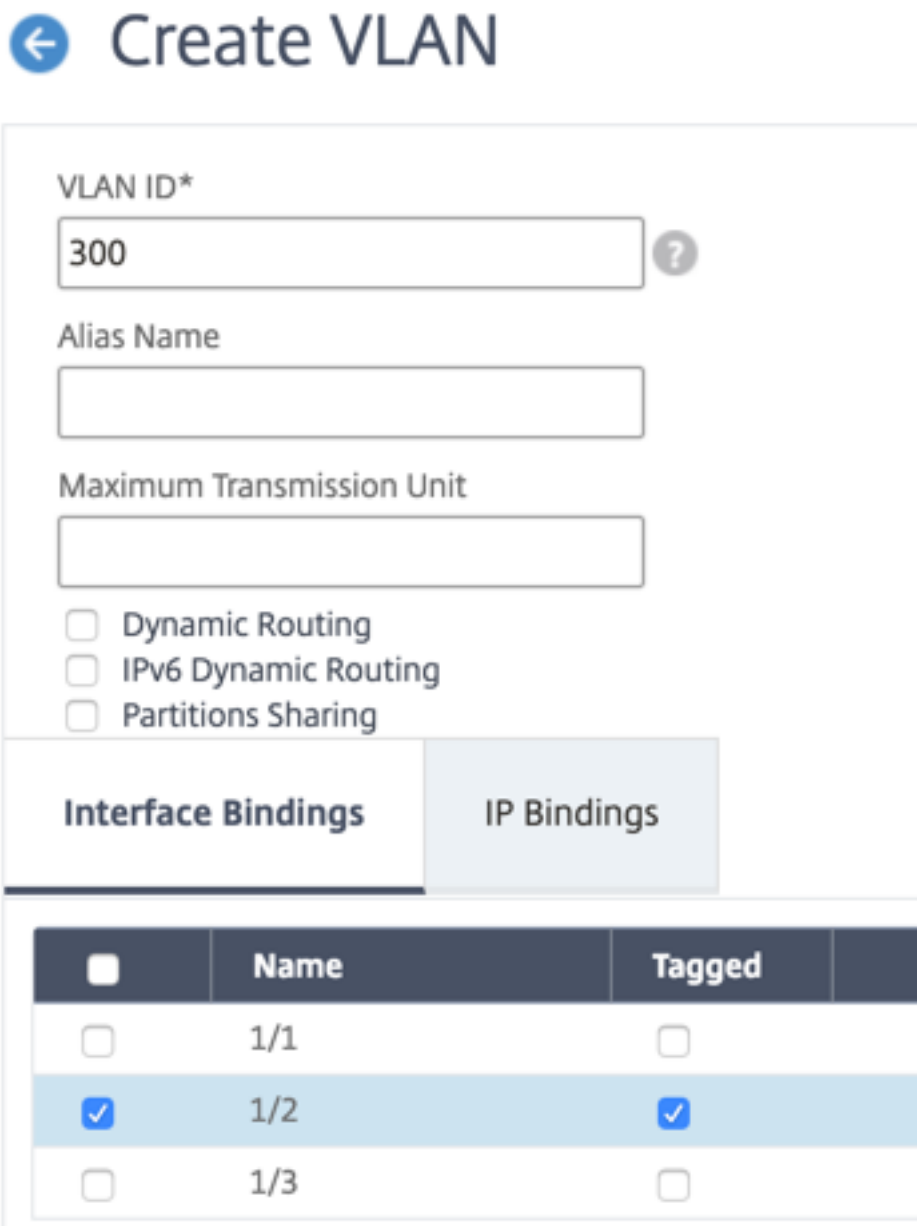


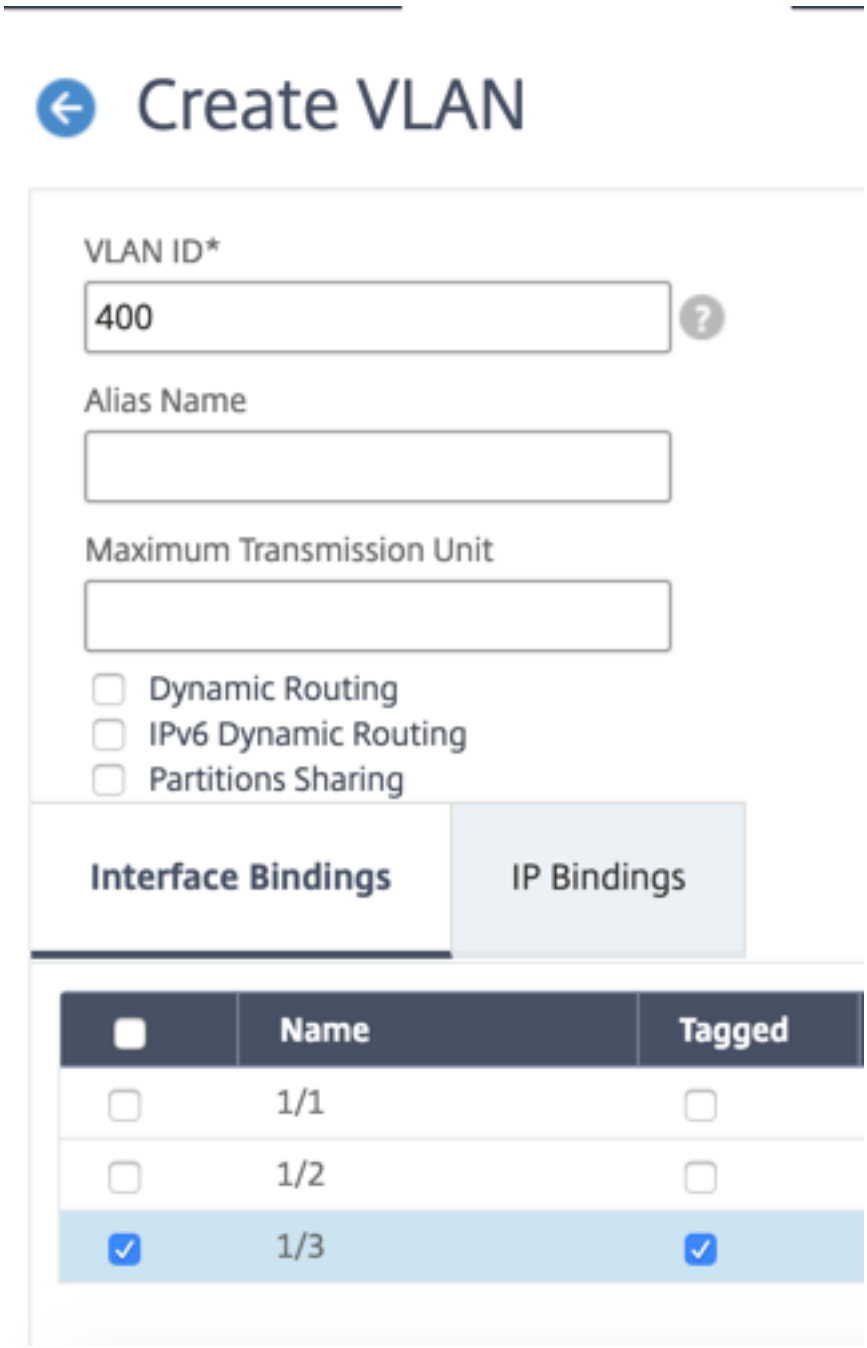


3. Navigate to **System > Network > VLANs > Add**. Add four VLANs and tag them to the interfaces.

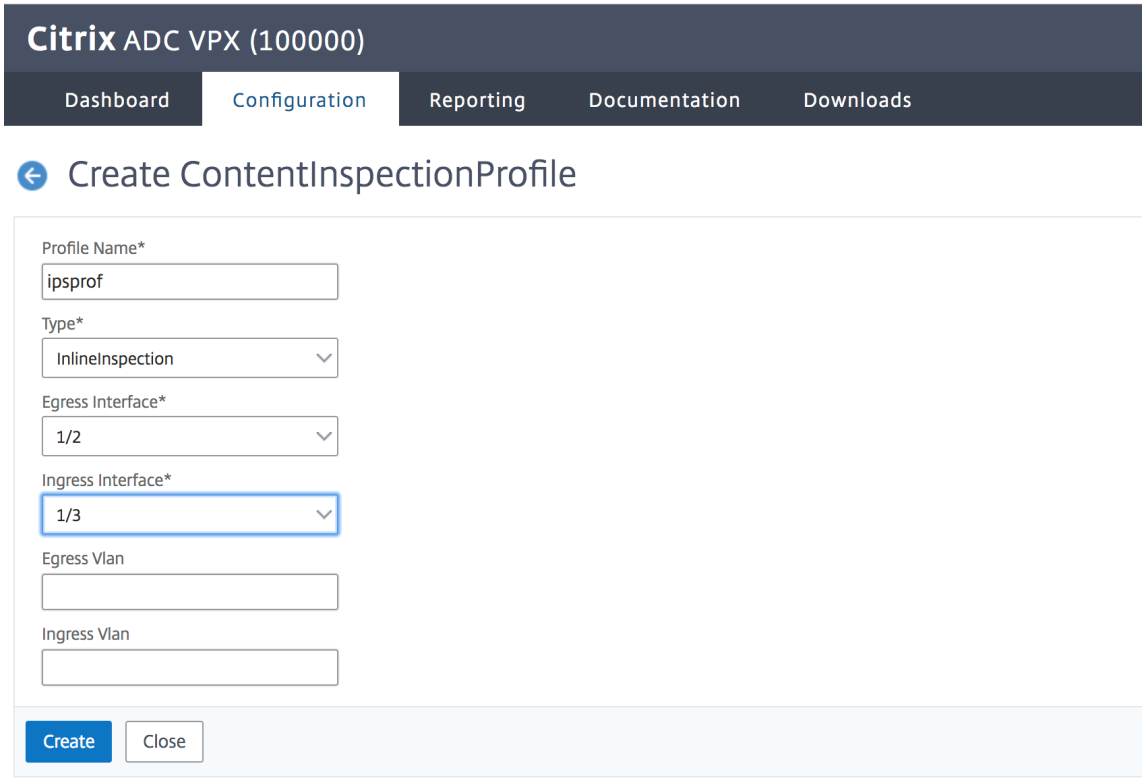




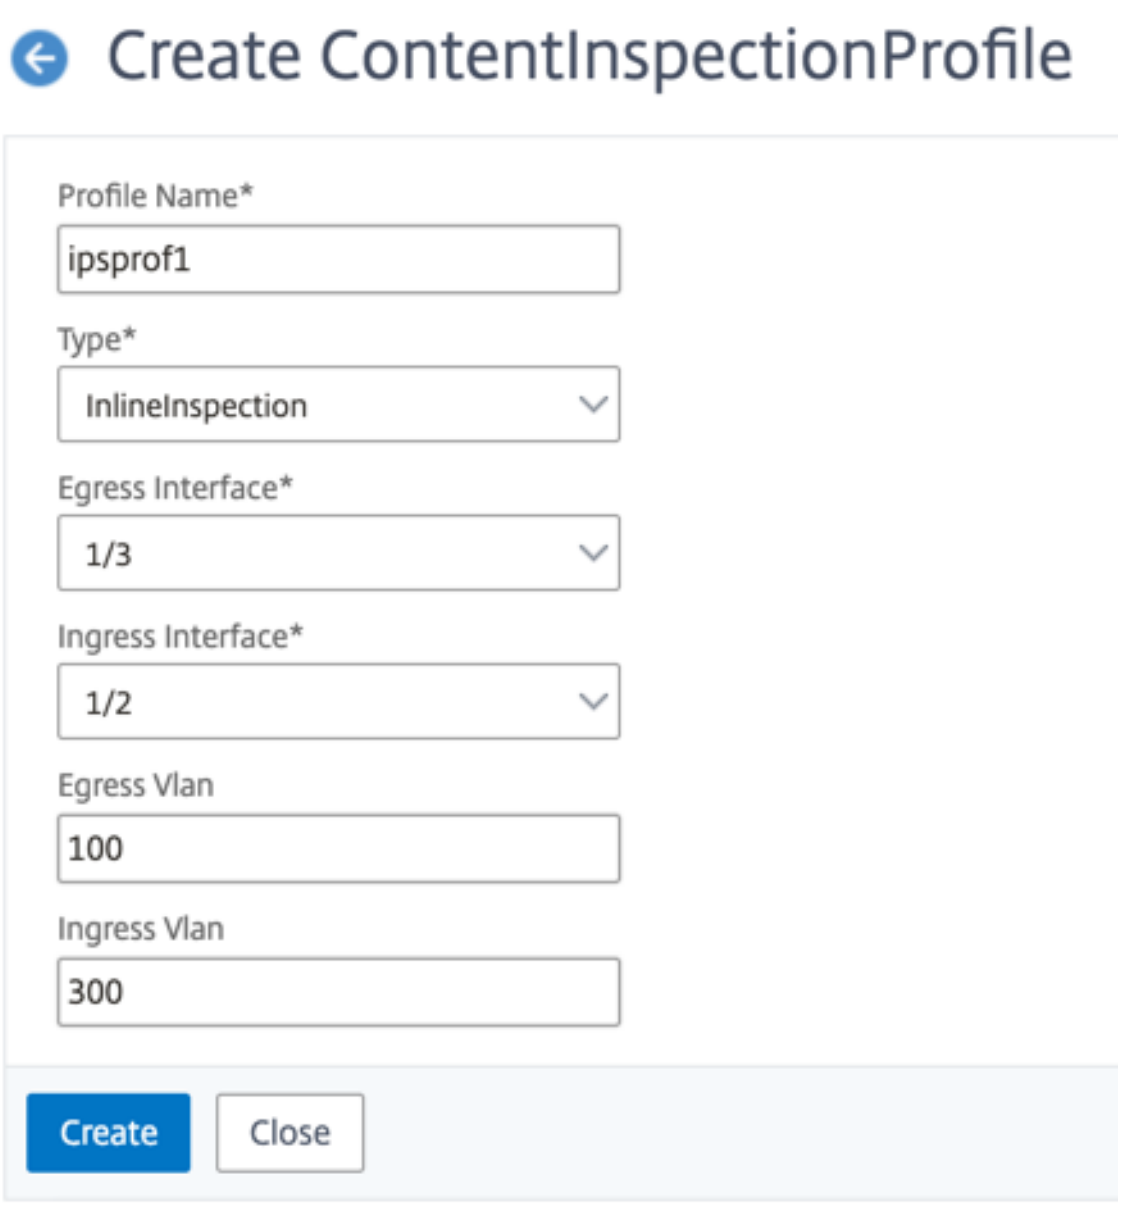




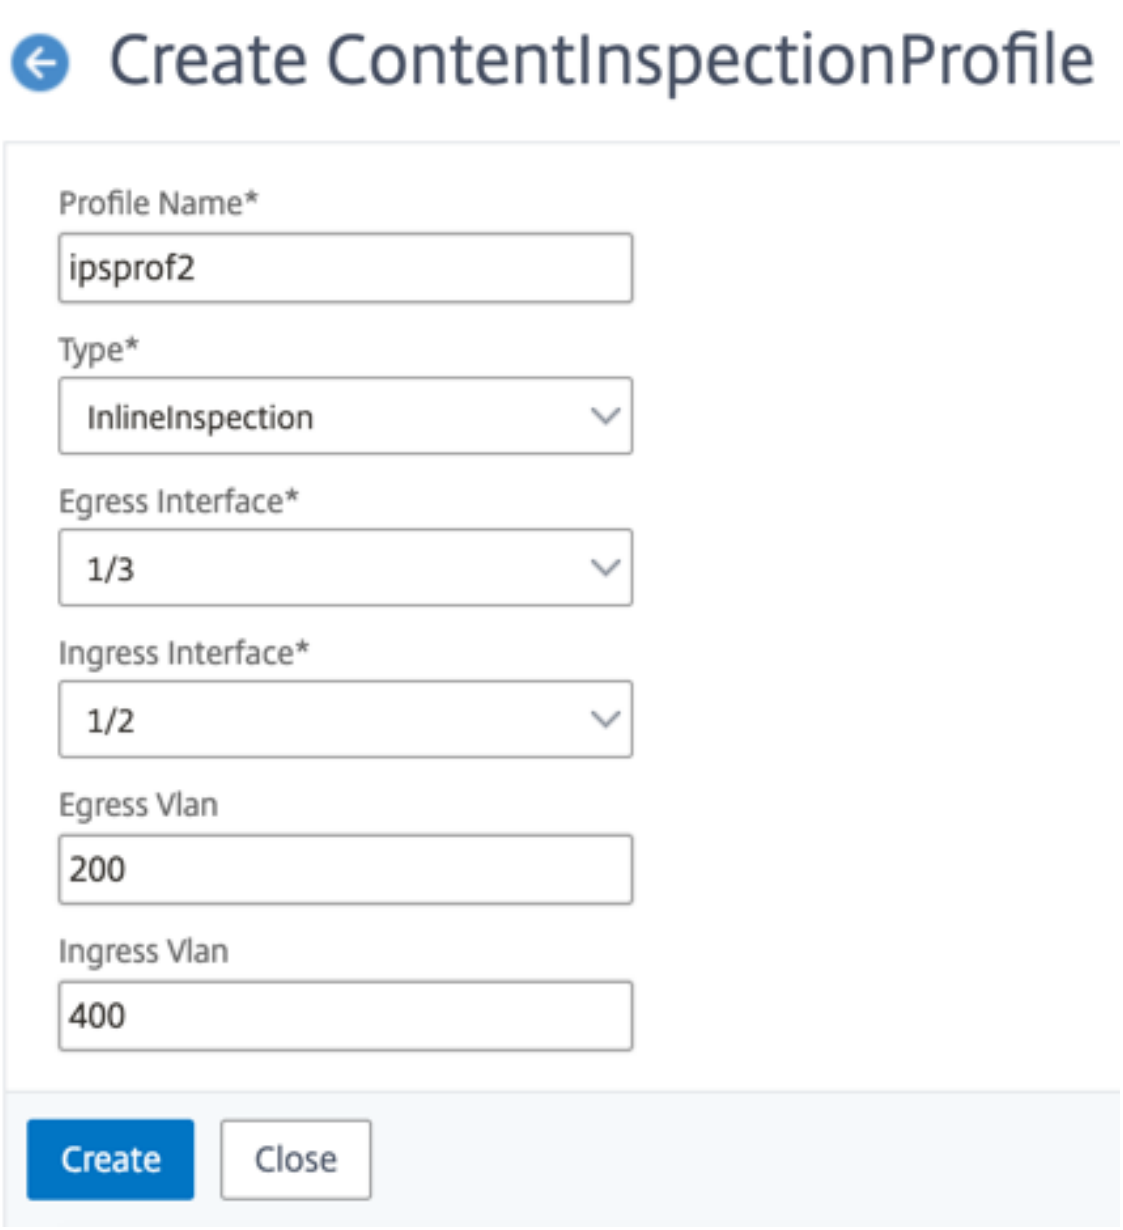
4. Navigate to **Secure Web Gateway > Content Inspection > Content Inspection Profiles**. Click **Add**.



Specify the ingress and egress VLANs.

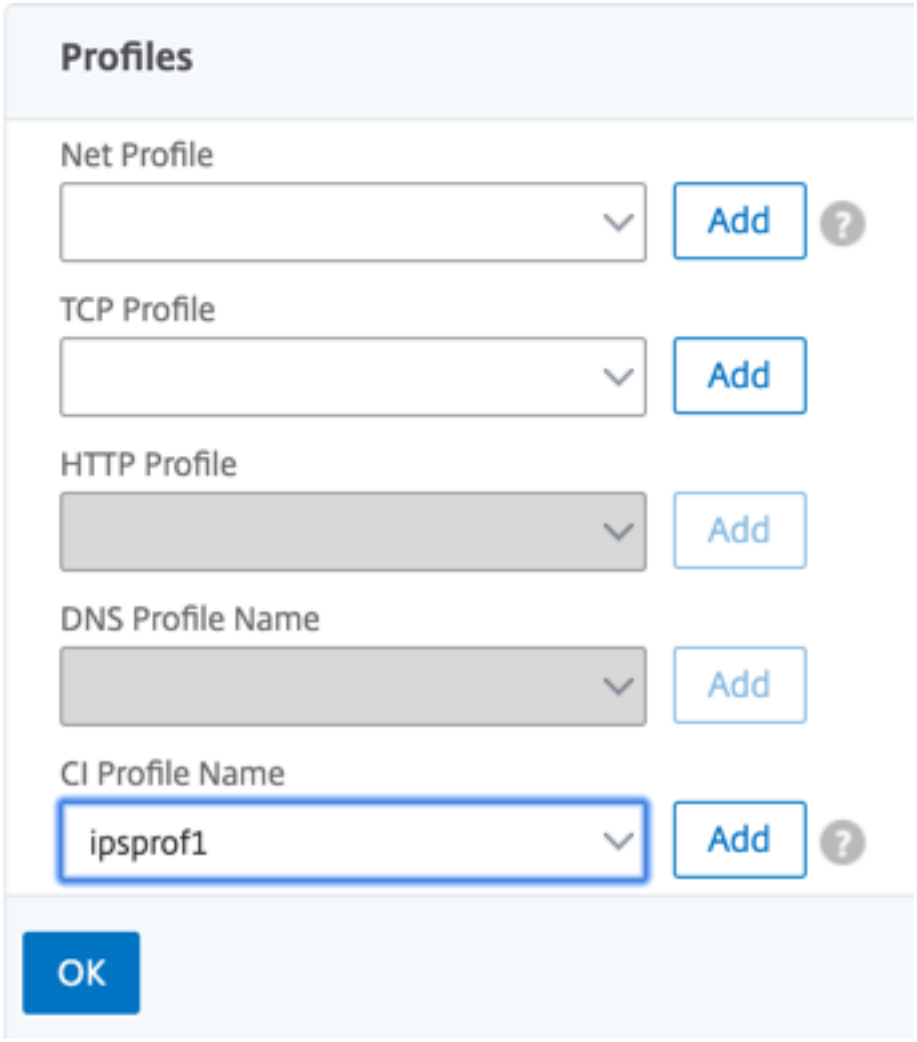


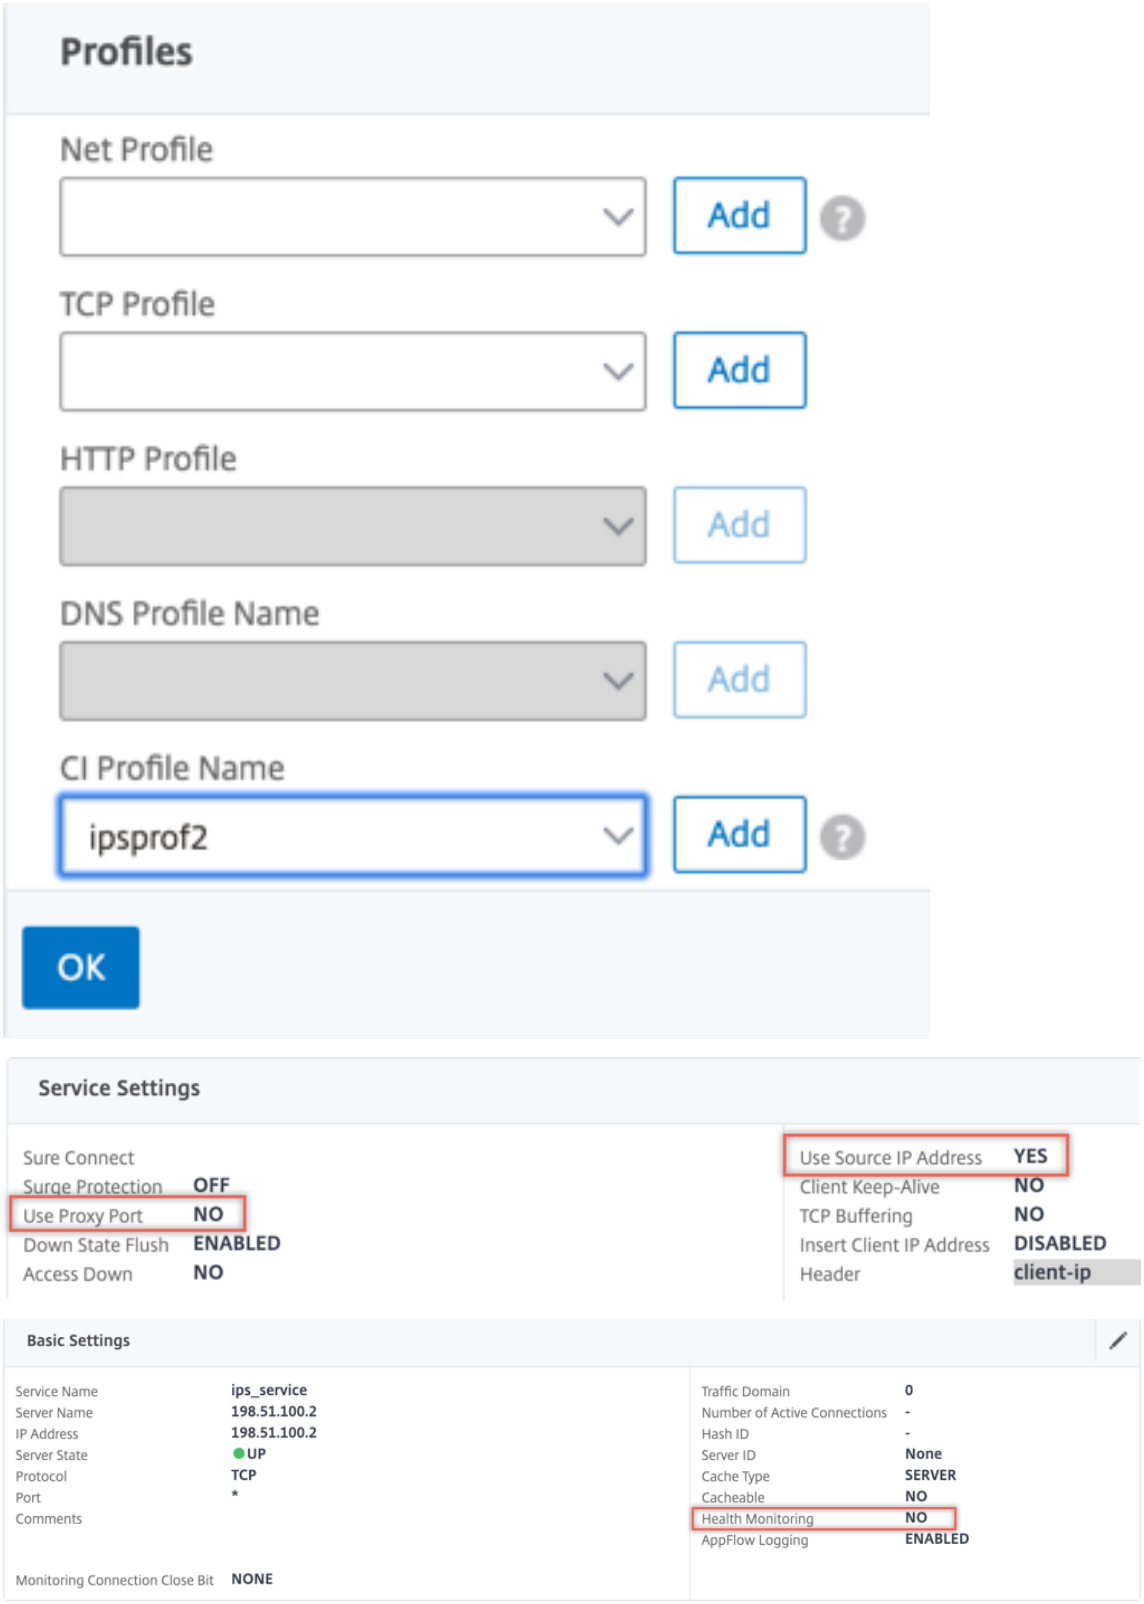
Create another profiles. Specify a different ingress and egress VLAN in the second profile.



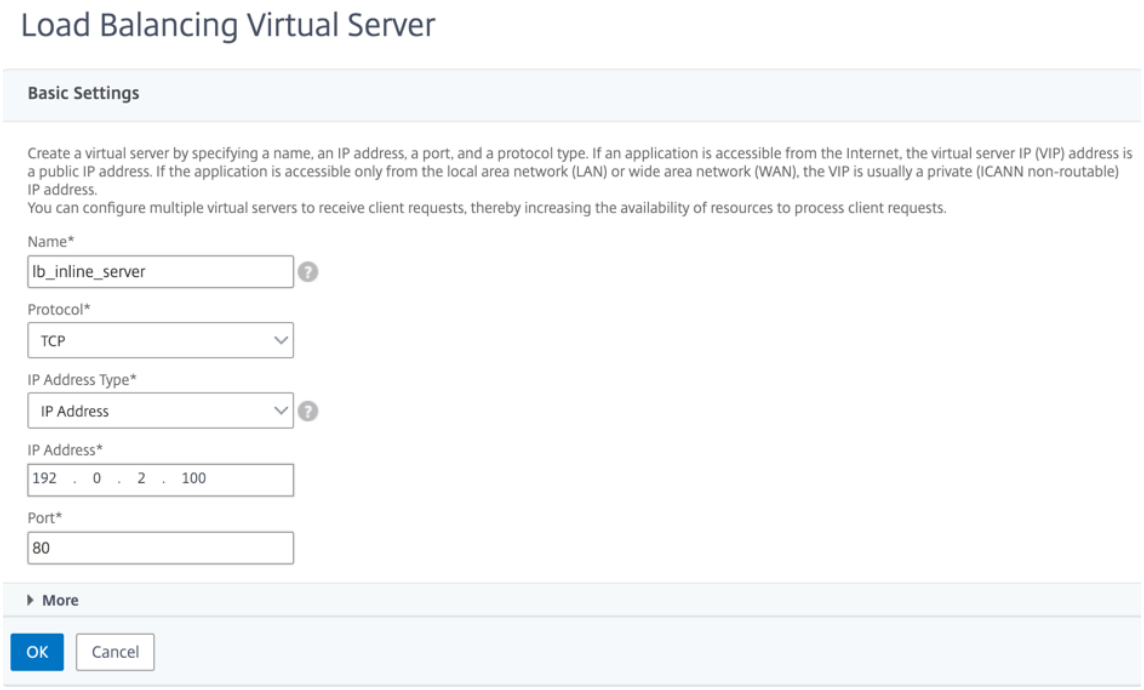
5. Navigate to **Load Balancing > Services > Add** and add a service. In **Advanced Settings**, click **Profiles**. In the **CI Profile Name** list, select the content inspection profile created earlier. In **Service Settings**, set **Use Source IP Address** to YES and **Use Proxy Port** to No. In **Basic Settings**, set **Health Monitoring** to NO.

   Create two services. Specify dummy IP addresses that are not owned by any of the devices, including the inline devices. Specify profile 1 in service 1, and profile 2 in service 2.

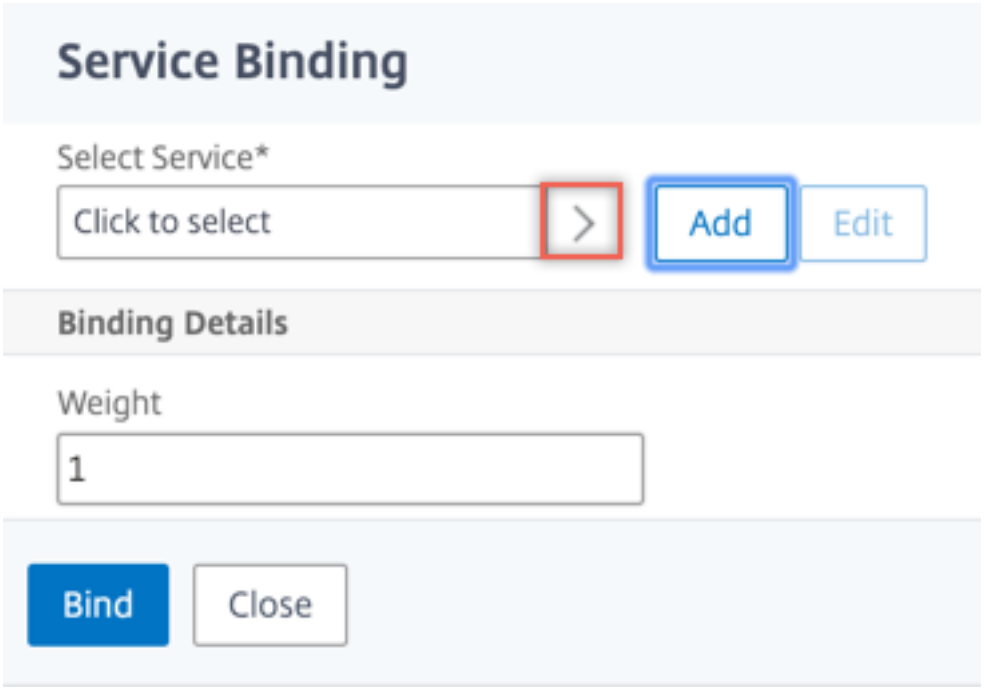


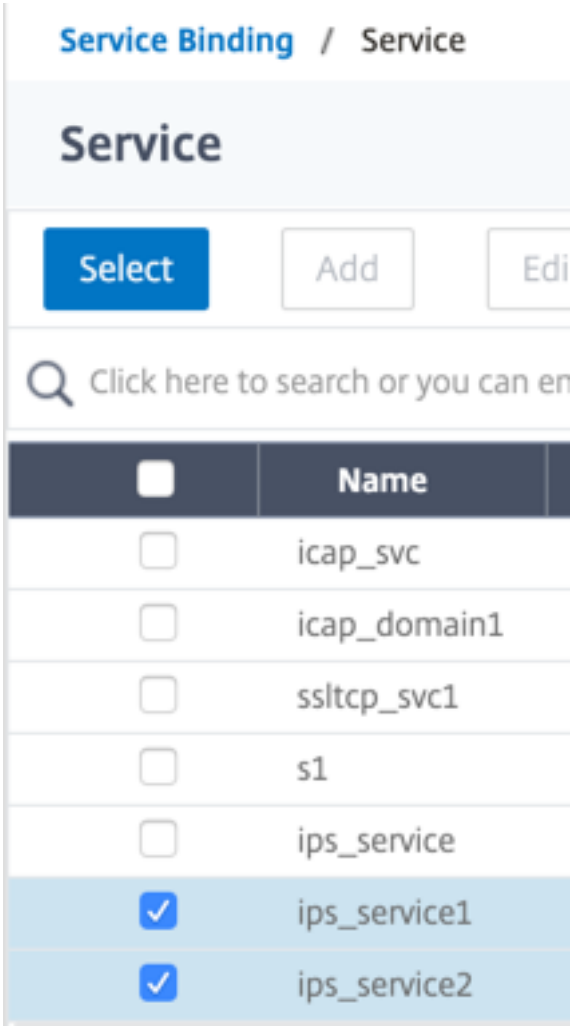


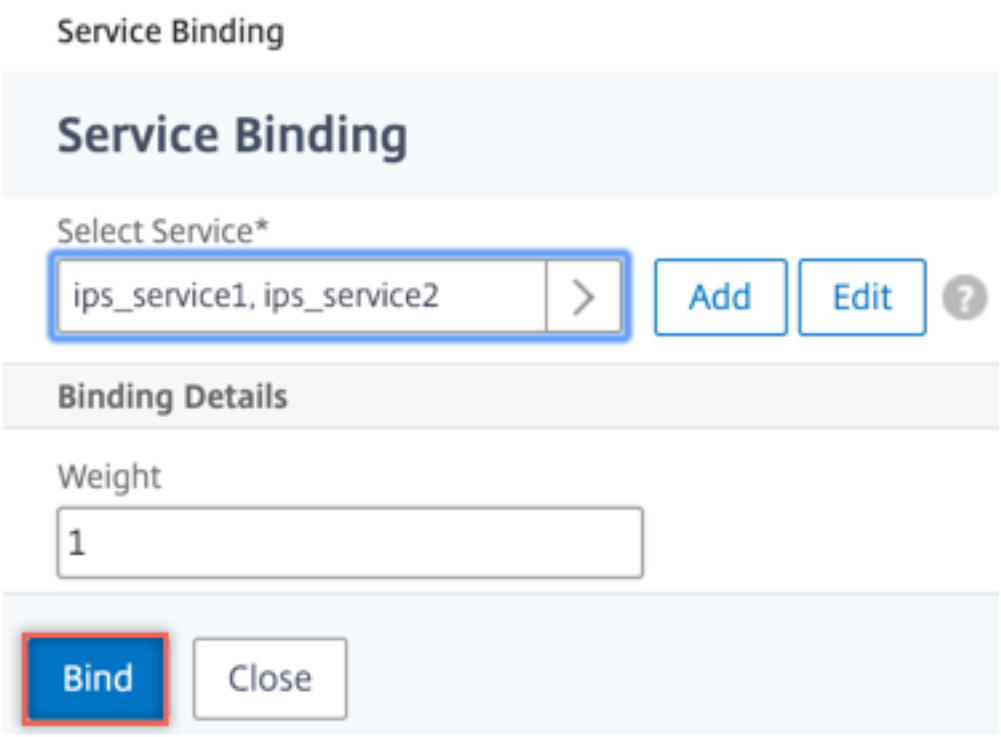
6. Navigate to **Load Balancing > Virtual Servers > Add**. Create a TCP load balancing virtual server.



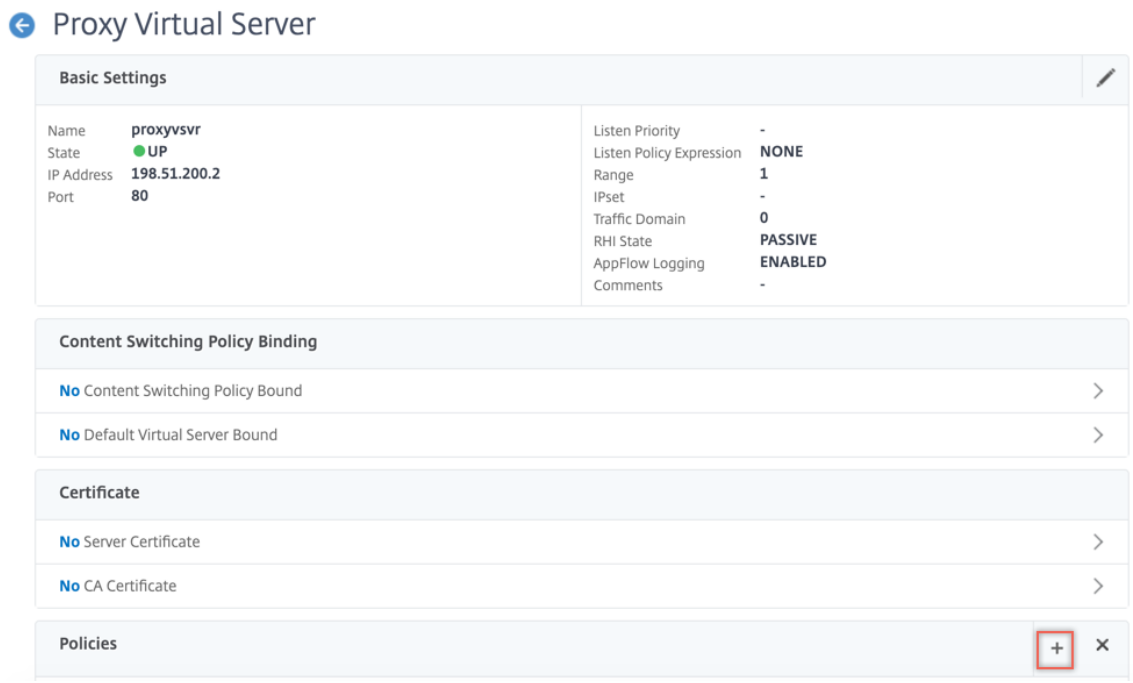
7. Click **OK**.
8. Click inside the **Load Balancing Virtual Server Service Binding** section. In **Service Binding**, click the arrow in **Select Service**. Select the two services created earlier, and click **Select**. Click **Bind**.



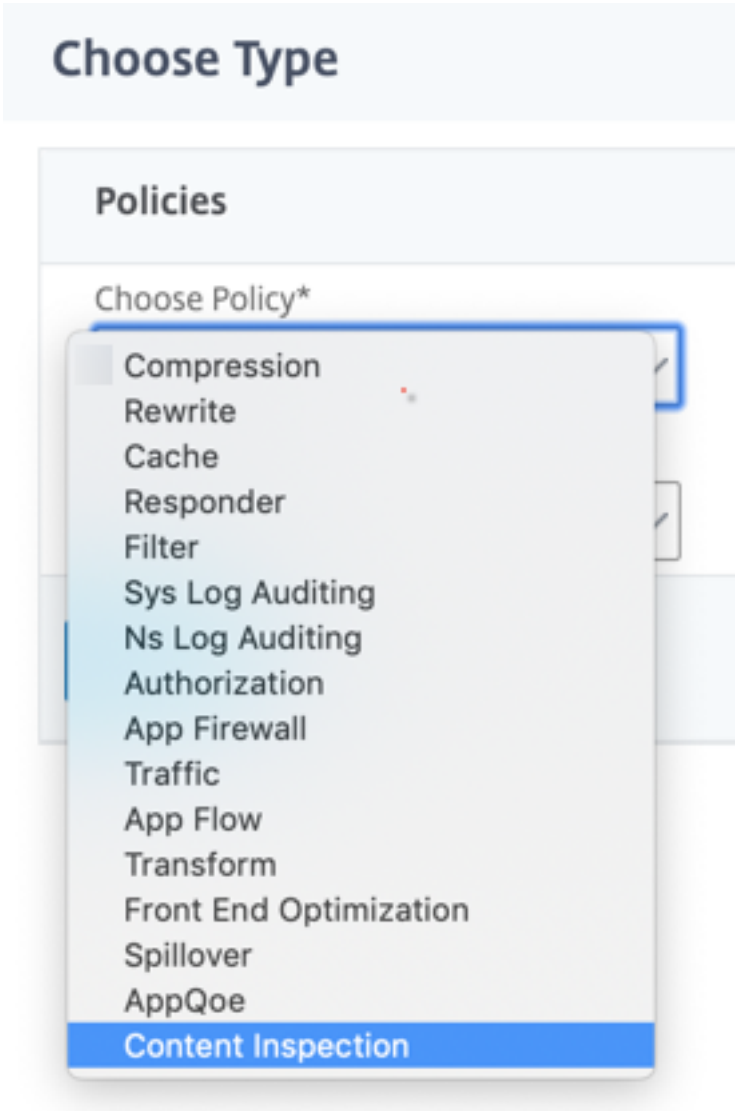




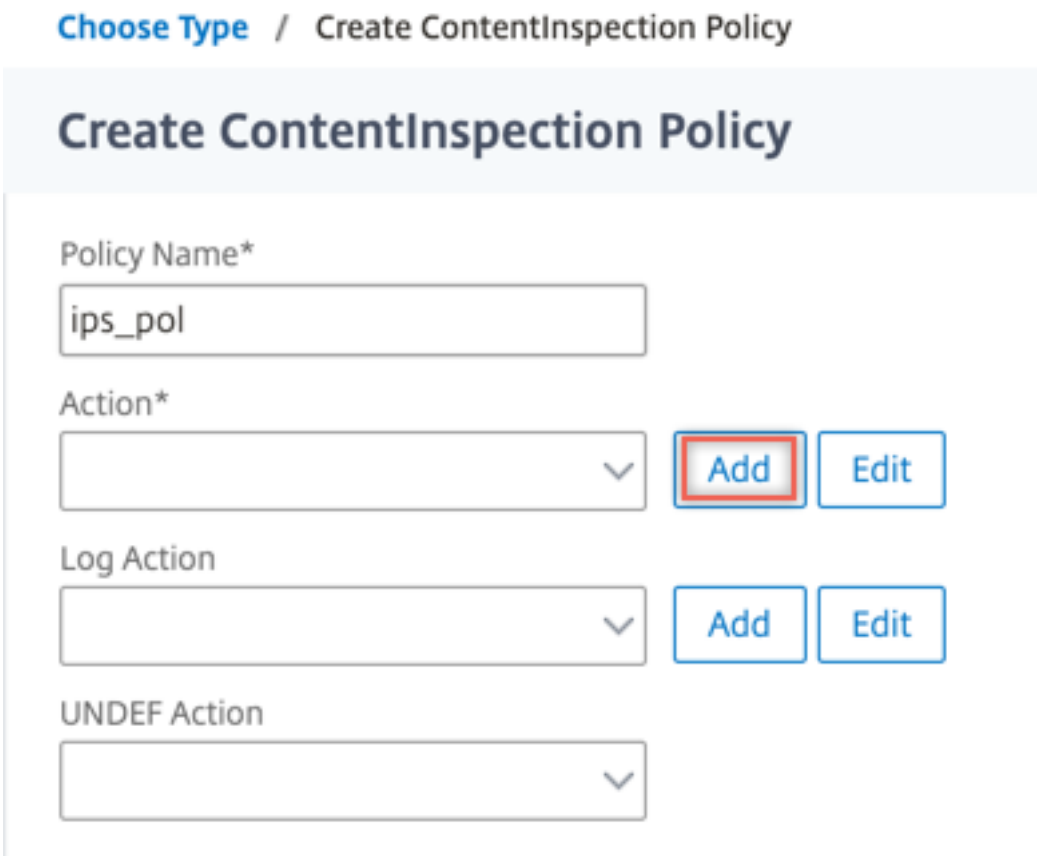
9. Navigate to **Secure Web Gateway > Proxy Virtual Servers> Add**. Specify a name, IP address, and port. In **Advanced Settings**, select **Policies**. Click the “+” sign.



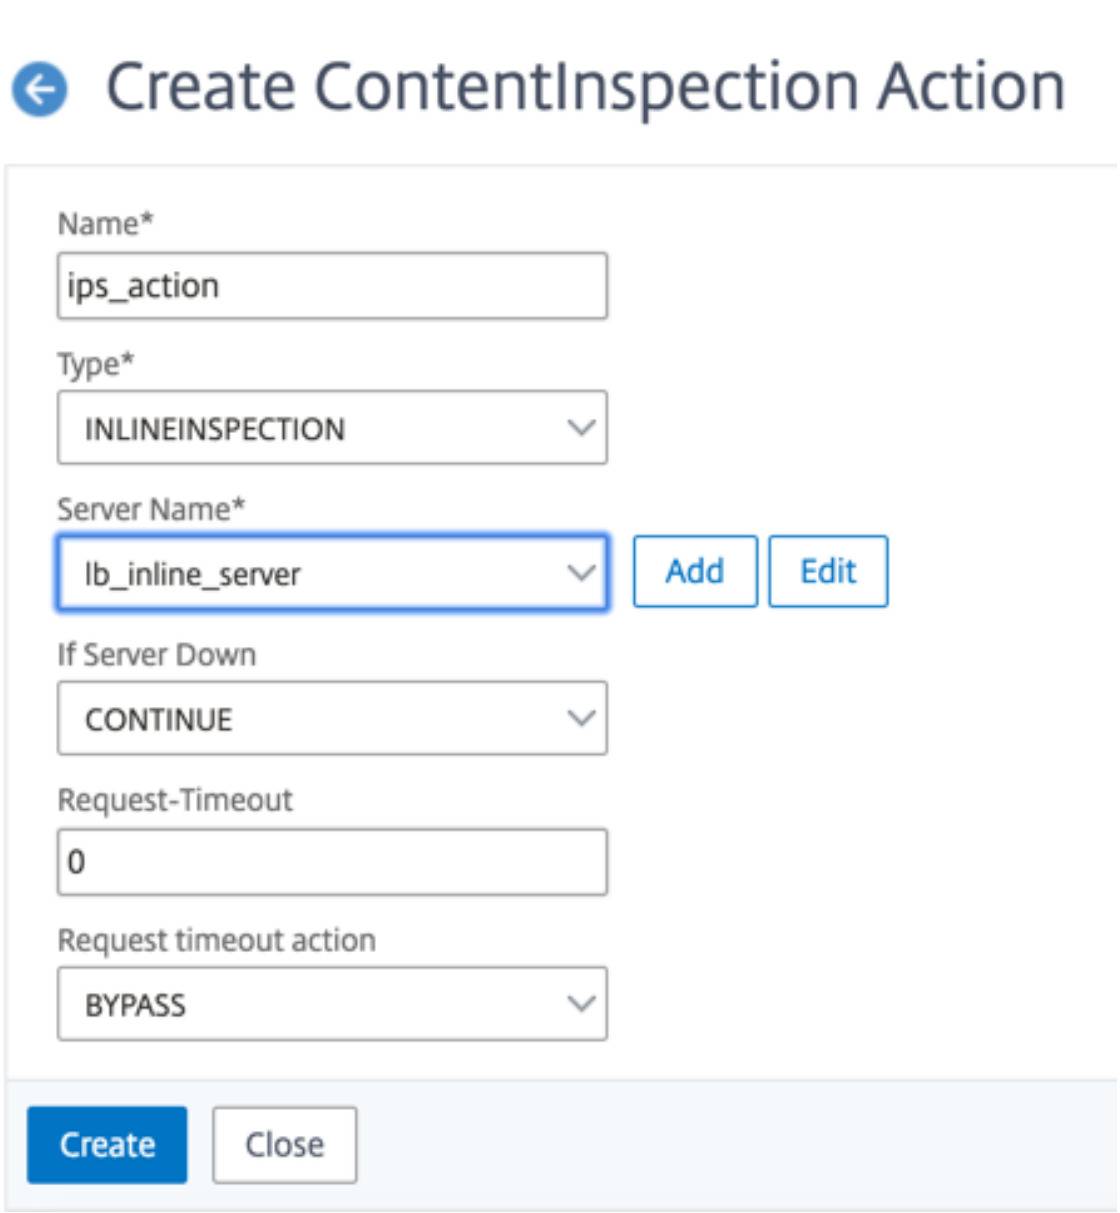
10. In **Choose Policy** select **Content Inspection**. Click **Continue**.



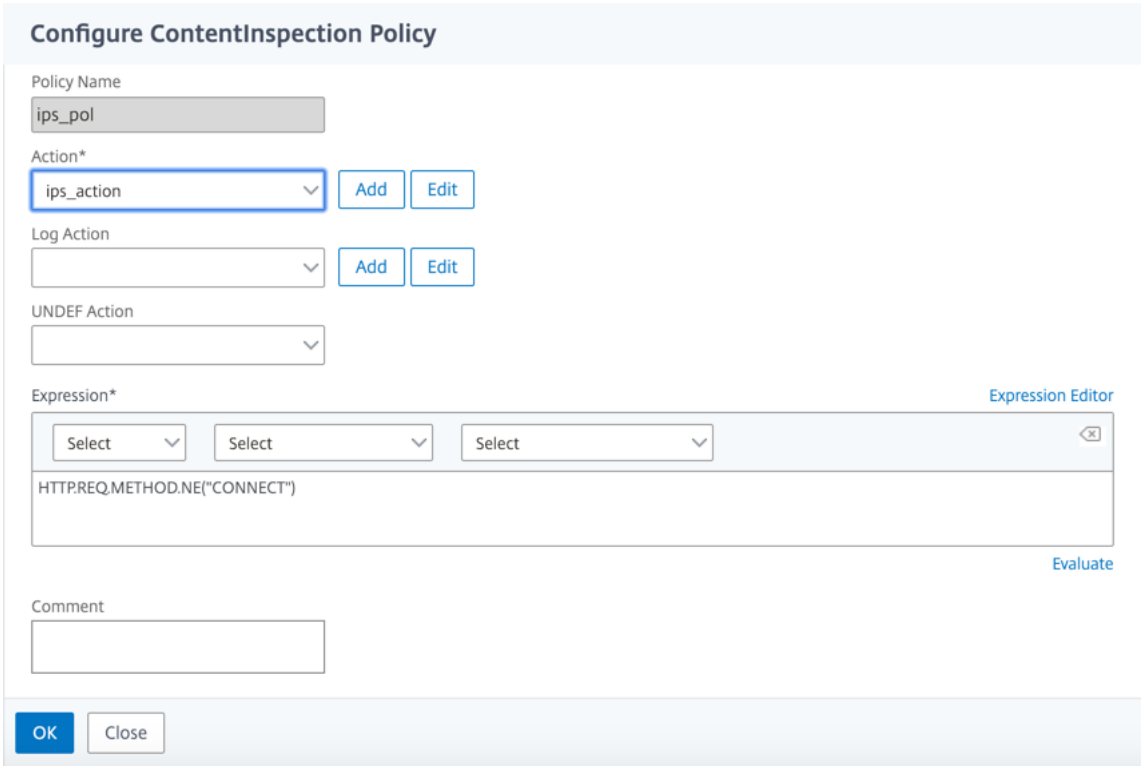
11. Click **Add**. Specify a name. In **Action**, click **Add**.



12. Specify a name. In **Type**, select **INLINEINSPECTION**. In **Server Name**, select the load balancing virtual server created earlier.



13. Click **Create**. Specify the rule and click **Create**.



14. Click **Bind**.
15. Click **Done**.

Integrating Citrix ADC with passive security devices (Intrusion Detection System)

September 14, 2021

A Citrix ADC appliance is now integrated with passive security devices such as the Intrusion Detection System (IDS). These passive devices store logs and trigger alerts when it detects a bad or non-compliant traffic. It also generates reports for the compliance purpose. If the Citrix ADC appliance is integrated with two or more IDS devices and when there is a high volume of traffic, the appliance can load balance the devices by cloning traffic at the virtual server level.

For advanced security protection, a Citrix ADC appliance is integrated with passive security devices such as IDS deployed in detection-only mode. These devices store log and trigger alerts when it sees a bad or non-compliant traffic. It also generates reports for the compliance purpose. Following are some of the benefits of integrating the Citrix ADC with an IDS device.

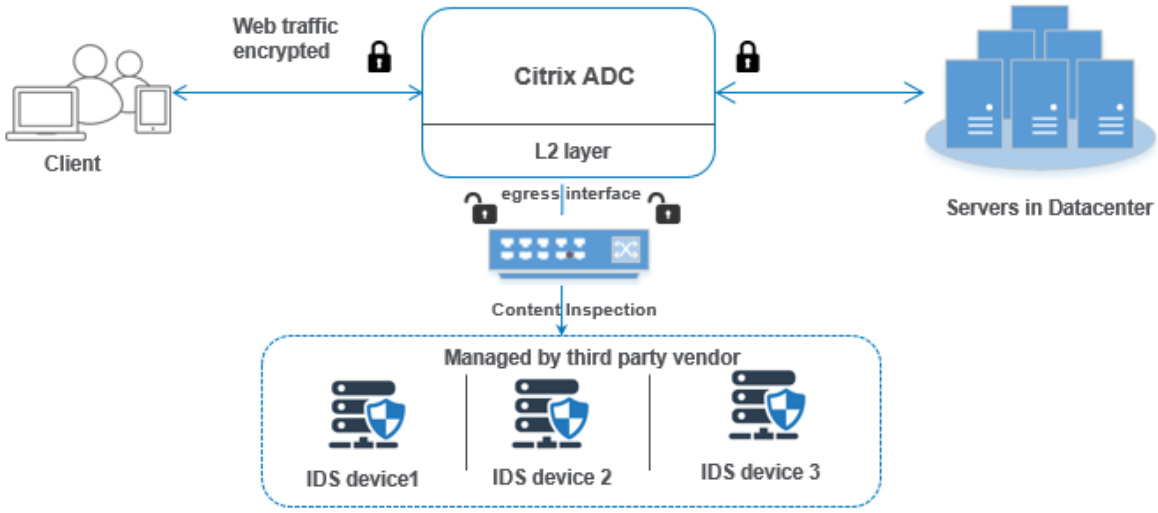
- **Inspecting encrypted traffic**. Most security devices bypass encrypted traffic, thereby leaving servers vulnerable to attacks. A Citrix ADC appliance can decrypt traffic and send it to IDS de-

vices for enhancing the customer's network security.

- **Offloading inline devices from TLS/SSL processing**. TLS/SSL processing is expensive and it results in high system CPU in intrusion detection devices if they decrypt the traffic. As encrypted traffic is growing at a fast pace, these systems fail to decrypt and inspect encrypted traffic. Citrix ADC helps in offloading traffic to IDS devices from TLS/SSL processing. This way of offloading data results in an IDS device supporting a high volume of traffic inspection.
- **Loading balancing IDS devices**. The Citrix ADC appliance load balances multiple IDS devices when there is a high volume of traffic by cloning traffic at the virtual server level.
- **Replicating traffic to passive devices**. The traffic flowing into the appliance can be replicated to other passive devices for generating compliance reports. For example, few government agencies mandate every transaction to be logged in some passive devices.
- **Fanning traffic to multiple passive devices**. Some customers prefer to fan out or replicate incoming traffic into multiple passive devices.
- **Smart selection of traffic**. Every packet flowing into the appliance might not be must be content inspected, for example download of text files. User can configure the Citrix ADC appliance to select specific traffic (for example .exe files) for inspection and send the traffic to IDS devices for processing data.

How Citrix ADC is integrated with IDS device with L2 connectivity

The following diagram shows how IDS is integrated with a Citrix ADC appliance.



The component interaction is given as follows:

1. A client sends an HTTP/HTTPS request to the Citrix ADC appliance.
2. The appliance intercepts the traffic and replicates it to an IDS device based on content inspection policy evaluation.

3. If the traffic is an encrypted one, the appliance decrypts the data and sends it as a plain text.
4. Based on policy evaluation, the appliance applies a “MIRROR” type content inspection action.
5. The action has the IDS service or load balancing service (for multiple IDS device integrations) configured in it.
6. The IDS device is configured as content inspection service type “Any” on the appliance. The content inspection service is then associated to the content inspection profile of type “MIRROR” which specifies the egress interface through which the data has to be forwarded to the IDS device. Note: Optionally, you can also configure a VLAN tag in the content inspection profile.
7. The appliance then, replicates the data through the egress interface to one or more IDS devices.
8. Similarly, when the back-end server sends a response to the Citrix ADC, the appliance replicates the data and forwards it to the IDS device.
9. If your appliance is integrated to one or more IDS devices and if you prefer to load balance the devices, then you can use the load balancing virtual server.

Software licensing

To deploy the inline device integration, your Citrix ADC appliance must be provisioned with one of the following licenses:

1. ADC Premium
2. ADC Advanced
3. Telco Advanced
4. Telco Premium

Configuring intrusion detection system integration

You can integrate the IDS device with the Citrix ADC in two different ways.

Scenario 1: Integration with a single IDS device

Following are the steps you must configure using the command line interface.

1. Enable content inspection
2. Add content inspection profile of type MIRROR for service representing IDS device.
3. Add IDS service of type “ANY”
4. Add content inspection action of type “MIRROR”
5. Add content inspection policy for IDS inspection
6. Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

Enable Content Inspection

If you want the Citrix ADC appliance to send the content for inspection to the IDS devices, you must enable the Content Inspection and load balancing features irrespective of performing decryption.

At the command prompt, type:

```
enable ns feature contentInspection LoadBalancing
```

Add Content Inspection profile of type “MIRROR

The Content Inspection profile of type “MIRROR” explains how you can connect to the IDS device.
At the command prompt, type.

```
add contentInspection profile <name> -type MIRROR -egressInterface <interface_name
> [-egressVlan <positive_integer>]
```

Example:

```
add contentInspection profile IDS_profile1 -type MIRROR -egressInterface
1/1 -egressVLAN 10
```

Add IDS service

You must configure a service of type “ANY” for each IDS device that is integrated with the appliance. The service has the IDS device configuration details. The service represents the IDS device.

At the command prompt, type:

```
add service <Service_name> <IP> ANY <Port> - contentinspectionProfileName <
Name> -healthMonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service 1.1.1.1 ANY 8080 -contentInspectionProfileName
IDS_profile1 -healthMonitor OFF
```

Add content inspection action of type MIRROR for IDS service

After you enable the Content Inspection feature and then add the IDS profile and service, you must add the Content Inspection action for handling the request. Based on the content inspection action, the appliance can drop, reset, block, or send data to the IDS device.

At the command prompt, type:

```
add ContentInspection action < action_name > -type MIRROR -serverName
Service_name/Vserver_name>
```

Example:

```
add ContentInspection action IDS_action -type MIRROR -serverName IDS_service
```

Add content inspection policy for IDS inspection

After you create a Content Inspection action, you must add Content Inspection policies to evaluate requests for inspection. The policy is based on a rule which consists of one or more expressions. The policy evaluates and selects the traffic for inspection based on the rule.

At the command prompt, type the following:

```
add contentInspection policy < policy_name > -rule <Rule> -action <action_name
>
```

Example:

```
add contentInspection policy IDS_pol1 -rule true -action IDS_action
```

Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

To receive the web traffic, you must add a load balancing virtual server.
At the command prompt, type:

```
add lb vserver <name> <vserver name>
```

Example:

```
add lb vserver HTTP_vserver HTTP 1.1.1.3 8080
```

Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL

You must bind the load balancing virtual server or content switching virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

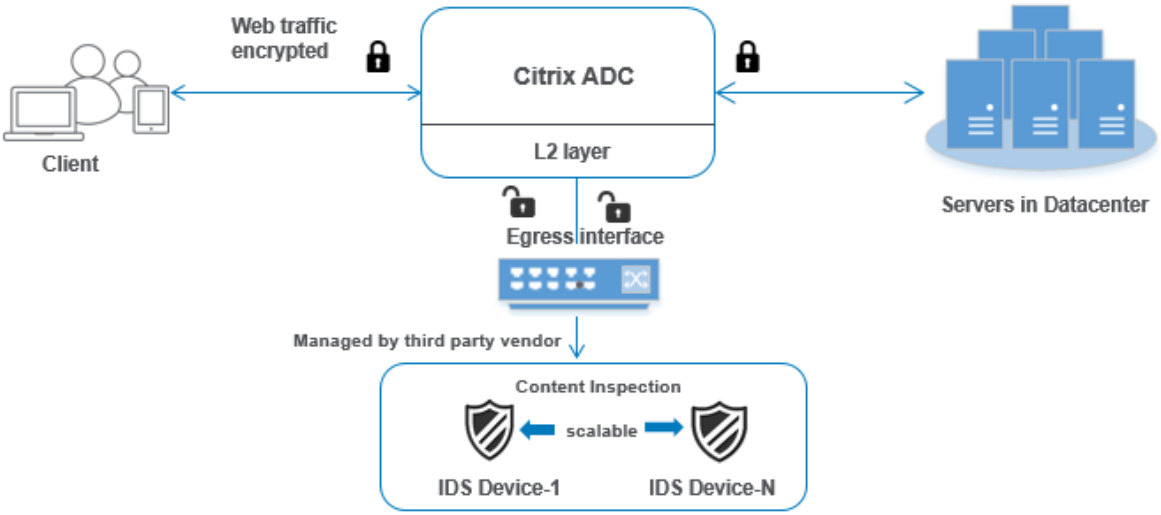
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <
priority > -type <REQUEST>
```

Example:

```
bind lb vserver HTTP_vserver -policyName IDS_pol1 -priority 100 -type
REQUEST
```

Scenario 2: Load balancing multiple IDS devices

If you are using two or more IDS devices, you must load balance the devices using different content inspection services. In this case, the Citrix ADC appliance load balances the devices on top of sending a subset of traffic to each device.
For basic configuration steps, refer to scenario 1.



Following are the steps you must configure using the command line interface.

1. Add content inspection profile 1 of type MIRROR for IDS service 1
2. Add content inspection profile 2 of type MIRROR for IDS service 2
3. Add IDS service 1 of type ANY for IDS device 1
4. Add IDS service 2 of type ANY for IDS device 2
5. Add load balancing virtual server of type ANY
6. Bind IDS service 1 to load balancing virtual server
7. Bind IDS service 2 to load balancing virtual server
8. Add content inspection action for the load balancing of IDS devices.
9. Add content inspection policy for inspection
10. Add content switching or load balancing virtual server of type HTTP/SSL
11. Bind content inspection policy to load balancing virtual server of type HTTP/SSL

Add content inspection profile1 of type MIRROR for IDS service 1

IDS configuration can be specified in an entity called the Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile1 is created for IDS service 1.

At the command prompt, type:

```
add contentInspection profile <name> -type ANY -egressInterface <interface_name
> [-egressVlan <positive_integer>]
```

Example:

```
add contentInspection profile IDS_profile1 -type MIRROR -egressInterface
1/1 -egressVLAN 1
```

Add content inspection profile 2 for type MIRROR for IDS service 2

The Content Inspection profile 2 is added for service 2 and the inline device communicates with the appliance through the egress 1/1 interface.

At the command prompt, type:

```
add contentInspection profile <name> -type MIRROR -egressInterface -egressVlan
 <positive_integer>]
```

Example:

```
add contentInspection profile IDS_profile1 -type MIRROR -egressInterface
1/1 -egressVLAN 1
```

Add IDS service 1 of type ANY for IDS device 1

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 1 for inline device 1 to be part of the load balancing setup. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY <Port> -contentInspectionProfileName
 <IDS_Profile_1> -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service1 1.1.1.1 ANY 80 -contentInspectionProfileName
IDS_profile1 -usip ON -useproxyport OFF
```

> **Note**
>
> The IP address mentioned in the example is a dummy one.

Add IDS service 2 of type ANY for IDS device 2

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 2 for inline device 2. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY -contentInspectionProfileName <
Inline_Profile_2> -healthmonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service 1 1.1.2 ANY 80 -contentInspectionProfileName
IDS_profile2
```

> **Note**
>
> The IP address mentioned in the example is a dummy one.

Add load balancing virtual server

After you have added the inline profile and the services, you must add a load balancing virtual server for load balancing the services.

At the command prompt, type:

```
add lb vserver <vserver_name> ANY <Pvt_IP3> <port>
```

Example:

```
add lb vserver lb-IDS_vserver ANY 1.1.1.2
```

Bind IDS service 1 to load balancing virtual server

After you add the load balancing virtual server, now bind the load balancing virtual server to the first service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:

```
bind lb vserver lb-IDS_vserver IDS_service1
```

Bind IDS service 2 to load balancing virtual server

After you add the load balancing virtual server, now bind the server to the second service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:

```
bind lb vserver lb-IDS_vserver IDS_service2
```

Add content inspection action for the IDS service

After you enable the Content Inspection feature, you must add the Content Inspection action for handling the inline request information. Based on the action selected, the appliance drops, resets, blocks, or sends traffic to the IDS device.

At the command prompt, type:

```
add contentInspection action <name> -type <type> (-serverName <string> [-
ifserverdown <ifserverdown>]
```

Example:

```
add ContentInspection action IDS_action -type MIRROR -serverName lb-IDS_vserver
```

Add content inspection policy for inspection

After you create a Content Inspection action, you must add a Content Inspection policy to evaluate requests for service.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name
>
```

Example:

```
add contentInspection policy IDS_pol1 -rule true -action IDS_action
```

Add content switching or load balancing virtual server of type HTTP/SSL

Add a content switching or load balancing virtual server to accept web traffic. Also you must enable the layer2 connection on the virtual server.

For more information about load balancing, refer to How load balancing works topic.

At the command prompt, type:

```
add lb vserver <name> <vserver name>
```

Example:

```
add lb vserver http_vserver HTTP 1.1.1.1 8080
```

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL

You must bind the content switching or load balancing virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

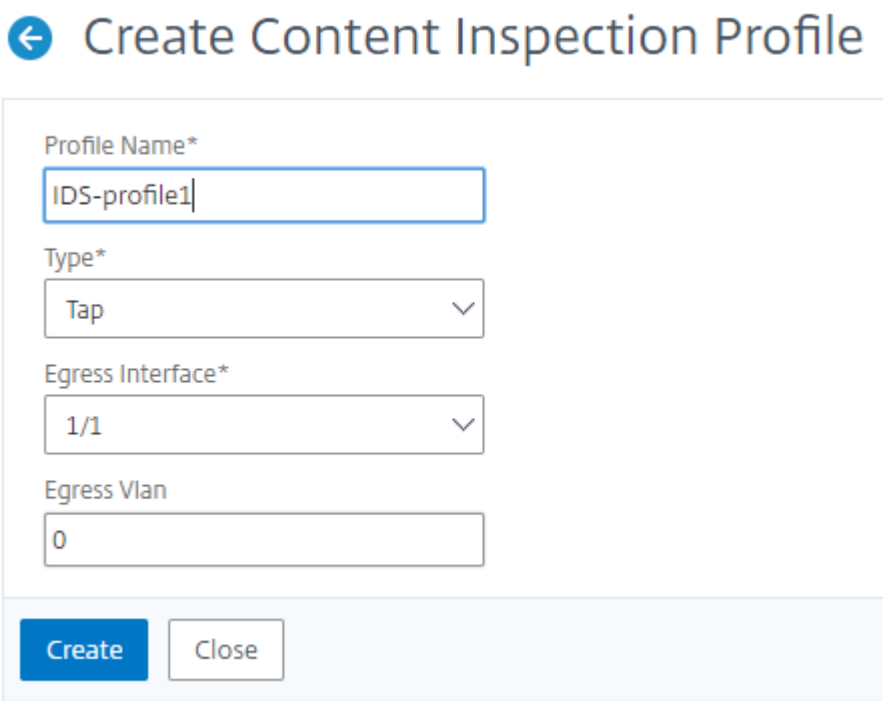
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <> -
type <REQUEST>
```

Example:

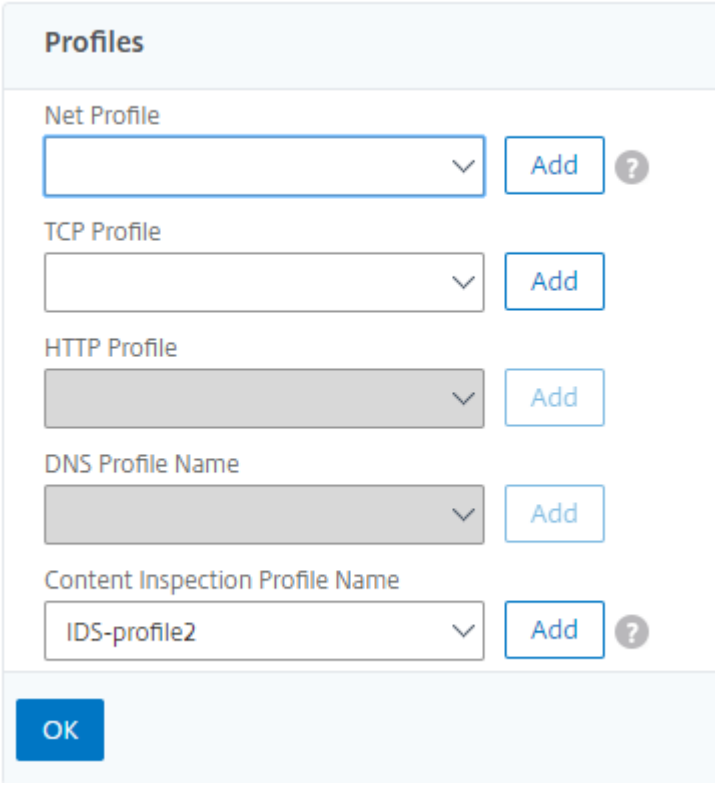
```
bind lb vserver http_vserver -policyName IDS_pol1 -priority 100 -type
REQUEST
```

Configure inline service integration using the Citrix ADC GUI

1. Navigate to **Security** > **Content Inspection** > **Content Inspection Profiles**.
2. In the **Content Inspection Profile** page, click **Add**.
3. In the **Create Content Inspection Profile** page, set the following parameters.
   a) Profile Name. Name of the content inspection profile for IDS.
   b) Type. Select the profile types as MIRROR.
   c) Egress Interface. The interface through which the traffic is sent from the Citrix ADC to the IDS device.
   d) Egress VLAN (optional). The interface VLAN ID through which the traffic is sent to the IDS device.
4. Click **Create**.



5. Navigate to **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
6. In the **Load Balancing Service** page, enter the content inspection service details.
7. In the **Advanced Settings** section, click **Profiles**.
8. Go to the **Profiles** section and click the **Pencil** icon to add the content inspection profile.
9. Click **OK**.

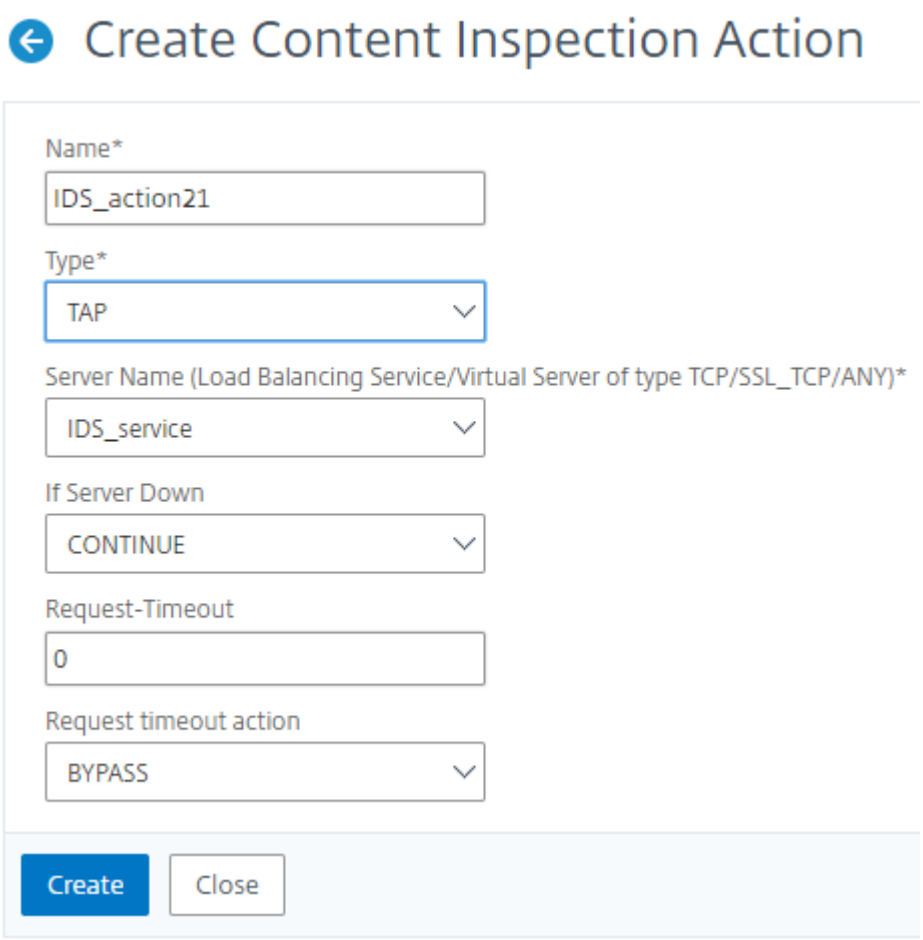


10. Navigate to **Load Balancing** > **Servers**. Add a virtual server of type HTTP or SSL.
11. After entering the server details, click **OK** and again **OK**.
12. In the **Advanced Settings** section, click **Policies**.
13. Go the **Policies** section and click the **Pencil** icon to configure the content inspection policy.
14. On the **Choose Policy** page, select **Content Inspection**. Click **Continue**.
15. In the **Policy Binding** section, click "+" to add a Content Inspection policy.
16. In the **Create CI Policy** page, enter a name for the Inline content inspection policy.
17. In the **Action** field, click the "+" sign to create an IDS content inspection action of type MIRROR.
18. In the **Create CI Action** page, set the following parameters.

    a. Name. Name of the content inspection Inline policy.

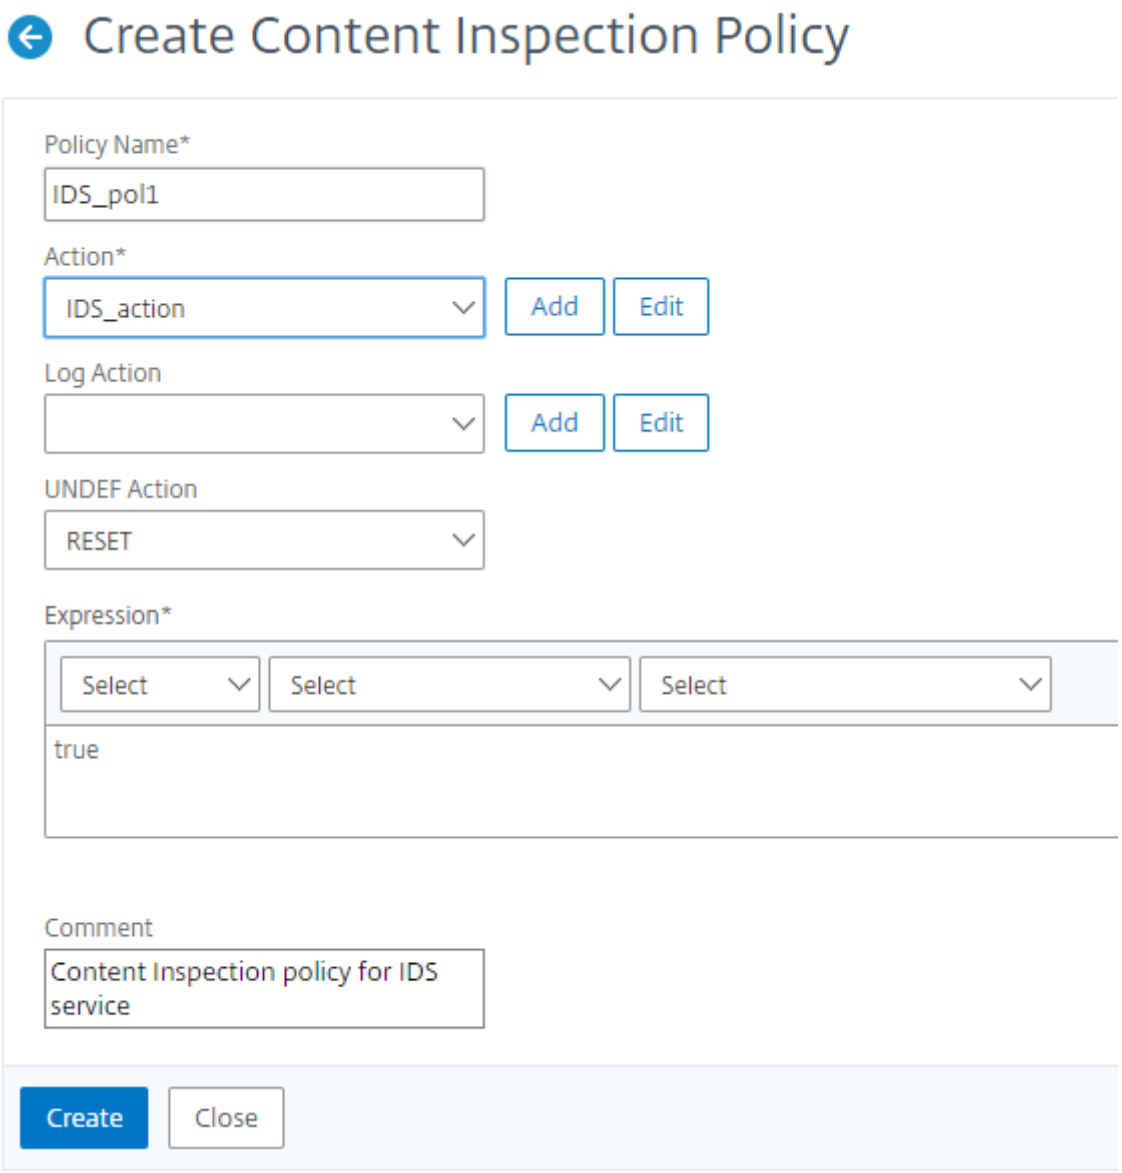
b. Type. Select the type as MIRROR.
c. Server Name. Select the server/service name as Inline devices.
d. If Server Down. Select an operation if the server goes down.
e. Request Time-out. Select a time-out value. Default values can be used.
f. Request Time-out Action. Select a time-out action. Default values can be used.

19. Click **Create**.



20. In the **Create CI Policy** page, enter other details.
21. Click **OK** and **Close**.

For information about the Citrix ADC GUI configuration for load balancing and replicating the traffic to IDS devices, see Load Balancing.



For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to the back-end origin server after content transformation, see Load Balancing topic.

Integrating Citrix ADC layer 3 with passive security devices (Intrusion Detection System)

September 14, 2021

A Citrix ADC appliance is now integrated with passive security devices such as the Intrusion Detection System (IDS). In this setup, the appliance sends a copy of the original traffic securely to remote IDS

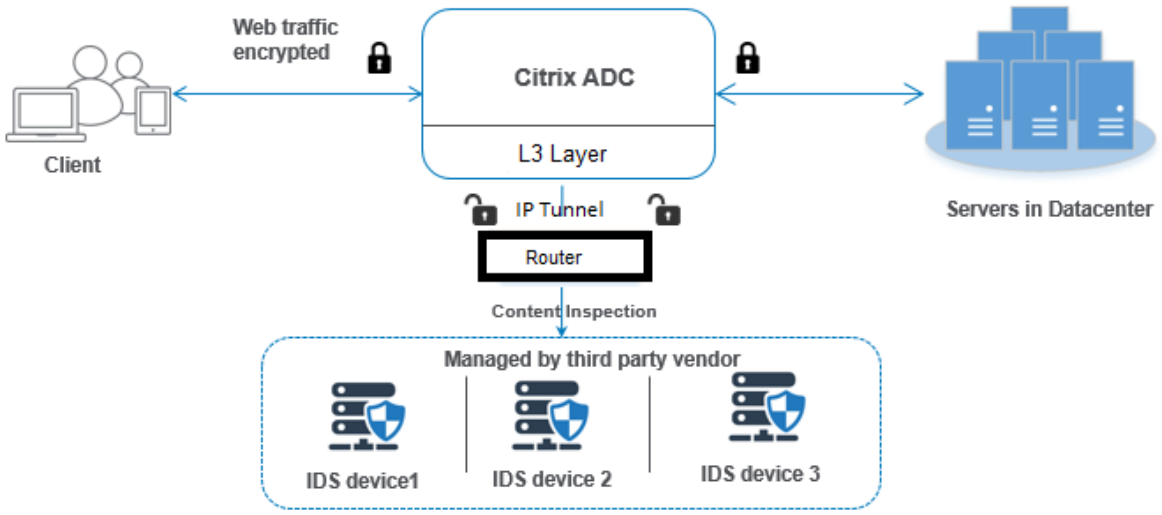
devices. These passive devices store logs and trigger alerts when it detects a bad or non-compliant traffic. It also generates reports for the compliance purpose. If a Citrix ADC appliance is integrated with two or more IDS devices and when there is a high volume of traffic, the appliance can load balance the devices by cloning traffic at the virtual server level.

For advanced security protection, a Citrix ADC appliance is integrated with passive security devices such as IDS deployed in detection-only mode. These devices store log and trigger alerts when it sees a bad or non-compliant traffic. It also generates reports for the compliance purpose. Following are some of the benefits of integrating the Citrix ADC with an IDS device.

- **Inspecting encrypted traffic**. Most security devices bypass encrypted traffic, thereby leaving servers vulnerable to attacks. A Citrix ADC appliance can decrypt traffic and send it to IDS devices for enhancing the customer's network security.
- **Offloading inline devices from TLS/SSL processing**. TLS/SSL processing is expensive and it results in high system CPU in intrusion detection devices if they decrypt the traffic. As encrypted traffic is growing at a fast pace, these systems fail to decrypt and inspect encrypted traffic. Citrix ADC helps in offloading traffic to IDS devices from TLS/SSL processing. This way of offloading data results in an IDS device supporting a high volume of traffic inspection.
- **Loading balancing IDS devices**. The Citrix ADC appliance load balances multiple IDS devices when there is a high volume of traffic by cloning traffic at the virtual server level.
- **Replicating traffic to passive devices**. The traffic flowing into the appliance can be replicated to other passive devices for generating compliance reports. For example, few government agencies mandate every transaction to be logged in some passive devices.
- **Fanning traffic to multiple passive devices**. Some customers prefer to fan out or replicate incoming traffic into multiple passive devices.
- **Smart selection of traffic**. Every packet flowing into the appliance might not be must be content inspected, for example download of text files. User can configure the Citrix ADC appliance to select specific traffic (for example .exe files) for inspection and send the traffic to IDS devices for processing data.

How Citrix ADC is integrated with IDS device with L3 connectivity

The following diagram shows how the IDS is integrated with a Citrix ADC appliance.



The component interaction is given as follows:

1. A client sends an HTTP/HTTPS request to the Citrix ADC appliance.
2. The appliance intercepts the traffic and sends the data to remote IDS devices across different data centers or even in a cloud. This integration is done through IP tunneled layer 3. For more information about IP tunneling in a Citrix ADC appliance, see IP tunnels topic.
3. If the traffic is an encrypted one, the appliance decrypts the data and sends it as a plain text.
4. Based on policy evaluation, the appliance applies a “MIRROR” type content inspection action.
5. The action has an IDS service or load balancing service (for multiple IDS device integrations) configured in it.
6. The IDS device is configured as content inspection service type “Any” on the appliance. The content inspection service is then associated to the content inspection profile of type “MIRROR” and the tunnel parameter which specifies the IP tunneled layer 3 interface through which the data is forwarded to the IDS device.

> **Note** Optionally, you can also configure a VLAN tag in the content inspection profile.

1. Similarly, when the back-end server sends a response to the Citrix ADC, the appliance replicates the data and forwards it to the IDS device.
2. If your appliance is integrated to one or more IDS devices and if you prefer to load balance the devices, then you can use the load balancing virtual server.

Software licensing

To deploy the IDS integration, your Citrix ADC appliance must be provisioned with one of the following licenses:

1. ADC Premium
2. ADC Advanced

Configuring intrusion detection system integration

You can integrate IDS device with a Citrix ADC in two different ways.

Scenario 1: Integration with a single IDS device

Following are the steps you must configure using the command line interface.

1. Enable content inspection
2. Add content inspection profile of type MIRROR for service representing IDS device.
3. Add IDS service of type “ANY”
4. Add content inspection action of type “MIRROR”
5. Add content inspection policy for IDS inspection
6. Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

Enable Content Inspection

If you want the Citrix ADC appliance to send the content for inspection to the IDS devices, you must enable the Content Inspection and load balancing features irrespective of performing decryption.

At the command prompt, type:

```
enable ns feature contentInspection LoadBalancing
```

Add Content Inspection profile of type “MIRROR”

The Content Inspection profile of type “MIRROR” explains how you can connect to the IDS device.
At the command prompt, type.

> **Note**
> The IP tunnel parameter must be used only for layer 3 IDS topology. Otherwise, you must use the egress interface with the egress VLAN option.

```
add contentInspection profile <name> -type MIRROR -ipTunnel <iptunnel_name>
```

Example:

```
add contentInspection profile IDS_profile1 -type MIRROR -ipTunnel ipsect-
tunnel1
```

Add IDS service

You must configure a service of type “ANY” for each IDS device that is integrated with the appliance. The service has the IDS device configuration details. The service represents the IDS device.

At the command prompt, type:

```
add service <Service_name> <IP> ANY <Port> - contentinspectionProfileName <
Name> -healthMonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service 1.1.1.1 ANY 8080 -contentInspectionProfileName
IDS_profile1 -healthMonitor OFF
```

Add content inspection action of type MIRROR for IDS service

After you enable the Content Inspection feature and then add the IDS profile and service, you must add the Content Inspection action for handling the request. Based on the content inspection action, the appliance can drop, reset, block, or send data to the IDS device.

At the command prompt, type:

```
add ContentInspection action < action_name > -type MIRROR -serverName
Service_name/Vserver_name>
```

Example:

```
add ContentInspection action IDS_action -type MIRROR -serverName IDS_service
```

Add content inspection policy for IDS inspection

After you create a Content Inspection action, you must add Content Inspection policies to evaluate requests for inspection. The policy is based on a rule which consists of one or more expressions. The policy evaluates and selects the traffic for inspection based on the rule.

At the command prompt, type the following:

```
add contentInspection policy < policy_name > -rule <Rule> -action <action_name
>
```

Example:

```
add contentInspection policy IDS_pol1 -rule true -action IDS_action
```

Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

To receive the web traffic, you must add a load balancing virtual server.
At the command prompt, type:

```
add lb vserver <name> <vserver name>
```

Example:

```
add lb vserver HTTP_vserver HTTP 1.1.1.3 8080
```

Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL

You must bind the load balancing virtual server or content switching virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

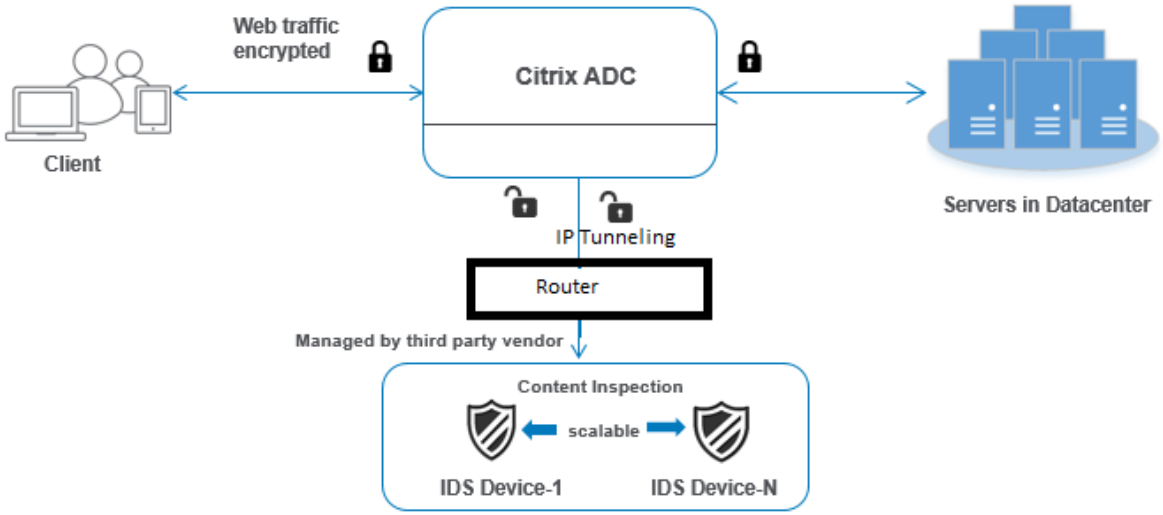
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <
priority > -type <REQUEST>
```

Example:

```
bind lb vserver HTTP_vserver -policyName IDS_pol1 -priority 100 -type
REQUEST
```

Scenario 2: Load balancing multiple IDS devices

If you are using two or more IDS devices, you must load balance the IDS devices using different content inspection services. In this case, the Citrix ADC appliance load balances the devices on top of sending a subset of traffic to each device.
For basic configuration steps, refer to scenario 1.



Following are the steps you must configure using the command line interface.

1. Add content inspection profile 1 of type MIRROR for IDS service 1
2. Add content inspection profile 2 of type MIRROR for IDS service 2
3. Add IDS service 1 of type ANY for IDS device 1

4. Add IDS service 2 of type ANY for IDS device 2
5. Add load balancing virtual server of type ANY
6. Bind IDS service 1 to load balancing virtual server
7. Bind IDS service 2 to load balancing virtual server
8. Add content inspection action for the load balancing of IDS devices.
9. Add content inspection policy for inspection
10. Add content switching or load balancing virtual server of type HTTP/SSL
11. Bind content inspection policy to load balancing virtual server of type HTTP/SSL

Add content inspection profile1 of type MIRROR for IDS service 1

IDS configuration can be specified in an entity called the Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile1 is created for IDS service 1.

> **Note**:
> IP tunnel parameter must be used only for layer 3 IDS topology. Otherwise, you must use the egress interface with the egress VLAN option.

At the command prompt, type:

```
add contentInspection profile <name> -type ANY - ipTunnel <iptunnel_name>
```

Example:

```
add contentInspection profile IDS_profile1 -type MIRROR - ipTunnel ipsect_tunnel1
```

Add content inspection profile 2 for type MIRROR for IDS service 2

The Content Inspection profile 2 is added for service 2 and the inline device communicates with the appliance through the egress 1/1 interface.

At the command prompt, type:

```
add contentInspection profile <name> -type ANY - ipTunnel <iptunnel_name>
```

Example:

```
add contentInspection profile IDS_profile2 -type ANY - ipTunnel ipsect_tunnel2
```

Add IDS service 1 of type ANY for IDS device 1

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 1 for inline device 1 to be part of the load balancing setup. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY <Port> -contentInspectionProfileName
 <IDS_Profile_1> -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service1 1.1.1.1 ANY 80 -contentInspectionProfileName
IDS_profile1 -usip ON -useproxyport OFF
```

> **Note**:
>
> The IP address mentioned in the example is a dummy one.

Add IDS service 2 of type ANY for IDS device 2

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 2 for inline device 2. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY -contentInspectionProfileName <
Inline_Profile_2> -healthmonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service 1 1.1.2 ANY 80 -contentInspectionProfileName
IDS_profile2
```

> **Note**:
>
> The IP address mentioned in the example is a dummy one.

Add load balancing virtual server

After you have added the inline profile and the services, you must add a load balancing virtual server for load balancing the services.

At the command prompt, type:

```
add lb vserver <vserver_name> ANY <Pvt_IP3> <port>
```

Example:

```
add lb vserver lb-IDS_vserver ANY 1.1.1.2
```

Bind IDS service 1 to load balancing virtual server

After you add the load balancing virtual server, now bind the load balancing virtual server to the first service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:

```
bind lb vserver lb-IDS_vserver IDS_service1
```

Bind IDS service 2 to load balancing virtual server

After you add the load balancing virtual server, now bind the server to the second service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:

```
bind lb vserver lb-IDS_vserver IDS_service2
```

Add content inspection action for the IDS service

After you enable the Content Inspection feature, you must add the Content Inspection action for handling the inline request information. Based on the action selected, the appliance drops, resets, blocks, or sends traffic to the IDS device.

At the command prompt, type:

```
add contentInspection action <name> -type <type> (-serverName <string> [-
ifserverdown <ifserverdown>]
```

Example:

```
add ContentInspection action IDS_action -type MIRROR -serverName lb-IDS_vserver
```

Add content inspection policy for inspection

After you create a Content Inspection action, you must add the Content Inspection policy to evaluate requests for service.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name
>
```

Example:

```
add contentInspection policy IDS_pol1 -rule true -action IDS_action
```

Add content switching or load balancing virtual server of type HTTP/SSL

Add a content switching or load balancing virtual server to accept web traffic. Also you must enable the layer2 connection on the virtual server.

For more information about load balancing, refer to How load balancing works topic.

At the command prompt, type:

```
add lb vserver <name> <vserver name>
```

Example:

```
add lb vserver http_vserver HTTP 1.1.1.1 8080
```

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL

You must bind the content switching or load balancing virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

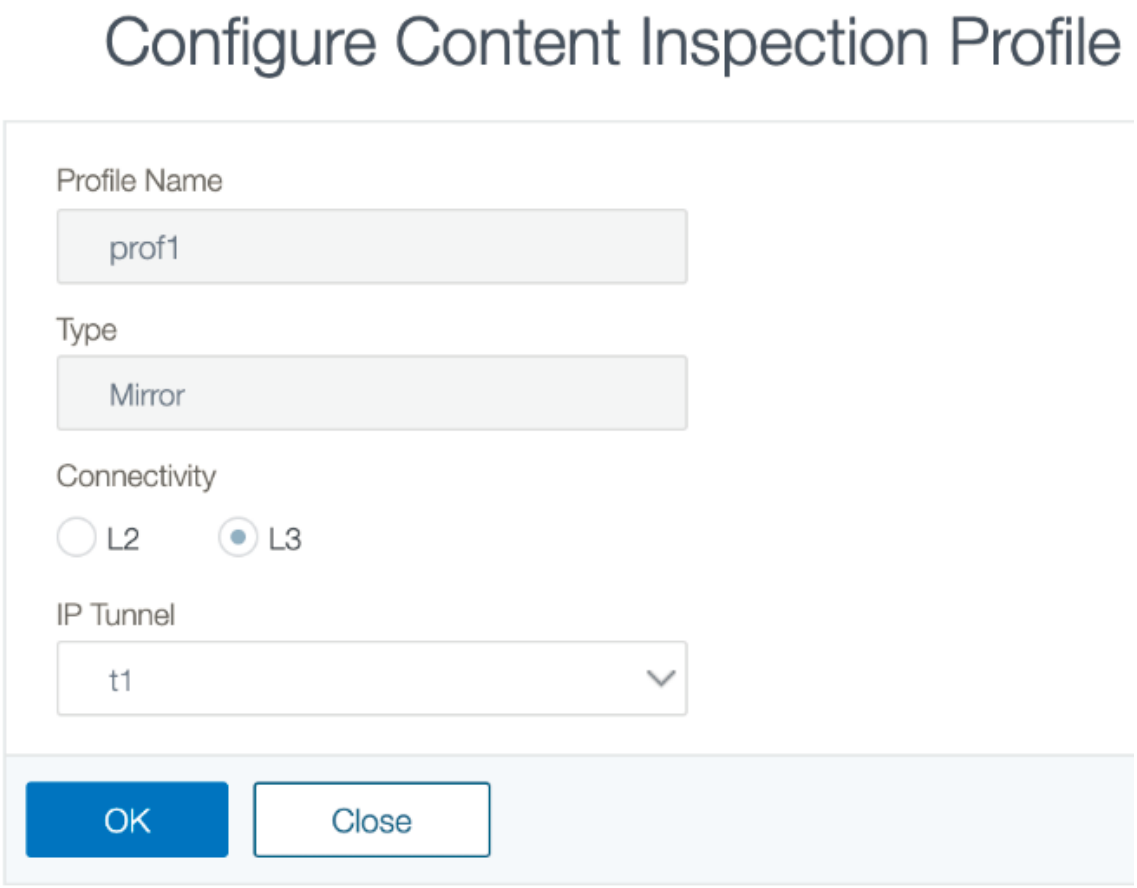
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <> -
type <REQUEST>
```

Example:

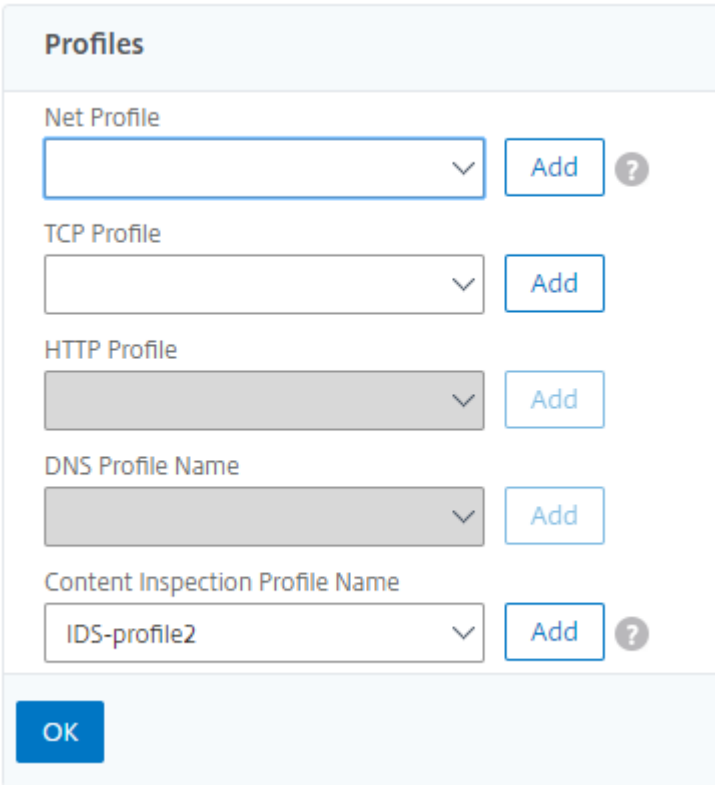
```
bind lb vserver http_vserver -policyName IDS_pol1 -priority 100 -type
REQUEST
```

Configure inline service integration using the Citrix ADC GUI

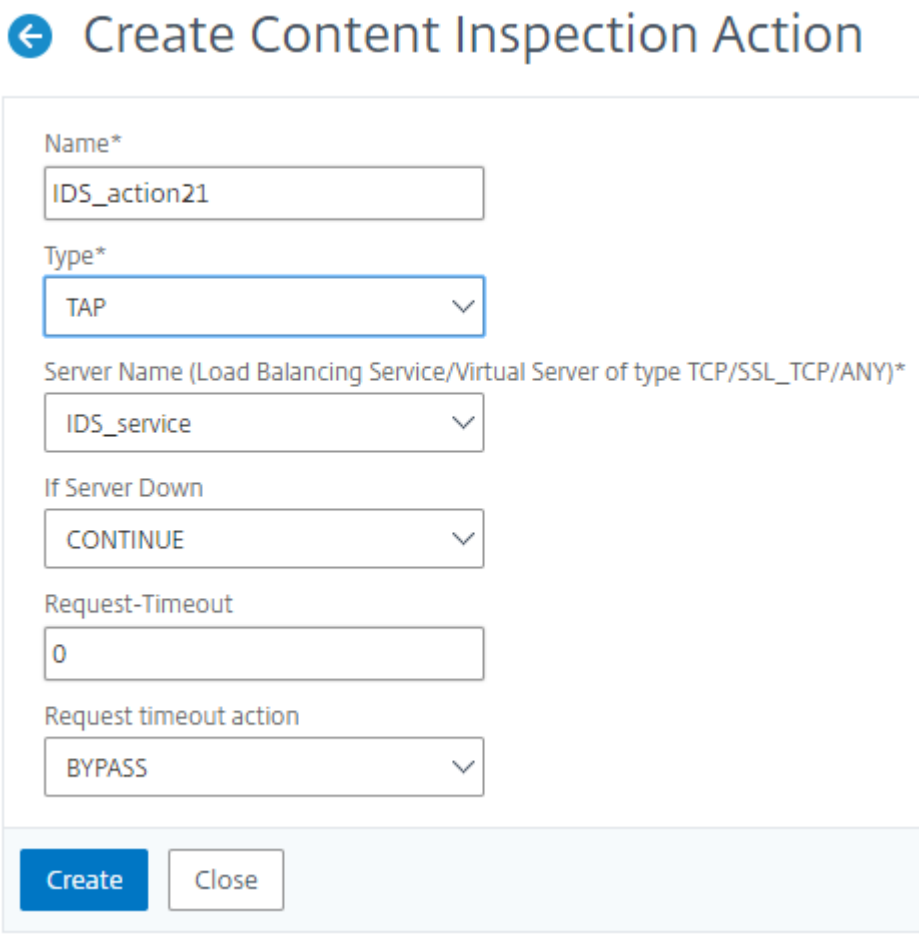
1. Navigate to **Security** > **Content Inspection** > **ContentInspection Profiles**.
2. In the **ContentInspection Profile** page, click **Add**.
3. In the **Create ContentInspectionProfile** page, set the following parameters.
    a) Profile Name. Name of the content inspection profile for IDS.
    b) Type. Select the profile types as MIRROR.
    c) Connectivity. Layer 2 or Layer 3 interface.
    d) IP Tunnel. Select the network communication channel between the two networks.
4. Click **Create**.



5. Navigate to **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
6. In the **Load Balancing Service** page, enter the content inspection service details.
7. In the **Advanced Settings** section, click **Profiles**.
8. Go to the **Profiles** section and click the **Pencil** icon to add the content inspection profile.
9. Click **OK**.

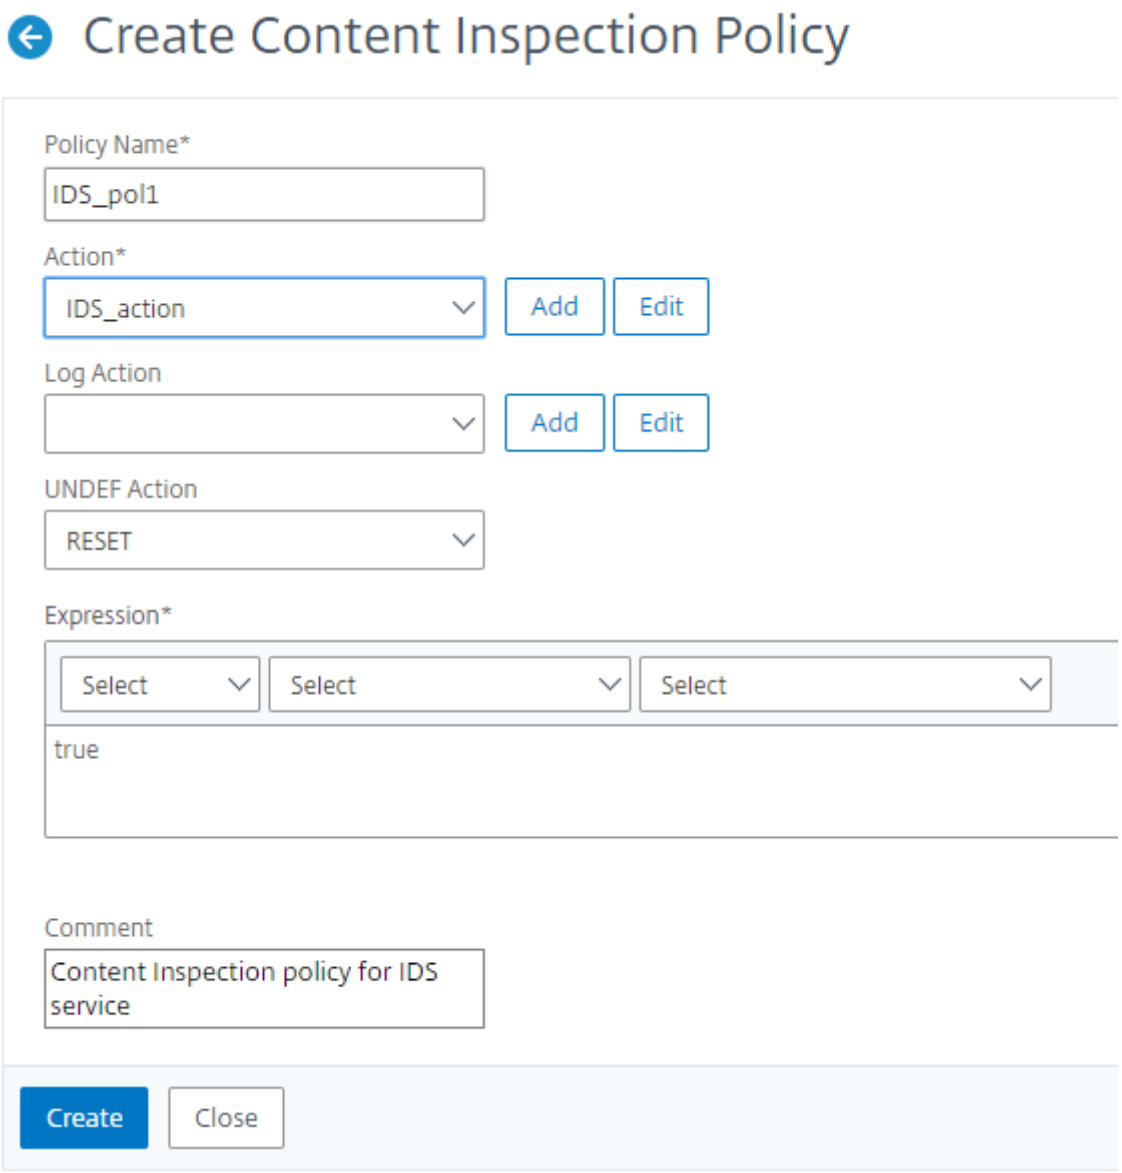


10. Navigate to **Load Balancing** > **Servers**. Add a virtual server of type HTTP or SSL.
11. After entering the server details, click **OK** and again **OK**.
12. In the **Advanced Settings** section, click **Policies**.
13. Go the **Policies** section and click the **Pencil** icon to configure the content inspection policy.
14. On the **Choose Policy** page, select **Content Inspection**. Click **Continue**.
15. In the **Policy Binding** section, click "+" to add a Content Inspection policy.
16. In the **Create CI Policy** page, enter a name for the Inline content inspection policy.
17. In the **Action** field, click the "+" sign to create an IDS content inspection action of type MIRROR.
18. In the **Create CI Action** page, set the following parameters.
    a) Name. Name of the content inspection Inline policy.
    b) Type. Select the type as MIRROR.
    c) Server Name. Select the server/service name as Inline devices.
    d) If Server Down. Select an operation if the server goes down.
    e) Request Time-out. Select a time-out value. Default values can be used.
    f) Request Time-out Action. Select a time-out action. Default values can be used.
19. Click **Create**.



20. In the **Create CI Policy** page, enter other details.
21. Click **OK** and **Close**.

For information about the Citrix ADC GUI configuration for load balancing and replicating the traffic to IDS devices, see Load Balancing.



For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to the back-end origin server after content transformation, see Load Balancing.

Content inspection statistics for ICAP, IPS, and IDS

September 14, 2021

The content inspection statistics for ICAP, inline device integration (IDS), and Intrusion Prevention System (IPS) devices is a detailed output (summary) of request, response, and server action details.

The content inspection statistics is a collection of statistical data that includes the HTTP/HTTPS re-

quest sent for content inspection. HTTP/HTTPS response received from IPS, IDS, and ICAP devices and back-end server action.

To display Content inspection statistics by using the CLI:

At the command prompt, type:

```
> stat contentInspection
```

```
ContentInspection Stats

SSL forward proxy

September 14, 2021

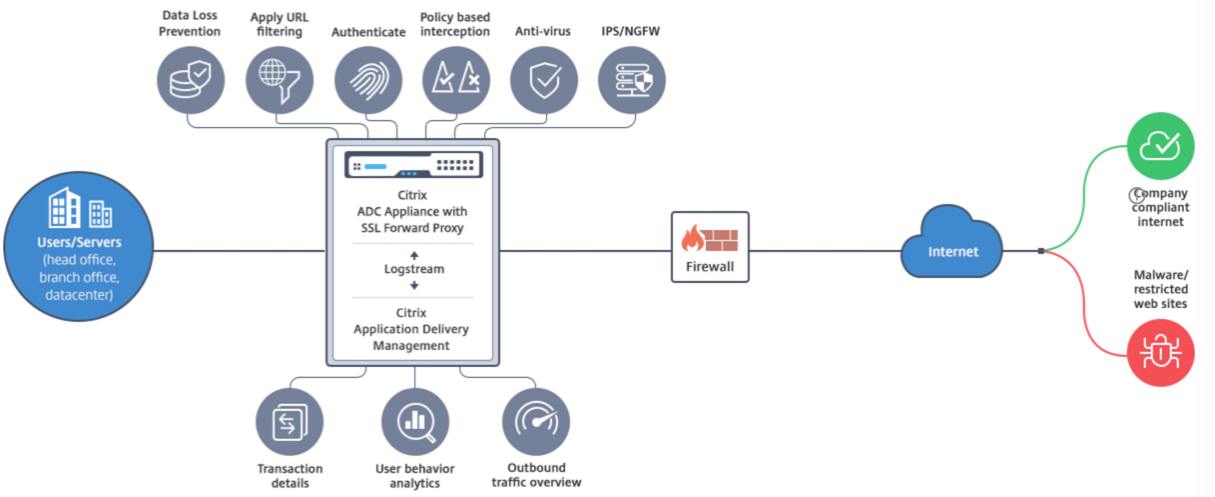
Note: SSL forward proxy feature is available with the ADC Premium license.

Web traffic has increased exponentially in recent years, and corporations are increasingly relying on the internet for their day to day operations. That, combined with the emergence of more diverse endpoints, mobility, and BYOD, along with a growing attacker base, is making users easy targets of modern malware. They are increasingly vulnerable to identity theft and having their data compromised. Traditionally, enterprises have inspected HTTP traffic for malware and viruses. They bypassed HTTPS/TLS traffic, because it was not as prominent. It was used sparingly for content that was sensitive and trusted. But that has changed rapidly as most public internet websites now prefer to use HTTPS to protect user privacy. As a result, the inability to inspect encrypted packets allows malware or intrusions into the enterprise network. The SSL forward proxy solution offers tools that enterprises can use to protect against internet threats.

A proxy is a server that controls all the traffic between users and the Internet or SaaS applications. Since all the traffic passes through this proxy, it performs security-related functions, such as user authentication and URL categorization.

The following figure is an overview of the SSL forward proxy implementation. Traffic flows through the enterprise network from the head office, branch offices, data center, and remote employees. A Citrix ADC appliance at the edge of the network acts a proxy. The appliance can operate in transparent proxy mode or explicit proxy mode and offers controls to intercept internet traffic, including HTTPS. Policies configured on the appliance determine whether it intercepts, bypasses, or blocks a particular request. Access to restricted sites can be blocked by using URL filtering. A user is authenticated before logging on to the enterprise network. All requests and responses are tagged to identify the user, and internet-site access is categorized. User activity is logged and used to generate reports. If a breach occurs, administrators can isolate the infected system, determine whether the devices of any other users who visited that website are compromised, and take appropriate action. When you integrate Citrix Application Delivery Management (ADM) with SSL forward proxy, the logged user activity and the subsequent records in the appliance are exported to Citrix ADM by using `logstream`. Citrix ADM

collates and presents information about the activities of users, from websites visited to the time spent online. It also provides information about bandwidth use and detected threats, such as malware and phishing sites. You can use these key metrics to monitor your network, and use the SSL forward proxy feature to take corrective actions.



SSL forward proxy enables IT directors to do the following:

- Gain visibility into the otherwise bypassed secure traffic.
- Block access to malicious or unknown sites and avoid infecting users within the enterprise.
- Control access to some websites, such as personal mail, social networking, and job search websites, from the enterprise network.
- Apply intelligent content control policies to ensure maximum user productivity.

Getting started with the SSL forward proxy feature

September 14, 2021

Important:

- OCSP check requires an internet connection to check the validity of certificates. If your appliance is not accessible from the internet by using the NSIP address, add access control lists (ACLs) to perform NAT from the NSIP address to the subnet IP (SNIP) address. The SNIP must be able to access the internet. For example,

```
1  add ns acl a1 ALLOW -srcIP = <NSIP> -destIP  "!="
       10.0.0.0-10.255.255.255
2
3  add rnat RNAT-1 a1
4
5  bind rnat RNAT-1 -<SNIP>
```

```
6
7   apply acls
8   <!--NeedCopy-->
```

- Specify a DNS name server to resolve domain names.
- Make sure that the date on the appliance is synchronized with the NTP servers. If the date is not synchronized, the appliance cannot effectively verify whether an origin server certificate is an expired one.

To use the SSL forward proxy feature, you must perform the following tasks:

- Add a proxy server in explicit or transparent mode.
- Enable SSL interception.
  - Configure an SSL profile.
  - Add and bind SSL policies to the proxy server.
  - Add and bind a CA certificate-key pair for SSL interception.

Note:

An ADC appliance configured in transparent proxy mode can intercept only HTTP and HTTPS protocols. To bypass any other protocol, such as telnet, you must add the following listen policy on the proxy virtual server.

The virtual server now accepts only HTTP and HTTPS incoming traffic.

```
1 set cs vserver transparent-pxy1 PROXY * * -cltTimeout 180 -Listenpolicy
      "CLIENT.TCP.DSTPORT.EQ(80) || CLIENT.TCP.DSTPORT.EQ(443)"`
2 <!--NeedCopy-->
```

You might need to configure the following features, depending on your deployment:

- Authentication Service (recommended) – to authenticate users. Without the Authentication Service, user activity is based on client IP address.
- URL Filtering – to filter URLs by categories, reputation score, and URL lists.
- Analytics – to view user activity, user risk indicators, bandwidth consumption, and transactions break down in Citrix Application Delivery Management (ADM).

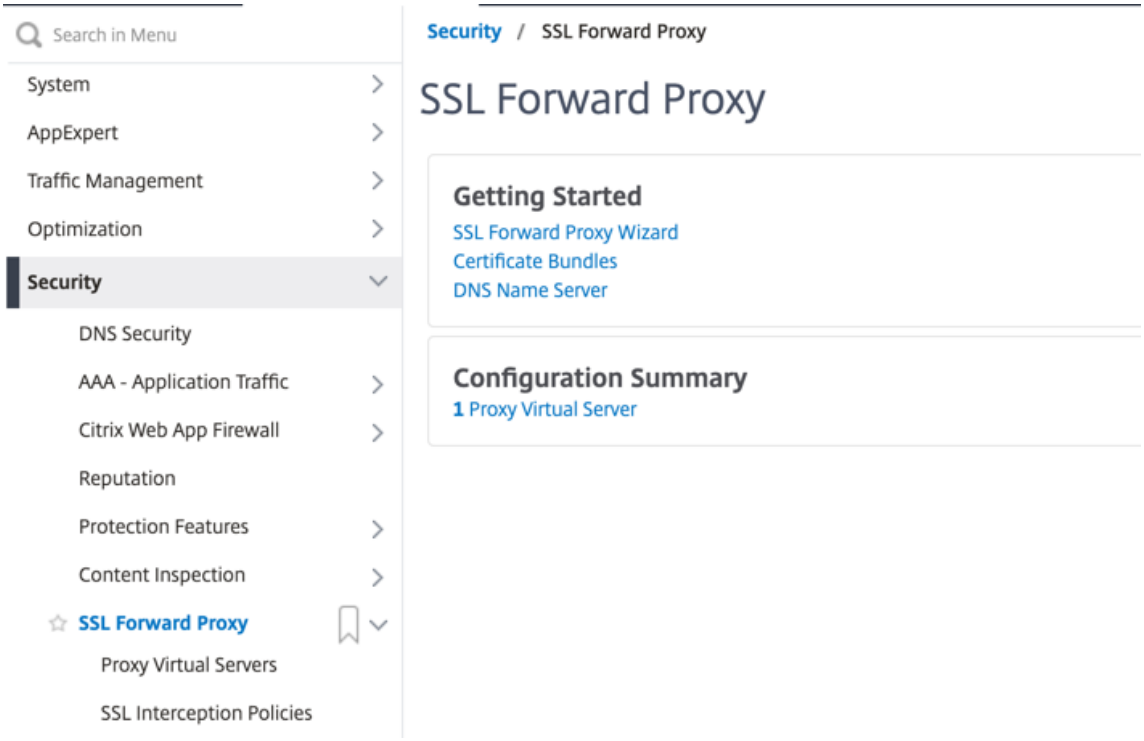
Note: SSL Forward Proxy implements most typical HTTP and HTTPS standards followed by similar products. This implementation is done with no specific browser in mind and is compatible with most common browsers. SSL Forward Proxy has been tested with common browsers and recent versions of Google Chrome, Internet Explorer, and Mozilla Firefox.

SSL forward proxy wizard

The SSL forward proxy wizard provides administrators with a tool for managing the entire SSL forward proxy deployment by using a web browser. It helps guide the customers to bring up an SSL forward

proxy service quickly and helps simplify the configuration by following a sequence of well-defined steps.

1. Navigate to **Security > SSL Forward Proxy**. In **Getting Started**, click **SSL Forward Proxy Wizard**.



2. Follow the steps in the wizard to configure your deployment.

Add a listen policy to the transparent proxy server

1. Navigate to **Security >SSL Forward Proxy** > **Proxy Virtual Servers**. Select the transparent proxy server and click **Edit**.
2. Edit **Basic Settings**, and click **More**.
3. In **Listen priority**, enter 1.
4. In **Listen Policy Expression**, enter the following expression:

```
(CLIENT.TCP.DSTPORT.EQ(80)||CLIENT.TCP.DSTPORT.EQ(443))
<!--NeedCopy-->
```

This expression assumes standard ports for HTTP and HTTPS traffic. If you have configured different ports, for example 8080 for HTTP or 8443 for HTTPS, modify the expression to reflect those ports.

Limitations

SSL forward proxy is not supported in a cluster setup, in admin partitions, and on a Citrix ADC FIPS appliance.

Proxy modes

September 14, 2021

The Citrix ADC appliance acts as a client's proxy to connect to the internet and SaaS applications. As a proxy, it accepts all the traffic and determines the traffic's protocol. Unless the traffic is HTTP or SSL, it is forwarded to the destination as is. When the appliance receives a request from a client, it intercepts the request and performs some actions, such as user authentication, site categorization, and redirection. It uses policies to determine which traffic to allow and which traffic to block.

The appliance maintains two different sessions, one between the client and the proxy and the other between the proxy and the origin server. The proxy relies on customer defined policies to allow or block HTTP and HTTPS traffic. Therefore, it is important that you define policies to bypass sensitive data, such as financial information. The appliance offers a rich set of Layer 4 to Layer 7 traffic attributes and user-identity attributes to create traffic management policies.

For SSL traffic, the proxy verifies the origin server's certificate and establishes a legitimate connection with the server. It then emulates the server certificate, signs it using a CA certificate installed on Citrix ADC, and presents the created server certificate to the client. You must add the CA certificate as a trusted certificate to the client's browser for the SSL session to be successfully established.

The appliance supports transparent and explicit proxy modes. In explicit proxy mode, the client must specify an IP address in their browser, unless the organization pushes the setting onto the client's device. This address is the IP address of a proxy server that is configured on the ADC appliance. All client requests are sent to this IP address. For explicit proxy, you must configure a content switching virtual server of type PROXY and specify an IP address and a valid port number.

Transparent proxy, as the name implies, is transparent to the client. That is, the clients might not be aware that a proxy server is mediating their requests. The ADC appliance is configured in an inline deployment, and transparently accepts all HTTP and HTTPS traffic. For transparent proxy, you must configure a content switching virtual server of type PROXY, with asterisks (* *) as the IP address and port. When using the **SSL Forward Proxy Wizard** in the GUI, you do not have to specify an IP address and port.

> **Note**
>
> To intercept protocols other than HTTP and HTTPS in transparent proxy mode, you must add a

> listen policy and bind it to the proxy server.

Configure SSL forward proxy by using the CLI

At the command prompt, type:

```
add cs vserver <name> PROXY <ipaddress> <port>
<!--NeedCopy-->
```

Arguments:

Name:

Name for the proxy server. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CS virtual server is created.

The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my server” or ‘my server’).

This argument is mandatory. Maximum Length: 127

IPAddress:

IP address of the proxy server.

Port:

Port number for the proxy server. Minimum value: 1

Example for explicit proxy:

```
add cs vserver swgVS PROXY 192.0.2.100 80
<!--NeedCopy-->
```

Example for transparent proxy:

```
add cs vserver swgVS PROXY * *
<!--NeedCopy-->
```

Add a listen policy to the transparent proxy server by using the GUI

1. Navigate to **Security** > **SSL Forward Proxy** > **Proxy Virtual Servers**. Select the transparent proxy server and click **Edit**.
2. Edit **Basic Settings**, and click **More**.

3. In **Listen priority**, enter 1.
4. In **Listen Policy Expression**, enter the following expression:

```
(CLIENT.TCP.DSTPORT.EQ(80)||CLIENT.TCP.DSTPORT.EQ(443))
<!--NeedCopy-->
```

> **Note**
>
> This expression assumes standard ports for HTTP and HTTPS traffic. If you have configured different ports, for example 8080 for HTTP or 8443 for HTTPS, modify the preceding expression to specify those ports.

SSL interception

September 14, 2021

A Citrix ADC appliance configured for SSL interception acts as a proxy. It can intercept and decrypt SSL/TLS traffic, inspect the unencrypted request, and enable an admin to enforce compliance rules and security checks. SSL interception uses a policy that specifies which traffic to intercept, block, or allow. For example, traffic to and from financial websites, such as banks, must not be intercepted, but other traffic can be intercepted, and blacklisted sites can be identified and blocked. Citrix recommends that you configure one generic policy to intercept traffic and more specific policies to bypass some traffic.

The client and the proxy establish an HTTPS/TLS handshake. The proxy establishes another HTTPS/TLS handshake with the server and receives the server certificate. The proxy verifies the server certificate on behalf of the client, and also checks the validity of the server certificate by using the Online Certificate Status Protocol (OCSP). It regenerates the server certificate, signs it by using the key of the CA certificate installed on the appliance, and presents it to the client. Therefore, one certificate is used between the client and the Citrix ADC appliance, and another certificate between the appliance and the back-end server.

> **Important**
>
> The CA certificate that is used to sign the server certificate must be preinstalled on all the client devices, so that the regenerated server certificate is trusted by the client.

For intercepted HTTPS traffic, the proxy server decrypts the outbound traffic, accesses the clear text HTTP request, and can use any Layer 7 application to process the traffic, such as by looking into the plain text URL and allowing or blocking access based on the corporate policy and URL reputation. If the policy decision is to allow access to the origin server, the proxy server forwards the re-encrypted

request to the destination service (on the origin server). The proxy decrypts the response from the origin server, accesses the clear text HTTP response, and optionally applies any policies to the response. The proxy then reencrypts the response and forwards it to the client. If the policy decision is to block the request to the origin server, the proxy can send an error response, such as HTTP 403, to the client.

To perform SSL interception, in addition to the proxy server configured earlier, you must configure the following on the ADC appliance:

- SSL profile
- SSL policy
- CA certificate store
- SSL-error autolearning and caching

> **Note:**
>
> HTTP/2 traffic is not intercepted by the SSL Interception feature.

SSL interception certificate store

An SSL certificate, which is a part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. An SSL certificate is issued by a certificate authority (CA). A CA can be private or public. Certificates issued by public CAs, such as Verisign, are trusted by applications that conduct SSL transactions. These applications maintain a list of CAs that they trust.

As a forward proxy, the ADC appliance performs encryption and decryption of traffic between a client and a server. It acts as a server to the client (user) and as a client to the server. Before an appliance can process HTTPS traffic, it must validate the identity of a server to prevent any fraudulent transactions. Therefore, as a client to the origin server, the appliance must verify the origin server certificate before accepting it. To verify a server certificate, all the certificates (for example, root and intermediate certificates) that are used to sign and issue the server certificate must be present on the appliance. A default set of CA certificates is preinstalled on an appliance. The appliance can use these certificates to verify almost all the common origin-server certificates. This default set cannot be modified. However, if your deployment requires more CA certificates, you can create a bundle of such certificates and import the bundle to the appliance. A bundle can also contain a single certificate.

When you import a certificate bundle to the appliance, the appliance downloads the bundle from the remote location and, after verifying that the bundle contains only certificates, installs it on the appliance. You must apply a certificate bundle before you can use it to validate a server certificate. You can also export a certificate bundle for editing or to store it in an offline location as a backup.

Import and apply a CA certificate bundle on the appliance by using the CLI

At the command prompt, type:

```
import ssl certBundle <name> <src>
apply ssl certBundle <name>
<!--NeedCopy-->
```

```
show ssl certBundle
<!--NeedCopy-->
```

ARGUMENTS:

Name:

Name to assign to the imported certificate bundle. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my file” or ‘my file’).

Maximum Length: 31

src:

URL specifying the protocol, host, and path, including file name, to the certificate bundle to be imported or exported. For example, `http://www.example.com/cert_bundle_file`.

NOTE: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access.

Maximum Length: 2047

Example:

```
import ssl certbundle swg-certbundle http://www.example.com/cert_bundle
apply ssl certBundle swg-certbundle
<!--NeedCopy-->
```

```
show ssl certbundle

            Name : swg-certbundle(Inuse)

            URL : http://www.example.com/cert_bundle

    Done
<!--NeedCopy-->
```

Import and apply a CA certificate bundle on the appliance by using the GUI

1. Navigate to **Security > SSL Forward Proxy > Getting Started > Certificate Bundles**.
2. Do one of the following:
   - Select a certificate bundle from the list.
   - To add a certificate bundle, click "+" and specify a name and source URL. Click **OK**.
3. Click **OK**.

Remove a CA certificate bundle from the appliance by using the CLI

At the command prompt, type:

```
remove certBundle <cert bundle name>
<!--NeedCopy-->
```

Example:

```
remove certBundle mytest-cacert
<!--NeedCopy-->
```

Export a CA certificate bundle from the appliance by using the CLI

At the command prompt, type:

```
export certBundle <cert bundle name> <Path to export>
<!--NeedCopy-->
```

ARGUMENTS:

Name:

Name to assign to the imported certificate bundle. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my file" or 'my file').

Maximum Length: 31

src:

URL specifying the protocol, host, and path, including file name, to the certificate bundle to be imported or exported. For example, `http://www.example.com/cert_bundle_file`.

NOTE: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access.

Maximum Length: 2047

Example:

```
export certBundle mytest-cacert http://192.0.2.20/
<!--NeedCopy-->
```

Import, apply, and verify a CA certificate bundle from the Mozilla CA certificate store

At the command prompt, type:

```
> import certbundle mozilla_public_ca https://curl.haxx.se/ca/cacert.
   pem
Done
<!--NeedCopy-->
```

To apply the bundle, type:

```
> apply certbundle mozilla_public_ca
Done
<!--NeedCopy-->
```

To verify the certificate bundle in use, type:

```
> sh certbundle | grep mozilla
                Name : mozilla_public_ca (Inuse)
<!--NeedCopy-->
```

Limitations

- Certificate bundles are not supported in a cluster setup, or on a partitioned appliance.
- TLSv1.3 protocol is not supported with SSL Forward Proxy.

SSL policy infrastructure for SSL interception

A policy acts like a filter on incoming traffic. Policies on the ADC appliance help define how to manage proxied connections and requests. The processing is based on the actions that are configured for that policy. That is, data in connection requests is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression). After defining an action to assign to

the policy and create the policy, you must bind it to a proxy server, so that it applies to traffic flowing through that proxy server.

An SSL policy for SSL interception evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). A decision to intercept, bypass, or reset a connection is made based on the defined SSL policy. You can configure one of three actions for a policy—INTERCEPT, BYPASS, or RESET. You must specify an action when you create a policy. To put a policy into effect, you must bind it to a proxy server on the appliance. To specify that a policy is intended for SSL interception, you must specify the type (bind point) as INTERCEPT_REQ when you bind the policy to a proxy server. When unbinding a policy, you must specify the type as INTERCEPT_REQ.

> **Note**:
>
> The proxy server cannot make a decision to intercept unless you specify a policy.

Traffic interception can be based on any SSL handshake attribute. The most commonly used is the SSL domain. The SSL domain is usually indicated by the attributes of the SSL handshake. It can be the Server Name Indicator value extracted from the SSL Client Hello message, if present, or the Server Alternate Name (SAN) value extracted from the origin server certificate. The SSL interception policy presents a special attribute, DETECTED_DOMAIN. This attribute makes it easier for the customers to author interception policies based on the SSL domain from the origin server certificate. The customer can match the domain name against a string, URL list (URL set or `patset`), or a URL category derived from the domain.

Create an SSL policy by using the CLI

At the command prompt, type:

```
add ssl policy <name> -rule <expression> -action <string>
<!--NeedCopy-->
```

Examples:

The following examples are for policies with expressions that use the `detected_domain` attribute to check for a domain name.

Do not intercept traffic to a financial institution, such as XYZBANK

```
add ssl policy pol1 -rule client.ssl.detected_domain.contains("XYZBANK"
    ) -action BYPASS
<!--NeedCopy-->
```

Do not allow a user to connect to YouTube from the corporate network

```
add ssl policy pol2 -rule client.ssl.client.ssl.detected_domain.
    url_categorize(0,0).category.eq ("YouTube") -action RESET
```

```
<!--NeedCopy-->
```

Intercept all user traffic

```
add ssl policy pol3 -rule true -action INTERCEPT
<!--NeedCopy-->
```

If the customer doesn't want to use the detected_domain, they can use any of the SSL handshake attributes to extract and infer the domain.

For example, a domain name is not found in the SNI extension of the client hello message. The domain name must be taken from the origin server certificate. The following examples are for policies with expressions that check for a domain name in the subject name of the origin server certificate.

Intercept all user traffic to any Yahoo domain

```
add ssl policy pol4 -rule client.ssl.origin_server_cert.subject.
   contains("yahoo") -action INTERCEPT
<!--NeedCopy-->
```

Intercept all user traffic for the category "Shopping/Retail"

```
add ssl policy pol_url_category -rule client.ssl.origin_server_cert.
   subject.URL_CATEGORIZE(0,0).CATEGORY.eq("Shopping/Retail") -action
   INTERCEPT
<!--NeedCopy-->
```

Intercept all user traffic to an uncategorized URL

```
add ssl policy pol_url_category -rule client.ssl.origin_server_cert.
   subject.url_categorize(0,0).category.eq("Uncategorized") -action
   INTERCEPT
<!--NeedCopy-->
```

The following examples are for policies that match the domain against an entry in a URL set.

Intercept all user traffic if the domain name in SNI matches an entry in the URL set "top100"

```
add ssl policy pol_url_set -rule client.ssl.client_hello.SNI.
   URLSET_MATCHES_ANY("top100") -action INTERCEPT
<!--NeedCopy-->
```

Intercept all user traffic of the domain name if the origin server certificate matches an entry in the URL set "top100"

```
add ssl policy pol_url_set  -rule client.ssl.origin_server_cert.subject
   .URLSET_MATCHES_ANY("top100") -action INTERCEPT
<!--NeedCopy-->
```

Create an SSL policy to a proxy server by using the GUI

1. Navigate to **Traffic Management > SSL > Policies**.
2. On the **SSL Policies** tab, click **Add** and specify the following parameters:
   - Policy name
   - Policy action – Select from intercept, bypass, or reset.
   - Expression
3. Click **Create**.

Bind an SSL policy to a proxy server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type  INTERCEPT_REQ
<!--NeedCopy-->
```

Example:

```
bind ssl vserver <name> -policyName pol1 -priority 10 -type
   INTERCEPT_REQ
<!--NeedCopy-->
```

Bind an SSL policy to a proxy server by using the GUI

1. Navigate to **Security > SSL Forward Proxy > Proxy Virtual Servers**.
2. Select a virtual server and click **Edit**.
3. In **Advanced Settings**, click **SSL Policies**.
4. Click inside the **SSL Policy** box.
5. In **Select Policy**, select a policy to bind.
6. In **Type**, select **INTERCEPT_REQ**.
7. Click **Bind** and then click **OK**.

Unbind an SSL policy to a proxy server by using the CLI

At the command prompt, type:

```
unbind ssl vserver <vServerName> -policyName <string> -type
    INTERCEPT_REQ
<!--NeedCopy-->
```

SSL expressions used in SSL policies

Expression	Description
CLIENT.SSL.CLIENT_HELLO.SNI.*	Returns the SNI extension in a string format. Evaluate the string to see if it contains the specified text. Example: client.ssl.client_hello.sni.contains("xyz.com")
CLIENT.SSL.ORIGIN_SERVER_CERT.*	Returns a certificate, received from a back-end server, in a string format. Evaluate the string to see if it contains the specified text. Example: client.ssl.origin_server_cert.subject.contains("xyz.com")
CLIENT.SSL.DETECTED_DOMAIN.*	Returns a domain, either from the SNI extension or from the origin server certificate, in a string format. Evaluate the string to see if it contains the specified text. Example: client.ssl.detected_domain.contains("xyz.com")

SSL error autolearning

The appliance adds a domain to the SSL bypass list if learning mode is on. The learning mode is based on the SSL alert message received from either a client or an origin server. That is, learning depends the client or server sending an alert message. There is no learning if an alert message is not sent. The appliance learns if any of the following conditions are met:

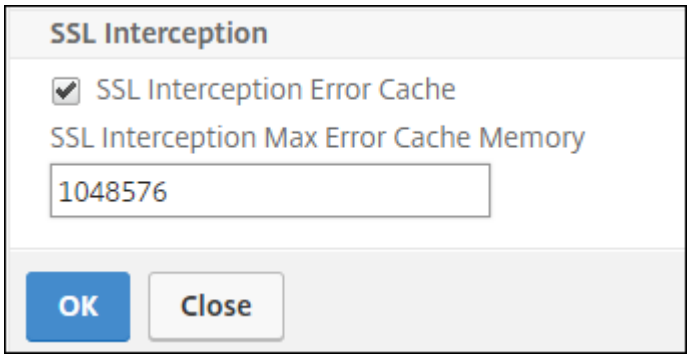
1. A request for a client certificate is received from the server.
2. Any one of the following alerts is received as part of the handshake:
   - BAD_CERTIFICATE
   - UNSUPPORTED_CERTIFICATE
   - CERTIFICATE_REVOKED
   - CERTIFICATE_EXPIRED

- CERTIFICATE_UNKNOWN
- UNKNOWN_CA (If a client uses pinning, it sends this alert message if it receives a server certificate.)
- HANDSHAKE_FAILURE

To enable learning, you must enable the error cache and specify the memory reserved for learning.

Enable learning by using the GUI

1. Navigate to **Traffic Management > SSL**.
2. In **Settings**, click **Change advanced SSL settings**.
3. In **SSL Interception**, select **SSL Interception Error Cache**.
4. In **SSL Interception Max Error Cache Memory**, specify the memory (in bytes) to reserve.



5. Click **OK**.

Enable learning by using the CLI

At the command prompt type:

```
set ssl parameter -ssliErrorCache ( ENABLED | DISABLED ) -
    ssliMaxErrorCacheMem <positive_integer>
<!--NeedCopy-->
```

Arguments:

ssliErrorCache:

Enable or disable dynamic learning, and cache the learned information to make subsequent decisions to intercept or bypass requests. When enabled, the appliance performs a cache lookup to decide whether to bypass the request.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssliMaxErrorCacheMem:

Specify the maximum memory, in bytes, that can be used to cache the learned data. This memory is used as an LRU cache so that the old entries are replaced with new entries after the set memory limit is exhausted. A value of 0 decides the limit automatically.

Default value: 0

Minimum value: 0

Maximum value: 4294967294

SSL profile

An SSL profile is a collection of SSL settings, such as ciphers and protocols. A profile is helpful if you have common settings for different servers. Instead of specifying the same settings for each server, you can create a profile, specify the settings in the profile, and then bind the profile to different servers. If a custom front-end SSL profile is not created, the default front-end profile is bound to client-side entities. This profile enables you to configure settings for managing the client-side connections.

For SSL interception, you must create an SSL profile and enable SSL interception in the profile. A default cipher group is bound to this profile, but you can configure more ciphers to suit your deployment. Bind an SSL interception CA certificate to this profile and then bind the profile to a proxy server. For SSL interception, the essential parameters in a profile are the ones used for the following actions:

- Check the OCSP status of the origin server certificate.
- Trigger client renegotiation if the origin server requests renegotiation.
- Verify the origin server certificate before reusing the front-end SSL session.

Use the default back-end profile when communicating with the origin servers. Set any server-side parameters, such as cipher suites, in the default back-end profile. A custom back-end profile is not supported.

For examples of the most commonly used SSL settings, see “Sample Profile” at the end of this section.

Cipher/protocol support differs on the internal and external network. In the following tables, the connection between the users and an ADC appliance is the internal network. The external network is between the appliance and the internet.

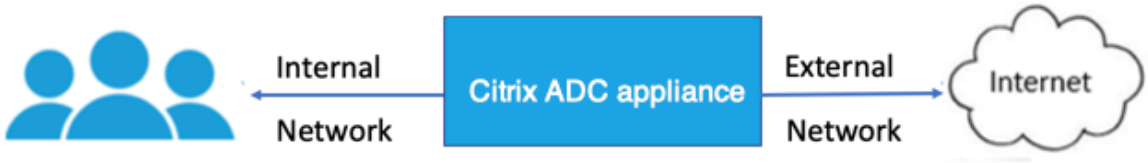


Table 1: Cipher/protocol support matrix for the internal network

See Table 1-Support on virtual server/frontend service/internal service in Ciphers available on the Citrix ADC appliances.

Table 2: Cipher/protocol support matrix for the external network

See Table 2-Support on back-end services in Ciphers available on the Citrix ADC appliances.

Add an SSL profile and enable SSL interception by using the CLI

At the command prompt, type:

```
add ssl profile <name> -sslinterception ENABLED -ssliReneg ( ENABLED |
 DISABLED )-ssliOCSPCheck ( ENABLED | DISABLED )-ssliMaxSessPerServer <
positive_integer>
```

Arguments:

sslInterception:

Enable or disable interception of SSL sessions.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssliReneg:

Enable or disable triggering client renegotiation when a renegotiation request is received from the origin server.

Possible values: ENABLED, DISABLED

Default value: ENABLED

ssliOCSPCheck:

Enable or disable OCSP check for an origin-server certificate.

Possible values: ENABLED, DISABLED

Default value: ENABLED

ssliMaxSessPerServer:

Maximum number of SSL sessions to be cached per dynamic origin server. A unique SSL session is created for each SNI extension received from the client in a client hello message. The matching session is used for server-session reuse.

Default value: 10

Minimum value: 1

Maximum value: 1000

Example:

```
add ssl profile swg_ssl_profile  -sslinterception ENABLED

Done

sh ssl profile swg_ssl_profile

1)    Name: swg_ssl_profile (Front-End)

                SSLv3: DISABLED               TLSv1.0: ENABLED  TLSv1

82 <!--NeedCopy-->
```

Bind an SSL interception CA certificate to an SSL profile by using the GUI

1. Navigate to **System** > **Profiles** > **SSL Profile**.
2. Click **Add**.
3. Specify a name for the profile.
4. Enable **SSL Sessions Interception**.
5. Click **OK**.
6. In **Advanced Settings**, click **Certificate Key**.
7. Specify an SSL interception CA certificate key to bind to the profile.
8. Click **Select** and then click **Bind**.
9. Optionally, configure ciphers to suit your deployment.
    - Click the edit icon, and then click **Add**.
    - Select one or more cipher groups, and click the right arrow.
    - Click **OK**.
10. Click **Done**.

Bind an SSL profile to a proxy server by using the GUI

1. Navigate to **Security** >**SSL Forward Proxy** > **Proxy Virtual Servers**, and add a server or select a server to modify.
2. In **SSL Profile**, click the edit icon.
3. In the **SSL Profile** list, select the SSL profile that you created earlier.
4. Click **OK**.
5. Click **Done**.

Sample Profile:

```
1 Name: swg_ssl_profile (Front-End)
2
```

```
3                   SSLv3: DISABLED               TLSv1.0: ENABLED  TLSv1
                        .1: ENABLED  TLSv1.2: ENABLED
4
5                   Client Auth: DISABLED
6
7                   Use only bound CA certificates: DISABLED
8
9                   Strict CA checks:                                 NO
10
11                  Session Reuse: ENABLED
                        Timeout: 120 seconds
12
13                  DH: DISABLED
14
15                  DH Private-Key Exponent Size Limit: DISABLED
                        Ephemeral RSA: ENABLED
                        Refresh Count: 0
16
17                  Deny SSL Renegotiation
                        ALL
18
19                  Non FIPS Ciphers: DISABLED
20
21                  Cipher Redirect: DISABLED
22
23                  SSL Redirect: DISABLED
24
25                  Send Close-Notify: YES
26
27                  Strict Sig-Digest Check: DISABLED
28
29                  Push Encryption Trigger: Always
30
31                  PUSH encryption trigger timeout:              1 ms
32
33                  SNI: DISABLED
34
35                  OCSP Stapling: DISABLED

```

User identity management

September 14, 2021

An increasing number of security breaches and the growing popularity of mobile devices has emphasized the need to ensure that use of the external internet is compliant with the corporate policies. Only authorized users must be allowed access to external resources provisioned by the corporate personnel. Identity Management makes it possible by verifying the identity of a person or a device. It does not determine what tasks the individual can take or what files the individual can see.

An SSL forward proxy deployment identifies the user before allowing access to the internet. All requests and responses from the user are inspected. User activity is logged, and records are exported to the Citrix Application Delivery Management (ADM) for reporting. In Citrix ADM, you can view the statistics about the user activities, transactions, and bandwidth consumption.

By default, only the user's IP address is saved, but you can configure the feature to record more details about the user. You can use this identity information to create richer internet usage policies for specific users.

The Citrix ADC appliance supports the following authentication modes for an explicit-proxy configuration.

- **Lightweight Directory Access Protocol (LDAP)**. Authenticates the user through an external LDAP authentication server. For more information, see LDAP Authentication Policies.
- **RADIUS**. Authenticates the user through an external RADIUS server. For more information, see RADIUS Authentication Policies.
- **TACACS+**. Authenticates the user through an external Terminal Access Controller Access-Control System (TACACS) authentication server. For more information, see Authentication Policies.
- **Negotiate**. Authenticates the user through a Kerberos authentication server. If there is an error in Kerberos authentication, the appliance uses NTLM authentication. For more information, see Negotiate Authentication Policies.

For transparent proxy, only IP-based LDAP authentication is supported. When a client request is received, the proxy authenticates the user by checking an entry for the client IP address in the active directory. It then creates a session based on the user IP address. However, if you configure the ssoNameAttribute in an LDAP action, a session is created by using the user name instead of the IP address. Classic policies are not supported for authentication in a transparent proxy setup.

> **Note**
>
> For explicit proxy, you must set the LDAP login name to **sAMAccountName**. For transparent proxy, you must set the LDAP login name to **networkAddress** and attribute1 to **sAMAccountName**.

Example for explicit proxy:

```
1 add authentication ldapAction swg-auth-action-explicit -serverIP
     10.105.157.116 -ldapBase "CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDn "
     CN=Administrator,CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDnPassword
     freebsd123$ -ldapLoginName sAMAccountName
2 <!--NeedCopy-->
```

Example for transparent proxy:

```
add authentication ldapAction swg-auth-action-explicit -serverIP
    10.105.157.116 -ldapBase "CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDn "
    CN=Administrator,CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDnPassword
    freebsd123$ -ldapLoginName networkAddress -authentication disable -
    Attribute1 sAMAccountName
<!--NeedCopy-->
```

Set up user authentication by using the CLI

At the command prompt type:

```
add authentication vserver <vserver name> SSL

bind ssl vserver <vserver name> -certkeyName <certkey name>

add authentication ldapAction <action name> -serverIP <ip_addr> -
    ldapBase <string> -ldapBindDn <string> -ldapBindDnPassword -
    ldapLoginName <string>

add authentication Policy <policy name> -rule <expression> -action <
    string>

bind authentication vserver <vserver name> -policy <string> -priority <
    positive_integer>

set cs vserver <name> -authn401 ON -authnVsName <string>
<!--NeedCopy-->
```

Arguments:

Vserver name:

Name of the authentication virtual server to which to bind the policy.

Maximum Length: 127

serviceType:

Protocol type of the authentication virtual server. Always SSL.

Possible values: SSL

Default value: SSL

Action name:

Name for the new LDAP action. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@),

equals (=), colon (:), and underscore characters. Cannot be changed after the LDAP action is added. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my authentication action” or ‘my authentication action’).

Maximum Length: 127

serverIP:

IP address assigned to the LDAP server.

ldapBase:

Base (node) from which to start LDAP searches. If the LDAP server is running locally, the default value of base is dc=netscaler, dc=com. Maximum Length: 127

ldapBindDn:

Full distinguished name (DN) that is used to bind to the LDAP server.

Default: cn=Manager,dc=netscaler,dc=com

Maximum Length: 127

ldapBindDnPassword:

Password used to bind to the LDAP server.

Maximum Length: 127

ldapLoginName:

LDAP login name attribute. The Citrix ADC appliance uses the LDAP login name to query external LDAP servers or Active Directories. Maximum Length: 127

Policy name:

Name for the advance AUTHENTICATION policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after an AUTHENTICATION policy is created. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my authentication policy” or ‘my authentication policy’).

Maximum Length: 127

rule:

Name of the rule, or a default syntax expression, that the policy uses to determine whether to attempt to authenticate the user with the AUTHENTICATION server.

Maximum Length: 1499

action:

Name of the authentication action to be performed if the policy matches.

Maximum Length: 127

priority:

Positive integer specifying the priority of the policy. A lower number specifies a higher priority. Policies are evaluated in the order of their priorities, and the first policy that matches the request is applied. Must be unique within the list of policies bound to the authentication virtual server.

Minimum value: 0

Maximum Value: 4294967295

Example:

```
add authentication vserver swg-auth-vs SSL

Done

bind ssl vserver explicit-auth-vs -certkeyName ns-swg-ca-certkey

Done

add authentication ldapAction swg-auth-action-explicit -serverIP
    192.0.2.116 -ldapBase "CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDn "CN=
    Administrator,CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDnPassword zzzzz
     -ldapLoginName sAMAccountName

Done

add authenticationpolicy swg-auth-policy -rule true -action swg-auth-
    action-explicit
Done

bind authentication vserver swg-auth-vs -policy swg-auth-policy -
    priority 1

Done

set cs vserver testswg -authn401 ON -authnVsName swg-auth-vs

Done
<!--NeedCopy-->
```

Enable user name logging by using the CLI

At the command prompt, type:

```
set appflow param -AAAUserName ENABLED
<!--NeedCopy-->
```

Arguments:

AAAUserName

Enable AppFlow authentication, authorization, and auditing user name logging.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example:

```
set appflow param -AAAUserName ENABLED
<!--NeedCopy-->
```

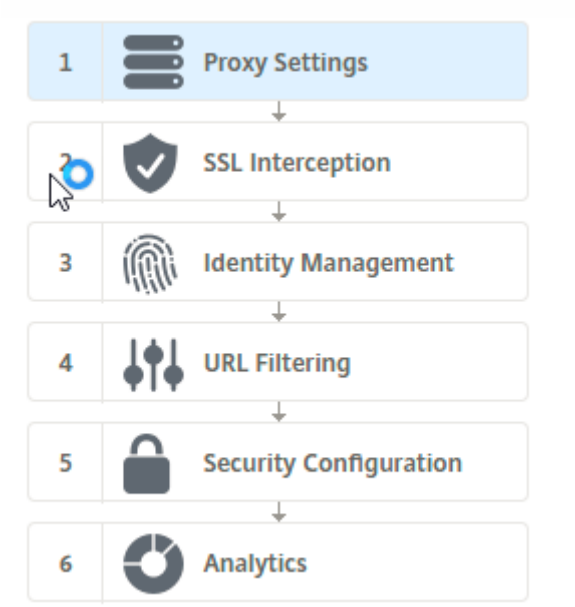
URL filtering

September 14, 2021

URL Filtering provides policy based control of websites by using the information contained in URLs. This feature helps network administrators monitor and control user access to malicious websites on the network.

Get started

If you are a new user and want to configure URL filtering, you must complete the initial SSL forward proxy setup. To get started with URL Filtering, you must first log on to the SSL forward proxy wizard. The wizard takes you through a series of configuration steps before you apply the URL Filtering policies.



> **Note**
>
> Before you begin, be sure you have a valid URL Threat Intelligence feature license installed on your appliance. If you are using a trial version, be sure to purchase a valid license to continue using this feature on the ADC appliance.

Log on to SSL forward proxy wizard

The SSL forward proxy wizard guides you through a series of simplified configuration tasks and the right pane displays the corresponding flow sequence. You can use this wizard to apply URL Filtering policies to a URL list or a predefined list of categories.

Step 1: Configure proxy settings

First configure a proxy server through which the client accesses the gateway. This server is of type SSL, and it operates in explicit or transparent mode. For more information about proxy server configuration, see Proxy Modes.

Step 2: Configure SSL interception

After configuring the proxy server, you must configure the SSL interception proxy to intercept encrypted traffic at the Citrix ADC appliance. In the case of URL filtering, the SSL proxy intercepts the traffic and does not allow blocked URLs while all other traffic can be bypassed. For more information about configuring SSL interception, see SSL Interception.

Step 3: Configure identity management

A user is authenticated before being allowed to log on to the enterprise network. Authentication provides the flexibility to define specific policies for a user or a group of users, based on their roles. For more information about user authentication, see User Identify Management.

Step 4: Configure URL filtering

The administrator can apply a URL filtering policy either by using the URL Categorization feature or by using the URL List feature.

URL Categorization. Controls access to websites and webpages by filtering traffic based on a predefined list of categories.

URL List. Controls access to blacklisted websites and webpages by denying access to URLs that are in a URL set imported into the appliance.

Step 5: Configure security configuration

This step enables you to configure a reputation score and allow users to control access to the websites by denying access if the score is too low. Your reputation score can range from one to four, and you can configure the threshold at which the score becomes unacceptable. For scores that exceed the threshold, you can select a policy action to allow, block, or redirect traffic. For more information, see URL Reputation Score.

Step 6: Configure SSL forward proxy analytics

This step enables you to activate SSL forward proxy analytics for categorizing web traffic, logging URL category in the user transaction logs and viewing traffic analytics. For more information about SSL forward proxy analytics, see Analytics.

Step 7: Click "Done" to complete the initial configuration and continue managing the URL filtering configuration

URL list

September 14, 2021

The URL List feature enables enterprise customers to control access to specific websites and website categories. The feature filters websites by applying a responder policy bound to a URL matching algorithm. The algorithm matches the incoming URL against a URL set consisting of up to one million

(1,000,000) entries. If the incoming URL request matches an entry in the set, the appliance uses the responder policy to evaluate the request (HTTP/HTTPS) and control access to it.

URL set types

Each entry in a URL set can include a URL and, optionally, its metadata (URL category, category groups, or any other related data). For URLs with metadata, the appliance uses a policy expression that evaluates the metadata. For more information, see URL Set.

SSL forward proxy supports custom URL sets. You can also use pattern sets to filter URLs.

Custom URL set. You can create a customized URL set with up to 1,000,000 URL entries and import it as a text file into your appliance.

Pattern set. An ADC appliance can use pattern sets to filter URLs before granting access to websites. A pattern set is a string-matching algorithm that looks for an exact string match between an incoming URL and up to 5000 entries. For more information, see Pattern Set.

Each URL in an imported URL set can have a custom category in the form of URL metadata. Your organization can host the set and configure the ADC appliance to periodically update the set without requiring manual intervention.

After the set is updated, the Citrix ADC appliance automatically detects the metadata. The category is now available as a policy expression for evaluating the URL and applying an action such as allow, block, redirect, or notify the user.

Advanced policy expressions used with URL sets

The following table describes the basic expressions you can use to evaluate incoming traffic.

1. .URLSET_MATCHES_ANY - Evaluates to TRUE if the URL exactly matches any entry in the URL set.
2. .GET_URLSET_METADATA() - The GET_URLSET_METADATA() expression returns the associated metadata if the URL exactly matches any pattern within the URL set. An empty string is returned if there is no match.
3. `.GET_ URLSET_METADATA().EQ(<METADATA)- .GET_ URLSET_METADATA().EQ(<METADATA)`
4. .GET_URLSET_METADATA ().TYPECAST_LIST_T(‘,’).GET(0).EQ() - Evaluates to TRUE if the matched metadata is at the beginning of the category. This pattern can be used to encode separate fields within metadata but match only the first field.
5. HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL) - Joins the host and URL parameters, which can then be used for matching.

Responder action types

> **Note:** In the table, HTTP.REQ.URL is generalized as <URL expression>.

The following table describes the actions that can be applied to incoming internet traffic.

Responder Action	Description
Allow	Allow the request to access the target URL.
Redirect	Redirect the request to the URL specified as the target.
Block	Deny the request.

Prerequisites

Configure a DNS server if you import a URL Set from a host name URL. This configuration is not required if you use an IP address.

At the command prompt, type:

```
add dns nameServer ((<IP> [-local])| <dnsVserverName>)[-state (ENABLED |
DISABLED )] [-type <type>] [-dnsProfileName <string>]
```

Example:

```
add dns nameServer 10.140.50.5
```

Configure a URL list

To configure a URL list, you can use the Citrix SSL forward proxy wizard or the Citrix ADC command-line interface (CLI). On the Citrix ADC appliance, you must first configure the responder policy and then bind the policy to a URL set.

Citrix recommends that you use the Citrix SSL forward proxy wizard as the preferred option to configure a URL list. Use the wizard to bind a responder policy to a URL set. Alternatively, you can bind the policy to a pattern set.

Configure a URL list by using the SSL forward proxy wizard

To configure URL List for HTTPS traffic by using the GUI:

1. Navigate to **Security** > **SSL Forward Proxy** page.
2. In the details pane, do one of the following:
   a) Click **SSL Forward Proxy Wizard**.

b) Select an existing configuration and click **Edit**.

3. In the **URL Filtering** section, click **Edit**.
4. Select the **URL List** check box to enable the feature.
5. Select a **URL List** policy and Click **Bind**.
6. Click **Continue** and then **Done**.

For more information, see How to Create a URL List Policy.

Configure a URL list by using the CLI

To configure a URL list, do the following.

1. Configure a proxy virtual server for HTTP and HTTPS traffic.
2. Configure SSL interception for intercepting HTTPS traffic.
3. Configure a URL list containing a URL set for HTTP traffic.
4. Configure URL list containing URL set for HTTPS traffic.
5. Configure a private URL set.

> **Note**
>
> If you have already configured an ADC appliance, you can skip steps 1 and 2, and configure with step 3.

Configuring a proxy virtual server for Internet traffic

The Citrix ADC appliance supports transparent and explicit proxy virtual servers. To configure a proxy virtual server for internet traffic in explicit mode, do the following:

1. Add a proxy SSL virtual server.
2. Bind a responder policy to the proxy virtual server.

To add a proxy virtual server by using the CLI:

At the command prompt, type:

```
add cs vserver <name> <serviceType> <IPAddress> <port>
<!--NeedCopy-->
```

Example:

```
add cs vserver starcs PROXY 10.102.107.121 80 -cltTimeout 180
<!--NeedCopy-->
```

To bind a responder policy to a proxy virtual server by using the CLI:

```
bind ssl vserver <vServerName> -policyName <string> [-priority <
    positive_integer>]
<!--NeedCopy-->
```

> **Note**
>
> If you have already configured the SSL interceptor as part of the Citrix ADC configuration, you can skip the following procedure.

Configure SSL interception for HTTPS traffic

To configure SSL interception for HTTPS traffic, do the following:

1. Bind a CA certificate-key pair to the proxy virtual server.
2. Enable the default SSL profile.
3. Create a front-end SSL profile, and bind it to the proxy virtual server and enable SSL interception in the front-end SSL profile.

To bind a CA certificate-key pair to the proxy virtual server by using the CLI:

At the command prompt, type:

```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>
<!--NeedCopy-->
```

To configure a front-end SSL profile by using the CLI:

At the command prompt, type:

```
set ssl parameter -defaultProfile ENABLED

add ssl profile <name> -sslInterception ENABLED -ssliMaxSessPerServer <
    positive_integer>
<!--NeedCopy-->
```

To bind a front-end SSL profile to a proxy virtual server by using the CLI

At the command prompt, type:

```
set ssl vserver <vServer name>  -sslProfile <name>
<!--NeedCopy-->
```

Configure a URL list by importing a URL set for HTTP traffic

For information about how to configure a URL Set for HTTP traffic, see URL Set.

Perform explicit subdomain match

You can now perform an explicit subdomain match for an imported URL set. A new parameter, "subdomainExactMatch" is added to the `import policy URLset` command.

When you enable the parameter, the URL Filtering algorithm performs an explicit subdomain match. For example, if the incoming URL is `news.example.com` and if the entry in the URL set is `example.com`, the algorithm does not match the URLs.

At the command prompt, type:

```
import policy urlset <name> [-overwrite] [-delimiter <character>][-rowSeparator
 <character>] -url [-interval <secs>] [-privateSet][-subdomainExactMatch]
[-canaryUrl <URL>]
```

Example

```
import policy urlset test -url http://10.78.79.80/top-1k.csv -privateSet -
subdomainExactMatch -interval 900
```

Configure a URL set for HTTPS traffic

To configure a URL Set for HTTPS traffic by using the CLI

At the command prompt type:

```
1 add ssl policy <name> -rule <expression> -action <string> [-undefAction
      <string>] [-comment <string>]
2 <!--NeedCopy-->
```

Example:

```
1 add ssl policy pol1 -rule "client.ssl.client_hello.SNI.
     URLSET_MATCHES_ANY("top1m") -action INTERCEPT
2 <!--NeedCopy-->
```

To configure a URL set for HTTPS traffic by using the SSL forward proxy wizard

Citrix recommends that you use the SSL forward proxy wizard as the preferred option to configure a URL list. Use the wizard to import a custom URL set and bind to a responder policy.

1. Navigate to **Security > SSL Forward proxy > URL Filtering > URL Lists**.
2. In the details pane, click **Add**.
3. On the **URL List Policy** page, specify the policy name.
4. Select an option to import a URL set.
5. On the **URL List Policy** tab page, select the **Import URL Set** check box and specify the following URL Set parameters.

a) URL Set Name—Name of the custom URL set.
b) URL—Web address of the location at which to access the URL Set.
c) Overwrite—Overwrite a previously imported URL set.
d) Delimiter—Character sequence that delimits a CSV file record.
e) Row Separator—Row separator used in the CSV file.
f) Interval—Interval in seconds, rounded off to the nearest number of seconds equal to 15 minutes, at which the URL set is updated.
g) Private Set—Option to prevent exporting the URL set.
h) Canary URL—Internal URL for testing whether the content of the URL set is to be kept confidential. The maximum length of the URL is 2047 characters.

6. Select a responder action from the drop-down list.
7. Click **Create** and **Close**.

Configure a private URL set

If you configure a private URL set and keep its contents confidential, the network administrator might not know the blacklisted URLs in the set. For such cases, you can configure a Canary URL and add it to the URL set. Using the Canary URL, the administrator can request the private URL Set to be used for every lookup request. You can refer to the wizard section for descriptions of each parameter.

To import a URL set by using the CLI:

At the command prompt, type:

```
import policy urlset <name> [-overwrite] [-delimiter <character>] [-
   rowSeparator <character>] -url <URL> [-interval <secs>] [-privateSet
   ] [-canaryUrl <URL>]
<!--NeedCopy-->
```

Example:

```
import policy urlset test1 -url http://10.78.79.80/alytra/top-1k.csv -
   private -canaryUrl http://www.in.gr
<!--NeedCopy-->
```

Display imported URL set

You can now display imported URL sets in addition to added URL sets. A new parameter “imported” is added to the `show urlset` command. If you enable this option, the appliance displays all imported URL sets and distinguishes the imported URL sets from the added URL sets.

At the command prompt, type:

```
show policy urlset [<name>] [-imported]
```

Example

```
show policy urlset -imported
```

Configure audit log messaging

Audit logging enables you to review a condition or a situation in any phase of a URL List process. When a Citrix ADC appliance receives an incoming URL, if the responder policy has a URL Set advanced policy expression, the audit log feature collects URL Set information in the URL. It stores the details as a log message for any target allowed by audit logging.

The log message contains the following information:

1. Timestamp.
2. Log message type.
3. The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency).
4. Log message information, such as URL set name, policy action, URL.

To configure audit logging for the URL List feature, you must complete the following tasks:

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging topic.

URL pattern semantics

September 14, 2021

The following table shows the URL patterns used for specifying the list of pages you to want to filter. For example, the pattern, www.example.com/bar matches only one page at www.example.com/bar. To match all the pages whose URL starts with ‘ www.example.com/bar’, you add an asterisk (*) at the end of the URL.

Semantics for URL pattern to match metadata mapping

The pattern matching semantics is available in a table format. For more information, see Pattern Semantics PDF page.

Mapping URL categories

September 14, 2021

A list of third party categories and category groups. For more information, see URL Category Mapping page.

Use case: URL filtering by using custom URL set

September 14, 2021

If you are an enterprise customer looking to control access to specific websites and website categories, use a custom URL set bound to a responder policy. Your organization's network infrastructure can use a URL filter to block access to malicious or dangerous websites. For example, websites featuring adult, violence, gaming, drugs, politics, or job portals. In addition to filtering the URLs, you can create a customized list of URLs and import it to the ADC appliance. For example, your organization's policies might call for blocking access to certain websites such as social networking, shopping portals, and job portals.

Each URL in the list can have a custom category in the form of metadata. The organization can host the list of URLs as a URL set on the Citrix ADC appliance. Configure the appliance to periodically update the set without requiring manual intervention.

After the set is updated, the Citrix ADC appliance automatically detects the metadata. The responder policy uses the URL metadata (category details) to evaluate the incoming URL and apply an action such as allow, block, redirect, or notify the user.

To do so, configure in your network, you can perform the following tasks:

1. Import a custom URL set
2. Add a custom URL set
3. Configure a custom URL list in the SSL Forward Proxy wizard.

Import a custom URL set by using the CLI

At the command prompt, type:

```
import policy urlset <name> [-overwrite] [-delimiter <character>] [-
   rowSeparator <character>] -url <URL> [-interval <secs>] [-privateSet
   ] [-canaryUrl <URL>]

import policy urlset test1  -url http://10.78.79.80/alytra/top-1k.csv
```

```
<!--NeedCopy-->
```

Add a custom URL set by using the CLI

At the command prompt, type:

```
add urlset <urlset_name>
```

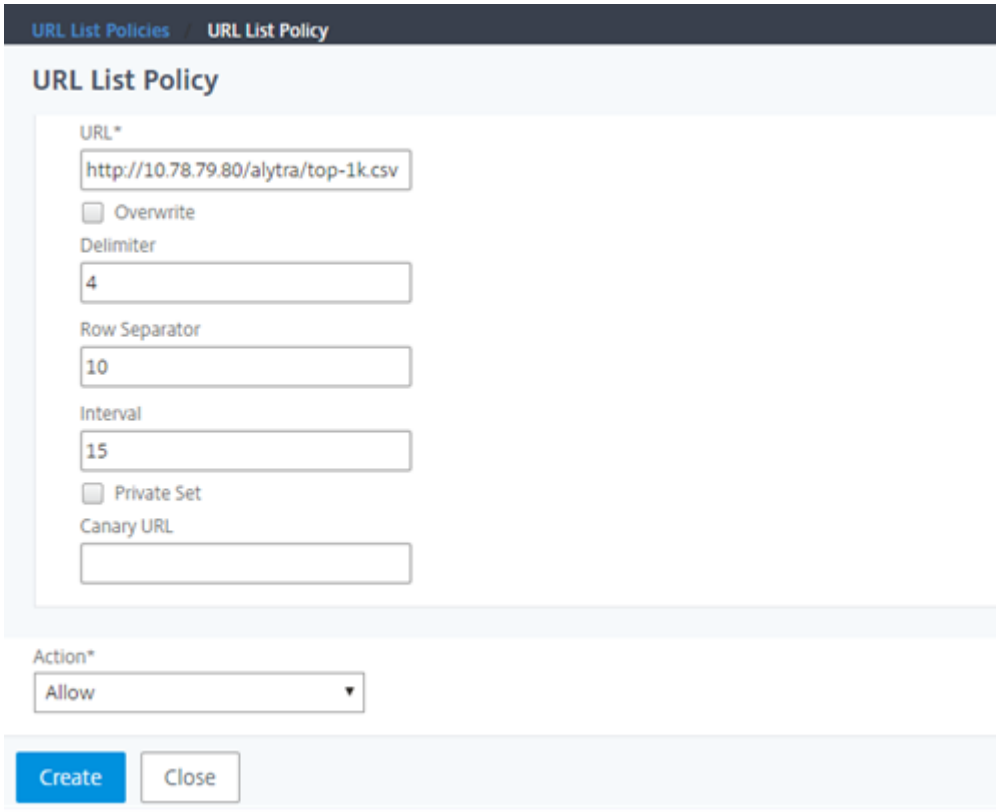
Example:

```
add urlset test1
```

Configure a URL list by using the SSL Forward Proxy wizard

Citrix recommends that you use the SSL Forward Proxy wizard as the preferred option to configure a URL list. Use the wizard to import a custom URL set and bind it to a responder policy.

1. Navigate to **Security > SSL Forward Proxy > URL Filtering > URL Lists**.
2. In the details pane, click **Add**.
3. On the **URL List Policy** page, specify the policy name.
4. Select an option to either import a URL set.
5. In the **URL List Policy** tab page, select the **Import URL Set** check box and specify the following URL Set parameters.
   a) URL Set Name—Name of the custom URL set.
   b) URL—Web address of the location at which to access the URL Set.
   c) Overwrite—Overwrite a previously imported URL set.
   d) Delimiter—Character sequence that delimits a CSV file record.
   e) Row Separator—Row separator used in the CSV file.
   f) Interval—Interval in seconds, rounded off to the nearest 15 minutes, at which the URL set is updated.
   g) Private Set—Option to prevent exporting the URL set.
   h) Canary URL—Internal URL for testing if the content of the URL set is to be kept confidential. The maximum length of the URL is 2047 characters.
6. Select a responder action from the drop-down list.
7. Click **Create** and **Close**.



Metadata semantics for custom URL sets

To import a custom URL set, add the URLs to a text file and bind it to a responder policy to block Social networking URLs.

Following are examples of URLs that you might add to the text file:

cnn.com, News

bbc.com, News

google.com, Search Engine

yahoo.com, Search Engine

facebook.com, Social Media

twitter.com, Social Media

Configure a responder policy to block social media URLs by using the CLI

```
1 add responder action act_url_unauthorized respondwith '"HTTP/1.1 451
     Unavailable For Legal Reasons\r\n\r\nURL is NOT authorized\n"
2
```

```
add responder policy pol_url_meta_match 'HTTP.REQ.HOSTNAME.APPEND(HTTP.
    REQ.URL).GET_URLSET_METADATA("u1").EQ("Social Media")'
    act_url_meta_match
<!--NeedCopy-->
```

URL categorization

September 14, 2021

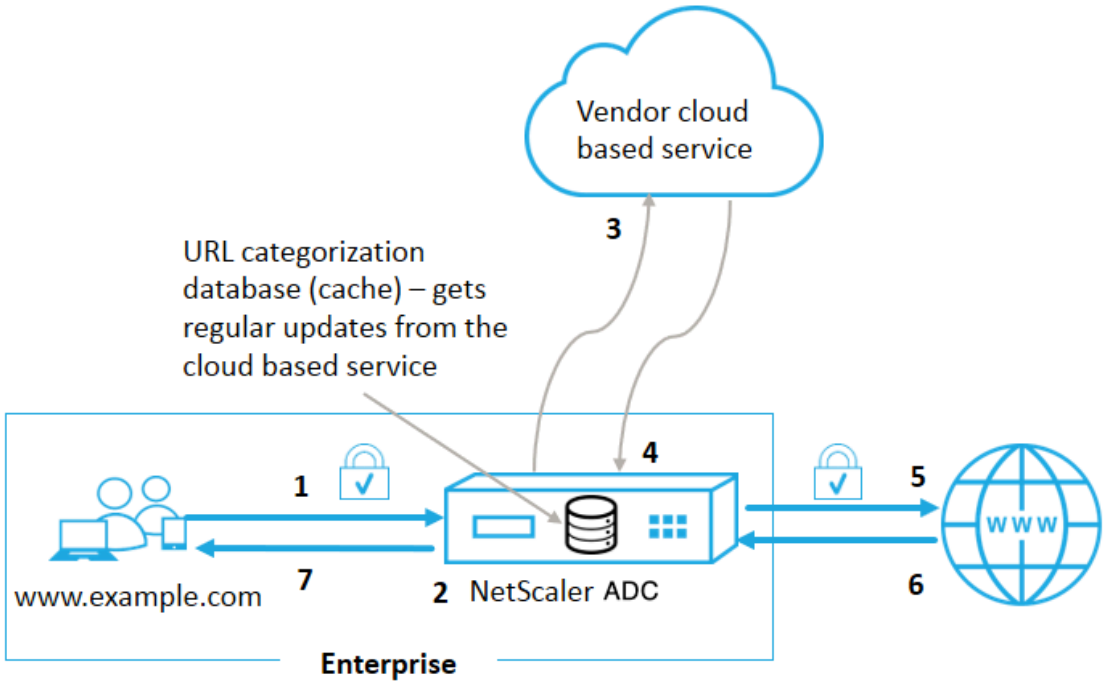
URL Categorization restricts user access to specific websites and website categories. As a subscribed service in collaboration with NetSTAR, the feature enables enterprise customers to filter web traffic using a commercial categorization database. The NetSTAR database has a vast number (billions) of URLs classified into different categories, such as social networking, gambling, adult content, new media, and shopping. In addition to categorization, each URL has a reputation score kept up to date based on the site's historical risk profile. We can use NetSTAR data to filter the traffic by configuring advanced policies based on categories, category groups (such as Terrorism, Illegal drugs), or site-reputation scores.

For example, you might block access to dangerous sites, such as sites known to be infected with malware. You might also selectively restrict access to content such as adult content or entertainment streaming media for enterprise users. You can also capture the user's transactional details and outbound traffic details for monitoring web traffic analytics on the Citrix ADM server.

Citrix ADC uploads or downloads data from the pre-configured NetSTAR device nsv10.netstar-inc.com and incompasshybridpc.netstar-inc.com is used as a cloud host by default for cloud-categorization requests. The appliance uses its NSIP address as a source IP address and 443 as the destination port for communication.

How URL categorization works

The following figure shows how a Citrix ADC URL categorization service is integrated with a commercial URL Categorization database and cloud services for frequent updates.



The components interact as follows:

1. A client sends an internet bound URL request.
2. The SSL forward proxy applies a policy enforcement to the request based on the category details, such as, category, category group, and site-reputation score. The category details are retrieved from the URL categorization database. If the database returns the category details, the process jumps to step 5.
3. If the database misses the categorization details, the request is sent to a cloud-based lookup service maintained by a URL categorization vendor. However, the appliance does not wait for a response, instead, the URL is marked as uncategorized and a policy enforcement is performed (jump to step 5). The appliance continues to monitor the cloud query feedback and updates the cache so that future requests can benefit from the cloud lookup.
4. The ADC appliance receives the URL category details (category, category group, and reputation score) from the cloud-based service and stores it in the categorization database.
5. The policy allows the URL and the request is sent to the origin server. Otherwise, the appliance drops, redirects, or responds with a custom HTML page.
6. The origin server responds with the requested data to the ADC appliance.
7. The appliance sends the response to the client.

Use Case: Internet usage under corporate compliance for enterprises

You can use the URL Filtering feature to detect and implement compliance policies to block sites that violate corporate compliance. For example, sites such as adult, streaming media, social networking which can be deemed nonproductive or consume excess internet bandwidth in an enterprise network. Blocking access to these websites can improve employee productivity, reduce operating costs for bandwidth usage, and reduce the overhead of network consumption.

Prerequisites

The URL Categorization feature works on a Citrix ADC platform only if it has an optional subscription service with URL filtering capabilities and threat intelligence for SSL forward proxy. The subscription allows customers to download the latest threat categorizations for websites and then enforce those categories on the Secure Web Gateway. Before enabling and configuring the feature, you must install the following licenses:

- CNS_WEBF_SSERVER_Retail.lic
- CNS_XXXX_SERVER_PLT_Retail.lic

Where, XXXXX is the platform type, for example: V25000

Responder policy expressions

The following table lists the different policy expressions that you can use to verify if an incoming URL must be allowed, redirected, or blocked.

1. `<text>. URL_CATEGORIZE (<min_reputation>, <max_reputation>)` - Returns a URL_CATEGORY object. If `<min_reputation>` is greater than 0, the returned object does not contain a category with a reputation lower than `<min_reputation>`. If `<max_reputation>` is greater than 0, the returned object does not contain a category with a reputation higher than `<max_reputation>`. If the category fails to resolve in a timely manner, the undef value is returned.
2. `<url_category>. CATEGORY()` - Returns the category string for this object. If the URL does not have a category, or if the URL is malformed, the returned value is “Unknown.”
3. `<url_category>. CATEGORY_GROUP()` - Returns a string identifying the object’s category group. This grouping is a higher level grouping of categories, which is useful in operations that require less detailed information about the URL category. If the URL does not have a category, or if the URL is malformed, the returned value is “Unknown.”
4. `<url_category>. REPUTATION()` - Returns the reputation score as a number from 0 to 5, where 5 indicates the riskiest reputation. If there is the category “Unknown”, the reputation value is 1.

Policy types:

1. Policy to select requests for URLs that are in the Search Engine category - `add responder policy p1 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0). CATEGORY().EQ( "Search Engine" )`
2. Policy to select requests for URLs that are in the Adult category group - `add responder policy p1 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0). CATEGORY_GROUP().EQ( "Adult" )'`
3. Policy to select requests for Search Engine URLs with a reputation score lower than 4 - `add responder policy p2 'HTTP.REQ.HOSTNAME.APPEND (HTTP.REQ.URL). URL_CATEGORIZE(4,0).HAS_CATEGORY( "Search Engine" )`
4. Policy to select requests for Search Engine and Shopping URLs - `add responder policy p3 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY ().EQ ( "good_categories" )`
5. Policy to select requests for Search Engine URLs with a reputation score equal to or greater than 4 - `add responder policy p5 'CLIENT.SSL.DETECTED_DOMAIN.URL_CATEGORIZE (4,0). CATEGORY().EQ( "Search Engines" )`
6. Policy to select requests for URLs that are in the Search Engine category and compare them with a URL Set - `'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0) . CATEGORY().EQ( "Search Engine" )&& HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ. URL).URLSET_MATCHES_ANY( "u1" )'`

Responder policy types

There are two types of policies used in a URL Categorization feature and each of these policy types is explained the following table:

Policy Type	Description
URL Category	Categorize web traffic and based on evaluation result blocks, allows, or redirects traffic.
URL Reputation Score	Determines the reputation score of the website and allows you to control access based on the reputation score threshold level set by the administrator.

Configure URL categorization

To configure URL categorization on a Citrix ADC appliance, do the following:

1. Enable URL filtering.
2. Configure a proxy server for Web traffic.

3. Configure SSL interception for Web traffic in explicit mode.
4. Configure shared memory to limit cache memory.
5. Configure URL categorization parameters.
6. Configure URL categorization by using the Citrix SSL forward proxy wizard.
7. Configure URL categorization parameters by using the SSL forward proxy wizard.
8. Configure seed database path and cloud server name

Step 1: Enabling URL Filtering

To enable URL categorization, enable the URL filtering feature and enable modes for URL categorization.

To enable URL Categorization by using the CLI

At the command prompt, type:

```
enable ns feature URLFiltering
```

```
disable ns feature URLFiltering
```

Step 2: Configure a proxy server for web traffic in explicit mode

The Citrix ADC appliance supports transparent and explicit proxy virtual servers. To configure a proxy virtual server for SSL traffic in explicit mode, do the following:

1. Add a proxy server.
2. Bind an SSL policy to the proxy server.

To add a proxy server by using the CLI

At the command prompt, type:

```
add cs vserver <name> [-td <positive_integer>] <serviceType> [-cltTimeout <
secs>]
```

Example:

```
add cs vserver starcs PROXY 10.102.107.121 80 -cltTimeout 180
```

Bind an SSL policy to a proxy virtual server by using the CLI

```
bind ssl vserver <vServerName> -policyName <string> [-priority <positive_integer
>]
```

Step 3: Configure SSL interception for HTTPS traffic

To configure SSL interception for HTTPS traffic, do the following:

1. Bind a CA certificate-key pair to the proxy virtual server.
2. Configure the default SSL profile with SSL parameters.
3. Bind a front-end SSL profile to the proxy virtual server and enable SSL interception in the front-end SSL profile.

To bind a CA certificate-key pair to the proxy virtual server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -
skipCAName
```

To configure the default SSL profile by using the CLI

At the command prompt, type:

```
set ssl profile <name> -denySSLReneg <denySSLReneg> -sslInterception (
ENABLED | DISABLED)-ssliMaxSessPerServer positive_integer>
```

Bind a front-end SSL profile to a proxy virtual server by using the CLI

At the command prompt, type:

```
set ssl vserver <vServer name> -sslProfile ssl_profile_interception
```

Step 4: Configure shared memory to limit cache memory

To configure shared memory to limit cache memory by using the CLI

At the command prompt, type:

```
set cache parameter [-memLimit <megaBytes>]
```

Where, the memory limit configured for caching is set as 10 MB.

Step 5: Configure URL categorization parameters

To configure the URL categorization parameters by using the CLI

At the command prompt, type:

```
set urlfiltering parameter [-HoursBetweenDBUpdates <positive_integer>] [-
TimeOfDayToUpdateDB <HH:MM>]
```

Example:

```
set urlfiltering parameter -urlfilt_hours_betweenDB_updates 20
```

Step 6: Configure URL Categorization by using the Citrix SSL forward proxy wizard

1. Log on to the Citrix ADC appliance and navigate to **Security** > **SSL Forward Proxy** page.
2. In the details pane, do one of the following:
   a) Click **SSL Forward Proxy Wizard** to create a new configuration.
   b) Select an existing configuration and click **Edit**.
3. In the **URL Filtering** section, click **Edit**.
4. Select the **URL Categorization** check box to enable the feature.
5. Select a **URL Categorization** policy and Click **Bind**.
6. Click **Continue** and then **Done**.

For more information about URL Categorization policy, see How to Create a URL Categorization Policy.

Step 7: Configuring URL Categorization parameters by using an SSL forward proxy Wizard

1. Log on to **Citrix ADC** appliance and navigate to **Security > URL Filtering**.
2. In the **URL Filtering** page, click **Change URL filtering settings** link.
3. In the **Configuring URL Filtering Params** page, specify the following parameters.
   a) Hours Between DB Updates. URL Filtering hours between database updates. Minimum value: 0 and Maximum value: 720.
   b) Time of Day to Update DB. URL Filtering time of day to update database.
   c) Cloud Host. The URL path of the cloud server.
   d) Seed DB Path. The URL path of the seed database lookup server.
4. Click **OK** and **Close**.

Sample Configuration:

```
enable ns feature LB CS SSL IC RESPONDER AppFlow URLFiltering

enable ns mode FR L3 Edge USNIP PMTUD

set ssl profile ns_default_ssl_profile_frontend -denySSLReneg NONSECURE
    -sslInterception ENABLED -ssliMaxSessPerServer 100

add ssl certKey swg_ca_cert -cert ns_swg_ca.crt -key ns_swg_ca.key

set cache parameter -memLimit 100

add cs vserver starcs PROXY 10.102.107.121 80 -cltTimeout 180

add responder action act1 respondwith "\"HTTP/1.1 200 OK\r\n\r\n\" +
   http.req.url.url_categorize(0,0).reputation + \"\n\""

```

```
15 add responder policy p1 "HTTP.REQ.URL.URL_CATEGORIZE(0,0).CATEGORY.eq
   (\"Shopping/Retail\") || HTTP.REQ.URL.URL_CATEGORIZE(0,0).CATEGORY.
   eq(\"Search Engines & Portals
16
17 \")" act1
18
19 bind cs vserver starcs_PROXY -policyName p1 -priority 10 -
   gotoPriorityExpression END -type REQUEST
20
21 add dns nameServer 10.140.50.5
22
23 set ssl parameter -denySSLReneg NONSECURE -defaultProfile ENABLED -
   sigDigestType RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-SHA256 RSA-SHA384 RSA-
   SHA512 -ssliErrorCache ENABLED
24
25 -ssliMaxErrorCacheMem 100000000
26
27 add ssl policy pol1 -rule "client.ssl.origin_server_cert.subject.
   URL_CATEGORIZE(0,0).CATEGORY.eq(\"Search Engines & Portals\")"" -
   action INTERCEPT
28
29 add ssl policy pol3 -rule "client.ssl.origin_server_cert.subject.ne(\"
   citrix\")" -action INTERCEPT
30
31 add ssl policy swg_pol -rule "client.ssl.client_hello.SNI.
   URL_CATEGORIZE(0,0).CATEGORY.ne(\"Uncategorized\")" -action
   INTERCEPT
32
33 set urlfiltering parameter -HoursBetweenDBUpdates 3 -
   TimeOfDayToUpdateDB 03:00
34 <!--NeedCopy-->
```

Configure seed database path and cloud server name

You can now configure the seed database path and cloud lookup server name for manual setting of the cloud lookup server name and the seed database path. To do this, two new parameters, “CloudHost” and “SeedDBPath”, are added to the URL filtering parameter.

At the command prompt, type:

```
set urlfiltering parameter [-HoursBetweenDBUpdates <positive_integer>] [-
TimeOfDayToUpdateDB <HH:MM>] [-LocalDatabaseThreads <positive_integer>] [-
CloudHost <string>] [-SeedDBPath <string>]
```

Example:

```
set urlfiltering parameter -HoursBetweenDBUpdates 3 -TimeOfDayToUpdateDB
03:00 -CloudHost localhost -SeedDBPath /mypath
```

The Communication between a Citrix ADC appliance and NetSTAR might require a domain name server. You can test using a simple console or telnet connection from the appliance.

Example:

```
root@ns# telnet nsv10.netstar-inc.com 443
Trying 1.1.1.1...
Connected to nsv10.netstar-inc.com.
Escape character is '^]'.

root@ns# telnet incompasshybridpc.netstar-inc.com 443
Trying 10.10.10.10...
Connected to incompasshybridpc.netstar-inc.com.
Escape character is '^]'.
<!--NeedCopy-->
```

Configure audit log messaging

Audit logging enables you to review a condition or a situation in any phase of the URL Categorization process. When a Citrix ADC appliance receives an incoming URL, if the responder policy has a URL Filtering expression, the audit log feature collects URL Set information in the URL. It stores the information as log messages for any target allowed by audit logging.

- Source IP address (the IP address of the client that made the request).
- Destination IP address (the IP address of the requested server).
- Requested URL containing the schema, the host, and the domain name (http://www.example.com).
- URL category that the URL filtering framework returns.
- URL category group that the URL filtering framework returned.
- URL reputation number that the URL filtering framework returned.
- Audit log action taken by the policy.

To configure audit logging for a URL List feature, you must complete the following tasks:

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging topic.

Storing failure errors using SYSLOG messaging

At any stage of the URL Filtering process, if there is a system-level failure, the ADC appliance uses the audit log mechanism to store logs in the ns.log file. The errors are stored as text messages in SYSLOG format so that, an administrator can view it later in a chronological order of event occurrence. These logs are also sent to an external SYSLOG server for archival. For more information, see article CTX229399.

For example, if a failure occurs when you initialize the URL Filtering SDK, the error message is stored in the following messaging format.

```
Oct 3 15:43:40 <local0.err> ns URLFiltering[1349]: Error initializing
NetStar SDK (SDK error=-1). (status=1).
```

The Citrix ADC appliance stores the error messages under four different failure categories:

- **Download failure**. If an error occurs when you try to download the categorization database.
- **Integration failure**. If an error occurs when you integrate an update into the existing categorization database.
- **Initialization failure**. If an error occurs when you initialize the URL Categorization feature, set categorization parameters, or end a categorization service.
- **Retrieval failure**. If an error occurs when the appliance retrieves the categorization details of the request.

Configure SNMP traps for NetSTAR events

The URL Filtering feature generates SNMP traps, if the following conditions occur:

- NetSTAR database update fails or succeeds.
- NetSTAR SDK initialization fails or succeeds.

The appliance has a set of conditional entities called SNMP alarms. When a condition in the SNMP alarm is met, the appliance generates traps and sends it to a specified trap destination. For example, if the NetSTAR SDK initialization fails, an SNMP OID 1.3.6.1.4.1.5951.1.1.0.183 is generated and sent to the trap destination.

For the appliance to generate traps, you must first enable and configure SNMP alarms. Then, you specify the trap destination to which the appliance sends the generated trap messages

Enable an SNMP alarm

The Citrix ADC appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the URL filtering feature generates trap messages when a success or failure event occurs. Some alarms are enabled by default.

To enable an SNMP alarm by using the command line interface:

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
enable snmp alarm <trapName>
show snmp alarm <trapName>
```

To enable an SNMP alarm by using the Citrix ADC GUI

1. Navigate to **System** > **SNMP** > **Alarms**, and select the alarm.
2. Click **Actions** and select **Enable**.

Configure SNMP alarm by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue
 <positive_integer>]] [-time <secs>] [-state ( ENABLED | DISABLED )] [-
severity <severity>] [-logging ( ENABLED | DISABLED )]
```

Example:

```
set snmp alarm URL-FIL-DB-UPDATE-STATUS -state ENABLED
set snmp alarm URL-FIL-INIT-SDK -state ENABLED
```

Configure SNMP alarms by using the GUI

Navigate to **System** > **SNMP** > **Alarms**, select an alarm, and configure the alarm parameters.

For more information about SNMP traps, see SNMP topic

URL reputation score

September 14, 2021

The URL Categorization feature provides policy-based control to restrict blacklisted URLs. You can control access to websites based on URL category, reputation score, or URL category and reputation score. If network administrators monitor a user accessing highly risky websites, they can use a responder policy bound to the URL reputation score to block such risky websites.

Upon receiving an incoming URL request, the appliance retrieves the category and reputation score from the URL categorization database. Based on the reputation score returned by the database, the

appliance assigns a reputation rating for websites. The value can range from 1 to 4, where 4 is the riskiest type of websites, as shown in the following table.

URL Reputation Rating	Reputation Comment
1	Clean site
2	Unknown site
3	Potentially dangerous or affiliated to a dangerous site
4	Malicious site

Use Case: Filtering by URL reputation score

Consider an enterprise organization with a network administrator monitoring user transactions and network bandwidth consumption. If malware can enter the network, the administrator must enhance the data security and control access to malicious and dangerous websites accessing the network. To protect the network against such threats, the administrator can configure the URL filtering feature to allow or deny access by URL reputation score.

For more information about monitoring outbound traffic and user activities on the network, see Analytics.

If an employee of the organization tries to access a social networking website, the ADC appliance receives a URL request. It queries the URL Categorization database to retrieve the URL category as social networking and a reputation score 3, which indicates a potentially dangerous website. The appliance then checks the security policy configured by the administrator, such as block access to sites with a reputation rating of 3 or more. It then applies the policy action to control access to the website.

To implement this feature, you must configure the URL reputation score and security threshold levels by using the SSL Forward Proxy wizard.

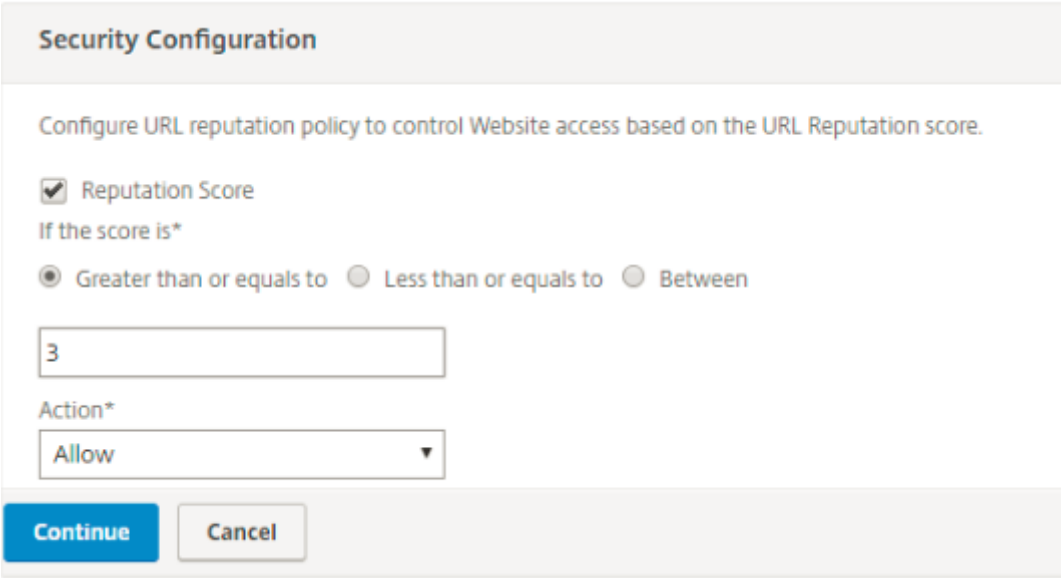
Configure reputation score by using the GUI

Citrix recommends that you use the SSL forward proxy wizard to configure the reputation score and security levels. Based on the configured threshold, you can select a policy action to allow, block, or redirect traffic.

1. Navigate to **Security** > **SSL Forward Proxy**.
2. In the details pane, click **SSL Forward Proxy Wizard**.
3. In the details page, specify the proxy server settings.
4. Click **Continue** to specify other settings such as SSL interception and identify management.

5. Click **Continue** to access the **Security Configuration** section.
6. In the **Security Configuration** section, select the **Reputation Score** check box to control access based on URL reputation score.
7. Select the security level and specify the reputation score threshold value:
   a) Greater than or equals to—Allow or block a website if the threshold value is greater than or equal to N, where N ranges from one to four.
   b) Less than or equals to— Allow or block a website if the threshold value is less than or equal to N, where N ranges from one to four.
   c) In between— Allow or block a website if the threshold value is between N1 and N2 and the range is from one to four.
8. Select a responder action from the drop-down list.
9. Click **Continue** and **Close**.

The following image shows the **Security Configuration** section on the SSL Forward Proxy wizard. Enable the URL Reputation Score option to configure the policy settings.



Analytics

September 14, 2021

In the Citrix ADC appliance, all the user records and subsequent records are logged. When you integrate Citrix Application Delivery Management (ADM) with the Citrix ADC appliance, the logged user activity and the subsequent records in the appliance are exported to Citrix ADM using the `logstream` feature.

Citrix ADM collates and presents information on the activities of users, such as, websites visited and

the bandwidth spent. It also reports bandwidth use and detected threats, such as malware and phishing sites. You can use these key metrics to monitor your network and take corrective actions with the Citrix SWG appliance. For more information, see Citrix SSL Forward Proxy Analytics.

To integrate Citrix ADC appliance with Citrix ADM:

1. In the Citrix ADC appliance, while configuring the SSL forward proxy feature, enable Analytics and provide the details of the Citrix ADM instance that you want to use for analytics.
2. In Citrix ADM, add the Citrix ADC appliance as an instance to Citrix ADM. For more information see Add Instances to Citrix ADM.

Use case: Making an enterprise network secure by using ICAP for remote malware inspection

September 14, 2021

The Citrix ADC appliance acts as a proxy and intercepts all the client traffic. The appliance uses policies to evaluate the traffic and forwards client requests to the origin server on which the resource resides. The appliance decrypts the response from the origin server and forwards the plain text content to the ICAP server for an antimalware check. The ICAP server responds with a message indicating "No adaptation required," or error, or modified request. Depending on the response from the ICAP server, the content requested is either forwarded to the client, or an appropriate message is sent.

For this use case, you must perform some general configuration, proxy and SSL interception related configuration, and ICAP configuration on the Citrix ADC appliance.

General configuration

Configure the following entities:

- NSIP address
- Subnet IP (SNIP) address
- DNS name server
- CA certificate-key pair to sign the server certificate for SSL interception

Proxy server and SSL interception configuration

Configure the following entities:

- Proxy server in explicit mode to intercept all outbound HTTP and HTTPS traffic.
- SSL profile to define SSL settings, such as ciphers and parameters, for connections.

- SSL policy to define rules for intercepting traffic. Set to true to intercept all client requests.

For more details, see the following topics:

- Proxy modes
- SSL interception

In the following sample configuration, the antimalware detection service resides at `www.example.com`.

Sample general configuration:

```
add dns nameServer 203.0.113.2

add ssl certKey ns-swg-ca-certkey -cert ns_swg_ca.crt -key ns_swg_ca.key
<!--NeedCopy-->
```

Sample proxy server and SSL interception configuration:

```
add cs vserver explicitswg PROXY 192.0.2.100 80 -Authn401 ENABLED -authnVsName explicit-auth-vs

set ssl parameter -defaultProfile ENABLED

add ssl profile swg_profile -sslInterception ENABLED

bind ssl profile swg_profile -ssliCACertkey ns-swg-ca-certkey

set ssl vserver explicitswg -sslProfile swg_profile

add ssl policy ssli-pol_ssli -rule true -action INTERCEPT

bind ssl vserver explicitswg -policyName ssli-pol_ssli -priority 100 -type INTERCEPT_REQ
<!--NeedCopy-->
```

Sample ICAP Configuration:

```
add service icap_svc 203.0.113.225 TCP 1344

enable ns feature contentinspection

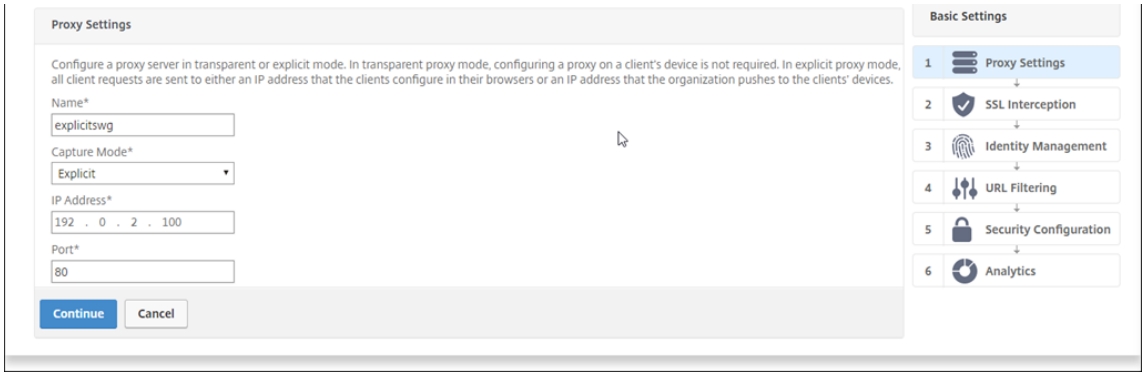
add icapprofile icapprofile1 -uri /example.com -Mode RESMOD

add contentInspection action CiRemoteAction -type ICAP -serverName icap_svc -icapProfileName icapprofile1
```

```
8
9  add contentInspection policy CiPolicy -rule "HTTP.REQ.METHOD.NE("
       CONNECT")" -action CiRemoteAction
10
11 bind cs vserver explicitswg -policyName  CiPolicy -priority 200 -type
       response
12 <!--NeedCopy-->
```

Configure the proxy settings

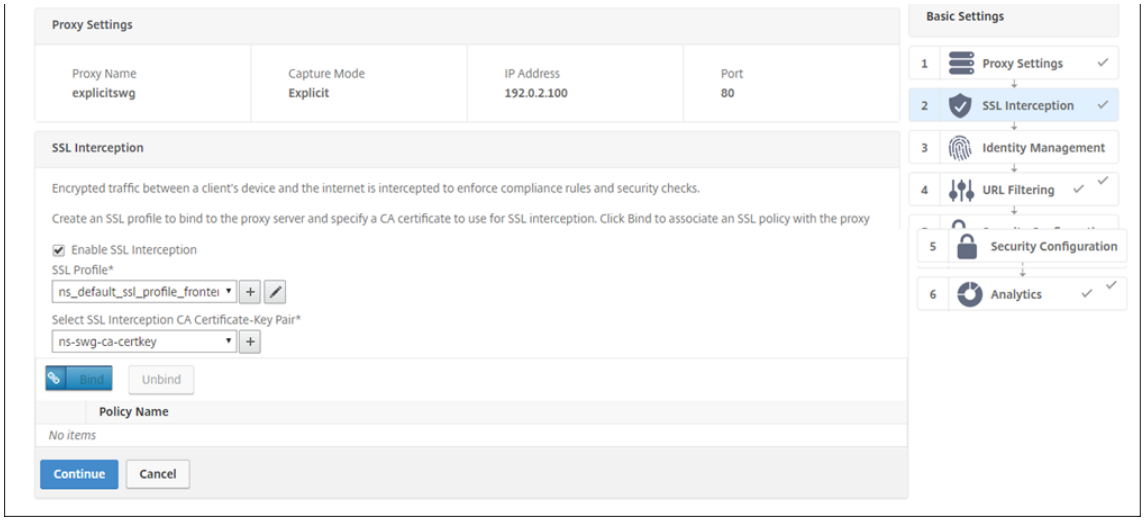
1. Navigate to **Security** > **SSL Forward Proxy** > **SSL Forward Proxy Wizard**.
2. Click **Get Started** and then click **Continue**.
3. In the **Proxy Settings** dialog box, enter a name for the explicit proxy server.
4. For **Capture Mode,** select **Explicit**.
5. Enter an IP address and port number.



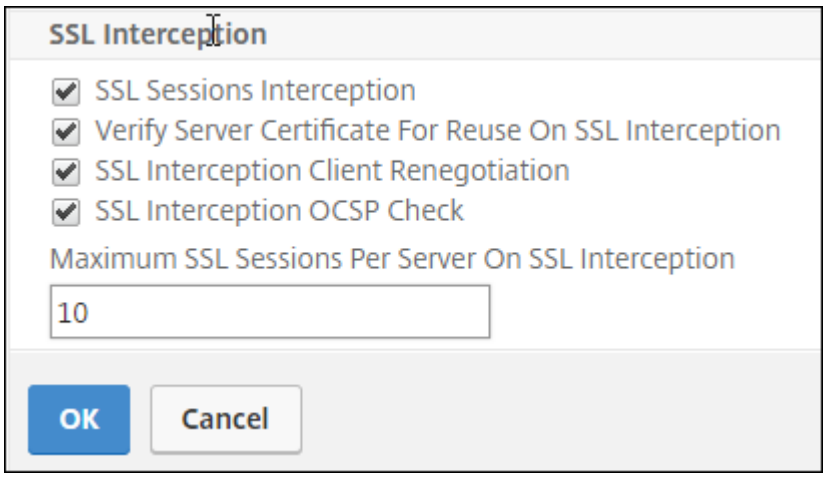
6. Click **Continue**.

Configure the SSL interception settings

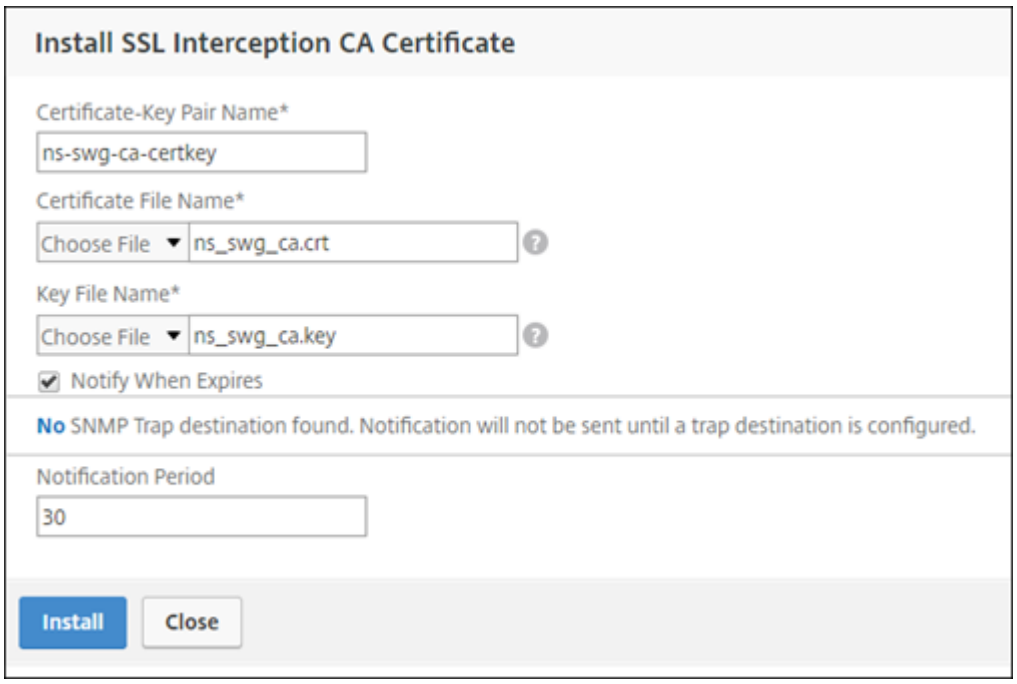
1. Select **Enable SSL Interception**.



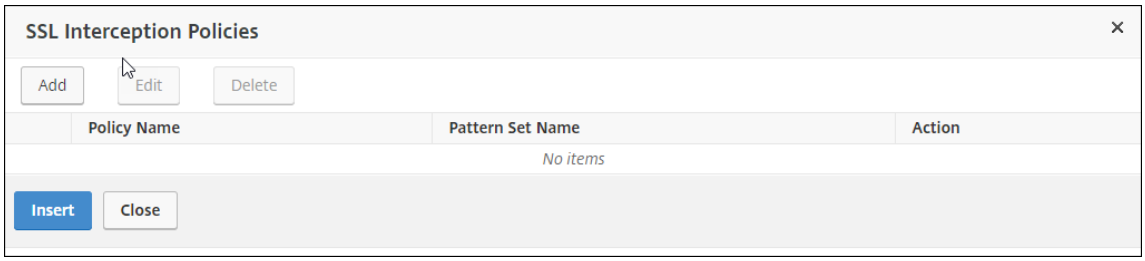
2. In **SSL Profile**, select an existing profile or click "+" to add a new front-end SSL profile. Enable **SSL Sessions Interception** in this profile. If you select an existing profile, skip the next step.



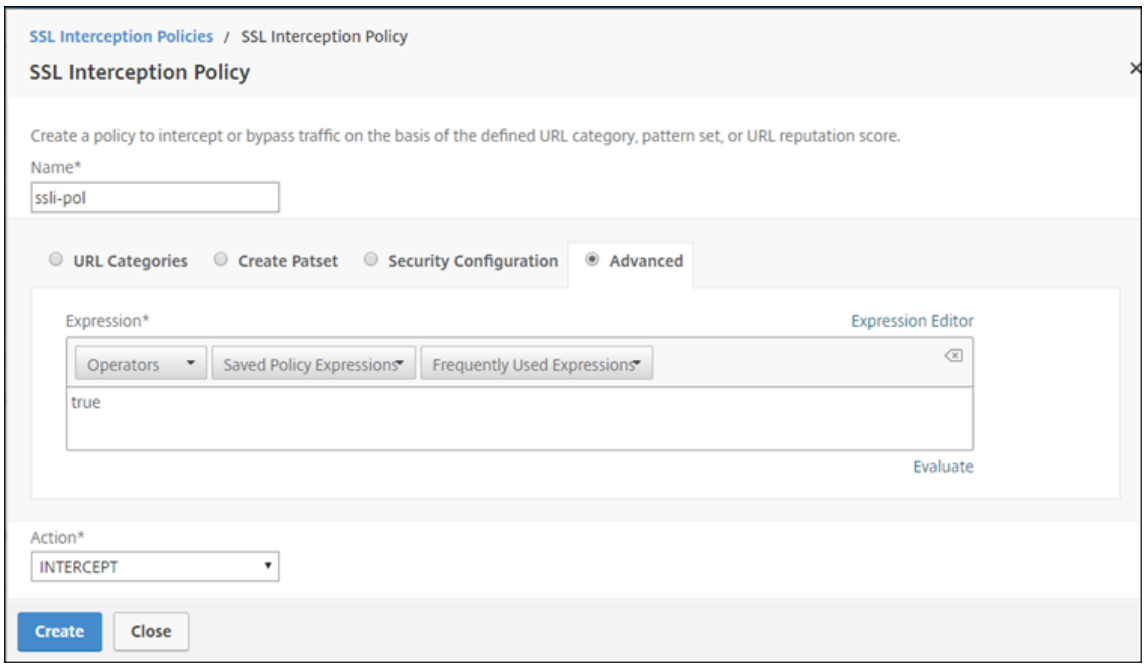
3. Click **OK** and then click **Done**.
4. In **Select SSL interception CA Certificate-Key Pair**, select an existing certificate or click "+" to install a CA certificate-key pair for SSL interception. If you select an existing certificate, skip the next step.



5. Click **Install** and then click **Close**.
6. Add a policy to intercept all the traffic. Click **Bind**. Click **Add** to add a new policy or select an existing policy. If you select an existing policy, click **Insert**, and skip the next three steps.



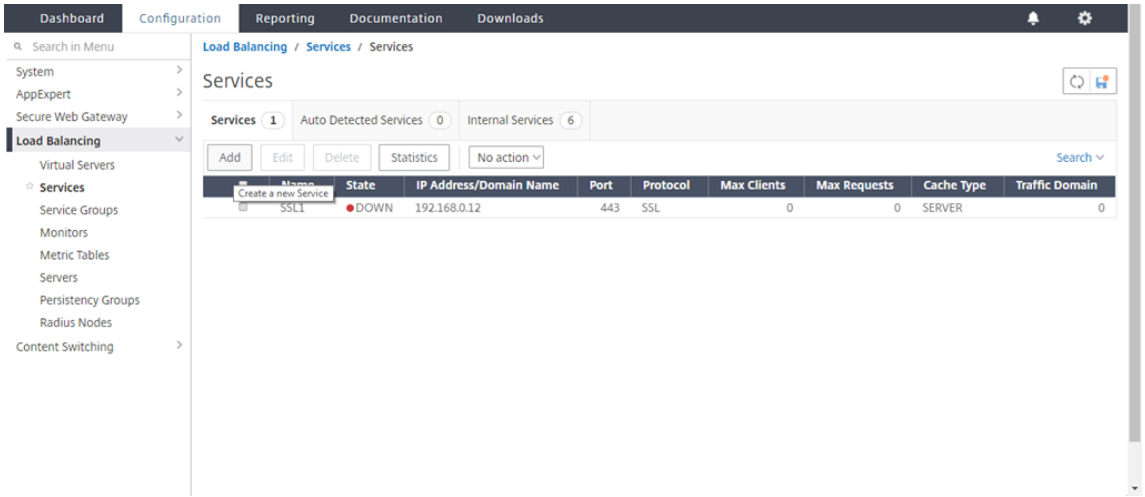
7. Enter a name for the policy and select **Advanced**. In the Expression editor, enter true.
8. For **Action**, select **INTERCEPT**.



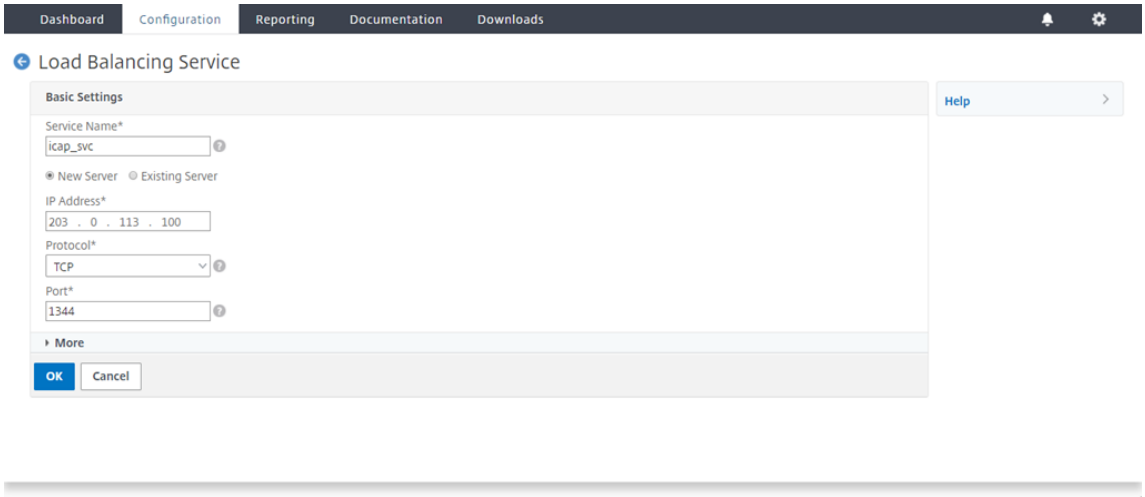
9. Click **Create**.
10. Click **Continue** four times, and then click **Done**.

Configure the ICAP settings

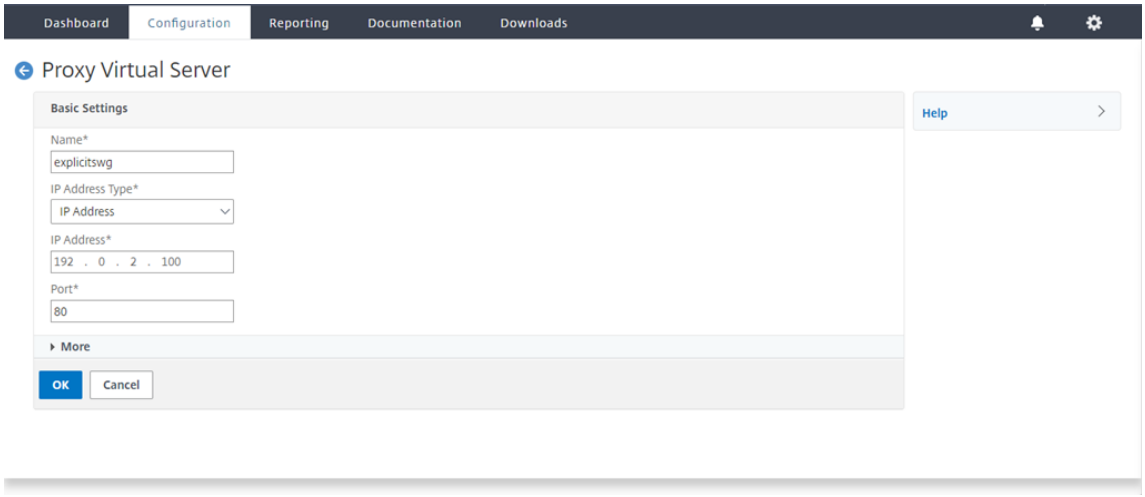
1. Navigate to **Load Balancing** > **Services** and click **Add**.



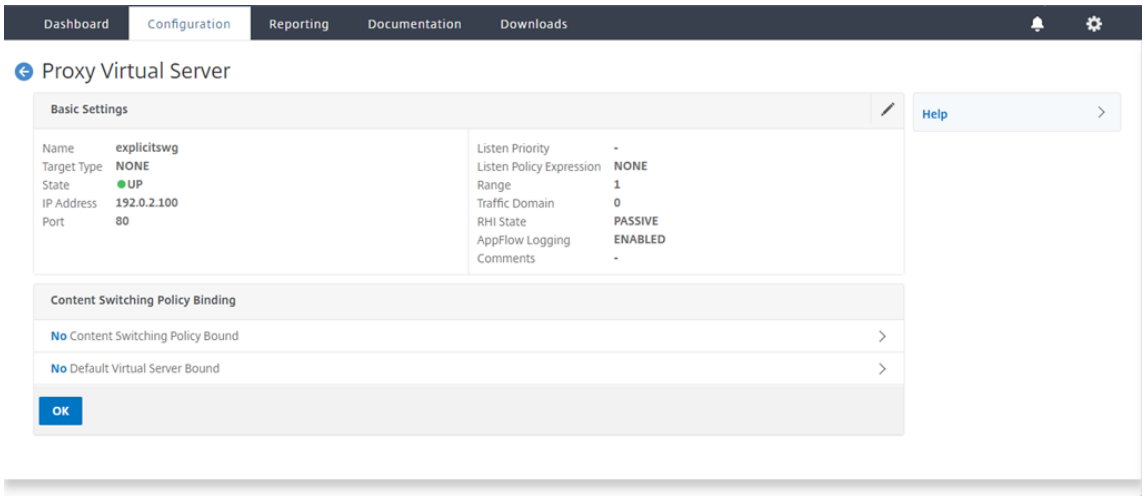
2. Type a name and IP address. In **Protocol**, select **TCP**. In **Port**, type **1344**. Click **OK**.



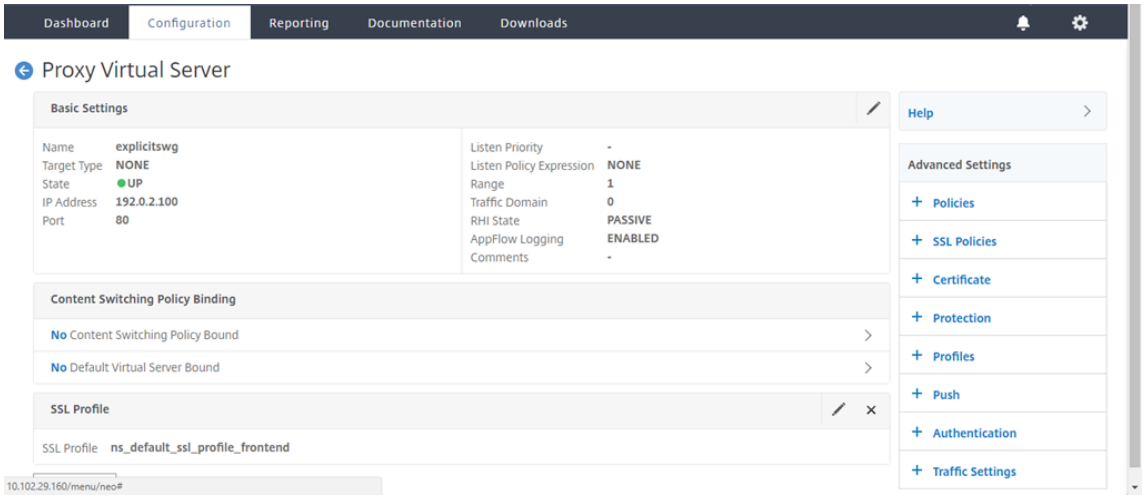
3. Navigate to **SSL Forward Proxy** > **Proxy Virtual Servers**. Add a proxy virtual server or select a virtual server and click **Edit**. After entering details, click **OK**.



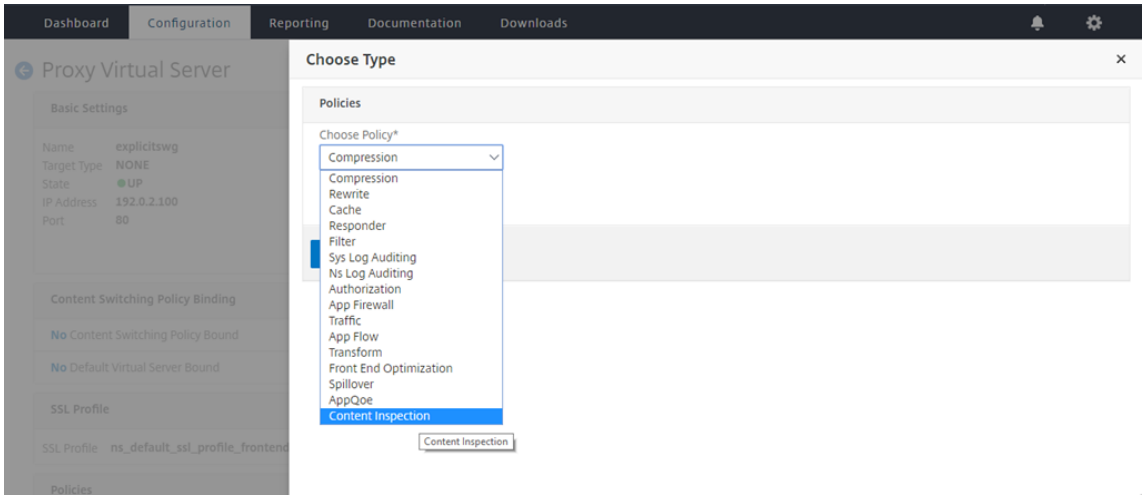
Click **OK** again.



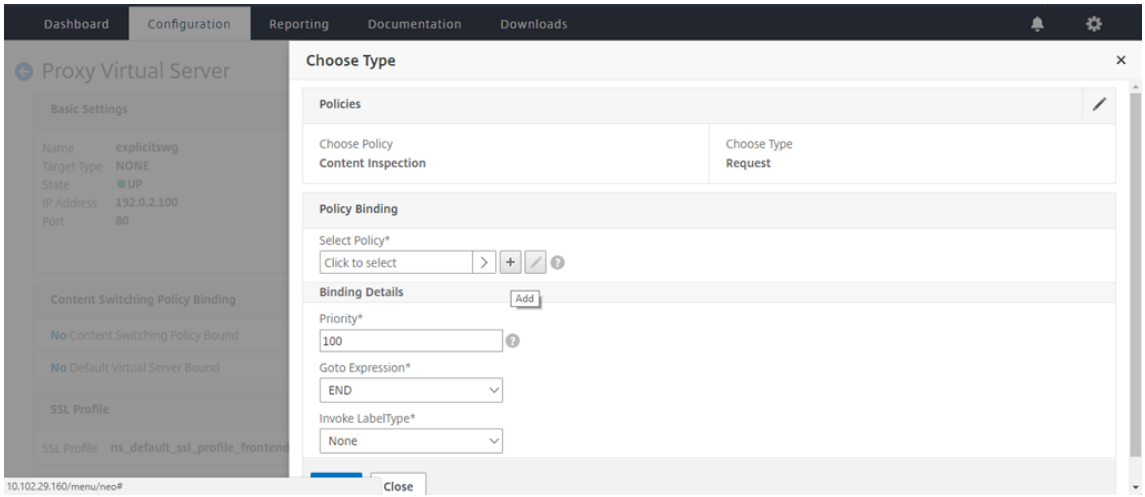
4. In **Advanced Settings**, click **Policies**.



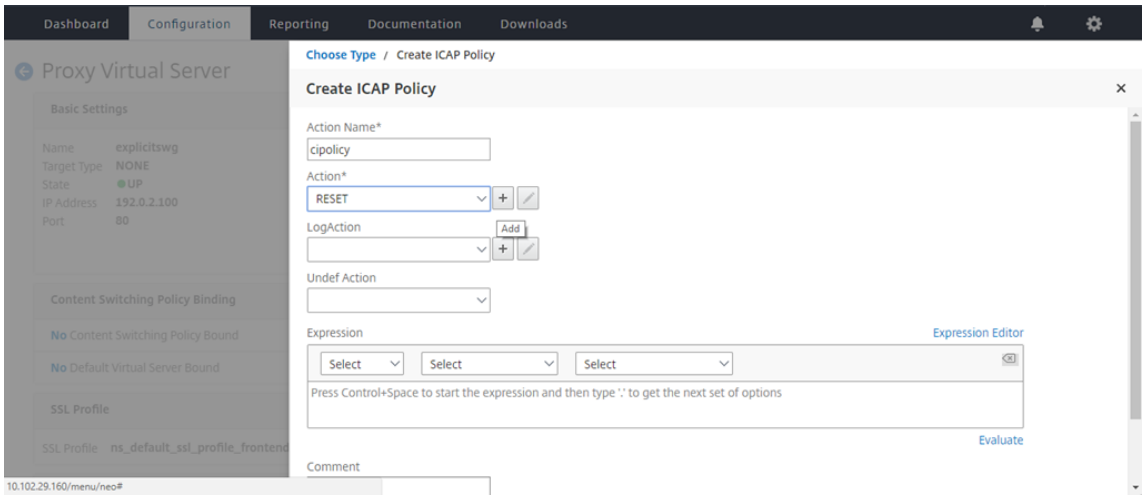
5. In **Choose Policy**, select **Content Inspection**. Click **Continue**.



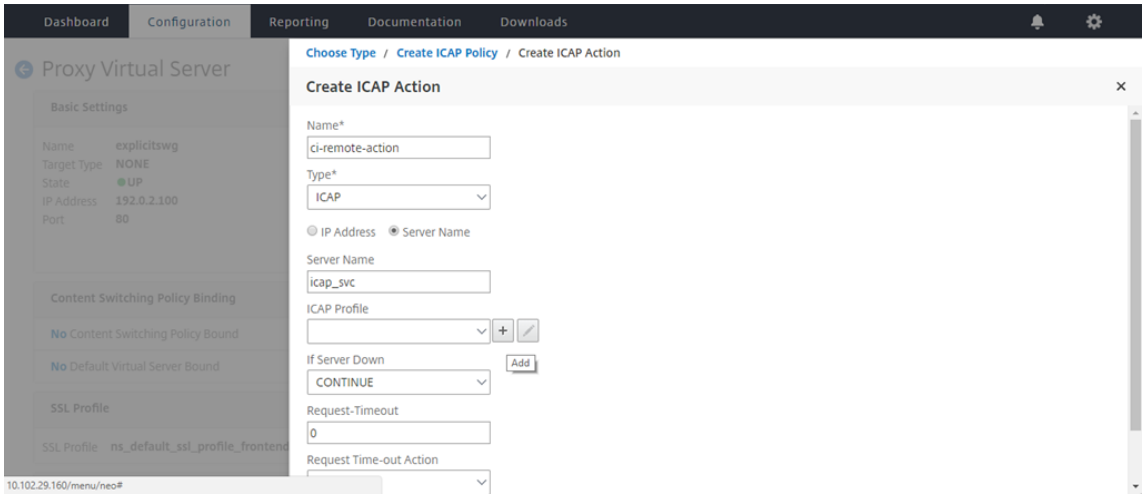
6. In **Select Policy**, click the “+” sign to add a policy.



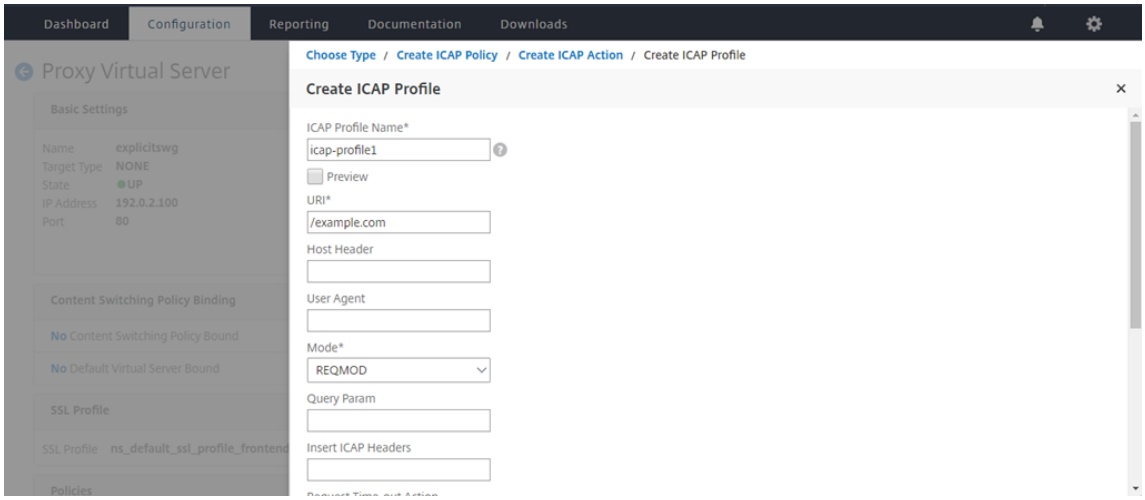
7. Enter a name for the policy. In **Action**, click the “+” sign to add an action.



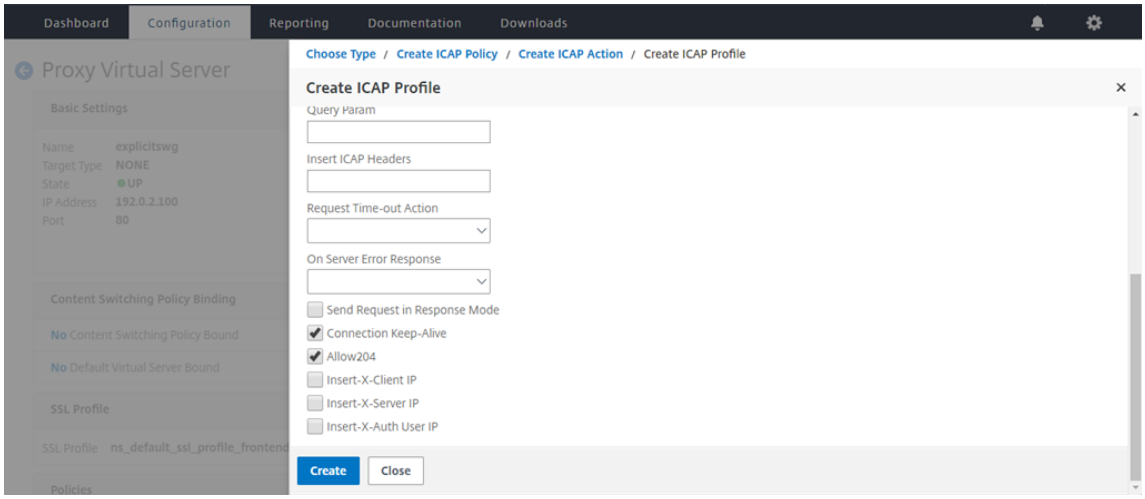
8. Type a name for the action. In **Server Name**, type the name of the TCP service created earlier. In **ICAP Profile**, click the “+” sign to add an ICAP profile.



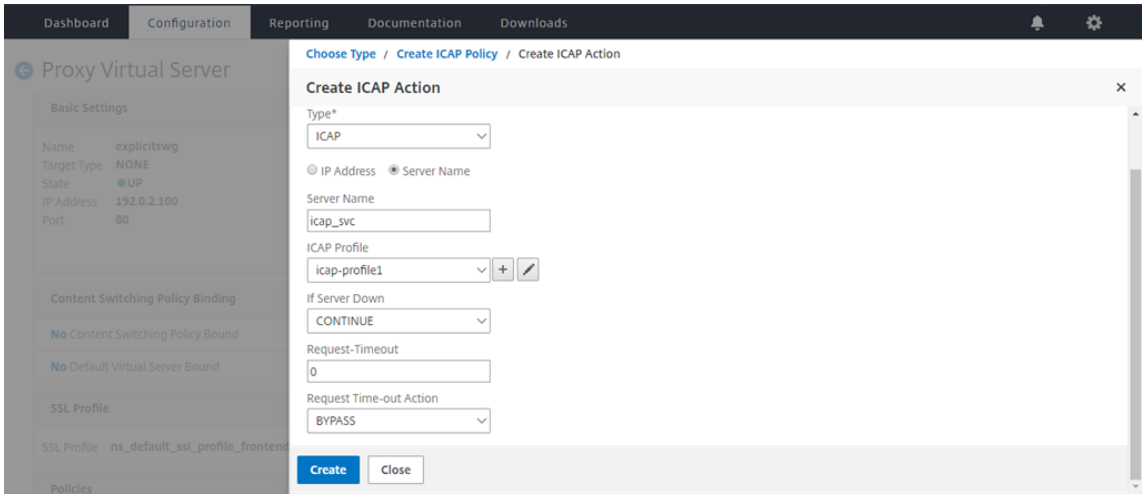
9. Type a profile name, URI. In **Mode**, select **REQMOD**.



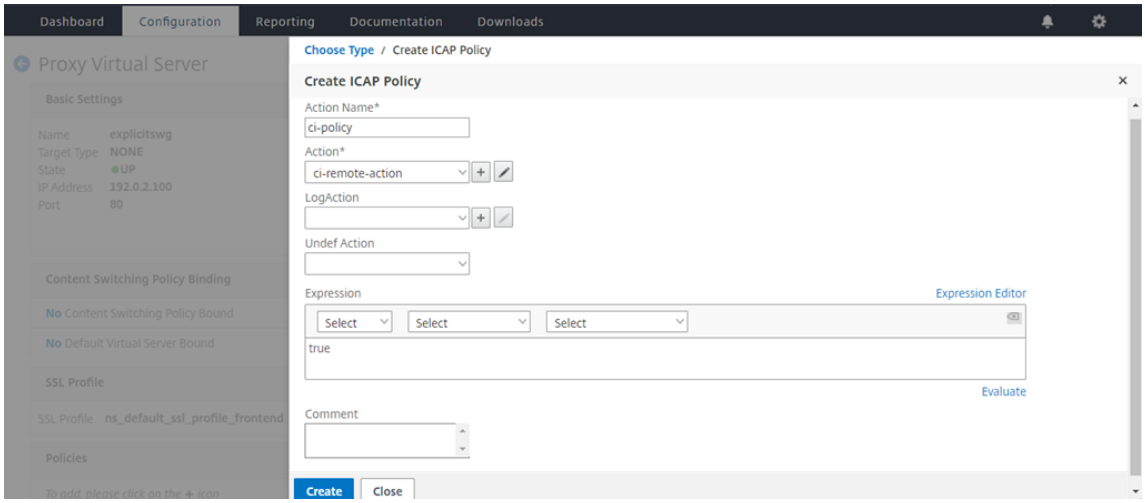
10. Click **Create**.



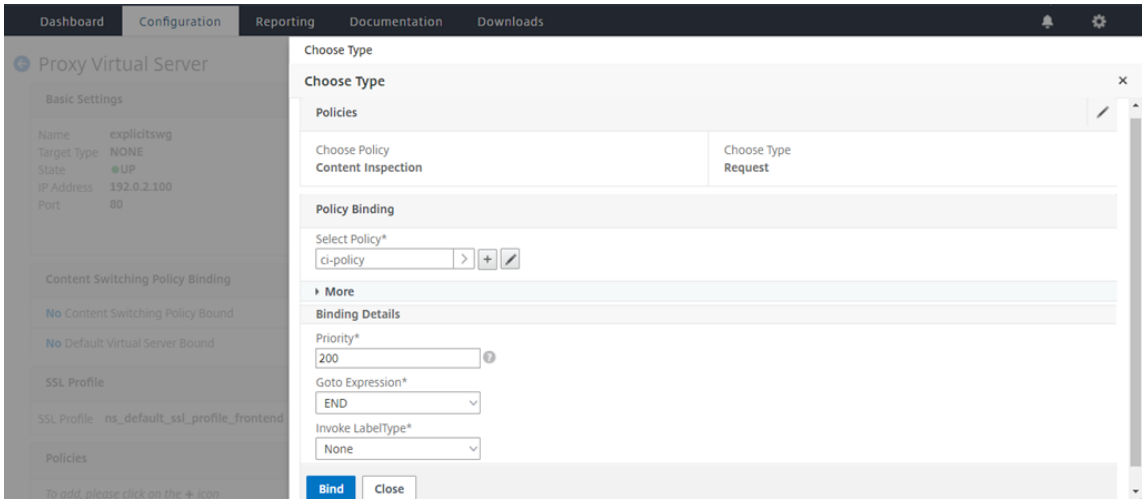
11. In the **Create ICAP Action** page, click **Create**.



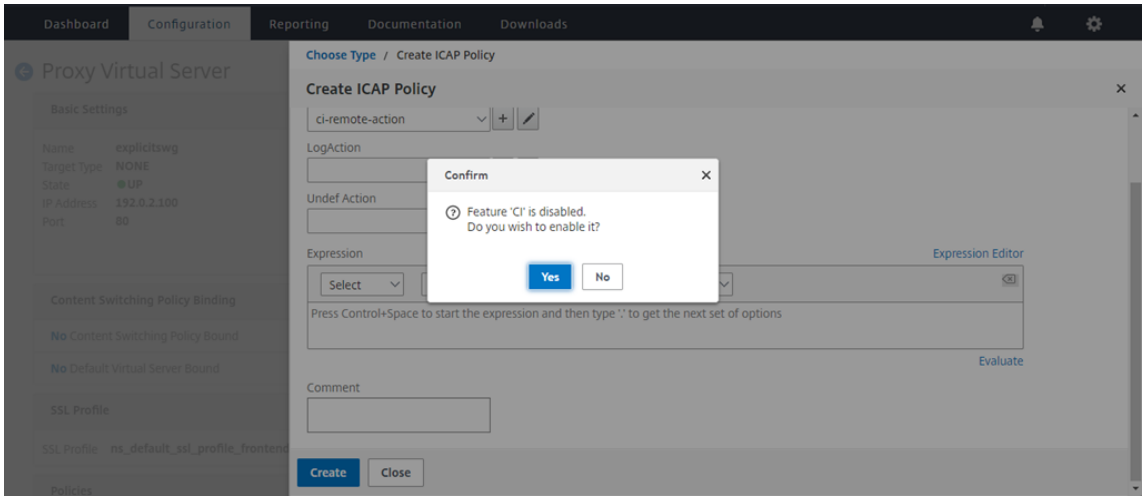
12. In the **Create ICAP Policy** page, enter true in the **Expression Editor**. Then, click **Create**.



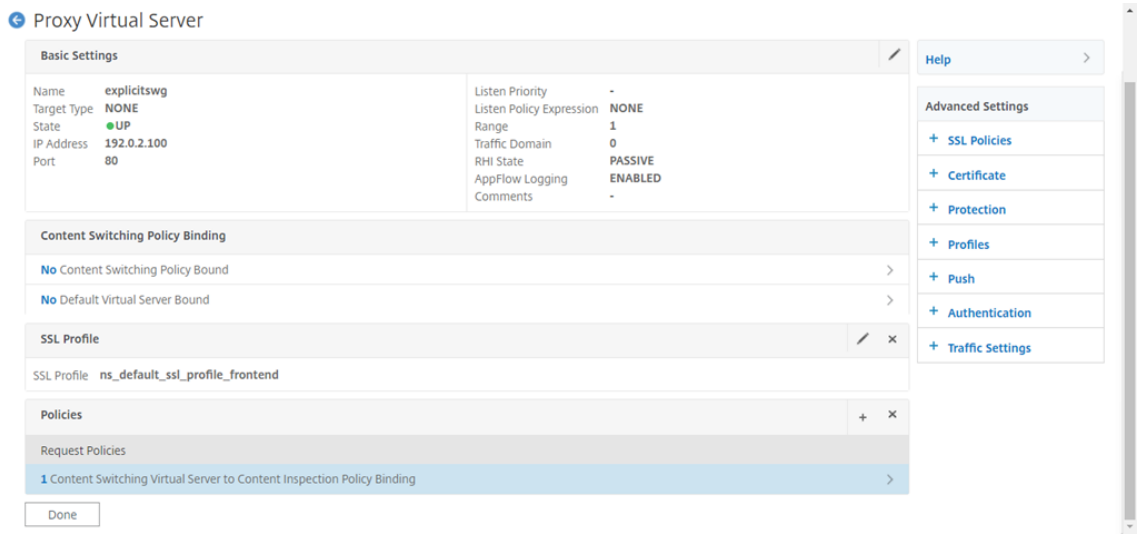
13. Click **Bind**.



14. When prompted to enable the content inspection feature, select **Yes**.



15. Click **Done**.



Sample ICAP transactions between the Citrix ADC appliance and the ICAP server in RESPMOD

Request from the Citrix ADC appliance to the ICAP server:

```
RESPMOD icap://10.106.137.15:1344/resp ICAP/1.0

Host: 10.106.137.15

Connection: Keep-Alive

Encapsulated: res-hdr=0, res-body=282

HTTP/1.1 200 OK

Date: Fri, 01 Dec 2017 11:55:18 GMT

Server: Apache/2.2.21 (Fedora)

Last-Modified: Fri, 01 Dec 2017 11:16:16 GMT

ETag: "20169-45-55f457f42aee4"

Accept-Ranges: bytes

Content-Length: 69

Keep-Alive: timeout=15, max=100

```

How-to articles

September 14, 2021

Following are some configuration instructions or functional use cases available as “How to” articles to help you manage your SSL forward proxy deployment.

URL filtering

How to create a URL categorization policy

How to create a URL list policy

How to allow an exceptional URL

How to block adult category websites

Security

September 14, 2021

The following topics cover configuration and installation information for Citrix ADC security features. Most of these features are policy based.

Content Filtering	Blocks inappropriate HTML requests, preventing the requests from reaching the Web servers.
Surge Protection	Detects any rapid rise in connection attempts and adjusts the rate at which connections are allowed to proceed to the server, preventing server overload.
DNS Security Options	Simplified UI wizard to create policies to protect against DNS attacks.

Content filtering

September 16, 2021

> **Warning:**
>
> Filter actions are deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the Responder, Rewrite, or Content Switching features. However, Filter actions are removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see Responder, Rewrite, or Content Switching topics.

Content filtering can do some of the same tasks as the Citrix Web App Firewall, and is a less CPU-intensive tool. It is limited, however, to examining the header portion of the HTTP request or response and to performing a few simple actions on connections that match. If you have a complex website that makes extensive use of scripts and accesses back-end databases, the Application Firewall might be the better tool for protecting that website. For more information about the Citrix Web App Firewall, see Application Firewall.

Content filtering is based on regular expressions that you can apply to either HTTP requests or HTTP responses. To block requests from a particular site, for example, you can use an expression that compares each request's URL to the URL specified in the expression. The expression is part of a policy, which also specifies an action to be performed on requests or responses that match the expression. For example, an action might drop a request or reset the connection.

Following are some examples of things you can do with content filtering policies:

- Prevent users from accessing certain parts of your websites unless they are connecting from authorized locations.
- Prevent inappropriate HTTP headers from being sent to your Web server, possibly breaching security.
- Redirect specified requests to a different server or service.

To configure content filtering, once you have made sure that the feature is enabled, you configure filtering actions for your servers to perform on selected connections (unless the predefined actions are adequate for your purposes). Then you can configure policies to apply the actions to selected connections. Your policies can use predefined expressions, or you can create your own. To activate the policies you configured, you bind them either globally or to specific virtual servers.

Enabling content filtering

September 14, 2021

By default, content filtering is enabled on Citrix ADC appliances running the Citrix ADC operating system 8.0 or above. If you are upgrading an existing appliance from an operating system version earlier than 8.0, you must update the licenses before you can use content filtering, and you might need to enable the content filtering feature itself manually.

Enable content filtering by using the CLI

At the command prompt, type the following commands to enable content filtering and verify the configuration:

```
-  enable ns feature ContentFiltering
-  show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature ContentFiltering
 Done
> show ns feature

        Feature                         Acronym              Status
        -------                         -------              ------
 1)     Web Logging                     WL                   ON
 2)     Surge Protection                SP                   OFF
 .
 .
 .
 .
 11)    Http DoS Protection             HDOSP                OFF
 12)    Content Filtering               CF                   ON
 .
 .
 23)    HTML Injection                  HTMLInjection        ON
 24)    Citrix ADC Push                  push                 OFF
 Done
<!--NeedCopy-->
```

Enable content by filtering by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Configure basic features.
3. In the Configure Basic Features pane, select the Content Filter check box, and then click OK.

Configure a content filtering action

September 14, 2021

After you enable the content filtering feature, you create one or more actions to tell your Citrix ADC appliance how to handle the connections it receives.

Content filtering supports the following actions for HTTP requests:

- **Add:** Adds the specified HTTP header before sending the request to the web server.
- **Reset:** Terminates the connection, sending the appropriate termination notice to the user's browser.
- **Forward:** Redirects the request to the designated service.
- **Drop:** Silently deletes the request, without sending a response to the user's browser.
- **Corrupt:** Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the request to the server.

Content filtering supports the following actions for HTTP responses:

- **Add:** Adds the specified HTTP header before sending the response to the user's browser.
- **ErrorCode:** Returns the designated HTTP error code to the user's browser.
- **Corrupt:** Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the response to the user's browser.

Configure a content filtering action by using the CLI

At the command prompt, type the following commands to configure a Content Filtering action and verify the configuration:

```
1 -  add filter action <name> <qualifier> [<serviceName>] [<value>] [<
     respCode>] [<page>]
2 -  show filter action <name>
3 <!--NeedCopy-->
```

Example:

```
1 > add filter action act_drop Drop
2  Done
3 > show filter action act_drop
4 1)      Name: act_drop   Filter Type: drop
5  Done
6 <!--NeedCopy-->
```

Configure a content filtering action by using the GUI

1. Navigate to **Security > Protection Features > Filter**.
2. In the details pane, do one of the following:
   - To create a new action, click **Add**.
   - To modify an existing action, select the action, and then click **Open**.
3. In the **Add Filter Action** or **Configure Filter Action** dialog box, specify values for the parameters:
   - Action Name*—name
   - Qualifier*—qualifier (Determines which of the following parameters you can configure)
   - Service Name—service name
   - HeaderName:Value—value
   - Response Code—`respcode`
   - Response Page—page
4. Fill in any other required information. For example, if you are configuring an action to send an HTTP error code, you must choose the appropriate error code from a drop-down list. If necessary, you can then modify the text of the error message, which is displayed beneath the drop-down list.
5. Click Create or OK, and then click Close. The Actions list displays the action you configured, and a message in the status bar indicates that your action has been created.

Configure a content filtering policy

September 14, 2021

To implement content filtering, you must configure at least one policy to tell your Citrix ADC appliance how to distinguish the connections you want to filter. You must first have configured at least one filtering action, because when you configure a policy, you associate it with an action.

Content filtering policies examine a combination of one or more of the following elements to select requests or responses for filtering:

- **URL:** The URL in the HTTP request.
- **URL query:** Only the query portion of the URL, which is the portion after the query (?) symbol.
- **URL token:** Only the tokens in the URL, if any, which are the parts that begin with an ampersand (&) and consist of the token name, followed by an equals sign (=), followed by the token value.
- **HTTP method:** The HTTP method used in the request, which is usually GET or POST, but can be any of the eight defined HTTP methods.
- **HTTP version:** The HTTP version in the request, which is usually HTTP 1.1.

- **Standard HTTP header:** Any of the standard HTTP headers defined in the HTTP 1.1 specification.
- **Standard HTTP header value:** The value portion of the HTTP header, which is the portion after the colon and space (:).
- **Custom HTTP header:** A non-standard HTTP header issued by your website or that appears in a user request.
- **Custom header value:** The value portion of the custom HTTP header, which (as with the standard HTTP header) is the portion after the colon and space (:).
- **Client Source IP:** The IP from which the client request was sent.

Content filtering policies use the simpler of two Citrix ADC expressions languages, called classic expressions. For a complete description of classic expressions, how they work, and how to configure them manually, see "Policies and Expressions."

Note: Users who are not experienced in configuring policies at the Citrix ADC command line will usually find using the configuration utility considerably easier.

Configure a content filtering policy by using the CLI

At the command prompt, type the following commands to configure a content filtering policy and verify the configuration:

```
1 -  add filter policy <name> -rule <expression> (-reqAction <action> | -
     resAction <string>
2 -  show filter policy <name>
3 <!--NeedCopy-->
```

Example:

```
1 > add filter policy cf-pol -rule "REQ.HTTP.URL CONTAINS http://abc.com"
      -reqaction DROP
2  Done
3 > show filter policy cf-pol
4 1)      Name: cf-pol    Rule: REQ.HTTP.URL CONTAINS http://abc.com
5         Request action: DROP
6         Response action:
7         Hits: 0
8  Done
9 <!--NeedCopy-->
```

Configure a content filtering policy by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. Navigate to Protection Features > Filter.
3. In the details pane, to create a new policy, click Add.
4. If you are creating a new policy, in the Create Filter Policy dialog box, in the Filter Name text box, type a name for your new policy.
5. Select either Request Action or Response Action to activate the drop-down list to the right of that item.
6. Click the down arrow to the right of the drop-down list and select the action to be performed on the request or response. The default choices are RESET and DROP. Any other actions you have created will also appear in this list.

   Note: You can also click New to create a new Content Filtering action, or Modify to modify an existing Content Filtering action. You can only modify actions you created; the default actions are read-only.
7. If you want to use a predefined expression (or named expression) to define your policy, choose one from the Named Expressions list.
   a) Click the down arrow to the right of the first Named Expressions drop-down list, and choose the category of named expressions that contains the named expression you want to use.
   b) Click the down arrow to the right of the second Named Expressions drop-down list, and choose the named expression you want. As you choose a named expression, the regular expression definition of that named expression appears in the Preview Expression pane beneath the Named Expression list boxes.
   c) Click Add Expression to add that named expression to the Expression list.
   Note: You must perform either this step or step 7, but not both.
8. If you want to create a new expression to define your policy, use the Expression Editor.
   a) Click the Add button. The Add Expression dialog box appears.
   b) In the Add Expression dialog box, choose the type of connection you want to filter. The Flow Type is set to REQ by default, which tells the Citrix ADC appliance to look at incoming connections, or requests. If you want to filter outgoing connections (responses), you click the right arrow beside the drop-down list and choose RES.
   c) If the Protocol is not already set to HTTP, click the down arrow to the right of the Protocol drop-down list and choose HTTP.
   Note: In the Citrix ADC classic expressions language, “HTTP” includes HTTPS requests, as well.
   d) Click the down arrow to the right of the Qualifier drop-down list, and then choose a qualifier for your expression. Your choices are:
      - **METHOD:** The HTTP method used in the request.
      - **URL:** The contents of the URL header.

- **URLTOKENS:** The URL tokens in the HTTP header.
- **VERSION:** The HTTP version of the connection.
- **HEADER:** The header portion of the HTTP request.
- **URLLEN:** The length of the contents of the URL header.
- **URLQUERY:** The query portion of the contents of the URL header.
- **URLQUERYLEN:** The length of the query portion of the URL header.

  The contents of the remaining list boxes change to the choices appropriate to the Qualifier you pick. For example, if you choose HEADER, a text field labeled Header Name* appears below the Flow Type list box.

e) Click the down arrow to the right of the Operator drop-down list, and choose an operator for your expression. Your choices will vary depending on the Protocol you chose in the preceding step. The following list includes all of the operators:
   - **==:** Matches the following text string exactly.
   - **!=:** Does not exactly match the following text string.
   - **>:** Is greater than the following integer.
   - **CONTAINS:** Contains the following text string.
   - **CONTENTS:** The contents of the designated header, URL, or URL query.
   - **EXISTS:** The specified header or query exists.
   - **NOTCONTAINS:** Does not contain the following text string.
   - **NOTEXISTS:** The specified header or query does not exist.

f) If the Value text box is visible, type the appropriate string or number. If you are testing a string in any way, type the string into the Value text box. If you are testing an integer in any way, type the integer into the Value text box.

g) If you chose HEADER as the Protocol, type the header you want in the Header Name* text box.

h) Click OK to add your expression to the Expressions list.

i) Repeat steps B through H to create any additional expressions you want for your profile.

j) Click Close to close the Expressions Editor.

9. If you created a new expression, in the Expression frame select an option from the Match Any Expression drop-down list. Your choices are:
   - Match Any Expression. If a request matches any expression in the Expressions list, the request matches this policy.
   - Match All Expressions If a request matches all expressions in the Expressions list, the request matches this policy. If it does not match all of them, it does not match this policy.
   - Tabular Expression Switches the Expressions list to a tabular format with three columns. In the first column you can place a BEGIN [(] operator. The second column contains the expressions you have selected or created. In the third column, you can place any of the other operators in the following list, to create complex policy groups in which each group can be configured for match any expression or match all expressions.

- The AND [&&] operator tells the appliance to require that a request match both the current expression and the following expression.
- The OR [||] operator tells the appliance to require that a request match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.
- The END [)] operator tells the appliance that this is the last expression in this expression group or policy.
  Note: The Tabular format allows you to create a complex policy that contains both “Match Any Expression” and “Match All Expressions” on a per-expression basis. You are not limited to just one or the other.
- Advanced Free-Form Switches off the Expressions Editor entirely and modifies the Expressions list into a text area. In the text area, you can type the PCRE-format regular expression of your choice to define this policy. This is both the most powerful and the most difficult method of creating a policy, and is recommended only for those thoroughly familiar with the Citrix ADC appliance and PCRE-format regular expressions.
  Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that is what you want.

10. Repeat steps 6 through 8 to add any additional expressions you want to the Expressions list. You can mix named expressions and expressions created in the Expressions Editor. To the Citrix ADC appliance, they are all the same.
11. Click Create to create your new policy. Your new policy appears in the Policies pane list.
12. Click **Close**. To create additional Content Filtering policies, repeat the previous procedure. To remove a Content Filtering policy, select the policy in the **Policies** tab and click **Remove**.

Binding a content filtering policy

September 14, 2021

You must bind each content filtering policy to put it into effect. You can bind policies globally or to a particular virtual server. Globally bound policies are evaluated each time traffic directed to any virtual server matches the policy. Policies bound to a specific virtual server are evaluated only when that virtual server receives traffic that matches the policy.

Bind a policy to a virtual server by using the CLI

At the command prompt, type the following commands to bind a policy to a virtual server and verify the configuration:

```
- bind lb vserver <name>@ -policyName <string> -priority <
   positive_integer>
- show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
> bind lb vserver vs-loadbal -policyName policyTwo -priority 100
 Done
> show lb vserver vs-loadbal
1)      vs-loadbal (10.102.29.20:80) - HTTP     Type: ADDRESS
        State: OUT OF SERVICE
        Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
        Time since last state change: 2 days, 00:58:03.260
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

 Done
<!--NeedCopy-->
```

Globally bind a policy by using the CLI

At the command prompt, type the following commands to globally bind a policy and verify the configuration:

```
- bind filter global (<policyName> [-priority <positive_integer>]) [-
   state ( ENABLED | DISABLED )]
- show filter global
<!--NeedCopy-->
```

Example:

```
 bind filter global cf-pol -priority 1
 Done show filter global
1)      Policy Name: cf-pol     Priority: 1
 Done
<!--NeedCopy-->
```

Bind a policy to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server to which you want to bind the content filtering policy from the list, and click **Open**.
3. In the **Configure Virtual Server** (Load Balancing) dialog box, select the **Policies** tab, and then select the check box in the Active column of the filter policy that you want to bind to the virtual server.
4. Click **OK**. The policies you have bound display a check mark and the word Yes in the Policies Bound column of the Policies tab.

Globally bind a policy by using the GUI

1. Navigate to **Security > Protection Features > Filter**.
2. In the details pane, in the **Policies** tab, select the policy that you want to bind, and then click **Global Bindings**.
3. In the Bind/Unbind Filter Policies dialog box, in the **Policy Name** drop-down list, select a policy, and then click **Add**. The policy is added to the Configured list.

   > **Note**
   >
   > To select multiple policies from the list, drag the Ctrl key, then click each policy you want.

4. Click **OK**, and then click **Close**. The policies you have bound display a check mark and the word Yes in the Globally Bound column of the Policies tab.

Configuring content filtering for a commonly used deployment scenario

September 14, 2021

This example provides instructions for using the configuration utility to implement a content filtering policy in which, if a requested URL contains root.exe or cmd.exe, the content filtering policy `filter-CF-nimda` is evaluated and the connection is reset.

To configure this content filtering policy, you must do the following:

- Enable content filtering
- Configure content filtering policy
- Bind content filtering policy globally or to a virtual server
- Verify the configuration

Note: Since this example uses a default content filtering action, you do not need to create a separate content filtering action.

Enable content filtering

1. In the navigation pane, expand System, and click Settings.
2. In the details pane, under Modes & Features, click Change Basic Features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

Configure the content filtering policy `filter-CF-nimda`

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, click Add. The Create Filter Policy dialog box appears.
3. In the Create Filter Policy dialog box, in the Filter Name text box, type the name `filter-CF-nimda`.
4. Select the Request Action option, and in the drop-down list, select RESET.
5. In the Expression frame, select Match Any Expression from the drop-down list, and then click Add.
6. In the Add Expression dialog box, Expression Type drop-down list, select General.
7. In the Flow Type drop-down list, select REQ.
8. In the Protocol drop-down list, select HTTP.
9. In the Qualifier drop-down list, select URL.
10. In the Operator drop-down list, select CONTAINS.
11. In the Value text box, type cmd.exe, and then click OK. The expression is added in the Expression text box.
12. To create another expression, repeat Steps 7 through 11, but in the Value text box, type root.exe. Then click OK, and finally click Close.
13. Click Create on the Create Filter Policy dialog box. The filter policy `filter-CF-nimda` appears in the Filter list.
14. Click Close.

Globally bind the content filtering policy

1. Navigate to Security > Protection Features > Filter. The Filter page appears in the right pane.
2. In the details pane, Policies tab, select the policy that you want to bind and click Global Bindings. The Bind/Unbind Filter Policies dialog box appears.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select the policy `filter-CF-nimda`, and click Add. The policy is added to the Configured list.
4. Click OK, and then click Close. The policy you have bound displays a check mark and Yes in the Globally Bound column of the Policies tab.

Bind the content filtering policy to a virtual server

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane virtual servers list, select vserver-CF-1 to which you want to bind the content filtering policy and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab.
4. In the Active column, select the check box for the policy `filter-CF-nimda`, and then click OK. Your content filtering policy is now active, and must be filtering requests. If it is functioning correctly, the select counter is incremented every time there is a request for a URL containing either root.exe or cmd.exe. This allows you to confirm that your content filtering policy is working. The content filtering policy is bound to the virtual server.

Verify the content filtering configuration by using the command line interface

At the command prompt, type the following command to verify the content filtering configuration:

```
show filter policy filter-CF-nimda
```

Example:

```
1 sh filter policy filter-CF-nimda
2         Name: filter-CF-nimda   Rule: REQ.HTTP.URL CONTAINS cmd.exe ||
             REQ.HTTP.URL CONTAINS root.exe
3         Request action: RESET
4         Response action:
5         Hits: 0
6 Done
7 <!--NeedCopy-->
```

> **Note**
>
> The select counter displays an integer that denotes the number of times the `filter-CF-nimda` policy is evaluated. In the preceding steps, the select counter is set to zero because no requests

> for a URL containing either cmd.exe or root.exe has been made yet. If you want to see the counter increment in real time, you can simply request a URL that contains either of these strings.

Verify the content filtering configuration by using the GUI

1. Navigate to **Security > Protection Features > Filter**.
2. In the details pane, select the filter policy `filter-CF-nimda`. The bottom of the pane must display the following:

```
    **Request Action:**

    RESET

    **Rule:**

    REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe

    **Hits:**

    0
<!--NeedCopy-->
```

Troubleshooting

September 14, 2021

If the content filtering feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

You can use the following tools and resources to troubleshoot most Content Filtering issues on a Citrix ADC appliance:

- The Wireshark application customized for the Citrix ADC trace files
- Trace files recorded when accessing the resource
- The configuration files
- The ns.log file
- The `iehttpheaders`, or a Fiddler trace or a similar utility

Troubleshooting content filtering issues

To troubleshoot a content filtering issue, proceed as follows:

- Verify that the feature is enabled.
- Verify that the content filtering policy is configured correctly. Pay special attention to the expression that evaluates the incoming requests.

  > **Note**
  >
  > Most content filtering issues are caused by incorrect configuration, and the error is most often in the policy configuration.

- Check the policy's select counter to verify that it is incrementing. If it is not, the policy is not getting evaluated.
- If the policy is getting evaluated and the required filtering is still not performed, you need to look into the policy expressions and action.
- If the policy's expression seems valid, test it by assigning a simple NSTRUE value to see if the evaluation of the expression is creating any issue.
- Reevaluate whether the filtering must be based on the request or the response.
- Verify that the action is configured correctly. For example, if a custom action is used to corrupt a header in the request, verify that the header name in the action is correct. If you are not sure about the header name, start a browser with `iehttpheaders` or a similar utility, and then verify the headers in the request. When this feature is used, you can use ns trace to find out if appropriate action is performed when the packets leave Citrix ADC appliance.
- An `iehttpheaders` or Fiddler trace can help you find header options and names, client-side request headers, and response headers recorded on the client.
- To check the modifications made to the request header, record an ns trace on the Citrix ADC appliance or a Wireshark trace on the server.
- If none of the above measures resolves the issue, verify that the connection has not become untrackable, which can happen in certain circumstances. If a connection becomes untrackable, the appliance does not perform any application-level processing of the requests. In that event, contact Citrix Technical Support.

Surge protection

September 14, 2021

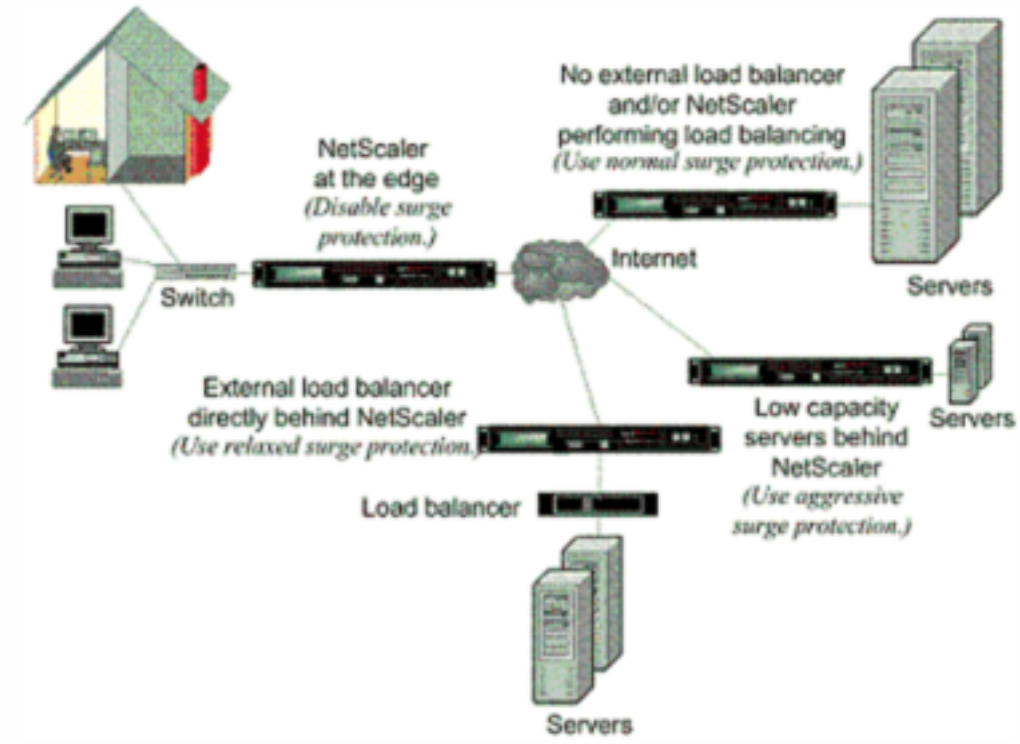
When a surge in client requests overloads a server, server response becomes slow, and the server is unable to respond to new requests. The Surge Protection feature ensures that connections to the server occur at a rate that the server can handle. The response rate depends on how surge protection is configured. The Citrix ADC appliance also tracks the number of connections to the server, and uses that information to adjust the rate at which it opens new server connections.

Surge protection is enabled by default. If you do not want to use surge protection, as is the case with some special configurations, you must disable it.

The default surge protection settings are sufficient for most uses, but you can configure surge protection to tune it for your needs. First, you can set the throttle value to tell it how aggressively to manage connection attempts. Second you can set the base threshold value to control the maximum number of concurrent connections that the Citrix ADC appliance allows before triggering surge protection. (The default base threshold value is set by the throttle value, but after setting the throttle value you can change it to any number you want.)

The following figure illustrates how surge protection is configured to handle traffic to a website.

Figure 1. A Functional Illustration of Citrix ADC Surge Protection



Note

If the Citrix ADC appliance is installed at the edge of the network, where it interacts with network devices on the client side of the Internet, the surge protection feature must be disabled. Surge protection must also be disabled if you enable USIP (Using Source IP) mode on your appliance.

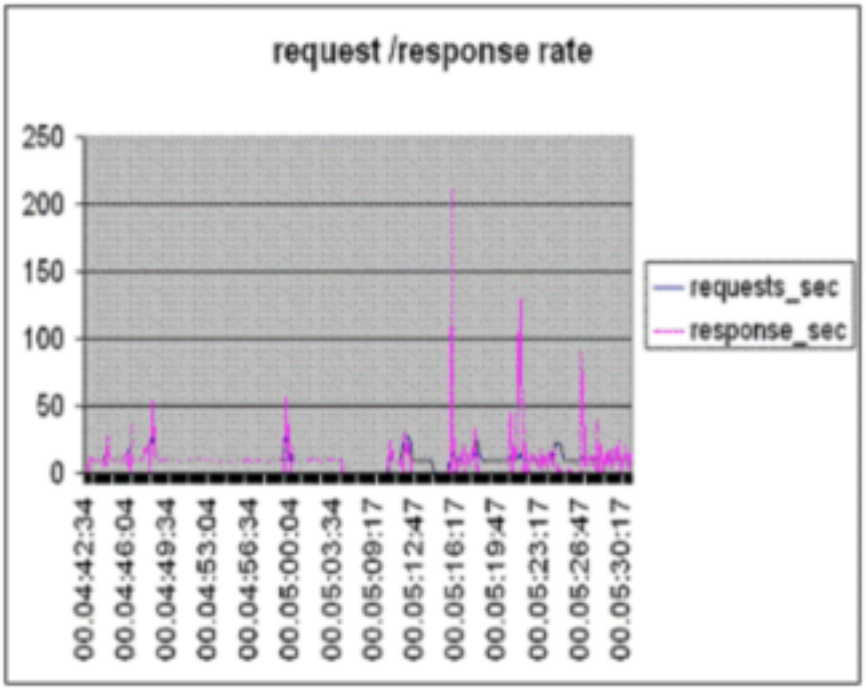
The following example and illustration show the request and response rates for two cases. In one case, surge protection is disabled, and in the other it is enabled.

When surge protection is disabled and a surge in requests occurs, the server accepts as many requests as it can process concurrently, and then begins to drop requests. As the server becomes more overloaded, it goes down and the response rate is reduced to zero. When the server recovers from the crash, several minutes later, it sends resets for all pending requests, which are abnormal behavior, and also responds to new requests with resets. The process repeats for each surge in requests. Therefore, a server that is under DDoS attack and receives multiple surges of requests can become unavailable to legitimate users.

When surge protection is enabled and a surge in requests occurs, surge protection manages the rate of requests to the server, sending requests to the server only as fast as the server can handle those requests. This enables the server to respond to each request correctly in the order it was received. When the surge is over, the backlogged requests are cleared as fast as the server can handle them, until the request rate matches the response rate.

The following figure compares the request and response scenarios when surge protection is enabled to that when it is disabled.

Figure 2. Request/Response Rate with and without Surge Protection



Disable and reenable surge protection

September 14, 2021

The surge protection feature is enabled by default. When surge protection is enabled, it is active for any service that you add.

Disable or reenable surge protection by using the CLI

At the command prompt, type one of the following sets of commands to disable or reenable surge protection and verify the configuration:

```
- disable ns feature SurgeProtection
- show ns feature
- enable ns feature SurgeProtection
- show ns feature
<!--NeedCopy-->
```

Example:

```
disable ns feature SurgeProtection
 Done show ns feature

        Feature                         Acronym              Status
        -------                         -------              ------
 1)     Web Logging                     WL                   ON
 2)     Surge Protection                SP                   OFF
 .
 .
 .
 23)    HTML Injection                  HTMLInjection        ON
 24)    Citrix ADC Push                  push                 OFF
 Done
<!--NeedCopy-->
```

```
 enable ns feature SurgeProtection
 Done
> show ns feature

        Feature                         Acronym              Status
        -------                         -------              ------
 1)     Web Logging                     WL                   ON
 2)     Surge Protection                SP                   ON
 .
```

```
10   .
11   .
12
13   23)    HTML Injection                HTMLInjection        ON
14   24)    Citrix ADC Push                push                 OFF
15   Done
16  >
17  <!--NeedCopy-->
```

Disable or reenable surge protection by using the GUI

1. In the navigation pane, expand **System**, and then select **Settings**.
2. In the details pane, click **Change Advanced Features**.
3. In the **Configure Advanced Features** dialog box, clear the selection from the **Surge Protection** check box to disable the surge protection feature, or select the check box to enable the feature.
4. Click **OK**.
5. In the Enable/Disable Features dialog box, click Yes. A message appears in the status bar, stating that the feature has been enabled or disabled.

Disable or reenable surge protection for a particular service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services. The list of configured services is displayed in the details pane.
2. In the details pane, select the service for which you want to disable or reenable the surge protection feature, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab and scroll down.
4. In the Others frame, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
5. Click OK. A message appears in the status bar, stating that the feature has been enabled or disabled.
   Note: Surge protection works only when both the feature and the service setting are enabled.

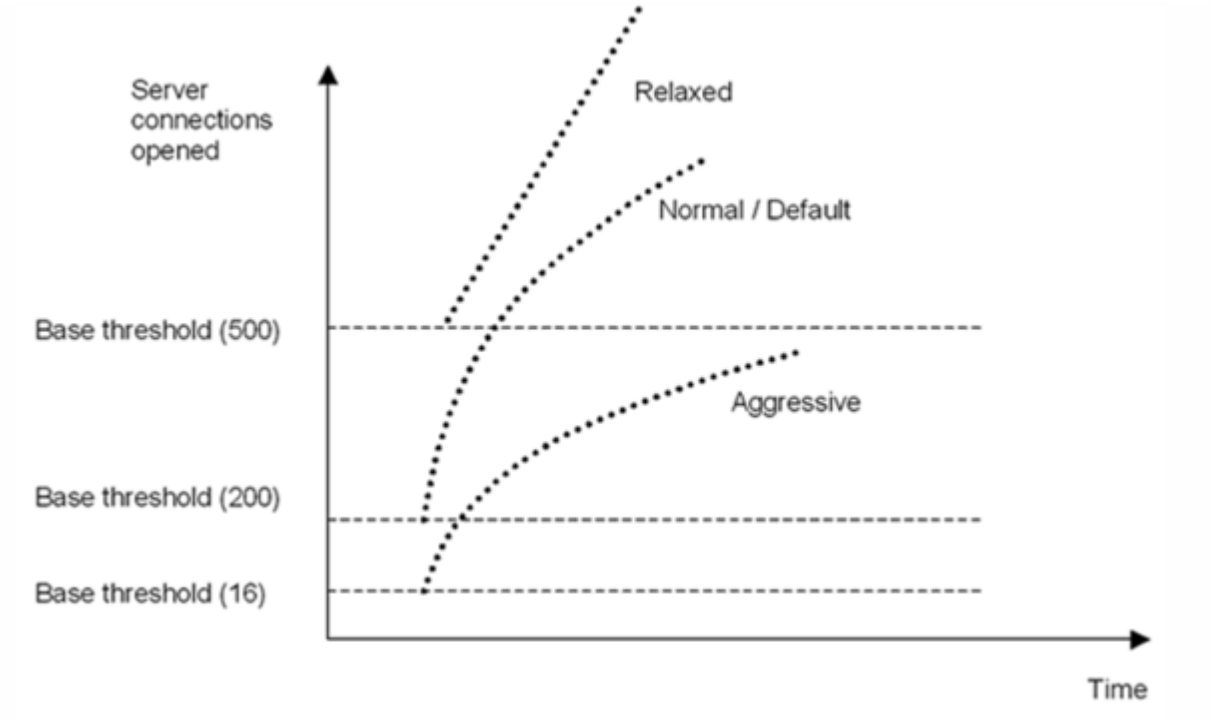
Set thresholds for surge protection

September 14, 2021

To set the rate at which the Citrix ADC appliance opens connections to the server, you must configure the threshold and throttle values for surge protection.

The following figure shows the surge protection curves that result from setting the throttle rate to relaxed, normal, or aggressive. Depending on the configuration of the server capacity, you can set base threshold values to generate appropriate surge protection curves.

Figure 1. Surge Protection Curves

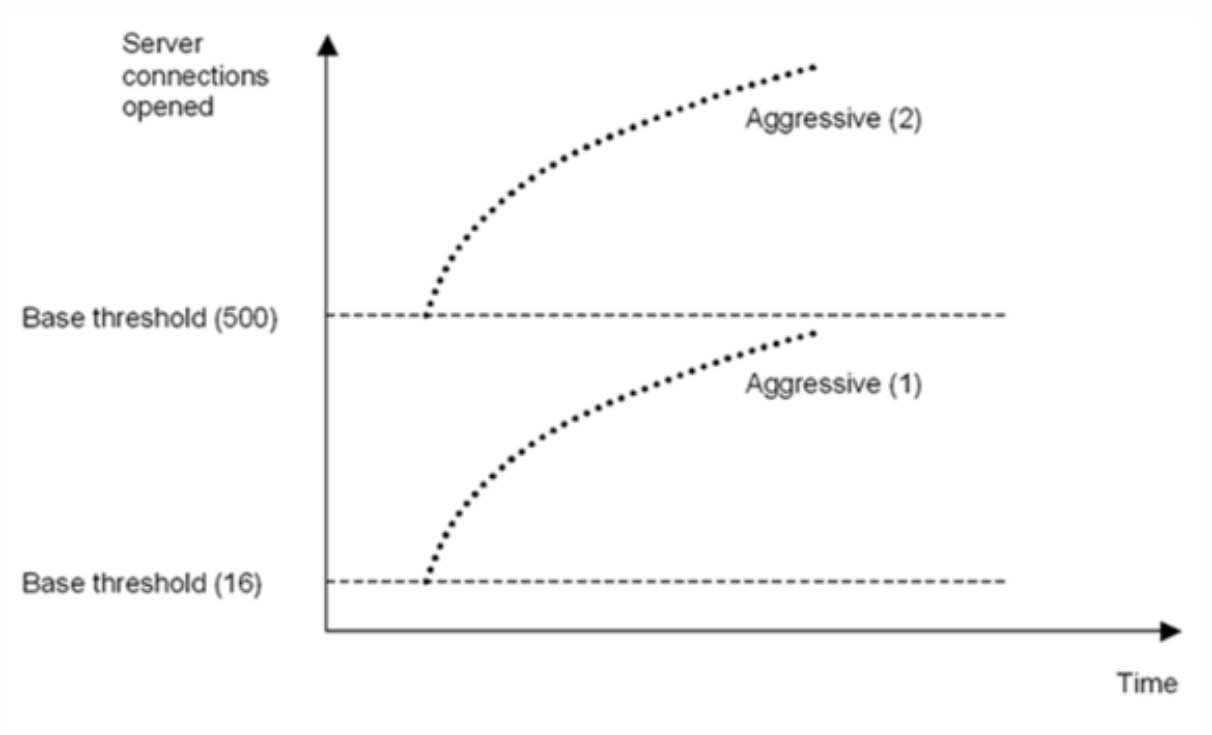


Your configuration settings affect the behavior of surge protection in the following manner:

- If you do not specify a throttle rate, it is set to normal (the default value), and the base threshold is set to 200, as shown in the preceding figure.
- If you specify a throttle rate (aggressive, normal, or relaxed) without specifying a base threshold, the curve reflects the default values of the base threshold for that throttle rate. For example, if you set the throttle rate to relaxed, the resulting curve will have the base threshold value of 500.
- If you specify only the base threshold, the entire surge protection curve shifts up or down, depending on the value you specify, as shown in the figure that follows.
- If you specify both a base threshold and a throttle rate, the resulting surge protection curve is based on the set throttle rate and adjusted according to the value set for the base threshold.

In the following figure, the lower curve (Aggressive 1) results when the throttle rate is set to aggressive but the base threshold is not set. The upper curve (Aggressive 2) results when the base threshold is set to 500, but the throttle rate is not set. The second upper curve (Aggressive 2) also results when the base threshold is set to 500, and the throttle rate is set to aggressive.

Figure 2. Aggressive Rate with the Default or a Set Base Threshold



Set the threshold for surge protection by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Global System Settings.
3. If you want to set a base threshold different from the default for the throttle rate, in the Configure Global Settings dialog box, Base Threshold text box, enter the maximum number of concurrent server connections allowed before surge protection is triggered. The base threshold is the maximum number of server connections that can be open before surge protection is activated. The maximum value for this setting is 32,767 server connections. The default setting for this value is controlled by the throttle rate you choose in the next step.

   Note: If you do not set an explicit value here, the default value will be used.
4. In the Throttle drop-down list, select a throttle rate. The throttle is the rate at which the Citrix ADC appliance allows connections to the server to be opened. The throttle can be set to the following values:

   - **Aggressive:** Choose this option when the connection-handling and surge-handling capacity of the server is low and the connection needs to be managed carefully. When you set the throttle to aggressive, the base threshold is set to a default value of 16, which means that surge protection is triggered whenever there are 17 or more concurrent connections to the server.

- **Normal:** Choose this option when there is no external load balancer behind the Citrix ADC appliance or downstream. The base threshold is set to a value of 200, which means that surge protection is triggered whenever there are 201 or more concurrent connections to the server. Normal is the default throttle option.
- **Relaxed:** Choose this option when the Citrix ADC appliance is performing load balancing between a large number of Web servers, and can therefore handle a high number of concurrent connections. The base threshold is set to a value of 500, which means that surge protection is triggered only when there are 501 or more concurrent connections to the server.

5. Click OK. A message appears in the status bar, stating that the global settings are configured.

Flush the surge queue

September 14, 2021

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between a client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups

bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed. The other requests in the surge queue of the load balancing virtual server are not flushed.

Note:

> - You cannot flush the surge queues of cache redirection, authentication, VPN, or GSLB virtual servers or GSLB services.
> - Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

Flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while running the command, the surge queue of the specified entity is flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while running the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member <serverName> and <port> without specifying the name of the service group <name> and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you run the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
```

Examples

1. `flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80`

The preceding command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

2. `flush ns surgeQ`

   The preceding command flushes all the surge queues on the appliance.

Flush a surge queue by using the GUI

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

DNS security options

September 14, 2021

You can now configure the DNS security options from the Add DNS Security Profile page in the Citrix ADC GUI. To configure the DNS security options from the Citrix ADC CLI or the NITRO API, use the AppExpert components. For instructions, see the NITRO API documentation and the Citrix ADC Command Reference Guide.

One option, cache poisoning protection, is enabled by default and cannot be disabled. You can apply the other options to all DNS endpoints or to specific DNS virtual servers in your deployment, as shown in the following table:

Security option	Can be applied to all DNS endpoints?	Can be applied to specific DNS virtual servers?
DNS DDoS protection	Yes	Yes
Manage exceptions – whitelist/blacklist servers	Yes	Yes
Prevent random subdomain attacks	Yes	Yes
Bypass the cache	Yes	No
Enforce DNS transactions over TCP	Yes	Yes
Provide root details in the DNS response	Yes	No

Cache poisoning protection

A cache poisoning attack redirects users from legitimate sites to malicious websites.

For example, the attacker replaces a genuine IP address in the DNS cache with a fake IP address that they control. When the server responds to requests from these IP addresses, the cache is poisoned. Subsequent requests for the addresses of the domain are redirected to the attacker's site.

The Cache Poisoning Protection option prevents insertion of corrupt data into the database that caches DNS server requests and responses. This feature is inbuilt in the Citrix ADC appliances and is always enabled.

DNS DDoS protection

You can configure the DNS DDoS Protection option for each type of request that you suspect might be used in a DDoS attack. For each type, the appliance drops any requests received after a threshold value for the number of requests received in a specified time period (time slice) is exceeded. You can also configure this option to log a warning to the SYSLOG server. For example:

- **DROP:** - Select this option to DROP requests without logging. Assume that you have enabled A record protection with threshold value 15, time slice as 1 second, and chosen DROP. When the incoming requests exceed 15 queries in 1 second, then the packets start getting dropped.
- **WARN:** - Select this option to LOG and DROP requests. Assume that you have enabled A record protection with threshold value 15, time slice as 1 second, and chosen WARN. When the incoming requests exceed 15 queries in 1 second, a warning message is logged indicating a threat and then the packets are dropped. Citrix recommends you to set threshold values for WARN smaller than the threshold value of DROP for a record type. Such a setting helps administrators identify an attack by logging a warning message before the actual attack happens and Citrix ADC starts dropping incoming requests.

Set a threshold for incoming traffic by using the GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profile** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
4. Expand **DNS DDoS Protection**.
    a) Select the record type and enter the threshold limit and the time slice value.
    b) Select **DROP** or **WARN**.
    c) Repeat steps a and b for each of the other record types that you want to protect against.
5. Click **Submit**.

Manage exceptions – allowlist/blocklist servers

Manage exceptions enables you to add exceptions either to block list or allow list domain name and IP addresses. For example:

- When a particular IP address is identified posting an attack, such IP address can be added to the block list.
- When administrators find that there is an unexpectedly high number of requests for a particular domain name, then that domain name can be added to the block list.
- `NXDomains` and some of the existent domains which can consume the server resources can be blacklisted.
- When administrators allow list domain names or IP addresses, queries or requests only from these domains or IP addresses are answered and all others are dropped.

Create an allow list or a block list by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   a) Expand **Manage exceptions – Whitelist/Blacklist Servers**.
   b) Select **Block** to block queries from blacklisted domains/addresses, or select **Allow** only to allow queries from whitelisted domains/addresses.
   c) In the **Domain name / IP Address** box, enter the domain names, IP addresses, or IP address ranges. Use commas to separate the entries.
   Note: If you select **Advanced Option**, you can use the “start with,” “contains,” and “ends with” options to set the criteria.
   For example, you can set criteria to block a DNS query that starts with “image” or ends with “.co.ru” or contains “mobile sites.”
4. Click **Submit**.

Prevent random subdomain attacks

In random subdomain attacks, queries are sent to random, nonexistent subdomains of legitimate domains. This action increases the load on the DNS resolvers and servers. As a result, they can become overloaded and slow down.

The Prevent Random Subdomain Attacks option directs the DNS responder to drop DNS queries that exceed a specified length.

Assume that example.com is a domain name owned by you and hence the resolution request comes to your DNS server. The attacker can append a random subdomain to example.com and send a request. Based on the specified query length and the FQDN, the random queries are dropped.

For example, if the query is www.image987trending.example.com, it is dropped if the query length is set to 20.

Specify a DNS query length by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   a) Expand **Prevent Random Subdomain Attacks**.
   b) Enter the numerical value for the query length.
4. Click **Submit**.

Bypassing the cache

During an attack, the data that is already cached must be protected. To protect the cache, new requests for certain domains or record types or response codes can be sent to the origin servers instead of cached.

The Bypassing the cache option directs the Citrix ADC appliance to bypass the cache for specified domains, record types, or response codes when an attack is detected.

Bypass the cache for specified domains or record types or response types by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Bypassing the cache** and enter the domain names. Optionally, choose the record types or the response types for which the cache has to be bypassed.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
   - Click **Response Types** and choose the response type.
4. Click **Submit**.

Enforce DNS transactions over TCP

Some DNS attacks can be prevented if the transactions are forced to use TCP instead of UDP. For example, during a bot attack, the client sends a flood of queries but cannot handle responses. If the use of TCP is enforced for these transactions, then the bots cannot understand the responses and therefore cannot send requests over TCP.

Force domains or record types to operate at the TCP level by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Enforce DNS Transactions over TCP** and enter the domain names and / or choose the record types for which the DNS transactions must be enforced over TCP.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
4. Click **Submit**.

Provide root details in the DNS response

In some attacks, the attacker sends a flood of queries for unrelated domains that are not configured or cached on the Citrix ADC appliance. If the `dnsRootReferral` parameter is ENABLED, it exposes all the root servers.

The Provide Root Details in the DNS Response option directs the Citrix ADC appliance to restrict access to root referrals for a query that is not configured or cached. The appliance sends a blank response.

The Provide Root Details in the DNS Response option can also mitigate or block amplification attacks. When the dnsRootReferral parameter is DISABLED, there are no root referrals in the Citrix ADC responses and hence they do not get amplified.

Enable or disable access to the root server by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   a) Expand **Provide Root Details in the DNS Response**.
   b) Click **ON** or **OFF** to allow or restrict access to the root server.
4. Click **Submit**.

System

September 14, 2021

This section provides system-level information of the Citrix ADC. This includes a detailed explanation of system-level features, the scenarios in which the features can be used, the configuration steps, and examples to help you better understand the features.

- Basic Operations
- Authentication and Authorization
- TCP Configurations
- HTTP Configurations
- SNMP
- Audit Logging
- Web Server Logging
- Call Home
- Reporting Tool
- CloudBridge Connector
- High Availability
- TCP Optimization

System base operations

September 14, 2021

The following configurations enable you to perform system base operations on a Citrix ADC appliance.

How to view, save, and clear Citrix ADC configuration

Citrix ADC configurations are stored in the `/nsconfig/ns.conf directory`. For configurations to be available across sessions, you must save the configuration after every configuration change.

View running configuration by using the command interface

At the command prompt, type:

```
show ns runningConfig
```

View running configuration by using the GUI

1. Navigate to **System** > **Diagnostics** and, in the **View Configuration group**, click **Running Configuration.**

View the difference between the two configuration files by using the command interface

At the command prompt, type:

```
diff ns config <configfile> <configfile2>
```

View the difference between the two configuration files by using the GUI

1. Navigate to **System** > **Diagnostics** and, in the **View Configuration group**, click **Configuration difference**.

Save Citrix ADC configurations by using the command interface

At the command prompt, type:

```
save ns config
```

Save Citrix ADC configurations by using the GUI

1. On the **Configuration** tab, in the top-right corner, click the **Save** icon.

View saved configurations by using the command interface

At the command prompt, type:

```
show ns ns.conf
```

View saved configurations by using the GUI

Navigate to **System** > **Diagnostics** and, in the **View Configuration** group, click **Saved Configuration**.

Clear Citrix ADC configuration by using the command interface

You have the following three options for clearing the Citrix ADC configuration.

Basic level. Clearing your configuration at the basic level clears all settings except the following:

- `Nsroot` password
- Time Zone
- NTP server
- ADM server connect
- License fie information
- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions
- Feature and mode settings
- Default administrator password (`nsroot`)

Extended level. Clearing your configuration at the extended level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions

Feature and mode settings revert to their default values.

Full level. Clearing your configuration at the full level returns all settings to their factory default values. However, the NSIP and default gateway are not changed, because changing them can cause the appliance to lose network connectivity.

At the command prompt, type:

```
clear ns config -force
```

Example: To forcefully clear the basic configurations on an appliance.

```
clear ns config -force basic
```

Clear Citrix ADC configuration by using the GUI

Navigate to **System** > **Diagnostics** and, in the Maintenance group, click **Clear Configuration** and select the configuration level to be cleared from the appliance.

How to restart or shut down appliance for unsaved Citrix ADC configurations

The Citrix ADC appliance can be remotely restarted or shut down from the available user interfaces. When you restart or shut down a standalone Citrix ADC appliance, the unsaved configurations (configurations performed since the last
save ns config command was issued) are lost.

In a high availability setup, when the primary appliance is rebooted or shut down, the secondary appliance takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance.

You can also restart the appliance by only rebooting the Citrix ADC software and not rebooting the underlying operating system. This is called a warm reboot. For example, when you add a new license or change the IP address, you can warm reboot the Citrix ADC appliance for these changes to take place.

> **Note:**
>
> You can perform warm reboot only on a standalone Citrix ADC appliance.

Restart the appliance by using the command interface

At the command prompt, type:

```
reboot [-warm]
```

Restart a Citrix ADC appliance by using the GUI

1. In the configuration page, click **Reboot**.
2. When prompted to reboot, select **Save configuration** to make sure that you do not lose any configurations.

> **Note:**
>
> You can perform a warm reboot by selecting Warm reboot.

Shut down an appliance by using the command interface

At the command prompt, type:

- `shutdown -p now`: Shuts down the software and switches off the Citrix ADC. To restart Citrix ADC MPX, press the AC power switch. To Restart Citrix ADC VPX, restart the VPX instance.
- `shutdown -h now`: Shuts down the software and leaves the Citrix ADC switched on. Press any key to restart the Citrix ADC. This command does not switch off the Citrix ADC. Therefore, do not switch off the AC power or remove the AC power cables.

> **Note:**
>
> You cannot shut down an appliance through the Citrix ADC GUI.

How to synchronize system clock with servers on the network

You can configure your Citrix ADC appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network.

You can configure clock synchronization on your appliance by adding NTP server entries to the ntp.conf file from either the GUI or the command line interface, or by manually modifying the ntp.conf file and then starting the NTP daemon (NTPD). The clock synchronization configuration does not change if the appliance is restarted, upgraded, or downgraded. However, the configuration does not get propagated to the secondary Citrix ADC in a high availability setup.

Citrix ADC GUI allows you to configure the time zone and the NTP server IP address required for clock synchronization on the first-time-user (FTU) screen.

> **Note:**
>
> If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site, <http://www.ntp.org>, under Public Time Servers List. Before configuring

> your Citrix ADC to use a public NTP server, be sure to read the Rules of Engagement page (link included on all Public Time Servers pages).
>
> In Citrix ADC release 11, the NTP version has been updated from 4.2.6p3 to 4.2.8p2.

Pre-requisite

To configure clock synchronization, you must configure the following entities:

1. NTP servers
2. NTP synchronization.

Add an NTP server by using the command interface

At the command prompt, type the following commands to add an NTP server and verify the configuration:

- `add ntp server (<serverIP> | <serverName>)[-minpoll <positive_integer>] [-maxpoll <positive_integer>]`
- `show ntp server`

Example:

```
add ntp server 10.102.29.30 -minpoll 6 -maxpoll 11
```

Add an NTP server by using the GUI

Navigate to **System** > **NTP Servers**, and create the NTP server.

Enable NTP synchronization by using the command interface

When you enable NTP synchronization, the Citrix ADC starts the NTP daemon and uses the NTP server entries in the ntp.conf file to synchronize its local time setting. If you do not want to synchronize the appliance time with the other servers in the network, you can disable NTP synchronization, which stops the NTP daemon (NTPD).

At the command prompt, type one of the following commands:

```
enable ntp sync
```

Enable NTP synchronization by using the GUI

Navigate to **System** > **NTP Servers**, click **Action** and select **NTP Synchronization**.

Configure clock synchronization to edit a ntp.conf file by using the GUI

1. Log on to the command line interface.
2. Switch to the shell prompt.
3. Copy the /etc/ntp.conf file to /nsconfig/ntp.conf, unless the /nsconfig directory already contains an ntp.conf file.
4. For each NTP server you want to add, you must add the following two lines to the /nsconfig/ntp.conf file:

```
server <IP address for NTP server> iburst

restrict <IP address for NTP server> mask <netmask> nomodify notrap nopeer
noquery
```

```
1  > Note:
2  >
3  > For security reasons, there should be a corresponding restrict entry
       for each server entry.
4
5  Example
6
7  In the following example, an administrator has inserted # characters to
       “comment out” an existing NTP entry, and then added an entry:
8
9  `#server 1.2.3.4 iburst`
10
11 `#restrict 1.2.3.4 mask 55.255.255.255 nomodify notrap nopeer noquery`
12
13 `server 10.102.29.160 iburst`
14
15 `restrict 10.102.29.160 mask 255.255.255.255 nomodify notrap nopeer
       noquery`
```

1. If the /nsconfig directory does not contain a file named rc.netscaler, create the file.
2. Add the following entry to /nsconfig/rc.netscaler: /bin/sh /etc/ntpd_ctl full_start

   This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory.

   This process runs every time the Citrix ADC is restarted.
3. Restart the Citrix ADC appliance to enable clock synchronization. Or, to start the time synchronization process without restarting the appliance, enter the following commands at the shell prompt:

- `rm /etc/ntp.conf`
- `ln -s /nsconfig/ntp.conf /etc/ntp.conf`
- `/bin/sh /etc/ntpd_ctl full_start`

How to configure session timeout for idle client connections

A session timeout interval is provided to restrict the time duration for which a session (GUI, CLI, or API) remains active when not in use. For the Citrix ADC, the system session timeout can be configured at the following levels:

- **User level timeout.** Applicable to the specific user.

Interface type	Time out configuration
GUI	Navigate to **System > User Administration > Users**, select a user, and edit the user's timeout setting.
CLI	At the command prompt, enter the following command: `set system user <name> -timeout <secs>`

- **User group level timeout.** Applicable to all users in the group.

Interface type	Time out configuration
GUI	Navigate to **System > User Administration > Groups**, select a group, and edit the group's timeout setting.
CLI	At the command prompt, enter the following command:`set system group <groupName> -timeout <secs>`

- **Global system timeout.** Applicable to all users and users from groups who do not have a time-out configured.

Interface type	Time out configuration
GUI	Navigate to **System > Settings**, click Change global system settings, and update the timeout value as required.

Interface type	Time out configuration
CLI	At the command prompt, enter the following command: `set system parameter -timeout <secs>`

```
The timeout value specified for a user has the highest priority. If timeout is not configured for the user, the timeout configured for a member group is considered. If timeout is not specified for a group (or the user does not belong to a group), the globally configured timeout value is considered. If timeout is not configured at any level, the default value of 900 seconds is set as the system session timeout.

Additionally, you can specify timeout durations for each of the interfaces you are accessing. However, the timeout value specified for a specific interface is restricted to the timeout value configured for the user that is accessing the interface. For example, let us consider an user "publicadmin" who has a timeout value of 20 minutes. Now, when accessing an interface, the user must specify a timeout value that is within 20 minutes.

> **Note:**
>
> You can choose to keep a check on the minimum and maximum timeout values by specifying the timeout as restricted (in CLI by specifying the *restrictedTimeout* parameter). This parameter is provided to account for previous Citrix ADC versions where the timeout value was not restricted.
```

- When enabled, the minimum configurable timeout value is 5 minutes (300 secs) and the maximum value is 1 day (86400 secs). If the timeout value is already configured to a value larger than 1 day, when this parameter is enabled, you are prompted to change it. If you do not change the value, the timeout value will automatically be reconfigured to the default timeout duration of 15 minutes (900 secs) on the next reboot. The same will happen is the configured timeout value is less than 5 minutes.
- When disabled, the configured timeout durations are considered.
- **Timeout duration at each interface:**

Interface type	Time out configuration
CLI	Specify the timeout value on the command prompt by using the following command: `set cli mode -timeout <secs>`
API	Specify the timeout value in the login payload.

How to set system date and time to synchronize clock with a time server

To change the system date and time, you must use the shell interface to the underlying FreeBSD OS. However, to view the system date and time, you can use the command line interface or the GUI.

View system date and time by using the command interface

At the command prompt, type:

```
show ns config
```

View system date and time by using the GUI

Navigate to **System** and select the **System Information** tab to view the system date.

How to configure HTTP and HTTPS management ports for internal services

In a single-IP mode deployment of a Citrix ADC appliance, a single IP address is used as NSIP, SNIP, and VIP addresses. This single IP address uses different port numbers to function as NSIP, SNIP, and VIP addresses.

Port numbers 80 and 443 are well-known ports for HTTP and HTTPS services. Earlier, port 80 and 443 of the Citrix ADC IP address (NSIP) were dedicated ports for internal HTTP and HTTPS management services. Because these ports were reserved for internal services, you cannot use these well-known ports for providing HTTP and HTTPS data services from a VIP address, which has the same address as the NSIP address in a single-IP mode deployment.

To address this requirement, you can now configure ports for internal HTTP and HTTPS management services (of the NSIP address) other than port 80 and 443.

The following lists the default port numbers for internal HTTP and HTTPS management services in Citrix ADC MPX, VPX, and CPX appliances:

- Citrix ADC MPX and VPX appliances: 80 (HTTP) and 443 (HTTPS)
- Citrix ADC CPX appliances: 9080 (HTTP) and 9443 (HTTPS)

Configure HTTP and HTTPS management ports by using the command interface

You can configure an HTTP and an HTTPS port to any value on the Citrix ADC appliance to support the HTTP and HTTPS management service. However, by default, the Citrix ADC appliance uses 80 and 443 ports for HTTP and HTTPS connection.

At the command prompt, type:

```
set ns param -mgmtHttpPort<port>
```

Example:

```
set ns param -mgmtHttpPort 2000
```

To configure an HTTPS port by using the command interface

At the command prompt, type:

```
set ns param -mgmtHttpsPort<port>
```

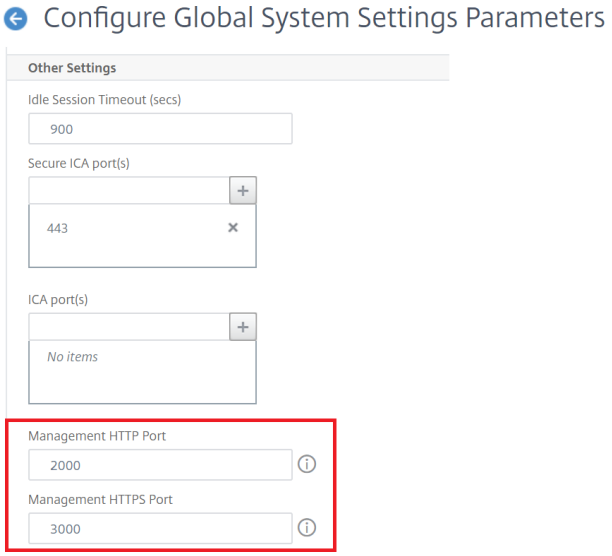
Example:

```
set ns param -mgmtHttpsPort 3000
```

Configure HTTP and HTTPS management ports by using the GUI

Follow the steps given below to configure HTTP and HTTPS port values:

1. Navigate to **System** > **settings** > **Change global system settings**.
2. In **Configure Global System Settings Parameters** page, under **Other Setting** section, set the following parameters.
   a) Management HTTP Port. set port value to 2000. Default = 80, Min = 1, Max = 65534.
   b) Management HTTPS Port. set port value to 3000. Default = 443, Min = 1, Max = 65534.



How to allocate extra management CPU for data processing and monitoring

If you need better performance for configuration and monitoring of a Citrix ADC MPX appliance, you can allocate an extra management CPU from the appliance's packet engine pool. This feature is supported on certain Citrix ADC MPX models and all VPX models except the VPX instances that run on Citrix ADC SDX appliances. It affects the output of the stat system CPU and stat system commands.

Supported Citrix ADC MPX models:

- 25xxx
- 22xxx
- 14xxx
- 115xx
- 15xxx
- 26xxx

> **Note:**
>
> For Citrix ADC MPX 26xxx models with more than 20 cores, the mandatory extra management CPU feature is enabled by default. For Citrix ADC VPX models, a license that supports at least 12 vCPUs is required to enable this feature.

Allocate an extra management CPU by using the command interface

At the command prompt, type one of the following commands:

- `enable extramgmtcpu`
- `disable extramgmtcpu`

> **Note:**
>
> After you enable and disable this feature, the Citrix ADC appliance displays a warning to restart the appliance, for the changes to take effect.

To show the configured and effective state of an extra management CPU.

At the command prompt, type:

```
1 `show extramgmtcpu`
```

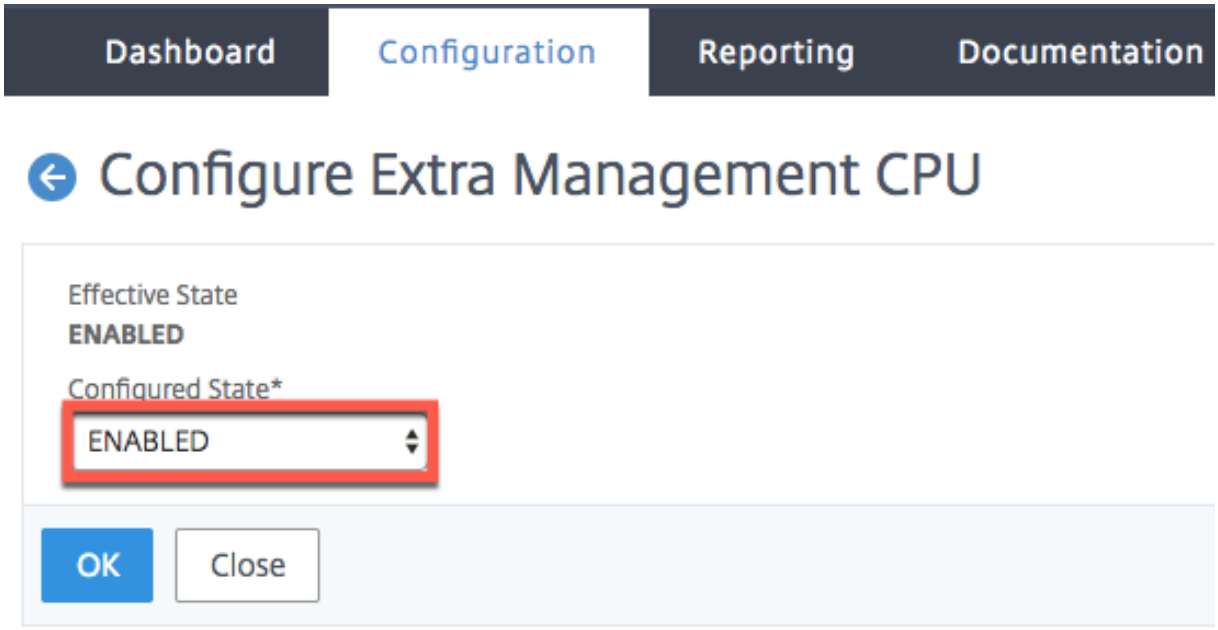
Example:

```
> show extramgmtcpu ConfiguredState: ENABLED EffectiveState: ENABLED
```

> **Note:**
>
> In this example, the show command is entered before restarting the appliance.

Allocate an extra management CPU by using the GUI

To allocate an extra management CPU by using the GUI, navigate to **System** > **Settings** and click **Configure Extra Management CPU**. From the **Configured State** drop-down menu, select **Enabled** and then select **OK**.



To check CPU usage, go to **System** > **Settings** > **Dashboard**.

Configure an extra management CPU by using the NITRO API

Use the following NITRO methods and formats to enable, disable, and show an extra management CPU.

To enable an extra management CPU:

```
HTTP Method: POST
```

```
URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=enable
```

```
Payload: { "systemextramgmtcpu":{ } }
```

```
curl -v -X POST -H "Content-Type: application/json"-u nsroot:nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?action=enable -d '{ "systemextramgmtcpu":{ } } '
```

To disable an extra management CPU

```
HTTP Method: POST
```

```
URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=disable
```

```
Payload: { "systemextramgmtcpu":{ } }
```

```
curl -v -X POST -H "Content-Type: application/json"-u nsroot:nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?action=disable -d '{ "systemextramgmtcpu":{ } } '
```

To show an extra management CPU

```
HTTP Method: GET
```

```
URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu
```

Example:

```
curl -v -X GET -H "Content-Type: application/json"-u nsroot:nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu
```

Statistics and monitoring before and after adding extra management CPU

The following examples show the differences in the output of the stat system CPU and stat system commands before and after adding an extra management CPU.

```
stat system cpu
```

This command displays statistics of CPUs.

Here is a sample output before adding an extra management CPU on one of the supported models.

Example

```
```
> stat system cpu

CPU statistics

ID   Usage

8   1

7   1

11   2

1   1

6   1

9   1

3   1
```

 
```

```
21
22 5               1
23
24 4               1
25
26 10              1
27
28 2               1
29 <!--NeedCopy--> ```
```

Here is the output after adding an extra management CPU on the same MPX appliance.

```
1  ```
2  > stat system cpu
3
4  CPU statistics
5
6  ID          Usage
7
8  9               1
9
10 7               1
11
12 5               1
13
14 8               1
15
16 11              2
17
18 10              1
19
20 6               1
21
22 4               1
23
24 3               1
25
26 2               1
27 <!--NeedCopy--> ```
```

`stat system`

This command displays CPU use. In the following example, the output before adding an extra management CPU on one of the supported models is:

Mgmt Additional-CPU usage (%) 0.00

Example

```
```
> stat system

Citrix ADC Executive View

System Information:

Up since   Wed Oct 11 11:17:54 2017

/flash Used (%)   0

Packet CPU usage (%)   1.30

Management CPU usage (%)   4.00

Mgmt CPU0 usage (%)   4.00

Mgmt Additional-CPU usage (%)   0.00

Memory usage (MB)   2167

InUse Memory (%)   5.76

/var Used (%)   0
<!--NeedCopy--> ```
```

In the following example, the output after adding an extra management CPU on the same MPX appliance is:

Mgmt Additional-CPU usage (%) 0.80

```
```    > stat system

Citrix ADC Executive View

System Information:

Up since        Wed Oct 11 11:55:56 2017

/flash Used (%)                          0

Packet CPU usage (%)                 1.20

Management CPU usage (%)             5.70
```

```
14
15 Mgmt CPU0 usage (%)                10.60
16
17 Mgmt Additional-CPU  usage (%)      0.80

How to backup and restore your appliance to recover lost configuration

When your appliance gets corrupted or needs an upgrade, you can back up your system configuration. The backup procedure is done either through the Citrix CLI or GUI interface. The appliance also enables you to import the backup file from an external source. However, you can do this only through the GUI interface and there is no support through the CLI interface.

Points to remember

You must remember the following points when your backup and restore your appliance.

- There must be a support for network configuration on a new platform.
- The new platform build must be same as the backup file or a later version.

Back up a Citrix ADC appliance

Depending on data and backup requirement, you can create a “basic” backup or a “full” backup.

- **Basic backup.** You can perform this type of backup if you want to back up files that constantly change. The files that you can back up are in the following table.

For information about the basic backup details, see the Table topic.

- **Full backup.** In addition to the files that are backed up by a basic backup, a full backup has less frequently updated files. The files that are backed up when you use the “Full” backup option are:

Directory	Sub-Directory or Files
nsconfig	ssl*, license*, fips*

Directory	Sub-Directory or Files
/var/	netscaler/ssl/*, wi/java_home/jre/lib/security/cacerts/*, wi/java_home/lib/security/cacerts/*

The backed-up data is stored as a compressed TAR file in the `/var/ns_sys_backup/` directory. To avoid issues due to non-availability of disk space, you can store up to 50 backup files in this directory. You can use the `rm system backup` command to delete existing backup files and create more backups.

> **Note:**
>
> When the backup operation is in progress, do not run commands that affect the configuration.
>
> If a file that is required to be backed up is not available, the operation skips that file.

Back up a Citrix ADC appliance using command interface

Follow the procedure given below to back up a Citrix ADC appliance by using the Citrix ADC command interface.

At the command prompt, do the following:

1. Save the Citrix ADC configurations.

```
save ns config
```

1. Create the backup file.

```
create system backup [<fileName>] -level <basic ¦ full> -comment <string>
```

> **Note:**
>
> If the file name is not specified, the appliance creates a TAR file with the following naming convention:`backup_<level>_<nsip_address>_<date-timestamp>.tgz`.

Example: To back up the full appliance using the default naming convention for the backup file.

```
> create system backup -level full
```

1. Verify that the backup file was created.

```
show system backup
```

You can view the properties of a specific backup file by using the `fileName` parameter.

Restore a Citrix ADC appliance by using the command interface

> **Important:**
>
> You cannot successfully restore your appliance, if you rename or modify your backup file.

When you restore your appliance, the restore operation untars the backup file from the `/var/ns_sys_backup/` directory. Once the files are untarred, the files are copied to the respective directories.

Restore the Citrix ADC from a local backup file by using the command interface

> **Note:**
>
> Citrix recommends you to back up the current configuration before restoring a previous configuration. However, if you do not want the restore command to automatically create a backup of the current configuration, use the `-skipBackup` parameter.

At the command prompt, do the following:

1. Obtain a list of the backup files available on the appliance.

   ```
   show system backup
   ```

2. Restore the appliance by specifying one of the backup files.

   ```
   restore system backup <filename> [-skipBackup]
   ```

   Example: To restore by using a full backup of an appliance

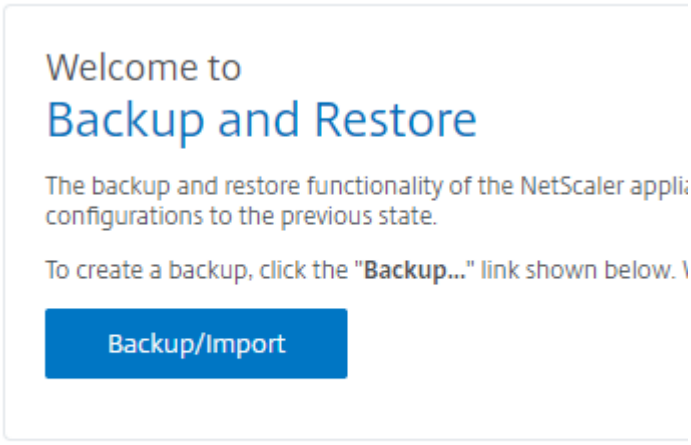
   ```
   > restore system backup backup_full_<nsip_address>_<date-timestamp>.tgz
   ```

3. Reboot the appliance.

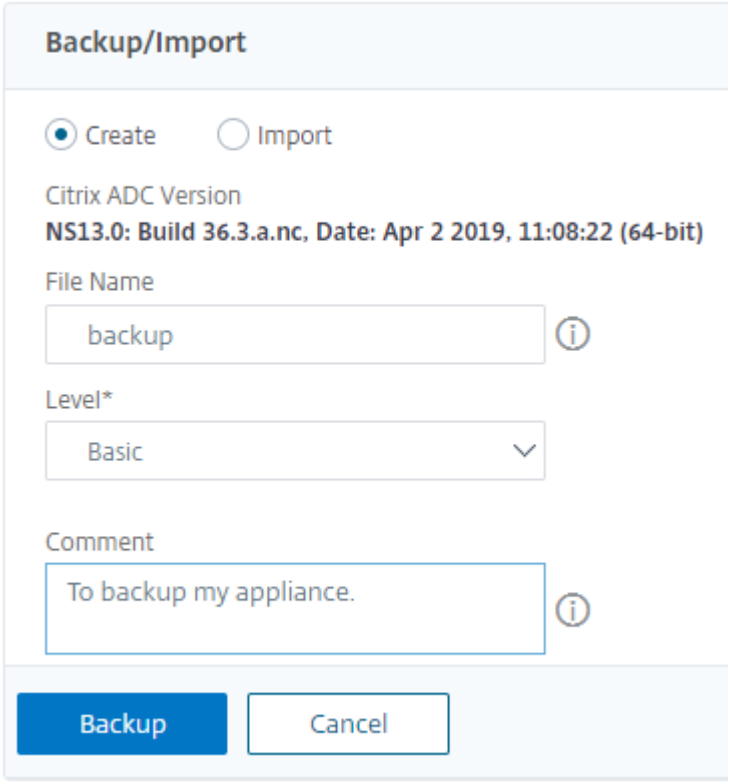
   ```
   reboot
   ```

Backup and restore a Citrix ADC appliance by using the GUI

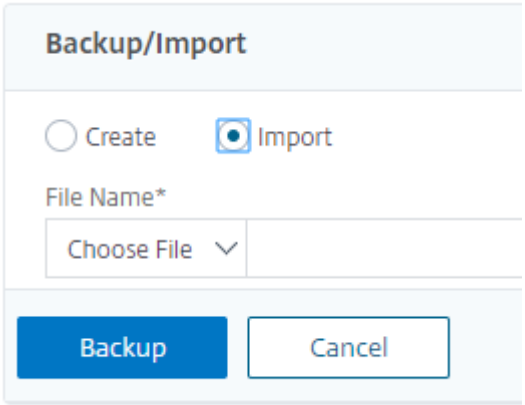
1. Navigate to **System** > **Backup and Restore**.



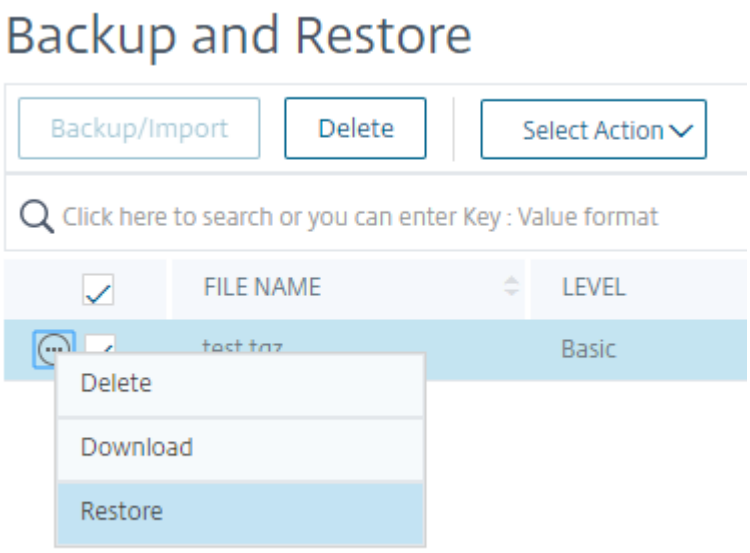
2. Click **Backup/Import** to start the process.
3. In the **Backup/Import** page, select **Create** and set the following parameters.
    a) File Name. Name of the appliance backup file.
    b) Level. Select a backup level as basic or full.
    c) Comment. Provide a brief description for the backup.
4. Click **Backup**.



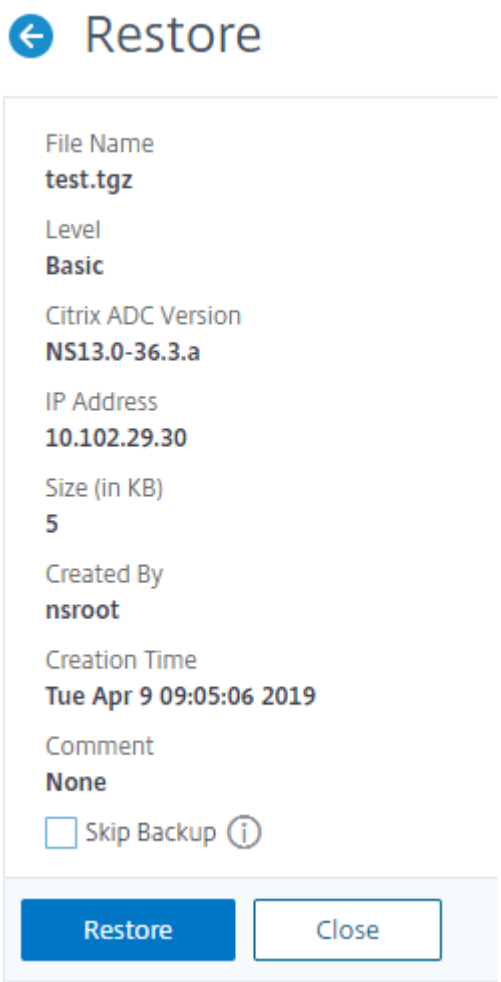
5. If you want to import a backup, you must select **Import**.



6. Once backup is complete, you can select the file and click **Download**.
7. To restore, select the backup file and click **Restore**.



8. In the **Restore** page, verify backup file details and click **Restore**.



9. After you restore, you must reboot the appliance.

For more information on how to backup and restore Citrix ADC instances, see Backup and Restore using Citrix ADM topic.

For more information on how to backup and restore an SDX appliance, see Backup and restore SDX appliance

For information about operations performed on system backup, see System Backup topic.

How to generate technical support bundle for resolving appliance issues

For help with analyzing and resolving any issues with a Citrix ADC appliance, you can generate a technical support bundle on the appliance and send the bundle to Citrix Technical Support. The Citrix ADC technical support bundle is a zipped tar archive of system configuration data and statistics. It collects the following data from the Citrix ADC appliance on which you generate the bundle:

- **Configuration files**. All files in the /flash/nsconfig directory.
- **Newnslog files**. The currently running newnslog and some previous files. To minimize the archive file size, `newnslog` collection is restricted to 500 MB, 6 files, or 7 days, whichever occurs first. If older data is needed, it might require manual collection.
- **Log files**. Files in /var/log/messages, */var/log/ns.log*, and other files under /var/log and /var/nslog.
- **Application core files**. Files created in the /var/core directory within the last week, if any.
- **Output of some CLI show commands**.
- **Output of some CLI stat commands**.
- **Output of BSD shell commands**.

You can use a single command to generate the technical support bundle and securely upload it to the Citrix Technical Support server. To upload, you must specify your Citrix credentials. When you generate the bundle, you can specify the case or service request number that was allotted to you by Citrix Technical Support. If you have already generated a technical support bundle, you can upload the existing archive file to the Citrix Technical Support server by specifying the file name with the full path.

The technical support bundle is saved on the Citrix ADC appliance in an archive at the following location:

`/var/tmp/support/support.tgz`

The path is a symlink to the most recent collector for easy access. The full file name varies, depending on the deployment topology, but generally follows a format similar to:

`collector_<P/S>_<NS IP>_<DateTime>.tgz.`

If your Citrix ADC appliance does not have direct internet connectivity, you can use a proxy server to directly upload the technical support bundle to the Citrix technical support server. The basic format of the proxy string is:

```
proxy_IP:<proxy_port>
```

If the proxy server requires authentication, the format is:

```
username:password@proxsy_IP:<proxy_port>
```

> **Note:**
>
> For Citrix ADC appliances in a high availability pair, you must generate the technical support bundle on each of the two nodes.
>
> For Citrix ADC appliances in a cluster setup, you can generate the technical support bundle on each node individually, or you can generate smaller abbreviated archives for all nodes by using the cluster IP address.
>
> For Citrix ADC admin partitions, you must generate the technical support bundle from the default admin partition. To get the technical support bundle for a specific partition, you must specify the name of the partition for which you want to generate the technical support bundle. If you do not specify the name of the partition, data is collected from all admin partitions.

Generate the Citrix ADC technical support bundle by using the command interface

At the command prompt, type:

```
show techsupport [-scope <scope> <partitionName>] [-upload [-proxy <string
>] [-casenumber <string>] [-file <string>] [-description <string>] [-
userName <string> -password ]]
```

Sr. No	Task	Command
1	Generate and upload the technical support bundle to the Citrix Technical Support server.	show techsupport –upload –userName account1 –password xxxxxxx
2	Generate and upload the technical support bundle to the Citrix Technical Support server through a proxy server	show techsupport –upload –proxy 1.1.1.1:80 –userName account1 –password xxxxxxx

Sr. No	Task	Command
3	Upload an existing technical support bundle to the Citrix Technical Support server.	show techsupport –upload -file,/var/tmp/support/collector_P_10.102.29. –userName account1 –password xxxxxxx
4	Generate small, abbreviated archives for all nodes in a Cluster setup. Run this command by using the cluster IP address	show techsupport –scope CLUSTER
5	Generate a technical support bundle specific to an admin partition. Run this command on the default admin partition.	show techsupport –scope PARTITION partition1

How to collect the technical support bundle from SDX and VPX appliances for insight analysis

A Citrix ADC appliance has a built-in mechanism to collect log files. The log files are in turn sent to Citrix Insight Services for analysis.

> **Note:**
>
> All procedures are applicable for software release 9.2 or later.

Download technical support bundle from Citrix ADC MPX and VPX appliances

To run a collector file by using the Citrix ADC GUI, you must complete the following procedure:

> **Note:**
>
> The procedure is applicable for software release 9.2 or later.

1. Navigate to **System** > **Diagnostic**.
2. In the **Technical Support Tools** section, click **Generate Support File** link.
3. In the **Tech Support** page, set the following parameters:
    a) Scope. To collect data from one or more nodes.
    b) Partition. Name of the partition.

c) Citrix Technical Support load Options. Set all options such as proxy server, service case number, collector archive file name and a brief description of the archive file for uploading the technical support bundle.

d) Citrix Account. Enter your Citrix credentials.

4. Click **Run**.
5. The Technical Support bundle is generated.
6. Click **Yes** to download the Technical support bundle to your local desktop.

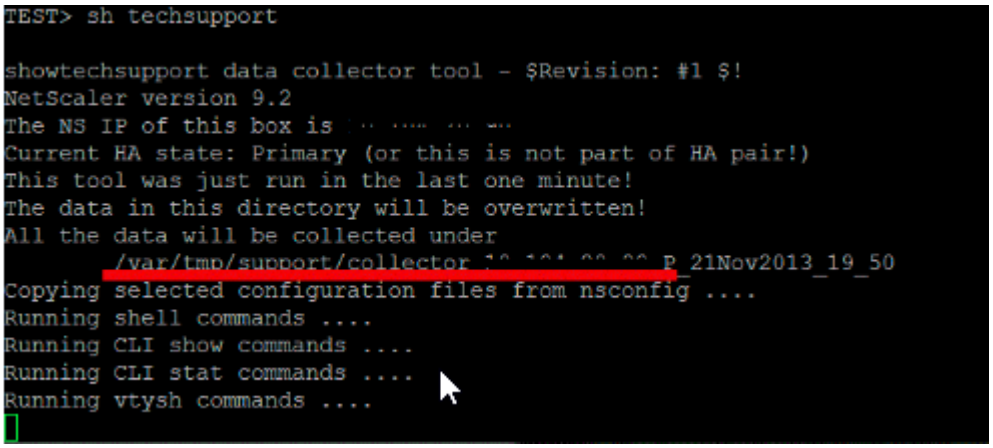
Obtain technical support bundle by using the command interface

1. Download the file from the appliance using a Secure FTP (SFTP) or Secure Copy (SCP) utility, such as WinSCP, and upload it to Citrix Insight Services for analysis.

> **Note:**
>
> In the Citrix ADC software release earlier than 9.0, the collector script must be downloaded separately and ran.

```
> show techsupport -scope CLUSTER
```

1. This collects show technical support information from all nodes in the cluster and compress the files into a single archive.
2. After the appliance generates the collector archive the location of the file is displayed as shown in the following screenshot.



The file is stored in /var/tmp/support and you can verify it by logging into a Citrix ADC appliance and running the following command from a shell prompt.

```
root@NS## cd /var/tmp/support/
root@NS## ls -l
```

Obtain diagnostic bundle from Citrix ADC SDX using the GUI

1. Open the Citrix SDX GUI.
2. Expand the **Diagnostics** node.
3. Select the **Technical Support** node.
4. Click Generate Technical Support File.
5. Select **Appliance** (Including Instances) from the drop-down menu.
6. Click **Add**.
7. Select one or more instances to add in.
8. Click **OK**. Wait for the process to complete.
9. Select the bundle name that was generated and then click **Download**
10. Upload the bundle file to Citrix Insight Services.

Command Reference Doc

System user authentication and authorization

September 14, 2021

To configure Citrix ADC user authentication and authorization, you must first define the users who have access to the Citrix ADC appliance, and then you can organize these users into groups. After configuring users and groups, you need to configure command policies to define types of access, and assign the policies to users and/or groups.

You must log on as an administrator to configure users, groups, and command policies. The default Citrix ADC administrator user name is *nsroot*. After logging on as the default administrator, you should change the password for the nsroot account. Once you have changed the password, no user can access the Citrix ADC appliance until you create an account for that user. If you forget the administrator password after changing it from the default, you can reset it to nsroot.

> **Note:**
>
> - Local users can authenticate to the Citrix ADC even if external authentication servers are configured. You can restrict this by disabling the localAuth parameter of the set system parameter command.
> - For enhanced security, Citrix recommends that you change the nsroot password. Fre-

> quently changing the password is advisable. For information about how to change the nsroot password, see Resetting the default administrator (nsroot) password topic.

User, user groups, and command policies

September 14, 2021

You must first define a user with an account and then organize all users into groups. You can create command policies, or use built-in command policies to regulate user access to commands.

> **Note:**
>
> If you prefer to know more about configuring user and user groups as part of Citrix ADC authentication and authorization setup for traffic management, see Configure users and groups topic.

You can also customize the command-line prompt for a user. Prompts can be defined in a user's configuration, in a user-group configuration, and in the global system configuration settings. The prompt displayed for a user is in the following order of precedence:

1. Display the prompt as defined in the user's configuration.
2. Display the prompt as defined in the group configuration for the user's group.
3. Display the prompt as defined in the system global configuration settings.

You can now specify a timeout value for inactive CLI sessions for a system user. If a user's CLI session is idle for a time that exceeds the timeout value, the Citrix ADC appliance terminates the connection. The timeout can be defined in a user configuration, in a user-group configuration, or in the global system configuration settings. The timeout for inactive CLI sessions for a user is determined in the following order of precedence:

1. User configuration.
2. Group configuration for the user's group.
3. Global system configuration settings.

A Citrix ADC root administrator can configure the maximum concurrent session limit for system users. By restricting the limit, you can reduce the number of open connections and improve server performance. As long as the CLI count is within the configured limit, concurrent users can log on the GUI any number of times. However, if the number of CLI sessions reaches the configured limit, users can no longer log on to the GUI. For example, if the number of concurrent sessions is configured to 20, concurrent users can log on to 19 CLI sessions. But if the user is logged on to the `20<sup>th</sup` > CLI session, any attempt to log on to the GUI, CLI, or NITRO results in an error message ((ERROR: Connection limit to CFE exceeded).

> **Note:**
>
> The default the number of concurrent sessions is configured to 20 and the maximum number of concurrent sessions is configured to 40.

Configure user accounts

To configure user accounts, you simply specify user names and passwords. You can change passwords and remove user accounts at any time.

> **Note:**
>
> All characters in a password are not accepted. However, it works if you type the characters within quotes.
>
> Also, the string must not exceed a maximum length of 127 characters.

To create a user account by using the command line interface

At the command prompt, type the following commands to create a user account and verify the configuration:

- `add system user <username> [-externalAuth ( ENABLED | DISABLED )] [-promptString <string>] [-timeout \<secs>] [-logging ( ENABLED | DISABLED )] [-maxsession <positive_integer>]`
- `show system user <userName>`

External users can configure the “logging” parameter to collect external logs using web logging or audit logging mechanism. If the parameter is enabled, the auditing client authenticates itself with Citrix ADC appliance to collect logs.

Example:

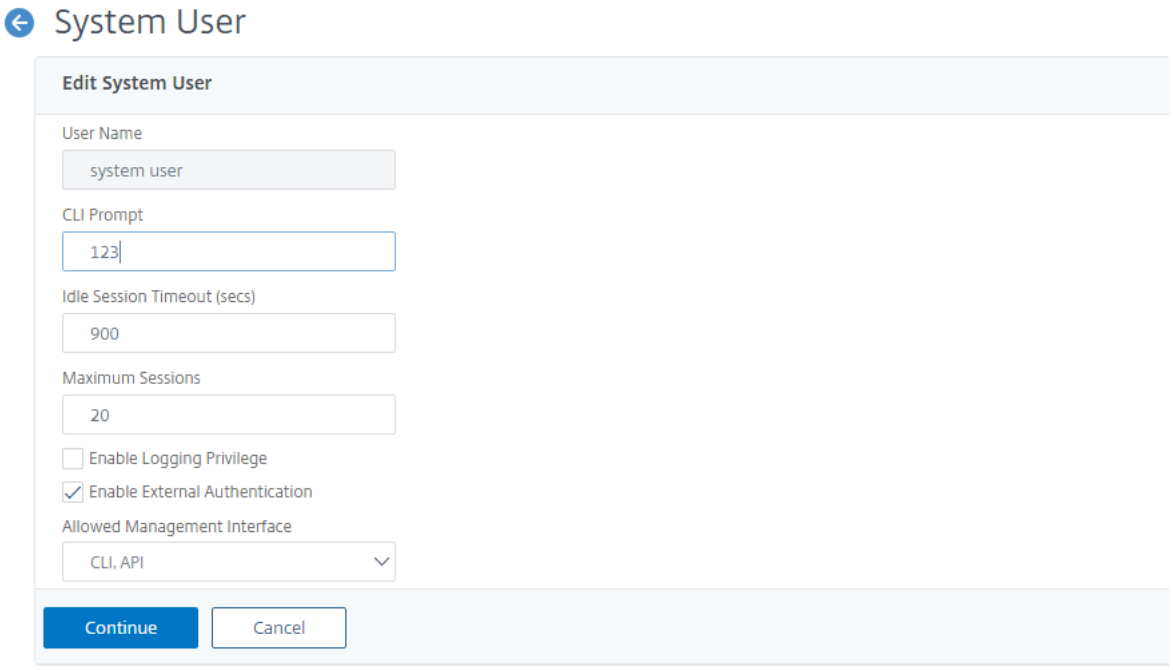
```
> add system user johnd -promptString user-%u-at-%T
```

```
Enter password:
Confirm password:
> show system user johnd
user name: john
     Timeout:900 Timeout Inherited From: Global
     External Authentication: ENABLED
     Logging: DISABLED
     Maximum Client Sessions: 20
<!--NeedCopy-->
```

For parameter description, see Authentication and authorization user command reference topic.

Configure a user account by using the Citrix ADC GUI

1. Navigate to **System** > **User Administration** > **Users**, and create the user.
2. In the details pane, click **Add** to create a system user.
3. In the **Create System Group** page, set the following parameters:
   a) User Name. Name of the user group.
   b) CLI Prompt. The prompt that you prefer to set for the CLI interface access.
   c) Idle Session Timeout (secs). Set the amount of time a user can be inactive before the session times out and closes.
   d) Maximum sessions. Set the maximum of sessions a user can try.
   e) Enable Logging Privilege. Enable logging privilege for the user.
   f) Enable external Authentication. Select the option if you want to user external authentication server for authenticating the user.
   g) Allowed Management Interface. Select the Citrix ADC interfaces for which the user group is granted permission to access.
   h) Command Policies. Bind command policies to the user group.
   i) Partitions. Bind partitions to the user group.
4. Click **Create** and **Close**.



Configure user groups

After configuring a user group, you can easily grant the same access rights to everyone in the group. To configure a group, you create the group and bind users to the group. You can bind each user account

to more than one group. Binding user accounts to multiple groups might allow more flexibility when applying command policies.

To create a user group by using the command line interface

At the command prompt, type the following commands to create a user group and verify the configuration:

- `add system group <groupName> [-promptString <string>] [-timeout <secs>]`
- `show system group <groupName>`

Example:

```
> add system group Managers -promptString Group-Managers-at-%h
```

Bind a user account to a group by using the CLI

At the command prompt, type the following commands to bind a user account to a group and verify the configuration:

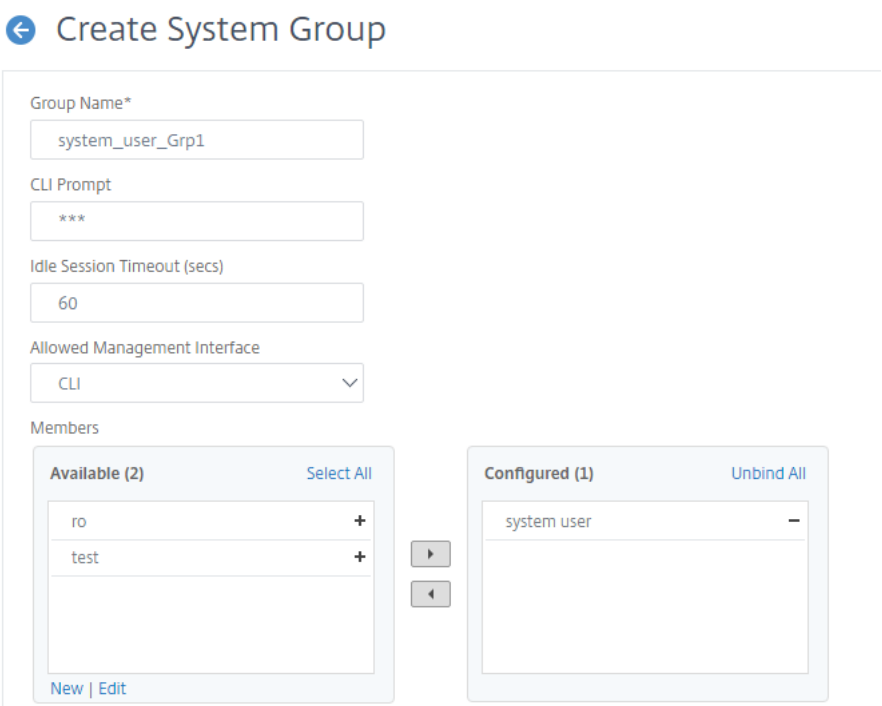
- `bind system group <groupName> -userName <userName>`
- `show system group <groupName>`

Example:

```
> bind system group Managers -userName user1
```

Configure a user group by using the Citrix ADC GUI

1. Navigate to **System** > **User Administration** > **Groups**, and create the user group.
2. In the details pane, click **Add** to create a system user group.
3. In the **Create System Group** page, set the following parameters:
   a) Group Name. Name of the user group.
   b) CLI Prompt. The prompt that you prefer to set for the CLI interface access.
   c) Idle Session Timeout (secs). Set the amount of time a user can be inactive before the session times out and closes.
   d) Allowed Management Interface. Select the Citrix ADC interfaces for which the user group is granted permission to access.
   e) Members. Add user accounts to the group.
   f) Command Policies. Bind command policies to the user group.
   g) Partitions. Bind partitions to the user group.
4. Click **Create** and **Close**.



> **Note:**
>
> To add members to the group, in the Members section, click **Add**. Select users from the Available list and add them to the Configured list.

Configure command policies

Command policies regulate which commands, command groups, virtual servers, and other entities that users and user groups are permitted to use.

The appliance provides a set of built-in command policies, and you can configure custom policies. To apply the policies, you bind them either to users or to groups.

Here are the key points to keep in mind when defining and applying command policies.

- You cannot create global command policies. Command policies must be bound directly to the users and groups on the appliance.
- Users or groups with no associated command policies are subject to the default (DENY-ALL) command policy, and are therefore unable to run any configuration commands until the proper command policies are bound to their accounts.
- All users inherit the policies of the groups to which they belong.
- You must assign a priority to a command policy when you bind it to a user account or group account. This enables the appliance to determine which policy has priority when two or more conflicting policies apply to the same user or group.

- The following commands are available by default to any user and are unaffected by any command you specify:
- help, show CLI attribute, set CLI prompt, clear CLI prompt, show CLI prompt, alias, unalias, history, quit, exit,whoami, config, set CLI mode, unset CLI mode, and show CLI mode.

The following table describes the built-in policies.

Policy name	Allows
read-only	Read-only access to all show commands except show ns runningConfig, show ns ns.conf, and the show commands for the Citrix ADC command group.
operator	Read-only access and access to commands to enable and disable services and servers.
network	Full access, except to the set and unset SSL commands, show ns ns.conf, show ns runningConfig, and show gslb runningConfig commands.
sysadmin	[Included in Citrix ADC 12.0 and later] A sysadmin is lower than a superuser is terms of access allowed on the appliance. A sysadmin user can perform all Citrix ADC operations with the following exceptions: no access to the Citrix ADC shell, cannot perform user configurations, cannot perform partition configurations, and some other configurations as stated in the sysadmin command policy.
superuser	Full access. Same privileges as the nsroot user.

Create custom command policies

Regular expression support is offered for users with the resources to maintain more customized expressions, and for those deployments that require the flexibility that regular expressions offer. For most users, the built-in command policies are sufficient. Users who need more levels of control but are unfamiliar with regular expressions might want to use only simple expressions, such as those in the examples provided in this section, to maintain policy readability.

When you use a regular expression to create a command policy, keep the following in mind.

- When you use regular expressions to define commands that is affected by a command policy, you must enclose the commands in double quotation marks. For example, to create a command policy that includes all commands that begin with show, type the following:
- “^show .*$”
- To create a command policy that includes all commands that begin with rm, type the following:
- “^rm .*$”
- Regular expressions used in command policies are not case sensitive.

The following table lists examples of regular expressions for Command Policies:

Command specification	Matches these commands
“^rm\s+.*$”	All remove actions, because all remove actions begin with the rm string, followed by a space and more parameters such as command groups, command object types, and arguments.
“^show\s+.*$”	All show commands, because all show actions begin with the show string, followed by a space and more parameters such as command groups, command object types, and arguments.
“^shell$”	The shell command alone, but not combined with any additional parameters such as command groups, command object types, and arguments.
“^add\s+vserver\s+.*$”	All create virtual server actions, which consist of add virtual server command followed by a space and more parameters such as command groups, command object types, and arguments.
“^add\s+(lb\s+vserver)\s+.*”	All create lb virtual server actions, which consist of the add lb virtual server command followed by a space and more parameters such as command groups, command object types, and arguments.

For information about built-in command policies, see table Built-in command policy table.

To create a command policy by using the command line interface

At the command prompt, type the following commands to create a command policy and verify the configuration:

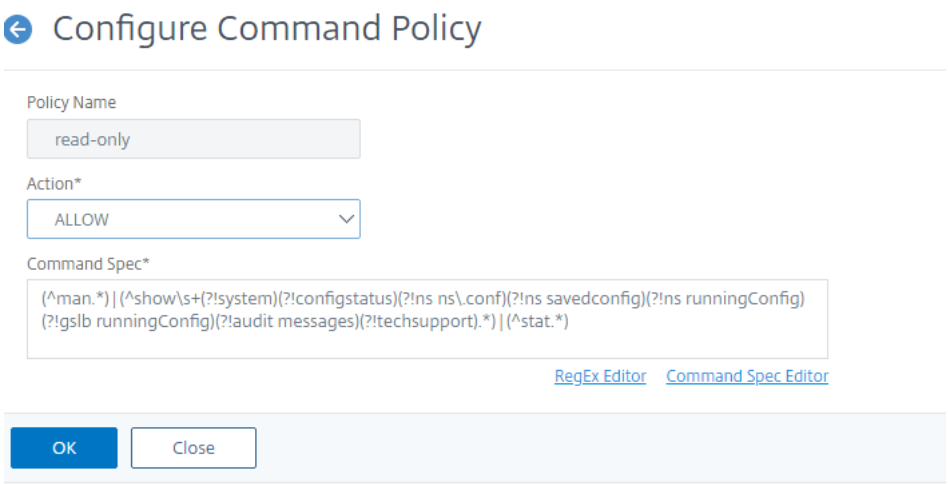
- `add system cmdPolicy <policyname> <action> <cmdspec>`
- `show system cmdPolicy <policyName>`

Example:

```
add system cmdPolicy USER-POLICY ALLOW (\ server\ )|(\ service(Group)*\ )
|(\ vserver\ )|(\ policy\ )|(\ policylabel\ )|(\ limitIdentifier\ )|(^show\
 (?!(system|ns\ (ns.conf|runningConfig)))|(save)|(stat\ .*serv)
```

Configure a command policy by using the Citrix ADC GUI

1. Navigate to **System** > **User Administration** > **Command Policies**.
2. In the details pane, click **Add** to create a new command policy.
3. In the **Configure Command Policy** page, set the following parameters:
   a) Policy name
   b) Action
   c) Command Spec.
4. Click **OK**.



Bind command policies to user accounts and user groups

Once you have defined your command policies, you must bind them to the appropriate user accounts and groups. When you bind a policy, you must assign it a priority so that the appliance can determine which command policy to follow when two or more applicable command policies are in conflict.

Command policies are evaluated in the following order:

- Command policies bound directly to users and the corresponding groups are evaluated according to a priority number. A command policy with a lower priority number is evaluated before one with a higher priority number. Therefore, any privileges the lower-numbered command policy explicitly grants or denies are not overridden by a higher-numbered command policy.
- When two command policies, one bound to a user account and other to a group, have the same priority number, the command policy bound directly to the user account is evaluated first.

To bind command policies to a user by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user and verify the configuration:

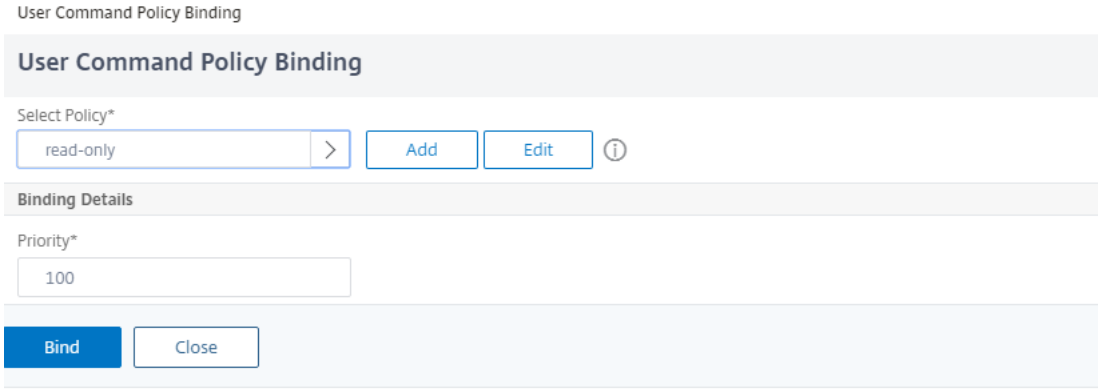
- `bind system user <userName> -policyName <policyName> <priority>`
- `show system user <userName>`

Example:

```
> bind system user user1 -policyName read_all 1
```

Bind command policies to a user account by using the Citrix ADC GUI

Navigate to **System** > **User Administration** > **Users**, select the user and bind command policies.



Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

To bind command policies to a group by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user group and verify the configuration:

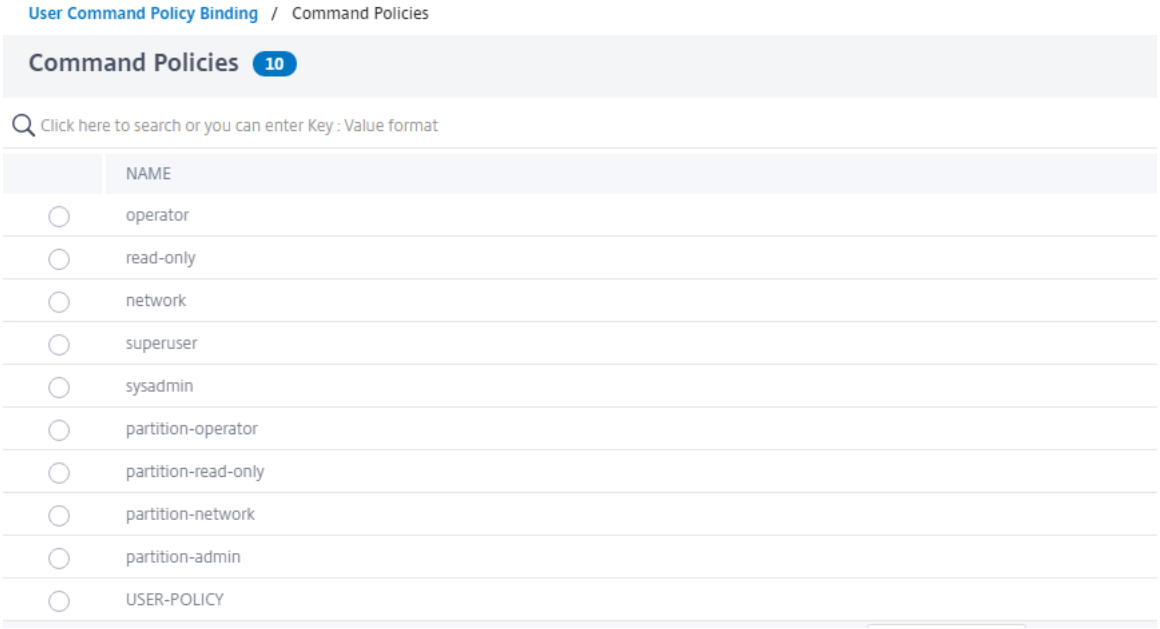
- `bind system group <groupName> -policyName <policyName> <priority>`
- `show system group <groupName>`

Example:

```
> bind system group Managers -policyName read_all 1
```

Bind command policies to a user group by using the Citrix ADC GUI

Navigate to **System** > **User Administration** > **Groups**, select the group and bind command policies.



Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

Example use case: Manage user accounts, user groups, and command policies in a manufacturing organization

The following example shows how to create a complete set of user accounts, groups, and command policies and bind each policy to the appropriate groups and users. The company, Example Manufacturing, Inc., has three users who can access the Citrix ADC appliance:

- **John Doe.** The IT manager. John must be able to see all parts of the Citrix ADC configuration but does not need to modify anything.
- **Maria Ramiez.** The lead IT administrator. Maria must be able to see and modify all parts of the Citrix ADC configuration except for Citrix ADC commands (which local policy dictates must be performed while logged on as nsroot).
- **Michael Baldrock.** The IT administrator in charge of load balancing. Michael must be able to see all parts of the Citrix ADC configuration, but must modify only the load balancing functions.

The following table shows the breakdown of network information, user account names, group names, and command policies for the sample company.

Field	Value	Note
Citrix ADC host name	ns01.example.net	N/A
User accounts	johnd, mariar, and michaelb	John Doe, IT manager, Maria Ramirez, IT administrator and Michael Baldrock, IT administrator.
Groups	Managers and SysOps	All managers and all IT administrators.
Command Policies	read_all, modify_lb, and modify_all	Allow complete read-only access, Allow modify access to load balancing, and Allow complete modify access.

The following description walks you through the process of creating a complete set of user accounts, groups, and command policies on the Citrix ADC appliance named ns01.example.net.

The description includes procedures for binding the appropriate user accounts and groups to one another, and binding appropriate command policies to the user accounts and groups.

This example illustrates how you can use prioritization to grant precise access and privileges to each user in the IT department.

The example assumes that initial installation and configuration have already been performed on the Citrix ADC.

Configure user accounts, groups, and command policies for a sample organization

1. Use the procedure described in Configuring User Accounts section to create user accounts **johnd**, **mariar**, and **michaelb**.
2. Use the procedure described in Configuring User Groups to create user groups **Managers** and **SysOps**, and then bind the users **mariar** and **michaelb** to the **SysOps** group and the user **johnd** to the **Managers** group.
3. Use the procedure described in Creating Custom Command Policies to create the following command policies:
   - **read_all** with action **Allow** and command spec `"(^show\s+(?!system)(?!ns ns.conf)(?!ns runningConfig).*)|(^stat.*)"`
   - **modify_lb** with action as **Allow** and the command spec `"^set\s+lb\s+.*$"`
   - modify_all with action as Allow and the command spec `"^\S+\s+(?!system).*"`

4. Use the procedure described in "Binding Command Policies to Users and Groups" to bind the **read_all** command policy to the **SysOps** group, with priority value **1**.
5. Use the procedure described in "Binding Command Policies to Users and Groups" to bind the **modify_lb** command policy to user **michaelb**, with priority value **5**.

The configuration you just created results in the following:

- John Doe, the IT manager, has read-only access to the entire Citrix ADC configuration, but he cannot make modifications.
- Maria Ramirez, the IT lead, has near-complete access to all areas of the Citrix ADC configuration, having to log on only to perform Citrix ADC-level commands.
- Michael Baldrock, the IT administrator responsible for load balancing, has read-only access to the Citrix ADC configuration, and can modify the configuration options for load balancing.

The set of command policies that applies to a specific user is a combination of command policies applied directly to the user's account and command policies applied to one or more groups of which the user is a member.

Each time a user enters a command, the operating system searches the command policies for that user until it finds a policy with an ALLOW or DENY action that matches the command. When it finds a match, the operating system stops its command policy search and allows or denies access to the command.

If the operating system finds no matching command policy, it denies the user access to the command, in accordance with the Citrix ADC appliance's default deny policy.

> **Note:**
>
> When placing a user into multiple groups, take care not to cause unintended user command restrictions or privileges. To avoid these conflicts, when organizing your users in groups, bear in mind the Citrix ADC command policy search procedure and policy ordering rules.

User account and password management

September 14, 2021

Citrix ADC enables you to manage user accounts and password configuration. Following are some of the activities that you can perform for a system user account or `nsroot` administrative user account on the appliance.

- System user account lockout
- Lock system user account for management access
- Unlock a locked system user account for management access

- Disable management access for system user account
- Force password change for `nsroot` administrative users
- Remove sensitive files in a system user account
- Strong password configuration for system users

System user account lockout

To prevent brute force security attacks, you can configure the user lockout configuration. The configuration enables a network administrator to prevent a system user to log on to a Citrix ADC appliance. And also unlock the user account before the lock period expires.

At the command prompt, type:

```
set aaa parameter -maxloginAttempts <value> -failedLoginTimeout <value> -
persistentLoginAttempts (ENABLED | DISABLED)
```

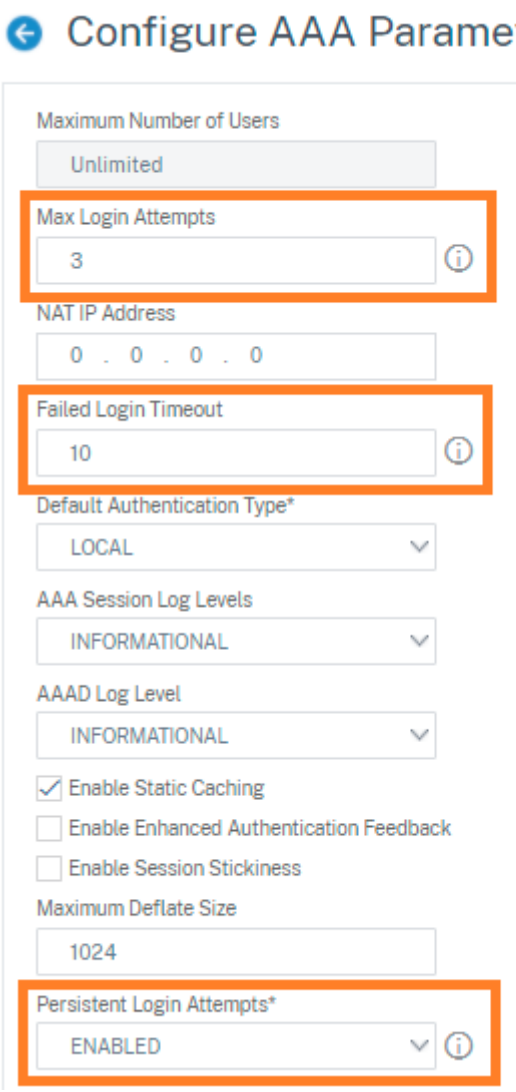
> **Note**
>
> The "persistentLoginAttempts" parameter must be ENABLED to get the details of persistent storage of unsuccessful user login attempts.

Example:

```
set aaa parameter -maxloginAttempts 3 -failedLoginTimeout 10 -persistentLoginAttempts
 ENABLED
```

Configure system user account lockout by using the GUI

1. Navigate to **Configuration > Security > AAA-Application Traffic > Authentication Settings > Change authentication AAA Settings**.
2. In the **Configure AAA Parameter** page, set the following parameters:
   a) Max Login Attempts. The maximum number of logon attempts allowed for the user to try.
   b) Failed Login Timeout. The maximum number of invalid logon attempts by the user.
   c) Persistent Login Attempts. Persistent storage of unsuccessful user login attempts.
3. Click **OK**.



When you set the parameters, the user account gets locked for 10 minutes for three or more invalid login attempts. Also, the user cannot log on even with valid credentials for 10 minutes.

> **Note**
>
> If a locked user tries to log on to the appliance, an error message, `RBA Authentication Failure: maxlogin attempt reached for test.` displays.

Lock system user account for management access

The Citrix ADC appliance enables you to lock a system user for 24 hours and deny access to the user.

Citrix ADC appliance supports the configuration for both system user and external users.

> **Note**
>
> The feature is supported only if you disable the `persistentLoginAttempts` option in the `aaa` parameter.

At the command prompt type:

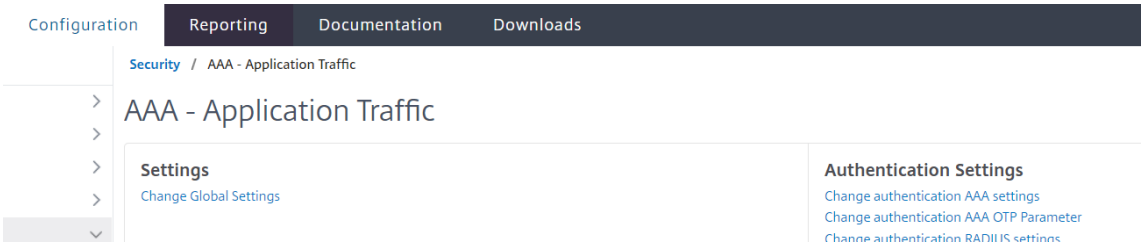
```
set aaa parameter -persistentLoginAttempts DISABLED
```

Now, to lock a user account, at the command prompt, type:

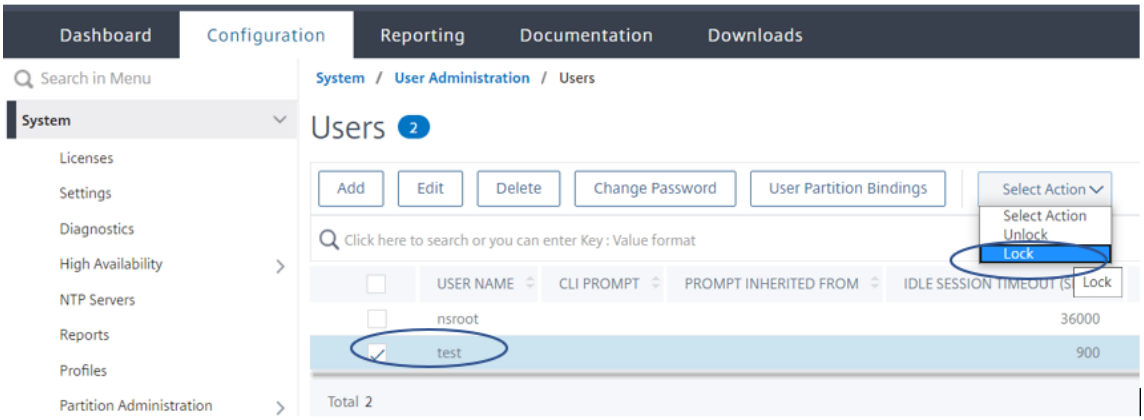
```
lock aaa user test
```

Lock a system user account by using the GUI

1. Navigate to **Configuration > Security > AAA-Application Traffic > Authentication Settings > Change authentication AAA Settings**.



2. In **Configure AAA Parameter**, in the **Persistent Login Attempts** list, select **DISABLED**.
3. Navigate to **System > User Administration > Users**.
4. Select a user.
5. In the Select Action list, select **Lock**.



> **Note**
>
> The Citrix ADC GUI does not have an option to lock external users. To lock an external user, the ADC administrator must use the CLI.

> When a locked system user (locked with lock authentication, authorization, and auditing user command) attempts to log in to Citrix ADC, the appliance displays an error message, “RBA Authentication Failure: User test is locked down for 24 hours.”
>
> When a user is locked to log on to management access, console access is exempted. Locked user is able to log on to console.

Unlock a locked system user account for management access

System users and external users can be locked for 24 hours using the lock authentication, authorization, and auditing user command.

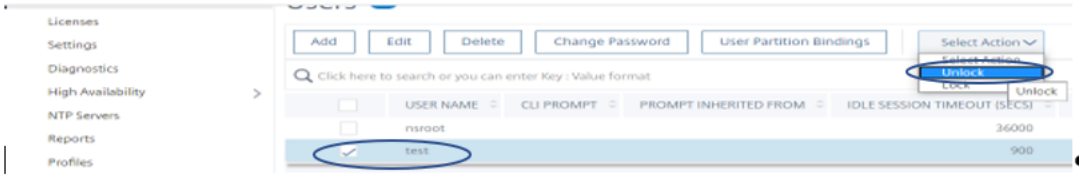
> **Note**
>
> The ADC appliance allows admins to unlock the locked user and the feature does not require any settings in “persistentloginAttempts” command.

At the command prompt, type:

```
unlock aaa user test
```

Configure system user unlock by using the GUI

1. Navigate to **System > User Administration > Users**.
2. Select a user.
3. Click **Unlock**.



The Citrix ADC GUI only lists system users created in the ADC, so there is no option in the GUI to unlock external users. To unlock an external user, the `nsroot` administrator must use the CLI.

Disable management access for system user account

When external authentication is configured on the appliance and as an admin you prefer to deny access to system users to log on to management access, you must disable the localAuth option in the system parameter.

At the command prompt, type the following:

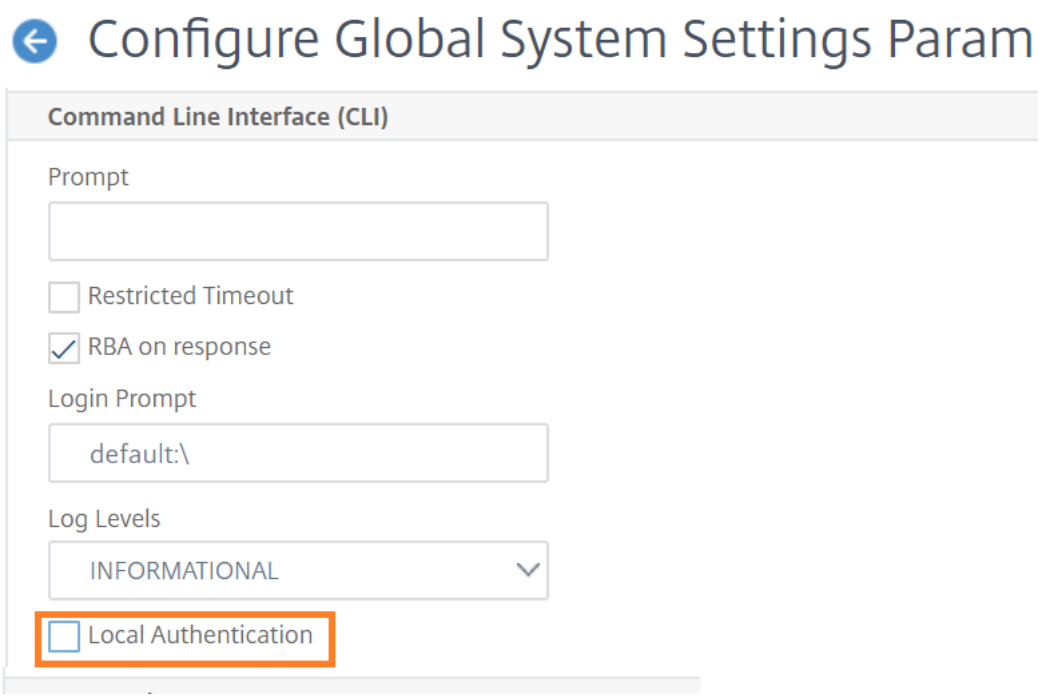
```
set system parameter localAuth <ENABLED|DISABLED>
```

Example:

```
set system parameter localAuth DISABLED
```

Disable management access to system user by using the GUI

1. Navigate to **Configuration > System > Settings > Change Global System Settings**.
2. In **Command Line Interface (CLI)** section, unselect the **Local Authentication** check box.



By disabling the option, local system users cannot log on to ADC management access.

> **Note**
>
> External authentication server must be configured and reachable to disallow local system user authentication in the system parameter. If external server configured in ADC for management access is unreachable, local system users can log on to the appliance. The behavior is set up for recovery purpose.

Force password change for administrative users

For `nsroot` secured authentication, the Citrix ADC appliance prompts the user to change the default password to a new one if the `forcePasswordChange` option is enabled in the system parameter. You can change your `nsroot` password either from CLI or GUI, on your first login with the default credentials.

At the command prompt, type:

```
set system parameter -forcePasswordChange ( ENABLED | DISABLED )
```

SSH session example for NSIP:

```
ssh nsroot@1.1.1.1
Connecting to 1.1.1.1:22...
Connection established.
To escape to local shell, press Ctrl+Alt+].
###############################################################################

WARNING: Access to this system is for authorized users only #
Disconnect IMMEDIATELY if you are not an authorized user! #

###############################################################################

Please change the default NSROOT password.
Enter new password:
Please re-enter your password:
Done
<!--NeedCopy-->
```

Remove sensitive files in a system user account

To manage sensitive data such as authorized keys and public keys for a system user account, you must enable the `removeSensitiveFiles` option. The commands that remove sensitive files when the system parameter is enabled are:

- rm cluster instance
- rm cluster node
- rm high availability node
- clear config full
- join cluster
- add cluster instance

At the command prompt, type:

```
set system parameter removeSensitiveFiles ( ENABLED | DISABLED )
```

Example:

```
set system parameter -removeSensitiveFiles ENABLED
```

Strong password configuration for system users

For secured authentication, the Citrix ADC appliance prompts system users and administrators to set strong passwords to log on to the appliance. The password must be long and must be a combination of:

- One lower case character
- One upper case character
- One numeric character
- One special character

At the command prompt, type:

```
set system parameter -strongpassword <value> -minpasswordlen <value>
```

Where,

`Strongpassword`. After enabling strong password (`enable all` / `enablelocal`) all the passwords or sensitive information must have the following:

- At least 1 lower case character
- At least 1 upper case character
- At least 1 numeric character
- At least 1 special character

Exclude the list in `enablelocal` is - `NS_FIPS`, `NS_CRL`, `NS_RSAKEY`, `NS_PKCS12`, NS_PKCS8, NS_LDAP, `NS_TACACS`, `NS_TACACSACTION`, `NS_RADIUS`, `NS_RADIUSACTION`, `NS_ENCRYPTION_PARAMS` . So no Strong Password checks are performed on these ObjectType commands for the system user.

Possible values: `enableall`, `enablelocal`, disabled
Default value: disabled

`minpasswordlen`. Minimum length of the system user password. When the strong password is enabled by default, the minimum length is 4. User entered value can be greater than or equal to 4. Default minimum value is 1 when the strong password is disabled. Maximum value is 127 in both cases.

Minimum value: 1
Maximum value: 127

Example:

```
set system parameter -strongpassword enablelocal -minpasswordlen 6
```

Default user account

The `nsrecover` user account can be used by the administrator to recover the Citrix ADC appliance. You can log in to the ADC appliance by `nsrecover` if the default system users (`nsroot`) are unable to log in due to any unforeseen issues. The `nsrecover` login is independent of user configurations and

lets you access the shell prompt directly. You are always allowed to log in through the `nsrecover` irrespective of the maximum configuration limit is reached.

How to reset root administrator (nsroot) password

September 14, 2021

The Citrix ADC root administrator (`nsroot`) account provides complete access to all ADC features. So, to preserve security, the administrative account must be used only if necessary.

As an admin, the recommendation is to change your password. If you forget your password, you must first reset to the default one and then change it to a new password.

As a `nsroot` administrator, to reset your password, you must log on to your appliance and change the password. However, if you do not remember the password, you can reboot the appliance in single user mode. Mount the file system in read/write mode, and then remove the **Citrix ADC** entry from the ns.conf file. As a final step, reboot and log on to your appliance with the default one and then set a new password.

Complete the following steps to reset your root administrator password:

1. Connect a computer to the console port of the Citrix ADC and log on.

   > **Note**
   >
   > You cannot log on by using SSH to do this procedure; you must connect directly to the appliance.

2. Reboot the Citrix ADC.
3. Press CTRL+C when the following message appears:

   ```
   Press [Ctrl-C] for command prompt, or any other key to boot immediately
   .
   Booting [kernel] in ## seconds.
   ```

   > **Note**
   >
   > In an Azure serial console, the Citrix ADC appliance does not support single boot until the ADC appliance is booted.

4. Run the following command to start the Citrix ADC in a single user mode:
   `boot -s`

   After the appliance boots, it displays the following message:

   Enter full path name of shell or `RETURN for /bin/sh:`

5. Press ENTER to display the # prompt, and type the following commands to mount the file systems:
   a) Run the following command to check the disk consistency:

      ```
      fsck_ufs /dev/ad0s1a
      ```

      > **Note**
      >
      > Your flash drive has a specific device name depending on your Citrix ADC; so, you have to replace ad0s1a in the preceding command with the appropriate device name.

   b) Access the dev directory and enter 'ls' to check the drive details.
   c) Run the following command to display the mounted partitions:

      ```
      df
      ```

      > **Note**
      >
      > If the flash partition is not listed, you must mount it manually.

   d) Run the following command to mount the flash drive:

      ```
      mount dev/ad0s1a /flash
      ```

6. Run the following command to change to the `nsconfig` directory:

   ```
   cd /flash/nsconfig
   ```

7. Run the following commands to rewrite the ns.conf file and remove the set of system commands defaulting to the admin:
   a) Run the following command to create a configuration file that does not have commands defaulting to the administrator:

      ```
      grep -v "set system user nsroot" ns.conf > new.conf
      ```

   b) Run the following command to make a backup of the existing configuration file:

      ```
      mv ns.conf old.ns.conf
      ```

   c) Run the following command to rename the new.conf file to ns.conf:

      ```
      mv new.conf ns.conf
      ```

8. Run the following command to reboot the Citrix ADC:

   ```
   reboot
   ```

9. Log on using the default administrator credentials.
10. Run the following command to reset the administrator password:

    ```
    set system user nsroot <New_Password>
    ```

> **Note**
>
> To use the "?" character in a password string, precede this character with the \ character.

For example, `yourexamplepasswd\?` is set for the administrator account after you perform the following operation:

```
> set system user nsroot yourexamplepasswd\?
```

> **Note**
>
> For resetting a forgotten (`nsroot`) password in a high availability setup, Citrix recommends you to shut down the peer node. If the peer node is active, the password is overwritten, as the config sync is triggered when the node comes up after reboot.

Also, read Citrix article, CTX224027 to know how secure SSH access to Citrix ADC appliance works.

External user authentication

September 14, 2021

Authentication service in a Citrix ADC appliance can be local or external. In external user authentication, the appliance uses an external server such as LDAP, RADIUS, or TACACS+ to authenticate the user. To authenticate an external user and grant the user access into the appliance, you must apply an authentication policy. The Citrix ADC system authentication uses Advanced authentication policies with advanced policy expressions. The Advanced authentication policies are also used for the system user management in a partitioned Citrix ADC appliance.

> **Note**
>
> If your appliance is still using Classic policies and its expressions, you must stop using it and migrate your Classic policy usage to the Advanced policy infrastructure.

Once you create an authentication policy, you must bind it to the system global entity. You can configure an external authentication server (for example, TACACS) by binding a single authentication policy to the system global entity. Or, you can configure a cascade of authentication servers by binding multiple policies to the system global entity.

> **Note**
>
> When an external user logs into the appliance, the system generates an error message, "User does not exist" in the `ns.log` file. The occurrence is because the system runs the systemuser_systemcmdpolicy_binding command to initialize the GUI for the user.

LDAP authentication (using external LDAP servers)

You can configure the Citrix ADC appliance to authenticate user access with one or more LDAP servers. LDAP authorization requires identical group names in the Active directory, on the LDAP server, and on the appliance. The characters and case must also be the same.

For more information about LDAP authentication policies, see LDAP authentication policies topic.

By default, LDAP authentication is secured by using the SSL/TLS protocol. There are two types of secure LDAP connections. In the first type, the LDAP server accepts the SSL/TLS connection on a port separate from the port used to accept clear LDAP connections. After users establish the SSL/TLS connection, LDAP traffic can be sent over the connection. The second type allows both unsecure and secure LDAP connections and the single port handles it on the server. In this scenario, to create a secure connection, the client first establishes a clear LDAP connection. Then the **LDAP** command StartTLS is sent to the server over the connection. If the LDAP server supports StartTLS, the connection is converted to a secure LDAP connection by using TLS.

The port numbers for LDAP connections are:

- 389 for unsecured LDAP connections
- 636 for secure LDAP connections
- 3268 for Microsoft unsecure LDAP connections
- 3269 for Microsoft secure LDAP connections

LDAP connections that use the StartTLS command use port number 389. If port numbers 389 or 3268 are configured on the appliance, it tries to use StartTLS to make the connection. If any other port number is used, connection attempts use SSL/TLS. If StartTLS or SSL/TLS cannot be used, the connection fails.

When configuring the LDAP server, the case of the alphabetic characters must match that on the server and on the appliance. If the root directory of the LDAP server is specified, all subdirectories are also searched to find the user attribute. In large directories, it can affect performance. For this reason, Citrix recommends that you use a specific organizational unit (OU).

The following table lists examples of the base distinguished name (DN).

LDAP server	Base DN
Microsoft Active Directory	DC=Citrix, DC=local
Novell eDirectory	dc=Citrix, dc=net
IBM Directory Server	cn=users
Lotus Domino	OU=City, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	ou=People, dc=Citrix, dc=com

The following table lists examples of the bind distinguished name (DN).

LDAP server	Bind DN
Microsoft Active Directory	CN=Administrator, CN=Users, DC=Citrix, DC=local
Novell eDirectory	cn=admin, dc=Citrix, dc=net
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	uid=admin, ou=Administrators, ou=TopologyManagement, o=NetscapeRoot

LDAP server	Bind DN
Microsoft Active Directory	CN=Administrator, CN=Users, DC=Citrix, DC=local
Novell eDirectory	cn=admin, dc=Citrix, dc=net
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	uid=admin, ou=Administrators, ou=TopologyManagement, o=NetscapeRoot

Configure LDAP user authentication by using the CLI

Complete the following steps to configure LDAP authentication for external users

Configure LDAP policy

At the command prompt, do the following:

Step 1: Create an LDAP action.

```
add authentication ldapAction <name> { -serverIP <ip_addr|ipv6_addr|*> | {
 -serverName <string> } } >] [-authTimeout <positive_integer>] [-ldapBase
<string>] [-ldapBindDn <string>] { -ldapBindDnPassword } [-ldapLoginName <
string>] [-groupAttrName <string>] [-subAttributeName <string>]
```

Example:

```
add authentication ldapAction ldap_act -serverIP <IP> -authTimeout 30 -
ldapBase "CN=xxxxx,DC=xxxx,DC=xxx"-ldapBindDn "CN=xxxxx,CN=xxxxx,DC=xxxx,DC
=xxx"-ldapBindDnPassword abcd -ldapLoginName sAMAccountName -groupattrName
memberOf -subAttributeName CN
```

For parameter description, see Authentication and authorization command reference topic.

Step 2: Create a classic LDAP policy.

```
add authentication ldapPolicy <name> <rule> [<reqAction>]
```

Example:

```
add authentication ldappolicy ldap_pol_classic ns_true ldap_act
```

> **Note**
>
> You can configure using a classic or an advanced LDAP policy but Citrix recommends you to use advanced authentication policy because classic policies are deprecated from the Citrix ADC 13.0 release onwards.

Step 3: Create an advanced LDAP policy

```
add authentication Policy <name> <rule> [<reqAction>]
```

Example:

```
add authentication policy ldap_pol_advance -rule true -action ldap_act
```

Step 4: Bind the LDAP policy to system global

At the command line prompt, do the following:

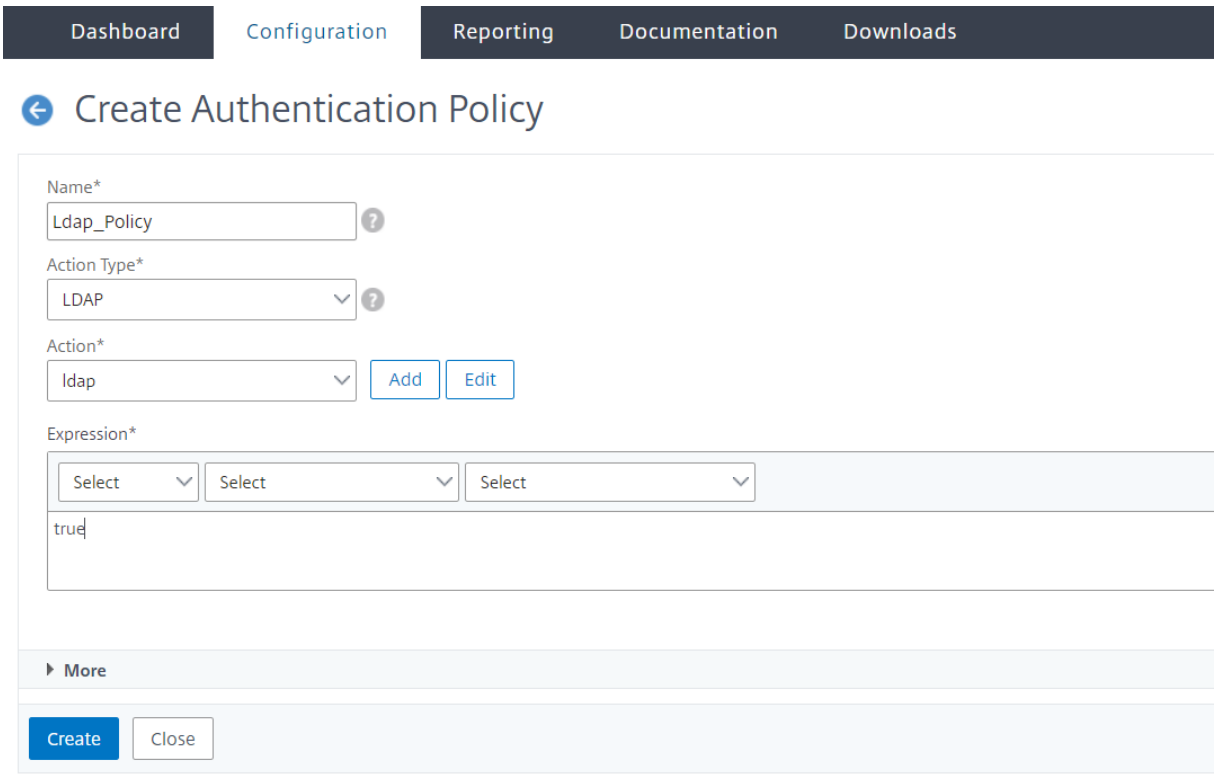
```
bind system global <policyName> [-priority <positive_integer]
```

Example:

```
bind system global ldap_pol_advanced -priority 10
```

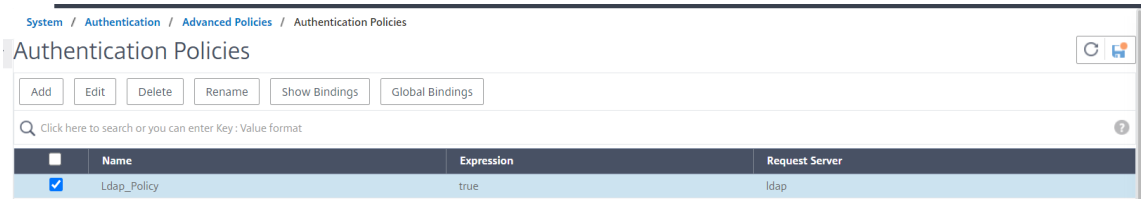
Configure LDAP user authentication by using the Citrix ADC GUI

1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Policy**.
2. Click **Add** to create an authentication policy of type LDAP.
3. Click **Create** and **Close**.

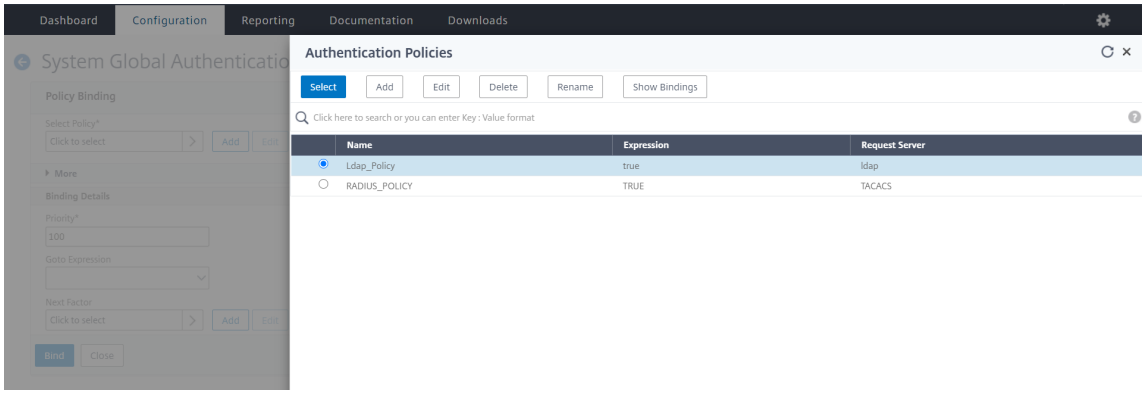


Bind an authentication policy to the system global for LDAP authentication using the Citrix ADC GUI

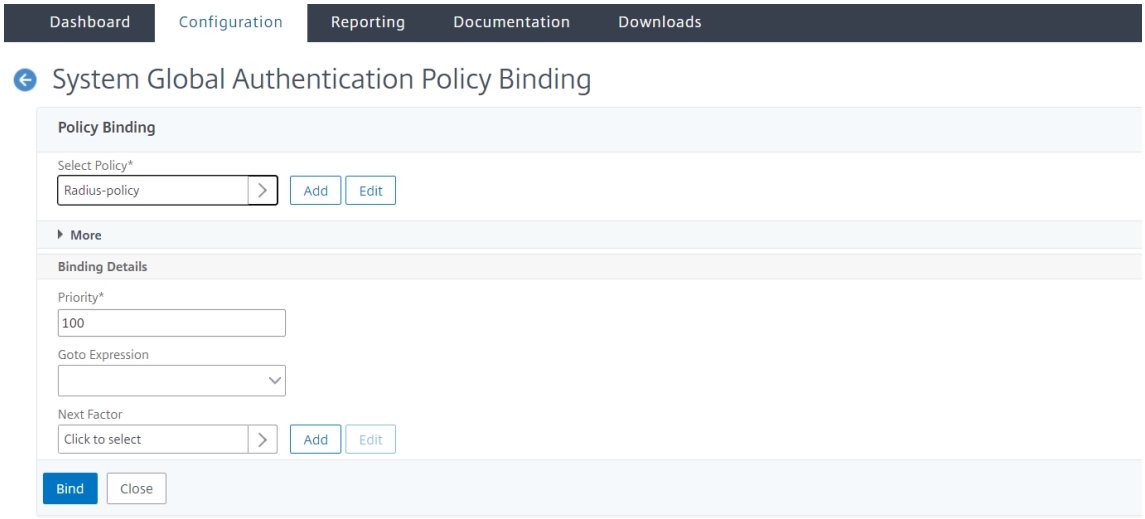
1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Authentication PoliciesPolicy**.
2. In the details pane, click **Global Bindings** to create system global authentication policy binding.
3. Click **Global Bindings**.



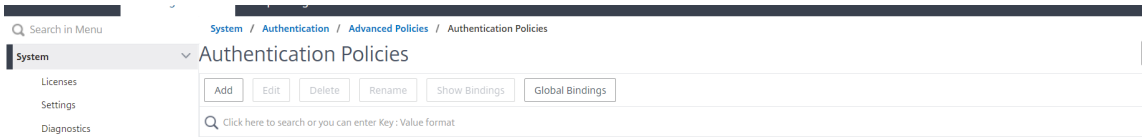
4. Select an authentication profile.



5. Select the LDAP policy.
6. In the **System Global Authentication Policy Binding** page, set the following parameters:
   a) Select Policy.
   b) Binding Details



7. Click **Bind** and **Done**.
8. Click **Global Bindings** to confirm the policy bounded to the system global.



Determining attributes in the LDAP directory

If you need help with determining your LDAP directory attributes, you can easily look them up with the free LDAP browser from Softerra.

You can download the LDAP browser from the Softerra LDAP Administrator website at <http://www.ldapbrowser.com>. After the browser is installed, set the following attributes:

- The host name or IP address of your LDAP server.
- The port of your LDAP server. The default is 389.
- The base DN field can be left blank.
- The information provided by the LDAP browser can help you determine the base DN needed for the Authentication tab.
- The Anonymous Bind check determines whether the LDAP server requires user credentials for the browser to connect to it. If the LDAP server requires credentials, leave the check box cleared.

After completing the settings, the LDAP browser displays the profile name in the left pane and connects to the LDAP server.

For more information, see LDAP topic.

Key-based authentication support for LDAP users

With key-based authentication, you can now fetch the list of public keys that are stored on the user object in the LDAP server through SSH. The Citrix ADC appliance during the role-based authentication (RBA) process must extract public SSH keys from the LDAP server. The retrieved public key, which is compatible with SSH, must allow you to log in through the RBA method.

A new attribute "sshPublicKey" is introduced in the "add authentication ldapAction" and "set authentication ldapAction" commands. By using this attribute, you can obtain the following benefits:

- Can store the retrieved public key, and the LDAP action uses this attribute to retrieve SSH key information from LDAP server.
- Can extract attribute names of up to 24 KB.

> **Note**
>
> The external authentication server, such as LDAP is used only to retrieve SSH key information. It is not used for authentication purpose.

Following is an example of the flow of events through SSH:

- SSH daemon sends an AAA_AUTHENTICATE request with password field empty to authentication, authorization, and auditing daemon port.
- If LDAP is configured to store the SSH public key, authentication, authorization, and auditing responds with "sshPublicKey" attribute along with other attributes.
- SSH daemon verifies these keys with the client keys.
- SSH daemon passes user name in the request payload, and authentication, authorization, and auditing returns the keys specific to this user along with generic keys.

To configure the sshPublicKey attribute, at the command prompt type the following commands:

- With add operation, you can add “sshPublicKey” attribute while configuring ldapAction command.

```
add authentication ldapAction <name> { -serverIP <ip_addr|ipv6_addr
|*> | { -serverName <string> } } [-serverPort <port>] … [-Attribute1 <
string>] … [-Attribute16 <string>][-sshPublicKey <string>][-authentication
 off]<!--NeedCopy-->
```

- With set operation, you can configure “sshPublicKey” attribute to an already added ldapAction command.

```
set authentication ldapAction <name> [-sshPublicKey <string>][-authentication
 off]<!--NeedCopy-->
```

RADIUS authentication (using external RADIUS servers)

You can configure the Citrix ADC appliance to authenticate user access with one or more RADIUS servers. If you are using RSA SecurID, SafeWord, or Gemalto Protiva products, use a RADIUS server.

For more information about RADIUS authentication policies, see RADIUS authentication policies topic.

Your configuration might require using a network access server IP address (NAS IP) or a network access server identifier (NAS ID). When configuring the appliance to use a RADIUS authentication server, use the following guidelines:

- If you enable use of the NAS IP, the appliance sends its configured IP address to the RADIUS server, rather than the source IP address used in establishing the RADIUS connection.
- If you configure the NAS ID, the appliance sends the identifier to the RADIUS server. If you do not configure the NAS ID, the appliance sends its host name to the RADIUS server.
- When the NAS IP address is enabled, the appliance ignores any NAS ID that it used for communicating with the RADIUS server.

Configure RADIUS user authentication by using the CLI

At the command prompt, do the following:

Step 1: Create an RADIUS action

```
add authentication radiusaction <name> -serverip <ip> -radkey <key> -
radVendorID <id> -radattributetype <value>
```

Where,
`radVendorID` RADIUS vendor ID attribute, used for RADIUS group extraction.
`radAttributeType` RADIUS attribute type, used for RADIUS group extraction.

Example:

```
add authentication radiusaction RADserver531 rad_action -serverip 1.1.1.1 -
radkey key123 -radVendorID 66 -radattributetype 6
```

Step 2: Create a classic RADIUS policy.

```
add authentication radiusPolicy <name> <rule> [<reqAction>]
```

Example:

```
add authentication radiuspolicy radius_pol_classic ns_true radius_act
```

> **Note**
>
> You can configure using a classic or an advanced RADIUS policy. Citrix recommends you to use the advanced authentication policy because classic policies are deprecated from the Citrix ADC 13.0 release onwards.

Step 3: Create an advanced RADIUS policy

```
add authentication policy <policyname> -rule true -action <radius action
name>
```

Example:

```
add authentication policy rad_pol_advanced -rule true -action radserver531rad_action
```

Step 4: Bind the RADIUS policy to the system global.

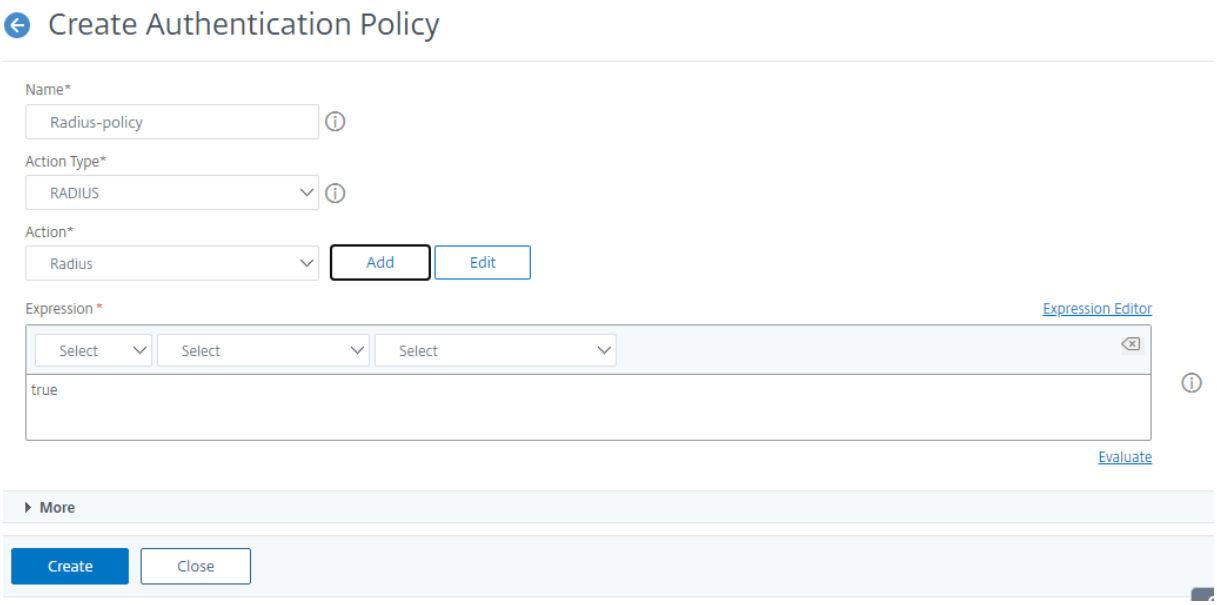
```
bind system global <policyName> -priority <positive_integer
```

Example:

```
bind system global radius_pol_advanced -priority 10
```

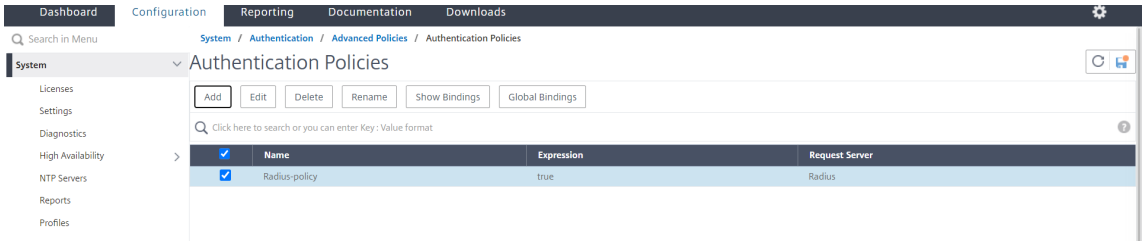
Configure RADIUS user authentication by using the GUI

1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Policy**.
2. Click **Add** to create an authentication policy of type RADIUS.
3. Click **Create** and **Close**.

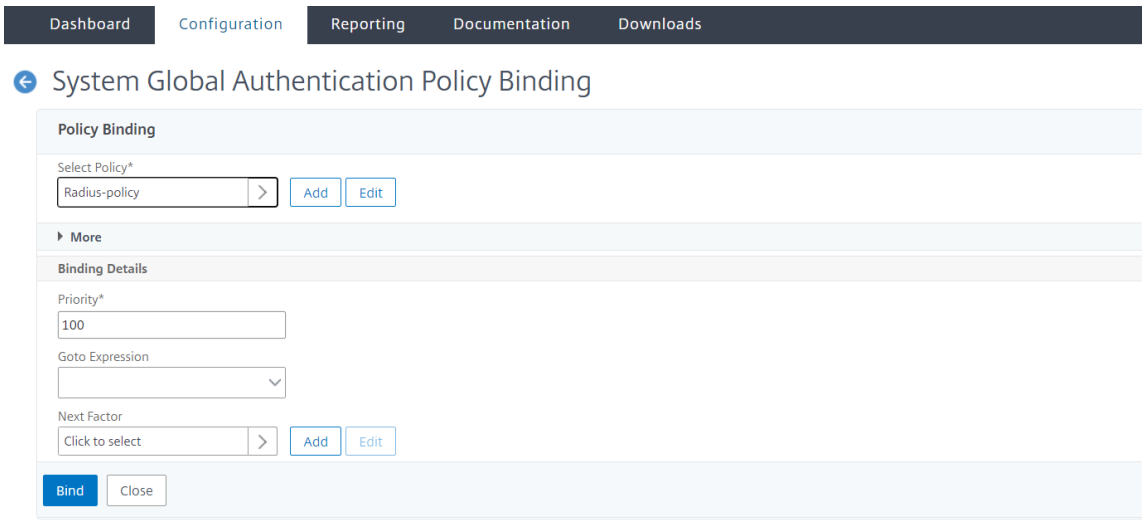


Bind the authentication policy to the system global for RADIUS authentication by using the GUI

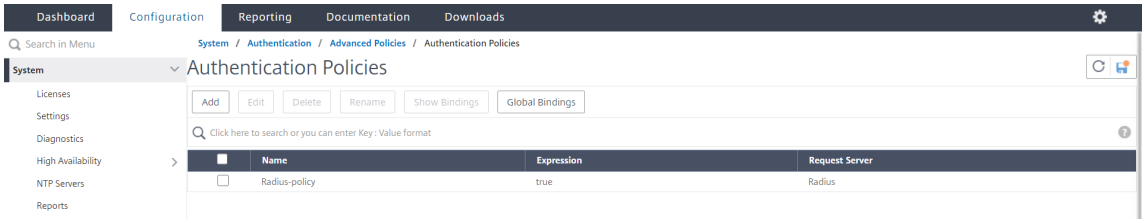
1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Policy**.
2. In the details pane, click **Global Bindings** to create system global authentication policy binding.
3. Click **Global Bindings**.



4. Select RADIUS.
5. In the **System Global Authentication Policy Binding** page, set the following parameters:
   a) Select Policy.
   b) Binding Details.



6. Click **Bind** and **Close**.
7. Click **Global Bindings** to confirm the policy bounded to the system global.



Choose RADIUS user authentication protocols

The Citrix ADC appliance supports implementations of RADIUS that are configured to use any of several protocols for user authentication, including:

- Password Authentication Protocol
- Challenge-Handshake Authentication Protocol (CHAP)
- Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP Version 1 and Version 2)

If your deployment is configured to use RADIUS authentication and your RADIUS server is configured with a Password Authentication Protocol. You can strengthen user authentication by assigning a strong shared secret to the RADIUS server. Strong RADIUS shared secrets consist of random sequences of uppercase and lowercase letters, numbers, and punctuation, and are minimum 22 characters in length. If possible, use a random character generation program to determine RADIUS shared secrets.

To further protect RADIUS traffic, assign a different shared secret to each appliance or virtual server. When you define clients on the RADIUS server, you can also assign a separate shared secret to each client. Also, you must configure separately each policy that uses RADIUS authentication.

Configure IP address extraction

You can configure the appliance to extract the IP address from a RADIUS server. When a user authenticates with the RADIUS server, the server returns a framed IP address that is assigned to the user. The following are attributes for IP address extraction:

- Allows a remote RADIUS server to supply an IP address from the internal network for a user logged on to the appliance.
- Allows configuration for any RADIUS attribute using the type ip-address, including that are vendor encoded.

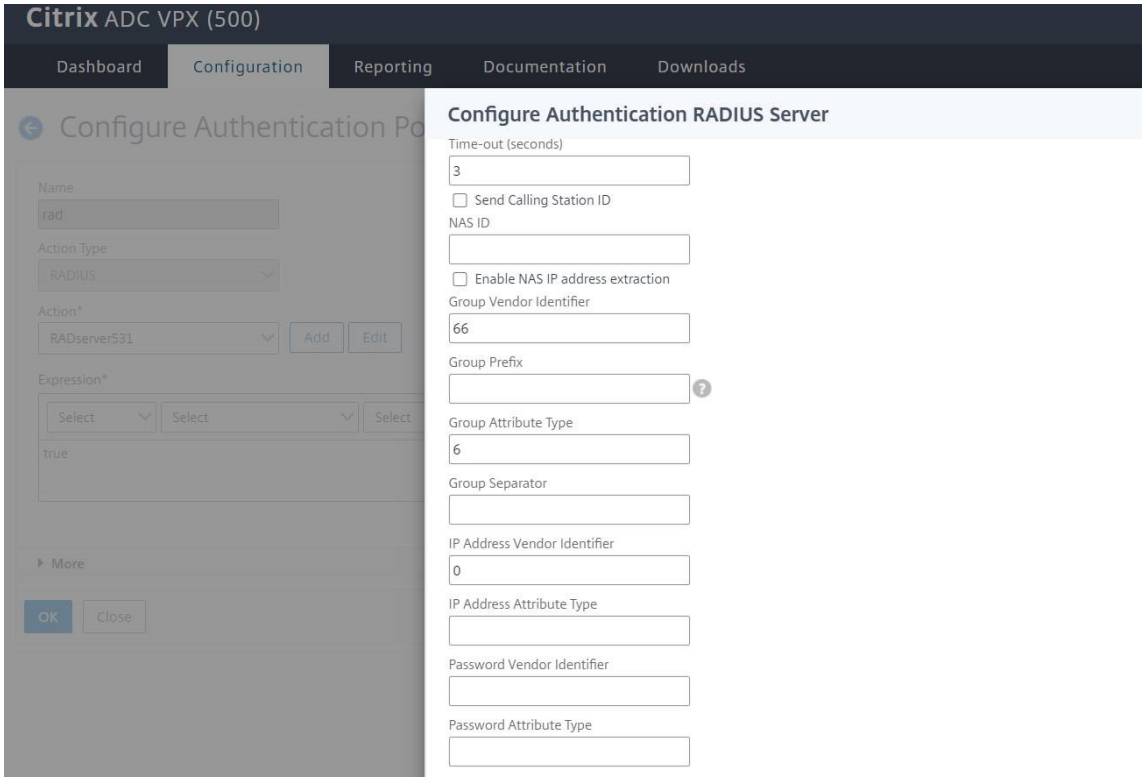
When configuring the RADIUS server for IP address extraction, you configure the vendor identifier and the attribute type.

The vendor identifier enables the RADIUS server to assign an IP address to the client from a pool of IP addresses that are configured on the RADIUS server. The vendor ID and attributes are used to make the association between the RADIUS client and the RADIUS server. The vendor ID is the attribute in the RADIUS response that provides the IP address of the internal network. A value of zero indicates that the attribute is not vendor encoded. The attribute type is the remote IP address attribute in a RADIUS response. The minimum value is one and the maximum value is 255.

A common configuration is to extract the **RADIUS** attribute *framed IP address*. The vendor ID is set to zero or is not specified. The attribute type is set to eight.

Group extraction for RADIUS by using the GUI

1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Radius**, and select a policy.
2. Select or create RADIUS policy.
3. In the **Configure Authentication RADIUS Server** page, set the following parameters.
    a) **Group Vendor Identifier**
    b) **Group Attribute Type**
4. Click **OK** and **Close**.



TACACS+ authentication (using external TACACS+ servers)

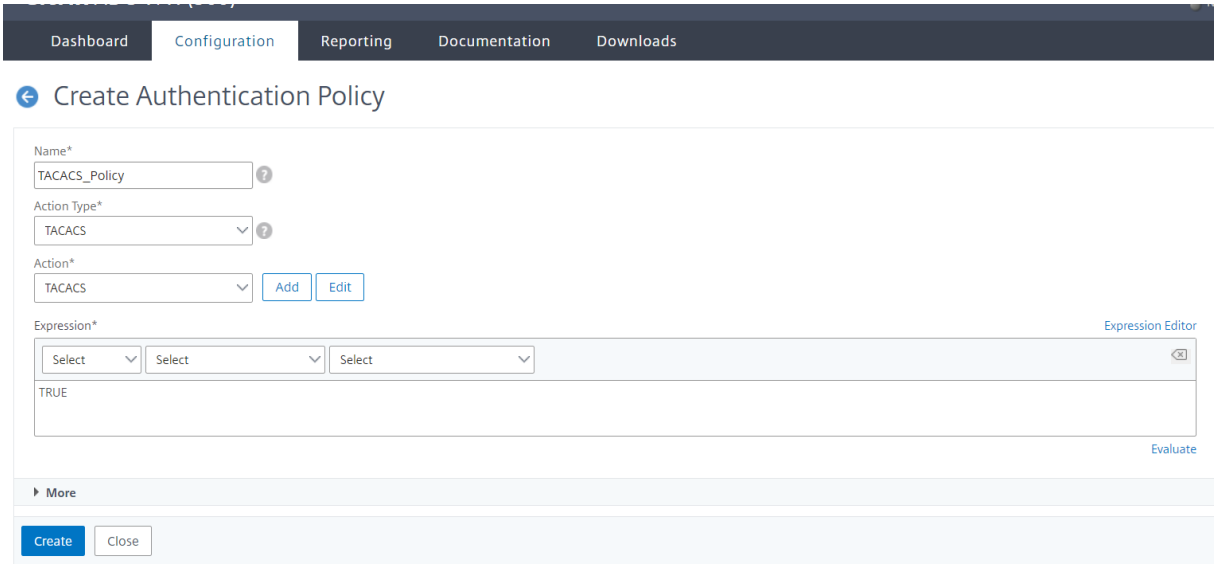
> **Important**
>
> - Citrix recommends you do not modify any TACACS related configurations when you run a "clear ns config" command.
> - TACACS related configuration related to advanced policies is cleared and reapplied when the `RBAconfig` parameter is set to NO in "clear ns config" command for advanced policy.

You can configure a TACACS+ server for authentication. Similar to RADIUS authentication, TACACS+ uses a secret key, an IP address, and the port number. The default port number is 49. To configure the appliance to use a TACACS+ server, provide the server IP address and the TACACS+ secret. You must specify port only when the server port number in use is something other than the default port number of 49.

For more information, see TACACS authentication.

Configure TACACS+ authentication by using the GUI

1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Policy**.
2. Click **Add** to create an authentication policy of type TACACS.
3. Click **Create** and **Close**.



After the TACACS+ server settings are configured on the appliance, bind the policy to the system global entity.

Bind authentication policies to the system global entity by using the CLI

When the authentication policies are configured, bind the policies to the system global entity.

At the command line prompt, do the following:

```
bind system global <policyName> [-priority <positive_integer>]
```

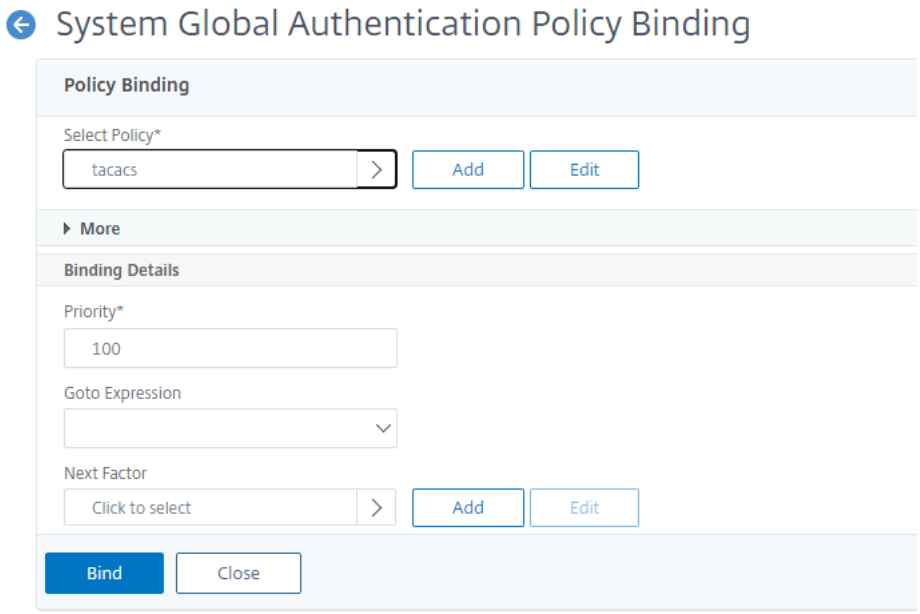
Example:

```
bind system global pol_classic -priority 10
```

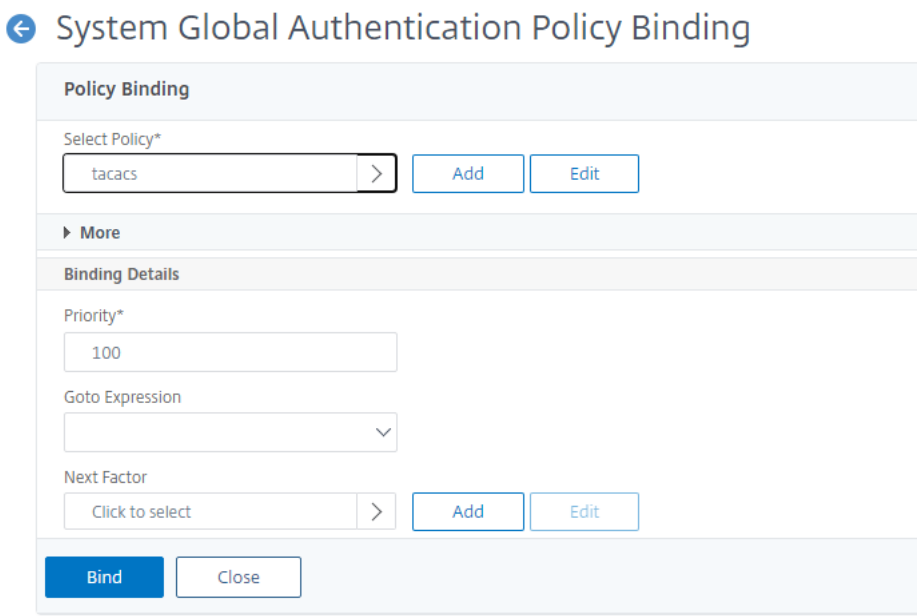
Also, read the Citrix article, CTX113820 to know about external authentication using TACACS.

Bind authentication policies to the system global entity by using the GUI

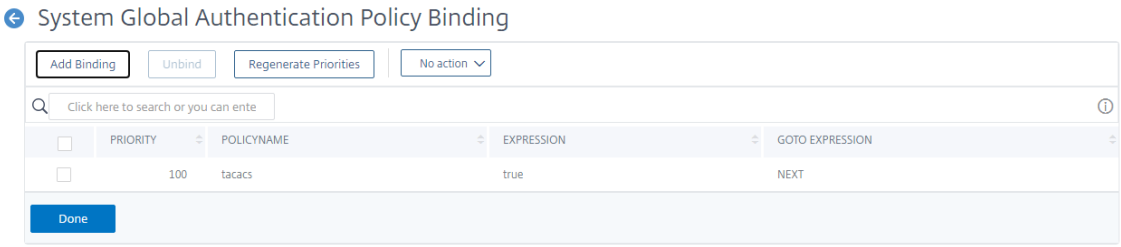
1. Navigate to **System** > **Authentication** > **Advanced Policies** > **Authentication Policies** > **Policy**.
2. In the details pane, click **Global Bindings** to create system global authentication policy binding.
3. Click **Global Bindings**.



4. Select the TACACS policy.
5. In the System Global Authentication Policy Binding page, set the following parameters:
   a) Select Policy.
   b) Binding Details



6. Click **Bind** and **Close**.
7. Click **Global Bindings** to confirm the policy bounded to the system global.



For more information about TACACS group extraction, read Citrix article CTX220024.

Display number of unsuccessful logon attempts for external users

The Citrix ADC appliance displays the number of invalid login attempts to the external user when you attempt at least one unsuccessful login before successfully logging on to the Citrix ADC management console.

> **Note**
>
> Currently, Citrix supports only keyboard interactive authentication for external users with the "persistentLoginAttempts" parameter enabled in the system parameter.

At the command prompt, type:

```
set aaa parameter -maxloginAttempts <value> -failedLoginTimeout <value> -
persistentLoginAttempts (ENABLED | DISABLED )]
```

Example:

```
set aaa parameter -maxloginAttempts 5 -failedLoginTimeout 4 -persistentLoginAttempts
 ENABLED
```

```
1  Following msg will be seen to external user when he tries 1 invalid
       login attempt before successfully login to the ADC management access
       .
2
3  Connection established.
4  To escape to local shell, press 'Ctrl+Alt+]'.

SSH key-based authentication for local system users

September 14, 2021

To have a secured user access for the Citrix ADC appliance you can have the public key authentication of the SSH server. The SSH key-based authentication is preferred over traditional user name or password based authentication for the following reasons:

- Provides better cryptographic strength than user passwords.
- Eliminates the need of remembering complicated passwords and prevents shoulder-surfing attacks which are possible if passwords are used.
- Provides a password-less login for making automation scenarios more secured.

Citrix ADC supports SSH key-based authentication by applying the public and private key concept. The SSH key-based authentication in Citrix ADC can be enabled either for a specific user or for all local users.

> **Note**
>
> The feature is supported only for Citrix ADC local users and not supported for external users.

SSH key-based authentication for local system users

In a Citrix ADC appliance, an administrator can set up SSH key-based authentication for a secured system access. When a user logs into the Citrix ADC using a private key, the system authenticates the user using the public key configured on the appliance.

Configure SSH key-based authentication for the Citrix ADC local system users by using CLI

Following configuration helps you to configure key-based authentication for Citrix ADC local system users.

1. Log on to a Citrix ADC appliance using administrator credentials.
2. By default your `sshd_config` file accesses this path: **AuthorizedKeysFile /nsconfig/ssh/authorized_keys**.
3. Append the public key to the authorized_keys file: **/nsconfig/ssh/authorized_keys**. The file path for `sshd_config` is `/etc/sshd_config`.
4. Copy the `sshd_config` file into `/nsconfig` to ensure that the changes persist even after restarting the appliance.
5. You can use the following command to restart your `sshd` process.

```
    kill -HUP `cat /var/run/sshd.pid`
<!--NeedCopy-->
```

> **Note**
>
> If the authorized_keys file is not available, you must first create one and then append the public key. **Make sure the file has the following permission for the authorized_keys**.
>
> `root@Citrix ADC## chmod 0644 authorized_keys`

```
> shell

root@ns# vi authorized_keys
### Add public keys in authorized_keys file
<!--NeedCopy-->
```

User-specific SSH key-based authentication for local system users

In a Citrix ADC appliance, an administrator can now set up a user specific SSH key-based authentication for a secured system access. The administrator must first configure the `Authorizedkeysfile`

option in the sshd_config file and then add the public key in the authorized_keys file for a system user.

> **Note**
>
> If the authorized_keys file is not available for a user, the administrator must first create one and then add the public key to it.

Configure user-specific SSH key-based authentication by using the CLI

Following procedure helps you to configure user-specific SSH key-based authentication for Citrix ADC local system users.

1. Log on to a Citrix ADC appliance using administrator credentials.
2. At the shell prompt, access the sshd_config file and add the following configuration line:

   AuthorizedKeysFile ~/.ssh/authorized_keys

   > **Note**
   >
   > The ~ is the home directory and differs for different users. It expands to the different home directory.

3. Change the directory to the system user folder and add the public keys in the authorized_keys file.

   /var/pubkey/<username>/.ssh/authorized_keys

Once you have completed the earlier steps, restart the sshd process on your appliance by the following command:

```
    kill -HUP `cat /var/run/sshd.pid`

<!--NeedCopy-->
```

> **Note**
>
> If the authorized_keys file is not available, you must first create one and then add the public key.

```
> shell

root@ns# cd /var/pubkey/<username>/
root@ns# ls
.ssh
root@ns# cd .ssh
```

```
root@ns# vi authorized_keys
### Add public keys in authorized_keys file

<!--NeedCopy-->
```

Also, read Citrix article, CTX109011 to know how secure SSH access to Citrix ADC appliance works.

Two factor authentication for system users and external users

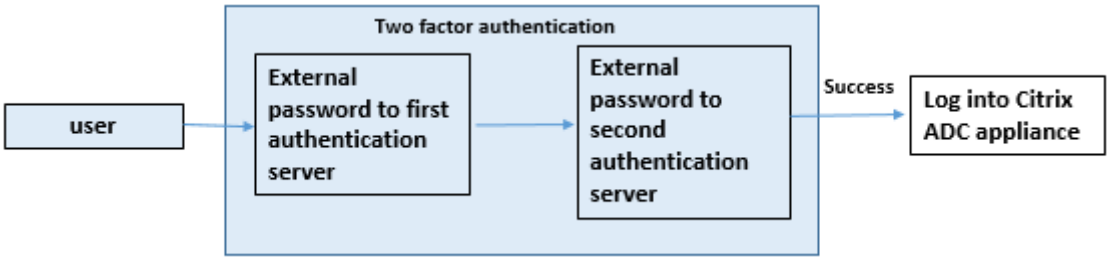
September 14, 2021

Two factor authentication is a security mechanism where a Citrix ADC appliance authenticates a system user at two authenticator levels. The appliance grants access to the user only after successful validation of passwords by both levels of authentication. If a user is authenticated locally, the user profile must be created in the Citrix ADC database. If the user is authenticated externally then, the user name and password must match the user identity registered in the external authentication server.

> **Note**
>
> Two factor authentication feature works only from Citrix ADC 12.1 build 51.16 onwards.

How two factor authentication works

Consider a user trying to log on to a Citrix ADC appliance. The requested application server sends the user name and password to the first external authentication server (RADIUS, TACACS, LDAP, or AD). Once the user name and password are validated, the user is prompted for a second level of authentication. The user can now provide the second password. Only if both passwords are correct, the user is allowed to access the Citrix ADC appliance. The following diagram is an illustration of how two-factor authentication works for a Citrix ADC appliance.



Following are the different use cases for configuring two factor authentication for external and system users.

You can configure two-factor authentication on a Citrix ADC appliance in different ways. The following are the different configuration scenarios for two factor authentication on a Citrix ADC appliance.

1. Two factor authentication (2FA) across Citrix ADC, GUI, CLI, API and SSH.
2. External authentication enabled and local authentication disabled for system users.
3. External authentication enabled with policy based local authentication for system users.
4. External authentication disabled for system users with local authentication enabled.
5. External authentication enabled and local authentication enabled for system users.
6. External authentication enabled for selected LDAP users

Use case 1: Two factor authentication (2FA) across Citrix ADC, GUI, CLI, API and SSH interfaces

Two-factor authentication is enabled and available across all Citrix ADC management access for GUI, API, and SSH.

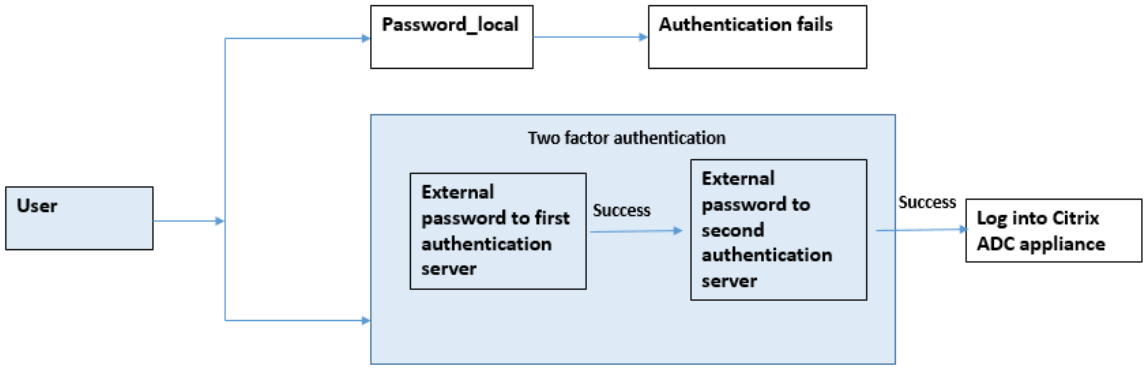
Use case 2: Two factor authentication supported on external authentication servers such as LDAP, RADIUS, Active Directory and TACACS

You can configure two-factor authentication on the following external authentication servers for first-level and second-level user authentication.

- RADIUS
- LDAP
- Active Directory
- TACACS

Use case 3: External authentication enabled and local authentication disabled for system users

You begin the authentication process by enabling the external authentication option and disabling local authentication for system users.



Complete the following steps by using the command line interface:

1. Add authentication action for LDAP policy
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add and bind authentication policy label to RADIUS server
7. Bind system global authentication for LDAP policy
8. Disable local authentication in system parameter

Add authentication action for LDAP server (first level authentication)

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase
<> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname <
loginname> -groupattrname <grp attribute name> -subAttributename <string>-
ssoNameAttribute <string>
```

Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
 name -subAttributeName name -ssoNameAttribute name
```

Add authentication policy for LDAP server (first level authentication)

At the command prompt, type:

```
add authentication policy <ldap policy name> -rule true -action <ldap
action name>
```

Example:

```
add authentication policy pol1 -rule true -action ldapact1
```

Add authentication action for RADIUS server (second level authentication)

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip>
 -radkey <key> -radVendorID <ID >-radattributetype <rad attribute type>
```

Example:

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -
radVendorID 1234 -radAttributeType 2
```

Add authentication policy for RADIUS server (second level authentication)

At the command prompt, type:

```
add authentication policy <radius policy name> -rule true -action <rad
action name>
```

Example:

```
add authentication policy radpol11 -rule true -action radact1
```

Add authentication login schema

You can use the “SingleAuth.xml” login schema for system users to provide the second password for the Citrix ADC appliance. At the command prompt, type:

```
add authentication loginSchema <login schema name> -authenticationSchema
LoginSchema/SingleAuth.xml
```

Example:

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/
SingleAuth.xml
```

Add and bind authentication policy label to RADIUS server

At the command prompt, type:

```
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )]
[-comment <string>][-loginSchema <string>]
```

```
bind authentication policylabel <labelName> -policyName <string> -priority
 <positive_integer> [-gotoPriorityExpression <expression>][-nextFactor <
string>]
```

Example:

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
```

```
bind authentication policylabel label1 -policyName radpol11 -priority 1
```

Bind authentication system global for LDAP policy

At the command prompt, type:

```
bind system global ldappolicy -priority <priority> -nextFactor <policy
label name>
```

Example:

```
bind system global pol11 -priority 1 -nextFactor label1
```

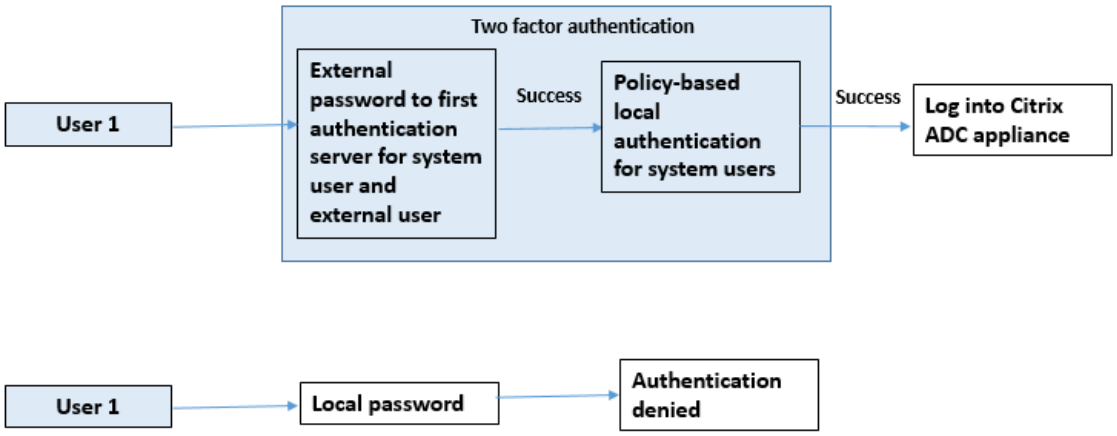
Disable local authentication in system parameter

At the command prompt, type:

```
set system parameter -localauth disabled
```

Use case 4: External authentication enabled for system user with local authentication policy attached

In this scenario, the user is allowed to log on to the appliance using two-factor authentication with local authentication policy evaluation at the second level of user identification.



Complete the following steps by using the command line interface.

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add local authentication policy
4. Add authentication policy label
5. Bind LDAP policy as system global
6. Disable local authentication in system parameter

Add authentication action for LDAP server (first level authentication)

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase
<> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname <
loginname> -groupattrname <grp attribute name> -subAttributename <string>-
ssoNameAttribute <string>
```

Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
 name -subAttributeName name -ssoNameAttribute name -ssoNameAttribute name
```

Add authentication policy for LDAP server (first level authentication)

At the command prompt, type:

```
add authentication policy <ldap policy name> -rule true -action <ldap
action name>
```

Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
 name -subAttributeName name -ssoNameAttribute name
```

Add local authentication policy for system users (second level authentication)

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip>
 -radkey <key> -radVendorID <ID >-radattributetype <rad attribute type
```

Example:

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -
radVendorID 1234 -radAttributeType 2
```

Add and bind authentication policy label

At the command prompt, type:

```
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )]
[-comment <string>][-loginSchema <string>]
bind authentication policylabel <labelName> -policyName <string> -priority
 <positive_integer> [-gotoPriorityExpression <expression>][-nextFactor <
string>]
```

Example:

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel label1 -policyName radpol11 -priority 1 -
gotoPriorityExpression NEXT
```

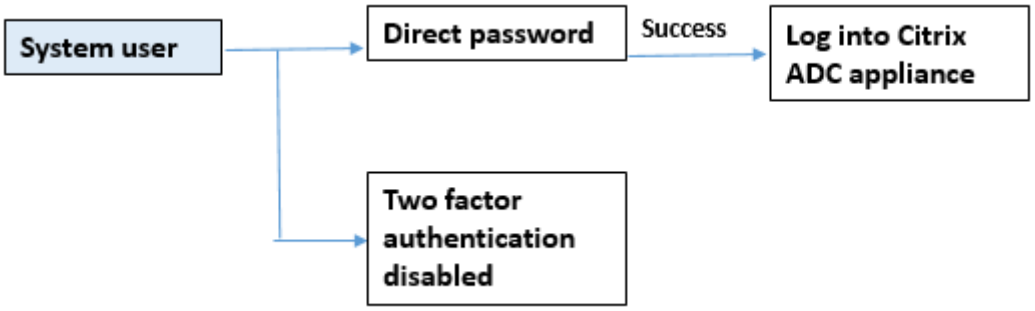
Disable local authentication in system parameter

At the command prompt, type:

```
set system parameter -localauth disabled
```

Use case 5: External authentication disabled and local authentication enabled for system user

If the user has “externalAuth” disabled, it indicates the user does not exist on the authentication server. User is not authenticated with the external authentication server even if a user with the same user name exists on the external authenticated server. User is authenticated locally.



To enable system user password and disable external authentication

At the command prompt, type the following:

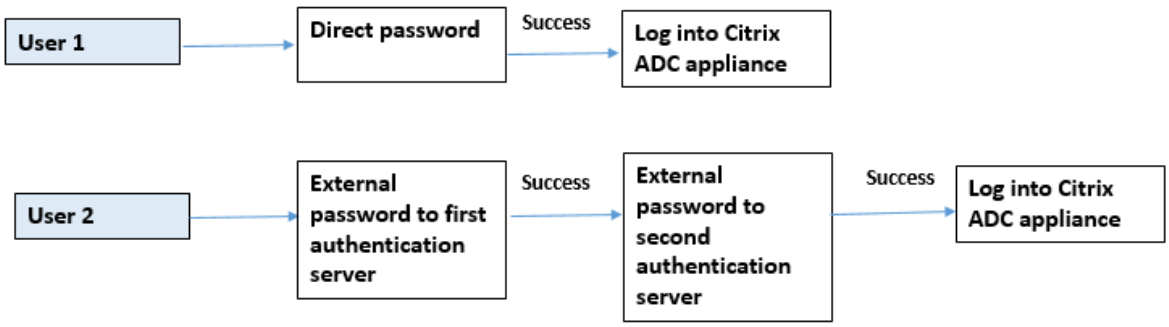
```
add system user <name> <password> -externalAuth DISABLED
```

Example:

```
add system user user1 password1 -externalAuth DISABLED
```

Use case 6: External authentication enabled and local authentication enabled for system users

To configure the appliance to authenticate system users by using a local password. If this authentication fails, the user is then authenticated by using an external authentication password on the external authentication servers at two levels.



Configure the following steps by using the CLI.

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add authentication policy label
7. Bind authentication policy label for login schema
8. Bind authentication system global for RADIUS policy
9. Bind authentication system global for LDAP policy

Add authentication action for LDAP server

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase
<> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname
 <loginname> -groupattrname <grp attribute name> -subAttributename <>-
ssoNameAttribute <>
```

Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
 name -subAttributeName name -ssoNameAttribute name
```

Add authentication policy for LDAP policy

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action
name>
```

Example:

```
add authentication policy pol1 -rule true -action ldapact1
```

Add authentication action for RADIUS server

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip>
 -radkey <key> -radVendorID <ID >-radattributetype <rad attribute type>
```

Example:

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -
radVendorID 1234 -radAttributeType 2
```

Add advanced authentication policy for RADIUS server

At the command prompt, type:

```
add authentication policy <policy name> -rule true -action <rad action name
>
```

Example:

```
add authentication policy radpol11 -rule true -action radact1
```

Add authentication login schema

You can use the SingleAuth.xml login schema to display the login page and authenticate the system user at the second level authentication.

At the command prompt, type:

```
add authentication loginSchema <name> -authenticationSchema <string>
```

Example:

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/
SingleAuth.xml
```

Add and bind authentication policy label to RADIUS authentication policy for user login

At the command prompt, type:

```
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )]
[-comment <string>][-loginSchema <string>]
```

Example:

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel <labelName> -policyName <string> -priority
 <positive_integer> [-gotoPriorityExpression <expression>][-nextFactor <
string>]
```

Example:

```
bind authentication policylabel label1 -policyName rad pol11 -priority 1
```

Bind authentication policy global

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>] [-nextFactor
 <string>] [-gotoPriorityExpression <expression>]]
```

Example:

```
bind system global radpol11 -priority 1 -nextFactor label11
```

Use case 7: External authentication enabled for selected external users only

To configure selective external users with two-factor authentication as per the search filter configured in the LDAP action while other system users are authenticated using single factor authentication.

Configure the following steps by using the CLI.

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add authentication policy label
7. Bind authentication policy label for login schema
8. Bind authentication system global for RADIUS policy

Add authentication action for LDAP server

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase
<> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname
 <loginname> -groupattrname <grp attribute name> -subAttributename <>-
ssoNameAttribute <>
```

Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
 name -subAttributeName name -ssoNameAttribute name
```

Add authentication policy for LDAP policy

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action
name>
```

Example:

```
add authentication policy pol1 -rule true -action ldapact1
```

Add authentication action for RADIUS server

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip>
 -radkey <key> -radVendorID <ID >-radattributetype <rad attribute type>
```

Example:

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -
radVendorID 1234 -radAttributeType 2
```

Add advanced authentication policy for RADIUS server

At the command prompt, type:

```
add authentication policy <policy name> -rule true -action <rad action name
>
```

Example:

```
add authentication policy radpol11 -rule true -action radact1
```

Add authentication login schema

You can use the SingleAuth.xml login schema to provide the login page for the appliance to authenticate a system user at a second level of authentication.

At the command prompt, type:

```
add authentication loginSchema <name> -authenticationSchema <string>
```

Example:

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/
SingleAuth.xml
```

Add and bind authentication policy label to RADIUS authentication policy for user login

At the command prompt, type:

```
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )]
[-comment <string>][-loginSchema <string>]
```

Example:

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel <labelName> -policyName <string> -priority
 <positive_integer> [-gotoPriorityExpression <expression>][-nextFactor <
string>]
```

Example:

```
bind authentication policylabel label1 -policyName radpol11 -priority
```

Bind authentication policy global

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>] [-nextFactor
 <string>] [-gotoPriorityExpression <expression>]]
```

Example:

```
bind system global radpol11 -priority 1 -nextFactor label11
```

To configure without two-factor authentication for group users using the search filter:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP server
3. Bind authentication system global for LDAP server

Add authentication action for LDAP server

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase
<> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname
 <loginname> -groupattrname <grp attribute name> -subAttributename <>-
searchFilter<>
```

Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
 name -subAttributeName name - searchFilter "memberOf=CN=grp4,CN=Users,DC=
aaatm-test,DC=com"
```

Add authentication policy for LDAP server

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action
name>
```

Example:

```
add authentication policy pol1 -rule true -action ldapact1
```

Bind authentication system global for LDAP policy

At the command prompt, type:

```
bind system global ldappolicy -priority <priority> -nextFactor <policy
label name>
```

Example:

```
bind system global pol11 -priority 1 -nextFactor label11
```

Display customized prompt message for two factor authentication

When you configure two factor password field with SingleAuth.xml file at /flash/nsconfig/loginschema/LoginSchema

Following is the snippet of a SingleAuth.xml file where ‘SecondPassword:’ is the second password field name which is prompted to the user to enter a second password.

```
1 <?xml version="1.0" encoding="UTF-8"?>
2 <AuthenticateResponse xmlns="http://citrix.com/authentication/response
     /1">
3 <Status>success</Status>
4 <Result>more-info</Result>
5 <StateContext/>
6 <AuthenticationRequirements>
7 <PostBack>/nf/auth/doAuthentication.do</PostBack>
8 <CancelPostBack>/nf/auth/doLogoff.do</CancelPostBack>
9 <CancelButtonText>Cancel</CancelButtonText>
```

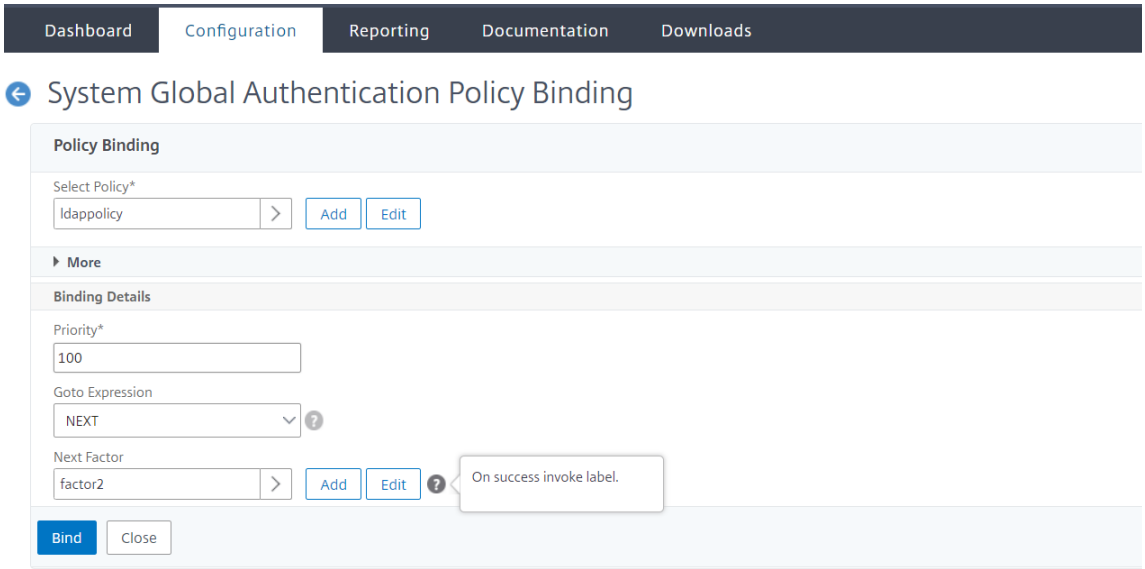
```
<Requirements>
<Requirement><Credential><ID>login</ID><SaveID>ExplicitForms-Username</SaveID><Type>username</Type></Credential><Label><Text>singleauth_user_name</Text><Type>nsg-login-label</Type></Label><Input><AssistiveText>singleauth_please_supply_either_domain\username_or_user@fully.qualified.domain</AssistiveText><Text><Secret>false</Secret><ReadOnly>false</ReadOnly><InitialValue/><Constraint>.+</Constraint></Text></Input></Requirement>
<Requirement><Credential><ID>passwd</ID><SaveID>ExplicitForms-Password</SaveID><Type>password</Type></Credential><Label><Text>SecondPassword:</Text><Type>nsg-login-label</Type></Label><Input><Text><Secret>true</Secret><ReadOnly>false</ReadOnly><InitialValue/><Constraint>.+</Constraint></Text></Input></Requirement>
<Requirement><Credential><Type>none</Type></Credential><Label><Text>singleauth_first_factor</Text><Type>nsg_confirmation</Type></Label><Input/></Requirement>
<Requirement><Credential><ID>saveCredentials</ID><Type>savecredentials</Type></Credential><Label><Text>singleauth_remember_my_password</Text><Type>nsg-login-label</Type></Label><Input><CheckBox><InitialValue>false</InitialValue></CheckBox></Input></Requirement>
<Requirement><Credential><ID>loginBtn</ID><Type>none</Type></Credential><Label><Type>none</Type></Label><Input><Button>singleauth_log_on</Button></Input></Requirement>
</Requirements>
</AuthenticationRequirements>
</AuthenticateResponse>
<!--NeedCopy-->
```

Configuring two-factor authentication by using the Citrix ADC GUI

1. Log on to Citrix ADC appliance.
2. Go to **System** > **Authentication** > **Advanced Policies** > **Policy**.
3. Click Add to create the first level authentication policy.
4. In **Create Authentication Policy** page, set the following parameters.
   a) Name. Name of the policy
   b) Action Type. Select action type as LDAP, Active Directory, RADIUS, TACACS, and so on
   c) Action. The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create an action of the proper type.
   d) Expression. Provide an advanced policy expression.
5. Click **Create** and then **Close**.

a) Expression. Provide an advanced policy expression.

6. Click **Create**.
7. Click **Add** to create the second level authentication policy.
8. In the **Create Authentication Policy** page, set the follow parameters
   a) Name. Name of the policy
   b) Action Type. Select action type as LDAP, Active Directory, RADIUS, TACACS, and so on
   c) Action. The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the + icon to create an action of the proper type.
   d) Expression. Provide an advanced policy expression
9. Click **Create** and then **Close**.
   a) Expression. Provide an advanced policy expression.
10. Click **Create**.
11. In the **Authentication Policies** page, click **Global Binding**.
12. In the **Create Global Authentication Policy Binding** page, select the first level authentication policy, and click **Add Binding**.
13. In the **Policy Binding** page, select the authentication policy and set the following policy binding parameter.
    a) Next Factor. Select the second level authentication policy label.
14. Click **Bind** and **Close**.



15. Click **Done**.

16. Log on to the Citrix ADC appliance for the second level authentication. The user can now provide the second password. Only if both passwords are correct, the user is allowed to access the Citrix ADC appliance.

> **Note**
>
> The TACACS configured for a second factor authentication does not support authorization and accounting even if you enable it on the "tacacsAction" command. The second factor is used for the authentication purpose only.

Also, see Two factor authentication in Citrix ADC nFactor authentication topic.

Restricted system user authentication to Citrix ADC management interfaces

September 14, 2021

You can restrict system user access to specific Citrix ADC management interfaces such as CLI or API. The `allowedManagementInterface` parameter defines the list of permitted management interfaces. For example, if the management interface for a user or a group is set to API, all users in the group can access Citrix ADC through API and not through CLI. However, the Citrix ADC GUI is part of the API interface and users with API permission can also access the GUI interface.

> **Note:**
>
> By default, users and groups have access to all interfaces (CLI, API, and the GUI).

You can configure the parameter either at the user level or at the user group level. When you configure at the group level, the configuration is applied across all user accounts in the group. If a user is bound to multiple groups, the appliance allows access to an aggregated set of management interfaces. You can specify settings for a user in a group by configuring the parameter at user level. In this case – user level setting is configured for a group.
In certain scenarios, when the customer is using an external authentication server for managing user accounts, the server details are configured on the appliance. In this case, the administrator can create a user group in the Citrix ADC appliance and add all users (grouped in the external server) to the group. For example, all users managed in the external server are added to the API_users group and the admin can configure the group locally on the appliance.

> **Note:**
>
> The Citrix ADC appliance allows only `nsroot` administrator (superuser) to configure the parameter and does not allow any system user to change the parameter setting.

Configure user access to Citrix ADC management interfaces by using the CLI

To allow user access to a specific management interface, you must set the allowed management interface parameter. At the command prompt, type:

```
set system group <groupName> [-allowedManagementInterface ( CLI | API )]
```

Example:

```
set system group network_usergroup -allowedManagementInterface CLI
```

For parameter description, see Authentication and authorization command reference topic.

To know about Citrix GUI and CLI interfaces, see Access Citrix ADC topic.

TCP Configurations

October 4, 2021

TCP configurations for a Citrix ADC appliance can be specified in an entity called a TCP profile, which is a collection of TCP settings. The TCP profile can then be associated with services or virtual servers that want to use these TCP configurations.

A default TCP profile can be configured to set the TCP configurations that will be applied by default, globally to all services and virtual servers.

> **Note:**
>
> When a TCP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence. The Citrix ADC appliance also provides other approaches for configuring TCP. Read on for more information.

Supported TCP configuration

The Citrix ADC appliance supports the following TCP capabilities:

Defending TCP against spoofing attacks

The **Citrix ADC implementation of** window attenuation is RFC 4953 compliant.

Explicit Congestion Notification (ECN)

The appliance sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption. The Citrix ADC implementation of ECN is RFC 3168 compliant.

Round trip time measurement (RTTM) using the timestamp option

For the TimeStamp option to work, at least one side of the connection (client or server) must support it. The Citrix ADC implementation of the `TimeStamp` option is RFC 1323 compliant.

Detection of spurious retransmissions

This can be done using TCP duplicate selective acknowledgment (D-SACK) and forward RTO-Recovery (F-RTO). If there are spurious retransmissions, the congestion control configurations are reverted to their original state. The Citrix ADC implementation of D-SACK is RFC 2883 compliant, and F-RTO is RFC 5682 compliant.

Congestion control

This functionality use New-Reno, BIC, CUBIC, Nile, and TCP Westwood algorithms.

Window scaling

This increases the **TCP receive** window size beyond its maximum value of 65,535 bytes.

Points to consider before you configure window scaling

- You do not set a high value for the scale factor, because this might have adverse effects on the appliance and the network.
- You do not configure window scaling unless you clearly know why you want to change the window size.
- Both hosts in the TCP connection send a window scale option during connection establishment. If only one side of a connection sets this option, window scaling is not used for the connection.
- Each connection for the same session is an independent window scaling session. For example, when a client's request and the server's response flow through the appliance, it is possible to have window scaling between the client and the appliance without window scaling between the appliance and the server.

TCP maximum congestion window

The window size is a user configurable one. The default value is 8190 bytes.

Selective acknowledgment (SACK)

This uses the data receiver (either a Citrix ADC appliance or a client) notifies the sender about all the segments that have been received successfully.

Forward acknowledgment (FACK)

This functionality avoids TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either a Citrix ADC or a client) control the amount of data injected into the network during retransmission timeouts.

TCP connection multiplexing

This functionality enables reuse of existing TCP connections. The Citrix ADC appliance stores established TCP connections to the reuse pool. Whenever a client request is received, the appliance checks for an available connection in the reuse pool and serves the new client if the connection is available. If it is unavailable, the appliance creates a connection for the client request and stores the connection to the reuse pool. The Citrix ADC supports connection multiplexing for HTTP, SSL, and DataStream connection types.

Dynamic receive buffering

This allows the receive buffer to be adjusted dynamically based on memory and network conditions.

Multipath TCP Connection

Multipath TCP (MPTCP) connections between the client and the Citrix ADC appliance. MPTCP connections are not supported between the Citrix ADC appliace and the back-end server. The Citrix ADC implementation of MPTCP is RFC 6824 and RFC 8684 compliant supporting both MPTCP version 0 and 1.

You can view MPTCP statistics such as active MPTCP connections and active subflow connections by using the command line interface.

At the command prompt, type one of the following commands to display a summary or detailed summary of MPTCP statistics, or to clear the statistics display:

1. `Stat MPTCP`
2. `Stat mptcp -detail`
3. `Clearstats basic`

> **Note:**
>
> To establish an MPTCP connection, both the client and the Citrix ADC appliance must support the same MPTCP version. If you use the Citrix ADC appliance as an MPTCP gateway for your servers, the servers do not have to support MPTCP. When the client starts a new MPTCP connection, the appliance identifies the client's MPTPC version from the MP_CAPABALE option in the SYN packet. If the client's version is higher than the one supported on the appliance, the appli-

> ance indicates its highest version in the MP_CAPABALE option of the SYN-ACK packet. The client then falls back to a lower version and sends the version number in the MP_CAPABALE option of the ACK packet. If that version is supportable, the appliance continues the MPTCP connection. Otherwise, the appliance falls back to a regular TCP. The Citrix ADC appliance does not initiate subflows (MP_JOIN's). The appliance expects the client to initiate subflows.

Support for additional address advertisement (ADD_ADDR) in MPTCP

In an MPTCP deployment, if you have a virtual server bound with an IP set that has additional virtual server IP addresses, then the additional address advertisement (ADD_ADDR) functionality advertises the IP address of the virtual servers bound to the IP set. Clients can initiate more `MP-JOIN` sub flows to the advertised IP addresses.

Points to remember about MPTCP ADD_ADDR functionality

- You can send a maximum of 10 IP addresses as part of the `ADD_ADDR` option. If there are more than 10 IP addresses with the `mptcpAdvertise` parameter enabled, after advertising the 10 IP address, the appliance ignore the rest of the IP addresses.
- If the MP-CAPABLE subflow is made to one of the IP addresses in the IP set instead of the primary virtual server IP address, then the virtual server IP address is advertised if the `mptcpAdvertise` parameter is enabled for the virtual server IP address

Configure more address advertisement (ADD_ADDR) feature to advertise more VIP address by using the CLI

You can configure the `MPTCP ADD_ADDR` functionality for both IPv4 and IPv6 address types. In general, multiple IPv4 and IPv6 IPs can be attached to a single IP set and the parameter can be enabled on any subset of IP addresses. In the ADD_ADDR feature, only the IP addresses that have the "mptcpAdvertise" option enabled is advertised and the remaining IP addresses from the IP set is ignored. Complete the following steps to configure the `ADD_ADDR` feature:

1. Add an IP set.
2. Add an IP address of type virtual server IP (VIP) with MPTCP advertise enabled.
3. Bind the IP address with the IP set.
4. Configure IP set with the load balancing virtual server.

Add an IP set

At the command prompt, type:

```
add ipset <name> [-td <positive_integer>]
<!--NeedCopy-->
```

Example:

```
add ipset ipset_1
<!--NeedCopy-->
```

Add an IP address of type virtual server IP (VIP) with MPTCP advertise enabled

At the command type:

```
add ns ip <IPAddress>@ <netmask> [-mptcpAdvertise ( YES | NO )] -type <
   type>
<!--NeedCopy-->
```

Example:

```
add ns ip 10.10.10.10 255.255.255.255 -mptcpAdvertise YES -type VIP
```

Bind IP addresses to the IP set

At the command prompt, type:

```
bind ipset <name> <IPAddress>
<!--NeedCopy-->
```

Example:

```
bind ipset ipset_1 10.10.10.10
```

Configure IP set to load balancing virtual server

At the command prompt, type:

```
set lb vserver <name> [-ipset  <string>]
<!--NeedCopy-->
```

Example:

```
set lb vserver lb1 -ipset ipset_1
<!--NeedCopy-->
```

Sample Configuration:

```
Add ipset ipset_1
add ns ip 10.10.10.10 255.255.255.255 -mptcpAdvertise YES -type VIP
bind ipset ipset_1 10.10.10.10
```

```
4 set lb vserver lb1 -ipset ipset_1
5 <!--NeedCopy-->
```

Configure advertising external IP address using ADD_ADDR functionality

If the advertised IP address is owned by the external entity and the Citrix ADC appliance needs to advertise the IP address, the "MPTCPAdvertise" parameter must be enabled with state and ARP parameters disabled.

Complete the following steps to configure ADD_ADDR for advertising the external IP address.

1. Add an IP address of type virtual server IP (VIP) with MPTCP advertise enabled.
2. Bind the IP address with the IP set.
3. Bind IP set with the load balancing virtual server

Add external IP address of type virtual server IP (VIP) with MPTCP advertise enabled

At the command prompt, type:

```
1 add ns ip <IPAddress>@ <External-IP-mask -type VIP> [-mptcpAdvertise (
     YES | NO )] -type <type> -state DISABLED -arp DISABLED
2 <!--NeedCopy-->
```

Example:

```
add ns ip 10.10.10.10 255.255.255.255 -mptcpAdvertise YES -type VIP -state
DISABLED -arp DISABLED
```

Bind IP addresses to the IP set

At the command prompt, type:

```
1 bind ipset <name> <IPAddress>
2 <!--NeedCopy-->
```

Example:

```
bind ipset ipset_1 10.10.10.10
```

Configure IP set to load balancing virtual server

At the command prompt, type:

```
1 set lb vserver <name> [-ipset  <string>]
2 <!--NeedCopy-->
```

Example:

```
set lb vserver lb1 -ipset ipset_1
```

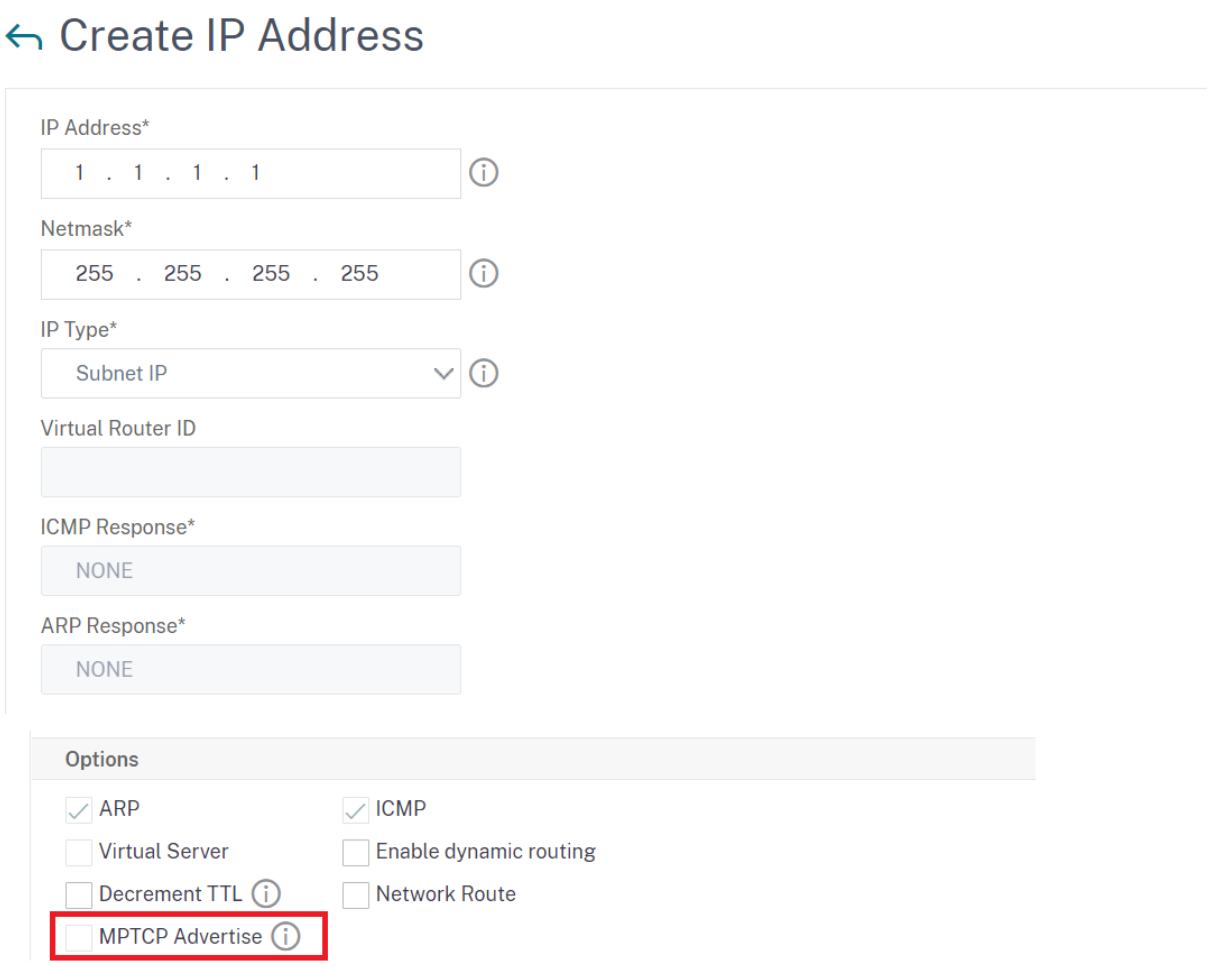
Sample Configuration:

```
add ns ip 10.10.10.10 255.255.255.255 -mptcpAdvertise YES -type VIP
   state DISABLED -arp DISABLED
bind ipset ipset_1 10.10.10.10
set lb vserver lb1 -ipset ipset_1
<!--NeedCopy-->
```

Advertise IP address to MPTCP enabled clients by using the Citrix ADC GUI

Complete the following step to advertise the IP address to the MPTCP enabled clients:

1. Navigate to **System > Network > IPs**.
2. In the details pane, click **Add**.
3. In the **Create IP Address** page, select the **MPTCP Advertise** check box to set the parameter. By default, it is disabled.



Extracting the TCP/IP path overlay option and inserting the client-IP HTTP header

Extracting TCP/IP path overlay and inserting client-IP HTTP header. Data transport through overlay networks often uses connection termination or Network Address Translation (NAT), in which the IP address of the source client is lost. To avoid this, the Citrix ADC appliance extracts the TCP/IP path overlay option and inserts the source client's IP address into the HTTP header. With the IP address in the header, the web server can identify the source client that made the connection. The extracted data is valid for a lifetime of the TCP connection and therefore, this prevents the next hop host from having to interpret the option again. This option is applicable only for web services that have the client-IP insertion option enabled.

TCP segmentation offload

Offloads TCP segmentation to the NIC. If you set the option as "AUTOMATIC", TCP segmentation is offloaded to the NIC, if NIC is supported.

Synchronizing cookie for TCP handshake with clients

This is used for resisting SYN flood attacks. You can enable or disable the `SYNCOOKIE` mechanism for TCP handshake with clients. Disabling `SYNCOOKIE` prevents `SYN` attack protection on the Citrix ADC appliance.

Learning MSS to enable MSS learning for all the virtual servers configured on the appliance

Supportable TCP Parameters

The following table provides a list of TCP parameters and its default value configured on a Citrix ADC appliance.

Parameter	Default Value	Description
Window Management		
TCP Delayed-ACK Timer	100 millisec	Timeout for TCP delayed ACK, in milliseconds.
TCP minimum Retransmission Timeout(RTO) in milli sec	1000 milli sec	Minimum retransmission timeout, in milliseconds, specified in 10-millisecond increments (value must yield a whole number if divided by 10)
Connection idle time before starting keep-alive probes	900 seconds	Silently drop TCP established connections on idle timeouts established connections on idle timeout
TCP Timestamp Option	DISABLED	The timestamp option allows for accurate RTT measurement. Enable or Disable TCP Timestamp option.
Multipath TCP session timeout	0 seconds	MPTCP session timeout in seconds. If this value is not set, idle. MPTCP sessions are flushed after the virtual server's client idle timeout.
Silently Drop HalfClosed connections on idle timeout	0 seconds	Silently drop TCP half closed connections on idle timeout.

Parameter	Default Value	Description
Silently Drop Established connections on idle timeout	DISABLED	Silently drop TCP established connections on idle timeout
Memory Management		
TCP Buffer Size	131072 bytes	TCP buffer size is the receive buffer size on the Citrix ADC. This buffer size is advertised to clients and servers from Citrix ADC and it controls their ability to send data to Citrix ADC. The default buffer size is 8K and usually it is safe to increment this when talking to internal server farms. The buffer size is also impact by the actual application layer in Citrix ADC like for SSL endpoint cases it is set to 40 K and for Compression it is set to 96 K. **Note:** The buffer size argument must be set for dynamic adjustments to take place.
TCP Send Buffer Size	8190 bytes	TCP Send Buffer Size
TCP Dynamic Receive Buffering	DISABLED	Enable or disable dynamic receive buffering. When enabled, it allows the receive buffer to be adjusted dynamically based on memory and network conditions. **Note:** The buffer size argument must be set for dynamic adjustments to take place
TCP Max congestion window(CWND)	524288 bytes	TCP Maximum Congestion Window

Parameter	Default Value	Description
Window Scaling status	ENALBED	Enable or disable window scaling.
Window Scaling factor	8	Factor used to calculate the new window size. This argument is needed only when window scaling is enabled.
Connection Setup		
Keep-alive probes	DISABLED	Send periodic TCP keep-alive (KA) probes to check if peer is still up.
Connection idle time before starting keep-alive probes	900 seconds	Duration, in seconds, for the connection to be idle, before sending a keep-alive (KA) probe.
Keep-alive probe interval	75 seconds	Time interval, in seconds, before the next keep-alive (KA) probe, if the peer does not respond.
Maximum keep-alive probes to be missed before dropping connection.	3	Number of keep-alive (KA) probes to be sent when not acknowledged, before assuming the peer to be down.
RST window attenuation (spoof protection).	DISABLED	Enable or disable RST window attenuation to protect against spoofing. When enabled, the reply is with corrective ACK when a sequence number is invalid.
Accept RST with last acknowledged sequence number.	ENABLED	
Data transfer		

Parameter	Default Value	Description
Immediate ACK on PUSH packet	ENABLED	Send immediate positive acknowledgment (ACK) on receipt of TCP packets with PUSH flag.
Maximum packets per MSS	0	Maximum number of octets to allow in a TCP data segment
Nagle's Algorithm	DISABLED	Nagle's Algorithm fights with the problem of small packets in TCP transmission. Applications like Telnet and other real time engines which require every key stroke to be passed to the other side often create small packets. With Nagle's algorithm Citrix ADC can buffer such small packets and sends them together to increase on the connection efficiency. This algorithm needs to work along with other TCP optimization techniques in the Citrix ADC.
Maximum TCP segments allowed in a burst	10 MSS	Maximum number of TCP segments allowed in a burst
Maximum out-of-order packets to queue	300	Maximum size of out-of-order packets queue. A value of 0 means no limit
Congestion Control		
TCP Flavor	CUBIC	
Initial congestion window(cwnd) setting	4 MSS	Initial maximum upper limit on the number of TCP packets that can be outstanding on the TCP link to the server

Parameter	Default Value	Description
TCP Explicit Congestion Notification(ECN)	DISABLED	Explicit Congestion Notification (ECN) provides end to end notification of network congestion without dropping packets.
TCP Max congestion window(CWND)	524288 bytes	TCP maintains a congestion window (CWND), limiting the total number of unacknowledged packets that may be in transit end-to-end. In TCP, the congestion window is one of the factors that determines the number of bytes that can be outstanding at any time. The congestion window is a means of stopping a link between the sender and the receiver from becoming overloaded with too much traffic. It is calculated by estimating how much congestion there is on the link.
TCP Hybrid Start (HyStart)	8 bytes	
TCP minimum Retransmission Timeout(RTO) in milli sec	1000	Minimum retransmission timeout, in milliseconds, specified in 10-millisecond increments (value must yield a whole number if divided by 10).
TCP dupack threshold	DISABLED	
Burst Rate Control	3	TCP Burst Rate Control DISABLED/FIXED/DYNAMIC. FIXED requires a TCP rate to be set

Parameter	Default Value	Description
TCP Rate	DISABLED	TCP connection payload send rate in Kb/s
TCP Rate Maximum Queue	0	Maximum connection queue size in bytes, when BurstRateControl is used.
MPTCP		
Multipath TCP	DISABLED	Multipath TCP (MPTCP) is a set of extensions to regular TCP to provide a Multipath TCP service, which enables a transport connection to operate across multiple paths simultaneously.
Multipath TCP drop data on pre-established subflow	DISABLED	Enable or disable silently dropping the data on Pre-Established subflow. When enabled, DSS data packets are dropped silently instead of dropping the connection when data is received on pre established subflow.
Multipath TCP fastopen	DISABLED	Enable or disable Multipath TCP fastopen. When enabled, DSS data packets are accepted before receiving the third ack of SYN handshake.
Multipath TCP session timeout	0 seconds	MPTCP session timeout in seconds. If this value is not set, idle MPTCP sessions are flushed after the virtual server's client idle timeout.
Security		

Parameter	Default Value	Description
SYN spoof protection	DISABLED	Enable or disable drop of invalid SYN packets to protect against spoofing. When disabled, established connections are reset when a SYN packet is received.
TCP Syncookie	DISABLED	This is used for resisting SYN flood attacks. Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the Citrix ADC appliance.
Loss Detection and Recovery		
Duplicate Selective Acknowledgment (DSACK)	ENABLED	A Citrix ADC appliance uses Duplicate Selective Acknowledgment (DSACK) to determine if a retransmission was sent in error.

Parameter	Default Value	Description
Forward RTO recovery (FRTO)	ENABLED	Detects spurious TCP retransmission timeouts. After retransmitting the first unacknowledged segment triggered by a timeout, the algorithm of the TCP sender monitors the incoming acknowledgments to determine whether the timeout was spurious. It then decides whether to send new segments or retransmit unacknowledged segments. The algorithm effectively helps to avoid another unnecessary retransmissions and thereby improves TCP performance in the case of a spurious timeout.
TCP Forward Acknowledgment (FACK)	ENABLED	Enable or disable FACK (Forward ACK).
Selective Acknowledgement(SACK) status	ENABLED	TCP SACK addresses the problem of multiple packet losses which reduces the overall throughput capacity. With selective acknowledgment the receiver can inform the sender about all the segments which are received successfully, enabling the sender to only retransmit the segments which were lost. This technique helps Citrix ADC improve overall throughput and reduce the connection latency.

Parameter	Default Value	Description
Maximum packets per retransmission	1	Allows Citrix ADC to control how many packets to be retransmitted in one attempt. When Citrix ADC receives a partial ACK and it has to do retransmission then this setting is considered. This does not impact the RTO based retransmissions.
TCP Delayed-ACK Timer	100 millisec	Timeout for TCP delayed ACK, in milliseconds
TCO Optimization		
TCP Optimization mode	TRANSPARENT	TCP Optimization modes TRANSPARENT/ENDPOINT
Apply adaptive TCP optimizations	DISABLED	Apply Adaptive TCP optimizations
TCP Segmentation Offload	AUTOMATIC	Offload TCP segmentation to the NIC. If set to AUTOMATIC, TCP segmentation is offloaded to the NIC, if the NIC supports it.
ACK Aggregation	DISABLED	Enable or disable ACK Aggregation
TCP Time-wait(or Time_wait)	40 secs	Time to elapse before releasing a closed TCP connection
Delink client and server on RST	DISABLED	Delink client and server connection, when there is outstanding data to be sent to the other side.

Setting Global TCP Parameters

The Citrix ADC appliance allows you to specify values for TCP parameters that are applicable to all Citrix ADC services and virtual servers. This can be done using:

- Default TCP profile
- Global TCP command
- TCP buffering feature

> **Note**:
>
> The `recvBuffSize` parameter of the set ns tcpParam command is deprecated from release 9.2 onwards. In later releases, set the buffer size by using the `bufferSize` parameter of the set ns tcpProfile command. If you upgrade to a release where the `recvBuffSize` parameter is deprecated, the `bufferSize` parameter is set to its default value.

Default TCP profile

A TCP profile, named as `nstcp_default_profile`, is used to specify TCP configurations that is used if no TCP configurations are provided at the service or virtual server level.

> **Notes:**
>
> - Not all TCP parameters can be configured through the default TCP profile. Some settings have to be performed by using the global TCP command (see section below).
> - The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default TCP profile

- Using the command line interface, at the command prompt enter:

```
1 set ns tcpProfile nstcp_default_profile...
2 <!--NeedCopy-->
```

- On the GUI, navigate to **System** > **Profiles**, click **TCP Profiles** and update nstcp_default_profile.

Global TCP command

Another approach you can use to configure global TCP parameters is the global TCP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a TCP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default TCP profile.

For example, if the SACK parameter is updated using this approach, the value is reflected in the SACK parameter of the default TCP profile (nstcp_default_profile).

> **Note:**
>
> Citrix recommends that you use this approach only for TCP parameters that are not available in the default TCP profile.

To configure the global TCP command

- Using the command line interface, at the command prompt enter:

```
set ns tcpParam …
<!--NeedCopy-->
```

- On the GUI, navigate to **System > Settings**. Click **Change TCP parameters** and, update the required TCP parameters.

TCP buffering feature

Citrix ADC provides a feature called TCP buffering that you can use to specify the TCP buffer size. The feature can be enabled globally or at service level.

> **Note:**
>
> The buffer size can also be configured in the default TCP profile. If the buffer size has different values in the TCP buffering feature and the default TCP profile, the greater value is applied.

To configure the TCP buffering feature globally

- At the command prompt enter:

  enable ns mode TCPB

  ```
  set ns tcpbufParam -size <positiveInteger> -memLimit <positiveInteger>
  ```

- On the GUI, navigate to **System** > **Settings**, click **Configure Modes** and, select **TCP Buffering**.

  And, navigate to **System** > **Settings**, click **Change TCP parameters**, specify values for **Buffer size** and **Memory usage limit**.

Setting Service or Virtual Server Specific TCP Parameters

Using TCP profiles, you can specify TCP parameters for services and virtual servers. You must define a TCP profile (or use a built-in TCP profile) and associate the profile with the appropriate service and virtual server.

> **Note:**
>
> You can also modify the TCP parameters of default profiles as per your requirements.

You can specify the TCP buffer size at service level using the parameters specified by the TCP buffering feature.

To specify service or virtual server level TCP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the TCP profile.

```
set ns tcpProfile <profile-name>...
<!--NeedCopy-->
```

2. Bind the TCP profile to the service or virtual server.

```
    set service <name> ....
    <!--NeedCopy-->
```

Example:

```
> set service service1 -tcpProfileName profile1
```

To bind the TCP profile to the virtual server:

```
set lb vserver <name> ....
<!--NeedCopy-->
```

Example:

```
> set lb vserver lbvserver1 -tcpProfileName profile1
<!--NeedCopy-->
```

To specify service or virtual server level TCP configurations by using the GUI

At the GUI, perform the following:

1. Configure the TCP profile.

   Navigate to **System** > **Profiles** > **TCP Profiles**, and create the TCP profile.

2. Bind the TCP profile to the service or virtual server.

   Navigate to **Traffic Management** > **Load Balancing** > **Services/Virtual Servers**, and create the TCP profile, which should be bound to the service or virtual server.

Built-in TCP Profiles

For convenience of configuration, the Citrix ADC provides some built-in TCP profiles. Review the built-in profiles listed for the following and select a profile and use it as it is or modify it to meet your requirements. You can bind these profiles to your required services or virtual servers.

Built-in profile	Description
nstcp_default_profile	Represents the default global TCP settings on the appliance.
nstcp_default_tcp_lan	Useful for back-end server connections, where these servers reside on the same LAN as the appliance.
nstcp_default_WAN	useful for WAN deployments.
nstcp_default_tcp_lan_thin_stream	Similar to the nstcp_default_tcp_lan profile. However, the settings are tuned for small size packet flows.
nstcp_default_tcp_interactive_stream	Similar to the nstcp_default_tcp_lan profile. However, it has a reduced delayed ACK timer and ACK on **PUSH packet** settings.
nstcp_default_tcp_lfp	Useful for long fat pipe networks (WAN) on the client side. Long fat pipe networks have long delay, high bandwidth lines with minimal packet drops.
nstcp_default_tcp_lfp_thin_stream	Similar to the nstcp_default_tcp_lfp profile. However, the settings are tuned for small size packet flows.
nstcp_default_tcp_lnp	Useful for long narrow pipe networks (WAN) on the client side. Long narrow pipe networks have considerable packet loss occasionally.
nstcp_default_tcp_lnp_thin_stream	Similar to the nstcp_default_tcp_lnp profile. However, the settings are tuned for small size packet flows.
nstcp_internal_apps	Useful for internal applications on the appliance (for example, GSLB site syncing). This contains tuned window scaling and SACK options for the desired applications. This profile should not be bound to applications other than internal applications.
nstcp_default_Mobile_profile	Useful for mobile devices.
nstcp_default_XA_XD_profile	Useful for a XenApp or XenDesktop deployment.

Sample TCP Configurations

Sample command line interface examples for configuring the following:

Defending TCP against spoofing attacks

Enable the Citrix ADC to defend TCP against spoof attacks. By default the “rstWindowAttenuation” parameter is disabled. This parameter is enabled to protect the appliance against spoofing. If you enable, it replies with corrective acknowledgment (ACK) for an invalid sequence number. Possible values are Enabled, Disabled.

Where, the RST window attenuate parameter protects the appliance against spoofing. When enabled, reply with corrective ACK when a sequence number is invalid.

```
1      > set ns tcpProfile profile1 -rstWindowAttenuate ENABLED -
          spoofSynDrop ENABLED
2      Done
3      > set lb vserver lbvserver1 -tcpProfileName profile1
4      Done
5  <!--NeedCopy-->
```

Explicit Congestion Notification (ECN)

Enable ECN on the required TCP profile

```
1      > set ns tcpProfile profile1 -ECN ENABLED
2      Done
3      > set lb vserver lbvserver1 -tcpProfileName profile1
4      Done
5  <!--NeedCopy-->
```

Selective Acknowledgment (SACK)

Enable SACK on the required TCP profile.

```
1      > set ns tcpProfile profile1 -SACK ENABLED
2      Done
3      > set lb vserver lbvserver1 -tcpProfileName profile1
4      Done
5  <!--NeedCopy-->
```

Forward Acknowledgment (FACK)

Enable FACK on the required TCP profile.

```
> set ns tcpProfile profile1 -FACK ENABLED
> set lb vserver lbvserver1 -tcpProfileName profile1
<!--NeedCopy-->
```

Window Scaling (WS)

Enable window scaling and set the window scaling factor on the required TCP profile.

```
set ns tcpProfile profile1  - WS ENABLED  - WSVal 9
Done
set lb vserver lbvserver1 -tcpProfileName profile1
Done
<!--NeedCopy-->
```

Maximum Segment Size (MSS)

Update the MSS related configurations.

```
> set ns tcpProfile profile1  - mss 1460 - maxPktPerMss 512
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
<!--NeedCopy-->
```

Citrix ADC to learn the MSS of a virtual server

Enable the Citrix ADC to learn the VSS and update other related configurations.

```
> set ns tcpParam -learnVsvrMSS ENABLED  - mssLearnInterval 180 -
    mssLearnDelay 3600
Done
<!--NeedCopy-->
```

TCP keep-alive

Enable TCP keep-alive and update other related configurations.

```
> set ns tcpProfile profile1 -KA ENABLED -KaprobeUpdateLastactivity ENABLED
-KAconnIdleTime 900 -KAmaxProbes 3 -KaprobeInterval 75
```

```
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Buffer size - using TCP profile

Specify the buffer size.

```
> set ns tcpProfile profile1 -bufferSize 8190
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Buffer size - using TCP buffering feature

Enable the TCP buffering feature (globally or for a service) and then specify the buffer size and the memory limit.

```
> enable ns feature TCPB
Done
> set ns tcpbufParam -size 64 -memLimit 64
Done
```

MPTCP

Enable MPTCP and then set the optional MPTCP configurations.

```
> set ns tcpProfile profile1 -mptcp ENABLED
Done
> set ns tcpProfile profile1 -mptcpDropDataOnPreEstSF ENABLED -mptcpFastOpen
 ENABLED -mptcpSessionTimeout 7200
Done
> set ns tcpparam -mptcpConCloseOnPassiveSF ENABLED -mptcpChecksum ENABLED
-mptcpSFtimeout 0 -mptcpSFReplaceTimeout 10
-mptcpMaxSF 4 -mptcpMaxPendingSF 4 -mptcpPendingJoinThreshold 0 -mptcpRTOsToSwitchSF
 2 -mptcpUseBackupOnDSS ENABLED
Done
```

Congestion control

Set the required TCP congestion control algorithm.

```
set ns tcpProfile profile1 -flavor Westwood
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Dynamic receive buffering

Enable dynamic receive buffering on the required TCP profile.

```
> set ns tcpProfile profile1 -dynamicReceiveBuffering ENABLED
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Support for TCP Fast Open (TFO) in Multipath TCP (MPTCP)

A Citrix ADC appliance now supports the TCP Fast Open (TFO) mechanism for establishing Multipath TCP (MPTCP) connections and speed up data transfers. The mechanism allows subflow data to be carried during the initial MPTCP connection handshake in SYN and SYN-ACK packets and also enables data to be consumed by the receiving node during the MPTCP connection establishment.

For more information, see TCP Fast Open topic.

Support for Variable TFO Cookie Size for MPTCP

A Citrix ADC appliance now enables you to configure a variable length TCP Fast Open (TFO) cookie of a minimum size of 4 bytes and a maximum size of 16 bytes in a TCP profile. By doing this, the appliance can respond with the configured TFO cookie size in the SYN-ACK packet to the client.

To configure the TCP Fast Open (TFO) cookie in a TCP profile by using the command line interface

At the command prompt, type:

```
set tcpProfile nstcp_default_profile -tcpFastOpenCookieSize <positive_integer
>
```

Example

```
set tcpProfile nstcp_default_profile -tcpFastOpenCookieSize 8
```

To configure the TCP Fast Open (TFO) cookie in a TCP profile by using the GUI

1. Navigate to **Configuration** > **System** > Profiles.
2. In the details pane, go to **TCP Profiles** tab and select a TCP profile.
3. In the **Configure TCP Profile** page, set the **TCP Fast Open** cookie size.
4. Click **OK** and **Done**.

SYN-Cookie timeout interval

The TCPSyncookie parameter is enabled by default in TCP profiles to provide robust (RFC 4987) based protection against SYN Attacks. If you need to accommodate custom TCP clients that are not compatible with this protection but still want to ensure a fallback in case of attack, the synAttackDetection handles this for you by automatically activating the SYNCookie behavior internally for time determined by the autosyncookietimeout parameter..

To configure the maximum SYN ACK retransmission threshold by using the command line interface:

At the command prompt, type:

```
    set ns tcpparam [-maxSynAckRetx <positive_integer>]

    Set ns tcpparam [-maxSynAckRetx 150]
<!--NeedCopy-->
```

To configure auto SYN cookie timeout interval by using the command line interface

At the command prompt, type:

```
set ns tcpparam [-autosyncookietimeout <positive_integer>]
```

```
Set ns tcpparam [-autosyncookietimeout 90]
```

Delink client and server connection

When enabled, the parameter delinks client and server connection when there is outstanding data to be sent to the other side. By default, the parameter is disabled.

```
set ns tcpparam -delinkClientServerOnRST ENABLED
Done

<!--NeedCopy-->
```

HTTP configurations

September 14, 2021

> **Important:**
>
> Starting from Citrix ADC release 13.0 build 71.x, a Citrix ADC appliance can handle large header

> size HTTP requests to accommodate the L7 application requests. The header size can be configurable up to 128 KB.

HTTP configurations for a Citrix ADC appliance can be specified in an entity called an HTTP profile, which is a collection of HTTP settings. The HTTP profile can then be associated with services or virtual servers that want to use these HTTP configurations.

A default HTTP profile can be configured to set the HTTP configurations that is applied by default, globally to all services and virtual servers.

> **Note:**
>
> When an HTTP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence.

The Citrix ADC appliance also provides other approaches for configuring HTTP. Read on for more information.

The Citrix ADC supports a WebSocket protocol which allows browsers and other clients to create a bidirectional, full duplex TCP connection to the servers. The Citrix ADC implementation of WebSocket is RFC 6455 compliant.

> **Note:**
>
> A Citrix ADC appliance now supports the User Source IP (USIP) address configuration for both HTTP/1.1 and HTTP/2 protocols.

Setting global HTTP parameters

The Citrix ADC appliance allows you to specify values for HTTP parameters that are applicable to all Citrix ADC services and virtual servers. This can be done using:

- Default HTTP profile
- Global HTTP command

Default HTTP profile

An HTTP profile, named as nshttp_default_profile, is used to specify HTTP configurations that is used if no HTTP configurations are provided at the service or virtual server level.

> **Notes:**
>
> - Not all HTTP parameters can be configured through the default HTTP profile. Some settings are performed by using the global HTTP command (see the following section).
> - The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default HTTP profile

- Using the command line interface, at the command prompt enter:

  ```
  set ns httpProfile nshttp_default_profile …
  ```

- On the GUI, navigate to **System** > **Profiles**, click **HTTP Profiles** and update nshttp_default_profile.

Global HTTP command

Another approach you can use to configure global HTTP parameters is the global HTTP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using an HTTP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default HTTP profile.

For example, if the maxReusePool parameter is updated using this approach, the value is reflected in the maxReusePool parameter of the default HTTP profile (nshttp_default_profile).

> **Note:**
>
> Citrix recommends that you use this approach only for HTTP parameters that are not available in the default HTTP profile.

To configure the global HTTP command

- Using the command line interface, at the command prompt enter:

  ```
  set ns httpParam …
  ```

- On the GUI, navigate to **System > Settings**, click **Change HTTP parameters** and update the required HTTP parameters.

To configure an ignore Coding scheme for connect request

To enable HTTP/2 and set HTTP/2 parameters to ignore the Coding scheme in the connect request, at the command prompt, type:

```
set ns httpParam [-ignoreConnectCodingScheme ( ENABLED | DISABLED )]
```

Example:

```
set ns httpParam -ignoreConnectCodingScheme ENABLED
```

To bind the HTTP profile to a virtual server by using the Citrix ADC command line

Configure HTTP profile to drop TRACE or TRACK invalid requests

You can enable the markTraceReqInval parameter to mark TRACK and TRACK requests as invalid. When you enable this option along with the dropInvalidReqs option on the virtual IP address, you can reset a client sending TRACE or TRACK requests to a Citrix ADC appliance.

To configure the HTTP profile using the CLI

At the command prompt, type:

```
set ns httpProfile <profile name> [-markTraceReqInval ENABLED | DISABLED ]
```

Example:

```
set ns httpProfile profile1 -markTraceReqInval ENABLED
```

Configure HTTP profile for a service group

At the command prompt, type:

```
1 add serviceGroup <serviceGroupName>@ <serviceType> [-cacheType <
     cacheType>] [-td <positive_integer>] [-maxClient <positive_integer>]
      [-maxReq <positive_integer>] [-cacheable ( YES | NO )] [-cip (
     ENABLED | DISABLED ) [<cipHeader>]] [-usip ( YES | NO )] [-
     pathMonitor ( YES | NO )] [-pathMonitorIndv ( YES | NO )] [-
     useproxyport ( YES | NO )] [-healthMonitor ( YES | NO )] [-sp ( ON |
      OFF )] [-rtspSessionidRemap ( ON | OFF )] [-cltTimeout <secs>] [-
     svrTimeout <secs>] [-CKA ( YES | NO )] [-TCPB ( YES | NO )] [-CMP (
     YES | NO )] [-maxBandwidth
2 <positive_integer>] [-monThreshold <positive_integer>] [-state ENABLED
     DISABLED )][-downStateFlush ( ENABLED | DISABLED )] [-tcpProfileName
      <string>] [-httpProfileName <string>] [-comment <string>] [-
     appflowLog ( ENABLED | DISABLED )] [-netProfile <string>] [-
     autoScale <autoScale> -memberPort <port> [-autoDisablegraceful ( YES
      | NO )] [-autoDisabledelay <secs>] ] [-monConnectionClose ( RESET |
      FIN )]
3
4 <!--NeedCopy-->
```

Example:

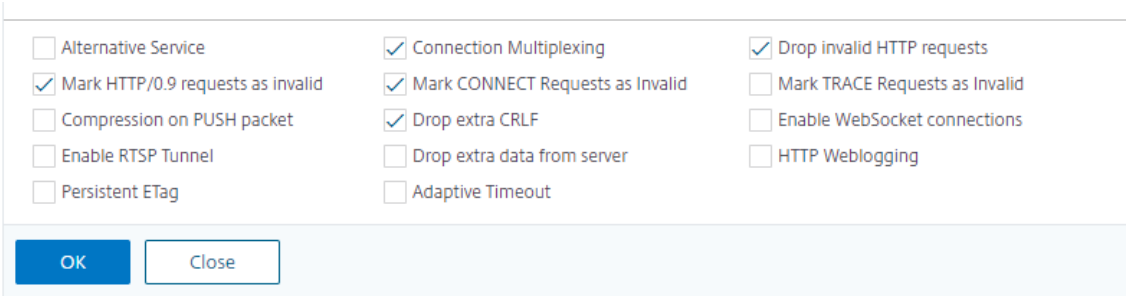
```
add serviceGroup rl-lips-30016 HTTP -maxClient 0 -maxReq 0 -cip ENABLED X-
Forwarded-For -usip NO -useproxyport YES -cltTimeout 180 -svrTimeout 360 -
CKA NO -TCPB NO -CMP NO -tcpProfileName live-tcp-profile-sg -httpProfileName
 profile1
```

Configure the HTTP profile using the Citrix ADC GUI

To mark TRACE or TRACK invalid requests, complete the following procedure.

1. Sign into Citrix ADC appliance and navigate to **Configuration** > **System** > **Profiles**.
2. In the **HTTP Profiles** tab page, click **Add**.
3. In the **Create HTTP Profile** page, select **Mark TRACE Requests as Invalid** option.

4. Click **Create**.



Setting service or virtual server specific HTTP parameters

Using HTTP profiles, you can specify HTTP parameters for services and virtual servers. You have to define an HTTP profile (or use a built-in HTTP profile) and associate the profile with the appropriate service and virtual server.

> **Note:**
>
> You can also modify the HTTP parameters of default profiles as per your requirements.

To specify service or virtual server level HTTP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the HTTP profile.

   ```
   set ns httpProfile <profile-name>...
   ```

2. Bind the HTTP profile to the service or virtual server.

   To bind the HTTP profile to the service:

```
set service <name> .....
```

Example:

```
1 > set service service1 -httpProfileName profile1
2 <!--NeedCopy-->
```

To bind the HTTP profile to the virtual server:

```
set lb vserver <name> .....
```

Example:

```
1 > set lb vserver lbvserver1 -httpProfileName profile1
2 <!--NeedCopy-->
```

To specify service or virtual server level HTTP configurations by using the GUI

At the GUI, perform the following:

1. Configure the HTTP profile.

   Navigate to **System** > **Profiles** > **HTTP Profiles**, and create the HTTP profile.

2. Bind the HTTP profile to the service or virtual server.

   Navigate to **Traffic Management** > **Load Balancing** > **Services/Virtual Servers**, and create the HTTP profile, which must be bound to the service/virtual server.

Built-in HTTP profiles

For convenience of configuration, the Citrix ADC provides some built-in HTTP profiles. Review the profiles listed and use it as it is or modify it to meet your requirements. You can bind these profiles to the required services or virtual servers.

Built-in profile	Description
nshttp_default_profile	Represents the default global HTTP settings on the appliance.
nshttp_default_strict_validation	Settings for deployments that require strict validation of HTTP requests and responses.

Sample HTTP configurations

Sample command line interface examples to configure the following:

- HTTP band statistics
- WebSocket connections

HTTP band statistics

Specify the band size for HTTP requests and responses.

```
1 > set protocol httpBand reqBandSize 300 respBandSize 2048
2 Done
3 > show protocol httpband -type REQUEST
4 <!--NeedCopy-->
```

WebSocket connections

Enable WebSocket on the required HTTP profile.

```
> set ns httpProfile http_profile1 -webSocket ENABLED
Done
> set lb vserver lbvserver1 -httpProfileName profile1
Done
<!--NeedCopy-->
```

HTTP/2 configuration

September 14, 2021

Note: The HTTP/2 functionality is supported on the Citrix ADC MPX, VPX, and SDX models. In a Citrix ADC VPX appliance, the HTTP/2 functionality is supported from 11.0 release onwards.

The problem with web application performance is directly related to the trend toward increasing the page size and the number of objects on the webpages. HTTP/1.1 was developed to support smaller webpages, slower Internet connections, and more limited server hardware than are common today. It is not suitable for new technologies such as JavaScript and cascading style sheets (CSS) or new media types such as Flash videos and graphics-rich images. This is because it can request only one resource per connection to the server. The limitation significantly increases the number of round trips, causing longer page-rendering and reduced network performance.

The HTTP/2 protocol addresses these limitations by allowing communication to occur with less data transmitted over the network, and providing the ability to send multiple requests and responses across a single connection. At its core, HTTP/2 addresses the key limitations of HTTP/1.1 by using the underlying network connections more efficiently. It changes the way requests and responses travel over the network.

HTTP/2 is a binary protocol. It is more efficient to parse, more compact on the wire, and most importantly, it is less error-prone, compared to textual protocols like HTTP/1.1. The HTTP/2 protocol uses a binary framing layer that defines the frame type and how HTTP messages are encapsulated and transferred between the client and server. The HTTP/2 functionality supports the use of the CONNECT method to establish a tunnel connection through a single HTTP/2 stream to a remote host.

The HTTP/2 protocol includes much performance-enhancing changes that significantly improve performance, particularly for clients connecting over a mobile network.

The following table lists the major improvements in HTTP/2 over HTTP/1.1:

HTTP/2 features	Description
Header Compression	HTTP headers have much repetitive information and therefore consume unnecessary bandwidth during data transmission. HTTP/2 reduces bandwidth requirements by compressing the header and minimizing the requirement to transport HTTP headers with every request and response.
Connection Multiplexing	Latency can have a huge impact on page load times and the end user experience. Connection multiplexing overcomes this problem by sending multiple requests and responses across a single connection.
Server Push	Server push enables the server to proactively push content to the client browser, avoiding round trip delay. This feature caches the responses it thinks the client needs, reduces the number round trips, and improves the page rendering time. Important: The Citrix ADC appliance does not support the server push functionality.
No Head-of-line Blocking	Under HTTP 1.1, browsers can download one resource at a time per connection. When a browser has to download a large resource, it blocks all other resources from downloading until the first download is complete. HTTP/2 overcomes this problem with a multiplexing approach. It allows the client browser to download other web components in parallel over the same connection and display them as they become available.

HTTP/2 features	Description
Request Prioritization	Not all resources have equal priority when the browser renders a webpage. To accelerate the load time, all modern browsers prioritize requests by type of asset, their location on the page, and even by learned priority from previous visits. With HTTP/1.1, the browser has limited ability to use the priority data, because this protocol does not support multiplexing, and there is no way to communicate request prioritization by the server. The result is unnecessary network latency. HTTP/2 overcomes this problem by allowing the browser to dispatch all requests. The browser can communicate its stream prioritization preference via stream dependencies and weights, enabling the servers to optimize response delivery. Important: The Citrix ADC appliance does not support the request prioritization functionality.

How HTTP/2 works

A Citrix ADC appliance supports HTTP/2 on the client side as well on the server side. On the client side, the Citrix ADC appliance acts as a server that hosts an HTTP/HTTPS virtual server for HTTP/2. On the back-end side, the Citrix ADC acts as a client to the servers that are bound to the virtual server.

Therefore, the Citrix ADC appliance maintains separate connections on the client side as well on the server side. The Citrix ADC appliance has separate HTTP/2 configurations for the client side and the server side.

HTTP/2 for HTTPS (SSL) load balancing configuration

For an HTTPS load balancing configuration, the Citrix ADC appliance uses the TLS ALPN extension (RFC 7301) to determine whether the client/server supports HTTP/2. If it does, the appliance chooses HTTP/2 as the application-layer protocol to transmit data (as described in RFC 7540 - Section 3.3) on the client/server side.
The appliance uses the following order of preference when choosing the application-layer protocol through the TLS ALPN extension:

- HTTP/2 (if enabled in the HTTP profile)
- SPDY (if enabled in the HTTP profile)
- HTTP/1.1

HTTP/2 for HTTP load balancing configuration

For an HTTP load balancing configuration, the Citrix ADC appliance uses one of the following methods to start communicating with the client/server using HTTP/2.

> **Note:**
>
> In the following method descriptions, client and server are generals terms for an HTTP/2 connection. For example, for a load balancing setup of a Citrix ADC appliance using HTTP/2, the Citrix ADC appliance acts as a server on the client side and acts as a client to the server side.

- **HTTP/2 Upgrade**. A client sends an HTTP/1.1 request to a server. The request includes an upgrade header, which asks the server for upgrading the connection to HTTP/2. If the server supports HTTP/2, the server accepts the upgrade request and notifies it in its response. The client and the server start communicating using HTTP/2 after the client receives the upgrade confirmation response.
- **Direct HTTP/2**. A client directly starts communicating to a server in HTTP/2 instead of using the HTTP/2 upgrade method. If the server does not support HTTP/2 or is not configured to directly accept HTTP/2 requests, it drops the HTTP/2 packets from the client. This method is helpful if the admin of the client device already knows that the server supports HTTP/2.
- **Direct HTTP/2 using Alternative Service (ALT-SVC).** A server advertises that it supports HTTP/2 to a client by including an Alternative Service (ALT-SVC) field in its HTTP/1.1 response. If the client is configured to understand the ALT-SVC field, the client and the server start directly communicating using HTTP/2 after the client receives the response.

The Citrix ADC appliance provides configurable options in an HTTP profile for the HTTP/2 methods. These HTTP/2 options can be applied to the client side as well to the server side of an HTTPS or HTTP load balancing setup. For more information for HTTP/2 methods and options, refer to the HTTP/2 options PDF.

Before you Begin

Before you begin configuring HTTP/2 on a Citrix ADC appliance, note the following points:

- The Citrix ADC appliance supports HTTP/2 on the client side as well on the server side.
- The Citrix ADC appliance does not support the HTTP/2 server push functionality.
- The Citrix ADC appliance does not support the HTTP/2 request prioritization functionality.

- The Citrix ADC appliance does not support HTTP/2 SSL renegotiation for HTTPS load balancing setups.
- The Citrix ADC appliance does not support HTTP/2 NTLM authentication.
- HTTP/2 does not work if User Source IP (USIP) mode is enabled and the proxy mode is disabled on the Citrix ADC appliance.

Configuring HTTP/2

Configuring HTTP/2 for a load balancing setup (HTTPS or HTTP) consists of the following tasks:

- **Enable HTTP/2 and set optional HTTP/2 parameters in an HTTP Profile**. Enable HTTP/2 in an HTTP profile. When you only enable HTTP/2 in an HTTP profile, the Citrix ADC appliance uses only the upgrade method (for HTTP) or TLS ALPN method (for HTTPS) for communicating in HTTP/2.

  For the Citrix ADC appliance to use the direct HTTP/2 method, **Direct HTTP/2** option must be enabled in the HTTP profile. For the Citrix ADC appliance to use the direct HTTP/2 using the alternative service method, the **Alternative Service (altsvc)** option must be enabled in the HTTP profile.

- **Bind the HTTP profile to a virtual server or a service**. Bind the HTTP profile to a virtual server to configure HTTP/2 for the client side of the load balancing setup. Bind the HTTP profile to a service to configure HTTP2 for the server side of the load balancing setup.

> **Note:**
>
> Citrix recommends binding separate HTTP profiles for the client side and the server side.

- **Enable the global parameter for HTTP/2 server side support**. Enable the **HTTP/2 Service Side** (**HTTP2Serverside**) global HTTP parameter for enabling the HTTP/2 support on the server side of all the load balancing setups that has HTTP/2 configured.

  HTTP/2 does not work on the server side of any load balancing setups if **HTTP/2 Service Side** is disabled even if the **HTTP/2** is enabled on the HTTP profile bound to the related load balancing services.

Citrix ADC Command Line procedures:

To enable HTTP/2 and set HTTP/2 parameters by using the Citrix ADC command line

- To enable HTTP/2 and set HTTP/2 parameters while adding an HTTP profile, at the command prompt, type:

```
add ns httpProfile <name> - http2 ( ENABLED | DISABLED )[-http2Direct (
ENABLED | DISABLED )] [-altsvc ( ENABLED | DISABLED )]
show ns httpProfile <name>
```

- To enable HTTP/2 and set HTTP/2 parameters while modifying an HTTP profile, at the command prompt, type:

```
set ns httpProfile <name> -http2 ( ENABLED | DISABLED )[-http2Direct (
ENABLED | DISABLED)] [-altsvc (ENABLED | DISABLED )]
show ns httpProfile <name>
```

To bind the HTTP profile to a virtual server by using the Citrix ADC command line

At the command prompt, type:

```
set lb vserver <name> - httpProfileName <string>
show lb vserver <name>
```

To bind the HTTP profile to a load balancing service by using the Citrix ADC command line

At the command prompt, type:

```
set service <name> -httpProfileName <string>
show service <name>
```

To enable HTTP/2 support globally on the server side by using the Citrix ADC command line

At the command prompt, type:

```
set ns httpParam -HTTP2Serverside( ENABLED | DISABLED )
show ns httpParam
```

To enable HTTP/2 and set HTTP/2 parameters by using the Citrix ADC GUI

1. Navigate to **System** > **Profiles**, and click **HTTP Profiles** tab.
2. Enable **HTTP/2** while adding an HTTP profile or modifying an existing HTTP profile.

To bind the HTTP profile to a virtual server by using the Citrix ADC GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In **Advanced Settings**, click **+ HTTP Profile** to bind the created HTTP profile to the virtual server.

To bind the HTTP profile to a load balancing service by using the Citrix ADC GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service**, and open the service.
2. In **Advanced Settings**, click **+ HTTP Profile** to bind the created HTTP profile to the service.

To enable HTTP/2 support globally on the server side by using the GUI

Navigate to **System** > **Settings**, click **Change HTTP parameters** and enable **HTTP/2 Server Side**.

Sample configurations

In the following sample configuration, HTTP/2 and direct HTTP/2 is enabled on HTTP profile HTTP-PROFILE-HTTP2-CLIENT-SIDE. The profile is bound to virtual server LB-VS-1.

```
set ns httpProfile HTTP-PROFILE-HTTP2-CLIENT-SIDE -http2 enabled -
   http2Direct enabled
Done

set lb vserver LB-VS-1 -httpProfileName HTTP-PROFILE-HTTP2-CLIENT-SIDE

Done
<!--NeedCopy-->
```

In the following sample configuration, HTTP/2 and alternative service (ALT-SVC) is enabled on HTTP profile HTTP-PROFILE-HTTP2-SERVER-SIDE. The profile is bound to service LB-SERVICE-1.

```
set ns httpparam -HTTP2Serverside ENABLED
Done

set ns httpProfile HTTP-PROFILE-HTTP2-SERVER-SIDE -http2 ENABLED -
   altsvc ENABLED
Done

set service LB-SERVICE-1 -httpProfileName HTTP-PROFILE-HTTP2-SERVER-
   SIDE
Done
<!--NeedCopy-->
```

Configure HTTP/2 initial connection window size

As per RFC 7540, the flow-control window for HTTP2 stream and connection must be set to 64 K (65535) octets, and any change made to this value must be communicated to the peer. The ADC appliance communicates the change in flow-control window size as follows:

- Using the `SETTINGS` frame for the stream.
- Using the `WINDOW_UPDATE` frame for the connection.

In an HTTP profile, you must configure the `http2InitialWindowSize` parameter to set the initial window size at the stream level. Because of an internal system error, the ADC appliance initializes the flow-control window for the connection also. When there is a change in the configured flow-control window for the stream, the ADC appliance communicates to the peer using the SETTINGS frame. But the ADC appliance fails to communicate the change in flow-control window for the connection using the `WINDOW_UPDATE` frame. This leads to a connection freeze.

To overcome the issue, the `http2InitialConnWindowSize` parameter (in bytes) is now added to control the flow-control window for connection. By using separate configurable parameters, you can

now enable the appliance to send updates for changed window size at both stream and connection levels.

Configure the HTTP/2 initial connection window size parameter by using the CLI

At the command prompt, type:

```
set http profile p1 -http2InitialConnWindowSize 8290
Initial window size for stream level flow control, in bytes.
Default value: 65535
Minimum value: 8192
Maximum value: 20971520
<!--NeedCopy-->
```

HTTP/2 DoS mitigation

September 14, 2021

The Http/2 Denial-of-Service (DoS) attacks no longer have any impact on a Citrix ADC appliance. If the appliance receives frames more than the maximum limit, the appliance silently closes the connection.

To mitigate attacks, HTTP profile enables you to change the default configuration of frames received in a HTTP/2 connection.

The HTTP/2 DoS mitigation table shows the list of HTTP/2 DoS attacks and its mitigation.

Configure the maximum limit for HTTP/2 frames to mitigate DoS attacks by using the command line interface

At the command prompt, type the following:

```
set ns httpprofile <profile_name> - http2MaxEmptyFramesPerMin <positive_integer
> -http2MaxPingFramesPerMin <positive_integer> -http2MaxSettingsFramesPerMin
 <positive_integer> -http2MaxResetFramesPerMin <positive_integer>
```

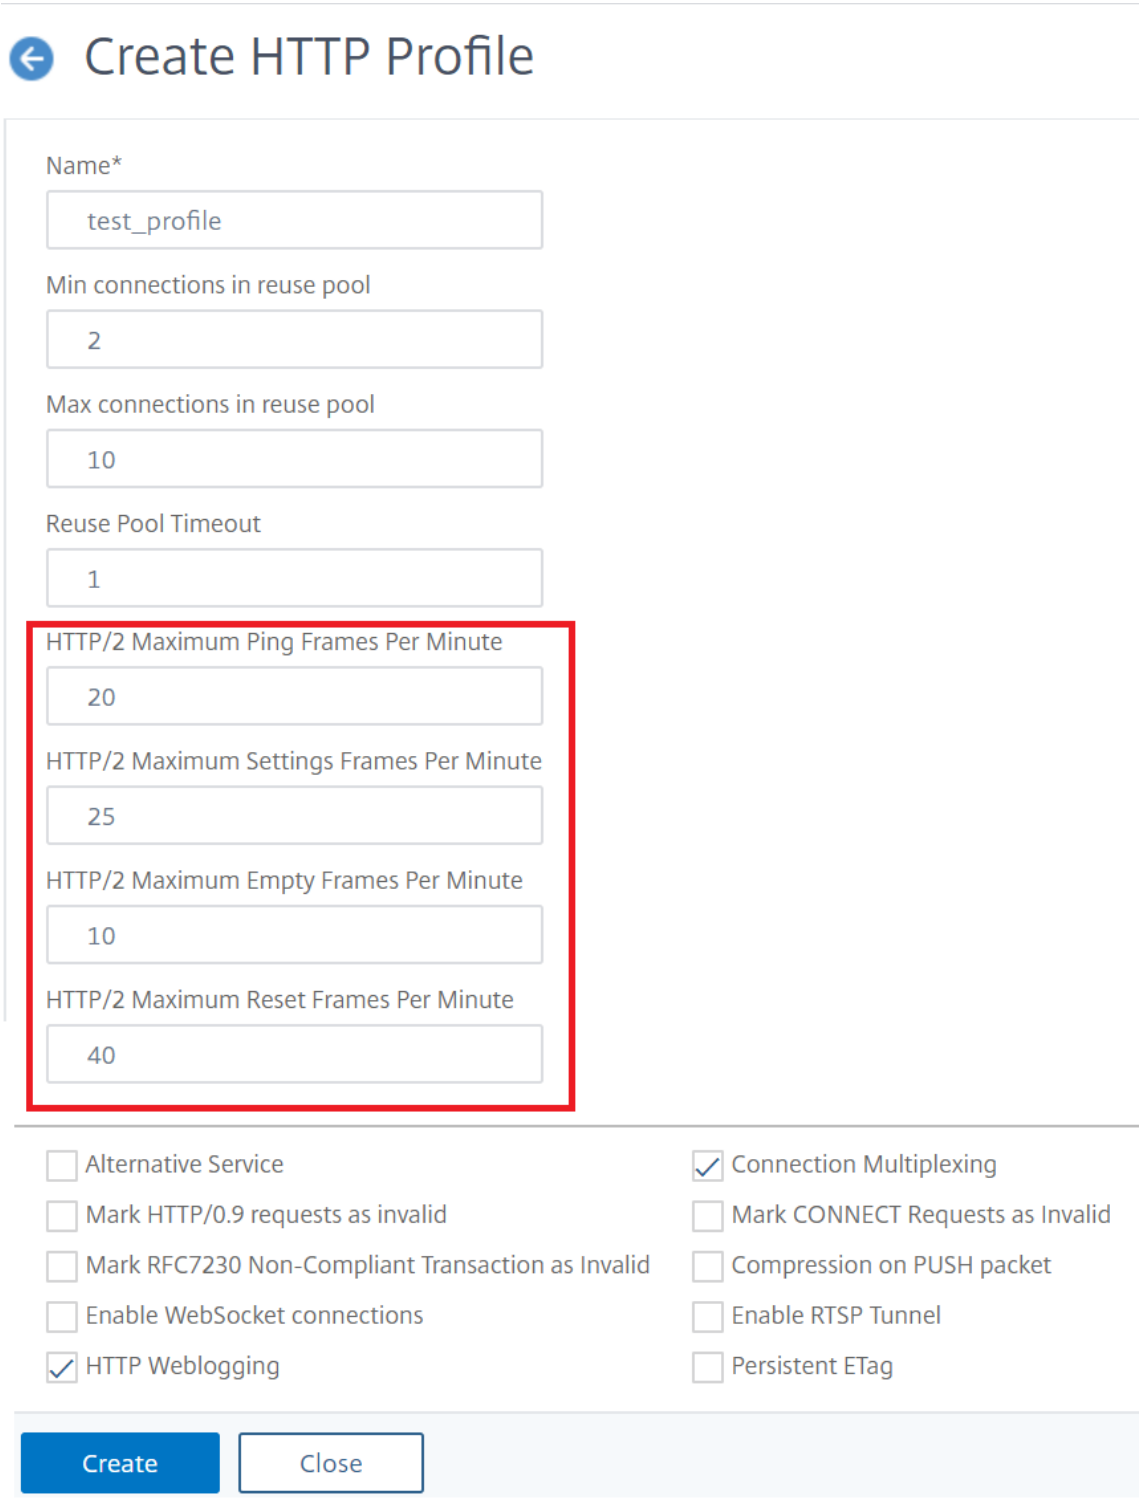
Example:

```
set ns httpprofile profile1 -http2MaxEmptyFramesPerMin 20 -http2MaxPingFramesPerMin
 20 -http2MaxSettingsFramesPerMin 20 -http2MaxResetFramesPerMin 20
```

Configure the maximum limit for frames received in a HTTP/2 connection by using the Citrix ADC GUI

Follow the steps given below to configure the maximum limit for frames received in a HTTP/2 connection:

1. On the navigation pane, expand **System** and then click **Profiles**.
2. On the **Profile** page, select the **HTTP Profiles** tab.
3. In the **HTTP Profiles** tab page, click **Add**.
4. In the **Configure HTTP Profile** page, set the following parameter.
    a) http2MaxPingFramesPerMin. Set the maximum PING frames received per connection in a minute. If the number of PING frames exceed configuration limit, the appliance silently drops packets on the connection.
    b) http2MaxSettingsFramesPerMin. Set the maximum SETTINGS frames received per connection in a minute. If the number of SETTINGS frames exceed configuration limit, ADC silently drops packets on the connection.
    c) http2MaxResetFramesPerMin. Set the maximum RESET frames sent per connection in a minute. If the number of RESET frames exceed configuration limit, ADC silently drops packets on the connection.
    d) http2MaxEmptyFramesPerMin. Set the maximum empty frames sent per connection in a minute. If the number of empty frames exceed configuration limit, ADC silently drops packets on the connection.
5. Click **OK** and **Close**.



HTTP3 over QUIC protocol

September 14, 2021

HTTP/2 over TCP is the preferred standard for sending multiple streams of HTTP requests over a single connection. But, in TCP transport mechanism there are certain limitations and latency issues in accessing websites and web applications. When you multiplex several requests over the same connection they are subjected to reliability of the same connection. If packet for one request is lost, all other multiplexed requests are delayed until the lost packet is detected and retransmitted. This causes head-of-line-blocking delays and latency issues.

For connection and transport delays, HTTP/3 uses QUIC instead of TCP protocol. The QUIC is an emerging protocol that uses UDP instead of TCP as its base transport. In HTTP-over-QUIC, you can multiplex several independent requests without depending on a single TCP connection. QUIC implements a reliable connection upon which, you can stream multiple HTTP requests. QUIC also incorporates TLS as an integrated component and not as an additional layer as in HTTP/1.1 or HTTP/2.

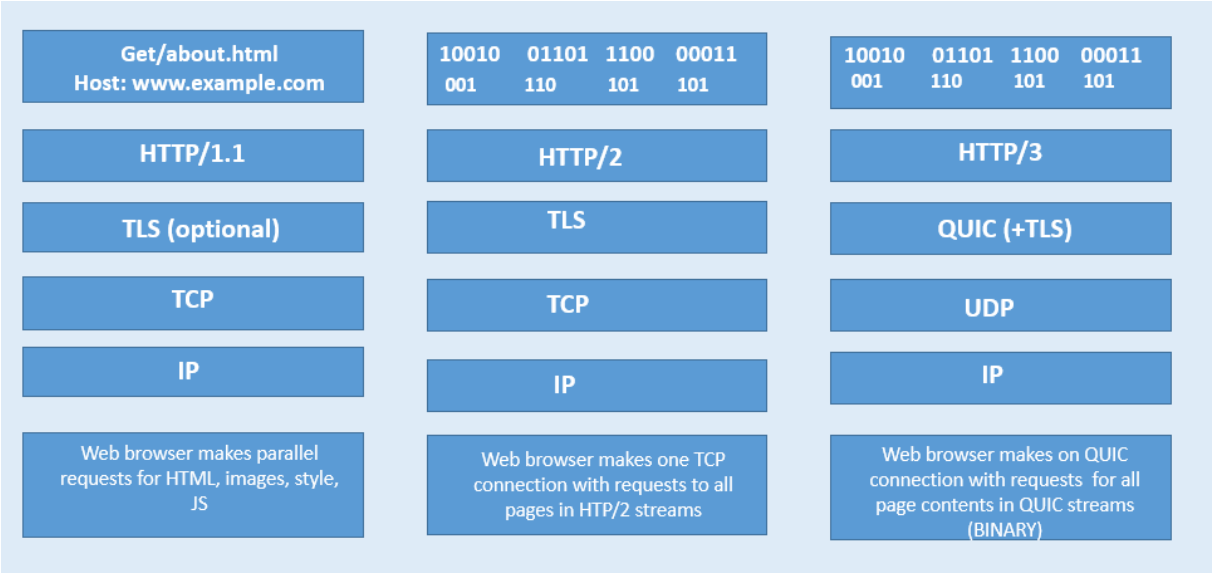
Advantage of using HTTP/3 protocol

Some of the important benefits of using QUIC protocol for HTTP/3 data transport is given below:

- Stream multiplexing
- Stream and connection-level flow control
- Low-latency connection establishment
- Connection migration and resilience to NAT rebinding
- Authenticated and encrypted header and payload

Transport stack in HTTP protocols

The below illustration shows transport stack in HTTP/1.1, HTTP/2 and HTTP/3 protocols.



How QUIC and HTTP/3 connection management works in Citrix ADC

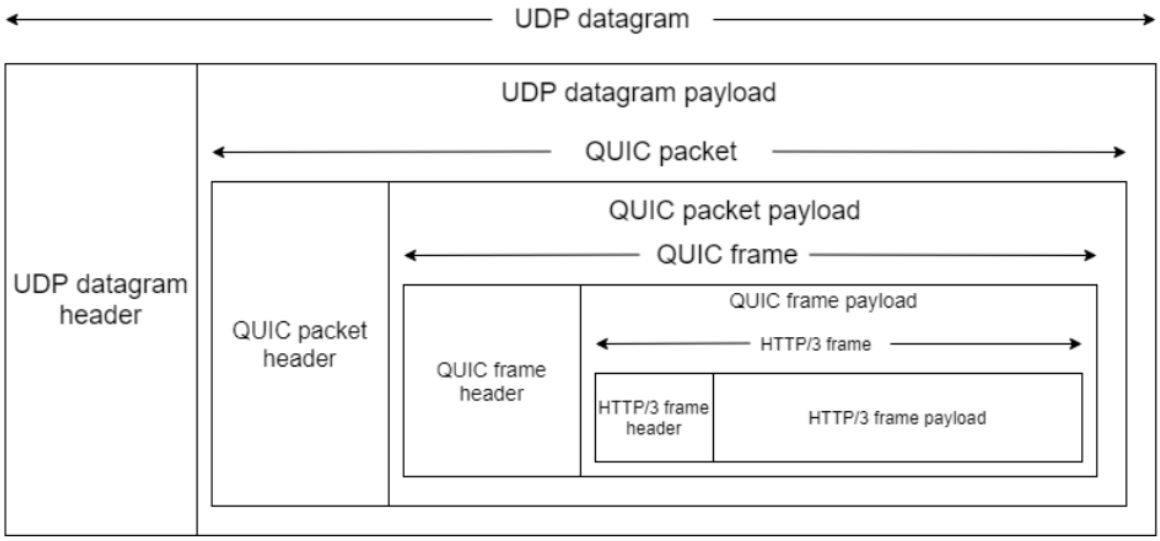
The following illustration shows how QUIC and HTTP/3 connection management in a Citrix ADC appliance and how the components interact with each other.

Step 1: Client-side HTTP/3 request over QUIC protocol to Citrix ADC appliance.
Step 2: Request forwarded by Citrix ADC AS HTTP/1.1 or HTTP/2 depending on back-end server support.
Step 3: Response through HTTP/2 or HTTP/1.1 from back-end server to Citrix ADC.
Step 4: ADC forwards the response as HTTP/3 response to client.

How HTTP/3 protocol works

In HTTP/3, when a client knows that an HTTP/3 server exists at a certain endpoint, it opens a QUIC connection. The QUIC protocol provides multiplexing and flow control. Within each stream, the basic unit of HTTP/3 communication is a frame. Each frame type serves a different purpose. For example, HEADERS and DATA frames form the basis of HTTP requests and responses.

Multiplexing of requests is performed using the QUIC stream abstraction. Each request-response pair consumes a single QUIC stream. Streams are independent of each other, so one stream that is blocked or suffers packet loss does not prevent progress on other streams. Server push is an interaction mode introduced in HTTP/2 which permits a server to push a request-response exchange to a client in anticipation of the client making the indicated request. This trades off network usage against a potential latency gain. Several HTTP/3 frames are used to manage server push, such as PUSH_PROMISE, MAX_PUSH_ID, and CANCEL_PUSH. As in HTTP/2, request and response fields are compressed for transmission. Because HPACK relies on in-order transmission of compressed field sections (a guarantee not provided by QUIC), HTTP/3 replaces HPACK with QPACK. QPACK uses separate unidirectional streams to modify and track field table state, while encoded field sections refer to the state of the table without modifying it.



HTTP/3 configuration and Stat summary

September 14, 2021

To configure a HTTP/3 protocol for sending multiple streams of HTTP/3 data using QUIC, you must complete the following steps:

1. Enable SSL and load balancing features.
2. Add load balancing and content switching (optional) virtual servers of type HTTP_QUIC.
3. Associate QUIC protocol parameters with the HTTP_QUIC virtual server.
4. Enable HTTP/3 on the HTTP_QUIC virtual server.
5. Bind SSL certificate-key pair with HTTP_QUIC virtual server.
6. Associate SSL/TLS protocol parameters with the HTTP_QUIC virtual server.

Enable SSL and load balancing

Before you begin, make sure that the SSL and Load Balancing features is enabled on the appliance. At the command prompt type:

```
enable ns feature ssl lb
<!--NeedCopy-->
```

Add load balancing and content switching (optional) virtual servers of type HTTP_QUIC for HTTP/3 service

You add a load balancing virtual server to accept HTTP/3 traffic over QUIC.
Note: The load balancing virtual server of type HTTP_QUIC has built-in QUIC, SSL, and HTTP3 profiles. If you prefer to create user-define profiles, you can add new profiles and bind it with the load balancing virtual server.

```
add lb vserver <vserver-name> HTTP_QUIC <IP-address> <UDP-listening-
   port>
add cs vserver <vserver-name> HTTP_QUIC <IP-address> <UDP-listening-
   port>
<!--NeedCopy-->
```

Example:

```
add lb vserver lb-http3 HTTP_QUIC 1.1.1.1 443
add cs vserver cs-http3 HTTP_QUIC 10.10.10.10 443
```

Associate QUIC protocol parameters with HTTP_QUIC virtual server

You can create a QUIC profile and specify QUIC parameters for the QUIC service and associate it to the load balancing virtual server. You must either create a user-defined profile or use the in-built QUIC profile and bind the profile to the load balancing virtual server.

Step 1: configure a user-defined QUIC profile
At the command prompt, type:

```
set quic profile <profile_name> -transport_param <value>
<!--NeedCopy-->
```

Example:

```
set quic profile quic_http3 -ackDelayExponent 10 -activeConnectionIDlimit 4
```

The different QUIC transport parameters are as follows:

-ackDelayExponent. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, indicating an exponent that the remote QUIC endpoint should use, to decode the ACK Delay field in QUIC ACK frames sent by the Citrix ADC.

-activeConnectionIDlimit. An integer value advertised by the Citrix ADC to the remote QUIC endpoint. It specifies the maximum number of QUIC connection IDs from the remote QUIC endpoint, that the Citrix ADC is willing to store.

-activeConnectionMigration. Specify whether the Citrix ADC must allow the remote QUIC endpoint to perform active QUIC connection migration.

-congestionCtrlAlgorithm. Specify the congestion control algorithm to be used for QUIC connections.

-initialMaxData. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the initial value, in bytes, for the maximum amount of data that can be sent on a QUIC connection.

-initialMaxStreamDataBidiLocal. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the initial flow control limit, in bytes, for bi-directional QUIC streams initiated by the Citrix ADC.

-initialMaxStreamDataBidiRemote. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the initial flow control limit, in bytes, for bi-directional QUIC streams initiated by the remote QUIC endpoint.

-initialMaxStreamDataUni. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the initial flow control limit, in bytes, for uni-directional streams initiated by the remote QUIC endpoint.

-initialMaxStreamsBidi. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the initial maximum number of bi-directional streams the remote QUIC endpoint must initiate.

-initialMaxStreamsUni. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the initial maximum number of uni-directional streams the remote QUIC endpoint must initiate.

-maxAckDelay. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the maximum amount of time, in milliseconds, by which the Citrix ADC delays sending acknowledgments.

-maxIdleTimeout. An integer value advertised by the Citrix ADC to the remote QUIC endpoint, specifying the maximum idle timeout, in seconds, for a QUIC connection. A QUIC connection that remains idle, for longer than the minimum of the idle timeout values advertised by the Citrix ADC and the remote QUIC endpoint, and three times the current Probe Timeout (PTO), will be silently discarded by the Citrix ADC.

-maxUDPPayloadSize. An integer value advertised by the Citrix ADC to the remote QUIC endpoint,

specifying the size of the largest UDP datagram payload, in bytes, that the Citrix ADC is willing to receive on a QUIC connection.

-newTokenValidityPeriod. An integer value, specifying the validity period, in seconds, of address validation tokens issued through QUIC NEW_TOKEN frames sent by the Citrix ADC.
-retryTokenValidityPeriod. An integer value, specifying the validity period, in seconds, of address validation tokens issued through QUIC Retry packets sent by the Citrix ADC.
-statelessAddressValidation. Specify whether the Citrix ADC must perform stateless address validation for QUIC clients, by sending tokens in QUIC Retry packets during QUIC connection establishment, and by sending tokens in QUIC NEW_TOKEN frames after QUIC connection establishment.

Step 2: Associate the user-defined QUIC profile to a load balancing virtual server of type http_quic

At the command prompt, type:

```
set lb vserver <name>@ [-IPAddress <ip_addr|ipv6_addr|*>@]  <
    serviceName>@] [-persistenceType <persistenceType>] [-
    quicProfileName <string>]
<!--NeedCopy-->
```

Example:

```
set lb vserver lb-http3 -quicProfileName quic_http3
```

Enable and bind HTTP/3 on a HTTP_QUIC virtual server

To enable HTTP/3 on an HTTP_QUIC virtual server, a set of configuration parameters is added to the HTTP profile configuration. To facilitate ease of configuration, when you add an HTTP_QUIC virtual server, a new default/built-in HTTP profile is available on the appliance. The profile has the HTTP/3 protocol support parameters set to ENABLED, and also bounded to the HTTP_QUIC virtual servers (applicable if you choose not to associate the HTTP_QUIC virtual server with a user-added HTTP profile). The value of the HTTP/3 parameters in the HTTP profile decides whether to select the HTTP/3 protocol and advertise when processing the TLS ALPN (Application Layer Protocol Negotiation) extension, during the QUIC protocol handshake.

You can create a HTTP/3 profile and specify HTTP parameters for the HTTP/3 service and load balancing virtual server. You must either create a user-defined profile or use the in-built HTTP/3 profile and bind the profile to the load balancing virtual server.

Step 1: configure a user-defined HTTP/3 profile
At the command prompt, type:

```
Add ns httpProfile <profile_name> -http3 ENABLED
<!--NeedCopy-->
```

Example:

```
add ns httpProfile http3_quic -http3 ENABLED
```

Step 2: Bind the user-defined HTTP/3 profile to a load balancing virtual server of type http_quic
At the command prompt, type:

```
1 set lb vserver <name>@ [-IPAddress <ip_addr|ipv6_addr|*>@]  <
     serviceName>@] [-persistenceType <persistenceType>] [-
     httpProfileName <string>]
2 <!--NeedCopy-->
```

Example:

```
set lb vserver lb-http3 -httpProfileName http3_quic
```

Bind SSL certificate-key pair with HTTP_QUIC virtual server

For processing encrypted traffic, you must add an SSL certificate-key pair and bind it to the HTTP_QUIC virtual server.

At the command prompt, type:

```
1 bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>
2
3 <!--NeedCopy-->
```

Example:

```
bind ssl vserver lb-http3 -certkeyName rsa_certkeypair
```

For more information, see Bind SSL certificate topic.

Bind SSL/TLS protocol parameters with a HTTP_QUIC virtual server

Virtual servers of type HTTP_QUIC has in-built TLS 1.3 server functionality because the QUIC protocol uses TLS 1.3 as a mandatory security component. To facilitate the configuration when adding a HTTP_QUIC virtual server, a new default or built-in SSL profile of type - QUIC-FrontEnd is added. The SSL profile has TLS 1.3 version enabled with TLS 1.3 cipher suites (and elliptic curves) configured. The SSL profile must then be bound to the newly added HTTP_QUIC virtual servers.
You can create an SSL profile and specify SSL encryption parameters for the TLP 1.1 service and load balancing virtual server. You must either create a user-defined profile or use the in-built SSL profile and bind the profile to the load balancing virtual server.

Step 1: configure a user-defined SSL profile
At the command prompt, type:

```
add ssl profile <name> -sslprofileType QUIC-FrontEnd
<!--NeedCopy-->
```

Example:

```
add ssl profile ssl_profile1 -sslprofileType QUIC-FrontEnd -tls13 ENABLED -
tls12 DISABLED -tls11 DISABLED -tls1 DISABLED
```

Step 2: Bind the user-defined SSL profile to a load balancing virtual server of type HTTP_QUIC
At the command prompt, type:

```
set lb vserver <name>@ [-IPAddress <ip_addr|ipv6_addr|*>@]  <
    serviceName>@] [-persistenceType <persistenceType>] [-
    httpProfileName <string>]
<!--NeedCopy-->
```

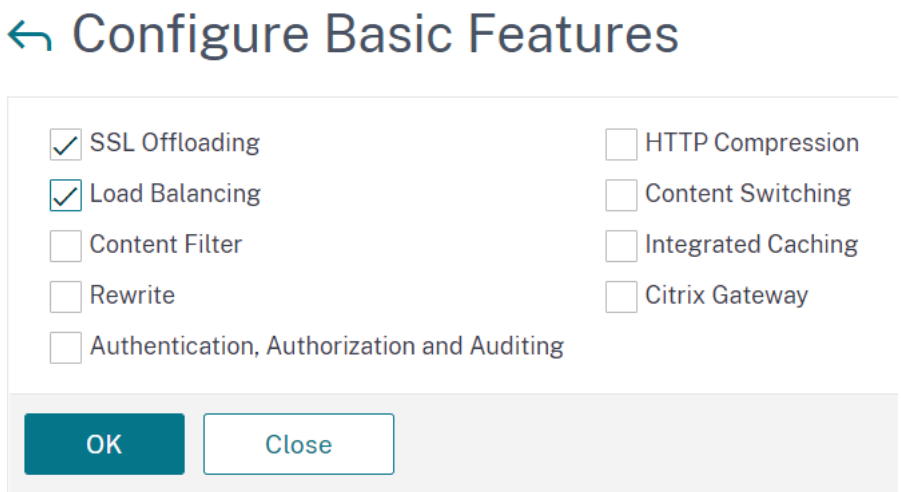
Example:

```
set ssl vserver lb-http3 -sslprofile ssl_profile1
```

Enable SSL and load balancing features by using the GUI

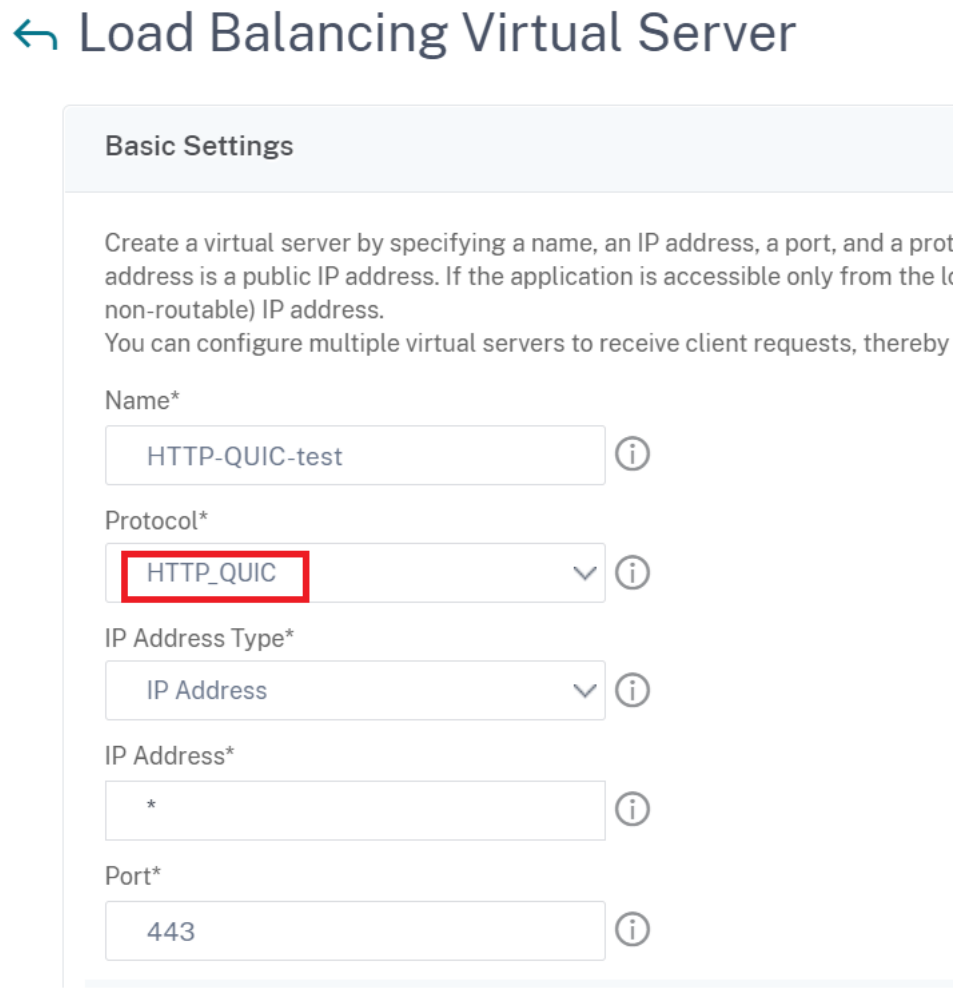
Complete the following steps to enable SSL and load balancing features:

1. On the navigation pane, expand **System** and then click **Settings**.
2. On the **Configure Basic Features** page, select the **SSL** and **Load Balancing**.
3. Click **OK**, and then click **Close**.



Add load balancing and content switching (optional) virtual servers of type HTTP_QUIC by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click **Add** to create a load balancing virtual server of type HTTP_QUIC.
3. In **Load Balancing Virtual Server** page, click **Profiles**.
4. In the **Profiles** section, select the profile type as QUIC. Note: QUIC, HTTP/3 and SSL profiles are built-in ones.
5. Click **OK** and then **Done**.



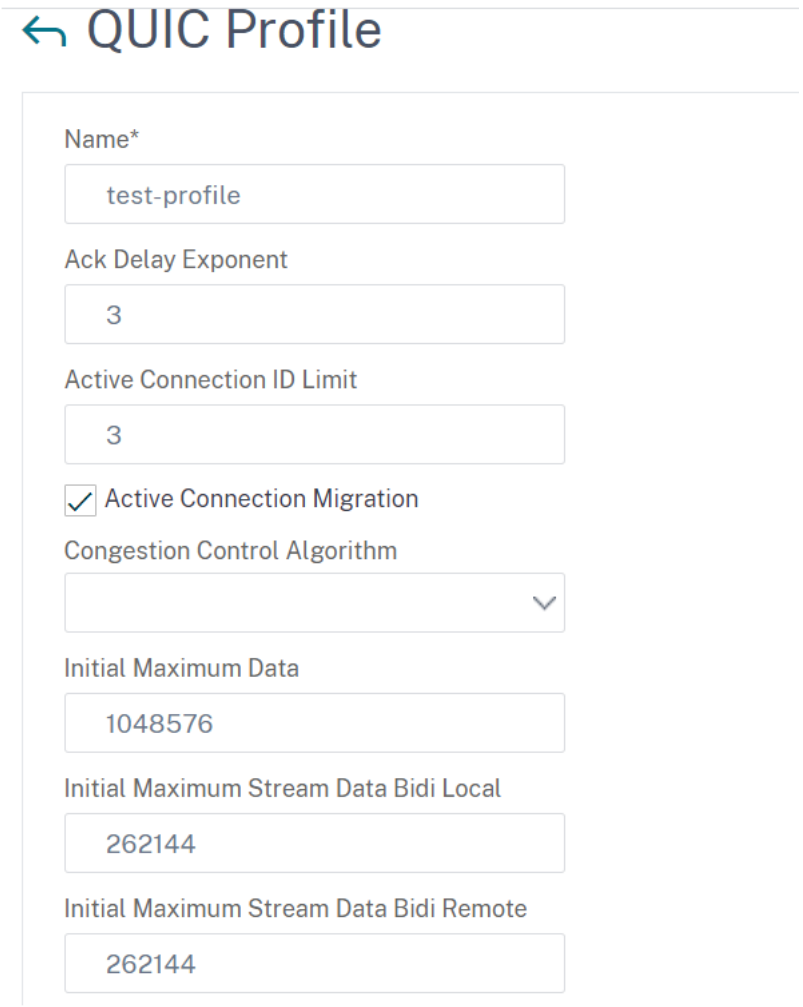
Associate QUIC protocol parameters with the HTTP_QUIC virtual server by using the GUI

Step 1: Add QUIC profile

1. Navigate to **System > Profiles > QUIC Profile**.
2. Click **Add**.

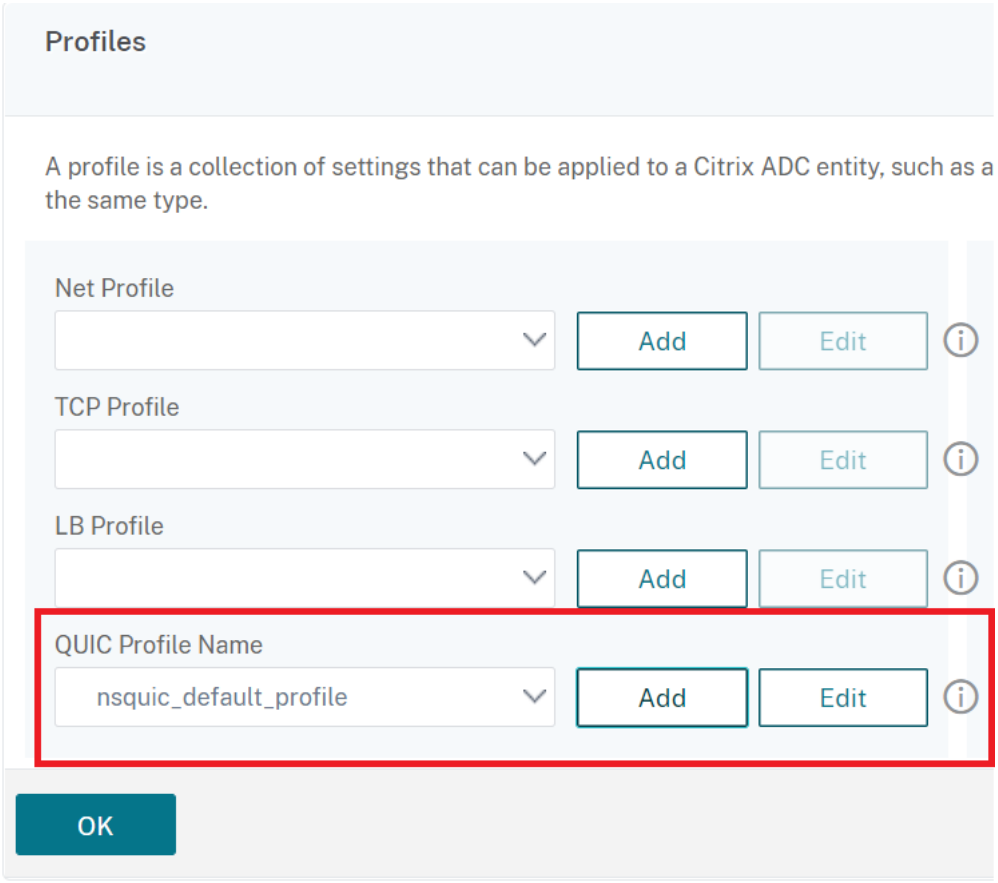
3. In the QUIC Profile page, set the following parameters. For detailed description of each parameter, see the Associate QUIC protocol CLI section.

   a) `Ack Delay` Exponent
   b) Active Connection ID Limit
   c) Active Connection Migration
   d) Congestion Control Algorithm
   e) Initial Maximum Data
   f) Initial Maximum Stream Data Bidi Local
   g) Initial Maximum Stream Data Bidi Remote
   h) Initial Maximum Stream Data Unit
   i) Initial Maximum Stream bidi
   j) Initial Maximum Stream Uni
   k) Maximum Acknowledgment Delay
   l) Maximum Idle Timeout
   m) Maximum UDP Data GramsperBurst
   n) New Token Validity Period
   o) Retry Token Validity Period
   p) Stateless Address Validation



Step 2: Associate QUIC profile with load balancing virtual server of type HTTP_QUIC

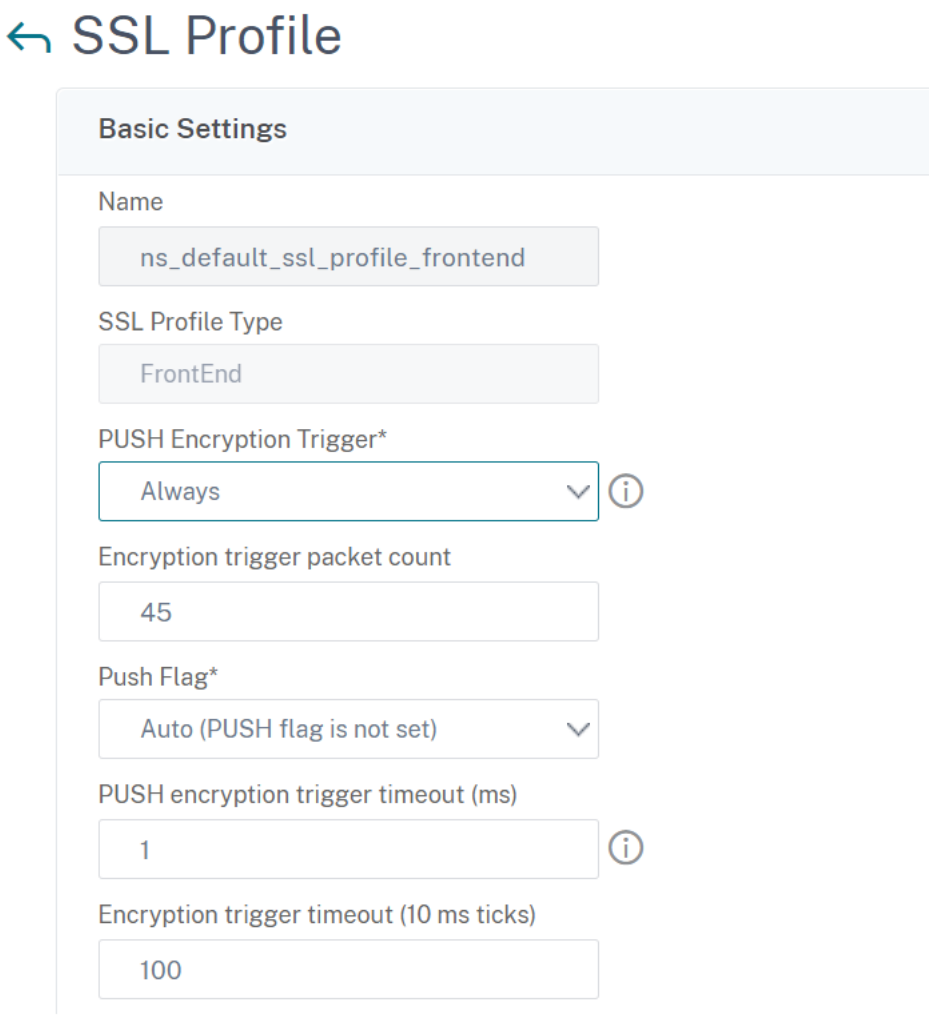
1. In the **Profiles** section, select the QUIC profile. Note: QUIC, HTTP/3 and SSL profiles are built-in ones.
2. Click **OK** and then **Done**.



Associate SSL/TLS protocol parameters with the virtual server of type SSL by using the GUI

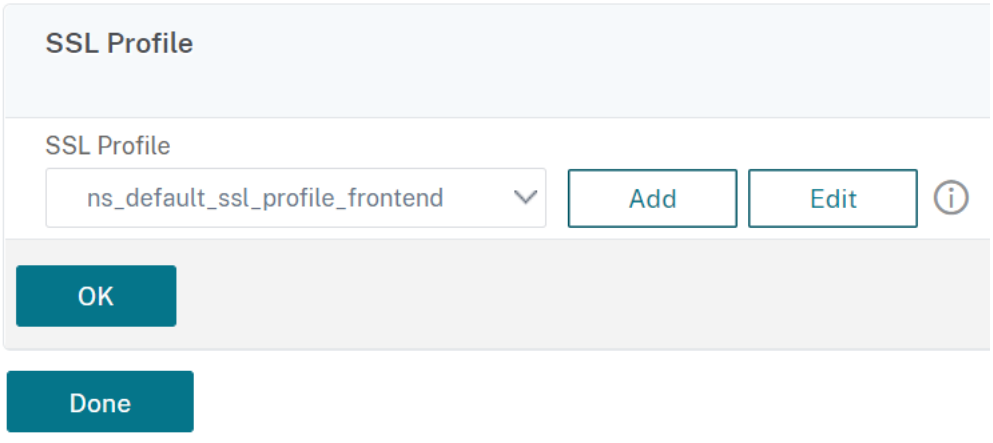
Step 1: Add SSL profile

1. Navigate to **System > Profiles > SSL Profile**.
2. Click **Add**.
3. In the **QUIC Profile** page, set the SSL parameters. For detailed description see, SSL Profile configuration topic.
4. Click **OK** and **Close**.



Step 2: Associate SSL profile with load balancing virtual server of type SSL.

1. In the **Profiles** section, select the SSL profile.
2. Click **OK** and then **Done**.



View QUIC, and HTTP/3 statistics

The following commands display a detailed summary of QUIC, and HTTP3 statistics. At the command prompt, type the following:

```
> stat quic
> stat quic  - detail
<!--NeedCopy-->
```

To clear the statistics display, type one of the following:

```
> stat quic -clearstats basic
> stat quic -clearstats full

<!--NeedCopy-->
```

To display a detailed summary of HTTP/3 statistics:

```
> stat http3
> stat http3  - detail
<!--NeedCopy-->
```

To clear the statistics display, type one of the following:

```
> stat http3 -clearstats basic
> stat http3 -clearstats full
<!--NeedCopy-->
```

Policy configuration for HTTP/3 traffic

September 14, 2021

HTTP/3 uses QUIC transport which is based on UDP. If you had policy expression defined for the HTTP or SSL virtual server that includes TCP policy expressions, it can no longer be used with a HTTP_QUIC virtual server. All other policies that do not have TCP or classic expressions can be bound with a HTTP_QUIC virtual server. For the policies to take effect, you must ensure that the feature policies are bound to the newly added global bind points as per the following.

- HTTPQUIC_REQ_DEFAULT
- HTTPQUIC_REQ_OVERRIDE
- HTTPQUIC_RES_DEFAULT
- HTTPQUIC_RES_OVERRIDE

Or, the policies can be bound to specific virtual server bind points:

- REQUEST
- RESPONSE

For more information, see Bind policy using advanced policy infrastructure topic.

Following are the policies supported for HTTP over QUIC configuration:

- Responder
- Rewrite
- HTTP Compression
- Integrated Caching
- Web Application Firewall
- URL transformation
- SSL
- Front end optimization (FEO)
- AppQoE

Responder policy configuration for HTTP/3 traffic

HTTP over QUIC type virtual servers have responder policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included.

New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 QUIC virtual servers or HTTP over QUIC global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Add responder action for redirecting URLs

To add a responder action, at the command prompt, type:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment <
    string>] [-responseStatusCode <positive_integer>] [-reasonPhrase <
    expression>] [-headers <name(value)> ...]
<!--NeedCopy-->
```

Example:

```
add responder action redirectURL redirect "\"https://www.citrix.com/\""
```

Add responder policy

To add a responder policy, at the command prompt, type:

```
1 add responder policy <name> <rule> <action> [<undefAction>] [-comment <
     string>] [-logAction <string>] [-appflowAction <string>]
2 <!--NeedCopy-->
```

Example:

```
add responder policy res-pol "CLIENT.IP.SRC.IN_SUBNET(10.10.10.10/32)"
redirectURL
```

Add responder policy based UDP expression

To add a responder policy based UDP expression, at the command prompt, type:

```
1 add responder policy <name> <rule> <action> [<undefAction>] [-comment <
     string>] [-logAction <string>] [-appflowAction <string>]
2 <!--NeedCopy-->
```

Example:

```
add responder policy redirectCitrixUdp "CLIENT.UDP.DSTPORT.EQ(443)"redirectURL
```

Bind responder policy based UDP expression with HTTP/3 QUIC based load balancing virtual server

To bind a responder policy based UDP expression to a load balancing virtual server, at the command prompt, type:

```
1 bind lb vserver <name>@ ((<serviceName>@   [-weight <positive_integer>]
      ) | <serviceGroupName>@ |         (-policyName <string>@  [-
     priority <positive_integer>]  [-gotoPriorityExpression <expression>]
       [-type <type>]  [-invoke  (<labelType>  <labelName>) ]  ) | -
     analyticsProfile <string>@)
2 <!--NeedCopy-->
```

Example:

```
bind lb vserver lb-http3 -policyName redirectCitrixUdp -priority 9 -gotoPriorityExpres
 END -type REQUEST
```

Bind responder policy with HTTP/3 QUIC based load balancing virtual server

To bind a responder policy to a load balancing virtual server, at the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@   [-weight <positive_integer>]
     ) | <serviceGroupName>@ |         (-policyName <string>@  [-
    priority <positive_integer>]  [-gotoPriorityExpression <expression>]
      [-type <type>]  [-invoke  (<labelType>  <labelName>) ]  ) | -
    analyticsProfile <string>@)
<!--NeedCopy-->
```

Example:

```
bind lb vserver lb-http3 -policyName redirectCitrixUdp -priority 10 -
gotoPriorityExpression END -type REQUEST
```

Bind responder policy to HTTP/3 global bind point

To bind a responder policy with the HTTP/3 global bind point, at the command prompt, type:

```
bind responder global <policyName> <priority>  [<gotoPriorityExpression
    >] [-type <type>] [-invoke (<labelType>  <labelName>) ] bind
    responder global redirectCitrixUdp 3 -type HTTPQUIC_REQ_DEFAULT
<!--NeedCopy-->
```

Example:

```
bind responder global redirectCitrixUdp 3 -type HTTPQUIC_REQ_DEFAULT
```

> **Note:**
>
> For more information, see Responder policy documentation.

Rewrite policy configuration for HTTP/3 traffic

HTTP over QUIC type virtual servers have rewrite policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included.

New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Following are the configuration steps to configure the rewrite policy for HTTP3 over QUIC.

Add rewrite action for HTTP over QUIC

To add rewrite action, at the command prompt, type:

```
add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-
    pattern <expression> | -search <expression>] [-refineSearch <
    expression>] [-comment <string>]
<!--NeedCopy-->
```

Example:

```
add rewrite action http3-altsvc-action insert_http_header Alt-Svc q/"h3
-29=\":443\"; ma=3600; persist=1"/
```

Add rewrite policy for HTTP over QUIC

To add a write action, at the command prompt, type:

```
add rewrite policy <name> <rule> <action> [<undefAction>] [-comment  <
    string>] [-logAction <string>]
<!--NeedCopy-->
```

Example:

```
add rewrite policy http3-altsvc-policy true http3-altsvc-action
```

Bind rewrite policy to load balancing virtual server of type HTTP/3_QUIC

To bind rewrite policy to the load balancing virtual server, at the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@ [-weight <positive_integer>] )
     | <serviceGroupName>@ | (-policyName <string>@ [-priority <
    positive_integer>] [-gotoPriorityExpression <expression>] [-type <
    type>] [-invoke (<labelType> <labelName>) ] ) | -analyticsProfile  <
    string>@)
<!--NeedCopy-->
```

Example:

```
bind lb vserver lb-http3 -policyName http3-altsvc-policy -priority 10 -type
 RESPONSE
```

Bind rewrite policy to HTTP/3 global bind point

```
To bind a responder policy with HTTP/3 global bind point, at the
    command prompt, type:
bind rewrite global <policyName> <priority> [<gotoPriorityExpression>]
     [-type <type>] [-invoke (<labelType> <labelName>)]
```

```
<!--NeedCopy-->
```

Example:

```
bind rewrite global http3-altsvc-policy 3 -type HTTPQUIC_RES_DEFAULT
```

> **Note:**
>
> For more information, see Rewrite policy documentation.

Compression policy configuration for HTTP/3 traffic

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.
HTTP over QUIC type virtual servers have compression policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included.
New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Add compression policy

To add compression policy, at the command prompt, type:

```
add cmp policy <name> -rule <expression> -resAction <string>
<!--NeedCopy-->
```

Example:

```
add cmp policy udp_port_cmp_policy -rule "CLIENT.UDP.DSTPORT.EQ(443)"-
resAction COMPRESS
```

Bind compression policy with load balancing virtual server of type HTTP/3_QUIC

To bind URL transformation policy with load balancing virtual server of type HTTP/3_QUIC, at the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@  [-weight <positive_integer>]
    ) | <serviceGroupName>@ |  (-policyName <string>@  [-priority <
    positive_integer>]  [-gotoPriorityExpression <expression>]  [-type (
     REQUEST | RESPONSE )] [-invoke  (<labelType>  <labelName>) ]  ) |
    -analyticsProfile <string>@)
<!--NeedCopy-->
```

Example:

```
bind lb vserver lb-http3 -policyName udp_port_cmp_policy -priority 10 -type
 RESPONSE
```

Bind compression global to HTTP/3 global bind point

To bind a compression policy with the HTTP/3 global bind point, at the command prompt, type:

```
bind compression global <policyName> <priority>  [<
    gotoPriorityExpression>] [-type <type>] [-invoke (<labelType>  <
    labelName>) ] bind responder global redirectCitrixUdp 3 -type
    HTTPQUIC_REQ_DEFAULT
<!--NeedCopy-->
```

Example:

```
bind cmp global udp_port_cmp_policy -priority 100 -type HTTPQUIC_RES_DEFAULT
 Global built-in compression policies
```

After you upgrade your appliance to Citrix ADC release 13.0 build 82.x, the following compression policies will be automatically bound to the HTTP/3 default bind point.

```
> sho cmp global -type HTTPQUIC_RES_DEFAULT
        Policy Name: ns_adv_nocmp_xml_ie
        Priority: 8700
        GotoPriorityExpression: END
        Type: HTTPQUIC_RES_DEFAULT

        Policy Name: ns_adv_nocmp_mozilla_47
        Priority: 8800
        GotoPriorityExpression: END
        Type: HTTPQUIC_RES_DEFAULT

        Policy Name: ns_adv_cmp_mscss
        Priority: 8900
        GotoPriorityExpression: END
        Type: HTTPQUIC_RES_DEFAULT

```

```
17          Policy Name: ns_adv_cmp_msapp
18          Priority: 9000
19          GotoPriorityExpression: END
20          Type: HTTPQUIC_RES_DEFAULT
21
22          Policy Name: ns_adv_cmp_content_type
23          Priority: 10000
24          GotoPriorityExpression: END
25          Type: HTTPQUIC_RES_DEFAULT
26  <!--NeedCopy-->
```

If not bound, the following commands can be configured through the command prompt and you can configuration on your appliance.

```
bind cmp global ns_adv_nocmp_xml_ie -priority 8700 -gotoPriorityExpression
END -type HTTPQUIC_RES_DEFAULT

bind cmp global ns_adv_nocmp_mozilla_47 -priority 8800 -gotoPriorityExpression
 END -type HTTPQUIC_RES_DEFAULT

bind cmp global ns_adv_cmp_mscss -priority 8900 -gotoPriorityExpression END
 -type HTTPQUIC_RES_DEFAULT

bind cmp global ns_adv_cmp_msapp -priority 9000 -gotoPriorityExpression END
 -type HTTPQUIC_RES_DEFAULT

bind cmp global ns_adv_cmp_content_type -priority 10000 -gotoPriorityExpression
 END -type HTTPQUIC_RES_DEFAULT
```

For more information, see Compression policy configuration.

Caching policy configuration for HTTP/3 traffic

The integrated cache provides in-memory storage on the Citrix ADC appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of Citrix ADC appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple webpages and image files. You can also configure the integrated cache to store and serve dynamic content that is marked as non-cacheable by Web and application servers (for example, database records and stock quotes).
HTTP over QUIC type virtual servers have cache policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included.

New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can

be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Add cache content group

To add the cache content group, at the command prompt, type:

```
1 add cache contentGroup <name> [-weakPosRelExpiry <secs> | -relExpiry <
      secs> | -relExpiryMilliSec <msecs> | -absExpiry <HH:MM> ... | -
      absExpiryGMT <HH:MM> ...] [-heurExpiryParam <positive_integer>] [-
      weakNegRelExpiry <secs>] [-maxResSize <KBytes>] [-memLimit <MBytes>]
      ...
2 <!--NeedCopy-->
```

Example::

```
add cache contentGroup DEFAULT -maxResSize 500
```

Add cache policy

To add cache policy, at the command prompt, type:

```
1 add cache policy <policyName> -rule <expression> -action <action>  [-
      storeInGroup <string>] [-invalGroups <string> ...] [-invalObjects <
      string> ...] [-undefAction ( NOCACHE | RESET )] add cache policy <
      name> <rule> <profileName> [-comment <string>]  [-logAction <string
      >]
2 <!--NeedCopy-->
```

Example:

```
add cache policy ctx_doc_pdf -rule "HTTP.REQ.URL.ENDSWITH(\".pdf\")"-action
 CACHE -storeInGroup DEFAULT
```

Bind cache policy with load balancing virtual server of type HTTP/3_QUIC

To bind cache policy with load balancing virtual server of type HTTP/3_QUIC, at the command prompt, type:

```
1 bind lb vserver <name>@ ((<serviceName>@  [-weight <positive_integer>]
      ) | <serviceGroupName>@ |  (-policyName <string>@  [-priority <
      positive_integer>]  [-gotoPriorityExpression <expression>]  [-type (
       REQUEST | RESPONSE )] [-invoke  (<labelType>  <labelName>) ]  ) |
      -analyticsProfile <string>@)
2 <!--NeedCopy-->
```

Example:

```
bind lb vserver lb-http3 -policyName ctx_doc_pdf -priority 100 -type
REQUEST
```

Bind cache policy global to HTTP/3 global bind point

To bind a cache policy HTTP/3 global bind point:

```
1 bind cache global <policy> -priority <positive_integer>  [-
     gotoPriorityExpression <expression>] [-type <type>] [-invoke (<
     labelType> <labelName>) ]
2 <!--NeedCopy-->
```

Example:

```
bind cache global ctx_doc_pdf -priority 3 -type HTTPQUIC_REQ_DEFAULT
```

For more information, see Integrated cache policy configuration.

Global built-in cache policies

After you upgrade your appliance to Citrix ADC release 13.0 build 82.x, the following cache policies will be automatically bound to the HTTP/3 default bind point.

On upgrade to the 13.0 82.x release, the following cache policies are automatically bound to the HTTP/3 default bind point.

```
1  > sho cache global -type HTTPQUIC_REQ_DEFAULT
2  1)      Policy Name: NOPOLICY
3          Priority: 185883
4          GotoPriorityExpression: USE_INVOCATION_RESULT
5          Invoke type: policylabel        Invoke name:
               _httpquicReqBuiltinDefaults
6          Global bindpoint: HTTPQUIC_REQ_DEFAULT
7
8   Done
9  > sho cache global -type HTTPQUIC_RES_DEFAULT
10 1)      Policy Name: NOPOLICY
11         Priority: 185883
12         GotoPriorityExpression: USE_INVOCATION_RESULT
13         Invoke type: policylabel        Invoke name:
               _httpquicResBuiltinDefaults
14         Global bindpoint: HTTPQUIC_RES_DEFAULT
15
16 <!--NeedCopy-->
```

After an upgrade, if the policies are not bound, you can use the following commands to manually bind and save the configuration.

```
add cache policylabel _httpquicReqBuiltinDefaults -evaluates
    HTTPQUIC_REQ

add cache policylabel _httpquicResBuiltinDefaults -evaluates
    HTTPQUIC_RES

bind cache policylabel _httpquicReqBuiltinDefaults -policyName
    _nonGetReq -priority 100

bind cache policylabel _httpquicReqBuiltinDefaults -policyName
    _advancedConditionalReq -priority 200

bind cache policylabel _httpquicReqBuiltinDefaults -policyName
    _personalizedReq -priority 300

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _uncacheableStatusRes -priority 100

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _uncacheableVaryRes -priority 200

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _uncacheableCacheControlRes -priority 300

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _cacheableCacheControlRes -priority 400

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _uncacheablePragmaRes -priority 500

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _cacheableExpiryRes -priority 600

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _imageRes -priority 700

bind cache policylabel _httpquicResBuiltinDefaults -policyName
    _personalizedRes -priority 800

bind cache global NOPOLICY -priority 185883 -gotoPriorityExpression
    USE_INVOCATION_RESULT -type HTTPQUIC_REQ_DEFAULT -invoke policylabel
     _httpquicReqBuiltinDefaults
```

```
28
29 bind cache global NOPOLICY -priority 185883 -gotoPriorityExpression
       USE_INVOCATION_RESULT -type HTTPQUIC_RES_DEFAULT -invoke policylabel
        _httpquicResBuiltinDefaults
30
31 <!--NeedCopy-->
```

> **Note:**
>
> The first two commands in the list of commands, and the last two commands in the same list, are included for the sake of completeness. You might encounter an error when running the four commands, since the commands are already run at the time of appliance restart. But you can ignore these errors.

URL Transformation policy configuration for HTTP/3 traffic

The URL transformation modifies all URLs in designated requests from an external version seen by outside users to an internal URL seen only by your Web servers and administrators. You can redirect user requests seamlessly, without exposing your network structure to users. You can also modify complex internal URLs that users might find difficult to remember into simpler, more easily remembered external URLs.
HTTP over QUIC type virtual servers have cache policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included. New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Add URL Transform profile

To add a URL transformation profile, at the command prompt, type:

```
1 add transform profile <name> [-type URL]
2 <!--NeedCopy-->
```

Example:

```
add transform profile msapps
```

Add URL Transform action

To add URL transformation action, at the command prompt, type:

```
add transform action <name> <profileName> <priority> [-state ( ENABLED
    | DISABLED )]
<!--NeedCopy-->
```

Example:

```
add transform action docx2doc msapps 2
```

Add URL Transform action

To add URL transform action to replace URL, at the command prompt, type:

```
add transform action <name> <profileName> <priority> [-state ( ENABLED
    | DISABLED )]
<!--NeedCopy-->
```

Example:

```
add transform action docx2doc msapps 1
```

Add URL Transform policy

To add a URL transformation policy, at the command prompt, type:

```
add transform policy <name> <rule> <profileName> [-comment <string>]
   [-logAction <string>]
<!--NeedCopy-->
```

Example:

```
add transform policy urltrans_udp "CLIENT.UDP.DSTPORT.EQ(443)"msapps
```

Bind URL Transform policy with load balancing virtual server of type HTTP/3_QUIC

To bind URL transformation policy with load balancing virtual server of type HTTP/3_QUIC, at the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@  [-weight <positive_integer>]
   ) | <serviceGroupName>@ |  (-policyName <string>@  [-priority <
   positive_integer>]  [-gotoPriorityExpression <expression>]  [-type (
    REQUEST | RESPONSE )] [-invoke  (<labelType>  <labelName>) ]  ) |
   -analyticsProfile <string>@)
<!--NeedCopy-->
```

Example:

```
bind lb vs lb-http3 -policyName urltrans_udp -type REQUEST -priority 8
```

Bind URL transform policy global with HTTP/3 QUIC based load balancing virtual server

To bind a URL transform policy HTTP/3 global bind point, at the command prompt, type:

```
1 bind transform global <policyName> <priority>  [<gotoPriorityExpression
     >] [-type <type>] [-invoke (<labelType>  <labelName>) ]
2 <!--NeedCopy-->
```

Example:

```
bind transform global urltrans_udp 100 -type HTTPQUIC_REQ_DEFAULT
```

For more information, see URL transformation policy configuration.

Front end optimization (FEO) policy configuration for HTTP/3 traffic

The HTTP protocols that underlie web applications were originally developed to support the transmission and rendering of simple webpages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level. The Citrix ADC front end optimization (FEO) feature addresses such issues and reduces the load time and render time of webpages.

> **Note:**
>
> `HTTP_QUIC _Override/Default_Request` Type is not supported for FEO policy global binding.

Add Front end optimization (FEO) action

To add a FEO action, at the command prompt, type:

```
1 add feo action <name> [-pageExtendCache] [<cacheMaxage>][-
     imgShrinkToAttrib] [-imgGifToPng] [-imgToWebp] [-imgToJpegXR] [-
     imgInline] [-cssImgInline] [-jpgOptimize] [-imgLazyLoad] [-cssMinify
     ] [-cssInline] [-cssCombine] [-convertImportToLink] [-jsMinify] [-
     jsInline] [-htmlMinify] [-cssMoveToHead] [-jsMoveToEND][-
     domainSharding <string> <dnsShards> ...] [-clientSideMeasurements]
2
3 <!--NeedCopy-->
```

Example:

```
add feo action feoact -imgGifToPng -pageExtendCache
```

Add Front end optimization (FEO) policy

To add a FEO policy, at the command prompt, type:

```
add feo policy <name> <rule> <action>
```

Example:

```
add feo policy udp_feo_img "CLIENT.UDP.DSTPORT.EQ(443)"IMG_OPTIMIZE
```

Bind FEO policy with load balancing virtual server of type HTTP/3_QUIC

To bind FEO policy with load balancing virtual server of type HTTP/3_QUIC, at the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@   [-weight <positive_integer>]
     ) | <serviceGroupName>@ |         (-policyName <string>@  [-
    priority <positive_integer>]  [-gotoPriorityExpression <expression>]
      [-type <type>]  [-invoke  (<labelType>  <labelName>) ]  ) | -
    analyticsProfile <string>@)
<!--NeedCopy-->
```

Example:

```
bind lb vserver lb-http3 -policyName udp_feo_img -priority 4 -gotoPriorityExpression
 END -type REQUEST
```

Bind FEO policy to HTTP/3 global bind point

To bind a cache policy to the HTTP/3 global bind point, at the command prompt, type:

```
bind cache global <policy> -priority <positive_integer>  [-
    gotoPriorityExpression <expression>] [-type <type>] [-invoke (<
    labelType> <labelName>) ]
<!--NeedCopy-->
```

Example:

```
bind cache global ctx_doc_pdf -priority 3 -type HTTPQUIC_REQ_DEFAULT
```

For more information, see Front end optimization policy configuration.

SSL Policy configuration for HTTP/3 traffic

HTTP over QUIC type virtual servers have SSL policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included.
New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.
SSL policies with actions that are supported for TLSv1.3 are only applicable for HTTP/3 bind points or virtual servers.

Add SSL Policy

To add a FEO policy, at the command prompt, type:

```
1 add ssl policy <name> -rule <expression> [-action <string>] [-
     undefAction <string>] [-comment <string>]
2 <!--NeedCopy-->
```

Example:

```
add ssl policy ssl-pol -rule CLIENT.SSL.IS_SSL -action NOOP
```

Bind SSL Policy to HTTP/3 virtual server

To bind an SSL policy to the HTTP/3 virtual server, at the command prompt:

```
1 bind ssl policylabel <labelName> <policyName> <priority> [<
     gotoPriorityExpression>] [-invoke (<labelType> <labelName>)
2 <!--NeedCopy-->
```

Example:

```
bind ssl vserver lb-http3 -policyName ssl-pol -priority 4 -type REQUEST
```

Add SSL policy with UDP expression for SSL Policy

To add an SSL policy with UDP expression, at the command prompt:

```
1 add ssl policy <name> -rule <expression> [-action <string>] [-
     undefAction <string>] [-comment <string>]
2 <!--NeedCopy-->
```

Example:

```
add ssl policy ssl_udp_clnt -rule "CLIENT.UDP.DSTPORT.EQ(443)"-action NOOP
```

Bind SSL Policy with UDP expression to HTTP/3 virtual server

To bind an SSL policy with UDP expression to the HTTP/3 virtual server, at the command prompt, type

```
1 bind ssl policylabel <labelName> <policyName> <priority> [<
     gotoPriorityExpression>] [-invoke (<labelType> <labelName>)
2 <!--NeedCopy-->
```

Example:

```
bind ssl vs lb-http3 -policyName ssl_udp_clnt -priority 8 -type REQUEST
```

Add SSL policy for CLIENTHELLO bind point for HTTP/3 traffic

To bind SSL policy for CLIENTHELLO bind point for HTTP/3 traffic, at the command prompt, type:

```
1 bind ssl policylabel <labelName> <policyName> <priority> [<
     gotoPriorityExpression>] [-invoke (<labelType> <labelName>)
2 <!--NeedCopy-->
```

Example:

```
add ssl policy ssl-pol-ch -rule "CLIENT.SSL.CLIENT_HELLO.CIPHERS.HAS_HEXCODE
(0x1301)"-action RESET
```

Bind SSL policy to CLIENTHELLO bind point

To bind an SSL policy to the CLIENTHELLO bind point, at the command prompt, type:

```
1 bind ssl policylabel <labelName> <policyName> <priority> [<
     gotoPriorityExpression>] [-invoke (<labelType> <labelName>)
2 <!--NeedCopy-->
```

Example:

```
bind ssl vs lb-http3 -policyName ssl-pol-ch -type CLIENTHELLO_REQ -priority
 100
```

Bind SSL policy to HTTP/3 global bind point

To bind an SSL policy to the HTTP/3 global bind point, at the command prompt, type:

```
bind cache global <policy> -priority <positive_integer> [-gotoPriorityExpression
 <expression>] [-type <type>] [-invoke (<labelType> <labelName>)]
```

Example:

Following is an example of a DATA policy being bound to a HTTP/3 global bind point:

```
Bind ssl global -policyName ssl-pol-ch -priority 7 -type HTTPQUIC_DATA_DEFAULT
```

> **Note:**
>
> Forward action that can be set for CLIENTHELLO bind point for SSL virtual servers is currently not supported for HTTP_QUIC type virtual servers.

Application Firewall Policy configuration for HTTP/3 traffic

HTTP over QUIC type virtual servers have web application firewall policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included.
New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Add Web Application Firewall policy with UDP expression

To add Web Application Firewall policy with UDP expression, at the command prompt:

```
1 add appfw policy <name> <rule> <profileName> [-comment <string>] [-
     logAction <string>]
2 <!--NeedCopy-->
```

Example:

```
add appfw policy appfw_udp "CLIENT.UDP.DSTPORT.EQ(443)"APPFW_BYPASS
```

Bind log expressions with UDP based expression for Web Application Firewall profile

To bind log expressions with UDP for Web Application Firewall profile, at the command prompt:

Example:

```
bind appfw profile APPFW_BLOCK -logExpression logexp-1 "CLIENT.UDP.DSTPORT.
EQ(443)"
```

Bind Application Firewall policy with HTTP/3 virtual server

To bind Web Application Firewall policy with HTTP/3 virtual server, at the command prompt:

```
bind appfw policylabel <labelName> <policyName> <priority> [<
    gotoPriorityExpression>] [-invoke (<labelType> <labelName>)
<!--NeedCopy-->
```

Example:

```
bind lb vs lb-http3 -policyName appfw_udp -priority 3 -type REQUEST
```

Bind Web Application Firewall policy to HTTP/3 global bind point

To bind a Web Application Firewall policy to the HTTP/3 global bind point, at the command prompt, type:

```
bind appfw global <policy> -priority <positive_integer>  [-
    gotoPriorityExpression <expression>] [-type <type>] [-invoke (<
    labelType> <labelName>) ]
<!--NeedCopy-->
```

Example:

```
bind appfw global appfw_udp 100 -type HTTPQUIC_REQ_DEFAULT
```

AppQoE Policy configuration for HTTP/3 traffic

HTTP over QUIC type virtual servers have AppQoE policy support. However, as QUIC uses UDP as its transport mechanism, TCP based expressions are excluded and UDP based expressions are included. New or existing policy configurations with TCP expressions cannot be bound to HTTP/3 virtual servers or to the newly added HTTP/3 global bind points. Instead of TCP expressions, UDP expressions can be included in the policy configurations that are bound to HTTP/3 QUIC virtual servers or HTTP over QUIC bind points.

Add AppQoE policy with UDP based expression

To add AppQoE policy with UDP expression, at the command prompt:

```
add AppQoE policy <name> <rule> <profileName> [-comment <string>] [-
    logAction <string>]
<!--NeedCopy-->
```

Example:

```
add appqoe policy appqoe-pol-udp -rule "CLIENT.UDP.DSTPORT.EQ(443)"-action
appqoe-act-basic-prhigh
```

Bind AppQoE policy with HTTP/3 virtual server

To bind the AppQoE policy with the HTTP/3 virtual server, at the command prompt, type:

```
1 bind appqoe policylabel <labelName> <policyName> <priority> [<
     gotoPriorityExpression>] [-invoke (<labelType> <labelName>)
2 <!--NeedCopy-->
```

Example:

```
bind lb vs lb-http3 -policyName appqoe-pol-udp -type REQUEST -priority 3
```

Bind AppQoE policy to HTTP_QUIC virtual server

To bind AppQoE policy to `HTTP_QUIC` virtual server, at the command prompt, type:

```
1 bind appqoe <policy> -priority <positive_integer>  [-
     gotoPriorityExpression <expression>] [-type <type>] [-invoke (<
     labelType> <labelName>) ]
2 <!--NeedCopy-->
```

Example:

```
bind lb vs lb-http3 -policyName appqoe-pol-primd -priority 8 -type REQUEST
```

HTTP/3 service discovery

September 14, 2021

HTTP protocol relies on using HTTP Alternative Services for origin server to advertise the availability of an equivalent service. HTTP/3 service discovery also uses the same principle. An alternative HTTP/3 endpoint can be advertised using any one of the following methods:

- HTTP Alt-Svc response header
- HTTP/2 Alt-Svc Frame in the response
- Application Layer Protocol Negotiation (ALPN)

The alternative service advertises the usage of an HTTP Alt-Svc response header and the HTTP/2 Alt-Svc frame as HTTP/3 endpoint. Servers may serve HTTP/3 on any UDP port. An alternative service

advertisement includes an explicit port, and URLs contain either an explicit port or a default port associated with the scheme.

Clients receiving alternate service headers or frames are not bound to use them. The client, if made aware of an alternate service and if it supports the alternate service mechanism should use the appropriate alternate service advertised. In other words, a HTTP/1.1 service or a HTTP/2 service may advertise an equivalent endpoint that supports HTTP/3 protocol. The client on receiving this alternate service information can choose to establish a QUIC connection with the specified alternate service and once available, this connection can be used for any subsequent requests. If the establishment of the connection with the selected alternate service fails, the client can fall back to the original endpoint. When the client starts using the alternate service advertised, will indicate this by including a Alt-Used header.

Citrix ADC supports advertising equivalent HTTP/3 endpoints on HTTP and SSL type virtual servers.

Configure HTTP/3 service discovery

Complete the following steps to configure HTTP/3 service discovery:

1. Configure HTTP/3 alternative service endpoint by using an HTTP Alt-Svc Header
2. Configure HTTP/3 alternative service endpoint by using an HTTP/2 Alt-Svc frame
   Configure HTTP/3 alternative service endpoint by using an HTTP Alt-Svc Header
   To advertise an HTTP/3 endpoint by using a HTTP Alt-Svc Header, type the following command:

Note: The main purpose of advertising alternative service is to let user know that HTTP/3 capability can be accessed on HTTP/1.1 or HTTP/2 service on a.b.c.d:443 also.

```
add ns httpProfile <name> -custom -altsvc [ ENABLED | DISABLED ]
<!--NeedCopy-->
```

Example:

```
add ns httpProfile http-profile -altsvc ENABLED -altSvcValue  "h3
   -29=\":443\"; ma=3600; persist=1"
<!--NeedCopy-->
```

or

```
set ns httpProfile http-custom -altsvc ENABLED -altSvcValue  "h3
   -29=\":443\"; ma=3600; persist=1"
<!--NeedCopy-->
```

Configure HTTP/3 alternative service endpoint by using an HTTP/2 Alt-Svc frame

To advertise an HTTP/3 endpoint by using a HTTP/2 Alt-svc frame, type the following command:

```
add ns httpProfile <name> -custom -altsvc [ ENABLED | DISABLED ] -
    http2AltSvcFrame [ ENABLED | DISABLED ]
<!--NeedCopy-->
```

Example:

```
add ns httpProfile http-custom -http2 ENABLED -http2Direct ENABLED -http2AltSvcFrame
 ENABLED -altsvc ENABLED -altSvcValue "h3-29=\":443\"; ma=3600; persist=1"
```

or

```
set ns httpProfile http-custom -http2 ENABLED -http2Direct ENABLED -http2AltSvcFrame
 ENABLED -altsvc ENABLED -altSvcValue "h3-29=\":443\"; ma=3600; persist=1"
```

Configure HTTP/3 alternative service with HTTP Alt-Svc header value by using GUI

1. Navigate to **System > Profiles > HTTP Profiles**.
2. Click **Add**.
3. In **Create HTTP Profile** page, go to HTTP/3 section and select **Alternative Service** checkbox.
4. The system displays the **Alternative Service Value** text box in the http2 section.
5. Enter the alternative service value as “h3-29=”:443”; ma=3600; persist=1”
6. Click **OK** and **Close**.

gRPC

September 14, 2021

gRPC in a Citrix ADC appliance is a lightweight, high performance, and open-source universal Remote Procedure Call (RPC) framework. The framework is optimal to work across multiple languages running on any operation system. Also when compared to other protocols, gRPC offers better performance and security.

gRPC for Citrix ADC is preferred for the following reasons:

- Build distributed applications for data-center and public/private cloud infrastructure.
- Provide client-server communication for mobile, web, or cloud.
- Access cloud services and applications
- Microservice deployments

Why gRPC in Citrix ADC

gRPC in Citrix ADC is implemented over HTTP/2 to support highly performance and scalable APIs. The use of binary than text keeps the payload compact and efficient. In Citrix ADC, the HTTP/2 requests are multiplexed over a single TCP connection, allowing multiple concurrent messages to be in flight without compromising the network resource usage. It also uses header compression to reduce the size of requests and responses.

gRPC supports the following types of service methods for a client to remotely invoke parameters and return types.

1. **Unary RPC**. Client sends a single request to the gRPC server and gets a single response back.

   Example:

   ```
   rpc SayHello(HelloRequest)returns (HelloResponse);
   ```

2. **Server streaming RPC**. Client sends a single request to the gRPC server and gets a stream response.

   Example:

   ```
   rpc StreamingResponse(HelloRequest)returns (HelloResponse);
   ```

3. **Client streaming RPC**. Client sends a sequence of messages and waits for the server to read and return its response.

   Example:

   ```
   rpc IntroduceYourself(stream HelloRequest)returns (HelloResponse)
   ```

4. **Bidirectional streaming RPC**. Both client and server from both sides send a stream of messages using the read-write stream. The two streams operate independently.

   Example:

   ```
   rpc ChatSession (stream HelloRequest)returns (stream HelloResponse)
   ```

Citrix ADC supports the following capabilities for its services with gRPC endpoints:

- Load balancing
- Content switching
- Secure end-point services like Web Application Firewall, authentication .
- Policy configuration

- Stats and logging
- Content rewriting, content filtering
- Layer 4 and Layer 7 optimizations, TLS offering
- Gateway solutions for protocol translations

gRPC end-to-end configuration

September 14, 2021

The gRPC end-to-end configuration works by sending a gRPC request from a client over HTTP/2 protocol and again forwarding gRPC messages responded by the gRPC server.

How end-to-end gRPC configuration works

The following diagram shows a gRPC configuration works in a Citrix ADC appliance.

1. To deploy the gRPC configuration, you must first enable HTTP/2 in the HTTP profile and also enable HTTP/2 support globally on server side.
2. When a client sends a gRPC request, the load balancing virtual server evaluates the gRPC traffic using policies.
3. Based on policy evaluation, the load balancing virtual server (with gRPC service bound to it) terminates the request and forwards it as a gRPC request to the back-end gRPC server.
4. Similarly, when the gRPC server responds to the client, the appliance terminates the response and forwards it as a gRPC response to the client.

Example for gRPC request sent to gRPC server

The request header is sent as HTTP/2 headers in HEADERS+CONTINUATION Frames.

```
1 ```
```

```
HEADERS (flags = END_HEADERS)
: method = POST
: scheme = http
: path = /helloworld.citrix-adc/SayHello
: authority = 10.10.10.10.:80
grpc-timeout = 15
content-type = application/grpc+proto
grpc-encoding = gzip
DATA (flags = END_STREAM)
<Length-Prefixed Message>
<!--NeedCopy--> ```
```

Example for gRPC response header from gRPC server to Citrix ADC appliance

Response-Headers & Trailers-Only are delivered in a single HTTP/2 HEADERS frame block. Most responses are expected to have both headers and trailers but Trailers-Only is permitted for calls that produce an immediate error. Status must be sent in Trailers even if the HTTP status code is OK.

```
```
HEADERS (flags = END_HEADERS)
: status = 200
Grpc-encoding= gzip
Content-type = application/grpc+proto
DATA
<Length-Prefixed Message>
HEADERS (flags = END_STREAM, END_HEADERS)
grpc-status = 0 # OK

<!--NeedCopy--> ```
```

### Configure gRPC by using the CLI

To configure an end-to-end gRPC deployment, you must complete the following:

- Add HTTP profile with HTTP/2 and HTTP/2 direct enabled.
- Enable global back end HTTP/2 support in HTTP parameter
- Add load balancing virtual server of type SSL/HTTP and set HTTP profile
- Add Service for gRPC endpoint and set HTTP profile
- Bind gRPC end point service to load balancing virtual server

 
```

Add HTTP profile with HTTP/2 and HTTP/2 direct enabled

You must enable HTTP/2 and HTTP/2 direct parameters in the HTTP profile. Also, you must enable the HTTP/2 direct parameter if gRPC over HTTP/2 cleartext is required.

At the command prompt, type:

```
add ns httpProfile <name> - http2 ( ENABLED | DISABLED )[-http2Direct (
ENABLED | DISABLED )]
```

Example:

```
add ns httpProfile http2gRPC -http2Direct ENABLED -http2 ENABLED
```

Enable global back-end HTTP/2 support through HTTP parameter

To enable HTTP/2 support globally on the server side by using the Citrix ADC command line.

At the command prompt, type:

```
set ns httpParam -http2ServerSide( ON | OFF )
```

Example:

```
set ns httpParam -http2ServerSide ON
```

Add load balancing virtual server of type SSL/HTTP and set HTTP profile

To add a load balancing virtual server by using the **Citrix ADC** command interface:

At the command prompt, type:

```
add lb vserver <name> <service type> [(<IP address>@ <port>)] [-httpProfileName
 <string>]
```

Example:

```
add lb vserver lb-grpc HTTP 10.10.10.11 80 -httpProfileName http2gRPC
```

> **Note:**
>
> If you are using a load balancing virtual server of type SSL, then you must bind the server certificate. See Bind server certificate topic for more information.

Add Service for gRPC endpoint and set HTTP profile

To add a gRPC service with HTTP profile by using the **Citrix ADC** command interface:
At the command prompt, type:

```
add service <name> (<IP> | <serverName> )<serviceType> <port> [-httpProfileName
 <string>]
```

Example:

```
add service svc-grpc 10.10.10.10 HTTP 80 -httpProfileName http2gRPC
```

Bind gRPC end point service to load balancing virtual server

To bind a gRPC service to load balancing virtual server by using the **Citrix ADC** command interface:

At the command interface, type:

```
bind lb vserver <name> <serviceName>
```

Example:

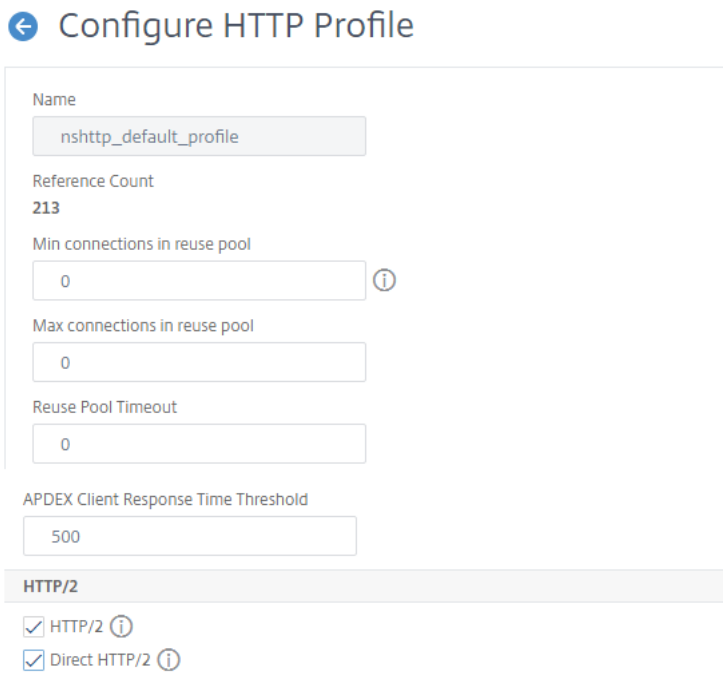
```
bind lb vserver lb-grpc svc-grpc
```

Configure end-to-end gRPC deployment by using the GUI

Complete the following steps to configure gRPC by using the GUI.

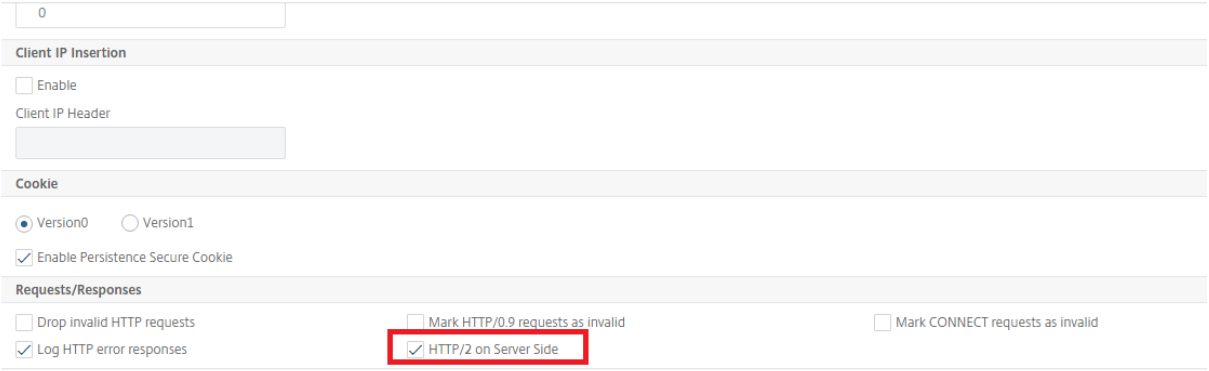
Add HTTP profile with HTTP/2 and HTTP/2 direct enabled

1. Navigate to **System > Profiles** and click **HTTP Profiles**.
2. Enable HTTP/2 option in a new HTTP profile or existing HTTP profile



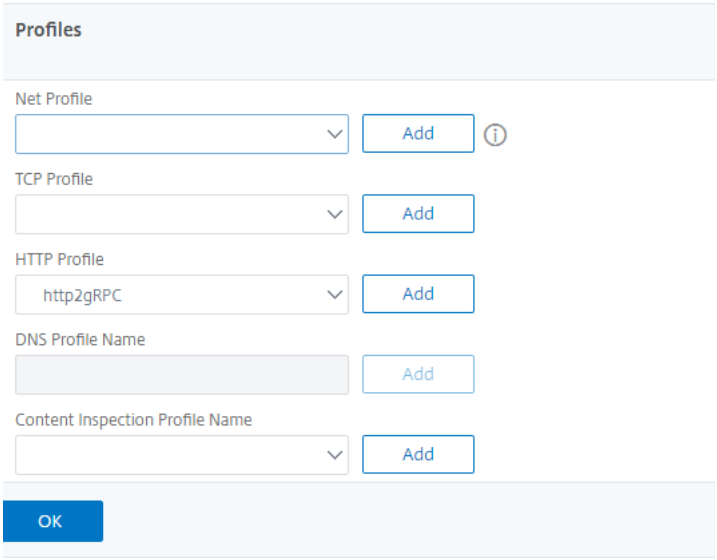
Enable global back end HTTP/2 support in HTTP parameter

1. Navigate to **System > Settings > HTTP Parameters**.
2. In the Configure HTTP Parameter page, select HTTP/2 on Server Side.
3. Click **OK**.



Add load balancing virtual server of type SSL/HTTP and set HTTP profile

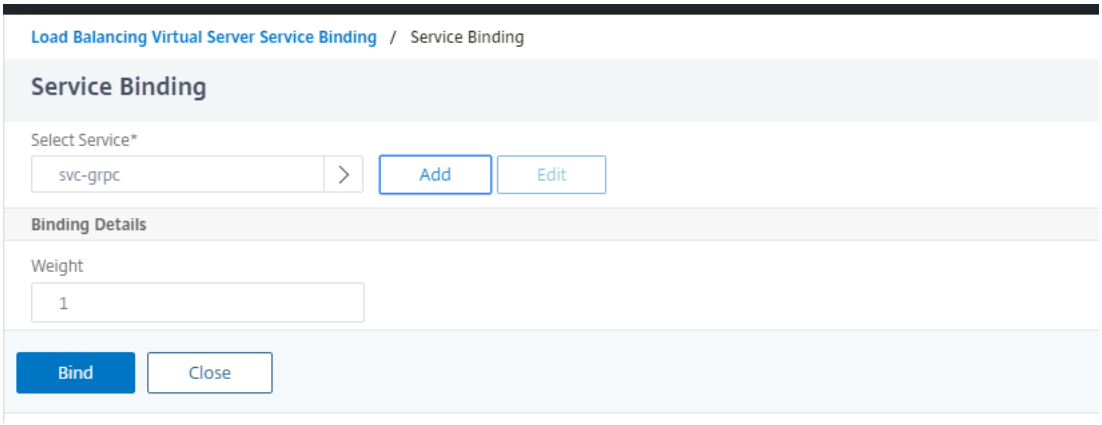
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click Add to create a load balancing virtual server for gRPC traffic.
3. In Load Balancing Virtual Server page, click Profiles.
4. In the Profiles section, select the profile type as HTTP.
5. Click OK and then Done.



Add Service for gRPC endpoint and set HTTP profile

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click Add to create an application server for gRPC traffic.

3. In Load Balancing Service page, go to Profile section.
4. Under Profiles, add HTTP profile for gRPC endpoint.
5. Click OK and then Done.



For detailed GUI procedures related to loading balancing, see Load Balancing topic.

gRPC bridging

September 14, 2021

When a client sends a request over HTTP/1.1 protocol, the Citrix ADC appliance supports bridging of the gRPC requests over HTTP/1.1 protocol which is in compliance with the gRPC server over HTTP/2 protocol. Similarly, in reverse bridging, the appliance receives the client gRPC request over the HTTP/2 protocol and performs reverse bridging for the gRPC requests in compliance with the gRPC server of the HTTP/1.1 protocol.

How gRPC bridging works

In this scenario, the Citrix ADC appliance seamlessly bridges gRPC content received on an HTTP/1.1 connection and forwards it to the back-end gRPC server over HTTP/2.

The following diagram shows how components interact with each other in a gRPC bridging configuration.

1. When a gRPC request is sent, the Citrix ADC appliance checks if the connection is HTTP/1.1 and the content type is application/grpc. The HTTP/1.1 requests translate to the following pseudo headers.
2. On receiving a gRPC request on HTTP/1.1. connection as indicated by the Content-Type header, the ADC appliance transforms the request into gRPC over HTTP/2 as given below:

```
1     :method: Method-name in HTTP/1.1 request
2     :path: Path is HTTP/1.1 request
3     content-type: application/grpc
4 <!--NeedCopy-->
```

1. Based on policy evaluation, the load balancing virtual server (with the gRPC service bound to it) terminates the request or forwards it over HTTP/2 frames to the back-end gRPC server.
2. On receiving the response on a HTTP/2 connection from the gRPC server, the appliance buffers until it receives the HTTP/2 trailer and then checks for the gRPC-status code. If it is non-zero gRPC error status, the appliance looks for the mapping HTTP Status code and send a suitable HTTP/1.1 error response.

Configure gRPC bridging by using the CLI

To configure gRPC bridging, you must complete the following steps:

1. Add HTTP profile with HTTP/2 and HTTP/2 direct enabled
2. Enable global back-end HTTP/2 support in the HTTP parameter
3. Add load balancing virtual server of type SSL/HTTP and set the HTTP profile
4. Add Service for gRPC endpoint and set the HTTP profile
5. Bind gRPC end point service to load balancing virtual server
6. Map gRPC status code to the HTTP response for non-zero gRPC status
7. Configure gRPC buffering by time and/or size

Add HTTP profile with the HTTP/2 and HTTP/2 direct enabled

To begin the configuration, you must enable the HTTP/2 feature in the HTTP profile. If the client sends the HTTP 1.1 requests, the appliance bridges the request and forward it to the back-end server.

At the command prompt, type:

```
add ns httpProfile <name> - http2 ( ENABLED | DISABLED )[-http2Direct (
ENABLED | DISABLED )]
```

Example:

```
add ns httpProfile http2gRPC -http2Direct ENABLED -http2 ENABLED
```

Enable global back end HTTP/2 support in the HTTP parameter

To enable the HTTP/2 support globally on the server side by using the Citrix ADC command line.

At the command prompt, type:

```
set ns httpParam -http2ServerSide( ON | OFF )
```

Example:

```
set ns httpParam -http2ServerSide ON
```

Add load balancing virtual server of type SSL/HTTP and set the HTTP profile

To add a load balancing virtual server by using the **Citrix ADC** command interface

At the command prompt, type:

```
add lb vserver <name> <service type> [(<IP address>@ <port>)] [-httpProfileName
 <string>]
```

Example:

```
add lb vserver lb-grpc HTTP 10.10.10.10 80 -httpProfileName http2gRPC
```

> **Note:**
>
> If you are using a load balancing virtual server of type SSL, then you must bind the server certificate. See Bind server certificate topic for more information.

Add Service for gRPC endpoint and set the HTTP profile

To add a gRPC service with the HTTP profile by using the **Citrix ADC** command interface.

At the command prompt, type:

```
add service <name> (<IP> | <serverName> )<serviceType> <port> [-httpProfileName
 <string>]
```

Example:

```
add service svc-grpc 10.10.10.10 HTTP 80 -httpProfileName http2gRPC
```

Bind gRPC end point service to load balancing virtual server

To bind a gRPC end point service to the load balancing virtual server by using the CLI.

At the command interface, type:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver lb-grpc svc-grpc
```

Map gRPC status code to HTTP status-code in the HTTP/1.1 response

In gRPC bridging scenario, the gRPC service responds to the request with a gRPC status-code. The appliance maps the gRPC status code to a corresponding HTTP response code and reason phrase. The mapping is done based on the table provided below. The Citrix ADC appliance when sending the HTTP/1.1 response to the client sends the HTTP status code and the reason phrase.

gRPC status-code	HTTP response status-code	HTTP response reason-phrase
OK = 0	200	OK
CANCELLED = 1	499	*
UNKNOWN = 2	500	Internal Server Error
INVALID_ARGUMENT = 3	400	Bad Request
DEADLINE_EXCEEDED = 4	504	Gateway Timeout
NOT_FOUND = 5	404	*
ALREADY_EXISTS = 6	409	Conflict
PERMISSION_DENIED = 7	403	Forbidden
UNAUTHENTICATED = 16	401	Unauthorized
RESOURCE_EXHAUSTED = 8	429	*
FAILED_PRECONDITION = 9	400	Bad Request
ABORTED = 10	409	Conflict
OUT_OF_RANGE = 11	400	Bad Request
UNIMPLEMENTED = 12	501	Not Implemented
INTERNAL = 13	500	Internal Server Error
UNAVAILABLE = 14	503	Service Unavailable
DATA_LOSS = 15	500	Internal Server Error

Configure gRPC buffering by time and/or size

The Citrix ADC appliance buffers the gRPC response from the back-end server until the response trailer is received. This breaks bi-directional gRPC calls. Also, if the gRPC response is huge, it consumes a significant amount of memory to buffer the response completely. To resolve the issue, the gRPC bridging configuration is enhanced to limit buffering by time and/or size. If the buffer size or time limit exceeds threshold, the appliance stops buffering and forwards the response to the client even when any one of the limitations triggers (either the trailer is not received within the configured buffer size or if the configured timeout occurs). As a result, the configured policies and its expressions (based on grpc-status code) do not work as expected.

To limit gRPC buffering by time and/or size by the CLI, you can configure when you add a new HTTP profile or configure when you modify an existing profile.

At the command prompt, type:

```
add ns httpProfile http2gRPC [-grpcHoldLimit <positive_integer>] [-grpcHoldTimeout
 <positive_integer>]
```

Or

```
set ns httpProfile http2gRPC [-grpcHoldLimit <positive_integer>] [-grpcHoldTimeout
 <positive_integer>]
```

Where,

`grpcholdlimit`. Maximum size in bytes allowed to buffer gRPC packets until trailer is received. You can configure both the parameters and any one.

Default value: 131072
Minimum value: 0
Maximum value: 33554432

`grpcholdtimeout`. Maximum time in milliseconds allowed to buffer gRPC packets until trailer is received. The value should be in multiples of 100.
Default value: 1000
Minimum value: 0
Maximum value: 180000

Example:

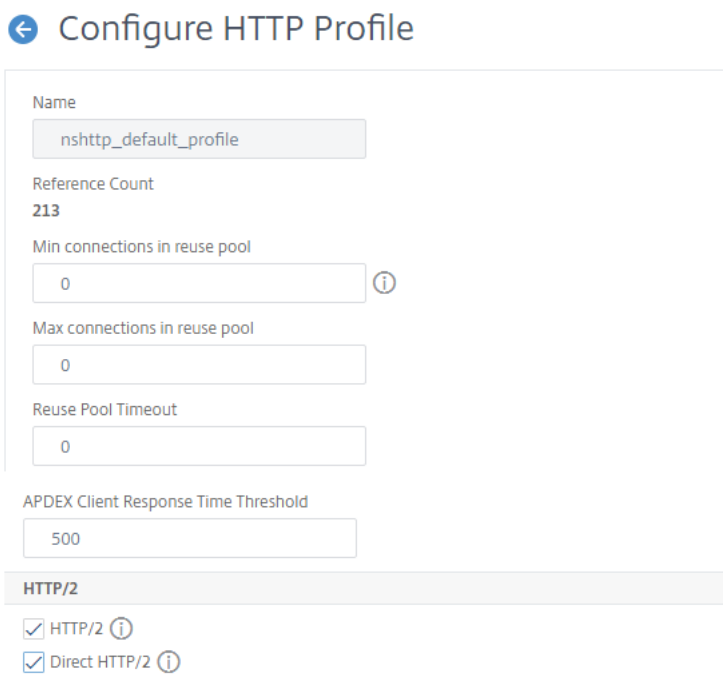
```
add httpprofile http2gRPC -grpcholdlimit 1048576 -grpcholdtimeout 5000
set httpprofile http2gRPC -grpcholdlimit 1048576 -grpcholdtimeout 5000
```

Configure gRPC bridging by using the GUI

Complete the following steps to configure gRPC bridging by using the Citrix ADC GUI.

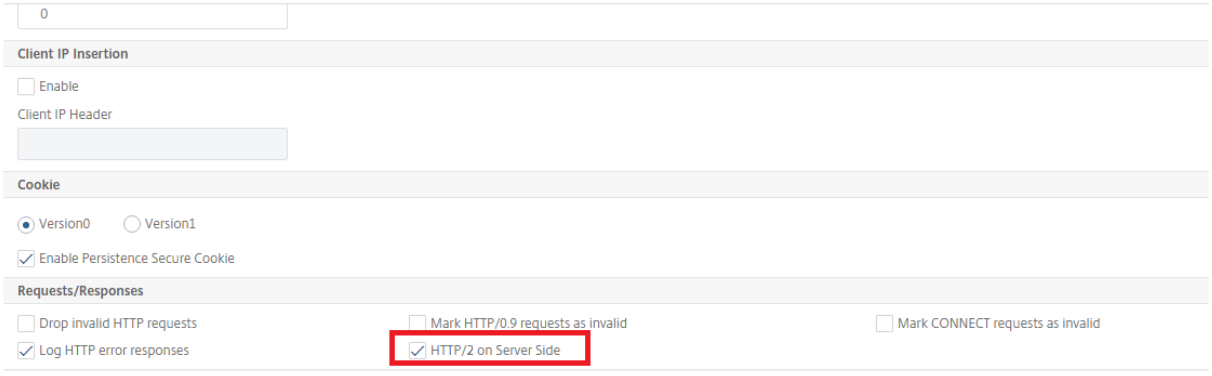
Add HTTP profile with HTTP/2 and HTTP/2 direct enabled

1. Navigate to **System > Profiles** and click **HTTP Profiles**.
2. Select **HTTP/2** in the HTTP profile.



Enable global back-end HTTP/2 support in the HTTP parameter

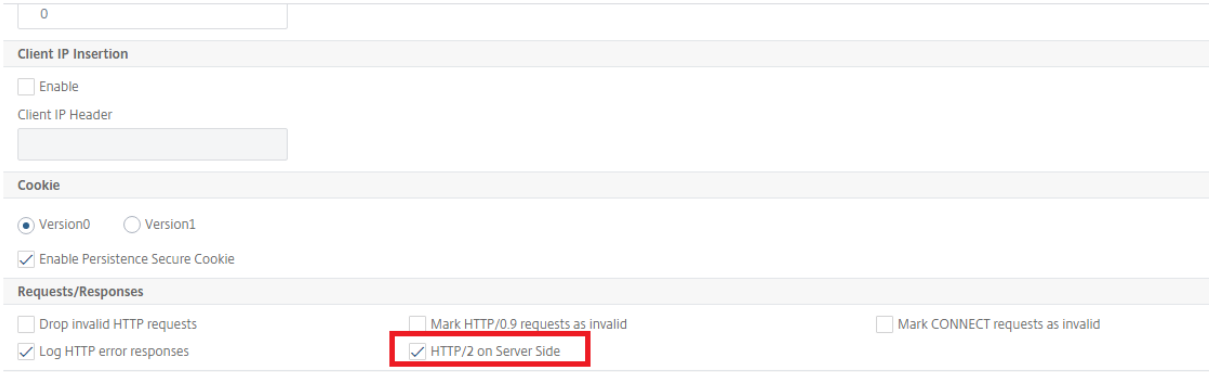
1. Navigate to **System > Settings > HTTP Parameters**.
2. In the **Configure HTTP Parameter** page, select **HTTP/2 on Server Side** option.
3. Click **OK**.



Add load balancing virtual server of type SSL/HTTP and set HTTP profile

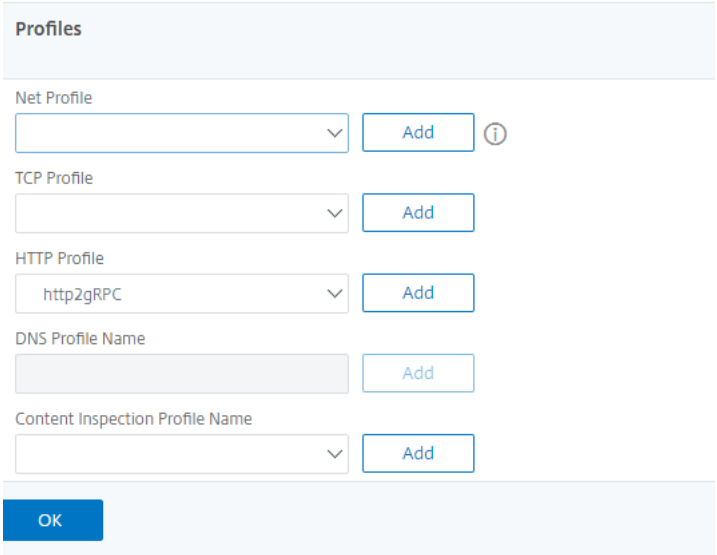
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

2. Click **Add** to create a load balancing virtual server for gRPC traffic.
3. In **Load Balancing Virtual Server** page, click **Profiles**.
4. In the **Profiles** section, select the profile type as HTTP.
5. Click **OK** and then **Done**.



Add Service for gRPC endpoint and set HTTP profile

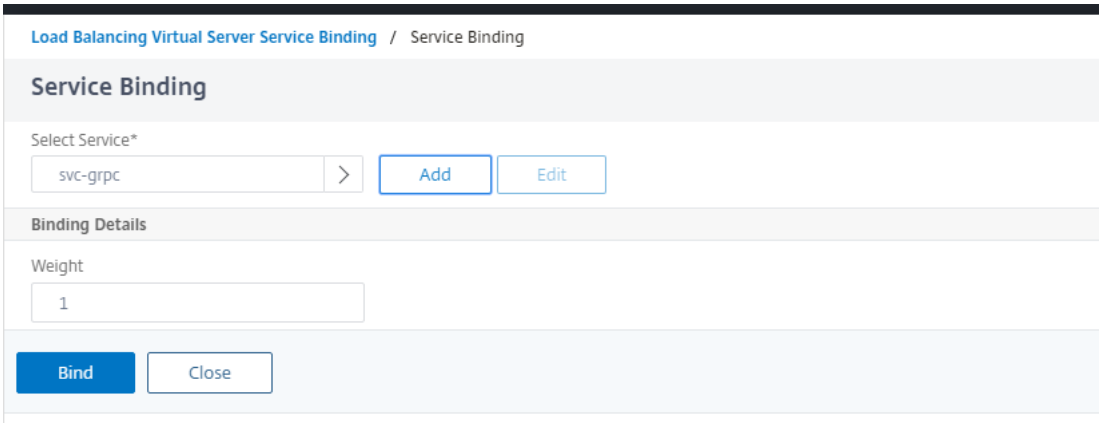
1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **Add** to create an application server for gRPC traffic.
3. In **Load Balancing Service** page, go to **Profile** section.
4. Under **Profiles**, add **HTTP profile** for gRPC endpoint.
5. Click **OK** and then **Done**.



Bind Service for gRPC endpoint to load balancing virtual server

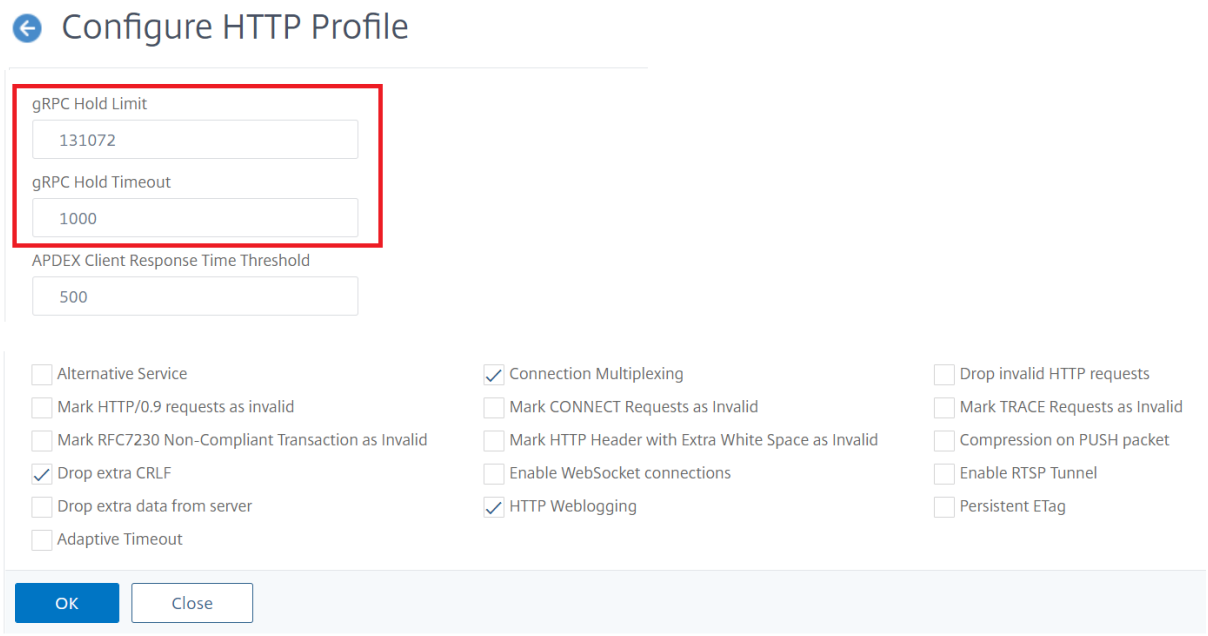
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click **Add** to create a load balancing virtual server for gRPC traffic.

3. In **Load Balancing Virtual Server** page, click **Service and Service Groups** section.
4. In the **Load Balancing Virtual Server Service Binding** page, select the gRPC service to bind.
5. Click **Close** and then **Done**.



Configure gRPC buffering by time and size by using the GUI

1. Navigate to **System > Profiles** and click **HTTP Profiles**.
2. Select **HTTP/2** in the HTTP profile.
3. In the **Configure HTTP Profile** page, set the following parameters:
   a) grpcHoldTimeout. Enter the time in milliseconds to buffer gRPC packets until the trailer is received.
   b) grpcHoldLimit. Enter the maximum size in bytes to buffer gRPC packets until the trailer is received.
4. Click **OK** and **Close**.



For detail GUI procedures for binding service and load balancing virtual servers, see Load Balancing topic.

gRPC reverse bridging

September 14, 2021

In this scenario, the Citrix ADC appliance seamlessly bridges gRPC content received on an HTTP/2 connection and forwards it to the back-end gRPC server over HTTP/1.1.

How reverse bridging works

The following diagram shows how components interact with each other in a gRPC bridging configuration.

1. Client sends a gRPC request on HTTP/2 connection with gRPC headers in HTTP/2 frames and proto-buf payload.
2. Based on policy evaluation, the load balancing virtual server (with gRPC service bound to it) translates and forwards the request over HTTP/1.1 connection to backend server.
3. On receiving the HTTP/1.1 response, if there is no grpc-status code in the response, ADC derives a grpc status-case from the HTTP response code.
4. The appliance then inserts the gRPC headers into HTTP/2 trailer before forwarding the response to the client.

Configure gRPC reverse bridging by using the CLI

To configure gRPC reverse bridging, you must complete the following steps:

- Add HTTP profile 1 with HTTP/2 and HTTP/2 direct enabled for load balancing virtual server
- Add HTTP profile 2 with HTTP/2 disabled for back-end server
- Add load balancing virtual server of type SSL/HTTP and set to HTTP profile 1
- Add service for gRPC endpoint and set to HTTP profile 2
- Bind Service for gRPC endpoint to load balancing virtual server
- Map HTTP-status code to gRPC status code if the response does not have a grpc status code

Add HTTP profile 1 with HTTP/2 and HTTP/2 direct enabled for load balancing virtual server

To begin the reverse bridging configuration, you must add two HTTP profiles. One profile for enabling HTTP/2 for gRPC client requests and another profile for disabling HTTP/2 for non-gRPC server response.

At the command prompt, type:

```
add ns httpProfile <name> - http2 ( ENABLED | DISABLED )[-http2Direct (
ENABLED | DISABLED )]
```

Example:

add ns httpProfile profile1 –http2 ENABLED -http2Direct ENABLED

Add HTTP profile 2 with HTTP/2 disabled for back-end server

To disable HTTP/2 support on the HTTP profile for back-end server response by using the Citrix ADC command line.

At the command prompt, type:

```
add ns httpProfile <name> - http2 ( ENABLED | DISABLED )[-http2Direct (
ENABLED | DISABLED )]
```

Example:

add ns httpProfile profile2 –http2 DISABLED http2Direct DISABLED

Add load balancing virtual server of type SSL/HTTP and set to HTTP profile 1

To add a load balancing virtual server by using the Citrix ADC command interface.

At the command prompt, type:

```
add lb vserver <name> <service type> [(<IP address>@ <port>)] [-httpProfileName
 <string>]
```

Example:

add lb vserver lb-grpc HTTP 10.10.10.10 80 -httpProfileName profile1

> **Note:**
>
> If you are using a load balancing virtual server of type SSL, then you must bind the server certificate. See Bind server certificate topic for more information.

Add service for gRPC endpoint and set to HTTP profile 2

To add a service with gRPC endpoint and set HTTP profile 2 by using the Citrix ADC command interface.

At the command prompt, type:

```
add service <name> (<IP> | <serverName> )<serviceType> <port> [-httpProfileName
 <string>]
```

Example:

```
add service svc-grpc 10.10.10.11 HTTP 80 -httpProfileName profile2
```

Bind service for gRPC endpoint to load balancing virtual server

To bind a gRPC service to load balancing virtual server by using the Citrix ADC command interface.

At the command interface, type:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver lb-grpc svc-grpc
```

Map HTTP response code to gRPC status code

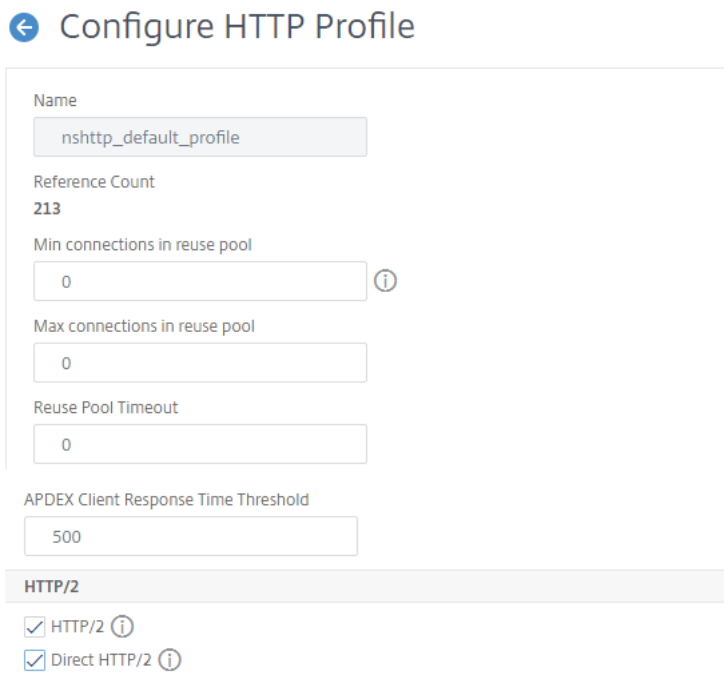
If the server does not generate a gRPC status code, the Citrix ADC appliance generates a suitable gRPC status code based on the HTTP response received. The status codes are listed in the below mapping table.

HTTP Response status-code	gRPC status code
200	OK
400	INTERNAL = 13
403	PERMISSION_DENIED = 7
401	UNAUTHENTICATED = 16
429, 502, 503, 504	UNAVAILABLE = 14
404	UNIMPLEMENTED = 12

Configure gRPC reverse bridging by using the GUI

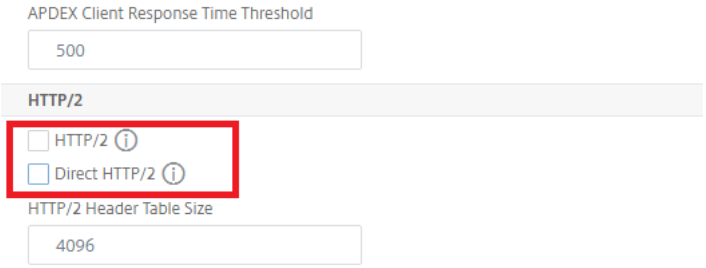
Add HTTP profile 1 with HTTP/2 and HTTP/2 direct enabled for load balancing virtual server

1. Navigate to System > Profiles and click HTTP Profiles.
2. Enable HTTP/2 option in a HTTP profile 1.



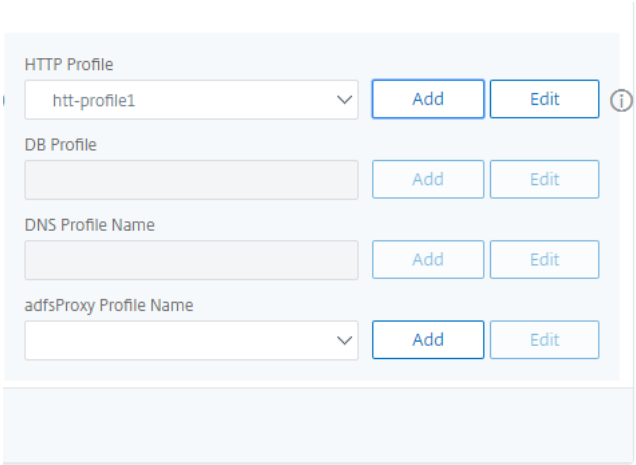
Add HTTP profile 2 with HTTP/2 disabled for back-end server

1. Navigate to **System > Profiles** and click **HTTP Profiles**.
2. Enable **HTTP/2** option in a HTTP profile 2.
3. Click **OK**.



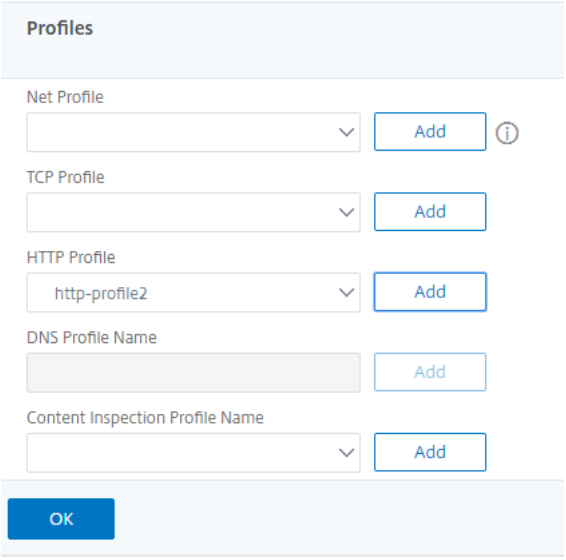
Add load balancing virtual server of type SSL/HTTP and set to HTTP profile 1

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click **Add** to create a load balancing virtual server for gRPC traffic.
3. In **Load Balancing Virtual Server** page, click **Profiles**.
4. In the **Profiles** section, select the profile type as HTTP.
5. Click **OK** and then **Done**.



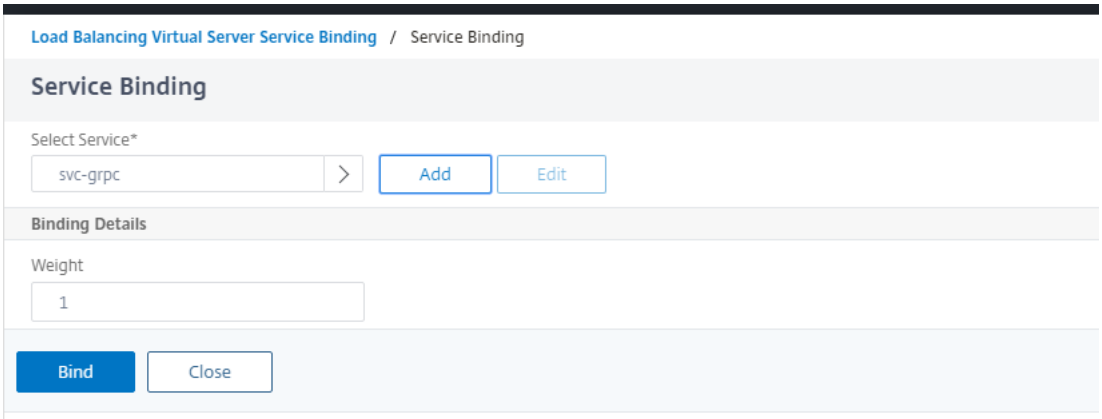
Add service with gRPC endpoint and set to HTTP profile 2

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **Add** to create an application server for gRPC traffic.
3. In **Load Balancing Service** page, go to **Profile** section.
4. Under **Profiles**, add **HTTP profile** for gRPC endpoint.
5. Click **OK** and then **Done**.



Bind Service for gRPC endpoint to load balancing virtual server

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click **Add** to create a load balancing virtual server for gRPC traffic.
3. In **Load Balancing Virtual Server** page, click **Service** and **Service Groups** section.
4. In the **Load Balancing Virtual Server Service Binding** page, select the gRPC service to bind.
5. Click **Close** and then **Done**.



For detail GUI procedures, see Load Balancing topic.

gRPC call termination

September 14, 2021

When a Citrix ADC appliance has policies such as rate limiting, Web App Firewall security configured

and if a policy evaluates to true, the appliance can terminate the call and respond with a computable gRPC error message to the client.

gRPC with rewrite policy

September 14, 2021

The gRPC with rewrite policy use case explains how Citrix ADC appliance works in rewriting some information in the gRPC requests or responses. The following diagram shows the components interact.

The following diagram shows how components interact with each other in a gRPC with rewrite policy configuration.

1. Enable rewrite feature on the appliance.
2. Configure rewrite action to modify, add, or delete gRPC headers.
3. Configure rewrite policy for determining the gRPC requests (traffic) on which an action has to be taken.
4. Bind the rewrite policy to the load balancing virtual server to examine if the traffic matches the policy expression.
5. By using a rewrite policy, you can perform the following based on gRPC status code.
    a) Modify responses from gRPC web server.
    b) Modify, add, or delete gRPC headers.
    c) Modify the URL of the request to the gRRC server.

Configure gRPC call termination with rewrite policy

To configure gRPC call termination with rewrite policy, you must complete the following steps:

1. Enable rewrite feature
2. Add rewrite policy
3. Bind rewrite policy to load balancing virtual server

Enable rewrite feature

To use the rewrite feature, you must first enable it.

At the command prompt, type:

```
enable ns rewrite
```

Add rewrite policy

After you configure a rewrite action, you must next configure a rewrite policy to select the gRPC requests to which the Citrix ADC appliance must rewrite.

At the command prompt, type:

```
add rewrite policy <name> <expression> <action> [<undefaction>]-appFlowaction
 <actionName>
```

Example:

```
add rewrite policy grpc-rewr_pol1 "http.res.header(\"grpc-status\").NE
(\"0\")"RESET
```

Bind rewrite policy to load balancing virtual server

To put a policy into effect, you must bind it to the load balancing virtual server with the gRPC service.

At the command prompt, type:

```
bind rewrite global <policyName> <priority> [<gotoPriorityExpression> [-
type <type>] [-invoke (<labelType> <labelName>)]
```

Example:

```
bind lb vserver lb-grpc -policyName grpc-rewr_pol1 -priority 100
```

gRPC with the responder policy

September 14, 2021

The gRPC with responder policy configuration explains how a Citrix ADC appliance provides different responses to gRPC requests over the HTTP/2 protocol. When users request a website home page, you might want to provide a different home page depending on where each user is located or the browser the user is using.

The following diagram shows the components that interact.

1. Enable the responder feature on the appliance.
2. Configure the responder action to generate a custom response, redirect a request to a different webpage, or reset a connection.
3. Configure the responder policy for determining the gRPC requests (traffic) on which an action has to be taken.
4. Bind the responder policy to the load balancing virtual server to examine if the traffic matches the policy expression.
5. By using a responder policy, you can perform the following based on the gRPC status code.

Configure gRPC call termination with the responder policy by using the CLI

To configure gRPC call termination with the responder policy, you must complete the following steps:

1. Enable the responder feature
2. Add a responder action
3. Add a responder policy and associate responder action
4. Bind the responder policy to load balancing virtual server

Enable the responder feature

To use the responder feature, you must first enable it.

At the command prompt, type:

```
enable ns responder
```

Add the responder action

After enabling the feature, you must configure the responder action for handling the gRPC response based on the status code returned by the back-end server.

At the command prompt, type:

```
add responder action <name> <type>
```

Example:

```
add responder action grpc-act respondwith "HTTP/1.1 200 OK\r\nServer: NS
-Responder\r\nContent-Type:application/grpc\r\ngrpc-status: 12\r\ngrpc
-message: Not Implemented\r\n\r\n"+ "Method: "+ HTTP.REQ.URL+ "is not
implemented."
```

Adding responder policy

After you configure a responder action, you must next configure a responder policy to select the gRPC request to which the Citrix ADC appliance must respond.

At the command prompt, type:

```
add responder policy <name> <expression> <action> [<undefaction>]-appFlowaction
 <actionName>
```

Example:

```
add responder policy grpc-resp-pol1 HTTP.REQ.URL.NE( “/helloworld.Greeter/
SayHello” )grpc-act
```

Bind responder policy to load balancing virtual server

To put a policy into effect, you must bind it to the load balancing virtual server with the gRPC service.

At the command prompt, type:

```
bind responder global <policyName> <priority> [<gotoPriorityExpression> [-
type <type>] [-invoke (<labelType> <labelName>)]
```

Example:

```
bind lb vserver lb-grpc svc-grpc -policyName grpc-resp-pol1 -priority 100
```

For more information about the responder policy, see Responder Policy topic.

Policy expressions for matching gRPC protocol buffer fields

The Citrix ADC appliance supports the following policy expressions in the gRPC configuration:

- **gRPC protocol buffer field access.** The arbitrary gRPC API call matches the message field number with the new policy expressions. In a PI configuration, the matches are done using only the ‘field numbers’ and ‘API path’.
- **gRPC header filtering.** The “HttpProfile” parameters for gRPC is used to adjust the default behavior of gRPC parsing (including gRPC policy expressions). The following parameters are applicable to gRPC policy expressions:

- **gRPCLengthDelimitation.** It is enabled by default and expects the protocol buffers to be presented with a length delimited message.
- **gRPCHoldLimit.** The default value is 131072. It is the maximum protocol buffer message size in bytes. It is also the maximum string length and the maximum 'byte' field length as well.

Configure gRPC advance policy expressions by using the CLI

At the command prompt, type:

```
set ns httpProfile <name> -http2 ( ENABLED | DISABLED ) -
    gRPCLengthDelimitation ( ENABLED | DISABLED ) -gRPCHoldLimit <int>
```

Example:

```
set ns httpProfile http2gRPC -http2 ENABLED -gRPCLengthDelimitation
    ENABLED -gRPCHoldLimit 131072
```

Configure gRPC header filtering parameters by using the GUI

1. Navigate to **System > Profiles** and click **HTTP Profiles**.
2. On the **Create HTTP Profile** page, scroll down to **HTTP/3** section, select **gRPC Length Delimitation**.

The following policy expression example shows a value in message 5, submessage 4, and field 3. It is a 32-bit int equal to 2.

```
http.req.body(1000).grpc.message(5).message(4).int32(3).eq(2)
```

The following policy expressions are added for matching gRPC protocol buffer message fields by number:

- message
- double
- float
- int32
- int64
- uint32
- uint64
- sint64
- sint32
- fixed32

- fixed64
- sfixed32
- sfixed64
- bool
- string
- enum
- bytes

API path matching

The API path matching is used to match the correct gRPC API call when more than one API is used. Match the API path, which can be found in the ': path' pseudo header in the HTTP request.

Example:

```
http.req.header(":path").eq("acme.inventory.v1/ListBooks")
```

QUIC

September 14, 2021

Quick UDP Internet Protocol (QUIC) is a combination of (TCP+TLS+HTTP/2) protocols implemented on UDP. The QUIC transport protocol multiplexes the connections between two endpoints using UDP. Also when compared to other protocols, QUIC provides a high-performance in terms of security, fast delivery of traffic, and lower latency.

A QUIC bridge is configured in a Citrix ADC appliance for load balancing QUIC traffic between a QUIC client and QUIC back-end server. The QUIC bridge enables you to have persistent QUIC connections between client and server if there is a NAT rebinding or a connection migration. This configuration however does not process data. It is used only for load balancing of QUIC traffic through the Citrix ADC appliance.

QUIC packets contain connection ID to allow endpoints to associate the packets with different address or 4-tuple to the same connection. The connection ID contains the details of the server ID that are shared to the Citrix ADC appliance and to the back end servers. The Citrix ADC appliance extracts the connection ID details of the server ID and sends the traffic back to the back end server. The connection IDs are in protected packets that makes the connections robust in the event of connection migration.

> **Important**
>
> The back end servers must have support to encode server ID in QUIC connection ID.

Benefits of QUIC bridge

QUIC bridge for the Citrix ADC appliance is preferred for the following reasons:

- No expensive crypto operations.
- Stateless routing is possible (no 4-tuple based load balancing).

QUIC bridge configuration

September 14, 2021

To configure QUIC bridge, you must complete the following:

- Add QUIC bridge profile
- Add QUIC back-end servers
- Add QUIC service on the appliance
- Add load balancing virtual server of type QUIC bridge
- Bind QUIC bridge to load balancing virtual server of type QUIC bridge

> **Important**
>
> Before you configure the QUIC bridge, ensure you first enable the load balancing feature on the appliance. For more information, see Set up basic load balancing.

Configure QUIC bridge by using the CLI

The following sections must be configured by using the CLI.

Add a QUIC bridge profile

You must add a QUIC bridge profile.

At the command prompt, type:

```
add quicBridge profile <name> -routingAlgorithm <PLAINTEXT> -
    serveridlen <value>
```

Example:

```
add quicBridge profile q1 -routingAlgorithm PLAINTEXT -serveridlen 6
```

> **Note**
>
> The `serveridlen` parameter configured in the example is the length of a custom server ID,

> which is the hex string of IP and PORT.

Add QUIC back-end application server

You must add QUIC back-end application servers.

At the command prompt, type:

```
1 -  add server <name> (<IPAddress>)
2 -  add server <name> (<IPAddress>)
```

Example:

```
1 -  add server s1 192.0.2.20
2 -  add server s2 192.0.2.30
```

Add QUIC bridge service

You must add QUIC bridge service to the application servers.

At the command prompt, type:

```
1 -  add service  <name>  (<IP> | <serverName>) <serviceType> <port> [-
     CustomServerID <string>]
2
3 -  add service  <name>  (<IP> | <serverName>) <serviceType> <port> [-
     CustomServerID <string>]
```

Example:

```
1 -  add service src1 s1 QUIC_BRIDGE 443 -CUSTOMSERVERID C0A8026401BB
2
3 -  add service src2 s2 QUIC_BRIDGE 443 -CUSTOMSERVERID C0A802C801BB
```

> **Note**
>
> The `CustomServerID` parameters configured in the preceding example are the hex string of a corresponding IP and the PORT of the server (s1 and s2). For the QUIC bridge feature, Citrix recommends you to configure the `CustomServerID` parameter in the hex string format only.

Add a load balancing virtual server of type QUIC bridge

You must add a load balancing virtual server of type QUIC bridge.

At the command prompt, type:

```
add lb vserver <name> [<IPAddress>@ <port> [-persistenceType <
    persistenceType >] [-lbMethod < lbMethod > [-cltTimeout <secs>] [-
    quickBridgeProfilename <name>]
```

Example:

```
add lb vserver quic_bridge_vip QUIC_BRIDGE 192.0.2.10 443 -
    persistenceType CUSTOMSERVERID -lbMethod TOKEN -cltTimeout 120 -
    quicBridgeProfilename q1
```

> **Note**
>
> While configuring the QUIC bridge virtual server, you must configure `persistenceType` parameter as `CUSTOMSERVERID` and "LbMethod" parameter as `TOKEN`.

Bind QUIC bridge service to the load balancing virtual server of type QUIC bridge

You must bind the QUIC bridge service to the load balancing virtual server of type QUIC bridge.

At the command prompt, type:

```
-  bind lb vserver <name> (<serviceName>)

-  bind lb vserver <name> (<serviceName>)
```

Example:

```
-  bind lb vserver quic_bridge_vip src1

-  bind lb vserver quic_bridge_vip src2
```

Configure QUIC bridge for service groups

You can also configure QUIC bridge capabilities to service groups. The following steps guide you to configure QUIC bridge for service groups.

To configure QUIC bridge for service groups, you must complete the following:

Add QUIC bridge profile

At the command prompt, type:

```
add quicBridge profile <name> -routingAlgorithm <PLAINTEXT> -
    serveridlen <value>
```

Example:

```
add quicBridge profile q1 -routingAlgorithm PLAINTEXT -serveridlen 6
```

Add server of type QUIC

At the command prompt, type:

```
- add server <name> (<IPAddress>)
- add server <name> (<IPAddress>)
```

Example:

```
- add server s1 192.0.2.20
- add server s2 192.0.2.30
```

Add QUIC bridge service group

At the command prompt, type:

```
add serviceGroup <serviceGroupName> (<IP> | <serverName>) <serviceType>
```

Example:

```
add serviceGroup svg1 QUIC_BRIDGE
```

Bind the QUIC servers to the service group

At the command prompt, type:

```
- bind serviceGroup <serviceGroupName> (<IP>@ | (<serverName>) [-
  CustomServerID <string>]
- bind serviceGroup <serviceGroupName> (<IP>@ | (<serverName>) [-
  CustomServerID <string>]
```

Example:

```
- bind serviceGroup svg1 s1 443 -customServerID C0A8026401BB
- bind serviceGroup svg1 s2 443 -customServerID C0A802C801BB
```

Add load balancing virtual server of type QUIC bridge

At the command prompt, type:

```
add lb vserver <name> [<IPAddress>@ <port> [-persistenceType <
    persistenceType >] [-lbMethod < lbMethod > [-cltTimeout <secs>] [-
    quickBridgeProfilename <name>]
```

Example:

```
add lb vserver quic_bridge_vip QUIC_BRIDGE 192.0.2.10 443 -
    persistenceType CUSTOMSERVERID -lbMethod TOKEN -cltTimeout 120 -
    quicBridgeProfilename q1
```

Bind the load balancing virtual server of type QUIC bridge to the service group

At the command prompt, type:

```
bind lb vserver <name>@ (<serviceName>@ <serviceGroupName>
```

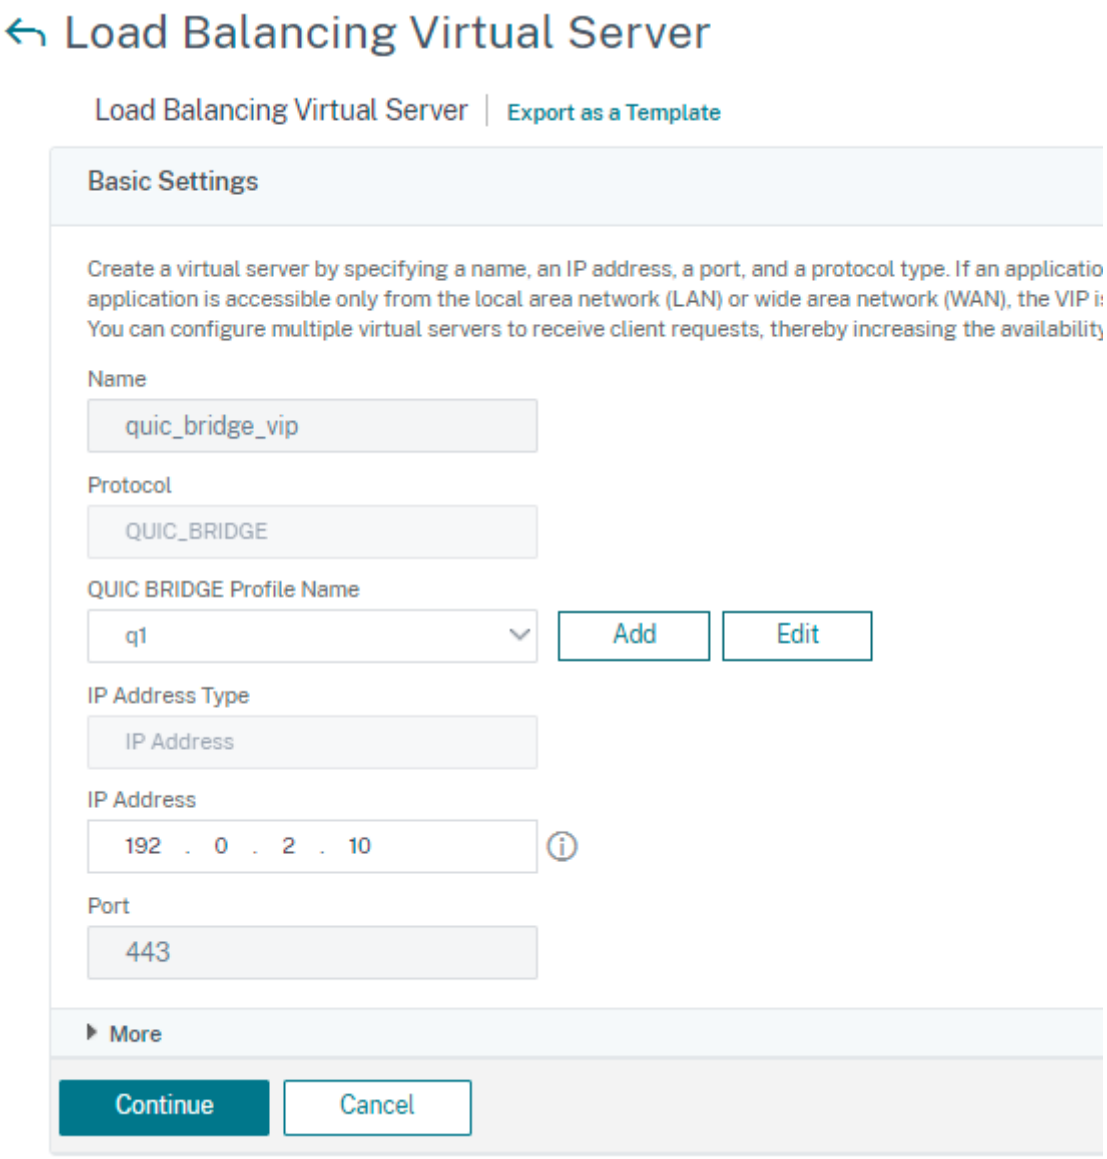
Example:

```
bind lb vserver quic_bridge_vip svg1
```

Configure QUIC bridge using the GUI

Complete the following steps to configure QUIC bridge by using the GUI.

1. Navigate to **Traffic Management > Load balancing > Virtual Servers**.
2. On the **Virtual Servers** page, click **Add**.
3. On the **Load Balancing Virtual Server** page, select the Protocol as QUIC_BRIDGE and enter the details. Click **OK**.

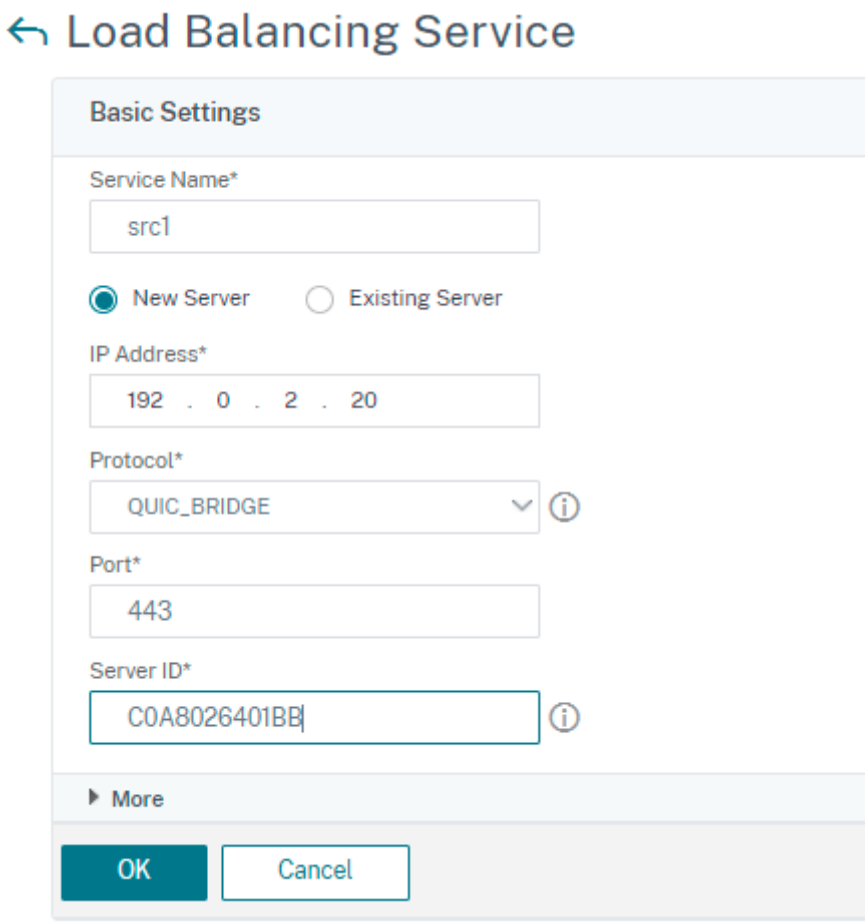


4. On the **Load Balancing Virtual Server** page, click **Continue** and **Done**.

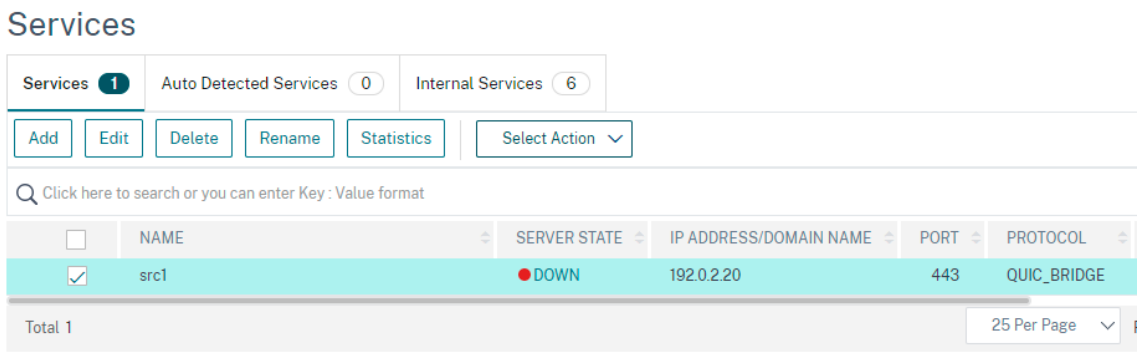
Configure load balancing for the services by using the GUI

Complete the following steps to configure load balancing for the services by using the GUI.

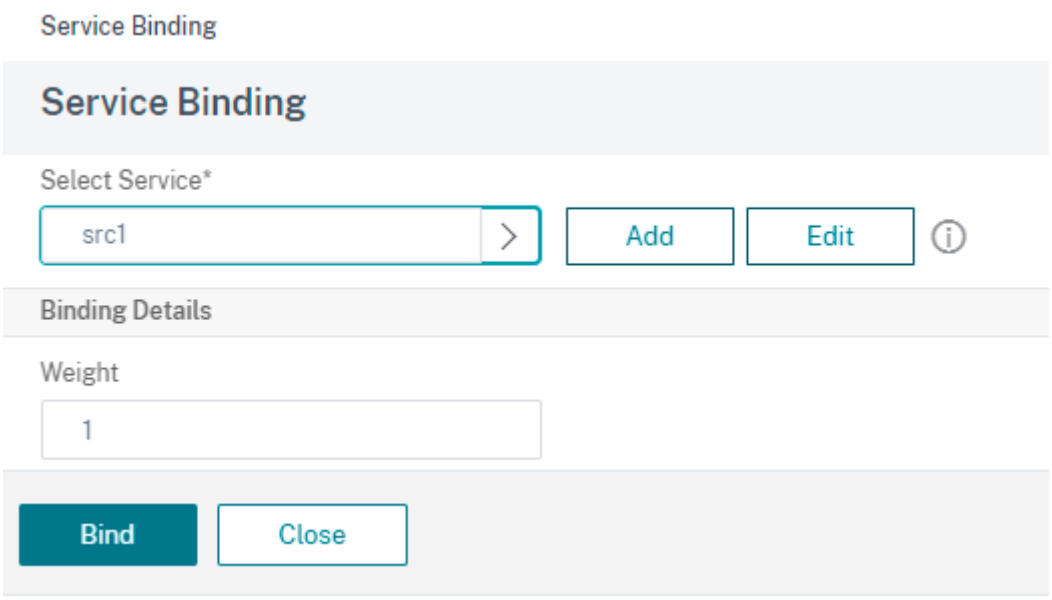
1. Navigate to **Traffic Management > Load Balancing > Services**. On the **Services** page, click **Add**.
2. On the **Load Balancing Service** page, enter the details and click **OK**.



3. On the **Virtual Servers** page, select the created virtual server to bind the service.
4. Scroll down on the **Load Balancing Virtual Server** page and select the **Services and Service Groups**.
5. On the **Service Binding** screen, click **Select Service** field.
6. On the **Service** screen, select the service to bind to the load balancing virtual server, and click **Select**.



7. The src1 service is selected and on the **Service Binding** screen, click **Bind**.



8. On the **Load Balancing Virtual Server** page, click **Done**.

Proxy protocol

October 8, 2021

Proxy protocol safely transports client details from client to server across Citrix ADC appliances. The appliance adds a proxy protocol header with client details and forwards it to the back-end server. Following are some of the usage scenarios for proxy protocol in a Citrix ADC appliance.

- Learning original client IP address
- Selecting a language for a website
- Block listing selected IP addresses
- Logging and collecting statistics.

Following are the three modes of operation:

- Insert. The appliance inserts the client details and sends it to the back-end server.
- Forward. The appliance forwards the client details to the back-end server.
- Stripped. The appliance stores the client details for logging purpose. Also, if the proxy protocol is not supported on the back-end server, sends the client details to the server by using the rewrite policy configuration

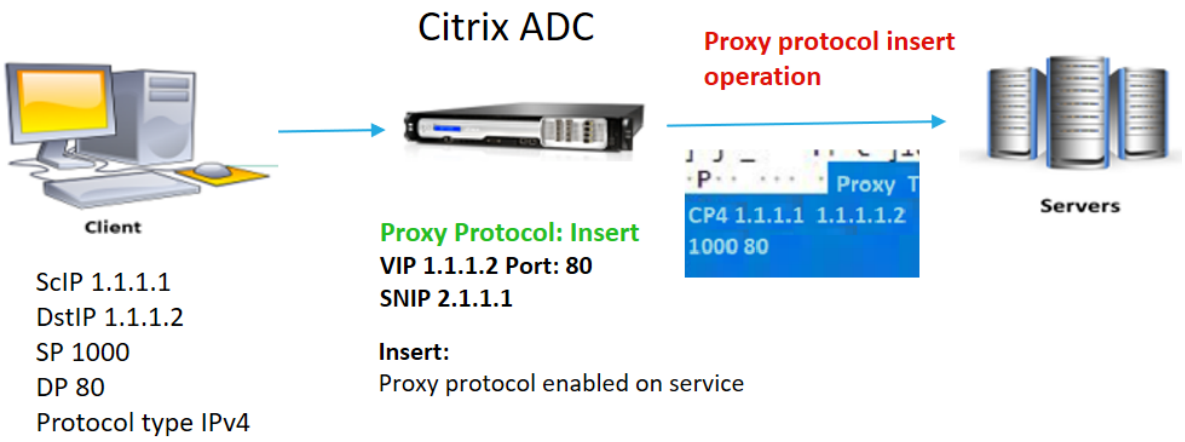
Limitations

The proxy protocol is not supported for the TCP Fast Open (TFO) and MultiPath TCP features. The feature is supported only for services for which the Citrix ADC appliance does TCP connection termination. It is not support for other services, for example, “ANY”.

How proxy protocol works in a Citrix ADC appliance

The following flow diagrams show how you can configure the proxy protocol across Citrix ADC appliances for Insert, Forwards, and Stripped operation:

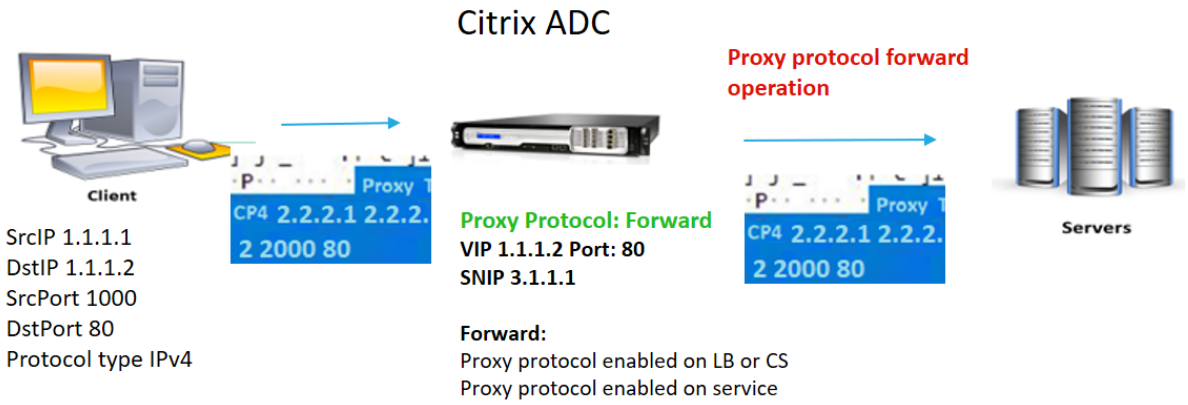
Insert operation



The component interact is as follows:

- At the Citrix ADC instance, you must enable proxy protocol in the net profile and bind it to the service.
- In the Insert operation, Citrix ADC adds a proxy header with client connection details and forwards it to the back-end server.
- On the sending side, the appliance decides the proxy protocol version based on CLI configuration.

Forward operation

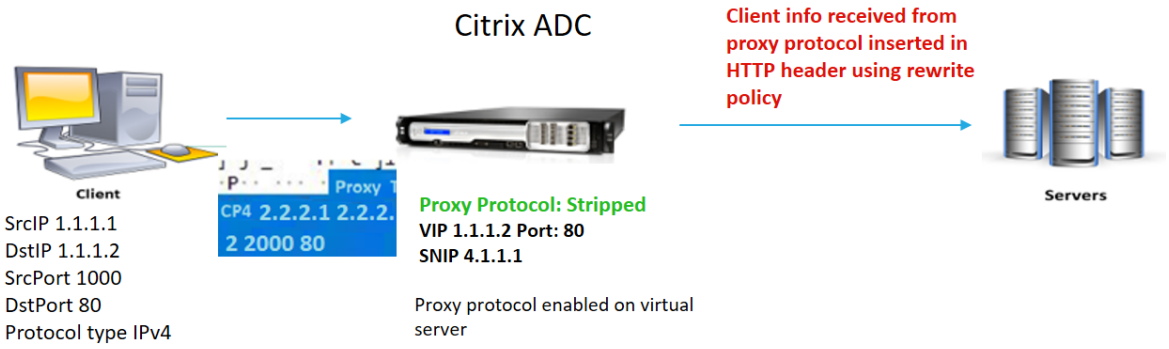


*** The original client details 2.2.2.1, 2.2.2.2, 2000, 80 in the proxy header is forwarded to the back-end server**

The component interact is as follows:

- A client sends a request along with the proxy header to the Citrix ADC. The appliance dynamically identifies the version.
- In the Citrix ADC appliance, it is a Forward operation. The proxy protocol is enabled on the load balancing virtual server or content switching virtual server and enabled on the service. The appliance receives the proxy header and forwards the header details to the back-end server.
- If the proxy header details are in invalid format, the appliance resets the connection.
- On the sending side, the appliance decides the proxy protocol version based on CLI configuration.

Stripped operation



The component interact is as follows:

- A client sends a request along with a proxy header to the Citrix ADC appliance.

- In the Citrix ADC appliance, if it is a Stripped operation, the appliance forwards the client information obtained from the proxy protocol and inserts it into the HTTP header using rewrite policy expressions.
- The client details such as source IP address, destination IP address, source port, and destination port are added in an HTTP header using rewrite policy expressions. The rewrite policy evaluates the expression and if "true," the corresponding rewrite policy action is triggered. And the client details are forwarded to the back-end server in an HTTP header.
- If the proxy header details are in invalid format, the appliance resets the connection.

Proxy protocol version formats

The Proxy protocol version is available as two formats. The appliance decides to use a format based on the incoming data length. For detailed information, see Proxy Protocol RFP.

1. Proxy protocol version-1 format

   ```
   PROXY TCP4/TCP6/UNKNOWN <SRC IP> <DST IP> <SRC PORT> <DST PORT>
   ```

   - PROXY -> Unique string format for Proxy header version -1.
   - Support protocols TCP over IPv4 and TCP over IPv6. For the remaining protocols, this is UNKNOWN.
   - SRC IP – Source IP (Original Client IP) address of a packet.
   - DST IP – Destination IP address of a packet.
   - SRC port – Source port of a packet.
   - DST port – Destination port of a packet.

2. Proxy protocol version-2 format

   ```
   0D 0A 0D 0A 00 0D 0A 51 55 49 54 0A <13th byte> <14th byte> <15-16th
   byte> <17th byte onwards>
   ```

   - D 0A 0D 0A 00 0D 0A 51 55 49 54 0A -> Unique binary string for Proxy header version -2.
   - Support protocols TCP over IPv4 and TCP over IPv6. For the remaining protocols, this is UNKNOWN.
   - Thirteenth byte – protocol version and command.
   - Fourteenth byte – address and protocol family.
   - 15-16th byte – Address length in network order.
   - Seventeenth byte onwards – Addresses info present in network order- src IP, dst IP, src port, dst port.

Configure Proxy protocol in Citrix ADC appliance

Complete the following steps to configure the Proxy protocol in your Citrix ADC appliance.

1. Enable proxy protocol as global.
2. Configure proxy protocol for Insert operation
3. Configure proxy protocol for Forward operation
4. Configure proxy protocol for Strip operation
5. Configure proxy protocol for no operation

Enable the proxy protocol as global

At the command prompt, type the following:

```
set ns param -proxyProtocol ENABLED
```

Configure proxy protocol for Insert operation

To configure the proxy protocol for Insert operation, you must enable or disable the protocol on the load balancing virtual server and enable it on the service.

Add net profile with Proxy protocol disabled for load balancing virtual server

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED> -proxyprotocoltxversion
 <V1/V2>
```

Example:

```
Add netprofile proxyprofile-1 -proxyProtocol DISABLED -proxyprotocoltxversion
 V1
```

> **Note:**
>
> If you disable proxy protocol on your appliance, you need not set the protocol version parameter.

Add net profile with a proxy protocol enabled for service

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED> -proxyprotocoltxversion
 <V1/V2>
```

Example:

```
add netprofile proxyprofile-2 -proxyProtocol ENABLED -proxyprotocoltxversion
 V1
```

Add load balancing virtual server for Citrix ADC appliance in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port>)]
```

Example:

```
add lb vserver lbvserver-1 http 1.1.1.1 80
```

Add HTTP service for Citrix ADC appliance in the proxy layer

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@)<serviceType> <port>
```

Example:

```
Add service http-service-1 2.2.2.1 http 80
```

Set net profile with load balancing virtual server in Citrix ADC appliance

At the command prompt, type the following:

```
set lb vserver <vserver name> -netprofile <name>
```

Example:

```
set lb vserver lbvserver-1 -netprofile proxyProfile-1
```

Set net profile with HTTP service in Citrix ADC appliance

At the command prompt, type the following:

```
set service <service name> -netprofile <name>
```

Example:

```
set service http-service-1 -netprofile proxyProfile-1
```

Configure proxy protocol for forward operation

To configure the proxy protocol for Forward operation for the next Citrix ADC instance in the proxy layer. You must enable or disable the protocol and bind to the virtual server or service.

Add net profile with proxy protocol enabled for load balancing virtual server

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED> -proxyprotocoltxversion
 <V1/V2>
```

Example:

```
add netprofile proxyprofile-3 -proxyProtocol ENABLED -proxyprotocoltxversion
 V1
```

Add net profile with proxy protocol enabled for service

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED> -proxyprotocoltxversion
 <V1/V2>
```

Example:

```
add netprofile proxyprofile-4 -proxyProtocol ENABLED -proxyprotocoltxversion
 V1
```

Add load balancing virtual server for Citrix ADC appliance in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port>)]
```

Example:

```
add lb vserver lbvserver-2 http 2.2.2.2 80
```

Add HTTP service for Citrix ADC appliance in the proxy layer

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@)<serviceType> <port>
```

Example:

```
Add service http-service-2 3.3.3.1 http 80
```

Set net profile with load balancing virtual server in Citrix ADC appliance

At the command prompt, type the following:

```
set lb vserver <vserver name> -netprofile <name>
```

Example:

```
set lb vserver lbvserver-2 -netprofile proxyProfile-3
```

Set net profile with HTTP service in Citrix ADC appliance

At the command prompt, type the following:

```
set service <service name> -netprofile <name>
```

Example:

```
set service http-service-2 -netprofile proxyProfile-4
```

Configure proxy protocol for strip operation

To configure the proxy protocol for strip operation, you must enable the proxy protocol on the load balancing virtual server and disable the proxy protocol on the service.

Add net profile with proxy protocol enabled for virtual server

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED> -proxyprotocoltxversion <V1/
V2>
```

Example:

```
add netprofile proxyprofile-5 -proxyProtocol ENABLED -proxyprotocoltxversion
 V1
```

Add load balancing or content switching virtual server for Citrix ADC appliance in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port>)]
```

Example:

```
add lb vserver lbvserver-3 http 2.2.2.2 80
```

Add HTTP service for Citrix ADC appliance in the proxy layer

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@)<serviceType> <port>
```

Example:

```
Add service http-service-3 3.3.3.1 http 80
```

Set net profile with load balancing or content switching virtual server in Citrix ADC appliance

At the command prompt, type the following:

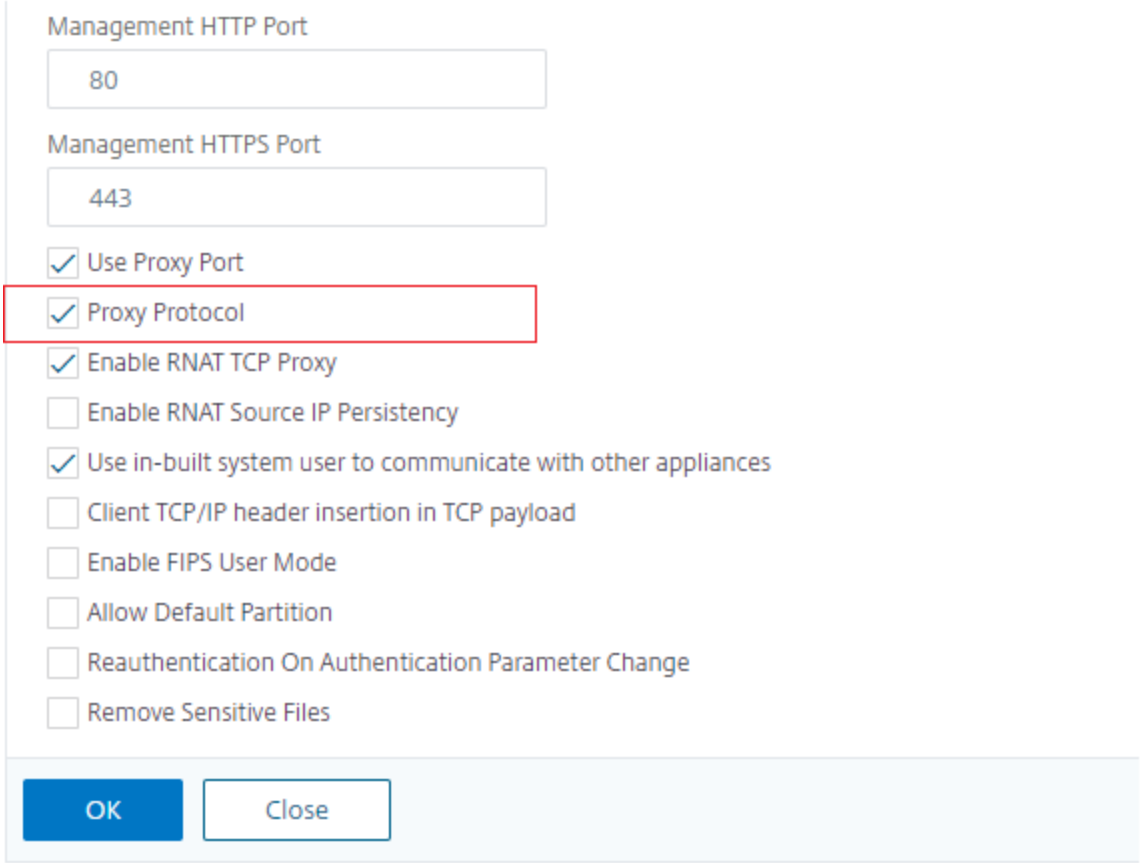
```
set lb vserver <vserver name> -netprofile <name>
```

Example:

```
set lb vserver lbvserver-3 -netprofile proxyProfile-5
```

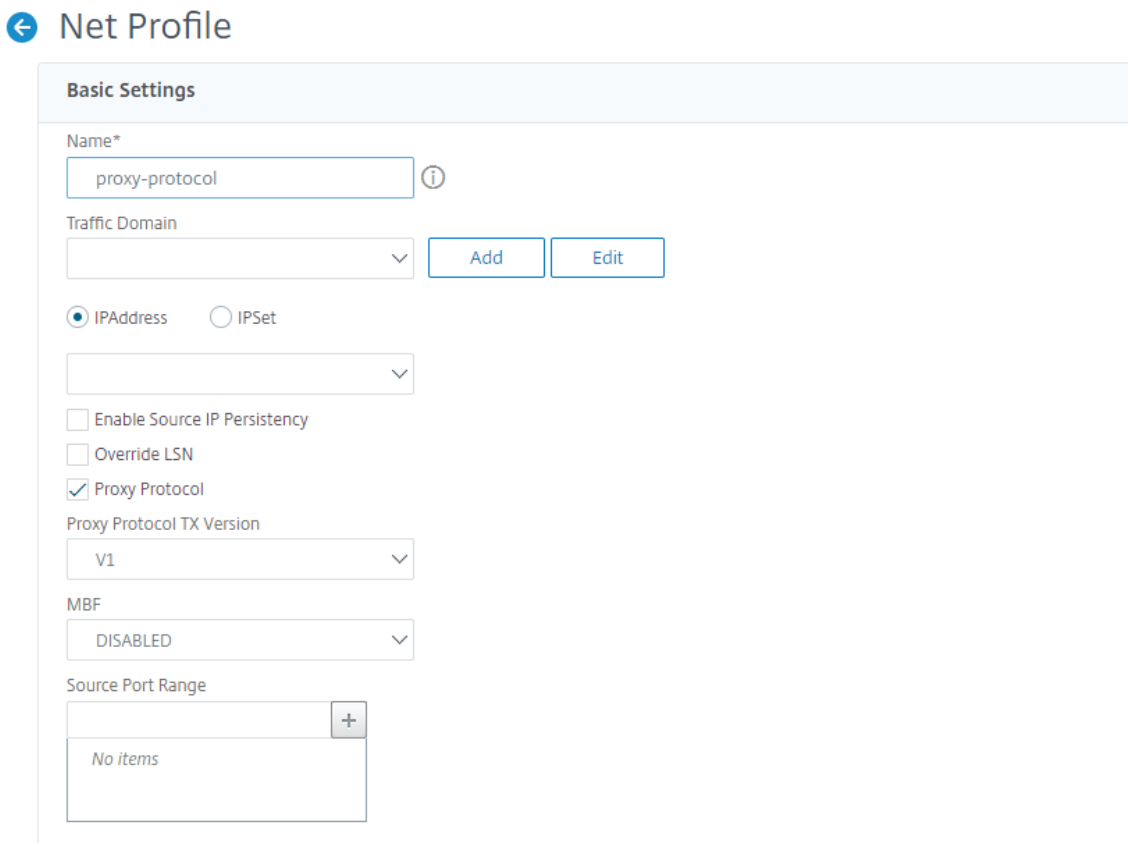
Configure Proxy protocol by using Citrix ADC GUI

1. Navigate to **System** > **Settings** > **Change Global System Settings**.
2. In the **Configure Global System Settings Parameters** page, select **Proxy Protocol** check box.
3. Click **OK** and **Close**.

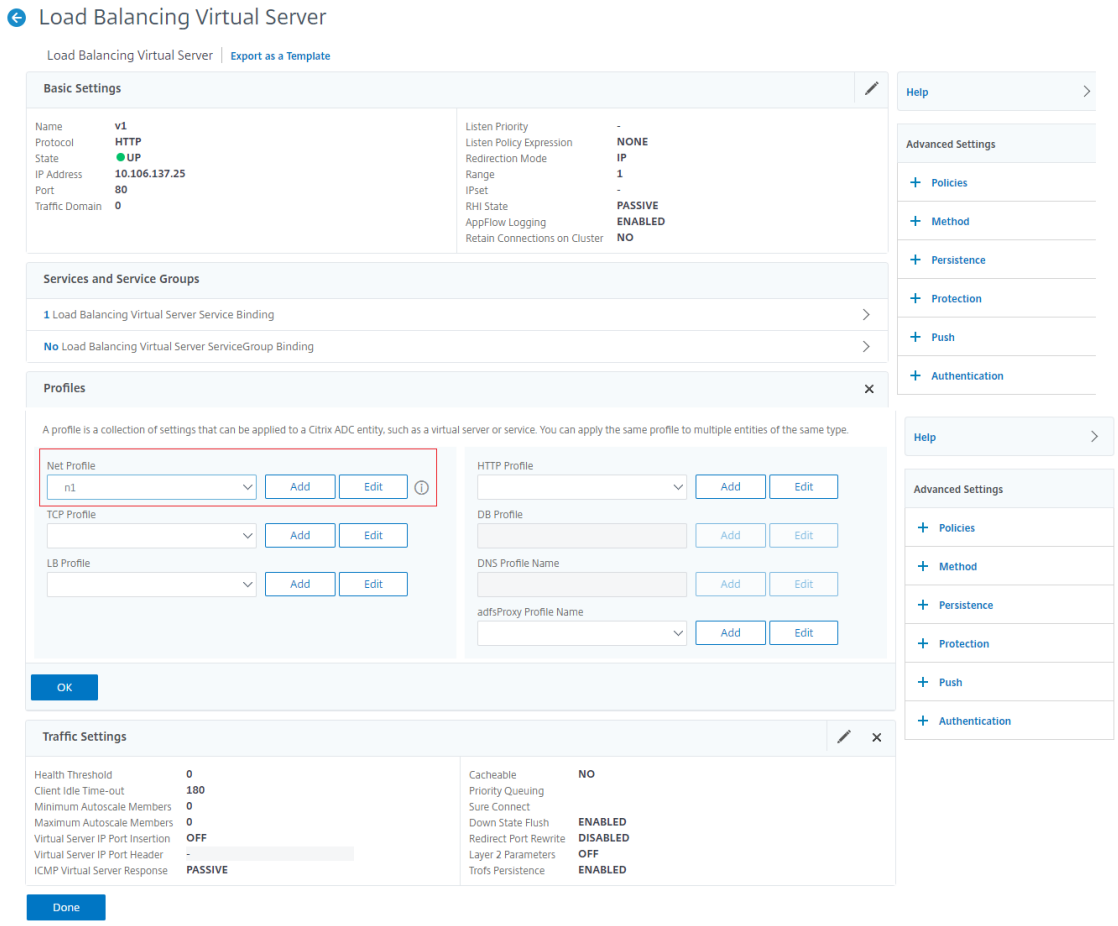


4. Navigate to **System** > **Network** > **Net Profiles**.

5. In the details pane, click **Add** to create a net profile for the load balancing virtual server.
6. In the **Net Profile** page, set the following parameters:
   a) Name. Name of the net profile.
   b) Proxy Protocol. Enable or disable proxy protocol for the load balancing virtual server.
   c) Proxy Protocol TX Version. Set proxy protocol version as V1 or V2 based on incoming data format.
7. Click **OK**.

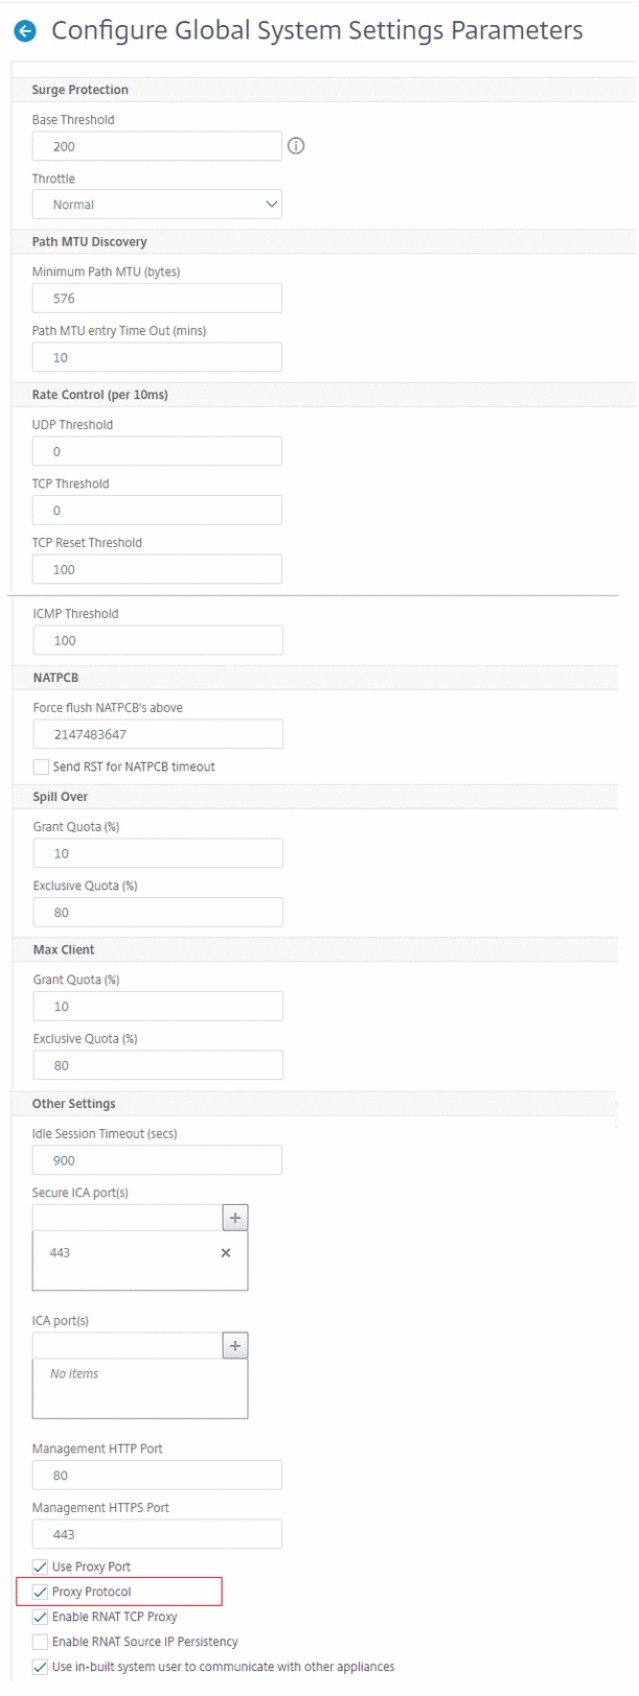


8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
9. In the details pane, click **Add**.
10. In the **Load Balancing Virtual Server** page, the set the basic parameters.
11. In the **Advanced Settings** section, select **Profiles**.
12. In the **Profiles** section, click the pencil icon.
13. Select a net profile and click **OK**.
14. Click **Done**.



15. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
16. In the details pane, click **Add**.
17. In the **Load Balancing Service** page, set the basic parameters.
18. In the **Advanced Settings** section, select **Profiles**.
19. In the **Profiles** section, click the pencil icon.
20. Select a net profile and click **OK**.
21. Click **Done**.

> **Note:**
>
> If you have more than one Citrix ADC appliance as part of the proxy layer, you must set the proxy protocol configuration on each appliance for the Forward operation.



Client IP address in TCP option

September 14, 2021

The Citrix ADC appliance uses many ways to send the client information to the back-end server. One such method is by sending the client IP address in the TCP option of the first data packet. The appliance uses the TCP option number in the TCP profile, if the back-end server using TCP option to read the client IP address. The IP address is carried in the TCP option number 28 (configurable on the appliance service).

The TCP option method includes both insert and forward functionality in carrying the client IP address to the back-end server.

In the TCP option configuration, the appliance adds a TCP option, 28 to insert the client IP address and forward it to the back-end server. Following are some the of usage scenarios for TCP option configuration in a Citrix ADC appliance.

Multiplexing is disabled if this feature is enabled for traffic coming to TCP profile. Also, if nsapimgr and clientip tcp-options in TCP profile are enabled, clientip tcp-option takes precedence.

> **Note:**
>
> However, multiplexing is disabled on the appliance if Client IP TCP option is enabled for the traffic that comes to the TCP profile.

- Learning original client IP address
- Selecting a language for a website
- Block listing selected IP addresses

Following are the two modes of operation:

- Insert. The appliance adds the client details in the TCP option 28 (configurable but preferable value is 28) field and sends it to the back-end server.
- Forward. The appliance forwards the client details in the TCP option 28 (configurable on the front-end of the appliance service). However, the option number at the back-end can be modified based on the value configured in the back-end

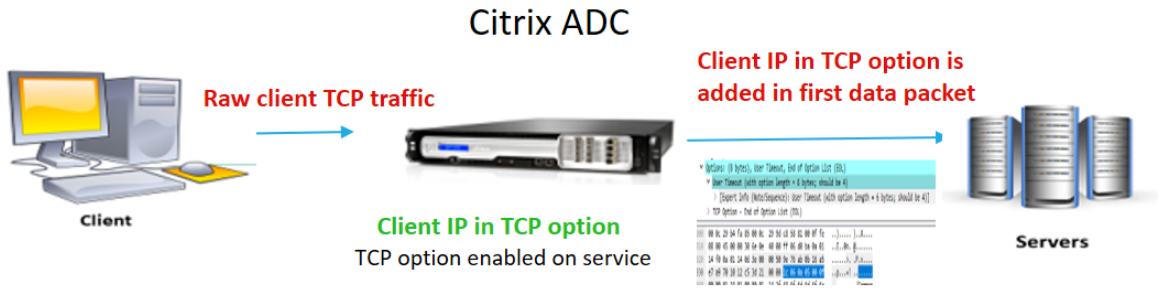
> **Note:**
>
> In case of TCP or HTTP virtual server, the TCP option number is forwarded with or without this feature enabled in transparent mode.

Limitations

The TCP option configuration feature is not supported in TFO, MultiPath TCP, and HTTP2 features.

How TCP option configuration in a Citrix ADC appliance

The following flow diagrams show how you can configure TCP option in the Citrix ADC appliances for Insert and forward operations.

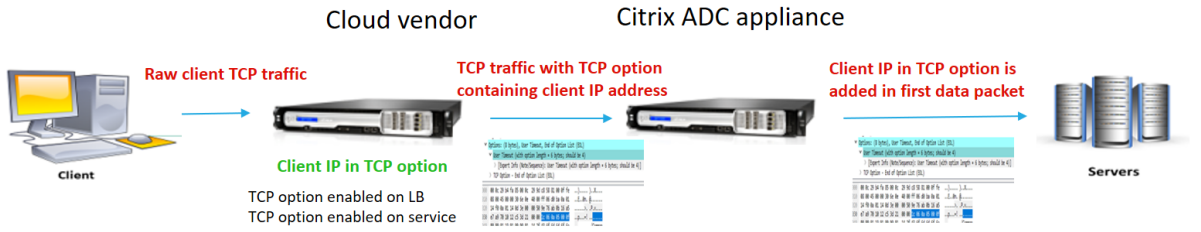


The component interact is as follows:

- A client sends a request to Citrix ADC.
- In Citrix ADC appliance, you must create a TCP profile, enable the TCP option feature, and specify the TCP option number.

  Note: It is advisable to configure TCP option number as 28 in the TCP profile.
- In Insert operation, Citrix ADC inserts the client details in the TCP option 28 bound to the service. The client details are then sent it to the back-end server. If the incoming traffic is HTTPS, the client IP address in the TCP option will be sent in the SSL client hello message which is the first data packet at the TCP level

Forward operation:



The component interact is as follows:

- A client sends a HTTP/HTTPS request to Citrix ADC.
- At Citrix ADC appliance, if is a Forward operation, the TCP option is enabled on load balancing virtual server or content switching virtual server and also enabled on the service. The appliance receives the client info in the TCP option number specified in the virtual server and forwards it to the back-end server in the TCP option number (configurable in the service) added in the first data packet

Configure TCP option for Insert operation

Following the procedure given below to configure TCP option in your Citrix ADC appliance.

1. Add a TCP profile.
2. Configure TCP option for Insert operation
3. Bind TCP profile to service

Add a TCP profile

At the command prompt, type:

```
add tcpprofile <name> -clientIpTcpOption (enabled | disabled> -clientIpTcpOptionNumber
 <positive_integer>
```

Example:

```
add tcprofile p1
```

Configure TCP option for Insert operation

At the command prompt, type:

```
add tcpprofile <name> -clientIpTcpOption (enabled | disabled> -clientIpTcpOptionNumber
 <positive_integer>
```

Example:

```
add tcpprofile p1 -clientIpTcpOption ENABLED -clientIpTcpOptionNumber 28
```

Add service

At the command prompt, type:

```
add service <name> <server name> <service type> <port>
```

Example:

```
add service service-http1 1.1.1.1 HTTP 80
```

Bind TCP profile to service

At the command prompt, type:

```
set service <name> -tcpprofileName <name>
```

Example:

```
set service s1 -tcpprofileName p1
```

> **Note:**
>
> The basic configuration for service must be taken care.

Configure TCP option for Forward operation

Following the procedure given below to configure TCP option in the TCP profile for Forward operation.

1. Add TCP profile with TCP option number
2. Bind TCP profile to virtual server
3. Bind TCP profile to service.

Add TCP profile with TCP option number

At the command prompt, type:

```
add tcpprofile <name> -clientIpTcpOption (enabled | disabled> -clientIpTcpOptionNumber
 <positive_integer>
```

Example:

```
add tcpprofile p1 -clientIpTcpOption ENABLED -clientIpTcpOptionNumber 29
```

Bind TCP profile to virtual server (load balancing or content switching)

At the command prompt, type:

```
set lb vserver <name> -tcpprofileName <name>
```

Example:

```
set lb vservice s1 -tcpprofileName p1
```

Bind TCP profile to service

At the command prompt, type:

```
set service <name> -tcpprofileName p1
```

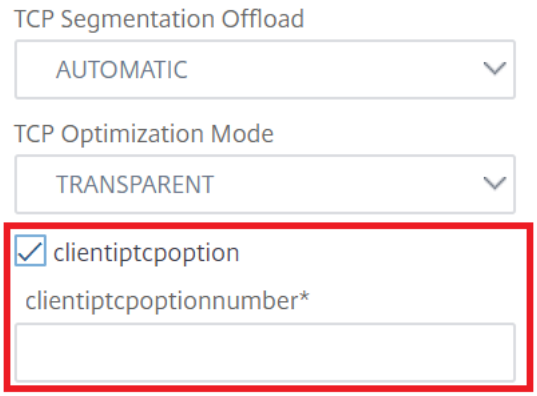
Example:

```
set service s1 -tcpprofileName p1
```

Configure TCP option by using Citrix ADC GUI

1. Navigate to **System** > **Profiles**.

2. In the **TCP Profile** tab page, click **Add**.
3. In the **Configure TCP profile** page, configure the following parameters:
   a. clientIptcpoption. TCP option to send or receive client IP address.
   b. clientiptcpoptionnumber. Configurable TCP option number to receive the client IP address.



4. Click **OK** and **Close**.

SNMP

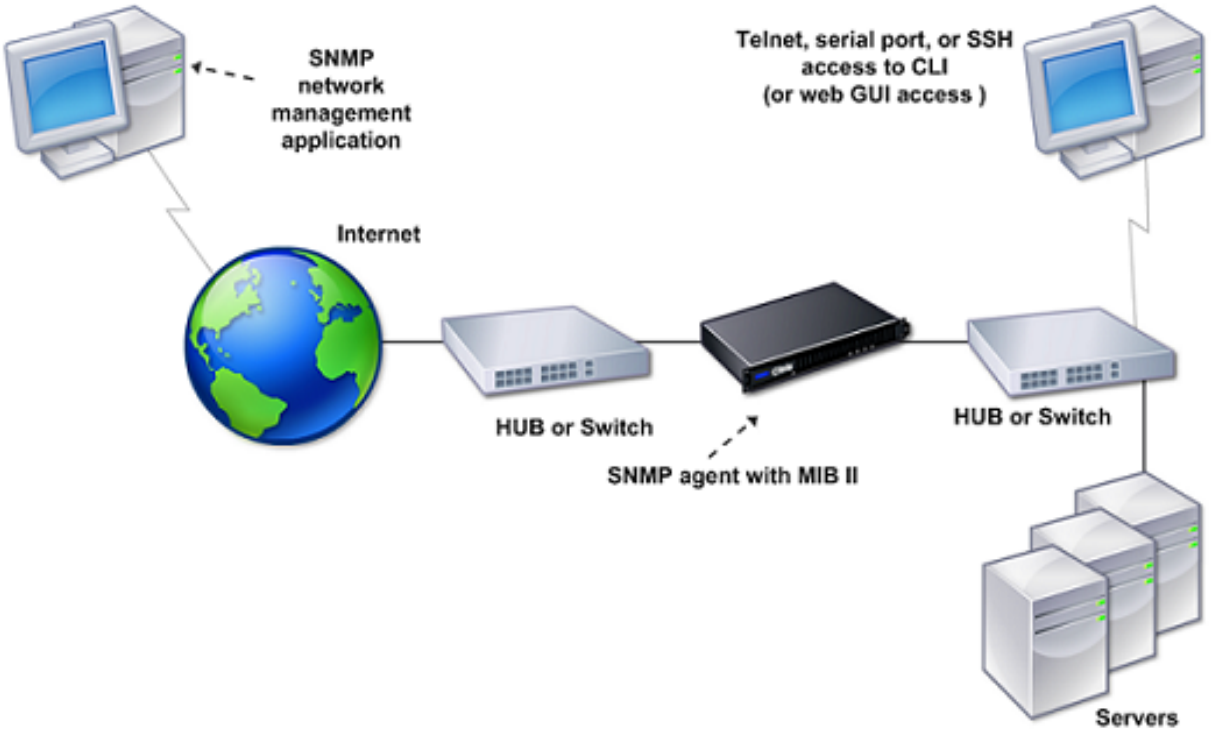
September 14, 2021

You can use Simple Network Management Protocol (SNMP) to configure the SNMP agent on the Citrix ADC appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the Citrix ADC. The traps are then sent to a remote device called a *trap listener*, which signals the abnormal condition on the Citrix ADC appliance. Or, you can query the SNMP agent for System-specific information from a remote device called an *SNMP manager*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The SNMP agent on the Citrix ADC can generate traps compliant with SNMPv1, SNMPv2, and SNMPv3. For querying, the SNMP agent supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3).

For information about SNMP parameters, traps, and its descriptions, see Citrix ADC SNMP OID Reference.

The following figure illustrates a network with a Citrix ADC that has SNMP enabled and configured. In the figure, each SNMP network management application uses SNMP to communicate with the SNMP agent on the Citrix ADC. The SNMP agent searches its management information base (MIB) to collect the data requested by the SNMP Manager and provides the information to the application.



> **Important**
>
> The SNMP module in a Citrix ADC appliance supports a maximum length of 128 bytes (as compliant with RFC 3416) for an SNMP OID. A long index variable name for an object can result in an SNMP OID exceeding 128 bytes in length.
>
> To resolve this issue, the Citrix ADC SNMP module supports a maximum length of 31 characters for an index variable name. If an index variable name exceeds 31 characters in length, the SNMP module using an hash algorithm converts the name to a 31 characters hash value. This hashed value is used in the SNMP OID for that variable.
>
> The original index variable name is stored in another variable, which has the following name format: `<variable type>FullName`. For example, When the name of a load balancing virtual server has more the 31 characters, `vserverName` SNMP OID contains the hashed value and `vsvrFullName` SNMP OID contains the full (original) name of the virtual server.
>
> Similarly, for SNMP traps, the index variable displays a hashed valued. `<variable type>FullName`, which stores the full name of the original index variable name, is also part of the trap messages.

Importing MIB Files to the SNMP Manager and Trap Listener

To monitor a Citrix ADC appliance, you must download the MIB object definition files. The Citrix ADC appliance supports the following enterprise-specific MIBs:

- **A subset of standard MIB-2 groups**. Provides MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.
- **A system enterprise MIB**. Provides system-specific configuration and statistics.

You can obtain the MIB object definition files from the /netscaler/snmp directory or from the Downloads tab of the GUI.

Configuring the Citrix ADC to generate SNMP traps

September 14, 2021

You can configure the Citrix ADC appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the appliance. The traps are sent to a remote device called a *trap listener*. It helps administrators monitor the appliance and respond promptly to any issues.

The Citrix ADC appliance provides a set of condition entities called *SNMP alarms*. When the condition in any SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

To configure the Citrix ADC appliance to generate traps, you need to enable and configure alarms. Then, you specify the trap listeners to which the appliance sends the generated trap messages.

Enabling an SNMP alarm

The Citrix ADC appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the appliance generates corresponding trap messages when some events occur. Some alarms are enabled by default.

To enable an SNMP alarm by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `enable snmp alarm <trapName>`
- `show snmp alarm <trapName>`

To enable an SNMP alarm by using the GUI

1. Navigate to **System > SNMP > Alarms**, and select the alarm.
2. Click **Actions** and select **Enable**.

Configuring alarms

The Citrix ADC appliance provides a set of condition entities called *SNMP alarms*. When the condition set for an SNMP alarm is met, the appliance generates SNMP traps messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

You can assign an SNMP alarm with a severity level. When you do this, the corresponding trap messages are assigned that severity level.

The following are the severity levels, defined on the appliance, in decreasing order of severity.

- Critical
- Major
- Minor
- Warning
- Informational

For example, if you set a warning severity level for the SNMP alarm named LOGIN-FAILURE, the trap messages generated when there is a login failure is assigned with the warning severity level.

> **Note**
>
> Citrix ADC supports various SNMP alarms. For more information, see SNMP alarms.

You can also configure an SNMP alarm to log the corresponding trap messages generated whenever the condition on that alarm is met.

To configure an SNMP alarm by using the CLI

At the command prompt, type the following commands to configure an SNMP alarm and verify the configuration:

- `set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-time <secs>] [-state ( ENABLED | DISABLED )] [-severity <severity>] [-logging ( ENABLED | DISABLED )]`
- `show snmp alarm <trapName>`

Where,

ThresholdValue: Value for the high threshold. The Citrix ADC appliance generates an SNMP trap message when the value of the attribute associated with the alarm is greater than or equal to the specified high threshold value.

NormalValue: Value for the normal threshold. A trap message is generated if the value of the respective attribute falls to or below this value after exceeding the high threshold.

To configure SNMP alarms by using the GUI

Navigate to **System > SNMP > Alarms**, select an alarm, and configure the alarm parameters.

Configuring SNMPv1 or SNMPv2 traps

After configuring the alarms, you need to specify the trap listener to which the appliance sends the trap messages. Apart from specifying parameters such as IP or IPv6 address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

You can also configure the appliance to send SNMP trap messages with a source IP address other than the Citrix ADC IP (NSIP or NSIP6) address to a particular trap listener. For a trap listener that has an IPv4 address, you can set the source IP to either a mapped IP (MIP) address or a subnet IP (SNIP) address configured on the appliance. For a trap listener that has an IPv6 address, you can set the source IP to a subnet IPv6 (SNIP6) address configured on the appliance.

You can also configure the appliance to send trap messages to a trap listener based on a severity level. For example, if you set the severity level as Minor for a trap listener, all trap messages of the severity level equal to or greater than Minor (Minor, Major, and Critical) are sent to the trap listener.

If you have defined a community string for the trap listener, you must also specify a community string for each trap that is to be sent to the listener. A trap listener for which a community string has been defined accepts only trap messages that include a community string matching the community string defined in the trap listener. Other trap messages are dropped.

To add an SNMP trap by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp trap <trapClass> <trapDestination> -version ( V1 | V2 )-destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>`
- `show snmp trap`

Example:

```
1 > `add snmp trap specific 192.0.2.10 -version V2 -destPort 80 -
     communityName com1 -severity Major`
2 <!--NeedCopy-->
```

To configure SNMP traps by using the GUI

Navigate to **System > SNMP > Traps**, and create the SNMP trap.

Configuring SNMPv3 traps

SNMPv3 provides security capabilities such as authentication and encryption by using the credentials of SNMP users. An SNMP manager can receive SNMPv3 trap messages only if its configuration includes the password assigned to the SNMP user.

The trap destination can now receive SNMPv1, SNMPv2, and SNMPv3 trap messages.

To configure an SNMPv3 trap by using the CLI

At the command prompt, do the following:

1. Add an SNMPv3 trap.

   ```
   add snmp trap <trapClass> <trapDestination> -version ( V1 | V2 | V3)
   -destPort <port> -communityName <string> -srcIP <ip_addr> -severity <
   severity>
   ```

   > **Note**
   >
   > Once set, the SNMP trap version cannot be modified.

   Example

   ```
   1 > add snmp trap specific 192.0.2.10 -version V3 -destPort 80 -
       communityName com1 -severity Major
   2 <!--NeedCopy-->
   ```

2. Add an SNMP user.

   ```
   add snmp user <name> -group <string> [ -authType ( MD5 | SHA ){ -
   authPasswd } [-privType ( DES | AES ){ -privPasswd } ]]
   ```

   Example

   ```
   1 > add snmp user edocs_user -group edocs_group
   2 <!--NeedCopy-->
   ```

3. Bind the SNMPv3 trap to the SNMP user.

```
bind snmp trap <trapClass> <trapDestination> [-version <version>] (-userName
 <string> [-securityLevel <securityLevel>])
```

Example

```
1      > bind snmp trap specific 192.0.2.10 -version V3 -userName
          edocs_user -securityLevel authPriv
2  <!--NeedCopy-->
```

To configure an SNMPv3 trap by using the GUI

1. Add an SNMPv3 trap.

   Navigate to **System > SNMP > Traps**, and create the SNMP trap by selecting V3 as the SNMP version.

2. Add an SNMP user.

   Navigate to **System > SNMP > Users** and create the SNMP user.

3. Bind the SNMPv3 trap to the SNMP user.

   - Navigate to **System > SNMP > Traps**, and select the SNMP version 3 trap.
   - Select the user to which the trap should be bound and define the appropriate Security Level.

SNMP trap logging

A Citrix ADC appliance can log SNMP trap messages (for SNMP alarms in which logging capability is enabled) when you enable the SNMP trap logging option and at least one trap listener is configured on the appliance. Now, you can specify the audit log level of trap messages sent to an external log server. The default log level is Informational. Possible values are Emergency, Alert, Critical, Error, Warning, Debug, and Notice.

For example, you can set the audit log level to Critical for an SNMP trap message generated by a logon failure. That information is then available on the NSLOG or SYSLOG server for troubleshooting.

To enable SNMP trap logging and configure trap log level by using the CLI

At the command prompt, type the following commands to configure SNMP trap logging and verify the configuration:

- `set snmp option [-snmpTrapLogging (ENABLED | DISABLED)][-snmpTrapLoggingLevel <snmpTrapLoggingLevel>]`
- `show snmp option`

To enable SNMP trap logging and configure SNMP trap log level by using the GUI

Navigate to **System > SNMP**, click Change SNMP Options, and set the following parameters:

1. SNMP Trap Logging—Select this check box to enable SNMP trap logging when at least one trap listener is configured on the appliance.
2. SNMP Trap Logging Level—Select an audit log level for the SNMP trap. By default, the audit level for an SNMP trap is set to "Informational."

Configuring Citrix ADC for SNMP v1 and v2 queries

September 14, 2021

You can query the Citrix ADC SNMP agent for system-specific information from a remote device called *SNMP managers*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The following types of SNMP v1 and v2 queries are supported by the SNMP agent:

- GET
- GET NEXT
- ALL
- GET BULK

You can create strings called community strings and associate each of these to query types. You can associate one or more community strings to each query type. Community string are passwords and used to authenticate SNMP queries from SNMP managers.

For example, if you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the Citrix ADC appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

Specifying an SNMP manager

You must configure the Citrix ADC appliance to allow the appropriate SNMP managers to query it. You must also provide the SNMP manager with the required Citrix ADC-specific information. You can add up to a maximum of 100 SNMP managers or networks.

For an IPv4 SNMP manager you can specify a host name instead of the manager's IP address. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address. You can add up to a maximum of five host-name based SNMP managers.

> **Note**:
> The appliance does not support use of host names for SNMP managers that have IPv6 addresses. You must specify the IPv6 address.

If you do not configure at least one SNMP manager, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds only to SNMP queries from those specific IP addresses.

If you remove an SNMP manager from the configuration, that manager can no longer query the appliance.

To add SNMP managers by specifying IP addresses by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp manager <IPAddress> ... [-netmask <netmask>]`
- `show snmp manager`

Example

```
> add snmp manager 10.102.29.10 10.102.29.15 10.102.29.30
```

To add an SNMP manager by specifying its host name by using the command line interface

Important: If you specify the SNMP manager's host name instead of its IP address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address. For more information, see "Adding a Name Server."

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp manager <IPAddress> [-domainResolveRetry ****<integer>]`
- `show snmp manager`

Example

```
add nameserver 10.103.128.15
add snmp manager engwiki.eng.example.net -domainResolveRetry 10
```

To add an SNMP manager by using the GUI

1. Navigate to **System** > **SNMP** > **Managers**, and create the SNMP manager.

> **Important**:
>
> If you specify the SNMP manager's host name instead of its IPv4 address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address.

> **Note**:
> The appliance does not support host names for SNMP managers that have IPv6 addresses.

Specifying an SNMP community

You can create strings called community strings and associate them with the following SNMP query types on the appliance:

- GET
- GET NEXT
- ALL
- GET BULK

You can associate one or more community strings to each query types. For example, when you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

If you do not associate any community string to a query type then the SNMP agent responds to all SNMP queries of that type.

To specify an SNMP community by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp community <communityName> <permissions>`
- `show snmp community`

Example

```
> add snmp community com all
```

To configure an SNMP community string by using the GUI

Navigate to **System** > **SNMP** > **Community**, and create the SNMP community.

Configuring Citrix ADC for SNMPv3 queries

September 14, 2021

Simple Network Management Protocol Version 3 (SNMPv3) is based on the basic structure and architecture of SNMPv1 and SNMPv2. However, SNMPv3 enhances the basic architecture to incorporate administration and security capabilities, such as authentication, access control, data integrity check, data origin verification, message timeliness check, and data confidentiality.

To implement message level security and access control, SNMPv3 introduces the user-based security model (USM) and the view-based access control model (VACM).

- **User-Based Security Model.** The user-based security model (USM) provides message-level security. It enables you to configure users and security parameters for the SNMP agent and the SNMP manager. USM offers the following features:
  - **Data integrity:** To protect messages from being modified during transmission through the network.
  - **Data origin verification:** To authenticate the user who sent the message request.
  - **Message timeliness:** To protect against message delays or replays.
  - **Data confidentiality:** To protect the content of messages from being disclosed to unauthorized entities or individuals.
- **View-Based Access Control Model.** The view-based access control model (VACM) enables you to configure access rights to a specific subtree of the MIB based on various parameters, such as security level, security model, user name, and view type. It enables you to configure agents to provide different levels of access to the MIB to different managers.

Citrix ADC supports the following entities that enable you to implement the security features of SNMPv3:

- SNMP Engines
- SNMP Views
- SNMP Groups
- SNMP Users

These entities function together to implement the SNMPv3 security features. Views are created to allow access to subtrees of the MIB. Then, groups are created with the required security level and access to the defined views. Finally, users are created and assigned to the groups.

> **Note**:
>
> The view, group, and user configuration are synchronized and propagated to the secondary node in a high availability (HA) pair. However, the engine ID is neither propagated nor synchronized as it is unique to each Citrix ADC appliance.

To implement message authentication and access control, you need to do the following:

Setting the engine ID

SNMP engines are service providers that reside in the SNMP agent. They provide services such as sending, receiving, and authenticating messages. SNMP engines are uniquely identified using engine IDs.

The Citrix ADC appliance has a unique engineID based on the MAC address of one of its interfaces. It is not necessary to override the engineID. However, if you want to change the engine ID, you can reset it.

To set the engine ID by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `set snmp engineId <engineID>`
- `show snmp engineId`

Example

```
> set snmp engineId 8000173f0300c095f80c68
```

To set the engine ID by using GUI

Navigate to **System** > **SNMP** > **Users**, click **Configure Engine ID** and type an engine ID.

Configure a view

SNMP views restrict user access to specific portions of the MIB. SNMP views are used to implement access control.

To add an SNMP view by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp view <name> <subtree> -type ( included | excluded )`
- `show snmp view <name>`
- `rm snmp view <name> <subtree>`

Where,

Name. Name for the SNMPv3 view. It can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=),

colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 view.

Subtree. A particular branch (subtree) of the MIB tree that you want to associate with this SNMPv3 view. You must specify the subtree as an SNMP OID. This is an argument of maximum Length: 99.

type. Include or exclude the subtree, specified by the subtree parameter, in or from this view. This setting can be useful when you have included a subtree, such as A, in an SNMPv3 view and you want to exclude a specific subtree of A, such as B, from the SNMPv3 view. This is a mandatory argument. Possible values: included, excluded.

Examples

add snmp view SNMPv3test 1.1.1.1 -type included
sh snmp view SNMPv3test
rm snmp view SNMPv3test 1.1.1.1

To configure an SNMP view by using the GUI

Navigate to **System** > **SNMP** > **Views**,and create the SNMP view.

Configure a group

SNMP groups are logical aggregations of SNMP users. They are used to implement access control and to define the security levels. You can configure an SNMP group to set access rights for users assigned to that group, thereby restricting the users to specific views.

You need to configure an SNMP group to set access rights for users assigned to that group.

To add an SNMP group by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp group <name> <securityLevel> -readViewName <string>`
- `show snmp group <name> <securityLevel>`

Where,

Name. Name for the SNMPv3 group. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 group.

securityLevel. Security level required for communication between the Citrix ADC appliance and the SNMPv3 users who belong to the group. Specify one of the following options:

noAuthNoPriv. Require neither authentication nor encryption.

authNoPriv. Require authentication but no encryption.

authPriv. Require authentication and encryption. Note: If you specify authentication, you must specify an encryption algorithm when you assign an SNMPv3 user to the group. If you also specify encryption, you must assign both an authentication and an encryption algorithm for each group member. This is a mandatory argument. Possible values: noAuthNoPriv, authNoPriv, authPriv.

readViewName. Name of the configured SNMPv3 view that you want to bind to this SNMPv3 group. An SNMPv3 user bound to this group can access the subtrees that are bound to this SNMPv3 view as type INCLUDED, but cannot access the ones that are type EXCLUDED. If the Citrix ADC appliance has multiple SNMPv3 view entries with the same name, all such entries are associated with the SNMPv3 group. This is a mandatory argument. Maximum Length: 31

To configure an SNMP group by using the GUI

Navigate to **System** > **SNMP** > **Groups**, and create the SNMP group.

Configuring a user

SNMP users are the SNMP managers that the agents allow to access the MIBs. Each SNMP user is assigned to an SNMP group.

You need to configure users at the agent and assign each user to a group.

To configure a user by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp user <name> -group <string> [-authType ( MD5 | SHA ){ -authPasswd } [-privType ( DES | AES ){ -privPasswd } ]]`
- `show snmp user <name>`

Where,

authType is the authentication option available while configuring an user. There are two authentication types such as MD5 and SHA.

privType is the encryption option available while configuring an user. There are two types of encryption such as DES of key size 128 bit, and AES of key size 128 bit.

Example

```
> add snmp user edocs_user -group edocs_group
<!--NeedCopy-->
```

To configure an SNMP user by using the GUI

Navigate to **System** > **SNMP** > **Users**, and create the SNMP user.

Configuring SNMP Alarms for rate limiting

September 14, 2021

Citrix ADC appliances such as the Citrix ADC MPX 10500, 12500, and 15500 are rate limited. The maximum throughput (Mbps) and packets per second (PPS) are determined by the license purchased for the appliance. For rate-limited platforms, you can configure SNMP traps to send notifications when throughput and PPS approach their limits and when they return to normal.

Throughput and PPS are monitored every seven seconds. You can configure traps with high-threshold and normal-threshold values, which are expressed as a percentage of the licensed limits. The appliance then generates a trap when throughput or PPS exceeds the high threshold, and a second trap when the monitored parameter falls to the normal threshold. In addition to sending the traps to the configured destination device, the Citrix ADC logs the events associated with the traps in the /var/log/ns.log file as EVENT ALERTSTARTED and EVENT ALERTENDED.

Exceeding the throughput limit can result in packet loss. You can configure SNMP alarms to report packet loss.

For more information about SNMP alarms and traps, see "Configuring the Citrix ADC to generate SNMP v1 and v2 Traps."

This document includes the following details:

- Configuring an SNMP Alarm for Throughput or PPS
- Configuring SNMP Alarm for Dropped Packets

Configuring an SNMP alarm for throughput or PPS

To monitor both throughout and PPS, you must configure seperate alarms and set threshold pps value in Mbps.

To configure an SNMP alarm for the throughput rate by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm, set threshold value in Mbps and verify the configuration:

- `set snmp alarm PF-RL-RATE-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state ( **ENABLED** | **DISABLED** )] [-severity <severity>] [-logging ( **ENABLED** | **DISABLED** )]`
- `show snmp alarm PF-RL-RATE-THRESHOLD`

Example

```
1 > set snmp alarm PF-RL-RATE-THRESHOLD -thresholdValue 70 -normalValue
     50
2 <!--NeedCopy-->
```

To configure an SNMP alarm for PPS by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm for PPS and verify the configuration:

- `set snmp alarm PF-RL-PPS-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state ( **ENABLED** | **DISABLED** )] [-severity <severity>] [-logging ( **ENABLED** | **DISABLED** )]`
- `show snmp alarm PF-RL-PPS-THRESHOLD`

Example

```
1 > set snmp alarm PF-RL-PPS-THRESHOLD -thresholdValue 70 -normalValue 50
2 <!--NeedCopy-->
```

To configure an SNMP alarm for throughput or PPS by using the GUI

1. Navigate to **System** > **SNMP** > **Alarms**, and select **PF-RL-RATE-THRESHOLD** (for throughput rate) or **PF-RL-PPS-THRESHOLD** (for packets per second).
2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP alarm for dropped packets

You can configure an alarm for packets dropped as a result of exceeding the throughput limit and an alarm for packets dropped as a result of exceeding the PPS limit.

To configure an SNMP alarm for packets dropped because of excessive throughput, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-RATE-PKTS-DROPPED [-state (ENABLED | DISABLED)] [-
severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for packets dropped because of excessive PPS, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-PPS-PKTS-DROPPED [-state (ENABLED | DISABLED)] [-
severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for dropped packets by using the GUI

1. Navigate to **System** > **SNMP** > **Alarms**, and select **PF-RL-RATE-PKTS-DROPPED** (for packets dropped because of excessive throughput) or **PF-RL-PPS-PKTS-DROPPED** (for packets dropped because of excessive PPS).
2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP in FIPS mode

September 14, 2021

FIPS mode requires Simple Network Management Protocol version 3 (SNMPv3) with the authentication and privacy (authPriv) option. SNMP version 1 and version 2 use a community string mechanism to provide secured access to management data. The community string is sent as clear text between an SNMP manager and an SNMP agent. This type of communication is unsecure, allowing intruders to access SNMP information on the network.

The SNMPv3 protocol uses the User-based Security Model (USM) and View-based Access Control Model (VACM) to authenticate and control management access to SNMP messaging data. SNMPv3 has three security levels: no authentication no privacy (noAuthNoPriv), authentication and no privacy (authNoPriv), and authentication and privacy (authPriv).

Enabling FIPS mode and restarting the Citrix ADC appliance removes the following SNMP configurations from the appliance:

1. Community configuration for SNMPv1 and SNMPv2 protocols.
2. SNMPv3 groups configured with the noAuthNoPriv or authNoPriv security-level option.

3. Traps configured for SNMPv1 or SNMPv2, or SNMPv3 with the noAuthNoPriv security-level option.

After restarting the appliance, configure SNMPv3 with the authPriv option. For more information about configuring authPriv option in SMNP v3, see SNMPV3 topic

> **Note**:
>
> Enabling FIPS mode and restarting your appliance blocks execution of the following SNMP trap and group commands:

```
1.  add snmp community <communityName> <permissions>

2.  add snmp trap <trapClass> <trapDestination> ... [-version: v1/
   v2]   [-td <positive_integer>] [-destPort <port>] [-
   communityName <string>] [-srcIP <ip_addr|ipv6_addr>] [-severity
   <severity>] [-allPartitions ( ENABLED | DISABLED )]

3.  add snmp group <name> <securityLevel : noAuthNoPriv/ authNoPriv
    > -readViewName <string>

4.  bind snmp trap specific <TrapIp>-userName <v3 user name> -
   securityLevel <noAuthNoPriv/ authNoPriv>
<!--NeedCopy-->
```

Audit logging

September 14, 2021

> **Important**
>
> Citrix recommends you to update a SYSLOG or NSLOG configuration only during maintenance or downtime. If you update a configuration after creating a session, the changes are not applied to the existing session logs.

Auditing is a methodical examination or review of a condition or situation. The audit logging feature enables you to log the Citrix ADC states and status information collected by various modules. The log information can be in the kernel and in the user-level daemons. For audit logging, you can use the SYSLOG protocol, the native NSLOG protocol, or both.

SYSLOG is a standard protocol for logging. It has two components:

- **SYSLOG auditing module.** Runs on the Citrix ADC appliance.
- **SYSLOG server.** Runs on the underlying FreeBSD operating system (OS) of the Citrix ADC appliance or on a remote system.

SYSLOG uses a user data protocol (UDP) for data transfer.

Similarly, the native NSLOG protocol has two components:

- **NSLOG auditing module.** Runs on the Citrix ADC appliance.
- **NSLOG server.** Runs on the underlying FreeBSD OS of the Citrix ADC appliance or on a remote system.

NSLOG uses TCP for data transfer.

When you run a SYSLOG or NSLOG server, it connects to the Citrix ADC appliance. The Citrix ADC appliance then starts sending all the log information to the SYSLOG or NSLOG server. And the server filters the log entries before storing them in a log file. An NSLOG or SYSLOG server receives log information from more than one Citrix ADC appliance. The Citrix ADC appliance sends log information to more than one SYSLOG server or NSLOG server.

If multiple SYSLOG servers are configured, the Citrix ADC appliance sends its SYSLOG events and messages to all the configured external log servers. It results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms. The appliance can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastPackets, and AuditlogHash.

> **Note**
>
> The Citrix ADC appliance can send audit log messages up to 16 KB to an external SYSLOG server.

The log information that a SYSLOG or NSLOG server collects from a Citrix ADC appliance is stored in a log file in the form of messages. These messages typically contain the following information:

- The IP address of a Citrix ADC appliance that generated the log message.
- A time stamp
- The message type
- The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency)
- The message information

To configure audit logging, you first configure the audit modules on the Citrix ADC appliance. The appliance involves creating audit policies and specifying the NSLOG server or SYSLOG server information. You then install and configure the SYSLOG or the NSLOG server on the underlying FreeBSD OS of the Citrix ADC appliance or on a remote system.

> **Note**
>
> SYSLOG is an industry standard for logging program messages, and various vendors provide support. The documentation does not include SYSLOG server configuration information.

The NSLOG server has its own configuration file (auditlog.conf). You can customize logging on the NSLOG server system by making extra modifications to the configuration file (auditlog.conf).

Configuring Citrix ADC appliance for audit logging

November 24, 2021

> **Warning:**
>
> Classic policy expressions and its usage are deprecated (discouraged from use but still supported) from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Advanced Policies.

Audit-logging displays status information from different modules so that an administrator can see event history in the chronological order. Main components of an Audit framework are 'audit action', 'audit policy'. 'Audit action' describes Audit Server configuration information whereas 'audit policy' links a bind entity to an 'audit action'. The audit policies use 'Classic Policy Engine'(CPE) framework or Progress Integration (PI) framework to link 'audit action' to 'system global bind entities'.

However, the policy frameworks differ from each other in binding audit-log policies to global entities. Previously, the audit module supported only Classic expression but now it supports both Classic and Advanced policy expressions. Currently, the Advanced expression can bind audit-log policies only to System global entities.

> **Note**
>
> When you bind a policy to global entities, you must bind it to a system global entity of the same expression. For example, you cannot bind a classic policy to an advanced global entity or bind an advanced policy to a classic global entity.
>
> Also, you cannot bind both classic audit-log policy and advanced audit-log policy to a load balancing virtual server.

Configuring audit-log policies in a Classic policy expression

Configuring audit-logging in Classic policy consists of the following steps:

1. **Configuring an audit-log action**. You can configure an audit action for different servers and for different log levels. 'Audit action' describes Audit Server configuration information whereas 'audit policy' links a bind entity to an 'audit action'. By default, the SYSLOG, and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the Citrix ADC appliance to store the logs. After which the logs are sent to the SYSLOG server.

2. **Configuring audit-log policy**. You can either configure SYSLOG policies to log messages to a SYSLOG server or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.
3. **Binding audit-log policies to global entities**. You must globally bind the audit log policies to global entities such SYSTEM, VPN, Citrix ADC AAA and so on. You can do it to enable logging of all Citrix ADC system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

Each of these steps is explained in the following sections.

Configuring audit-log action

To configure SYSLOG action in Advanced Policy infrastructure by using the command line interface.

> **Note**
>
> The Citrix ADC appliance allows you to configure only one SYSLOG action to SYSLOG server IP address and port. The appliance does not allow you to configure multiple SYSLOG actions to the same server IP address and port.

A syslog action contains a reference to a syslog server. It specifies which information to log and mentions how to log that information.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 -  add audit syslogAction <name> <serverIP> [-serverPort <port>] -
     logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-
     transport ( TCP | UDP )]`
2 -  show audit syslogAction [<name>]
3
4 <!--NeedCopy-->
```

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface

A ns log action contains a reference to a nslog server. It specifies which information to log and mentions how to log that information.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 -  add audit nslogAction <name> <serverIP> [-serverPort <port>] -
     logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )]
2 -  show audit nslogAction [<name>]
3 <!--NeedCopy-->
```

Configuring audit-log policies

To configure audit-log Policies in Classic Policy infrastructure by using the command line interface

At the command prompt, type:

```
1 -  add audit syslogpolicy <name> <-rule> <action>
2 -  add audit nslogpolicy <name> < rule> <action>rm audit nslogpolicy <
     name>show audit nslogpolicy [<name>]set audit nslogpolicy <name>  [-
     rule <expression>] [-action <name>]
3 <!--NeedCopy-->
```

Binding audit syslog policies to audit syslog global

To bind audit-log policy in Classic policy framework by using the command line interface

At the command prompt, type:

```
bind audit syslogGlobal <policyName> [-globalBindType <globalBindType
```

```
unbind audit syslogGlobal <policyName>[-globalBindType <globalBindType>]
```

Configuring audit-log policies using advanced policy expression

Configuring audit-logging in Advanced policy consists of the following steps:

1. **Configuring an audit-log action**. You can configure an audit action for different servers and for different log levels. 'Audit action' describes Audit Server configuration information whereas 'audit policy' links a bind entity to an 'audit action'. By default, the SYSLOG, and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the Citrix ADC appliance to store the logs. After which the logs are sent to the SYSLOG server.
2. **Configuring audit-log policy**. You can either configure SYSLOG policies to log messages to a SYSLOG server or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.
3. **Binding audit-log policies to global entities**. You must globally bind the audit log policies to SYSTEM global entity to enable logging of all Citrix ADC system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

> **Note**
>
> The Citrix ADC appliance evaluates all the policies that are bind to true.

Configuring audit-log action

To configure syslog action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 -  add audit syslogAction <name> <serverIP> [-serverPort <port>] -
     logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-
     transport ( TCP | UDP )]
2 -  show audit syslogAction [<name>]
3 <!--NeedCopy-->
```

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 -  add audit nslogAction <name> <serverIP> [-serverPort <port>] -
     logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )]
2 -  show audit nslogAction [<name>]
3 <!--NeedCopy-->
```

Configuring audit-log policies

To add a syslog audit action by using the command line interface

At the command prompt, type:

```
1     add audit syslogAction <name> (<serverIP> | ((<serverDomainName>[-
          domainResolveRetry <integer>])
2     | -lbVserverName <string>))[-serverPort <port>] -logLevel <logLevel
          >[-dateFormat <dateFormat>]
3      [-logFacility <logFacility>][-tcp ( NONE | ALL )] [-acl ( ENABLED
           | DISABLED )]
4     [-timeZone ( GMT_TIME | LOCAL_TIME )][-userDefinedAuditlog ( YES |
          NO )]
5      [-appflowExport ( ENABLED | DISABLED )] [-lsn ( ENABLED | DISABLED
           )][-alg ( ENABLED | DISABLED )]
6     [-subscriberLog ( ENABLED | DISABLED )][-transport ( TCP | UDP )]
          [-tcpProfileName <string>][-maxLogDataSizeToHold
7 <!--NeedCopy-->
```

Example

```
1      > add audit syslogaction audit-action1 10.102.1.1 -loglevel
          INFORMATIONAL -dateformat MMDDYYYY
2      > add audit nslogAction nslog-action1 10.102.1.3 -serverport 520 -
          loglevel INFORMATIONAL -dateFormat MMDDYYYY
3      > add audit syslogpolicy syslog-pol1 TRUE audit-action1
4      > add audit nslogPolicy nslog-pol1 TRUE nslog-action1
5      > bind system global nslog-pol1 -priority 20
6  <!--NeedCopy-->
```

To add a nslog audit action by using the command line interface

At the command prompt, type:

```
1      add audit nslogAction <name> (<serverIP> | (<serverDomainName>[-
          domainResolveRetry <integer>])) [-serverPort <port>]       -
          logLevel <logLevel> ... [-dateFormat <dateFormat>][-logFacility
          <logFacility>] [-tcp ( NONE | ALL )][-acl ( ENABLED | DISABLED )
          ] [-timeZone ( GMT_TIME | LOCAL_TIME )][-userDefinedAuditlog (
          YES | NO )][-appflowExport ( ENABLED | DISABLED )] [-lsn (
          ENABLED | DISABLED )][-alg ( ENABLED | DISABLED )] [-
          subscriberLog ( ENABLED | DISABLED )]`
2  <!--NeedCopy-->
```

Binding audit-log policies to global entities

To bind syslog audit-log policy in Advanced policy framework by using the command line interface

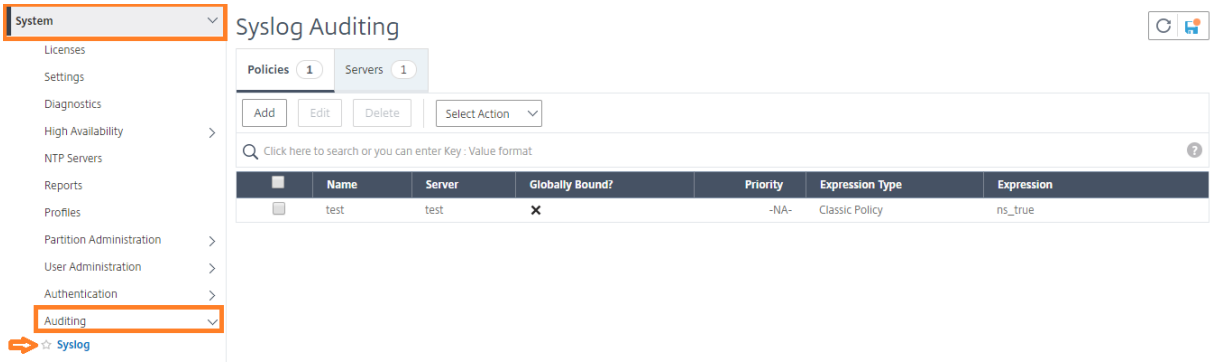
At the command prompt, type:

```
bind audit syslogGlobal <policyName> [-globalBindType <globalBindType
```

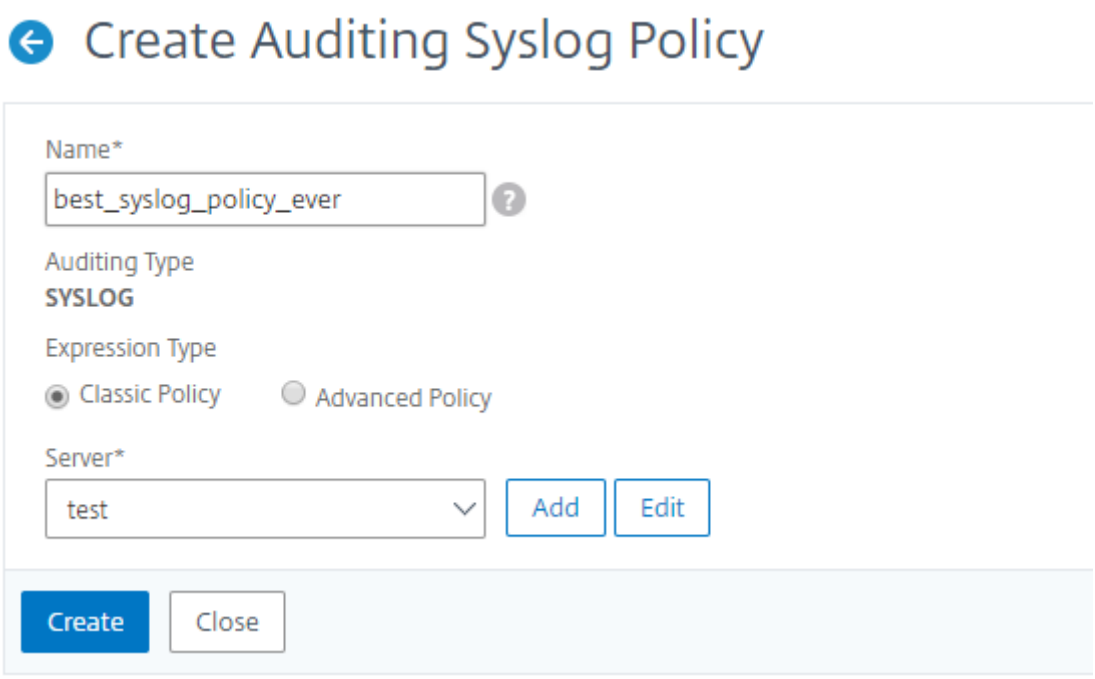
```
unbind audit syslogGlobal <policyName>[-globalBindType <globalBindType>]
```

Configuring audit-log policy by using the GUI

1. Navigate to **Configuration** > **System** > **Auditing** > **Syslog**.



1. Select **Servers** tab.
2. Click **Add**.
3. In the **Create Auditing Server** page, populate the relevant fields, and click **Create**.
4. To add the policy, select the **Policies** tab, and click **Add**.
5. In the **Create Auditing Syslog Policy** page, populate the relevant fields, and click **Create**.



6. To bind the policy globally, select **Advanced Policy Global Bindings** from the drop-down list. Select the **best_syslog_policy_ever** policy. Click **Select**.
7. From the drop-down list, select the bind point as **SYSTEM_GLOBAL** and click **Bind**, and then click **Done**.

Configuring policy-based logging

You can configure policy-based logging for rewrite and responder policies. Audit messages are then logged in a defined format when the rule in a policy evaluates to TRUE. To configure policy-based logging, you configure an audit-message action that uses default syntax expressions to specify the format of the audit messages. And associate the action with a policy. The policy can be bound either globally or to a load balancing or content switching virtual server. You can use audit-message actions to log messages at various log levels, either in syslog format only or in both syslog and new nslog formats

Prerequisites

- User Configurable Log Messages (userDefinedAuditlog) option is enabled for when configuring the audit action server to which you want to send the logs in a defined format.
- The related audit policy is bound to system global.

Configuring an audit message action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and new ns log formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

```
add audit messageaction <name> <logLevel> <stringBuilderExpr> [-
    logtoNewnslog (YES|NO)] [-bypassSafetyCheck (YES|NO)]
<!--NeedCopy-->
```

```
add audit messageaction log-act1 CRITICAL '"Client:"+CLIENT.IP.SRC+"
    accessed "+HTTP.REQ.URL' -bypassSafetyCheck YES
<!--NeedCopy-->
```

To configure an audit message action by using the GUI

Navigate to **System > Auditing > Message Actions**, and create the audit message action.

Binding audit message action to a policy

After you have created an audit message action, you must bind it to a rewrite or responder policy. For more information about binding log message actions to a rewrite or responder policy, see Rewrite or Responder.

Installing and configuring the NSLOG server

September 14, 2021

During installation, the NSLOG server executable file (auditserver) is installed along with other files. The auditserver executable file includes options for performing several actions on the NSLOG server,

including running and stopping the NSLOG server. In addition, you use the auditserver executable to configure the NSLOG server with the IP addresses of the Citrix ADC appliances from which the NSLOG server will start collecting logs. Configuration settings are applied in the NSLOG server configuration file (auditlog.conf).

Then, you start the NSLOG server by executing the auditserver executable. The NSLOG server configuration is based on the settings in the configuration file. You can further customize logging on the NSLOG server system by making additional modifications to the NSLOG server configuration file (auditlog.conf).

> **Attention**:
>
> The version of the NSLOG server package must be the same as that of the Citrix ADC. For example, if the version of the Citrix ADC is 10.1 Build 125.9, the NSLOG server must also be of the same version.

The following table lists the operating systems on which the NSLOG server is supported.

Operating system	Software requirements	Remarks
Windows	Windows XP Professional, Windows Server 2003, Windows 2000/NT, Windows Server 2008, Windows Server 2008 R2	
Linux	RedHat Linux 4 or later, SUSE Linux Enterprise 9.3 or later	
FreeBSD	FreeBSD 6.3 or later	For Citrix ADC 10.5, use only FreeBSD 8.4.
Mac OS	Mac OS 8.6 or later	Not supported on Citrix ADC 10.1 and later releases.

The minimum hardware specifications for the platform running the NSLOG server are as follows:

- Processor- Intel x86 ~501 megahertz (MHz)
- RAM - 512 megabytes (MB)
- Controller - SCSI

Installing NSLOG server on the Linux operating system

Log on to the Linux system as an administrator. Use the following procedure to install the NSLOG server executable files on the system.

To install the NSLOG server package on a Linux operating system

1. At a Linux command prompt, type the following command to copy the NSauditserver.rpm file to a temporary directory:

   ```
   cp <path_to_cd>/Utilities/auditserver/Linux/NSauditserver.rpm /tmp
   ```

2. Type the following command to install the NSauditserver.rpm file.

   rpm -i NSauditserver.rpm

   This command extracts the files and installs them in the following directories:

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

To uninstall the NSLOG server package on a Linux operating system

1. At a command prompt, type the following command to uninstall the audit server logging feature:

   ```
   rpm -e NSauditserver
   ```

2. For more information about the NSauditserver RPM file, use the following command:

   ```
   rpm -qpi \*.rpm
   ```

3. To view the installed audit server files use the following command:

   ```
   rpm -qpl *.rpm
   ```

   *.rpm: Specifies the file name.

Installing NSLOG server on the FreeBSD operating system

Before you can install the NSLOG server, you have to copy the NSLOG package from the Citrix ADC product CD or download it from www.citrix.com. The NSLOG package has the following name format:

```
AuditServer_<release number>-<build number>.zip
```

For example: `AuditServer_10.5-58.11.zip`

This package contains files for all supported platforms: Linux, Windows, and FreeBSD. On a FreeBSD operating system, install the NSLOG package that has the following name format:

```
audserver_bsd-<release number>-<build number>.tgz
```

For example: `audserver_bsd-10.5-58.11.tgz`

To download NSLOG package from www.citrix.com:

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click **Log In**.
3. Enter your login credentials, and then click **Log In**.
4. In the menu bar, click **Downloads**.
5. From the **Select a product** list, select **Citrix ADC**.
6. On the **Citrix ADC** page, select the release for which you want to download the NSLOG package (for example, Release 10.5), and then select **Firmware**.
7. Under **Firmware**, select the Citrix ADC firmware for the build number for which you want to download the NSLOG package.
8. On the page that appears, scroll down, select **Audit Servers**, and click **Download File** next to the package that you want to download.

To install the NSLOG server package on a FreeBSD operating system

1. On the system to which you have downloaded the NSLOG package `AuditServer_<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`), extract the `FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz` (for example, `audserver_bsd-9.3-51.5.tgz`) from the package.
2. Copy the FreeBSD NSLOG server package `audserver_bsd-<release number>-<build number>.tgz` (for example, `audserver_bsd-9.3-51.5.tgz`) to a directory on a system running FreeBSD OS.
3. At a command prompt for the directory into which the FreeBSD NSLOG server package was copied, run the following command to install the package:

   `pkg_add audserver_bsd-<release number>-<build number>.tgz`

   Example:

   ```
   pkg_add audserver_bsd-9.3-51.5.tgz
   <!--NeedCopy-->
   ```

   The following directories are extracted:

   - `<root directory extracted from the FreeBSD NSLOG server package tgz file>Citrix ADCbin` (for example, `/var/auditserver/netscaler/bin`)
   - `<root directory extracted from the FreeBSD NSLOG server package tgz file>netscaler/etc` (for example, `/var/auditserver/netscaler/etc`)
   - `<root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\samples` (for example, `/var/auditserver/samples`)
4. At a command prompt, type the following command to verify that the package is installed:

   `pkg_info | grep NSaudserver`

To uninstall the NSLOG server package on a FreeBSD operating system

At a command prompt, type:

```
pkg_delete NSaudserver
```

Installing NSLOG Server Files on the Windows Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the Citrix ADC product CD or download it from www.citrix.com. The NSLOG package has the following name format `AuditServer _<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`). This package contains NSLOG installation packages for all supported platforms.

To download NSLOG package from www.Citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format `AuditServer_<release number>-<build number>.zip`, to your local system (for example, `AuditServer_9.3-51.5.zip`).

To install NSLOG server on a Windows operating system

1. On the system, where you have downloaded the NSLOG package `AuditServer_<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`), extract `audserver_win-<release number>-<build number>.zip` (for example, `audserver_win-9.3-51.5.zip`) from the package.
2. Copy the extracted file `audserver_<release number>-<build number>.zip` (for example, `audserver_win-9.3-51.5.zip`) to a Windows system on which you want to install the NSLOG server.
3. Unzip the `audserver_<release number>-<build number>.zip` file (for example, `audserver_win-9.3-51.5.zip`).
4. The following directories are extracted:
   a) `<root directory extracted from the Windows NSLOG server package zip file>\bin`(for example, `C:\audserver_win-9.3-51.5\bin`)
   b) `<root directory extracted from the Windows NSLOG server package zip file>\etc` (for example, `C:\audserver_win-9.3-51.5\etc`)

c) <root directory extracted from the Windows NSLOG server **package** zip file>\samples (for example, C:\audserver_win-9.3-51.5\samples)

5. At a command prompt, run the following command from the <root directory extracted from the Windows NSLOG server **package** zip file>\bin path

   audserver -install -f <directorypath>\auditlog.conf

   <directorypath>: Specifies the path to the configuration file (auditlog.conf). By default, log.conf is under \<root directory extracted from Windows NSLOG server **package** zip file\>\samples directory. But you can copy auditlog.conf to your desired directory.

To uninstall the NSLOG server on a Windows operating system

At a command prompt, run the following from the <root directory extracted from Windows NSLOG server **package** zip file>\bin path:

```
audserver -remove
```

NSLOG Server Command Options

For information about NSLOG server commands, see Audit Server Options.

Run the audserver command from the directory in which the audit server executable is present:

- On Windows: \ns\bin
- On Solaris and Linux:\usr\local\netscaler\bin

The audit server configuration files are present in the following directories:

- On Windows: \ns\etc
- On Linux: \usr\local\netscaler\etc

The audit server executable is started as ./auditserver in Linux and FreeBSD.

Adding the Citrix ADC Appliance IP Addresses on the NSLOG Server

In the configuration file (auditlog.conf), add the IP addresses of the Citrix ADC appliances whose events must be logged.

To add the IP addresses of the Citrix ADC appliance

At a command prompt, type the following command:

```
audserver -addns -f <directorypath\>\auditlog.conf
```

<directorypath>: Specifies the path to the configuration file (auditlog.conf).

You are prompted to enter the information for the following parameters:

NSIP: Specifies the IP address of the Citrix ADC appliance, for example, 10.102.29.1.

Userid: Specifies the user name, for example, nsroot.

Password: Specifies the password, for example, nsroot.

If you add multiple Citrix ADC IP addresses (NSIP), and later you do not want to log all of the Citrix ADC appliance event details, you can delete the NSIPs manually by removing the NSIP statement at the end of the auditlog.conf file. For a high availability (HA) setup, you must add both primary and secondary Citrix ADC IP addresses to auditlog.conf by using the audserver command. Before adding the IP address, make sure the user name and password exist on the system.

Verifying the NSLOG Server Configuration File

Check the configuration file (audit log.conf) for syntax correctness to enable logging to start and function correctly.

To verify configuration, at a command prompt, type the following command:

```
audserver -verify -f <directorypath>\auditlog.conf
```

<directorypath>: Specifies the path to the configuration file (audit log.conf).

Running the NSLOG server

September 14, 2021

To start audit server logging

Type the following command at a command prompt:

audserver -start -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (audit log.conf).

To stop audit server logging that starts as a background process in FreeBSD or Linux

Type the following command:

```
audserver -stop
```

To stop audit server logging that starts as a service in Windows

Type the following command:

```
audserver -stopservice
```

Customizing logging on the NSLOG server

September 14, 2021

You can customize logging on the NSLOG server by making additional modifications to the NSLOG server configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the server system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information from a Citrix ADC appliance or a set of Citrix ADC appliances.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

- Creating Filters
- Specifying Log Properties

Creating filters

You can use the default filter definition located in the configuration file (audit log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

> Note:
> For consolidated logging, if a log transaction occurs for which there is no filter definition, the default filter is used (if it is enabled.) The only way you can configure consolidated logging of all the Citrix ADC appliances is by defining the default filter.

To create a filter

At the command prompt, type the following command in the configuration file (auditlog.conf):

```
1 filter <filterName> [IP <ip>] [NETMASK <mask>] ON | OFF]
2 <!--NeedCopy-->
```

filterName: Specify the name of the filter (maximum of 64 alphanumeric characters).

ip: Specify the IP addresses.

mask: Specify the subnet mask to be used on a subnet.

Specify ON to enable the filter to log transactions, or specify OFF to disable the filter. If no argument is specified, the filter is ON.

Examples:

```
filter F1 IP 192.168.100.151 ON
<!--NeedCopy-->
```

To apply the filter F2 to IP addresses 192.250.100.1 to 192.250.100.254:

```
filter F2 IP 192.250.100.0 NETMASK 255.255.255.0 ON
<!--NeedCopy-->
```

filterName is a required parameter if you are defining a filter with other optional parameters, such as IP address, or the combination of IP address and Netmask.

Specifying log properties

Log properties associated with the filter are applied to all the log entries present in the filter. The log property definition starts with the key word BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
    logFilenameFormat ...
    logDirectory ...
    logInterval ...
    logFileSizeLimit ....
END
<!--NeedCopy-->
```

Entries in the definition can include the following:

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: A constant string that specifies the absolute path and the file name.
  - Dynamic: An expression that includes the following format specifiers:
    - Date (%{format}t)
    - creates file name with NSIP

  Example:

```
LogFileNameFormat Ex%`{
`%m%d%y }
t.log
<!--NeedCopy-->
```

This creates the first file name as Exmmddyy.log. New files are named: Exmmddyy.log.0, Exmmddyy.log.1, and so on. In the following example, the new files are created when the file size reaches 100MB.

Example:

```
LogInterval size
LogFileSize 100
LogFileNameFormat Ex%`{
`%m%d%y }
t
<!--NeedCopy-->
```

> **Caution**
>
> The date format %t specified in the LogFilenameFormat parameter overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat parameter.

- **logDirectory** specifies the directory name format of the log file. The name of the file can be either of the following:
  - Static: Is a constant string that specifies the absolute path and file name.
  - Dynamic: Is an expression containing the following format specifiers:
    - Date (%{format}t)
    - creates directory with NSIP

  The directory separator depends on the operating system. In Windows, use the directory separator.

  Example:

  ```
  LogDirectory dir1\dir2\dir3
  <!--NeedCopy-->
  ```

  In the other operating systems (Linux, FreeBsd, and so forth.), use the directory separator.

- **LogInterval** specifies the interval at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour. Default value.

- Daily: A file is created very day at midnight.
- Weekly: A file is created every Sunday at midnight.
- Monthly : A file is created on the first day of the month at midnight.
- None: A file is created only once, when audit server logging starts.
- Size: A file is created only when the log file size limit is reached.

Example:

```
1  LogInterval Hourly
2  <!--NeedCopy-->
```

- **LogFileSizeLimit** specifies the maximum size (in MB) of the log file. A new file is created when the limit is reached.

> **Note**
>
> You can override the loginterval property by assigning size as its value.

The default LogFileSizeLimit is 10 MB.

Example:

```
1  LogFileSizeLimit 35
2  <!--NeedCopy-->
```

SYSLOG Over TCP

September 14, 2021

Syslog is a standard for sending event notification messages. These messages can be stored locally or on an external log server. Syslog enables network administrators to consolidate log messages and derive insights from the collected data.

Syslog is originally designed to work over UDP, which can transmit a huge amount of data within the same network with minimal packet loss. However, telco operators prefer to transmit syslog data over TCP, because they need reliable, ordered data transmission between networks. For example, telco tracks user activities, and TCP provides retransmission in the event of network failure.

How Syslog over TCP works

To understand how syslog over TCP works, consider two hypothetical cases:

Sam, a network administrator, wants to log significant events on an external syslog server.

XYZ Telecom, an ISP, has to transmit and store a significant amount of data on syslog servers to comply with government regulations.

In both cases, the log messages must be transmitted over a reliable channel and stored safely on an external syslog server. Unlike UDP, TCP establishes a connection, transmits messages securely, and retransmits (from sender to receiver) any data that is corrupted or lost because of network failure.

The Citrix ADC appliance sends log messages over UDP to the local syslog daemon, and sends log messages over TCP or UDP to external syslog servers.

SNIP support for Syslog

When the audit-log module generates syslog messages, it uses a Citrix ADC IP (NSIP) address as the source address for sending the messages to an external syslog server. To configure a SNIP as the source address, you must make it part of the netProfile option and bind the netProfile to the syslog action.

> **Note**
>
> TCP uses SNIP for sending monitoring probes to check the connectivity and then sends the logs over NSIP. Hence the syslog server must be reachable via SNIP. Net profiles can be used to redirect all the TCP syslog traffic through SNIP entirely.

Use of a SNIP address is not supported in internal logging.

Fully qualified domain name Support for audit Log

Previously, the audit-log module was configured with the destination IP address of the external syslog server to which the log messages are sent. Now, the audit-log server uses a fully qualified domain name (FQDN) instead of the destination IP address. The FQDN configuration resolves the configured domain name of the syslog server to the corresponding destination IP address for sending the log messages from the audit-log module. The name server must be properly configured to resolve the domain name and avoid domain based service issues.

> **Note**
>
> When configuring an FQDN, server domain name configuration of the same Citrix ADC appliance in syslog action or nslog action is not supported.

Configuring Syslog over TCP by using the Command Line Interface

To configure a Citrix ADC appliance to send syslog messages over TCP by using the command line interface

At the command prompt, type:

```
1     add audit syslogAction <name> (<serverIP> | ((<serverDomainName>[-
          domainResolveRetry <integer>]) | -lbVserverName<string>))[-
          serverPort <port>] -logLevel <logLevel>[-dateFormat <dateFormat
          >] [-logFacility <logFacility>]   [-tcp ( NONE | ALL )] [-acl (
          ENABLED | DISABLED )][-timeZone ( GMT_TIME | LOCAL_TIME )][-
          userDefinedAuditlog ( YES | NO )][-appflowExport ( ENABLED |
          DISABLED )] [-lsn ( ENABLED | DISABLED )][-alg ( ENABLED |
          DISABLED )] [-subscriberLog ( ENABLED | DISABLED )][-transport (
           TCP | UDP )] [-tcpProfileName <string>][-maxLogDataSizeToHold <
          positive_integer>][-dns ( ENABLED | DISABLED )] [-netProfile <
          string>]
2 <!--NeedCopy-->
```

```
1     add audit syslogaction audit-action1 10.102.1.1 -loglevel
          INFORMATIONAL -dateformat MMDDYYYY -transport TCP
2 <!--NeedCopy-->
```

Adding SNIP IP address to net profile option by using the command line interface

To add a SNIP IP address to the net profile by using the command line interface

At the command prompt, type:

```
1     add netProfile <name> [-td <positive_integer>] [-srcIP <string>][-
          srcippersistency ( ENABLED | DISABLED )][-overrideLsn ( ENABLED
          | DISABLED )]add syslogaction <name> <serverIP>  - loglevel all
           - netprofile net1
2 <!--NeedCopy-->
```

```
1     add netprofile net1  - srcip 10.102.147.204`
2 <!--NeedCopy-->
```

Where, srcIP is the SNIP.

Adding net profile in a syslog action by using the command line interface

To add a netProfile option in a syslog action by using the command line interface

At the command prompt, type:

```
1      add audit syslogaction <name> (<serverIP> | -lbVserverName <string
           >)  -logLevel <logLevel>
2     -netProfile <string> …
```

```
3
4 <!--NeedCopy-->
```

```
1     add syslogaction sys_act1 10.102.147.36 -loglevel all -netprofile
          net1
2 <!--NeedCopy-->
```

Where, -netprofile specifies the name of the configured net profile. The SNIP address is configured as part of the netProfile and this netProfile option is bound to the syslog action.

> **Note**
>
> You must always bind the netProfile option to the SYSLOGUDP or SYSLOGTCP services bound to the SYSLOGUDP or SYSLOGTCP load balancing virtual server, when an LB virtual server name is configured in syslog action.

Configuring FQDN support by using the command line interface

To add a server domain name to a Syslog action by using the command line interface

At the command prompt, type:

```
1 add audit syslogAction <name> (<serverIP> | ((<serverDomainName>[-
     domainResolveRetry <integer>]) | -lbVserverName <string>)) -logLevel
      <logLevel> ...
2     set audit syslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>]-
        serverDomainName <string>] [-lbVserverName <string>]-
        domainResolveRetry <integer>] [-domainResolveNow]
3 <!--NeedCopy-->
```

To add a server domain name to a Nslog action by using the command line interface.

At the command prompt, type:

```
1     add audit nslogAction <name> (<serverIP> | (<serverDomainName>[-
        domainResolveRetry <integer>]))  -logLevel <logLevel> ...
2     set audit nslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>][-
        serverDomainName <string>] [-domainResolveRetry <integer>][-
        domainResolveNow]
3 <!--NeedCopy-->
```

Where serverDomainName. Domain name of the log server. Is mutually exclusive with serverIP/ lbVserverName.

DomainResolveRetry integer. Time (in seconds) that the Citrix ADC appliance waits, after a DNS resolution fails, before sending the next DNS query to resolve the domain name.

DomainResolveNow. Included if the DNS query has to be sent immediately to resolve the server's domain name.

Configuring Syslog over TCP by using the GUI

To configure the Citrix ADC appliance to send Syslog messages over TCP by using the GUI

1. Navigate to **System** > **Auditing** > **Syslog** and select the **Servers** tab.
2. Click **Add** and select Transport Type as **TCP**.

Configuring a net profile for SNIP support by using the GUI

To configure net profile for SNIP support by using the GUI

1. Navigate to **System > Auditing > Syslog** and select the **Servers** tab.
2. Click **Add** and select a net profile from the list.

Configuring FQDN by using the GUI

To configure FQDN by using the GUI

1. Navigate to **System** > **Auditing** > **Syslog** and select the **Servers** tab.
2. Click **Add** and select a Server Type and Server Domain Name from the list.

Load balancing SYSLOG servers

September 14, 2021

The Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

At the command prompt, type:

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

```
add service <name>(<IP> | <serverName>)<serviceType (SYSLOGTCP |
SYSLOGUDP)> <port>
```

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGUDP, and load balancing method as AUDITLOGHASH.

   ```
   add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod
   <AUDITLOGHASH>]
   ```

3. Bing the service to the load balancing virtual server.

   ```
   Bind lb vserver <name> <serviceName>
   ```

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   ```
   add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel
    <logLevel>]
   ```

5. Add a SYSLOG policy by specifying the rule and action.

   ```
   add syslogpolicy <name> <rule> <action>
   ```

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   ```
   bind system global <policyName>
   ```

Load balancing of SYSLOG servers using the GUI

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

   Navigate to **Traffic Management** > **Services**, click **Add** and select **SYLOGTCP** or **SYSLOGUDP** as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

   Navigate to **Traffic Management** > **Virtual Servers**, click **Add** and select **SYLOGTCP** or **SYSLOGUDP** as protocol.

3. Bing the service to the load balancing virtual server to the service.

   Bing the service to the load balancing virtual server.

   Navigate to **Traffic Management** > **Virtual Servers**, select a virtual server and then select **AUDITLOGHASH** in the **Load Balancing Method.**

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   Navigate to **System** > **Auditing**, click **Servers** and add a server by selecting **LB Vserver** option in **Servers**.

5. Add a SYSLOG policy by specifying the rule and action.

   Navigate to **System** > **Syslog**, click **Policies** and add a SYSLOG policy.

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   Navigate to **System** > **Syslog**, select a SYSLOG policy and click **Action**, and then click **Global Bindings** and bind the policy to system global.

Example:

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. AUDITLOGHASH method load balances the traffic based on input hash value from the audit agents. The agents are the modules which generate auditlog in a Citrix ADC appliance. For example, if an agent LSN wants to load balance auditlogs based on client IP address, LSN module generates the hash value based on clientIP and passes the hash value to auditlog module. The auditlog module sends the auditlog messages which have same hash value to the external syslog server.

The Citrix ADC appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
add service service1 192.0.2.10 SYSLOGUDP 514
add service service2 192.0.2.11 SYSLOGUDP 514
add service service3 192.0.2.11 SYSLOGUDP 514
add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH
bind lb vserver lbvserver1 service1
bind lb vserver lbvserver1 service2
bind lb vserver lbvserver1 service3
add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All
add syslogpolicy syspol1 ns_true sysaction1
bind system global syspol1
<!--NeedCopy-->
```

Limitations:

- The Citrix ADC appliance does not support an external load balancing virtual server load balancing the SYSLOG messages among the log servers.

Default settings for the log properties

September 14, 2021

The following is an example of the default filter with default settings for the log properties:

```
begin default
 logInterval Hourly
 logFileSizeLimit 10
```

```
 logFilenameFormat  auditlog%`{
 `%y%m%d }
 t.log
 end default
<!--NeedCopy-->
```

Following are two examples of defining the default filters:

Example 1:

```
Filter f1 IP 192.168.10.1
<!--NeedCopy-->
```

This creates a log file for NSI 192.168.10.1 with the default values of the log in effect.

Example 2:

```
Filter f1 IP 192.168.10.1
begin f1
    logFilenameFormat logfiles.log
end f1
<!--NeedCopy-->
```

This creates a log file for NSIP 192.168.10.1. Since the log file name format is specified, the default values of the other log properties are in effect.

Sample configuration file (audit.conf)

September 14, 2021

Following is a sample configuration file:

```
##############################
# This is the Auditserver configuration file
# Only the default filter is active
# Remove leading # to activate other filters
##############################
MYIP <NSAuditserverIP>
MYPORT 3023
#   Filter filter_nsip  IP <Specify the Citrix ADC IP address to filter
    on > ON
#   begin filter_nsip
#       logInterval         Hourly
#       logFileSizeLimit    10
```

```
#       logDirectory          logdir\%A\
#       logFilenameFormat   nsip%\\{
 \\%d%m%Y }
 t.log
#   end filter_nsip
Filter default
begin default
    logInterval      Hourly
    logFileSizeLimit    10
    logFilenameFormat   auditlog%\{
 \%y%m%d }
 t.log
end default
<!--NeedCopy-->
```

Web server logging

September 14, 2021

You can use the Web server logging feature to send logs of HTTP and HTTPS requests to a client system for storage and retrieval. This feature has two components:

- The Web log server, which runs on the Citrix ADC.
- The Citrix ADC Web Logging (NSWL) client, which runs on the client system.

When you run the Citrix ADC Web Logging (NSWL) client:

1. It connects to the Citrix ADC.
2. The Citrix ADC buffers the HTTP and HTTPS request log entries before sending them to the client.
3. The client can filter the entries before storing them.

To configure Web server logging, you first enable the Web logging feature on the Citrix ADC and configure the size of the buffer for temporarily storing the log entries. Then, you install NSWL on the client system. You then add the Citrix ADC IP address (NSIP) to the NSWL configuration file. You are now ready to start the NSWL client to begin logging. You can customize Web server logging by making additional modifications to the NSWL configuration file (log.conf).

Configuring the Citrix ADC for web server logging

September 14, 2021

To configure the Citrix ADC for web server logging you are required to only enable the Web Server Logging feature. Optionally, you can perform the following configurations:

- Modify the size of the buffer (default size is 16 MB) that stores the logged information before it is sent to the Citrix ADC Web Logging (NSWL) client.
- Specify the custom HTTP headers that you want to export to the NSWL client. You can configure a maximum of two HTTP request and two HTTP response header names.

To configure web server logging by using the command line interface

At the command prompt, perform the following operations:

- Enable the web server logging feature.

  ```
  enable ns feature WL
  ```

- [Optional] Modify the buffer size for storing the logged information.

  ```
  set ns weblogparam -bufferSizeMB <size>
  ```

  > **Note**:
  >
  > To activate your modification, you must disable and then re-enable the Web server logging feature.

- [Optional] Specify the custom HTTP header names that you want to export.

  ```
  set ns weblogparam [-customReqHdrs <string> ...] [-customRspHdrs <
  string> ...]
  ```

```
1     > enable ns feature WL
2     Done
3     > set ns weblogparam -bufferSizeMB 60
4     Done
5     > show ns weblogparam
6         Web Logging parameters:
7         Log buffer size:  60MB
8         Custom HTTP request headers: (none)
9         Custom HTTP response headers: (none)
10    Done
11    > set ns weblogparam -customReqHdrs req1 req2 -customRspHdrs res1
          res2
12    Done
13    > show ns weblogparam
14        Web Logging parameters:
15        Log buffer size:  60MB
16        Custom HTTP request headers: req1, req2
17        Custom HTTP response headers: res1, res2
```

```
18       Done
19  <!--NeedCopy-->
```

To configure web server logging by using the GUI

1. Navigate to **System** > **Settings** and perform the following operations:
   a) To enable the web server logging feature, click **Change Advanced Features** and select **Web Logging**.
   b) To modify the buffer size, click **Change Global System Settings** and under **Web Logging**, enter the buffer size.
   c) To specify the custom HTTP headers to be exported, click **Change Global System Settings** and under **Web Logging**, specify the header values.

Installing the Citrix ADC web logging (NSWL) client

September 14, 2021

When you install NSWL, the client executable file (NSWL) is installed along with other files. The NSWL executable file provides a list of options that you can use. For details, see Configuring the NSWL Client.

> **Attention**
>
> The version of the NSWL client must be the same as Citrix ADC. For example, if the version of the Citrix ADC is 10.1 Build 125.9, the NSWL client must also be of the same version. Also, the web logging (NSWL) client works on both 32 bit and on 64 bit server machines. The download page has only a 32 bit weblog client. The 64 bit weblog client is available on request, and recommends you to contact Citrix support for more information.

The following table lists the operating systems on which the NSWL client can be installed.

Operating system	Version	Hardware requirements	Remarks
Windows	Windows Server 2016 or later	Processor - x86/amd64 CPU (1 GHz or higher), RAM - 4 GB (or higher)	
macOS	macOS 8.6 or later	Not supported on Citrix ADC 10.1 and later releases.	

Operating system	Version	Hardware requirements	Remarks
Linux	Ubuntu, SUSE Linux, CentOS, Red Hat Enterprise Linux released in 2016 or later	Processor - x86/amd64 CPU (1 GHz or higher), RAM - 4 GB (or higher)	
Solaris	Solaris Sun OS 5.6 or later	Processor - UltraSPARC-IIi 400 MHz, RAM - 512 MB, Controller - SCSI	Not supported on Citrix ADC 10.5 and later releases.
FreeBSD	FreeBSD 6.3 or later	Processor - x86/amd64 CPU (1 GHz or higher), RAM - 4 GB (or higher)	For Citrix ADC 10.5, use only FreeBSD 8.4.
AIX	AIX 6.1	-	Not supported on Citrix ADC 10.5 and later releases.

If the NSWL client system cannot process the log transaction because of a CPU limitation, the Web log buffer overruns and the logging process reinitiates.

> **Caution**
>
> Reinitiation of logging can result in loss of log transactions.

To temporarily solve an NSWL client system bottleneck caused by a CPU limitation, you can tune the Web server logging buffer size on the Citrix ADC appliance. To solve the problem, you need a client system that can handle the site's throughput.

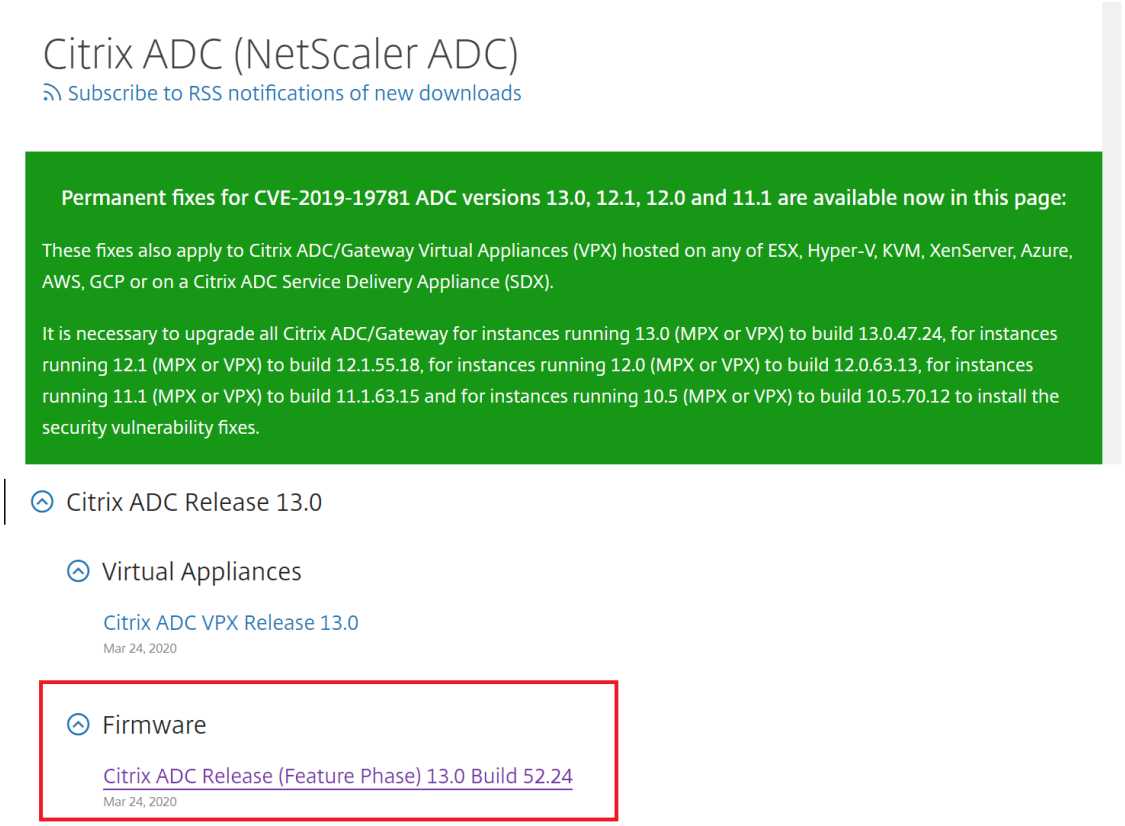
Download NSWL client

You can obtain the NSWL client package from either the Citrix ADC product CD or the Citrix downloads site. Within the package there are separate installation packages for each supported platform.

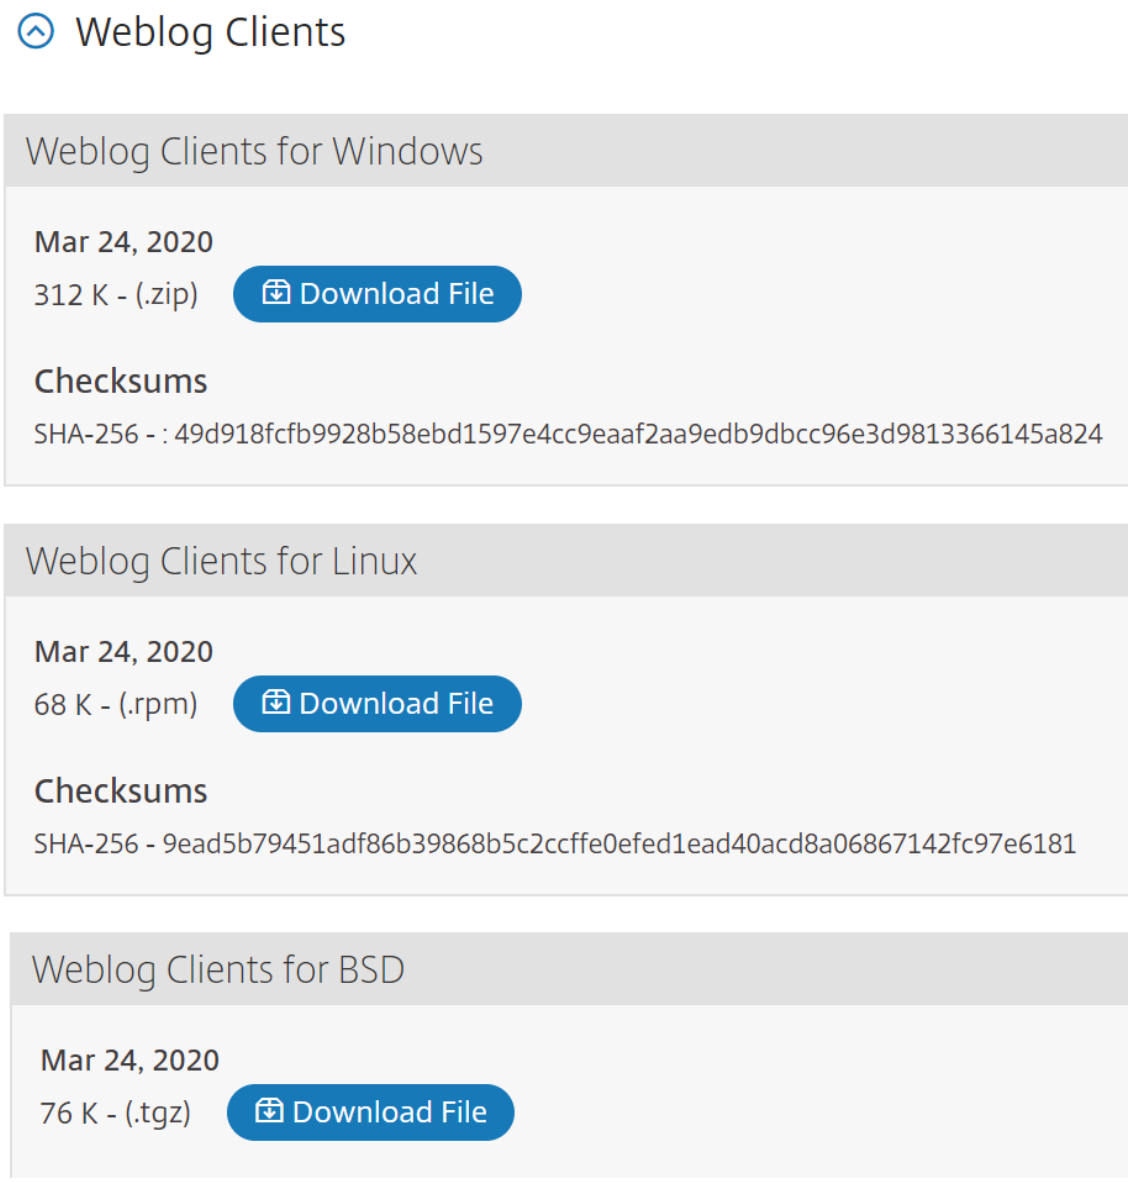
To download the NSWL client from the Citrix website

1. Log on to Citrix by accessing the URL `https://www.citrix.com/downloads/citrix-adc/`.

2. Navigate to a particular Citrix ADC release version and look for its Firmware.
3. Click **Firmware** (for example, Citrix ADC Release (Feature Phase) 13.0 Build 52.24).



4. In the **Citrix ADC Release (Feature Phase) Build** page, go to **Weblog Clients** section.
5. The section allows you to download Weblog clients for Windows, Linux, and BSD.



Install NSWL client on Solaris

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_solaris-<release number>-<build number>.tar file` from the package.
2. Copy the extracted file to a Solaris system on which you want to install the NSWL client.
3. Extract the files from the tar file with the following command:

   ```
   tar xvf nswl_solaris-9.3-51.5.tar
   ```

A directory Weblog is created in the temporary directory, and the files are extracted to the Weblog directory.

- Install the package with the following command:

  ```
  pkgadd -d
  ```

- The list of available packages appears. In the following example, one Weblog package is shown:

  ```
  1 NSweblog Citrix ADC Weblogging (SunOS,sparc)7.0
  ```

You are prompted to select the packages. Select the package number of the Weblog to be installed.

After you select the package number and press **Enter**, the files are extracted and installed in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

1. To check whether the NSWL package is installed, run the following command:

   ```
   pkginfo | grep NSweblog
   ```

2. To uninstall the NSWL package, run the following command:

   ```
   pkgrm NSweblog
   ```

Install NSWL client on Linux

> **Important**
>
> The installation of an NSWL client on Linux replaces the configuration file. You must take a backup before installing it.

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_linux-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running Linux OS, on which you want to install the NSWL client.
3. To install the NSWL package, run the following command:

   ```
   rpm -i nswl_linux-9.3-51.5.rpm
   ```

This command extracts the files and installs them in the following directories.

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

1. To uninstall the NSWL package, run the following command:

   ```
   rpm -e NSweblog
   ```

2. To get more information about the Weblog RPM file, run the following command:

   ```
   rpm -qpi *.rpm
   ```

3. To view the installed Web server logging files, run the following command:

   ```
   rpm -qpl *.rpm
   ```

Install NSWL client on FreeBSD

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_bsd-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running FreeBSD OS, on which you want to install the NSWL client.
3. To install the NSWL package, run the following command:

   ```
   pkg_add nswl_bsd-9.3-51.5.tgz
   ```

This command extracts the files and installs them in the following directories.

```
1 -  /usr/local/netscaler/etc
2 -  /usr/local/netscaler/bin
3 -  /usr/local/netscaler/samples
```

1. To uninstall the NSWL package, run the following command:

   ```
   pkg_delete NSweblog
   ```

2. To verify that the package is installed, run the following command:

   ```
   pkg_info | grep NSweblog
   ```

Install the NSWL client on Mac

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_macos-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running macOS, on which you want to install the NSWL client.

3. To install the NSWL package, run the following command:

   ```
   pkg_add nswl_macos-9.3-51.5.tgz
   ```

This command extracts the files and installs them in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

1. To uninstall the NSWL package, run the following command:

   ```
   pkg_delete NSweblog
   ```

2. To verify that the package is installed, run the following command:

   ```
   pkg_info | grep NSweblog
   ```

Install NSWL client on Windows

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_win-<release number>-<build number>.zip file from the package.
2. Copy the extracted file to a Windows system on which you want to install the NSWL client.
3. On the Windows system, unzip the file in a directory (referred as <NSWL-HOME>). The following directories are extracted: /bin, and /etc and /samples.
4. At the command prompt, run the following command from the <NSWL-HOME>\bin directory:

   ```
   nswl -install -f <directorypath>\log.conf
   ```

Where,

Directory path refers to the path of the configuration file (log.conf). By default, the file is in the <NSWL-HOME> and /etc directory. You can copy the configuration file to any other directory.

> **Note**
>
> To uninstall the NSWL client, at the command prompt, run the following command from the <NSWL-HOME>\bin directory:

```
1 > nswl -remove
```

Install NSWL client on AIX system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_aix-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running AIX OS, on which you want to install the NSWL client.
3. To install the NSWL package, run the following command:

   ```
   rpm -i nswl_aix-9.3-51.5.rpm
   ```

This command extracts the files and installs them in the following directories.

- `/usr/local/netscaler/etc`
- `/usr/local/netscaler/`
- `usr/local/netscaler/samples`

1. To uninstall the NSWL package, run the following command:

   ```
   rpm -e NSweblog
   ```

2. To get more information about the Weblog RPM file, run the following command:

   ```
   rpm -qpi *.rpm
   ```

3. To view the installed Web server logging files, run the following command:

   ```
   rpm -qpl *.rpm
   ```

Configure NSWL client

September 14, 2021

After you install the NSWL client, you can configure the NSWL client using the nswl executable. These configurations are stored in the NSWL client configuration file (log.conf).

> **Note:**
>
> You can further customize logging on the NSWL client by making additional modifications to the NSWL configuration file (log.conf). For details, see Customizing Logging on the NSWL Client System.

The following table describes the commands that you can use to configure the NSWL client.

NSWL command	Specifies
nswl -help	The available NSWL help options.
nswl -addns -f <path-to-configuration-file>	The system that gathers the log transaction data. You are prompted to enter the IP address of the Citrix ADC appliance. Enter a valid user name and password.
nswl -verify -f <path-to-configuration-file>	Check for syntax or semantic errors in the configuration file.
nswl -start -f <path-to-configuration-file>	Start the NSWL client based on the settings in the configuration file. Note: For Solaris and Linux: To start Web server logging as a background process, type the ampersand sign (&) at the end of the command.
nswl -stop (Solaris and Linux only)	Stop the NSWL client if it was started as a background process; otherwise, use CTRL+C to stop Web server logging.
nswl -install -f <path-to-configuration-file> (Windows only)	Install the NSWL client as a service in Windows.
nswl -startservice (Windows only)	Start the NSWL client by using the settings in the configuration file specified in the nswl install option. You can also start NSWL client from Start > Control Panel > Services. Note: The NSWL log files will be created in C:\Windows\SysWOW64.
nswl -stopservice (Windows only)	Stops the NSWL client.
nswl -remove	Remove the NSWL client service from the registry.

Run the following commands from the directory in which the NSWL executable is located:

- Windows: \ns\bin
- Solaris and Linux: \usr\local\netscaler\bin

The Web server logging configuration files are located in the following directory path:

- Windows: \ns\etc
- Solaris and Linux: \usr\local\netscaler\etc

The NSWL executable is started as .\nswl in Linux and Solaris.

Add the IP addresses of the Citrix ADC appliance

In the NSWL client configuration file (log.conf), add the Citrix ADC IP address (NSIP) from which the NSWL client will start collecting logs.

To add the NSIP address of the Citrix ADC appliance

1. At the client system command prompt, type:

   ```
   nswl -addns -f < directorypath > \log.conf
   < directorypath >: Specifies the path to the configuration file (log.
   conf).
   ```

2. At the next prompt, enter the following information:

   - **NSIP**: Specify the IP address of the Citrix ADC appliance.
   - User name and Password: Specify the nsroot user credentials of the Citrix ADC appliance.

> **Note**:
>
> If you add multiple Citrix ADC IP addresses (NSIP), and later you do not want to log all of Citrix ADC system log details, you can delete the NSIPs manually by removing the NSIP statement at the end of the log.conf file. During a failover setup, you must add both primary and secondary Citrix ADC IP addresses to the log.conf by using the command. Before adding the IP address, make sure the user name and password exist on the Citrix ADC appliances.

Verify the NSWL configuration file

To make sure that logging works correctly, check the NSWL configuration file (log.conf) on the client system for syntax errors.

To verify the configuration in the NSWL configuration file

At the client system command prompt, type:

```
nswl -verify -f <directorypath>\log.conf
```

< directorypath>: Specifies the path to the configuration file (log.conf).

Execute NSWL Client

Start Web server logging

At the client system command prompt, type:

```
nswl -start -f <directorypath>\log.conf
```

<directorypath>: Specifies the path to the configuration file (log.conf).

Stop Web server logging started as a background process on the Solaris or Linux operating systems

At the command prompt, type:

```
nswl -stop
```

To stop Web server logging started as a service on the Windows operating system

At the command prompt, type:

```
nswl -stopservice
```

Customize logging on the NSWL client system

September 14, 2021

You can customize logging on the Citrix ADC Web Logging (NSWL) client system by making more modifications to the NSWL client configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the client system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information based on the host IP address, domain name, and host name of the Web servers.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

Sample configuration file

Following is a sample configuration file:

```
1  ##########
2  # This is the NSWL configuration file
3  # Only the default filter is active
4  # Remove leading # to activate other filters
5  ##########
6  ##########
7  # Default filter (default on)
8  # W3C Format logging, new file is created every hour or on reaching 10
       MB file size,
9  # and the file name is Exyymmdd.log
10 ##########
11 Filter default
12 begin default
```

```
13          logFormat               W3C
14          logInterval             Hourly
15          logFileSizeLimit        10
16          logFilenameFormat       Ex%`{
17   `%y%m%d }
18   t.log
19  end default
20  ##########
21  # Citrix ADC caches example
22  # CACHE_F filter covers all the transaction with HOST name www.
       netscaler.com and the listed server ip's
23  ##########
24  #Filter CACHE_F HOST www.netscaler.com IP 192.168.100.89 192.168.100.95
        192.168.100.52 192.168.100.53 ON
25  ##########
26  # netscaler origin server example

93
94 ########## END FILTER CONFIGURATION ##########
95 <!--NeedCopy-->
```

Creating filters

You can use the default filter definition in the configuration file (log.conf), or you can modify the filter or create a filter. You can create more than one log filter.

> **Note**
>
> Consolidated logging, which logs transactions for which no filter is defined, uses the default filter if it is enabled. Consolidated logging of all servers can be done by defining only the default filter.

If the server hosts multiple websites and each website has its own domain name, and each domain is associated with a virtual server, you can configure Web server logging to create a separate log directory for each website. The following table displays the parameters for creating a filter.

Parameter	Specifies
filterName	Name of the filter. The filter name can include alphanumeric characters and cannot be longer than 59 characters. Filter names longer than 59 characters are truncated to 59 characters.
Host name	Host name of the server for which the transactions are being logged.
IP `ip`	IP address of the server for which transactions are to be logged (for example, if the server has multiple domains that have one IP address).
IP `ip 2...ip` n:	Multiple IP addresses (for example, if the server domain has multiple IP addresses).
ip6 IP	IPv6 address of the server for which transactions are to be logged.
IP ip NETMASK mask	IP addresses and netmask combination to be used on a subnet.
`ON | OFF`	Enable or disable the filter to log transactions. If no argument is selected, the filter is enabled (ON).

Table 1. Parameters for Creating a Filter

To create a filter

To create a filter, enter the following command in the log.conf file:

- `filter <filterName> <HOST name> | [IP<ip> ] | [IP<ip 2...ip n> ] | <IP ip NETMASK mask> [ON | OFF]`
- `filter <filterName> <HOST name> | [IP6 ip/<prefix length>] [ON | OFF]`

To create a filter for a virtual server

To create a filter for a virtual server, enter the following command in the log.conf file:

```
filter <filterName> <VirtualServer IP address>
```

Example

In the following example, you specify an IP address of 192.168.100.0 and netmask of 255.255.255.0. The filter applies to IP addresses 192.168.100.1 through 192.168.100.254.

```
1  Filter F1 HOST www.netscaler.com ON
2  Filter F2 HOST www.netscaler.com IP 192.168.100.151 ON
3  Filter F3 HOST www.netscaler.com IP 192.168.100.151 192.165.100.152 ON
4  Filter F4 IP 192.168.100.151
5  Filter F5 IP 192.168.100.151 HOST www.netscaler.com OFF
6  Filter F6 HOST www.netscaler.com HOST www.xyz.com HOST www.abcxyz.com
      IP 192.168.100.200 ON
7  Filter F7 IP 192.250.100.0 NETMASK 255.255.255.0
8  Filter F8 HOST www.xyz.com IP 192.250.100.0 NETMASK 255.255.255.0 OFF
9  For creating filters for servers having IPv6 addresses.
10 Filter F9 2002::8/112 ON
11 Filter F10 HOST www.abcd.com IP6 2002::8 ON
12
13 <!--NeedCopy-->
```

Specifying log properties

Log properties are applied to all log entries associated with the filter. The log property definition begins with the keyword BEGIN and ends with END as illustrated in the following example:

```
1 BEGIN <filtername>
2  logFormat ...
3  logFilenameFormat ...
```

```
 logInterval ...
 logFileSize ....
 logExclude ....
 logTime ….
 END
<!--NeedCopy-->
```

Entries in the definition can include the following:

- **LogFormat** specifies the Web server logging feature that supports NCSA, W3C Extended, and custom log file formats.

  By default, the `logformat` property is w3c. To override, enter custom or NCSA in the configuration file, for example:

```
     LogFormat NCSA
<!--NeedCopy-->
```

> **Note**
>
> For the NCSA and custom log formats, local time is used to time stamp transactions and for file rotation.

- **LogInterval** specifies the intervals at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour.
  - Daily: A file is created every day at midnight. Default value.
  - Weekly: A file is created every Sunday at midnight.
  - Monthly: A file is created on the first day of the month at midnight.
  - None: A file is created only once, when Web server logging starts.

Example:

```
LogInterval Daily
<!--NeedCopy-->
```

LogFileSizeLimit specifies the maximum size of the log file in MB. It can be used with any log interval (weekly, monthly, and so on.) A file is created when the maximum file size limit is reached or when the defined log interval time elapses.

To override this behavior, specify the size as the `loginterval` property so that a file is created only when the log file size limit is reached.

The default LogFileSizeLimit is 10 MB.

Example:

```
LogFileSizeLimit 35
<!--NeedCopy-->
```

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: Specifies a constant string that contains the absolute path and file name.

    Dynamic: Specifies an expression containing the following format:
    - Server IP address
    - Date (%{format}t)
    - URL suffix (%x)
    - Host name (%v)

Example:

```
LogFileNameFormat Ex%`{
 `%m%d%y }
 t.log
<!--NeedCopy-->
```

This command creates the first file name as Exmmddyy.log, then every hour creates a file with a file name: Exmmddyy.log.0, Exmmddyy.log.1,…, Exmmddyy.log.n.

Example:

```
      LogInterval size
      LogFileSize 100
      LogFileNameFormat Ex%`{
 `%m%d%y }
 t
<!--NeedCopy-->
```

> **Caution**
>
> The date format %t specified in the LogFilenameFormat command overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat.

- **LogExclude** prevents logging of transactions with the specified file name extensions.

Example:

```
      LogExclude .html
<!--NeedCopy-->
```

This command creates a log file that excludes log transactions for *.html files.

LogTime specifies log time as either GMT or LOCAL.

The defaults are:

- NCSA log file format: LOCAL
- W3C log file format: GMT.

Understanding NCSA and W3C log formats

The Citrix ADC supports the following standard log file formats:

- NCSA Common Log Format
- W3C Extended Log Format

NCSA Common Log Format

If the log file format is NCSA, the log file displays log information in the following format:

```
1 Client_IP_address -User_Name [Date:Time -TimeZone] "Method Object
     HTTP_version" HTTP_StatusCode BytesSent
2 <!--NeedCopy-->
```

To use the NCSA Common log format, enter NCSA in the LogFormat argument in the log.conf file.

The following table describes the NCSA Common log format.

Argument	Specifies
Client_IP_address	The IP address of the client computer.
User Name	The user name.
Date	The date of the transaction.
Time	The time when the transaction was completed.
Time Zone	The time zone (Greenwich Mean Time or local time).
Method	The request method (for example; GET, POST).
Object	The URL.
HTTP_version	The version of HTTP used by the client.
HTTP_StatusCode	The status code in the response.
Bytes Sent	The number of bytes sent from the server.

W3C extended log format

An extended log file contains a sequence of lines containing ASCII characters terminated by either a Line Feed (LF) or the sequence Carriage Return Line Feed (CRLF.) Log file generators must follow the line termination convention for the platform on which they are run.

Log analyzers must accept either LF or CRLF form. Each line might contain either a directive or an entry. If you want to use the W3C Extended log format, enter W3C as the Log-Format argument in the log.conf file.

By default, the standard W3C log format is defined internally as the custom log format, shown as follows:

```
%`{
 `%Y-%m-%d%H:%M:%S }
 t %a %u %S %A %p %m %U %q %s %j %J %T %H %+{
 user-agent }
 i %+{
 cookie }
  i%+{
 referer }
 i
<!--NeedCopy-->
```

You can also change the order or remove some fields in this W3C log format. For example:

```
logFormat W3C %`{
 `%Y-%m-%d%H:%M:%S }
 t %m %U
<!--NeedCopy-->
```

W3C log entries are created with the following format:

```
#Version: 1.0 #Fields: date time cs-method cs-uri #Date: 12-Jun-2001
   12:34 2001-06-12 12:34:23 GET /sports/football.html 2001-06-12
   12:34:30 GET /sports/football.html
<!--NeedCopy-->
```

Entries

Entries consist of a sequence of fields relating to a single HTTP transaction. Fields are separated by white space. Citrix recommends the use of tab characters. If a field in a particular entry is not used, a dash (-) marks the omitted field.

Directives

See the Directives table for the information about the logging process. Lines beginning with the pound sign (#) contain directives.

Example:

The following sample log file shows the log entries in W3C Extended log format:

```
1 #Version: 1.0 #Fields: time cs-method cs-uri #Date: 12-Jan-1996
     00:00:00 00:34:23 GET /sports/football.html 12:21:16 GET /sports/
     football.html 12:45:52 GET /sports/football.html 12:57:34 GET /
     sports/football.html
2 <!--NeedCopy-->
```

Fields

The Fields directive lists a sequence of field identifiers that specify the information recorded in each entry. Field identifiers might have one of the following forms:

- **identifier:** Relates to the transaction as a whole.
- **prefix-identifier:** Relates to information transfer between parties defined by the value prefix.
- **prefix (header):** Specifies the value of the HTTP header field header for transfer between parties defined by the value prefix. Fields specified in this manner always have the type.

The following table describes defined prefixes.

Prefix	Specifies
c	Client
s	Server
r	Remote
cs	Client to server
sc	Server to client
sr	Server to remote server (prefix used by proxies)
rs	Remote server to server (prefix used by proxies)
x	Application-specific identifier

Examples:

The following examples are defined identifiers that use prefixes:

cs-method: The method in the request sent by the client to the server.

sc(Referer): The `Referer` field in the reply.

c-ip: The IP address of the client.

Identifiers

The following table describes the W3C Extended log format identifiers that do not require a prefix.

Identifier	Description
date	The date on which the transaction was done.
time	The time when the transaction is done.
time-taken	The time taken (in seconds) for the transaction to complete.
bytes	The number of bytes transferred.
cached	Records whether a cache hit has occurred. A zero indicates a cache miss.

Table 5. W3C Extended Log Format Identifiers (No Prefix Required)

The following table describes the W3C Extended log format identifiers that require a prefix.

Identifier	Description
IP	The IP address and the port number.
DNS	The DNS name.
status	The status code.
comment	The comment returned with a status code.
method	The method.
url	The URL.
url-stem	The stem portion of the URL.
url-query	The query portion of the URL.

Table 6. W3C Extended Log Format Identifiers (Requires a Prefix)

The W3C Extended Log file format allows you to choose log fields. These fields are shown in the following table.

Field	Description
Date	The date on which the transaction is done.
Time	The time when the transaction is done.
Client IP	The IP address of the client.
User Name	The user name.
Service Name	The service name, which is always HTTP.
Server IP	The server IP address.
Server Port	The server port number
Method	The request method (for example; GET, POST).
Url Stem	The URL stem.
Url Query	The query portion of the URL.
HTTP Status	The status code in the response.
Bytes Sent	The number of bytes sent to the server (request size, including HTTP headers).
Bytes Received	The number of bytes received from the server (response size, including HTTP headers).
Time Taken	The time taken for a transaction to complete, in seconds.
Protocol Version	The version number of HTTP being used by the client.
User Agent	The User-Agent field in the HTTP protocol.
Cookie	The Cookie field of the HTTP protocol.
`Referer`	The `Referer` field of the HTTP protocol.

Table 7. W3C Extended Log File Format (Allows Log Fields)

Creating a custom log format

You can customize the display format of the log file data manually or by using the NSWL library. By using the custom log format, you can derive most of the log formats that Apache currently supports.

Creating a custom log format by using the NSWL library

Use one of the following NSWL libraries depending on whether the NSWL executable has been installed on a Windows or Solaris host computer:

- **Windows:** The nswl.lib library in the \ns\bin directory on the system manager host computer.
- **Solaris:** The libnswl.a library in /usr/local/netscaler/bin.

To create the custom log format by using the NSWL library

1. Add the following two C functions defined by the system in a C source file:

   ns_userDefFieldName(): This function returns the string that must be added as a custom field name in the log record.

   ns_userDefFieldVal(): This function implements the custom field value, then returns it as a string that must be added at the end of the log record.

2. Compile the file into an object file.
3. Link the object file with the NSWL library (and optionally, with third party libraries) to form a new NSWL executable.
4. Add a %d string at the end of the logFormat string in the configuration file (log.conf).

Example:

```
########## # A new file is created every midnight or on reaching 20MB
   file size, # and the file name is /datadisk5/netscaler/log/NS<
   hostname>/Nsmmddyy.log and create digital #signature field for each
   record. BEGIN CACHE_F logFormat custom "%a - "%{
 user-agent }
 i" [%d/%B/%Y %T -%g] "%x" %s %b%{
 referrer }
 i "%{
 user-agent }
 i" "%{
 cookie }
 i" %d " logInterval Daily logFileSizeLimit 20 logFilenameFormat /
    datadisk5/netscaler/log/%v/NS%`{
 `%m%d%y }
 t.log END CACHE_F
<!--NeedCopy-->
```

Creating a Custom log format manually

To customize the format in which log file data must appear, specify a character string as the argument of the LogFormat log property definition. The following is an example where character strings are used to create a log format:

```
LogFormat Custom ""%a - "%{
 user-agent }
 i" %[%d/%m/%Y]t %U %s %b %T"
<!--NeedCopy-->
```

- The string can contain the “c” type control characters \n and \t to represent new lines and tabs.
- Use the Esc key with literal quotes and backslashes.

The characteristics of the request are logged by placing % directives in the format string, which are replaced in the log file by the values.

If the %v (Host name) or %x (URL suffix) format specifier is present in a log file name format string, the following characters in the file name are replaced by an underscore symbol in the log configuration file name:

```
” *. /: < > ? \
```

Characters whose ASCII values lie in the range of 0-31 are replaced by the following:

%<ASCII value of character in hexadecimal>.

For example, the character with ASCII value 22 is replaced by %16.

> **Caution**
>
> If the %v format specifier is present in a log file name format string, a separate file is opened for each virtual host. To ensure continuous logging, the maximum number of files that a process can have open must be sufficiently large. See your operating system documentation for a procedure to change the number of files that can be opened.

Creating Apache log formats

You can derive from the custom logs most of the log formats that Apache currently supports. The custom log formats that match Apache log formats are:

NCSA/combined: LogFormat custom %h %l %u [%t] “%r” %s %B “%{referer}i” “%{user-agent}i”

NCSA/Common: LogFormat custom %h %l %u [%t] “%r” %s %B

Referer Log: LogFormat custom “%{referer}i” -> %U

User agent: LogFormat custom %{user-agent}i

Similarly, you can derive the other server log formats from the custom formats.

Arguments for defining a custom log format

See the Custom log format PDF table for more information about defining a custom log format.

> **Note**
>
> For instructions on how to export custom HTTP headers, see Configuring the Citrix ADC for Web Server Logging

For example, if you define the log format as %+{user-agent}i, and if the user agent value is Citrix ADC system Web Client, then the information is logged as Citrix ADC system+Web+Client. An alternative is to use double quotation marks. For example, "%{user-agent}i" logs it as "Citrix ADC system Web Client." Do not use the <Esc> key on strings from %.. .r, %. . .i and, %. . .o. It complies with the requirements of the Common Log Format. Clients can insert control characters into the log. Therefore, you must take care when working with raw log files.

Time format definition

See the Time format definition table to know about the format part of the %{format}t string described in the Custom Log Format table. Values within brackets ([ ]) show the range of values that appear. For example, [1,31] in the %d description in the following table shows %d ranges from 1 to 31.

> **Note**
>
> If you specify a conversion that does not correspond to any of the ones described in the preceding table, or to any of the modified conversion specifications listed in the next paragraph, the behavior is undefined and returns 0.

The difference between %U and %W (and also between modified conversions %OU and %OW) is the day considered to be the first day of the week. Week number 1 is the first week in January (starting with a Sunday for %U, or a Monday for %W). Week number 0 contains the days before the first Sunday or Monday in January for %U and %W.

Displaying server logs

You can configure an NSWL feature to display server logs on the console or redirect server logs to a directory on the Citrix ADC appliance.

There are two ways to display logs on the console (standard output):
Option 1: Display all logs on the console.
Option 2: Display only selected logs on the console with filters with `logfilenameformat` as STDOUT.

Call Home

September 14, 2021

Appliances might sometimes fail to perform well because of software or hardware issues. In such cases, Citrix needs to collect data and perform issue resolution before a potential impact can occur at the customer site. By enabling Call Home on your Citrix ADC appliance, you can automate the error notification process. Not only you avoid calling Citrix support, raising a service request, and uploading system data before the support team can troubleshoot the issue, but support can identify and address an issue before it occurs. Call Home periodically monitors the appliance and automatically uploads data to the Citrix technical support server. In addition, the incoming Call Home data provide insights about Citrix ADC usage. Multiple teams within Citrix can use this data to better design, support, and implement Citrix ADC.

By default, Call Home is enabled on all platforms and all flavors of Citrix ADC (MPX, VPX, SDX). By having this feature enabled, you allow Citrix to collect Citrix ADC deployment and telemetry data for better implementation, and support service.

> **Note**
>
> You can also see the Call Home FAQ page for information pertaining to Call Home.

Benefits

Call Home provides the following benefits.

- Monitor hardware and software error conditions. For more information, see Monitor critical error conditions section.
- Notify critical events that impact your network.
- Send performance data and system usage details to Citrix to:
  - Analyze and improve product quality.
  - Provide real-time troubleshooting information for proactive issue identification, and faster issue resolution.

Platform support

Call Home feature is supported on all Citrix ADC platforms and all appliance models (MPX, VPX, and SDX).

- Citrix ADC MPX: All MPX models.
- Citrix ADC VPX: All VPX models, including VPX appliances that obtain their license from external or central licensing pools.

- Citrix ADC SDX: Monitors the disk drive and assigned SSL chips for any errors or failures. The VPX instances, however, do not have access to the Power Supply Unit (PSU) and therefore their status is not monitored. In an SDX platform, you can configure Call Home either directly on an individual instance or through the SVM.

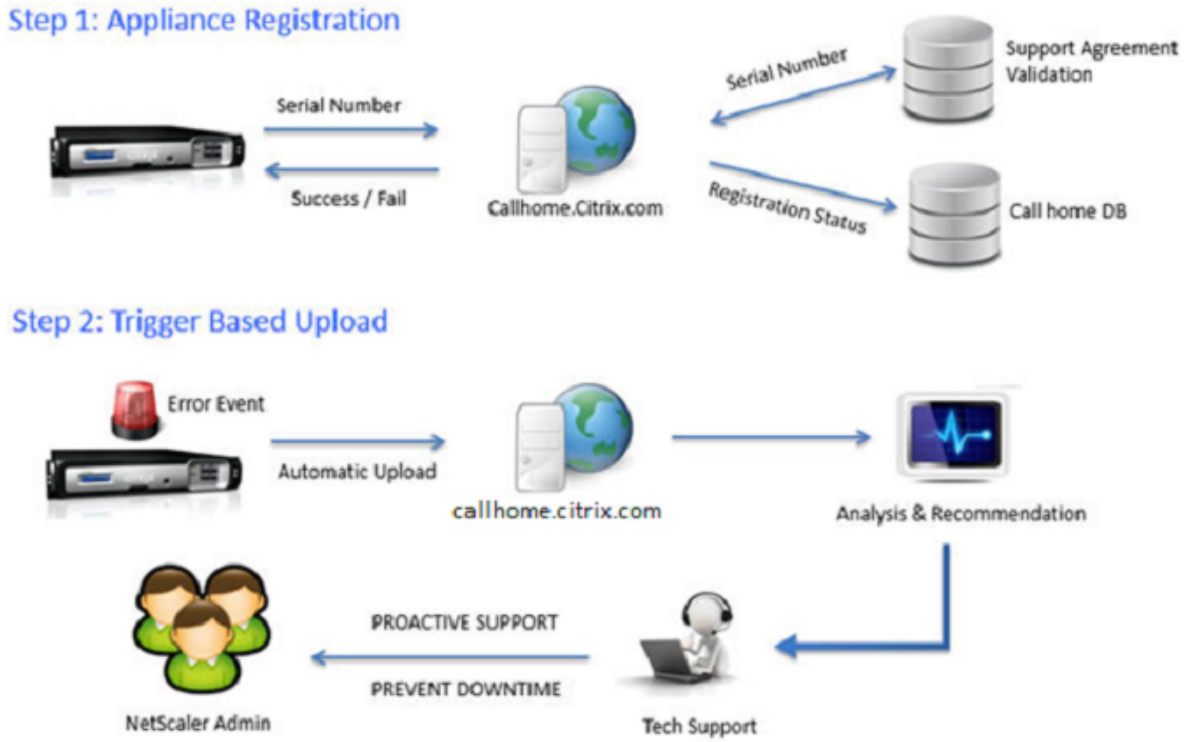
Prerequisites

To use Call Home, the Citrix ADC appliance must have the following:

- **Internet connection.** Call Home requires an internet connection for the Citrix ADC to connect to the Citrix support server for uploading a data archive.

How Call Home works

The following figure shows a basic workflow of Call Home in a Citrix ADC appliance deployed at a customer site.



The following are the workflow of a Call Home:

1. Set up Internet Connectivity. For Call Home to upload system data, your appliance must have an internet connectivity. If it does not, you can configure a proxy server configuration to provide internet connectivity. For more information, see Configuring Call Home section.

2. Enable Call Home. When upgrading your appliance to the latest software through either Citrix ADC command interface or GUI, Call Home is enabled by default and the system delays the registration process by 24 hours. During this period, you can choose to manually disable the feature, but Citrix recommends you to have it enabled.

> **Note**
>
> If you are upgrading your appliance from an older version that explicitly has Call Home disabled, the system still enables the feature by default and displays a notification message on your first login.

In addition, if you are doing any configuration changes for an internet connectivity, you must disable and enable Call Home. It enables Call Home to register with the Citrix Insight Services (CIS) server without any failure errors.

3. Register the Citrix ADC appliance on the Citrix Support Server. When Call Home registers the appliance with the Citrix Support server, the server checks the database for the validity of the appliance serial number. If the serial number is valid, the server registers the appliance for Call Home service and sends a successful registration response. Otherwise, the server sends back a registration failure message. The basic system information is sent as a separate message. The data includes memory and CPU usage details along with the throughput numbers. The data is sent periodically as part of the heartbeat message every 7 days, by default. However, a value of less than 5 days is not recommended, because frequent uploads are not useful.

4. Monitor critical error conditions. Once registered, Call Home starts monitoring the appliance. The following table lists the conditions Call Home can monitor on the appliance.

Critical Error Condition	Description	Call Home Monitoring Interval	Corresponding SNMP Alarm Name
Compact flash drive errors	The compact flash drive on the appliance encountered read or write failures.	24 hours	COMPACT-FLASH-ERRORS
Hard disk drive errors	The hard drives on the appliance encountered read or write failures.	24 hours	HARD-DISK-DRIVE-ERRORS
Power supply unit failure	One of the power supply units on the Citrix ADC appliance has failed.	7 seconds	POWER-SUPPLY-FAILURE

Critical Error Condition	Description	Call Home Monitoring Interval	Corresponding SNMP Alarm Name
SSL card failure	One of the SSL cards on the Citrix ADC appliance has failed.	7 seconds	SSL-CARD-FAILED
Warm restart	The appliance has warm restarted due to a failure of a system process.	After every restart of the Citrix ADC appliance.	WARM-RESTART-EVENT
Memory anomaly error	Memory utilization progressively increases above its normal limit and exceeds the threshold.	1 day	No SNMP alarm
Rate limit packet drop	The throughput limits or packets-per-second (pps) limits is reached.	7 seconds	PF-RL-PPS-PKTS-DROPPED, PF-RL-RATE-PKTS-DROPPED

5. Upload Call Home data. If any one of the previous critical conditions is identified on the appliance, the Call Home feature automatically notifies the Citrix support. The support archives are uploaded to the Citrix support server. Also, you can configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever Call Home upload happens. The SNMP alert notifies the local administrator about the critical event.

> **Note**
>
> Call Home creates the Call Home tar file and uploads it to the Citrix tech support server for only the first occurrence of a particular error condition since the last reboot. If you want the appliance to send alerts each time a particular error condition occurs, configure the corresponding SNMP alarm for the error condition.

6. Create Service Request. Call Home automatically creates a service request for all the critical hardware related events. The events are classified as; power supply failure, SSL card failure, hard disk drive errors, and compact flash errors. For other errors, after you review the System Logs, you can contact the Citrix support team to raise a service request for investigation.

Configuring Call Home

To configure Call Home, verify the internet connectivity on the appliance and ensure a DNS name-server is configured. If there is no internet connection, configure a proxy server or service. Then, enable Call Home on the appliance and verify the registration status of the appliance with the Citrix support server. Once registered, Call Home can monitor and upload data. In addition, you can configure SNMP alarms to notify the administrator at the customer site.

To configure Call Home, you can use either the Citrix ADC command interface or the GUI to do the following tasks:

- Enable Call Home.
- Configure Call Home for optional proxy server parameters.
- Verify Call Home Registration Status.
- View errors and timestamp details.
- Configure SNMP Alarms.

To configure Call Home by using the Citrix ADC command interface

The Citrix ADC command interface enables you to do the following:

`Enabling Call Home`

At the command prompt, type:

```
enable ns feature callhome
```

Configuring Call Home for optional proxy server parameters

Call Home enables you to configure the optional proxy server for internet connectivity. You can either configure a proxy server with IP address and port or configure a proxy authentication service with one-way or two-way authentication.

`To configure optional proxy server with IP address and port`

At the command prompt, type:

```
set callhome -proxyMode ( YES | NO )[-IPAddress <ip_addr|ipv6_addr|*>] [-port <port |*>]
```

```
1 set callhome -proxyMode YES -IPAddress 10.102.167.33 -port 80
2 <!--NeedCopy-->
```

> **Note**
>
> Call Home uses the proxy server only when you set the proxy-mode parameter to YES. If you set

> it to NO, the proxy functionality does not work, even if the IP address and port are configured. The port number must be for an HTTP service, not for an HTTPS service.

To configure optional proxy authentication service

This mode provides two types of security authentication: one-way and two-way. To set up either type, you must configure an SSL service. For more information, see Configuring an SSL Service topic.

In one-way authentication, only the Citrix ADC appliance authenticates the proxy server. In two-way authentication, the Citrix ADC appliance authenticates the proxy server and the proxy server, in turn, authenticates the appliance.

To configure proxy authentication service

At the command prompt, type:

```
set callhome -proxyMode ( YES | NO )[-proxyAuthService <string>]
```

```
1 set callhome  -proxyMode YES  -proxyAuthService callhome_proxy
2 <!--NeedCopy-->
```

To configure one-way proxy server authentication

Do the following tasks to configure one-way proxy server authentication.

1. Create an SSL service.
2. Bind a CA certificate to the service.
3. Bind an HTTPS Monitor to the service.
4. Configure Call Home to use the SSL service.

To configure two-way proxy server authentication

Do the following tasks to configure two-way proxy server authentication.

1. Create an SSL service
2. Bind a CA certificate to the service.
3. Bind a Client Certificate.
4. Bind an HTTPS Monitor to the service.
5. Configure Call Home to use the SSL service.

Verifying Call Home Registration status

At the command prompt, type:

```
1 show callhome
2
3     show callhome
4
5      Registration with Citrix upload server SUCCESSFUL
6
```

```
7       Mode: Default
8
9       Contact email address: exampleadmin@example.com
10
11      Heartbeat Custom Interval (days): 7
12
13      Proxy Mode: Yes
14
15         Proxy IP Address:10.102.29.200
16
17         Proxy Authentication Service:
18
19         Proxy Port: 80
20
21     Trigger event                   State   First occurrence
                      Latest occurrence
22
23      -------------                   -----   ----------------
                       -----------------
24
25      1) Warm boot                    Enabled N/A
                                        ..
26
27      2) Compact flash errors         Enabled ..
                                          ..
28
29      3) Hard disk drive errors       Enabled ..
                                          ..
30
31      4) SSL card failure             N/A     N/A
                                        N/A
32
33      5) Power supply unit failure    N/A     N/A
                                        N/A
34
35      6) Rate limit packet drops      Enabled ..
                                          ..
36
37      7) Memory anomaly               Enabled ..
                                          ..
38
39      Done
40 <!--NeedCopy-->
```

> **Note**
>
> If the Call Home fails to register with CIS, the appliance displays an error message.

Enabling SNMP Alarms

The Citrix ADC appliance provides a set of error condition entities called *SNMP alarms*. When an error condition in an SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the SSL-CARD-FAILED alarm is enabled, a trap message is generated and sent to the trap listener. The trap message is sent whenever there is an SSL card failure on the appliance. For more information, see SNMP.

At the command prompt, type:

```
enable snmp alarm <trapName>
```

```
show snmp alarm <trapName>
```

To configure Call Home by using GUI

To verify if the Call Home feature is enabled by default in the GUI

1. Navigate to **Configuration** > **System** > **Settings**.
2. In the **details** pane, click **Configure Advanced features** link.
3. In the **Configure Advanced Features** page, **Call Home** option must display as enabled.

To enable Call Home by using GUI

1. Navigate to **Configuration** > **System** > **Settings**.
2. In the **details** pane, click **Configure Advanced features** link and select **Callhome** option.

To configure Call Home for optional proxy mode authentication by using GUI

1. You can use any of the two ways to access the Call Home page:
   a) Navigate to **System** > **System Information**.
   b) Navigate to **System** > **Diagnostics**.
      i. In the details pane, under **Technical Support Tools**, select **Call Home**.
2. On the **Configure Call Home** page, set the following parameters.
   a) **Mode**. Call Home mode of operation. Possible types: Default, Citrix Service Provider (CSP) deployment.

      > **Note**
      >
      > This option is not user configurable. The mode is automatically determined and set based on the type of Citrix ADC deployment.

   b) **Email address**. Email address of the contact administrator at the customer site.
   c) **CallHome Heartbeats Interval (days).** Monitoring interval (in days) between Call Home heartbeats. Minimum value=1 and Maximum value=7.

d) **Enable Call Home**. Enable or disable the Call Home feature to view the status of appliance registration on the Citrix support server.
e) **Proxy Mode**. If you do not have an internet connectivity, enable proxy mode and set the optional proxy parameters.
f) **Proxy Server**. If you set the proxy mode by using a proxy server, specify the server IP address.
    i. **Proxy Service**. If you set the proxy mode by using a proxy service, specify the service name.
    ii. **IP Address**. IP address of the proxy server.
    iii. **Port**. Port number of the proxy server.
    iv. **Proxy Authentication SSL Service**. The name of the proxy service that provides proxy-mode authentication.

3. Click **OK** and **Done**.

To configure SSL service for proxy server authentication by using GUI

For information about configuring the SSL service by using the GUI, see Configuring an SSL Service topic.

To verify Call Home registration status by using the GUI

1. You can use any of the two ways to access the **Call Home** page:
    a) Navigate to **System** > **System Information**.
    b) Navigate to **System** > **Diagnostics**.
        i. In the details pane, under **Technical Support Tools**, select **Call Home**.
2. In the **Configure Call Home** page, the **Registration with Citrix upload server** field shows the registration status.

To configure an SNMP alarm

1. Navigate to **System** > **SNMP** > **Alarms**.
2. In the details pane, select an alarm and configure its parameters.
3. Click **OK** and **Close**.

Citrix Service Provider (CSP) deployment support

In a Citrix Service Provider (CSP) environment where Citrix ADC services are deployed on VPX instances, Call Home can monitor and track the license-specific information and securely send the information to Citrix Insight Services (CIS). CIS in turn sends the information to the License Usage Insights (LUI) portal for accounting purposes and for CSP customers to review their license usage. Currently, CSP environments support Citrix ADC services on VPX instances only, not on MPX or SDX appliances. The VPX instances can be deployed in either standalone or high availability mode.

Reporting tool

September 14, 2021

Use the Citrix® Citrix ADC® Reporting tool to view Citrix ADC performance statistics data as reports. Statistics data are collected by the `nscollect` utility and are stored in a database. When you want to view certain performance data over a period, the Reporting tool pulls out specified data from the database and displays them in charts.

Reports are a collection of charts. The Reporting tool provides built-in reports and the option to create custom reports. In a report, you can modify the charts and add new charts. You can also modify the operation of the data collection utility, `nscollect`, and stop or start its operation.

Using the reporting tool

The Reporting tool is a web-based interface accessed from the Citrix® Citrix ADC® appliance. Use the Reporting tool to display the performance statistics data as reports containing graphs. In addition to using the built-in reports, you can create custom reports, which you can modify at any time. Reports can have between one and four charts. You can create up to 256 custom reports. You can create a custom report for any number of entities.

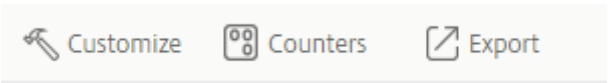
To invoke the reporting tool

1. Use the Web browser of your choice to connect to the IP address of the Citrix ADC (for example, `http://10.102.29.170/`). The Web Logon screen appears.
2. In the User Name text box, type the user name assigned to the Citrix ADC.
3. In the Password text box, type the password.
4. In the Start in drop-down list box, select Reporting.Click Login.

The following screenshots show the report toolbar and the chart toolbar, which are frequently referenced in this documentation.

Figure 1. *Report Toolbar*

Figure 2. *Chart Toolbar*



Working with reports

You can plot and monitor statistics for the various functional groups configured on the Citrix ADC over a specified time interval. Reports enable you to troubleshoot or analyze the behavior of your appliance. There are two types of reports: built-in reports and custom reports. Report content for built-in or custom reports can be viewed in a graphical format or a tabular format. The graphical view consists of line, area, and bar charts that can display up to 32 sets of data (counters). The tabular view displays the data in columns and rows. This view is useful for debugging error counters.

The default report that is displayed in the Reporting tool is CPU vs. Memory Usage and HTTP Requests Rate. You can change the default report view by displaying the report you want as your default view, and then clicking Default Report.

Reports can be generated for the last hour, last day, last week, last month, last year, or you can customize the duration.

You can do the following with reports:

- Toggle between a tabular view of data and a graphical view of data.
- Change the graphical display type, such as bar chart or line chart.
- Customize charts in a report.
- Export the chart as an Excel comma-separated value (CSV) file.
- View the charts in detail by zooming in, zooming out, or using a drag operation (scrolling).
- Set a report as the default report for viewing whenever you log on.
- Add or remove counters.
- Print reports.
- Refresh reports to view the latest performance data.

Using built-in reports

The Reporting tool provides built-in reports for frequently viewed data. Built-in reports are available for the following functional groups: System, Network, SSL, Compression, Integrated Cache, Citrix ADC Gateway, and Citrix ADC Application Firewall. By default, the built-in reports are displayed for the last day. However, you can view the reports for the last hour, last week, last month, or last year.

> **Note**:
>
> You cannot save changes to built-in reports, but you can save a modified built-in report as a custom report.

To display a built-in report

1. In the left pane of the Reporting tool, under Built-in Reports, expand a group (for example, SSL).
2. Click a report (for example, **SSL > All Backend Ciphers)**.

Creating and deleting reports

You can create your own custom reports and save them with user-defined names for reuse. You can plot different counters for different groups based on your requirements. You can create up to 256 custom reports.

You can either create a new report or save a built-in report as a custom report. By default, a newly created custom report contains one chart named System Overview, which displays the CPU Usage counter plotted for the last day. You can customize the interval and set the data source and time zone from the report toolbar.

To create a custom report

1. In the **Reporting** tool, on the report toolbar, click **Create**, or if you want to create a new custom report based on an existing report, open the existing report, and then click **Save As**.
2. In **Report Name** box, type a name for the custom report.
3. Do one of the following:
   - To add the report to an existing folder, in Create in or Save in, click the down arrow to choose an existing folder, and then click **OK**.
   - To create a new folder to store the report, click the Click to add folder icon, in Folder Name, type the name of the folder, and in Create in, specify where you want the new folder to reside in the hierarchy, and then click **OK**.

> **Note**:
> You can create up to 128 folders.

To delete a custom report

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage the custom reports icon.
2. Select the check box that corresponds with the report you want to delete, and then click Delete.

   > **Note**:
   >
   > When you delete a folder, all the contents of that folder are deleted.

Modifying the time interval

By default, built-in reports display data for the last day. However, if you want to change the time interval for a built-in report, you can save the report as a custom report. The new interval applies to all charts in the report. The following table describes the time-interval options.

To modify the time interval

1. In the left pane of the Reporting tool, click a report.
2. On the report toolbar, click **Duration**, and then click a time interval.

Setting the data Source and time zone

You can retrieve data from different data sources to display them in the reports. You can also define the time zone for the reports and apply the currently displayed report's time selection to all the reports, including the built-in reports.

To set the data source and time zone

1. In the **Reporting tool**, on the report toolbar, click **Settings**.
2. In the **Settings** dialog box, in Data Source, select the data source from which you want to retrieve the counter information.
3. Do one or both of the following:
   - If you want the tool to remember the time period for which a chart is plotted, select the **Remember time selection for charts** check box.
   - If you want the reports to use the time settings of your Citrix ADC appliance, select the **Use Appliance's time zone** check box.

Exporting and importing custom reports

You can share reports with other Citrix ADC administrators by exporting reports. You can also import reports.

To export or import custom reports

1. In the left pane of the Reporting tool, next to Custom Reports, click the **Click to manage custom reports** icon.
2. Select the check box that corresponds with the report you want to export or import, and then click **Export** or **Import**.

   > **Note**:
   >
   > When you export the file, it is exported in a .gz file format.

Working with charts

Use charts to plot and monitor counters or groups of counters. You can include up to four charts in one report. In each chart, you can plot up to 32 counters. The charts can use different graphical formats

(for example, area and bar). You can move the charts up or down within the report, customize the colors and visual display for each counter in a chart, and delete a chart when you do not want to monitor it.

In all report charts, the horizontal axis represents time and the vertical axis represents the value of the counter.

Adding a chart

When you add a chart to a report, the System Overview chart appears with the CPU Usage counter plotted for the last one day.

> **Note**:
>
> If you add charts to a built-in report, and you want to retain the report, you must save the report as a custom report.

Use the following procedure to add a chart to a report.

To add a chart to a report

1. In the left pane of the Reporting tool, click a report.
2. Under the chart where you want to add the new chart, click the Add icon.

Modifying a chart

You can modify a chart by changing the functional group for which the statistics are displayed and by selecting different counters.

To modify a chart

1. In the left pane of the Reporting tool, click a report.
2. Under the chart that you want to modify, click Counters.
3. In the dialog box that appears, in the Title box, type a name for the chart.
4. Next to the Plot chart for, do one of the following:
   - To plot counters for global counters, such as Integrated Cache and Compression, click System global statistics.
   - To plot entity counters for entity types, such as Load Balancing and GSLB, click System entities statistics.
5. In the Select group, click the desired entity.
6. Under Counters, in Available, click one or more counter names that you want to plot, and then click the > button.

7. If you selected System entities statistics in step 4, on the Entities tab, under Available, click one or more entity instance names you want to plot, and then click the > button.
8. Click OK.

Viewing a chart

You can specify the graphical formats of the plotted counters in a chart. Charts can be viewed as line charts, spline charts, step-line charts, scatter charts, area charts, bar charts, stacked area charts, and stacked bar charts. You can also zoom in, zoom out, or scroll inside the plot area of a chart. You can zoom in or out for all data sources for 1 hour, 1 day, 1 week, 1 month, 1 year, and 3 years.

Other options for customizing the view of a chart include customizing the axes of the charts, changing the background and edge color of the plot area, customizing the color and size of the grids, and customizing the display of each data set (counter) in a chart.

Data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

Whenever you modify a built-in report, you need to save the report as a custom report to retain your changes.

To change the graph type of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart you want to view, on the chart toolbar, click **Customize**.
3. On the **Chart** tab, under **Category**, click **Plot type**, and then click the graph type you want to display for the chart. If you want to display the graph is 3D, select the Use 3D check box.

To refocus a chart with detailed data

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click **Zoom In**, and do one or both of the following:
   - To refocus the chart to display data for a specific time window, drag the cursor from the start time to the end time. For example, you can view data for a one-hour period on a certain day.
   - To refocus the chart to display data for a data point, simply click once on the chart where you want to zoom in and get more detailed information.
3. Once you have the desired range of time for which you want to view detailed data, on the report toolbar, click Tabular View. Tabular view displays the data in numeric form in rows and columns.

To view numeric data for a graph

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Tabular View. To return to the graphical view, click **Graphical View**.

> **Note**: You can also view the numeric data in the graphical view by hovering your cursor over the notches in the gridlines.

To scroll through time in a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click **Scroll**, and then click inside the chart and drag the cursor in the direction for which you want to see data for a new time period. For example, if you want to view data in the past, drag to the left.

To change the background color and text color of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click **Customize**.
3. On the **Chart** tab, under **Category**, click one or more of the following:
   - To change the background color, click **Background Color**, and then select the options for color, transparency, and effects.
   - To change the text color, click Text **Color**, and then select the options for color, transparency, and effects.

To customize the axes of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click **Customize**.
3. On the **Chart** tab, under Category, click one or more of the following:
   - To change the scale of the left y-axis, click **Left Y-Axis**, and then select the scale you want.
   - To change the scale of the right y-axis, click Right Y-Axis, in the data set to plot, select the date set, and then select the scale you want.

     > Note:
     > The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

   - To plot each data set in its own hidden y-axis, click Multiple Axes, and then click Enable.

To change the background color, edge color, and gridlines for a plot area of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the plot area, click **Customize**.
3. On the **Plot Area** tab, under Category, click one or more of the following:
   - To change the background color and edge color of the chart, click **Background Color and Edge Color**, and then select the options for color, transparency, and effects.
   - To change the horizontal or vertical grids of the chart, click **Horizontal Grids** or **Vertical Grids**, and then select the options for displaying the grids, grid width, grid color, transparency, and effects.

To change the color and graph type of a data set

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the display of the data set (counters), click **Customize**.
3. On the **Data Set** tab, in Select Data Set, select the data set (counter) for which you want to customize the graphical display.
   Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if
   CPU usage and
   Memory usage are displayed in first and second order at the bottom of the chart,
   CPU usage is equal to
   Data Set 1 and
   Memory usage is equal to
   Data Set 2.
4. Under Category, do one of more of the following:
   - To change the background color, click **Color**, and then select the options for color, transparency, and effects.
   - To change the graph type, click **Plot type**, and then select the graph type you want to display for the data set. If you want to display the graph as 3D, select the Use 3D check box.

Exporting chart data to excel

For further data analysis, you can export charts to Excel in a comma-separated value (CSV) format.

To export chart data to excel

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart with the data you want to export to Excel, click **Export**.

Deleting a chart

If you do not want to use a chart, you can remove it from the report. You can permanently remove charts from custom reports only. If you delete a chart from a built-in report and want to retain the changes, you need to save the report as a custom report.

To delete a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart that you want to delete, click the **Delete** icon.

Examples

To display the trend report for CPU usage and memory usage for the last week

1. In the left pane of the Reporting tool, under Built-in Reports, expand System.
2. Click the report CPU vs. Memory Usage and HTTP Requests Rate.
3. In the right pane, on the report toolbar, click **Duration**, and then click **Last Week**.

To compare the bytes received rate and the bytes transmitted rate between the two interfaces for the last week

1. In the right pane, on the report toolbar, click Create.
2. In the **Report Name** box, type a name for the custom report (for example, Custom_Interfaces), and then click **OK**. The report is created with the default System Overview chart, which displays the CPU Usage counter plotted for the last hour.
3. Under System Overview, on the chart toolbar, click Counters.
4. In the counter selection pane, in Title, type a name for the chart (for example, Interfaces bytes data).
5. In Plot chart for, click System entities statistics, and then in Select Group, select Interface.
6. On the **Entities** tab, click one or more interface names you want to plot (for example, 1/1 and 1/2), and then click the > button.
7. On the Counters tab, click Bytes received (Rate) and Bytes transmitted (Rate) and then click the > button.
8. Click **OK**.
9. On the report toolbar, click **Duration**, and then click **Last Week**.

Stopping and starting the data collection utility

The data collection utility, `nscollect`, runs automatically when you start the Citrix ADC. This utility retrieves the application performance data and stores it in the form of data sources on the ADC. You

can create up to 32 data sources. The default data source is `/var/log/db/default`.

The data collection utility creates databases for global counters and entity-specific counters, and uses this data to generate reports. Global-counter databases are created at `/var/log/db/<DataSourceName>`. The entity-specific databases are created based on the entities configured on the Citrix ADC, and a separate folder is created for each entity type in `/var/log/db/<DataSourceName/EntityNameDB>`.

The `nscollect` retrieves data once every 5 minutes. It retains data in 5-minute granularity for one day, hourly for the last 30 days, and daily for three years.

You might have to stop and restart the data collection utility if data is not updated accurately or the reports display corrupted data.

To stop `nscollect`

At the command prompt, type:

```
/netscaler/nscollect stop
```

To start nscollect on the current SSH session to the Citrix ADC:

At the command prompt, type:

```
/netscaler/nscollect start
```

To start nscollect on the local system:

At the command prompt, type:

```
/netscaler/nscollect start &
```

CloudBridge Connector

September 14, 2021

Note: The current Citrix ADC 1000V release does not support this feature.

The CloudBridge Connector feature of the Citrix ADC appliance connects enterprise datacenters to external clouds and hosting environments, making the cloud a secure extension of your enterprise network. Cloud-hosted applications appear as though they are running on one contiguous enterprise network. With Citrix CloudBridge Connector, you can augment your datacenters with the capacity and efficiency available from cloud providers.

The CloudBridge Connector enables you to move your applications to the cloud to reduce costs and increase reliability.

In addition to using CloudBridge Connector between a datacenter and a cloud, you can use it to connect two datacenters for a high-capacity secure and accelerated link.

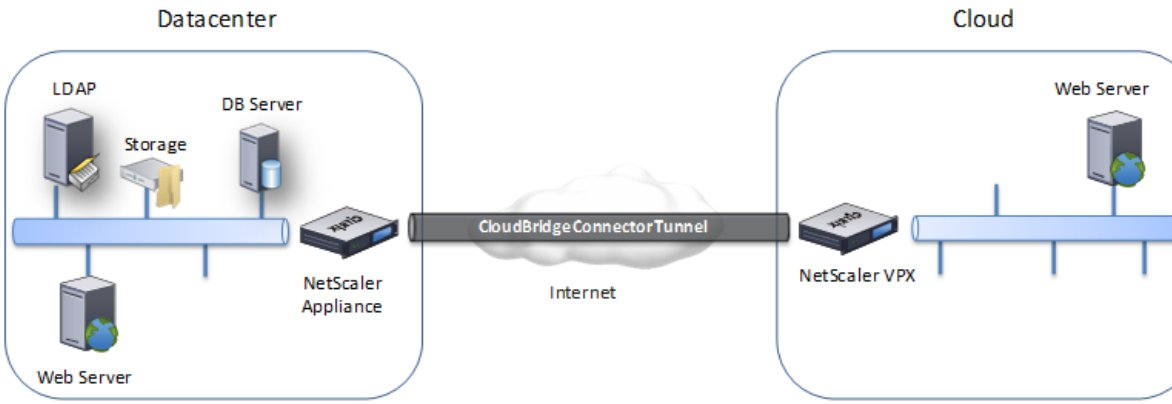
Understanding CloudBridge Connector

To implement the Citrix CloudBridge Connector solution, you connect a datacenter to another datacenter or an external cloud by setting up a tunnel called the CloudBridge Connector tunnel.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between two Citrix ADC appliances, one in each datacenter.

To connect a datacenter to an external cloud (for example, Amazon AWS cloud), you set up a CloudBridge Connector tunnel between a Citrix ADC appliance in the datacenter and a virtual appliance (VPX) that resides in the Cloud. The remote end point can be a CloudBridge Connector or a Citrix ADC VPX with Premium license.

The following illustration shows a CloudBridge Connector tunnel set up between a datacenter and an external cloud.



The appliances between which a CloudBridge Connector tunnel is set up are called the *end points* or *peers* of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel uses the following protocols:

- Generic Routing Encapsulation (GRE) protocol
- Open-standard IPSec Protocol suite, in transport mode

The GRE protocol provides a mechanism for encapsulating packets, from a wide variety of network protocols, to be forwarded over another protocol. GRE is used to:

- Connect networks running non-IP and non-routable protocols.
- Bridge across a wide area network (WAN).
- Create a transport tunnel for any type of traffic that needs to be sent unchanged across a different network.

The GRE protocol encapsulates packets by adding a GRE header and a GRE IP header to the packets.

The Internet Protocol security (IPSec) protocol suite secures communication between peers in the CloudBridge Connector tunnel.

In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the transport mode in which the GRE encapsulated packet is encrypted. The encryption is done by the Encapsulating Security Payload (ESP) protocol. The ESP protocol ensures the integrity of the packet by using a HMAC hash function, and ensures confidentiality by using an encryption algorithm. After the packet is encrypted and the HMAC is calculated, an ESP header is generated. The ESP header is inserted after the GRE IP header and, an ESP trailer is inserted at the end of the encrypted payload.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version (IKE) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

- The two peers mutually authenticate with each other, using one of the following authentication methods:
  - **Pre-shared key authentication**. A text string called a pre-shared key is manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
  - **Digital certificates authentication**. The initiator (sender) peer signs message interchange data by using its private key, and the other receiver peer uses the sender's public key to verify the signature. Typically, the public key is exchanged in messages containing an X.509v3 certificate. This certificate provides a level of assurance that a peer's identity as represented in the certificate is associated with a particular public key.
- The peers then negotiate to reach agreement on:
  - An encryption algorithm.
  - Cryptographic keys for encrypting data in one peer and decrypting the data in the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when two peers, CB1 and CB2, are communicating through a Connector tunnel, CB1 has two Security Associations. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets.

SAs expire after a specified length of time, which is called the *lifetime*. The two peers use the Internet Key Exchange (IKE) protocol (part of the IPSec protocol suite) to negotiate new cryptographic keys and establish new SAs. The purpose of the limited lifetime is to prevent attackers from cracking a key.

The following table lists some IPSec propeties supported by a Citrix ADC appliance:

IPSec Properties	Types Supported
IKE Versions	V1, V2
IKE DH group	A Citrix ADC appliance supports only DH group 2 (1024 bits MODP algorithm) for both IKEv1 and IKEv2.
IKE Authentication Methods	Pre-shared key authentication, Digital certificates authentication
Encryption Algorithm	AES (128 bits), AES 256 (256 bits), 3DES
Hash Algorithm	HMAC SHA1, HMAC SHA256, HMAC SHA384, HMAC SHA512, HMAC MD5

Monitoring CloudBridge Connector tunnels

September 14, 2021

You can display the statistics for monitoring the performance of a CloudBridge Connector tunnel. To display CloudBridge Connector tunnel statistics on a Citrix ADC appliance, use the GUI or the Citrix ADC command line.

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels on a Citrix ADC appliance.

Statistical counter	**Specifies**
Bytes Received	Total number of bytes received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Bytes Sent	Total number of bytes sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.

Statistical counter	Specifies
Packets Received	Total number of packets received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Sent	Total number of packets sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Bytes Received Rate	Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.
Bytes Sent Rate	Number of bytes per second sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels
Packets Received Rate	Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels
Packets Sent Rate	Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels

All these counters are reset to 0 when the Citrix ADC appliance is restarted. They do not increment during the following phases:

- Internet Key Exchange (IKE) authentication (pre-shared key) phase on any configured CloudBridge Connector tunnel.
- IKE Security Association (SA) establishment phase on any configured CloudBridge Connector tunnel.

To display CloudBridge Connector tunnel statistics by using the Citrix ADC command line

At the command prompt, type:

- **stat ipsec counters**

To display CloudBridge Connector tunnel statistics by using the GUI

1. Access the GUI by using a web browser to connect to the IP address of the Citrix ADC appliance.
2. On the **Configuation** tab, navigate to **System** > **CloudBridge Connector**.

3. On the CloudBridge Connector page, click **Create/Monitor CloudBridge Connector**. The **IPSec Bytes** and **IPSec Packets** charts display the bytes received rate, bytes sent rate, packets received rate, and packets sent rate of all the CloudBridge Connector tunnels configured on the Citrix ADC appliance.

```
    > stat ipsec counters
    Secure tunnel(s) summary
                        Rate (/s)        Total
    Bytes Received    0    2811248
    Bytes Sent            0    157460630
    Packets Received    0    56787
    Packets Sent        0    200910
    Done
    >
<!--NeedCopy-->
```

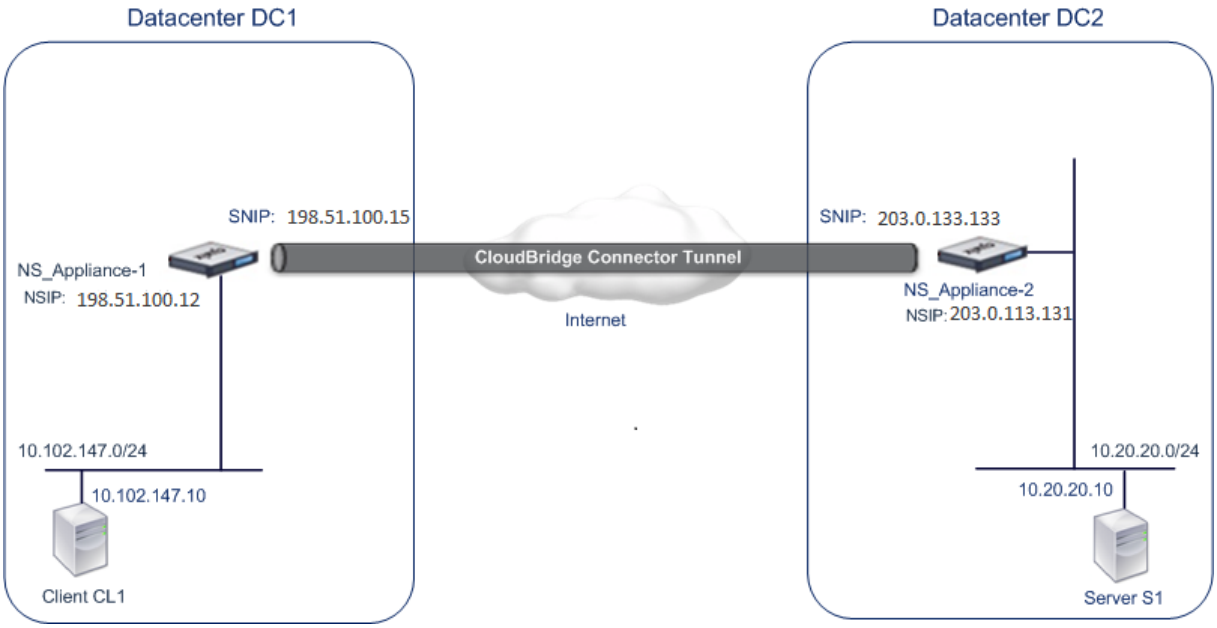
Configuring a CloudBridge Connector tunnel between two datacenters

September 14, 2021

You can configure a CloudBridge Connector tunnel between two different datacenters to extend your network without reconfiguring it, and leverage the capabilities of the two datacenters. A CloudBridge Connector tunnel between the two geographically separated datacenters enables you to implement redundancy and safeguard your setup from failure. The CloudBridge Connector tunnel helps achieve optimal utilization of infrastructure and resources across datacenters. The applications available across the two datacenters appear as local to the user.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance in one datacenter and a Citrix ADC appliance in the other datacenter.

As an illustration of CloudBridge Connector tunnel between datacenters, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-1 in datacenter DC1 and Citrix ADC appliance NS_Appliance-2 in datacenter DC2.



Both NS_Appliance-1 and NS_Appliance-2 function in L2 and L3 mode. They enable communication between private networks in datacenters DC1 and DC2. In L3 mode, NS_Appliance-1 and NS_Appliance-2 enable communication between client CL1 in datacenter DC1 and server S1 in the datacenter DC2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Because client CL1 and server S1 are on different private networks, L3 mode is enabled on NS_Appliance-1 and NS_Appliance-2, and routes are updated as follows:

- CL1 has a route to NS_Appliance-1 for reaching S1.
- NS_Appliance-1 has a route to NS_Appliance-2 for reaching S1.
- S1 has a route to NS_Appliance-2 for reaching CL1.
- NS_Appliance-2 has a route to NS_Appliance-1 for reaching CL1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-1 in datacenter DC1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-2 in datacenter DC2.

Entity	Name	Details
The NSIP address		198.51.100.12
SNIP address		198.51.100.15

Entity	Name	Details
CloudBridge Connector tunnel	Cloud_Connector_DC1-DC2	1. Local endpoint IP address of the CloudBridge Connector tunnel: 198.51.100.15, 2. Remote endpoint IP address of the CloudBridge Connector tunnel: 203.0.113.133. GRE Tunnel Details Name = Cloud_Connector_DC1-DC2, IPSec Profile Details Name = Cloud_Connector_DC1-DC2, Encryption algorithm = AES, Hash algorithm = HMAC SHA1

Points to consider for configuring CloudBridge Connector tunnel

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Deploy and set up a Citrix ADC appliance in each of the two datacenters.
2. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

Configuration procedure

To set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in one datacenter and another Citrix ADC appliance that resides in the other datacenter, use the GUI or the command line interface of one of the Citrix ADC appliances.

When you use the GUI, the CloudBridge Connector tunnel configuration created on the first Citrix ADC appliance is automatically pushed to the other endpoint (the other Citrix ADC appliance) of the CloudBridge Connector tunnel. Therefore, you do not have to access the GUI of the other Citrix ADC appliance to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on each of the Citrix ADC appliances consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **GRE tunnel**—An IP tunnel specifies the local IP address (a public SNIP address configured on the local Citrix ADC appliance), remote IP address (a public SNIP address configured on the remote Citrix ADC appliance), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the first datacenter and is destined to a server on the subnet in the second datacenter. If this packet matches the source and destination IP address range of the PBR entity on the Citrix ADC appliance in the first datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

- `add ipsec profile <name> [-ikeVersion (V1 | V2)] [-encAlgo (AES | 3 DES)...] [-hashAlgo <hashAlgo\> ...] [-lifetime <positive_integer>] (-psk | (-publickey<string> -privatekey <string>-peerPublicKey <string >))[-livenessCheckInterval <positive_intege>][-replayWindowSize \< positive_integer>] [-ikeRetryInterval <positive_integer>] [-retransmissiontime <positive_integer>]`
- `show ipsec profile <name>`

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

- `add ipTunnel <name> <remote><remoteSubnetMask> <local> [-protocol < protocol>] [-ipsecProfileName <string>]`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- `add ns pbr <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = < remote_subnet_range> -ipTunnel <tunnel_name>`
- `apply ns pbrs`
- `show ns pbr <pbr_name>`

Example

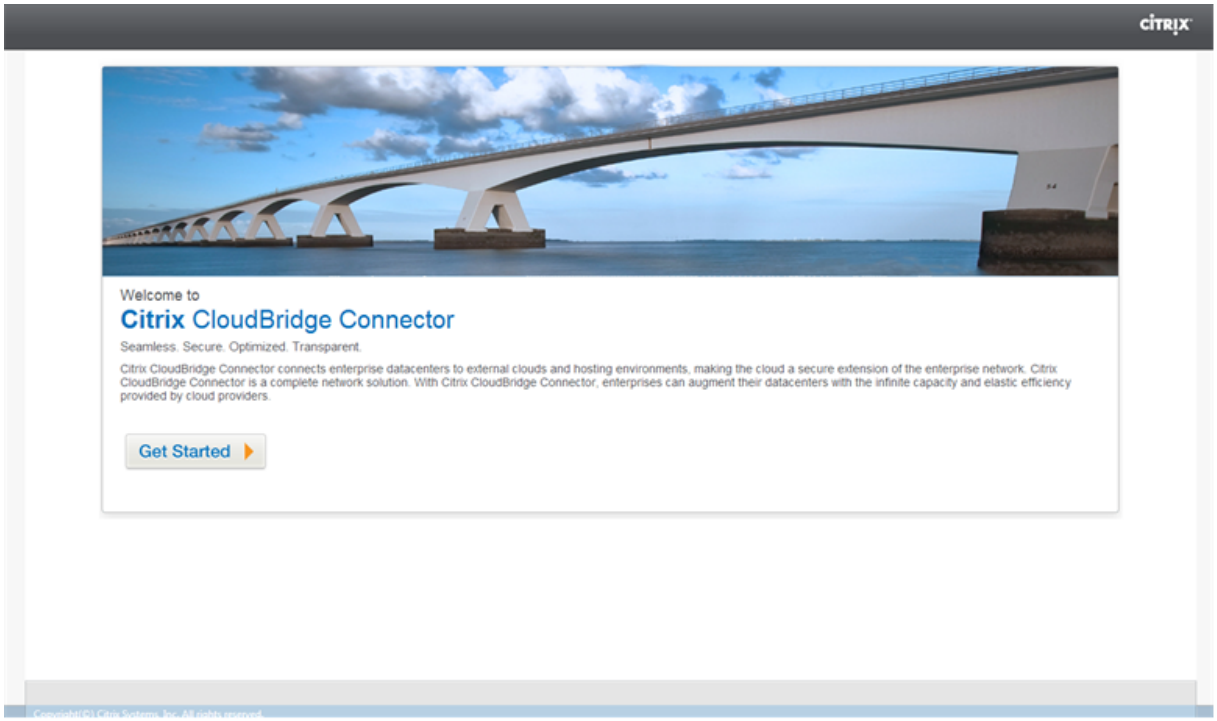
```
1  add ipsec profile Cloud_Connector_DC1-DC2  -encAlgo AES -hashAlgo
       HMAC_SHA1
```

```
2      Done
3      > add ipTunnel Cloud_Connector_DC1-DC2 203.0.113.133
           255.255.255.255 198.51.100.15 -protocol GRE -ipsecProfileName
           Cloud_Connector_DC1-DC2
4
5      Done
6      > add ns pbr PBR-DC1-DC2 ALLOW -srcIP 198.51.100.15 -destIP
           203.0.113.133 ipTunnel Cloud_Connector_DC1-DC2
7
8      Done
9      > apply ns pbrs
10
11     Done
12 <!--NeedCopy-->
```

To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI

1. Type the NSIP address of a Citrix ADC appliance in the address line of a web browser.
2. Log on to the GUI of the Citrix ADC appliance by using your account credentials for the appliance.
3. Navigate to **System** > **CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.

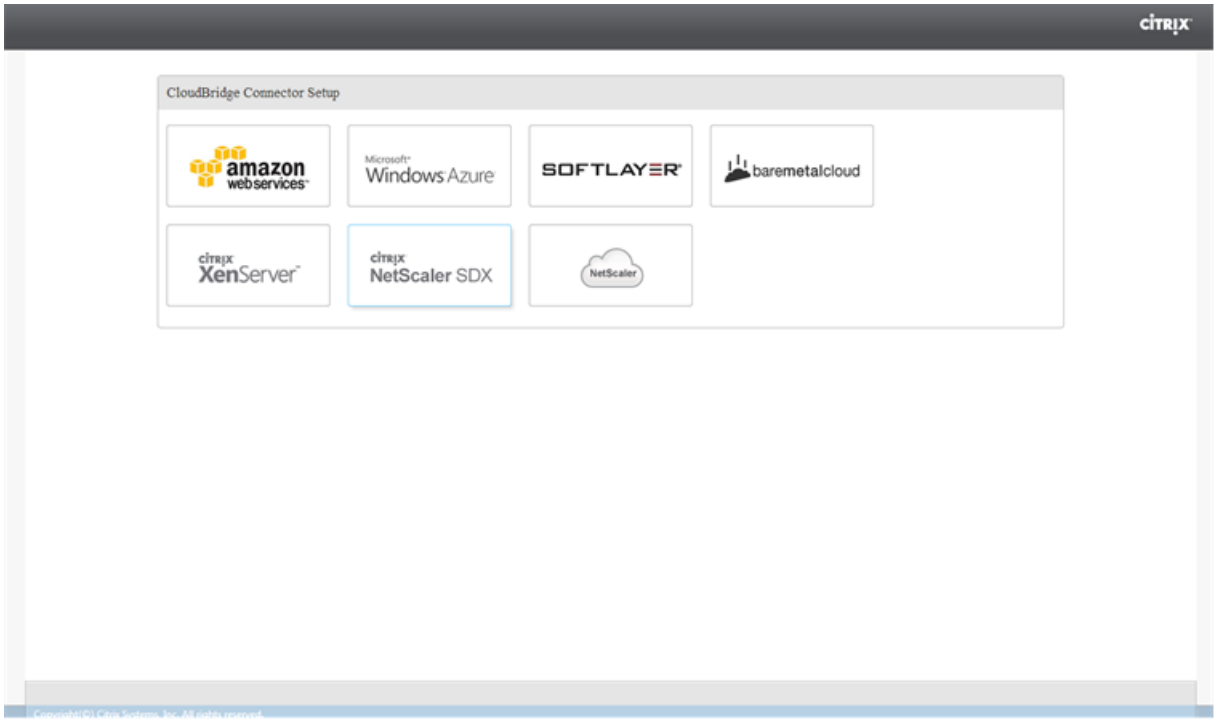
   The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.
5. On the **Welcome** screen click **Get Started**.



Note:

If you already have a CloudBridge Connector tunnel configured on the Citrix ADC appliance, the Welcome screen does not appear, so you do not click Get Started.

1. In the **CloudBridge Connector Setup** pane, click **Citrix ADC**.



1. In the Citrix ADC pane, provide your account credentials for the remote Citrix ADC appliance. Click **Continue**.
2. In the **CloudBridge Connector Setting** pane, set the following parameter:
   - **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.
3. Under **Local Setting**, set the following parameter:
   - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel.
4. Under **Remote Setting**, set the following parameter:
   - **Subnet IP**—IP address of the peer endpoint of the CloudBridge Connector tunnel.
5. Under **PBR** Setting, set the following parameters:
   - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   - **Source IP Low** —Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
   - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
   - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   - Destination IP Low*—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
   - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
6. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:
   - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   - **Key**—Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
     - **Auto Generate Key**—Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
     - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.

        * Pre Shared Security Key—The text string entered for pre-shared key based authentication.
    - **Upload Certificates**—Authentication based on digital certificates.
        * **Public Key**—A local digital certificate to be used to authenticate the local Citrix ADC appliance to the peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
        * **Private Key**—Private key of the local digital certificate.
        * **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

7. Click **Done**.

The new CloudBridge Connector tunnel configuration on both the Citrix ADC appliances appears on the Home tab of the respective GUI. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge Connectors pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring CloudBridge Connector between datacenter and AWS cloud

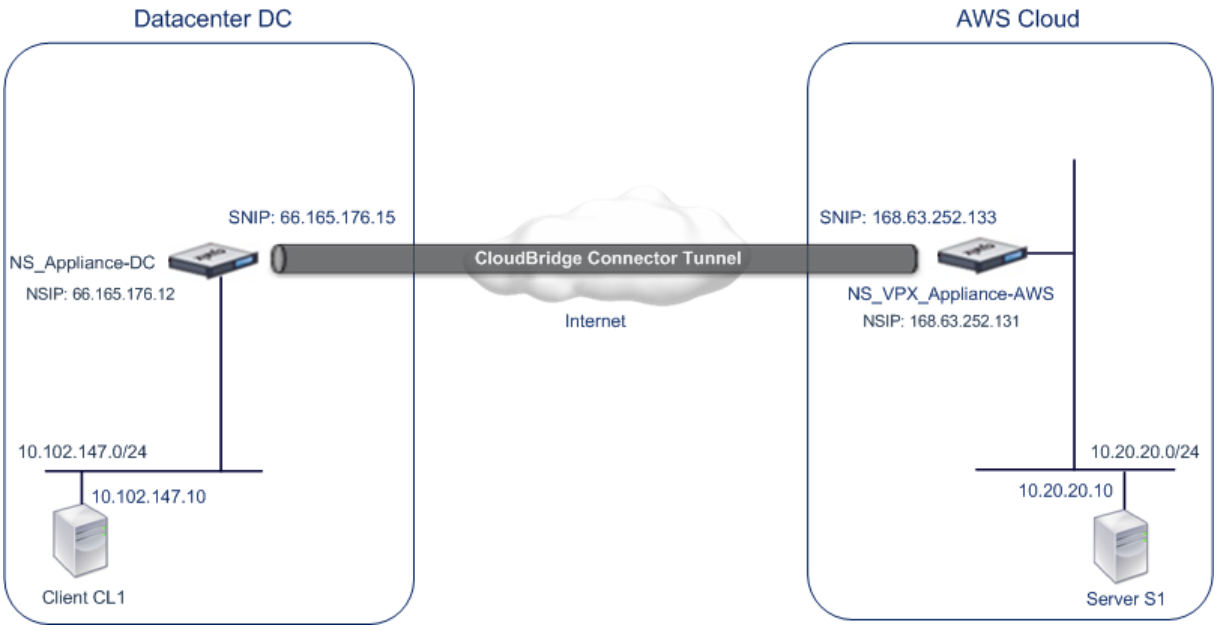
September 14, 2021

You can configure a CloudBridge Connector tunnel between a datacenter and AWS cloud to leverage the infrastructure and computing capabilities of the data center and the AWS cloud. With AWS, you can extend your network without initial capital investment or the cost of maintaining the extended network infrastructure. You can scale your infrastructure up or down, as required. For example, you can lease more server capabilities when the demand increases.

To connect a datacenter to AWS cloud, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in the datacenter and a Citrix ADC virtual appliance (VPX) that resides in AWS cloud.

As an illustration of a CloudBridge Connector tunnel between a datacenter and Amazon AWS cloud,

consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-DC, in datacenter DC, and Citrix ADC virtual appliance (VPX) NS_VPX_Appliance-AWS.



Both NS_Appliance-DC and NS_VPX_Appliance-AWS function in L3 mode. They enable communication between private networks in datacenter DC and the AWS cloud. NS_Appliance-DC and NS_VPX_Appliance-AWS enable communication between client CL1 in datacenter DC and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

> **Note**:
>
> AWS does not support L2 mode, hence it is necessary to have only L3 mode enabled on both the endpoints.

For proper communication between CL1 and S1, L3 mode is enabled on NS_Appliance-DC and NS_VPX_Appliance-AWS and routes are updated as such:

- CL1 have a route to NS_Appliance-DC for reaching S1.
- NS_Appliance-DC have a route to NS_VPX_Appliance-AWS for reaching S1.
- S1 should have a route to NS_VPX_Appliance-AWS for reaching CL1.
- NS_VPX_Appliance-AWS have a route to NS_Appliance-DC for reaching CL1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-DC in datacenter DC.

Entity	Name	Details
The NSIP address		66.165.176.12
SNIP address		66.165.176.15

Entity	Name	Details
CloudBridge Connector tunnel	CC_Tunnel_DC-AWS	Local endpoint IP address of the CloudBridge Connector tunnel: 66.165.176.15, Remote endpoint IP address of the CloudBridge Connector tunnel: 168.63.252.133, GRE Tunnel Details - Name= CC_Tunnel_DC-AWS

The following table lists the settings on Citrix ADC VPX NS_VPX_Appliance-AWS on AWS cloud.

Entity	Name	Details
NSIP address		10.102.25.30
Public EIP address mapped to the NSIP address		168.63.252.131
SNIP address		10.102.29.30
Public EIP address mapped to the SNIP address		168.63.252.133
CloudBridge Connector tunnel	CC_Tunnel_DC-AWS	Local endpoint IP address of the CloudBridge Connector tunnel:168.63.252.133, Remote endpoint IP address of the CloudBridge Connector tunnel: 66.165.176.15; **GRE Tunnel Details** Name= CC_Tunnel_DC-AWS, IPSec Profile Details, Name= CC_Tunnel_DC-AWS, Encryption algorithm= AES, Hash algorithm= HMAC SHA1

Prerequisites

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Install, configure, and launch an instance of Citrix ADC Virtual appliance (VPX) on AWS cloud. For instructions on installing Citrix ADC VPX on AWS, see Deploy a Citrix ADC VPX instance on AWS.
2. Deploy and configure a Citrix ADC physical appliance, or provisioning and configuring a Citrix ADC virtual appliance (VPX) on a virtualization platform in the datacenter.
3. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

Citrix ADC VPX license

After the initial instance launch, Citrix ADC VPX for AWS requires a license. If you are bringing your own license (BYOL), see the VPX Licensing Guide at: http://support.citrix.com/article/CTX122426.

You have to:

1. Use the licensing portal within Citrix website to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Configuration steps

To set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in a datacenter and a Citrix ADC virtual appliance (VPX) that resides on the AWS cloud, use the GUI of the Citrix ADC appliance.

When you use the GUI, the CloudBridge Connector tunnel configuration created on the Citrix ADC appliance, is automatically pushed to the other endpoint or peer (the Citrix ADC VPX on AWS) of the CloudBridge Connector tunnel. Therefore, you do not have to access the GUI (GUI) of the Citrix ADC VPX on AWS to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on both peers (the Citrix ADC appliance that resides in the datacenter and the Citrix ADC virtual appliance (VPX) that resides on the AWS cloud) consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in both the peers of the CloudBridge Connector tunnel.
- **GRE tunnel**—An IP tunnel specifies a local IP address (a public SNIP address configured on the local peer), remote IP address (a public SNIP address configured on the remote peer), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.

- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the datacenter and is destined to a server on the subnet in the AWS cloud. If this packet matches the source and destination IP address range of the PBR entity on the Citrix ADC appliance in the datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

- add ipsec profile <name> [-**ikeVersion** (V1 | V2)] [-**encAlgo** (AES | 3DES)...] [-**hashAlgo** <hashAlgo> ...] [-**lifetime** <positive_integer>] (-**psk** | (-**publickey** <string> -**privatekey** <string> -**peerPublicKey** <string>))[-**livenessCheckInterval** <positive_integer>] [-**replayWindowSize** <positive_integer>] [-**ikeRetryInterval** <positive_integer>] [-**retransmissiontime** <positive_integer>]
- **show ipsec profile** <name>

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

- add ipTunnel <name> <remote><remoteSubnetMask> <local> [-protocol <protocol>] [-ipsecProfileName <string>]
- show ipTunnel <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- add ns pbr <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel <tunnel_name>
- apply ns pbrs
- show ns pbr <pbr_name>

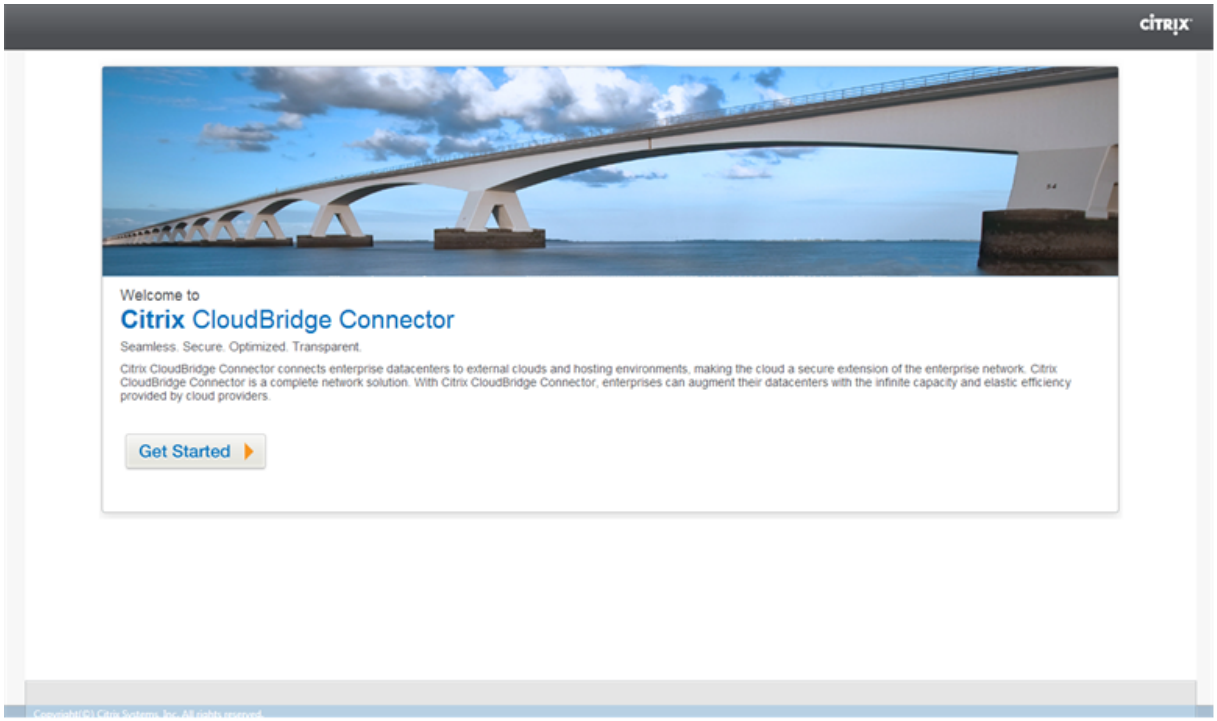
Example

```
1     > add ipsec profile CC_Tunnel_DC-AWS -encAlgo AES -hashAlgo
          HMAC_SHA1
2
3     Done
4     > add ipTunnel CC_Tunnel_DC-AWS 168.63.252.133 255.255.255.0
          66.165.176.15  - protocol GRE -ipsecProfileName CC_Tunnel_DC-AWS
```

```
5
6       Done
7       > add ns pbr PBR-DC-AWS ALLOW  -srcIP 66.165.176.15  -destIP
            168.63.252.133 ipTunnel CC_Tunnel_DC-AWS
8
9       Done
10      > apply ns pbrs
11
12      Done
13  <!--NeedCopy-->
```

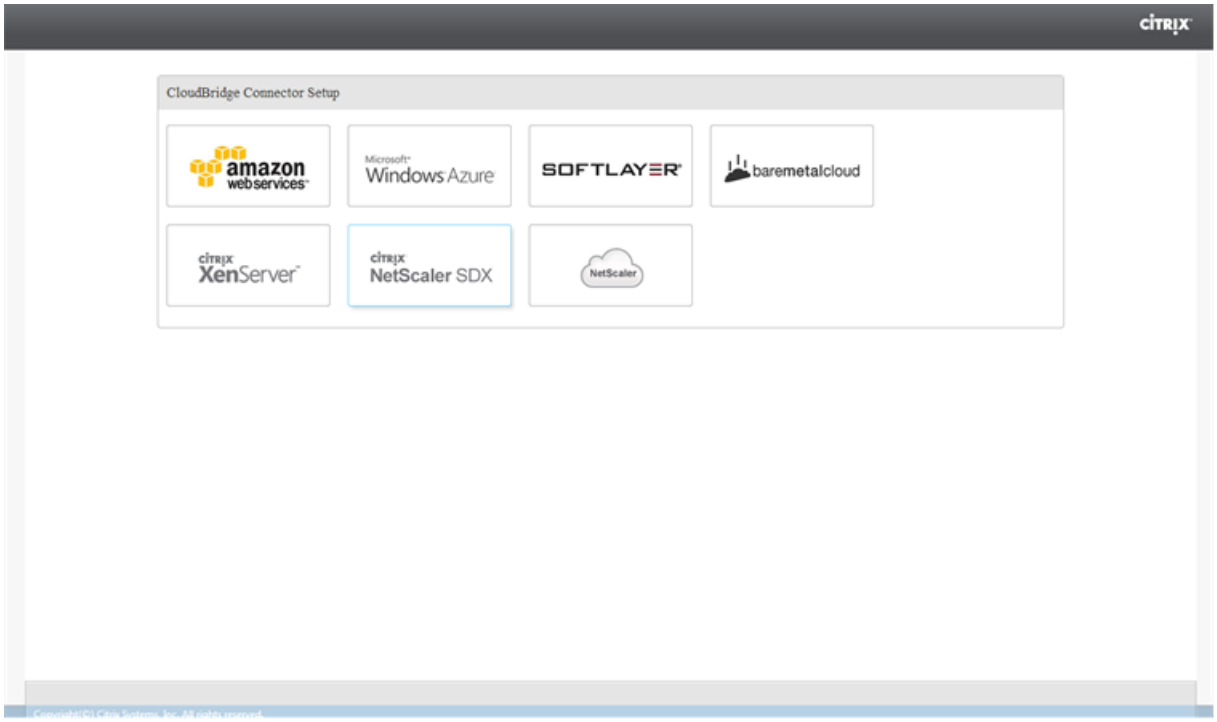
To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI

1. Type the NSIP address of a Citrix ADC appliance in the address line of a web browser.
2. Log on to the GUI of the Citrix ADC appliance by using your account credentials for the appliance.
3. Navigate to **System** > **CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.
5. The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.
6. On the **Welcome** screen click **Get Started**.



> **Note**:
>
> If you already have a CloudBridge Connector tunnel configured on the Citrix ADC appliance, the Welcome screen does not appear, so you do not click Get Started.

1. In the **CloudBridge Connector Setup** pane, click **amazon web services**



1. In the **Amazon** pane, provide your AWS account credentials: AWS Access Key ID and AWS Secret Access Key. You can obtain these access keys from the AWS GUI console. Click **Continue**.

> **Note**
>
> Earlier, the Setup wizard always connects to the same AWS region even when another region is selected. As a result, configuring CloudBridge Connector tunnel to a Citrix ADC VPX running on the selected AWS region used to fail. This issue has been fixed now.

1. In the **Citrix ADC** pane, select the NSIP address of the Citrix ADC virtual appliance running on AWS. Then, provide your account credentials for the Citrix ADC virtual appliance. Click **Continue**.
2. In the **CloudBridge Connector Setting** pane, set the following parameter:
   - **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.

3. Under **Local Setting**, set the following parameter:

    - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.

4. Under **Remote Setting**, set the following parameter:

    - **Subnet IP**—IP address of the CloudBridge Connector tunnel end point on the AWS side. Must be an IP address of type SNIP on the Citrix ADC VPX instance on AWS.
    - **NAT**—Public IP address (EIP) in AWS that is mapped to the SNIP configured on the Citrix ADC VPX instance on AWS.

5. Under **PBR Setting**, set the following parameters:

    - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
    - **Source IP Low**—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
    - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
    - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
    - **Destination IP Low**—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
    - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.

6. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:

    - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
    - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
    - **Key**— Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
        - **Auto Generate Key**— Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
        - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
            * **Pre Shared Security Key**—The text string entered for pre-shared key based authentication.
        - **Upload Certificates**—Authentication based on digital certificates.
            * **Public Key**—A local digital certificate to be used to authenticate the local peer to the remote peer before establishing IPSec security associations. The same certifi-

cate should be present and set for the Peer Public Key parameter in the peer.

* **Private Key**—Private key of the local digital certificate.
* **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

7. Click **Done**.

The new CloudBridge Connector tunnel configuration on the Citrix ADC appliance in the datacenter appears on the Home tab of the GUI. The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC VPX appliance in the AWS cloud appears on the GUI. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and virtual private gateway on AWS

September 14, 2021

To connect a datacenter to Amazon Web Services (AWS), you can configure a CloudBridge Connector tunnel between a Citrix ADC appliance in the datacenter and a virtual private gateway on AWS. The Citrix ADC appliance and the virtual private gateway form the endpoints of the CloudBridge Connector tunnel and are called peers.

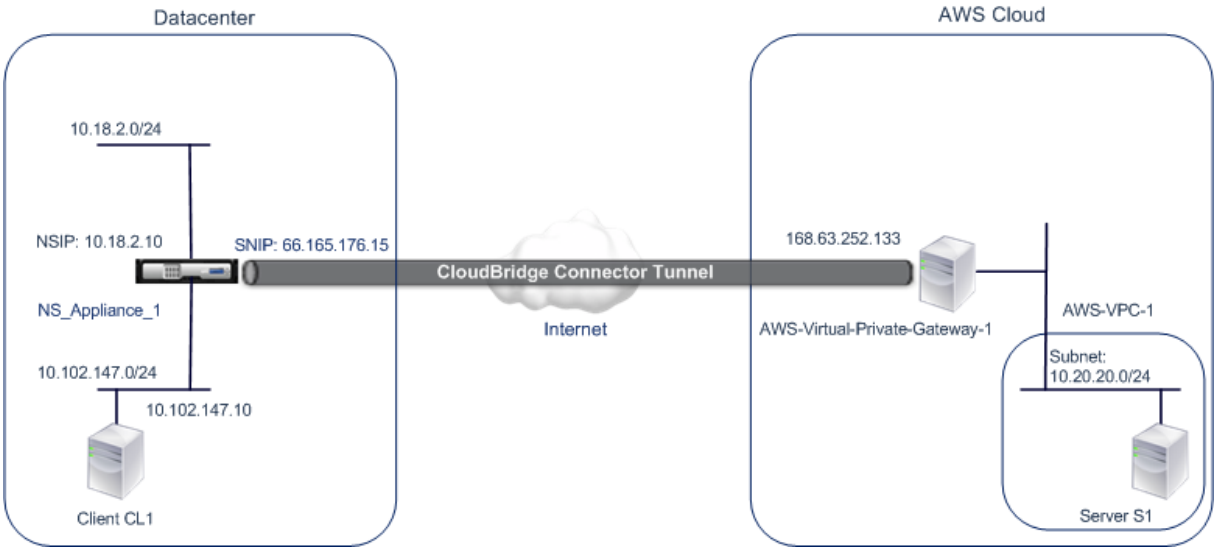
> **Note:**
>
> You can also set up a CloudBridge Connector tunnel between a Citrix ADC appliance in a datacenter and a Citrix ADC VPX instance (instead of a virtual private gateway) on AWS. For more information, see Configuring CloudBridge Connector between Datacenter and AWS Cloud.

Virtual private gateways on AWS support the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the Citrix ADC appliance for the CloudBridge Connector tunnel.

IPSec Properties	Setting
IPSec mode	Tunnel mode
IKE version	Version 1
IKE Authentication method	Pre-Shared Key
Encryption algorithm	AES
Hash algorithm	HMAC SHA1

Example of CloudBridge Connector tunnel configuration and data flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-1 in a datacenter and virtual private gateway gateway AWS-Virtual-Private-Gateway-1 on AWS cloud.



NS_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the AWS cloud through the CloudBridge Connector tunnel. As a router, NS_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named NS_AWS_IPSec_Profile, a CloudBridge Connector tunnel entity named NS_AWS_Tunnel, and a policy based routing (PBR) entity named NS_AWS_Pbr.

The IPSec profile entity NS_AWS_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. NS_AWS_IPSec_Profile is bound to IP tunnel entity NS_AWS_Tunnel.

CloudBridge Connector tunnel entity NS_AWS_Tunnel specifies the local IP address (a public IP—SNIP—address configured on the Citrix ADC appliance), the remote IP address (the IP address of the AWS-Virtual-Private-Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. NS_AWS_Tunnel is bound to policy based routing (PBR) entity NS_AWS_Pbr.

The PBR entity NS_AWS_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (NS_AWS_Tunnel). The source IP address range and the destination IP address range are the conditions for NS_AWS_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the AWS cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the AWS cloud matches the conditions in NS_AWS_Pbr. This packet is then considered for CloudBridge Connector processing and is sent across the CloudBridge Connector tunnel (NS_AWS_Tunnel) bound to the PBR entity.

The following table lists the settings used in this example.

IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in the datacenter side	66.165.176.15
IP address of the CloudBridge Connector tunnel end point (AWS-Virtual-Private-Gateway-1) in the AWS	168.63.252.133
Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel	10.102.147.0/24
AWS Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel	10.20.20.0/24

Settings on Amazon AWS

Customer Gateway	AWS-Customer-Gateway-1	Routing = Static, IP Address = Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side = 66.165.176.15
Virtual Private Gateway	AWS-Virtual-Private-Gateway-1	Associated VPC = AWS-VPC-1

Customer Gateway	AWS-Customer-Gateway-1	Routing = Static, IP Address = Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side = 66.165.176.15
VPN Connection	AWS-VPN-Connection-1	Customer Gateway = AWS-Customer-Gateway-1, Virtual Private Gateway= Virtual-Private-Gateway-1, Routing Options: Type = Static, Static IP Prefixes = Subnets on the Citrix ADC side = 10.102.147.0/24

Settings on Citrix ADC appliance NS_Appliance-1 in Datacenter-1:

Appliance	Settings	
SNIP1(for reference purposes only)	66.165.176.15	
IPSec profile	NS_AWS_IPSec_Profile	IKE version = v1, Encryption algorithm = AES, Hash algorithm = HMAC SHA1
CloudBridge Connector tunnel	NS_AWS_Tunnel	Remote IP = 168.63.252.133, Local IP= 66.165.176.15, Tunnel protocol = IPSec, IPSec profile= NS_AWS_IPSec_Profile
Policy based route	NS_AWS_Pbr	Source IP range = Subnet in the datacenter =10.102.147.0-10.102.147.255, Destination IP range =Subnet in AWS =10.20.20.0-10.20.20.255, IP Tunnel = NS_AWS_Tunnel

Points to consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and AWS gateway, consider the following points:

1. AWS supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the Citrix ADC appliance for the CloudBridge Connector tunnel.
    - IKE version = v1
    - Encryption algorithm = AES
    - Hash algorithm = HMAC SHA1
2. You must configure the firewall at the Citrix ADC end to allow the following.
    - Any UDP packets for port 500
    - Any UDP packets for port 4500
    - Any ESP (IP protocol number 50) packets
3. You must configure Amazon AWS before specifying the tunnel configuration on the Citrix ADC, because the public IP address of the AWS end (gateway) of the tunnel and the PSK are automatically generated when you set up the tunnel configuration in AWS. You need this information for specifying the tunnel configuration on the Citrix ADC appliance.
4. AWS gateway supports static routes and the BGP protocol for route updates. The Citrix ADC appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.

Configuring Amazon AWS for the CloudBridge Connector tunnel

To create a CloudBridge Connector tunnel configuration on Amazon AWS, use the Amazon AWS Management Console, which is a web based graphical interface for creating and managing resources on Amazon AWS.

Before you begin the CloudBridge Connector tunnel configuration on AWS cloud, make sure that:

- You have a user account for Amazon AWS cloud.
- You have a virtual private cloud whose networks you want to connect to the networks at the Citrix ADC side through the CloudBridge Connector tunnel.
- You are familiar with the Amazon AWS Management Console.

> **Note**:
>
> The procedures for configuring Amazon AWS for a CloudBridge Connector tunnel might change over time, depending on the Amazon AWS release cycle. Citrix recommends you refer Amazon

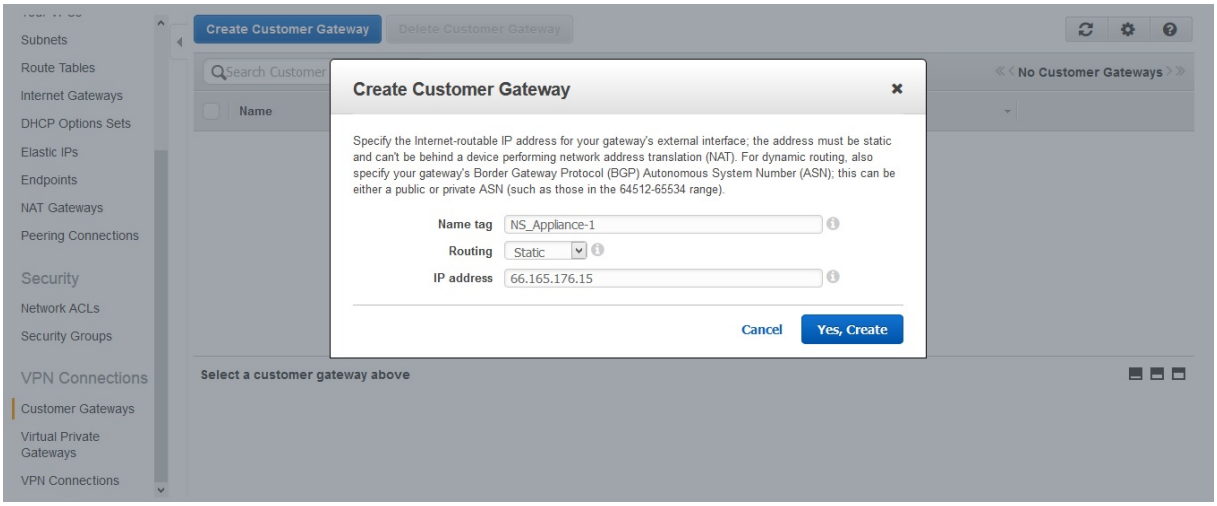
> AWS documentation for the latest procedures.

To configure a CloudBridge connector tunnel between a Citrix ADC and AWS gateway perform the following tasks on the AWS Management Console:

- **Create a Customer Gateway**. A customer gateway is an AWS entity that represents a CloudBridge Connector tunnel endpoint. For a CloudBridge Connector tunnel between a Citrix ADC appliance and AWS gateway, the customer gateway represents the Citrix ADC appliance on AWS. The customer gateway specifies a name, the type of routing (static or BGP) used in the tunnel, and the CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side. The IP address can be an Internet-routable Citrix ADC owned subnet IP (SNIP) address or, if the Citrix ADC appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.
- **Create a Virtual Private Gateway and attach it to a VPC**. A virtual private gateway is a CloudBridge Connector tunnel endpoint at the AWS side. When you create a virtual private gateway, you assigned it a name or allow AWS to assign the name. You then associate the virtual private gateway with a VPC. This association enables the subnets of the VPC to connect to the subnets at the Citrix ADC side through the CloudBridge Connector tunnel.
- **Create a VPN Connection**. A VPN connection specifies a customer gateway and a virtual private gateway between which a CloudBridge Connector tunnel is to be created. It also specifies an IP prefix for the networks at the Citrix ADC side. Only IP prefixes that are known to the virtual private gateway (through static route entry) can receive traffic from the VPC through the tunnel. Also, the virtual private gateway does not route any traffic not destined to the specified IP prefixes through the tunnel. After configuring a VPN connection, you might have to wait few minutes for it to be created.
- **Configure Routing Options**. For the VPC's network to reach the networks at the Citrix ADC side through the CloudBridge Connector tunnel, you must configure the VPC's routing table to include routes for the networks at the Citrix ADC side and point those routes to the virtual private gateway. You can include routes in a VPC's routing table in one of the following ways:
  - **Enable Route Propagation**. You can enable route propagation for your routing table, so that routes are automatically propagated to the table. The static IP prefixes that you specify for VPN configuration are propagated to the routing table after you've created the VPN connection.
  - **Enter Static Routes Manually**. If you do not enable route propagation, you must manually enter the static routes for the networks at the Citrix ADC side.
- **Download Configuration**. After the CloudBridge Connector tunnel (VPN connection) configuration is created on AWS, download the configuration file of the VPN connection to your local system. You might need the information in the configuration file for configuring the CloudBridge Connector tunnel on the Citrix ADC appliance.

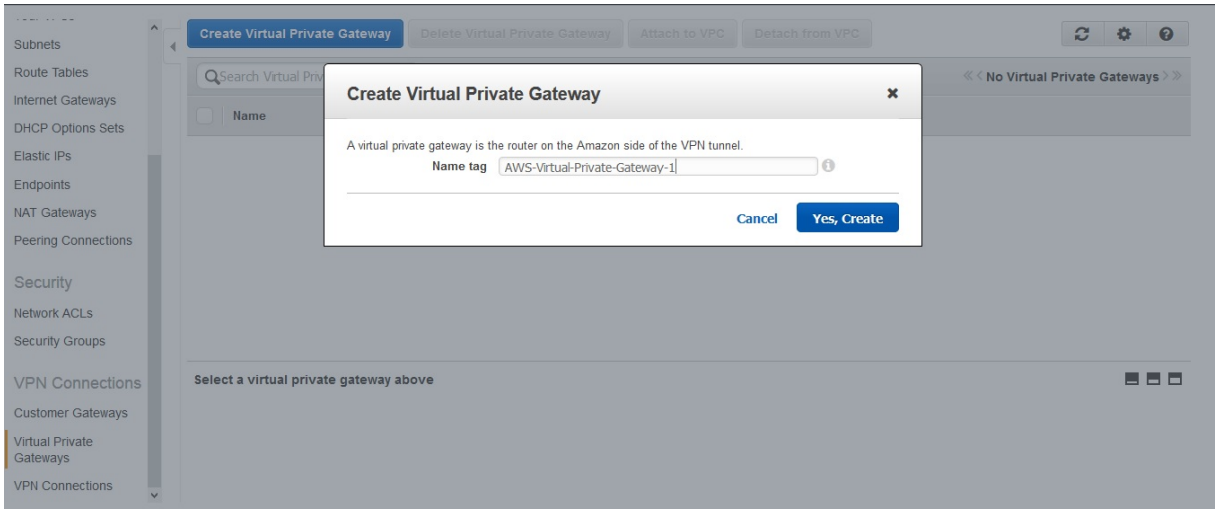
To create a customer gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Navigate to **VPN Connections** > **Customer Gateways** and click on **Create Customer Gateway**.
3. In the **Create Customer Gateway** dialog box, set the following parameters and then click **Yes, Create**:
    - **Name tag**. A name for the customer gateway.
    - **Routing list**. Type of routing between Citrix ADC appliance and AWS virtual private gateway for advertising routes to each other through the CloudBridge Connector tunnel. Select **Static Routing** from the **Routing** list. **Note**: The Citrix ADC appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.
    - **IP Address**. Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side. The IP address can be an Internet-routable Citrix ADC owned subnet IP (SNIP) address or, if the Citrix ADC appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.

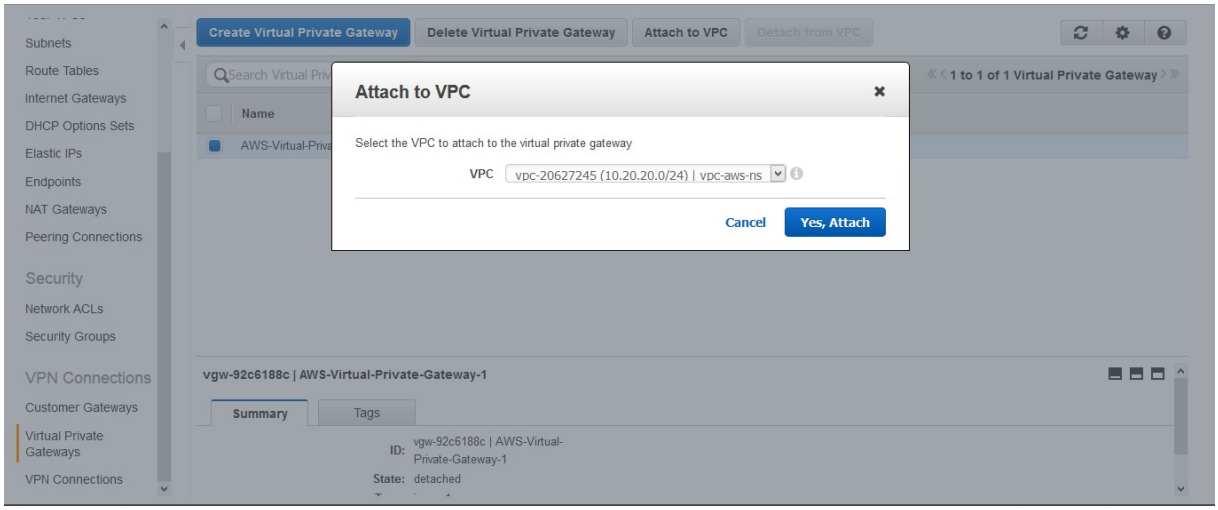


To create a virtual private gateway and attach it to a VPC

1. Navigate to **VPN Connections** > **Virtual Private Gateways**, and then click Create Virtual Private Gateway.
2. Enter a name for the virtual private gateway, and then click Yes, Create.

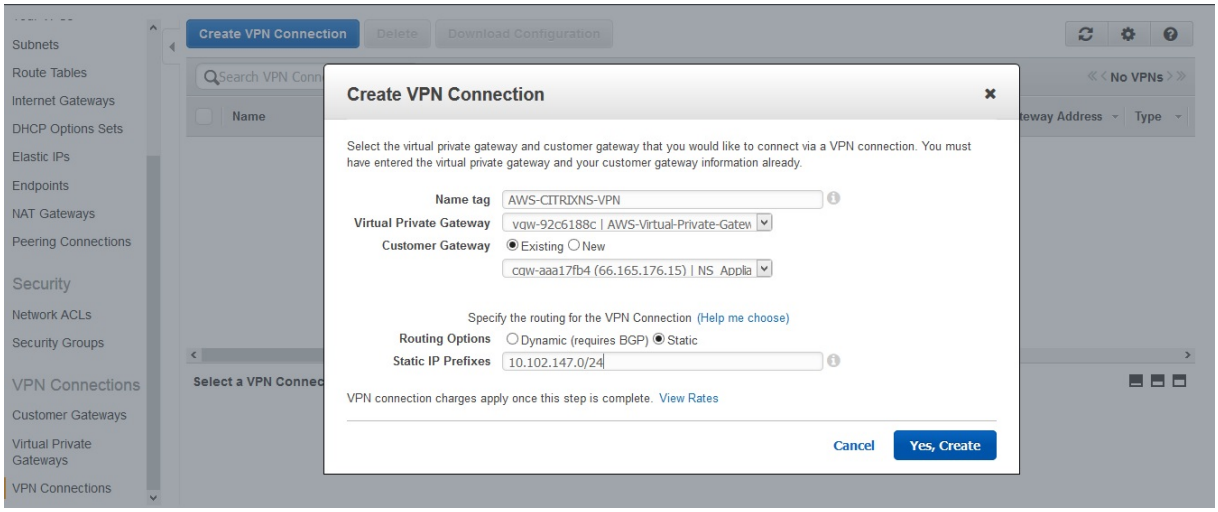


1. Select the virtual private gateway that you created, and then click Attach to VPC.
2. In the Attach to VPC dialog box, select your VPC from the list, and then choose Yes, Attach.



To create a VPN connection:

1. Navigate to VPN Connections > VPN Connections and then click Create VPN Connection.
2. In the Create VPN Connection dialog box set the following parameters and then choose Yes, Create:
   - **Name tag**. A name for the VPN connection.
   - **Virtual Private Gateway**. Select the virtual private gateway that you created earlier.
   - **Customer Gateway**. Select Existing. Then, from the drop down list, select the customer gateway that you created earlier.
   - **Routing Options**. Type of routing between the virtual private gateway and customer gateway (Citrix ADC appliance). Select Static. In the Static IP Prefixes field, specify the IP prefixes for the subnet on the Citrix ADC side, separated by commas.



To enable route propagation:

1. Navigate to **Route Tables** and select the routing table that's associated with the subnet whose traffic is to traverse the CloudBridge Connector tunnel.

> **Note**
>
> By default, this is the main routing table for the VPC.

1. On the **Route Propagation** tab in the details pane, choose **Edit**, select the virtual private gateway, and then choose **Save**.

To manually enter static routes:

1. Navigate to **Route Tables** and select your routing table.
2. On the **Routes** tab, click **Edit**.
3. In the **Destination** field, enter the static route used by your CloudBridge Connector tunnel (VPN connection).
4. Select the virtual private gateway ID from the **Target** list, and then click **Save**.

To download the configuration file:

1. Navigate to **VPN Connection**, select a VPN connection, and then click **Download Configuration**.
2. In the **Download Configuration** dialog box, set the following parameters, and then click **Yes, Download**.
   - **Vendor**. Select **Generic**.
   - **Platform**. Select **Generic**.
   - **Software**. Select **Vendor Agnostic**.

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a virtual private gateway on AWS cloud, perform the following tasks on the Citrix ADC appliance.
You can use either the Citrix ADC command line or the GUI.

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm and PSK to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (a SNIP address configured on the Citrix ADC appliance), remote IP address (the public IP address of the virtual private gateway in AWS), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to traverse the tunnel, and set the destination IP address range to specify the AWS VPC subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet that originates from a client in the subnet on the Citrix ADC side and is destined to a server in the AWS cloud subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the Citrix ADC command line

At the Command prompt, type:

- `add ipsec profile <name> -psk <string> -**ikeVersion** v1`
- `show ipsec profile** <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the Command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the Command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP** <subnet-range> -*ipTunnel <tunnelName>`
- `apply pbrs`

- `show pbr <pbrName>`

The following commands create all settings of Citrix ADC appliance NS_Appliance-1 used in "Example of CloudBridge Connector Configuration and Data Flow."

```
1      > add ipsec profile NS_AWS_IPSec_Profile -psk
          DkiMgMdcbqvYREEuIvxsbKkW0Foyabcd -ikeVersion v1  - lifetime
          31536000
2      Done
3      > add iptunnel NS_AWS_Tunnel 168.63.252.133 255.255.255.255
          66.165.176.15  - protocol IPSEC  - ipsecProfileName
          NS_AWS_IPSec_Profile
4
5      Done
6      > add pbr NS_AWS_Pbr -srcIP 10.102.147.0-10.102.147.255  - destIP
          10.20.0.0-10.20.255.255  - ipTunnel NS_AWS_Tunnel
7      Done
8
9      > apply pbrs
10
11     Done
12 <!--NeedCopy-->
```

To create an IPSEC profile by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version (select V1)
4. Select the **Pre-shared Key Authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click Add.
3. In the **Add IP Tunnel** dialog box, set the following parameters:
   - Name

- Remote IP
- Remote Mask
- Local IP Type (In the Local IP Type drop down list, select Subnet IP).
- Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
- Protocol
- IPSec Profile

4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** dialog box, set the following parameters:

   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High

4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters.
For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

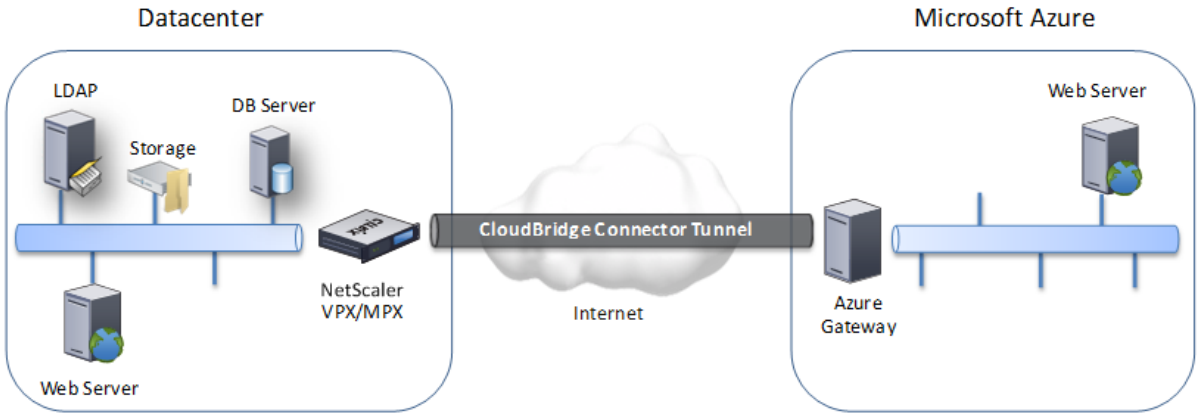
Configuring a CloudBridge Connector tunnel between a datacenter and Azure cloud

September 14, 2021

The Citrix ADC appliance provides connectivity between your enterprise datacenters and the Microsoft cloud hosting provider, Azure, making Azure a seamless extension of the enterprise network. Citrix ADC encrypts the connection between the enterprise datacenter and Azure cloud so that all data transferred between the two is secure.

How CloudBridge Connector tunnel works

To connect a datacenter to Azure cloud, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in the datacenter and a gateway that resides in the Azure cloud. The Citrix ADC appliance in the datacenter and the gateway in Azure cloud are the end points of the CloudBridge Connector tunnel and are called peers of the CloudBridge Connector tunnel.



A CloudBridge Connector tunnel between a datacenter and Azure cloud uses the open-standard Internet Protocol security (IPSec) protocol suite, in tunnel mode, to secure communications between peers in the CloudBridge Connector tunnel. In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the tunnel mode in which the complete IP packet is encrypted and then encapsulated. The encryption uses the Encapsulating Security Payload (ESP) protocol, which ensures the integrity of the packet by using a HMAC hash function and ensures confidentiality by using an encryption algorithm. The ESP protocol, after encrypting the payload and calculating the HMAC, generates an ESP header

and inserts it before the encrypted IP packet. The ESP protocol also generates an ESP trailer and inserts it at the end of the packet.

The IPSec protocol then encapsulates the resulting packet by adding an IP header before the ESP header. In the IP header, the destination IP address is set to the IP address of the CloudBridge Connecter peer.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version 1 (IKEv1) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

1. The two peers mutually authenticate with each other, using pre-shared key authentication, in which the peers exchange a text string called a pre-shared key (PSK). The pre-shared keys are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
2. The peers then negotiate to reach agreement on:
   - An encryption algorithm
   - Cryptographic keys for encrypting data on one peer and decrypting it on the other.

   This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when a CloudBridge Connector tunnel is set up between a Citrix ADC appliance in a datacenter and a gateway in an Azure cloud, both the datacenter appliance and the Azure gateway have two SAs. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets. SAs expire after a specified interval of time, which is called the lifetime.

Example of CloudBridge Connector tunnel configuration and data flow

As an illustration of CloudBridge Connector Tunnel, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance CB_Appliance-1 in a datacenter and gateway Azure_Gateway-1 in Azure cloud.

CB_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the Azure cloud through the CloudBridge Connector tunnel. As a router, CB_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the Azure cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On CB_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named CB_Azure_IPSec_Profile, a CloudBridge Connector tunnel entity named CB_Azure_Tunnel, and a policy based routing (PBR) entity named CB_Azure_Pbr.

The IPSec profile entity CB_Azure_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. CB_Azure_IPSec_Profile is bound to IP tunnel entity CB_Azure_Tunnel.

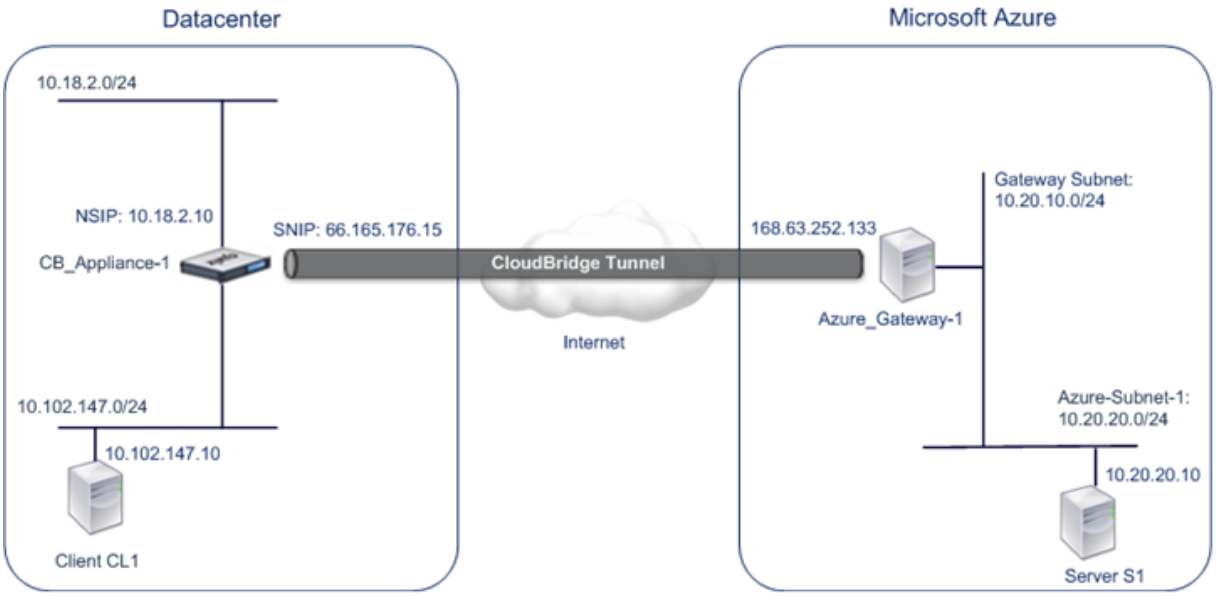
CloudBridge Connector tunnel entity CB_Azure_Tunnel specifies the local IP address (a public IP (SNIP) address configured on the Citrix ADC appliance), the remote IP address (the IP address of the Azure_Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. CB_Azure_Tunnel is bound to the PBR entity CB_Azure_Pbr.

The PBR entity CB_Azure_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (CB_Azure_Tunnel). The source IP address range and the destination IP address range are the conditions for CB_Azure_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the Azure cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the Azure cloud matches the conditions in CB_Azure_Pbr. This packet is then considered for CloudBridge processing and is sent across the CloudBridge Connector tunnel (CB_Azure_Tunnel) bound to the PBR entity.

On Microsoft Azure, the CloudBridge Connector tunnel configuration includes a local network entity named My-Datacenter-Network, a virtual network entity named Azure-Network-for-CloudBridge-Tunnel, and a gateway named Azure_Gateway-1.

The local (local to Azure) network entity My-Datacenter-Network specifies the IP address of the Citrix ADC appliance on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network entity Azure-Network-for-CloudBridge-Tunnel defines a private subnet named Azure-Subnet-1 in Azure. The traffic of the subnet traverses the CloudBridge Connector tunnel. The server S1 is provisioned in this subnet.

The local network entity My-Datacenter-Network is associated with the virtual network entity Azure-Network-for-CloudBridge-Tunnel. This association defines the remote and local network details of the CloudBridge Connector tunnel configuration in Azure. Gateway Azure_Gateway-1 was created for this association to become the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel.



For more information about the settings, refer to the CloudBridge Connector Tunnel Settings pdf.

Points to consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance in datacenter and Microsoft Azure, consider the following points:

1. The Citrix ADC appliance must have a public facing IPv4 address (type SNIP) to use as a tunnel end-point address for the CloudBridge Connector tunnel. Also, the Citrix ADC appliance should not be behind a NAT device.
2. Azure supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings while configuring the Citrix ADC for the CloudBridge Connector tunnel.
   - IKE version = v1
   - Encryption algorithm = AES
   - Hash algorithm = HMAC SHA1
3. You must configure the firewall in the datacenter edge to allow the following.
   - Any UDP packets for port 500
   - Any UDP packets for port 4500
   - Any ESP (IP protocol number 50) packets
4. IKE re-keying, which is renegotiation of new cryptographic keys between the CloudBridge Connector tunnel end points to establish new SAs, is not supported. When the Security Associations (SAs) expire, the tunnel goes into the DOWN state. Therefore, you must set a very large value for the lifetimes of SAs.
5. You must configure Microsoft Azure before specifying the tunnel configuration on the Citrix ADC, because the public IP address of the Azure end (gateway) of the tunnel, and the PSK, are auto-

matically generated when you set up the tunnel configuration in Azure. You need this information for specifying the tunnel configuration on the Citrix ADC.

Configuring the CloudBridge Connector tunnel

For setting up a CloudBridge Connector tunnel between your datacenter and Azure, you must install CloudBridge VPX/MPX in your datacenter, configure Microsoft Azure for the CloudBridge Connector tunnel, and then configure the Citrix ADC appliance in the data center for the CloudBridge Connector tunnel.

Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance in datacenter and Microsoft Azure consists of the following tasks:

1. **Setting up the Citrix ADC appliance in the datacenter**. This task involves deploying and configuring a Citrix ADC physical appliance (MPX), or provisioning and configuring a Citrix ADC virtual appliance (VPX) on a virtualization platform in the datacenter.
2. **Configuring Microsoft Azure for the CloudBridge Connector tunnel**. This task involves creating local network, virtual network, and gateway entities in Azure. The local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the Citrix ADC appliance) on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network defines a network on Azure. Creating the virtual network includes defining a subnet whose traffic is to traverse the CloudBridge Connector tunnel to be formed. You then associate the local network with the virtual network. Finally, you create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel.
3. **Configuring the Citrix ADC appliance in the datacenter for the CloudBridge Connector tunnel**. This task involves creating an IPSec profile, an IP tunnel entity, and a PBR entity in the Citrix ADC appliance in datacenter. The IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used in the CloudBridge Connector tunnel. The IP tunnel specifies the IP address of both the CloudBridge Connector tunnel end points (the Citrix ADC appliance in datacenter and the gateway in Azure) and the protocol to be used in the CloudBridge Connector tunnel. You then associate the IPSec profile entity with the IP tunnel entity. The PBR entity specifies the two subnets, in the datacenter and in the Azure cloud, that are to communicate with each other through the CloudBridge Connector tunnel. You then associate the IP tunnel entity with the PBR entity.

Configuring Microsoft Azure for the CloudBridge Connector tunnel

To create a CloudBridge Connector tunnel configuration on Microsoft Azure, use the Microsoft Windows Azure Management Portal, which is a web based graphical interface for creating and managing resources on Microsoft Azure.

Before you begin the CloudBridge Connector tunnel configuration on Azure cloud, make sure that:

- You have a user account for Microsoft Azure.
- You have a conceptual understanding of Microsoft Azure.
- You are familiar with the Microsoft Windows Azure Management Portal.

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on Microsoft Azure by using the Microsoft Windows Azure Management Portal:

- **Create a local network entity**. Create a local network entity in Windows Azure for specifying the network details of the datacenter. A local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the Citrix ADC) on the datacenter side and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel.
- **Create a Virtual Network**. Create virtual network entity that defines a network on Azure. This task includes defining a private address space, where you provide a range of private addresses and subnets belonging to the range specified in the address space. The traffic of the subnets will traverse the CloudBridge Connector tunnel. You then associate a local network entity with the virtual network entity. This association lets Azure create a configuration for a CloudBridge Connector tunnel between the virtual network and the data center network. A gateway (to be created) in Azure for this virtual network will be the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel. You then define a private subnet for the gateway to be created. This subnet belongs to the range specified in the address space in the virtual network entity.
- **Create a gateway in Windows Azure**. Create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel. Azure, from its pool of public IP addresses, assigns an IP address to the gateway created.
- **Gather the public IP address of the gateway and the pre-shared key.** For a CloudBridge Connector tunnel configuration on Azure, the public IP address of the gateway and the pre-shared Key (PSK) are automatically generated by Azure. Make a note of this information. You will need it for configuring the CloudBridge Connector tunnel on the Citrix ADC in datacenter.

> **Note:**
>
> The procedures for configuring Microsoft Azure for a CloudBridge Connector tunnel might change over time, depending on the Microsoft Azure release cycle. For the latest procedures, see the Microsoft Azure documentation.

Configuring the Citrix ADC Appliance in the datacenter for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on the Citrix ADC in the datacenter. You can use either the Citrix ADC command line or the GUI:

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol

in the CloudBridge Connector tunnel.

- **Create an IP tunnel with IPSec protocol and associate the IPSec profile to it**. An IP tunnel specifies the local IP address (a public SNIP address configured on the Citrix ADC appliance), remote IP address (the public IP address of the gateway in Azure), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate the IP tunnel to it**. A PBR entity specifies a set of conditions and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range to specify the datacenter subnet whose traffic is to traverse the tunnel, and the destination IP address range to specify the Azure subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet originated from a client in the subnet on the datacenter and destined to a server in the subnet on the Azure cloud matches the source and destination IP range of the PBR entity. This packet is then considered for CloudBridge Connector tunnel processing and is sent across sent across the CloudBridge Connector tunnel associated with the PBR entity.

The GUI combines all these tasks in a single wizard called the CloudBridge Connector wizard.
To create an IPSEC profile by using the Citrix ADC command line:

At the Command prompt, type:

```
add ipsec profile <name> -psk <string> -ikeVersion v1
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line:

At the Command prompt, type:

```
add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -
ipsecProfileName <string>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

```
add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> ipTunnel
 <tunnelName> apply pbrs
```

Sample Configuration

The following commands create all settings of Citrix ADC appliance CB_Appliance-1 used in “Example of CloudBridge Connector Configuration and Data Flow”.

```
1 > add ipsec profile CB_Azure_IPSec_Profile -psk
     DkiMgMdcbqvYREEuIvxsbKkW0FOyDiLM  -ikeVersion v1  - lifetime 31536000
2 Done
3
4 >  add iptunnel CB_Azure_Tunnel 168.63.252.133 255.255.255.255
     66.165.176.15  - protocol IPSEC  - ipsecProfileName
     CB_Azure_IPSec_Profile
```

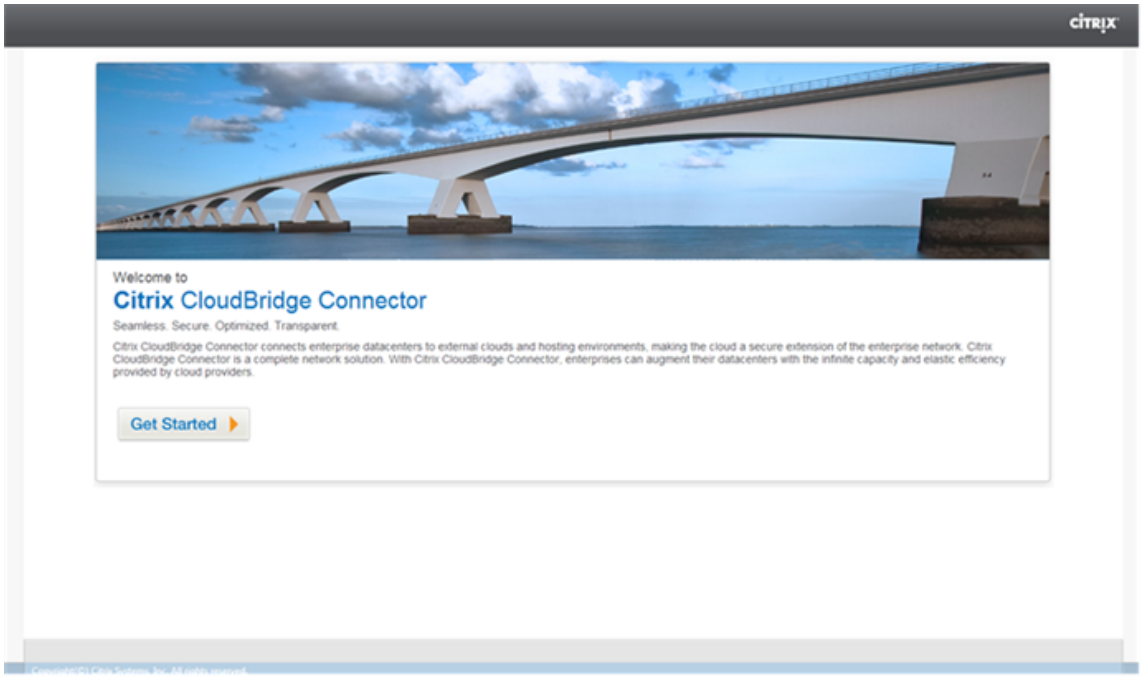
```
Done

> add pbr CB_Azure_Pbr -srcIP 10.102.147.0-10.102.147.255 -destIP
    10.20.0.0-10.20.255.255 -ipTunnelCB_Azure_Tunnel
Done

> apply pbrs
Done
<!--NeedCopy-->
```

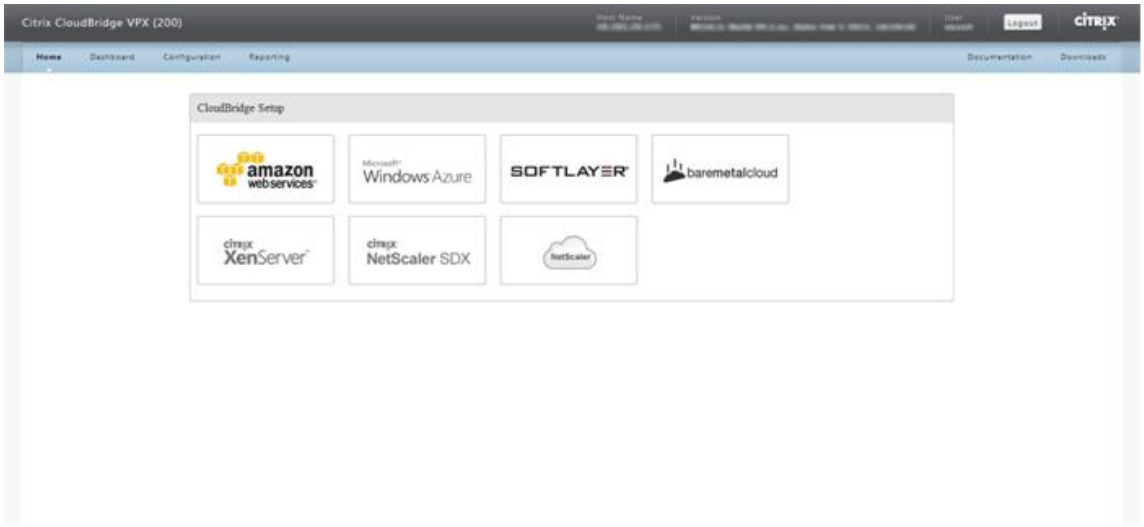
To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI

1. Access the GUI by using a web browser to connect to the IP address of the Citrix ADC appliance in the datacenter.
2. Navigate to **System** > **CloudBridge Connector**.
3. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.
4. Click **Get Started**.

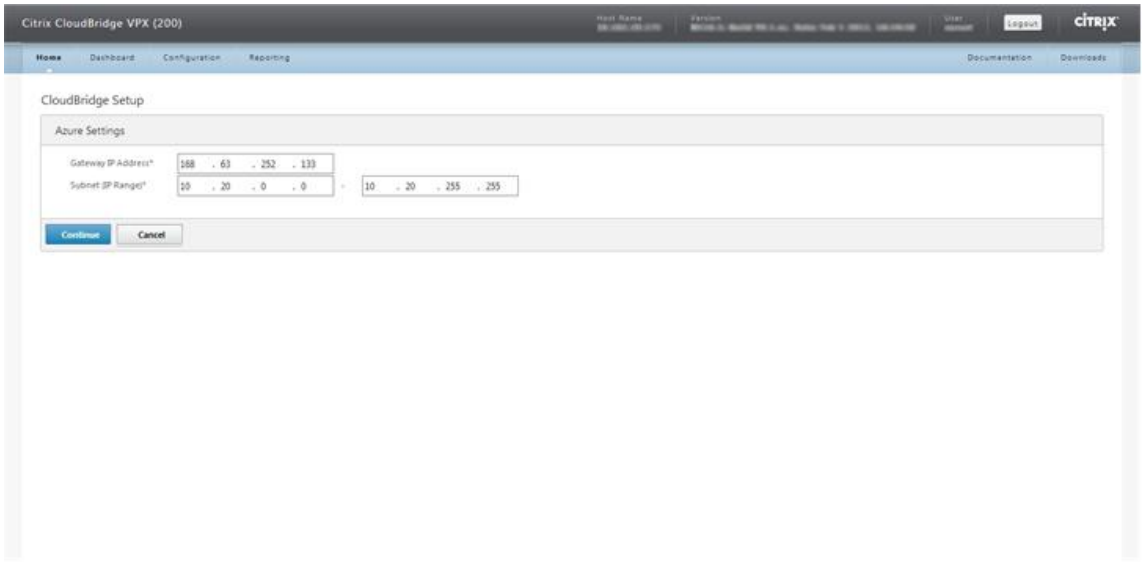


> **Note**: If you already have any CloudBridge Connector tunnel configured on the Citrix ADC appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

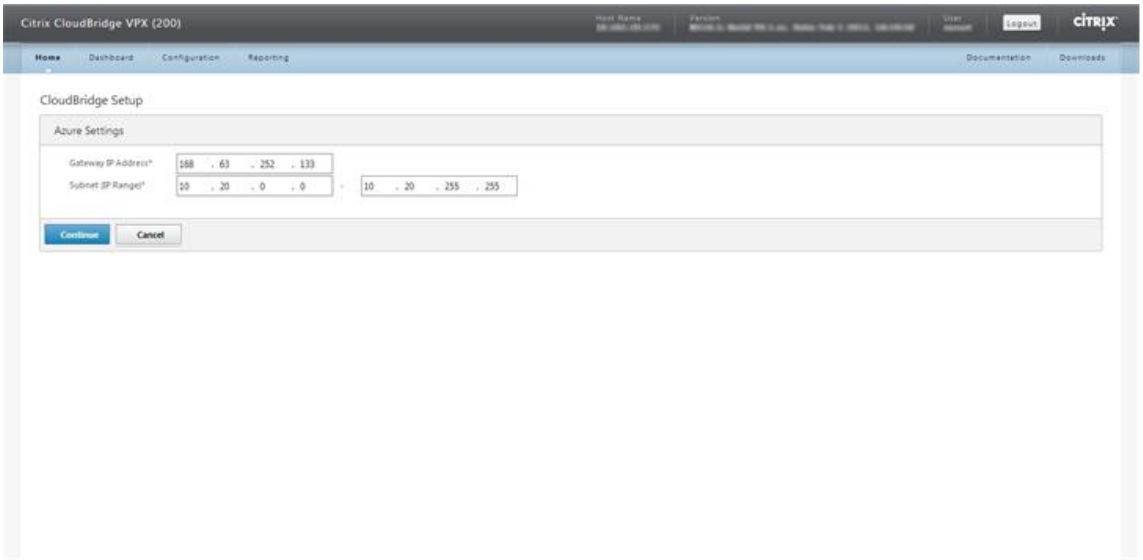
5. In the CloudBridge Setup pane, click **Microsoft Windows Azure**.



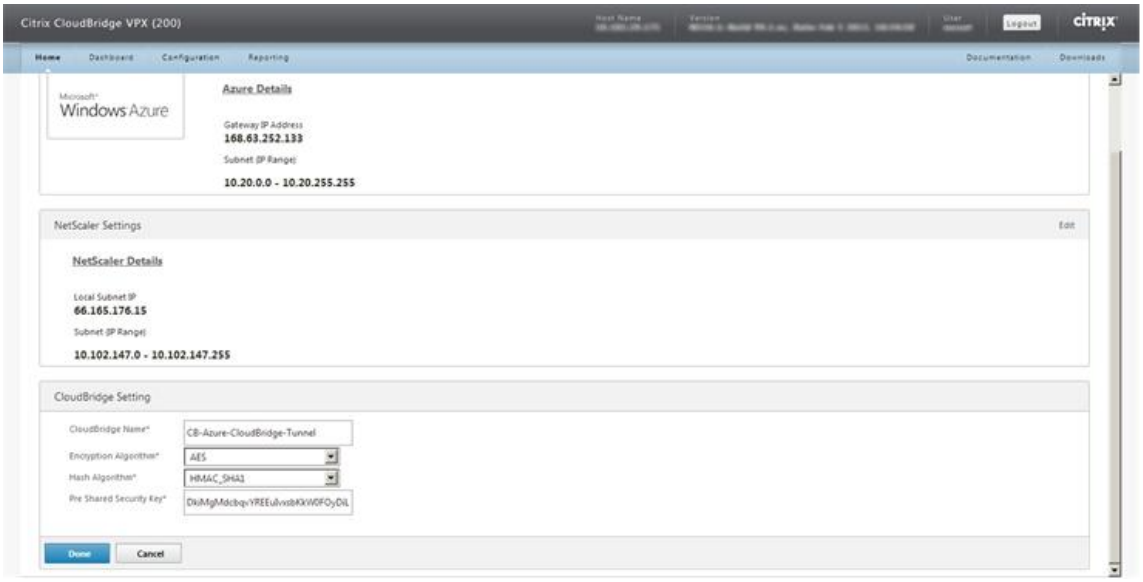
6. In the Azure Settings pane, in the **Gateway IP Address** field, type the IP address of the Azure gateway. The CloudBridge Connector tunnel is then set up between the Citrix ADC appliance and the gateway. In the **Subnet (IP Range)** text boxes, specify a subnet range (in Azure cloud), the traffic of which is to traverse the CloudBridge Connector tunnel. Click **Continue**.



7. In the Citrix ADC Settings pane, from the **Local Subnet IP** drop-down list, select a publicly accessible SNIP address configured on the Citrix ADC appliance. In **Subnet (IP Range)** text boxes, specify a local subnet range, the traffic of which is to traverse the CloudBridge Connector tunnel. Click **Continue**.



8. In the **CloudBridge Setting** pane, in the CloudBridge Name text box, type a name for the CloudBridge that you want to create.



9. From the Encryption Algorithm and Hash Algorithm drop-down lists, select the AES and HMAC_SHA1 algorithms, respectively. In the Pre Shared Security Key text box, type the security key.
10. Click **Done**.

Monitoring the CloudBridge Connector tunnel

You can view statistics for monitoring the performance of a CloudBridge Connector tunnel between the Citrix ADC appliance in the datacenter and Microsoft Azure. To view CloudBridge Connector tunnel statistics on the Citrix ADC appliance, use GUI or Citrix ADC command line. To view CloudBridge

Connector tunnel statistics in Microsoft Azure, use the Microsoft Windows Azure Management Portal.

Displaying CloudBridge Connector tunnel Statistics in the Citrix ADC appliance

For information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

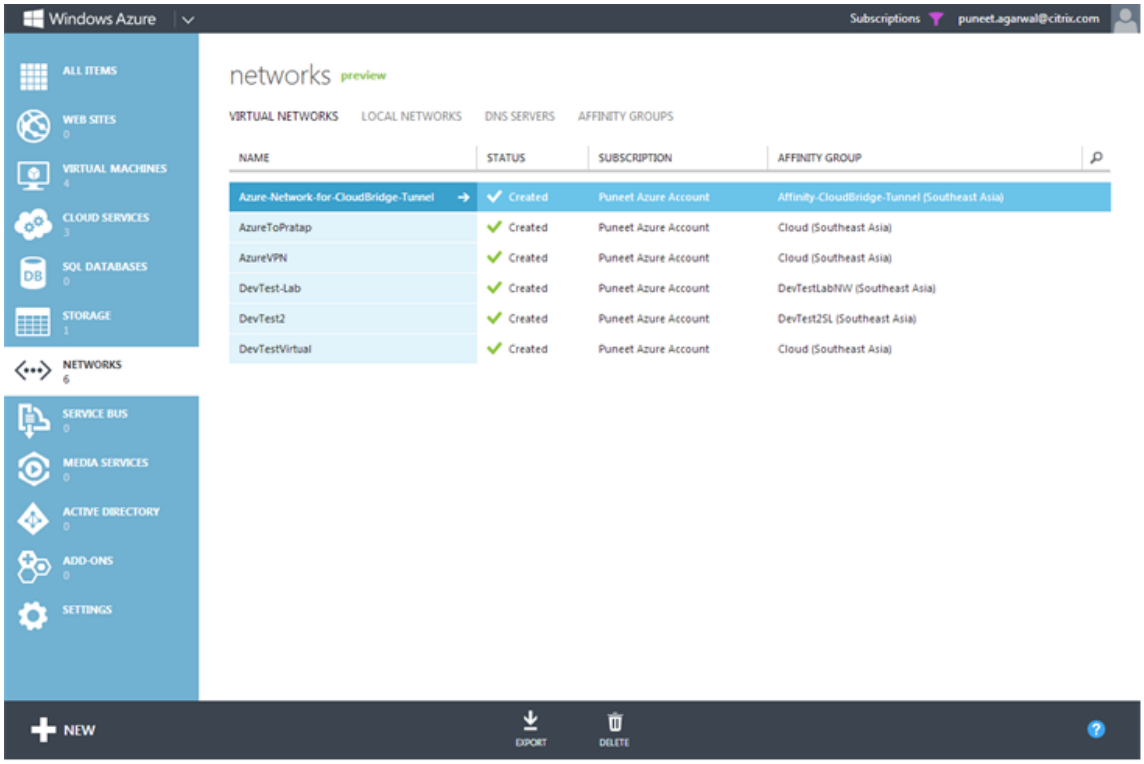
Displaying CloudBridge Connector tunnel Statistics in Microsoft Azure

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels in Microsoft Azure.

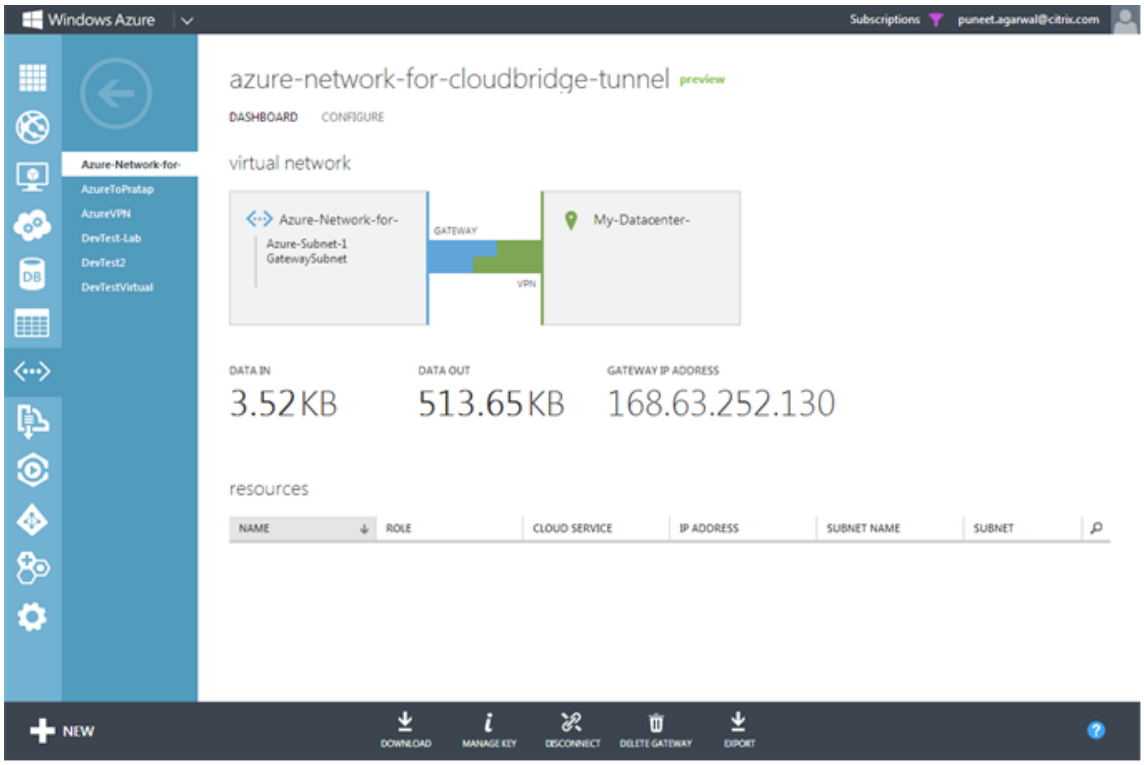
Statistical counter	Specifies
DATA IN	Total number of kilobytes received by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.
DATA OUT	Total number of kilobytes sent by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.

To display CloudBridge Connector tunnel statistics by using the Microsoft Windows Azure Management Portal

1. Log on to the Windows Azure Management Portal by using your Microsoft Azure account credentials.
2. In the left pane, click **NETWORKS**.
3. On the **Virtual Network** tab, in the Name column, select the virtual network entity associated with a CloudBridge Connector tunnel whose statistics you want to display.



4. On the **DASHBOARD** page of the virtual network, view the DATA IN and DATA OUT counters for the CloudBridge Connector tunnel.



Configuring CloudBridge Connector tunnel between datacenter and softlayer enterprise cloud

September 14, 2021

The GUI includes a wizard that helps you to easily configure a CloudBridge Connector tunnel between a Citrix ADC appliance in a datacenter and Citrix ADC VPX instances on the SoftLayer enterprise cloud.

When you use the wizard of the Citrix ADC appliance in the datacenter, the CloudBridge Connector tunnel configuration created on the Citrix ADC appliance, is automatically pushed to the other endpoint or peer (the Citrix ADC VPX on SoftLayer) of the CloudBridge Connector tunnel.

Using the wizard of the Citrix ADC appliance in the datacenter, you perform the following steps to configure a CloudBridge Connector tunnel.

1. Connect to the Softlayer enterprise cloud by providing the user log on credentials.
2. Select the Citrix XenServer that is running the Citrix ADC VPX appliance.
3. Select the Citrix ADC VPX appliance.
4. Provide CloudBridge Connector tunnel parameters to:
    - Configure a GRE Tunnel.
    - Configure IPsec on the GRE tunnel.
    - Create a netbridge, which is a logical representation of the CloudBridge connector, by specifying a name.
    - Bind the GRE Tunnel to the netbridge.

To configure a CloudBridge Connector tunnel by using the GUI

1. Log on to the GUI of the Citrix ADC appliance in the datacenter by using your account credentials for the appliance.
2. Navigate to **System** > **CloudBridge Connector** .
3. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge Connector**.
4. Click **Get Started**.

> **Note**:
>
> If you already have any CloudBridge Connector tunnel configured on the Citrix ADC appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

1. In the CloudBridge Connector Setup pane, click Softlayer, and then follow the instructions in the wizard.

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and Cisco IOS device

September 14, 2021

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco device to connect two datacenters or extend your network to a Cloud provider. The Citrix ADC appliance and the Cisco IOS device form the end points of the CloudBridge Connector tunnel and are called peers.

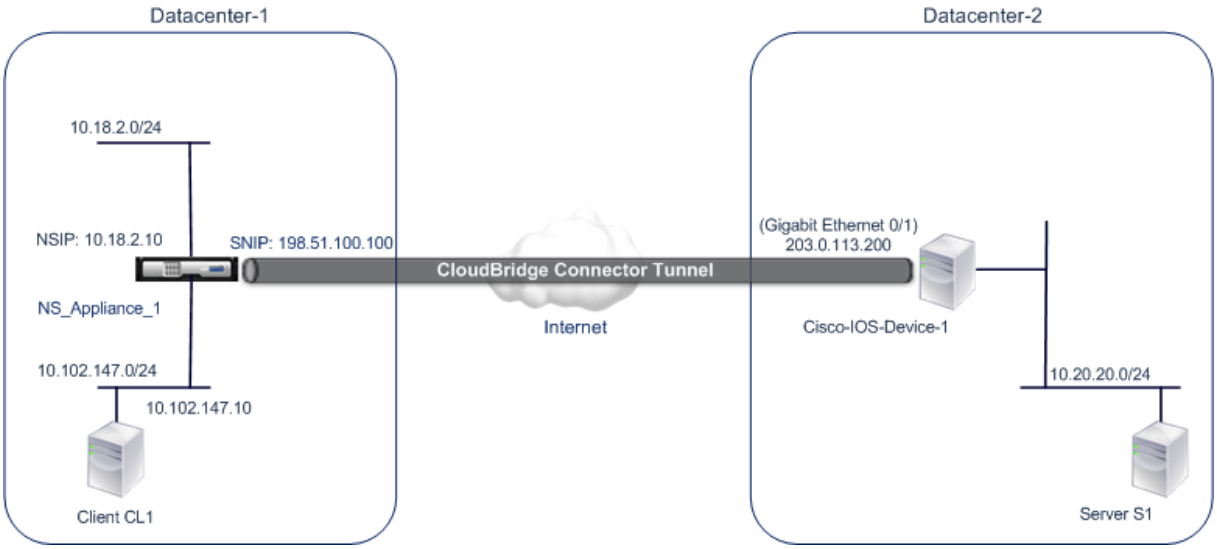
Example of CloudBridge Connector tunnel configuration and data flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco IOS device Cisco-IOS-Device-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco_Tunnel, and policy based routing (PBR) entity NS_Cisco_Pbr.



For more information, refer to the CloudBridge Connector tunnel between a Citrix ADC appliance and Cisco IOS device settings pdf.

Points to Consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device, consider the following points:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device.

IPSec Properties	Setting
IPSec mode	Tunnel mode
IKE version	Version 1
IKE DH group	DH group 2 (1024 bits MODP algorithm)
IKE authentication method	Pre-Shared Key
IKE encryption algorithm	AES, 3DES
IKE hash algorithm	HMAC SHA1, HMAC SHA256, HMAC SHA384, HMAC SHA512, HMAC MD5
ESP encryption algorithm	AES, 3DES
ESP hash algorithm	HMAC SHA1, HMAC SHA256, HMAC SHA256, HMAC SHA256, HMAC MD5

- You must specify the same IPSec settings on the Citrix ADC appliance and the Cisco IOS device

at the two ends of the CloudBridge Connector.

- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another, and a common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore on the Cisco device, you must specify the same hash algorithm and same encryption algorithm for IKE (while creating IKE policy) and ESP (while creating IPSec transform set).
- You must configure the firewall at the Citrix ADC end and Cisco device end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

Configuring the Cisco IOS device for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel on a Cisco IOS device, use the Cisco IOS command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco devices.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco IOS device, make sure that:

- You have a user account with administrator credentials on the Cisco IOS device.
- You are familiar with the Cisco IOS command line interface.
- The Cisco IOS device is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

> **Note**:
>
> The procedures for configuring CloudBridge Connector tunnel on a Cisco IOS device might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco product documention for more information, see Configuring IPSec VPN tunnels topic.

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a Cisco IOS device, perform the following tasks on the Cisco device's IOS command line:

- Create an IKE Policy.
- Configure a Pre-shared key for IKE authentication.
- Define a transform set and configure IPSec in tunnel mode.
- Create a crypto access List
- Create a crypto map
- Apply the crypto Map to an interface

The examples in the following procedures create settings in `Cisco IOS device Cisco-IOS-Device-1` mentioned in section "Example of CloudBridge Connector Configuration and Data Flow."

To create an IKE policy, refer to the IKE policy pdf.

To configure a pre-shared key by using the Cisco IOS command line:

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto isakmp identity address	Cisco-ios-device-1(config)# crypto isakmp identity address	Specify the ISAKMP identity (address) for the Cisco IOS device to use when communicating with the peer (Citrix ADC appliance) during IKE negotiations. This example specifies the address keyword, which uses IP address 203.0.113.200 (Gigabit Ethernet interface 0/1 of Cisco-IOS-Device-1) as the identity for the device.
crypto isakmp key keystringaddress peer-address	Cisco-ios-device-1 (config)# crypto isakmp key examplepresharedkey address 198.51.100.100	Specify a pre-shared key for the IKE authentication. This example configures shared key examplepresharedkey to be used with the Citrix ADC appliance NS_Appliance-1 (198.51.100.100). The same pre-shared key must be configured on the Citrix ADC appliance for IKE authentication to be successful between the Cisco IOS device and the Citrix ADC appliance.

To create a crypto access list by using the Cisco IOS command line:

At the Cisco IOS device's command prompt, type the following command in global configuration mode, in the order shown:

Command	Example	Command Description
access-listaccess-list-number permit IPsource source-wildcard destination destination-wildcard	Cisco-ios-device-1(config)# access-list 111 permit ip 10.20.20.0 0.0.0.255 10.102.147.0 0.0.0.255	Specify conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example configures access list 111 to protect traffic from subnets 10.20.20.0/24 (at the Cisco-IOS-Device-1 side) and 10.102.147.0/24 (at the NS_Appliance-1 side).

To define a transform and configure IPSec tunnel mode by using the Cisco IOS command line:

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:
Command	Example	Command Description
–	–	–
crypto ipsec transform-setname ESP_Authentication_Transform ESP_Encryption_Transform Note: ESP_Authentication_Transform can take the following values: esp-sha-hmac, esp-sha256-hmac, esp-sha384-hmac, esp-sha512-hmac, esp-md5-hmac. ESP_Encryption_Transform can take the following values: esp-aes or esp-3des	Cisco-ios-device-1(config)# crypto ipsec transform-set NS-CISCO-TS esp-sha256-hmac esp-3des	Define a transform set and specify the ESP hash algorithm (for authentication) and the ESP encryption algorithm to be used during exchange of data between the CloudBridge Connector tunnel peers. This example defines transform set NS-CISCO-TS and specifies ESP authentication algorithm as esp-sha256-hmac, and ESP encryption algorithm as esp-3des.
mode tunnel	Cisco-ios-device-1 (config-crypto-trans)# mode tunnel	Set IPSec in tunnel mode.
exit	Cisco-ios-device-1 (config-crypto-trans)# exit, Cisco-ios-device-1 (config)#	Exit back to global configuration mode.

To create a crypto map by using the Cisco IOS command line:

At the Cisco IOS device's command prompt, type the following commands starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto mapmap-name seq-num ipsec-isakmp	Cisco-ios-device-1 (config)# crypto map NS-CISCO-CM 2 ipsec-isakmp	Enter crypto map configuration mode, specify a sequence number for the crypto map, and configure the crypto map to use IKE to establish security associations (SAs). This example configures sequence number 2 and IKE for crypto map NS-CISCO-CM.
set peer ip-address	Cisco-ios-device-1 (config-crypto-map)# set peer 172.23.2.7	Specify the peer (Citrix ADC appliance) by its IP address. This example specifies 198.51.100.100, which is the CloudBridge Connector endpoint IP address on the Citrix ADC appliance.
match addressaccess-list-id	Cisco-ios-device-1 (config-crypto-map)# match address 111	Specify an extended access list. This access list specifies conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example specifies access list 111.
set transform-set transform-set-name	Cisco-ios-device-1 (config-crypto-map)# set transform-set NS-CISCO-TS	Specify which transform sets are allowed for this crypto map entry. This example specifies transform set NS-CISCO-TS.
exit	Cisco-ios-device-1 (config-crypto-map)# exit	
Cisco-ios-device-1 (config)#	Exit back to global configuration mode.	

To apply a crypto map to an interface by using the Cisco IOS command line:

At the Cisco IOS device's command prompt, type the following commands starting in global configuration mode, in the order shown:

Command	Example	Command Description
interfaceinterface-ID	Cisco-ios-device-1(config)# interface GigabitEthernet 0/1	Specify a physical interface to which to apply the crypto map and enter interface configuration mode. This example specifies Gigabit Ethernet interface 0/1 of the Cisco device Cisco-IOS-Device-1. IP address 203.0.113.200 is already set to this interface.
crypto mapmap-name	Cisco-ios-device-1 (config-if)# crypto map NS-CISCO-CM	Apply the crypto map to the physical interface. This example applies crypto map NS-CISCO-CM.
exit	Cisco-ios-device-1 (config-if)# exit, Cisco-ios-device-1 (config)#	Exit back to global configuration mode.

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- Create an IPSec profile.
- Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.
- Create a PBR rule and associate it with the IP tunnel.

To create an IPSEC profile by using the Citrix ADC command line:

At the Command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1`
- `show ipsec profile <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line:

At the Command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
- add ipTunnel <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line:

At the Command prompt, type:

- add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
- apply pbrs
- show pbrs <pbrName>

The following commands create settings in Citrix ADC appliance NS_Appliance-1 mentioned in section **Example of CloudBridge Connector Configuration and Data Flow**.

```
1      >  add ipsec profile NS_Cisco_IPSec_Profile -psk
           examplepresharedkey -ikeVersion v1  - lifetime 315360  - encAlgo 3
           DES
2      Done
3      >  add iptunnel NS_Cisco_Tunnel 203.0.113.200 255.255.255.255

```

To create an IPSEC profile by using the GUI:

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the **IPSec authentication** method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication** method and set

the **Pre-Shared Key Exists** parameter.

5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI:

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** dialog box, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop down list, select Subnet IP).
   - Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** dialog box, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

To apply a PBR by using the GUI:

1. Navigate to **System** > **Network** > **PBRs**.
2. On the **PBRs** tab, select the **PBR**, in the **Action list**, select **Apply**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and fortinet fortiGate appliance

September 14, 2021

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Fortinet FortiGate appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the FortiGate appliance form the end points of the CloudBridge Connector tunnel and are called peers.

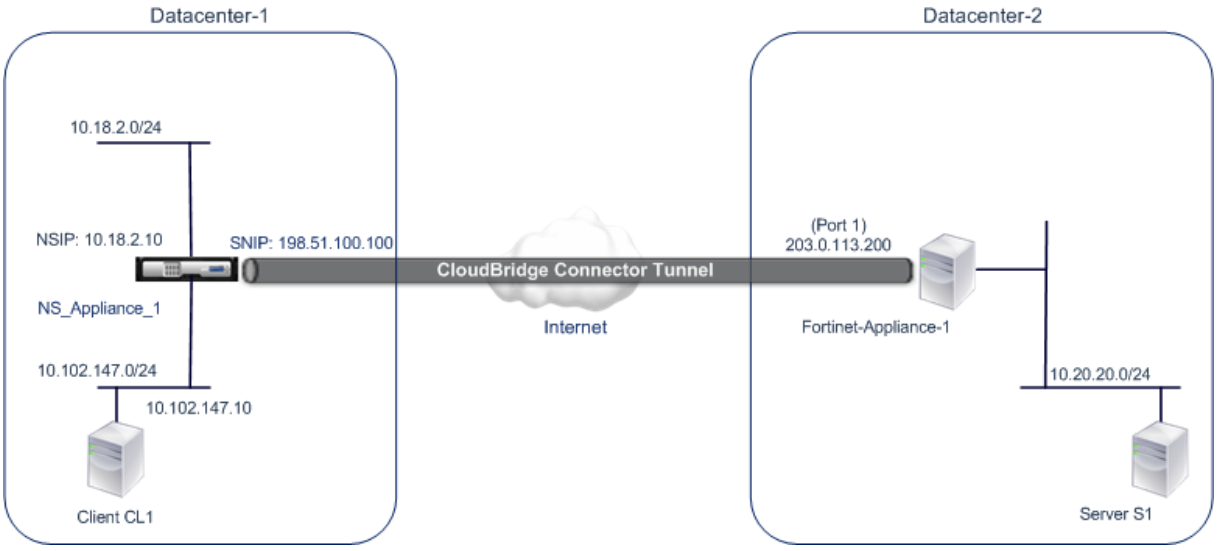
Example of a CloudBridge Connector Tunnel Configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- FortiGate appliance FortiGate-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and FortiGate-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and FortiGate-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Fortinet_IPSec_Profile, CloudBridge Connector tunnel entity NS_Fortinet_Tunnel, and policy based routing (PBR) entity NS_Fortinet_Pbr.



For more information, see CloudBridge Connector tunnel configuration table pdf.

For information about Settings on Fortinet FortiGate-Appliance-1 in Datacenter-2, see table.

Points to consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance, consider the following points:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance.

IPSec Properties	Settings
IPSec mode	Tunnel mode
IKE version	Version 1
IKE DH group	DH group 2 (1024 bits MODP algorithm)
IKE authentication method	Pre-Shared Key
IKE encryption algorithm	AES
IKE hash algorithm	HMAC SHA1
ESP encryption algorithm	AES
ESP hash algorithm	HMAC SHA1

- You must specify the same IPSec settings on the Citrix ADC appliance and the FortiGate appliance at the two ends of the CloudBridge Connector.

- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore in the FortiGate appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).
- You must configure the firewall at the Citrix ADC end and FortiGate end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets
- FortiGate appliance supports two types of VPN tunnels: Policy-based and Route-based. Only policy-based VPN tunnel is supported between a FortiGate appliance and a Citrix ADC appliance.

Configuring FortiGate appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel on a FortiGate appliance, use the Fortinet Web-based Manager, which is the primary user interface for configuring, monitoring, and maintaining FortiGate appliances.

Before you begin the CloudBridge Connector tunnel configuration on a FortiGate appliance, make sure that:

- You have a user account with administrator credentials on the FortiGate appliance.
- You are familiar with the Fortinet Web-based Manager.
- The FortiGate appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

> **Note**
>
> The procedures for configuring CloudBridge Connector tunnel on a FortiGate appliance might change over time, depending on the Fortinet release cycle. Citrix recommends that you follow the official Fortinet product documentation for Configuring IPSec VPN tunnels.

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a FortiGate appliance, perform the following tasks on the FortiGate appliance by using the Fortinet Web-based manager:

- **Enable Policy-based IPSec VPN feature**. Enable this feature for creating policy-based VPN tunnels on the FortiGate appliance. Only policy-based type of VPN tunnel is supported between a FortiGate appliance and a Citrix ADC appliance. A policy-based VPN tunnel configuration on a FortiGate appliance includes phase 1 settings, phase 2 settings, and an IPSec security policy.
- **Define phase 1 parameters.** Phase 1 parameters are used by the FortiGate appliance for IKE Authentication before forming a secure tunnel to the Citrix ADC appliance.

- **Define phase 2 parameters**. Phase 2 parameters are used by the FortiGate appliance for forming a secure tunnel to the Citrix ADC appliance by establishing IKE security associations (SA).
- **Specify private subnets**. Define the FortiGate-side and the Citrix ADC-side private subnets whose IP traffic is to be transported through the tunnel.
- **Define an IPSec security policy for the tunnel**. A security policy allow IP traffic to pass between interfaces on a FortiGate appliance. An IPSec security policy specifies the interface to the private subnet and the interface connecting the Citrix ADC appliance through the tunnel.

To enable Policy-based IPSec VPN feature by using the Fortinet Web-based Manager

1. Navigate to **System** > **Config** > **Features**.
2. On the **Feature Settings** page, select **Show More** and turn on **Policy-based IPSec VPN**.

To define phase 1 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN** > **IPsec** > **Auto Key (IKE)** and click **Create Phase1**.
2. On the **New Phase 1** page, set the following parameters:
    - Name: Enter a name for this phase 1 configuration.
    - Remote Gateway: Select *Static IP Address.*
    - Mode: Select *Main (ID Protection)*.
    - Authentication Method: Select *Preshared Key*.
    - Pre-Shared Key: Enter a pre-shared key. The same pre-shared key must be configured on the Citrix ADC appliance.
    - Peer Options: Set the following IKE paramters for authenticating a Citrix ADC appliance.
        - IKE Version: Select *1*.
        - Mode Config: Clear this option if it is selected.
        - Local Gateway IP: Select *Main Interface IP*.
        - P1 Proposal: Select the encryption and authentication algorithms for IKE Authentication before forming a secure tunnel to the Citrix ADC appliance.
            * 1 - Encryption: Select *AES128*.
            * Authentication: Select *SHA1*.
            * Keylife: Enter an amount of time (in seconds) for the phase 1 key life.
            * DH Group: Select 2.
        - X-Auth: Select *Disable*.
        - Deed Peer Detection: Select this option.
3. Click **OK**.

To specify private subnets by using the Fortinet Web-based Manager

1. Navigate to **Firewall Objects** > **Address** > **Addresses** and select **Create New**.
2. On the **New Address** page, set the following parameters:
    - Name: Enter a name for FortiGate-side subnet.
    - Type: Select *Subnet*.
    - Subnet / IP Range: Enter the address of the FortiGate-side subnet.

- Interface: Select the local interface to this subnet.

3. Click **OK**.
4. Repeat steps 1-3 to specify the Citrix ADC-side subnet.

To define phase 2 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN** > **IPsec** > **Auto Key (IKE)** and click **Create Phase 2**.
2. On the **New Phase 2** page, set the following parameters:
   - Name: Enter a name for this phase 2 configuration.
   - Phase 1: Select the Phase 1 configuration from the drop-down list.
3. Click **Advanced** and set the following parameters:
   - P2 Proposal: Select the encryption and authentication algorithms for forming a secure tunnel to the Citrix ADC appliance.
     - 1 - Encryption: Select *AES128*.
     - Authentication: Select *SHA1*.
     - Enable replay detection: Select this option.
     - Enable perfect forward secrecy (PFS): Select this option.
     - DH Group: Select *2*.
   - Keylife: Enter an amount of time (in seconds) for the phase 2 key life.
   - Autokey Keep Alive: Select this option.
   - Auto-negotiate: Select this option.
   - Quick Mode Selector: Specify the FortiGate-side and the Citrix ADC-side private subnets whose traffic is to be traversed through the tunnel.
     - Source Address: Select the FortiGate-side subnet from the drop-down list.
     - Source Port: Enter *0*.
     - Destination Address: Select the Citrix ADC-side subnet from the drop-down list.
     - Destination Port: Enter *0*.
     - Protocol: Enter *0*.
4. Click **OK**.

To define an IPSec security policy by using the Fortinet Web-based Manager

1. Navigate to **Policy** > **Policy** > **Policy** and click **Create New**.
2. On the **Edit Policy** page, set the following parameters:
   - Policy Type: Select *VPN*.
   - Policy Subtype: Select *IPSec*.
   - Local Interface: Select the local interface to the internal (private) network.
   - Local Protected Subnet: Select the FortiGate-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   - Outgoing VPN Interface: Select the local interface to the external (public) network.
   - Remote Protected Subnet: Select the Citrix ADC-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.

- Schedule: Keep the default setting (*always*) unless changes are needed to meet specific requirements.
- Service: Keep the default setting (*ANY*) unless changes are needed to meet your specific requirements.
- VPN Tunnel: Select *Use Existing* and select the tunnel from the drop-down list.
- Allow traffic to be initiated from the remote site: Select if traffic from the remote network will be allowed to initiate the tunnel.

3. Click **OK**.

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the FortiGate appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the FortiGate appliance side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE`
- `show ipsec profile <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName** <string>`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>`
- `apply pbrs`
- `show pbr <pbrName>`

To create an IPSEC profile by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
   - Perfect Forward Secrecy (Enable this paramter)
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select *Subnet IP*).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System** > **Network** > **PBR**.

2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select *IP Tunnel*)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in "Example of a CloudBridge Connector Configuration."

```
1      > add ipsec profile NS_Fortinet_IPSec_Profile -psk
          examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo
          HMAC_SHA1 -lifetime 315360 -perfectForwardSecrecy ENABLE
2
3       Done
4      > add iptunnel NS_Fortinet_Tunnel 203.0.113.200 255.255.255.255
          198.51.100.100 -protocol IPSEC -ipsecProfileName
          NS_Fortinet_IPSec_Profile
5
6       Done
7      > add pbr NS_Fortinet_Pbr -srcIP 10.102.147.0-10.102.147.255 -
          destIP 10.20.0.0-10.20.255.255 -ipTunnel NS_Fortinet_Tunnel
8
9       Done
10     > apply pbrs
11
12      Done
13 <!--NeedCopy-->
```

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying Cloud-

Bridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector tunnel diagnostics and troubleshooting

September 14, 2021

If you have problems with a CloudBridge Connector tunnel configuration, make sure that all prerequisites were observed before the tunnel was set up. If they were, the problem might be with the tunnel end-point IP addresses, a NAT configuration, the way the tunnel was set up, or with the data traffic.

Troubleshooting a CloudBridge Connector tunnel

If your CloudBridge Connector tunnel does not function properly, the issue could be with tunnel establishment or with the data traffic. If you are unsure which type of problem you have, look for an error message in the log file and see if the error message is in the list of tunnel-establishment issues. If you do not find your error message, check the list of possible issues related to data traffic.

Issues Related to tunnel establishment

After the requirements for configuring the IPSec tunnel are met and the CloudBridge Connector tunnel is configured, if the status of the tunnel is not UP, look for debugging information in the iked.log file on one or both Citrix ADC appliances configured as the tunnel end points.

On either appliance, type the following command at the Citrix ADC shell prompt:

```
cat /tmp/iked.debug | tee /var/iked.log
```

The Troubleshooting pdf lists some common errors and their solutions.

Issues related to data traffic

If the data in the CloudBridge Connector tunnel are not exchanged properly between the tunnel end points, do the following.

- For a CloudBridge Connector tunnel that uses GRE and IPSec protocols:
  - Make sure that L2 mode is enabled on both of the CloudBridge Connector tunnel end points. To enable L2 mode, type the following command at the Citrix ADC command line interface:

    ```
    enable mode L2
    ```

        * If one of the CloudBridge Connector tunnel end points is a CloudBridge virtual appliance (VPX) and is provisioned on a VMware ESXi hypervisor, make sure that Promiscuous mode is set to Accept for the vSwitch associated with the CloudBridge VPX appliance.
    - If a VLAN is extended through a CloudBridge Connector tunnel, verify one-to-one mapping on the extended VLAN entity on each of the tunnel end points
    - Make sure that the IP tunnel entity is bound to the correct netbridge entity in each of the tunnel end points.
    - Verify that the ARP entry for the peer CloudBridge Connector tunnel end point exists on the local tunnel end point, by typing the following command at the Citrix ADC command line interface:

      ```
      show arp
      ```
    - If the output shows an incomplete ARP entry, bidirectional traffic is not flowing through the tunnel. If bidirectional traffic is flowing, the ARP entry shows the name of tunnel interface for the devices on the other side of the tunnel.
    - Remove the IP tunnel entities from both tunnel end points and add them again with the same parameters, but with the IPSec profile set to NONE, so that the tunnel uses only the GRE protocol.

      After verifying the following in the IP tunnel (that uses GRE protocol), configure the tunnel with IPSec parameters by specifying a valid IPSec profile to the respective IP tunnel entities on each of the tunnel end points.

      Proper PING or TCP flow through the tunnel.

      Proper flow of data traffic through the tunnel.

      After the configured tunnel (that uses GRE and IPSec protocols) is in UP state, if the data traffic does not flow properly through the tunnel, and if a NAT device was deployed in front of any or both of the tunnel end points, analyze the ingress and egress packets on the NAT devices.
- If a Citrix ADC appliance is used as Router or Gateway.
    - Make sure that L3 mode is enabled on the Citrix ADC appliance. To enable L3 mode, run the following command in the CloudBridge command line.
    - enable mode L3
    - If subnets are bound to a netbridge entity, make sure that correct IP tunnel entity is also bound to the netbridge.
    - Run the following command in the Citrix ADC command line to see where the packets (Input and Output)are getting dropped:

      ```
      stat ipsec counters
      ```
    - Make sure that the correct routes are configured on both the tunnel end points.
    - If no NAT device is deployed in front of the Citrix ADC appliance, make sure that the firewalls are configured to allow any ESP (IP protocol number 50) packets and any UDP pack-

ets for port 4500.

If none of the above measures result in successful exchange of traffic between the tunnel end points, contact Citrix Technical Support.

Checklist before contacting Citrix technical Support

For a speedy resolution, make sure that you have the following items ready before contacting Citrix Technical Support.

- Details of the deployment and network topology.
- Log file collected by typing the following command at the Citrix ADC shell prompt.
  ```
  cat /tmp/iked.debug | tee /var/log/iked.log
  ```
- Tech support bundle captured by typing the following command at the Citrix ADC command line.
  ```
  show techsupport
  ```
- Packet traces captured on both CloudBridge Connector tunnel end points. To start a packet trace, type the following command at the Citrix ADC command line.
  ```
  start nstrace -size 0
  ```
  To stop packet trace, type the following command at the Citrix ADC command line.
  ```
  stop nstrace
  ```
- Output of the following command typed at the Citrix ADC command prompt.
  ```
  show arp
  ```

CloudBridge Connector interoperability – StrongSwan

September 14, 2021

StrongSwan is an opensource IPSec implementation for Linux platforms. You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the StrongSwan appliance form the end points of the CloudBridge Connector tunnel and are called peers.

Example of a CloudBridge Connector tunnel configuration

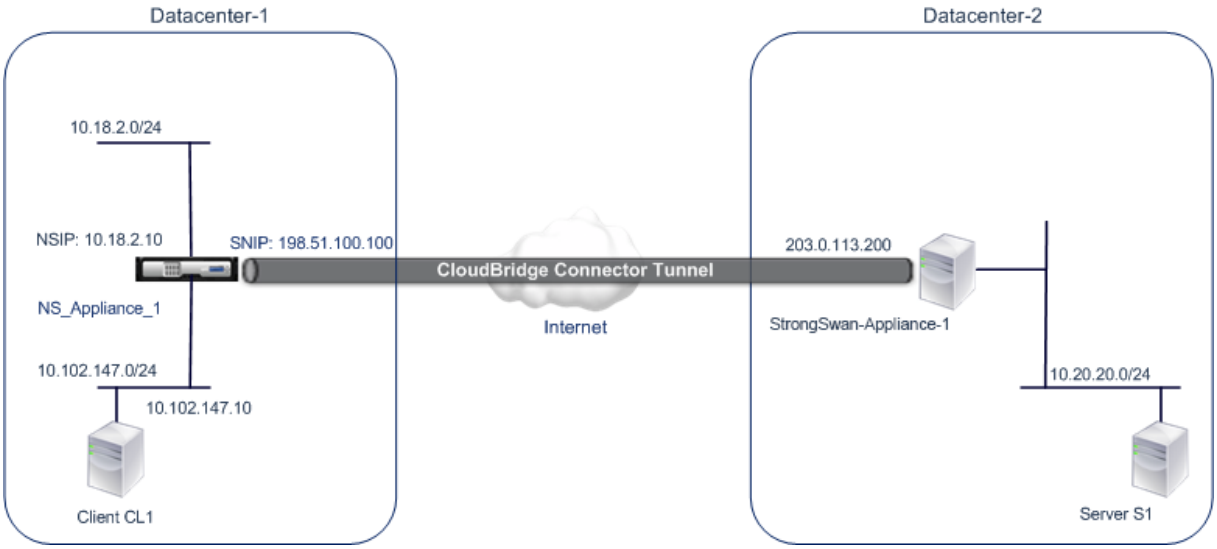
As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1

- StrongSwan appliance StrongSwan-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and StrongSwan-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and StrongSwan-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_StrongSwan_IPSec_Profile, CloudBridge Connector tunnel entity NS_StrongSwan_Tunnel, and policy based routing (PBR) entity NS_StrongSwan_Pbr.



The following table lists the settings used in this example.

Main settings of the CloudBridge Connector tunnel setup

Entity	Details
IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in Datacenter-1	198.51.100.100
IP address of the CloudBridge Connector tunnel end point (StrongSwan-Appliance-1) in Datacenter-2	203.0.113.200
Datacenter–1's subnet whose traffic is to be protected over the CloudBridge Connector tunnel	10.102.147.0/24

Entity	Details
Datacenter–2's subnet whose traffic is to be protected over the CloudBridge Connector tunnel	10.20.20.0/24

Settings on Citrix ADC appliance NS_Appliance-1 in Datacenter-1

SNIP1(for reference purposes only)	198.51.100.100	
IPSec profile	NS_StrongSwan_IPSec_Profile	IKE version: v1, Encryption algorithm: AES, Hash algorithm: HMAC_SHA1
psk = examplepresharedkey (Note: This is an example of a pre-share key, for illustration. Citrix does not recommend to use this string in your CloudBridge Connector configuration)		
CloudBridge Connector tunnel	NS_StrongSwan_Tunnel	Remote IP = 203.0.113.200, Local IP= 198.51.100.100, Tunnel protocol = IPSEC, IPSec profile= NS_StrongSwan_IPSec_Profile
Policy based route	NS_StrongSwan_Pbr	Source IP range = Subnet in the Datacenter-1=10.102.147.0-10.102.147.255, Destination IP range =Subnet in Datacenter-2=10.20.20.0-10.20.20.255, IP Tunnel = NS_StrongSwan_Tunnel

Points to consider for a CloudBridge Connector tunnel configuration

Before you begin configuring CloudBridge connector tunnel, make sure that:

- You have a basic knowledge about linux configurations.
- You have a basic Knowledge about IPSec protocol suite.
- The StrongSwan appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The Citrix ADC appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance.
  - IPSec mode: Tunnel mode
  - IKE version: Version 1
  - IKE authentication method: Pre-Shared Key
  - IKE encryption algorithm: AES
  - IKE hash algorithm: HMAC SHA1
  - ESP encryption algorithm: AES
  - ESP hash algorithm: HMAC SHA1
- You must specify the same IPSec settings on the Citrix ADC appliance and the StrongSwan appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the StrongSwan appliance, you must specify the same hash algorithm and same encryption algorithm in IKE and ESP parameters in the IPSec.conf file.
- You must configure the firewall at the Citrix ADC end and StrongSwan end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

Configure StrongSwan for the CloudBridge Connector tunnel

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a StrongSwan appliance, perform the following tasks on the StrongSwan appliance:

- **Specify IPsec connection information in ipsec.conf file**. ipsec.conf file defines all control and configuration information for IPsec connections in the strongSwan appliance.
- **Specify pre-shared key in ipsec.secrets file**. ipsec.secrets file defines secrets for IKE/IPsec authentication for IPsec connections in the strongSwan appliance.

The procedures for configuring IPsec VPN (CloudBridge Connector tunnel) on a StrongSwan appliance might change over time, depending on the StrongSwan release cycle. Citrix recommends that you follow the official StrongSwan documentation for Configuring IPSec VPN tunnels.

Following sample excerpt of ipsec.conf file specifies IPsec information for setting up the IPsec VPN tunnel, described in Example of a CloudBridge Connector Configuration topic. For more information, see CloudBridge Connector Configuration pdf.

Following sample excerpt of ipsec.secrets file specifies the IKE authentication pre-shared key for setting up the IPsec VPN tunnel, described in Example of a CloudBridge Connector Configuration topic.

`/etc/ipsec.secrets` PSK 'examplepresharedkey' #pre-shared key for IPsec IKE authentication

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (CloudBridge Connector tunnel endpoint IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the StrongSwan appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the StrongSwan side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1`
- `show ipsec profile <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`

- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>`
- `apply pbrs`
- `show pbr <pbrName>`

To create an IPSEC profile by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication method** and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the Add IP Tunnel page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select *Subnet IP*).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop-down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:

- Name
- Action
- Next Hop Type (Select *IP Tunnel*)
- IP Tunnel Name
- Source IP Low
- Source IP High
- Destination IP Low
- Destination IP High

4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration:

```
1      > add ipsec profile NS_StrongSwan_IPSec_Profile -psk
          examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo
          HMAC_SHA1
2
3
4      Done
5
6      > add iptunnel NS_StrongSwan_Tunnel 203.0.113.200 255.255.255.255
          198.51.100.100 -protocol IPSEC -ipsecProfileName
          NS_StrongSwan_IPSec_Profile
7
8
9      Done
10
11     > add pbr NS_StrongSwan_Pbr -srcIP 10.102.147.0-10.102.147.255 -
          destIP 10.20.0.0-10.20.255.255 -ipTunnel NS_StrongSwan_Tunnel
12
13
14     Done
15
16     > apply pbrs
17
18
19     Done
20 <!--NeedCopy-->
```

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector interoperability – F5 BIG-IP

September 14, 2021

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a F5 BIG-IP appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the F5 BIG-IP appliance form the end points of the CloudBridge Connector tunnel and are called peers.

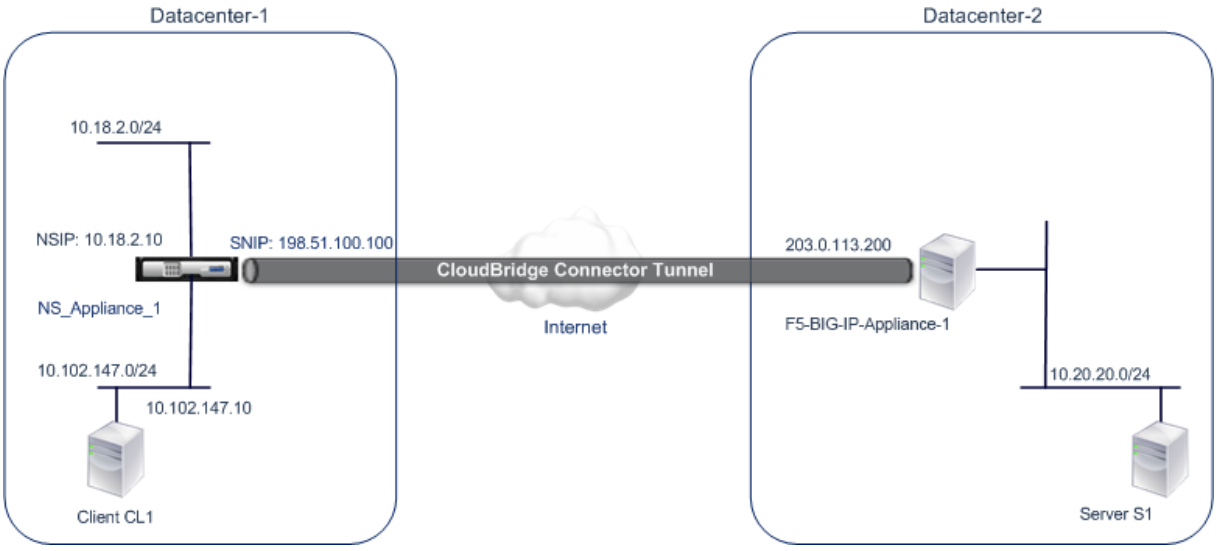
Example of a CloudBridge Connector tunnel configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- F5 BIG-IP appliance F5-BIG-IP-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and F5-BIG-IP-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and F5-BIG-IP-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_F5-BIG-IP_IPSec_Profile, CloudBridge Connector tunnel entity NS_F5-BIG-IP_Tunnel, and policy based routing (PBR) entity NS_F5-BIG-IP_Pbr.



For more information, refer to F5 big IP pdf.

Points to consider for a CloudBridge Connector tunnel configuration

- The Citrix ADC appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The F5 BIG-IP appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and an F5 BIG-IP appliance.
  - IPSec mode: Tunnel mode
  - IKE version: Version 1
  - IKE authentication method: Pre-Shared Key
  - IKE encryption algorithm: AES
  - IKE hash algorithm: HMAC SHA1
  - ESP encryption algorithm: AES
  - ESP hash algorithm: HMAC SHA1
- You must specify the same IPSec settings on the Citrix ADC appliance and the F5 BIG-IP appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the F5 BIG-IP appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).
- You must configure the firewall at the Citrix ADC end and F5 BIG-IP end to allow the following.
  - Any UDP packets for port 500

- Any UDP packets for port 4500
- Any ESP (IP protocol number 50) packets

Configuring F5 BIG-IP for the CloudBridge Connector tunnel

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and an F5 BIG-IP appliance, perform the following tasks on the F5 BIG-IP appliance:

- **Create a forwarding virtual server for IPsec**. A forwarding virtual server intercepts IP traffic for the IPsec tunnel.
- **Create an IKE peer.** An IKE peer specifies the local and remote IPsec tunnel endpoints. It also specifies algorithms and credentials to be used for IPsec IKE phase 1.
- **Create a custom IPsec policy.** A policy specifies the IPSec protocol (ESP) and the mode (tunnel) to be used for forming the IPsec tunnel. It also specifies the algorithms and security parameters to be used for IKE IPsec phase 2.
- **Create a bidirectional IPsec traffic selector**. A traffic selector specifies the F5 BIG-IP side and Citrix ADC side subnets whose IP traffic is to be traversed through the IPsec tunnel.

The procedures for configuring IPsec VPN (CloudBridge Connector tunnel) on an F5 BIG-IP appliance might change over time, depending on the F5 release cycle. Citrix recommends that you follow the official F5 BIG-IP documentation for configuring IPSec VPN tunnels, at:

https://f5.com

To create a forwarding virtual server for IPsec by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Local Traffic** > **Virtual Servers**, and then click **Create**.
2. On **New Virtual Server List** screen, set the following parameters:
   - **Name**. Type a unique name for the virtual server.
   - **Type**. Select **Forwarding (IP)**.
   - **Destination Address**. Type a wildcard network address in CIDR format, for example, 0.0.0.0/0 for IPv4 to accept any traffic.
   - **Service Port**. Select **All Ports** from the list.
   - **Protocol list**. Select **All Protocols** from the list.
   - **VLAN and Tunnel Traffic**. Retain the default selection, **All VLANs and Tunnels**.
3. Click **Finished**.

To create a custom IPsec policy by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Network** > **IPsec** > **IPsec Policies**, and then click **Create**.
2. On the **New Policy** screen, set the following parameters:
   - **Name**. Type a unique name for the policy.
   - **IPsec Protocol**. Retain the default selection, ESP.
   - **Mode**. Select Tunnel. The screen refreshes to show additional related settings.

- **Tunnel Local Address**. Type the local IPsec tunnel endpoint IP address (Configured on the F5 BIG-IP appliance).
- **Tunnel Remote Address**. Type the remote IPsec tunnel endpoint IP address (Configured on the Citrix ADC appliance).

3. For the IKE Phase 2 parameters, retain the default values, or select the options that are appropriate for your deployment.
4. Click **Finished**.

To create a bidirectional IPsec traffic selector by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Network** > **IPsec** > **Traffic Selectors**, and then click **Create**.
2. On the **New Traffic Selector** screen, set the following parameters:
   - **Name**. Type a unique name for the traffic selector.
   - **Order**. Retain the default value **(First)**. This setting specifies the order in which the traffic selector appears on the Traffic Selector List screen.
3. From the **Configuration** list, select **Advanced**, and set the following parameters:
   - **Source IP Address**. Click **Host** or **Network**, and in **Address** field, type the address of the F5 BIG-IP side subnet whose traffic is to be protected over the IPsec tunnel.
   - **Source Port**. Select *** All Ports**.
   - **Destination IP Address**. Click **Host**, and in the **Address** field, type the address of the Citrix ADC side subnet whose traffic is to be protected over the IPsec tunnel.
   - **Destination Port**. Select *** All Ports**.
   - **Protocol**. Select *** All Protocols**.
   - **Direction**. Select **Both**.
   - **Action**. Select **Protect**. The **IPsec Policy Name** setting appears.
   - **IPsec Policy Name**. Select the name of the custom IPsec policy that you created.
4. Click **Finished**.

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a F5 BIG-IP appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the F5 BIG-IP appliance), protocol (IPSec) used to set

up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the F5 BIG-IP side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecyENABLE`
- `show ipsec profile** <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>`
- `apply pbrs`
- `show pbr <pbrName>`

To create an IPSEC profile by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IPSecProfile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication method** and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select *Subnet IP*).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select *IP Tunnel*)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration.:

```
1     > add ipsec profile NS_F5-BIG-IP_IPSec_Profile -psk
        examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo
        HMAC_SHA1 -lifetime 315360 -perfectForwardSecrecy ENABLE
2
3
4     Done
```

```
5
6       >  add iptunnel NS_F5-BIG-IP_Tunnel 203.0.113.200 255.255.255.255
            198.51.100.100  -protocol IPSEC  -ipsecProfileName NS_F5-BIG-
            IP_IPSec_Profile
7
8
9       Done
10
11      > add pbr NS_F5-BIG-IP_Pbr -srcIP 10.102.147.0-10.102.147.255  -
            destIP 10.20.0.0-10.20.255.255  -ipTunnel NS_F5-BIG-IP_Tunnel
12
13
14      Done
15
16      > apply pbrs
17
18
19      Done
20  <!--NeedCopy-->
```

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector interoperability – Cisco ASA

September 14, 2021

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the Cisco ASA appliance form the end points of the CloudBridge Connector tunnel and are called peers.

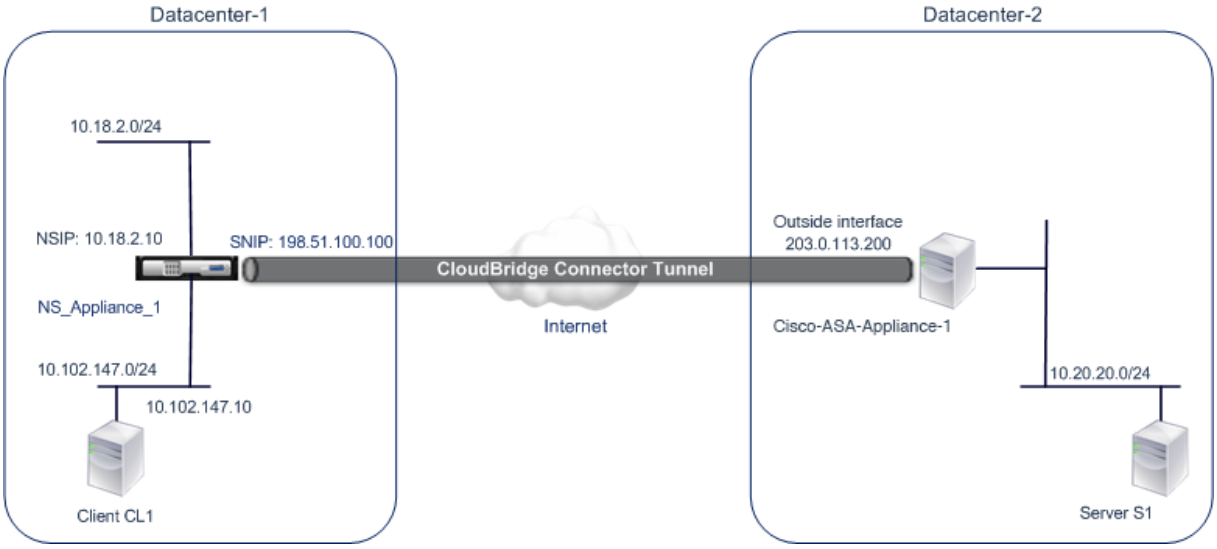
Example of a CloudBridge Connector tunnel configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following appliances:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco ASA appliance Cisco-ASA-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-ASA-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-ASA-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco-ASA_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco-ASA_Tunnel, and policy based routing (PBR) entity NS_Cisco-ASA_Pbr.



Points to consider for a CloudBridge Connector tunnel configuration

Before you begin configuring CloudBridge connector tunnel, make sure that:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance.

IPSec Properties	Settings
IPSec mode	Tunnel mode
IKE version	Version 1
IKE authentication method	Pre-Shared Key
IKE encryption algorithm	AES, 3DES
IKE hash algorithm	HMAC SHA1, HMAC MD5

IPSec Properties	Settings
ESP encryption algorithm	AES, 3DES
ESP hash algorithm	HMAC SHA1, HMAC MD5

- You must specify the same IPSec settings on the Citrix ADC appliance and the Cisco ASA appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the Cisco ASA appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).
- You must configure the firewall at the Citrix ADC end and Cisco ASA end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

Configuring Cisco ASA for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel on a Cisco ASA appliance, use the Cisco ASA command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco ASA appliances.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco ASA appliance, make sure that:

- You have a user account with administrator credentials on the Cisco ASA appliance.
- You are familiar with the Cisco ASA command line interface.
- The Cisco ASA appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

> **Note**
>
> The procedures for configuring CloudBridge Connector tunnel on a Cisco ASA appliance might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco ASA product documentation for Configuring IPSec VPN tunnels, at:

- http://www.cisco.com

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance, perform the following tasks on the Cisco ASA appliance's command line:

- **Create an IKE Policy**. An IKE policy defines a combination of security parameters to be used

during the IKE negotiation (phase 1). For example, parameters such as hash algorithm, encryption algorithm, and authentication method to be used in the IKE negotiation are set in this task.

- **Enable IKE on the outside interface**. Enable IKE on the outside interface through which the tunnel traffic will flow to the tunnel peer.
- **Create a tunnel group**. A tunnel group specifies the type of tunnel and the pre-shared key. The tunnel type must be set to ipsec-l2l, which stands for IPsec LAN to LAN. A pre-shared key is a text string, which the peers of a CloudBridge Connector tunnel use to mutually authenticate with each other. The pre-shared keys are matched against each other for IKE authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on the Cisco ASA appliance and the Citrix ADC appliance.
- **Define a transform set**. A transform set defines a combination of security parameters (phase 2) to be used in the exchange of data over the CloudBridge Connector tunnel after the IKE negotiation is successful.
- **Create an access List**. Crypto access lists are used to define the subnets whose IP traffic will be protected over the CloudBridge tunnel. The source and destination parameters in the access list specify the Cisco appliance side and Citrix ADC side subnets that are to be protected over the CloudBridge Connector Tunnel. The access list must be set to permit. Any request packet that originates from an appliance in the Cisco appliance side subnet and is destined to an appliance in the Citrix ADC side subnet, and that matches the source and destination parameters of the access list, is sent across the CloudBridge Connector tunnel.
- **Create a crypto map**. Crypto maps define the IPSec parameters for security associations (SAs). They include the following: Crypto access list to identify the subnets whose traffic is to be protected over the CloudBridge tunnel, peer (Citrix ADC) identification by IP address, and transform set to match the peer security settings.
- **Apply the crypto Map to the outside interface**. In this task, you apply the crypto map to the outside interface through which the tunnel traffic will flow to the tunnel peer. Applying the crypto map to an interface instructs the Cisco ASA appliance to evaluate all interface traffic against the crypto map set and to use the specified policy during connection or security association negotiations.

The examples in the following procedures create settings of Cisco ASA appliance Cisco-ASA-Appliance-1 used in Example of CloudBridge Connector Configuration and Data Flow.

To create an IKE policy by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands, starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto ikev1 policy priority	Cisco-ASA-appliance-1(config)# crypto ikev1 policy 1	Enter IKE policy configuration mode and identify the policy to create. (Each policy is uniquely identified by the priority number you assign.) This example configures policy 1.
encryption (3des | aes)	Cisco-ASA-appliance-1 (config-ikev1-policy)# encryption 3des	Specify the encryption algorithm. This example configures the 3DES algorithm.
hash (sha | md5)	Cisco-ASA-appliance-1 (config- ikev1-policy)# hash sha	Specify the hash algorithm. This example configures SHA.
authenticationpre-share	Cisco-ASA-appliance-1 (config- ikev1-policy)# authentication pre-share	Specify the pre-share authentication method.
group 2	Cisco-ASA-appliance-1 (config- ikev1-policy)# group 2	Specify 1024-bit Diffie-Hellman group identifier (2).
lifetime seconds	Cisco-ASA-appliance-1 (config- ikev1-policy)# lifetime 28800	Specify the security association's lifetime in seconds. This example configures 28800 seconds, which is the default value of lifetime in a Citrix ADC appliance.

To enable IKE on the outside interface by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands, starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto ikev1 enable outside	Cisco-ASA-appliance-1(config)# crypto ikev1 enable outside	Enable IKEv1 on the interface through which the tunnel traffic flows to the tunnel peer. This example enables IKEv1 on the interface named outside.

To create a tunnel group by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands, starting in global configuration mode, as show in the attached pdf Tunnel Group using Cisco ASA command line:

To create a crypto access list by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following command in global configuration mode, in the order shown:

Command	Example	Command Description
access-list access-list-number permit IP source source-wildcard destination destination-wildcard	Cisco-ASA-appliance-1(config)# access-list 111 permit ip 10.20.20.0 0.0.0.255 10.102.147.0 0.0.0.255	Specify conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example configures access list 111 to protect traffic from subnets 10.20.20.0/24 (at the Cisco-ASA-Appliance-1 side) and 10.102.147.0/24 (at the NS_Appliance-1 side).

To define a transform set by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands, starting in global configuration mode. See Transform set using ASA command line table pdf.

To create a crypto map by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto map map-name seq-num match address access-list-name	Cisco-ASA-appliance-1 (config)# crypto map NS-CISCO-CM 1 match address 111	Create a crypto map and specify an access list to it. This example configures crypto map NS-CISCO-CM with sequence number 1 and assigns access list 111 to NS-CISCO-CM.
crypto map map-name seq-num set peer ip-address	Cisco-ASA-appliance-1 (config)# crypto map NS-CISCO-CM 1 set peer 198.51.100.100	Specify the peer (Citrix ADC appliance) by its IP address. This example specifies 198.51.100.100, which is the tunnel endpoint IP address on the Citrix ADC appliance.
crypto map map-name seq-num set ikev1 transform-set transform-set-name	Cisco-ASA-appliance-1 (config)# crypto map NS-CISCO-CM 1 set ikev1 transform-set NS-CISCO-TS	Specify which transform set is allowed for this crypto map entry. This example specifies transform set NS-CISCO-TS.

To apply a crypto map to an interface by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto map map-nameinterface interface-name	Cisco-ASA-appliance-1(config)# crypto map NS-CISCO-CM interface outside	Apply the crypto map to the interface through which CloudBridge Connector tunnel traffic will flow. This example applies crypto map NS-CISCO-CM to interface outside.

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC com-

mand line or the Citrix ADC graphical user interface (GUI):

- Create an IPSec profile.
- Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.
- Create a PBR rule and associate it with the IP tunnel.

To create an IPSEC profile by using the Citrix ADC command line:

At the command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE`
- `show ipsec profile <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line:

At the command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line:

At the command prompt, type:

- `**add pbr** <pbrName> **ALLOW** -**srcIP** <subnet-range> -**destIP** <subnet-range>`
- `**ipTunnel** <tunnelName>`
- `**apply pbrs**`
- `**show pbr** <pbrName>`

To create an IPSEC profile by using the GUI:

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
   - Perfect Forward Secrecy (Enable this parameter)
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI:

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels tab**, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select Subnet IP).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI:

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration.”:

```
1 >  add ipsec profile NS_Cisco-ASA_IPSec_Profile -psk
     examplepresharedkey -ikeVersion v1  - encAlgo AES  - hashalgo
     HMAC_SHA1  - lifetime 315360 -perfectForwardSecrecy ENABLE
2
3 Done
4
5 >  add iptunnel NS_Cisco-ASA_Tunnel 203.0.113.200 255.255.255.255
     198.51.100.100  - protocol IPSEC  - ipsecProfileName NS_Cisco-
```

```
    ASA_IPSec_Profile
6
7
8 Done
9
10 > add pbr NS_Cisco-ASA_Pbr -srcIP 10.102.147.0-10.102.147.255 -destIP
    10.20.0.0-10.20.255.255 -ipTunnel NS_Cisco-ASA_Tunnel
11
12
13 Done
14
15 > apply pbrs
16
17 Done
18
19 <!--NeedCopy-->
```

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

High Availability

September 14, 2021

A high availability (HA) deployment of two Citrix ADC appliances can provide uninterrupted operation in any transaction. With one appliance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.

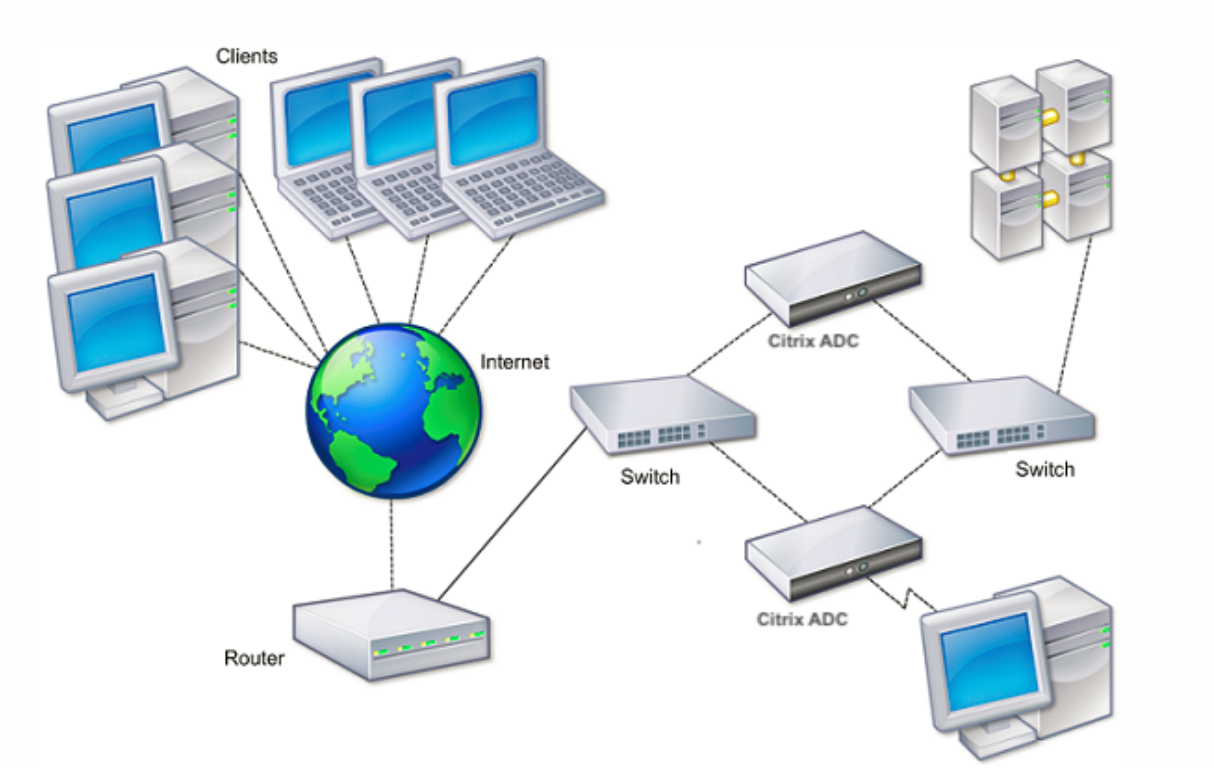
The secondary node monitors the primary by sending periodic messages (often called heartbeat messages or health checks) to determine whether the primary node is accepting connections. If a health check fails, the secondary node retries the connection for a specified period, after which it determines that the primary node is not functioning normally. The secondary node then takes over for the primary (a process called failover).

After a failover, all clients must reestablish their connections to the managed servers, but the session persistence rules are maintained as they were before the failover.

With Web server logging persistence enabled, no log data is lost due to the failover. For logging persistence to be enabled, the log server configuration must carry entries for both systems in the log.conf file.

The following figure shows a network configuration with an HA pair.

Figure 1. Citrix ADC Appliances in a High Availability Configuration



To configure HA, you might want to begin by creating a basic setup, with both nodes in the same subnet. You can then customize the intervals at which the nodes communicate health-check information, the process by which nodes maintain synchronization, and the propagation of commands from the primary to the secondary. You can configure fail-safe mode to prevent a situation in which neither node is primary. If your environment includes devices that do not accept Citrix ADC gratuitous ARP messages, you should configure virtual MAC addresses. When you are ready for a more complex configuration, you can configure HA nodes in different subnets.

To improve the reliability of your HA setup, you can configure route monitors and create redundant links. In some situations, such as when troubleshooting or performing maintenance tasks, you might want to force a node to fail over (assign primary status to the other node), or you might want to force the secondary node to stay secondary or the primary node to stay primary.

Points to consider for a high availability setup

September 14, 2021

> **Note**
>
> The following requirements for configuring systems in an HA setup:

- In an HA configuration, the primary and secondary Citrix ADC appliances should be of the same model. Different Citrix ADC models are not supported in an HA pair.
- In an HA setup, both nodes must run the same version of Citrix ADC.
- Entries in the configuration file (ns.conf) on both the primary and the secondary system must match, with the following exceptions:
  - The primary and the secondary systems must each be configured with their own unique IP addresses (NSIPs.)
  - In an HA pair, the node ID and associated IP address of one node must point to the other node. For example, if you have nodes NS1 and NS2, you must configure NS1 with a unique node ID and the IP address of NS2, and you must configure NS2 with a unique node ID and the IP address of NS1.
- If you create a configuration file on either node by using a method that does not go directly through the GUI or the CLI (for example, importing SSL certificates, or changing to startup scripts), you must copy the configuration file to the other node or create an identical file on that node.
- Initially, all Citrix ADC appliances are configured with the same RPC node password. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. For security, you should change the default RPC node passwords.

  One RPC node exists on each Citrix ADC. This node stores the password, which is checked against the password provided by the contacting system. To communicate with other systems, each Citrix ADC requires knowledge of those systems, including how to authenticate on those systems. RPC nodes maintain this information, which includes the IP addresses of the other systems, and the passwords they require for authentication.

  RPC nodes are implicitly created when adding a node or adding a Global Server Load Balancing (GSLB) site. You cannot create or delete RPC nodes manually.

  > **Note**:
  >
  > If the Citrix ADC appliances in a high availability setup are configured in one-arm mode, you must disable all system interfaces except the one connected to the switch or hub.

  For an IPv6 HA configuration, the following considerations apply:

- You must install the IPv6PT license on both Citrix ADC appliances.
- After installing the IPv6PT license, enable the IPv6 feature by using the GUI or the command line interface.
- Both Citrix ADC appliances require a global NSIP IPv6 address. In addition, network entities (for example, switches and routers) between the two nodes must support IPv6.

Configuring high availability

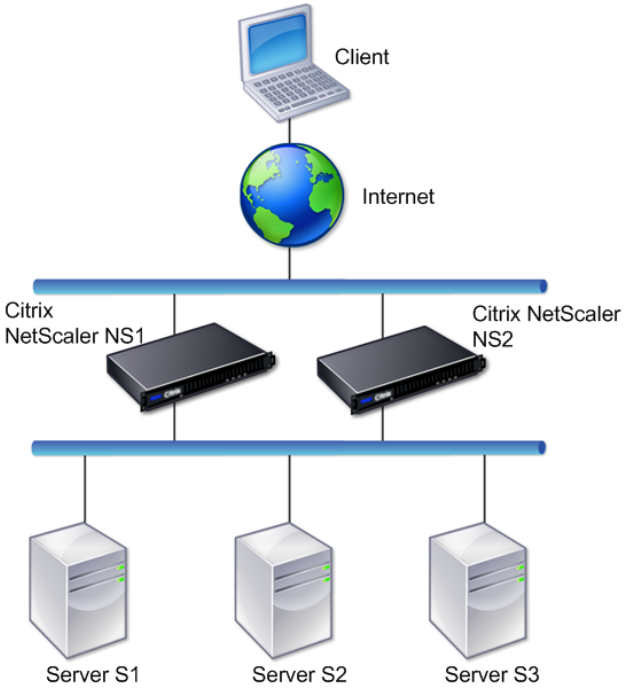
November 22, 2021

To set up a high availability configuration, you create two nodes, each of which defines the other's Citrix ADC IP (NSIP) address as a remote node. Begin by logging on to one of the two Citrix ADC appliances that you want to configure for high availability, and add a node. Specify the other appliance's Citrix ADC IP (NSIP) address as the address of the new node. Then, log on to the other appliance and add a node that has the NSIP address of the first appliance. An algorithm determines which node becomes primary and which becomes secondary.

> **Note**:
>
> The Citrix ADC GUI provides an option that avoids having to log on to the second appliance.

The following figure shows a simple HA setup, in which both nodes are in same subnet.

Figure 1. Two Citrix ADC Appliances Connected in a High Availability Configuration



Adding a remote node

To add a remote Citrix ADC appliance as a node in a high availability setup, you specify a unique node ID and the appliance's NSIP address. When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

> **Note**:
>
> To ensure that each node in the high availability configuration has the same settings, you should synchronize your SSL certificates, startup scripts, and other configuration files with those on the primary node.

To add a node by using the command line interface

At the command prompt, type:

- `add ha node <id> <IPAddress>`
- `show ha node`

Example

```
> add ha node 10 203.0.113.32
<!--NeedCopy-->
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- `set interface <ifNum> [-haMonitor ( ON | OFF )]`
- `show interface <ifNum>`

Example

```
> set interface 1/3 -haMonitor OFF
 Done
<!--NeedCopy-->
```

To add a remote node by using the GUI

Navigate to **System** > **High Availability** and, on the **Nodes** tab, add a new remote node, or edit an existing node.

Disabling or Enabling a Node

You can disable or enable only a secondary node. When you disable a secondary node, it stops sending heartbeat messages to the primary node, and therefore the primary node can no longer check the status of the secondary. When you enable a node, the node takes part in the high availability configuration.

To disable or enable a node by using the command line interface

At the command prompt, type one of the following commands:

- `set ha node -hastatus DISABLED`
- `set ha node -hastatus ENABLED`

To disable or enable a node by using the GUI

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, open the node.
2. In the **High Availability Status** list, select **ENABLED (Actively Participate in HA)** or **DISABLED (Do not participate in HA)**.

Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

```
rm ha node <id>
```

Example

```
1 > rm ha node 10
2   Done
3 <!--NeedCopy-->
```

To remove a node by using the GUI

Navigate to **System** > **High Availability** and, on the **Nodes** tab, delete the node.

Configuring the communication intervals

September 14, 2021

The hello interval is the interval at which the heartbeat messages are sent to the peer node. The dead interval is the time interval after which the peer node is marked DOWN if heartbeat packets are not received. The heartbeat messages are UDP packets sent to port 3003 of the other node in an HA pair. Dead interval must be set as a multiple of hello interval.

To set the hello and dead intervals by using the command line interface

At the command prompt, type:

- `set HA node [-helloInterval <msecs>] [-deadInterval <secs>]`
- `show HA node <id>`

To set the hello and dead intervals by using the GUI

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, open the node.
2. Set the following parameters:
   - Hello Interval (msecs)
   - Dead Interval (secs)

Configuring synchronization

September 14, 2021

Synchronization is a process of duplicating the configuration of the primary node on the secondary node. The purpose of synchronization is to ensure that there is no loss of configuration information between the primary and the secondary nodes, regardless of the number of failovers that occur. Synchronization uses port 3010.

Synchronization is triggered by either of the following circumstances:

- The secondary node in an HA setup comes up after a restart.
- The primary node becomes secondary after a failover.

Automatic synchronization is enabled by default. You can also force synchronization.

Disabling or enabling synchronization

Automatic HA synchronization is enabled by default on each node in an HA pair. You can enable or disable it on either node.

To disable or enable automatic synchronization by using the command line interface

At the command prompt, type:

- `set HA node -haSync DISABLED`
- `set HA node -haSync ENABLED`

To disable or enable synchronization by using the GUI

1. Navigate to **System** > **High Availability**.
2. Under HA Synchronization, clear or select the Secondary node will fetch the configuration from Primary option.

Forcing the secondary node to synchronize with the primary node

In addition to automatic synchronization, the Citrix ADC supports forced synchronization. You can force the synchronization from either the primary or the secondary node. When you force synchronization from the secondary node, it starts synchronizing its configuration with the primary node.

However, if synchronization is already in progress, forced synchronization fails and the system displays a warning. Forced synchronization also fails in any of the following circumstances:

- You force synchronization on a standalone system.

- The secondary node is disabled.
- HA synchronization is disabled on the secondary node.

To force synchronization by using the command line interface

At the command prompt, type:

```
force HA sync
```

To force synchronization by using the GUI

1. Navigate to **System** > **High Availability**.
2. On the **Nodes** tab, in the Action list, click **Force Synchronization**.

Synchronizing configuration files in a high availability setup

September 14, 2021

In a high availability setup, all configuration files are synchronised automatically from the primary node to the secondary node at an interval of one minute. Synchronizing configuration files can be performed manually by using the command line interface or the GUI at either the primary or the secondary node.

Files located on the secondary that are specific to the secondary (not present on the primary) are not deleted during the synchronization.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type:

```
sync HA files <mode>
```

Example

```
1 > sync HA files all
2  Done
3 <!--NeedCopy-->
```

```
1 > sync HA files ssl
2  Done
3 <!--NeedCopy-->
```

Parameter descriptions (of the command listed in the CLI procedure)

```
sync ha files <mode>
```

`mode`

Specify one of the following modes of synchronization.

- **all** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, and Application Firewall XML objects.
- **bookmarks** - Synchronize all Access Gateway bookmarks.
- **ssl** - Synchronize all certificates, keys, and CRLs for the SSL feature.
- **htmlinjection** - Synchronize all scripts configured for the HTML injection feature.
- **imports** - Synchronizeall XML objects (for example, WSDLs, schemas, error pages) configured for the application firewall.
- **misc** - Synchronize all license files and the rc.conf file.
- **all_plus_misc** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, application firewall XML objects, licenses, and the rc.conf file.

To synchronize files in a high availability setup by using the GUI

Navigate to **System** > **Diagnostics** and, in the **Utilities** group, click **Start HA files synchronization**.

Configuring command propagation

September 14, 2021

In an HA setup, any command issued on the primary node propagates automatically to, and is executed on, the secondary before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

In an HA pair configuration, command propagation is enabled by default on both the primary and secondary nodes. You can enable or disable command propagation on either node in an HA pair. If you disable command propagation on the primary node, commands are not propagated to the secondary node. If you disable command propagation on the secondary node, commands propagated from the primary are not executed on the secondary node.

> **Note**
>
> After reenabling propagation, remember to force synchronization.

If synchronization occurs while you are disabling propagation, any configuration-related changes that you make before the disabling of propagation takes effect are synchronized with the secondary node. This is also true for cases where propagation is disabled while synchronization is in progress.

To disable or enable command propagation by using the command line interface

At the command prompt, type:

- set HA node -haProp DISABLED
- set HA node -haProp ENABLED

To disable or enable command propagation by using the GUI

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, open the node.
2. Clear or select the Primary node will propagate configuration to the Secondary option.

Restricting high availability synchronization traffic to a VLAN

September 14, 2021

In a high availability (HA) deployment, traffic related to maintaining the HA configuration flows between the two HA nodes. This traffic is of the following types:

- Config synchronization
- Config propagation
- Connection mirroring
- Load balancing persistency config synchronization
- Persistent session synchronization
- Session state synchronization

Proper flow of this HA related traffic between the two nodes is critical for the functioning of the HA deployment. Typically, the HA related traffic is small in volume but can become very high during a failover. It becomes very high if stateful connection failover is enabled and the node that was primary before the failover was handling a large number of connections.

By default, the HA related traffic flows through the VLANs to which the NSIP address is bound. To accommodate a potential surge in this traffic, you can separate the HA related traffic from the management traffic and restrict its flow to a separate VLAN. This VLAN is called the HA SYNC VLAN.

Points to consider before Configuring an HA SYNC VLAN

- The configuration of an HA SYNC VLAN is neither propagated nor synchronized. In other words, the HA SYNC VLAN is node specific and is configured independently on each node.
- HA SYNC VLAN configuration is removed when you clear the configuration in only FULL mode.
- HA MON must be set to OFF for interfaces that are part of the HA SYNC VLAN, to avoid a situation in which both nodes function as the primary node.
- Management interfaces (for example, 0/1 and 0/2) must not be part of the HA SYNC VLAN, so that HA related traffic does not flow through management interfaces.
- Citrix recommends disabling high availability heartbeat messages on management interfaces and enabling on HA SYNC VLAN interfaces. After meeting these recommendations, high availability heartbeat messages can also be enabled on data interfaces.

  For more information on disabling high availability heartbeat messages on interfaces, see Managing high availability heartbeat messages on a Citrix ADC appliance.

To configure an HA SYNC VLAN on a Citrix ADC node, specify a configured VLAN with the HA SYNC VLAN parameter of the local node entity.

To configure an HA SYNC VLAN on a local node by using the command line:

At the command prompt, type:

- `set ha node -syncvlan <VLANID>`
- `show node`

Parameter Description:

syncvlan (Sync VLAN) - VLAN on which HA related traffic is sent. This includes traffic for synchronization, propagation, connection mirroring, load balancing persistency, configuration synchronization, persistent session synchronization, and session state synchronization. However, HA heartbeats can use any interface.

To configure an HA SYNC VLAN on a node by using the GUI:

1. Navigate to **System** > **High Availability**.
2. Set the **Sync VLAN** parameter while modifying the local node.

Configuring fail-safe mode

September 14, 2021

In an HA configuration, fail-safe mode ensures that one node is always primary when both nodes fail the health check. This is to ensure that when a node is only partially available, backup methods are

enabled to handle traffic as best as possible. The HA fail-safe mode is configured independently on each node.

The following table shows some of the fail-safe cases. The NOT_UP state means that the node failed the health check yet it is partially available. The UP state means that the node passed the health check.

Node A (Primary) Health State	Node B (Secondary) Health State	Default HA Behavior	Fail-Safe Enabled HA Behavior	Description
NOT_UP(failed last)	NOT_UP (failed first)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
NOT_UP (failed first)	NOT_UP(failed last)	A (Secondary), B (Secondary)	A(Secondary), B(Primary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
UP	UP	A (Primary), B (Secondary)	A (Primary), B (Secondary)	If both nodes pass the health check, no change in behavior with fail-safe enabled.
UP	NOT_UP	A(Primary), B(Secondary)	A (Primary), B (Secondary)	If only the secondary node fails, no change in behavior with fail-safe enabled.

Node A (Primary) Health State	Node B (Secondary) Health State	Default HA Behavior	Fail-Safe Enabled HA Behavior	Description
NOT_UP	UP	A(Secondary), B(Primary)	A(Secondary), B(Primary)	If only the primary fails, no change in behavior with fail-safe enabled.
NOT_UP	UP (STAYSEC-ONDARY)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If the secondary is configured as STAYSEC-ONDARY, the primary remains primary even if it fails.

To enable fail-safe mode by using the command line interface

At the command prompt, type:

```
set HA node [-failSafe ( **ON** | **OFF** )]
```

Example

```
1 set ha node -failsafe ON
2 <!--NeedCopy-->
```

To enable fail-safe mode by using the GUI

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, open the node.
2. Under **Fail-Safe Mode**, select the **Maintain one Primary** node even when both nodes are unhealthy option.

Configuring Virtual MAC Addresses

September 14, 2021

A virtual MAC address is a floating entity shared by the primary and the secondary nodes in an HA setup.

In an HA setup, the primary node owns all of the floating IP addresses, such as the MIPs, SNIPs, and VIPs. The primary node responds to Address Resolution Protocol (ARP) requests for these IP addresses with its own MAC address. As a result, the ARP table of an external device (for example, an upstream router) is updated with the floating IP address and the primary node's MAC address.

When a failover occurs, the secondary node takes over as the new primary node. It then uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it acquired from the primary. However, the MAC address that the new primary advertises is the MAC address of its own interface.

Some devices (notably a few routers) do not accept the GARP messages generated by the Citrix ADC appliance. As a result, some external devices retain the old IP to MAC mapping advertised by the old primary node. This can result in a site going down.

You can overcome this problem by configuring a virtual MAC on both nodes of an HA pair. Both nodes then possess identical MAC addresses. Therefore, when failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

To create a virtual MAC, you need to first create a Virtual Router ID (VRID) and bind it to an interface. (In an HA setup, you need to bind the VRID to the interfaces on both nodes.) Once the VRID is bound to an interface, the system generates a virtual MAC with the VRID as the last octet.

This section includes the following details:

- Configuring IPv4 virtual MACs
- Configuring IPv6 virtual MAC6s

Configuring IPv4 virtual MACs

When you create a IPv4 virtual MAC address and bind it to a interface, any IPv4 packet sent from the interface uses the virtual MAC address that is bound to the interface. If there is no IPv4 virtual MAC bound to an interface, the interface's physical MAC address is used.

The generic virtual MAC is of the form `00:00:5e:00:01:<VRID>`. For example, if you create a VRID with a value of 60 and bind it to an interface, the resulting virtual MAC is 00:00:5e:00:01:3c, where 3c is the hex representation of the VRID. You can create 255 VRIDs with values from 1 to 255.

Creating or modifying an IPv4 virtual MAC

You create an IPv4 virtual MAC by assigning it a virtual router ID. You can then you bind the virtual MAC to an interface. You cannot bind multiple VRIDs to the same interface. To verify the virtual MAC

configuration, you should display and examine the virtual MACs and the interfaces bound to the virtual MACs.

To add a virtual MAC by using the command line interface

At the command prompt, type:

- `add vrID`
- `bind vrid <id> -ifnum <interface_name>`
- `show vrID`

Example

```
> add vrID 100
 Done
> bind vrid 100 -ifnum 1/1 1/2 1/3
 Done
<!--NeedCopy-->
```

To unbind interfaces from a virtual MAC by using the command line interface

At the command prompt, type:

- `unbind vrid <id> -ifnum <interface_name>`
- `show vrID`

To configure a virtual MAC by using the GUI

Navigate to **System** > **Network** > **VMAC** and, on the **VMAC** tab, add a new virtual MAC, or edit an existing virtual MAC.

Removing an IPv4 virtual MAC

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove an IPv4 virtual MAC by using the command line interface

At the command prompt, type:

`rm vrid <id>`

Example

```
rm vrid 100s
<!--NeedCopy-->
```

To remove an IPv4 virtual MAC by using the GUI

Navigate to **System** > **Network** > **VMAC** and, on the **VMAC** tab, delete the IPv4 virtual MAC.

Configuring IPv6 virtual MAC6s

The Citrix ADC supports virtual MAC6 for IPv6 packets. You can bind any interface to a virtual MAC6, even if an IPv4 virtual MAC is bound to the interface. Any IPv6 packet sent from the interface uses the virtual MAC6 bound to that interface. If there is no virtual MAC6 bound to an interface, an IPv6 packet uses the physical MAC.

Creating or Modifying a virtual MAC6

You create an IPv6 virtual MAC by assigning it an IPv6 virtual router ID. You can then you bind the virtual MAC to an interface. You cannot bind multiple IPv6 VRIDs to an interface. To verify the virtual MAC6 configuration, you should display and examine the virtual MAC6s and the interfaces bound to the virtual MAC6s.

To add a virtual MAC6 by using the command line interface

At the command prompt, type:

- `add vrID6 <id>`
- `bind vrID6 <id> -ifnum <interface_name>`
- `show vrID6`

Example

```
1 > add vrID6 100
2 Done
3 > bind vrID6 100 -ifnum 1/1 1/2 1/3
4  Done
5 <!--NeedCopy-->
```

To unbind interfaces from a virtual MAC6 by using the command line interface

At the command prompt, type:

- `unbind vrID6 <id> -ifnum <interface_name>`
- `show vrID6`

To configure a virtual MAC6 by using the GUI

Navigate to **System** > **Network** > **VMAC** and, on the **VMAC6** tab, add a new virtual MAC6, or edit an existing virtual MAC6.

Removing a virtual MAC6

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove a virtual MAC6 by using the command line interface

At the command prompt, type:

```
rm vrid6 <id>
```

Example

```
1 rm vrid6 100s
2 <!--NeedCopy-->
```

To remove a virtual MAC6 by using the GUI

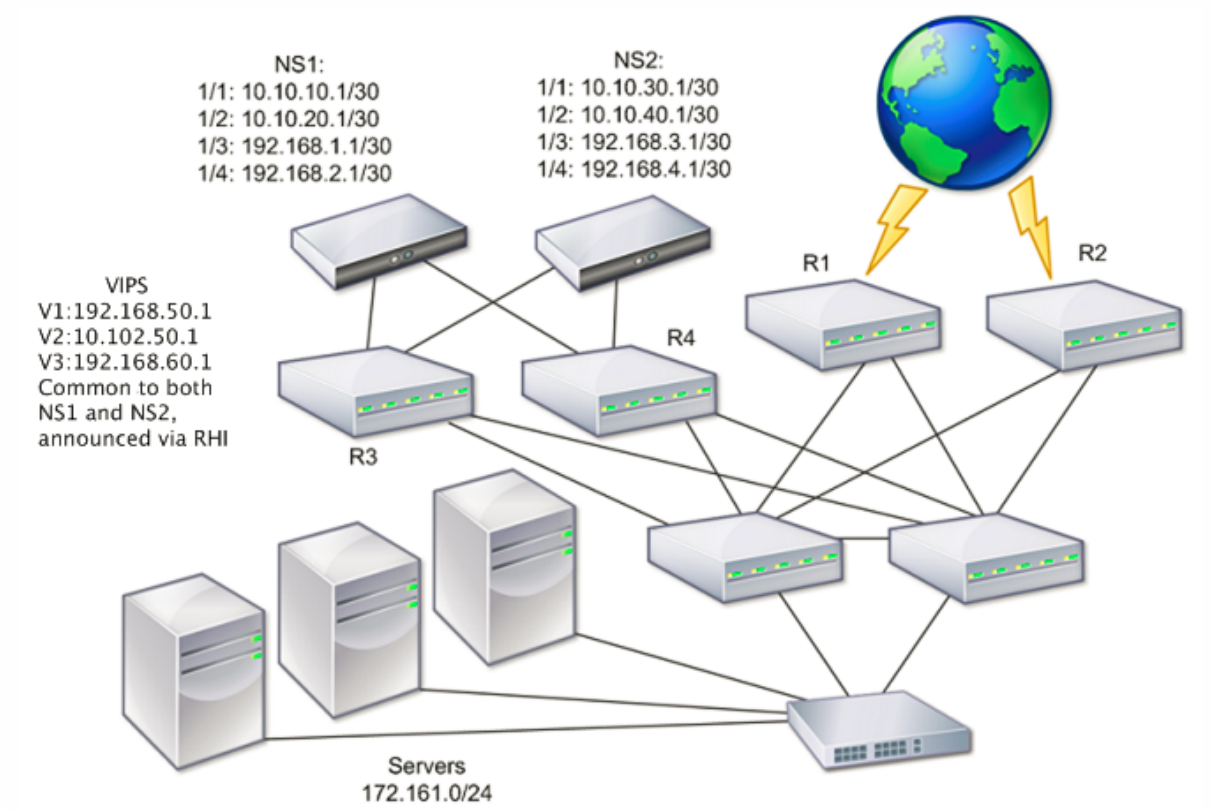
Navigate to **System** > **Network** > **VMAC** and, on the **VMAC6** tab, delete the virtual router ID.

Configuring high availability nodes in different subnets

September 14, 2021

The following figure shows an HA deployment with the two systems located in different subnets:

Figure 1. High Availability over a Routed Network



In the figure, the systems NS1 and NS2 are connected to two separate routers, R3 and R4, on two different subnets. The Citrix ADC appliances exchange heartbeat packets through the routers. This configuration could be expanded to accommodate deployments involving any number of interfaces.

> **Note**:
>
> If you use static routing on your network, you must add static routes between all the systems to ensure that heartbeat packets are sent and received successfully. (If you use dynamic routing on your systems, static routes are unnecessary.)

If the nodes in an HA pair reside on two separate networks, the primary and secondary node must have independent network configurations. This means that nodes on different networks cannot share entities such as SNIP address, VLANs, and routes. This type of configuration, where the nodes in an HA pair have different configurable parameters, is known as Independent Network Configuration (INC) or Symmetric Network Configuration (SNC).

The following table summarizes the configurable entities and options for an INC, and shows how they must be set on each node.

NetScaler entities	Options
IPs (NSIP/SNIPs)	Node-specific. Active only on that node.
VIPs	Floating.

NetScaler entities	Options
VLANs	Node-specific. Active only on that node.
Routes	Node-specific. Active only on that node. Link load balancing routes are floating.
ACLs	Floating (Common). Active on both nodes.
Dynamic routing	Node-specific. Active only on that node. The secondary node should also run the routing protocols and peer with upstream routers.
L2 mode	Floating (Common). Active on both nodes.
L3 mode	Floating (Common). Active on both nodes.
Reverse NAT (RNAT)	RNAT configuration with the NAT IP address set to a virtual server IP address (VIP) because the VIP address is floating (common).

As in configuring HA nodes in the same subnet, to configure HA nodes in different subnets, you log on to each of the two Citrix ADC appliances and add a remote node representing the other appliance.

Adding a Remote Node

When two nodes of an HA pair reside on different subnets, each node must have a different network configuration. Therefore, to configure two independent systems to function as an HA pair, you must specify INC mode during the configuration process.

When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

To add a node by using the command line interface

At the command prompt, type:

- `add ha node <id> <IPAddress> -inc ENABLED`
- `show ha node`

Example

```
1 > add ha node 3 10.102.29.170 -inc ENABLED
2  Done
3 > add ha node 3 1000:0000:0000:0000:0005:0600:700a:888b
4   Done
```

```
<!--NeedCopy-->
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- `set interface <ifNum> [-haMonitor ( **ON** | **OFF** )]`
- `show interface <ifNum>`

Example

```
> set interface 1/3 -haMonitor OFF
 Done
<!--NeedCopy-->
```

To add a remote node by using the GUI

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, add a new remote node.
2. Make sure to select the Turn off HA monitor on interfaces/channels that are down and Turn on INC (Independent Network Configuration) mode on self mode options.

Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

```
rm ha node <id>
```

Example

```
> rm ha node 2
  Done
<!--NeedCopy-->
```

To remove a node by using the GUI

Navigate to **System** > **High Availability** and, on the **Nodes** tab, delete the node.

> **Note**:
>
> You can use the Network Visualizer to view the Citrix ADC appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks.

Configuring route monitors

September 14, 2021

You can use route monitors to make the HA state dependent on the internal routing table, whether or not the table contains any dynamically learned or static routes. In an HA configuration, a route monitor on each node watches the internal routing table to make sure that a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

When a Citrix ADC appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes. MSR removes unreachable static routes from the internal routing table. If MSR is disabled on static routes, an unreachable static route can remain in the internal routing table, defeating the purpose of having the route monitor.

Route Monitors are supported both in non-INC and INC mode.

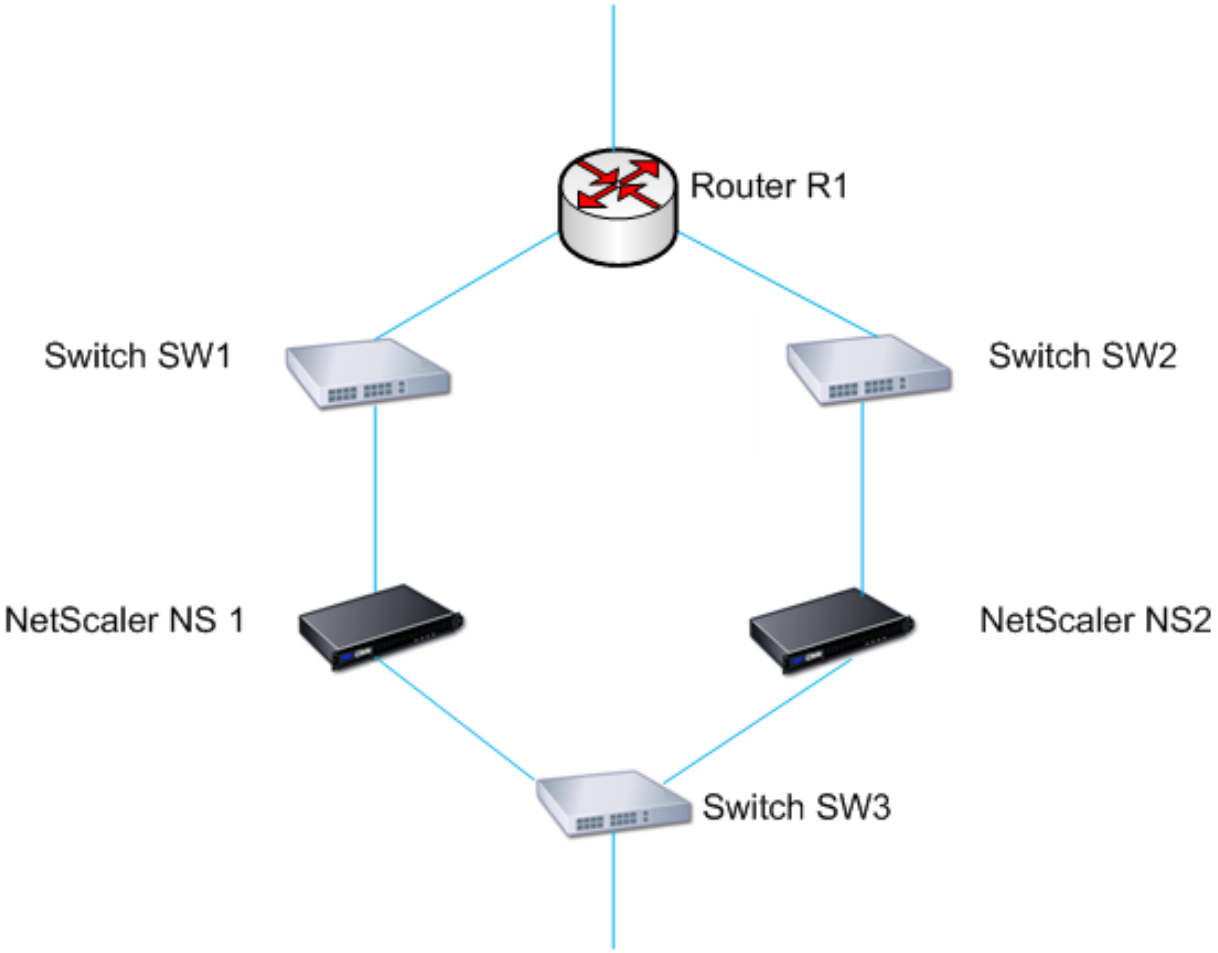
Route Monitors in HA in non-INC mode	Route Monitors in HA in INC mode
Route monitors are propagated by nodes and exchanged during synchronization.	Route monitors are neither propagated by nodes nor exchanged during synchronization.
Route monitors are active only in the current primary node.	Route monitors are active on both the primary and the secondary node.
The Citrix ADC appliance always displays the state of a route monitor as UP irrespective of the whether the route entry is present or not in the internal routing table.	The Citrix ADC appliance displays the state of the route monitor as DOWN if the corresponding route entry is not present in the internal routing table.
A route monitor starts monitoring its route after 180 seconds in the following cases [This is done to allow dynamic routes to get learnt, which may take 180 secs]: reboot, failover, set route6 command for v6 routes, set route msr enable/disable command for v4 routes, adding a new route monitor.	-

Route monitors are useful in a non-INC mode HA configuration where you want the non-reachability of a gateway from a primary node to be one of the conditions for HA failover.

Consider an example of a non-Inc mode HA setup in a two-arm topology that has Citrix ADC appliances NS1 and NS2 in the same subnet, with router R1 and switches SW1, SW2, and SW3.

Because R1 is the only router in this setup, you want the HA setup to failover whenever R1 is not reachable from the current primary node. You can configure a route monitor (say, RM1 and RM2, respectively) on each of the nodes to monitor the reachability of R1 from that node.

Figure 1.



With NS1 as the current primary node, the execution flow is as follows:

1. Route monitor RM1 on NS1 monitors NS1's internal routing table for the presence of a route entry for router R1. NS1 and NS2 exchange heartbeat messages through switch SW1 or SW3 at regular intervals.
2. If switch SW1 goes down, the routing protocol on NS1 detects that R1 is not reachable and therefore removes the route entry for R1 from the internal routing table. NS1 and NS2 exchanges heartbeat messages through switch SW3 at regular intervals.

3. Detecting that the route entry for R1 is not present in the internal routing table, RM1 initiates a failover. If route to R1 is down from both NS1 and NS2, failover happens every 180 seconds till one of the appliances is able to reach R1 and restore the connectivity.

Adding a route monitor to a high availability node

A single procedure creates a route monitor and binds it to an HA node.

To add a route monitor by using the command line interface

At the command prompt, type:

- `bind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])`
- `show HA node`

Example

```
> bind HA node 0 -routeMonitor 10.102.71.0 255.255.255.0
 Done
> bind HA node 0 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
 Done
<!--NeedCopy-->
```

To add a route monitor by using the GUI

Navigate to **System** > **High Availability** and, on the **Route Monitors** tab, click **Configure**.

Removing route monitors

To remove a route monitor by using the command line interface

At the command prompt, type:

- `unbind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])`
- show ha node

Example

```
unbind HA node 3 -routeMonitor 10.102.71.0 255.255.255.0
unbind HA node 3 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
<!--NeedCopy-->
```

To remove a route monitor by using the GUI

Navigate to **System** > **High Availability** and, on the **Route Monitors** tab, delete the route monitor.

Limiting failovers caused by route monitors in non-INC mode

September 14, 2021

In an HA configuration in non-INC mode, if route monitors fail on both nodes, failover happens every 180 seconds until one of the nodes is able to reach all of the routes monitored by the respective route monitors.

However, for a node, you can limit the number of failovers for a given interval by setting the Maximum Number of Flips and Maximum Flip Time parameters on the nodes. When either limit is reached, no more failovers occur, and the node is assigned as primary (but node state as NOT UP) even if any route monitor fails on that node. This combination of HA state as Primary and Node state as NOT UP is called Stick Primary state.

If the node is then able to reach all of the monitored routes, the next monitor failure triggers resetting of the Maximum Number of Flips and Maximum Flip Time parameters on the node and starting the time specified in the Maximum Flip Time parameter.

These parameters are set independently on each node and therefore are neither propagated nor synchronized.

Parameters for limiting the number of failovers

- **Maximum Number of Flips (maxFlips)**

  Maximum number of failovers allowed, within the Maximum Flip Time interval, for the node in HA in non INC mode, if the failovers are caused by route-monitor failure.

- **Maximum Flip Time (maxFlipTime)**

  Amount of time, in seconds, during which failovers resulting from route-monitor failure are allowed for the node in HA in non INC mode.

To limit the number of failovers by using the command line interface

At the command prompt, type:

- `set HA node [-maxFlips < positive_integer>] [-maxFlipTime <positive_integer >]`
- `show HA node [< id>]`

To limit the number of failovers by using the GUI

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, open the local node.

2. Set the following parameters:

- Maximum Number of Flips
- Maximum Flip Time

```
> set ha node -maxFlips 30 -maxFlipTime 60
Done
> sh ha node
1) Node ID: 0
IP: 10.102.169.82 (NS)
Node State: UP
Master State: Primary
Fail-Safe Mode: OFF
INC State: DISABLED
Sync State: ENABLED
Propagation: ENABLED
Enabled Interfaces : 1/1
Disabled Interfaces : None
HA MON ON Interfaces : 1/1
Interfaces on which heartbeats are not seen :None
Interfaces causing Partial Failure:None
SSL Card Status: NOT PRESENT
Hello Interval: 200 msecs
Dead Interval: 3 secs
Node in this Master State for: 0:4:24:1 (days:hrs:min:sec)

2) Node ID: 1
IP: 10.102.169.81
Node State: UP
Master State: Secondary
Fail-Safe Mode: OFF
INC State: DISABLED
Sync State: SUCCESS
Propagation: ENABLED
Enabled Interfaces : 1/1
Disabled Interfaces : None
HA MON ON Interfaces : 1/1
Interfaces on which heartbeats are not seen : None
Interfaces causing Partial Failure: None
SSL Card Status: NOT PRESENT

Local node information:
Configured/Completed Flips: 30/0
Configured Flip Time: 60
Critical Interfaces: 1/1
```

```
41
42      Done
43 <!--NeedCopy-->
```

SNMP Alarm for Sticky Primary State

Enable HA-STICKY-PRIMARY SNMP alarm in a node of a high availability set up if you want to be alerted of the node becoming sticky primary. When the node becomes sticky primary, it alerts by generating a trap message (stickyPrimary (1.3.6.1.4.1.5951.1.1.0.138)) and sends it to all the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see onfiguring the Citrix ADC to Generate SNMPv1 and SNMPv2 Traps.

Frequently Asked Questions

Consider an example of a high availability setup of two Citrix ADC appliances NS-1 and NS-2 in non-INC mode. Maximum numbers of flips and maximum flip time in both the nodes have been set with the same values.

The following table lists the settings used in this example:

Entity	Detail
IP address of NS-1	10.102.173.211
IP address of NS-2	10.102.173.212
Maximum number of flips	2
Maximum flip time	200

For information about the maximum number of flips and maximum flip time settings, refer to the pdf.

Configuring failover interface set

September 14, 2021

A Failover Interface Set (FIS) is a logical group of interfaces. In an HA configuration, using a FIS is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available. A FIS can also be configured for the nodes of a Citrix ADC cluster.

HA MON interfaces that are not bound to an FIS are known as critical interfaces (CI) because if any of them fails, failover is triggered.

> **Note**:
>
> An FIS does not create an active and standby configuration. It also does not prevent bridging loops when connecting to links to the same VLAN.

Creating or Modifying an FIS

To add an FIS and bind interfaces to it by using the command line interface

At the command prompt, type:

- `add fis <name>`
- `bind fis \<name\> \<ifnum\> ...`
- `show fis \<name\>`

Example

```
1 > add fis fis1
2  Done
3 > bind fis fis1 1/3 1/5
4  Done
5 <!--NeedCopy-->
```

An unbound interface becomes a critical interface (CI) if it is enabled and HA MON is on.

To unbind an interface from an FIS by using the command line interface

At the command prompt, type:

- `unbind fis \<name\> \<ifnum\> ...`
- `show fis \<name\>`

Example

```
1 > unbind fis fis1 1/3
2  Done
3 <!--NeedCopy-->
```

To configure an FIS by using the GUI

Navigate to System > High Availability and, on the Failover Interface Set tab, add a new FIS, or edit an existing FIS.

Removing an FIS

When the FIS is removed, its interfaces are marked as critical interfaces.

To remove an FIS by using the command line interface

At the command prompt, type:

```
rm fis <name>
```

Example

```
1 > rm fis fis1
2   Done
3 <!--NeedCopy-->
```

To remove an FIS by using the GUI

Navigate to **System** > **High Availability** and, on the **Failover Interface Set** tab, delete the FIS.

Understanding the causes of failover

September 14, 2021

The following events can cause failover in an high availability configuration:

1. If the secondary node does not receive a heartbeat packet from the primary for a period of time that exceeds the dead interval set on the secondary. (See Note 1.)
2. The primary node experiences a hardware failure of its SSL card.
3. The primary node does not receive any heartbeat packets on its network interfaces for three seconds.
4. On the primary node, a network interface that is not part of a Failover Interface Set (FIS) or a Link Aggregation (LA) channel and has the HA Monitor (HAMON) enabled, fails. (See Note 2.)
5. On the primary node, all interfaces in an FIS fail. (See Note 2.)
6. On the primary node, an LA channel with HAMON enabled fails. (See Note 2.)
7. On the primary node, all interfaces fail (see Note 2). In this case, failover occurs regardless of the HAMON configuration.
8. On the primary node, all interfaces are manually disabled. In this case, failover occurs regardless of the HAMON configuration.
9. You force a failover by issuing the force failover command on either node.
10. A route monitor that is bound to the primary node goes DOWN.

> **Note 1:**
>
> For more information about setting the dead interval, see Configuring the Communication Intervals. Possible causes for a node not receiving heartbeat packets from a peer node include:
>
> - A network configuration problem prevents heartbeats from traversing the network between the HA nodes.
> - The peer node experiences a hardware or software failure that causes it to freeze (hang), reboot, or otherwise stop processing and forwarding heartbeat packets.
>
> **Note 2:**
>
> In this case, fail means that the interface was enabled but goes to the DOWN state, as can be seen from the show interface command or from the GUI. Possible causes for an enabled interface to be in the DOWN state are LINK DOWN and TXSTALL.

Forcing a node to fail over

September 14, 2021

You might want to force a failover if, for example, you need to replace or upgrade the primary node. You can force failover from either the primary or the secondary node. A forced failover is not propagated or synchronized. To view the synchronization status after a forced failover, you can view the status of the node.

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.

The Citrix ADC appliance displays a warning message if it detects a potential issue when you run the force failover command. The message includes the information that triggered the warning, and requests confirmation before proceeding.

You can force a failover on a primary node, secondary node, and when nodes are in listen mode.

- **Forcing Failover on the Primary Node**.

  If you force failover on the primary node, the primary becomes the secondary and the secondary becomes the primary. Forced failover is possible only when the primary node can determine that the secondary node is UP.

  If the secondary node is DOWN, the force failover command returns the following error message: “Operation not possible due to invalid peer state. Rectify and retry.”

If the secondary system is in the claiming state or inactive, it returns the following error message:

```
Operation not possible now. Please wait for the system to stabilize
before retrying.
```

- **Forcing Failover on the Secondary Node**.

  If you run the force failover command from the secondary node, the secondary node becomes primary and the primary node becomes secondary. A force failover can occur only if the secondary node's health is good and it is not configured to stay secondary.

  If the secondary node cannot become the primary node, or if the secondary node was configured to stay secondary (using the STAYSECONDARY option), the node displays the following error message:

  ```
  Operation not possible as my state is invalid. View the node for more
  information.
  ```

- **Forcing Failover When Nodes Are in Listen Mode**.

  When the two nodes of an HA pair are running different versions of the system software, the node running the higher version switches to the listen mode. In this mode, neither command propagation nor synchronization works.

  Before upgrading the system software on both nodes, test the new version on one of the nodes. To do this, you must force a failover on the system that has already been upgraded. The upgraded system then takes over as the primary node, but neither command propagation or synchronization occurs. Also, all connections must be re-established.

> **Important!**
>
> If you force a failover when an HA synchronization operation is in progress, some active data sessions on the HA setup might be lost. So, wait for the HA synchronization operation to be completed before performing the force failover operation.

To force failover on a node by using the command line interface:

At the command prompt, type:

```
force HA failover
```

To force failover on a node by using the GUI:

Navigate to **System** > **High Availability** and, on the **Nodes** tab, select the node, in the Action list, select **Force Failover**.

Forcing the secondary node to stay secondary

September 14, 2021

In an HA setup, the secondary node can be forced to stay secondary regardless of the state of the primary node.

For example, suppose the primary node needs to be upgraded and the process will take a few seconds. During the upgrade, the primary node may go down for a few seconds, but you do not want the secondary node to take over; you want it to remain the secondary node even if it detects a failure in the primary node.

When you force the secondary node to stay secondary, it will remain secondary even if the primary node goes down. Also, when you force the status of a node in an HA pair to stay secondary, it does not participate in HA state machine transitions. The status of the node is displayed as STAYSECONDARY.

Forcing the node to stay secondary works on both standalone and secondary nodes. On a standalone node, you must use this option before you can add a node to create an HA pair. When you add the new node, the existing node stops processing traffic and becomes the secondary node. The new node becomes the primary node.

> **Note**:
>
> When you force a system to remain secondary, the forcing process is not propagated or synchronized. It affects only the node on which you run the command.

To force the secondary node to stay secondary by using the command line interface

At the command prompt, type:

```
set ha node -hastatus STAYSECONDARY
```

To force the secondary node to stay secondary by using the GUI

Navigate to **System** > **High Availability**, on the **Nodes** tab, open the local node, and select **STAY SECONDARY**.

Forcing the primary node to stay primary

September 14, 2021

In an HA setup, you can force a healthy primary node to remain primary even after a failover. You can enable this option either on a primary node in an HA pair. This option allows the primary node to be in primary state as long as it is healthy.

On a standalone node, you must use this option before you can add a node to create an HA pair. When you add the new node, the existing node continues to function as the primary node, and the new node becomes the secondary node.

To force the primary node to stay primary by using the command line interface

At the command prompt, type:

```
set ha node -hastatus STAYPRIMARY
```

To force the primary node to stay primary by using the GUI

Navigate to **System** > **High Availability**, on the **Nodes** tab, open the local node, and select **STAY PRIMARY**.

Understanding the high availability health check computation

September 14, 2021

The following table summarizes the factors examined in a health check computation:

- State of the failover interface sets
- State of the critical interfaces
- State of the route monitors

The following table summarizes the health check computation.

Failover interface sets	Critical interfaces	Route monitor	Condition
N	Y	N	If the system has any critical interfaces, all of those critical interfaces must be UP.
Y	Y	N	If the system has any failover interface sets, all of those failover interface sets must be UP.

Failover interface sets	Critical interfaces	Route monitor	Condition
Y	Y	Y	If the system has any route monitors configured, all monitored routes must be present in the failover interface set.

High Availability FAQs

September 14, 2021

1. What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?

   In an HA configuration, both nodes use the following ports to exchange HA related information:

   - UDP Port 3003, to exchange heartbeat packets.
   - Port 3010, for synchronization and command propagation.

2. What are the conditions that trigger synchronization?

   Synchronization is triggered by any of the following conditions:

   - The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.
     Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:
     a) All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.
     b) All Interface related commands. For example, set interface and unset interface.
     c) All channel-related commands. For example, add channel, set channel, and bind channel.
   - The secondary node comes up after a restart.
   - The primary node becomes secondary after a failover.

3. What configurations are not synced or propagated in an HA configuration in INC or non-INC mode?

The following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.

> **Note:**
>
> The following configurations are neither synced nor propagated only in HA in INC mode. Each node has its own:
>
> - SNIPs
> - VLANs
> - Routes (except LLB routes)
> - Route monitors
> - RNAT rules (except any RNAT rule with VIP as the NAT IP)
> - Dynamic routing configurations
> - Net profiles

4. Does a configuration added to the secondary node get synchronized on the primary?

   No, a configuration added to the secondary node is not synchronized to the primary.

5. What could be the reason for both nodes claiming to be the primary in an HA configuration?

   The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

6. Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

   Different system-clock settings on the two nodes can cause the following issues:

   - The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
   - After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
   - Similar considerations apply to any time related decisions on the nodes.

7. What are the conditions for failure of the *force HA sync* command?

   Forced synchronization fails in any of the following circumstances:

   - You force synchronization when synchronization is already in progress.

- You force synchronization on a standalone Citrix ADC appliance.
- The secondary node is disabled.
- HA synchronization is disabled on the current secondary node.
- HA propagation is disabled on the current primary node and you force synchronization from the primary.

8. What are the conditions for failure of the *sync HA files* command?

   Synchronizing configuration files fail in either of the following circumstances:

   - On a standalone system.
   - With the secondary node disabled.

9. In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

   No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the *force failover* command.

10. What are the conditions for failure of the force failover command?

    A forced failover fails in any of the following circumstances:

    - You force failover on a standalone system.
    - The secondary node is disabled.
    - The secondary node is configured to remain secondary.
    - The primary node is configured to remain primary.
    - The state of the peer node is unknown.

Troubleshooting high availability issues

September 14, 2021

The most common high availability issues involve the high availability feature not working at all, or working only intermittently. Following are common high availability issues, and probable causes and resolutions.

- **Issue**
  The inability of the Citrix ADC appliances to pair the Citrix ADC appliances in a high availability setup.
  - **Cause**
    Network connectivity
    Resolution
    Verify that both the appliances are connected to the switch and the interfaces are enabled.

- **Cause**
  Mismatch in the Password for the default Administrator account
  Resolution
  Verify that the password on both the appliances is the same.
- **Cause**
  IP conflict
  Resolution
  Verify that both the appliances have unique Citrix ADC IP (NSIP) address. The appliances should not have the same NSIP address.
- **Cause**
  Node ID mismatch
  Resolution
  Verify that the Node ID Configuration on both the appliances is unique. The appliances should not have the same Node ID configuration. Additionally, you must assign value for a Node ID between 1 and 64.
- **Cause**
  Mismatch in the password of the RPC node
  Resolution
  Verify that both the nodes have the same RPC node password.
- **Cause**
  An administrator has disabled the remote node
  Resolution
  Enable the remote node.
- **Cause**
  The Firewall application has blocked the heartbeat packets
  Resolution

Verify that the UDP port 3003 is allowed.

- **Issue**
  Both the appliances claim to be the primary appliance.
  - **Cause**
    Missing heartbeat packets between the appliances
    Resolution
    Verify that the UDP port 3003 is not blocked for communication between the appliances.
- **Issue**
  The Citrix ADC appliance is not able to synchronize the configuration.
  - **Cause**
    A Firewall application is blocking the required port.
    Resolution
    Verify that the UDP port 3010 (or UDP port 3008 with secure synchronization) is not blocked

for communication between the appliances.

- **Cause**
  An administrator has disabled synchronization.
  Resolution
  Enable synchronization on the appliance that has the issue.
- **Cause**
  Different Citrix ADC releases or builds are installed on appliances.
  Resolution
  Upgrade the appliances to the same Citrix ADC release or build.

- **Issue**
  Command propagation fails between the appliances.
  - **Cause**
    A Firewall application is blocking the port.
    Resolution
    Verify that the UDP port 3011 (or UDP port 3009 with secure propagation) is not blocked for communication between the appliances.
  - **Cause**
    An administrator has disabled command propagation.
    Resolution
    Enable command propagation on the appliance that has the issue.
  - **Cause**
    Different Citrix ADC releases or builds are installed on appliances.
    Resolution
    Upgrade the appliances to the same Citrix ADC release or build.
- **Issue**
  The Citrix ADC appliances in the high availability pair are unable to run the force failover process.
  - **Cause**
    The Secondary node is disabled.
    Resolution
    Enable the secondary node.
  - **Cause**
    The Secondary node is configured to stay secondary.
    Resolution
    Set the secondary high availability status of the secondary node to Enable from Stay Secondary.
- **Issue**
  The secondary appliance does not receive any traffic after the failover process.
  - **Cause**
    The upstream router does not understand GARP messages of Citrix ADC appliance.

Resolution
Configure virtual MAC address on the secondary appliance.

Managing high availability heartbeat messages on a Citrix ADC appliance

September 14, 2021

The two nodes in a high availability configuration send and receive heartbeat messages to and from each other on all interfaces that are enabled. The heartbeat messages flow regardless of the HA MON setting on these interfaces. If NSVLAN or both (NSVLAN and SYNC) are configured on an appliance, the heartbeat messages flow only through the enabled interfaces that are part of the NSVLAN and SYNCVLAN.

If a node does not receive the heartbeat messages on an enabled interface, it sends critical alerts to the specified Command Center and SNMP managers. These critical alerts give false alarms and draw unnecessary attention from the administrators for interfaces that are not configured as part of the connections to the peer node.

To resolve this issue, the HAHeartBeat option for interfaces and channels is used for enabling or disabling HA heartbeat-message flow on them.

To manage the high availability heartbeat messages on an interface by using the command line interface

At the command prompt, type:

- `set interface <ID> [-HAHeartBeat ( ON | OFF )]`
- `show interface <ID>`

To manage the high availability heartbeat messages on a channel by using the command line interface

At the command prompt, type:

- `set channel <ID> [-HAHeartBeat ( ON | OFF )]`
- `show channel <ID>`

To manage the high availability heartbeat messages for an interface by using the GUI

1. Navigate to **System** > **Network** > **Interfaces**.
2. Enable or disable the **HA Heart Beat** parameter.

To manage the high availability heartbeat messages on a channel by using the GUI

1. Navigate to **System** > **Network** > **Channels**.
2. Enable or disable the **HA Heart Beat** parameter.

Remove and Replace a Citrix ADC in a High Availability Setup

September 14, 2021

This topic helps you to address RMA replacements. Also, this topic has instructions on how to backup configurations, upgrade or downgrade shipped software version, and setup of RPC password on ADC.

Points to Consider

The following configurations are not synchronized or propagated in a high availability configuration in INC (Independent Network Configuration) or non-INC mode:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.
- All Interface HA Monitoring configuration commands.

The following configurations are not synced nor propagated in an HA configuration in INC mode (Independent Network Configuration):

- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations

Instructions

Complete the following steps to replace a Citrix ADC in high availability setup:

- Remove an Active Citrix ADC secondary node
- Configure Replacement secondary node
- Verify and Update the Software Build on Replacement ADC
- Set Password on New secondary to Match primary
- Add Licenses to Replacement ADC
- Creating HA Pair between primary and New secondary node

Remove an Active Secondary Node

1. Log on to both ADCs and run the following command to confirm which node is primary and which node is secondary:

```
show ha node
<!--NeedCopy-->
```

2. Log on to the primary ADC, backup the configurations on the primary node, and copy the files off of the ADC prior to the changes. These files are located under "/var /ns_sys_backup/" directory.

   The steps are as follows:

   a) Save the ADC running configurations to memory:

```
save ns config
<!--NeedCopy-->
```

   b) Create the full backup file package:

```
create system backup -level full
<!--NeedCopy-->
```

   c) Create the basic backup file package:

```
create system backup -level basic
<!--NeedCopy-->
```

3. After all backup files have been generated, be sure to copy them off of the device before proceeding.

   From a windows terminal, open a Command Prompt and copy the backup files off of the ADC and onto your local hard drive. This can be done using the following command:

```
pscp <username>@<NSIP>:<Target file source>  <Target file
   destination>
<!--NeedCopy-->
```

   Example:

```
pscp nsroot@10.125.245.78:/var/ns_sys_backup/backup_basic_10
   .125.245.78_2016_09_14_15_08.tgz c:\nsbackup\backup_basic_10
   .125.245.78_2016_09_14_15_08.tgz
<!--NeedCopy-->
```

   When prompted, enter the password for the specified administrator account, then hit Enter. Repeat these steps until all backup bundles are copied to the local PC before proceeding.

4. SSH into the secondary ADC, and set the unit to the “STAYSECONDARY” status. This will force the unit to not attempt to assume the primary role in the event of a detected failure during the swap. Confirm that you are connected to the secondary ADC before executing this step

```
set ha node  -haStatus <state>
set ha node  -haStatus STAYSECONDARY
<!--NeedCopy-->
```

5. Once the secondary ADC’s **Node State** successfully displays STAYSECONDARY, switch to the primary ADC and delete the secondary node and run the following command:

```
save ns config
<!--NeedCopy-->
```

While logged into the primary ADC, run the following commands

a) Run the following command to identify which numerical value represents the secondary HA node:

```
show ha node
<!--NeedCopy-->
```

b) Run the following command to remove the secondary ADC from the primary HA pair;

```
rm ha node <node ID>
<!--NeedCopy-->
```

c) Run the following command to save the configuration:

```
save ns config
<!--NeedCopy-->
```

d) With the secondary ADC now removed, shutdown, disconnect, and remove the secondary ADC from the network.

Note. Be sure to label all connections before disconnecting.

Configure Replacement Secondary Node

1. With the replacement ADC in place, power up the new device. DO NOT CONNECT the network connections at this point.
2. With boot-up complete, use the console port to connect to the ADC and configure the NSIP that you will use to connect to the unit.

3. When prompted, select **4**.

   Note. In this example, we are using a different NSIP for the replacement ADC. If you wish to use the original secondary unit's IP, You may change it on the replacement before binding the new ADC to the primary HA unit.

4. The ADC should now be booted. Now connect the network interface that will be used for Management traffic, and confirm that the IP address is reachable from your network.

Verify and Update the Software Build on Replacement ADC

Before syncing the new unit to the primary ADC, we need to ensure that both ADCs are running the same build.

1. To verify the version on ADC run the following command:

```
show version
<!--NeedCopy-->
```

2. While on the new secondary ADC, create a subfolder in **/var** to be used for the upgrade.
3. Go to Citrix Downloads and download the appropriate package that matches the build version running on the primary ADC.
4. Download and extract the .tgz file:

```
tar -xvzf "file.tgz"
<!--NeedCopy-->
```

5. Copy the extracted files to the secondary ADC. On your windows terminal, open a "Command Prompt" and navigate to the directory containing the extracted .tgz build package and run the following pscp command:

```
pscp <Target file source>  <username>@<NSIP>:<Target file
   destination>
<!--NeedCopy-->
```

   Example:

```
C:\inetpub>pscp c:\inetpub\build-12.1-47.14_nc.tgz nsroot@10
   .20.245.80:/var/NS_upg_12.1_47.14/build-12.1-47.14_nc.tgz
<!--NeedCopy-->
```

6. After the file has been transferred, return to the secondary ADC and upgrade. For detailed instructions, see Upgrading a Citrix ADX Standalone Appliance.

7. Once the new secondary has rebooted, SSH back into the unit and confirm that the upgrade is successful and the build matches that of the primary.

Set Password on Replacement Secondary Node to Match Primary

Note: If at this point you want to change the management IP (NSIP) address of the new secondary ADC, you may do so before moving forward.

Change the password on the new secondary ADC to match the password that is currently on the primary ADC.

1. Make that the default administrator (nsroot) account password is the same as the primary ADC. This is accomplished using the following command while logged in through SSH into the new secondary unit:

```
set system user <user> <password>
<!--NeedCopy-->
```

   This command set/resets the password for the specified user.

2. SSH into the primary and new secondary ADC and confirm that passwords match.

Add Licenses to Replacement Secondary Node

With the new ADC updated and ready for pairing, download and install the appropriate licensing for the replacement node.

1. Navigate to https://www.citrix.com to request and download licenses for the new replacement unit.
2. Once you have all appropriate licenses downloaded, SSH into the new secondary ADC and type the following command to see the current state of licensing:

```
show license
<!--NeedCopy-->
```

3. From the Windows terminal command prompt you must now upload the license files to the new secondary ADC using the following command:

   Note. If you have multiple licenses, repeat this step until all licenses are uploaded.

```
pscp <Target file source>  <username>@<NSIP>:<Target file
   destination>
<!--NeedCopy-->
```

   Example:

```
C:\inetpub>pscp c:\inetpub\NS-VPX-3K-LIC-020030ad0024.lic
   nsroot@10.125.245.80:/nsconfig/license/NS-VPX-3K-LIC-020030
   ad0024.lic
<!--NeedCopy-->
```

4. SSH into the new secondary ADC and perform a warm reboot using the following command:

```
reboot  -w
<!--NeedCopy-->
```

   After the unit is restarted, SSH into the unit and run show license command once again. At this point, the licenses should be applied.

Set up High Availability between primary and New Secondary Node

At this point, we are now ready to join the Citrix ADC units into a high availability pair. For more information, see Configuring high availability.

Request retry

November 22, 2021

When a Citrix ADC appliance receives an HTTP request but has a connection failure with a back-end server, the appliance uses a retry directive. The request retry addresses connection failure scenarios and enables the appliance to choose the next available service and forward the request. By doing a request retry, the client can save round trip time (RTT).

Request retry feature is applicable for the following connection failure scenarios:

- If a back-end server resets a TCP connection when an HTTP request is received. For more details, see Request retry.
- If a back-end server resets a TCP connection during connection establishment. For more details, see Request retry.
- If a response from a back-end server times out (based on the configured time-out value) when an appliance sends an HTTP request. For more details, see Request retry.

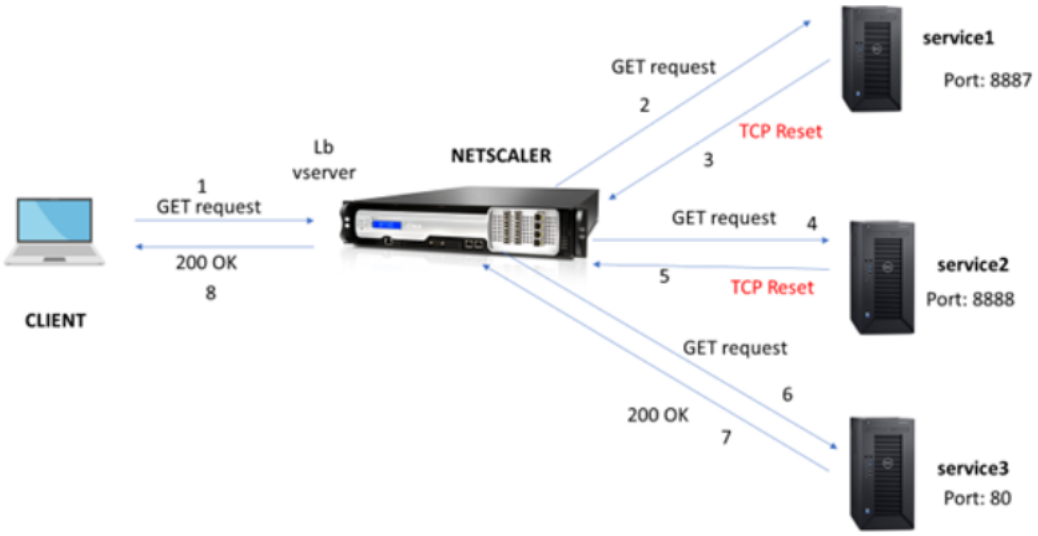
Request retry if back-end server resets TCP connection

September 14, 2021

When a back-end server resets a TCP connection, the request retry feature forwards the request to the next available server, instead of sending the reset to the client. By doing reload balancing, the client saves RTT when the appliance initiates the same request to next available service.

How request retry works when back-end server resets a TCP connection

The following diagram shows how components interact with each other.



1. The process starts by enabling appqoe feature on your appliance.
2. When the client sends an HTTP or HTTPS request, the load balancing virtual server sends the request to the back-end server.
3. If the requested service is unavailable, the back-end server resets the TCP connection.
4. If the appqoe configuration has “retry” enabled with the desired number of retry attempts specified, the load balancing virtual server uses the configured load balancing algorithm to forward the request to the next available application server.
5. After the load balancing virtual server receives the response, the appliance forwards the response to the client.
6. If the available back-end servers is equal or lesser than the retry count and if all the servers send reset, the appliance would respond a 500 internal server error. Consider a scenario with five available servers and the retry count set as six. If all the five servers resets the connection, then the appliance returns a 500 internal server error to the client.
7. Similarly, if the number of back-end servers is more than the retry count and if the back-end servers resets the connection, the appliance forwards the reset to the client. Consider a scenario with three back-end servers and the retry count set as two. If the three servers resets the connection, then the appliance sends a reset response to the client.

Configure request retry for GET method

For configuring retry feature for GET method, you must complete the following steps.

1. Enable AppQoE
2. Add AppQoE action
3. Add AppQoE policy
4. Bind AppQoE policy to load balancing virtual server

Enable AppQoE

At the command prompt, type:

```
enable ns feature appqoe
```

Add AppQoE action

You must configure an AppQoE action to specify if you want the appliance to retry after a TCP reset and the number of retry attempts.

```
add appqoe action reset_action -retryOnReset ( YES | NO )-numretries <
positive_integer>]
```

Example:

```
add appqoe action reset_action -retryOnReset YES -numretries 5
```

Where,
retryOnReset. Enable retry if the back-end server resets a TCP connection.
numretries. Retry count.

Add AppQoE policy

To implement AppQoE you must configure AppQoE policy to prioritize incoming HTTP or SSL request in a specific queue.

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
```

Example:

```
add appqoe policy reset_policy -rule http.req.method.eq(get)-action reset_action
```

Bind appqoe policy to load balancing virtual server

When a back-end server resets a TCP packet request and if you want the load balancing virtual server to forward the request to the next available service, you must bind the load balancing virtual server to the AppQoE policy.

At the command prompt, type:

```
bind lb vserver <name> ((<serviceName> (-policyName <string> [-priority <
positive_integer>] [-gotoPriorityExpression <expression>] [-type ( REQUEST
| RESPONSE )]
```

Example:

```
bind lb vserver v1 -policyName reset_policy -type REQUEST -priority 1
```

Configure request retry for POST requests

You must always exercise caution when you reload balance requests that write data into the back-end server. For such requests, ensure the content length is short. If the content length is long, then it might result in resource consumption. Follow the steps given below to configure reload balancing for POST requests.

1. Enable AppQoE
2. Add AppQoE action
3. Add AppQoE policy
4. Bind appQoE policy to load balancing virtual server

Enable AppQoE

At the command prompt, type:

```
enable ns feature appqoe
```

Add Appqoe action

You must add an AppQoE action to retry after a TCP reset and number of retry attempts.

```
add appqoe action reset_action -retryOnReset ( YES | NO )-numretries <
positive_integer>]
```

Example:

```
add appqoe action reset_action -retryOnReset YES -numretries 5
```

Add Appqoe policy

To implement AppQoE you must configure AppQoE policy to define how to queue the connections in a specific queue.

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
```

Example:

```
add appqoe policy reset_policy -rule HTTP.REQ.CONTENT_LENGTH.le(2000)-
action reset_action
```

> **Note:**
>
> You can use this configuration if you prefer to restrict the request retry feature for content length less than 2000.

Bind load balancing virtual server to AppQoE policy

When a back-end server resets a TCP packet request and if you want the load balancing virtual server to forward the request to the next available service through a specific queue, you must bind the load balancing virtual server to the AppQoE policy.

At the command prompt, type:

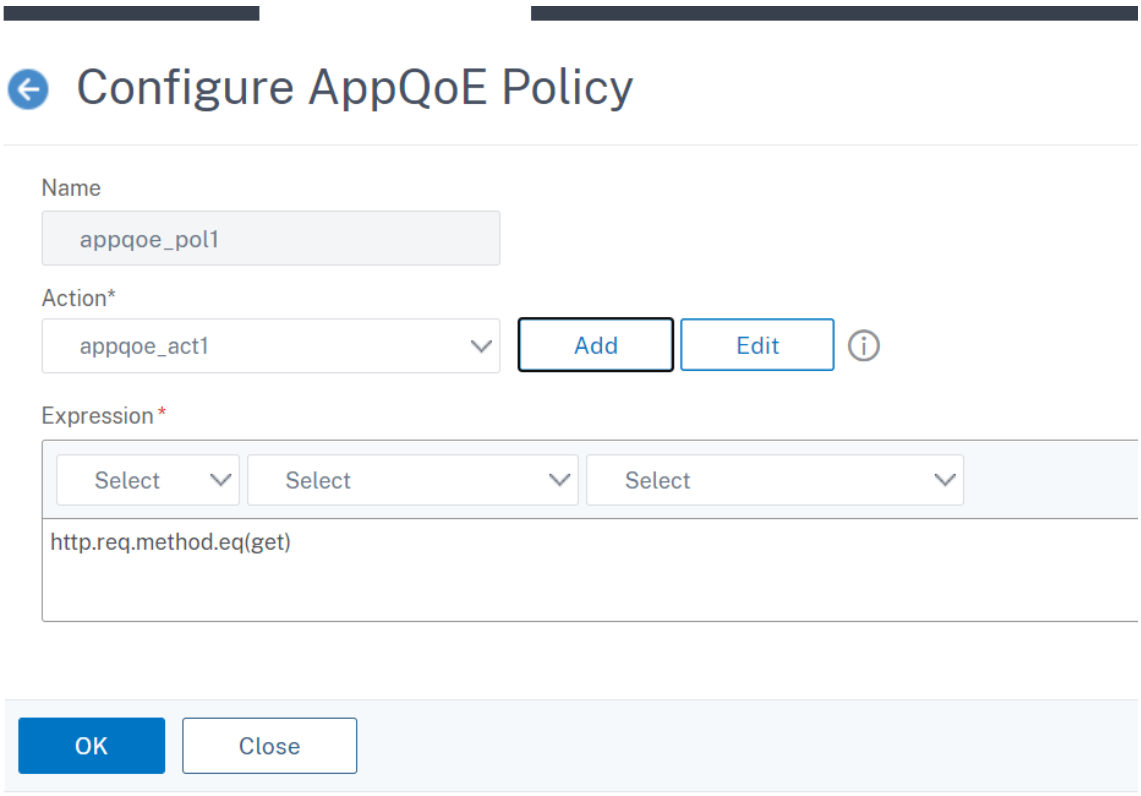
```
bind lb vserver <name> ((<serviceName> (-policyName <string> [-priority <
positive_integer>] [-gotoPriorityExpression <expression>] [-type ( REQUEST
| RESPONSE )]
```

Example:

```
bind lb vserver v1 -policyName reset_policy -type REQUEST -priority 1
```

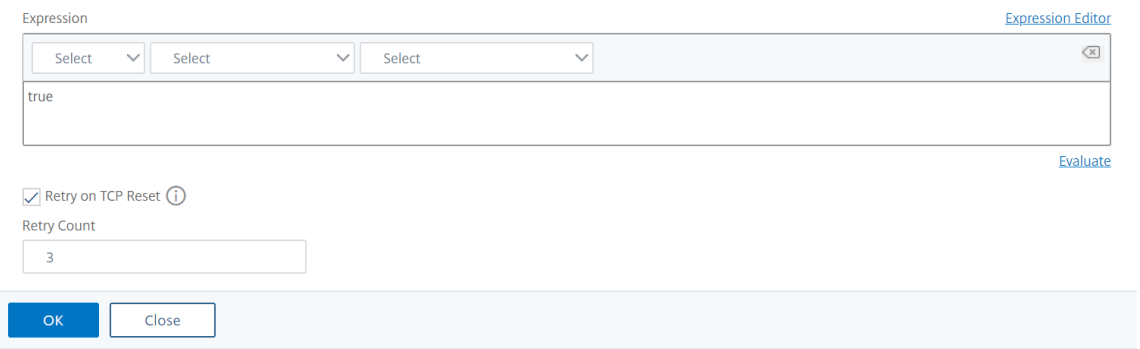
Configure AppQoE policy for request retry by using the Citrix ADC GUI

1. Navigate to **AppExpert** > **AppQoE** > **Policies**.
2. In the **AppQoE Policies** page, click **Add**.
3. In the **Create an AppQoE Policy** page, set the following parameters:
   a. Name. AppQoE policy name
   b. Action. Add or edit an action. To create an action, see section.
   c. Expression. Select or enter `HTTP.REQ.CONTENT_LENGTH.le (2000)` policy expression.
4. Click **Create** and **Close**.



Configure AppQoE action for request retry balancing by using the Citrix ADC GUI

1. Navigate to **AppExpert** > **AppQoE** > **Action**.
2. In the **AppQoE Actions** page, click **Add**.
3. In the **Create AppQoE Action** page, set the following parameters for retry on TCP reset:
   a. Retry on TCP Reset. Select the check box to enable retry action for TCP reset.
   b. Retry Count. Enter the retry count.
4. Click **Create** and **Close**.



Configure request retry for GET method when back-end server resets on TCP SYN establishment

The CLI and GUI configuration is similar to steps followed for GET method. For more information, see Configure request try for GET method section. when back-end server resets a connection section.

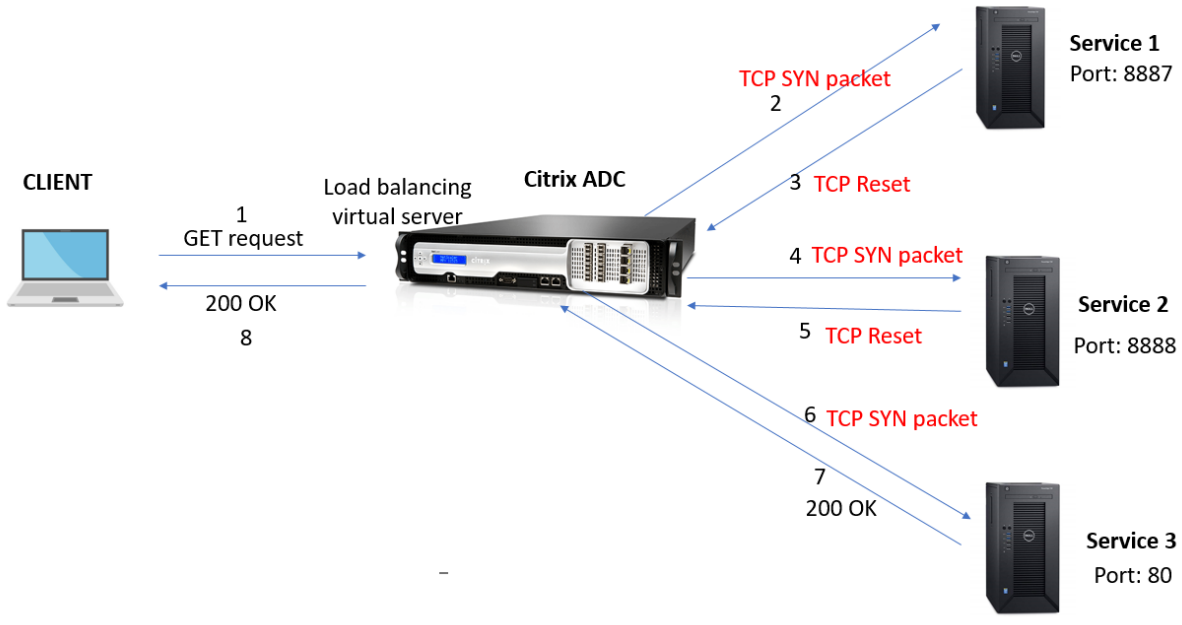
Request retry if back-end server resets TCP connection during connection establishment

September 14, 2021

When a back-end server resets a TCP connection during connection establishment, the request retry feature forwards the request to the next available server, instead of sending the reset to the client. By doing reload balancing, the client saves RTT when the appliance initiates the same request to next available service.

How request retry works when back-end server resets a TCP connection on SYN establishment

The following diagram show the components interact with each other:



1. The process starts by enabling appqoe feature on your appliance.
2. When the client sends an HTTP or HTTPS request, the load balancing virtual server initiates connection to backend server.

3. If the requested service is unavailable on TCP SYN establishment, the back-end server resets the TCP connection.
4. If the appqoe configuration has “retry” enabled with the desired number of retry attempts specified, the load balancing virtual server uses the configured load balancing algorithm to forward the request to the next available application server.
5. After the load balancing virtual server receives the response, the appliance forwards the response to the client.
6. If the available back-end servers is equal or lesser than the retry count and if all the servers send reset, the appliance would respond a 500 internal server error. Consider a scenario with five available servers and the retry count set as six. If all the five servers resets the connection, then the appliance returns a 500 internal server error to the client.
7. Similarly, if the number of back-end servers is more than the retry count and if the back-end servers resets the connection on TCP SYN establishment, the appliance forwards the reset to the client. Consider a scenario with three back-end servers and the retry count set as two. If the three servers resets the connection, then the appliance sends a reset packet to the client.

Configure request retry (GET and POST method) when back-end server resets on TCP SYN establishment

The CLI and GUI configuration is similar to steps followed for GET and POST method. For more information, see Configure request retry for GET method topic, Configure request retry for POST method when back-end server resets a connection section.

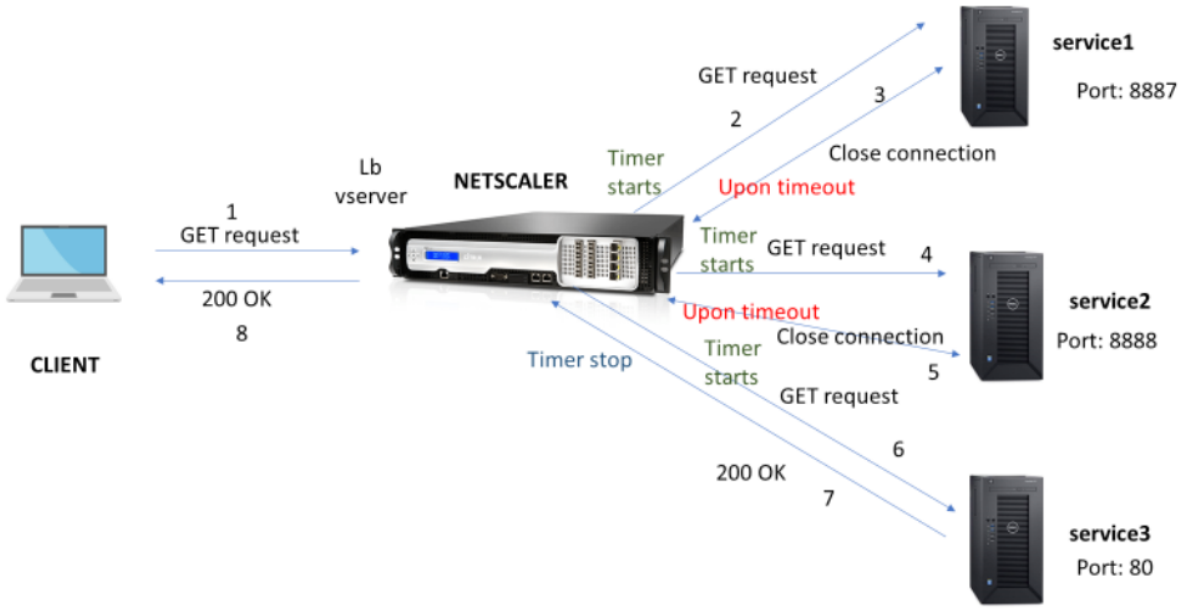
Request retry if back-end server response times out

September 14, 2021

Request retry is available for one more scenario where, if a back-end server takes more time to respond to requests, the appliance performs re-load balancing upon timeout and forwards the request to the next available server.

How request retry works when back-end server response times out

The following diagram show the components interact with each other:



1. The process starts by enabling appqoe feature on your appliance.
2. The appqoe configuration has “retryOnTimeout” parameter in milliseconds.
3. When the appliance sends a request and if the server takes more time to respond, the appliance performs re-load balancing based on the configured timeout value. The appliance resets the connection, chooses another service and forwards the request instead of waiting for the server response.
4. After the load balancing virtual server receives the response, the appliance forwards the response to the client. The usage of a time out parameter prevents the appliance to keep waiting for server response leading to an increased RTT.
5. If the available back-end servers is equal or lesser than the retry count and if all the servers times out for the request , the appliance would respond a 500 internal server error. Consider a scenario with five available servers and the retry count set as six. If all the five servers times out for the request, then the appliance returns a 500 internal server error to the client.
6. Similarly if the number of backend servers is more than the retry count and if the back-end server times out upon a request, the appliance keeps waiting upon the last service until the server sends out a response or client idle connection times out. Consider a scenario with three back-end servers and the retry count set as two. If all the three servers times out upon the request, the appliance keeps waiting upon the third service until the server sends out a response or client idle connection times out.

Configure request retry (GET and POST method) when back-end server response times out

For configuring request retry for GET method on timeout, you must complete the following steps.

1. Enable appqoe
2. Configure appqoe action
3. Add appqoe policy
4. Bind appqoe policy to load balancing virtual server

> **Note:**
>
> The request retry upon timeout scenario is also applicable for POST method.

Enable appqoe

At the command prompt, type:

```
enable ns feature appqoe
```

Add appqoe action for timeout

You must configure the appqoe action to retry on timeout and define the number of retry attempts.

At the command prompt, type:

```
add appqoe action <name> -retryOnTimeout <msecs> -numRetries <positive_integer
>
```

Example:

```
add appqoe action appact1 -retryOnTimeout 35 -numRetries 5
```

Add appqoe policy

To implement appqoe you must configure appqoe policy to define how to queue the connections.

At the command prompt, type:

```
add appqoe policy <name> -rule <rule> -action <name>
```

Example:

```
add appqoe policy timeout_policy -rule http.req.method.eq(get)-action
appact1
```

Bind appqoe policy to load balancing virtual server

When a back-end server takes a long time to respond and if you want the load balancing virtual server to forward the request to the next available service, you must bind the appqoe policy to balancing virtual server.

At the command prompt, type:

```
bind lb vserver <name> ((<serviceName> (-policyName <string> [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type ( REQUEST | RESPONSE )]
```

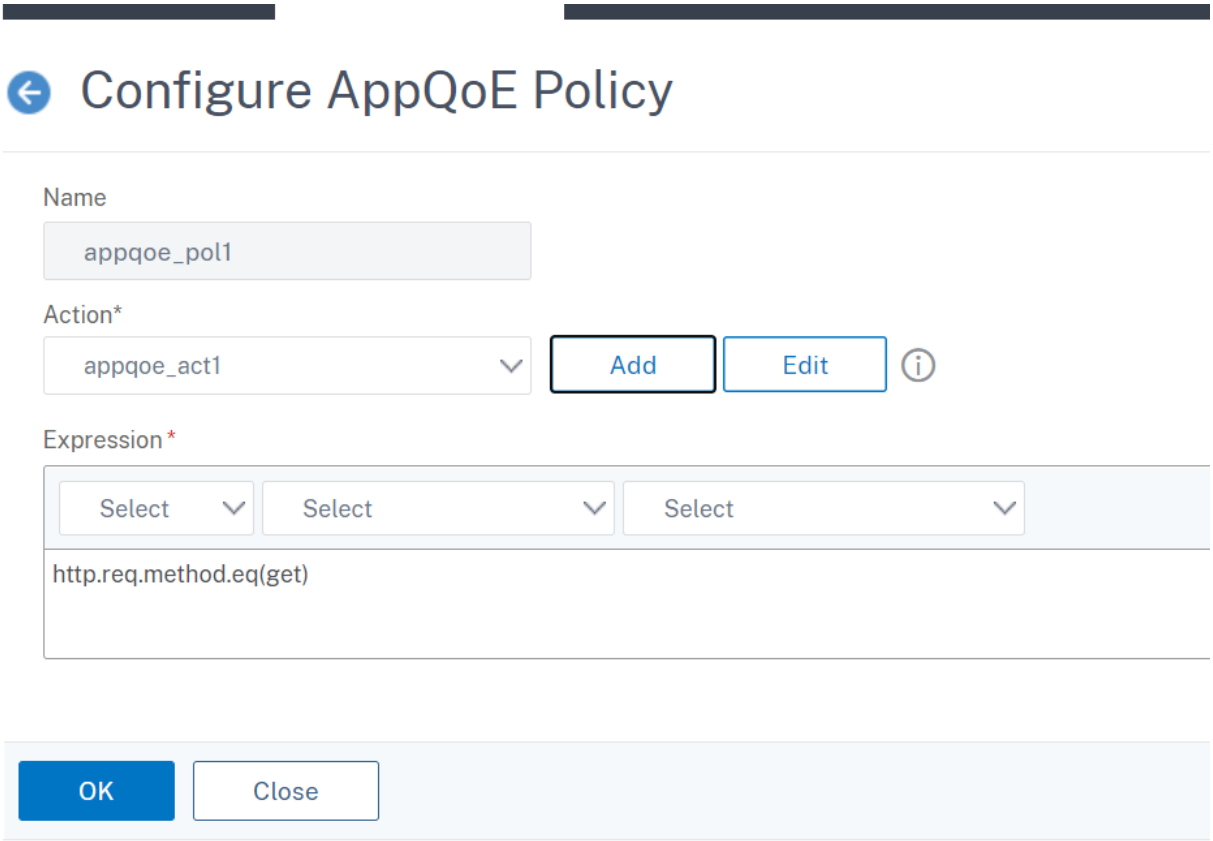
Example:

```
bind lb vserver v1 -policyName timeout_policy -type REQUEST -priority 1
```

Configure AppQoE policy for re-loadbalancing on timeout by using the Citrix ADC GUI

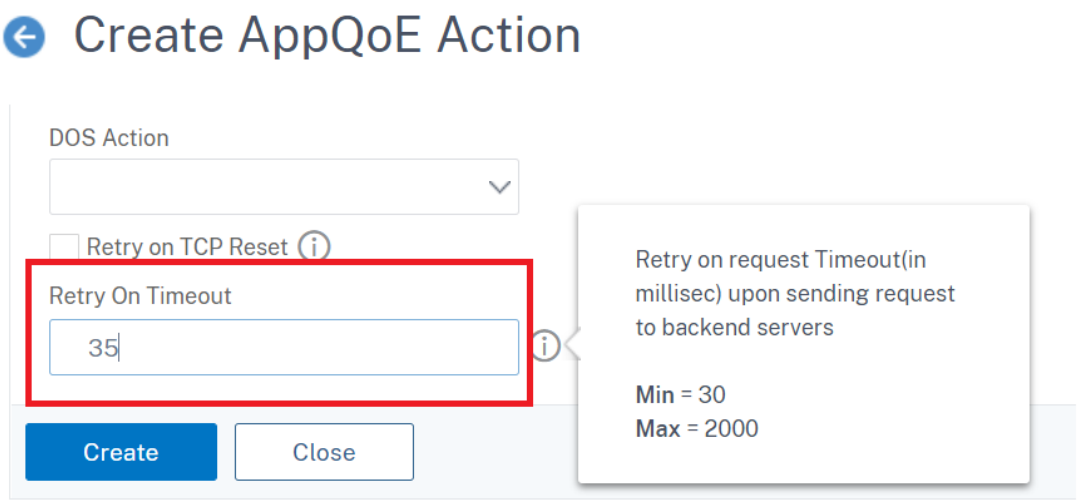
1. Navigate to **AppExpert > AppQoE > Policies**.
2. In the **AppQoE Policies** page, click **Add**.
3. In the **Create an AppQoE Policy** page, set the following parameters:

   a. Name. AppQoE policy name
   b. Action. Add or edit an action. To create a new action, see Create AppQoE Action section.
   c. Expression. Select or enter “http.req.method.eq(get)” policy expression.
4. Click **Create** and **Close**.



Configure AppQoE action for request retry by using the Citrix ADC GUI

1. Navigate to **AppExpert > AppQoE > Action**.
2. In the **AppQoE Actions** page, click **Add**.
3. In the **Create AppQoE Action** page, set the following parameter for retry on back-end server response time out:
   a. Retry on Timeout. Retry on request timeout (in millisec) upon sending request to backend servers.
4. Click **Create** and **Close**.



TCP optimization

September 14, 2021

TCP uses the following optimization techniques and congestion control strategies (or algorithms) to avoid network congestion in data transmission.

Congestion Control Strategies

The TCP has long been used to establish and manage Internet connections, handle transmission errors, and smoothly connect web applications with client devices. But network traffic has become more difficult to control, because packet loss does not depend only on the congestion in the network, and congestion does not necessarily cause packet loss. Therefore, to measure congestion, a TCP algorithm should focus on both packet loss and bandwidth.

Proportional Rate Recovery (PRR) algorithm

TCP Fast Recovery mechanisms reduce web latency caused by packet losses. The new Proportional Rate Recovery (PRR) algorithm is a fast recovery algorithm that evaluates TCP data during a loss recovery. It is patterned after Rate-Halving, by using the fraction that is appropriate for the target window chosen by the congestion control algorithm. It minimizes window adjustment, and the actual window size at the end of recovery is close to the Slow-Start threshold (ssthresh).

TCP Fast Open (TFO)

TCP Fast Open (TFO) is a TCP mechanism that enables speedy and safe data exchange between a client and a server during TCP's initial handshake. This feature is available as a TCP option in the TCP profile bound to a virtual server of a Citrix ADC appliance. TFO uses a TCP Fast Open Cookie (a security cookie) that the Citrix ADC appliance generates to validate and authenticate the client initiating a TFO connection to the virtual server. By using this TFO mechanism, you can reduce an application's network latency by the time required for one full round trip, which significantly reduces the delay experienced in short TCP transfers.

How TFO works

When a client tries to establish a TFO connection, it includes a TCP Fast Open Cookie with the initial SYN segment to authenticate itself. If authentication is successful, the virtual server on the Citrix ADC appliance can include data in the SYN-ACK segment even though it has not received the final ACK segment of the three-way handshake. This saves up to one full round-trip compared to a normal TCP connection, which requires a three-way handshake before any data can be exchanged.

A client and a back-end server perform the following steps to establish a TFO connection and exchange data securely during the initial TCP handshake.

1. If the client does not have a TCP Fast Open Cookie to authenticate itself, it sends a Fast Open Cookie request in the SYN packet to the virtual server on the Citrix ADC appliance.
2. If the TFO option is enabled in the TCP profile bound to the virtual server, the appliance generates a cookie (by encrypting the client's IP address under a secret key) and responds to the client with an SYN-ACK that includes the generated Fast Open Cookie in a TCP option field.
3. The client caches the cookie for future TFO connections to the same virtual server on the appliance.
4. When the client tries to establish a TFO connection to the same virtual server, it sends SYN that includes the cached Fast Open Cookie (as a TCP option) along with HTTP data.
5. The Citrix ADC appliance validates the cookie, and if the authentication is successful, the server accepts the data in the SYN packet and acknowledges the event with an SYN-ACK, TFO Cookie, and HTTP Response.

> **Note:**
>
> If the client authentication fails, the server drops the data and acknowledges the event only with a SYN indicating a session timeout.

1. On the server side, if the TFO option is enabled in a TCP profile bound to a service, the Citrix ADC appliance determines whether the TCP Fast Open Cookie is present in the service to which it is trying to connect.

2. If the TCP Fast Open Cookie is not present, the appliance sends a cookie request in the SYN packet.
3. When the back-end server sends the Cookie, the appliance stores the cookie in the server information cache.
4. If the appliance already has a cookie for the given destination IP pair, it replaces the old cookie with the new one.
5. If the cookie is available in the server information cache when the virtual server tries to reconnect to the same back-end server by using the same SNIP address, the appliance combines the data in SYN packet with the cookie and sends it to the back-end server.
6. The back-end server acknowledges the event with both data and a SYN.

Note: If the server acknowledges the event with only a SYN segment, the Citrix ADC appliance immediately resends the data packet after removing the SYN segment and the TCP options from the original packet.

Configuring TCP fast open

To use the TCP Fast Open (TFO) feature, enable the TCP Fast Open option in the relevant TCP profile and set the TFO Cookie Timeout parameter to a value that suits the security requirement for that profile.

Enable or disable TFO by using the CLI

At the command prompt, type one of the following commands to enable or disable TFO in a new or existing profile.

Note: The default value is DISABLED.

```
1     add tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED
2     set tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED
3     unset tcpprofile <TCP Profile Name> - tcpFastOpen
4     Examples
5     add tcpprofile Profile1 - tcpFastOpen
6     Set tcpprofile Profile1 - tcpFastOpen Enabled
7     unset tcpprofile Profile1 - tcpFastOpen
8 <!--NeedCopy-->
```

To set TCP Fast Open cookie timeout value by using the command line interface

At the command prompt, type:

```
1     set tcpparam - tcpfastOpenCookieTimeout <Timeout Value>
2     Example
```

```
3     set tcpprofile  - tcpfastOpenCookieTimeout 30secs
4 <!--NeedCopy-->
```

To configure the TCP Fast Open by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **TCP Fast Open** check box.
3. Click **OK** and then **Done**.

To Configure the TCP Fast Cookie timeout value by using the GUI

Navigate to **Configuration** > **System** > **Settings** > **Change TCP Parameters** and then **Configure TCP Parameters** page to set the TCP Fast Open Cookie timeout value.

TCP HyStart

A new TCP profile parameter, HyStart, enables the HyStart algorithm, which is a slow-start algorithm that dynamically determines a safe point at which to terminate (ssthresh). It enables a transition to congestion avoidance without heavy packet losses. This new parameter is disabled by default.

If congestion is detected, HyStart enters a congestion avoidance phase. Enabling it gives you better throughput in high-speed networks with high packet loss. This algorithm helps maintain close to maximum bandwidth while processing transactions. It can therefore improve throughput.

Configuring TCP HyStart

To use the HyStart feature, enable the Cubic HyStart option in the relevant TCP profile.

To configure HyStart by using the command line interface (CLI)

At the command prompt, type one of the following commands to enable or disable HyStart in a new or existing TCP profile.

```
1 add tcpprofile <profileName> -hystart ENABLED
2 set tcpprofile <profileName> -hystart ENABLED
3 unset tcprofile <profileName> -hystart
4 <!--NeedCopy-->
```

Examples:

```
    add tcpprofile profile1 -hystart ENABLED
    set tcpprofile profile1 -hystart ENABLED
    unset tcprofile profile1 -hystart
<!--NeedCopy-->
```

To configure HyStart support by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **Cubic Hystart** check box.
3. Click **OK** and then **Done**.

TCP burst rate control

It is observed that TCP control mechanisms can lead to a bursty traffic flow on high speed mobile networks with a negative impact on the overall network efficiency. Due to mobile network conditions such as congestion or Layer-2 retransmission of data, TCP acknowledgments arrive clumped at the sender triggering a burst of transmission. These groups of consecutive packets sent with a short inter-packet gap it is called TCP packet burst. To overcome traffic burst, the Citrix ADC appliance uses a TCP Burst Rate Control technique. This technique evenly spaces data into the network for an entire round-trip-time so that the data is not sent into a burst. By using this burst rate control technique, you can achieve better throughput and lower packet drop rates.

How TCP burst rate control works

In a Citrix ADC appliance, this technique evenly spreads the transmission of a packet across the entire duration of the round-trip-time (RTT). This is achieved by using a TCP stack and network packet scheduler that identifies the various network conditions to output packets for ongoing TCP sessions to reduce the bursts.

At the sender, instead of transmitting packets immediately upon receipt of an acknowledgment, the sender can delay transmitting packets to spread them out at the rate defined by scheduler (Dynamic configuration) or by the TCP profile (Fixed configuration).

Configuring TCP burst rate control

To use the TCP Burst Rate Control option in the relevant TCP profile and set the burst rate control parameters.

To set TCP burst rate control by using the command line

At the command prompt, set one of the following TCP Burst Rate Control commands are configured in a new or existing profile.

Note: The default value is DISABLED.

```
add tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic
    | Fixed

set tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic
    | Fixed

unset tcpprofile <TCP Profile Name> -burstRateControl Disabled |
    Dynamic | Fixed
<!--NeedCopy-->
```

Where,

Disabled – If the Burst rate control is disabled, then a Citrix ADC appliance does not perform burst management other than the maxBurst setting.

Fixed – If the TCP burst rate control is Fixed, the appliance uses the TCP Connection Payload Send Rate value mentioned in the TCP Profile.

Dynamic – If the Burst Rate Control is “Dynamic” the connection is being regulated based on various network conditions to reduce TCP bursts. This mode works only when the TCP connection is in END-POINT mode. When Dynamic Burst Rate control is enabled the maxBurst parameter of the TCP profile is not in effect.

```
add tcpProfile  profile1 -burstRateControl Disabled

set tcpProfile profile1 -burstRateControl Dynamic

unset tcpProfile profile1 -burstRateControl Fixed
<!--NeedCopy-->
```

To set TCP Burst Rate Control parameters by using the command line interface

At the command prompt, type:

```
    set ns tcpprofile nstcp_default_profile  - burstRateControl <type of
        burst rate control>  - tcprate <TCP rate> -rateqmax <maximum
       bytes in queue>

    T1300-10-2> show ns tcpprofile nstcp_default_profile
            Name: nstcp_default_profile
            Window Scaling status:  ENABLED
            Window Scaling factor: 8
            SACK status: ENABLED
```

```
8               MSS: 1460
9               MaxBurst setting: 30 MSS
10              Initial cwnd setting: 16 MSS
11              TCP Delayed-ACK Timer: 100 millisec
12              Nagle's Algorithm: DISABLED
13              Maximum out-of-order packets to queue: 15000
14              Immediate ACK on PUSH packet: ENABLED
15              Maximum packets per MSS: 0
16              Maximum packets per retransmission: 1
17              TCP minimum RTO in millisec: 1000
18              TCP Slow start increment: 1
19              TCP Buffer Size: 8000000 bytes
20              TCP Send Buffer Size: 8000000 bytes
21              TCP Syncookie: ENABLED
22              Update Last activity on KA Probes: ENABLED
23              TCP flavor: BIC
24              TCP Dynamic Receive Buffering: DISABLED
25              Keep-alive probes: ENABLED
26              Connection idle time before starting keep-alive probes: 900
                    seconds
27              Keep-alive probe interval: 75 seconds
28              Maximum keep-alive probes to be missed before dropping
                   connection: 3
29              Establishing Client Connection: AUTOMATIC
30              TCP Segmentation Offload: AUTOMATIC
31              TCP Timestamp Option: DISABLED
32              RST window attenuation (spoof protection): ENABLED
33              Accept RST with last acknowledged sequence number: ENABLED
34              SYN spoof protection: ENABLED
35              TCP Explicit Congestion Notification: DISABLED
36              Multipath TCP: DISABLED
37              Multipath TCP drop data on pre-established subflow:
                   DISABLED
38              Multipath TCP fastopen: DISABLED
39              Multipath TCP session timeout: 0 seconds
40              DSACK: ENABLED
41              ACK Aggregation: DISABLED
42              FRTO: ENABLED
43              TCP Max CWND : 4000000 bytes
44              FACK: ENABLED
45              TCP Optimization mode: ENDPOINT
46              TCP Fastopen: DISABLED
47              HYSTART: DISABLED
48              TCP dupack threshold: 3
49              Burst Rate Control: Dynamic
```

```
50                TCP Rate: 0
51                TCP Rate Maximum Queue: 0
52  <!--NeedCopy-->
```

To configure the TCP Burst Rate Control by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select **TCP Burst Control** option from the drop-down list:
   a) BurstRateCntrl
   b) CreditBytePrms
   c) RateBytePerms
   d) RateSchedulerQ
3. Click **OK** and then **Done**.

Protection against wrapped sequence (PAWS) algorithm

If you enable the TCP timestamp option in the default TCP profile, the Citrix ADC appliance uses the Protection Against Wrapped Sequence (PAWS) algorithm to identify and reject old packets whose sequence numbers are within the current TCP connection's receive window because the sequence has "wrapped" (reached its maximum value and restarted from 0).

If network congestion delays a non-SYN data packet and you open a new connection before the packet arrives, sequence-number wrapping might cause the new connection to accept the packet as valid, leading to data corruption. But if the TCP timestamp option is enabled, the packet is discarded.

By default, the TCP timestamp option is disabled. If you enable it, the appliance compares the TCP timestamp (SEG.TSval) in a packet's header with the recent timestamp (Ts.recent) value. If SEG.TSval is equal to or greater than Ts.recent, the packet is processed. Otherwise, the appliance drops the packet and sends a corrective acknowledgment.

How PAWS works

The PAWS algorithm processes all the incoming TCP packets of a synchronized connection as follows:

1. If `SEG.TSval` < `Ts.recent`: The incoming packet is not acceptable. PAWS sends an acknowledgment (as specified in RFC-793) and drops the packet. Note: Sending an ACK segment is necessary to retain TCP's mechanisms for detecting and recovering from half-open connections.
2. If packet is outside the window: PAWS rejects the packet, as in normal TCP processing.
3. If `SEG.TSval` > `Ts.recent`: `PAWS` accepts the packet and processes it.
4. If `SEG.TSval` <= `Last.ACK.sent`(arriving segment satisfies): PAWS must copies `SEG.TSval` value to `Ts.recent` (is it copied to Ts. Recent field in the db?.
5. If the packet is in sequence: PAWS accepts the packet.

6. If packet is not in sequence: The packet is treated as a normal in-window, out-of-sequence TCP segment. For example, it might be queued for later delivery.
7. If the `Ts.recent` value is idle for more than 24 days: The validity of `Ts.recent` is checked if the PAWS timestamp check fails. If the Ts.recent value is found to be invalid, the segment is accepted and the `PAWS rule` updates the `Ts.recent` with the TSval value from the new segment.

To enable or disable TCP timestamp by using the command line interface

At the command prompt, type:

```
`set nstcpprofile nstcp_default_profile -TimeStamp (ENABLED | DISABLED)
    `
```

To enable or disable TCP timestamp by using the GUI

Navigate to **System** > **Profile** > **TCP Profile**, select the default TCP profile, click **Edit**, and select or clear the **TCP timestamp** check box.

Optimization Techniques

TCP uses the following optimization techniques and methods for optimized flow controls.

Policy based TCP Profile Selection

Network traffic today is more diverse and bandwidth-intensive than ever before. With the increased traffic, the effect that Quality of Service (QoS) has on TCP performance is significant. To enhance QoS, you can now configure AppQoE policies with different TCP profiles for different classes of network traffic. The AppQoE policy classifies a virtual server's traffic to associate a TCP profile optimized for a particular type of traffic, such as 3G, 4G, LAN, or WAN.

To use this feature, create a policy action for each TCP profile, associate an action with AppQoE policies, and bind the policies to the load balancing virtual servers.

For information about using subscriber attributes to perform TCP optimization, see Policy-based TCP Profile.

Configuring policy based TCP profile selection

Configuring policy based TCP profile selection consists of the following tasks:

- Enabling AppQoE. Before configuring the TCP profile feature, you must enable the AppQoE feature.

- Adding AppQoE Action. After enabling the AppQoE feature, configure an AppQoE action with a TCP profile.
- Configuring AppQoE based TCP Profile Selection. To implement TCP profile selection for different classes of traffic, you must configure AppQoE policies with which your Citrix ADC can distinguish the connections and bind the correct AppQoE action to each policy.
- Binding AppQoE Policy to Virtual Server. Once you have configured the AppQoE policies, you must bind them to one or more load balancing, content switching, or cache redirection virtual servers.

Configuring using the command line interface

To enable AppQoE by using the command line interface

At the command prompt, type the following commands to enable the feature and verify that it is enabled:

- `enable ns feature appqoe`
- `show ns feature`

To bind a TCP profile while creating an AppQoE action using the command line interface

At the command prompt, type the following AppQoE action command with the `tcpprofiletobind` option.

```
add appqoe action <name> [-priority <priority>] [-respondWith ( ACS | NS ) [<CustomFile>] [-altContentSvcName <string>] [-altContentPath <string>] [-maxConn <positive_integer>] [-delay <usecs>]] [-polqDepth <positive_integer>] [-priqDepth <positive_integer>] [-dosTrigExpression <expression>] [-dosAction ( SimpleResponse |HICResponse )] [-tcpprofiletobind <string>]
show appqoe action
```

To configure an AppQoE policy by using the command line interface

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
```

To bind an AppQoE policy to load balancing, cache redirection or content switching virtual servers by using the command line interface

At the command prompt, type:

```
bind cs vserver cs1 -policyName <appqoe_policy_name> -priority <priority>
bind lb vserver <name> - policyName <appqoe_policy_name> -priority <priority
>
bind cr vserver <name> -policyName <appqoe_policy_name> -priority <priority
>
```

Example

```
1     add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -nagle
         ENABLED -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 500
          -slowStartIncr 1 -bufferSize 4194304 -flavor BIC -KA ENABLED -
         sendBuffsize 4194304 -rstWindowAttenuate ENABLED -spoofSynDrop
         ENABLED -dsack enabled -frto ENABLED -maxcwnd 4000000 -fack
         ENABLED -tcpmode ENDPOINT
2     add appqoe action appact1 -priority HIGH -tcpprofile tcp1
3     add appqoe policy apppol1 -rule "client.ip.src.eq(10.102.71.31)" -
         action appact1
4     bind lb vserver lb2 -policyName apppol1 -priority 1 -
         gotoPriorityExpression END -type REQUEST
5     bind cs vserver cs1 -policyName apppol1 -priority 1 -
         gotoPriorityExpression END -type REQUEST
6  <!--NeedCopy-->
```

Configuring policy based TCP profiling using the GUI

To enable AppQoE by using the GUI

1. Navigate to **System** > **Settings**.
2. In the details pane, click **Configure Advanced Features**.
3. In the **Configure Advanced Features** dialog box, select the **AppQoE** check box.
4. Click **OK**.

To configure AppQoE policy by using the GUI

1. Navigate to **App-Expert** > **AppQoE** > **Actions**.
2. In the details pane, do one of the following:
3. To create a new action, click **Add**.
4. To modify an existing action, select the action, and then click **Edit**.
5. In the **Create AppQoE Action** or the **Configure AppQoE Action** screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Action" as follows (asterisk indicates a required parameter):

a) Name—name
b) Action type—respondWith
c) Priority—priority
d) Policy Queue Depth—polqDepth
e) Queue Depth—priqDepth
f) DOS Action—dosAction

6. Click **Create**.

To bind AppQoE policy by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select a server and then click **Edit**.
2. In the **Policies** section and click (+) to bind an AppQoE policy.
3. In the **Policies** slider, do the following:
   a) Select a policy type as AppQoE from the drop-down list.
   b) Select a traffic type from the drop-down list.
4. In the **Policy Binding** section, do the following:
   a) Click **New** to create a new AppQoE policy.
   b) Click **Existing Policy** to select an AppQoE policy from the drop-down list.
5. Set the binding priority and click **Bind** to the policy to the virtual server.
6. Click **Done**.

SACK block generation

TCP performance slows down when multiple packets are lost in one window of data. In such a scenario, a Selective Acknowledgment (SACK) mechanism combined with a selective repeat retransmission policy overcomes this limitation. For every incoming out-of-order packet, you must generate a SACK block.

If the out-of-order packet fits in the reassembly queue block, insert packet info in the block, and set the complete block info as SACK-0. If an out-of-order packet does not fit into the reassembly block, send the packet as SACK-0 and repeat the earlier SACK blocks. If an out-of-order packet is a duplicate and packet info is set as SACK-0 then D-SACK the block.

Note: A packet is considered as D-SACK if it is an acknowledged packet, or an out of order packet which is already received.

Client reneging

A Citrix ADC appliance can handle client reneging during SACK based recovery.

Memory checks for marking end_point on PCB are not considering total available memory

In a Citrix ADC appliance, if the memory usage threshold is set to 75 percent instead of using the total available memory, it causes new TCP connections to bypass TCP optimization.

Unnecessary retransmissions due to missing SACK blocks

In a non-endpoint mode, when you send DUPACKS, if SACK blocks are missing for few out of order packets, triggers more retransmissions from the server.

SNMP for connections bypassed optimization because of overload

The following SNMP ids have been added to a Citrix ADC appliance to track number of connections bypassed TCP optimizations due to overload.

1. 1.3.6.1.4.1.5951.4.1.1.46.131 (tcpOptimizationEnabled). To track the total number of connections enabled with TCP optimization.
2. 1.3.6.1.4.1.5951.4.1.1.46.132 (tcpOptimizationBypassed). To track the total number of connections bypassed TCP Optimization.

Dynamic receive buffer

To maximize TCP performance, a Citrix ADC appliance can now dynamically adjust the TCP receive buffer size.

Tail Loss Probe algorithm

A retransmission timeout (RTO) is a loss of segments at the tail end of a transaction. An RTO occurs if there are application latency issues, especially in short web transactions. To recover loss of segments at the end of a transaction, TCP uses the Tail Loss Probe (TLP) algorithm.
TLP is a sender only algorithm. If a TCP connection is not receiving any acknowledgment for a certain period, TLP transmits the last unacknowledged packet (loss probe). In the event of a tail loss in original transmission, acknowledge from loss probe triggers a SACK or FACK recovery.

Configuring the Tail Loss Probe

To use the Tail Loss Probe (TLP) algorithm, you must enable the TLP option in the TCP profile and set the parameter to a value that suits the security requirement for that profile.

Enable TLP by using the command line

At the command prompt, type one of the following commands to enable or disable TLP in a new or existing profile.

> **Note**:
>
> The default value is DISABLED.

```
add tcpprofile <TCP Profile Name> - taillossprobe ENABLED | DISABLED

set tcpprofile <TCP Profile Name> - taillossprobe ENABLED | DISABLED

unset tcpprofile <TCP Profile Name> - taillossprobe
```

Examples:

```
add tcpprofile nstcp_default_profile - taillossprobe

set tcpprofile nstcp_default_profile -taillossprobe Enabled

unset tcpprofile nstcp_default_profile -taillossprobe
```

Configure the Tail Loss Probe algorithm by using the Citrix ADC GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **Tail Loss Probe** check box.
3. Click **OK** and then **Done**.

Troubleshooting solutions for Citrix ADC

September 14, 2021

This topic gives you some basic troubleshooting solutions needed to resolve issues that occur in your appliance. It gives you an understanding of NetScaler appliance, how it integrates with the network, and what issues you can expect in basic system features.

How to record a packet trace on Citrix ADC

September 14, 2021

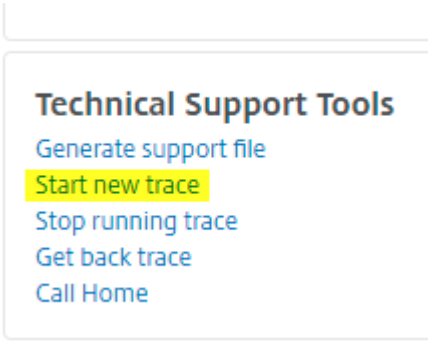
This troubleshooting article explains how an administrator can record a network packet trace using the Citrix ADC GUI.

Points to remember

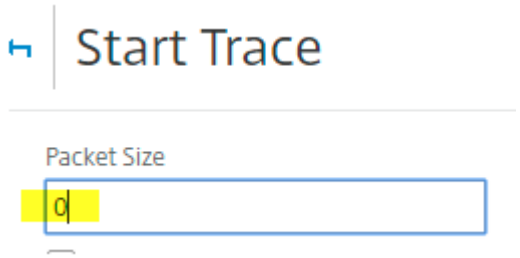
- Citrix recommends you to use the recent Wireshark version from the “automated build section” available in the following webpage: http://www.wireshark.org/download/automated.
- In Citrix ADC version 10.5 or later, to decrypt the capture and ensure ECC (Elliptic Curve Cryptography), Session Reuse and DH parameters are disabled from the virtual server. You must do before you capture a trace.

Record packet trace on NetScaler version 11.1

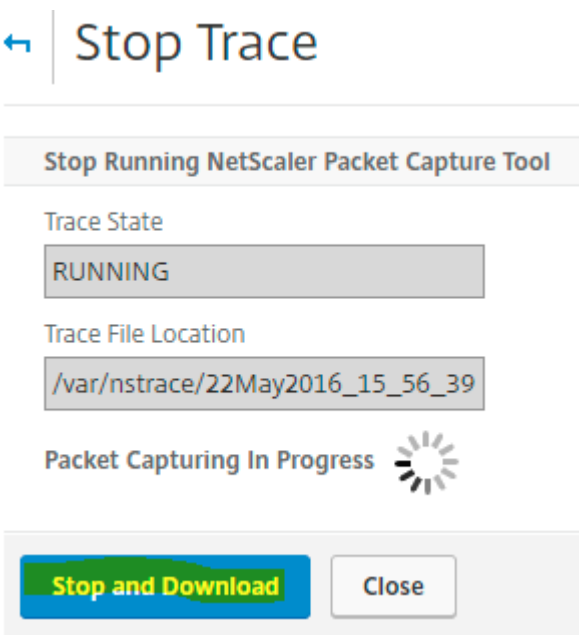
1. Navigate to **System** > **Diagnostics** page.
2. click the **Start new trace** link in the **Diagnostic** page, as shown in the following screenshot.



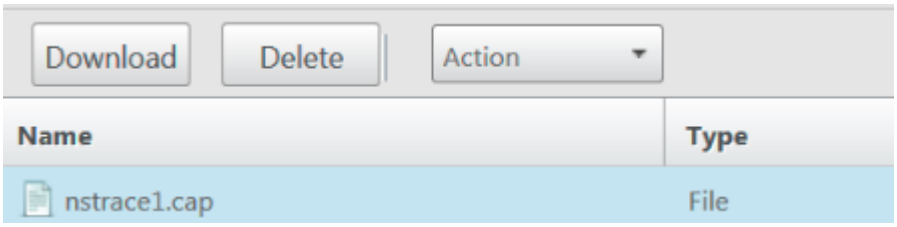
3. Update the packet size to 0 in the **Packet size** field.



4. Click **Start** to start recording the network packet trace.
5. Click **Stop and Download** to stop recording the network packet trace after the test is complete.



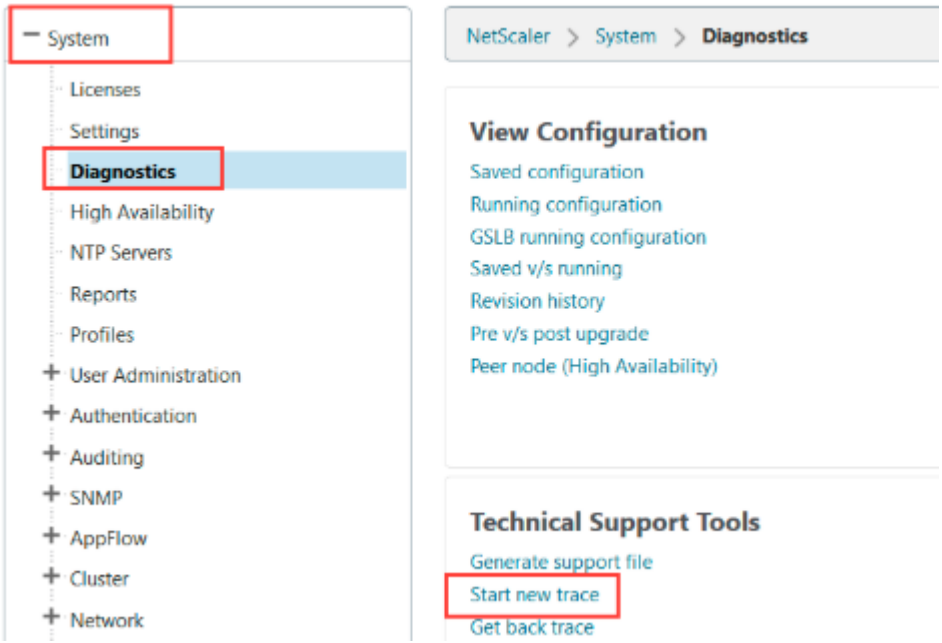
6. Select the required file and click **Select** and click **Download**.



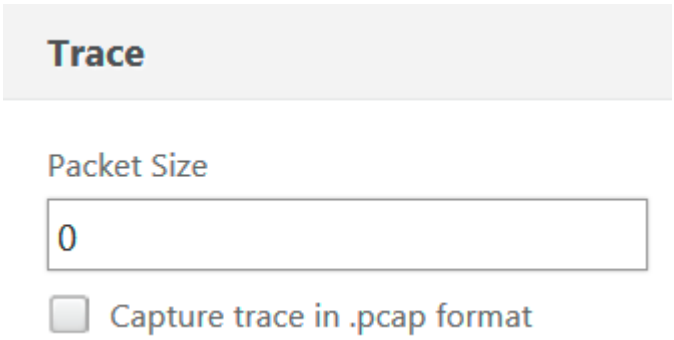
7. Open the network packet trace file with the Wireshark utility to display the content of the file.

Record packet trace on NetScaler 10.5 appliance

1. Navigate to **System** > **Diagnostics** page.

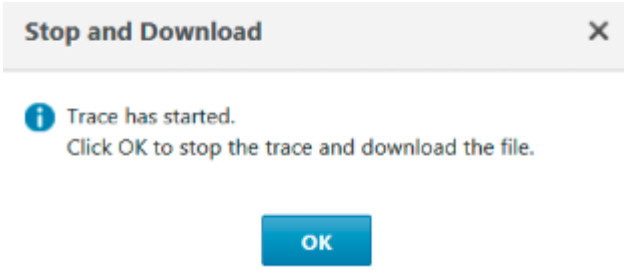


2. Click the **Start new trace** link under **Technical Support Tool**s as shown in the following screen-shot.
3. Update the packet size to 0 in the **Packet Size** field.



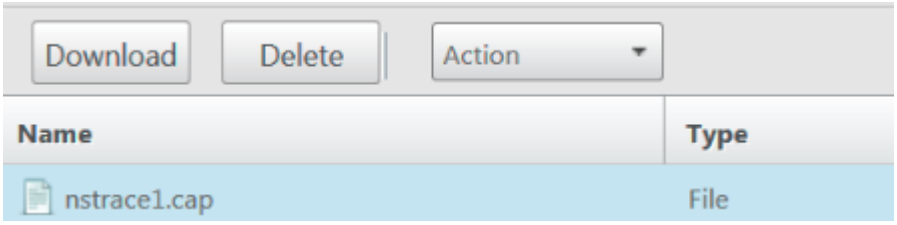
> **Note**: If appliance headers are not required then select Capture trace in .pcap format.

4. Click **Start** to start recording the network packet trace.
5. Click **OK** to stop recording the network packet trace after the test is complete.



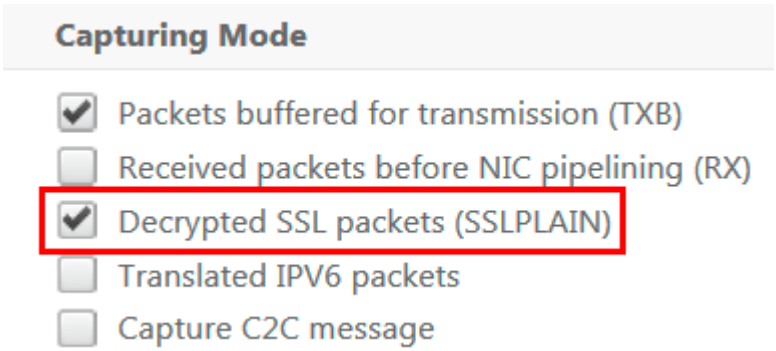
An nstrace.cap file is generated, which contains the network packet trace.

6. Highlight the required file and click **Download**.



7. Specify a destination and save the packet trace.
8. Open the network packet trace file with the Wireshark utility to display the content of the file.

> **Note**: Select Decrypted SSL packets (SSLPLAIN) to decrypt the packet trace without the private key.



Capture SSL master keys

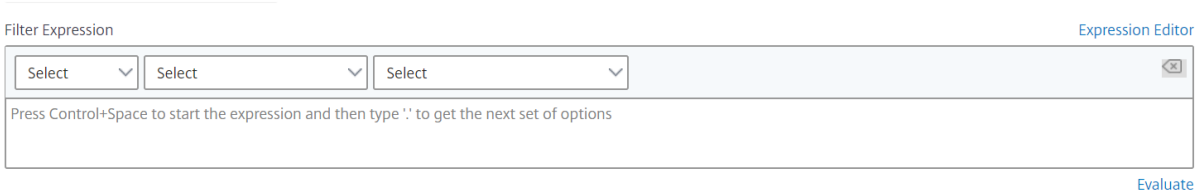
In the 11.0, 11.1 version and above there is an option to capture the session keys which is valid for only for that particular session/nstrace and this option can be used if you do not want to share the private key or use SSLPLAIN mode. For more information, see https://support.citrix.com/article/CTX135889.

Export Session Keys without sharing Private key

In most of the scenarios the private key is not available or shared. In such scenarios we can suggest exporting the **SSL session** keys instead of the private key. Read,
[How to Export and Use SSL Session Keys to Decrypt SSL Traces Without Sharing the SSL Private Key, see https://support.citrix.com/article/CTX135889.

Filters

Also, it is always recommended to add IP based filters while taking traces. The process ensures that you capture only interested traffic which eases your troubleshooting. Adding filters also decreases the load on the appliance while taking traces.



Simple IP-based filters are enough to get the right captures. For more information about `nstrace` filters and examples, see Citrix Documentation page.

Use case to capture a packet trace with virtual server IP filter (both front-end and back end)

Using a filter of the virtual server IP address and enabling the option "–link" in CLI or selecting the option "Trace filtered connection peer traffic" in GUI (available 10.1 and above), you can capture both the front-end and back-end traffic for the IP address.

```
start nstrace -size 0 -filter "CONNECTION.IP.EQ(1.1.1.1)" -link ENABLED

show nstrace
        State:  RUNNING          Scope:  LOCAL            TraceLocation
            :  "/var/nstrace/24Mar2017_16_00_19/..." Nf:  24
                           Time:  3600             Size:  0
                          Mode:  TXB NEW_RX
        Traceformat:  NSCAP      PerNIC:  DISABLED        FileName:  24
            Mar2017_16_00_19 Filter:  "CONNECTION.IP.EQ(1.1.1.1)" Link:
             ENABLED          Merge:  ONSTOP           Doruntimecleanup
            :  ENABLED
        TraceBuffers:  5000      SkipRPC:  DISABLED       Capsslkeys:
            DISABLED    InMemoryTrace:  DISABLED
<!--NeedCopy-->
```

Capturing cyclic traces

It is always challenging to troubleshoot an intermittent issue. Cyclic tracing is best suited for issues which are intermittent. The traces can be run over a span of few hours or days before the issue occurs. Also, you can use a specific filter and evaluate the size of the trace files that are generated before you run it for a longer time.

Run the following command from the CLI:

```
start nstrace -nf 60 -time 30 -size 0
This particular trace will create 60 files each of them for 30 sec.
   This means the files will start getting overwritten after 60 trace
   files or 30 mins
Show nstrace à To check the status of the nstrace
Stop nstrace à To stop the nstrace.

<!--NeedCopy-->
```

Best Practices

On a unit handling GB of traffic per second, capturing traffic is a very resource intensive process. The impact to resources is mainly in terms of the CPU and the disk space. Disk space impact can be reduced by using filtering expressions. However, the impact on the CPU remains and sometimes causes a slight increase as the appliance now needs to process packets according to the filter before capturing them.

The best practice with regard to tracing is:

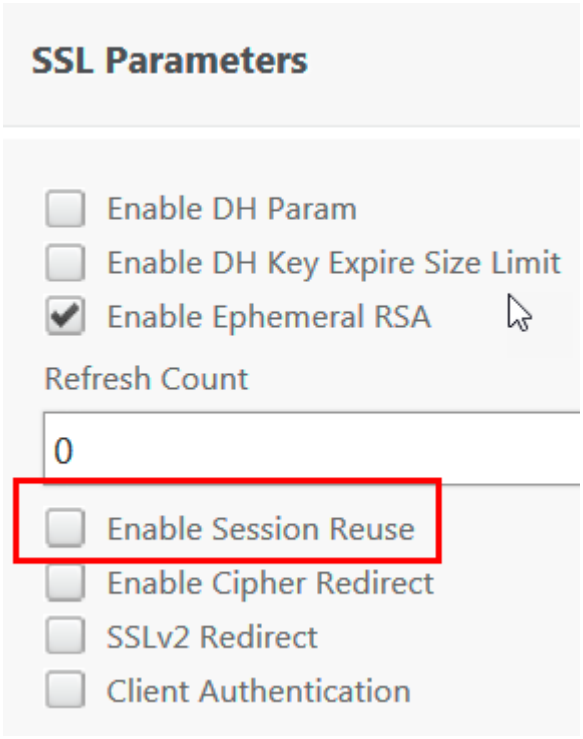
1. The duration for which the trace is run must be as limited as possible when you still ensure the packets of interest are captured.
2. Schedule the tracing activity to happen at a time when the number of users (and hence the traffic) is greatly reduced, such as during off hours.

More resources

Disable session reuse on virtual server from the GUI

Session reuse is disabled when you capture a trace to complete an SSL handshake in the trace. When it is enabled, you can capture a partial handshake in the trace. Ensure you enable the option after the trace collection.
Do not disable an SSL session reuse when the persistence method is sslsession, as it breaks the persistence for existing connections. For more information refer to https://support.citrix.com/article/CTX121925.

1. Open the virtual server and navigate to SSL Parameters.
2. Disable Enable Session Reuse if enabled.



Disable session reuse on virtual server from the CLI

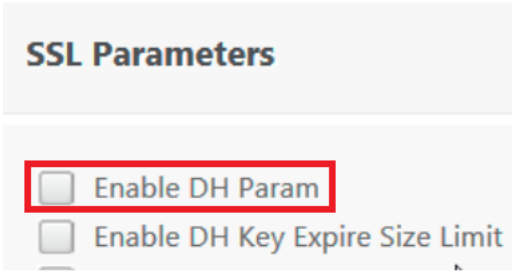
1. SSH to the appliance console.
2. Run the following command to disable DH Param from the virtual server:

```
set ssl vserver "vServer_Name"-sessReuse DISABLED
```

Disable DH parameter on virtual server from the GUI

Refer to https://support.citrix.com/article/CTX213335 To understand about DH Parameter.

1. Open the virtual server and navigate to SSL Parameters.
2. Disable DH Param if enabled.



Disable DH parameter on virtual server from the CLI

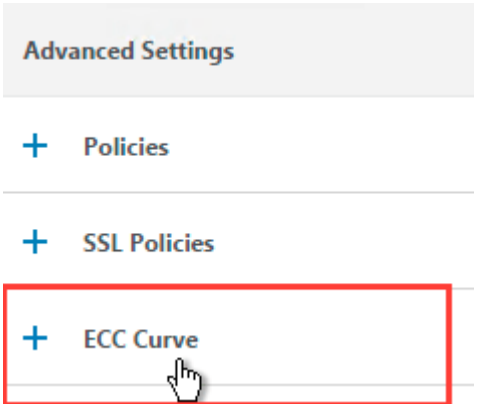
1. SSH to the appliance console.
2. Run the following command to disable DH Param from the virtual server:

```
set ssl vserver "vServer_Name"-dh DISABLED
```

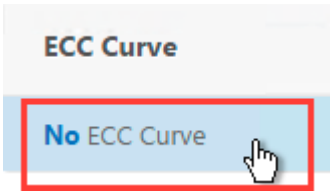
Disable ECC curve on virtual server from the GUI

ECC curve is disabled to decrypt the captured SSL trace with private key. You must not disable the keys if the related SSL ciphers are used. For more information about the ECC curve, see https://support.citrix.com/article/CTX205289

1. Open the virtual server and navigate to ECC Curve.



2. If there is no ECC Curve bound to the virtual server then no other action is required.



3. If any ECC Curve is bound to the virtual server then click the ECC Curve and Unbind it from the virtual server.

Disable ECC curve on virtual server from the CLI

1. SSH to the appliance console.
2. Run the following command for each ECC Curve bound to the virtual server:

```
unbind ssl vserver "vServer_Name"-eccCurveName "ECC_Curve_Name"
```

How to free space on the VAR directory for logging issues with a Citrix ADC appliance

September 14, 2021

The following article explains how an administrator can free the space from the `/var` directory of a Citrix ADC appliance. You can follow the steps when the Citrix GUI is not accessible.

When the amount of disk space is low in the /var directory of the appliance, you might not be able to sign in to the Citrix GUI. In this scenario, you can remove the old log files to create free space in the /var directory.

Points to remember

- Ensure that you back up the files before removing the files from the appliance.

To free space in the `/var` directory of a Citrix ADC appliance, complete the following procedure:

1. Log on to the CLI of Citrix ADC by using SSH. For more information to complete this task, see the Citrix ADC Documentation.
2. After you log on to the Citrix ADC CLI, switch to the shell prompt using the following command. `shell`
3. Run the following command to see the availability of space on the Citrix ADC appliance. `df -h`
4. If the memory capacity of the `/var` directory is filled up to 90 percent, then you must delete few files from this directory.

   - Run the following commands to view the contents of the /var directory:

     ```
     cd /var
     ls -l
     ```

   The directories that are usually of interest are as follows:

   ```
   /var/nstrace - This directory contains trace files.This is the
      most common reason for HDD being filled on the Citrix ADC
      appliance. This is due to an nstrace being left running for
      indefinite amount of time. All traces that are not of interest
      can and should be deleted. To stop an nstrace, go back to the
      CLI and issue stop nstrace command.

   /var/log - This directory contains system specific log files.

   /var/nslog - This directory contains Citrix ADC log files.

   ```

```
/var/tmp/support - This directory contains technical support files, also known as, support bundles. All files not of interest should be deleted.

/var/core - Core dumps are stored in this directory. There will be directories within this directory and they will be labeled with numbers starting with 1. These files can be quite large in size. Clear all files unless the core dumps are recent and investigation is required.

/var/crash - Crash files, such as process crashes are stored in this directory. Clear all files unless the crashes are recent and investigation is required.

/var/nsinstall -  Firmware is placed in this directory when upgrading. Clear all files, except the firmware that is currently being used.
```

- Verify if any of the directories are using more space:

```
du -hs *
44k     cache
2.0k    clusterd
2.0k    configdb
6.0k    core
989M    crash
4.0k    cron
2.0k    dev
6.0k    download
2.0k    gui
2.0k    install
2.0k    krb
2.0k    learnt_data
122M    log
366M    NetScaler
14k     ns_gui
86k     ns_sys_backup

52k     run
28M     safenet
72M     tmp
2.0k    vmtools
14k     vpn
```

- Delete the files which are not required:

```
rm -r nstrace/*
```

For more help on deleting files see FreeBSD Man Pages.

- Delete the files which are not required.

  `rm -r nstrace/*`

  For more help on deleting files see FreeBSD Man Pages.

- If the log or `nslog` directory is using more space, then run the following commands to open the log directory and view its contents:

```
cd /var/log
ls -l
cd /var/nslog
ls -l
```

1. Ensure that all files are compressed. This is indicated by the .tar.gz file name extension.
2. If you are using Citrix ADM or Command Center, then verify the /var/ns_system_backup directory. Ensure that Citrix ADM or Command Center clears the backup files it creates.

How to download core or crashed files from Citrix ADC appliance

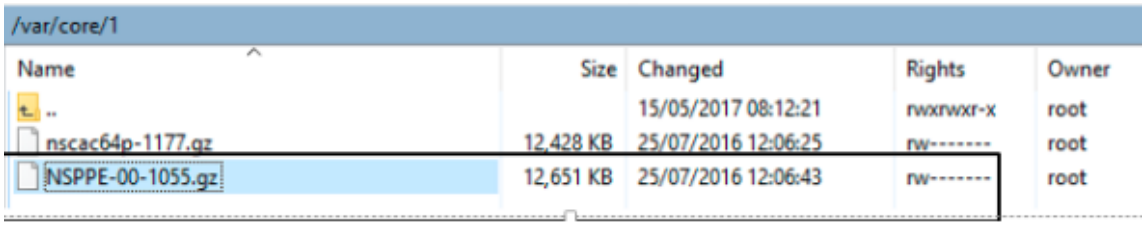
September 14, 2021

This troubleshooting article explains how an administrator can download core or crash files from the Citrix ADC appliance.

Download core or crash files from Citrix ADC appliance using SFTP client

To download the core or crash files from a NetScaler appliance, complete the following procedure:

1. Open WinSCP and log on to the NetScaler Management IP address.
2. Navigate to the `/var/core/1` to download the files.



> **Note:**
>
> To download the latest crash or core file, you can also use the WinSCP tool through command interface. The files can be located either in the core or crash directory.

How to collect performance statistics and event logs

September 14, 2021

You can collect performance statistics of virtual servers and associated services from an archived `newnslog` file present in the `/var/nslog` directory. The `newnslog` files are interpreted by running `/netscaler/nsconmsg`.

Collect performance statistics and event logs using the CLI

You can run the `nsconmsg` command from the Citrix ADC shell prompt to report events.

At the command prompt, type:

`/netscaler/nsconmsg -K /var/nslog/newnslog -d event`

```
1 Displaying event information
2 NetScaler V20 Performance Data
3 NetScaler NS10.5: Build 57.7.nc, Date: May 14 2015, 07:35:21
4 rtime: Relative time between two records in milliseconds
5 seqno rtime event-message                          event-time
6 11648 16310 PPE-0 MonServiceBinding_10.104.20.110:443_(tcp-default)
7 <!--NeedCopy-->
```

View the time span covered by a given “newnslog” file

At the command prompt, type:

```
/netscaler/nsconmsg -K /var/nslog/newnslog -d setime
```

The current data is appended to the `/var/nslog/newnslog` file. NetScaler archives the `newnslog` file automatically every two days by default. To read the archived data, you must extract the archive as shown in the following example:

`cd /var/nslog` - command to go to a particular directory from NetScaler Shell Prompt.

`tar xvfz newnslog.100.tar.gz` - command to extract the tar file.

`/netscaler/nsconmsg -K newnslog.100 -d setime` - Command to check the time span covered by the particular file, in this example `newnslog.100`.

`ls -l` Command checks all the logs file and time stamp associated with those files.

```
root@NETSCALER## cd /var/nslog
root@NETSCALER## ls -l
```

```

```

Display the time span within a file

Use the nsconmsg command to only display a span of time within the given file, as shown in the following example:

```
/netscaler/nsconmsg -K /var/nslog/newnslog -s time=22Mar2007:20:00 -T 7 -s ConLb=2 -d oldconmsg
```

Where,

s - time=22Mar2007:20:00:00 is start at March 22, 2007 at exactly 20:00.

T 7 - Displays seven seconds of data

s - Displays detail level of load balancing statistics.

d - Displays statistical information.

> **Note:**
>
> From ADC release 12.1 you need add at the “time” seconds as well, that is: 22Mar2007:20:00:00

The statistical information provided by the -d oldconmsg parameter is recorded every seven seconds. The following is a sample output.

```
1  VIP(10.128.58.149:80:UP:WEIGHTEDRR): Hits(38200495, 18/sec) Mbps(1.02)

14 Other: Pkt(38/sec, 670 bytes) Wt(10000) RHits(31556)
15 Conn: CSvr(32, 0/sec) MCSvr(20) OE(10) RP(7) SQ(0)
16 <!--NeedCopy-->
```

> **Note:**
>
> The client connection counts of the individual services do not add up to the client connection count of the virtual server. The reason is because of session reuse between the Citrix ADC appliance and the back-end service.

Virtual Server Output

```
VIP(10.128.58.149:80:UP:WEIGHTEDRR): Hits(38200495, 18/sec)Mbps(1.02)Pers(
OFF)Err(0)Pkt(186/sec, 610 bytes)actSvc(4)DefPol(NONE)override(0)Conn: Clt
(253, 1/sec, OE[252])Svr(3)
```

The following list describes the virtual server statistics:

1. `IP (IP address:port:state:Load balancing method)`. The IP address and port of the Virtual IP address as configured. The virtual server state or virtual IP address is UP, DOWN, or OUT OF SERVICE; Load balancing method configured for the Virtual IP address.
2. `Hits (##)`. Number of requests that reached the virtual server.
3. `Mbps (##)`. Total traffic Volume on the virtual server (Rx + Tx) converted into Mbits/s
4. `Pers`: Type of persistence configured.
5. `Err (##)`. Number of times an error page was generated by the virtual server.
6. `Pkt (##/sec, ## bytes)`: Volume of network traffic (as packets) passing through the virtual server and average packet size flowing through the virtual server.
7. `actSvc(##)`. Number of active services that are bound to the virtual server.
8. `DefPol (RR)`. Indicates whether the default load balancing method is active. Default load balancing method is used for some number of initial requests to smooth the behavior of the other methods.
9. `Clt (##, ##/sec)`. Number of current client connections to the virtual server rate.
10. `OE [##]`. Number of server connections from the virtual server in open established state.
11. `Svr (##)`. Number of current server connections from the virtual server.

In the preceding output, `Svr(3)` indicates the command collects he statistical sample. There are three active connections for the virtual server to the back-end server, even though there are four services in total. When a client establishes a connection with the virtual server, it is not necessary that the client sends or receives any traffic when the command collects the information. Therefore, it is common to see the `Svr` counter lower than the `OE[]` number. The `Svr` counter represents the number of active connections that are actively sending or receiving data. The Mapped IP address (MIP) or Subnet IP address (SNIP) is connected to the associated back-end server. And, the Citrix ADC tracks the virtual server connected to the back-end server and calculates the counter.

Virtual service output

```
S(10.128.49.40:80:UP) Hits(9443063, 4/sec, P[2602342, 0/sec]) ATr(5)
   Mbps(0.23) BWlmt(0 kbits) RspTime(112.58 ms)
Other: Pkt(36/sec, 712 bytes) Wt(10000) RHits(31555)
Conn: CSvr(42, 0/sec) MCSvr(20) OE(16) RP(11) SQ(0)
<!--NeedCopy-->
```

The following list describes the service statistics:

1. `S (IP address:port:state)`. IP address, port, and state of the service such as, DOWN, UP, or OUT OF SERVICE.
2. `Hits (##, P[##])`. Number of requests directed to the service, Number of requests directed to the service due to configured server persistence.
3. `ATr (##)`. Number of active connections to the service.

> **Note:**
>
> Active connections are ones which have the outstanding request to the service or currently have traffic activity.

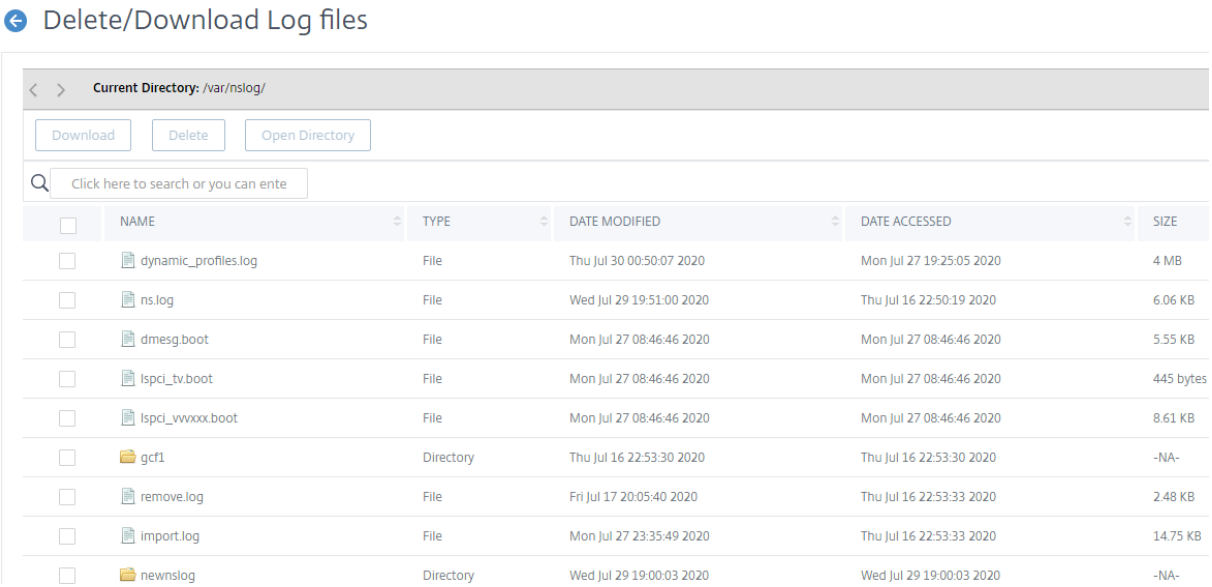
1. `Mbps (##.####)`. Total traffic Volume on the Service (Rx + Tx) converted into Mbits/s
2. `BWlmt (## kbits)`: Defined bandwidth limit.
3. `RspTime (## ms)`. Average response time of the service in milliseconds.
4. `Pkt(##/sec, ##bytes)`. Traffic volume in terms of packets per second going to the service; Average size of the packets.
5. `Wt (##)`. Weight index, used in load balancing algorithm.

> **Note:**
>
> If you divide this value by 10,000, then you get the actual configured weight of the service.

1. `RHits (##)`. Running requests counter used in Round Robin load balancing algorithm.
2. `CSvr (##, ##/sec)`. Number of connections to the service rate.
3. `MCSvr (##)`. Maximum number of connections to the service.
4. `OE (##)`. Number of connections to the service in the established state.
5. `RP (##)`. Number of connections to the service, residing in the reuse pool.
6. `SQ (##)`. Number of connections to the service, waiting in the surge queue.

Collect performance statistics and event logs using the Citrix ADC GUI

1. Navigate to **System > Diagnostics > Maintenance > Delete/Download log files**.
2. Select a file and click **Download** to download the file.



How to configure log file rotation

September 14, 2021

The Citrix ADC appliance generates logs in multiple directories and in various formats. Some of these logs are not rotated by default and can grow in size consuming too much disk space. By using the included utilities for log rotation (`newsyslog`), you can manage these logs consistently, by keeping only relevant information for easier management and administration.

The `newsyslog` utility included in the Citrix ADC firmware archives log files and rotates the system logs so the current log is empty during rotation. The system crontab runs this utility every hour and it reads the configuration file which specifies the files to rotate and the conditions. The archived files might be compressed if necessary.

The existing configuration is located in `/etc/newsyslog.conf`. However, because this file resides in the memory filesystem, the administrator must save the modifications to `/nsconfig/newsyslog.conf` so the configuration survives restarting the NetScaler.

The entries contained in this file have the following format:

```
logfilename [owner:group] mode count size when flags [/pid_file] [sig_num]
```

> **Note:**
>
> Fields within squared brackets are optional and can be omitted.

Each line on the file represents a log file and the conditions under which rotation must occur.

In the example, the `size` field indicates that the size of `ns.log` as 100 Kilobytes. The `count` field

indicates that the number of archived `ns.log` files as 25. A size of 100 K and count of 25 are the default size and count values.

> **Note:**
>
> When the field is configured with an asterisk (*), meaning that the ns.log file is not rotated based on time. Every hour, a crontab job runs the `newsyslog` utility which checks if the size of ns.log is greater than or equal to the size configured in this file. In this example, if it is greater than or equal to 100 K, it rotates that file.

```
root@ns# cat /etc/newsyslog.conf
# Netscaler newsyslog.conf

# This file is present in the memory filesystem by default, and any
    changes
# to this file will be lost following a reboot. If changes to this file
# require persistence between reboots, copy this file to the /nsconfig
# directory and make the required changes to that file.
#
# logfilename [owner:group] mode count size when flags [/pid_file] [
    sig_num]
/var/log/cron 600 3 100 * Z
/var/log/amd.log 644 7 100 * Z
/var/log/auth.log 600 7 100 * Z
/var/log/ns.log 600 25 100 * Z
<!--NeedCopy-->
```

The `size` field can be changed to modify the minimum size of the `ns.log` file or the field can be changed to rotate the `ns.log` file based on a certain time.

The daily, weekly, and/or monthly specification is given as: `[Dhh]`, and `[Dhh [Mdd]]`, respectively. The time-of-day fields, which are optional, default to midnight. The ranges and meanings for these specifications are:

```
Hh hours, range 0 ... 23
w day of week, range 0 ... 6, 0 = Sunday
dd day of month, range 1 ... 31, or the letter L or l to specify the
    last day of the month.
<!--NeedCopy-->
```

Examples:

Here are some examples with explanations for the logs that are rotated by default:

`/var/log/auth.log 600 7 100 * Z`

The authentication log is rotated when the file reaches 100 K, the last 7 copies of the auth.log are

archived and compressed with gzip (Z flag), and the resulting archives are assigned the following permissions –rw——-.

```
/var/log/all.log 600 7 * @T00 Z
```

The catch-all log is rotated 7 times at midnight every night (@T00) and compressed with gzip. The resulting archives are assigned the following permissions –rw-r—-.

```
/var/log/weekly.log 640 5 * $W6D0 Z
```

The weekly log is rotated 5 times at midnight every Monday. The resulting archives are assigned with permissions.

Common Rotation Patterns:

- `D0`. rotate every night at midnight
- `D23`. rotate every day at 23:00
- `W0D23`. rotate every week on Sunday at 23:00
- `W5`. rotate every week on Friday at midnight
- `MLD6`. rotate at the last day of every month at 6:00
- `M5`. rotate on every fifth day of the month at midnight

If an interval and a time specification are both given, then both conditions must be met. That is, the file must be as old as or older than the specified interval and the current time must match the time specification.

You can control the minimum file size but there is no limit on the file size before the `newsyslog` utility gets its turn in the next hour slot.

Debug newsyslog:

To debug the behavior of the `newsyslog` utility, add the verbose flag.

```
root@dj_ns# newsyslog -v
/var/log/cron <3Z>: size (Kb): 31 [100] --> skipping
/var/log/amd.log <7Z>: does not exist, skipped.

How to free space on a /flash directory in a Citrix ADC appliance

September 14, 2021

This troubleshooting article explains how an administrator can free space from the /flash directory of a Citrix ADC appliance.

Procedure to free space in the /flash directory of a Citrix ADC appliance

1. Log on to the CLI of Citrix ADC by using SSH.
2. After you log on to the Citrix ADC CLI, switch to the shell prompt using the following command.`shell`.
3. Run the `df -h` command to see the availability of space on the Citrix ADC appliance.
4. If the capacity of the /flash directory is more than 90 percent or low, you must delete few files from this directory.
5. Run the following commands to view the contents of the /flash directory:

   ```
   cd /flash
   ls -l
   ```

6. You might find multiple files of various versions of the NetScaler software release. Ensure that the files present in this location are the ones applicable to the current version of the NetScaler software on your appliance. Run the following command to remove any other files from the appliance.

   ```
   rm <filename>
   ```

> **Note**
>
> Remove only the older versions of the kernel. The /flash directory must contain the files that the current version or build of the NetScaler software release is using and the kernel.gz file. Citrix recommends not to remove these files from the /flash directory.

Reference Material

October 15, 2021

Use this reference information to get an in-depth understanding of the following Citrix ADC components:

Citrix ADC SNMP OIDs - Details of the SNMP OIDs that can be used to obtain information from a Citrix ADC appliance.

Citrix ADC Syslog Messages - Details of the Syslog messages given by the Citrix ADC appliance.

Citrix ADC CLI Commands - Details of the commands that can be used to configure the Citrix ADC appliance through the CLI. You can also view the details of each command in the CLI, by entering the `man <ns-command-name>` command.

Citrix NITRO API Reference - Details of all operations that can be performed on the Citrix ADC appliance by using the REST API.

Citrix ADC Advanced Policy Expressions - Details of the expressions that can be used to define advanced policies.
