You can designate web-form fields as confidential to protect the information users type into them. Normally, any information a user types into a web form on one of your protected web servers is logged in the Citrix ADC logs. The information typed into a web-form field designated as confidential, however, is not logged. That information is saved only where the website is configured to save such data, normally in a secure database.

Common types of information that you may want to protect with a confidential field designation include:

- Passwords
- Credit card numbers, validation codes, and expiration dates
- Social security numbers
- Tax ID numbers
- Home addresses
- Private telephone numbers

In addition to being good practice, proper use of confidential field designations may be necessary for PCI-DSS compliance on ecommerce servers, HIPAA compliance on servers that manage medical information in the United States, and compliance with other data protection standards.

> **Important**:
>
> In the following two cases, the Confidential Field designation does not function as expected:

- If a Web form has either a confidential field or an action URL longer than 256 characters, the field or action URL is truncated in the Citrix ADC logs.
- With certain SSL transactions, the logs are truncated if either the confidential field or the action URL is longer than 127 characters.

In either of these cases, the Web App Firewall masks a fifteen-character string with the letter “x,” instead of the normal eight character string. To ensure that any confidential information is removed, the user must use form field name and action URL expressions that match the first 256, or (in cases where SSL is used) the first 127 characters.

To configure your Web App Firewall to treat a web-form field on a protected website as confidential, you add that field to the Confidential Fields list. You can enter the field name as a string, or you can enter a PCRE-compatible regular expression specifying one or more fields. You can enable the confidential-field designation when you add the field, or you can modify the designation later.

To add a confidential field by using the command line interface

At the command prompt, type the following commands:

- `add appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX )] [-comment "<string>"] [-state ( ENABLED | DISABLED )]`
- `save ns config`

Example

The following example adds all web form fields whose names begin withPassword to the confidential fields list.

```
add appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^a-z]password[0-9a-z._-]*[.](asp|cgi|htm|html|htp|js|php)" -isRegex REGEX -state ENABLED
save ns config
<!--NeedCopy-->
```

To modify a confidential field by using the command line interface

At the command prompt, type the following commands:

- `set appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX ) ][-comment "<string>"] [-state ( ENABLED | DISABLED )]`
- `save ns config`

Example

The following example modifies the confidential field designation to add a comment.

```
set appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^a-z]password[0-9a-z._-]*[.](asp|cgi|htm|html|htp|js|php)" -comment "Protect password fields." -isRegex REGEX -state ENABLED
save ns config
<!--NeedCopy-->
```

To remove a confidential field by using the command line interface

At the command prompt, type the following commands:

- `rm appfw confidField <fieldName> <url>`
- `save ns config`

To configure a confidential field by using the GUI

1. Navigate to **Security** > **Application Firewall**.
2. In the details pane, under **Settings**, click **Manage Confidential Fields**.
3. In the Manage Confidential Fields dialog box, do one of the following:
    - To add a new form field to the list, click Add.

- To change an existing confidential field designation, select the field, and then click **Edit**. The **Web App Firewall Confidential Fields** dialog box appears.

  > **Note**:
  > If you select an existing confidential field designation and then click **Add**, the **Create Confidential Form Field** dialog box displays the information for that confidential field. You can modify that information to create your new confidential field.

4. In the dialog box, fill out the elements. They are:
   - **Enabled check box.** Select or clear to enable/disable this confidential field designation.
   - **Is form field name a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **Field Name.** Enter a literal string or PCRE-format regular expression that either represents a specific field name or that matches multiple fields with names that follow a pattern.
   - **Action URL.** Enter a literal URL or a regular expression that defines one or more URLs of the web page(s) on which the web form(s) that contains the confidential field are located.
   - **Comments.** Enter a comment. Optional.
5. Click **Create** or **OK**.
6. To remove a confidential field designation from the confidential fields list, select the confidential field listing you want to remove, then click Remove to remove it, and then click **OK** to confirm your choice.
7. When you have finished adding, modifying, and removing confidential field designations, click **Close**.

Examples

Following are some regular expressions that define form field names that you might find useful:

- `^passwd_ (Applies confidential-field status to all field names that begin with the “passwd_” string.)`
- `^((\[0-9a-zA-Z._-]*||\\x\[0-9A-Fa-f][0-9A-Fa-f])+-)?passwd_ (Applies confidential-field status to all field names that begin with the string passwd_, or that contain the string -passwd_ after another string that might contain non-ASCII special characters.)`

Following are some regular expressions that define specific URL types that you might find useful. Substitute your own web host(s) and domain(s) for those in the examples.

- If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you can use the following regular expression:

```
1 https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_.-]*/)*logon
     [.]pl\?
2 <!--NeedCopy-->
```

- If the web form appears on multiple web pages on the web host www.example-español.com, which contains the n-tilde (ñ) special character, you can use the following regular expression, which represents the n-tilde special character as an encoded UTF-8 string containing C3 B1, the hexadecimal code assigned to that character in the UTF-8 charset:

```
https?://www[.]example-espa\xC3\xB1ol[.]com/([0-9A-Za-z][0-9A-Za-z_.-]*/)* logon[.]pl\?
<!--NeedCopy-->
```

- If the web form containing query.pl appears on multiple web pages on different hosts within the example.com domain, you can use the following regular expression:

```
https?://([0-9A-Za-z][0-9A-Za-z_-.]*[.])*example[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*/)*logon[.]pl\?
<!--NeedCopy-->
```

- If the web form containing query.pl appears on multiple web pages on different hosts in different domains, you can use the following regular expression:

```
https?://([0-9A-Za-z][0-9A-Za-z_-.]*[.])*[0-9A-Za-z][0-9A-Za-z_-.]+[.][a-z]{
2,6 }
/([0-9A-Za-z][0-9A-Za-z_-.]*/)*logon[.]pl\?
<!--NeedCopy-->
```

- If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you can use the following regular expression:

```
https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*/)*logon[.]pl\?
<!--NeedCopy-->
```

Field types

September 14, 2021

A field type is a PCRE-format regular expression that defines a particular data format and minimum/-maximum data lengths for a form field in a web form. Field types are used in the Field Formats check.

The Web App Firewall comes with several default field types, which are:

- integer. A string of any length consisting of numbers only, without a decimal point, and with an optional preceding minus sign (-).

- alpha. A string of any length consisting of letters only.
- alphanum. A string of any length consisting of letters and/or numbers.
- nohtml. A string of any length consisting of characters, including punctuation and spaces, that does not contain HTML symbols or queries.
- any. Anything at all.

> **Important:**
>
> Assigning the any field type as the default field type, or to a field, allows active scripts, SQL commands, and other possibly dangerous content to be sent to your protected websites and applications in that form field. You must use the any type sparingly, if you use it at all.

You can also add your own field types to the Field Types list. For example, you might want to add a field type for a social security number, postal code, or phone number in your country. You might also want to add a field type for a customer identification number or store credit card number.

To add a field type to the Field Types list, you enter the field name as a literal string or PCRE-format regular expression.

To add a field type by using the command line interface

At the command prompt, type the following commands:

- `add appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

Example

The following example adds a field type named SSN that matches US Social Security numbers to the Field Types list, and sets its priority to 1.

```
add appfw fieldType SSN "^[1-9][0-9]{
 2,2 }
 -[0-9 }
 {
 2,2 }
 -[0-9]{
 4,4 }
 $" 1
save ns config
<!--NeedCopy-->
```

To modify a field type by using the command line interface

At the command prompt, type the following commands:

- `set appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

Example

The following example modifies the field type to add a comment.

```
set appfw fieldType SSN "^[1-9][0-9]{
 2,2 }
 -[0-9 }
 {
 2,2 }
 -[0-9]{
 4,4 }
 $" 1 -comment "US Social Security Number"
save ns config
<!--NeedCopy-->
```

To remove a field type by using the command line interface

At the command prompt, type the following commands:

- `>rm appfw fieldType <name>`
- `save ns config`

To configure a field type by using the GUI

1. Navigate to Security > Application Firewall.
2. In the details pane, under **Settings**, click **Manage Field Types**.
3. In the **Manage Field Types** dialog box, do one of the following:
   - To add a new field type to the list, click **Add**.
   - To change an existing field type, select the field type, and then click **Edit**.
     The **Configure Field Type** dialog box appears.

> **Note:**
>
> If you select an existing field type designation and then click **Add**, the dialog box displays the information for that field type. You can modify that information to create your new

> field type.

4. In the dialog box, fill out the elements. They are:
   - Name
   - Regular Expression
   - Priority
   - Comment
5. Click Create or OK.
6. To remove a field type from the Field Types list, select the field type listing you want to remove, then click **Remove** to remove it, and then click **OK** to confirm your choice.
7. When you have finished adding, modifying, and removing field types, click **Close**.

Examples

Following are some regular expressions for field types that you might find useful:

`^[1-9][0-9]{ 2,2 } -[0-9 } { 2,2 } -[0-9]{ 4,4 } $` U.S. Social Security numbers

`^\[A-C\]\[0-9\]{ 7,7 } $` California driver's license numbers

`^+[0-9]{ 1,3 } [0-9()-]{ 1,40 } $` International phone numbers with country codes

`^[0-9]{ 5,5 } -[0-9]{ 4,4 } $` U.S. ZIP code numbers

`^[0-9A-Za-z][0-9A-Za-z.+_-]{ 0,25 } @([0-9A-Za-z][0-9A-Za-z_-]*[.]){ 1,4 } [A-Za-z]{ 2,6 } $` Email addresses

XML content types

September 14, 2021

By default, the Web App Firewall treats files that follow certain naming conventions as XML. You can configure the Web App Firewall to examine web content for additional strings or patterns that indicate that those files are XML files. This can ensure that the Web App Firewall recognizes all XML content on your site, even if certain XML content does not follow normal XML naming conventions, ensuring that XML content is subjected to XML security checks.

To configure the XML content types, you add the appropriate patterns to the XML Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing XML content types patterns.

To add an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `add appfw XMLContentType <XMLContenttypevalue> [-isRegex ( REGEX | NOTREGEX )]`
- `save ns config`

Example

The following example adds the pattern .*/xml to the XML Content Types list and designates it as a regular expression.

```
1 add appfw XMLContentType ".*/xml" -isRegex REGEX
2 <!--NeedCopy-->
```

To remove an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `rm appfw XMLContentType <XMLContenttypevalue>`
- `save ns config`

To configure the XML content type list by using the GUI

1. Navigate to **Security** > **Web App Firewall**.
2. In the details pane, under **Settings**, click **Manage XML Content Types**.
3. In the **Manage XML Content Types** dialog box, do one of the following:
   - To add a new XML content type, click Add.
   - To modify an existing XML content type, select that type and then click Edit.
     The Configure Web App Firewall XML Content Type dialog appears. Note: If you select an existing XML content type pattern and then click Add, the dialog box displays the information for that XML content type pattern. You can modify that information to create your new XML content type pattern.
4. In the dialog box, fill out the elements. They are:
   - **IsRegex.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **XML Content Type** Enter a literal string or PCRE-format regular expression that matches the XML content type pattern that you want to add.
5. Click **Create**.
6. To remove an XML content type pattern from the list, select it, then click **Remove** to remove it, and then click **OK** to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click **Close**.

JSON content types

September 14, 2021

By default, the Web App Firewall treats files with the content type “application/json” as JSON files.The default setting enables the Web App Firewall to recognize JSON content in requests and responses, and to handle that content appropriately.

You can configure the Web App Firewall to examine web content for additional strings or patterns that indicate that those files are JSON files. This can ensure that the Web App Firewall recognizes all JSON content on your site, even if certain JSON content does not follow normal JSON naming conventions, ensuring that JSON content is subjected to JSON security checks.

To configure the JSON content types, you add the appropriate patterns to the JSON Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing JSON content types patterns.

To add a JSON content type pattern by using the command line interface

At the command prompt, type the following commands:

- `add appfw JSONContentType <JSONContenttypevalue> [-isRegex ( REGEX | NOTREGEX )]`
- `save ns config`

Example

The following example adds the pattern .*/json to the JSON Content Types list and designates it as a regular expression.

```
1 add appfw JSONContentType ".*/json" -isRegex REGEX
2 <!--NeedCopy-->
```

To configure the JSON content type list by using the GUI

1. Navigate to **Security** > **Application Firewall**.
2. In the details pane, under **Settings**, click **Manage JSON Content Types**.
3. In the Manage JSON Content Types dialog box, do one of the following:
   - To add a new JSON content type, click Add.
   - To modify an existing JSON content type, select that type and then click Edit.
     The Configure Web App Firewall JSON Content Type dialog appears.
     Note: If you select an existing JSON content type pattern and then click Add, the dialog

box displays the information for that JSON content type pattern. You can modify that information to create your new JSON content type pattern.

4. In the dialog box, fill out the elements. They are:
   - **IsRegex.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **JSON Content Type** Enter a literal string or PCRE-format regular expression that matches the JSON content type pattern that you want to add.
5. Click **Create** or **OK**.
6. To remove a JSON content type pattern from the list, select it, then click **Remove** to remove it, and then click **OK** to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click **Close**.

Statistics and reports

September 14, 2021

The information maintained in the logs and statistics, and displayed in the reports, provides important guidance for configuring and maintaining the Web App Firewall.

The Web App Firewall statistics

When you enable the statistics action for Web App Firewall signatures or security checks, the Web App Firewall maintains information about connections that match that signature or security check. You can view the accumulated statistics information on the
Monitoring tab by selecting one of the following choices in the Select Group list box:

- **Web App Firewall.** A summary of all statistics information gathered by your Web App Firewall appliance for all profiles.
- **Web App Firewall (per profile).** The same information, but displayed per-profile rather than summarized.

You can use this information to monitor how your Web App Firewall is operating and determine whether there is any abnormal activity or abnormal amounts of hits on a signature or security check. If you see such a pattern of abnormal activity, you can check the logs for that signature or security check to diagnose and take corrective action.

Relaxation hit statistical counter

Based on the relaxation that is applied on the violated traffic, you can also display statistical details such as number of times a violation is occurring on the appliance, number of relaxation rules applied at the time of violation, and its last applied timestamp. By performing this, the centralized learning

engine can automatically deletes unused or redundant relaxation bindings. For more information, see WAF Learn Engine topic.

The relaxation hit statistical counter is available only for the following security checks.

- Starturl
- Denyurl
- Cross-site scripting
- SQL Injection

To display statistics for relaxation rule hit counters by using the CLI

At the command prompt, type:

```
stat appfw profile p1
```

Example:

```
stat appfw profile p1 -fullvalues
```

Starturl Rules Statistics

Rule	hits	Rate	last hit time
87a4…51177	0	0	Thu … 1970
5b83…dc12a	0	0	Thu … 1970
12345	0	0	Thu … 1970

To display statistics for relaxation rule hit counters by using the GUI

Complete the following steps to view the relaxation rule hit counter statistics:

1. Navigate to **Security > Citrix Web App Firewall > Profiles**.
2. In the details pane, select a **Web App Firewall profile** and click **Statistics**.
3. The **Citrix Web App Firewall Statistics** page displays the statistics details.
4. You can select Tabular View or switch to Graphical View to display the data in a tabular or graphical format.

The Web App Firewall Reports

The Web App Firewall reports provide information about your Web App Firewall configuration and how it is handling traffic for your protected websites.

The PCI DSS report

The Payment Card Industry (PCI) Data Security Standard (DSS), version 1.2, consists of 12 security criteria that most credit card companies require businesses who accept online payments via credit and debit cards to meet. These criteria are designed to prevent identity theft, hacking, and other types of fraud. If an internet service provider does not meet the PCI DSS criteria, that ISP or merchant might lose authorization to accept credit card payments through the website.

ISPs and online merchants prove that they are in compliance with PCI DSS by having an audit conducted by a PCI DSS Qualified Security Assessor (QSA) Company. The PCI DSS report is designed to assist them both before and during the audit. Before the audit, it shows which Web App Firewall settings are relevant to PCI DSS, how they must be configured, and (most important) whether your current Web App Firewall configuration meets the standard. During the audit, the report can be used to demonstrate compliance with relevant PCI DSS criteria.

The PCI DSS report consists of a list of those criteria that are relevant to your Web App Firewall configuration. Under each criterion, it lists your current configuration options, indicates whether your current configuration complies with the PCI DSS criterion, and explains how to configure the Web App Firewall so that your protected websites are in compliance with the criterion.

The PCI DSS report is located under **System > Reports**. To generate the report as an Adobe PDF file, click Generate PCI DSS Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

> **Note:**
>
> To view this and other reports, you must have the Adobe Reader program installed on your computer.

The PCI DSS report consists of the following sections:

- **Description.** A description of the PCI DSS Compliance Summary report.
- **Firewall License and Feature Status.** Tells you whether the Web App Firewall is licensed and enabled on your Citrix ADC appliance.
- **Executive Summary.** A table that lists the PCI DSS criteria and tells you which of those criteria are relevant to the Web App Firewall.
- **Detailed PCI DSS Criteria Information.** For each PCI DSS criterion that is relevant to your Web App Firewall configuration, the PCI DSS report provides a section that contains information about whether your configuration is in compliance and, if it is not, how to bring it into compliance.
- **Configuration.** Data for individual profiles, which you access either by clicking Web App Firewall Configuration at the top of the report, or directly from the Reports pane. The Web App Firewall Configuration report is the same as the PCI DSS report, with the PCI DSS-specific summary

omitted.

The Web App Firewall configuration report

The Web App Firewall Configuration report is located under **System > Reports**. To display it, click **Generate Web App Firewall Configuration Report**. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

The Web App Firewall Configuration report starts with a Summary page, which consists of the following sections:

- **Web App Firewall Policies.** A table that lists your current Web App Firewall policies, showing the policy name, the content of the policy, the action (or profile) it is associated with, and global binding information.
- **Web App Firewall Profiles.** A table that lists your current Web App Firewall profiles and indicates which policy each profile is associated with. If a profile is not associated with a policy, the table displays INACTIVE in that location.

To download all report pages for all policies, at the top of the Profiles Summary page click **Download All Profiles**. You display the report page for each individual profile by selecting that profile in the table at the bottom of the screen. The Profile page for an individual profile shows whether each check action is enabled or disabled for each check, and the other configuration settings for the check.

To download a PDF file containing the PCI DSS report page for the current profile, click **Download Current Profile** at the top of the page. To return to the Profiles Summary page, click **Web App Firewall Profiles**. To go back to the main page, click **Home**. You can refresh the PCI DSS report at any time by clicking **Refresh** in the upper right corner of the browser.

Web App Firewall logs

September 14, 2021

The Web App Firewall generated log messages can be quite useful for keeping track of the configurational changes, Web App Firewall policy invocations, and security check violations.

When the log action is enabled for security checks or signatures, the resulting log messages provide information about the requests and responses that the Web App Firewall has observed while protecting your websites and applications. The most important information is the action taken by the Web App Firewall when a signature or a security check violation was observed. For some security checks, the log message can provide additional useful information, such as the location and the detected pattern that triggered the violation. You can deploy security checks in non-block mode and monitor the logs to determine whether the transactions that are triggering security violations are valid transactions

(false positives). If they are, you can either remove, or reconfigure the signature or security checks, deploy relaxations, or take other appropriate measures to mitigate the false positives before you enable blocking for that signature or security check. An excessive increase in the number of violation messages in logs can indicate a surge in malicious requests. This can alert you that your application might be under attack to exploit a specific vulnerability that is detected and thwarted by Web App Firewall protections.

> **Note:**
>
> Citrix Web App Firewall logging must be used only with external SYSLOG servers.

Citrix ADC (Native) format logs

The Web App Firewall uses the Citrix ADC format logs (also called native format logs) by default. These logs have the same format as those generated by other Citrix ADC features. Each log contains the following fields:

- Timestamp. Date and time when the connection occurred.
- Severity. Severity level of the log.
- Module. Citrix ADC module that generated the log entry.
- Event Type. Type of event, such as signature violation or security check violation.
- Event ID. ID assigned to the event.
- Client IP. IP address of the user whose connection was logged.
- Transaction ID. ID assigned to the transaction that caused the log.
- Session ID. ID assigned to the user session that caused the log.
- Message. The log message. Contains information identifying the signature or security check that triggered the log entry.

You can search for any of these fields, or any combination of information from different fields. Your selection is limited only by the capabilities of the tools you use to view the logs. You can observe the Web App Firewall log messages in the GUI by accessing the Citrix ADC syslog viewer, or you can manually connect to the Citrix ADC appliance and access logs from the command line interface, or you can drop into shell and tail the logs directly from the /var/log/folder.

Example of a Native Format Log message

```
1 Jun 22 19:14:37 <local0.info> 10.217.31.98 06/22/2015:19:14:37 GMT ns
     0-PPE-1 :
2 default APPFW APPFW_cross-site scripting 60 0 :  10.217.253.62 616-PPE1
      y/3upt2K8ySWWId3Kavbxyni7Rw0000
3 pr_ffc http://aaron.stratum8.net/FFC/login.php?login_name=abc&passwd=

7 %3D&as_fid=feeec8758b41740eedeeb6b35b85dfd3d5def30c Cross-site script
     check failed for
8 field text_area="Bad tag: script" <blocked>
9 <!--NeedCopy-->
```

Common Event Format (CEF) Logs

The Web App Firewall also supports CEF logs. CEF is an open log management standard that improves the interoperability of security-related information from different security and network devices and applications. CEF enables customers to use a common event log format so that data can easily be collected and aggregated for analysis by an enterprise management system. The log message is broken into different fields so that you can easily parse the message and write scripts to identify important information.

Analyzing the CEF Log Message

In addition to date, timestamp, client IP, log format, appliance, company, build version, module, and security check information, Web App Firewall CEF Log messages include the following details:

- src – source IP address
- spt – source port number
- request – request URL
- act – action (e.g. blocked, transformed)
- msg – message (Message regarding the observed security check violation)
- cn1 – event ID
- cn2 – HTTP Transaction ID
- cs1 – profile name
- cs2 – PPE ID (e.g. PPE1)
- cs3 - Session ID
- cs4 – Severity (e.g. INFO, ALERT)
- cs5 – event year
- cs6 - Signature Violation Category
- method – Method (e.g. GET/POST)

For example, consider the following CEF format log message, which was generated when a Start URL violation was triggered:

```
1 Jun 12 23:37:17 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11
     .0
2 |APPFW|APPFW_STARTURL|6|src=10.217.253.62 spt=47606 method=GET
```

```
request=http://aaron.stratum8.net/FFC/login.html msg=Disallow Illegal
    URL. cn1=1340
cn2=653 cs1=pr_ffc cs2=PPE1 cs3=EsdGd3VD0OaaURLcZnj05Y6DOmE0002 cs4=
    ALERT cs5=2015
act=blocked
<!--NeedCopy-->
```

The above message can be broken down into different components. Refer to the CEP log components table.

Example of a request check violation in CEF log format: request is not blocked

```

Logging geolocation in the Web App Firewall violation messages

Geolocation, which identifies the geographic location from which requests originate, can help you configure the Web App Firewall for the optimal level of security. To bypass security implementations such as rate limiting, which rely on the IP addresses of the clients, malware or rogue computers can keep changing the source IP address in requests. Identifying the specific region from where requests are coming can help determine whether the requests are from a valid user or a device attempting to launch cyberattacks. For example, if an excessively large number of requests are received from a specific area, it is easy to determine whether they are being sent by users or a rogue machine. Geolocation analysis of the received traffic can be very useful in deflecting attacks such as denial of service (DoS) attacks.

The Web App Firewall offers you the convenience of using the built-in Citrix ADC database for identifying the locations corresponding to the IP addresses from which malicious requests are originating. You can then enforce a higher level of security for requests from those locations. Citrix default syntax (PI) expressions give you the flexibility to configure location based policies that can be used in conjunction with the built-in location database to customize firewall protection, bolstering your defense against coordinated attacks launched from rogue clients in a specific region.

You can use the Citrix ADC built-in database, or you can use any other database. If the database does not have any location information for the particular client IP address, the CEF log shows geolocation as an Unknown geolocation.

Note: Geolocation logging uses the Common Event Format (CEF). By default, CEF logging and GeoLocationLogging are OFF. You must explicitly enable both parameters.

Example of a CEF log message showing geolocation information

```
1 June 8 00:21:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11

```

Using the command line to configure the log action and other log parameters

To configure the log action for a security checks of a profile by using the command line

At the command prompt, type one of the following commands:

- `set appfw profile <name> SecurityCheckAction ([log] | [none])`
- `unset appfw profile <name> SecurityCheckAction`

Examples

```
set appfw profile pr_ffc StartURLAction log
```

```
unset appfw profile pr_ffc StartURLAction
```

To configure CEF logging by using the command line

The CEF logging is disabled by default. At the command prompt, type one of the following commands to change or display the current setting:

- `set appfw settings CEFLogging on`
- `unset appfw settings CEFLogging`
- `sh appfw settings | grep CEFLogging`

To configure the logging of the credit card numbers by using the command line

At the command prompt, type one of the following commands:

- `set appfw profile <name> -doSecureCreditCardLogging ([ON] | [OFF])`
- `unset appfw profile <name> -doSecureCreditCardLogging`

To configure Geolocation logging by using the command line

1. Use the set command to enable GeoLocationLogging. You can enable the CEF logging at the same time. Use the unset command to disable geolocation logging. The show command shows the current settings of all the Web App Firewall parameters, unless you include the grep command to show the setting for a specific parameter.

- `set appfw settings GeoLocationLogging ON [CEFLogging ON]`
- `unset appfw settings GeoLocationLogging`
- `sh appfw settings | grep GeoLocationLogging`

2. Specify the database

```
add locationfile /var/netscaler/inbuilt_db/Citrix_netscaler_InBuilt_GeoIP_DB
.csv
```

or

```
add locationfile <path to database file>
```

Customizing Web App Firewall Logs

Default format (PI) expressions give you the flexibility to customize the information included in the logs. You have the option to include the specific data that you want to capture in the Web App Firewall generated log messages. For example, if you are using AAA-TM authentication along with the Web App Firewall security checks, and would like to know the accessed URL that triggered the security check violation, the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request, you can use the following commands to specify customized log messages that include all the data:

```
> sh version
NetScaler NS12.1: Build 50.0013.nc, Date: Aug 28 2018, 10:51:08   (64-
   bit)
 Done
<!--NeedCopy-->
```

```
> add audit messageaction custom1 ALERT 'HTTP.REQ.URL + " " + HTTP.REQ.
   USER.NAME + " " + CLIENT.IP.SRC + ":" + CLIENT.TCP.SRCPORT'
Warning: HTTP.REQ.USER has been deprecated. Use AAA.USER instead.
 Done
<!--NeedCopy-->
```

```
> add appfw profile test_profile
 Done
<!--NeedCopy-->
```

```
> add appfw policy appfw_pol true test_profile -logAction custom1
 Done
<!--NeedCopy-->
```

Configuring Syslog policy to segregate Web App Firewall logs

The Web App Firewall offers you an option to isolate and redirect the Web App Firewall security log messages to a different log file. This might be desirable if the Web App Firewall is generating a large number of logs, making it difficult to view other Citrix ADC log messages. You can also use this option when you are interested only in viewing the Web App Firewall log messages and do not want to see the other log messages.

To redirect the Web App Firewall logs to a different log file, configure a syslog action to send the Web App Firewall logs to a different log facility. You can use this action when configuring the syslog policy, and bind it globally for use by Web App Firewall.

Example:

1. Switch to the shell and use an editor such as vi to edit the /etc/syslog.conf file. Add a new entry to use local2.* to send logs to a separate file as shown in the following example:

   ```
   local2.\* /var/log/ns.log.appfw
   ```

2. Restart the syslog process. You can use the grep command to identify the syslog process ID (PID), as shown in the following example:

   ```
   root@ns\## **ps -A | grep syslog**

   1063 ?? Ss 0:03.00 /usr/sbin/syslogd -b 127.0.0.1 -n -v -v -8 -C

   root@ns## **kill -HUP** 1063
   ```

3. From the command line interface, configure the syslog action and policy. Bind it as a global Web App Firewall policy.

```
> add audit syslogAction sysact 1.1.1.1 -logLevel ALL -logFacility LOCAL2

> add audit syslogPolicy syspol1 ns_true sysact1

> bind appfw global syspol1 100
```

1. All Web App Firewall security check violations will now be redirected to the /var/log/ns.log.appfw file. You can tail this file to view the Web App Firewall violations that are getting triggered during the processing of the ongoing traffic.

   ```
   root@ns## tail -f ns.log.appfw
   ```

Warning: If you have configured the syslog policy to redirect the logs to a different log facility, the Web App Firewall log messages no longer appear in the /var/log/ns.log file.

Viewing the Web App Firewall Logs

You can view the logs by using the syslog viewer, or by logging onto the Citrix ADC appliance, opening a UNIX shell, and using the UNIX text editor of your choice.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Web App Firewall security check violations:

- `Shell`
- `tail -f /var/log/ns.log`

You can use the vi editor, or any Unix text editor or text search tool, to view and filter the logs for specific entries. For example, you can use grep command to access the log messages pertaining to the Credit Card violations:

- `tail -f /var/log/ns.log | grep SAFECOMMERCE`

To access the log messages by using the GUI

The Citrix GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- To view log messages for a specific security check of a profile, navigate to **Web App Firewall** > **Profiles**, select the target profile, and click Security Checks. Highlight the row for the target security check and click Logs. When you access the logs directly from the selected security check of the profile, it filters out the log messages and displays only the logs pertaining to the violations for the selected security check. Syslog viewer can display Web App Firewall logs in the Native format as well as the CEF format. However, in order for the syslog viewer to filter out the target profile specific log messages, the logs must be in the CEF log format when accessed from the profile.
- You can also access the Syslog Viewer by navigating to **Citrix ADC** > **System** > **Auditing**. In the Audit Messages section, click Syslog messages link to display the Syslog Viewer, which displays all log messages, including all Web App Firewall security check violation logs for all profiles. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Web App Firewall** > **policies** > **Auditing**. In the Audit Messages section, click Syslog messages link to display the Syslog Viewer, which displays all log messages, including all security check violation logs for all profiles.

The HTML based Syslog Viewer provides the following filter options for selecting only the log messages that are of interest to you:

- **File**—The current /var/log/ns.log file is selected by default, and the corresponding messages appear in the Syslog Viewer. A list of other log files in the /var/log directory are available in a compressed .gz format. To download and un-compress an archived log file, just select the log file from the dropdown option. The log messages pertaining to the selected file are then displayed in the syslog viewer. To refresh the display, click the Refresh icon (a circle of two arrows).

- **Module list box**—You can select the Citrix ADC module whose logs you want to view. You can set it to APPFW for Web App Firewall logs.
- **Event Type list box**—This box contains a set of check boxes for selecting the type of event you are interested in. For example, to view the log messages pertaining to the signature violations, you can select the **APPFW_SIGNATURE_MATCH** check box. Similarly, you can select a check box to enable the specific security check that is of interest to you. You can select multiple options.
- **Severity**—You can select a specific severity level to show just the logs for that severity level. Leave all the check boxes blank if you want to see all logs.

  To access the Web App Firewall security check violation log messages for a specific security check, filter by selecting **APPFW** in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the **APPFW_FIELDFORMAT** check box and click the Apply button, only log messages pertaining to the Field Formats security check violations appear in the Syslog Viewer. Similarly, if you select the **APPFW_SQL** and **APPFW_STARTURL** check boxes and click the **Apply** button, only log messages pertaining to these two security check violations will appear in the syslog viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **EventType**, **EventID**, **ClientIP**, **TransactionID**, and so on appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

Click to Deploy: This functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy relaxation rules based on the log messages for the Web App Firewall security check violations. The log messages must be in CEF log format for this operation. If the relaxation rule can be deployed for a log message, a check box appears at the right edge of the Syslog Viewer box in the row. Select the check box, and then select an option from the Action list to deploy the relaxation rule.
Edit & Deploy,
Deploy, and
Deploy All are available as Action options. For example, you can select an individual log message to edit and deploy. You can also select the check boxes for multiple log messages from one or more security checks and use the Deploy or Deploy All option. Click to Deploy functionality is currently supported for the following security checks:

- StartURL
- URL Buffer overflow
- SQL Injection
- cross-site scripting
- Field consistency
- Cookie consistency

To use Click to Deploy functionality in the GUI

1. In the **Syslog Viewer**, select **APPFW** in the **Module** options.
2. Select the security check for which to filter corresponding log messages.
3. Enable the check box to select the rule.
4. Use the **Action** drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

> **Note:**
>
> SQL Injection and cross-site scripting rules that are deployed by using Click **Deploy** option do not include the fine grain relaxation recommendations.

Highlights

- **CEF Log Format support**—The CEF log format option provides a convenient option to monitor, parse, and analyze the Web App Firewall log messages to identify attacks, fine tune configured settings to decrease false positives, and gather statistics.
- **Click to Deploy**—The Syslog viewer provides an option to filter, evaluate, and deploy relaxation rules for single or multiple security check violations from one convenient location.
- **Option to customize log message**—You can use advanced PI expressions to customize log messages and include the data you want to see in the logs.
- **Segregate Web App Firewall specific logs**—You have an option to filter and redirect application-firewall specific logs to a separate log file.
- **Remote Logging**—You can redirect the log messages to a remote syslog server.
- **Geolocation Logging**—You can configure the Web App Firewall to include the geolocation of the area from where the request is received. A built-in geolocation database is available, but you have the option to use an external geolocation database. The Citrix ADC appliance supports both IPv4 and IPv6 static geolocation databases.
- **Information rich log message**—Following are some examples of the type of information that can be included in the logs, depending on the configuration:
  - An Web App Firewall policy was triggered.
  - A security check violation was triggered.
  - A request was considered to be malformed.
  - A request or the response was blocked or not blocked.
  - Request data (such as SQL or cross-site scripting special characters) or response data (such as Credit card numbers or safe object strings) was transformed.
  - The number of credit cards in the response exceeded the configured limit.
  - The credit card number and type.
  - The log strings configured in the signature rules, and the signature ID.
  - Geolocation information about the source of the request.
  - Masked (X'd out) user input for protected confidential fields.

Mask sensitive data using regex pattern

The REGEX_REPLACE advanced policy (PI) function in a log expression (bound to a Web Application Firewall (WAF) profile) enables you to mask sensitive data in WAF logs. You can use the option to mask data using a regex pattern and provide a character or a string pattern to mask the data. Also, you can configure the PI function to replace the first occurrence or all occurrences of the regex pattern.

By default the Citrix GUI interface provides the following mask:

- SSN
- Credit Card
- Password
- Username

Mask sensitive data in Web Application Firewall logs

You can mask sensitive data in WAF logs by configuring the REGEX_REPLACE advanced policy expression in the log expression bound to a WAF profile.
To mask sensitive data, you must complete the following steps:

1. Add a Web Application Firewall profile
2. Bind a log expression to the WAF profile

Add a Web Application Firewall profile

At the command prompt, type:

```
add appfw profile <name>
```

Example:

```
Add appfw profile testprofile1
```

Bind a log expression with the Web Application Firewall profile

At the command prompt, type:

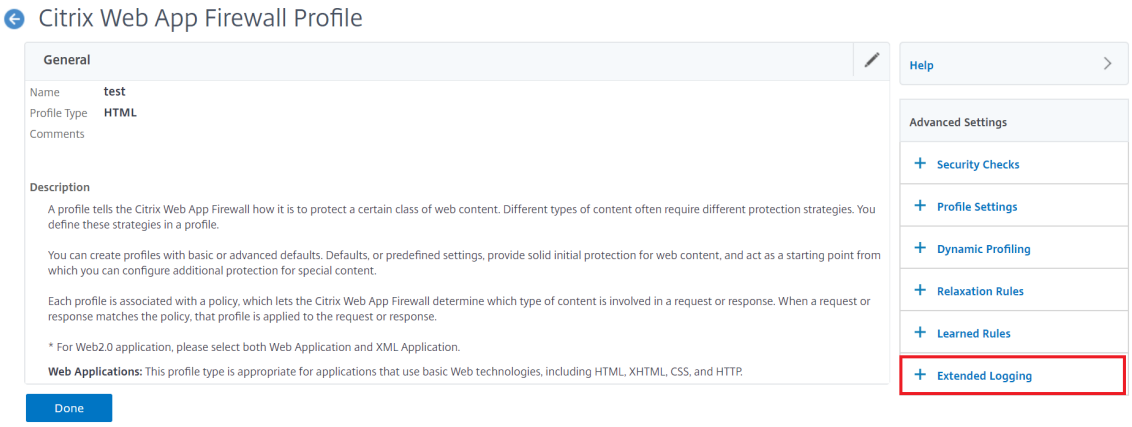
```
bind appfw profile <name> -logExpression <string> <expression> -comment <
string>
```

Example:

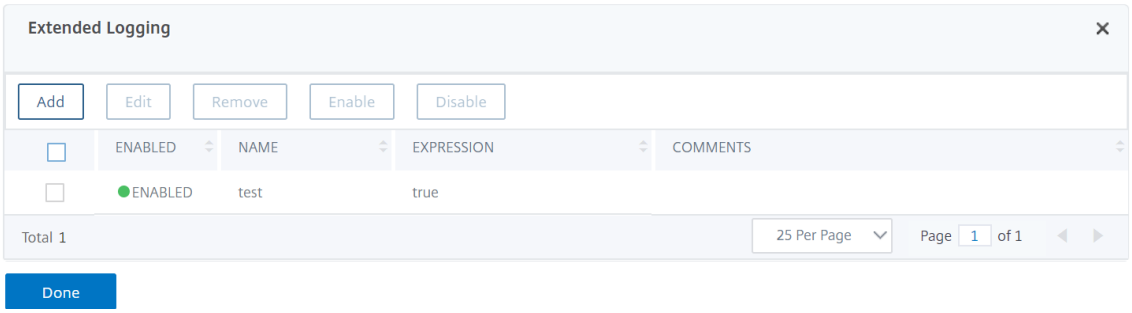
```
bind appfw profile testProfile -logExpression "MaskSSN""HTTP.REQ.BODY
(10000).REGEX_REPLACE(re!\b\d{ 3 } -\d{ 2 } -\d{ 4 } \b!, “xxx” , ALL)"-
comment "SSN Masked"
```

Mask sensitive data in Web Application Firewall logs by using Citrix ADC GUI

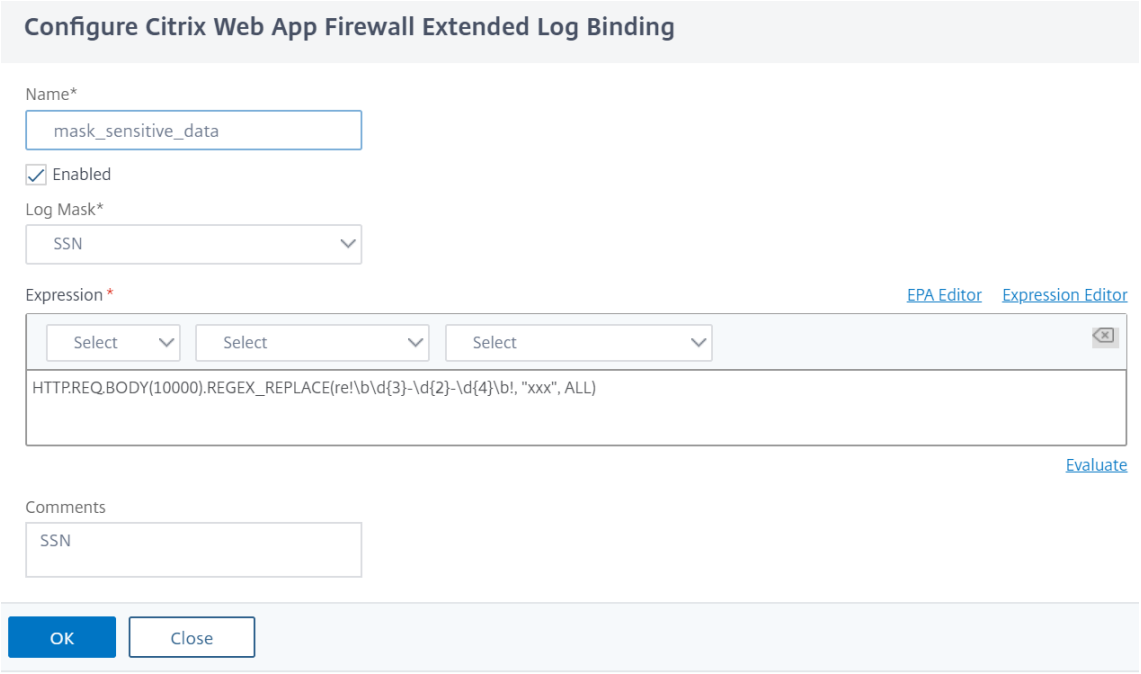
1. On the navigation pane, expand **Security** > **Citrix Web App Firewall** > **Profiles**.
2. On the **Profiles** page, click **Edit**.
3. On the **Citrix Web App Firewall Profile** page, navigate to **Advanced Settings** section and click **Extended Logging**.



4. In the **Extended Logging** section, click **Add**.



5. On the **Create Citrix Web App Firewall Extended Log Binding** page, set the following parameters:
   a) Name. Name of the log expression.
   b) Enabled. Select this option to mask sensitive data.
   c) Log mask. Select the data to be masked.
   d) Expression. Enter the advanced policy expression that enables you to mask sensitive data in WAF logs
   e) Comments. Brief description about the masking sensitive data.
6. Click **Create** and **Close**.



Appendices

September 14, 2021

The following supplemental material provides additional detail about complex or peripheral Web App Firewall tasks.

PCRE character encoding format

September 14, 2021

The **Citrix ADC operating system supports direct** entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your Web App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

Many character types require encoding using a PCRE regular expression if you include them in your Web App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not

included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.

- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

  ASCII control characters. Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters must never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The Citrix ADC appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, "English US," the Web App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.
- **Chinese Traditional (Big5).** The Web App Firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.
- **Chinese Simplified (GB2312).** The Web App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.
- **Japanese (SJIS).** The Web App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.
- **Japanese (EUC-JP).** The Web App Firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.
- **Korean (EUC-KR).** The Web App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.
- **Turkish (ISO-8859-9).** The Web App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.
- **Unicode (UTF-8).** The Web App Firewall supports certain more characters in the UTF-8 character set, including those used in modern Russian.

When configuring the Web App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which is assigned single, two-digit codes in that

character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the Web App Firewall configuration is "\xNN" for ASCII characters; "\xNN\xNN" for non-ASCII characters used in English, Russian, and Turkish; and "\xNN\xNN\xNN" for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in a Web App Firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

> **Note:**
>
> Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character's UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the Web App Firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

  Actual URL: `http://www.josénuñez.com`
  Encoded URL: `^http://www\[.\]jos\\xC3\\xA9nu\\xC3\\xB1ez\[.\]com$`

- Another URL containing extended ASCII characters.

  Actual URL: `http://www.example.de/trömso.html`
  Encoded URL: `^http://www[.]example[.\]de/tr\xC3\xB6mso[.]html$`

  A form field name containing extended ASCII characters.

  Actual Name: nome_do_usuário
  Encoded Name: ^nome_do_usu\xC3\xA1rio$

- A safe object expression containing extended ASCII characters.

  Unencoded Expression [A-Z]{3,6}¥[1-9][0-9]{6,6}
  Encoded Expression: [A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}

You can find several tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful website that contains this information is available in the following table.

`http://www.utf8-chartable.de/unicode-utf8-table.pl`

For the characters in the table on this website to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of webpages are correct.

Whitehat WASC signature types for WAF use

September 14, 2021

The Citrix Web App Firewall accepts and generates blocking rules for all vulnerability types that the Whitehat scanners generate. However, certain vulnerabilities are most applicable to a web App Firewall. Following are lists of those vulnerabilities, categorized by whether they are addressed by WASC 1.0, WASC 2.0, or best practices signature types.

WASC 1.0 signature types

- HTTP Request Smuggling
- HTTP Response Splitting
- HTTP Response Smuggling
- Null Byte Injection
- Remote File Inclusion
- URL Redirector Abuse

WASC 2.0 signature types

- Abuse of Functionality
- Brute Force
- Content Spoofing
- Denial of Service
- Directory Indexing
- Information Leakage
- Insufficient Anti-automation
- Insufficient Authentication
- Insufficient Authorizatio
- Insufficient Session Expiration
- LDAP Injection
- Session Fixation

Best Practices

- Autocomplete Attribute
- Insufficient Cookie Access Control
- Insufficient Password Strength
- Invalid HTTP Method Usage
- Non-HttpOnly Session Cookie
- Persistent Session Cookie
- Personally Identifiable Information
- Secured Cachable HTTP Messages
- Unsecured Session Cookie

Streaming support for request processing

September 14, 2021

Citrix Web App Firewall supports request side streaming to provide a significant performance boost. Instead of buffering a request, the appliance examines the incoming traffic for security violation such as SQL, cross-site scripting, field consistency, field formats. When the appliance completes processing data for a field, the request is forwarded to the back-end server while the appliance continues to evaluate other fields. This data processing significantly improves the processing time in handling forms have many fields.

> **Note:**
>
> Citrix Web App Firewall supports a maximum post size of 20 MB without streaming. For better resource utilization, Citrix recommends you to enable streaming only for payloads greater than 20 MB. Also, the back-end server must accept the chunked requests if streaming is enabled.

Although the streaming process is transparent to the users, minor configuration adjustments are required due to the following changes:

RegEx Pattern Match: RegEx pattern match is now restricted to 4K for contiguous character string match.

Field Name Match: The Web App Firewall learning engine can only distinguish the first 128 bytes of the name. If a form has multiple fields with names that have an identical string match for the first 128 bytes, the learning engine does not distinguish them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Removal of white spaces, percent decoding, Unicode decoding, and charset conversion are done during canonicalization to provide security check inspection. The 128 byte limit is applicable for the canonicalized representation of the field name in UTF-8 character format. The ASCII characters are 1

byte in length but the UTF-8 representation of the characters in some international languages might range from 1 byte to 4 bytes. If each character in a name takes 4 bytes for converting to UTF-8 format, only first 32 characters in the name might be distinguished by the learned rule.

Field Consistency Check: When you enable Field Consistency, all the forms in the session are stored based on the "as_fid" tag inserted by the Web App Firewall without considering the "action_url."

- **Mandatory Form tagging for Form Field consistency:** When the field consistency check is enabled, the form tag must be enabled also. The Field Consistency protection might not work if form tagging is turned off.
- **Sessionless Form Field Consistency:** The Web App Firewall no longer carries out the "GET" to "POST" conversion of forms when the sessionless field consistency parameter is enabled. The form tag is required for sessionless field consistency also.
- **Tampering of as_fid:** If a form is submitted after tampering as_fid, it triggers field consistency violation even if no field was tampered. In non-streaming requests, this was allowed because the forms can be validated using the "action_url" stored in the session.

Signatures: The signatures now have the following specifications:

- **Location:** It is now a mandatory requirement that location must be specified for each pattern. All patterns in the rule **MUST** have a `<Location>` tag.
- **Fast Match:** All signature rules must have a fast match pattern. If there is no fast match pattern, an attempt is made to select one if possible. Fast match is a literal string but PCRE can be used for fast match if they contain a usable literal string.
- **Deprecated Locations:** Following locations are no longer supported in signature rules.
  - HTTP_ANY
  - HTTP_RAW_COOKIE
  - HTTP_RAW_HEADER
  - HTTP_RAW_RESP_HEADER
  - HTTP_RAW_SET_COOKIE

cross-site scripting/SQL Transform: Raw data is used for transformation because the SQL special characters such as single quote(‘), backslash (), and semicolon (;)), and cross-site scripting tags are same and do not require canonicalization of data. Representation of special characters such as HTML entity encoding, percent encoding, or ASCII are evaluated for transform operation.

The Web App Firewall no longer inspects both the attribute name and value for the cross-site scripting transform operation. Now only cross-site scripting attribute names are transformed when streaming is engaged.

Processing cross-site scripting Tags: As part of the streaming changes in NetScaler 10.5.e build and later, the processing of the cross-site scripting tags has changed. In earlier releases, the presence of either open bracket (<), or close bracket (>), or both open and close brackets (<>) was flagged as

cross-site scripting Violation. The behavior has changed in 10.5.e build onwards. Presence of only the open bracket character (<), or only the close bracket character (>) is no longer considered as an attack. This is when an open bracket character (<) is followed by a close bracket character (>), the Cross-site scripting attack gets flagged. Both characters must be present in the right order (< followed by >) to trigger the Cross-site scripting violation.

> **Note:**
>
> **Change in SQL violation log Message:** As part of the streaming changes in 10.5.e build onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input are separated by many bytes. The appliance has a track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message includes SQL keyword, SQL special character, or both the SQL keyword and the SQL special character. The rest of the input is no longer included in the log message, as shown in the following example:
>
> **Example:**
>
> In 10.5, when the Web App Firewall detects the SQL violation, the entire input string might be included in the following log message:
>
> SQL Keyword check failed for field **text=”select a name from testbed1\;\(\;\)”.*<blocked>**
>
> In 11.0, we log only the field name, keyword, and special character (if applicable) in the following log message.
>
> SQL Keyword check failed for field `text="select(;)"<blocked>`
>
> This change is applicable to requests that contain **application/x-www-form-urlencoded**, or **multipart/form-data**, or **text/x-gwt-rpc** content-types. Log messages generated during processing of **JSON** or **XML** payloads are not affected in this change.

RAW POST Body: The security check inspections are always done on RAW POST body.

Form ID: The Web App Firewall inserted “as_fid” tag, which is a computed hash of the form is longer unique for the user session. It is an identical value for a specific form irrespective of the user or the session.

Charset: If a request does not have a charset, the default charset specified in the application profile is used when processing the request.

Counters:

Counters with prefix “se” and “appfwreq” are added to track the streaming engine and streaming engine request counters.

```
nsconsmg -d statswt0 -g se_err_
```

```
nsconsmg -d statswt0 -g se_tot_
nsconsmg -d statswt0 -g se_cur_
nsconsmg -d statswt0 -g appfwreq_err_
nsconsmg -d statswt0 -g appfwreq_tot_
nsconsmg -d statswt0 -g appfwreq_cur_
```

`_err counters`: indicate the rare event which must have succeeded but failed due to either memory allocation problem or some other resource crunch.

`_tot counters`: ever increasing counters.

`_cur counters`: counters indicating current values that keep changing based on usage from current transactions.

Tips:

- The Web App Firewall security checks must work the same as before.
- There is no set ordering for the processing of the security checks.
- The response side processing is not affected and remains unchanged.
- Streaming is not engaged if clientless VPN is used.

> **Important:**
>
> **Calculating the Cookie length:** In release 10.5.e in addition to 11.0 release (in builds before 65.x), Web App Firewall way of processing the cookie header was changed. The appliance evaluated the cookie individually, and if the length of a cookie in the cookie header exceeded the configured length, the Buffer Overflow violation was triggered. As a result, requests blocked in NetScaler 10.5 version or earlier releases might be allowed. The length of the entire cookie header is not calculated for determining the cookie length. In some situations, the total cookie size might be larger than the accepted value, and the server might respond with “400 Bad Request”.
>
> **Note:**
> The change has been reverted. The behavior in NetScaler version 10.5.e to version 59.13xx.e and its subsequent builds is similar to the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.

Trace HTML requests with security logs

September 14, 2021

> **Note:**
>
> This feature is available in Citrix ADC release 10.5.e.

Troubleshooting requires analysis of data received in the client request and can be challenging. Especially if there is heavy traffic flowing through the appliance. Diagnosing issues might affect the functionality or application security might require a quick response.

The Citrix ADC isolates traffic for a Web App Firewall profile and collects `nstrace` for the HTML requests. The `nstrace` collected in appfw mode includes request details with log messages. You can use “Follow TCP stream” in the trace to view the details of the individual transaction including headers, payload, and the corresponding log message in the same screen.

This gives you a comprehensive overview regarding your traffic. Having a detailed view of the request, payload, and associated log records can be useful to analyze security check violation. You can easily identify the pattern that is triggering the violation. If the pattern must be allowed, you can take a decision to modify the configuration or add a relaxation rule.

Benefits

1. **Isolate traffic for specific profile**: This enhancement is useful when you isolate traffic for only one profile or specific transactions of a profile for troubleshooting. You no longer have to skim through the entire data collected in the trace or need special filters to isolate requests interest you which can be tedious with heavy traffic. You can view the data that you prefer.
2. **Collect data for specific requests**: The trace can be collected for a specified duration. You can collect trace for only a couple of requests to isolate, analyze, and debug specific transactions if needed.
3. **Identify resets or aborts**: Unexpected closing of connections is not easily visible. The trace collected in –appfw mode captures a reset or an abort, triggered by the Web App Firewall. This allows a quicker isolation of an issue when you do not see a security check violation message. Malformed requests or other non-RFC compliant requests terminated by Web App Firewall will now be easier to identify.
4. **View decrypted SSL traffic**: HTTPS traffic is captured in plain text to allow for easier troubleshooting.
5. **Provides comprehensive view**: Allows you to look at the entire request at the packet level, check the payload, look at the logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n and so forth), they are easy to discover in the trace.
6. **Modify configuration**: The debugging can provide useful information to decide if the observed behavior is the correct behavior or the configuration must be modified.

7. **Expedite response time**: Faster debugging on target traffic can improve the response time to provide explanations or root cause analysis by the Citrix engineering and support team.

For more information, see Manual Configuration by using the command line interface topic.

To configure debug tracing for a profile by using the command line interface

Step 1. Enable ns trace.

You can use the show command to verify the configured setting.

- `set appfw profile <profile> -trace ON`

Step 2. Collect trace. You can continue to use all the options which are applicable for the `nstrace` command.

- `start nstrace -mode APPFW`

Step 3. Stop trace.

- `stop nstrace`

Location of the trace: The `nstrace` is stored in a time-stamped folder which is created in the /var/nstrace directory and can be viewed using `wireshark`. You can tail the `/var/log/ns.log` to see the log messages providing details regarding the location of the new trace.

Tips:

- When the appfw mode option is used, the `nstrace` will only collect the data for one or more profiles for which the "nstrace" was enabled.
- Enabling the trace on the profile will not automatically start collecting the traces until you explicitly run the "start ns trace" command to collect the trace.
- Although enabling trace on a profile may not have any adverse effect on the performance of the Web App Firewall but you may want to enable this feature only for the duration for which you want to collect the data. It is recommended that you turn the –trace flag off after you have collected the trace. The option prevents the risk of inadvertently getting data from profiles for which you had enabled this flag in the past.
- The block or log action must be enabled for the security check for the transaction record to be included in the `nstrace`.
- Resets and aborts are logged independently of security checks actions when trace is "On" for the profiles.
- The feature is only applicable for troubleshooting the requests received from the client. The traces in –appfw mode do not include the responses received from the server.
- You can continue to use all the options which are applicable for the `nstrace` command. For example,

```
start nstrace -tcpdump enabled -size 0 -mode appFW
```

- If a request triggers multiple violations, the `nstrace` for that record includes all the corresponding log messages.
- CEF log message format is supported for this functionality.
- Signature violations triggering block or log action for request side checks will also be included in the trace.
- Only HTML (non-XML) requests are collected in the trace.

Web App Firewall support for cluster configurations

September 14, 2021

> **Note:**
>
> Citrix Web App Firewall for striped and partially striped configurations was introduced in Citrix ADC 11.0 version.

A cluster is a group of Citrix ADC appliances configured and managed as a single system. Each appliance in the cluster is called a node. Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations. The Web App Firewall is fully supported in all configurations.

The two main advantages of striped and partially striped virtual server support in cluster configurations are the following:

1. Session failover support—striped and partially striped virtual server configurations support session failover. The advanced Web App Firewall security features, such as Start URL closure and the Form Field Consistency check, maintain, and use sessions during transaction processing. In a high availability configuration, or in a spotted cluster configuration, when the node that is processing the Web App Firewall traffic fails, all the session information is lost and the user has to re-establish the session. In striped virtual server configurations, user sessions are replicated across multiple nodes. If a node goes down, a node running the replica becomes the owner. Session information is maintained without any visible impact to the user.
2. Scalability—Any node in the cluster can process the traffic. Multiple nodes of the cluster can process the incoming requests served by the striped virtual server. This improves the Web App Firewall's ability to handle multiple simultaneous requests, thereby improving the overall performance.

Security checks and signature protections can be deployed without the need for any additional cluster-specific Web App Firewall configuration. You can do the usual Web App Firewall configuration on the configuration coordinator (CCO) node for propagation to all the nodes.

> **Note:**
>
> The session information is replicated across multiple nodes, but not across all the nodes in the striped configuration. Therefore, failover support accommodates a limited number of simultaneous failures. If multiple nodes fail simultaneously, the Web App Firewall might lose the session information if a failure occurs before the session is replicated on another node.

Highlights

- Web App Firewall offers scalability, high throughput, and session failover support in cluster deployments.
- All Web App Firewall security checks and signature protections are supported in all cluster configurations.
- Character-maps are not yet supported for a cluster. The learning engine recommends FieldTypes in learned rules for the Field Format security check.
- Stats and learned rules are aggregated from all the nodes in a cluster.
- Distributed Hash Table (DHT) provides the caching of the session and offers the ability to replicate session information across multiple nodes. When a request comes to the virtual server, the Citrix ADC appliance creates Web App Firewall sessions in the DHT, and can also retrieve the session information from the DHT.
- Clustering is licensed with the Advanced and Premium licenses. This feature is not available with the Standard license.

Debugging and troubleshooting

September 14, 2021

Refer to the following troubleshooting and debugging information related to each of the Web App Firewall functionality:

- Application Firewall - High CPU
- Memory
- Large File Upload Failure
- Learning
- Signatures
- Trace log
- Miscellaneous

High CPU

September 14, 2021

Following are some of the functionality and high CPU related debugging issues encoutered and the best practices to follow when working with Web App Firewall:

Check Policy hits, Bindings, Network configuration, Web App Firewall configuration:

- Identify misconfiguration
- Identify *vserver* that is serving the affected traffic

Inspect logs in the following log files for security violations and recent configuration changes:

- `/var/log/ns.log`
- `/var/nslog/import.log`
- `/var/nslog/aslearn.log`
- `tail -f /var/log/ns.log | grep APPFW_SIGNATURE_MATCH`

Example:

```
Jun 13 01:11:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11
    .0|APPFW| APPFW_SIGNATURE_MATCH|6|src=10.217.253.62 spt=61141 method
    =GET request= http://aaron.stratum8.net/FFC/wwwboard/passwd.txt msg=
    Signature violation rule ID 807: web-cgi /wwwboard/passwd.txt access
     cn1=140 cn2=841 cs1=pr_ffc cs2=PPE0 cs3=
    OyTgjbXBqcpBFeENKDlde3OkMQ00001 cs4=ALERT cs5=2015 cs6=web-cgi act=
    not blocked
<!--NeedCopy-->
```

Isolate the traffic that is effected:

- Isolate the profile
- Isolate the security check
- Isolate the URL, virtual server and traffic parameters

Conditional profile level trace helps identify the traffic and violation records:

- `set appfw profile <profile> -trace ON`
- `start nstrace -mode APPFW -size 0`
- `stop nstrace`

Note: Ensure that the trace is collected with -size 0 option.

Check appfw, dht, IP reputation activity counters:

- `nsconmsg -g as_ -g appfwreq_ -g iprep -d current`

Monitor window size for resets in connection:

Appfw sets the window size to 9845 when Citrix ADC resets the connection due to an invalid http message.

Examples:

- Malformed request received - connection reset
- High CPU related issues
- Check data sheets for system limits
- Inspect for cpu usage, appfw, DHT and memory related activity. Monitor appfw sessions
- nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -g mem_AS_OBJ -g mem_AS_COMPONENT -d current

Monitor memory allocated and freed from Web App Firewall components and objects during the target time period. It helps in isolating the protection leading to high CPU usage.

- Profiler output
- Observe logs

Isolate appfw check leading to high CPU:

- startURLClosure
- Formfiledconsistency
- CSRF
- Cookie protections
- Referer header check

Ascertain that autoupdate of signatures is not leading to high CPU (Disable to confirm).

Memory

September 14, 2021

Following are some of the best practices to follow when encountered with Web App Firewall usage memory related issues:

nsconmsg command usage:

- Look for global memory statistics to ascertain that there is enough memory in the system and there are no memory allocation failures by executing the following command:

  ```
  * *- nsconmsg -d memstats
  ```

- Observe current allocated and maximum memory limits for appsecure, IP reputation, cache and compression by executing the following command:

```
nsconmsg -d memstats | egrep -i APPSECURE|IPREP|CACHE|CMP
```

- Check appfw, DHT, IP reputation activity counters by executing the following command:

  ```
  nsconmsg -g as -g appfwreq_ -g iprep -d current
  ```

- Check all Web App Firewall error counters by executing the following command:

  ```
  nsconmsg -g as_ -g appfwreq_ -g iprep_ -d stats | grep err
  ```

- Check all system error counters by executing the following command:

  ```
  nsconmsg -g err -d current
  ```

- Inspect for CPU, APPFWREQ, AS and DHT counters by executing the following command:

  ```
  nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -d current
  ```

- Check the configured Cache memory by executing the following command:
- `show cacheparameter`
- Check the configured memory by executing the following command:

  ```
  nsconmsg -d memstats | egrep -i CACHE
  ```

- Identify distribution of memory in Web App Firewall components and objects:

Display AS_OBJ_ memory:

```
nsconmsg -K newnslog -d stats | grep AS_OBJ | egrep -v AppFW_cpu0|total |
sort -k3
```

Display AS_COMPONENT_ memory:

```
nsconmsg -K newnslog -d stats | grep AS_COMPONENT | egrep -v AppFW_cpu0|
total | sort -k3
```

Check for number of alive sessions by executing the following command:

Monitor/plot active session counts:

```
nsconmsg -g as_alive_sessions -d current
```

Monitor/plot total allocated, free, updated sessions:

- `nsconmsg -g as_tot_alloc_sessions -g as_tot_free_sessions -d current`
- `nsconmsg -g as_tot_update_sessions -d current`

If required, reduce session timeout to ensure that session limits are not used by executing the following command:

```
set appfwsettings -sessionTimeout <300>
```

If required, set maximum lifetime of session by executing the following command:

```
set appfwsettings -sessionLifetime <7200>
```

Checking allocated and used memory

To check the total allocated memory and used memory:

- Use the **nsconmsg –d memstats** command. Observe the **MEM_APPSECURE** field.
- Use the **stat appfw** command to obtain meory consumption information.

Web App Firewall does not automatically delete the logs after certain period of time or size.

- `All AppFw logs are archived in the */var/log/ns.log*` file. The *ns.log* file performs the rollover task.

For more information, refer to the following link: <http://support.citrix.com/article/CTX121898>

Increasing Web App Firewall memory:

- There is no CLI option to increase Web App Firewall memory. Web App Firewall memory is platform-specific.
- You may use the *nsapimgr* option to increase memory but it is not recommended.

The max allowed memory for Web App Firewall is determined by the platform and disabling IC does not impact memory allocation.

Large file upload failures

September 14, 2021

When you encounter large file upload failures, ensure that you check the following:

– Misconfigured application firewall postbody limit
– Enabled file upload scanning leading to increased processing time.
– Hitting system limits.

For payloads greater than 20 MB, Citrix recommends you to enable streaming on the application firewall profile. Also, you must ensure the back-end server supports chunked requests before enabling streaming.

Since release 11.0, the streaming flag can be enabled on per profile basis to avoid buffering by executing the following command:

```
set appfw profile <profile name> -streaming on
```

Learning

September 14, 2021

Following are some of the best practices recommended when encountered with Learning functionality issues:

Aslearn process:

- Verify that the process *aslearn* is running.
- Check top command output
- Check output of ps command by executing the following command:

  ```
  ps -ax | grep aslearn | grep -v "grep"
  ```

  Example:

  ```
  root@ns\# ps -ax | grep aslearn | grep -v "grep"
  1439  ??  Ss     0:03.86 /netscaler/aslearn -start -f /netscaler/
     aslearn.conf
  <!--NeedCopy-->
  ```

- Identify recent configuration commands ran prior to the observed problem by verifying the *ns.log* file:

  ```
  /var/log/ns.log
  ```

- Inspect aslearn logs to check for aslearn messages:

  ```
  /var/log/aslearn.log
  ```

- Isolate the profile and security check that is effected
- Identify the GUI and CLI command which is failing by executing the following command:

  ```
  show appfw learningdata <profileName> <securityCheck>
  ```

  Examples:

  - `show learningdata test_profile starturl`
  - `show learningdata test_profile crosssiteScripting`
  - `show learningdata test_profile sqLInjection`
  - `show learningdata test_profile csRFtag`
  - `show learningdata test_profile fieldformat`
  - `show learningdata test_profile fieldconsistency`

- Perform integrity check of sqlite from bsd shell prompt:

```
nsshell ## sqlite3 /var/nslog/asl/<profile_name_in_lowercase>.db '
pragma integrity_check;
```

Examples:

```
root@ns# sqlite3 /var/nslog/asl/tsk0247284.db 'pragma
   integrity_check;'
ok
<!--NeedCopy-->
```

- Deploy or remove rules to start learning again:
  - If 2000 learn items (per protection) are reached, you cannot start learning any more for that protection
  - If 20 MB size is reached for the database, stop learning for all protections
  - Restart aslearn process

```
*/netscaler/aslearn -start -f/netscaler/aslearn.conf*
```

- Check the space in the /var folder by executing the following:

```
du -h /var
```

- Check the learning threshold limits by executing the following command:

```
show appfwlearningsettings <profile_name> <securityCheck>
```

- Collect learned data by executing the following command:

```
export appfwlearningdata <profile_name> <securityCheck>
```

- Ascertain that learned data is uploaded in the collector.

Signatures

September 14, 2021

Getting started with signatures

To add signature:

1. Select the **Default**-signature and click **add** to make a copy.
2. Give a meaningful name. The new sig object is added as a User-Defined object.
3. Enable the target rules that are pertinent to your specific need.
   - The rules are disabled by default.

    - more rules require more processing

4. Configure the actions:

   Block and Log actions are enabled by default. Stats is another option

5. Set the signature to be used by your profile.

Tips for Using Signatures

- Optimize the processing overhead by enabling only those signatures that are applicable for protecting your application.
- Every pattern in the rule must match to trigger a signature match.
- You can add your own customized rules to inspect incoming requests to detect various types of attacks, such as SQL injection or cross-site scripting attacks.
- You can also add rules to inspect the responses to detect and block leakage of sensitive information such as credit card numbers.
- Add multiple security check conditions to create your own customized check.

Best Practices for Using Signatures

Following are some of the best practices you can follow when encountered with issues related to Signatures:

- Verify that the import command has succeeded on primary as well as secondary.
- Verify that CLI and GUI outputs are consistent.
- Check ns.log to identify any errors during signature import and auto update.
- Check if the DNS name server is configured properly.
- Check schema version incompatibility.
- Check if the device is unable to access the Signature Update URL hosted on AWS for auto-update.
- Check for the version mismatch between Default signature and user-added ones.
- Check for version mismatch between signature objects on the primary and secondary nodes.
- Monitor for High CPU Utilization (disable auto-update to rule out issue with signature update).

Trace Log

September 14, 2021

To record trace logs:

1. Enable tracing for the profile. You can use the show command to verify the configured setting.

```
set appfw profile <profile> -trace ON
```

1. Start collecting trace. You can continue to use all the options which are applicable for the nstrace command.

```
start nstrace -mode APPFW
```

1. Stop collecting the trace

```
stop nstrace
```

Location of the trace: The nstrace is stored in a time-stamped folder which is created in the */var/nstrace* directory and can be viewed using wireshark. You can tail the */var/log/ns.log* file to see the log messages providing details regarding the location of the new trace.

Advantages of trace logs:

- Isolate traffic for specific profile
- Collect data for specific requests
- Identify resets or aborts
- View decrypted SSL traffic: HTTPS traffic is captured in plain text to allow for easier troubleshooting.
- Provides comprehensive view: Allows you to look at the entire request at the packet level, check the payload, view logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.
- Expedite response time: Faster debugging on target traffic to do root cause analysis.

Miscellaneous

September 14, 2021

Following are the resolutions for some of the issues that you might encounter when using Web App Firewall.

- Web App Firewall sets window size to 9845 when resetting connection for invalid http messages.

  – Malformed request received - connection reset [Client/Server sending invalid content-length header]
  – Unknown content-type in request headers

- System Limit: the application appears frozen

– Occurs when maximum session limit is reached. (100K)
– Less system memory for operation.

- IP Reputation feature not working
  – The iprep process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.

- Unexpected Web App Firewall violations being triggered

  – Session timeout has a default value of 900 seconds. If session timeout is set to a low value, browser may trigger false positives for checks which rely on sessionization (e.g CSRF, FFC). Check for session timeout and look at the session ID (cs3 in CEF logs). If the sessionID is different, the session timeout might be the reason.
  – If form is dynamically generated by javascript, it may trigger false FFC violations.

- Empty field name in FFC violation logs (prior to 11.0 release)

  This may be seen in scenarios where we come across a form field which is not in the forms in our session.

  Scenarios where this may occur:

  – The session has timed out from when the form was sent to the client and when it was received.
  – The form was generated on the client side using a java script.

Signature alert Articles

September 14, 2021

Citrix Web Application Firewall (WAF) announces signature updates that you can download and apply on your appliance. When you detect a security attack, you will receive an email notification about the new signature update. You can download the signature and apply it on your appliance.

How to receive signature alert notification

September 14, 2021

This article explains how to configure signature alert settings to receive email notifications for new signature updates.

Summary

Network administrators would like to receive an email notification for new Web Application Firewall signature updates and notification.

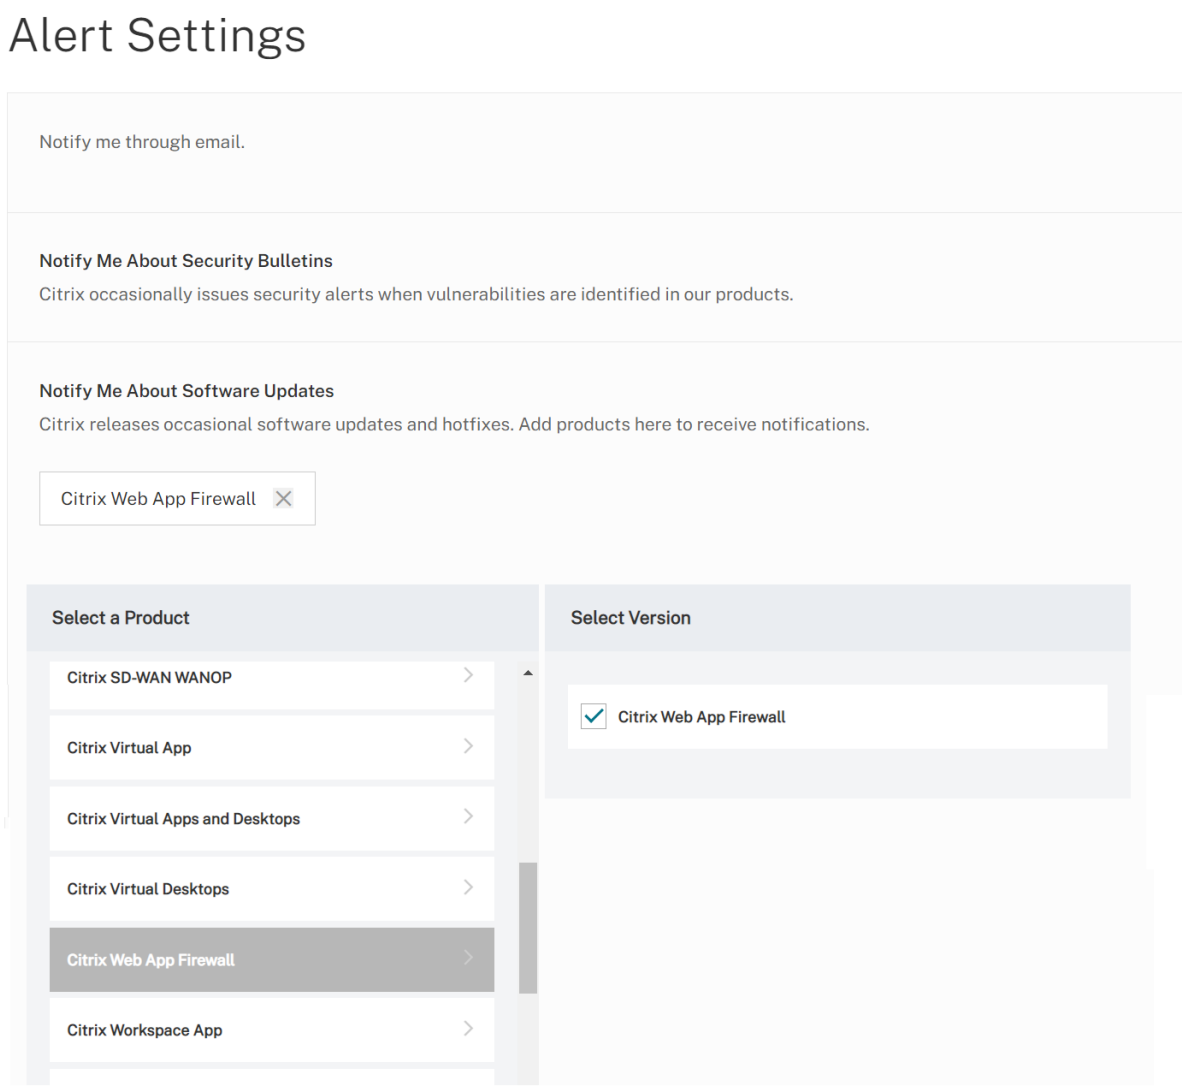
Problem

A Network administrator who wants to be notified when a new signature is available for the Web Application Firewall can elect to be notified by email. The administrator will receive an email notification when new signatures are available to be downloaded.
Network administrators to receive email notification for new signature updates.

Solution

To receive email notification for new signature updates, follow the steps given below:

1. Sign into Citrix support website, `https://support.citrix.com/user/alerts`.
2. In the **Alert Settings** section, enable the Notify me through email option.
3. Select **Add Products** to view the product catalog.
4. Click **Citrix Web App Firewall** and then select **Citrix Web App Firewall** check box.
5. Click **Save Settings**.



1. In the **Alert Settings** section, enable the Notify me through email option.
2. Select **Add Products** to view the product catalog.
3. Click **Application Firewall** and then click the **Signatures** check box.
4. Click **Save Settings**.

Signature update version 27

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 27. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

Signature version

Signature version 27 applicable to NetScaler VPX 11.1, NetScaler 12.0, and Citrix ADC 12.1 platforms.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999921	cve-2018-1002000	WEB-MISCWordpress Arigato Autoresponder and Newsletter SQL Injection vulnerability.
999920		WEB-MISCWordPress plug-in Corner Ad 1.0.7 - Stored Cross-Site Scripting
999919	cve-2018-1002009	WEB-MISCWordpress Arigato Autoresponder and Newsletter bft_unsubscribe cross-site scripting vulnerability.
999918	cve-2018-1002002	WEB-MISCWordpress Arigato Autoresponder and Newsletter multiple cross-site scripting vulnerability.
999918	cve-2018-1002003	WEB-MISCWordpress Arigato Autoresponder and Newsletter multiple cross-site scripting vulnerability.

Signature rule	CVE ID	Description
999918	cve-2018-1002004	WEB-MISCWordpress Arigato Autoresponder and Newsletter multiple cross-site scripting vulnerability.
999918	cve-2018-1002005	WEB-MISCWordpress Arigato Autoresponder and Newsletter multiple cross-site scripting vulnerability.
999918	cve-2018-1002006	WEB-MISCWordpress Arigato Autoresponder and Newsletter multiple cross-site scripting vulnerability.
999918	cve-2018-1002007	WEB-MISCWordpress Arigato Autoresponder and Newsletter multiple cross-site scripting vulnerability.

Signature rule	CVE ID	Description
999914		WEB-MISCWordpress plug-in E-mail Subscribers and Newsletters 3.4.7 information disclosure vulnerability
999913		WEB-MISCWordPress plug-in AD Manager WD v1.0.11 - wd_ads_admin_class.php Arbitrary File Download
999912		WEB-IISMicrosoft IIS - Short File/Folder Name Disclosure

Signature update version 28

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 28. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

Signature version

Signature version 28 applicable to NetScaler VPX 11.1, NetScaler 12.0, and Citrix ADC 12.1 and Citrix ADM 13.0 platforms.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999898	CVE-2018-12895	WEB-MISC WordPress before 4.9.7-Directory Traversal Vulnerability.

Signature rule	CVE ID	Description
999899	CVE-2019-9618	WEB-MISC-GraceMedia Media Player WordPress plug-in 1.0 Arbitrary Local File Inclusion Vulnerability
999900	CVE-2018-20714	WEB-MISC WordPress plug-in WooCommerce before 3.4.6 - File Deletion Vulnerability.
999901	CVE-2018-11868	WEB-MISC FlowPaper FlexPaper before 2.3.7 can Allow Remote Code Execution-Reset of Config Files.
999902	CVE-2018-11868	WEB-MISC FlowPaper FlexPaper before 2.3.7 can Allow Remote Code Execution.
999903	CVE-2019-9184	WEB-MISC-Joomla! J2Store plug-in 3.x Before 3.3.7 Allows SQL Injection.
999904	CVE-2019-9168	WEB-MISC WordPress plug-in WooCommerce before 3.5.5-cross-site scripting via Photoswipe caption.
999905		WEB-MISC WordPress plug-in Abandoned Cart before 5.1.3 for WooCommerce-Stored Cross-Site Scripting.
999906	CVE-2019-8942	WEB-MISC WordPress before 4.9.9 and 5.x before 5.0.1-remote code execution.
999907	CVE-2019-8942	WEB-MISC WordPress before 4.9.9 and 5.x before 5.0.1-remote code execution.

Signature rule	CVE ID	Description
999908	CVE-2019-8942	WEB-MISC WordPress before 4.9.9 and 5.x before 5.0.1-remote code execution
999909	CVE-2017-16562	WEB-MISC-Deluxe Theme UserPro WordPress plug-in Security Bypass Vulnerability Via up_auto_log=true Parameter
999910	CVE-2018-20782	WEB-MISC WordPress plug-in GloBee before 1.1.2 for WooCommerce-IPN Messages Spoofing
999911	CVE-2019-6340	Drupal-Arbitrary Remote Code Execution in Drupal Core 8 RESTFul WebServices

Signature update version 29

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 29. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 29 applicable to NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

> **Note**:
>
> Enabling Post body and Response body signature rules may affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999896	CVE-2019-2725	Weblogic 10.3.6 Remote Code Execution
999897	CVE-2019-2725	Weblogic 10.3.6 Remote Code Execution

Signature update version 30

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 30. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 30 applicable to NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules may affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999879	<>	WEB-MISC WordPress plug-in WooCommerce Checkout Manager - Arbitrary File Upload Vulnerability
999880	<>	WEB-MISC WordPress plug-in Advance Contact Form 7 DB Prior To 1.6.1 - SQL Injection Vulnerability

Signature rule	CVE ID	Description
999881	<>	WEB-MISC WordPress plug-in Contact Form Builder Prior To 1.0.67 - Local File Inclusion Vulnerability
999882	<>	SQL HTTP URI Blind Injection Attempt
999883	<>	WEB-MISC Loco Translate WordPress plug-in 2.1.1 and prior - Local File Inclusion Vulnerability
999884	<>	WEB-MISC WordPress plug-in Duplicate-Page Prior To 3.4 - SQL Injection Vulnerability
999885	CVE-2019-0232	WEB-MISC Apache Tomcat RCE Via .CMD CGI Scripts When enableCmdLineArguments=true in MS Windows
999886	CVE-2019-0232	WEB-MISC Apache Tomcat RCE Via .BAT CGI Scripts When enableCmdLineArguments=true in MS Windows
999887	CVE-2019-10692	WWEB-MISC WordPress plug-in wp-google-maps Prior To 7.11.18 - SQL Injection Vulnerability.
999888	CVE-2019-10946	WEB-MISC Joomla! Prior To 3.9.5 - Security Bypass Vulnerability
999889	CVE-2019-10945	WEB-MISC Joomla! Prior To 3.9.5 - Directory Traversal Vulnerability
999890	CVE-2019-9912	WEB-MISC WpGoogleMaps WordPress plug-in prior to 7.10.41 Reflected cross-site scripting Vulnerability

Signature rule	CVE ID	Description
999890	CVE-2019-9912	WEB-MISC WpGoogleMaps WordPress plug-in prior to 7.10.41 Reflected cross-site scripting Vulnerability
999891	CVE-2019-9911	WEB-MISC WordPress plug-in Social Networks Auto-Poster Prior To 4.2.8 - Reflected cross-site scripting Vulnerability
999892	CVE-2019-9908	WEB-MISC WordPress plug-in Font_Organizer 2.1.1 - Reflected cross-site scripting
999893	CVE-2019-9787	WEB-MISC WordPress before 4.9.7 - Remote Code Execution Vulnerability
999894	CVE-2019-9568	WEB-MISC Forminator Contact Form, Poll & Quiz Builder WordPress plug-in prior to 1.6 Blind SQLi Vulnerability
999895	CVE-2019-9567	WEB-MISC Forminator Contact Form, Poll & Quiz Builder WP plug-in prior to 1.6 Persistent cross-site scripting Vulnerability
999877	CVE-2018-20062	WEB-MISC NoneCms V1.3 - ThinkPHP Filter Arbitrary PHP Code Execution Vulnerability
999878	CVE-2019-9082	WEB-MISC Remote Code Execution Vulnerability in ThinkPHP 5.x prior to 5.1.32

Signature update version 32

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 32. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 32 applicable to NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules may affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999875	CVE-2016-4438, CVE-2016-3087	WEB-STRUTS Apache Struts 2.3.20 Through 2.3.28.1 Remote Execution Vulnerability Via URL
999876	CVE-2019-10867	WEB-MISC Pimcore Prior to 5.7.1 - Deserializing Vulnerability (CVE-2019-10867)

Signature update version 33

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 33. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 33 applicable to NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules may affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Rule	CVE	Description	Vulnerability Reference
999860		WordPress plug-in Yuzo Related Posts cross-site scripting Vulnerability	https://www.wordfence.com/blog/2019/04/yuzo-related-posts-zero-day-vulnerability-exploited-in-the-wild
999861	CVE-2019-12099		cve,2019-12099
999862		WordPress plug-in Database Backup <= 5.2 - Remote Code Execution	https://www.wordfence.com/blog/2019/05/os-command-injection-vulnerability-patched-in-wp-database-backup-plug-in
999863		WordPress plug-in Slick Popup - Privilege Escalation	https://www.wordfence.com/blog/2019/05/privilege-escalation-flaw-present-in-slick-popup-plug-in

Rule	CVE	Description	Vulnerability Reference
999864	CVE-2019-10866	WordPress plug-in Form Maker 1.13.3 - SQL Injection	cve,2019-10866
999865		WordPress plug-in Give – Stored cross-site scripting for Donors	https://blog.sucuri.net/2019/05/wordpress-plug-in-give-stored-xss-for-donors.html
999866		WordPress plug-in My Calendar <= 3.1.9 - Unauthenticated cross-site scripting Vulnerability	https://wpvulndb.com/vulnerabilities/9267
999867		WordPress plug-in Slimstat <= 4.8 - Unauthenticated Stored cross-site scripting	https://blog.sucuri.net/2019/05/slimstat-stored-xss-from-visitors.html
999868	CVE-2019-2618	WebLogic Arbitrary Upload Vulnerability	cve,2019-2618
999869	CVE-2019-11871	WEB-WORDPRESS WordPress plug-in Custom Field Suite Prior To 2.5.15 - Cross-Site Scripting Vulnerability	cve,2019-11871

Rule	CVE	Description	Vulnerability Reference
999870		WEB-WORDPRESS WordPress Live Chat Support plug-in Persistent cross-site scripting Vulnerability prior 8.0.27 via wplc_custom_js parameter	https://blog.sucuri.net/2019/05/persistent-cross-site-scripting-in-wp-live-chat-support-plug-in.html
999871		WEB-WORDPRESS WordPress plug-in W3 Total Cache Prior To 0.9.7.4 - PHAR Remote Code Execution Vulnerability	https://wpvulndb.com/vulnerabilities/9270
999872		WEB-WORDPRESS WordPress plug-in W3 Total Cache Prior To 0.9.7.4 - PHAR Remote Code Execution Vulnerability	https://wpvulndb.com/vulnerabilities/9269
999873	CVE-2019-0604	WEB-MISC Microsoft Windows Sharepoint Server - Remote Code Execution Vulnerability	cve,2019-0604
999874		WEB-WORDPRESS Yuzo Related Posts Unauthenticated Stored cross-site scripting Vulnerability in 5.12.91	https://www.wordfence.com/blog/2019/04/yuzo-related-posts-zero-day-vulnerability-exploited-in-the-wild

Signature update version 34

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 34. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 34 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999843		WEB-WORDPRESS WordPress plug-in Ultimate Member Prior to Version 2.0.46 - Setting Arbitrary File For Read
999844		WEB-WORDPRESS WordPress plug-in Ultimate Member Prior to Version 2.0.46 - Arbitrary File Read
999845		WEB-WORDPRESS WordPress plug-in Ultimate Member Prior to Version 2.0.46 - File Removal Via File Replacement
999846		WEB-WORDPRESS WordPress plug-in Ultimate Member Prior to Version 2.0.46 - File Removal

Signature rule	CVE ID	Description
999847		WEB-WORDPRESS WordPress plug-in Shortlinks Prior To 2.1.10 - CSV Injection Vulnerability
999848		WEB-WORDPRESS WordPress plug-in Shortlinks Prior To 2.1.10 - Unauthenticated Stored cross-site scripting Vulnerability
999849		WEB-WORDPRESS WordPress plug-in FV Flowplayer Video Player Prior To 7.3.13.727 - Unauthenticated Stored cross-site scripting Vulnerability
999850		WEB-WORDPRESS WordPress plug-in Easy Digital Downloads Prior To 2.9.16 - Unauthenticated Stored cross-site scripting Vulnerability
999851		WEB-WORDPRESS WordPress plug-in Crelly Slider Prior to version 1.3.5 - Arbitrary File Upload Vulnerability
999853	CVE-2019-2615	WEB-MISC Oracle WebLogic Server Information Disclosure Vulnerability
999854	CVE-2019-11872	WordPress plug-in Hustle Prior To 6.0.8.1 - CSV Injection Vulnerability
999855	CVE-2019-11231	WEB-MISC GetSimple CMS Version 3.3.15 and Prior - Arbitrary File Upload Vulnerability

Signature rule	CVE ID	Description
999856	CVE-2019-11231	WEB-MISC GetSimple CMS Version 3.3.15 and Prior - API Key Information Disclosure
999857		WEB-WORDPRESS WordPress plug-in WP Database Backup Prior To 5.2 - Command Injection Vulnerability
999858		WEB-WORDPRESS WordPress plug-in Slick Popup Up To 1.7.1 - Privilege Escalation Vulnerability
999859	CVE-2019-12099	WEB-MISC PHP Fusion CMS Remote Code Execution Vulnerability in Version 9.03.00 and Prior

Signature update version 35

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 35. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 35 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999834	CVE-2019-13024	WEB-MISC Centreon Version 19.04 and Prior - Command Injection Vulnerability
999835	CVE-2019-5420	WEB-MISC Rails Development Mode - Secret Token Disclosure Vulnerability
999836	CVE-2019-5418	WEB-MISC Rails Action View - File Content Disclosure Vulnerability
999837	CVE-2018-12426, CVE-2019-11185	WEB-WORDPRESS WP Live Chat Support Pro plug-in Prior to 8.0.26 - Arbitrary File Upload
999838	CVE-2019-10270	WEB-WORDPRESS WordPress plug-in Ultimate Member Prior to Version 2.0.40 - Arbitrary Password Reset
999839	CVE-2019-12826	WEB-WORDPRESS WordPress plug-in Widget Logic Prior To 5.10.2 - CSRF Vulnerability
999840		WEB-WORDPRESS WordPress plug-in All-In-One Event Calendar Prior To 2.5.39 - cross-site scripting Vulnerability
999841	CVE-2019-11565	WEB-WORDPRESS WordPress plug-in Print My Blog Prior To 1.6.7 - Unauthenticated SSRF Vulnerability
999842		WEB-WORDPRESS WordPress plug-in Ultimate Member Prior to Version 2.0.46 - Multiple `cross-site scripting</LogString`

Signature update version 36

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 36. You can download and configure the signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 36 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note**:
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999817		WEB-WORDPRESS WordPress Ad Inserter plug-in Prior to Version 2.4.22 - Remote Code Execution
999818	CVE-2019-7839	WEB-MISC Adobe ColdFusion Multiple Versions - Remote Code Execution Vulnerability Via HTTP/SOAP DotNet-to-Java (CVE-2019-7839)
999819	CVE-2019-7839	WEB-MISC Adobe ColdFusion Multiple Versions - Remote Code Execution Vulnerability Via HTTP/SOAP Java-to-DotNet (CVE-2019-7839)

Signature rule	CVE ID	Description
999820	CVE-2019-11469	WEB-MISC Zoho ManageEngine Applications Manager Prior to 14 Build 14150 Allows SQLi Via resourceid Parameter (CVE-2019-11469)
999821	CVE-2019-11448	WEB-MISC Zoho ManageEngine Application Manager 11.0 Through 14.0 - Unauthenticated SQL Injection (CVE-2019-11448)
999822	CVE-2019-1003000	WEB-MISC Jenkins Script Security plug-in Up To 1.49 - Sandbox Bypass Vulnerability (CVE-2019-1003000)
999823		WEB-WORDPRESS WordPress Cforms2 plug-in Up To 15.0.1 - Unauthenticated HTML Injection Vulnerability
999824	CVE-2019-0193	WEB-MISC Apache Solr Prior To 8.2 - DIH Remote Code Execution Vulnerability Via dataConfig Parameter (CVE-2019-0193)
999825	CVE-2019-11580	WEB-MISC Atlassian Crowd Pdkinstall Development plug-in Enabled - Unauthenticated RCE (CVE-2019-11580)
999826	CVE-2019-0192	WEB-MISC Apache Solr Up To 5.5.5 / 6.6.5 - Config API Remote Code Execution Vulnerability (CVE-2019-0192)

Signature rule	CVE ID	Description
999827		WEB-WORDPRESS WooCommerce Variation Swatches plug-in Up To 1.0.61 - Reflected cross-site scripting Vulnerability
999828	CVE-2019-1003001	WEB-MISC Jenkins Pipeline Groovy plug-in Up To 2.61 - Sandbox Bypass Vulnerability Via Job Creation (CVE-2019-1003001)
999829	CVE-2019-1003001	WEB-MISC Jenkins Pipeline Groovy plug-in Up To 2.61 - Sandbox Bypass Vulnerability (CVE-2019-1003001)
999830		WEB-WORDPRESS WordPress Bold Page Builder plug-in Prior To 2.3.2 - Security Bypass Vulnerability
999831	CVE-2019-15107	WEB-MISC Webmin Prior To 1.930 - Unauthenticated Remote Code Execution Vulnerability (CVE-2019-15107)
999832	CVE-2019-2767	WEB-MISC Oracle BI Publisher 11.1.1.9.0 and 12.2.1.4 - XXE Vulnerability (CVE-2019-2767)
999833	CVE-2019-15106	WEB-MISC Zoho ManageEngine OpManager Through 12.4x - Authentication Bypass Vulnerability (CVE-2019-15106)

Signature rule	CVE ID	Description
999948	CVE-2014-0114	Apache Struts 1 through 1.3.10 allows ClassLoader manipulation allowing arbitrary code execution via HTTP_FORM_FIELD
999949	CVE-2013-4316	Apache Struts 2 before 2.3.15.2 allows Dynamic Method Invocation by affecting confidentiality, integrity or availability
999950	CVE-2013-4316	Apache Struts 2 before 2.3.15.2 allows Dynamic Method Invocation by affecting confidentiality, integrity or availability

> **Note:**
>
> Signature rule 999947 is deleted because of performance issue.

Signature update version 37

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 37. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 37 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999806	CVE-2019-3394	WEB-MISC Atlassian Confluence or Data Center - Local File Disclosure Vulnerability (CVE-2019-3394)
999807	CVE-2019-13569	WEB-WORDPRESS Icegram Email Subscribers & Newsletters plug-in Prior to 4.1.8 - SQLi Via Esfpx_lists Param (CVE-2019-13569)
999808	CVE-2019-13569	WEB-WORDPRESS Icegram Email Subscribers & Newsletters plug-in Prior to 4.1.8 - SQLi Via Order Param (CVE-2019-13569)
999809	CVE-2019-2768	WEB-MISC Oracle BI Publisher - Predictable Session Token Vulnerability (CVE-2019-2768)
999810	CVE-2019-1003001	WEB-MISC Jenkins Pipeline Groovy plug-in Up To 2.61 - Sandbox Bypass Vulnerability Via Job Update (CVE-2019-1003001)
999811	CVE-2019-13575	WEB-WORDPRESS WPEverest Everest Forms plug-in Prior to 1.5.0 - SQL Injection (CVE-2019-13575)
999812	CVE-2019-15896	WEB-WORDPRESS LifterLMS plug-in Up To 3.34.5 - Security Bypass Vulnerability (CVE-2019-15896)

Signature rule	CVE ID	Description
999813	CVE-2019-3396	WEB-MISC Atlassian Confluence or Data Center - Remote Code Execution Vulnerability (CVE-2019-3396)
999814	CVE-2019-5475	WEB-MISC Sonatype Nexus Repository Manager Prior to 2.14.14 - Remote Code Execution Via Createrepo Path (CVE-2019-5475)
999815	CVE-2019-5475	WEB-MISC Sonatype Nexus Repository Manager Prior to 2.14.14 - Remote Code Execution Via Mergerepo Path (CVE-2019-5475)
999816	CVE-2019-15104	WEB-MISC Zoho ManageEngine OpManager Version Prior to 12.4 - SQL Injection Vulnerability (CVE-2019-15104)

Signature update version 38

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in version 38. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 38 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999800	CVE-2019-12517	WEB-WORDPRESS SlickQuiz plug-in Version 1.3.7.1 and Prior - cross-site scripting Vulnerability (CVE-2019-12517)
999801	CVE-2019-10392	WEB-MISC Jenkins Git Client plug-in 2.8.4 And Prior - OS Command Injection Vulnerability (CVE-2019-10392)
999802	CVE-2019-8371	WEB-MISC OpenEMR Prior to 5.0.2 - Remote Code Execution Vulnerability Via Form_Filedata Field (CVE-2019-8371)
999803	CVE-2019-8371	WEB-MISC OpenEMR Prior to 5.0.2 - Remote Code Execution Vulnerability Via Form_Image Field (CVE-2019-8371)
999804	CVE-2019-12516	WEB-WORDPRESS SlickQuiz plug-in Version 1.3.7.1 and Prior - SQL Injection Vulnerability (CVE-2019-12516)
999805	CVE-2019-1262	WEB-MISC Microsoft Sharepoint Server - Cross Site Scripting Vulnerability (CVE-2019-1262)

Signature update for December 2019

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2019-12-19. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 39 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999760		WEB-MISC FusionPBX Versions Prior to 4.4.7 and 4.5.5 - Remote Code Execution Vulnerability Via /app/exec/exec.php
999761	CVE-2019-12747	WEB-MISC Typo3 Prior to 8.7.27 and 9.5.8 - Deserialization of Untrusted Data (CVE-2019-12747)
999762	CVE-2019-13608	WEB-MISC Citrix StoreFront Server - XML External Entity Injection Vulnerability (CVE-2019-13608)
999763		WEB-WORDPRESS WordPress Prior To 5.2.4 - Unauthenticated View Of Private or Draft Posts/Pages Vulnerability Via FORM

Signature rule	CVE ID	Description
999764		WEB-WORDPRESS WordPress Prior To 5.2.4 - Unauthenticated View Of Private or Draft Posts/Pages Vulnerability Via URL
999765	CVE-2019-15954	WEB-MISC Total.js CMS 12.0.0 - Widget JavaScript Code Injection Vulnerability Via JSON (CVE-2019-15954)
999766	CVE-2019-15954	WEB-MISC Total.js CMS 12.0.0 - Widget JavaScript Code Injection Vulnerability Via FORM (CVE-2019-15954)
999767		WEB-WORDPRESS SyntaxHighlighter Evolved plug-in Prior To 5.3.1 - Stored Cross-Site Scripting Vulnerability Via Comment
999768		WEB-WORDPRESS SyntaxHighlighter Evolved plug-in Prior To 5.3.1 - Stored Cross-Site Scripting Vulnerability Via POST
999769		WEB-WORDPRESS SyntaxHighlighter Evolved plug-in Prior To 5.3.1 - Stored Cross-Site Scripting Vulnerability Via JSON
999770	CVE-2019-16120	WEB-WORDPRESS Event Tickets plug-in Before 4.10.7.2 - CSV Injection Vulnerability (CVE-2019-16120)
999771	CVE-2019-15029	WEB-MISC FusionPBX Prior to 4.4.8 - Remote Code Execution Vulnerability (CVE-2019-15029)

Signature rule	CVE ID	Description
999772		WEB-WORDPRESS Sassy Social Share plug-in Prior To 3.3.4 - Unauthenticated Cross-Site Scripting Vulnerability
999773		WEB-WORDPRESS Email Subscribers & Newsletters plug-in Version 4.3.1 and Prior - Unauthenticated Blind SQLi Vulnerability
999774	CVE-2019-3398	WEB-MISC Atlassian Confluence or Data Center - downloadallattachments Path Traversal Vulnerability (CVE-2019-3398)
999775	CVE-2019-15952	WEB-MISC Total.js CMS 12.0.0 - Page Template Path Traversal Vulnerability (CVE-2019-15952)
999776	CVE-2019-17236	WEB-WORDPRESS IgniteUp Coming Soon and Maintenance Mode plug-in Up To 3.4.0 - Stored cross-site scripting (CVE-2019-17236)
999777	CVE-2019-10475	WEB-MISC Jenkins Build-Metrics plug-in 1.3 - Reflected cross-site scripting Vulnerability (CVE-2019-10475)
999778	CVE-2019-17132	WEB-MISC vBulletin Prior to 5.5.4 Patch Level 2 - UpdateAvatar API Endpoint Remote Code Execution Vulnerability (CVE-2019-17132)

Signature rule	CVE ID	Description
999779	CVE-2019-14994	WEB-MISC Atlassian Jira Service Desk - Path Traversal Vulnerability (CVE-2019-14994)
999780	CVE-2019-19367	WEB-MISC FusionPBX 4.4.1 and Prior - Cross-Site Scripting Vulnerability (CVE-2019-19367)
999781	CVE-2019-18668	WEB-WORDPRESS Currency Switcher plug-in Before 2.11.2 - Currency Setting Bypass Vulnerability Via POST (CVE-2019-18668)
999782	CVE-2019-18668	WEB-WORDPRESS Currency Switcher plug-in Before 2.11.2 - Currency Setting Bypass Vulnerability Via GET (CVE-2019-18668)
999783	CVE-2019-16663	WEB-MISC rConfig 3.9.2 and Prior - Remote Code Execution Vulnerability via Search.crud.php (CVE-2019-16663)
999784		WEB-MISC Apache Solr Up to 8.3.0 - Unauthenticated Remote Code Execution Via VelocityResponseWriter Custom Template
999785	CVE-2019-17235	WEB-WORDPRESS IgniteUp Coming Soon and Maintenance Mode plug-in Up To 3.4.0 - Information Disclosure Via Csv (CVE-2019-17235)

Signature rule	CVE ID	Description
999786	CVE-2019-17235	WEB-WORDPRESS IgniteUp Coming Soon and Maintenance Mode plug-in Up To 3.4.0 - Information Disclosure Via Bcc (CVE-2019-17235)
999787	CVE-2019-12276	WEB-MISC GrandNode 4.40 - LetsEncryptController Path Traversal Vulnerability (CVE-2019-12276)
999788		WEB-WORDPRESS Email Subscribers & Newsletters plug-in Prior to Version 4.2.3 - Unauthenticated Information Disclosure
999789	CVE-2019-4013	WEB-MISC IBM BigFix Platform 9.5 - Authenticated Arbitrary File Upload With Root Privileges (CVE-2019-4013)
999790	CVE-2019-11409	WEB-MISC FusionPBX Version 4.4.3 and Prior - Remote Code Execution Via /app/basic_operator_panel/exec.php (CVE-2019-11409)
999791	CVE-2019-11409	WEB-MISC FusionPBX Version 4.4.3 and Prior - Remote Code Execution Via /app/operator_panel/exec.php (CVE-2019-11409)
999792	CVE-2019-16662	WEB-MISC rConfig 3.9.2 and Prior - Unauthenticated Remote Code Execution Via AjaxServerSettingsChk.php (CVE-2019-16662)

Signature rule	CVE ID	Description
999793	CVE-2019-7609	WEB-MISC Elastic Kibana Prior to 5.6.15 and 6.6.1 - Prototype Pollution Vulnerability Allows Unauthenticated RCE (CVE-2019-7609)
999794	CVE-2019-10092	WEB-MISC Apache HTTP Server Up To 2.4.39 - mod_proxy Limited Cross-Site Scripting (CVE-2019-10092)
999795	CVE-2019-16520	WEB-WORDPRESS All In One SEO Pack plug-in Before 3.2.7 - Stored cross-site scripting Vulnerability (CVE-2019-16520)
999796	CVE-2019-17234	WEB-WORDPRESS IgniteUp Coming Soon and Maintenance Mode plug-in Up to 3.4.0 - Arbitrary File Deletion (CVE-2019-17234)
999797	CVE-2019-16525	WEB-WORDPRESS Checklist plug-in Prior to Version 1.1.9 - cross-site scripting Vulnerability (CVE-2019-16525)
999798		WEB-WORDPRESS Safe SVG plug-in Prior to 1.9.6 - cross-site scripting Vulnerability
999799		WEB-WORDPRESS Email Subscribers & Newsletters plug-in Prior to Version 4.2.3 - Unauthenticated Arbitrary Option Creation

Signature update version 40

September 14, 2021

New signatures rules are generated for the vulnerabilities identified for the week 2020-01-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

Signature version

Signature version 40 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> The signature update version 40 includes a fix for the incorrect signature rule 1861.
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999732	CVE-2019-1620	WEB-MISC Cisco Data Center Network Manager Prior To 11.2(1) - Arbitrary File Upload Vulnerability (CVE-2019-1620)
999733	CVE-2019-16702	WEB-MISC Integard Pro 2.2.0.9026 - NoJs Buffer Overflow Vulnerability (CVE-2019-16702)
999734	CVE-2019-1621	WEB-MISC Cisco Data Center Network Manager Prior To 11.2(1) - Arbitrary File Download Vulnerability (CVE-2019-1621)
999735	CVE-2019-8451	WEB-MISC Atlassian Jira Server Before 8.4.0 - Server Side Request Forgery Vulnerability (CVE-2019-8451)

Signature rule	CVE ID	Description
999736		WEB-WORDPRESS GDPR Cookie Compliance plug-in Prior to 4.0.3 - Authenticated Arbitrary Settings Deletion Vulnerability
999737	CVE-2019-11287	WEB-MISC Pivotal RabbitMQ 3.7.x prior to 3.7.21 and 3.8.x prior to 3.8.1 - Denial of Service Vulnerability (CVE-2019-11287)
999738		WEB-WORDPRESS Ultimate Addons For Elementor Prior To 1.20.1 - Authentication Bypass Via Facebook Login Vulnerability
999739		WEB-WORDPRESS Ultimate Addons For Elementor Prior To 1.20.1 - Authentication Bypass Via Google Login Vulnerability
999740	CVE-2019-19366	WEB-MISC FusionPBX Prior to 4.4.10 - cross-site scripting Vulnerability in xml_cdr_search.php Via Redirect Parameter (CVE-2019-19366)
999741	CVE-2019-16931	WEB-WORDPRESS Visualizer plug-in Prior to Version 3.3.1 - Unauthenticated cross-site scripting Vulnerability (CVE-2019-16931)
999742	CVE-2019-16932	WEB-WORDPRESS Visualizer plug-in Prior to Version 3.3.1 - Unauthenticated SSRF (CVE-2019-16932)

Signature rule	CVE ID	Description
999743	CVE-2019-1619	WEB-MISC Cisco Data Center Network Manager Prior To 11.1(1) - Authentication Bypass Vulnerability (CVE-2019-1619)
999744	CVE-2019-12562	WEB-MISC DotNetNuke Before 9.4.0 - Stored Cross Site Scripting Vulnerability (CVE-2019-12562)
999745	CVE-2019-8371	WEB-MISC OpenEMR Prior to 5.0.2 - Remote Code Execution Vulnerability Via Form_Filedata Field (CVE-2019-8371)
999746	CVE-2019-8371	WEB-MISC OpenEMR Prior to 5.0.2 - Remote Code Execution Vulnerability Via Form_Image Field (CVE-2019-8371)
999747		WEB-WORDPRESS Beaver Builder Ultimate Addons Prior To 1.24.1 - Authentication Bypass Via Facebook Login Vulnerability
999748		WEB-WORDPRESS Beaver Builder Ultimate Addons Prior To 1.24.1 - Authentication Bypass Via Google Login Vulnerability
999749	CVE-2019-19650	WEB-MISC Zoho ManageEngine AM Prior to Build 13640 - SQLi Via Agent Servlet (CVE-2019-19650)

Signature rule	CVE ID	Description
999750		WEB-MISC Zoho ManageEngine AM Prior to Build 13620 - API Key Disclosure Via OPMRequestHandlerServlet Servlet
999751	CVE-2019-1622	WEB-MISC Cisco Data Center Network Manager 11.0(1) - Information Disclosure Vulnerability (CVE-2019-1622)
999752	CVE-2019-16759	WEB-MISC vBulletin Prior to 5.5.4 Patch Level 1 - Remote Code Execution Vulnerability (CVE-2019-16759)
999753		WEB-WORDPRESS Featured Image from URL plug-in Prior to 2.7.8 - Missing Access Controls on REST API Vulnerability
999754	CVE-2019-10098	WEB-MISC Apache HTTP Server Up To 2.4.39 - mod_rewrite Self-Referential Redirect Vulnerability (CVE-2019-10098)
999755	CVE-2019-1936	WEB-MISC Cisco UCS Director 6.0 to 6.6.1.0 and 6.7.0.0 to 6.7.1.0 - Command Injection Vulnerability (CVE-2019-1936)
999756	CVE-2019-19649	WEB-MISC Zoho ManageEngine AM Prior to Build 13620 - Unauthenticated SQLi Via EventID Parameter (CVE-2019-19649)

Signature rule	CVE ID	Description
999757	CVE-2019-19649	WEB-MISC Zoho ManageEngine AM Prior to Build 13620 - Unauthenticated SQLi Via Entity Parameter (CVE-2019-19649)
999758	CVE-2019-15036	WEB-MISC JetBrains TeamCity Before 2019.1 - OS Command Injection Vulnerability (CVE-2019-15036)
999759	CVE-2019-17239	WEB-WORDPRESS Download plug-ins and Themes from Dashboard plug-in Up To 1.5 - Stored cross-site scripting Vulnerability (CVE-2019-17239)

Signature update version 41

September 14, 2021

New signatures rules are generated for the vulnerabilities identified for the week 2020-02-04. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

Signature version

Signature version 41 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> The signature update version 41 includes a fix for the incorrect signature rule 1861. Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999717		WEB-WORDPRESS WordPress Version 5.3.x and Prior - Denial of Service Vulnerability Via xmlrpc.php pingback.ping Method
999718		WEB-WORDPRESS Backup And Staging By WP Time Capsule plug-in Prior To 1.21.16 - Authentication Bypass Vulnerability
999719	CVE-2019-19731	WEB-MISC Roxy Fileman For .NET 1.4.5 - Path Traversal Vulnerability Via RENAMEFILE (CVE-2019-19731)
999720	CVE-2019-19915	WEB-WORDPRESS 301 Redirects – Easy Redirect Manager plug-in Up To 2.4.0 - Multiple Vulnerabilities (CVE-2019-19915)
999721	CVE-2019-17662	WEB-MISC Cybele Software ThinVNC Prior to Version 1.0b1 - Directory Traversal Vulnerability (CVE-2019-17662)
999722	CVE-2020-6168	WEB-WORDPRESS Minimal Coming Soon And Maintenance Mode plug-in Prior To 2.17 - Maintenance Setting Vulnerability (CVE-2020-6168)

Signature rule	CVE ID	Description
999723	CVE-2020-6166	WEB-WORDPRESS Minimal Coming Soon And Maintenance Mode plug-in Prior To 2.17 - Theme Change Vulnerability (CVE-2020-6166)
999724	CVE-2020-6166	WEB-WORDPRESS Minimal Coming Soon And Maintenance Mode plug-in Prior To 2.17 - Export Settings Vulnerability (CVE-2020-6166)
999725		WEB-WORDPRESS InifiniteWP Client plug-in Prior to 1.9.4.5 - Authentication Bypass Vulnerability
999726	CVE-2019-16773	WEB-WORDPRESS WordPress Versions Prior to 5.3.1 - cross-site scripting Vulnerability Via REST API With JSON Object (CVE-2019-16773)
999727	CVE-2019-16773	WEB-WORDPRESS WordPress Versions Prior to 5.3.1 - cross-site scripting Vulnerability Via REST API With FORM FIELD (CVE-2019-16773)
999728	CVE-2019-16773	WEB-WORDPRESS WordPress Versions Prior to 5.3.1 - cross-site scripting Vulnerability Via user-edit.php (CVE-2019-16773)

Signature rule	CVE ID	Description
999729	CVE-2019-16773	WEB-WORDPRESS WordPress Versions Prior to 5.3.1 - cross-site scripting Vulnerability Via profile.php (CVE-2019-16773)
999730	CVE-2019-16113	WEB-MISC Bludit 3.9.2 - Image Upload Remote Code Execution Vulnerability Via uuid (CVE-2019-16113)
999731	CVE-2019-16113	WEB-MISC Bludit 3.9.2 - Image Upload Remote Code Execution Vulnerability Via filename (CVE-2019-16113)

Signature update for February 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-02-11. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 42 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999707		WEB-WORDPRESS WPCentral plug-in Prior to Version 1.4.8 - Privilege Escalation Vulnerability
999708	CVE-2019-15979	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - Command Injection Vulnerability (CVE-2019-15979)
999709	CVE-2019-15978	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - Command Injection Vulnerability (CVE-2019-15978)
999710	CVE-2019-15975	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - Authentication Bypass Vulnerability (CVE-2019-15975)
999711	CVE-2019-15976	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - Authentication Bypass Vulnerability (CVE-2019-15976)
999712	CVE-2019-16405	WEB-MISC Centreon Prior to Version 19.10.2 - Remote Code Execution Vulnerability (CVE-2019-16405)
999713	CVE-2020-7048	WEB-WORDPRESS WP Database Reset plug-in Up To 3.1 - Unauthenticated DataBase Table Reset Vulnerability (CVE-2020-7048)

Signature rule	CVE ID	Description
999714	CVE-2020-7108	WEB-WORDPRESS LearnDash plug-in Prior to Version 3.1.2 - Reflected cross-site scripting Vulnerability (CVE-2020-7108)
999715	CVE-2019-15977	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - Authentication Bypass Vulnerability (CVE-2019-15977)
999716	CVE-2020-2096	WEB-MISC Jenkins Gitlab Hook plug-in Version 1.4.2 and Prior - cross-site scripting Vulnerability (CVE-2020-2096)

Signature update for February 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-02-27. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 43 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999696	CVE-2019-15983	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - XML External Entity Vulnerability (CVE-2019-15983) Via CablePlans
999697	CVE-2019-20197	WEB-MISC Nagios XI 5.6.9 - Authenticated Arbitrary Command Execution Vulnerability (CVE-2019-20197)
999698	CVE-2020-8417	WEB-WORDPRESS Code Snippets plug-in Prior to 2.14.0 - CSRF Vulnerability (CVE-2020-8417)
999699		WEB-WORDPRESS WPCentral plug-in Prior to Version 1.4.8 - Privilege Escalation Vulnerability
999700	CVE-2020-8596	WEB-WORDPRESS Participants Database plug-in Prior To 1.9.5.6 - Authenticated SQL Injection Vulnerability (CVE-2020-8596)
999701	CVE-2020-8426	WEB-WORDPRESS Elementor Page Builder plug-in Prior To 2.8.5 - Authenticated Reflected cross-site scripting Vulnerability (CVE-2020-8426)
999702	CVE-2019-19509	WEB-MISC RConfig 3.9.3 - Remote Code Execution Vulnerability Via ajaxArchiveFiles.php (CVE-2019-19509)

Signature rule	CVE ID	Description
999703	CVE-2019-8449	WEB-MISC Atlassian Jira Server Before 8.4.0 - Information Disclosure Vulnerability (CVE-2019-8449)
999704	CVE-2019-9194	WEB-MISC elFinder Prior To 2.1.48 - PHP Connector Command Injection Vulnerability (CVE-2019-9194)
999705	CVE-2019-15985	WEB-MISC Cisco Data Center Network Manager Prior To 11.3(1) - SQL Injection Vulnerability (CVE-2019-15985) Via getVmHostData
999706	CVE-2020-8549	WEB-WORDPRESS Strong Testimonials plug-in Prior To 2.40.1 - Stored Cross Site Scripting Vulnerability (CVE-2020-8549)

Signature update for April 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-04-27. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 44 is applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999683	CVE-2020-9043	WEB-WORDPRESS wpCentral plug-in Prior To 1.5.1 - Connection Key Disclosure Vulnerability (CVE-2020-9043)
999684		WEB-WORDPRESS Duplicate-Post plug-in Version 3.2.3 and Prior - Persistent Cross-site Scripting
999685		WEB-WORDPRESS Duplicate-Post plug-in Version 3.2.3 and Prior - Persistent Cross-site Scripting
999686	CVE-2020-0618	WEB-MISC Microsoft SQL Server Reporting Services - Remote Code Execution Vulnerability (CVE-2020-0618)
999687	CVE-2019-16278	WEB-MISC Nostromo Nhttpd Prior to 1.3.7 - Strcutl Function Allows Unauthenticated Remote Code Execution (CVE-2019-16278)
999688	CVE-2019-1937	WEB-MISC Cisco UCS Director 6.6.0.0 to 6.6.1.0 and 6.7.0.0 to 6.7.1.0 - Authentication Bypass Vulnerability (CVE-2019-1937)
999689		WEB-WORDPRESS Duplicate-Post plug-in Version 3.2.3 and Prior - Persistent Cross-site Scripting

Signature rule	CVE ID	Description
999690	CVE-2020-9006	WEB-WORDPRESS Popup Builder plug-in Prior to 3.0 - SQL Injection Via PHP Deserialization Vulnerability (CVE-2020-9006)
999691		WEB-WORDPRESS Duplicate-Post plug-in Version 3.2.3 and Prior - Persistent Cross-site Scripting
999692		WEB-MISC prevent request smuggling via content-length and transfer-encoding header
999693		WEB-WORDPRESS ThemeGrill Demo Importer plug-in Prior To 1.6.3 - Authentication Bypass And Database Wipe Vulnerability
999694	CVE-2019-17237	WEB-WORDPRESS IgniteUp Coming Soon and Maintenance Mode plug-in Prior to 3.4.1 - CSRF Vulnerability Via Message (CVE-2019-17237)
999695	CVE-2019-17237	WEB-WORDPRESS IgniteUp Coming Soon and Maintenance Mode plug-in Prior to 3.4.1 - CSRF Vulnerability Via Subject (CVE-2019-17237)

Signature update for May 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-05-26. You can

download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 45 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU. According to the latest Snort release, the signature rules with ID 1258, 1306, 2520, 2661, 5695, 10996, 11817, 12056, 15471, 17049 and 21634 have been removed.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999666		WEB-WORDPRESS Duplicator plug-in Prior To 1.3.28 - Unauthenticated Arbitrary File Download Vulnerability
999667	CVE-2020-10220	WEB-MISC rConfig Through 3.94 - SQL Injection Vulnerability (CVE-2020-10220)
999668	CVE-2020-5844	WEB-MISC Artica Pandora FMS 7.0 - Execution of Arbitrary Files of Dangerous Type Via /attachment/files_repo/ (CVE-2020-5844)
999669	CVE-2020-8813	WEB-MISC Cacti Prior to 1.2.10 - Remote Code Execution Vulnerability Via graph_realtime.php (CVE-2020-8813)

Signature rule	CVE ID	Description
999670	CVE-2020-8654	WEB-MISC EyesOfNetwork 5.3 - Remote Code Execution Vulnerability (CVE-2020-8654)
999671	CVE-2020-10196	WEB-WORDPRESS Sygnoos Popup Builder plug-in Prior to 3.64.1 - Unauthenticated cross-site scripting Vulnerability (CVE-2020-10196)
999672	CVE-2019-15949	WEB-MISC Nagios XI Prior To 5.6.6 - Remote Code Execution As Root Vulnerability (CVE-2019-15949)
999673	CVE-2020-10879	WEB-MISC RConfig 3.9.5 and Prior - Remote Code Execution Vulnerability Via search.crud.php (CVE-2020-10879)
999674	CVE-2020-8656	WEB-MISC EyesOfNetwork 5.3 - EyesOfNetwork API 2.4.2 SQL Injection Vulnerability (CVE-2020-8656)
999675	CVE-2020-10195	WEB-WORDPRESS Sygnoos Popup Builder plug-in Prior to 3.64.1 - Authenticated System Information Disclosure (CVE-2020-10195)
999676	CVE-2020-10195	WEB-WORDPRESS Sygnoos Popup Builder plug-in Prior to 3.64.1 - Authenticated Subscriber Information Disclosure (CVE-2020-10195)

Signature rule	CVE ID	Description
999677	CVE-2020-10195	WEB-WORDPRESS Sygnoos Popup Builder plug-in Prior to 3.64.1 - Authenticated Settings Modification (CVE-2020-10195)
999678	CVE-2020-0646	Microsoft SharePoint Server - .NET Framework Workflow Remote Code Execution Vulnerability Via SOAP 1.2 (CVE-2020-0646)
999679	CVE-2020-0646	Microsoft SharePoint Server - .NET Framework Workflow Remote Code Execution Vulnerability Via SOAP 1.1 (CVE-2020-0646)
999680	CVE-2020-10221	WEB-MISC rConfig Through 3.94 - Remote Code Execution Vulnerability (CVE-2020-10221)
999681	CVE-2019-19134	WEB-WORDPRESS Hero Maps Premium Prior to 2.2.3 - Unauthenticated Reflected cross-site scripting Vulnerability (CVE-2019-19134)
999682	CVE-2020-10385	WEB-WORDPRESS WPForms plug-in Prior to 1.5.9 - Stored cross-site scripting Vulnerability (CVE-2020-10385)

Signature update for June 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-06-03. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 46 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999643		WEB-WORDPRESS 10Web Map Builder for Google Maps plug-in Prior to 10.0.64 - Unauthenticated cross-site scripting Vulnerability Via gmwd_setup Page
999644		WEB-WORDPRESS 10Web Map Builder for Google Maps plug-in 10.0.64 and Prior - cross-site scripting Vulnerability Via options_gmwd Page
999645	CVE-2020-5187	WEB-MISC DNN Up To 9.4.4 - Path Traversal Vulnerability Via URL (CVE-2020-5187)
999646	CVE-2020-5187	WEB-MISC DNN Up To 9.4.4 - Path Traversal Vulnerability Via Local (CVE-2020-5187)

Signature rule	CVE ID	Description
999647	CVE-2020-9335	WEB-WORDPRESS Photo Gallery plug-in Prior to 1.5.46 - cross-site scripting Vulnerability Via image_alt_text_ Field (CVE-2020-9335)
999648	CVE-2020-9335	WEB-WORDPRESS Photo Gallery plug-in Prior to 1.5.46 - cross-site scripting Vulnerability Via Name Field (CVE-2020-9335)
999649	CVE-2020-9335	WEB-WORDPRESS Photo Gallery plug-in Prior to 1.5.46 - cross-site scripting Vulnerability Via Description Fields (CVE-2020-9335)
999650	CVE-2020-10189	WEB-MISC Zoho ManageEngine Desktop Central Prior to 10.0.479 - Unauthenticated Remote Code Execution Vuln (CVE-2020-10189)
999651	CVE-2020-10189	WEB-MISC Zoho ManageEngine Desktop Central Prior to 10.0.479 - Unauthenticated Arbitrary File Upload Vuln (CVE-2020-10189)
999652		WEB-WORDPRESS Flexible Checkout Fields for WooCommerce plug-in Prior to 2.3.2 - Unauthenticated Settings Modification Vuln

Signature rule	CVE ID	Description
999653	CVE-2020-0688	WEB-MISC Microsoft Exchange Server - Validation Key Remote Code Execution Vulnerability (CVE-2020-0688)
999654	CVE-2020-8947, CVE-2019-20224	WEB-MISC Artica Pandora FMS 7.0 - Remote Code Execution Vulnerability Via ip_src Parameter (CVE-2020-8947, CVE-2019-20224)
999655	CVE-2020-8947, CVE-2019-20224	WEB-MISC Artica Pandora FMS 7.0 - Remote Code Execution Vulnerability Via dst_port Parameter (CVE-2020-8947, CVE-2019-20224)
999656	CVE-2020-8947, CVE-2019-20224	WEB-MISC Artica Pandora FMS 7.0 - Remote Code Execution Vulnerability Via src_port Parameter (CVE-2020-8947, CVE-2019-20224)
999657	CVE-2020-8947, CVE-2019-20224	WEB-MISC Artica Pandora FMS 7.0 - Remote Code Execution Vulnerability Via ip_dst Parameter (CVE-2020-8947, CVE-2019-20224)
999658	CVE-2020-5186	WEB-MISC DNN Up To 9.5.0 - Cross Site Scripting Vulnerability Via Journal XML Upload (CVE-2020-5186)

Signature rule	CVE ID	Description
999659		WEB-WORDPRESS WP Sitemap Page plug-in 1.6.2 and Prior - cross-site scripting Vulnerability Via wsp_exclude_pages
999660	CVE-2020-5188	WEB-MISC DNN Up To 9.5.0 - Insecure Permissions Vulnerability Via UploadFromUrl (CVE-2020-5188)
999661	CVE-2020-5188	WEB-MISC DNN Up To 9.5.0 - Insecure Permissions Vulnerability Via UploadFromLocal (CVE-2020-5188)
999662	CVE-2020-7799	WEB-MISC FusionAuth Prior To 1.11.0 - Remote Code Execution Vulnerability Via API Theme (CVE-2020-7799)
999663	CVE-2020-7799	WEB-MISC FusionAuth Prior To 1.11.0 - Remote Code Execution Vulnerability Via API Email Template (CVE-2020-7799)
999664	CVE-2020-7799	WEB-MISC FusionAuth Prior To 1.11.0 - Remote Code Execution Vulnerability Via GUI Theme (CVE-2020-7799)
999665	CVE-2020-7799	WEB-MISC FusionAuth Prior To 1.11.0 - Remote Code Execution Vulnerability Via GUI Email Template (CVE-2020-7799)

Signature update for June 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-06-12. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 47 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999580	CVE-2020-6010	WEB-WORDPRESS LearnPress LMS plug-in Prior to 3.2.6.9 - SQL Injection Vulnerability (CVE-2020-6010)
999581		WEB-MISC Nagios XI Up To 5.6.13 - Service Command_Test Arbitrary Command Execution Vulnerability
999582	CVE-2020-0932	Microsoft SharePoint Server - WebPart Source Markup Remote Code Execution Vulnerability Via SOAP 1.2 (CVE-2020-0932)

Signature rule	CVE ID	Description
999583	CVE-2020-0932	Microsoft SharePoint Server - WebPart Source Markup Remote Code Execution Vulnerability Via SOAP 1.1 (CVE-2020-0932)
999584	CVE-2020-12642	WEB-WORDPRESS Ninja Forms plug-in Prior to 3.4.24.2 - Cross-Site Request Forgery Vulnerability via Import Fields (CVE-2020-12642)
999585	CVE-2020-12642	WEB-WORDPRESS Ninja Forms plug-in Prior to 3.4.24.2 - Cross-Site Request Forgery Vulnerability via Import Form (CVE-2020-12642)
999586	CVE-2020-11450	WEB-MISC Microstrategy Web 10.4 - Information Disclosure Vulnerability (CVE-2020-11450)
999587	CVE-2020-7935	WEB-MISC Artica Pandora FMS 7.0 - Unrestricted Upload of File With Dangerous Type Vulnerability Allows RCE (CVE-2020-7935)
999588	CVE-2020-12116	WEB-MISC Zoho ManageEngine OpManager Prior to Build 125125 - Information Disclosure Vulnerability (CVE-2020-12116)
999589		WEB-WORDPRESS Elementor Page Builder Prior to 2.9.6 - Privilege Escalation Vulnerability

Signature rule	CVE ID	Description
999590	CVE-2020-11738	WEB-WORDPRESS - Snap Creek Duplicator plug-in Prior to 1.3.28 - Path Traversal Vulnerability (CVE-2020-11738)
999591	CVE-2020-10389	WEB-MISC Chadha PHPKB Standard Multi-Language 9 - Remote Code Execution vulnerability (CVE-2020-10389)
999592	CVE-2020-11516	WEB-WORDPRESS Contact Form 7 Datepicker plug-in Up To 2.6.0 - Stored cross-site scripting Vulnerability (CVE-2020-11516)
999593		WEB-MISC Nagios XI Up To 5.6.13 - Export-RRD Arbitrary Command Execution Vulnerability Via Step
999594		WEB-MISC Nagios XI Up To 5.6.13 - Export-RRD Arbitrary Command Execution Vulnerability Via End
999595		WEB-MISC Nagios XI Up To 5.6.13 - Export-RRD Arbitrary Command Execution Vulnerability Via Start
999596	CVE-2019-19799	Zoho ManageEngine Applications Manager Previous To 14600 - Information Disclosure Vulnerability (CVE-2019-19799)

Signature rule	CVE ID	Description
999597	CVE-2020-10458	WEB-MISC Chadha PHPKB Standard Multi-Language 9 - Arbitrary Folder Deletion Vulnerability (CVE-2020-10458)
999598	CVE-2017-9822	WEB-MISC DNN Before 9.1.1 - Remote Code Execution Vulnerability Via DNNPersonalization Cookie (CVE-2017-9822)
999599	CVE-2020-7953	WEB-MISC OpServices OpMon 9.3.2 - Unauthenticated Information Disclosure Vulnerability Via nmap_options Param (CVE-2020-7953)
999600	CVE-2020-7953	WEB-MISC OpServices OpMon 9.3.2 - Unauthenticated Information Disclosure Vulnerability Via host Param (CVE-2020-7953)
999601		WEB-MISC Bolt CMS 3.7.0 - File Rename to a Dangerous Type Vulnerability Via newname Parameter
999602		WEB-MISC Bolt CMS 3.7.0 - Path Traversal Vulnerability Via newname Parameter
999603		WEB-MISC Bolt CMS 3.7.0 - Path Traversal Vulnerability Via oldname Parameter
999604		WEB-MISC Bolt CMS 3.7.0 - Path Traversal Vulnerability Via parent Parameter

Signature rule	CVE ID	Description
999605		WEB-MISC Bolt CMS 3.7.0 - Improper Field Validation Vulnerability in displayname Parameter
999606	CVE-2020-9004	WEB-MISC - Wowza Streaming Engine 4.7.8 - Incorrect Authorization Vulnerability in View Logs (CVE-2020-9004)
999607	CVE-2020-9004	WEB-MISC - Wowza Streaming Engine 4.7.8 - Incorrect Authorization Vulnerability in Media Cache Settings (CVE-2020-9004)
999608	CVE-2020-9004	WEB-MISC - Wowza Streaming Engine 4.7.8 - Incorrect Authorization Vulnerability in Applications Settings (CVE-2020-9004)
999609	CVE-2020-9004	WEB-MISC - Wowza Streaming Engine 4.7.8 - Incorrect Authorization Vulnerability in Server Settings (CVE-2020-9004)
999610		WEB-MISC PrestaShop 1.7.6.5 - CSRF Vulnerability via Filemanager
999611	CVE-2020-10238	WEB-MISC Joomla! Previous To 3.9.16 - Security Bypass Vulnerability via com_templates (CVE-2020-10238)
999612	CVE-2020-11510	WEB-WORDPRESS LearnPress LMS plug-in Prior to 3.2.6.9 - Privilege Escalation Via learnpress_create_page (CVE-2020-11510)

Signature rule	CVE ID	Description
999613	CVE-2020-11510	WEB-WORDPRESS LearnPress LMS plug-in Prior to 3.2.6.9 - Privilege Escalation Via learn-press_update_order_status (CVE-2020-11510)
999614	CVE-2020-8636	WEB-MISC OpServices OpMon 9.3.2 - Unauthenticated Remote Code Execution Vulnerability Via nmap_options Parameter (CVE-2020-8636)
999615	CVE-2020-8636	WEB-MISC OpServices OpMon 9.3.2 - Unauthenticated Remote Code Execution Vulnerability Via host Parameter (CVE-2020-8636)
999616	CVE-2020-11511	WEB-WORDPRESS LearnPress LMS plug-in Prior to 3.2.6.9 - Privilege Escalation Via accept-to-be-teacher (CVE-2020-11511)
999617	CVE-2020-11451	WEB-MISC Microstrategy Web - Unsecure File Type Upload Vulnerability Via JSP (CVE-2020-11451)
999618	CVE-2020-11451	WEB-MISC Microstrategy Web - Unsecure File Type Upload Vulnerability Via ASP (CVE-2020-11451)
999619	CVE-2020-11515	WEB-WORDPRESS WP SEO plug-in Rank Math Prior to 1.0.41 - Redirection Vulnerability Via REST API Through URL (CVE-2020-11515)

Signature rule	CVE ID	Description
999620	CVE-2020-11515	WEB-WORDPRESS WP SEO plug-in Rank Math Prior to 1.0.41 - Redirection Vulnerability Via REST API rest_route Param (CVE-2020-11515)
999621	CVE-2020-10457	WEB-MISC Chadha PHPKB Standard Multi-Language 9 - Arbitrary File Renaming Vulnerability Via imgName (CVE-2020-10457)
999622	CVE-2020-10457	WEB-MISC Chadha PHPKB Standard Multi-Language 9 - Arbitrary File Renaming Vulnerability Via imgUrl (CVE-2020-10457)
999623	CVE-2019-1821	WEB-MISC Cisco Prime Infrastructure - Remote Code Execution Vulnerability (CVE-2019-1821)
999624		WEB-WORDPRESS Page Builder plug-in Prior to 2.10.16 - CSRF Vulnerability Via Ajax action_builder_content
999625		WEB-WORDPRESS Page Builder plug-in Prior to 2.10.16 - CSRF Vulnerability Via Live Editor
999626	CVE-2020-11514	WEB-WORDPRESS WP SEO plug-in Rank Math Prior to 1.0.41 - Privilege Escalation Via REST API Through URL (CVE-2020-11514)

Signature rule	CVE ID	Description
999627	CVE-2020-11514	WEB-WORDPRESS WP SEO plug-in Rank Math Prior to 1.0.41 - Privilege Escalation Via REST API rest_route Param (CVE-2020-11514)
999628	CVE-2019-6713	WEB-MISC ThinkCMF Prior to 5.0.190312 - Code Injection Vulnerability Via /route/editpost.html (CVE-2019-6713)
999629	CVE-2019-6713	WEB-MISC ThinkCMF Prior to 5.0.190312 - Code Injection Vulnerability Via /route/addpost.html (CVE-2019-6713)
999630		WEB-WORDPRESS Google Site Kit plug-in Prior to 1.8.0 - Unprotected Verification Vulnerability
999631	CVE-2020-9315	WEB-MISC Oracle iPlanet Web Server 7.0.x - Incorrect Access Control Vulnerability (CVE-2020-9315)
999632	CVE-2020-1947	WEB-MISC Apache ShardingSphere 4.0.0-RC3 and 4.0.0 - SnakeYAML Remote Code Execution Vulnerability (CVE-2020-1947)
999633	CVE-2020-7961	Liferay Portal Prior To 7.2.1 CE GA2 - JSONWS Deserialization RCE Vulnerability Via JSON-RPC (CVE-2020-7961)
999634	CVE-2020-7961	Liferay Portal Prior To 7.2.1 CE GA2 - JSONWS Deserialization RCE Vulnerability Via URL Path (CVE-2020-7961)

Signature rule	CVE ID	Description
999635	CVE-2020-7961	Liferay Portal Prior To 7.2.1 CE GA2 - JSONWS Deserialization RCE Vulnerability Via Form And URI Query (CVE-2020-7961)
999636	CVE-2020-8518	WEB-MISC Horde Groupware Webmail Edition 5.2.22 - Remote Code Execution Vulnerability (CVE-2020-8518)
999637	CVE-2020-7351	WEB-MISC Fonality Trixbox CE 2.8.0.4 and Prior - Remote Code Execution Vulnerability (CVE-2020-7351)
999638	CVE-2020-12720	WEB-MISC vBulletin Prior to 5.6.1 Patch Level 1 - Unauthenticated SQL Injection Vulnerability (CVE-2020-12720)
999639	CVE-2019-19800	Zoho ManageEngine Applications Manager Previous To 14520 - Path Traversal Vulnerability (CVE-2019-19800)
999640	CVE-2020-10386	WEB-MISC Chadha PHPKB Standard Multi-Language 9 - Remote Code Execution (CVE-2020-10386)
999641	CVE-2020-8497	WEB-MISC Artica Pandora FMS 7.0 - Unauthenticated Information Disclosure Vulnerability (CVE-2020-8497)

Signature rule	CVE ID	Description
999642	CVE-2020-6009	WEB-WORDPRESS LearnDash LMS plug-in Prior to 3.1.6 - Unauthenticated SQL Injection Vulnerability (CVE-2020-6009)

Signature update for July 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-07-01. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 48 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999563		WEB-WORDPRESS Page Builder PageLayer plug-in Prior to 1.1.2 - cross-site scripting Vulnerability Via pagelayer_cf_to_email

Signature rule	CVE ID	Description
999564		WEB-WORDPRESS Page Builder PageLayer plug-in Prior to 1.1.2 - cross-site scripting Vulnerability Via pagelayer-phone
999565		WEB-WORDPRESS Page Builder PageLayer plug-in Prior to 1.1.2 - cross-site scripting Vulnerability Via pagelayer-address
999566	CVE-2020-1961	WEB-MISC Apache Syncope - Server-Side Template Injection Vulnerability (CVE-2020-1961)
999567	CVE-2019-18935	WEB-MISC Progress Telerik UI For ASP.NET AJAX - RadAsyncUpload .NET Deserialization Vulnerability (CVE-2019-18935)
999568	CVE-2020-9463	WEB-MISC Centreon 19.10 - OS Command Injection Vulnerability (CVE-2020-9463)
999569		WEB-WORDPRESS Support Review plug-in Prior to 3.7.6 - Unauthenticated Stored Cross Site Scripting Vulnerability
999570		WEB-WORDPRESS Page Builder PageLayer plug-in Prior to 1.1.2 - Improper Access Control Vuln Via pagelayer_save_template
999571		WEB-WORDPRESS Page Builder PageLayer plug-in Prior to 1.1.2 - Improper Access Control Vuln Via pagelayer_update_site_title

Signature rule	CVE ID	Description
999572		WEB-WORDPRESS Page Builder PageLayer plug-in Prior to 1.1.2 - Improper Access Control Vuln Via pagelayer_save_content
999573		WEB-WORDPRESS Drag And Drop Upload For Contact Form 7 Prior To 1.3.3.3 - Arbitrary File Extension Upload Vulnerability
999574	CVE-2020-9314	WEB-MISC Oracle iPlanet Web Server 7.0.x - Image Injection Vulnerability (CVE-2020-9314)
999575	CVE-2020-9484	WEB-MISC Apache Tomcat Multiple Versions - Deserialization of Untrusted Data (CVE-2020-9484)
999576	CVE-2020-13252	WEB-MISC Centreon Prior to 19.04.15 - Remote Code Execution Vulnerability (CVE-2020-13252)
999577	CVE-2020-11453	WEB-MISC Microstrategy Web - CSRF Vulnerability Via SOAP (CVE-2020-11453)
999578	CVE-2020-11453	WEB-MISC Microstrategy Web - CSRF Vulnerability (CVE-2020-11453)
999579	CVE-2020-7237	WEB-MISC Cacti Prior to 1.2.8 - Remote Code Execution Vulnerability (CVE-2020-7237)

Signature update for August 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-08-26. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 49 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999556	CVE-2020-13241	WEB-MISC Microweber 1.1.18 - Unrestricted Upload of File with Dangerous Type Vulnerability (CVE-2020-13241)
999557	CVE-2020-3250	WEB-MISC Cisco UCS Director - REST API Path Traversal Vulnerability Via userAPIDownloadFile (CVE-2020-3250)
999558		WEB-WORDPRESS PageBuilder KingComposer plug-in Prior to 2.9.4 - Arbitrary Deletion of Directories Via action=bulk-delete
999559		WEB-WORDPRESS PageBuilder KingComposer plug-in Prior to 2.9.4 - Remote Code Execution Vulnerability Via action=upload

Signature rule	CVE ID	Description
999560	CVE-2018-1999024	WEB-MISC Moodle - MathJax Unicode cross-site scripting Vulnerability (CVE-2018-1999024)
999561	CVE-2020-13693	WEB-WORDPRESS bbPress plug-in Prior To 2.6.5 - Unauthenticated Privilege Escalation Vulnerability (CVE-2020-13693)
999562	CVE-2020-12847	WEB-MISC Pydio Cells Prior to 2.0.7 - Remote Code Execution Vulnerability (CVE-2020-12847)

Signature update for September 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-09-26. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 50 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999532	CVE-2020-1956	WEB-MISC Apache Kylin - Cube Migrate Remote Code Execution Via dest-config (CVE-2020-1956)
999533	CVE-2020-1956	WEB-MISC Apache Kylin - Cube Migrate Remote Code Execution Via src-config (CVE-2020-1956)
999534	CVE-2020-1956	WEB-MISC Apache Kylin - Cube Migrate Remote Code Execution Via projectName (CVE-2020-1956)
999535	CVE-2020-3247	WEB-MISC Cisco UCS Director - CopyFileRunnable Arbitrary Symlink Creation Vulnerability (CVE-2020-3247)
999536	CVE-2019-16872	WEB-MISC Portainer Prior To 1.22.1 - Incorrect Access Control Vulnerability Via Update Stacks (CVE-2019-16872)
999537	CVE-2019-16872	WEB-MISC Portainer Prior To 1.22.1 - Incorrect Access Control Vulnerability Via Create Stacks (CVE-2019-16872)
999538	CVE-2020-13855	WEB-MISC Artica Pandora FMS 7.44 - Arbitrary File Upload Vulnerability Via File Repository Manager (CVE-2020-13855)
999539	CVE-2020-5902	WEB-MISC F5 BIG-IP - Traffic Management User Interface RCE Vulnerability Via /hsqldb (CVE-2020-5902)

Signature rule	CVE ID	Description
999540	CVE-2020-5902	WEB-MISC F5 BIG-IP - Traffic Management User Interface RCE Vulnerability Via /tmui (CVE-2020-5902)
999541		WEB-MISC WebERP 4.15.1 and Prior - Unauthenticated Information Disclosure Vulnerability
999542	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via timeline.php and timestamp Param (CVE-2020-7209)
999543	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via kivis.php and ts Param (CVE-2020-7209)
999544	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via kivis.php and end Param (CVE-2020-7209)
999545	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via kivis.php and start Param (CVE-2020-7209)
999546	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via kivis.php and pid Param (CVE-2020-7209)
999547	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via kidsk_trace_view.php and end Param (CVE-2020-7209)

Signature rule	CVE ID	Description
999548	CVE-2020-7209	WEB-MISC HP LinuxKI Prior to 6.0-2 - Unauthenticated RCE Vulnerability Via kidsk_trace_view.php and start Param (CVE-2020-7209)
999549		WEB-MISC PHP-Fusion Prior to 9.03.70 - PHP Object Injection Vulnerability
999550	CVE-2020-1181	WEB-MISC Microsoft SharePoint Server - Remote Code Execution via Web Parts (CVE-2020-1181)
999551	CVE-2020-10547	WEB-MISC rConfig Prior to 3.9.5 - Unauthenticated SQLi Vulnerability in Policy Elements Via searchColumn (CVE-2020-10547)
999552	CVE-2020-10547	WEB-MISC rConfig Prior to 3.9.5 - Unauthenticated SQLi Vulnerability in Policy Elements Via searchField (CVE-2020-10547)
999553	CVE-2020-8605	WEB-MISC Trend Micro InterScan Web Security Virtual Appliance Prior to 6.5 SP2 Patch 4 - RCE Vulnerability (CVE-2020-8605)
999554	CVE-2019-10068	WEB-MISC Kentico CMS Multiple Versions - Unauthenticated Remote Code Execution Vulnerability (CVE-2019-10068)

Signature rule	CVE ID	Description
999555	CVE-2020-11108	WEB-MISC Pi-hole Up To 4.4 - Authenticated RCE Vulnerability (CVE-2020-11108)

Signature update for Oct 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-10-13. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 51 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999505		WEB-WORDPRESS WordPress plug-in wpDiscuz 7.0.0 Up To 7.0.4 - Unauthenticated Arbitrary File Upload Vulnerability
999506		WEB-WORDPRESS Quiz & Survey Master - cross-site scripting Vulnerability in Questions Feature

Signature rule	CVE ID	Description
999507	CVE-2020-8604	WEB-MISC Trend Micro IWS VA Prior to 6.5 SP2 Patch 4 - Path Traversal Vuln Via /log_search and cf Param (CVE-2020-8604)
999508	CVE-2020-8604	WEB-MISC Trend Micro IWS VA Prior to 6.5 SP2 Patch 4 - Path Traversal Vuln Via /collection and cf Param (CVE-2020-8604)
999509	CVE-2020-8604	WEB-MISC Trend Micro IWS VA Prior to 6.5 SP2 Patch 4 - Path Traversal Vuln Via /log_search and File Param (CVE-2020-8604)
999510	CVE-2020-8604	WEB-MISC Trend Micro IWS VA Prior to 6.5 SP2 Patch 4 - Path Traversal Vuln Via /collection and File Param (CVE-2020-8604)
999511	CVE-2020-7361	WEB-MISC ZenTao Enterprise 8.8.3 and Prior - Remote Code Execution Vulnerability Via Repo-Edit (CVE-2020-7361)
999512	CVE-2020-7361	WEB-MISC ZenTao Pro 8.8.3 and Prior - Remote Code Execution Vulnerability Via Repo-Edit (CVE-2020-7361)
999513	CVE-2020-7361	WEB-MISC ZenTao Enterprise 8.8.3 and Prior - Remote Code Execution Vulnerability Via Repo-Create (CVE-2020-7361)
999514	CVE-2020-7361	WEB-MISC ZenTao Pro 8.8.3 and Prior - Remote Code Execution Vulnerability Via Repo-Create (CVE-2020-7361)

Signature rule	CVE ID	Description
999515	CVE-2020-5768	WEB-WORDPRESS Icegram Email Subscribers & Newsletters plug-in Prior to 4.5.1 - SQL Injection Vulnerability (CVE-2020-5768)
999516	CVE-2020-5767	WEB-WORDPRESS Icegram Email Subscribers & Newsletters plug-in Prior to 4.5.1 - CSRF Vulnerability (CVE-2020-5767)
999517	CVE-2020-15299	WEB-WORDPRESS KingComposer plug-in Prior To 2.9.5 - cross-site scripting Vulnerability (CVE-2020-15299)
999518	CVE-2020-13854	WEB-MISC Artica Pandora FMS - Privilege Escalation Vulnerability (CVE-2020-13854)
999519	CVE-2020-13852	WEB-MISC Artica Pandora FMS - Arbitrary File Upload Vulnerability Via File Manager (CVE-2020-13852)
999520	CVE-2020-13700	WEB-WORDPRESS WordPress plug-in acf-to-rest-api Before 3.3.0 - Information Disclosure Vulnerability Via URI (CVE-2020-13700)
999521	CVE-2020-13700	WEB-WORDPRESS WordPress plug-in acf-to-rest-api Before 3.3.0 - Information Disclosure Vulnerability Via URL (CVE-2020-13700)

Signature rule	CVE ID	Description
999522	CVE-2020-13379	WEB-MISC Grafana 3.0.1 Through 7.0.1 - CSRF Bypass Leading To DOS Vulnerability (CVE-2020-13379)
999523	CVE-2020-12851	WEB-MISC Pydio Cells Prior to 2.0.7 - Arbitrary File Write Vulnerability (CVE-2020-12851)
999524	CVE-2020-12848	WEB-MISC Pydio Cells Prior to 2.0.7 - Login as Temporary Shared User Vulnerability (CVE-2020-12848)
999525	CVE-2020-11749	WEB-MISC Artica Pandora FMS Prior To 7.47 - cross-site scripting Vulnerability Via SNMP Browser (CVE-2020-11749)
999526	CVE-2020-11579	WEB-MISC PHPKBV9 - File Exfiltration Vulnerability (CVE-2020-11579)
999527	CVE-2020-10546	WEB-MISC rConfig Prior to 3.9.5 - Unauthenticated SQLi Vulnerability in Compliance Policies Via searchColumn (CVE-2020-10546)
999528	CVE-2020-10546	WEB-MISC rConfig Prior to 3.9.5 - Unauthenticated SQLi Vulnerability in Compliance Policies Via searchField (CVE-2020-10546)
999529	CVE-2019-16876	WEB-MISC Portainer Prior To 1.22.1 - Directory Traversal Vulnerability (CVE-2019-16876)

Signature rule	CVE ID	Description
999530		WEB-WORDPRESS - ADning plug-in Prior to 1.5.6 - Unauthenticated Arbitrary File Deletion Vulnerability
999531		WEB-WORDPRESS - ADning plug-in Prior to 1.5.6 - Unauthenticated Arbitrary File Upload Vulnerability

Signature update for October 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-10-29. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 52 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU. Also, vulnerable versions are mentioned in some of the signature rule log string. You must enable it accordingly.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999500	CVE-2018-14667	WEB-MISC RichFaces Framework 3.X Through 3.3.4 - EL Injection Via UserResource (CVE-2018-14667)
999501	CVE-2018-12533	WEB-MISC RichFaces Framework 3.1.0 Through 3.3.4 - EL Injection Via Paint2DResource (CVE-2018-12533)
999502	CVE-2015-0279, CVE-2018-12532	WEB-MISC RichFaces Framework 4.X Through 4.5.17 - EL Injection Via MediaOutputResource (CVE-2015-0279,CVE-2018-12532)
999503	CVE-2013-2165	WEB-MISC RichFaces v4 Prior to 4.3.3 - Java Object Deserialization Vulnerability (CVE-2013-2165)
999504	CVE-2013-2165	WEB-MISC RichFaces v3 Prior to 3.3.4 - Java Object Deserialization Vulnerability (CVE-2013-2165)

Signature update for November 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-11-10. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 53 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999411		WEB-WORDPRESS WordPress plug-in wpDiscuz 7.0.0 Up To 7.0.4 - Unauthenticated Arbitrary File Upload Vulnerability
999412		WEB-WORDPRESS Quiz & Survey Master - cross-site scripting Vulnerability in Questions Feature
999413		WEB-WORDPRESS WordPress plug-in File Manager Prior To 6.9 - Unauthenticated elFinder Commands Execution Vulnerability
999414	CVE-2020-11700	WEB-MISC Titan SpamTitan Prior To 7.08 - Information Disclosure Vulnerability (CVE-2020-11700)
999415	CVE-2020-9446	WEB-MISC Apache OFBiz 17.12.03 - XML-RPC Unsafe Deserialization Vulnerability (CVE-2020-9446)
999416	CVE-2020-9446	WEB-MISC Apache OFBiz 17.12.03 - XML-RPC Cross-Site Scripting Vulnerability (CVE-2020-9446)

Signature rule	CVE ID	Description
999417	CVE-2020-9047	WEB-MISC exacqVision Web Service Up To 20.06.3.0 - OS Command Injection Vulnerability (CVE-2020-9047)
999418	CVE-2020-8866	WEB-MISC Horde Groupware Webmail Edition 5.2.22 - Unrestricted Upload of File Vulnerability Via edit.php (CVE-2020-8866)
999419	CVE-2020-8866	WEB-MISC Horde Groupware Webmail Edition 5.2.22 - Unrestricted Upload of File Vulnerability Via add.php (CVE-2020-8866)
999420	CVE-2020-8865	WEB-MISC Horde Groupware Webmail Edition 5.2.22 - Arbitrary File Inclusion Vulnerability Via edit.php (CVE-2020-8865)
999421	CVE-2020-8816	WEB-MISC Pi-hole Prior To 4.3.2 - Remote Code Execution Vulnerability Via removestatic (CVE-2020-8816)
999422	CVE-2020-8816	WEB-MISC Pi-hole Prior To 4.3.2 - Remote Code Execution Vulnerability Via AddMAC (CVE-2020-8816)
999423	CVE-2020-8243	WEB-MISC Pulse Connect Secure Prior To 9.1R8.2 - Remote Code Execution Vulnerability (CVE-2020-8243)
999424	CVE-2020-8218	WEB-MISC Pulse Connect Secure Prior To 9.1R8 - Remote Code Execution Vulnerability (CVE-2020-8218)

Signature rule	CVE ID	Description
999425	CVE-2020-6143, CVE-2020-6144	WEB-MISC OS4Ed OpenSIS - Code Injection Vulnerability Via /install/Ins1.php (CVE-2020-6143, CVE-2020-6144)
999426	CVE-2020-6142	WEB-MISC OS4Ed OpenSIS - Path Traversal Vulnerability Via modname (CVE-2020-6142)
999427	CVE-2020-6141	WEB-MISC OS4Ed OpenSIS Prior to 7.4 - Unauthenticated SQLi Vulnerability Via USERNAME (CVE-2020-6141)
999428	CVE-2020-6140	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - Unauthenticated SQLi Vulnerability Via username_stn_id (CVE-2020-6140)
999429	CVE-2020-6139	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - Unauthenticated SQLi Vulnerability Via username_stf_email (CVE-2020-6139)
999430	CVE-2020-6138	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - Unauthenticated SQLi Vulnerability Via uname (CVE-2020-6138)
999431	CVE-2020-6137	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - Unauthenticated SQLi Vulnerability Via password_stf_email (CVE-2020-6137)

Signature rule	CVE ID	Description
999432	CVE-2020-6125	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via GetSchool.php and u Parameter (CVE-2020-6125)
999433	CVE-2020-6124	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via EmailCheckOthers.php (CVE-2020-6124)
999434	CVE-2020-6123	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via EmailCheck.php and p_id Parameter (CVE-2020-6123)
999435	CVE-2020-6123	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via EmailCheck.php and email Parameter (CVE-2020-6123)
999436	CVE-2020-6122	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CheckDuplicateStudent.php and mn Parameter (CVE-2020-6122)
999437	CVE-2020-6121	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CheckDuplicateStudent.php and ln Parameter (CVE-2020-6121)

Signature rule	CVE ID	Description
999438	CVE-2020-6120	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CheckDuplicateStudent.php and fn Parameter (CVE-2020-6120)
999439	CVE-2020-6119	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CheckDuplicateStudent.php and byear Parameter (CVE-2020-6119)
999440	CVE-2020-6118	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CheckDuplicateStudent.php and bmonth Parameter (CVE-2020-6118)
999441	CVE-2020-6117	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CheckDuplicateStudent.php and bday Parameter (CVE-2020-6117)
999442	CVE-2020-5780	WEB-WORDPRESS WordPress plug-in Email Subscribers And Newsletters Prior To 4.5.6 - Email Forgery Vulnerability (CVE-2020-5780)
999443	CVE-2020-4280	WEB-MISC IBM QRadar SIEM 7.3 and 7.4 - Insecure Java Deserialization Vulnerability Via JSON-RPC (CVE-2020-4280)

Signature rule	CVE ID	Description
999444	CVE-2020-4280	WEB-MISC IBM QRadar SIEM 7.3 and 7.4 - Insecure Java Deserialization Vulnerability Via remoteMethod (CVE-2020-4280)
999445	CVE-2020-4280	WEB-MISC IBM QRadar SIEM 7.3 and 7.4 - Insecure Java Deserialization Vulnerability Via remoteJavaScript (CVE-2020-4280)
999446	CVE-2020-4280	WEB-MISC IBM QRadar SIEM 7.3 and 7.4 - Insecure Java Deserialization Vulnerability Via JSON-RPC (CVE-2020-4280)
999447	CVE-2020-4280	WEB-MISC IBM QRadar SIEM 7.3 and 7.4 - Insecure Java Deserialization Vulnerability Via remoteMethod (CVE-2020-4280)
999448	CVE-2020-4280	WEB-MISC IBM QRadar SIEM 7.3 and 7.4 - Insecure Java Deserialization Vulnerability Via remoteJavaScript (CVE-2020-4280)
999449	CVE-2020-24786	WEB-MISC Zoho ManageEngine ADManager Plus 7.0 Prior to Build 55 - Improper Authentication Vulnerability (CVE-2020-24786)
999450	CVE-2020-24389	WEB-WORDPRESS Drag and Drop Multiple File Uploader plug-in Prior To 1.3.5.5 - Security Bypass Vulnerability (CVE-2020-24389)

Signature rule	CVE ID	Description
999451	CVE-2020-24046	WEB-MISC TitanHQ SpamTitan Gateway 7.08 - Privilege Escalation Vulnerability (CVE-2020-24046)
999452	CVE-2020-17506	WEB-MISC Artica Web Proxy 4.30.000000 - PreAuth SQL Injection Vulnerability Via Apikey Parameter (CVE-2020-17506)
999453	CVE-2020-17505	WEB-MISC Artica Web Proxy 4.30.000000 - OS Command Injection Vulnerability Via Service-cmds-peform Parameter (CVE-2020-17505)
999454	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/users/items (CVE-2020-17463)
999455	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/sitevariables/items (CVE-2020-17463)
999456	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/permissions/items (CVE-2020-17463)
999457	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/pages/items (CVE-2020-17463)
999458	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/navigation/items (CVE-2020-17463)

Signature rule	CVE ID	Description
999459	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/logs/items (CVE-2020-17463)
999460	CVE-2020-17463	WEB-MISC Fuel CMS 1.4.8 - SQLi Vulnerability Via /fuel/blocks/items (CVE-2020-17463)
999461	CVE-2020-16875	WEB-MISC Microsoft Exchange Server - DLP Policy Remote Code Execution Vulnerability (CVE-2020-16875)
999462	CVE-2020-16171	WEB-MISC Acronis Cyber Backup Prior To 12.5 Build 16342 - SSRF Via Shard Header Vulnerability (CVE-2020-16171)
999463	CVE-2020-14947	WEB-MISC OCS Inventory Prior to 2.8 - OS Command Injection Vulnerability Via SNMP_MIB_DIRECTORY (CVE-2020-14947)
999464	CVE-2020-14947	WEB-MISC OCS Inventory Prior to 2.8 - OS Command Injection Vulnerability Via mib_file (CVE-2020-14947)
999465	CVE-2020-14008	WEB-MISC Zoho ManageEngine Applications Manager Up To 14710 - Remote Code Execution Vulnerability (CVE-2020-14008)
999466	CVE-2020-13925	WEB-MISC Apache Kylin Prior To 3.1.0 - Remote Code Execution Vulnerability Via Job (CVE-2020-13925)

Signature rule	CVE ID	Description
999467	CVE-2020-13925	WEB-MISC Apache Kylin Prior To 3.1.0 - Remote Code Execution Vulnerability Via Project (CVE-2020-13925)
999468	CVE-2020-13854	WEB-MISC Artica Pandora FMS - Privilege Escalation Vulnerability (CVE-2020-13854)
999469	CVE-2020-13405	WEB-MISC Microweber Prior to 1.1.20 - Unauthenticated Information Disclosure Vulnerability (CVE-2020-13405)
999470	CVE-2020-13376	WEB-MISC SecurEnvoy SecurMail 9.3.503 - SecurEnvoyReply Cookie Path Traversal Vulnerability (CVE-2020-13376)
999471	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via domain (CVE-2020-13159)
999472	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via netbiosname (CVE-2020-13159)
999473	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via alias (CVE-2020-13159)

Signature rule	CVE ID	Description
999474	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via hostname (CVE-2020-13159)
999475	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via dhclient_server (CVE-2020-13159)
999476	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via dhclient_interface (CVE-2020-13159)
999477	CVE-2020-13159	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - OS Command Injection Vulnerability Via dhclient_mac (CVE-2020-13159)
999478	CVE-2020-13158	WEB-MISC Artica Web Proxy Prior to 4.30.000000 - Path Traversal Vulnerability Via popup (CVE-2020-13158)
999479	CVE-2020-12851	WEB-MISC Pydio Cells Prior to 2.0.7 - Arbitrary File Write Vulnerability (CVE-2020-12851)
999480	CVE-2020-12848	WEB-MISC Pydio Cells Prior to 2.0.7 - Login as Temporary Shared User Vulnerability (CVE-2020-12848)

Signature rule	CVE ID	Description
999481	CVE-2020-11699	WEB-MISC Titan SpamTitan Prior To 7.08 - Remote Code Execution Vulnerability (CVE-2020-11699)
999482	CVE-2020-11579	WEB-MISC PHPKBV9 - File Exfiltration Vulnerability (CVE-2020-11579)
999483	CVE-2020-10818	WEB-MISC Artica Web Proxy 4.26 - OS Command Injection Vulnerability Via fw.system.info.php (CVE-2020-10818)
999484	CVE-2020-10228	WEB-MISC Vtenext CE Prior to Version 20 - Unrestricted Upload of File with Dangerous Type Vulnerability (CVE-2020-10228)
999485	CVE-2020-10204	WEB-MISC Sonatype Nexus Repository Manager Prior to 3.21.2 - RCE Vulnerability Via coreui_User roles (CVE-2020-10204)
999486	CVE-2020-10204	WEB-MISC Sonatype Nexus Repository Manager Prior to 3.21.2 - RCE Vulnerability Via coreui_Role privileges (CVE-2020-10204)
999487	CVE-2020-10204	WEB-MISC Sonatype Nexus Repository Manager Prior to 3.21.2 - RCE Vulnerability Via coreui_Role roles (CVE-2020-10204)

Signature rule	CVE ID	Description
999488	CVE-2020-10199	WEB-MISC Sonatype Nexus Repository Manager Prior to 3.21.2 - RCE Vulnerability Via REST Endpoint /bower/group (CVE-2020-10199)
999489	CVE-2020-10199	WEB-MISC Sonatype Nexus Repository Manager Prior to 3.21.2 - RCE Vulnerability Via REST Endpoint /go/group (CVE-2020-10199)
999490	CVE-2020-10199	WEB-MISC Sonatype Nexus Repository Manager Prior to 3.21.2 - RCE Vulnerability Via REST Endpoint /docker/group (CVE-2020-10199)
999491	CVE-2019-19699	WEB-MISC Centreon Up To 19.10 - Remote Code Execution Vulnerability (CVE-2019-19699)
999492	CVE-2019-19499	WEB-MISC Apache Grafana Up To 6.4.3 - Arbitrary File Read Vulnerability (CVE-2019-19499)
999493	CVE-2019-18394	WEB-MISC Ignite Realtime Openfire Up To 4.4.2 - FaviconServlet Server Side Request Forgery Vulnerability (CVE-2019-18394)
999494	CVE-2019-18393	WEB-MISC Ignite Realtime Openfire Up To 4.4.2 - plug-inServlet Directory Traversal Vulnerability (CVE-2019-18393)

Signature rule	CVE ID	Description
999495	CVE-2019-16759	WEB-MISC vBulletin Prior to 5.6.2 - Remote Code Execution Vulnerability Via Nested Template (CVE-2019-16759)
999496	CVE-2019-15715	WEB-MISC MantisBT Prior to 1.3.20 and 2.22.1 - Remote Code Execution Vulnerability Via neato_tool (CVE-2019-15715)
999497	CVE-2019-15715	WEB-MISC MantisBT Prior to 1.3.20 and 2.22.1 - Remote Code Execution Vulnerability Via dot_tool (CVE-2019-15715)
999498	CVE-2019-11043	WEB-MISC PHP-FPM Multiple Versions - Out-Of-Bounds Write Vulnerability Allows Arbitrary Code Execution (CVE-2019-11043)
999499		WEB-WORDPRESS WordPress plug-in Autoptimize Up To 2.7.6 - Authenticated Arbitrary File Upload Vulnerability

Signature update for December 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-12-02. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 54 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU. As part of signature update version 54, log string for signature 999720 is changed to ensure that it includes only ASCI characters.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999394	CVE-2020-8255	WEB-MISC Pulse Connect Secure Prior To 9.1R9 - Information Disclosure Vulnerability (CVE-2020-8255)
999395	CVE-2020-6128	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CoursePeriodModal.php (CVE-2020-6128)
999396	CVE-2020-6126, CVE-2020-6127	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CoursePeriodModal.php (CVE-2020-6126, CVE-2020-6127)
999397	CVE-2020-28328	WEB-MISC SuiteCRM Prior to 7.11.16 - Remote Code Execution Vulnerability (CVE-2020-28328)

Signature rule	CVE ID	Description
999398	CVE-2020-27995	WEB-MISC Zoho ManageEngine Applications Manager 14 Prior to Build 14560 - SQL Injection Vulnerability (CVE-2020-27995)
999399	CVE-2020-26879	WEB-MISC Ruckus vRIoT Server Prior to 1.6.0 - Authorization Bypass Vulnerability Via /service/ (CVE-2020-26879)
999400	CVE-2020-26879	WEB-MISC Ruckus vRIoT Server Prior to 1.6.0 - Authorization Bypass Vulnerability Via /reboot (CVE-2020-26879)
999401	CVE-2020-26879	WEB-MISC Ruckus vRIoT Server Prior to 1.6.0 - Authorization Bypass Vulnerability Via /patch/ (CVE-2020-26879)
999402	CVE-2020-26879	WEB-MISC Ruckus vRIoT Server Prior to 1.6.0 - Authorization Bypass Vulnerability Via /upgrade/ (CVE-2020-26879)
999403	CVE-2020-26879	WEB-MISC Ruckus vRIoT Server Prior to 1.6.0 - Authorization Bypass Vulnerability Via /module/ (CVE-2020-26879)
999404	CVE-2020-26878	WEB-MISC Ruckus vRIoT Server Prior to 1.6.0 - Arbitrary OS Command Injection Vulnerability (CVE-2020-26878)

Signature rule	CVE ID	Description
999405	CVE-2020-25790	WEB-MISC Typesetter CMS 5.x Through 5.1 - Unsecure File Upload Vulnerability (CVE-2020-25790)
999406	CVE-2020-25540	WEB-MISC ThinkAdmin v6 - Directory Traversal Vulnerability (CVE-2020-25540)
999407	CVE-2020-14883	WEB-MISC Oracle WebLogic Server - Authenticated Remote Code Execution Vulnerability (CVE-2020-14883)
999408	CVE-2020-14882, CVE-2020-14750	WEB-MISC Oracle WebLogic Server - Authentication Bypass Vulnerability (CVE-2020-14882, CVE-2020-14750)
999409	CVE-2020-11975, CVE-2020-13942	WEB-MISC Apache Unomi Prior to 1.5.2 - Remote Code Execution Vulnerability (CVE-2020-11975, CVE-2020-13942)
999410	CVE-2020-11803	WEB-MISC Titan SpamTitan Prior To 7.08 - Remote Code Execution Vulnerability (CVE-2020-11803)

Signature update for December 2020

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2020-12-17. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 55 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999377		WEB-WORDPRESS TI WooCommerce Wishlist Plugin Prior To 1.21.11 - Information Disclosure Vulnerability Via tinvwl_export_settings
999378		WEB-WORDPRESS TI WooCommerce Wishlist Plugin Prior To 1.21.11 - WP Options Change Vulnerability Via tinvwl_import_settings
999379	CVE-2020-6134	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via MassDropModal.php (CVE-2020-6134)
999380	CVE-2020-6133	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CourseMoreInfo.php (CVE-2020-6133)
999381	CVE-2020-6132	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via ChooseCP.php (CVE-2020-6132)

Signature rule	CVE ID	Description
999382	CVE-2020-6131	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via MassScheduleSessionSet.php (CVE-2020-6131)
999383	CVE-2020-6130	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via MassDropSessionSet.php (CVE-2020-6130)
999384	CVE-2020-6129	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via CpSessionSet.php (CVE-2020-6129)
999385	CVE-2020-35234	WEB-WORDPRES Easy WP SMTP Plugin Prior to 1.4.4 - Information Disclosure Vulnerability (CVE-2020-35234)
999386	CVE-2020-25042	WEB-MISC Mara CMS 7.5 - Arbitrary File Upload Vulnerability (CVE-2020-25042)
999387	CVE-2020-13526	WEB-MISC ProcessMaker - SQL Injection Vulnerability Via clientSetupAjax (CVE-2020-13526)
999388	CVE-2020-13525	WEB-MISC ProcessMaker - SQL Injection Vulnerability Via reportTables_Ajax (CVE-2020-13525)

Signature rule	CVE ID	Description
999389	CVE-2020-12147	WEB-MISC Silver Peak Unity Orchestrator - Arbitrary MySQL Queries Vulnerability Via sqlExecution REST API (CVE-2020-12147)
999390	CVE-2020-12146	WEB-MISC Silver Peak Unity Orchestrator - Path Traversal Vulnerability Via debugFiles REST API (CVE-2020-12146)
999391	CVE-2020-12145	WEB-MISC Silver Peak Unity Orchestrator - Authentication Bypass Vulnerability (CVE-2020-12145)
999392	CVE-2019-8394	WEB-MISC Zoho ManageEngine ServiceDesk Plus Prior to 10.0 Build 10012 - Arbitrary File Upload Vulnerability (CVE-2019-8394)
999393	CVE-2019-11447	WEB-MISC CutePHP CuteNews 2.1.2 - Remote Code Execution Vulnerability (CVE-2019-11447)

Signature update for January 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-01-18. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 56 applicable for NetScaler VPX 11.1, NetScaler 12.0,Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999366	CVE-2020-8466	WEB-MISC Trend Micro IWSSVA 6.5 SP2 Prior to Build 1919 - Unauthenticated OS Command Injection Vulnerability (CVE-2020-8466)
999367	CVE-2020-6135	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via Validator.php (CVE-2020-6135)
999368	CVE-2020-4001	WEB-MISC VMWare SD-WAN Orchestrator - Pass-the-Hash Vulnerability (CVE-2020-4001)
999369	CVE-2020-4000	WEB-MISC VMWare SD-WAN Orchestrator - Path Traversal Vulnerability (CVE-2020-4000)
999370	CVE-2020-3984	WEB-MISC VMWare SD-WAN Orchestrator - SQL Injection Vulnerability Via Modulus (CVE-2020-3984)
999371	CVE-2020-35606	WEB-MISC Webmin Up to 1.962 - Remote Code Execution Vulnerability (CVE-2020-35606)
999372	CVE-2020-17143	WEB-MISC Microsoft Exchange Server - Information Disclosure Vulnerability (CVE-2020-17143)

Signature rule	CVE ID	Description
999373	CVE-2020-17141	WEB-MISC Microsoft Exchange Server - Remote Code Execution Vulnerability Via RouteComplaint (CVE-2020-17141)
999374	CVE-2020-10816	WEB-MISC Zoho ManageEngine Applications Manager 14 Prior to Build 14790 - Improper Authentication Vulnerability (CVE-2020-10816)
999375	CVE-2019-5533	WEB-MISC VMWare SD-WAN Orchestrator - Information Disclosure Vulnerability (CVE-2019-5533)
999376	CVE-2018-15961	WEB-MISC Adobe ColdFusion 12 Prior to Update 6 or 14 - Arbitrary File Upload Vulnerability (CVE-2018-15961)

Signature update for February 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-02-03. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 57 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999339		WEB-MISC Zoom Meeting Connector 4.6.348.20201217 - Remote Code Execution Vulnerability Via proxyPasswd
999340		WEB-MISC Zoom Meeting Connector 4.6.348.20201217 - Remote Code Execution Vulnerability Via proxyName
999341	CVE-2021-3129	WEB-MISC Ignition Prior to 2.5.2 - Unauthenticated Remote Code Execution Vulnerability (CVE-2021-3129)
999342	CVE-2021-3025	WEB-MISC Invision Community IPS Community Suite Prior to 4.5.4.2 - SQL Injection Vulnerability Via sortDir (CVE-2021-3025)
999343	CVE-2021-2109	WEB-MISC Oracle WebLogic Server - Remote Code Execution Vulnerability Via JNDI Injection (CVE-2021-2109)
999344	CVE-2020-7200	WEB-MISC HPE Systems Insight Manager 7.6.x - AMF Unsecure Deserialization Vulnerability (CVE-2020-7200)

Signature rule	CVE ID	Description
999345	CVE-2020-7199	WEB-MISC HPE EIM Prior to 1.21 - Improper Authentication Vulnerability in /private/EIMApplianceIP (CVE-2020-7199)
999346	CVE-2020-7199	WEB-MISC HPE EIM Prior to 1.21 - Improper Authentication Vulnerability in /private/AdminPassReset (CVE-2020-7199)
999347	CVE-2020-7199	WEB-MISC HPE EIM Prior to 1.21 - Improper Authentication Vulnerability in /private/ResetAppliance (CVE-2020-7199)
999348	CVE-2020-6136	WEB-MISC OS4Ed OpenSIS Prior to 7.5 - SQLi Vulnerability Via DownloadWindow.php (CVE-2020-6136)
999349	CVE-2020-35729	WEB-MISC KLog Server 2.4.1 and Prior - OS Command Injection Vulnerability (CVE-2020-35729)
999350	CVE-2020-35701	WEB-MISC Cacti 1.2.16 and Prior - SQL Injection Vulnerability Via site_id (CVE-2020-35701)
999351	CVE-2020-35489	WEB-WORDPRESS Contact Form 7 Prior to 5.3.2 - Unrestricted File Upload Vulnerability (CVE-2020-35489)

Signature rule	CVE ID	Description
999352	CVE-2020-27615	WEB-WORDPRESS Loginizer Plugin Prior to 1.6.4 - SQL Injection Vulnerability (CVE-2020-27615)
999353	CVE-2020-26046	WEB-MISC Fuel CMS 1.4.11 and Prior - XSS Vulnerability Via /fuel/sitevariables/create (CVE-2020-26046)
999354	CVE-2020-26046	WEB-MISC Fuel CMS 1.4.11 and Prior - XSS Vulnerability Via /fuel/sitevariables/edit (CVE-2020-26046)
999355	CVE-2020-26046	WEB-MISC Fuel CMS 1.4.11 and Prior - XSS Vulnerability Via /fuel/navigation/create (CVE-2020-26046)
999356	CVE-2020-26046	WEB-MISC Fuel CMS 1.4.11 and Prior - XSS Vulnerability Via /fuel/navigation/edit (CVE-2020-26046)
999357	CVE-2020-26046	WEB-MISC Fuel CMS 1.4.11 and Prior - XSS Vulnerability Via /fuel/blocks/create (CVE-2020-26046)
999358	CVE-2020-26046	WEB-MISC Fuel CMS 1.4.11 and Prior - XSS Vulnerability Via /fuel/blocks/edit (CVE-2020-26046)
999359	CVE-2020-26045	WEB-MISC Fuel CMS 1.4.11 - SQLi Vulnerability Via /fuel/permissions/create (CVE-2020-26045)
999360	CVE-2020-17519	WEB-MISC Apache Flink Prior to 1.11.3 - Arbitrary File Disclosure Vulnerability (CVE-2020-17519)

Signature rule	CVE ID	Description
999361	CVE-2020-17518	WEB-MISC Apache Flink 1.5.1 to 1.11.2 - Arbitrary Location File Upload Vulnerability (CVE-2020-17518)
999362	CVE-2019-16010	WEB-MISC Cisco SD-WAN vManage Prior to 19.2.2 - Stored XSS Vulnerability (CVE-2019-16010)
999363	CVE-2019-15000	WEB-MISC VMWare Bitbucket Server and Data Center - Git Command Injection Vulnerability Via at (CVE-2019-15000)
999364	CVE-2019-15000	WEB-MISC VMWare Bitbucket Server and Data Center - Git Command Injection Vulnerability Via until/untilID (CVE-2019-15000)
999365	CVE-2019-15000	WEB-MISC VMWare Bitbucket Server and Data Center - Git Command Injection Vulnerability Via since/sinceID (CVE-2019-15000)

Signature update for February 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-02-17. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 58 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999328	CVE-2021-3317	WEB-MISC KLog Server 2.4.1 and Prior - OS Command Injection Vulnerability (CVE-2021-3317)
999329	CVE-2021-3110	WEB-MISC PrestaShop Prior to 1.7.7.1 - SQL Injection Vulnerability Via id_products (CVE-2021-3110)
999330	CVE-2021-3110	WEB-MISC PrestaShop Prior to 1.7.7.1 - SQL Injection Vulnerability Via /module/productcomments/-CommentGrade (CVE-2021-3110)
999331	CVE-2021-25646	WEB-MISC Apache Druid Prior to 0.20.1 - Remote Code Execution Vulnerability (CVE-2021-25646)
999332	CVE-2020-36171	WEB-WORDPRESS Elementor Page Builder Plugin Prior to 3.0.14 - XSS Vulnerability (CVE-2020-36171)

Signature rule	CVE ID	Description
999333	CVE-2020-35765	WEB-MISC Zoho ManageEngine Applications Manager Prior to Build 15000 - SQL Injection Vulnerability (CVE-2020-35765)
999334	CVE-2020-35589	WEB-WORDPRESS Limit Login Attempts Reloaded Prior to 2.15.2 - Reflected Cross-Site Scripting Vulnerability (CVE-2020-35589)
999335	CVE-2020-26282	WEB-MISC BrowserUp Proxy Prior to 2.1.2 - Template Injection Leading To RCE Vulnerability Via mostRecentEntry (CVE-2020-26282)
999336	CVE-2020-26282	WEB-MISC BrowserUp Proxy Prior to 2.1.2 - Template Injection Leading To RCE Vulnerability Via entries (CVE-2020-26282)
999337	CVE-2020-14815	WEB-MISC Oracle Business Intelligence Enterprise Edition - Reflected Cross-Site Scripting Vulnerability (CVE-2020-14815)
999338		WEB-WORDPRESS Contact Form 7 Database Addon Prior to 1.2.5.4 - SQLi Vulnerability Via Delete Bulk Action

Signature update for March 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-03-08. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 59 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999313	CVE-2021-25299	WEB-MISC NagiosXI Up to 5.7.5 - XSS Vulnerability via url (CVE-2021-25299)
999314	CVE-2021-25298	WEB-MISC NagiosXI Up to 5.7.5 - Remote Code Execution Vulnerability via DigitalOcean Wizard (CVE-2021-25298)
999315	CVE-2021-25297	WEB-MISC NagiosXI Up to 5.7.5 - Remote Code Execution Vulnerability via Switch Wizard (CVE-2021-25297)
999316	CVE-2021-25296	WEB-MISC NagiosXI Up to 5.7.5 - Remote Code Execution Vulnerability via WindowsWMI Wizard (CVE-2021-25296)

Signature rule	CVE ID	Description
999317	CVE-2021-24164	WEB-WORDPRESS Ninja Forms Plugin Prior to 3.4.34.1 - Information Disclosure Vulnerability (CVE-2021-24164)
999318	CVE-2021-24163	WEB-WORDPRESS Ninja Forms Plugin Prior to 3.4.34 - Authorization Bypass Vulnerability (CVE-2021-24163)
999319	CVE-2021-21972	WEB-MISC VMWare vCenter Server Plugin - Remote Code Execution Vulnerability (CVE-2021-21972)
999320	CVE-2020-35129	WEB-MISC Mautic Prior to 3.2.4 - XSS Vulnerability Via New Social Monitoring Form (CVE-2020-35129)
999321	CVE-2020-35129	WEB-MISC Mautic Prior to 3.2.4 - XSS Vulnerability Via Edit Social Monitoring Form (CVE-2020-35129)
999322	CVE-2020-35128	WEB-MISC Mautic Prior to 3.2.4 - XSS Vulnerability Via New Companies Form (CVE-2020-35128)
999323	CVE-2020-35128	WEB-MISC Mautic Prior to 3.2.4 - XSS Vulnerability Via Edit Companies Form (CVE-2020-35128)
999324	CVE-2020-35125	WEB-MISC Mautic Prior to 3.2.4 - XSS Vulnerability Via Referer Header (CVE-2020-35125)

Signature rule	CVE ID	Description
999325	CVE-2020-35125	WEB-MISC Mautic Prior to 3.2.4 - XSS Vulnerability Via mauticform[return] (CVE-2020-35125)
999326	CVE-2020-13933	WEB-MISC Apache Shiro Prior to 1.6.0 - Authentication Bypass Vulnerability Via Semicolon (CVE-2020-13933)
999327	CVE-2020-13921, CVE-2020-9483	WEB-MISC Apache SkyWalking Prior to 8.4.0 - SQL Injection Vulnerability Via queryLogs Feature (CVE-2020-13921, CVE-2020-9483)

Signature update for March 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-03-09. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 60 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999311	CVE-2021-26855	WEB-MISC Microsoft Exchange Server - Remote Code Execution Vulnerability Via X-AnonResource-Backend (CVE-2021-26855)
999312	CVE-2021-26855	WEB-MISC Microsoft Exchange Server - Remote Code Execution Vulnerability Via X-BEResource (CVE-2021-26855)

Signature update for March 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-03-11. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 61 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999308	CVE-2021-21302	WEB-MISC PrestaShop Prior to 1.7.7.2 - CSV Injection Vulnerability (CVE-2021-21302)
999309	CVE-2020-35749	WEB-WORDPRESS Simple Job Board Prior to 2.9.4 - Arbitrary File Disclosure Vulnerability (CVE-2020-35749)
999310	CVE-2019-16012	WEB-MISC Cisco SD-WAN vManage Prior to 19.2.2 - SQL Injection Vulnerability (CVE-2019-16012)

Signature update for March 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-03-11. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 62 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999307	CVE-2021-27065	WEB-MISC Microsoft Exchange Server - Remote Code Execution Vulnerability (CVE-2021-27065)

Signature update for April 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-04-08. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 63 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999294	CVE-2021-3273	WEB-MISC NagiosXI Prior to 5.7 - Code Injection Vulnerability (CVE-2021-3273)
999295	CVE-2021-3197	WEB-MISC SaltStack Prior to 3002.3 - Remote Code Execution Vulnerability Via ssh_priv (CVE-2021-3197)

Signature rule	CVE ID	Description
999296	CVE-2021-3197	WEB-MISC SaltStack Prior to 3002.3 - Remote Code Execution Vulnerability Via ssh_port (CVE-2021-3197)
999297	CVE-2021-3197	WEB-MISC SaltStack Prior to 3002.3 - Remote Code Execution Vulnerability Via ssh_options (CVE-2021-3197)
999298	CVE-2021-3197	WEB-MISC SaltStack Prior to 3002.3 - Remote Code Execution Vulnerability Via ProxyCommand in JSON Object (CVE-2021-3197)
999299	CVE-2021-25282	WEB-MISC SaltStack Prior to 3002.3 - Path Traversal Vulnerability Via pillar_roots.write (CVE-2021-25282)
999300	CVE-2021-24166	WEB-WORDPRESS Ninja Forms Plugin Prior to 3.4.34 - CSRF Vulnerability (CVE-2021-24166)
999301	CVE-2021-24085	WEB-MISC Microsoft Exchange Server - Spoofing Vulnerability (CVE-2021-24085)
999302	CVE-2021-22986	WEB-MISC F5 iControl REST API - Remote Code Execution Vulnerability (CVE-2021-22986)
999303	CVE-2021-21978	WEB-MISC VMWare View Planner Harness 4.x prior to 4.6 Security Patch 1 - Remote Code Execution Vulnerability (CVE-2021-21978)

Signature rule	CVE ID	Description
999304	CVE-2020-23132	WEB-MISC Joomla! Prior to 3.9.25 - Unsafe com_media Upload Path Vulnerability Via file_path (CVE-2020-23132)
999305	CVE-2020-23132	WEB-MISC Joomla! Prior to 3.9.25 - Unsafe com_media Upload Path Vulnerability Via image_path (CVE-2020-23132)
999306	CVE-2020-22425	WEB-MISC Centreon Prior to 20.10.4 - SQL Injection Vulnerability (CVE-2020-22425)

Signature update for April 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-04-22. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 64 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999275	CVE-2021-3378	WEB-MISC FortiLogger 4.4.2.2 - Unauthenticated Arbitrary File Upload Vulnerability (CVE-2021-3378)
999276	CVE-2021-28925	WEB-MISC Nagios Network Analyzer Prior to 2.4.3 - SQL Injection Vulnerability (CVE-2021-28925)
999277	CVE-2021-28924	WEB-MISC Nagios Network Analyzer Prior to 2.4.3 - XSS Vulnerability (CVE-2021-28924)
999278	CVE-2021-27927	WEB-MISC Zabbix - CSRF Vulnerability Via action=authentication.update (CVE-2021-27927)
999279	CVE-2021-26295	WEB-MISC Apache OFBiz 17.12.06 - Unauthenticated Arbitrary Deserialization Vulnerability (CVE-2021-26295)
999280	CVE-2021-25770	WEB-MISC JetBrains YouTrack Prior to 2020.5.3123 - Server-Side Template Injection Vulnerability (CVE-2021-25770)
999281	CVE-2021-25283	WEB-MISC SaltStack Prior to 3002.5 - Remote Code Execution Vulnerability (CVE-2021-25283)
999282	CVE-2021-25283	WEB-MISC SaltStack Prior to 3002.5 - Remote Code Execution Vulnerability Via JSON Object (CVE-2021-25283)

Signature rule	CVE ID	Description
999283	CVE-2021-24218	WEB-WORDPRESS Facebook for WordPress Plugin Prior to 3.0.4 - Stored Cross-Site Scripting Vulnerability (CVE-2021-24218)
999284	CVE-2021-24217	WEB-WORDPRESS Facebook for WordPress Plugin Prior to 3.0.2 - PHP Object Injection Vulnerability (CVE-2021-24217)
999285	CVE-2021-24209	WEB-WORDPRESS WP Super Cache Plugin Prior to 1.7.2 - Remote Code Execution Vulnerability in wp-cache-config.php (CVE-2021-24209)
999286	CVE-2021-24209	WEB-WORDPRESS WP Super Cache Plugin Prior to 1.7.2 - Arbitrary Code Injection Vulnerability (CVE-2021-24209)
999287	CVE-2021-24165	WEB-WORDPRESS Ninja Forms Plugin Prior to 3.4.34 - Open Redirect Vulnerability (CVE-2021-24165)
999288	CVE-2021-21975	WEB-MISC vRealize Operations Manager - Unauthenticated Server Side Request Forgery Vulnerability (CVE-2021-21975)
999289	CVE-2020-35578	WEB-MISC Nagios XI Prior to 5.8.0 - Remote Code Execution Vulnerability (CVE-2020-35578)

Signature rule	CVE ID	Description
999290	CVE-2020-2766	WEB-MISC Oracle WebLogic Server - Unauthenticated SSRF Vulnerability (CVE-2020-2766)
999291	CVE-2020-17523	WEB-MISC Apache Shiro Prior to 1.7.1 - Authentication Bypass Vulnerability Via Space (CVE-2020-17523)
999292	CVE-2020-17523	WEB-MISC Apache Shiro Prior to 1.7.1 - Authentication Bypass Vulnerability Via Dot (CVE-2020-17523)
999293	CVE-2020-15160	WEB-MISC PrestaShop Prior to 1.7.6.8 - SQL Injection Vulnerability (CVE-2020-15160)

Signature update for June 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-06-02. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 65 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999243	CVE-2021-31761	WEB-MISC Webmin Prior to 1.974 - XSS Vulnerability Via /servers/link.cgi/ (CVE-2021-31761)
999244	CVE-2021-31761	WEB-MISC Webmin Prior to 1.974 - XSS Vulnerability Via /tunnel/link.cgi/ (CVE-2021-31761)
999245	CVE-2021-31166	WEB-IIS Microsoft HTTP Protocol Stack - Remote Code Execution Vulnerability (CVE-2021-31166)
999246	CVE-2021-29447	WEB-WORDPRESS WordPress Prior to 5.7.1 - Media Library XXE Vulnerability (CVE-2021-29447)
999247	CVE-2021-28157	WEB-MISC Devolutions Server Prior to 2021.1 and 2020.3.18 - SQL Injection Vulnerability Via User Delete (CVE-2021-28157)
999248	CVE-2021-27905	WEB-MISC Apache Solr Prior to 8.2.2 - ReplicationHandler SSRF Vulnerability via leaderUrl (CVE-2021-27905)
999249	CVE-2021-27905	WEB-MISC Apache Solr Prior to 8.2.2 - ReplicationHandler SSRF Vulnerability via masterUrl (CVE-2021-27905)
999250	CVE-2021-27890	WEB-MISC MyBB Prior to 1.8.26 - Theme Properties SQL Injection Vulnerability (CVE-2021-27890)

Signature rule	CVE ID	Description
999251	CVE-2021-27850, CVE-2019-0195	WEB-MISC Apache Tapestry - Unauthenticated Information Disclosure Vulnerability (CVE-2021-27850 and CVE-2019-0195)
999252	CVE-2021-27183	WEB-MISC MDaemon Prior to 20.0.4 - Arbitrary File Write Vulnerability (CVE-2021-27183)
999253	CVE-2021-27181	WEB-MISC MDaemon Prior to 20.0.4 - Anti-CSRF Token Fixation Vulnerability (CVE-2021-27181)
999254	CVE-2021-27180	WEB-MISC MDaemon Prior to 20.0.4 - Reflected XSS Vulnerability (CVE-2021-27180)
999255	CVE-2021-24340	WEB-WORDPRESS WP Statistics Prior to 13.0.8 - Unauthenticated SQL Injection Vulnerability (CVE-2021-24340)
999256	CVE-2021-24171	WEB-WORDPRESS WooCommerce Upload Files Plugin Prior to 59.4 - Path Traversal Vulnerability (CVE-2021-24171)
999257	CVE-2021-24171	WEB-WORDPRESS WooCommerce Upload Files Plugin Prior to 59.4 - Arbitrary File Upload Vulnerability (CVE-2021-24171)

Signature rule	CVE ID	Description
999258	CVE-2021-22658	WEB-MISC Advantech iView Prior to 5.7.03.6112 - SQLi Vulnerability Via UserServlet and user_password (CVE-2021-22658)
999259	CVE-2021-22658	WEB-MISC Advantech iView Prior to 5.7.03.6112 - SQLi Vulnerability Via UserServlet and user_name (CVE-2021-22658)
999260	CVE-2021-22658	WEB-MISC Advantech iView Prior to 5.7.03.6112 - SQLi Vulnerability Via CommandServlet and user_password (CVE-2021-22658)
999261	CVE-2021-22658	WEB-MISC Advantech iView Prior to 5.7.03.6112 - SQLi Vulnerability Via CommandServlet and user_name (CVE-2021-22658)
999262	CVE-2021-21983	WEB-MISC VMWare vRealize Operations Manager Prior to 8.4 - Arbitrary File Write Vulnerability (CVE-2021-21983)
999263	CVE-2020-6754	WEB-MISC dotCMS Prior to 5.2.4 - Directory Traversal Vulnerability Via assets (CVE-2020-6754)
999264	CVE-2020-27128	WEB-MISC Cisco SD-WAN vManage Prior to 20.3.1 - Arbitrary File Write Vulnerability Via remoteprocessing (CVE-2020-27128)

Signature rule	CVE ID	Description
999265	CVE-2020-27128	WEB-MISC Cisco SD-WAN vManage Prior to 20.3.1 - Arbitrary File Write Vulnerability Via dr (CVE-2020-27128)
999266	CVE-2020-15714	WEB-MISC rConfig 3.9.5 and Prior - SQL Injection Vulnerability (CVE-2020-15714)
999267	CVE-2020-15713	WEB-MISC rConfig Prior to 3.9.6 - SQL Injection Vulnerability (CVE-2020-15713)
999268	CVE-2020-14295	WEB-MISC Cacti Prior to 1.2.13 - SQL Injection Vulnerability (CVE-2020-14295)
999269	CVE-2020-13778	WEB-MISC rConfig Prior to 3.9.5 - Remote Code Execution Vulnerability Via ajaxEditTemplate.php (CVE-2020-13778)
999270	CVE-2020-13778	WEB-MISC rConfig Prior to 3.9.5 - Remote Code Execution Vulnerability Via ajaxAddTemplate.php (CVE-2020-13778)
999271	CVE-2020-13592	WEB-MISC Rukovoditel Project Management App - SQL Injection Vulnerability Via selected_fields (CVE-2020-13592)
999272	CVE-2020-13592	WEB-MISC Rukovoditel Project Management App - SQL Injection Vulnerability Via lists_id (CVE-2020-13592)

Signature rule	CVE ID	Description
999273	CVE-2020-13591	WEB-MISC Rukovoditel Project Management App - SQL Injection Vulnerability (CVE-2020-13591)
999274	CVE-2020-13550	WEB-MISC Advantech WebAccess/SCADA - Path Traversal Vulnerability Via fileName (CVE-2020-13550)

Signature update for July 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-07-08. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 66 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999231	CVE-2021-34074	WEB-MISC Artica Pandora FMS Up to 7.54 - Arbitrary File Upload Vulnerability Via Relative Path (CVE-2021-34074)

Signature rule	CVE ID	Description
999232	CVE-2021-32633	WEB-MISC Plone CMS - Zope Page Templates Remote Code Execution Vulnerability Via Upload (CVE-2021-32633)
999233	CVE-2021-32633	WEB-MISC Plone CMS - Zope Page Templates Remote Code Execution Vulnerability Via New (CVE-2021-32633)
999234	CVE-2021-31181	WEB-MISC Microsoft SharePoint Server - Remote Code Execution Vulnerability (CVE-2021-31181)
999235	CVE-2021-24370	WEB-WORDPRESS Fancy Product Designer Plugin Prior to 5.6.9 - RCE Vulnerability Via fpd_custom_uplod_file (CVE-2021-24370)
999236	CVE-2021-24370	WEB-WORDPRESS Fancy Product Designer Plugin Prior to 5.6.9 - RCE Vulnerability Via custom-image-handler.php (CVE-2021-24370)
999237	CVE-2021-24354	WEB-WORDPRESS Simple 301 Redirects Plugin Prior to 2.0.4 - Arbitrary Plugin Installation Vulnerability (CVE-2021-24354)
999238	CVE-2021-24352	WEB-WORDPRESS Simple 301 Redirects Plugin Prior to 2.0.4 - Redirect Export Vulnerability (CVE-2021-24352)
999239	CVE-2021-1497, CVE-2021-1498	WEB-MISC Cisco HyperFlex HX Prior to 4.0(2e) - Remote Code Execution Vulnerability (CVE-2021-1497, CVE-2021-1498)

Signature rule	CVE ID	Description
999240	CVE-2020-21057	WEB-MISC FusionPBX 4.5.7 - Path Traversal Vulnerability Via folderdelete Feature (CVE-2020-21057)
999241	CVE-2020-16245	WEB-MISC Advantech iView Prior to 5.7.03.6112 - Path Traversal Vulnerability Via backupDatabase (CVE-2020-16245)
999242	CVE-2020-10148	WEB-MISC SolarWinds Orion Multiple Versions - Authentication Bypass Vulnerability (CVE-2020-10148)

Signature update for August 2021

September 14, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-08-29. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 67 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999183	CVE-2021-37557	WEB-MISC Centreon Multiple Versions - SQL Injection Vulnerability (CVE-2021-37557)
999184	CVE-2021-35501	WEB-MISC Artica Pandora FMS Up to 7.54 - Visual Console Stored XSS Vulnerability (CVE-2021-35501)
999185	CVE-2021-35464	WEB-MISC ForgeRock Access Management and OpenAM - Remote Code Execution Vulnerability (CVE-2021-35464)
999186	CVE-2021-34523	WEB-MISC Microsoft Exchange Server - Elevation of Privilege Vulnerability (CVE-2021-34523)
999187	CVE-2021-34473	WEB-MISC Microsoft Exchange Server - Server Side Request Forgery Authentication Bypass Vulnerability Via Query (CVE-2021-34473)
999188	CVE-2021-34473	WEB-MISC Microsoft Exchange Server - Server Side Request Forgery Authentication Bypass Vulnerability Via Cookie (CVE-2021-34473)
999189	CVE-2021-33203	WEB-MISC Django - TemplateDetailView File Existence Disclosure Vulnerability via Absolute Path (CVE-2021-33203)

Signature rule	CVE ID	Description
999190	CVE-2021-33203	WEB-MISC Django - TemplateDetailView File Existence Disclosure Vulnerability via Path Traversal (CVE-2021-33203)
999191	CVE-2021-33203	WEB-MISC Django - TemplateDetailView File Existence Disclosure Vulnerability via backslash (CVE-2021-33203)
999192	CVE-2021-33203	WEB-MISC Django - TemplateDetailView File Existence Disclosure Vulnerability Via Slash (CVE-2021-33203)
999193	CVE-2021-3287, CVE-2020-28653	WEB-MISC Zoho ManageEngine OpManager Prior to 12.5.329 - Unauthenticated RCE Vulnerability (CVE-2021-3287, CVE-2020-28653)
999194	CVE-2021-32789	WEB-WORDPRESS WooCommerce Plugin Up to 5.5.0 - SQL Injection Vulnerability Via taxonomy and rest_route (CVE-2021-32789)
999195	CVE-2021-32789	WEB-WORDPRESS WooCommerce Plugin Up to 5.5.0 - SQL Injection Vulnerability Via taxonomy (CVE-2021-32789)

Signature rule	CVE ID	Description
999196	CVE-2021-32604	WEB-MISC SolarWinds Serv-U Prior to 15.2.3 - Cross-Site Scripting Vulnerability Via SenderEmail Parameter (CVE-2021-32604)
999197	CVE-2021-32093	WEB-MISC National Security Agency Emissary 5.9.0 - Arbitrary File Read Vulnerability (CVE-2021-32093)
999198	CVE-2021-31760	WEB-MISC Webmin Prior to 1.974 - CSRF Vulnerability Lead to RCE Via run.cgi (CVE-2021-31760)
999199	CVE-2021-31207	WEB-MISC Microsoft Exchange Server - Security Feature Bypass Vulnerability (CVE-2021-31207)
999200	CVE-2021-31195	WEB-MISC Microsoft Exchange Server - Remote Code Execution Vunerability (CVE-2021-31195)
999201	CVE-2021-28474	WEB-MISC Microsoft SharePoint Server - Remote Code Execution Vulnerability (CVE-2021-28474)
999202	CVE-2021-24385	WEB-WORDPRESS FileBird Plugin 4.7.3 - SQL Injection Vulnerability Via selectedFolder Parameter and rest_route (CVE-2021-24385)
999203	CVE-2021-24385	WEB-WORDPRESS FileBird Plugin 4.7.3 - SQL Injection Vulnerability Via selectedFolder Parameter (CVE-2021-24385)

Signature rule	CVE ID	Description
999204	CVE-2021-24385	WEB-WORDPRESS FileBird Plugin 4.7.3 - SQL Injection Vulnerability Via JSON-Encoded Body (CVE-2021-24385)
999205	CVE-2021-24356	WEB-WORDPRESS Simple 301 Redirects Plugin Prior to 2.0.4 - Arbitrary Plugin Activation Vulnerability (CVE-2021-24356)
999206	CVE-2021-23024	WEB-MISC F5 BIG-IQ Multiple Versions - Remote Code Execution Vulnerability (CVE-2021-23024)
999207	CVE-2021-22911	WEB-MISC Rocket.Chat Server 3.11, 3.12 and 3.13 - Blind NOSQL Injection Vulnerability (CVE-2021-22911)
999208	CVE-2021-22900	WEB-MISC Pulse Connect Secure Prior To 9.1R11.4 - Remote Code Execution Vulnerability Via smimeCert.cgi (CVE-2021-22900)
999209	CVE-2021-22900	WEB-MISC Pulse Connect Secure Prior To 9.1R11.4 - Remote Code Execution Vulnerability Via admincert.cgi (CVE-2021-22900)
999210	CVE-2021-22900	WEB-MISC Pulse Connect Secure Prior To 9.1R11.4 - Remote Code Execution Vulnerability Via clientauthcert.cgi (CVE-2021-22900)

Signature rule	CVE ID	Description
999211	CVE-2021-22160	WEB-MISC Apache Pulsar - JSON Web Tokens Authentication Bypass Vulnerability (CVE-2021-22160)
999212	CVE-2021-21809	WEB-MISC Moodle - Remote Code Execution Vulnerability Via Spellchecker Plugin and getSuggestions Method (CVE-2021-21809)
999213	CVE-2021-21809	WEB-MISC Moodle - Remote Code Execution Vulnerability Via Spellchecker Plugin and checkWords Method (CVE-2021-21809)
999214	CVE-2021-21809	WEB-MISC Moodle - Remote Code Execution Vulnerability Via s__aspellpath (CVE-2021-21809)
999215	CVE-2021-21805	WEB-MISC Advantech R-SeeNet - Unauthenticated Remote Code Execution Vulnerability (CVE-2021-21805)
999216	CVE-2021-21804	WEB-MISC Advantech R-SeeNet - Local File Inclusion Vulnerability Via sub_opt (CVE-2021-21804)
999217	CVE-2021-21587	WEB-MISC Dell Wyse Management Suite Prior to 3.3 - Path Traversal Vulnerability Via /image/os/listfiles (CVE-2021-21587)

Signature rule	CVE ID	Description
999218	CVE-2021-21587	WEB-MISC Dell Wyse Management Suite Prior to 3.3 - Path Traversal Vulnerability Via /image/app/rsp/listfiles (CVE-2021-21587)
999219	CVE-2021-21586	WEB-MISC Dell Wyse Management Suite Prior to 3.3 - Path Traversal Vulnerability Via /image/app and fileName (CVE-2021-21586)
999220	CVE-2021-21586	WEB-MISC Dell Wyse Management Suite Prior to 3.3 - Path Traversal Vulnerability Via /image/os and fileName (CVE-2021-21586)
999221	CVE-2021-21586	WEB-MISC Dell Wyse Management Suite Prior to 3.3 - Path Traversal Vulnerability Via /image/os and filePath (CVE-2021-21586)
999222	CVE-2020-25223	WEB-MISC Sophos SG UTM - Remote Code Execution Via SID and /var (CVE-2020-25223)
999223	CVE-2020-25223	WEB-MISC Sophos SG UTM - Remote Code Execution Via SID and /webadmin.plx (CVE-2020-25223)
999224	CVE-2020-21056	WEB-MISC FusionPBX 4.5.7 - Path Traversal Vulnerability Via foldernew (CVE-2020-21056)

Signature rule	CVE ID	Description
999225	CVE-2020-21055	WEB-MISC FusionPBX 4.5.7 - Path Traversal Vulnerability Via File Rename Feature (CVE-2020-21055)
999226	CVE-2020-16245	WEB-MISC Advantech iView Prior to 5.7.03.6112 - Path Traversal Vulnerability in findSummaryUpdateDeviceListExpo (CVE-2020-16245)
999227	CVE-2020-16245	WEB-MISC Advantech iView Prior to 5.7.03.6112 - Path Traversal Vulnerability Via findCfgDeviceListExport (CVE-2020-16245)
999228	CVE-2020-14181	WEB-MISC Atlassian Jira Server - Information Disclosure Vulnerability Via ViewUserHover.jspa (CVE-2020-14181)
999229	CVE-2020-14005	WEB-MISC SolarWinds Orion Prior to 2020.2.1 HF 2 - Remote Code Execution Via ExecuteVBScript Action Type (CVE-2020-14005)
999230	CVE-2020-14005	WEB-MISC SolarWinds Orion Prior to 2020.2.1 HF 2 - Remote Code Execution Via ExecuteExternalProgram Action Type (CVE-2020-14005)

Signature update for September 2021

September 20, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-09-11. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 68 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 and Citrix ADC 13.1 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999163	CVE-2021-37556	WEB-MISC Centreon Multiple Versions - SQL Injection Vulnerability Via End Parameter (CVE-2021-37556)
999164	CVE-2021-37556	WEB-MISC Centreon Multiple Versions - SQL Injection Vulnerability Via Start Parameter (CVE-2021-37556)
999165	CVE-2021-37353	WEB-MISC Nagios XI Docker Wizard Prior to 1.1.3 - SSRF Vulnerability Via host Parameter Without URI Scheme (CVE-2021-37353)
999166	CVE-2021-37353	WEB-MISC Nagios XI Docker Wizard Prior to 1.1.3 - SSRF Vulnerability Via host Parameter With URI Scheme (CVE-2021-37353)

Signature rule	CVE ID	Description
999167	CVE-2021-34638	WEB-WORDPRESS Download Manager Plugin Prior to 3.1.25 - Directory Traversal Vulnerability (CVE-2021-34638)
999168	CVE-2021-33766	WEB-MISC Microsoft Exchange Server - Information Disclosure Vulnerability (CVE-2021-33766)
999169	CVE-2021-32682	WEB-MISC elFinder Prior To 2.1.59 - Command Injection Vulnerability Via Archive (CVE-2021-32682)
999170	CVE-2021-26084	WEB-MISC Confluence Server and Data Center - OGNL Injection Vulnerability Via doenterpagevariables (CVE-2021-26084)
999171	CVE-2021-26084	WEB-MISC Confluence Server and Data Center - OGNL Injection Vulnerability Via createpage-entervariables (CVE-2021-26084)
999172	CVE-2021-23394	WEB-MISC elFinder Prior To 2.1.59 - Remote Code Execution Vulnerability Via Phar Makefile (CVE-2021-23394)
999173	CVE-2021-23394	WEB-MISC elFinder Prior To 2.1.59 - Remote Code Execution Vulnerability Via Phar Rename (CVE-2021-23394)

Signature rule	CVE ID	Description
999174	CVE-2021-23394	WEB-MISC elFinder Prior To 2.1.59 - Remote Code Execution Vulnerability Via Phar Upload (CVE-2021-23394)
999175	CVE-2020-36289	WEB-MISC Atlassian Jira Server - Information Disclosure Vulnerability Via QueryComponentRenderer-Value (CVE-2020-36289)
999176	CVE-2020-16245	WEB-MISC Advantech iView Prior to 5.7.03.6112 - Path Traversal Vulnerability Via findSummaryCfgDeviceListExport (CVE-2020-16245)
999177	CVE-2020-16245	WEB-MISC Advantech iView Prior to 5.7.03.6112 - Path Traversal Vulnerability Via findUpdateDeviceListExport (CVE-2020-16245)
999178	CVE-2020-13774	WEB-MISC Ivanti Endpoint Manager Multiple Versions - RCE Vulnerability Via EditLaunchPadDialog.aspx (CVE-2020-13774)
999179	CVE-2020-1147	WEB-MISC Microsoft SharePoint Server - Remote Code Execution Vulnerability Via Custom Page (CVE-2020-1147)
999180	CVE-2020-1147	WEB-MISC Microsoft SharePoint Server - Remote Code Execution Vulnerability Via quicklinksdialogform.aspx (CVE-2020-1147)

Signature rule	CVE ID	Description
999181	CVE-2020-1147	WEB-MISC Microsoft SharePoint Server - Remote Code Execution Vulnerability Via quicklinks.aspx (CVE-2020-1147)
999182	CVE-2020-11110	WEB-MISC Apache Grafana Up to 6.7.1 - XSS Vulnerability (CVE-2020-11110)
999522	CVE-2020-13379	WEB-MISC Grafana 3.0.1 Through 7.0.1 - CSRF Bypass Leading To DOS Vulnerability (CVE-2020-13379)

Signature update for October 2021

October 22, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-10-09. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 69 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 and Citrix ADC 13.1 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999149	CVE-2021-38312	WEB-WORDPRESS Gutenberg Template Library and Redux Framework Plugin Prior to 4.2.12 - REST_ROUTE Vulnerability (CVE-2021-38312)
999150	CVE-2021-38312	WEB-WORDPRESS Gutenberg Template Library and Redux Framework Plugin Prior to 4.2.12 - REST API Vulnerability (CVE-2021-38312)
999151	CVE-2021-34639	WEB-WORDPRESS Download Manager Plugin Prior to 3.1.25 - Double Extension Upload Vulnerability (CVE-2021-34639)
999152	CVE-2021-34621	WEB-WORDPRESS ProfilePress Plugin Prior to 3.1.3 - Elevation of Privilege Vulnerability Via wp_capabilities (CVE-2021-34621)
999153	CVE-2021-32682	WEB-MISC elFinder Prior To 2.1.59 - Path Traversal Vulnerability Via Rename Command (CVE-2021-32682)
999154	CVE-2021-32682	WEB-MISC elFinder Prior To 2.1.59 - Path Traversal Vulnerability Via Abort Command (CVE-2021-32682)
999155	CVE-2021-26086	WEB-MISC Atlassian Jira Server and Data Center - Information Disclosure Vulnerability Via WEB-INF (CVE-2021-26086)

Signature rule	CVE ID	Description
999156	CVE-2021-26086	WEB-MISC Atlassian Jira Server and Data Center - Information Disclosure Vulnerability Via META-INF (CVE-2021-26086)
999157	CVE-2021-22005	WEB-MISC VMWare vCenter - File Upload Vulnerability Via Data App (CVE-2021-22005)
999158	CVE-2021-22005	WEB-MISC VMWare vCenter - File Upload Vulnerability Via Telemetry Stage Log (CVE-2021-22005)
999159	CVE-2021-22005	WEB-MISC VMWare vCenter - File Upload Vulnerability Via Telemetry Prod Log (CVE-2021-22005)
999160	CVE-2021-20081	WEB-MISC Zoho ManageEngine Service Desk Prior to 11.2.0.5 - Remote Code Execution Vulnerability (CVE-2021-20081)
999161	CVE-2020-29453	WEB-MISC Atlassian Jira Server and Data Center - Information Disclosure Vulnerability Via WEB-INF (CVE-2020-29453)
999162	CVE-2020-29453	WEB-MISC Atlassian Jira Server and Data Center - Information Disclosure Vulnerability Via META-INF (CVE-2020-29453)

Signature update for October 2021

November 19, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-10-26. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 70 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999127	CVE-2021-42013	WEB-MISC Apache HTTP Server 2.4.49 and 2.4.50 - Path Traversal Vulnerability Via %%32 (CVE-2021-42013)
999128	CVE-2021-42013	WEB-MISC Apache HTTP Server 2.4.49 and 2.4.50 - Path Traversal Vulnerability Via %2% (CVE-2021-42013)
999129	CVE-2021-41773	WEB-MISC Apache HTTP Server 2.4.49 - Path Traversal Vulnerability Via %2e%2e (CVE-2021-41773)
999130	CVE-2021-41773	WEB-MISC Apache HTTP Server 2.4.49 - Path Traversal Vulnerability Via .%2e (CVE-2021-41773)

Signature rule	CVE ID	Description
999131	CVE-2021-40539	WEB-MISC Zoho ManageEngine ADSelfService Plus 6.1 Prior to Build 6114 - Authentication Bypass Vulnerability (CVE-2021-40539)
999132	CVE-2021-34648	WEB-WORDPRESS Ninja Forms Plugin Up to 3.5.7 - REST_ROUTE Vulnerability via submissions email-action (CVE-2021-34648)
999133	CVE-2021-34648	WEB-WORDPRESS Ninja Forms Plugin Up to 3.5.7 - REST API Vulnerability via submissions email-action (CVE-2021-34648)
999134	CVE-2021-34647	WEB-WORDPRESS Ninja Forms Plugin Up to 3.5.7 - REST_ROUTE Vulnerability via Submissions Export (CVE-2021-34647)
999135	CVE-2021-34647	WEB-WORDPRESS Ninja Forms Plugin Up to 3.5.7 - REST API Vulnerability via Submissions Export (CVE-2021-34647)
999136	CVE-2021-34623	WEB-WORDPRESS ProfilePress Plugin Prior to 3.1.4 - Arbitrary File Upload Vulnerability Via eup_cover_image (CVE-2021-34623)

Signature rule	CVE ID	Description
999137	CVE-2021-34623	WEB-WORDPRESS ProfilePress Plugin Prior to 3.1.4 - Arbitrary File Upload Vulnerability Via eup_avatar (CVE-2021-34623)
999138	CVE-2021-2400	WEB-MISC Oracle BI Publisher - SAXParser XXE Vulnerability Via mobile X ReportTemplateService(CVE-2021-2400)
999139	CVE-2021-2400	WEB-MISC Oracle BI Publisher - SAXParser XXE Vulnerability Via mobile ReportTemplateService(CVE-2021-2400)
999140	CVE-2021-2400	WEB-MISC Oracle BI Publisher - SAXParser XXE Vulnerability Via xmlpservice X ReportTemplateService (CVE-2021-2400)
999141	CVE-2021-2400	WEB-MISC Oracle BI Publisher - SAXParser XXE Vulnerability Via xmlpservice ReportTemplateService (CVE-2021-2400)
999142	CVE-2021-21985	WEB-MISC VMWare vCenter - Virtual SAN Health Check Plugin Remote Code Execution Vulnerability (CVE-2021-21985)
999143	CVE-2021-20078	WEB-MISC Zoho ManageEngine OpManager 12.5 Prior to Build 125362 - Path Traversal Vulnerability (CVE-2021-20078)

Signature rule	CVE ID	Description
999144	CVE-2020-29448	WEB-MISC Atlassian Confluence Server and Data Center - Information Disclosure Vulnerability Via WEB-INF (CVE-2020-29448)
999145	CVE-2020-29448	WEB-MISC Atlassian Confluence Server and Data Center - Information Disclosure Vulnerability Via META-INF (CVE-2020-29448)
999146	CVE-2020-12442	WEB-MISC Ivanti Avalanche 6.3 - Unauthenticated SQL Injection Vulnerability Via osupdate Endpoint (CVE-2020-12442)
999147	CVE-2020-12442	WEB-MISC Ivanti Avalanche 6.3 - Unauthenticated SQL Injection Vulnerability Via wapl Endpoint (CVE-2020-12442)
999148		WEB-WORDPRESS BuddyPress Plugin Prior to 9.1.1 - SQL Injection Vulnerability Via bp-members-invitations Feature

Signature update for November 2021

November 19, 2021

New signatures rules are generated for the vulnerabilities identified in the week 2021-11-18. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 71 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

> **Note:**
>
> Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

Signature rule	CVE ID	Description
999098	CVE-2021-41765	WEB-MISC ResourceSpace 9.5 and 9.6 prior to rev 18274 - SQL Injection Vulnerability (CVE-2021-41765)
999099	CVE-2021-41288	WEB-MISC Zoho ManageEngine OpManager Prior to Build 125467 - SQL Injection Vulnerability Via getReportData API (CVE-2021-41288)
999100	CVE-2021-40493	WEB-MISC Zoho ManageEngine OpManager Prior to Build 125437 - SQL Injection Vulnerability Via deviceName (CVE-2021-40493)
999101	CVE-2021-40493	WEB-MISC Zoho ManageEngine OpManager Prior to Build 125437 - SQL Injection Vulnerability Via pollingObject (CVE-2021-40493)
999102	CVE-2021-40438	WEB-MISC Apache HTTP Server - mod_proxy Request Forward Vulnerability (CVE-2021-40438)

Signature rule	CVE ID	Description
999103	CVE-2021-39341	WEB-WORDPRESS OptinMonster Plugin Up to 2.6.4 - REST_ROUTE Permission Bypass Vulnerability (CVE-2021-39341)
999104	CVE-2021-39341	WEB-WORDPRESS OptinMonster Plugin Up to 2.6.4 - REST API Permission Bypass Vulnerability (CVE-2021-39341)
999105	CVE-2021-37344	WEB-MISC Nagios XI Switch Wizard Prior to 2.5.7 - Remote Code Execution Vulnerability Via ip_address Parameter (CVE-2021-37344)
999106	CVE-2021-35218	WEB-MISC SolarWinds Orion Prior to 2020.2.6 - Deserialization Vulnerability Via Chart.ashx (CVE-2021-35218)
999107	CVE-2021-35215	WEB-MISC SolarWinds Orion Platform Prior to 2020.2.6 - Remote Code Execution Vulnerability Via Reporting (CVE-2021-35215)
999108	CVE-2021-35215	WEB-MISC SolarWinds Orion Platform Prior to 2020.2.6 - Remote Code Execution Vulnerability Via Alerting (CVE-2021-35215)
999109	CVE-2021-24889	WEB-WORDPRESS Ninja Forms Plugin Prior to 3.6.4 - SQL Injection Vulnerability (CVE-2021-24889)

Signature rule	CVE ID	Description
999110	CVE-2021-24381	WEB-WORDPRESS Ninja Forms Plugin Prior to 3.5.8.2 - Custom Class Name Stored Cross-Site Scripting Vulnerability (CVE-2021-24381)
999111	CVE-2021-2401	WEB-MISC Oracle BI Publisher - DOMParser XXE Vulnerability Via mobile X ReportTemplateService (CVE-2021-2401)
999112	CVE-2021-2401	WEB-MISC Oracle BI Publisher - DOMParser XXE Vulnerability Via mobile ReportTemplateService (CVE-2021-2401)
999113	CVE-2021-2401	WEB-MISC Oracle BI Publisher - DOMParser XXE Vulnerability Via xmlpservice X ReportTemplateService (CVE-2021-2401)
999114	CVE-2021-2401	WEB-MISC Oracle BI Publisher - DOMParser XXE Vulnerability Via xmlpservice ReportTemplateService (CVE-2021-2401)
999115	CVE-2021-2392	WEB-MISC Oracle BI Publisher - Arbitrary Files Upload Vulnerability (CVE-2021-2392)
999116	CVE-2021-2244	WEB-MISC Oracle Hyperion-Essbase Analytic Provider Services - Remote Code Execution Vulnerability Via Essbase (CVE-2021-2244)

Signature rule	CVE ID	Description
999117	CVE-2021-2244	WEB-MISC Oracle Hyperion-Essbase Analytic Provider Services - Remote Code Execution Vulnerability Via admin (CVE-2021-2244)
999118	CVE-2021-2244	WEB-MISC Oracle Hyperion-Essbase Analytic Provider Services - Remote Code Execution Vulnerability Via JAPI (CVE-2021-2244)
999119	CVE-2021-22205	WEB-MISC GitLab CE/EE - Remote Code Execution Vulnerability Via Maliciously Crafted JPEG/TIFF Files (CVE-2021-22205)
999120	CVE-2021-22017	WEB-MISC VMWare vCenter - Path Traversal Vulnerability Via rhhtproxy (CVE-2021-22017)
999121	CVE-2021-20837	WEB-MISC Movable Type Prior to r.5003 - Remote Code Execution Via mt.handler_to_coderef (CVE-2021-20837)
999122	CVE-2021-20131	WEB-MISC Zoho ManageEngine ADManager Prior to Build 7115 - Remote Code Execution Vulnerability Via File Upload (CVE-2021-20131)
999123	CVE-2021-20130	WEB-MISC Zoho ManageEngine ADManager Prior to Build 7115 - Remote Code Execution Vulnerability Via File Upload (CVE-2021-20130)

Signature rule	CVE ID	Description
999124	CVE-2021-20034	WEB-MISC SonicWall Secure Mobile Access - Path Traversal Vulnerability (CVE-2021-20034)
999125		WEB-WORDPRESS BuddyPress Plugin Prior to 9.1.1 - Information Disclosure Vulnerability Via signup REST API and rest_route
999126		WEB-WORDPRESS BuddyPress Plugin Prior to 9.1.1 - Information Disclosure Vulnerability Via signup REST API

Bot Management

September 14, 2021

Sometimes the incoming web traffic is comprised of bots and most organizations suffer from bot attacks. Web and mobile applications are significant revenue drivers for business and most companies are under the threat of advanced cyberattacks, such as bots.

A bot is a software program that automatically performs certain actions repeatedly at a much faster rate than a human. Bots can interact with webpages, submit forms, run actions, scan texts, or download content. They can access videos, post comments, and tweet on social media platforms. Some bots, known as chatbots, can hold basic conversations with human users.

A bot that performs a helpful service, such as customer service, automated chat, and search engine crawlers are good bots. At the same time, a bot that can scrape or download content from a website, steal user credentials, spam content, and perform other kinds of cyberattacks are bad bots.

With a good number of bad bots performing malicious tasks, it is essential to manage bot traffic and protect your web applications from bot attacks. By using Citrix bot management, you can detect the incoming bot traffic and mitigate bot attacks to protect your web applications.

Citrix bot management helps identify bad bots and protect your appliance from advanced security attacks. It detects good and bad bots and identifies if incoming traffic is a bot attack. By using bot management, you can mitigate attacks and protect your web applications.

Citrix ADC bot management provides the following benefits:

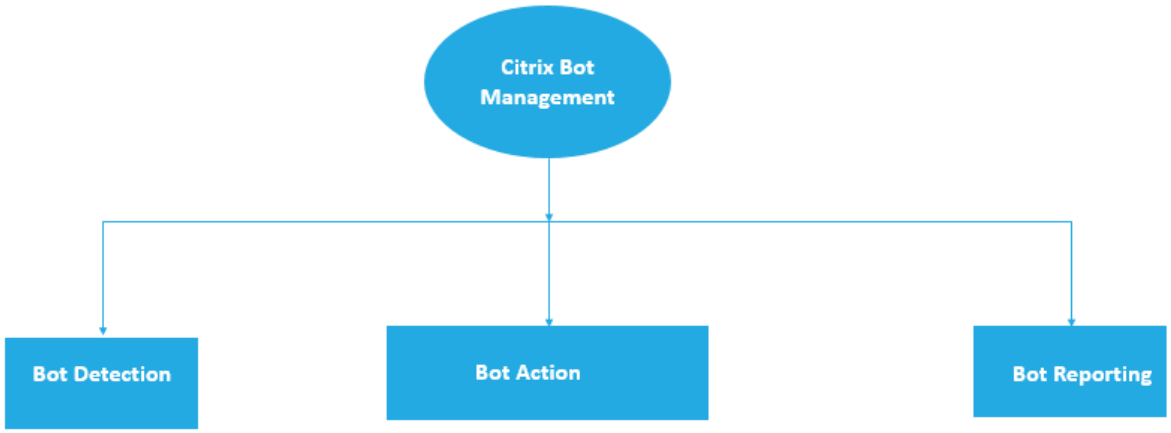
- **Defend against bots, scripts, and toolkits**. Provides real-time threat mitigation using static signature based defense and device fingerprinting.
- **Neutralize automated basic and advanced attacks**. Prevents attacks, such as App layer DDoS, password spraying, password stuffing, price scrapers, and content scrapers.
- **Protect your APIs and investments**. Protects your APIs from unwarranted misuse and protects infrastructure investments from automated traffic.

Some use cases where you can benefit by using the Citrix bot management system are:

- Brute force login. A government web portal is constantly under attack by bots attempting to brute force user logins. The organization discovered the attack by looking through web logs and seeing specific users being select over and over again with rapid login attempts and passwords incrementing using a dictionary attack approach. By law, they must protect themselves and their users. By deploying the Citrix bot management, they can stop brute force login using device fingerprinting and rate limiting techniques.
- Block bad bots and device fingerprint unknown bots. A web entity gets 100,000 visitors each day. They have to upgrade the underlying footprint and they are spending a fortune. In a recent audit, the team discovered that 40 percent of the traffic came from bots, scraping content, picking news, checking user profiles, and more. They want to block this traffic to protect their users and reduce their hosting costs. Using bot management, they can block known bad bots, and fingerprint unknown bots that are hammering their site. By blocking these bots, they can reduce bot traffic by 90 percent.

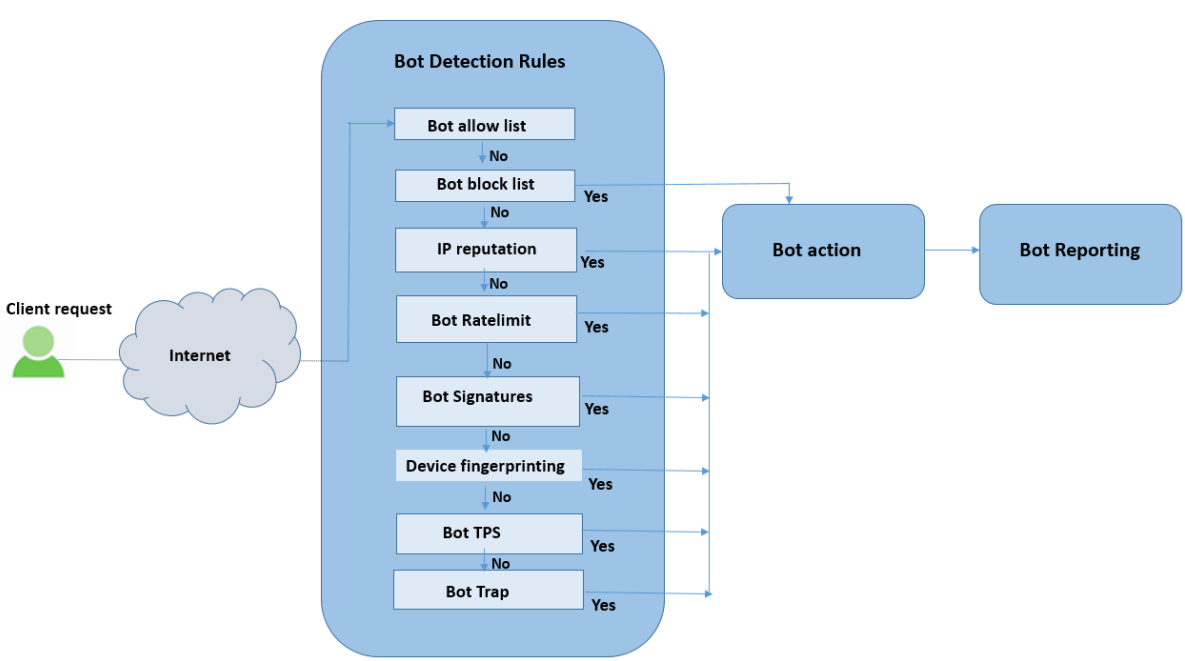
What does Citrix bot management do

The Citrix bot management helps organizations protect their web applications and public assets from advanced security attacks. When an incoming traffic is a bot, the bot management system detects the bot type, assigns an action, and generates bot insights, as shown in the following diagram.



How does Citrix ADC bot management work

The following diagram shows how the Citrix ADC bot management works. The process involves eight detection techniques that help in detecting the incoming traffic as a good or a bad bot. By default good bots detected by signatures are allowed and bad bots detected by signatures are dropped.



1. The process starts by enabling the bot management feature on the appliance.
2. When a client sends a request, the appliance evaluates the traffic using bot policy rules. If the incoming request is identified as a bot, the appliance applies a bot detection profile.
3. You must bind the default or custom bot signature file to the bot detection profile. The bot signature file has a list of bot signature rules for identifying the incoming bot type.
4. The bot detection rules are available under eight detection categories in the signature file. The categories are allow list, block list, static signature, IP reputation, device fingerprint, and rate limiting. Based on the bot traffic, the system applies a detection rule to the traffic.
5. If the incoming bot traffic matches an entry in the bot allow list, the system bypasses other detection techniques and the associated action logs the data.
6. For detection techniques other than bot allow list, if an incoming request matches a configured rule, the corresponding action is applied. The possible actions are drop, redirect, reset, mitigation, and log. CAPTCHA is a mitigation action which is supported for IP reputation, device fingerprinting, and TPS detection techniques.

Bot Detection

November 23, 2021

The Citrix ADC bot management system uses six different techniques to detect the incoming bot traffic. The techniques are used as detection rules to detect the bot type. The techniques are bot allow list, bot block list, IP reputation, device fingerprinting, rate limiting, bot trap, TPS, and CAPTCHA.

> **Note:**
>
> Bot management supports a maximum of 32 configuration entities for block list, allow list, and rate limiting techniques.

Bot white list. A customized list of IP addresses, subnets, and policy expressions that can be bypassed as an allowed list.

Bot black list. A customized list of IP addresses, subnets, and policy expressions that has to be blocked from accessing your web applications.

IP reputation. This rule detects if the incoming bot traffic is from a malicious IP address.

Device fingerprint. This rule detects if the incoming bot traffic has the device fingerprint ID in the incoming request header and browser attributes of an incoming client bot traffic.

> **Limitation:**
>
> 1. Java Script must be enabled in the client browser.
> 2. Does not work for XML responses.

Bot log expression. The detection technique enables you to capture additional information as log messages. The data can be the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request or data generated from an expression.

Rate limit. This rule rate limits multiple requests coming from the same client.

Bot trap. Detects and blocks automated bots by advertising a trap URL in the client response. The URL appears invisible and not accessible if the client is a human user. The detection technique is effective in blocking attacks from automated bots.

TPS. Detects incoming traffic as bots if the maximum number of requests and percentage increase in requests exceeds the configured time interval.

CAPTCHA. This rule uses a CAPTCHA for mitigating bot attacks. A CAPTCHA is a challenge-response validation to determine if the incoming traffic is from a human user or an automated bot. The validation helps block automated bots that cause security violations to web applications. You can configure CAPTCHA as a bot action in IP reputation and device fingerprint detection techniques.

Now, let us see how you can configure each technique to detect and manage your bot traffic.

How to upgrade your appliance to Citrix ADC CLI-based bot management configuration

If you are upgrading your appliance from an older version (Citrix ADC release 13.0 build 58.32 or earlier), you must first manually convert the existing bot management configuration to the Citrix ADC CLI based bot management configuration only once. Complete the following steps to manually convert your bot management configuration.

1. After upgrading to the latest version connect to the upgrade tool “upgrade_bot_config.py” by using the following command

   At the command prompt, type:

   ```
   shell "/var/python/bin/python /netscaler/upgrade_bot_config.py > /var/bot_upgrade_commands.txt"
   ```

2. Run the configuration using the following command.

   At the command prompt, type:

   ```
   batch -f /var/bot_upgrade_commands.txt
   ```

3. Save the upgraded configuration.

```
save ns config
```

Configure Citrix ADC CLI-based bot management

The bot management configuration enables you to bind one or more bot detection techniques to a specific bot profile. You begin the process by enabling the bot management feature on your appliance. Once you enable, you import the bot signature file into the appliance. After import, you must create a bot profile. You then create a bot policy with the bot profile bound to it for evaluating the incoming traffic as bot and bind the policy globally or to a virtual server.

> **Note:**
>
> If you are upgrading your appliance from an older version, you must first manually convert the existing bot management configuration. For more information, see How to upgrade to Citrix ADC CLI-based bot management configuration section.

You must complete the following steps to configure Citrix ADC-based bot management:

1. Enable bot management
2. Import bot signature
3. Add bot profile
4. Bind bot profile
5. Add bot policy
6. Bind bot policy
7. Configure bot settings

Enable bot management

Before you can begin, ensure that the Bot Management feature is enabled on the appliance. If you have a new Citrix ADC or VPX, you must enable the feature before you configure it. If you are upgrading a Citrix ADC or VPX appliance from an earlier version of the Citrix ADC software version to the current version, you must need to enable the feature before you configure it. At the command prompt, type:

```
enable ns feature Bot
```

Import bot signature

You can import the default signature bot file and bind it to the bot profile. At the command prompt, type:

```
import bot signature [<src>] <name> [-comment <string>] [-overwrite]
```

Where,
src. Local path to and name of, or URL (protocol, host, path, and file name) for, the file in which to store the imported signature file. Note: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access. Maximum Length: 2047
name. Name to assign to the bot signature file object on the Citrix ADC. This is a mandatory argument. Maximum Length: 31
comment. Any comments to preserve information about the signature file object. Maximum Length: 255.
Overwrite. Overwrites the existing file.
Note: Use the `overwrite` option to update the content in the signature file. Alternately, use the `update bot signature <name>` command to update the signature file on the Citrix ADC appliance

Example

```
import bot signature http://www.example.com/signature.json signaturefile -comment commentsforbot -overwrite
```

> **Note:**
>
> You can use the overwrite option to update the content in the signature file. Also, you can use the `update bot signature <name>` command to update the signature file in the Citrix ADC appliance.

Add bot profile

A bot profile is a collection of profile settings to configure bot management on the appliance. You can configure the settings to perform bot detection.

At the command prompt, type:

```
add bot profile <name> [-signature <string>] [-errorURL <string>] [-trapURL
 <string>] [-comment <string>] [-whiteList ( ON | OFF )] [-blackList ( ON
 | OFF )] [-rateLimit ( ON | OFF )] [-deviceFingerprint ( ON | OFF )] [-
deviceFingerprintAction ( none | log | drop | redirect | reset | mitigation
 )] [-ipReputation ( ON | OFF )] [-trap ( ON | OFF )] [-trapAction ( none |
 log | drop | redirect | reset )] [-tps ( ON | OFF )]
```

Example:

```
add bot profile profile1 -signature signature -errorURL http://www.example
.com/error.html -trapURL /trap.html -whitelist ON -blacklist ON -ratelimit
 ON -deviceFingerprint ON -deviceFingerprintAction drop -ipReputation ON -
trap ON
```

Bind bot profile

After you create a bot profile, you must bind the bot detection mechanism to the profile.

At the command prompt, type:

```
bind bot profile <name> ((-blackList [-type ( IPv4 | Subnet | Expression
 )] [-enabled ( ON | OFF )] [-value <string>] [-action ( log | drop |
reset )] [-logMessage <string>] [-comment <string>])| (-whiteList [-type
 ( IPv4 | Subnet | Expression )] [-enabled ( ON | OFF )] [-value <string
>] [-log ( ON | OFF )] [-logMessage <string>] [-comment <string>]))|
(-rateLimit [-type ( session |SOURCE_IP | url )] [-enabled ( ON | OFF
)] [-url <string>] [-cookieName <string>] [-rate <positive_integer>] [-
timeslice <positive_integer>] [-action ( none | log | drop | redirect |
reset )] [-logMessage <string>] [-comment <string>])| (-ipReputation [-
category <ipReputationCategory>] [-enabled ( ON | OFF )] [-action ( none
 | log | drop | redirect | reset | mitigation )] [-logMessage <string>]
[-comment <string>])| (-captchaResource [-url <string>] [-enabled ( ON |
 OFF )] [-waitTime <positive_integer>] [-gracePeriod <positive_integer>]
 [-mutePeriod <positive_integer>] [-requestLengthLimit <positive_integer
>] [-retryAttempts <positive_integer>] [-action ( none | log | drop |
redirect | reset )] [-logMessage <string>] [-comment <string>])| (-tps
 [-type ( SOURCE_IP | GeoLocation | REQUEST_URL | Host )] [-threshold <
positive_integer>] [-percentage <positive_integer>] [-action ( none | log |
 drop | redirect | reset | mitigation )] [-logMessage <string>] [-comment <
string>])
```

Example:

The following example is for binding the IP reputation detection technique to a specific bot profile.

```
bind bot profile profile5 -ipReputation -category BOTNET -enabled ON -
action drop -logMessage message
```

Add bot policy

You must add the bot policy for evaluating bot traffic.

At the command prompt, type:

```
add bot policy <name> -rule <expression> -profileName <string> [-undefAction
 <string>] [-comment <string>] [-logAction <string>]
```

Where,

Name. Name for the bot policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the bot policy is added.

Rule. Expression that the policy uses to determine whether to apply the bot profile on the specified request. This is a mandatory argument. Maximum Length: 1499

profileName. Name of the bot profile to apply if the request matches this bot policy. This is a mandatory argument. Maximum Length: 127

undefAction. Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition. Maximum Length: 127

Comment. Any type of information about this bot policy. Maximum Length: 255

logAction. Name of the log action to use for requests that match this policy. Maximum Length: 127

Example:

```
add bot policy pol1 -rule "HTTP.REQ.HEADER(\"header\").CONTAINS(\"custom
\")"- profileName profile1 -undefAction drop -comment commentforbotpolicy -
logAction log1
```

Bind bot policy global

At the command prompt, type:

```
bind bot global -policyName <string> -priority <positive_integer> [-gotoPriorityExpres
 <expression>][-type ( REQ_OVERRIDE | REQ_DEFAULT )] [-invoke (-labelType (
 vserver | policylabel )-labelName <string>)]
```

Example:

```
bind bot global -policyName pol1 -priority 100 -gotoPriorityExpression NEXT
-type REQ_OVERRIDE
```

Bind bot policy to a virtual server

At the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@ [-weight <positive_integer>] )| <
serviceGroupName>@ | (-policyName <string>@ [-priority <positive_integer>]
 [-gotoPriorityExpression <expression>] [-type ( REQUEST | RESPONSE )] [-
invoke (<labelType> <labelName>)] )| -analyticsProfile <string>@)
```

Example:

```
bind lb vserver lb-server1 -policyName pol1 -priority 100 -gotoPriorityExpression
 NEXT -type REQ_OVERRIDE
```

Configure bot settings

You can customize the default settings if necessary.
At the command prompt, type:

```
set bot settings [-defaultProfile <string>] [-javaScriptName <string>]
 [-sessionTimeout <positive_integer>] [-sessionCookieName <string>] [-
dfpRequestLimit <positive_integer>] [-signatureAutoUpdate ( ON | OFF )]
[-signatureUrl <URL>] [-proxyServer <ip_addr|ipv6_addr|*>] [-proxyPort <
port|*>]
```

Where,

defaultProfile. Profile to use when a connection does not match any policy. Default setting is “, which sends unmatched connections back to the Citrix ADC without attempting to filter them further. Maximum Length: 31

javaScriptName. Name of the JavaScript that the BotNet feature uses in response. Must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-) and underscore (_) symbols. The following requirement applies only to the Citrix ADC CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my cookie name” or ‘my cookie name’). Maximum Length: 31

sessionTimeout. Session times out, in seconds, after which a user session is terminated.

Minimum value: 1, Maximum value: 65535

sessionCookieName. Name of the SessionCookie that the BotNet feature uses it for tracking. Must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-)

and underscore (_) symbols. The following requirement applies only to the Citrix ADC CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my cookie name” or ‘my cookie name’). Maximum Length: 31

dfpRequestLimit. Number of requests to allow without bot session cookie if device fingerprint is enabled.

Minimum value: 1, Maximum Value: 4294967295

signatureAutoUpdate. Flag used to enable/disable bot auto update signatures.

Possible values: ON, OFF

Default value: OFF

signatureUrl. URL to download the bot signature mapping file from the server.

Default value: `https://nsbotsignatures.s3.amazonaws.com/BotSignatureMapping.json`.

Maximum Length: 2047

ProxyServer. Proxy Server IP to get updated signatures from AWS.

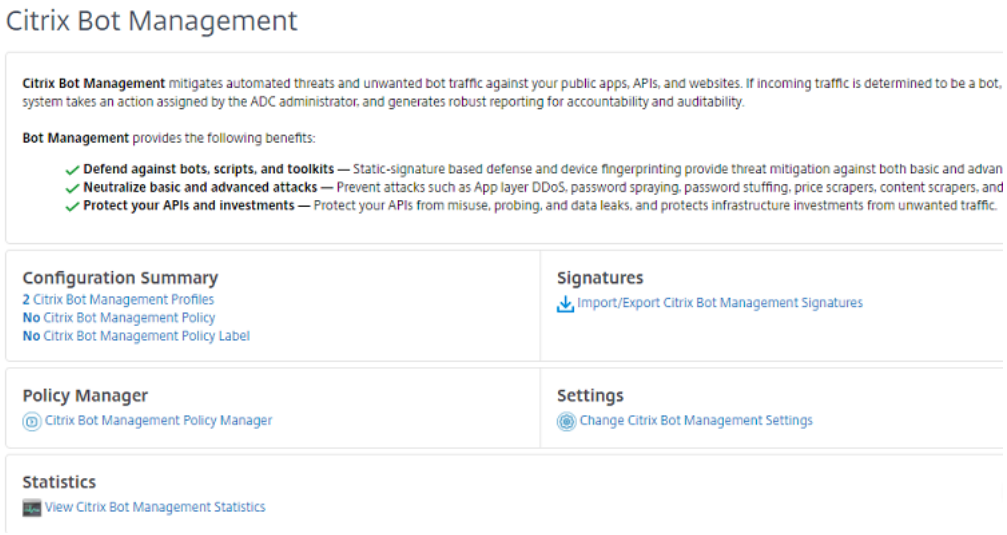
proxyPort. Proxy Server Port to get updated signatures from AWS. Default value: 8080

Example:

```
set bot settings -defaultProfile profile1 -javaScriptName json.js -sessionTimeout
 1000 -sessionCookieName session
```

Configuring bot management by using Citrix ADC GUI

You can configure Citrix ADC bot management by first enabling the feature on the appliance. Once you enable, you can create a bot policy to evaluate the incoming traffic as bot and send the traffic to the bot profile. Then, you create a bot profile and then bind the profile to a bot signature. As an alternative, you can also clone the default bot signature file and use the signature file to configure the detection techniques. After creating the signature file, you can import it into the bot profile.

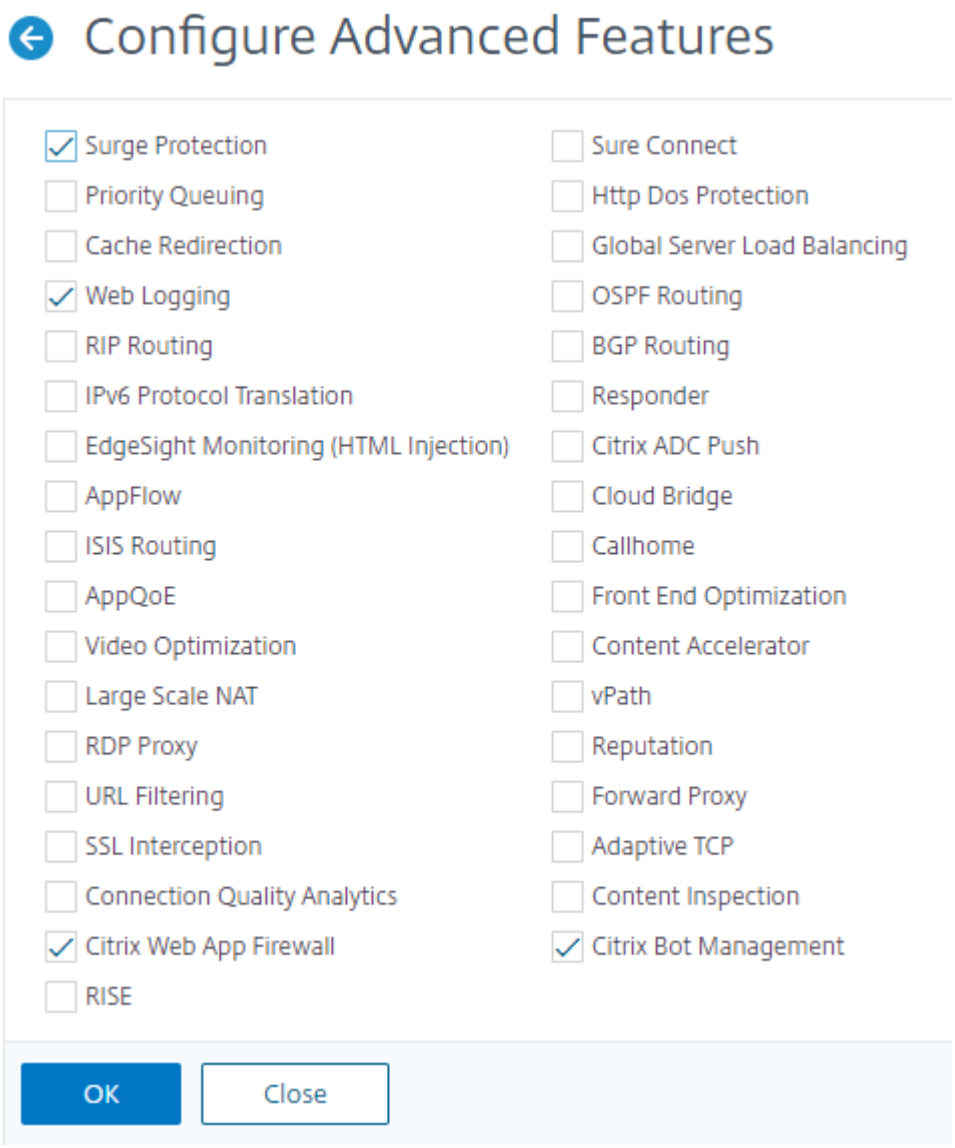


1. Enable bot management feature
2. Configure bot management settings
3. Clone Citrix bot default signature
4. Import Citrix bot signature
5. Configure bot signature settings
6. Create bot profile
7. Create bot policy

Enable bot management feature

Complete the following steps to enable bot management:

1. On the navigation pane, expand **System** and then click **Settings**.
2. On the **Configure Advanced Features** page, select the **Bot Management** check box.
3. Click **OK**, and then click **Close**.



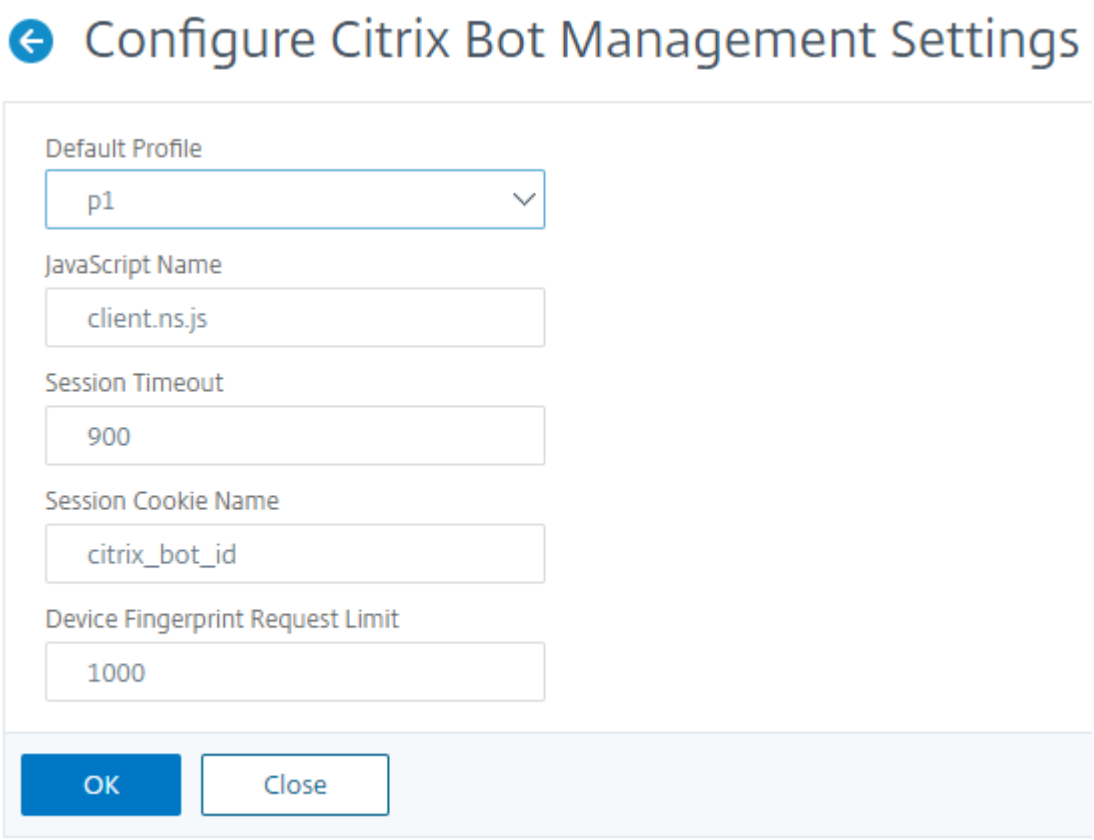
Configure bot management settings for device fingerprint technique

Complete the following step to configure the device fingerprint technique:

1. Navigate to **Security** > **Citrix Bot Management**.
2. In the details pane, under **Settings** click **Change Citrix Bot Management Settings**.
3. In the **Configure Citrix Bot Management Settings**, set the following parameters.
   a) Default Profile. Select a bot profile.
   b) JavaScript Name. Name of the JavaScript file that bot management uses in its response to the client.
   c) Session Timeout. Timeout in seconds after which the user session is terminated.

d) Session Cookie. Name of the session cookie that the bot management system uses for tracking.

e) Device Fingerprint Request Limit. Number of requests to allow without a bot session cookie, if device fingerprint is enabled

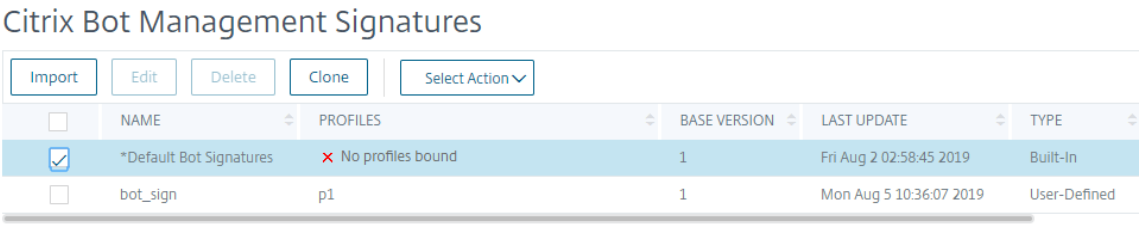


4. Click **OK**.

Clone bot signature file

Complete the following step to clone the bot signature file:

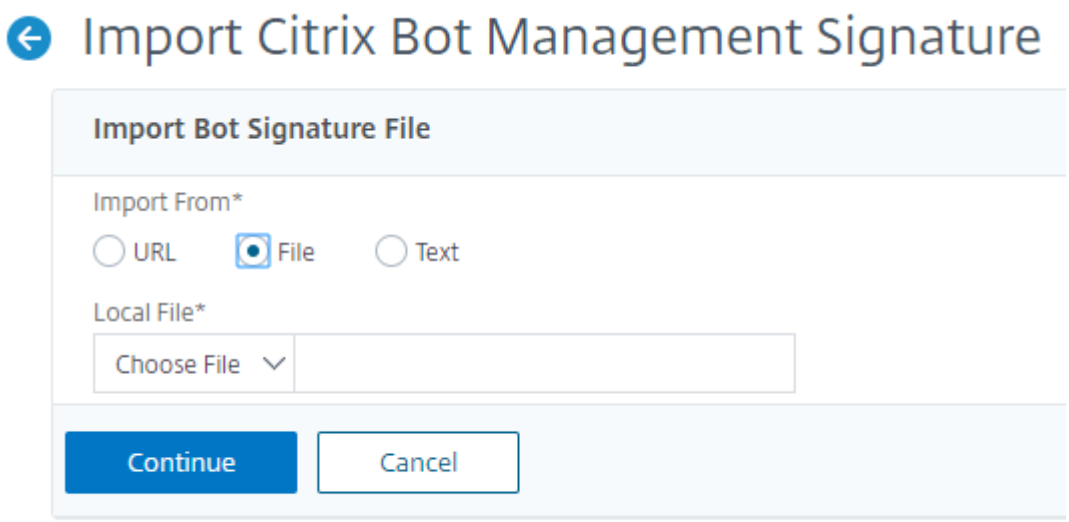
1. Navigate to **Security** > **Citrix Bot Management** and **Signatures**.
2. In **Citrix Bot Management Signatures** page, select the default bot signatures record and click **Clone**.
3. In the **Clone Bot Signature** page, enter a name and edit the signature data.
4. Click **Create**.



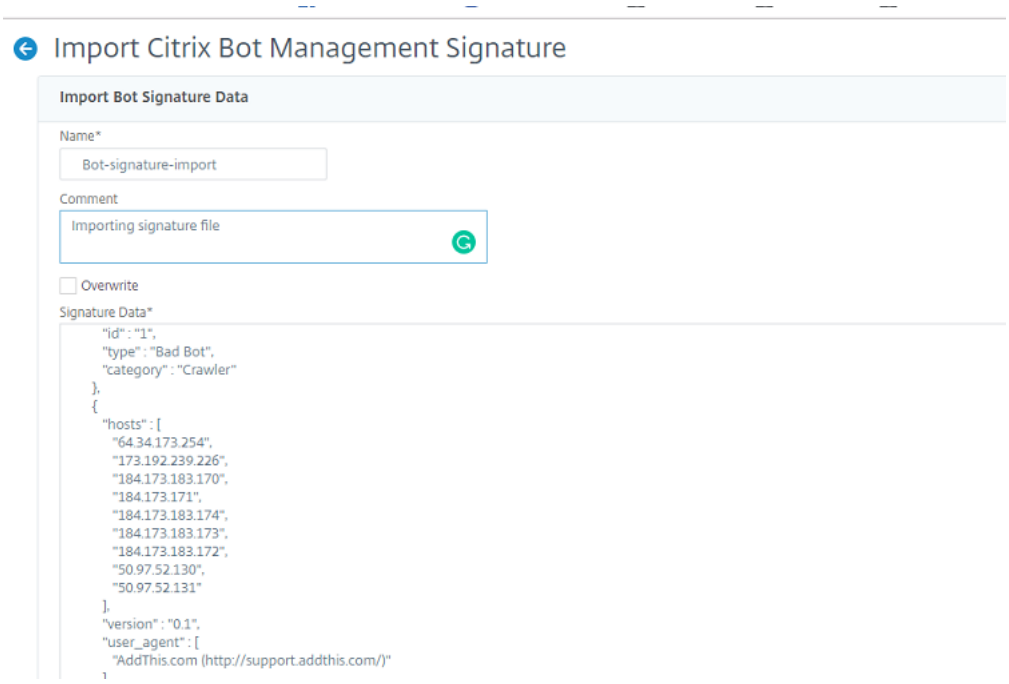
Import bot signature file

If you have your own signature file, then you can import it as a file, text, or URL. Perform the following the steps to import the bot signature file:

1. Navigate to **Security** > **Citrix Bot Management** and **Signatures**.
2. On the **Citrix Bot Management Signatures** page, import the file as URL, File, or text.
3. Click **Continue**.



4. On the Import Citrix Bot Management Signature page, set the following parameters.
   a) Name. Name of the bot signature file.
   b) Comment. Brief description about the imported file.
   c) Overwrite. Select the check box to allow overwriting of data during file update.
   d) Signature Data. Modify signature parameters
5. Click **Done**.



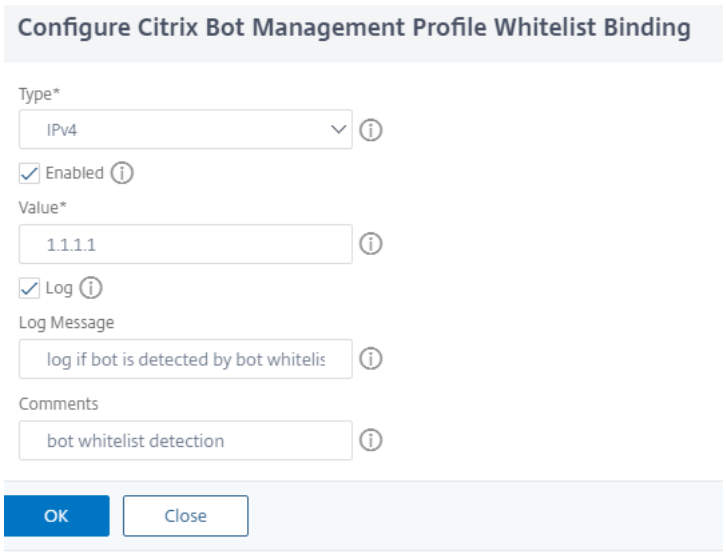
Configure bot allow list by using Citrix ADC GUI

This detection technique enables you to bypass URLs that you configure an allowed listed one. Complete the following step to configure an allow list URL:

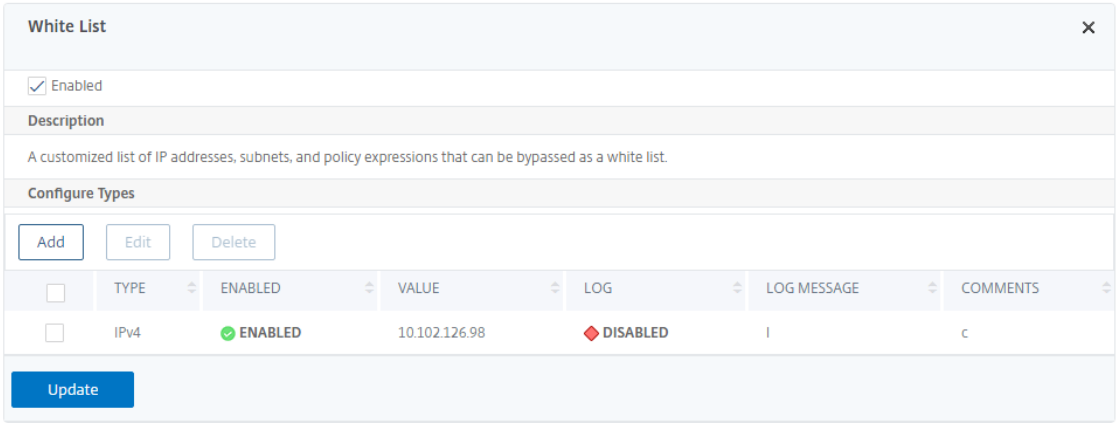
1. Navigate to **Security** > **Citrix Bot Management** and **Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to the **Signature Settings** section and click **White List**.
4. In the **White List** section, set the following parameters:
    a) Enabled. Select the check box to validate the allow list URLs as part of the detection process.
    b) Configure Types. Configure an allow list URL. The URL is bypassed during bot detection. Click Add to add a URL to the bot allow list.
    c) In the **Configure Citrix Bot Management Profile Whitelist Binding** page, set the following parameters:
        i. Type. URL type can be an IPv4 address, subnet IP address, or an IP address matching a policy expression.
        ii. Enabled. Select the check box to validate the URL.
        iii. Value. URL address.
        iv. Log. Select the check box to store log entries.
        v. Log Message. Brief description of the log.

vi. Comments. Brief description about the allow list URL.

vii. Click **OK**.



5. Click **Update**.
6. Click **Done**.



Configure bot block list by using Citrix ADC GUI

This detection technique enables you to drop the URLs that you configure as block listed one. Complete the following step to configure a block list URL.

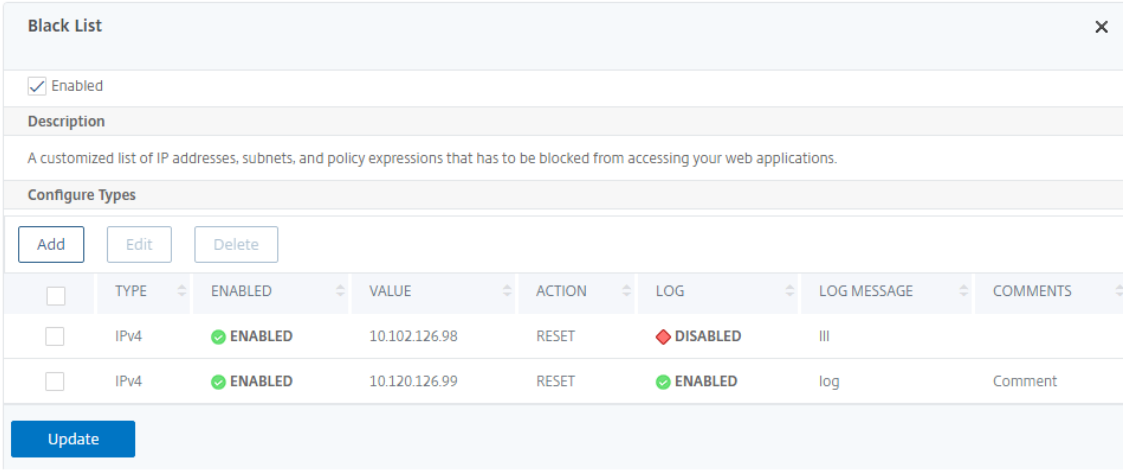
1. Navigate to **Security** > **Citrix Bot Management** and **Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to **Signature Settings** section and click **Black List**.
4. In the **Black List** section, set the following parameters:

a) Enabled. Select the check box to validate block list URLs as part of the detection process.

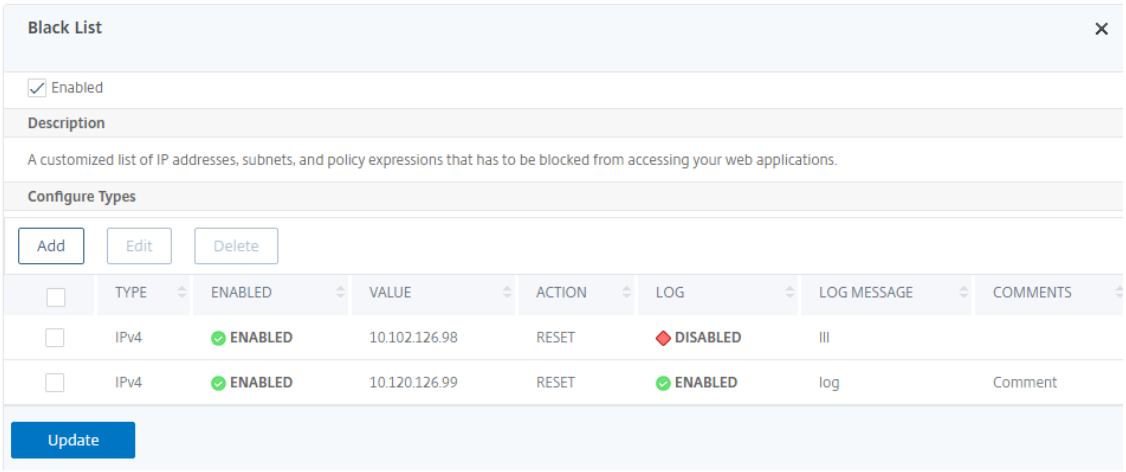
b) Configure Types. Configure a URL to be part of the bot block list detection process. These URLs are dropped during bot detection. Click Add to add a URL to the bot block list

c) In the **Configure Citrix Bot Management Profile Blacklist Binding** page, set the following parameters.

i. Type. URL type can be an IPv4 address, subnet IP address, or IP address.
ii. Enabled. Select the check box to validate the URL.
iii. Value. URL address.
iv. Log. Select the check box to store log entries.
v. Log Message. Brief description of the login.
vi. Comments. Brief description about the block list URL.
vii. Click **OK**.



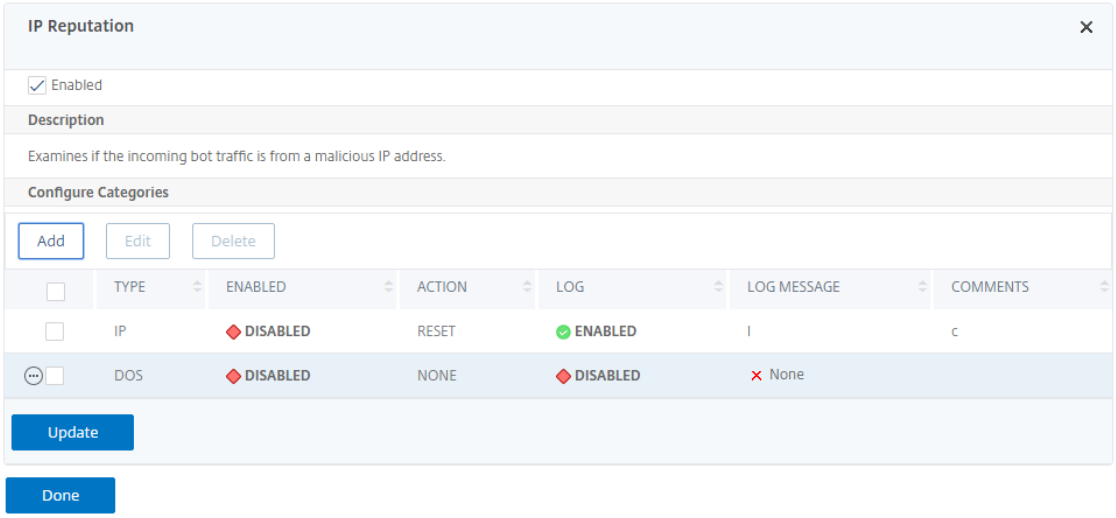
5. Click **Update**.
6. Click **Done**.



Configure IP reputation by using Citrix ADC GUI

This configuration is a pre-requisite for the bot IP reputation feature. The detection technique enables you to identify if there is any malicious activity from an incoming IP address. As part of the configuration, we set different malicious bot categories and associate a bot action to each of it. Complete the following step to configure the IP reputation technique.

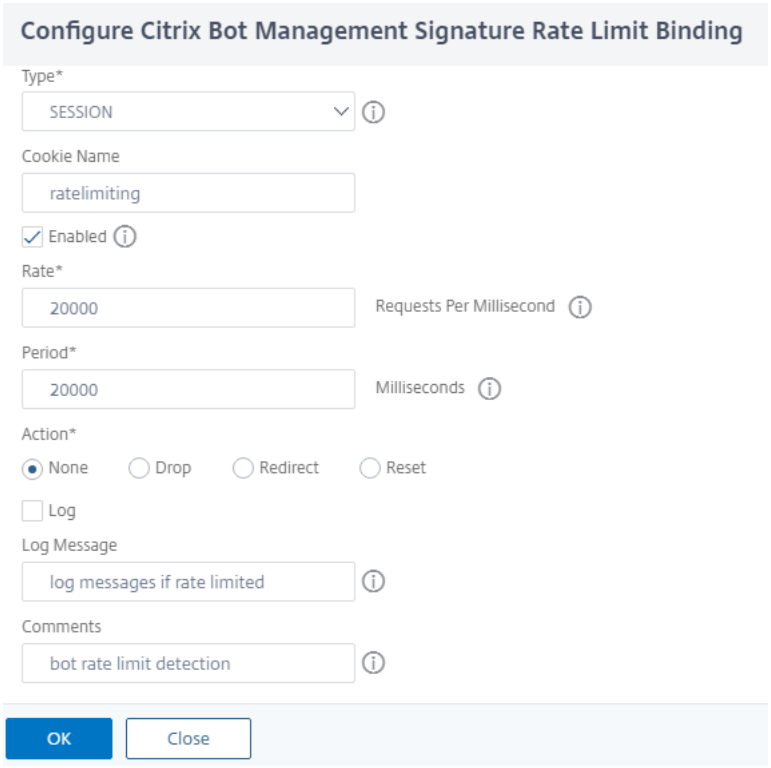
1. Navigate to **Security** > **Citrix Bot Management** and **Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to **Signature Settings** section and click **IP Reputation**.
4. On the **IP Reputation** section, set the following parameters:
    a) Enabled. Select the check box to validate incoming bot traffic as part of the detection process.
    b) Configure Categories. You can use the IP reputation technique for incoming bot traffic under different categories. Based on the configured category, you can drop or redirect the bot traffic. Click **Add** to configure a malicious bot category.
    c) In the **Configure Citrix Bot Management Profile IP Reputation Binding** page, set the following parameters:
        i. Category. Select a malicious bot category from the list. Associate a bot action based on category.
        ii. Enabled. Select the check box to validate the IP reputation signature detection.
        iii. Bot action. Based on the configured category, you can assign no action, drop, redirect, mitigation, or CAPTCHA action.
        iv. Log. Select the check box to store log entries.
        v. Log Message. Brief description of the log.
        vi. Comments. Brief description about the bot category.
5. Click **OK**.
6. Click **Update**.
7. Click **Done**.



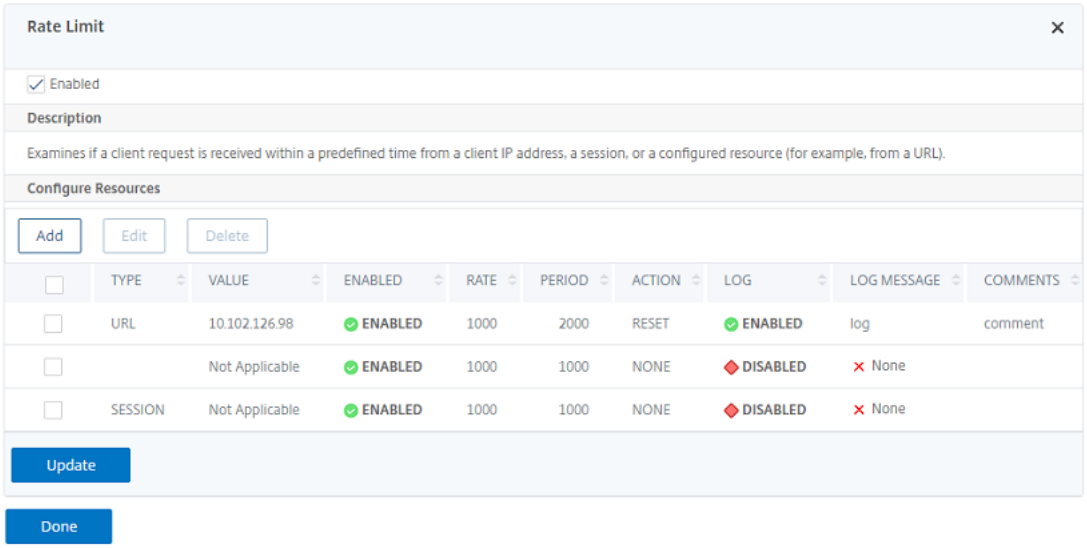
Configure bot rate limit by using Citrix ADC GUI

This detection technique enables you to block bots based on the number of requests received within a predefined time from a client IP address, a session, or a configured resource (for example, from a URL). Complete the following step to configure the rate limit technique.

1. Navigate to **Security** > **Citrix Bot Management** and **Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to **Signature Settings** section and click **Rate Limit**.
4. On the **Rate Limit** section, set the following parameters:
    a) Enabled. Select the check box to validate the incoming bot traffic as part of the detection process.
    b) Session. Rate limit requests based on a session. Click Add to configure rate limit requests based on a session.
    c) In the **Configure Citrix Bot Management Signature Rate Limit** page, set the following parameters.
        i. Category. Select a malicious bot category from the list. Associate an action based on the category.
        ii. Enabled. Select the check box to validate the incoming bot traffic.
        iii. Bot action. Choose a bot action for the selected category.
        iv. Log. Select the check box to store log entries.
        v. Log Message. Brief description of the log.
        vi. Comments. Brief description about the bot category.
        vii. Click **OK**.



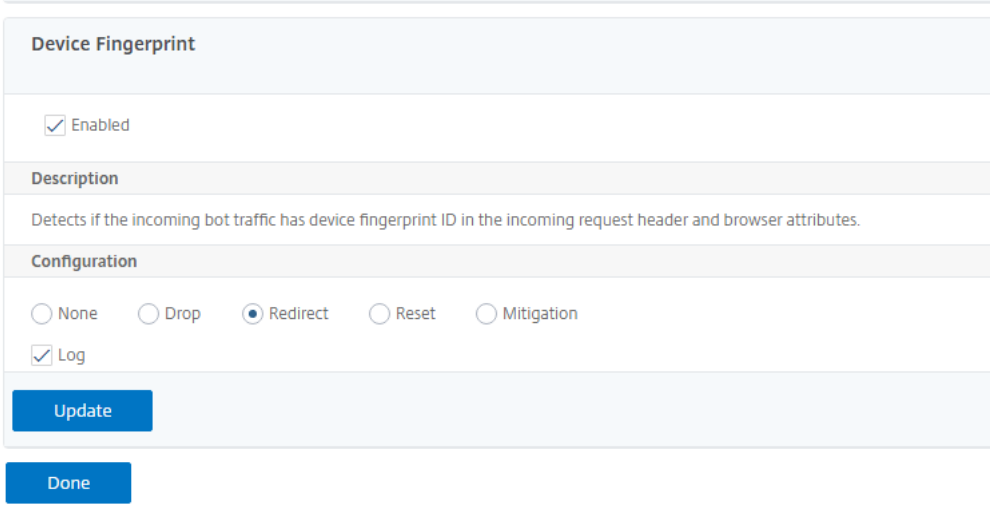
5. Click **Update**.
6. Click **Done**.



Configure device fingerprint technique by using Citrix ADC GUI

This detection technique sends a java script challenge to the client and extracts the device information. Based on device information, the technique drops or bypasses the bot traffic. Follow the steps to configure the detection technique.

1. Navigate to **Security** > **Citrix Bot Management** and **Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to the **Signature Settings** section and click **Device Fingerprint**.
4. In the **Device Fingerprint** section, set the following parameters:
   a) Enabled. Set this option to enable the rule.
   b) Configuration. For the given device fingerprint, assign no action, drop, or redirect, mitigation, or CAPTCHA action.
   c) Log. Select the check box to store log entries.
5. Click **Update**.
6. Click **Done**.



Configure device fingerprint technique for mobile (Android) applications

Device fingerprint technique detects an incoming traffic as a bot by inserting a JavaScript script in the HTML response to the client. The JavaScript script when invoked by the browser, it collects browser and client attributes and sends a request to the appliance. The attributes are examined to determine whether the traffic is a Bot or a human.

The detection technique is further extended to detect bots on a mobile (Android) platform. Unlike web applications, in mobile (Android) traffic, bot detection based on JavaScript script do not apply. To detect bots in a mobile network, the technique uses a bot mobile SDK which is integrated with mobile applications on the client-side. The SDK intercepts the mobile traffic, collects device details, and sends the data to the appliance. On the appliance side, the detection technique examines the data and determines whether the connection is from a Bot or a human.

How the device fingerprint technique for mobile application works

The following steps explain the bot detection workflow to detect if a request from a mobile device is from a human or a bot.

1. When a user interacts with a mobile application, the device behavior is recorded by the bot mobile SDK.
2. Client sends a request to Citrix ADC appliance.
3. When sending the response, the appliance inserts a bot session cookie with session details, and parameters to collect client parameters.
4. When the mobile application receives the response, the Citrix bot SDK which is integrated with the mobile application validates the response, retrieves the recorded device fingerprint parameters, and sends it to the appliance.
5. The device fingerprint detection technique on the appliance side validates the device details and updates the bot session cookie if it is a suspected bot or not.
6. When the cookie is expired or device fingerprint protection prefers to validate and collect device parameters periodically, the whole procedure or challenge is repeated.

Pre-requisite

To get started with the Citrix ADC device fingerprint detection technique for mobile applications, you must download and install the bot mobile SDK in your mobile application.

Configure fingerprint detection technique for mobile (Android) applications by using the CLI

At the command prompt, type:

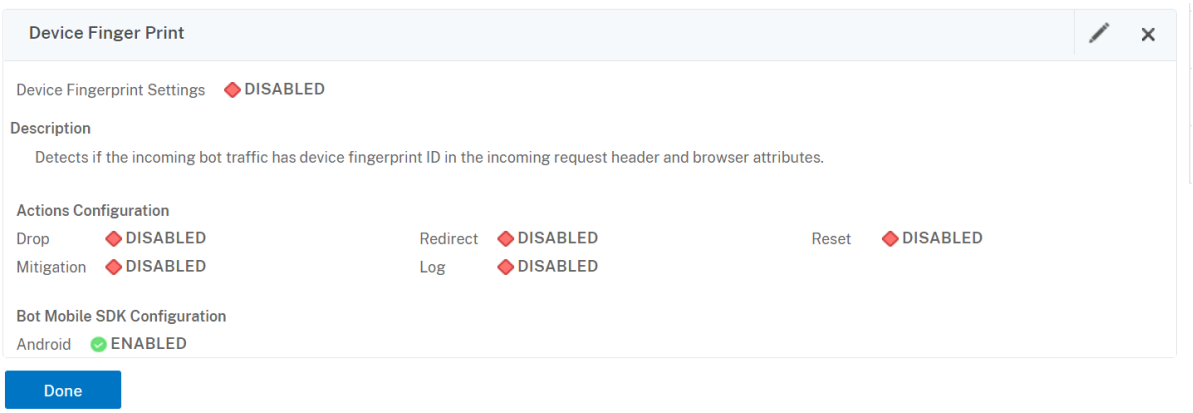
```
set bot profile <profile name> -deviceFingerprintMobile ( NONE | Android )
```

Example:

```
set bot profile profile 1 -deviceFingerprintMobile Android
```

Configure device fingerprint detection technique for mobile (Android) applications by using the GUI

1. Navigate to **Security** > **Citrix Bot Management** and **Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, click **Device Fingerprint** under **Profile Settings**.
4. In the **Configure Bot Mobile SDK** section, select the mobile client type.
5. Click **Update** and **Done**.



Configure bot log expression

If the client is identified as a bot, the Citrix bot management enables you to capture additional information as log messages. The data can be the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request or data generated from an expression. To perform custom logging, you must configure a log expression in the bot management profile.

Bind the log expression in the bot profile by using the CLI

At the command prompt, type:

```
1 bind bot profile <name> (-logExpression -name <string> -expression <
     expression> [-enabled ( ON | OFF )]) -comment <string>
2 <!--NeedCopy-->
```

Example:

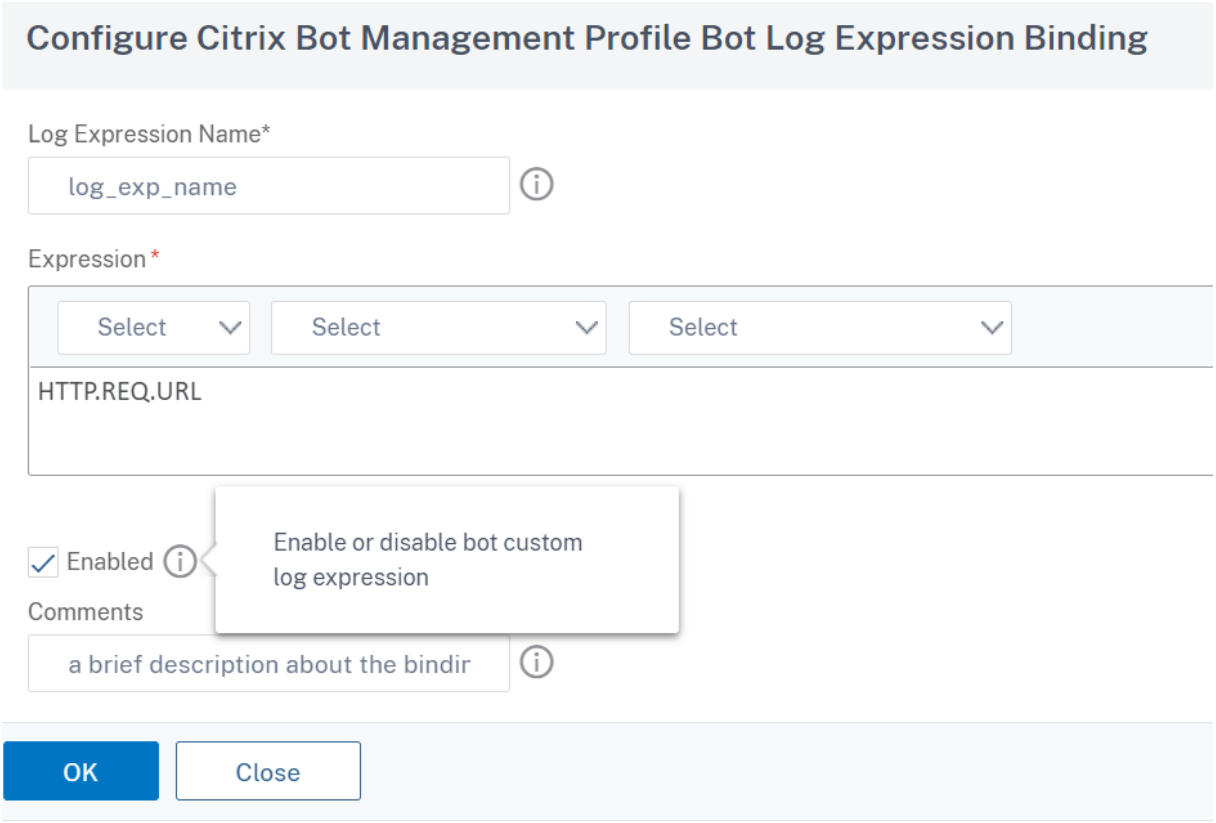
```
bind bot profile profile1 -logExpression exp1 -expression HTTP.REQ.URL -
enabled ON -comment "testing log expression"
```

Bind log expression to bot profile by using the GUI

1. Navigate to **Security > Citrix Bot Management > Profiles**.
2. On the **Citrix Bot Management Profiles** page, select **Bot Log Expressions** from **Profile Settings** section.
3. In the **Bot Log Expression Settings* section, click **Add**.
4. In the **Configure Citrix Bot Management Profile Bot Log Expression Binding** page, set the following parameters.
    a) Log Expression Name. Name of the log expression.

b) Expression. Enter the log expression.
c) Enabled. Enable or disable the log expression binding.
d) Comments. A brief description about the bot log expression binding.

5. Click**OK** and **Done**.



Configure bot trap technique

The Citrix bot trap technique randomly or periodically inserts a trap URL in the client response. You can also create a trap URL list and add URLs for that The URL appears invisible and not accessible if the client is a human user. However, if the client is an automated bot, the URL is accessible and when accessed, the attacker is categorized as bot and any subsequent request from the bot is blocked. The trap technique is effective in blocking attacks from bots.

The trap URL is an alpha-numeric URL of configurable length and it is auto-generated at configurable interval. Also the technique allows you to configure a trap injection URL for top visited websites or frequently visited websites. By doing this, you can mandate the purpose of injecting the bot trap URL for requests matching the trap injection URL.

> **Note:**
>
> Although the bot trap URL is auto-generated, the Citrix ADC bot management still allows you to configure a customized trap URL in the bot profile. This is done to strengthen the bot detection technique and make it harder for attackers to access the trap URL.

To complete the bot trap configuration, you must complete the following steps.

1. Enable bot trap URL
2. Configure bot trap URL in bot profile
3. Bind bot trap injection URL to bot profile
4. Configure bot trap URL length and interval in bot settings

Enable bot trap URL protection

Before you can begin, you must ensure the Bot trap URL protection is enabled on the appliance. At the command prompt, type:

```
enable ns feature Bot
```

Configure bot trap URL in bot profile

You can configure the bot trap URL and specify a trap action in the bot profile.
At the command prompt, type:

```
add bot profile <name> -trapURL <string> -trap ( ON | OFF )-trapAction <
trapAction>
```

Where,

`trapURL`. URL that Bot protection uses as the Trap URL. Maximum Length: 127

`trap`. Enable bot trap detection. Possible values: ON, OFF, Default value: OFF

`trapAction`. Action to be taken based bot detection. Possible values: NONE, LOG, DROP, REDIRECT, RESET, MITIGATION. Default value: NONE

Example:

```
add bot profile profile1 -trapURL www.bottrap1.com trap ON -trapAction
RESET
```

Bind bot trap injection URL to bot profile

You can configure the bot trap injection URL and bind it to the bot profile.
At the command prompt, type:

```
bind bot profile <profile_name> trapInjectionURL -url <url> -enabled ON|OFF
-comment <comment>
```

Where,

URL. Request URL regex pattern for which the bot trap URL is inserted. Maximum Length: 127

Example:

```
bind bot profile profile1 trapInjectionURL -url www.example.com -enabled ON
-comment insert a trap URL randomly
```

Configure bot trap URL length and interval in bot settings

You can configure the bot trap URL length and also set the interval to auto generate the bot trap URL. At the command prompt, type:

```
set bot settings -trapURLAutoGenerate ( ON | OFF )-trapURLInterval <positive_integer
> -trapURLLength <positive_integer>
```

Where,

trapURLInterval. Time in seconds after which the bot trap URL is updated. Default value: 3600, Minimum value: 300, Maximum value: 86400

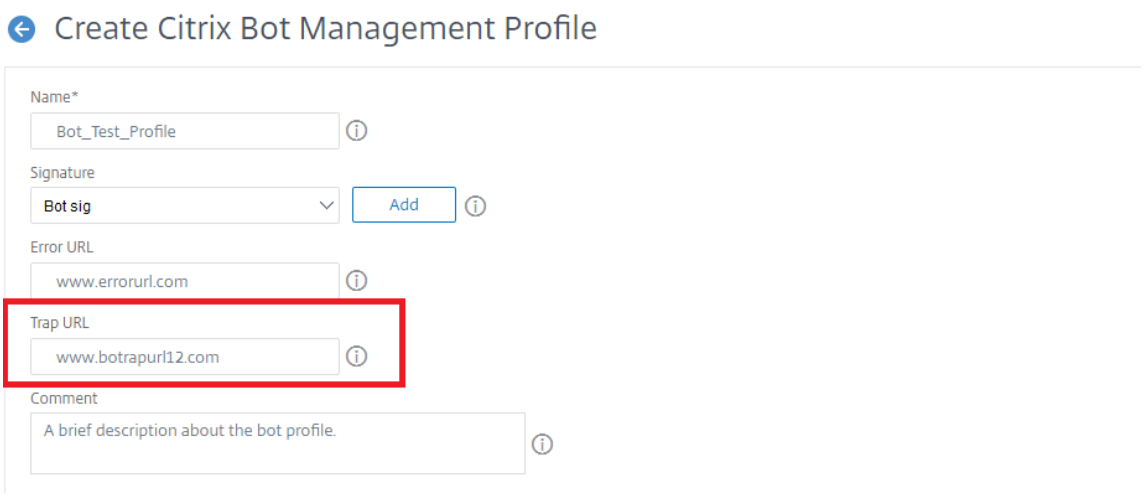
trapURLLength. Length of the auto-generated bot trap URL. Default value: 32, Minimum value: 10, Maximum value: 255

Example:

```
set bot settings -trapURLAutoGenerate ON -trapURLInterval 300 -trapURLLength
 60
```

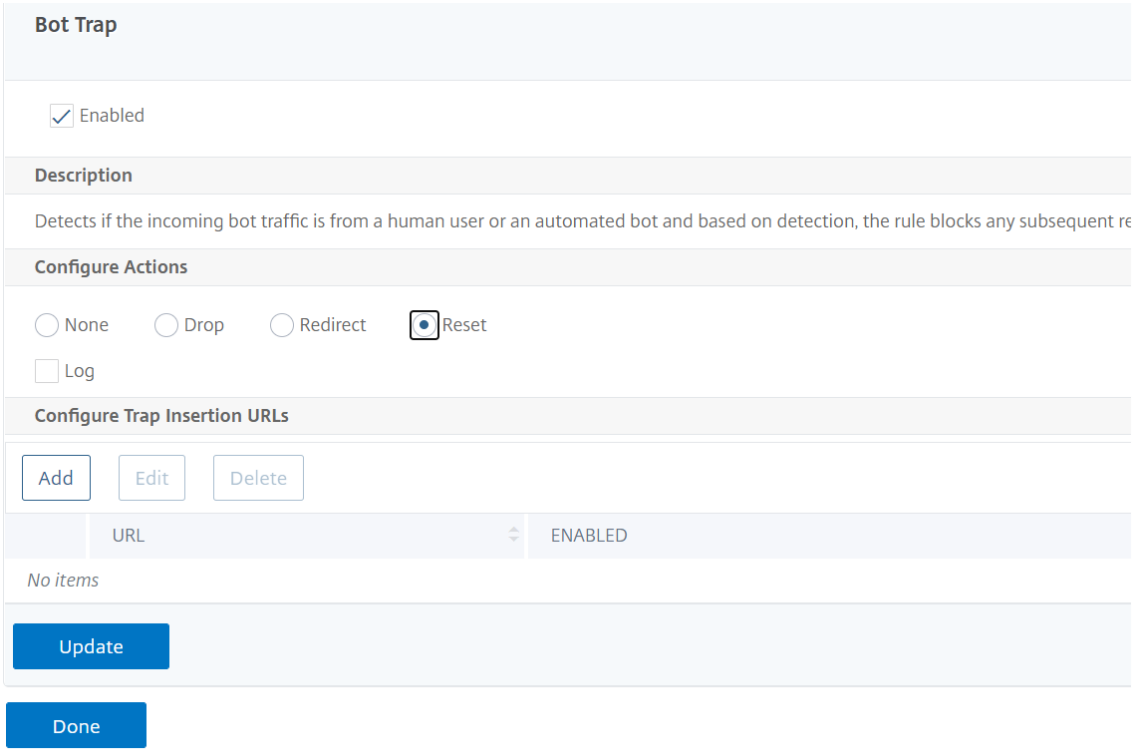
Configure bot trap URL by using the GUI

1. Navigate to **Security > Citrix Bot Management > Profiles**.
2. In the **Citrix Bot Management Profiles** page, click **Edit** to configure the bot trap URL technique.
3. In the **Create Citrix Bot Management Profile** page, enter the bot trap URL in the general section.



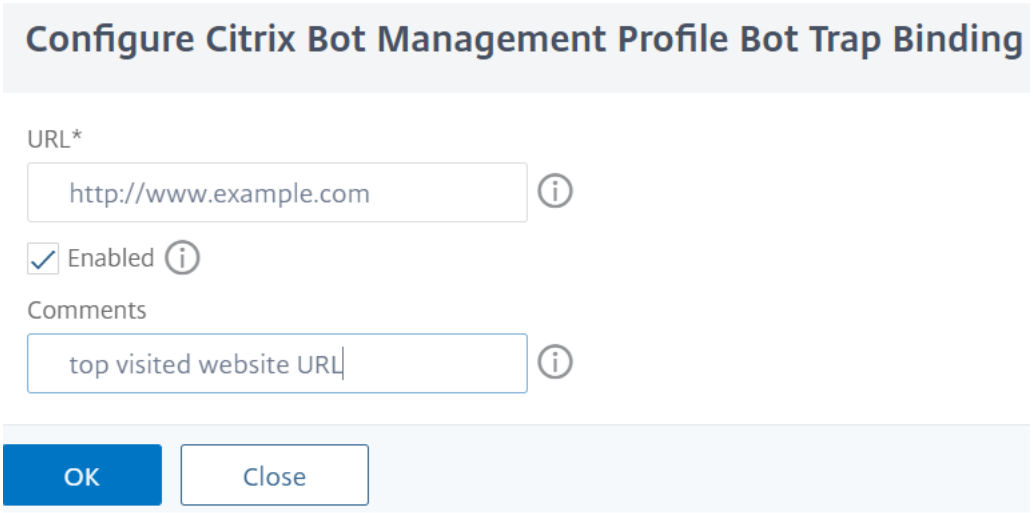
4. In the **Create Citrix Bot Management Profile** page, click **Bot Trap** from **Profile Settings**.
5. In the **Bot Trap** section, set the following parameters.

   a. Enabled. Select the check box to enable bot trap detection
   b. Description. Brief description about the URL.
   c. Configure Actions. Action to be taken for bot detected by bot trap access.



6. In the **Configure Trap Insertion URLs** section, click **Add**.
7. In the **Configure Citrix Bot Management Profile Bot Trap Binding** page, set the following parameters.

a) Trap URL. Type the URL that you want to confirm as the bot trap Injection URL.
b) Enabled. Enable or disable bot trap injection URL.
c) Comment. A brief description about the trap injection URL.

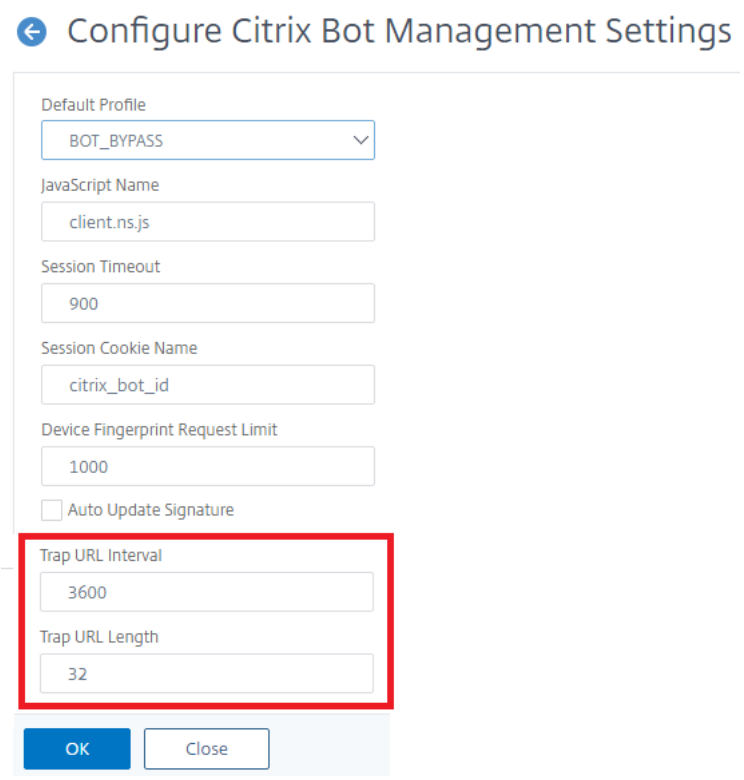


8. In the **Signature Settings** section, click **Bot Trap**.
9. In the **Bot Trap** section, set the following parameters:
   a) Enabled. Select the check box to enable bot trap detection.
   b) In the Configure section, set the following parameters.
      i. Action. Action to be taken for bot detected by bot trap access.
      ii. Log. Enable or disable logging for bot trap binding.
10. Click **Update** and **Done**.

Configure bot trap URL settings

Complete the following steps to configure bot trap URL settings:

1. Navigate to **Security > Citrix Bot Management**.
2. In the details pane, under **Settings** click **Change Citrix Bot Management Settings**.
3. In the **Configure Citrix Bot Management Settings**, set the following parameters.
   a) Trap URL Interval. Time in seconds after which the bot trap URL is updated.
   b) Trap URL Length. Length of the auto-generated bot trap URL.
4. Click **OK** and **Done**.



Client IP policy expression for bot detection

The Citrix bot management now enables you to configure an advanced policy expression to extract the client IP address from an HTTP request header, HTTP request body, HTTP request URL, or using an advanced policy expression. The extracted value can be used by a bot detection mechanism (such as TPS, bot trap, or rate limit) to detect if the incoming request is a bot.

> **Note:**
>
> If you have not configured a client IP expression, the default or existing source client IP address is used for bot detection. If an expression is configured, then the evaluation result provides the client IP address that can be used for bot detection.

You can configure and use the client IP expression to extract the actual client IP address if the incoming request is coming through a proxy server and if the client IP address is present in the header. By adding this configuration, the appliance can use the bot detection mechanism in providing more security to software clients and servers.

Configure client IP policy expression in bot profile by using the CLI

At the command prompt, type:

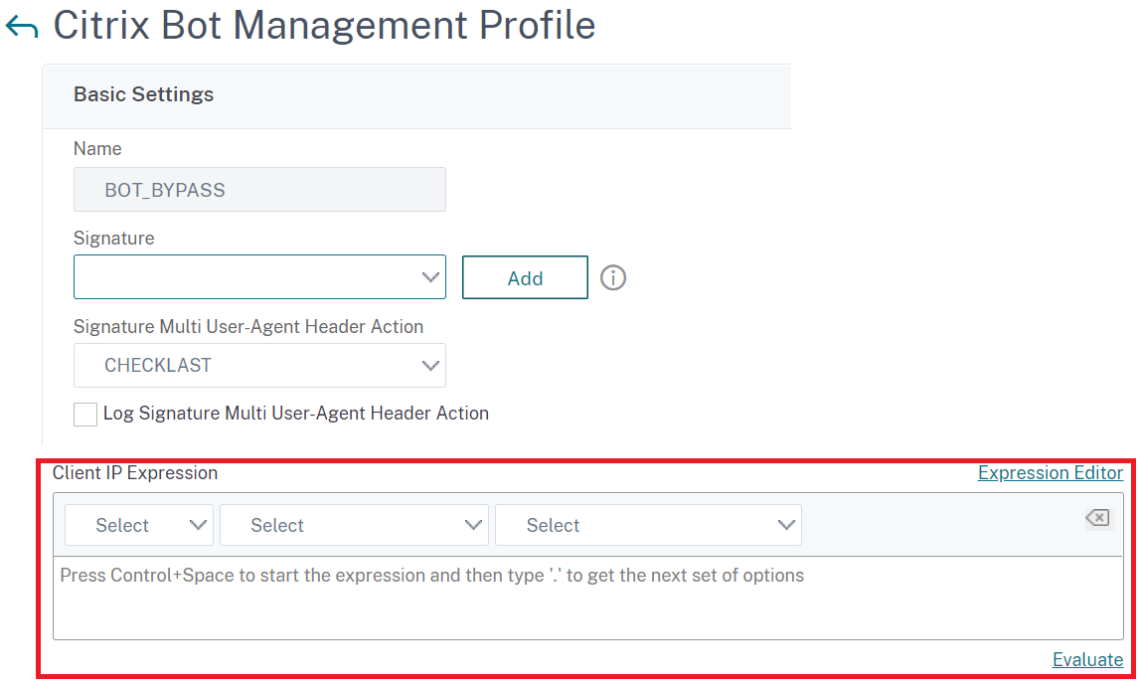
```
add bot profile <name> [-clientIPExpression <expression>]
<!--NeedCopy-->
```

Example:

```
add bot profile profile1 -clientIPExpression 'HTTP.REQ.HEADER("X-Forwarded-For")ALT CLIENT.IP.SRC.TYPECAST_TEXT_T'
```

Configure client IP policy expression in bot profile by using the GUI

1. Navigate to **Security > Citrix Bot Management > Profiles**.
2. In the details pane, click **Add**.
3. In the **Create Citrix Bot Management Profile** page, set the Client IP Expression.
4. Click **Create** and **Close**.



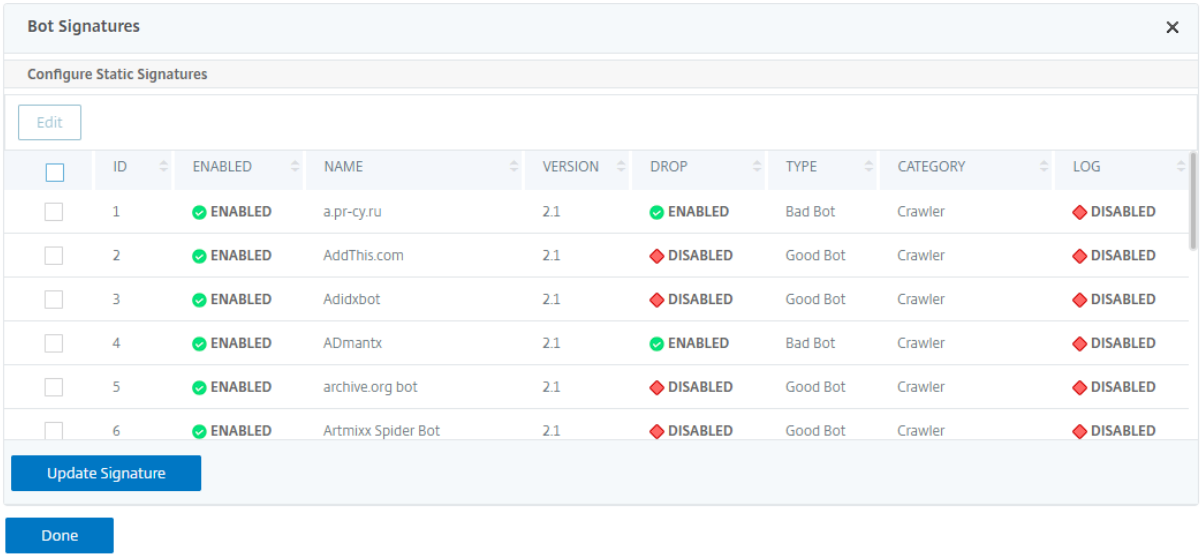
Configure CAPTCHA for IP reputation and device fingerprint detection

CAPTCHA is an acronym that stands for “Completely Automated Public Turing test to tell Computers and Humans Apart”. CAPTCHA is designed to test if an incoming traffic is from a human user or an automated bot. CAPTCHA helps to block automated bots that cause security violations to web applications. In the ADC appliance, CAPTCHA uses the challenge-response module to identify if the incoming traffic is from a human user and not an automated bot.

Configure bot static signatures

This detection technique enables you to identify the user agent info from the browser details. Based on user agent information, the bot is identified as a bad or a good bot and then you assign a bot action to it. Follow the steps below to configure the static signature technique:

1. On the navigation pane, expand **Security > Citrix Bot Management > Signatures**.
2. On the **Citrix Bot Management Signatures** page, select a signature file and click **Edit**.
3. On the **Citrix Bot Management Signature** page, go to the **Signature Settings** section and click the **Bot Signatures**.
4. In the **Bot Signatures** section, set the following parameters:
   a) Configure Static Signatures. This section has a list of bot static signature records. You can select a record and click **Edit** to assign a bot action to it.
   b) Click **OK**.
5. Click **Update Signature**.
6. Click **Done**.



Bot static signature delineation

Citrix ADC bot management protects your web application against bots. Bot static signatures help in identifying good and bad bots based on request parameters such as user-agent in the incoming request.

The list of signatures in the file is huge and also new rules get added and stale ones are removed periodically. As an administrator, you might want to search for a specific signature or list of signatures under a category. To filter signatures easily, the bot signature page provides an enhanced search capability. The search function enables you to find signature rules and configure its property based on one or more signature parameters like action, signature ID, developer and signature name.

Action. Select a bot action that you prefer to configure for a specific category of signature rules. Following are the available action types:

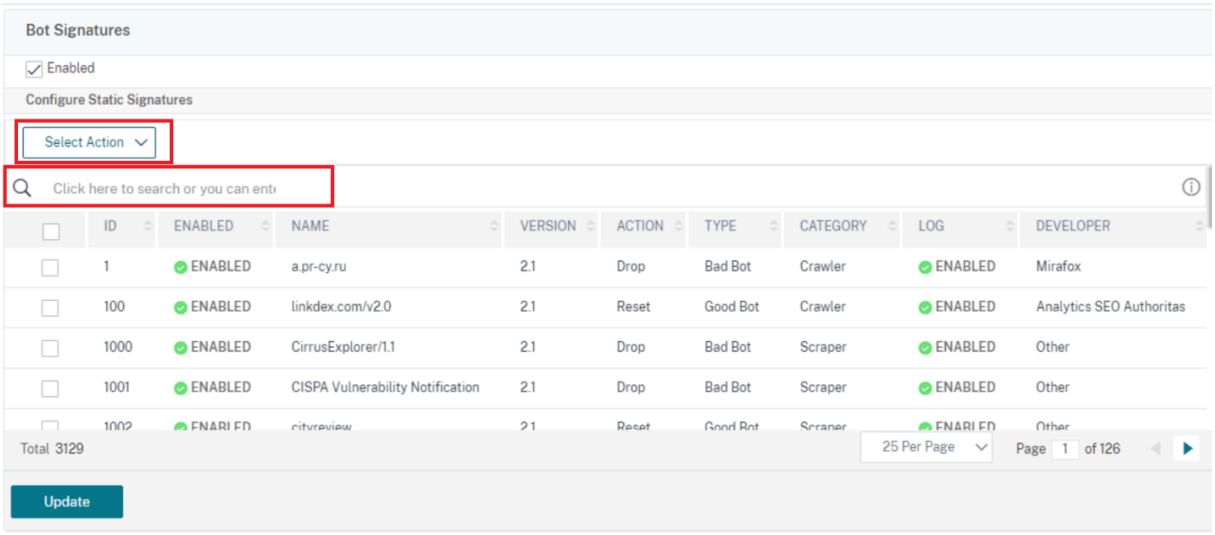
- Enable Selected. Enable all the selected signature rules.
- Disable Selected. Disable all the selected signatures rules.
- Drop Selected. Apply the action as “Drop” to all the selected signature rules.
- Redirect Selected. Apply action as “Redirect” to all the selected signature rules.
- Reset Selected. Apply action as “Reset” to all the selected signature rules.
- Log Selected. Apply action as “Log” to all the selected signature rules.
- Remove Drop Selected. Unset the drop action to all the selected signature rules.
- Remove Redirect Selected. Unset the redirect action to all the selected signature rules.
- Remove Reset Selected. Unset the reset action to all the selected signature rules.
- Remove Log Selected. Unset the log action to all the selected signature rules.

Category. Select a category to filter signature rules accordingly. Following is the list of categories that are available for sorting signature rules.

- Action. Sort based on bot action.
- Category. Sort based on bot category.
- Developer. Sort based on the host company publisher.
- Enabled. Sort based on signature rules that are enabled.
- Id. Sort based on signature rule ID.
- Log. Sort based on signature rules that have logging enabled.
- Name. Sort based on signature rule name.
- Type. Sort based on signature type.
- Version. Sort based on signature rule version.

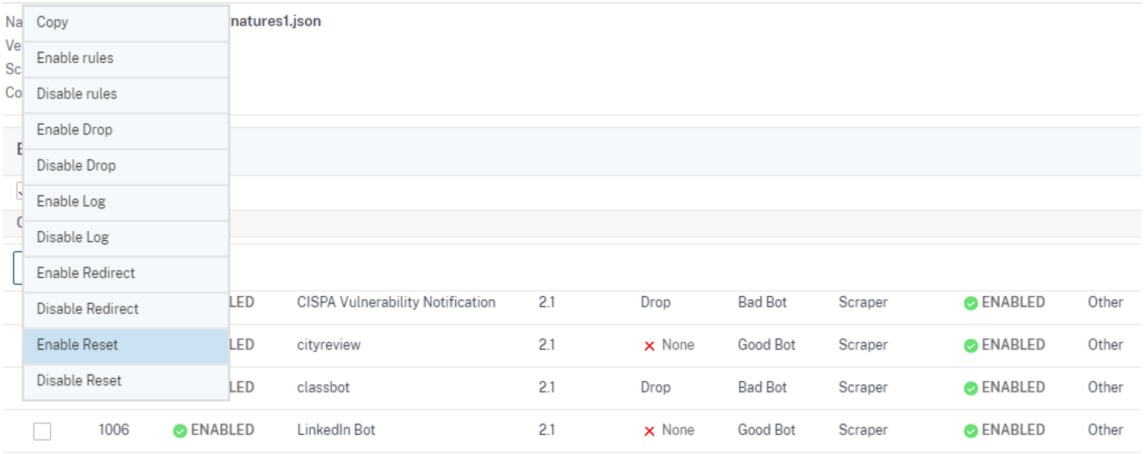
Search bot static signature rules based on action and category types by using the Citrix ADC GUI

1. Navigate to **Security > Citrix Bot Management > Signature**.
2. In the details page, click **Add**.
3. In the **Citrix Bot Management Signatures** page, click edit in the **Static Signature** section.
4. In the **Configure Static Signature** section, select a signature action from the drop-down list.
5. Use the search function to select a category and filter the rules accordingly.
6. Click **Update**.



Edit bot static signature rule property by using the Citrix ADC GUI

1. Navigate to **Security > Citrix Bot Management > Signature**.
2. In the details page, click **Add**.
3. In the **Citrix Bot Management Signatures** page, click edit in the **Static Signature** section.
4. In the **Configure Static Signature** section, select an action from the drop-down list.
5. Use the search function to select a category and filter rules accordingly.
6. From the static signature list, select a signature to modify its property.



7. Click **OK** to confirm.

How CAPTCHA works in Citrix ADC bot management

In Citrix ADC bot management, CAPTCHA validation is configured as a policy action to be run after bot policy is evaluated. The CAPTCHA action is available only for IP reputation and device fingerprint detection techniques. Following are the steps to understand how CAPTCHA works:

1. If a security violation is observed during IP reputation or device fingerprint bot detection, the ADC appliance sends a CAPTCHA challenge.
2. The client sends the CAPTCHA response.
3. The appliance validates the CAPTCHA response and if the CAPTCHA is valid, the request is allowed and it is forwarded to the back-end server.
4. If the CATCHA response is invalid, the appliance sends a new CAPTCHA challenge until the maximum number of attempts is reached.
5. If the CAPTCHA response is invalid even after the maximum number of attempts, the appliance drops or redirects the request to the configured error URL.
6. If you have configured log action, then the appliance stores the request details in the ns.log file.

Configure CAPTCHA settings by using the Citrix ADC GUI

The bot management CAPTCHA action is supported only for IP reputation and device fingerprint detection techniques. Complete the following steps to configure the **CAPTCHA** settings.

1. Navigate to **Security > Citrix Bot Management and Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a profile and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to the **Signature Settings** section and click **CAPTCHA**.
4. In the **CAPTCHA Settings** section, click **Add to configure CAPTCHA** settings to the profile:
5. In the **Configure Citrix Bot Management CAPTCHA** page, set the following parameters.
    a) URL. Bot URL for which the CAPTCHA action is applied during IP reputation and device fingerprint detection techniques.
    b) Enabled. Set this option to enable CAPTCHA support.
    c) Grace time. Duration until when no new CAPTCHA challenge is sent after the current valid CAPTCHA response is received.
    d) Wait time. Duration taken for the ADC appliance to wait until the client sends the CAPTCHA response.
    e) Mute Period. Duration for which the client which sent an incorrect CAPTCHA response must wait until allowed to try next. During this mute period, the ADC appliance does not allow any requests. Range: 60–900 seconds, Recommended: 300 seconds

f) Request Length limit. Length of the request for which the CAPTCHA challenge is sent to the client. If the length is greater than the threshold value, the request is dropped. Default value is 10–3000 bytes.

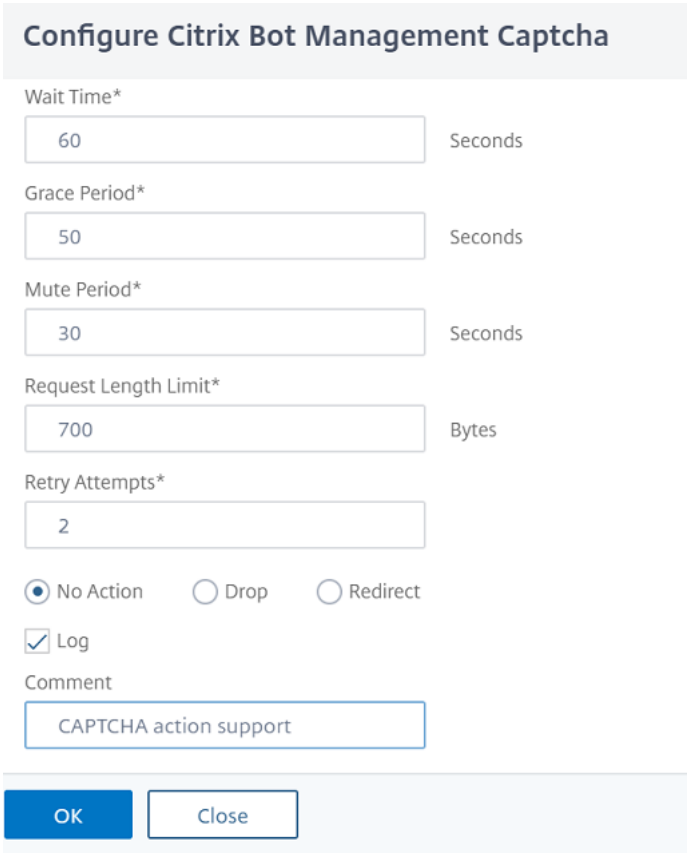
g) Retry Attempts. Number of attempts the client is allowed to retry to solve the CAPTCHA challenge. Range: 1–10, Recommended: 5.

h) No Action/Drop/Redirect action to be taken if the client fails the CAPTCHA validation.

i) Log. Set this option to store request information from the client when response CAPTCHA fails. The data is store in `ns.log` file.

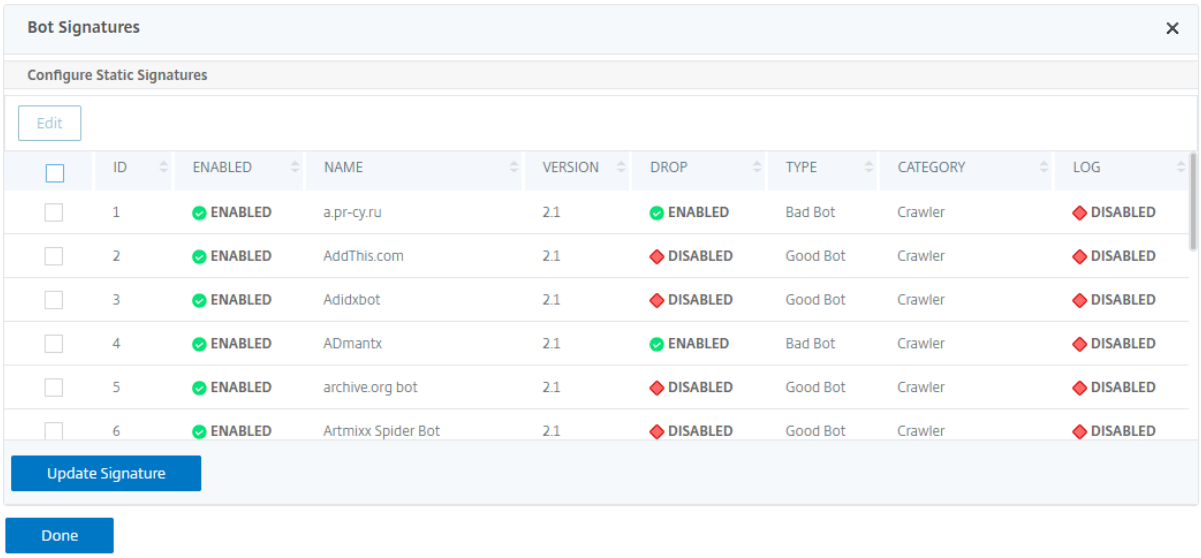
j) Comment. A brief description about the CAPTCHA configuration.

6. Click **OK** and **Done**.



7. Navigate to **Security > Citrix Bot Management > Signatures**.
8. On the **Citrix Bot Management Signatures** page, select a signature file and click **Edit**.
9. On the **Citrix Bot Management Signature** page, go to **Signature Settings** section and click **Bot Signatures**.
10. In the **Bot Signatures** section, set the following parameters:

11. Configure **Static Signatures**. Select a bot static signature record and click Edit to assign a bot action to it.
12. Click **OK**.
13. Click **Update Signature**.
14. Click **Done**.



Auto update for bot signatures

The bot static signature technique uses a signature lookup table with a list of good bots and bad bots. The bots are categorized based on user-agent string and domain names. If the user-agent string and domain name in incoming bot traffic matches a value in the lookup table, a configured bot action is applied.
The bot signature updates are hosted on the AWS cloud and the signature lookup table communicates with the AWS database for signature updates. The auto signature update scheduler runs every 1-hour to check the **AWS database** and updates the signature table in the Citrix ADC appliance.

The signature auto update URL to configure is, `https://nsbotsignatures.s3.amazonaws.com/BotSignatureMapping.json`

> **Note:**
>
> You can also configure a proxy server and periodically update signatures from the AWS cloud to the appliance through the proxy. For proxy configuration, you must set the proxy IP address and port address in the bot settings.

How bot signature auto update works

The following diagram shows how the bot signatures are retrieved from the AWS cloud, updated on Citrix ADC, and viewed on Citrix ADM for signature update summary.

The bot signature auto-update scheduler does the following:

1. Retrieves the mapping file from the AWS URI.
2. Checks the latest signatures in the mapping file with the existing signatures in the ADC appliance.
3. Downloads the new signatures from AWS and verifies the signature integrity.
4. Updates the existing bot signatures with the new signatures in the bot signature file.
5. Generates an SNMP alert and sends the signature update summary to Citrix ADM.

Configure bot signature auto update

For configuring bot signature auto update, complete the following steps:

Enable bot signature auto update

You must enable the auto update option in the bot settings on the ADC appliance.
At the command prompt, type:

```
set bot settings -signatureAutoUpdate ON
```

Configure proxy server settings (optional)

If you are accessing the AWS signature database through a proxy server, you must configure the proxy server and port.

```
set bot settings -proxyserver -proxyport
```

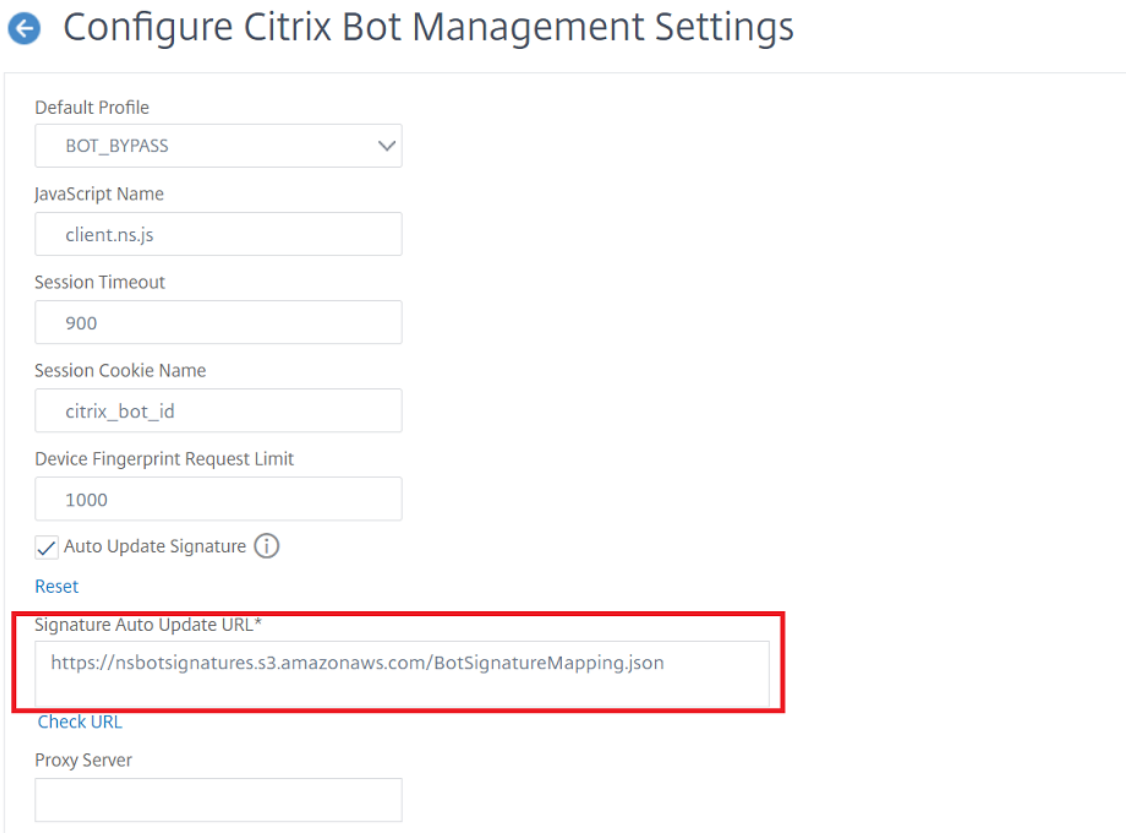
Example:

```
set bot settings -proxy server 1.1.1.1 -proxyport 1356
```

Configure bot signature auto update using the Citrix ADC GUI

Complete the following steps to configure bot signature auto update:

1. Navigate to **Security > Citrix Bot Management**.
2. In the details pane, under **Settings** click **Change Citrix Bot Management Settings**.
3. In the **Configure Citrix Bot Management Settings**, select the **Auto Update Signature** check box.



4. Click **OK** and **Close**.

Create bot management profile

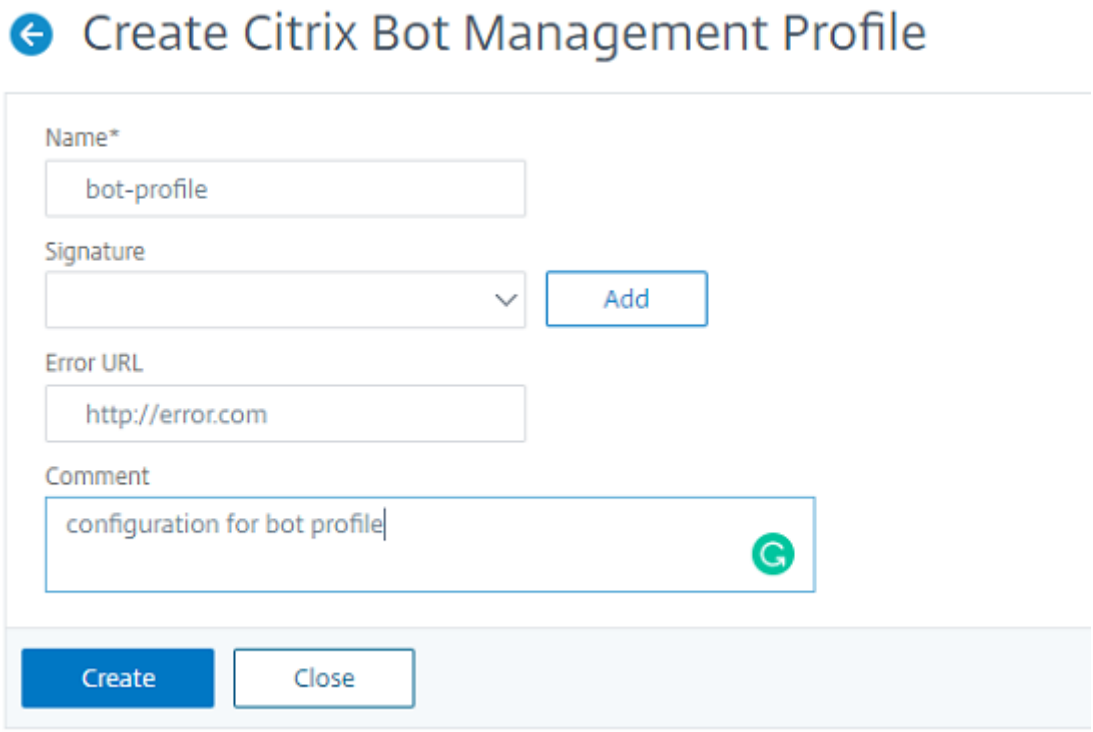
A bot profile is a collection of bot management settings that are used for detecting the bot type. In a profile, you determine how the Web App Firewall applies each of its filters (or checks) to bot traffic to your websites, and responses from them.

Complete the following steps to configure the bot profile:

1. Navigate to **Security** > **Citrix Bot Management** > **Profiles**.
2. In the details pane, click **Add**.
3. In the **Create Citrix Bot Management Profile** page, set the following parameters.

a) Name. Bot profile name.
b) Signature. Name of the bot signature file.
c) Error URL. URL for redirects.
d) Comment. Brief description about the profile.

4. Click **Create** and **Close**.

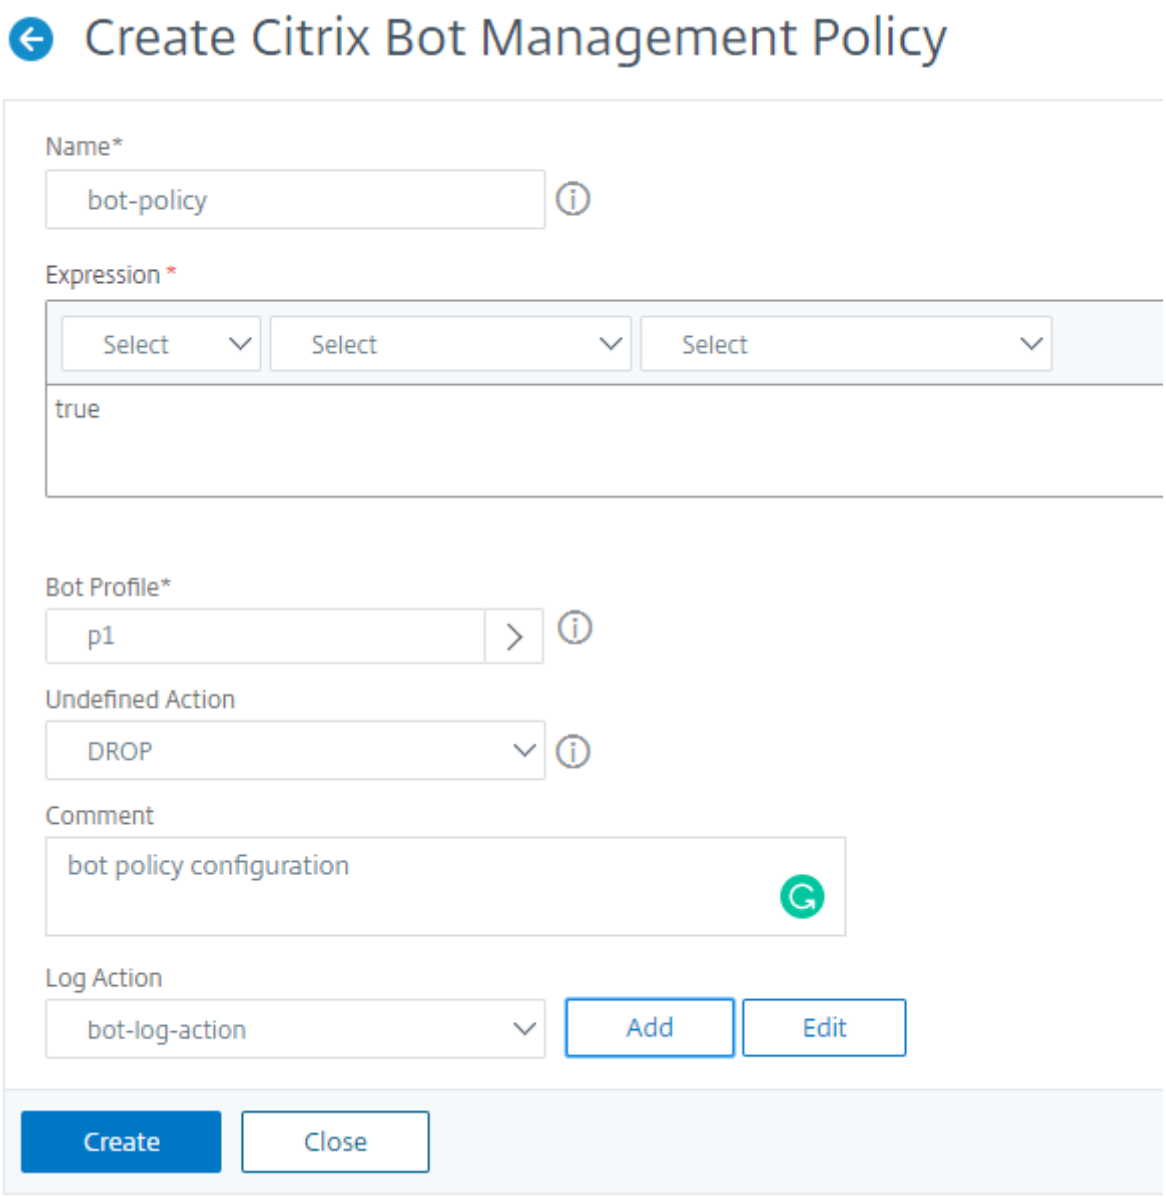


Create bot policy

The bot policy controls the traffic going to the bot management system and also to control the bot logs sent to the auditlog server. Follow the procedure to configure the bot policy.

1. Navigate to **Security** > **Citrix Bot Management** > **Bot Policies**.
2. In the details pane, click **Add**.
3. In the **Create Citrix Bot Management Policy** page, set the following parameters.
   a) Name. Name of the Bot policy.
   b) Expression. Type the policy expression or rule directly in the text area.
   c) Bot Profile. Bot profile to apply the bot policy.
   d) Undefined Action. Select an action that you prefer to assign.
   e) Comment. Brief description about the policy.
   f) Log Action. Audit log message action for logging bot traffic. For more information about audit log action, see Audit logging topic.

4. Click **Create** and **Close**.



Bot Transactions Per second (TPS)

The Transactions Per Second (TPS) bot technique detects incoming traffic as a bot if the number of requests per second (RPS) and percentage increase in RPS exceeds the configured threshold value. The detection technique protects your web applications from automated bots that can cause web scraping activities, brute forcing login, and other malicious attacks.

> **Note:**
>
> The bot technique detects an incoming traffic as bot only if both the parameters are configured

> and if both values increase beyond the threshold limit.
> Let us consider a scenario, where the appliance receives many requests coming from a specific URL and you want the Citrix ADC bot management to detect if there is a bot attack. The TPS detection technique examines the number of requests (configured value) coming from the URL within 1 second and the percentage increase (configured value) in the number of requests received within 30 minutes. If the values exceed the threshold limit, the traffic is considered as bot and the appliance runs the configured action.

Configure bot transactions per second (TPS) technique

To configure TPS, you must complete the following steps:

1. Enable bot TPS
2. Bind TPS settings to bot management profile

Bind TPS settings to bot management profile

Once you enable the bot TPS feature, you must bind the TPS settings to the bot management profile.

At the command prompt, type:

```
bind bot profile <name>… (-tps [-type ( SourceIP | GeoLocation | RequestURL
 | Host )] [-threshold <positive_integer>] [-percentage <positive_integer
>] [-action ( none | log | drop | redirect | reset | mitigation )] [-
logMessage <string>])
```

Example:

```
bind bot profile profile1 -tps -type RequestURL -threshold 1 -percentage
100000 -action drop -logMessage log
```

Enable bot transaction per second (TPS)

Before you can begin, you must ensure that the Bot TPS feature is enabled on the appliance. At the command prompt, type:

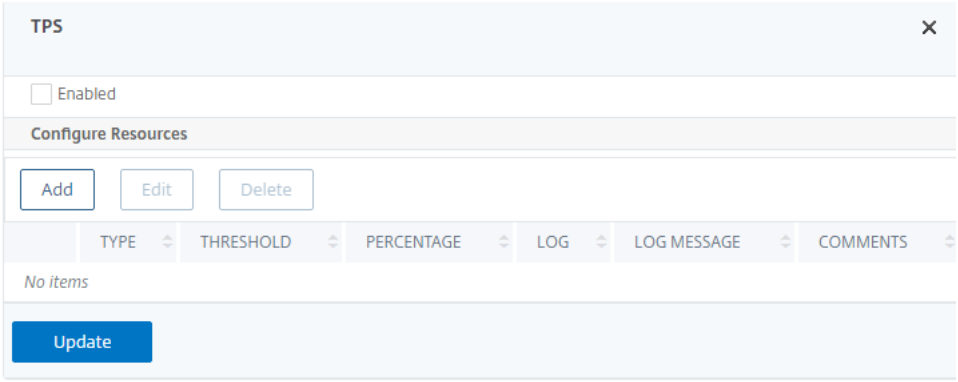
```
set bot profile profile1 -enableTPS ON
```

Configure bot transactions per second (TPS) by using the Citrix ADC GUI

Complete the following steps to configure bot transactions per second:

1. Navigate to **Security > Citrix Bot Management > Profiles**.
2. In the **Citrix Bot Management Profiles** page, select a profile and click **Edit**.

3. In the **Create Citrix Bot Management Profile** page, click **TPS** under **Signature Settings** section.
4. In the **TPS** section, enable the feature and click **Add**.



5. In **Configure Citrix Bot Management Profile TPS Binding** page, set the following parameters.
   a) Type. Input types allowed by the detection technique. Possible values: SOURCE IP, GEOLOCATION, HOST, URL.

      SOURCE_IP – TPS based on client IP address.

      GEOLOCATION – TPS based on the client's geographic location.

      HOST - TPS based on client requests forwarded to a specific back-end server IP address.

      URL – TPS based on client requests coming from a specific URL.

   b) Fixed Threshold. Maximum number of requests allowed from a TPS input type within 1 second time interval.

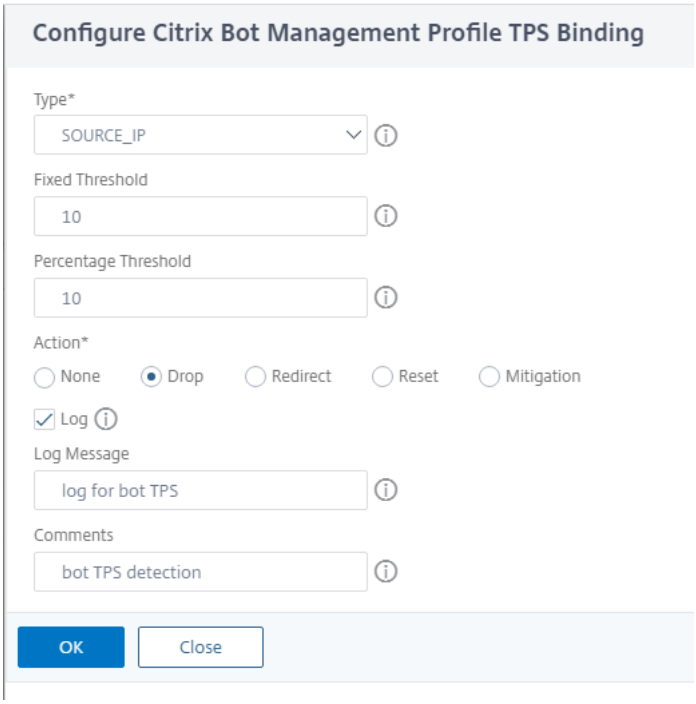
   c) Percentage Threshold. Maximum percentage increase in requests from a TPS input type within 30 minute time interval.

   d) Action. Action to be taken for bot detected by TPS binding.

   e) Log. Enable or disable logging for TPS binding.

   f) Log Message. Message to log for bot detected by TPS binding. Maximum Length: 255.

   g) Comments. A brief description about the TPS configuration. Maximum Length: 255
6. Click **OK** and then **Close**.



Bot detection based on mouse and keyboard dynamics

To detect bots and mitigate web scraping anomalies, the Citrix ADC bot management uses an enhanced bot detection technique based on mouse and keyboard behavior. Unlike conventional bot techniques that require direct human interaction (for example, CAPTCHA validation), the enhanced technique passively monitors the mouse and the keyboard dynamics. The Citrix ADC appliance then collects the real-time user data and analyses the behavioral between a human and a bot.

The passive bot detection using mouse and keyboard dynamics has the following benefits over existing bot detection mechanisms:

- Provides continuous monitoring throughout the user session, and eliminates single checkpoint.
- Requires no human interaction and it is completely transparent to users.

How bot detection using mouse and keyboard dynamics works

The bot detection technique using keyboard and mouse dynamics consists of two components, a webpage logger and bot detector. The webpage logger is a JavaScript that records keyboard and mouse movements when a user is performing a task on the webpage (for example, filling a registration form). The logger then sends the data in batches to the Citrix ADC appliance. The appliance then stores the data as a KM record and sends it to the bot detector on the Citrix ADM server, which analyses if the user is a human or bot.

The following steps explain how the components interact with each other:

1. The Citrix ADC admin configures policy expression through the ADM StyleBook, CLI, or NITRO or any other method.
2. The URL is set in the bot profile when the admin enables the feature on the appliance.
3. When a client sends a request, the Citrix ADC appliance tracks the session and all requests in the session.
4. The appliance inserts a JavaScript (webpage logger) in the response if the request matches the configured expression on the bot profile.
5. The JavaScript then collects all the keyboard, mouse activity and sends the KM data in a POST URL (transient).
6. The Citrix ADC appliance stores the data and sends it to the Citrix ADM server at the end of the session. Once the appliance receives the complete data of a POST request, the data is sent it to ADM server.
7. The Citrix ADM Service analyses the data and based on the analysis, the result is available on the Citrix ADM service GUI.

The JavaScript logger records the following mouse and keyboard movements:

- Keyboard events – all events
- Mouse events - mouse move, mouse up, mouse down
- Clipboard events - paste
- Custom events - autofill, autofillcancel
- timestamp of each event

Configure bot detection using mouse and keyboard dynamics

The Citrix ADC bot management configuration includes enabling or disabling keyboard and mouse-based detection feature, and configures the JavaScript URL in the bot profile.
Complete the following steps to configure bot detection using mouse and keyboard dynamics:

1. Enable keyboard and mouse-based detection
2. Configure expression to decide when the JavaScript can be injected in the HTTP response

Enable keyboard mouse-based bot detection

Before you begin the configuration, ensure you have enabled the keyboard and mouse-based bot detection feature on the appliance.

At the command prompt, type:

```
add bot profile <name> -KMDetection ( ON | OFF )
<!--NeedCopy-->
```

Example:

```
add bot profile profile1 -KMDetection ON
```

Configure bot expression for JavaScript insertion

Configure bot expression to evaluate the traffic and insert JavaScript. The JavaScript is inserted only if the expression is evaluated as true.

At the command prompt, type:

```
1 bind bot profile <name> -KMDetectionExpr -name <string> -expression <
     expression> -enabled ( ON | OFF ) - comment <string>
2 <!--NeedCopy-->
```

Example:

```
bind bot profile profile1 -KMDetectionExpr -name test -expression http.req.
url.startswith("/testsite")-enabled ON
```

Configure JavaScript file name inserted in the HTTP response for keyboard-mouse based bot detection

To collect the user action details, the appliance sends a JavaScript file name in the HTTP response. The JavaScript file collects all the data in a KM record and sends it to the appliance.

At the command prompt, type:

```
1 set bot profile profile1 - KMJavaScriptName <string>
2 <!--NeedCopy-->
```

Example:

```
set bot profile profile1 -KMJavaScriptName script1
```

Configure behavior biometrics size

You can configure the maximum size of mouse and keyboard behavior data that can be sent as KM record to the appliance and processed by ADM server.

At the command prompt, type:

```
1 set bot profile profile1 -KMEventsPostBodyLimit <positive_integer>
2 <!--NeedCopy-->
```

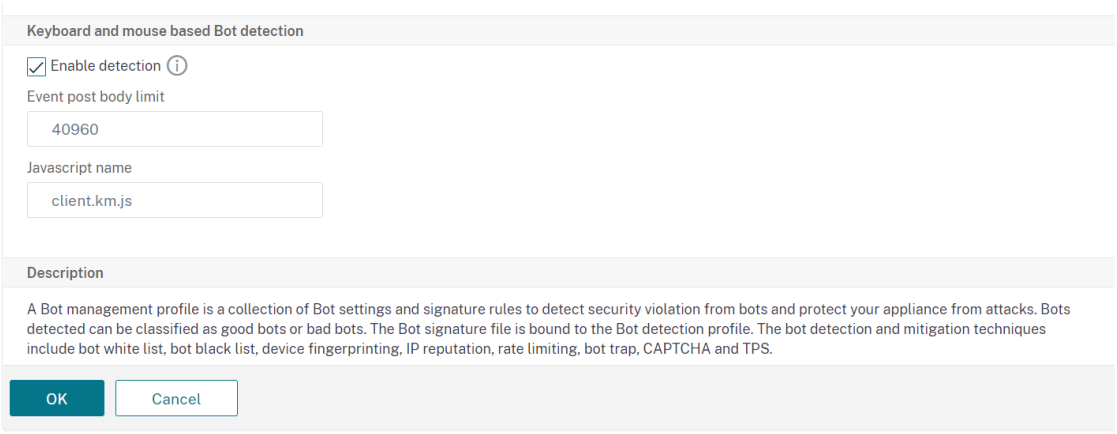
Example:

```
set bot profile profile1 - KMEventsPostBodyLimit 25
```

After you have configured the Citrix ADC appliance to configure the JavaScript and collect keyboard and mouse behavior biometrics, the appliance sends the data to the Citrix ADM server. For more information on how the Citrix ADM server detects bots from behavior biometrics, see Bot Violations topic.

Configure keyboard and mouse bot expression settings by using the GUI

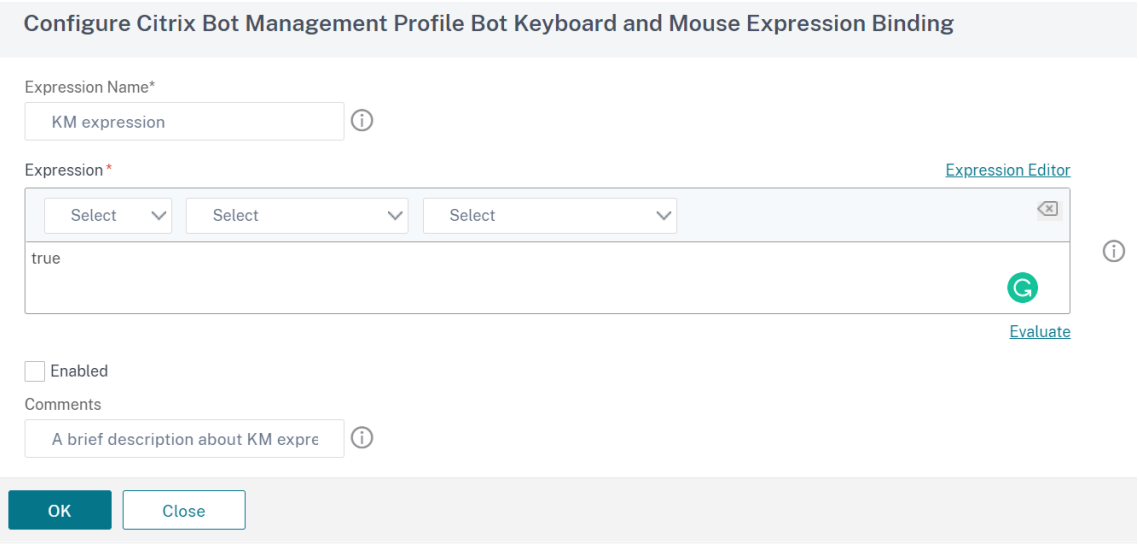
1. Navigate to **Security > Citrix Bot Management and Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a profile and click **Edit**.
3. In the **Keyboard and mouse based bot detection** section, set the following parameters:
   a) Enable detection. Select the check box to detect the bot based keyboard and mouse dynamics behavior.
   b) Event post body limit. Size of the keyboard and mouse dynamics data sent by the browser to be processed by the Citrix ADC appliance.
4. Click **OK**.



5. On the **Citrix Bot Management Profile** page, go to the **Profile Settings** section and click **Keyboard and Mouse Based Bot Expression Settings**.
6. In the **Keyboard and Mouse Based Bot Expression Settings** section, click **Add**.
7. In the **Configure Citrix Bot Management Profile Bot Keyboard and Mouse Expression Binding** page, set the following parameters:
   a) Expression Name. Name of the bot policy expression for detection keyboard and mouse dynamics.
   b) Expression. Bot policy expression.
   c) Enabled. Select the check box to enable the keyboard and bot keyboard and mouse expression binding.
   d) Comments. A brief description about the bot policy expression and its binding to the bot profile.

e) Click **OK** and **Close**.

8. In the **Keyboard and Mouse Based Bot Expression Settings** section, Click **Update**.



Bot Management

September 14, 2021

Following are some of the troubleshooting scenarios covered in Citrix ADC bot management.

1. How to handle false positive cases?

   You can use the bot allow list functionality to manage false positive cases and these transactions can be bypassed.

2. How to find more details about bad bot traffic?

   You can use the audit logging functionality to get details about the traffic classified as bad bots.

3. Why should you change the default signature name?

   You can change the default signature name if there are conflicts detected at the end point resources served by the Citrix ADC appliance.

Bot Management

September 21, 2021

What is Citrix ADC bot management?

```
Citrix ADC bot management detects and distinguishes traffic from good
    bots, bad bots, and human clients. The bot management functionality
    protects your web applications from bad bots by applying a
    configured action on incoming requests.
```

1. Why Citrix ADC must manage bots for your web application?

   Malicious bots constitute 30% of your internet traffic. Malicious bots impact web applications in various ways such as initiating a DoS attack, spamming email addresses, slowing down the application using downloader programs, downloading the content from websites and so forth. In addition, bots can easily bypass some of the well known detection mechanisms leading to loss of data, revenue, and reputation to your organization.

2. What are the techniques used for detecting an incoming bot?

   The appliance uses detection techniques such as IP reputation, rate limiting, device fingerprinting, TPS, and Bot trap detection techniques. In addition, you can configure a customized block list on the Citrix ADC GUI to categorize organization specific bad bots.

3. What is a bot signature file and its purpose?

   The bot signature file contains the footprint of known good and bad bots. The signature file is updated periodically to include the latest bot signatures for better bot protection.

4. What type of Citrix ADC license must I purchase?

   Bot management is available with the ADC Premium license.

5. Where can I find bot logs for troubleshooting?

   Citrix ADC audit logs provide detected bot details. For more information, see Audit Logging topic.

6. Is there an auto update functionality for the bot signature files?

   Yes, Citrix ADC bot management supports auto update functionality.

7. Is there a pre-requisite for using the bot IP reputation technique?

   Enable the IP reputation feature before enabling and configuring the IP reputation in the bot profile.

Bot signature alert Articles

September 14, 2021

Citrix bot management announces signature updates that you can download and apply on your appliance. When you detect a bot attack, you will receive an email notification about the new signature update. You can download the signature and apply it on your appliance.

Bot signature update for November 2020

September 14, 2021

New signatures rules are generated for the bots identified in the week 2020-11-11. You can download and configure these signature rules to protect your appliance from bot attacks.

Bot signature version

Signature version 5 applicable for Citrix ADC 13.0 platform.

New Bots Insight

Following is a list of bot signature rules, category, and its type.

Category	Bot Type	Signature Count
Scraper	Good Bot	3

Bot signature update for January 2021

September 20, 2021

Some of existing bot signatures are updated. You can download and configure these signature rules to protect your appliance from bot attacks.

Bot signature version

Signature version 6 is applicable for Citrix ADC platforms with 13.0 61.x builds or later.

Updated bot signatures in this version

Following is a list of bot signature rule IDs, category and its type.

Bot signature rule	ID	Description
143	Crawler	Good Bot

Bot signature update for March 2021

September 20, 2021

Some of existing bot signatures are updated. You can download and configure these signature rules to protect your appliance from bot attacks.

Bot signature version

Signature version 7 is applicable for Citrix ADC platforms with 13.0 61.x builds or later.

Updated bot signatures in this version

Following is a list of bot signature rule IDs, category, and its type.

Cache Redirection

September 14, 2021

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a Citrix ADC appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The Citrix ADC appliance analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A Citrix ADC appliance configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the Citrix ADC appliance resides directly in front of the clients. In a server-side deployment, the Citrix ADC appliance is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache redirection policies

September 14, 2021

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the Citrix ADC appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The appliance provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

Note: Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure

at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

Built-in cache redirection policies

September 14, 2021

The Citrix ADC appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers and their values in the request.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use two types of appliance expressions languages, classic and default syntax. For more information about these languages, see Policies and expressions.

Built-in classic cache redirection policies

Built-in cache redirection policies based on classic expressions are called *classic cache redirection policies*. For a complete description of classic expressions and how to configure them, see Policies and Expressions.

The classic cache redirection policies evaluate basic characteristics of traffic and other data. For example, classic cache redirection policies can determine whether an HTTP request or response contains a particular type of header or URL.

The Citrix ADC appliance provides the following built-in classic cache redirection policies:

Built-In Policy Name	Description
bypass-non-get	Bypass the cache if the request uses an HTTP method other than GET.
bypass-cache-control	Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.

Built-In Policy Name	Description
bypass-dynamic-url	Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/.
bypass-urltokens	Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.
bypass-cookie	Bypass the cache for any URL that has a cookie header and an extension other than .png or .jpg.

Built-in default syntax cache redirection policies

Built-in cache redirection policies based on default syntax expressions are called *default syntax cache redirection policies*. For a complete description of default syntax expressions and how to configure them, see Policies and Expressions.

In addition to the same types of evaluations done by classic cache redirection policies, default syntax cache redirection policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, directing the request to either cache or origin server).

Citrix ADC appliances provide the following two built-in actions for the default syntax cache redirection policies:

- CACHE
- ORIGIN

As implied by their names, they direct the request to the cache server or the origin server, respectively.

Note: If you are using the built-in default syntax cache redirection policy, you cannot modify the action.

The Citrix ADC appliance provides the following built-in default syntax cache redirection policies:

Built-In Policy Name	Description
bypass-non-get_adv	Bypass the cache if the request uses an HTTP method other than GET.
bypass-cache-control_adv	Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.
bypass-dynamic-url_adv	Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/.
bypass-urltokens_adv	Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.
bypass-cookie_adv	Bypass the cache for any URL that has a cookie header and an extension other than .png or .jpg.

Display the built-in cache redirection policies

You can display the available cache redirection polices by using the command line interface or the configuration utility.

Display the built-in cache redirection policies by using the CLI

At the command prompt, type:

```
show cr policy [<policyName>]
```

Example:

```
1 > show cr policy
2 1)       Cache-By-Pass RULE: NS_NON_GET          Policy:bypass-non-get
3 2)       Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE ||
     NS_CACHECONTROL_NOCACHE || NS_HEADER_PRAGMA)    Policy:bypass-cache-
     control
4 3)       Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE ||
      NS_EXT_CFM || NS_EXT_EX || NS_EXT_SHTML || NS_EXT_HTX) || (
```

```
      NS_URL_PATH_CGIBIN || NS_URL_PATH_EXEC || NS_URL_PATH_BIN)
      Policy:bypass-dynamic-url
4)       Cache-By-Pass RULE: NS_URL_TOKENS       Policy:bypass-
   urltokens
5)       Cache-By-Pass RULE: (NS_HEADER_COOKIE && NS_EXT_NOT_GIF &&
   NS_EXT_NOT_JPEG)     Policy:bypass-cookie
 Done
<!--NeedCopy-->
```

Display the built-in cache redirection policies by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Policies. The configured cache redirection policies appear in the details pane.
2. Select one of the configured policies to view details.

Configure a cache redirection policy

September 14, 2021

A cache redirection policy includes one or more expressions (also called *rules*). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the Citrix ADC appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection policies based on the classic policy format are called *classic cache redirection policies*. Each such policy has a name and includes a classic expression or a set of classic expressions that are combined by using logical operators.

For classic cache redirection policies, you do not explicitly configure actions for the policies. By default, the Citrix ADC appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection policies based on the newer policy format are called *Advanced redirection policies*. Such policy has a name and includes a default syntax expression, or a set of default syntax expressions that are combined by using logical operators, and the following built-in actions:

- CACHE
- ORIGIN

For more information about classic expressions and default syntax expressions, see Policies and Expressions.

Add a cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

```
-  add cr policy <policyName> **-rule** <expression>
-  show cr policy [<policyName>]
<!--NeedCopy-->
```

Examples:

Policy with a simple expression:

```
> add cr policy Policy-CRD-1 -rule "REQ.HTTP.URL != /*.jpeg"
 Done
> show cr policy Policy-CRD-1
         Cache-By-Pass RULE: REQ.HTTP.URL != '/*.jpeg'   Policy:Policy-
            CRD-1
 Done
<!--NeedCopy-->
```

Policy with a compound expression:

```
> add cr policy Policy-CRD-2 -rule "REQ.HTTP.METHOD == POST && (REQ.
   HTTP.URL == /*.cgi || REQ.HTTP.URL != /*.png)"
 Done
> show cr policy Policy-CRD-2
         Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL
            == '/*.cgi' || REQ.HTTP.URL != '/*.png')   Policy:Policy-
            CRD-2
 Done
<!--NeedCopy-->
```

Policy that evaluates a header:

```
> add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since
   EXISTS"
 Done
> show cr policy Policy-CRD-3
         Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS
               Policy:Policy-CRD-3
 Done
<!--NeedCopy-->
```

Add a default syntax cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

```
1 -  add cr policy <policyName> **-rule** <expression> [-action<string>]
     [-logAction<string>]
2 -  show cr policy [<policyName>]
3 <!--NeedCopy-->
```

Examples:

Policy with a simple expression:

```
1 > add cr policy crpol1 -rule !(HTTP.REQ.URL.ENDSWITH(".jpeg" )) -action
     origin
2  Done
3 > show cr policy crpoll
4          Policy: crpol1 Rule: !(HTTP.REQ.URL.ENDSWITH(".jpeg")) Action:
               ORIGIN
5  Done
6 <!--NeedCopy-->
```

Policy with a compound expression:

```
1 > add cr policy crpol11 -rule "http.req.method.eq(post) && (HTTP.REQ.
    URL.ENDSWITH(".png") || HTTP.REQ.URL.ENDSWITH(".cgi"))"  -action
    cache
2  Done
3 > show cr policy crpol11
4          Policy: crpol11    Rule: http.req.method.eq(post) && (HTTP.REQ
              .URL.ENDSWITH(".png") || HTTP.REQ.URL.ENDSWITH(".cgi"))
              Action: CACHE
5  Done
6 <!--NeedCopy-->
```

Policy that evaluates a header:

```
1 > add cr policy crpol12 -rule http.req.header("If-Modified-Since").
    exists -action origin
2  Done
3 > show cr policy crpol12
4          Policy: crpol12    Rule: http.req.header("If-Modified-Since").
              exists   Action: ORIGIN
5  Done
6 <!--NeedCopy-->
```

Modify or remove a cache redirection policy by using the CLI

- To modify a cache redirection policy, use the set cr policy command, which is just like add cr policy command, except that you enter the name of an existing policy.
- To remove a policy, use the `rm cr policy` command, which accepts only the <name> argument. If the policy is bound to a virtual server, you have to unbind the policy, before you can remove it.

For the details of unbinding a cache redirection policy, see Unbind a policy from a cache redirection virtual server.

Configure a cache redirection policy with a simple expression by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Policies.
2. In the details pane, click Add.
3. In the Create Cache Redirection Policy dialog box, in the Name* text box, type the name of the policy, and then in the Expression area, click Add.
4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:

   - Expression Type-General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -URL
   - Operator - !=
   - Value - /*.jpeg

   The simple expression in the following example checks for an If-Modified-Since header in a request:

   - Expression Type -General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -HEADER
   - Operator -EXISTS
   - Header Name -If-Modified-Since

5. When you are finished entering the expression, click OK or Create, and then click Close.

Configure a cache redirection policy with a compound expression by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Policies.

2. In the details pane, click Add.
3. In the Name text box, enter a name for the policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore (_) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.
4. Choose the type of compound expression that you want to create. Your choices are:
   - **Match Any Expression**. The policy matches the traffic if one or more individual expressions match the traffic.
   - **Match All Expressions**. The policy matches the traffic only if every individual expression matches the traffic.
   - **Tabular Expressions**. Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:
     - The AND [&&] operator, to require that, to match the policy, a request must match both the current expression and the following expression.

The OR [	] operator, to require that, to match the policy, a request must match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

     -

     You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:
     - The BEGIN SUBGROUP [+ ( ] operator, which tells the Citrix ADC appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -(.)
     - The END SUBGROUP [+)] operator, which tells the Citrix ADC appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .)
   - **Advanced Free-Form**. Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you can type a compound expression. This is both the

most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the Citrix ADC classic expressions language.

For more information about creating classic expressions in the Advanced Free-Form text area, see Configuring Classic Policies and Expressions.

Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that you want to use it.

5. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click **Add** to display the Add Expression dialog box.

   You should leave the expression type set to General for cache redirection policies.

6. In the Flow Type drop-down list, choose a flow type for your expression.

   The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

   - **REQ**. Configures the Citrix ADC appliance to examine incoming connections, or requests.
   - **RES**. Configures the appliance to examine outgoing connections, or responses.

7. In the Protocol drop-down list, choose a protocol for your expression.

   The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four or only three of the following choices are available:

   - **HTTP**. Configures the appliance to examine the HTTP header.
   - **SSL**. Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
   - **TCP**. Configures the appliance to examine the TCP header.
   - **IP**. Configures the appliance to examine the source or destination IP address.

8. Choose a qualifier for your expression from the Qualifier drop-down list.

   The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

   Table 1. Cache Redirection Policy Qualifiers Available for Each Protocol

Protocol	Qualifier	Definition
HTTP	METHOD	HTTP method used in the request.
-	URL	Contents of the URL header.

Protocol	Qualifier	Definition
-	URLTOKENS	URL tokens in the HTTP header.
-	VERSION	HTTP version of the connection.
-	HEADER	Header portion of the HTTP request.
-	URLLEN	Length of the contents of the URL header.
-	URLQUERY	Query portion of the contents of the URL header.
-	URLQUERYLEN	Length of the query portion of the URL header.
SSL	CLIENT.CERT	SSL client certificate as a whole.
-	CLIENT.CERT.SUBJECT	Contents of the client certificate subject field.
-	CLIENT.CERT.ISSUER	Client certificate issuer.
-	CLIENT.CERT.SIGALGO	Signature algorithm used in the client certificate.
-	CLIENT.CERT.VERSION	Client certificate version.
-	CLIENT.CERT.VALIDFROM	Date from which the client certificate is valid. (The start date.)
-	CLIENT.CERT.VALIDTO	Date after which the client certificate is no longer valid. (The end date.)
-	CLIENT.CERT.SERIALNUMBER	Client certificate serial number.
-	CLIENT.CIPHER.TYPE	Encryption method used in the client certificate.
-	CLIENT.CIPHER.BITS	Number of significant bits in the encryption key.
-	CLIENT.SSL.VERSION	SSL version of the client certificate.

Protocol	Qualifier	Definition
TCP	SOURCEPORT	Source port of the TCP connection.
-	DESTPORT	Destination port of the TCP connection.
-	MSS	Maximum segment size (MSS) of the TCP connection.
IP	SOURCEIP	Source IP address of the connection.
-	DESTIP	Destination IP address of the connection.

9. Choose the operator for your expression from the Operator drop-down list.

   Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

   - == . Matches the following text string exactly.
   - != . Does not match the following text string.
   - > . Is greater than the following integer.
   - CONTAINS . Contains the following text string.
   - CONTENTS . The contents of the designated header, URL, or URL query.
   - EXISTS . The specified header or query exists.
   - NOTCONTAINS . Does not contain the following text string.
   - NOTEXISTS . The specified header or query does not exist.

   If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.

    For example, if you want this policy to select requests sent to the host shopping.example.com, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.
12. Click OK to add your expression to the Expression list.
13. Repeat steps 4 through 11 to create additional expressions.
14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.

Cache redirection configurations

September 14, 2021

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent**. A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the Citrix ADC appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.
- **Forward proxy**. A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.
- **Reverse proxy**. Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

Configure transparent redirection

September 14, 2021

When you configure transparent cache redirection, the Citrix ADC appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the Citrix ADC appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the request does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see Direct policy hits to the cache instead of the origin.

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this virtual server can receive traffic coming to the appliance on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection

virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.

Enable cache redirection and load balancing

September 14, 2021

The appliance cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

Enable cache redirection and load balancing by using the CLI

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

```
-  enable ns feature cr lb
-  show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature cr lb
 Done
> show ns feature

        Feature                         Acronym              Status
        -------                         -------              ------
 1)     Web Logging                     WL                   ON
 2)     Surge Protection                SP                   ON
 3)     Load Balancing                  LB                   ON
 4)     Content Switching               CS                   ON
 5)     Cache Redirection               CR                   ON
 6)     Sure Connect

            ...
            ...
            ...

 23)    HTML Injection                  HTMLInjection        ON
 24)    appliance Push                  push                 OF
 Done
<!--NeedCopy-->
```

Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
   a) In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
   b) In Enable/Disable Feature(s)? dialog box, click Yes.
3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
   a) In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
   b) In Enable/Disable Feature(s)? dialog box, click Yes.

Configure edge mode

September 14, 2021

When deployed at the edge of a network, the Citrix ADC appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns on the collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

Enable edge mode by using the CLI

At the command prompt, type the following commands to enable edge mode and verify the setting:

```
1 -  enable ns mode Edge
2 -  show ns mode
3 <!--NeedCopy-->
```

Example:

```
1 > enable ns mode edge
2  Done
3
4 > show ns mode
5
6         Mode                          Acronym             Status
7         -------                       -------             ------
```

```
          ...
          ...
          ...
 6)     MAC-based forwarding          MBF                 ON
 7)     Edge configuration            Edge                ON
 8)     Use Subnet IP                 USNIP               OFF
          ...
          ...
          ...
 16)    Bridge BPDUs                  BridgeBPDUs         OFF
 Done
<!--NeedCopy-->
```

Enable edge mode by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configure a cache redirection virtual server

September 14, 2021

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the appliance represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

add a cache redirection virtual server in transparent mode by using the cli

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

```
1 -  add cr vserver <name> <serviceType> [<IPAddress> <port> ] [-
     cacheType <cacheType>] [-redirect <redirect>]
2 -  show cr vserver [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect
      POLICY
2 > show cr vserver Vserver-CRD-1
3         Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
4         State: UP  ARP:DISABLED
5         Client Idle Timeout: 180 sec
6         Down state flush: ENABLED
7         Disable Primary Vserver On Down : DISABLED
8         Default:        Content Precedence: RULE        Cache:
             TRANSPARENT
9         On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
10        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
11  Done
12 <!--NeedCopy-->
```

Modify or remove a cache redirection virtual server by using the CLI

- To modify a virtual server, use the set cr vserver command, which is just like using the add cr vserver command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the `rm cr vserver` command, which accepts only the <name> argument.

Add a cache redirection virtual server in transparent mode by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters as shown:
   - Name*—name
   - Port*—port

   *A required parameter

4. In the Protocol drop-down list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.
5. Click the Advanced tab.
6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.
7. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.
8. Select the new cache redirection virtual server to display the details of its configuration.

Bind policies to the cache redirection virtual server

September 14, 2021

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

Bind policies to a cache redirection virtual server by using the CLI

At the command prompt, type:

```
-  bind cr vserver <name> -policyName <string>
-  show cr vserver [<name>]
<!--NeedCopy-->
```

Example:

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
 Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
 Done

> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
```

```
15          Disable Primary Vserver On Down : DISABLED
16          Default:        Content Precedence: RULE        Cache:
               TRANSPARENT
17          On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
18          Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
19
20  1)      Cache bypass  Policy: bypass-cache-control
21  2)      Cache bypass  Policy: bypass-dynamic-url
22  3)      Cache bypass  Policy: bypass-urltokens
23  4)      Cache bypass  Policy: bypass-cookie
24   Done
25  <!--NeedCopy-->
```

Bind a user-defined policy to a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.

Unbind a policy from a cache redirection virtual server

September 14, 2021

When you unbind a policy from the cache redirection virtual server, the Citrix ADC appliance no longer applies the policy when evaluating client requests.

Unbind a policy from a cache redirection virtual server by using the command CLI

At the command prompt, type:

```
1  -  unbind cr vserver <name> -policyName <string>
2  -  show cr vserver [<name>]
3  <!--NeedCopy-->
```

Example:

```
1  unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
2  > show cr vserver Vserver-CRD-1
3          Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
```

```
4          State: UP  ARP:DISABLED
5          Client Idle Timeout: 180 sec
6          Down state flush: ENABLED
7          Disable Primary Vserver On Down : DISABLED
8          Default:        Content Precedence: RULE        Cache:
               TRANSPARENT
9          On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
10         Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
11
12 1)      Cache bypass  Policy: bypass-cache-control
13  Done
14 <!--NeedCopy-->
```

Unbind a user-defined policy from a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

Create a load balancing virtual server

September 14, 2021

The cache redirection virtual server on the Citrix ADC appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see Load Balancing.

Create a load balancing virtual server by using the CLI

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

```
1 -  add lb vserver <name> <serviceType> [<IPAddress>] [<port>]
2 -  show lb vserver [<name>]
3 <!--NeedCopy-->
```

Example:

```
> add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
 Done
> show lb vserver Vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 00:00:08.470
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none
 Done
<!--NeedCopy-->
```

Create a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name*-name
   - IP Address*- IPAddress
   - Port*-port

   *A required parameter
4. In the Protocol list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.
5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

Configure an HTTP service

September 14, 2021

On the Citrix ADC appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

Configure an HTTP service by using the CLI

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

```
-  add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
-  show service [<name>]
<!--NeedCopy-->
```

Example:

```
> add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType
   TRANSPARENT
 Done
> show service Service-HTTP-1
        Service-HTTP-1 (10.102.29.40:80) - HTTP
        State: DOWN
        Last state change was at Fri Jul  2 09:14:17 2010
        Time since last state change: 0 days, 00:00:13.820
        Server Name: 10.102.29.40
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): YES
        Idle timeout: Client: 180 sec   Server: 360 sec
        Client IP: DISABLED
        Cache Type: TRANSPARENT Redirect Mode:
        Cacheable: NO
        SC: OFF
        SP: ON
        Down state flush: ENABLED

```

```
1)      Monitor Name: tcp-default
                State: DOWN     Weight: 1
                Probes: 3       Failed [Total: 3 Current: 3]
                Last response: Failure - Time out during TCP connection
                    establishment stage
                Response Time: N/A
 Done
<!--NeedCopy-->
```

Modify or remove a service by using the CLI

- To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.
- To remove a service, use the `rm service` command, which accepts only the <name> argument.

Add an HTTP service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name*—name
   - Server*— IP
   - Port*—port

   *A required parameter
4. In the Protocol* drop-down list, select a supported protocol (for example, **HTTP**).
5. Click Create, and then click Close.

Bind/unbind a service to/from a load balancing virtual server

September 14, 2021

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

Bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```
-  bind lb vserver <name> <serviceName>
-  show lb vserver [<name>]
<!--NeedCopy-->
```

Example:

```
> bind lb vserver vserver-LB-CR service-HTTP-1
 Done
> show lb vserver Vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 00:42:25.610
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
 Done
<!--NeedCopy-->
```

Unbind a service from a load balancing virtual server by using the CLI

To unbind a service, use the `unbind lb vserver` command instead of `bind lb vserver`.

Bind/unbind a service from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.

3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Disable the use the proxy port setting for transparent caching

September 14, 2021

If the use source IP (USIP) option is disabled on a cache service configured on the Citrix ADC appliance, the appliance forwards client requests to the cache service by using a appliance-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client's IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client's source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see Configuring the Source Port for Server-Side Connections.

Assign a port range to the Citrix ADC appliance

September 14, 2021

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other Citrix ADC appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the Citrix ADC appliance. This allotment enables network devices to unambiguously identify the Citrix ADC appliance that sent the request.

Assign a source port range to a Citrix ADC appliance by using the CLI

At the command prompt, type:

```
set ns param -crPortRange <startPortNumber-endPortNumber>
```

Assign a source port range to a Citrix ADC appliance by using the appliance GUI

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
4. Click OK.

Enable load balancing virtual servers to redirect requests to cache

September 14, 2021

If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a Citrix ADC appliance at the edge of its network and all traffic flows through the appliance.

Enable load balancing virtual servers to redirect requests to the cache by using the CLI

At the command prompt, type:

```
-  set lb vserver <name> [-cacheable ( YES | NO)]
-  show lb vserver [<name>]
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-CR  - cacheable YES
> show lb vserver vserver-LB-CR
        Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 08:47:52 2010
        Time since last state change: 0 days, 01:05:51.510
        Effective State: DOWN
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
```

```
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE
        Cacheable: YES  PQ: OFF SC: OFF
        Vserver IP and Port insertion: OFF
        Push: DISABLED  Push VServer:
        Push Multi Clients: NO
        Push Label Rule: none

1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
 Done
<!--NeedCopy-->
```

For transparent cache redirection, the appliance intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server.

When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

Turn off caching for a load balancing virtual server by using the CLI

To turn off caching for a load balancing virtual, use the unset lb vserver command instead of set lb vserver. Specify a value of NO value for the **cacheable** parameter.

Enable or disable load balancing virtual servers to redirect requests to the cache by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

Configure forward proxy redirection

September 14, 2021

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the Citrix ADC appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the appliance is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the appliance compares the request with a policy for caching. If the request is not cacheable, the appliance queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the appliance forwards the request to a load balancing virtual server for the cache.

The appliance relies on a host domain name or IP address in the request's HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the Citrix ADC appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the appliance. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a forward proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see Configure a cache redirection policy.

Create a DNS service

September 14, 2021

A DNS service is a representation, on the Citrix ADC appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

Create a DNS service by using the CLI

At the command line, type the following commands to create a DNS service and verify the configuration :

```
-  add service <name> <IP> <serviceType> <port>
-  show service [<name>]
<!--NeedCopy-->
```

Example:

```
add service Service-DNS-1 10.102.29.41 DNS 53
show service Service-DNS-1
        Service-DNS-1 (10.102.29.41:53) - DNS
        State: DOWN
        Last state change was at Fri Jul  2 10:14:32 2010
        Time since last state change: 0 days, 00:00:13.550
        Server Name: 10.102.29.41
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: ping-default
                State: DOWN     Weight: 1
                Probes: 3       Failed [Total: 3 Current: 3]
                Last response: Failure - Probe timed out.
```

```
                Response Time: 2000.0 millisec
 Done
<!--NeedCopy-->
```

Add a DNS service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name*—name
   - Server*—IP
   - Port*—port

*A required parameter

1. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
2. Click Create, and then click Close.

Create a DNS load balancing virtual server

September 14, 2021

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

Create a DNS load balancing virtual server by using the CLI

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

```
-  add lb vserver <name> <serviceType>
-  show lb vserver [<name>]
<!--NeedCopy-->
```

Example:

```
> add lb vserver Vserver-DNS-1 DNS
 Done
> show lb vserver Vserver-DNS-1
```

```
4          Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
5          State: DOWN
6          Last state change was at Fri Jul  2 10:32:28 2010
7          Time since last state change: 0 days, 00:00:08.10
8          Effective State: DOWN  ARP:DISABLED
9          Client Idle Timeout: 120 sec
10         Down state flush: ENABLED
11         Disable Primary Vserver On Down : DISABLED
12         No. of Bound Services :  0 (Total)       0 (Active)
13         Configured Method: LEASTCONNECTION
14         Mode: IP
15         Persistence: NONE
16  Done
17 <!--NeedCopy-->
```

Create a DNS load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

Bind the DNS service to the virtual server

September 14, 2021

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

Bind the DNS service to the load balancing virtual server by using the CLI

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

```
1 -  bind lb vserver <name> <serviceName>
2 -  show lb vserver <name>
3 <!--NeedCopy-->
```

Example:

```
> bind lb vserver Vserver-DNS-1 Service-DNS-1
 Done
> show lb vserver Vserver-DNS-1
        Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
        State: DOWN
        Last state change was at Fri Jul  2 10:32:28 2010
        Time since last state change: 0 days, 00:12:16.80
        Effective State: DOWN  ARP:DISABLED
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: LEASTCONNECTION
        Mode: IP
        Persistence: NONE

1) Service-DNS-1 (10.102.29.41: 53) - DNS State: DOWN   Weight: 1
 Done
>
<!--NeedCopy-->
```

Unbind a DNS service from the load balancing virtual server by using the CLI

Use the `unbind lb vserver` command instead of `bind lb vserver`.

Bind/Unbind a DNS service to/from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Configure a client web browser to use a forward proxy

September 14, 2021

When you configure the Citrix ADC appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically,

when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.

Configure reverse proxy redirection

September 14, 2021

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. The reverse proxy cache is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the appliance receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before they it is sent to the back-end server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a reverse proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type REVERSE.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see Bind policies to the cache redirection virtual server.

Configure mapping policies

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping www.mycompany.com to www.myrealcompany.com).
- Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/news/index.html).
- Suffix mapping: You can replace the file suffix in the URL (for example, mapping www.mycompany.com/sport to www.mycompany.com/sports/index.asp).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

Configure a mapping policy for reverse proxy mode by using the CLI

At the command prompt, type the following command to add a policy map and verify the configuration:

```
1 -  add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <
     string>] [-tu <string>]
2 -  show policy map [<mapPolicyName>]
3 <!--NeedCopy-->
```

Example:

The following command maps a domain in a client request to a target domain:

```
1 > add policy map myMappingPolicy -sd www.mycompany.com -td www.
     myrealcompany.com
2  Done
3 > show policy map myMappingPolicy
4 1)      Name: myMappingPolicy
5         Source Domain: www.mycompany.com        Source Url:
6         Target Domain: www.myrealcompany.com    Target Url:
7  Done
8 <!--NeedCopy-->
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
1 > add policy map myOtherMappingPolicy -sd www.mycompany.com -td www.
     myrealcompany.com -su /news.html -tu /realnews.html
2  Done
3 > show policy map myOtherMappingPolicy
4 1)      Name: myOtherMappingPolicy
5         Source Domain: www.mycompany.com        Source Url: /news.html
6         Target Domain: www.myrealcompany.com    Target Url: /realnews.
             html
7  Done
8 <!--NeedCopy-->
```

Configure a mapping policy for reverse proxy mode by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Map Policies**.
2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters as shown:
   - Name*- mapPolicyName

- Source Domain*-sd
- Target Domain*-td
- Source URL-su
- Target URL-tu

*A required parameter

4. Click Create, and then click Close. The Map pane displays the new mapping policy.

Bind the mapping policy to the cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

```
-  bind cr vserver <name> -policyName <string> [<targetVserver>]
-  show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-
    CR
 Done
> show cr vserver Vserver-CRD-3
        Vserver-CRD-3 (10.102.29.50:88) - HTTP  Type: CONTENT
        State: UP
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default: Vserver-LB-CR  Content Precedence: RULE        Cache:
           REVERSE
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Policy:         Target: Vserver-LB-CR   Priority: 0     Hits: 0
1)      Map: myMappingPolicy Target: Vserver-LB-CR
 Done
<!--NeedCopy-->
```

Bind the mapping policy to the cache redirection virtual server by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.
2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click **Open**.

3. In the **Configure Virtual Server**(Cache Redirection), on the **Policies** tab, select **Map**, and then click **Insert Policy**.
4. In the **Policy Name** column, select the policy from the drop-down list.
5. In the **Target** column, click the down arrow, and then select the virtual server from the drop-down list.
6. Click **OK**.

Selective cache redirection

September 14, 2021

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the Citrix ADC appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The appliance first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the appliance evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the Citrix ADC appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the appliance sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the appliance, which is configured as a Layer 4 switch that receives traffic on port 80.

The appliance can direct requests for images (for example, .png and .jpg files) to one server in the

transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

Note: The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

Enable content switching

September 14, 2021

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the appliance, you must enable content switching.

Enable content switching by using the CLI

At the command prompt, type:

```
-  enable ns feature CS

-  show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature cs
 Done
> show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  ON
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 4)     Content Switching               CS                  ON
```

```
5)     Cache Redirection              CR                    ON
          ...
          ...
          ...
23)    HTML Injection                 HTMLInjection         ON
24)    appliance Push                 push                  OFF
Done
<!--NeedCopy-->
```

Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configure a load balancing virtual server for the cache

September 14, 2021

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a transparent proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see Bind policies to the cache redirection virtual server.

Configure a cache redirection policy for a specific type of content

To identify requests that contain a .png or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

Note: If a request matches a policy, the Citrix ADC appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do *not* have ".png" or ".jpeg" extensions.

To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in Configure a cache redirection policy.

Configure policies for content switching

September 14, 2021

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .png and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see Content switching.

You must first create the content switching policy and then bind it to the cache redirection virtual server.

Create a content switching policy by using the command CLI

At the command line, type:

```
-  add cs policy <policyName> [-url <string> | -rule <expression>]
-  show cs policy [<policyName>]
<!--NeedCopy-->
```

Examples:

```
> add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.jpeg'"
 Done
```

```
> show cs policy Policy-CS-JPEG
         Rule: REQ.HTTP.URL == '/*.jpeg'         Policy: Policy-CS-JPEG
         Hits: 0
 Done
>

> add cs policy Policy-CS-GIF -rule "REQ.HTTP.URL == '/ *.png'"
 Done
> show cs policy Policy-CS-GIF
         Rule: REQ.HTTP.URL == '/ *.png'         Policy: Policy-CS-GIF
         Hits: 0
 Done
>

> add cs policy Policy-CS-JPEG-URL -url /*.jpg
 Done
> show cs policy Policy-CS-JPEG-URL
         URL: /*.jpg     Policy: Policy-CS-JPEG-URL
         Hits: 0
 Done
>

> add cs policy Policy-CS-GIF-URL -url /*.png
 Done
> show cs policy Policy-CS-GIF-URL
         URL: /*.png     Policy: Policy-CS-GIF-URL
         Hits: 0
 Done
<!--NeedCopy-->
```

Create a URL-based content switching policy by using the GUI

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the URL radio button.
5. In the Value text box, type the string value (for example, **/sports**).
6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.

Create a rule-based content switching policy by using the GUI

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the Expression radio button, and then click Configure.
5. In the Create Expression dialog box, choose the expression syntax that you want to use.
   - If you want to use default syntax, accept the default and proceed to the next step.
   - If you want to use classic syntax, click Switch to Classic Syntax.

   The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.
6. Enter your policy expressions.

   For information about using the advanced syntax, see Configure advanced policy expression: Get started.
7. Click **Create** and click **Close**. The policy you created appears in the **Content Switching Policies** pane.

Bind the content switching policy to a cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

```
-  bind cs vserver <name> <targetVserver> [-policyName <string>]
-  show cs vserver [<name>]
<!--NeedCopy-->
```

Example:

```
> bind cs vserver Vserver-CR-1 lbcachejpeg -policyName Policy-CS-JPEG
 Done
> bind cs vserver Vserver-CR-1 lbcachegif -policyName Policy-CS-GIF
 Done
> show cs vserver Vserver-CR-1
        Vserver-CR-1 (10.102.29.60:80) - HTTP   Type: CONTENT
        State: UP
```

```
        Last state change was at Fri Jul  2 12:53:45 2010
        Time since last state change: 0 days, 00:00:58.920
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Port Rewrite : DISABLED
        State Update: DISABLED
        Default:        Content Precedence: RULE
        Cacheable: YES
        Vserver IP and Port insertion: OFF
        Case Sensitivity: ON
        Push: DISABLED  Push VServer:
        Push Label Rule: none

1)      Policy: Policy-CS-JPEG  Target: lbcachejpeg     Priority: 0
       Hits: 0
2)      Policy: Policy-CS-GIF   Target: lbcachegif      Priority: 0
       Hits: 0
 Done
>
<!--NeedCopy-->
```

Bind the content switching policy to a cache redirection virtual server by using the GUI

1. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers**.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, **Vserver-CS-1**), and then click **Open**.
3. In the Configure Virtual Server (Content Switching) dialog box, on the **Policies** tab, click CSW, and then click **Insert Policy**.
4. In the **Policy Name** column, select the policy that you want to configure for the content switching virtual server.
5. In the **Target** column, click the green arrow, and select the target load balancing virtual server from the list.
6. Click **OK**.

Configure precedence for policy evaluation

September 14, 2021

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

Configure precedence for policy evaluation by using the CLI

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

```
-  set cr vserver <name> [-precedence (RULE | URL)]
-  show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> set cr vserver Vserver-CRD-1 -precedence URL
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
>
<!--NeedCopy-->
```

Configure precedence for policy evaluation by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, **Vserver-CS-1**), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

Administer a cache redirection virtual server

September 14, 2021

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

View cache redirection virtual server statistics

September 14, 2021

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed. Maximum Length: 127

View statistics for a cache redirection virtual server by using the CLI

At the command prompt, type:

```
stat cr vserver [<name>]
```

Example:

```
1 > stat cr vserver Vserver-CRD-1
2
3 Vserver Summary
4                          IP  port     Protocol        State
```

```
Vser...CRD-1          0.0.0.0    80          HTTP            UP

VServer Stats:
                                          Rate (/s)
                                             Total
Requests                                          0
                        0
Responses                                         0
                        0
Request bytes                                     0
                        0
Response bytes                                    0
                        0

 Done
>
<!--NeedCopy-->
```

View statistics for a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers
2. In the details pane, select the virtual server for which you want to view statistics, (for example, **Vserver-CRD-1**), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server

View the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.
4. Click Applet Client or Web Start Client next to Statistical Utility.
5. In the Select Group drop-down menu, choose CR Virtual Servers. The dashboard displays summary statistics for the cache redirection virtual servers.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

Enable or disable a cache redirection virtual server

September 14, 2021

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the Citrix ADC appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

Enable or disable a cache redirection virtual server by using the CLI

At the command line, type one of the following commands:

```
-  enable cr vserver <name>
-  show cr vserver <name>
-  disable cr vserver <name>
-  show cr vserver <name>
<!--NeedCopy-->
```

Examples:

```
> enable cr vserver Vserver-CRD-1
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
>

> disable cr vserver Vserver-CRD-1
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: OUT OF SERVICE  ARP:DISABLED
        Client Idle Timeout: 180 sec
```

```
24          Down state flush: ENABLED
25          Disable Primary Vserver On Down : DISABLED
26          Default:        Content Precedence: URL Cache: TRANSPARENT
27          On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
28          Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
29
30  1)      Cache bypass  Policy: bypass-cache-control
31  2)      Cache bypass  Policy: Policy-CRD
32   Done
33  >
34  <!--NeedCopy-->
```

Enable or disable a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, **Vserver-CRD-1**), and then click Statistics.
4. In the Proceed dialog box, click Yes.

Direct policy requests to cache instead of origin web server

September 14, 2021

By default, when a request matches a policy, the Citrix ADC appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy request to the origin or the cache, use the `onPolicyMatch` parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. `CACHE` - Directs all matching requests to the cache.
2. `ORIGIN` - Directs all matching requests to the origin server.

> **Note:**
>
> For this option to work, you must select the cache redirection type as `POLICY`.

Possible values: CACHE, ORIGIN

Default value: ORIGIN

Change the destination for a policy request to the origin or the cache by using the CLI

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

```
set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]
<!--NeedCopy-->
```

```
show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
<!--NeedCopy-->
```

Change the destination for a policy hit to the origin or the cache by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to change the destination for a policy request, (for example, **Vserver-CRD-1**), and then click Open.
3. In the **Configure Virtual Server (Cache Redirection)** dialog box, click **Advanced**.
4. Select **CACHE** or **ORIGIN** from the **Redirect To** drop-down list.
5. Click **OK**.

Back up a cache redirection virtual server

September 14, 2021

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the backupVServer parameter, which specifies Backup Virtual Server. Maximum Length: 127

Specify a backup cache redirection virtual server by using the CLI

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

```
-  set cr vserver <name> [-backupVServer <string>]
-  show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> set cr vserver Vserver-CRD-1 -backupVServer Vserver-CRD-2
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
        Backup: Vserver-CRD-2

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
<!--NeedCopy-->
```

Specify a backup cache redirection virtual server by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.

2. In the details pane, select the virtual server for which you want to change the destination for a policy request, (for example, **Vserver-CRD-1**), and then click Open.
3. In the Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the virtual server.
5. Click OK.

Manage client connections for a virtual server

September 14, 2021

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion, you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, appliance responds even if one virtual server set to ACTIVE is UP.

This document includes the following information:

- Configure client timeout
- Insert Via headers in the requests
- Reuse TCP connections
- Configure delayed connection cleanup

Configure client timeout

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the cltTimeout parameter, which specifies the time, in seconds, after which the Citrix ADC appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.

Configure client timeout by using the CLI

At the command prompt, type the following commands to configure client timeout and verify the configuration:

```
-  set cr vserver <name> [-cltTimeout <secs>]
-  show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> set cr vserver Vserver-CRD-1 -cltTimeout 6000
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 6000 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
        Backup: Vserver-CRD-2

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
<!--NeedCopy-->
```

Configure client timeout by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Client Time-out(secs) text box, enter the time-out value in seconds.
5. Click OK.

Insert Via headers in the requests

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.

To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF

Default value: ON

Enable or disable Via-header insertion in client requests by using the CLI

At the command prompt, type:

```
-  set cr vserver <name> [-via (ON|OFF)]
-  show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> set cr vserver Vserver-CRD-1 -via ON
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 6000 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
        Backup: Vserver-CRD-2

1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
 Done
>
<!--NeedCopy-->
```

Enable or disable Via-header insertion in client requests by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Via check box.
5. Click OK.

Reuse TCP connections

You can configure the Citrix ADC appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the appliance. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF

Default value: ON

Enable or disable the reuse of TCP connections by using the CLI

At the command prompt, type:

```
-  set cr vserver <name> [-reuse (ON|OFF)]
-  show cr vserver <name>
<!--NeedCopy-->
```

Example:

```
> set cr vserver Vserver-CRD-1 -reuse ON
 Done
> show cr vserver Vserver-CRD-1
        Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
        State: UP  ARP:DISABLED
        Client Idle Timeout: 6000 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Default:        Content Precedence: URL Cache: TRANSPARENT
        On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
        Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
        Backup: Vserver-CRD-2
```

```
13
14 1)      Cache bypass  Policy: bypass-cache-control
15 2)      Cache bypass  Policy: Policy-CRD
16  Done
17 <!--NeedCopy-->
```

Enable or disable the reuse of TCP connections by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Reuse check box.
5. Click OK.

Configure delayed connection cleanup

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Enable of disable the down state flush option by using the CLI

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

```
1 -  set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
2 -  show cr vserver <name>
3 <!--NeedCopy-->
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
2  Done
3 > show cr vserver Vserver-CRD-1
4         Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
5         State: UP  ARP:DISABLED
6         Client Idle Timeout: 6000 sec
```

```
7          Down state flush: ENABLED
8          Disable Primary Vserver On Down : DISABLED
9          Default:        Content Precedence: URL Cache: TRANSPARENT
10         On Policy Match: CACHE  L2Conn: OFF     OriginUSIP: OFF
11         Redirect: POLICY        Reuse: ON       Via: ON ARP: OFF
12         Backup: Vserver-CRD-2
13
14 1)      Cache bypass  Policy: bypass-cache-control
15 2)      Cache bypass  Policy: Policy-CRD
16  Done
17 <!--NeedCopy-->
```

Enable or disable the reuse of TCP connections by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select the Down state flush check box.
5. Click OK.

Enable external TCP health check for UDP virtual servers

September 14, 2021

In public clouds, you can use the Citrix ADC appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. To monitor the health of the UDP application, public clouds recommend adding a TCP-based endpoint to your service. The endpoint reflects the health of the UDP application.

The Citrix ADC appliance supports external TCP-based health check for a UDP virtual server. This feature introduces a TCP listener on the VIP of the cache redirection virtual server and the configured port. The TCP listener reflects the status of the virtual server.

To enable external TCP health check for UDP virtual servers by using CLI

At the command prompt, type the following command to enable an external TCP health check with the tcpProbePort option:

```
add cr vserver <name> <serviceType> -tcpProbePort <tcpProbePort>

<!--NeedCopy-->
```

Example:

```
add cr vserver Vserver-CR-1 HTTP -tcpProbePort 80
<!--NeedCopy-->
```

To enable external TCP health check for UDP virtual servers by using GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, add the port number in the **TCP Probe Port** field.
4. Click **OK**.

N-Tier cache redirection

September 14, 2021

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the Citrix ADC appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the Citrix ADC appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called *n-tier cache redirection*.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a Citrix ADC appliance have to be fully transparent. However, if you configure transparent cache redirection, with the Citrix ADC appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such as routers, cache servers, origin servers, and other Citrix ADC appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

How N-tier cache redirection Is implemented

To solve the problem, appliance n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier Citrix ADC appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier Citrix ADC appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the appliance from which it received the request and send the response to the same appliance.

The lower-tier Citrix ADC appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the appliance to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier appliance, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier Citrix ADC appliances. Each lower-tier appliance is exclusively assigned a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier Citrix ADC appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.

The upper-tier Citrix ADC appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination appliance from the source port range.

Setup necessary for configuring N-Tier CRD

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier Citrix ADC appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination port.
- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (*).
- Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier Citrix ADC appliances.
- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier appliance and bind all the services to the virtual server.

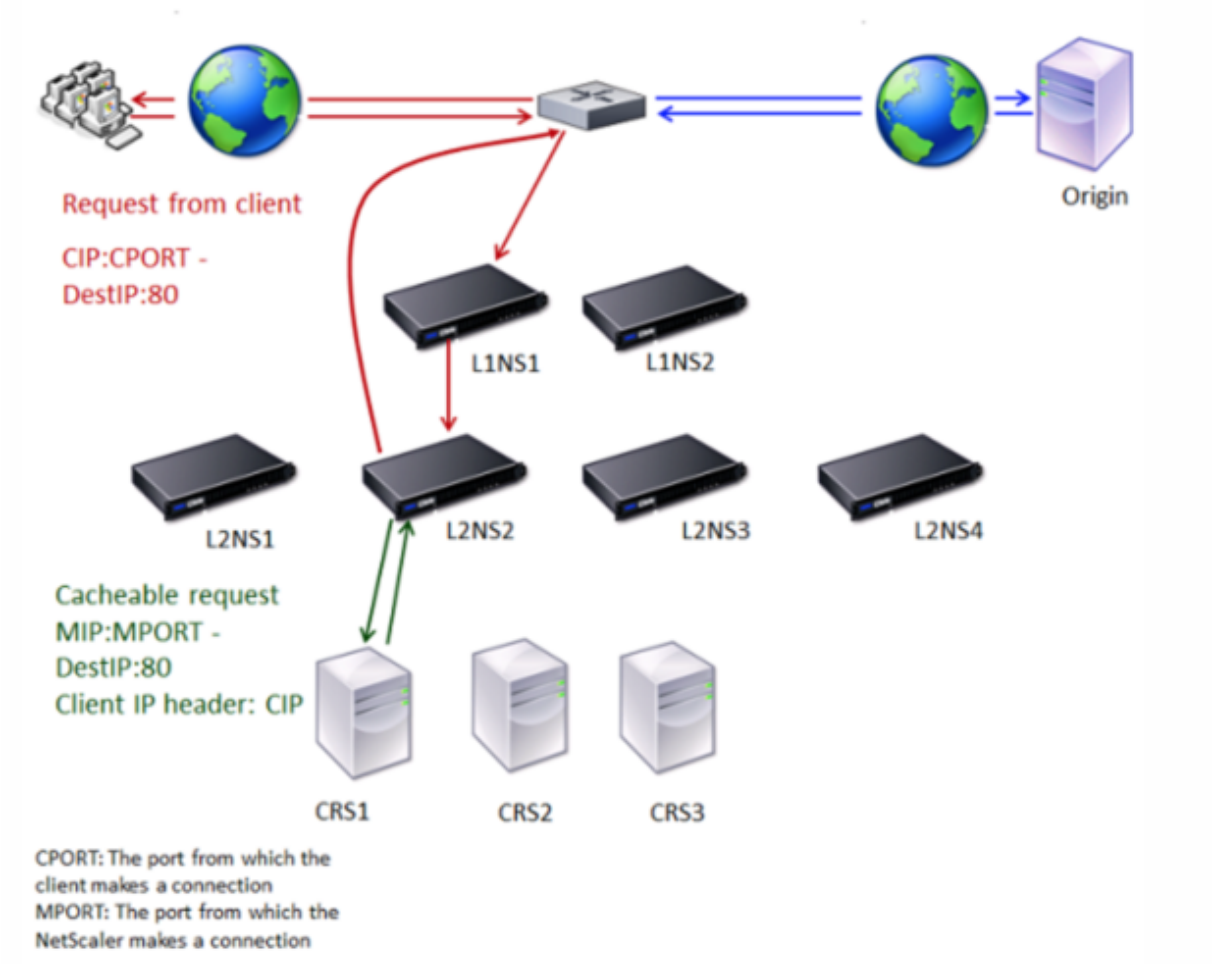
For each lower-tier Citrix ADC appliance,

- Configure the cache redirection port range on the appliance. Assign an exclusive range to each lower-tier appliance.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this appliance. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
  - Enable the Origin USIP option.
  - Add a source IP expression to include the client IP in the header.
  - Enable the Use Port Range option.

How N-tier cache redirection works during a cache hit

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit



Two Citrix ADC appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four Citrix ADC appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

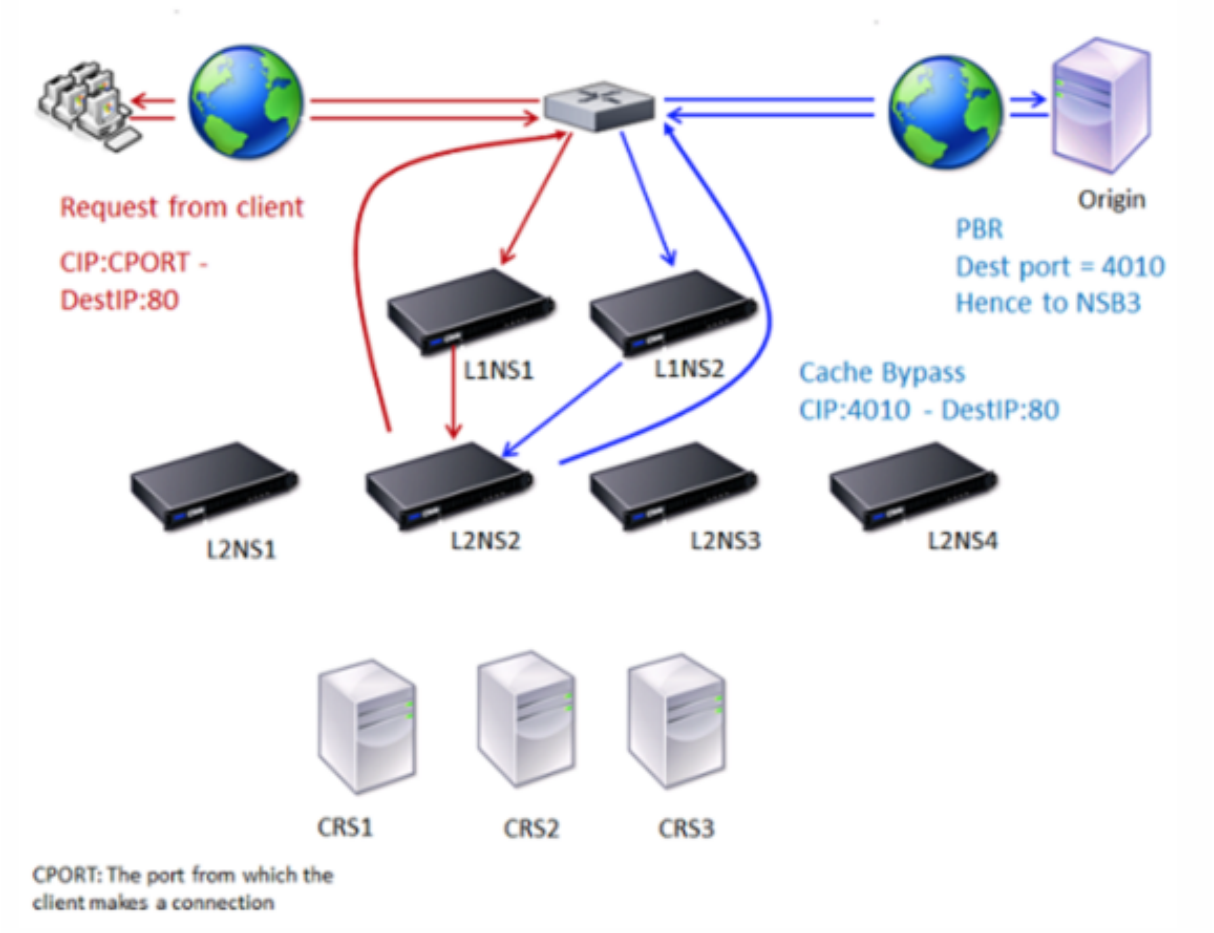
Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.
4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.
5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary load on the appliance in the upper tier.
6. The router forwards the response to Client A.

How N-tier cache redirection works during a cache bypass

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.

Figure 2. Cache Redirection in Case of a Cache Bypass



Two Citrix ADC appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four Citrix ADC appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

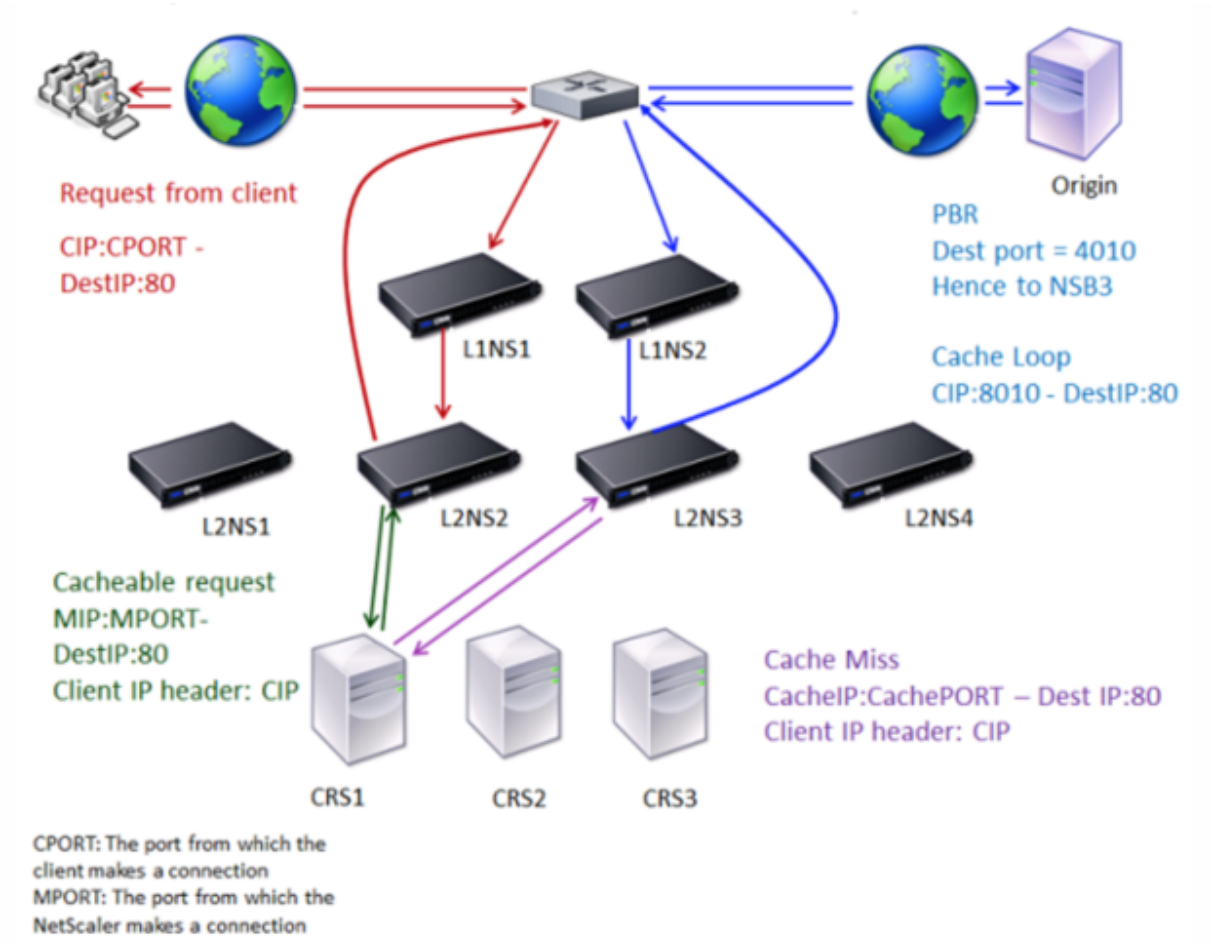
1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. The request is uncacheable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier appliance, L1NS2.
5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the appliance in the upper tier.

7. The router forwards the response to Client A.

How N-tier cache redirection works during a cache miss

The following figure shows how cache redirection works when a client request is not cached.

Figure 3. Cache Redirection in Case of a Cache Miss



Two Citrix ADC appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four Citrix ADC appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.

4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the appliance in the lower tier. L2NS3 intercepts the traffic.
5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.
6. The origin server sends the response to an upper-tier appliance, L1NS2.
7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS3.
8. L2NS3 forwards the response to the router.
9. The router forwards the response to Client A.

Configure the upper-tier Citrix ADC appliances

September 14, 2021

Configure each of the upper-tier Citrix ADC appliances as follows.

Configure an upper-tier appliance for n-tier cache redirection by using the command CLI

At the command prompt, type the following commands:

- `add service \<name\>@ \<serviceIP\> \<serviceType\> \<port\>`

  Run this command for each service to be added.

- `add lb vserver \<name\>@ ANY \* \<port\> -persistenceType \<persistenceMethod \> -lbMethod \<lbMethod\> -m MAC -sessionless ENABLED -cltTimeout \< client\\_Timeout\\_Value\>`

- `bind lb vserver \<name\>@ \<serviceName\>`

  Run this command for each service to be bound.

- `enable ns mode l3`

- `add ns pbr \<name\> \<action\> -srcPort \<sourcePortNumber\> -destPort \<startPortNumber-endPortNumber\> -nexthop \<serviceIpAddress\> -protocol TCP`

- `apply ns pbrs`

  Run this command after adding all the necessary PBRs.

Configure an upper-tier appliance for n-tier cache redirection by using the GUI

1. Enable L3 mode:
   a) In the navigation pane, click System, and then click Settings.
   b) In the Settings group, click the Configure modes link.
   c) Select the Layer 3 Mode (IP Forwarding) check box.
   d) Click OK.
2. Configure policy-based routing (PBR):
   a) Navigate to System > Network > PBRs.
   b) In the Policy-Based Routing (PBRs) pane, click Add.
   c) Type a name for the PBR.
   d) Select the action as Allow.
   e) In the Next Hop box, type the IP address of the service, which represents a lower-tier appliance.
   f) Select TCP from the Protocol drop-down list.
   g) Type the source port and the range of the destination port corresponding to the lower-tier appliance being added.
   h) Click Create.
   i) In the details pane, select the PBR and click Apply.
   j) Repeat Step (i) to Step (vii) for each lower-tier appliance.
3. Create a service for each lower-tier appliance:
   a) Navigate to Traffic Management > Load Balancing > Services.
   b) In the details pane, click Add.
   c) Specify the name, protocol, IP address, and port. The protocol should be ANY.
   d) Click Create.
4. Configure a load balancing virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Servers.
   b) In the details pane, click Add.
   c) Specify the name, protocol, IP address, and port. The protocol should be ANY and the IP address should be *.
   d) In the Services tab, select the services that represent the lower-tier Citrix ADC appliances.
   e) In the Advanced tab, select the Redirection Mode as MAC Based and select the Sessionless check box.
   f) Click Create.

Configure the lower-tier Citrix ADC appliances

September 14, 2021

Configure each of the lower-tier Citrix ADC appliances as follows.

Configure a lower-tier appliance for n-tier cache redirection by using the CLI

At the command prompt, type the following commands:

- `add service <name>@ <cacheServiceIP> <serviceType> <port> -cip ENABLED "ClientIP"-cachetype transparent`

  Repeat for each cache server.

- `add lb vserver <name>@ <serviceType> -m MAC`
- `bind lb vserver <name>@ <cacheServiceName>`

  Repeat for each cache server.

- `add cr vserver <name> <serviceType> * <port> -srcIPExpr "HTTP.REQ. HEADER("ClientIP")"-originusip ON -usePortRange ON`
- `set ns param-crPortRange <startPortNumber-endPortNumber>`

Configure a lower-tier appliance for n-tier cache redirection by using the GUI

1. Create a service for each cache server. To create a service:
   a) Navigate to Traffic Management > Load Balancing > Services.
   b) In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
   c) In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.
   d) In the Cache Type box, select Transparent Cache.
   e) Click Create.
2. Configure a load balancing virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Services.
   b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (*).
   c) In the Services tab, select the services that represent the cache servers.
   d) In the Advanced tab, for Redirection Mode, select MAC Based.
   e) Click Create.
3. Configure a cache redirection virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Services.
   b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be *.
   c) For Cache Type, select Transparent.

d) On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type HTTP.REQ.HEADER("ClientIP").
e) Click Create.

4. Assign a source port range for the appliance:
a) In the navigation pane, click System, and then click Settings.
b) In the Settings group, click the Change global system settings link.
c) In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
d) Click OK.

Translate destination IP address of a request to origin IP address

September 14, 2021

You can configure the forward proxy cache redirection virtual server on the Citrix ADC appliance to translate the destination IP address of the request landing on the cache redirection virtual server to the origin server IP address. This translation occurs irrespective of whether the request is sent to the cached servers or the origin server.
Previously, forward proxy cache redirection virtual server in service provider environment could not be effectively used to send traffic across firewall because of the limitations in cache redirection using content switching policies. The cache redirection virtual server did not translate the origin IP address into the destination IP when the packet was sent to cache. The destination IP address was that of the origin server only when the requests were served from cached server.

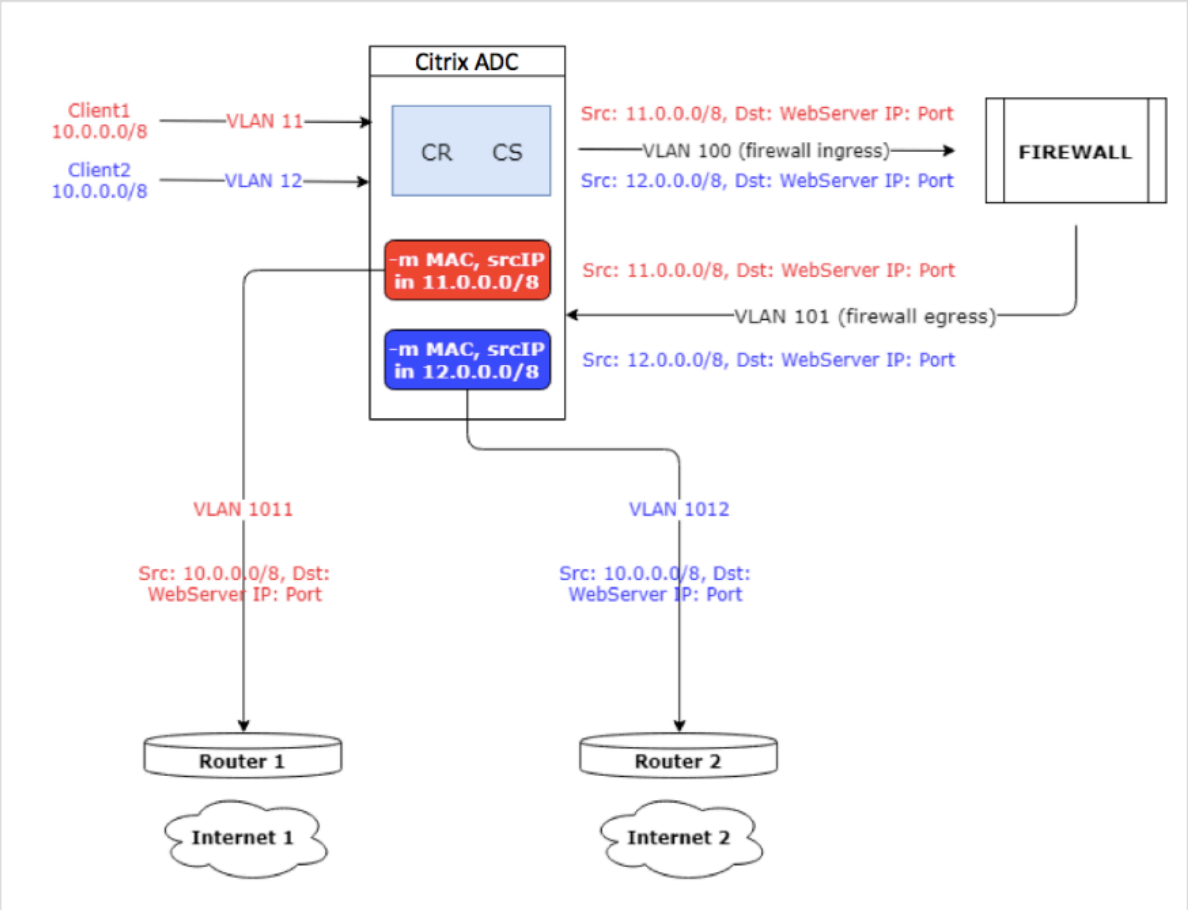
Note: Translation of destination IP address of a request to origin IP address is not supported for a transparent cache redirection virtual server. For a transparent cache redirection virtual server, this option must be set to OFF.

Use case

In a deployment that has Citrix ADC appliance configured for forward proxy cache redirection, firewall, and reused client IP addresses, firewall cannot distinguish/use the reused IP addresses. Therefore, these reused IP addresses must be translated to different IP addresses. To translate the reused IP addresses, the Citrix ADC appliance must perform the following:

1. Query a DNS load balancing virtual server for resolution of the destination.
2. Update the origin IP address and port number in the destination.
3. Send the request back to the firewall.

Consider the following deployment that has a Citrix ADC appliance configured for forward proxy cache redirection, firewall, two routers (Router 1 and Router 2). Network traffic flows to Internet 1 through Router 1 and to Internet 2 through Router 2 respectively.



In this example, input requests from clients come from two different VLANs, VLAN11 or VLAN12. The client IP address (10.0.0.0) is reused.
Based on the cache redirection and content switching policies, the request can go directly to the origin server or to the firewall.

- If the request has to bypass the firewall and go to the internet, then based on the input request VLAN, either Router 1 or Router 2 is selected and the request is sent to Internet 1 or Internet 2.
- If the request has to go through the firewall, then the source IP of the request must be translated to specific IP address. The translated IP address can be used to identify the VLAN through which request has come. For example, if the input request is coming from VLAN11, then the source IP address is translated to 11.x.x.x. If the request is coming from VLAN12, then the source IP address is translated to 12.x.x.x.

After the firewall processes the request, the request is sent back to the appliance. Using the combination of listen policy and net profiles, the appliance then translates the source IP address back to the

original IP address and sends the request to Router 1 or Router 2 based on the input VLAN ID.

Note: The mode of the load balancing virtual server that is bound to the cache must always be set to MAC mode. Though IP mode for this feature is not blocked, setting to IP mode leads to unexpected behavior.

To translate the destination IP address and port number of the request to origin IP address by using the CLI

At the command prompt, type;

```
set cr vserver <vsname> -useoriginIpPortForCache <YES|NO>
<!--NeedCopy-->
```

Example:

```
set cr vserver cvsrv1 -useoriginIpPortForCache YES
<!--NeedCopy-->
```

When useoriginIpPortForCache is set to Yes and if the request must be served from the cached servers, then the request's destination IP is translated to the origin server IP address.

Note: If useoriginIpPortForCache is enabled, always set the load balancing virtual server that is bound to the cache to MAC mode.

To translate the destination IP address and port of the request to origin IP address by using the GUI

1. Navigate to **Traffic Management** > **Cache Redirection** > **Virtual Servers** and click **Add**.
2. Specify the details of the cache redirection virtual server.
3. Select **Use Origin IP Port** for cache to enable translation of the destination IP address of the request to origin IP address.
4. Click **OK**.

Clustering

September 14, 2021

> **Note**
>
> This feature is available with a Citrix ADC Advanced or Premium edition license.

A Citrix ADC cluster is a group of nCore appliances working together as a single system image. Each appliance of the cluster is called a node. The cluster can have one appliance or as many as 32 Citrix ADC nCore hardware or virtual appliances as nodes.

The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

To create a cluster, you must perform the following steps:

- Add the appliances as cluster nodes.
- Set up communication between the nodes.
- Set up links to the client and server networks.
- Configure the appliances, and configure the distribution of client and server traffic.

Supportability matrix for Citrix ADC cluster

September 14, 2021

Clustering in the Citrix ADC appliance supports a wide-spread of features in Citrix ADC configurations.

The following table lists the Citrix ADC features and provides the supportability status across different Citrix ADC releases of cluster setups. The supportability status of some Citrix ADC features in a 13.0 Citrix ADC BLX cluster is different than a 13.0 Citrix ADC non-BLX (MPX, or VPX, SDX ADC) cluster.

> **Important**
>
> The “Node-level” entry in the table indicates that the feature is supported only on individual cluster nodes.

Citrix ADC features	11.1	12.1	13.0	13.0 Citrix ADC BLX cluster
SSL FIPS	No	No	No	No
SSL Certificate Bundle	No	No	No	No
SSL interception	NA	No	No	No
Content switching actions	Yes	Yes	Yes	Yes

Citrix ADC features	11.1	12.1	13.0	13.0 Citrix ADC BLX cluster
Policy-based logging for content switching policies	Yes	Yes	Yes	Yes
Rate limiting	Yes	Yes	Yes	Yes

Policy Based Routing (PBR/PBR6)	Yes	Yes	Yes	No
IPv4 Policy Based Routing (PBR) with LLB virtual server as next hop	No	No	Yes	No
IPv6 Policy Based Routing (PBR6) with LLB virtual server as next hop	No	No	No	No
Subscriber awareness	No	No	No	No

Citrix ADC features	11.1	12.1	13.0	13.0 Citrix ADC BLX cluster
Dynamic Routing	Yes with v6 protocols (ospfv3, RIPng, ISIS6, BGP6) support	Yes with v6 protocols (ospfv3, RIPng, ISIS6, BGP6) support	Yes with v6 protocols (ospfv3, RIPng, ISIS6, BGP6) support	Yes
SYSLOG-TCP, load balancing of syslog servers, SNIP support, and FQDN support for syslog	Yes; **Note:** Supported from NetScaler 11.1 Build 54.16 onwards.	Yes	Yes	Yes
Bot management	No	No	Yes	No
VXLAN	No	No	No	No

Also, the following Citrix ADC configurations are supported:

Load balancing, load balancing persistency, DNS load balancing, SIP, maxClient, Spillover (connection and dynamic). Spillover based on bandwidth, DataStream, Compression control, Content filtering, TCP buffering, Cache redirection, distributed denial-of-service (DDoS). Client Keep-alive, Basic networking (IPv4 and IPv6), OSPF (IPv4 and IPv6), RIP (IPv4 and IPv6), RIP (IPv4 and IPv6). VLAN, ICMP, Fragmentation, MBF, ACL, Simple ACL, MSR, Path MTU discovery, IP-IP, SNMP, Policies (classic and advanced). Rewrite, Responder, HTTP callout, Web server logging, Audit logging (NSLOG and syslog). USIP, Location commands, HTML injection, NITRO API, AppExpert, KRPC.

Prerequisites

September 14, 2021

Citrix ADC appliances (MPX, VPX, SDX ADC, BLX) that are to be added to a cluster must meet the following prerequisites:

- All appliances must have the same software version and build.
- All appliances must be of the same platform type. This means that a cluster must have either

all hardware appliances (Citrix ADC MPX) or all Citrix ADC VPX appliances, or all Citrix BLX appliances, or all Citrix SDX ADC instances.

Note:

- For a cluster of hardware appliances (MPX), the appliances must be of the same model type.
- For the formation of the heterogeneous cluster, all appliances must be of MPX platform type.
- For a cluster of virtual appliances (VPX), the appliances must be deployed on the following hypervisors: XenServer, Hyper-V, VMware ESX, and KVM.
- For setting up a cluster of SDX Citrix ADC instances, see Set up a cluster of Citrix ADC instances.
- Jumbo frames are supported on a Citrix ADC cluster that is made up of Citrix ADC SDX instances.
- You can create L3 clusters of SDX instances.
- For information about setting up a Citrix ADC BLX cluster, see Citrix ADC BLX cluster.

- Appliances can belong to different networks.
- Be initially configured and connected to a common client-side and server-side network.
- For a cluster of virtual appliances (Citrix ADC VPX, or Citrix ADC BLX, or Citrix SDX ADC instance), that has large configurations, it is recommended to use 6 GB RAM for each node of the cluster.

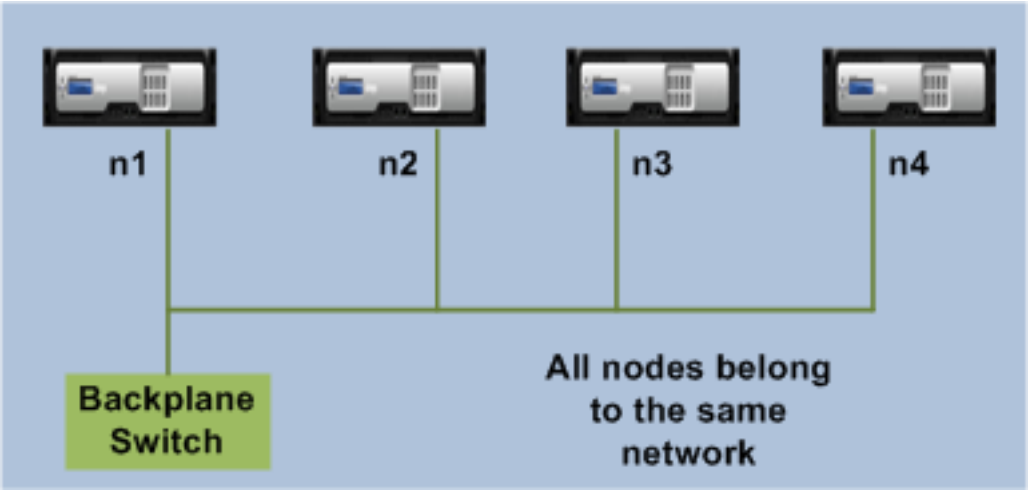
Cluster overview

September 14, 2021

A Citrix ADC cluster is formed by grouping Citrix ADC appliances together. Based on the network location of the Citrix ADC appliances that you intend to add the cluster, you must be aware of the following cluster setups:

> **Note**
>
> Unless specified otherwise, cluster features and configurations are the same for L2 and L3 clusters.

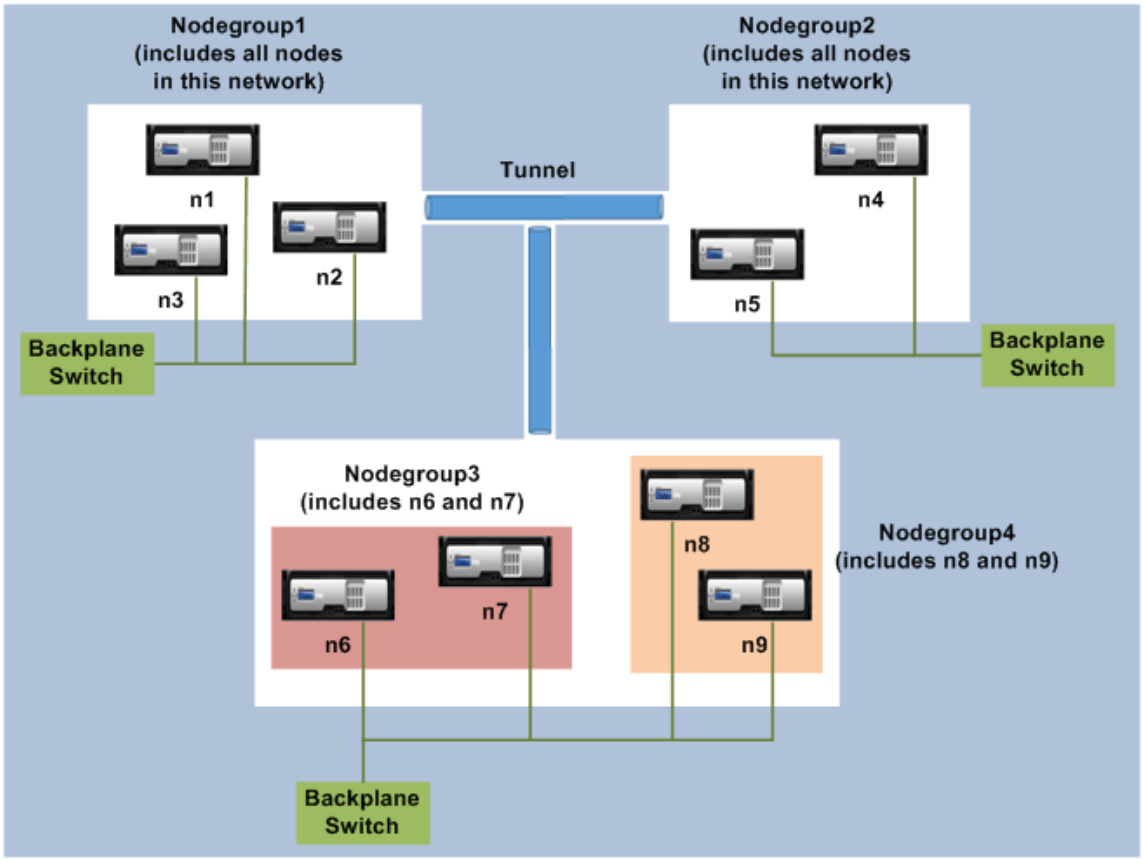
- **L2 cluster:** In this cluster deployment, all cluster nodes belong to the same network.



- **L3 cluster (also referred to as 'cluster in INC mode'):** In this cluster deployment, cluster nodes can belong to different networks. The cluster nodes from a specific network must be grouped into node groups that include only nodes from that network. From the following figure, we see that nodes n1, n2, n3 are in the same network and are grouped into Nodegroup1.

  Similarly, the case for nodes n4 and n5, that are grouped in Nodegroup2. In the third network, there are two node groups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.

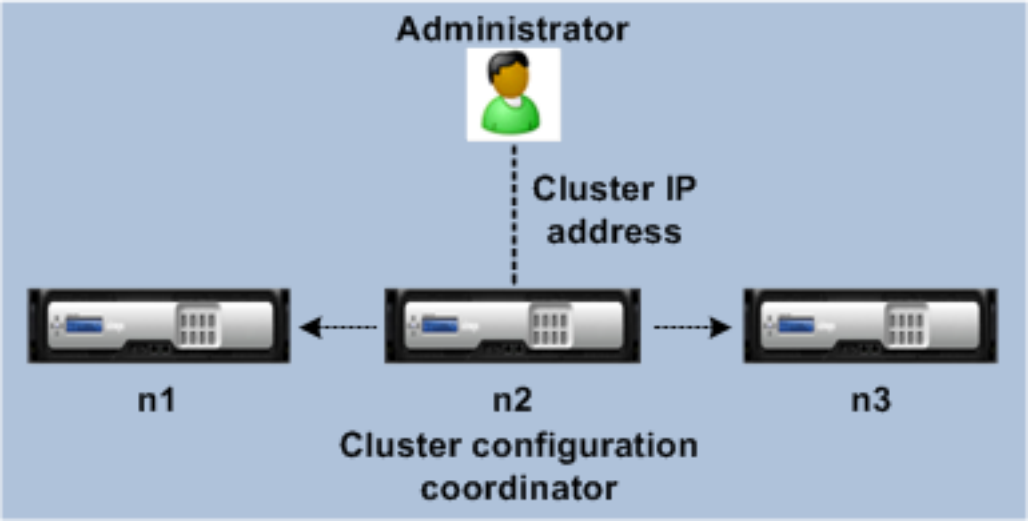
  > **Note**
  >
  > Supported from NetScaler 11.0 onwards.



Synchronization across cluster nodes

September 14, 2021

All configurations on a Citrix ADC cluster are performed on the cluster IP address, which is the management address of the cluster. The cluster node owns the cluster IP address that is referred to as the cluster configuration coordinator (CCO) as shown in the following figure:



The configurations that are available on the CCO are automatically propagated to the other cluster nodes and therefore all cluster nodes have the same configurations.

- Citrix ADC allows only a few configurations to be performed on individual cluster nodes through their NSIP address. In these cases, you must ensure configuration consistency manually across all nodes in the cluster. These configurations are not propagated across the other cluster nodes. For more information on operations supported on each cluster node, see Operations Supported on Individual Cluster Nodes.
- The following commands when ran on the cluster IP address are not propagated to other cluster nodes:
  - **shutdown.** Shuts down only the configuration coordinator.
  - **reboot.** Reboots only the configuration coordinator.
  - **rm cluster instance.** Removes the cluster instance from the node that you are running the command on.
- For a command to propagate to other cluster nodes:
  - The quorum must be configured on the cluster instance.
  - Most the cluster quorum with (n/2 + 1) of the cluster nodes must be active for the cluster to be operational.
  - A cluster can run with a minimum number of nodes when the majority rule (n/2 + 1) is relaxed.

When a node is added to a cluster, the configurations and the files (SSL certificates, licenses, DNS, and so on) that are available on the CCO are synchronized to the newly added cluster node. When an existing cluster node, that was intentionally disabled or that had failed, is once again added, the cluster compares the configurations available on the node with the configurations available on the CCO. If there is a mismatch in configurations, the node is synchronized by using one of the following:

- **Full synchronization.** If the difference between configurations exceeds 255 commands, all the configurations of the CCO are applied to the node that is rejoining the cluster. The node remains

operationally unavailable during the synchronization.

- **Incremental Synchronization.** If the difference between configurations is less than or equal to 255 commands, only the configurations that are not available are applied to the node that is rejoining the cluster. The operational state of the node remains unaffected.

> **Note**
>
> You can also manually synchronize the configurations and files. For more information, seeSynchronizing Cluster Configurations and Synchronizing Cluster Files.

Striped, partially striped, and spotted configurations

September 14, 2021

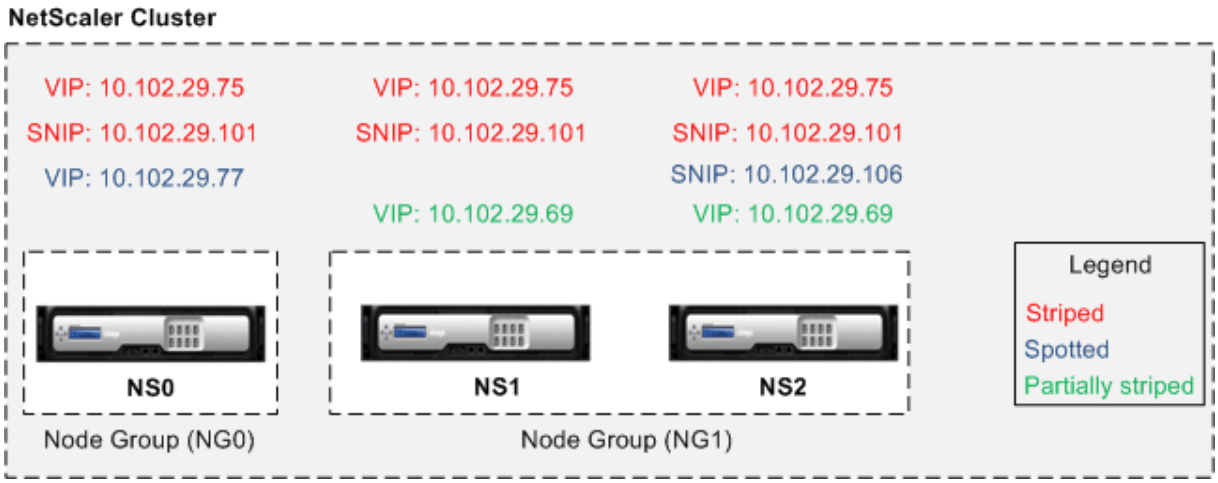
By virtue of command propagation, all nodes in a cluster have the same configurations. However, you might want some configurations to be available only on certain cluster nodes. While you cannot restrict the nodes on which the configurations are available, you can specify the nodes on which the configurations are active.

For example, you can:

- define a SNIP address to be active on only one node, or
- define a SNIP address to be active on all nodes, or
- define a VIP address to be active on only one node, or
- define a VIP address to be active on all nodes, or
- define a VIP address to be active only on two nodes of a 3-node cluster

Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations.

Figure 1. Three-node cluster with striped, partially striped, and spotted configurations



The following table provides more details on the types of configurations:

Configuration Type	Active on	Applicable to	Configurations
Striped configuration	All the cluster nodes	All entries	No specific configuration required to make an entity striped. By default, all entities defined on a cluster IP address are striped on all the cluster nodes.
Partially striped configuration	A subset of cluster nodes	Refer to Cluster Node groups.	Bind the entities that you want to be partially striped, to a node group. The configuration is active only on the cluster nodes that belong to the node group.

Configuration Type	Active on	Applicable to	Configurations
Spotted configuration	Single cluster node	SNIP address, SNMP Engine ID, host name of cluster nodes, Entities that can be bound to a node group	A spotted configuration can be defined using one of two approaches. **SNIP address** When creating the SNIP address, specify the node on which you want the SNIP address to be active, as the owner node. **Example**, `add ns ip 10.102.29.106 255.255.255.0 -type SNIP -ownerNode 2` (assuming node NS2 ID is 2). **Note**: You cannot change the ownership of a spotted SNIP address at run time. To change the ownership, you must first delete the SNIP address and add it again by specifying the new owner. **Entities that can be bound to a node group.** By binding the entity to a single-member node group.

> **Note**
>
> - When you disable USIP, Citrix recommends you to use spotted SNIP addresses. You can use striped SNIP addresses only if there is a shortage of IP addresses. The use of striped IP addresses can result in ARP flux issues if no spotted IP addresses are present in the same subnet for ARP resolution.
> - When you enable USIP, Citrix recommends you to use striped SNIP addresses as a gateway for server initiated traffic.

ARP owner support for striped IP

In a cluster setup, you can configure a specific node to respond to the ARP request for a striped IP. The configured node responds to the ARP traffic.

A new parameter “arpOwner” is introduced in the “add, set, and unset IP” commands.

To enable the ARP owner on a node by using the CLI.

At the command prompt, type:

```
add ns ip <ip_address> -arpOwner <node_id>
```

> **Note**
>
> The ARP owner parameter is supported only in the L2 cluster.

Neighbor discovery owner support for striped IPv6 address

In a cluster setup, you can configure a specific node as neighbor discovery (ND) owner for the striped IPv6 address to determine the link-layer address. A client sends a Neighbor Solicitation (NS) message to all the nodes in the cluster setup. The ND owner responds with a Neighbor Advertisement (NA) message with the link-layer address for the striped IPv6 address, and serves traffic.

To enable ND owner on a node by using the CLI

At the command prompt, type:

```
add ns ip6 <IPv6Address> -ndOwner <node id>

set  ns ip6 <IPv6Address> -ndOwner <node id>
<!--NeedCopy-->
```

Example:

```
add ns ip6 2001::21/64 -ndOwner 1

set ns ip6 2001::21/64 -ndOwner 1
<!--NeedCopy-->
```

To enable ND owner on a node by using the GUI

1. Navigate to **System > Network > IPs**.
2. In the **IPs** page, go to the **IPv6s** tab and click **Add**.
3. In the **Create IPv6** page, select one of the node IDs listed in **NdOwner in Cluster** drop-down menu.

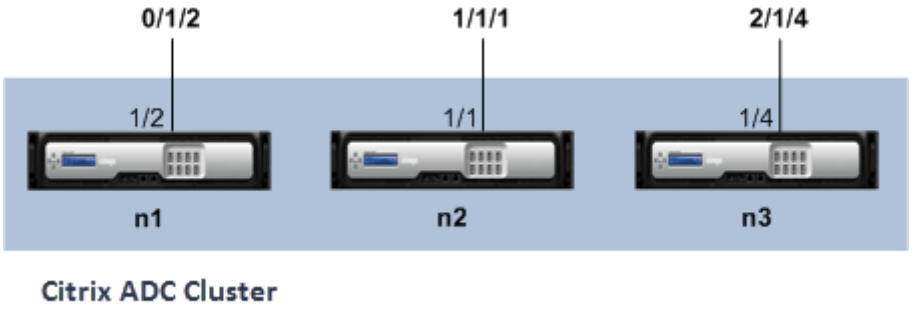
> **Note**
>
> The ND owner parameter is supported only in the L2 cluster.

Communication in a cluster setup

September 14, 2021

The interfaces of Citrix ADC appliances that are added to a cluster are prefixed with a node ID. It helps identify the cluster node to which the interface belongs. Therefore, the interface identifier c/u, where c is the controller number and u is the unit number, now becomes n/c/u, where n is the node ID. For example, in the following figure, interface 1/2 of node n1 is represented as 0/1/2, interface 1/1 of node n2 is represented as 1/1/1, and interface 1/4 of node n3 is represented as 2/1/4.

Figure 1. Interface naming convention in a cluster



- **Server communication**-
  The cluster communicates with the server through the physical connections between the cluster node and the server-side connecting device. The logical grouping of these physical connections is called the server data plane.

- **Client communication**- The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
- **Inter-node communication**- The cluster nodes can also communicate with each other. The manner in which they communicate depends on whether the node exists on the same network or across networks.
  - Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through the backplane, which is used by internode communication are:
    * Node to Node Messaging (NNM)
    * Steered traffic
    * Configuration propagation and synchronization
  - Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: `0x02 0x00 0x6F <cluster_id> <node_id> <reserved>)`, where `cluster_id` is the cluster instance ID, `node_id` is the node number of the Citrix ADC appliance that is added to a cluster.

The following figures shows the communication interfaces in L2 clusters and L3 clusters.

Figure 2. Cluster communication interfaces - L2 cluster

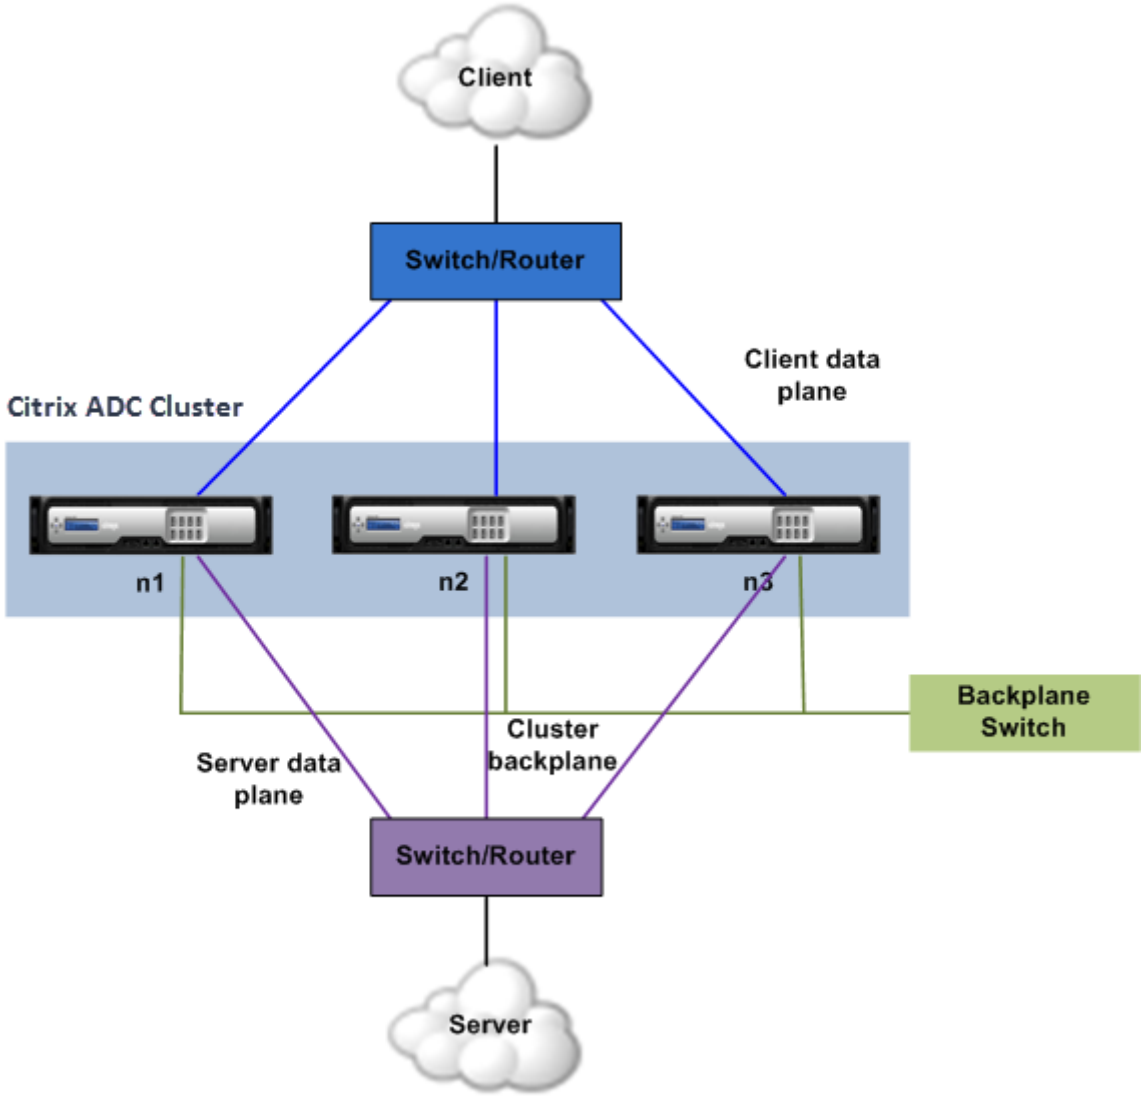


Figure 3. Cluster communication interfaces - L3 cluster

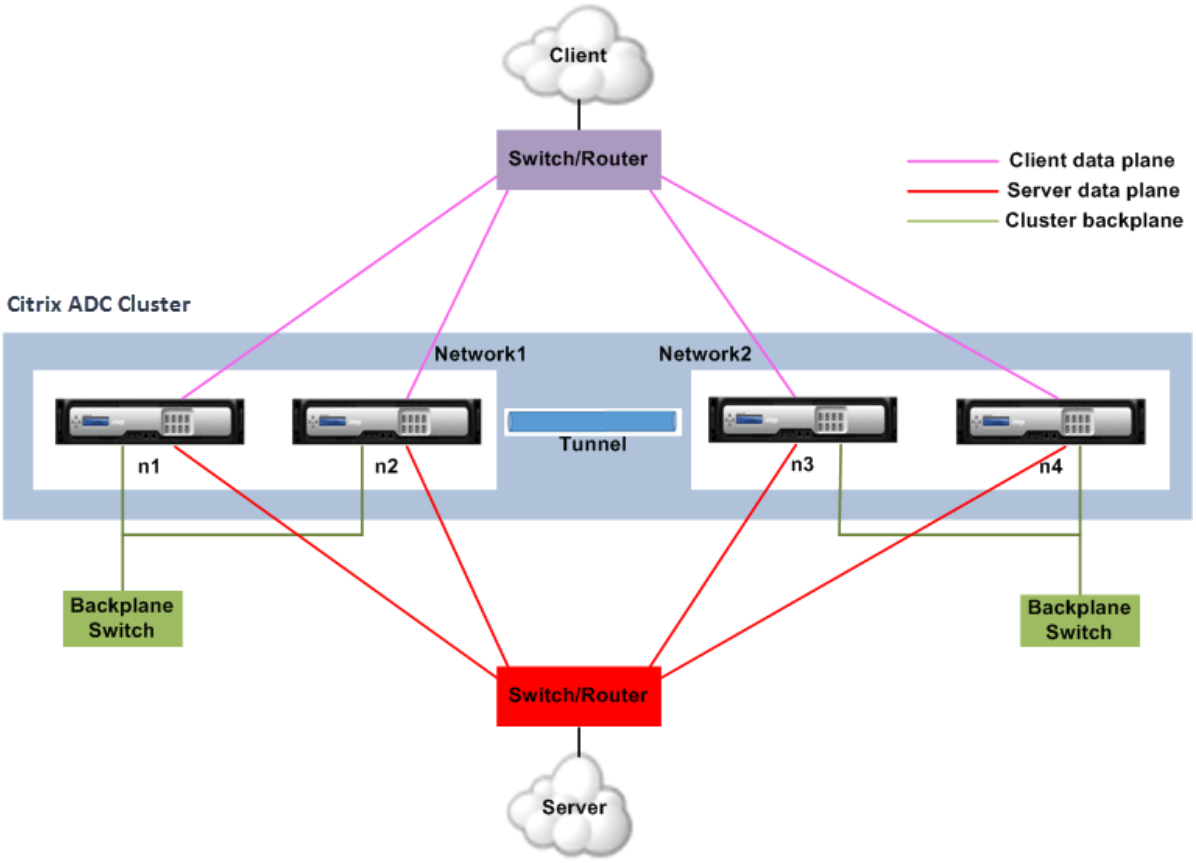


Traffic distribution in a cluster setup

September 14, 2021

In a cluster setup, external networks view the collection of Citrix ADC appliances as a single entity. So, the cluster must select a single node that must receive the traffic. The cluster does this selection by using the Equal Cost Multiple Path (ECMP) or cluster link aggregation traffic distribution mechanism. The selected node is called the flow receiver.

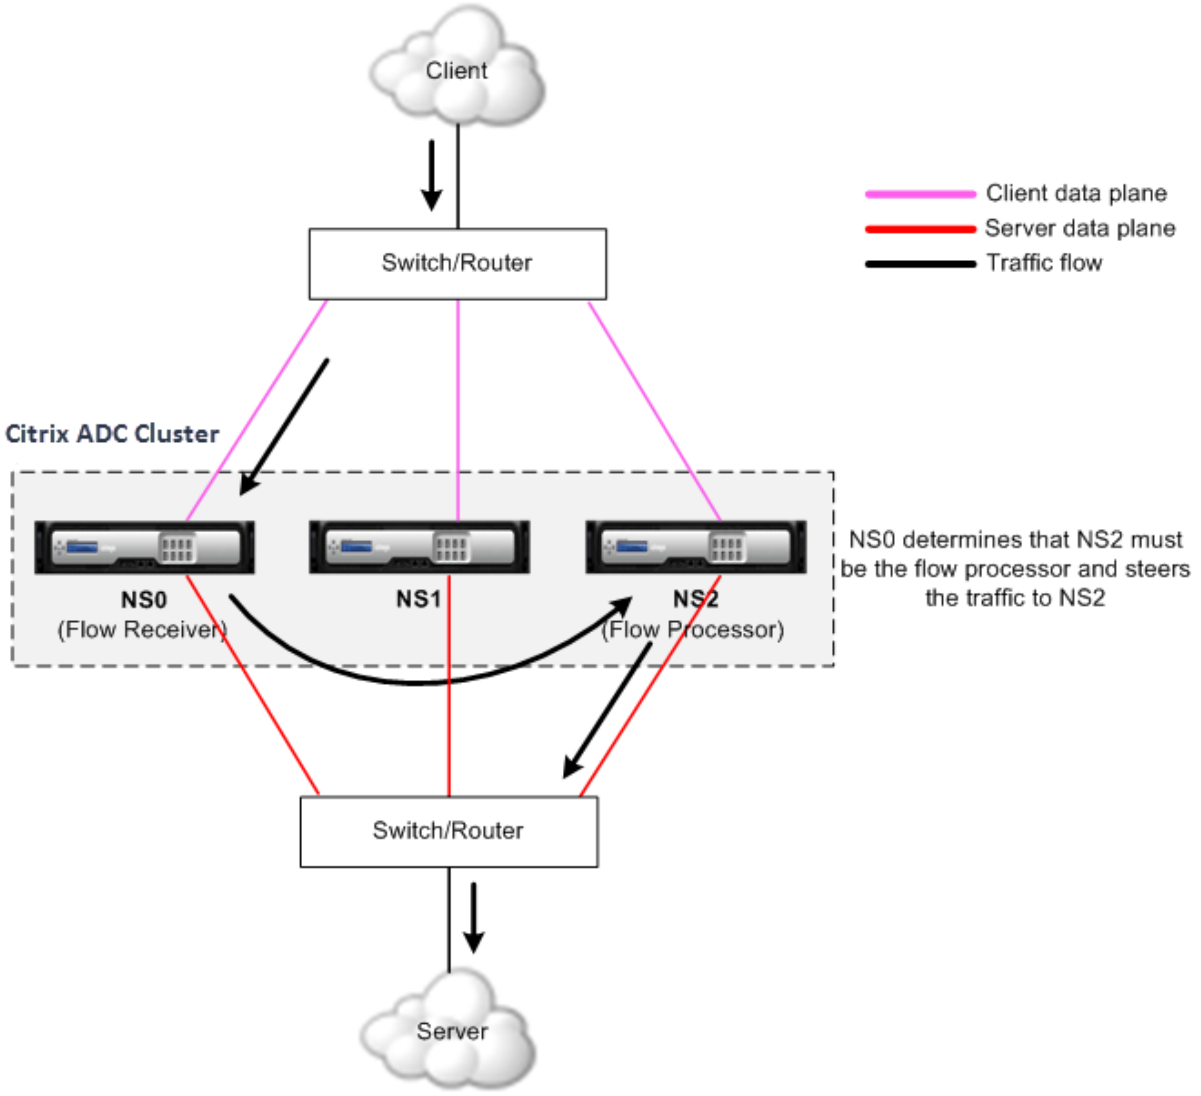
> **Note**
>
> For an L3 cluster (nodes across different networks), only the ECMP traffic distribution can be used.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow processor over the backplane if the flow receiver and the flow processor are on the same network. The traffic is steered through the tunnel if the flow receiver and the flow processor are on different networks.

Note

- The flow receiver and flow processor must be nodes capable of serving traffic.
- From NetScaler 11 onwards, you can disable steering on the cluster backplane. For more information, see Disabling Steering on the Cluster Backplane.

Figure 1. Traffic distribution in a cluster



The preceding figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor).

The flow processor establishes a connection with the server. The server processes the request and

sends the response to the subnet IP (SNIP) address that sent the request to the server.

- If the SNIP address is a striped or partially striped IP address, the traffic distribution mechanism configured on the server data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the flow processor, and steers the request to the flow processor through the cluster backplane.
- If the SNIP address is a spotted IP address, the node that owns the SNIP address receives the response from the server.

In an asymmetric cluster topology (all cluster nodes are not connected to the external switch), you must use linksets either exclusively or combined with ECMP or cluster link aggregation. For more information, see Using Linksets.

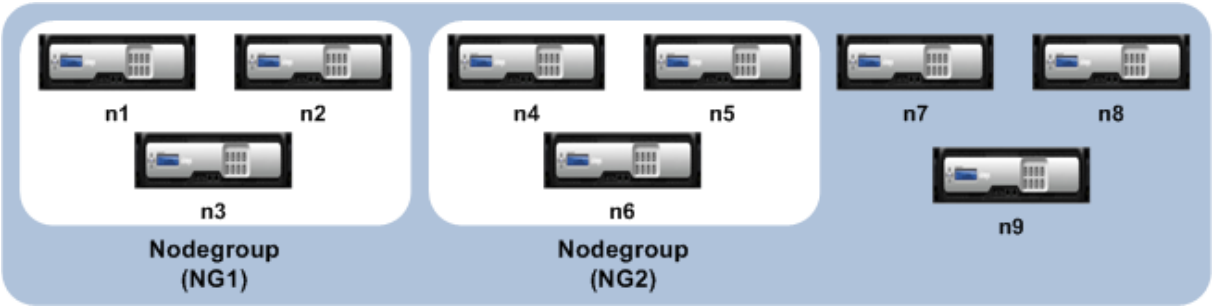
Cluster node groups

September 14, 2021

> **Note**
>
> Node groups are supported from NetScaler 10.1 onwards.

As the name indicates, a cluster node group is a group of cluster nodes.

Figure 1. Citrix ADC cluster with node groups



The preceding figure shows a cluster which has node groups NG1 and NG2 that include 3 cluster nodes each. The cluster also has 3 nodes that are not part of any node group.

A node group can be configured for the following:

- To define spotted and partially striped configurations. For more information, see Node groups for Spotted and Partially Striped Configurations.
- To configure redundancy of node groups. For more information, see Configuring Redundancy for Node groups.
  Note: Supported from NetScaler 10.5 Build 52.1115.e onwards.

- To define an L3 cluster (also called a cluster in INC mode). In an L3 cluster, cluster nodes can be from different networks. You must group nodes that belong to a network in a single node group. For example, if n1, n2, n3 are in network1 and n4, n5, n6 are in network2, then NG1 must include nodes of network1 and NG2 must include nodes of network2. For setting up an L3 cluster, see Creating a Citrix ADC cluster.

> **Note**
>
> - Supported from NetScaler 11 onwards.
> - The preceding functions of a node group are mutually exclusive. It means that a node group can provide only one of the preceding mentioned functionalities.

Cluster and node states

September 14, 2021

For a cluster to be functional, most of the nodes (n/2 + 1) must be operationally active (operational state is ACTIVE).

> **Important**
>
> From NetScaler release 10.5, you can configure the cluster to be functional even when the majority criteria is not satisfied. This configuration must be performed when creating a cluster.

For more information on states of a cluster node, refer to States of a cluster node.

Routing in a cluster

September 14, 2021

Routing in a cluster works in much the same way as routing in a standalone system. A few points to note:

- All routing configurations must be performed from the cluster IP address and the configurations are propagated to the other cluster nodes.
- Routes are limited to the maximum number of ECMP routes supported by the upstream router.
- Node-specific routing configurations must be performed by using the owner-node argument as follows:

```
1   router ospf
2     owner-node 0
```

```
3        ospf router-id 97.131.0.1
4      exit-owner-node
5    !
6  <!--NeedCopy-->
```

The following command displays the consolidated cluster configuration for all nodes in VTYSH.

```
show cluster-config
```

The following command displays the cluster status on each node.

```
show cluser node
```

IPv4 routing in L2 cluster

The following section contains sample configurations that help you to configure IPv4 OSPF and BGP routing in the L2 cluster.

Adding spotted SNIP address and enabling dynamic routing

In the following configuration, OSPF, and BGP routing are enabled. Also, spotted SNIP addresses are added and dynamic routing is enabled on these SNIP addresses.

```
1 en ns fea ospf bgp
2 add vlan 10
3 add ns ip 10.10.10.1 255.255.255.0 -dynamicrouting enabled -ownernode 1
4 add ns ip 10.10.10.2 255.255.255.0 -dynamicrouting enabled -ownernode 2
5 add ns ip 10.10.10.3 255.255.255.0 -dynamicrouting enabled -ownernode 3
6 bind vlan 10 -ipaddress 10.10.10.1 255.255.255.0
7 <!--NeedCopy-->
```

VTYSH IPv4 OSPF configuration

For configuring IPv4 OSPF in the L2 cluster, you must:

- Set the priority to zero.
- Configure the Router-id as a spotted configuration.

> **Note**
>
> The OSPF configuration guidelines for the L2 cluster are applicable for OSPFv3 also.

In the following sample configuration IPv4 OSPF is configured.

```
1       interface vlan10
2        IP OSPF PRIORITY 0
```

```
        !
       router ospf
           owner-node 1
             ospf router-id 97.131.0.1
           exit-owner-node
           owner-node 2
             ospf router-id 97.131.0.2
           exit-owner-node
           owner-node 3
             ospf router-id 97.131.0.3
           exit-owner-node
       network 10.10.10.0/24 area 0
       redistribute kernel
        !
<!--NeedCopy-->
```

VTYSH IPv4 BGP configuration

In the following VTYSH sample configuration, IPv4 BGP is configured.

```
     router bgp 100
       neighbor 10.10.10.10 remote-as 200
      owner-node 1
       neighbor 10.10.10.10 update-source 10.10.10.1
      exit-owner-node
      owner-node 2
       neighbor 10.10.10.10 update-source 10.10.10.2
      exit-owner-node
      owner-node 3
       neighbor 10.10.10.10 update-source 10.10.10.3
      exit-owner-node
     redistribute kernel
     !
<!--NeedCopy-->
```

> **Note**
>
> The update-source command is used for each neighbor with the owner-node argument in the following configuration to connect with proper source IP.

IPv6 routing in L2 cluster

The following section contains sample configurations that help you to configure IPv6 OSPF and BGP routing in the L2 cluster.

Enable IPv6 routing

Before configuring IPv6 routing in a L2 cluster, you must enable the IPv6 feature.

To enable IPv6 routing by using the CLI,

At the command prompt, type:

- `enable ns fea ipv6pt`

Adding spotted SNIP6 address and enabling dynamic routing

In the following configuration, OSPF, and BGP routing are enabled. Also, spotted SNIP6 addresses are added and dynamic routing is enabled on these SNIP6 addresses.

```
add ns ip6 3ffa::1/64 -dynamicrouting enabled -ownernode 1
add ns ip6 3ffa::2/64 -dynamicrouting enabled -ownernode 2
add ns ip6 3ffa::3/64 -dynamicrouting enabled -ownernode 3
add vlan 10
bind vlan 10 -ipaddress 3ffa::1/64
<!--NeedCopy-->
```

VTYSH IPv6 BGP configuration

In the following VTYSH sample configuration, IPv6 BGP is configured.

```
  router bgp 100
   neighbor 3ffa::10 remote-as 200
     owner-node 1
      neighbor 3ffa::10 update-source 3ffa::1
     exit-owner-node

  !
<!--NeedCopy-->
```

Install IPv6 learned routes

The Citrix ADC cluster can use routes learned by various routing protocols after you install the routes in the Citrix ADC cluster routing table.

To install IPv6 learned routes to the internal routing table by using the CLI:

At the command prompt, type:

- `ns route-install ipv6 bgp`
- `ns route-install ipv6 ospf`
- `ns route-install default`

> **Note**
>
> - If you have to exchange IPv4 routes on a IPv6 neighbor, you must remove the `no neighbor 3ffa::10 active` VTYSH command from the earlier configuration.
> - The `update-source` VTYSH command must be used for each owner node to specify the right IPv6 source IP while connecting to the BGP peer as given in the BGP IPv4 configuration.

Routing in a L3 cluster

The routing in a L3 cluster works only when the following configurations are done on the Citrix ADC appliance.

- Enable the dynamic routing for a VLAN.

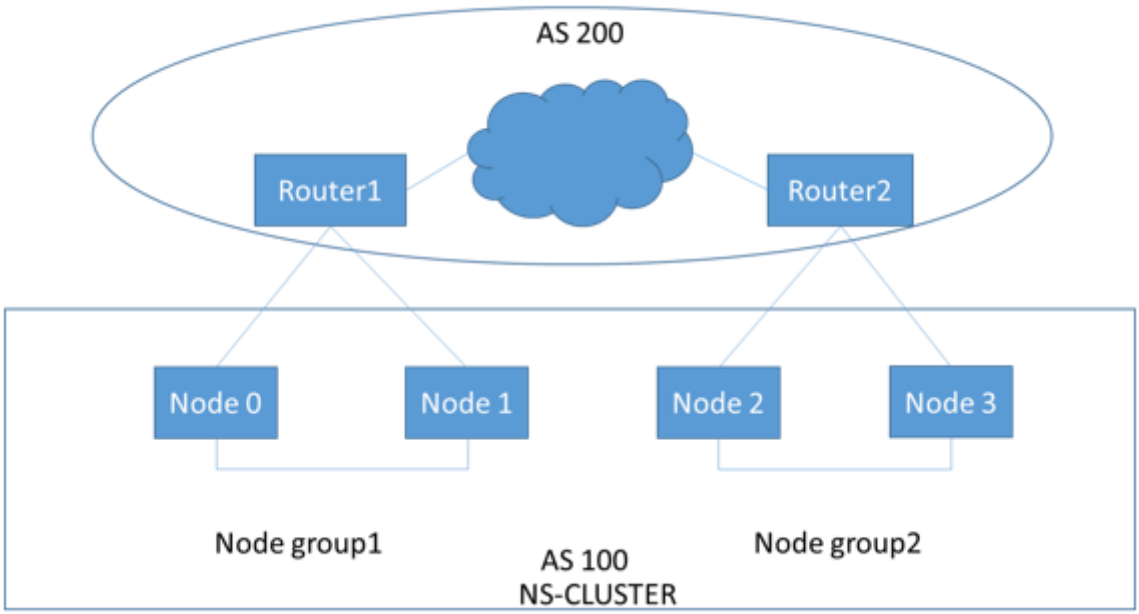
```
set vlan <id> -dynamicrouting enabled
<!--NeedCopy-->
```

- To reach all cluster nodes, the VIP, CLIP, and Citrix ADC IP (NSIP) must be advertised by routing protocols along with the `set vlan` command.

Deployment scenario for BGP in L3 cluster

Consider an example where all the cluster nodes are grouped in the AS 100 network, and the upstream routers are in a different AS 200.

The following figure depicts the AS 100 and AS 200 deployment in a cluster setup.



In this deployment, CLIP advertises CCO to upstream routers. Some cluster nodes drop the advertised traffic, as an AS loop is detected.

To overcome the issue, configure the following command in VTYSH BGP router mode for each neighbor.

At the VTYSH command prompt, type:

```
neighbor <peer_ip> allowas-in 1
```

As a best practice, Citrix recommends you to configure any one of the following:

- Configure route-maps to learn only desired networks such as; default route, Citrix ADC IP (NSIP), and NSIP subnets on cluster nodes.
- Configure upstream routes to advertise only desired networks such as; CLIP and Citrix ADC IP (NSIP) in cluster.

IP addressing for a cluster

September 14, 2021

In addition to the standard types of Citrix ADC-owned IP addresses—Citrix ADC NSIP, Virtual IP (VIP), and Subnet IP (SNIP)—a clustered Citrix ADC appliance can have a cluster management IP (CLIP) address. It can also have striped and spotted IP addresses.

- **CLIP address.** An IP address owned by the cluster coordinator node (CCO). The CLIP address can float between different nodes in a cluster setup. If the CLIP is moved to a different node of the cluster, that node becomes the CCO. The CCO is the Citrix ADC appliance that is responsible for management tasks in the cluster. A network administrator uses the CLIP address to connect to the cluster to perform configuration and management tasks, such as accessing the unified GUI, reporting, tracing packet flow, and collecting logs. You can add multiple CLIP addresses in a cluster on the same or different networks. Only configurations performed on the CCO through the cluster IP address are propagated to other nodes in the cluster.
- **Striped IP address**. A logical IP address available on all nodes of the cluster, it can be either a VIP or SNIP address.
- **Spotted IP address**. A logical IP (preferably SNIP address) is available only on one node. A spotted IP address has visibility on only that node. To minimize traffic-steering overhead, Citrix recommends that you use a spotted SNIP address for back-end communication with the server.

The following table provides the details of the configurations.

IP Address	NSIP	VIP	SNIP
Spotted	Yes	Yes	Yes
Striped	No	Yes	Yes

For example, in a four-node cluster group, you must configure each node with a spotted SNIP address. For more information on how to configure a spotted IP configuration, see Striped, Partially Striped, and Spotted Configurations.

You can define a SNIP address to be active on only one node, or active on all nodes. If the virtual IP address and subnet IP address are available only on a specific node, it is of spotted configuration. The configuration is defined as striped if the subnet IP address and virtual server IP address are available on all nodes. Spotted SNIP addresses help in reducing the steering and backplane traffic.

Best practices for VLAN bindings and route configuration while joining a node to the cluster

VLAN IP bindings

When you bind a VLAN with the spotted IP address, the Citrix ADC cluster must be configured with the spotted IP addresses in the same subnet on all the nodes. For example, in a two-node cluster with Node 0 and Node 1, you can have the following configuration:

```
1 add ns ip 192.254.101.101 255.255.255.0 -vServer DISABLED -
    dynamicRouting ENABLED -ownerNode 1
```

```
2 add ns ip 192.254.101.102 255.255.255.0 -vServer DISABLED -
     dynamicRouting ENABLED -ownerNode 0
3 add vlan 100
4 bind vlan 100 -IPAddress 192.254.101.101 255.255.255.0
5 <!--NeedCopy-->
```

Routing configuration

When routing configuration is required with the spotted IP address as the default gateway, then the ADC cluster must be configured with the spotted IP addresses in the same subnet on all the nodes. For example, in a two-node cluster with Node 0 and Node 1, you can have the following configuration:

```
1 add ns ip 192.254.101.101 255.255.255.0 -vServer DISABLED -
     dynamicRouting ENABLED -ownerNode 1
2 add ns ip 192.254.101.102 255.255.255.0 -vServer DISABLED -
     dynamicRouting ENABLED -ownerNode 0
3
4 add route 192.254.102.0 255.255.255.0 192.254.101.103
5 <!--NeedCopy-->
```

> **Note**
>
> In an L3 cluster setup, only spotted SNIP configuration is supported.

Configuring layer 3 clustering

September 14, 2021

Understanding the L3 cluster

The demand to expand the high availability deployment and increase the scalability of the client traffic across different networks guided to establish the L3 cluster. The L3 cluster lets you group Citrix ADC appliances across individual subnets (L2 cluster).

L3 cluster is also referred to as “cluster in Independent Network Configuration (INC) mode”. In L3 cluster deployment, the cluster nodes in the same network are grouped to form a Node group. L3 cluster uses GRE tunneling to steer the packets across networks. The heartbeat messages across the L3 clusters are routed.

This document includes the following details:

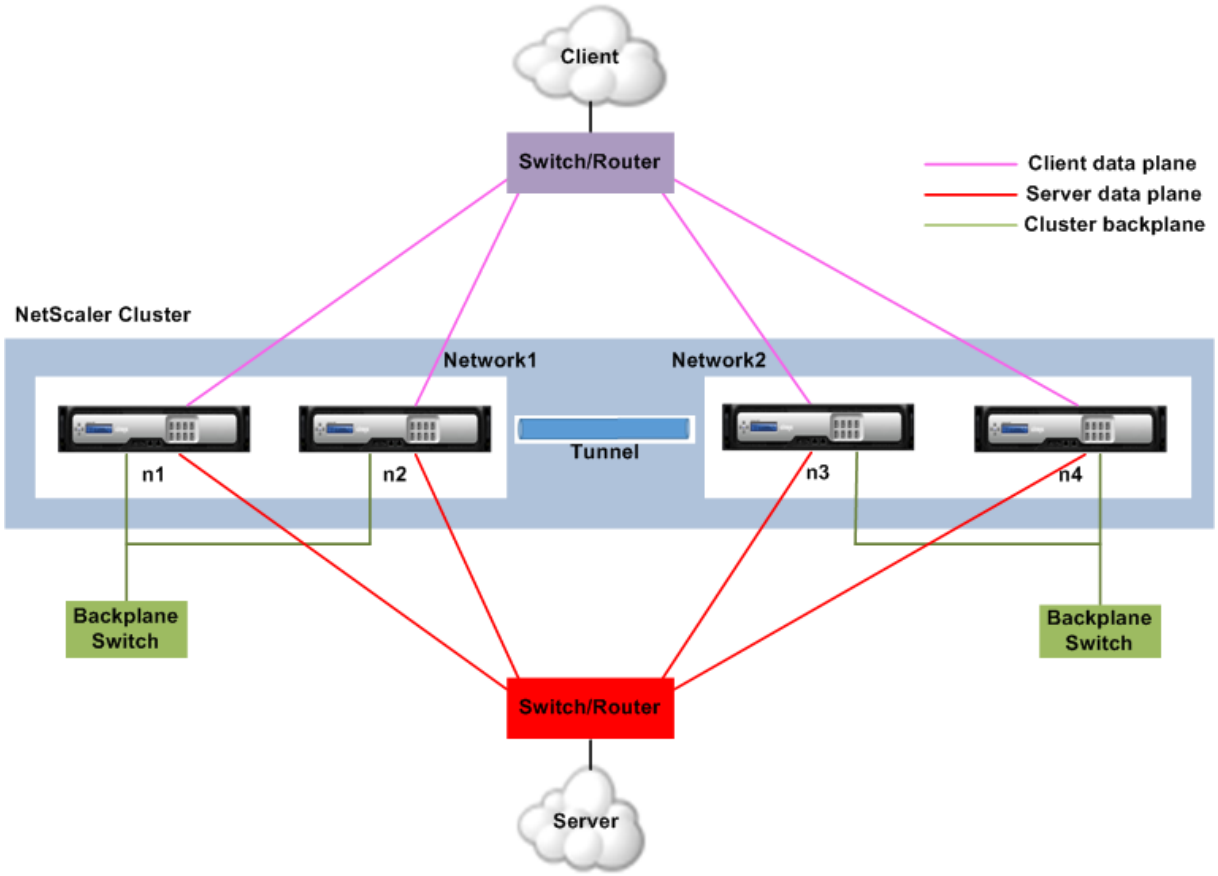
- Architecture

- Example

Architecture

The L3 cluster architecture comprises the following components:

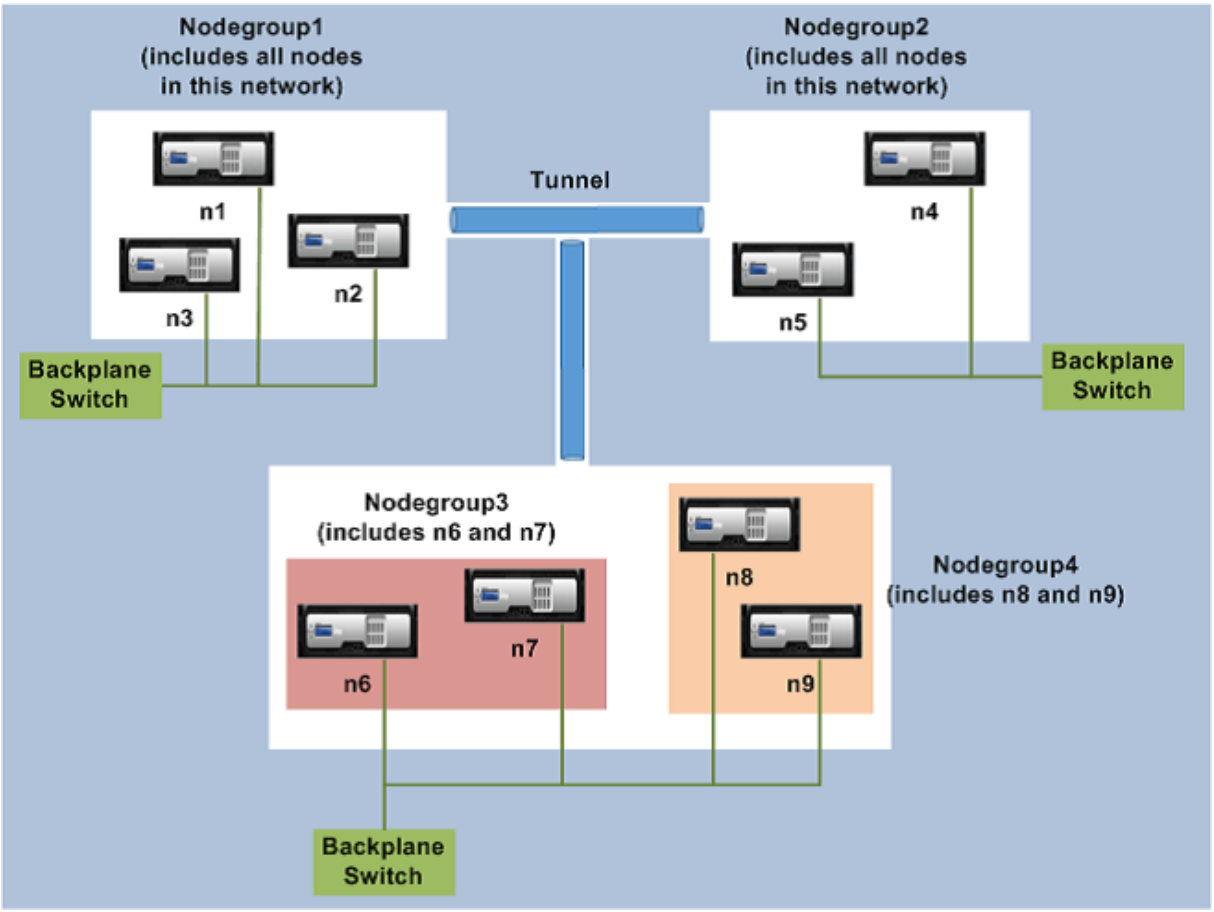
- **Nodegroup**. The cluster nodes from each network (n1, n2) and (n3, n4), as depicted in the following figure, are grouped to form a Node group. These Node groups are terminated to the layer 3 switch on either side of the network.
  - The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
  - The cluster communicates with the server through the physical connections between the cluster node and the server side connecting device. The logical grouping of these physical connections is called the server data plane.
- **Backplane Switch.** Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch.
- **GRE Tunnel.** The packets between nodes in a L3 cluster are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. The steering mechanism changes for nodes belonging to the different network. The packets are steered through a GRE tunnel to the node on the other subnet, instead of rewriting the MAC.



Example

Consider an example of an L3 cluster deployment consisting of the following:

- Three Citrix ADC appliances (n1, n2, and n3) nodes are grouped into Nodegroup1.
- Similarly, the nodes n4 and n5 are grouped in Nodegroup2. In the third network, there are two node groups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.
- The Citrix ADC appliances that belong to the same network are combined to form a node group.



Points to consider before configuring the L3 cluster

Consider the following points before configuring the L3 cluster on a Citrix ADC appliance:

- The backplane is not mandatory while configuring L3 subnets. If the backplane is not specified, the node does not go to the backplane fail state.

  > **Note**
  >
  > If you have more than one node in the same L2 network, it is mandatory to define the backplane interface. If the backplane interface is not mentioned, the nodes go to the backplane fail state.

- L2 features and striped SNIPs are not supported in the L3 cluster.
- The external traffic distribution in the L3 cluster supports only Equal Cost Multiple Path (ECMP).
- The ICMP errors and fragmentation are not processed when steering is disabled in an L3 cluster deployment:
- The networking entities (`route`, `route6`, `pbr`, and `pbr6`) must be bound to the configuration node group.

- VLAN, RNAT, and IP tunnel cannot be bound to a configuration node group.
- Configuration node group must always have property STRICT “YES.
- The cluster nodes must not be added to a config node group via “add cluster node” command.
- The `add cluster instance -INC enabled` command clears the networking entities (route, route6, PBR, pb6, RNAT, IP tunnel, ip6tunnel).
- The `clear config extended+` command does not clear the entities (route, route6, PBR, pb6, RNAT, IP tunnel, ip6tunnel) in an L3 cluster.

Configuring the L3 cluster

In an L3 cluster configuration, the cluster command has different attributes to configure that is based on nodes, and node groups. The L3 cluster configuration also includes an IPv6 profile apart from IPv4 profiles.

Configuring an L3 cluster on a Citrix ADC appliance consists of the following tasks:

- Create a cluster instance
- Create a node group in L3 cluster
- Add a Citrix ADC appliance to the cluster and group with node group
- Add cluster IP address to the node
- Enable the cluster instance
- Save the configuration
- Add a node to an existing node group
- Create a node group in L3 cluster
- Group new nodes to the newly created node group
- Join the node to the cluster

Configuring the following by using the CLI

- **To create a cluster instance**

  ```
  add cluster instance <clid> -inc (<ENABLED|DISABLED>)[-processLocal <
  ENABLED | DISABLED]
  ```

- **To create a nodegroup in L3 cluster**

  ```
  add cluster nodegroup <name>
  ```

- **To add a Citrix ADC appliance to the cluster and to associate with nodegroup**

  ```
  add cluster node <nodeid> <nodeip> -backplane <interface_name> node
  group <ng>
  ```

- **To add the cluster IP address on this node**

  ```
  add ns ip <IPAddress> <netmask> -type clip
  ```

- **Enable the cluster instance**

  ```
  enable cluster instance <clId>
  ```

- **Save the configuration**

  ```
  save ns config
  ```

- **Warm reboot the appliance**

  ```
  reboot -warm
  ```

- **To add a new node to an existing nodegroup**

  ```
  add cluster node <nodeid> <nodeip> -nodegroup <ng>
  ```

- **To create a new nodegroup in L3 cluster**

  ```
  add cluster nodegroup <ng>
  ```

- **To group new nodes to the newly created nodegroup**

  ```
  add cluster node <nodeid> <nodeip> -nodegroup <ng>
  ```

- **To join the node to the cluster**

```
1     join cluster  - clip <ip_addr> -password <password>
2
3     add cluster instance 1  - inc ENABLED  - processLocal  ENABLED
4
5        Done
6 <!--NeedCopy-->
```

> **Note**
>
> The “inc” parameter must be ENABLED for an L3 cluster.

```
1     add cluster nodegroup ng1
2
3        Done
4
5     > add cluster node 0 1.1.1.1  - state ACTIVE -backplane 0/1/1  -
          nodegroup ng1
6
7        Done
8
9     > add ns ip 1.1.1.100 255.255.255.255  - type clip
10
```

```
11         Done
12
13      > enable cluster instance 1
14
15         Done
16
17      > save ns config
18
19         Done
20
21      > add cluster node 1 1.1.1.2  -state ACTIVE  -nodegroup ng1
22
23         Done
24
25      > add cluster nodegroup ng2
26
27         Done
28
29      > add cluster node 4 2.2.2.1  -state ACTIVE  -nodegroup ng2
30
31         Done
32
33      > add cluster node 5 2.2.2.2  -state ACTIVE  -nodegroup ng2
34
35         Done
36
37      > join cluster -clip 1.1.1.100 -password nsroot
38  <!--NeedCopy-->
```

Advertising cluster IP address of a L3 cluster

Configure the cluster IP address to be advertised to the upstream router to make the cluster configuration accessible from any subnet. The cluster IP address is advertised as a kernel route by the dynamic routing protocols configured on a node.

Advertising the cluster IP address consists of the following tasks:

- **Enable the host route option of the cluster IP address**. The host route option pushes the cluster IP address to a ZebOS routing table for kernel route redistribution through dynamic routing protocols.
- **Configuring a dynamic routing protocol on a node**. A dynamic routing protocol advertises the cluster IP address to the upstream router. For more information on configuring a dynamic routing protocol, see Configuring Dynamic Routes.

To enable the host route option of the cluster IP address by using the CLI

At the command prompt, type:

```
-  add nsip <IPAddress> <netmask> -hostRoute ENABLED

-  show nsip \<IPAddress\>

    > add ns ip 10.102.29.60 255.255.255.255 -hostRoute ENABLED

       Done
<!--NeedCopy-->
```

Spotted, partially striped configurations on L3 cluster

The spotted and partially striped configurations on the L3 cluster slightly differ from the L2 cluster. The configuration might differ from node to node as the nodes reside on different subnets. The network configurations can be node specific in the L3 cluster, hence you have to configure the spotted or partially striped configurations based on the below-mentioned parameters.

To configure spotted, partially striped configurations on a Citrix ADC appliance over the L3 cluster, perform the following tasks:

- Add a cluster owner group to an IPv4 static routing table
- Add a cluster owner group to an IPv6 static routing table
- Add a cluster owner group to an IPv4 policy based routing (PBR)
- Add a cluster owner group to an IPv6 PBR
- Add a VLAN
- Bind a VLAN to a specific owner group of cluster node group

Configuring the following by using the CLI

- **To add a cluster ownergroup to an IPv4 static route table of the Citrix ADC appliance**

  ```
  add route <network> <netmask> <gateway> -owner group <ng>
  ```

- **To add a cluster ownergroup to an IPv6 static route table of the Citrix ADC appliance**

  ```
  add route6 <network> -owner group <ng>
  ```

- **To add a cluster ownergroup to an IPv4 PBR**

  ```
  add pbr <name> <action> -owner group <ng>
  ```

- **To add a cluster ownergroup to an IPv6 PBR**

  ```
  add pbr6 <name> <action> -owner group <ng>
  ```

- **To add a VLAN**

  ```
  add vlan <id>
  ```

- **To bind a VLAN to a specific ownergroup of cluster nodegroup**

  ```
  bind vlan <id> -ifnum - [IPAddress <ip_addr | ipv6_addr> [-owner group
  <ng>]
  ```

  The following commands are sample examples of spotted and partially striped configurations which can be configured by using the CLI.

```
1     > add route 10.102.29.0 255.255.255.0 10.102.29.2  - ownergroup ng2
2
3         Done
4
5     > add route6 fe80::9404:60ff:fedd:a464/64  - ownergroup ng1
6
7         Done
8
9     > add pbr pbr1 allow  - ownergroup ng1
10
11        Done
12
13    > add pbr6 pbr2 allow  - ownergroup ng2
14
15        Done
16
17    > add vlan 2
18
19        Done
20
21    > bind vlan 2  - ifnum 1/2  - [IPAddress 10.102.29.80 | fe80::9404:60
         ff:fedd:a464/64-ownergroup ng1
22
23        Done
24 <!--NeedCopy-->
```

Configure node group

In an L3 cluster, to replicate the same set of configurations on more than one node group, the following commands are used:

Configuring the following by using the CLU

- **To add an IPv4 static route to the routing table of the Citrix ADC appliance**

```
add route <network> <netmask> <gateway> -ownerGroup <ng>
```

Sample Configuration:

```
add route 0 0 10.102.53.1 -ownerGroup ng1

add route 0 0 10.102.53.1 -ownerGroup ng2
<!--NeedCopy-->
```

You define a new node group 'all' to support the preceding configuration, and have to configure the following commands:

Configuring the following by using the CLI

- **To add a new nodegroup to cluster with strict parameter**

```
add cluster node group <name> -strict <YES | NO>
```

- **To bind a cluster node or an entity to the given nodegroup**

```
bind cluster nodegroup <name> -node <nodeid>
```

- **To add IPv4 static route to all ownergroup**

```
add route <network> <netmask> <gateway> -ownerGroup <ng>
```

Sample configuration:

```
add cluster nodegroup all -strict YES

bind cluster nodegroup all -node 1

bind cluster nodegroup all -node 2

add route 0 0 10.102.53.1 -ownerGroup all
<!--NeedCopy-->
```

Traffic distribution in a L3 cluster

In a cluster setup, external networks view the collection of Citrix ADC appliances as a single entity. So, the cluster must select a single node that must receive the traffic. In the L3 cluster this selection is done using the ECMP. The selected node is called the flow receiver.

> **Note**
>
> For an L3 cluster (nodes across different networks), only the ECMP traffic distribution can be used.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow processor over the backplane if the flow receiver and the flow processor are on the same network. The traffic is steered through the tunnel if the flow receiver and the flow processor are on different networks.

> **Note**
>
> - The flow receiver and flow processor must be nodes capable of serving traffic.
> - From NetScaler 11 onwards, you can disable steering on the cluster backplane. For more information, see Disabling steering on the cluster backplane.

The preceding figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor). If the flow processor and flow receiver are in the same node group, the packet is steered over the backplane. And if the flow processor and flow receiver are in different node groups, then the packet is steered through the tunnel over the routed path.

The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server. Since in the L3 cluster the SNIP is always a spotted SNIP, the node that owns the SNIP address receives the response from the server.

Setting up a Citrix ADC cluster

September 14, 2021

Citrix ADC appliances that you want to add to the cluster must satisfy the criteria specified in Prerequisites for Cluster Nodes. Before actually setting up a cluster, you must be aware of cluster basics. For information, see Cluster Overview.

Forming a cluster requires you to set up inter-node communication, create the cluster (by adding the first Citrix ADC appliance), and then add the other cluster nodes. Each of these steps is explained with relevant details in subsequent topics.

> **Note**
>
> While there are some differences in setting up an L2 and L3 cluster, there are many similarities too. The subsequent topics explain the setup for both cluster types while highlighting the configurations that are specific to L3 clusters.

Setting up inter-node communication

September 14, 2021

The nodes in a cluster setup communicate with one another using the following inter-node communication mechanisms:

- Nodes that are within the network (same subnet) communicate with each other through the cluster backplane. The backplane must be explicitly set up. The following are the detailed steps.
- Across networks, steering of packets is done through a GRE tunnel and other node-to-node communication is routed across nodes as required.

> **Important**
>
> - From Release 11.0 all builds, a cluster can include nodes from different networks.
> - From Release 13.0 build 58.3, GRE steering is supported on Fortville NICs in an L3 cluster.

To set up the cluster backplane, do the following for every node

1. Identify the network interface that you want to use for the backplane.
2. Connect an Ethernet or optical cable from the selected network interface to the cluster backplane switch.

For example, to use interface 1/2 as the backplane interface for node 4, connect a cable from the 1/2 interface of node 4 to the backplane switch.

Important points to note when setting up the cluster backplane

- Do not use the appliance's management interface (0/x) as the backplane interface. In a cluster, the interface 0/1/x is read as:

  0 -> node ID 0
  1/x -> Citrix ADC interface

- Do not use the backplane interfaces for the client or server data planes.
- Citrix recommends using the link aggregate (LA) channel for the cluster backplane.

- In a two-node cluster, where the backplane is connected back-to-back, the cluster is operationally DOWN under any of the following conditions:
  - One of the nodes is rebooted.
  - Backplane interface of one of the nodes is disabled.

  Therefore, Citrix recommends that you dedicate a separate switch for the backplane, so that the other cluster node and traffic are not impacted. You cannot scale out the cluster with a back-to-back link. You might encounter a downtime in the production environment when you scale out the cluster nodes.
- Backplane interfaces of all nodes of a cluster must be connected to the same switch and bound to the same L2 VLAN.
- If you have multiple clusters with the same cluster instance ID, make sure that the backplane interfaces of each cluster are bound to a different VLAN.
- The backplane interface is always monitored, regardless of the HA monitoring settings of that interface.
- The state of MAC spoofing on the different virtualization platforms can affect the steering mechanism on the cluster backplane. Therefore, make sure the appropriate state is configured:
  - XenServer - Disable MAC spoofing
  - Hyper-V - Enable MAC spoofing
  - VMware ESX - Enable MAC spoofing (also make sure “Forged Transmits” is enabled)
- The MTU for the cluster backplane is automatically updated. However, if jumbo frames are configured on the cluster, the MTU of the cluster backplane must be explicitly configured. The value must be set to 78 + X, where X is the maximum MTU of the client and server data planes. For example, if the MTU of a server data plane is 7500 and of the client data plane is 8922. The MTU of a cluster backplane must be set to 78 + 8922 = 9000. To set this MTU, use the following command:

  ```
  > set interface <backplane_interface> -mtu <value>
  ```
- The MTU for the interfaces of the backplane switch must be specified to be greater than or equal to 1,578 bytes. It is applicable if the cluster has features like MBF, L2 policies, ACLs, routing in CLAG deployments, and vPath.

UDP based tunnel support for L2 and L3 cluster

Starting from Citrix ADC release 13.0 build 36.x, Citrix ADC L2 and L3 cluster can steer the traffic using UDP based tunneling. It is defined for the inter-node communications of two nodes in a cluster. By using the “tunnel mode” parameter, you can set GRE or UDP tunnel mode from the add and set cluster node command.

In an L3 cluster deployment, packets between Citrix ADC nodes are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. When this exchange occurs over the internet, in the absence of an IPsec tunnel, the NSIPs is exposed on the internet, and might result in security issues.

> **Important**
>
> Citrix recommends customers to establish their own IPsec solution when using a L3 cluster.

The following table helps you to categorize the tunnel support based on different deployments.

Steering Types	AWS	Microsoft Azure	On -premises
MAC	Not supported	Not supported	Supported
GRE tunnel	Supported	Not supported	Supported
UDP tunnel	Supported	Supported	Supported

> **Important**
>
> In a L3 cluster, the tunnel mode is set to GRE by default.

Configuring UDP based tunnel

You can add a cluster node by setting the parameters of node ID and mention the state. Configure the backplane by providing the interface name, and select the tunnel mode of your choice (GRE or UDP).

CLI procedures

To enable the UDP tunnel mode by using the CLI.

At the command prompt, type:

- `add cluster node <nodeId>@ [-state <state>] [-backplane <interface_name>] [-tunnelmode <tunnelmode>]`
- `set cluster node <nodeId>@ [-state <state>] [-tunnelmode <tunnelmode>]`

> **Note**
>
> Possible values for tunnel mode are NONE, GRE, UDP.

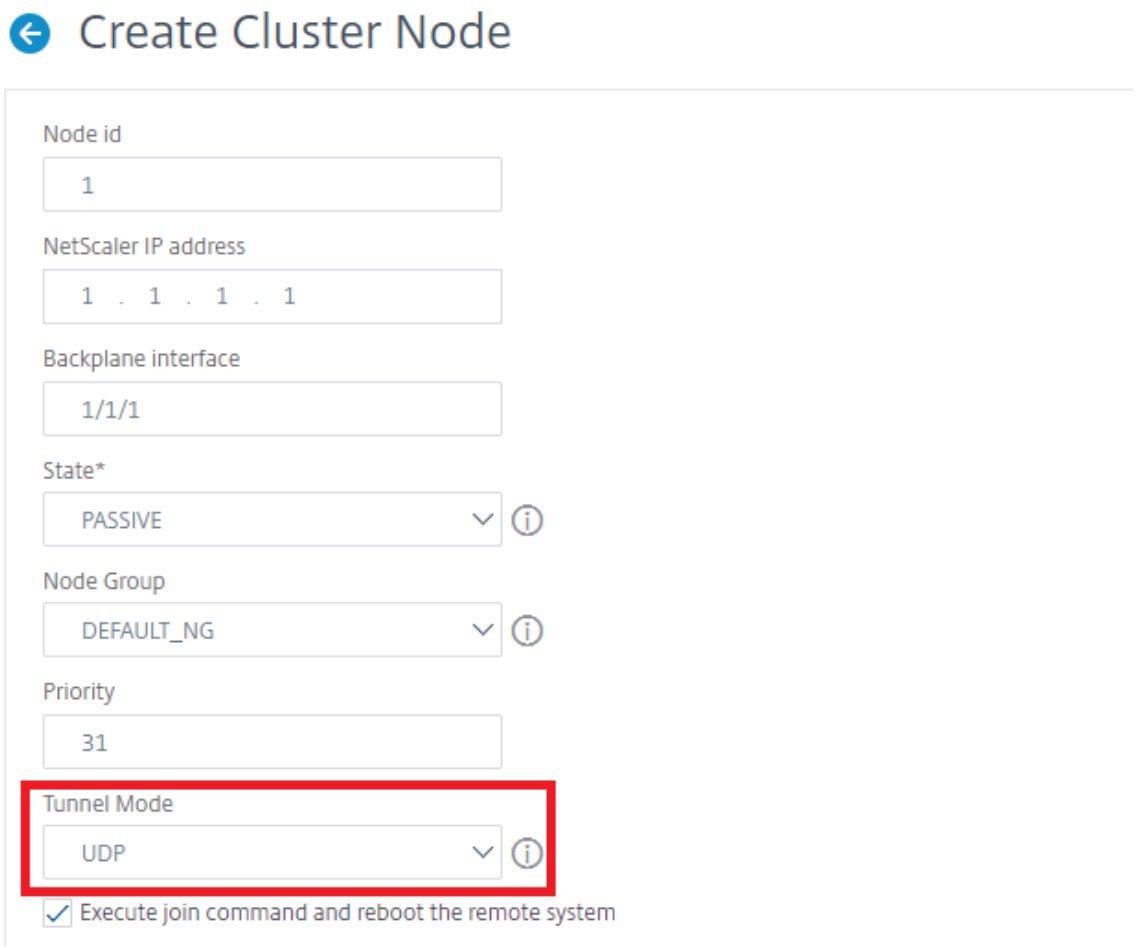
Example

- `add cluster node 1 -state ACTIVE -backplane 1/1/1 -tunnelmode UDP`
- `set cluster node 1 -state ACTIVE -tunnelmode UDP`

GUI procedures

To enable the UDP tunnel mode by using the GUI.

1. Navigate to **System > Cluster > Nodes**.
2. In the **Cluster Nodes** page, click **Add**.
3. In the **Create Cluster Node**, set the **Tunnel Mode** parameter to UDP and click **Create**.



4. Click **Close**.

Creating a Citrix ADC cluster

September 14, 2021

To create a cluster, start by taking one of the Citrix ADC appliances that you want to add to the cluster. On this node, you must create the cluster instance and define the cluster IP address. This node is the first cluster node and is called the cluster configuration coordinator (CCO). All configurations that are

performed on the cluster IP address are stored on this node and then propagated to the other cluster nodes.

The responsibility of CCO in a cluster is not fixed to a specific node. It can change over time depending on the following factors:

- The priority of the node. The node with the highest priority (lowest priority number) is made the CCO. Therefore, if a node with a priority number lower than the existing CCO is added, the new node takes over as the CCO.

  > **Note**
  >
  > Node priority can be configured from NetScaler 10.1 onwards.

- If the current CCO goes down, the node with the next lowest priority number takes over as the CCO. If the priority is not set or if there are multiple nodes with the lowest priority number, the CCO is selected from one of the available nodes.

> **Note**
>
> The configurations of the appliance (including SNIP addresses and VLANs) are cleared by implicitly running the `clear ns config extended` command. However, the default VLAN and NSVLAN are not cleared from the appliance. Therefore, if you want the NSVLAN on the cluster, make sure it is created before the appliance is added to the cluster. For an L3 cluster (cluster nodes on different networks), networking configurations are not cleared from the appliance.
>
> **Important**
>
> HA Monitor (HAMON) on a cluster setup is used to monitor the health of an interface on each node. The HAMON parameter must be enabled on each node to monitor the state of the interface. If the operational state of the HAMON enabled interface goes down due to any reason, the respective cluster node is marked as unhealthy (NOT UP) and that node cannot serve traffic.

To create a cluster by using the command line interface

1. Log on to an appliance (for example, appliance with NSIP address 10.102.29.60) that you want to add to the cluster.
2. Add a cluster instance.

   ```
   add cluster instance <clId> -quorumType <NONE | MAJORITY> -inc <ENABLED
    | DISABLED> -backplanebasedview <ENABLED | DISABLED><!--NeedCopy-->
   ```

   > **Note**
   >
   > - The cluster instance ID must be unique within a LAN.
   > - The `-quorumType` parameter must be set to MAJORITY and not NONE in the following

scenarios:
  - Topologies which do not have redundant links between cluster nodes. These topologies might be prone to network partition due to a single point of failure.
  - During any cluster operations such as node addition or removal.
- For an L3 cluster, make sure the `-inc` parameter is set to ENABLED. The `-inc` parameter must be disabled for an L2 cluster.
- When the `-backplanebasedview` parameter is enabled, the operational view (set of nodes that serve traffic) is decided based on heartbeats received only on the backplane interface. By default, this parameter is disabled. When this parameter is disabled, a node does not depend on the heartbeat reception only on the backplane.

3. [Only for an L3 cluster] Create a node group. In the next step, the newly added cluster node must be associated with this node group.

> **Note**
>
> This node group includes all or a subset of the Citrix ADC appliances that belong to the same network.

```
add cluster nodegroup <name><!--NeedCopy-->
```

4. Add the Citrix ADC appliance to the cluster.

"'add cluster node -state -backplane -nodegroup

```
> **Note** For an L3 cluster:
>
>-  The node group parameter must be set to the name of the node group that is created.
>-  The backplane parameter is mandatory for nodes that are associated with a node group that has more than one node, so that the nodes within the network can communicate with each other.</span>

Example:

Adding a node for an L2 cluster (all cluster nodes are in the same network).
```

add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1

```
  Adding a node for an L3 cluster which includes a single node from each network. Here, you do not have to set the backplane .
```

add cluster node 0 10.102.29.60 -state PASSIVE -nodegroup ng1

```
Adding a node for an L3 cluster which includes multiple nodes
   from each network. Here, you have to set the backplane so
   that nodes within a network can communicate with each other.
```

add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1 -nodegroup ng1
“‘

5. Add the cluster IP address (for example, 10.102.29.61) on this node.

```
add ns ip <IPAddress> <netmask> -type clip
<!--NeedCopy-->
```

Example

```
> add ns ip 10.102.29.61 255.255.255.255 -type clip
<!--NeedCopy-->
```

6. Enable the cluster instance.

```
enable cluster instance <clId><!--NeedCopy-->
```

7. Save the configuration.

```
save ns config<!--NeedCopy-->
```

8. Warm reboot the appliance.

```
reboot -warm<!--NeedCopy-->
```

Verify the cluster configurations by using the show cluster instance command. Verify that the output of the command displays the NSIP address of the appliance as a node of the cluster.

9. After the node is UP, login to the CLIP and change RPC credentials for both cluster IP address and Node IP address. For more information about changing an RPC node password, see Change an RPC node password.

To create a cluster by using the GUI

1. Log on to an appliance (for example, an appliance with NSIP address 10.102.29.60) that you intend to add to the cluster.
2. Navigate to **System > Cluster.**
3. In the details pane, click the **Manage Cluster** link.
4. In the Cluster Configuration dialog box, set the parameters required to create a cluster. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **Create.**
6. In the Configure cluster instance dialog box, select the Enable cluster instance check box.

7. In the Cluster Nodes pane, select the node and click **Open.**
8. In the Configure Cluster Node dialog box, set the State.
9. Click **OK**, and then click **Save.**
10. Warm reboot the appliance.
11. After the node is UP, login to the CLIP and change RPC credentials for both cluster IP address and Node IP address. For more information about changing an RPC node password, see Change an RPC node password.

Strict mode support for sync status of the cluster

You can now configure a cluster node to view errors when applying the configuration. A new parameter, “syncStatusStrictMode” is introduced in both the add and set cluster instance command to track the status of each node in a cluster. By default, the “syncStatusStrictMode” parameter is disabled.

To enable the strict mode by using the CLI

At the command prompt, type:

```
set cluster instance <clID> [-syncStatusStrictMode (ENABLED | DISABLED)]
```

Example:

```
set cluster instance 1 -syncStatusStrictMode ENABLED
```

To view the status of strict mode by using the CLI

```
>show cluster instance
1) Cluster ID: 1
    Dead Interval: 3 secs
    Hello Interval: 200 msecs
    Preemption: DISABLED
    Propagation: ENABLED
    Quorum Type: MAJORITY
    INC State: DISABLED
    Process Local: DISABLED
    Retain Connections: NO
    Heterogeneous: NO
    Backplane based view: DISABLED
    Cluster sync strict mode: ENABLED
    Cluster Status: ENABLED(admin), ENABLED(operational), UP

  WARNING(s):
    (1) - There are no spotted SNIPs configured on the cluster.
       Spotted SNIPs can help improve cluster performance
```

```
18
19          Member Nodes:
20          Node ID     Node IP      Health     Admin State  Operational
               State
21          -------     -------      ------     -----------
               -----------------
22      1)      1           192.0.2.20      UP          ACTIVE       ACTIVE(
           Configuration Coordinator)
23      2)      2           192.0.2.21      UP          ACTIVE       ACTIVE
24      3)      3           192.0.2.19*     UP          ACTIVE       ACTIVE
25  <!--NeedCopy-->
```

To view the sync failure reason of a cluster node by using the GUI

1. Navigate to **System > Cluster > Cluster Nodes**.
2. In the **Cluster Nodes** page, scroll to the extreme right to view the details of the synchronization failure reason of the cluster nodes.

Adding a node to the cluster

September 14, 2021

You can seamlessly scale the size of a cluster to include a maximum of 32 nodes. When a Citrix ADC appliance is added to the cluster, the configurations from that appliance are cleared (by internally running the clear ns config -extended command). The SNIP addresses, **MTU** settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

The cluster configurations are then synchronized on this node. There can be an intermittent drop in traffic while the synchronization is in progress.

> **Important**
>
> Before you add a Citrix ADC appliance to a cluster:
>
> - Set up the backplane interface for the node. Check preceding topic.
> - Check if the licenses that are available on the appliance match that are available on the configuration coordinator. The appliance is added only if the licenses match.
> - If you want the NSVLAN on the cluster, make sure that the NSVLAN is created on the appliance before it is added to the cluster.
> - Citrix recommends that you add the node as a passive node. Then, after joining the node to

the cluster, complete the node specific configuration from the cluster IP address. Run the force cluster sync command if the cluster has only spotted IP addresses. And which has L3 VLAN binding, or has static routes.

- When an appliance with a preconfigured link aggregate (LA) channel is added to a cluster, the LA channel continues to exist in the cluster environment. The LA channel is renamed from LA/x to nodeId/LA/x, where LA/x is the LA channel identifier.

To add a node to the cluster by using the CLI

Note

When you add a node to a cluster setup, if the node has a default static route, it gets added to the cluster coordinator node (CCO). If this default static route points to an incorrect gateway, it might result in downtime of the services. Hence, verify the default static route of the new node, before adding it to the cluster setup.

1. Log on to the cluster IP address, at the command prompt, do the following:
   - Add the appliance (for example, 10.102.29.70) to the cluster.

   Note

   For an L3 cluster:

   - The node group parameter must be set to a node group that has nodes of the same network.
   - If this node belongs to the same network as the first node that was added, then configure the node group that was used for that node.
   - If this node belongs to a different network, then create a node group and bind this node to the node group.
   - The backplane parameter is mandatory for nodes that are associated with a node group that has more than one node, so that the nodes within the network can communicate with each other.

```
add cluster node <nodeId> <IPAddress> -state <state> -backplane <
   interface_name> -nodegroup <name>

Example:

add cluster node 1 10.102.29.70 -state PASSIVE -backplane 1/1/1
<!--NeedCopy-->
```

   - Save the configuration.

```
save ns config
<!--NeedCopy-->
```

2. Log on to the newly added node (for example, 10.102.29.70) and join the node to the cluster.

```
join cluster -clip <ip_addr> -password <password>

Example:

join cluster -clip 10.102.29.61 -password nsroot
<!--NeedCopy-->
```

3. Configure the following commands on the CLIP.

   - Bind VLAN to an interface

```
bind vlan <id> -ifnum <interface_name>
<!--NeedCopy-->
```

     Example:

```
bind vlan 1 -ifnum 2/1/2
<!--NeedCopy-->
```

   - Add spotted IP address to the newly added node

```
add ns ip <IpAddress> <netmask> -ownerNode <positive_interger
    >
<!--NeedCopy-->
```

     Example:

```
add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2
<!--NeedCopy-->
```

   - Verify VLAN on NSIP

```
show vlan <id>
<!--NeedCopy-->
```

     Example:

```
show vlan 1
<!--NeedCopy-->
```

4. Perform the following configurations:

   - If the node is added to a cluster that has only spotted IPs, the configurations are synchronized before the spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings.

- Define the required spotted configurations.
- Set the MTU for the backplane interface.

5. Save the configuration.

```
save ns config
<!--NeedCopy-->
```

6. Warm reboot the appliance.

```
reboot -warm
<!--NeedCopy-->
```

7. After the node is UP and sync is successful, change RPC credentials for the node from the cluster IP address. For more information about changing an RPC node password, see Change an RPC node password.

```
set rpcNode <node-NSIP> -password <passwd>

Example:

set rpcNode 192.0.2.4 -password mypassword
<!--NeedCopy-->
```

8. Set the cluster node to Active.

```
set cluster node <nodeID> -state active.

Example:

set cluster node 1 -state active
<!--NeedCopy-->
```

To add a node to the cluster by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, click **Add** to add the new node (for example, 10.102.29.70).
4. In the **Create Cluster Node** dialog box, configure the new node. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **Create**. When prompted to perform a warm reboot, click **Yes.**
6. After the node is UP and sync is successful, change RPC credentials for the node from the cluster IP address. For more information about changing an RPC node password, see Change an RPC node password.

7. Navigate to **System > Cluster > Nodes > Edit**.
8. Modify the State to **ACTIVE** and confirm.

To join a previously added node to the cluster by using the GUI

If you have used the CLI to add a node to the cluster, but have not joined the node to the cluster, you can use the following procedure.

> **Note**
>
> When a node joins the cluster, it takes over its share of traffic from the cluster and hence an existing connection can get terminated.

1. Log on to the node that you want to join to the cluster (for example, 10.102.29.70).
2. Navigate to **System > Cluster.**
3. In the details pane, under Get Started, click the Join Cluster link.
4. In the Join to existing cluster dialog box, set the cluster IP address and the `nsroot` password of the configuration coordinator. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **OK.**

Viewing the details of a cluster

September 14, 2021

You can view the details of the cluster instance and the cluster nodes by logging on to the cluster IP address.

To view details of a cluster instance by using the CLI

Log on to the cluster IP address and, at the command prompt, type:

```
show cluster instance <clId>
```

> **Note**
>
> When the preceding command is run from the NSIP address of the non-CCO node, the command displays the status of the cluster on this node.

To view details of a cluster node by using the CLI

Log on to the cluster IP address and, at the command prompt, type:

```
show cluster node <nodeId>
```

To view details of a cluster instance by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster.**
3. In the details pane, under **Get Started**, click the **Manage Cluster** link to view the details of the cluster.

To view details of a cluster node by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes.**
3. In the details pane, click the node for which you want to view the details.

Distributing traffic across cluster nodes

September 14, 2021

After you have created the Citrix ADC cluster and performed the required configurations, you must deploy Equal Cost Multiple Path (ECMP) or cluster Link Aggregation (LA) on the client data plane (for client traffic) or server data plane (for server traffic). These mechanisms distribute external traffic across the cluster nodes.

Policy-based backplane steering

The policy-based backplane steering (PBS) is a mechanism in cluster deployment, which steers the traffic across cluster nodes based on the hash method defined for the flow. The flow is defined by a combination of L2 and L3 parameters similar to the Access Control List (ACL).

The PBS supports both IPv4 and IPv6 traffic. In the case of IPv6 deployments, the steering supports an extra option `[dfdprefix <positive_integer>]`. It provides the flexibility to choose the same flow processor for the same IP prefix. The prefix option is supported for source IP or destination IP hash methods only.

> **Note**
>
> If the PBS mechanism is not used to steer the traffic, the traffic is steered through the default method.

To configure the new ACL attributes, at the CLI, type the following commands:

CLI commands for IPv4

- add ns acl <aclname> <aclaction> [-type (classic | dfd)] [-dfdhash <dfdhash>]
- set ns acl <aclname> <aclaction> [-dfdhash <dfdhash>
- show ns acl [<aclname>][-type (classic | DFD)]
- apply ns acls [-type (classic | DFD)]
- clear ns acls [-type (classic | DFD)]
- renumber ns acls [-type (classic | DFD)]

CLI commands for IPv6

- add ns acl6 <acl6name> <acl6action> [-type (classic | dfd)][-dfdhash <dfdhash>][-dfdprefix <positive_interger>]
- set ns acl6 <acl6name> <acl6action> [-dfdhash <dfdhash>][-dfdprefix <positive_interger>]
- show ns acl6 [<acl6name>][-type (classic | DFD)]
- apply ns acls6 [-type (classic | DFD)]
- clear ns acls6 [-type (classic | DFD)]
- renumber ns acls6 [-type (classic | DFD)]

The following are the different types of hash methods that you can specify to steer the packet to the flow processor:

- SIP-SPORT-DIP-DPORT
- SIP
- DIP
- SIP-DIP
- SIP-SPORT

Limitations

1. The traffic flow distribution across the cluster nodes is not ensured, as the flow processor is decided by the admin configured rules.
2. L2 mode is not supported.
3. The node groups and striped SNIPs are not supported, as there is no deployment scenarios.
4. MPTCP is not supported.
5. Support only for TCP, UDP, and ICMP traffic.
6. Cluster over L3 mode is not supported.
7. Process local at service level is not supported.

Using the Equal Cost Multiple Path (ECMP)

September 14, 2021

By using the Equal Cost Multiple Path (ECMP) mechanism on a cluster deployment, active cluster nodes advertise the virtual server IP addresses. The cluster node which receives the advertised traffic steers the traffic to the node that must process the traffic. There can be redundant steering in spotted and partially striped virtual servers. Therefore, from NetScaler 11 onwards, spotted and partially striped virtual server IP addresses advertise the owner nodes, which reduce the redundant steering.

You must have detailed knowledge of routing protocols to use ECMP. For more information, see Configuring Dynamic Routes. For more information on routing in a cluster, see Routing in a Cluster.

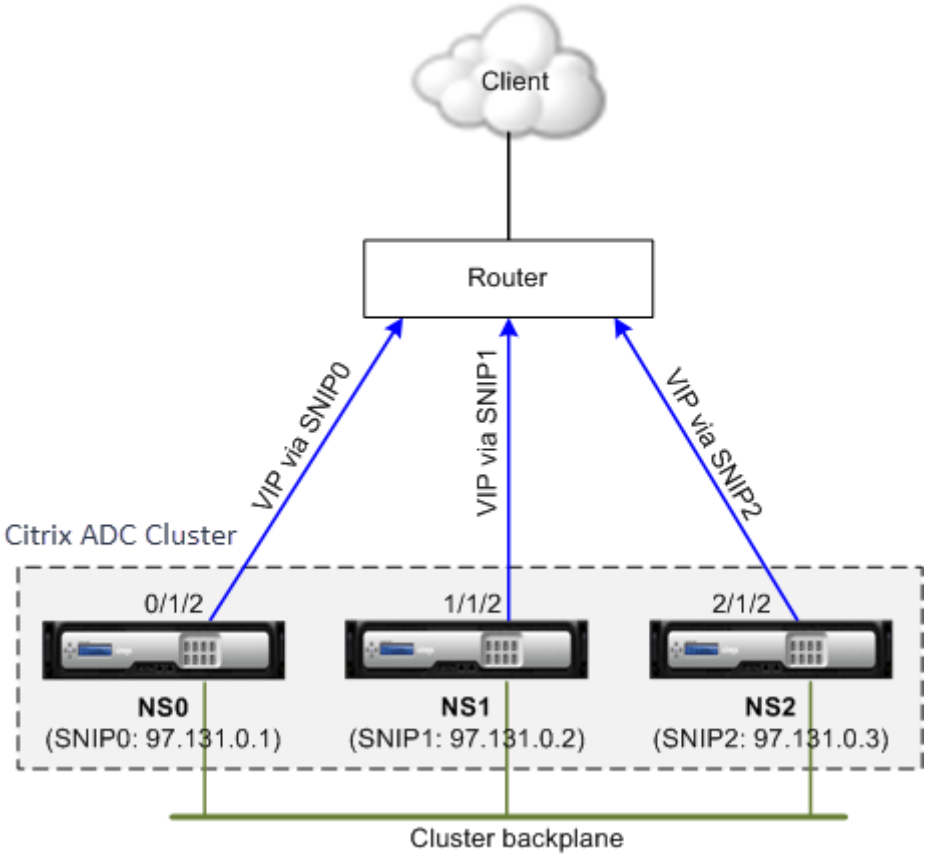
To use ECMP, you must first perform the following:

- Enable the required routing protocol (OSPF, RIP, BGP, or ISIS) on the cluster IP address.
- Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN.
- Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the VTYSH shell.

Perform similar configurations on the cluster IP address and on the external connecting device.

> **Note**
>
> - Make sure that the licenses on the cluster support dynamic routing, otherwise ECMP does not work.
> - ECMP is not supported for wildcard virtual servers since RHI needs a VIP address to advertise to a router and wildcard virtual servers. As they do not have associated VIP addresses.

Figure 1. ECMP topology



When you use the ECMP mechanism for traffic distribution on a cluster deployment, the active cluster nodes advertise the virtual server IP addresses to the upstream router. The ECMP router can reach the VIP address via SNIP0, SNIP1, or SNIP2. The traffic flow in the Figure 1 is described as follows:

1. The client sends a request to the VIP hosted on the cluster.
2. The upstream router, based on the learned routes of the VIP, forwards the packet to any one of the nodes. Let's say NS1. The node NS1 is the flow receiver.
3. The flow receiver (NS1) determines the node that must process the traffic, which is called the flow processor. For example, Node NS2 is the flow processor.
4. The flow receiver (NS1) with SNIP1 (97.131.0.2) steers the request to the flow processor (NS2) with SNIP2 (97.131.0.3).
5. The flow processor (NS2) establishes a connection with the server.
6. The server processes the request and sends the response to the SNIP address that sent the request to the server.

Notes:

- Only ACTIVE nodes advertise VIP routes.
- INACTIVE nodes do not advertise VIP routes.
- All ACTIVE nodes advertise striped VIPs.

- Only ACTIVE owner nodes advertise spotted or partially striped VIPs.

To configure ECMP on the cluster by using the command line interface

1. Log on to the cluster IP address.
2. Enable the routing protocol.

```
enable ns feature <feature>
```

Example: To enable the OSPF routing protocol.

```
enable ns feature ospf
```

3. Add a VLAN.

```
add vlan <id>
```

Example

```
add vlan 97
```

4. Bind the interfaces of the cluster nodes to the VLAN.

```
bind vlan <id> -ifnum <interface_name>
```

Example

```
bind vlan 97 -ifnum 0/1/2 1/1/2 2/1/2
```

5. Add a spotted SNIP address for each node and enable dynamic routing on it.

```
add ns ip <SNIP> <netmask> -ownerNode <positive_integer> -
   dynamicRouting ENABLED
```

Example

```
add ns ip 97.131.0.1 255.0.0.0 -ownerNode 0 -dynamicRouting
   ENABLED -type SNIP
add ns ip 97.131.0.2 255.0.0.0 -ownerNode 1 -dynamicRouting
   ENABLED -type SNIP
add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2 -dynamicRouting
   ENABLED -type SNIP
```

6. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

```
bind vlan <id> -IPAddress <SNIP> <netmask>
```

Example

```
bind vlan 97 -ipAddress 97.131.0.1 255.0.0.0
```

> **Note**
>
> You can use NSIP addresses of the cluster nodes instead of adding SNIP addresses. If so, you do not have to perform steps 3–6.

7. Configure the routing protocol on ZebOS using the VTYSH shell.

Example:

To configure an OSPF routing protocol on node IDs 0, 1, and 2.

```
vtysh
! interface vlan97 !
 router ospf   owner-node 0
ospf router-id 97.131.0.1   exit-owner-node
owner-node 1    ospf router-id 97.131.0.2
exit-owner-node
owner-node 2
ospf router-id 97.131.0.3   exit-owner-node   redistribute kernel
   network 97.0.0.0/8 area 0  !
```

> **Note**
>
> For VIP addresses to be advertised, RHI setting is done by using the vserverRHILevel parameter as follows:

```
add ns ip <IPAddress> <netmask> -type VIP -vserverRHILevel <
   vserverRHILevel>
```

For OSPF specific RHI settings, there are more settings that can be done as follows:

```
add ns ip <IPAddress> <netmask> -type VIP -ospfLSAType ( TYPE1 |
   TYPE5 ) -ospfArea <positive_integer>
```

Use the add ns ip6 command to perform the preceding commands on IPv6 addresses.

8. Configure ECMP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
1 //For OSPF (IPv4 addresses) Global config: Configure terminal
      feature ospf    Interface config:  Configure terminal
      interface Vlan10      no shutdown      ip address 97.131.0.5/8
         Configure terminal  router ospf 1  network 97.0.0.0/8 area
      0.0.0.0  --------------------------------
2
3 //For OSPFv3 (IPv6 addresses) Global config:  Configure terminal
      feature ospfv3    Configure terminal  interface Vlan10      no
      shutdown      ipv6 address use-link-local-only      ipv6 router
       ospfv3 1 area 0.0.0.0    Configure terminal  router ospfv3 1
```

Router monitoring cluster nodes in ECMP deployment

In a cluster setup, on an owner node that has a spotted SNIP address configuration, you can now disable the ownerDownResponse option. By default, the option is enabled, allowing the node to respond to an ICMP/ARP/ICMP6/ND6 request coming from the upstream router. You can now disable this option to allow the router to monitor if a cluster node is active or inactive. When the router sends a request, if the option is disabled, it identifies the owner node to be inactive and unavailable for traffic distribution.

To configure ECMP for static routes traffic distribution by using the command line interface

```
1 add ns ip <ipddress> <netmask> -ownernode <node-id>  - ownerDownResponse
      disable
```

Use Case: ECMP with BGP routing

September 14, 2021

To configure ECMP with BGP routing protocol, perform the following steps:

1. Log on to the cluster IP address.
2. Enable BGP routing protocol.

```
1 > enable ns feature bgp
```

3. Add VLAN and bind the required interfaces.

```
> add vlan 985
> bind vlan 985 -ifnum 0/0/1 1/0/1
```

4. Add the spotted IP address and bind them to the VLAN.

```
> add ns ip 10.100.26.14 255.255.255.0 -ownerNode 1 -
   dynamicRouting ENABLED
> add ns ip 10.100.26.15 255.255.255.0 -ownerNode 2 -
   dynamicRouting ENABLED
> bind vlan 985 -ipAddress 10.100.26.10 255.255.255.0
```

5. Configure BGP routing protocol on ZebOS using the VTYSH shell.

```
> vtysh conf t router bgp 65535 neighbor 10.100.26.1 remote-as
   65535
```

6. Configure BGP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
> router bgp 65535 no synchronization
  bgp log-neighbor-changes neighbor 10.100.26.14 remote-as 65535
     neighbor 10.100.26.15 remote-as 65535 no auto-summary
  dont-capability-negotiate
  dont-capability-negotiate
  no dynamic-capability
```

Configuration of cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol

September 14, 2021

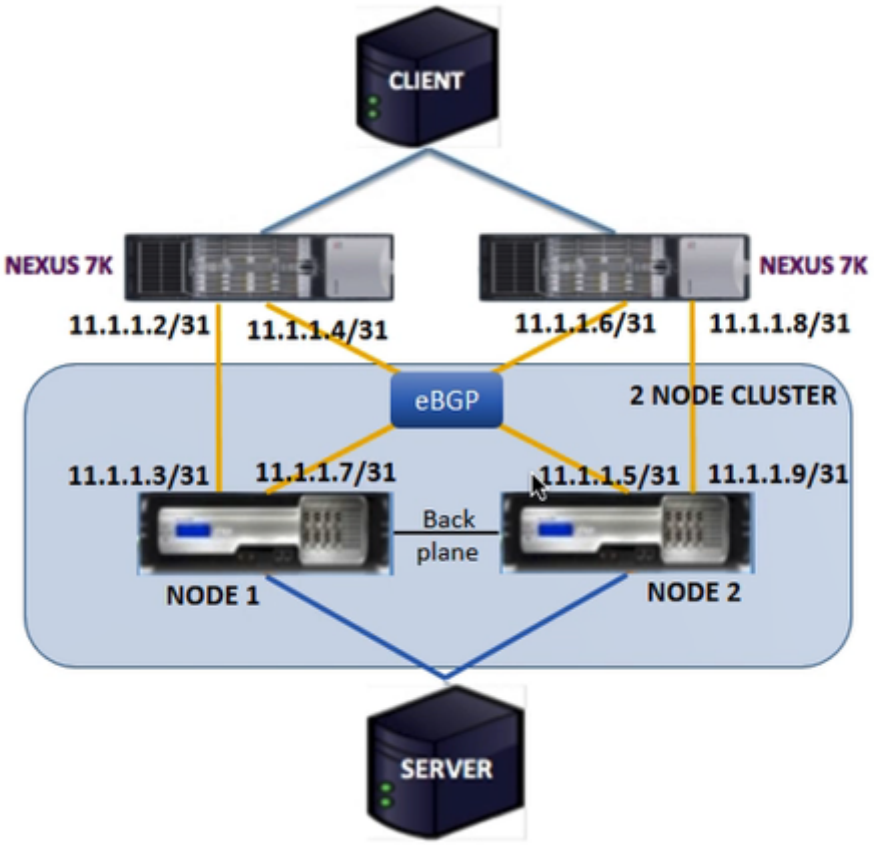
With ECMP over a cluster setup, a Citrix ADC appliance is able to handle the traffic through a routing protocol. The ECMP mechanism helps in advertising the virtual server IP addresses through all active cluster nodes.

To use ECMP, you must first enable the BGP protocol on the cluster IP address. Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN. Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the VTYSH shell.

Use Case: Cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol

Consider an example of a cluster deployment with a Cisco Nexus 7000 switch:

- Two Citrix ADC appliances (Node 1 and Node 2), connected to the Nexus switch (upstream).
- Two Cisco Nexus 7000 switch.
- Client and server (drawing HTTP traffic through the Nexus switch). With Hot Standby Router Protocol (HSRP) enabled on the client-side.



Prerequisites

Consider the following points before configuring cluster nodes on a Citrix ADC appliance.

1. All appliances must be of the same platform type.
2. Border Gateway Protocol (BGP) must be enabled on the cluster nodes.

Configuring by using the CLI on a Citrix ADC appliance

1. Log on to an appliance (for example, appliance with NSIP address 1.1.1.1)
2. To add a cluster node.

```
1 add cluster node 0 1.1.1.2 -state ACTIVE -backplane 0/10/8
```

3. To add the cluster IP address

```
1 add ns ip 1.1.1.10 255.255.255.254 -type clip
```

4. Save the configuration

```
1 save ns config
```

5. Warm reboot the appliance

```
1 reboot -warm
```

6. To add node 1 using CLIP

```
1 add cluster node 1 2.2.2.2 -state ACTIVE -backplane 1/10/8
```

7. To join a node to the cluster

```
1 join cluster -clip 1.1.1.10 -password nsroot
```

8. Perform the following configuration on CLIP
   - `enable ns feature bgp ospf DYNAMICROUTING`
   - `add ns ip 11.1.1.3 255.255.255.254 -dynamicRouting ENABLED -ownerNode 0`
   - `add ns ip 11.1.1.7 255.255.255.254 -dynamicRouting ENABLED -ownerNode 0`
   - `add ns ip 11.1.1.5 255.255.255.254 -dynamicRouting ENABLED -ownerNode 1`
   - `add ns ip 11.1.1.9 255.255.255.254 -dynamicRouting ENABLED -ownerNode 1`

On the Cisco Nexus router (11.1.1.2/31 and 11.1.1.4/31), you must perform the following configurations by using the command line:

- `feature ospf`
- `feature bgp`
- `feature interface-vlan`
- `feature hsrp`

```
> interface vlan100
  no shutdown
  ip address 50.1.1.1/8
   hsrp 50
    ip 50.50.50.50

> interface Ethernet 4/15
   ip address 11.1.1.2/31
   no shutdown

> interface Ethernet 4/19
   ip address 11.1.1.4/31
   no shutdown

> interface Ethernet 4/22
   switchport
    switchport access vlan 100
```

On the Cisco Nexus router (11.1.1.6/31 and 11.1.1.8/31), you must perform the following configurations by using the command line:

- `feature ospf`
- `feature bgp`
- `feature interface-vlan`
- `feature hsrp`

```
> interface vlan100
  no shutdown
  no ip redirects
  ip address 50.1.1.2/8
   hsrp 50
   ip 50.50.50.50

> interface Ethernet 4/13
  ip address 11.1.1.6/31
  no shutdown

> interface Ethernet 4/15
  ip address 11.1.1.8/31
  no shutdown

> interface Ethernet 4/22
  switchport
```

```
18       switchport access vlan 100
```

For the BGP protocol, you must perform the following configurations on CLIP of the Citrix ADC appliance:

```
1  >  vtysh
2  ns# router bgp 1
3   redistribute kernel
4   owner-node 0
5   neighbor 11.1.1.2 remote-as 2
6   neighbor 11.1.1.2 as-origination-interval 1
7   neighbor 11.1.1.2 advertisement-interval 0
8   neighbor 11.1.1.6 remote-as 2
9   neighbor 11.1.1.6 as-origination-interval 1
10  neighbor 11.1.1.6 advertisement-interval 0
11 owner-node 1
12  neighbor 11.1.1.4 remote-as 2
13  neighbor 11.1.1.4 as-origination-interval 1
14  neighbor 11.1.1.4 advertisement-interval 0
15  neighbor 11.1.1.8 remote-as 2
16  neighbor 11.1.1.8 as-origination-interval 1
17  neighbor 11.1.1.8 advertisement-interval 0
18 exit-owner-node
```

Perform the following configurations on the Cisco Nexus router (11.1.1.3 and 11.1.1.5)

```
1  > ip access-list acl1
2    10 permit ip 50.0.0.0/8 any
3    route-map test permit
4    match ip address acl1
5   router bgp 2
6    address-family ipv4 unicast
7     redistribute direct route-map test
8     maximum-paths 2
9   neighbor 11.1.1.3 remote-as 1
10   address-family ipv4 unicast
11   neighbor 11.1.1.5 remote-as 1
12  address-family ipv4 unicast
```

Perform the following configurations on the Cisco Nexus router (11.1.1.7 and 11.1.1.9)

```
1  > ip access-list acl1
2     10 permit ip 50.0.0.0/8 any
3    route-map test permit 1
4     match ip address acl1
```

```
  router bgp 2
   address-family ipv4 unicast
   redistribute direct route-map test
   maximum-paths 2
  neighbor 11.1.1.7 remote-as 1
   address-family ipv4 unicast
  neighbor 11.1.1.9 remote-as 1
   address-family ipv4 unicast
```

For the OSPF protocol, you must perform the following configurations on CLIP of the Citrix ADC appliance:

```
> vtysh
ns# router osfp 1
redistribute kernel
owner-node 0
 network 15.1.1.2/31 area 0
 network 15.1.1.6/31 area 0
exit-owner-node

owner-node 1
 network 15.1.1.4/31 area 0
 network 15.1.1.8/31 area 0
exit-owner-node

route-map map2 permit 1
set metric 10
```

On the Cisco Nexus router (11.1.1.2/31 and 11.1.1.4/31), you must perform the following configurations by using the command line:

```
> route-map- map2 permit 1
   set metric 10

   interface Ethernet4/15
     ip address 15.1.1.2/31
     ip router ospf 1 area 0.0.0.0
     no shutdown

   interface Ethernet4/19
     ip address 15.1.1.4/31
     ip router ospf 1 area 0.0.0.0
     no shutdown

   router ospf 1
```

```
15      router-id 1.1.1.1
16      redistribute direct route-map map2
```

On the Cisco Nexus router (11.1.1.7/31 and 11.1.1.9/31), you must perform the following configurations by using the command line:

```
1  > route-map- map2 permit 1
2      set metric 10
3
4     interface Ethernet4/13
5       ip address 15.1.1.6/31
6       ip router ospf 1 area 0.0.0.0
7       no shutdown
8
9      interface Ethernet4/15
10      ip address 15.1.1.8/31
11      ip router ospf 1 area 0.0.0.0
12      no shutdown
13
14     router ospf 1
15       router-id 1.1.1.2
16       redistribute direct route-map map2
```

Using cluster link aggregation

September 14, 2021

Cluster link aggregation is a group of interfaces of cluster nodes. It is an extension of Citrix ADC link aggregation. The only difference is that, while link aggregation requires the interfaces to be from the same device, in cluster link aggregation, the interfaces are from different nodes of the cluster. For more information about link aggregation, see Configuring Link Aggregation.

> **Important**
>
> - Cluster link aggregation is supported for a cluster of hardware (MPX) appliances.
> - Cluster link aggregation is supported for a cluster of virtual (VPX) appliances that are deployed on ESX and KVM hypervisors, with the following restrictions:
> - Dedicated interfaces must be used. It means that the interfaces must not be shared with other virtual machines.
> - When a node becomes INACTIVE, the corresponding cluster LA interface is marked as power

DOWN, so that the data traffic is not sent to an INACTIVE node.

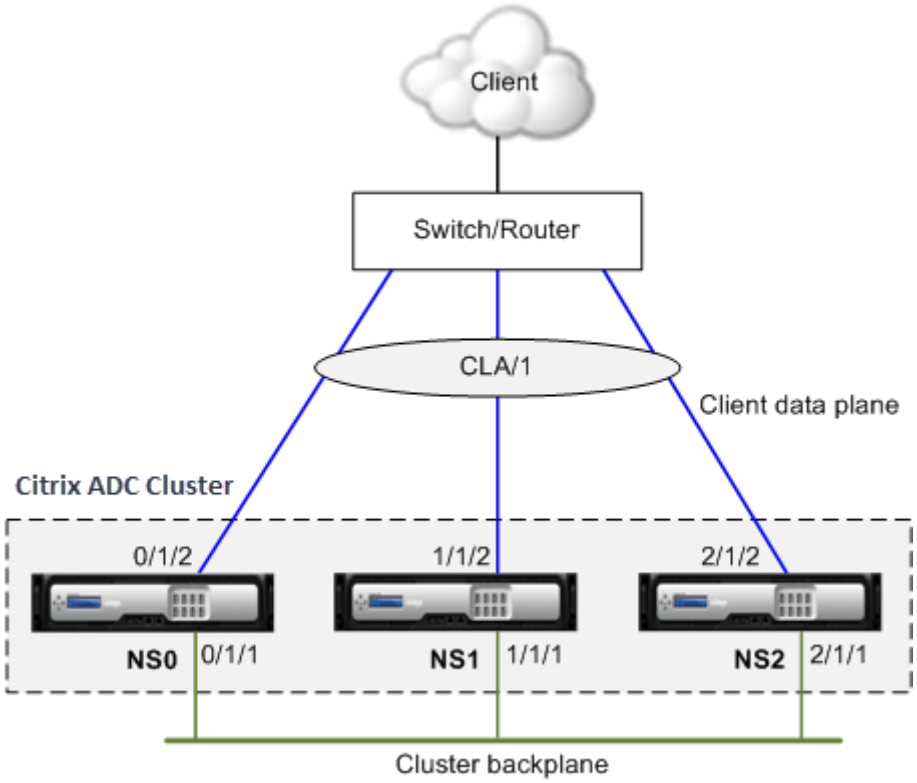
- When a node becomes ACTIVE, the corresponding cluster LA interface is marked as power ON.
- If the cluster link aggregation member interfaces are manually disabled or if cluster link aggregation itself is manually disabled, then interface power down capability is achieved only by the LACP timeout mechanism.
- Jumbo MTU is not supported on LACP cluster link aggregation.

Note: Cluster link aggregation is not supported on VPX appliances that are deployed on XenServer, AWS, and Hyper-V.

- Starting from 12. 0 release, cluster link aggregation is supported on Citrix ADC SDX appliances.
- The number of interfaces that can be bound to cluster LA is 16 (from each node). The maximum number of interfaces in cluster LA can be (16 * n), where n is the number of nodes in a cluster. The total number of interfaces in cluster LA depends on the number of interfaces for every port channel on the upstream switch.
- If a Citrix ADC appliance uses Intel Fortville interfaces, the switchover of a cluster node to passive mode might cause a few seconds of outage with CLAG. The issue occurs because LACP is enabled for CLAG to function properly, and the outage time depends on NIC LACP timers.

For example, consider a three-node cluster where all three nodes are connected to the upstream switch. A cluster LA channel (CLA/1) is formed by binding interfaces 0/1/2, 1/1/2, and 2/1/2.

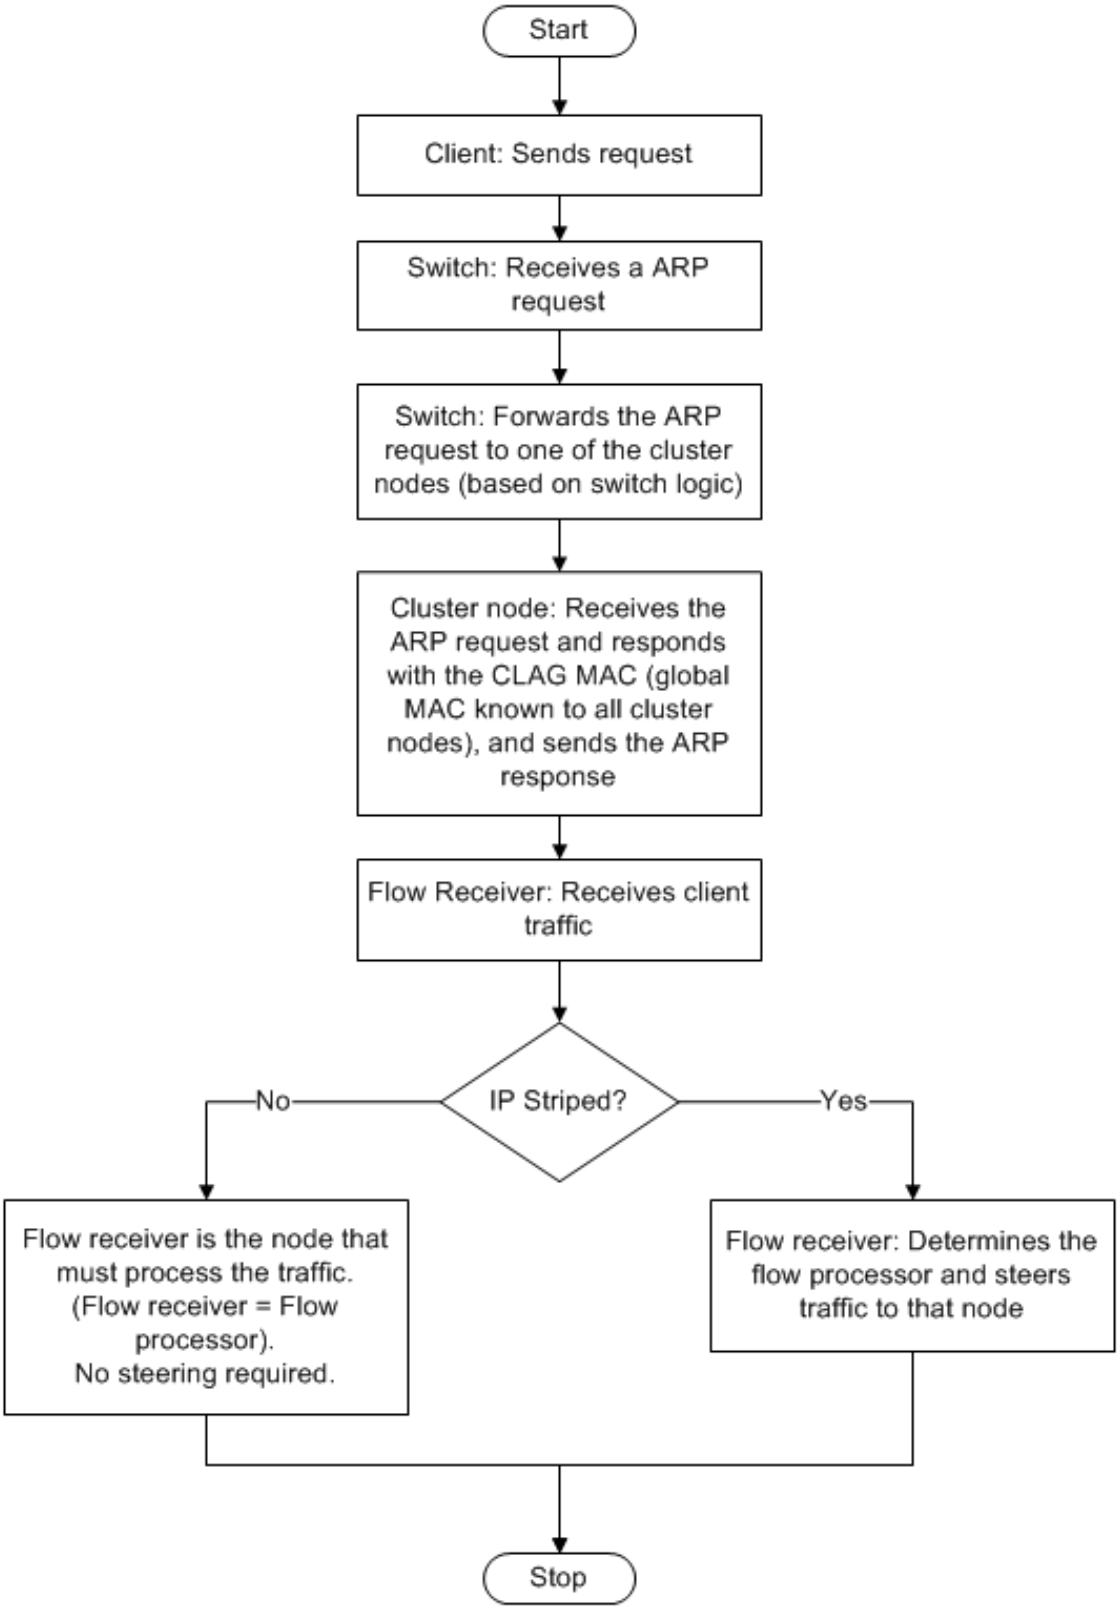
Figure 1. Cluster Link Aggregation topology



A cluster LA channel has the following attributes:

- Each channel has a unique MAC agreed upon by cluster nodes.
- The channel can bind both local and remote nodes' interfaces.
- A maximum of four cluster LA channels are supported in a cluster.
- Backplane interfaces cannot be part of a cluster LA channel.
- When an interface is bound to a cluster LA channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to one channel only.
- Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down, and therefore looses management access.

Figure 2. Traffic distribution flow using cluster LA



Backup and restore support of cluster LA on Citrix ADC MPX

You can backup and restore the cluster setup of LA on Citrix ADC MPX. The cluster LA MAC address is independent of the physical interface MAC address of the cluster nodes, and can change after the backup and restore process. The cluster LA can serve the traffic after a cluster restore process is complete. For more information about backup and restore, see Backup and restore of cluster setup

Static cluster link aggregation

September 14, 2021

You must configure a static cluster LA channel on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

To configure a static cluster LA channel by using the CLI

1. Log on to the cluster IP address.

   > **Note**
   >
   > Make sure that you configure the cluster LA channel on the cluster IP address before configuring link aggregation on the external switch. Otherwise, the switch forwards traffic to the cluster even though the cluster LA channel is not configured. It can lead to loss of traffic.

2. Create a cluster LA channel.

   ```
   add channel <id> -speed <speed>
   ```

   Example

   ```
   add channel CLA/1 -speed 1000
   ```

   > **Note**
   >
   > You must not specify the speed as AUTO. Rather, you must explicitly specify the speed as 10, 100, 1000, or 10000. Only interfaces that have the speed matching the `<speed>` attribute in the cluster LA channel are added to the active distribution list.

3. Bind the required interfaces to the cluster LA channel. Make sure that the interfaces are not used for the cluster backplane.

   ```
   bind channel <id> <ifnum>
   ```

Example

```
bind channel CLA/1 0/1/2 1/1/2 2/1/2
```

4. Verify the configurations.

```
show channel <id>
```

Example

```
show channel CLA/1
```

> **Note**
>
> You can bind the cluster LA channel to a VLAN by using the `bind vlan` command. The interfaces of the channel are automatically bound to the VLAN.

5. Configure static LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```
Global config:
Configure terminal

Interface level config:

interface Ethernet2/47
switchport
switchport access vlan 10
channel-group 7 mode on
no shutdown

interface Ethernet2/48
switchport
switchport access vlan 10
channel-group 7 mode on
no shutdown
```

Dynamic cluster link aggregation

September 14, 2021

Dynamic cluster LA channel uses the Link Aggregation Control Protocol (LACP).

You must perform similar configurations on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

> **Points to remember**
>
> - Enable LACP (by specifying the LACP mode as either ACTIVE or PASSIVE).

```
>**Note**
>
> Make sure the LACP mode is not set as PASSIVE on both the Citrix ADC
    cluster and the external connecting device.
```

> - Specify the same LACP key on each interface that you want to be the part of the channel. For creating a cluster LA channel, the LACP key can have a value from 5 through 8. For example, if you set the LACP key on interfaces 0/1/2, 1/1/2, and 2/1/2 to 5, CLA/1 is created. The interfaces 0/1/2, 1/1/2, and 2/1/2 are automatically bound to CLA/1. Similarly, if you set the LACP key to 6, the CLA/2 channel is created.
> - Specify the LAG type as Cluster.

To configure a dynamic cluster LA channel by using the CLI

On the cluster IP address, for each interface that you want to add to the cluster LA channel, type:

```
set interface <id> -lacpMode <lacpMode> -lacpKey <positive_integer> -
lagType CLUSTER<!--NeedCopy-->
```

Example:

To configure a cluster LA channel CLA/1 of 3 interfaces.

```
> set interface 0/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
> set interface 1/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
> set interface 2/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
```

> **Note**
>
> Optionally, you can enable Link Redundancy in a Cluster with LACP.

Similarly, configure dynamic LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```
Global config:
Configure terminal
feature lacp
```

```
Interface level config:

interface Ethernet2/47
switchport
switchport access vlan 10
channel-group 7 mode active
no shutdown

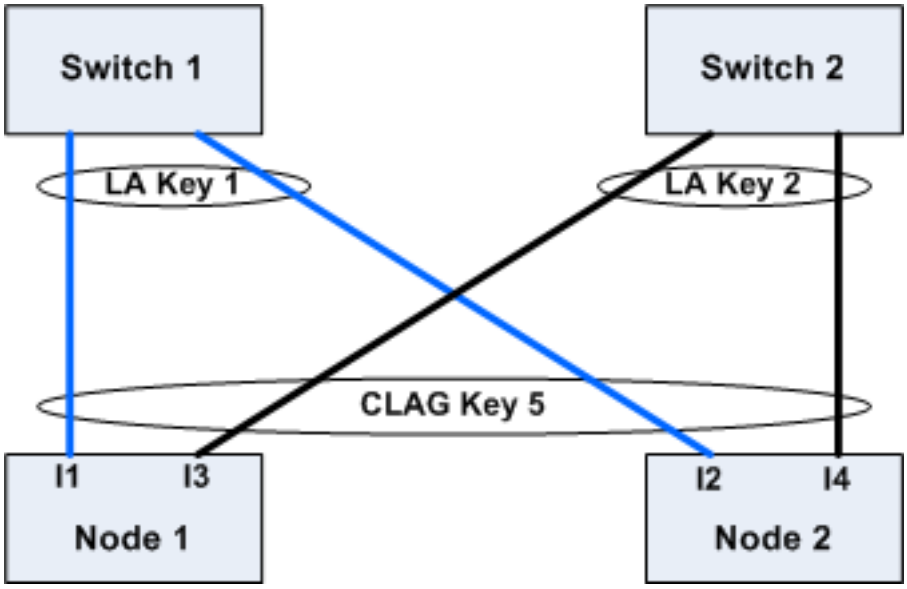
interface Ethernet2/48
switchport
switchport access vlan 10
channel-group 7 mode active
no shutdown
```

Link redundancy in a cluster with LACP

September 14, 2021

A Citrix ADC cluster provides link redundancy for LACP to ensure that all nodes have the same partner key.

To understand the need for link redundancy, let us consider the example of the following cluster setup along with the accompanying cases (with attention to case 3):



In this setup, interfaces I1, I2, I3, and I4 are bound to the LACP channel with KEY 5. On the partner side, I1 and I2 are connected to Switch 1 to form a single LA channel with KEY 1. Similarly, I3 and I4 are connected to Switch 2 to form a single LA channel with KEY 2.

Now let us consider the following cases to understand the need for link redundancy:

- **Case 1: Switch 1 is up and Switch 2 is down**

  In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key2 and would start receiving LACPDUs from Key1. On both the nodes, cluster LA is connected to KEY 1 and I1 and I2 is UP and the channel on both the nodes would be UP.

- **Case 2: Switch1 goes down and Switch2 becomes UP**

  In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key1 and would start receiving LACPDUs from Key2. On both the nodes, cluster LA is connected to Key2 and I3 and I4 is UP and the channel on both the nodes would be UP.

- **Case 3: Both Switch1 and Switch2 are UP**

  In this case, it is possible that cluster LA on node1 chooses Key1 as its partner and cluster LA on node2 chooses Key2 as its partner. It means that I1 on node1 and I4 on node2 are receiving traffic which is undesirable. It can happen because the LACP state machine is node-level and chooses its partners on first-come first-serve basis.

  To solve these concerns, link redundancy of dynamic cluster LA is supported. To configure link redundancy on a channel or interface, you must enable it and optionally specify the threshold throughput as follows:

  ```
  set channel CLA/1 -linkRedundancy ON -lrMinThroughput <positive_integer
  >
  ```

  The throughput of the partner channels is checked against the configured threshold throughput. The partner channel that satisfies the threshold throughput is selected in a first-in-first-out (FIFO) manner. If none of the partner channel meets the threshold, or if threshold throughput is not configured, the partner channel with the maximum number of links is selected.

  > **Note**
  >
  > The threshold throughput can be configured from NetScaler 11 onwards.

Using USIP mode in cluster

September 14, 2021

In use source IP (USIP) mode, the cluster, or Citrix ADC appliance forwards each packet to the appropriate back-end server with the client IP address.

USIP mode traffic distribution

The USIP mode behavior differs traffic distribution across client data plane and server data plane in ECMP and CLAG deployment. The following section provides more information about USIP mode behavior. For more information related to CLAG on USIP mode, see Using cluster link aggregation.

USIP mode

The cluster uses the client IP to open the server-side connection. The source port may or might not be preserved based on the `useproxyport` setting.

USIP `useproxyport` scenarios

The USIP `useproxyport` is ON for the traffic flow, the source port is selected in a way that the reverse traffic hashes to the flow processor. It ensures single steering on the server side.

The USIP `useproxyport` is OFF for the traffic flow, the source port is preserved and hence there is double steering on the server side.

> **Important**
>
> - When USIP is ON, the client IP is used in back end server connection, and traffic distribution for response is needed across cluster nodes. You can use ECMP or CLAG deployment for traffic distribution on the server side. In the absence of traffic distribution on the server side, the whole return traffic might land on a single cluster node, resulting in congestion.
> - The `set rsskeytype -rsskey symmetric` command is used to reduce double steering to single steering of traffic in the `useproxyport` off deployments. Where the 4-tuple for the connection remains the same for the server and client side. For example, wildcard MAC mode virtual server.

Limitations

The USIP does not work when the process local is disabled.

USIP mode deployment

The following figure depicts a USIP mode deployment in a cluster setup.

Configure the following using CLI

1. Enable the routing protocol.

```
1 enable ns feature <feature>
```

Example:

```
enable ns feature ospf
```

2. Add a spotted SNIP address for each node and enable dynamic routing on it.

```
add ns ip <SNIP> <netmask> -dynamicRouting ( ENABLED | DISABLED )
    -ownerNode <positive_interger>  -ownerdownResponse ( YES | NO
    )
```

Example

```
-  add ns ip 192.0.2.1 255.255.255.0 -dynamicRouting ENABLED  -
   ownerNode 0  -ownerDownResponse NO
-  add ns ip 192.0.2.2 255.255.255.0 -dynamicRouting ENABLED  -
   ownerNode 1  -ownerDownResponse NO
-  add ns ip 192.0.2.3 255.255.255.0 -dynamicRouting ENABLED  -
   ownerNode 2  -ownerDownResponse NO
```

3. Add a VLAN.

```
add vlan <id>
```

Example

```
add vlan 300
```

4. Bind the interfaces of the cluster nodes to the VLAN.

```
bind vlan <id> -ifnum <interface_name>
```

Example

```
bind vlan 300 -ifnum 0/1/2 1/1/2 2/1/2
```

5. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

```
bind vlan <id> -IPAddress <ip_addr | ipv6_addr> -netmask
```

Example

```
bind vlan 300  -IPAddress 192.0.2.1 255.255.255.0
```

6. Configure the routing protocol on ZebOS using the VTYSH shell. Configure OSPF routing protocol on node IDs 0, 1, and 2.

```
vtysh
configure terminal
ns block-sec-rtadv
router ospf
owner -node 0
router-id 192.0.2.1
exit-owner-node
owner-node 1
router-id 192.0.2.2
exit-owner-node
owner-node 2
router-id 192.0.2.3
exit-owner-node
network 192.0.2.0/24 area 0

default-information originate always
```

7. Perform the following configurations on the Cisco 3750 router by using the CLI.

```
Configure terminal
feature ospf
interface vlan300
no shutdown
ip address 192.0.2.100/24
Configure terminal
router ospf 1
router-id 192.0.2.100
network 192.0.2.0 0.0.0.255 area 0
```

Notes

- Traffic distribution on client and server need not be the same. For example, you can configure ECMP on the client side and CLAG on the server side or the opposite way.
- Plan for extra capacity of the backplane as there is more steering overhead in the USIP deployment.
- The Configuration related to CLAG and Monitor Static Route (MSR) must remain the same on the server side.
- Traffic steering is more in the USIP mode deployments.

Managing the Citrix ADC cluster

September 14, 2021

After you have created a cluster and configured the required traffic distribution mechanism, the cluster is able to serve traffic. During the lifetime of the cluster, you can perform the following cluster tasks:

- Configuring node groups
- Disabling nodes of a cluster
- Discovering Citrix ADC appliances
- Viewing statistics
- Synchronizing cluster configurations, and cluster files
- Synchronizing the time across the nodes
- Upgrading or downgrading the software of cluster nodes

Configuring linksets

September 14, 2021

Linkset is a group of interfaces of cluster nodes that belong to the same broadcast domain. In linksets, each node has the information about which interfaces of other nodes are connected to the same broadcast domain.

> **Note**
>
> Linksets are a mandatory configuration in the following scenarios:
>
> - For deployments that require MAC-Based Forwarding (MBF).
> - For "-m MAC" mode that is enabled at the virtual server along with MBF mode enabled globally.
> - To improve the manageability of ACL and L2 policies involving interfaces. You define a linkset of the interfaces and add ACL and L2 policies based on linksets.

In a cluster setup, the following features use MBF internally.

- Forwarding session
- L2Conn
- MAC mode virtual server
- Transparent monitor
- LLB

Linksets must be configured only through the cluster IP address.

Consider an example with a three node cluster. In the following figure, the interfaces 0/1/2, 1/1/2, and 2/1/2 are in the same broadcast domain and therefore can be configured as linkset (LS/1).

Figure 1. Linksets topology

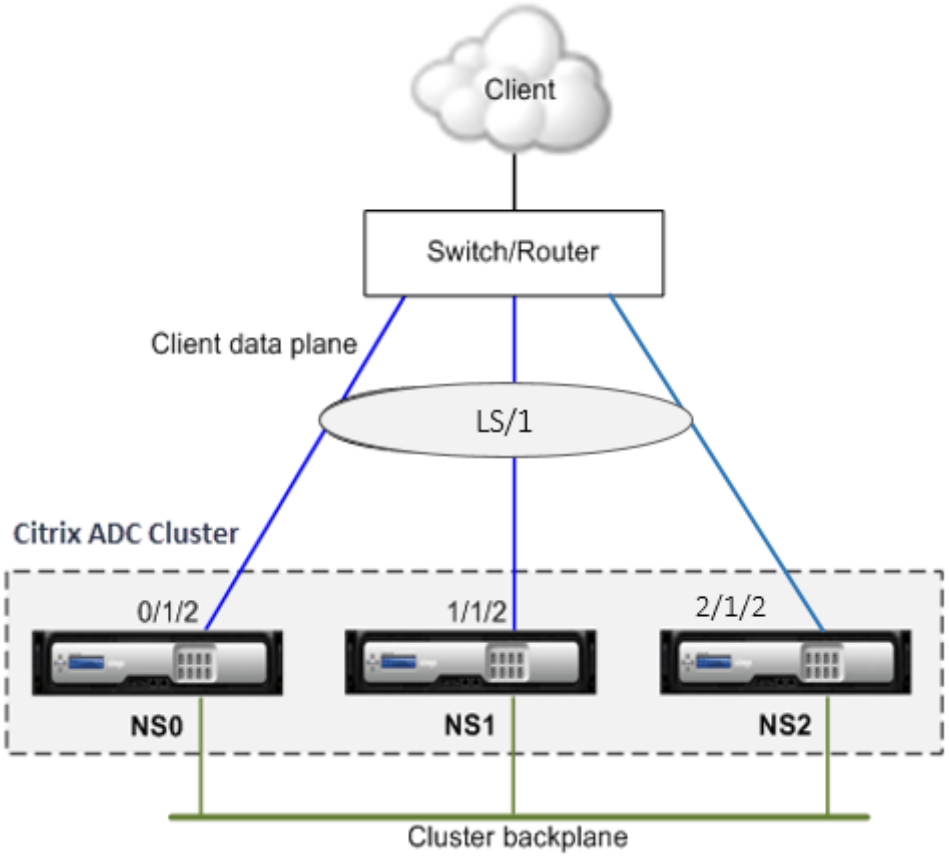


Figure 2. Traffic distribution flow using linksets

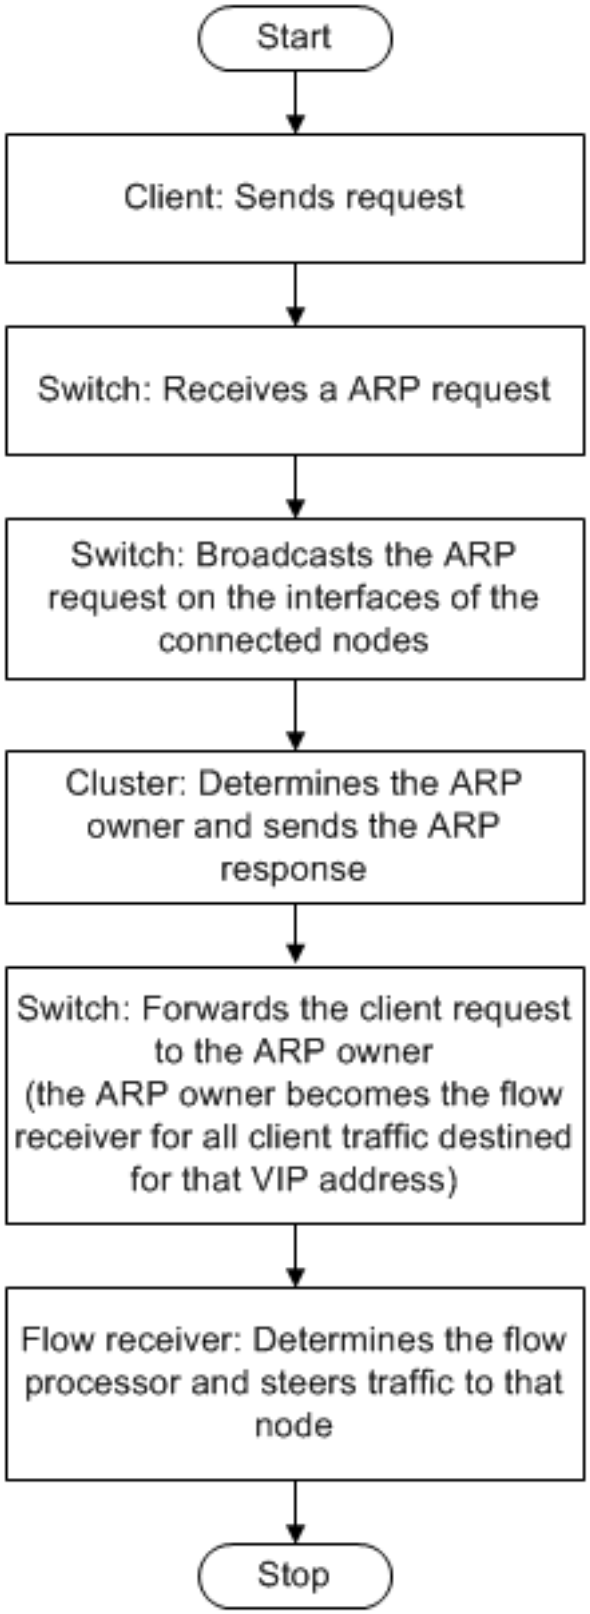


To configure a linkset by using the CLI

1. Log on to the cluster IP address.
2. Create a linkset.

   “‘add linkset

```
**Example**

```add linkset LS/1<!--NeedCopy-->
```

3. Bind the required interfaces to the linkset. Make sure the interfaces are not used for the cluster backplane.

   “‘bind linkset -ifnum ...

```
**Example**

```bind linkset LS/1 -ifnum 0/1/2 1/1/2 2/1/2<!--NeedCopy-->
```

4. Verify the linkset configurations.

   “‘show linkset

```
**Example**

```show linkset LS/1<!--NeedCopy-->
```

> **Note**
>
> You can bind the linkset to a VLAN by using the `bind vlan` command. The interfaces of the linkset are automatically bound to the VLAN.

To configure a linkset by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Network > Linksets**.
3. In the details pane, click **Add**.
4. In the **Create Linkset** dialog box:
   - Specify the name of the linkset by setting the Linkset parameter.
   - Specify the Interfaces to be added to the linkset and click Add. Repeat this step for each interface you want to add to the linkset.
5. Click **Create**, and then click **Close**.

```

# Node groups for spotted and partially striped configurations

September 14, 2021

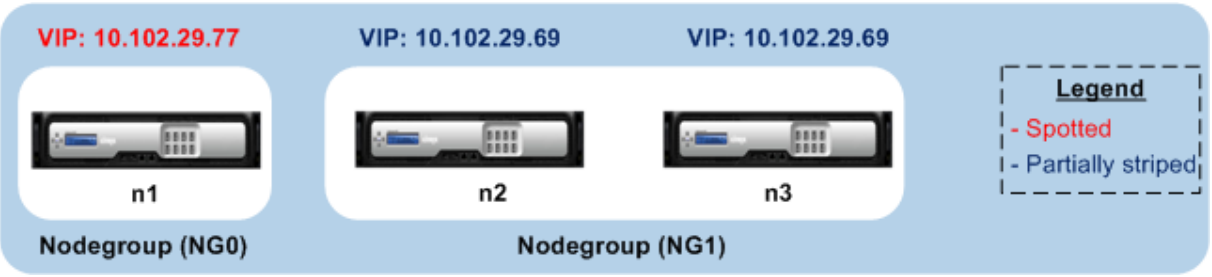
By virtue of the default cluster behavior, all configurations performed on the cluster IP address are available on all nodes of the cluster. However, there might be cases where you need some configurations to be available only on specific cluster nodes.

You can achieve this requirement by defining a node group that includes the specific cluster nodes, and then binding the configuration to that node group. It ensures that the configuration is active only on those cluster nodes. These configurations are called partially striped or spotted (if active only one a single node). For more information, see Striped, Partially Striped, and Spotted Configurations.

For example, consider a cluster with three nodes. You create a node group NG0 that includes node n1 and another node group NG1 that includes n2 and n3. Bind load balancing virtual servers 0.77 to NG0 and load balancing virtual server 0.69 to NG1.

It means that virtual server 0.77 is active only on n1 and therefore only n1 receives the traffic that is directed to 0.77. Similarly, virtual server 0.69 is active only on nodes n2 and n3 and therefore only n2 and n3 receives traffic that is directed to 0.69.

Figure 1. Citrix ADC cluster with node groups configured for spotted and partial-striped configurations



The entities or configurations that you can bind to a node group are:

- Load balancing, content switching, cache redirection, authentication, authorization, and auditing virtual servers

  > **Note**
  >
  > FTP load balancing virtual servers cannot be bound to node groups.

- VPN virtual server (Supported from NetScaler 10.5 Build 50.10 onwards)
- Global Server Load Balancing (GSLB) sites and other GSLB entities (Supported from NetScaler 10.5 Build 52.11 onwards)
- Limit identifiers and stream identifiers

# Behavior of node groups

September 14, 2021

Due to the interoperability of node groups with different Citrix ADC features and entities, there are some behavioral aspects to be noted. Nodes in a node group can also be backed up. Read on for more information.

## General behavior of a cluster node group

- A node group that has entities bound to it cannot be removed.
- A cluster node that belongs to a node group with entities bound to it, cannot be removed.
- A cluster instance that has node groups with entities bound to it, cannot be removed.
- You cannot add an entity that has a dependency on another entity. It must not be a part of the node group. If you must do so, first remove the dependency. Then, add both the entities to the node group and reassociate the entities.

  **Examples:**

  - Assume you have a virtual server, VS1, whose backup is virtual server VS2. To add VS1 to a node group, first make sure that VS2 is removed as the backup server of VS1. Then, bind each server individually to the node group, and then configure VS2 as the backup for VS1.
  - Assume you have a content switching virtual server, CSVS1, whose target load balancing virtual server is LBVS1. To add CSVS1 to a node group, first remove LBVS1 as the target. Then, bind each server individually to the node group, and then configure LBVS1 as the target.
  - Assume you have a load balancing virtual server, LBVS1, that has a policy which invokes another load balancing virtual server, LBVS2. To add either one of the virtual servers, first remove the association. Then, bind each server individually to the node group, and then reassociate the virtual servers.
- You cannot bind an entity to a node group. It has no nodes and that has the strict option enabled. Therefore, you cannot unbind the last node of a node group that has entities bound to it and that has the strict option enabled.
- The strict option cannot be modified for a node group that has no nodes but has entities bound to it.

## Backing up nodes in a node group

By default, a node group is designed to provide back up nodes for members of a node group. If a node group member goes down, a cluster node that is not a member of the node group dynamically

replaces the failed node. This node is called the replacement node.

> **Note**
>
> For a single-member node group, a backup node is automatically preselected when an entity is bound to the node group.

When the original member of the node group comes up, the replacement node, by default, is replaced by the original member node.

From NetScaler 10.5 Build 50.10 onwards, however, the Citrix ADC allows you to change this replacement behavior. When you enable the sticky option, the replacement node is retained even after the original member node comes up. The original node takes over only when the replacement node goes down.

You can also disable the backup functionality. To do it, you must enable the strict option. In this scenario, when a node group member goes down, no other cluster node is picked up as a backup node. The original node continues being part of the node group when it comes up. This option ensures that entities bound to a node group are active only on node group members.

> **Note**
>
> The strict and sticky option can be set only when creating a node group.

## Configuring node groups for spotted and partially striped configurations

September 14, 2021

To configure a node group for spotted and partially striped configurations you must first create a node group and then bind the required nodes to the node group. You then associate the required entities to that node group. The entities that are bound to the node group are of the following:

- **Spotted** - If bound to a node group that has a single node.
- **Partially Striped** - If bound to a node group that has more than one node.

**Some points to remember:**

- GSLB is supported on a cluster only when GSLB sites are bound to node groups that have a single cluster node. For more information, see Setting Up GSLB in a Cluster.
- Citrix Gateway is supported on a cluster only when the VPN virtual servers are bound to node groups that have a single cluster node. The sticky option must be enabled on the node group.
- For versions prior to NetScaler 11, the application firewall is supported only on individual cluster nodes (spotted configuration). Application firewall profiles can be associated only with virtual

servers that are bound to node groups that have a single cluster node. It means that application you are not allowed to do the following:
  - Bind application firewall profiles to striped or partially striped virtual servers.
  - Bind the policy to a global bind point or to user-defined policy labels.
  - Unbind, from a node group, a virtual server that has application firewall profiles.
- NetScaler 11 introduced application firewall support for striped and partially striped configurations. For more information, see Application Firewall Support for Cluster Configurations.

Check Citrix ADC Features Supported in a Cluster to see the NetScaler versions from which GSLB, Citrix Gateway, and application firewall are supported in a cluster.

### To configure a node group by using the command line interface

1. Log on to the cluster IP address.
2. Create a node group. Type:

   ```
   add cluster nodegroup <name> -strict (YES | NO)<!--NeedCopy-->
   ```

   Example

   ```
   1 add cluster nodegroup NG0 -strict YES
   ```

3. Bind the required nodes to the node group. Type the following command for each member of the node group:

   ```
   bind cluster nodegroup <name> -node <nodeId><!--NeedCopy-->
   ```

   Example

   To bind nodes with IDs 1, 5, and 6.

   ```
   1 > bind cluster nodegroup NG0 -node 1
   2 > bind cluster nodegroup NG0 -node 5
   3 > bind cluster nodegroup NG0 -node 6
   ```

4. Bind the entity to the node group. Type the following command once for every entity that you want to bind:

   ```
   bind cluster nodegroup <name> (-vServer <string> | -identifierName <
   string> | -gslbSite <string> -service <string>)<!--NeedCopy-->
   ```

   > **Note**
   >
   > The gslbSite and service parameters are available from NetScaler 10.5 onwards.

   Example

   To bind virtual servers VS1 and VS2 and rate limit identifier named identifier1.

```
1 > bind cluster nodegroup NG0 -vServer VS1
2 > bind cluster nodegroup NG0 -vServer VS2
3 > bind cluster nodegroup NG0 -identifierName identifier1
```

5. Verify the configurations by viewing the details of the node group. Type:

   ```
   show cluster nodegroup <name><!--NeedCopy-->
   ```

   Example

   ```
   1 > show cluster nodegroup NG0
   ```

To configure a node group by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Node Groups.**
3. In the details pane, click **Add.**
4. In the **Create Node Group** dialog box, configure the node group:
   a) Under **Cluster Nodes**, click the **Add** button.
      - The Available list displays the nodes that you can bind to the node group and the Configured list displays the nodes that are bound to the node group.
      - Click the **+** sign in the Available list to bind the node. Similarly, click the **-** sign in the Configured list to unbind the node.
   b) Under **Virtual Servers**, select the tab corresponding to the type of virtual server that you want to bind to the node group. Click the **Add** button.
      - The Available list displays the virtual servers that you can bind to the node group and the Configured list displays the virtual servers that are bound to the node group.
      - Click the **+** sign in the Available list to bind the virtual server. Similarly, click the - sign in the Configured list to unbind the virtual server.

Configuring redundancy for node groups

September 14, 2021

> **Note**
>
> Supported from NetScaler 10.5 Build 52.1115.e onwards.

Node groups can be configured such that when one node group goes down, another node group can take over and process traffic. For example, when a node group NG1 goes down, NG2 takes over.

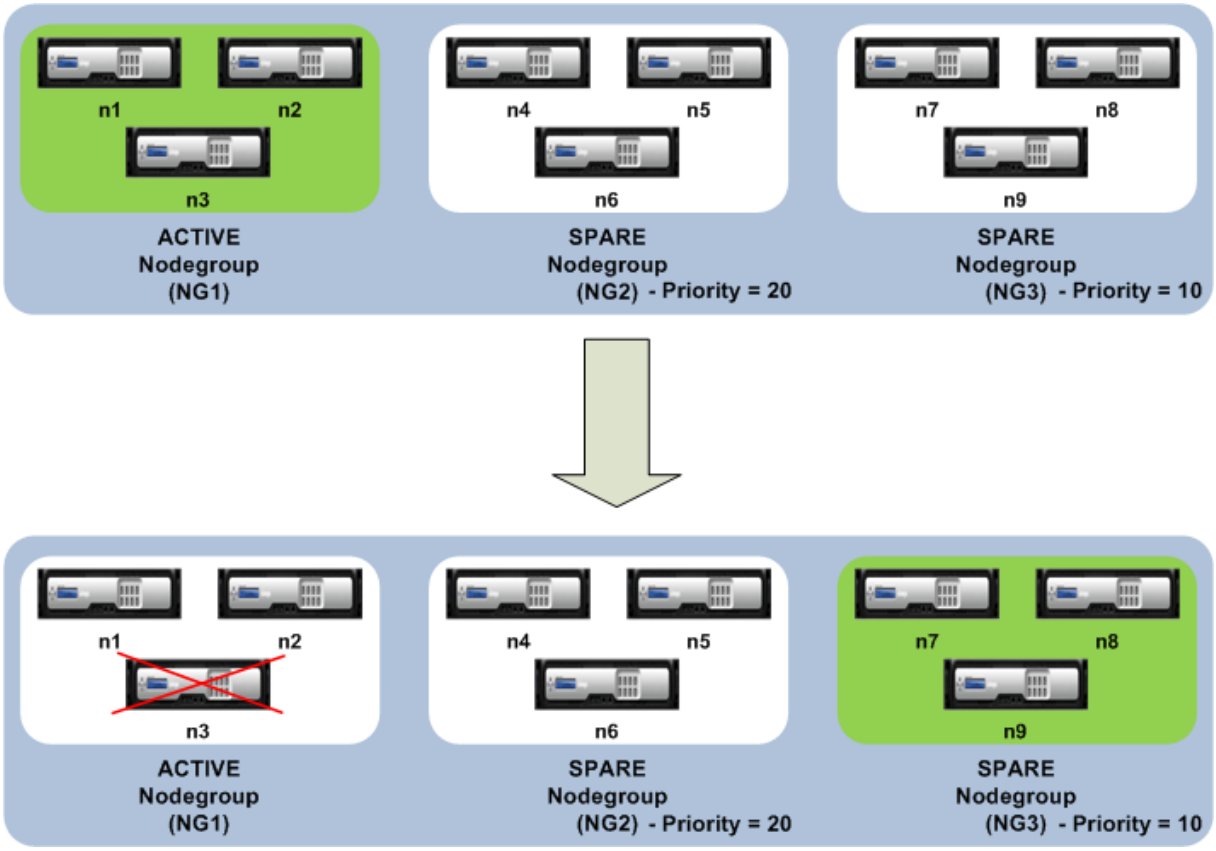
> **Note**
>
> This functionality can be used to configure data center redundancy where each node group is configured as a data center.

To achieve this use case, cluster nodes must be logically grouped into node groups, where some node groups must be configured as ACTIVE and others as SPARE. The active node group with the highest priority (that is, the lowest priority number) is made operationally active and therefore serves traffic. When a node from this operationally active node group goes down, the node count of this node group is compared with the node count of the other active node groups in order of their priority. If a node group has a higher or equal node count, that node group is made operationally active. Else, the spare node groups are checked.

> **Note**
>
> - Only one state-specific node group can be active at a given point in time.
> - A cluster node inherits the state of the node group. So, if a node with "SPARE" state is added to the node group with state as "ACTIVE", the node automatically behaves as an active node.
> - The pre-emption parameter that is defined for the cluster instance decides whether the initial active node group takes the control when it comes up again.
> - A spare node group can take up a node group and host active traffic when an active node group goes down.

The following figure shows a node group setup that has node group redundancy defined. NG1 is initially the active node group. When it loses one of the nodes, the spare node group (NG3) with the highest priority starts serving traffic.

Figure 1. Citrix ADC cluster with node group redundancy configured.



Configuring redundancy for node groups

1. Log on to the cluster IP address.
2. Create the active node group and bind the required cluster nodes.

```
1 > add cluster nodegroup NG1 -state ACTIVE
2 > bind cluster nodegroup NG1 -node n1
3 > bind cluster nodegroup NG1 -node n2
4 > bind cluster nodegroup NG1 -node n3
```

3. Create the spare node group and bind the requisite nodes.

```
1 > add cluster nodegroup NG2 -state SPARE -priority 20
2 > bind cluster nodegroup NG2 -node n4
3 > bind cluster nodegroup NG2 -node n5
4 > bind cluster nodegroup NG2 -node n6
```

4. Create another spare node group and bind the requisite nodes.

```
1 > add cluster nodegroup NG3 -state SPARE -priority 10
2 > bind cluster nodegroup NG3 -node n7
```

```
3 > bind cluster nodegroup NG3 -node n8
4 > bind cluster nodegroup NG3 -node n9
```

Disabling steering on the cluster backplane

September 14, 2021

> **Note**
>
> Supported from NetScaler 11 onwards.

The default behavior of a Citrix ADC cluster is to direct the traffic that it receives (flow receiver) to another node (flow processor). The flow processor must then process the traffic. This process of directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

If necessary, you can disable steering so that the process becomes local to the flow receiver and therefore makes the flow receiver as the flow processor. Such a configuration setup can come handy when you have a high latency link.

> **Note**
>
> This configuration is applicable only for striped virtual servers.

- For partially striped virtual servers, if the flow receiver is a non-owner node, the traffic is steered to an owner node. If however, the flow receiver is an owner node, then steering is disabled.
- For spotted virtual servers, the flow receiver is the flow processor, and hence there is no need for steering.

Some points to remember when disabling the steering mechanism:

- Striped SNIPs are not supported as steering is disabled.
- MPTCP and FTP do not work.
- L2 mode must be disabled.
- If USIP is enabled, traffic might not reach back to the same node as the steering is disabled.
- Traffic that is directed to the cluster IP address is steered to the configuration coordinator.
- When a node joins or leaves a cluster, it is possible that more than 1/N connections are affected. It is because a change in the nodes available, might cause the routes to be rehashed. As a result, the traffic is routed to another node and due to the non-availability of steering, the traffic is not processed.

Steering can be disabled at the individual virtual server level or at the global level. The global configuration takes precedence over the virtual server setting.

- Disabling backplane steering for all striped virtual servers

  Configured at cluster instance level. Traffic meant for any striped virtual server is not steered on the cluster backplane.

  ```
  add cluster instance \<clId\> -processLocal ENABLED<!--NeedCopy-->
  ```

- Disabling backplane steering for a specific striped virtual server

  Configured on a striped virtual server. Traffic meant for the virtual server is not steered on the cluster backplane.

  ```
  add lb vserver <name> <serviceType> -processLocal ENABLED<!--NeedCopy
  -->
  ```

Synchronizing cluster configurations

September 14, 2021

Citrix ADC configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

- A node joins the cluster
- A node rejoins the cluster
- A new command is run through the cluster IP address

Also, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

To synchronize cluster configurations by using the CLI

At the command prompt of the appliance on which you want to synchronize the configurations, type:

```
1 force cluster sync
```

To synchronize cluster configurations by using the GUI

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to **System > Cluster.**
3. In the details pane, under **Utilities**, click Force cluster sync.
4. Click **OK.**

Synchronizing time across cluster nodes

September 14, 2021

The cluster uses a Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

To enable/disable PTP by using the command line interface

At the command prompt of the cluster IP address, type:

```
set ptp -state disable
```

To enable/disable PTP by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster.**
3. In the details pane, under **Utilities**, click **Configure PTP Settings.**
4. In the **Enable/Disable PTP** dialog box, select whether you want to enable or disable PTP.
5. Click **OK.**

Synchronizing cluster files

September 14, 2021

The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Also, you can manually synchronize the cluster files.

Important: Removing any certificate or key files in a cluster environment restricts further configuration on the ADC appliance. Add the files back at the same location to make any configuration changes.

The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netscaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/htmlinjection/
- /netscaler/htmlinjection/ens/

- /nsconfig/monitors/
- /nsconfig/nstemplates/
- /nsconfig/ssh/
- /nsconfig/rc.netscaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd_config
- /nsconfig/hosts
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab
- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java_home/lib/security/cacerts
- /var/wi/java_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

> **Tip**
>
> Files (certificates and key files) that are copied to the cluster configuration coordinator manually (or through the shell) are not automatically available on the other cluster nodes. Run the "sync cluster files" command from the cluster IP address before running a command that depends on these files.

To synchronize cluster files by using the command line interface

At the command prompt of the cluster IP address, type:

```
sync cluster files <mode>
```

To synchronize cluster files by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster.**

3. In the details pane, under **Utilities**, click Synchronize cluster files.
4. In the **Synchronize** cluster files dialog box, select the files to be synchronized in the Mode drop-down list.
5. Click **OK.**

Viewing the statistics of a cluster

September 14, 2021

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

```
stat cluster instance <clId>
```

To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

```
stat cluster node <nodeid>
```

> **Note**
>
> The `stat cluster node <nodeid>` command displays the cluster level statistics when you run the command from the cluster IP address. However, when you run from the NSIP address of a cluster node, the command displays node level statistics.

To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster.**
3. In the details pane, in the center of the page, click **Statistics.**

To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes.**

3. In the details pane, select a node and click **Statistics** to view the statistics of the node. To view the statistics of all the nodes, click **Statistics** without selecting a specific node.

Discovering Citrix ADC appliances

September 14, 2021

You can discover the appliances present in the same subnet as the current node. The required discovered appliances can then be selectively added to the cluster. This operation can be performed to either create a cluster or to add nodes to an existing cluster.

> **Note**
>
> - The discover operation can be performed only through the configuration utility.
> - This operation cannot discover Citrix ADC appliances from different networks.
> - When performing this operation to add nodes to an existing cluster, the L3 VLAN configurations are cleared from the node. You make sure to define these configurations once the appliance is added to the cluster.

To discover appliances by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes.**
3. In the details pane, at the bottom of the page, click **Discover NetScalers.**
4. In the **Discover NetScalers** dialog box, set the following parameters:
   - **IP address range** - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
   - **Backplane interface** - Specify the interfaces to be used as the backplane interface. It is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.
5. Click **OK.**
6. Select the appliances that you want to add to the cluster.
7. Click **OK.**

Disabling a cluster node

September 14, 2021

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations. When the node is enabled again, the cluster configurations are automatically synchronized on it. For more information, see Synchronization across cluster nodes.

A disabled node cannot serve traffic and all existing connections on this node are terminated.

> **Note**
>
> If the configurations of a disabled non-configuration coordinator node are modified (through the NSIP address of the node), the configurations are not automatically synchronized on that node. You can manually synchronize the configurations as described in Synchronizing Cluster Configurations.

To disable a cluster node by using the command line interface

At the command prompt of the node that you want to disable, type:

```
disable cluster instance <clId>
```

> **Note**
>
> To disable the cluster, run the
> disable cluster instance command on the cluster IP address.

To disable a cluster node by using the configuration utility

1. On the node that you want to disable, navigate to **System > Cluster**, and click **Manage Cluster.**
2. In the **Configure** cluster instance dialog box, unselect the **Enable** cluster instance check box.

   > **Note**
   >
   > To disable the cluster instance on all the nodes, perform the preceding procedure on the cluster IP address.

Removing a cluster node

September 14, 2021

When a node is removed from the cluster, the cluster configurations are cleared from the node (by internally running the clear ns config -extended command). The SNIP addresses, **MTU** settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

> **Note**
>
> - If the deleted node was the cluster configuration coordinator (CCO), another node is automatically selected as the CCO, and the cluster IP address is assigned to that node. All the current cluster IP address sessions are invalid and you have to start a new session.
> - To delete the whole cluster, you must remove each node individually. When you remove the last node, the cluster IP addresses are deleted.
> - When an active node is removed, the traffic serving capability of the cluster is reduced by one node. Existing connections on this node are terminated.

To remove a cluster node by using the CLI

For NetScaler 10.1 and later versions

1. Log on to the cluster IP address and at the command prompt, type:

```
rm cluster node <nodeId>

save ns config
```

2. Log on to the removed node, NSIP address, and at the command prompt, type:

```
save ns config
```

> **Note**
>
> If the cluster IP address is unreachable from the node, run the rm cluster instance command on the NSIP address of that node itself.

For NetScaler 10

1. Log on to the node that you want to remove from the cluster and remove the reference to the cluster instance.

```
rm cluster instance <clId>

save ns config
```

2. Log on to the cluster IP address and remove the node from which you removed the cluster instance.

```
rm cluster node <nodeId>

save ns config
```

Make sure you do not run the `rm cluster node` command from the local node. It results in inconsistent configurations between the CCO and the node.

To remove a cluster node by using the GUI

On the cluster IP address, navigate to **System > Cluster > Nodes**, select the node you want to remove and click **Remove.**

Removing a node from a cluster deployed using cluster link aggregation

September 14, 2021

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see Using Cluster Link Aggregation.

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to PASSIVE.

```
set cluster node <nodeId> -state PASSIVE
```

3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.

> **Note**
>
> You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.

4. Remove the node from the cluster.

```
rm cluster node <nodeId>
```

Detecting jumbo probe on a cluster

September 14, 2021

If a Jumbo frame is enabled on a cluster interface, the backplane interface must be large enough to support the all packets in the Jumbo frame. It is achieved by setting the Maximum Transmission Unit (MTU) of the backplane as:

Backplane_MTU = maximum (all cluster interface MTUs) + 78

To verify the preceding configuration, you must send a jumbo probe (of the preceding computational size) to all the peer nodes of a Cluster setup. If the probe does not succeed, the appliance displays a warning message in the output of the “show cluster instance” command.

In the command interface mode, type the following command:

```
> show cluster instance
  Cluster ID: 1
  Dead Interval: 3 secs
  Hello Interval: 200 msecs
  Preemption: DISABLED
  Propagation: ENABLED
  Quorum Type: MAJORITY
  INC State: DISABLED
  Process Local: DISABLED
  Cluster Status: ENABLED(admin),    ENABLED(operational), UP
```

Warning

The MTU for a backplane interface must be large enough to handle all packets in the frame. It must be equal to <MTU_VAL>. If the recommended value is not user configurable, you must review the MTU value of jumbo interfaces.

Sl. no	Member Nodes	Health	Admin State	Operation State
1	Node ID: 1; Node IP: 10.102.53.167	UP	Active	ACTIVE (Configuration Coordinator)
2	Node ID: 2; Node IP: 10.102.53.168	UP	Active	Active

Route monitoring for dynamic routes in cluster

September 14, 2021

You can use a route monitor to make a cluster node dependent on the internal routing table whether

it contains or does not contain a dynamically learned route. A route monitor on each node checks the internal routing table to ensure there is a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

In a cluster deployment, if the client-side or server side-link of a node goes down, traffic is steered to this node through the peer nodes for processing. The steering of traffic is implemented by configuring dynamic routing and adding static ARP entries, pointing to the special MAC address of each node, on all the nodes. If there are many nodes in a cluster deployment, adding and managing static ARP entries with special MAC addresses on all the nodes is a cumbersome task. Now, nodes implicitly use special MAC addresses for steering packets. Therefore, static ARP entries pointing to special MAC addresses are no longer required to be added to the cluster nodes.

To bind a cluster node using the CLI

At the command prompt, type:

```
bind cluster node <nodeId> (-routeMonitor <ip_addr|ipv6_addr|*> [<
    netmask>])
unbind cluster node <nodeId> (-routeMonitor <ip_addr|ipv6_addr|*> [<
    netmask>])
```

Consider a scenario where Node 1 is bound to route monitor 1.1.1.0 255.255.255.0. When a dynamic route fails, Node 1 become INACTIVE. The health status is available in the `show cluster node` command by node id as per following.

```
Node ID: 1
IP:  10.102.169.96
Backplane:  1/1/2
Health: NOT UP
Reason(s): Route Monitor(s) of the node have failed
Route Monitor -  Network: 1.1.1.0   Netmask: 255.255.255.0   State:
    DOWN
```

Monitoring cluster setup using SNMP MIB with SNMP link

September 14, 2021

SNMP MIB is device specific information that is configured on the SNMP agent for identifying a Citrix ADC appliance. It can identify information such as, appliance name, administrator, and location. In a cluster setup, you can now configure the SNMP MIB in any node by including the “ownerNode” pa-

rameter in the set SNMP MIB command. Without this parameter, the set SNMP MIB command applies only to the Cluster Coordinator (CCO) node.

To display the MIB configuration for a cluster node other than the CCO, include the “ownerNode” parameter in the show SNMP MIB command.

Configuring SNMP MIB on CLIP

To configure and view MIB configuration on CLIP by using the command line interface.

```
set snmp mib [-contact <string>] [-name <string>] [-location <string>]
      [-customID <string>] [-ownerNode <positive_integer>]
Done
show snmp mib [-ownerNode <positive_integer>]

 > set mib -contact John -name NS59 -location San Jose -customID 123 -
    ownerNode 3
Done
> sh mib -ownerNode 3
        --------------------
         Cluster Node ID: 3
        --------------------
        NetScaler system MIB:
        sysDescr:    NetScaler NS11.1: Build 46.4.a.nc, Date: Jun  7
           2016, 10:27:29
        sysUpTime:   124300
        sysObjectID: .1.3.6.1.4.1.5951.1.1
        sysContact:  John
        sysName:     NS59
        sysLocation: San Jose
        sysServices: 72
        Custom ID: 123
 Done

> unset mib -contact -name -location -customID -ownerNode 3
 Done
> sh mib -ownerNode 3
        --------------------
         Cluster Node ID: 3
        --------------------
        NetScaler system MIB:
        sysDescr:    NetScaler NS11.1: Build 46.4.a.nc, Date: Jun 7
           2016, 10:27:29
        sysUpTime:   146023
        sysObjectID: .1.3.6.1.4.1.5951.1.1
```

```
        sysContact:  WebMaster (default)
        sysName:     NetScaler
        sysLocation: POP (default)
        sysServices: 72
        Custom ID: Default
Done
```

Cluster SNMP trap messages

In cluster setup, the SNMP trap alarm configurations must be done from the CLIP. The commands are propagated to each of the nodes.

For more information on configuring SNMP, see Configuring the Citrix ADC to generate SNMP traps.

The following are the cluster specific traps that are available:

```
>sh snmp alarm | grep cluster
    CLUSTER-BACKPLANE-HB-MISSING N/A N/A 86400   ENABLED - ENABLED
    CLUSTER-CCO-CHANGE N/A N/A N/A ENABLED - ENABLED
    CLUSTER-NODE-HEALTH N/A N/A 86400 ENABLED - ENABLED
    CLUSTER-NODE-QUORUM N/A N/A 86400 ENABLED - ENABLED
    CLUSTER-OVS-CHANGE N/A N/A N/A ENABLED - ENABLED
    CLUSTER-PROP-FAILURE N/A N/A N/A ENABLED - ENABLED
    CLUSTER-SYNC-FAILURE N/A N/A N/A ENABLED - ENABLED
    CLUSTER-SYNC-PARTIAL-SUCCESS N/A N/A N/A ENABLED - ENABLED
    CLUSTER-VERSION-MISMATCH N/A N/A 86400 ENABLED - ENABLED
```

Monitoring command propagation failures in a cluster deployment

September 14, 2021

In a cluster deployment, you can use the new command “show prop status” for faster monitoring and troubleshooting of issues. The issues related to command-propagation failure on non-CCO nodes. This command displays up to 20 of the most recent command propagation failures on all non-CCO nodes. You can use either the Citrix ADC appliance CLI or GUI to perform this operation. You can access them through the CLIP address or through the NSIP address of any node in the cluster deployment.

Graceful shutdown of nodes

September 14, 2021

In a cluster setup, some of the existing connections (1/Nth connections, where N is the cluster size) at the cluster level or specific virtual server level are lost. This behavior is observed if a node leaves or joins the system. To address the loss, you must gracefully handle the existing connections. Graceful handling is done by configuring the “retain connections on cluster” option in the CLIP address and specifying a timeout interval in the node’s NSIP.

Graceful handling of connections is applicable in two scenarios:

1. Cluster upgrade
2. New node addition

Graceful handling of Nodes in cluster upgrade

To upgrade a cluster, you must upgrade one node at a time. Before upgrading a node, you must set it to passive state and then set it to active state after the upgrade. To avoid terminating existing connections when upgrading the node, shut it down gracefully with a configured timeout interval. Otherwise, 1/Nth (where N is the cluster size) of the cluster’s connections are terminated.

> **Note**
>
> If existing sessions are not completed within the configured timeout interval, they get terminated after the grace time.

Following are the steps to gracefully handle nodes in a cluster upgrade scenario:

1. Consider a cluster setup of five nodes (n0, n1, n2, n3, n4).
2. Before you shut down a node, you must configure the “retainConnectionsOnCluster” option. It helps to retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

   Example

   On CLIP

   “‘set cluster instance –retainConnectionsOnCluster YES

   ```
   OR

   ```set lb vserver <vserver name>  - retainConnectionsOnCluster Yes
      <!--NeedCopy-->
   ```

3. Now, log on to the NSIP address of node n3 and set the node n3 to PASSIVE with a timeout internal.

   Example

   “‘set cluster node n3 –state PASSIVE –delay 60

   ```

```
1 ```saveconfig<!--NeedCopy-->
```

4. After the grace period expires, close all connections, shut down n3 and reboot the Citrix ADC appliance.
5. Upgrade the appliance. Then, with the CLI connected to the appliance's NSIP address, set the node to ACTIVE.

   Example

   "'set cluster node n3 –state ACTIVE

```
1 ```saveconfig<!--NeedCopy-->
```

6. Repeat steps 4–6 for all nodes in the cluster.
7. After all nodes are upgraded and set to ACTIVE, reset the retainConnectionsOnCluster option from the CLIP address.

   Example

   "'set cluster instance -retainConnectionsOnCluster NO

```
1 OR
2
3 ```set lb vserver <vserver name>  - retainConnectionsOnCluster NO
     <!--NeedCopy-->
```

> **Note**
>
> If there is a version mismatch when upgrading a cluster, cluster propagation is automatically disabled and no commands are allowed on the CLIP.

Graceful handling of nodes during a new node addition

The graceful handling of nodes describes how a new node can be added to the existing Citrix ADC cluster. Consider you have a Citrix ADC cluster that is already serving traffic. And you want to add an extra appliance as a node to the cluster without terminating its existing connections. To accomplish the preceding scenario, set the option to retain existing connections either at a Global level or at a specific virtual server level. Once done, save the configuration. Now set the option to retain connections to NO, to allow existing connections from other nodes to be reassigned to the new node.

Following are the steps to gracefully handle nodes if a node newly added:

1. You save the existing configuration that has the “retainConnectionsOnCluster” option enabled. By doing so, you can retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

   On CLIP

   ```
   1 set cluster instance x - retainConnectionsOnCluster YES
   ```

   OR

   ```
   1 set lb vserver xxxx -retainConnectionsOnCluster Yes
   ```

2. Add a node ‘n5’ to the cluster setup.
3. Disable “the retainConnectionOnCluster” option to “NO” for distributing existing connections from other nodes to the newly added node n5.

   On CLIP

   ```
   1 set cluster instance x - retainConnectionsOnCluster NO
   ```

   OR

   ```
   1 set lb vserver xxxx -retainConnectionsOnCluster NO
   ```

> **Note**
>
> The backplane steering depends on the type of traffic distribution mechanism (ECMP, CLAG, and USIP) on a cluster setup. The increase in backplane steering is based on the traffic type.

Configuring graceful shutdown of nodes in a cluster

To configure graceful shutdown of nodes in a cluster, do the following:

1. Configure the “retainConnectionsonCluster” option at Global (cluster) level.
2. Configure the “retainConnectionsonCluster” option at the virtual server level.
3. Set the node (leaving the system) to the passive state with a graceful timeout interval specified in the node’s NSIP address.
4. Monitor the existing connections to make sure all transactions are completed within the grace period.

To retain existing connections at the global (cluster) level by using the CLI

You can retain existing connections either at a global level or at a specific virtual server level. This option is configured to retain all existing connections at the global level. By default, this option is disabled.

At the command prompt type:

```
- set cluster instance <clusterID> -retainConnectionsOnCluster YES

- set cluster instance 60 - retainConnectionsOnCluster YES
```

To retain existing connections of a specific virtual server in the cluster by using the CLI

This option is configured to retain existing connections specific to a load balancing virtual server. To retain those connections, we enable this option at the virtual server level. By default, this option is disabled.

At the command prompt, type:

```
- set lb vserver <clusterID> -retainConnectionsOnCluster Yes

- set lb vserver v1 -retainConnectionsOnCluster Yes
```

To set a cluster node to passive state by using the CLI

To set a cluster node to passive state with a graceful timeout interval. This setting is performed in the node's NSIP as propagation is disabled during cluster upgrade.

At the command prompt, type:

```
- set cluster node <clusterID> -state passive
-backplane <interface_name>@
-priority <positive_integer>
-delay <mins>

- set cluster node 4 -state PASSIVE -delay 60

- set cluster instance 60 - retainConnectionsOnCluster YES
- set lb vserver v1 -retainConnectionsOnCluster Yes
- set cluster node 4 -state PASSIVE -delay 60
```

> **Note**
>
> You might observe the following behavior on a cluster node when it is set to passive with a delay option configured from a CLIP:
>
> - After the timeout, the node shows as passive from the NSIP of the node.

> - The **show cluster instance** command on CLIP displays the node as active from the CLIP. Whereas the **show cluster node** command on the CLIP displays the node as passive.

To configure graceful shutdown of nodes by using the GUI

1. Navigate to **Configuration > System > Cluster** and click **Manage Cluster.**
2. On the **Manage Cluster** page, select **Retain Connections on Cluster** option.
3. Click **OK**, and then click **Done**.

Graceful shutdown of services

September 14, 2021

Starting with NetScaler 12.1 build 49.xx, Citrix ADC clusters support graceful shutdown of services. To gracefully shut down the services, you can perform one of the following tasks.

- Explicitly disable the service, and
  - Set a delay (in seconds).
  - Enable graceful shutdown.
- Add a TROFS code or string to the monitor.

For more details, see Graceful shutdown of services.

To configure graceful shutdown for a service by using the CLI

Disable with graceful option only:

At the command prompt, type:

```
disable service <name> [-graceFul (YES|NO)]

show service <name>
<!--NeedCopy-->
```

Example

```
disable service svc1 -graceFul YES
Done
sh service svc1
                svc1 (10.102.225.11:80) - HTTP
                State: GOING OUT OF SERVICE   Graceful (number of
                   active clients: 1)
```

```
6                   Last state change was at Wed Jul 25 10:46:29 2018
7                   Time since last state change: 0 days, 00:00:02.680
8                   ... ... ... .
9                   ... ... ... .
10                  Traffic Domain: 0
11
12 1)            Monitor Name: tcp-default
13                                  State: UP              Weight: 1
                                                        Passive: 0
14                                  Probes: 26             Failed [Total: 0
                                        Current: 0]
15                                  Last response: Success - TCP syn+ack
                                        received.
16                                  Response Time: 0.0 millisec
17 <!--NeedCopy-->
```

Disable with timeout and graceful option:

At the command prompt, type:

```
1 disable service <name> [<delay>] [-graceFul (YES|NO)]
2
3 show service <name>
4 <!--NeedCopy-->
```

Example

```
1 disable service svc1 2000 -graceFul YES
2
3 Done
4 > sh service svc1
5                   svc1 (10.102.225.11:80) - HTTP
6                   State: GOING OUT OF SERVICE (Graceful (number of active
                        clients: 1), Out Of Service in 1998 seconds)
7                   Last state change was at Wed Jul 25 10:49:08 2018
8                   Time since last state change: 0 days, 00:00:01.710
9                   ... ... ... .
10                  ... ... ... .
11                  Traffic Domain: 0
12
13 1)            Monitor Name: tcp-default
14                                  State: UP              Weight: 1
                                                        Passive: 0
15                                  Probes: 57             Failed [Total: 0
                                        Current: 0]
```

```
16                                  Last response: Success - TCP syn+ack
                                        received.
17                                  Response Time: 0.0 millisec
18 Done
19 <!--NeedCopy-->
```

Disable service group with timeout and graceful option:

At the command prompt, type:

```
1 disable serviceGroup <serviceGroupName>@ [<serverName>@ <port>] [-delay
2 <secs>] [-graceFul ( YES | NO )]
3 Show service group <serviceGroupName>
4 <!--NeedCopy-->
```

Example:

```
1  disable servicegroup sg -delay 2000 -graceFul yes
2  sh servicegroup sg
3                   sg - HTTP
4                   State: DISABLED                Effective State: OUT OF
                        SERVICE Monitor Threshold : 0
5                   Max Conn: 0       Max Req: 0          Max Bandwidth: 0
                        kbits
6                   Use Source IP: NO
7                   Client Keepalive(CKA): NO
8                    … … … .
9                    … … …

```

> **Note**
> CLIP displays the aggregated value of all active clients connections from all cluster nodes.

To configure graceful shutdown for a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service, and from the Action list, click **Disable**. Enter a wait time, and select Graceful.

To configure a TROFS code or string in a monitor by using the CLI

At the command prompt, type one of the following commands:

```
add lb monitor <monitor-name> HTTP -trofsCode <respcode>
add lb monitor <monitor-name> HTTP-ECV  -trofsString <resp string>
add lb monitor <monitor-name> TCP-ECV  -trofsString <resp string>
<!--NeedCopy-->
```

To configure a TROFS code or string in a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. On the Monitors pane, click Add, and do one of the following steps:
   - Select Type as HTTP, and specify a TROFS Code.
   - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

IPv6 ready logo support for clusters

September 14, 2021

You can test clustered appliances for IPv6 Ready Logo certification. Modified commands for testing IPv6 core protocols, such as for ND test cases, Router Solicitation processing, and sending route advertisement and router redirection messages are available in a clustered setup. Following are the IPv6 functionalities available for testing the IPv6 core protocols.

Following are the modified functionalities available to pass IPv6 core protocols, such as ND test cases, Router Solicitation processing and sending Route advertisement and router redirection messaging in the IPv6readylogo phase2 test suite.

- Link Local SNIPs
- Address Resolution and Neighbor Unreachability
- Router and Prefix Discovery
- Router Redirection
- DoDAD

With these modified commands, the following configurations are supported in a clustered appliance.

Supportable configurations for testing IPv6 core protocols

For a clustered setup to pass IPv6 Ready Logo test cases, you can run the following configurations on the Cluster Management IP address (CLIP).

- global IP6 configuration
- basic IPv6 configuration
- more IPv6 configurations

Global configuration

A global IPv6 configuration enables you to set the global IPv6 parameters (such as relearning, routeRedirection, ndBasereachTime, nRetransmissionTime, `natprefix`, td, and doodad) to run the basic IPv6 configuration.

At the command prompt, type the following:

```
set ipv6 [-ralearning ( ENABLED | DISABLED )] [-routerRedirection (
    ENABLED | DISABLED )] [-ndBasereachTime<positive_integer>][-
    ndRetransmissionTime <positive_integer>] [-natprefix <ipv6_addr|*>[-
    td<positive_integer>]] [-doDAD ( ENABLED | DISABLED )]
```

Basic IPv6 configuration

The basic IPv6 configuration enables you to create an IPv6 address and bind to a VLAN interface. You can perform the following configurations to test the IPv6 core protocols.

To add a VLAN to the clustered setup by using the CLI

At the command prompt, type:

```
add vlan <id>
```

To add another VLAN to the clustered setup by using the CLI

At the command prompt, type:

```
add vlan <id>
```

To bind an interface to a VLAN by using the CLI

At the command prompt, type:

```
bind vlan <id> -ifnum <interface_name>
```

To bind an interface to a VLAN by using the CLI

This command adds the global prefix as on-link prefix into RA information for subsequent Router Advertisements. At the command prompt, type:

```
bind vlan <id> -ifnum <interface_name>
```

To add the IPv6 SNIP address on a VLAN by using the CLI

At the command prompt, type the following:

```
add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To add the IPv6 address on VLAN by using the CLI

At the command prompt, type the following:

```
add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To bind IPv6 address to VLAN by using the CLI

At the command prompt, type the following:

```
bind vlan <id> [-ifnum <interface_name> [-tagged]][-IPAddress <ip_addr|
    ipv6_addr|
```

To bind the IPv6 address to VLAN by using the CLI

At the command prompt, type the following:

```
bind vlan <id> [-ifnum <interface_name> [-tagged]][-IPAddress <ip_addr|
    ipv6_addr|
```

To display the link local IPv6 address attached to VLAN by using the CLI

At the command prompt, type the following:

```
sh VLAN
```

Example 1

```
add vlan 2
add vlan 3
bind vlan 2 -ifnum 1/2
bind vlan 3 -ifnum 1/3
add ip6 fe80::9404:60ff:fedd:a464/64 -vlan 2 -scope link-local -type
    SNIP
add ip6 fe80::c0ee:7bff:fede:263f/64 -vlan 3 -scope link-local -type
    SNIP
add ip6 3ffe:501:ffff:100:9404:60ff:fedd:a464/64 -vlan 2
add ip6 3ffe:501:ffff:101:c0ee:7bff:fede:263f/64 -vlan 3
bind vlan 2 -ipAddress 3ffe:501:ffff:100:9404:60ff:fedd:a464/64
bind vlan 3 -ipAddress 3ffe:501:ffff:101:c0ee:7bff:fede:263f/64
```

Example 2

```
sh vlan
1)      VLAN ID: 2      VLAN Alias Name:
        Interfaces : 1/6
        IPs :
             3ffe:501:ffff:100:2e0:edff:fe15:ea2a/64
3)      VLAN ID: 3      VLAN Alias Name:
        Link-local IPv6 addr: fe80::9404:60ff:fedd:a464/64
        Interfaces : 1/5
        IPs :
             3ffe:501:ffff:101:2e0:edff:fe15:ea2b/64
 Done
```

More IPv6 cluster configuration

To test IPv6 core protocols, you can use the following new or modified IPv6 configurations.

To set VLAN specific Router Advertisement parameters by using the CLI

At the command prompt, type:

```
set nd6RAvariables -vlan <positive_integer> [-ceaseRouterAdv ( YES | NO
    )] [-sendRouterAdv ( YES | NO )] [-srcLinkLayerAddrOption ( YES | NO
     )][-onlyUnicastRtAdvResponse ( YES | NO )] [-managedAddrConfig (
    YES | NO)] [-otherAddrConfig ( YES | NO )] [-currHopLimit <
    positive_integer>][-maxRtAdvInterval <positive_integer>] [-
    minRtAdvInterval<positive_integer>] [-linkMTU <positive_integer>] [-
```

```
    reachableTime<positive_integer>] [-retransTime <positive_integer>]
    [-defaultLifeTime<integer>]
```

To set an on-link global prefix's configurable parameters by using the CLI

At the command prompt, type:

```
set onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )][-
    autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )][-
    decrementPrefixLifeTimes ( YES | NO )] [-prefixValideLifeTime   <
    positive_integer>] [-prefixPreferredLifeTime <positive_integer>]
```

To add configurable parameters to an on-link global prefix by using the CLI

At the command prompt, type:

```
add onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )][-
    autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )][-
    decrementPrefixLifeTimes ( YES | NO )]-prefixValideLifeTime <
    positive_integer>][-prefixPreferredLifeTime <positive_integer>]
```

To set an on-link link to the IPv6 prefix's configurable parameters by using the CLI

At the command prompt, type the following:

```
help set onLinkIPv6Prefix
```

To bind an on-link link to the IPv6 prefix's configurable parameters by using the CLI

At the command prompt, type:

```
help bind nd6RAvariables
```

To show nd6RAvariables by using the CLI

At the command prompt, type:

```
help sh nd6RAvariables
```

Example

```
> sh nd6RAvariables
  1) Vlan : 1
     SendAdvert     : NO   CeaseAdv       : NO        SourceLLAddress:
        YES
     UnicastOnly    : NO   ManagedFlag    : NO        OtherConfigFlag:
        NO
```

```
5       CurHopLimit     : 64    MaxRtrAdvInterv: 600        MinRtrAdvInterv:
            198
6       LinkMTU         : 0     ReachableTime  : 0          RetransTimer    :
            0
7       DefaultLifetime: 1800 LastRAsentTime : 0          NextRAdelay     :
            0
8
9     2) Vlan : 2
10      SendAdvert      : NO    CeaseAdv       : NO         SourceLLAddress:
            YES
11      UnicastOnly     : NO    ManagedFlag    : NO         OtherConfigFlag:
            NO
12      CurHopLimit     : 64    MaxRtrAdvInterv: 600        MinRtrAdvInterv:
            198
13      LinkMTU         : 0     ReachableTime  : 0          RetransTimer    :
            0
14      DefaultLifetime: 1800 LastRAsentTime : 0          NextRAdelay     :
            0
15  Done
16  >
17  > sh nd6Ravariables  - vlan 2
18    1) Vlan : 2
19      SendAdvert      : NO    CeaseAdv       : NO         SourceLLAddress:
            YES
20      UnicastOnly     : NO    ManagedFlag    : NO         OtherConfigFlag:
            NO
21      CurHopLimit     : 64    MaxRtrAdvInterv: 600        MinRtrAdvInterv:
            198
22      LinkMTU         : 0     ReachableTime  : 0          RetransTimer    :
            0
23      DefaultLifetime: 1800 LastRAsentTime : 0          NextRAdelay     :
            0
24      Prefix :
25  3ffe:501:ffff:100::/64
26  Done
```

Managing cluster heartbeat messages

September 14, 2021

Managing heartbeat messages in a cluster is similar to managing them in a high availability (HA) configuration. Nodes can send and receive heartbeat messages to and from each other on all interfaces

that are enabled. To avoid increased traffic resulting from heartbeat messages, you can now disable the heartbeat option on node interfaces. However, the heartbeat option on the backplane interface cannot be disabled, because it is required for maintaining connectivity among the cluster nodes.

For more information about managing heart messages, see Managing High Availability Heartbeat Messages on a NetScaler Appliance.

To manage heartbeat messages on a node interface by using the Citrix ADC CLI

At the command prompt, type:

```
set interface <ID> [-HAHeartBeat (ON | OFF)]
Show interface <ID>
```

Configuring owner node response status

September 14, 2021

You can configure the ownerDownResponse option on a node which has a spotted SNIP address. By default, the option is enabled. It allows the spotted IP address to respond to PING or ARP requests (coming from the upstream router) when the node is inactive. If you disable the option, the IP address cannot respond to the router requests when the owner node is inactive.

To know how this feature is used for monitoring static routes in ECMP deployment, see Using Equal Cost Multiple Path (ECMP) topic.

To set owner node response status by using the Citrix ADC CLI

At the command prompt, type:

```
add ns ip <IPAddress> [-ownerNode <positive_integer>] [-
    ownerDownResponse (YES | NO )] [-td <positive_integer>]
```

Example

```
add ns ip 2.2.2.2 255.255.255.0 -ownernode 6  - ownerdownResponse YES
```

To set owner node response status by using the Citrix ADC GUI

1. Navigate to **System > Network > IPs** and click **Add** to create a spotted SNIP address.
2. On the **Create IP Address** page, select, or clear the **ownerDownResponse** check box.

To edit owner node response status by using the Citrix ADC GUI

Navigate to **System > Network > IPs**, select an IP address, and click **Edit** to select or clear the **ownerDownResponse** check box.

Monitor static route (MSR) support for inactive nodes in a spotted cluster configuration

September 14, 2021

In a cluster set up with the MSR option enabled on the route, only active nodes can probe to a static route. It can reach a network while inactive and spare nodes have no link to the route and cannot probe to it. You can now configure an inactive or spare node to send PING and ARP probe to IPv4 route and send ping6 and nd6 probe to IPv6 route. You can perform this only in a spotted cluster configuration in which the SNIP address is active and owned exclusively only by one node.

VRRP interface binding in a single node active cluster

September 14, 2021

When you migrate a high availability (HA) setup to a cluster setup, all configurations must be compatible and must be supportable in the cluster. To achieve this, you can now configure virtual router IDs (VRIDs and VRID6s) on a node interface.

> **Important**
>
> Currently, only a single-node active cluster system supports VRIDs and VRID6s.

For instructions for configuring VRIDs and VRID6s, see Configuring Virtual MAC Addresses.

To configure a virtual router ID on a single-node active cluster, add the VRID or VRID6 and bind it to the cluster-node interface.

To add a VRID by using the Citrix ADC CLI

At the command prompt, type:

```
add vrID <ID>
```

To bind a VRID to the cluster-node interface by using the Citrix ADC CLI

At the command prompt, type:

```
Bind vrid <ID> -ifnum <interface_name> | -trackifNum <interface_name

Add vrID 100
Bind vrid 100  - ifnum 1/1  1/2
done
```

To add a VRID6 by using the Citrix ADC CLI

At the command prompt, type:

```
add vrID6 <ID>
```

To bind a VRID6 to a cluster node interface by using the CLI

At the command prompt, type:

```
bind vrid6 <ID> -ifnum <interface_name> | -trackifNum <interface_name>

Add vrID6 100
Bind vrid6 100  - ifnum 1/1  1/2
Done
```

Cluster setup and usage scenarios

September 14, 2021

This section explains some scenarios in which the Citrix ADC cluster can be set up, and configured for different features and network topologies. Provide feedback if you want any other scenarios to be documented.

Creating a two-node cluster

September 14, 2021

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of (n/2 +1) nodes, where n is the number of cluster nodes, are able to serve traffic. If the same formula is applied to a two-node cluster, the cluster would fail if one node went down (n/2 +1=2).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You add a one node as the configuration coordinator and the other node as the other cluster node.

> **Note**
>
> Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

Migrating an HA setup to a cluster setup

September 14, 2021

Migrating an existing high availability (HA) setup to a cluster setup requires you to first remove the Citrix ADC appliances from the HA setup and create a backup of the HA configuration file. You can then use the two appliances to create a cluster and upload the backed-up configuration file to the cluster.

> **Note**
>
> - Before uploading the backed-up HA configuration file to the cluster, you must modify it to make it cluster compatible. Refer to the relevant step of the procedure.
> - Use the **batch -f <backup_filename>** command to upload the backed-up configuration file.

The preceding approach is a basic migration solution which results in downtime for the deployed application. As such, it must be used only in deployments where there is no consideration to application availability.

However, in most deployments, the availability of the application is of paramount importance. For such cases, you must use the approach where an HA setup can be migrated to a cluster setup without any resulting downtime. In this approach, an existing HA setup is migrated to a cluster setup by first removing the secondary appliance and using that appliance to create a single-node cluster. After the cluster becomes operational and serves traffic, the primary appliance of the HA setup is added to the cluster.

To convert a HA setup to cluster setup (without any downtime) by using the command line interface

Let us consider the example of a HA setup with primary appliance (NS1) - 10.102.97.131 and secondary appliance (NS2) - 10.102.97.132.

1. Make sure the configurations of the HA pair are stable.
2. Log on to any one of the HA appliances, go to the shell, and create a copy of the ns.conf file (for example, ns_backup.conf).
3. Log on to the secondary appliance, NS2, and clear the configurations. This operation removes NS2 from the HA setup and makes it a standalone appliance.

```
> clear ns config full
```

> **Note**
>
> - This step is required to make sure that NS2 does not start owning VIP addresses, now that it is a standalone appliance.
> - At this stage, the primary appliance, NS1, is still active and continues to serve traffic.

4. Create a cluster on NS2 (now no longer a secondary appliance) and configure it as a PASSIVE node.

```
> add cluster instance 1

> add cluster node 0 10.102.97.132 -state PASSIVE -backplane
   0/1/1

> add ns ip 10.102.97.133 255.255.255.255 -type CLIP

> enable cluster instance 1

> save ns config

> reboot -warm
```

5. Modify the backed-up configuration file as follows:
   - Remove the features that are not supported on a cluster. For the list of unsupported features, see Citrix ADC Features Supported by a Cluster. It is an optional step. If you do not perform this step, the execution of unsupported commands fails.
   - Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

     Example

```
> add vlan 10 -ifnum 0/1
```

must be changed to

```
> add vlan 10 -ifnum 0/0/1 1/0/1
```

- The backup configuration file can have SNIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

  Example

```
> add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0

> add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

- Update the host name to specify the owner node.

  Example

```
> set ns hostname ns0 -ownerNode 0

> set ns hostname ns1 -ownerNode 1
```

- Change all other relevant networking configuration that depends on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).

6. On the cluster, do the following:

   - Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.
   - Apply configurations from the backed-up and modified configuration file to the configuration coordinator through the cluster IP address.

```
> batch -f ns_backup.conf
```

   - Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.

7. Switch the traffic from the HA setup to the cluster.

   - Log on to the primary appliance, NS1, and disable all the interfaces on it.

```
> disable interface <interface_id>
```

   - Log on to the cluster IP address and configure NS2 as an ACTIVE node.

```
> set cluster node 0 -state ACTIVE
```

> **Note**
>
> There might be a small amount (in the order of seconds) of downtime between disabling the interfaces and making the cluster node active.

8. Log on to the primary appliance, NS1, and remove it from the HA setup.
   - Clear all the configurations. This operation removes NS1 from the HA setup and makes it a standalone appliance.

     ```
     > clear ns config full
     ```

   - Enable all the interfaces.

     ```
     > enable interface <interface_id>
     ```

9. Add NS1 to the cluster.
   - Log on to the cluster IP address and add NS1 to the cluster.

     ```
     > add cluster node 1 10.102.97.131 -state PASSIVE -backplane
        1/1/1
     ```

   - Log on to NS1 and join it to the cluster by sequentially running the following commands:

     ```
     > join cluster -clip 10.102.97.133 -password nsroot

     > save ns config

     > reboot -warm
     ```

10. Log on to NS1 and perform the required topological and configuration changes.
11. Log on to the cluster IP address and set NS1 as an ACTIVE node.

    ```
    > set cluster node 1 -state ACTIVE
    ```

Transitioning between a L2 and L3 Cluster

September 14, 2021

> **Note**
>
> Supported from NetScaler 11 onwards.

An L2 cluster is one where all the nodes are from the same network and an L3 cluster is one that can include nodes from different networks. You can seamlessly transition from one type of cluster to the other without any downtime for the applications that are deployed on the Citrix ADC.

Transitioning a cluster from L2 to L3

You can transition to an L3 cluster when you want the cluster to include nodes from other networks.

On the cluster IP address, do the following:

1. Create a node group.

   Example

   ```
   1 > add cluster nodegroup NG0
   ```

   This node group is used in the next step to group all the nodes from the existing L2 cluster.

2. Transition the L2 cluster to an L3 cluster.

   Example

   ```
   1 > set cluster instance 1 -inc ENABLED -nodegroup NG0
   ```

   This command achieves the dual purpose of transitioning to the L3 cluster and also adding all the nodes of the L2 cluster to the node group.

3. Now, you can add more nodes to the cluster as explained in Adding a Node to the Cluster.

Transitioning a cluster from L3 to L2

You can transition to an L2 cluster when you want to retain nodes that belong to a single network.

On the cluster IP address, do the following:

1. Remove the cluster nodes from the networks that you do not want to retain.

   Example

   ```
   1 > rm cluster node <nodeId>
   ```

2. Transition the L3 cluster to a L2 cluster.

   Example

```
1 > set cluster instance 1 -inc DISABLED
```

The cluster now includes nodes only of a single network.

Setting up GSLB in a cluster

September 14, 2021

> **Note**
>
> Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

> **Notes**
>
> - If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. It happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than /var/netscaler/locdb/, you must manually sync the file to all the cluster nodes.
> - The `show gslb domain` command is not supported in a cluster setup.

To set up GSLB in a cluster by using the CLI:

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see GSLB Configuration Entities.

   > **Note**
   >
   > When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address. The public cluster IP address is needed only when the cluster is deployed behind a NAT device. While configuring a GSLB site, you must use the cluster IP address of the same site. These parameters are required to ensure the availability of the GSLB auto-sync functionality.

   ```
   add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr>
    -clip <ip_addr> <publicCLIP><!--NeedCopy-->
   ```

2. Create a cluster node group.

   ```
   add cluster nodegroup <name> <name>@ [-strict ( YES | NO )] [-sticky (
   YES | NO )] [-state <state>] [-priority <positive_integer>]<!--NeedCopy
   -->
   ```

> **Note**
>
> Enable the sticky option if you want to set up GSLB based for VPN users.

3. Bind a single cluster node to the node group.

   ```
   bind cluster nodegroup <name> -node <nodeId><!--NeedCopy-->
   ```

4. Bind the local GSLB site to the node group.

   ```
   bind cluster nodegroup <name> -gslbSite <string><!--NeedCopy-->
   ```

   > **Note**
   >
   > Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

   To bind the ADNS service:

   “‘bind cluster nodegroup -service

   ```
   **To bind the DNS load balancing virtual server:**

   ```bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
   ```

6. Bind the GSLB virtual server to the node group.

   ```
   bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
   ```

7. [Optional] To set up GSLB based on VPN users, bind the VPN virtual server to the GSLB node group.

   ```
   bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
   ```

8. Verify the configurations.

   ```
   show gslb runningConfig<!--NeedCopy-->
   ```

To set up GSLB in a cluster by using the GUI:

Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.

   Navigate to **Traffic Management > GSLB** to perform the required configurations.

2. Create a node group and perform other node group related configurations.

   Navigate to **System > Cluster > Node Groups** to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the preceding CLI procedure.

   ```

### Support for GSLB parent-child topology in a cluster

Starting with NetScaler 12.1 build 49.xx, GSLB parent-child topology is supported in cluster.

For more information about the parent-child topology, see Parent-child topology deployment using the MEP protocol.

#### To set up GSLB parent-child topology in a cluster by using the CLI

**Parent site**

Perform the following configuration:

1. Create a cluster node group.

   ```
   add cluster nodegroup <name>
   ```

   Example:

   ```
   add cluster nodegroup parentng
   ```

2. Bind a single cluster node to the node group.

   ```
   bind cluster nodegroup <name> -node <nodeId>
   ```

   Example:

   ```
   bind cluster nodegroup parentng -node n2
   ```

3. Bind the local GSLB site to the node group.

   ```
   bind cluster nodegroup <name> -gslbSite <string>
   ```

   Example:

   ```
   bind cluster nodegroup parentng -gslbSite site1
   ```

4. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

   ```
   bind cluster nodegroup <name> -service <string>
   ```

   Example:

   ```
   bind cluster nodegroup parentng - service ADNS
   ```

5. Bind the GSLB virtual server to the node group.

   ```
   bind cluster nodegroup <name> -vServer <string>
   ```

   Example:

   ```
   bind cluster nodegroup parentng -vServce gslbvs1
   ```

Child site

Perform the following configuration:

1. Create a cluster node group.

   ```
   add cluster nodegroup <name>
   ```

   Example:

   ```
   add cluster nodegroup childng
   ```

2. Bind a single cluster node to the node group.

   ```
   bind cluster nodegroup <name> -node <nodeId>
   ```

   Example:

   ```
   bind cluster nodegroup childng -node -n3
   ```

3. Bind the local GSLB site to the node group.

   ```
   bind cluster nodegroup <name> -gslbSite <string>
   ```

   Example:

   ```
   bind cluster nodegroup childng -gslbSite site1
   ```

> **Note**
>
> For parent and child sites to exchange aggregated statistics in metric-based load balancing methods, you must add local GSLB services on the child site. The metric-based load balancing methods are least connection, least bandwidth, and least packets.

To set up GSLB parent-child topology in a cluster by using the GUI

1. Configure the GSLB entities.

   Navigate to **Traffic Management** > **GSLB** to perform the required configurations.

2. Create a node group.

   Navigate to **System** > **Cluster** > **Node Groups** to perform the required configurations.

3. In the Node Group page, select the node group to which you want to bind a node, click **Edit**, and perform the following tasks. You can also perform these tasks when adding a node group.

   - Bind a node to the node group.

     In **Advance Settings**, click **Cluster Nodes** and perform the following tasks:

     - In **Cluster Nodes** section, click **No Cluster Node**.
     - In **Select Cluster Node**, click > and select the node that you want to bind to the node group. You can also add a cluster node.

- Bind the local GSLB site to the node group.

  In Advance Settings, click GSLB Sites and perform the following tasks:

  - In the **GSLB Sites** section, click No GSLB Site.
  - In the **Select GSLB Site**, click > and select the GSLB site that you want to bind to the node group. You can also add a GSLB site.

- Bind the GSLB virtual server to the node group.

  In **Advance Settings**, click **Virtual Servers** and perform the following task:

  - In the **Virtual Servers** pane, click +.
  - In **Choose Virtual Server**, select the server that you want to bind to the node group.

- Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

  In **Advance Settings**, click **Services** and perform the following tasks:

  - In **Services** section, click **No Service**.
  - In **Select Service**, select the service that you want to bind to the node group. You can also add a service.

> **Note**
>
> For child sites, you only have to bind the cluster node and local GSLB site to the node group.

Using cache redirection in a cluster

September 14, 2021

Cache redirection in a cluster works in the same way as it does on a standalone Citrix ADC appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see Cache Redirection.

Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests are dropped.
- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the enable ns mode MBF command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

Using L2 mode in a cluster setup

September 14, 2021

> **Note**
>
> Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.

Using cluster LA channel with linksets

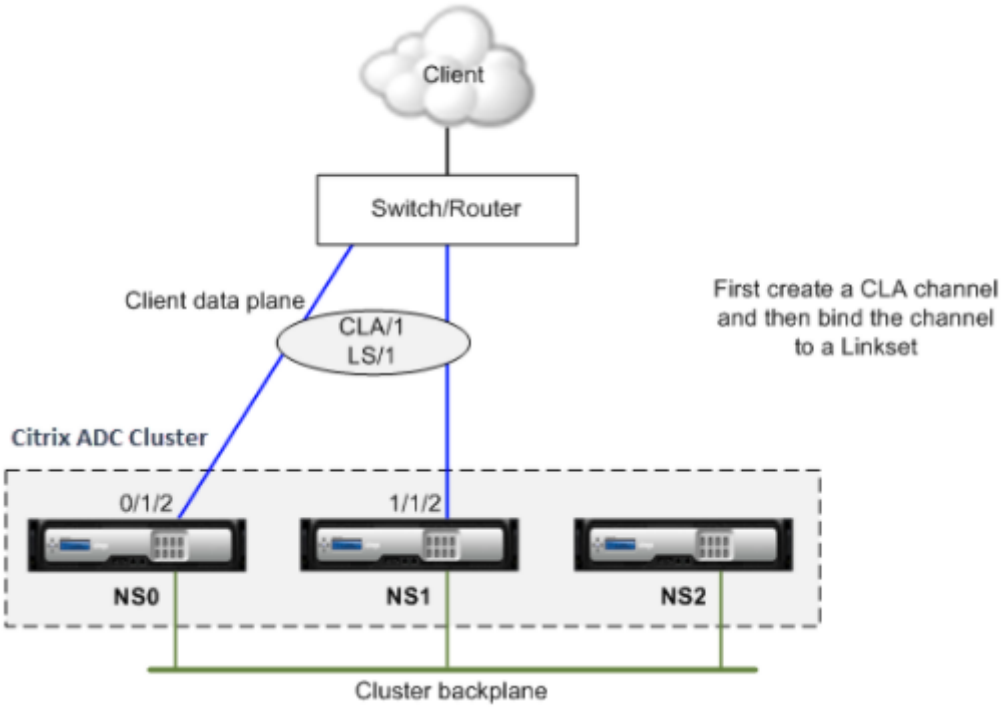
September 14, 2021

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

> **Note**
>
> Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

Figure 1. Linksets and cluster LA channel topology



To configure cluster LA channel and linksets by using the CLI

1. Log on to the cluster IP address.
2. Bind the connected interfaces to a cluster LA channel.

```
add channel CLA/1 -ifnum 0/1/2 1/1/2
```

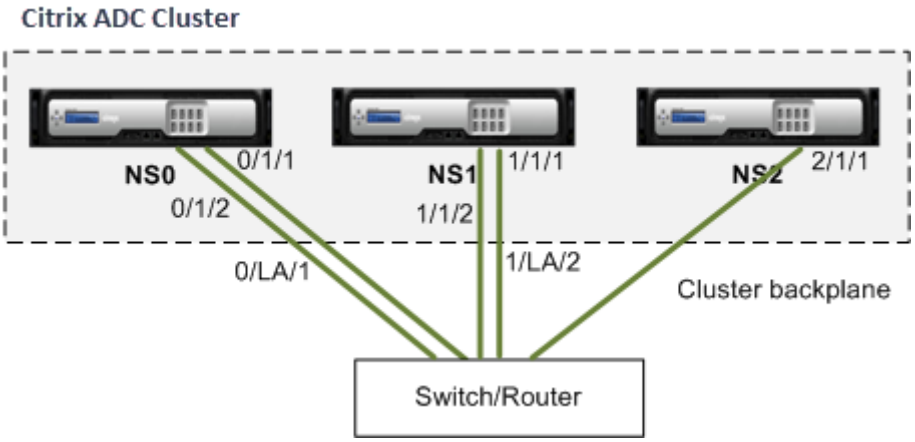
3. Bind the cluster LA channel to the linkset.

```
add linkset LS/1 -ifnum CLA/1
```

Backplane on LA channel

September 14, 2021

In this deployment, LA channels are used for the cluster backplane.



- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.

   a) Log on to the first node that you want to add to the cluster and do the following:

   ```
   > create cluster instance 1
   > add cluster node 0 10.102.29.60 -state ACTIVE
   > enable cluster instance 1
   > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
   > save ns config
   > reboot -warm
   ```

   b) Log on to the cluster IP address and do the following:

   ```
   > add cluster node 1 10.102.29.70 -state ACTIVE
   > add cluster node 2 10.102.29.80 -state ACTIVE
   ```

   c) Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

   ```
   > join cluster -clip 10.102.29.61 -password nsroot
   > save ns config
   > reboot -warm
   ```

   As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:

a) Create the LA channels for nodes NS0 and NS1.

```
> add channel 0/LA/1 -ifnum 0/1/1 0/1/2
> add channel 1/LA/2 -ifnum 1/1/1 1/1/2
```

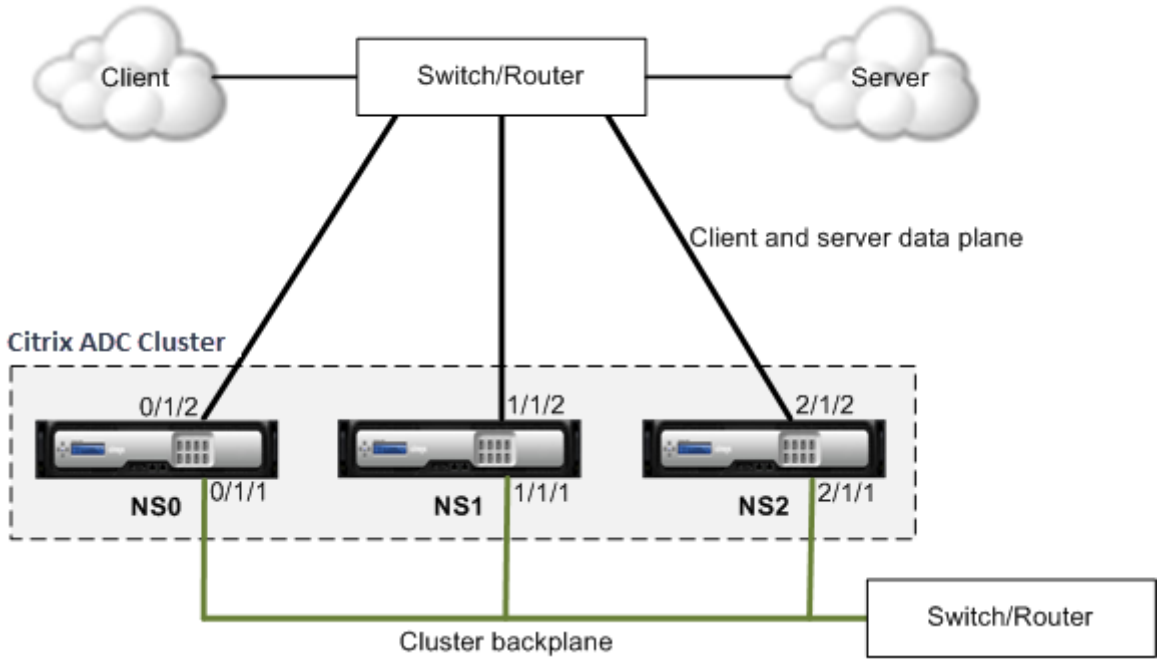
b) Configure the backplane for the cluster nodes.

```
> set cluster node 0 -backplane 0/LA/1
> set cluster node 1 -backplane 1/LA/2
> set cluster node 2 -backplane 2/1/1
```

Common interfaces for client and server and dedicated interfaces for backplane

September 14, 2021

It is a one-arm deployment of the Citrix ADC cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.



- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```
> create cluster instance 1
> add cluster node 0 10.102.29.60 -state ACTIVE -backplane
   0/1/1
> enable cluster instance 1
> add ns ip 10.102.29.61 255.255.255.255 -type CLIP
> save ns config
> reboot -warm
```

3. Log on to the cluster IP address and do the following:

```
> add cluster node 1 10.102.29.70 -state ACTIVE -backplane
   1/1/1
> add cluster node 2 10.102.29.80 -state ACTIVE -backplane
   2/1/1
```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
> join cluster -clip 10.102.29.61 -password nsroot
> save ns config
> reboot -warm
```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

   //For the backplane interfaces

```
> add vlan 10
> bind vlan 10 0/1/1 1/1/1 2/1/1
```

   //For the interfaces that are connected to the client and server networks.

```
> add vlan 20
> bind vlan 20 0/1/2 1/1/2 2/1/2
```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco®

Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface…

```
> interface Ethernet2/47
  switchport access vlan 100
  switchport mode access
  end
```

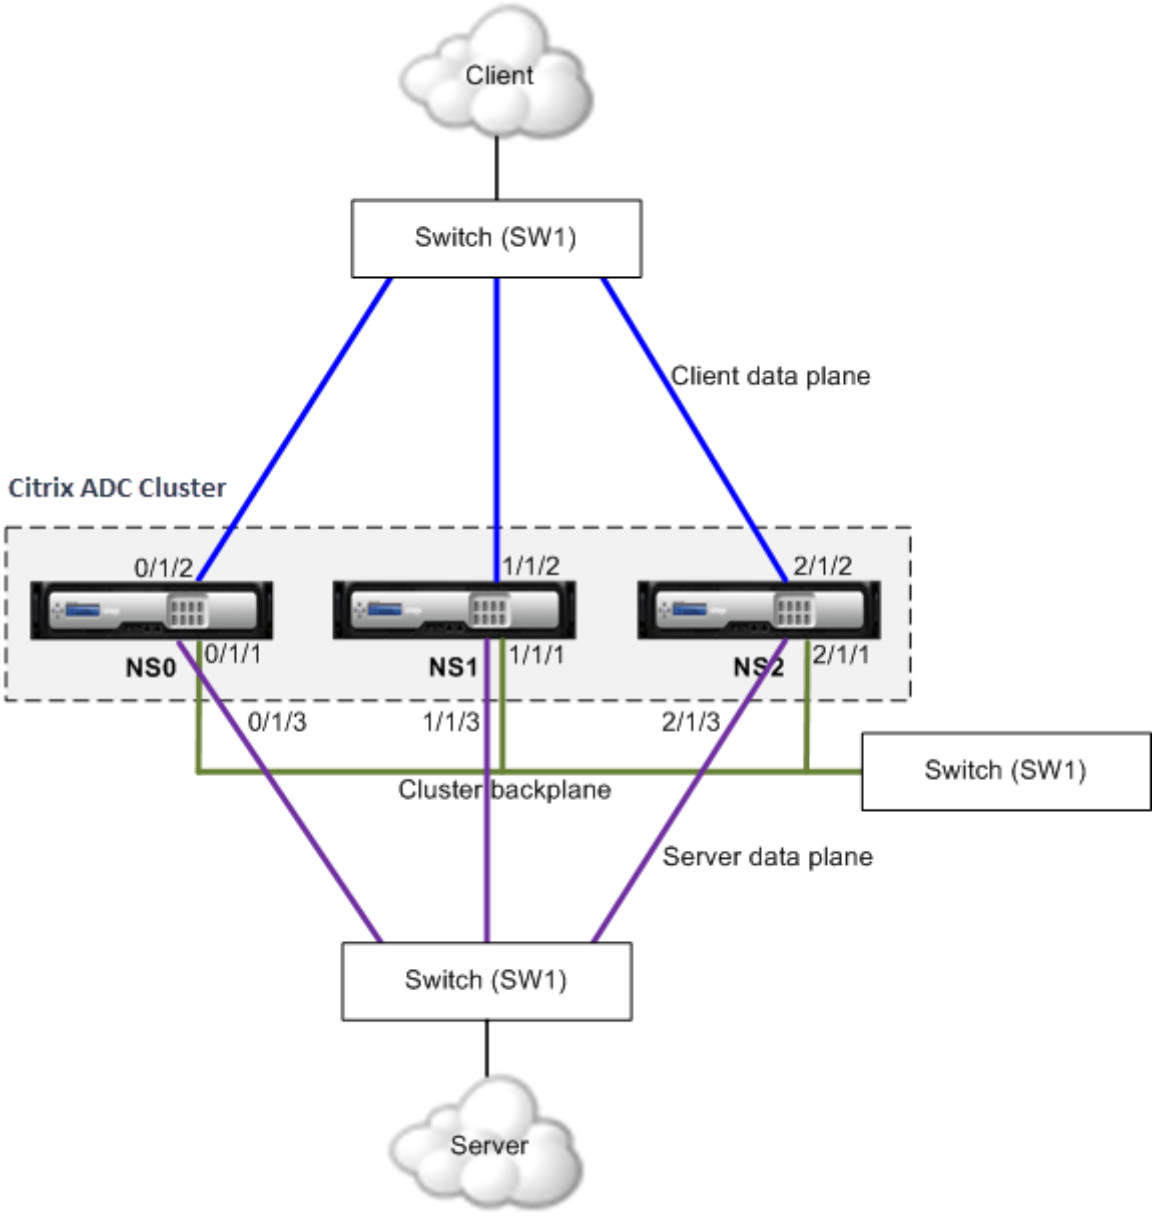
//For the interfaces connected to the client and server networks. Repeat for each interface…

```
> interface Ethernet2/47
  switchport access vlan 200
  switchport mode access
  end
```

Common switch for client, server, and backplane

September 14, 2021

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the Citrix ADC cluster.



- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common switch for the client, server, and backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```
1 > create cluster instance 1
```

```
> add cluster node 0 10.102.29.60 -state ACTIVE -backplane
   0/1/1
> enable cluster instance 1
> add ns ip 10.102.29.61 255.255.255.255 -type CLIP
> save ns config
> reboot -warm
```

3. Log on to the cluster IP address and do the following:

```
> add cluster node 1 10.102.29.70 -state ACTIVE -backplane
   1/1/1
> add cluster node 2 10.102.29.80 -state ACTIVE -backplane
   2/1/1
```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
> join cluster -clip 10.102.29.61 -password nsroot
> save ns config
> reboot -warm
```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   //For the backplane interfaces

```
> add vlan 10
> bind vlan 10 0/1/1 1/1/1 2/1/1
```

   //For the client-side interfaces

```
> add vlan 20
> bind vlan 20 0/1/2 1/1/2 2/1/2
```

   //For the server-side interfaces

```
> add vlan 30
> bind vlan 30 0/1/3 1/1/3 2/1/3
```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

   //For the backplane interfaces. Repeat for each interface…

```
> interface Ethernet2/47
  switchport access vlan 100
  switchport mode access
  end
```

//For the client interfaces. Repeat for each interface…

```
> interface Ethernet2/48
  switchport access vlan 200
  switchport mode access
  end
```

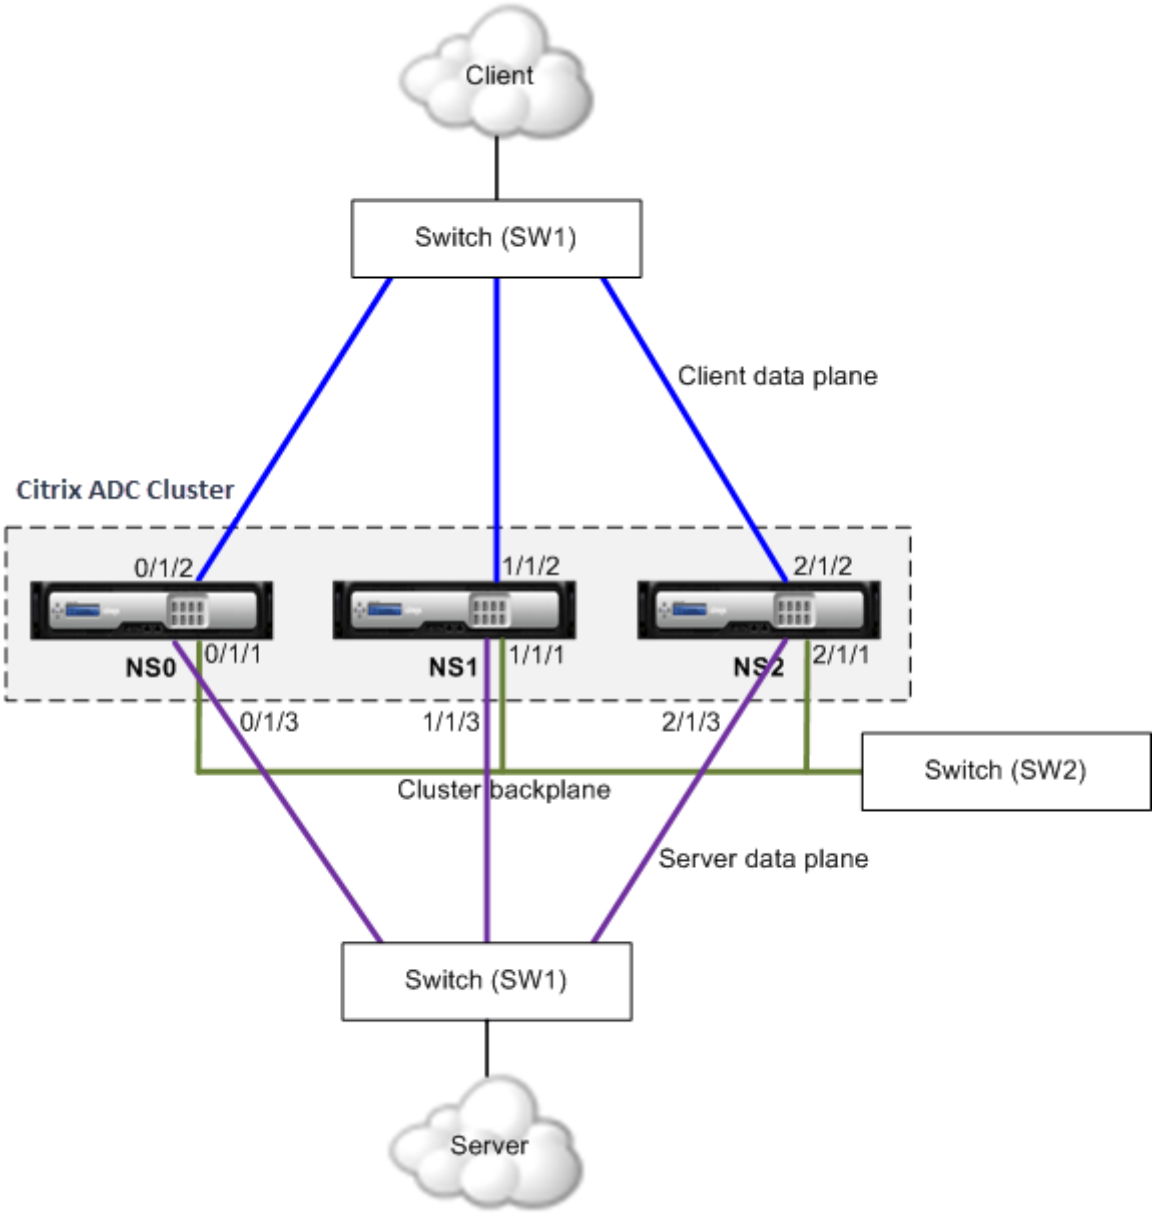
//For the server interfaces. Repeat for each interface…

```
> interface Ethernet2/49
  switchport access vlan 300
  switchport mode access
  end
```

Common switch for client and server and dedicated switch for backplane

September 14, 2021

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the Citrix ADC cluster. The cluster backplane uses a dedicated switch for inter-node communication.



- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
   - Log on to the first node that you want to add to the cluster and do the following:

```
> create cluster instance 1
> add cluster node 0 10.102.29.60 -state ACTIVE -backplane
   0/1/1
> enable cluster instance 1
> add ns ip 10.102.29.61 255.255.255.255 -type CLIP
> save ns config
> reboot -warm
```

- Log on to the cluster IP address and do the following:

```
> add cluster node 1 10.102.29.70 -state ACTIVE -backplane
   1/1/1
> add cluster node 2 10.102.29.80 -state ACTIVE -backplane
   2/1/1
```

- Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
> join cluster -clip 10.102.29.61 -password nsroot
> save ns config
> reboot -warm
```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   //For the backplane interfaces

```
> add vlan 10
> bind vlan 10 0/1/1 1/1/1 2/1/1
```

   //For the client-side interfaces

```
> add vlan 20
> bind vlan 20 0/1/2 1/1/2 2/1/2
```

   //For the server-side interfaces

```
> add vlan 30
> bind vlan 30 0/1/3 1/1/3 2/1/3
```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

   //For the backplane interfaces. Repeat for each interface…

```
> interface Ethernet2/47
> switchport access vlan 100
> switchport mode access
> end
```

//For the client interfaces. Repeat for each interface…

```
> interface Ethernet2/48
> switchport access vlan 200
> switchport mode access
> end
```

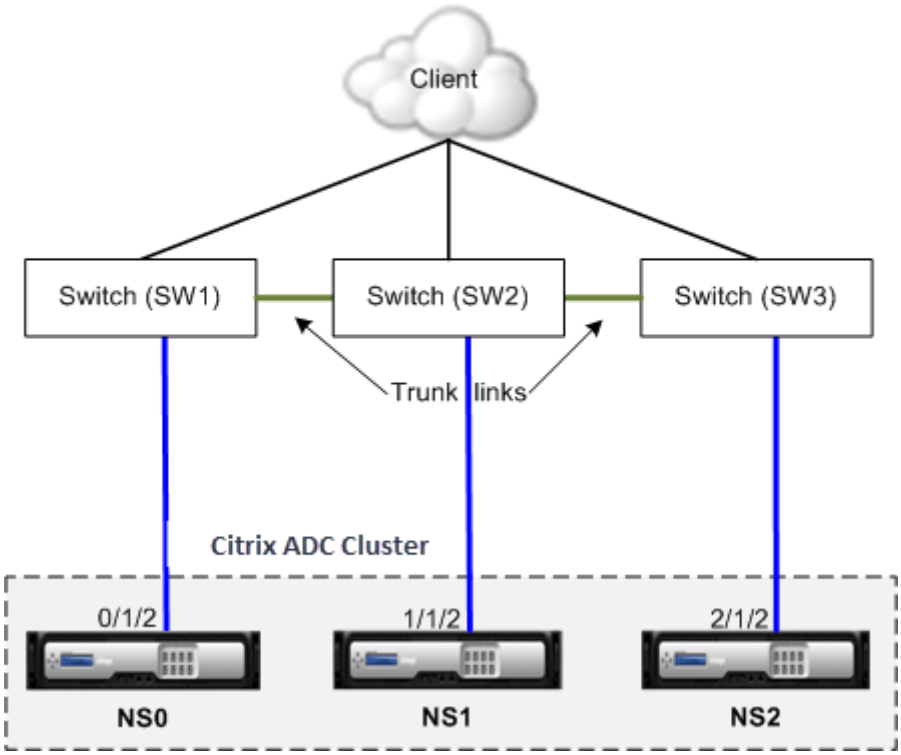
//For the server interfaces. Repeat for each interface…

```
> interface Ethernet2/49
> switchport access vlan 300
> switchport mode access
> end
```

Different switch for every node

September 14, 2021

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.



The cluster configurations are the same as the other deployments scenarios. Most of the client-side configurations is done on the client-side switches.

Sample cluster configurations

September 14, 2021

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.

1. Create the cluster.
   - Log on to the first node.
   - Add the cluster instance.

     ```
     1   > add cluster instance 1
     ```

   - Add the first node to the cluster.

     ```
     1   > add cluster node 0 10.102.33.184 -backplane 0/1/1
     ```

   - Enable the cluster instance.

     ```
     1   > enable cluster instance 1
     ```

- Add the cluster IP address.

```
1   > add ns ip 10.102.33.185 255.255.255.255 -type CLIP
```

- Save the configurations.

```
1   > save ns config
```

- Warm reboot the appliance.

```
1   > reboot -warm
```

2. Add the other three nodes to the cluster.
   - Log on to cluster IP address.
   - Add the second node to the cluster.

```
1   > add cluster node 1 10.102.33.187 -backplane 1/1/1
```

   - Add the third node to the cluster.

```
1   > add cluster node 2 10.102.33.188 -backplane 2/1/1
```

   - Add the fourth node to the cluster.

```
1   > add cluster node 3 10.102.33.189 -backplane 3/1/1
```

3. Join the added nodes to the cluster. This step is not applicable for the first node.
   - Log on to each newly added node.
   - Join the node to the cluster.

```
1   > join cluster -clip 10.102.33.185 -password nsroot
```

   - Save the configuration.

```
1   > save ns config
```

   - Warm reboot the appliance.

```
1   > reboot -warm
```

4. Configure the Citrix ADC cluster through the cluster IP address.

   // Enable load balancing feature

```
1      > enable ns feature lb
```

// Add a load balancing virtual server

```
1      > add lb vserver first_lbvserver http
2      ....
3      ....
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

   ECMP

   - Log on to the cluster IP address.
   - Enable the OSPF routing protocol.

     ```
     1   > enable ns feature ospf
     ```

   - Add a VLAN.

     ```
     1   > add vlan 97
     ```

   - Bind the interfaces of the cluster nodes to the VLAN.

     ```
     1   > bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
     ```

   - Add a spotted SNIP on each node and enable dynamic routing on it.

     ```
     1   > add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -
           dynamicRouting ENABLED
     2   > add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -
           dynamicRouting ENABLED
     3   > add ns ip 1.1.1.12 255.255.255.0 -ownerNode 2 -
           dynamicRouting ENABLED
     4   > add ns ip 1.1.1.13 255.255.255.0 -ownerNode 3 -
           dynamicRouting ENABLED
     ```

   - Bind one of the SNIP addresses to the VLAN.

     ```
     1   > bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
     ```

   - Configure the routing protocol on ZebOS by using the VTYSH shell.

     Static cluster LA

     - Log on to the cluster IP address.

- Add a cluster LA channel.

```
> add channel CLA/1 -speed 1000
```

- Bind the interfaces to the cluster LA channel.

```
> bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
```

- Perform an equivalent configuration on the switch.

  Dynamic cluster LA

  * Log on to the cluster IP address.
  * Add the interfaces to the cluster LA channel.

```
> set interface 0/1/5 -lacpmode active -lacpkey 5 -
    lagtype cluster
> set interface 1/1/5 -lacpmode active -lacpkey 5 -
    lagtype cluster
> set interface 2/1/5 -lacpmode active -lacpkey 5 -
    lagtype cluster
> set interface 3/1/5 -lacpmode active -lacpkey 5 -
    lagtype  cluster
```

  * Perform an equivalent configuration on the switch.

  Linksets. Assume that the node with nodeId 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

a) Log on to the cluster IP address.

b) Add a linkset.

```
> add linkset LS/1
```

c) Bind the connected interfaces to the linkset.

```
> bind linkset LS/1 -ifnum 0/1/6 1/1/6 2/1/6
```

6. Update the state of the cluster nodes to ACTIVE.

```
> set cluster node 0 -state ACTIVE
> set cluster node 1 -state ACTIVE
> set cluster node 2 -state ACTIVE
> set cluster node 3 -state ACTIVE
```

Using VRRP in a cluster setup

September 14, 2021

Virtual Router Redundancy Protocol (VRRP) is supported in a cluster setup for both IPv4 and IPv6. The two VRRP features supported in a cluster setup are Interface based VRRP and IP based VRRP.

IP based VRRP

In IP based VRRP, striped VIP addresses bound to the same VRID are configured on all nodes of a cluster setup. These VIP addresses are active on all the nodes

One of the cluster nodes acts as the VRID owner and sends out the VRRP advertisement to other nodes. If there is failure of the VRID owner node, another node in the cluster assumes the ownership of the VRID and starts sending VRRP advertisements. You can also assign a specific cluster node as the owner of the VRID.

> **Note**
>
> Citrix recommends you to use IP based method for VRRP deployment in cluster.

Configuring IP based VRRP for IPv4

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv4:

- **Add a VRID**. A VRID is an integer used by the Cluster setup to form a virtual MAC address. The generic VMAC address is in the form of 00:00:5e:00:02:<VRID>.
- **(Optional) Assign a node as the owner of the virtual MAC address**. You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC address. You can set the owner node using the `set vrID <id> -ownerNode <positive_interger>` command.
- **Bind the VRID to the VIP address of the nodes**. Bind the created VRID to the striped VIP address.

To add a VRID by using the CLI

At the command prompt, type:

```
1 -  add vrid <ID> [-ownerNode <positive_integer>]
2 -  show vrid <ID>
```

To bind the VRID to VIP address by using the CLI

At the command prompt, type:

- `set ns ip <IPv4Address> -vrid <ID><!--NeedCopy-->`
- `show vrid <ID><!--NeedCopy-->`

To add a VRID by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the Create **VMAC** page, specify a value in the **Virtual Router ID** field and then click **Create**.

To bind the VRID to a VIP address by using the GUI

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP configuration.

```
1 > add vrid 90
2  Done
3 > set ns ip 192.0.2.90  - vrid 90
4  Done
```

Configuring IP based VRRP for IPv6

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv6:

- **Add a VRID6**. A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:02:<VRID6>.
- **(Optional) Assign a node as the owner of the virtual MAC6 address**. You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC6 address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC6 address.
- **Bind the VRID6 to the VIP6 address of the nodes**. Bind the created VRID6 to the striped VIP6 address.

To add a VRID6 by using the CLI

At the command prompt, type:

- `add vrid6 <ID> [-ownerNode <positive_integer>]<!--NeedCopy-->`
- `show vrid6 <ID><!--NeedCopy-->`

To bind the VRID6 to VIP6 address by using the CLI

At the command prompt, type:

- `set ns ip6 <IPv6Address> -vrid6 <ID><!--NeedCopy-->`
- `show vrid6 <ID><!--NeedCopy-->`

To add a VRID6 by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field and then click **Create**.

To bind the VRID6 to a VIP6 address by using the GUI

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP6 configuration.

```
1 > add vrid6 90
2  Done
3 > set ns ip6 2001:db8::5001  - vrid6 90
4  Done
```

Interface based VRRP

In the interface based VRRP feature, the same virtual MAC address is configured on both the nodes of the cluster. This virtual MAC address is used in GARP advertisements and ARP responses for the IP addresses configured on a node. This feature is useful in an active-spare two-node cluster setup that has external devices/routers that do not accept GARP advertisements.

> **Note**
>
> The interface based VRRP feature is applicable only to a two-node cluster with one node in active state and the other node serving as a spare.

With the same virtual MAC address on both cluster nodes, when the active node goes down and the spare node takes over as active, the MAC address for the IP addresses on the new active node remain unchanged and the ARP tables on the external devices/routers do not need to be updated.

Configuring interface based VRRP for IPv4

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv4:

- **Add a VRID**. A VRID is an integer used by the Cluster setup to form a virtual MAC address.
- **Bind the VRID to node interfaces**. Bind the interfaces to the created VRID. The bound interfaces (in the current active node) use the virtual MAC address in GARP advertisements and ARP responses for its IPv4 addresses. You must associate the VRID to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

To add a VRID by using the CLI

At the command prompt, type:

```
- add vrid <ID>
- show vrid <ID>
```

To bind the VRID to an interface by using the CLI

At the command prompt, type:

```
- bind vrid <ID> -ifnum <interface_name>
- show vrid <ID>
```

To add a VRID and bind it to interfaces by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the **Create virtual MAC** page, specify a value in the **Virtual Router ID*** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
> add vrid 300
 Done
> bind vrid 300 -ifnum 1/1/2 2/1/3
 Done
```

Configuring interface based VRRP for IPv6

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv6:

- **Add a VRID6**. A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:01:<VRID6>.
- **Bind the VRID6 to node interfaces**. Bind the interfaces to the created VRID6. The bound interfaces (in the current active node) use the virtual MAC6 address in GARP advertisements and ARP responses for its IPv6 addresses. You must associate the VRID6 to the interfaces of both nodes

of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

To add a VRID6 by using the CLI

At the command prompt, type:

```
1 -  add vrid6 <ID>
2 -  show vrid6 <ID>
```

To bind the VRID6 to an interface by using the CLI

At the command prompt, type:

- `bind vrid6 <ID> -ifnum <interface_name><!--NeedCopy-->`
- `show vrid6 <ID><!--NeedCopy-->`

To add a VRID6 and bind it to interfaces by using the GUI

1. Navigate **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
1 > add vrid6 100
2  Done
3 > bind vrid6 100 -ifnum 0/1/1 1/1/2 2/1/3
4  Done
```

Monitoring services in a cluster using path monitoring

September 14, 2021

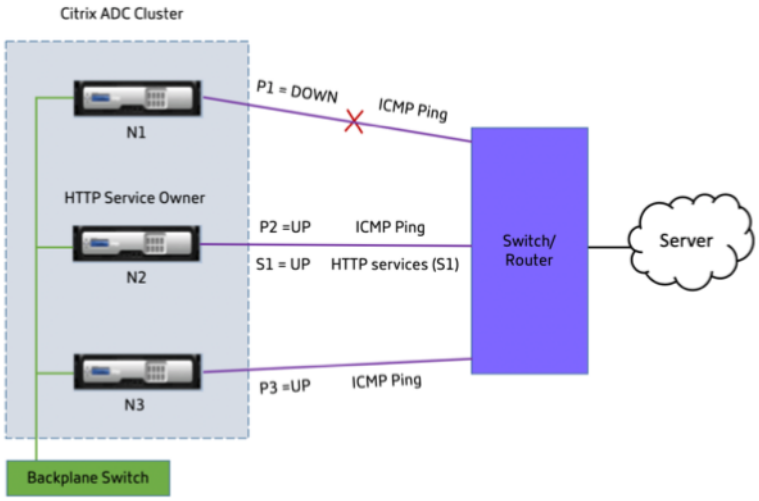
In a cluster setup, ownership for monitoring services is distributed among the nodes. Therefore, different nodes monitor different services. The node that monitors a service is called the service owner. Only the service owner probes the server to monitor the status of the services assigned to it. It further communicates the status of the services to all other nodes within the cluster. The drawback with distributed monitoring is that the network connectivity and link state between all nodes and the server is not determined. To overcome this drawback, you can use path monitoring.

> **Note**
>
> You cannot select a node to monitor a service. The selection of nodes to monitor a service is done through an internal mechanism. You can see the owner node to monitor services by using the `show service <service name>` and `show serviceGroup <service group name>` command.

Path monitoring checks the network connectivity and link state between a node and the service provided by the server. A node sends ICMP pings to verify whether the server is reachable or not.

How path monitoring works

Consider an example of a Citrix ADC cluster consisting of three nodes N1, N2, and N3. N2 is the service owner that monitors the state of HTTP services (S1). It advertises the service state to other nodes in the cluster. Path monitoring is enabled on all nodes in the cluster, for all the services. Each node sends only an ICMP ping to the server. The service owner sends both the HTTP service request and an ICMP ping. Each node reports its path monitoring state to the service owner.



The following two parameters determine the service state of a node:

- S = service state advertised by the service owner
- P = path monitoring state of each node

Whether a node can reach a server or not, determines the path monitoring state for that node.

The following table shows the service state set based on the path monitoring state, when the pathMonitorIndv parameter is enabled or disabled.

Parameter	Path monitoring state	Service state
pathMonitorIndv = NO; Is the default configuration.	P1 = DOWN	S1 = DOWN
	P2 = UP	S1 = DOWN
	P3 = UP	S1 = DOWN
pathMonitorIndv = YES	P1 = DOWN	S1 = DOWN
	P2 = UP	S1 = UP
	P3 = UP	S1 = UP

In this example, the service owner decides the service state for all the nodes based on the node whose path monitoring state is set to DOWN. If the path monitoring state for any of the nodes is DOWN, then the service owner sets the service state for all the nodes as DOWN. The service state for all the nodes is set to UP only if the path monitoring state for each of the node is UP.

You can use path monitoring for individual nodes by enabling the pathMonitorIndv parameter. This parameter enables the service owner to set the service state for each node based on the path monitoring state of that respective node.

> **Note**
>
> If the pathMonitorIndv parameter is set, some features like persistence might break.

Configuring path monitoring

Path monitoring is applicable for all the services and service groups. Path monitoring parameter is disabled by default.

To enable path monitoring for services/service groups by using the CLI

At the command prompt, type:

```
add service <service name> <IP address> <service type> <port> [-
    pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]

add servicegroup <servicegroup name> <service type> [-pathMonitor <YES
    | NO>] [-pathMonitorIndv <YES | NO>]
<!--NeedCopy-->
```

Example:

```
add service s1 1.1.1.1 HTTP 80 -pathMonitor YES
add servicegroup sg_1 HTTP -pathMonitor YES

add service s1 1.1.1.1 HTTP 80 -pathMonitor YES -pathMonitorIndv YES
add servicegroup sg_1 HTTP -pathMonitor YES -pathMonitorIndv YES
<!--NeedCopy-->
```

You can also set the path monitoring parameter from the set command, as follows:

```
set service <service name> [-pathMonitor <YES | NO>] [-pathMonitorIndv
   <YES | NO>]
set servicegroup <servicegroup name> [-pathMonitor <YES | NO>] [-
   pathMonitorIndv <YES | NO>]
<!--NeedCopy-->
```

Example:

```
set service s1 -pathMonitor YES
set servicegroup sg_1 -pathMonitor YES

set service s1 -pathMonitorIndv YES
set servicegroup sg_1 -pathMonitorIndv NO
<!--NeedCopy-->
```

To enable path monitoring for services/service groups by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.

   For service groups, navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.

2. In the **Services/Service Groups** pane, select a service/service group from the list, and then double-click to open it.
3. On the **Service Settings** tab, click **Edit**.
4. Select **Path Monitoring**.
5. Select **Individual Path Monitoring**, if you want to apply it, and then click **OK**.

> **Note**
>
> You can enable Individual Path Monitoring only if you enable Path Monitoring.

Backup and restore of cluster setup

September 14, 2021

You can back up the current state of a Citrix ADC cluster node. Later, you can use the backed-up files to restore the node to the same cluster state. As a precautionary measure, you must use this feature before performing an upgrade on the cluster nodes.

Back up a cluster Setup

You can take a basic or full backup depending on the following:

- Type of data to be backed up.
- Frequency at which you create a backup.
- **Basic back up.** Backs up only configuration files. You might want to perform this type of backup frequently, because the files it backs up change constantly. The files that are backed up are listed in the table.

Directory

Sub-Directory or Files

/nsconfig/

- ns.conf
- ZebOS.conf
- rc.netscaler
- snmpd.conf
- nsbefore.sh
- nsafter.sh
- inetd.conf
- ntp.conf
- syslog.conf
- newsyslog.conf
- crontab
- host.conf
- hosts
- ttys
- sshd_config
- httpd.conf
- monitrc
- rc.conf

- ssh_config
- local time
- issue
- issue.net

/var/

- download/*
- log/wicmd.log
- wi/tomcat/webapps/*
- wi/tomcat/logs/*
- wi/tomcat/conf/catalina/localhost/*
- nslw.bin/etc/krb.conf
- nslw.bin/etc/krb.keytab
- netscaler/locdb/*
- lib/likewise/db/*
- vpn/bookmark/*
- netscaler/crl
- nstemplates/*
- learnt_data/*

/netscaler/

- custom.html
- vsr.html
- **Full back up.** Apart from the files that are backed up by a basic backup, a full backup backs up some less frequently updated files. The files that are backed up when using the full backup option are listed in the table.

Directory

Sub-Directory or Files

/nsconfig/

- ssl/*
- license/*
- fips/*

/var/

- netscaler/ssl/*
- wi/java_home/jre/lib/security/cacerts/*
- wi/java_home/lib/security/cacerts/*

> **Important**
>
> The backup and restore do not work if CLAG is configured on an SDX cluster setup.

The backup is stored as a compressed TAR file in the /var/ns_sys_backup/ directory. To avoid issues due to non-availability of disk space, you can store a maximum of 50 backup files in this directory. You can use the rm system backup command to delete existing backup files so that you can create more backups.

When you perform the back-up operation on a CLIP of a cluster setup, back up files are created on each of the cluster nodes.

How to back up a cluster setup

To back up the cluster setup on CLIP by using the Citrix ADC CLI.

At the command prompt, do the following:

- Save the configuration.

  ```
  save ns config<!--NeedCopy-->
  ```

- Create the backup file (basic or full).

  "'create system backup [][–level (basic | full)][-comment]

  ```
  **Example**

  ```create system backup cluster-backup-1  -level basic<!--
     NeedCopy-->
  ```

The preceding command creates a back-up TAR file on each of the cluster node with the specified file name. For example, the CLUSTER-backup-1.tgz file is created on each of the cluster node.

> **Note**
>
> If the file name is not specified, back up TAR files are created on each of the cluster nodes with the following naming convention:
>
> - backup_<level>_<nsip_address of the cluster node 0>_<date-timestamp>.tgz<!--NeedCopy-->
> - backup_<level>_<nsip_address of the cluster node 1>_<date-timestamp>.tgz<!--NeedCopy-->
>
> For example, on a three node cluster setup,
>
> - backup_<level>_<nsip_address of the cluster node 0>_<date-timestamp>.tgz<!--NeedCopy--> is created on node0

  ```

- backup _<level>_<nsip_address of the cluster node 1>_<date-timestamp >.tgz<!--NeedCopy--> is created on node1
- backup_<level>_<nsip_address of the cluster node 2>_<date-timestamp >.tgz<!--NeedCopy--> is created on node2

- Verify the created backup files on CLIP.

  ```
  show system backup<!--NeedCopy-->
  ```

Restore a cluster setup

When a cluster node becomes faulty, you can replace this node with a new node. You can set the new node for a cluster, using a backup file of the faulty node.

For example, in a three-node cluster setup, if node1 becomes faulty, you can replace this faulty node with a new node as node1. Using the restore operation, you can restore one of the faulty node's backup files on the new node.

> **Note**
>
> The restore operation does not succeed if the backup file is renamed or if the contents of the file are modified.

How to restore a cluster node

To restore a cluster node by using the CLI

At the command prompt, do the following:

- Obtain a list of the backup files available on CLIP.

  ```
  show system backup<!--NeedCopy-->
  ```

- Copy the backup tar file to the /var/ns_sys_backup directory of the cluster node, which is to be restored.
- Add the backup tar file to the cluster node memory by running the following command on the cluster node.

  "'add system backup

  ```
  **Example**

  ```add system backup CLUSTER-BACKUP-1.tgz<!--NeedCopy-->
  ```

  > **Note**
  >
  > The command must be run on the cluster node to be restored.

  ```

- Restore the cluster node by specifying the backup file.

  “‘restore system backup

```
Example

```restore system backup CLUSTER-BACKUP-1.tgz<!--NeedCopy-->
```

> **Note**
>
> The command must be run on the cluster node to be restored.

- Reboot the cluster node.

  reboot

> **Note**
>
> The command must be run on the cluster node to be restored.

Upgrading or downgrading the Citrix ADC cluster

September 14, 2021

All the nodes of a Citrix ADC cluster must be running the same software version. Therefore, to upgrade or downgrade the cluster, you must upgrade or downgrade each Citrix ADC appliance of the cluster, one node at a time.

A node that is being upgraded or downgraded is not removed from the cluster. The node remains a part of the cluster and serves traffic uninterrupted, except for the downtime when the node reboots after it is upgraded or downgraded.

However, due to software version mismatch among the cluster nodes, configuration propagation is disabled on the cluster. Configuration propagation is enabled only after all the cluster nodes are of the same version. Since configuration propagation is disabled during upgrading on downgrading a cluster, you cannot perform any configurations through the cluster IP address during this time.

> **Important**
>
> - In a cluster setup with maximum connection (maxConn) global parameter set to a non-zero value, CLIP connections might fail if any of the following conditions is met:
>
```
- Upgrading the setup from Citrix ADC 13.0 76.x build to
  Citrix ADC 13.0 79.x build.
- Restarting the CCO node in a cluster setup running Citrix
  ADC 13.0 76.x build.
```

```

Workarounds:

```
- Before upgrading a cluster setup from Citrix ADC 13.0 76.x build to Citrix ADC 13.0 79.x build, maximum connection (maxConn) global parameter must be set to zero. After upgrading the setup, you can set the maxConn parameter to a desired value and then save the configuration.
- Citrix ADC 13.0 76.x build is not suitable for cluster setups. Citrix recommends not to use the Citrix ADC 13.0 76.x build for a cluster setup.
```

- In a cluster setup, a Citrix ADC appliance might crash, when:

```
- upgrading the setup from Citrix ADC 13.0 47.x or 13.0 52.x build to a later build, or
- upgrading the setup to Citrix ADC 13.0 47.x or 13.0 52.x build
```

Workaround: During the upgrade process, perform the following steps:

```
- Disable all cluster nodes and then upgrade each cluster node.
- Enable all cluster nodes after all the nodes are upgraded.
```

Points to note before upgrading or downgrading the cluster

- You cannot add cluster nodes while upgrading or downgrading the cluster software version.
- You can perform node-level configurations through the NSIP address of individual nodes. Make sure to perform the same configurations on all the nodes to maintain them in sync.
- You cannot run the `start nstrace` command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes using their NSIP address.
- Citrix ADC 13.0 76.x build is not suitable for cluster setups. Citrix recommends not to use the Citrix ADC 13.0 76.x build for a cluster setup.
- Citrix ADC 13.0 47.x and 13.0 52.x builds are not suitable for a cluster setup. It is because the inter-node communications are not compatible in these builds.
- When a cluster is being upgraded, it is possible that the upgraded nodes have some additional features activated that are unavailable on the nodes that are not yet upgraded. It results in a license mismatch warning while the cluster is being upgraded. This warning is automatically resolved when all the cluster nodes are upgraded.

> **Important**
>
> - Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.
> - Citrix recommends that the cluster configuration node must be upgraded/downgraded last to avoid multiple disconnects of cluster IP sessions.

To upgrade or downgrade the software of the cluster nodes

1. Make sure the cluster is stable and the configurations are synchronized on all the nodes.
2. Access each node through its NSIP address and perform the following:
   - Upgrade or downgrade the cluster node. For detailed information about upgrading and downgrading the software of an appliance, see Upgrade and downgrade a NetScaler appliance.
   - Save the configurations.
   - Reboot the appliance.
3. Repeat step 2 for each of the other cluster nodes.

Operations supported on individual cluster nodes

September 14, 2021

As a rule, Citrix ADC appliances that are a part of a cluster cannot be individually configured from their NSIP address. However, there are some operations that are an exception to this rule. These operations, when run from the NSIP address, are not propagated to other cluster nodes.

The operations are:

cluster instance (set	rm	enable	disable)

-

cluster node (set	rm)

-

ns trace (start	show	stop)

-

interface (set	enable	disable)

-

route (add	rm	set	unset)

-

ARP (add	rm	send -all)

-
- force cluster sync
- sync cluster files
- disable NTP sync
- save ns config
- reboot
- shutdown

For example, when you run the command `disable interface 1/1/1` from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

Support for heterogeneous cluster

September 14, 2021

Citrix ADC appliance supports a heterogeneous cluster in a cluster deployment. A heterogeneous cluster spans nodes of different Citrix ADC hardware and you can have a combination of different platforms in the same cluster.

> **Important**
>
> The formation or supportability of a heterogeneous cluster is possible and limited only to MPX hardware platforms.

The supportability and formation of the heterogeneous cluster depend on certain Citrix ADC models. The following table lists the platforms that are supported in the formation of a heterogeneous cluster, with an equal number of packet engines.

Number of Packet Engines	MPX Hardware Platforms	Supported MPX Hardware Platforms to form Heterogeneous Cluster
5	MPX 11500	MPX 14020
7	MPX 11515	MPX 14040
9	MPX 11530	MPX 14060

The following table lists the platforms that are supported in the formation of a heterogeneous cluster, with an unequal number of packet engines.

Hardware Platforms	Supported Hardware Platforms to form Heterogeneous Cluster
MPX 150XX	MPX 140XX

For more information on how to form a heterogeneous cluster deployment of Citrix ADC MPX appliances with the different number of packet engines across different SSL chipsets, see the **Heterogeneous cluster deployments** section in SSL offloading configuration.

> **Note**
>
> Before release 13.0 build 47.x, if you run the “join cluster” command from the node that has an unequal number of packet engines, the following error message appears: “Mismatch in the number of active PPEs between CCO and local node”.

Points to note

1. The extra management CPU setting must be the same on all the cluster nodes.
2. The newly added node must have the same capacity on the data planes and backplane, as that of existing cluster nodes.

3. If there are mixed platform devices supporting different ciphers, then the cluster would agree upon a common cipher list.

FAQs

September 14, 2021

A list of the FAQ about clustering.

How many Citrix ADC appliances can be included in a single Citrix ADC cluster?

A Citrix ADC cluster can include one appliance or as many as 32 Citrix ADC nCore hardware or virtual appliances. Each of these nodes must satisfy the criteria specified in Prerequisites for Cluster Nodes.

Can a Citrix ADC appliance be a part of multiple clusters?

No. A Citrix ADC appliance can belong to one cluster only.

What is a cluster IP address? What is its subnet mask?

The cluster IP address is the management address of a Citrix ADC cluster. All cluster configurations must be performed by accessing the cluster through this address. The subnet mask of the cluster IP address is fixed at 255.255.255.255.

How can I make a specific cluster node as the cluster configuration coordinator?

To manually set a specific node as the cluster configuration coordinator, you must set the priority of that node to the lowest numeric value (highest priority). To understand, let us consider a cluster with three nodes that have the following priorities:

n1 - 29, n2 - 30, n3 - 31

Here, n1 is the configuration coordinator. If you want to make n2 the configuration coordinator, you must set its priority to a value that is lower than n1, for example, 28. On saving the configuration, n2 becomes the configuration coordinator.

> **Note**
>
> n2 with its original priority value of 30 becomes the configuration coordinator when n1 goes down. The node with the next lowest priority value is selected in case the configuration coordinator goes down.

Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation?

When a Citrix ADC appliance is part of a cluster, you must be able to identify the node to which the interface belongs. Therefore, the network interface naming convention for cluster nodes is modified from u/c to n/u/c, where n denotes the node Id.

How can I set the host name for a cluster node?

The host name of a cluster node must be specified by running the **set ns hostname** command through the cluster IP address. For example, to set the host name of the cluster node with ID 2, the command is:

set ns hostname hostName1 -**ownerNode** 2

Can I automatically detect Citrix ADC appliances so that I can add them to a cluster?

Yes. The configuration utility allows you to discover appliances that are present in the same subnet as the NSIP address of the configuration coordinator. For more information, see Discovering NetScaler Appliances.

Is the traffic serving capability of a cluster affected if a node is removed or disabled or reboot or shutdown or made inactive?

Yes. When any of these operations are performed on an active node of the cluster, the cluster has one less node to serve traffic. Also, existing connections on this node are terminated.

I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster?

Yes. You can add appliances that have different configurations to a single cluster. However, when the appliance is added to the cluster, the existing configurations are cleared. To use the configurations that are available on each of the individual appliances, you must:

1. Create a single *.conf file for all the configurations.
2. Edit the configuration file to remove features that are not supported in a cluster environment.
3. Update the naming convention of interfaces from 2-tuple (u/c) format to 3-tuple (n/u/c) format.
4. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.

Can I migrate the configurations of a standalone Citrix ADC appliance or an HA setup to the clustered setup?

No. When a node is added to a clustered setup, its configurations are implicitly cleared by using the **clear ns config** command (with the **extended** option). In addition, the SNIP addresses and all VLAN configurations (except default VLAN and NSVLAN) are cleared. Therefore, it is recommended that you back up the configurations before adding the appliance to a cluster. Before using the backed-up configuration file for the cluster, you must:

1. Edit the configuration file to remove features that are not supported in a cluster environment.
2. Update the naming convention of interfaces from two-tuple (x/y) format to three-tuple (x/y/z) format.
3. Apply the configurations to the configuration coordinator node of the cluster by using the **batch** command.

Is backplane interfaces part of the L3 VLANs?

Yes, by default, backplane interfaces have presence on all the L3 VLANs that are configured on the cluster.

How can I configure a cluster that includes nodes from different networks?

> **Note**
>
> Supported from NetScaler 11.0 onwards.

A cluster that includes nodes from different networks is called a L3 cluster (sometimes referred to as a cluster in INC mode). In an L3 cluster, all nodes that belong to a single network must be grouped in a single node group. Therefore, if a cluster includes two nodes each from three different networks, you have to create 3 node groups (one for each network) and associate each of these node groups with the nodes that belong to that network. For configuration information, see the steps to set up a cluster.

How can I configure/un-configure the NSVLAN on a cluster?

Do either one of the following:

- To make the NSVLAN available in a cluster, make sure that each appliance has the same NSVLAN configured before it is added to a cluster.
- To remove the NSVLAN from a cluster node, first remove the node from the cluster and then delete the NSVLAN from the appliance.

I have a cluster set up where some Citrix ADC nodes are not connected to the external network. Can the cluster still function normally?

Yes. The cluster supports a mechanism called linksets, which allows unconnected nodes to serve traffic by using the interfaces of connected nodes. The unconnected nodes communicate with the connected nodes through the cluster backplane. For more information, see Using Linksets.

How can deployments that require MAC-Based Forwarding (MBF) be supported in a clustered setup?

Deployments that use MBF must use linksets. For more information, see Using Linksets.

Can I run commands from the NSIP address of a cluster node?

No. Access to individual cluster nodes through the NSIP addresses is read-only. Therefore, when you log on to the NSIP address of a cluster node you can only view the configurations and the statistics. You cannot configure anything. However, there are some operations you can run from the NSIP address of a cluster node. For more information, see Operations Supported on Individual Nodes.

Can I disable configuration propagation among cluster nodes?

No, you cannot explicitly disable the propagation of cluster configurations among cluster nodes. However, during a software upgrade or downgrade, a version mismatch error can automatically disable configuration propagation.

Can I change the NSIP address or change the NSVLAN of a Citrix ADC appliance when it is a part of the cluster?

No. To make such changes you must first remove the appliance from the cluster, perform the changes, and then add the appliance to the cluster.

Does the Citrix ADC cluster support L2 and L3 VLANs?

Yes. A cluster supports VLANs between cluster nodes. The VLANs must be configured on the cluster IP address.

- **L2 VLAN.** You can create a layer2 VLAN by binding interfaces that belong to different nodes of the cluster.
- **L3 VLAN.** You can create a layer3 VLAN by binding IP addresses that belong to different nodes of the cluster. The IP addresses must belong to the same subnet. Make sure that one of the following criteria is satisfied. Otherwise, the L3 VLAN bindings can fail.

- All nodes have an IP address on the same subnet as the one bound to the VLAN.
- The cluster has a striped IP address and the subnet of that IP address is bound to the VLAN.

When you add a node to a cluster that has only spotted IPs, the sync happens before spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings on the NSIP of the newly added node.

How can I configure SNMP on a Citrix ADC cluster?

SNMP monitors the cluster, and all the nodes of the cluster, in the same way that it monitors a standalone appliance. The only difference is that SNMP on a cluster must be configured through the cluster IP address. When generating hardware specific traps, two more varbinds are included to identify the node of the cluster: node ID and NSIP address of the node.

What details must I have available when I contact technical support for cluster-related issues?

The Citrix ADC appliance provides a **show techsupport -scope cluster** command that extracts configuration data, statistical information, and logs of all the cluster nodes. Run this command on the cluster IP address.

The output of this command is saved in a file named *collector_cluster_<nsip_CCO>_P_<date-timestamp>.tar.gz* which is available in the */var/tmp/support/cluster/* directory of the configuration coordinator.

Send this archive to the technical support team to debug the issue.

Can I use striped IP addresses as the default gateway of servers?

In cluster deployments, make sure the default gateway of the server points to a striped IP address (if you are using a Citrix ADC-owned IP address). For example, in the case of LB deployments with USIP enabled, the default gateway must be a striped SNIP address.

Can I view the routing configurations of a specific cluster node from the cluster IP address?

Yes. You can view and clear the configurations specific to a node by specifying the owner node while entering the VTYSH shell.

For example, to view the output of a command on nodes 0 and 1, the command is as follows:

```
1 \> vtysh
2 ns# owner-node 0 1
```

```
ns(node-0 1)\# show cluster state
ns(node-0 1)\# exit-cluster-node
ns\#
```

How can I specify the node for which I want to set the LACP system priority?

> **Note**
>
> Supported from NetScaler 10.1 onwards.

In a cluster, you must set that node as the owner node by using the **set lacp** command.

For example: To set the LACP system priority for a node with ID 2:

```
set lacp -sysPriority 5 -ownerNode 2<!--NeedCopy-->
```

How are IP tunnels configured in a cluster setup?

> **Note**
>
> Supported from NetScaler 10.1 onwards.

Configuring IP tunnels in a cluster is the same as on a standalone appliance. The only difference is that in a cluster setup, the local IP address must be a striped SNIP address.

How can I add a failover interface set (FIS) on the nodes of a Citrix ADC cluster?

> **Note**
>
> Supported from NetScaler 10.5 onwards.

On the cluster IP address, specify the ID of the cluster node on which the FIS must be added, using the command as follows:

```
add fis <name> -ownerNode <nodeId>
```

> **Notes**
>
> - The FIS name for each cluster node must be unique.
> - A cluster LA channel can be added to a FIS. You make sure that the cluster LA channel has a local interface as a member interface.

For more information on FIS, see Configuring failover interface set.

How are net profiles configured in a cluster setup?

> **Note**
>
> Supported from NetScaler 10.5 onwards.

You can bind spotted IP addresses to a net profile. This net profile can then be bound to a spotted load balancing virtual server or service (that is defined using a node group). The following recommendations must be followed, failing which, the net profile configurations are not honored and the USIP/USNIP settings are used:

> **Note**
>
> - If the **strict** parameter of the node group is set to **Yes**, the net profile must contain a minimum of one IP address from each node group member.
> - If the **strict** parameter of the node group is set to **No**, the net profile must include at least one IP address from each of the cluster nodes.

How can I configure WIonNS in a cluster setup?

> **Note**
>
> Supported from NetScaler 11.0 Build 62.x onwards.

To use WIonNS on a cluster, you must do the following:

1. Make sure that the Java package and the WI package are present in the same directory on all the cluster nodes.
2. Create a load balancing virtual server that has persistency configured.
3. Create services with IP addresses as the NSIP address of each of the cluster nodes that you want to serve WI traffic. This step can only be configured using the Citrix ADC CLI.
4. Bind the services to the load balancing virtual server.

> **Note**
>
> If you are using WIonNS over a VPN connection, make sure that the load balancing virtual server is set as WIHOME.

Can the cluster LA channel be used for management access?

No. Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. It is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down, and therefore looses management access.

How cluster nodes communicate to each other and what are the different types of traffic that goes through the backplane?

A backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through a backplane, which is used by internode communication are:

- Node to Node Messaging (NNM)
- Steered traffic
- Configuration propagation and synchronization

Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: **0x02 0x00 0x6F <cluster_id> <node_id> <reserved>**, where <cluster_id> is the cluster instance ID. The <node_id> is the node number of the Citrix ADC appliance that is added to a cluster.

> **Note**
>
> The amount of traffic that is handled by a backplane has negligible CPU overhead.

What gets routed over the GRE tunnel for the Layer 3 cluster?

Only steered data traffic goes over the GRE tunnel. The packets are steered through the GRE tunnel to the node on the other subnet.

How Node to Node Messaging (NNM) and heartbeat messages are exchanged, and how are they routed?

The NNM, heartbeat messages, and cluster protocol are non-steering traffic. These messages are not sent through the tunnel, but they are routed directly.

What are the MTU recommendations when Jumbo frames are enabled for layer 3 cluster tunneled traffic?

The following are the layer 3 cluster recommendations of Jumbo MTU over GRE tunnel:

- The Jumbo MTU can be configured among cluster nodes across the L3 path to accommodate GRE tunnel overhead.
- The fragmentation does not happen for full sized packets which must be steered.
- Steering of traffic continues to work even if Jumbo frames are not allowed, but with more overhead due to fragmentation.

How the global hash key is generated and shared across all nodes?

The `rsskey` for a standalone appliance is generated at the boot time. In a cluster setup, the first node holds the `rsskey` of the cluster. Every new node joining to the cluster synchronizes the `rsskey`.

What is the need of `set rsskeytype -rsskey symmetric` command for *:*, USIP on, `useproxyport` off, topologies?

It is not specific to a cluster, applies to a standalone appliance as well. With USIP ON, and use proxy port disabled, symmetric `rsskey` reduces both Core to Core (C2C) steering and node to node steering.

What are the factors that contribute to change the CCO node?

The first node added to form a cluster setup becomes the configuration coordinator (CCO) node. The following factors contribute to change the CCO node in the cluster setup:

- When the current CCO node is removed from the cluster setup
- When the current CCO node crashes
- When the priority of the non-CCO node is changed (lower priority has higher precedence)
- In dynamic conditions like, network reachability between the nodes
- When there is change in node states – active, spare, and passive. Active nodes are preferred as CCO.
- When there is a change in configuration, and the node having the latest configuration is preferred as CCO.

Troubleshooting the Citrix ADC cluster

September 14, 2021

If a failure occurs in a Citrix ADC cluster, the first step in troubleshooting is to get information on the cluster instance. You can get the information by running the `show cluster instance clId` and `show cluster node nodeId` commands on the cluster nodes respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.
- **Check the commands recently executed.** Run the history command to check the recent configurations performed on the cluster. You can also review the ns.conf file to verify the configurations that have been implemented.

- **Check the ns.log files.** Use the log files, available in the /var/log/ directory of each node, to identify the commands run, the status of commands, and the state changes.
- **Check the newnslog files.** Use the `newnslog` files, available in the /var/nslog/ directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple `newnslog` files as a single file, by copying the files to a single directory, and then running the following command:

```
nsconmsg -K newnslog-node<id> -K     newnslog.node<id> -d current
```

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the show `techsupport -scope cluster` command. You can use the command to send the report to the technical support team.

Tracing the packets of a Citrix ADC cluster

September 14, 2021

The Citrix ADC operating system provides a utility called *ns trace* to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the Wireshark application.

Some salient aspects of the ns trace utility are:

- Can be configured to trace packets selectively by using classic expressions and default expressions.
- Can capture the trace in multiple formats: ns trace format (.cap) and TCP dump format (.pcap).
- Can aggregate the trace files of all cluster nodes on the configuration coordinator.
- Can merge multiple trace files into a single trace file (only for.cap files).

You can use the ns trace utility from the Citrix ADC command line or the Citrix ADC shell.

To trace packets of a standalone appliance

Run the start ns trace command on the appliance. The command creates trace files in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id\ >.cap.

You can view the status by running the show ns trace command. You can stop tracing the packets by running the stop ns trace command.

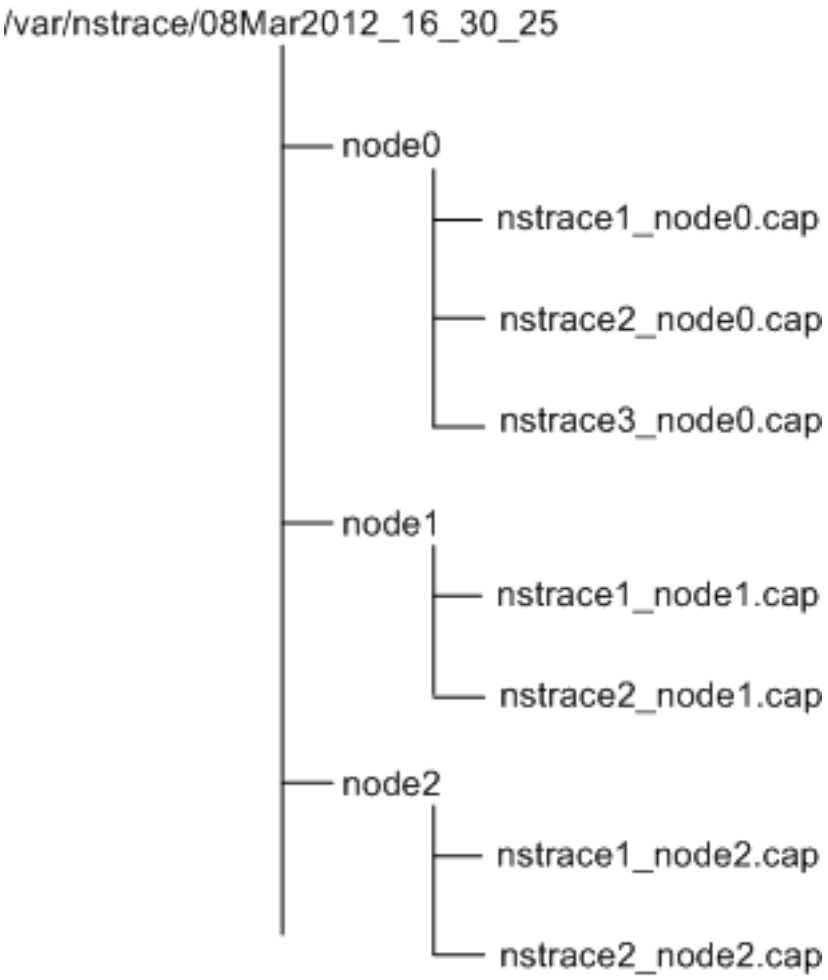
> **Note**
>
> You can also run the ns trace utility from the Citrix ADC shell by running the nstrace.sh file. However, it is recommended that you use the ns trace utility through the Citrix ADC command line interface.

To trace packets of a cluster

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the start ns trace command on the cluster IP address. The command is propagated and run on all the cluster nodes. The trace files are stored in individual cluster nodes in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>_node<id\ >.cap.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the stop ns trace command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the /var/nstrace/<date-timestamp> directory as follows:



Merge multiple trace files

You can prepare a single file from the trace files (supported only for. Cap files) obtained from the cluster nodes. The single trace files give you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the Citrix ADC shell, type:

```
1 > nstracemerge.sh -srcdir \<DIR\> -dstdir \<DIR\> -filename \<name\> -
    filesize \<num\>
```

Where,

- `srcdir` is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- `dstdir` is the directory where the merged trace file is created.
- `Filename` is the name of the trace file that is created.

- `Filesize` is the size of the trace file.

Examples

Following are some examples of using the ns trace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:

  Using classic expressions:

```
1   > start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF
      == 2/1/1"
```

  Using default expressions:

```
1   > start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") &&
      CONNECTION.INTF.EQ("1/1/1") && CONNECTION.INTF.EQ("2/1/1")"
```

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not “s1”:

  Using classic expressions

```
1   > start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME !=
      s1 && SOURCEPORT > 80)"
```

  Using default expressions

```
1   > start nstrace -filter "CONNECTION.SRCIP.EQ(10.102.34.201) || (
      CONNECTION.SVCNAME.NE("s1") && CONNECTION.SRCPORT.GT(80))"
```

> **Note**
>
> For more information about filters used in ns trace, see ns trace.

Capturing SSL Session Keys During a Trace

When you run the “start ns trace” command, you can set the new `capsslkeys` parameter to capture the SSL master keys for all SSL sessions. If you include this parameter, a file named nstrace.sslkeys is generated along with the packet trace. This file can be imported into Wireshark to decrypt the SSL traffic in the corresponding trace file.

This functionality is similar to web browsers exporting session keys that can later be imported into Wireshark for decrypting SSL traffic.

Advantages of using SSL session keys

Following are the advantages of using SSL session keys:

1. Generates smaller trace files that do not include the extra packets created by the SSLPLAIN mode of capturing.
2. Provides the ability to view plaintext [SP(1] from the trace and choose whether to share the master keys file or protect sensitive data by not sharing it.

Limitations of using SSL session keys

Following are the limitations of using SSL session keys:

1. SSL sessions cannot be decrypted if the initial packets of the session are not captured.
2. SSL sessions cannot be captured if the Federal Information Processing Standard (FIPS) mode is enabled.

To capture SSL session keys by using the command line interface (CLI)

At the command prompt, type the following commands to enable or disable SSL session keys in a trace file and verify trace operation.

```
1  > start nstrace -capsslkeys ENABLED
2  > show nstrace
3  Example
4  > start nstrace -capsslkeys ENABLED
5  > show nstrace
6        State:  RUNNING          Scope:  LOCAL            TraceLocation:
             "/var/nstrace/04May2016_17_51_54/..."
7        Nf:  24                  Time:  3600              Size:  164
                        Mode:  TXB NEW_RX
8        Traceformat:  NSCAP      PerNIC:  DISABLED        FileName:  04
            May2016_17_51_54 Link:  DISABLED
9        Merge:  ONSTOP           Doruntimecleanup:  ENABLED TraceBuffers:
              5000      SkipRPC:  DISABLED
10       SkipLocalSSH:  DISABLED  Capsslkeys:  ENABLED     InMemoryTrace:
             DISABLED
11   Done
```

To configure SSL session keys by using the Citrix ADC GUI

1. Navigate to **Configuration > System > Diagnostics > Technical Support Tools** and click **Start new Trace** to start tracing encrypted packets on an appliance.

2. On the **Start Trace** page, select the **Capture SSL Master Keys** check box.
3. Click **OK** and **Done**.

To import the SSL Master Keys into Wireshark

On the Wireshark GUI, navigate to **Edit > Preferences > Protocols > SSL > (Pre)-Master-Secret log filename** and specify the master key files obtained from the appliance.

Troubleshooting common issues

September 14, 2021

While joining a node to the cluster, I get the following message, "ERROR: Invalid interface name/number." What must I do to resolve this error?

The said error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance's management interface as the backplane interface, and that the <nodeId> bit of the interface is the same as the node's Id. For example, if the nodeId is 3, the backplane interface must be 3/<c>/<u>.

While joining a node to the cluster, I get the following message, "ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster." What must I do to resolve this error?

This error occurs when you try to join a node without adding the node's NSIP to the cluster. To resolve this error, you must first add the node's NSIP address to the cluster by using the **add cluster node** command and then run the **join cluster** command.

While joining a node to the cluster, I get the following message, "ERROR: Connection refused." What must I do to resolve this error?

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.
- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a cluster IP address and try rejoining the cluster.

While joining a node to the cluster, I get the following message, “ERROR: License mismatch between the configuration coordinator and the local node.” What must I do to resolve this error?

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

From the command line:

- `show ns hardware`
- `show ns license`

From the shell:

- `nsconmsg -g feature -d stats`
- `ls /nsconfig/license`
- View the contents of the /var/log/license.log file

What must I do when the configurations of a cluster node are not in synchronize with the cluster configurations?

Usually, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by running the force cluster sync command from the node that you want to synchronize. For more information, see Synchronizing Cluster Configurations.

When configuring a cluster node, I get the following message, “ERROR: Session is read-only; connect to the cluster IP address to modify the configuration.”

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NSIP address of individual nodes are read-only.

Why does the node state show “INACTIVE” when the node health shows “UP”?

A healthy node can be in the INACTIVE state for various reasons. A scan of the ns.log or error counters can help you determine the exact reason.

How can I resolve the health of a node when its health shows “NOT UP”?

Node health “**Not UP**” indicates that there are some issues with the node. To know the root cause, you must run the **show cluster node** command. This command displays the node properties and the

reason for the node failure.

What must I do when the health of a node shows as "NOT UP" and the reason indicates that configuration commands have failed on a node?

This issue arises when some commands are not run on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see Synchronizing Cluster Configurations.
- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.

When I run the set virtual server command, I get the following message, "No such resource." What must I do to resolve this issue?

The **set vserver** command is not supported in clustering. The **unset vserver, enable vserver, disable vserver,** and **rm vserver** commands are also not supported. However, the **show vserver** command is supported.

I cannot configure the cluster over a Telnet session. What must I do?

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?

When PTP packets are dropped due to the backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized.

To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.

   set ptp -state disable

2. Configure Network Time Protocol (NTP) for the cluster. For more information, see Setting up Clock Synchronization.

What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?

If you cannot access to the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by running the following command at the shell prompt:

"'# ssh nsroot@

```
## What must I do to recover a cluster node that has connectivity
   issues?

To recover a node that has connectivity issues:

1.  Disable the cluster instance on that node (since you cannot run
   commands from the NSIP of a cluster node).

1.  Run the commands required to recover the node.

1.  Enable the cluster instance on that node.

## Some nodes of the cluster have two default routes. How can I remove
   the second default route from the cluster node?

To delete the additional default route, do the following on each node
   that has the extra route:

1.  Disable the cluster instance.

    ```disable cluster instance <clId><!--NeedCopy-->
```

1. Remove the route.

   ```
   rm route <network> <netmask> <gateway><!--NeedCopy-->
   ```

2. Enable the cluster instance.

   ```
   enable cluster instance <clId><!--NeedCopy-->
   ```

The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue?

If the RPC password of a node is changed from the cluster IP address when that node is out of the cluster, then, when the node comes online, there is a mismatch in RPC credentials and can affect cluster functionality. To solve this issue, use the set ns rpcNode command to update the password on the NSIP of the node which has come online.

   ```

# Content Switching

September 14, 2021

In today's complex websites, you might want to present different content to different users. For example, you might want to allow users from the IP range of a customer or partner to have access to a special Web portal. You might want to present content relevant to a specific geographical area to users from that area. You might want to present content in different languages to the speakers of those languages. You might want to present content tailored to specific devices, such as smartphones, to them who use the devices. The Citrix ADC content switching feature enables the appliance to distribute client requests across multiple servers based on specific content that you want to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.

## How Content Switching Works

Content Switching enables the Citrix ADC appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content based on various client attributes. Some of those client attributes are:

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server, capable of serving content that the user can view on the cell phone. A request from a computer is directed to a different server, capable of serving content designed for a computer screen.
- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client's browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on

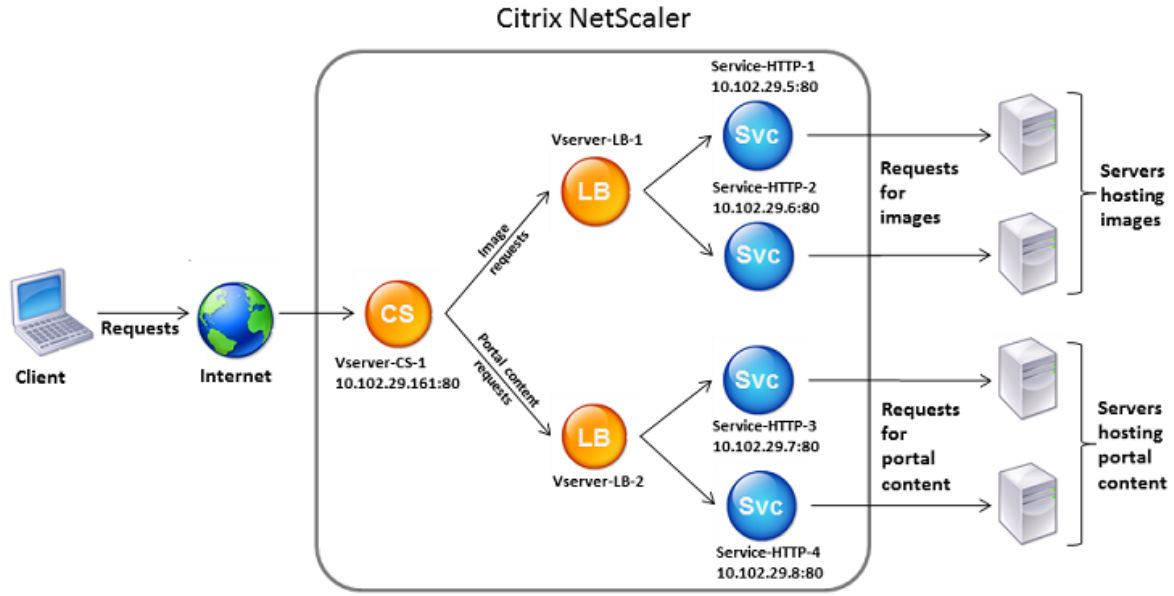
 

language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.

- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.
- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to a faster server that handles dynamic content.
- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

Figure 1. Content Switching Architecture



A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies

and load balancing virtual servers. This process creates a *content group*—a group of all virtual servers and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using Citrix ADC classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the Citrix ADC appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see Configuring Default Syntax Policies.

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer, you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.

## Configuring basic content switching

September 14, 2021

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of websites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create more content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

> **Note**
>
> After creating a content group, you can modify its content switching virtual server to customize the configuration.

### Enabling content switching

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.

### To enable content switching by using the CLI

At the command prompt, type the following commands to enable content switching and verify the configuration:

```
enable ns feature CS

show ns feature
<!--NeedCopy-->
```

Example:

```
> enable  feature ContentSwitch
    Done
> show feature

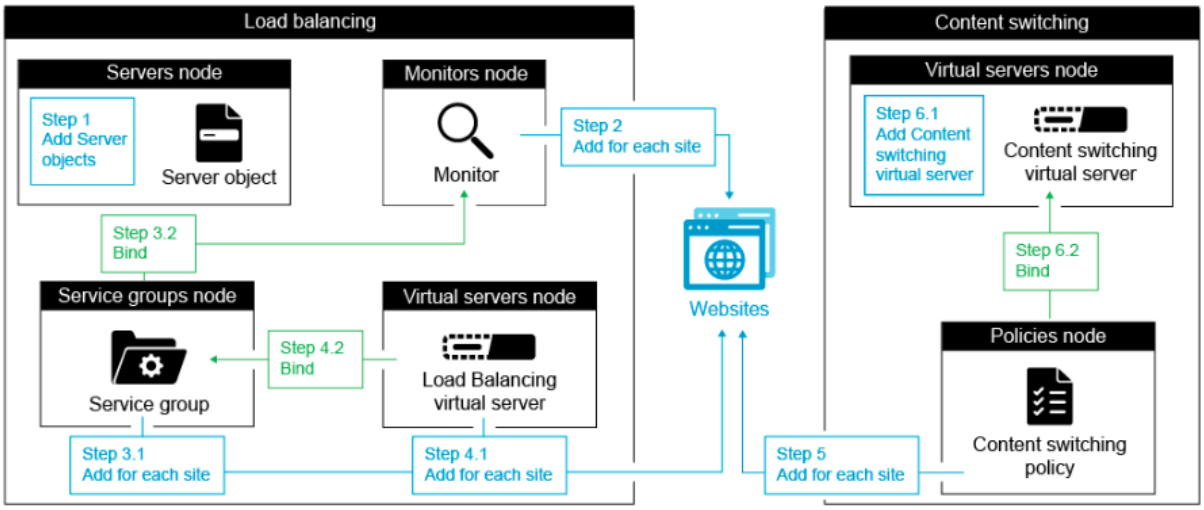
    Feature                       Acronym             Status
    -------                       -------             ------
1)     Web Logging                   WL                  OFF
2)     Surge Protection              SP                  ON
3)     Load Balancing                LB                  ON
4)     Content Switching             CS                  ON
.
.
.
22)    Responder                     RESPONDER           ON
23)    HTML Injection                HTMLInjection       ON
24)    NetScaler Push                push                OFF
Done
```

```
<!--NeedCopy-->
```

To enable content switching by using the GUI

Navigate to **System > Settings** and, in the **Modes and Features** group, select **Configure Basic Features**, and select **Content Switching**.

The following figure illustrates the step wise configuration of Content Switching.



Creating content switching virtual servers

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

To create a virtual server by using the CLI

At the command prompt, type:

```
add cs vserver <name> <protocol> <IPAddress> <port>
<!--NeedCopy-->
```

Example:

```
add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
<!--NeedCopy-->
```

To add a content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and add a virtual server.
2. Specify a name for content switching virtual server.

   > **Note**
   >
   > There is different Content Switching virtual server for each protocol. (For example, HTTP and SSL).

3. Populate the relevant fields and click **OK**.

Content switching virtual server statistics

The content switching virtual server statistics display information such as virtual server select, request bytes, response bytes, total packets received, total packets sent, spillover threshold, spillover select, current client established connections, and virtual server down backup select.

The content switching virtual server statistics also display the summary details of the bound default load balancing virtual server.

To view statistics of content switching virtual server by using the CLI

At the command prompt, type:

```
stat cs vserver <name>
<!--NeedCopy-->
```

Example:

```
stat cs vserver CS_stats
<!--NeedCopy-->
```

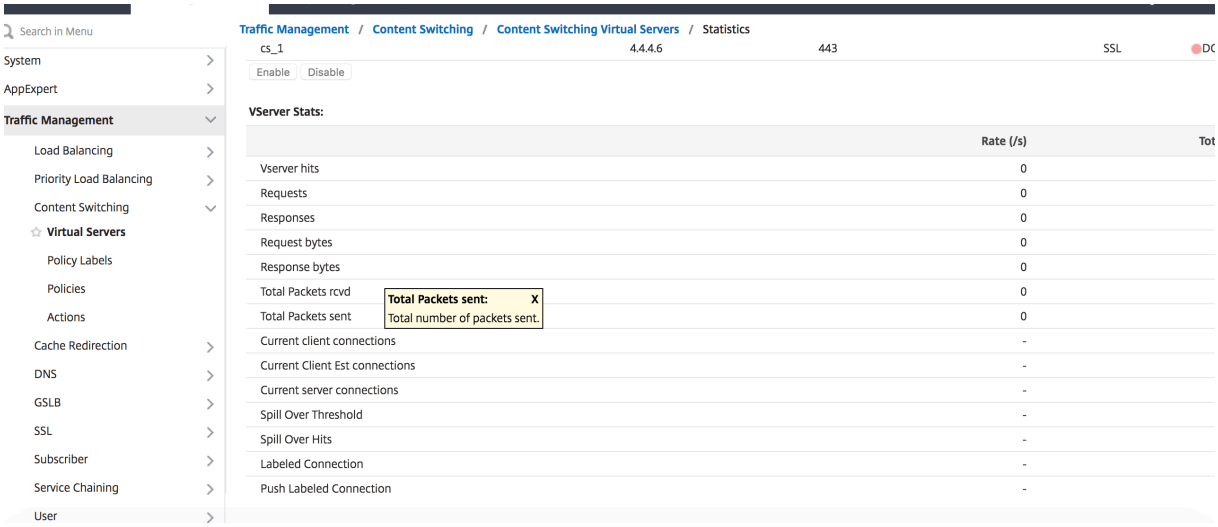
```
Vserver Summary
                                IP  port     Protocol        State
CS_stats                   1.1.1.1    80         HTTP           UP

VServer Stats:
                                                  Rate (/s)                Total
Vserver hits                                              0                    0
Requests                                                  0                    0
Responses                                                 0                    0
Request bytes                                             0                    0
Response bytes                                            0                    0
Total Packets rcvd                                        0                    0
Total Packets sent                                        0                    0
Current client connections                               --                    0
Current Client Est connections                           --                    0
Current server connections                               --                    0
Spill Over Threshold                                     --                    0
Spill Over Hits                                          --                    0
Labeled Connection                                       --                    0
Push Labeled Connection                                  --                    0
Deferred Request                                          0                    0
Invalid Request/Response                                 --                    0
Invalid Request/Response Dropped                         --                    0
Vserver Down Backup Hits                                 --                    0
Current Multipath TCP sessions                           --                    0
Current Multipath TCP subflows                           --                    0
Apdex for client response times.                         --                 1.00
Average client TTLB                                      --                    0

 Done
```

To view statistics of content switching virtual server by using the GUI

1. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers**.
2. Select the virtual server and click **Statistics**.



Configuring a load balancing setup for content switching

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. It is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see How load balancing works. For detailed instructions on setting up a basic load balancing configuration, see Set up basic load balancing.

Configuring a content switching action

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Therefore, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

> **Note**
>
> You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server.

Configuring an action that specifies the name of the target load balancing virtual server

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the CLI

At the command prompt, type:

```
add cs action <name> -targetLBVserver <string> [-comment <string>]

show cs action <name>
<!--NeedCopy-->
```

Example:

```
> add cs action mycsaction -targetLBVserver mylbvserver -comment "
    Forwards requests to mylbvserver."
 Done
> show cs action mycsaction
    Name: mycsaction
    Target LB Vserver: mylbvserver
    Hits: 0
    Undef Hits: 0
    Action Reference Count: 0
    Comment: "Forwards requests to mylbvserver."

 Done
>
<!--NeedCopy-->
```

To configure a content switching action that specifies the name of the target load balancing virtual server, by using the GUI

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify the name of the target load balancing virtual server.

Configuring an action that specifies an expression for selecting the target at run time

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests based on the URL suffix (extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as `mylb_`. For example, load balancing virtual servers for HTML pages and PDF files can be named `mylb_html` and `mylb_pdf`, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is `"mylb_"+HTTP.REQ.URL.SUFFIX`. If the content switching virtual server receives a request for an HTML page, the expression returns `mylb_html`, and the request is switched to the virtual server `mylb_html`.

To create a content switching action that specifies an expression, by using the CLI

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

```
add cs action <name> -targetVserverExpr <expression>) [-comment <string
    >]

show cs action <name>
<!--NeedCopy-->
```

Example:

```
> add cs action mycsaction1 -targetvserverExpr '"mylb_" + HTTP.REQ.URL.
   SUFFIX'
 Done
> show cs action mycsaction1
    Name: mycsaction1
    Target Vserver Expression: "mylb_" + HTTP.REQ.URL.SUFFIX
    Target LB Vserver: No_Target
                ...
 Done
>
<!--NeedCopy-->
```

To configure a content switching action that specifies an expression by using the GUI

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify an expression that will dynamically compute the name of the target load balancing virtual server.

Configuring content switching policies

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using Citrix ADC classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The Citrix ADC appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content. Domain-based policies must be classic policies. Default syntax policies are not supported for this type of content switching policy.
- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies. Default syntax policies are not supported for this type of content switching policy.
- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

> **Note**
>
> A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about Citrix ADC classic policies and expressions, see Configuring Classic Policies and Expressions. For information about Default Syntax policies, see Configuring Default Syntax Expressions.

To create a content switching policy by using the CLI

At the command prompt, type one of the following commands:

```
add cs policy <policyName> -domain <domain>

add cs policy <policyName> -url <URLValue>

add cs policy <policyName> -rule <RULEValue>

add cs policy <policyName> -rule <RULEValue> -action <actionName>
<!--NeedCopy-->
```

Example:

```
add cs policy Policy-CS-1 -url "http://example.com"

add cs policy Policy-CS-1 -domain "example.com"

add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ
    (10.217.84.0)"

add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009
     Dec)"

add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1
<!--NeedCopy-->
```

To rename a content switching policy by using the CLI

At the command prompt, type:

```
rename cs policy <policyName> <newName>
<!--NeedCopy-->
```

Example:

```
rename cs policy myCSPolicy myCSPolicy1
<!--NeedCopy-->
```

To rename a content switching policy by using the GUI

Navigate to **Traffic Management > Content Switching > Policies**, select a policy and, in the Action list, select Rename.

To create a content switching policy by using the GUI

1. Navigate to **Traffic Management > Content Switching > Policies**, and click **Add**.
2. Populate the relevant fields and click **Create**.

Configuring content switching policy labels

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and the invoke option. Also, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the Citrix ADC CLI or the GUI to configure content switching policy labels. In the Citrix ADC CLI, you first create a policy label by using the add cs policy label command. Then, you

bind policies to the policy label, one policy at a time, by using the bind cs policy label command. In the Citrix ADC GUI, you perform both tasks in a single dialog box.

To create a content switching policy label by using the CLI

At the command prompt, type:

```
add cs policylabel <labelName> <cspolicylabelTypetype>`
<!--NeedCopy-->
```

Example:

```
add cs policylabel testpollab http
<!--NeedCopy-->
```

To rename a content switching policy label by using the CLI

At the command prompt, type:

```
rename cs policylabel <labelName> <newName>`
<!--NeedCopy-->
```

Example:

```
rename cs policylabel oldPolicyLabelName newPolicyLabelName
<!--NeedCopy-->
```

To rename a content switching policy label by using the GUI

Navigate to **Traffic Management > Content Switching > Policy Labels**, select a policy label and, in the Action list, select Rename.

To bind a policy to a content switching policy label by using the CLI

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

```
bind cs policylabel <labelName> <policyName> <priority>[-targetVserver
    <string>] | [-gotoPriorityExpression <expression>] | [-invoke <
    labeltype> <labelName>] ]

show cs policylabel <labelName>
<!--NeedCopy-->
```

Example:

```
bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
show cs policylabel testpollab
        Label Name: testpollab
        Label Type: HTTP
        Number of bound policies: 1
        Number of times invoked: 0
        Policy Name: test_Pol
        Priority: 100
        Target Virtual Server: LBVIP
<!--NeedCopy-->
```

> **Note**
>
> If a policy is configured with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configure with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

To unbind a policy from a policy label by using the CLI

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

```
unbind cs policylabel <labelName> <policyName>

show cs policylabel <labelName>
<!--NeedCopy-->
```

Example:

```
unbind cs policylabel testpollab test_Pol
show cs policylabel testpollab
        Label Name: testpollab
        Label Type: HTTP
        Number of bound policies: 0
        Number of times invoked: 0
<!--NeedCopy-->
```

To remove a policy label by using the CLI

At the command prompt, type:

```
rm cs policylabel <labelName>
<!--NeedCopy-->
```

To manage a content switching policy label by using the GUI

Navigate to **Traffic Management > Content Switching > Policy Labels**, configure a policy label, bind policies to the label, and optionally specify a priority, gotoPriority expression, and an invoke option.

Binding Policies to a Content Switching Virtual Server

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

> **Note**
>
> If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see Configuring a Content Switching Action section.

To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the CLI

At the command prompt, type:

```
bind cs vserver <name>[-lbvserver<string> -targetLBVServer<string> -
    policyname <string> -priority <positive_integer>] [-
    gotoPriorityExpression <expression>] [-type ( REQUEST | RESPONSE )]
    [-invoke (<labelType> <labelName>)]
<!--NeedCopy-->
```

Example:

```
bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -
    gotoPriorityExpression NEXT

bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -
    gotoPriorityExpression
'q.header("a").count' -flowtype REQUEST -invoke policylabel label1

```

```
bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -
    priority 20
<!--NeedCopy-->
```

> **Note**
>
> The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.

To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, open a virtual server and, in the
Content Switching Policy Binding section, bind a policy to the virtual server, and specify a target load balancing virtual server.

Configuring policy based logging for content switching

You can configure policy based logging for a content switching policy. Policy based logging enables you to specify a format for log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified in the policy is performed, the Citrix ADC appliance constructs the log message from the expression and writes the message to the log file. Policy based logging is particularly useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.

> **Note**
>
> If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, the Citrix ADC appliance does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.

To configure policy based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see Configuring the Citrix ADC appliance for audit logging. After you configure the audit message action, you specify the action in a content switching policy.

To configure policy based logging for a content switching policy by using the CLI

At the command line, type the following commands to configure policy based logging for a content switching policy and verify the configuration:

```
set cs policy <policyName> -logAction <string>

show cs policy <policyName>
<!--NeedCopy-->
```

Example:

```
> set cs policy cspol1 -logAction csLogAction
 Done
> show cs policy cspol1

    Policy: cspol1  Rule: TRUE  Action: csact1
    LogAction: csLogAction
    Hits: 0

1)  CS Vserver: csvs1
    Priority: 10
 Done
>
<!--NeedCopy-->
```

To configure policy based logging for a content switching policy by using the GUI

Navigate to **Traffic Management > Content Switching > Policies**, open a policy and, in the Log Action list, select a log action for the policy.

Verifying the configuration

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

Viewing the properties of content switching virtual servers

You can view the properties of content switching virtual servers that you have configured on the Citrix ADC appliance. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

> **Note**
>
> If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

To view the properties of content switching virtual servers by using the CLI

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

```
show cs vserver

show cs vserver <name>
<!--NeedCopy-->
```

Example

```
1.
show cs vserver Vserver-CS-1
Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
State: UP
Last state change was at Thu Jun 30 10:48:59 2011
Time since last state change: 6 days, 20:03:00.760
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Appflow logging: DISABLED
Port Rewrite : DISABLED
State Update: DISABLED
Default: Content Precedence: RULE
Vserver IP and Port insertion: OFF
Case Sensitivity: ON

```

Viewing content switching policies

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it must.

To view the properties of content switching policies by using the CLI

To list either the basic properties of all content switching policies in your configuration or the detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

```
show cs policy

show cs policy <PolicyName>
<!--NeedCopy-->
```

Example:

```
show cs policy

show cs policy Policy-CS-1
<!--NeedCopy-->
```

To view the properties of content switching policies by using the GUI

Navigate to **Traffic Management** > **Content Switching** > **Policies**, select a policy and, in the Action list, select **Show Bindings**.

Viewing a content switching virtual server configuration by using the visualizer

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.

- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

> **Note**
>
> The Visualizer requires a graphical interface, so it is available only through the GUI.

To view a content switching configuration by using the Visualizer in the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.
3. In the **Content Switching Visualizer** window, you can adjust the viewable area as follows:
   - Click the **Zoom In** and **Zoom Out** icons to increase or decrease the viewable area.
   - Click the **Save Image** icon to save the graph as an image file.
   - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.
4. To view configuration details for entities that are bound to this virtual server, you can do the following:
   - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
   - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
   - To view the configuration details for a monitor, click the icon for the monitor, click the **Related Tasks** tab, and then click **View Monitor**.
5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click **Statistics**.
6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the **Related Tasks** tab, and then click **Service Attributes Diff**.
7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click **Details**. This comparative list helps you

determine which service container has the configuration you want to apply to all the service containers.

8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of select per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It is refreshed manually. To refresh the information, click Refresh Stats.

   > **Note**
   >
   > This option is available only on Citrix ADC nCore builds.

9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.
10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information about creating the application template file and configuring variables for a template, see AppExpert.

Customizing the basic content switching configuration

September 14, 2021

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. You can configure HTTP and SSL content switching virtual servers to listen on multiple ports instead of creating separate virtual servers. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.

Configuring case sensitivity for policy evaluation

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the Citrix ADC appliance considers the case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

To configure case sensitivity by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -caseSensitive (ON|OFF)
```

Example:

```
set cs vserver Vserver-CS-1 -caseSensitive ON
<!--NeedCopy-->
```

To configure case sensitivity by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select Case Sensitive.

Setting the Precedence for Policy Evaluation

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You need not configure precedence, the default precedence often works correctly.

You can configure either URL-based precedence or rule-based precedence in the following scenarios:

- One policy or set of policies must be applied first
- Another policy or set of policies is applied only if the first set does not match a request.

Precedence with URL-Based Policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only
6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an "HTTP 404 Not Found" error message is sent to the client.

> **Note**
>
> You must configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served based on client attributes (such as Accept-Language), you must use rule-based precedence.

Precedence with Rule-Based Policies

If you configure precedence based on rules, which is the default setting, the request is tested based on the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an "HTTP 404 Not Found" error message is sent to the client.

To configure precedence by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -precedence ( RULE | URL )
```

Example:

```
set cs vserver Vserver-CS-1 -precedence RULE
```

To configure precedence by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and then specify Precedence.

Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers

You can configure the Citrix ADC so that HTTP and SSL content switching virtual servers listen on multiple ports, without having to configure separate virtual servers. This feature is especially useful if you want to base a content switching decision on a part of the URL and other L7 parameters. Instead of configuring multiple virtual servers with the same IP address and different ports, you can configure one IP address and specify the port as *. As a result, the configuration size is also reduced.

To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line

At the command prompt, type:

```
add cs vserver \<name\> \<serviceType\> \<IPAddress\> Port \*
```

Example

```
> add cs vserver cs1 HTTP 10.102.92.215 *
 Done
> sh cs vserver cs1
        cs1 (10.102.92.215:*) - HTTP    Type: CONTENT
        State: UP
        Last state change was at Tue May 20 01:15:49 2014
        Time since last state change: 0 days, 00:00:03.270
        Client Idle Timeout: 180 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Appflow logging: ENABLED
        Port Rewrite : DISABLED
        State Update: DISABLED
        Default:        Content Precedence: RULE
        Vserver IP and Port insertion: OFF
        L2Conn: OFF     Case Sensitivity: ON
        Authentication: OFF
        401 Based Authentication: OFF
        Push: DISABLED  Push VServer:
        Push Label Rule: none
        IcmpResponse: PASSIVE
        RHIstate:  PASSIVE
        TD: 0
 Done
<!--NeedCopy-->
```

To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and create a virtual server of type HTTP or SSL.
2. Use an asterisk (*) to specify the port.

Configuring per-VLAN Wildcard Virtual Servers

If you want to configure content switching for traffic on a specific VLAN, you can create a wildcard virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcard virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```
add cs vserver \<name\> \<serviceType\> IPAddress `* Port *` -
   listenpolicy \<expression\> \[-listenpriority \<positive\_integer
   \>\]
<!--NeedCopy-->
```

Example:

```
add cs vserver Vserver-CS-vlan1 ANY * *
-listenpolicy "CLIENT.VLAN.ID.EQ(2)"  -listenpriority 10
<!--NeedCopy-->
```

To configure a wildcard virtual server that listens to a specific VLAN by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, and configure a virtual server. Specify a listen policy that restricts it to processing traffic only on the specified VLAN.

After you have created this virtual server, you bind it to one or more services as described in Setup basic load balancing.

Configuring the Microsoft SQL Server Version Setting

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the

same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- `set cs vserver \<name\> -mssqlServerVersion \<mssqlServerVersion\>`
- `show cs vserver \<name\>`

Example

```
1 > set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2 Done > show cs
      vserver myMSSQLcsvip myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type:
     CONTENT State: UP . . . . . MSsql Server Version: 2008R2 . . . . .
      . Done >
2 <!--NeedCopy-->
```

To set the Microsoft SQL Server version parameter by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MSSQL.
2. In **Advanced Settings**, specify the **Server Version**.

Enable external TCP health check for UDP virtual servers

In public clouds, you can use the Citrix ADC appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. To monitor the health of the UDP application, public clouds recommend adding a TCP-based endpoint to your service. The endpoint reflects the health of the UDP application.

The Citrix ADC appliance supports the external TCP-based health check for a UDP virtual server. This feature introduces a TCP listener on the VIP of the content switching virtual server and the configured port. The TCP listener reflects the status of the virtual server.

To enable external TCP health check for UDP virtual servers by using CLI

At the command prompt, type the following command to enable an external TCP health check with the tcpProbePort option:

```
add cs vserver <name> <protocol> <IPAddress> <port> -tcpProbePort <
    tcpProbePort>
<!--NeedCopy-->
```

Example:

```
add cs vserver Vserver-CS-1 UDP 10.102.29.161 5002 -tcpProbePort 5000
<!--NeedCopy-->
```

To enable external TCP health check for UDP virtual servers by using GUI

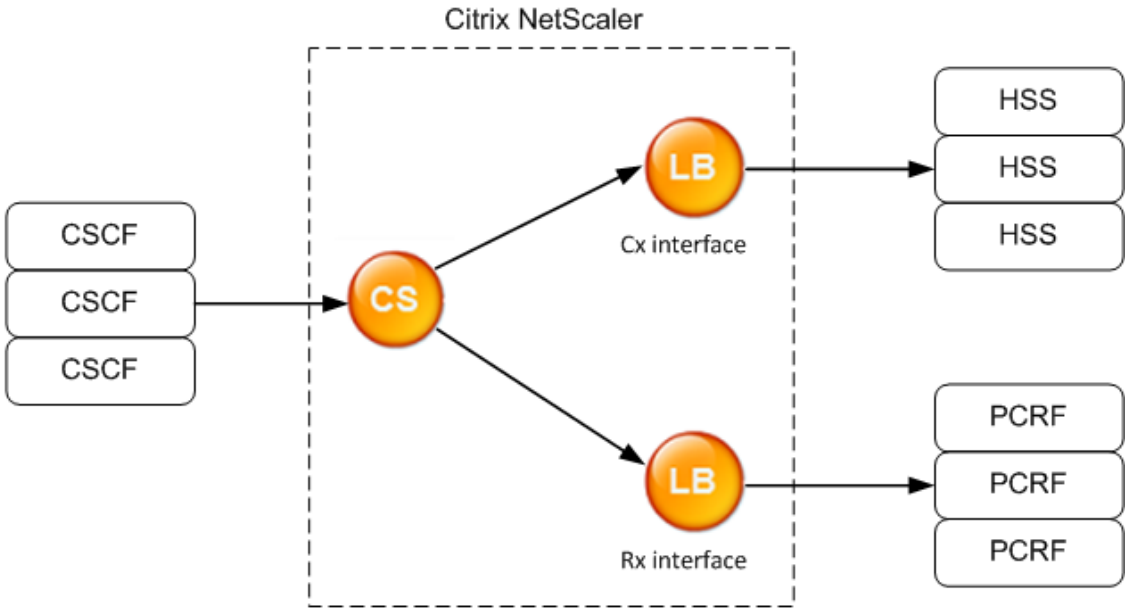
1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, add the port number in the **TCP Probe Port** field.
4. Click **OK**.

Content Switching for Diameter Protocol

September 14, 2021

For Diameter-protocol traffic, you can configure the Citrix ADC appliance (or virtual appliance) to act as a relay agent that load balances and forwards a packet to the appropriate destination on the basis of the message content (AVP value in the message). Since the appliance does not perform any application-level processing, it provides relaying services for all diameter applications as specified by the configured content switching policies. Therefore, the appliance advertises the Relay Application ID in the capability exchange answer (CEA) message when the client establishes a diameter connection. You must configure a content switching virtual server, load balancing virtual servers, and services to represent the diameter nodes. When a request reaches the content switching virtual server, the virtual server applies the content switching policies associated with that type of request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

A diameter interface provides a connection between the different diameter nodes. The following sample deployment uses Cx and Rx interfaces. A Cx interface provides a connection between a CSCF and an HSS. An Rx interface provides a connection between a CSCF and a PCRF. All the messages reach the Citrix ADC appliance. Depending on whether the message is for a Cx or an Rx interface, and on the content switching policies defined, the Citrix ADC selects an appropriate load balancing server pool.



CSCF=Call Session Control Function
HSS=Home Subscriber Server
PCRF=Policy and Charging Rules Function

Sample Configuration

1. For each entity, create a service, a load balancing server, and bind the service to the virtual server.

```
add service svc_pcrf[1-3] 1.1.1.1[1-3] DIAMETER 3868
add service svc_hss[1-3] 1.1.1.2[1-3] DIAMETER 3868
add lb vserver vs_rx DIAMETER -persistenceType DIAMETER -
   persistavpno 263
add lb vserver vs_cx DIAMETER -persistenceType DIAMETER -
   persistavpno 263
bind lb vserver vs_rx svc_pcrf[1-3]
bind lb vserver vs_cx svc_hss[1-3]
<!--NeedCopy-->
```

2. Create a content switching virtual server and two actions (one for each load balancing virtual server). Create two content switching policies and bind these policies to the content switching virtual server, specifying a priority for each policy.

```
add cs vserver cs_diameter DIAMETER 10.1.1.10 3868
add cs action cx_action -targetLBVserver vs_cx
add cs action rx_action  - targetLBvserver vs_rx
```

```
add cs policy cx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ
    (16777216)" -action cx_action
add cs policy rx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ
    (16777236)" -action rx_action
bind cs vserver cs_diameter -policyName rx_policy -priority 100
bind cs vserver cs_diameter -policyName cx_policy -priority 110
<!--NeedCopy-->
```

Protecting the content switching setup against failure

September 14, 2021

Content switching might fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

Configuring a backup virtual server

If the primary content switching virtual server is marked DOWN or DISABLED, the Citrix ADC appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter Disable Primary When Down to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. It is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

> **Note**
>
> If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the

> redirect URL. The redirect is used when the primary and backup virtual servers are down.

To set up a backup content switching virtual server by using the CLI

At the command prompt, type:

```
set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON
    |OFF)
<!--NeedCopy-->
```

Example

```
set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -
    disablePrimaryOnDown ON
<!--NeedCopy-->
```

To set up a backup content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MYSQL.
2. In **Advanced Settings**, select **Protection**, and specify a **Backup Virtual Server**.

Diverting excess traffic to a backup virtual server

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

To configure a content switching virtual server to divert new connections to a backup virtual server by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -soMethod \<methodType\> -soThreshold \<
    thresholdValue\> -soPersistence \<persistenceValue\> -
    soPersistenceTimeout \<timeoutValue\>
<!--NeedCopy-->
```

Example

```
set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -
    soPersistence enabled -soPersistenceTimeout 2
<!--NeedCopy-->
```

To set a content switching virtual server to divert new connections to a backup virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MYSQL.
2. In **Advanced Settings**, select **Protection**, and configure spillover.

Configuring a redirection URL

You can configure a redirect URL to communicate the status of the Citrix ADC appliance if a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example www.example.com/ instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

> **Note**
>
> If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.

When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user's browser.

To configure a redirect URL for when the content switching virtual server is unavailable by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -redirectURL \<URLValue\>
<!--NeedCopy-->
```

Example

```
set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/
   mysite/maintenance
<!--NeedCopy-->
```

To configure a redirect URL for when the content switching virtual server is unavailable by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MYSQL.
2. In **Advanced Settings**, select **Protection**, and specify a Redirect URL.

Configuring the state update option

The content switching feature enables the distribution of client requests across multiple servers based on the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

When State Update is disabled:

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

When State Update is enabled:

When you add a content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

To configure the state update option by using the CLI

At the command prompt, type:

```
add cs vserver \<name\> \<protocol\> \<ipAddress\> \<port\> -
   stateUpdate ENABLED
<!--NeedCopy-->
```

Example

```
 add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED
    -cltTimeout 180
<!--NeedCopy-->
```

To configure the state update option by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MYSQL.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **State Update**.

Flushing the surge queue

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between the client

and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you might want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed. The other requests in the surge queue of the load balancing virtual server are not flushed.

> **Note**
>
> You cannot flush the surge queues of cache redirection, authentication, VPN, or GSLB virtual servers or GSLB services.
> Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while running the command, the surge queue of the specified entity is flushed. If more than one entity has the same name, the appliance flushes the surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while running the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a

<serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.

- If you run the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>].
<!--NeedCopy-->
```

Examples

```
1. flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80
The above command flushes the surge queue of the service or virtual
    server that is named SVC1ANZGB and has IP address as 10.10.10

2. flush ns surgeQ
The above command flushes all the surge queues on the appliance.
<!--NeedCopy-->
```

To flush a surge queue by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

Managing a content switching setup

September 14, 2021

After a content switching setup is configured, it might require periodic changes. When operating systems or software is updated, or hardware wears out and is replaced, you might need to take down your setup. Load on your setup might increase, requiring more resources. You might also modify the configuration to improve performance.

These tasks might require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have changed your setup, you might need to re-enable servers and rebind policies. You might also want to rename your virtual servers.

Unbinding policies from the content switching virtual server

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

To unbind a policy from a content switching virtual server by using the CLI

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

Example:

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

To unbind a policy from a content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open the virtual server.
2. Click **Policies** section, select the policy, and click **Unbind**.

Removing Content Switching Virtual Servers

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the Citrix ADC appliance first unbinds all policies from the content switching virtual server, and then removes it.

To remove a content switching virtual server by using the CLI

At the command prompt, type:

```
rm cs vserver <name>
```

Example:

```
rm cs vserver Vserver-CS-1
```

To remove a content switching virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server, and click **Delete**.

Disabling and Re-Enabling Content Switching Virtual Servers

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

To disable or re-enable a virtual server by using the CLI

At the command prompt, type one of the following commands:

- `disable cs vserver <name>`
- `enable cs vserver <name>`

Example:

```
disable cs vserver Vserver-CS-1
enable cs vserver Vserver-CS-1
```

To disable or re-enable a virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the **Action** list, select **Enable** or **Disable**.

Renaming Content Switching Virtual Servers

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the Citrix ADC configuration.

To rename a virtual server by using the CLI

At the command prompt, type:

```
rename cs vserver <name> <newName>
```

Example:

```
1 `rename cs vserver Vserver-CS-1 Vserver-CS-2`
```

To rename a virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the **Action** list, select **Rename**.

Managing content switching policies

You can modify an existing policy by configuring the rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

For more information, see Examples of URL-Based Policies.

> **Note**
>
> You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

To modify, remove, or rename a policy by using the CLI

At the command prompt, type one of the following commands:

- `set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]`
- `rm cs policy <policyName>`
- `rename cs policy <policyName> <newPolicyName>`

Example:

```
set cs policy Policy-CS-1 -domain "www.domainxyz.com"

set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ
   (10.100.148.0)"

set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010
    Jul)"

set cs policy Policy-CS-1 -url /sports/*

rename cs policy Policy-CS-1 Policy-CS-11

rm cs policy Policy-CS-1
```

To modify, remove, or rename a policy by using the GUI

1. Navigate to **Traffic Management > Content Switching > Policies**.
2. Select the policy, and either delete it, edit it or, in the **Action** list, click **Rename**.

Managing client connections

September 14, 2021

To ensure efficient management of client connections, you can configure the content switching virtual servers on the Citrix ADC appliance to use the following features:

- **Configuring the ICMP Response.** You can configure the Citrix ADC appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP virtual server RESPONSE.
  The following settings can be made on a virtual server:
  - When you set ICMP virtual server RESPONSE to PASSIVE on all virtual servers, the Citrix ADC appliance always responds.
  - When you set ICMP virtual server RESPONSE to ACTIVE on all virtual servers, the ADC appliance responds even if one virtual server is UP.
  - When you set ICMP virtual server RESPONSE to ACTIVE on some and PASSIVE on others, the ADC appliance responds even if one virtual server set to ACTIVE is UP.

Redirecting Client Requests to a Cache

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your website performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see "Cache Redirection.

To configure cache redirection on a virtual server by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -cacheable \<Value\>
```

Example

```
set cs vserver Vserver-CS-1 -cacheable yes
```

To configure cache redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Cacheable**.

Enabling Delayed Cleanup of Virtual Server Connections

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

To configure the down state flush setting on a virtual server by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -downStateFlush \<Value\>
```

Example

```
1 set cs vserver Vserver-CS-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

To configure the down state flush setting on a virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **Down State Flush**.

Rewriting Ports and Protocols for Redirection

Virtual servers and the services that are bound to them might use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the Citrix ADC appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do it by enabling and configuring the redirectPortRewrite setting.

To configure HTTP redirection on a virtual server by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -redirectPortRewrite \<Value\>
```

Example

```
set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
<!--NeedCopy-->
```

To configure HTTP redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Rewrite**.

Inserting the IP Address and Port of a Virtual Server in the Request Header

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

> **Note**
>
> This option is not supported for wildcard virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -insertVserverIPPort \<vServerIPPORT\>
```

Example

```
set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
<!--NeedCopy-->
```

To insert the IP address and port of the virtual server in the client requests by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.

2. In **Advanced Settings**, select **Traffic Settings** and, in the Virtual Server IP Port Insertion list, select VIPADDR or V6TOV4MAPPING, and specify a port header in the virtual server IP Port Insertion Value.

Setting a Time-out Value for Idle Client Connections

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the CLI

At the command prompt, type:

```
set cs vserver \<name\> -cltTimeout \<Value\>
```

Example

```
1 set cs vserver Vserver-CS-1 -cltTimeout 100
2 <!--NeedCopy-->
```

To set a time-out value for idle client connections by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and specify a **Client Idle Time-Out** value.

Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

To set the L2Conn option for a content switching virtual server by using the CLI

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

```
1 -  set cs vserver \<name\> -l2Conn (**ON** | **OFF**)
2 -  show cs vserver \<name\>
```

Example

```
> set cs vserver mycsvserver -l2Conn ON
Done
> show cs vserver mycsvserver
     mycsvserver (192.0.2.56:80) - HTTP   Type: CONTENT
     State: UP
          . . .
          . . .
     L2Conn: ON Case Sensitivity: ON
          . . .
          . . .
Done
>
<!--NeedCopy-->
```

To set the L2Conn option for a content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **Layer 2 Parameters**.

Persistence support for content switching virtual server

September 14, 2021

Applications are moving from monolithic architectures toward microservices architecture. Different versions of the same application can co-exist in the microservices architecture. Citrix ADC appliance must support continuous deployment of applications. It is achieved by platforms that perform Canary deployments (such as Spinnaker). In a continuous deployment setup, a newer version of an application is deployed automatically and exposed to client traffic in stages until the application is stable to take complete traffic. Also, there must be uninterrupted services to the client.

The Citrix ADC content switching feature enables Citrix ADC the appliance to distribute client requests across multiple load balancing virtual servers based on the policies bound to the content switching virtual server.

For continuous deployments, content switching is used to select the load balancing virtual server serving various versions of an application.

In content switching, the selection of a load balancing virtual server for a specific application version changes at runtime because of the change in the content switching policies. During this transition,

if some sessions are present with older versions of the application, such traffic must continue to be served by older versions only. To support the requirement, the Citrix ADC appliance maintains persistence across multiple load balancing groups behind a content switching virtual server. Persistence for content switching virtual server enables seamless transition of clients from one version to another.

Supported persistence types on content switching virtual server

The following persistence types are supported on content switching virtual servers.

Persistence type	Description
Source IP	**SOURCEIP**. Connections from the same client IP address are parts of the same persistence session. For more details, see Source IP address persistence.
HTTP Cookie	**COOKIEINSERT**. Connections that have the same HTTP Cookie header are parts of the same persistence session. The format of the cookie that the Citrix ADC appliance inserts is: **NSC_<vid_str of CSvserver>=<vid_str of Lbvserver>** where NSC_XXXX is the virtual server ID that is derived from the virtual server name. For more details, see HTTP cookie persistence.
SSL Session ID	**SSLSESSION**. Connections that have the same SSL Session ID are parts of the same persistence session. For more details, see SSL session ID persistence.

You can configure a timeout value for persistence that is based on HTTP cookies. If you set the timeout value to 0, the ADC appliance does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are valid only if the software is running.

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of memory on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

Persistence type	Number of simultaneous persistent connections supported
Source IP, SSL Session ID	250,000
HTTP Cookie	Memory limit. In CookieInsert, if the timeout is not 0, the number of connections is limited by memory.

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

Persistence type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
SOURCEI	Yes	Yes	Yes	Yes	Yes	Yes	No	No
COOKIEINSERT	Yes	Yes	No	No	No	No	No	No
SSLSESSI	No	Yes	No	No	Yes	Yes	No	No

Backup persistence support

You can configure the content switching virtual server to use the source IP persistence type as the backup persistence type when the cookie persistence type fails. It is useful for canary deployments in the microservices architecture.

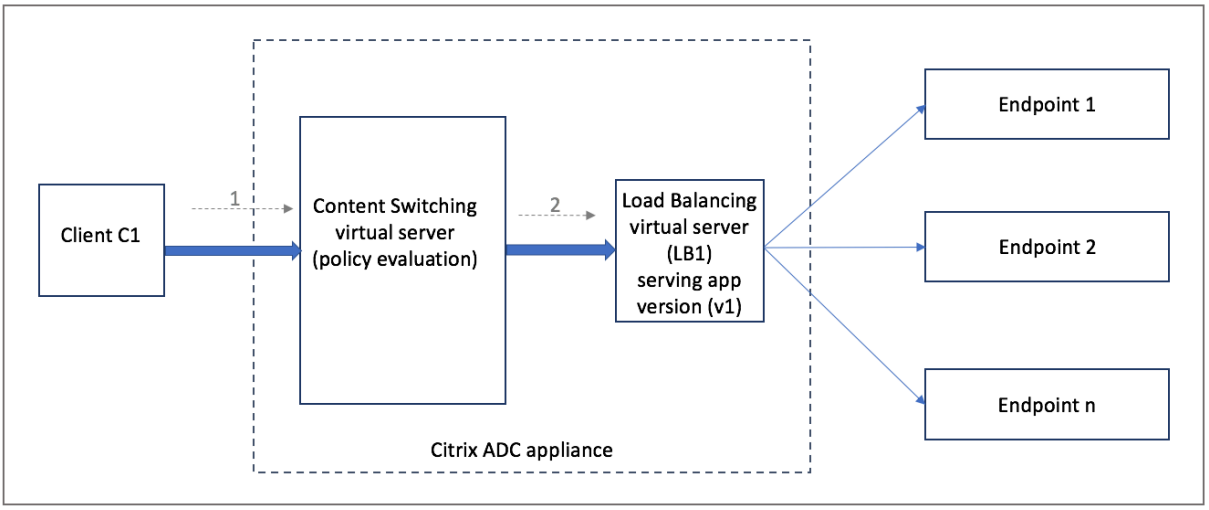
When the cookie persistence type fails, the appliance falls back to source IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.

You can also set a timeout value for backup persistence. Timeout is the time period for which a persistence session is in effect.

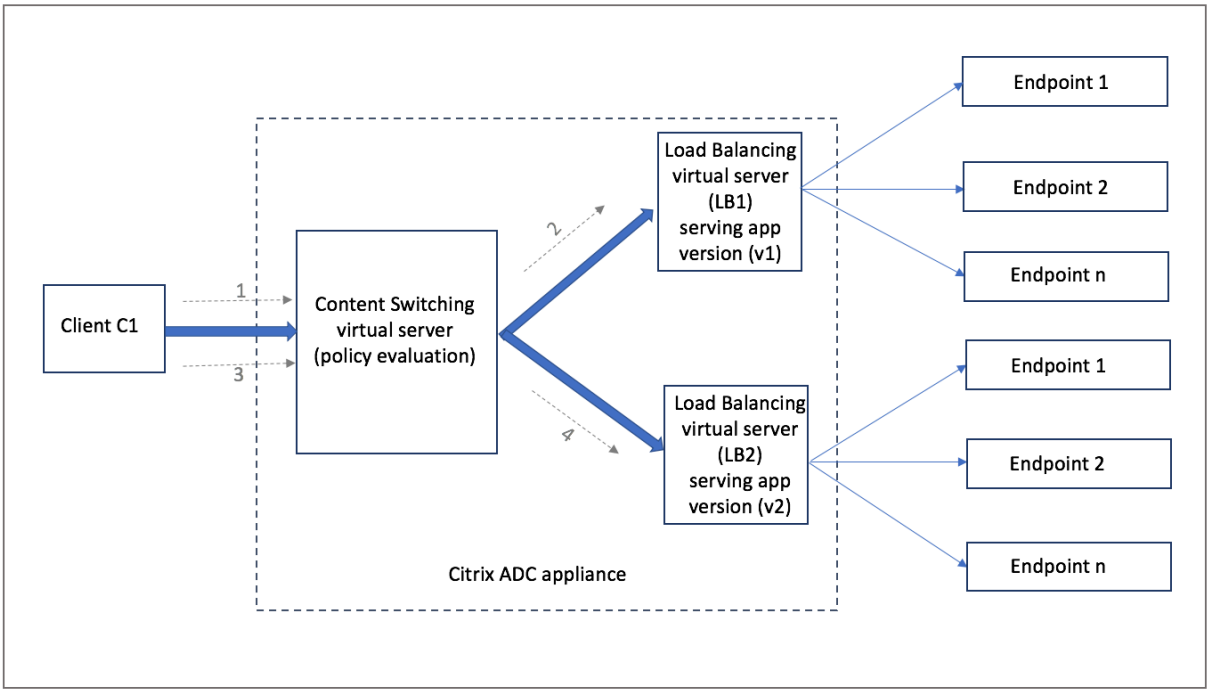
How persistence on content switching virtual server works

Scenario 1: A content switching virtual server without persistence

The following example illustrates the deployment of multiple versions of an application with a content switching virtual server without persistence.



When client C1 sends a request to the application, the request is sent to the content switching virtual server in the Citrix ADC appliance. The content switching virtual server evaluates the policy and forwards the request to the load balancing virtual server (LB1) that is serving version v1 of the application.

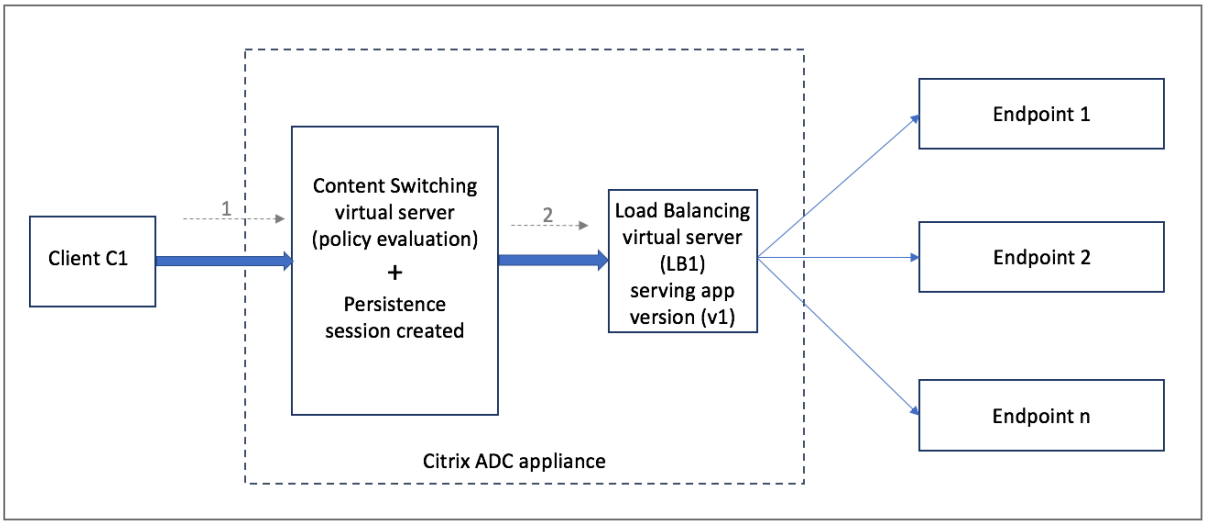


Consider a new version v2 of the application is deployed and has to be exposed to a subset of users. The new load balancing virtual server (LB2) serving the v2 version is bound to the content switching virtual server by the appropriate content switching policy.

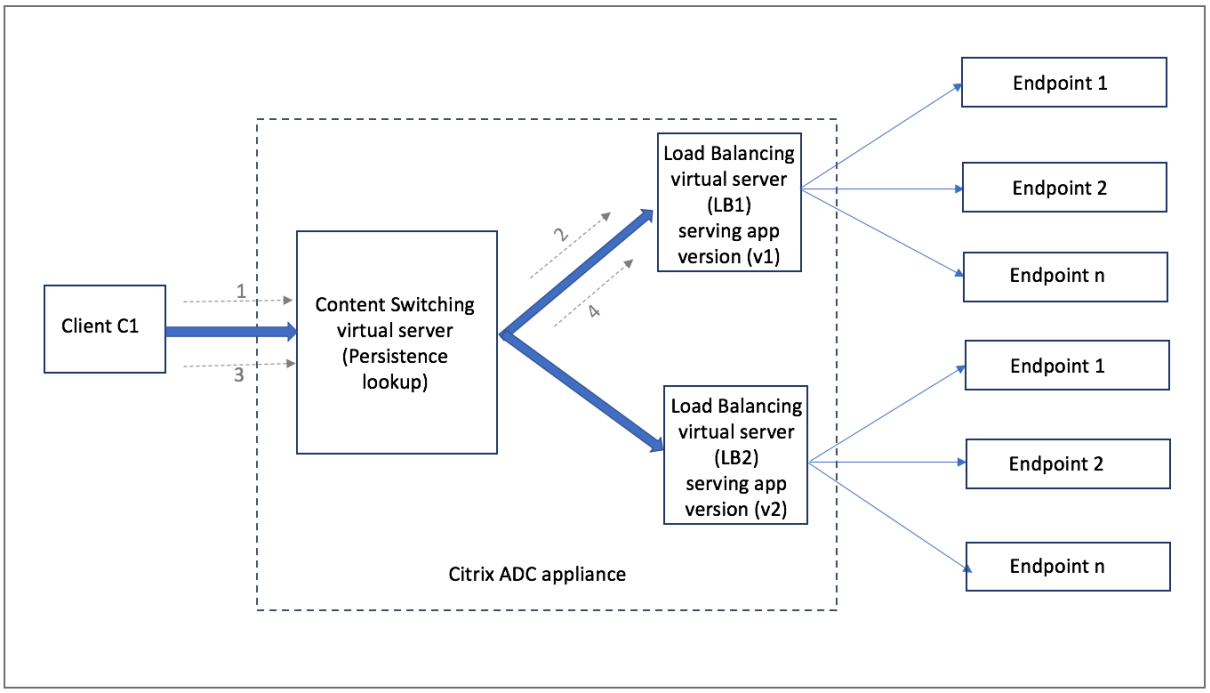
When client C1 sends a new request, the policy is evaluated again and the request is forwarded to the load balancing virtual server LB2. Thus, the transactions for stateful applications fail if multiple versions of the application are deployed.

Scenario 2: Content switching virtual server with persistence

The following example illustrates the deployment of multiple versions of the application with a content switching virtual server with persistence.

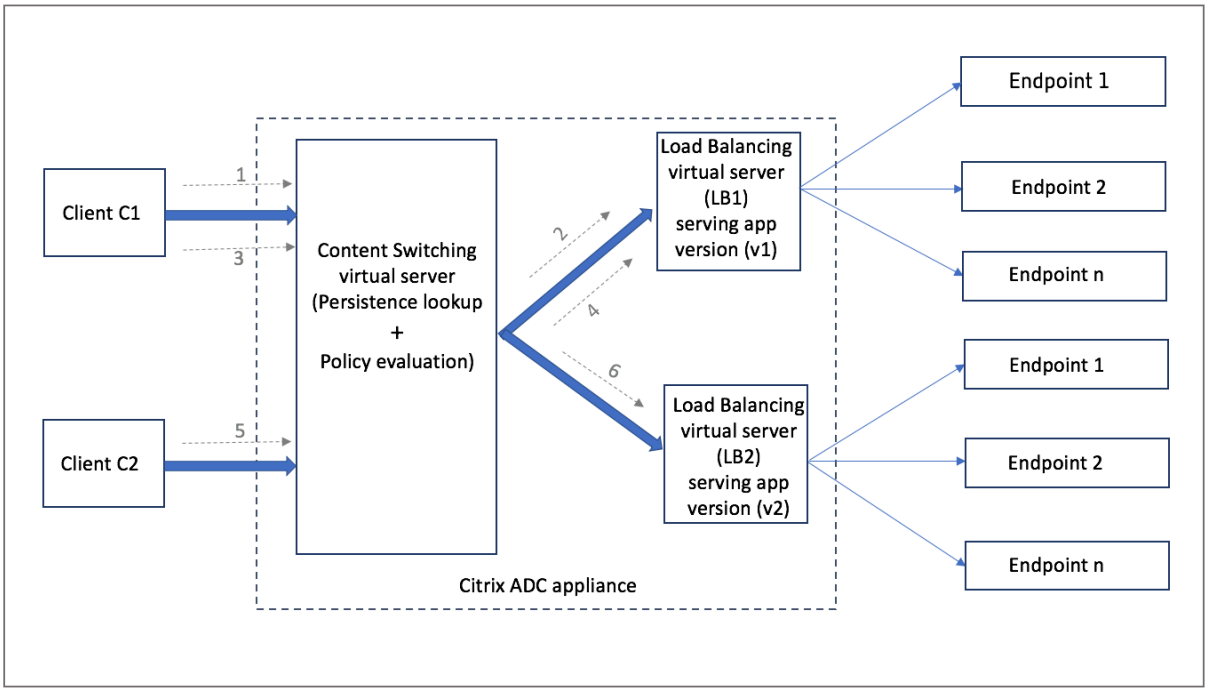


When client C1 sends a request to the application, the request is sent to the content switching virtual server in the Citrix ADC appliance. The content switching virtual server evaluates the policy, creates a persistence session entry, and forwards the request to the load balancing virtual server LB1 that is serving version v1 of the application.



The same client C1 requests again for the application, and the request is sent to the content switching virtual server in the Citrix ADC appliance. A lookup for the persistence session is done, and the

load balancing virtual server LB1 is taken from the existing persistence session and the request is forwarded to LB1. No breakage of the existing transaction happens with this solution; thus, maintaining the stateful nature of the application.



Let's consider a new client C2. The new request C2 is sent to the newer version of the application through policy evaluation as there is no existing persistence session for this client. It results in a successful rollout of the newer version of the application without breaking its statefulness.

Because of the persistence support, customers can deploy multiple content or different versions of the application seamlessly without impacting the existing transactions, specifically for stateful applications. It is not possible without persistence in the picture.

Configure persistence type on content switching virtual server by using the CLI

At the command prompt, type:

```
set cs vserver <name> -PersistenceType <type> [-timeout <integer>]
<!--NeedCopy-->
```

Example:

```
set cs vserver Vserver-CS-1 -persistenceType SOURCEIP -timeout 60
<!--NeedCopy-->
```

Configure persistence type on content switching virtual server by using the GUI

1. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and click **Add**.
2. In **Basic Settings**, configure the persistence details.

Troubleshooting

September 14, 2021

If the content switching feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting content switching

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Configuration file
- Relevant `newnslog` file
- Trace files
- Network topology diagram for the network setup of the customer
- Citrix documentation, such as release notes, Knowledge Center articles, and Product documentation.

In addition to the preceding resources, the following tools expedite troubleshooting:

- The `iehttpheaders` or a similar utility
- The Wireshark application customized for the Citrix ADC trace files
- An SSH utility for command line access
- A HyperTerminal utility to access the console

Troubleshooting content switching issues

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

- **Issue**

  The content switching feature is not functioning.

  Resolution

  Check the configuration as follows:

- Verify that the appliance is licensed for content switching.
- Verify that the feature is enabled.
- From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.

- **Issue**

  Client receives a 503 - Service Unavailable response.

  Resolution

  - Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
  - From the configuration, verify the policies and the URL is accessed by the client.
  - Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy expression and update it if necessary.
  - Verify the URL and HTTP request and response headers. To do so, record an `HTTPHeader` trace and, if necessary, record the packet traces on the appliance and the client.

- **Issue**

  Intermittently, the content switching feature is not working as expected.

  Resolution

  - Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the servers.
  - Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
  - Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
  - Run the following commands to verify the bindings and the values of the policy select counters in the output of the commands:

    ```
    show cs vserver \<CS VServer\>

    show cs policy \<CS Policy\>

    stat cs vserver \<CS VServer\>
    ```

  - Using `iehttpheaders` or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
  - Check the release notes and Knowledge Center articles.
  - If the issue is still not resolved, contact Citrix Technical Support with appropriate data for further investigation.

DataStream

September 14, 2021

The Citrix ADC DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a Citrix ADC appliance ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and based on database names, user names, character sets, and packet size.

You can configure load balancing to switch requests based on load balancing algorithms. Alternately, you can elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameter. You can further configure monitors to track the state of database servers.

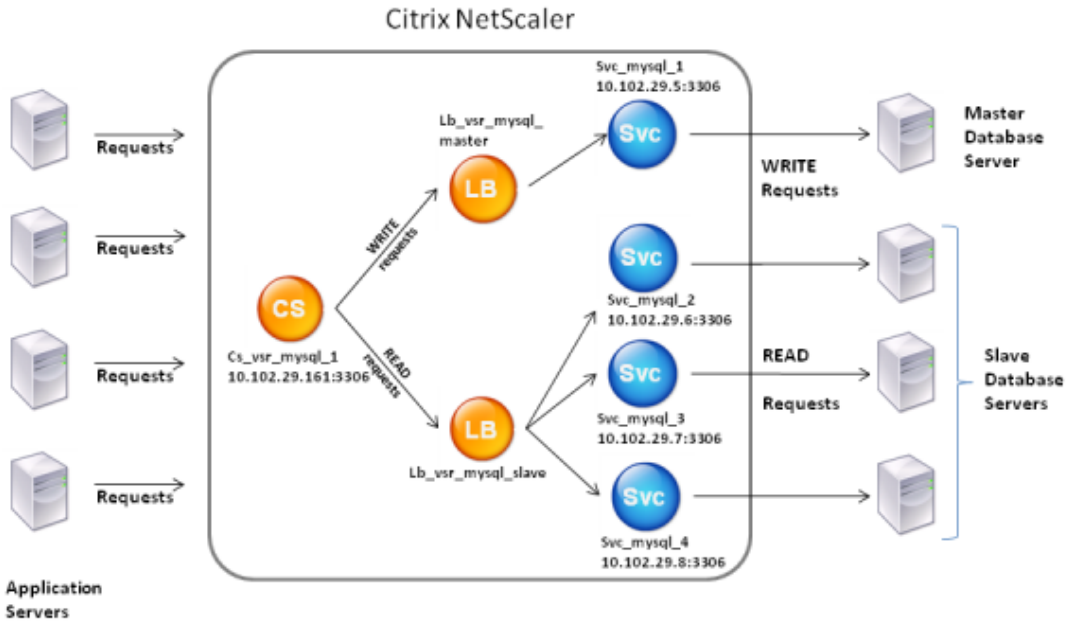
> **Note**
>
> Citrix ADC DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

How DataStream works

In DataStream, the ADC appliance is placed in-line between the application or Web servers and the database servers. On the appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

Figure 1. DataStream Entity Model



As shown in this figure, a DataStream configuration can consist of:

- An optional content switching virtual server (CS).
- A load balancing setup consisting of load balancing virtual servers (LB1 and LB2).
- Services (Svc1, Svc2, Svc3, and Svc4).
- Content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the Citrix ADC appliance. The appliance, then, authenticates the clients using the database user credentials configured on the appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2). Then, the load balancing virtual server distributes the requests to the appropriate database servers (represented by services on the appliance) based on the load balancing algorithm. The Citrix ADC appliance uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the appliance, the clients (application or Web servers) send their requests to a load balancing virtual server configured on the appliance. The Citrix ADC appliance authenticates the client by using the database user credentials configured on the ap-

pliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set

Configure database users

September 14, 2021

In databases, a connection is always stateful, which means that when a connection is established, it must be authenticated.

Configure your database user name and password on the NetScaler appliance. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. Adding database user names and passwords on the ADC adds them to the `nsconfig` file.

> **Note**
>
> Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

Add a database user by using the CLI

At the command prompt, type

```
add db user <username> - password <password>
```

Example:

```
1 add db user nsdbuser -password dd260427edf
2 <!--NeedCopy-->
```

Add a database user by using the GUI

Navigate to **System > User Administration > Database Users**, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the ADC appliance.

Reset the password of a database user by using the CLI

At the command prompt, type

```
set db user <username> -password <password>
<!--NeedCopy-->
```

Example:

```
set db user nsdbuser -password dd260538abs
<!--NeedCopy-->
```

Reset the password of database users by using the GUI

Navigate to **System > User Administration > Database Users**, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated. As a result, the request is not routed to the database server.

Remove a database user by using the CLI

At the command prompt, type

```
rm db user <username>
<!--NeedCopy-->
```

Example:

```
rm db user nsdbuser
<!--NeedCopy-->
```

Remove a database user by using the GUI

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

Configure a database profile

September 14, 2021

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

Create a database profile by using the CLI

At the command line, type the following commands to create a database profile and verify the configuration:

```
add db dbProfile <name> [-interpretQuery ( YES | NO )] [-stickiness (
    YES | NO )] [-kcdAccount <string>]

show db dbProfile
<!--NeedCopy-->
```

Example:

```
> add dbProfile myDBProfile -interpretQuery YES -stickiness YES -
    kcdAccount mykcdaccnt
 Done
> show dbProfile myDBProfile
    Name: myDBProfile
    Interpret Query: YES
    Stickyness: YES
    KCD Account: mykcdaccnt
    Reference count: 0

 Done
>
<!--NeedCopy-->
```

Create a database profile by using the GUI

Navigate to **System > Profiles** and, on the **Database Profiles** tab, configure a database profile.

Bind a database profile to a load balancing or content switching virtual server by using the CLI

At the command line, type:

```
set (lb | cs) vserver <name> -dbProfileName <string>
<!--NeedCopy-->
```

Bind a database profile to a load balancing or content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Profiles** and, in the **DB Profile** list, select a profile to bind to the virtual server. To create a profile, click plus (+).

Configure load balancing for DataStream

September 14, 2021

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

> **Note**:
>
> For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.
>
> The Citrix ADC appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

Parameter values specific to DataStream

- Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

- Port

  Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- Method

  It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

  Note: URL Hash method is not supported for DataStream.

- MS SQL Server version

  If you are using the Microsoft SQL Server, and you expect some clients running a different version from your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the MySQL and Microsoft SQL server version setting.

- MySQL Server version

  If you are using the MySQL Server, and you expect some clients running a different version from your MySQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the MySQL and Microsoft SQL server version setting.

Configure content switching for DataStream

September 14, 2021

You can segment traffic according to information in the SQL query, based on database names, user names, character sets, and packet size.

You can configure content switching policies with default syntax expressions to switch content based on connection properties. For example, user name and database name, command parameters, and the SQL query to select the server.

The default syntax expressions evaluate traffic associated with MYSQL and MS SQL database servers. Use request-based expressions in default syntax policies to make request switching decisions at the content switching virtual server bind point. Use response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

For information about default syntax expressions, see Default Syntax Expressions: DataStream.

> **Note:**
>
> For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.
>
> The Citrix ADC appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

Parameter values specific to DataStream

- Protocol

  Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

- Port

  Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- MS SQL Server Version

  If you use Microsoft SQL Server, and expect some clients running a different version from your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side

connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the Microsoft SQL Server Version Setting.

Configure monitors for DataStream

September 14, 2021

To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service, sometimes referred to as performing a health check. If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors: MYSQL-ECV and MSSQL-ECV. Using this monitor you can send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler appliance. For information about configuring monitors, see Configure monitors in a load balancing setup.

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run an SQL query to the database server and evaluate the server response to check whether it matches the configured rule.

The following examples are for MYSQL servers.

Examples:

In the following example, the value of the error message is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon1 MYSQL-ECV -sqlQuery "select * from
2 table2;" -evalrule "mysql.res.error.message.contains("Invalid
3 User")"-database "NS" -userName "user1"
4 <!--NeedCopy-->
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon4 MYSQL-ECV -sqlQuery "select * from
2 table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -
     userName "user2"
```

```
<!--NeedCopy-->
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
add lb monitor lb_mon3 MYSQL-ECV
-sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem
   (2) == 345.12"
-database "NS" -userName "user3"
<!--NeedCopy-->
```

The following examples are for MSSQL servers.

Examples:

In the following example, the value of the error message is evaluated to determine the state of the server.

```
add lb monitor lb_mon1 MSSQL-ECV -sqlQuery "select * from
table2;" -evalrule "mssql.res.error.message.contains("Invalid
User")"-database "NS" -userName "user1"
<!--NeedCopy-->
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
add lb monitor lb_mon4 MSSQL-ECV -sqlQuery "select * from
table4;" -evalrule "mssql.res.atleast_rows_count(7)" -database "NS" -
   userName "user2"
<!--NeedCopy-->
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
add lb monitor lb_mon3 MSSQL-ECV
-sqlQuery "select * from ABC;" -evalrule "mssql.res.row(1).double_elem
   (2) == 345.12"
-database "NS" -userName "user3"
<!--NeedCopy-->
```

Use Case 1: Configure DataStream for a primary/secondary database architecture

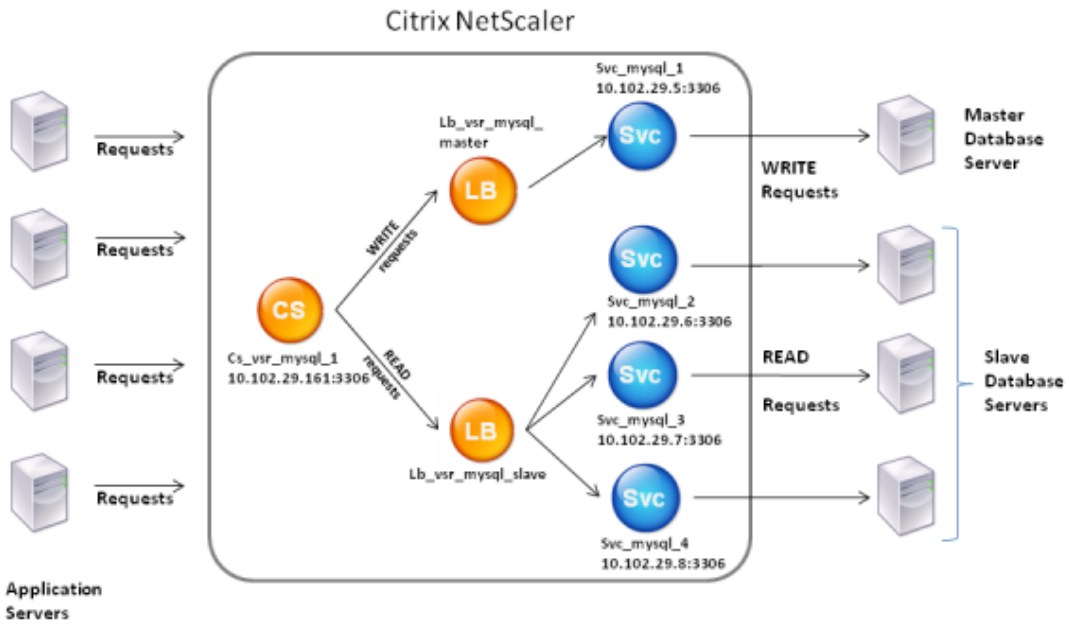
September 14, 2021

A commonly used deployment scenario is the primary/secondary database architecture where the primary database replicates all information to the secondary databases.

For primary/secondary database architecture, you might want all WRITE requests to be sent to the primary database and all READ requests to the secondary databases.

The following figure shows the entities and the values of the parameters you need to configure on the appliance.

Figure 1. DataStream Entity Model for Primary/Secondary Database Setup



In this example scenario, a service (Svc_mysql_1) is created to represent the primary database and is bound to a load balancing virtual server (Lb_vsr_mysql_primary). Three more services (Svc_mysql_2, Svc_mysql_3, and Svc_mysql_4) are created to represent the three secondary databases, and they are bound to another load balancing virtual server (Lb_vsr_mysql_secondary).

A content switching virtual server (Cs_vsr_mysql_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server, Lb_vsr_mysql_primary. All READ requests are sent to the load balancing virtual server, Lb_vsr_mysql_secondary.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the Citrix ADC appliance.

Entity Type	Name	IP Address	Protocol	Port	Expression
Services	Svc_mysql_1	198.51.100.5	MYSQL	3306	NA
	Svc_mysql_2	198.51.100.6	MYSQL	3306	NA
	Svc_mysql_3	198.51.100.7	MYSQL	3306	NA
	Svc_mysql_4	198.51.100.8	MYSQL	3306	NA
Load balancing virtual servers	Lb_vsr_mysql_	198.51.100.201	MYSQL	3306	NA
	Lb_vsr_mysql_secondary	198.51.100.202	MYSQL	3306	NA
Content switching virtual server	Cs_vsr_mysql_	198.51.100.161	MYSQL	3306	NA
Content switching policy	Cs_select	NA	NA	NA	`MYSQL.REQ.QUERY.COMMAND.contains("select")`

Table 1. Entity and Policy Names and Values

To configure DataStream for a primary/secondary database setup by using the command line interface

At the command prompt, type

```
add service Svc_mysql_1 198.51.100.5 mysql 3306

add service Svc_mysql_2 198.51.100.6 mysql 3306

add service Svc_mysql_3 198.51.100.7 mysql 3306

add service Svc_mysql_4 198.51.100.8 mysql 3306

add lb vserver Lb_vsr_mysql_primary mysql 198.51.100.201 3306

add lb vserver Lb_vsr_mysql_secondary mysql 198.51.100.202 3306

bind lb vserver Lb_vsr_mysql_primary svc_mysql_1

bind lb vserver Lb_vsr_mysql_secondary svc_mysql_2

bind lb vserver Lb_vsr_mysql_secondary svc_mysql_3

bind lb vserver Lb_vsr_mysql_secondary svc_mysql_4

add cs vserver Cs_vsr_mysql_1 mysql 198.51.100.161 3306

add cs policy Cs_select -rule "MYSQL.REQ.QUERY.COMMAND.contains(\"
   select"\)"

bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_primary

bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_secondary -policy
   Cs_select -priority 10
<!--NeedCopy-->
```

Use Case 2: Configure the token method of load balancing for DataStream

September 14, 2021

You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the Citrix ADC appliance sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the

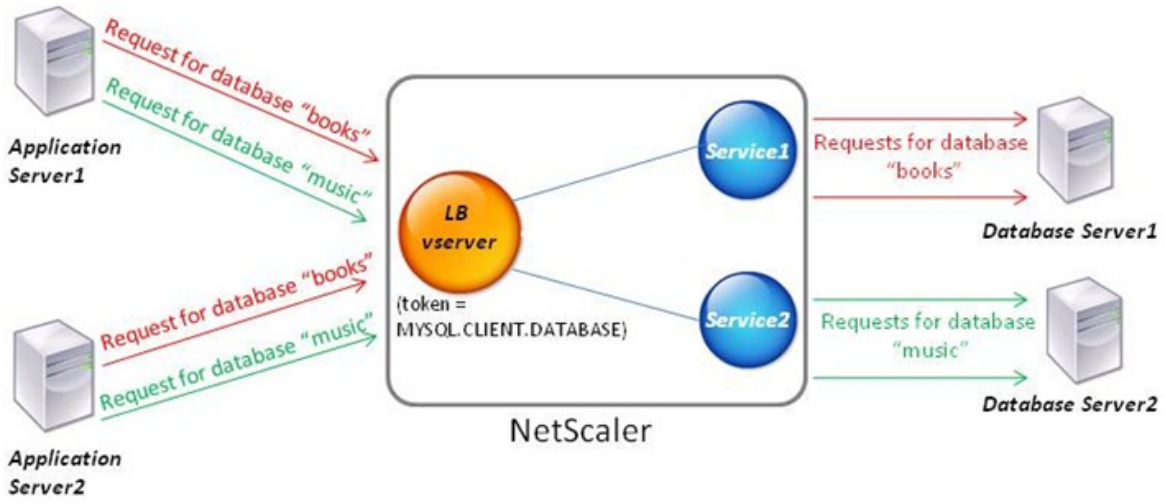
maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

MySQL	MS SQL
MYSQL.REQ.QUERY.TEXT	MSSQL.REQ.QUERY.TEXT
MYSQL.REQ.QUERY.TEXT(n)	MSSQL. REQ.QUERY.TEXT(n)
MYSQL.REQ.QUERY.COMMAND	MSSQL.REQ.QUERY.COMMAND
MYSQL.CLIENT.USER	MSSQL.CLIENT.USER
MYSQL.CLIENT.DATABASE	MSSQL.CLIENT.DATABASE
MYSQL.CLIENT.CAPABILITIES	

The following example shows how the Citrix ADC DataStream feature works when you configure the token method of load balancing.

Figure 1. DataStream and the Token Method of Load Balancing



In this example, the token is the name of the database. A request with token books is sent to Database Server1 and a request with token music is sent to Database Server2. All subsequent requests with token books are sent to Database Server1 and requests with token music are sent to Database Server2. This configuration provides pseudo persistence with the database servers.

Configure this example by using the CLI

At the command prompt, type:

```
add service Service1 192.0.2.9 MYSQL 3306

add service Service2 192.0.2.11 MYSQL 3306

add lb vserver token_lb_vserver MYSQL 192.0.2.15 3306 -lbmethod token -
    rule MYSQL.CLIENT.DATABASE

bind lb vserver token_lb_vserver Service1

bind lb vserver token_lb_vserver Service2
<!--NeedCopy-->
```

Configure this example by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, configure a virtual server, and specify the protocol as **MYSQL**.
2. Click in the **Service** section, and configure two services specifying the protocol as MYSQL. Bind these services to the virtual server.
3. In **Advanced Settings**, click **Method** and, in the **Load Balancing Method** list, select **TOKEN** and specify the expression as **MYSQL.CLIENT.DATABASE**.

Use Case 3: Log MSSQL transactions in transparent mode

September 14, 2021

You can configure the Citrix ADC appliance to operate transparently between MSSQL clients and servers, and to only log or analyze details of all client-server transactions. Transparent mode is designed so that the Citrix ADC appliance only forwards MSSQL requests to the server, and then relays the server's responses to the clients. As the requests and responses pass through the appliance, the appliance logs information gathered from them, as specified by the audit logging or AppFlow configuration, or collects statistics, as specified by the Action Analytics configuration. You do not have to add database users to the appliance.

When operating in transparent mode, the Citrix ADC appliance does not perform load balancing, content switching, or connection multiplexing for the requests. However, it responds to a client's pre-login packet on behalf of the server so that it can prevent encryption from being agreed upon during the pre-login handshake. The login packet and subsequent packets are forwarded to the server.

Summary of configuration tasks

For logging or analyzing MSSQL requests in transparent mode, you have to do the following:

- Configure the Citrix ADC appliance as the default gateway for both clients and servers.
- Do one of the following on the Citrix ADC appliance:
  - **Configure the use source IP address (USIP) option globally:** Create a load balancing virtual server with a wildcard IP address and the port number on which the MSSQL servers listen for requests (a port-specific wildcard virtual server). Then, enable the USIP option globally. If you configure a port-specific wildcard virtual server, you do not have to create MSSQL services on the appliance. The appliance discovers the services based on the destination IP address in the client requests.
  - **If you do not want to configure the USIP option globally:** Create MSSQL services with the USIP option enabled on each of them. If you configure services, you do not have to create a port-specific wildcard virtual server.
- Configure audit logging, AppFlow, or Action Analytics to log or collect statistics about the requests. If you configure a virtual server, you can bind your policies either to the virtual server or to the global bind point. If you do not configure a virtual server, you can bind your policies to only the global bind point.

Configure transparent mode by using a wildcard virtual server

You can configure transparent mode by configuring a port-specific wildcard virtual server and enabling Use Source IP (USIP) mode globally. When a client sends its default gateway (the Citrix ADC appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance checks whether the destination IP address is available. If the IP address is available, the virtual server forwards the request to the server. Otherwise, it drops the request.

Create a wildcard virtual server by using the CLI

At the command prompt, type the following commands to create a wildcard virtual server and verify the configuration:

```
add lb vserver <name> <serviceType> <IPAddress> <port>

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
> add lb vserver wildcardLbVs MSSQL * 1433
 Done
> show lb vserver wildcardLbVs
```

```
    wildcardLbVs (*:1433) - MSSQL   Type: ADDRESS
    State: UP
    . . .

 Done
>
<!--NeedCopy-->
```

Create a wildcard virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server. Specify MSSQL as the protocol and * as the IP address.

Enable Use Source IP (USIP) mode globally by using the CLI

At the command prompt, type the following commands to enable USIP mode globally and verify the configuration:

```
enable ns mode USIP

show ns mode
<!--NeedCopy-->
```

Example:

```
> enable ns mode USIP
 Done
> show ns mode

    Mode                              Acronym
       Status
    -------                           -------
       ------
                . . .
 3) Use Source IP                  USIP                            ON
                . . .
 Done
>
<!--NeedCopy-->
```

Enable USIP mode globally by using the GUI

1. Navigate to **System > Settings** and, in Modes and Features, select **Configure Modes**.

2. Select **Use Source IP**.

Configure transparent mode by using MSSQL services

You can configure transparent mode by configuring MSSQL services and enabling USIP on each service. When a client sends its default gateway (the Citrix ADC appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance forwards the request to the destination server.

Create an MSSQL service and enable USIP mode on the service by using the CLI

At the command prompt, type the following commands to create an MSSQL service, with USIP enabled, and verify the configuration:

```
add service <name> (<IP> | <serverName>) <serviceType> <port> -usip YES
    `

show service <name>
<!--NeedCopy-->
```

Example

```
> add service myDBservice 192.0.2.0 MSSQL 1433 -usip YES
 Done
> show service myDBservice
    myDBservice (192.0.2.0:1433) - MSSQL
    State: UP
                . . .
    Use Source IP: YES      Use Proxy Port: YES
                . . .
 Done
>
<!--NeedCopy-->
```

Create an MSSQL service, with USIP enabled, by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and configure a service.
2. Specify the protocol as **MSSQL** and, in **Settings**, select **Use Source IP**.

Use Case 4: Database specific load balancing

September 14, 2021

A database server farm must be load balanced not only based on the states of the servers, but also based on the availability of the database on each server. A service might be up, and a load balancing device might show it as being in the UP state, but the requested database might be unavailable on that service. The request is not served if a query is forwarded to a service on which the database in unavailable. Therefore, a load balancing device must be aware of the availability of a database on each service. And when making a load balancing decision, it must consider only those services on which the database is available.

As an example, consider that database servers server1, server2, and server3 host databases mydatabase1 and mydatabase2. If mydatabase1 becomes unavailable on server2, the load balancing device must be aware of that change in state. It must load balance requests for mydatabase1 across only server1 and server3. After mydatabase1 becomes available on server2, the load balancing device must include server2 in load balancing decisions. Similarly, if mydatabase2 becomes unavailable on server3, the device must load balance requests for mydatabase2 across only server1 and server2. It must include server3 in its load balancing decisions only when mydatabase2 becomes available. This load balancing behavior must be consistent across all the databases that are hosted on the server farm.

The Citrix ADC appliance implements this behavior by retrieving a list of all the databases that are active on a service. To retrieve the list of active databases, the appliance uses a monitor that is configured with an appropriate SQL query. If the requested database is unavailable on a service, the appliance excludes the service from load balancing decisions until it becomes available. This behavior ensures uninterrupted service to clients.

> **Note**
>
> Database specific load balancing is supported for only MSSQL and MySQL service types. This support is also available for Microsoft SQL Server 2012 high availability deployment.

To set up database specific load balancing, you must configure the following:

- Enable the load balancing feature, and configure a load balancing virtual server of type MSSQL or MySQL.
- Configure the services that host the database, and bind the services to the virtual server. The monitor needs valid user credentials to log on to the database server, so you must configure a database user account on each of the servers and then add the user account to the Citrix ADC appliance.
- Then, you configure an MSSQL-ECV or MYSQL-ECV monitor and bind the monitor to each service.
- Finally, you must test the configuration to ensure that it is working as intended. Before you

perform these configuration tasks, make sure you understand how database specific load balancing works.

How database specific load balancing works

For database specific load balancing, you configure a monitor that periodically queries each database server for the names of all the active databases on it. The Citrix ADC appliance stores the results, and regularly updates the records based on the information retrieved through monitoring. When a client queries a particular database, the appliance uses the configured load balancing method to select a service, and then checks its records to determine whether the database is available on that service. If the records indicate that the database is not available, it uses the configured load balancing method to select the next available service, and then repeats the check. The appliance forwards the query to the first available service on which the database is active.

Enable load balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled. The entities do not function until you enable the feature.

Enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
enable ns feature LB

show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature LoadBalancing
 Done
> show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  OFF
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 .
 .
 .
```

```
 24)    NetScaler Push                  push                  OFF
 Done
<!--NeedCopy-->
```

Enable load balancing by using the GUI

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

Configure a load balancing virtual server for database specific load balancing

To configure a virtual server to load balance databases based on availability, you enable the database specific load balancing parameter on the virtual server. Enabling the parameter modifies the load balancing logic so that the Citrix ADC appliance refers the results of the monitoring probe sent to the selected service, before forwarding the query to that service.

Configure a load balancing virtual server for database specific load balancing using the CLI

At the command prompt, type the following command to configure a load balancing virtual server for database specific load balancing and verify the configuration:

```
add lb vserver <name> <serviceType> <ipAddress> <port> -dbsLb ENABLED

show lb vserver <name>
<!--NeedCopy-->
```

Configure services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

Configure database users

In databases, a connection is always stateful, which means that when a connection is established, it must be authenticated.

Configure your database user name and password on the Citrix ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. Database user names and passwords added to the ADC are added to the `nsconfig` file.

> **Note**
>
> Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

Add a database user by using the CLI

At the command prompt, type

```
add db user <username> - password <password>
<!--NeedCopy-->
```

Example:

```
add db user nsdbuser -password dd260427edf
<!--NeedCopy-->
```

Add a database user by using the GUI

Navigate to **System > User Administration > Database Users**, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the Citrix ADC appliance.

Reset the password of a database user by using the CLI

At the command prompt, type

```
set db user <username> -password <password>
<!--NeedCopy-->
```

Example:

```
set db user nsdbuser -password dd260538abs
<!--NeedCopy-->
```

Reset the password of database users by using the GUI

Navigate to **System > User Administration > Database Users**, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the Citrix ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated. Therefore, the user name does not get routed to the database server.

Remove a database user by using the CLI

At the command prompt, type

```
rm db user <username>
<!--NeedCopy-->
```

Example:

```
rm db user nsdbuser
<!--NeedCopy-->
```

Remove a database user by using the GUI

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

Configure a monitor to retrieve the names of active databases

You can create a monitor to retrieve the list of all active databases on a database instance. The monitor logs on to the database server by using a valid user credentials and runs an appropriate SQL query. The SQL query you need to use depends on your SQL server deployment. For example, in an MSSQL database mirroring setup, you can use the following query to retrieve a list of active databases available on a server instance.

```
select name from sys.databases where state=0
<!--NeedCopy-->
```

In a MySQL database setup you can use the following queries to retrieve a list of active databases available on a server instance.

Show databases:

You also configure the monitor to evaluate the response for an error condition, and to store the results if there is no error. If the response contains an error, the monitor marks the service as DOWN. The appliance excludes the service from load balancing decisions until an error is no longer returned.

> **Note**
>
> The database specific load balancing feature is supported only for the MSSQL and MySQL service types. Therefore, the monitor type must be MSSQL-ECV or MYSQL-ECV.

Configure a monitor to retrieve the names of all the active databases hosted on a service by using the CLI

At the command prompt, type the following commands to retrieve the names of all the active databases hosted on a service and verify the configuration:

```
add lb monitor <monitorName> <type> -userName <string> -sqlQuery <text>
    -evalRule <expression> -storedb ENABLED

show lb monitor <monitorName>
<!--NeedCopy-->
```

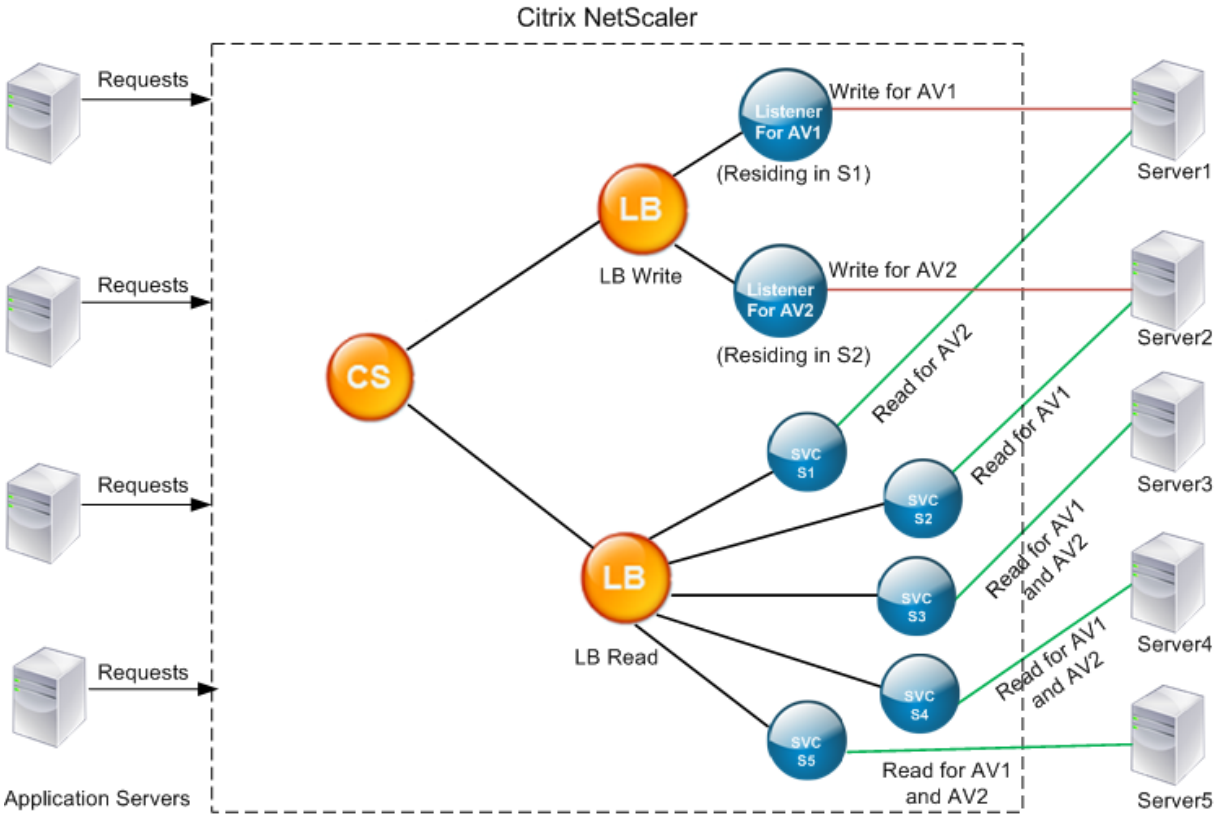
Configure a monitor to retrieve the names of all the active databases hosted on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors** and configure a monitor of type MSSQL-ECV or MYSQL-ECV.
2. In **Special Parameters**, specify a user name, query, and a rule. For example, for MSSQL-ECV, the query must be “select name from sys.databases where state=0”), and a rule must be MSSQL.RES.TYPE.NE(ERROR). For MYSQL-ECV, the query must be “show databases” and a rule must be MYSQL.RES.TYPE.NE(ERROR).

Availability groups deployment support for MSSQL

Consider the following scenario in which database specific load balancing is configured in a high availability group deployment. S1 through S5 is the services on the ADC appliance. DB1 through DB4 is the databases on the servers represented by the services S1 through S5. AV1 and AV2 are the availability groups. Each availability group contains up to one primary database server instance and up to four secondary database server instances. A service, representing the servers in the availability group, can be primary for one availability group and secondary for another availability group. Each availability group contains different databases and one listener, which is a service. All requests arrive on the listener service that resides on the primary database. AVI contains databases DB1 and DB2. AV2 contains

databases DB3 and DB4. L1 and L2 are the listeners on AV1 and AV2 respectively. S1 is the primary service for AV1 and S2 is the primary service for AV2.



Service	List of Active Databases on the Service
S1	DB1, DB2, DB3, DB4
S2	DB3, DB4
S3	DB3, DB4
S4	DB1, DB2
S5	DB1, DB2

Availability Group	Databases	Services representing the Servers in the Availability Group
AV1	DB1, DB2	S1, S4, S5
AV2	DB3, DB4	S1, S2, S3

Queries flow as follows:

1. A READ query for AV1 is load balanced between S4 and S5. S1 is the primary for AV1.
2. A WRITE query for AV1 is directed to L1.
3. A READ query for AV2 is load balanced between S1 and S3. S2 is the primary for AV2.
4. A WRITE query for AV1 is directed to L2.

Sample configuration

1. Configure load balancing and content switching virtual servers.
   - `add lb vserver lbwrite -dbslb enabled`
   - `add lbvserver lbread MSSQL -dbslb enabled`
   - `add csvserver csv MSSQL 1.1.1.10 1433`
2. Configure two listener services, one for each availability group, and five services S1 through S5 representing databases DB1 through DB4.
   - `add service L1 1.1.1.11 MSSQL 1433`
   - `add service L2 1.1.1.12 MSSQL 1433`
   - `add service s1 1.1.1.13 MSSQL 1433`
   - `add service s2 1.1.1.14 MSSQL 1433`
   - `add service s3 1.1.1.15 MSSQL 1433`
   - `add service s4 1.1.1.16 MSSQL 1433`
   - `add service s5 1.1.1.17 MSSQL 1433`
3. Bind the services to the load balancing virtual servers.
   - `bind lbvserver lbwrite L1`
   - `bind lbvserver lbwrite L2`
   - `bind lbvserver lbread s1`
   - `bind lbvserver lbread s2`
   - `bind lbvserver lbread s3`
   - `bind lbvserver lbread s4`
   - `bind lbvserver lbread s5`
4. Configure database users.
   - `add db user nsdbuser1 -password dd260427edf`
   - `add db user nsdbuser2 -password ccd1234xyzw`
5. Configure two monitors, monitor_L1 and monitor_L2 for each listener service, to retrieve the list of active databases in that availability group. Add a monitor, monitor1 to retrieve the list of databases for the secondary database server instance.
   - ```
     add lb monitor monitor_L1 MSSQL-ECV -userName user1 -sqlQuery "
     SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_
      b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners
      c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_a
     ```

     ```

```
 d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address
 like '1.1.1.11'"-evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb
ENABLED
```

- `add lb monitor monitor_L2 MSSQL-ECV -userNameuser1 -sqlQuery "`
  `SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replicca`
  `b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners`
  `c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_a`
  `d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address`
  `like '1.1.1.12'"-evalRule "MSSQL.RES.TYPE.NE(ERROR)"-storedb`
  `ENABLED`
- `add lb monitor monitor1 MSSQL-ECV -userNameuser1 -sqlQuery "SELECT`
  `name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_states`
  `b ON a.replica_id=b.replica_id WHERE b.role = 2"-evalRule "MSSQL.`
  `RES.TYPE.NE(ERROR)"-storedb ENABLED`

6. Configure read and write policies.
   - `add cs policy pol_write -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS("`
     `insert")"`
   - `add cs policy pol_read -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS("select`
     `")"`
7. Bind the policies to the content switching virtual server.
   - `bind csvserver csv -targetLBVserver lbwrite -policyName pol_write -`
     `priority 11`
   - `bind csvserver csv -targetLBVserver lbread -policyName pol_read -`
     `priority 12`
8. Bind monitors to the services. Bind monitors to services L1 and L2 to get the list of active databases for the availability group for which it is the listener. Bind monitors to all the services that are bound to the read-only virtual server.
   - `bind service L1 -monitorName monitor_L1`
   - `bind service L2 -monitorName monitor_L2`
   - `bind service s1 -monitorName monitor1`
   - `bind service s2 -monitorName monitor1`
   - `bind service s3 -monitorName monitor1`
   - `bind service s4 -monitorName monitor1`
   - `bind service s5 -monitorName monitor1`

Configuration examples for MSSQL virtual server

To configure a load balancing virtual server for database specific load balancing:

```
1 add lb vserver DBSpecificLB1 MSSQL 192.0.2.10 1433 -dbsLb ENABLED
```

```
2
3 Done
4
5 show lb vserver DBSpecificLB1
6
7 DBSpecificLB1 (192.0.2.10:1433) - MSSQL Type: ADDRESS
8 . . .
9 DBS_LB: ENABLED
10
11 Done
12 <!--NeedCopy-->
```

To configure services:

add service msservice1 5.5.5.5 MSSQL 1433

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:

```
1 add lb monitor mssql-monitor1 MSSQL-ECV -userName user1 -sqlQuery "
     select name from sys.databases where state=0" -evalRule "MSSQL.RES.
     TYPE.NE(ERROR)" -storedb EN
2
3 Done
4
5 show lb monitor mssql-monitor1
6
7 1)   Name.......: mssql-monitor1    Type......: MSSQL-ECV
8
9 ...
10
11 Special parameters: Database.....:""
12
13 User name.....:"user1"
14
15 Query..:select name from sys.databases where state=0 EvalRule...:MSSQL.
     RES.TYPE.NE(ERROR)
16
17 Version...:70 STORE_DB...:ENABLED
18
19 Done
20 <!--NeedCopy-->
```

Configuration examples for MySQL virtual server

To configure a load balancing virtual server for database specific load balancing:

```
add lb vserver DBSpecificLB1 MYSQL 192.0.2.10 3306 -dbsLb ENABLED

Done

show lb vserver DBSpecificLB1

DBSpecificLB1 (192.0.2.10:3306) - MYSQL Type: ADDRESS

. . .

DBS_LB: ENABLED

Done
<!--NeedCopy-->
```

To configure services:

```
add service msservice1 5.5.5.5 MYSQL 3306
<!--NeedCopy-->
```

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:

```
add lb monitor mysql-monitor1 MYSQL-ECV -userName user1 -sqlQuery "show
    databases" -evalRule "MYSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED

Done

show lb monitor mysql-monitor1

1)     Name.......: mysql-monitor1  Type......: MYSQL-ECV  State....:
   ENABLED

...

Special parameters: Database.....:""

User name.....:"user1" Query..:show databases

EvalRule...:MYSQL.RES.TYPE.NE(ERROR) STORE_DB...:ENABLED

Done
```

```
<!--NeedCopy-->
```

DataStream reference

September 14, 2021

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how the Citrix ADC handles transaction requests and special queries that modify the state of a connection.

You can also configure the Citrix ADC appliance to generate audit log messages for the DataStream feature.

Supported database versions, protocols, and authentication methods

	MySQL Database	MS SQL Database
Database Versions	MySQL database versions 4.1, 5.0, 5.1, 5.4, 5.5, 5.6	MS SQL database versions 2000, 2000SP1, 2005, 2008, 2008R2, 2012, 2014 (Kerberos Authentication support)
Protocols	MySQL protocol version 10. For information about the MySQL protocol, see MySQL Client/Server Protocol	Tabular Data Stream (TDS) protocol version 7.1 and higher. For information about the TDS protocol, see Tabular Data Stream Protocol
Authentication Methods	MySQL native authentication is supported.	SQL server authentication and Windows Authentication (Kerberos/NTLM) are supported.

Character sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request might be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set cannot be

multiplexed onto a connection with a different character set.

The Citrix ADC appliance parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

```
SET NAMES <charset> COLLATION <collation>

SET CHARACTER SET <charset>
<!--NeedCopy-->
```

Transactions

In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the query SET AUTOCOMMIT.

The Citrix ADC appliance explicitly parses each query to determine the beginning and end of a transaction.

In the MySQL protocol, the response contains two flags to indicate whether the connection is a transaction: the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag is not set. The ADC appliance parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag is not set, it does not do connection multiplexing. When these conditions are no longer true, the ADC appliance begins connection multiplexing.

> **Note**
>
> Transactions are also supported for MS SQL.

Special queries

There are special queries, such as SET and PREPARE, that modify the state of the connection and might break request switching, and therefore, these queries need to be handled differently.

On receiving a request with special queries, the Citrix ADC appliance sends an OK response to the client and also, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the ADC appliance looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, the ADC appliance creates a connection, and sends the stored query first, and then, sends the request with the non-special query.

In SET, USE db, and INIT_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This modification results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which the ADC appliance has a modified behavior.

- SET query

  The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, the ADC appliance is unable to differentiate between local and global variables. For this query, the ADC appliance uses the 'store and forward' mechanism.

- USE <db> query

  Using this query, the user can change the database associated with a connection. In this case, the ADC appliance parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

- INIT_DB command

  Using this query, the user can change the database associated with a connection. In this case, the ADC appliance parses the <init_db> value sent and modifies a field in the server side connection to reflect the new database to be used.

- COM_PREPARE

  The ADC appliance stops request switching on receiving this command.

- PREPARE query

  This query is used to create prepared statements that are associated with a connection. For this query, the ADC appliance uses the 'store and forward' mechanism.

Audit log message support

You can now configure the Citrix ADC appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with "CS" and error messages for server-side connections begin with "SS." Additional information is provided where necessary. For example, log messages for closed connections (CS_CONN_CLOSED) include only the connection ID. However, log messages for established connections (CS_CONN_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.

Domain Name System

September 14, 2021

Note: From release 13.0 build 41.x, the Citrix ADC appliance in ADNS and proxy mode is fully compliant with DNS flag day 2019.

You can configure the Citrix ADC appliance to function as an authoritative domain name server (ADNS server) for a domain. Add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within or outside your network. Configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the appliance as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the TCP for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).

How DNS Works on the Citrix ADC

You can configure the Citrix ADC appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the Citrix ADC appliance, including the following records:

- Service (SRV) records
- IPv6 (AAAA) records
- Address (A) records
- Mail exchange (MX) records
- Canonical name (CNAME) records
- Pointer (PTR) records
- Start of authority (SOA) records
- Text (TXT) records

Also, you can configure the Citrix ADC to load balance external DNS name servers.

The Citrix ADC appliance can be configured as the authority for a domain. Add valid SOA and NS records for the domain.

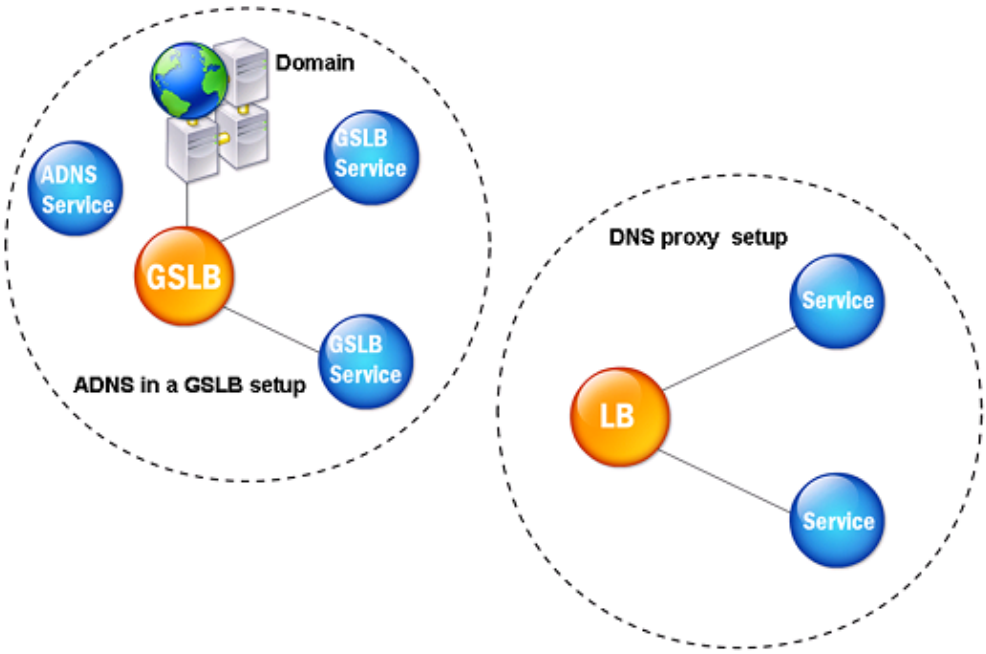
An ADNS server is a DNS server that contains complete information about a zone.

To configure the Citrix ADC appliance as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a

client sends a DNS request, the Citrix ADC appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the Citrix ADC Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the Citrix ADC authoritative for the subdomain, by adding a “glue record” for each of the subdomain name servers. If GSLB is configured, the Citrix ADC makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server. The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.

Figure 1. DNS Proxy Entity Model



The Citrix ADC appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the Citrix ADC appliance. Caching enables the Citrix ADC appliance to provide quick responses for repeated translations. Create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The Citrix ADC provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The Citrix ADC checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is

greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The Citrix ADC also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called *negative caching*. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- NXDOMAIN error message - If a negative response is present in the local cache, the Citrix ADC returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the Citrix ADC. The Citrix ADC caches the response locally, then returns the error message to the client.
- NODATA error message - The Citrix ADC sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.

The Citrix ADC supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the Citrix ADC queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the Citrix ADC as a DNS forwarder. A forwarder passes DNS requests to external name servers. The Citrix ADC allows you to add external name servers and provides name resolution for domains outside the network. The Citrix ADC also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).

Enable the ADC appliance to use DNS to resolve the host name to its respective IP address

Note: You require an SSH utility to access the command line interface (CLI) of the appliance.

By default, the ADC appliance cannot resolve the host name to its respective IP address. Complete the following tasks to enable the name resolution on the appliance:

1. Define name servers.
2. Define a DNS suffix.

Points to note

Perform the DNS lookup from the CLI. DNS lookups from the shell prompt of the FreeBSD operating system fail because the entry in the /etc/resolv.conf file points to the 127.0.0.2 IP address.

The following commands are not available in the CLI of the appliance:

```
- host
- dig
- getent/MIP
- nslookup
<!--NeedCopy-->
```

If the appliance cannot ping the DNS server on its SNIP address, the server status shows as down. Successful ping is important when the appliance is behind a firewall.

CLI configuration

At the command prompt, type:

```
add dns nameServer <Name_Server_IP_Address>
add dns suffix <DNS_Suffix>
<!--NeedCopy-->
```

To verify the configuration, type:

```
show dns nameServer
show dns suffix
<!--NeedCopy-->
```

To test DNS resolution, type:

```
show dns addrec <Host_Name>
<!--NeedCopy-->
```

GUI configuration

1. Navigate to **Traffic Management > DNS > Names Servers > Add**.
2. In the **Create Name Server** dialog box enter the name server IP Address and click **Create**.
3. Navigate to **Traffic Management > DNS > DNS Suffix > Add**.
4. In the **Create DNS Suffix** dialog box, enter the DNS Suffix, such as example.com, to be used for all host queries and click **Create**.

Round Robin DNS

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when many requests arrive.

When the Citrix ADC receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The Citrix ADC performs this function automatically. You do not have to configure this behavior.

Functional Overview

If the Citrix ADC is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. When the Citrix ADC is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The Citrix ADC then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

Round Robin DNS Example

As an example of round robin DNS, consider DNS records that have been added as follows:

```
1   add dns addRec ns1 1.1.1.1  add dns addRec ns1 1.1.1.2  add dns
       addRec ns1 1.1.1.3  add dns addRec ns1 1.1.1.4
2 <!--NeedCopy-->
```

The domain, abc.com is linked to an NS record as follows:

```
1   add dns nsrec abc.com. ns1
2 <!--NeedCopy-->
```

When the Citrix ADC receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

```
1   ns1.                    1H IN A         1.1.1.1  ns1.
                           1H IN A         1.1.1.2  ns1.
                           1H IN A         1.1.1.3  ns1.
                           1H IN A         1.1.1.4
2 <!--NeedCopy-->
```

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

```
1   ns1.                    1H IN A         1.1.1.2  ns1.
                           1H IN A         1.1.1.3  ns1.
                           1H IN A         1.1.1.4  ns1.
                           1H IN A         1.1.1.1
```

```
<!--NeedCopy-->
```

In the third DNS response, the third IP address, 1.1.1.2 is served as the first record:

```
  ns1.                    1H IN A         1.1.1.3  ns1.
                         1H IN A         1.1.1.4  ns1.
                         1H IN A         1.1.1.1  ns1.
                         1H IN A         1.1.1.2
<!--NeedCopy-->
```

Configure DNS resource records

September 14, 2021

You configure resource records on the Citrix® ADC appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records
- Mail Exchange records
- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records

The following table lists the record types that you can configure for a domain name record on the Citrix ADC appliance. For example, you can configure a maximum of 25 IP addresses for one record.

Table 1. Record Type and Number Configurable

Record Type	Number of Records
Address (A)	25
IPv6 (AAAA)	5
Mail exchange (MX)	12
Name server (NS)	16

Record Type	Number of Records
Service (SRV)	8
Pointer (PTR)	20
Canonical name (CNAME)	1
Start of Authority (SOA)	1
Text (TXT)	20
Naming Authority Pointer (NAPTR)	20

> **Note:**
>
> The maximum number of IP addresses for a specific host name is 25. However, the number of different address records can be more than 25.

Create SRV records for a service

September 14, 2021

The SRV record provides information about the services available on the Citrix ADC appliance. An SRV record contains the following information:

- Name of the service and the protocol
- Domain name
- TTL
- DNS class
- Priority of the target
- Weight of records with the same priority
- Port of the service
- Host name of the service.

The Citrix ADC chooses the SRV record that has the lowest priority setting first. If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

Add an SRV record by using the CLI

At the command prompt, type the following commands to add an SRV record and verify the configuration:

```
1 -  add dns srvRec <domain> <target> -priority <positive_integer> -
     weight <positive_integer> -port <positive_integer> [-TTL <secs>]
2 -  sh dns srvRec <domain>
3 <!--NeedCopy-->
```

Example:

```
1 > add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -
     weight 1 -port 80
2  Done
3 > show dns srvRec _http._tcp.example.com
4 1)      Domain Name : _http._tcp.example.com
5         Target Host : nameserver1.com
6         Priority : 1    Weight : 1
7         Port : 80       TTL : 3600 secs
8  Done
9 <!--NeedCopy-->
```

Modify or remove an SRV record by using the CLI

- To modify an SRV record, type:
  - The `set dns srvRec` command
  - The name of the domain for which the SRV record is configured
  - The name of the target host that hosts the associated service
  - The parameters to be changed, with their new values
- To remove an SRV record, type:
  - The `rm dns srvRec` command
  - The name of the domain for which the SRV record is configured
  - The name of the target host that hosts the associated service

Configure an SRV record by using the GUI

Navigate to **Traffic Management > DNS > Records > SRV Records** and create an SRV record.

Create AAAA records for a domain name

September 14, 2021

An AAAA resource record stores a single IPv6 address.

Add an AAAA record by using the CLI

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

```
-  add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
-  show dns aaaaRec <hostName>
<!--NeedCopy-->
```

Example:

```
> add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57
   ab
 Done
> show dns aaaaRec www.example.com
1)      Host Name : www.example.com
        Record Type : ADNS              TTL : 5 secs
        IPV6 Address : 2001:db8::1428:57ab
 Done
<!--NeedCopy-->
```

To remove an AAAA record and all the IPv6 addresses associated with the domain name, type the `rm dns aaaaRec` command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the following:

- `rm dns aaaaRec` command
- The domain name for which the AAAA record is configured
- The IPv6 addresses that you want to remove

Add an AAAA record by using the GUI

Navigate to **Traffic Management > DNS > Records > AAAA Records** and create an AAAA record.

Create address records for a domain name

September 14, 2021

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the Citrix ADC deletes Address records added for GSLB domains when you unbind the domain

from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.

Add an Address record by using the CLI

At the command prompt, type the following commands to add an Address record and verify the configuration:

```
-  add dns addRec <hostName> <IPAddress> [-TTL <secs>]
-  show dns addRec <hostName>
<!--NeedCopy-->
```

Example:

```
> add dns addRec ns.example.com 192.0.2.0
 Done
> show dns addRec ns.example.com
1)      Host Name : ns.example.com
        Record Type : ADNS                      TTL : 5 secs
        IP Address : 192.0.2.0
 Done
<!--NeedCopy-->
```

To remove an Address record and all the IP addresses associated with the domain name, type the `rm dns addRec` command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the following:

- `rm dns addRec` command
- The domain name for which the Address record is configured
- The IP addresses that you want to remove

Add an Address record by using the GUI

Navigate to **Traffic Management > DNS > Records > Address Records** and create an Address record.

Create MX records for a mail exchange server

September 14, 2021

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0

through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.

Add an MX record by using the CLI

At the command prompt, type the following commands to add an MX record and verify the configuration:

```
1 -  add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <
     secs>]
2 -  show dns mxRec <domain>
3 <!--NeedCopy-->
```

Example:

```
1 > add dns mxRec example.com -mx mail.example.com -pref 1
2  Done
3 > show dns mxRec example.com
4 1)      Domain : example.com    MX Name : mail.example.com
5         Preference :   1        TTL : 5 secs
6  Done
7 <!--NeedCopy-->
```

Modify or remove an MX record by using the CLI

- To modify an MX record, type the `set dns mxRec` command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.
- To set the TTL parameter to its default value, type the `unset dns mxRec` command, the name of the domain for which the MX record is configured, the name of the MX record, and -TTL without any TTL value. You can use the `unset dns mxRec` command to unset only the TTL parameter.
- To remove an MX record, type the `rm dns mxRec` command, the name of the domain for which the MX record is configured, and the name of the MX record.

Add an MX record by using the GUI

Navigate to **Traffic Management > DNS > Records > Mail Exchange Records** and create an MX record.

Create NS Records for an authoritative server

September 14, 2021

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.

Create an NS record by using the CLI

At the command prompt, type the following commands to create an NS record and verify the configuration:

```
-  add dns nsRec <domain> <nameServer> [-TTL <secs>]
-  show dns nsRec <domain>
<!--NeedCopy-->
```

Example:

```
> add dns nsRec example.com nameserver1.example.com
 Done
> show dns nsRec example.com
1)      Domain : example.com    NameServer : nameserver1.example.com
        TTL : 5 sec
 Done
<!--NeedCopy-->
```

To remove an NS record, type the `rm dns nsRec` command, the name of the domain to which the NS record belongs, and the name of the name server.

Create an NS record by using the GUI

Navigate to **Traffic Management > DNS > Records > Name Server Records** and create an NS record.

Create CNAME records for a subdomain

September 14, 2021

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

Sometimes, a Citrix ADC appliance in proxy mode requests an address record from the cache instead of the server.

Add a CNAME record by using the CLI

At the command prompt, type the following commands to create a CNAME record and verify the configuration:

```
-  add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]
-  show dns cnameRec <aliasName>
<!--NeedCopy-->
```

Example:

```
> add dns cnameRec www.example.com www.examplenw.com
 Done
> show dns cnameRec www.example.com
        Alias Name      Canonical Name  TTL
1)      www.example.com        www.examplenw.com       5 secs
 Done
<!--NeedCopy-->
```

To remove a CNAME record for a given domain, type the `rm dns cnameRec` command and the alias of the domain name.

Add a CNAME record by using the GUI

Navigate to **Traffic Management > DNS > Records > Canonical Records** and create a CNAME record.

Cache CNAME records

When deployed in a proxy mode, the ADC appliance does not always send the query for an address record to the back-end server. This behavior occurs when for an answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache. Following are the conditions:

- Citrix ADC must be deployed in a proxy mode.
- The response from the back-end server must have a CNAME chain, for which the record type of the last entry in the answer section must be a CNAME and the question type not a CNAME.

- The response from the back-end server cannot be a No-data or NX-Domain.
- The response from the back-end server has to be an authoritative response.

Create NAPTR records for telecommunications domain

September 14, 2021

NAPTR (Naming Address Pointer) is one of the most commonly used DNS records in the telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

Citrix ADCs support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in Citrix ADC. Citrix ADC caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record are served from the cache.

Create a NAPTR record by using CLI

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

```
add dns naptrRec <order> <preference>[flags<string>][services<string>](
regexp<expressions>|-replacement<string>)[-TTL<secs>]
```

Remove a NAPTR record by using CLU

```
rm dns naptrRec<domain> (<order> <preference> [-flags <string>] [-services
 <string>] (-regexp <expression> | -replacement <string>))| -recordId <
positive_integer>@)
```

Configure a NAPTR record using GUI

Navigate to **Traffic Management > DNS > Records > NAPTR Records** and create an NAPTR record.

Create PTR records for IPv4 and IPv6 addresses

September 14, 2021

A pointer (PTR) record translates an IP address to its domain name. IPv4 PTR records are represented by the octets of an IP address in reverse order with the string "in-addr.arpa." appended at the end. For example, the PTR record for the IP address 1.2.3.4 is 4.3.2.1.in-addr.arpa.

IPv6 addresses are reverse mapped under the domain IP6.ARPA. IPv6 reverse-maps use a sequence of nibbles separated by dots with the suffix ".IP6.ARPA" as defined in RFC 3596. For example, the reverse lookup domain name corresponding to the address, 4321:0:1:2:3:4:567:89ab would be b.a.9.8.7.6.5.0.4.0.0.0.3.0.0.0.2.0.0.0.1.0.0.0.0.0.0.0.1.2.3.4.IP6.ARPA.

Add a PTR record by using the CLI

At the command prompt, type the following commands to add a PTR record and verify the configuration:

```
1 -  add dns ptrRec <reverseDomain> <domain> [-TTL <secs>]
2 -  show dns ptrRec <reverseDomain>
3 <!--NeedCopy-->
```

Example:

```
1 > add dns ptrRec 0.2.0.192.in-addr.arpa example.com
2  Done
3 > show dns ptrRec 0.2.0.192.in-addr.arpa
4 1)      Reverse Domain Name : 0.2.0.192.in-addr.arpa
5         Domain Name : example.com              TTL : 3600 secs
6  Done
7 <!--NeedCopy-->
```

To remove a PTR record, type the `rm dns ptrRec` command and the reverse domain name associated with the PTR record

Add a PTR record by using the GUI

Navigate to **Traffic Management > DNS > Records > PTR Records** and create a PTR record.

Create SOA records for authoritative information

September 14, 2021

A Start of Authority (SOA) record is created only at the zone apex and contains information about the zone. The record includes, among other parameters, the primary name server, contact information (email), and default (minimum) time-to-live (TTL) values for records.

Create an SOA record by using the CLI

At the command prompt, type the following commands to add an SOA record and verify the configuration:

```
1 - add dns soaRec <domain> -originServer <originServerName> -contact <
    contactName>
2 - sh dns soaRec <do main>
3 <!--NeedCopy-->
```

Example:

```
1 > add dns soaRec example.com -originServer nameserver1.example.com -
    contact admin.example.com
2  Done
3 > show dns soaRec example.com
4 1)      Domain Name : example.com
5         Origin Server : nameserver1.example.com
6         Contact : admin.example.com
7         Serial No. : 100        Refresh : 3600 secs     Retry : 3 secs
8         Expire : 3600 secs      Minimum : 5 secs        TTL : 3600 secs
9  Done
10 <!--NeedCopy-->
```

Modify or remove an SOA record by using the CLI

- To modify an SOA record, type the `set dns soaRec` command, the name of the domain for which the record is configured, and the parameters to be changed, with their new values.
- To remove an SOA record, type the `rm dns soaRec` command and the name of the domain for which the record is configured.

Configure an SOA record by using the GUI

Navigate to **Traffic Management > DNS > Records > SOA Records** and create an SOA record.

Create TXT records for holding descriptive text

September 14, 2021

Domain hosts store TXT records for informative purposes. A TXT record's RDATA component, which consists of one or more character strings of variable length, can store practically any information that a recipient might need to know about the domain. It can also include information about the service provider, contact person, email addresses, and associated details. SPF (Sender Policy Framework) protection has been the most prominent use case for the TXT record.

All configuration types (authoritative DNS, DNS proxy, end resolver, and forwarder configurations) on the Citrix ADC appliance support TXT records. You can add a maximum of 20 TXT resource records to a domain. Each resource record is stored with a unique, internally generated record ID. You can view the ID of a record and use it to delete the record. However, you cannot modify a TXT resource record.

Create a TXT resource record by using the CLI

At the command prompt, type the following commands to create a TXT resource record and verify the configuration:

```
1 -  add dns txtRec <domain> <string> ... [-TTL <secs>]
2 -  show dns txtRec [<domain> | -type <type>]
3 <!--NeedCopy-->
```

Example:

```
1 > add dns txtRec www.example.com "Contact: Mark" "Email: mark@example.
     com" -TTL 36000
2  Done
3 > show dns txtRec www.example.com
4 1)  Domain : www.example.com    Record id: 13783       TTL : 36000 secs
      Record Type : ADNS
5         "Contact: Mark"
6         "Email: mark@example.com"
7  Done
8 <!--NeedCopy-->
```

Remove a TXT resource record by using the CLI

At the command prompt, type the following commands to remove a TXT resource record and verify the configuration:

```
-  rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>)
-  show dns txtRec [<domain> | -type <type>]
<!--NeedCopy-->
```

Example:

You can use the `show dns txtRec` command first to view the record ID of the TXT resource record that you want to remove, as shown:

```
> show dns txtRec www.example.com
1)  Domain : www.example.com    Record id: 36865       TTL : 36000 secs
     Record Type : ADNS
         "Contact: Evan"
         "Email: evan@example.com"
2)  Domain : www.example.com    Record id: 14373       TTL : 36000 secs
     Record Type : ADNS
         "Contact: Mark"
         "Email: mark1@example.com"
 Done
<!--NeedCopy-->
```

The simpler method of deleting a TXT record is to use the record ID. If you want to provide the strings, enter them in the order in which they are stored in the record. In the following example, the TXT record is deleted by using its record ID.

```
>rm dns txtRec www.example.com -recordID 36865
 Done
> show dns txtRec www.example.com
1)  Domain : www.example.com    Record id: 14373       TTL : 36000 secs
     Record Type : ADNS
         "Contact: Mark"
         "Email: mark1@example.com"
 Done
<!--NeedCopy-->
```

Configure a TXT record by using the GUI

Navigate to **Traffic Management > DNS > Records > TXT Records** and create a TXT record.

View DNS statistics

September 14, 2021

You can view the DNS statistics generated by the Citrix ADC appliance. The DNS statistics include run-time, configuration, and error statistics.

View DNS records statistics by using the CLI

At the command prompt, type:

```
stat dns
```

Example:

```
> stat dns
DNS Statistics

Runtime Statistics
Dns queries                             21
NS queries                               8
SOA queries                             18
.
.
.
Configuration Statistics
AAAA records                            17
A records                               36
MX records                               9
.
.
.
Error Statistics

.
.
.
Done
<!--NeedCopy-->
```

View DNS records statistics by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click **Statistics**.

Configure a DNS zone

September 14, 2021

A DNS zone entity on the Citrix ADC appliance facilitates the ownership of a domain on the appliance. A zone on the appliance also enables you to implement DNS Security Extensions (DNSSEC) for the zone, or to offload the zone's DNSSEC operations from the DNS servers to the appliance. DNSSEC sign operations are performed on all the resource records in a DNS zone. Therefore, if you want to sign a zone, or if you want to offload DNSSEC operations for a zone, you must first create the zone on the Citrix ADC appliance.

Create a DNS zone on the appliance in the following scenarios:

- The Citrix ADC appliance owns all the records in a zone, that is, the appliance is operating as the authoritative DNS server for the zone. The zone must be created with the proxyMode parameter set to NO.
- The Citrix ADC appliance owns only a subset of the records in a zone. All the other resource records in the zone are hosted on a set of back-end name servers. The appliance is configured as a DNS proxy server for these back-end servers. A typical configuration where the Citrix ADC appliance owns only a subset of the resource records in the zone is a global server load balancing (GSLB) configuration. The Citrix ADC appliance owns only the GSLB domain names, while the back-end name servers own all the other records. The zone must be created with the proxyMode parameter set to YES.
- You want to offload DNSSEC operations for a zone from your authoritative DNS servers to the appliance. The zone must be created with the proxyMode parameter set to YES. You might have to configure more settings for the zone.

The current topic describes how to create a zone for the first two scenarios. For more information about how to configure a zone for offloading DNSSEC operations to the appliance, see Offload DNSSEC operations to the Citrix ADC appliance.

> **Note**
>
> If the ADC appliance is operating as the authoritative DNS server for a zone, you must create the Start of Authority (SOA) and name server (NS) records for the zone before you create the zone. If the Citrix ADC is operating as the DNS proxy server for a zone, SOA and NS records must not be created on the Citrix ADC appliance. For more information about creating SOA and NS records, see Configure DNS resource records.

When you create a zone, all existing domain names and resource records that end with the name of the zone are automatically treated as a part of the zone. Also, any new resource records created with a suffix that matches the name of the zone are implicitly included in the zone.

Create a DNS zone on the Citrix ADC appliance by using the CLI

At the command prompt, type the following command to add a DNS zone to the Citrix ADC appliance and verify the configuration:

```
-  add dns zone <zoneName> -proxyMode ( YES | NO )
-  show dns zone [<zoneName> | -type <type>]
<!--NeedCopy-->
```

Example:

```
> add dns zone example.com -proxyMode Yes
 Done
> show dns zone example.com
          Zone Name : example.com
          Proxy Mode : YES
Done
<!--NeedCopy-->
```

Modify or remove a DNS zone by using the CLI

- To modify a DNS zone, type the `set dns zone` command, the name of the DNS zone, and the parameters to be changed, with their new values.
- To remove a DNS zone, type the `rm dns zone` command and the name of the DNS zone.

Configure a DNS zone by using the GUI

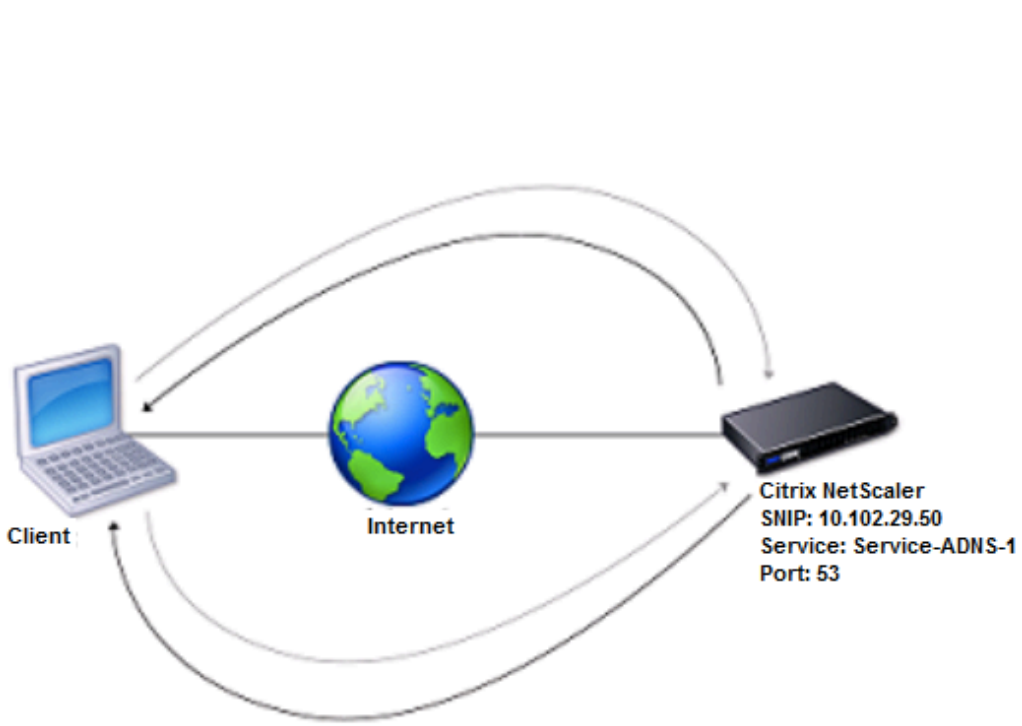
Navigate to **Traffic Management > DNS > Zones** and create a DNS zone.

Configure the Citrix ADC as an ADNS server

September 14, 2021

You can configure the ADC appliance to function as an authoritative domain name server (ADNS) for a domain. As an ADNS server for a domain, the Citrix ADC resolves DNS requests for all types of DNS records that belong to the domain. To configure the Citrix ADC to function as an ADNS server for a domain, you must create an ADNS service and configure NS and Address records for the domain on the Citrix ADC. The ADNS service can be configured using the subnet IP address (SNIP) or a separate IP address. The following topology diagram shows a sample configuration and the flow of requests and responses.

Figure 1. Citrix ADC as an ADNS



The following table shows the parameters that are configured for the ADNS service illustrated in the preceding topology diagram.

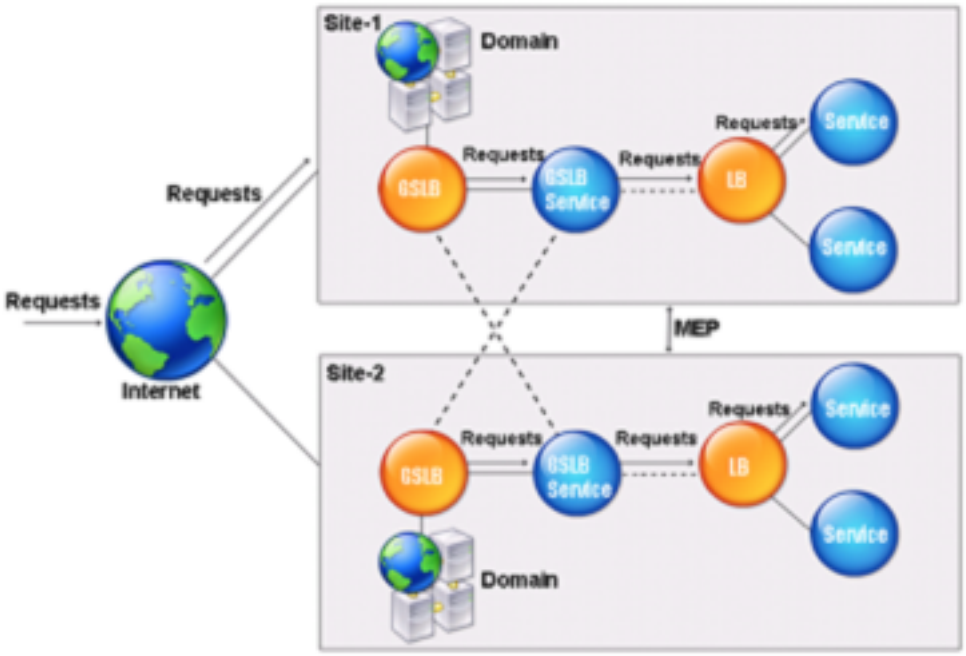
Entity type	Name	IP address	Type	Port
ADNS Service	Service-ADNS-1	10.102.29.51	ADNS	53

Table 1. Example of ADNS Service Configuration

To configure an ADNS setup, you must configure the ADNS service. For instructions on configuring the ADNS service, see Load balancing.

During DNS resolution, the ADNS server directs the DNS proxy or local DNS server to query the Citrix ADC for the IP address of the domain. Because the Citrix ADC is authoritative for the domain, it sends the IP address to the DNS proxy or local DNS server. The following diagram describes the placement and role of the ADNS server in a GSLB configuration.

Figure 2. GSLB Entity Model



Note: In ADNS mode, if you remove SOA and ADNS records, the following do not function for the domain hosted by the Citrix ADC: ANY query (for more information about the ANY query, see DNS ANY query), and negative responses, such as NODATA and NXDOMAIN.

Create an ADNS service

An ADNS service is used for global service load balancing. For more information about creating a GSLB setup, see Global server load balancing. You can add, modify, enable, disable, and remove an ADNS service. For instructions on creating an ADNS service, see Configure services.

Note: You can configure the ADNS service to use SNIP or any new IP address.

When you create an ADNS service, the Citrix ADC responds to DNS queries on the configured ADNS service IP and port.

You can verify the configuration by viewing the properties of the ADNS service. You can view properties such as name, state, IP address, port, protocol, and maximum client connections.

Configure the ADNS setup to use TCP

By default, some clients use the User Datagram Protocol (UDP) for DNS, which specifies a limit of 512 bytes for the payload length of UDP packets. To handle payloads that exceed 512 bytes in size, the

client must use TCP. To enable DNS communications over TCP, you must configure the Citrix ADC appliance to use the TCP protocol for DNS. The Citrix ADC then sets the truncation bit in the DNS response packets. The truncation bit specifies that the response is too large for UDP and that the client must send the request over a TCP connection. The client then uses the TCP protocol on port 53 and opens a new connection to the Citrix ADC. The Citrix ADC listens on port 53 with the IP address of the ADNS service to accept the new TCP connections from the client.

To configure the Citrix ADC to use the TCP protocol, you must configure an ADNS_TCP service. For instructions on creating an ADNS_TCP service, see Load balancing.

> **Important**
>
> To configure the Citrix ADC to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure the ADNS and ADNS_TCP services. The IP address of the ADNS_TCP service must be the same as the IP address of the ADNS service.

Add DNS resource records

After you create an ADNS service, you can add DNS records. For instructions on adding DNS records, see Configure DNS resource records.

Remove ADNS services

For instructions on removing services, see Load balancing

Configure domain delegation

Domain delegation is the process of assigning responsibility for a part of the domain space to another name server. Therefore, during domain delegation, the responsibility for responding to the query is delegated to another DNS server. Delegation uses NS records.

In the following example, sub1.abc.com is the subdomain for abc.com. The procedure describes the steps to delegate the subdomain to the name server ns2.sub1.abc.com and add an Address record for ns2.sub1.abc.com.

To configure domain delegation, you need to perform the following tasks, which are described in the sections that follow:

1. Create an SOA record for a domain.
2. Create an NS record to add a name server for the domain.
3. Create an Address record for the name server.
4. Create an NS record to delegate the subdomain.
5. Create a glue record for the name server.

Create an SOA record

For instructions on configuring SOA records, see Create SOA records for authoritative information.

Create an NS record for a name server

For instructions on configuring an NS record, see Create NS records for an authoritative server. In the **Name Server** list, select the primary authoritative name server, for example, ns1.abc.com.

Create an address record

For instructions on configuring Address records, see Create address records for a domain name. In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns1.abc.com and 10.102.11.135, respectively.

Create an NS record for domain delegation

For instructions on configuring NS records, see Create NS records for an authoritative server. In the **Name Server** list, select the primary authoritative name server, for example, ns2.sub1.abc.com.

Create a glue record

NS records are typically defined immediately after the SOA record (not a restriction.) A domain must have at least two NS records. If an NS record is defined within a domain, it must have a matching Address record. This Address record is referred to as a glue record. Glue records speed up DNS queries.

For instructions on adding glue records for a subdomain, see the procedure for adding an Address (A) record, Configure DNS resource records.

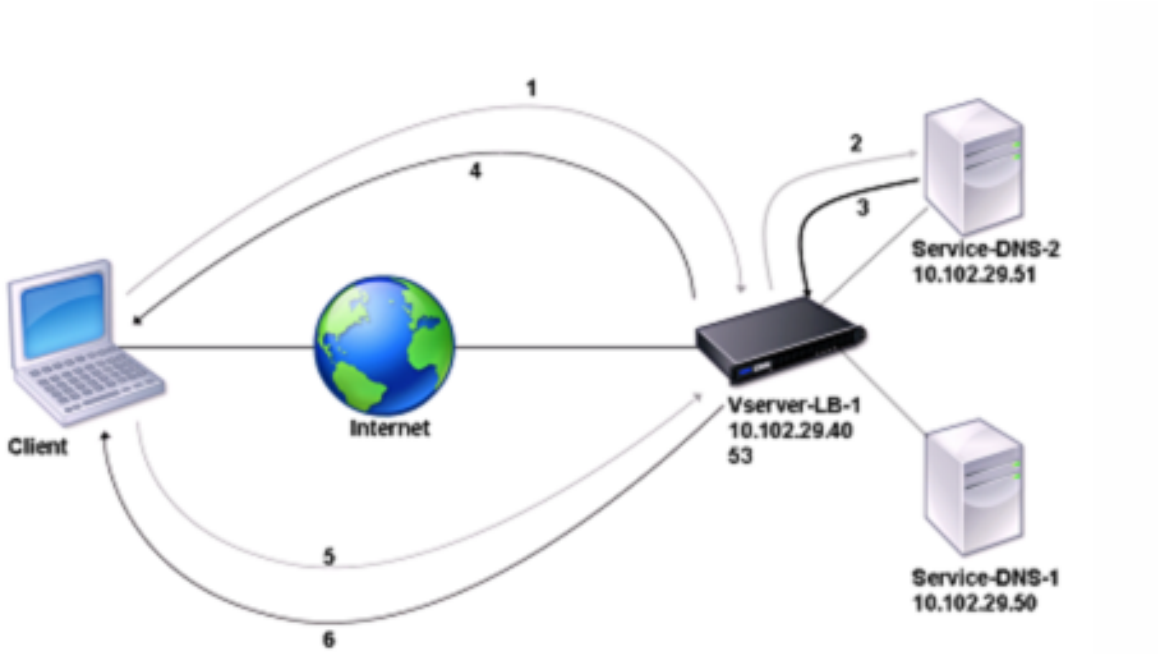
For instructions on configuring Address records, see Create address records for a domain name. In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns2.sub1.abc.com and 10.102.12.135, respectively.

Configure the Citrix ADC appliance as a DNS proxy server

September 14, 2021

As a DNS proxy server, the ADC appliance can function as a proxy for either a single DNS server or a group of DNS servers. The flow of requests and responses is illustrated in the following sample topology diagram.

Figure 1. Citrix ADC as DNS proxy



By default, the Citrix ADC appliance caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the Citrix ADC returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the Citrix ADC. The Citrix ADC then returns the address to the client.

For requests for a domain that has been cached earlier, the Citrix ADC serves the Address record of the domain from the cache without querying the configured DNS server.

The appliance discards a record stored in its cache when the time-to-live (TTL) value of the record reaches the configured value. A client that requests an expired record has to wait until the Citrix ADC retrieves the record from the server and updates its cache. To avoid this delay, the Citrix ADC proactively updates the cache by retrieving the record from the server before the record expires.

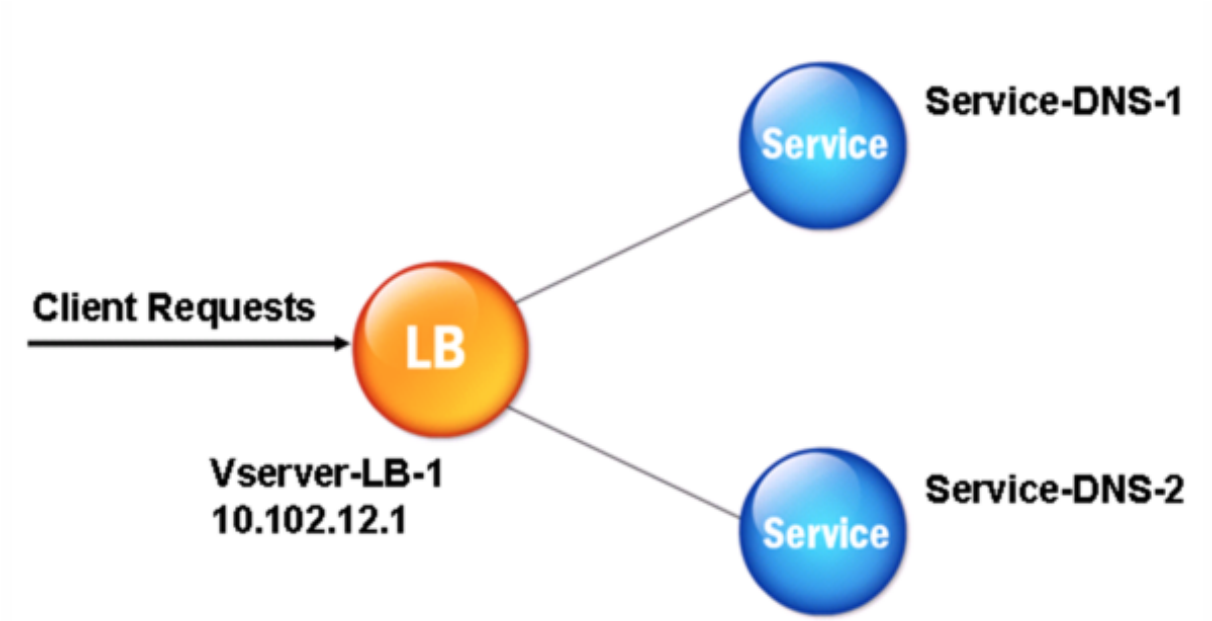
The following table lists sample names and the values of the entities that need to be configured on the Citrix ADC.

Table 1. Example of DNS Proxy Entity Configuration

Entity type	Name	IP address	Type	Port
LB virtual server	Vserver-DNS-1	10.102.29.40	DNS	53
Services	Service-DNS-1	10.102.29.50	DNS	53
Services	Service-DNS-2	10.102.29.51	DNS	53

The following diagram shows the entities of a DNS Proxy and the values of the parameters to be configured on the Citrix ADC.

Figure 2. DNS Proxy Entity Model



> **Note**
>
> To configure the DNS proxy feature, you need to know how to configure load balancing services and virtual servers.

Create a load balancing virtual server

To configure a DNS Proxy on the Citrix ADC, configure a load balancing virtual server of type DNS. To configure a DNS virtual server to load balance a set of DNS servers that support recursive queries, you must set the Recursion Available option. With this option, the RA bit is set to ON in the DNS replies from the DNS virtual server.

For instructions on creating a load balancing virtual server, see Load Balancing.

Create DNS services

After creating a load balancing virtual server of type DNS, you must create DNS services. You can add, modify, enable, disable, and remove a DNS service. For instructions on creating a DNS service, see Load Balancing.

Bind a load balancing virtual server to DNS services

To complete the DNS Proxy configuration, you must bind the DNS services to the load balancing virtual server. For instructions on binding a service to a load balancing virtual server, see Load Balancing.

Configure the DNS proxy setup to use TCP

Some clients use the User Datagram Protocol (UDP) for DNS communications. However, UDP specifies a maximum packet size of 512 bytes. When payload lengths exceed 512 bytes, the client must use TCP. When a client sends the Citrix ADC appliance a DNS query, the appliance forwards the query to one of the name servers. If the response is too large for a UDP packet, the name server sets the truncation bit in its response to the Citrix ADC. The truncation bit indicates that the response is too large for UDP and that the client must send the query over a TCP connection. The ADC appliance relays the response to the client with the truncation bit intact. It waits for the client to initiate a TCP connection with the IP address of the DNS load balancing virtual server, on port 53. The client sends the request over a TCP connection. The Citrix ADC appliance then forwards the request to the name server and relays the response to the client.

To configure the Citrix ADC to use the TCP protocol for DNS, you must configure a load balancing virtual server and services, both of type DNS_TCP. You can configure monitors of type DNS_TCP to check the state of the services. For instructions on creating DNS_TCP virtual servers, services, and monitors, see Load Balancing.

For updating the records proactively, the Citrix ADC uses a TCP connection to the server to retrieve the records.

> **Important**
>
> To configure the Citrix ADC to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure both DNS and DNS_TCP services. The IP address of the DNS_TCP service must be the same as the IP address of the DNS service.

Configure time-to-live values for DNS entries

The TTL is the same for all DNS records with the same domain name and record type. If the TTL value is changed for one of the records, the new value is reflected in all records of the same domain name and type. The default TTL value is 3600 seconds. The minimum is 0, and the maximum is 604800. If a DNS entry has a TTL value less than the minimum or greater than the maximum, it is saved as the minimum or maximum TTL value, respectively.

Specify the minimum and maximum TTL by using the CLI

At the Citrix ADC command prompt, type the following commands to specify the minimum and maximum TTL and verify the configuration:

```
-  set dns parameter [-minTTL <secs>] [-maxTTL <secs>]
-  show dns parameter
<!--NeedCopy-->
```

Example:

```
> set dns parameter -minTTL 1200 -maxTTL 1800
 Done
> show dns parameter
        DNS parameters:
        DNS retries: 5
        Minimum TTL: 1200               Maximum TTL: 1800
            .
            .
            .
 Done
>
<!--NeedCopy-->
```

Specify the minimum and maximum TTL by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in TTL, in the Minimum and Maximum text boxes, type the minimum and maximum time to live (in seconds), respectively, and then click OK.

Note: When the TTL expires, the record is deleted from the cache. The Citrix ADC proactively contacts the servers and obtains the DNS record just before the DNS record expires.

Flush DNS records

You can delete all DNS records present in the cache. For example, you might want to flush DNS records when a server is restarted after modifications are made.

Delete all proxy records by using the CLI

At the Citrix ADC command prompt, type:

```
flush dns proxyRecords
```

Delete all proxy records by using the GUI

1. Navigate to **Traffic Management > DNS > Records**.
2. In the details pane, click Flush Proxy Records.

Add DNS resource records

You can add DNS records to a domain for which the Citrix ADC appliance is configured as a DNS proxy server. For information about adding DNS records, see Configuring DNS Resource Records.

Remove a load balancing DNS virtual server

For information about removing a load balancing virtual server, see Load Balancing.

Limit the number of concurrent DNS requests on a client connection

You can limit the number of concurrent DNS requests on a single client connection, which is identified by the <clientip:port>-<vserver ip:port> tuple. Concurrent DNS requests are those requests that the Citrix ADC appliance has forwarded to the name servers and for which the appliance is awaiting responses. Limiting the number of concurrent requests on a client connection enables you to protect the name servers when a hostile client attempts a Distributed Denial of Service (DDoS) attack by sending a flood of DNS requests. When the limit for a client connection is reached, subsequent DNS requests on the connection are dropped until the outstanding request count goes below the limit. This limit does not apply to the requests that the Citrix ADC appliance serves out of its cache.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve many concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This parameter is a global parameter and applies to all the DNS virtual servers that are configured on the Citrix ADC appliance.
The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve many concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This parameter is a global parameter and applies to all the DNS virtual servers that are configured on the Citrix ADC appliance.
The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve many concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This parameter

is a global parameter and applies to all the DNS virtual servers that are configured on the Citrix ADC appliance.

Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the CLI

At the command prompt, type the following commands to specify the maximum number of concurrent DNS requests allowed on a single client connection and verify the configuration:

```
-  set dns parameter -maxPipeline <positive_integer>
-  show dns parameter
<!--NeedCopy-->
```

Example:

```
> set dns parameter -maxPipeline 1000
 Done
> show dns parameter
        DNS parameters:
        DNS retries: 5
        .
        .
        .
        Max DNS Pipeline Requests: 1000
 Done
<!--NeedCopy-->
```

Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, specify a value for Max DNS Pipeline Requests.
4. Click OK.

Configure the Citrix ADC as an end resolver

September 14, 2021

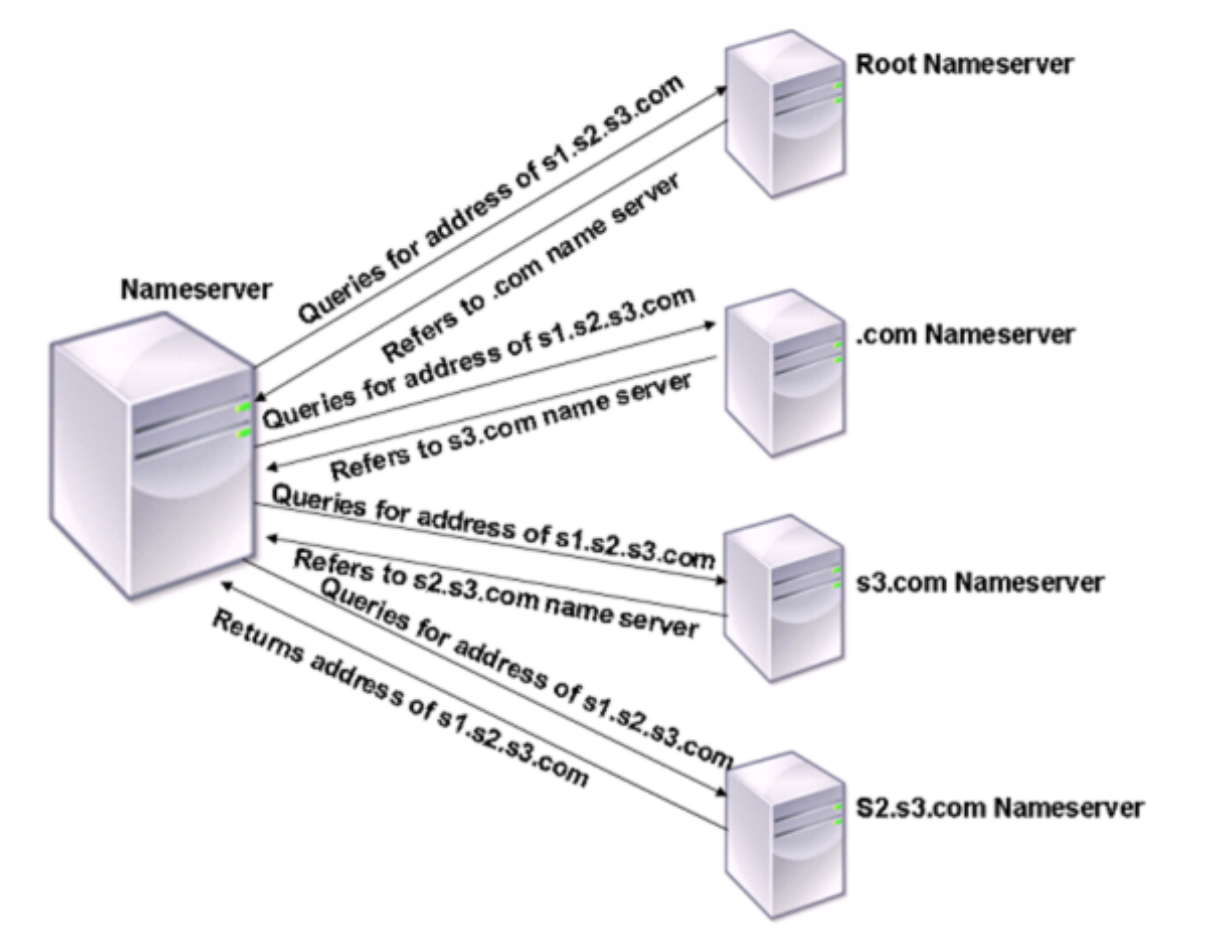
A resolver is a procedure that is invoked by an application program that translates a domain/host name to its resource record. The resolver interacts with the LDNS, which looks up the domain name

to obtain its IP address. The Citrix ADC can provide end-to-end resolution for DNS queries.

In recursive resolution, the Citrix ADC appliance queries different name servers recursively to access the IP address of a domain. When the Citrix ADC receives a DNS request, it checks its cache for the DNS record. If the record is not present in the cache, it queries the root servers configured in the ns.conf file. The root name server reports back with the address of a DNS server that has detailed information about the second-level domain. The process is repeated until the required record is found.

When you start the Citrix ADC appliance for the first time, 13 root name servers are added to the ns.conf file. The NS and Address records for the 13 root servers are also added. You can modify the ns.conf file, but the Citrix ADC does not allow you to delete all 13 records. At least one name server entry is required for the appliance to perform name resolution. The following diagram illustrates the process of name resolution.

Figure 1. Recursive resolution



In the process shown in the diagram, when the name server receives a query for the address of s1.s2.s3.com, it first checks the root name servers for s1.s2.s3.com. A root name server reports back with the address of the .com name server. If the address of s1.s2.s3.com is found in the name server, it responds with a suitable IP address. Otherwise, it queries other name servers for s3.com, then

for s2.s3.com to retrieve the address of s1.s2.s3.com. In this way, resolution always starts from root name servers and ends with the domain's authoritative name server.

Note: For recursive resolution functionality, caching must be enabled.

Enable recursive resolution

To configure the Citrix ADC appliance to function as an end resolver, you must enable recursive resolution on the appliance.

Enable recursive resolution by using the CLI

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

```
-  set dns parameter -recursion ENABLED
-  show dns parameter
<!--NeedCopy-->
```

Example:

```
> set dns parameter -recursion ENABLED
 Done
> show dns parameter
        DNS parameters:
            .
            .
            .
        Recursive Resolution : ENABLED
            .
            .
            .
 Done
<!--NeedCopy-->
```

Enable recursive resolution by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable recursion check box, and then click OK.

Set the Number of Retries

Configure the ADC appliance to make a preconfigured number of attempts (called DNS retries) when it does not receive a response from the server to which it sends a query. By default, the number of DNS retries is set to 5.

Set the number of DNS retries by using the CLI

At the command prompt, type the following commands to set the number of retries and verify the configuration:

```
-  set dns parameter -retries <positive_integer>
-  show dns parameter
<!--NeedCopy-->
```

Example:

```
> set DNS parameter -retries 3
 Done
> show dns parameter
        DNS parameters:
        DNS retries: 3
            .
            .
            .
 Done
<!--NeedCopy-->
```

Set the number of retries by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in the DNS Retries text box, type the DNS resolver request retry count, and then click OK.

Configure the Citrix ADC appliance as a forwarder

September 14, 2021

A forwarder is a server that forwards DNS queries to DNS servers that are outside the forwarder server's network. Queries that cannot be resolved locally are forwarded to other DNS servers. A forwarder ac-

cumulates external DNS information in its cache as it resolves DNS queries. To configure the Citrix ADC appliance as a forwarder, you must add an external name server.

The Citrix ADC appliance allows you to add external name servers to which it can forward the name resolution queries that cannot be resolved locally. To configure the Citrix ADC appliance as a forwarder, you must add the name servers to which it must forward name resolution queries. You can specify the lookup priority to specify the name service that the Citrix ADC appliance must use for name resolution.

> **Note:**
>
> The Citrix ADC appliance in forwarder mode supports TCP, UDP, and UDP-TCP name servers.
>
> - If you have configured a TCP name server, then the Citrix ADC appliance sends the DNS request over TCP.
> - If you have configured a UDP name server, then the Citrix ADC appliance sends the DNS request over UDP.
> - If you have configured a UDP-TCP name server, then the Citrix ADC appliance sends the DNS request over UDP. However if the truncated bit is set in the DNS response, the appliance sends such DNS requests over TCP.

Add a name server

September 14, 2021

You can create a name server by specifying its IP address or by configuring an existing virtual server as the name server.

- **IP address-based name server** - An external name server to contact for domain name resolution. If multiple IP address-based name servers are configured on the appliance, and the local parameter is not set on any of them, incoming DNS queries are load balanced across all the name servers, in round robin fashion.
- **Virtual server-based name server** - A DNS virtual server configured in the Citrix ADC. For more fine-grained control on how external DNS name servers are load balanced (for example, you want a load balancing method other than round robin), do the following:
- Configure a DNS virtual server on the appliance
- Bind the external name servers as its services
- Specify the name of the virtual server in this command.

To verify the configuration, you can use the `show dns nameServer` command.

To remove a name server, at the Citrix ADC CLI, type the `rm dns nameServer` command followed by the IP address of the name server.

To view the details of the DNS nameserver, at the Citrix ADC CLI, type the `show dns nameServer` command followed by the IP address of the name server.

Add a name server (when the Citrix ADC appliance acts as a forwarder) by using the CLI

At the command prompt, type;

```
add dns nameServer ((<IP>) | <dnsVserverName>)
<!--NeedCopy-->
```

Or

```
add dns nameServer ((<IP> | <dnsVserverName>) [-type <type>]
<!--NeedCopy-->
```

Examples:

```
add dns nameServer dnsVirtualNS

add dns nameServer 192.0.2.11 -type TCP

add dns nameServer 192.0.2.12 -type UDP_TCP

add dns nameServer 192.0.2.10
show dns nameServer 192.0.2.10

1) 192.0.2.10  -  State: UP  Protocol: UDP
Done
<!--NeedCopy-->
```

> **Note:**
>
> If the name server type is not specified, a UDP name server is created by default. To create a name server of type TCP or UDP_TCP, you must specify the type.
>
> When you specify the type as UDP_TCP, two name servers (one UDP name server and one TCP name server) are created for the given IP address.

Add a name server (when the Citrix ADC appliance acts as a resolver) by using the CLI

At the command prompt, type:

```
add dns nameServer ((<IP> [-local]) | <dnsVserverName>)
<!--NeedCopy-->
```

Example:

```
add dns nameServer 10.102.9.19 -local
show dns nameServer
1)  10.102.9.19 LOCAL -  State: UP  Protocol: UDP
Done
<!--NeedCopy-->
```

Local - Mark the IP address as one that belongs to a local recursive DNS server on the Citrix ADC appliance. The appliance recursively resolves queries received on an IP address that is marked as being local.
For recursive resolution to work, the global DNS parameter, `recursion`, must also be set.
If no name server is marked as being local, the appliance functions as a stub resolver and load balances the name servers.

Add a name server by using the GUI

Navigate to **Traffic Management** > **DNS** > **Name Servers** and create a name server.

Set DNS lookup priority

September 14, 2021

You can set the lookup priority to either DNS or WINS. This option is used in the SSL VPN mode of operation.

Set the lookup priority to DNS by using the CLI

At the command prompt, type the following commands to set the lookup priority to DNS and verify the configuration:

```
-  set dns parameter -nameLookupPriority (DNS | WINS)
-  show dns parameter
<!--NeedCopy-->
```

Example:

```
> set dns parameter -nameLookupPriority DNS
 Done
> show dns parameter
            .
            .
```

```
6               .
7          Name lookup priority : DNS
8               .
9               .
10              .
11   Done
12 <!--NeedCopy-->
```

Set lookup priority to DNS by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under **Settings**, click Change DNS settings.
3. In the **Configure DNS Parameters** dialog box, under **Name Lookup Priority**, select DNS or WINS, and then click OK.

> **Note**
>
> If the DNS virtual server that you have configured is DOWN and if you set the `-nameLookupPriority` to DNS, the Citrix ADC does not attempt WINS lookup. Therefore, if a DNS virtual server is not configured or is disabled, set the `-nameLookupPriority` to WINS.

Disable and enable name servers

September 14, 2021

The following procedure describes the steps to enable or disable an existing name server.

Enable or disable a name server by using the CLI

At the command prompt, type the following commands to enable or disable a name server and verify the configuration:

```
1 -  (enable | disable) dns nameServer <IPAddress>
2 -  show dns nameServer <IPAddress>
3 <!--NeedCopy-->
```

Example:

```
1 > disable dns nameServer 10.102.9.19
2  Done
3 > show dns nameServer 10.102.9.19
4 1)       10.102.9.19: LOCAL  -  State: OUT OF SERVICE
```

```
5   Done
6 <!--NeedCopy-->
```

Enable or disable a name server by using the GUI

1. Navigate to **Traffic Management > DNS > Name Servers**.
2. In the details pane, select the name server that you want to enable or disable.
3. Click Enable or Disable. If a name server is enabled, the Disable option is available. If a name server is disabled, the Enable option is available.

Configure Citrix ADC as a non-validating security aware stub-resolver

September 14, 2021

Starting with Citrix ADC 12.1 build 49.xx, Citrix ADC acts as a non-validating security aware stub-resolver. To enable this support, the AD bit is set in the DNS header and the DO bit is unset in the OPT header. When the AD bit is set and the DO bit is unset, the upstream recursive resolver validates the DNSSEC response. If the validation is successful, the recursive resolver responds without DNSSEC RRs. If the DNSSEC validation fails, then the recursive resolver returns with a SERVFAIL response.

> **Important:**
>
> The AD bit is set by default in the ADC forwarder. The AD bit is not set for DBS initiated queries.

Jumbo frames support for DNS to handle responses of large sizes

September 14, 2021

Starting with Citrix ADC 12.1 build 49.xx, DNS supports jumbo frames for handling UDP responses greater than 1,280 bytes. Previously, the Citrix ADC appliance only supported UDP packet size only up to 1,280 bytes.

You can set the maximum UDP packet size that the appliance can handle in proxy, ADNS, and forwarder modes by configuring the Maximum UDP Packet Size parameter value. For example, if the Maximum UDP Packet Size parameter value is set to 4096, the appliance can handle DNS response of size 4,096 bytes.

> **Important**
>
> - In proxy mode, the least size between the client request OPT payload size and the Maximum

> UDP Packet Size value is considered for sending DNS queries to the back end. For example, if the client request OPT payload size is 3000, and the Maximum UDP Packet Size value is 4096, 3,000 bytes DNS queries are sent to the back end.
>
> Also, from the back end, the appliance can receive responses of large sizes and process responses of large sizes.
>
> - In forwarder mode, the appliance sets the OPT payload size equal to the UDP packet size parameter value.
> - If the DNS records are local to the appliance, then the appliance can compose response sizes as large as the Maximum UDP Packet Size parameter value. This setting is applicable for ADNS, proxy, and recursive resolvers.

To configure the maximum UDP packet size using the CLI

At the command prompt, type:

```
set dns parameter [-maxUDPPacketSize <positive_integer>]
<!--NeedCopy-->
```

Example:

```
set dns parameter -maxUDPPacketSize 10000
<!--NeedCopy-->
```

> **Note**: The minimum and maximum value that you can set for the Maximum UDP Packet Size parameter is 512 and 16384 respectively. Default value is 1280.

To configure the maximum UDP packet size using the CLI

1. Navigate to **Traffic Management** > **DNS**.
2. In the details pane, click **Change DNS settings**.
3. In Maximum UDP Packet Size, specify the maximum UDP packet size.
4. Click **OK**.

Configure DNS logging

September 14, 2021

You can configure the Citrix ADC appliance to log the DNS requests and responses that it handles. The appliance logs the DNS requests and responses in SYSLOG format. You can choose to log either DNS

requests or DNS responses, or both, and send the syslog messages to a remote log server. The log messages can be used to:

- Audit the DNS responses to the client
- Audit DNS clients
- Detect and prevent DNS attacks
- Troubleshoot

A Citrix ADC appliance can log the following sections in the DNS request or response, based on your configuration:

- Header Section
- Questions Section
- Answer Section
- Authority Section
- **Additional** Section

DNS profiles

You can use a DNS profile to configure the various DNS parameters that you want the DNS endpoint to apply to the DNS traffic. In the profile, you can enable logging, caching, and negative caching.

Important: From the NetScaler 11.0 release, enabling DNS caching using global DNS parameters have been deprecated. You can enable or disable DNS caching using DNS profiles. You can now enable DNS caching for an individual virtual server by enabling DNS caching in a DNS profile and setting the DNS profile to the individual virtual server.

DNS profiles support the following types of DNS logging:

- DNS Query Logging
- DNS Answer Section Logging
- DNS Extended Logging
- DNS Error Logging

DNS query logging

You can configure a Citrix ADC appliance to log only the DNS queries that are received by the DNS endpoints on the appliance.

Note: If errors occur during processing of a query, they are logged if this option is set in the DNS profile.

Following is an example of a query log message:

```
1 DNS DNS_QUERY 143 0 :  U:10.102.27.70#61297:10.102.27.73#53/22142/Q/
2 (RD)/NO/1/0/0/0#test.com./1#
3 <!--NeedCopy-->
```

DNS answer section logging

You can configure a Citrix ADC appliance to log all the **Answer** sections in the DNS responses that the appliance sends to the client. DNS Answer Section logging is useful when the Citrix ADC is configured as a DNS resolver, or in GLSB use cases.

Following is an example of a DNS answer section log:

```
DNS DNS_RESPONSE 6678 0 :  U:100.100.100.210#32776:100.100.100.10#
53/61373/Q/(RD,AA,RA,R)/NO/1/1/2/4#n1.citrix.com1./
28#ANS#AAAA/120/1111:2345:6789:ffab:abcd:effa:1234:3212##
<!--NeedCopy-->
```

DNS extended logging

To configure a Citrix ADC appliance to log Authority and **Additional** sections in the DNS responses, enable Extended logging with Answer Section logging.

Note: If errors occur during processing of either queries or responses, the errors are logged if this option is set in the DNS profile.

Following is an example of a message logged when the cache lookup is completed and the response is embedded in the packet:

```
DNS DNS_RESPONSE 2252 0 :  T:100.100.100.118#21411:100.100.100.10
#53/48537/Q/(RD,AA,CD,RA,R)/NO/1/1/2/6#a1.citrix.com1./1#ANS#A/
120/1.1.1.1##AUTH#citrix.com1/NS/120/n2.citrix.com1#n1.citrix.com1##ADD
   #n1.citrix.com1
/A/120/1.1.1.1#1.1.1.2##n1.citrix.com1/AAAA/120/
1111:2345:6789:ffab:abcd:effa:1234:3212##n2.citrix.com1/A/120/2.1.1.2
##n2.citrix.com1/AAAA/120/2222:faff:3212:8976:123:1241:64:ff9b##OPT
   /0/1280/DO##
<!--NeedCopy-->
```

DNS error logging

You can configure a Citrix ADC appliance to log the errors or failures that occur when it processes a DNS query or response. For these errors, the appliance logs the DNS header, **Question** sections and OPT records.

Following is an example of a message logged when an error occurs during processing of a DNS request or response:

```
DNS DNS_ERROR 149 0 :  U:10.102.27.70#27832:10.102.27.73#53/61153/Q/
(RD)/NO/1/0/0/0#test.com./1140#Packet Dropped
```

```
<!--NeedCopy-->
```

Policy based logging

You can configure custom logging based on DNS expressions by configuring the logAction on DNS policies, Rewrite, or Responder policies. You can specify that logging occurs only when a particular DNS policy evaluates to true. For more information, see Configure policy based logging for DNS.

Understand the Citrix ADC syslog log message format

Citrix ADC appliance log DNS requests and responses in the following Syslog format:

```
<transport> :<client IP>#<client ephemeral port>:<DNS endpoint IP>#<
    port>
 : <query id> /opcode/header flags/rcode/question section count/answer
     section count
/ auth section count / additional section count #<queried domain name>
/<queried type>#...
<!--NeedCopy-->
```

- **<transport>:**
  - T = TCP
  - U = UDP
- **<client IP>#< client ephemeral port >:** DNS client IP address and port number
- **<DNS endpoint IP>#<port>:** Citrix ADC DNS endpoint IP address and port number
- **<query id>:**
  Query ID
- **<opcode>:** Operation code. Supported Values:
  - Q: query
  - I: inverse query
  - S: status
  - X0: unassigned
  - N: notify
  - U: update
  - X1-10: unassigned values
- **<header flags>:** Flags. Supported Values:
  - RD: recursion desired
  - TC: truncated

  - AA: authoritative response
  - CD: check disabled
  - AD: authenticated data
  - Z: unassigned
  - RA: recursion available
  - R: response

- **<rcode>:** Response Code. Supported Values:
  - NO: no error
  - F format error
  - S: server failure
  - NX: non-existent domain
  - NI: not implemented
  - R: query refused
  - YX: Name Exists when it must not
  - YXR: RR Set Exists when it must not
  - NXR: RR Set that must exist does not
  - NAS: Server Not Authoritative for zone
  - NA: Not Authorized
  - NZ: Name not contained in zone
  - X1-5: unassigned
- **/question section count/answer section count/auth section count/additional section count:** Question section, Authority section count, and **Additional** section count in the DNS request
- **<queried domain name>/<queried type>:** Queried domain and queried type in the DNS request
- **#ANS#<record type>/<ttl>/.. #AUTH#<domain name>/<record type>/<ttl>.. #ADD#<domain name>/<record type>/<ttl>...:**

  In DNS responses:

  Answer Section is logged if answer section logging is enabled in the DNS profile. Authority and **Additional** sections are logged if extended logging is enabled in the DNS profile. The log format would differ depending on the type of record. For more information see Understanding the Record Logging Format.

  - ANS: answer section
  - AUTH: authority
  - ADD: **Additional** section
- **OPT/<edns version>/UDP max payload size/DO:** OPT record format in the DNS log

- **OPT/<EDNS version>/<UDP payload size>/<“DO”or empty based on whether DNSSEC OK bit is set or not>/<value of RDLEN>/ECS/<Q/R>/<option length>/<Family>/<Source Prefix-Length>/<Scope Prefix-Length>/<ECS Address>:**

  If the DNS query or response includes the EDNS Client Subnet (ECS) option, then that is also logged in the OPT record format in the DNS log file.

  When a DNS query with an ECS option that includes either an IPv4 or IPv6 address is sent, the ECS option is logged with either of the following options;

  - “ECS/Q” indicating that the values in the log are from the query
  - “ECS/R” indicating that the values in the log are from the response.

  The value of Scope Prefix-Length is also set appropriately. In the DNS Query, it is set to zero, and for response, it is set to the calculated value.

  The following table describes the logged details in various scenarios:

Scenario	ECS option set in the DNS Query	ECS option set in the DNS Response	Logged Details
Both query logging and extended logging enabled	Yes	Yes	ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value.
Both query logging and extended logging enabled	Yes	No	ECS option is logged with the string “ECS/Q” and the Scope Prefix-Length is set to zero.
Query logging is enabled, but extended logging is not enabled	Yes	Yes	ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.
Query logging & extended logging are not enabled	Yes	Yes	ECS option is not logged.

Scenario	ECS option set in the DNS Query	ECS option set in the DNS Response	Logged Details
Query logging is enabled, but extended logging is not enabled	Yes	No	ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.
Query logging is not enabled, but extended logging is enabled	Yes	Yes	ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value.
Query logging is not enabled, but extended logging is enabled	Yes	No	ECS option is not logged.

Understand the record logging format

Following is an example of the record logging format in a Syslog message:

```
<domainname>/<record type>/ <record ttl> / <resource record data>#<
   resource record data>#......##
<!--NeedCopy-->
```

Where:

Record Type	Sample Format	Resource Record Data / Format
Address (A) record	A/5/1.1.1.1#1.1.1.2#1.1.1.3##	IPv4 address
AAAA record	AAAA/5/1::1#1::2#1::3##	IPv6 address
SOA record	SOA/3600/ns1.dnslogging.test./	Origin server, contact, and other details. Resource record format is: <originServer>/<contact>/<serial number>/<refresh rate>/<retry>/<expire>/<minimum>##

Record Type	Sample Format	Resource Record Data / Format
NS record	NS/5/ns1.dnslogging.test	Host name of the nameserver.
MX record	#MX/5/10/host1.dnslogging.test	Preference followed by mail exchange server host name
CNAME record logging	CNAME/5/host1.dnslogging.test.##	Canonical name
SRV record	SRV/5/1/2/3/host1.dnslogging.t .##	Resource record format: <priority>/<weight>/<port>/<target>#
TXT record	TXT/5/dns+logging##	Data comprises all the texts.
NAPTR record	NAPTR/5/10/11////dnslogging#. ##	Resource record format: <order>/<preference>/<flags>/<services>/<re expression>/<replacement string>#
DNSKEY record	DNSKEY/5/1/3/5/AwEAAanP0K+i5... I2Ccx6JZgiDBZhSON	Resource record format: <flags>/<protocol>/<algorithm>/<public key in base64 encoding>#
PTR record	PTR/3600/test.com.#test4.com.	Domain name

Limitations of DNS logging

DNS logging has the following limitations:

- If response logging is enabled, only the following record types are logged:
  - Address (A) record
  - AAAA record
  - SOA record
  - NS record
  - MX record
  - CNAME record
  - SRV record
  - TXT record
  - NAPTR record
  - DNSKEY record
  - PTR record

  For all other record types, only L3/L4 parameters, DNS Header, and Question section are logged.
- RRSIG records are not logged even if response logging is enabled.

- DNS64 is not supported.
- DNS proactive update requests or responses are logged according to the settings in the default profile.
- On the virtual server, if sessionless option and response logging is enabled, L3/L4 parameters, DNS Header, and DNS Question section are logged instead of the response.
- The maximum size of the syslog message is 1024 bytes.
- If you have set a DNS profile for a DNS policy with action type Rewrite Response, the Citrix ADC appliance does not log the query or the manipulated responses. To log the required information you must use an audit message action in the DNS policy.
- DNS transactions that are due to DNS monitoring traffic are not logged.

Configuring DNS logging

Following is an overview of configuring DNS logging:

1. Create a Syslog action and enable DNS in the action.
2. Create a Syslog policy and specify the Syslog action in the policy.
3. Globally bind the Syslog policy to enable logging of all Citrix ADC system events. Or, bind the Syslog policy to a specific load balancing virtual server.
4. Create a DNS profile and define any of the following types of logging that you want to enable:
   - DNS Query Logging
   - DNS Answer Section Logging
   - DNS Extended Logging
   - DNS Error Logging
5. Configure any of the following, based on your requirement:
   - DNS service and virtual server for DNS
   - ADNS service
   - Citrix ADC as a forwarder
   - Citrix ADC as a resolver
6. Set the created DNS profile to one of the DNS entities.

Configure DNS logging for Citrix ADC configured as DNS Proxy by using the CLI

1. Add a syslog action and enable DNS in the action. At the command prompt, type:

```
add audit syslogAction <name> (<serverIP> | -lbVserverName <string
    >) [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat <
    dateFormat>] [-logFacility <logFacility>] [-tcp ( NONE | ALL )]
     [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME |
    LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-
```

```
      appflowExport ( ENABLED |DISABLED )] [-lsn ( ENABLED | DISABLED
       )] [-alg ( ENABLED | DISABLED )] [-transport ( TCP | UDP )] [-
      tcpProfileName <string>] [-maxLogDataSizeToHold <
      positive_integer>] [-dns ( ENABLED | DISABLED)]
2 <!--NeedCopy-->
```

Example:

```
add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
LOCAL_TIME -dns ENABLED
```

2. Create a syslog policy and specify the created syslog action in the policy. At the command prompt, type:

   ```
   add audit syslogPolicy <name> <rule> <action>
   ```

   Example:

   ```
   add audit syslogPolicy syslogpol1 ns_true nssyslogact1
   ```

3. Bind the syslog policy globally. At the command prompt, type:

   ```
   bind system global [<policyName> [-priority <positive_integer>]]
   ```

   Example:

   ```
   bind system global syslogpol1
   ```

4. Create a DNS profile and enable any of the following type of logs that you want to configure:

   - DNS Query Logging
   - DNS Answer Section Logging
   - DNS Extended Logging
   - DNS Error Logging

   At the command prompt, type:

   ```
   add dns profile <dnsProfileName> [-dnsQueryLogging ( ENABLED | DISABLED
    )] [-dnsAnswerSecLogging ( ENABLED | DISABLED )] [-dnsExtendedLogging
    (ENABLED | DISABLED )] [-dnsErrorLogging ( ENABLED | DISABLED )] [-
   cacheRecords ( ENABLED | DISABLED )] [-cacheNegativeResponses ( ENABLED
    | DISABLED )]
   ```

   Example:

   ```
   add dns profile dnsprofile1 -dnsQueryLogging ENABLED
   ```

5. Configure service of type DNS. At the command prompt, type:

   ```
   add service <name> <serverName> <serviceType> <port>
   ```

Example:

```
add service svc1 10.102.84.140 dns 53
```

6. Configure a load balancing virtual server of service type DNS.

   ```
   add lb vserver <name> <serviceType> <ip> <port>
   ```

   Example:

   ```
   add lb vserver lb1 dns 100.100.100.10 53
   ```

7. Bind the service to the virtual server. At the command prompt, type:

   ```
   bind lb vserver <name> <serviceName>
   ```

   Example:

   ```
   bind lb vserver lb1 svc1
   ```

8. Set the created DNS profile to the virtual server. At the command prompt, type:

   ```
   set lb vserver <name> [ - dnsProfileName <string>]
   ```

   Example:

   ```
   set lb vserver lb1 -dnsProfileName dnsprofile1
   ```

Sample DNS logging configuration for Citrix ADC appliance configured as DNS proxy

```
1  > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel
2  CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -
       timeZone
3  LOCAL_TIME -dns ENABLED
4  Done
5  > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6  Done
7  > bind system global syslogpol1
8  Done
9  > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add lb vserver lb1 dns 100.100.100.10 53  - dnsProfileName dnsprofile1
12 Done
13 > add service svc1 10.102.84.140 dns 53
14 Done
15 > bind lb vserver lb1 svc1
16 Done
17 <!--NeedCopy-->
```

Sample DNS logging configuration for Citrix ADC appliance configured as ADNS

```
> add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
    LOCAL_TIME
-dns ENABLED
Done
> add audit syslogPolicy syslogpol1 ns_true nssyslogact1
Done
> bind system global syslogpol1
Done
> add dns profile dnsprofile1 -dnsqueryLogging ENABLED
Done
> add lb vserver lb1 dns 100.100.100.10 53  - dnsProfileName dnsprofile1
Done
> add service svc1 10.102.84.140 dns 53
Done
> bind lb vserver lb1 svc1
Done
<!--NeedCopy-->
```

Sample DNS logging configuration for Citrix ADC appliance configured as a forwarder

```
> add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
    LOCAL_TIME
-dns ENABLED
Done
> add audit syslogPolicy syslogpol1 ns_true nssyslogact1
Done
> bind system global syslogpol1
Done
> add dns profile dnsprofile1 -dnsqueryLogging ENABLED
Done
> add dns nameserver 8.8.8.8  - dnsProfileName dnsprofile1
Done
<!--NeedCopy-->
```

Sample DNS logging configuration for Citrix ADC appliance configured as a resolver

```
> add audit syslogAction nssyslogact1 10.102.151.136
-logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -
    logFacility LOCAL4
```

```
-timeZone LOCAL_TIME -dns ENABLED
Done
> add audit syslogPolicy syslogpol1 ns_true nssyslogact1
Done
> bind system global syslogpol1
Done
> add dns profile dnsprofile1 -dnsqueryLogging ENABLED
Done
> set dns parameter -recursion enABLED
Done
> add nameserver 1.1.1.100 -local dnsProfileName dnsprofile1
Done
<!--NeedCopy-->
```

Configure policy based logging for DNS

Policy based logging enables you to specify a format for log messages. The contents of a log message are defined by using a default syntax expression. When the message action specified in the policy is performed, the Citrix ADC appliance constructs the log message from the expression and writes the message to the log file. You can configure the appliance to log only when a particular DNS policy evaluates to True.

> **Note**
>
> If you have set a DNS policy with a DNS profile for the request side, the Citrix ADC appliance logs only the query.

To configure policy based logging for a DNS policy, you must first configure an audit message action. For more information about configuring an audit message action, see Configure the NetScaler appliance for audit logging. After configuring the audit message action, specify the message action in a DNS policy.

Configure policy based logging for a DNS policy by using the CLI

At the command prompt, type the following commands to configure policy based logging for a DNS policy and verify the configuration:

```
-  add dns action <actionName> <actionType> [-IPAddress <ip_addr|
   ipv6_addr> ... | -viewName <string> | -preferredLocList <string>
   ...] [-TTL <secs>] [-dnsProfileName <string>]
-  set dns policy <name> [<rule>] [-actionName <string>] [-logAction <
   string>]
-  show dns policy [<name>]
<!--NeedCopy-->
```

Example 1:

In a GSLB deployment, if you want to respond with different IP addresses to the client requests coming from a particular subnet, instead of responding with IP addresses used for general purposes (such as the IP addresses of internal users), you can configure a DNS policy with the action type as DNS view. In this case, you can configure DNS logging on the specified DNS action such that you can log the specific responses.

```
> add dns profile dns_prof1 -dnsqueryLogging enABLED -
   dnsanswerSecLogging enABLED
 Done
> add dns view dns_view1
 Done
> add dns action dns_act1 viewName -view dns_view1  - dnsprofilename
   dns_prof1
 Done
> add dns policy dns_pol1 "CLIENT.IP.SRC.APPLY_MASK(255.255.255.0).EQ
   (100.100.100.0)”
dns_act1
 Done
> bind dns global dns_pol1 100 -gotoPriorityExpression END -type
   REQ_DEFAULT
 Done
> bind gslb service site_1_svc -viewName dns_view1 123.1.1.1
 Done
> bind gslb service site_5_svc -view dns_view1 132.1.1.1
 Done
<!--NeedCopy-->
```

Note: In the preceding configuration, if you query for the domain configured on a GSLB virtual server, for example, *sampletest.com*, all the internal users of subnet 100.100.100.0/24 are served with the DNS view IP addresses, and the responses are logged. Client requests for other subnets are not logged.

Example 2:

If you want to log only the queries for the domain *example.com*, you can create a DNS profile with query logging enabled and set the DNS profile to a DNS action with the action type **NOOP**, and then create a DNS policy and set the DNS action. For example:

```
>add dns profile query_logging -dnsqueryLogging ENABLED
Done
>add dns action dns_act1 NOOP -dnsprofileName query_logging
Done
>add dns policy dns_pol1 DNS.REQ.QUESTION.DOMAIN.EQ("example.com")
   dns_act1
Done
```

```
<!--NeedCopy-->
```

Configuring DNS suffixes

September 14, 2021

You can configure DNS suffixes that enable the Citrix ADC appliance to complete non-fully qualified domain names during name resolution. For example, while resolving a not fully qualified domain name abc, if a DNS suffix example.com is configured, the appliance appends the suffix to the domain name. Then it resolves the domain name. In this case, it would resolve abc.example.com. If DNS suffixes are not configured, the appliance appends a period to the non-fully qualified domain names and resolves the domain name.

Create DNS suffixes

DNS suffixes have significance and are valid only when the Citrix ADC is configured as an end resolver or forwarder. You can specify a suffix of up to 127 characters.

Note: The order of DNS suffixes is important. The ADC appliance tries the configured suffixes in a serial order and stops when it gets a successful response for a suffix.

Create DNS suffixes by using the CLI

At the command prompt, type the following commands to create a DNS suffix and verify the configuration:

```
-  add dns suffix <dnsSuffix>
-  show dns suffix <dnsSuffix>
<!--NeedCopy-->
```

Example:

```
> add dns suffix example.com
 Done
> show dns suffix example.com
1)      Suffix: example.com
Done

<!--NeedCopy-->
```

To remove a DNS suffix by using the Citrix ADC command line, at the command prompt, type the `rm dns suffix` command and the name of the DNS suffix.

Create DNS suffixes by using the GUI

Navigate to **Traffic Management > DNS > DNS Suffix** and create DNS suffixes.

DNS ANY query

September 14, 2021

An ANY query is a type of DNS query that retrieves all records available for a domain name. The ANY query must be sent to a name server that is authoritative for a domain.

Behavior in ADNS mode

In the ADNS mode, the Citrix ADC appliance returns the records held in its local cache. If there are no records in the cache, the appliance returns the NXDOMAIN (negative) response.

If the Citrix ADC can match the domain delegation records, it returns the NS records. Otherwise, it returns the NS records of the root domain.

Behavior in DNS proxy mode

In proxy mode, the Citrix ADC appliance checks its local cache. If there are no records in the cache, the appliance passes the query to the server.

Behavior for Global Server Load Balancing (GSLB) domains

If a GSLB domain is configured on the ADC appliance and an ANY query is sent for the GSLB (site) domain, the appliance returns the IP address of the GSLB service. It selects this service through a load balancing decision. If the multiple IP response (MIR) option is enabled, the IP addresses of all GSLB services are sent.

For the Citrix ADC to return these records when it responds to the ANY query, all records corresponding to a GSLB domain must be configured on the Citrix ADC.

> **Note**
>
> If records for a domain are distributed between the Citrix ADC and a server, only records configured on the Citrix ADC are returned.

The Citrix ADC provides the option to configure DNS views and DNS policies. These views and policies are used for performing global server load balancing. For more information, see Global Server Load Balancing.

Configure negative caching of DNS records

September 14, 2021

The Citrix ADC appliance supports caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called negative caching. Negative caching helps speed up responses to queries about a domain.

> **Note:**
>
> Negative caching is supported only when the back-end server is configured as an authoritative DNS (ADNS) server for the queried domain.

A negative response can be one of the following:

- NXDOMAIN error message — The authoritative DNS servers respond with the NXDOMAIN error message when the queried domain name does not have any records configured on the server. This message implies that the queried domain is an invalid or a non-existent domain name.
- NODATA error message — If the domain name in the query is valid but records of the given type are not available, the appliance sends a NODATA error message.

When negative caching is enabled, the appliance caches the negative response from the DNS server and serves the future requests from the cache only. This action helps speed up responses to queries and also to reduce the back-end DNS traffic. Negative caching can be used in all deployments, that is, when a Citrix ADC appliance is serving as a proxy, as an end resolver, or as a forwarder.

You can enable or disable negative caching using a DNS profile, for more information see, DNS profiles. By default, negative caching is enabled in the default DNS profile (**default**-dns-profile) that are bound by default to a DNS virtual server or in the newly created DNS profile.

Enable or disable negative caching by using the CLI

At the command prompt, type the following commands to enable or disable negative caching and verify the configuration:

```
1 -  add dns profile <dnsProfileName> [-cacheRecords ( ENABLED | DISABLED
     )] [-cacheNegativeResponses (ENABLED | DISABLED )]
2 -  show dns profile [<dnsProfileName>]
3 <!--NeedCopy-->
```

Example of a default DNS profile:

```
1 > sh dns profile default-dns-profile
2     1)   default-dns-profile
```

```
3         Query logging : DISABLED        Answer section logging :
             DISABLED
4         Extended logging : DISABLED     Error logging : DISABLED
5         Cache Records : ENABLED     Cache Negative Responses: ENABLED
6  Done
7  <!--NeedCopy-->
```

Example of a newly created DNS profile:

```
1  > add dnsprofile dns_profile1 -cacheRecords ENABLED -
      cacheNegativeResponses ENABLED
2  Done
3  > show dns profile dns_profile1
4      1)   dns_profile1
5         Query logging : DISABLED        Answer section logging :
             DISABLED
6         Extended logging : DISABLED     Error logging : DISABLED
7         Cache Records : ENABLED     Cache Negative Responses: ENABLED
8  Done
9  <!--NeedCopy-->
```

Specify service or virtual server level DNS parameters by using the CLI

At the command prompt, perform the following:

1. Configure the DNS profile.

   ```
   add dns profile <dnsProfileName> [-cacheRecords ( ENABLED | DISABLED )]
    [-cacheNegativeResponses (ENABLED | DISABLED )]
   ```

2. Bind the DNS profile to the service or virtual server.

   To bind the DNS profile to the service:

   ```
   set service <name> [-dnsProfileName <string>]
   ```

Example:

```
1  >set service service1 -dnsProfileName dns_profile1
2  Done
3  <!--NeedCopy-->
```

To bind the DNS profile to the virtual server:

```
set lb vserver <name> [-dnsProfileName <string>]
```

Example:

```
>set lb vserver lbvserver1 -dnsProfileName dns_profile1
Done
<!--NeedCopy-->
```

Specify service or virtual server level DNS parameters by using the GUI

1. Configure the HTTP profile.

   Navigate to **System** > **Profiles**> **DNS Profile**, and create the DNS profile.

2. Bind the HTTP profile to the service or virtual server.

   Navigate to **Traffic Management** > **Load Balancing**> **Services/Virtual Servers**, and create the DNS profile, that must be bound to the service or the virtual server.

Rate limiting negative response served by the appliance

You can set a threshold for negative responses being served by the Citrix ADC appliance from the cache. When the threshold is set, the appliance serves the response from the cache until the threshold is reached. Once the threshold is reached, the appliance drops the requests instead of responding with an NXDOMAIN response.

Setting a rate limit for negative responses has the following advantages.

- Save the resources on the Citrix ADC appliance.
- Prevent any malicious queries for non-existent domain names.

> **Note:** You can set a threshold for negative responses only for the domains for which the ADC appliance is configured as an authoritative domain name server. You cannot set a threshold for cached records received from the authoritative back-end name servers.

Rate limiting negative response served by the cache by using the CLI

At the command prompt, type

```
set dns parameter -NXDOMainRateLimitThreshold <positive-integer>
<!--NeedCopy-->
```

Example:

```
set dns parameter -NXDOMainRateLimitThreshold 1000
<!--NeedCopy-->
```

NXDOMainRateLimitThreshold: When this parameter is set to a positive integer value, responses are served from the cache until this threshold (in seconds) is reached. Once the threshold exceeds, the requests are dropped. The threshold configured is per packet engine.

Rate limiting negative response served by the cache by using the GUI

1. Navigate to **Traffic Management > DNS** and click **Change DNS Settings**.
2. In the **Configure DNS parameters** page, in the **NXDOMAIN Rate Limit Threshold** field, enter the threshold value until which the responses must be served from the cache.

Note: The value in the **NXDOMAIN Threshold Crossed** displays the number of times the requests are dropped after the threshold is reached.

Cache EDNS0 client subnet data when the Citrix ADC appliance is in proxy mode

September 14, 2021

In Citrix ADC Proxy mode, if a back-end server that supports an EDNS0 Client Subnet (ECS) sends a response containing the ECS option, the Citrix ADC appliance does the following:

- It forwards the response as-is to the client and
- Stores the response in the cache, along with the client subnet information.

DNS requests that are from the same subnet of the same domain, and for which the server would send the same response, are then served from the cache.

Note:

- ECS caching is disabled by default. Enable caching of EDNS0 client-subnet data in the associated DNS profile.
- The number of subnets that you can cache for a domain is limited to the available subnet IDs, that is, 1270 in the Citrix ADC appliance. Optionally, you can set the limit to a lower number (minimum value: 1 ipv4/ipv6).

Enable caching of ECS responses by using the CLI

At the command prompt, type:

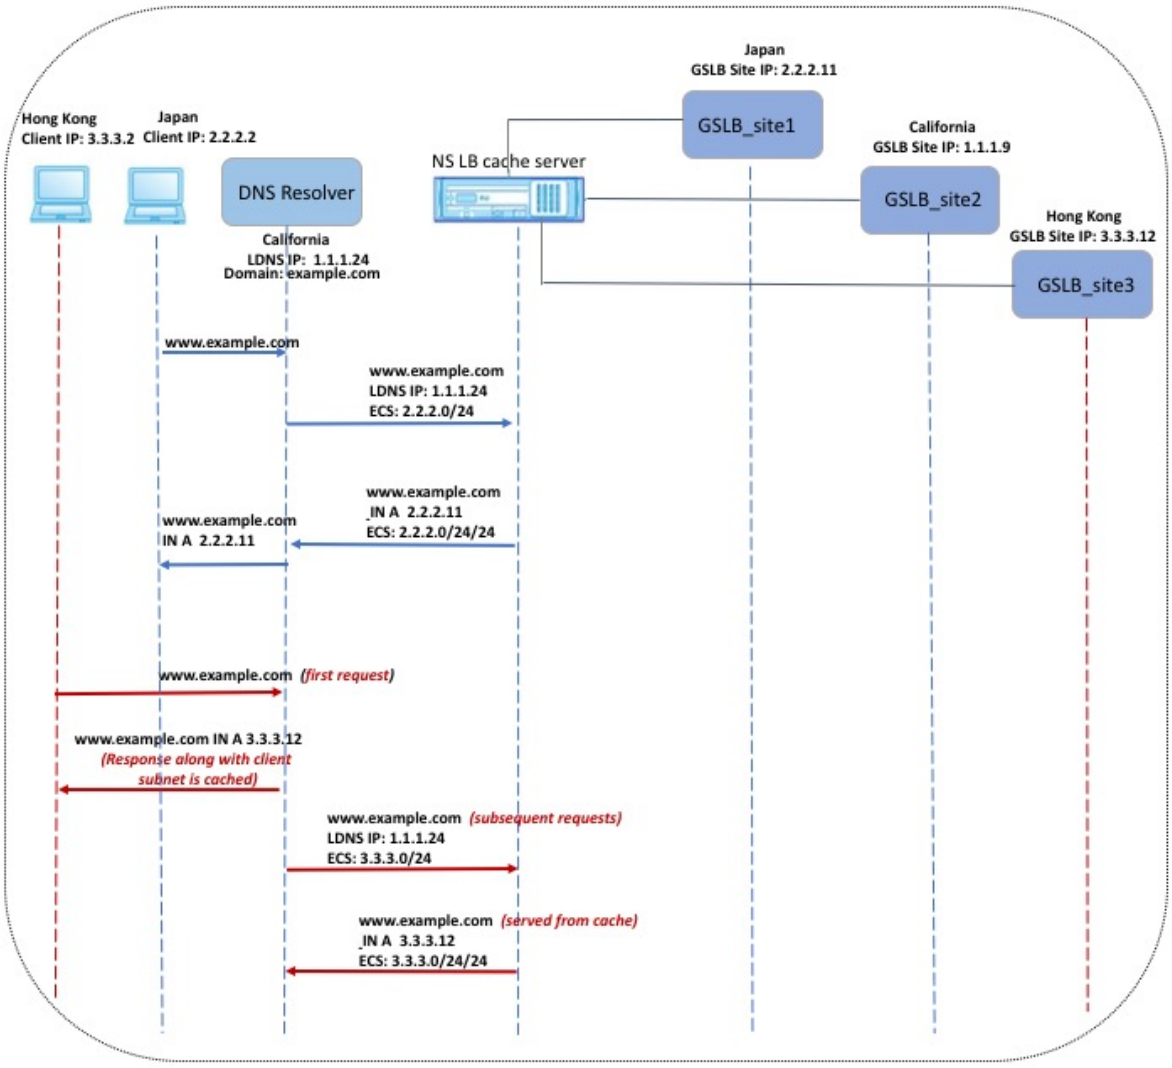
```
set dns profile <dnsProfileName> -cacheECSSubnet ( ENABLED | DISABLED )
```

Limit the number of subnets that can be cached per domain by using the CLI

At the command prompt, type:

```
set dns profile <dnsProfileName> -maxSubnetsPerDomain <positive_integer>
```

Example:



In the example shown in the preceding figure, the client at IP address 2.2.2.2 sends a query for www.example.com to the DNS resolver. The DNS resolver sends the following response:

www.example.com IN A, IP is 2.2.2.11, and ECS 2.2.2.0/24/24

At this point, the response and the client-subnet identifier (2.2.2.0/24) are cached. Further requests from the same subnet and domain are served from the cache.

For example, if the client's IP address is 2.2.2.100 and the query is for www.example.com, the query is served from the cache instead of being sent to the back-end server.

Domain name system security extensions

September 14, 2021

DNS Security Extensions (DNSSEC) is an Internet Engineering Task Force (IETF) standard. It aims to provide data integrity and data origin authentication in communications between name servers and clients while still transmitting UDP responses in clear text. DNSSEC specifies a mechanism that uses asymmetric key cryptography and a set of new resource records that are specific to its implementation.

The DNSSEC specification is described in:

- RFC 4033, "DNS Security Introduction and Requirements"
- RFC 4034, "Resource Records for the DNS Security Extensions"
- RFC 4035, "Protocol Modifications for the DNS Security Extensions"

The operational aspects of implementing DNSSEC within DNS are discussed in RFC 4641, "DNSSEC Operational Practices."

You can configure DNSSEC on the Citrix ADC. You can generate and import keys for signing DNS zones. You can configure DNSSEC for zones for which the Citrix ADC is authoritative. You can configure the ADC as a DNS proxy server for signed zones hosted on a farm of back-end name servers. If the ADC is authoritative for a subset of the records belonging to a zone for which the ADC is configured as a DNS proxy server, you can include the subset of records in the DNSSEC implementation.

Configure DNSSEC

September 14, 2021

Perform the following steps to configure DNSSEC:

1. Enable DNSSEC on the Citrix ADC appliance.
2. Create a zone signing key and a key signing key for the zone.
3. Add the two keys to the zone.
4. Sign the zone with the keys.

The Citrix ADC appliance does not act as a DNSSEC resolver. DNSSEC on the ADC is supported only in the following deployment scenarios:

1. ADNS—Citrix ADC is the ADNS and generates the signatures itself.
2. Proxy—Citrix ADC acts as a DNSSEC proxy. It is assumed that the Citrix ADC is placed in front of the ADNS/LDNS servers in a trusted mode. The ADC acts only as a proxy caching entity and does not validate any signatures.

Enable and disable DNSSEC

Enable DNSSEC on the Citrix ADC for the ADC to respond to DNSSEC-aware clients. By default, DNSSEC is enabled.

You can disable the DNSSEC feature if you do not want the Citrix ADC to respond to clients with DNSSEC-specific information.

Enable or disable DNSSEC by using the CLI

At the command prompt, type the following commands to enable or disable DNSSEC and verify the configuration:

```
-  set dns parameter -dnssec ( ENABLED | DISABLED )
-  show dns parameter
<!--NeedCopy-->
```

Example:

```
> set dns parameter -dnssec ENABLED
 Done
> show dns parameter
        DNS parameters:
        DNS retries: 5
         .
         .
         .
         DNSEC Extension: ENABLED
        Max DNS Pipeline Requests: 255
 Done

<!--NeedCopy-->
```

Enable or disable DNSSEC by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click Change DNS settings.
3. In the **Configure DNS Parameters** dialog box, select or clear the **Enable DNSSEC Extension** check box.

Create DNS keys for a zone

For each DNS zone that you want to sign, you must create two pairs of asymmetric keys. One pair, called the zone signing key (ZSK), is used to sign all the resource record sets in the zone. The second

pair is called the key signing key (KSK) and is used to sign only the DNSKEY resource records in the zone.

When the ZSK and the KSK are created, the `suffix.key` is appended to the names of the public components of the keys. The `suffix.private` is appended to the names of their private components. The appending happens automatically.

The Citrix ADC also creates a Delegation Signer (DS) record and appends the suffix .ds to the name of the record. If the parent zone is a signed zone, you must publish the DS record in the parent zone to establish the chain of trust.

When you create a key, the key is stored in the `/nsconfig/dns/` directory, but it is not automatically published in the zone. After you create a key by using the `create dns key` command, you must explicitly publish the key in the zone by using the `add dns key` command. The process of generating a key is separate from the process of publishing the key in a zone to enable you to use alternative means to generate keys. For example, you can import keys generated by other key-generation programs (such as `bind-keygen`) by using the Secure FTP (SFTP) and then publish the keys in the zone. For more information about publishing a key in a zone, see Publish a DNS key in a zone.

Perform the steps described in this topic to create a zone signing key and then repeat the steps to create a key signing key. The example that follows the command syntax first creates a zone signing key pair for the zone example.com. The example then uses the command to create a key signing key pair for the zone.

From release 13.0 build 61.x, the Citrix ADC appliance now supports stronger crypto algorithms, such as RSASHA256 and RSASHA512, to authenticate a DNS zone. Previously, only the RSASHA1 algorithm was supported.

Create a DNS key by using the CLI

At the command prompt, type:

```
create dns key -zoneName <string> -keyType <keyType> -algorithm <algorithm>
 -keySize <positive_integer> -fileNamePrefix <string>
```

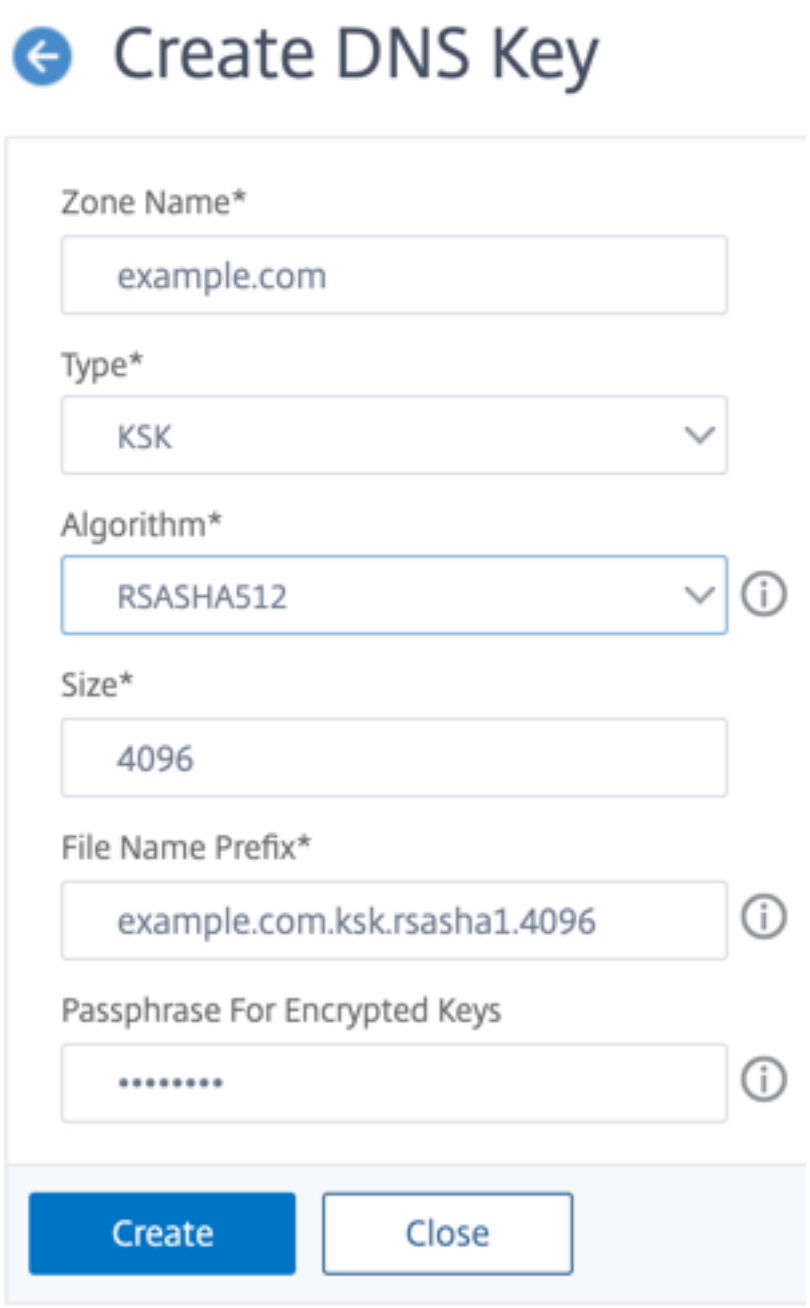
Example:

```
1 > create dns key -zoneName example.com -keyType zsk -algorithm
     RSASHA256 -keySize 1024 -fileNamePrefix example.com.zsk.rsasha1.1024
2 File Name: /nsconfig/dns/example.com.zsk.rsasha1.1024.key (public); /
     nsconfig/dns/example.com.zsk.rsasha1.1024.private (private); /
     nsconfig/dns/example.com.zsk.rsasha1.1024.ds (ds)
3 This operation may take some time, Please wait...
4  Done
5 > create dns key -zoneName example.com -keyType ksk -algorithm
     RSASHA512 -keySize 4096 -fileNamePrefix example.com.ksk.rsasha1.4096
```

```
File Name: /nsconfig/dns/example.com.ksk.rsasha1.4096.key (public); /
   nsconfig/dns/example.com.ksk.rsasha1.4096.private (private); /
   nsconfig/dns/example.com.ksk.rsasha1.4096.ds (ds)
This operation may take some time, Please wait...
 Done
<!--NeedCopy-->
```

Create a DNS key by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details area, click **Create DNS Key**.
3. Enter values for the different parameters and click **Create**.



Note: To modify the file name prefix of an existing key:

- Click the arrow next to the **Browse** button.
- Click either **Local** or **Appliance** (depending on whether the existing key is stored on your local computer or in the `/nsconfig/dns/` directory on the appliance)
- Browse to the location of the key, and then double-click the key.
  The **File Name Prefix** box is populated with only the prefix of the existing key. Modify the prefix accordingly.

Publish a DNS key in a zone

A key (zone signing key or key signing key) is published in a zone by adding the key to the ADC appliance. A key must be published in a zone before you sign the zone.

Before you publish a key in a zone, the key must be available in the **/nsconfig/dns/** directory. If you created the DNS key on another computer (for example, by using the `bind-keygen` program), ensure that the key is added to the `/nsconfig/dns/` directory. Then publish the key in the zone. Use the ADC GUI to add the key to the `/nsconfig/dns/` directory. Or, use some other program to import the key to the directory, such as the Secure FTP (SFTP).

Use the `add dns key` command for each public-private key pair that you want to publish in a given zone. If you created a ZSK pair and a KSK pair for a zone, use the `add dns key` command to first publish one of the key pairs in the zone. Repeat the command to publish the other key pair. For each key that you publish in a zone, a DNSKEY resource record is created in the zone.

The example that follows the command syntax first publishes the zone signing key pair (that was created for the example.com zone) in the zone. The example then uses the command to publish the key signing key pair in the zone.

Publish a key in a zone by using the CLI

At the command prompt, type the following command to publish a key in a zone and verify the configuration:

```
1 -  add dns key <keyName> <publickey> <privatekey> [-expires <
     positive_integer> [<units>]] [-notificationPeriod <positive_integer>
      [<units>]] [-TTL <secs>]
2 -  show dns zone [<zoneName> | -type <type>]
3 <!--NeedCopy-->
```

Example:

```
1 > add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.
     com.zsk.rsasha1.1024.private
2  Done
3 > add dns key example.com.ksk example.com.ksk.rsasha1.4096.key example.
     com.ksk.rsasha1.4096.private
4  Done
5 > show dns zone example.com
6          Zone Name : example.com
7          Proxy Mode : NO
8          Domain Name : example.com
9                  Record Types : NS SOA DNSKEY
10         Domain Name : ns1.example.com
```

```
                  Record Types : A
          Domain Name : ns2.example.com
                  Record Types : A
 Done
<!--NeedCopy-->
```

Publish a key in a DNS zone by using the GUI

Navigate to **Traffic Management > DNS > Keys**.

Note: For Public Key and Private Key, to add a key that is stored on your local computer, click the arrow next to the **Browse** button, click **Local**, browse to the location of the key, and then double-click the key.

Configure a DNS key

You can configure the parameters of a key that has been published in a zone. You can modify the key's expiry time period, notification period, and time-to-live (TTL) parameters. If you change the expiry time period of a key, the appliance automatically re-signs all the resource records in the zone with the key. The re-signing happens if the zone is signed with the particular key.

Configure a key by using the CLI

At the command prompt, type the following command to configure a key and verify the configuration:

```
-  set dns key <keyName> [-expires <positive_integer> [<units>]] [-
   notificationPeriod <positive_integer> [<units>]] [-TTL <secs>]
-  show dns key [<keyName>]
<!--NeedCopy-->
```

Example:

```
> set dns key example.com.ksk -expires 30 DAYS -notificationPeriod 3
   DAYS -TTL 3600
 Done
> show dns key example.com.ksk
1)      Key Name: example.com.ksk
        Expires: 30 DAYS        Notification: 3 DAYS    TTL: 3600
        Public Key File: example.com.ksk.rsasha1.4096.key
        Private Key File: example.com.ksk.rsasha1.4096.private
 Done
<!--NeedCopy-->
```

Configure a key by using the GUI

1. Navigate to **Traffic Management > DNS > Keys**.
2. In the details pane, click the key that you want to configure, and then click Open.
3. In the Configure DNS Key dialog box, modify the values of the following parameters as shown:
   - Expires—expires
   - Notification Period—notificationPeriod
   - TTL—TTL
4. Click OK.

Sign and unsign a DNS zone

To secure a DNS zone, you must sign the zone with the keys that have been published in the zone. When you sign a zone, the Citrix ADC creates a Next Secure (NSEC) resource record for each owner name. Then, it uses the key signing key to sign the DNSKEY resource record set. Finally, it uses the ZSK to sign all the resource record sets in the zone, including the DNSKEY resource record sets and NSEC resource record sets. Each sign operation results in a signature for the resource record sets in the zone. The signature is captured in a new resource record called the RRSIG resource record.

After you sign a zone, save the configuration.

Sign a zone by using the CLI

At the command prompt, type the following command to sign a zone and verify the configuration:

```
-  sign dns zone <zoneName> [-keyName <string> ...]
-  show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
-  save config
<!--NeedCopy-->
```

Example:

```
> sign dns zone example.com -keyName example.com.zsk example.com.ksk
 Done
> show dns zone example.com
         Zone Name : example.com
         Proxy Mode : NO
         Domain Name : example.com
                 Record Types : NS SOA DNSKEY RRSIG NSEC
         Domain Name : ns1.example.com
                 Record Types : A RRSIG NSEC
         Domain Name : ns2.example.com
```

```
                  Record Types : A RRSIG
          Domain Name : ns2.example.com
                  Record Types : RRSIG NSEC
Done
> save config
 Done
<!--NeedCopy-->
```

Unsign a zone by using the CLI

At the command prompt, type the following command to unsign a zone and verify the configuration:

```
-  unsign dns zone <zoneName> [-keyName <string> ...]
-  show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
<!--NeedCopy-->
```

Example:

```
> unsign dns zone example.com -keyName example.com.zsk example.com.ksk
 Done
> show dns zone example.com
          Zone Name : example.com
          Proxy Mode : NO
          Domain Name : example.com
                  Record Types : NS SOA DNSKEY
          Domain Name : ns1.example.com
                  Record Types : A
          Domain Name : ns2.example.com
                  Record Types : A
 Done
<!--NeedCopy-->
```

Sign or unsign a zone by using the GUI

1. Navigate to **Traffic Management > DNS > Zones**.
2. In the details pane, click the zone that you want to sign, and then click Sign/Unsign.
3. In the Sign/Unsign DNS Zone dialog box, do one of the following:
   - To sign the zone, select the check boxes for the keys (zone signing key and key signing key) with which you want to sign the zone.
     You can sign the zone with more than one zone signing key or key signing key pair.
   - To unsign the zone, clear the check boxes for the keys (zone signing key and key signing key) with which you want to unsign the zone.

You can unsign the zone with more than one zone signing key or key signing key pair.

4. Click OK.

View the NSEC records for a given record in a zone

You can view the NSEC records that the Citrix ADC automatically creates for each owner name in the zone.

View the NSEC record for a given record in a zone by using the CLI

At the command prompt, type the following command to view the NSEC record for a given record in a zone:

```
show dns nsecRec [<hostName> | -type (ADNS | PROXY | ALL)]
```

Example:

```
> show dns nsecRec example.com
1)      Domain Name : example.com
        Next Nsec Name: ns1.example.com
        Record Types : NS SOA DNSKEY RRSIG NSEC
 Done
<!--NeedCopy-->
```

View the NSEC record for a given record in a zone by using the GUI

1. Navigate to **Traffic Management > DNS > Records > Next Secure Records**.
2. In the details pane, click the name of the record for which you want to view the NSEC record. The NSEC record for the record you select is displayed in the Details area.

Remove a DNS key

Remove a key from the zone in which it is published when the key has expired or if the key has been compromised. When you remove a key from the zone, the zone is automatically unsigned with the key. Removing the key with this command does not remove the key files present in the /nsconfig/dns/ directory. If the key files are no longer needed, they have to be explicitly removed from the directory.

Remove a key from the Citrix ADC by using the CLI

At the command prompt, type the following command to remove a key and verify the configuration:

```
-  rm dns key <keyName>
-  show dns key <keyName>
<!--NeedCopy-->
```

Example:

```
> rm dns key example.com.zsk
 Done
> show dns key example.com.zsk
ERROR: No such resource [keyName, example.com.zsk]

<!--NeedCopy-->
```

Remove a key from the Citrix ADC by using the GUI

1. Navigate to **Traffic Management > DNS > Keys**.
2. In the details pane, click the name of the key that you want to remove from the ADC, and then click Remove.

Configure DNSSEC when the Citrix ADC is authoritative for a zone

September 14, 2021

When the Citrix ADC is authoritative for a given zone, all the resource records in the zone are configured on the ADC. To sign the authoritative zone, you must create the zone signing and the key signing keys for the zone, add the keys to the ADC, and then sign the zone. For more information, see:

- Create DNS keys for a zone
- Publish a DNS key in a zone
- Sign and unsign a DNS zone.

If any GSLB domains configured on the ADC belong to the zone being signed, the GSLB domain names are signed along with the other records that belong to the zone.

After you sign a zone, responses to requests from DNSSEC-aware clients include the RRSIG resource records along with the requested resource records. DNSSEC must be enabled on the ADC. For more information about enabling DNSSEC, see Enable and disable DNSSEC.

Finally, after you configure DNSSEC for the authoritative zone, you must save the Citrix ADC configuration.

Configure DNSSEC for a zone for which the Citrix ADC is a DNS proxy server

September 14, 2021

The procedure for signing a zone for which the Citrix ADC is configured as a DNS proxy server depends on whether the ADC owns a subset of the zone information owned by the back-end name servers. If it does, the configuration is considered a partial zone ownership configuration. If the ADC does not own a subset of the zone information, the Citrix ADC configuration for managing the back-end servers is considered a zone-less DNS proxy server configuration. The basic DNSSEC configuration tasks for both Citrix ADC configurations are the same. However, signing the partial zone on the Citrix ADC requires some additional configuration steps.

Note: The terms zone-less proxy server configuration and partial zone are used only in the context of the Citrix ADC appliance.

Important: When configured in proxy mode, the ADC does not perform signature verification on DNSSEC responses before updating the cache.

If you configure the ADC as a DNS proxy to load balance DNSSEC aware resolvers (servers), you must set the Recursion Available option while configuring the DNS virtual server. If a DNSSEC query arrives with Checking Disabled (CD) bit set, the query is passed on to the server with the CD bit retained. The response from the server is not cached.

Configure DNSSEC for a zone-less DNS proxy server configuration

For a zone-less DNS proxy server configuration, zone signing must be performed on the back-end name servers. On the Citrix ADC, you configure the ADC as a DNS proxy server for the zone. Create a load balancing virtual server of protocol type DNS. Configure services on the ADC to represent the name servers. Then bind the services to the load balancing virtual server. For more information about these configuration tasks, see Configure the NetScaler as a DNS proxy server.

When a client sends the ADC a DNS request with the DNSSEC OK (DO) bit set, the ADC checks its cache for the requested information. If the resource records are not available in its cache, the ADC forwards the request to one of the DNS name servers. Then, it relays the response from the name server to the client. Also, the ADC caches the RRSIG resource records along with the response from the name server. Subsequent requests from DNSSEC-aware clients are served from the cache (including the RRSIG resource records), subject to the time-to-live (TTL) parameter. If a client sends a DNS request without setting the DO bit, the ADC responds with only the requested resource records. It does not include the RRSIG resource records that are specific to DNSSEC.

Configure DNSSEC for a partial zone ownership configuration

In some ADC configurations, even though the authority for a zone lies with the back-end name servers, a subset of the resource records belonging to the zone might be configured on the ADC. The ADC owns (or is authoritative for) only this subset of records. Such a subset of records can be considered to constitute a *partial zone* on the ADC. The ADC owns the partial zone. All other records are owned by the back-end name servers.

A typical partial zone configuration on the Citrix ADC is seen when:

- Global Server Load Balancing (GSLB) domains are configured on the ADC
- The GSLB domains are a part of a zone for which the back-end name servers are authoritative.

Signing a zone that includes only a partial zone on the ADC involves:

- Including the partial zone information in the back-end name server zone files
- Signing the zone on the back-end name servers
- Signing the partial zone on the ADC.

The same key set must be used to sign the zone on the name servers and the partial zone on the ADC.

Sign the zone on the back-end name servers

1. Include the resource records that are contained in the partial zone, in the zone files of the name servers.
2. Create keys and use the keys to sign the zone on the back-end name servers.

Sign the partial zone on the Citrix ADC

1. Create a zone with the name of the zone owned by the back-end name servers. When configuring the partial zone, set the proxyMode parameter to YES. This zone is the partial zone that contains the resource records owned by the ADC.

   For example, if the name of the zone that is configured on the back-end name servers is example.com, you must create a zone named example.com on the ADC. Set the proxyMode parameter to YES. For more information about adding a zone, see Configure a DNS zone.

   > **Note**
   >
   > Do not add SOA and NS records for the zone. These records must exist on the ADC for a zone for which the ADC is authoritative.

2. Import the keys (from one of the back-end name servers) to the ADC and then add them to the /nsconfig/dns/ directory. For more information about how you can import a key and add it to the ADC, see Publish a DNS key in a zone.

3. Sign the partial zone with the imported keys. When you sign the partial zone with the keys, the ADC generates RRSIG and NSEC records for the resource record sets and individual resource records in the partial zone, respectively. For more information about signing a zone, see sign and unsign a DNS zone.

Configure DNSSEC for global server load balancing (GSLB) domain names

September 14, 2021

If GSLB is configured on the Citrix ADC and the ADC is authoritative for the zone to which the GSLB domain names belong, all GLSB domain names are signed when the zone is signed. For more information about signing a zone for which the ADC is authoritative, see Configure DNSSEC when the Citrix ADC appliance is authoritative for a zone.

If the GSLB domains belong to a zone for which the back-end name servers are authoritative, you must:

- First sign the zone on the name servers.
- Then sign the partial zone on the ADC to complete the DNSSEC configuration for the zone.

For more information, see Configure DNSSEC for a partial zone ownership configuration.

Zone maintenance

September 14, 2021

From a DNSSEC perspective, zone maintenance involves rolling over Zone Signing Keys and Key Signing Keys when key expiry is imminent. These zone maintenance tasks must be performed manually. The zone is re-signed automatically and does not require any manual intervention.

Re-sign an updated zone

When a zone is updated (add a record or modify an existing record), the appliance automatically re-signs the new (or modified) record. If a zone contains multiple zone signing keys, the appliance re-signs the new (or modified) record with the key used to sign the zone.

Roll over DNSSEC keys

Note: Manually roll over the DNSSEC keys (KSK, ZSK) before they expire.

On the Citrix ADC, you can use the prepublish and double signature methods to perform a rollover of the Zone Signing Key and Key Signing Key. More information about these two rollover methods is available in RFC 4641, "DNSSEC Operational Practices."

The following topics map commands on the ADC to the steps in the rollover procedures discussed in RFC 4641.

The key expiry notification is sent through an SNMP trap called dnskeyExpiry. Three MIB variables, dnskeyName, dnskeyTimeToExpire, and dnskeyUnitsOfExpiry are sent along with the dnskeyExpiry SNMP trap. For more information, see *Citrix NetScaler SNMP OID Reference* at NetScaler 12.0 SNMP OID Reference.

Prepublish key rollover

RFC 4641, "DNSSEC Operational Practices" defines four stages for the prepublish-key rollover method: initial, new DNSKEY, new RRSIGs, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

  Example:

  Consider the key, example.com.zsk1, with which the zone example.com is signed. The zone contains only those RRSIGs generated by the example.com.zsk1 key, which is due for expiry. The Key Signing Key is example.com.ksk1.

- **Stage 2: New DNSKEY.** A new key is created and published in the zone. That is, the key is added to the ADC, but the zone is not signed with the new key until the pre-roll phase is complete. In this stage, the zone contains the old key, the new key, and the RRSIGs generated by the old key. Publishing the new key for the complete duration of the pre-roll phase gives the DNSKEY resource record corresponding to the new key time to propagate to the secondary name servers.

  Example:

  A new key example.com.zsk2 is added to the example.com zone. The zone is not signed with example.com.zsk2 until the pre-roll phase is complete. The example.com zone contains DNSKEY resource records for both example.com.zsk1 and example.com.zsk2.

  Citrix ADC commands:

  Perform the following tasks on the ADC:

  - Create a DNS key by using the `create dns key` command.

    For more information about creating a DNS key, including an example, see Create DNS keys for a zone.

  - Publish the new DNS key in the zone by using the `add dns key` command.

    For more information about publishing the key in the zone, including an example, see Publish a DNS key in a zone.

- **Stage 3: New RRSIGs.** The zone is signed with the new DNS key and then unsigned with the old DNS key. The old DNS key is not removed from the zone and remains published until the RRSIGs generated by the old key expire.

  Example:

  The zone is signed with example.com.zsk2 and then unsigned with example.com.zsk1. The zone continues to publish example.com.zsk1 until the RRSIGs generated by example.com.zsk1 expire.

  Citrix ADC commands:

  Perform the following tasks on the ADC:

  - Sign the zone with the new DNS key by using the `sign dns zone` command.
  - Unsign the zone with the old DNS key by using the `unsign dns zone` command.

  For more information about signing and unsigning a zone, including examples, see Sign and unsign a DNS zone.

- **Stage 4: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

  Example:

  The old DNS key example.com.zsk1 is removed from the example.com zone.

  Citrix ADC commands

  On the ADC, you remove the old DNS key by using the `rm dns key` command. For more information about removing a key from a zone, including an example, see Remove a DNS key.

Double signature key rollover

RFC 4641, “DNSSEC Operational Practices” defines three stages for double signature key rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

  Example:

  Consider the key, example.com.zsk1, with which the zone example.com is signed. The zone contains only those RRSIGs generated by the example.com.zsk1 key, which is due for expiry. The Key Signing Key is example.com.ksk1.

- **Stage 2: New DNSKEY.** The new key is published in the zone and the zone is signed with the new key. The zone contains the RRSIGs that are generated by the old and the new keys. The minimum duration for which the zone must contain both sets of RRSIGs is the time required for all the RRSIGs to expire.

  Example:

  A new key example.com.zsk2 is added to the example.com zone. The zone is signed with example.com.zsk2. The example.com zone now contains the RRSIGs generated from both keys.

  Citrix ADC commands

  Perform the following tasks on the ADC:

  - Create a DNS key by using the `create dns key` command.

    For more information about creating a DNS key, including an example, see Create DNS keys for a zone.

  - Publish the new key in the zone by using the `add dns key` command.

    For more information about publishing the key in the zone, including an example, see Publish a DNS key in a zone.

  - Sign the zone with the new key by using the `sign dns zone` command.

    For more information about signing a zone, including examples, see Sign and unsign a DNS zone.

- **Stage 3: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

  Example:

  The old DNS key example.com.zsk1 is removed from the example.com zone.

  Citrix ADC commands:

  On the ADC, you remove the old DNS key by using the `rm dns key` command.

  For more information about removing a key from a zone, including an example, see Remove a DNS key.

Offload DNSSEC operations to the Citrix ADC

September 14, 2021

For DNS zones for which your DNS servers are authoritative, DNSSEC operations can be offloaded to the ADC appliance. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response dynamically before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see Configure a DNS zone.

Create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see Domain name system security extensions.

After you configure DNS offloading, you must flush the DNS cache on the Citrix ADC. Flushing the DNS cache ensures that any unsigned records in the cache are removed and then replaced by signed records. For information about flushing the DNS cache, see Flush DNS records.

Enable DNSSEC offloading for a zone by using the CLI

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

```
1 -  add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec
      ( ENABLED | DISABLED )
2 -  show dns zone
3 <!--NeedCopy-->
```

Example:

```
> add dns zone example.com -proxyMode YES -dnssecOffload ENABLED nsec
    ENABLED
 Done
> show dns zone example.com
     Zone Name : example.com
     Proxy Mode : YES
     DNSSEC Offload: ENABLED    NSEC: ENABLED
 Done
<!--NeedCopy-->
```

Enable DNSSEC offloading for a zone by using the GUI

1. Navigate to **Traffic Management > DNS > Zones**.
2. In the details pane, do one of the following:
   - To create a zone on the Citrix ADC, click Add.
   - To configure DNSSEC offloading for an existing zone, double-click the zone.
3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.
4. Optionally, if you want the Citrix ADC to generate NSEC records for the zone, select the NSEC check box.

Admin partition support for DNSSEC

September 14, 2021

In a partitioned Citrix ADC appliance, the DNS keys that are generated are stored in the following locations:

- Default partition: /nsconfig/dns/
- Non-default partition: /nsconfig/partitions/<partitionname>/dns/

You can now add a password to the DNS key. To add a password to the DNS key, you must first add the password in the `create dns key` command. Then provide the same password in the `add dns key` command when adding the DNS key to the ADC appliance. For example:

```
create dns key -zoneName com -keytype ksK -algorithm rsASHA1 -keysize 4096
- fileNamePrefix com.ksk.rsasha1.4096 -password 1jsfd3Wa

add dns key com.zsk.4096 /nsconfig/dns/com.zsk.rsasha1.4096.private -
password 1jsfd3Wa
```

Note:

- For a default partitioned environment, the keys are read from the default location/nsconfig/dns/. However, if the keys are stored in a different location, the path name has to be provided in the `add dns key -private` command. Example, `add dns key -private <path name>`.
- For a non-default partitioned environment, the keys are read from the default location `/nsconfig/partitions/<partitionname>/dns/`.

Supporting wildcard DNS domains

September 14, 2021

Wildcard DNS domains are used to handle requests for nonexistent domains and subdomains. In a zone, use wildcard domains to redirect queries for all nonexistent domains or subdomains to a particular server, instead of creating a separate Resource Record (RR) for each domain. The most common use of a wildcard DNS domain is to create a zone that can be used to forward mail from the internet to some other mail system.

In DNS resolution, wildcard RRs support the wildcard domain. The wildcard RRs are used to synthesize the responses to queries for a nonexistent domain name. For example, if you queried `http://image.example.com`, and the subdomain "image" did not exist, you might be redirected to example.com.

A wildcard record has an asterisk (*) character as the leftmost label of a domain name. For example, `*.example.com`. An asterisk at any other place in the domain name does signify a wildcard DNS record. For example, **`new`**`.*.example.com` is not a valid wildcard DNS record.

> **Note**
>
> - Wildcard domain is supported only when the Citrix ADC appliance is authoritative for the zone and is configured as an ADNS or a DNS proxy server.
> - Wildcard domain is not supported for NS and SOA records.
> - Wildcard domain cannot be applied when the query is in another zone.
> - Wildcard domain cannot be applied when the QNAME or a name between the wildcard domain and the QNAME is known to exist.

Example configuration

```
1 add dns soaRec example.com -originServer n1.example.com -contact admin.
     example.com
2
3 add dns nsRec example.com n1.example.com
```

```
4
5  add dns nsRec example.com n2.example.com
6
7  add dns zone example.com  -proxyMode no
8
9  add dns addrec www.example.com 2.2.2.2
10
11 add dns addrec *.example.com 10.10.10.10
12
13 add dns addrec *.example.com 10.10.10.11
14
15 add dns aaaarec *.example.com 2001::1
16 <!--NeedCopy-->
```

In the example, a wildcard domain name is added for an A and AAAA record.

When a query is received for a domain name that exists in the zone, the Citrix ADC appliance responds with the corresponding response. For example, for `www.example.com`, the appliance responds with 2.2.2.2 in the example.

For a nonexistent domain name that matches with a wildcard type, a synthesized response is delivered.

In the example, the Citrix ADC appliance responds with 10.10.10.10 and 10.10.10.11 for a domain name nonexist.example.com or xyz.example.com.

Wildcard synthesis is not applicable for a domain name that exists in the zone.

For example, for the query `www.example.com` and type AAAA, the Citrix ADC appliance does not synthesize with wildcard, because `www.example.com` exists with type A. In the example, the Citrix ADC appliance responds with a NODATA response.

For a query say abc.example.com and type AAAA, the Citrix ADC appliance responds with a synthesized response. For example, for `www.example.com`, the appliance responds with 2001::1 in the example.

Mitigate DNS DDoS attacks

September 14, 2021

DNS servers are one of the most critical components of a network, and they must be defended against attacks. One of the most basic types of DNS attacks is the DDoS attack. Attacks of this type are on the rise and can be destructive. You can do the following to mitigate DDoS attacks:

- Flush negative records.
- Restrict the time to live (TTL) of negative records.

- Preserve Citrix ADC memory by limiting the memory consumed by the DNS cache.
- Retain DNS records in the cache.
- Enable DNS cache bypass.

Flush negative records

A DNS attack fills the cache with negative records (NXDOMAIN and NODATA). As a result, responses to legitimate requests are not cached, so new requests are sent to a back-end server for DNS resolution. Responses are therefore delayed.

You can now flush the negative DNS records from the Citrix ADC appliance's DNS cache.

Flush negative cache records by using the CLI

At the command prompt, type:

```
flush dns proxyrecords -type (dnsRecordType | negRecType)NXDOMAIN | NODATA
```

Example:

```
flush dns proxyrecords -negRecType NODATA
```

Flush of negative cache records by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **DNS** > **Records**.
2. In the details pane, click **Flush Proxy Records**.
3. In the **Flush Type** box, select **Negative Records**.
4. In the **Negative Records Type** box, select either **NXDOMAIN** or **NODATA**.

Protection against random subdomain and NXDOMAIN attacks

To prevent random subdomain and NXDOMAIN attacks, you can restrict the DNS cache memory, and you can adjust the TTL values for negative records.

To limit the amount of memory consumed by the DNS cache, specify the maximum cache size (in MB), and also the cache size (in MB) for storing negative responses. When either limit is reached, no more entries are added to the cache. Also, syslog messages are logged and, if you have configured SNMP traps, SNMP traps are generated. If these limits are not set, caching continues until the system memory is exhausted.

A higher TTL value for negative records can result in storing records that are not valuable for a long time. A lower TTL value results in sending more requests to the back-end server.

The TTL of the negative record is set to a value that can be the lesser of the TTL value or the "Expires" value of the SOA record.

Note:

- This limitation is added per packet engine. For example, if the maxCacheSize is set to 5 MB and the appliance has 3 packet engines, the total cache size is 15 MB.
- The cache size for the negative records must be less than or equal to the maximum cache size.
- If you reduce the DNS cache memory limit to a value lower than the amount of data already cached, the cache size remains above the limit until the data ages out. That is, exceeds its TTL0 or is flushed (`flush dns proxyrecords` command, or Flush Proxy Records in the Citrix ADC GUI).
- To configure SNMP traps, see Configuring the NetScaler to Generate SNMP Traps.

Limit the memory consumed by the DNS Cache by using the CLI

At the command prompt, type:

```
set dns parameter -maxCacheSize <MBytes> -maxNegativeCacheSize <MBytes>
```

Example:

```
set dns parameter - maxCacheSize 100 -maxNegativeCacheSize 25
```

Limit the memory consumed by the DNS Cache by using the GUI

Navigate to **Configuration** > **Traffic Management** > **DNS**, click **Change DNS Settings**, and set the following parameters:

- Max Cache Size in MB
- Max Negative Cache Size in MB

Restrict the TTL of negative records by using the CLI

At the command prompt, type:

```
set dns parameter -maxnegcacheTTL <secs>
```

Example:

```
set dns parameter -maxnegcacheTTL 360
```

Restrict the TTL of negative records by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **DNS**.
2. Click **Change DNS Settings** and set the **Max Negative Cache TTL in sec** parameter.

Retain DNS records in the cache

An attack can flood the DNS cache with non-important entries but can cause flushing of the already cached legitimate records to make room for the new entries. To prevent attacks from filling the cache with invalid data, you can retain the legitimate records even after they exceed their TTL values.

If you enable the cacheNoExpire parameter, the records currently in the cache are retained until you disable the parameter.

Note:

- This option can be used only when the maximum cache size is specified (maxCacheSize parameter).
- If maxnegcacheTTL is configured and cacheNoExpire is enabled, cacheNoExpire takes priority.

Retain DNS records in the cache by using the CLI

At the command prompt, type:

```
set dns parameter -cacheNoExpire ( ENABLED | DISABLED)
```

Example:

```
set dns parameter -cacheNoExpire ENABLED
```

Retain DNS records in the cache by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **DNS** and click **Change DNS Settings**.
2. Select **Cache No Expire**.

Enable DNS cache bypass

For greater visibility and control of DNS requests, set the cacheHitBypass parameter to forward all requests to the back-end servers and allow the cache to be built but not used. After the cache is built, you can disable the parameter so that requests are served from the cache.

Enable DNS cache bypass by using the CLI

At the command prompt, type:

```
set dns parameter -cacheHitBypass ( ENABLED | DISABLED )
```

Example:

```
set dns parameter -cacheHitBypass ENABLED
```

Enable DNS cache bypass by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **DNS** and click **Change DNS Settings**.
2. Select **Cache Hit Bypass**.

Prevent the `Slowloris` attack

A DNS query spanning multiple packets, presents the potential threat of a `Slowloris` attack. The Citrix ADC appliance can silently drop DNS queries that are split into multiple packets.

You can set the `splitPktQueryProcessing` parameter to ALLOW or DROP a DNS query if the query is split into multiple packets.

Note: This setting is applicable only for DNS TCP.

Limit the DNS queries to a single packet by using the CLI

At the command prompt, type:

```
set dns parameter -splitPktQueryProcessing ( ALLOW | DROP )
```

Example:

```
set dns parameter -splitPktQueryProcessing DROP
```

Limit DNS queries to a single packet by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **DNS** and click **Change DNS Settings**.
2. In the **Split Packet Query Processing** box, choose **ALLOW** or **DROP**.

Collect statistics of the DNS responses served from the cache

You can collect statistics of the DNS responses served from the cache. Then use these statistics to create a threshold beyond which more DNS traffic is dropped, and enforce this threshold with a bandwidth based policy. Previously, bandwidth calculation for a DNS load balancing virtual server was not accurate, because the number of requests served from the cache was not reported.

In proxy mode, the statistics for Request bytes, Response bytes, Total Packets received, and Total Packets sent statistics are continuously updated. Previously, these statistics were not always updated, particularly for a DNS load balancing virtual server.

Proxy mode also now enables you to determine the number of DNS responses served from the cache. To collect these statistics, the following options have been added to the `stat lb vserver <DNSvirtualServerName>` command:

- **Requests** – Total number of requests received by the DNS or DNS_TCP virtual server. Includes the requests forwarded to the back end and the requests answered from the cache.
- **Vserver hits** –Total number of requests forwarded to the back end. The number of requests served from the cache is the difference between the total number of requests and the number of requests served from the virtual server.
- **Responses** – Total number of responses sent by this virtual server. For example, if a DNS LB virtual server received 5 DNS requests, forwarded 3 of them to the back end, and served 2 of them from the cache, the corresponding value of each of these statistics would be as follows:
  - **Vserver hits**: 3
  - **Requests**: 5
  - **Responses**: 5

Firewall Load Balancing

September 14, 2021

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput. Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a Citrix ADC appliance for firewall load balancing is similar to configuring load balancing, with the exception that the recommended service type is ANY, recommended monitor type is PING, and the load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration. The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet and involves configuring two Citrix ADC appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet. The enterprise environment involves configuring a single Citrix ADC appliance between the internal network and the firewalls that provide access to the Internet. The multiple-firewall environment is used for load balance traffic coming from another firewall. Having firewall load balancing enabled on both the sides of Citrix ADC appliance improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic. The multiple-firewall environment involves configuring a Citrix ADC appliance sandwiched between two firewalls.

Important: If you configure static routes on the Citrix ADC appliance for the destination IP address and enable L3 mode, the Citrix ADC appliance uses its routing table to route the traffic instead of sending

the traffic to the load balancing vserver.

Note: For FTP to work, an additional virtual server or service should be configured on the Citrix ADC appliance with IP address and port as * and 21 respectively, and the service type specified as FTP. In this case, the Citrix ADC appliance manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.

Firewall Load Balancing supports only some of the load balancing methods supported on the Citrix ADC appliance. Also, you can configure only a few types of persistence and monitors.

Firewall Load Balancing Methods

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
- Least Bandwidth
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

Firewall Persistence

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

Firewall Server Monitoring

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the backend service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.

Sandwich Environment

September 14, 2021

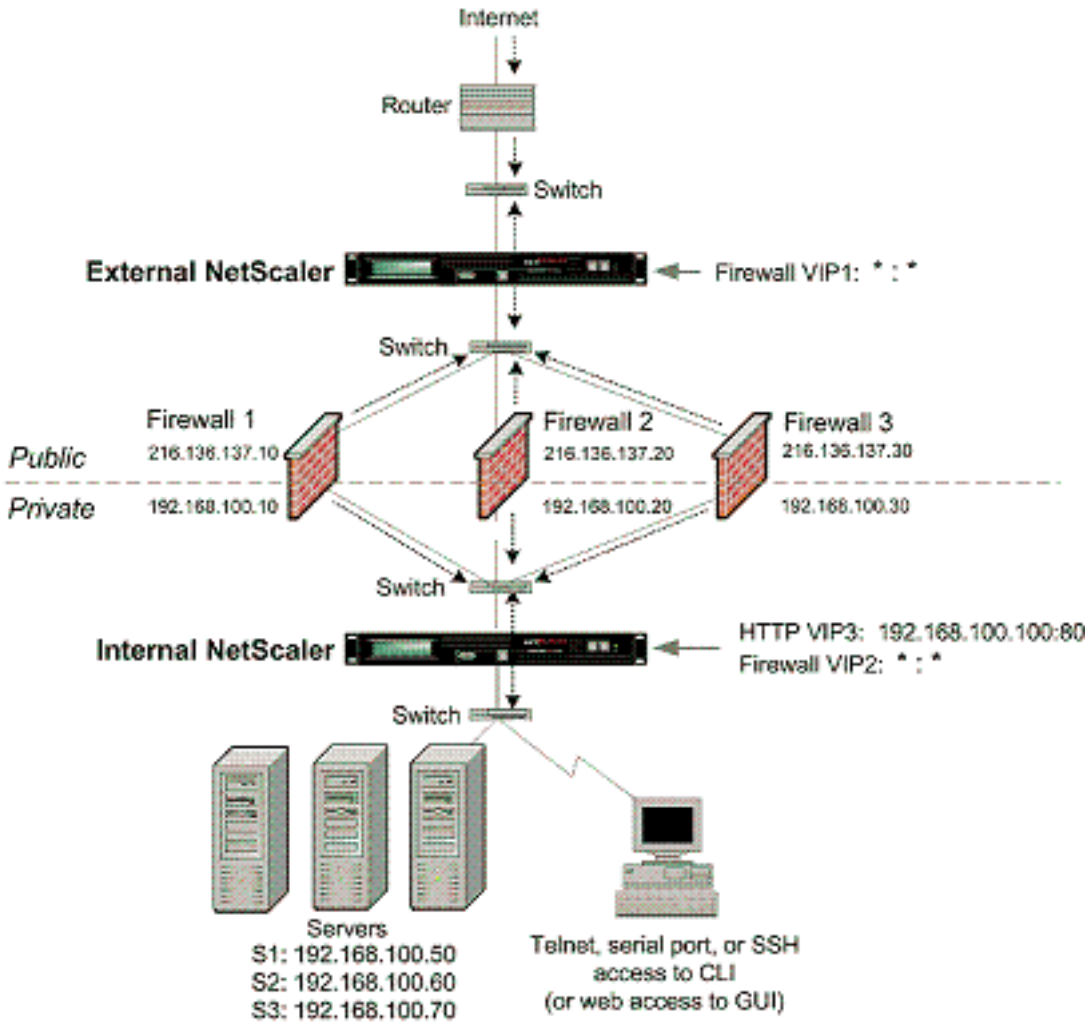
A Citrix ADC deployment in a sandwich mode can load balance network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

In this setup, a Citrix ADC is located on each side of a set of firewalls. The Citrix ADC placed between the firewalls and the Internet, called the external Citrix ADC that handles ingress traffic selects the best firewall, based on the configured method. The Citrix ADC between the firewalls and the private network, called the internal Citrix ADC tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal Citrix ADC can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.

Figure 1. Firewall Load Balancing (Sandwich)



The service type ANY configures the Citrix ADC to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

Configuring the External Citrix ADC in a Sandwich Environment

Perform the following tasks to configure the external Citrix ADC in a sandwich environment

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
enable ns feature LB
show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature LoadBalancing
 Done
> show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  OFF
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 .
 .
 .
 24)    NetScaler Push                  push                OFF
 Done
<!--NeedCopy-->
```

To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 10.102.29.5 ANY *
<!--NeedCopy-->
```

To configure a wildcard service for each firewall by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services** and add a service. Specify **ANY** in the **Protocol** field and * in the Port field.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-
    transparent (YES | NO )]
bind lb monitor <monitorName> <serviceName>
<!--NeedCopy-->
```

Example:

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
To bind a PING monitor, type the following command:
bind monitor PING fw-svc1
<!--NeedCopy-->
```

To create and bind a transparent monitor by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Monitors**, and then create and bind a transparent monitor.

Configure a wildcard virtual server for traffic coming from the Internet

To configure a wildcard virtual server for traffic coming from the Internet by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 ANY * *
<!--NeedCopy-->
```

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers** and create a wildcard virtual server. Specify **ANY** in the **Protocol** field and * in the Port field.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
<!--NeedCopy-->
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section, and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

Bind services to the wildcard virtual server

To bind a service to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind a service to the wildcard virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server for which you want to bind the service.
2. Click in the **Services** section and select a service to bind.

Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. Ensure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
save ns config
show vserver
<!--NeedCopy-->
```

Example:

```
save config
sh lb vserver FWLBVIP1
FWLBVIP1 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 06:40:14 2010
        Time since last state change: 0 days, 00:00:11.240
        Effective State: UP  ARP:DISABLED
        Client Idle Timeout: 120 sec

Configuring the Internal Citrix ADC in a Sandwich Environment

Perform the following tasks to configure the internal Citrix ADC in a sandwich environment

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled. But they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
enable ns feature LB
show ns feature
<!--NeedCopy-->
```

Example:

```
> enable ns feature LoadBalancing
 Done
> show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  OFF
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 .
 .
 .
 24)    NetScaler Push                  push                OFF
 Done
<!--NeedCopy-->
```

To enable load balancing by using the configuration utility

Navigate to **System > Settings** and, in Configure Basic Features, select **Load Balancing**.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 10.102.29.5 ANY *
<!--NeedCopy-->
```

To configure a wildcard service for each firewall by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services** and add a service. Specify **ANY** in the **Protocol** field and * in the Port field.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-
    transparent (YES | NO )]
bind lb monitor <monitorName> <serviceName>
<!--NeedCopy-->
```

Example:

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
<!--NeedCopy-->
```

To create and bind a transparent monitor by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors** and create a monitor.
2. In the **Create Monitor** dialog box, enter the required parameters, and select **Transparent**.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 ANY * *
<!--NeedCopy-->
```

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and create a wildcard virtual server.
2. Specify **ANY** in the Protocol field and ***** in the Port field.

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
<!--NeedCopy-->
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section, and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> HTTP <port>
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
<!--NeedCopy-->
```

To configure a service for each virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**, and configure a service for each virtual server.
2. Specify **HTTP** in the **Protocol** field, and select **HTTP** under **Available Monitors**.

To configure a service for each virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each service

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
<!--NeedCopy-->
```

Example:

```
bind mon monitor-HTTP-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind a monitor to a service by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services**, double-click a service, and add a monitor.

Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
<!--NeedCopy-->
```

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Services**, and configure an HTTP virtual server.
2. Specify **HTTP** in the **Protocol** field.

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
   - IP Address—IP Address
     Note: If the virtual server uses IPv6, select the
     IPv6 check box and enter the address in IPv6 format (for example,
     1000:0000:0000:0000:0005:0600:700a:888b).
   - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `save ns config`
- `show vserver`

Example:

```
save config
show lb vserver FWLBVIP2
        FWLBVIP2 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 07:22:54 2010
        Time since last state change: 0 days, 00:00:32.760
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)       2 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
 Done
show service fw-int-svc1
        fw-int-svc1 (10.102.29.5:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 14:44:51 2010
        Time since last state change: 0 days, 00:01:50.240
        Server Name: 10.102.29.5
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
```

```
32          TCP Buffering(TCPB): NO
33          HTTP Compression(CMP): NO
34          Idle timeout: Client: 120 sec   Server: 120 sec
35          Client IP: DISABLED
36          Cacheable: NO
37          SC: OFF
38          SP: OFF
39          Down state flush: ENABLED
40
41  1)      Monitor Name: monitor-HTTP-1
42                  State: DOWN     Weight: 1
43                  Probes: 9       Failed [Total: 9 Current: 9]
44                  Last response: Failure - Time out during TCP connection
                        establishment stage
45                  Response Time: 2000.0 millisec
46  2)      Monitor Name: ping
47                  State: UP       Weight: 1
48                  Probes: 3       Failed [Total: 0 Current: 0]
49                  Last response: Success - ICMP echo reply received.
50                  Response Time: 1.275 millisec
51   Done
52  <!--NeedCopy-->
```

To save and verify the configuration by using the configuration utility

1. In the **Details** pane, click **Save**.
2. In the **Save Config** dialog box, click **Yes**.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
4. In the **Details** pane, select the virtual server that you created in step 5.
5. Verify that the settings displayed in the **Details** pane are correct.
6. Navigate to **Traffic Management > Load Balancing > Services**.
7. In the **Details** pane, select the services that you created in step 5.
8. Verify that the settings displayed in the **Details** pane are correct.

Monitoring a Firewall Load Balancing Set up in a Sandwich Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
<!--NeedCopy-->
```

Example:

```
>stat lb vserver -detail
Virtual Server(s) Summary
                        vsvrIP  port     Protocol        State    Req/s
                             Hits/s
One                          *    80         HTTP           UP      5/s
         0/s
Two                          *     0          TCP         DOWN      0/s
         0/s
Three                        *  2598          TCP         DOWN      0/s
         0/s
dnsVirtualNS    10.102.29.90    53          DNS         DOWN      0/s
         0/s
BRVSERV            10.10.1.1    80         HTTP         DOWN      0/s
         0/s
LBVIP           10.102.29.66    80         HTTP           UP      0/s
         0/s
 Done

<!--NeedCopy-->
```

To display virtual server statistics by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click **Statistics**.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
<!--NeedCopy-->
```

Example:

```
stat service Service-HTTP-1
<!--NeedCopy-->
```

To view the statistics of a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click **Statistics**.

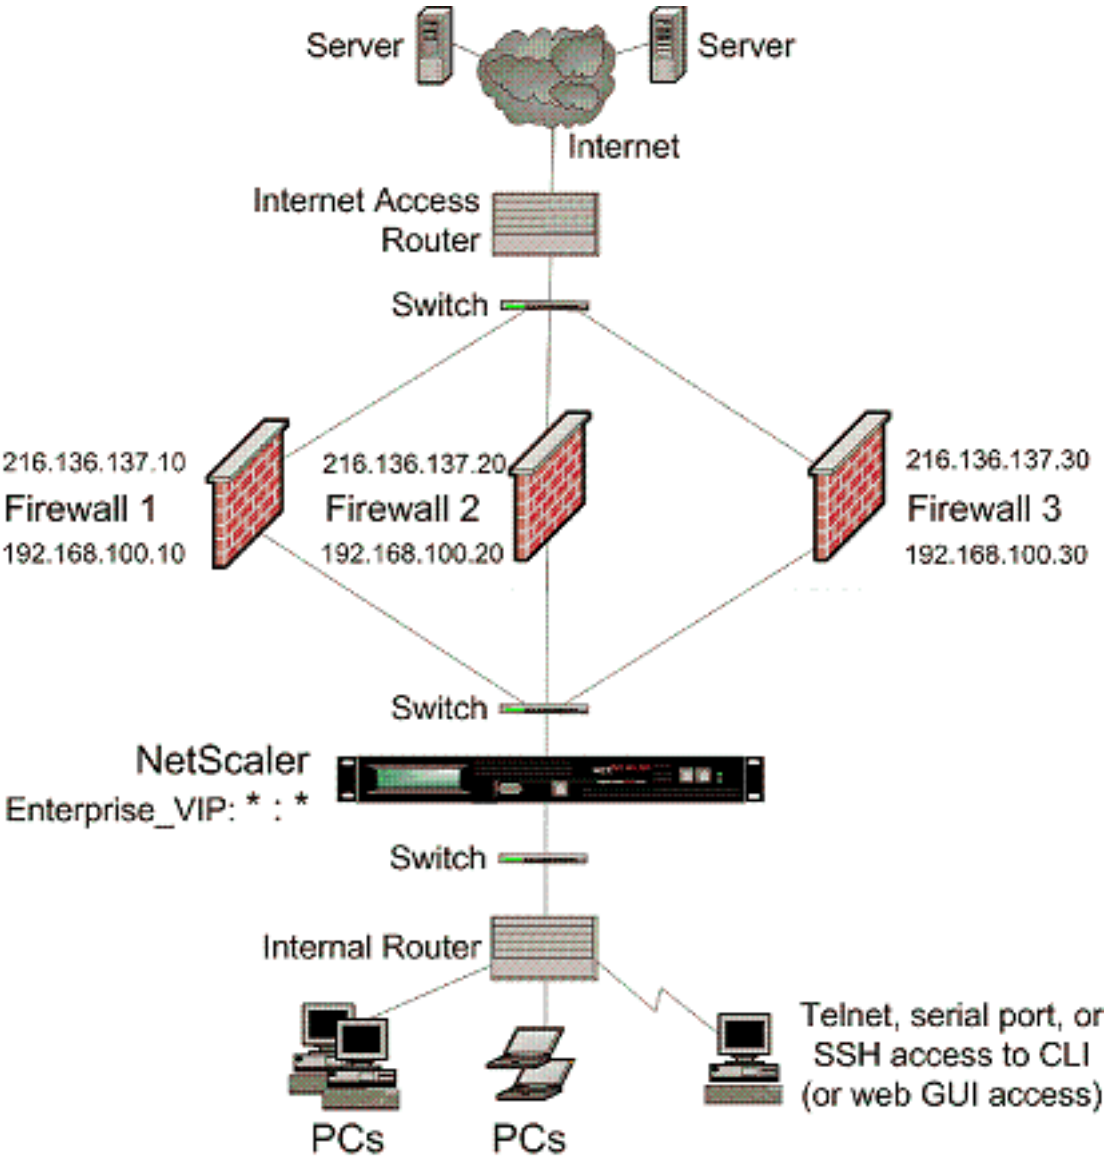
Enterprise Environment

September 14, 2021

In the enterprise setup, the Citrix ADC is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The Citrix ADC selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)



The service type ANY configures the Citrix ADC to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and vserver with type HTTP or TCP. For FTP to work, configure the service with type FTP.

Configuring the Citrix ADC in an Enterprise Environment

Perform the following tasks to configure a Citrix ADC in an enterprise environment.

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.

- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example:

```
> enable ns feature LoadBalancing
 Done
> show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  OFF
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 .
 .
 .
 24)    NetScaler Push                  push                OFF
 Done
<!--NeedCopy-->
```

To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 10.102.29.5 ANY *
<!--NeedCopy-->
```

To configure a wildcard service for each firewall by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
4. In Protocol, select ANY, and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-
    transparent (YES | NO )]
bind lb monitor <monitorName> <serviceName>
<!--NeedCopy-->
```

Example:

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
<!--NeedCopy-->
```

To create and bind a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values as shown:
   - Name*
   - Type*—type
   - Destination IP
   - Transparent

   -* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 ANY * *
<!--NeedCopy-->
```

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
<!--NeedCopy-->
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> HTTP <port>
<!--NeedCopy-->
```

Example:

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
<!--NeedCopy-->
```

To configure a service for each virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each service

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
<!--NeedCopy-->
```

Example:

```
bind mon monitor-HTTP-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
<!--NeedCopy-->
```

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name

- IP Address—IPAddress
  Note: If the virtual server uses IPv6, select the
  IPv6 check box and enter the address in IPv6 format (for example,
  1000:0000:0000:0000:0005:0600:700a:888b).
- Port—port

4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Bind HTTP services to the HTTP virtual server

To bind HTTP services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind HTTP services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example:

```
save config
show lb vserver FWLBVIP2
        FWLBVIP2 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 07:22:54 2010
        Time since last state change: 0 days, 00:00:32.760
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)       2 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
 Done
show service fw-int-svc1
        fw-int-svc1 (10.102.29.5:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 14:44:51 2010
        Time since last state change: 0 days, 00:01:50.240
        Server Name: 10.102.29.5
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: monitor-HTTP-1
                State: DOWN     Weight: 1
                Probes: 9       Failed [Total: 9 Current: 9]
                Last response: Failure - Time out during TCP connection
```

```
                        establishment stage
45                  Response Time: 2000.0 millisec
46 2)      Monitor Name: ping
47                  State: UP       Weight: 1
48                  Probes: 3       Failed [Total: 0 Current: 0]
49                  Last response: Success - ICMP echo reply received.
50                  Response Time: 1.275 millisec
51  Done
52 <!--NeedCopy-->
```

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

Monitoring a Firewall Load Balancing Setup in an Enterprise Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
<!--NeedCopy-->
```

Example:

```
>stat lb vserver -detail
Virtual Server(s) Summary
                        vsvrIP  port     Protocol        State    Req/s
                             Hits/s
One                          *    80         HTTP           UP      5/s
        0/s
Two                          *     0          TCP         DOWN      0/s
        0/s
Three                        *  2598          TCP         DOWN      0/s
        0/s
dnsVirtualNS    10.102.29.90    53          DNS         DOWN      0/s
        0/s
BRVSERV            10.10.1.1    80         HTTP         DOWN      0/s
        0/s
LBVIP           10.102.29.66    80         HTTP           UP      0/s
        0/s
 Done

<!--NeedCopy-->
```

To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
<!--NeedCopy-->
```

Example:

```
stat service Service-HTTP-1
<!--NeedCopy-->
```

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

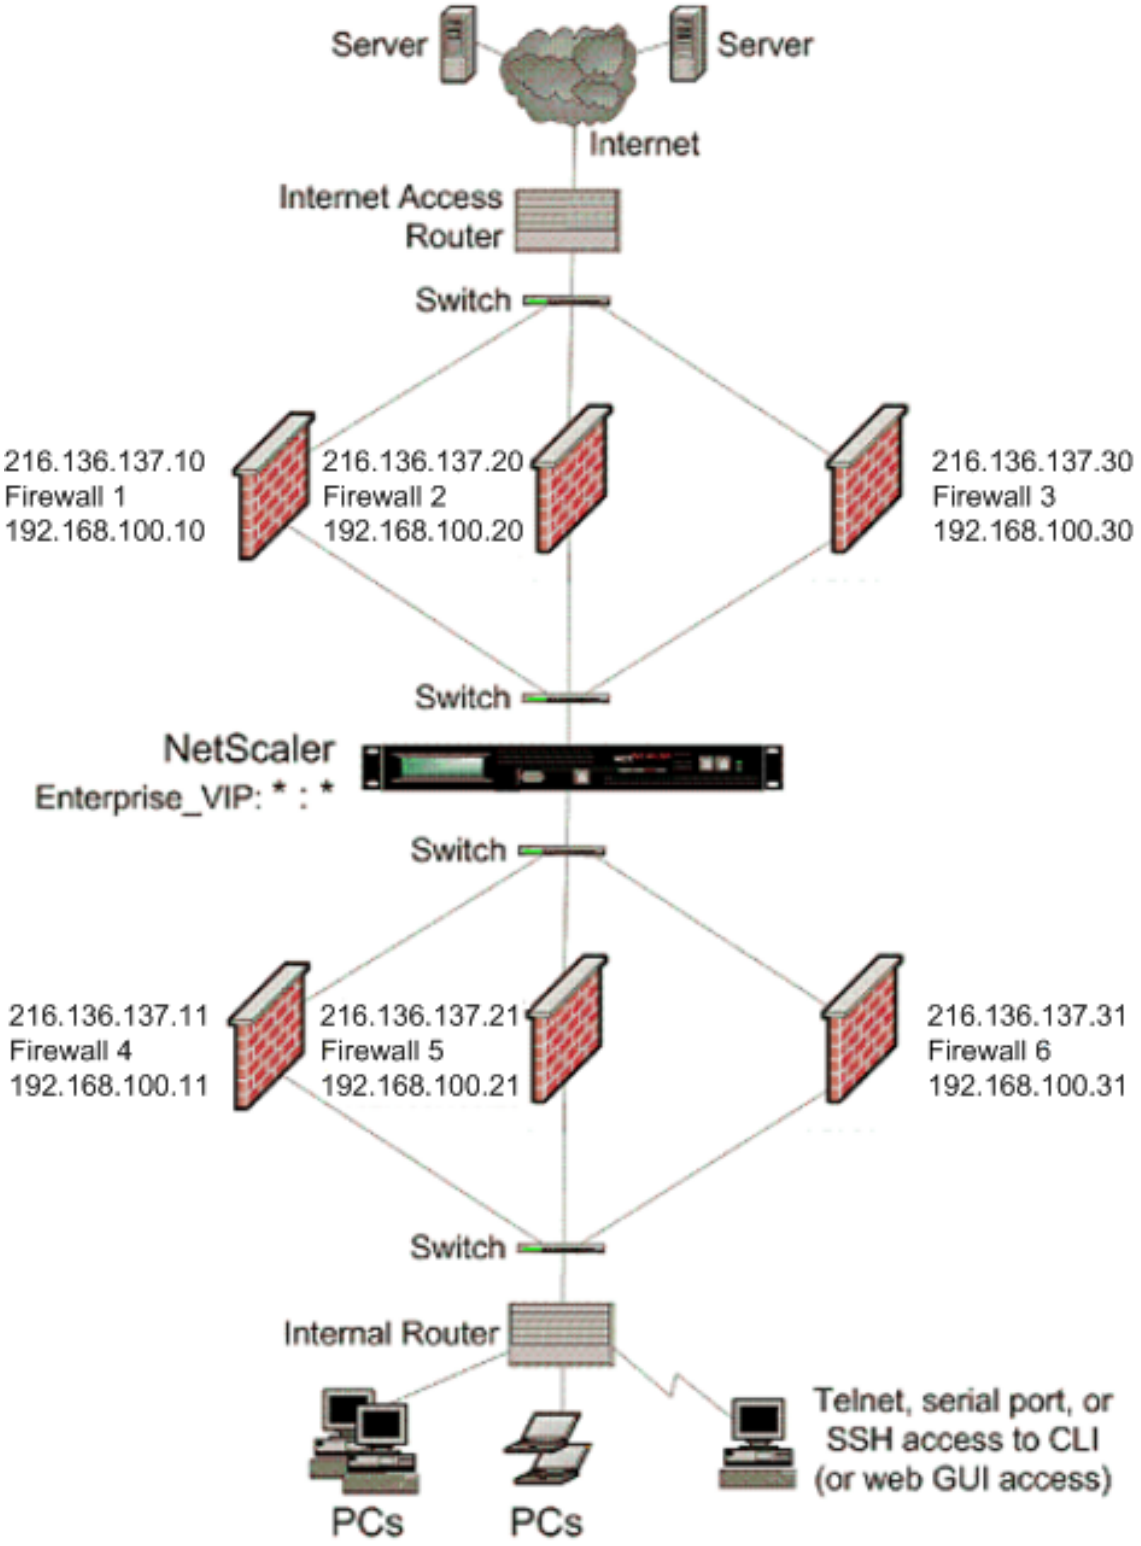
Multiple-Firewall Environment

September 14, 2021

In a multiple-firewall environment, the Citrix ADC appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a Citrix ADC appliance. Having firewall load balancing enabled on both the sides of Citrix ADC improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

The following figure shows a multiple-firewall load balancing environment

Figure 1. Firewall Load Balancing (multiple-firewall)



With a configuration like the one shown in Figure 1, you can configure the Citrix ADC to load balance the traffic through the an internal firewall even if it is load balanced by an external firewall. For example,

with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and vice versa.

Firewall load balancing is supported only for MAC mode LB virtual server.

The service type ANY configures the Citrix ADC to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

Configuring the Citrix ADC in a Multiple-Firewall Environment

To configure a Citrix ADC appliance in a multiple-firewall environment, you have to enable the load balancing feature, configure a virtual server to load balance the egress traffic across the external firewalls, configure a virtual server to load balance the ingress traffic across the internal firewalls, and enable firewall load balancing on the Citrix ADC appliance. To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. Configure a wildcard service for each firewall
2. Configure a monitor for each wildcard service
3. Configure a wildcard virtual server to load balance the traffic sent to the firewalls
4. Configure the virtual server in MAC rewrite mode
5. Bind firewall services to the wildcard virtual server

Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the Citrix ADC device.

To enable load balancing by using the CLI:

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
enable ns feature <featureName>
show ns feature
<!--NeedCopy-->
```

Example:

```
enable ns feature LoadBalancing
Done
show ns feature
Feature Acronym Status
------- ------- ------
```

```
1) Web Logging WL OFF
2) Surge Protection SP ON
3) Load Balancing LB ON
.
.
.
24) NetScaler Push push OFF
Done
<!--NeedCopy-->
```

To enable load balancing by using the GUI:

1. In the navigation pane, expand System, and then click Settings.
2. In the Settings pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click Ok.

Configuring a wildcard service for each firewall

To accept traffic from all the protocols, you need to configure wildcard service for each firewall by specifying support for all the protocols and ports.

To configure a wildcard service for each firewall by using the CLI:

At the command prompt, type the following command to configure support for all the protocols and ports:

```
add service <name>@ <serverName> <serviceType> <port_number>
<!--NeedCopy-->
```

Example:

```
add service fw-svc1 10.102.29.5 ANY *
<!--NeedCopy-->
```

To configure a wildcard service for each firewall by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Services dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName

   -* A required parameter

4. In Protocol, select Any and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configuring a monitor for each service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the CLI:

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-
    transparent (YES | NO )]
bind lb monitor <monitorName> <serviceName>
<!--NeedCopy-->
```

Example:

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
<!--NeedCopy-->
```

The Citrix ADC appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.

To configure a receive string by using the CLI:

At the command prompt, type the following command:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-
    transparent (YES | NO )] [-send <string>] [-recv <string>]
<!--NeedCopy-->
```

Example:

```
add lb monitor monitor-udp-1 udp-ecv -destip 10.10.10.11 -transparent
    YES  -send "test message"  -recv "site_is_up"
<!--NeedCopy-->
```

To create and bind a transparent monitor by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters as shown:
   - Name*
   - Type*—type
   - Destination IP
   - Transparent

   -* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configuring a virtual server to load balance the traffic sent to the firewalls

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.

To configure a virtual server to load balance the traffic sent to the firewalls by using the CLI:

At the command prompt, type the following command:

```
add lb vserver <name>@ <serviceType> <IPAddress> <port_number>
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 ANY * *
<!--NeedCopy-->
```

To configure a virtual server to load balance the traffic sent to the firewalls by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In Protocol, select Any, and in IP Address and Port, select *.
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configuring the virtual server to MAC rewrite mode

To configure the virtual server to use MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.

To configure the virtual server in MAC rewrite mode by using the CLI:

At the command prompt, type the following command:

```
set lb vserver <name>@ -m <RedirectionMode>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
<!--NeedCopy-->
```

To configure the virtual server in MAC rewrite mode by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. On the Advanced tab, under the Redirection Mode mode, click Open.
4. Click Ok.

Binding firewall services to the virtual server

To access a service on Citrix ADC appliance, you need to bind it to a wildcard virtual server.

To bind firewall services to the virtual server by using the CLI:

At the command prompt, type the following command:

```
bind lb vserver <name>@ <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind firewall services to the virtual server by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server(for example, Service-HTTP-1).
4. Click Ok.

Configuring the multiple-firewall load balancing on the Citrix ADC appliance

To load balance traffic on both the sides of a Citrix ADC using firewall load balancing, you need to enable mulitpl-firewall load balancing by using the vServerSpecificMac parameter.

To configure multiple-firewall load balancing by using the CLI:

At the command prompt, type the following command:

```
set lb parameter -vServerSpecificMac <status>
<!--NeedCopy-->
```

Example:

```
set lb parameter -vServerSpecificMac ENABLED
<!--NeedCopy-->
```

To configure multiple-firewall load balancing by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click Ok.

Saving and Verifying the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the CLI:

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example:

```
save config
show lb vserver FWLBVIP2
        FWLBVIP2 (*:*) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Mon Jun 14 07:22:54 2010
        Time since last state change: 0 days, 00:00:32.760
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  2 (Total)       2 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: MAC
        Persistence: NONE
        Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
 Done
show service fw-int-svc1
        fw-int-svc1 (10.102.29.5:*) - ANY
        State: DOWN
        Last state change was at Thu Jul  8 14:44:51 2010
        Time since last state change: 0 days, 00:01:50.240
        Server Name: 10.102.29.5
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): NO
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

```

```
1)      Monitor Name: monitor-HTTP-1
                State: DOWN     Weight: 1
                Probes: 9       Failed [Total: 9 Current: 9]
                Last response: Failure - Time out during TCP connection
                    establishment stage
                Response Time: 2000.0 millisec
2)      Monitor Name: ping
                State: UP       Weight: 1
                Probes: 3       Failed [Total: 0 Current: 0]
                Last response: Success - ICMP echo reply received.
                Response Time: 1.275 millisec
 Done
<!--NeedCopy-->
```

To save and verify the configuration by using the GUI:

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

Monitoring a Firewall Load Balancing Setup in a Multiple-Firewall Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received

- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
<!--NeedCopy-->
```

Example:

```
>stat lb vserver -detail
Virtual Server(s) Summary
                        vsvrIP  port     Protocol        State    Req/s
                             Hits/s
One                          *    80         HTTP           UP      5/s
        0/s
Two                          *     0          TCP         DOWN      0/s
        0/s
Three                        *  2598          TCP         DOWN      0/s
        0/s

 Done

<!--NeedCopy-->
```

To display virtual server statistics by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the CLI:

At the command prompt, type:

```
stat service <name>
<!--NeedCopy-->
```

Example:

```
stat service Service-HTTP-1
<!--NeedCopy-->
```

To view the statistics of a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Global Server Load Balancing

September 14, 2021

> **Notes:**
>
> - From release 13.0 build 41.x, global server load balancing (GSLB) deployments using the Citrix ADC appliance are fully compliant with DNS flag day 2019.
> - The GSLB feature is included with the Citrix ADC Advance and Premium edition licenses. The Citrix ADC option license is supported with the Standard edition.

Citrix ADC appliances configured for GSLB provide disaster recovery and ensure continuous availability of applications by protecting against points of failure in a WAN. GSLB balances the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers if there is an outage.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server's IP address to the DNS server. The DNS server sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.

> **Note:**
>
> To take full advantage of GSLB features, use ADC appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary MEP to exchange site metrics.

How GSLB works

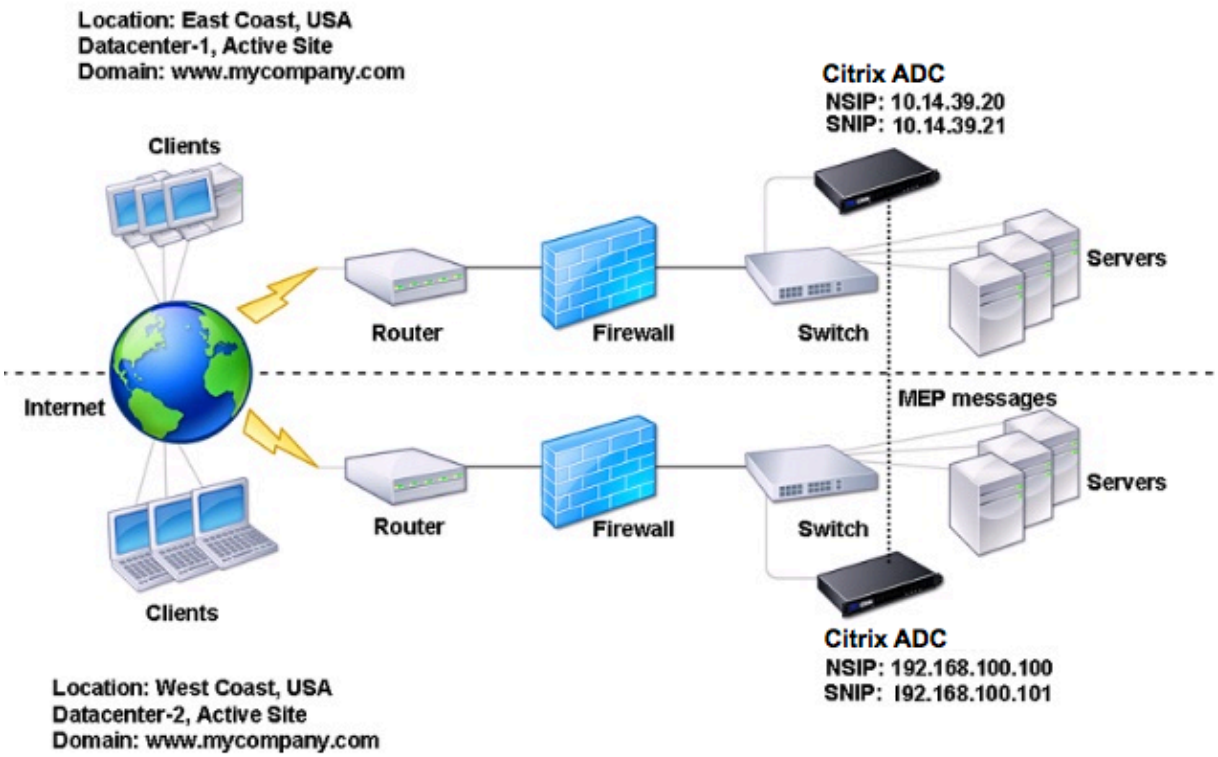
With ordinary DNS, when a client sends a domain name system (DNS) request, it receives a list of IP addresses of the domain or service. Generally, the client chooses the first IP address in the list and initiates a connection with that server. The DNS server uses a technique called DNS round robin to rotate through the IPs on the list. It sends the first IP address to the end of the list and promotes the others after it responds to each DNS request. This technique ensures equal distribution of the load, but it does not support disaster recovery, load balancing based on load or proximity of servers, or persistency.

When you configure GSLB on ADC appliances and enable MEP, the DNS infrastructure is used to connect the client to the data center that best meets the set criteria. The criteria can designate the following:

- Least loaded data center
- Closest data center
- Data center that responds most quickly to requests from the client's location
- A combination of those metrics and SNMP metrics.

An appliance tracks the location, performance, load, and availability of each data center. It uses these factors to select the data center to send the client request.

The following figure illustrates a basic GSLB topology.



A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB service groups, GSLB virtual servers, load balancing servers, content switching servers, and ADNS services.

GSLB deployment types

September 14, 2021

Citrix ADC appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

The following are some of the typical GSLB deployment types:

- Active-active site deployment
- Active-passive site deployment
- Parent-child topology deployment

Active-active site deployment

September 14, 2021

An active-active site consists of multiple active data centers. Client requests are load balanced across active data centers. This deployment type can be used when you have a need for global distribution of traffic in a distributed environment.

All the sites in an active-active deployment are active, and all the services for a particular application/domain are bound to the same GSLB virtual server. Sites exchange metrics through the Metrics Exchange Protocol (MEP). Site metrics exchanged between the sites include the status of each load balancing and content switching virtual server, current number of connections, current packet rate, and current bandwidth usage. The Citrix ADC appliance needs this information to perform load balancing across the sites.

An active-active deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites. No backup sites are configured in this deployment type.

The Citrix ADC appliance sends client requests to the appropriate GSLB site as determined by the GSLB method specified in the GSLB configuration.

For an active-active deployment, you can configure the following GSLB methods.

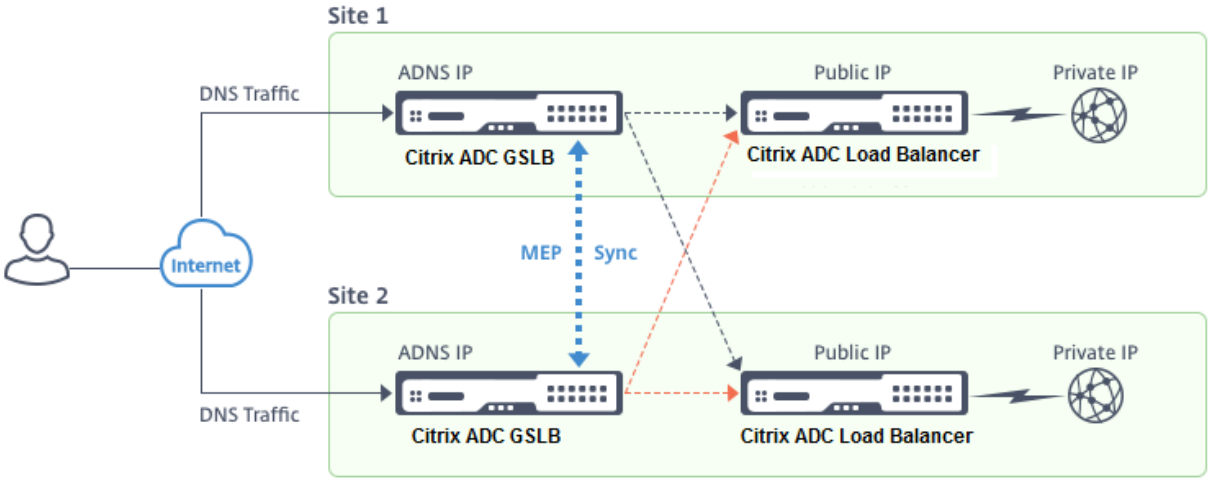
- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

> Note:
>
> - If MEP is disabled, the following GSLB methods default to the Round Robin method.
>   - RTT
>   - Least Connections
>   - Least Bandwidth
>   - Least Packets
>   - Least Response Time
> - In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.

- In the Round Trip Time method, the dynamic round trip time (RTT) values are to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client's local DNS server and a data resource.

GSLB active-active data center topology

In the diagram, Site 1 and Site 2 are active GLSB sites.



When the client sends a DNS request, it lands in one of the active sites.

If Site 1 receives the client request, the GSLB virtual server in Site 1 selects a load balancing or content switching virtual server and sends the virtual server's IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP address.

As both sites are active, the GSLB algorithm evaluates the services at both sites when making a selection as determined by the configured GSLB method.

Active-passive site deployment

September 14, 2021

An active-passive site consists of an active and a passive data center. This deployment type is ideal for disaster recovery.

In this type of deployment, some of the sites (remote sites) are reserved only for disaster recovery. These sites do not participate in any decision making until all the active sites are DOWN. A passive site does not become operational unless a disaster event triggers a failover.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the passive GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

An active-passive deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites.

For an active-passive deployment, you can configure the following GSLB methods.

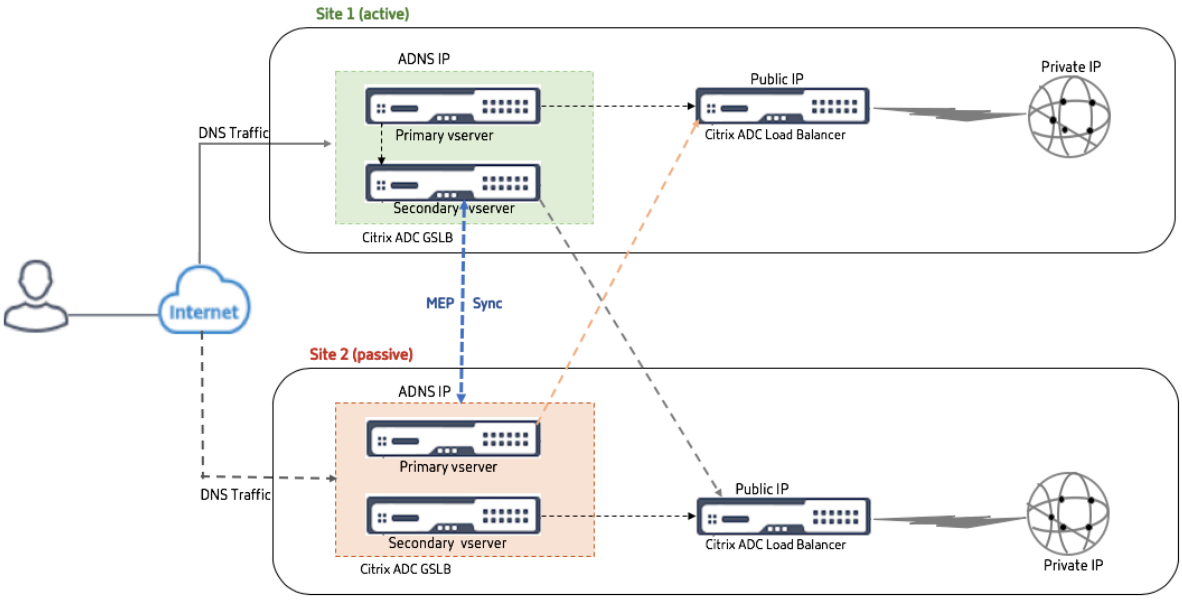
- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

Note:

- If MEP is disabled, the following algorithm methods default to Round Robin.
  - RTT
  - Least Connections
  - Least Bandwidth
  - Least Packets
  - Least Response Time
- In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.
- In the Round Trip Time method, the dynamic round trip time (RTT) values are to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client's local DNS server and a data resource.

GSLB active-passive datacenter topology

In the diagram, Site 1 is an active site and Site 2 is a passive site, which has the same configuration as that of Site 1.



If Site 1 goes DOWN, Site 2 becomes operational.

When the client sends a DNS request, the request can land in any of the sites. However, the services are selected only from the active site (Site1) as long as it is UP.

Services from the passive site (Site 2) are selected only if the active site (Site 1) is DOWN.

Parent-child topology deployment using the MEP protocol

September 14, 2021

Citrix ADC GSLB provides global server load balancing and disaster recovery by creating mesh connections between all the involved sites and making intelligent load balancing decisions. Each site communicates with the others to exchange server and network metrics through Metric Exchange Protocol (MEP), at regular intervals. However, with the increase in number of peer sites, the volume of MEP traffic increases exponentially because of the mesh topology. To overcome this, you can use a parent-child topology. The parent-child topology also supports larger deployments. In addition to the 32 parent sites, you can configure 1024 child sites.

The GSLB parent-child topology is a two-level hierarchical design with the following characteristics:

- At the top level are parent sites, which have peer relationships with other parents.
- Each parent can have multiple child sites.
- Each parent site exchanges health information with its child sites and with other parent sites.
- A child site communicates only with its parent site.

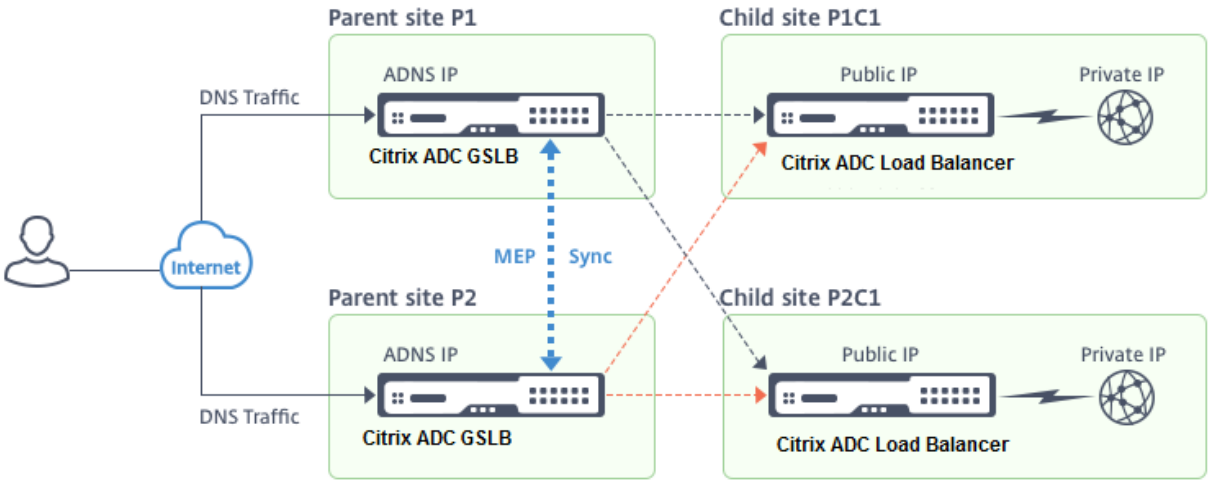
- In a parent-child relationship for GSLB, only the parent site responds to ADNS queries. The child sites act as normal load balancing sites.
- Configure an ADNS service or DNS load balancing virtual server only in the parent site.
- A parent site can have a normal GSLB configuration, that is, services from local and all remote sites, but a child site can have local services only. Also, only the parent sites have GSLB virtual servers configured.

> **Note**
>
> - In a parent-child topology, the exchange of site metrics is initiated from the lower of two IP addresses. However, from Citrix ADC release 11.1 build 51.x, the parent sites initiate connections to the child sites, and not the opposite way. Because the parent sites have information about all the child sites in the GSLB setup.

- In a parent-parent connection, the exchange of site metrics is still initiated from the lower IP of two IP addresses.
- In a parent-child topology, GSLB services are not always required to be configured on a child site. However, if you have more configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the child site and configure it accordingly.
- In a parent-child topology, the parent site and the child site can be on differentCitrix ADC software versions. However, to use the GSLB automaticConfigSync option to synchronize the configuration across the parent sites, all parent sites must be on the sameCitrix ADC software versions. If you are not using the automaticConfigSync option, then the parent site and the child site can be on differentCitrix ADC software versions but make sure that you are not using any of the new features in the latest release. This is also applicable, in general, to two Citrix ADC nodes participating in GSLB.

Basic parent-child topology

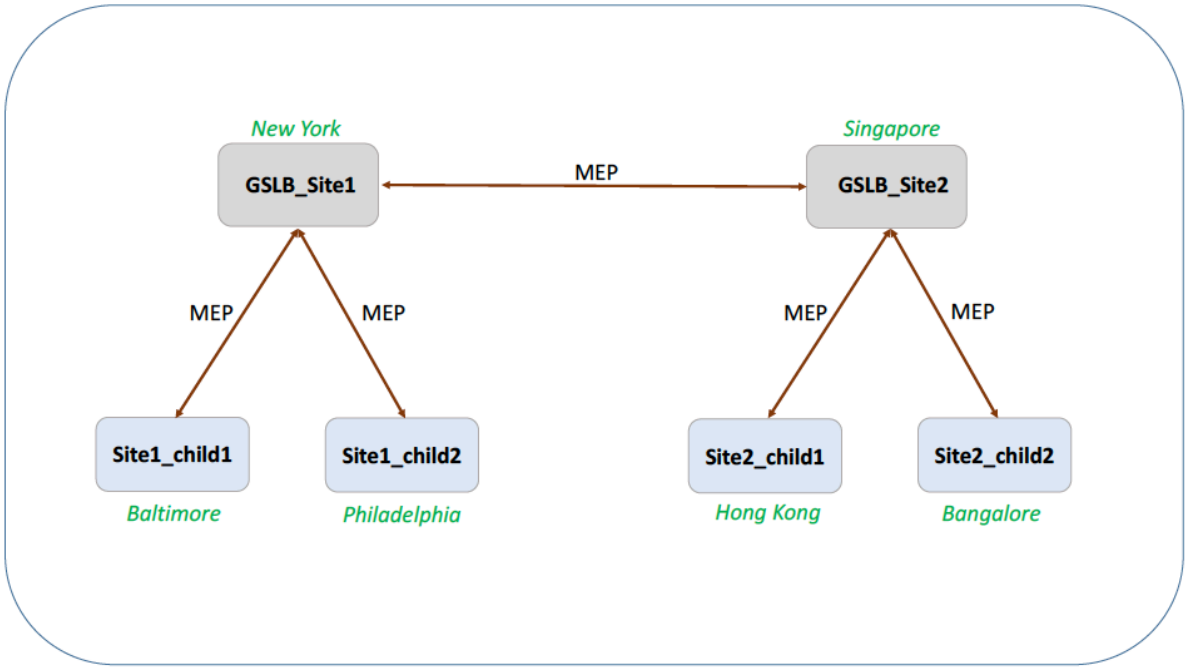
In the diagram, SiteP1 and SiteP2 are parent sites in a peer relationship. Site P1C1 and P2C1 are the child sites of P1 and P2 respectively.



Setting up a parent-child configuration for GSLB

If you have a firewall configured at a GSLB site, make sure that port 3011 is open.

The following diagram displays a sample parent-child configuration.



- The configuration of a child site includes the child site and its parent site, but no other parent or child sites.
- Network metrics, such as RTT and persistence session information, are synchronized only across the parent sites. Therefore, parameters such as nwMetricExchange and sessionExchange are disabled by default on all the child sites.
- To verify correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

To set up a parent-child configuration for GSLB by using the CLI:

1. On each parent site, enter the following commands:

```
add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|
   ipv6_addr|*>]

add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|
   ipv6_addr|*>] [-parentSite <string>]
<!--NeedCopy-->
```

   Example:

```
add gslb site GSLB_Site1 10.1.1.1 - publicIP 10.1.1.1

add gslb site Site1_child1 1 10.1.1.2 -publicIP 10.1.1.2 -
   parentSite GSLB_Site1
<!--NeedCopy-->
```

2. On each child site, enter the following commands:

```
add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|
   ipv6_addr|*>]

add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|
   ipv6_addr|*>] [-parentSite <string>]
<!--NeedCopy-->
```

   Example:

```
add gslb site GSLB_Site1 10.1.1.1 - publicIP 10.1.1.1

add gslb site Site1_child1 1 10.1.1.2 -publicIP 10.1.1.2 -
   parentSite GSLB_Site1
<!--NeedCopy-->
```

For a complete example of a parent-child configuration, using the command line interface, see Example of a Complete Parent-Child Configuration, Using the CLI

> **Note**
>
> If the load balancing virtual server IP address is a private IP address and the public IP address is different from this IP address, you need to configure a GSLB service for the local load balancing virtual server on the child site. This is required for statistics collection between the parent and the child site.

> On the child site, at the command prompt, type:
>
> ```
> add gslb service <name> <private IP/lb vserver IP> http 80 -sitename <
> childsite name> -publicip <public IP of LB vserver>
> ```
>
> **Example:**
>
> add gslb service Service-GSLB 192.168.1.3 http 80 -GSLB_Site11 site 11_lb1 172.16.1.1
>
> Where 192.168.1.3 is a private IP address of the load balancing virtual server and 172.16.1.1 is a public IP address of the load balancing virtual server.

Backing up a parent site

Note: This feature was introduced in Citrix ADC release 11.1 build 51.x. To use the backup parent site topology, make sure that the parent site and the child sites are on Citrix ADC 11.1 build 51.x and later.

The backup parent site topology is useful in scenarios wherein many child sites are associated with a parent site. If this parent site goes DOWN, all of its child sites become unavailable. To prevent this, you can now configure a backup parent site to which the child sites can connect if the original parent site is DOWN. The parent site sends the backup parent list to the child sites through the MEP messages.

When a parent site is DOWN, the other parent sites in the GSLB get to know that a particular parent site is DOWN through MEP because MEP to that parent site is DOWN. The other parent sites in the GSLB setup look up the backup chain of the peer parent. The parent site with the highest preference adopts the child sites of the parent that went DOWN. The new parent then initiates a connection with the child site. A child site can accept or reject the connection after evaluating its existing connections and the information in the backup list. It takes a few seconds for the backup parent to adopt the child sites.
When the original parent site is back UP, it tries to establish connections with its child sites that have migrated to a different parent. When a connection attempt is successful, the child site is reassigned to its original parent site.

Note:

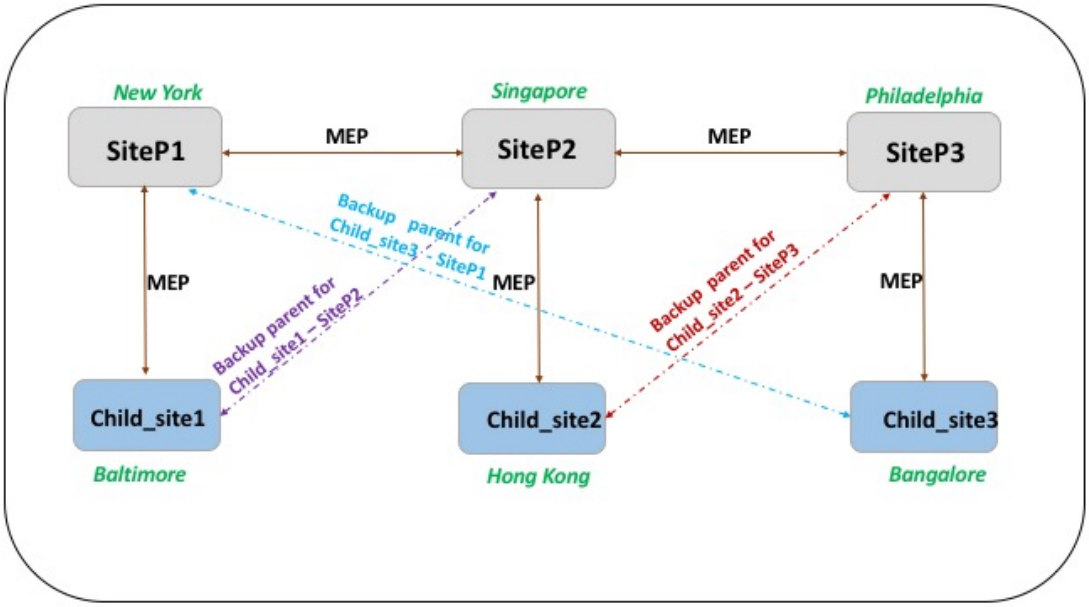
- Only parent sites can be configured as backups, and this configuration can only be done at the parent site.
- All child sites use the backup parent set.
- Synchronization is done only on the parent sites. GSLB child sites' configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.

Consider the configuration shown in the following figure, in which:

- SiteP1, SiteP2, and SiteP3 are the parent sites.

- Child_site1, Child_site2, and Child_site3 are the child sites of SiteP1, SiteP2, and SiteP3 respectively.
- Backup parent sites;
  - SiteP1 backup parents - SiteP2 (higher preference) and SiteP3
  - SiteP2 backup parents – SiteP3 (higher preference) and SiteP1
  - SiteP3 backup parents – SiteP1 (higher preference) and SiteP2

Note: For illustration purposes, the figure shows only one backup parent for each parent site.



The following list summarizes the behavior of the parent and child sites under various scenarios:

- Scenario 1: SiteP1 goes DOWN.
  - SiteP2 and SiteP3 detect that SiteP1's MEP connection is DOWN. SiteP2 is higher in the preference list of backup parents for SiteP1, so it tries to initiate a connection to Child_site1. SiteP3 assumes that Child_site1 is now the child site of parent SiteP2.
  - SiteP2 sends Child_Site1 the list of SiteP1's backup parents (SiteP2 and SiteP3) to Child_site1. Child_site1 uses the list to decide whether to accept or reject the connection from SiteP2. It accepts the connection and becomes a child of SiteP2.
  - When SiteP1 is back UP, it sends Child_site1 a connection request. The new request takes precedence and Child_site 1 migrates to SiteP1.
- Scenario 2: Only the MEP connection between SiteP1 and SiteP2 has gone DOWN. Child_site1 rejects SiteP2's connection request, because its parent, SiteP1, is still UP.
- Scenario 3: SiteP3 and Child_Site1 detect that SiteP1 is DOWN, and the MEP connection between SiteP3 and SiteP2 is also DOWN. However, SiteP2 detects that SiteP1 is UP, and the MEP

connection between SiteP1 and SiteP2 is UP.

- SiteP2 does not take any action.
- SiteP3 checks SiteP1's backup list and finds that SiteP2 has a higher preference than SiteP3. But SiteP2 is DOWN, so SiteP3 tries to establish a connection with Child_site1. Child_site1 has detected that SiteP1 is DOWN, so it accepts SiteP3's connection request.
- Now the connection between SiteP1 and SiteP2 goes DOWN. SiteP2 checks SiteP1's backup list and finds itself as the most preferred backup, so it tries to connect to Child_site1. Child_site1 evaluates the new connection request based on SiteP1's list and finds SiteP2 as the most preferred backup, so it migrates to SiteP2 from SiteP3.

To configure a backup parent site by using the command line interface

At the command prompt type:

```
set gslb site <sitename> -backupParentlist <bkp_site1> <bkp_site2> … <
   bkp_site5>
<!--NeedCopy-->
```

<sitename> is the current parent site.

Example:

For the parent site (SiteP1), the sites (SiteP2 and SiteP3) are configured as the backup parent sites.

```
set gslb site SiteP1 -backupParentlist SiteP2 SiteP3
<!--NeedCopy-->
```

Note:

- You cannot add a new site as a backup parent. You must first add all the sites, and then configure the site as a backup parent.
- To remove a backup parent, you must use the unset command, which unsets all the sites that were previously configured as backup parent sites.

To configure a backup parent site by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Sites**.
2. Add a new site or select an existing site.
3. Choose the **Backup Parent Sites** option box while creating or configuring the GSLB site.

GSLB configuration entities

September 14, 2021

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include the following:

- GSLB Sites
- GSLB Services
- GSLB Virtual Servers
- Load Balancing or Content Switching Virtual Servers
- ADNS Services
- DNS VIPs

GSLB Sites

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be Citrix ADC appliances. The data centers are called GSLB sites. Each GSLB site is managed by a Citrix ADC appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only Citrix ADC appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.

Relationships among GSLB Sites

The concept of sites is central to Citrix ADC GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be;

- To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.
- To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites.

GSLB Services

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server's IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the Citrix ADC appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in a different data center is remote from that GSLB virtual server.

> **Note**
>
> Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

GSLB Virtual Servers

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a Citrix ADC appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

Load Balancing or Content Switching Virtual Servers

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server's virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server's VIP address.

For more information about load balancing or content switching virtual servers and services, see Load Balancing or Content Switching.

ADNS Services

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the Citrix ADC appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

DNS VIPs

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the Citrix ADC appliance. DNS requests for domains for which the Citrix ADC appliance is authoritative can be sent to a DNS VIP.

GSLB methods

September 14, 2021

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a Citrix ADC appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the appliance responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The Citrix ADC appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least

Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

Specifying a GSLB method other than static proximity or dynamic RTT

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see Load Balancing.

To change the GSLB method by using the CLI

At the command prompt, type:

```
set gslb vserver <name> -lbMethod GSLBMethod
<!--NeedCopy-->
```

Example:

```
set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
<!--NeedCopy-->
```

To change the GSLB method by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**.
2. In the details pane, select a GSLB virtual server and click **Open**.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.
4. Click **OK**, and verify that the method you selected appears under Details at the bottom of the screen.

GSLB algorithms

September 14, 2021

The following algorithm are supported for GSLB.

- **Round Robin**: When a GSLB virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

- **Least Response Time**: When the GSLB virtual server is configured to use the least response time method, it selects the service with the lowest value. Where, lowest value = current active connections X average response time.

  You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

- **Least Connections**: When a GSLB virtual server is configured to use the least connection GSLB algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

- **Least Bandwidth**: A GSLB virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps).

- **Least Packets**: A GSLB virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

- **Source IP Hash**: A GSLB virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

- **Custom Load**: Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all of the services in the GSLB setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the GSLB decision when those services are not UP.

For more details, see Load Balancing.

Static proximity

September 14, 2021

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The Citrix ADC appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the Citrix ADC appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

For details about configuring static proximity, see Configuring Static Proximity.

Dynamic round trip time method

September 14, 2021

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the Citrix ADC appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client's DNS request for a domain comes to the Citrix ADC appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The Citrix ADC appliance uses different mechanisms, such as ICMP echo request or reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the Citrix ADC appliance as Load Balancing Monitors and are easily identified due to their use of the "ldns" prefix. The three monitors, in their default order, are:

- `ldns-ping`
- `ldns-dns`
- `ldns-tcp`

These monitors are built into the appliance and are set to safe defaults. But they are customizable like any other monitor on the appliance.

You can change the default order by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```
1 set gslb parameter -ldnsprobeOrder DNS PING TCP
```

```
<!--NeedCopy-->
```

Unless they have been customized, the Citrix ADC appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the appliance uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric."

If RTT information is not available (for example, when a client's local DNS server accesses the site for the first time), the Citrix ADC appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site's GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

Configure a GSLB virtual server for dynamic RTT

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The Citrix ADC appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all Citrix ADC appliances deployed in the GSLB domain.

To configure a GSLB virtual server for dynamic RTT by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -lbMethod RTT -tolerance <value>
<!--NeedCopy-->
```

Example:

```
set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10
<!--NeedCopy-->
```

To configure a GSLB virtual server for dynamic RTT by using the configuration utility

Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click the virtual server.

Set the probing interval of local DNS servers

The Citrix ADC appliance uses different mechanisms, such as ICMP echo request or reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response. If a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

To modify the probing interval by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <integer> <units> -
    resptimeout <integer> <units>
<!--NeedCopy-->
```

Example:

```
set lb monitor ldns-tcp LDNS-TCP -interval 10 sec -resptimeout 5 sec
<!--NeedCopy-->
```

To modify the probing interval by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Monitors**, and double-click the monitor that you want to modify (for example, ping).

API method

September 14, 2021

You can use the API method to determine the best performing GSLB service. The API method for GSLB uses a REST API to determine the best performing GSLB service.

In the API method, when GSLB receives a DNS request from a client, it evaluates the request against the specified rule. If GSLB encounters the HTTP callout expression, SYS.HTTP_CALLOUT(<name>), it

invokes a REST API request to an HTTP callout agent. GSLB uses the response from the HTTP callout agent to decide the best performing service. In the DNS response, GSLB returns the IP address of the best performing service, back to the client.

To configure a GSLB API method by using the CLI

Perform the following to configure the GSLB API method:

1. Configure an HTTP callout.

   For more information, see Configuring an HTTP callout.

   At the command prompt, type:

```
add policy httpCallout <name> [-IPAddress <ip_addr|ipv6_addr>] [-
    port <port>] [-vServer <string>] [-returnType <returnType>] [-
    httpMethod (GET | POST)] [-hostExpr <string>] [-urlStemExpr <
    string>] [-headers <name(value)> ...] [-parameters <name(value)
    > ...] [-bodyExpr <string>] [-fullReqExpr <string>] [-scheme (
    http | https)] [-resultExpr <string>] [-cacheForSecs <secs>] [-
    comment <string>]
<!--NeedCopy-->
```

   Example:

```
add policy httpCallout GSLB_Method_API -IPAddress 208.111.39.237 -
    port 443 -returnType TEXT -hostExpr  "\" hopx.gslb.com\ ""  -
    urlStemExpr  "\" /zones/1/customers/92395/apps/6/decision\ ""
    -headers Authorization( "Basic 19fbe6db-4332-4e3f-a8bc-
    ee47bdc726f8") -parameters ip(DNS.REQ.OPT.ECS.IP.
    TYPECAST_TEXT_T ALT CLIENT.IP.SRC.TYPECAST_TEXT_T) -scheme
    https -resultExpr  "HTTP.RES.BODY(HTTP.RES.CONTENT_LENGTH).
    XPATH_JSON(xp%/providers/Val[1]/provider%)"  -cacheForSecs 30
<!--NeedCopy-->
```

2. Specify the API method for load balancing. GSLB evaluates the DNS request against the specified rule.

   At the command prompt, type:

```
add gslb vserver <name> <serviceType>  [-lbMethod <lbMethod>] [-
    backupLBMethod <backupLBMethod>] -rule <expression>
<!--NeedCopy-->
```

   Example:

```
1 add gslb vserver vs1 HTTP -lbMethod API -backupLBMethod ROUNDROBIN
      -rule  “sys.http_callout(GSLB_Method_API)”
2 <!--NeedCopy-->
```

Sample configuration for integrating GSLB and ITM using API as the LB method

This configuration allows GSLB to use the internet visibility aspects of the Citrix intelligent traffic management (ITM) to determine the best performing GSLB service.

```
1  /* Enable ns features */
2
3  enable ns feature lb gslb cs
4
5  /* This is a named expression that is used in the HTTP callout, used
      for result expression. */
6
7  add policy expression exp1 "HTTP.RES.BODY(HTTP.RES.CONTENT_LENGTH).
      XPATH_JSON(xp%/providers/Val[1]/provider%)"
8
9  /* This is a named expression that is used in HTTP callout, used for
      host expression. */
10
11 add policy expression exp2 "\"hopx.cedexis.com\""
12
13 /* This is the HTTP callout configured to request the ITM for the GSLB
      decision. */
14
15 add policy httpCallout ITM_OpenMix_API -IPAddress 208.111.39.237 -port
      80 -returnType TEXT -hostExpr exp2 -urlStemExpr "\"/zones/1/
      customers/61770/apps/3/decision\"" -headers Authorization("Basic
      a310697a-1d69-48bf-8f36-55742a8e894e") -parameters ip(DNS.REQ.OPT.
      ECS.IP.TYPECAST_TEXT_T ALT CLIENT.IP.SRC.TYPECAST_TEXT_T) -scheme
      http -resultExpr exp1 -cacheForSecs 30
16
17 /* Add service 1 */
18 add service sg1 98.136.103.24 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0
       -cip DISABLED -usip NO -useproxyport YES -sp OFF -cltTimeout 180 -
      svrTimeout 360 -CKA NO -TCPB NO -CMP NO
19
20 /* Add service 2 */
21 add service sg2 172.217.194.113 HTTP 80 -gslb NONE -maxClient 0 -maxReq
       0 -cip DISABLED -usip NO -useproxyport YES -sp OFF -cltTimeout 180
      -svrTimeout 360 -CKA NO -TCPB NO -CMP NO
```

```
22
23 /* Add ADNS service */
24
25 add service adns1 10.102.217.106 ADNS 53 -gslb NONE -maxClient 0 -
      maxReq 0 -cip DISABLED -usip NO -useproxyport NO -sp OFF -cltTimeout
       120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO
26
27 /* Add lb vserver 1 for service 1 */
28 add lb vserver lbvs1 HTTP 10.102.217.116 80 -persistenceType NONE -
      cltTimeout 180
29
30 /* Add lb vserver 2 for service 2 */
31 add lb vserver lbvs2 HTTP 10.102.217.117 80 -persistenceType NONE -
      cltTimeout 180
32
33 /* Bind service 1 to lb vserver 1 */
34
35 bind lb vserver lbvs1 sg1
36
37 /* Bind service 2 to lb vserver 2 */
38
39 bind lb vserver lbvs2 sg2
40
41 /* Configure API GSLB method on GSLB virtual server to call the HTTP
      callout. This HTTP callout requests the ITM for the GSLB decision
      and returns GSLB service name, which should serve the request. */
42
43 add gslb vserver vs1 HTTP -lbMethod API -backupLBMethod ROUNDROBIN -
      rule "sys.http_callout(ITM_OpenMix_API)" -tolerance 0
44
45 /* Add GSLB site */
46
47 add gslb site site1 10.102.217.106 -publicIP 10.102.217.106
48
49 /* Add GSLB service 1 */
50
51 add gslb service aws_ec2_ap_south_1_asia_pacific_mumbai_1
      10.102.217.116 HTTP 80 -publicIP 10.102.217.116 -publicPort 80 -
      maxClient 0 -siteName site1 -sitePersistence HTTPRedirect -
      sitePrefix gs2. -cltTimeout 180 -svrTimeout 360 -downStateFlush
      ENABLED
52
53 /* Add GSLB service 2 */
54
55 add gslb service aws_ec2_ap_south_1_asia_pacific_mumbai 10.102.217.117
```

```
    HTTP 80 -publicIP 10.102.217.117 -publicPort 80 -maxClient 0 -
    siteName site1 -sitePersistence HTTPRedirect -sitePrefix gs1. -
    cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
56
57 /* Bind the GSLB service 1 to GSLB server 1 */
58 bind gslb vserver vs1 -serviceName
    aws_ec2_ap_south_1_asia_pacific_mumbai_1
59
60 /* Bind the GSLB service 2 to GSLB server 2 */
61 bind gslb vserver vs1 -serviceName
    aws_ec2_ap_south_1_asia_pacific_mumbai
62
63 /* Bind a domain name to the GSLB virtual server */
64 bind gslb vserver vs1 -domainName testruchit104.com -TTL 5
65
66 <!--NeedCopy-->
```

Configure static proximity

September 14, 2021

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

This document includes the following information:

- Adding a Location File to Create a Static Proximity Database
- Adding Custom Entries to a Static Proximity Database
- Setting the Location Qualifiers
- Specifying the Proximity Method
- Synchronizing GSLB Static Proximity Database

Add a location file to create a static proximity database

September 14, 2021

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a Citrix ADC appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the Citrix ADC appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as www.maxmind.com and www.ip2location.com).

The Citrix ADC appliance includes the following two IP geolocation database files. These are GeoLite2 files, published by MaxMind.

- Citrix_Netscaler_InBuilt_GeoIP_DB_IPv4
- Citrix_Netscaler_InBuilt_GeoIP_DB_IPv6

These database files are available in a format supported by the Citrix ADC appliance in the directory /var/netscaler/inbuilt_db.

You can use these IP geolocation databases as the location file for the static proximity based GSLB method, or in location based policies.

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the Citrix ADC appliance. Specifying an incorrect value for the format option can corrupt the internal data.

> **Note**
>
> - After an upgrade, if the /var/netscaler/inbuilt_db/ directory contains the database file (Citrix_Netscaler_InBuilt_GeoIP_DB.csv) from the earlier Citrix ADC software versions, the file is retained.
> - The default location of the database file is /var/netscaler/locdb, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both Citrix ADC appliances.
> - If the location file is stored in a location other than the default location, then specify the path of the location file.
> - For admin partitions, the default path is: /var/partitions/<partitionName>/netscaler/locdb.
> - Some databases provide short country names according to ISO-3166 and long country names as well. The Citrix ADC uses short names when storing and matching qualifiers.
> - To create a static proximity database, log on to the UNIX shell of the Citrix ADC appliance and use an editor to create a file with the location details in one of the Citrix ADC supported formats.

To add a static location file by using the CLI

At the command prompt, type:

```
add locationFile <locationFile> [-format <format>]
-  show locationFile
<!--NeedCopy-->
```

Example:

```
add locationFile /var/netscaler/locdb/nsgeo1.0 -format netscaler
Done

show locationFile
Location File: /var/netscaler/locdb/nsgeo1.0
Format: netscaler
 Done
>
<!--NeedCopy-->
```

Example:

```
add locationFile /var/netscaler/inbuilt_db/
   Citrix_Netscaler_InBuilt_GeoIP_DB_IPv4 -format netscaler

add locationFile6 /var/netscaler/inbuilt_db/
   Citrix_Netscaler_InBuilt_GeoIP_DB_IPv6 -format netscaler
<!--NeedCopy-->
```

To add a static location file by using the GUI:

1. Navigate to **AppExpert** > **Location**, click the **Static Database** tab.
2. Click **Add** to add a static location file.

You can view an imported location file database by using the **View Database** dialog box in the configuration utility. There is no CLI equivalent.

To view a static location file by using the GUI:

1. Navigate to **AppExpert** > **Location**, click the **Static Database** tab.
2. Select a static location file, and from the **Action** list, click **View Database**.

To convert a location file into the Citrix ADC format:

By default, when you add a location file, it is saved in the Citrix ADC format. You can convert a location file of other formats into the Citrix ADC format.

> **Note**: The nsmap option can be accessed only from the command line interface. The conversion is possible only into the Citrix ADC format.

To convert the static database format, at the CLI prompt, type the following command:

```
nsmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
<!--NeedCopy-->
```

Example:

```
 nsmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.
    csv
<!--NeedCopy-->
```

Script to convert Maxmind GeoLite2 database format to Citrix ADC database format

MaxMind GeoIP database cannot be used directly in Citrix ADC. The MaxMind GeoIP database must be converted into Citrix ADC format and then loaded for IP location detection in GSLB static proximity method and other features like policies.
You can use a script to convert the GeoLite2 database format to Citrix ADC database format. This script can be used to convert both IPv4 and IPv6 files.
The script is available in the location: https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format

Steps to convert GeoIP2 database to Citrix ADC format

1. Download the GeoLite2 City or GeoLite2 Country database in .csv format from https://dev.maxmind.com/geoip/geoip2/geolite2/.
2. Copy the file in a Citrix ADC directory (say /var). Unzip the file using the following shell command, which would create a directory with the same name.

   ```
   tar -xf <filename>
   ```

3. Download the script Convert_GeoIPDB_To_Netscaler_Format.pl from https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format and copy it to the directory created in step #2.
4. To check the acceptable options for the script execution, run the following command:

   ```
   perl Convert_GeoIPDB_To_Netscaler_Format.pl -help
   ```

   Various options available are:

   - <filename> IPv4 output file. Default output file name: Netscaler_Maxmind_GeoIP_DB_IPv4.csv

- `-p <filename>` IPv6 output file. Default output file name: Netscaler_Maxmind_GeoIP_DB_IPv6.csv
- `-logfile <filename>` File containing list of events/messages
- `-debug` Prints all the messages to STDOUT

5. Execute the following command to convert the GeoLite2 database format to Citrix ADC database format.

   ```
   perl Convert_GeoIPDB_To_Netscaler_Format.pl
   ```

   > **Note:** The operation can take up to 5 minutes.

   The default file names used in the script are that of the Maxmind GeoLite2 City based database. If you have downloaded GeoLite2 Country database, you must provide the input file names accordingly as listed.

   - `-b <filename>` name of IPv4 block file to be converted. Default file name: GeoLite2-City-Blocks-IPv4.csv
   - `-i <filename>` name of IPv6 block file to be converted. Default file name: GeoLite2-City-Blocks-IPv6.csv
   - `-l <filename>` name of location file to be converted. Default file name: GeoLite2-City-Locations-en.csv

   Example:

   ```
   perl Convert_GeoIPDB_To_Netscaler_Format.pl -b GeoLite2-Country-
      Blocks-IPv4.csv -i GeoLite2-Country-Blocks-IPv6.csv -l
      GeoLite2-Country-Locations-en.cs
   <!--NeedCopy-->
   ```

   The following are the output files generated after running the script.

   - Netscaler_Maxmind_GeoIP_DB_IPv4.csv
   - Netscaler_Maxmind_GeoIP_DB_IPv6.csv

6. Once the conversion of the database into Citrix ADC format is complete, use the following command to start using it.

   ```
   add locationFile <locationFile>
   ```

Add a third-party static database file on a Citrix ADC appliance

Perform the following steps to add a third-party static database file on a Citrix ADC appliance.

1. Obtain the location database file from a third-party vendor, such as www.maxmind.com or www.ip2location.com.
2. Copy the location database file to the Citrix ADC appliance using the WinSCP utility.

> **Note**
>
> The default location of the database file on the appliance is **/var/netscaler/locdb**.

3. Execute the following command to add a static location file:

```
add location file <locationfile Name> -format LocationFormat
<!--NeedCopy-->
```

4. Execute the following command to ensure that the location database is loaded:

```
show location parameter
<!--NeedCopy-->
```

   This command displays the parameters, such as number of static entries. If the database is not loaded correctly, this command also displays an error message. A maximum of 3M-1 (3 million minus one) entries can be loaded.

5. Execute the following command to view the location of the GSLB site:

```
show gslb service
<!--NeedCopy-->
```

> **Note**
>
> - If the database is loaded correctly, the location of the GSLB sites is automatically populated in the database.
> - You can specify only one location file in the configuration on the appliance.
> - If the appliances are in a high availability setup, then one appliance must copy the database from the other appliance.
> - If no match is found for an incoming IP address, the request is processed using the Round Robin method.

6. Execute the following command to configure the GSLB method on the appliance:

```
set gslb vserver GSLBVserverName -lbMethod MethodType
<!--NeedCopy-->
```

Add custom entries to a static proximity database

September 14, 2021

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 500 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (*) and, if

qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration:

```
add location < IPfrom> < IPto> <preferredLocation> [-longitude <integer
   >[-latitude <integer>]]
show location
<!--NeedCopy-->
```

Example:

```
>add location 192.168.100.1 192.168.100.100 *.us.ca.mycity
<!--NeedCopy-->
```

```
>show location
<!--NeedCopy-->
```

Parameters for adding custom entries

- IPfrom

  First IP address in the range, in dotted decimal notation. This is a mandatory argument.

- IPto

  Last IP address in the range, in dotted decimal notation. This is a mandatory argument.

- preferredLocation

  String of qualifiers, in dotted notation, describing the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example,”NA.US.CA.San Jose.ATT.citrix”.

  Note: A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks.

  This is a mandatory argument. Maximum Length: 197

- longitude

  Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range.

Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

- latitude

  Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range.

  Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

  Maximum value: 180

To add custom entries by using the configuration utility

Navigate to **AppExpert** > **Location**, click the **Custom Entries** tab, and add the custom entries.

Set location parameters

September 14, 2021

The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The qualifier labels define the meaning of the qualifiers (context), which are user defined. Citrix ADC has two built-in contexts:

Geographic context, which has the following qualifier labels:

- Qualifier 1 – “Continent”
- Qualifier 2 – “Country”
- Qualifier 3 – “State”
- Qualifier 4 – “City”
- Qualifier 5 – “ISP”
- Qualifier 6 – “Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 – “Qualifier 1”
- Qualifier 2 – “Qualifier 2”
- Qualifier 3 – “Qualifier 3”

- Qualifier 4 – “Qualifier 4”
- Qualifier 5 – “Qualifier 5”
- Qualifier 6 – “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the Citrix ADC appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

The GEO rules for location-based policy expression allow you to check wildcard matches. This feature checks whether wildcard qualifiers match any other qualifier including non-wildcard or not. The wildcard match is performed by using the `matchWildcardtoany` attribute that is added to the `set locationParameter` command.

The `matchWildcardtoany` attribute can be set to the following values:

- **Yes:** Wildcard qualifiers match any other qualifiers.
- **No:** Wildcard qualifiers do not match non-wildcard qualifiers but match other wildcard qualifiers. The default option is **No**.
- **Expression:** Wildcard qualifiers in an expression match any qualifier in an LDNS location but wildcard qualifiers in the LDNS location do not match non-wildcard qualifiers in an expression.

Example:

```
1 add dns policy policy1 "CLIENT.IP.SRC.MATCHES_LOCATION(\"Continent.
     country *.*.*.* \ “)”  <action>
2 <!--NeedCopy-->
```

To set the location parameters by using the CLI

At the command prompt, type:

```
1 set locationparameter -context <context> -q1label <string> [-q2label <
     string>] [-q3label <string>] [-q4label <string>] [-q5label <string>]
      [-q6label <string>] -matchWildcardtoany [Yes | No | Expression]
2 <!--NeedCopy-->
```

Example:

```
set locationparameter -context custom -q1label asia -matchWildcardtoany
    Yes
<!--NeedCopy-->
```

To set the location parameters by using the GUI

1. Navigate to **Traffic Management > GSLB > Database and Entries**.
2. Under **Settings**, click **Change Location Parameters**.
3. In the **Configure Location Parameters** page, set the location parameters.

Specify proximity method

September 14, 2021

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
set gslb vserver <name> -lbMethod STATICPROXIMITY
show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
show gslb vserver
<!--NeedCopy-->
```

To specify static proximity by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.
2. Click the **Method** section and from the **Choose Method** drop-down list, select **STATICPROXIMITY**.

Synchronize GSLB static proximity database

September 14, 2021

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the /var/netscaler/locdb directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the rsync program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the rsync program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the **sync gslb config** command on Site1:

```
sync gslb config -nowarn
Sync Time: Feb 24 2014 14:56:16
Retrieving local site info: ok
Retrieving all participating gslb sites info:
0 bytes in 0 blocks
ok
site1[Master]:
        Getting Config: ok
site2[Slave]:
        Syncing gslb static proximity database: ok
        Getting Config: ok
        Comparing config: ok
        Applying changes: ok
 Done
<!--NeedCopy-->
```

Configure site-to-site communication

September 14, 2021

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The Citrix ADC appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a Citrix ADC owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use either a subnet IP (SNIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the Citrix ADC appliance:

Changing the password of an RPC node

Citrix recommends you to secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the show rpcNode command to compare the encrypted form of the password before and after the change.

> **Note:** GSLB uses internal user account. For enhanced security, Citrix recommends that you change the internal user account password as well. Internal user account password is changed through RPC node password.

To change the password of an RPC node by using the command line interface

At the command line, type the following commands to change the password of an RPC node:

```
set ns rpcNode <IPAddress> {
 -password }

show ns rpcNode
<!--NeedCopy-->
```

Example:

```
> set rpcNode 192.0.2.4 -password mypassword
 Done
> show rpcNode
.
.
.
```

```
2)  IPAddress:  192.0.2.4 Password:  d336004164d4352ce39e
    SrcIP:  *               Secure:  OFF
Done
>

<!--NeedCopy-->
```

To unset the password of an RPC node by using the command line interface

To unset the password of an RPC node by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the password parameter, without a value.

To change the password of an RPC node by using the configuration utility

Navigate to System > Network > RPC, select the RPC node, and change the password.

Encrypt the exchange of site metrics

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the Citrix ADC appliance encrypts all communication sent from the node to other RPC nodes.

To encrypt the exchange of site metrics by using the command line interface

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

```
set ns rpcNode <IPAddress> [-secure ( YES | NO )]
show rpcNode
<!--NeedCopy-->
```

Example:

```
> set rpcNode 192.0.2.4 -secure YES
 Done
>
> show rpcNode
.
.
.
3)  IPAddress:  192.0.2.4 Password:  d336004164d4352ce39e SrcIP:
    192.0.2.3     Secure:  ON
```

```
 Done
>
<!--NeedCopy-->
```

To unset the secure parameter by using the command line interface

To unset the secure parameter by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the secure parameter, without a value.

To encrypt the exchange of site metrics by using the Citrix ADC configuration utility

1. Navigate to System > Network > RPC and double-click a RPC node.
2. Select the **Secure** option, and click **OK**.

Configure source IP address for an RPC node

By default, the Citrix ADC appliance uses a Citrix ADC owned subnet IP (SNIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address. If a SNIP address is not available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NSIP address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address.

> **Note**
>
> From NetScaler 11.0.64.x release onwards, you can configure the appliance to use GSLB Site IP address as the source IP address for an RPC node.

To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

```
set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr|*>]
show ns rpcNode
<!--NeedCopy-->
```

Example:

```
set rpcNode 192.0.2.4 -srcIP 192.0.2.3
Done
```

```
3 show rpcNode
4 <!--NeedCopy-->
```

```
1 IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3
     Secure: OFF
2 Done
3 <!--NeedCopy-->
```

To unset the source IP address parameter by using the command line interface

To unset the source IP address parameter by using the CLI, type the unset rpcNodecommand, the IP address of the RPC node, and the srcIP parameter, without a value.

To specify a source IP address for an RPC node by using the Citrix ADC configuration utility

1. Navigate to System > Network > RPC and double-click a RPC node.
2. In the Source IP Address field, enter the IP address that you want the RPC node to use as the source IP address and click OK.

> **Important**
>
> The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each Citrix ADC appliance. Therefore, after you force a synchronization (using the sync gslb config –forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other Citrix ADC appliances.

Configure metrics exchange protocol

September 14, 2021

The data centers in a GSLB setup exchange metric with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for Citrix ADC appliance. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metric (round-trip time) can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, virtual IP

(VIP) address, or the NSIP address, as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the Citrix ADC appliances.

Note: You can configure a SNIP or a GSLB site IP address as the source IP address for metrics exchange. For more information, see Configure source IP address for an RPC node.

If the source and target sites (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services as described in "Monitoring GSLB Services." When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metric exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service enables the Citrix ADC appliance to interact with a non-citrix ADC load balancing device. The Citrix ADC appliance can monitor non-citrix ADC devices but cannot perform load balancing on them unless monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.

With NetScaler release 11.1.51.x or later, to avoid unnecessary disruption of services, you can set a time delay for marking GSLB services as DOWN when a MEP connection goes DOWN.

MEP state in a high availability setup

In a high availability setup, the primary node establishes connections with the remote sites and the MEP state is not synchronized from the primary node to secondary nodes. Therefore, the MEP state in secondary node remains DOWN. When the secondary node becomes primary, it establishes MEP connections with the new GSLB site and updates the MEP state accordingly.

Enable site metrics exchange

Site metrics exchanged between the GSLB sites include the status of each load balancing, or content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The Citrix ADC appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

To enable or disable site metrics exchange by using the command line interface

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

```
set gslb site <siteName> -metricExchange (ENABLED|DISABLED)
show gslb site** <siteName>
<!--NeedCopy-->
```

Example:

```
set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
show gslb site Site-GSLB-East-Coast
<!--NeedCopy-->
```

To enable or disable site metric exchange by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Sites**, and select the site.
2. In the **Configure GSLB Site** dialog box, select the **Metric Exchange** option.

Enable network metric exchange

If your GSLB sites use the round-trip time (RTT) load balancing method, you can enable or disable the exchange of RTT information about the client's local DNS service. This information is exchanged every 5 seconds.

For details about changing the GSLB method to a method based on RTT, see GSLB Methods.

To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

```
set gslb site <siteName> -nwmetricExchange (ENABLED|DISABLED)
show gslb site <<siteName>
<!--NeedCopy-->
```

Example:

```
set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

```
<!--NeedCopy-->
```

To enable or disable network metric information exchange by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Sites**.
2. In the **Configure GSLB Site** dialog box, select the **Network Metric Exchange** option.

Configuring a time delay for the GSLB services to be marked as DOWN when a MEP connection goes DOWN

If the status of a MEP connection to a remote site changes to DOWN, the status of every GSLB service on that remote site is marked as DOWN, although the site might not actually be DOWN.

You can now set a delay to allow some time for reestablishment of the MEP connection before the site is marked as DOWN. If the MEP connection is back UP before the delay expires, the services are not affected.

For example, if you set the delay 10, the GSLB services are marked as DOWN until the MEP connection has been DOWN for 10 seconds. If the MEP connection is back UP within 10 seconds, the GSLB services remain in the UP state.

Note: This delay is applicable only to services not bound to a monitor. The delay does not affect the trigger monitors.

To set a time delay by using the command line interface

At the command prompt, type the following command:

```
set gslb parameter** - GSLBSvcStateDelayTime <sec>
<!--NeedCopy-->
```

Example:

set gslb parameter - GSLBSvcStateDelayTime 10

> **Note**
>
> In a hierarchical deployment (parent-child topology), if you configure the GSLB service on both the parent and child sites, set the GSLB parameter on both the parent and child sites. If you do not configure the GSLB service on the child site, set the GSLB parameter only on the parent site.

To set a time delay by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Change GSLB Settings**.
2. In the **GSLB Service State Delay Time (secs)** box, type the time delay in seconds.

Configure a learning time for GSLB services when MEP connection status comes up to avoid flaps on GSLB services

When a node reboots or during HA failover, the system is initialized. Then, the node must learn current information about the configured local and child services to communicate the service state to remote nodes through MEP. The node takes some time to learn the correct information. Meanwhile, if a peer node connects to this node and requests for an update, the node might send an incorrect service state and statistics. This incorrect information might cause service flap and other functionality related issues on the remote peer nodes. To avoid this scenario, you can now set a learning time for the local and child GSLB service.

When a learning timeout is configured, the GSLB site gets some buffer time (learning timeout) to learn the correct statistics about its local and child services. When a service is in a learning phase, the remote GSLB site gets this information in MEP update, and does not honor the primary site state and statistics received through MEP for that service.

GSLB services enter the learning phase in any of the following scenarios.

- Citrix ADC appliance is rebooted
- High availability failover has occurred
- Owner node in a cluster GSLB setup is changed
- MEP is enabled on a local node
- GSLB site comes out of island scenario. A GSLB Site becomes island when it is not connected to any other site.

In a parent-child deployment, the backup parent (if configured) selectively moves the adopted child site's GSLB services to the learning phase when the primary parent goes DOWN.

To set a service state learning time by using the CLI

At the command prompt, type the following command:

```
set gslb parameter - SvcStateLearningTime <sec>
<!--NeedCopy-->
```

You can set "SvcStateLearningTime" in seconds. Default value is 0 and maximum value is 3600. This parameter is applicable only if monitors are not bound to GSLB services.

Example:

```
set gslb parameter - SvcStateLearningTime 10
<!--NeedCopy-->
```

To set a service state learning time by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard > Change GSLB Settings**.

   The **Set GSLB Parameters** page appears.

2. In the **GSLB Service State Learning Time (secs)** field, type the learning time in seconds.

Enable persistence information exchange

You can configure Citrix ADC appliance to provide persistent connections, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

You can enable or disable the exchange of persistence information at each site. This information is exchanged once every 5 seconds between Citrix ADC appliances participating in GSLB.

For details about configuring persistence, see Configuring Persistent Connections.

To enable or disable persistence information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable persistence-information exchange and verify the configuration:

```
set gslb site <siteName> -sessionExchange (ENABLED|DISABLED)
show gslb site** <siteName>
<!--NeedCopy-->
```

Example:

```
set gslb site Site-GSLB-East-Coast -sessionExchange  ENABLED
set gslb site Site-GSLB-East-Coast -sessionExchange  DISABLED
show gslb site Site-GSLB-East-Coast
<!--NeedCopy-->
```

To enable or disable persistence information exchange by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Sites**, and double-click the site.

2. In the **Configure GSLB Site** dialog box, select, or clear the **Persistence Session Entry Exchange** check box.

Configure GSLB by using a wizard

September 14, 2021

You can now use a wizard to configure the GSLB deployment types: active-active, active-passive, and parent-child.

This wizard is available in the GUI. To access the wizard, navigate to **Configuration** > **Traffic Management** > **GSLB** and click **Get Started**.

You can also access this wizard from the GSLB dashboard. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Dashboard** and click **Configure GSLB**.

Note: You can also configure the GSLB entities individually.

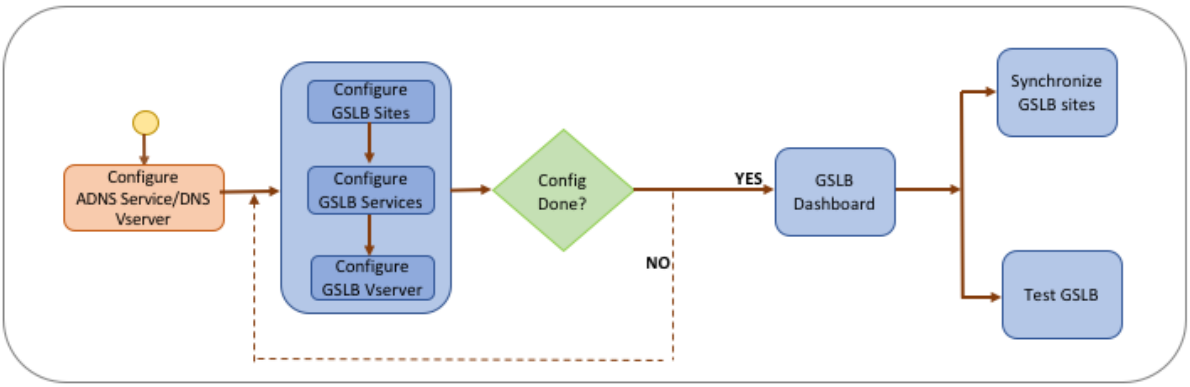
- Active-Active Site Configuration
- Active-Passive Site Configuraiton
- Parent-Child Topology Configuration

> **Important**
>
> This feature is supported in High Availability deployment and not in Admin Partition and Cluster deployments.

Configure active-active site

September 14, 2021

The following figure shows the workflow involved in a GSLB active-active site configuration.



Before you begin configuring an active-active site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave Citrix ADC appliances are running the same Citrix ADC software versions.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure an active-active site by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management** > **GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
   a) Click **View** and then click **Add**.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
3. Select **Active-Active Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select either REMOTE or LOCAL site type.
   c) Optionally, change the RPC password and, if necessary, secure it.
   d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      - **ALWAYS**. Monitor the GSLB service at all times.
      - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      - **MEP Fails and Service ID Down**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services. To create an active-active site you must add at least two GSLB services.

a) Enter the service details, such as service name, service type, and port number.
b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
d) To associate an existing server, select the server name. The service IP address is automatically populated.
   - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
   - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
   - To associate a virtual server, select an already existing virtual server, or click + and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.

7. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click **>** in the **Domain Binding** box to select the domain to be bound to this GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
      - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking **+** in the Select a location database box.
      - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.
8. Click **Done** if the configuration is complete. The GSLB dashboard appears.
9. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
   - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other Citrix ADC appliances.
   - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the

following:

a) Navigate to **Traffic Management** > **GSLB** > **Dashboard** and click **Change GSLB Settings**.

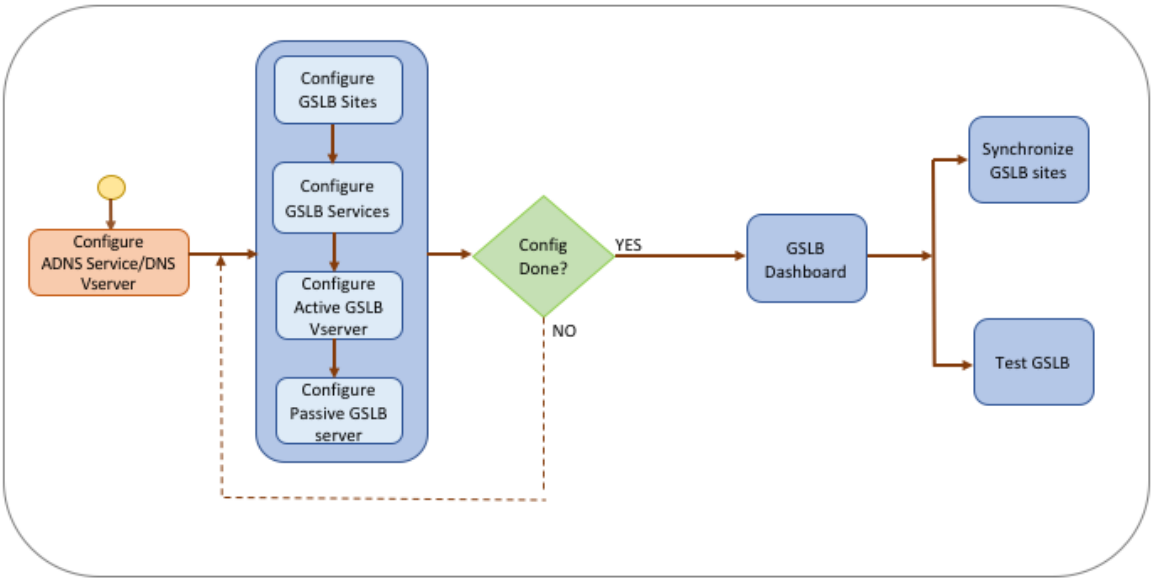
b) Select the **Automatic Config Sync** check box.

10. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

Configure active-passive site

September 14, 2021

The following figure shows the workflow involved in the active-passive site configuration.



Before you begin configuring an active-passive site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave Citrix ADC appliances are running the same Citrix ADC software versions.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure an active-passive site by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management** > **GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
   a) Click **View** and then click **Add**.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
3. Select **Active-Passive Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select either REMOTE or LOCAL site type.
   c) Optionally, change the RPC password and, if necessary, secure it.
   d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      - **ALWAYS**. Monitor the GSLB service at all times.
      - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      - **MEP Fails and Service ID Down**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services.
   a) Enter the service details, such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
   d) To associate an existing server, select the server name. The service IP address is automatically populated.
      - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
      - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      - To associate a virtual server, select an already existing virtual server, or click **+** and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.

7. Configure the GSLB backup virtual servers. The GSLB backup virtual servers become operational only when the primary GSLB virtual servers is inaccessible or it is marked DOWN for any reason.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click **>** in **Service Binding**, and choose the GSLB services that must be bound to the GSLB virtual server.
   c) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      - If you choose the **Algorithm based** method, select the primary and backup methods.
      - If you choose the **Static Proximity** method, select the backup method and provide the location of the database file.
      - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.
8. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click **>** in the **Domain Binding** box to select the domain to be bound to this GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
      - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the **>** icon or add a new location by clicking **+** in the Select a location database box.
      - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.
9. Click **Done** if the configuration is complete. The GSLB dashboard appears.
10. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
    - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other Citrix ADC appliances.
    - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**.

The synchronization happens automatically. To enable real time synchronization, do the following:

a) Navigate to **Traffic Management** > **GSLB** > **Dashboard** and click **Change GSLB Settings**.

b) Select the **Automatic Config Sync** check box.

11. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

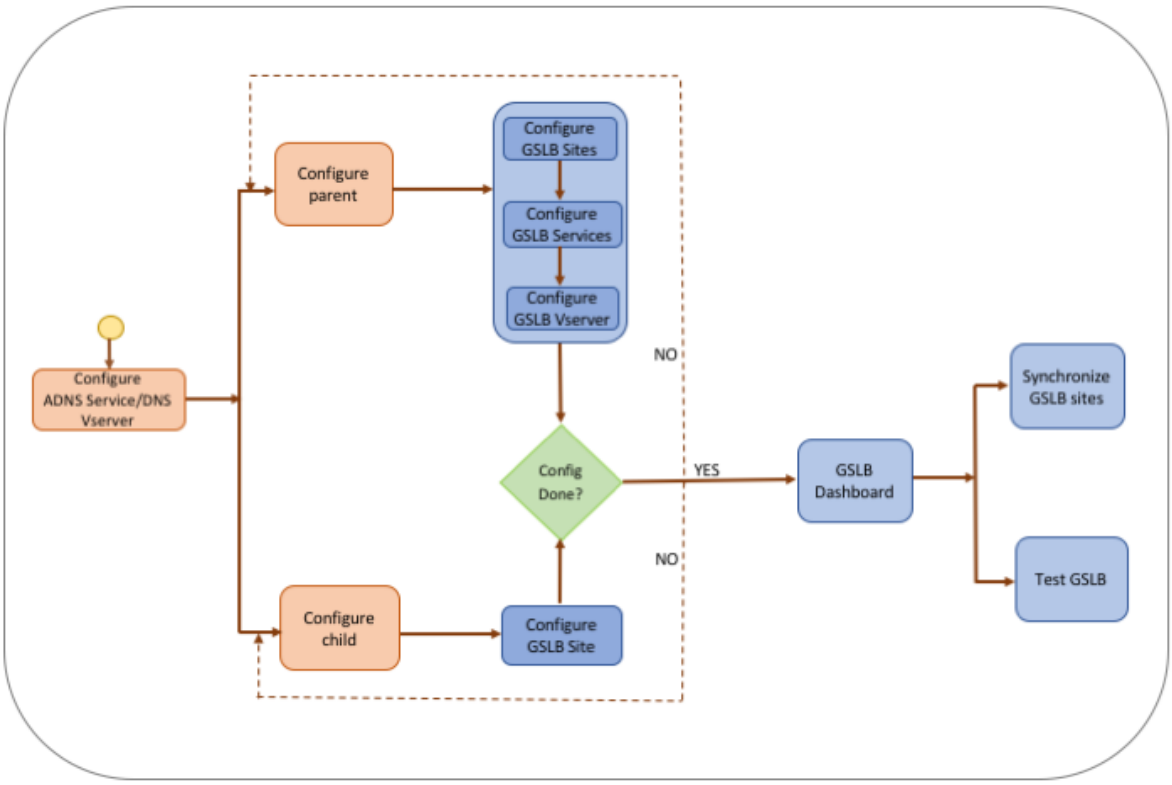
> **Note**
>
> For details about configuring GSLB entities of an active-passive GSLB setup for disaster recovery, see Configuring GSLB for Disaster Recovery.

Configure parent-child topology

September 14, 2021

In a parent-child topology, at the top level are parent sites, which have peer relationships with other parents. Each parent can have multiple child sites, and each parent site exchanges health information with its child sites and with other parent sites. However, a child site communicates only with its parent site.

The following figure shows the workflow involved in a GSLB parent-child topology configuration.



Before you begin configuring the parent-child topology deployment, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- All the Citrix ADC appliances participating as sites should have the sameCitrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure a parent-child deployment by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management** > **GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS server or a DNS virtual server for the site, you can do it now.
   a) Click **View** and then click **Add**.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.

3. Select **Parent-Child Topology**.
4. In the Select the site type field, choose;
   - **Parent** – When configuring the parent site, you must configure its associated child sites and also configure the other parent sites in the GSLB setup.
   - **Child** – When configuring the child site, you must configure only the child site and its parent site.

To configure a parent site

1. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
2. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site. All other sites are remote sites. If the specified site IP address is owned by the appliance (for example, a MIP address or SNIP address), the site is a local site. Otherwise, it is a remote site.
3. Enter the site details, such as the site name and site IP address.
   a) Select the site type.
   b) Optionally, change the RPC password and, if necessary, secure it.
   c) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      - **Always**. Monitor the GSLB service at all times.
      - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      - **MEP Fails and Service is DOWN**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
4. Configure the GSLB services.
   a) Enter the service details such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site to which the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
      - To associate an existing server, select the server name. The service IP address is auto-populated.
      - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      - To associate a virtual server, select an already existing virtual server or click **+** and add a new virtual server. This vserver is the load balancing vserver to which this GSLB service will be associated. If the public IP address is different from the server IP, which

can happen in a NAT environment, enter the public IP address and the public port number.

5. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click **>** in the **Domain Binding** box to view the domain name that is bound to the GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are automatically populated by default. You can change them if required.
      - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
      - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the **>** icon or add a new location by clicking **+** in the Select a location database box.
      - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.
6. Click **Done** if the configuration is complete. The GSLB dashboard appears.
7. If you have modified the GSLB parent-site configuration, click **Auto Synchronize GSLB** to synchronize the configuration to the other parent sites in the GSLB setup. In a parent-child topology, synchronization for the child sites is skipped.
   - Before synchronization, make sure that the local site's configuration includes information about the remote sites.
   - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
     a) Navigate to **Traffic Management** > **GSLB** > **Dashboard** and click **Change GSLB Settings**.
     b) Select the **Automatic Config Sync** check box.
8. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

To configure a child site

1. Configure the GSLB sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select the site type.
   c) Optionally, change the RPC password and, if necessary, secure it. 4. If a monitor is bound

to the GSLB service, select the condition under which the monitor is to monitor the service. The possible conditions are:

- **Always**. Monitor the GSLB service at all times.
- **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
- **MEP Fails and Service is DOWN**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.

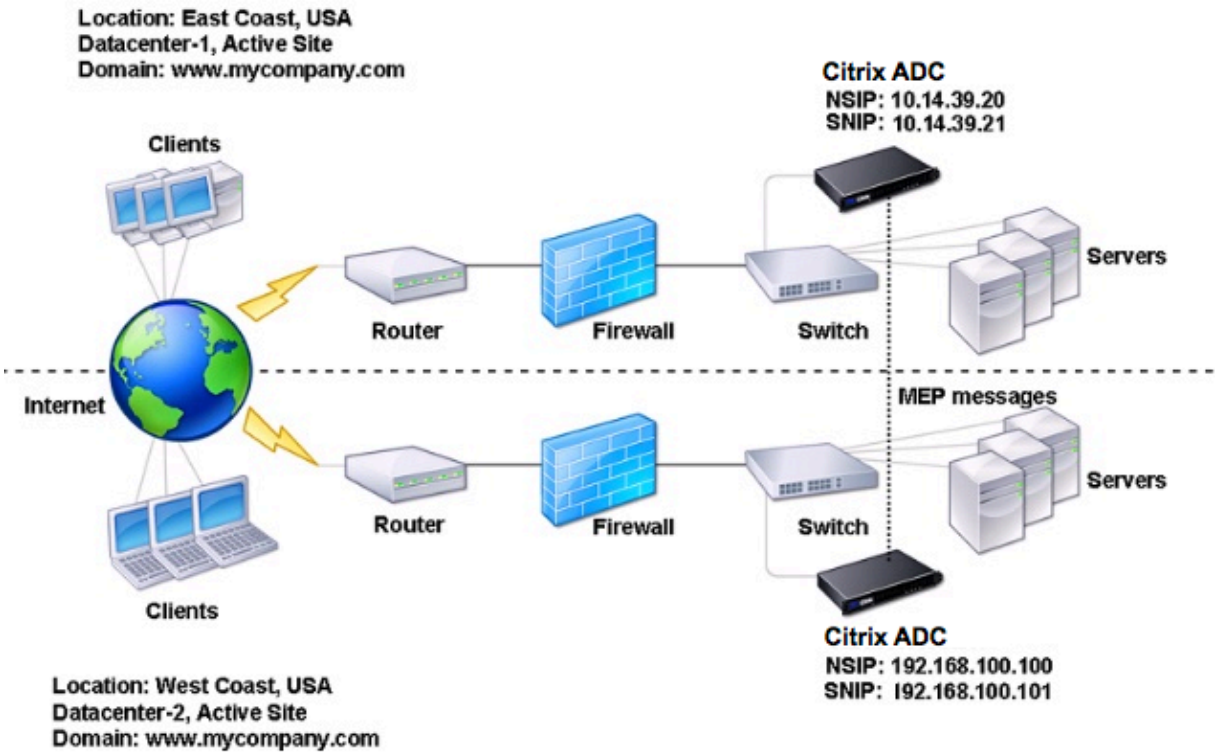
2. Click **Done** if the configuration is complete. The GSLB dashboard appears.
3. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

Configure GSLB entities individually

September 14, 2021

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, www.mycompany.com, which is hosted on two geographically separated server farms or data centers. Both server farms use Citrix ADC appliances. The Citrix ADC appliances in these server farms are set up in one-arm mode and function as authoritative DNS servers for the www.mycompany.com domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology



To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both Citrix ADC appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a Citrix ADC cluster setup, see Setting Up GSLB in a Cluster.

Configuring a Standard Load Balancing Setup

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the Citrix ADC appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see Load Balancing.

Configure an authoritative DNS service

September 14, 2021

When you configure the Citrix ADC appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the Citrix ADC appliance to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see Domain Name System.

To create an ADNS service by using the command line interface

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

```
add service <name> <IP>@ ADNS <port>

show service <name>
<!--NeedCopy-->
```

Example:

```
add service Service-ADNS-1 10.14.39.21 ADNS 53

show service Service-ADNS-1
<!--NeedCopy-->
```

To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

```
set service <name> <IPAddress> ADNS <port>
<!--NeedCopy-->
```

Example:

```
set service Service-ADNS-1 10.14.39.21 ADNS 53
<!--NeedCopy-->
```

To remove an ADNS service by using the command line interface

At the command prompt, type the following command:

```
rm service <name>
<!--NeedCopy-->
```

Example:

```
rm service Service-ADNS-1
<!--NeedCopy-->
```

To configure an ADNS service by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Add a new ADNS service, or select an existing service and edit its settings.

Configure a basic GSLB site

September 14, 2021

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB set up, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every Citrix ADC appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the Citrix ADC appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

To create a GSLB site by using the command line interface

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

```
add gslb site <siteName> <siteIPAddress>
show gslb site <siteName>
<!--NeedCopy-->
```

Example:

```
add gslb site Site-GSLB-East-Coast 10.14.39.21
show glsb site Site-GSLB-East-Coast
<!--NeedCopy-->
```

To modify or remove a GSLB Site by using the command line interface

- To modify a GSLB site, use the set gslb site command, which is just like using the add gslb site command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the unset gslb site command, followed by the siteName value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the rm gslb site command, which accepts only the <name> argument.

To configure a basic GSLB site by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Sites**.
2. Add a new GSLB site, or select an existing GSLB site and edit its settings.

To view the statistics of a GSLB site by using the command line interface

At the command prompt, type:

```
stat gslb site <siteName>
<!--NeedCopy-->
```

Example:

```
stat gslb site Site-GSLB-East-Coast
<!--NeedCopy-->
```

To view the statistics of a GSLB site by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Sites**.
2. Select the GSLB site and click **Statistics**.

Configure a GSLB service

September 14, 2021

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

> **Important**
>
> If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:
>
> The GLSB service IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

```
add gslb service <serviceName> <serverName | IP> <serviceType> <port>-
   siteName <string>
show gslb service <serviceName>
<!--NeedCopy-->
```

Example:

```
add gslb service Service-GSLB-1 10.14.39.14 HTTP 80  -siteName Site-
   GSLB-East-Coast
show gslb service Service-GSLB-1
<!--NeedCopy-->
```

To modify or remove a GSLB service by using the command line interface

- To modify a GSLB service, use the set gslb service <serviceName> command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the add gslb service command for details about the parameters. Example

  ```
  > set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandWidth 25 -
     maxClient 8
  Done
  > sh gslb service SKP_GSLB_NOTCNAME_SVC2
  SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
  ...
  Max Conn: 8  Max Bandwidth: 25 kbits
  <!--NeedCopy-->
  ```

- To reset a parameter to its default value, you can use the unset gslb service <serviceName> command and the parameters to be unset. Example

```
> unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandWidth
Done
> sh gslb service SKP_GSLB_NOTCNAME_SVC2
SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
...
Max Conn: 8  Max Bandwidth: 0 kbits
<!--NeedCopy-->
```

- To remove a GSLB service, use the rm gslb service <serviceName> command.

To create a GSLB service by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Services**.
2. Add a new GSLB service, or select an existing service and edit its settings.

To view the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
stat gslb service <serviceName>
<!--NeedCopy-->
```

Example:

```
stat gslb service Service-GSLB-1
<!--NeedCopy-->
```

To view the statistics of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Services**.
2. Select the GSLB Service and click **Statistics**.

Configure a GSLB service group

September 14, 2021

Service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable an option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled or disabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to the service groups.

> **Important**
>
> If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:
>
> The GLSB service group IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

The Citrix ADC supports the following types of GSLB service groups.

- IP address based service groups
- Domain name based service groups
- Domain name based autoscale service groups

GSLB domain name based autoscale service groups

The Citrix ADC hybrid and multi-cloud global server load balancing (GSLB) solution enables customers to distribute application traffic across multiple data centers in hybrid clouds, multiple clouds, and on premises. The Citrix ADC GSLB solution supports various load balancing solutions, such as the Citrix ADC load balancer, Elastic Load Balancing (ELB) for Amazon Web Services (AWS), and other third-party load balancers. Also, the GSLB solution performs global load balancing even if the GSLB and load balancing layers are independently managed.

In cloud deployments, users are given a domain name as a reference when accessing the load balancing solution for management purposes. It is recommended that external entities do not use the IP addresses that these domain names resolve to. Also, the load balancing layers scale up or down based on the load, and the IP addresses are not guaranteed to be static. Therefore, it is recommended to use the domain name to refer to the load balancing endpoints instead of IP addresses. This requires the GSLB services to be referred using the domain name instead of IP addresses and it must consume all the IP addresses returned for the load balancing layer domain name and have a representation for the same in GSLB.

To use domain names instead of IP addresses when referring to the load balancing endpoints, you can use the domain name based service groups for GSLB.

Monitor GSLB domain name based service groups

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications; tcp-default and ping-default. The tcp-default monitor is bound to all TCP services and the ping-default monitor is bound to all non-TCP services. The built-in monitors are bound by default to the GSLB service groups. However, it is recommended to bind an application specific monitor to the GSLB service groups.

Recommendation for setting the trigger monitors option to MEPDOWN

The Trigger Monitors option can be used to indicate if the GSLB site must use the monitors always, or use monitors when metrics exchange protocol (MEP) is DOWN.

The Trigger Monitors option is set to ALWAYS by default.

When the Trigger Monitors option is set to ALWAYS, each GSLB node triggers the monitors independently. If each GSLB node triggers the monitors independently, then each GSLB node might operate on different set of GSLB services. This might result in discrepancies in the DNS responses for the DNS requests landing on these GSLB nodes. Also, if each GSLB node is monitoring independently, then the number of monitor probes reaching the load balancer entity increases. The persistence entries also become incompatible across the GSLB nodes.

Therefore, it is recommended that the Trigger Monitors option on GSLB site entity is set to MEPDOWN. When the Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and monitoring ownership lies with the local GSLB node. When Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and subsequent monitoring is done by the local GSLB node of a GSLB service group. The results are then propagated to all other nodes participating in GSLB by using the metrics exchange protocol (MEP).

Also, whenever the set of IP addresses associated with a load balancing domain are updated, it is notified through MEP.

Limitations of GSLB service groups

- For a load balancing domain, the IP address that is returned in the DNS response is generally the public IP address. The private IP address cannot be applied dynamically when the load balancing domain is resolved. Therefore, public IP port and private IP port for the GSLB domain name based autoscale service groups IP port bindings are the same. These parameters cannot be set explicitly for the domain name based autoscale service groups.
- Site persistence, DNS views, and clustering are not supported for GSLB service groups.

Configure and manage GSLB service groups by using the CLI

Operation	CLI Command
To add a GSLB service group|`add gslb serviceGroup <serviceGroupName>@ <serviceType> [-autoScale (DISABLED	DNS)] -siteName <string>`
	Example: **add gslb serviceGroup** Service-Group-1 http -siteName Site1 -autoScale DNS
To bind a GSLB service group to a virtual server|`bind gslb serviceGroup <serviceGroupName> ((<IP>@ <port>)| <serviceName>@	((-monitorName <string>@`

||Example: **bind gslb serviceGroup** Service-Group-1 203.0.113.2; **bind gslb serviceGroup** Service-Group-1 S1 80; **bind gslb serviceGroup** Service-Group-1 -monitorName Mon1
|To unbind a GSLB service group to a virtual server|unbind gslb serviceGroup <serviceGroupName> ((<IP>@ <port>)| <serverName>@ | -monitorName <string>@)
||Example:**unbind gslb serviceGroup** Service-Group-1 -monitorName Mon1
|To set parameters for a GSLB service group|set gslb serviceGroup <serviceGroupName>@ [(<serverName>@ <port> [-weight <positive_integer>] [-hashId <positive_integer>] [-publicIP <ip_addr|ipv6_addr|*>] [-publicPort <port>])| -maxClient <positive_integer> | -cip (ENABLED | DISABLED)| <cipHeader> | -cltTimeout <secs> | -svrTimeout <secs> | -maxBandwidth <positive_integer> | -monThreshold <positive_integer> | -downStateFlush (ENABLED | DISABLED)] [-monitorName <string> -weight <positive_integer>] [-healthMonitor (YES | NO)] [-comment <string>] [-appflowLog (ENABLED | DISABLED)]
|To unset parameters from a GSLB service group|unset gslb serviceGroup <serviceGroupName>@ [<serverName>@ <port> [-weight] [-hashId] [-publicIP] [-publicPort]] [-maxClient] [-cip] [-cltTimeout] [-svrTimeout] [-maxBandwidth] [-monThreshold] [-appflowLog] [-monitorName] [-weight] [-healthMonitor] [-cipHeader] [-downStateFlush] [-comment]
|To enable a GSLB service group|enable gslb serviceGroup <serviceGroupName>@ [<serverName>@ <port>]
||Example:**enable gslb serviceGroup** SG1 S1 80
|To disable a GSLB service group|“‘disable gslb serviceGroup @ [@] [-delay] [-graceFul (YES /| NO)]

```
||Example:**disable gslb serviceGroup** SRG2 S1 80
||**Note**: The service group that has to be disabled must be a DBS service group and not an autoscale service group.
|To remove a GSLB service group|``rm gslb serviceGroup <serviceGroupName>``
||Example:**rm gslb serviceGroup** Service-Group-1
|To view the statistics of a GSLB service group|``stat gslb serviceGroup [<serviceGroupName>]``
||Example:**stat gslb serviceGroup** Service-Group-1
|To view the properties of a GSLB service group|``show gslb serviceGroup [<serviceGroupName>  -includeMembers]``
||Example: **show gslb serviceGroup** SG1; **show gslb serviceGroup** -includeMembers

### Changes to the existing GSLB CLI commands

The following table lists some of the changes that are done to the existing GSLBs commands after the introduction of the GSLB service groups.
```

```
13
14 |CLI Command|Change
15 |--|--|
16 |bind gslb vserver|The service group name is added to the bind command.
17 ||Example:```bind gslb vserver <name> ((-serviceName <string> [-weight
      <positive_integer>] ) | <serviceGroupName>@ | | (-domainName <string
      > [-TTL <secs>] [-backupIP<ip_addr|ipv6_addr|*>] [-cookieDomain <
      string>] [-cookieTimeout <mins>][-sitedomainTTL <secs>]) | (-
      policyName <string>@ [-priority<positive_integer>] [-
      gotoPriorityExpression <expression>] [-type REQUEST | RESPONSE )]))
      <!--NeedCopy-->
```

|unbind gslb vserver|The service group is added to the unbind command.
|Example:|“‘unbind gslb vserver (-serviceName @ /(-domainName [-backupIP] [-cookieDomain]) | -policyName @)

```
1  |show gslb site|When this command is executed, the GSLB service groups
      are also displayed.
2  |show gslb vs|When this command is executed, the GSLB service groups
      are be displayed.
3  |stat gslb vs|When this command is executed, the GSLB service groups
      statistics are also displayed.
4  |show lb monitor bindings|When this command is executed the GSLB
      service group bindings are also displayed.
5
6  ### Configure GSLB service groups by using the GUI
7
8  1.  Navigate to **Traffic Management** > **GSLB** > **Service Groups**.
9  1.  Create a service group and set the AutoScale Mode to DNS.
10
11 ### Configure site persistence for the GSLB service groups
12
13 You can configure site persistence for the IP address based and domain
      name based service groups. Site persistence is not supported for
      domain name based autoscale service groups.
14
15 #### To set site persistence based on HTTP cookies by using the CLI
16
17 -  For connection proxy persistence, you do not have to set the site
      prefix.
18
19  At the command prompt, type:
```

set gslb service group [-sitePersistence]

```
- For HTTP redirect persistence, you must first set the site prefix
  for a member of the service group and then set the HTTPRedirect
  persistence parameter for the service group.

At the command prompt, type:
```

set gslb servicegroup <serviceGroup member name|Ip> [-sitePrefix]

set gslb servicegroup [-sitePersistence]
‘‘‘

Examples:

- Connection proxy persistence

  set gslbservicegroup sg1 -sitePersistence connectionProxy

- HTTPRedirect persistence

  set gslb servicegroup sg2 test1 80 -sitePrefix vserver-GSLB-1

  set gslb servicegroup sg2 -sitePersistence hTTPRedirect

To set site persistence based on cookies by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Services Groups** and select the service group that you want to configure for site persistence (for example, servicegroup-GSLB-1).
2. Click the **Site Persistence** section and set the persistence that meets your requirement.

> **Tip**
>
> For deployment scenario and example configuration of GSLB service groups, see the following topics:
>
> - Use Case: Deployment of Domain Name Based Autoscale Service Group
> - Use Case: Deployment of IP Address Based Autoscale Service Group

Configure a GSLB virtual server

September 14, 2021

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

> **Note**
>
> A GSLB virtual server protocol requirement is mainly to create a relation between the virtual server and the services that are bound to the virtual server. This also keeps CLI/APIs consistent for other types of virtual servers. The Service Type parameter on a service or a virtual server is not used while serving the DNS requests. It is instead referenced during site persistence, monitoring, and for doing lookups via MEP.

To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

```
1 -  add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)
2 -  show gslb vserver <name>
3 <!--NeedCopy-->
```

Example:

```
1 add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
2 add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
3 show gslb vserver Vserver-GSLB-1
4 show gslb vserver Vserver-GSLB-2
5 <!--NeedCopy-->
```

To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the `set gslb vserver` command. This command works similar to the `add gslb vserver` command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to is default value, you can use the `unset gslb vserver` command followed by the vserverName value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the `rm gslb vserver` command, which accepts only the name argument.

To configure a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
stat gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
stat gslb vserver Vserver-GSLB-1
<!--NeedCopy-->
```

To view the statistics of a GSLB virtual server by using the configuration utility

Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**, select the virtual server and click **Statistics**.

GSLB virtual server statistics

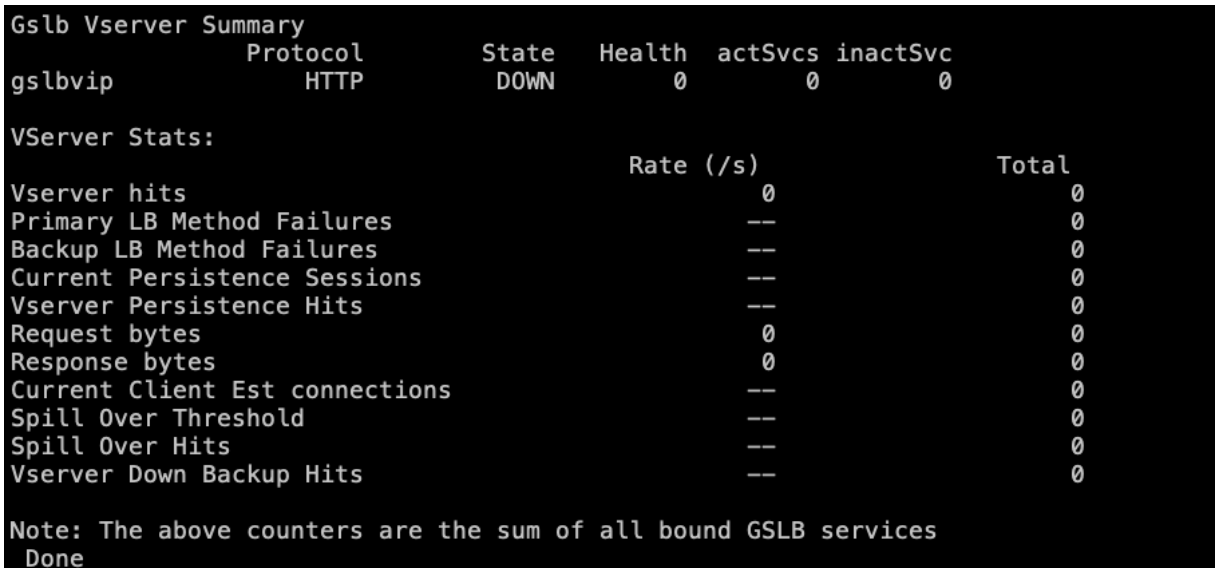
Starting from Citrix ADC version 12.1 build 51.xx and later, the GSLB virtual server statistics also display the following information in addition to details such as; vserver hits, current persistence session, request bytes, response bytes, spillover threshold, spillover hits, current client established connections, and vserver down backup hits.

- **Primary LB method failures**: Number of times the primary GSLB method has failed.
- **Backup LB method failures**: Number of times the backup GSLB method has failed.
- **Vserver persistence hits**: The number of times the request is served through the persistence sessions.

The GSLB virtual server statistics also display the statistics of the service group members bound to the virtual server.

> **Note:**
> The primary or the backup method can fail when the primary method is static proximity and the backup method is RTT. In this scenario, if there is no location corresponding to LDNS IP, the static proximity fails and backup method is attempted. The statistics are updated based on the following:
>
> - If the backup method is successful, only primary method failure statistics are incremented.
> - If RTT calculation is not successful, then backup method also fails. In this case, both primary and backup method failure statistics are incremented.
>
> When the backup method fails, the last resort method of round robin is used.

The following image is a sample of GSLB virtual server statistics from CLI.

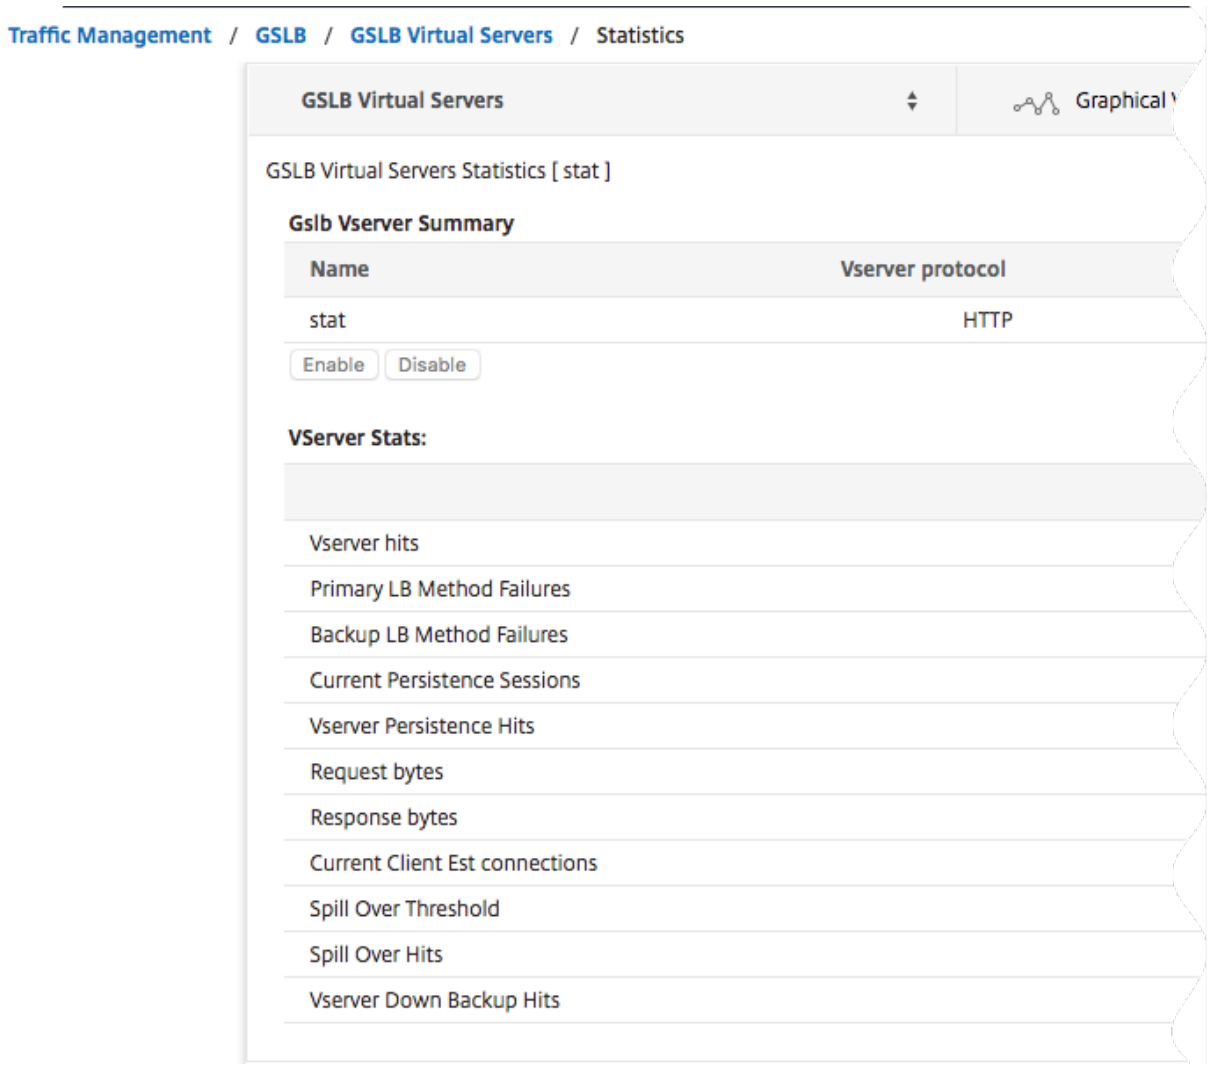


```
Gslb Vserver Summary
                Protocol        State   Health  actSvcs inactSvc
gslbvip             HTTP         DOWN        0        0        0

VServer Stats:
                                        Rate (/s)               Total
Vserver hits                                 0                      0
Primary LB Method Failures                  --                      0
Backup LB Method Failures                   --                      0
Current Persistence Sessions                --                      0
Vserver Persistence Hits                    --                      0
Request bytes                                0                      0
Response bytes                               0                      0
Current Client Est connections              --                      0
Spill Over Threshold                        --                      0
Spill Over Hits                             --                      0
Vserver Down Backup Hits                    --                      0

Note: The above counters are the sum of all bound GSLB services
 Done
```

The following image is a sample of GSLB virtual server statistics from GUI.



GSLB service statistics

When you run the stat gslb service command from the command line or click the **Statistics link** from the configuration utility, the following details of the service are displayed:

- **Request bytes.** Total number of request bytes received on this service or virtual server.
- **Response bytes.** Number of response bytes received by this service or virtual server.
- **Current client established connections.** Number of client connections in ESTABLISHED state.
- **Current load on the service.** Load on the service (Calculated from the load monitor bound to the service).

The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

Clearing the GSLB virtual server or service statistics

Note: This feature is available in NetScaler release 10.5.e.

You can now clear the statistics of a GSLB virtual server and service. Citrix ADC provides the following two options to clear the statistics:

- **Basic**: Clears the statistics that are specific to the virtual server but retains the statistics that are contributed by the bound GLSB service.
- **Full**: Clears both the virtual server and the bound GSLB service statistics.

To clear the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
stat gslb vserver <name> -clearstats <basic | full>
<!--NeedCopy-->
```

Example:

```
stat gslb vserver Vserver-GSLB-1 -clearstats basic
<!--NeedCopy-->
```

To clear the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
stat gslb service <name> -clearstats <basic | full>
<!--NeedCopy-->
```

Example:

```
stat gslb service service-GSLB-1 -clearstats basic
<!--NeedCopy-->
```

To clear the statistics of a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**.
2. Select the GSLB virtual server and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

To clear the statistics of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Services**.
2. Select the GSLB service and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

Enabling and Disabling GSLB Virtual Servers

When you create a GSLB virtual server, it is enabled by default. If you disable the GSLB virtual server, upon receiving a DNS request, the Citrix ADC appliance does not make any GSLB decision based on the GSLB method that is configured. Instead, the response to the DNS query contains the IP addresses of all the services bound to the virtual server.

To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

```
enable gslb vserver <name>@

disable gslb vserver <name>@
<!--NeedCopy-->
```

Example:

```
enable gslb vserver Vserver-GSLB-1
disable gslb vserver Vserver-GSLB-1
<!--NeedCopy-->
```

To enable or disable a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**.
2. Select a virtual server and, from the **Action** list, select **enable** or **disable**.

Bind GSLB services to a GSLB virtual server

September 14, 2021

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

To bind a GSLB service to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

```
bind gslb vserver <name> -serviceName <string>

show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
show gslb vserver Vserver-GSLB-1
<!--NeedCopy-->
```

To unbind a GSLB service from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
unbind gslb vserver <name> -serviceName <string>
<!--NeedCopy-->
```

To bind GSLB services by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click a virtual server.
2. Click in the **Domains** section, and configure a domain and bind the domain.

Bind a domain to a GSLB virtual server

September 14, 2021

To make a Citrix ADC appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the Citrix ADC appliance adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see Domain Name System.

To bind a domain to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

```
bind gslb vserver <name> -domainName <string>
show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
show gslb vserver Vserver-GSLB-1
<!--NeedCopy-->
```

To unbind a GSLB domain from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
unbind gslb vserver <name> -domainName <string>
<!--NeedCopy-->
```

To bind a domain to a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
   - To create a new Domain, click **Add**.
   - To modify an existing Domain, select the domain, and then click **Open**.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:
   - Domain Name*—domainName (for example, www.mycompany.com)

   * A required parameter
5. Click Create.
6. Click OK.

To view the statistics of a domain by using the command line interface

At the command prompt, type:

```
stat gslb domain <name>
<!--NeedCopy-->
```

Example:

```
stat gslb domain www.mycompany.com
<!--NeedCopy-->
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the Citrix ADC appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

To view the statistics of a domain by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click **Statistic**s.

To view the configuration details of the entities bound to a GSLB domain using the command line

Note: This feature is available in NetScaler release 10.5.e.

At the command prompt, type:

```
show gslb domain <name>
<!--NeedCopy-->
```

Example:

```
show gslb domain gslb1.com
       gslb1.com
       gvs1 - HTTP    state: DOWN
       DNS Record Type: A
       Configured Method: LEASTCONNECTION
       Backup Method: ROUNDROBIN
       Persistence Type: NONE
       Empty Down Response: DISABLED
```

```
9         Multi IP Response: DISABLED
10        Dynamic Weights: DISABLED
11
12        gsvc1 (10.102.239.165: 80)- HTTP State: DOWN    Weight: 1
13               Dynamic Weight: 0    Cumulative Weight: 1
14               Effective State: DOWN
15               Threshold : BELOW
16
17               Monitor Name : http
18                      State: DOWN   Weight: 1
19                      Probes: 144   Failed [Total: 144 Current: 144]
20                      Last response: Failure - TCP syn sent, reset
                           received.
21                      Response Time: 2000 millisec
22
23        gsvc2 (10.102.239.179: 80)- HTTP State: DOWN    Weight: 1
24               Dynamic Weight: 0    Cumulative Weight: 1
25               Effective State: DOWN
26               Threshold : BELOW
27
28               Monitor Name : http-ecv
29                      State: DOWN   Weight: 1
30                      Probes: 141   Failed [Total: 141 Current: 141]
31                      Last response: Failure - TCP syn sent, reset
                           received.
32                      Response Time: 2000 millisec
33 Done
34 <!--NeedCopy-->
```

To view the configuration details of the entities bound to a GSLB domain by using the configuration utility

Note: This feature is available in NetScaler release 10.5.e.

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click a virtual server.
2. Click the field below the **Domains** pane.
3. In the **GSLB Virtual Server Domain Binding** dialog box, select a domain, and then click **Show Bindings**.

Example of a GSLB setup and configuration

September 14, 2021

An organization has a geographically dispersed network and has three data centers located in the United States, Mexico, and Colombia. In the configuration related to these locations, these are referred to as US, MX, and CO respectively. At each location, the company has a server farm, which provides the same content and the setup is working as expected. The Citrix ADC appliance at each location is configured through a virtual server with the HTTP protocol on port 80.

The organization has implemented the GSLB setup by adding a site identifier at each site. The site identifier includes a site name and an IP address that is owned by the Citrix ADC appliance and is used for the GSLB communications.
Each site has a site local to the appliance. Also, each site has two sites remote to the local appliance. On each site, a GSLB virtual server is created with the same name. This virtual server identifies the website of the organization globally and does not have any IP address associated with it.
The setup also has GSLB services configured that point to the load balancing virtual servers configured on each GSLB site by specifying the IP address, protocol, and port number of the respective virtual server. These services are bound to the GSLB virtual server.

Note: In the procedure below, the commands use private IP addresses for the GSLB sites. For public sites and GSLB services, ensure that you use public IP addresses for these sites.

The following table lists the IP addresses and locations used in the example:

IP Address	Location
10.3.1.101	Site IP of local Citrix ADC.
172.16.1.101	Site IP of remote location site-MX.
192.168.1.101	Site IP of remote location site-CO.
172.16.1.100	Service IP of remote location site-MX.
10.3.1.100	Service IP of local Citrix ADC.
192.168.1.100	Service IP of remote location site-CO.

When adding a GSLB site, if the site communicates over the internet only then use the “Public IP” field. For example, when there is no site to site VPN connectivity between the GSLB sites.

To configure the GSLB setup with Citrix ADC appliances by using the CLI commands

1. Enable the GSLB feature, if not already done.

```
enable ns feature gslb
<!--NeedCopy-->
```

2. Identify a SNIP that for adding local GSLB site.
3. Add the GSLB site for the local Citrix ADC appliance.

```
add gslb site site-US 10.3.1.101
<!--NeedCopy-->
```

4. Add the GSLB sites for the remote Citrix ADC appliances.

```
add gslb site site-MX 172.16.1.101
add gslb site site-CO 192.168.1.101
<!--NeedCopy-->
```

5. Add the GSLB virtual server that references a service being used in the GSLB setup:

```
add gslb vserver gslb-lb HTTP
<!--NeedCopy-->
```

6. Add the GSLB services for each site participating in the GSLB setup:

```
add gslb service gslb_SVC30 172.16.1.100 HTTP 80 -siteName site-MX
add gslb service gslb_SVC10 10.3.1.100 HTTP 80 -siteName site-US
add gslb service gslb_SVC20 192.168.1.100 HTTP 80 -siteName site-
   CO
<!--NeedCopy-->
```

7. Bind the GSLB services to the GSLB virtual server:

```
bind gslb vserver gslb-lb -serviceName gslb_SVC10
bind gslb vserver gslb-lb -serviceName gslb_SVC20
bind gslb vserver gslb-lb -serviceName gslb_SVC30
<!--NeedCopy-->
```

8. Bind the domain to the GSLB virtual server.

```
bind gslb vserver gslb-lb -domainName www.mycompany.com -TTL 30
<!--NeedCopy-->
```

9. Add an ADNS service that listens to the DNS queries.

```
set service Service-ADNS-1 10.14.39.21 ADNS 53
<!--NeedCopy-->
```

Synchronize the configuration in a GSLB setup

September 14, 2021

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each Citrix ADC, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point, you must ensure that the configuration across all GSLB sites is identical. You can use the Citrix ADC's GSLB configuration synchronization option to synchronize the configuration across the GSLB sites.

The Citrix ADC appliance from which you use the synchronization option is referred to as the 'main site' and the GSLB sites on which the configuration is copied as the 'subordinate sites'. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to the configuration on the main site.

Synchronization is done only on the parent sites. Synchronization does not affect GSLB child sites' configuration. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.

- The main node finds the differences between the configuration of the main node and subordinate node, and changes the configuration of the subordinate node to make it similar to the main node.

  If you force a synchronization (use the 'force sync' option), the appliance deletes the GSLB configuration from the subordinate node and then configures the subordinate to make it similar to the main node.

- During synchronization, if a command fails, synchronization is not aborted and the error message are logged into a **.err** file in the **/var/netscaler/gslb** directory.
- Synchronization is done only on the parent sites. Synchronization does not affect the GSLB child sites' configuration. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.
- If you disable the internal user login, the GSLB auto sync uses the SSH keys to synchronize the configuration. But, to use GSLB auto sync in the partition environment, you must enable the internal user login and make sure that the partition user name in the local and remote GSLB sites is the same.

> **Note**
>
> - On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC

> and 3008 for secure RPC). If the default route to reach the remote sites is in the management subnet, as in most cases, then NSIP is used as the source IP address.
>
> To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through a GSLB site IP subnet.
>
> For enhanced security, Citrix recommends that you change the internal user account and RPC node passwords. Internal user account password is changed through RPC node password. For details, see Change an RPC node password.

If you use the saveconfig option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). If the default route to reach the remote sites is in a management subnet, as in most cases, then NSIP is used as the source IP address.

To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through the GSLB site IP subnet. The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for an RPC node is specific to each Citrix ADC appliance. Therefore, after you force a synchronization (using the sync gslb config -forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other Citrix ADC appliances. Port 22 is also required for synchronizing the database files to the remote site.

To improve the time taken for configuration synchronization on all GSLB sites

Configure the TCP profile settings at the command prompt as follows:

```
1 set tcpprofile nstcp_internal_apps -bufferSize 4194304 -sendBuffsize
     4194304 -tcpmode ENDPOINT
2 <!--NeedCopy-->
```

Limitations of synchronization

- On the main site, the names of the remote GSLB sites must be identical to the names of sites configured on the Citrix ADC appliances hosting those sites.
- During the synchronization, traffic disruptions may occur.
- Citrix ADC is tested to synchronize up to 200,000 lines of the configuration.
- Synchronization may fail:
  - If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.

  - If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the main node and then try to synchronize.
  - If the RPC node passwords are different for NSIP and loopback IP address.
  - If you perform synchronization on GSLB sites that are configured in different partitions of the same Citrix ADC appliance.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes must be the same.
- If you rename any GLSB entity that is part of your GSLB configuration (use the "show gslb runningConfig" command to display the GSLB configuration). You must use the force sync option to synchronize the configuration to other GSLB sites.

> **Note:**
>
> - In incremental synchronization, you don't have to use the force sync option to synchronize the configuration to other GSLB sites. This is applicable starting Citrix ADC release 13.0 build 79.x onwards.

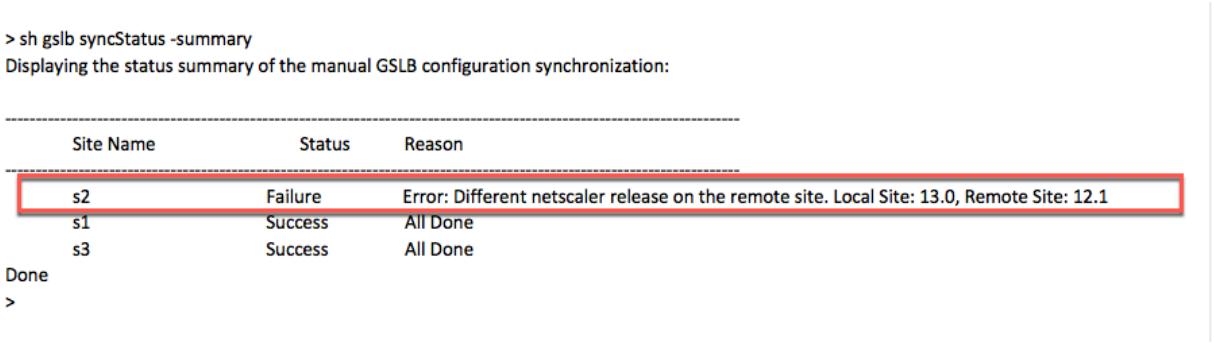
Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and readded to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

Points to note before starting the synchronization of a GSLB setup

Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the main site, management access and SSH must be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the Citrix ADC appliance. For more information about adding the GSLB site IP addresses and enabling Management Access, see "Configuring a Basic GSLB Site".
- The GSLB configuration on the Citrix ADC appliance that is considered as the main site is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB must have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.
- The main site and the subordinate sites run the same Citrix ADC versions. Starting from release 12.1, build 50.x, the appliance checks for the firmware version on main and subordinate sites before initiating synchronization. If the main and the subordinate sites run different versions, the synchronization is aborted for that remote site to avoid pushing any incompatible changes across the versions. Also, an error message displaying the site details on which the synchronization aborted appears.

The following figures display sample error messages from the CLI and the GUI.



```
> sh gslb syncStatus -summary
Displaying the status summary of the manual GSLB configuration synchronization:

-------------------------------------------------------------------------------------------------------------
        Site Name                Status          Reason
-------------------------------------------------------------------------------------------------------------
        s2                       Failure         Error: Different netscaler release on the remote site. Local Site: 13.0, Remote Site: 12.1
        s1                       Success         All Done
        s3                       Success         All Done
Done

Manual synchronization between sites participating in GSLB

September 14, 2021

The manual synchronization of GSLB configuration across the master site and the slave sites is performed in the following manner:

- The master site detects the differences between the configuration of its own site and the slave site.
- The master site applies the difference in configuration to the slave site.
- The master site performs the configuration synchronization with all the slave sites in the GSLB setup, and completes the synchronization process.

Important: After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Perform the synchronization only if you are sure that the synchronization process

does not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, which leads to site outage. If some commands fail and some commands succeed, the successful commands are not rolled back.

Points to note

- If you force a synchronization (use the 'force sync' option), the Citrix ADC appliance deletes the GSLB configuration from the slave site. Then, master site configures the slave site to make it similar to its own site.
- During synchronization, if a command fails, synchronization is not aborted. The error messages are logged into an .err file in the /var/netscaler/gslb directory.
- If you use the `saveconfig` option, the sites participating in the synchronization process automatically save their configuration, in the following way:
  - The master site saves its configuration immediately before it initiates the synchronization process.
  - The slave sites save their configuration after the process of synchronization is complete. A slave site saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave site, you must manually investigate the cause of the failure and take corrective actions.

To synchronize a GSLB configuration by using the CLI:

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

```
sync gslb config [-preview | -forceSync <string> | -nowarn | -
   saveconfig] [-debug]
show gslb syncStatus
<!--NeedCopy-->
```

Example:

```
sync gslb config

[WARNING]: Syncing config may cause configuration loss on other site.

Please confirm whether you want to sync-config (Y/N)? [N]:y

Sync Time: Dec 9 2011 10:56:9

Retrieving local site info: ok

Retrieving all participating gslb sites info: ok

```

```
Gslb_site1[Master]:

Getting Config: ok

Gslb_site2[Slave]:

Getting Config: ok

Comparing config: ok

Applying changes: ok

Done
<!--NeedCopy-->
```

To synchronize a GSLB configuration by using the GUI:

1. Navigate to **Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **ForceSyn**.
3. In **GSLB Site Name**, select the GSLB sites that are to be synchronized with the master node configuration.

Previewing GSLB synchronization

By previewing the GSLB synchronization operation, you can see the differences between the master node and each slave node. If there are any discrepancies, you can troubleshoot before synchronizing the GSLB configuration.

To preview the GSLB synchronization output by using the CLI:

At the command prompt, type the following command:

```
sync gslb config -preview
<!--NeedCopy-->
```

To preview the GSLB synchronization output by using the GUI:

1. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Dashboard**.
2. Click **Auto Synchronization GSLB** and select **Preview**.
3. Click **Run**.
   A progress window displays any discrepancies in the configuration.

Debugging the commands triggered during synchronization process

You can view the status (success or failure) of each command triggered during the synchronization process and troubleshoot accordingly.

To debug the GSLB synchronization commands by using the CLI:

At the command prompt, type the following command:

```
sync gslb config -debug
<!--NeedCopy-->
```

To debug the GSLB synchronization commands by using the GUI:

1. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Dashboard.**
2. Click **Auto Synchronization GSLB** and select **Debug**.
3. Click **Run**. A progress window displays the status of each command triggered during synchronization.

Real-time synchronization between sites participating in GSLB

September 14, 2021

You can use the “AutomaticConfigSync” option to automatically synchronize the real-time GSLB configuration of main site to all the subordinate sites. You do not have to manually trigger the AutoSync option to synchronize the configuration.

You can automatically synchronize the GSLB configuration of main site to all the subordinate sites by using incremental synchronization or full synchronization. The “GSLBSyncMode” parameter allows you to choose the synchronization mode.

> Note:
>
> Starting from Citrix ADC release 13.0 build 79.x, incremental synchronization of GSLB synchronization is supported. By default, the synchronization is performed using incremental synchronization. Incremental synchronization can be performed by enabling the “IncrementalSync” parameter. For details, see Incremental synchronization of GSLB configuration.

Best practices for using the real-time synchronization feature

- It is recommended that all the Citrix ADC appliances participating as sites have the sameCitrix ADC software version.
- To change the RPC node password, first change the password on the subordinate site and then on the main site.

- Configure local GSLB sites on each site participating in GSLB.
- Enable automaticConfigSync on one of the sites where the configuration is performed. This site eventually gets synchronized to other GSLB sites.
- If there is a new configuration or changes are made to the existing configuration, make sure to check the status using the “show gslb syncStatus” command to confirm if the changes are synchronized across all sites or if there was any error.
- RSYNC port monitoring must be enabled.

To enable real-time synchronization by using the CLI

At the command prompt, type:

```
set gslb parameter -automaticConfigSync (ENABLED | DISABLED)
<!--NeedCopy-->
```

Example:

```
set gslb parameter -automaticConfigSync ENABLED
<!--NeedCopy-->
```

To enable real-time synchronization by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Change GSLB Settings**.
2. Select **Automatic ConfigSync**.

   Note: This option must be enabled only in the site where the configuration is performed.

For information on the following topics, see Manual synchronization between sites participating in GSLB.

- Previewing GSLB synchronization
- Debugging the commands triggered during synchronization process

Points to note

- The consolidated log file related to the real-time synchronization is stored in the /var/netscaler/gslb/periodic_sync.log directory.
- The default configuration file is stored in the /var/netscaler/gslb_sync/ directory.
- The main site uses the following directory structure:
  - The main site stores all its files in the /var/netscaler/gslb_sync/master directory.
  - The main site stores its configuration file that must be synced to the subordinate sites, in the /var/netscaler/gslb_sync/master/gslbconf/ directory.

  - The status files pulled from all the subordinate sites are stored in the /var/netscaler/gslb_sync/master/sl directory.
- The subordinate site uses the following directory structure:
  - The subordinate site picks up the latest configuration file to be applied from the /var/netscaler/gslb_sync/slave/gslbconf directory.
  - The subordinate site stores its status file in the /var/netscaler/gslb_sync/slave/gslbstatus directory.
- In an admin partition setup, the same directory structure is maintained in the location: /var/-partitions/`partition name`/netscaler/gslb_sync.
- The clocks on all the sites must be set accurately to a real-time standard like Coordinated Universal Time (UTC).

Incremental synchronization of GSLB configuration

The automatic GSLB configuration synchronization feature checks for the configuration changes on the main site at the interval of every 10 seconds, and performs a synchronization. This sync interval value is configurable.

In incremental synchronization, only the configurations that have changed on the main site between the last synchronization and the subsequent sync interval (10 secs) is synchronized across all the subordinate sites. Incremental synchronization is the default behavior. Pushing only the incremental configurations considerably reduces the configuration file size, and thus the synchronization time. If an incremental synchronization fails, the system automatically performs a full configuration synchronization.

Incremental synchronization is performed in the following manner:

- The main site pushes the configuration file comprising of only its latest changes to all the subordinate sites. The latest change refers to the configurations that has changed between the last synchronization and the subsequent sync interval (10 secs).
- Each subordinate site applies the latest change to its own site.
- Incremental synchronization in not attempted on the subordinate sites, which are in DOWN state. When the site comes back UP, again synchronization is performed.
- The subordinate site generates status logs at each step and copies them to a file at a specific location.
- The main site pulls the status log files from the specified location.
- The main site prepares a log file with logs combined from all the subordinate sites.
- This combined log file is stored in /var/netscaler/gslb/periodic_sync.log file.

For more information on the directories where the configuration files are stored, see “Points to note” section.

To enable GSLB configuration incremental synchronization by using the CLI

```
set gslb parameter -AutomaticConfigSync (ENABLED | DISABLED) -
    GSLBSyncMode (IncrementalSync | FullSync) -GslbConfigSyncMonitor (
    ENABLED | DISABLED) -GSLBSyncInterval <secs> -GSLBSyncLocFiles (
    ENABLED | DISABLED)
<!--NeedCopy-->
```

Example:

```
set gslb parameter -AutomaticConfigSync ENABLED -GSLBSyncMode
    IncrementalSync
<!--NeedCopy-->
```

The incremental synchronization provides the following configurable parameters, which reduce the overall time taken to synchronize the GSLB configuration.

- **GslbConfigSyncMonitor**—Enable the GSLB Config Sync Monitor parameter to monitor the state of the subordinate sites' RSYNC port, which is the SSH port 22 on remote GSLB site IP address. If the monitor shows the subordinate site state as DOWN, the RSYNC operation to that site is skipped. This reduces the synchronization delays caused by attempting to connect to the remote sites that are DOWN.

  Example to enable RSYNC port monitoring in CLI:

  ```
  set gslb parameter -GSLBSyncMode IncrementalSync -
      GslbConfigSyncMonitor ENABLED
  <!--NeedCopy-->
  ```

- **GSLBSyncInterval**—Set the time interval (in seconds) at which the GSLB configuration synchronization occurs. By default, the automatic GSLB configuration sync feature synchronizes the GSLB configuration automatically at every 10 seconds. You can change the time interval to any desired value. Refrain from setting this to a lower value, for example, not lesser than 5 seconds. Because, synchronizing frequently might increase the management CPU consumption.

  > Note:
  >
  > In an admin partition setup, the time interval can be set only in the default partition because it is a global parameter.

  Example to set the sync interval:

  ```
  set gslb parameter -AutomaticConfigSync ENABLED -GSLBSyncMode
      IncrementalSync -GSLBSyncInterval 7
  <!--NeedCopy-->
  ```

- **GSLBSyncLocFiles**—During GSLB config synchronization, by default, the changes in the location DB files are detected and automatically synchronized. Because the location DB directories do not change often, admins can disable automatically synchronizing the location DB files. Instead, admins must manually copy the location DB files to the GSLB subordinate sites. Synchronizing location DB files takes much time. Thus, avoiding it reduces the overall synchronization time.

  Example to disable automatically synchronizing the location DB files:

```
set gslb parameter -GSLBSyncMode IncrementalSync -
   GSLBSyncLocFiles DISABLED
<!--NeedCopy-->
```

To enable GSLB incremental synchronization by using the GUI

1. Navigate to **Traffic Management > GSLB > Dashboard > Change GSLB settings**.
2. In the **Set GSLB Parameters** page, you can perform the following:
   - To enable incremental synchronization, choose **IncrementalSync** from the **GSLB Sync Mode** drop-down menu.
   - To set the Automatic GSLB config sync interval, enter the time in seconds in the **GSLB Sync Interval** field.
   - To enable RSYNC port monitoring, select the **GSLB Config Sync Monitor** check box.
   - To disable automatically synchronizing the location DB files, clear the **GSLB Sync Loc Files** check box.

Full synchronization of GSLB configuration

Whenever there is a configuration change in the main site, the complete GSLB running configuration on the main site is pushed to all the subordinate sites.
Even if incremental synchronization is configured, a full synchronization is performed when the main site does not know the configuration status of the subordinate site. Some of such scenarios are as follows:

- Enable the automatic GSLB configuration synchronization feature for the first time.
- Reboot the Citrix ADC appliance.
- GSLB deployment has multiple main sites, and another main site becomes the active main site.
- Add a new subordinate site to the GSLB deployment.

GSLB configuration full synchronization is performed in the following manner:

- The main site pushes its latest configuration file to all the subordinate sites.

- Each subordinate site compares its own configuration with the latest configuration file sent by the main site. The subordinate site identifies the difference in configuration, and applies the delta configuration for its own site.
- The subordinate site generates status logs at each step and copies them to a file at a specific location.
- The main site pulls the status log files from the specified location.
- The main site prepares a log file with logs combined from all the subordinate sites.
- This combined log file is stored in /var/netscaler/gslb/periodic_sync.log file.

If you attempt to manually synchronize (with the `sync gslb config` command) a site while it is being autosynchronized, a "Sync in progress" error message appears. Autosynchronization cannot be triggered for a site that is in the process of being synchronized manually.

> **Attention:**
>
> Starting with Citrix ADC 12.1 build 49.37, SNMP traps are generated when you synchronize the GSLB configuration. In real-time synchronization, the synchronization status in the first SNMP trap is captured as failure. You can ignore this status because a second SNMP trap is automatically generated immediately after the first trap with the actual synchronization status. However, if the synchronization failed in the second attempt also, SNMP trap is not generated because the synchronization status has not changed from the previous synchronization status.

For details on configuring Citrix ADC appliance to generate traps, see Configuring the Citrix ADC to generate SNMP traps.

To enable GSLB full synchronization by using the CLI

```
set gslb parameter -GSLBSyncMode (IncrementalSync | FullSync)
<!--NeedCopy-->
```

Example:

```
set gslb parameter -GSLBSyncMode FullSync
<!--NeedCopy-->
```

To enable GSLB incremental synchronization by using the GUI:

1. Navigate to **Traffic Management > GSLB > Dashboard > Change GSLB settings**.
2. In the **Set GSLB Parameters** page, choose **FullSync** from the **GSLB Sync Mode** drop-down menu.

Multiple main sites in a GSLB deployment

The Citrix ADC appliance supports multiple main sites in an active-passive deployment. It is recommended to have two main sites in a GSLB deployment to cope against GSLB main site failure. Having two main sites can avoid single point of failure of GSLB configuration synchronization. At any time, only one main site can actively process the GSLB configuration from the user. If the configuration changes are performed simultaneously in more than one main site, it might lead to configuration inconsistency or configuration losses. Hence, it is recommended to perform configuration changes from only one main site at a time, and use the other main site as a backup when the active main site fails.

> Note:
>
> When multiple main sites are used in a GSLB deployment, RSYNC monitoring must be enabled.

To make a GSLB node as one of the main sites for GSLB configuration synchronization, run the following command:

```
set gslb parameter -automaticConfigSync Enabled
<!--NeedCopy-->
```

View GSLB synchronization status and summary

September 14, 2021

After the GSLB configuration is synchronized across the GSLB sites, you can view the detailed status and the summary of the last GSLB sync operation. This is applicable to both manual and real-time GSLB synchronization.

To view the GSLB synchronization status or summary by using the CLI

At the command prompt, type:

```
show gslb sync status
<!--NeedCopy-->
```

or

```
show gslb syncStatus -summary
<!--NeedCopy-->
```

Sample configuration output for GSLB manual synchronization

The following output displays the status of the manual GSLB configuration synchronization.

```
> sh gslb syncStatus
Displaying the status of the manual GSLB configuration synchronization:

gslb_site1[Master]:
        Getting Config:  ok
gslb_site2[Slave]:
        Syncing gslb static proximity database:  ok
        Syncing inbuilt gslb static proximity database : ok
        Getting Config:  ok
        Comparing config:  ok
        Applying changes:  ok
gslb_natsite1[Slave]:
        Syncing gslb static proximity database:  ok
        Syncing inbuilt gslb static proximity database : ok
        Getting Config:  ok
        Comparing config:  ok
        Applying changes:  ok
 Done
>
```

The following output displays the status summary of the manual GSLB configuration synchronization.

```
> sh gslb syncStatus -summary
Displaying the status summary of the manual GSLB configuration synchronization:

-------------------------------------------------------------------------------------------------------------------
        Site Name                Status          Reason
-------------------------------------------------------------------------------------------------------------------
        gslb_site1               Success         All Done
        gslb_site2               Failure         Error executing command on gslb site...ERROR: Connection failed
        gslb_natsite1            Success         All Done
Done
>
```

Sample configuration output for GSLB real-time synchronization

The following output displays the status of the real-time GSLB configuration synchronization for the master site:

```
> sh gslb syncStatus
Displaying the status of the real time GSLB configuration
    synchronization as master node:

site2[Master]:
                New GSLB configuration detected at Fri Jan 23 20:54:24
                    2020
                Fetching current configuration: Done
                Updating default.conf file: Done
site1[Slave]:
                Syncing gslb static proximity database to node site1:
                    Done
                Syncing inbuilt GSLB static proximity database to node
                    site1: Done
                Syncing ssl certificates, keys and CRLS to node site1:
                    Done
                Syncing current configuration to site1: Done
                Pulling status files from site1: Status file not
                    available yet(Sync in progress)
                Pulling status files from site1: Done
                site1 received new configuration from 10.102.217.205 in
                     file 2JNSzClRHK5+pdek6szQ3g-default-10.102.217.210.
                    conf
                Firing set gslb parameter -startConfigSync ENABLED
                    command: Done
                Fetching running GSLB Config: Done
                Comparing config: Done
                Applying changes: Done
                Firing set gslb parameter -startConfigSync DISABLED
                    command: Done
                Updating default.conf file: Done
Done
<!--NeedCopy-->
```

The following output displays the status of the real-time GSLB configuration synchronization for the slave site:

```
> sh gslb syncStatus
Displaying the status of the real time GSLB configuration
    synchronization as slave node:

                site1 received new configuration from 10.102.217.205 in
                     file 2JNSzClRHK5+pdek6szQ3g-default-10.102.217.210.
                    conf
```

```
                Firing set gslb parameter -startConfigSync ENABLED
                    command: Done
                Fetching running GSLB Config: Done
                Comparing config: Done
                Applying changes: Done
                Firing set gslb parameter -startConfigSync DISABLED
                    command: Done
                Updating default.conf file: Done
Done
<!--NeedCopy-->
```

The following output displays the status summary of the real-time GSLB configuration synchronization for the master site:

```
> sh gslb syncStatus -summary
Displaying the status summary of the real time GSLB configuration
    synchronization as master node:

---------------------------------------------------------------------------

                Site Name                                   Status
                                Reason
---------------------------------------------------------------------------

                site2                                       Success
                             All Done
                site1                                       Success
                             All Done

Done
<!--NeedCopy-->
```

The following output displays the status summary of the real-time GSLB configuration synchronization for slave site:

```
> sh gslb syncStatus  - summary
Displaying the status summary of the real time GSLB configuration
    synchronization as slave node:

---------------------------------------------------------------------------

                Site Name                                   Status
                                Reason
---------------------------------------------------------------------------
```

```
7                  site1                                        Success
                                  All Done
8
9  Done
10 <!--NeedCopy-->
```

To view the GSLB synchronization status or summary by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **GSLB** > **Dashboard**.
2. Click **View Synchronization Summary** or **View Synchronization Status**, as required.

SNMP traps for GSLB configuration synchronization

September 14, 2021

Starting with Citrix ADC 12.1 build 49.xx, the Citrix ADC appliance generates SNMP traps for both local and remote sites when you synchronize the GSLB configuration. SNMP traps are generated for both manual synchronization and real-time synchronization.

When you synchronize the GSLB configuration for the first time, SNMP traps are generated. In the subsequent synchronization attempts, the SNMP traps are generated only if there is a change in the synchronization status from the previous synchronization status. Also, the SNMP traps are generated only for sites for which the synchronization status changed from the previous state.

For example, consider that the first GSLB configuration synchronization is successful. When you synchronize the configuration for the second time and if the synchronization is successful again, then SNMP traps are not generated because the status is not changed. However, in the third attempt, if the synchronization fails for one of the sites, then SNMP trap is generated for that site alone.

In a high availability and a cluster setup, the appliance generates the SNMP traps when you synchronize the GSLB configuration from the new node irrespective of the previous synchronization status. Also, if SNMP trap option was previously disabled and then enabled, SNMP traps are generated from that point onwards irrespective of previous synchronization status.

The SNMP traps of GSLB configuration synchronization provide the following details:

- Name of the GSLB site for which the SNMP trap is sent.
- GSLB configuration synchronization status: Success or Failure.
- GSLB configuration synchronization mode: Incremental sync or Full sync.
- (Optional) Detailed information about the SNMP traps.

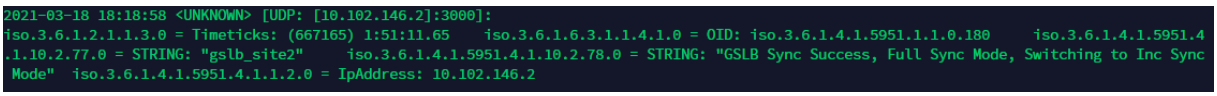
The SNMP traps are generated in the following scenarios:

- GSLB synchronization status for a GSLB site flips from Success to Failure, and conversely.
- GSLB synchronization mode changes from incremental synchronization to full synchronization, and conversely.

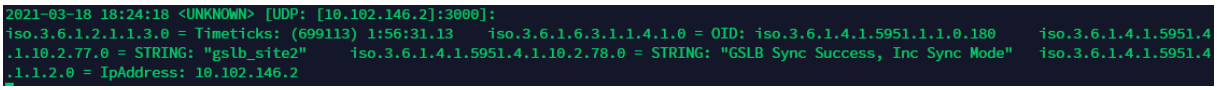
> Note:
>
> Even when incremental synchronization is enabled, if full synchronization is performed on a GSLB site for some reason, the reason for Full sync is mentioned in the "Detailed information" section of the trap message. For example, when a new GSLB site is added to the GSLB configuration.

Sample SNMP trap messages

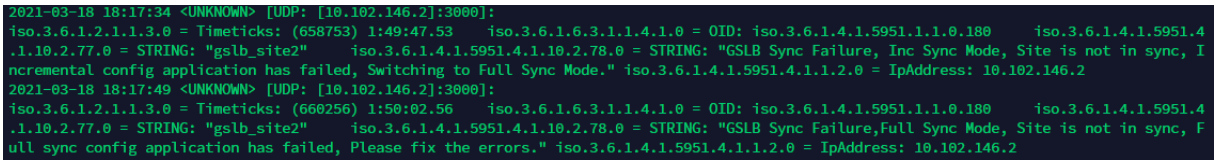
The following figure displays a sample SNMP trap for gslb_site2, where the GSLB configuration synchronization is successful using the Full sync mode.



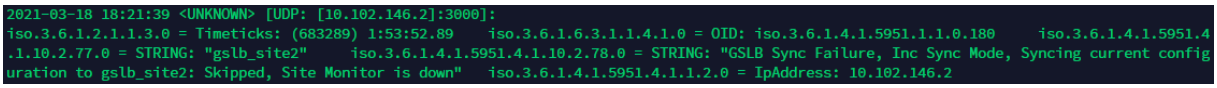
The following figure displays a sample SNMP trap for gslb_site2, where the GSLB configuration synchronization is successful using the incremental sync mode.



The following figure displays a sample SNMP trap for gslb_site2, where the GSLB configuration synchronization using the incremental sync mode is failed. The error message indicates that you must manually fix the errors to complete the synchronization.



The following figure displays a sample SNMP trap for gslb_site2, where the GSLB configuration synchronization using the incremental sync mode is failed. It also indicates the reason for sync failure, that is the site monitor is DOWN.



GSLB dashboard

September 14, 2021

You can view the overall status of the GSLB sites participating in GSLB on the GSLB dashboard.

You can access the GSLB settings from the dashboard. You can also start the GSLB configuration wizard from the dashboard. Additionally, you can perform the synchronization and test the GSLB setup from the dashboard.

To access the GSLB dashboard, navigate to **Configuration** > **Traffic Management** > **GSLB** > **Dashboard**.

Monitor GSLB services

September 14, 2021

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric Information, which is the round-trip-time and persistence Information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The Citrix ADC appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the Citrix ADC appliance uses the state of the service reported by the monitor. However, you can configure the Citrix ADC appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the appliance to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.

Configure monitor trigger

You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the Citrix ADC appliance stops monitoring when MEP returns to the UP state.

To configure monitor triggering by using the command line interface

At the command prompt, type:

```
set gslb site <siteName> -triggerMonitor (ALWAYS | MEPDOWN |
   MEPDOWN_SVCDOWN)
<!--NeedCopy-->
```

Example:

```
set gslb site Site-GSLB-North-America -triggerMonitor Always
<!--NeedCopy-->
```

To configure monitor triggering by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Sites**, and double-click the site.
2. In the **Trigger Monitors** drop-down list, select an option for when to trigger monitoring.

Add or remove monitors

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

```
add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>

show lb monitor <monitorName>
<!--NeedCopy-->
```

Example:

```
add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
show lb monitor monitor-HTTP-1
```

```
<!--NeedCopy-->
```

To remove a monitor by using the command line interface

At the command prompt, type:

```
rm lb monitor <monitorName>
<!--NeedCopy-->
```

To add a monitor by using the configuration utility

Navigate to
Traffic Management > Load Balancing > Monitors, and add or delete a monitor.

Bind monitors to a GSLB service

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service's monitoring threshold.

To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

```
bind monitor <name> <serviceName> [ -state (Enabled | Disabled) ] -
   weight <positiveInteger>
<!--NeedCopy-->
```

Example:

```
bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
<!--NeedCopy-->
```

To set the monitoring threshold for a GSLB service by using the command line interface

At the command prompt, type:

```
set gslb service <ServiceName> -monThreshold <PositiveInteger>
<!--NeedCopy-->
```

Example:

```
set gslb service service-GSLB-1 -monThreshold 9
<!--NeedCopy-->
```

To bind the monitor to the GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor** section and bind the monitor to the GSLB service.

To set the monitoring threshold for a GSLB service by using the configuration utility

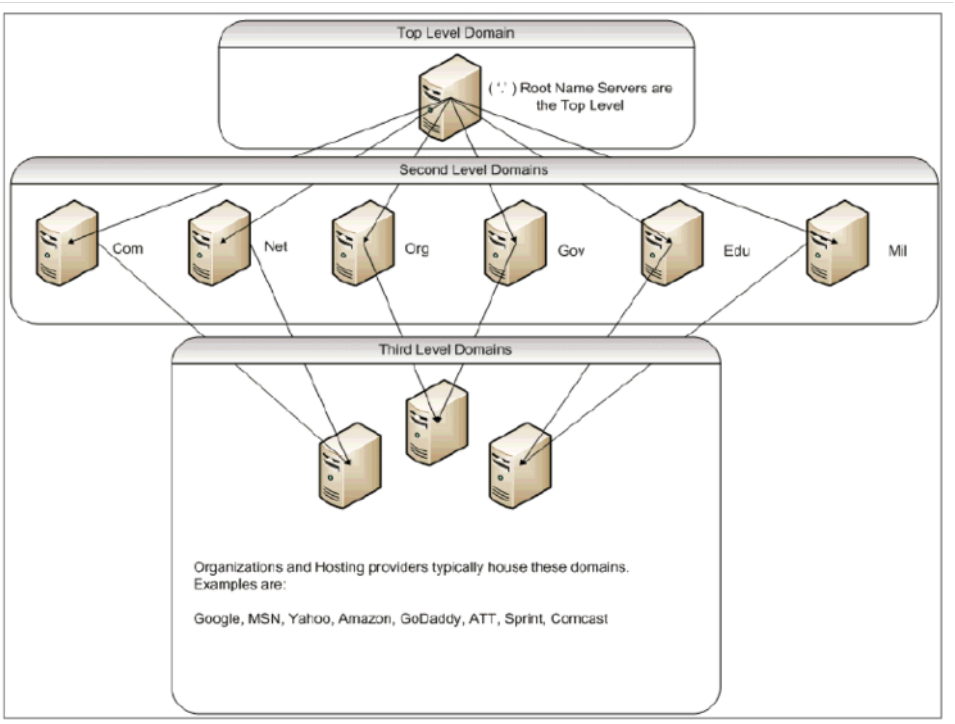
1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor Threshold** section and enter a threshold value.

How domain name system supports GSLB

September 14, 2021

The domain name system (DNS) is considered as a distributed database, which uses the Client/Server architecture. Name Servers are the servers in the architecture, and the resolvers are the clients that are library routines installed on an operating system that create and send queries across the network.

The logical hierarchy of the DNS is shown in the following diagram:



> Note:
>
> The second-level root servers are responsible for maintaining Name server to Address mappings for Name server delegations within the .com, .net, .org, .gov domains, and so on. Each domain within the second-level domains is responsible for maintaining Name Server to Address mappings for the lower-level organizational domains. At the organization level, the individual host addresses are resolved for www, FTP, and other service providing hosts.

Delegation

The main purpose of the current DNS topology is to ease the burden of maintaining all address records on one authority. This allows for delegation of an organization name space to that particular organization. The organization can then further delegate its space to subdomains within the organization. For example, under citrix.com you can create subdomains called `sales.citrix.com`, `education.citrix.com`, and `support.citrix.com`. The corresponding departments can maintain their own set of Name servers that are authoritative for their subdomain, and then maintain their own set of host name to address mappings. No single department is responsible for maintaining all of Citrix address records. Each department can change addresses and modify topologies, and not impose more work at the higher-level domain or organization.

Benefits of the hierarchical topology

Some of the benefits of the hierarchical topology include:

- Scalability
- Adding caching functionality into Name servers at each level, where a DNS request is served by a host that is not authoritative for a particular domain but can contribute the answer to the query, and cut down on congestion and response time.
- Caching also creates redundancy and resiliency to server failure. If one name server fails, it is still possible that records can be served from other servers that have recent cached copies of the same records.

Resolvers

Resolvers are the client component in the DNS system. Programs that are running on a host that need information from the domain name space use the resolver. The resolver handles:

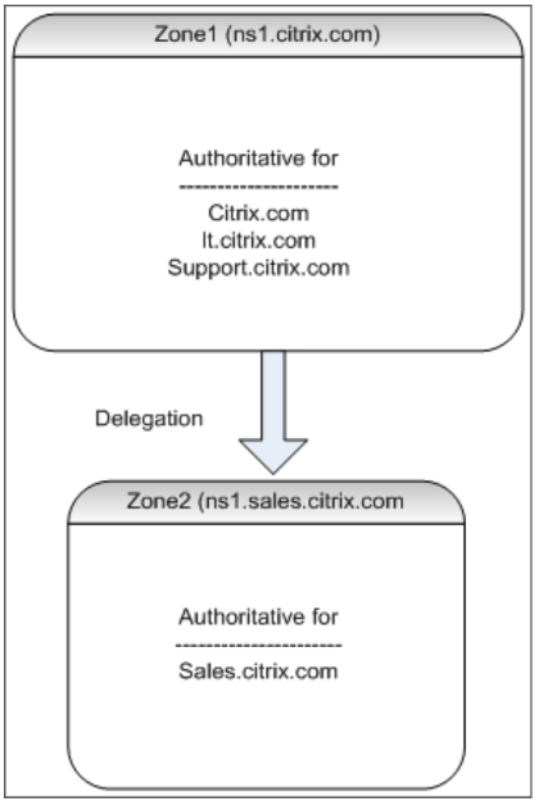
- Querying a name server.
- Interpreting responses (which might be resource records or an error).
- Returning the information to the programs that requested it.

The resolver is a set of library routines that are compiled into programs like telnet, FTP, and ping. They are not separate processes. The resolvers can put together a query, send it, and wait for an answer. And, send it again (possibly to a secondary Name Server) if it is not answered within a certain time. These types of resolvers are known as stub resolvers. Some resolvers have the added functionality to cache records, and honor time to live (TTL). In Windows, this functionality is available through the DNS Client service; viewable through the “services.msc” console.

Name Servers

Name Servers generally store complete information about a particular part of a domain name space (called a zone). The Name Server is then said to have authority for that zone. They can also be authoritative for multiple zones.

The difference between a domain and a zone is subtle. A domain is the full set of entities including its subdomains while a zone is only the information within a domain that is not delegated to another Name Server. An example of a zone is `citrix.com`, while `sales.citrix.com` is a separate zone if that zone is delegated to another Name Server within the subdomain. In this case, the primary Citrix zone can include `citrix.com`, `it.citrix.com`, and `support.citrix.com`. Because the `sales.citrix.com` is delegated, it is not part of the zone that the `citrix.com` Name Server is authoritative over. The following diagram shows the two zones.

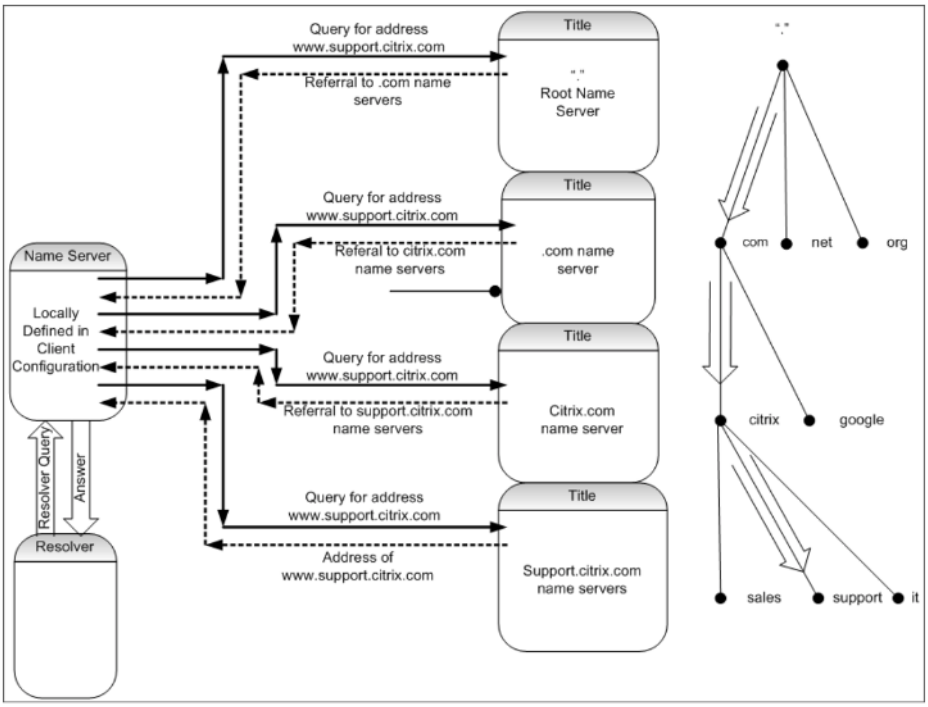


To properly delegate a subdomain, you must assign authority for the subdomain to different Name Servers. In the preceding example, the `ns1.citrix.com` does not contain information about the `sales.citrix.com` subdomain. Instead, it contains pointers to the Name servers that are authoritative for the `ns1.sales.citrix.com` subdomain.

Root name servers and query resolution

Root Name servers know the IP addresses of all the Name servers authoritative for the second-level domains. If a Name Server does not have information about a given domain in its own data files, then it only needs to contact a root server to begin traversing the proper branch of the **DNS** tree structure to eventually get to the given domain. This involves a series of requests to multiple Name servers to help with the tree traversal to find the next authoritative Name server, which needs to be contacted for further resolution.

The following diagram shows a typical DNS request, assuming that there is no cached record for the requested name during the traversal. The following example uses a mock up of the Citrix domain.



Recursive and non-recursive queries

The preceding example demonstrates the two types of queries that can occur.

- Recursive query: The query between the resolver and the locally configured Name server is recursive. This means that the Name server receives the query and does not respond to the resolver until the query is fully answered, or an error is returned. If the Name Server receives a referral to the query, then the Name server follows the referral until the Name server finally receives the answer (IP address) returned.
- Non-recursive query: The query that the locally configured Name server makes to the subsequent authoritative domain-level Name server is non-recursive (or iterative). Each request is immediately responded with either a referral to a lower-level authoritative server or the answer to the query, if the queried Name server contains the answer in its data files or its cache.

Caching

Although the resolution process is involved, and might potentially require small requests to several hosts, it is fast. One of the factors that increases the speed of DNS resolution is caching. Each time a Name server receives a recursive query, it might have to communicate to other servers to eventually get to the proper authoritative server for the specific request. It stores all of the information that it receives for future reference. When the next client makes a similar request, such as a different host

but in the same domain, it already knows the Name server that is authoritative for that domain, and can send a request directly there instead of starting at the root Name server.

Caching can occur for negative responses also, such as the queries for hosts that do not exist. In this case, the server must not query the authoritative Name server for the requested domain to figure out that the host does not exist. To save time, the Name server simply checks the cache and responds back with the negative record.

Name servers do not cache records indefinitely, or else you can never update the IP addresses. To avoid synchronization problems, DNS responses contain a time to live (TTL). This field describes the time interval for which the cache can store a record before it must discard it and check with the authoritative Name server for any updated records. If the records have not changed, the use of TTL also allows rapid dynamic responses from devices performing GSLB.

Resource record types

Various RFCs provide a comprehensive list of DNS resource record types and its description. The following table lists the common resource record types.

Resource record type	Description	RFC
A	A host address	RFC 1035
NS	An authoritative name server	RFC 1035
MD	A mail destination (Obsolete - use MX)	RFC 1035
MF	A mail forwarder (Obsolete - use MX)	RFC 1035
CNAME	The canonical name for an alias	RFC 1035
SOA	Marks the start of a zone of authority	RFC 1035
WKS	A well known service description	RFC 1035
PTR	A domain name pointer	RFC 1035
HINFO	Host information	RFC 1035
MINFO	Mailbox or mail list information	RFC 1035
MX	Mail exchange	RFC 1035
TXT	Text strings	RFC 1035

Resource record type	Description	RFC
AAAA	IP6 Address	RFC 3596
SRV	Server selection	RFC 2782]

How GSLB supports DNS

GSLB uses algorithms and protocols that decide which IP address must be sent for a DNS query. GSLB sites are geographically distributed and there is a DNS authoritative Name server at each site running as a service on the Citrix ADC appliance. All Name servers at the various sites involved are authoritative for the same domain. Each of the GSLB domains is a subdomain for which a delegation is configured. Therefore, the GSLB Name servers are authoritative and can use one of the various load balancing algorithms to decide which IP address to return.

A delegation is created by adding a Name server record for the GSLB domain in the parent domain database files and a subsequent address record for the Name servers that are used for the delegation. For example, if you want to use GSLB for `www.citrix.com`, then the following Bind SOA file can be used to delegate requests to `www.citrix.com` to Name Servers: Netscaler1 and Netscaler2.

```
################################################################################

@ IN SOA citrix.com. hostmaster.citrix.com. (
1 ; serial
3h ; refresh
1h ; retry
1w ; expire
1h ) ; negative caching TTL
IN NS ns1
IN NS ns2
IN MX 10 mail

ns1   IN A 10.10.10.10
ns2   IN A 10.10.10.20
mail  IN A 10.20.20.50

### Old Configuration if www was not delegated to a GSLB name server
www IN A 10.20.20.50

### Updated Configuration
Netscaler1 IN A xxx.xxx.xxx.xxx
Netscaler2 IN A yyy.yyy.yyy.yyy
www IN NS Netscaler1.citrix.com.
```

```
www IN NS Netscaler2.citrix.com.
###
IN MX 20 mail2
mail2 IN A 10.50.50.20
##############################################################################

<!--NeedCopy-->
```

Understanding BIND is not a requirement for configuring DNS. All compliant DNS server implementations have a method of creating the equivalent delegation. Microsoft DNS servers can be configured for delegation using the instructions at Create a zone delegation.

What makes GSLB on Citrix ADC appliance different from using the standard DNS service for distributing traffic is that the Citrix ADC GSLB sites exchange data using a proprietary protocol called Metric Exchange Protocol (MEP). With MEP, the GSLB sites are able to maintain information about all other sites. When a DNS request is received, the MEP considers the GSLB metrics to determine information such as the following:

- Site with the least number of current connections
- Site that is closest to the LDNS server, which sent the request based on round trip times (RTT).

There are several load balancing algorithms that can be used, but GSLB is a DNS with the brain underneath telling the Name Server (hosted on the Citrix ADC appliance) which address must be sent based on metrics of the participating sites.

Other benefits that GSLB provides are the ability to maintain persistence (or site affinity). Responses to the incoming DNS queries can be compared with the source IP address to determine if that address was directed to a particular site in the recent past. If so, then the same address is sent in the DNS response to ensure that the client session is maintained.

Another form of persistence is obtained at the site level by using HTTP redirects, or HTTP proxying. These forms of persistence occur after the DNS response occurs. Therefore, if you get an HTTP request at a site that contains a cookie to direct the request to a different participating site, then you can either respond with a redirect or proxy the request to the appropriate site.

Metric exchange protocol

Metric Exchange Protocol (MEP) is used to share the data used in GSLB calculations across sites. Using MEP connections, you exchange three types of data. These connections need not be secure over TCP port 3011 or can be secure using SSL over TCP port 3009.

The following three types of data are exchanged, and have their own intervals and exchange methods.

- **Site metric exchange:** This is a polling exchange model. For example, if site1 has a configuration for site2 services, then every second site1 asks site2 for the status of the GSLB services. Site2 responds with the state and other load details.
- **Network metric exchange:** This is the LDNS RTT information exchange, which is used in the dynamic proximity load balancing algorithm. This is a push exchange model. Every five seconds, each site pushes its data to other participating sites.
- **Persistency exchange:** This is for SOURCEIP persistency exchange. This is also a push exchange model. Every five seconds, each site pushes its data to other participating sites.

By default, site services are monitored over MEP based on polling information only. If you bind monitors based on monitor interval, the state is updated and you can control the frequency of the updates by setting the monitoring interval accordingly.

Upgrade recommendations for GSLB deployment

September 14, 2021

This section provides recommendations on the sequence in which GSLB nodes need to be upgraded in various GSLB setups. It also addresses a few FAQs.

Note: The Citrix ADC appliance from which the GSLB synchronization is started is referred to as the 'main site' and the GSLB sites on which the configuration is copied as the 'subordinate sites'.

Before you start the upgrade process, read the prerequisites mentioned in the following topics:

- Before you begin
- Upgrade a high availability pair.
- Upgrade a cluster.

Points to note when upgrading GSLB setups

- In an HA setup, first upgrade the subordinate sites and then the main site.
- In an HA setup, service states might not propagate from an older build primary node to a newer build secondary node. However, if the builds are of different versions, but have the same HA version, the service state might still propagate.
- If GSLB is configured within a cluster, first upgrade the non-owner nodes, and then upgrade the owner node. If there is one site or multiple sites in a cluster, follow the same upgrade sequence in each of the site.
- Enable new GSLB features only after you upgrade all nodes to a newer build.

- Upgrade all GSLB nodes to the latest build. There is no functional impact on the available features when some of the GSLB nodes are using an older version and some of the GSLB nodes are upgraded to a newer version.

FAQs

- **Are GSLB service states propagated when instances run different software versions?**

  GSLB MEP is functional when instances run on different versions and GSLB service states are propagated across GSLB sites. There is no impact on the MEP communication when instances run different versions after an upgrade.

- **Is it recommended to do configuration changes during an upgrade?**

  In a GSLB setup, when a main site is being upgraded, it is not recommended to do configuration changes on any other GSLB nodes.

Use case: Deployment of domain name based autoscale service group

September 14, 2021

> **Tip**
>
> For information about the GSLB service groups, see Configuring a GSLB Service Group

Deployment scenario

Two datacenters are deployed in two AWS regions, one in Sydney and one in North Virginia. Another datacenter is deployed in Azure. An AWS ELB in each AWS region is used to load balance the application servers. ALB is used for Azure to load balancing the application server. The Citrix ADC appliances are configured for GSLB for the ELBs and ALB using GSLB domain name based autoscale service group.

> **Important**
>
> You must configure the required security groups in AWS and attach it to the GSLB instance. Port 53 must be allowed in the security group inbound and outbound rules. Also, ports (3009 or 3011 depending on secure MEP configuration) for MEP communication must be open. For application monitoring, the corresponding ports must be allowed in the security group outbound rules.

The configuration steps for the above deployment scenario and the corresponding CLI commands are as follows:

1. Create datacenters (represented by GSLB sites).

   ```
   add gslb site aws-sydney 192.0.2.2

   add gslb site aws-nvirginia 198.51.100.111

   add gslb site alb-southindia 203.0.113.6
   ```

2. Add a name server with the DNS gateway IP address where the GSLB node is added. This must be done in all datacenters.

   ```
   add dns nameServer 8.8.8.8
   ```

3. Add servers for ELB and ALB.

   ```
   add server aws-sydney_server lb-sydney-1052691850.ap-southeast-2.elb.
   amazonaws.com

   add server aws-nvirginia_server LB-nvirginia-860559595.us-east-1.elb.
   amazonaws.com

   add server alb-southindia_server alb.southindia.cloudapp.azure.com
   ```

4. Add GSLB autoscale service groups for each ELB and ALB and bind each server to the respective service group.

   ```
   add gslb serviceGroup aws-nvirginia_sg HTTP -autoScale DNS -siteName
   aws-nvirginia

   add gslb serviceGroup aws-sydney_sg HTTP -autoScale DNS -siteName aws-
   sydney

   add gslb serviceGroup alb-southindia_sg HTTP -autoScale DNS -siteName
   alb-southindia

   bind gslb serviceGroup aws-nvirginia_sg aws-nvirginia_server 80

   bind gslb serviceGroup aws-sydney_sg aws-sydney_server 80

   bind gslb serviceGroup alb-southindia_sg alb-southindia_server 80
   ```

5. Add a GSLB virtual server and bind the application domain and the service groups to this virtual server.

```
add gslb vserver gv1 HTTP

bind gslb vserver gv1 -serviceGroupName aws-nvirginia_sg

bind gslb vserver gv1 -serviceGroupName aws-sydney_sg

bind gslb vserver gv1 -serviceGroupName alb-southindia_sg
```

Use case: Deployment of IP address based GSLB service group

September 14, 2021

> **Tip**
>
> For information about the GSLB service groups, see Configuring a GSLB Service Group.

Deployment scenario

If there are multiple applications hosted on the same application server, the GSLB should probe these applications to see if the applications are responding or not. If an application is not responding, the user must be directed to the server on which the application is UP. Also, if one of the applications is DOWN, then the server should not be marked DOWN, because the other applications are UP.

In the following example, multiple applications (HTTPS) are hosted on one server in each GSLB site and hence all these applications resolve to one IP address of the respective site.

Using the GSLB service groups, you can have the same server with an IP address and port bound to multiple service groups where each service group represents a different application.

An application specific monitor is bound to the service groups that marks the service group as DOWN if the application is DOWN. Thus, whenever an application is DOWN, only that application is taken out from the setup and not the server.

```
```
add gslb serviceGroup app1_site1 HTTP -maxClient 0 -cip DISABLED -
    cltTimeout 180 -svrTimeout 360 -siteName s1

add gslb serviceGroup app2_site1 HTTP -maxClient 0 -cip DISABLED -
    cltTimeout 180 -svrTimeout 360 -siteName s1

add gslb serviceGroup app1_site2 HTTP -maxClient 0 -cip DISABLED -
    cltTimeout 180 -svrTimeout 360 -siteName s2
```

 
```

```
7
8  add gslb serviceGroup app2_site2 HTTP -maxClient 0 -cip DISABLED -
       cltTimeout 180 -svrTimeout 360 -siteName s2
9
10 add lb monitor http_app2 HTTP -respCode 200 -httpRequest "GET /testsite
       /app2.html"
11
12 add lb monitor http_app1 HTTP -respCode 200 -httpRequest "GET /testsite
       /app1.html"
13
14 bind gslb serviceGroup app1_site1 192.0.2.140 80
15
16 bind gslb serviceGroup app1_site1 -monitorName http_app1
17
18 bind gslb serviceGroup app2_site1 192.0.2.140 80
19
20 bind gslb serviceGroup app2_site1 -monitorName http_app2
21
22 bind gslb serviceGroup app1_site2 192.0.2.142 80
23
24 bind gslb serviceGroup app1_site2 -monitorName http_app1
25
26 bind gslb serviceGroup app2_site2 192.0.2.142 80
27
28 bind gslb serviceGroup app2_site2 -monitorName http_app2
29 <!--NeedCopy--> ```
```

How-to articles

September 14, 2021

The GSLB how-to articles contain information about some of the important GSLB configurations such as customizing GSLB configuration, configuring persistent connections, disaster recovery, and so on.

Customizing Your GSLB Configuration

Configuring Persistent Connections

Managing Client Connections

Configuring GSLB for Proximity

Protecting the GSLB Setup Against Failure

Configuring GSLB for Disaster Recovery

Customize your GSLB configuration

September 14, 2021

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.

Modify maximum connections or maximum bandwidth for a GSLB service

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

```
set gslb service <serviceName> [-maxClients <positive_integer>] [-
    maxBandwidth <positive_integer>]
show gslb service <serviceName>
<!--NeedCopy-->
```

Example:

```
set glsb service Service-GSLB-1 -maxBandwidth 100 -maxClients 100
show gslb service Service-GSLB-1
<!--NeedCopy-->
```

To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Services**, and double-click a service.
2. Click in the **Other Settings** section and set the following parameters:
    - Max Clients—maxClients
    - Max Bandwidth—maxBandwidth

Create CNAME-based GSLB services

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMES) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the Citrix ADC appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the Citrix ADC appliance provides the CNAME with the corresponding A record (IP address). The Citrix ADC appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different Citrix ADC appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a Citrix ADC appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

To create a CNAME-based GSLB service by using the command line interface

At the command prompt, type:

```
add gslb service <serviceName> -cnameEntry <string> -siteName <string>
<!--NeedCopy-->
```

Example:

```
add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -
    siteName Site-GSLB-East-Coast
add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -
    siteName Site-GSLB-West-Coast
<!--NeedCopy-->
```

To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Services**.
2. Create a service, and set the **Type to Canonical Name Based**.

Configure transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

Configure dynamic weights for services

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore, when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see Assigning Weights to Services.

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled**:The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.

- **SERVICECOUNT**: The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWEIGHT**: The dynamic weight is the sum of the weights of services bound to the load balancing virtual servers corresponding to the GSLB service (3), and the cumulative weight is the product of the dynamic weight (3) and the weight of the GSLB service (3), which is 9.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT
<!--NeedCopy-->
```

Example:

```
set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT
<!--NeedCopy-->
```

To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list, select **SERVICECOUNT** or **SERVICEWEIGHT**.

How to configure persistence in GSLB

September 14, 2021

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. You can use persistence for deployments where an information related to a client transaction is stored locally on an instance, which has served the initial requests. For example, the deployments for e-commerce that uses a shopping cart, where the server needs to maintain the state of the connection to track the transaction. The Citrix ADC appliance selects a data center to process a client request. With persistence enabled, it forwards the same IP address of the selected data center for all subsequent Domain Name System (DNS) requests. If a

persistence session points to a data center that is DOWN, the Citrix ADC appliance uses the configured GSLB method to select a new data center. It then becomes persistent for subsequent requests from the client.
For persistence in GSLB, the same set of persistence identifiers (persistID) must be configured on the GSLB virtual servers in all data centers. The GSLB module uses the persistence identifier to uniquely identify a GSLB virtual server. When Source IP persistence is enabled on the GSLB virtual server, the persistence sessions are also exchanged as part of the metrics exchange. For the Citrix ADC appliance to support persistence across sites, persistence related configuration must be done on all the participating GSLB sites. Citrix recommends persistence in GSLB for stateful applications, which requires clients to reconnect to the same application instance for the subsequent requests.

You can achieve persistence in GSLB by the following ways:

- Persistence on GSLB virtual server
- Site persistence on GSLB services

Persistence on GSLB virtual server

Persistence on GSLB virtual server is used during the DNS requests. The Source IP address of the DNS request is used to create persistence session between the client and the data center. DNS clients are generally the Local DNS (LDNS) or DNS gateways proxying a set of clients sitting behind them (in ISPs). Persistence on a GSLB virtual server is application protocol agnostic.
In general, multiple DNS gateways or Local Domain Name Servers (LDNS) are configured in the client network. Citrix recommends you to configure an appropriate persistence mask because for the subsequent DNS requests, irrespective of the upstream LDNS devices used to connect to the ADC appliance, the client is able to persist to the same data center, which had served the earlier requests. After the persistence session is created for an LDNS IP address, all the end clients connecting using that LDNS are given the same data center IP address.

Site persistence on GSLB services

Site persistence becomes effective while processing the application requests. Site persistence works only for HTTP and HTTPS traffic because the persistency is achieved using HTTP cookie. As cookies are maintained on HTTP clients (browsers), it gives visibility into the clients sitting behind the DNS gateways. When you use cookies to achieve persistency for clients, no resources are consumed on the ADC appliance for each incoming client. When you bring a GSLB service DOWN with a delay time, the service goes into the transition to out of service (TROFS) state. Persistence is supported as long as the service is in the UP or TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

If you access an application through an alias, ensure that the CNAME record is also configured on the Citrix ADC appliance. In a parent-child topology, site persistence does not work when you access an application through an alias.

> Note
>
> If the connection proxy is specified as the site persistence method and you also want to configure persistence on LB virtual servers, source IP persistence is not recommended. When the connection is proxied, an IP address owned by the ADC appliance is used, and not the actual IP address of the client.
> Configure an appropriate persistence, which does not use source IP of the HTTP(S) request to identify the client, for example, cookie persistence or rule-based persistence.

Configure persistence based on source IP address

If source IP persistence is configured on GSLB virtual server, persistence sessions are created for the source IP address of the DNS request. Depending on the Extended Client Subnet (ECS) feature, the source IP address of the DNS request is taken from any of the following:

- The source IP in the IP header of the incoming DNS request packet
- The ECS option in the DNS request For more information on ECS, see Use the EDNS0 client subnet option for Global Server Load Balancing.

Persistence sessions for a client last until the persistence timeout. After the timeout period expires, existing persistence sessions are cleared. For subsequent requests, a new GSLB decision is made and a different GSLB service IP address might be selected.
The source IP persistence on GSLB virtual server and site persistence on GSLB service complements each other. If source IP persistence is disabled on GSLB virtual server, the GSLB virtual server chooses a different GSLB service each time the DNS tries to do the resolution. The client also connects to a different GSLB service and the data center which receives the application request proxy the connection to the data center which served the client first. This might add some latency. So by enabling source IP persistence on GSLB virtual server can avoid frequent such multiple hops for application requests. If the source IP persistence session has expired and the client reconnects after that, the site persistence connects the client back to the data center, which had served the client initially. Also, if the client connects back through a DNS gateway, which does not fall within the persistence mask range configured, then as well site persistence helps clients stick to the data center that served the first request.

To configure persistence based on source IP address by using the CLI

At the command prompt, type:

```
set gslb vserver <name> -persistenceType (SOURCEIP|NONE) -persistenceId
    <positive_integer> [-persistMask <netmask>]  -[timeout <mins>]
```

```
2 <!--NeedCopy-->
```

Example:

```
1 set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -
     persistenceId 23 -persistMask 255.255.255.255  - timeout 2
2 <!--NeedCopy-->
```

To configure persistence based on source IP address by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Persistence** section and, from the **Persistence** drop-down list, select **SOURCEIP** and set the following parameters:
   - Persistence Id—persistenceID
   - Time-out—timeout
   - IPv4 Netmask or IPv6 Mask length—persistMask

Configure site persistence based on HTTP cookies

Site persistence is achieved using HTTP cookies (known as a “site cookie”) to reconnect the client to the same server. When the GSLB appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. Application endpoint in that GSLB site adds a site cookie to the HTTP header, and site persistence is in effect.
If the client sends a DNS query after the client cache is expired, the DNS request might be directed to a different GSLB site. The new GSLB site uses the site cookie present in the client request header to implement persistence. Site persistence feature becomes active under the following conditions:

- When the domain name in the host header matches one of the GSLB domains
- When site persistence is enabled on the GSLB service that represents the virtual server receiving the application traffic.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. If the GSLB service pointed by the cookie is DOWN or removed from the GLSB configuration, then the virtual server that receives the traffic continues to process the traffic. The cookie expiration is based on the cookie timeout configured on the Citrix ADC appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

Citrix ADC supports two types of site persistence:

- Connection Proxy
- HTTP redirect

Connection Proxy

In the Connection Proxy mode of site persistence, the data center that receives the subsequent application request performs the following tasks to establish a connection:

1. Creates a connection to the GSLB site that inserted the site cookie.
2. Proxies the client request to the original site.

   > **Note:**
   >
   > The proxy server establishes connection with the original site using the following details:
   >
   > - The SNIP of the new site is the source IP address.
   > - The GSLB service public IP address of the original site is the destination IP address.
   > - An ephemeral port is the source port and GSLB service port is the destination port.
   > - Uses either HTTP or HTTPS protocols depending on the GSLB service type.

3. Receives a response from the original GSLB site.
4. Relays that response back to the client.
5. Closes the connection.

HTTP redirect

If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie. Domain name in the redirect URL is the site domain. Ensure that both cookies and SSL certificates are applicable to both GSLB domain and site domain. To apply cookies for both GSLB and site domain, the cookie domain must be the site to GSLB domain. To apply SSL certificates to both GSLB and site domain, certificate bound to the SSL virtual server must be a wildcard certificate.

Connection proxy occurs when the following conditions are satisfied:

- Requests are sent for a domain participating in GSLB. The domain is obtained from the URL/Host header.
- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

> **Note**
>
> In a GSLB parent-child configuration, the connection proxy works as intended even when a GSLB service is not configured on a child site. However, if you have extra configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the site and configure it accordingly.

> For more information about parent-child topology, see Parent-Child Topology Deployment Using the MEP Protocol.

To set persistence based on HTTP cookies by using the CLI

At the command prompt, type:

```
set gslb service <serviceName> -sitePersistence (ConnectionProxy [-
   sitePrefix <prefix>] | HTTPredirect -sitePrefix <prefix>)
<!--NeedCopy-->
```

Example:

```
set gslb service service-GSLB-1 -sitePersistence ConnectionProxy
set gslb service service-GSLB-1 -sitePersistence HTTPRedirect -
   sitePrefix vserver-GSLB-1
<!--NeedCopy-->
```

To set persistence based on cookies by using the GUI

1. Navigate to **Traffic Management** > **GSLB** > **Services** and select the service that you want to configure for site persistence (for example, service-GSLB-1).
2. Click the **Site Persistence** section and set persistence based on cookies.

Manage client connections

September 14, 2021

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

Enable delayed cleanup of virtual server connections

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the Citrix ADC appliance performs a delayed cleanup of connections to a GSLB service that is down.

To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

```
set gslb service <name> -downStateFlush (ENABLED | DISABLED)
show gslb service <name>
<!--NeedCopy-->
```

Example:

```
set gslb service Service-GSLB-1 -downStateFlush ENABLED
Done

show gslb service Service-GSLB-1
Done
<!--NeedCopy-->
```

To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Services** and double-click the service.
2. Click the **Other Settings** section and select the **Down State Flush** option.

Manage local DNS traffic by using DNS policies

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the Citrix ADC appliance.

DNS expressions

The Citrix ADC appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called *rules*) are combined to create DNS policies that are then bound globally on the Citrix ADC appliance.

Following is the list of predefined DNS qualifiers available on the Citrix ADC appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ(“domainname”)
- CLIENT.UDP.DNS.IS_AREC
- CLIENT.UDP.DNS.IS_AAAAREC
- CLIENT.UDP.DNS.IS_SRVREC
- CLIENT.UDP.DNS.IS_MXREC
- CLIENT.UDP.DNS.IS_SOAREC
- CLIENT.UDP.DNS.IS_PTRREC
- CLIENT.UDP.DNS.IS_CNAME
- CLIENT.UDP.DNS.IS_NSREC
- CLIENT.UDP.DNS.IS_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH(“abc.com.”)

To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).
4. In the Value box, type a value (for example, Asia, Japan….).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

Configure DNS actions

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see Adding DNS Views.
- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see Overriding Static Proximity Behavior by Configuring Preferred Locations.
- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
- Forward a request to the name server without performing a lookup in the appliance’s DNS cache.
- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, dns_default_act_Drop. If you want to bypass the DNS cache, use the built-in action, dns_default_act_Cachebypass. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

```
add dns action <actionName> <actionType> (-IPAddress <ip_addr |
    ipv6_addr> ... | -viewName <string> | -preferredLocList <string>
    ...) [-TTL <secs>]

show dns action [<actionName>]
<!--NeedCopy-->
```

Examples

Example 1: Configuring DNS Response Rewrite. The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:

```
add dns action dns_act_response_rewrite Rewrite_Response -IPAddress
    192.0.2.20 192.0.2.56 198.51.100.10
 Done

show dns action dns_act_response_rewrite
1)  ActionName:  dns_act_response_rewrite ActionType:  Rewrite_Response
     TTL:  3600               IPAddress:  192.0.2.20 192.0.2.56
    198.51.100.10
 Done
<!--NeedCopy-->
```

Example 2: Configuring a DNS-View Based Response. The following DNS action sends the client an IP address for which you have configured a DNS view:

```
add dns action send_ip_from_view_internal_ip ViewName -viewName
    view_internal_ip
Done

show dns action send_ip_from_view_internal_ip
1)  ActionName:  send_ip_from_view_internal_ip ActionType:  ViewName
      ViewName:  view_internal_ip
```

```
6   Done
7  <!--NeedCopy-->
```

Example 3: Configuring a Response Based on a Preferred Location List. The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```
1  add dns action send_preferred_location GslbPrefLoc -preferredLocList NA
      .tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
2  Done
3
4  show dns action  send_preferred_location
5  1)  ActionName:  send_preferred_location ActionType:  GslbPrefLoc
      PreferredLocList:  "NA.tx.ns1.*.*.*" "NA.tx.ns2.*.*.*" "NA.tx.ns3
      .*.*.*"
6   Done
7  <!--NeedCopy-->
```

To configure a DNS action by using the Citrix ADC configuration utility

1. Navigate to Traffic Management > DNS > Actions, create or edit a DNS action.
2. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
   - Action Name (cannot be changed for an existing DNS action)
   - Type (cannot be changed for an existing DNS action)
     To set the
     Type parameter, do one of the following:
     - To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
     - To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
     - To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.
   - TTL (applicable only to the Rewrite Response action type)

Configure DNS policies

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation

marks (‘’) as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the Citrix ADC appliance.

- A maximum of 64 policies are supported.
- DNS policies are global to the Citrix ADC appliance and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure

- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see "Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol" in "Policy Configuration and Reference".

To add a DNS policy by using the command line interface

At the command prompt, type the following commands to create a DNS policy and verify the configuration:

```
add dns policy <name> <rule> <actionName>
show dns policy <name>
<!--NeedCopy-->
```

Example:

```
> add dns policy policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ("domainname")'
    my_dns_action
 Done
> show dns policy policy-GSLB-1
    Name: policy-GSLB-1
    Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
    Action Name: my_dns_action
    Hits: 0
    Undef Hits: 0

 Done
<!--NeedCopy-->
```

To remove a configured DNS policy by using the command line interface

At the command prompt, type:

```
rm dns policy <name>
<!--NeedCopy-->
```

To configure a DNS policy by using the Citrix ADC configuration utility

1. Navigate to Traffic Management > DNS > Policies and create a DNS policy.

2. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
   - Policy Name (cannot be changed for an existing policy)
   - Action
   - Expression

     To specify an expression, do the following:
     a) Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the firs expression element.
     b) In the second list, select the expression element that you want, and then enter a period.
     c) After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.
3. Click Create or OK, and then click Close.

Bind DNS policies

DNS policies are bound globally on the Citrix ADC appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the bind dns global command accepts REQ_OVERRIDE and RES_OVERRIDE as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the REQ_DEFAULT and RES_DEFAULT bind points.

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

```
bind dns global <policyName> <priority> [-gotoPriorityExpression <
    string>] [-type <type>]
show dns global -type <type>
<!--NeedCopy-->
```

Example:

```
bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
 Done
show dns global -type REQ_DEFAULT
1)  Policy Name: policy-GSLB-1
```

```
    Priority: 10
    GotoPriorityExpression: END
 Done
<!--NeedCopy-->
```

To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.

To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

```
show dns global
```

To view the global bindings of a DNS policy by using the configuration utility

1. Navigate to **Traffic Management** > **DNS** > **Policies**.
2. In the details pane, click **Global Bindings**. The global bindings of all DNS policies appear in this dialog box.

Adding DNS Views

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company's domain and have the server hosted in your company's network, clients querying for the domain from within your company's internal network can be provided with the server's internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain's public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see **Managing Local DNS Traffic by Using DNS Policies**.

To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

```
1 add dns view <viewName>
2 show dns view <viewName>
3 <!--NeedCopy-->
```

Example:

```
1 add dns view PrivateSubnet
2 show dns view PrivateSubnet
3 <!--NeedCopy-->
```

To remove a DNS view by using the command line interface

At the command prompt, type:

```
1 rm dns view <viewName>
2 <!--NeedCopy-->
```

To add a DNS view by using the configuration utility

Navigate to Traffic Management > DNS > Views and add a DNS view.

For details on how to create a DNS policy and how to bind DNS policies globally, see **Managing Local DNS Traffic by Using DNS Policies**.

Configure GSLB for proximity

September 14, 2021

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

Configure dynamic round trip time (RTT) method

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the Citrix ADC appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see Configuring Dynamic RTT.

Configure static proximity

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The Citrix ADC appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the Citrix ADC appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB set up and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see Configuring Static Proximity.

Configure static proximity and dynamic RTT

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see Configuring Static Proximity and for details on how to configure dynamic RTT, see Configuring Dynamic RTT.

Protect the GSLB setup against failure

September 14, 2021

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring the following:

- A backup GSLB virtual server
- A Citrix ADC appliance to respond with multiple IP addresses

- A backup IP address for a GSLB domain

You can also divert excess traffic to a backup virtual server by using spillover.

Configure a backup GSLB virtual server

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what must happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the disablePrimaryOnDown option).

Note: You can configure a single backup entity as backup for multiple GSLB virtual servers.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as backup virtual server and verify the configuration:

```
set gslb vserver <name> -backupVServer <name> [-disablePrimaryOnDown (
    ENABLED | DISABLED)]

show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -
    disablePrimaryOnDown ENABLED
show gslb vserver vserver-GSLB-1
<!--NeedCopy-->
```

To set GSLB virtual server as a backup virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers**, and double-click the GSLB virtual server.
2. Select the **Backup Virtual Server** section and choose the backup virtual server.

Configure a GSLB setup to respond with multiple IP addresses

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP responses (MIR), the Citrix ADC appliance sends the best GSLB service as the first

record in the response and adds the remaining active services as extra records. If MIR is disabled (the default), the Citrix ADC appliance sends the best service as the only record in response.

To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

```
set gslb vserver<name> -MIR (ENABLED | DISABLED)
-  show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
set gslb vserver vserver-GSLB-1 -MIR ENABLED
 show gslb vserver <vserverName>
<!--NeedCopy-->
```

To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the **Advanced** tab, under When this virtual server is "UP," select the Send all "active" service IP in response (MIR) check box, and select **OK**.

Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.

To configure a GSLB virtual server for empty down responses by using the command line interface

At the command prompt, type:

```
set gslb vserver<name> -EDR (ENABLED | DISABLED)
<!--NeedCopy-->
```

Example:

```
> set gslb vserver vserver-GSLB-1 -EDR ENABLED
 Done
<!--NeedCopy-->
```

To set a GSLB virtual server for empty down responses by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this virtual server is “Down,” select the Do not send any service’s IP address in response (EDR) check box.
3. Click **OK**.

Configure a backup IP address for a GSLB domain

You can configure a backup site for your GSLB configuration. With this configuration in place, if all the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site’s IP address.

Note: When a backup IP address is sent, persistence is not honored.

To set a backup IP address for a domain by using the command line interface

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

```
set gslb vserver <name> -domainName <string> -backupIP <IPAddress>
show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP
   10.102.29.66
show gslb vserver vserver-GSLB-1
<!--NeedCopy-->
```

To set a backup IP address for a domain by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
2. Click the **Domains** section, configure the GSLB domain and specify the IP address of the backup domain in the **Backup IP** field.

Divert excess traffic to a backup virtual server

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured by the number of connections, bandwidth, and health of the services.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective

state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIPs is absent or down, the effective state is set to DOWN.
- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.
- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

To configure backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure backup GSLB virtual server and verify the configuration:

```
set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -
    soPersistence ( **ENABLED** | **DISABLED** ) -soPersistenceTimeout <
    timeout>
show gslb vserver <name>
<!--NeedCopy-->
```

Example:

```
set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000
    -soPersistence ENABLED -soPersistenceTimeout 2
show gslb vserver Vserver-GSLB-1
<!--NeedCopy-->
```

To configure backup GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **GSLB** > **Virtual Servers** and double-click the virtual server that you want to configure as backup (for example, Vserver-LB-1).
2. Click the **SpillOver** section and set the following parameters:
   - Method— soMethod
   - Threshold— soThreshold
   - Persistence Time-out (min) — soPersistenceTimeout
3. Select the Persistence option and click **OK**.

Configure GSLB for disaster recovery

September 14, 2021

Disaster recovery capability is critical, because downtime is costly. A Citrix ADC appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

Configure GSLB for disaster recovery in an active-standby data center setup

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
  - Add a local GSLB site.
  - Add a GSLB vserver, which represents the active data center.
  - Bind the domain to the GSLB virtual server.
  - Add gslb services and bind the services to active GSLB virtual server.
- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

```
set gslb vserver <name> -backupVserver <string>
<!--NeedCopy-->
```

Example:

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
<!--NeedCopy-->
```

To configure the standby site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for the primary site.
2. Click the **Backup Virtual Server** section and select a backup virtual server.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the
'disable primary on down' option.

Configure for disaster recovery in an active-active data center setup

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Configuring for Disaster Recovery with Weighted Round Robin

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the Citrix ADC appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual server. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

```
add lb vserver <name>@ -weight <WeightValue> <ServiceName>
set lb vserver <name>@ -weight <WeightValue> <ServiceName>
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
set lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1
<!--NeedCopy-->
```

To set dynamic weight by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -dynamicWeight DynamicWeightType
<!--NeedCopy-->
```

Example:

```
set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight
<!--NeedCopy-->
```

To add weights to the GSLB services by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -serviceName GSLBServiceName -weight
   WeightValue
<!--NeedCopy-->
```

Example:

```
set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1
<!--NeedCopy-->
```

To configure a virtual server to assign weights to services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and double-click the virtual server (for example, Vserver-LB-1).
2. Click the Services section and set the weight of a service.

To add weights to the GSLB services by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1)
2. Click the Services section and set the weight of the service in the Weight field.

To set dynamic weight by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list select **SERVICEWEIGHT**.

Configuring for Disaster Recovery with Data Center Persistence

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB set up and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the Citrix ADC appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

```
set gslb service <serviceName> -sitePersistence <sitePersistence> -
   sitePrefix <string>
show gslb service <serviceName>
<!--NeedCopy-->
```

Example:

```
set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -
   sitePrefix vserver-GSLB-1
show gslb service Service-GSLB-1
<!--NeedCopy-->
```

To configure HTTP redirect by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the GSLB service to be configured.
2. Click the **Site Persistence** section, select the **HTTPRedirect** option, and in the **Site Prefix** text box, enter the site prefix (for example, vserver-GSLB-1).

> **Note**
>
> When site persistence is not configured and if a load balancing virtual server that is configured as a local GSLB service is DOWN, the HTTP requests are redirected to other healthy GSLB sites using a 302 redirect.

Override static proximity behavior by configuring preferred locations

September 14, 2021

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a *preferred location* for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see Configuring a DNS Action.
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see Adding Custom Entries to a Static Proximity Database. When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to
TRUE, the Citrix ADC appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of *.UK.*.* or Europe.UK.*.* is a perfect match for the preferred location *.UK.*.*.

- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to
TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

   If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

   If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

   In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```
> add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "
   Europe.UK"
 Done
> add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION("*.ZMB
   .*.*")" prefLoc11
 Done
<!--NeedCopy-->
```

When the appliance receives a request from the location *.ZMB..**, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.

Configure GSLB service selection using content switching

September 14, 2021

In a typical GSLB deployment, you can prioritize the selection of a set of GSLB services bound to a GSLB virtual server, but you cannot do the following:

- Restrict the selection of a GSLB service from a subset of GSLB services bound to a GSLB virtual server for the given domain.

- Apply different load balancing methods on the different subsets of GSLB services in the deployment.
- Apply spillover policies on a subset of GSLB services, and you cannot have a backup for a subset of GSLB services.
- Configure a subset of GSLB services to serve different content. That is, you cannot content switch between servers in different GSLB sites. The GSLB configuration assumes that the servers contain the same content.
- Define a subset GSLB service with different priorities and specify an order in which the services in the subset are applied to a request.

You can now configure a content switching (CS) policy to customize the GSLB deployment. First configure a set of GSLB services and bind it to a GSLB virtual server. Then, configure a CS virtual server of target type GSLB, define a CS policy and action with the GSLB virtual server as target virtual server, and bind the CS policy to CS virtual server.

> **Important**
>
> - Only CS policies with DNS based expressions can be bound to a CS virtual server of target type GSLB.
> - If a GLSB service is bound to a CS virtual server through a GSLB virtual server, you cannot bind another GSLB virtual server bound with the same GSLB service to the CS virtual server.

Example

Consider a GLSB deployment that includes two GSLB sites. At each site, four GSLB services (S-1, S-2, S-3, and S-4) are bound to GSLB virtual server VS-1. You can configure a content switching (CS) virtual server of target type GSLB and define a CS policy and action with VS-1 as the target virtual server, so that requests for content in English are served only by S-1 and S-2, and requests for content in the local language are served only by S-3 and S-4.

You can give S-1 priority by configuring a backup virtual server to VS-1 and binding S-2 to the backup virtual server. S-1 serves the client requests. If the server S-1 represents goes down, S-2 serves the requests. If both S-1 and S-2 are down, clients receive an empty response.

To configure GSLB Service Selection using Content Switching:

1. Configure GSLB. For instructions, see Configuring Global Server Load Balancing.
2. Configure a Content Switching (CS) virtual server of target type GSLB. For more information, see Creating Content Switching Virtual Servers.
3. Configure Content Switching (CS) policies. For more information, see Configuring Content Switching Policies.
4. Configure CS actions that designate a GSLB virtual server as the target virtual server. For more information, see Configuring a Content Switching Action.
5. Bind the CS policies to the CS virtual server. For more information, see Binding Policies to a Content Switching Virtual Server.

6. Bind the domain to the CS virtual server instead of the GSLB virtual server.

Sample Configuration

The following sample configuration sends requests from the client with IP address 5.5.5.5 to SERVICE_GSLB1 and SERVICE_GSLB2. SERVICE_GSLB1 has a higher priority than SERVICE_GSLB2, and SERVICE_GSLB2 serves the client requests only when SERVICE_GSLB1 is down. If both SERVICE_GSLB1 and SERVICE_GSLB2 are down, SERVICE_GSLB3 and service-GSLB4 are not considered, and a blank response is sent to the client.

```
add cs vs CSVSERVER_GSLB http  -targettype GSLB

Associate a target virtual server expression to a GSLB content switching action

You can now associate a target virtual server expression to a GSLB content switching action. This allows GSLB content switching virtual server to use policy expressions to compose the target GSLB virtual server name while processing the DNS requests.

To configure a content switching action that specifies an expression by using the CLI

At the command prompt, type the following command to configure the content switching action to retrieve the HTTP callout response.

```
add cs action <name> -targetVserverExpr <expression>
<!--NeedCopy-->
```

Example:

```
add cs action csact_GSLB_VServer -targetVserverExpr "SYS.HTTP_CALLOUT(
   GSLB_Method_API)"
<!--NeedCopy-->
```

To configure a content switching action that specifies an expression by using the GUI

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify an **Expression** that dynamically computes the name of the target load balancing virtual server.

Configure GSLB for DNS queries with NAPTR records

September 14, 2021

In a typical Global Server Load Balancing (GSLB) deployment, the Citrix ADC appliance receives DNS queries for A/AAAA records, selects the most appropriate GSLB service according to the configured

load balancing method, and returns the service's IP address as a reply to the DNS query. You can now configure the appliance to receive DNS queries for NAPTR records and respond with the list of services configured for a domain. The appliance also monitors the health of the services, and in the response it provides a list of only the services that are up.

Example:

In Telco deployments, you can configure a Citrix ADC appliance to receive DNS queries with NAPTR records from clients such as mobile management entities (MMEs), which play the role of a DNS resolver to discover all the services that are offered by the domain name. The appliance responds to the query with NAPTR records for all the services that are up. The MME can use this NAPTR response to run the S-NAPTR procedure to select the nodes on the basis of the service offered, colocation, topological closeness, and so on.

If multiple nodes qualify for selection, the MME can use the preference field in the NAPTR record from the Citrix ADC appliance to determine the node.

NAPTR Record Format

While responding to a DNS query with NAPTR record, a Citrix ADC appliance constructs a response NAPTR record for each GSLB service.

The following table lists the files in the NAPTR record:

Field	
Domain	The GSLB domain
TTL	The amount of time for which the NAPTR record can be cached.
Class	The class of the record. By default, this value is set to IN.
Type	The DNS record type.
Order	Specifies the order in which the NAPTR record MUST be processed. You can specify the order in the GSLB service. Otherwise, it is set to 1.
Preference	Specifies the order in which NAPTR records with equal "order" values SHOULD be processed, low numbers being processed before high numbers. If the order is not specified in the GSLB service, it is set to 1.

Field	
Flags	Controls the aspects of the rewriting and interpretation of the fields in the record. The Citrix ADC appliance sets this value to A.
Service	Specifies the available service(s).
Regular Expression	Regular expressions are not supported, so this value is set to NULL.
Replacement	The domain name of the node that hosts the services.

Configuration procedure

For detailed GSLB configuration instructions, see Configuring Global Server Load Balancing (GSLB). Make sure that you do the following:

- Set the following parameters while adding the GSLB virtual server:
  - serviceType: ANY
  - dnsRecordType: NAPTR
  - lbMethod: CUSTOMLOAD

Example:

```
add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
<!--NeedCopy-->
```

- While adding a GSLB site, set the *naptrReplacementSuffix* parameter to the domain name that you want to embed in the NAPTR records.

Example:

```
add gslb site site1 10.102.218.200  -naptrReplacementSuffix example.com
<!--NeedCopy-->
```

- Set the following parameters while adding the GSLB service:
  - naptrreplacement
  - naptrOrder
  - naptrServices
  - naptrDomainTTL
  - naptrPreference

Sample configuration

```
add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD

Done

add gslb site site1 10.102.218.200  -naptrReplacementSuffix example.com

Done

add gslb service sgw1 3.3.3.13 ANY *  -siteName site1 -naptrreplacement
     sgw1.site1. -naptrOrder 2 -naptrServices x-3gpp-sgw:x-s5-gtp -
    naptrDomainTTL 20 -naptrPreference   200

Done

add gslb service sgw2 3.3.3.11 ANY *  -siteName site1 -naptrreplacement
     sgw2.site1. -naptrOrder 5 -naptrServices x-3gpp-sgw:x-s5-gtp  -
    naptrDomainTTL 20  naptrPreference  100

Done

add gslb service sgw3 3.3.3.12 ANY *  -siteName site2 -naptrreplacement
     sgw3.site1. -naptrOrder 10 -naptrServices x-3gpp-sgw:x-s5-gtp  -
    naptrDomainTTL 20 naptrPreference   300

bind gslb vserver gslb_vs -serviceName sgw1

Done

bind gslb vserver gslb_vs -serviceName sgw2

Done

bind gslb vserver gslb_vs -serviceName sgw3

Done

bind gslb service sgw1 -monitorName ping

Done

bind gslb service sgw2 -monitorName ping

Done
```

```
38
39 bind gslb service sgw3 -monitorName ping
40
41 Done
42
43 bind gslb vserver gslb_vs -domainName gslb.com -TTL 5
44
45 Done
46 <!--NeedCopy-->
```

> **Note**
>
> DNS queries with NAPTR records are not supported in parent-child configuration.

Configure GSLB for wildcard domain

September 14, 2021

You can bind a wildcard DNS domain to a GSLB virtual server. Users accessing the applications behind a wildcard domain are routed to the best optimal data center, which hosts those applications. The wildcard domain handles requests for non-existent domains and subdomains. For more information about wildcard domains, see Supporting wildcard DNS domains.

To configure GSLB for a wildcard domain, you must first configure the basic GSLB setup. For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

To configure a GSLB setup for wildcard domain by using the CLI

Perform the following steps to configure a GSLB setup for wildcard domain:

1. Create the GSLB sites.

```
1 add gslb site site1 10.0.1.10
2 add gslb site site2 20.0.1.10
3 <!--NeedCopy-->
```

2. Add the GSLB services for each site participating in the GSLB setup.

```
1 add gslb service svc1 -sitename site1 10.0.1.10  http 80
2 add gslb service svc2 -sitename site1 10.0.1.10  http 80
3 add gslb service svc3 -sitename site2 20.0.1.10  http 80
4 add gslb service svc4 -sitename site2 20.0.1.10  http 80
5 <!--NeedCopy-->
```

3. Add the GSLB virtual server that references a service being used in the GSLB setup.

```
add gslb vserver gslb_vs http
<!--NeedCopy-->
```

4. Add an ADNS service that listens to the DNS queries.

```
add service adns_udp 10.14.39.21 ADNS 53
<!--NeedCopy-->
```

5. Bind the GSLB services to the GSLB virtual server.

```
bind gslb vserver gslb_vs -service svc1
bind gslb vserver gslb_vs -service svc2
bind gslb vserver gslb_vs -service svc3
bind gslb vserver gslb_vs -service svc4
<!--NeedCopy-->
```

6. Create a zone.

```
add dns soaRec test.com -originServer n1.test.com -contact n1.test
    .com
add dns nsrec test.com n1.test.com
add dns nsrec test.com n2.test.com
add dns zone test.com -proxymode no
<!--NeedCopy-->
```

7. Bind the domain name to the GSLB virtual server.

```
bind gslb vserver gslb_vs -domainName *.test.com
<!--NeedCopy-->
```

Use the EDNS0 client subnet option for Global Server Load Balancing

September 14, 2021

EDNS Client Subnet (ECS) is a Domain Name Server (DNS) header extension that provides the client subnet details. You can use these details to improve the accuracy of Citrix ADC Global Server Load Balancing (GSLB) by using the client network location rather than the DNS resolver location to determine the topological closeness of the client.

> **Note**
>
> Citrix ADC supports only EDNS0.

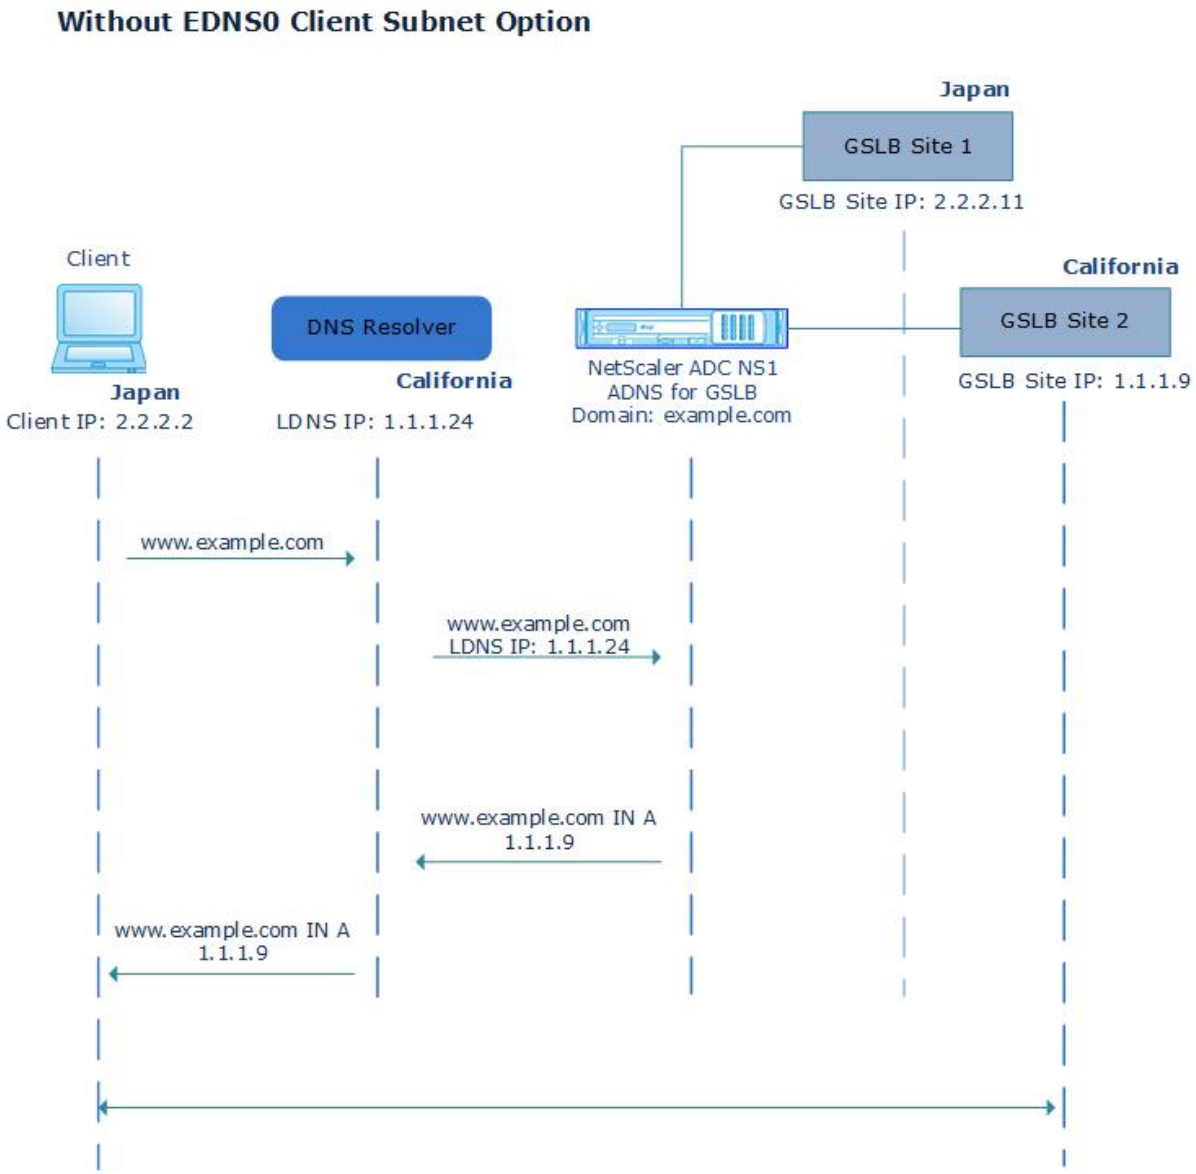
Important:

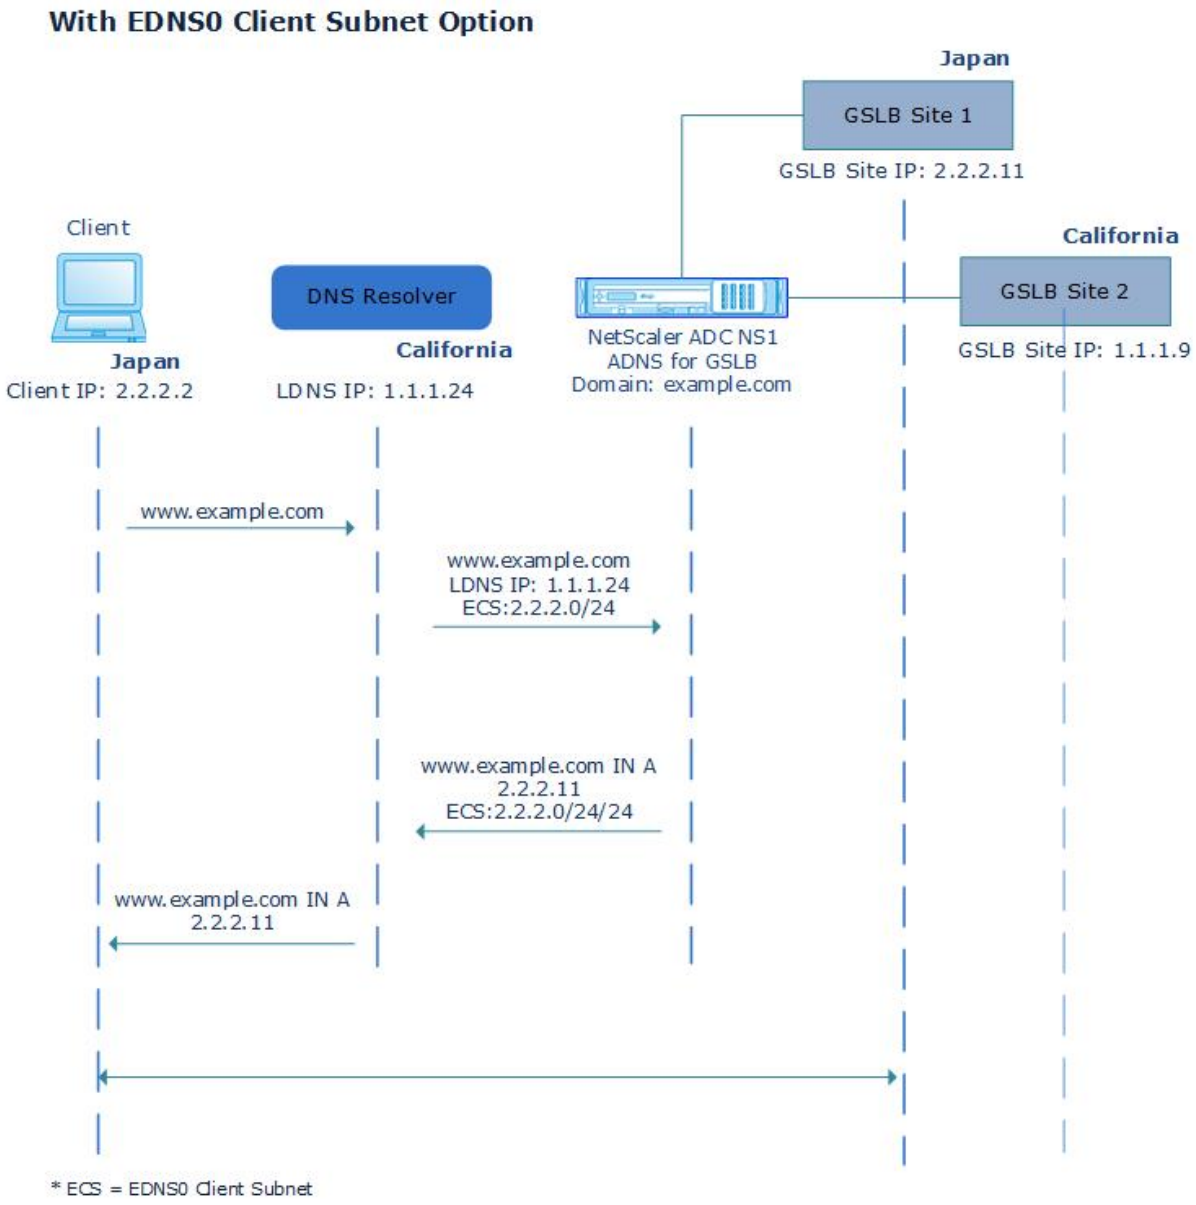
> Make sure that the Local Domain Name Server (LDNS) in your deployment supports the EDNS0 Client Subnet so that the incoming DNS queries contain the EDNS0 Client Subnet option and the Citrix ADC appliance uses the ECS address while processing the DNS query.

The Citrix ADC appliance uses the LDNS IP address for determining the topological closeness of the client and performs GSLB so, when you use proximity-based load balancing methods like static proximity or dynamic round-trip time (RTT). It happens in a typical GSLB deployment. But when a centralized DNS resolver, such as Google DNS or OpenDNS, is involved in the deployment, the Citrix ADC appliance sends the DNS request to a data center close to the centralized DNS resolver, which might not be close to the client. For example, in a typical Citrix ADC GSLB deployment using the static proximity load balancing method, an end-user request from Japan is sent to a data center in Japan and an end user request from California is sent to a data center in California. But if a centralized DNS resolver is involved, the Citrix ADC appliance might send a request from Japan to a data center in California.

You can use the ECS option in deployments that include the Citrix ADC appliance configured as an Authoritative DNS (ADNS) server for a GSLB domain. If you use static proximity as the load balancing method, you can use the IP subnet in the EDNS header instead of the LDNS IP address. This helps to determine the geographical proximity of the client. In proxy mode deployment, the Citrix ADC appliance forwards an ECS-enabled DNS query as-is to the back-end servers. The appliance does not cache ECS-enabled DNS responses.

> **Note**
>
> The ECS option is not applicable for all other deployment modes, such as ADNS mode for non-GSLB domains, resolver mode, and forwarder mode. The ECS option is ignored by the Citrix ADC appliance in the preceding mentioned modes. Also, by default, ECS is disabled for GSLB deployment.





To enable the EDNS0 Client Subnet option by using the command line interface:

At the command prompt, type:

```
set gslb vserver <vserver_name> **-ECS ENABLED

set gslb vserver vserver-GSLB-1 -ECS ENABLED
<!--NeedCopy-->
```

Address validation

You can configure a GSLB virtual server to verify that the address returned by the EDNS0 Client Subnet (ECS) option of the DNS query is not a private or an unroutable IP address. With address validation enabled, the Citrix ADC appliance ignores the ECS address in the DNS query if it is listed in the following table, and instead uses the LDNS IP address for global server load balancing.

> **Note**
>
> By default, address validation is disabled.

Address Type	Address	Description
IPV4	10.0.0.0/8	For private use
	172.16.0.0/12	For private use
	192.168.0.0/16	For private use
	0.0.0.0/8	Refers to the host on the network
	100.64.0.0/10	Shared address space
	127.0.0.0/8	Loopback address
	169.254.0.0/16	Link Local IPv4 address as defined in RFC 3927
	192.0.0.0/24	Used for IETF protocol assignments, includes the private space 192.168.0.0/16
	192.0.2.0/24	Used for documentation purposes
	192.88.99.0/24	Used for 6to4 Relay Anycast
	198.18.0.0/15	Used in Device benchmark testing
	198.51.100.0/24	Used for documentation purposes
	203.0.113.0/24	Used for documentation purposes
	240.0.0.0/4	Used as reserved
	255.255.255.255/32	Used for broadcast

Address Type	Address	Description
IPv6	::1/128	loopback address
	::/128	unspecified address
	::ffff:0:0/96	IPv4-mapped address
	100::/64	discard-only address block
	2001::/23	Used for IETF protocol assignments
	2001::/32	TEREDO
	2001:2::/48	Used for benchmarking
	2001:db8::/32	Used for documentation purposes
	2001:10::/28	ORCHID
	2002::/16	Used for 6to4 Relay Anycast
	fc00::/7	Unique-local
	fe80::/10	Link-local Unicast addresses

To enable address validation by using the command line interface

At the command prompt, type:

```
set gslb vserver <vserver_name> -ecsAddrValidation ENABLED

set gslb vserver vserver-GSLB-1 -ecsAddrValidation ENABLED
<!--NeedCopy-->
```

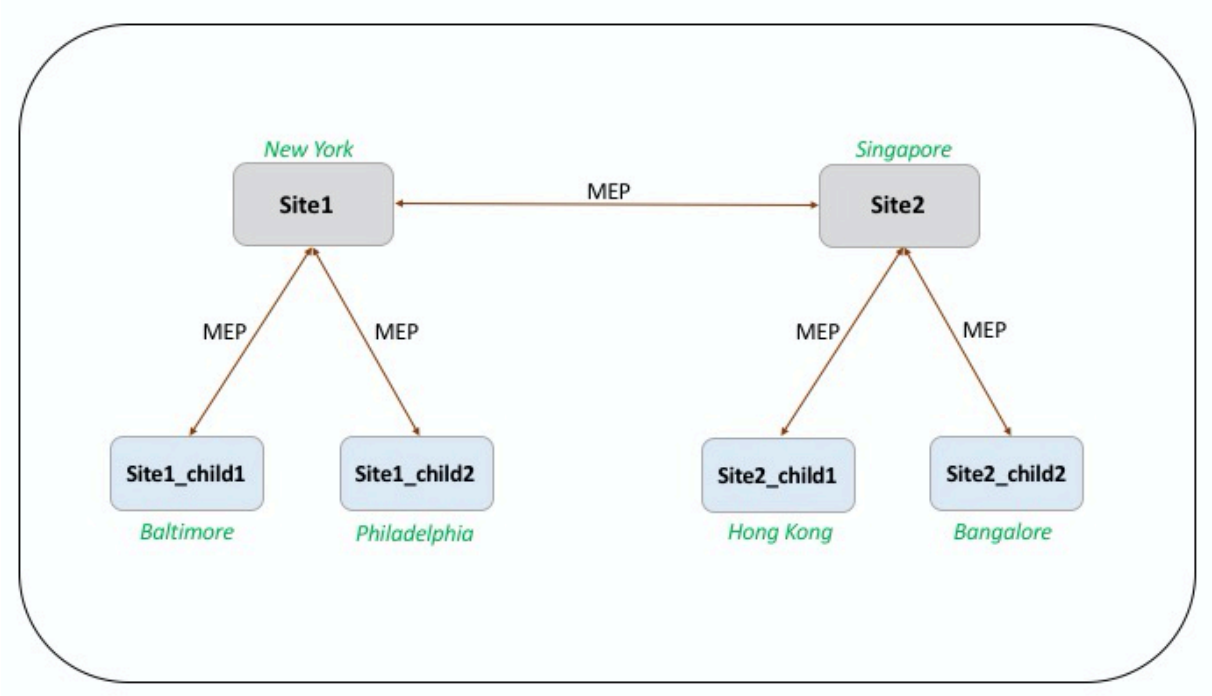
Example of a complete parent-child configuration using the metrics exchange protocol

September 14, 2021

Consider the following parent-child topology in which the GSLB sites are distributed globally.

- Site1 and Site2 are the parent sites.
- Site1_child1 and Site1_child2 are the child sites of Site1.

- Site2_child1 and Site2_child2 are the child sites of Site2.



The following commands illustrate the complete configuration of the parent-child topology.

site1

```
add gslb site site1 10.102.82.164 -publicIP 10.102.82.164

add gslb site site2 10.106.24.164 -publicIP 10.106.24.164

add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site1

add gslb site site1_child2 10.102.82.67 -publicIP 10.102.82.67 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site1

add gslb site site2_child1 10.106.24.132 -publicIP 10.106.24.132 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site2

add gslb site site2_child2 10.106.24.67 -publicIP 10.106.24.67 -
    nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
    site2

```

```
add gslb service site1_child1_http_gsvc1 10.102.82.132 HTTP 80 -

    cltTimeout 180

bind lb vserver lb1 svc1
<!--NeedCopy-->
```

Link load balancing

September 14, 2021

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the Citrix ADC appliance to monitor and control traffic so

that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the Citrix ADC appliance and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. A basic setup involves services, virtual servers, monitors, routes, an LLB method, and persistence (optional). Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.

Configuring a Basic LLB Setup

September 14, 2021

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical routers represented by the services. The virtual server selects a router by using the load balancing method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.

To configure a basic LLB setup, do the following:

- Configure services
- Configure an LLB virtual server and binding a service
- Configure the LLB method and persistence
- Configure an LLB route
- Create and bind a transparent monitor

Configure services

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in Creating and Binding a Transparent Monitor.

To create a service by using the command line interface

At the command prompt, type:

```
add service <name> <IP> <serviceType> <port>

show service <name>
<!--NeedCopy-->
```

Example:

```
add service ISP1R_svc_any 10.10.10.254 any *
show service ISP1R_svc_any
        ISP1R_svc_any (10.10.10.254:*) - ANY
        State: DOWN
        Last state change was at Tue Aug 31 04:31:13 2010
        Time since last state change: 2 days, 05:34:18.600
        Server Name: 10.10.10.254
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): YES
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: ping
                State: UP       Weight: 1
                Probes: 244705  Failed [Total: 0 Current: 0]
                Last response: Success - ICMP echo reply received.
                Response Time: 1.322 millisec
 Done
<!--NeedCopy-->
```

To create services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
   - Service Name*—name
   - Server—IP
   - Protocol*—serviceType (Select ANY from the drop-down list.)
   - Port*—port

A required parameter

1. Click Create.
2. Repeat Steps 2-4 to create another service.
3. Click Close.
4. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure an LLB virtual server and bind a service

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method, see Configuring the LLB Method and Persistence.

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

```
add lb vserver <name> <serviceType>

bind lb vserver < name> <serviceName>

show lb vserver < name>
<!--NeedCopy-->
```

Example:

```
add lb vserver LLB-vip any
bind lb vserver LLB-vip ISP1R_svc_any
sh lb vserver LLB-vip
```

```
        LLB-vip (0.0.0.0:0) - ANY    Type: ADDRESS
        State: DOWN
        Last state change was at Thu Sep  2 10:51:32 2010
        Time since last state change: 0 days, 17:51:46.770
        Effective State: DOWN
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  1 (Total)       0 (Active)
        Configured Method: ROUNDROBIN
        Mode: IP
        Persistence: NONE
        Connection Failover: DISABLED

1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN    Weight: 1
 Done
<!--NeedCopy-->
```

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
2. In the **IP Address Type** drop-down list, select the desired option. Select **Non Addressable** to create a virtual server that is not directly accessible.
3. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

Configure the LLB method and persistence

By default, the Citrix ADC appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

To configure the LLB method and/or persistence by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name> -lbMethod <lbMethod> -persistenceType <
    persistenceType>

```

```
show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver LLB-vip -lbmethod ROUNDROBIN -persistencetype SOURCEIP

show lb vserver LLB-vip
        LLB-vip (0.0.0.0:0) - ANY    Type: ADDRESS
        State: DOWN
        Last state change was at Fri Sep  3 04:46:48 2010
        Time since last state change: 0 days, 00:52:21.200
        Effective State: DOWN
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  0 (Total)       0 (Active)
        Configured Method: ROUNDROBIN
        Mode: IP
        Persistence: SOURCEIP
     Persistence Mask: 255.255.255.255       Persistence v6MaskLength:
         128   Persistence Timeout: 2 min
        Connection Failover: DISABLED
<!--NeedCopy-->
```

To configure the link load balancing method and/or persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the load balancing method and/or persistence settings.
2. In the **Advanced Settings** section, select Method and configure the load balancing method.
3. In the **Advanced Settings** section, select **Persistence** and configure the persistence parameters.

Configure an LLB route

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the LLB virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the LLB virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

```
add lb route <network> <netmask> <gatewayName>

show lb route [<network> <netmask>]
<!--NeedCopy-->
```

Example:

```
add lb route 0.0.0.0 0.0.0.0 LLB-vip
show lb route 0.0.0.0 0.0.0.0
       Network          Netmask        Gateway/VIP             Flags
     -----------      -------------   --------------          --------
1)     0.0.0.0          0.0.0.0        LLB-vip               UP
<!--NeedCopy-->
```

To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

```
add lb route6 <network> <gatewayName>

show lb route6
<!--NeedCopy-->
```

Example:

```
add lb route6 ::/0 llb6_vs show lb route6 Network VIP Flags -----------
    --------- -------- 1) ::/0 llb6_vs UP
<!--NeedCopy-->
```

To configure an LLB route by using the configuration utility

Navigate to System > Network > Routes, and select **LLB**, and configure the LLB route.

Note: Select LLBV6 to configure an IPV6 route.

To configure an LLB route by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the details pane, select one of the following:

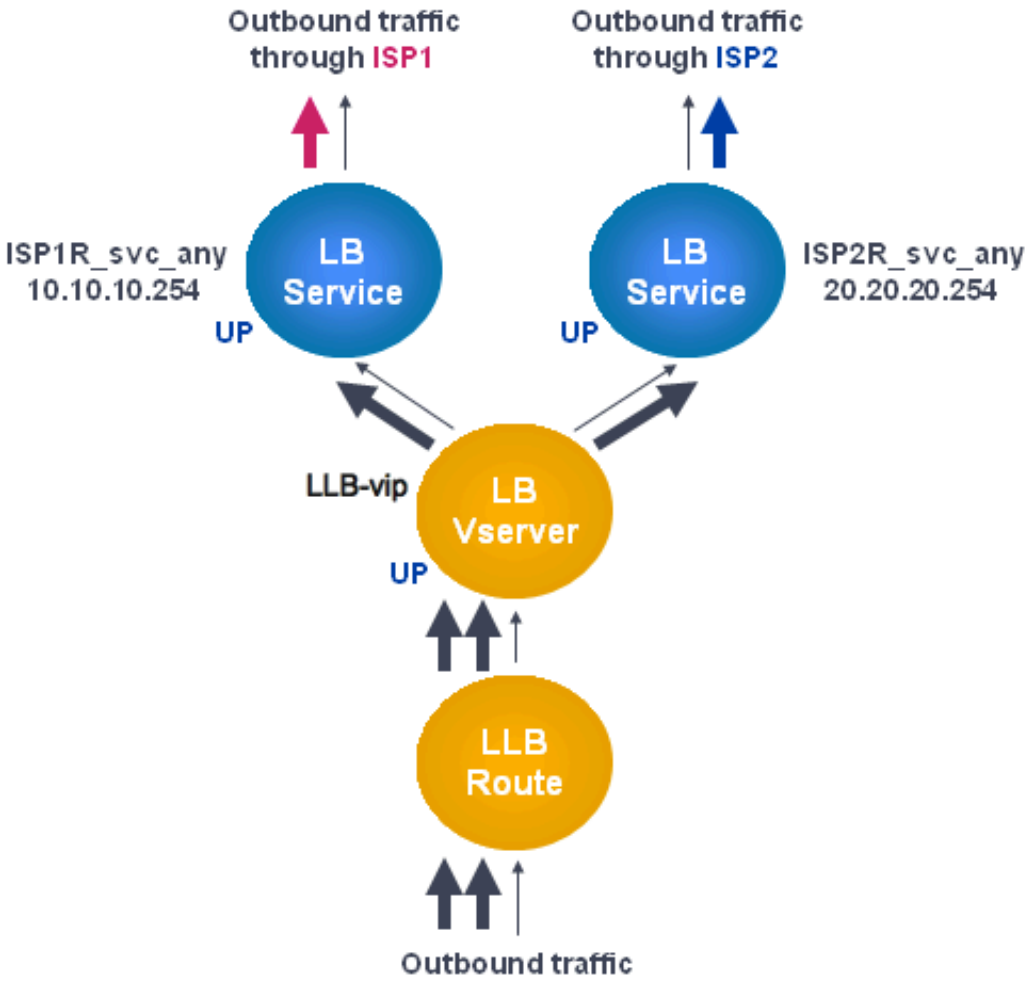
- Click LLB to configure an IPv4 route.
- Click LLBV6 to configure an IPv4 route.

3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:
   - Network*
   - Netmask*—Required for IPV4 routes.
   - Gateway Name*—gatewayName

     *A required parameter
4. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.

Figure 1. Basic LLB Setup



> **Note**
>
> If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

Create and bind a transparent monitor

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor,

if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

To create a transparent monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent
   YES

show lb monitor [<monitorName>]
<!--NeedCopy-->
```

Example:

```
add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
> show lb monitor monitor-1
1)   Name.......: monitor-1  Type......:      PING   State....:
   ENABLED
Standard parameters:
  Interval.........:            5 sec   Retries..........:
                    3
  Response timeout.:            2 sec   Down time........:
      30 sec
  Reverse..........:              NO   Transparent.......:
                  YES
  Secure...........:              NO   LRTM.............:
      ENABLED
  Action...........:   Not applicable   Deviation........:
      0 sec
  Destination IP...:      10.10.10.11
  Destination port.:    Bound service
  Iptunnel.........:              NO
  TOS..............:              NO   TOS ID...........:
                    0
  SNMP Alert Retries:               0     Success Retries..:
                    1
  Failure Retries..:                0
<!--NeedCopy-->
```

To create a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors and configure a transparent monitor.

To create a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:
   - Name*
   - Type*
   - Destination IP
   - Transparent

   *A required parameter
4. Click Create, and then click Close.
5. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the **Monitors** tab, under **Available**, select the monitor that you want to bind to the service, and then click **Add**.

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <serviceName>

show service <name>
<!--NeedCopy-->
```

Example:

```
bind lb monitor monitor-HTTP-1 ISP1R_svc_any
 Done
> show service ISP1R_svc_any
        ISP1R_svc_any (10.10.10.254:*) - ANY
        State: UP
        Last state change was at Thu Sep  2 10:51:07 2010
        Time since last state change: 0 days, 18:41:55.130
        Server Name: 10.10.10.254
```

```
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): YES
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: monitor-HTTP-1
                State: UP  Weight: 1
                Probes: 1256       Failed [Total: 0 Current: 0]
                Last response: Success - ICMP echo reply received.
                Response Time: 1.322 millisec
 Done
<!--NeedCopy-->
```

To bind a monitor to a service by using the configuration utility

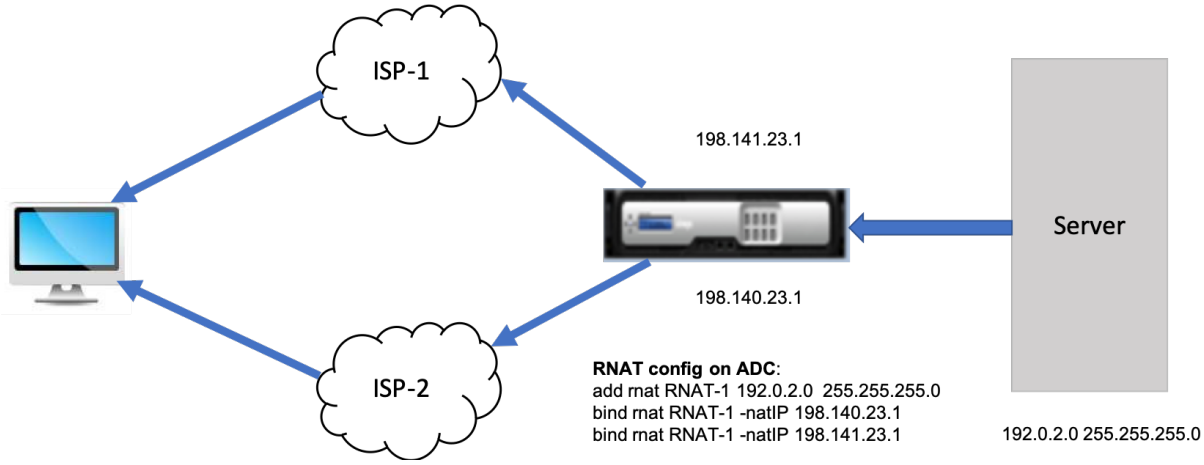
1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select a service to which you want to bind a monitor, and then click Open.
3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.
4. Click OK.
5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.

Configure RNAT with LLB

September 14, 2021

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. It ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in Configuring a Basic LLB Setup, and then configure RNAT as described in Configure RNAT. Then enable “use subnet IP (USNIP)” mode.

In the following diagram, the Citrix ADC appliance uses LLB to route outbound traffic to different links. During the RNAT operation, the ADC appliance replaces the source IP addresses of the outbound traffic with the public NAT IP address (198.141.23.1) to route the traffic through ISP-1. Similarly, the ADC appliance replaces the source IP addresses with 198.140.23.1 to route the traffic through ISP-2.



To add SNIPs for ISP routers by using the CLI

At the command prompt, type:

```
add NS IP <subnet of first ISP in the IP router> <subnet mask> -type
   SNIP

add NS IP <subnet of second ISP in the IP router> <subnet mask> -type
   SNIP
<!--NeedCopy-->
```

Example:

```
add ns ip 198.140.23.1 255.255.255.0 -type snip

add ns ip 198.141.23.1 255.255.255.0 -type snip
<!--NeedCopy-->
```

To configure RNAT by using the CLI

At the command prompt, type:

```
add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))

bind rnat <name> <natIP>@ ...

```

```
show rnat <name>
<!--NeedCopy-->
```

Example:

```
add rnat RNAT-1 192.0.2.0 255.255.255.0
bind rnat RNAT-1 -natIP 198.140.23.1
bind rnat RNAT-1 -natIP 198.141.23.1

> show rnat RNAT-1
    1) RNAT Name: RNAT-1     Network: 192.0.2.0      Netmask:
       255.255.255.0     Traffic Domain: 0
        UseProxyPort: ENABLED

        NatIP: 198.140.23.1
        NatIP: 198.141.23.1
<!--NeedCopy-->
```

To configure RNAT by using the GUI

1. Navigate to **System** > **Network** > **NATs**.
2. On the **RNAT** tab, click **Configure RNAT**.
3. Specify the network on which to perform RNAT.

> **Note**
>
> You can also configure RNAT by using Access Control Lists (ACLs). Refer Configuring RNAT for details.

To enable Use Subnet IP mode by using the CLI

At the command prompt, type:

```
enable ns mode USNIP

show ns mode
<!--NeedCopy-->
```

Example:

```
enable ns mode USNIP

show ns mode
        Mode                            Acronym             Status
```

```
5          -------                          -------              ------
6    1)    Fast Ramp                        FR                   ON
7    2)    … .
8    8)    Use Subnet IP                    USNIP                ON
9    9)    …
10 <!--NeedCopy-->
```

To enable Use Subnet IP mode by using the GUI

1. Navigate to **System** > **Settings** and, under **Modes and Features**, click **Configure Modes**.
2. In the **Configure Modes** dialog box, select **Use Subnet IP**, and then click **OK**.

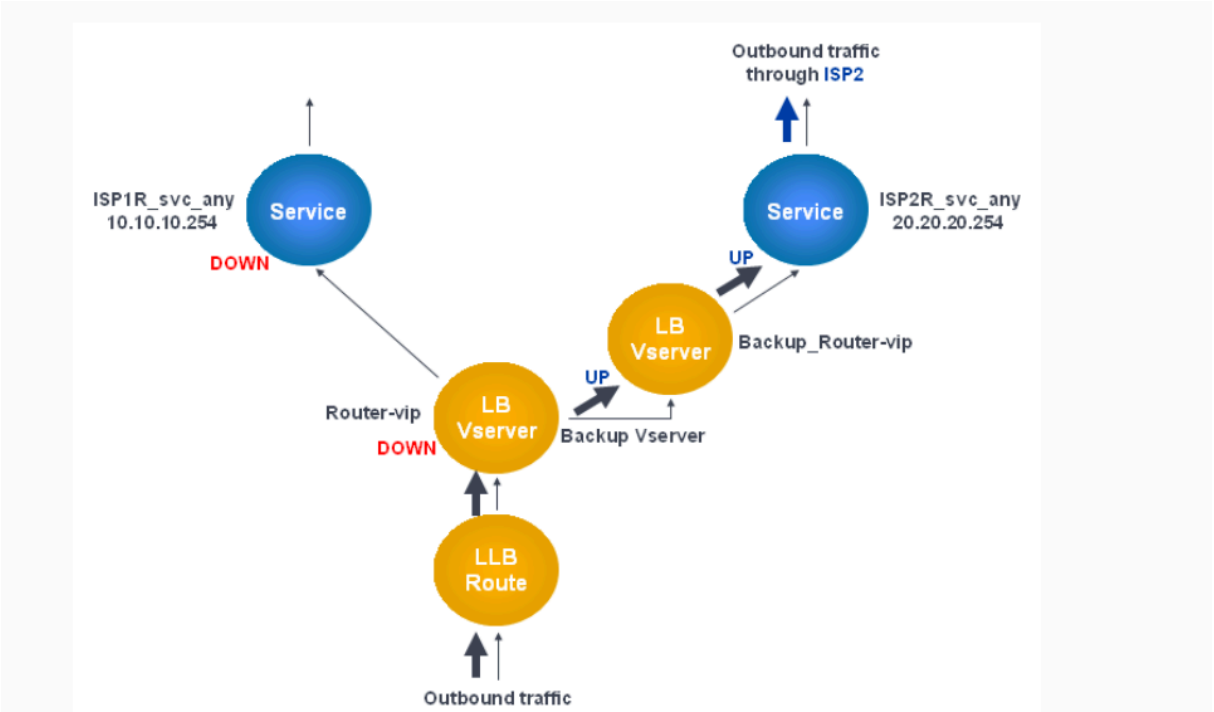
Configure a backup route

September 14, 2021

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the Citrix ADC appliance automatically uses it when the primary route fails. First create a primary virtual server as described in Configuring an LLB Virtual Server and Binding a Service. To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup_Router-vip** is the secondary virtual server designated as the backup virtual server.

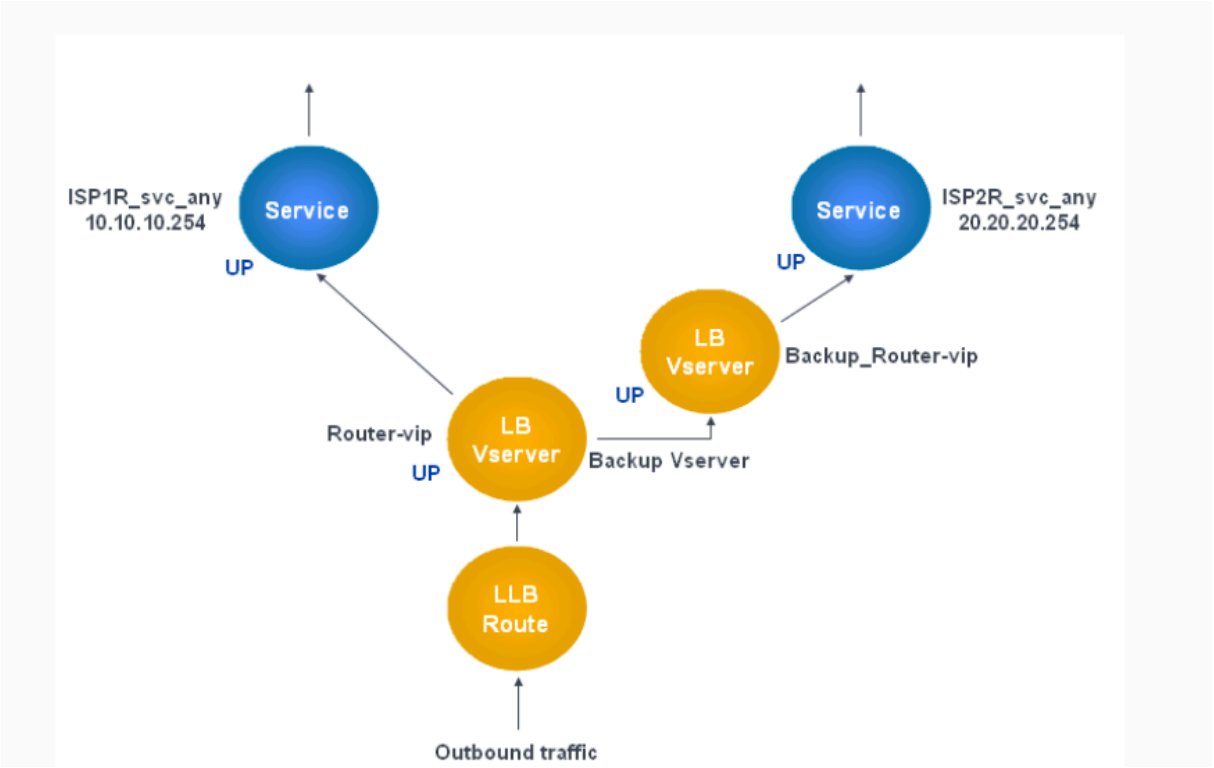
Figure 1. Backup Route Setup



Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Back up Routing in Operation



Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -backupVserver <string>
<!--NeedCopy-->
```

Example:

```
set lb vserver Router-vip -backupVServer Backup_Router-vip
> show lb vserver Router-vip
        Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Fri Sep  3 04:46:48 2010
        Time since last state change: 0 days, 03:09:45.600
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        No. of Bound Services :  1 (Total)       1 (Active)
```

```
12          Configured Method: ROUNDROBIN
13          Mode: IP
14          Persistence: DESTIP     Persistence Mask: 255.255.255.255
                    Persistence v6MaskLength: 128   Persistence Timeout: 2
                min
15          Backup: Router2-vip
16          Connection Failover: DISABLED
17   Done
18  <!--NeedCopy-->
```

To set the secondary virtual server as the backup virtual server by using the configuration utility

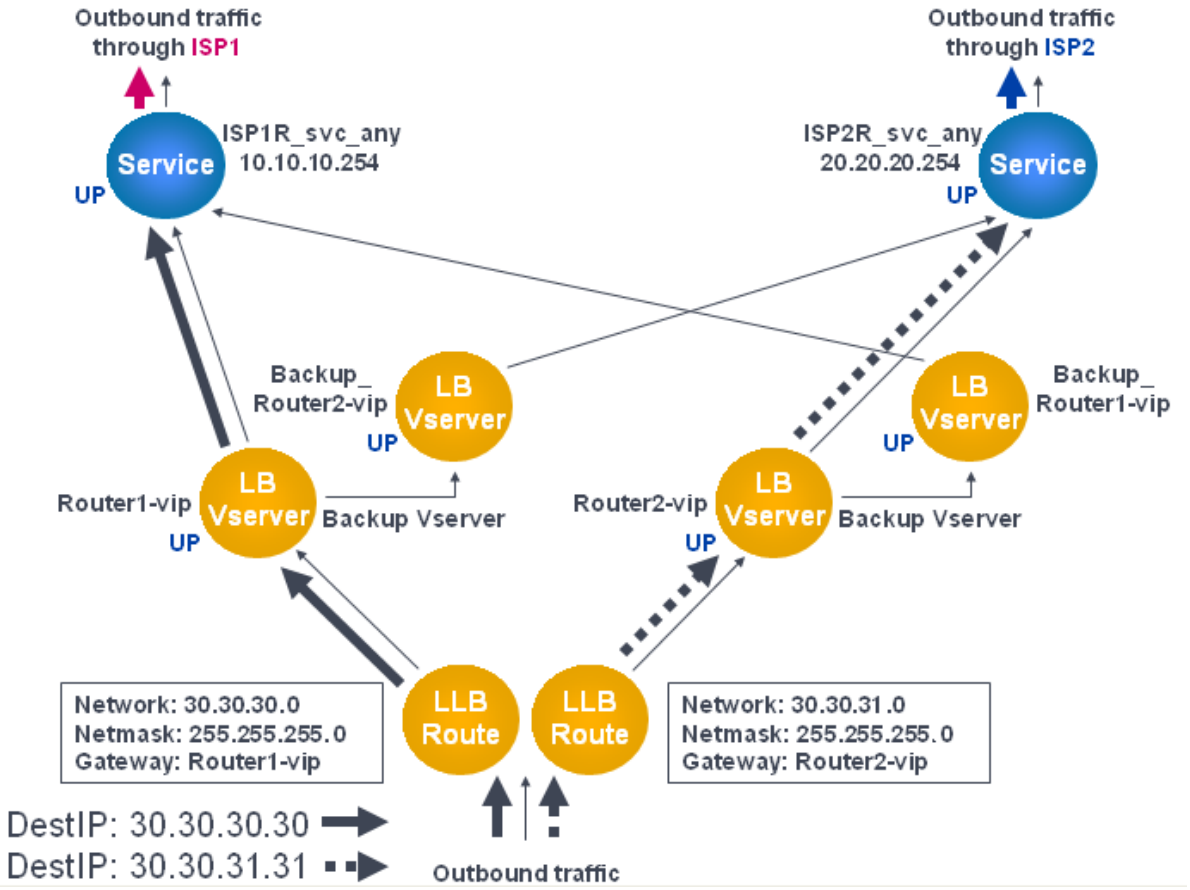
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the secondary virtual server for which you want to configure the backup virtual server.
2. In the **Load Balancing Virtual Server** dialog box, under **Advanced**, select **Protection**.
3. In the **Backup Virtual Server** drop-down list, select the secondary backup virtual server, and then click **OK**.

Resilient LLB deployment scenario

September 14, 2021

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways **Router1-vip** and **Router2-vip**, respectively. **Router1-vip** is configured as a backup to **Router2-vip** and the opposite way. All traffic with the destination IP specified as 30.30.30.30 is sent through **Router1-vip** and traffic with the destination IP specified as 30.30.31.31 is sent through **Router2-vip**.

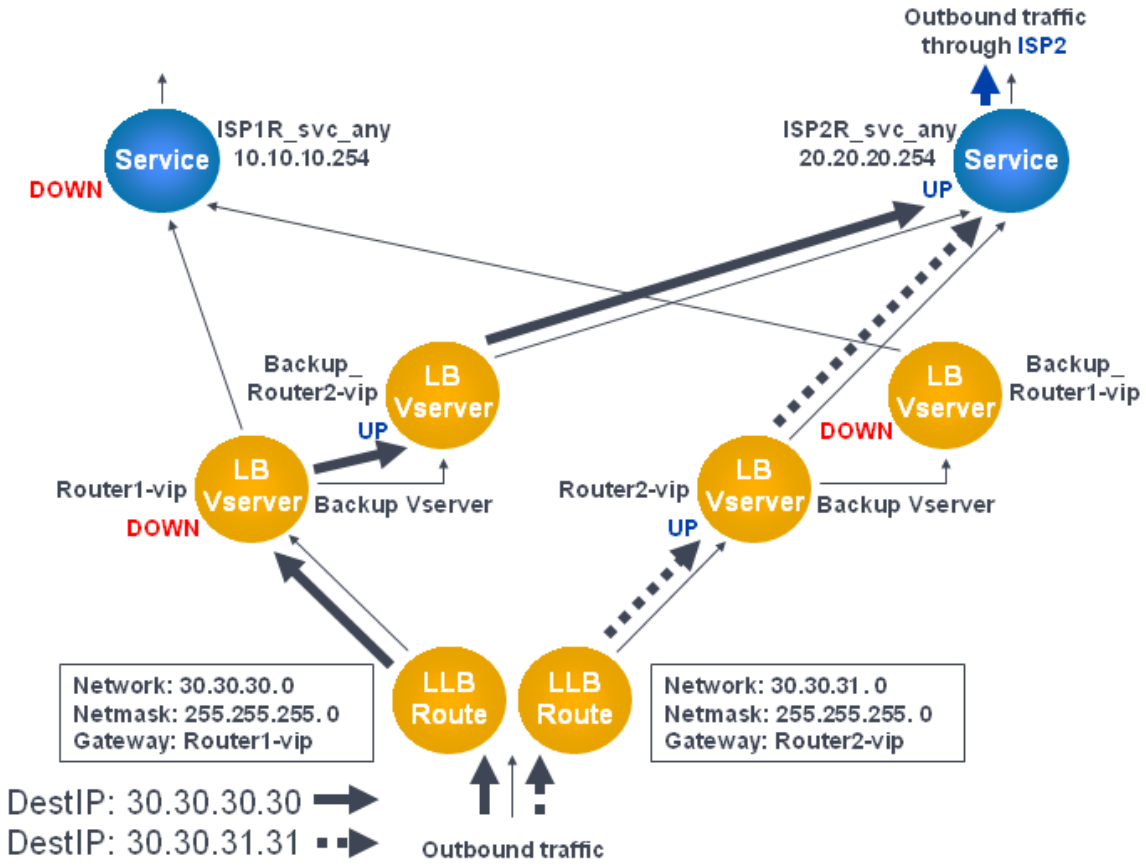
Figure 1. Resilient LLB Deployment Setup



Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

However, if any one of the gateways (**Router1-vip** or **Router2-vip**) is DOWN, traffic is routed through the backup router. In the following diagram, **Router1-vip** for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario



Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

Monitor an LLB setup

September 14, 2021

After the configuration is up and running, you can view the statistics for each service and virtual server to check for possible problems.

View the statistics of a virtual server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers. You can also specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name

- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

Display virtual server statistics by using the CLI

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC, or for a single virtual server, at the command prompt, type:

```
stat lb vserver -detail] [<name>]
<!--NeedCopy-->
```

Example:

```
stat lb vserver -detail
Virtual Server(s) Summary
                        vsvrIP  port     Protocol        State    Req/s
                             Hits/s
One                          *    80         HTTP           UP      5/s
         0/s
Two                          *     0          TCP         DOWN      0/s
         0/s
Three                        *  2598          TCP         DOWN      0/s
         0/s
dnsVirtualNS    10.102.29.90    53          DNS         DOWN      0/s
         0/s
BRVSERV            10.10.1.1    80         HTTP         DOWN      0/s
         0/s
LBVIP           10.102.29.66    80         HTTP           UP      0/s
         0/s
 Done
<!--NeedCopy-->
```

Display virtual server statistics by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

View the statistics of a service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

View the statistics of a service by using the CLI

At the command prompt, type:

```
stat service <name>
<!--NeedCopy-->
```

Example:

```
stat service Service-HTTP-1
<!--NeedCopy-->
```

View the statistics of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Load Balancing

September 14, 2021

The load balancing feature distributes user requests for webpages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance. When one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to;

- Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
- Use any of several different algorithms to determine which server must receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the Citrix ADC appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

How load balancing works

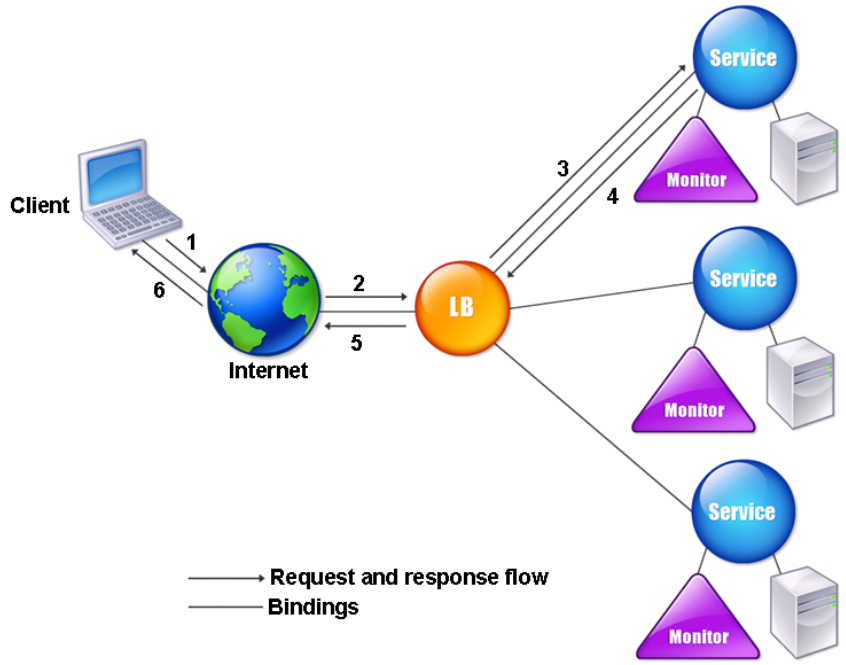
September 14, 2021

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the Citrix ADC appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. Sometimes, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see **Global HTTP Ports**.

Load balancing basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture



The load balancing virtual server can use several algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the Citrix ADC appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical Citrix ADC load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the LAN or WAN, the VIP is usually a private (ICANN non-routable) IP address.
- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.
- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the server's IP address when you create a service, and the IP address becomes the name of the

server.

- **Monitor.** An entity on the Citrix ADC appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The Citrix ADC appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

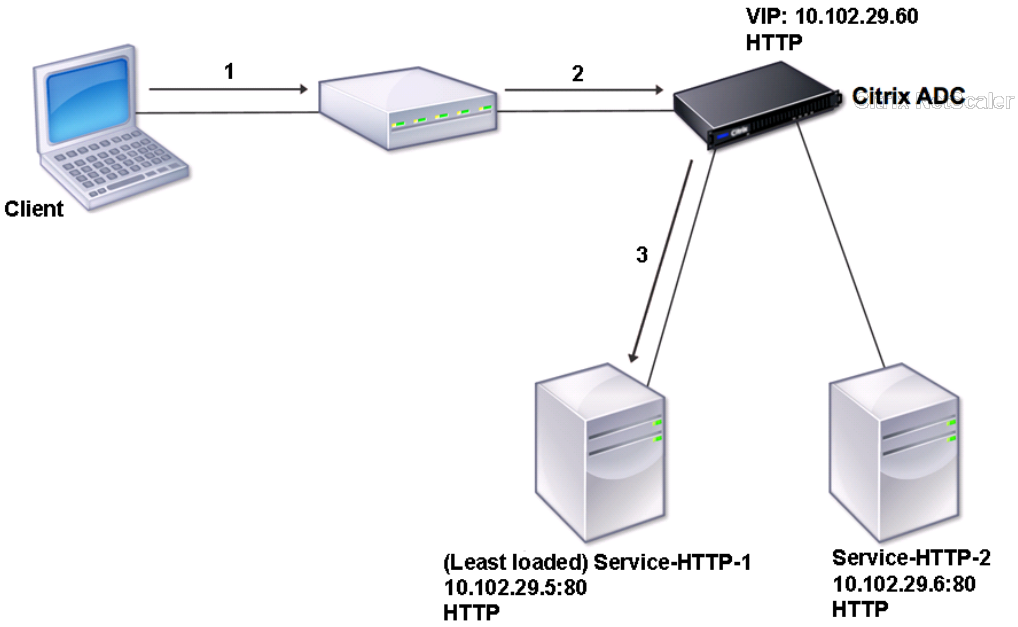
For variations in the load balancing setup, see the following use cases:

- Configuring Load Balancing in Direct Server Return Mode
- Configuring LINUX Servers in DSR Mode
- Configuring DSR Mode When Using TOS
- Configuring Load Balancing in DSR Mode by Using IP Over IP
- Configuring Load Balancing in One-arm Mode
- Configuring Load Balancing in the Inline Mode
- Load Balancing of Intrusion Detection System Servers
- Load balance remote desktop protocol servers

Understanding the topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the Citrix ADC appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

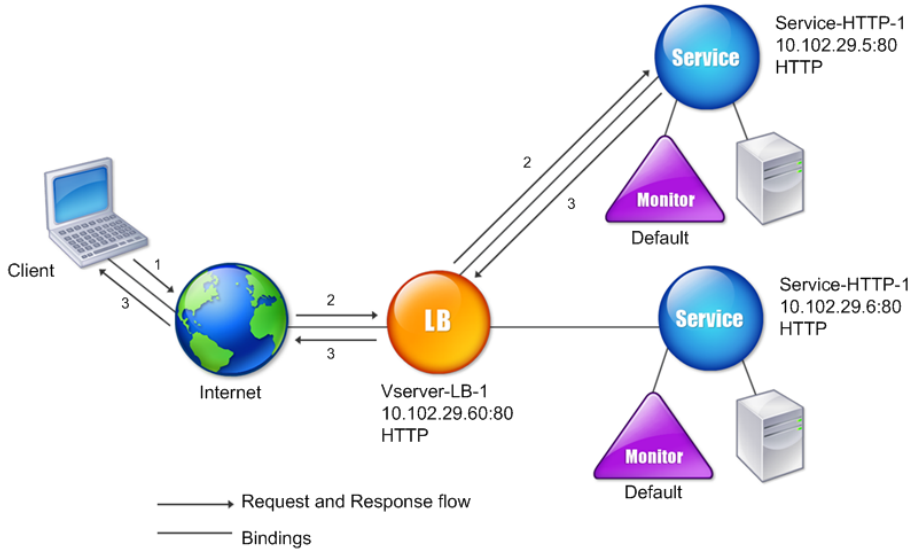


In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The Citrix ADC appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.

Entity	Name	IPAddress	Port	Protocol
Virtual server	Vserver-LB-1	10.102.29.60	80	HTTP
Services	Service-HTTP-1	10.102.29.5	80	HTTP
	Service-HTTP-2	10.102.29.6	80	HTTP
Monitors	Default	None	None	None

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model



Use of wildcards instead of IP addresses and ports

Sometimes you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases might require using a wildcard:

- If the Citrix ADC appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single Citrix ADC appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the Citrix ADC appliance determines the actual IP address or port and creates records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server

receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each must be used.

IP	Port	Protocol	Description
*	*	TCP	A general wildcard virtual server that accepts traffic sent to any IP address and port on the Citrix ADC appliance. When using a wildcard virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.
*	*	TCP	A firewall load balancing virtual server. You can bind firewall services to this virtual server, and the Citrix ADC appliance passes traffic through the firewall to the destination.

IP	Port	Protocol	Description
IP Address	*	TCP, UDP, and ANY	A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It does not learn them dynamically. **Note**: You do not configure services or virtual servers for a global HTTP port. In this case, you configure a specific port as a global HTTP port (for example, set ns param -httpPort 80). The appliance then accepts all traffic that matches the port number, and processes it as HTTP traffic. The appliance dynamically learns and creates services for this traffic.

IP	Port	Protocol	Description
*	port	SSL, SSL_TCP	A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it must use. If –cleartext is not specified, the Citrix ADC appliance uses end-to-end SSL.
*	port	Not applicable	All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers. The Citrix ADC appliance learns them dynamically.

Note: If you have configured your Citrix ADC appliance as a transparent pass through that uses global (wildcard) ports, you might want to turn on Edge mode.
For more information, see "Configuring Edge Mode."

The Citrix ADC appliance attempts to locate virtual servers and services by first attempting an exact

match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a * (wildcard) port
3. • (wildcard) IP address and a specific port
4. • (wildcard) IP address and a * (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server based on the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

Configuring global HTTP ports

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the set ns param command. After configuring this port, the Citrix ADC appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single set ns param command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the show ns param command to view the ports that are currently configured.

To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

```
set ns param -httpPort <port>

show ns param
<!--NeedCopy-->
```

Example 1: Configuring a port as a global HTTP port

In this example, port 80 is configured as a global HTTP port.

```
set ns param -httpPort 80
Done
show ns param
         Global configuration settings:
                          HTTP port(s): 80
                       Max connections: 0
            Max requests per connection: 0
                    Client IP insertion: DISABLED
                         Cookie version: 0
         Persistence Cookie Secure Flag: ENABLED
         ...
         ...
<!--NeedCopy-->
```

Example 2: Adding ports when one or more global HTTP ports are already configured**

In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
> show ns param
        Global configuration settings:
                          HTTP port(s): 80
                       Max connections: 0
           Max requests per connection: 0
                    Client IP insertion: DISABLED
                         Cookie version: 0
        Persistence Cookie Secure Flag: ENABLED
                          Min Path MTU: 576
        ...
        ...
 Done
> set ns param -httpPort 80 8888
 Done
>  show ns param

        Global configuration settings:
                          HTTP port(s): 80,8888
                       Max connections: 0
           Max requests per connection: 0
                    Client IP insertion: DISABLED
                         Cookie version: 0
        Persistence Cookie Secure Flag: ENABLED
                          Min Path MTU: 576
```

```
25
26          ...
27          ...
28  Done
29 >
30 <!--NeedCopy-->
```

To configure a global HTTP port by using the configuration utility

1. Navigate to **System > Settings > Change HTTP Parameters**, and then add an HTTP port number.

Set up basic load balancing

September 14, 2021

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

Example

```
1      > enable ns feature LoadBalancing
2
3       Done
```

```
4
5      > show ns feature
6
7
8
9              Feature                          Acronym              Status
10
11             -------                          -------              ------
12
13      1)     Web Logging                      WL                   OFF
14
15      2)     Surge Protection                 SP                   ON
16
17      3) Load Balancing LB ON
18
19      .
20
21      .
22
23      .
24
25      24)    NetScaler Push                   push                 OFF
26
27      Done
28 <!--NeedCopy-->
```

To enable load balancing by using the GUI

Navigate to **System** > **Settings** and, in **Configure Basic Features**, select **Load Balancing**.

Configuring a Server Object

Create an entry for your server on the Citrix ADC appliance. The Citrix ADC appliance supports IP address based servers and domain-based servers. If you create an IP address based server, you can specify the name of the server instead of its IP address when you create a service. For information about setting up DNS for a domain-based server, see Domain Name System.

To create a server object by using the CLI

At the command prompt, type:

```
1 add server `<name>`@ `<IPAddress>`@ | `<domain>`
2 <!--NeedCopy-->
```

Example for adding IP address-based name server:

```
add server web_serv 10.102.27.150
<!--NeedCopy-->
```

Example for adding domain-based server:

```
add server web_serv test.com
<!--NeedCopy-->
```

To create a server object by using the GUI

Navigate to **Traffic Management** > **Load Balancing** > **Servers**, and add a server object.

Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

Creating a Service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the Citrix ADC appliance.

HTTP

Used for load-balanced servers that accept HTTP traffic, such as standard websites and web applications. The HTTP service type enables the Citrix ADC appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also

supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the Citrix ADC appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 supports described earlier.

SSL

Used for servers that accept HTTPS traffic, such as ecommerce websites and shopping cart applications. The SSL service type enables the Citrix ADC appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL_BRIDGE, SSL_TCP, or TCP service types. If you do so, however, the appliance performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 supports described.

FTP

Used for servers that accept FTP traffic. The FTP service type enables the Citrix ADC appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service types for FTP servers.

TCP

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

SSL_TCP

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the Citrix ADC appliance performs both the Layer 4 load balancing and SSL offloading.

UDP

Used for servers that accept UDP traffic. You can also use the ANY service type.

SSL_BRIDGE

Used for servers that accept SSL traffic when you do not want the Citrix ADC appliance to perform SSL offloading. Alternatively, you can use the SSL_TCP service type.

NNTP

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

DNS

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the Citrix ADC appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the Citrix ADC appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

ANY

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

SIP-UDP

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the Citrix ADC appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

DNS-TCP

Used for servers that accept DNS traffic, where the Citrix ADC appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the Citrix ADC appliance validates the packet format of each DNS request and response and can cache DNS responses, as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the Citrix ADC appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

RTSP

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

You can also use the TCP service type for these services. If you do, however, the Citrix ADC appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NAT.

DHCPRA

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

DIAMETER

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

SSL_DIAMETER

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the Citrix ADC appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the Citrix ADC appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

Note: You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

QUIC

Used by load balancing servers that accept UDP based QUIC video traffic. The service enables the Citrix ADC appliance to optimize encrypted ABR video traffic over UDP protocol.

To create a service by using the CLI

At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>

add service Service-HTTP-1 192.0.2.5 HTTP 80
<!--NeedCopy-->
```

To create a service by using the GUI

1. Navigate to **Traffic Management**> **Load Balancing** > **Services**.
2. In the details pane, click **Add**.
3. In the Create Service dialog box, specify values for the following parameters:
   - Service Name—name
   - Server—serverName
   - Protocol—serviceType
   - Port—port
4. Click **Create**, and then click **Close**. The service you created appears in the Services pane.

Creating a Virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced websites, applications, or servers. Once load balancing is configured, users connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.

Note:

- Virtual server names prefixed with "app_" do not appear in the GUI though they are present in the ns.conf file and are displayed when you run the show command. However, virtual server names prefixed with "app" are displayed in the GUI.
- The virtual server is designated as DOWN until you bind the services that you created to it, and until the Citrix ADC appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.

To create a virtual server by using the CLI

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>

```

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
<!--NeedCopy-->
```

To create a virtual server by using the GUI

Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and then create a virtual server.

Binding Services to the Virtual Server

Note: A service can be bound to a maximum of 500 virtual servers.

After you have created services and a virtual server, you must bind the services to the virtual server. Usually, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

Virtual Server Type	Service Type	Comment
HTTP	SSL	You would normally bind an SSL service to an HTTP virtual server to do encryption.
SSL	HTTP	You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.
SSL_TCP	TCP	You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness).

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

To bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```
bind lb vserver <name> <serviceName>

```

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management**> **Load Balancing** > **Virtual Servers**, and select a virtual server.
2. Click in the **Service** section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Verifying the Configuration

After finishing your basic configuration, you can view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you can view the statistics for each service and load balancing virtual server to check for possible problems.

Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your Citrix ADC appliance configuration.

To view the properties of server objects by using the command line interface

At the command prompt, type:

```
show server <serverName>

show server server-1
<!--NeedCopy-->
```

To view the properties of server objects by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Servers**. The parameter values of the available servers appear in the details pane.

Viewing the Properties of a Virtual Server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic

load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

To view the properties of a load balancing virtual server by using the CLI

At the command prompt, type:

```
show lb vserver <name>

show lb vserver Vserver-LB-1
<!--NeedCopy-->
```

To view the properties of a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.
3. To view the cache redirection and content switching virtual servers that are bound to this virtual server, click **Show CS/CR Bindings**.

Viewing the Properties of a Service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

To view the properties of services by using the CLI

At the command prompt, type:

```
show service <name>

show service Service-HTTP-1
<!--NeedCopy-->
```

To view the properties of services by using the GUI

Navigate to **Traffic Management** > **Load Balancing** > **Services**. The details of the available services appear on the Services pane.

Viewing the Bindings of a Service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port, and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

To view the bindings of a service by using the CLI

At the command prompt, type:

```
show service bindings <name>

show service bindings Service-HTTP-1
<!--NeedCopy-->
```

To view the bindings of a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. In the details pane, select the service whose binding information you want to view.
3. In the **Action** tab, click **Show Bindings**.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the CLI

To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [`<name>`]
<!--NeedCopy-->
```

Example:

```
stat lb vserver server-1
<!--NeedCopy-->
```

The following figure displays a sample statistic.

```
> stat lbvserver
[
Virtual Server(s) Summary
                        vsvrIP  port     Protocol        State    Req/s
vserver1        10.102.20.200    80          SSL         DOWN      0/s

lb1               203.1.113.5   443         DTLS         DOWN      0/s

```

To display virtual server statistics by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click **Statistics**.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the CLI

At the command prompt, type:

```
stat service <name>
<!--NeedCopy-->
```

Example:

```
stat service Service-HTTP-1
<!--NeedCopy-->
```

To view the statistics of a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click **Statistics**. The statistics appear in a new window.

Load balance virtual server and service states

September 14, 2021

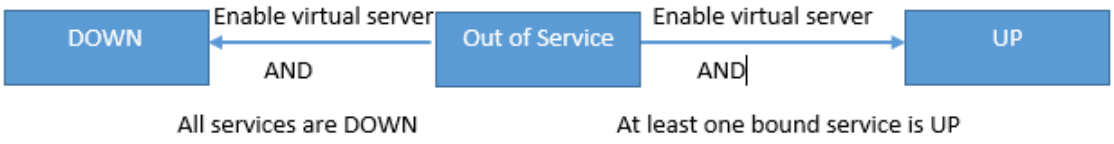
A load balancing virtual server that does not have a backup virtual server can take the following states, depending on the states of the services bound to it and whether it is administratively disabled:

- **UP**: At least one of the services bound to the virtual server is UP.

- **DOWN**: All the services bound to the virtual server are DOWN, or the load balancing feature is not enabled.
- **Out of Service (OFS)**: If you administratively disable the virtual server, it enters the OFS state but its effective state is DOWN. Administrator can control the transitioning to the OFS state from the DOWN or UP state, or to the DOWN or UP state from the OFS state.

The state and effective state of a virtual server are the same if a backup virtual server is not configured. However, if a backup virtual server or a chain of backup virtual servers is configured, the effective state is derived from the states of the services that are bound to the primary virtual server and the backup virtual servers. If any of the backup virtual servers in the chain is UP, the effective state of the primary virtual server is UP, even if all the services bound to the primary virtual server are DOWN.

The following diagrams show the conditions under which a virtual server transitions from one state to another.



A service can take the following states:

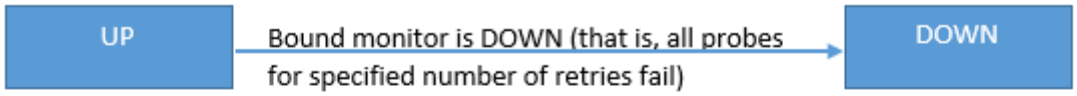
- **UP:** If probes from all the monitors bound to the service are successful.
- **DOWN**: If monitoring probes to the service are not answered within the configured time limit.
- **OUT OF SERVICE**: If you administratively disable the service, or if you gracefully shut down the service and there are no active transactions to the service

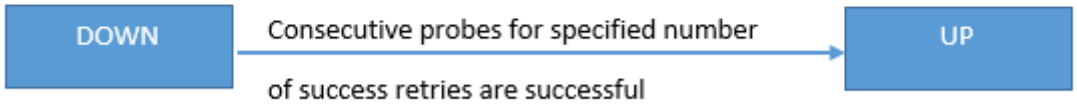
- **GOING OUT OF SERVICE (TROFS)**: If you administratively disable the service with delay, or gracefully shut down the service and there are active transactions to the service. For more information, see Graceful Shut down of Services.
- **DOWN WHEN GOING OUT OF SERVICE (TROFS_DOWN)[]** A monitoring probe fails while the service is in the GOING OUT OF SERVICE state.

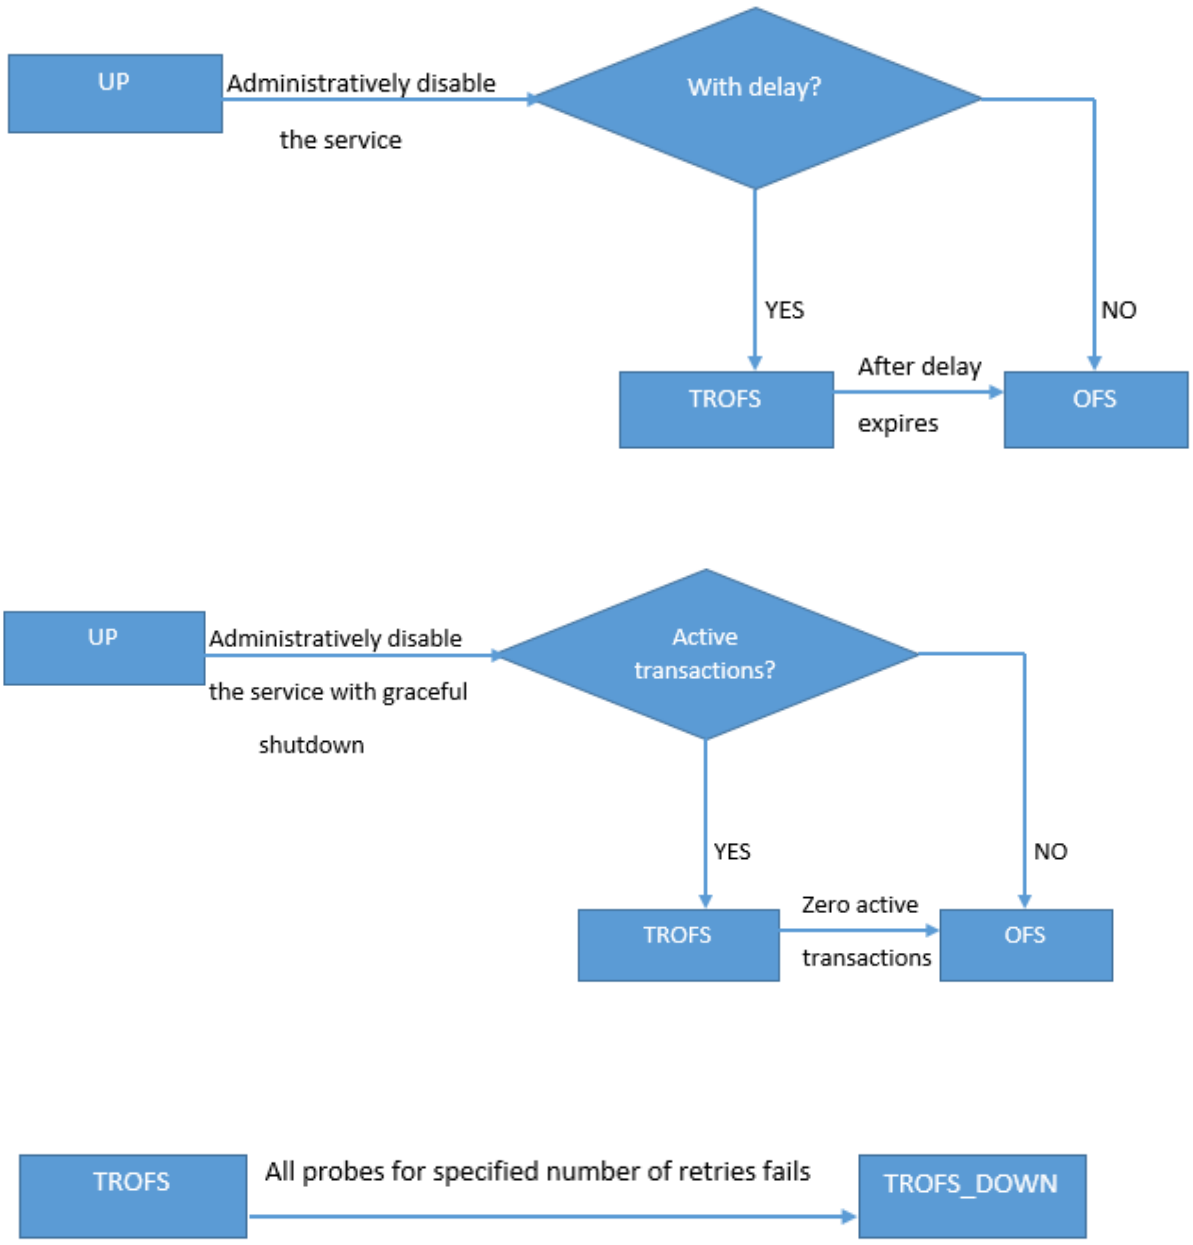
A service in the process of transitioning from UP to OFS is in the GOING OUT OF SERVICE state. A service transitioning from DOWN to OFS is in the DOWN WHEN GOING OUT OF SERVICE state. For example, if a service is DOWN and you disable it with delay, the service transitions to DOWN WHEN GOING OUT OF SERVICE and then to the OUT OF SERVICE state. If a service is UP and you disable it with delay, the service transitions to GOING OUT OF SERVICE. During this time, if a monitoring probe to the server fails, the service transitions to DOWN WHEN GOING OUT OF SERVICE and, after the delay time expires, enters the OFS state.

> **Note**
>
> You can configure spillover to a backup virtual server by setting the “healthThreshold” parameter to a non-zero positive value. Then, if a single service bound to the primary virtual server transitions to the DOWN WHEN GOING OUT OF SERVICE state and the health threshold is not reached, the primary virtual server is marked DOWN and new connections are directed to the backup virtual server.

The following diagrams show the conditions under which a service transitions from one state to another.







Support for load balancing profile

September 14, 2021

A load balancing configuration has many parameters, so setting the same parameters on several virtual servers can become tedious. From release 11.1, a load balancing (LB) profile makes this task

easier. You can now set load balancing parameters in a profile and associate this profile with virtual servers, instead of setting these parameters on each virtual server.

The following parameters are presently supported in an LB profile:

- `HTTPonlyflag`—Include the HttpOnly attribute in persistence cookies. The HttpOnly attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.
- UseSecuredPersistenceCookie—Encrypt the persistence cookie values by using the SHA2 hash algorithm.
- `Cookiepassphrase`—Specify the passphrase used to generate a secured persistence cookie value.
- DBS_LB—Enable database specific load balancing for MySQL and MSSQL service types.
- Cl_process_local—Packets destined to a virtual server in a cluster are not steered. Enable the option for single packet request response mode or when the upstream device is performing a proper RSS for connection based distribution.
- lbHashAlgorithm—Specify the hashing algorithm to be used for the following hash-based load balancing methods:
  - URL hash method
  - Domain hash method
  - Destination IP hash method
  - Source IP hash method
  - Source IP Destination IP hash method
  - Source IP Source Port hash method
  - Call ID hash method
  - Token method

  Possible values: DEFAULT, PRAC, JARH
  Default value: DEFAULT
- lbHashFingers—Specify the number of fingers to be used in PRAC and JARH algorithms for hash-based LB methods. Increasing the number of fingers provides better distribution of traffic at the expense of additional memory.

Default value: 256
Minimum value: 1
Maximum value: 1024

> **Note**
>
> You can set DBS_LB and Cl_process_local parameters on a virtual server and in the profile. If you enable these parameters on a virtual server and then set a profile to this virtual server, the

> parameters appear as disabled in the output of the "show lb vserver" command for that virtual server. Check the profile to see the actual status of these parameters. In addition, if you set and then unset a profile to a virtual server, the parameters are set with default values for that virtual server.

To create an LB profile by using the CLI

At the command prompt, type:

```
add lb profile <lbprofilename> -dbsLb ( ENABLED | DISABLED ) -
    processLocal ( ENABLED | DISABLED ) -httpOnlyCookieFlag ( ENABLED |
    DISABLED ) -cookiePassphrase -useSecuredPersistenceCookie ( ENABLED
    | DISABLED ) -lbHashAlgorithm <lbHashAlgorithm> -lbHashFingers <
    positive_integer>
<!--NeedCopy-->
```

Example:

```
> sh lb profile p1
LB Profile name:  p1
DBS LB : DISABLED   Process Local: DISABLED
Persistence Cookie HttpOnly Flag: ENABLED
Use Encrypted Persistence Cookie: DISABLED
No of vservers bound: 0
Store MQTT clientid and username in transactional logs: NO
Hash LB algorithm used in LB decision: DEFAULT
Number of fingers for Hash LB algorithm: 256
Done

<!--NeedCopy-->
```

To create an LB profile by using the GUI

Navigate to **System** > **Profiles** > **LB Profile**, and add a profile.

To associate an LB profile with an LB virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -lbprofilename <string>
<!--NeedCopy-->
```

Example

```
set lbvserver lbvip1 -lbprofile p1

Done

sh lb vserver lbvip1

lbvip1 (203.0.113.1:80) - HTTP       Type: ADDRESS
State: UP

```

To associate an LB profile with an LB virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Select a virtual server, and click **Edit**.
3. In **Advanced Settings**, click **Profiles**.

4. In the **LB Profile** list, select the profile to associate with this virtual server.

Load balancing algorithms

September 14, 2021

The load balancing algorithm defines the criteria that the Citrix ADC appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the Citrix ADC appliance supports, with a brief description of how each operates.

Name	Server selection based on
LEASTCONNECTION	Which service currently has the fewest client connections. This is the default load balancing algorithm.
ROUNDROBIN	Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list.
LEASTRESPONSETIME	Which load balanced server currently has the quickest response time.
URLHASH	A hash of the destination URL.
DOMAINHASH	A hash of the destination domain.
DESTINATIONIPHASH	A hash of the destination IP address.
SOURCEIPHASH	A hash of the source IP address.
SRCIPDESTIPHASH	A hash of the source and destination IP addresses.
CALLIDHASH	A hash of the call ID in the SIP header.
SRCIPSRCPORTHASH	A hash of the client's IP address and port.
LEASTBANDWIDTH	Which service currently has the fewest bandwidth constraints.

Name	Server selection based on
LEASTPACKETS	Which service currently is receiving the fewest packets.
CUSTOMLOAD	Data from a load monitor.
TOKEN	The configured token.
LRTM	Fewest active connections and the lowest average response time.

Depending on the protocol of the service that it is load balancing, the Citrix ADC appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

Granularity	Types of Load Balanced Service	Specifies
Request -based	HTTP or HTTPS	A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.
Connection-based	TCP and TCP-based protocols other than HTTP	A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.

Granularity	Types of Load Balanced Service	Specifies
Time-based	UDP and other IP protocols	A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client.

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin,* helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the appliance switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, the appliance uses the round robin method for the specified number of requests before switching to the specified load balancing method.
- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the Citrix ADC appliance.

To set the startup round-robin factor by using the CLI

At the command prompt, type:

```
set lb parameter -startupRRFactor <positive_integer>
```

Example

```
set lb parameter -startupRRFactor 25000
```

To set the startup round-robin factor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, and set the Startup RR Factor.

Least connection method

September 14, 2021

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL_TCP services, the Citrix ADC appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.
- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server's connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the Citrix ADC appliance creates a session between the source IP address and port and the destination IP address and port.

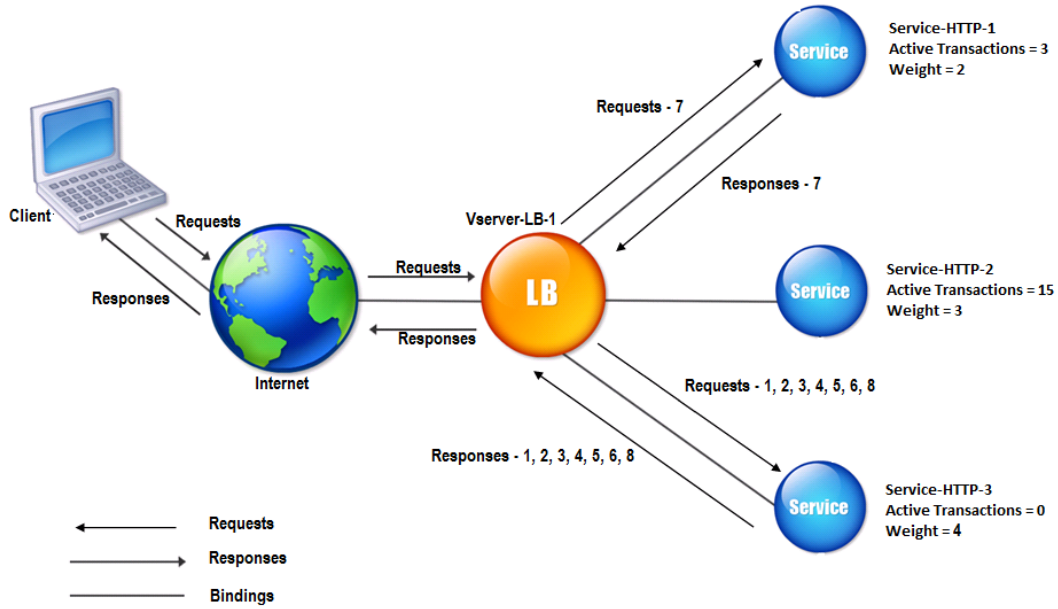
For Real-Time Streaming Protocol (RTSP) connections, the Citrix ADC appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the Citrix ADC appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method



In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  Note: The service with no active transaction is selected first.

- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
- Service-HTTP-1 receives the fourth request because Service-HTTP-1 and Service-HTTP-3 have the same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.

- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. Then, the Citrix ADC appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

  Note: If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Incoming Connection	Service Selected	Current Number of Active Connections	Remarks
Request-1	Service-HTTP-3; (N = 0)	1	Service-HTTP-3 has the fewest active connections.
Request-2	Service-HTTP-3; (N = 1)	2	Service-HTTP-3 has the fewest active connections.
Request-3	Service-HTTP-3; (N = 2)	3	-
Request-4	Service-HTTP-1; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-5	Service-HTTP-3; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-6	Service-HTTP-1;(N = 4)	5	-
Request-7	Service-HTTP-3; (N = 4)	5	-
Request-8	Service-HTTP-1; (N = 5)	6	-

Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.

The Citrix ADC appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

Nw = (Number of active transactions) * (10000 / weight)

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.

  Note: If the services are not handling any active transactions, the Citrix ADC appliance uses the round robin method regardless of the weights assigned to each of the services.
- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has the lowest Nw value.
- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have the same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described earlier.

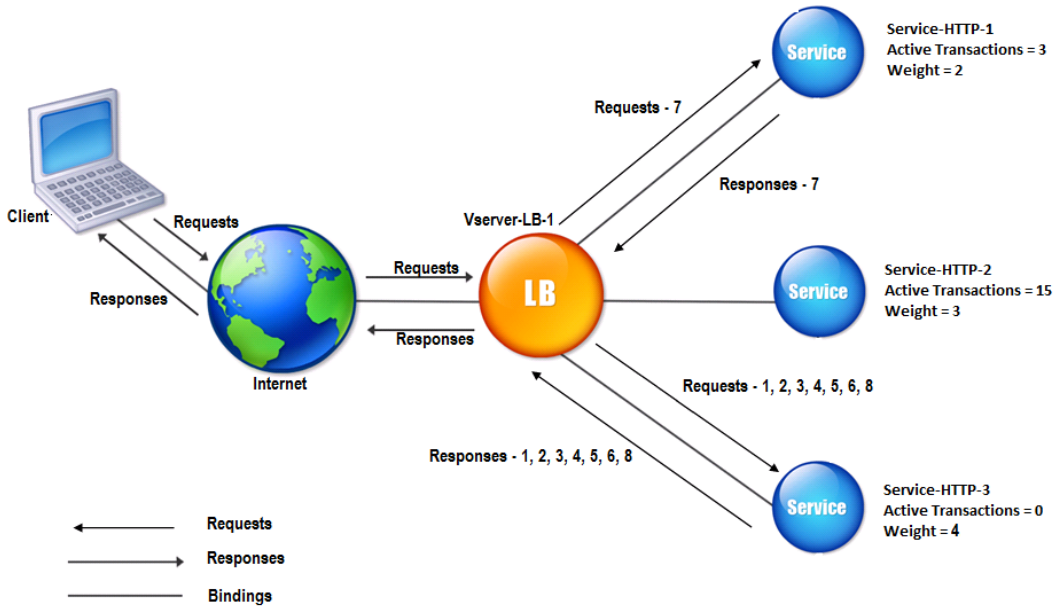
Request Received	Service Selected	Current Nw (Number of active transactions) * (10000 / weight) value	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 2500)	Nw = 5000	
Request-3	Service-HTTP-3; (Nw = 5000)	Nw = 7500	
Request-4	Service-HTTP-3; (Nw = 7500)	Nw = 10000	
Request-5	Service-HTTP-3; (Nw = 10000)	Nw = 12500	
Request-6	Service-HTTP-3; (Nw = 12500)	Nw = 15000	

Request Received	Service Selected	Current Nw (Number of active transactions) * (10000 / weight) value	Remarks
Request-7	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw values
Request-8	Service-HTTP-3; (Nw = 15000)	Nw = 17500	

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the Citrix ADC appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned



To configure the least connection method, see Configuring a Load Balancing Method that Does Not Include a Policy.

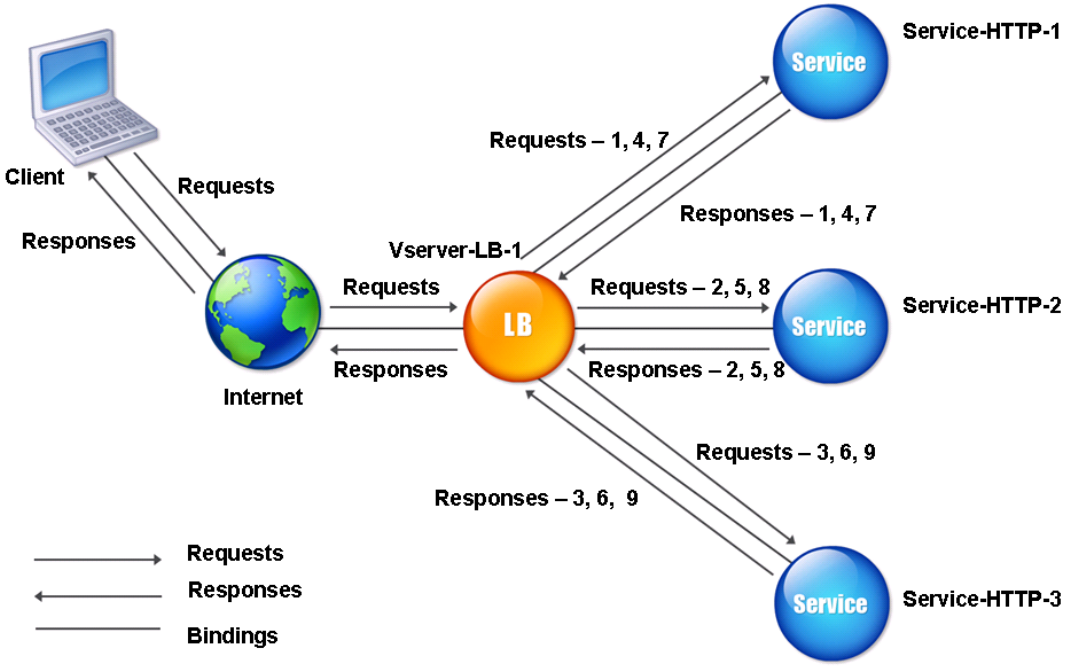
Round robin method

September 14, 2021

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the Citrix ADC appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works



If you assign a different weight to each service, the Citrix ADC appliance performs the weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

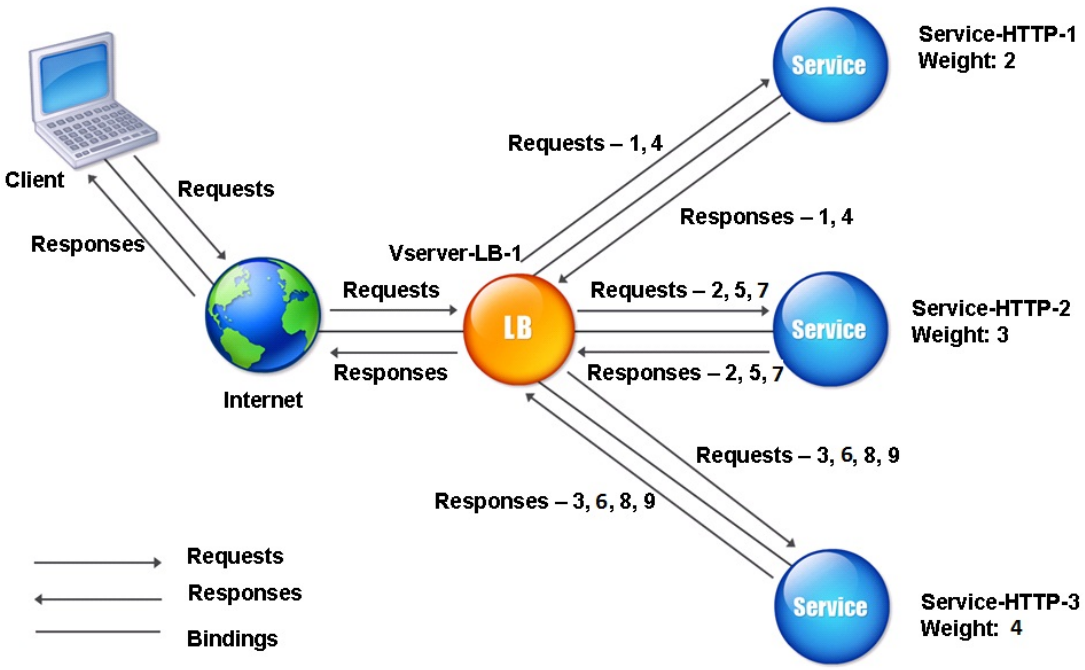
- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

Note: You can also configure weights on services to prevent multiple services from using the same server and overloading the server.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

Figure 2. How the Round Robin Load Balancing Method supports Weighted Services



To configure the round robin method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least response time method

September 14, 2021

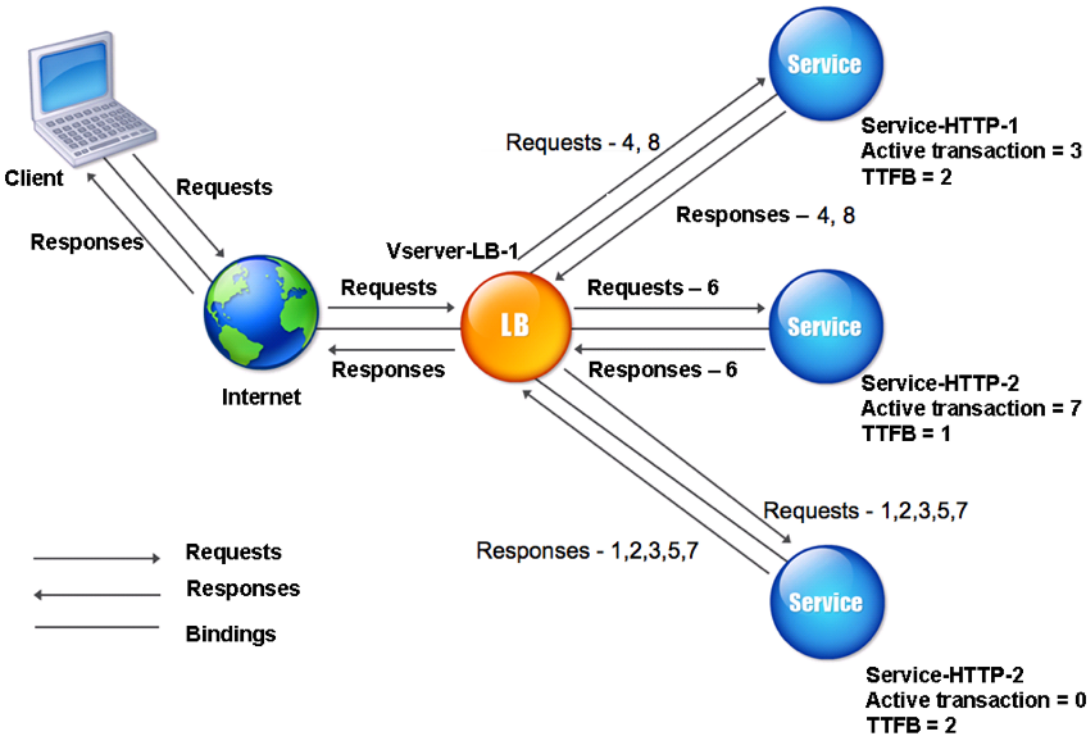
When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) load balancing virtual servers only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The Citrix ADC appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works



The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is the lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the Citrix ADC appliance chooses between them by applying the Round Robin method.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the appliance switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3;(N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3; (N = 2)	N = 4	Service-HTTP-3 has the lowest N value.
Request-3	Service-HTTP-3; (N = 4)	N = 6	Service-HTTP-3 has the lowest N value.
Request-4	Service-HTTP-1; (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values. The appliance uses the round robin method to distribute the requests.
Request-5	Service-HTTP-3; (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values.

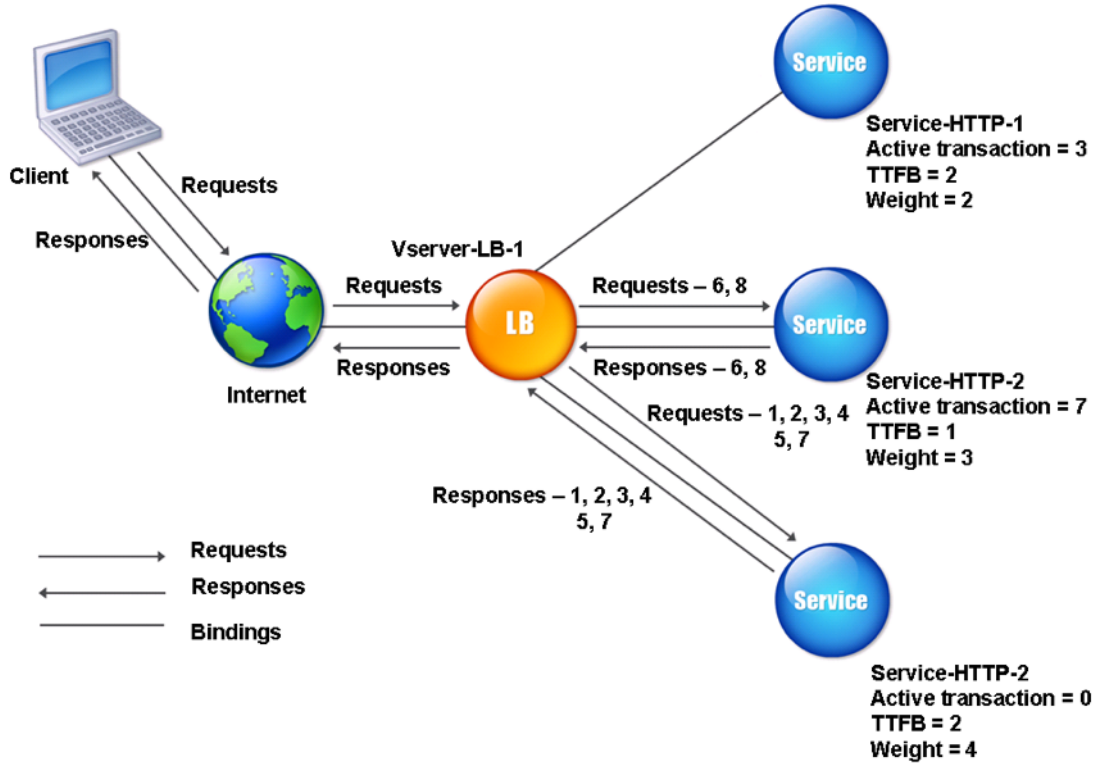
Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-6	Service-HTTP-2; (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-7	Service-HTTP-3; (N = 8)	N = 10	Service-HTTP-1,Service-HTTP-2 and Service-HTTP-3 have the same N values. The Citrix ADC appliance uses the round robin method to distribute the requests.
Request-8	Service-HTTP-1; (N = 8)	N = 10	Service-HTTP-1 and Service-HTTP-2 have the same N values, the appliance uses the round robin method to distribute the requests.

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

Selection of services when weights are assigned

The following diagram illustrates how the Citrix ADC appliance uses the least response time method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned



The virtual server selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight), where N = (number of active transactions * TTFB)

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The Citrix ADC appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  If the services are not handling any active transactions, the appliance selects them regardless of the weights assigned to them.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Request Received	Service Selected	Current Nw Value = (N) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000	Nw = 10000	Service-HTTP-3 has the lowest Nw value.
Request-3	Service-HTTP-3; (Nw = 10000)	Nw = 15000	Service-HTTP-3 has the lowest Nw value.
Request-4	Service-HTTP-3; (Nw = 15000)	Nw = 20000	Service-HTTP-3 has the lowest Nw value.
Request-5	Service-HTTP-3; (Nw = 20000)	Nw = 25000	Service-HTTP-3 has the lowest Nw value.
Request-6	Service-HTTP-2; (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3; (Nw = 25000)	Nw= 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2; (Nw = 26666.67)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

To configure the least response time load balancing method by using the CLI

At the command prompt type;

```
set lb vserver <name> -lbMethod LEASTRESPONSETIME
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod LEASTRESPONSETIME
<!--NeedCopy-->
```

To configure the least response time load balancing method by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LEASTRESPONSETIME**.

For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

LRTM method

September 14, 2021

Note: LRTM stands for Least response time method using monitors (LRTM).

When a load balancing virtual server is configured to use the LRTM method, it uses the existing monitoring infrastructure to get the fastest response time. The load balancing virtual server then selects the service with the smallest number of active transactions and lowest response time. Before you use the LRTM method, you must bind application-specific monitors to each service and enable LRTM mode on these monitors. The Citrix ADC appliance then makes load balancing decisions based on the response times it calculates from monitoring probes.

You can use the LRTM method to load balance non-HTTP and non-HTTPS services also. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for the various monitors.

Monitor	Response time calculation
PING	Time difference between the ICMP ECHO request and the ICMP ECHO response.
TCP	Time difference between the SYN request and the SYN+ACK response.
HTTP	Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.
TCP-ECV	Time difference between the time the data send string is sent and the data receive string is returned. A TCP-ECV monitor without the send and receive strings is considered to have an incorrect configuration.

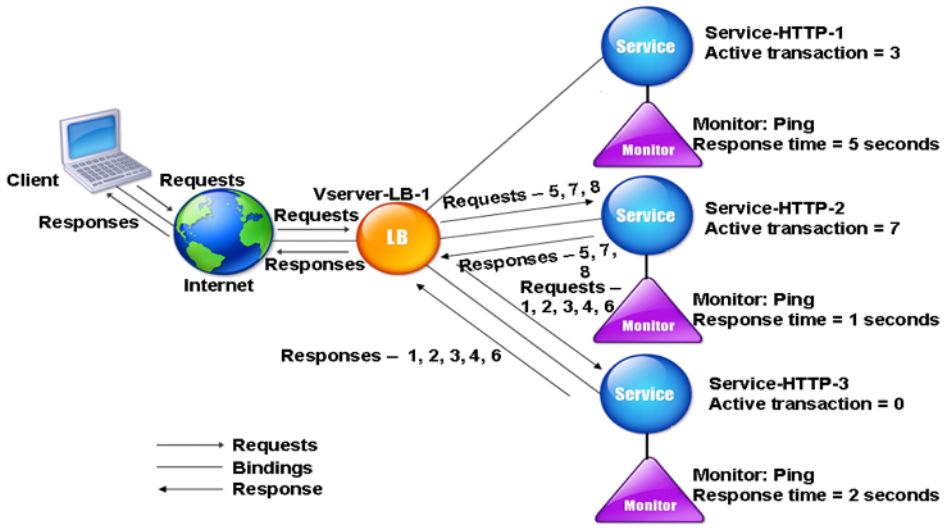
Monitor	Response time calculation
HTTP-ECV	Time difference between the HTTP request and the HTTP response.
UDP-ECV	Time difference between the UDP's send string and the receive string. A UDP-ECV monitor without the receive string is considered to have an incorrect configuration.
DNS	Time difference between a DNS query and the DNS response.
TCPS	Time difference between a SYN request and the SSL handshake completion.
FTP	Time difference between the sending of the user name and the completion of user authentication.
HTTPS (monitors HTTPS requests)	Time difference is the same as for the HTTP monitor.
HTTPS-ECV (monitors HTTPS requests)	Time difference is the same as for the HTTP-ECV monitor
USER	Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the LRTM method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the Citrix ADC appliance follows when it forwards requests.

Figure 1. How the LRTM Method Works



The virtual server selects a service by using the value (N) in the following expression:

N = (Number of active transactions * Response time that is determined by the monitor)

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
- Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the Citrix ADC appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the Citrix ADC appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3;(N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3; (N = 2)	N = 4	Service-HTTP-3 has the lowest N value.
Request-3	Service-HTTP-3; (N = 4)	N = 6	Service-HTTP-3 has the lowest N value.
Request-4	Service-HTTP-3; (N = 6)	N = 8	Service-HTTP-3 has the lowest N value.
Request-5	Service-HTTP-2; (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-6	Service-HTTP-3; (N = 8)	N = 10	Service-HTTP-2 and Service-HTTP-3 have the same N values. Citrix ADC appliance switches to the round robin method and selects Service-HTTP-3
Request-7	Service-HTTP-2; (N = 8)	N = 9	Service-HTTP-2 has the lowest N value.
Request-8	Service-HTTP-2; (N = 9)	N = 10	Service-HTTP-2 has the lowest N value.

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

Selection of services when weights are assigned

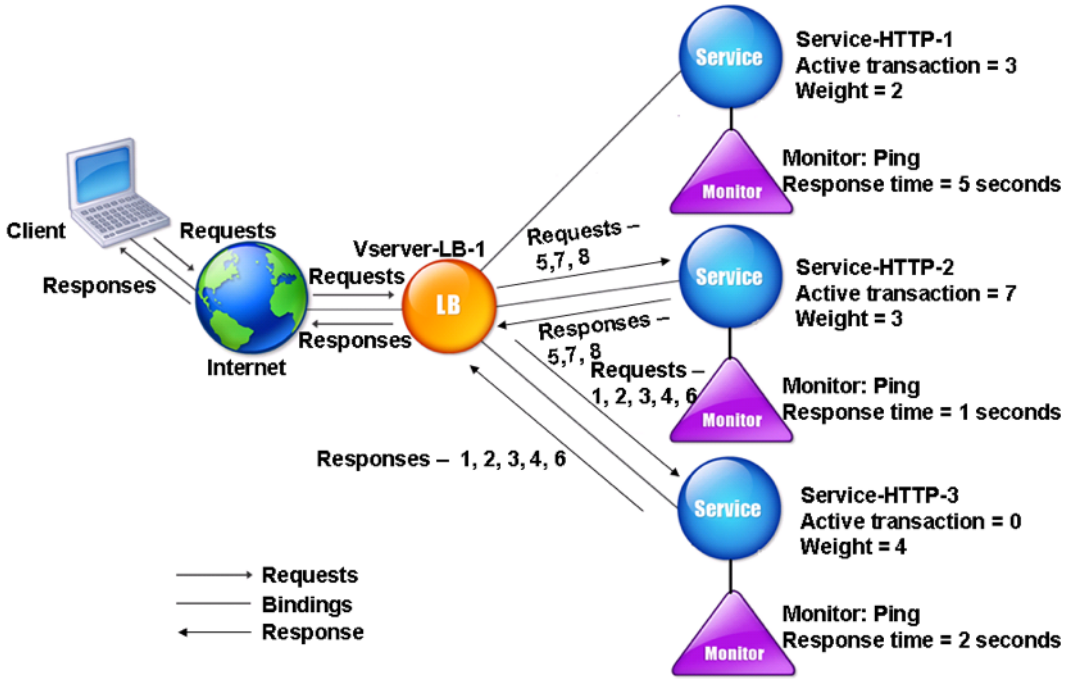
The Citrix ADC appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The Citrix ADC appliance selects the service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

Where N = (Number of active transactions * Response time that is determined by the monitor)

The following diagram illustrates how the virtual server uses the LRTM method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned



In this example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the Citrix ADC appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

Request Received	Service Selected	Current Nw Value (N) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000	Nw = 10000	Service-HTTP-3 has the lowest Nw value.
Request-3	Service-HTTP-3; (Nw = 10000)	Nw = 15000	Service-HTTP-3 has the lowest Nw value.
Request-4	Service-HTTP-3; (Nw = 15000)	Nw = 20000	Service-HTTP-3 has the lowest Nw value.
Request-5	Service-HTTP-3; (Nw = 20000)	Nw = 25000	Service-HTTP-3 has the lowest Nw value.
Request-6	Service-HTTP-2; (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3; (Nw = 25000)	Nw= 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2; (Nw = 26666.67)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

To configure the LRTM load balancing method by using the CLI

At the command prompt type;

```
set lb vserver <name> [-lbMethod <lbMethod>]
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod LRTM
<!--NeedCopy-->
```

To configure the LRTM load balancing method by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LRTM**.

To enable the LRTM option in monitors by using the CLI

At the command prompt type;

```
set lb monitor <monitorName> <type> [-LRTM ( ENABLED | DISABLED )]
<!--NeedCopy-->
```

Example:

```
set lb monitor monitor-HTTP-1 HTTP -LRTM ENABLED
<!--NeedCopy-->
```

To enable the LRTM option in monitors by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**, and open a monitor.
2. In Advanced Parameters, select **LRTM (Least Response Time using Monitoring)**.

For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

Hashing methods

September 14, 2021

Load balancing methods based on hashes of certain connection information or header information constitute most the Citrix ADC appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used websites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The Citrix ADC appliance provides the following hashing methods:

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method

- Source IP Source Port hash method
- Call ID hash method
- Token method

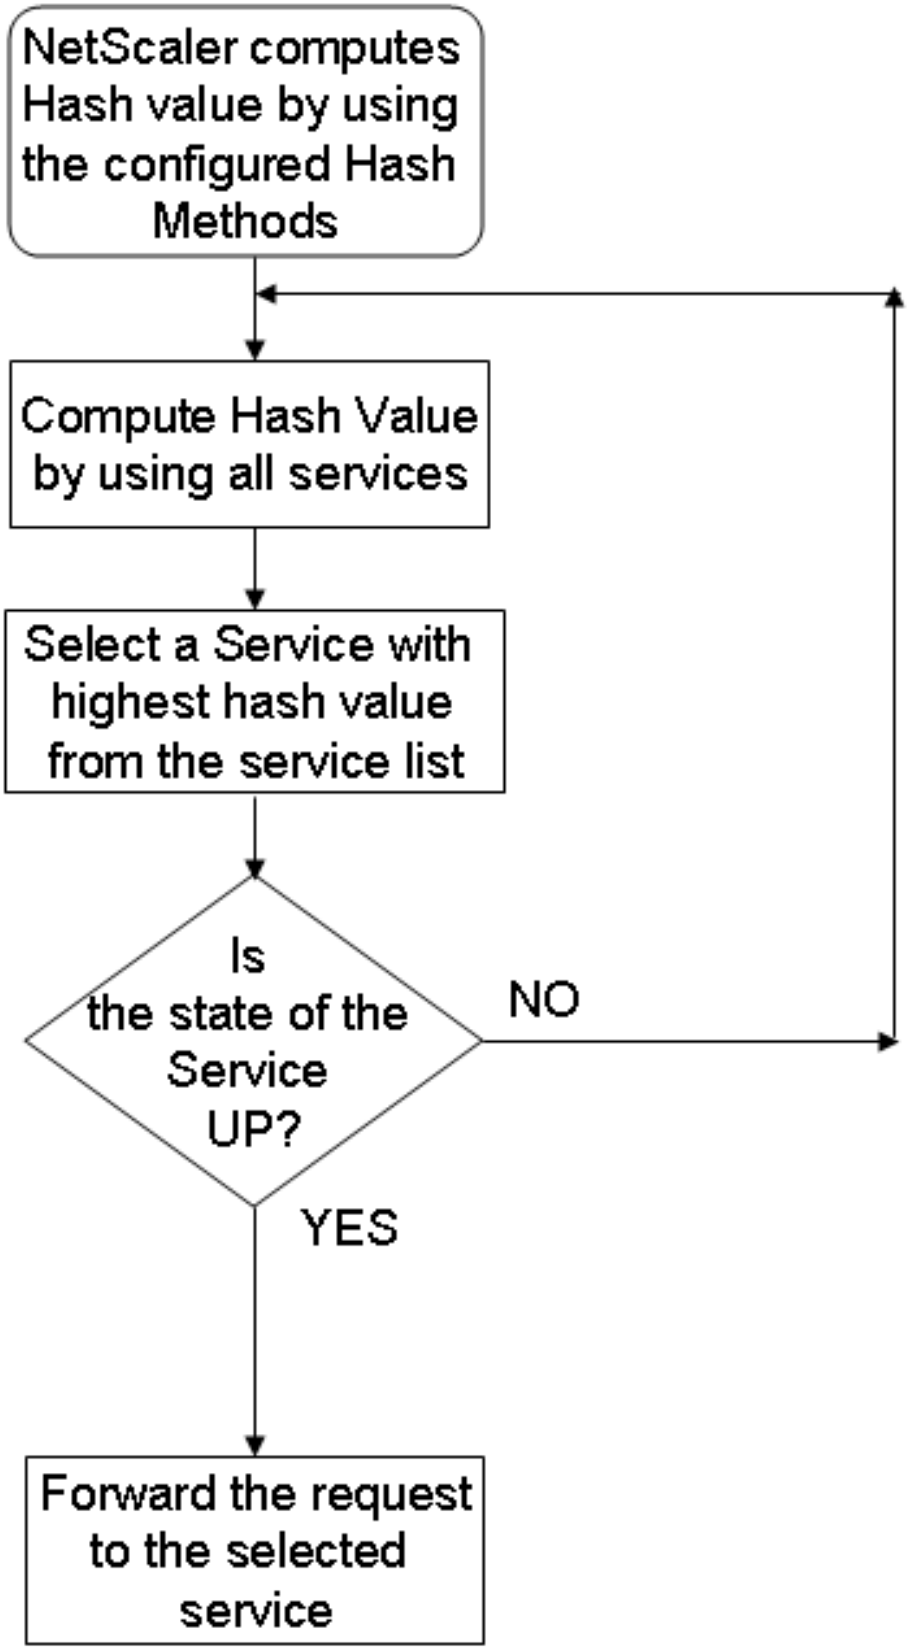
Most of the hashing algorithms calculate two hash values:

- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The Citrix ADC appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with the highest hash value. As the appliance computes a hash value for each request and selects the service that processes the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

> Note
>
> Starting from Citrix ADC release 13.0 build 79.x, Prime Re-Shuffled Assisted CARP (PRAC) and Jump table Assisted Ring Hash (JARH) consistent hashing algorithms are supported. The consistent hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup, or during a service flap event in load balancing setup. For more details, see Consistent hashing algorithms.

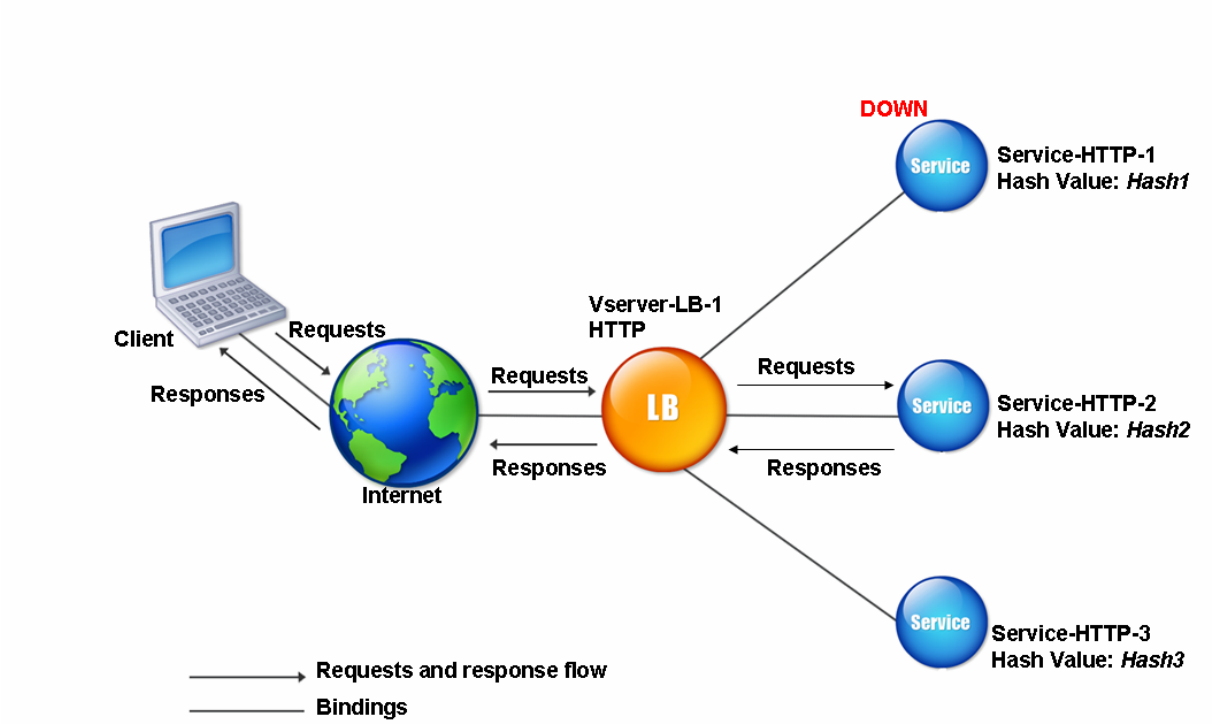
Figure 1. How the Hashing Methods Distribute Requests



Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the Citrix ADC appliance calculates the hash value for the last log of the number of services. The appliance then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods



> Note
>
> If the Citrix ADC appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. Adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

Consistent hashing algorithms

The consistent hashing algorithms are used to achieve stateless persistency. The hash-based LB methods use one of the following three consistent hashing algorithms:

- **Cache Array Routing Protocol (CARP)**

  The CARP algorithm is used in load-balancing HTTP requests across multiple proxy cache

servers. This algorithm is enabled by default.

- **Prime Re-Shuffled Assisted CARP (PRAC)**

  The Citrix ADC appliance uses the proprietary PRAC algorithm to provide uniform traffic distribution.

- **Jump table Assisted Ring Hash (JARH)**

  The Citrix ADC appliance uses the proprietary JARH algorithm to provide consistency and uniform distribution of the traffic. This algorithm uses hash fingers. Higher number of fingers provide better distribution of traffic. However, increasing the number of fingers increases the memory usage as well.

To choose the consistent hashing algorithm by using CLI

```
set lb parameter [-lbHashAlgorithm [DEFAULT|JARH|PRAC] [-lbHashFingers
    <positive_integer>]
<!--NeedCopy-->
```

Example:

```
set lb parameter -lbHashAlgorithm JARH -lbHashFingers 10
<!--NeedCopy-->
```

ARGUMENTS:

- **lbHashAlgorithm**-Specify the hashing algorithm to be used for the following hash-based load balancing methods:
  - URL hash method
  - Domain hash method
  - Destination IP hash method
  - Source IP hash method
  - Source IP Destination IP hash method
  - Source IP Source Port hash method
  - Call ID hash method
  - Token method

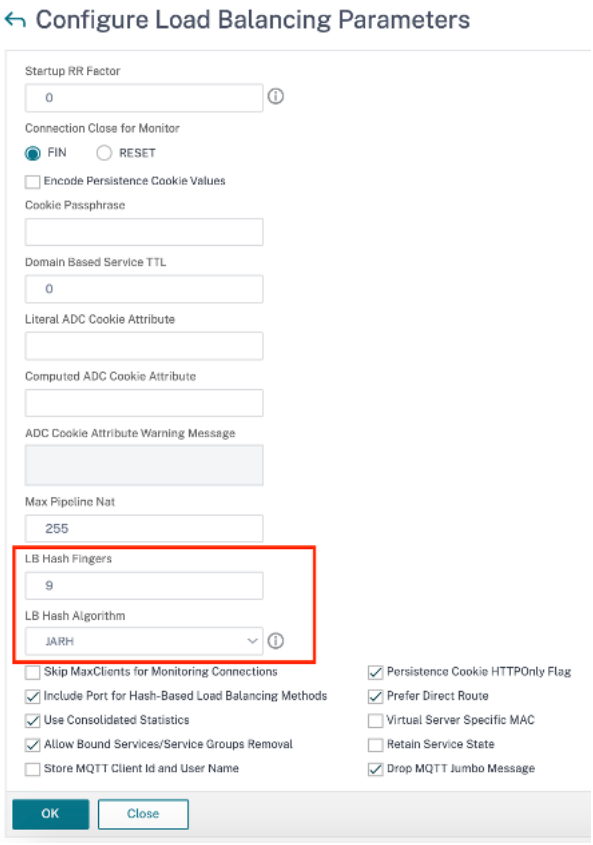
  Possible values: DEFAULT, PRAC, JARH
  Default value: DEFAULT

- **lbHashFingers**-Specify the number of fingers to be used in PRAC and JARH algorithms for hash-based LB methods. Increasing the number of fingers provides better distribution of traffic at the expense of extra memory.

Default value: 256
Minimum value: 1
Maximum value: 1024

To choose the consistent hashing algorithm by using GUI

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters**.
2. In the **Configure Load Balancing Parameters** pane, enter appropriate values for the following fields based on your requirement:
   - LB Hash Fingers
   - In the **LB Hash Algorithm** field, choose the consistent hashing algorithm from the drop-down menu.



The URL Hash Method

When you configure the Citrix ADC appliance to use the URL hash method for load balancing the services, for selecting a service, the appliance generates a hash value of the HTTP URL present in the incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The appliance caches the hashed value of the

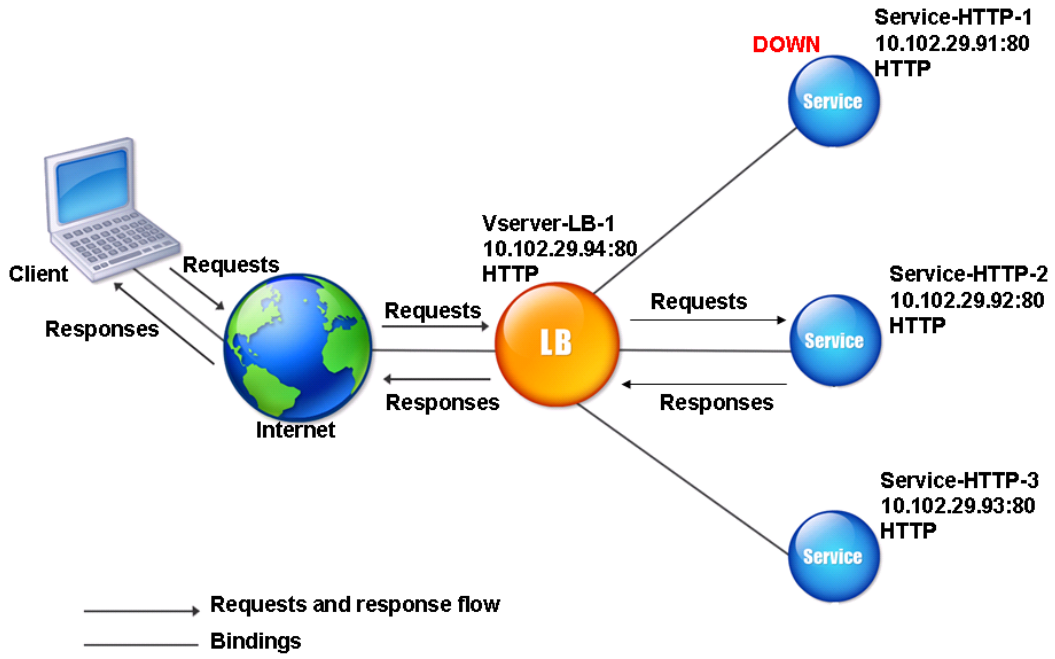
URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the appliance cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, the appliance uses a specific algorithm and considers a part of the URL. By default, the appliance considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 byte to 4096 bytes. Generally, if long URLs are used where only a few characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. Appliance selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the appliance selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates



If both Service-HTTP-1 and Service-HTTP-2 are DOWN, the appliance sends requests with hash value U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to

Service-HTTP-3. If these services are UP, the requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see Configuring a Load Balancing Method that Does Not Include a Policy. Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash value.

The Domain Hash Method

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the appliance gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the Citrix ADC appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the Citrix ADC appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Destination IP Hash Method

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the **Destination IP Hash method**.

To configure the destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Hash Method

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Destination IP Hash Method

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric. The hash value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Source Port Hash Method

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and the source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see Connection Failover.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP source port hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure the call ID hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least bandwidth method

September 14, 2021

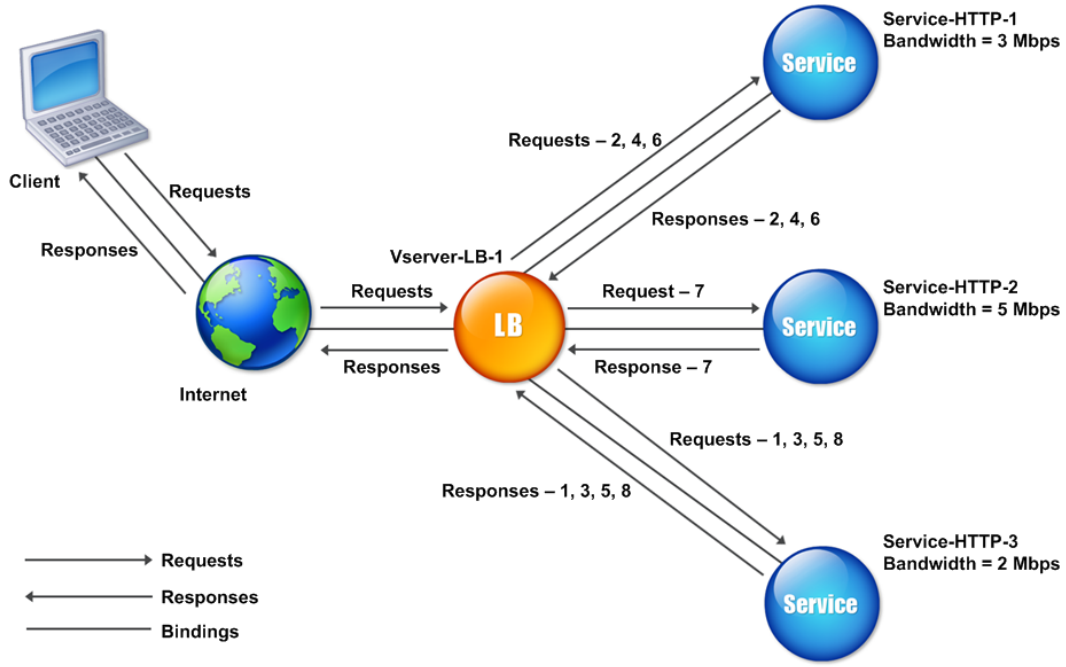
A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.

Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works



The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Because Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have the same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3; (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.

Request Received	Service Selected	Current N Value	Remarks
Request-2	Service-HTTP-1; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3;(N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-4	Service-HTTP-1; (N = 4)	N = 5	-
Request-5	Service-HTTP-3; (N = 4)	N = 5	-
Request-6	Service-HTTP-1; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-3; (N = 5)	N = 6	-

Note: If you enable the RTSP NAT option on the virtual server, the Citrix ADC appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about the RTSP NAT option, see Managing RTSP Connections.

The Citrix ADC appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.

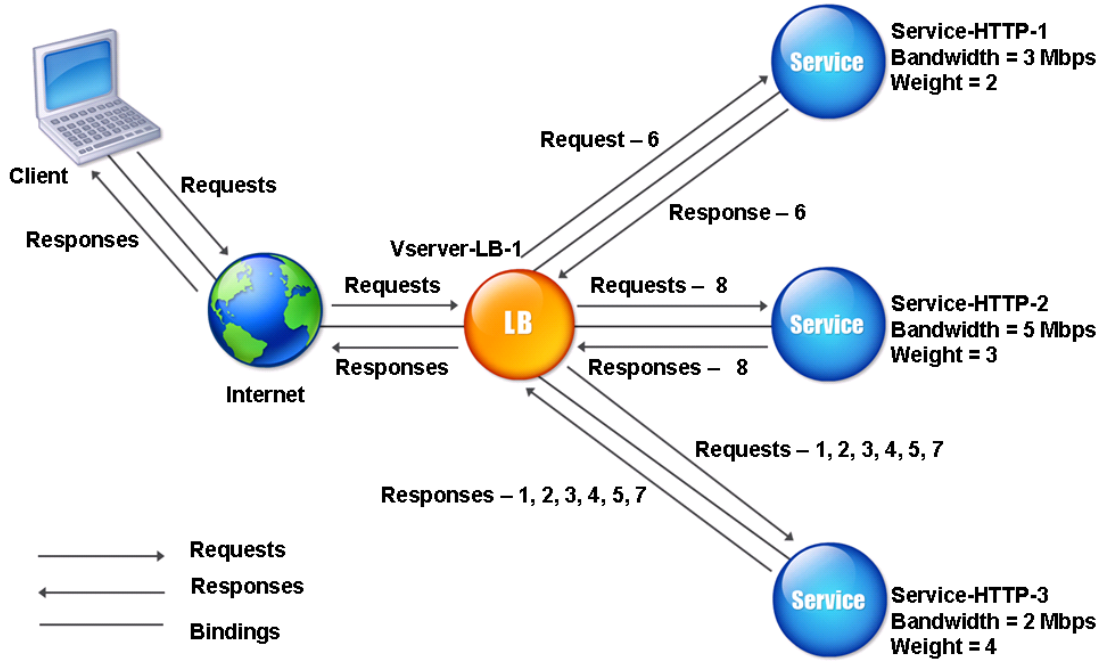
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 7500	-
Request-3	Service-HTTP-3; (Nw = 7500)	Nw = 10000	-
Request-4	Service-HTTP-3; (Nw = 10000)	Nw = 12500	-
Request-5	Service-HTTP-3; (Nw = 12500)	Nw = 15000	-
Request-6	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3; (Nw = 15000)	Nw = 17500	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-8	Service-HTTP-2; (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned



To configure the least bandwidth method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least packets method

September 14, 2021

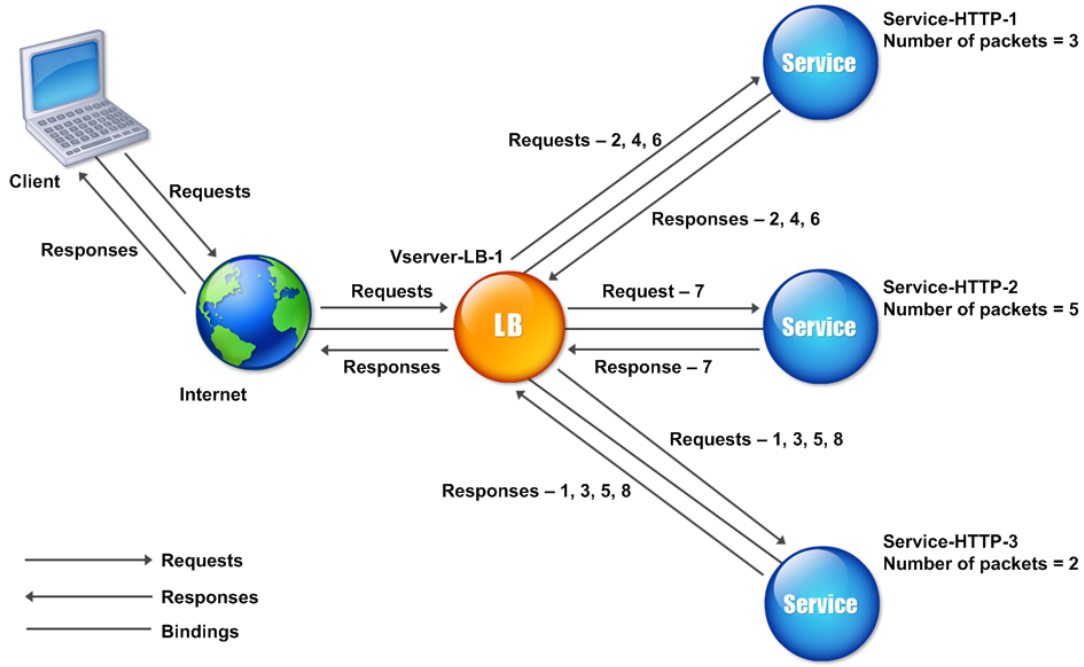
A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in the last 14 seconds.
- Service-HTTP-2 has handled five packets in the last 14 seconds.
- Service-HTTP-3 has handled two packets in the last 14 seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works



The Citrix ADC appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3; (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.

Request Received	Service Selected	Current N Value	Remarks
Request-2	Service-HTTP-1; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-4	Service-HTTP-1; (N = 4)	N = 5	-
Request-5	Service-HTTP-3; (N = 4)	N = 5	-
Request-6	Service-HTTP-1; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-3; (N = 5)	N = 6	-

Note: If you enable the RTSP NAT option on the virtual server, the appliance uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about the RTSP NAT option, see Managing RTSP Connections.

The Citrix ADC appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.

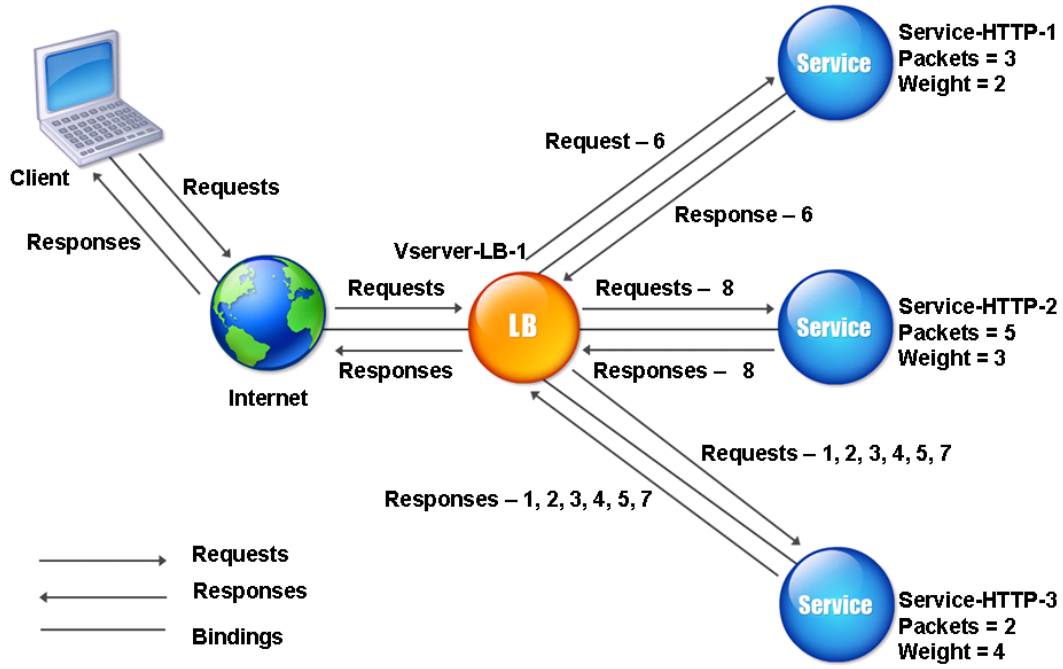
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 7500	-
Request-3	Service-HTTP-3;(Nw = 7500)	Nw = 10000	-
Request-4	Service-HTTP-3; (Nw = 10000)	Nw = 12500	-
Request-5	Service-HTTP-3; (Nw = 12500)	Nw = 15000	-
Request-6	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3; (Nw = 15000)	Nw = 17500	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-8	Service-HTTP-2; (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.

Figure 2. How the Least Packets Method Works When Weights Are Assigned



To configure the least packets method, see Configuring a Load Balancing Method that Does Not Include a Policy.

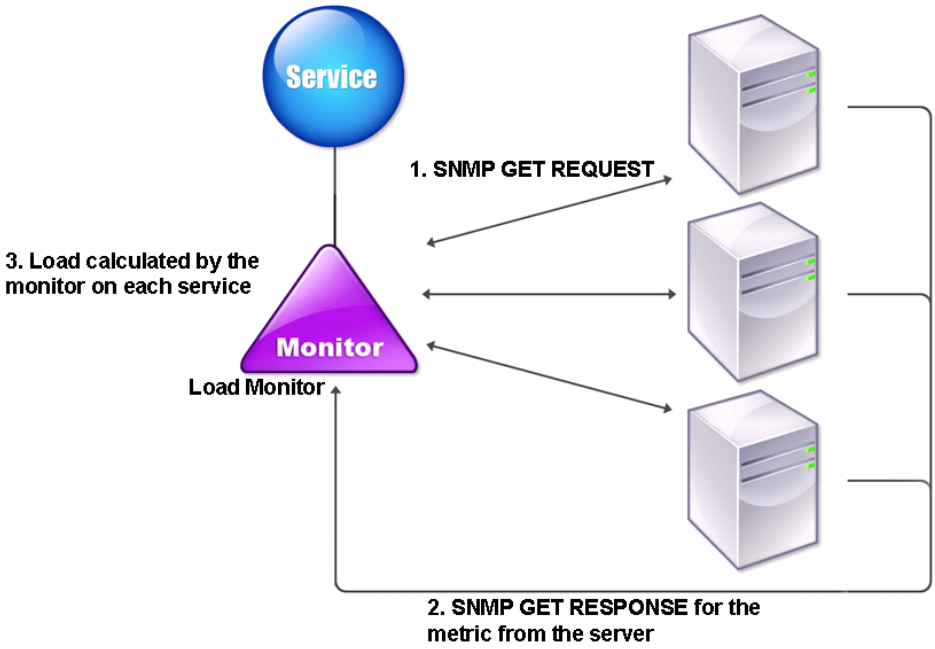
Custom load method

September 14, 2021

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see Understanding Load Monitors. The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate



The load monitor uses SNMP probes to calculate the load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

- Metrics values retrieved through SNMP probes that exist as tables in the Citrix ADC appliance.
- Threshold value set for each metric.
- Weight assigned to each metric.

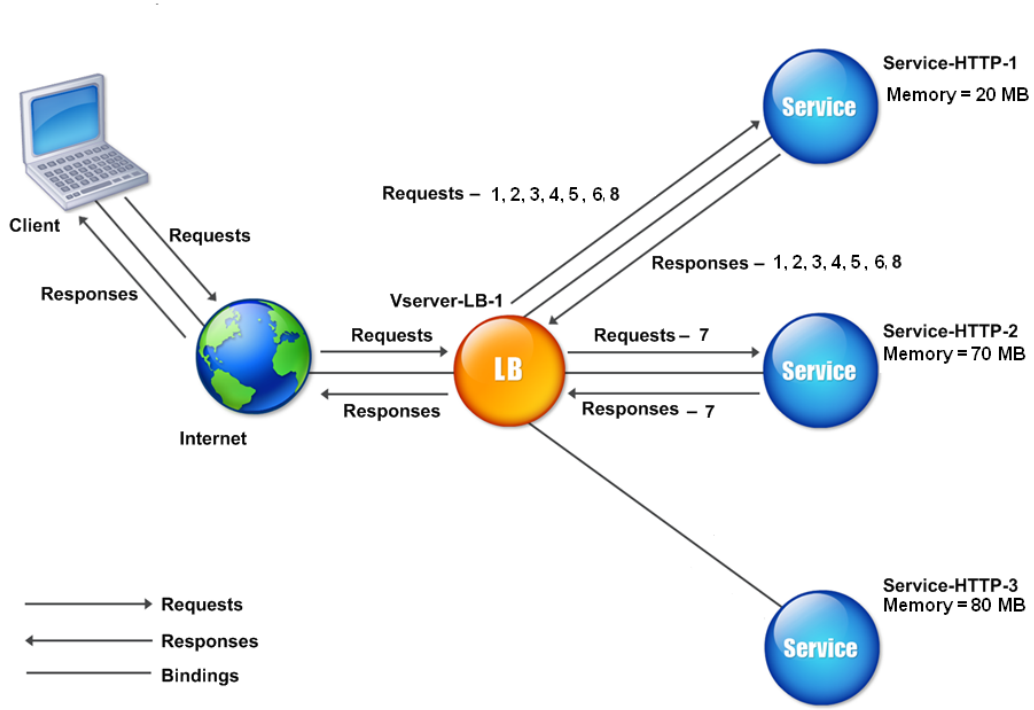
For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 MB of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The

three services respond to the request. The Citrix ADC appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works



If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

Request received	Service selected	Current N Value (Number of Active Transactions)	Remarks
Request-1	Service-HTTP-1; (N = 20)	N = 30	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-1; (N = 30)	N = 40	-
Request-3	Service-HTTP-1; (N = 40)	N = 50	-
Request-4	Service-HTTP-1; (N = 50)	N = 60	-
Request-5	Service-HTTP-1; (N = 60)	N = 70	-
Request-6	Service-HTTP-1; (N = 70)	N = 80	Service-HTTP-2 and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 70)	N = 80	Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-1; (N = 80)	N = 90	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

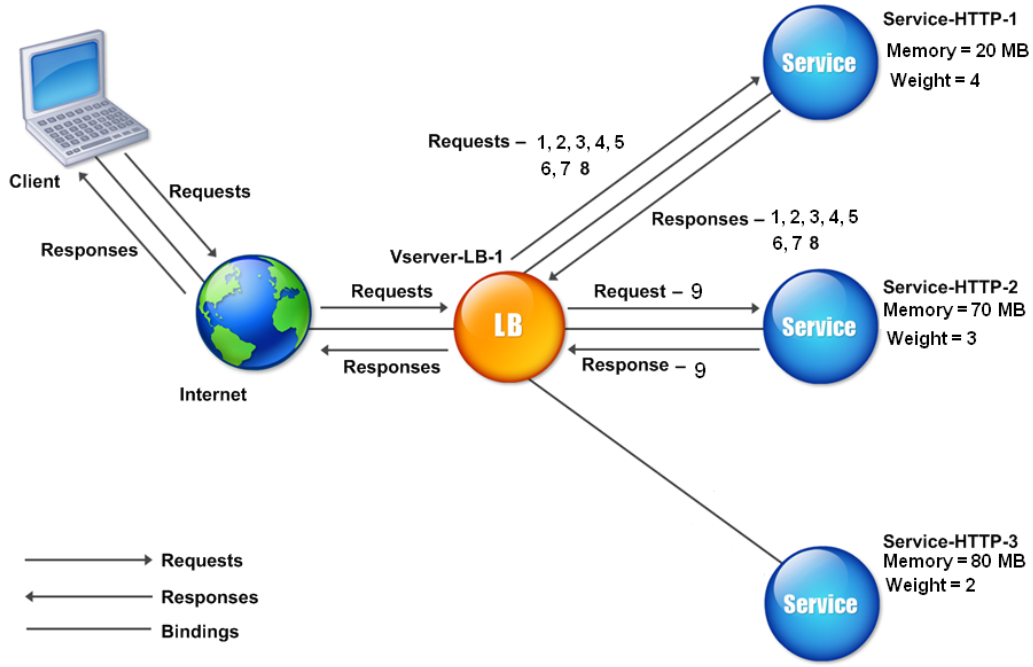
The following table summarizes how Nw is calculated.

Request received	Service selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-1; (Nw = 50000)	Nw = 75000	Service-HTTP-1 has the lowest Nw value.
Request-2	Service-HTTP-1; (Nw = 5000)	Nw = 100000	-
Request-3	Service-HTTP-1; (Nw = 15000)	Nw = 125000	-
Request-4	Service-HTTP-1; (Nw = 20000)	Nw = 150000	-
Request-5	Service-HTTP-1; (Nw = 23333.34)	Nw = 175000	-
Request-6	Service-HTTP-1; (Nw = 25000)	Nw = 200000	-
Request-7	Service-HTTP-1; (Nw = 23333.34)	Nw = 225000	-
Request-8	Service-HTTP-1; (Nw = 25000)	Nw = 250000	-
Request-9	Service-HTTP-2; (Nw = 233333.34)	Nw = 266666.67	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the Citrix ADC appliance uses the custom load method when weights are assigned.

Figure 3. How the Custom Load Method Works When Weights Are Assigned



To configure the custom load method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Static proximity method

September 14, 2021

When a virtual server is configured to use the static proximity method, it selects the service that best matches the proximity criteria.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the load balancing method.

For more details, see the following topics.

- Adding a Location File to Create a Static Proximity Database
- Adding Custom Entries to a Static Proximity Database
- Setting the Location Qualifiers

- Specifying the Static Proximity method

Specifying the Proximity Method

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
set lb vserver <name> -lbMethod STATICPROXIMITY

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod STATICPROXIMITY

show lb vserver
<!--NeedCopy-->
```

To specify static proximity by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and select the virtual server.
2. Click **Edit** and expand the **Method** section.
3. In the **Load Balancing Method** list, select **STATICPROXIMITY**.

Token method

September 14, 2021

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

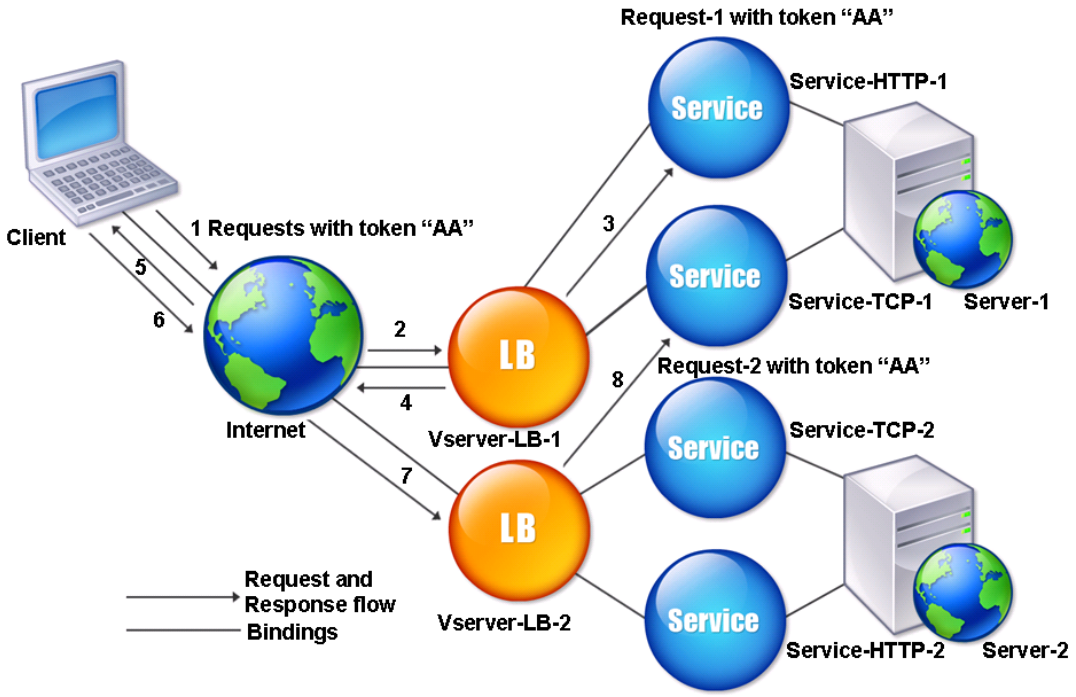
This method is content aware. It operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see Policy Configuration and Reference.

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the appliance searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the Citrix ADC appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works



To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

```
set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length>
     -dataoffset <offset>

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -
   dataoffset 25

show lb vserver LB-VServer-1
<!--NeedCopy-->
```

To configure the token load balancing method by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, click Method
3. In the Load Balancing Method list, select Token, and specify an expression.

Configure a load balancing method that does not include a policy

September 14, 2021

After you select a load balancing algorithm for your load balancing setup, you must configure the Citrix ADC appliance to use that algorithm. You can configure it by using the CLI or by using the configuration utility.

Note:

The token method is policy based and requires more configuration than is described here. To configure the token method, see Token method.

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see Hashing methods.

To set the load balancing method by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -lbMethod <method>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod LeastConnection
<!--NeedCopy-->
```

To set the load balancing method by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, click **Method**, and in the Load Balancing Method list, select a method.

Persistence and persistent connections

September 14, 2021

A load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections if persistence is not configured. Different transmissions from the same client might be directed to different servers even though all the transmissions are part of the same session. You can configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what the implications of each type is. You then need to configure the Citrix ADC appliance to provide persistent connections for those websites and Web applications that require them.

You can also configure backup persistence, which takes effect if the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see Configuring RADIUS Load Balancing with Persistence.

About Persistence

September 14, 2021

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, web-based email, or other network application. The persistence session remains in effect for the time which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the Citrix ADC appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that

allows the appliance to match connections with the proper persistence session and is used as the basis for persistence.

The following table summarizes the persistence types available on the Citrix ADC appliance.

Persistence Type	Description
Source IP	SOURCEIP. Connections from the same client IP address are parts of the same persistence session.
HTTP Cookie	COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.
SSL Session ID	SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.
URL Passive	URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.
Custom Server ID	CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.
Destination IP	DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.
Source and Destination IPs	SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP are treated as parts of the same persistence session.
SIP Call ID	CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session.
RTSP Session ID	RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.
User-Defined Rule	RULE. Connections that match a user-defined rule are treated as parts of the same persistence session.

Table 1. Types of Persistence

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

Persistence Type	Number of Simultaneous Persistent Connections Supported
Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID	250 K
Cookie, URL Server ID, Custom Server ID	Memory limit. In CookieInsert, if timeout is not 0, the number of connections is limited by memory.

Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

Persistence Type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
SOURCEI	YES	YES	YES	YES	YES	YES	NO	NO
COOKIEINSERT	YES	YES	NO	NO	NO	NO	NO	NO
SSLSESS	NO	YES	NO	NO	YES	YES	NO	NO
URLPASSIVE	S	YES	NO	NO	NO	NO	NO	NO
CUSTOM	YES	YES	NO	NO	NO	NO	NO	NO
RULE	YES	YES	YES	NO	NO		NO	NO
SRCIPDE	YES	YES	YES	YES	YES	YES	NO	NO
DESTIP	YES	YES	YES	YES	YES	YES	NO	NO
CALLID	NO	NO	NO	NO	NO	NO	NO	YES
RTSPID	NO	NO	NO	NO	NO	NO	YES	NO

Table 3. Relationship of Persistence Type to Virtual Server Type

Source IP address persistence

September 14, 2021

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

Caution: In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single website or application are routed through the single gateway to the Citrix ADC appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session must be created. This issue is called the "Mega Proxy problem." You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see Configuring Persistence Types That Do Not Require a Rule.

Note: If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the Citrix ADC appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.

HTTP cookie persistence

September 14, 2021

When HTTP cookie persistence is configured, the Citrix ADC appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the Citrix ADC appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any appliance resources and therefore can accommodate an unlimited number of persistent clients.

Note: If the client's Web browser is configured to refuse cookies, HTTP cookie-based persistence does not work. It might be advisable to configure a cookie check on the website, and warn clients that do not appear to be storing cookies properly that they need to enable cookies for the website if they want to use it.

The format of the cookie that the Citrix ADC appliance inserts is:

```
NSC_XXXX=<ServiceIP ><ServicePort>
```

Where:

- NSC_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period, the Citrix ADC appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the Citrix ADC appliance does not specify an expiration time, but sets a session cookie that is not saved when the client's browser is shut down.

By default, the Citrix ADC appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the "Max-Age" attribute of the HTTP cookie. In this case, the client's browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see Configuring Persistence Types That Do Not Require a Rule.

In the HTTP cookie, the appliance by default sets the `HTTPOnly` flag to indicate that the cookie is nonscriptable and must not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the `HTTPOnly` flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the `HTTPOnly` flag in the persistence cookie.

To change the HTTPOnly flag setting by using the CLI

At the command prompt, type:

```
set lb parameter -httpOnlyCookieFlag (ENABLED|DISABLED)
<!--NeedCopy-->
```

Example:

```
>  set lb parameter -httpOnlyCookieFlag disabled
   Done
> show lb parameter
  Global LB parameters:
       Persistence Cookie HttpOnly Flag: DISABLED
       Use port for hash LB: YES
 Done
<!--NeedCopy-->
```

To change the HTTPOnly flag setting by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, and select or clear the **Persistence Cookie HTTPOnly** flag.

Encrypting the Cookie

From release 10.5 build 55.8, you can encrypt the cookie in addition to any SSL encryption.

To encrypt the cookie by using the command line interface, at the command prompt, type

```
set lb parameter -UseEncryptedPersistenceCookie ENABLED -
   cookiePassphrase test
<!--NeedCopy-->
```

To encrypt the cookie by using the configuration utility

1. Navigate to **Traffic Management** > **Change Load Balancing Parameters**, and select **Encode Persistence Cookie Values** and enter a passphrase in **Cookie Passphrase**.

SSL session ID persistence

September 14, 2021

When SSL session ID persistence is configured, the Citrix ADC appliance uses the SSL session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

Note:

There are two issues that users must consider before choosing this type of persistence. First, this type of persistence consumes resources on the Citrix ADC appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support multiple persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server must renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client's next request is received. This might result in the client's activity on the website being interrupted and the client might be asked to reauthenticate or restart the session. It might also result in large numbers of abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see Configuring Persistence Types That Do Not Require a Rule.

> **Note**
>
> SSL session ID persistence is not supported with session tickets.

Back up persistence support for SSL session ID

From NetScaler release 12.0 build 56.20, source IP persistence is supported as a backup persistence type for SSL session ID persistence. If the client and load-balanced server renegotiate the session, and source IP persistence is configured as the backup persistence, client requests are forwarded to the same server.

To support backup persistence for SSL session ID, the Citrix ADC appliance creates session entries for both source IP and SSL session ID when a client request is received for the first time. For the subsequent requests containing the same session ID, the SSL session ID is used. However, when the client and the load-balanced server renegotiate the session, the client request is forwarded to the same server by using the Source IP persistence and a new SSL Session ID persistence entry is created.

For information about configuring backup persistence, see Configuring Backup Persistence.

Diameter AVP number persistence

September 14, 2021

You can use persistence based on the Attribute-Value Pair (AVP) number of a Diameter message to create persistent Diameter sessions. When the Citrix ADC appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if the persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

To configure Diameter-based persistence on a virtual server by using the command line interface

At the command prompt, type the following command:

```
1 set lb vserver <name> -PersistenceType <type-> persistAVPno <
     positive_integer>
2 <!--NeedCopy-->
```

Example:

```
1 set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
2 <!--NeedCopy-->
```

Custom server ID persistence

September 14, 2021

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The Citrix ADC appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider must make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the Citrix ADC appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

Note: The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

Example:

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789

set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
<!--NeedCopy-->
```

On virtual server Web11, enable Custom Server ID persistence.

Create the following expression so that all URL queries containing the string “sid=” are examined.

HTTP.REQ.URL.AFTER_STR(“sid=”)

Example:

```
set lb vserver Web11 -persistenceType customserverID -rule "HTTP.REQ.
   URL.AFTER_STR("sid=")"

bind lb vserver Web11 Service-[1-2]
<!--NeedCopy-->
```

When a client sends a request with the following URL to the IP address of Web11, the appliance directs the request to Service-2 and honors persistence.

Example:

```
http://www.example.com/index.asp?&sid=2345-drawing-abb123
```

For more information about default-syntax policy expressions, see the Policy Configuration and Reference.

To configure custom server ID persistence by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.

2. Open the service and set a server ID.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
4. In Advanced Settings, select Persistence.
5. Select CUSTOMESERVERID, and specify an expression.

IP address persistence

September 14, 2021

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

Persistence Based on Destination IP Addresses

With destination IP address-based persistence, when the Citrix ADC appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the virtual server (the destination IP address). Later, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see Link Load Balancing.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on the destination IP address, see Configuring Persistence Types That Do Not Require a Rule.

Persistence Based on Source and Destination IP Addresses

With source and destination IP address-based persistence, when the Citrix ADC appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address). Later, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on both source and destination IP addresses, see Configuring Persistence Types That Do Not Require a Rule.

SIP Call ID persistence

September 14, 2021

With SIP Call ID persistence, the Citrix ADC appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure persistence based on SIP Call ID, see Configuring Persistence Types That Do Not Require a Rule.

RTSP session ID persistence

September 14, 2021

With RTSP Session ID persistence, when the Citrix ADC appliance receives a request from a new client, it creates a persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

Note: RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting.

Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that might issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see Configuring Persistence Types That Do Not Require a Rule.

Important: If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

Configure URL passive persistence

September 14, 2021

With URL Passive persistence, when the Citrix ADC appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see Policies and Expressions.

The following expression configures the appliance to examine requests for URL queries that contain the string "urlp=", extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

HTTP.REQ.URL.AFTER_STR("urlp=")

If URL passive persistence is enabled and the previous expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

```
http://www.example.com/index.asp?&urlp=0A661D0A0050
```

The persistence time-out value does not affect this persistence type. Persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any appliance resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule. You set the persistence type to URLPASSIVE. You then perform the following procedures.

To configure URL passive persistence by using the CLI

At the command prompt, type:

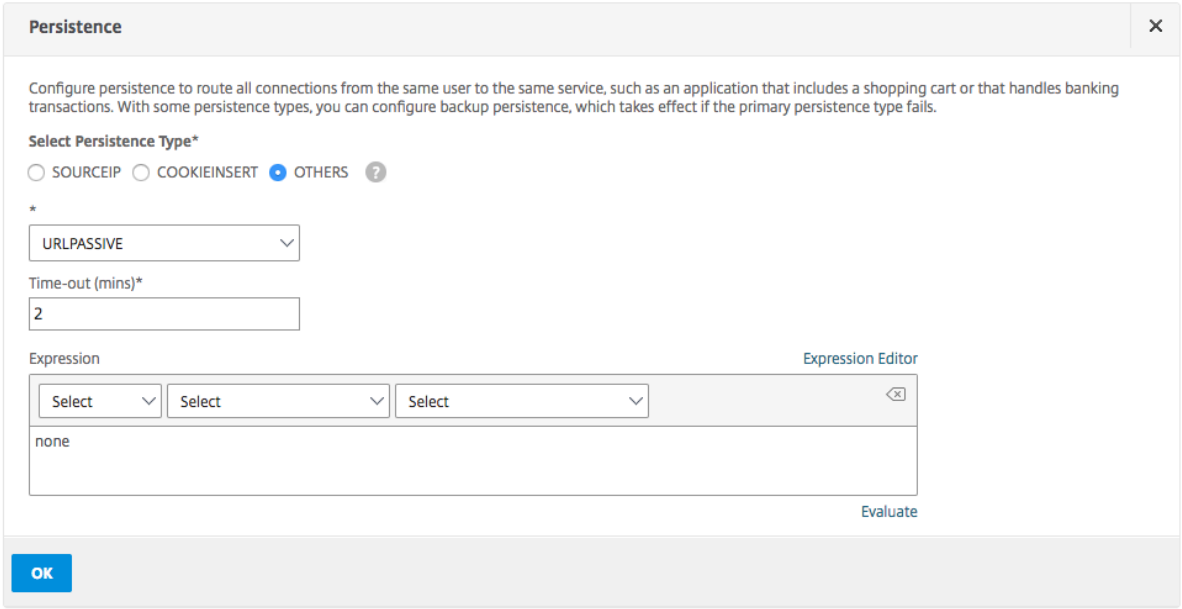
```
set lb vserver <vserverName>  [-persistenceType <persistenceType>]  [-
    rule <expression>]
<!--NeedCopy-->
```

Example:

```
set lb vserver LB-VServer-1 -persistenceType URLPASSIVE  -rule HTTP.REQ
    .URL.AFTER_STR( "urlp=" )
<!--NeedCopy-->
```

To configure persistence on a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.



> **Note:**
>
> Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Configure persistence based on user-defined rules

September 20, 2021

> **Warning:**
>
> The use of Classic expressions for the persistence rule in the load balancing feature is deprecated. However Classic expressions are removed and no longer available for the filter rule on the Citrix ADC appliance release 13.1 onwards.

When rule based persistence is configured, the Citrix ADC appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Later, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP,

and SSL_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you can use a classic expression to configure persistence based on the contents of the HTTP Host header. You can also use a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see Policies and Expressions.

The expressions that you can configure depend on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

Note: For a use case that involves configuring rule based persistence based on Financial Information eXchange ("FIX") Protocol data transmitted over TCP, see Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream.

Rule based persistence can be used for maintaining persistence with entities such as Citrix SD-WAN appliances, Citrix SD-WAN plug-ins, cache servers, and application servers.

Note: On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule, and set the persistence type to RULE. You can then perform the following procedures. You can configure rule based persistence by using the configuration utility or the CLI.

To configure persistence based on user-defined rules by using the CLI

At the command prompt, type:

```
set lb vserver <vserverName> [-rule <expression>][-resRule <expression
    >]
<!--NeedCopy-->
```

Example:

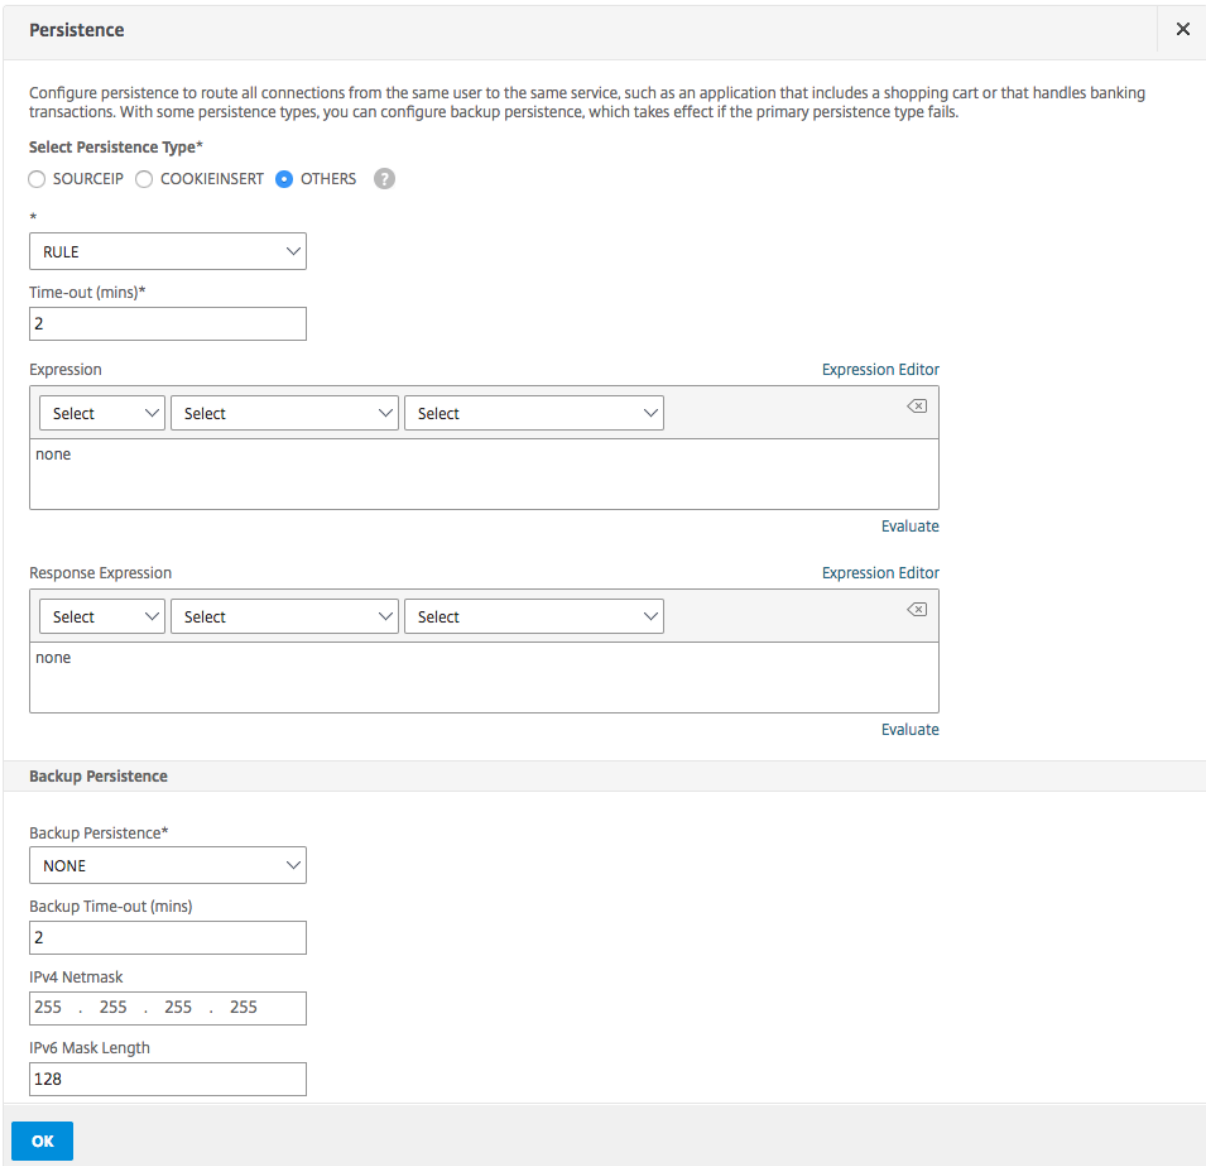
```
set lb vserver vsvr_name -rule http.req.header("cookie").value(0).
    typecast_nvlist_t('=',';').value("server")

set lb vserver vsvr_name -resrule http.res.header("set-cookie").value
    (0).typecast_nvlist_t('=',';').value("server")
```

```
4
5 <!--NeedCopy-->
```

To configure persistence based on user-defined rules by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.



> **Note**
>
> Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Example: Classic Expression for a Request Payload

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, “MyBrowser”, and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

```
http header User-Agent contains MyBrowser
<!--NeedCopy-->
```

Example: Default syntax Expression for a Request Header

The following default syntax expression does the same thing as the previous classic expression.

HTTP.REQ.HEADER(“User-Agent”).CONTAINS (“MyBrowser”)

Example: Default syntax Expression for a Response Cookie

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

HTTP.RES.HEADER(“SET-COOKIE”).VALUE(0).TYPECAST_NVLIST_T(‘=’,’;’).VALUE(“server”)

Configure persistence types that do not require a rule

September 14, 2021

To configure persistence, you must first set up a load balancing virtual server, as described in Setting Up Basic Load Balancing. You then configure persistence on the virtual server.

To configure persistence on a virtual server by using the CLI

At the command prompt, type the following commands to configure persistence and verify the configuration:

```
set lb vserver <name> -PersistenceType <type> [-timeout <integer>]

```

```
3 show lb vserver
4 <!--NeedCopy-->
```

Example:

```
1 set lb vserver Vserver-LB-1 -persistenceType SOURCEIP -timeout 60
2
3 show lb vserver
4 <!--NeedCopy-->
```

Timeout is the time period for which a persistence session is in effect. The timeout default and minimum values (in minutes) vary based on the persistence type as listed in the following table.

persistence type	Default value	Minimum value	Maximum value
Cookie insert/group cookie insert	2	0	1440
Other persistence types	2	2	1440

Note

- Group cookie insert persistence type can be set on the load balancing group.
- For IP-based persistence, you can also set the persistMask parameter.
- The persistence type by default is set to NONE.

To configure persistence on a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the **Others** list.

> **Note** Prior to Citrix ADC release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Configure backup persistence

September 14, 2021

You can configure a virtual server to use the source IP persistence type when the primary persistence type fails.

The following table describes the combinations of primary and secondary backup persistence types, and the conditions when the backup persistence is used.

Primary persistence	Backup persistence	When the primary persistence lookup fails…
Cookie Insert	Source IP	The appliance falls back to source-IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.
Rule	Source IP	The appliance uses source-IP based persistence when the parameter specified in the rule is missing in the incoming request.

Note

- If the primary persistence type is HTTP-cookie based persistence, and the backup persistence type is Source IP-based, you can set a timeout value for backup persistence. For instructions, see Setting a Timeout Value for Idle Client Connections.
- You cannot set a timeout value for backup persistence when the primary persistence is rule based, because in that case the timeout value for secondary persistence must be the same as for the primary persistence. Therefore, the primary and secondary expire at the same time.

To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -persistenceType <PersistenceType> -
    persistenceBackup <BackupPersistenceType>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -persistenceType CookieInsert -
    persistenceBackup SourceIP
```

```
2
3 set lb vserver Vserver-LB-1 -persistenceType sslsession -
     persistenceBackup SourceIP
4
5 set lb vserver Vserver-LB-1  - persistenceType RULE  - rule http.req.
     header("User-Agent").value(0).contains("MyBrowser")  -
     persistenceBackup SOURCEIP
6
7 set lb vserver Vserver-LB-1 -persistenceType sslsession -
     persistenceBackup SourceIP
8 <!--NeedCopy-->
```

To set backup persistence for a virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In **Advanced Settings**, select **Persistence**, and specify a backup persistence type.

Note: The primary persistence must be set to COOKIEINSERT, RULE, or SSLSESSION.

Configure persistence groups

September 14, 2021

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

When you add a virtual server that has persistence sessions to a load balancing group with a different persistence type, the existing persistent sessions specific to an old persistence type are deleted.

The persistent sessions decide whether the traffic must go to the same virtual server or to a different server. Therefore, existing established connections are not impacted.

The persistence type of a load balancing group is applied to all the virtual servers bound to that group, irrespective of the virtual servers' protocol type. A load balancing group supports the following persistence types:

- SourceIP
- CookieInsert
- Rule

Some virtual servers support only certain persistence types. For example, a virtual server of type SSL_BRIDGE can use only SourceIP persistence type for an LB group.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see Persistence Based on HTTP Cookies.

To create a virtual server persistency group by using the command line interface

At the command prompt, type:

```
bind lb group <vServerGroupName> <vServerName> -persistenceType <
    PersistenceType>
<!--NeedCopy-->
```

Example:

```
bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType
    CookieInsert
<!--NeedCopy-->
```

To modify a virtual server group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Persistency Groups**, create a persistency group, and specify the virtual servers that must be part of this group.

To modify a virtual server group by using the command line interface

At the command prompt, type:

```
set lb group <vServerGroupName> -PersistenceBackup <
    BackupPersistenceType> -persistMask <SubnetMaskAddress>
```

```
<!--NeedCopy-->
```

Example:

```
set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask
   255.255.255.255
<!--NeedCopy-->
```

Share persistent sessions between virtual servers

September 14, 2021

In some customer environments (telecom and ISP), a single server handles both control and data traffic. For a given client IP address, both control and data traffic have to be directed to the same back-end server. For this, one virtual server is required for handling client authentication traffic, and usually rule based persistency is configured on it. For example, Radius.req.avp(8).value.typecast_text_t'. The second virtual server for handling data traffic. Usually, SourceIP persistence is configured on it.

Previously, persistence entries were local to the virtual server. If you had to apply persistence across multiple virtual servers, you had to add the virtual server to a load balancing group and then apply a common persistence type to the group. This requirement cannot be achieved, because all the virtual servers bound to a load balancing group inherited the persistency configured on the group.

With the persistency sharing between virtual server feature, you can set the new `useVserverPersistency` parameter for a load balancing group to allow the virtual server in the group to use their own persistency parameters instead of inheriting them from the group settings. You can configure separate rule-based persistency on each virtual server.

Optionally, you can also designate one of the virtual servers in the group as a main virtual server. When a virtual server is designated as a main virtual server, only that virtual server creates the persistence entries, which are used by all the virtual server in the group. If the main virtual server is down, the Citrix ADC appliance does not create any persistence entries.

Note: Persistence sharing across the virtual servers is supported only for rule based persistency methods. Configure compatible rule based persistence parameters on the member virtual servers.

Example:

Assume v1 and v2 are bound to a load balancing group, v1 is a RADIUS type virtual server and v2 is an HTTP type virtual server. 'Radius.req.avp(8).value.typecast_text_t' persistency is configured on v1 and 'client.ip.src' is configured on v2.

When traffic flows through the RADIUS virtual server v1, it creates a persistent entry based on the evaluated rule string. Later, when traffic reaches the HTTP type virtual server v2, v2 checks for the

persistence entries on the load balancing group and uses the same persistence session to direct traffic to the same back-end server.

Configuring Sharing of Persistent Sessions

To share persistency parameters across the virtual server in a load balancing group, you must first enable the useVserverPersistency parameter and then designate one of the virtual servers in the group as a main server.

To enable the useVserverPersistency parameter by using the command line interface

At the command prompt, type:

```
set lb group <name> -useVserverPersistency ( ENABLED)
<!--NeedCopy-->
```

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED
<!--NeedCopy-->
```

To enable the useVserverPersistency parameter by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.

To designate a virtual server as a main virtual server by using the command line interface

At the command prompt, type:

```
set lb group <name> -useVserverPersistency ( ENABLED ) -masterVserver <
    string>
<!--NeedCopy-->
```

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED - masterVserver vs1
<!--NeedCopy-->
```

To designate a virtual server as a main virtual server by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.
4. In the **Virtual Server Name** box, click **+** to add the virtual server to the group. You can select the available virtual server or create a virtual server.
5. Click **Create** if you are adding a new group or **Close** if you are modifying an existing group.
6. Select the group for which you have enabled the useVserverPersistency parameter and click **Edit** to set a virtual server as a main to create persistence entries.
7. From the **Master vServer** list, select the virtual server that has to be designated as a main virtual server.

Arguments

useVserverPersistency

Allow the virtual servers in a group to use their own persistency parameters to create persistent sessions, instead of inheriting the persistency settings from the group settings. When this parameter is enabled, persistence cannot be set on the load balancing group.

When this parameter is disabled, the group's virtual servers inherit the persistency parameters from the group settings.

When this parameter is toggled on the load balancing group, the Citrix ADC appliance flushes all the corresponding persistence entries of the group and the member virtual servers.

Possible values: ENABLED, DISABLED

Default: DISABLED

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED
<!--NeedCopy-->
```

masterVserver

Designate a virtual server as a main virtual server in its load balancing group. Once designated, only the main virtual server can create the persistent entries used by the group.

Note: This parameter can be set only if the useVserverPersistency parameter is enabled.

Example:

```
set lb group lb_grp1 -masterVserver vs1
<!--NeedCopy-->
```

Example Configuration of Sharing Persistent Sessions by Using the Command Line Interface

The virtual servers are created

```
add lb vs vs1 http 10.1.10.11 80 -persistence rule -rule 'client.ip.src'

add lb vs vs2 radius 10.2.2.2 1812 -persistenceType rule -rule 'Radius.req.avp(8).value.typecast_text_t'
<!--NeedCopy-->
```

The groups are created.

```
add lb group lb_grp1 -persistenceType NONE -useVserverPersistency ENABLED
<!--NeedCopy-->
```

A virtual server in a group is designated as the main virtual server.

```
set lb group lb_grp1 -masterVserver vs1
<!--NeedCopy-->
```

The virtual servers are bound to the group.

```
bind lb group lb_grp1 vs1
bind lb group lb_grp1 vs2
<!--NeedCopy-->
```

For more details, see Setting Up Basic Load Balancing and Configuring Persistence Groups.

Configure RADIUS load balancing with persistence

September 14, 2021

Today's complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users might connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections,

WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the Citrix ADC appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in AAA Application Traffic. Also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

Enabling the Load Balancing or Content Switching Feature

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new Citrix ADC appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a Citrix ADC appliance with a previous configuration on it, and you are not certain that the feature you use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see Enabling Load Balancing.
- For instructions on enabling the content switching feature, see Enabling Content Switching

Configuring Virtual Servers

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service handles authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service handles accounting connections to your RADIUS server. Accounting traffic consists of connections that

track an authenticated user's activities on your protected application or VPN.

Important: You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a load balancing virtual server and verify the configuration:

```
1 add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
     <rule>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

To configure an existing load balancing virtual server, replace the preceding `add lb virtual server` command with the `set lb vserver` command, which takes the same arguments.

To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a content switching virtual server and verify the configuration:

```
1 add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
     <rule>
2
3 show cs vserver <name>
4 <!--NeedCopy-->
```

To configure an existing content switching virtual server, replace the preceding `add cs vserver` command with the `set cs vserver` command, which takes the same arguments.

Example:

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
     TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2
3 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
     TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
4
5 set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
     TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
6
```

```
set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813 -lbmethod
   TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
<!--NeedCopy-->
```

To configure a load balancing or content switching virtual server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers** or navigate to **Traffic Management > Content Switching > Virtual Servers»**, and configure a virtual server.

Configuring Services

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created.

Note: Once configured, these services are in the DISABLED state until the Citrix ADC appliance can connect to your RADIUS server's authentication and accounting IPs and monitor their status. For instructions, see Configuring Services.

Binding Virtual Servers to Services

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service.For instructions, see Binding Services to the Virtual Server.

Configuring a Persistency Group for Radius

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. A persistency group is required because the authentication and accounting virtual servers are different and both the authentication & accounting message for a single user should reach the same RADIUS server. Persistency group enables to use the same session for both virtual servers. For instructions, see Configuring Persistence Groups.

Configuring RADIUS Shared Secret

From release 12.0, a Citrix ADC appliance supports RADIUS shared secret. A RADIUS client and server communicate with each other by using a shared secret that is configured on the client and on the server. Transactions between a RADIUS client and server are authenticated by using a shared secret. This secret is also used to encrypt some of the information in the RADIUS packet.

RADIUS shared secret key validation scenarios

The validation of the **RADIUS shared secret** key happens in the following scenarios:

- **RADIUS shared secret key is configured for both the radius client and the radius server:** The Citrix ADC appliance uses the RADIUS secret key for both the client side and the server side. If the verification succeeds, the appliance allows the RADIUS message to go through. Otherwise, it drops the RADIUS message.
- **RADIUS shared secret key is not configured for either the radius client or the radius server:** The Citrix ADC appliance drops the RADIUS message, because shared-secret-key validation cannot be performed on a node that has no radkey configured.
- **RADIUS shared secret key is not configured for both the RADIUS client and the RADIUS server:** The Citrix ADC appliance bypasses the RADIUS secret key validation and allows the RADIUS messages to go through.

You can configure a default RADIUS shared secret or configure on a per client or a subnet basis. It is recommended to add a RADIUS shared secret key for all deployments with RADIUS policy configured. The appliance uses the source IP address of the RADIUS packet to decide which shared secret to use. You might configure a RADIUS client and server and the corresponding shared secret as follows:

At the CLI prompt, type:

```
add radiusNode <clientPrefix/Subnet> -radKey <Shared_secret_key>
<!--NeedCopy-->
```

Arguments

IPaddress

IP address or subnet of the RADIUS client in CIDR format. The appliance uses the source IP address of an incoming request packet to match the client IP address. Instead of configuring a client IP address, you can configure the client network address. Longest prefix is matched to identify the shared secret for an incoming client request.

Radkey

Shared secret between the client, Citrix ADC appliance, and the server. Maximum length: 31.

```
add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

```

```
add service radius_auth_service1 192.168.41.68 RADIUS 1812

add service radius_acct_service1 192.168.41.70 RADIUS 1813

bind lb vserver radius_auth_vs1 radius_auth_service1

bind lb vserver radius_acct_vs1 radius_acct_service[1-3]

add radiusNode 192.168.41.0/24 -radKey  serverkey123

add radiusNode 203.0.113.0/24 -radkey clientkey123
<!--NeedCopy-->
```

A shared secret must be configured both for a RADIUS client and server. The command is the same. The subnet determines whether the shared secret is for a client or for a server.

For example, if the subnet specified is a client subnet, the shared secret is for the client. If the subnet specified is a server subnet (192.168.41.0/24 in the earlier example), the shared secret is for the server.

A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients and servers.

> **Note:**
>
> Only the PAP and CHAP authentication methods are supported with RADIUS shared secret.

View persistence sessions

September 14, 2021

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

> **Note**: A Citrix ADC nCore appliance uses multiple CPU cores for packet handling. The CPU core owns every session on the appliance. If the appliance receives a request for which a session does not exist, a session is created, and one of the cores is designated as the owner of that session.
>
> Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current.

However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session.

Therefore, in the output of successively run show lb persistentSessions commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to

0 (zero), even if the persistence session remains active.

To view persistence sessions by using the command line interface

At the command prompt, to view persistence sessions related to all virtual servers, type:

```
show lb persistentSessions [<vServer>]
<!--NeedCopy-->
```

At the command prompt, to view persistence sessions related a virtual server, type:

```
show lb persistentSessions <vServername>
<!--NeedCopy-->
```

Example:

```
show lb persistentSessions myVserver
<!--NeedCopy-->
```

To view persistence sessions by using the GUI

Navigate to **Traffic Management** > **Virtual server persistent sessions**.

Clear persistence sessions

September 14, 2021

You might need to clear persistence sessions from the Citrix ADC appliance if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

To clear a persistence session by using the command line interface

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

```
clear lb persistentSessions [<vServer> [-persistenceParam <string>]]

show persistentSessions <vServer>
```

```
<!--NeedCopy-->
```

Examples:

Example 1 clears all persistence sessions for load balancing virtual server lbvip1.

Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with the persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

Example 1:

```
> clear persistentSessions lbvip1
 Done
> show persistentSessions
 Done
>
<!--NeedCopy-->
```

Example 2:

```
> show persistentSessions lbvip1
Type        SRC-IP    ...    PERSISTENCE-PARAMETER
RULE        0.0.0.0   ...    xls
RULE        0.0.0.0   ...    txt
RULE        0.0.0.0   ...    html
 Done
> clear persistentSessions lbvip1 -persistenceParam xls
 Done
> show persistentSessions lbvip1
Type        SRC-IP    ...    PERSISTENCE-PARAMETER
RULE        0.0.0.0   ...    txt
RULE        0.0.0.0   ...    html
 Done
>
<!--NeedCopy-->
```

To clear persistence sessions by using the configuration utility

1. Navigate to **Traffic Management > Clear Persistent Sessions**.

Override persistence settings for overloaded services

September 14, 2021

When a service is loaded or is otherwise unavailable, service to clients is degraded. In this case, you might have to configure the Citrix ADC appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the skippersistency parameter. When this skippersistence parameter is set, and if the virtual server receives new connections for an overloaded service, the following happens.

- The virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests.
- Persistence sessions associated with other services are not affected.

This functionality is available for only virtual servers whose type is ANY or UDP.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see Understanding Load Monitors.

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services based on the load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.

  Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server based on the destination IP address in the request.

  Only wildcard virtual servers of type ANY and UDP support the bypass option. Wildcard virtual servers have a *:* IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the Citrix ADC appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. The virtual server sends requests directly to their destination IP addresses in the following conditions.

- You configure the virtual server to bypass the virtual server–service configuration for overloaded services.
- The Branch Repeater appliance or firewall gets overloaded.

The virtual server sends requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

To override persistence settings for overloaded services by using the CLI

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

```
set lb vserver <name> -skippersistency <skippersistency>

show lb vserver <name>
<!--NeedCopy-->
```

Example

```
> set lb vserver mylbvserver -skippersistency ReLb
 Done
> show lb vserver mylbvserver
    mylbvserver (*:*) - ANY Type: ADDRESS
       . . .
       . . .
 Skip Persistency: ReLb
       . . .
 Done
>
<!--NeedCopy-->
```

To override persistence settings for overloaded services by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server of type UDP or ANY.
2. In the Advanced Settings pane, select Traffic Settings, and specify the type of Skip Persistency.

Troubleshooting

September 14, 2021

- **The statistics from the Citrix ADC VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?**

  Cause: The Citrix ADC appliance has the system limit of 250,000 persistence session for a core.

  Resolution: To resolve this issue, you can perform any of the following tasks:

  - Reduce the time-out value for persistence
  - Increase the number of cores for the appliance

- **After configuring Cookie Insert persistence on the Citrix ADC appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?**

  Cause: By default, the time-out value for Cookie Insert persistence is 120 seconds.

  Resolution: When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

- **After configuring an HTTP virtual server on the Citrix ADC appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?**

  Resolution: Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

- **After configuring Cookie Insert persistence on the Citrix ADC appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.**

  Cause: Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and Citrix ADC appliance are in different time zones, the cookie is not valid. For example, when a client in the EST time zone sends a cookie at 11:00 AM EST to a Citrix ADC appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

  Resolution: Set the time-out value for Cookie Insert persistence to 0.

- **A Citrix ADC appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and,**

as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?

Cause: The Citrix ADC appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

Resolution: To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

- **The Citrix ADC appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the "State Error" error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.**

  Cause: Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

  Resolution: Citrix recommends that you specify the Cookie Insert persistence method on the Citrix ADC appliance when load balancing Web Interface servers.

Insert cookie attributes to ADC generated cookies

September 14, 2021

The web administrators can insert other cookie attributes to the cookies generated by the Citrix ADC appliance. These additional cookie attributes help in enforcing the required policies for the ADC generated cookies based on the application access pattern.

The following features use the ADC generated cookies to achieve persistency.

- Load balancing cookie persistence
- Load balancing group cookie persistence
- GSLB site persistence
- Content switching cookie persistence

You can insert other cookie attributes to the ADC generated cookies using the following parameters:

- **LiteralADCCookieAttribute:** Append other cookie attributes to the ADC generated cookie, as a string.

- **ComputedADCCookieAttribute:** Use an ADC ns variable to conditionally append cookie attributes to the ADC generated cookie, based on the client or server attributes, for example, user agent version.

> **Note**
>
> You cannot configure both Literal ADC Cookie Attribute and Computed ADC Cookie Attribute, simultaneously on the load balancing parameter or in a single load balancing profile.

Use case: Configure SameSite cookie attribute

Every cookie has a domain associated with it. When a cookie's domain matches the website domain in the user's address bar, this is considered a same-site (or first party) context. If the domain associated with a cookie matches an external service and not the website in the user's address bar, this is considered a cross-site (or third party) context.

The **SameSite** attribute indicates the browser whether the cookie can be used for cross-site context or only for same-site context. Also, if an application intends to be accessed in the cross-site context then it can do so only via the HTTPS connection. For details, see RFC6265.

Until Feb 2020, the **SameSite** property was not explicitly set in Citrix ADC. The browser took the default value as None, and did not impact the Citrix ADC deployments.

However with certain browsers upgrade, such as Google Chrome 80, there is a change in the default cross-domain behavior of cookies. The **SameSite** attribute can be set to one of the following values. Default value for Google Chrome is set to Lax.

- **None:** Indicates the browser to use a cookie in cross-site context only on secure connections.
- **Lax:** Indicates the browser to use a cookie for requests in the same-site context. In the cross-site context, only safe HTTP methods like GET request can use the cookie.
- **Strict:** Use the cookie only in the same-site context.

If there is no SameSite attribute in the cookie, the Google Chrome assumes the functionality of SameSite=Lax.

> **Note**
>
> For certain version of other browsers, the default value for the SameSite attribute might be set to **None**. In some browser versions, "SameSite = none" can be treated differently. For example, the following browsers reject a cookie with "SameSite = none":
>
> - Versions of Chrome from Chrome 51 to Chrome 66 (inclusive on both ends)
> - Versions of UC browser on Android earlier to version 12.13.2

Configure ADC generated cookies

To configure ADC generated cookie attributes, you must perform the following:

1. Create a load balancing virtual server
2. Set the ADC Cookie attributes for the load balancing virtual server, either through LB parameters or LB profile.
3. If you use an LB profile, set the LB profile to a load balancing virtual server.
4. If you choose to use the Computed ADC Cookie Attribute, configure the related rewrite policy.

> **Note**
>
> If an LB profile is bound to an LB virtual server, then the profile parameter configuration is considered instead of the global LB parameter configuration.

You can set the ADC generated cookie attributes by the following methods:

- Setting the ADC cookie attributes in load balancing parameters
- Setting the ADC cookie attributes in the load balancing profile

Setting the ADC cookie attributes in the load balancing parameters by using the CLI

To apply a policy uniformly to ADC generated cookies of all applications configured on the Citrix ADC appliance, you can set the ADC cookie attribute in the global LB parameters.

The **Literal ADC Cookie Attribute** setting allows you to unconditionally insert the cookie attributes to the ADC generated cookie.

At the command prompt, type:

```
set lb parameter -LiteralADCCookieAttribute <string>
<!--NeedCopy-->
```

Example:

```
set lb parameter -LiteralADCCookieAttribute SameSite=None
<!--NeedCopy-->
```

The **Computed ADC Cookie Attribute** setting allows you to conditionally insert the cookie attributes, based on the client or server attributes, to the ADC generated cookie.

At the command prompt, type:

```
set lb parameter -ComputedADCCookieAttribute <ns variable>
<!--NeedCopy-->
```

Example:

```
add ns variable cookieattribute_var -type "text(100)" -scope
    transaction
set lb parameter -ComputedADCCookieAttributE "$cookieattribute_var"
```

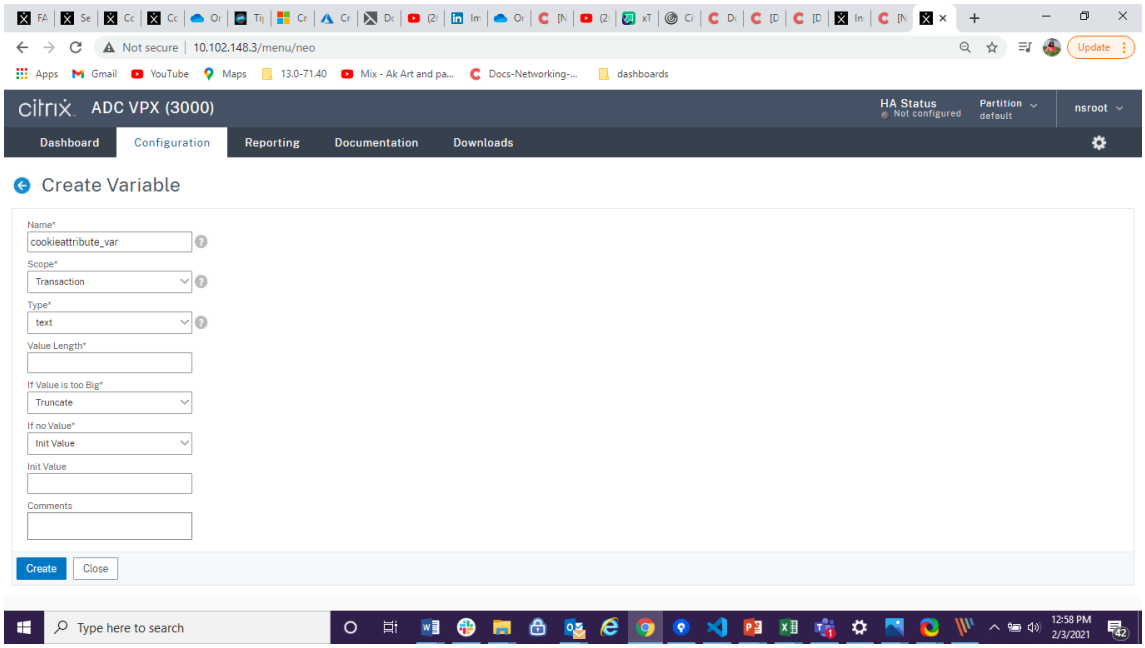
```
add ns assignment samesiteassign -variable "$cookieattribute_var" -set
    "\"SameSite=None\""

add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
    /OS \\d+\\_/).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).EQ(12).
    typecast_text_t ALT \"false\").eq(\"true\"))"
add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
    (re/Chrom.*\\d+./).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).
    BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
add rewrite policy exception_samesite_attribute "pol_iphone ||
    pol_chrome " NOREWRITE
add rewrite policy append_samesite_attribute true samesiteassign

bind rewrite global exception_samesite_attribute 90 110 -type
    RES_OVERRIDE
bind rewrite global append_samesite_attribute 100 110 -type
    RES_OVERRIDE
<!--NeedCopy-->
```

Configure variables by using the GUI

1. Navigate to **AppExpert > Variables**, and click **Add**.
2. In the **Create Variable** page, select **Scope** as **Transaction** and **Type** as **text** from the drop-down menu.

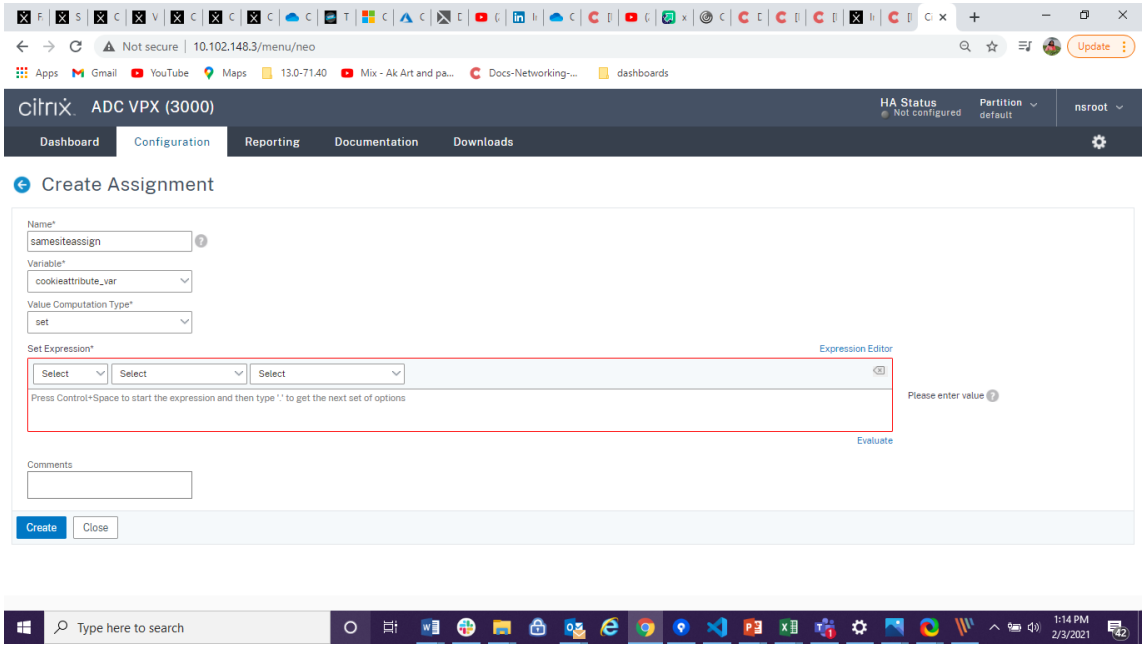


3. Enter other details, and click **Create**.

Create an assignment by using the GUI

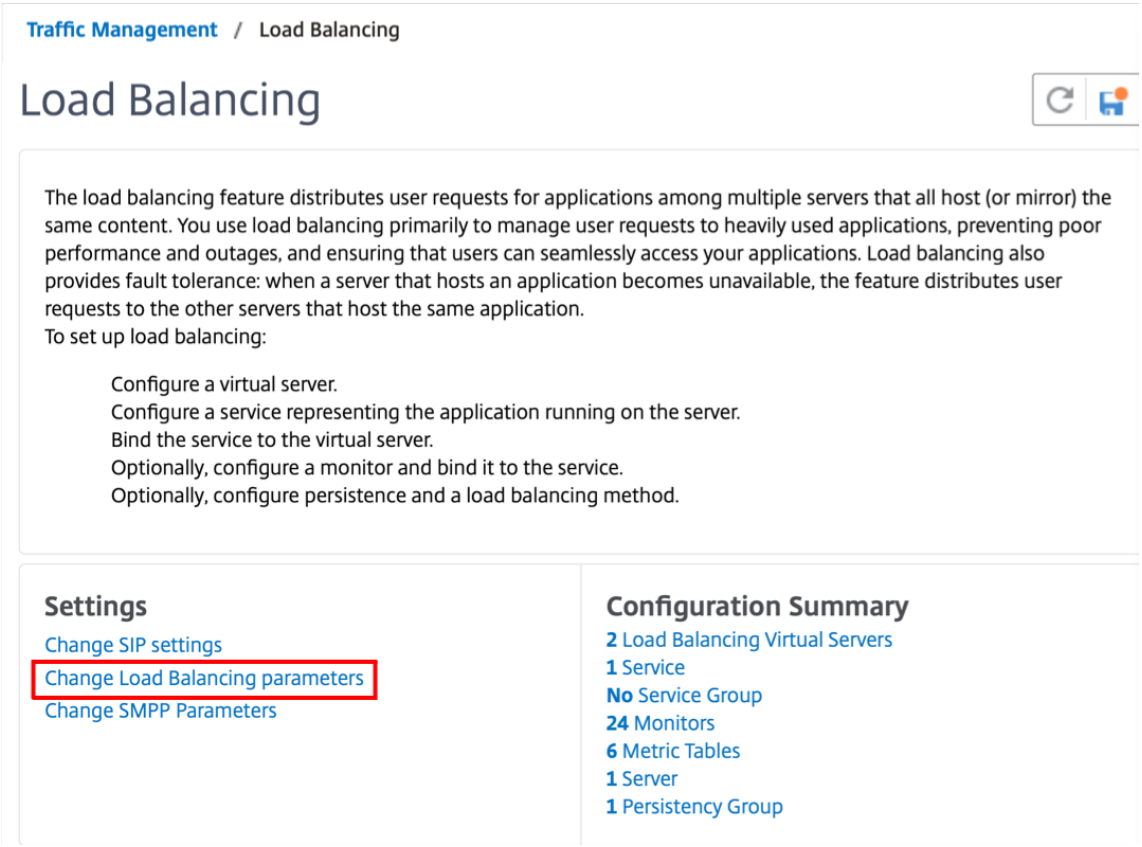
After configuring a variable, you can assign a value or specify the operation to be performed on the variable by creating an assignment.

1. Navigate to **AppExpert > Assignments**, and click **Add**.
2. In the **Create Assignment** page, enter the details, and click **Create**.



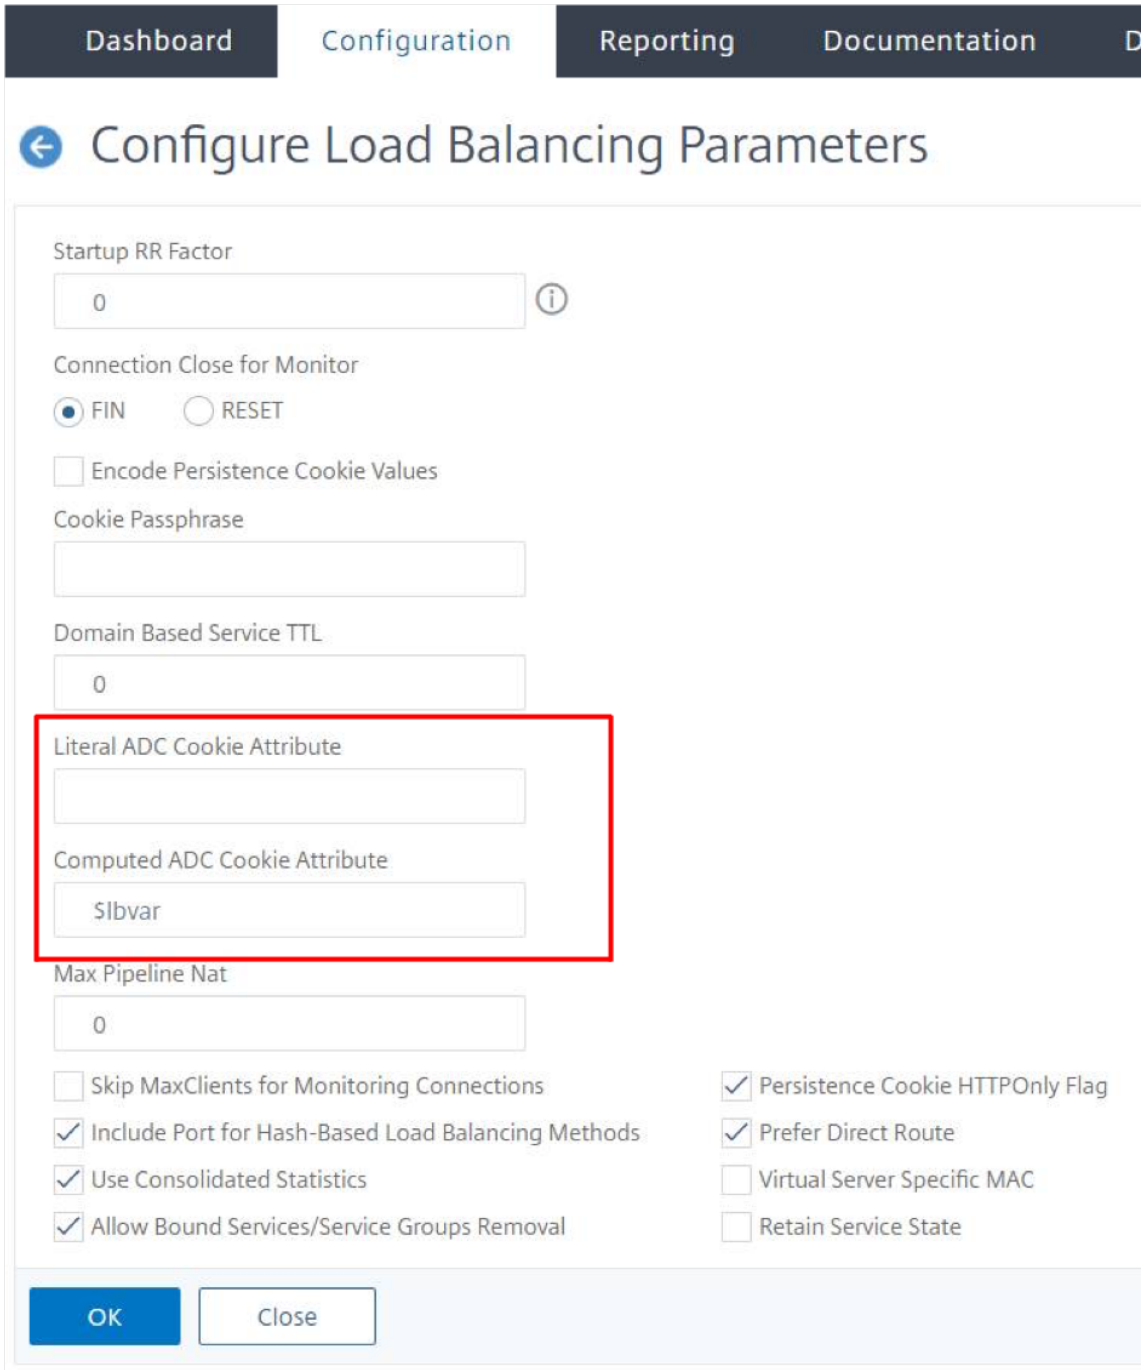
Setting the ADC cookie attributes in load balancing parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters**.



2. In the **Configure Load Balancing Parameters** pane, enter appropriate values for either one of the fields based on your requirement:

   - **Literal ADC Cookie Attribute**
   - **Computed ADC Cookie Attribute**



3. Click **OK**.

Setting the ADC cookie attributes in the load balancing profile by using the CLI

To apply a policy for a specific application that is configured on the Citrix ADC appliance, you can set the cookie attribute parameters in the LB profile bound to the application-specific LB virtual server.

The **Literal ADC Cookie Attribute** setting in the LB profile allows you to unconditionally insert the

cookie attributes to the ADC generated cookie that is specific to a virtual server.

At the command prompt, type:

```
add lb profile <profile name> -LiteralADCCookieAttribute <string>
<!--NeedCopy-->
```

Example:

```
add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
    =None
add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
    COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
<!--NeedCopy-->
```

The **Computed ADC Cookie Attribute** setting in the LB profile allows you to conditionally insert the cookie attributes based on the client or server attributes, to the ADC generated cookie. Then, set this LB profile to an LB virtual server.

At the command prompt, type:

```
add lb profile <profile name> -ComputedADCCookieAttribute <ns variable>
<!--NeedCopy-->
```

Example:

```
add ns variable cookieattribute_var -type "text(100)" -scope
    transaction
add ns assignment samesiteassign -variable "$cookieattribute_var" -set
    "\"SameSite=None\""
add lb profile LB-Vserver-Profile-1 -ComputedADCCookieAttributE "
    $cookieattribute_var"

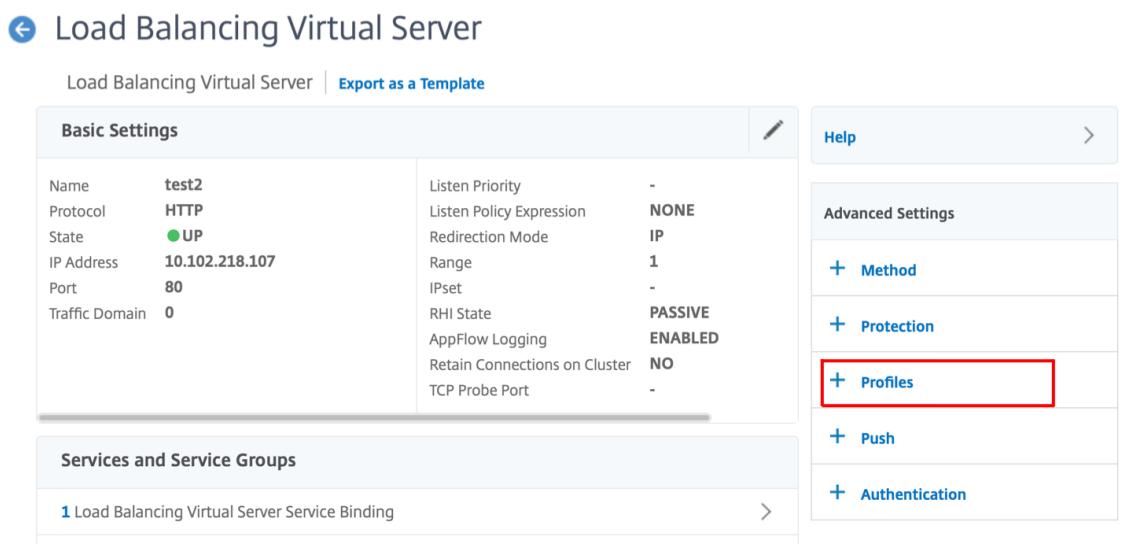
add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
    /OS \\d+\\_/).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).EQ(12).
    typecast_text_t ALT \"false\").eq(\"true\"))"
add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
    (re/Chrom.*\\d+./).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).
    BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
add rewrite policy exception_samesite_attribute "pol_iphone ||
    pol_chrome " NOREWRITE
add rewrite policy append_samesite_attribute true samesiteassign

add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
    COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
```

```
bind lb vserver LB-VServer-1 -policyName exception_samesite_attribute -
    priority 90 -gotoPriorityExpression 110 -type RESPONSE
bind lb vserver LB-VServer-1 -policyName append_samesite_attribute -
    priority 100 -gotoPriorityExpression 110 -type RESPONSE
<!--NeedCopy-->
```

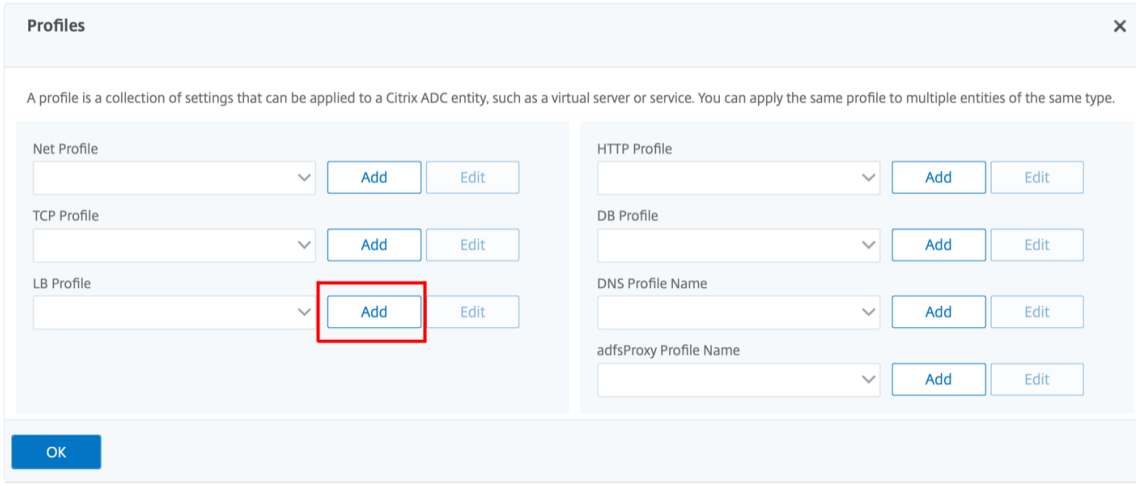
Setting the ADC Cookie attributes in the load balancing profile by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers**.
2. Select a virtual server and click **Edit**.
3. Under **Advanced Settings** section, click **Add profiles**.



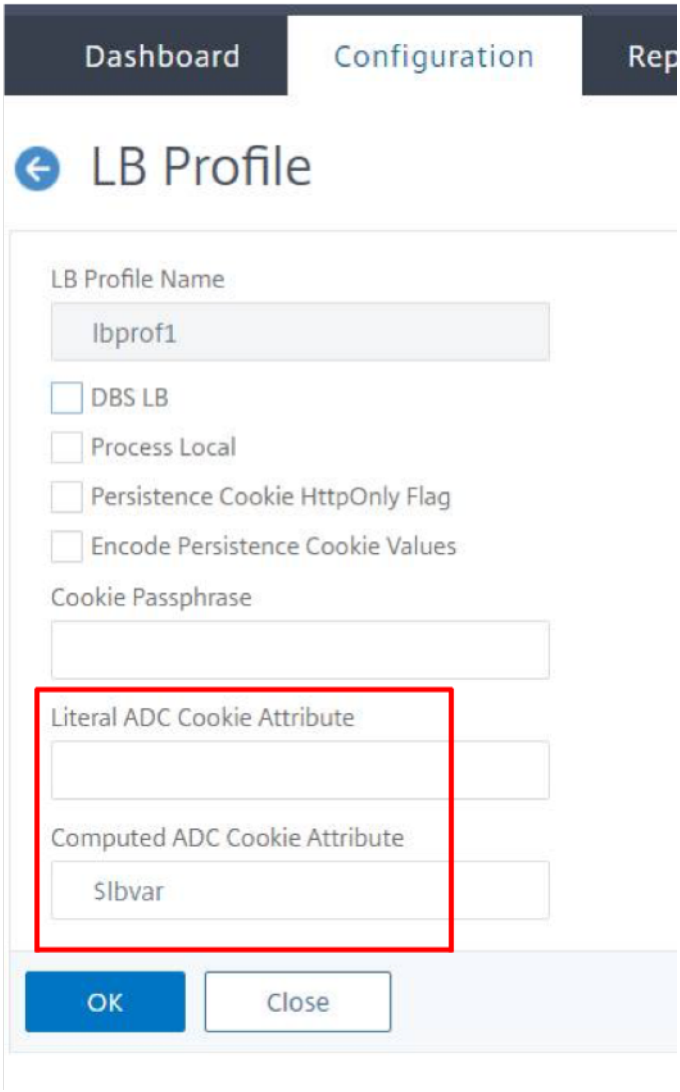
4. In the **Profiles** section, click **Add** to create an LB Profile.

   If you have already created a profile, choose it from the **LB Profile** drop-down menu.



5. In the **LB Profile** pane, enter appropriate values for either one of the fields based on your requirement:

- **Literal ADC Cookie Attribute**
- **Computed ADC Cookie Attribute**



1. Click **OK**.
2. Set the created LB profile to the LB virtual server created in **Step 1**.

Verify ns variable configuration

To verify that the ADC ns variable is configured appropriately in LB parameters or LB profile, use the show lb parameter or show lb profile commands.

The following table lists the various warning messages and its cause, when the ns variable is not cor-

rectly configured.

Warning message	Reasons
NS Variable is not configured. Configure it with type text() and scope transaction for variable	NS variable is not yet configured.
Scope of configured NS variable is not transaction.	Variable is configured but scope is not set to “transaction.”
Type of variable is not Text().	Variable is configured but type is not set to “Text”.
Configured value-max-size for the NS Variable is greater than 255.	The value configured for the NS variable is greater than 255 characters. **Note:** A maximum length of 255 characters can be appended to an ADC generated cookie. The characters that exceed the maximum length are truncated.

Sample output

In the following example, the warning message is displayed when the ns variable is not configured.

```
set lb parameter -ComputedADCCookieAttribute "$lbvar"

Warning: NS Variable is not configured. Please configure it with type
    text() and scope transaction
Done
<!--NeedCopy-->
```

The warning message is displayed in the following output of the `show lb parameter` command.

```
show lb parameter

Global LB parameters:
Persistence Cookie HttpOnly Flag: ENABLED
Use Encrypted Persistence Cookie: DISABLED
Use Port For Hash LB: YES
Prefer direct route: YES
Retain Service State: OFF
Start RR Factor: 0
Skip Maxclient for Monitoring: DISABLED
Monitor Connection Close: FIN
Use consolidated stats for LeastConnection: YES
```

```
13 Allow mac mode based vserver to pick thereturn traffic from services:
      DISABLED
14 Allow bound service removal: ENABLED

16
17 Citrix ADC Cookie Variable Name: $lbvar(NS Variable is not configured.
      Please configure it with type text() and scope transaction)
18
19 Done
20 <!--NeedCopy-->
```

Sample configuration for inserting cookie attributes in GSLB deployment

The following sample configuration applies to site persistence configured on GSLB services corresponding to an LB virtual server. To append some additional cookie attributes to the GSLB cookies, perform the following configuration.

- Set the ADC cookie attributes in the LB profile (LB-Vserver-Profile-1).
- Set the Literal ADC Cookie Attribute value, for example “SameSite=None”, in the LB profile.
- Set the LB profile to the load balancing virtual server (LB-VServer-1), which represents the GSLB service.

```
1  add gslb vserver GSLB-VServer-1 SSL -backupLBMethod ROUNDROBIN -
      tolerance 0 -appflowLog DISABLED
2  add gslb site site1 10.102.148.4 -publicIP 10.102.148.4
3  add gslb service site1_gsvc1 10.102.148.35 SSL 443 -publicIP
      10.102.148.35 -publicPort 443 -maxClient 0 -siteName site1 -
      sitePersistence HTTPRedirect -sitePrefix ss1 -cltTimeout 180 -
      svrTimeout 360 -downStateFlush ENABLED
4
5  bind gslb vserver GSLB-VServer-1 -serviceName site1_gsvc1
6  bind gslb vserver GSLB-VServer-1 -domainName www.gslb.com -TTL 5
7
8  add service service-1 10.102.84.140 SSL 443
9
10 add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
      =None
11 add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
      COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
12
13 bind lb vserver LB-VServer-1 service-1
14 <!--NeedCopy-->
```

> **Note**
>
> You can also conditionally insert the cookie attributes using the Computed ADC Cookie Attribute.

Sample configuration for inserting cookie attribute in content switching deployment

The following sample configuration applies when multiple applications are hosted behind a content switching virtual server. To apply the same policy to all the applications, bind the rewrite policies to content switching virtual server instead of LB virtual server, as follows:

- Set the ADC cookie attributes in the LB parameters.

  > **Note:**
  >
  > You can set the ADC cookie attributes in the LB profile as well.

- Configure the ns variable (cookieattribute_var) of Type set to Text and Scope set to Transaction.
- Set the Computed ADC Cookie Attribute in the global LB parameters using the ns variable.
- Set the rewrite policies (exception_samesite_attribute and append_samesite_attribute) to the content switching virtual servers for inserting the cookie attributes.

```
add ns variable cookieattribute_var -type "text(100)" -scope
    transaction
set lb parameter -ComputedADCCookieAttributE "$cookieattribute_var"
add ns assignment samesiteassign -variable "$cookieattribute_var" -set
    "\"SameSite=None\""

add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
    /OS \\d+\\_/).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).EQ(12).
    typecast_text_t ALT \"false\").eq(\"true\"))"
add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
    (re/Chrom.*\\d+./).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).
    BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
add rewrite policy exception_samesite_attribute "pol_iphone ||
    pol_chrome " NOREWRITE
add rewrite policy append_samesite_attribute true samesiteassign

add lb vserver LB-VServer-1 SSL 10.102.148.35 443
add lb vserver LB-VServer-2 SSL 10.102.148.36 443

add cs vserver CS-VServer-1 SSL 10.102.148.42 443 -persistenceType
    COOKIEINSERT

```

```
15 add cs action act1 -targetLBVserver v1
16 add cs action act2 -targetLBVserver v2
17 add cs policy CS-policy-1 -rule "HTTP.REQ.URL.CONTAINS(\"file1.html\")"
       -action act1
18 add cs policy CS-policy-2 -rule "HTTP.REQ.URL.CONTAINS(\"file2.html\")"
       -action act2
19
20 bind cs vserver CS-VServer-1 -policyName CS-policy-1 -priority 1

Customize a load balancing configuration

September 14, 2021

After you configure a basic load balancing setup, you can make several modifications to it so that it distributes the load exactly as you need. The load balancing feature is complex. You can modify the basic elements by doing one or more of the following:

- Changing the load balancing algorithm
- Configuring load balancing groups and using them to create your load balancing configuration
- Configuring persistent client-server connections
- Configuring the redirection mode
- Assigning different weights to different services that have different capacities.

The default load balancing algorithm on the Citrix ADC appliance is the least connection method. In the least connection method, the appliance sends each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers. Persistence lets the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user

requests, choosing between IP-based and MAC-based forwarding. You can also assign weights to different services, specifying what percentage of incoming load must be directed to each service. Assigning weights enable you to include servers with different capacities in the same load balancing setup without;

- overloading the lower-capacity servers or
- allowing the higher-capacity servers to sit idle.

Customize the hash algorithm for persistence across virtual servers

September 14, 2021

The Citrix ADC appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the CLI to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

To change the use-port-number global setting by using the CLI

At the command prompt, type:

set lb parameter -usePortForHashLb (YES NO)

Example:

```
> set lb parameter -usePortForHashLb NO
 Done
>show lb parameter
Global LB parameters:
        Persistence Cookie HttpOnly Flag: DISABLED
        Use port for hash LB: NO
 Done
<!--NeedCopy-->
```

To change the use-port-number global setting by using the GUI

1. Navigate to Traffic Managment > Load Balancing > Configure Load Balancing parameters.
2. Select or clear Use Port for Hash Based LB Methods.

To create a new service and specify a hash identifier for a service by using the CLI

At the command prompt, type the following commands to set the hash ID and verify the setting:

add service < name > (< ip > < serverName >) < serviceType > < port > -hashId < positive_integer >

```
show service <name>
<!--NeedCopy-->
```

Example:

```
> add service flbkng 10.101.10.1 http 80 -hashId 12345
 Done
>show service flbkng
        flbkng (10.101.10.1:80) - HTTP
        State: DOWN
        Last state change was at Thu Nov  4 10:14:52 2010
        Time since last state change: 0 days, 00:00:15.990
        Server Name: 10.101.10.1
        Server ID : 0   Monitor Threshold : 0

```

```
        Down state flush: ENABLED
        Hash Id: 12345

1)      Monitor Name: tcp-default
                State: DOWN     Weight: 1

 Done
<!--NeedCopy-->
```

To specify a hash identifier for an existing service by using the CLI

Type the set service command, the name of the service, and **-hashID** followed by the ID value.

To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

```
bind servicegroup <serviceGroupName> <memberName> <port> -hashId <
   positive_integer>

show servicegroup <serviceGroupName>
<!--NeedCopy-->
```

Example:

```
 bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222

>show servicegroup SRV
        SRV - HTTP
        State: ENABLED  Monitor Threshold : 0
        ...

        1)         1.1.1.1:80   State: DOWN     Server Name: 1.1.1.1
              Server ID: 123  Weight: 1
        Hash Id: 32211

                Monitor Name: tcp-default       State: DOWN
        ...

        2)         2.2.2.2:80   State: DOWN     Server Name: 2.2.2.2
              Server ID: 123  Weight: 1
```

```
        Hash Id: 12345

                Monitor Name: tcp-default       State: DOWN
        ...
Done

<!--NeedCopy-->
```

To specify a hash identifier for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a new service, or open an existing service and specify the hash ID.

To specify a hash identifier for an already configured service group member by using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a member and type a unique hash ID.

Configure the redirection mode

September 30, 2021

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The Citrix ADC appliance supports the following redirection modes. Before forwarding the request to a server, the redirection modes function as follows:

- IP-Based forwarding (the default): The destination IP address is changed to the server's IP address.
- MAC-Based forwarding: The destination MAC address is changed to the server's MAC address. However, the destination IP address is not changed. MAC-based redirection mode is used mostly in firewall load balancing deployments.
- IP TUNNEL Based: An IP-in-IP encapsulation is performed for the client IP packets. In the outer IP headers, the destination IP address is set to the IP address of the server and the source IP address is set to the subnet IP (SNIP). The client IP packets are not modified. This is applicable to both IPv4 and IPv6 packets.
- TOS ID Based: The virtual server's TOS ID is encoded in the TOS field of the IP header.

You can use either the IP TUNNEL or the TOS option to implement Direct Server Return (DSR). For more information see:

- Configure DSR mode when using TOS
- Configure load balancing in DSR mode for IPv6 networks by using the TOS field
- Configure load balancing in DSR mode by using IP Over IP

You can configure MAC-Based forwarding on networks that use DSR topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding for load balancing, see Configure MBF for load balancing configuration.

To configure the redirection mode by using the CLI

At the command prompt, type:

```
set lb vserver <name> -m <RedirectionMode>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
<!--NeedCopy-->
```

> **Note**
>
> For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

To configure the redirection mode by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and select the redirection mode.

Configure per-VLAN wildcarded virtual servers

September 14, 2021

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the CLI

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

```
add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <
    expression> [-listenpriority <positive_integer>]

show vserver
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)
    " -listenpriority 10

show vserver Vserver-LB-vlan1
<!--NeedCopy-->
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Create a new virtual server or open an existing virtual server.
3. Specify a listen policy priority and expression.

After you have created this virtual server, you bind it to one or more services as described in Setting Up Basic Load Balancing.

Assign weights to services

September 14, 2021

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the Citrix ADC appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

Load Balancing Methods	Service Selection with Weights
Round Robin	The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see The Round Robin Method.
Least Connection	The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see The Least Connection Method.
Least Response Time and Least Response Time Method using Monitors	The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see The Least Response Time Method.
Least Bandwidth	The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see The Least Bandwidth Method.
Least Packets	The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see The Least Packets Method.
Custom Load	The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see The Custom Load Method.
Hashing methods and Token method	Weighting is not supported by these load balancing methods.

To configure a virtual server to assign weights to services by using the CLI

At the command prompt, type:

```
set lb vserver <name> -weight <Value> <ServiceName>
```

```
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
<!--NeedCopy-->
```

To configure a virtual server to assign weights to services by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Open the virtual server, and then click in the **Services** section.
3. In the weight column for the service, assign a weight to the service.

Configure the MySQL and Microsoft SQL server version setting

September 14, 2021

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

To set the Microsoft SQL server version parameter by using the CLI

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

```
set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>

show lb vserver <name>
<!--NeedCopy-->
```

Example

```
> set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
 Done
> show lb vserver myMSSQLvip
    myMSSQLvip (190.0.2.12:1433) - MSSQL    Type: ADDRESS
 . . .
```

```
 . . .
    MSsql Server Version: 2008R2
    . . .
    . . .
 Done
>
<!--NeedCopy-->
```

To set the MySQL server version parameter by using the CLI

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

```
set lb vserver <name> -mysqlServerVersion <string>

show lb vserver <name>
<!--NeedCopy-->
```

Example

```
> set lb vserver mysqlsvr -mysqlserverversion 5.5.30
 Done
> sh lb vserver mysqlsvr
     mysqlsvr (2.22.2.222:3306) - MYSQL      Type: ADDRESS
 . . .
 . . .
     Mysql Server Version: 5.5.30
    . . .
    . . .
 Done
>
<!--NeedCopy-->
```

To set the MySQL or Microsoft SQL server version parameter by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Open a virtual server of type MySQL or MSSQL, and set the server version.

Multi-IP virtual servers

September 14, 2021

The Citrix ADC supports creating a single load balancing virtual server with multiple non-consecutive/consecutive IPv4 and IPv6 addresses of type VIP. Each VIP address bound to a virtual server is treated as an individual virtual server. These virtual servers have the same protocol and other virtual server level settings. A virtual server with multiple VIP addresses is also called multi-IP virtual server.

The following are some advantages of using multi-IP virtual servers:

- A multi-IP virtual server offloads the work of creating many virtual servers with the same settings and service bindings.
- Multi-IP virtual servers effectively reduces the possibility of reaching the maximum limit on virtual server entities.
- One multi-IP virtual server can be used for clients in different subnets to connect to the same set of servers.
- Only one multi-IP virtual server can be used for IPv6 and IPv4 clients to connect to the same set of servers.

Configure a multi-IP virtual server

Configuring a multi-IP virtual server consists of the following tasks:

- Create an IPset and bind multiple IP addresses to it.
- Bind the IPset to load balancing virtual servers.

Note the following points related to IPset configuration:

- An IPset can have:
  - non-consecutive/consecutive IPv4 addresses and IPv6 addresses
  - combinations of IPv4 and IPv6 addresses.
- All IPv4/IPv6 addresses to be associated with virtual servers using IPset must be of type VIP.
- A single IPset can be bound to multiple virtual servers.
- IPv4/IPv6 addresses can be bound/unbound to/from IPset irrespective any existing IPset bindings to virtual servers.
- You must unset the IPset binding to a virtual server before binding a new IPset to it.

To add an IPset and bind multiple VIP addresses to it by using the CLI

At the command prompt, type:

```
add ipset <name>

bind ipset <name> <IPaddress1 … >

bind ipset <name> <IPaddress2… >

show ipset <name>
<!--NeedCopy-->
```

To bind the IPset to a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -ipset <ipset name>

show lb vserver <name>
<!--NeedCopy-->
```

To add an IPset and bind multiple VIP addresses to it by using the GUI

Navigate to **System** > **Network** > **IPSets**, and create an IPset with multiple VIP addresses.

To bind the IPSet to a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server to which you want to bind the created IPset.
2. In **Basic Settings**, set the **IPset** parameter to the name of the created IPset.

```
> add ipset IPSET-1

Done

> bind ipset IPSET-1 9.9.9.10

Done

> bind ipset IPSET-1 1000::20

Done
```

```
15
16 > add lb vserver LBVS-1 HTTP 8.8.8.10 80  - ipset IPSET-1
17
18
19 Done
20
21 > add service SVC-1 3.3.3.10 HTTP 80
22
23
24 Done
25
26 > add service SVC-2 3.3.3.100 HTTP 80
27
28
29 Done
30
31 > bind lb vserver LBVS-1 SVC-1
32
33
34 Done
35
36 > bind lb vserver LBVS-1 SVC-2
37
38
39 Done
```

GSLB support for multi-IP virtual servers

In cloud deployments, floating IP addresses are not supported. These IP addresses are required for high availability deployments. With IPset support, you can associate a private IP address to each of the primary and secondary instances. One of the private IP addresses is added when creating the virtual server. The other IP address is bound to an IPset. This IPset is then associated with the virtual server. Typically a public IP is mapped to one of the private IPs based on which appliance is taking the traffic. During failover, this mapping changes dynamically to route the traffic to the new primary.

In GSLB deployments, the GSLB service represents the virtual server's IP address, port number, and service type. This IP address can be the IP address that is configured while adding the virtual server or it can be one of the IP addresses in the IPset. Irrespective of the IP address used in GSLB service, statistics and state are inherited from the same load balancing virtual server entity.

Parent child topology is also supported with IPset. The load balancing virtual servers on the child sites can have the IPset associated with it. Communication between the parent and the child sites is always using public IP address and the public port of the GSLB service

Also, with IPset support, you can have a single virtual server endpoint for both IPv4 and IPv6 traffic. Previously, you had to configure different virtual servers for IPv4 and IPv6 traffic. With IPset support, you can associate IPv4 and IPv6 IP addresses to the same IP set. You can add different GSLB services representing the IPv4 and IPv6 endpoints.

Note: Only one IP address is associated with a GSLB service. You cannot associate an IPset with a GSLB service. For details on configuring GSLB entities, see the topic Configure GSLB entities individually.

Limit the number of concurrent requests on a client connection

September 14, 2021

You can limit the number of concurrent requests on a single client connection. You can protect the servers from security vulnerabilities by limiting the number of concurrent requests. When the client connection reaches the specified maximum limit, the Citrix ADC appliance drops subsequent requests on the connection until the outstanding request count goes below the limit.

You can configure the maxPipelineNat parameter to limit the number of concurrent requests on a single client connection. This parameter is applicable only to the following service types and when "svrTimeout" is set to zero:

- ANY
- All UDP service types except DNS

The default value of maxPipelineNat parameter is 255. A value of zero (0) applies no limit to the number of concurrent requests. When no limit is set, the Citrix ADC appliance executes all requests.

> **Note**
>
> If you set MaxpipelineNAT to a higher value, then the probability of spoofing attack can be higher. Hence, it is recommended to set MaxpipelineNAT to a lower value.

To limit the number of concurrent connections for a client by using the CLI

At the command prompt, type:

```
set lb parameter -maxPipelineNat <positive_integer>
<!--NeedCopy-->
```

Example:

```
set lb parameter -maxPipelineNat 199
<!--NeedCopy-->
```

To limit the number of concurrent connections for a client by using the GUI

Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, specify a value for Max Pipeline NAT requests.

Configure diameter load balancing

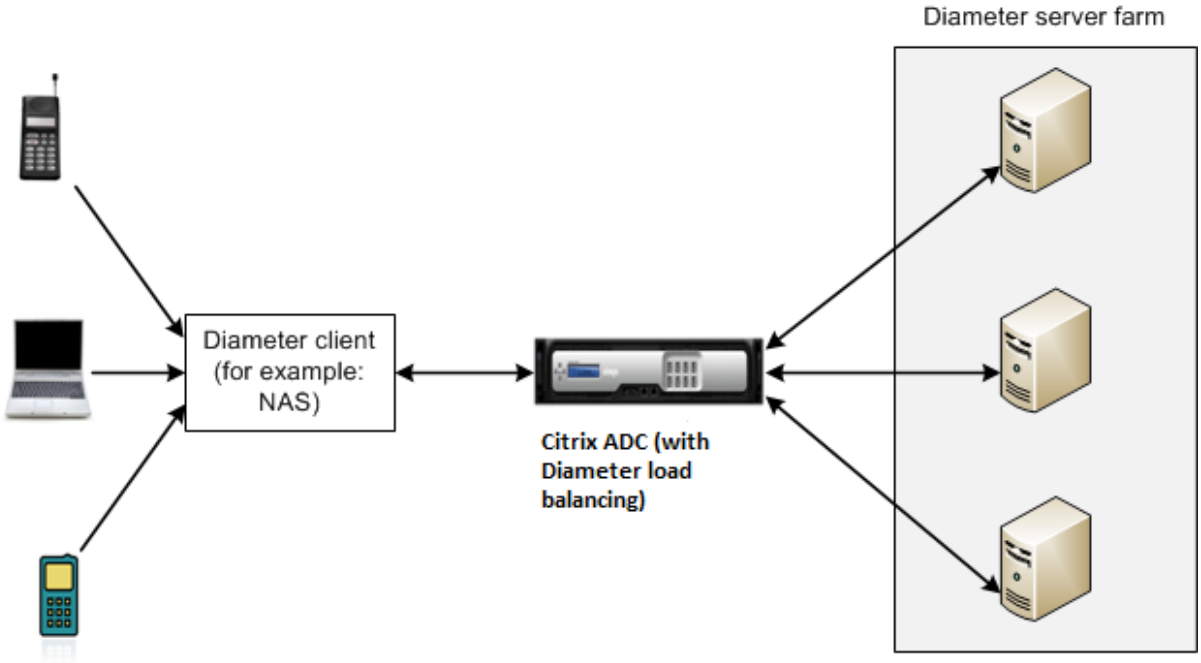
September 14, 2021

The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a Citrix ADC deployment:



A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The Citrix ADC appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The Citrix ADC uses message based load balancing.

Example:

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there

is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

How diameter load balancing works

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

Load balancing diameter traffic

When a client sends a request to the Citrix ADC appliance, the appliance parses the request and contextually load balances it to a Diameter server based on a persist AVP. The appliance has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the appliance maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- The Citrix ADC appliance adds a route entry by putting its identity, because the client sees the appliance as a relay agent.

Note: If a Diameter message spans more than one packet, the appliance accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the appliance splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

Disconnect a session

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the Citrix ADC appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

Configure load balancing for diameter traffic

To configure the Citrix ADC appliance to load balance diameter traffic, you must first set the Diameter parameters on the appliance, then add the diameter monitor, add the diameter services, bind the services to the monitor, add the diameter load balancing virtual server, and bind the services to the virtual server.

To configure load balancing for diameter traffic by using the command line interface

Configure the diameter parameters.

```
set ns diameter -identity <string> -realm <string> -
   serverClosePropagation <YES|NO>
<!--NeedCopy-->
```

Example:

```
set ns diameter -identity mydomain.org -realm org -
   serverClosePropagation YES
<!--NeedCopy-->
```

Add a Diameter monitor.

```
add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm
    <string>
<!--NeedCopy-->
```

Example:

```
add lb monitor diameter_mon DIAMETER -originHost mydomain.org -
    originRealm org
<!--NeedCopy-->
```

Create the Diameter services.

```
add service <name> <IP> DIAMETER <port>
<!--NeedCopy-->
```

Example:

```
add service diameter_svc0 10.102.82.86 DIAMETER 3868

add service diameter_svc1 10.102.82.87 DIAMETER 3868

add service diameter_svc2 10.102.82.88 DIAMETER 3868

add service diameter_svc3 10.102.82.89 DIAMETER 3868
<!--NeedCopy-->
```

Bind the Diameter services to the Diameter monitor.

```
bind service <name>@ monitorName <monitorName>
<!--NeedCopy-->
```

Example:

```
bind service diameter_svc0 -monitorName diameter_mon

bind service diameter_svc1 -monitorName diameter_mon

bind service diameter_svc2 -monitorName diameter_mon

bind service diameter_svc3 -monitorName diameter_mon
<!--NeedCopy-->
```

Add a Diameter load balancing virtual server with Diameter persistence.

```
add lb vserver <name> DIAMETER <IPAddress> <port> -persistenceType
    DIAMETER -persistAVPno <positive_integer>
<!--NeedCopy-->
```

Example:

```
add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -
   persistenceType DIAMETER -persistAVPno 263
<!--NeedCopy-->
```

Bind the Diameter services to the Diameter load balancing virtual server.

```
bind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver diameter_vs diameter_svc0

bind lb vserver diameter_vs diameter_svc1

bind lb vserver diameter_vs diameter_svc2

bind lb vserver diameter_vs diameter_svc3
<!--NeedCopy-->
```

Save the configuration.

```
save ns config
<!--NeedCopy-->
```

Note: You can also configure load balancing of Diameter traffic over SSL by using the **SSL_DIAMETER** service type.

To configure load balancing for Diameter traffic by using the configuration utility

1. Navigate to **System** > **Settings** > **Change Diameter Parameters** and set the diameter parameters.
2. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and create a load balancing virtual server of type Diameter.
3. Create a service of type Diameter.
4. Create a monitor of type Diameter. In Special parameters, set the origin host and origin realm.
5. Bind the monitor to the service, and bind the service to the Diameter virtual server.
6. In Advanced Settings, click **Persistence**, specify the diameter, and enter a persistence AVP number.
7. Click **Save**, and click **Done**.

Configure FIX load balancing

September 14, 2021

Financial Information eXchange (FIX) protocol is an open message standard used in the financial industry for electronic exchange of information related to securities transaction between trading partners. FIX/SSL_FIX protocol is used extensively by buy-side and sell-side firms, trading platforms, and regulators for communicating trade information.

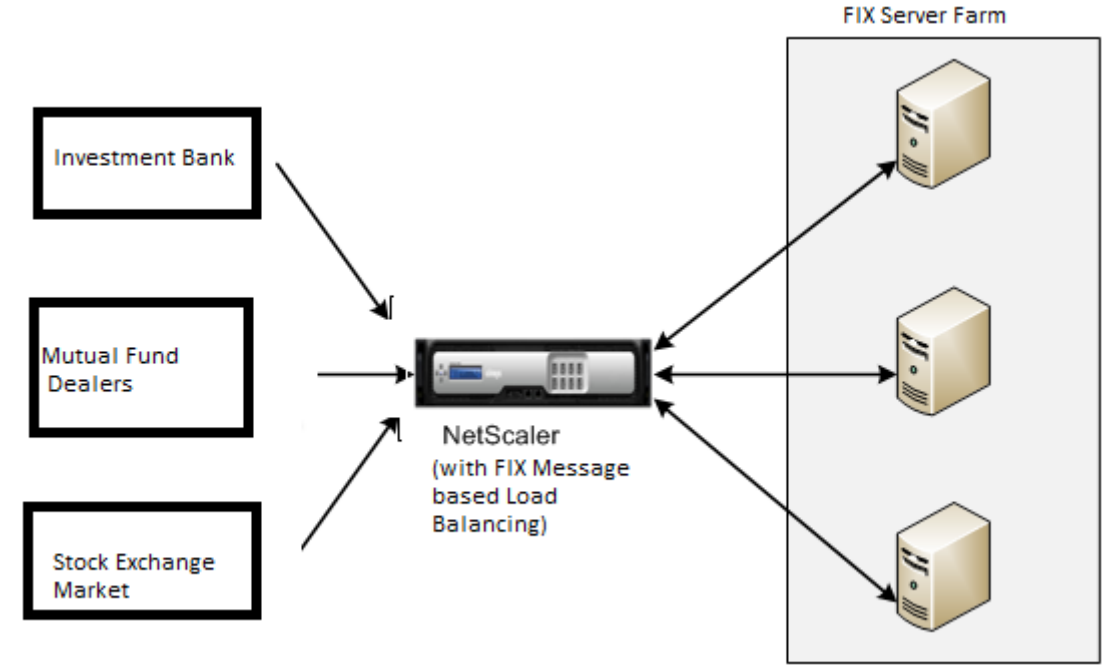
This feature enables you to configure a FIX or SSL_FIX load balancing virtual server to distribute incoming FIX messages and provide security in FIX messaging. Citrix ADC supports FIX message based load balancing (MBLB) for FIX 4.1, FIX 4.2, FIX 4.3, and FIX 4.4 versions.

FIX MBLB on a Citrix ADC appliance provides the following benefits:

1. Efficient management of FIX or SSL_FIX servers with superior HA and health monitoring.
2. SYN protection to all FIX or SSL_FIX servers.
3. FIX session persistence.

How FIX load balancing works

A FIX MBLB setup includes a FIX load-balancing virtual server and multiple load-balanced FIX servers. The FIX virtual server receives incoming client traffic, parses the incoming traffic into FIX messages, selects a FIX server for each FIX message, and forwards the message to the selected FIX server. The following conceptual drawing illustrates a typical FIX load balancing setup.



In a basic FIX MBLB setup, the FIX virtual server distributes FIX messages coming from clients to the load-balanced FIX servers using the round robin load-balancing method. With persistence of type FIXSESSION enabled, the FIX virtual server selects the same server for different FIX messages belonging to the same FIX session. The FIX session is determined based on the values of the **FIX** fields SenderCompID (tag 49) and TargetCompID (tag 56).

Configure and monitor load balancing for FIX traffic

Following are the configurations that you must do to load balance FIX message traffic:

1. Configuring FIX load balancing virtual server
2. Configuring SSL_FIX load balancing virtual server
3. Configuring FIX load balancing service
4. Configuring SSL_FIX load balancing service
5. Configuring FIXSESSION persistence
6. Setting persistence timeout
7. Displaying FIX/SSL_FIX stats
8. Monitoring FIX/SSL_FIX persistent sessions

To configure a FIX load balancing server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> FIX <IP> <PORT>
<!--NeedCopy-->
```

Example

```
add lb vserver vs1 FIX 10.102.82.86 3868
<!--NeedCopy-->
```

To configure a SSL_FIX load balancing virtual server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> SSL_FIX <IP> <PORT>
<!--NeedCopy-->
```

Example

```
add lb vserver vs1 SSL_FIX 10.102.82.86 3868
<!--NeedCopy-->
```

To configure a FIX service by using the command line interface

At the command prompt, type:

```
add service <name> <ip-addr> FIX <port>
<!--NeedCopy-->
```

Example

```
add service_svc1 10.102.82.86 FIX 3868
<!--NeedCopy-->
```

To configure a SSL_FIX service by using the command line interface

At the command prompt, type:

```
add service <name> <ip-addr> SSL_FIX <port>
<!--NeedCopy-->
```

Example

```
add service svc1 10.102.82.86 SSL_FIX 3868
<!--NeedCopy-->
```

To configure FIXSESSION persistence by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -persistenceType FIXSESSION
<!--NeedCopy-->
```

Example

```
set lb vserver vs1 -persistenceType FIXSESSION
<!--NeedCopy-->
```

To set persistence timeout by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -timeout <value>
<!--NeedCopy-->
```

Example

```
set lb vserver vs1  -timeout 2
<!--NeedCopy-->
```

To display FIX stats by using the command line interface

At the command prompt, type:

```
stat lb vserver <name>
<!--NeedCopy-->
```

Example

```
stat lb vserver_svc1
<!--NeedCopy-->
```

To bind FIX service to FIX virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <service name>
<!--NeedCopy-->
```

Example

```
bind lb vserver vs1 svc1
<!--NeedCopy-->
```

To display FIX persistent sessions by using the command line interface

At the command prompt, type:

```
show lb persistentSessions <name>
<!--NeedCopy-->
```

Example

```
show lb persistentSessions vs1
<!--NeedCopy-->
```

> **Note**
>
> Note: You can now configure the load balancing of FIX traffic over SSL by using the SSL_FIX service type. This service provides secured communication for FIX messages.

To configure FIX load balancing virtual server by using the GUI

1. Navigate to the **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page and click **Add** to create a FIX Load Balancing virtual server.
2. On the **Load Balancing Virtual Server** page, set the server parameters:
   a) Virtual Server Name
   b) Protocol type as “FIX”
   c) Server IP Address Type
   d) Server IP Address
   e) Server Port Number
3. Click **OK** and **Continue** to set other parameters.
4. In the **Services** section, select or add a new FIX load balancing virtual service, and bind it to the FIX server.
5. In the **Persistence** section, set the following parameters:
   a) Persistence type as ‘FIXSESSION’
   b) Time-out interval
6. Click **OK** and then **Done**.

To edit a FIX load balancing virtual server by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page, select a FIX server and click **Edit**.

To delete a FIX load balancing virtual server by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page, select a FIX server, and click **Delete**.

To configure FIX Load Balancing Virtual Service by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** page and click **Add** to create a FIX Load Balancing virtual service.
2. On the **Services** page, set the following parameters. You can click the ‘More’ arrow to set other parameters such as Traffic Domain, Hash ID, Server ID, Cache Type, and Number of Active Connections.

a) Service Name – FIX Virtual Service Name
b) Choose Virtual Server type as (New or Existing)
c) Protocol – Protocol Type as 'FIX'
d) Server – Virtual Server IP address
e) Port – Server Port Number

3. Click **OK** and **Continue** to set other parameters such as Monitors, Threshold & Timeout, Profiles, and Policies.
4. Click **OK** and then **Done**.

To edit a FIX load balancing virtual service by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** page, select a **FIX service** and click **Edit**.

To delete a FIX load balancing virtual service by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** page, select a FIX service, and click **Delete**.

To display FIX load balancing server statistics

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page and then click **Statistics** to display the FIX server statistics.

To display Persistent sessions for a FIX server by using the GUI

Navigate to **Configuration** > **Traffic Management** page and, under **Monitor Sessions** click **Virtual Server Persistent Sessions**.

To clear Persistent sessions for a FIX server by using the GUI

1. Navigate to **Configuration** > **Traffic Management** page and, under **Monitor Sessions** click **Clear Persistent Sessions**.
2. On the **Clear Persistent Sessions** page, set the following parameters:
   a) Virtual Server – Choose a FIX virtual server
   b) Persistence Parameter – Choose a FIX persistence parameter
3. Click **OK**.

MQTT load balancing

September 14, 2021

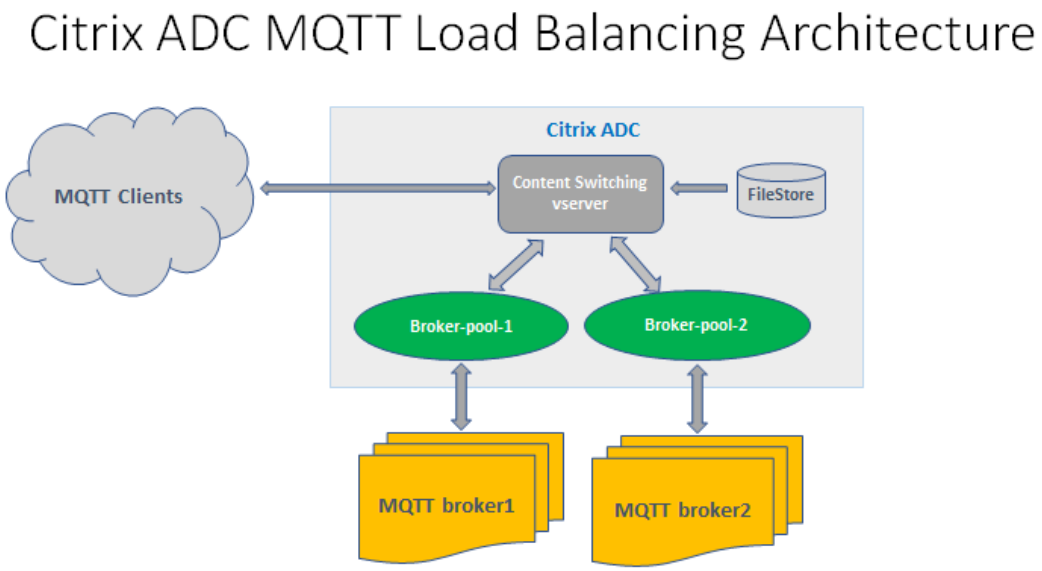
The Message Queuing Telemetry Transport (MQTT) is an OASIS standard messaging protocol for the Internet of Things (IoT). MQTT is a flexible and easy-to-use technology that provides effective communication within an IoT system. MQTT is a broker-based protocol and is widely used to facilitate the exchange of messages between clients and broker.

The following key benefits of MQTT make it a well-suited option for your IoT device:

- Reliability
- Fast response time
- Capability to support unlimited devices
- Publish/subscribe messaging that is perfect for many-to-many communication

IoT is the network of interconnected devices that are embedded with sensors, software, network connectivity, and necessary electronics. The embedded components enable IoT devices to collect and exchange data. The increase in use of IoT devices brings in multiple challenges for network infrastructure, with Scale being the prominent one. In a large scale deployment of IoT devices, the data generated by each IoT device needs to be analyzed swiftly. To achieve the scale requirement and efficient usage of resources, the load on the broker pool must be distributed evenly. With the support of the MQTT protocol, you can use the Citrix ADC appliance in IoT deployments to load balance the MQTT traffic.

The following figure depicts the MQTT architecture using a Citrix ADC appliance to load balance the MQTT traffic.



An IoT deployment with MQTT protocol has the following components:

- **MQTT broker.** A server that receives all messages from the clients and then routes the messages to the appropriate destination clients. The broker is responsible for receiving all messages, filtering the messages, determining who is subscribed to each message, and sending the message to these subscribed clients. The broker is the central hub through which every message must pass.
- **MQTT client.** Any device, from a micro controller up to a full-fledged server, which runs an MQTT library and connects to an MQTT broker over a network. Both publishers and subscribers are MQTT clients. The publisher and subscriber labels refer to whether the client is publishing messages or subscribed to receive messages.
- **MQTT load balancer.** The Citrix ADC appliance is configured with an MQTT load balancing virtual server to load balance MQTT traffic.

In a typical IoT deployment, the broker (cluster of servers) manages the group of IoT devices (IoT clients). The Citrix ADC appliance load balances the MQTT traffic to the brokers based on various parameters, such as Client ID, topic, and user name.

Configure load balancing for MQTT traffic

For the Citrix ADC appliance to load balance MQTT traffic, perform the following configuration tasks:

1. Configure MQTT/MQTT_TLS services or service groups.
2. Configure MQTT/MQTT_TLS load balancing virtual server.
3. Bind the MQTT/MQTT_TLS services to the MQTT/MQTT_TLS load balancing virtual server.

4. Configure MQTT/MQTT_TLS content switching virtual server.
5. Configure a content switching action that specifies the target load balancing virtual server
6. Configure a content switching policy.
7. Bind the content switching policy to a content switching virtual server that is already configured to redirect to the specific load balancing virtual server.
8. Save the configuration.

To configure load balancing for MQTT traffic by using the CLI

Configure MQTT/MQTT_TLS services or service groups.

```
add service <name> <IP> <protocol> <port>
add servicegroup <ServiceGroupName> <Protocol>
bind servicegroup <serviceGroupName> <IP> <port>
<!--NeedCopy-->
```

Example:

```
add service srvc1 10.106.163.3 MQTT 1883
add servicegroup srvcg1 MQTT
bind servicegroup srvcg1 10.106.163.3 1883
<!--NeedCopy-->
```

Configure MQTT/MQTT_TLS load balancing virtual server.

```
add lb vserver <name> <protocol> <IPAddress> <port>
<!--NeedCopy-->
```

Example:

```
add lb vserver lb1 MQTT 10.106.163.9 1883
<!--NeedCopy-->
```

Bind the MQTT/MQTT_TLS services or service groups to the MQTT load balancing virtual server.

```
bind lb vserver <name> <serviceName>
bind lb vserver <name> <servicegroupName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver lb1 srvc1
bind lb vserver lb1 srvcg1
<!--NeedCopy-->
```

Configure MQTT/MQTT_TLS content switching virtual server.

```
add cs vserver <name> <protocol> <IPAddress> <port>
<!--NeedCopy-->
```

Example:

```
add cs vserver cs1 MQTT 10.106.163.13 1883
<!--NeedCopy-->
```

Configure a content switching action that specifies the target load balancing virtual server.

```
add cs action <name> -targetLBVserver <string> [-comment <string>]
<!--NeedCopy-->
```

Example:

```
add cs action act1 -targetlbvserver lbv1
<!--NeedCopy-->
```

Configure a content switching policy.

```
add cs policy <policyName> [-url <string> | -rule <expression>] -
    action <actName>
<!--NeedCopy-->
```

Example:

```
add cs policy cspol1  -rule   “MQTT.COMMAND.EQ(CONNECT) && MQTT.CONNECT
    .FLAGS.QOS.eq(2)”  -action act1
<!--NeedCopy-->
```

Bind the content switching policy to a content switching virtual server that is already configured to redirect to the specific load balancing virtual server.

```
bind cs vserver <virtualServerName> -policyName <policyName> -priority
    <positiveInteger>
<!--NeedCopy-->
```

Example:

```
bind cs vserver cs1  -policyName cspol1 -priority 20
<!--NeedCopy-->
```

Save the configuration.

```
save ns config
<!--NeedCopy-->
```

To configure load balancing for MQTT traffic by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and create a load balancing virtual server of type **MQTT** or **MQTT_TLS**.
2. Create a service or service group of type MQTT.
3. Bind the service to the MQTT virtual server.
4. Click **Save**.

MQTT message length limit

The Citrix ADC appliance treats the messages with message length greater than 65536 bytes as jumbo packets, and discard them by default. The `dropmqttjumbomessage` lb parameter decides whether to process the jumbo packets or not. This parameter is by default set to **YES**, which implies that the jumbo MQTT packets are dropped by default. If this parameter is set to **NO**, the ADC appliance handles even the packets with message length greater than 65536 bytes.

To configure the ADC appliance to handle jumbo packets by using CLI:

```
Set lb parameter -dropMqttJumboMessage [YES | NO]
<!--NeedCopy-->
```

Example:

```
set lb parameter -dropMqttJumboMessage no
<!--NeedCopy-->
```

Protect a load balancing configuration against failure

September 14, 2021

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring;

- the Citrix ADC appliance to redirect excess traffic to an alternate URL,
- a backup load balancing virtual server, and
- a stateful connection failover.

Redirect client requests to an alternate URL

September 14, 2021

You can redirect requests to an alternate URL by using an HTTP 302 redirect if a load balancing virtual server of type HTTP or HTTPS goes DOWN or is disabled. The alternate URL can provide information about the status of the server. The configured redirect URL is specified in the location header of the HTTP response. The exact URL specified in the response depends on the following configuration options:

- If the configured redirect URL contains only the domain name, such as http://www.sample1.example.com, the redirect URL specified in the HTTP response appends the Uniform Resource Identifier (URI). It is specified in the HTTP request to the configured domain name. For example, if the request contains the GET http://www.sample2.example.com/images/site_nav.png header, then the location header in the redirect response specifies the location: http://www.sample1.example.com/images/site_nav.png header.

  > **Note**
  >
  > The domain names in the request and response can differ. In this topic, the two domains are referred to as sample1.example.com and sample2.example.com to explain the concept.

- If the configured redirect URL contains a complete path, then the redirect response specifies the complete configured URL, irrespective of the URI in the request. For example, the following are such URLs:
  - Requested URL - http://www.redirect.com/en/index.html
  - Redirect URL - http://www.redirect.com/en/site_down.html

The following table lists the preceding configuration options:

Configured Redirect URL	URL in HTTP Request	Header in HTTP Response
http://www.sample1.example.com	http://www.sample2.example.com/en/index.html	http://www.sample1.example.com/en/index.html
http://www.sample1.example.com/en/error.html	http://www.sample2.example.com/en/index.html	http://www.sample1.example.com/en/error.html

> **Note**
>
> - When configuring a redirect URL, the http://example.com URL is not the same as the http://example.com/ URL, because the latter contains the complete path to the Webroot path,

> /.
>
> - If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

To configure a virtual server to redirect the client request to a URL by using the CLI

1. Create a load balancing virtual server.

   ```
   set lb vserver -redirect url
   ```

2. Verify that the redirect URL option is working as expected. Disable the virtual server.

   ```
   disable vserver <vserver_name>
   ```

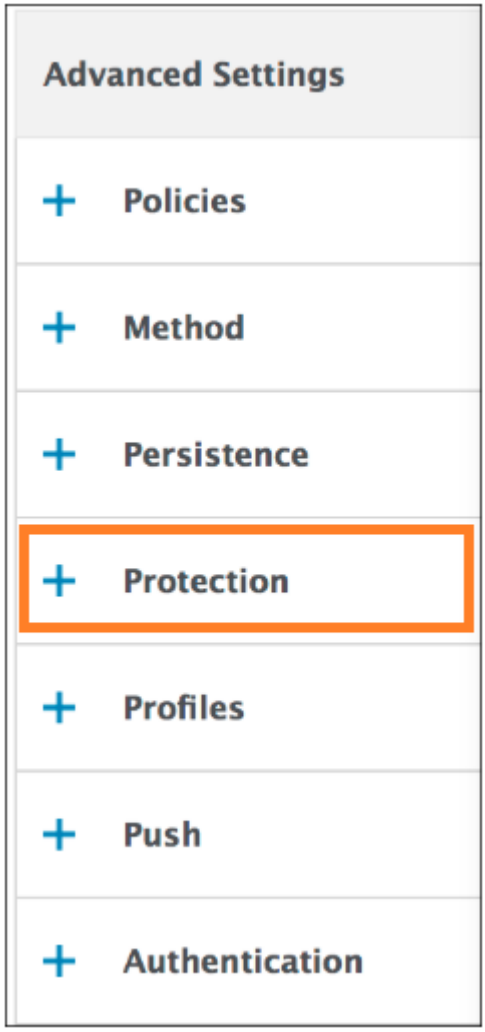
3. Access the website URL from a web browser to verify that the request is redirected as expected. You might have to clear the web browser cache and make a new connection before accessing the website.

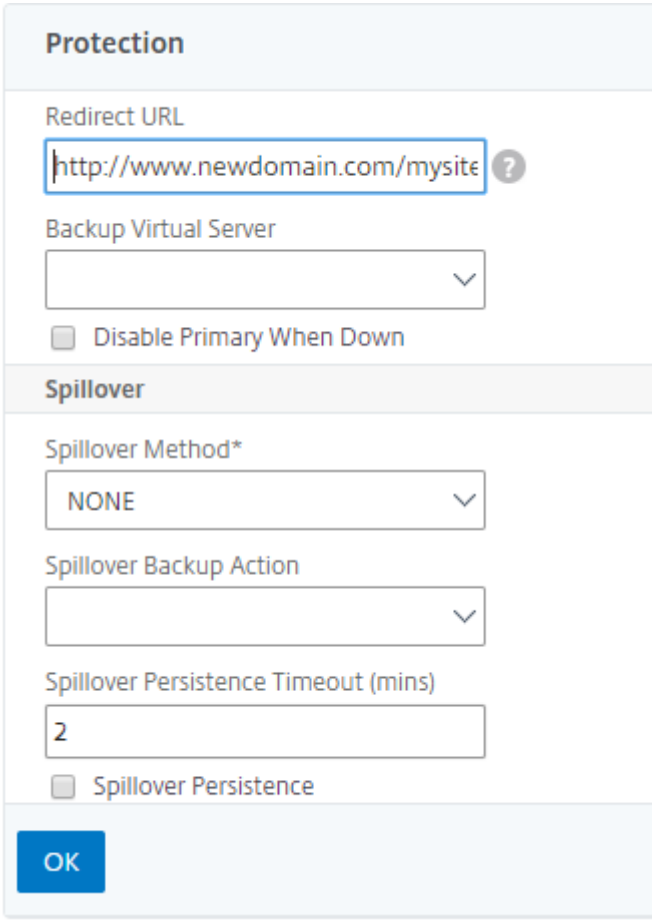
4. Enable virtual server.

   ```
   enable vserver <vserver_name>
   ```

To configure a virtual server to redirect the client request to a URL by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, to add a new virtual server, click **Add**.
3. To edit an existing virtual server, select the virtual server from the list and click **Edit**.
4. On the **Advanced Settings** tab, click **Protection**. In the **Redirect URL** field, type the redirect URL (for example, http://www.newdomain.com/mysite/maintenance).





5. Click **OK**.

Configure a backup load balancing virtual server

September 14, 2021

You can configure the Citrix ADC appliance to direct requests to a backup virtual server when the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

> Note:
>
> The backup virtual server continues to handle the existing connections, even after the primary virtual server is deleted or disabled.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an

existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you can configure the backup virtual server to remain in control when it takes over. For example, you can sync the updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control when the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

To set a backup virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <vServerName> -backupVserver <BackupVServerName> [-
   disablePrimaryOnDown]
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -
   disablePrimaryOnDown
<!--NeedCopy-->
```

To set a backup virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and select a backup virtual server.
3. If you want the backup virtual server to remain in control until you manually enable the primary virtual server even if the primary virtual server comes back up, select **Disable Primary When Down**.

> **Note:** Starting from Citrix ADC version 12.1 build 51.xx, the GUI displays the effective state of that server indicating if the backup is active or not.
>
> The effective state of the current server can be one of the following:
>
> - **UP** – Indicates that the server is UP
> - **DOWN** – Indicates that the server is DOWN
> - **UP (Backup Active)** – Indicates that either the primary or the secondary virtual server is UP and traffic is directed to the backup virtual server.
> - **DOWN (Backup Active)** – Indicates that both the primary and the backup virtual servers are down and traffic is routed to the backup virtual server.
>
> When the **Disable Primary When Down** option is enabled on the primary virtual server and the primary server goes DOWN and is back UP again, the traffic is still served by the backup virtual server until the primary virtual server is re-enabled explicitly. You can use the command `enable lb vserver <vserver_name>` command to re-enable the primary virtual server.

Configure spillover

September 14, 2021

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period after the load on the primary falls below the threshold.

Note: Usually, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). However with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.

You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, you use a Citrix ADC rule to specify the conditions for spillover to occur. Citrix ADC rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

For instructions for assigning a virtual server as the backup for another virtual server, see Configuring a Backup Load Balancing Virtual Server.

Configure a predefined spillover method

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the Citrix ADC appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP, it diverts new requests to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the Citrix ADC appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

Note: With RTSP virtual servers, the Citrix ADC appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

To configure a predefined spillover method for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -soMethod <spillOverType> -soThreshold <
    positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <
    positiveInteger>
<!--NeedCopy-->
```

Example

```
set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -
    soPersistence enabled -soPersistenceTimeout 2
<!--NeedCopy-->
```

To configure a predefined spillover method for a virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and set the spillover parameters.

Configure policy based spillover

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover based on the virtual server's response time, or based on the number of connections in the virtual server's surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy, configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

Configuring a Spillover Action

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

To configure policy based spillover by using the command line interface

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
add spillover action <name> -action SPILLOVER

show spillover action <name>
<!--NeedCopy-->
```

Example

```
add spillover action mySoAction -action SPILLOVER
Done
<!--NeedCopy-->
```

```
show spillover action mySoAction
1) Name: mySoAction Action: SPILLOVER
Done
<!--NeedCopy-->
```

Selecting an Expression for the Spillover Policy

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you can use one of the following expressions:

```
SYS.VSERVER("vserver").RESPTIME.GT(<int>)
SYS.VSERVER("vserver").STATE.EQ( " <string> " ), and
SYS.VSERVER("vserver").THROUGHPUT.LT    (<int>)
<!--NeedCopy-->
```

In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

`Averagesurgecount`

Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

`Activeservices`

Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

`Activetransactions`

Returns the value of the virtual-server-level counter for current active transactions.

is_dynamic_limit_reached

Returns a Boolean TRUE if the number of connections that the virtual server manages is equal to the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

Table 1. Converting predefined spillover methods to policy expressions

Predefined spillover method	Corresponding expression
CONNECTION	SYS.VSERVER("<vserver-name>").CONNECTIONS, used with the GT(int) arithmetic function.
BANDWIDTH	SYS.VSERVER("<vserver-name>").THROUGHPUT, used with the GT(int) arithmetic function.
HEALTH	SYS.VSERVER("<vserver-name>").HEALTH, used with the LT(int) arithmetic function.

Predefined spillover method	Corresponding expression
DYNAMICCONNECTION	SYS.VSERVER("<vserver-name>").IS_DYNAMIC_LIMIT_REACHED **Note**: If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that the statistics required for spillover to work are collected.

Configuring a Spillover Policy

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

To configure a spillover policy by using the command line interface

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
add spillover policy <name> -rule <expression> -action <string> [-
    comment <string>]

show spillover policy <name>
<!--NeedCopy-->
```

Example

```
> add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT
    (50) -action mySoAction -comment "Triggers spillover when the
    vserver's response time is greater than 50 ms."
Done

> show spillover policy mySoPolicy

1)  Name: mySoPolicy Rule: "SYS.VSERVER("v1").RESPTIME.GT(50)" Action:
    mySoAction Hits: 0 ActivePolicy: 0
Comment: "Triggers spillover when the vserver's response time is
    greater than 50 ms."
Done
```

```
>
<!--NeedCopy-->
```

Binding a Spillover Policy to a Virtual Server

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers). You can bind multiple policies to a virtual server, with Goto expressions controlling the flow of evaluation.

To bind a spillover policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

```
bind (lb | cs | gslb) vserver <name> -policyName <string> -priority <
    positive_integer> [-gotoPriorityExpression <expression>]

show (lb | cs | gslb) vserver <name>
<!--NeedCopy-->
```

Example

```
> bind lb vserver vserver1 -policyName mySoPolicy -priority 5
Done
> show lb vserver vserver1
vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS
. . .

1)  Spillover Policy Name: mySoPolicy Priority: 5
GotoPriority Expression: END
Flowtype: REQUEST
Done
>
<!--NeedCopy-->
```

Configuring a Backup Action for a Spillover Event

A backup action specifies what to do when the spillover threshold is reached but one or more backup virtual serves are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance

sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests even before establishing TCP or SSL connections until the number of requests falls below the threshold. Therefore, lesser memory resources are utilized as the connections are reset even before allocating any data structures.

To configure a backup action for spillover by using the CLI

At the command prompt, type the following commands to configure a backup action and verify the configuration:

```
set lb vserver <name> -soBackupAction <soBackupAction>

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
set lb vserver vs1 -soBackupAction REDIRECT -redirectURL `http://www.
   mysite.com/maintenance`
Done
> show lb vserver vs1
vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
State: UP
. . .
Redirect URL: `http://www.mysite.com/maintenance`
. . .
Done
<!--NeedCopy-->
```

To configure a backup action for spillover by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and then specify a spillover backup action.

Connection failover

September 14, 2021

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a Citrix ADC High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary Citrix ADC appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

> Note:
>
> Consider a HA setup, where a client establishes a session with the primary node, which in turn establishes a session with the back end server. When a failover is triggered in this state, the packets received on a new primary from the existing client and server nodes are treated as stale packets, and the client and server connections are reset. Whereas if stateless connection failover is enabled (USIP is ON), after the failover, the connections are not reset when you receive packets from client or server nodes. Instead, the client and server connections are created dynamically.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

Connection failover is helpful if your deployment has long lasting connections. For example, if you are downloading a large file over FTP and a failover occurs during the download, the connection breaks and the download is aborted. However, if you configure the connection failover in stateful mode, the download continues even after the failover.

How connection failover works on Citrix ADC appliances

In a stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

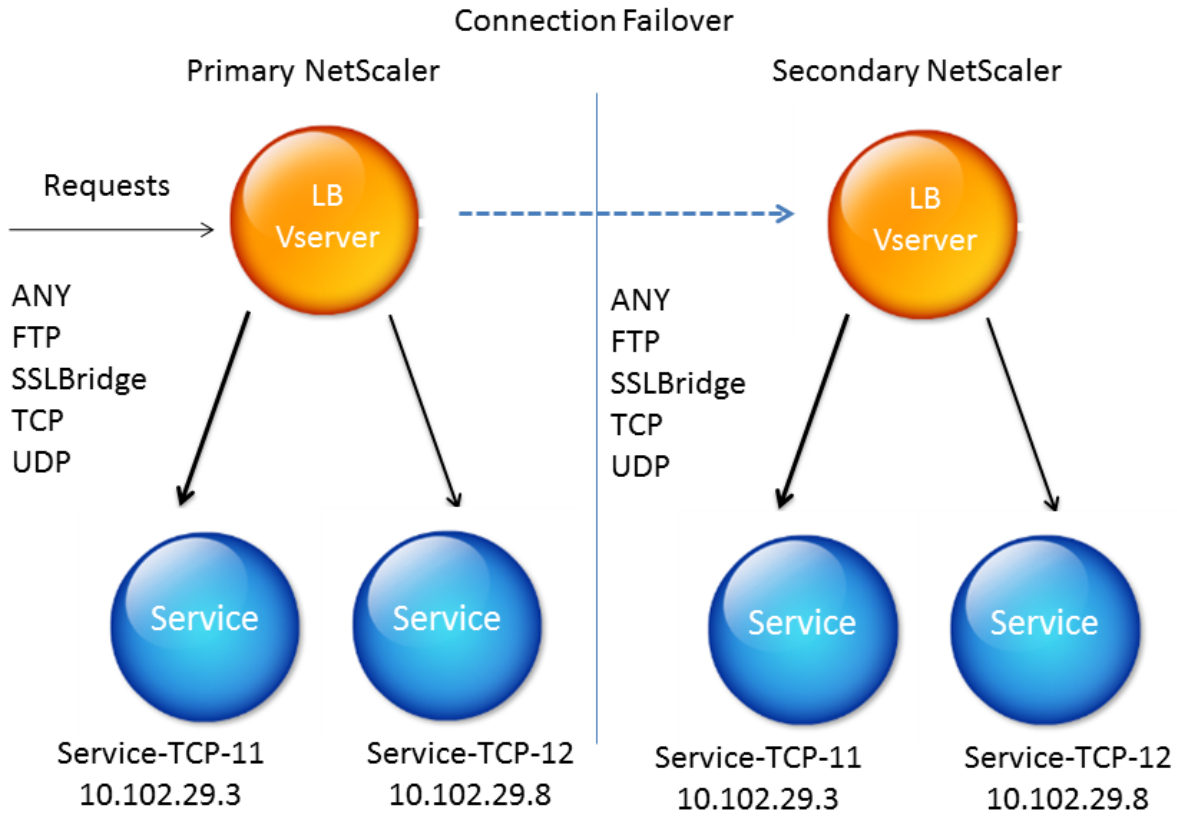
In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server might experience a brief disruption and retransmissions.

Note:

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify the correct configuration of the passwords, use the show `rpcnode` command from the command line or use the RPC option of the **Network** menu in the GUI.

A basic HA configuration with connection failover contains the entities shown in the following figure.

Figure 1. Connection Failover Entity Diagram



Note

Connection failover is not supported after either of the following events:

```
- An upgrade to a later release.
- An upgrade to a later build within the same release, if the new
    build uses a different HA version.
```

Supported setup

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content switching virtual servers. If you enable connection failover on load balancing virtual servers that are attached to a content switching virtual server, connection failover does not work be-

cause the load balancing virtual servers do not initially accept the traffic.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

Setting	Stateless	Stateful
Service type	ANY.	ANY, UDP, TCP, FTP, SSL_BRIDGE.
Load balancing methods	All methods supported for the service type ANY. However, if Source IP persistence is not set, the SRCIPSRCPORTHASH method must be used.	All methods applicable to the supported service types.
Persistence types	SOURCEIP persistence.	All types applicable to the supported service types are supported.
USIP	Must be ON.	No restriction. It can be ON or OFF.
Service bindings	Service can be bound to only one virtual server.	Service can be bound to one or more virtual servers.
Internet Protocol (IP) versions	IPv4 and IPv6	IPV4 and IPv6
Redundancy support	Clustering and high availability	High availability

> Note:
>
> Stateful connection failover is supported only for connection-based switching services, for example, TCP. Because HTTP uses request-based switching, it does not support connection failover. In SSL, the existing connections are reset after the failover.

Features affected by connection failover

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects Citrix ADC Features

Feature	Impact of Connection Failover
SYN protection	For any connection, if a failover occurs after the appliance issues SYN-ACK but before it receives the final ACK, the connection is not supported by the connection failover. The client must reissue the request to establish the connection.
Surge protection	If the failover occurs before a connection with the server is established, the new primary appliance tries to establish the connection with the server. It also retransmits all the packets held during surge protection.
Access down	If enabled, the access-down functionality takes precedence over the connection failover.
Application firewall	The Application firewall feature is not supported.
INC	Independent network configuration is not supported in the high availability mode.
TCP buffering	TCP buffering is not compatible with connection mirroring.
Close on response	After failover, the NATPCBs might not be closed on response.

To configure connection failover by using GUI

Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**. Open the virtual server, and in **Advanced Settings**, click **Protection**, and select **Connection Failover** as **Stateful**.

To configure connection failover by using CLI

At the command prompt:

```
set lb vserver <vServerName> -connFailover <Value>
show lb vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -connFailover stateful
```

```
Done
<!--NeedCopy-->
```

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

To disable connection failover by using CLI

At the command prompt:

```
set lb vserver <vServerName> -connFailover <Value>
show lb vserver <vServerName>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -connFailover disable
Done
<!--NeedCopy-->
```

To disable connection failover by using GUI

Navigate to **Traffic Management**> **Load Balancing**> **Virtual Servers**. Open the virtual server, in **Protection**, select **Connection Failover** as Disabled.

Flush the surge queue

September 14, 2021

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. The Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established and thus avoid overloads.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between the client and the server. However, if the appliance cannot establish a new connection with the server, it sends

the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection. The length of a surge queue decreases in any of the following conditions:

- A request in the queue gets sent to the server.
- A request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you might want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed. The other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN, or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while running the command, the surge queue of the specified entity is flushed. If more than one entity has the same name, the appliance flushes the surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while running the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a

<serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.

- If you run the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
<!--NeedCopy-->
```

Examples

```
flush ns surgeQ  -name SVC1ANZGB  -serverName 10.10.10.1 80
<!--NeedCopy-->
```

The previous command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

```
flush ns surgeQ
<!--NeedCopy-->
```

The previous command flushes all the surge queues on the appliance.

To flush a surge queue by using the GUI

Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

Manage a load balancing setup

September 14, 2021

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new Citrix ADC appliances, which must be configured and added to the existing setup. Old servers wear out and must be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology might also require modifications to your load balancing setup. Therefore, you need to perform operations on server objects,

services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of other features that facilitate management of the traffic through your load balancing setup.

Manage server objects

September 14, 2021

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the Citrix ADC appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

To enable a server by using the CLI

At the command prompt, type:

```
enable server <name>
<!--NeedCopy-->
```

Example:

```
enable server 10.102.29.5
<!--NeedCopy-->
```

To enable or disable a server object by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Servers**.
2. Select the server and, in the Action list, select **Enable** or **Disable**.

To disable a server object by using the CLI

At the command prompt, type:

```
disable server <name> <delay>
<!--NeedCopy-->
```

Example:

```
disable server 10.102.29.5 30
<!--NeedCopy-->
```

To remove a server object by using the CLI

At the command prompt, type:

```
rm server <name>
<!--NeedCopy-->
```

Example:

```
rm server 10.102.29.5
<!--NeedCopy-->
```

To remove a server object by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Servers**.
2. Select a server, and click **Remove**.

Manage services

September 14, 2021

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service's state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the Citrix ADC configuration.

To enable or disable a service by using the CLI

At the command prompt, type:

```
enable service <name>

disable service <name> <DelayInSeconds>
<!--NeedCopy-->
```

Examples:

```
enable service Service-HTTP-1
disable service Service-HTTP-1 30
<!--NeedCopy-->
```

To enable or disable a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service and, in the **Action** list, select **Enable** or **Disable**.

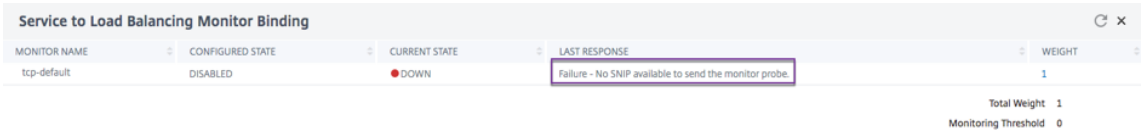
Identify the cause for the service state marked DOWN by using the GUI

Starting from Citrix ADC version 13.0 build 41.20, you can view the monitor probe information on the GUI for the services that are DOWN without navigating to the monitor binding interface. The value in the **Server State** column of the Services page is clickable. You can click **DOWN** to identify the root cause because of which the service is marked DOWN.

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **DOWN** in the **Server State** column corresponding to the service that is DOWN.

The Service to Load Balancing Monitor Binding page appears.

The **Last Response** column displays the reason because of which the service is marked DOWN.



Manage a load balancing virtual server

September 14, 2021

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual service's state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the downStateFLush parameter. If downStateFLush is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

To enable or disable a virtual server by using the CLI

At the command prompt, type:

```
enable lb vserver <name>
<!--NeedCopy-->
```

```
disable lb vserver <name>
<!--NeedCopy-->
```

Examples:

```
enable lb vserver Vserver-LB-1
disable lb vserver Vserver-LB-1
<!--NeedCopy-->
```

To enable or disable a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server, and in the **Action** list, select **Enable** or **Disable**.

To unbind a service from a virtual server by using the CLI

At the command prompt, type:

```
unbind lb vserver <name> <serviceName>
<!--NeedCopy-->
```

Example:

```
unbind lb vserver Vserver-LB-1 Service-HTTP-1
<!--NeedCopy-->
```

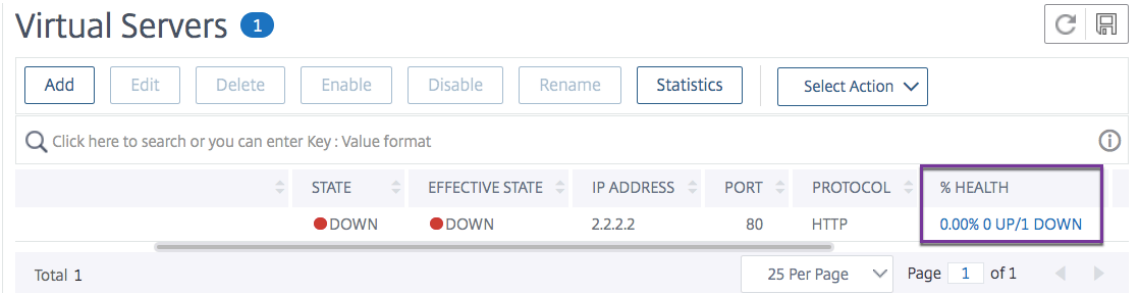
To unbind a service from a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section.
3. Select a service and click **Unbind**.

Identify the cause for the virtual server state marked DOWN by using the GUI

Starting from Citrix ADC version 13.0 build 41.20, you can view the monitor probe information on the GUI for the virtual servers that are DOWN without navigating to the monitor binding interface. The value in the **% HEALTH** column of the Virtual Server page is clickable. You can click the value in the **% HEALTH** column to identify the root cause because of which the virtual server is marked DOWN.

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click the value in the **% HEALTH** column corresponding to the virtual server that is down.

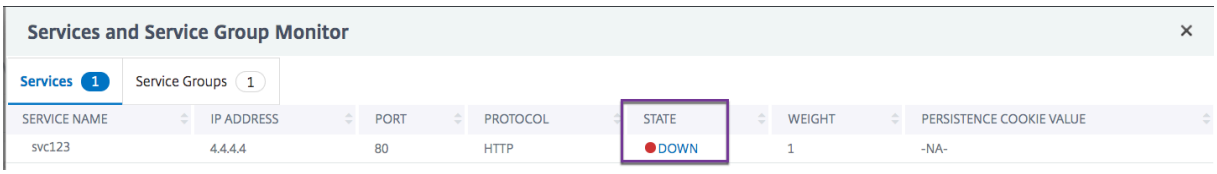


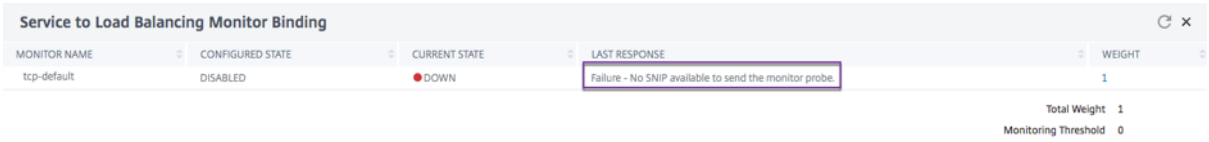
The Service and Service Group Monitor page appears. The services and service groups bound to this virtual server are displayed in the respective tabs.

If you are using services bound to load balancing virtual, perform the following:

In the **Services** tab, click **DOWN** corresponding to the service that is down.

The **Last Response** column in the Service to Load Balancing Monitor Binding page displays the reason because of which the virtual server is marked down.

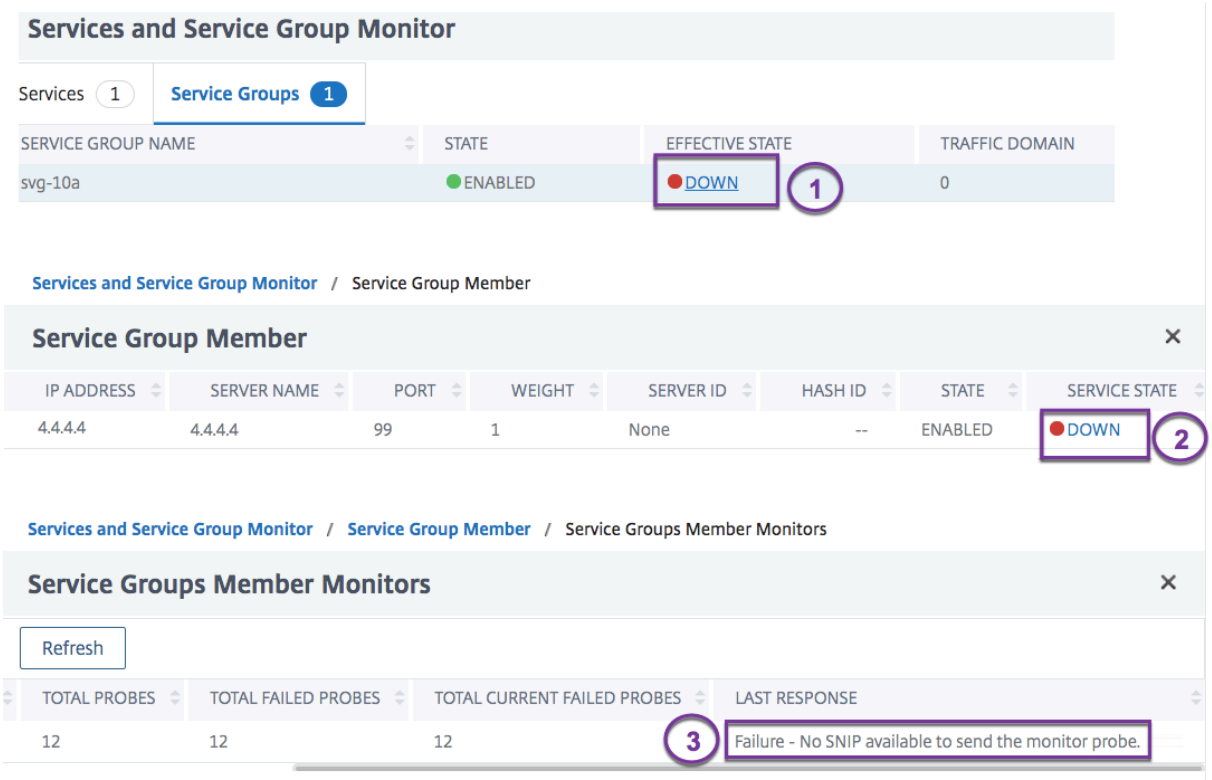




If you are using service groups bound to load balancing virtual, perform the following:

In the **Service Groups** tab, Click **DOWN** in the Services and Service Group Monitor page and then click **DOWN** in the Service Group Member page.

The **Last Response** column in the Service Groups Member Monitors page displays the reason because of which the virtual server is marked down.

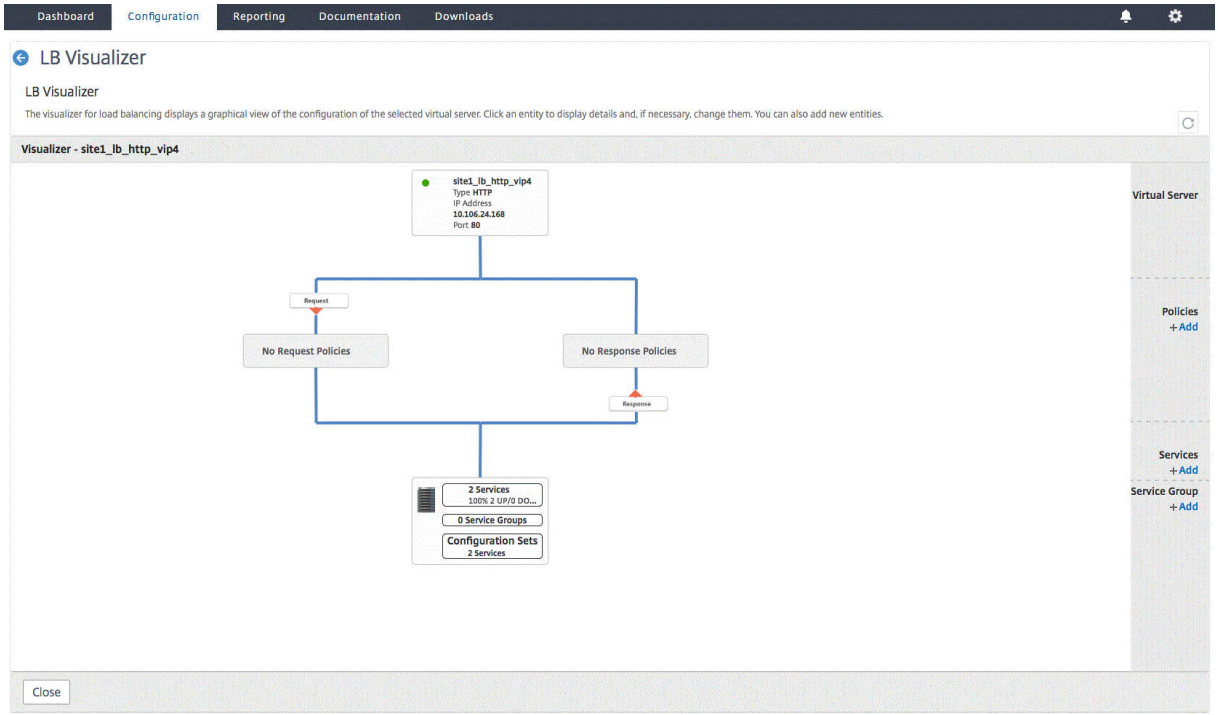


Load balancing visualizer

September 14, 2021

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in a graphical format. Following is an example of the Visualizer display.

Figure 1. Load Balancing Visualizer Display



You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. The services in the container have the same properties, except for the name, IP address, and port, and their monitor bindings must have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services. Otherwise, it is placed in its own container.

The following procedures provide only the basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration util-

ity.

To view load balancing virtual server properties by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.

To view configuration details for services, service groups, and monitors by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.
3. In the Load Balancing Visualizer dialog box, double-click the entity to view the configuration details of the entity that is bound to this virtual server, you can do the following:

To view configuration details for policies and policy labels by using the Visualizer in the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click the policies entity to view the policies that are bound to this virtual server.

To modify a resource in a load balancing configuration by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.

To add a load balancing configuration by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click **+** to add the resource.

Manage client traffic

September 14, 2021

Managing client connections properly helps to ensure that your applications remain available to users even when your Citrix ADC appliance is experiencing high loads. Various load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.
- **SureConnect.** You can use load balancing with the Sure Connect feature to redirect important requests to a custom webpage, insulating them from delays due to network congestion.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the Citrix ADC appliance is experiencing high loads.
- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response**. You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the `ICMP VSERVER RESPONSE`. The following settings can be made on a virtual server:
  - When you set `ICMP VSERVER RESPONSE` to PASSIVE on all virtual servers, the appliance always responds.
  - When you set `ICMP VSERVER RESPONSE` to ACTIVE on all virtual servers, the appliance responds even if one virtual server is UP.
  - When you set `ICMP VSERVER RESPONSE` to ACTIVE on some and PASSIVE on others, the appliance responds even if one virtual server set to ACTIVE is UP.

Configure sessionless load balancing virtual servers

September 14, 2021

When the Citrix ADC appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the appliance

resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

Supported setup

Citrix ADC sessionless load balancing supports the following service types and load balancing methods:

Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

Limitations

Sessionless load balancing has the following limitations:

- The appliance must be deployed in two-arm mode.
- A service must be bound to only one virtual server.

- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.
- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address is not changed.

Note:

- While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.
- To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the Citrix ADC appliance.

To add a sessionless virtual server by using the CLI

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

```
add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -m <
   redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <
   load_balancing_method>

show lb vserver <name>
<!--NeedCopy-->
```

Example:

```
 add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -
    lbMethod roundrobin -m ip
      Done
 show lb vserver sesslessv1
      sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
      State: DOWN
      ...
      Effective State: DOWN
      Client Idle Timeout: 120 sec
      Down state flush: ENABLED
      ...
      Persistence: NONE
      Sessionless LB: ENABLED
```

```
13        Connection Failover: DISABLED
14        L2Conn: OFF
15        1) Policy : cmp_text Priority:8680 Inherited
16        2) Policy : cmp_nocmp_ie60 Priority:8690 Inherited
17  <!--NeedCopy-->
```

To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

```
1  set lb vserver <name>@ -m <redirectionMode> -sessionless <(ENABLED|
       DISABLED)> -lbMethod <load_balancing_method>
2  <!--NeedCopy-->
```

Example

```
1  set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
2    Done
3  <!--NeedCopy-->
```

> **Note**
>
> For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

To configure a sessionless virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in Advanced Settings, click Traffic Settings, and then select Sessionless Load Balancing.

Redirect HTTP requests to a cache

September 14, 2021

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your website performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

To configure cache redirection on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -cacheable <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -cacheable yes
<!--NeedCopy-->
```

To configure cache redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Cacheable.

Direct requests according to priority

September 16, 2021

> **Warning:**
>
> Priority Queuing (PQ) deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. However, Priority Queuing (PQ) is removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see AppQoE topic.

The Citrix ADC appliance supports prioritization of client requests with its priority queuing feature. This feature allows you to designate certain requests, such as those from important clients, as priority requests and sends them to the “front of the line,” so that the appliance responds to them first. This allows you to provide uninterrupted service to those clients through demand surges or DDoS attacks on your website.

To configure priority queuing on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -pq <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -pq yes
<!--NeedCopy-->
```

To configure priority queuing on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Priority Queuing.

Note: Configure priority queuing globally for it to function correctly.

Direct requests to a custom webpage

September 16, 2021

> **Warning:**
>
> SureConnect is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. However, SureConnect is removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see AppQoE topic.

The Citrix ADC appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative webpage of your choice when the server that hosts the primary webpage is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see SureConnect. After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom webpage in use.

Note: For SureConnect to function correctly, you must configure it globally.

To enable SureConnect on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -sc <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -sc yes
<!--NeedCopy-->
```

To enable SureConnect on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select SureConnect.

Enable cleanup of virtual server connections

September 14, 2021

Under certain conditions, you can configure the downStateFlush setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

Do not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-TCP-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

Vserver-LB-1	Service-TCP-1	State of connections
E	E	Both client and server connections are terminated.
E	D	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.
D	E	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see Graceful Shutdown of Services.

To configure the down state flush setting on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -downStateFlush <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -downStateFlush enabled
<!--NeedCopy-->
```

To configure the down state flush setting on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Down State Flush.

Rewrite ports and protocols for HTTP redirection

September 14, 2021

Virtual servers and the services that are bound to them might use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the Citrix ADC appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The redirectPortRewrite setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.

- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

Only SSL redirect is enabled. The virtual server can be configured on any port. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled. The virtual server is configured on port 80. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com/

SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	http://domain.com:8080/
https://domain.com:444/	http://domain.com:8080/

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled,

only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table.

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com/
http://domain.com:8080/	https://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com/
http://domain.com:8080/	https://domain.com/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled. The virtual server is configured on port 444. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com:444/
http://domain.com:8080/	https://domain.com:444/
https://domain.com/	https://domain.com/
https://domain.com:445/	https://domain.com:445/

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

The virtual server is configured on port 80. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

The virtual server is configured on port 8080. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com:8080/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:445/	https://domain.com:445/

Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/

Redirect URL from the Server	Redirect URL sent to the Client
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com/

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com:444/
https://domain.com:445/	https://domain.com:444/

To configure HTTP redirection on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -redirectPortRewrite (ENABLED | DISABLED)
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
<!--NeedCopy-->
```

To configure HTTP redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Rewrite.

To configure SSL Redirect on an SSL virtual server or service by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)

```

```
set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)
<!--NeedCopy-->
```

Example:

```
set ssl vserver Vserver-SSL-1 -sslRedirect enabled

set ssl service service-SSL-1 -sslRedirect enabled
<!--NeedCopy-->
```

To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click SSL Parameters, and select SSL Redirect.

Insert IP address and port of a virtual server in the request header

September 14, 2021

If you have multiple virtual servers that communicate with different applications on the same service, you must do the following:

Configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

Note: This option is not supported for wild card virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the CLI

At the command prompt, type:

```
set lb vserver <name> -insertVserverIPPort <insertVserverIPPort> [<
    vipHeader>]
```

```
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr
<!--NeedCopy-->
```

To insert the IP address and port of the virtual server in the client requests by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in the Advanced Settings pane, click **Traffic Settings**, and then select Virtual Server IP Port Insertion and specify a virtual server IP port header.

Use a specified source IP for back-end communication

October 27, 2021

For communication with the physical servers or other peer devices, the Citrix ADC appliance uses an IP address owned by it as the source IP address. The Citrix ADC appliance maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, the appliance decides which IP address to use. This address pool is used for sending traffic and monitor probes.

In many situations, you might want the appliance to use a specific IP address or any IP address from a specific set of IP addresses for back-end communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server might be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the appliance can use only the IP addresses accepted by the server as the source IP address.
- The appliance can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the appliance to use a specified source IP address, create net profiles (network profiles) and configure the appliance entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, Citrix Gateway VPN virtual servers, services, service groups, or monitors. A net profile has Citrix ADC owned IP addresses (SNIPs and VIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a

net profile has an IP set, the appliance dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile is used for sending traffic to all the services bound to it. If a net profile is bound to a service group, the appliance uses the profile for all the members of the service group. If a net profile is bound to a monitor, the appliance uses the profile for all the probes sent from the monitor.

> **Note:**
>
> - When a Citrix ADC appliance uses a VIP address to communicate with a server, it uses session entries to identify whether the traffic destined to the VIP address is a response from a server or a request from a client.
> - You can bind a net profile to Citrix Gateway VPN virtual servers. However, you need to note some points when binding a net profile. For more information, see Points to note when binding a net profile to VPN virtual server.
> - The net profile IPs bound to a service or service group are not only used for sending traffic towards the corresponding back-end servers, but also for the DNS requests that are triggered by any unresolved back-end FQDN.

Usage of a net profile for sending traffic

If the Use Source IP Address (USIP) option is enabled, the appliance uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, the appliance selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, the appliance uses the default method.
- If there is a net profile only on the service/service group, the appliance uses that net profile.
- If there is a net profile only on the virtual server, the appliance uses the net profile.
- If there is a net profile both on the virtual server and service/service group, the appliance uses the net profile bound to the service/service group.

Usage of a net profile for sending monitor probes:

For monitor probes, the appliance selects the source IP in the following manner:

- If there is a net profile bound to the monitor, the appliance uses the net profile of the monitor. It ignores the net profiles bound to the virtual server or service/service group.
- If there is no net profile bound to the monitor,
  - If there is a net profile on the service/service group, the appliance uses the net profile of the service/service group.
  - If there is no net profile even on the service/service group, the appliance uses the default method of selecting a source IP.

Note: If there is no net profile bound to a service, the appliance looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs and VIPs owned by the Citrix ADC appliance. An IP set can consist of both SNIP and VIP addresses. For instructions, see Creating IP Sets.
2. Create net profiles. For instructions, see Creating a Net Profile.
3. Bind the net profiles to the appliance entities. For instructions, see Binding a Net Profile to a Citrix ADC Entity.

> **Note:**
>
> - A net profile can have only the IP addresses specified as SNIP and VIP on the Citrix ADC appliance.
> - Source IP persistence is not honored for Citrix ADC initiated packets.

Manage net profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the Citrix ADC appliance uses the addresses specified in the profile as the source IP address.

- For instructions on creating a network profile, see Creating a Network Profile.
- For instructions on binding a network profile to a Citrix ADC entity, see Binding a Net Profile to a Citrix ADC Entity.

Create an IP set

An IP set is a set of IP addresses, which are configured on the Citrix ADC appliance as Subnet IP addresses (SNIPs) or Virtual IP addresses (VIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set, and bind Citrix ADC owned IP addresses to it. SNIP addresses and VIP addresses can be present in the same IP set.

To create an IP set by using the CLI

At the command prompt, type the following commands:

```
add ipset <name>

bind ipset <name> <IPAddress>
<!--NeedCopy-->
```

Or

```
bind ipset <name> <IPAddress>

show ipset [<name>]
<!--NeedCopy-->
```

The preceding command shows the names of all the IP sets on the appliance if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

Examples

```
1.
> add ipset skpnwipset
 Done
> bind ipset skpnwipset 21.21.20.1
 Done

2.
 > add ipset testnwipset
 Done
> bind ipset testnwipset 21.21.21.[21-25]
 IPAddress "21.21.21.21" bound
 IPAddress "21.21.21.22" bound
 IPAddress "21.21.21.23" bound
 IPAddress "21.21.21.24" bound
 IPAddress "21.21.21.25" bound
 Done

3.
 > bind ipset skpipset 11.11.11.101
 ERROR: Invalid IP address
[This IP address could not be added because this is not an IP address
   owned by the Citrix ADC appliance]
 > add ns ip 11.11.11.101 255.255.255.0 -type SNIP
 ip "11.11.11.101" added
 Done
 > bind ipset skpipset 11.11.11.101
 IPAddress "11.11.11.101" bound
 Done
4.
> sh ipset
1) Name: ipset-1
2) Name: ipset-2
```

```
3) Name: ipset-3
4) Name: skpnewipset
 Done

5.
> sh ipset skpnewipset
IP:21.21.21.21
IP:21.21.21.22
IP:21.21.21.23
IP:21.21.21.24
IP:21.21.21.25
 Done
<!--NeedCopy-->
```

To create an IP set by using the GUI

Navigate to **System > Network > IP Sets**, and create an IP set.

Create a net profile

A net profile (network profile) consists of one or more SNIP or VIP addresses of the Citrix ADC appliance.

To create a net profile by using the CLI

At the command prompt, type:

```
add netprofile <name> [-srcIp <srcIpVal>]
<!--NeedCopy-->
```

If the srcIpVal is not provided in this command, it can be provided later by using the `set netprofile` command.

Examples

```
add netprofile skpnetprofile1 -srcIp 21.21.20.1
Done

add netprofile baksnp -srcIp bakipset
Done

set netprofile yahnp -srcIp 12.12.23.1
```

```
Done

set netprofile citkbnp -srcIp citkbipset
Done
<!--NeedCopy-->
```

Bind a net profile to a Citrix ADC entity

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor.

Note: You can bind a net profile at the time of creating a Citrix ADC entity or bind it to an existing entity.

To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

```
set lb vserver <name> -netProfile <net_profile_name>
<!--NeedCopy-->
```

Or

```
set cs vserver <name> -netProfile <net_profile_name>
<!--NeedCopy-->
```

Examples

```
set lb vserver skpnwvs1 -netProfile gntnp
 Done
set cs vserver mmdcsv -netProfile mmdnp
 Done
<!--NeedCopy-->
```

To bind a net profile to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Profiles**, and set a net profile.

To bind a net profile to a service by using the CLI

At the command prompt, type:

```
set service <name> -netProfile <net_profile_name>
<!--NeedCopy-->
```

Example

```
set service brnssvc1 -netProfile brnsnp
 Done
<!--NeedCopy-->
```

To bind a net profile to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, click **Profiles**, and set a net profile.

To bind a net profile to a service group by using the CLI

At the command prompt, type:

```
set servicegroup <serviceGroupName> -netProfile <net_profile_name>
<!--NeedCopy-->
```

Example

```
set servicegroup ndhsvcgrp -netProfile ndhnp
 Done
<!--NeedCopy-->
```

To bind a net profile to a service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and open a service group.
2. In Advanced Settings, click **Profiles**, and set a net profile.

To bind a net profile to a monitor by using the CLI

At the command prompt, type:

```
set monitor <monitor_name> -netProfile <net_profile_name>
```

Example

```
set monitor brnsecvmon1 -netProfile brnsmonnp
 Done
<!--NeedCopy-->
```

To bind a net profile to a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Open a monitor, and set the net profile.

Set a time-out value for idle client connections

September 14, 2021

You can configure a virtual server to terminate any idle client connections after a configured time-out period (in seconds) elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection. By default, the client idle time-out value is set to 180 seconds.

To set a time-out value for idle client connections by using the CLI

At the command prompt, type:

```
set lb vserver <name> -cltTimeout <Value>
<!--NeedCopy-->
```

Example:

```
set lb vserver Vserver-LB-1 -cltTimeout 100
<!--NeedCopy-->
```

To set a time-out value for idle client connections by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In **Advanced Settings,** click **Traffic Settings**, and set the client idle time-out value in seconds.

Manage RTSP connections

September 14, 2021

The Citrix ADC appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see IP Addressing.

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see Configuring Load Balancing in Direct Server Return Mode. For more information about configuring DNS, see Domain Name System. In either case, when you configure RTSP load balancing, you must also configure rtspNat to match the topology of your load balancing setup.

To configure RTSP NAT by using the CLI

At the command prompt, type:

```
set lb vserver <name>  -RTSPNAT <ValueOfRTSPNAT>
<!--NeedCopy-->
```

Example:

```
set lb vserver vserver-LB-1  -RTSPNAT ON
<!--NeedCopy-->
```

To configure RTSP NAT by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server of type RTSP.
2. In Advanced Settings, click **Traffic Settings**, and select **RTSP Natting**.

Manage client traffic based on traffic rate

September 14, 2021

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the Citrix ADC appliance based on the traffic rate. For example:

- Throttle the traffic flow if it is too high.
- Cache information based on the traffic rate.
- If the traffic rate is too high, redirect excess traffic to a different load balancing virtual server.
- Apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see Rate Limiting.

Identify a connection with layer 2 parameters

September 14, 2021

Generally, to identify a connection, the Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) to co-exist on the Citrix ADC appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the Citrix ADC appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore Citrix ADC appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

To configure the L2 connection option by using the CLI

At the command prompt, type:

```
add lb vserver <name> <serviceType> <IPAddress>@ <port> -l2Conn ON
<!--NeedCopy-->
```

Example

```
 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
<!--NeedCopy-->
```

To configure the L2 connection option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Layer 2 Parameters.

Configure the Prefer Direct Route option

September 14, 2021

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the Citrix ADC appliance forwards traffic according to the configured route. If you want the appliance to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a Citrix ADC appliance, the appliance directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, sometimes, you might want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the Citrix ADC appliance.

To set the Prefer Direct Route option by using the CLI

At the command prompt, type:

```
set lb parameter -preferDirectRoute (YES | NO)
<!--NeedCopy-->
```

Example:

```
set lb parameter -preferDirectRoute YES
<!--NeedCopy-->
```

To set the Prefer Direct Route option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing parameters**.
2. Select Prefer Direct Route.

Use a source port from a specified port range for back-end communication

September 14, 2021

By default, for configurations with USIP option disabled or with USIP and use proxy port options enabled, the Citrix ADC appliance communicates to the servers from a random source port (greater than 1024).

The appliance supports using a source port from a specified port range for communicating to the servers. One of the use cases of this feature is for servers that are configured to identify received traffic belonging to a specific set based on the source port for logging and monitoring purposes. For example, identifying internal and external traffic for logging purpose.

Configuring the Citrix ADC appliance to use a source port from a port range for communicating to the servers consists of the following tasks:

- **Create a net profile and set the source port range parameter**. A source port range parameter specifies one or more port ranges. The appliance randomly selects one of the free ports from the specified port ranges and used it as the source port for each connection to servers.
- **Bind the net profile to load balancing virtual servers, services, or service groups**: A net profile with source port range setting can be bound to a virtual server, service, or a service group of a load balancing configuration. For a connection to a virtual server, the appliance randomly selects one of the free ports from the specified port ranges of a net profile and use this port as the source port for connecting to one of the bound servers.

To specify a source port range or ranges by using the CLI

At the command prompt, type:

```
bind netProfile <name> (-srcPortRange <int[-int]> ...)

show netprofile <name>
<!--NeedCopy-->
```

To specify a source port range or ranges by using the GUI

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Set the **Source Port Range** parameter while adding or modifying NetProfiles.

Sample Configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has partial NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1  ```
2  > add netprofile CUSTOM-SRCPORT-NP-1
3  Done
4  > bind netprofile CUSTOM-SRCPRT-NP-1  - srcportrange 2000-3000
5
6  Done
7  > bind netprofile CUSTOM-SRCPRT-NP-1  - srcportrange 5000-6000
8
9  Done
10 > add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
11
12 Done
13 <!--NeedCopy--> ```
```

Configure source IP persistency for back-end communication

September 14, 2021

By default, for a load balancing configuration with the USIP option disabled and a net profile bound to a virtual server or services or service groups, the Citrix ADC appliance uses the round robin algorithm to select an IP address from the net profile for communicating with the servers. Because of this selection method, the IP address selected can be different for different sessions of a specific client.

Some situations require that the Citrix ADC appliance route all of a specific client's traffic from the same IP address when sending the traffic to servers. The servers can then, for example, identify traffic belonging to a specific set for logging and monitoring purposes.

The source IP persistency option of a net profile enables the Citrix ADC appliance to use the same address, specified in the net profile, to communicate with servers about all sessions initiated from a

specific client to a virtual server.

To enable source IP persistency in a net profile by using the CLI

To enable source IP persistency while adding a net profile, at the command prompt, type:

```
add netProfile <name> -srcippersistency ( ENABLED | DISABLED )

show netprofile <name>
<!--NeedCopy-->
```

To enable source IP persistency in an existing net profile, at the command prompt, type:

```
set netProfile <name> -srcippersistency ( ENABLED | DISABLED )

show netprofile <name>
<!--NeedCopy-->
```

To enable source IP persistency in a net profile by using the GUI

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Select **Source IP Persistency** while adding or modifying a net profile.

Example

In the following sample configuration, net profile NETPROFILE-IPPRSTNCY-1 has the source IP persistency option enabled and is bound to load balancing virtual server LBVS-1.

The Citrix ADC appliance always uses the same IP address (in this example, 192.0.2.11) to communicate with servers bound to LBVS-1, for all sessions initiated from a specific client to the virtual server.

```
```
> add ipset IPSET-1

Done
> bind ipset IPSET-1 192.0.2.[11-15]
 IPAddress "192.0.2.11" bound
 IPAddress "192.0.2.12" bound
 IPAddress "192.0.2.13" bound
 IPAddress "192.0.2.14" bound
 IPAddress "192.0.2.15" bound
 Done
```

 
```

```
> add netprofile NETPROFILE-IPPRSTNCY-1 -srcIp IPSET-1 -
   srcippersistency ENABLED

Done
> set lb vserver LBVS-1 -netprofile NETPROFILE-IPPRSTNCY-1

 Done
<!--NeedCopy--> ```
```

Use IPv6 link local addresses on the server side of a load balancing setup

September 14, 2021

IPv6 link local address is supported for services, service groups, and servers of a load balancing configuration. You can specify a link local IPv6 address along with the associated VLAN ID in services, service groups, and servers configurations. The Citrix ADC appliance uses the link local SNIP6 address from the same VLAN as specified in the services, service groups, and servers configurations to communicate with them.

A link local IPv6 address and the associated VLAN ID are specified in the following format in services, service groups, and servers configurations: `<IPv6_Addrs>%<vlan_id>`

For example, `fe80:123:4567::a%2048:`, `fe80:123:4567::a` is the link local address AND 2048 is the VLAN ID.

```
> add service SERVICE-1 fe80:123:4567::a%2048 HTTP 80

Done
> bind servicegroup SERVICE-GROUP-1 fe80::1%24 80

Done
> add server SERVER-1 fe80:b:c:d::e:f:a/64%1028

Done
```

Advanced load balancing settings

September 14, 2021

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

Gradually step up the load on a new service with virtual server–level slow start

September 14, 2021

You can configure the Citrix ADC appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (in this document, the term "new service" is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other

services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

  Note: In an automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With an automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

Manual slow start

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and

unit parameters to 25 and “per second,” respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

Table 1. Parameter Values

Parameter	Value
Interval in seconds	0
New service request rate	10, 20, 40, and 0, at intervals that you choose
Units for the new service request rate	Requests per second

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

Table 2. Load Distribution on Services when Manually Stepping Up the Load

	new service request rate = 10 req/sec (Service3added)	new service request rate = 20 req/sec	new service request rate = 40 req/sec (Service4added)	new service request rate = 0 req/sec (new services exit slow start mode)
Service1	115	110	80	60
Service2	115	110	80	60
Service3	10	20	40	60
Service4	-	-	40	60

	new service request rate = 10 req/sec (Service3added)	new service request rate = 20 req/sec	new service request rate = 40 req/sec (Service4added)	new service request rate = 0 req/sec (new services exit slow start mode)
Total req/sec (load on the virtual server)	240	240	240	240

Automated slow start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving its full share of the load.

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 3. Parameter Values

Parameter	**Value**
Interval in seconds	10
Increment value	4
Units for the new service request rate	Requests per second

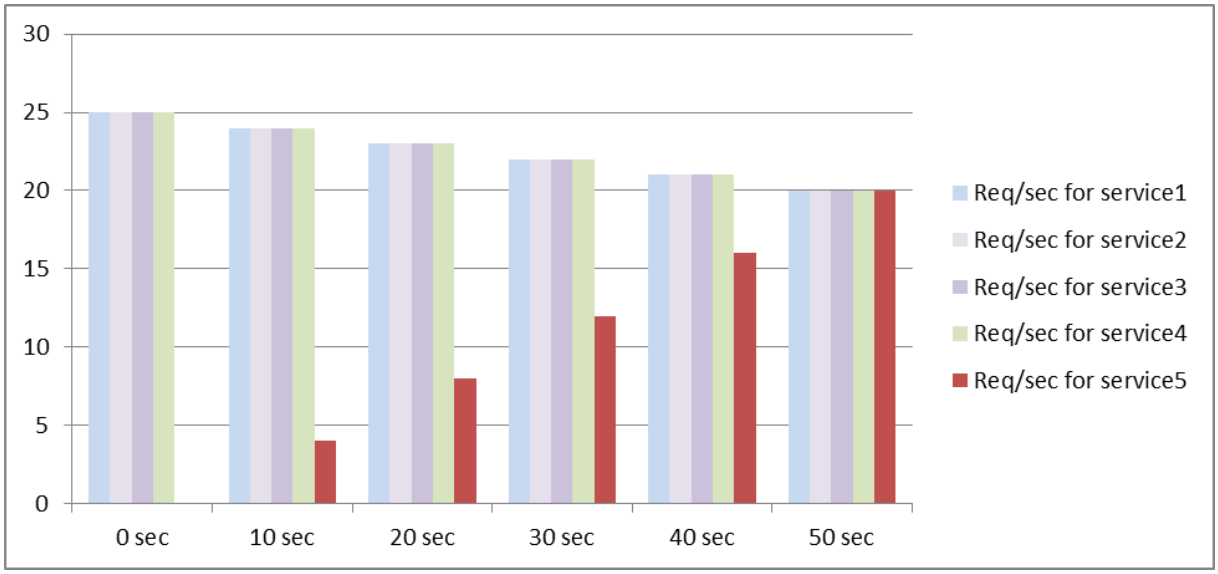
With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second,

the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

	0 sec	10 sec	20 sec	30 sec	40 sec	50 sec
Req/sec forService1	25	24	23	22	21	20
Req/sec forService2	25	24	23	22	21	20
Req/sec forService3	25	24	23	22	21	20
Req/sec forService4	25	24	23	22	21	20
Req/sec forService5	0	4	8	12	16	20
Total req/sec (load on the virtual server)	100	100	100	100	100	100

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added



An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

Table 5. Parameter Values

Parameter	Value
Interval in seconds	5
Increment value	25
Units for the new service request rate	Percent

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”

Set the slow start parameters

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

To configure stepwise load increments for a new service by using the command line interface

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

```
add lb vserver <name> <serviceType> <IPAddress> <port> [-
    newServiceRequest <positive_integer>] [<newServiceRequestUnit>] [-
    newServiceRequestIncrementInterval <positive_integer>]

show lb vserver <name>
<!--NeedCopy-->
```

Example

```
set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -
    newServiceRequestIncrementInterval 10
Done

show lb vserver BR_LB
BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
State: UP
...
...
New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
...
...
Done
<!--NeedCopy-->
```

To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select Method, and set the following slow start parameters:
   - New Service Startup Request Rate.
   - New Service Request Unit.
   - Increment Interval.

The no-monitor option for services

September 14, 2021

If you use an external system to perform health checks on the services and do not want the Citrix ADC appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the appliance continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports a service as DOWN, remove the service from the Citrix ADC configuration.
- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

To set the no-monitor option for a new service by using the CLI

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```
add service <serviceName> <IP | serverName> <serviceType> <port> -
   healthMonitor (YES|NO)
<!--NeedCopy-->
```

Example:

```
add service nomonsrvc 10.102.21.21 http 80 -healthMonitor no
Done

show service nomonsrvc
nomonsrvc (10.102.21.21:80) - HTTP
State: UP
Last state change was at Mon Nov 15 22:41:29 2010
Time since last state change: 0 days, 00:00:00.970
Server Name: 10.102.21.21
 Server ID : 0 Monitor Threshold : 0
```

```
...
Access Down Service: NO
...
Down state flush: ENABLED
Health monitoring: OFF

1 bound monitor:
1) Monitor Name: tcp-default
State: UNKNOWN Weight: 1
Probes: 3 Failed [Total: 3 Current: 3]
Last response: Probe skipped - Health monitoring is turned off.
Response Time: N/A
Done
<!--NeedCopy-->
```

To set the no-monitor option for an existing service by using the CLI

At the command prompt, type the following command to set the health monitor option:

```
set service <name> -healthMonitor (YES|NO)
<!--NeedCopy-->
```

Example:

```
By default, the state of a service and the state of the corresponding
   monitor are UP.
 >show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP

1) Monitor Name: http-ecv
 State: UP Weight: 1
Probes: 99992 Failed [Total: 0 Current: 0]
Last response: Success - Pattern found in response.
Response Time: 3.76 millisec
Done

When the no-monitor option is set on a service, the state of the
   monitor changes to UNKNOWN.
set service LB-SVC1 -healthMonitor NO
Done

show service LB-SVC1
```

```
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010.
Time since last state change: 5 days, 18:55:48.710
Health monitoring: OFF

1) Monitor Name: http-ecv
   State: UNKNOWN Weight: 1
         Probes: 100028 Failed [Total: 0 Current: 0]
   Last response: Probe skipped - Health monitoring is turned off.
     Response Time: 0.0 millisec
  Done
When the no-monitor option is removed, the earlier state of the monitor
    is resumed.
> set service LB-SVC1 -healthMonitor YES
Done
>show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010
Time since last state change: 5 days, 18:57:47.880
1) Monitor Name: http-ecv
   State: UP Weight: 1
   Probes: 100029 Failed [Total: 0 Current: 0]
   Last response: Success - Pattern found in response.
   Response Time: 5.690 millisec
   Done
<!--NeedCopy-->
```

To set the no-monitor option for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and clear Health Monitoring.

Protect applications on protected servers against traffic surges

September 14, 2021

The Citrix ADC appliance provides the surge protection option to maintain the capacity of a server or cache. The appliance regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The appliance blocks any surges passed to the server, thus preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see Surge Protection.

To set surge protection on the service by using the CLI

At the command prompt, type:

```
set service <name> -sp <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -sp ON
<!--NeedCopy-->
```

To set surge protection on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a source.
2. In Advanced Settings, select **Traffic Settings**, and select **Surge Protection**.

Enable cleanup of virtual server and service connections

September 14, 2021

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes or health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN. If a service or virtual server is marked DOWN, the server and client side connections must be flushed. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

Under certain conditions, you can configure the **downStateFlush** setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Do not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

Vserver-LB-1	Service-1	State of Connections
E	E	Both client and server connections are terminated.
E	D	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.
D	E	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see Graceful Shutdown of Services.

To set down state flush on the service by using the CLI

At the command prompt, type:

```
set service <name>  -downStateFlush (ENABLED | DISABLED )
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -downStateFlush enabled
<!--NeedCopy-->
```

To set down state flush on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Down State Flush**.

To set down state flush on the virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name>  -downStateFlush (ENABLED | DISABLED )
<!--NeedCopy-->
```

Example:

```
set lb vserver vsvr1 -downStateFlush enabled
<!--NeedCopy-->
```

To set down state flush on the virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and select **Down State Flush**.

Graceful shutdown of services

September 14, 2021

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. You can later enable the service by using the "enable service <name> command.

To avoid disrupting established sessions, you can place a service in the Transition Out of Service (TROFS) state by doing one of the following:

- Adding a TROFS code or string to the monitor—Configure the server to send a specific code or string in response to a monitor probe.
- Explicitly disable the service and:
  - Set a delay (in seconds).
  - Enable graceful shutdown.

Adding a TROFS Code or String

If you bind only one monitor to a service, and the monitor is TROFS-enabled, it can place the service in the TROFS state on the basis of the server's response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the persistent connections.

If multiple monitors are bound to a service, the effective state of the service is calculated on the basis of the state of all the monitors that are bound to the service. Upon receiving a TROFS response, the state of the TROFS-enabled monitor is considered as UP for the purpose of this calculation. For more information about how a Citrix ADC appliance designates a service as UP, see Setting a Threshold Value for the Monitors Bound to a Service.

Important:

- You can bind multiple monitors to a service, but must not TROFS-enable more than one of them.
- You can convert a TROFS-enabled monitor to a monitor that is not TROFS-enabled, but not vice versa.

To configure a TROFS code or string in a monitor by using the command line interface

At the command prompt, type one of the following commands:

```
add lb monitor <monitor-name> HTTP -trofsCode <respcode>

add lb monitor <monitor-name> HTTP-ECV  -trofsString <resp string>
```

```
4
5 add lb monitor <monitor-name> TCP-ECV  -trofsString <resp string>
6 <!--NeedCopy-->
```

To modify the TROFS code or string by using the command line interface

At the command prompt, type one of the following commands:

```
1 set lb monitor <trofs monitorname> HTTP -trofscode <newcode>
2
3 set lb monitor <trofs monitorname> HTTP-ECV -trofsstring <new string>
4
5 set lb monitor <trofs monitorname> TCP-ECV -trofsstring <new string>
6 <!--NeedCopy-->
```

Note: You can use the set command only if a TROFS-enabled monitor was added earlier. You cannot use this command to set the TROFS code or string for a monitor that is not TROFS-enabled.

To configure a TROFS code or string in a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following:
   - Select Type as HTTP, and specify a TROFS Code.
   - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

Disabling a Service

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes the graceful shutdown options.

State	Results
Graceful shutdown is enabled and a wait time is specified.	Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed.
Graceful shutdown is disabled and a wait time is specified.	Service is shut down only after the wait time expires, even if all established connections are served before expiration.
Graceful shutdown is enabled and no wait time is specified.	Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.
Graceful shutdown is disabled and no wait time is specified.	No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see Enabling Cleanup of Virtual Server Connections.

To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

```
disable service <name> [<delay>] [-graceFul (YES|NO)]

show service <name>
<!--NeedCopy-->
```

Example:

```
> disable service svc1 6000 -graceFul YES
Done
>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
```

```
Last state change was at Mon Nov 15 22:44:15 2010
Time since last state change: 0 days, 00:00:01.160
...
Down state flush: ENABLED

1 bound monitor:
1) Monitor Name: tcp-default
State: UP              Weight: 1
Probes: 13898    Failed [Total: 0 Current: 0]
Last response: Probe skipped - live traffic to service.
Response Time: N/A
Done

>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: OUT OF SERVICE
Last state change was at Mon Nov 15 22:44:19 2010
Time since last state change: 0 days, 00:00:03.250
Down state flush: ENABLED

1 bound monitor:
1)  Monitor Name: tcp-default
State: UNKNOWN           Weight: 1
Probes: 13898    Failed [Total: 0 Current: 0]
Last response: Probe skipped - service state OFS.
Response Time: N/A
Done
<!--NeedCopy-->
```

To configure graceful shutdown for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

Enable or disable persistence session on TROFS services

September 14, 2021

You can set the trofsPersistence flag to specify whether a service in the transition out of service (TROFS) state must maintain persistent sessions. When a monitor is TROFS enabled, it can place a service in the TROFS state on the basis of the server's response to a monitor probe. This response

is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the active client connections. In some cases, the honored active sessions might have to include persistent sessions. But in other cases, especially those involving long-lived persistence sessions or persistence methods such as custom server ID, honoring the persistent sessions can prevent the service from transitioning to the out-of-service state.

If you set the trofsPersistence flag to ENABLED, persistent sessions are honored. If you set it to DISABLED, they are not.

To set the trofsPersistence flag by using the command line interface

At the command prompt, type one of the following commands to set the `trofsPersistence` flag for a new virtual server or an existing virtual server, or to return the setting to its default value:

```
add lb vserver <name> [-trofsPersistence ( ENABLED | DISABLED )]

set lb vserver <name> [-trofsPersistence ( ENABLED | DISABLED )]

unset lb vserver <name> [-trofsPersistence]
<!--NeedCopy-->
```

Argument

trofsPersistence. Honor current active client connections and new requests on persistence sessions when the service is in TROFS state.

Possible values: ENABLED, DISABLED. Default: ENABLED.

Examples:

```
add lb vserver v1 http 10.102.217.42 80 -persistencetype SOURCEIP -
    trofsPersistence ENABLED

set lb vserver v1 -trofsPersistence DISABLED

unset lb vserver v1 -trofsPersistence
<!--NeedCopy-->
```

Direct requests to a custom webpage

September 14, 2021

> **Warning**
>
> SureConnect (SC) is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. For more information, see AppQoE.

For SureConnect to function correctly, you must set it globally. The Citrix ADC provides the SureConnect option to ensure the response from an application.
For more information about the SureConnect option, see Sure Connect.

To set SureConnect on the service by using the CLI

At the command prompt, type:

```
set service <name> -sc <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -sc ON
<!--NeedCopy-->
```

To set SureConnect on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select Traffic Settings, and select **Sure Connect**.

Enable access to services when down

September 14, 2021

You can enable access to a service when it is disabled or in a DOWN state by configuring the Citrix ADC appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the **Access Down** setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see IP Addressing.

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the access-Down parameter.

To enable access down on a service by using the CLI

At the command prompt, type:

```
set service <name> -accessDown <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -accessDown YES
<!--NeedCopy-->
```

To enable access down on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Access Down**.

Enable TCP buffering of responses

September 14, 2021

The Citrix ADC appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 MB (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting.
For more information about configuring TCP buffering globally, see TCP Buffering.

To enable TCP Buffering on a service by using the CLI

At the command prompt, type:

```
set service <name> -TCPB <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -TCPB YES
<!--NeedCopy-->
```

To enable TCP Buffering on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **TCP Buffering**.

Enable compression

September 14, 2021

The Citrix ADC appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally. For more information about configuring compression globally, see Compression.

To enable compression on a service by using the CLI

At the command prompt, type:

```
set service <name> -CMP <YES | NO>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -CMP YES
<!--NeedCopy-->
```

To enable compression on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Compression**.

Enable external TCP health check for UDP virtual servers

September 14, 2021

In public clouds, you can use the Citrix ADC appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. To monitor the health of the UDP application, public clouds recommend adding a TCP-based endpoint to your service. The endpoint reflects the health of the UDP application.

The Citrix ADC appliance supports the external TCP-based health check for a UDP virtual server. This feature introduces a TCP listener on the VIP of the virtual server and the configured port. The TCP listener reflects the status of the virtual server.

To enable an external TCP health check for UDP virtual servers by CLI

At the command prompt, type the following command to enable an external TCP health check with the tcpProbePort option:

```
1 add lb vserver <name> <serviceType> <IPAddress> <port> -tcpProbePort <
     tcpProbePort>
2 <!--NeedCopy-->
```

Example:

```
1 add lb vserver Vserver-UDP-1 UDP 10.102.29.60 80 tcpProbePort 5000
2 <!--NeedCopy-->
```

To enable an external TCP health check for UDP virtual servers by GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, add the port number in the **TCP Probe Port** field.
4. Click **OK**.

Maintain client connection for multiple client requests

September 14, 2021

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a website open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the Citrix ADC appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client opens a new connection for every request that it sends to the website. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see Client Keep-Alive.

To enable the client keep-alive on a service by using the CLI

At the command prompt, type:

```
set service <name> -CKA <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -CKA YES
<!--NeedCopy-->
```

To enable the client keep-alive on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Client Keep-Alive**.

Insert the IP address of the client in the request header

September 14, 2021

A Citrix ADC uses the subnet IP (SNIP) address to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the appliance inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

> **Note**: To insert multiple headers, you need to perform one of the following:
>
> - Add rewrite policies to check CLIENT.IS_SSL and insert appropriate header.
> - Bind the appropriate rewrite policy for each virtual server based on the type.

To insert the client IP address in the client request by using the CLI

At the command prompt, type:

```
set service <name> -CIP <Value> <cipHeader>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -CIP enabled X-Forwarded-For
<!--NeedCopy-->
```

To insert the client IP address in the client request by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, and edit a service.
2. In the **Service Settings** pane, click the **edit icon**.
3. In the **Load Balancing Service** pane, select the **Insert Client IP Address** check box.

Retrieve location details from user IP address using geolocation database

September 14, 2021

> **Note** This feature is available from Citrix ADC release 12.1 build 50.x and later.

The Citrix ADC appliance can get user location details like continent, county, and city. For any public IP address from a geo location database. It is performed using the advanced policy infrastructure. The retrieved location details are then used in a rewrite action or a responder action for performing the following use cases.

- Insert an HTTP header with user location details (such as country, city information) when sending the client request to the back-end server.
- Add country name in the HTML page response for an invalid user.

The appliance can also log the location details using the audit logging mechanism.

Getting user location details using geolocation functions

The components interact as per the following:

1. User sends a client request from a particular geographic location.
2. The Citrix ADC appliance looks for the user IP address from the client request and retrieves the geo location details. The details include continent, country, region, city, ISP, organization, or custom details from a geolocation database.
3. Once the location details are retrieved, the appliance uses either a responder policy or a rewrite policy to evaluate the request.
4. In a rewrite policy, the appliance adds a header with the geo location details and sends it to the back-end server. For example, insert a custom HTTP header with country information.
5. In a responder policy, the appliance evaluates the HTTP request and based on policy evaluation, allows access to the users or redirects the user to an error page. It states the region from where they are accessing the application does not have access.

Setting up geolocation database

As a pre-requisite, you must have a geolocation database to run on the Citrix ADC appliance. The geolocation database files are available with Citrix ADC firmware. To download the database files from a vendor, convert it into Citrix ADC format and import it into your appliance.
For more information about the geolocation database, see Add a location file to create static proximity database topic.

Geolocation functions

The following table gives a list of geolocation functions that retrieves location details of any public IP address. These functions can be used in rewrite or responder policies.

Geolocation function	Example
CLIENT.IP.SRC.LOCATION	Asia.In.Karnataka.Bangalore
CLIENT.IP.SRC.LOCATION.GET (1).LOCATION_LONG	India
CLIENT.IP.SRC.LOCATION(3)	Asia.In.Karnataka
CLIENT.IP.SRC.LAT_LONG	12,77
CLIENT.IPV6.SRC.LOCATION	North America.US.California.Santa Clara.Verizon.Citrix
CLIENT.IPV6.SRC.LOCATION(3)	North America.US.California
CLIENT.IPV6.SRC.LOCATION.GET(1).LOCATION_L	United States

Geolocation function	Example
CLIENT.IPV6.SRC.LOCATION.GET(3)	California
CLIENT.IPV6.SRC.LAT_LONG	36, -119

Configuring geolocation functions

To configure geolocation functions using advanced policy infrastructure, you must enable the load balancing, rewrite, and responder features and then complete the following use cases.

Enable load balancing, responder, rewrite features

If you want the Citrix ADC appliance to authorize user access from a particular geo location, you must enable the load balancing, rewrite, and responder features.

```
enable ns feature loadbalancing rewrite responder
<!--NeedCopy-->
```

Use case 1: Configuring geolocation function for redirecting invalid users outside geo location

When a user from India is requesting access to a webpage, block the request and respond with an HTML page with country name.

The following steps help you to complete the configuration of this use case.

- Add responder action
- Add responder policy
- Bind responder policy to load balancing server

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see Responder topic

Add responder action

Add a responder action to respond with HTML page with country name.
At the command prompt, type:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment <
    string>] [-responseStatusCode <positive_integer>][-reasonPhrase <
    string>]
<!--NeedCopy-->
```

Example:

```
add responder action responder_act respondwith "HTTP.REQ.VERSION + \"
    304 Requested Page not allowed in your country - \" + CLIENT.IP.SRC.
    LOCATION.GET (1).LOCATION_LONG + \"\r\n\""
<!--NeedCopy-->
```

Add audit log message action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.
To create an audit message action by using the command line interface

At the command prompt, type:

```
add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog
 (YES|NO)] [-bypassSafetyCheck (YES|NO)]
```

Example:

```
add audit messageaction msg1 DEBUG "\"Request Location: \"+CLIENT.IP.
    SRC.LOCATION"
<!--NeedCopy-->
```

Add responder policy

Add a responder policy to identify requests coming from India and associate the responder action to this policy.
At the command prompt, type:

```
add responder policy <name> <rule> <action> [<undefAction>] [-comment <
    string>] [-logAction <string>] [-appflowAction <string>]
<!--NeedCopy-->
```

Example:

```
add responder policy responder_pol CLIENT.IP.SRC.MATCHES_LOCATION("Asia
    .India.*.*.*.*") responder_act -logaction msg1
<!--NeedCopy-->
```

Bind responder policy to load balancing server

Bind the responder policy to a load balancing virtual server of type HTTP/SSL.
At the command prompt, type:

```
bind lb vserver <vserver name> -policyName < policy_name >  -priority
    <> -type <L7InlineREQUEST | L4Inline-REQUEST>
<!--NeedCopy-->
```

Example:

```
bind lb vserver http_vserver -policyName responder_pol -priority 100 -
    type REQUEST
<!--NeedCopy-->
```

Use case 2: Configuring geolocation function for inserting new HTTP header with location details for back-end to respond

Consider a scenario, where a Citrix ADC appliance must insert the user location in the HTTP header of a request sent to the application server so that the server can use the information for some business logic.
The following steps help you to complete the configuration of this use case.

- Add rewrite action
- Add rewrite policy
- Bind rewrite policy to load balancing

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see Responder topic.

Add rewrite action

Add a rewrite action to insert a custom HTTP header with user geolocation details in the request and send it back-end servers.
At the command prompt, type:

```
add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-
    pattern <expression> | -search <expression>] [-refineSearch <string
    >][-comment <string>]
<!--NeedCopy-->
```

Example:

```
add rewrite action rewrite_act insert_http_header "User_location"
    CLIENT.IP.SRC.LOCATION
<!--NeedCopy-->
```

Add rewrite policy

Add a rewrite policy to evaluate if the rewrite action must be run. In this case, all requests going to the application server must have a custom HTTP header, so the rule can be “true.”
At the command prompt, type:

```
add rewrite policy <name> <rule> <action> [<undefAction>] [-comment <
   string>] [-logAction <string>]
<!--NeedCopy-->
```

Example:

```
add rewrite policy rewrite_pol true rewrite_act -logaction log_act
<!--NeedCopy-->
```

Bind rewrite policy to load balancing

Bind the rewrite policy to the required load balancing virtual server of type HTTP/SSL.
At the command prompt, type:

```
bind lb vserver <vserver name> -policyName < policy_name >  -priority
   <> -type <L7InlineREQUEST | L4Inline-REQUEST>
<!--NeedCopy-->
```

Example:

```
bind lb vserver http_vserver -policyName rewrite_pol -priority 100 -
   type REQUEST
<!--NeedCopy-->
```

Syslog support for logging geolocation details (optional)

If you prefer to log the user’s geolocation details, you must specify the SYSLOG action to be performed when a request matches the policy. The appliance stores the details as a log message in the ns.log file. For more information about SYSLOG and NSLOG auditing, see Audit logging topic.

Output for user geolocation details

The following output is logged in the appliance using the SYSLOG or `newnslog` action if you try to access an application from the Bangalore location and if the appliance uses the geolocation function, “CLIENT.IP.SRC.LOCATION’.

```
Asia.India.Karnataka.Banglore
<!--NeedCopy-->
```

Sample output log:

```
07/23/2018:19:03:54 GMT  Debug 0-PPE-0 : default REWRITE Message 22 0 :
     "Request Location: asia.in.karnataka.bangalore.*.*"
07/23/2018:19:23:55 GMT  Debug 0-PPE-0 : default RESPONDER Message 32 0
Done
<!--NeedCopy-->
```

Use the source IP address of the client when connecting to the server

September 14, 2021

You can configure the Citrix ADC appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see Enabling Use Source IP Mode.

To enable USIP mode for a service by using the CLI

At the command prompt, type:

```
set service <name> -usip (YES | NO)
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -usip YES
<!--NeedCopy-->
```

To enable USIP mode for a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, and open a service.
2. In Advanced Settings, in the Service Settings section, select **Use Source IP Address**.

Use client source IP address for back end communication in a v4-v6 load balancing configuration

September 14, 2021

In a v4-to-v6 load balancing configuration, for services with USIP disabled, the Citrix ADC appliance communicates to the related servers from one of the configured IPv6 SNIP (SNIP6) addresses.

For services with USIP enabled, you must set the global USIP NAT prefix parameter for making the related servers aware of the client's IP address of the request packets. USIP NAT prefix is a global IPv6 prefix of length 32/40/48/56/64/96 bits configured on the Citrix ADC appliance.

For a load balancing service that has USIP enabled, the appliance translates the IPv4 request packet to an IPv6 packet and sets the source IP address of the translated IPv6 packet to a concatenation of:

- the USIP NAT prefix of length of 32/40/48/56/64/96 bits.
- zeros padded if the USIP NAT prefix length is less than 96 bits. Number of bits padded with zeros = 96-USIP NAT prefix length. For example, if the USIP NAT prefix length is 64, then the number of bits padded with zeros = 96-64 = 32.
- the IPv4 source address [32 bits] that was received in the request packet. In other words, the last 32 bits of the source IPv6 address is set to the IPv4 address of the client.

On receiving an IPv6 response packet from the server, the Citrix ADC appliance translates the IPv6 packet to an IPv4 packet and sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

> **Note**: This feature is not supported for Citrix Gateway configuration and, content switching and cache redirection load balancing configurations.

Configuration Steps

Configuring USIP for a v4-to-v6 load balancing configuration consists of the following tasks:

- **Add global USIP NAT prefix**. It is a global IPv6 prefix of length 32/40/48/56/64/96 bits to be configured on the appliance.
- **Enable global USIP mode**. For more information, see Enable Use Source IP Mode.
- **Enable USIP mode for load balancing services**. For more information, see Use source IP address of the client when connecting to the server.

To add a global USIP NAT prefix by using the CLI:

- `set ipv6 -usipnatprefix <prefix/prefix_length>`
- `show ipv6`

To add a global USIP NAT prefix by using the GUI:

1. Navigate to **System** > **Network**, and click **Change IPv6 Settings**.
2. On the **Configure Configuration for IPV6** screen, set the **USIP NAT Prefix** parameter.

Sample configuration

```
> set ipv6 -usipnatprefix 2001:DB8:90::/64
Done

> enable ns mode USIP
Done

> add lb vserver LBVS-1 HTTP 203.0.113.90 80
Done

> add service SVC-1 2001:DB8:5001::30 HTTP 80 -usip yes
Done

> add service SVC-2 2001:DB8:5001::60 HTTP 80 -usip yes
Done

> bind lb vserver LBVS-1 SVC-1
Done

> bind lb vserver LBVS-1 SVC-2
Done

<!--NeedCopy-->
```

Configure the source port for server-side connections

September 14, 2021

When the Citrix ADC appliance connects to a physical server, it can use the source port from the client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The Citrix ADC appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- LBVS1 receives Req1 and LBVS2 receives Req2.

- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, LBVS1 and LBVS2 forward the response to the client.
- Consider two cases:
  - Use the client port. When the appliance uses the client port, both the virtual servers use the client's IP address (because USIP is ON) and the client's port when connecting to the server. Therefore, when the service sends the response, the appliance cannot determine which virtual server must receive the response.
  - Use proxy port. When the appliance uses a proxy port, the virtual servers use the client's IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that must receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the Citrix ADC appliance can use the source port from the client's request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see "Enabling Use Source IP Mode."

You can configure the **Use Proxy Port** setting either globally or on a given service.

Configure the use proxy port setting on a service

You configure the **Use ProxyPort** setting on the service if you want to override the global setting.

To configure the Use Proxy Port setting on a service by using the CLI

At the command prompt, type:

```
set service <name> -useProxyPort (YES | NO)
<!--NeedCopy-->
```

Example:

```
set service svc1 -useproxyport YES
Done

show service svc1
svc1 (10.102.29.30:80) - HTTP
State: UP
. . .
Use Source IP: YES Use Proxy Port: YES
```

```
. . .
Done
<!--NeedCopy-->
```

To configure the Use Proxy Port setting on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select Traffic Settings, and select **Use Proxy Port**.

Configure the use proxy port setting globally

You configure the **Use Proxy Port** setting globally if you want to apply the setting to all the services on the Citrix ADC appliance. The service-specific **Use Proxy Port** settings overrides the global setting.

To configure the Use Proxy Port setting globally by using the CLI

At the command prompt, type the following commands to configure the **Use Proxy Port** setting globally and verify the configuration:

```
set ns param -useproxyport ( ENABLED | DISABLED )`
show ns param`
<!--NeedCopy-->
```

Example:

```
set ns param -useproxyport ENABLED

Done

show ns param
Global configuration settings:
. . .
Use Proxy Port: ENABLED
Done
<!--NeedCopy-->
```

To configure the Use Proxy Port setting globally by using the GUI

Navigate to **System > Settings > Change global system** settings, and select or clear Use Proxy Port.

Set a limit on the number of client connections

September 14, 2021

You can specify a maximum number of client connections that each load balanced server can handle. The Citrix ADC appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the **Maximum Client** setting, see Load Balancing Domain-Name Based Services.

Note: Connections that are in the process of closing are not considered for this limit.

To set a limit to the number of client connections by using the CLI

At the command prompt, type:

```
set service <name> -maxclient <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -maxClient 1000
<!--NeedCopy-->
```

To set a limit to the number of client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Clients**.

Set a limit on the number of requests per connection to the server

September 14, 2021

The Citrix ADC appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers might have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

To limit the number of client requests per connection by using the CLI

At the command prompt, type:

```
set service <ServiceName> -maxReq <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -maxReq 100
<!--NeedCopy-->
```

To limit the number of client requests per connection by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Requests**.

Set a threshold value for the monitors bound to a service

September 14, 2021

The Citrix ADC appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

By default, the monitor threshold is set to 0 and monitor weights are set to 1. All monitors have equal weightage then and a service can go DOWN when any one of the monitors goes DOWN.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

To set the monitor threshold value on a service by using the CLI

At the command prompt, type:

```
set service <name> -monThreshold <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -monThreshold 100
<!--NeedCopy-->
```

To set the monitor threshold value on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Monitor Threshold**.

Set a timeout value for idle client connections

September 14, 2021

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the Citrix ADC appliance closes the client connection.

To set a timeout value for idle client connections by using the CLI

At the command prompt, type:

```
set service <name> -cltTimeout <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -cltTimeout 100
<!--NeedCopy-->
```

To set a timeout value for idle client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Client Idle Time-out**.

Set a timeout value for idle server connections

September 14, 2021

You can configure a service with a timeout value to terminate any idle server connections when the configured time (in seconds) elapses. If the server is idle for the configured amount of time, the Citrix ADC appliance closes the server connection.

To set a timeout value for idle server connections by using the CLI

At the command prompt, type:

```
set service <name> -svrTimeout <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -svrTimeout 100
<!--NeedCopy-->
```

To set a timeout value for idle server connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Server Idle Time-out**.

Set a limit on the bandwidth usage by clients

September 14, 2021

Sometimes, servers might have limited bandwidth to handle client requests and might become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth, in Kbps, processed by the server. The Citrix ADC appliance forwards requests to a load balanced server only until this limit is reached.

To set a maximum bandwidth limit on a service by using the CLI

At the command prompt, type:

```
set service <name> -maxBandwidth <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -maxBandwidth 100
<!--NeedCopy-->
```

To set a maximum bandwidth limit on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Bandwidth**.

Redirect client requests to a cache

September 14, 2021

You can configure a service to redirect client requests to a cache, and forward the non-cacheable requests to a service chosen by the configured load balancing method.

To set cache redirection on a service by using the CLI

At the command prompt, type:

```
set service <name> -cacheable <Value>
<!--NeedCopy-->
```

Example:

```
set service Service-HTTP-1 -cacheable YES
<!--NeedCopy-->
```

To set cache redirection on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and set the Cache Type.

Retain the VLAN identifier for VLAN transparency

September 14, 2021

You can configure a load balancing virtual server to retain the client's VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

To configure a load balancing virtual server to retain the client VLAN ID by using the CLI

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

```
set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED

show lb vserver <name>
<!--NeedCopy-->
```

> **Note**
>
> For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

To configure a load balancing virtual server to retain the client VLAN ID by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and select **Retain VLAN ID**.

Configure automatic state transition based on percentage health of bound services

September 14, 2021

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.

You can also enable an SNMP alarm called ENTITY-STATE if you want the Citrix ADC appliance to notify you when the percentage health of bound services causes a virtual server to change state.

To configure percentage based automatic state transition by using the CLI

At the command prompt, type the following commands to configure an automatic state transition for a virtual server and verify the configuration:

```
set lb vserver <name> -healthThreshold <positive_integer>

show lb vserver <name>
<!--NeedCopy-->
```

To configure percentage based automatic state transition by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and set a **Health Threshold**.

To enable the ENTITY-STATE alarm by using the CLI

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

```
enable snmp alarm ENTITY-STATE

show snmp alarm
<!--NeedCopy-->
```

To enable the ENTITY-STATE alarm by using the GUI

1. Navigate to **System > SNMP > Alarms**.
2. Select **ENTITY-STATE** and, in the Action list, select **Enable**.

Built-in monitors

September 14, 2021

The Citrix ADC appliance contains various built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. They provide options to modify some parameters, such as interval, response time-out to meet your requirements. However, you cannot modify the monitor name and protocol. For more information, see Modifying Monitors. You can also bind a built-in monitor to a service and unbind it from the service.

> **Note**
>
> You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see Configuring Monitors in a Load Balancing Setup.

TCP-based application monitoring

September 14, 2021

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications: `tcp-default` and `ping-default`. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services. The ping-default monitor is bound to all non-TCP services.

You can't delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

Monitor type	Specific parameters	Process
tcp	Not applicable	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination, and then closes the connection. If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor.

Monitor type	Specific parameters	Process
http	httprequest [“HEAD /”] - HTTP request that is sent to the service. respcode [200] - A set of HTTP response codes are expected from the service.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.
tcp-ecv	send [””] - is the data that is sent to the service. The maximum permissible length of the string is 512 bytes. recv [””] - expected response from the service. The maximum permissible length of the string is 128 bytes. The last character is NULL termination.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.

Monitor type	Specific parameters	Process
http-ecv	send [””] - HTTP data that is sent to the service; recv [””] - the expected HTTP response data from the service	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data might be anywhere in the first 24 K bytes of the HTTP body of the response.
ping	Not Applicable	The Citrix ADC appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.

To configure built-in monitors for TCP-based applications, see Configuring Monitors in a Load Balancing Setup.

To configure TCP-based monitors by using CLI

Type the following command:

```
add lb monitor <monitorName> <type> -respCode <int[-int]> -httpRequest
    <string> -resptimeout <integer> [<units>] -retries <integer> -
    downTime <integer> [<units>] -action <action>
<!--NeedCopy-->
```

Example for TCP monitor type:

```
add lb monitor Exch2010-RPC-AddressBook TCP -LRTM ENABLED -interval 10
    -resptimeout 5 -destPort 59601
<!--NeedCopy-->
```

Example for HTTP monitor type:

```
add lb monitor Mon_S4B_FE_2 HTTP -respCode 200 -httpRequest "GET /
    Autodiscover/XFrame/XFrame.html" -LRTM ENABLED -retries 10 -secure
    YES
<!--NeedCopy-->
```

Example for HTTP-ECV monitor type:

```
add lb monitor STM_EXC2016_SSLBridge_MON HTTP-ECV -send "GET /owa/
    healthcheck.htm" -recv "200 OK" -LRTM ENABLED -destPort 443 -secure
    YES
<!--NeedCopy-->
```

Example for PING monitor type:

```
add lb monitor lbmon-localhost-ping PING -LRTM DISABLED -destIP
    127.0.0.1
<!--NeedCopy-->
```

SSL service monitoring

September 14, 2021

The Citrix ADC appliance has built-in secure monitors, TCPS, and HTTPS. You can use the secure monitors to monitor HTTP and non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and then set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and then set the secure flag. The secure monitors work as follows:

- **Secure TCP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.
- **Secure HTTP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

Monitor type	Probe	Success criteria (Direct condition)
TCP	TCP connection; SSL handshake	Successful TCP connection established and successful SSL handshake.
HTTP	TCP connection; SSL handshake; Encrypted HTTP request	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted.
TCP-ECV	TCP connection. SSL handshake (Data sent to a server is encrypted.)	Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.
HTTP-ECV	TCP connection; SSL handshake (Encrypted HTTP request)	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.

Sample configuration for HTTPS-ECV health check monitor

HTTP services have predefined monitors capable of Extended Content Verification (ECV).
These monitors are used when a validation is required beyond a successful TCP connection. These monitors validate the service as UP, when all the following criteria are met:

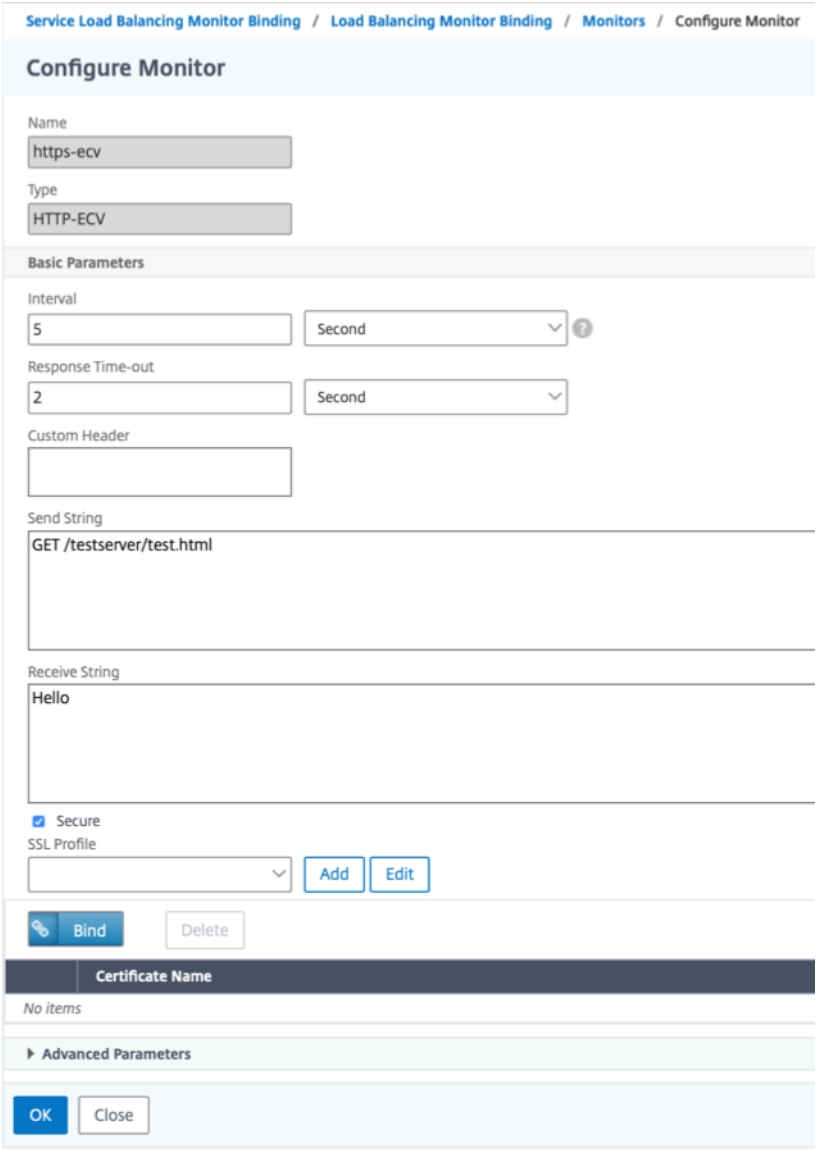
- A successful TCP connection.
- A particular type of request must be generated.
- A specific message is expected in reply from the **Receive String**.

For these monitors, a request string is configured along with a reply string. If the reply string received by the Citrix ADC monitor matches the configured string, then the service is marked UP.

Bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, create a service, and specify the protocol as **SSL**. Click **OK**.

2. Click in the **Service to Load Balancing Monitor Binding** pane, and click **Add Binding**.
3. Choose the monitor type as **HTTPS-ECV** and click **Edit**.
4. In the **Configure Monitor** pane under **Basic Parameters** tab, enter values for the following parameters:
   - **Send String** – The string that the monitor must send to the service.
   - **Receive String** – The string that the monitor must receive to mark the service as UP.



5. Click **OK** to complete the monitor configuration.
6. Click **Select**.
7. Click **Bind** to bind the **HTTPS-ECV** monitor to the service.
8. Click **Close**.

Bind a monitor to a service by using the CLI

At the command prompt, type:

```
bind service <servicename> -monitorName https-ecv
<!--NeedCopy-->
```

Example:

```
bind services1 -monitorName https-ecv
<!--NeedCopy-->
```

HTTP/2 service monitoring

September 14, 2021

Citrix ADC appliance supports HTTP/2 monitors for monitoring the health status of HTTP/2 services.

HTTP/2 monitor can be configured in two different ways. Depending on the traffic type, you can configure an HTTP/2 monitor.

- **HTTP/2 Direct.** You can configure HTTP/2 Direct for monitoring non-secure HTTP/2 services.
- **HTTP/2 SSL.** You can configure HTTP/2 SSL for monitoring secure traffic over SSL. Enable the secure flag parameter in the HTTP/2 to monitor the SSL traffic.

The http2direct and http2ssl are the two different built-in monitors that are supported for the HTTP/2 protocol.

The following table lists the configuration types, and monitoring processes associated with each type.

Configuration type	Probe	Success criteria
HTTP/2 Direct	TCP Connection; HTTP2 Connection preface & Settings Negotiation; HTTP2 Request	HTTP/2 response status code must match the configured response code.
HTTP/2 SSL	TCP Connection; SSL Handshake; HTTP2 Connection preface & Settings Negotiation; HTTP2 Request	The server must always select ALPN with the HTTP/2 protocol and the HTTP/2 response status code must match the configured response code.

Bind the HTTP/2 monitor to a service by using the CLI

At the command prompt, type:

- `bind service <servicename> -monitorName <name>`
- `bind service <servicename> -monitorName <name>`

Example:

- `bind service s1 -monitorName http2direct`
- `bind service s2 -monitorName http2ssl`

Proxy protocol service monitoring

September 14, 2021

Citrix ADC appliance with a proxy protocol supports monitor check. The monitor check ensures that the back end server also supports the proxy protocol. The Citrix ADC appliance has four built-in monitor types for HTTP or TCP related services: HTTP, HTTPS, HTTP-ECV, and TCP-ECV.

The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

Configuration type	Probe	Success criteria
HTTP	`httprequest` ["HEAD /"] - HTTP request that is sent to the service. `respcode` [200] - A set of HTTP response codes are expected from the service.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.

Configuration type	Probe	Success criteria
HTTPS	`httprequest` [“HEAD /”] - HTTPS request that is sent to the service. `respcode` [200] - A set of HTTPS response codes are expected from the service.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTPS requests, and then compares the response code with the configured set of response codes.
HTTP-ECV	send [””] - HTTP data that is sent to the service. Received [””] - the expected HTTP response data from the service	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data might be anywhere in the first 24 K bytes of the HTTP body of the response.

Configuration type	Probe	Success criteria
TCP-ECV	send [””] - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes. received [””] - the expected response from the service. The maximum permissible length of the string is 128 K bytes.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.

You can configure the proxy protocol monitor using `netprofile`.

Configure proxy protocol monitor by using the CLI

At the command prompt, type:

1. Add net profile with proxy protocol enabled

```
add netprofile <name> -proxyProtocol ( ENABLED | DISABLED )
```

Example:

```
1 add netprofile profile1 -proxyProtocol ENABLED
```

1. Bind the net profile to a service.

```
set service <name> -netprofile <netprofile-name>
```

Example:

```
1 set service S1 -netprofile profile1
```

> **Note**
>
> You can run the preceding command if you want net profile to bound to a service.

1. Bind the net profile to a monitor.

```
set lb monitor <monitor-name> <type> -netprofile <netprofile-name>
```

Example:

```
1 set lb monitor http1 HTTPS  - netprofile profile1
```

> **Note**
>
> - You can run the preceding command if you want the net profile to bound to a monitor.
> - You can select a monitor type of your choice. It can be HTTP, HTTPS, TCP-ECV, or HTTP-ECV.
>
> **Important**
>
> - In a general case, the net profile (proxy protocol enabled) bound to a service is considered.
> - If the net profile is bound to both monitor and service, the net profile bound to monitor is considered. The net profile bound to service is ignored.

FTP service monitoring

September 14, 2021

To monitor FTP services, the Citrix ADC appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected, on both the connections, it is marked UP.

Note: Monitor probes originate from the NSIP address.

The Citrix ADC appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP-EXTENDED monitor is a scriptable monitor. It uses the nsftp.pl script. The FTP-EXTENDED monitor script is enhanced to send secure probes to FTP services. You can create a monitor of type FTP-EXTENDED. The nsftp.pl script is automatically taken from the default directory.

To send secure FTP probes to FTP services by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -username <string> -password <
     string> -filename <filename>
2 <!--NeedCopy-->
```

Example

```
add monitor mon1 FTP-EXTENDED -username root -password freebsd -
    filename fsdf
<!--NeedCopy-->
```

To send secure FTP probes to FTP services by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Specify the monitor type as **FTP-EXTENDED**, and set the parameters.
3. In **Special Parameters**, specify a **File Name**, **User Name**, and **Password**.

To configure built-in monitors to check the state of FTP services, see Configuring Monitors in a Load Balancing Setup.

Secure monitoring of servers by using SFTP

September 14, 2021

A user script 'nssftp.pl' is added to support SSH File Transfer Protocol (SFTP) monitoring. It is available in the current list of in-built Citrix ADC user monitors and is located in the /netscaler/monitors directory. The SFTP monitor uses the specified user name and password to check if the file is present on the server.

To configure secure monitoring using SFTP by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
    string> -secure ( YES | NO )
<!--NeedCopy-->
```

Example:

```
add monitor SFTP_MON USER -scriptname nssftp.pl -scriptargs "file=
    example.txt;user=sam;password=sam_passwd"
<!--NeedCopy-->
```

To configure secure monitoring using SFTP by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors** and in **Type** specify **USER**.

2. In **Special Parameters**, in **Script Name**, select nssftp.pl.
3. Specify the **Script Arguments**.

Set SSL parameters on a secure monitor

September 14, 2021

> **Important**
>
> This feature is supported only on the new Default profiles. For more information about these profiles, see Enhanced SSL Profiles Infrastructure Overview.

A monitor inherits either the global settings or the settings of the service to which it is bound. If a monitor is bound to a non-SSL or non-SSL_TCP service, such as SSL_BRIDGE, you cannot configure it with SSL settings such as the protocol version or the ciphers to be used. Therefore, if your deployment requires SSL-based monitoring of the back-end servers, the monitoring is ineffective.

You can have more control over SSL-based monitoring of back-end servers, by binding an SSL profile to a monitor. An SSL profile contains SSL parameters, cipher bindings, and ECC bindings. For example, you can set server authentication, ciphers, and protocol version in an SSL profile and bind the profile to a monitor. To perform server authentication, you must also bind a CA certificate to a monitor. To perform client authentication, you must bind a client certificate to the monitor. New parameters for the “bind lb monitor” command enable you to do so.

> **Note**
>
> The SSL settings take effect only if you add a secure monitor. Also, the SSL profile type must be **BackEnd**.

Monitor Types that Support SSL Profiles

SSL profiles can be bound to the following monitor types:

- HTTP
- HTTP-ECV
- TCP
- TCP-ECV
- HTTP-INLINE

To specify an SSL profile while adding a monitor by using the command line

At the command prompt, type:

```
add lb monitor <monitorName> <type> -secure  YES   -sslprofile <string>

set lb monitor <monitorName> <type> -secure YES -sslprofile <string>
<!--NeedCopy-->
```

Example:

```
add ssl profile prof1 -sslProfileType  BackEnd

add lb monitor mon1 HTTP -secure  YES -sslprofile prof1
<!--NeedCopy-->
```

To bind a certificate-key pair to a monitor by using the command line

At the command prompt, type:

```
bind monitor  <monitor name> -certkeyName <string>  [(-CA  [-crlCheck (
    Mandatory | Optional ) | -ocspCheck ( Mandatory | Optional )]
<!--NeedCopy-->
```

SIP service monitoring

September 14, 2021

A Citrix ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

Parameter	Specifies
sipURI	SIP addressing schema of the SIP server.
sipmethod	Type of SIP request used to probe the SIP service. Specify one of the following methods: INVITE, OPTION (the default), REGISTER
respcode	SIP response code with which the SIP service responds the probe request. Default: 200.

RADIUS service monitoring

September 14, 2021

The Citrix ADC appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

Parameter	Specifies
`userName`	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
password	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
radKey	Shared secret key value that the RADIUS server uses during client authentication.
radNASid	NAS-ID that is encapsulated in the payload when an access request is made.
radNASip	The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the Citrix ADC appliance sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address.

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor uses for authentication to the

RADIUS authentication database.

2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the Citrix ADC appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all the IP addresses.

   Caution: If the IP address used by the appliance is not added to the RADIUS database, the RADIUS server discards all packets.

To configure built-in monitors to check the state of the RADIUS server, see Configuring Monitors in a Load Balancing Setup.

Monitor accounting information delivery from a RADIUS server

September 14, 2021

You can configure a monitor called a *RADIUS accounting* monitor to determine whether the RADIUS server used for Authentication, Authorization, and Accounting (Citrix ADC AAA) is delivering accounting information as expected. The monitor is of type RADIUS_ACCOUNTING. The probe is generated by a Perl script called nsbmradius.pl, which is located in the /nsconfig/monitors/ directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as Acct-Status-Type and Framed-IP-Address. For information about these attributes, see RFC 2865, "Remote Authentication Dial In User Service (RADIUS)," and RFC 2866, "RADIUS Accounting."

To configure a RADIUS accounting monitor by using the command line interface

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

```
add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {
 -password  }
  {
 -radKey  }
  [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-
     radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-
     radAccountSession <string>]
```

```
6
7 show lb monitor <monitorName>
8 <!--NeedCopy-->
```

Example

```
1 add lb monitor radAccntMon RADIUS_ACCOUNTING -radKey "8d#>9jr4rV)L7%a2-
     zW13sM"
2 <!--NeedCopy-->
```

DNS and DNS-TCP service monitoring

September 14, 2021

The Citrix ADC appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

Parameter	Description
query	The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007” If the DNS query succeeds, the service is marked as UP. Otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN. Otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.
queryType	The type of DNS query that is sent. Possible values: Address, Zone.
IPAddress	List of IP addresses that are checked against the response to the DNS monitoring probe.
IPv6	Select this check box if the IP address uses the IPv6 format.

To configure the built-in DNS or DNS-TCP monitors, see Configuring Monitors in a Load Balancing Setup.

LDAP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

Configure the LDAP monitor to define the search that it must perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server must start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
baseDN	Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=`netscaler`, dc=com.
bindDN	BDN name for the LDAP monitor.
filter	Filter for the LDAP monitor. Use the filter parameter in a query to limit the number of results. If you do not specify this parameter in the query, the filter applies for the entire object class, which might be a costly operation, such as a high CPU usage.
password	Password used in monitoring LDAP servers.
attribute	Attribute for the LDAP monitor.

To configure the built-in LDAP monitor, see Configuring Monitors in a Load Balancing Setup.

MySQL service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
database	Database that is used for the MySQL monitor.
sqlQuery	SQL query that is used for the MySQL monitor.

To configure a built-in MySQL monitor, see Configuring Monitors in a Load Balancing Setup.

To configure MySQL monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
     string>
2 <!--NeedCopy-->
```

Example:

```
1 add lb monitor mysql1 USER -scriptName nsmysql.pl -scriptArgs "database
     =cloud;user=cloud;password=password;query=show tables from cloud"
2 <!--NeedCopy-->
```

SNMP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor SMNP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query

succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
SNMPOID	OID that is used for the SNMP monitor.
snmpCommunity	Community that is used for the SNMP monitor.
snmpThreshold	Threshold that is used for the SNMP monitor.
snmpVersion	SNMP version that is used for load monitoring. Possible Values: V1, V2.

To configure the built-in SNMP monitor, see Configuring Monitors in a Load Balancing Setup.

NNTP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

Parameter	Specifies
`userName`	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
password	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
group	Group name to be queried for NNTP monitor.

To configure the built-in NNTP monitor, see Configuring Monitors in a Load Balancing Setup.

POP3 service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
userName	User name POP3 server. This user name is used in the probe.
password	Password used in monitoring POP3 servers.
scriptName	The path and name of the script to execute.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

To configure the built-in POP3 monitor, see Configuring Monitors in a Load Balancing Setup.

To configure POP3 monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
     string>
2 <!--NeedCopy-->
```

Example:

```
1 add lb monitor pop31 USER -scriptName nspop3.pl -scriptArgs "user=
     test@lbmon1.net;password=Freebsd123"
2
```

```
<!--NeedCopy-->
```

SMTP service monitoring

September 14, 2021

The Citrix ADC appliance has a built-in monitor that can be used to monitor SMTP services: the SMTP monitor. The monitor checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. Else, if the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
scriptName	The path and name of the script to run.
dispatcherIP	The IP Address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

To configure the built-in SMTP monitor, see Configuring Monitors in a Load Balancing Setup.

RTSP service monitoring

September 14, 2021

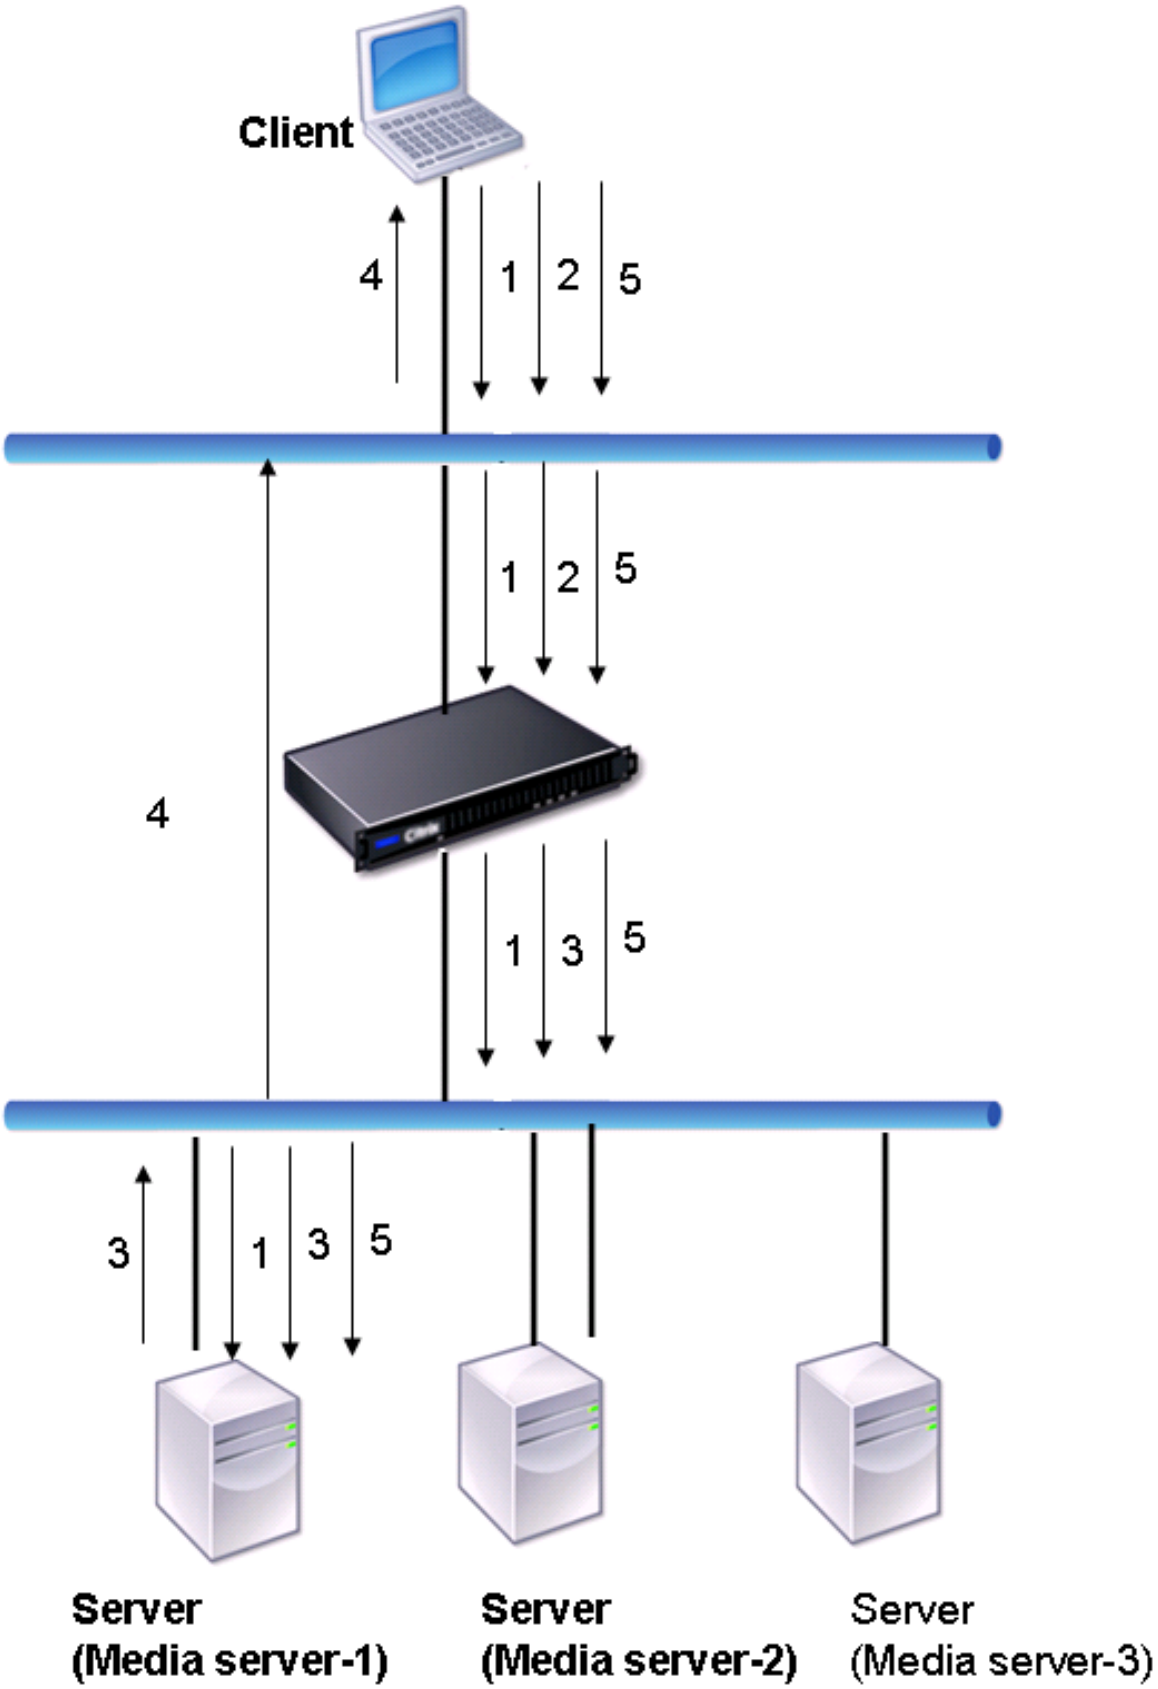
The Citrix ADC appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The Citrix ADC appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology

your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode



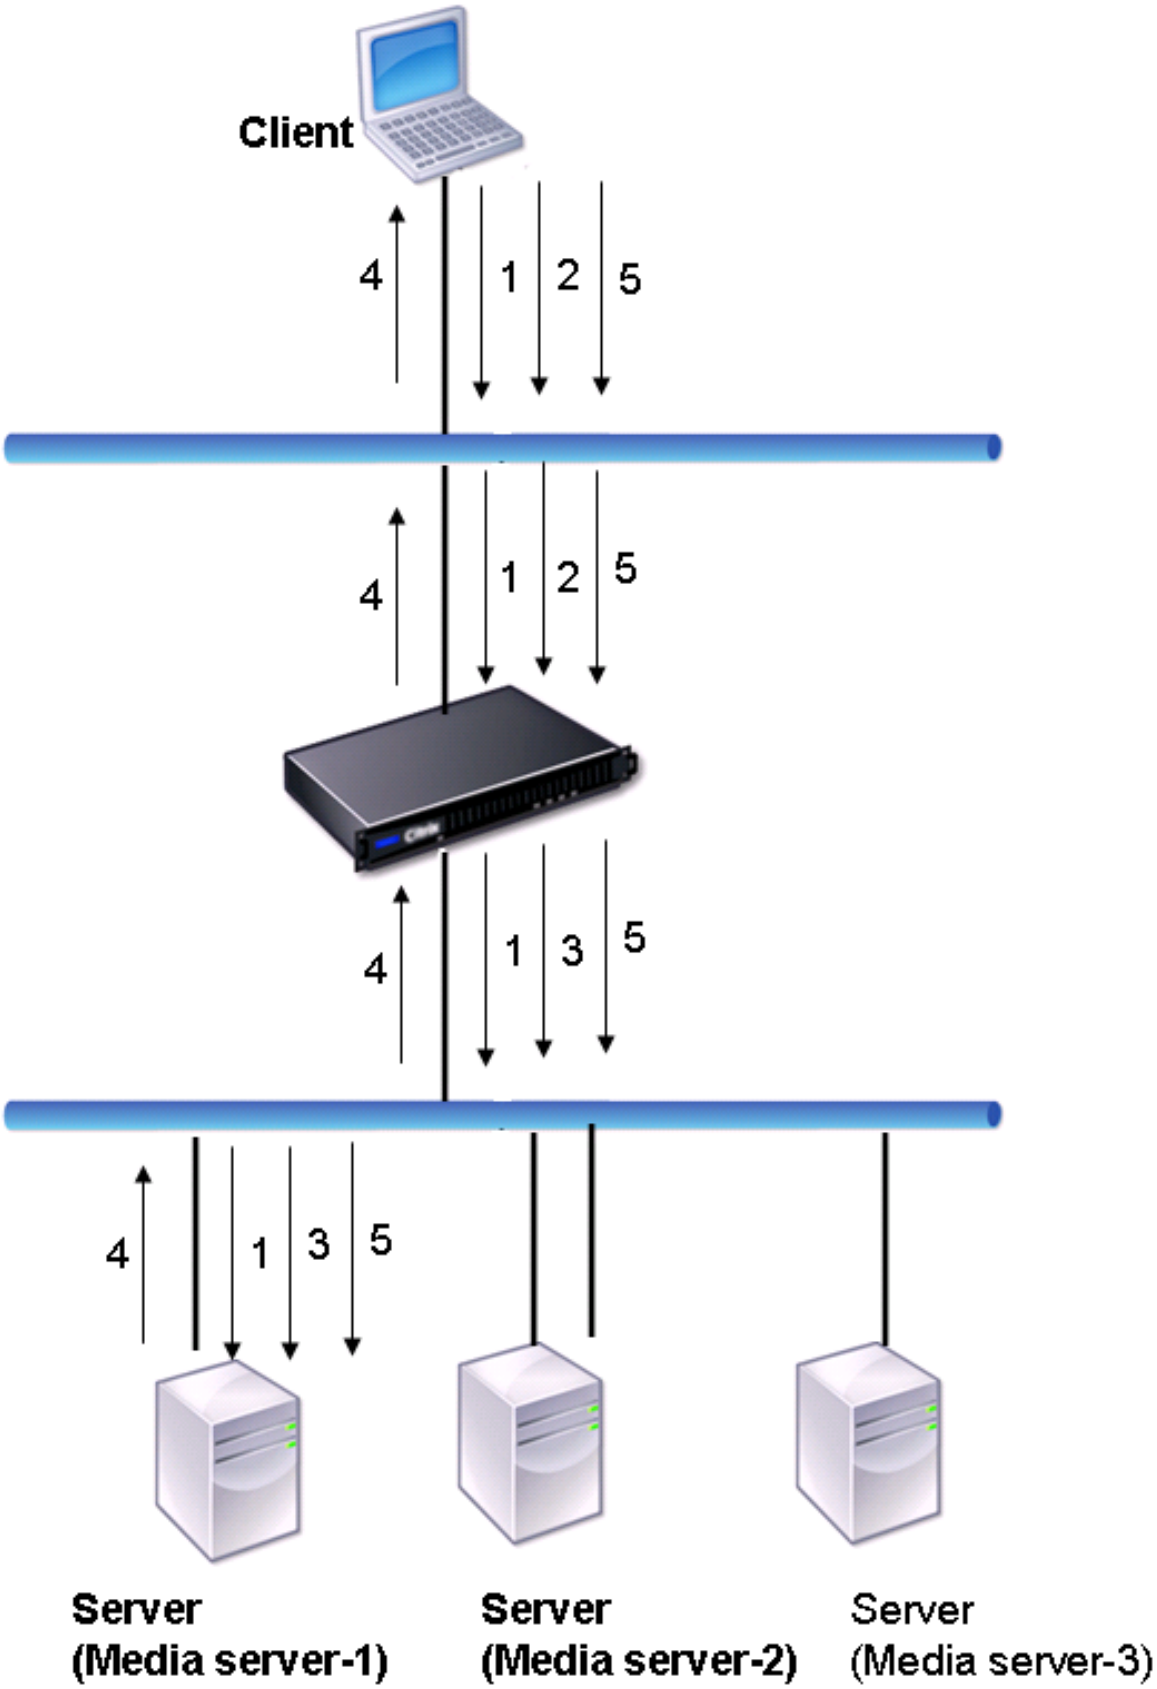
The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request might be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

   Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.
4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode



The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request might be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.
4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.
5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

Parameter	Specifies
rtspRequest	The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters.
respCode	Set of response codes that are expected from the service.

For instructions on configuring an RTSP monitor, see Configuring Monitors in a Load Balancing Setup.

XML Broker Service monitoring

September 14, 2021

The Citrix ADC appliance has a built-in monitor type, CITRIX-XML-SERVICE, with which you can create monitors to monitor the XML Broker Services. The XML Broker Services are used by Citrix XenApp. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a CITRIX-XML-SERVICE monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker Service. The default application is Notepad.

To configure monitors for XML Broker Services, see Configuring Monitors in a Load Balancing Setup.

> **Note**
>
> The parameter "Application Name" for the Citrix-XML-Service monitor is invalid for XenApp and Citrix Virtual Desktops versions 7 and later. It is recommended not to use this parameter in XA/XD 7. In case you configure this parameter, this parameter is not used internally. The probing criteria is different starting XA/XD 7. However, you can use the "Application Name" parameters in versions earlier to XA/XD 7.

ARP request monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP is compatible with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see Configuring Monitors in a Load Balancing Setup.

XenDesktop Delivery Controller service monitoring

September 14, 2021

In desktop virtualization, the Citrix ADC appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by the Citrix XenDesktop environment. The Citrix ADC appliance provides a built-in monitor, `CITRIX-XD-DDC` monitor, which monitors the XenDesktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.

The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether the user credentials (user name, password, and domain) are specified on the
`CITRIX-XD-DDC` monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the XenDesktop servers, the `CITRIX-XD-DDC` monitor is automatically created and bound to the XenDesktop Delivery Controller services.

To add an XD-DDC monitor with the validate credentials option by using the command line interface

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

```
add lb monitor <monitorName> <monitorType> -userName <userName> -
    password <password> -domain <domain_name> -validateCred YES

show lb monitor <monitorName>
<!--NeedCopy-->
```

Example:

```
 > add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -
    password E12Dc35450a1 -domain dhop -validateCred YES
```

```
 Done
> show lb monitor xdddcmon
1) Name......:xdddcmon Type......:CITRIX-XD-DDC State......: ENABLED

Standard parameters:
Interval......:..5 sec...Retries......:..3
Response timeout......:..2 sec...Down time......:..30 sec
Reverse......:..NO...Transparent......:..NO
Secure......:..NO...LRTM......:..ENABLED
Action......:..Not applicable...Deviation......:..0 sec
Destination IP......:..Bound service
Destination port......:..Bound service
Iptunnel......:..NO
TOS......:..NO...TOS ID......:..0
SNMP Alert Retries......:..0...Success Retries......:..1
Failure Retries......:..0

Special parameters:
User Name..........:"Administrator"
Password..........:*****
DDC Domain.........: "dhop"
Done
<!--NeedCopy-->
```

To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <monitorType> -userName -password -domain
   <domain_name> -validateCred YES
<!--NeedCopy-->
```

Example:

```
 set lb monitor XD_DDC_21.21.21.22_443_mn CITRIX-xd-ddc -userName
    Administrator -password D123S1R2A123 -domain dhop -validateCred YES
Done
<!--NeedCopy-->
```

To configure an XD-DDC monitor with the validate credentials option by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type `Citrix-XD-DDC`.

Citrix StoreFront stores monitoring

September 14, 2021

You can configure a user monitor for a Citrix StoreFront store. The monitor determines the state of the StoreFront store by successively probing the account service, discovery service, and authentication endpoint (if the Citrix StoreFront Store is an authenticated store). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service. For more information, see Citrix StoreFront Store Services API.

Note: Monitor probes originate from the NSIP address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.

Beginning with release 10.1 build 120.13, you can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member's IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

In earlier releases, the StoreFront monitor tried to authenticate anonymous stores. As a result, a service can be marked as DOWN and you cannot launch XenApp or XenDesktop by using the URL of the load balancing virtual server.

From build 64.x, the probe order has changed. The monitor now determines the state of the StoreFront store by successively probing the account service, the discovery document, and then the authentication service, and skips authentication for anonymous stores.

The host name parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

To create a StoreFront monitor by using the command line interface

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

```
add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-
    storefrontacctservice ( YES | NO )] -secure ( YES | NO )

show lb monitor <monitorName>
<!--NeedCopy-->
```

Example

```
add lb monitor storefront_ssl STOREFRONT -storename myStore -
    storefrontacctservice YES -secure YES
<!--NeedCopy-->
```

To create a StoreFront monitor by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type **STOREFRONT**.

> **Note**
>
> For more information about the StoreFront monitors, see StoreFront documentation.

Custom monitors

September 14, 2021

In addition to built-in monitors, you can use custom monitors to check the state of your services. The Citrix ADC appliance provides several types of custom monitors based on scripts that are included with the Citrix ADC operating system. The scripts can be used to determine the state of services based on the load on the service or network traffic sent to the service. Custom monitors are the inline monitors, user monitors, and load monitors.

With these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

Configure HTTP-inline monitors

September 14, 2021

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the Citrix ADC appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured downtime. After the downtime elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

To configure inline monitors, see Configuring Monitors in a Load Balancing Setup.

To configure HTTP-inline monitors by using CLI

Type the following command:

```
add lb monitor <monitorName> <type> -respCode <int[-int]> -httpRequest
    <string> -resptimeout <integer> [<units>] -retries <integer> -
    downTime <integer> [<units>] -action <action>
<!--NeedCopy-->
```

Example:

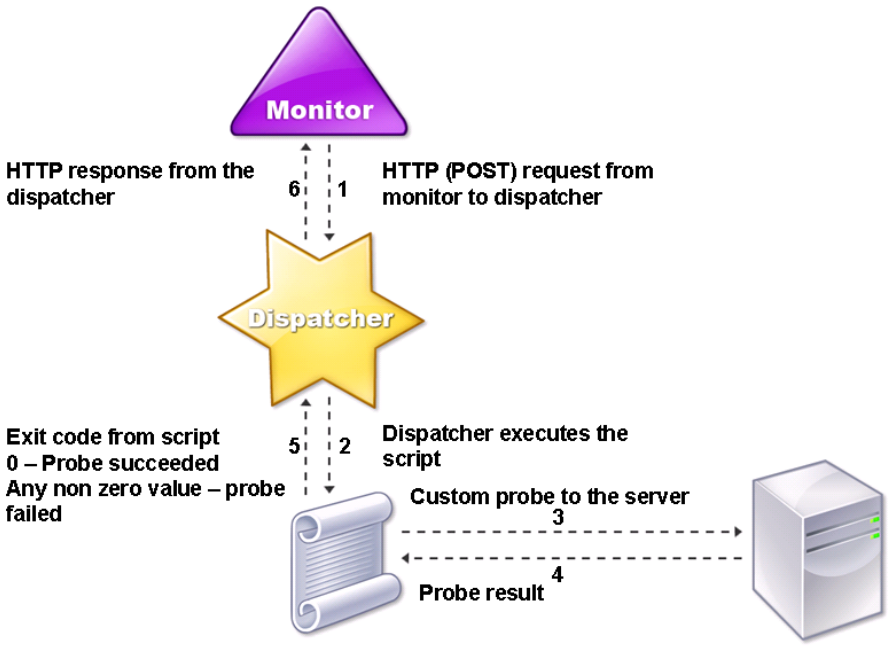
```
add lb monitor http_inline HTTP-INLINE -respCode 200 304 -httpRequest "
    HEAD /var/static/empty.htm" -resptimeout 4 -retries 1 -downTime 2 -
    action NONE
<!--NeedCopy-->
```

Understand user monitors

September 14, 2021

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the Citrix ADC appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors



A user monitor requires the following components.

- **Dispatcher.** A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports the Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

  Note: You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the “secure” option on the monitor, and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

In a HA setup, the dispatcher runs on both the primary and secondary Citrix ADC appliances. The dispatcher remains inactive on the secondary appliance.

Script. The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

The Citrix ADC appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the /nsconfig/monitors directory. If you want to add a script, add it there. To customize an existing script, create a copy with a new name and modify it.

Important:

- Starting with Citrix ADC release 13.0 build 41.20, you can use the `nsntlm-lwp.pl` script to create a monitor for monitoring a secure NTLM server.
- Starting with release 10.1 build 122.17, the script files for user monitors are in a new location.

  If you upgrade an MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

  - A new directory named conflicts is created in /nsconfig/monitors/ and all the built-in scripts of the previous builds are moved to this directory.
  - All new built-in scripts are available in the /netscaler/monitors/ directory. All custom scripts are available in the /nsconfig/monitors/ directory.
  - Save a new custom script in the /nsconfig/monitors/ directory.
  - After the upgrade is completed, if a custom script is created and saved in the /nsconfig/monitors/ directory, with the same name as the built-in script, the script in the /netscaler/monitors/ directory takes priority. The custom script does not run.

  If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:

  - All built-in scripts are available in the /netscaler/monitors/ directory.
  - The /nsconfig/monitors/ directory is empty.
  - If you create a custom script, you must save it in the /nsconfig/monitors/ directory.

For the scripts to function correctly:

- The maximum number of characters in the name of the script must not exceed 63.
- The maximum number of script arguments that can be provided to a script must not exceed 512.
- The maximum number of characters that can be provided in the parameter script arguments must not exceed 639.

To debug the script, you must run it by using the nsumon-debug.pl script from the CLI. You use the script name (with its arguments), IP address, and the port as the arguments of the nsumon-debug.pl

script. Users must use the script name, IP address, port, time-out, and the script arguments for the nsumon-debug.pl script.

At the CLI, type:

```
nsumon-debug.pl <scriptname> <IP> <port> <timeout> <partitionID> [
    scriptarguments][is_secure]
<!--NeedCopy-->
```

Important: Starting with release 10.5 build 57.x, and 11.0 script files for user monitors support IPv6 addresses and include the following changes:

- For the following protocols, new `pm files` have been included for IPv6 support.
  - RADIUS
  - NNTP
  - POP3
  - SMTP
- The following sample scripts in /netscaler/monitors/ has been updated for IPv6 support:
  - nsbmradius.pl
  - nsldap.pl
  - nsnntp.pl
  - nspop3 nssf.pl
  - nssnmp.pl
  - nswi.pl
  - nstftp.pl
  - nssmtp.pl
  - nsrdp.pl
  - nsntlm-lwp.pl
  - nsftp.pl
  - nsappc.pl

  After upgrading to release 10.5 build 57.x, or 11.0, if you want to use your existing custom scripts with IPv6 services, make sure that you update the existing custom scripts with the changes provided in the updated sample scripts in /netscaler/monitors/.

  Note: The sample script nsmysql.pl does not support the IPv6 address. If an IPv6 service is bound to a user monitor that uses nsmysql.pl, the probe fails.
- The following LB monitor types have been updated to support IPv6 addresses:

- USER
- SMTP
- NNTP
- LDAP
- SNMP
- POP3
- FTP_EXTENDED
- StoreFront
- APPC
- CITRIX_WI_EXTENDED

If you are creating a custom script that uses one of these LB monitors types, ensure to include IPv6 support in the custom script. Refer to the associated sample script in /netscaler/monitors/ for the changes that you have to make in the custom script for IPv6 support.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be run. The dispatcher runs the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The Citrix ADC appliance logs the error messages to the /var/nslog/nsumond.log file when user monitor probes fail. These detailed error messages are displayed in the GUI, and in the CLI for the `show service`/`service group` commands.

The following table lists the user monitors and the possible reasons for failure.

User monitor type	Probe failure reasons
SMTP	Monitor fails to establish a connection to the server.
NNTP	Monitor fails to establish a connection to the server.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Monitor fails to find the NNTP group.

User monitor type	Probe failure reasons
LDAP	Monitor fails to establish a connection to the server.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Monitor fails to bind to the LDAP server.
	Monitor fails to locate an entry for the target entity in the LDAP server.
FTP	The connection to the server times out.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
	Monitor fails to find the file on the server.
POP3	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
POP3	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
	Preparation of the SQL query fails.
	Execution of the SQL query fails.
SNMP	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.

User monitor type	Probe failure reasons
	Logon fails.
	Monitor fails to create the SNMP session.
	Monitor fails to find the object identifier.
	The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.
RDP (Windows Terminal Server)	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Monitor fails to create a socket.
	Mismatch in versions.
	Monitor fails to confirm connection.

You can view the log file from the CLI by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the CLI:

```
> shell
root@ns# cat /var/nslog/nsumond.log
root@ns# exit
>
<!--NeedCopy-->
```

Before Citrix ADC release 13.0 build 52.X, the `show service/service group` command displayed a generic error message saying “probe failed” as the cause for the user monitor probe failure.

Example:

```
show service ftp

Monitor Name: mon2
State: UNKNOWN  Weight: 1   Passive: 0
Probes: 3    Failed [Total: 0 Current: 0]
Last response: Failure - Probe failed.
Response Time: 1071.838 millisec
<!--NeedCopy-->
```

From Citrix ADC release 13.0 build 52.X onwards, the `show service/service group` command displays the actual cause for the user monitor probe failure.

Example:

```
show service ftp

Monitor Name: mon2
State: DOWN   Weight: 1   Passive: 0
Probes: 729   Failed [Total: 726 Current: 726]
Last response: Failure - Login failed.
Response Time: 8000.0 millisec
<!--NeedCopy-->
```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

> **Note:**
>
> For scriptable monitors, the response timeout must be configured to a value equal to the expected timeout + 1 second.
>
> For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.
>
> **Example command:**

```
add lb monitor <name> USER  - scriptname <script-name> -resptimeout 5
    seconds
<!--NeedCopy-->
```

How to use a user monitor to check websites

September 14, 2021

You can configure a user monitor to check for specific website problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

HTTP response code	Meaning
200 - success	Probe success.
503 - service unavailable	Probe failure.

HTTP response code	Meaning
404 - not found	Script not found or cannot run.
500 - Internal server error	Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.
400 - bad request	Error parsing HTTP request.
502 - bad gateway	Error decoding script's response.

You configure the user monitor for HTTP by using the following parameters.

Parameter	Specifies
scriptName	The path and name of the script to run.
scriptArgs	The strings that are added in the POST data. They are copied to the request verbatim.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.
localfileName	The name of a monitor script file on the local system.
destPath	A particular location on the Citrix ADC appliance where the uploaded local file is stored.

To create a user monitor to monitor HTTP, see Configuring Monitors in a Load Balancing Setup.

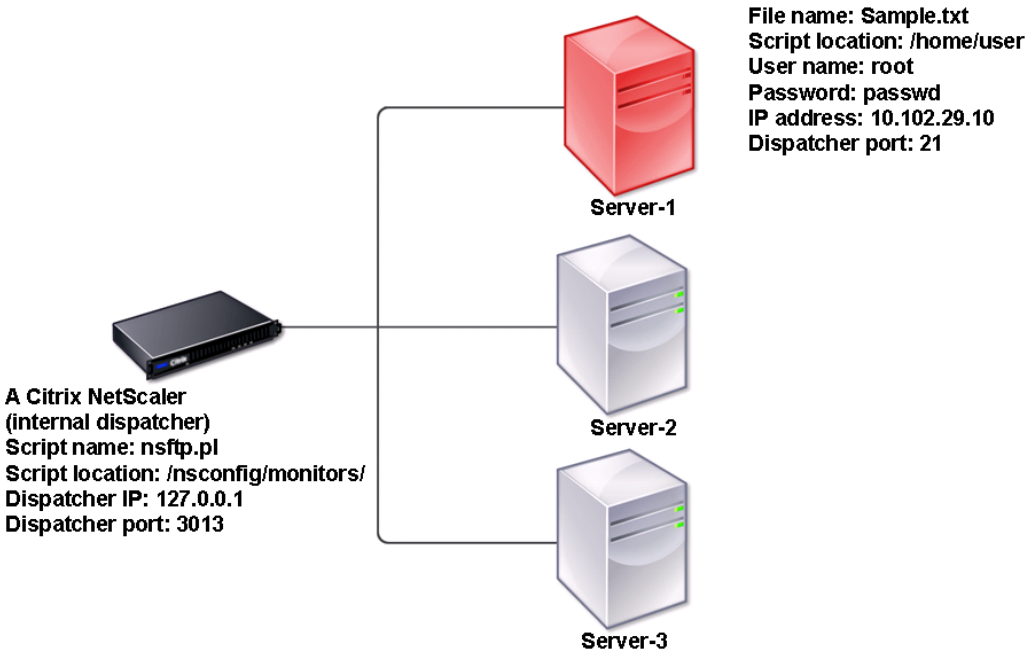
Understand the internal dispatcher

September 14, 2021

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram

illustrates this scenario.

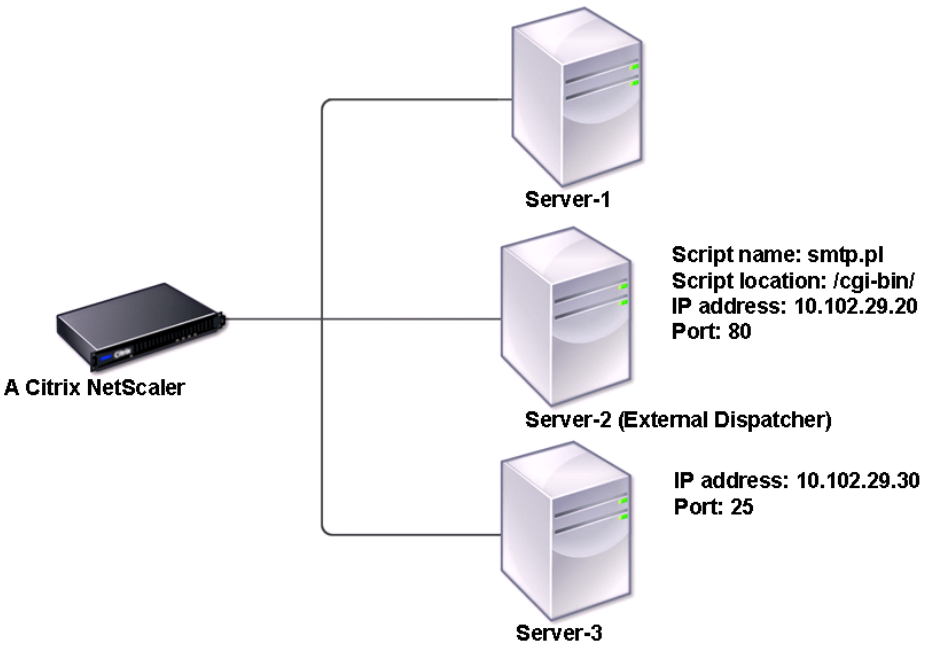
Figure 1. Using a user monitor with the internal dispatcher



A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The Citrix ADC appliance includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a user monitor with an external dispatcher



A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

Configure a user monitor

September 14, 2021

To configure a user monitor, you must write a script that the monitor uses to check the services that are bound to it. Upload the script to the /nsconfig/monitors directory on the Citrix ADC appliance. Give executable permission to the script. If the monitor type is a protocol that the Citrix ADC appliance does not support, only then you must use the monitor of type **USER**. The user monitors support Perl and Bash scripts. Python scripts are not supported.

> **Note**
>
> Monitor probes originate from the NSIP address. The `scriptargs` configured for the monitor of type USER is displayed in the running configuration and ns.conf files.

To configure a user monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> USER -scriptname <NameOfScript> -
   scriptargs <Arguments>
<!--NeedCopy-->
```

Example:

```
add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file
   =/home/user/
sample.txt;user=root;password=passwd"
<!--NeedCopy-->
```

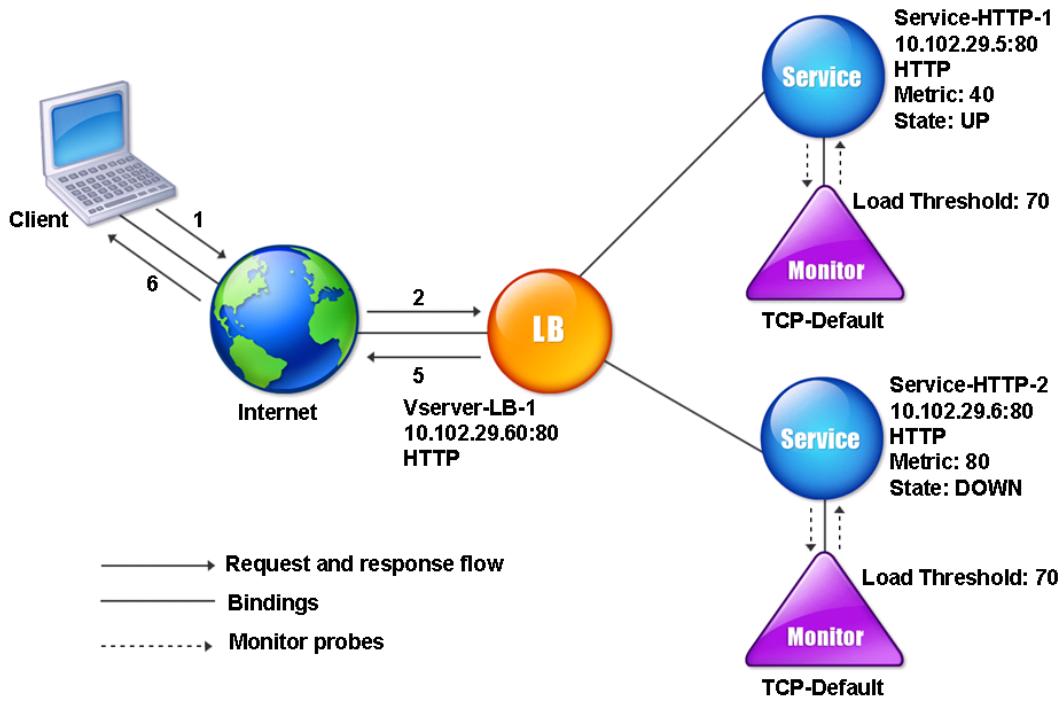
Understand load monitors

September 14, 2021

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The Citrix ADC appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in Setting Up Basic Load Balancing.

Figure 1. Operation of Load Monitors



Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL
- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing,

as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

Metric name	OIDs	Weight	Threshold
CPU	1.2.3.4	2	70
Memory	4.5.6.7	3	80
Connections	5.6.7.8	4	90

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

Configure load monitors

September 14, 2021

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see Creating Monitors. Next, select, or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

```
add lb metricTable <metricTableName>

bind lb metricTable <metricTableName> <metric> <SNMPOID>
<!--NeedCopy-->
```

Example:

```
add metricTable Table-Custom-1

bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
<!--NeedCopy-->
```

To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Metric Tables** and create a metric table.
2. To bind metrics, click **Bind** and specify a metric and an SNMP OID.

Unbind metrics from a metrics table

September 14, 2021

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

```
unbind lb metricTable <metricTable> <metric>
<!--NeedCopy-->
```

Example:

```
unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5
<!--NeedCopy-->
```

To unbind metrics from a metric table by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Metric Tables**.
2. Open a metric table, select a metric, and click **Delete**.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

Configure reverse monitoring for a service

September 14, 2021

A reverse monitor marks a service as DOWN if the probe criteria are satisfied and UP if they are not satisfied. For example, if you want a backup service to receive traffic only when the primary service is DOWN, you can bind a reverse monitor to the secondary service but configure it to probe the primary service.

The Citrix ADC appliance supports the following reverse monitors:

- HTTP
- ICMP
- TCP (from release 11.1 build 49.x)

Configuring HTTP Reverse Monitoring for a Service

The following table describes the conditions of HTTP direct and reverse monitoring for a service:

Condition	Direct	Reverse
Connection not established.	Fail	Fail
HTTP response code matches the probe's specifications.	Success	Fail
HTTP response code does not match the probe's specifications.	Fail	Success
Probe timed out.	Fail	Fail

To configure HTTP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
add lb monitor <Monitor_Name> HTTP -respCode 200 -httpRequest "HEAD /"
    -destIP <Primary_Service_IP_Address> -destPort 80 -reverse YES

bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
<!--NeedCopy-->
```

Configuring ICMP Reverse Monitoring for a Service

The following table describes the conditions of ICMP direct and reverse monitoring for a service:

Condition	Direct	Reverse
ICMP echo reply is received.	Success	Fail
Probe timed out.	Fail	Success

To configure ICMP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
add lb monitor <Monitor_Name> PING -destIP <Primary_Service_IP_Address>
    -reverse YES

bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
<!--NeedCopy-->
```

Configuring TCP Reverse Monitoring for a Service

If a direct TCP monitor receives a RESET in response to a monitor probe, the service is marked DOWN. However, if a reverse TCP monitor receives a RESET response, the probe is considered successful, and the service is marked UP.

The following table describes the conditions of TCP reverse monitoring for a service:

Condition	Direct	Reverse
TCP connection is established.	Success	Fail
Probe timed out.	Fail	Fail
Response to probe is RESET.	Fail	Success

To configure TCP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
add lb monitor <Monitor_Name> TCP  - destip <Primary_Service_IP_Address>
    -destport <primary_service_port>  - reverse YES

bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
<!--NeedCopy-->
```

To configure reverse monitoring by using the GUI

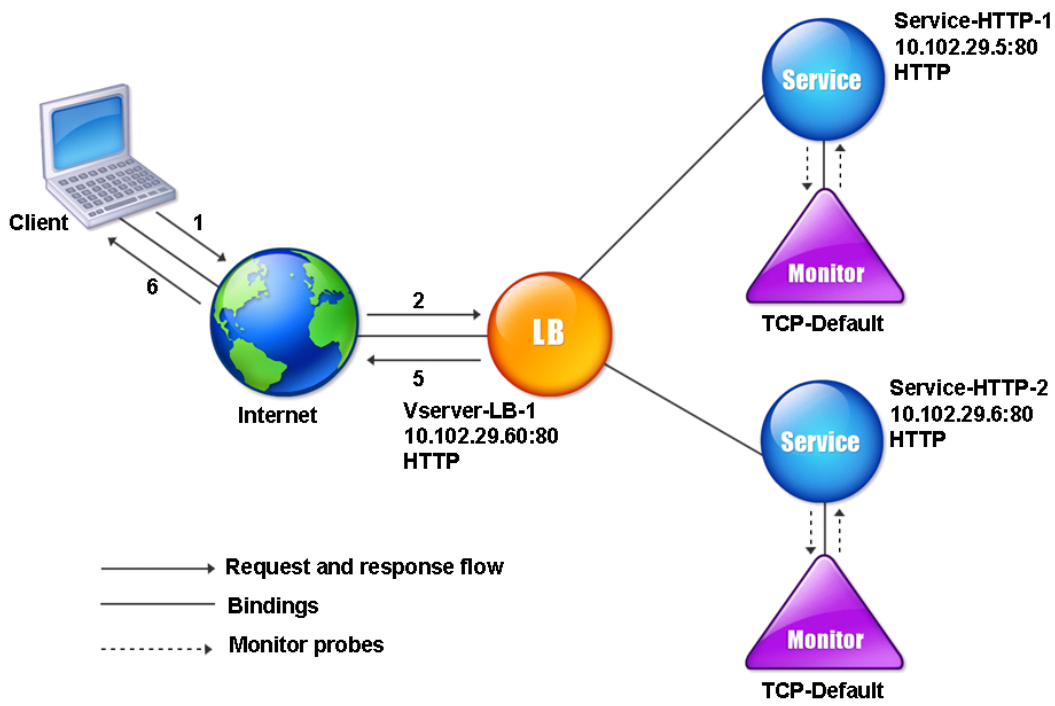
1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Create an HTTP, ICMP, or TCP monitor and select **Reverse**.

Configure monitors in a load balancing setup

September 14, 2021

To configure monitors on a website, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see Custom Monitors. Once you have chosen or created a monitor, you then bind it to the appropriate service. The monitor names can be up to 255 characters in length. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How monitors operate



As shown, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server fails to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

Create monitors

September 14, 2021

The Citrix ADC appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

To create a monitor by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> [<interval>]

add lb mon monitor-HTTP-1 HTTP

add lb mon monitor-HTTP-2 TCP 2
<!--NeedCopy-->
```

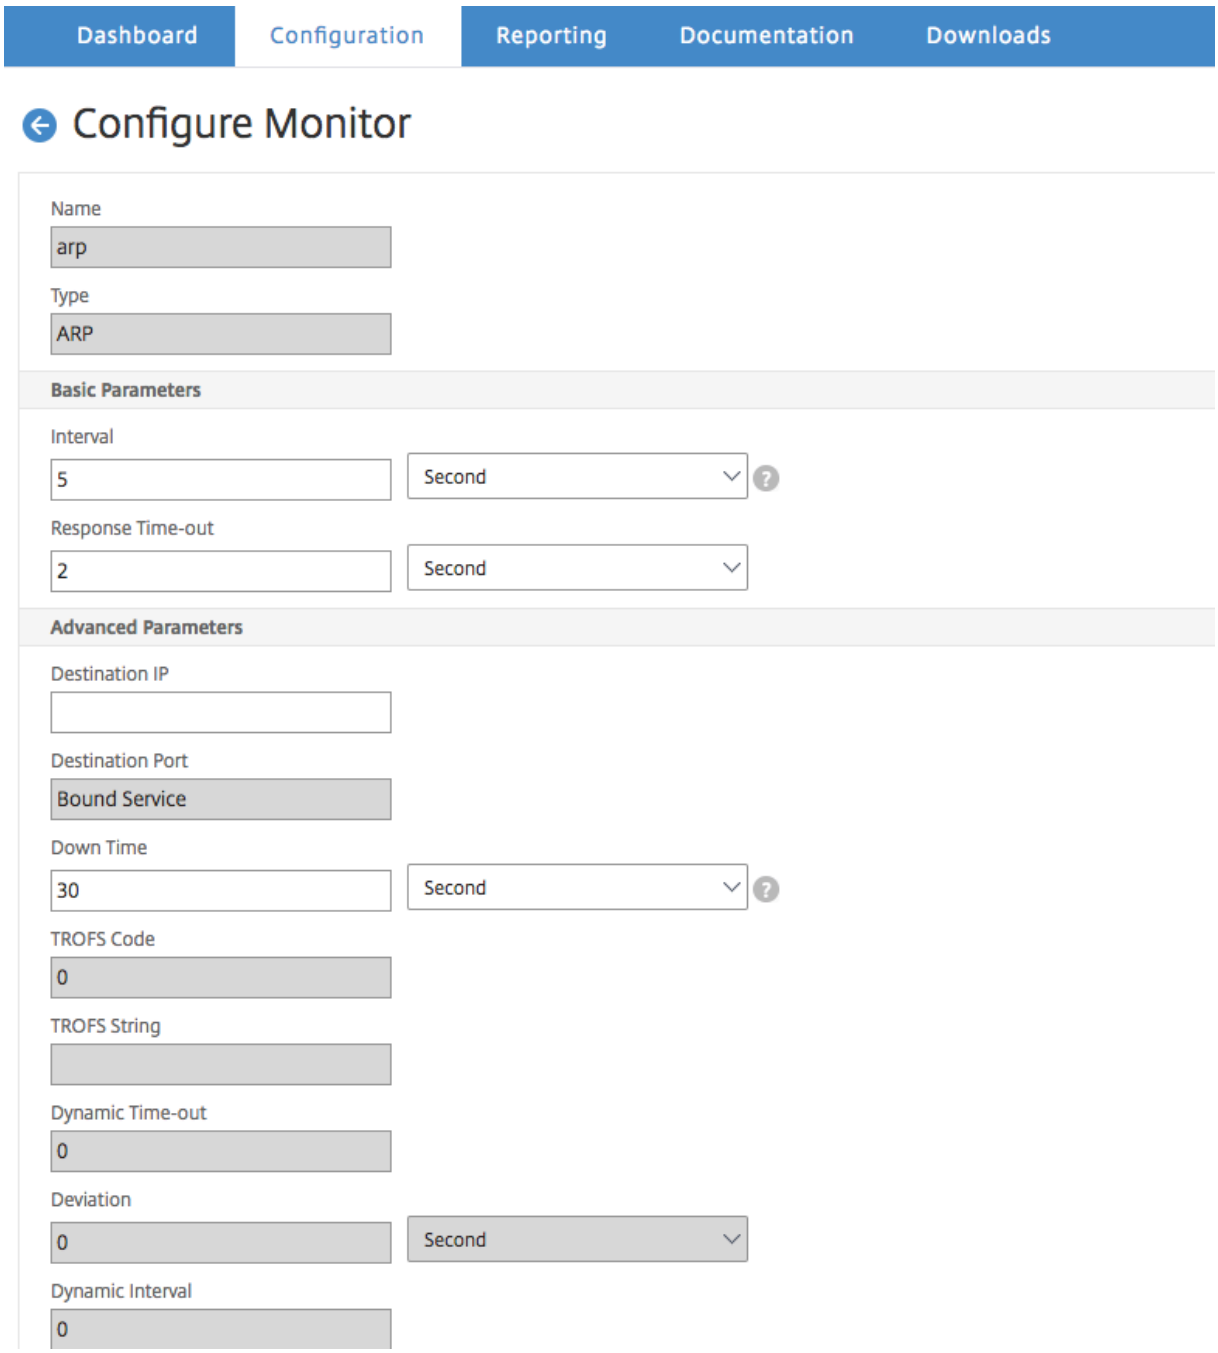
To create a monitor by using the GUI

1. Navigate to **Traffic Management**> **Load Balancing**> **Monitors**.
2. Click **Add** and create a monitor type that meets your requirement.

The Create Monitor screen contains two sections, **Basic Parameters** and **Advanced Parameters**.

Depending on the monitor type, the **Basic Parameters** section contains the parameters that must be set for each monitor. The **Advanced Parameters** section contains the parameters that can be used in advanced use cases.

The following figure is a sample of a Create Monitor page of the ARP monitor type.



Note

Prior to NetScaler release 12.0 build 56.20, Basic Parameters and Advanced Parameters are named Standard Parameters and Special Parameters respectively.

Configure monitor parameters to determine the service health

September 14, 2021

You can configure the following monitoring parameters to mark a service as DOWN based on the monitoring probes.

Retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe fails.

failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the 10 probes sent, at least six probes must fail if the service is to be marked as DOWN.

alertRetries

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

Setting alertRetries to a value higher than the Retries value

The alertRetries parameter, which specifies the maximum number of consecutive monitoring-probe failures after which the Citrix ADC appliance generates an SNMP trap called monProbeFailed, can now be set to a value higher than the Retries value (which specifies the maximum number of probes to send to establish the state of a service for which a monitoring probe failed). If the alertRetries value is higher than the Retries value, the SNMP trap is not sent until after the service is DOWN.

For example, if you set Retries to 3, alertRetries to 12, and the time interval to 5 seconds, the service is marked DOWN after 15 seconds (3*5), but no alert is generated. If the monitor probes are still failing after 60 seconds (12*5), the Citrix ADC appliance generates a monProbeFailed trap. If a probe succeeds at some time between 15 and 60 seconds, the service is marked UP and no alert is generated.

Setting the alertRetries value to a value higher than the Retries value helps in generating only genuine alerts and avoid false positives during scheduled restarts.

To set the alertRetries parameter value to a higher value than the Retries value by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> [-retries <integer>] [-alertRetries <
    integer>]
<!--NeedCopy-->
```

Example:

add lb monitor monitor-HTTP-1 HTTP -retries 3 -alertRetries 12

To set the alertRetries parameter value to a higher value than the Retries value by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Monitors**.
2. Click **Add** to add a new monitor or select an existing monitor and click **Edit**.
3. In the **Retries** box, type the value for the Retries parameter.
4. In the **SNMP Alert Retries** box, type the value for the `alertRetries` parameter.

Bind monitors to services

September 14, 2021

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN.

If you bind multiple monitors to a service, the Citrix ADC appliance checks the state of all the monitors and then decides the state of the service. You can configure different weights to a monitor. The weight of a monitor specifies how much that monitor contributes to designating the service as UP or DOWN. A monitor with a greater weight has a higher preference in marking the service UP or DOWN. Default weight is 1. Therefore, even if one of the monitors fails, the service is marked as DOWN. For more information, see Set a threshold value for the monitors bound to a service.

Note: The destination IP address of a monitor probe can be different than the server IP address and port.

To bind a monitor to a service by using the CLI

At the command prompt, type:

```
bind service <name> (-monitorName <string>)
<!--NeedCopy-->
```

Example:

```
bind service s1 -monitorName tcp
<!--NeedCopy-->
```

To bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service, and add a monitor.

Modify monitors

September 14, 2021

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the CLI

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <interval> -resptimeout <
    resptimeout>
<!--NeedCopy-->
```

Example:

```
set mon monitor-HTTP-1 HTTP -interval 50 milli
-resptimeout 20 milli
<!--NeedCopy-->
```

To modify an existing monitor by using the GUI

Navigate to **Traffic Management > Load Balancing > Monitors**, and open a monitor to modify.

Enable and disable monitors

September 14, 2021

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the CLI

At the command prompt, type:

```
enable lb monitor <monitorName>
<!--NeedCopy-->
```

Example:

```
enable lb mon monitor-HTTP-1
<!--NeedCopy-->
```

To enable a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and from the Action list, select Enable or Disable.

To disable a monitor by using the CLI

At the command prompt, type:

```
disable lb monitor <monitorName>
<!--NeedCopy-->
```

Example:

```
disable lb mon monitor-HTTP-1
<!--NeedCopy-->
```

Unbind monitors

September 14, 2021

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

To unbind a monitor from a service by using the CLI

At the command prompt, type:

```
unbind lb monitor <monitorName>
<!--NeedCopy-->
```

Example:

```
unbind mon monitor-HTTP-1 Service-HTTP-1
<!--NeedCopy-->
```

To unbind a monitor from a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click **Unbind**.

Remove monitors

September 14, 2021

After you unbind a monitor that you created from its service, you can remove that monitor from the Citrix ADC configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

To remove a monitor by using the CLI

At the command prompt, type:

```
rm lb monitor <monitorName> <type>
<!--NeedCopy-->
```

Example:

```
rm lb monitor monitor-HTTP-1 HTTP
<!--NeedCopy-->
```

To remove a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and click **Delete**.

View monitors

September 14, 2021

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your Citrix ADC configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the CLI

At the command prompt, type:

```
show lb monbindings <MonitorName>
<!--NeedCopy-->
```

Example:

```
show lb monbindings monitor-HTTP-1
<!--NeedCopy-->
```

To view monitor bindings by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and in the Action list, click **Show Bindings**.

To view monitors by using the CLI

At the command prompt, type:

```
show lb monitor <monitorName>
<!--NeedCopy-->
```

Example:

```
show lb mon monitor-HTTP-1
<!--NeedCopy-->
```

To view monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**. The details of the available monitors appear in the Monitors pane.

Close monitor connections

September 14, 2021

The Citrix ADC appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the appliance and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and might not be always necessary.

For the TCP type monitor, you can configure the appliance to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

Note: The monitorConnectionClose setting is applicable only for type TCP and TCP-Default monitors.

To configure monitor-connection closure by using the command line interface:

At the command prompt, type:

```
set lb parameter -monitorConnectionClose <monitor_conn_close_option>
<!--NeedCopy-->
```

Example

```
set lb parameter -monitorConnectionClose RESET
<!--NeedCopy-->
```

To configure monitor-connection closure by using the configuration utility:

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**.
2. Select **FIN** or **Reset**.

Closing Monitor Connections at the Service or Service Group Level

You can also configure the appliance to close a monitor-probe connection at the service and service group level by setting the monConnectionClose parameter. If this parameter is not set, the monitor connection is closed by using the value set in the global load balancing parameters. If this parameter is set at the service or service group level, the monitor connection is closed by sending a connection termination message, with the FIN or RESET bit set, to the service or service group.

To configure monitor-connection closure at the service level by using the CLI

At the command prompt, type:

```
set service <service_name> -monConnectionClose ( RESET | FIN )
<!--NeedCopy-->
```

To configure monitor-connection closure at the service group level by using the CLI

At the command prompt, type:

```
 set serviceGroup <service_name> -monConnectionClose ( RESET | FIN )
<!--NeedCopy-->
```

To configure monitor-connection closure at the service level by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Add or edit a service, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

To configure monitor-connection closure at the service group level by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Add or edit a service group, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

> **Note:** For closing a monitor-probe connection using global load balancing parameters, you can configure monitorConnectionClose to FIN or RESET. When you configure the monitorConnectionClose parameter to;
>
> - FIN: The appliance performs a complete TCP handshake.

> - RESET: The appliance closes the connection after receiving the SYN-ACK from the service.
>
> In the lighter version of Citrix ADC CPX, the monitorConnectionClose parameter value is set to RESET by default and cannot be changed to FIN at the global level. However, you can change the monitorConnectionClose parameter to FIN at the service level.

Ignore the upper limit on client connections for monitor probes

September 14, 2021

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the Citrix ADC appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the appliance to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the Citrix ADC appliance.

To set the Skip MaxClients for Monitor Connections option by using the CLI

At the command prompt, type:

```
set lb parameter -monitorSkipMaxClient (ENABLED|DISABLED)
<!--NeedCopy-->
```

Example:

```
set lb parameter -monitorSkipMaxClient enabled
<!--NeedCopy-->
```

To set the Skip MaxClients for Monitor Connections option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**.
2. Select **Skip MaxClients for Monitoring Connections**.

Manage a large scale deployment

September 14, 2021

The Citrix ADC appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure. This significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services. You can then make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

Ranges of virtual servers and services

September 14, 2021

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

  For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers are created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

  Note: The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

For example, if you have three virtual servers named `Vserver-x`, `Vserver-y`, and `Vserver-z`, instead of configuring them separately, you can type `vserver [x-z]` to configure them all.

Creating a range of virtual servers

To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
    port>]

add lb vserver <name>@[<rangeValue>]> <protocol> <IPAddress[<rangeValue
    >]> [<port>]
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
<!--NeedCopy-->
```

OR

```
add lb vserver vserver[P-R] http 10.102.29.[26-28] 80

vserver "vserverP" added

vserver "vserverQ" added

vserver "vserverR" added

Done
<!--NeedCopy-->
```

To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
    port>]

add lb vserver <name>@**[**<rangeValue>**]**> <protocol> <IPAddress[<
    rangeValue>]> [<port>]
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
<!--NeedCopy-->
```

OR

```
add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
vserver "vserverP" added
vserver "vserverQ" added
vserver "vserverR" added
Done
<!--NeedCopy-->
```

To create range of virtual servers by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Add a virtual server, and specify a range.

Creating a range of services

If you specify a range for the service name, specify a range for the IP address too.

To create range of services by using the CLI

At the command prompt, type the command:

```
add service <name>@ <IP>@ <protocol> <port>
<!--NeedCopy-->
```

Example:

```
> add service serv[1-3] 10.102.29.[102-104] http 80
service "serv1" added
service "serv2" added
service "serv3" added
 Done
<!--NeedCopy-->
```

Configure service groups

September 14, 2021

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group are identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the Citrix ADC appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the appliance learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the Citrix ADC appliance. A domain name is resolved into an IP address only if the corresponding address record is present on the appliance or the name server.

Create service groups

You can configure up to 8192 service groups on the Citrix ADC appliance.

To create a service group by using the command line

At the command prompt, type:

```
add servicegroup <ServiceGroupName> <Protocol>
<!--NeedCopy-->
```

Example:

```
add servicegroup Service-Group-1 HTTP
<!--NeedCopy-->
```

To create a service group by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**, and add a service group.

Bind a service group to a virtual server

When you bind a service group to a virtual server, the member services are bound to the virtual server.

To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@ <serviceGroupName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-Group-1
<!--NeedCopy-->
```

To bind a service group to a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Service Groups**.

Bind a member to a service group

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the GUI, if you want to add a domain-name based service group member, select **Server Based**.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
<!--NeedCopy-->
```

Examples:

```
bind servicegroup Service-Group-1 10.102.29.30 80

bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a
    :888b 80
```

```
4
5 bind servicegroup CitrixEdu s1.citrite.net
6 <!--NeedCopy-->
```

To add members to a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups** and open a service group.
2. Click in the Service Group section, and do one of the following:
   - To add an IP based service group member, select IP Based.
   - To add a server-name based service group member, select Server Based.

   If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.
3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box

   Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.
4. Click Create.

Bind a monitor to a service group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

To bind a monitor to a service group by using the command line interface

At the command prompt, type:

```
1 bind serviceGroup <serviceGroupName> -monitorName <string> -monState (
     ENABLED | DISABLED)
2 <!--NeedCopy-->
```

Example:

```
bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
<!--NeedCopy-->
```

To a bind monitor to a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Open a service group and, in Advanced Settings, click **Monitors**.

Retain the original state of a service group member after disabling and enabling a virtual server

From build 64.x, a new global option, –retainDisableServer, enables you to retain a service-group member's state when a server is disabled and reenabled.

Previously, a member's state would change from DISABLED to ENABLED under the following set of conditions:

- Two applications are deployed on the same port on a virtual server.
- Two service groups with a common member are bound to this virtual server, and the common member is enabled in one group and disabled in the other.
- The server is disabled and then reenabled.

Under these conditions, disabling the server disables all the service group members, and reenabling the server enables all the members, by default, regardless of their earlier states. To bring the members back to the original states, you must manually disable those members in the service group. This is a cumbersome task and prone to errors.

Manage service groups

September 14, 2021

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group. For more information about service groups, see Configure service groups.

Modify a service group

You can modify the attributes of service group members. You can set several attributes of the service group, such as maximum client, Sure Connect, and compression. The attributes are set on the indi-

vidual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

```
set servicegroup <serviceGroupName> [-type <type>] [-maxClient <
    maxClient>] [-maxReq <maxReq>] [-cacheable (YES|NO)] [-cip (ENABLED|
    DISABLED)] [-cipHeader <cipHeader>] [-usip (YES|NO)] [-sc (ON|OFF)]
    [-sp (ON|OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>]
     [-cka (YES|NO)] [-TCPB (YES|NO)] [-CMP (**YES**|**NO**)] [-
    maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state
    (ENABLED|DISABLED)] [-downStateFlush (ENABLED|DISABLED)
<!--NeedCopy-->
```

Example:

```
set servicegroup Service-Group-1 -type TRANSPARENT

set servicegroup Service-Group-1 -maxClient 4096

set servicegroup Service-Group-1 -maxReq 16384

set servicegroup Service-Group-1 -cacheable YES
<!--NeedCopy-->
```

To modify a service group by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**, and open the service group to modify.

Remove a service group

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the Citrix ADC appliance.

To remove a service group by using the command line interface

At the command prompt, type:

```
rm servicegroup <ServiceGroupName>
<!--NeedCopy-->
```

Example:

```
rm servicegroup Service-Group-1
<!--NeedCopy-->
```

To remove a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and click **Delete**.

Unbind a member from a service group

When you unbind a member from the service group, the attributes set on the service group no longer apply to the member that you unbound. The member services retain its individual settings, however, and continue to exist on the Citrix ADC appliance.

To unbind members from a service group by using the command line interface

At the command prompt, type:

```
unbind servicegroup <serviceGroupName> <IP>@ [<port>]
<!--NeedCopy-->
```

Example:

```
unbind servicegroup Service-Group-1 10.102.29.30 80
<!--NeedCopy-->
```

To unbind members from a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click **Unbind**.

Unbind a service group from a virtual server

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the Citrix ADC appliance.

To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

```
unbind lb vserver <name>@ <ServiceGroupName>
<!--NeedCopy-->
```

Example:

```
unbind lb vserver Vserver-LB-1 Service-Group-1
<!--NeedCopy-->
```

To unbind a service group from a virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click **Unbind**.

Unbind monitors from service groups

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

To unbind a monitor from a service group using the command line interface

At the command prompt, type:

```
unbind serviceGroup <serviceGroupName> -monitorName <string>
<!--NeedCopy-->
```

Example:

```
unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
<!--NeedCopy-->
```

To unbind a monitor from a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click **Unbind**.

Enable or Disable a service group

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

To disable a service group by using the command line interface

At the command prompt, type:

```
disable servicegroup <ServiceGroupName>
<!--NeedCopy-->
```

Example:

```
disable servicegroup Service-Group-1
<!--NeedCopy-->
```

To disable a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and in the Action list, click **Disable**.

To enable a service group by using the command line interface

At the command prompt, type:

```
enable servicegroup <ServiceGroupName>
<!--NeedCopy-->
```

Example:

```
enable servicegroup Service-Group-1
<!--NeedCopy-->
```

To enable a service group by using the configuration utility

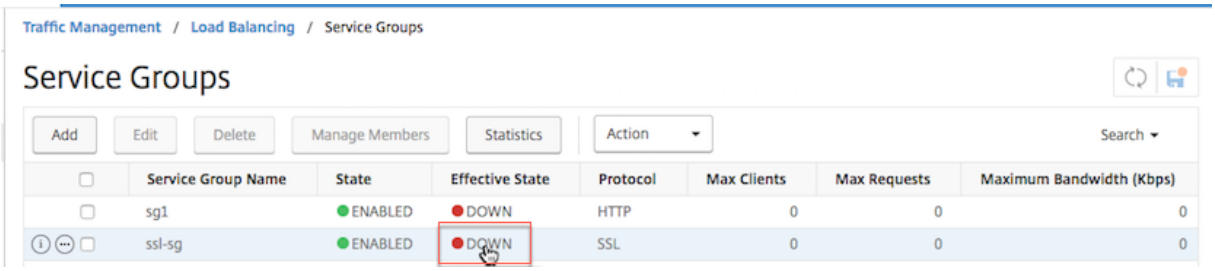
1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and in the Action list, click **Enable**.

View the status of service groups members

Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.

In the Service Groups page, the **Effective State** column displays the status of the service groups. Status UP/DOWN in the **Effective State** column is clickable. You can click the status and get the list of members along with their status in the same view. Select a member and click the **Monitor Details** button to view the reason for the status being DOWN.

Note: Before NetScaler release 12.0 build 56.20, the status in the **Effective State** column was not clickable.



Viewing the properties of a service group

You can view the following settings of the configured service groups:

- Name
- IP address
- State
- Protocol
- Maximum client connections
- Maximum requests per connection
- Maximum bandwidth
- Monitor threshold

Viewing the details of the configuration can be helpful for troubleshooting your configuration.

To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

```
show servicegroup <ServiceGroupName>

show servicegroup <ServiceGroupName> -includemembers
<!--NeedCopy-->
```

Example:

```
show servicegroup Service-Group-1
<!--NeedCopy-->
```

To view the properties of a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Click the arrow next to the service group.

Viewing service group statistics

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The Citrix ADC appliance uses the statistics of a service group to balance the load on the services.

To view the statistics of a service group by using the command line interface

At the command prompt, type:

```
stat servicegroup <ServiceGroupName>
<!--NeedCopy-->
```

Example:

```
stat servicegroup Service-Group-1
<!--NeedCopy-->
```

To view the statistics of a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and click **Statistics**.

Load balancing virtual servers bound to a service group

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State

- IP address
- Port

To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
show servicegroupbindings <serviceGroupName>
<!--NeedCopy-->
```

Example:

```
> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State :ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
2) BRVSERV (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
>
<!--NeedCopy-->
```

To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and in the Action list, click **Show Bindings**.

Configure a desired set of service group members for a service group in one NITRO API call

September 14, 2021

Support is added to configure a desired set of service group members for a service group in one NITRO API call. A new API, Desired State API, is added to support this configuration. Using Desired State API, you can:

- Provide a list of service group members in a single PUT request on “servicegroup_servicegroupmemberlist_b resource.
- Provide their weight and state (optional) in that PUT request.

- Effectively synchronize the appliance configuration with deployment changes around application servers.

The Citrix ADC appliance compares the requested desired member set with the configured member set. Then, it automatically binds the new members and unbinds the members that are not present in the request.

Note:

- This feature is supported only for service groups of type `API`.
- You can only bind IP address based services using Desired State API, domain name based services are not allowed.
- Previously, only one service group member can be bound in a NITRO call.

> **Important**
>
> Desired State API for ServiceGroup membership is supported in Citrix ADC cluster deployment.

Use case: Synchronize deployment changes to Citrix ADC appliance in large scale deployments, such as Kubernetes

In large scale and highly dynamic deployments (for example Kubernetes), the challenge is to keep the appliance configuration up-to-date with the rate of change of deployments to accurately serve the application traffic. In such deployments, controllers (Ingress or E-W Controller) are responsible for updating ADC configuration. Whenever there are changes to deployment, `kube-api server` sends the effective set of endpoints through 'Endpoints event' to the controller. The controller uses the Read-Delta-Modify approach where it performs the following:

- Fetches the currently configured endpoint set (service group member set of a service group) for the service from ADC appliance.
- Compares the configured endpoint set with the set in the received event.
- Binds the new endpoints (service group members) or unbinds the deleted endpoints.

Because the rate of change and the size of services is high in this environment, this configuration method is not efficient and might delay configuration updates.

Desired State API solves the problem by accepting the intended member set for a service group in a single API, and effectively updates the configuration.

Create a service group of type API by using the CLI

At the command prompt, type;

```
add serviceGroup <serviceGroupName>@ <serviceType> [-autoScale <
    autoScale>]
```

Example:

```
add serviceGroup svg1 HTTP -autoScale API
```

You can configure the autoDisablegraceful and autoDisabledelay and autoScale parameters by using add serviceGroup or set serviceGroup command.

```
add serviceGroup <serviceGroupName>@ <serviceType> [-autoScale <
    autoScale>] [-autoDisablegraceful ( YES | NO)] [-autoDisabledelay <
    secs>]

add serviceGroup <serviceGroupName>@ <serviceType> [-autoScale (API |
    CLOUD | DISABLED| DNS |POLICY)]

set serviceGroup <serviceGroupName [-autoDisablegraceful ( YES | NO)]
    [-autoDisabledelay <secs>]

set serviceGroup <serviceGroupName [-autoScale (API |CLOUD | DISABLED|
    DNS |POLICY)]
```

Example:

```
add serviceGroup svg1 HTTP autoDisablegraceful YES -autoDisabledelay
    100

add serviceGroup svg1 HTTP -autoScale API

set serviceGroup svg1 -autoDisablegraceful  YES -autoDisabledelay 100

set serviceGroup svg1 -autoScale API
```

Arguments

autoDisablegraceful

Indicates graceful shutdown of the service. If this option is enabled, the appliance waits for all outstanding connections to this service to be closed before deleting the service. For clients that already have a persistent session on the system, new connections or requests continue to be sent to this service. The service member is deleted only if there are no outstanding connections. Default value: NO

autoDisabledelay

Indicates the time allowed (in seconds) for a graceful shutdown. During this period new connections or requests continue to be sent to this service for clients that already have a persistent session on

the system. Connections or requests from new clients that do not have persistence sessions on the system are not sent to the service. Instead, they are load balanced among other available services. After the delay time expires, the service member is deleted.

Autoscale API

Enables using Desired State API for binding the member set to an intended service group. You can set the service group from non-autoscale to Autoscale type of Desired State API, if all provided conditions match.

The set serviceGroup Autoscale command might fail if the existing member bindings meet any of these conditions:

- If the server bound to the service group is either a name server or a domain-based server.
- If the name of the server bound to the service group is an IP address, then it must match the actual server IP address. In the following example, the server name and server IP address do not match.
  - **CLI:** add server *IP address server name*
  - **Example:** add server 1.2.3.4 4.3.2.1
- If the loopback server name is anything other than 127.0.0.1 or 0000:0000:0000:0000:0000:0000:0000:0001.
- If you choose different types of Autoscale (Cloud, API, DNS, and Policy) in a set serviceGroup command and add serviceGroup command.

Important:

- The autoDisablegraceful and autoDisabledelay parameters are applicable only for the service groups of Autoscale type “API” and “CLOUD.”
- If the autoDisablegraceful or the autoDisabledelay parameters are not configured, then service members are deleted immediately.

Unbind a service group member gracefully

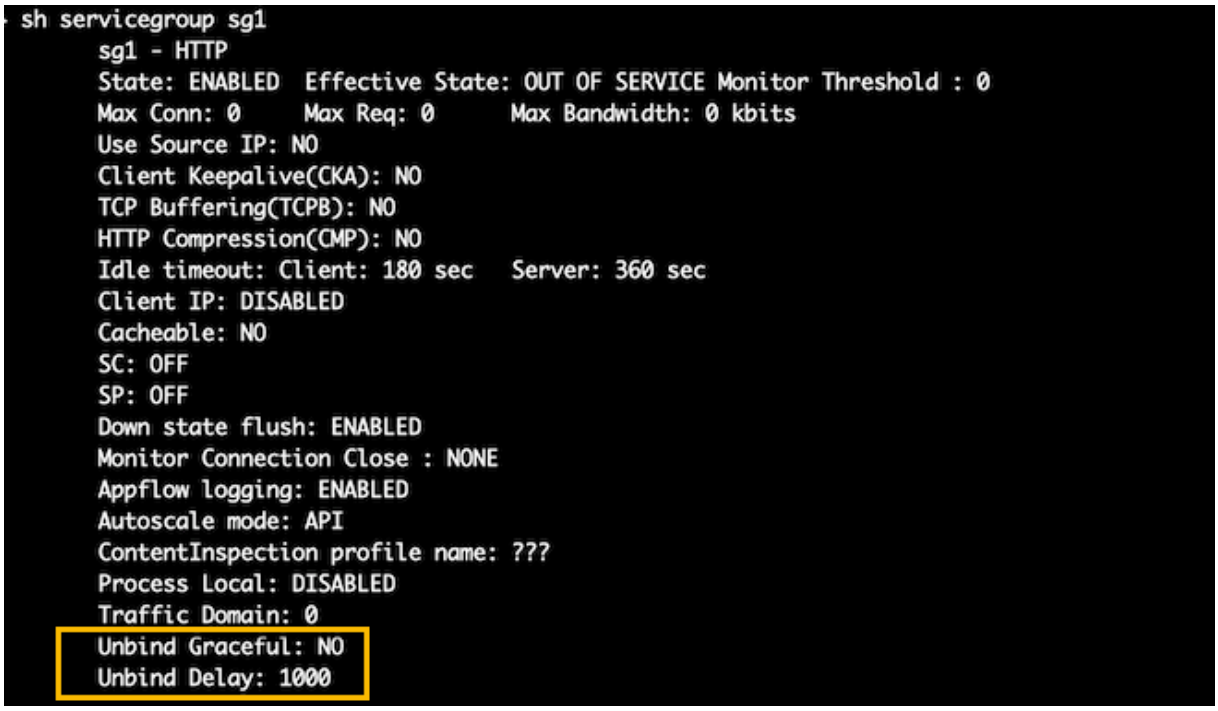
If any of the service group members is not in the desired state list, those members are gracefully unbound based on the `autoDisablegraceful` or `autoDisabledelay` parameter configuration.

- If one of these parameters is set, then the service group member is unbound gracefully.
- If none of these parameters are set, then the service group member is unbound immediately.

Note:

- Service group members identified for graceful unbind are displayed only when the show service group command is run.
- You cannot perform any operation (such as set, unset) on the service group member identified for graceful unbind.

The following figure displays a sample show service group command.

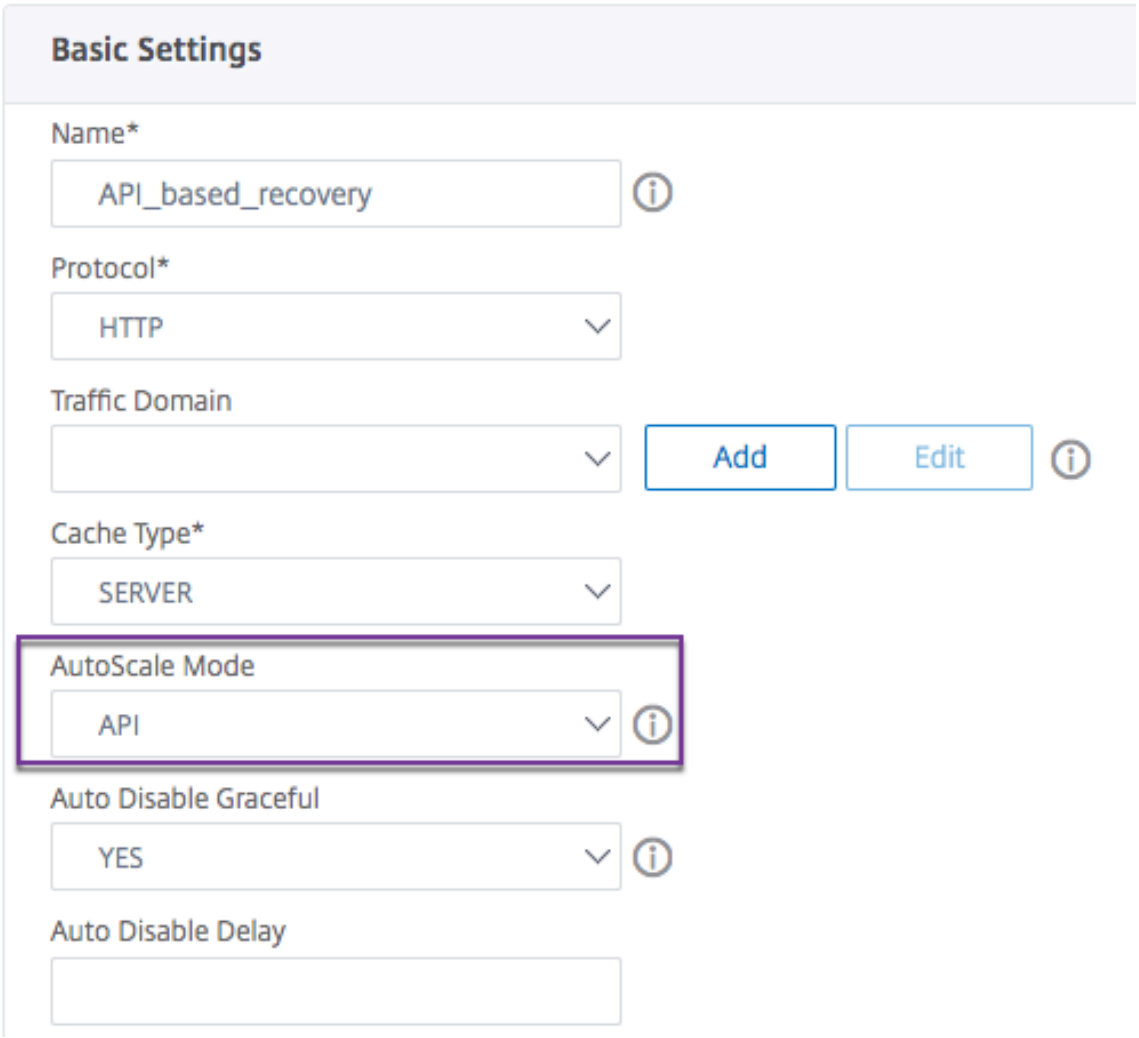


Create a service group of type API by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and click **Add**.
2. In **AutoScale Mode**, select **API**.

Configure graceful shutdown or a time delay for an API type service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.



2. In **AutoScale Mode**, select **API**.
3. In **Auto Disable Graceful**, select **YES**.
4. In **Auto Disable Delay**, enter the wait time for a graceful shutdown.

Note: The **Auto Disable Graceful** or **Auto Display Delay** fields are enabled only if you select **API** or **CLOUD** in **AutoScale Mode**.

Configure automatic domain based service group scaling

September 14, 2021

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a

name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind other domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically based on the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see Adding a Name Server.
- Add a domain-based server. For information about adding a domain-based server, see Configuring a server object.
- Add a service group and associate the domain based server to the service group, with the Autoscale option set to DNS. For information about adding a service group, see Configuring Service Groups.

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

> **Important**
>
> - DNS Autoscale is supported in a cluster deployment.
> - Path monitoring for Autoscale service groups is not supported in cluster deployment.

To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

```
add serviceGroup <serviceGroupName> -autoScale (YES | NO)

show serviceGroup <serviceGroupName>
<!--NeedCopy-->
```

Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
> add serviceGroup servGroup server1 80 -autoScale YES
 Done
> sh servicegroup servGroup
       servGroup - HTTP
        State: ENABLED  Monitor Threshold : 0
              . . .
              . . .
        1)   192.0.2.31:80   State: UP       Server Name: server1 (Auto
             scale)    Server ID: None Weight: 1

               Monitor Name: tcp-default       State: UP
               Probes: 2       Failed [Total: 0 Current: 0]
               Last response: Success - TCP syn+ack received.

        2)   192.0.2.32:80   State: UP       Server Name: server1 (Auto

```

To configure a service group to scale automatically by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Create a service group, and set the Autoscale mode to DNS.

Overwriting TTL values

> **Note**: This option is supported from Citrix ADC 12.1 build 51.xx and later.

Citrix ADC appliance is configured to periodically query the DNS server for any update in the SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL

parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding the service group member and also globally, then the TTL value specified while binding the service group member takes precedence.
If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs
   >])
<!--NeedCopy-->
```

Example:

```
bind servicegroup svc_grp_1 web_serv -dbsTTL 10
<!--NeedCopy-->
```

- To overwrite the TTL value globally, at the command prompt, type:

```
set lb parameter [-dbsTTL <secs>]
<!--NeedCopy-->
```

Example:

```
set lb parameter -dbsTTL 15
<!--NeedCopy-->
```

Overwriting the TTL values using the GUI

To overwrite the TTL value while binding:

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.

5. In **Domain Based Service TTL**, enter the TTL value.

To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management** > **Load Balancing** > **Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

> **Note:** If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

Specifying different name servers for service group and domain name bindings

> **Note:** This option is supported from Citrix ADC 12.1 build 51.xx and later.

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a nameserver is not specified while binding a member to the service group, the globally configured nameserver is considered.

Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
   ip_addr>] [-dbsTTL <secs>])
<!--NeedCopy-->
```

Example:

```
bind servicegroup svc_grp_1 web_serv  -ns.nameserver.com 10.102.27.155
   -dbsTTL 10
<!--NeedCopy-->
```

Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for the bound domain must be sent.

Service discovery using DNS SRV records

September 14, 2021

An SRV record (service record) is a specification of data in the Domain Name System that defines the location, that is the host name and the port number of servers for specified services. The record also defines the weight and priority of each server.

Example of an SRV record:

_http._tcp.example.com. 100 IN SRV 10 60 5060 a.example.com.

The following table describes each item in an SRV record:

Service	Protocol	Name	TTL	Class	SRV	Priority	Weight	Port	Target
HTTP	TCP	example.com	100	IN	SRV	10	60	5060	a.example.com

You can use the DNS SRV records to discover the service endpoints. Citrix ADC appliance is configured to periodically query the DNS servers with the SRV record associated with a service. On receiving the SRV record, each of the target host published in the SRV record is bound to a service group associated with the service. Each of the bindings inherits the port, priority, and weight from the SRV record. For each service deployment the user has to configure the Citrix ADC appliance once while bringing it up, thus making it a single touch deployment for applications.

Important: The weight of dynamically learned service group members cannot be modified using the CLI or the GUI.

Use case: Load balancing microservices

Applications are moving toward microservice architecture from monolithic architectures. Movement to microservice architecture along with back-end server autoscale solution, is making application deployment more dynamic. To support such a dynamic deployment, the proxies or ADC must be able to dynamically detect the back-end application or service instances and absorb them into the proxy configuration.
The service discovery using DNS SRV records feature aids configuration of the Citrix ADC appliance in such a dynamic deployment scenario. Application developers can use some of the orchestration platforms to deploy the application. Orchestration platforms while instantiating containers during application deployment, might not assign the protocol specific standard port for each of these containers. In such scenarios, discovering the port information becomes the key to configuring the Citrix ADC appliance. SRV records are helpful in such a scenario. SRV record parameters such as the priority and weight can be used for better load balancing of applications.

- Priority parameter can be used to dictate the priority of the server pool.

- Weight parameter can be used to dictate the capacity of the back-end service instances and hence can be used for weighted load balancing.
- Whenever there is a change in the back-end server pool, for example a back-end instance is removed from the pool, the instance is removed graciously only after all the existing client connections are honored.

> **Note:**
>
> - An A/AAAA records based service discovery, all resolved IP addresses have the same weight because you assign the weight to the domain being resolved.
> - If the weight in SRV response is greater than 100, then services are not created.

Priority based load balancing using SRV records

You can use SRV records to perform priority-based load balancing. The priority based server pool can be an alternative for the backup virtual servers. The ns.conf file requires minimal configuration compared to the backup virtual servers.

In priority based load balancing using SRV records, a priority number is assigned to each of the server pool. The least number has the highest priority. One of the servers in the highest priority pool is selected for load balancing based on the server's health and availability. If all the servers in the highest priority server pool are down, then the servers that have the next highest priority are selected for load balancing. However, if the servers in the highest priority server pool are up again, then the servers are selected from the highest priority pool again.

Switching from one priority server pool to another server pool occurs graciously by bleeding the existing client transactions. Therefore, the current clients do not see any break in the application access.

To enable querying for SRV records using the CLI

Perform the following tasks to enable querying for SRV records:

1. Create a server by specifying the query type parameter as SRV.

   At the command prompt, type:

   ```
   add server <name> <domain> [-queryType <queryType>])
   <!--NeedCopy-->
   ```

   Example:

   ```
   add server web_serv example.com -queryType SRV
   <!--NeedCopy-->
   ```

   Note:

- By default, IPv4 queries are sent. To send IPv6 queries, you must enable the IPv6 domain.
- The SRV target domain name must not exceed 127 characters.

2. Create a service group with the autoscale mode as DNS.

   At the command prompt, type:

```
add serviceGroup <serviceGroupName> <serviceType> [-autoScale <
   autoScale>]
<!--NeedCopy-->
```

   Example:

```
add servicegroup svc_grp_1 http -autoscale dns
<!--NeedCopy-->
```

3. Bind the server created in step 1 to the service group as a member.

   At the command prompt, type:

```
bind serviceGroup <serviceGroupName> <serverName>
<!--NeedCopy-->
```

   Example:

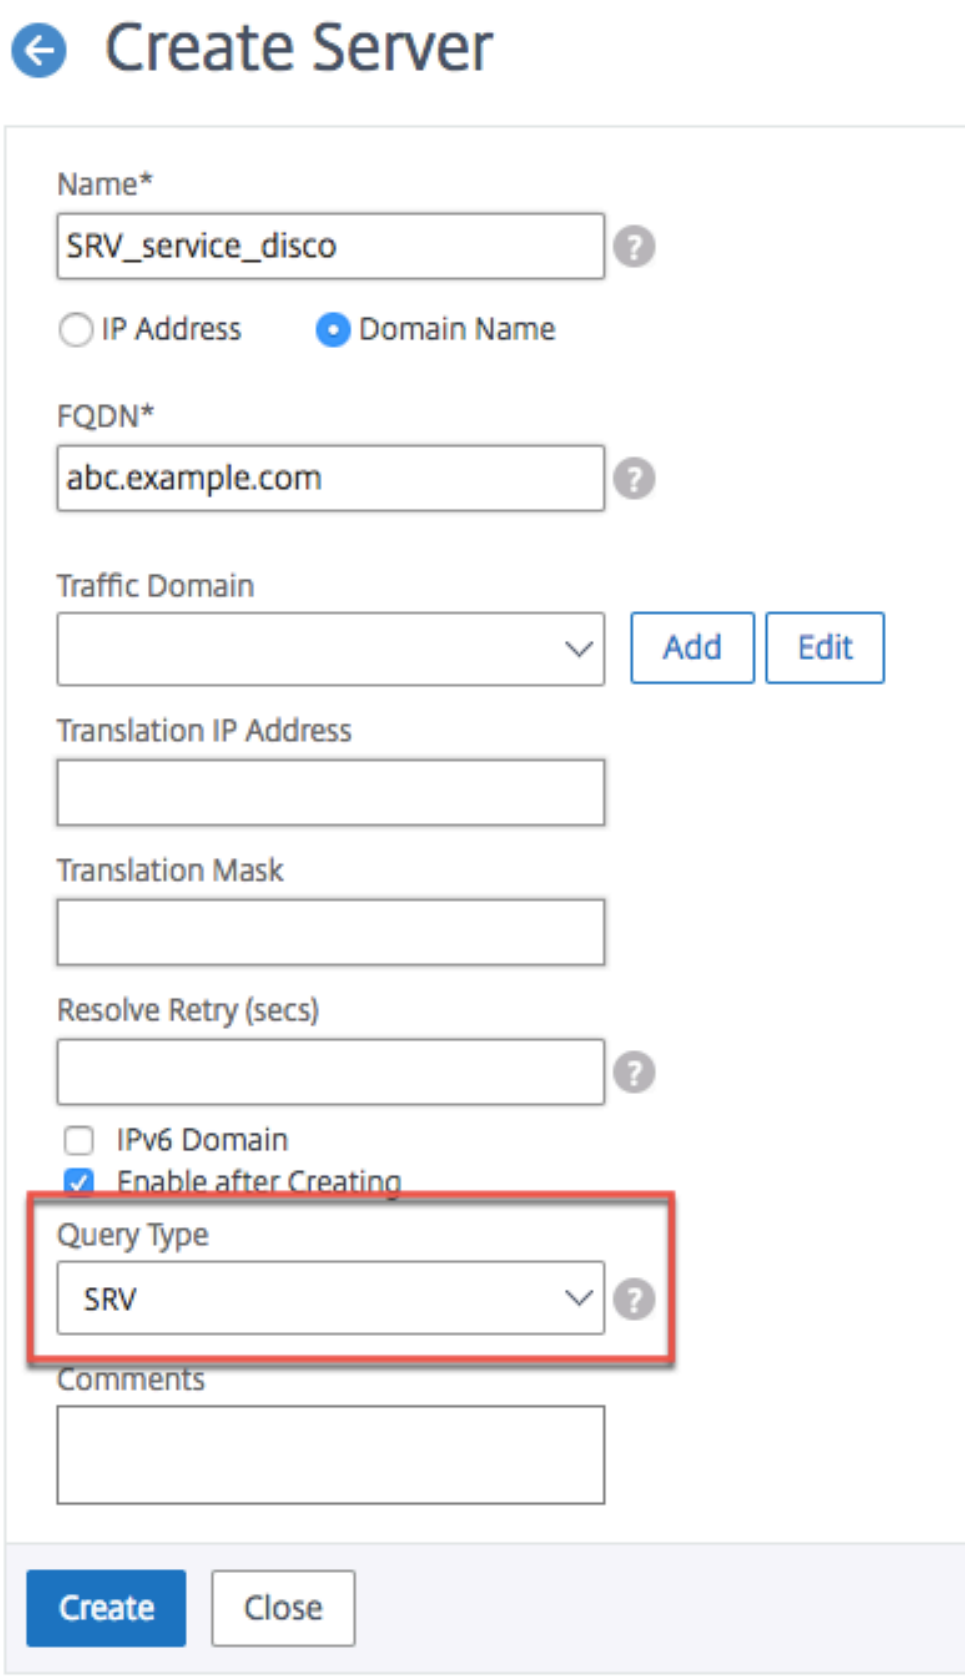
```
bind servicegroup svc_grp_1 web_serv
<!--NeedCopy-->
```

> **Note:**
>
> - When binding servers to service group members, you do not have to enter the port number for SRV server types. In case you specify a port number for SRV server type, an error message appears.
> - You can optionally specify a name server and a TTL value while binding a server to the service group.

To enable querying for SRV records using the GUI

Create a server

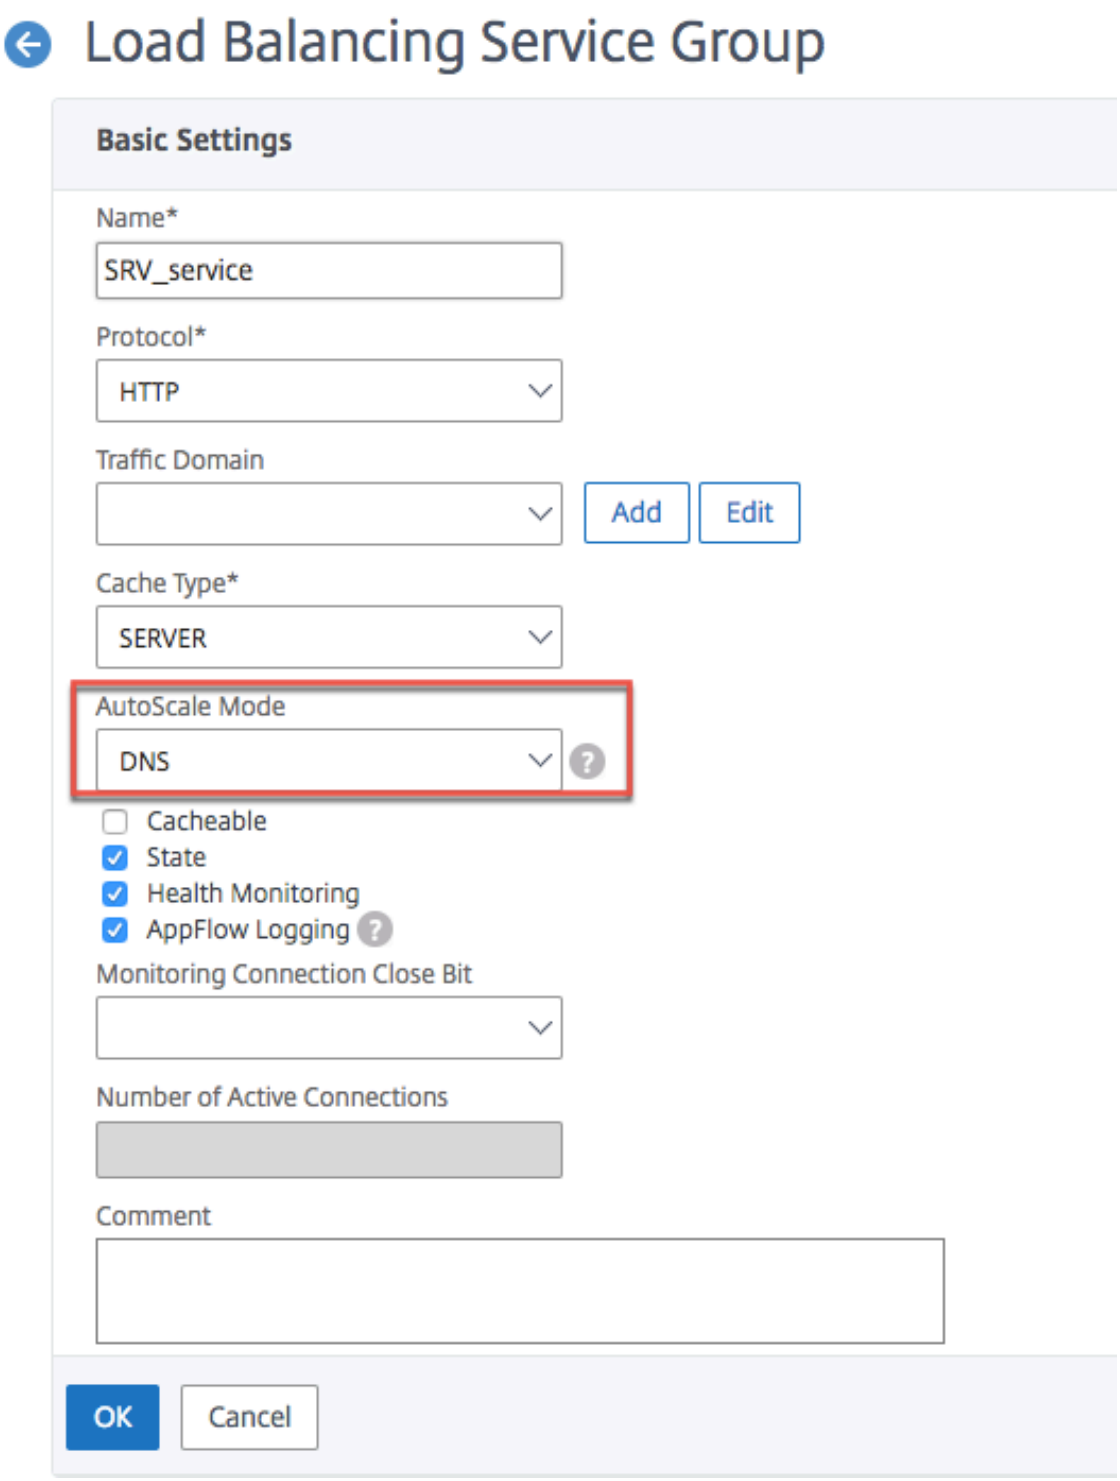
1. Navigate to **Traffic Management** > **Load Balancing** > **Servers** and click **Add**.



2. In **Create Server** page, select domain name.
3. Enter the details of all the required parameters.
4. In **Query Type**, select **SRV**.
5. Click **Create**.

Create a service group with autoscale mode as DNS

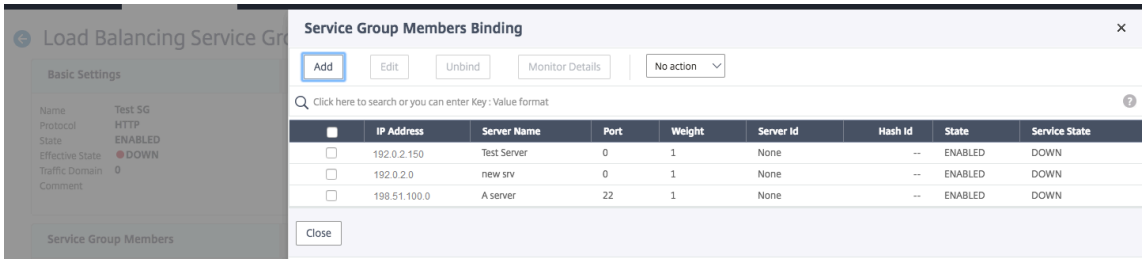
1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Load Balancing Service Group** page, enter details of all the required parameters.
3. In **AutoScale Mode**, select **DNS**.



4. Click **OK**.

Bind server to the service group member

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Close**.



Note:

- While binding, you do not have to enter the port number for SRV server types. In case you enter a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

Overwriting TTL values

Citrix ADC appliance is configured to periodically query the DNS server for any update in the SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding the service group member and also globally, then the TTL value specified while binding the service group member takes precedence.
If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs
    >])
<!--NeedCopy-->
```

Example:

```
bind servicegroup svc_grp_1 web_serv -dbsTTL 10
<!--NeedCopy-->
```

- To overwrite the TTL value globally, at the command prompt, type:

```
set lb parameter [-dbsTTL <secs>]
<!--NeedCopy-->
```

Example:

```
set lb parameter -dbsTTL 15
<!--NeedCopy-->
```

Overwriting the TTL values using the GUI

To overwrite the TTL value while binding:

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management** > **Load Balancing** > **Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

> **Note**: If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

Specifying different name servers for service group and domain name bindings

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-

server is not specified while binding a member to the service group, the globally configured name-server is considered.

Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
    ip_addr>] [-dbsTTL <secs>])
<!--NeedCopy-->
```

Example:

```
bind servicegroup svc_grp_1 web_serv  -ns.nameserver.com 10.102.27.155
    -dbsTTL 10
<!--NeedCopy-->
```

Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for the bound domain must be sent.

Translate the IP address of a domain-based server

September 14, 2021

To simplify maintenance on the Citrix ADC appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address when you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

```
1 add server <name>@ <serverDomainName> -translationIp <
     translationIPAddress> -translationMask <netMask> -state <ENABLED|
     DISABLED>
2 <!--NeedCopy-->
```

Example:

```
1 add server myMaskedServer www.example.com -translationIp 10.10.10.10 -
     translationMask
2 255.255.0.0 -state ENABLED
3 <!--NeedCopy-->
```

To configure a translation IP address for a server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Servers**, create a domain-based server, and specify a translation IP address.

Mask a virtual server IP address

September 17, 2021

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works differently from the IP pattern definition for a server described in Translating the IP Address of a Domain-Based Server. For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Also, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The Citrix ADC appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers.

When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it is sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

```
add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <
   ipMask> <listenPort>
<!--NeedCopy-->
```

Example:

Pattern matching based on prefix octets:

```
add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask
   255.255.0.0 80
<!--NeedCopy-->
```

Pattern matching based on trailing octets:

```
add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask
   0.0.255.255 80
<!--NeedCopy-->
```

Modify a pattern-based virtual server:

```
set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
<!--NeedCopy-->
```

If you configure the Virtual Server 1 as follows:

```
add lb vserver vs1 HTTP -ippattern 100.1.1.0 -ipmask 255.255.255.0 80
<!--NeedCopy-->
```

The Citrix ADC appliance will not respond to an ARP request on all the IP addresses. However, it responds to the virtual server traffic routed to all the IP addresses in that pattern.

To configure a virtual server IP address mask by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

Configure load balancing for commonly used protocols

September 14, 2021

In addition to websites and web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your Citrix ADC appliance to use domain names for your servers rather than IPs, you might also need to set up IP translation and masking for those servers.

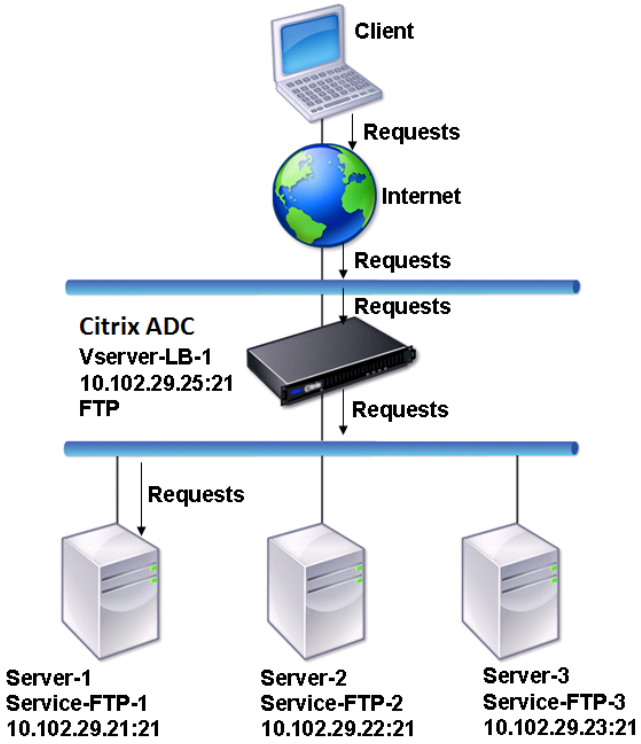
Load balance a group of FTP servers

September 14, 2021

The Citrix ADC appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers



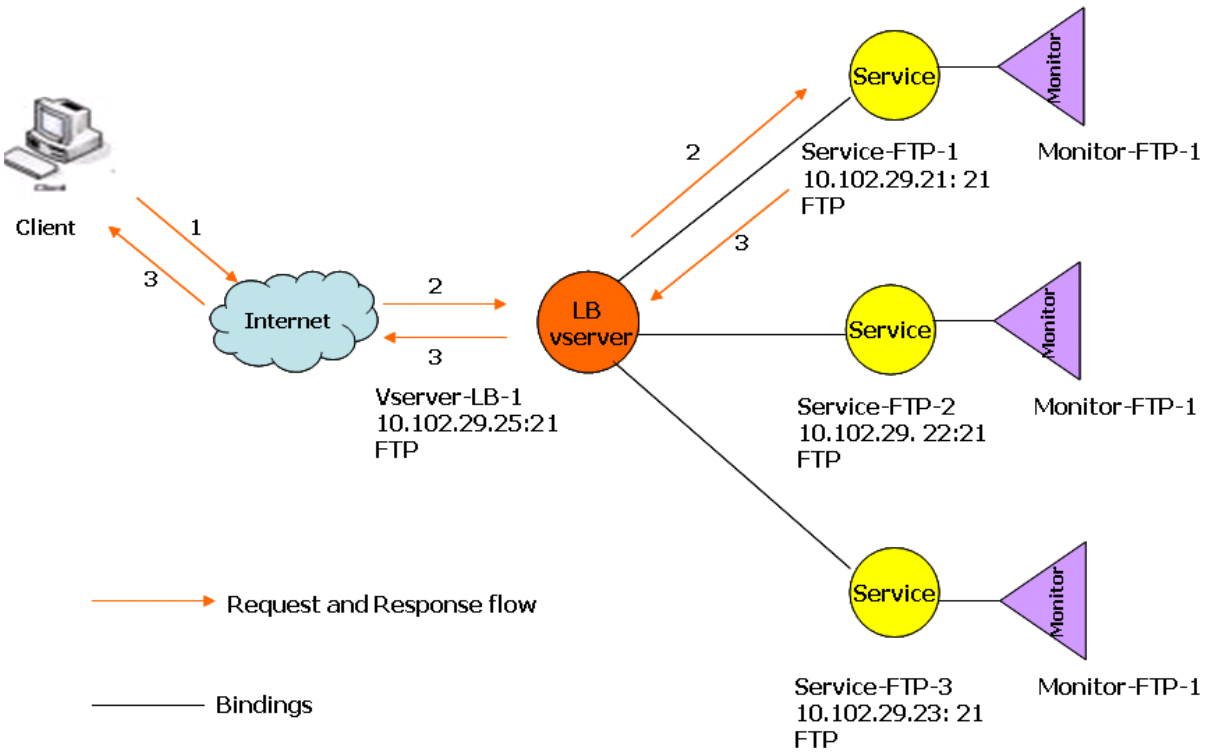
In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client's connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Vserver	Vserver-LB-1	10.102.29.25	21	FTP
Services	Service-FTP-1	10.102.29.21	21	FTP
	Service-FTP-2	10.102.29.22	21	FTP
	Service-FTP-3	10.102.29.23	21	FTP
Monitors	FTP	None	None	None

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model



The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see Setting Up Basic Load Balancing. Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section Binding Monitors to Services.

To create FTP monitors by using the CLI

At the command prompt, type:

```
add lb monitor <MonitorName> FTP -interval <Interval> -userName <
    UserName> -password <Password>
<!--NeedCopy-->
```

Example:

```
add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password
    User
<!--NeedCopy-->
```

To create FTP monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.

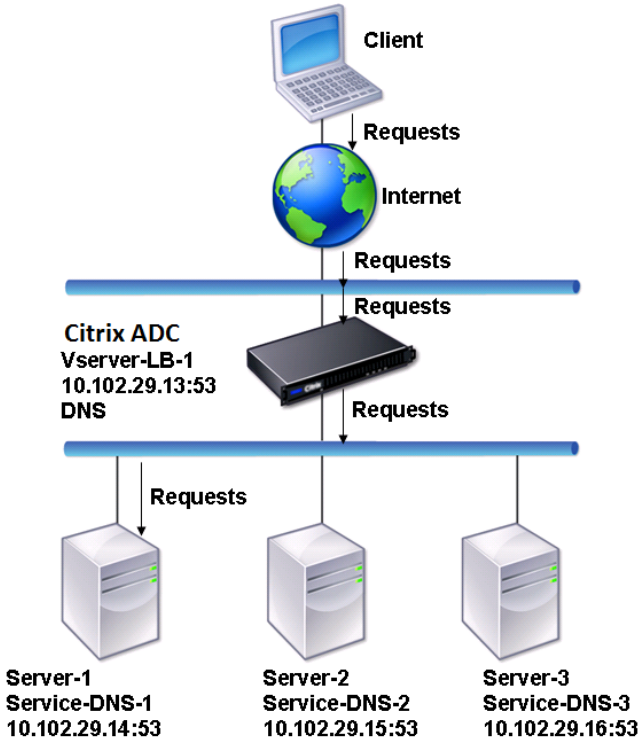
Load balance DNS servers

September 14, 2021

When you request DNS resolution of a domain name, the Citrix ADC appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improve DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

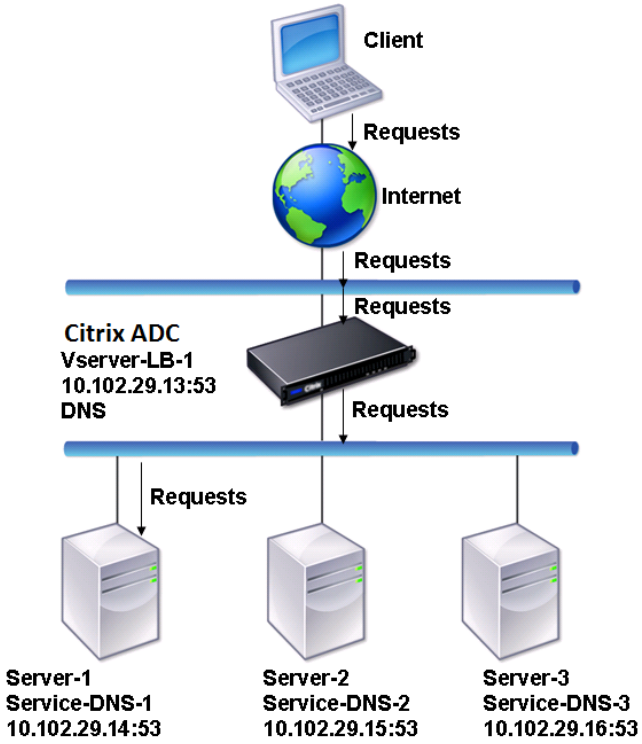


In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.13	53	DNS
Services	Service-DNS-1	10.102.29.14	53	DNS
	Service-DNS-2	10.102.29.15	53	DNS
	Service-DNS-3	10.102.29.16	53	DNS
Monitors	monitor-DNS-1	None	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model



To configure a basic DNS load balancing setup, see Setting Up Basic Load Balancing. Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see Binding Monitors to Services.

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

To configure DNS monitors by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> DNS -query <domainName> -queryType <
    Address|ZONE> -IPAddress <ipAddress>
<!--NeedCopy-->
```

Example:

```
add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType
    Address -IPAddress 10.102.29.66
```

```
2
3 add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType
     Address -IPAddress
4 1000:0000:0000:0000:0005:0600:700a::888b-888d
5 <!--NeedCopy-->
```

To configure DNS monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

Load balance domain-name based services

September 14, 2021

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the Citrix ADC configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor can be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

Note: When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

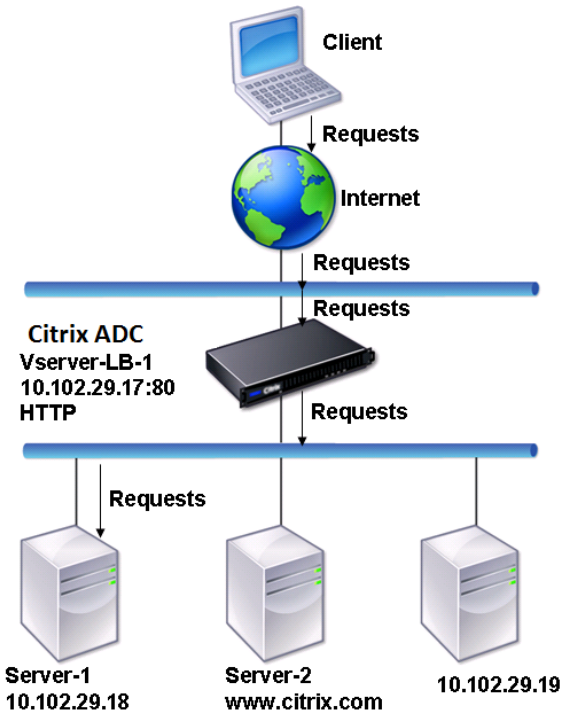
Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.

- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error” (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances the load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers



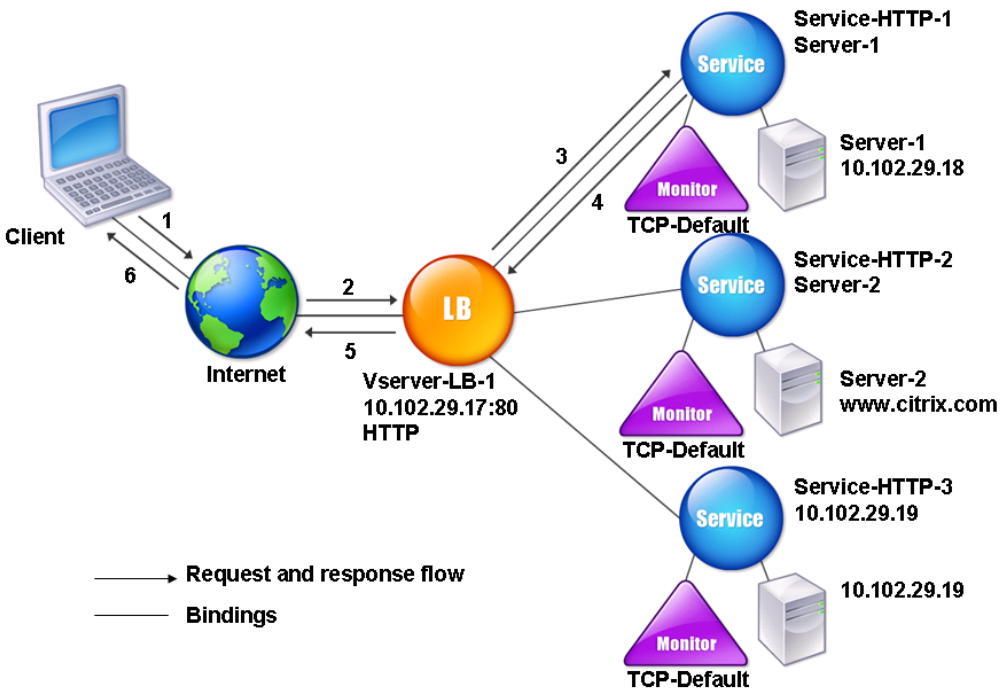
The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.17	80	HTTP
	Vserver-LB-2	10.102.29.20	53	DNS
Servers	server-1	10.102.29.18	80	HTTP
	server-2	www.citrix.com	80	HTTP
Services	Service-HTTP-1	server-1	80	HTTP
	Service-HTTP-2	server-2	80	HTTP
	Service-HTTP-2	10.102.29.19	80	HTTP
Monitors	Default	None	None	None
Name Server	None	10.102.29.19	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model



To configure a basic load balancing setup, see Setting Up Basic Load Balancing. Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

To add a name server by using the command line interface

At the command prompt, type:

```
add dns nameServer <dnsVserverName>
<!--NeedCopy-->
```

Example:

```
add dns nameServer Vserver-LB-2
<!--NeedCopy-->
```

To add a name server by using the configuration utility

1. Navigate to **Traffic Management** > **DNS** > **Name Servers**.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

You can also add an authoritative name server that resolves the domain name to an IP address.

> **Note**
>
> You can add a name server of type TCP, UDP, or UDP_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with the truncated bit, this response is not retried over the TCP name server.

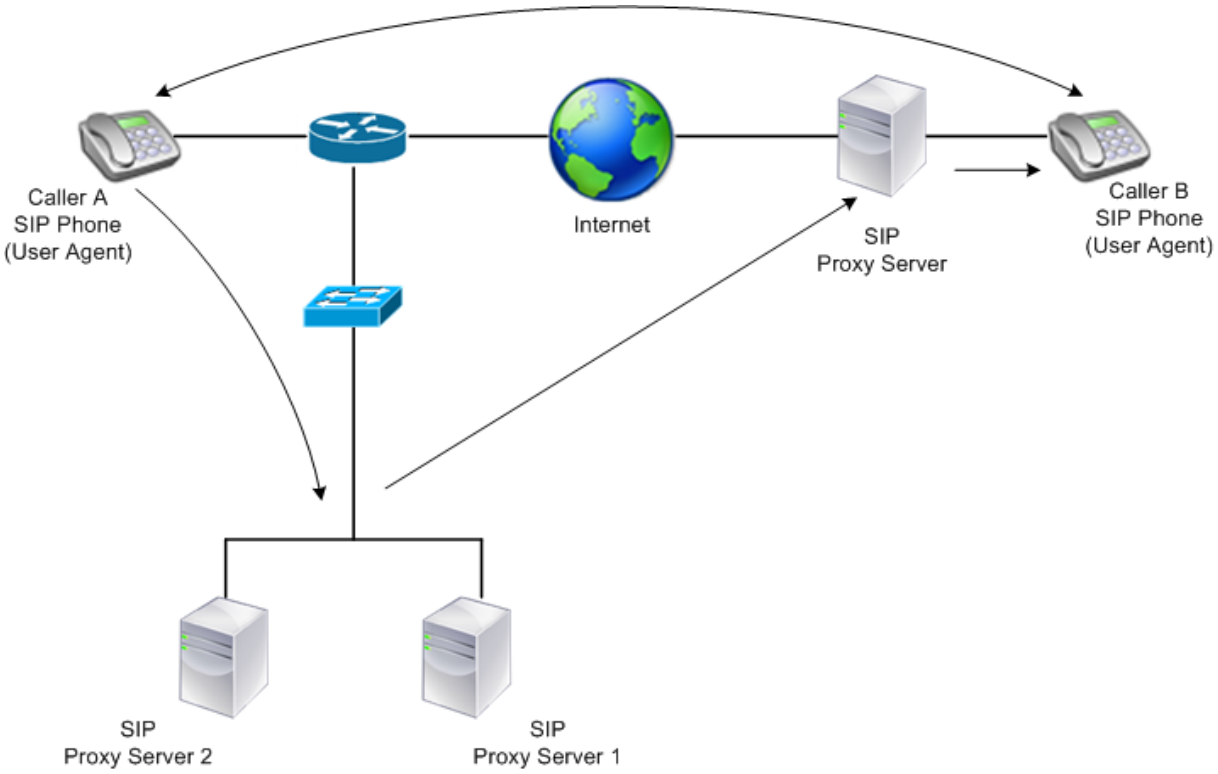
Load balance a group of SIP servers

September 14, 2021

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System



A Citrix ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the Citrix ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the Citrix ADC appends RPORT via the header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the Citrix ADC so that the private IP addresses used by the clients are translated into public IP addresses.

If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the Citrix ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named **nsrnatsip-127.0.0.1-5061**.

Support for Policies and Expressions

The Citrix ADC default expressions language contains several expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip_udp, sip_tcp or sip_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

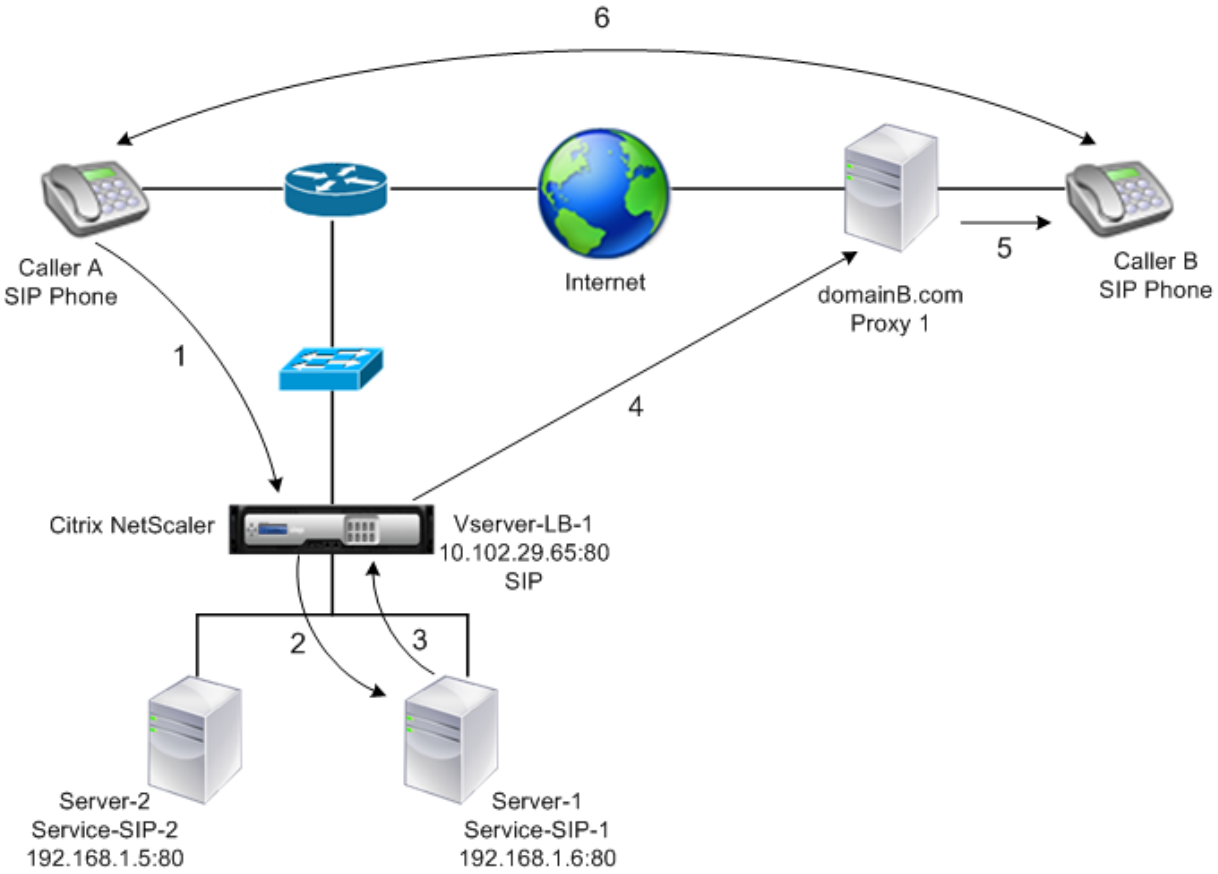
Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The Citrix ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- SIP_UDP – Used when SIP servers send SIP messages over UDP.
- SIP_TCP – Used when SIP servers send SIP messages over TCP.
- SIP_SSL – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The Citrix ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 2. SIP Load Balancing Topology



Entity type	Name	IP address	Port	Service type / Protocol
Virtual Server	Vserver-LB-1	10.102.29.65	80	SIP_UDP / SIP_TCP / SIP_SSL
Services	Service-SIP-1	192.168.1.6	80	SIP_UDP / SIP_TCP / SIP_SSL
	Service-SIP-2	192.168.1.5	80	SIP_UDP / SIP_TCP / SIP_SSL
Monitors	Default	None	80	SIP_UDP / SIP_TCP / SIP_SSL

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:

   - **SIP_UDP** – If you are load balancing the SIP traffic over UDP.
   - **SIP_TCP** – If you are load balancing the SIP traffic over TCP.
   - **SIP_SSL** – If you are load balancing and securing the SIP traffic over TCP.

   Note: If you use SIP_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.
3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The Citrix ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.
4. If using a SIP_SSL virtual server, bind an SSL certificate-key pair to the virtual server.
5. If you are using the Citrix ADC as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

To configure a basic load balancing setup for SIP traffic by using the command line interface

Create one or more services. At the command prompt, type:

```
add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
<!--NeedCopy-->
```

Example:

```
add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
<!--NeedCopy-->
```

Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you bind to it. At the command prompt, type:

```
add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
<!--NeedCopy-->
```

Example:

```
add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
<!--NeedCopy-->
```

Bind each service to a virtual server. At the command prompt, type:

```
bind lb vserver <name> <serverName>
<!--NeedCopy-->
```

Example:

```
bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
<!--NeedCopy-->
```

(Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> [<interval>]

bind lb monitor <monitorName> <ServiceName>
<!--NeedCopy-->
```

Example:

```
add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipuRI sip:mon@test.
   com -sipregURI sip:mon@test.com -respcode 200

bind monitor mon1 Service-SIP-UDP-1
<!--NeedCopy-->
```

If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:

```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -
   CA - skipCAName
<!--NeedCopy-->
```

Example:

```
bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
<!--NeedCopy-->
```

Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

```
add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))

bind rnat <name> <natIP>@ …

show rnat
<!--NeedCopy-->
```

Example:

```
add rnat RNAT-1 192.168.1.0 255.255.255.0

bind rnat RNAT-1 -natip 10.102.29.50
<!--NeedCopy-->
```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named nsrnatsip-127.0.0.1-5061.

```
add ssl certKey <certkeyName> -cert <string> [-key <string>]

bind ssl service <serviceName> -certkeyName <string>
<!--NeedCopy-->
```

Example:

```
add ssl certKey c1 -cert cert.epm -key key.ky

bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
<!--NeedCopy-->
```

If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:

```
set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<
    rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -
    sip503RateThreshold <sip503_rate_threshold_value>
<!--NeedCopy-->
```

Sample Configuration for load balancing the SIP traffic over UDP

```
add service service-UDP-1 10.102.29.5 SIP_UDP 80

Done

```

```
5  add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80
6
7  Done
8
9  bind lb vserver vserver-LB-1 service-UDP-1
10
11 Done
12
13 add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -
       sipregURI sip:mon@test.com -respcode 200
14
15 Done
16
17 bind mon mon1 service-UDP-1
18
19 Done
20
21 add rnat RNAT-1 192.168.1.0 255.255.255.0
22
23 Done
24
25 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
       -addRportVip ENABLED -sip503RateThreshold 1000
26
27 Done
28 <!--NeedCopy-->
```

Sample Configuration for load balancing the SIP traffic over TCP

```
1  add service service-TCP-1 10.102.29.5 SIP_TCP 80
2
3  Done
4
5  add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80
6
7  Done
8
9  bind lb vserver vserver-LB-1 service-TCP-1
10
11 Done
12
13 add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -
       sipregURI sip:mon@test.com -respcode 200
14
```

```
Done

bind mon mon1 service-TCP-1

Done

add rnat RNAT-1 192.168.1.0 255.255.255.0

Done

set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
    -addRportVip ENABLED -sip503RateThreshold 1000

Done
<!--NeedCopy-->
```

Sample Configuration for load balancing and securing SIP traffic over TCP

```
add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80

Done

add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80

Done

bind lb vserver vserver-LB-1 service-SIP-SSL

Done

add lb mon mon1 sip-tCP -sipMethod REGISTER -sipuRI sip:mon@test.com -
   sipregURI sip:mon@test.com -respcode 200

Done

bind mon mon1 service-SIP-SSL

Done

bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1

Done

add rnat RNAT-1 192.168.1.0 255.255.255.0
```

```
26
27 Done
28
29 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
       -addRportVip ENABLED -sip503RateThreshold 1000
30
31 Done
32 <!--NeedCopy-->
```

To configure a basic load balancing setup for SIP traffic by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and add a virtual server of type SIP_UDP, SIP_TCP, or SIP_SSL.
2. Click the **Service** section, and add a service of type SIP_UDP, SIP_TCP, or SIP_SSL.
3. (Optional) Click the **Monitor** section, and add a monitor of the type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
   a) Navigate to **System > Network > Routes**.
   b) On the Routes page, click the **RNAT** tab.
   c) In the details pane, click **Configure RNAT**.
   d) In the Configure RNAT dialog box, do one of the following:
      - If you want to use the network address as a condition for creating an RNAT entry, click **Network** and set the following parameters:
        - Network
        - Netmask
      - If you want to use an extended ACL as a condition for creating an RNAT entry, click **ACL** and set the following parameters:
        - ACL Name
        - Redirect Port
   e) To set a SNIP address as a NAT IP address, skip to step 7.
   f) To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IPs' list.
   g) Click Create, and then click Close.

   If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

a) Navigate to **Traffic Management > Load Balancing > Services** and click the Internal Services tab.
b) Select nsrnatsip-127.0.0.1-5061 and click **Edit**.
c) Click the **Certificates** section and bind a certificate key pair to the internal service.

7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to **Traffic Management > Load Balancing** and click Change SIP settings, set the various SIP parameters.

SIP Expression and Policy Example: Compression Enabled in Client Requests

A Citrix ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with "400 Bad Request," so that the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
add responder action sipaction1 respondwith q{
 "SIP/2.0 400 Bad Requestrnrn" }

Done

add responder policy sippol1

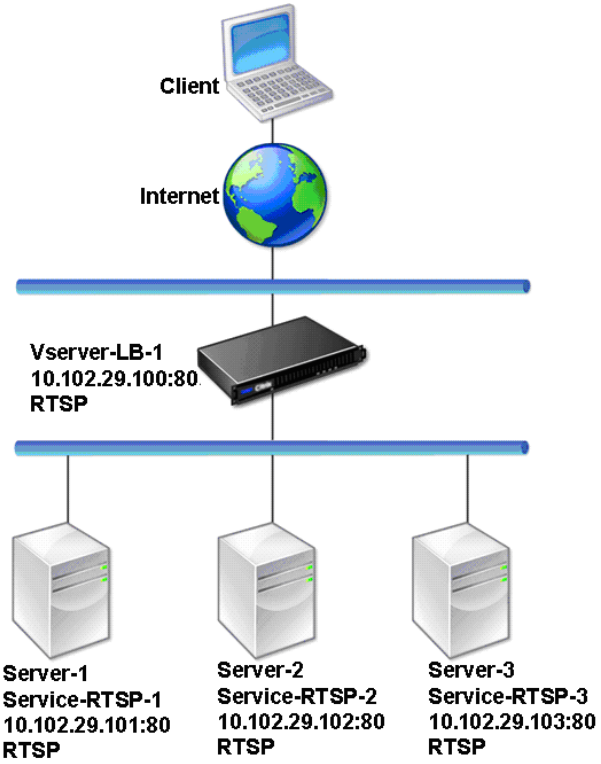
add responder policy sippol1 "SIP.REQ.METHOD.EQ("NEGOTIATE")&&SIP.REQ.
   HEADER("Compression").EXISTS" sipaction1
<!--NeedCopy-->
```

Load balance RTSP servers

September 14, 2021

The Citrix ADC appliance can balance the load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of a load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

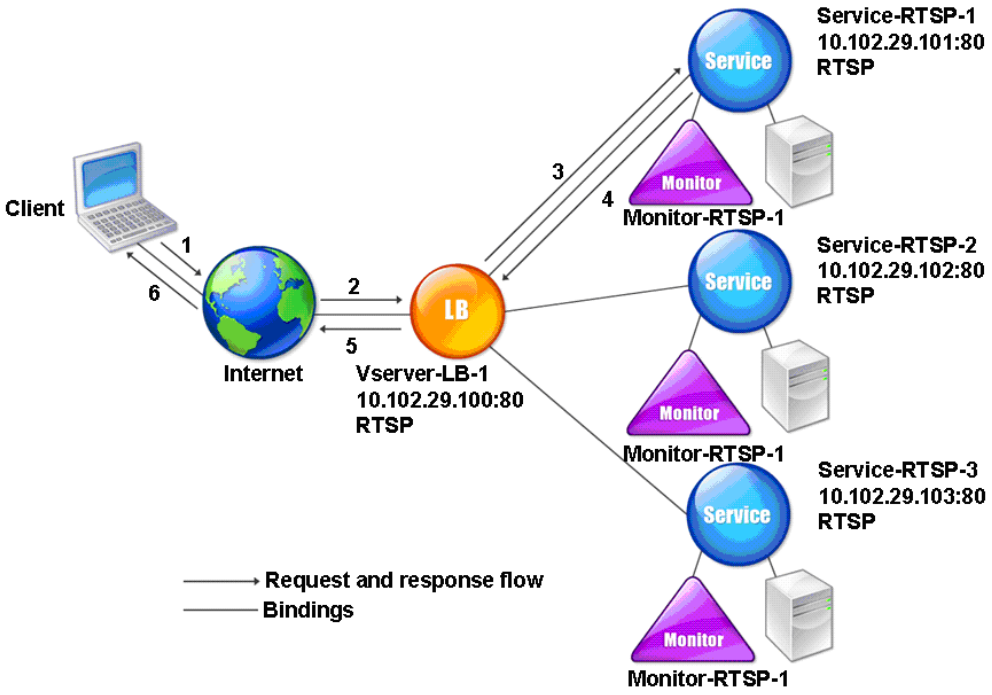


In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.100	554	RTSP
Services	Service-RTSP-1	10.102.29.101	554	RTSP
	Service-RTSP-2	10.102.29.102	554	RTSP
	Service-RTSP-3	10.102.29.103	554	RTSP
Monitors	Monitor-RTSP-1	None	554	RTSP

The following diagram shows the load balancing entities used in the RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model



To configure a basic load balancing setup for RTSP servers, see Setting Up Basic Load Balancing. Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see Binding Monitors to Services. The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type>
<!--NeedCopy-->
```

Example:

```
add lb monitor Monitor-RTSP-1 RTSP
<!--NeedCopy-->
```

To configure RTSP monitors by using the GUI

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.

Load balance remote desktop protocol servers

September 14, 2021

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a GUI to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the Citrix ADC appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). Sometimes, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user must be able to continue with the remote application. To provide this functionality, the Citrix ADC RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the Citrix ADC applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the Citrix ADC appliance forwards the response to the client.

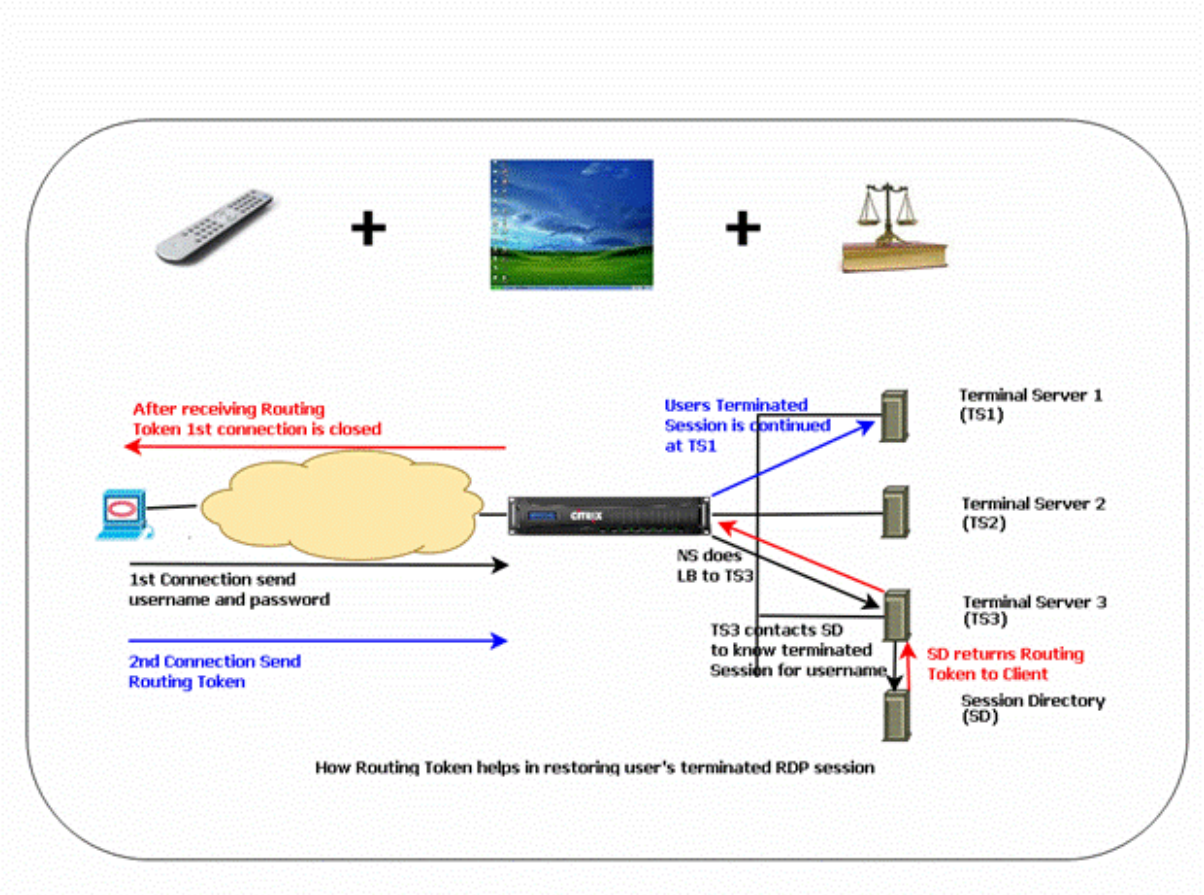
If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as the routing token) with the details of the active session and returns the packets to the Citrix ADC appliance, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the Citrix ADC reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.

The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP



Note

- When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
- The Citrix ADC appliance supports only IP-based cookies.
- The nsrdp.pl script is not supported on any current version of Windows servers.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the back end to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see `https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2003/cc758177(v=ws.10)##BKMK_2`

When you add an RDP service, by default, Citrix ADC adds a monitor of the type TCP and binds it to the

service. The default monitor is a simple TCP monitor that checks whether a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, Citrix ADC marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the Citrix ADC opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the Citrix ADC can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the Citrix ADC at /nsconfig/monitors/nsrdp.pl. When you configure the user monitor, the Citrix ADC runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

To configure RDP load balancing services by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

```
add service <name>@ <serverName> <serviceType> <port>
<!--NeedCopy-->
```

Note: Repeat the preceding command to add more services.

Example

```
> add service ser1 10.102.27.182 RDP 3389
Done
> add service ser2 10.102.27.183 RDP 3389
Done
>show service ser1
ser1 (10.102. 27.182:3389) - RDP
        State: UP
…
            Server Name: 10.102.27.182
            Server ID : 0           Monitor Threshold : 0
        Down state flush: ENABLED
…
1)      Monitor Name: tcp-default
                State: UP       Weight: 1
…
                Response Time: 4.152 millisec
```

```
 Done
<!--NeedCopy-->
```

To configure RDP load balancing services by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services**, and create services of type RDP.

To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

```
add lb vserver <name>@ <serviceType> <ipAddress> <port>

bind lb vserver <name>@ <serviceName>

Bind all the RDP services to be load balanced to the virtual server.
<!--NeedCopy-->
```

Example:

This example has two RDP services bound to the RDP virtual server.

```
add lb vs v1 rdP 10.102.27.186 3389
Done

bind lb vs v1 ser1
service "ser1" bound

bind lb vs v1 ser2
service "ser2" bound
Done

sh lb vs v1
v1 (10.102.27.186:3389) - RDP   Type: ADDRESS
State: UP
…
No. of Bound Services :  2 (Total)       2 (Active)
Configured Method: LEASTCONNECTION
  Current Method: Round Robin, Reason: A new service is bound
Mode: IP
Persistence: NONE
  L2Conn: OFF

```

```
1) ser1 (10.102.27.182: 3389) - RDPState: UP   Weight: 1
2) ser2 (10.102.27.183: 3389) - RDPState: UP   Weight: 1
Done
<!--NeedCopy-->
```

To configure an RDP load balancing virtual server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, create a virtual server of type RDP, and bind RDP services to this virtual server.

To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

```
add lb monitor <monitorName> USER -scriptName nsrdp.pl

bind lb monitor <monitorName> <rdpServiceName>
<!--NeedCopy-->
```

Example:

```
add service ser1 10.102.27.182 RDP 3389

add lb monitor RDP_MON USER -scriptName nsrdp.pl

bind lb monitor RDP_MON ser1

<!--NeedCopy-->
```

To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type USER.
2. In Special Parameters, in the Script Name list, select nsrdp.pl, and then bind this monitor to an RDP service.

Load balance the Microsoft Exchange server

September 14, 2021

This document provides the recommended configuration examples for load balancing of the Microsoft Exchange server using the Citrix ADC appliance.

Citrix ADM StyleBooks simplifies Citrix ADC load balancing configurations for Exchange. For more information, see Microsoft Exchange StyleBook.

> Note:
>
> Load balancing of Microsoft Exchange is not possible using a single load balancing virtual server. Instead, follow the recommended configurations provided in this document.

Differences in Microsoft Exchange 2016 and newer versions

- You need not configure static Remote Procedure Call (RPC) ports on Exchange 2016 because RPC ports are not used.
- All sections named "for versions of Exchange below 2016" are not necessary with Exchange 2016.
- If you have configured any of the non-2016 versions already and you migrate to 2016, you do not have to remove them. Because even if they exist there are no issues.

Points to note

- For Remote Procedure Calls (RPC) with the Exchange server below 2016, the Exchange CAS servers must be configured for Static port assignments. For more information, see Exchange 2010 Client Access Server: Configure Static RPC Ports Microsoft documentation.
- This configuration assumes using the Citrix ADC appliance for SSL Offload. For more information, see How to Configure SSL Offloading in Exchange 2010 or Configuring SSL offloading in Exchange 2013.
- If you do not want to use the SSL Offload feature of the Citrix ADC appliance, change the service group `CAS_servicegroup_http` and monitors to type `SSL` and its bindings to port `443`.
- Surge Protection is not compatible with Microsoft Exchange. Do not enable it on any service or service group related to Microsoft Exchange. Enabling Surge Protection causes connectivity and reliability issues.
- Replace the following Variables with the proper information:
  - {HTTP Public IP}—IP Address for public Exchange HTTP endpoint
  - {RPC Public IP}—IP Address for public Exchange RPC endpoint (can be the same as HTTP Public IP)
  - {Timeout}—Desired timeout (in seconds). Recommended to be as long as standard work shift time (that is, 8 hours)

- {PersTimeout}—Desired timeout (in minutes). Must correspond to the preceding Timeout setting.
- {AB Port}—RPC Address Book TCP Port (usually 59601)
- {CA Port}—RPC Client Access TCP Port (usually 59600)
- {CertKey}—SSL Certificate Key
- {CAS-1 Server}—IP Address of CAS Server
- {CAS-2 Server}—IP Address of CAS Server

Recommended configuration examples for all versions of Microsoft Exchange server

Service Groups:

```
add serviceGroup CAS_servicegroup_http HTTP -maxClient 0 -maxReq 0 -cip
    DISABLED -usip NO -SP OFF -useproxyport YES -cltTimeout {
 Timeout }
  -svrTimeout {
 Timeout }
  -CKA NO -TCPB NO -CMP YES
add serviceGroup CAS_servicegroup_rpc_epm TCP -maxClient 0 -maxReq 0 -
   cip DISABLED -usip NO -SP OFF -useproxyport YES -cltTimeout {
 Timeout }
  -svrTimeout {
 Timeout }
  -CKA NO -TCPB NO -CMP NO
bind serviceGroup CAS_servicegroup_http {
 CAS-1 Server }
  80 -CustomServerID "\"None\""
bind serviceGroup CAS_servicegroup_http {
 CAS-2 Server }
  80 -CustomServerID "\"None\""
bind serviceGroup CAS_servicegroup_rpc_epm {
 CAS-1 Server }
  135 -CustomServerID "\"None\""
bind serviceGroup CAS_servicegroup_rpc_epm {
 CAS-2 Server }
  135 -CustomServerID "\"None\""
<!--NeedCopy-->
```

Monitors:

```
add lb monitor CAS_monitor_rpc_epm TCP -LRTM ENABLED -destPort 135
set lb monitor http-ecv HTTP-ECV -recv 403 -LRTM DISABLED
bind serviceGroup CAS_servicegroup_http -monitorName http-ecv
```

```
bind serviceGroup CAS_servicegroup_rpc_epm -monitorName
   CAS_monitor_rpc_epm
<!--NeedCopy-->
```

Load balancing virtual servers:

```
add lb vserver CAS_vserver_owa SSL 0.0.0.0 0 -persistenceType
   COOKIEINSERT -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

add lb vserver CAS_vserver_as SSL 0.0.0.0 0 -persistenceType RULE -
   timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -rule "HTTP.REQ.HEADER(\"Authorization\")"
     -cltTimeout {
 Timeout }

add lb vserver CAS_vserver_oa SSL 0.0.0.0 0 -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

add lb vserver CAS_vserver_ews SSL 0.0.0.0 0 -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

add lb vserver CAS_vserver_ad SSL 0.0.0.0 0 -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

set ssl vserver CAS_vserver_owa -sslRedirect ENABLED
bind ssl vserver CAS_vserver_owa -certkeyName {
 CertKey }

bind ssl vserver CAS_vserver_oab -certkeyName {
 CertKey }

bind ssl vserver CAS_vserver_as -certkeyName {
 CertKey }

bind ssl vserver CAS_vserver_oa -certkeyName {
```

```
 CertKey }

bind ssl vserver CAS_vserver_ews -certkeyName {
 CertKey }

bind ssl vserver CAS_vserver_ad -certkeyName {
 CertKey }

bind lb vserver CAS_vserver_owa CAS_servicegroup_http
bind lb vserver CAS_vserver_oab CAS_servicegroup_http
bind lb vserver CAS_vserver_as CAS_servicegroup_http
bind lb vserver CAS_vserver_oa CAS_servicegroup_http
bind lb vserver CAS_vserver_ews CAS_servicegroup_http
bind lb vserver CAS_vserver_ad CAS_servicegroup_http
add lb vserver CAS_vserver_rpc_epm TCP {
 RPC Public IP }
  135 -timeout {
 PersTimeout }
  -cltTimeout {
 Timeout }
  -comment "vserver for RPC End Point Mapper"
bind lb vserver CAS_vserver_rpc_epm CAS_servicegroup_rpc_epm
<!--NeedCopy-->
```

Persistency group:

```
add lb group CAS_persistency_group_sourceip
bind lb group CAS_persistency_group_sourceip CAS_vserver_oa
bind lb group CAS_persistency_group_sourceip CAS_vserver_oab
bind lb group CAS_persistency_group_sourceip CAS_vserver_ews
bind lb group CAS_persistency_group_sourceip CAS_vserver_ad
bind lb group CAS_persistency_group_sourceip CAS_vserver_rpc_epm
set lb group CAS_persistency_group_sourceip -persistenceType SOURCEIP -
    timeout {
 PersTimeout }

<!--NeedCopy-->
```

Content Switching for HTTP services:

```
add cs vserver CAS_vserver_cs SSL {
 Public IP }
  443 -cltTimeout {
 Timeout }
  -caseSensitive OFF -comment "Exchange CS VServer"
```

```
bind ssl vserver CAS_vserver_cs -certkeyName {
 CertKey }

add cs action CAS_action_cs_owa -targetLBVserver CAS_vserver_owa
add cs action CAS_action_cs_oab -targetLBVserver CAS_vserver_oab
add cs action CAS_action_cs_as -targetLBVserver CAS_vserver_as
add cs action CAS_action_cs_oa -targetLBVserver CAS_vserver_oa
add cs action CAS_action_cs_ews -targetLBVserver CAS_vserver_ews
add cs action CAS_action_cs_autodiscover -targetLBVserver
   CAS_vserver_ad
add cs policy CAS_policy_cs_owa -rule "HTTP.REQ.URL.SET_TEXT_MODE(
   IGNORECASE).STARTSWITH(\"/owa\")" -action CAS_action_cs_owa

```

Recommended configuration examples for versions of Microsoft Exchange server below 2016

Additional service groups:

```
add serviceGroup CAS_servicegroup_rpc_ca TCP -maxClient 0 -maxReq 0 -
    cip DISABLED -usip NO -SP OFF -useproxyport YES -cltTimeout {
 Timeout }
  -svrTimeout {
 Timeout }
  -CKA NO -TCPB NO -CMP NO
add serviceGroup CAS_servicegroup_rpc_ab TCP -maxClient 0 -maxReq 0 -
    cip DISABLED -usip NO -SP OFF -useproxyport YES -cltTimeout {
 Timeout }
  -svrTimeout {
 Timeout }
  -CKA NO -TCPB NO -CMP NO
bind serviceGroup CAS_servicegroup_rpc_ca {
 CAS-1 Server }
  {
 CA Port }
  -CustomServerID "\"None\""
bind serviceGroup CAS_servicegroup_rpc_ca {
 CAS-2 Server }
  {
 CA Port }
  -CustomServerID "\"None\""
bind serviceGroup CAS_servicegroup_rpc_ab {
 CAS-1 Server }
  {
 AB Port }
  -CustomServerID "\"None\""
bind serviceGroup CAS_servicegroup_rpc_ab {
 CAS-2 Server }
  {
 AB Port }
  -CustomServerID "\"None\""
<!--NeedCopy-->
```

Additional monitors:

```
add lb monitor CAS_monitor_rpc_ca TCP -LRTM ENABLED -destPort {
 CA Port }

add lb monitor CAS_monitor_rpc_ab TCP -LRTM ENABLED -destPort {
 AB Port }

bind serviceGroup CAS_servicegroup_rpc_ca -monitorName
    CAS_monitor_rpc_ca
```

```
bind serviceGroup CAS_servicegroup_rpc_ab -monitorName
    CAS_monitor_rpc_ab
<!--NeedCopy-->
```

Additional load balancing virtual servers:

```
add lb vserver CAS_vserver_rpc_ab TCP {
 RPC Public IP }
  {
 AB Port }
  -timeout {
 PersTimeout }
  -cltTimeout {
 Timeout }
  -comment "vserver for  RPC Address Book"
add lb vserver CAS_vserver_rpc_ca TCP {
 RPC Public IP }
  {
 CA Port }
  -timeout {
 PersTimeout }
  -cltTimeout {
 Timeout }
  -comment "vserver for  RPC Client Access"
bind lb vserver CAS_vserver_rpc_ab CAS_servicegroup_rpc_ab
bind lb vserver CAS_vserver_rpc_ca CAS_servicegroup_rpc_ca
<!--NeedCopy-->
```

Additional persistency group:

```
bind lb group CAS_persistency_group_sourceip CAS_vserver_rpc_ab
bind lb group CAS_persistency_group_sourceip CAS_vserver_rpc_ca
<!--NeedCopy-->
```

Recommended configuration examples for versions of Microsoft Exchange server 2016 and newer

Additional load balancing virtual server:

```
add lb vserver CAS_vserver_mapi SSL 0.0.0.0 0 -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

```

```
bind ssl vserver CAS_vserver_mapi -certkeyName {
 CertKey }

bind lb vserver CAS_vserver_mapi CAS_servicegroup_http
<!--NeedCopy-->
```

Additional persistency group:

```
bind lb group CAS_persistency_group_sourceip CAS_vserver_mapi
<!--NeedCopy-->
```

Content switching for HTTP services:

```
add cs action CAS_action_cs_mapi -targetLBVserver CAS_vserver_mapi
add cs policy CAS_policy_cs_mapi -rule "HTTP.REQ.URL.SET_TEXT_MODE(
    IGNORECASE).STARTSWITH(\"/mapi\")" -action CAS_action_cs_mapi
bind cs vserver CAS_vserver_cs -policyName CAS_policy_cs_mapi -priority
     140
<!--NeedCopy-->
```

Optional configurations

HTTPS redirect for Outlook Web App (OWA):

```
add lb vserver CAS_vserver_owa_http_redirect HTTP {
 HTTP Public IP }
  80 -persistenceType COOKIEINSERT -timeout {
 PersTimeout }
  -lbMethod ROUNDROBIN -redirectURL "https://mail.example.com/owa" -
     cltTimeout {
 Timeout }

<!--NeedCopy-->
```

NOTE: Replace with proper HTTPS Redirect URL.

Policy for /owa rewrite:

```
add rewrite action owa_rewrite replace http.REQ.URL "\"/owa\""
add rewrite policy owa_rewrite_policy "http.req.url.eq(\"/\")"
    owa_rewrite
bind lb vserver CAS_vserver_owa -policyName owa_rewrite_policy -
    priority 100 -gotoPriorityExpression END -type REQUEST
add responder action action_responder_owa redirect "\"https://www.
    example.com/owa\""
```

```
add responder policy policy_responder_owa HTTP.REQ.IS_VALID
    action_responder_owa
set responder param -undefAction NOOP
bind lb vserver CAS_vserver_owa -policyName policy_responder_owa -
    priority 100 -gotoPriorityExpression END -type REQUEST
<!--NeedCopy-->
```

NOTE: Replace with proper HTTPS Redirect URL.

Support for SMTP:

For the following configuration, USIP must be enabled so that the CAS servers can see the sending SMTP server's IP address for validation. This configuration also requires that the default gateway of the CAS server is configured to point at the ADC appliance's SNIP address.

```
add lb vserver CAS_vserver_smtp TCP {
 HTTP Public IP }
  25 -persistenceType SOURCEIP -timeout 60 -lbMethod LEASTCONNECTION -
     cltTimeout 30
add serviceGroup CAS_servicegroup_smtp TCP -maxClient 0 -maxReq 0 -cip
    DISABLED -usip YES -SP OFF -useproxyport YES -cltTimeout 30 -
    svrTimeout 30 -CKA NO -TCPB NO -CMP NO
bind serviceGroup CAS_servicegroup_smtp {
 CAS-1 Server }
  25 -CustomServerID "\"None\"" bind serviceGroup CAS_servicegroup_smtp
      {
 CAS-2 Server }
  25 -CustomServerID "\"None\""
bind lb vserver CAS_vserver_smtp CAS_servicegroup_smtp
<!--NeedCopy-->
```

Support for Post Office Protocol version 3 (POP3):

```
add lb vserver CAS_vserver_pop3 TCP {
 HTTP Public IP }
  110 -persistenceType SOURCEIP -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

add serviceGroup CAS_servicegroup_pop3 TCP -maxClient 0 -maxReq 0 -cip
    DISABLED -usip NO -SP OFF -useproxyport YES -cltTimeout {
 Timeout }
  -svrTimeout {
 Timeout }
  -CKA NO -TCPB NO -CMP NO
```

```
bind serviceGroup CAS_servicegroup_pop3 {
 CAS-1 Server }
  110 -CustomServerID "\"None\"" bind serviceGroup
     CAS_servicegroup_pop3 {
 CAS-2 Server }
  110 -CustomServerID "\"None\""
bind lb vserver CAS_vserver_pop3 CAS_servicegroup_pop3
<!--NeedCopy-->
```

> Note:
>
> You can perform the preceding configuration for SSL-encrypted POP3 by changing the port to 995 and the virtual server/service types to SSL. Also bind a suitable SSL certificate.

Support for IMAP:

```
add lb vserver CAS_vserver_imap TCP {
 HTTP Public IP }
  143 -persistenceType SOURCEIP -timeout {
 PersTimeout }
  -lbMethod LEASTCONNECTION -cltTimeout {
 Timeout }

add serviceGroup CAS_servicegroup_imap TCP -maxClient 0 -maxReq 0 -cip
    DISABLED -usip NO -SP OFF -useproxyport YES -cltTimeout {
 Timeout }
  -svrTimeout {
 Timeout }
  -CKA NO -TCPB NO -CMP NO
bind serviceGroup CAS_servicegroup_imap {
 CAS-1 Server }
  143 -CustomServerID "\"None\"" bind serviceGroup
     CAS_servicegroup_imap {
 CAS-2 Server }
  143 -CustomServerID "\"None\""
bind lb vserver CAS_vserver_imap CAS_servicegroup_imap
<!--NeedCopy-->
```

> Note:
>
> You can perform the preceding configuration for SSL-encrypted IMAP by changing the port to 993 and the virtual server/service types to SSL. Also bind a suitable SSL certificate.

Use case 1: SMPP load balancing

September 14, 2021

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The Citrix ADC supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

The Citrix ADC performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.

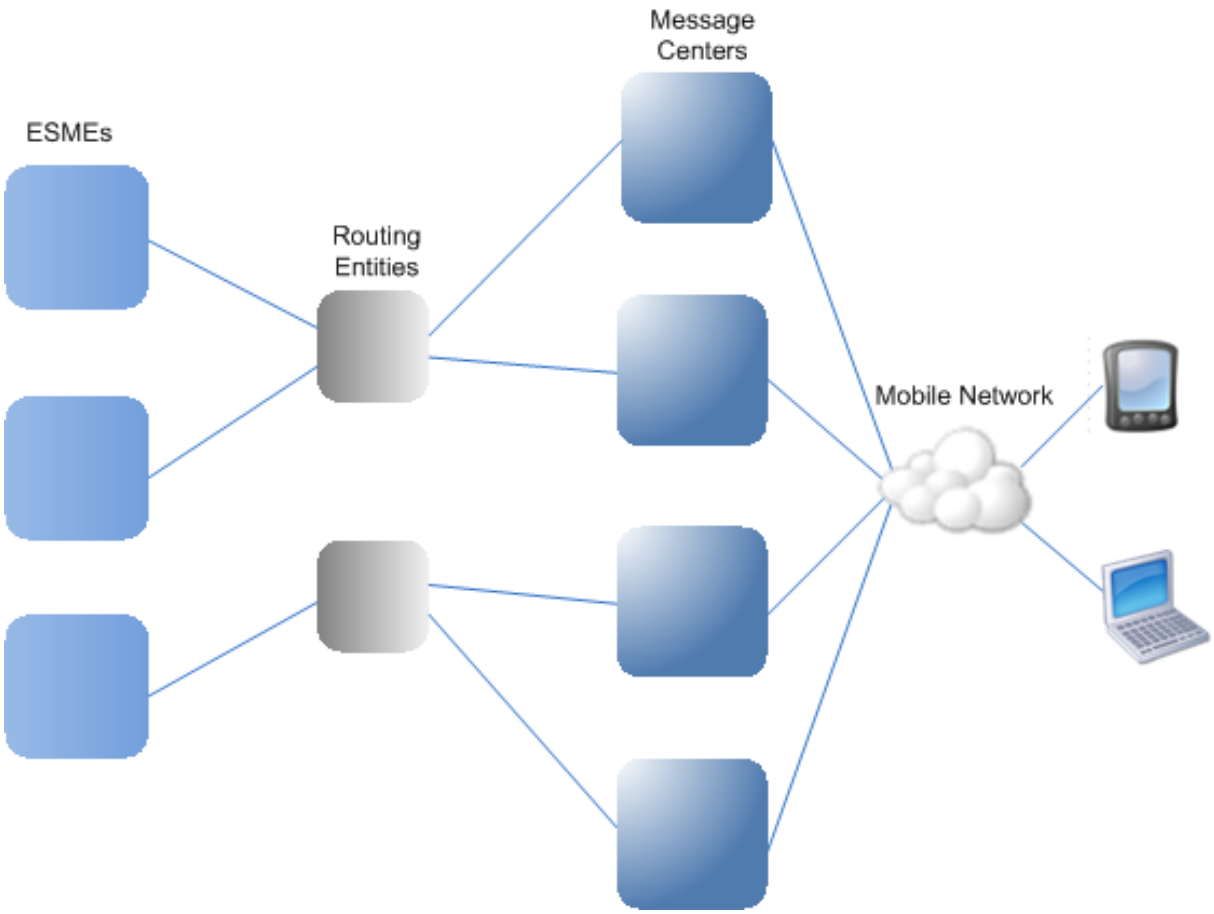
Load balancing of SMPP messages by the Citrix ADC provides the following benefits:

- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

Introduction to SMPP

SMPP is an application layer protocol for the transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections. It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.

The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.



Architecture Overview of the Different SMPP Entities in a Mobile Network

Note: The terms client and ESME are used interchangeably throughout the document.

An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receives messages. The ESME sends the MC one of the three messages (also known as PDUs): bind_transmitter, bind_receiver, or bind_transceiver. The MC responds with a bind_transmitter_resp, bind_receiver_resp, or bind_transceiver_resp, as appropriate for the request.

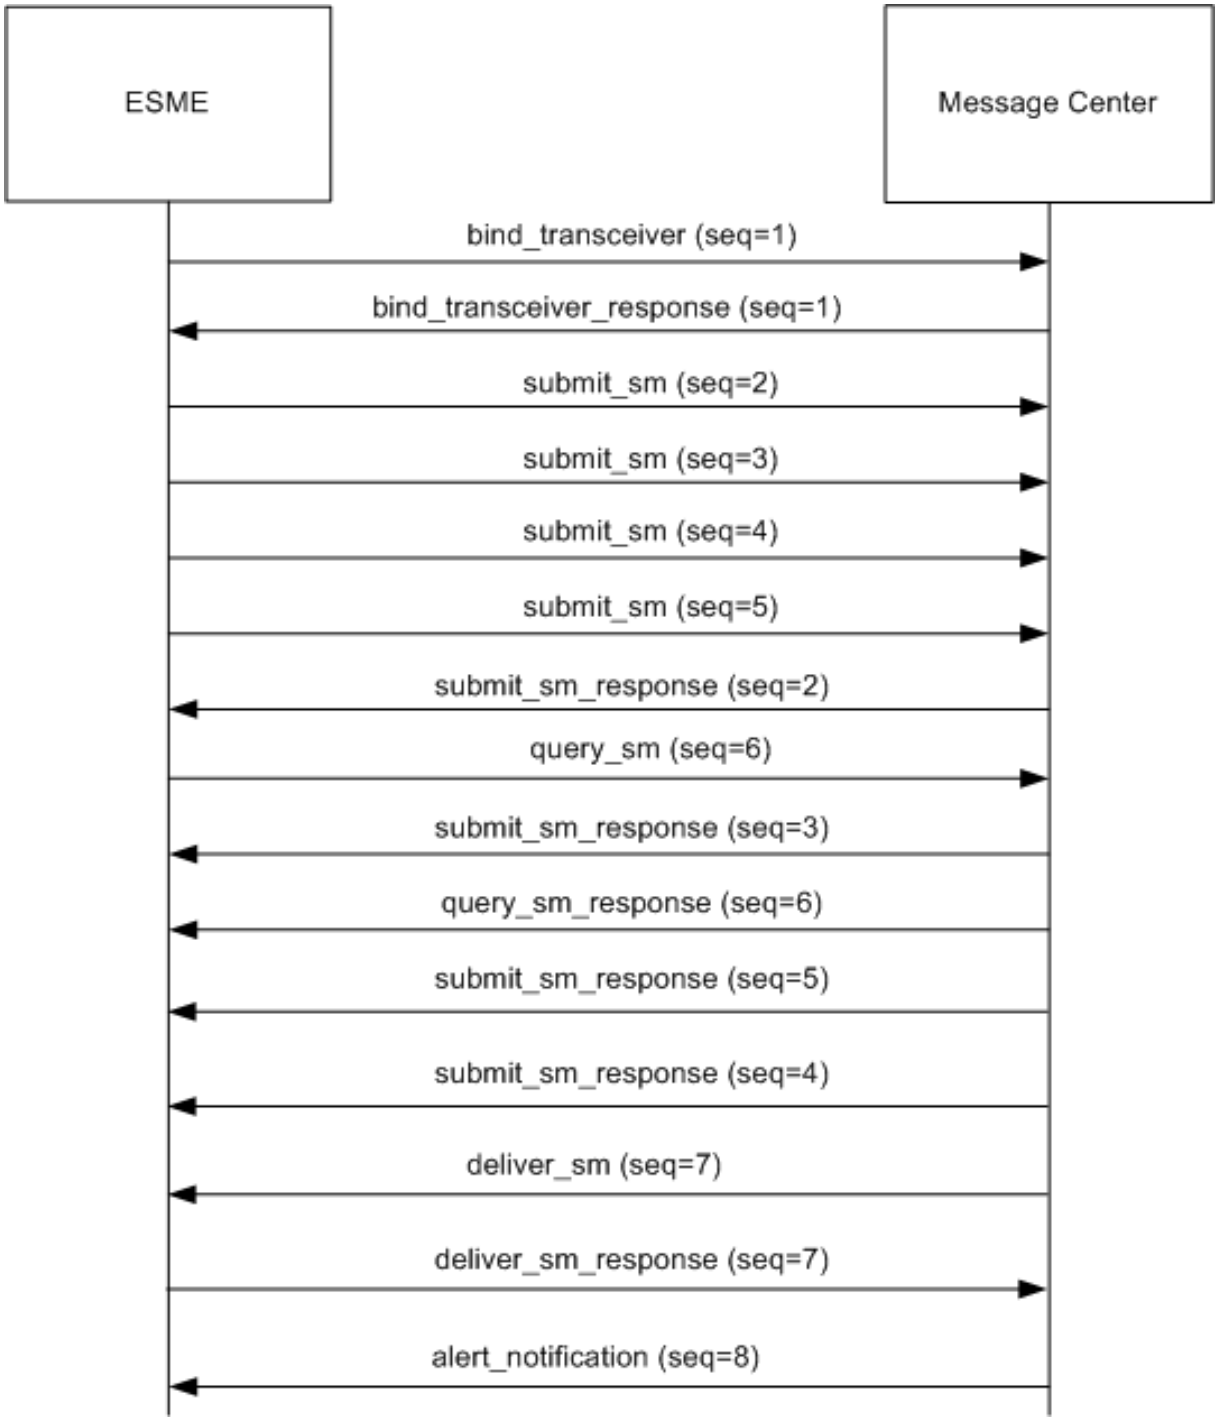
After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a submit_sm or data_sm message, receive a deliver_sm or data_sm message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as query_sm, replace_sm, and cancel_sm, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends

an alert_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.

Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.



Limitation:

The Citrix ADC appliance does not support out bound operations. That is, a message center cannot initiate an SMPP session with an ESME through the Citrix ADC appliance.

How SMPP Load Balancing Works on the Citrix ADC

An ESME (client) sends a bind message to open a connection to the Citrix ADC. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The Citrix ADC establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

Messages Originating from the ESMEs

Each ESME must be added as a user on the Citrix ADC for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center.

Before forwarding the response (submit_sm_resp or data_sm_resp) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

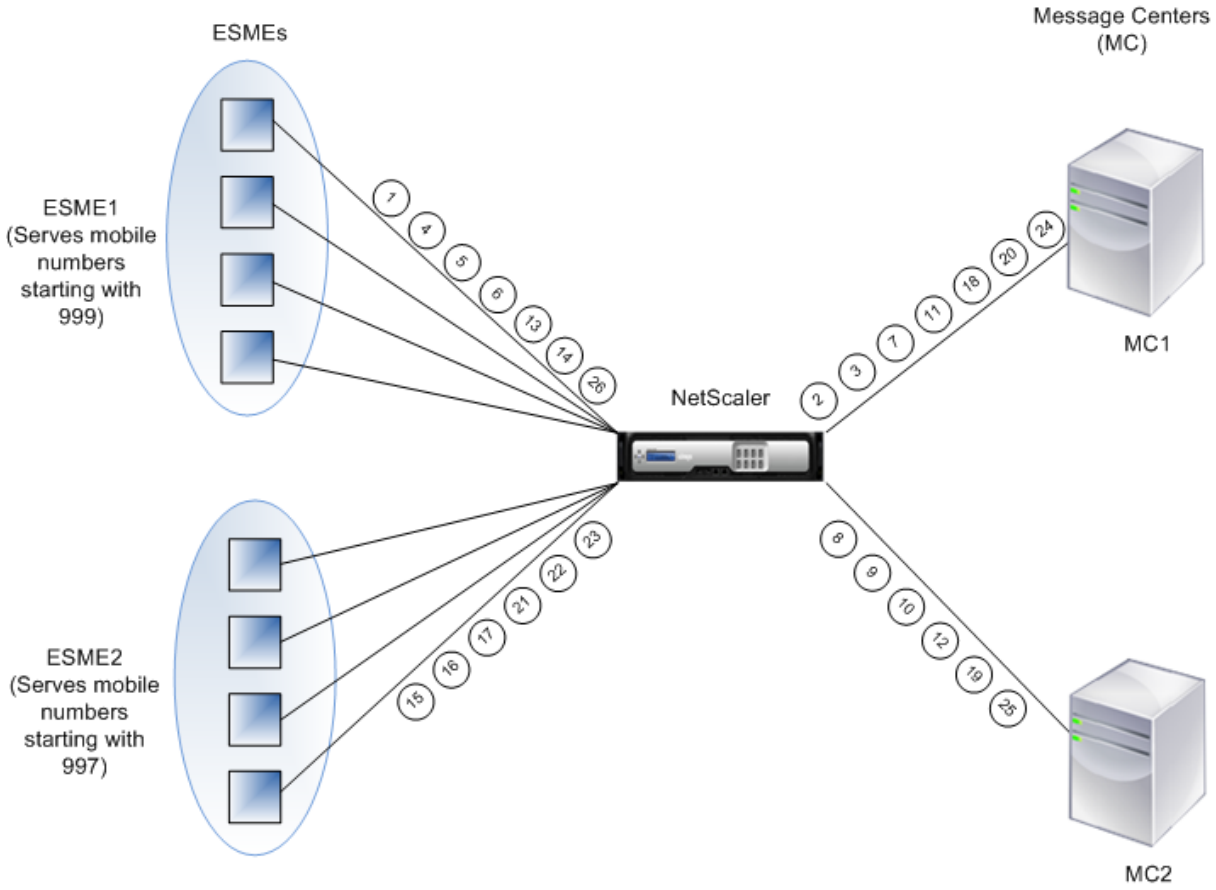
In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding deliver_sm or data_sm messages from the message centers to the clients.

Messages Originating from a Message Center

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a deliver_sm message to the Citrix ADC. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve deliver_sm messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

The following diagram illustrates the internal flow of PDUs between ESMEs, Citrix ADC, and the message centers. For simplicity, only two ESMEs and two message centers are shown.



Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit_sm(1) to NetScaler
6. ESME1 sends submit_sm(2) to NetScaler
7. NetScaler forwards submit_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit_sm(2) to MC2
11. MC1 sends submit_sm_resp(1) to NetScaler
12. MC2 sends submit_sm_resp(2) to NetScaler
13. NetScaler forwards submit_sm_resp(1) to ESME1
14. NetScaler forwards submit_sm_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler
16. NetScaler sends bind response to ESME2
17. ESME2 sends submit_sm(3) to NetScaler

18. NetScaler forwards submit_sm(3) to MC1
19. MC2 sends deliver_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit_sm_resp(3) to NetScaler
21. NetScaler forwards submit_sm_resp(3) to ESME2
22. NetScaler forwards deliver_sm to ESME2
23. ESME2 sends deliver_sm_resp to NetScaler
24. MC1 sends alert_notification to NetScaler (ESME1 serves the address range specified in the message)
25. NetScaler forwards deliver_sm_resp to MC2
26. NetScaler forwards the alert_notification to ESME1

Health Monitoring of Message Centers

By default, a TCP_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the Citrix ADC to content switch these requests based on the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.

Example:

SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS("^988")

- Based the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.

Example:

SMPP.BINDINFO.SYSTEM_ID.EQ("ESME1")

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.

Example:

SMPP.BINDINFO.SYSTEM_TYPE.EQ("VMS")

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)

Example:

SMPP.BINDINFO.ADDR_TON.EQ(1)

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)

Example:

SMPP.BINDINFO.ADDR_NPI.EQ(0)

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)

Example:

SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)

Concatenated Message Handling
