Displays the statistical data collected for a global server load balancing (GSLB) service.

stat gslb service [<serviceName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

serviceName

Name of the GSLB service.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Current Client Est connections (ClntEstConn)

Number of client connections in ESTABLISHED state.

IP address (IP)

The IP address on which the service is running.

Port (port)

The port on which the service is running.

Service type (Type)

The service type of this service.Possible values are ADNS, DNS, MYSQL, RTSP, SSL_DIAMETER, ADNS_TCP, DNS_TCP, NNTP, SIP_UDP, SSL_TCP,

ANY, FTP, RADIUS, SNMP, TCP, DHCPRA, HTTP, RDP, SSL, TFTP, DIAMETER, MSSQL, RPCSVR, SSL_BRIDGE, UDP

State

Current state of the server. Possible values are UP, DOWN, UNKNOWN, OFS(Out of Service), TROFS(Transition Out of Service), TROFS_DOWN(Down When going Out of Service)

Request bytes (Reqb)

Total number of request bytes received on this service or virtual server.

Response bytes (Rspb)

Number of response bytes received by this service or virtual server.

Current load on the service (Load)

Load on the service that is calculated from the bound load based monitor.

Requests (Req)

Total number of requests received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Responses (Rsp)

Number of responses received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Current client connections (ClntConn)

Number of current client connections.

Current server connections (SvrConn)

Number of current connections to the actual servers behind the virtual server.

Service hits (Hits)

Number of times that the service has been provided.

Current Server Est connections (SvrEstConn)

Number of server connections in ESTABLISHED state.

Renames a global server load balancing (GSLB) service.

rename gslb service <serviceName>@ <newName>@

serviceName

Existing name of the GSLB service.

newName

New name for the GSLB service.

rename gslb service gsl_svc gslb_svc_new

---

gslb site

Sep 22, 2015

The following operations can be performed on "gslb site":

add | rm | set | unset | show | stat

Creates a global server load balancing site.

add gslb site <siteName> [<siteType>] <siteIPAddress> [-publicIP <ip_addr|ipv6_addr|*>] [-metricExchange (ENABLED | DISABLED)] [-nwMetricExchange (ENABLED | DISABLED)] [-sessionExchange (ENABLED | DISABLED)] [-triggerMonitor <triggerMonitor>] [-parentSite <string>]

siteName

Name for the GSLB site. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the virtual server is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my gslbsite" or 'my gslbsite').

siteType

Type of site to create. If the type is not specified, the appliance automatically detects and sets the type on the basis of the IP address being assigned to the site. If the specified site IP address is owned by the appliance (for example, a MIP address or SNIP address), the site is a local site. Otherwise, it is a remote site.

Possible values: REMOTE, LOCAL

Default value: NS_NORMAL

siteIPAddress

IP address for the GSLB site. The GSLB site uses this IP address to communicate with other GSLB sites. For a local site, use any IP address that is owned by the appliance (for example, a SNIP or MIP address, or the IP address of the ADNS service).

publicIP

Public IP address for the local site. Required only if the appliance is deployed in a private address space and the site has a public IP address hosted on an external firewall or a NAT device.

metricExchange

Exchange metrics with other sites. Metrics are exchanged by using Metric Exchange Protocol (MEP). The appliances

in the GSLB setup exchange health information once every second.

If you disable metrics exchange, you can use only static load balancing methods (such as round robin, static proximity, or the hash-based methods), and if you disable metrics exchange when a dynamic load balancing method (such as least connection) is in operation, the appliance falls back to round robin. Also, if you disable metrics exchange, you must use a monitor to determine the state of GSLB services. Otherwise, the service is marked as DOWN.

Possible values: ENABLED, DISABLED

Default value: ENABLED

nwMetricExchange

Exchange, with other GSLB sites, network metrics such as round-trip time (RTT), learned from communications with various local DNS (LDNS) servers used by clients. RTT information is used in the dynamic RTT load balancing method, and is exchanged every 5 seconds.

Possible values: ENABLED, DISABLED

Default value: ENABLED

sessionExchange

Exchange persistent session entries with other GSLB sites every five seconds.

Possible values: ENABLED, DISABLED

Default value: ENABLED

triggerMonitor

Specify the conditions under which the GSLB service must be monitored by a monitor, if one is bound. Available settings function as follows:

* ALWAYS - Monitor the GSLB service at all times.

* MEPDOWN - Monitor the GSLB service only when the exchange of metrics through the Metrics Exchange Protocol (MEP) is disabled.

MEPDOWN_SVCDOWN - Monitor the service in either of the following situations:

* The exchange of metrics through MEP is disabled.

* The exchange of metrics through MEP is enabled but the status of the service, learned through metrics exchange, is DOWN.

Possible values: ALWAYS, MEPDOWN, MEPDOWN_SVCDOWN

Default value: NSGSLB_TRIGMON_ALWAYS

parentSite

Parent site of the GSLB site, in a parent-child topology.

```
add site new_york  LOCAL  192.168.100.12 -publicIP  65.200.211.139
```

Removes a global server load balancing (GSLB) site and all its constituent GSLB services.

```
rm gslb site <siteName>
```

siteName

Name of the GSLB site to remove.

```
rm gslb site new_york
```

Modifies the specified parameters of a global server load balancing (GSLB) site.

```
set gslb site <siteName> [-metricExchange ( ENABLED | DISABLED )] [-nwMetricExchange ( ENABLED | DISABLED )] [-sessionExchange ( ENABLED | DISABLED )] [-triggerMonitor <triggerMonitor>]
```

siteName

Name of the GSLB site.

metricExchange

Exchange metrics with other sites. Metrics are exchanged by using Metric Exchange Protocol (MEP). The appliances in the GSLB setup exchange health information once every second.

If you disable metrics exchange, you can use only static load balancing methods (such as round robin, static proximity, or the hash-based methods), and if you disable metrics exchange when a dynamic load balancing method (such as least connection) is in operation, the appliance falls back to round robin. Also, if you disable metrics exchange, you must use a monitor to determine the state of GSLB services. Otherwise, the service is marked as DOWN.

Possible values: ENABLED, DISABLED

Default value: ENABLED

nwMetricExchange

Exchange, with other GSLB sites, network metrics such as round-trip time (RTT), learned from communications with various local DNS (LDNS) servers used by clients. RTT information is used in the dynamic RTT load balancing method, and is exchanged every 5 seconds.

Possible values: ENABLED, DISABLED

Default value: ENABLED

sessionExchange

Exchange persistent session entries with other GSLB sites every five seconds.

Possible values: ENABLED, DISABLED

Default value: ENABLED

triggerMonitor

Specify the conditions under which the GSLB service must be monitored by a monitor, if one is bound. Available settings function as follows:

* ALWAYS - Monitor the GSLB service at all times.

* MEPDOWN - Monitor the GSLB service only when the exchange of metrics through the Metrics Exchange Protocol (MEP) is disabled.

MEPDOWN_SVCDOWN - Monitor the service in either of the following situations:

* The exchange of metrics through MEP is disabled.

* The exchange of metrics through MEP is enabled but the status of the service, learned through metrics exchange, is DOWN.

Possible values: ALWAYS, MEPDOWN, MEPDOWN_SVCDOWN

Default value: NSGSLB_TRIGMON_ALWAYS

set gslb site new_york - metricExchange DISABLED

Use this command to remove gslb site settings.Refer to the set gslb site command for meanings of the arguments.

unset gslb site <siteName> [-metricExchange] [-nwMetricExchange] [-sessionExchange] [-triggerMonitor]

Displays the parameters of all the GSLB sites configured on the appliance, or the parameters of the specified GSLB site.

show gslb site [<siteName>] show gslb site stats - alias for 'stat gslb site'

siteName

Name of the GSLB site. If you specify a site name, details of all the site's constituent services are also displayed.

summary

fullValues

format

level

siteType

Specifies whether the site is LOCAL or REMOTE.

siteIPAddress

The IP address of the site.

publicIP

The Public IP of the gslb site.

metricExchange

Exchange metrics with other sites. Metrics are exchanged by using Metric Exchange Protocol (MEP). The appliances in the GSLB setup exchange health information once every second.

If you disable metrics exchange, you can use only static load balancing methods (such as round robin, static proximity, or the hash-based methods), and if you disable metrics exchange when a dynamic load balancing method (such as least connection) is in operation, the appliance falls back to round robin. Also, if you disable metrics exchange, you must use a monitor to determine the state of GSLB services. Otherwise, the service is marked as DOWN.

serviceName

Service name.

IPAddress

IP Address of the gslb service.

port

Port number of the gslb service.

state

State of the gslb service.

status

Current metric exchange status.

persistenceMEPStatus

Network metric and persistence exchange MEP connection status

serviceType

Service type.

nwMetricExchange

Specifies whether the exchange of network metrics like RTT is enabled or disabled.

sessionExchange

Specifies whether the exchange of persistence session entries is enabled or disabled.

triggerMonitor

Specify the conditions under which the GSLB service must be monitored by a monitor, if one is bound. Available settings function as follows:

* ALWAYS - Monitor the GSLB service at all times.

* MEPDOWN - Monitor the GSLB service only when the exchange of metrics through the Metrics Exchange Protocol (MEP) is disabled.

MEPDOWN_SVCDOWN - Monitor the service in either of the following situations:

* The exchange of metrics through MEP is disabled.

* The exchange of metrics through MEP is enabled but the status of the service, learned through metrics exchange, is DOWN.

parentSite

Parent site of the GSLB site, in a parent-child topology.

cnameEntry

The cname of the gslb service.

stateflag

stateflag

version

will be true if the remote site's version is ncore compatible with the local site.(>= 9.2)

devno

count

show site new_york

Displays statistics for a GSLB site.

stat gslb site [<siteName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

siteName

Name of the GSLB site for which to display detailed statistics. If a name is not specified, basic information about all GSLB sites is displayed.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Gslb Site Public IP address (Public IP)

The public IP address of this GSLB site.

Gslb Site private IP address (Private IP)

The private IP address of this GSLB site.

Metric Exchange State (MEPstate)

Indicates the status of the Metric Exchange Policy at this GSLB site.

Persistence Exchange (PersMEP)

Indicates whether Persistence entries exchange is enabled or disabled at this GSLB site.

Network Metric Exchange (NwMEP)

Indicates whether network metric exchange is enabled or disabled at this GSLB site.

Metric Exchange (MEP)

Indicates whether metric exchange is enabled or disabled at this GSLB site.

GSLB Site type (sitetype)

Indicates whether this GSLB site is local or remote.

Gslb Site public IP address (Public IP)

The public IP address of this GSLB site.

Site Metric Metric Exchange State (SiteMetricMEPstate)

Indicates the status of the site metric Metric Exchange connection at this GSLB site.

Netowrk Metric Metric Exchange State (NwMetricMEPstate)

Indicates the status of the network metric Metric Exchange connection at this GSLB site.

Request bytes (Reqb)

Total number of request bytes received by the virtual servers represented by all GSLB services associated with this GSLB site.

Response bytes (Rspb)

Number of response bytes received by the virtual servers represented by all GSLB services associated with this GSLB site.

Requests (Req)

Total number of requests received by the virtual servers represented by all GSLB services associated with this GSLB site.

Responses (Rsp)

Number of responses received by the virtual servers represented by all GSLB services associated with this GSLB site.

Current client connections (ClntConn)

Number of current client connections to the virtual servers represented by all GSLB services associated with this GSLB site.

Current server connections (SvrConn)

Number of current connections to the real servers behind the virtual servers represented by all GSLB services associated with this GSLB site.

gslb syncStatus

Sep 22, 2015

The following operations can be performed on "gslb syncStatus":

Displays the status of the last GSLB configuration synchronization.

show gslb syncStatus

response

gslb sync status as text blob

gslb vserver

Sep 22, 2015

The following operations can be performed on "gslb vserver":

add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename

Creates a global server load balancing (GSLB) virtual server.

add gslb vserver <name> <serviceType> [-dnsRecordType <dnsRecordType>] [-lbMethod <lbMethod>] [-backupLBMethod <backupLBMethod>] [-netmask <netmask>] [-v6netmasklen <positive_integer>] [-tolerance <positive_integer>] [-persistenceType (SOURCEIP | NONE)] [-persistenceId <positive_integer>] [-persistMask <netmask>] [-v6persistmasklen <positive_integer>] [-timeout <mins>] [-EDR (ENABLED | DISABLED)] [-MIR (ENABLED | DISABLED)] [-disablePrimaryOnDown (ENABLED | DISABLED)] [-dynamicWeight <dynamicWeight>] [-state (ENABLED | DISABLED)] [-considerEffectiveState (NONE | STATE_ONLY)] [-comment <string>] [-soMethod <soMethod>] [-soPersistence (ENABLED | DISABLED)] [-soPersistenceTimeOut <positive_integer>] [-soThreshold <positive_integer>] [-soBackupAction <soBackupAction>] [-appflowLog (ENABLED | DISABLED)]

name

Name for the GSLB virtual server. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the virtual server is created.

CLI Users:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my vserver" or 'my vserver').

serviceType

Protocol used by services bound to the virtual server.

Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, ANY, SIP_UDP, RADIUS, RDP, RTSP, MYSQL, MSSQL

ipType

The IP type for this GSLB vserver.

Possible values: IPV4, IPV6

Default value: NSGSLB_IPV4

dnsRecordType

DNS record type to associate with the GSLB virtual server's domain name.

Possible values: A, AAAA, CNAME

Default value: NSGSLB_A

lbMethod

Load balancing method for the GSLB virtual server.

Possible values: ROUNDROBIN, LEASTCONNECTION, LEASTRESPONSETIME, SOURCEIPHASH, LEASTBANDWIDTH, LEASTPACKETS, STATICPROXIMITY, RTT, CUSTOMLOAD

Default value: PEMGMT_LB_LEASTCONNS

backupSessionTimeout

A non zero value enables the feature whose minimum value is 2 minutes. The feature can be disabled by setting the value to zero. The created session is in effect for a specific client per domain.

Maximum value: 1440

backupLBMethod

Backup load balancing method. Becomes operational if the primary load balancing method fails or cannot be used. Valid only if the primary method is based on either round-trip time (RTT) or static proximity.

Possible values: ROUNDROBIN, LEASTCONNECTION, LEASTRESPONSETIME, SOURCEIPHASH, LEASTBANDWIDTH, LEASTPACKETS, STATICPROXIMITY, RTT, CUSTOMLOAD

netmask

IPv4 network mask for use in the SOURCEIPHASH load balancing method.

Default value: 0xFFFFFFFF

v6netmasklen

Number of bits to consider, in an IPv6 source IP address, for creating the hash that is required by the SOURCEIPHASH load balancing method.

Default value: 128

Minimum value: 1

Maximum value: 128

tolerance

Site selection tolerance, in milliseconds, for implementing the RTT load balancing method. If a site's RTT deviates from the lowest RTT by more than the specified tolerance, the site is not considered when the NetScaler appliance makes a GSLB decision. The appliance implements the round robin method of global server load balancing between sites whose RTT values are within the specified tolerance. If the tolerance is 0 (zero), the appliance always sends clients the IP address of the site with the lowest RTT.

Maximum value: 100

persistenceType

Use source IP address based persistence for the virtual server.

After the load balancing method selects a service for the first packet, the IP address received in response to the DNS query is used for subsequent requests from the same client.

Possible values: SOURCEIP, NONE

persistenceId

The persistence ID for the GSLB virtual server. The ID is a positive integer that enables GSLB sites to identify the GSLB virtual server, and is required if source IP address based or spill over based persistence is enabled on the virtual server.

Maximum value: 65535

persistMask

The optional IPv4 network mask applied to IPv4 addresses to establish source IP address based persistence.

Default value: 0xFFFFFFFF

v6persistmasklen

Number of bits to consider in an IPv6 source IP address when creating source IP address based persistence sessions.

Default value: 128

Minimum value: 1

Maximum value: 128

timeout

Idle time, in minutes, after which a persistence entry is cleared.

Default value: 2

Minimum value: 2

Maximum value: 1440

EDR

Send clients an empty DNS response when the GSLB virtual server is DOWN.

Possible values: ENABLED, DISABLED

Default value: DISABLED

MIR

Include multiple IP addresses in the DNS responses sent to clients.

Possible values: ENABLED, DISABLED

Default value: DISABLED

disablePrimaryOnDown

Continue to direct traffic to the backup chain even after the primary GSLB virtual server returns to the UP state. Used when spillover is configured for the virtual server.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dynamicWeight

Specify if the appliance should consider the service count, service weights, or ignore both when using weight-based load balancing methods. The state of the number of services bound to the virtual server help the appliance to select the service.

Possible values: SERVICECOUNT, SERVICEWEIGHT, DISABLED

Default value: DISABLED

state

State of the GSLB virtual server.

Possible values: ENABLED, DISABLED

Default value: ENABLED

considerEffectiveState

If the primary state of all bound GSLB services is DOWN, consider the effective states of all the GSLB services, obtained through the Metrics Exchange Protocol (MEP), when determining the state of the GSLB virtual server. To consider the effective state, set the parameter to STATE_ONLY. To disregard the effective state, set the parameter to NONE.

The effective state of a GSLB service is the ability of the corresponding virtual server to serve traffic. The effective state of the load balancing virtual server, which is transferred to the GSLB service, is UP even if only one virtual server in the backup chain of virtual servers is in the UP state.

Possible values: NONE, STATE_ONLY

Default value: NS_GSLB_DONOT_CONSIDER_BKPS

comment

Any comments that you might want to associate with the GSLB virtual server.

soMethod

Type of threshold that, when exceeded, triggers spillover. Available settings function as follows:

* CONNECTION - Spillover occurs when the number of client connections exceeds the threshold.

* DYNAMICCONNECTION - Spillover occurs when the number of client connections at the GSLB virtual server exceeds the sum of the maximum client (Max Clients) settings for bound GSLB services. Do not specify a spillover threshold for this setting, because the threshold is implied by the Max Clients settings of the bound GSLB services.

* BANDWIDTH - Spillover occurs when the bandwidth consumed by the GSLB virtual server's incoming and outgoing traffic exceeds the threshold.

* HEALTH - Spillover occurs when the percentage of weights of the GSLB services that are UP drops below the threshold. For example, if services gslbSvc1, gslbSvc2, and gslbSvc3 are bound to a virtual server, with weights 1, 2, and 3, and the spillover threshold is 50%, spillover occurs if gslbSvc1 and gslbSvc3 or gslbSvc2 and gslbSvc3 transition to DOWN.

* NONE - Spillover does not occur.

Possible values: CONNECTION, DYNAMICCONNECTION, BANDWIDTH, HEALTH, NONE

soPersistence

If spillover occurs, maintain source IP address based persistence for both primary and backup GSLB virtual servers.

Possible values: ENABLED, DISABLED

Default value: DISABLED

soPersistenceTimeOut

Timeout for spillover persistence, in minutes.

Default value: 2

Minimum value: 2

Maximum value: 1440

soThreshold

Threshold at which spillover occurs. Specify an integer for the CONNECTION spillover method, a bandwidth value in kilobits per second for the BANDWIDTH method (do not enter the units), or a percentage for the HEALTH method (do not enter the percentage symbol).

Minimum value: 1

Maximum value: 4294967287

soBackupAction

Action to be performed if spillover is to take effect, but no backup chain to spillover is usable or exists

Possible values: DROP, ACCEPT, REDIRECT

appflowLog

Enable logging appflow flow information

Possible values: ENABLED, DISABLED

Default value: ENABLED

```
add gslb vserver gvip http
```

Removes a global server load balancing (GSLB) virtual server configured on the appliance.

rm gslb vserver <name>

name

Name of the GSLB virtual server to remove.

rm gslb vserver gvip

Modifies the specified parameters of a global server load balancing (GSLB) virtual server.

set gslb vserver <name> [-dnsRecordType <dnsRecordType>] [-backupVServer <string>] [-lbMethod <lbMethod>] [-backupLBMethod <backupLBMethod>] [-netmask <netmask>] [-v6netmasklen <positive_integer>] [-tolerance <positive_integer>] [-persistenceType (SOURCEIP | NONE)] [-persistenceId <positive_integer>] [-persistMask <netmask>] [-v6persistmasklen <positive_integer>] [-timeout <mins>] [-EDR (ENABLED | DISABLED)] [-MIR (ENABLED | DISABLED)] [-disablePrimaryOnDown (ENABLED | DISABLED)] [-dynamicWeight <dynamicWeight>] [-considerEffectiveState (NONE | STATE_ONLY)] [-soMethod <soMethod>] [-soPersistence (ENABLED | DISABLED)] [-soPersistenceTimeOut <positive_integer>] [-soThreshold <positive_integer>] [-soBackupAction <soBackupAction>] [-serviceName <string> -weight <positive_integer>] [-domainName <string> [-TTL <secs>] [-backupIP <ip_addr|ipv6_addr|*>] [-cookieDomain <string>] [-cookieTimeout <mins>] [-sitedomainTTL <secs>]] [-comment <string>] [-appflowLog (ENABLED | DISABLED)]

name

Name of the GSLB virtual server.

ipType

The IP type for this GSLB vserver.

Possible values: IPV4, IPV6

Default value: NSGSLB_IPV4

dnsRecordType

DNS record type to associate with the GSLB virtual server's domain name.

Possible values: A, AAAA, CNAME

Default value: NSGSLB_A

backupVServer

Name of the backup GSLB virtual server to which the appliance should to forward requests if the status of the primary GSLB virtual server is down or exceeds its spillover threshold.

backupSessionTimeout

A non zero value enables the feature whose minimum value is 2 minutes. The feature can be disabled by setting the value to zero. The created session is in effect for a specific client per domain.

Maximum value: 1440

lbMethod

Load balancing method for the GSLB virtual server.

Possible values: ROUNDROBIN, LEASTCONNECTION, LEASTRESPONSETIME, SOURCEIPHASH, LEASTBANDWIDTH, LEASTPACKETS, STATICPROXIMITY, RTT, CUSTOMLOAD

Default value: PEMGMT_LB_LEASTCONNS

netmask

IPv4 network mask for use in the SOURCEIPHASH load balancing method.

Default value: 0xFFFFFFFF

v6netmasklen

Number of bits to consider, in an IPv6 source IP address, for creating the hash that is required by the SOURCEIPHASH load balancing method.

Default value: 128

Minimum value: 1

Maximum value: 128

tolerance

Site selection tolerance, in milliseconds, for implementing the RTT load balancing method. If a site's RTT deviates from the lowest RTT by more than the specified tolerance, the site is not considered when the NetScaler appliance makes a GSLB decision. The appliance implements the round robin method of global server load balancing between sites whose RTT values are within the specified tolerance. If the tolerance is 0 (zero), the appliance always sends clients the IP address of the site with the lowest RTT.

Maximum value: 100

persistenceType

Persistence type for the virtual server. Possible value for this parameter is SOURCEIP, which specifies persistence based on the source IP address of inbound packets. After the load balancing method selects a link for transmission of the first packet, the IP address received in response to the DNS query is used for subsequent requests from the same client.

Possible values: SOURCEIP, NONE

persistenceId

The persistence ID for the GSLB virtual server. The ID is a positive integer that enables GSLB sites to identify the GSLB virtual server, and is required if source IP address based or spill over based persistence is enabled on the virtual server.

Maximum value: 65535

persistMask

The optional IPv4 network mask applied to IPv4 addresses to establish source IP address based persistence.

Default value: 0xFFFFFFFF

v6persistmasklen

Number of bits to consider in an IPv6 source IP address when creating source IP address based persistence sessions.

Default value: 128

Minimum value: 1

Maximum value: 128

timeout

Idle time, in minutes, after which a persistence entry is cleared.

Default value: 2

Minimum value: 2

Maximum value: 1440

EDR

Send clients an empty DNS response when the GSLB virtual server is DOWN.

Possible values: ENABLED, DISABLED

Default value: DISABLED

MIR

Include multiple IP addresses in the DNS responses sent to clients.

Possible values: ENABLED, DISABLED

Default value: DISABLED

disablePrimaryOnDown

Continue to direct traffic to the backup chain even after the primary GSLB virtual server returns to the UP state. Used when spillover is configured for the virtual server.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dynamicWeight

Specify if the appliance should consider the service count, service weights, or ignore both when using weight-based load balancing methods. The state of the number of services bound to the virtual server help the appliance to select the service.

Possible values: SERVICECOUNT, SERVICEWEIGHT, DISABLED

Default value: DISABLED

considerEffectiveState

If the primary state of all bound GSLB services is DOWN, consider the effective states of all the GSLB services, obtained through the Metrics Exchange Protocol (MEP), when determining the state of the GSLB virtual server. To consider the effective state, set the parameter to STATE_ONLY. To disregard the effective state, set the parameter to NONE.

The effective state of a GSLB service is the ability of the corresponding virtual server to serve traffic. The effective state of the load balancing virtual server, which is transferred to the GSLB service, is UP even if only one virtual server in the backup chain of virtual servers is in the UP state.

Possible values: NONE, STATE_ONLY

Default value: NS_GSLB_DONOT_CONSIDER_BKPS

soMethod

Type of threshold that, when exceeded, triggers spillover. Available settings function as follows:

* CONNECTION - Spillover occurs when the number of client connections exceeds the threshold.

* DYNAMICCONNECTION - Spillover occurs when the number of client connections at the GSLB virtual server exceeds the sum of the maximum client (Max Clients) settings for bound GSLB services. Do not specify a spillover threshold for this setting, because the threshold is implied by the Max Clients settings of the bound GSLB services.

Default value: 2

Minimum value: 2

Maximum value: 1440

soThreshold

Threshold at which spillover occurs. Specify an integer for the CONNECTION spillover method, a bandwidth value in kilobits per second for the BANDWIDTH method (do not enter the units), or a percentage for the HEALTH method (do not enter the percentage symbol).

Minimum value: 1

Maximum value: 4294967287

soBackupAction

Action to be performed if spillover is to take effect, but no backup chain to spillover is usable or exists

Possible values: DROP, ACCEPT, REDIRECT

serviceName

Name of the GSLB service for which to change the weight.

domainName

Domain name for which to change the time to live (TTL) and/or backup service IP address.

comment

Any comments that you might want to associate with the GSLB virtual server.

appflowLog

Enable logging appflow flow information

Possible values: ENABLED, DISABLED

Default value: ENABLED

```
set gslb vserver gvip -persistenceType SOURCEIP
```

Removes the specified settings from the specified global server load balancing (GSLB) virtual server. Attributes for which a default value is available revert to their default values..Refer to the set gslb vserver command for meanings of the arguments.

unset gslb vserver <name>@ [-backupVServer] [-dnsRecordType] [-lbMethod] [-backupLBMethod] [-netmask] [-v6netmasklen] [-tolerance] [-persistenceType] [-persistenceId] [-persistMask] [-v6persistmasklen] [-timeout] [-EDR] [-MIR] [-disablePrimaryOnDown] [-dynamicWeight] [-considerEffectiveState] [-soMethod] [-soPersistence] [-soPersistenceTimeOut] [-soBackupAction] [-serviceName] [-weight] [-comment] [-appflowLog]

unset gslb vserver lb_vip -backupVServer For multiple gslb vservers the command is: unset gslb vserver lb_vip[1-3] -backupVServer

---

Binds a domain, service, backup IP address, or cookie domain to a GSLB virtual server.

bind gslb vserver <name> ((-serviceName <string> [-weight <positive_integer>]) | (-domainName <string> [-TTL <secs>] [-backupIP <ip_addr|ipv6_addr|*>] [-cookieDomain <string>] [-cookieTimeout <mins>] [-sitedomainTTL <secs>]) | (-policyName <string>@ [-priority <positive_integer>])) [-gotoPriorityExpression <expression>]

name

Name of the virtual server on which to perform the binding operation.

serviceName

Name of the GSLB service for which to change the weight.

domainName

Domain name for which to change the time to live (TTL) and/or backup service IP address.

policyName

Name of the policy bound to the GSLB vserver.

bind gslb vserver gvip -domainName www.mynw.com

Unbinds the domain or service from the GSLB virtual server.

unbind gslb vserver <name> (-serviceName <string> | (-domainName <string> [-backupIP] [-cookieDomain]) | -policyName <string>@)

name

Name of the GSLB virtual server.

serviceName

Name of the GSLB service for which to change the weight.

domainName

Domain name for which to change the time to live (TTL) and/or backup service IP address.

policyName

The policy that has been bound to this load balancing virtual server, using the ###bind gslb vserver### command.

unbind gslb vserver gvip -domainName www.mynw.com

Enables a global server load balancing (GSLB) virtual server that has been disabled. (A GSLB virtual server is enabled by default.)

enable gslb vserver <name>@

name

Name of the GSLB virtual server to enable.

enable gslb vserver gslb_vip To enable multiple gslb vservers use the following command: enable gslb vserver gslb_vip[1-3]

Disables a global server load balancing (GSLB) virtual server and takes it out of service.

disable gslb vserver <name>@

name

Name of the GSLB virtual server to disable.

disable gslb vserver gslb_vip To disable multiple gslb vservers use the following command: disable gslb vserver gslb_vip[1-3]

Displays the parameters of all the global server load balancing (GSLB) virtual servers configured on the appliance, or the parameters of the specified GSLB virtual server.

show gslb vserver [<name>] show gslb vserver stats - alias for 'stat gslb vserver'

name

Name of the GSLB virtual server.

summary

fullValues

format

level

serviceType

Protocol used by services bound to the virtual server.

ipType

The IP type for this GSLB vserver.NOTE: This attribute is deprecated.

dnsRecordType

The IP type for this GSLB vserver.

persistenceType

Indicates if persistence is set on the gslb vserver

persistenceId

Persistence id of the gslb vserver

lbMethod

The load balancing method set for the virtual server

backupLBMethod

Indicates the backup method in case the primary fails

tolerance

Indicates the deviation we can tolerate when we have the LB method as RTT

timeout

Idle timeout for persistence entries.

state

State of the gslb vserver.

netmask

The netmask used in the SOURCEIPHASH policy.

v6netmasklen

The netmask used for ipv6 traffic in the SOURCE/DEST IPHASH policy.

persistMask

The netmask used while SOURCEIP based persistency is ENABLED.

v6persistmasklen

The netmask applied for ipv6 traffic when the persistency type is SOURCEIP.

serviceName

The service name.

weight

Weight for the service.

domainName

The name of the domain for which TTL and/or backupIP has changed.

TTL

TTL for the given domain.

backupIP

Backup IP for the given domain.

cookieDomain

cookieTimeout

Time out value of the cookie in minutes

sitedomainTTL

Site domain TTL.

IPAddress

IP address.

port

Port number.

status

Current status of the gslb vserver. During the initial phase if the configured lb method is not round robin , the vserver will adopt round robin to distribute traffic for a predefined number of requests.

lbrrreason

Reason why a vserver is in RR. The following are the reasons:

1 - MEP is DOWN (GSLB)

2 - LB method has changed

3 - Bound service's state changed to UP

4 - A new service is bound

5 - Startup RR factor has changed

6 - LB feature is enabled

7 - Load monitor is not active on a service

8 - Vserver is Enabled

9 - SSL feature is Enabled

10 - All bound services have reached threshold. Using effective state to load balance (GSLB)

11 - Primary state of bound services are not UP. Using effective state to load balance (GSLB)

12 - No LB decision can be made as all bound services have either reached threshold or are not UP (GSLB)

13 - All load monitors are active

preferredLocation

The target site to be returned in the DNS response when a policy is successfully evaluated against the incoming DNS request. Target site is specified in dotted notation with up to 6 qualifiers. Wildcard `*' is accepted as a valid qualifier token.

backupVServer

Backup vserver in case the primary fails

backupSessionTimeout

A non zero value enables the feature. The minimum value is 2 minutes. To disable the feature set the value to zero. The created session is in effect for a specific client per domain.NOTE: This attribute is deprecated.This is a deprecated attribute.

EDR

Indicates if Empty Down Response is enabled/disabled

MIR

Indicates if Multi IP Response is enabled/disabled

disablePrimaryOnDown

Continue to direct traffic to the backup chain even after the primary GSLB virtual server returns to the UP state. Used when spillover is configured for the virtual server.

dynamicWeight

Dynamic weight method. Possible values are, the svc count or the svc weights or ignore both.

isCname

is cname feature set on vserver

cumulativeWeight

Cumulative weight is the weight of GSLB service considering both its configured weight and dynamic weight. It is equal to product of dynamic weight and configured weight of the gslb service

dynamicConfWt

Weight obtained by the virtue of bound service count or weight

thresholdValue

Tells whether threshold exceeded for this service participating in CUSTOMLB

sitePersistence

Type of Site Persistence set

svrEffGslbState

Effective state of the gslb svc

gslbthreshold

Indicates if gslb svc has reached threshold

considerEffectiveState

If the primary state of all bound GSLB services is DOWN, consider the effective states of all the GSLB services, obtained through the Metrics Exchange Protocol (MEP), when determining the state of the GSLB virtual server. To consider the effective state, set the parameter to STATE_ONLY. To disregard the effective state, set the parameter to NONE.

The effective state of a GSLB service is the ability of the corresponding virtual server to serve traffic. The effective state of the load balancing virtual server, which is transferred to the GSLB service, is UP even if only one virtual server in the backup chain of virtual servers is in the UP state.

cnameEntry

The cname of the gslb service.

totalServices

Total number of services bound to the vserver.

activeServices

Total number of active services bound to the vserver.

stateChangeTimeSec

Time when last state change happened. Seconds part.

stateChangeTimemSec

Time at which last state change happened. Milliseconds part.

ticksSinceLastStateChange

Time in 10 millisecond ticks since the last state change.

comment

Any comments that you might want to associate with the GSLB virtual server.

soPersistenceTimeOut

Timeout for spillover persistence, in minutes.

soMethod

Type of threshold that, when exceeded, triggers spillover. Available settings function as follows:

* CONNECTION - Spillover occurs when the number of client connections exceeds the threshold.

* DYNAMICCONNECTION - Spillover occurs when the number of client connections at the GSLB virtual server exceeds the sum of the maximum client (Max Clients) settings for bound GSLB services. Do not specify a spillover threshold for this setting, because the threshold is implied by the Max Clients settings of the bound GSLB services.

* BANDWIDTH - Spillover occurs when the bandwidth consumed by the GSLB virtual server's incoming and outgoing traffic exceeds the threshold.

* HEALTH - Spillover occurs when the percentage of weights of the GSLB services that are UP drops below the threshold. For example, if services gslbSvc1, gslbSvc2, and gslbSvc3 are bound to a virtual server, with weights 1, 2, and 3, and the spillover threshold is 50%, spillover occurs if gslbSvc1 and gslbSvc3 or gslbSvc2 and gslbSvc3 transition to DOWN.

* NONE - Spillover does not occur.

soBackupAction

Action to be performed if spillover is to take effect, but no backup chain to spillover is usable or exists

soPersistence

If spillover occurs, maintain source IP address based persistence for both primary and backup GSLB virtual servers.

soThreshold

Threshold at which spillover occurs. Specify an integer for the CONNECTION spillover method, a bandwidth value in kilobits per second for the BANDWIDTH method (do not enter the units), or a percentage for the HEALTH method (do not enter the percentage symbol).

health

Health of vserver based on percentage of weights of active svcs/all svcs. This does not consider administratively disabled svcs

stateflag

stateflag

appflowLog

Enable logging appflow flow information

policyName

Name of the policy bound to the GSLB vserver.

priority

Priority.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

o If gotoPriorityExpression is not present or if it is equal to END then the policy bank evaluation ends here

o Else if the gotoPriorityExpression is equal to NEXT then the next policy in the priority order is evaluated.

o Else gotoPriorityExpression is evaluated. The result of gotoPriorityExpression (which has to be a number) is processed as follows:

- An UNDEF event is triggered if

. gotoPriorityExpression cannot be evaluated

. gotoPriorityExpression evaluates to number which is smaller than the maximum priority in the policy bank but is not same as any policy's priority

. gotoPriorityExpression evaluates to a priority that is smaller than the current policy's priority

- If the gotoPriorityExpression evaluates to the priority of the current policy then the next policy in the priority order is evaluated.

- If the gotoPriorityExpression evaluates to the priority of a policy further ahead in the list then that policy will be evaluated next.

This field is applicable only to rewrite and responder policies.

type

The bindpoint to which the policy is bound

devno

count

show gslb vserver gvip

Displays statistics associated with a global server load balancing (GSLB) virtual server.

stat gslb vserver [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

name

Name of the GSLB virtual server for which to display statistics. If you do not specify a name, statistics are displayed for all GSLB virtual servers.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Current Client Est connections (ClntEstConn)

Number of client connections in ESTABLISHED state.

total INACTIVE services (inactSvcs)

number of INACTIVE services bound to a vserver

Vserver Health (Health)

Health of the vserver. This gives percentage of UP services bound to this vserver.

Vserver protocol (Protocol)

Protocol associated with the vserver

State

Current state of the server. Possible values are UP, DOWN, UNKNOWN, OFS(Out of Service), TROFS(Transition Out of Service), TROFS_DOWN(Down When going Out of Service)

total ACTIVE services (actSvcs)

number of ACTIVE services bound to a vserver

Vserver hits (Hits)

Total vserver hits

Request bytes (Reqb)

Total number of request bytes received on this service or virtual server.

Response bytes (Rspb)

Number of response bytes received by this service or virtual server.

Spill Over Threshold (SOThresh)

Spill Over Threshold set on the VServer.

Spill Over Hits (NumSo)

Number of times vserver experienced spill over.

Requests (Req)

Total number of requests received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Responses (Rsp)

Number of responses received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Current client connections (ClntConn)

Number of current client connections.

Current server connections (SvrConn)

Number of current connections to the actual servers behind the virtual server.

Current Server Est connections (SvrEstConn)

Number of server connections in ESTABLISHED state.

Renames a global server load balancing (GSLB) virtual server.

rename gslb vserver <name>@ <newName>@

name

Existing name of the GSLB virtual server.

newName

New name for the GSLB virtual server.

```
rename gslb vserver gsl_vsvr gslb_vsvr_new
```

High Availability Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- HA failover
- HA files
- HA node
- HA sync

HA failover

Sep 22, 2015

The following operations can be performed on "HA failover":

Forces an HA failover. Can be initiated from either node. A forced failover is not propagated or synchronized., Note: This command fails under any of the following conditions: * The secondary node is disabled or configured to remain secondary. * The primary node is configured to remain primary. * The state of the peer node is unknown. * You run the command on a standalone appliance.

force HA failover [-force]

force

Force a failover without prompting for confirmation.

HA files

Sep 22, 2015

The following operations can be performed on "HA files":

Synchronize various configuration files from the primary node to the secondary. You can run this command from either node. Files that are present on only the secondary and are specific to the secondary are not deleted. This command fails if the secondary node is disabled, the secondary node is not accessible from the primary, or you enter the command on a standalone appliance.

sync HA files [<Mode> ...]

Mode

Specify one of the following modes of synchronization.

* all - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, and Application Firewall XML objects.

* bookmarks - Synchronize all Access Gateway bookmarks.

* ssl - Synchronize all certificates, keys, and CRLs for the SSL feature.

* htmlinjection. Synchronize all scripts configured for the HTML injection feature.

* imports. Synchronize all XML objects (for example, WSDLs, schemas, error pages) configured for the application firewall.

* misc - Synchronize all license files and the rc.conf file.

* all_plus_misc - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, application firewall XML objects, licenses, and the rc.conf file.

sync files all

HA node

Sep 22, 2015

The following operations can be performed on "HA node":

add | rm | set | unset | bind | unbind | show | stat

Adds a peer node to an HA configuration. Each node must add the other as a peer. An algorithm determines which node becomes primary and which becomes secondary.

add HA node <id> <IPAddress> [-inc (ENABLED | DISABLED)]

id

Number that uniquely identifies the node. For self node, it will always be 0. Peer node values can range from 1-64.

Minimum value: 1

Maximum value: 64

IPAddress

The NSIP or NSIP6 address of the node to be added for an HA configuration. This setting is neither propagated nor synchronized.

inc

This option is required if the HA nodes reside on different networks. When this mode is enabled, the following independent network entities and configurations are neither propagated nor synced to the other node: MIPs, SNIPs, VLANs, routes (except LLB routes), route monitors, RNAT rules (except any RNAT rule with a VIP as the NAT IP), and dynamic routing configurations. They are maintained independently on each node.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Removes the peer node from the HA configuration. To completely remove both the nodes from the HA configuration, you have to log on to each node and remove its peer node.

rm HA node <id>

id

Number that uniquely identifies the peer node.

CLI users: To learn the ID of the peer node, run the show HA node command on the local node.

Maximum value: 64

Sets the specified HA related parameters for the node. The settings are neither propagated nor synchronized to the peer node.

set HA node [-haStatus <haStatus>] [-haSync (ENABLED | DISABLED)] [-haProp (ENABLED | DISABLED)] [-helloInterval <msecs>] [-deadInterval <secs>] [-failSafe (ON | OFF)] [-maxFlips <positive_integer>] [-maxFlipTime <positive_integer>] [-syncvlan <positive_integer>]

id

Number that uniquely identifies the node. For self node, it will always be 0. Peer node values can range from 1-64.

Maximum value: 64

haStatus

The HA status of the node. The HA status STAYSECONDARY is used to force the secondary device stay as secondary independent of the state of the Primary device. For example, in an existing HA setup, the Primary node has to be upgraded and this process would take few seconds. During the upgradation, it is possible that the Primary node may suffer from a downtime for a few seconds. However, the Secondary should not take over as the Primary node. Thus, the Secondary node should remain as Secondary even if there is a failure in the Primary node.

STAYPRIMARY configuration keeps the node in primary state in case if it is healthy, even if the peer node was the primary node initially. If the node with STAYPRIMARY setting (and no peer node) is added to a primary node (which has this node as the peer) then this node takes over as the new primary and the older node becomes secondary. ENABLED state means normal HA operation without any constraints/preferences. DISABLED state disables the normal HA operation of the node.

Possible values: ENABLED, STAYSECONDARY, DISABLED, STAYPRIMARY

haSync

Automatically maintain synchronization by duplicating the configuration of the primary node on the secondary node. This setting is not propagated. Automatic synchronization requires that this setting be enabled (the default) on the current secondary node. Synchronization uses TCP port 3010.

Possible values: ENABLED, DISABLED

Default value: ENABLED

haProp

Automatically propagate all commands from the primary to the secondary node, except the following:

* All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.

* All Interface related commands. For example, set interface and unset interface.

* All channels related commands. For example, add channel, set channel, and bind channel.

The propagated command is executed on the secondary node before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

Note: After enabling propagation, run force synchronization on either node.

Possible values: ENABLED, DISABLED

Default value: ENABLED

helloInterval

Interval, in milliseconds, between heartbeat messages sent to the peer node. The heartbeat messages are UDP packets sent to port 3003 of the peer node.

Default value: 200

Minimum value: 200

Maximum value: 1000

deadInterval

Number of seconds after which a peer node is marked DOWN if heartbeat messages are not received from the peer node.

Default value: 3

Minimum value: 3

Maximum value: 60

failSafe

Keep one node primary if both nodes fail the health check, so that a partially available node can back up data and handle traffic. This mode is set independently on each node.

Possible values: ON, OFF

Default value: OFF

maxFlips

Max number of flips allowed before becoming sticky primary

maxFlipTime

Interval after which flipping of node states can again start

syncvlan

Vlan on which HA related communication is sent. This include sync, propagation , connection mirroring , LB persistency config sync, persistent session sync and session state sync. However HA heartbeats can go all interfaces.

Minimum value: 1

Maximum value: 4094

Use this command to remove HA node settings.Refer to the set HA node command for meanings of the arguments.

unset HA node [-haStatus] [-haSync] [-haProp] [-helloInterval] [-deadInterval] [-failSafe] [-maxFlips] [-maxFlipTime] [-syncvlan]

Adds a route monitor to the local node. When a NetScaler appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes. Route Monitors are supported both in non-INC and INC modes.

bind HA node [<id>] (-routeMonitor <ip_addr|ipv6_addr|*> [<netmask>])

id

Number that uniquely identifies the local node. The ID of the local node is always 0.

Maximum value: 64

routeMonitor

A route that you want the NetScaler appliance to monitor in its internal routing table. You can specify an IPv4 address or network, or an IPv6 address or network prefix. If you specify an IPv4 network address or IPv6 network prefix, the appliance monitors any route that matches the network or prefix.

Removes a route monitor entry from the local node. The NetScaler appliance stops monitoring the route in its internal routing table.

unbind HA node [<id>] (-routeMonitor <ip_addr|ipv6_addr|*> [<netmask>])

id

Number that uniquely identifies the local node. The ID of the local node is always 0.

Maximum value: 64

routeMonitor

The route specified in the route monitor entry that you want to remove from the NetScaler appliance. Can be an IPv4 address or network, or an IPv6 address or network prefix.

Displays the HA settings of both nodes or, if you specify a node, just the specified node. You can use this command to display the master state (primary or secondary) of the nodes in a HA configuration.

show HA node [<id>]

id

ID of the node whose HA settings you want to display. (The ID of the local node is always 0.)

Maximum value: 64

summary

fullValues

format

level

name

Node Name.

IPAddress

IP Address of the node.

flags

The flags for this entry.

stateflag

haStatus

HA status.

state

HA Master State.

haSync

HA Sync State.

haProp

HA Propagation Status.

enaifaces

Enabled interfaces.

disifaces

Disabled interfaces.

hamonifaces

HAMON ON interfaces.

pfifaces

Interfaces causing Partial Failure.

ifaces

Interfaces on which non-multicast is not seen.

network

The network.

netmask

The netmask.

inc

INC state.

ssl2

SSL card status.

helloInterval

Hello Interval.

deadInterval

Dead Interval.

masterStateTime

Time elapsed in current master state

failSafe

Keep one node primary if both nodes fail the health check, so that a partially available node can back up data and handle traffic. This mode is set independently on each node.

routeMonitor

The IP address (IPv4 or IPv6).

maxFlips

Max number of flips allowed before becoming sticky primary

maxFlipTime

Interval after which flipping of node states can again start

curFlips

Keeps track of number of flips that have happened till now in current interval

completedFlipTime

To inform user whether flip time is elapsed or not

syncvlan

Vlan on which HA related communication is sent. This include sync, propagation , connection mirroring , LB persistency config sync, persistent session sync and session state sync. However HA heartbeats can go all interfaces.

routeMonitorState

State for route monitor

devno

count

An example of the command's output is as follows: 2 configured nodes: 1) Node ID: 0 IP: 192.168.100.5 Primary node 2) Node ID: 2 IP

Display the statistics related to HA configuration.

stat HA node [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

High Availability (HA)

Whether a NetScaler appliance is configured for high availability. Possible values are YES and NO. If the value is NO, the high availability statistics below are invalid.

System state (HAState)

State of the HA node, based on its health, in a high availability setup. Possible values are:

UP ? Indicates that the node is accessible and can function as either a primary or secondary node.

DISABLED ? Indicates that the high availability status of the node has been manually disabled. Synchronization and propagation cannot take place between the peer nodes.

INIT ? Indicates that the node is in the process of becoming part of the high availability configuration.

PARTIALFAIL ? Indicates that one of the high availability monitored interfaces has failed because of a card or link failure. This state triggers a failover.

COMPLETEFAIL ? Indicates that all the interfaces of the node are unusable, because the interfaces on which high availability monitoring is enabled are not connected or are manually disabled. This state triggers a failover.

DUMB ? Indicates that the node is in listening mode. It does not participate in high availability transitions or transfer configuration from the peer node. This is a configured value, not a statistic.

PARTIALFAILSSL ? Indicates that the SSL card has failed. This state triggers a failover.

ROUTEMONITORFAIL ? Indicates that the route monitor has failed. This state triggers a failover.

Master state (mastate)

Indicates the high availability state of the node. Possible values are:

STAYSECONDARY ? Indicates that the selected node remains the secondary node in a high availability setup. In this case a forced failover does not change the state but, instead, returns an appropriate error message. This is a configured value and not a statistic.

PRIMARY ? Indicates that the selected node is the primary node in a high availability setup.

SECONDARY ? Indicates that the selected node is the secondary node in a high availability setup.

CLAIMING ? Indicates that the secondary node is in the process of taking over as the primary node. This is the intermediate state in the transition of the secondary node to primary status.

FORCE CHANGE - Indicates that the secondary node is forcibly changing its status to primary due to a forced failover issued on the secondary node.

Last Transition time (TransTime)

Time when the last master state transition occurred. You can use this statistic for debugging.

Heartbeats received (HApktrx)

Number of heartbeat packets received from the peer node. Heartbeats are sent at regular intervals (default is 200 milliseconds) to determine the state of the peer node.

Heartbeats sent (HApkttx)

Number of heartbeat packets sent to the peer node. Heartbeats are sent at regular intervals (default is 200 milliseconds) to determine the state of

the peer node.

Propagation timeouts (ptimeout)

Number of times propagation timed out.

Sync failure (syncfail)

Number of times the configuration of the primary and secondary nodes failed to synchronize since that last transition. A synchronization failure results in mismatched configuration. It can be caused by a mismatch in the Remote Procedural Call (RPC) password on the two nodes forming the high availability pair.

HA sync

Sep 22, 2015

The following operations can be performed on "HA sync":

Forces duplication of the primary node's configuration on the secondary node. Can be executed from either node. Note: This command fails under any of the following conditions: * Synchronization is already in progress. * The secondary node is disabled. * Synchronization is disabled on either node * The secondary node is not accessible from the primary. * You run the command on a standalone appliance.

force HA sync [-force [-save (YES | NO)]]

force

Force synchronization regardless of the state of HA propagation and HA synchronization on either node.

save

After synchronization, automatically save the configuration in the secondary node configuration file (ns.conf) without prompting for confirmation.

Possible values: YES, NO

Default value: VAL_NOT_SET

Can be used in following formats: >force sync <cr> >force sync -force <cr> >force sync -force -save [yes|no]<cr>

IPSec Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- ipsec counters
- ipsec parameter
- ipsec profile

ipsec counters

Sep 22, 2015

The following operations can be performed on "ipsec counters":

stat ipsec counters

Display statistics for secure tunnel sessions.

Synopsys

stat ipsec counters [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

Bytes Received (ipsecRxBytes)

Bytes received during IPsec sessions.

Bytes Sent (ipsecTxBytes)

Bytes sent during IPsec sessions.

Packets Received (ipsecRxPkts)

Packets received during IPsec sessions.

Packets Sent (ipsecTxPkts)

Packets sent during IPsec sessions.

Example

stat ipsec

ipsec parameter

Sep 22, 2015

The following operations can be performed on "ipsec parameter":

set | unset | show

set ipsec parameter

Set global parameters for IPSEC

Synopsys

set ipsec parameter [-ikeVersion (V1 | V2)] [-encAlgo (AES | 3DES) ...] [-hashAlgo <hashAlgo> ...] [-lifetime <positive_integer>] [-livenessCheckInterval <positive_integer>] [-replayWindowSize <positive_integer>] [-ikeRetryInterval <positive_integer>] [-retransmissiontime <positive_integer>]

Arguments

ikeVersion

IKE Protocol Version

Possible values: V1, V2

Default value: KMP_IKEV2

encAlgo

Type of encryption algorithm

Default value: ENC_AES

hashAlgo

Type of hashing algorithm

Default value: HMAC_SHA256

lifetime

Lifetime of SA in seconds

Minimum value: 60

Maximum value: 31536000

livenessCheckInterval

Number of seconds after which a notify payload is sent to check the liveliness of the peer. Additional retries are done as per retransmit interval setting. Zero value disables liveliness checks.

Maximum value: 64999

replayWindowSize

IPSec Replay window size for the data traffic

Maximum value: 16384

ikeRetryInterval

IKE retry interval for bringing up the connection

Minimum value: 60

Maximum value: 3600

retransmissiontime

The interval in seconds to retry sending the IKE messages to peer, three consecutive attempts are done with doubled interval after every failure.,

increases for every retransmit till 6 retransmits.

Minimum value: 1

Maximum value: 99

---

unset ipsec parameter

Set global parameters for IPSEC.Refer to the set ipsec parameter command for meanings of the arguments.

Synopsys

unset ipsec parameter [-ikeVersion] [-encAlgo] [-hashAlgo] [-lifetime] [-livenessCheckInterval] [-replayWindowSize] [-ikeRetryInterval] [-retransmissiontime]

---

show ipsec parameter

Show global parameters for IPSEC

Synopsys

show ipsec parameter

Arguments

summary

fullValues

format

level

Outputs

ikeVersion

IKE Protocol Version

encAlgo

Type of encryption algorithm

hashAlgo

Type of hashing algorithm

lifetime

Lifetime of SA in seconds

livenessCheckInterval

Number of seconds after which a notify payload is sent to check the liveliness of the peer. Additional retries are done as per retransmit interval setting. Zero value disables liveliness checks.

replayWindowSize

IPSec Replay window size for the data traffic

ikeRetryInterval

IKE retry interval for bringing up the connection

retransmissiontime

The interval in seconds to retry sending the IKE messages to peer, three consecutive attempts are done with doubled interval after every failure.,

increases for every retransmit till 6 retransmits.

ipsec profile

Sep 22, 2015

The following operations can be performed on "ipsec profile":

add | show | rm

add ipsec profile

Add an ipsec profile.

Synopsys

add ipsec profile <name> [-ikeVersion (V1 | V2)] [-encAlgo (AES | 3DES) ...] [-hashAlgo <hashAlgo> ...] [-lifetime <positive_integer>] (-psk | (-publickey <string> -privatekey <string> -peerPublicKey <string>)) [-livenessCheckInterval <positive_integer>] [-replayWindowSize <positive_integer>] [-ikeRetryInterval <positive_integer>] [-retransmissiontime <positive_integer>]

Arguments

name

The name of the ipsec profile

ikeVersion

IKE Protocol Version

Possible values: V1, V2

encAlgo

Type of encryption algorithm

hashAlgo

Type of hashing algorithm

lifetime

Lifetime of SA in seconds

Minimum value: 60

Maximum value: 31536000

psk

Pre shared key value

publickey

Public key file path

livenessCheckInterval

Number of seconds after which a notify payload is sent to check the liveliness of the peer. Additional retries are done as per retransmit interval setting. Zero value disables liveliness checks.

Maximum value: 64999

replayWindowSize

IPSec Replay window size for the data traffic

Maximum value: 16384

ikeRetryInterval

IKE retry interval for bringing up the connection

Minimum value: 60

Maximum value: 3600

retransmissiontime

The interval in seconds to retry sending the IKE messages to peer, three consecutive attempts are done with doubled interval after every failure.

Minimum value: 1

Maximum value: 99

---

show ipsec profile

Display all of the configured ipsec peers

Synopsys

show ipsec profile [<name>]

Arguments

name

The name of the ipsec profile

summary

fullValues

format

level

Outputs

ikeVersion

IKE Protocol Version

encAlgo

Type of encryption algorithm.

hashAlgo

Type of hashing algorithm

lifetime

Lifetime of SA in seconds

livenessCheckInterval

Number of seconds after which a notify payload is sent to check the liveliness of the peer. Additional retries are done as per retransmit interval setting. Zero value disables liveliness checks.

replayWindowSize

IPSec Replay window size for the data traffic

retransmissiontime

The interval in seconds to retry sending the IKE messages to peer, three consecutive attempts are done with doubled interval after every failure.

psk

Pre shared key value

publickey

Public key file path

privatekey

Private key file path

peerPublicKey

Peer public key file path

ikeRetryInterval

IKE retry interval for bringing up the connection

builtin

Indicates that a variable is a built-in (SYSTEM INTERNAL) type.

devno

count

stateflag

Example

show ipsec profile

---

rm ipsec profile

Remove an ipsec peer

Synopsys

rm ipsec profile <name>

Arguments

name

The name of the ipsec profile.

Example

rm ipsec profile

Load Balancing Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- lb group
- lb metricTable
- lb monbindings
- lb monitor
- lb parameter
- lb persistentSessions
- lb route
- lb route6
- lb sipParameters
- lb vserver
- lb wlm

lb group

Sep 22, 2015

The following operations can be performed on "lb group":

set | unset | bind | unbind | show | rename

set lb group

Configures persistence for the specified load balancing group. The persistence settings are applied to all the members of the group.

Synopsys

set lb group <name>@ [-persistenceType <persistenceType>] [-persistenceBackup (SOURCEIP | NONE)] [-backupPersistenceTimeout <mins>] [-persistMask <netmask>] [-cookieName <string>] [-v6persistmasklen <positive_integer>] [-cookieDomain <string>] [-timeout <mins>] [-rule <expression>]

Arguments

name

Name of the load balancing virtual server group.

persistenceType

Type of persistence for the group. Available settings function as follows:

* SOURCEIP - Create persistence sessions based on the client IP.

* COOKIEINSERT - Create persistence sessions based on a cookie in client requests. The cookie is inserted by a Set-Cookie directive from the server, in its first response to a client.

* RULE - Create persistence sessions based on a user defined rule.

* NONE - Disable persistence for the group.

Possible values: SOURCEIP, COOKIEINSERT, RULE, NONE

persistenceBackup

Type of backup persistence for the group.

Possible values: SOURCEIP, NONE

backupPersistenceTimeout

Time period, in minutes, for which backup persistence is in effect.

Default value: 2

Minimum value: 2

Maximum value: 1440

persistMask

Persistence mask to apply to source IPv4 addresses when creating source IP based persistence sessions.

Default value: 0xFFFFFFFF

cookieName

Use this parameter to specify the cookie name for COOKIE peristence type. It specifies the name of cookie with a maximum of 32 characters. If not specified, cookie name is internally generated.

v6persistmasklen

Persistence mask to apply to source IPv6 addresses when creating source IP based persistence sessions.

Default value: 128

Minimum value: 1

Maximum value: 128

cookieDomain

Domain attribute for the HTTP cookie.

timeout

Time period for which a persistence session is in effect.

Default value: 2

Maximum value: 1440

rule

Expression, or name of a named expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: "'<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

Default value: "None"

Example

set lb group webgrp -persistenceType COOKIEINSERT To set the persistence type for multiple groups use the following command: set lb group webgrp[1-3] -persisten

---

unset lb group

Use this command to remove lb group settings.Refer to the set lb group command for meanings of the arguments.

Synopsys

unset lb group <name>@ [-persistenceType] [-persistenceBackup] [-backupPersistenceTimeout] [-persistMask] [-cookieName] [-v6persistmasklen] [-cookieDomain] [-timeout] [-rule]

---

bind lb group

Binds one or more virtual servers to a load balancing virtual server group. If the specified group does not exist, the NetScaler appliance first creates the group, and then binds the virtual servers to it. A virtual server group enables you to specify common persistence settings for all of its members through a single set lb group command. Only address-based virtual servers can be added to a group. Content-based virtual servers (content switching and cache redirection virtual servers) cannot be added. A virtual server can be assigned to only one group at any given time. To move a virtual server from one group to another, the virtual server must first be unbound from the group to which it belongs.

Synopsys

bind lb group <name>@ <vServerName>@ ...

Arguments

name

Name for the load balancing virtual server group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the virtual server is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my lbgroup" or 'my lbgroup').

vServerName

Name of the virtual server to bind to the group. Multiple names can be specified.

Example

bind lb group webgrp http_vip To bind multiple vservers to a group use the following command: bind lb group webgrp v[1-4] To bind vserver v1 to group webgrp1, v2 to w

---

unbind lb group

Unbinds one or more virtual servers from a group. When the last virtual server is unbound, the group is removed.

Synopsys

unbind lb group <name> <vServerName>@ ...

Arguments

name

Name of the load balancing virtual server group.

vServerName

Name of the virtual server to unbind. Multiple names can be specified.

Example

unbind lb group webgroup http_vip To unbind multiple vservers use the following command: unbind lb group webgroup v[1-3]

---

show lb group

Displays the virtual servers bound to the specified group.

Synopsys

show lb group [<name>]

Arguments

name

Name of the load balancing virtual server group.

summary

fullValues

format

level

Outputs

vServerName

Virtual server name.

persistenceType

The type of the persistence set for the group.

persistenceBackup

The type of the backup persistence set for the group.

backupPersistenceTimeout

Time period, in minutes, for which backup persistence is in effect.

persistMask

The netmask applied for ipv4 traffic when the persistency type is SOURCEIP.

v6persistmasklen

The netmask applied for ipv6 traffic when the persistency type is SOURCEIP.

cookieName

Use this parameter to specify the cookie name for COOKIE peristence type. It specifies the name of cookie with a maximum of 32 characters. If not specified, cookie name is internally generated.

cookieDomain

Domain attribute for the HTTP cookie.

timeout

Time period for which a persistence session is in effect.

rule

Rule type.

td

Traffic Domain ID

stateflag

devno

count

Example

show lb group webgrp

---

rename lb group

Renames a load balancing virtual server group.

Synopsys

rename lb group <name>@ <newName>@

Arguments

name

Existing name of the load balancing virtual server group.

newName

New name for the load balancing virtual server group.

Example

```
rename lb group gv1 gv-new1
```

lb metricTable

Sep 22, 2015

The following operations can be performed on "lb metricTable":

add | rm | set | bind | unbind | show

add lb metricTable

Creates a metric table for load monitoring.

Synopsys

add lb metricTable <metricTable>

Arguments

metricTable

Name for the metric table. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my metrictable" or 'my metrictable').

Example

```
add metrictable newtable
```

---

rm lb metricTable

Removes a metric table.

Synopsys

rm lb metricTable <metricTable>

Arguments

metricTable

Name of the metric table.

Example

```
rm metric table netscaler
```

---

set lb metricTable

Modifies the SNMP OID of a metric in a metric table.

Synopsys

set lb metricTable <metricTable> <metric> <snmpOID>

Arguments

metricTable

Name of the metric table.

Example

```
set metrictable table met1 aliasname oidstr
```

---

bind lb metricTable

Binds a metric to a metric table. You must also specify the SNMP OID of the metric.

Synopsys

bind lb metricTable <metricTable> <metric> <snmpOID>

Arguments

metricTable

Name of the metric table.

metric

Name of the metric.

Example

bind metrictable tablename aliasname 1.2.3.4

---

unbind lb metricTable

Unbinds a metric from a metric table.

Synopsys

unbind lb metricTable <metricTable> <metric>

Arguments

metricTable

Name of the metric table.

metric

Name of the metric to unbind.

Example

unbind metrictable tablename aliasname

---

show lb metricTable

Displays the parameters of the specified metric table. If no metric table name is specified, a list of all configured metric tables is displayed.

Synopsys

show lb metricTable [<metricTable>]

Arguments

metricTable

Name of the metric table.

summary

fullValues

format

level

Outputs

metric

Metric name of the oid.

snmpOID

OID corresponding to the metric

flags

flags controlling displayNOTE: This attribute is deprecated.This is deprecated attribute.

stateflag

flags controlling display

metricType

Indication if it is a configured or internal

type

Adds a temporary or permanent table.

Example

An example of the show metrictable command output is as follows: Name : ALTEON Type : INTERNAL Name : CISCO-

---

lb monbindings

Sep 22, 2015

The following operations can be performed on "lb monbindings":

show lb monbindings

Display the services to which this monitor is bound

Synopsys

show lb monbindings <monitorName>

Arguments

monitorName

The name of the monitor.

summary

fullValues

Outputs

type

The type of monitor.

state

The state of the monitor.

boundServiceGroupSvrState

The state of the servicegroup.

monsvcState

The configured state (enable/disable) of Monitor on this service.

monState

The configured state (enable/disable) of Monitor on this service.

IPAddress

The IPAddress of the service.

port

The port of the service.

serviceName

The name of the service.

serviceGroupName

The name of the service group.

serviceType

The type of service

svrState

The state of the service

stateflag

devno

count

lb monitor

Sep 22, 2015

The following operations can be performed on "lb monitor":

add | rm | set | unset | enable | disable | bind | unbind | show

add lb monitor

Creates a monitor that you can bind to load balancing services. The monitor periodically sends probes to those services to test their availability.

Synopsys

add lb monitor <monitorName> <type> [-action <action>] [-respCode <int[-int]> ...] [-httpRequest <string>] [-rtspRequest <string>] [-customHeaders <string>] [-maxForwards <positive_integer>] [-sipMethod <sipMethod>] [-sipURI <string>] [-sipregURI <string>] [-send <string>] [-recv <string>] [-query <string>] [-queryType <queryType>] [-scriptName <string>] [-scriptArgs <string>] [-dispatcherIP <ip_addr>] [-dispatcherPort <port>] [-userName <string>] {-password } {-secondaryPassword } [-logonpointName <string>] [-lasVersion <string>] {-radKey } [-radNASid <string>] [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-radAccountSession <string>] [-LRTM (ENABLED | DISABLED)] [-deviation <positive_integer> [<units>]] [-interval <integer> [<units>]] [-resptimeout <integer> [<units>]] [-resptimeoutThresh <positive_integer>] [-retries <integer>] [-failureRetries <integer>] [-alertRetries <integer>] [-successRetries <integer>] [-downTime <integer> [<units>]] [-destIP <ip_addr|ipv6_addr>] [-destPort <port>] [-state (ENABLED | DISABLED)] [-reverse (YES | NO)] [-transparent (YES | NO)] [-ipTunnel (YES | NO)] [-tos (YES | NO)] [-tosId <positive_integer>] [-secure (YES | NO)] [-validateCred (YES | NO)] [-domain <string>] [-IPAddress <ip_addr|ipv6_addr|*> ...] [-group <string>] [-fileName <string>] [-baseDN <string>] [-bindDN <string>] [-filter <string>] [-attribute <string>] [-database <string>] [-sqlQuery <text>] [-evalRule <expression>] [-mssqlProtocolVersion <mssqlProtocolVersion>] [-snmpOID <string>] [-snmpCommunity <string>] [-snmpThreshold <string>] [-snmpVersion (V1 | V2)] [-metricTable <string>] [-application <string>] [-sitePath <string>] [-storename <string>] [-storefrontacctservice (YES | NO)] [-netProfile <string>] [-originHost <string>] [-originRealm <string>] [-hostIPAddress <ip_addr|ipv6_addr|*>] [-vendorId <positive_integer>] [-productName <string>] [-firmwareRevision <positive_integer>] [-authApplicationId <positive_integer> ...] [-acctApplicationId <positive_integer> ...] [-inbandSecurityId (NO_INBAND_SECURITY | TLS)] [-supportedVendorIds <positive_integer> ...] [-vendorSpecificVendorId <positive_integer> [-vendorSpecificAuthApplicationIds <positive_integer> ...] [-vendorSpecificAcctApplicationIds <positive_integer> ...]] [-kcdAccount <string>] [-storedb (ENABLED | DISABLED)]

Arguments

monitorName

Name for the monitor. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my monitor" or 'my monitor').

type

Type of monitor that you want to create.

Possible values: PING, TCP, HTTP, TCP-ECV, HTTP-ECV, UDP-ECV, DNS, FTP, LDNS-PING, LDNS-TCP, LDNS-DNS, RADIUS, USER, HTTP-INLINE, SIP-UDP, LOAD, FTP-EXTENDED, SMTP, SNMP, NNTP, MYSQL, MYSQL-ECV, MSSQL-ECV, ORACLE-ECV, LDAP, POP3, CITRIX-XML-SERVICE, CITRIX-WEB-INTERFACE, DNS-TCP, RTSP, ARP, CITRIX-AG, CITRIX-AAC-LOGINPAGE, CITRIX-AAC-LAS, CITRIX-XD-DDC, ND6, CITRIX-WI-EXTENDED, DIAMETER, RADIUS_ACCOUNTING, STOREFRONT

action

Action to perform when the response to an inline monitor (a monitor of type HTTP-INLINE) indicates that the service is down. A service monitored by an inline monitor is considered DOWN if the response code is not one of the codes that have been specified for the Response Code parameter.

Available settings function as follows:

* NONE - Do not take any action. However, the show service command and the show lb monitor command indicate the total number of responses that were checked and the number of consecutive error responses received after the last successful probe.

* LOG - Log the event in NSLOG or SYSLOG.

* DOWN - Mark the service as being down, and then do not direct any traffic to the service until the configured down time has expired. Persistent connections to the service are terminated as soon as the service is marked as DOWN. Also, log the event in NSLOG or SYSLOG.

Possible values: NONE, LOG, DOWN

Default value: SM_DOWN

respCode

Response codes for which to mark the service as UP. For any other response code, the action performed depends on the monitor type. HTTP monitors and RADIUS monitors mark the service as DOWN, while HTTP-INLINE monitors perform the action indicated by the Action parameter.

httpRequest

HTTP request to send to the server (for example, "HEAD /file.html").

rtspRequest

RTSP request to send to the server (for example, "OPTIONS *").

customHeaders

Custom header string to include in the monitoring probes.

maxForwards

Maximum number of hops that the SIP request used for monitoring can traverse to reach the server. Applicable only to monitors of type SIP-UDP.

Default value: 1

Maximum value: 255

sipMethod

SIP method to use for the query. Applicable only to monitors of type SIP-UDP.

Possible values: OPTIONS, INVITE, REGISTER

sipURI

SIP URI string to send to the service (for example, sip:sip.test). Applicable only to monitors of type SIP-UDP.

sipregURI

SIP user to be registered. Applicable only if the monitor is of type SIP-UDP and the SIP Method parameter is set to REGISTER.

send

String to send to the service. Applicable to TCP-ECV, HTTP-ECV, and UDP-ECV monitors.

recv

String expected from the server for the service to be marked as UP. Applicable to TCP-ECV, HTTP-ECV, and UDP-ECV monitors.

query

Domain name to resolve as part of monitoring the DNS service (for example, example.com).

queryType

Type of DNS record for which to send monitoring queries. Set to Address for querying A records, AAAA for querying AAAA records, and Zone for querying the SOA record.

Possible values: Address, Zone, AAAA

scriptName

Path and name of the script to execute. The script must be available on the NetScaler appliance, in the /nsconfig/monitors/ directory.

scriptArgs

String of arguments for the script. The string is copied verbatim into the request.

dispatcherIP

IP address of the dispatcher to which to send the probe.

dispatcherPort

Port number on which the dispatcher listens for the monitoring probe.

userName

User name with which to probe the RADIUS, NNTP, FTP, FTP-EXTENDED, MYSQL, MSSQL, POP3, CITRIX-AG, CITRIX-XD-DDC, or CITRIX-WI-EXTENDED server.

password

Password that is required for logging on to the RADIUS, NNTP, FTP, FTP-EXTENDED, MYSQL, MSSQL, POP3, CITRIX-AG, CITRIX-XD-DDC, or CITRIX-WI-EXTENDED server. Used in conjunction with the user name specified for the User Name parameter.

secondaryPassword

Secondary password that users might have to provide to log on to the Access Gateway server. Applicable to CITRIX-AG monitors.

logonpointName

Name of the logon point that is configured for the Citrix Access Gateway Advanced Access Control software. Required if you want to monitor the associated login page or Logon Agent. Applicable to CITRIX-AAC-LAS and CITRIX-AAC-LOGINPAGE monitors.

lasVersion

Version number of the Citrix Advanced Access Control Logon Agent. Required by the CITRIX-AAC-LAS monitor.

radKey

Authentication key (shared secret text string) for RADIUS clients and servers to exchange. Applicable to monitors of type RADIUS and RADIUS_ACCOUNTING.

radNASid

NAS-Identifier to send in the Access-Request packet. Applicable to monitors of type RADIUS.

radNASip

Network Access Server (NAS) IP address to use as the source IP address when monitoring a RADIUS server. Applicable to monitors of type RADIUS and RADIUS_ACCOUNTING.

radAccountType

Account Type to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

Default value: 1

Maximum value: 15

radFramedIP

Source ip with which the packet will go out . Applicable to monitors of type RADIUS_ACCOUNTING.

radAPN

Called Station Id to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radMSISDN

Calling Stations Id to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radAccountSession

Account Session ID to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

LRTM

Calculate the least response times for bound services. If this parameter is not enabled, the appliance does not learn the response times of the bound services. Also used for LRTM load balancing.

Possible values: ENABLED, DISABLED

deviation

Time value added to the learned average response time in dynamic response time monitoring (DRTM). When a deviation is specified, the appliance learns the average response time of bound services and adds the deviation to the average. The final value is then continually adjusted to accommodate response time variations over time. Specified in milliseconds, seconds, or minutes.

Maximum value: 20939000

interval

Time interval between two successive probes. Must be greater than the value of Response Time-out.

Default value: 5

Minimum value: 1

Maximum value: 20940000

resptimeout

Amount of time for which the appliance must wait before it marks a probe as FAILED. Must be less than the value specified for the Interval parameter.

Note: For UDP-ECV monitors for which a receive string is not configured, response timeout does not apply. For UDP-ECV monitors with no receive string, probe failure is indicated by an ICMP port unreachable error received from the service.

Default value: 2

Minimum value: 1

Maximum value: 20939000

resptimeoutThresh

Response time threshold, specified as a percentage of the Response Time-out parameter. If the response to a monitor probe has not arrived when the threshold is reached, the appliance generates an SNMP trap called monRespTimeoutAboveThresh. After the response time returns to a value below the threshold, the appliance generates a monRespTimeoutBelowThresh SNMP trap. For the traps to be generated, the "MONITOR-RTO-THRESHOLD" alarm must also be enabled.

Maximum value: 100

retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe failed.

Default value: 3

Minimum value: 1

Maximum value: 127

failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the ten probes sent, at least six probes must fail if the service is to be marked as DOWN. The default value of 0 means that all the retries must fail if the service is to be marked as DOWN.

Maximum value: 32

alertRetries

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

Maximum value: 32

successRetries

Number of consecutive successful probes required to transition a service's state from DOWN to UP.

Default value: 1

Minimum value: 1

Maximum value: 32

downTime

Time duration for which to wait before probing a service that has been marked as DOWN. Expressed in milliseconds, seconds, or minutes.

Default value: 30

Minimum value: 1

Maximum value: 20939000

destIP

IP address of the service to which to send probes. If the parameter is set to 0, the IP address of the server to which the monitor is bound is considered the destination IP address.

destPort

TCP or UDP port to which to send the probe. If the parameter is set to 0, the port number of the service to which the monitor is bound is considered the destination port. For a monitor of type USER, however, the destination port is the port number that is included in the HTTP request sent to the dispatcher. Does not apply to monitors of type PING.

state

State of the monitor. The DISABLED setting disables not only the monitor being configured, but all monitors of the same type, until the parameter is set to ENABLED. If the monitor is bound to a service, the state of the monitor is not taken into account when the state of the service is determined.

Possible values: ENABLED, DISABLED

Default value: ENABLED

reverse

Mark a service as DOWN, instead of UP, when probe criteria are satisfied, and as UP instead of DOWN when probe criteria are not satisfied.

Possible values: YES, NO

Default value: NO

transparent

The monitor is bound to a transparent device such as a firewall or router. The state of a transparent device depends on the responsiveness of the services behind it. If a transparent device is being monitored, a destination IP address must be specified. The probe is sent to the specified IP address by using the MAC address of the transparent device.

Possible values: YES, NO

Default value: NO

ipTunnel

Send the monitoring probe to the service through an IP tunnel. A destination IP address must be specified.

Possible values: YES, NO

Default value: NO

tos

Probe the service by encoding the destination IP address in the IP TOS (6) bits.

Possible values: YES, NO

tosId

The TOS ID of the specified destination IP. Applicable only when the TOS parameter is set.

Minimum value: 1

Maximum value: 63

secure

Use a secure SSL connection when monitoring a service. Applicable only to TCP based monitors. The secure option cannot be used with a CITRIX-AG monitor, because a CITRIX-AG monitor uses a secure connection by default.

Possible values: YES, NO

Default value: NO

validateCred

Validate the credentials of the Xen Desktop DDC server user. Applicable to monitors of type CITRIX-XD-DDC.

Possible values: YES, NO

Default value: NO

domain

Domain in which the XenDesktop Desktop Delivery Controller (DDC) servers or Web Interface servers are present. Required by CITRIX-XD-DDC and CITRIX-WI-EXTENDED monitors for logging on to the DDC servers and Web Interface servers, respectively.

IPAddress

Set of IP addresses expected in the monitoring response from the DNS server, if the record type is A or AAAA. Applicable to DNS monitors.

group

Name of a newsgroup available on the NNTP service that is to be monitored. The appliance periodically generates an NNTP query for the name of the newsgroup and evaluates the response. If the newsgroup is found on the server, the service is marked as UP. If the newsgroup does not exist or if the search fails, the service is marked as DOWN. Applicable to NNTP monitors.

fileName

Name of a file on the FTP server. The appliance monitors the FTP service by periodically checking the existence of the file on the server. Applicable to FTP-EXTENDED monitors.

baseDN

The base distinguished name of the LDAP service, from where the LDAP server can begin the search for the attributes in the monitoring query. Required for LDAP service monitoring.

bindDN

The distinguished name with which an LDAP monitor can perform the Bind operation on the LDAP server. Optional. Applicable to LDAP monitors.

filter

Filter criteria for the LDAP query. Optional.

attribute

Attribute to evaluate when the LDAP server responds to the query. Success or failure of the monitoring probe depends on whether the attribute exists in the response. Optional.

database

Name of the database to probe. The name is used to connect to the database during authentication.

sqlQuery

SQL query for a MYSQL-ECV or MSSQL-ECV monitor. Sent to the database server after the server authenticates the connection.

evalRule

Default syntax expression that evaluates the database server's response to a MYSQL-ECV or MSSQL-ECV monitoring query. Must produce a Boolean result. The result determines the state of the server. If the expression returns TRUE, the probe succeeds.

For example, if you want the appliance to evaluate the error message to determine the state of the server, use the rule MYSQL.RES.ROW(10) .TEXT_ELEM(2).EQ("MySQL").

mssqlProtocolVersion

Version of MSSQL server that is to be monitored.

Possible values: 70, 2000, 2000SP1, 2005, 2008, 2008R2, 2012

Default value: TDS_PROT_70

snmpOID

SNMP OID for SNMP monitors.

snmpCommunity

Community name for SNMP monitors.

snmpThreshold

Threshold for SNMP monitors.

snmpVersion

SNMP version to be used for SNMP monitors.

Possible values: V1, V2

metricTable

Metric table to which to bind metrics.

application

Name of the application used to determine the state of the service. Applicable to monitors of type CITRIX-XML-SERVICE.

sitePath

URL of the logon page. For monitors of type CITRIX-WEB-INTERFACE, to monitor a dynamic page under the site path, terminate the site path with a slash (/). Applicable to CITRIX-WEB-

INTERFACE and CITRIX-WI-EXTENDED monitors.

storename

Store Name. For monitors of type STOREFRONT, STORENAME is an optional argument defining storefront service store name. Applicable to STOREFRONT monitors.

storefrontacctservice

Enable/Disable probing for Account Service. Applicable only to Store Front monitors. For multi-tenancy configuration users my skip account service

Possible values: YES, NO

Default value: YES

hostName

Hostname in the FQDN format (Example: porche.cars.org). Applicable to STOREFRONT monitors.

netProfile

Name of the network profile.

originHost

Origin-Host value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

originRealm

Origin-Realm value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

hostIPAddress

Host-IP-Address value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. If Host-IP-Address is not specified, the appliance inserts the mapped IP (MIP) address or subnet IP (SNIP) address from which the CER request (the monitoring probe) is sent.

vendorId

Vendor-Id value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

productName

Product-Name value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

firmwareRevision

Firmware-Revision value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

authApplicationId

List of Auth-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring CER message.

Maximum value: 4294967295

acctApplicationId

List of Acct-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring message.

Maximum value: 4294967295

inbandSecurityId

Inband-Security-Id for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

Possible values: NO_INBAND_SECURITY, TLS

supportedVendorIds

List of Supported-Vendor-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum eight of these AVPs are supported in a monitoring message.

Minimum value: 1

Maximum value: 4294967295

vendorSpecificVendorId

Vendor-Id to use in the Vendor-Specific-Application-Id grouped attribute-value pair (AVP) in the monitoring CER message. To specify Auth-Application-Id or Acct-Application-Id in Vendor-Specific-Application-Id, use vendorSpecificAuthApplicationIds or vendorSpecificAcctApplicationIds, respectively. Only one Vendor-Id is supported for all the Vendor-Specific-Application-Id AVPs in a CER monitoring message.

Minimum value: 1

kcdAccount

KCD Account used by MSSQL monitor

storedb

Used in case of DB specific LB.If enalbed then we store the database list populated from monitors responses.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

add monitor http_mon http

---

rm lb monitor

Removes a monitor or a response code for an HTTP monitor. If you do not specify any response codes, the monitor is removed. If you provide any or all of the HTTP response codes that are configured for the monitor, only those specified response codes are removed; the monitor is not removed. Built-in monitors cannot be removed.

Synopsys

rm lb monitor <monitorName> <type> [-respCode <int[-int]> ...]

Arguments

monitorName

Name of the monitor.

type

Type of monitor that you want to create.

Possible values: PING, TCP, HTTP, TCP-ECV, HTTP-ECV, UDP-ECV, DNS, FTP, LDNS-PING, LDNS-TCP, LDNS-DNS, RADIUS, USER, HTTP-INLINE, SIP-UDP, LOAD, FTP-EXTENDED, SMTP, SNMP, NNTP, MYSQL, MYSQL-ECV, MSSQL-ECV, ORACLE-ECV, LDAP, POP3, CITRIX-XML-SERVICE, CITRIX-WEB-INTERFACE, DNS-TCP, RTSP, ARP, CITRIX-AG, CITRIX-AAC-LOGINPAGE, CITRIX-AAC-LAS, CITRIX-XD-DDC, ND6, CITRIX-WI-EXTENDED, DIAMETER, RADIUS_ACCOUNTING, STOREFRONT

respCode

Response codes to delete from the response code list configured for the HTTP monitor.

Example

rm monitor http_mon http

---

set lb monitor

Modifies the specified parameters of a monitor.

Synopsys

set lb monitor <monitorName> <type> [-action <action>] [-respCode <int[-int]> ...] [-httpRequest <string>] [-rtspRequest <string>] [-customHeaders <string>] [-maxForwards <positive_integer>] [-sipMethod <sipMethod>] [-sipregURI <string>] [-sipURI <string>] [-send <string>] [-recv <string>] [-query <string>] [-queryType <queryType>] [-userName <string>] {-password } {-secondaryPassword } [-logonpointName <string>] [-lasVersion <string>] {-radKey } [-radNASid <string>] [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-radAccountSession <string>] [-LRTM (ENABLED | DISABLED)] [-deviation <positive_integer> [<units>]] [-scriptName <string>] [-scriptArgs <string>] [-validateCred (YES | NO)] [-domain <string>] [-dispatcherIP <ip_addr>] [-dispatcherPort <port>] [-interval <integer> [<units>]] [-resptimeout <integer> [<units>]] [-resptimeoutThresh <positive_integer>] [-retries <integer>] [-failureRetries <integer>] [-alertRetries <integer>] [-successRetries <integer>] [-downTime <integer> [<units>]] [-destIP <ip_addr|ipv6_addr>] [-destPort <port>] [-state (ENABLED | DISABLED)] [-reverse (YES | NO)] [-transparent (YES | NO)] [-ipTunnel (YES | NO)] [-tos (YES | NO)] [-tosId <positive_integer>] [-secure (YES | NO)] [-IPAddress <ip_addr|ipv6_addr|*> ...] [-group <string>] [-fileName <string>] [-baseDN <string>] [-bindDN <string>] [-filter <string>] [-attribute <string>] [-database <string>] [-sqlQuery <text>] [-evalRule <expression>] [-snmpOID <string>] [-snmpCommunity <string>] [-snmpThreshold <string>] [-snmpVersion (V1 | V2)] [-metricTable <string>] [-metric <string> [-metricThreshold <positive_integer>] [-metricWeight <positive_integer>]] [-application <string>] [-sitePath <string>] [-storename <string>] [-storefrontacctservice (YES | NO)] [-netProfile <string>] [-mssqlProtocolVersion <mssqlProtocolVersion>] [-originHost <string>] [-originRealm <string>] [-hostIPAddress <ip_addr|ipv6_addr|*>] [-vendorId <positive_integer>] [-productName <string>] [-firmwareRevision <positive_integer>] [-authApplicationId <positive_integer> ...] [-acctApplicationId <positive_integer> ...] [-inbandSecurityId (NO_INBAND_SECURITY | TLS)] [-supportedVendorIds <positive_integer> ...] [-vendorSpecificVendorId <positive_integer> [-vendorSpecificAuthApplicationIds <positive_integer> ...] [-vendorSpecificAcctApplicationIds <positive_integer> ...]] [-kcdAccount <string>]

Arguments

monitorName

Name of the monitor.

type

Type of monitor that you want to create.

Possible values: PING, TCP, HTTP, TCP-ECV, HTTP-ECV, UDP-ECV, DNS, FTP, LDNS-PING, LDNS-TCP, LDNS-DNS, RADIUS, USER, HTTP-INLINE, SIP-UDP, LOAD, FTP-EXTENDED, SMTP, SNMP, NNTP, MYSQL, MYSQL-ECV, MSSQL-ECV, ORACLE-ECV, LDAP, POP3, CITRIX-XML-SERVICE, CITRIX-WEB-INTERFACE, DNS-TCP, RTSP, ARP, CITRIX-AG, CITRIX-AAC-LOGINPAGE, CITRIX-AAC-LAS, CITRIX-XD-DDC, ND6, CITRIX-WI-EXTENDED, DIAMETER, RADIUS_ACCOUNTING, STOREFRONT

action

Action to perform when the response to an inline monitor (a monitor of type HTTP-INLINE) indicates that the service is down. A service monitored by an inline monitor is considered DOWN if the response code is not one of the codes that have been specified for the Response Code parameter.

Available settings function as follows:

* NONE - Do not take any action. However, the show service command and the show lb monitor command indicate the total number of responses that were checked and the number of

consecutive error responses received after the last successful probe.

* LOG - Log the event in NSLOG or SYSLOG.

* DOWN - Mark the service as being down, and then do not direct any traffic to the service until the configured down time has expired. Persistent connections to the service are terminated as soon as the service is marked as DOWN. Also, log the event in NSLOG or SYSLOG.

Possible values: NONE, LOG, DOWN

Default value: SM_DOWN

respCode

Response codes for which to mark the service as UP. For any other response code, the action performed depends on the monitor type. HTTP monitors and RADIUS monitors mark the service as DOWN, while HTTP-INLINE monitors perform the action indicated by the Action parameter.

httpRequest

HTTP request to send to the server (for example, "HEAD /file.html").

rtspRequest

RTSP request to send to the server (for example, "OPTIONS *").

customHeaders

Custom header string to include in the monitoring probes.

maxForwards

Maximum number of hops that the SIP request used for monitoring can traverse to reach the server. Applicable only to monitors of type SIP-UDP.

Default value: 1

Maximum value: 255

sipMethod

SIP method to use for the query. Applicable only to monitors of type SIP-UDP.

Possible values: OPTIONS, INVITE, REGISTER

sipURI

SIP URI string to send to the service (for example, sip:sip.test). Applicable only to monitors of type SIP-UDP.

send

String to send to the service. Applicable to TCP-ECV, HTTP-ECV, and UDP-ECV monitors.

recv

String expected from the server for the service to be marked as UP. Applicable to TCP-ECV, HTTP-ECV, and UDP-ECV monitors.

query

Domain name to resolve as part of monitoring the DNS service (for example, example.com).

queryType

Type of DNS record for which to send monitoring queries. Set to Address for querying A records, AAAA for querying AAAA records, and Zone for querying the SOA record.

Possible values: Address, Zone, AAAA

userName

User name with which to probe the RADIUS, NNTP, FTP, FTP-EXTENDED, MYSQL, MSSQL, POP3, CITRIX-AG, CITRIX-XD-DDC, or CITRIX-WI-EXTENDED server.

password

Password that is required for logging on to the RADIUS, NNTP, FTP, FTP-EXTENDED, MYSQL, MSSQL, POP3, CITRIX-AG, CITRIX-XD-DDC, or CITRIX-WI-EXTENDED server. Used in conjunction with the user name specified for the User Name parameter.

secondaryPassword

Secondary password that users might have to provide to log on to the Access Gateway server. Applicable to CITRIX-AG monitors.

logonpointName

Name of the logon point that is configured for the Citrix Access Gateway Advanced Access Control software. Required if you want to monitor the associated login page or Logon Agent. Applicable to CITRIX-AAC-LAS and CITRIX-AAC-LOGINPAGE monitors.

lasVersion

Version number of the Citrix Advanced Access Control Logon Agent. Required by the CITRIX-AAC-LAS monitor.

radKey

Authentication key (shared secret text string) for RADIUS clients and servers to exchange. Applicable to monitors of type RADIUS and RADIUS_ACCOUNTING.

radNASid

NAS-Identifier to send in the Access-Request packet. Applicable to monitors of type RADIUS.

radNASip

Network Access Server (NAS) IP address to use as the source IP address when monitoring a RADIUS server. Applicable to monitors of type RADIUS and RADIUS_ACCOUNTING.

radAccountType

Account Type to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

Default value: 1

Maximum value: 15

radFramedIP

Source ip with which the packet will go out . Applicable to monitors of type RADIUS_ACCOUNTING.

radAPN

Called Station Id to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radMSISDN

Calling Stations Id to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radAccountSession

Account Session ID to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

LRTM

Calculate the least response times for bound services. If this parameter is not enabled, the appliance does not learn the response times of the bound services. Also used for LRTM load balancing.

Possible values: ENABLED, DISABLED

deviation

Time value added to the learned average response time in dynamic response time monitoring (DRTM). When a deviation is specified, the appliance learns the average response time of bound services and adds the deviation to the average. The final value is then continually adjusted to accommodate response time variations over time. Specified in milliseconds, seconds, or minutes.

Maximum value: 20939000

scriptName

Path and name of the script to execute. The script must be available on the NetScaler appliance, in the /nsconfig/monitors/ directory.

scriptArgs

String of arguments for the script. The string is copied verbatim into the request.

validateCred

Validate the credentials of the Xen Desktop DDC server user. Applicable to monitors of type CITRIX-XD-DDC.

Possible values: YES, NO

Default value: NO

domain

Domain in which the XenDesktop Desktop Delivery Controller (DDC) servers or Web Interface servers are present. Required by CITRIX-XD-DDC and CITRIX-WI-EXTENDED monitors for logging on to the DDC servers and Web Interface servers, respectively.

dispatcherIP

IP address of the dispatcher to which to send the probe.

dispatcherPort

Port number on which the dispatcher listens for the monitoring probe.

interval

Time interval between two successive probes. Must be greater than the value of Response Time-out.

Default value: 5

Minimum value: 1

Maximum value: 20940000

resptimeout

Amount of time for which the appliance must wait before it marks a probe as FAILED. Must be less than the value specified for the Interval parameter.

Note: For UDP-ECV monitors for which a receive string is not configured, response timeout does not apply. For UDP-ECV monitors with no receive string, probe failure is indicated by an ICMP

port unreachable error received from the service.

Default value: 2

Minimum value: 1

Maximum value: 20939000

resptimeoutThresh

Response time threshold, specified as a percentage of the Response Time-out parameter. If the response to a monitor probe has not arrived when the threshold is reached, the appliance generates an SNMP trap called monRespTimeoutAboveThresh. After the response time returns to a value below the threshold, the appliance generates a monRespTimeoutBelowThresh SNMP trap. For the traps to be generated, the "MONITOR-RTO-THRESHOLD" alarm must also be enabled.

Maximum value: 100

retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe failed.

Default value: 3

Minimum value: 1

Maximum value: 127

failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the ten probes sent, at least six probes must fail if the service is to be marked as DOWN. The default value of 0 means that all the retries must fail if the service is to be marked as DOWN.

Maximum value: 32

alertRetries

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

Maximum value: 32

successRetries

Number of consecutive successful probes required to transition a service's state from DOWN to UP.

Default value: 1

Minimum value: 1

Maximum value: 32

downTime

Time duration for which to wait before probing a service that has been marked as DOWN. Expressed in milliseconds, seconds, or minutes.

Default value: 30

Minimum value: 1

Maximum value: 20939000

destIP

IP address of the service to which to send probes. If the parameter is set to 0, the IP address of the server to which the monitor is bound is considered the destination IP address.

destPort

TCP or UDP port to which to send the probe. If the parameter is set to 0, the port number of the service to which the monitor is bound is considered the destination port. For a monitor of type USER, however, the destination port is the port number that is included in the HTTP request sent to the dispatcher. Does not apply to monitors of type PING.

state

State of the monitor. The DISABLED setting disables not only the monitor being configured, but all monitors of the same type, until the parameter is set to ENABLED. If the monitor is bound to a service, the state of the monitor is not taken into account when the state of the service is determined.

Possible values: ENABLED, DISABLED

Default value: ENABLED

reverse

Mark a service as DOWN, instead of UP, when probe criteria are satisfied, and as UP instead of DOWN when probe criteria are not satisfied.

Possible values: YES, NO

Default value: NO

transparent

The monitor is bound to a transparent device such as a firewall or router. The state of a transparent device depends on the responsiveness of the services behind it. If a transparent device is

being monitored, a destination IP address must be specified. The probe is sent to the specified IP address by using the MAC address of the transparent device.

Possible values: YES, NO

Default value: NO

ipTunnel

Send the monitoring probe to the service through an IP tunnel. A destination IP address must be specified.

Possible values: YES, NO

Default value: NO

tos

Probe the service by encoding the destination IP address in the IP TOS (6) bits.

Possible values: YES, NO

tosId

The TOS ID of the specified destination IP. Applicable only when the TOS parameter is set.

Minimum value: 1

Maximum value: 63

secure

Use a secure SSL connection when monitoring a service. Applicable only to TCP based monitors. The secure option cannot be used with a CITRIX-AG monitor, because a CITRIX-AG monitor uses a secure connection by default.

Possible values: YES, NO

Default value: NO

IPAddress

Set of IP addresses expected in the monitoring response from the DNS server, if the record type is A or AAAA. Applicable to DNS monitors.

group

Name of a newsgroup available on the NNTP service that is to be monitored. The appliance periodically generates an NNTP query for the name of the newsgroup and evaluates the response. If the newsgroup is found on the server, the service is marked as UP. If the newsgroup does not exist or if the search fails, the service is marked as DOWN. Applicable to NNTP monitors.

fileName

Name of a file on the FTP server. The appliance monitors the FTP service by periodically checking the existence of the file on the server. Applicable to FTP-EXTENDED monitors.

baseDN

The base distinguished name of the LDAP service, from where the LDAP server can begin the search for the attributes in the monitoring query. Required for LDAP service monitoring.

bindDN

The distinguished name with which an LDAP monitor can perform the Bind operation on the LDAP server. Optional. Applicable to LDAP monitors.

filter

Filter criteria for the LDAP query. Optional.

attribute

Attribute to evaluate when the LDAP server responds to the query. Success or failure of the monitoring probe depends on whether the attribute exists in the response. Optional.

database

Name of the database to probe. The name is used to connect to the database during authentication.

sqlQuery

SQL query for a MYSQL-ECV or MSSQL-ECV monitor. Sent to the database server after the server authenticates the connection.

evalRule

Default syntax expression that evaluates the database server's response to a MYSQL-ECV or MSSQL-ECV monitoring query. Must produce a Boolean result. The result determines the state of the server. If the expression returns TRUE, the probe succeeds.

For example, if you want the appliance to evaluate the error message to determine the state of the server, use the rule MYSQL.RES.ROW(10) .TEXT_ELEM(2).EQ("MySQL").

snmpOID

SNMP OID for SNMP monitors.

snmpCommunity

Community name for SNMP monitors.

snmpThreshold

Threshold for SNMP monitors.

snmpVersion

SNMP version to be used for SNMP monitors.

Possible values: V1, V2

metricTable

Metric table to which to bind metrics.

metric

Metric name in the metric table, whose setting is changed. A value zero disables the metric and it will not be used for load calculation

application

Name of the application used to determine the state of the service. Applicable to monitors of type CITRIX-XML-SERVICE.

sitePath

URL of the logon page. For monitors of type CITRIX-WEB-INTERFACE, to monitor a dynamic page under the site path, terminate the site path with a slash (/). Applicable to CITRIX-WEB-INTERFACE and CITRIX-WI-EXTENDED monitors.

storename

Store Name. For monitors of type STOREFRONT, STORENAME is an optional argument defining storefront service store name. Applicable to STOREFRONT monitors.

storefrontacctservice

Enable/Disable probing for Account Service. Applicable only to Store Front monitors. For multi-tenancy configuration users my skip account service

Possible values: YES, NO

Default value: YES

hostName

Hostname in the FQDN format (Example: porche.cars.org). Applicable to STOREFRONT monitors.

netProfile

Name of the network profile.

mssqlProtocolVersion

Version of MSSQL server that is to be monitored.

Possible values: 70, 2000, 2000SP1, 2005, 2008, 2008R2, 2012

Default value: TDS_PROT_70

originHost

Origin-Host value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

originRealm

Origin-Realm value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

hostIPAddress

Host-IP-Address value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. If Host-IP-Address is not specified, the appliance inserts the mapped IP (MIP) address or subnet IP (SNIP) address from which the CER request (the monitoring probe) is sent.

vendorId

Vendor-Id value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

productName

Product-Name value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

firmwareRevision

Firmware-Revision value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

authApplicationId

List of Auth-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring CER message.

Maximum value: 4294967295

acctApplicationId

List of Acct-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are

supported in a monitoring message.

Maximum value: 4294967295

inbandSecurityId

Inband-Security-Id for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

Possible values: NO_INBAND_SECURITY, TLS

supportedVendorIds

List of Supported-Vendor-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum eight of these AVPs are supported in a monitoring message.

Minimum value: 1

Maximum value: 4294967295

vendorSpecificVendorId

Vendor-Id to use in the Vendor-Specific-Application-Id grouped attribute-value pair (AVP) in the monitoring CER message. To specify Auth-Application-Id or Acct-Application-Id in Vendor-Specific-Application-Id, use vendorSpecificAuthApplicationIds or vendorSpecificAcctApplicationIds, respectively. Only one Vendor-Id is supported for all the Vendor-Specific-Application-Id AVPs in a CER monitoring message.

Minimum value: 1

kcdAccount

KCD Account used by MSSQL monitor

Example

```
set monitor http_mon http -respcode 100
```

---

unset lb monitor

Removes the specified parameter settings from the specified monitor. Attributes for which a default value is available revert to their default values..Refer to the set lb monitor command for meanings of the arguments.

Synopsys

```
unset lb monitor <monitorName> <type> [-IPAddress <ip_addr|ipv6_addr|*> ...] [-scriptName] [-destPort] [-netProfile] [-action] [-respCode] [-httpRequest] [-rtspRequest] [-customHeaders] [-maxForwards] [-sipMethod] [-sipregURI] [-send] [-recv] [-query] [-queryType] [-userName] [-password] [-secondaryPassword] [-logonpointName] [-lasVersion] [-radKey] [-radNASid] [-radNASip] [-radAccountType] [-radFramedIP] [-radAPN] [-radMSISDN] [-radAccountSession] [-LRTM] [-deviation] [-scriptArgs] [-validateCred] [-domain] [-dispatcherIP] [-dispatcherPort] [-interval] [-resptimeout] [-resptimeoutThresh] [-retries] [-failureRetries] [-alertRetries] [-successRetries] [-downTime] [-destIP] [-state] [-reverse] [-transparent] [-ipTunnel] [-tos] [-tosId] [-secure] [-group] [-fileName] [-baseDN] [-bindDN] [-filter] [-attribute] [-database] [-sqlQuery] [-evalRule] [-snmpOID] [-snmpCommunity] [-snmpThreshold] [-snmpVersion] [-metricTable] [-mssqlProtocolVersion] [-originHost] [-originRealm] [-hostIPAddress] [-vendorId] [-productName] [-firmwareRevision] [-authApplicationId] [-acctApplicationId] [-inbandSecurityId] [-supportedVendorIds] [-vendorSpecificVendorId] [-vendorSpecificAuthApplicationIds] [-vendorSpecificAcctApplicationIds] [-kcdAccount]
```

Example

```
set monitor dns_mon dns -ipaddress 10.102.27.230
```

---

enable lb monitor

Enable the monitor that is bound to a specific service. If no monitor name is specified, all monitors bound to the service are enabled.

Synopsys

```
enable lb monitor (<serviceName>@ | <serviceGroupName>@) [<monitorName>]
```

Arguments

serviceName

The name of the service to which the monitor is bound.

serviceGroupName

The name of the service group to which the monitor is to be bound.

monitorName

Name for the monitor. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my monitor" or 'my monitor').

Example

```
enable monitor http_svc http_mon  To enable monitor for multiple services use the following command:  enable monitor http_svc[1-3] http_mon
```

---

disable lb monitor

Disable the monitor for a service. If the monitor name is not specified, all monitors bound to the service are disabled.

Synopsys

disable lb monitor (<serviceName>@ | <serviceGroupName>@) [<monitorName>]

Arguments

serviceName

The name of the service being monitored.

serviceGroupName

The name of the service group being monitored.

monitorName

Name for the monitor. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my monitor" or 'my monitor').

Example

disable monitor http_svc http_mon To disable a monitor on multiple services use the following command: disable monitor http_svc[1-3] http_mon

---

bind lb monitor

Binds a monitor to a service or service group. Multiple monitors can be bound to a service or service group.

Synopsys

bind lb monitor <monitorName> [-state (ENABLED | DISABLED)] [-weight <positive_integer>] [-state (ENABLED | DISABLED)] [-weight <positive_integer>] [-metric <string> -metricThreshold <positive_integer> [-metricWeight <positive_integer>]]

Arguments

monitorName

Name of the monitor.

serviceName

Name of the service or service group.

serviceGroupName

Name of the service group.

metric

Name of the metric to be polled by the monitor.

Example

bind monitor http_mon http_svc To bind a monitor to multiple services use the following command: bind monitor http_mon http_svc[1-3]

---

unbind lb monitor

Unbinds a monitor from a service or service group.

Synopsys

unbind lb monitor <monitorName> -metric <string>

Arguments

monitorName

Name of the monitor.

serviceName

Name of the service or service group.

serviceGroupName

Name of the service group.

metric

Name of the metric to be polled by the monitor.

Example

unbind monitor http_mon http_svc To unbind a monitor to multiple services use the following command: unbind monitor http_mon http_svc[1-3]

---

show lb monitor

Displays the parameters of all the monitors configured on the appliance, or the parameters of the specified monitor.

Synopsys

show lb monitor [<monitorName>] [<type>] show lb monitor bindings - alias for 'show lb monbindings'

Arguments

monitorName

Name of the monitor.

type

Type of monitor that you want to create.

Possible values: PING, TCP, HTTP, TCP-ECV, HTTP-ECV, UDP-ECV, DNS, FTP, LDNS-PING, LDNS-TCP, LDNS-DNS, RADIUS, USER, HTTP-INLINE, SIP-UDP, LOAD, FTP-EXTENDED, SMTP, SNMP, NNTP, MYSQL, MYSQL-ECV, MSSQL-ECV, ORACLE-ECV, LDAP, POP3, CITRIX-XML-SERVICE, CITRIX-WEB-INTERFACE, DNS-TCP, RTSP, ARP, CITRIX-AG, CITRIX-AAC-LOGINPAGE, CITRIX-AAC-LAS, CITRIX-XD-DDC, ND6, CITRIX-WI-EXTENDED, DIAMETER, RADIUS_ACCOUNTING, STOREFRONT

summary

fullValues

format

level

Outputs

interval

The frequency at which the probe is sent to the service.

units

Giving the unit of the metric

resptimeout

The interval for which the system waits before it marks the probe as FAILED.

resptimeoutThresh

Response time threshold, specified as a percentage of the Response Time-out parameter. If the response to a monitor probe has not arrived when the threshold is reached, the appliance generates an SNMP trap called monRespTimeoutAboveThresh. After the response time returns to a value below the threshold, the appliance generates a monRespTimeoutBelowThresh SNMP trap. For the traps to be generated, the "MONITOR-RTO-THRESHOLD" alarm must also be enabled.

retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe failed.

failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the ten probes sent, at least six probes must fail if the service is to be marked as DOWN. The default value of 0 means that all the retries must fail if the service is to be marked as DOWN.

alertRetries

The number of failures after which the system generates a SNMP trap.

successRetries

Number of consecutive successful probes required to transition a service's state from DOWN to UP.

downTime

The duration in seconds for which the system waits to make the next probe once the service is marked as DOWN.

destIP

The IP address to which the probe is sent.

destPort

The TCP/UDP port to which the probe is sent.

state

reverse

Mark a service as DOWN, instead of UP, when probe criteria are satisfied, and as UP instead of DOWN when probe criteria are not satisfied.

transparent

The state of the monitor for transparent devices.

ipTunnel

The state of the monitor for tunneled devices.

tos

TOS setting.

tosId

TOS ID

secure

The state of the secure monitoring of services.

action

Action to perform when the response to an inline monitor (a monitor of type HTTP-INLINE) indicates that the service is down. A service monitored by an inline monitor is considered DOWN if the response code is not one of the codes that have been specified for the Response Code parameter.

Available settings function as follows:

* NONE - Do not take any action. However, the show service command and the show lb monitor command indicate the total number of responses that were checked and the number of consecutive error responses received after the last successful probe.

* LOG - Log the event in NSLOG or SYSLOG.

* DOWN - Mark the service as being down, and then do not direct any traffic to the service until the configured down time has expired. Persistent connections to the service are terminated as soon as the service is marked as DOWN. Also, log the event in NSLOG or SYSLOG.

respCode

The response codes.

httpRequest

The HTTP request that is sent to the server.

rtspRequest

The RTSP request that is sent to the server.

send

The string that is sent to the service.

recv

The string that is expected from the server to mark the server as UP.

query

Domain name to resolve as part of monitoring the DNS service (for example, example.com).

queryType

Type of DNS record for which to send monitoring queries. Set to Address for querying A records, AAAA for querying AAAA records, and Zone for querying the SOA record.

userName

Username on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/CITRIX-XD-DDC/CITRIX-WI-EXTENDED server. This user name is used in the probe.

password

Password used in RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP/CITRIX-XD-DDC/CITRIX-WI-EXTENDED server monitoring.

secondaryPassword

Secondary password that users might have to provide to log on to the Access Gateway server. Applicable to CITRIX-AG monitors.

logonpointName

Logonpoint name used in Citrix AAC login page monitoring.

lasVersion

Version number of the Citrix Advanced Access Control Logon Agent. Required by the CITRIX-AAC-LAS monitor.

validateCred

Validate the credentials of the Xen Desktop DDC server user. Applicable to monitors of type CITRIX-XD-DDC.

domain

Domain in which the XenDesktop Desktop Delivery Controller (DDC) servers or Web Interface servers are present. Required by CITRIX-XD-DDC and CITRIX-WI-EXTENDED monitors for logging on to the DDC servers and Web Interface servers, respectively.

radKey

Authentication key (shared secret text string) for RADIUS clients and servers to exchange. Applicable to monitors of type RADIUS and RADIUS_ACCOUNTING.

radNASid

NAS-Identifier to send in the Access-Request packet. Applicable to monitors of type RADIUS.

radNASip

Network Access Server (NAS) IP address to use as the source IP address when monitoring a RADIUS server. Applicable to monitors of type RADIUS and RADIUS_ACCOUNTING.

radAccountType

Account Type to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radFramedIP

Source ip with which the packet will go out . Applicable to monitors of type RADIUS_ACCOUNTING.

radAPN

Called Station Id to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radMSISDN

Calling Stations Id to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

radAccountSession

Account Session ID to be used in Account Request Packet. Applicable to monitors of type RADIUS_ACCOUNTING.

LRTM

Calculate the least response times for bound services. If this parameter is not enabled, the appliance does not learn the response times of the bound services. Also used for LRTM load balancing.

lrtmConf

State of LRTM configuration on the monitor.

lrtmConfStr

State of LRTM configuration on the monitor as STRING.

deviation

Deviation from the learnt response time for Dynamic Response Time monitoring.

dynamicResponseTimeout

Response timeout of the DRTM enabled monitor , calculated dynamically based on the history and current response time.

dynamicInterval

Interval between monitoring probes for DRTM enabled monitor , calculated dynamically based monitor response time.

scriptName

Path and name of the script to execute. The script must be available on the NetScaler appliance, in the /nsconfig/monitors/ directory.

scriptArgs

String of arguments for the script. The string is copied verbatim into the request.

dispatcherIP

IP address of the dispatcher to which to send the probe.

dispatcherPort

Port number on which the dispatcher listens for the monitoring probe.

sipURI

SIP URI string to send to the service (for example, sip:sip.test). Applicable only to monitors of type SIP-UDP.

sipMethod

Specifies SIP method to be used for the query

maxForwards

Maximum number of hops a sip monitor packet can go.

sipregURI

Specifies SIP user to be registered

customHeaders

The string that is sent to the service. Applicable to HTTP ,HTTP-ECV and RTSP monitor types.

IPAddress

Set of IP addresses expected in the monitoring response from the DNS server, if the record type is A or AAAA. Applicable to DNS monitors.

group

Name of a newsgroup available on the NNTP service that is to be monitored. The appliance periodically generates an NNTP query for the name of the newsgroup and evaluates the response. If the newsgroup is found on the server, the service is marked as UP. If the newsgroup does not exist or if the search fails, the service is marked as DOWN. Applicable to NNTP monitors.

fileName

Name of a file on the FTP server. The appliance monitors the FTP service by periodically checking the existence of the file on the server. Applicable to FTP-EXTENDED monitors.

baseDN

The base distinguished name of the LDAP service, from where the LDAP server can begin the search for the attributes in the monitoring query. Required for LDAP service monitoring.

bindDN

The distinguished name with which an LDAP monitor can perform the Bind operation on the LDAP server. Optional. Applicable to LDAP monitors.

filter

Filter criteria for the LDAP query. Optional.

attribute

Attribute to evaluate when the LDAP server responds to the query. Success or failure of the monitoring probe depends on whether the attribute exists in the response. Optional.

database

Name of the database to probe. The name is used to connect to the database during authentication.

sqlQuery

SQL query for a MYSQL-ECV or MSSQL-ECV monitor. Sent to the database server after the server authenticates the connection.

evalRule

Default syntax expression that evaluates the database server's response to a MYSQL-ECV or MSSQL-ECV monitoring query. Must produce a Boolean result. The result determines the state of the server. If the expression returns TRUE, the probe succeeds.

For example, if you want the appliance to evaluate the error message to determine the state of the server, use the rule MYSQL.RES.ROW(10) .TEXT_ELEM(2).EQ("MySQL").

snmpOID

SNMP OID for SNMP monitors.

snmpCommunity

Community name for SNMP monitors.

snmpThreshold

Threshold for SNMP monitors.

snmpVersion

SNMP version to be used for SNMP monitoring.

metric

Metric name in the metric table, whose setting is changed

metricTable

Metric table, whose setting is changed

multimetrictable

Metric table to which to bind metrics, to be used only for output purposes.

metricThreshold

Threshold to be used for that metric.

metricWeight

The weight for the specified service metric with respect to others.

stateflag

Flags controlling the display.

flags

Used by build-in monitors.

application

Name of the application used to determine the state of the service. Applicable to monitors of type CITRIX-XML-SERVICE.

sitePath

URL of the logon page. For monitors of type CITRIX-WEB-INTERFACE, to monitor a dynamic page under the site path, terminate the site path with a slash (/). Applicable to CITRIX-WEB-INTERFACE and CITRIX-WI-EXTENDED monitors.

storename

Store Name. For monitors of type STOREFRONT, STORENAME is an optional argument defining storefront service store name. Applicable to STOREFRONT monitors.

storefrontacctservice

Enable/Disable probing for Account Service. Applicable only to Store Front monitors. For multi-tenancy configuration users my skip account service

hostName

Hostname in the FQDN format (Example: porche.cars.org). Applicable to STOREFRONT monitors.NOTE: This attribute is deprecated.This is deprecated attribute.

netProfile

Name of the network profile.

mssqlProtocolVersion

Version of MSSQL server that is to be monitored.

originHost

Origin-Host value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

originRealm

Origin-Realm value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

hostIPAddress

Host-IP-Address value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. If Host-IP-Address is not specified, the appliance inserts the mapped IP (MIP) address or subnet IP (SNIP) address from which the CER request (the monitoring probe) is sent.

vendorId

Vendor-Id value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

productName

Product-Name value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

firmwareRevision

Firmware-Revision value for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

authApplicationId

List of Auth-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring CER message.

acctApplicationId

List of Acct-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring message.

inbandSecurityId

Inband-Security-Id for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers.

supportedVendorIds

List of Supported-Vendor-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum eight of these AVPs are supported in a monitoring message.

vendorSpecificVendorId

Vendor-Id to use in the Vendor-Specific-Application-Id grouped attribute-value pair (AVP) in the monitoring CER message. To specify Auth-Application-Id or Acct-Application-Id in Vendor-Specific-Application-Id, use vendorSpecificAuthApplicationIds or vendorSpecificAcctApplicationIds, respectively. Only one Vendor-Id is supported for all the Vendor-Specific-Application-Id AVPs in a CER monitoring message.

vendorSpecificAuthApplicationIds

List of Vendor-Specific-Auth-Application-Id attribute value pairs (AVPs) for the Capabilities-Exchange-Request (CER) message to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring message. The specified value is combined with the value of vendorSpecificVendorId to obtain the Vendor-Specific-Application-Id AVP in the CER monitoring message.

vendorSpecificAcctApplicationIds

List of Vendor-Specific-Acct-Application-Id attribute value pairs (AVPs) to use for monitoring Diameter servers. A maximum of eight of these AVPs are supported in a monitoring message. The specified value is combined with the value of vendorSpecificVendorId to obtain the Vendor-Specific-Application-Id AVP in the CER monitoring message.

serviceName

weight

serviceGroupName

kcdAccount

KCD Account used by MSSQL monitor

storedb

Used in case of DB specific LB.If enalbed then we store the database list populated from monitors responses.

devno

count

Example

An example of the show monitor command output is as follows: 8 configured monitors: 1) Name.....: ping

lb parameter

Sep 22, 2015

The following operations can be performed on "lb parameter":

set | unset | show

set lb parameter

Modifies the specified global load balancing parameters.

Synopsys

set lb parameter [-httpOnlyCookieFlag (ENABLED | DISABLED)] [-consolidatedLConn (YES | NO)] [-usePortForHashLb (YES | NO)] [-preferDirectRoute (YES | NO)] [-startupRRFactor <positive_integer>] [-monitorSkipMaxClient (ENABLED | DISABLED)] [-monitorConnectionClose (RESET | FIN)] [-vServerSpecificMac (ENABLED | DISABLED)]

Arguments

httpOnlyCookieFlag

Include the HttpOnly attribute in persistence cookies. The HttpOnly attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.

Possible values: ENABLED, DISABLED

Default value: ENABLED

consolidatedLConn

To find the service with the fewest connections, the virtual server uses the consolidated connection statistics from all the packet engines. The NO setting allows consideration of only the number of connections on the packet engine that received the new connection.

Possible values: YES, NO

Default value: YES

usePortForHashLb

Include the port number of the service when creating a hash for hash based load balancing methods. With the NO setting, only the IP address of the service is considered when creating a hash.

Possible values: YES, NO

Default value: YES

preferDirectRoute

Perform route lookup for traffic received by the NetScaler appliance, and forward the traffic according to configured routes. Do not set this parameter if you want a wildcard virtual server to direct packets received by the appliance to an intermediary device, such as a firewall, even if their destination is directly connected to the appliance. Route lookup is performed after the packets have been processed and returned by the intermediary

device.

Possible values: YES, NO

Default value: YES

startupRRFactor

Number of requests, per service, for which to apply the round robin load balancing method before switching to the configured load balancing method, thus allowing services to ramp up gradually to full load. Until the specified number of requests is distributed, the NetScaler appliance is said to be implementing the slow start mode (or startup round robin). Implemented for a virtual server when one of the following is true:

* The virtual server is newly created.

* One or more services are newly bound to the virtual server.

* One or more services bound to the virtual server are enabled.

* The load balancing method is changed.

This parameter applies to all the load balancing virtual servers configured on the NetScaler appliance, except for those virtual servers for which the virtual server-level slow start parameters (New Service Startup Request Rate and Increment Interval) are configured. If the global slow start parameter and the slow start parameters for a given virtual server are not set, the appliance implements a default slow start for the virtual server, as follows:

* For a newly configured virtual server, the appliance implements slow start for the first 100 requests received by the virtual server.

* For an existing virtual server, if one or more services are newly bound or newly enabled, or if the load balancing method is changed, the appliance dynamically computes the number of requests for which to implement startup round robin. It obtains this number by multiplying the request rate by the number of bound services (it includes services that are marked as DOWN). For example, if the current request rate is 20 requests/s and ten services are bound to the virtual server, the appliance performs startup round robin for 200 requests.

Not applicable to a virtual server for which a hash based load balancing method is configured.

monitorSkipMaxClient

When a monitor initiates a connection to a service, do not check to determine whether the number of connections to the service has reached the limit specified by the service's Max Clients setting. Enables monitoring to continue even if the service has reached its connection limit.

Possible values: ENABLED, DISABLED

Default value: DISABLED

monitorConnectionClose

Close monitoring connections by sending the service a connection termination message with the specified bit set.

Possible values: RESET, FIN

Default value: FIN

vServerSpecificMac

Allow a MAC-mode virtual server to accept traffic returned by an intermediary device, such as a firewall, to which the traffic was previously forwarded by another MAC-mode virtual server. The second virtual server can then distribute that traffic across the destination server farm. Also useful when load balancing Branch Repeater appliances.

Note: The second virtual server can also send the traffic to another set of intermediary devices, such as another set of firewalls. If necessary, you can configure multiple MAC-mode virtual servers to pass traffic successively through multiple sets of intermediary devices.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

set lb parameter -httponly (ENABLED|DISABLED)

---

unset lb parameter

Use this command to remove lb parameter settings.Refer to the set lb parameter command for meanings of the arguments.

Synopsys

unset lb parameter [-httpOnlyCookieFlag] [-consolidatedLConn] [-usePortForHashLb] [-preferDirectRoute] [-startupRRFactor] [-monitorSkipMaxClient] [-monitorConnectionClose] [-vServerSpecificMac]

---

show lb parameter

Displays the global load balancing parameters.

Synopsys

show lb parameter

Arguments

format

level

Outputs

httpOnlyCookieFlag

Include the HttpOnly attribute in persistence cookies. The HttpOnly attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.

consolidatedLConn

To find the service with the fewest connections, the virtual server uses the consolidated connection statistics from all the packet engines. The NO setting allows consideration of only the number of connections on the packet engine that received the new connection.

usePortForHashLb

Include the port number of the service when creating a hash for hash based load balancing methods. With the NO setting, only the IP address of the service is considered when creating a hash.

preferDirectRoute

Perform route lookup for traffic received by the NetScaler appliance, and forward the traffic according to configured routes. Do not set this parameter if you want a wildcard virtual server to direct packets received by the appliance to an intermediary device, such as a firewall, even if their destination is directly connected to the appliance. Route lookup is performed after the packets have been processed and returned by the intermediary device.

startupRRFactor

Used to change the factor of service hits after which vserver will come out of slowstart phase.

monitorSkipMaxClient

When a monitor initiates a connection to a service, do not check to determine whether the number of connections to the service has reached the limit specified by the service's Max Clients setting. Enables monitoring to continue even if the service has reached its connection limit.

monitorConnectionClose

Close monitoring connections by sending the service a connection termination message with the specified bit set.

vServerSpecificMac

Allow a MAC-mode virtual server to accept traffic returned by an intermediary device, such as a firewall, to which the traffic was previously forwarded by another MAC-mode virtual server. The second virtual server can then distribute that traffic across the destination server farm. Also useful when load balancing Branch Repeater appliances.

Note: The second virtual server can also send the traffic to another set of intermediary devices, such as another set of firewalls. If necessary, you can configure multiple MAC-mode virtual servers to pass traffic successively through multiple sets of intermediary devices.

sessionsThreshold

This option is used to get the upper-limit on the number of persistent sessions set by the administrator for this system

Example

```
show lb parameter
```

lb persistentSessions

Sep 22, 2015

The following operations can be performed on "lb persistentSessions":

show | clear

show lb persistentSessions

Get all vserver persistent sessions

Synopsys

show lb persistentSessions [<vServer>]

Arguments

vServer

The name of the virtual server.

summary

fullValues

Outputs

type

Type of Persistence.

typestring

Type of Persistence as String.

srcIP

SOURCE IP.

srcIPv6

SOURCE IPv6 ADDRESS.

destIP

DESTINATION IP.

destIPv6

DESTINATION IPv6 ADDRESS.

flags

IPv6 FLAGS.

destPort

Destination port.

vServerName

Virtual server name.

timeout

Persistent Session timeout.

referenceCount

Reference Count.

sipCallID

SIP CALLID.NOTE: This attribute is deprecated.Replaced by "persistenceParam" field

persistenceParam

Specific persistence information . Callid in case of SIP_CALLID persistence entry , RTSP session id in case of RTSP_SESSIONID persistence entry.

devno

count

stateflag

---

clear lb persistentSessions

Use this command to clear/flush persistent sessions

Synopsys

clear lb persistentSessions [<vServer>] [-persistenceParameter <string>]

Arguments

vServer

The name of the LB vserver whose persistence sessions are to be flushed. If not specified, all persistence sessions will be flushed .

persistenceParameter

The persistence parameter whose persistence sessions are to be flushed.

---

lb route

Sep 22, 2015

The following operations can be performed on "lb route":

add | rm | show

add lb route

Bind the route VIP to the route structure.

Synopsys

add lb route <network> <netmask> <gatewayName>

Arguments

network

The IP address of the network to which the route belongs.

netmask

The netmask to which the route belongs.

gatewayName

The name of the route.

---

rm lb route

Remove the route VIP from the route structure.

Synopsys

rm lb route <network> <netmask>

Arguments

network

The IP address of the network to which the route VIP belongs.

netmask

The netmask of the destination network.

---

show lb route

Display the names of the routes associated to the route structure using the ###add lb route### command.

Synopsys

show lb route [<network> <netmask>]

Arguments

network

The destination network or host.

summary

fullValues

format

level

Outputs

gatewayName

The name of the route.

flags

State of the configured gateway.

devno

count

stateflag

lb route6

Sep 22, 2015

The following operations can be performed on "lb route6":

add | rm | show

add lb route6

Bind the route VIP to the route structure.

Synopsys

add lb route6 <network> [<gatewayName>]

Arguments

network

The destination network.

gatewayName

The name of the route.

---

rm lb route6

Remove the route VIP from the route structure.

Synopsys

rm lb route6 <network>

Arguments

network

The IP address of the network to which the route VIP belongs.

---

show lb route6

Display the names of the routes associated to the route structure using the ###add lb route6### command.

Synopsys

show lb route6 [<network>]

Arguments

network

The destination network or host.

summary

fullValues

format

level

Outputs

gatewayName

The name of the route.

flags

State of the configured gateway.

stateflag

lb sipParameters

Sep 22, 2015

The following operations can be performed on "lb sipParameters":

set | unset | show

set lb sipParameters

Modifies the specified global SIP parameters.

Synopsys

set lb sipParameters [-rnatSrcPort <port>] [-rnatDstPort <port>] [-retryDur <integer>] [-addRportVip (ENABLED | DISABLED)] [-sip503RateThreshold <positive_integer>]

Arguments

rnatSrcPort

Port number with which to match the source port in server-initiated SIP traffic. The rport parameter is added, without a value, to SIP packets that have a matching source port number, and CALL-ID based persistence is implemented for the responses received by the virtual server.

rnatDstPort

Port number with which to match the destination port in server-initiated SIP traffic. The rport parameter is added, without a value, to SIP packets that have a matching source port number, and CALL-ID based persistence is implemented for the responses received by the virtual server.

retryDur

Time, in seconds, for which a client must wait before initiating a connection after receiving a 503 Service Unavailable response from the SIP server. The time value is sent in the "Retry-After" header in the 503 response.

Default value: 120

Minimum value: 1

addRportVip

Add the rport parameter to the VIA headers of SIP requests that virtual servers receive from clients or servers.

Possible values: ENABLED, DISABLED

Default value: ENABLED

sip503RateThreshold

Maximum number of 503 Service Unavailable responses to generate, once every 10 milliseconds, when a SIP virtual server becomes unavailable.

Default value: 100

Example

set sip parameter

---

unset lb sipParameters

Use this command to remove lb sipParameters settings.Refer to the set lb sipParameters command for meanings of the arguments.

Synopsys

unset lb sipParameters [-rnatSrcPort] [-rnatDstPort] [-retryDur] [-addRportVip] [-sip503RateThreshold]

---

show lb sipParameters

Displays the global SIP parameters.

Synopsys

show lb sipParameters

Arguments

format

level

Outputs

rnatSrcPort

Port number with which to match the source port in server-initiated SIP traffic. The rport parameter is added, without a value, to SIP packets that have a matching source port number, and CALL-ID based persistence is implemented for the responses received by the virtual server.

rnatDstPort

Port number with which to match the destination port in server-initiated SIP traffic. The rport parameter is added, without a value, to SIP packets that have a matching source port number, and CALL-ID based persistence is implemented for the responses received by the virtual server.

retryDur

Time, in seconds, for which a client must wait before initiating a connection after receiving a 503 Service Unavailable response from the SIP server. The time value is sent in the "Retry-After" header in the 503 response.

addRportVip

Add the rport parameter to the VIA headers of SIP requests that virtual servers receive from clients or

servers.

sip503RateThreshold

Maximum number of 503 Service Unavailable responses to generate, once every 10 milliseconds, when a SIP virtual server becomes unavailable.

Example

```
show sip parameter
```

lb vserver

Sep 22, 2015

The following operations can be performed on "lb vserver":

add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename

add lb vserver

Creates a load balancing virtual server.

Synopsys

add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port> [-range <positive_integer>]) | (-IPPattern <ippat> -IPMask <ipmask>)] [-persistenceType <persistenceType>] [-timeout <mins>] [-persistenceBackup (SOURCEIP | NONE)] [-backupPersistenceTimeout <mins>] [-lbMethod <lbMethod> [-hashLength <positive_integer>] [-netmask <netmask>] [-v6netmasklen <positive_integer>] [-dataLength <positive_integer>] [-dataOffset <positive_integer>]] [-cookieName <string>] [-rule <expression>] [-Listenpolicy <expression> [-Listenpriority <positive_integer>]] [-resRule <expression>] [-persistMask <netmask>] [-v6persistmasklen <positive_integer>] [-pq (ON | OFF)] [-sc (ON | OFF)] [-rtspNat (ON | OFF)] [-m <m>] [-tosId <positive_integer>] [-sessionless (ENABLED | DISABLED)] [-state (ENABLED | DISABLED)] [-connfailover <connfailover>] [-redirectURL <URL>] [-cacheable (YES | NO)] [-cltTimeout <secs>] [-soMethod <soMethod>] [-soPersistence (ENABLED | DISABLED)] [-soPersistenceTimeOut <positive_integer>] [-healthThreshold <positive_integer>] [-soThreshold <positive_integer>] [-soBackupAction <soBackupAction>] [-redirectPortRewrite (ENABLED | DISABLED)] [-downStateFlush (ENABLED | DISABLED)] [-backupVServer <string>] [-disablePrimaryOnDown (ENABLED | DISABLED)] [-insertVserverIPPort <insertVserverIPPort> [<vipHeader>]] [-AuthenticationHost <string>] [-Authentication (ON | OFF)] [-authn401 (ON | OFF)] [-authnVsName <string>] [-push (ENABLED | DISABLED)] [-pushVserver <string>] [-pushLabel <expression>] [-pushMultiClients (YES | NO)] [-tcpProfileName <string>] [-httpProfileName <string>] [-dbProfileName <string>] [-comment <string>] [-l2Conn (ON | OFF)] [-mssqlServerVersion <mssqlServerVersion>] [-mysqlProtocolVersion <positive_integer>] [-mysqlServerVersion <string>] [-mysqlCharacterSet <positive_integer>] [-mysqlServerCapabilities <positive_integer>] [-appflowLog (ENABLED | DISABLED)] [-netProfile <string>] [-icmpVsrResponse (PASSIVE | ACTIVE)] [-newServiceRequest <positive_integer> [<newServiceRequestUnit>]] [-newServiceRequestIncrementInterval <positive_integer>] [-minAutoscaleMembers <positive_integer>] [-maxAutoscaleMembers <positive_integer>] [-persistAVPno <positive_integer> ...] [-skippersistency <skippersistency>] [-td <positive_integer>] [-authnProfile <string>] [-macmodeRetainvlan (ENABLED | DISABLED)] [-dbsLb (ENABLED | DISABLED)] [-dns64 (ENABLED | DISABLED)] [-bypassAAAA (YES | NO)] [-RecursionAvailable (YES | NO)]

Arguments

name

Name for the virtual server. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign (@), equal sign (=), and hyphen (-) characters. Can be changed after the virtual server is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my vserver" or 'my vserver').

serviceType

Protocol used by the service (also called the service type).

Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, DTLS, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, SSL_DIAMETER, TFTP

IPAddress

IPv4 or IPv6 address to assign to the virtual server.

IPPattern

IP address pattern, in dotted decimal notation, for identifying packets to be accepted by the virtual server. The IP Mask parameter specifies which part of the destination IP address is matched against the pattern. Mutually exclusive with the IP Address parameter.

For example, if the IP pattern assigned to the virtual server is 198.51.100.0 and the IP mask is 255.255.240.0 (a forward mask), the first 20 bits in the destination IP addresses are matched with the first 20 bits in the pattern. The virtual server accepts requests with IP addresses that range from 198.51.96.1 to 198.51.111.254. You can also use a pattern such as 0.0.2.2 and a mask such as 0.0.255.255 (a reverse mask).

If a destination IP address matches more than one IP pattern, the pattern with the longest match is selected, and the associated virtual server processes the request. For example, if virtual servers vs1 and vs2 have the same IP pattern, 0.0.100.128, but different IP masks of 0.0.255.255 and 0.0.224.255, a destination IP address of 198.51.100.128 has the longest match with the IP pattern of vs1. If a destination IP address matches two or more virtual servers to the same extent, the request is processed by the virtual server whose port number matches the port number in the request.

port

Port number for the virtual server.

range

Number of IP addresses that the appliance must generate and assign to the virtual server. The virtual server then functions as a network virtual server, accepting traffic on any of the generated IP addresses. The IP addresses are generated automatically, as follows:

* For a range of n, the last octet of the address specified by the IP Address parameter increments n-1 times.

* If the last octet exceeds 255, it rolls over to 0 and the third octet increments by 1.

Note: The Range parameter assigns multiple IP addresses to one virtual server. To generate an array of virtual servers, each of which owns only one IP address, use brackets in the IP Address and Name parameters to specify the range. For example:

add lb vserver my_vserver[1-3] HTTP 192.0.2.[1-3] 80

Default value: 1

Minimum value: 1

Maximum value: 254

persistenceType

Type of persistence for the virtual server. Available settings function as follows:

* SOURCEIP - Connections from the same client IP address belong to the same persistence session.

* COOKIEINSERT - Connections that have the same HTTP Cookie, inserted by a Set-Cookie directive from a server, belong to the same persistence session.

* SSLSESSION - Connections that have the same SSL Session ID belong to the same persistence session.

* CUSTOMSERVERID - Connections with the same server ID form part of the same session. For this persistence type, set the Server ID (CustomServerID) parameter for each service and configure the Rule parameter to identify the server ID in a request.

* RULE - All connections that match a user defined rule belong to the same persistence session.

* URLPASSIVE - Requests that have the same server ID in the URL query belong to the same persistence session. The server ID is the hexadecimal representation of the IP address and port of the service to which the request must be forwarded. This persistence type requires a rule to identify the server ID in the request.

* DESTIP - Connections to the same destination IP address belong to the same persistence session.

* SRCIPDESTIP - Connections that have the same source IP address and destination IP address belong to the same persistence session.

* CALLID - Connections that have the same CALL-ID SIP header belong to the same persistence session.

* RTSPSID - Connections that have the same RTSP Session ID belong to the same persistence session.

Possible values: SOURCEIP, COOKIEINSERT, SSLSESSION, RULE, URLPASSIVE, CUSTOMSERVERID, DESTIP, SRCIPDESTIP, CALLID, RTSPSID, DIAMETER, NONE

timeout

Time period for which a persistence session is in effect.

Default value: 2

Maximum value: 1440

persistenceBackup

Backup persistence type for the virtual server. Becomes operational if the primary persistence mechanism fails.

Possible values: SOURCEIP, NONE

backupPersistenceTimeout

Time period for which backup persistence is in effect.

Default value: 2

Minimum value: 2

Maximum value: 1440

lbMethod

Load balancing method. The available settings function as follows:

* ROUNDROBIN - Distribute requests in rotation, regardless of the load. Weights can be assigned to services to enforce weighted round robin distribution.

* LEASTCONNECTION (default) - Select the service with the fewest connections.

* LEASTRESPONSETIME - Select the service with the lowest average response time.

* LEASTBANDWIDTH - Select the service currently handling the least traffic.

* LEASTPACKETS - Select the service currently serving the lowest number of packets per second.

* CUSTOMLOAD - Base service selection on the SNMP metrics obtained by custom load monitors.

* LRTM - Select the service with the lowest response time. Response times are learned through monitoring probes. This method also takes the number of active connections into account.

Also available are a number of hashing methods, in which the appliance extracts a predetermined portion of the request, creates a hash of the portion, and then checks whether any previous requests had the same hash value. If it finds a match, it forwards the request to the service that served those previous requests. Following are the hashing methods:

* URLHASH - Create a hash of the request URL (or part of the URL).

* DOMAINHASH - Create a hash of the domain name in the request (or part of the domain name). The domain name is taken from either the URL or the Host header. If the domain name appears in both locations, the URL is preferred. If the request does not contain a domain name, the load balancing method defaults to LEASTCONNECTION.

* DESTINATIONIPHASH - Create a hash of the destination IP address in the IP header.

* SOURCEIPHASH - Create a hash of the source IP address in the IP header.

* TOKEN - Extract a token from the request, create a hash of the token, and then select the service to which any previous requests with the same token hash value were sent.

* SRCIPDESTIPHASH - Create a hash of the string obtained by concatenating the source IP address and destination IP address in the IP header.

* SRCIPSRCPORTHASH - Create a hash of the source IP address and source port in the IP header.

* CALLIDHASH - Create a hash of the SIP Call-ID header.

Possible values: ROUNDROBIN, LEASTCONNECTION, LEASTRESPONSETIME, URLHASH, DOMAINHASH, DESTINATIONIPHASH, SOURCEIPHASH, SRCIPDESTIPHASH, LEASTBANDWIDTH, LEASTPACKETS, TOKEN, SRCIPSRCPORTHASH, LRTM, CALLIDHASH, CUSTOMLOAD, LEASTREQUEST

Default value: PEMGMT_LB_LEASTCONNS

cookieName

Use this parameter to specify the cookie name for COOKIE peristence type. It specifies the name of cookie with a maximum of 32 characters. If not specified, cookie name is internally generated.

rule

Expression, or name of a named expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

Default value: "none"

Listenpolicy

Default syntax expression identifying traffic accepted by the virtual server. Can be either an expression (for example, CLIENT.IP.DST.IN_SUBNET(192.0.2.0/24) or the name of a named expression. In the above example, the virtual server accepts all requests whose destination IP address is in the 192.0.2.0/24 subnet.

Default value: "none"

Listenpriority

Integer specifying the priority of the listen policy. A higher number specifies a lower priority. If a request matches the listen policies of more than one virtual server the virtual server whose listen policy has the highest priority (the lowest priority number) accepts the request.

Default value: 101

Maximum value: 101

resRule

Default syntax expression specifying which part of a server's response to use for creating rule based persistence sessions (persistence type RULE). Can be either an expression or the name of a named expression.

Example:

HTTP.RES.HEADER("setcookie").VALUE(0).TYPECAST_NVLIST_T('=',';').VALUE("server1").

Default value: "none"

persistMask

Persistence mask for IP based persistence types, for IPv4 virtual servers.

Default value: 0xFFFFFFFF

v6persistmasklen

Persistence mask for IP based persistence types, for IPv6 virtual servers.

Default value: 128

Minimum value: 1

Maximum value: 128

pq

Use priority queuing on the virtual server. based persistence types, for IPv6 virtual servers.

Possible values: ON, OFF

Default value: OFF

sc

Use SureConnect on the virtual server.

Possible values: ON, OFF

Default value: OFF

rtspNat

Use network address translation (NAT) for RTSP data connections.

Possible values: ON, OFF

Default value: OFF

m

Redirection mode for load balancing. Available settings function as follows:

* IP - Before forwarding a request to a server, change the destination IP address to the server's IP address.

* MAC - Before forwarding a request to a server, change the destination MAC address to the server's MAC address. The destination IP address is not changed. MAC-based redirection mode is used mostly in firewall load balancing deployments.

* IPTUNNEL - Perform IP-in-IP encapsulation for client IP packets. In the outer IP headers, set the destination IP address to the IP address of the server and the source IP address to the subnet IP (SNIP). The client IP packets are not modified. Applicable to both IPv4 and IPv6 packets.

* TOS - Encode the virtual server's TOS ID in the TOS field of the IP header.

You can use either the IPTUNNEL or the TOS option to implement Direct Server Return (DSR).

Possible values: IP, MAC, IPTUNNEL, TOS

Default value: NSFWD_IP

tosId

TOS ID of the virtual server. Applicable only when the load balancing redirection mode is set to TOS.

Minimum value: 1

Maximum value: 63

dataLength

Length of the token to be extracted from the data segment of an incoming packet, for use in the token method of load balancing. The length of the token, specified in bytes, must not be greater than 24 KB. Applicable to virtual servers of type TCP.

Minimum value: 1

Maximum value: 100

dataOffset

Offset to be considered when extracting a token from the TCP payload. Applicable to virtual servers, of type TCP, using the token method of load balancing. Must be within the first 24 KB of the TCP payload.

Maximum value: 25400

sessionless

Perform load balancing on a per-packet basis, without establishing sessions. Recommended for load balancing of intrusion detection system (IDS) servers and scenarios involving direct server return (DSR), where session information is unnecessary.

Possible values: ENABLED, DISABLED

Default value: DISABLED

state

State of the load balancing virtual server.

Possible values: ENABLED, DISABLED

Default value: ENABLED

connfailover

Mode in which the connection failover feature must operate for the virtual server. After a failover, established TCP connections and UDP packet flows are kept active and resumed on the secondary appliance. Clients remain connected to the same servers. Available settings function as follows:

* STATEFUL - The primary appliance shares state information with the secondary appliance, in real time, resulting in some runtime processing overhead.

* STATELESS - State information is not shared, and the new primary appliance tries to re-create the packet flow on the basis of the information contained in the packets it receives.

* DISABLED - Connection failover does not occur.

Possible values: DISABLED, STATEFUL, STATELESS

Default value: DISABLED

redirectURL

URL to which to redirect traffic if the virtual server becomes unavailable.

WARNING! Make sure that the domain in the URL does not match the domain specified for a content switching policy. If it does, requests are continuously redirected to the unavailable

virtual server.

cacheable

Route cacheable requests to a cache redirection virtual server. The load balancing virtual server can forward requests only to a transparent cache redirection virtual server that has an IP address and port combination of *:80, so such a cache redirection virtual server must be configured on the appliance.

Possible values: YES, NO

Default value: NO

cltTimeout

Idle time, in seconds, after which a client connection is terminated.

Default value: VAL_NOT_SET

Maximum value: 31536000

soMethod

Type of threshold that, when exceeded, triggers spillover. Available settings function as follows:

* CONNECTION - Spillover occurs when the number of client connections exceeds the threshold.

* DYNAMICCONNECTION - Spillover occurs when the number of client connections at the virtual server exceeds the sum of the maximum client (Max Clients) settings for bound services. Do not specify a spillover threshold for this setting, because the threshold is implied by the Max Clients settings of bound services.

* BANDWIDTH - Spillover occurs when the bandwidth consumed by the virtual server's incoming and outgoing traffic exceeds the threshold.

* HEALTH - Spillover occurs when the percentage of weights of the services that are UP drops below the threshold. For example, if services svc1, svc2, and svc3 are bound to a virtual server, with weights 1, 2, and 3, and the spillover threshold is 50%, spillover occurs if svc1 and svc3 or svc2 and svc3 transition to DOWN.

* NONE - Spillover does not occur.

Possible values: CONNECTION, DYNAMICCONNECTION, BANDWIDTH, HEALTH, NONE

soPersistence

If spillover occurs, maintain source IP address based persistence for both primary and backup virtual servers.

Possible values: ENABLED, DISABLED

Default value: DISABLED

soPersistenceTimeOut

Timeout for spillover persistence, in minutes.

Default value: 2

Minimum value: 2

Maximum value: 1440

healthThreshold

Threshold in percent of active services below which vserver state is made down. If this threshold is 0, vserver state will be up even if one bound service is up.

Maximum value: 100

soThreshold

Threshold at which spillover occurs. Specify an integer for the CONNECTION spillover method, a bandwidth value in kilobits per second for the BANDWIDTH method (do not enter the units), or a percentage for the HEALTH method (do not enter the percentage symbol).

Minimum value: 1

Maximum value: 4294967287

soBackupAction

Action to be performed if spillover is to take effect, but no backup chain to spillover is usable or exists

Possible values: DROP, ACCEPT, REDIRECT

redirectPortRewrite

Rewrite the port and change the protocol to ensure successful HTTP redirects from services.

Possible values: ENABLED, DISABLED

Default value: DISABLED

downStateFlush

Flush all active transactions associated with a virtual server whose state transitions from UP to DOWN. Do not enable this option for applications that must complete their transactions.

Possible values: ENABLED, DISABLED

Default value: ENABLED

backupVServer

Name of the backup virtual server to which to forward requests if the primary virtual server goes DOWN or reaches its spillover threshold.

disablePrimaryOnDown

If the primary virtual server goes down, do not allow it to return to primary status until manually enabled.

Possible values: ENABLED, DISABLED

Default value: DISABLED

insertVserverIPPort

Insert an HTTP header, whose value is the IP address and port number of the virtual server, before forwarding a request to the server. The format of the header is <vipHeader>: <virtual server IP address>_<port number >, where vipHeader is the name that you specify for the header. If the virtual server has an IPv6 address, the address in the header is enclosed in brackets ([and]) to separate it from the port number. If you have mapped an IPv4 address to a virtual server's IPv6 address, the value of this parameter determines which IP address is inserted in the header, as follows:

* VIPADDR - Insert the IP address of the virtual server in the HTTP header regardless of whether the virtual server has an IPv4 address or an IPv6 address. A mapped IPv4 address, if configured, is ignored.

* V6TOV4MAPPING - Insert the IPv4 address that is mapped to the virtual server's IPv6 address. If a mapped IPv4 address is not configured, insert the IPv6 address.

* OFF - Disable header insertion.

Possible values: OFF, VIPADDR, V6TOV4MAPPING

AuthenticationHost

Fully qualified domain name (FQDN) of the authentication virtual server to which the user must be redirected for authentication. Make sure that the Authentication parameter is set to ENABLED.

Authentication

Enable or disable user authentication.

Possible values: ON, OFF

Default value: OFF

authn401

Enable or disable user authentication with HTTP 401 responses.

Possible values: ON, OFF

Default value: OFF

authnVsName

Name of an authentication virtual server with which to authenticate users.

push

Process traffic with the push virtual server that is bound to this load balancing virtual server.

Possible values: ENABLED, DISABLED

Default value: DISABLED

pushVserver

Name of the load balancing virtual server, of type PUSH or SSL_PUSH, to which the server pushes updates received on the load balancing virtual server that you are configuring.

pushLabel

Expression for extracting a label from the server's response. Can be either an expression or the name of a named expression.

Default value: "none"

pushMultiClients

Allow multiple Web 2.0 connections from the same client to connect to the virtual server and expect updates.

Possible values: YES, NO

Default value: NO

tcpProfileName

Name of the TCP profile whose settings are to be applied to the virtual server.

httpProfileName

Name of the HTTP profile whose settings are to be applied to the virtual server.

dbProfileName

Name of the DB profile whose settings are to be applied to the virtual server.

comment

Any comments that you might want to associate with the virtual server.

l2Conn

Use Layer 2 parameters (channel number, MAC address, and VLAN ID) in addition to the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) that is used to identify a connection. Allows multiple TCP and non-TCP connections with the same 4-tuple to co-exist on the NetScaler appliance.

Possible values: ON, OFF

mssqlServerVersion

For a load balancing virtual server of type MSSQL, the Microsoft SQL Server version. Set this parameter if you expect some clients to run a version different from the version of the database. This setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

Possible values: 70, 2000, 2000SP1, 2005, 2008, 2008R2, 2012

Default value: TDS_PROT_2008B

mysqlProtocolVersion

MySQL protocol version that the virtual server advertises to clients.

Default value: NSA_MYSQL_PROTOCOL_VER_DEFAULT

mysqlServerVersion

MySQL server version string that the virtual server advertises to clients.

Default value: NSA_MYSQL_SERVER_VER_DEFAULT

mysqlCharacterSet

Character set that the virtual server advertises to clients.

Default value: NSA_MYSQL_CHAR_SET_DEFAULT

mysqlServerCapabilities

Server capabilities that the virtual server advertises to clients.

Default value: NSA_MYSQL_SVR_CAPABILITIES_DEFAULT

appflowLog

Apply AppFlow logging to the virtual server.

Possible values: ENABLED, DISABLED

Default value: ENABLED

netProfile

Name of the network profile to associate with the virtual server. If you set this parameter, the virtual server uses only the IP addresses in the network profile as source IP addresses when initiating connections with servers.

icmpVsrResponse

How the NetScaler appliance responds to ping requests received for an IP address that is common to one or more virtual servers. Available settings function as follows:

* If set to PASSIVE on all the virtual servers that share the IP address, the appliance always responds to the ping requests.

* If set to ACTIVE on all the virtual servers that share the IP address, the appliance responds to the ping requests if at least one of the virtual servers is UP. Otherwise, the appliance does not respond.

* If set to ACTIVE on some virtual servers and PASSIVE on the others, the appliance responds if at least one virtual server with the ACTIVE setting is UP. Otherwise, the appliance does not respond.

Note: This parameter is available at the virtual server level. A similar parameter, ICMP Response, is available at the IP address level, for IPv4 addresses of type VIP. To set that parameter, use the add ip command in the CLI or the Create IP dialog box in the GUI.

Possible values: PASSIVE, ACTIVE

Default value: NS_VSR_PASSIVE

newServiceRequest

Number of requests, or percentage of the load on existing services, by which to increase the load on a new service at each interval in slow-start mode. A value of 0 disables slow start for new services, and any services still ramping up. They immediately receive their full share of the load. If you use the CLI, be sure to set the newServiceRequestUnit parameter to specify the unit as number of requests or percentage of load.

newServiceRequestIncrementInterval

Interval, in seconds, between successive increments in the load on a new service or a service whose state has just changed from DOWN to UP. A value of 0 (zero) specifies manual slow start.

Maximum value: 3600

minAutoscaleMembers

Minimum number of members expected to be present when vserver is used in Autoscale.

Maximum value: 5000

maxAutoscaleMembers

Maximum number of members expected to be present when vserver is used in Autoscale.

Maximum value: 5000

persistAVPno

Persist AVP number for Diameter Persistency.

In case this AVP is not defined in Base RFC 3588 and it is nested inside a Grouped AVP,

define a sequence of AVP numbers (max 3) in order of parent to child. So say persist AVP number X

is nested inside AVP Y which is nested in Z, then define the list as Z Y X

Minimum value: 1

skippersistency

This argument decides the behavior incase the service which is selected from an existing persistence session has reached threshold.

Possible values: Bypass, ReLb, None

Default value: NS_DONT_SKIPPERSIST

td

Traffic Domain ID

Maximum value: 4094

authnProfile

Name of the authentication profile to be used when authentication is turned on.

macmodeRetainvlan

This option is used to retain vlan information of incoming packet when macmode is enabled

Possible values: ENABLED, DISABLED

Default value: DISABLED

dbsLb

For enabling database specific load-balacing..

Possible values: ENABLED, DISABLED

Default value: DISABLED

dns64

This argument is for enabling/disabling the dns64 on lbvserver

Possible values: ENABLED, DISABLED

bypassAAAA

If this option is enabled while resolving DNS64 query AAAA queries are not sent to back end dns server

Possible values: YES, NO

Default value: NO

RecursionAvailable

When set to YES, this option causes the DNS replies from this vserver to have the RA bit turned on. Typically one would set this option to YES, when the vserver is load balancing a set of DNS servers thatsupport recursive queries.

Possible values: YES, NO

Default value: NO

Example

add lb vserver http_vsvr http 10.102.1.10 80 To add multiple vservers at once use the following command: add lb vs http_vsvr[1-4] http 10.102.27.[115-118] 80 This com

---

rm lb vserver

Removes a virtual server from the NetScaler appliance.

Synopsys

rm lb vserver <name>@ ...

Arguments

name

Name of the virtual server.

Example

rm vserver lb_vip To remove multiple vservers use the following command: rm vserver lb_vip[1-3]

---

set lb vserver

Modifies the specified parameters of a load balancing virtual server.

Synopsys

set lb vserver <name>@ [-IPAddress <ip_addr|ipv6_addr|*>@] [-IPPattern <ippat>] [-IPMask <ipmask>] [-weight <positive_integer> <serviceName>@] [-persistenceType <persistenceType>] [-timeout <mins>] [-persistenceBackup (SOURCEIP | NONE)] [-backupPersistenceTimeout <mins>] [-lbMethod <lbMethod> [-hashLength <positive_integer>] [-netmask <netmask>] [-v6netmasklen <positive_integer>]] [-rule <expression>] [-cookieName <string>] [-resRule <expression>] [-persistMask <netmask>] [-v6persistmasklen <positive_integer>] [-pq (ON | OFF)] [-sc (ON | OFF)] [-rtspNat (ON | OFF)] [-m <m>] [-tosId <positive_integer>] [-dataLength <positive_integer>] [-dataOffset <positive_integer>] [-sessionless (ENABLED | DISABLED)] [-connfailover <connfailover>] [-backupVServer <string>] [-redirectURL <URL>] [-cacheable (YES | NO)] [-cltTimeout <secs>] [-soMethod <soMethod>] [-soThreshold <positive_integer>] [-soPersistence (ENABLED | DISABLED)] [-soPersistenceTimeOut <positive_integer>] [-healthThreshold <positive_integer>] [-soBackupAction <soBackupAction>] [-redirectPortRewrite (ENABLED | DISABLED)] [-downStateFlush (ENABLED | DISABLED)] [-insertVserverIPPort <insertVserverIPPort> [<vipHeader>]] [-disablePrimaryOnDown (ENABLED | DISABLED)] [-AuthenticationHost <string>] [-Authentication (ON | OFF)] [-authn401 (ON | OFF)] [-authnVsName <string>] [-push (ENABLED | DISABLED)] [-pushVserver <string>] [-pushLabel <expression>] [-pushMultiClients (YES | NO)] [-Listenpolicy <expression>] [-Listenpriority <positive_integer>] [-tcpProfileName <string>] [-httpProfileName <string>] [-dbProfileName <string>] [-comment <string>] [-l2Conn (ON | OFF)] [-mssqlServerVersion <mssqlServerVersion>] [-mysqlProtocolVersion <positive_integer>] [-mysqlServerVersion <string>] [-mysqlCharacterSet <positive_integer>] [-mysqlServerCapabilities <positive_integer>] [-appflowLog (ENABLED | DISABLED)] [-netProfile <string>] [-icmpVsrResponse (PASSIVE | ACTIVE)] [-newServiceRequest <positive_integer>] [<newServiceRequestUnit>] [-newServiceRequestIncrementInterval <positive_integer>] [-minAutoscaleMembers <positive_integer>] [-maxAutoscaleMembers <positive_integer>] [-persistAVPno <positive_integer> ...] [-skippersistency <skippersistency>] [-authnProfile <string>] [-macmodeRetainvlan (ENABLED | DISABLED)] [-dbsLb (ENABLED | DISABLED)] [-dns64 (ENABLED | DISABLED)] [-bypassAAAA (YES | NO)] [-RecursionAvailable (YES | NO)]

Arguments

name

Name of the virtual server.

IPAddress

IPv4 or IPv6 address to assign to the virtual server.

IPPattern

IP address pattern, in dotted decimal notation, for identifying packets to be accepted by the virtual server. The IP Mask parameter specifies which part of the destination IP address is matched against the pattern. Mutually exclusive with the IP Address parameter.

For example, if the IP pattern assigned to the virtual server is 198.51.100.0 and the IP mask is 255.255.240.0 (a forward mask), the first 20 bits in the destination IP addresses are matched with the first 20 bits in the pattern. The virtual server accepts requests with IP addresses that range from 198.51.96.1 to 198.51.111.254. You can also use a pattern such as 0.0.2.2 and a mask such as 0.0.255.255 (a reverse mask).

If a destination IP address matches more than one IP pattern, the pattern with the longest match is selected, and the associated virtual server processes the request. For example, if virtual servers vs1 and vs2 have the same IP pattern, 0.0.100.128, but different IP masks of 0.0.255.255 and 0.0.224.255, a destination IP address of 198.51.100.128 has the longest match with the IP pattern of vs1. If a destination IP address matches two or more virtual servers to the same extent, the request is processed by the virtual server whose port number matches the port number in the request.

IPMask

IP mask, in dotted decimal notation, for the IP Pattern parameter. Can have leading or trailing non-zero octets (for example, 255.255.240.0 or 0.0.255.255). Accordingly, the mask specifies whether the first n bits or the last n bits of the destination IP address in a client request are to be matched with the corresponding bits in the IP pattern. The former is called a forward mask. The latter is called a reverse mask.

weight

Weight to assign to the specified service.

Minimum value: 1

Maximum value: 100

persistenceType

Type of persistence for the virtual server. Available settings function as follows:

* SOURCEIP - Connections from the same client IP address belong to the same persistence session.

* COOKIEINSERT - Connections that have the same HTTP Cookie, inserted by a Set-Cookie directive from a server, belong to the same persistence session.

* SSLSESSION - Connections that have the same SSL Session ID belong to the same persistence session.

* CUSTOMSERVERID - Connections with the same server ID form part of the same session. For this persistence type, set the Server ID (CustomServerID) parameter for each service and configure the Rule parameter to identify the server ID in a request.

* RULE - All connections that match a user defined rule belong to the same persistence session.

* URLPASSIVE - Requests that have the same server ID in the URL query belong to the same persistence session. The server ID is the hexadecimal representation of the IP address and port of the service to which the request must be forwarded. This persistence type requires a rule to identify the server ID in the request.

* DESTIP - Connections to the same destination IP address belong to the same persistence session.

* SRCIPDESTIP - Connections that have the same source IP address and destination IP address belong to the same persistence session.

* CALLID - Connections that have the same CALL-ID SIP header belong to the same persistence session.

* RTSPSID - Connections that have the same RTSP Session ID belong to the same persistence session.

Possible values: SOURCEIP, COOKIEINSERT, SSLSESSION, RULE, URLPASSIVE, CUSTOMSERVERID, DESTIP, SRCIPDESTIP, CALLID, RTSPSID, DIAMETER, NONE

timeout

Time period for which a persistence session is in effect.

Default value: 2

Maximum value: 1440

persistenceBackup

Backup persistence type for the virtual server. Becomes operational if the primary persistence mechanism fails.

Possible values: SOURCEIP, NONE

backupPersistenceTimeout

Time period for which backup persistence is in effect.

Default value: 2

Minimum value: 2

Maximum value: 1440

lbMethod

Load balancing method. The available settings function as follows:

* ROUNDROBIN - Distribute requests in rotation, regardless of the load. Weights can be assigned to services to enforce weighted round robin distribution.

* LEASTCONNECTION (default) - Select the service with the fewest connections.

* LEASTRESPONSETIME - Select the service with the lowest average response time.

* LEASTBANDWIDTH - Select the service currently handling the least traffic.

* LEASTPACKETS - Select the service currently serving the lowest number of packets per second.

* CUSTOMLOAD - Base service selection on the SNMP metrics obtained by custom load monitors.

* LRTM - Select the service with the lowest response time. Response times are learned through monitoring probes. This method also takes the number of active connections into account.

Also available are a number of hashing methods, in which the appliance extracts a predetermined portion of the request, creates a hash of the portion, and then checks whether any previous requests had the same hash value. If it finds a match, it forwards the request to the service that served those previous requests. Following are the hashing methods:

* URLHASH - Create a hash of the request URL (or part of the URL).

* DOMAINHASH - Create a hash of the domain name in the request (or part of the domain name). The domain name is taken from either the URL or the Host header. If the domain name appears in both locations, the URL is preferred. If the request does not contain a domain name, the load balancing method defaults to LEASTCONNECTION.

* DESTINATIONIPHASH - Create a hash of the destination IP address in the IP header.

* SOURCEIPHASH - Create a hash of the source IP address in the IP header.

* TOKEN - Extract a token from the request, create a hash of the token, and then select the service to which any previous requests with the same token hash value were sent.

* SRCIPDESTIPHASH - Create a hash of the string obtained by concatenating the source IP address and destination IP address in the IP header.

* SRCIPSRCPORTHASH - Create a hash of the source IP address and source port in the IP header.

* CALLIDHASH - Create a hash of the SIP Call-ID header.

Possible values: ROUNDROBIN, LEASTCONNECTION, LEASTRESPONSETIME, URLHASH, DOMAINHASH, DESTINATIONIPHASH, SOURCEIPHASH, SRCIPDESTIPHASH, LEASTBANDWIDTH, LEASTPACKETS, TOKEN, SRCIPSRCPORTHASH, LRTM, CALLIDHASH, CUSTOMLOAD, LEASTREQUEST

Default value: PEMGMT_LB_LEASTCONNS

rule

Expression, or name of a named expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: "'<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

Default value: "none"

cookieName

Use this parameter to specify the cookie name for COOKIE peristence type. It specifies the name of cookie with a maximum of 32 characters. If not specified, cookie name is internally generated.

resRule

Default syntax expression specifying which part of a server's response to use for creating rule based persistence sessions (persistence type RULE). Can be either an expression or the name of a named expression.

Example:

HTTP.RES.HEADER("setcookie").VALUE(0).TYPECAST_NVLIST_T('=',';').VALUE("server1").

Default value: "none"

persistMask

Persistence mask for IP based persistence types, for IPv4 virtual servers.

Default value: 0xFFFFFFFF

v6persistmasklen

Persistence mask for IP based persistence types, for IPv6 virtual servers.

Default value: 128

Minimum value: 1

Maximum value: 128

pq

Use priority queuing on the virtual server. based persistence types, for IPv6 virtual servers.

Possible values: ON, OFF

Default value: OFF

sc

Use SureConnect on the virtual server.

Possible values: ON, OFF

Default value: OFF

rtspNat

Use network address translation (NAT) for RTSP data connections.

Possible values: ON, OFF

Default value: OFF

m

Redirection mode for load balancing. Available settings function as follows:

* IP - Before forwarding a request to a server, change the destination IP address to the server's IP address.

* MAC - Before forwarding a request to a server, change the destination MAC address to the server's MAC address. The destination IP address is not changed. MAC-based redirection mode is used mostly in firewall load balancing deployments.

* IPTUNNEL - Perform IP-in-IP encapsulation for client IP packets. In the outer IP headers, set the destination IP address to the IP address of the server and the source IP address to the subnet IP (SNIP). The client IP packets are not modified. Applicable to both IPv4 and IPv6 packets.

* TOS - Encode the virtual server's TOS ID in the TOS field of the IP header.

You can use either the IPTUNNEL or the TOS option to implement Direct Server Return (DSR).

Possible values: IP, MAC, IPTUNNEL, TOS

Default value: NSFWD_IP

tosId

TOS ID of the virtual server. Applicable only when the load balancing redirection mode is set to TOS.

Minimum value: 1

Maximum value: 63

dataLength

Length of the token to be extracted from the data segment of an incoming packet, for use in the token method of load balancing. The length of the token, specified in bytes, must not be greater than 24 KB. Applicable to virtual servers of type TCP.

Minimum value: 1

Maximum value: 100

dataOffset

Offset to be considered when extracting a token from the TCP payload. Applicable to virtual servers, of type TCP, using the token method of load balancing. Must be within the first 24 KB of the TCP payload.

Maximum value: 25400

sessionless

Perform load balancing on a per-packet basis, without establishing sessions. Recommended for load balancing of intrusion detection system (IDS) servers and scenarios involving direct server return (DSR), where session information is unnecessary.

Possible values: ENABLED, DISABLED

Default value: DISABLED

connfailover

Mode in which the connection failover feature must operate for the virtual server. After a failover, established TCP connections and UDP packet flows are kept active and resumed on the secondary appliance. Clients remain connected to the same servers. Available settings function as follows:

* STATEFUL - The primary appliance shares state information with the secondary appliance, in real time, resulting in some runtime processing overhead.

* STATELESS - State information is not shared, and the new primary appliance tries to re-create the packet flow on the basis of the information contained in the packets it receives.

* DISABLED - Connection failover does not occur.

Possible values: DISABLED, STATEFUL, STATELESS

Default value: DISABLED

backupVServer

Name of the backup virtual server to which to forward requests if the primary virtual server goes DOWN or reaches its spillover threshold.

redirectURL

URL to which to redirect traffic if the virtual server becomes unavailable.

WARNING! Make sure that the domain in the URL does not match the domain specified for a content switching policy. If it does, requests are continuously redirected to the unavailable virtual server.

cacheable

Route cacheable requests to a cache redirection virtual server. The load balancing virtual server can forward requests only to a transparent cache redirection virtual server that has an IP address and port combination of *:80, so such a cache redirection virtual server must be configured on the appliance.

Possible values: YES, NO

Default value: NO

cltTimeout

Idle time, in seconds, after which a client connection is terminated.

Default value: VAL_NOT_SET

Maximum value: 31536000

soMethod

Type of threshold that, when exceeded, triggers spillover. Available settings function as follows:

* CONNECTION - Spillover occurs when the number of client connections exceeds the threshold.

* DYNAMICCONNECTION - Spillover occurs when the number of client connections at the virtual server exceeds the sum of the maximum client (Max Clients) settings for bound services. Do not specify a spillover threshold for this setting, because the threshold is implied by the Max Clients settings of bound services.

* BANDWIDTH - Spillover occurs when the bandwidth consumed by the virtual server's incoming and outgoing traffic exceeds the threshold.

* HEALTH - Spillover occurs when the percentage of weights of the services that are UP drops below the threshold. For example, if services svc1, svc2, and svc3 are bound to a virtual server, with weights 1, 2, and 3, and the spillover threshold is 50%, spillover occurs if svc1 and svc3 or svc2 and svc3 transition to DOWN.

* NONE - Spillover does not occur.

Possible values: CONNECTION, DYNAMICCONNECTION, BANDWIDTH, HEALTH, NONE

soPersistence

If spillover occurs, maintain source IP address based persistence for both primary and backup virtual servers.

Possible values: ENABLED, DISABLED

Default value: DISABLED

soPersistenceTimeOut

Timeout for spillover persistence, in minutes.

Default value: 2

Minimum value: 2

Maximum value: 1440

healthThreshold

Threshold in percent of active services below which vserver state is made down. If this threshold is 0, vserver state will be up even if one bound service is up.

Maximum value: 100

soBackupAction

Action to be performed if spillover is to take effect, but no backup chain to spillover is usable or exists

Possible values: DROP, ACCEPT, REDIRECT

redirectPortRewrite

Rewrite the port and change the protocol to ensure successful HTTP redirects from services.

Possible values: ENABLED, DISABLED

Default value: DISABLED

downStateFlush

Flush all active transactions associated with a virtual server whose state transitions from UP to DOWN. Do not enable this option for applications that must complete their transactions.

Possible values: ENABLED, DISABLED

Default value: ENABLED

insertVserverIPPort

Insert an HTTP header, whose value is the IP address and port number of the virtual server, before forwarding a request to the server. The format of the header is <vipHeader>: <virtual server IP address>_<port number >, where vipHeader is the name that you specify for the header. If the virtual server has an IPv6 address, the address in the header is enclosed in brackets ([and]) to separate it from the port number. If you have mapped an IPv4 address to a virtual server's IPv6 address, the value of this parameter determines which IP address is inserted in the header, as follows:

* VIPADDR - Insert the IP address of the virtual server in the HTTP header regardless of whether the virtual server has an IPv4 address or an IPv6 address. A mapped IPv4 address, if configured, is ignored.

* V6TOV4MAPPING - Insert the IPv4 address that is mapped to the virtual server's IPv6 address. If a mapped IPv4 address is not configured, insert the IPv6 address.

* OFF - Disable header insertion.

Possible values: OFF, VIPADDR, V6TOV4MAPPING

disablePrimaryOnDown

If the primary virtual server goes down, do not allow it to return to primary status until manually enabled.

Possible values: ENABLED, DISABLED

Default value: DISABLED

AuthenticationHost

Fully qualified domain name (FQDN) of the authentication virtual server to which the user must be redirected for authentication. Make sure that the Authentication parameter is set to ENABLED.

Authentication

Enable or disable user authentication.

Possible values: ON, OFF

Default value: OFF

authn401

Enable or disable user authentication with HTTP 401 responses.

Possible values: ON, OFF

Default value: OFF

authnVsName

Name of an authentication virtual server with which to authenticate users.

push

Process traffic with the push virtual server that is bound to this load balancing virtual server.

Possible values: ENABLED, DISABLED

Default value: DISABLED

pushVserver

Name of the load balancing virtual server, of type PUSH or SSL_PUSH, to which the server pushes updates received on the load balancing virtual server that you are configuring.

pushLabel

Expression for extracting a label from the server's response. Can be either an expression or the name of a named expression.

Default value: "none"

pushMultiClients

Allow multiple Web 2.0 connections from the same client to connect to the virtual server and expect updates.

Possible values: YES, NO

Default value: NO

Listenpolicy

Default syntax expression identifying traffic accepted by the virtual server. Can be either an expression (for example, CLIENT.IP.DST.IN_SUBNET(192.0.2.0/24) or the name of a named expression. In the above example, the virtual server accepts all requests whose destination IP address is in the 192.0.2.0/24 subnet.

Default value: "none"

Listenpriority

Integer specifying the priority of the listen policy. A higher number specifies a lower priority. If a request matches the listen policies of more than one virtual server the virtual server whose listen policy has the highest priority (the lowest priority number) accepts the request.

Default value: 101

Maximum value: 101

tcpProfileName

Name of the TCP profile whose settings are to be applied to the virtual server.

httpProfileName

Name of the HTTP profile whose settings are to be applied to the virtual server.

dbProfileName

Name of the DB profile whose settings are to be applied to the virtual server.

comment

Any comments that you might want to associate with the virtual server.

l2Conn

Use Layer 2 parameters (channel number, MAC address, and VLAN ID) in addition to the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) that is used to identify a connection. Allows multiple TCP and non-TCP connections with the same 4-tuple to co-exist on the NetScaler appliance.

Possible values: ON, OFF

mssqlServerVersion

For a load balancing virtual server of type MSSQL, the Microsoft SQL Server version. Set this parameter if you expect some clients to run a version different from the version of the database. This setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

Possible values: 70, 2000, 2000SP1, 2005, 2008, 2008R2, 2012

Default value: TDS_PROT_2008B

mysqlProtocolVersion

MySQL protocol version that the virtual server advertises to clients.

Default value: NSA_MYSQL_PROTOCOL_VER_DEFAULT

mysqlServerVersion

MySQL server version string that the virtual server advertises to clients.

Default value: NSA_MYSQL_SERVER_VER_DEFAULT

mysqlCharacterSet

Character set that the virtual server advertises to clients.

Default value: NSA_MYSQL_CHAR_SET_DEFAULT

mysqlServerCapabilities

Server capabilities that the virtual server advertises to clients.

Default value: NSA_MYSQL_SVR_CAPABILITIES_DEFAULT

appflowLog

Apply AppFlow logging to the virtual server.

Possible values: ENABLED, DISABLED

Default value: ENABLED

netProfile

Name of the network profile to associate with the virtual server. If you set this parameter, the virtual server uses only the IP addresses in the network profile as source IP addresses when initiating connections with servers.

icmpVsrResponse

How the NetScaler appliance responds to ping requests received for an IP address that is common to one or more virtual servers. Available settings function as follows:

* If set to PASSIVE on all the virtual servers that share the IP address, the appliance always responds to the ping requests.

* If set to ACTIVE on all the virtual servers that share the IP address, the appliance responds to the ping requests if at least one of the virtual servers is UP. Otherwise, the appliance does not respond.

* If set to ACTIVE on some virtual servers and PASSIVE on the others, the appliance responds if at least one virtual server with the ACTIVE setting is UP. Otherwise, the appliance does not respond.

Note: This parameter is available at the virtual server level. A similar parameter, ICMP Response, is available at the IP address level, for IPv4 addresses of type VIP. To set that parameter, use the add ip command in the CLI or the Create IP dialog box in the GUI.

Possible values: PASSIVE, ACTIVE

Default value: NS_VSR_PASSIVE

newServiceRequest

Number of requests, or percentage of the load on existing services, by which to increase the load on a new service at each interval in slow-start mode. A value of 0 disables slow start for new services, and any services still ramping up. They immediately receive their full share of the load. If you use the CLI, be sure to set the newServiceRequestUnit parameter to specify the unit as number of requests or percentage of load.

newServiceRequestIncrementInterval

Interval, in seconds, between successive increments in the load on a new service or a service whose state has just changed from DOWN to UP. A value of 0 (zero) specifies manual slow start.

Maximum value: 3600

minAutoscaleMembers

Minimum number of members expected to be present when vserver is used in Autoscale.

Maximum value: 5000

maxAutoscaleMembers

Maximum number of members expected to be present when vserver is used in Autoscale.

Maximum value: 5000

persistAVPno

Persist AVP number for Diameter Persistency.

In case this AVP is not defined in Base RFC 3588 and it is nested inside a Grouped AVP,

define a sequence of AVP numbers (max 3) in order of parent to child. So say persist AVP number X

is nested inside AVP Y which is nested in Z, then define the list as Z Y X

Minimum value: 1

skippersistency

This argument decides the behavior incase the service which is selected from an existing persistence session has reached threshold.

Possible values: Bypass, ReLb, None

Default value: NS_DONT_SKIPPERSIST

authnProfile

Name of the authentication profile to be used when authentication is turned on.

macmodeRetainvlan

This option is used to retain vlan information of incoming packet when macmode is enabled

Possible values: ENABLED, DISABLED

Default value: DISABLED

dbsLb

For enabling database specific load-balacing..

Possible values: ENABLED, DISABLED

Default value: DISABLED

dns64

This argument is for enabling/disabling the dns64 on lbvserver

Possible values: ENABLED, DISABLED

bypassAAAA

If this option is enabled while resolving DNS64 query AAAA queries are not sent to back end dns server

Possible values: YES, NO

Default value: NO

RecursionAvailable

When set to YES, this option causes the DNS replies from this vserver to have the RA bit turned on. Typically one would set this option to YES, when the vserver is load balancing a set of DNS servers thatsupport recursive queries.

Possible values: YES, NO

Default value: NO

Example

set lb vserver http_vip -lbmethod LEASTRESPONSETIME To set the load balancing method for multiple vserver use the following command: set lb vserver http_vip[1-3] -

---

unset lb vserver

Removes the specified parameter settings from the virtual server..Refer to the set lb vserver command for meanings of the arguments.

Synopsys

unset lb vserver <name>@ [-backupVServer] [-cltTimeout] [-redirectURL] [-authn401] [-Authentication] [-AuthenticationHost] [-authnVsName] [-pushVserver] [-pushLabel] [-tcpProfileName] [-httpProfileName] [-dbProfileName] [-rule] [-l2Conn] [-mysqlProtocolVersion] [-mysqlServerVersion] [-mysqlCharacterSet] [-mysqlServerCapabilities] [-appflowLog] [-netProfile] [-icmpVsrResponse] [-skippersistency] [-minAutoscaleMembers] [-maxAutoscaleMembers] [-authnProfile] [-macmodeRetainvlan] [-dbsLb] [-serviceName] [-persistenceType] [-timeout] [-persistenceBackup] [-backupPersistenceTimeout] [-lbMethod] [-hashLength] [-netmask] [-v6netmasklen] [-cookieName] [-resRule] [-persistMask] [-v6persistmasklen] [-pq] [-sc] [-rtspNat] [-m] [-tosId] [-dataLength] [-dataOffset] [-sessionless] [-connfailover] [-cacheable] [-soMethod] [-soPersistence] [-soPersistenceTimeOut] [-healthThreshold] [-soBackupAction] [-redirectPortRewrite] [-downStateFlush] [-insertVserverIPPort] [-vipHeader] [-disablePrimaryOnDown] [-push] [-pushMultiClients] [-Listenpolicy] [-Listenpriority] [-comment] [-mssqlServerVersion] [-newServiceRequest] [-newServiceRequestUnit] [-newServiceRequestIncrementInterval] [-persistAVPno] [-RecursionAvailable]

Example

unset lb vserver lb_vip -backupVServer To unset the backup virtual server for multiple vservers use the following command: unset lb vserver lb_vip[1-3] -backupVServer

---

bind lb vserver

Binds a service, service group, or policy to a virtual server.

Synopsys

bind lb vserver <name>@ ((<serviceName>@ [-weight <positive_integer>]) | <serviceGroupName>@ | (-policyName <string>@ [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>)]))

Arguments

name

Name for the virtual server. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign

(@), equal sign (=), and hyphen (-) characters. Can be changed after the virtual server is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my vserver" or 'my vserver').

serviceName

Name of the service.

serviceGroupName

Name of the service group.

policyName

Name of the policy to bind to the virtual server.

Example

bind lb vserver http_vip http_svc To bind a service to multiple vservers use the following command: bind lb vs http_vip[1-3] http_svc To bind multiple services to a vserv

---

unbind lb vserver

Unbinds a service, service group, or policy from a virtual server.

Synopsys

unbind lb vserver <name>@ (<serviceName>@ | <serviceGroupName>@ | (-policyName <string>@ [-type (REQUEST | RESPONSE)])) [-priority <positive_integer>]

Arguments

name

Name for the virtual server. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign (@), equal sign (=), and hyphen (-) characters. Can be changed after the virtual server is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my vserver" or 'my vserver').

serviceName

Name of the service.

serviceGroupName

The name of the service group that is unbound.

policyName

Name of the policy to bind to the virtual server.

priority

Priority number of the policy.

Minimum value: 1

Maximum value: 2147483647

Example

unbind lb vserver http_vip http_svc To unbind a service from multiple vservers use the following command: unbind lb vs http_vip[1-3] http_svc To unbind multiple se

---

enable lb vserver

Enables a virtual server.

Synopsys

enable lb vserver <name>@

Arguments

name

Name of the virtual server.

Example

enable vserver lb_vip To enable multiple vservers at once use the following command: enable vserver lb_vip[1-3]

---

disable lb vserver

Disables a virtual server.

Synopsys

disable lb vserver <name>@

Arguments

name

Name of the virtual server.

Example

disable vserver lb_vip To disable multiple vservers at once use the following command: disable vserver lb_vip[1-3]

---

show lb vserver

Displays the statistical data collected for a load balancing virtual server.

Synopsys

show lb vserver [<name>] show lb vserver stats - alias for 'stat lb vserver'

Arguments

name

Name of the virtual server. If no name is provided, statistical data of all configured virtual servers is displayed.

summary

fullValues

format

level

Outputs

insertVserverIPPort

The virtual IP and port header insertion option for the vserver.

vipHeader

Name for the inserted header. The default name is vip-header.

value

SSL status.

stateflag

appfwPolicyFlag

IPAddress

IPv4 or IPv6 address to assign to the virtual server.

IPPattern

The IP pattern of the virtual server.

IPMask

The IP address mask of the virtual server.

Listenpolicy

The string is listenpolicy configured for lb vserver

Listenpriority

This parameter is the priority for listen policy of LB Vserver.

IPMapping

The permanent mapping for the V6 Address

port

Port number for the virtual server.

range

Number of IP addresses that the appliance must generate and assign to the virtual server. The virtual server then functions as a network virtual server, accepting traffic on any of the generated IP addresses. The IP addresses are generated automatically, as follows:

* For a range of n, the last octet of the address specified by the IP Address parameter increments n-1 times.

* If the last octet exceeds 255, it rolls over to 0 and the third octet increments by 1.

Note: The Range parameter assigns multiple IP addresses to one virtual server. To generate an array of virtual servers, each of which owns only one IP address, use brackets in the IP Address and Name parameters to specify the range. For example:

add lb vserver my_vserver[1-3] HTTP 192.0.2.[1-3] 80

serviceType

Protocol used by the service (also called the service type).

ngname

Nodegroup name to which this lbvsever belongs to

type

The bindpoint to which the policy is bound

state

State of the load balancing virtual server.

effectiveState

Effective state of the LB vserver , based on the state of backup vservers.

status

Current status of the lb vserver. During the initial phase if the configured lb method is not round robin , the vserver will adopt round robin to distribute traffic for a predefined number of requests.

lbrrreason

Reason why a vserver is in RR. The following are the reasons:

1 - MEP is DOWN (GSLB)

2 - LB method has changed

3 - Bound service's state changed to UP

4 - A new service is bound

5 - Startup RR factor has changed

6 - LB feature is enabled

7 - Load monitor is not active on a service

8 - Vserver is Enabled

9 - SSL feature is Enabled

10 - All bound services have reached threshold. Using effective state to load balance (GSLB)

11 - Primary state of bound services are not UP. Using effective state to load balance (GSLB)

12 - No LB decision can be made as all bound services have either reached threshold or are not UP (GSLB)

13 - All load monitors are active

cacheType

Cache type.

redirect

Cache redirect type.

precedence

Precedence.

redirectURL

The redirect URL.

Authentication

Authentication.

authn401

HTTP 401 response based authentication.

authnVsName

Name of an authentication virtual server with which to authenticate users.

homePage

Home page.

dnsVserverName

DNS vserver name.

domain

Domain.

policyName

Name of the policy bound to the LB vserver.

serviceName

Service to bind to the virtual server.

serviceGroupName

The service group name bound to the selected load balancing virtual server.

weight

Weight to assign to the specified service.

dynamicWeight

Dynamic weight

cacheVserver

Cache virtual server.

backupVServer

Name of the backup virtual server to which to forward requests if the primary virtual server goes DOWN or reaches its spillover threshold.

priority

Priority.

cltTimeout

The client timeout in seconds.

soMethod

The spillover method to be in effect.

soPersistence

State of spillover persistence.

soPersistenceTimeOut

The maximum time persistence is in effect for a specific client on a spillover vserver.

healthThreshold

Threshold in percent of active services below which vserver state is made down.

soThreshold

Threshold at which spillover occurs. Specify an integer for the CONNECTION spillover method, a bandwidth value in kilobits per second for the BANDWIDTH method (do not enter the units), or a percentage for the HEALTH method (do not enter the percentage symbol).

soBackupAction

Action to be performed if spillover is to take effect, but no backup chain to spillover is usable or exists

lbMethod

The load balancing method to be in effect

hashLength

The hash length.

dataOffset

The data offset length for TOKEN load balancing method.

health

Health of vserver based on percentage of weights of active svcs/all svcs. This does not consider administratively disabled svcs

dataLength

The data length for TOKEN load balancing method.

netmask

The netmask of the destination network.

v6netmasklen

The netmask of the destination network.

rule

Rule type.

resRule

Use this parameter to specify the expression to be used in response for RULE persistence type.

The string is an in-line expression with a maximum of 1499 characters.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

ruleType

Rule type.

groupName

LB group to which the lb vserver is to be bound.

m

The LB mode.

tosId

TOS ID

persistenceType

The persistence type for the specified virtual server

timeout

The maximum time persistence is in effect for a specific client.

cookieDomain

Domain name to be used in the set cookie header in case of cookie persistence.

persistMask

The persistence mask for v4 traffic

v6persistmasklen

The persistence mask for v6 traffic.

persistenceBackup

The maximum time backup persistence is in effect for a specific client.

backupPersistenceTimeout

Time period for which backup persistence is in effect.

cacheable

The state of caching.

pq

The state of priority queuing on the specified virtual server.

sc

The state of SureConnect the specified virtual server.

rtspNat

Use network address translation (NAT) for RTSP data connections.

sessionless

To enable sessionless load balancing, enable this option

map

Map.

connfailover

The connection failover mode of the virtual server

redirectPortRewrite

Rewrite the port and change the protocol to ensure successful HTTP redirects from services.

downStateFlush

Flush all active transactions associated with a virtual server whose state transitions from UP to DOWN. Do not enable this option for applications that must complete their transactions.

disablePrimaryOnDown

Tells whether traffic will continue reaching backup vservers even after primary comes UP from DOWN state.

gt2GB

Allow for greater than 2 GB transactions on this vserver.

consolidatedLConn

Use consolidated stats for LeastConnection.

consolidatedLConnGbl

Fetches Global setting.

thresholdValue

Tells whether threshold exceeded for this service participating in CUSTOMLB

invoke

Invoke policies bound to a virtual server or policy label.

labelType

The invocation type.

labelName

Name of the label invoked.

cookieIpPort

Encryped Ip address and port of the service that is inserted into the set-cookie http header

cookieName

Use this parameter to specify the cookie name for COOKIE peristence type. It specifies the name of cookie with a maximum of 32 characters. If not specified, cookie name is internally generated.

vserverId

Vserver Id

version

Cookie version

totalServices

Total number of services bound to the vserver.

activeServices

Total number of active services bound to the vserver.

stateChangeTimeSec

Time when last state change happened. Seconds part.

stateChangeTimeSeconds

Time when last state change happened. Seconds part.

stateChangeTimemSec

Time at which last state change happened. Milliseconds part.

ticksSinceLastStateChange

Time in 10 millisecond ticks since the last state change.

hits

Number of hits.

piPolicyhits

Number of hits.

AuthenticationHost

Fully qualified domain name (FQDN) of the authentication virtual server to which the user must be redirected for authentication. Make sure that the Authentication parameter is set to ENABLED.

push

Process traffic with the push virtual server that is bound to this load balancing virtual server.

pushVserver

Name of the load balancing virtual server, of type PUSH or SSL_PUSH, to which the server pushes updates received on the load balancing virtual server that you are configuring.

pushLabel

Expression for extracting a label from the server's response. Can be either an expression or the name of a named expression.

pushMultiClients

Allow multiple Web 2.0 connections from the same client to connect to the virtual server and expect updates.

tcpProfileName

Name of the TCP profile whose settings are to be applied to the virtual server.

httpProfileName

Name of the HTTP profile whose settings are to be applied to the virtual server.

dbProfileName

Name of the DB profile whose settings are to be applied to the virtual server.

comment

Any comments that you might want to associate with the virtual server.

flag

flags

policySubType

l2Conn

Use Layer 2 parameters (channel number, MAC address, and VLAN ID) in addition to the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) that is used to identify a connection. Allows multiple TCP and non-TCP connections with the same 4-tuple to co-exist on the NetScaler appliance.

oracleServerVersion

Oracle server version

mssqlServerVersion

For a load balancing virtual server of type MSSQL, the Microsoft SQL Server version. Set this parameter if you expect some clients to run a version different from the version of the database. This setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

mysqlProtocolVersion

MySQL protocol version that the virtual server advertises to clients.

mysqlServerVersion

MySQL server version string that the virtual server advertises to clients.

mysqlCharacterSet

Character set that the virtual server advertises to clients.

mysqlServerCapabilities

Server capabilities that the virtual server advertises to clients.

appflowLog

Apply AppFlow logging to the virtual server.

netProfile

Name of the network profile to associate with the virtual server. If you set this parameter, the virtual server uses only the IP addresses in the network profile as source IP addresses when initiating connections with servers.

isGslb

This field is set to true if it is a GSLBVserver.

icmpVsrResponse

How the NetScaler appliance responds to ping requests received for an IP address that is common to one or more virtual servers. Available settings function as follows:

* If set to PASSIVE on all the virtual servers that share the IP address, the appliance always responds to the ping requests.

* If set to ACTIVE on all the virtual servers that share the IP address, the appliance responds to the ping requests if at least one of the virtual servers is UP. Otherwise, the appliance does not respond.

* If set to ACTIVE on some virtual servers and PASSIVE on the others, the appliance responds if at least one virtual server with the ACTIVE setting is UP. Otherwise, the appliance does not respond.

Note: This parameter is available at the virtual server level. A similar parameter, ICMP Response, is available at the IP address level, for IPv4 addresses of type VIP. To set that parameter, use the add ip command in the CLI or the Create IP dialog box in the GUI.

newServiceRequest

Number of requests, or percentage of the load on existing services, by which to increase the load on a new service at each interval in slow-start mode. A value of 0 disables slow start for new services, and any services still ramping up. They immediately receive their full share of the load. If you use the CLI, be sure to set the newServiceRequestUnit parameter to specify the unit as number of requests or percentage of load.

newServiceRequestUnit

Units in which to increment load at each interval in slow-start mode.

newServiceRequestIncrementInterval

Interval, in seconds, between successive increments in the load on a new service or a service whose state has just changed from DOWN to UP. A value of 0 (zero) specifies manual slow start.

vsvrcfgflags

Contains the config info of vserver to be used at validation

vsvrbindsvcip

used for showing the ip of bound entities

vsvrbindsvcport

used for showing ports of bound entities

persistAVPno

Persist AVP number for Diameter Persistency.

In case this AVP is not defined in Base RFC 3588 and it is nested inside a Grouped AVP,

define a sequence of AVP numbers (max 3) in order of parent to child. So say persist AVP number X

is nested inside AVP Y which is nested in Z, then define the list as Z Y X

skippersistency

This argument decides the behavior incase the service which is selected from an existing persistence session has reached threshold.

td

Traffic Domain ID

minAutoscaleMembers

Minimum number of members expected to be present when vserver is used in Autoscale.

maxAutoscaleMembers

Maximum number of members expected to be present when vserver is used in Autoscale.

authnProfile

Name of the authentication profile to be used when authentication is turned on.

macmodeRetainvlan

This option is used to retain vlan information of incoming packet when macmode is enabled

dbsLb

For enabling database specific load-balacing..

dns64

This argument is for enabling/disabling the dns64 on lbvserver

bypassAAAA

If this option is enabled while resolving DNS64 query AAAA queries are not sent to back end dns server

RecursionAvailable

When set to YES, this option causes the DNS replies from this vserver to have the RA bit turned on. Typically one would set this option to YES, when the vserver is load balancing a set of DNS servers thatsupport recursive queries.

devno

count

---

stat lb vserver

Displays the statistical data collected for a load balancing virtual server.

Synopsys

stat lb vserver [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)] [-sortBy Hits [<sortOrder>]]

Arguments

name

Name of the virtual server. If no name is provided, statistical data of all configured virtual servers is displayed.

clearstats

Clear the statsistics / counters

Possible values: basic, full

sortBy

use this argument to sort by specific key

Possible values: Hits

Outputs

count

devno

stateflag

Outputs

s surgeQ (vSurgeQ)

Number of requests waiting on this vserver.

Current Client Est connections (ClntEstConn)

Number of client connections in ESTABLISHED state.

total INACTIVE services (inactSvcs)

number of INACTIVE services bound to a vserver

Vserver Health (Health)

Health of the vserver. This gives percentage of UP services bound to this vserver.

Vserver IP address (vsvrIP)

IP address of the vserver

Port (port)

The port on which the service is running.

Vserver protocol (Protocol)

Protocol associated with the vserver

State

Current state of the server. Possible values are UP, DOWN, UNKNOWN, OFS(Out of Service), TROFS(Transition Out of Service), TROFS_DOWN(Down When going Out of Service)

total ACTIVE services (actSvcs)

number of ACTIVE services bound to a vserver

Vserver hits (Hits)

Total vserver hits

Requests (Req)

Total number of requests received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Responses (Rsp)

Number of responses received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Request bytes (Reqb)

Total number of request bytes received on this service or virtual server.

Response bytes (Rspb)

Number of response bytes received by this service or virtual server.

Total Packets rcvd (PktRx)

Total number of packets received by this service or virtual server.

Total Packets sent (PktTx)

Total number of packets sent.

Current client connections (ClntConn)

Number of current client connections.

Current server connections (SvrConn)

Number of current connections to the actual servers behind the virtual server.

Requests in surge queue (SurgeQ)

Number of requests in the surge queue.

s surgeQs (SvcSurgeQ)

Total number of requests in the surge queues of all the services bound to this LB-vserver.

Spill Over Threshold (SOThresh)

Spill Over Threshold set on the VServer.

Spill Over Hits (NumSo)

Number of times vserver experienced spill over.

Labeled Connection (LblConn)

Number of Labeled connection on this vserver

Push Labeled Connection (PushLbl)

Number of labels for this push vserver.

Deferred Request (DefReq)

Number of deferred request on this vserver

Invalid Request/Response (IvldReqRsp)

Number invalid requests/responses on this vserver

Invalid Request/Response Dropped (IvldReqRspDrp)

Number invalid requests/responses dropped on this vserver

Current Server Est connections (SvrEstConn)

Number of server connections in ESTABLISHED state.

---

rename lb vserver

Renames a load balancing virtual server.

Synopsys

rename lb vserver <name>@ <newName>@

Arguments

name

Existing name of the virtual server.

newName

New name for the virtual server.

Example

```
rename lb vserver http_vsvr http_vsvr_new
```

lb wlm

Sep 22, 2015

The following operations can be performed on "lb wlm":

add | rm | set | unset | show | bind | unbind

add lb wlm

Add a Work Load Manager. NOTE: This command is deprecated.WLM feature has been deprecated from Kos onwards as classic build is not supported.

Synopsys

Arguments

wlmName

The name of the Work Load Manager.

IPAddress

The IP address of the WLM.

LBUID

The LBUID for the Load Balancer to communicate to the Work Load Manager.

KATimeout

The idle time period after which NS would probe the WLM. The value ranges from 1 to 1440 minutes.

Default value: 2

Maximum value: 1440

Example

```
add lb wlm ibm_wlm 10.102.1.10 3060
```

---

rm lb wlm

Removes a Work Load Manager. NOTE: This command is deprecated.WLM feature has been deprecated from Kos onwards as classic build is not supported.

Synopsys

Arguments

wlmName

The name of the Work Load Manager to be removed.

Example

```
rm lb wlm ibm_wlm
```

---

set lb wlm

set Work Load Manager attributes NOTE: This command is deprecated.

Synopsys

Arguments

wlmName

The name of the work load manager.

KATimeout

The idle time period after which NS would probe the WLM. The value ranges from 1 to 1440 minutes.

Default value: 2

Maximum value: 1440

Example

```
set lb wlm ibm_wlm -ka_timeout 6
```

---

unset lb wlm

Use this command to remove lb wlm settings.Refer to the set lb wlm command for meanings of the arguments.NOTE: This command is deprecated.

Synopsys

---

show lb wlm

show Work Load Manager details NOTE: This command is deprecated.WLM feature has been deprecated from Kos onwards as classic build is not supported.

Synopsys

Arguments

wlmName

The name of the work load manager.

summary

fullValues

format

level

Outputs

IPAddress

The IP address of the WLM.

port

A port number for the virtual server.

stateflag

secure

Use this parameter to enable secure mode of communication with WLM.

KATimeout

The idle time period after which NS would probe the WLM. The value ranges from 1 to 1440 minutes.

LBUID

The LBUID for the Load Balancer to communicate to the Work Load Manager.

state

State of the WLM.

vServerName

Name of the virtual server which is to be bound to the WLM.

devno

count

Example

show lb wlm ibm_wlm

---

bind lb wlm

Bind a vserver to Work Load Manager. NOTE: This command is deprecated.WLM feature has been deprecated from Kos onwards as classic build is not supported.

Synopsys

Arguments

wlmName

The name of the Work Load Manager.

vServerName

Name of the virtual server which is to be bound to the WLM.

Example

bind lb wlm ibm_wlm http_vip To bind multiple vservers to workload manager use the following command: bind lb wlm ibm_wlm http_

---

unbind lb wlm

Unbind a vserver from Work Load Manager. NOTE: This command is deprecated.WLM feature has been deprecated from Kos onwards as classic build is not supported.

Synopsys

Arguments

wlmName

The name of the Work Load Manager.

vServerName

Name of the virtual server which is to be unbound from the WLM.

Example

unbind lb wlm ibm_wlm http_vip To unbind multiple vservers from Work Load Manager use the following command: unbind lb wlm ibm

L2Param

Sep 22, 2015

The following operations can be performed on "L2Param":

set | unset | show

set L2Param

Set Layer 2 related global settings on the NetScaler

Synopsys

set L2Param [-mbfPeermacUpdate <positive_integer>] [-maxBridgeCollision <positive_integer>] [-bdggrpProxyArp (ENABLED | DISABLED)] [-bdgSetting (ENABLED | DISABLED)] [-garpOnVridIntf (ENABLED | DISABLED)] [-macModeFwdMyPkt (ENABLED | DISABLED)] [-useMyMAC (ENABLED | DISABLED)] [-proxyArp (ENABLED | DISABLED)] [-garpReply (ENABLED | DISABLED)] [-mbfInstLearning (ENABLED | DISABLED)] [-rstIntfOnHaFo (ENABLED | DISABLED)] [-skipProxyingBsdTraffic (ENABLED | DISABLED)] [-returnToEthernetSender (ENABLED | DISABLED)]

Arguments

mbfPeermacUpdate

When mbf_instant_learning is enabled, learn any changes in peer's MAC after this time interval, which is in 10ms ticks.

Default value: 10

maxBridgeCollision

Maximum bridge collision for loop detection

Default value: 20

bdggrpProxyArp

Set/reset proxy ARP in bridge group deployment

Possible values: ENABLED, DISABLED

Default value: ENABLED

bdgSetting

Bridging settings for C2C behavior

Possible values: ENABLED, DISABLED

Default value: DISABLED

garpOnVridIntf

Send GARP messagess on VRID-configured interfaces upon failover

Possible values: ENABLED, DISABLED

Default value: ENABLED

macModeFwdMyPkt

MAC mode vserver forward packets destined to VIPs.

Possible values: ENABLED, DISABLED

Default value: DISABLED

useMyMAC

Set/reset cfg_use_my_mac

Possible values: ENABLED, DISABLED

Default value: DISABLED

proxyArp

Set/reset cfg_proxy_arp_dr

Possible values: ENABLED, DISABLED

Default value: ENABLED

garpReply

Set/reset REPLY form of GARP

Possible values: ENABLED, DISABLED

Default value: DISABLED

mbfInstLearning

Enable instant learning of MAC changes in MBF mode.

Possible values: ENABLED, DISABLED

Default value: DISABLED

rstIntfOnHaFo

Enable the reset interface upon HA failover.

Possible values: ENABLED, DISABLED

Default value: DISABLED

skipProxyingBsdTraffic

Enable the proxying of FreeBSD traffic.

Possible values: ENABLED, DISABLED

Default value: DISABLED

returnToEthernetSender

Return to ethernet sender.

Possible values: ENABLED, DISABLED

Default value: DISABLED

---

unset L2Param

Use this command to remove L2Param settings.Refer to the set L2Param command for meanings of the arguments.

Synopsys

unset L2Param [-mbfPeermacUpdate] [-maxBridgeCollision] [-bdggrpProxyArp] [-bdgSetting] [-garpOnVridIntf] [-macModeFwdMyPkt] [-useMyMAC] [-proxyArp] [-garpReply] [-mbfInstLearning] [-rstIntfOnHaFo] [-skipProxyingBsdTraffic] [-returnToEthernetSender]

---

show L2Param

Displays the settings of global Layer 2 parameters on the NetScaler appliance.

Synopsys

show L2Param

Arguments

format

level

Outputs

maxBridgeCollision

Maximum bridge collision for loop detection

linkMTU

this MTU is used for Ready logo purpose, changing the Interface MTU at soft layer level.

mbfPeermacUpdate

When mbf_instant_learning is enabled, learn any changes in peer's MAC after this time interval, which is in

10ms ticks.

bdggrpProxyArp

Set/reset proxy ARP in bridge group deployment

bdgSetting

Bridging settings for C2C behavior

garpOnVridIntf

Send GARP messagess on VRID-configured interfaces upon failover

macModeFwdMyPkt

MAC mode vserver forward packets destined to VIPs.

useMyMAC

Set/reset cfg_use_my_mac

proxyArp

Set/reset cfg_proxy_arp_dr

garpReply

Set/reset REPLY form of GARP

mbfInstLearning

Enable instant learning of MAC changes in MBF mode.

rstIntfOnHaFo

Enable the reset interface upon HA failover.

skipProxyingBsdTraffic

Enable the proxying of FreeBSD traffic.

returnToEthernetSender

Return to ethernet sender.

L3Param

Sep 22, 2015

The following operations can be performed on "L3Param":

set | unset | show

set L3Param

Set Layer 3 related global settings on the NetScaler

Synopsys

set L3Param [-srcnat (ENABLED | DISABLED)] [-icmpGenRateThreshold <positive_integer>] [-overrideRnat (ENABLED | DISABLED)] [-dropDFFlag (ENABLED | DISABLED)] [-mipRoundRobin (ENABLED | DISABLED)] [-externalLoopBack (ENABLED | DISABLED)] [-tnlPmtuWoConn (ENABLED | DISABLED)] [-usipServerStrayPkt (ENABLED | DISABLED)] [-forwardICMPFragments (ENABLED | DISABLED)] [-dropIPFragments (ENABLED | DISABLED)] [-AclLogTime <positive_integer>] [-icmpErrGenerate (ENABLED | DISABLED)] [-implicitACLAllow (ENABLED | DISABLED)]

Arguments

srcnat

Perform NAT if only the source is in the private network

Possible values: ENABLED, DISABLED

Default value: ENABLED

icmpGenRateThreshold

NS generated ICMP pkts per 10ms rate threshold

Default value: 100

overrideRnat

USNIP/USIP settings override RNAT settings for configured

service/virtual server traffic..

Possible values: ENABLED, DISABLED

Default value: DISABLED

dropDFFlag

Enable dropping the IP DF flag.

Possible values: ENABLED, DISABLED

Default value: DISABLED

mipRoundRobin

Enable round robin usage of mapped IPs.

Possible values: ENABLED, DISABLED

Default value: ENABLED

externalLoopBack

Enable external loopback.

Possible values: ENABLED, DISABLED

Default value: DISABLED

tnlPmtuWoConn

Enable external loopback.

Possible values: ENABLED, DISABLED

Default value: ENABLED

usipServerStrayPkt

Enable detection of stray server side pkts in USIP mode.

Possible values: ENABLED, DISABLED

Default value: DISABLED

forwardICMPFragments

Enable forwarding of ICMP fragments.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dropIPFragments

Enable dropping of IP fragments.

Possible values: ENABLED, DISABLED

Default value: DISABLED

AclLogTime

Parameter to tune acl logging time

Default value: 5000

icmpErrGenerate

Enable/Disable fragmentation required icmp error generation, before encapsulating a packet with vPath header. This knob is only functional for vPath Environment

Possible values: ENABLED, DISABLED

Default value: ENABLED

implicitACLAllow

Do not apply ACLs for internal ports

Possible values: ENABLED, DISABLED

Default value: ENABLED

---

unset L3Param

Use this command to remove L3Param settings.Refer to the set L3Param command for meanings of the arguments.

Synopsys

unset L3Param [-srcnat] [-icmpGenRateThreshold] [-overrideRnat] [-dropDFFlag] [-mipRoundRobin] [-externalLoopBack] [-tnlPmtuWoConn] [-usipServerStrayPkt] [-forwardICMPFragments] [-dropIPFragments] [-AclLogTime] [-icmpErrGenerate] [-implicitACLAllow]

---

show L3Param

Displays the settings of global Layer 3 parameters.

Synopsys

show L3Param

Arguments

format

level

Outputs

srcnat

Perform NAT if only the source is in the private network

icmpGenRateThreshold

NS generated ICMP pkts per 10ms rate threshold

overrideRnat

USNIP/USIP settings override RNAT settings for configured

service/virtual server traffic..

dropDFFlag

Enable dropping the IP DF flag.

mipRoundRobin

Enable round robin usage of mapped IPs.

externalLoopBack

Enable external loopback.

tnlPmtuWoConn

Enable external loopback.

usipServerStrayPkt

Enable detection of stray server side pkts in USIP mode.

forwardICMPFragments

Enable forwarding of ICMP fragments.

dropIPFragments

Enable dropping of IP fragments.

AclLogTime

Parameter to tune acl logging time

icmpErrGenerate

Enable/Disable fragmentation required icmp error generation, before encapsulating a packet with vPath header. This knob is only functional for vPath Environment

implicitACLAllow

Do not apply ACLs for internal ports

L4Param

Sep 22, 2015

The following operations can be performed on "L4Param":

set | unset | show

set L4Param

Set Layer 4 related global settings on the NetScaler

Synopsys

set L4Param [-l2ConnMethod <l2ConnMethod>] [-l4switch (ENABLED | DISABLED)]

Arguments

l2ConnMethod

Layer 2 connection method based on the combination of channel number, MAC address and VLAN. It is tuned with l2conn param of lb vserver. If l2conn of lb vserver is ON then method specified here will be used to identify a connection in addition to the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>).

Possible values: Channel, Vlan, VlanChannel, Mac, MacChannel, MacVlan, MacVlanChannel

Default value: NS_L2CONN_MAC_VLAN_CHAN

l4switch

In L4 switch topology, always clients and servers are on the same side. Enable l4switch to allow such connections.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

set l4param

---

unset L4Param

Use this command to remove L4Param settings.Refer to the set L4Param command for meanings of the arguments.

Synopsys

unset L4Param [-l2ConnMethod] [-l4switch]

---

show L4Param

Displays the settings of global Layer 4 parameters.

Synopsys

show L4Param

Arguments

format

level

Outputs

l2ConnMethod

Layer 2 connection method based on the combination of channel number, MAC address and VLAN. It is tuned with l2conn param of lb vserver. If l2conn of lb vserver is ON then method specified here will be used to identify a connection in addition to the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>).

l4switch

In L4 switch topology, always clients and servers are on the same side. Enable l4switch to allow such connections.

arp

Sep 22, 2015

The following operations can be performed on "arp":

add | rm | send | show

add arp

Adds a static ARP entry to the ARP table of the NetScaler appliance.

Synopsys

add arp -IPAddress <ip_addr> [-td <positive_integer>] -mac <mac_addr> -ifnum <interface_name> [-ownerNode <positive_integer>]

Arguments

IPAddress

IP address of the network device that you want to add to the ARP table.

td

Traffic Domain Id.

Maximum value: 4094

mac

MAC address of the network device.

ifnum

Interface through which the network device is accessible. Specify the interface in (slot/port) notation. For example, 1/3.

ownerNode

The owner node for the Arp entry.

Default value: VAL_NOT_SET

Maximum value: 31

Example

```
add arp -ip 10.100.0.48 -mac 00:a0:cc:5f:76:3a -ifnum 1/1
```

---

rm arp

Removes a specified static ARP entry or all static ARP entries from the NetScaler appliance's ARP table.

Synopsys

rm arp (<IPAddress> | -all) [-td <positive_integer>] [-ownerNode <positive_integer>]

Arguments

IPAddress

IP address of the network device in the ARP entry that you want to remove from the ARP table.

td

Traffic Domain Id.

Maximum value: 4094

all

Remove all ARP entries from the ARP table of the NetScaler appliance.

ownerNode

The owner node for the Arp entry.

Default value: VAL_NOT_SET

Maximum value: 31

---

send arp

Sends Gratuitous Address Resolution Protocol (GARP) messages for the specified NetScaler owned IP addresses.

Synopsys

send arp ((-IPAddress <ip_addr> [-td <positive_integer>]) | -all)

Arguments

IPAddress

NetScaler owned IP address for which the NetScaler appliance sends Gratuitous Address Resolution Protocol (GARP) messages.

all

Send GARP messages for all NetScaler owned IP addresses on which the ARP option is enabled. In a secondary node of an high availability configuration, this option sends GARP messages for the node's NSIP address only.

Example

send arp 10.10.10.10

---

show arp

Display all the entries in the system's ARP table.

Synopsys

show arp [<IPAddress> [-td <positive_integer>] [-ownerNode <positive_integer>]]

Arguments

IPAddress

The IP address corresponding to an ARP entry.

ownerNode

The cluster node which owns the ARP entry.

Default value: VAL_NOT_SET

Maximum value: 31

summary

fullValues

format

level

Outputs

mac

The MAC address corresponding to an ARP entry.

ifnum

The interface on which this MAC address resides.

timeout

The time, in seconds, after which the entry times out.

state

The state of the ARP entry.

flags

The flags for the entry.

type

Indicates whether this ARP entry was added manually or dynamically. When you manually add an ARP entry, the value for this parameter is STATIC. Otherwise, it is DYNAMIC. For the NSIP and loopback IP addresses, the value is PERMANENT.

vlan

The VLAN ID through which packets are to be sent after matching the ARP entry. This is a numeric value.

channel

The tunnel, channel, or physical interface through which the ARP entry is identified.

flag

Flags for the entry.

devno

count

stateflag

Example

The output of the sh arp command is as follows: 5 configured arps: IP MAC Iface TD VLAN Origin TTL -------

arpparam

Sep 22, 2015

The following operations can be performed on "arpparam":

set | unset | show

set arpparam

Sets a global time-out value for dynamic ARP entries.

Synopsys

set arpparam [-timeout <positive_integer>] [-spoofValidation (ENABLED | DISABLED)]

Arguments

timeout

Time-out value (aging time) for the dynamically learned ARP entries, in seconds. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time.

Default value: 1200

Minimum value: 5

Maximum value: 1200

spoofValidation

enable/disable arp spoofing validation

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

```
set arpparam -timeout 200 -spoofvalidate ENABLE
```

---

unset arpparam

Use this command to remove arpparam settings.Refer to the set arpparam command for meanings of the arguments.

Synopsys

unset arpparam [-timeout] [-spoofValidation]

---

show arpparam

Display the global setting of dynamically learned ARP entries.

Synopsys

show arpparam

Arguments

format

level

Outputs

timeout

The ARP table entry aging time, in seconds.

spoofValidation

enable/disable arp spoofing validation

Example

```
show arpparam
```

bridge

Sep 22, 2015

The following operations can be performed on "bridge":

stat bridge

Display bridging statistics.

Synopsys

stat bridge [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

Loops

The number of times bridging registered MAC moved

Collisions (Collisns)

The number of bridging table collisions

Interface muted (Mutes)

The number of bridging related interface mutes

Total bridged packets (Tot_pkts)

The total number of bridged packets

Total bridged Mbits (Tot_Mbits)

The total number of bridged Mbits

bridgegroup

Sep 22, 2015

The following operations can be performed on "bridgegroup":

add | rm | set | unset | bind | unbind | show

add bridgegroup

Create a Bridge group.

Synopsys

add bridgegroup <id> [-ipv6DynamicRouting (ENABLED | DISABLED)]

Arguments

id

An integer that uniquely identifies the bridge group. Minimum value: 1. Maximum value: 1000.

Minimum value: 1

Maximum value: 1000

ipv6DynamicRouting

Enable all IPv6 dynamic routing protocols on this VLAN. Possible values: ENABLED, DISABLED Default: DISABLED. Note: For the ENABLED setting to work, you must configure IPv6 dynamic routing protocols from the VTYSH command line. For more information about configuring IPv6 dynamic routing protocols on the NetScaler appliance, see the 'Dynamic Routing' chapter of the Citrix NetScaler Networking Guide.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

```
add bridgegroup bg1
```

---

rm bridgegroup

Remove the bridge group created by the add bridge group command.

Synopsys

rm bridgegroup <id>

Arguments

id

An integer that uniquely identifies the bridge group that you want to remove from the NetScaler appliance.

Minimum value: 1

Maximum value: 1000

---

set bridgegroup

Set Bridge group parameters.

Synopsys

set bridgegroup <id> -ipv6DynamicRouting (ENABLED | DISABLED)

Arguments

id

An integer value that uniquely identifies the bridge group. Minimum value: 1. Maximum value: 1000.

Minimum value: 1

Maximum value: 1000

ipv6DynamicRouting

Enable all IPv6 dynamic routing protocols on this bridge group. For this setting to work, you must configure IPv6 dynamic routing protocols from the VTYSH command line. For more information about configuring IPv6 dynamic routing protocols on the NetScaler appliance, see the Dynamic Routing chapter of the Citrix NetScaler Networking Guide.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

```
set bridgegroup bg1 -dynamicRouting ENABLED
```

---

unset bridgegroup

Use this command to remove bridgegroup settings.Refer to the set bridgegroup command for meanings of the arguments.

Synopsys

```
unset bridgegroup <id> -ipv6DynamicRouting
```

---

bind bridgegroup

Bind a vlan or an ip address to a bridgegroup.

Synopsys

```
bind bridgegroup <id> [-vlan <positive_integer>] [-IPAddress <ip_addr|ipv6_addr|*> [<netmask>] [-td <positive_integer>]]
```

Arguments

id

The integer that uniquely identifies the bridge group.

Minimum value: 1

Maximum value: 1000

vlan

An integer that uniquely identifies the VLAN that you want to bind to this bridge group.

Minimum value: 2

Maximum value: 4094

IPAddress

A network address or addresses to be associated with the bridge group. You must add entries for these network addresses in the routing table before running this command.

Example

```
bind bridgegroup bg1 -vlan 2
```

---

unbind bridgegroup

Unbinds the specified VLANs or IP addresses from a bridge group.

Synopsys

```
unbind bridgegroup <id> [-vlan <positive_integer>] [-IPAddress <ip_addr|ipv6_addr|*> [<netmask>] [-td <positive_integer>]]
```

Arguments

id

Integer that uniquely identifies the bridge group.

Minimum value: 1

Maximum value: 1000

vlan

ID of the VLAN to unbind from this bridge group.

Minimum value: 2

Maximum value: 4094

IPAddress

Network address associated with the bridge group.

---

show bridgegroup

Display the configured bridge group. If a name is specified, only that particular bridge group information is displayed. Otherwise, all configured bridge groups are displayed.

Synopsys

show bridgegroup [<id>]

Arguments

id

The name of the bridge group.

Minimum value: 1

Maximum value: 1000

summary

fullValues

format

level

Outputs

td

Traffic Domain Id.

IPAddress

The IP address assigned to the bridge group.

netmask

The network mask for the subnet defined for the bridge group.

flags

Temporary flag used for internal purpose.

portbitmap

Member interfaces of this bridge group.

tagbitmap

Tagged members of this bridge group.

ifaces

Names of all member interfaces of this bridge group.

tagIfaces

Names of all tagged member interfaces of this bridge group.

vlan

Names of all member VLANs.

ipv6DynamicRouting

Whether dynamic routing is enabled or disabled.

rnat

Temporary flag used for internal purpose.

flag

devno

count

stateflag

Example

An example of the output of the show bridge group command is as follows: 2 configured Bridge Group: 1) Bridge Group: 1

bridgetable

Sep 22, 2015

The following operations can be performed on "bridgetable":

set | unset | show | clear

set bridgetable

Sets global parameters of bridge table entries.

Synopsys

set bridgetable -bridgeAge <positive_integer>

Arguments

bridgeAge

Time-out value for the bridge table entries, in seconds. The new value applies only to the entries that are dynamically learned after the new value is set. Previously existing bridge table entries expire after the previously configured time-out value.

Default value: 300

Minimum value: 60

Maximum value: 300

Example

```
set bridgetable -bridgeAge 200
```

---

unset bridgetable

Use this command to remove bridgetable settings.Refer to the set bridgetable command for meanings of the arguments.

Synopsys

unset bridgetable -bridgeAge

---

show bridgetable

Displays the bridge table entries and the configured time-out values for these entries.

Synopsys

show bridgetable

Arguments

summary

fullValues

format

level

Outputs

bridgeAge

Time-out value for the bridge table entries, in seconds. The new value applies only to the entries that are dynamically learned after the new value is set. Previously existing bridge table entries expire after the previously configured time-out value.

mac

The MAC address of the target.

ifnum

The interface on which the address was learned.

vlan

The VLAN in which this MAC address resides.

channel

The Tunnel through which bridge entry is learned.

devno

count

stateflag

Example

show bridgetable

---

clear bridgetable

Remove entries from bridge table

Synopsys

clear bridgetable [-vlan <positive_integer>] [-ifnum <interface_name>]

Arguments

vlan

VLAN whose entries are to be removed.

ifnum

INTERFACE whose entries are to be removed.

channel

Sep 22, 2015

The following operations can be performed on "channel":

add | rm | set | unset | bind | unbind | show

add channel

Creates a link aggregate channel on the NetScaler appliance or on a cluster configuration. Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the NetScaler appliance and other connected devices. When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. That is, the network interface parameters are ignored. A network interface can be bound only to one channel.

Synopsys

add channel <id> [-ifnum <interface_name> ...] [-state (ENABLED | DISABLED)] [-lamac <mac_addr>] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)] [-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]

Arguments

id

ID for the LA channel or cluster LA channel to be created. Specify an LA channel in LA/x notation, where x can range from 1 to 8 or cluster LA channel in CLA/x notation, where x can range from 1 to 4. Cannot be changed after the LA channel is created.

ifnum

Interfaces to be bound to the LA channel of a NetScaler appliance or to the LA channel of a cluster configuration.

For an LA channel of a NetScaler appliance, specify an interface in C/U notation (for example, 1/3).

For an LA channel of a cluster configuration, specify an interface in N/C/U notation (for example, 2/1/3).

where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

U is a unique integer for representing an interface in a particular port group.

N is the ID of the node to which an interface belongs in a cluster configuration.

Use spaces to separate multiple entries.

state

Enable or disable the LA channel.

Possible values: ENABLED, DISABLED

Default value: NSA_DVC_ENABLE

Mode

The initital mode for the LA channel.

Possible values: MANUAL, AUTO

connDistr

The 'connection' distribution mode for the LA channel.

Possible values: DISABLED, ENABLED

macdistr

The 'MAC' distribution mode for the LA channel.

Possible values: SOURCE, DESTINATION, BOTH

lamac

MAC address for LA channels on VPX Platforms namely VPX on SDX,Xen,ESX.

speed

Ethernet speed of the channel, in Mbps. If the speed of any bound interface is greater than or equal to the value set for this parameter, the state of the interface is UP. Otherwise, the state is INACTIVE. Bound Interfaces whose state is INACTIVE do not process any traffic.

Possible values: AUTO, 10, 100, 1000, 10000, 40000

Default value: NSA_DVC_SPEED_AUTO

flowControl

Flow control for the LA channel.

Possible values: OFF, RX, TX, RXTX

Default value: NSA_DVC_FC_OFF

haMonitor

In a High Availability (HA) configuration, monitor the LA channel for failure events. Failure of any LA channel that has HA MON enabled triggers HA failover.

Possible values: ON, OFF

Default value: NSA_DVC_MONITOR_ON

tagall

Adds a four-byte 802.1q tag to every packet sent on this channel. The ON setting applies tags for all VLANs that are bound to this channel. OFF applies the tag for all VLANs other than the native VLAN.

Possible values: ON, OFF

Default value: NSA_DVC_VTRUNK_OFF

trunk

This is deprecated by tagall

Possible values: ON, OFF

Default value: OFF

ifAlias

Alias name for the LA channel. Used only to enhance readability. To perform any operations, you have to specify the LA channel ID.

Default value: " "

throughput

Low threshold value for the throughput of the LA channel, in Mbps. In an HA configuration, failover is triggered if the LA channel has HA MON enabled and the throughput is below the specified threshold.

Maximum value: 80000

bandwidthHigh

High threshold value for the bandwidth usage of the LA channel, in Mbps. The NetScaler appliance generates an SNMP trap message when the bandwidth usage of the LA channel is greater than or equal to the specified high threshold value.

Maximum value: 80000

---

rm channel

Removes an LA channel from the NetScaler appliance or a cluster LA channel from a cluster configuration. Important: When a LA channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Synopsys

rm channel <id>

Arguments

id

ID of the LA channel or cluster LA channel that you want to remove. Specify an LA channel in LA/x notation, where

x can range from 1 to 8 or a cluster LA channel in CLA/x notation, where x can range from 1 to 4.

---

set channel

Modifies the specified parameters of an LA channel.

Synopsys

set channel <id> [-state (ENABLED | DISABLED)] [-lamac <mac_addr>] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)] [-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-lrMinThroughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]

Arguments

id

ID of the LA channel or the cluster LA channel whose parameters you want to modify. Specify an LA channel in LA/x, where x can range from 1 to 8 notation or a cluster LA channel in CLA/x notation, where x can range from 1 to 4. Required for identifying the LA channel and cannot be modified.

state

Enable or disable the LA channel.

Possible values: ENABLED, DISABLED

Default value: NSA_DVC_ENABLE

Mode

The mode for the LA channel.

Possible values: MANUAL, AUTO

connDistr

The 'connection' distribution mode for the LA channel.

Possible values: DISABLED, ENABLED

macdistr

The 'MAC' distribution mode for the LA channel.

Possible values: SOURCE, DESTINATION, BOTH

lamac

Allows User to set MAC address for LA channels on Hypervised platforms.

speed

The speed for the LA channel.

Possible values: AUTO, 10, 100, 1000, 10000, 40000

Default value: NSA_DVC_SPEED_AUTO

flowControl

Required flow control for the LA channel.

Possible values: OFF, RX, TX, RXTX

Default value: NSA_DVC_FC_OFF

haMonitor

The state of HA monitoring for the LA channel.

Possible values: ON, OFF

Default value: NSA_DVC_MONITOR_ON

tagall

The appliance adds a four-byte 802.1q tag to every packet sent on this channel. ON applies tags for all the VLANs that are bound to this channel. OFF, applies the tag for all VLANs other than the native VLAN.

Possible values: ON, OFF

Default value: NSA_DVC_VTRUNK_OFF

trunk

This is deprecated by tagall.

Possible values: ON, OFF

Default value: OFF

ifAlias

The alias name for the interface.

Default value: " "

throughput

Low threshold value for the throughput of the LA channel, in Mbps. In an HA configuration, failover is triggered if the LA channel has HA MON enabled and the throughput is below the specified threshold.

Maximum value: 80000

lrMinThroughput

Minimum required throughput for a channel where we require Link Redundancy. When throughput falls below the threshold, the subset of interfaces which can give maximum throughput will become active When configured in HA pair, this will work along with the throughput parameter set. If lrMinThroughput can be achieved Link Failover will be

attempted before Node Failover

Maximum value: 80000

bandwidthHigh

High threshold value for the bandwidth usage of the LA channel, in Mbps. The NetScaler appliance generates an SNMP trap message when the bandwidth usage of the LA channel is greater than or equal to the specified high threshold value.

Maximum value: 80000

---

unset channel

Use this command to remove channel settings.Refer to the set channel command for meanings of the arguments.

Synopsys

unset channel <id> [-state] [-speed] [-flowControl] [-haMonitor] [-tagall] [-ifAlias] [-throughput] [-lrMinThroughput] [-bandwidthHigh] [-bandwidthNormal]

---

bind channel

Binds the specified interfaces to a channel.

Synopsys

bind channel <id> <ifnum> ...

Arguments

id

ID of the LA channel or the cluster LA channel to which you want to bind interfaces. Specify an LA channel in LA/x notation, where x can range from 1 to 8 or a cluster LA channel in CLA/x notation, where x can range from 1 to 4.

ifnum

Interfaces to be bound to the LA channel of a NetScaler appliance or to the LA channel of a cluster configuration.

For an LA channel of a NetScaler appliance, specify an interface in C/U notation (for example, 1/3).

For an LA channel of a cluster configuration, specify an interface in N/C/U notation (for example, 2/1/3).

where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

U is a unique integer for representing an interface in a particular port group.

N is the ID of the node to which an interface belongs in a cluster configuration.

Use spaces to separate multiple entries.

---

unbind channel

Unbinds the specified interfaces from an LA channel.

Synopsys

unbind channel <id> <ifnum> ...

Arguments

id

ID of the LA channel or cluster LA channel from which you want to unbind interfaces. Specify an LA channel in LA/x notation, where x can range from 1 to 8 or a cluster LA channel in CLA/x notation, where x can range from 1 to 4.

ifnum

Interfaces to be unbound from the LA channel of a NetScaler appliance or from the LA channel of a cluster configuration.

For an LA channel of a NetScaler appliance, specify an interface in C/U notation (for example, 1/3).

For an LA channel of a cluster configuration, specify an interface in N/C/U notation (for example, 2/1/3).

where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

U is a unique integer for representing an interface in a particular port group.

N is the ID of the node to which an interface belongs in a cluster configuration.

Use spaces to separate multiple entries.

---

show channel

Displays the settings of all LA channels or of the specified channel. To display the settings of all channels, run the command without any parameters. To display the settings of a particular channel, specify the ID of the channel.

Synopsys

show channel [<id>]

Arguments

id

ID of an LA channel or LA channel in cluster configuration whose details you want the NetScaler appliance to display.

Specify an LA channel in LA/x notation, where x can range from 1 to 8 or a cluster LA channel in CLA/x notation, where x can range from 1 to 4.

Minimum value: 1

summary

fullValues

format

level

Outputs

stateflag

deviceName

LA channel name in form LA/x, where x is channel ID, which ranges from 1 to 8.

unit

Unit number of the channel. This is an internal reference number that the NetScaler uses to identify the channel.

description

The IEEE standard that the channel is based on.

flags

Flags of this channel.

mtu

MTU of the channel. This is the maximum frame size that the channel can process.

vlan

Native VLAN of the channel.

mac

MAC address of the channel.

lamac

MAC address for LA channels on VPX Platforms namely VPX on SDX,Xen,ESX.

uptime

Duration for which the channel is UP. (Example: 3 hours 1 minute 1 second). This value is reset when the channel state changes to DOWN.

downTime

Duration for which the channel is DOWN. (Example: 3 hours 1 minute 1 second). This value is reset when the channel state changes to UP.

reqMedia

Requested media setting for this channel. Since there is no media associated with LA, the displayed values carry no significance.

reqSpeed

Requested speed setting for this channel. Since no media are associated with LA, this speed is used to determine the threshold for the slave interfaces. If the speed of the member interface is less than the requested speed, that interface is considered inactive.

reqDuplex

Requested duplex setting for this channel. Since no media are associated with LA, the displayed values carry no significance.

reqFlowcontrol

Requested flow control setting for this channel. Since no media are associated with LA, the displayed values carry no significance.

media

Requested media setting for this interface.

speed

Actual speed setting for this channel.

duplex

Actualduplex setting for this interface.

flowControl

Actual flow control setting for this channel.

connDistr

Connection distribution setting on this Channel.

macdistr

MAC distribution setting on this Channel.

Mode

The mode(AUTO/MANNUAL) for the LA channel.

haMonitor

HA monitoring enabled or disabled for this channel.

state

Enable or disable the LA channel.

autoneg

Requested auto negotiation setting for this channel. Since no media are associated with LA, this setting has no effect.

autonegResult

Actual auto negotiation setting for this channel.

tagged

VLAN tags setting on this channel.

tagall

The appliance adds a four-byte 802.1q tag to every packet sent on this channel. ON applies tags for all the VLANs that are bound to this channel. OFF, applies the tag for all VLANs other than the native VLAN.

trunk

This is deprecated by tagallNOTE: This attribute is deprecated.The "trunk" argument is confused with LA-trunk, renaming this to "tagall" instead.

taggedAny

Channel setting to accept/drop all tagged packets.

taggedAutolearn

Dynaminc vlan membership on this channel.

hangDetect

Hang detect for this channel.

hangReset

Hang reset for this channel.

linkState

The current state of the link associated with the interface. For logical interfaces (LA), the state of the link is dependent on the state of the slave interfaces. For the link to be UP at least one of the slave interfaces needs to be UP.

intfState

Current state of the specified interface. The interface state set to UP only if the link state is UP and administrative state is ENABLED.

rxpackets

Number of bytes received by all the slave interfaces of the channel since the NetScaler appliance was started or the interface statistics were cleared.

rxbytes

Number of packets received by all member interfaces since the NetScaler appliance was started or the interface statistics were cleared.

rxerrors

Number of inbound packets dropped by the hardware of the slave interfaces since the NetScaler appliance was started or the interface statistics were cleared. Possible causes of dropped packets are CRC, length (undersize or oversize), and alignment errors.

rxdrops

Number of inbound packets dropped by the channel's slave interfaces. Commonly dropped packets are multicast frames, spanning tree BPDUs, packets destined to a MAC not owned by the NetScaler when L2 mode is disabled, or packets tagged for a VLAN that is not bound to the interface. In most healthy networks, this statistic increments at a steady rate regardless of traffic load. A sharp spike in dropped packets generally indicates an issue with connected L2 switches, such as a forwarding database overflow resulting in packets being broadcast on all ports.

txpackets

Number of packets transmitted by slave interfaces of a channel since the NetScaler appliance was started or the interface statistics were cleared.

txbytes

Number of bytes transmitted by slave interfaces of a channel since the NetScaler appliance was started or the interface statistics were cleared.

txerrors

Number of outbound packets dropped by the hardware of a channel's slave interfaces since the NetScaler appliance was started or the interface statistics

were cleared. Possible causes of dropped packets are length (undersize or oversize) errors and lack of resources.

txdrops

Number of packets dropped in transmission by a channel's slave interfaces for one of the following reasons:

(1) VLAN mismatch.

(2) Oversized packets.

(3) Interface congestion.

(4) Loopback packets sent on non-loopback interface.

inDisc

Number of error-free inbound packets discarded by a channel's slave interfaces because of a lack of resources (for example, insufficient receive buffers).

outDisc

Number of error-free outbound packets discarded by a channel's slave interfaces because of a lack of resources. This statistic is not available on:

(1) 10G ports of NetScaler MPX 12500/12500/15500-10G platforms.

(2) 10G data ports on NetScaler MPX 17500/19500/21500 platforms.

fctls

Number of times flow control is performed on a channel's slave interfaces because of pause frames.

hangs

Number of hangs that occurred on the channel's slave interfaces.

stsStalls

Number of status stalls that occurred on the channel's slave interfaces.

txStalls

Number of Tx stalls happened that occurred on the channel's slave interfaces.

rxStalls

Number of Rx stalls that occurred on the channel's slave interfaces.

bdgMuted

Number of times a channel's slave interfaces stopped transmitting and receiving packets because of MAC moves between ports.

vmac

Virtual MAC of this channel.

vmac6

Virtual MAC for IPv6 on this interface.

ifAlias

The alias name for the interface.

reqThroughput

Minimum required throughput for an interface. Failover is triggered if the operating throughput of a Link Aggregation (LA) channel for which HAMON is ON falls below this value.

lrMinThroughput

Minimum required throughput for a channel where we require Link Redundancy. When throughput falls below the threshold, the subset of interfaces which can give maximum throughput will become active When configured in HA pair, this will work along with the throughput parameter set. If lrMinThroughput can be achieved Link Failover will be attempted before Node Failover

throughput

Actual throughput for the interface.

bandwidthHigh

High threshold value for the bandwidth usage of the LA channel, in Mbps. The NetScaler appliance generates an SNMP trap message when the bandwidth usage of the LA channel is greater than or equal to the specified high threshold value.

bandwidthNormal

Normal threshold value for the bandwidth usage of the LA channel, in Mbps. When the bandwidth usage of the LA channel becomes less than or equal to the specified normal threshold after exceeding the high threshold, the NetScaler appliance generates an SNMP trap message to indicate that the bandwidth usage has returned to normal.

ifnum

The interfaces bound to link aggregate channel.

backplane

The cluster backplane status of the LA. If the status is enabled, the LA is part of the cluster backplane. By default, the backplane status is disabled.

clearTime

Time since the interface stats are cleared last time.

slavestate

State of the member interfaces.

slavemedia

Media type of the member interfaces.

slavespeed

Speed of the member interfaces.

slaveduplex

Duplex of the member interfaces.

slaveflowctl

Flowcontrol of the member interfaces.

slavetime

UP time of the member interfaces.

lacpMode

The LACP mode of the specified interface. The possible values are:

1. Active: A port in active mode generates LACP protocol messages on a regular basis, regardless of any need expressed by its partner to receive them.

2. Passive: A port in passive mode generally does not transmit LACP messages unless its partner is in the active mode; that is, it does not speak unless spoken to.

3. Disabled: Removes the interface from the LA channel. If this is only interface in the LA channel, the LA channel is also deleted.

lacpTimeout

Time to wait for the LACPDU. If a LACPDU is not received within this interval, the NetScaler markes the link partner port as DOWN. Possible values: Long and Short. Long lacptimeout is 90 sec and Short LACP timeout is 3 sec.

lacpActorPriority

LACP Actor Priority. A LACP port priority is configured on each port using LACP. LACP uses the port priority with the port number to form the port identifier. The port priority determines which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

lacpActorPortno

LACP Actor port number. LACP uses the port priority with the port number to form the port identifier.

lacpPartnerState

LACP Partner State. Whether the port is in Active or Passive negotiating state.

lacpPartnerTimeout

The timeout value for the information revieved in LACPDUs. It can have values as SHORT or LONG. The SHORT timeout is 3s and the LONG timeout is 90s.

lacpPartnerAggregation

The Aggregation flag indicates that the participant will allow the link to be used as part of an aggregate. Otherwise the link is to be used as an individual link, i.e. not aggregated with any other.

lacpPartnerInsync

The Synchronization flag indicates that the transmitting participant.s mux component is in sync with the system id and key information transmitted.

lacpPartnerCollecting

The Collecting flag indicates that the participant.s collector, i.e. the reception component of the mux, is definitely on. If set the flag communicates collecting.

lacpPartnerDistributing

The Distributing flag indicates that the participant.s distributor is not definitely off. If reset the flag indicates not distributing.

lacpPartnerDefaulted

If the timer expires in the Expired state, the Receive Machine enters the Defaulted state.

lacpPartnerExpired

If the LACPDUs are received for timeout period, the Receive Machine enters the Expired state and the timer is restarted with the timeout value of SHORT timeout

lacpPartnerPriority

LACP Partner Priority. A LACP port priority is configured on each port using LACP. LACP uses the port priority with the port number to form the port identifier.

The port priority determines which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

lacpPartnerSystemMac

LACP Partner System MAC.

lacpPartnerSystemPriority

LACP Partner System Priority. The LACP partner's system priority. The values for the priority range from 0 to 65535. The lower the value, the higher the system priority. The switch with the lower system priority value determines which links between LACP partner are active and which are in the standby for each LACP Channel.

lacpPartnerPortno

LACP Partner Port number. LACP uses the port priority with the port number to form the port identifier.

lacpPartnerKey

LACP Partner Key. The LACP key used by the partner port.

lacpActorAggregation

The Aggregation flag indicates that the participant will allow the link to be used as part of an aggregate. Otherwise the link is to be used as an individual link, i.e. not aggregated with any other.

lacpActorInsync

The Synchronization flag indicates that the transmitting participant.s mux component is in sync with the system id and key information transmitted.

lacpActorCollecting

The Collecting flag indicates that the participant.s collector, i.e. the reception component of the mux, is definitely on. If set the flag communicates collecting.

lacpActorDistributing

The Distributing flag indicates that the participant.s distributor is not definitely off. If reset the flag indicates not distributing.

lacpPortMuxState

LACP Port MUX state. The state of the MUX control machine. The Mux Control Machine attaches the physical port to an aggregate port, using the Selection Logic to choose an appropriate port, and turns the distributor and collector for the physical port on or off as required by protocol information.

lacpPortRxStat

LACP Port RX state. The state of the Receive machine. The Receive Machine maintains partner information, recording protocol information from LACPDUs

sent by remote partner(s). Received information is subject to a timeout, and if sufficient time elapses the receive machine will revert to using default partner information.

lacpPortSelectState

LACP Port SELECT state. The state of the SELECT state machine, It could be SELECTED or UNSELECTED.

devno

count

ci

Sep 22, 2015

The following operations can be performed on "ci":

show ci

Displays all the critical interfaces of the NetScaler appliance. In a High Availability configuration, an interface that has HA MON enabled and is not bound to any FIS, is a critical interface. Failure of any critical interface triggers HA failover.

Synopsys

show ci

Arguments

summary

fullValues

Outputs

ifaces

Interfaces that are critical for the appliance to operate in high availability mode.

devno

count

stateflag

Example

```
>show ci Critical Interfaces: LO/1 1/2
```

fis

Sep 22, 2015

The following operations can be performed on "fis":

add | rm | bind | unbind | show

add fis

Adds a failover interface set (FIS) to the NetScaler appliance. A FIS is a logical group of interfaces. In an HA configuration, using a FIS is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available.

Synopsys

add fis <name>

Arguments

name

Name for the FIS to be created. Leading character must be a number or letter. Other characters allowed, after the first character, are @ _ - . (period) : (colon) # and space ( ).

---

rm fis

Removes an FIS from the NetScaler appliance. When an FIS is removed, its interfaces are marked as critical interfaces.

Synopsys

rm fis <name>

Arguments

name

Name of the FIS that you want to remove from the NetScaler appliance.

---

bind fis

Binds the specified interfaces to a FIS.

Synopsys

bind fis <name> <ifnum> ...

Arguments

name

The name of the FIS to which you want to bind interfaces.

ifnum

Interface to be bound to the FIS, specified in slot/port notation (for example, 1/3).

---

unbind fis

Unbinds the specified interfaces from a FIS. An unbound interface becomes a critical interface if it is enabled and HA MON is on.

Synopsys

unbind fis <name> <ifnum> ...

Arguments

name

Name of the FIS from which to unbind interfaces.

ifnum

Interfaces to unbind from the FIS, specified in slot/port notation (for example, 1/3). Use spaces to separate multiple entries.

---

show fis

Displays the configured FISs.

Synopsys

show fis [<name>]

Arguments

name

The name of the FIS configured on the appliance.

summary

fullValues

format

level

Outputs

ifaces

forwardingSession

Sep 22, 2015

The following operations can be performed on "forwardingSession":

add | set | rm | show

add forwardingSession

Adds a forwarding session rule, which creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the NetScaler appliance. By default, the appliance does not create session entries for traffic that only forwards (L3 mode). Add a forwarding session rule for a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path

Synopsys

add forwardingSession <name> ((<network> [<netmask>]) | -acl6name <string> | -aclname <string>) [-connfailover (ENABLED | DISABLED)]

Arguments

name

Name for the forwarding session rule. Can begin with a letter, number, or the underscore character (_), and can consist of letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the rule is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rule" or 'my rule').

network

Network address from which the forwarded traffic originates or to which it is destined.

acl6name

Name of any configured ACL6 whose action is ALLOW. The rule of the ACL6 is used as an forwarding session rule.

aclname

Name of an extended ACL with action set to ALLOW. The rule specified in the ACL is used as a forwarding-session rule.

connfailover

Synchronize connection information with the secondary appliance in a high availability (HA) pair. That is, synchronize all connection-related information for the forwarding session.

Possible values: ENABLED, DISABLED

Default value: DISABLED

set forwardingSession

Modifies parameters of a forwarding session rule.

Synopsys

set forwardingSession <name> [-connfailover (ENABLED | DISABLED)]

Arguments

name

Name of the forwarding session rule. Required for identifying the forwarding session rule.

connfailover

Synchronize connection information with the secondary appliance in a high availability (HA) pair. That is, synchronize all connection-related information for the forwarding session.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

set forwardsession fw1 -connfailover enabled.

rm forwardingSession

Removes a forwarding session rule from the NetScaler appliance.

Synopsys

rm forwardingSession <name>

Arguments

name

Name of the forwarding session rule to be removed.

Example

rm forwardsession name.

show forwardingSession

Displays the settings of all forwarding session rules configured on the NetScaler appliance, or of the specified forwarding session rule.

Synopsys

show forwardingSession [<name>]

Arguments

name

Name of the forwarding session rule whose details you want to display.

format

level

Outputs

network

Network address from which the forwarded traffic originates or to which it is destined.

netmask

Subnet mask associated with the network.

aclname

Name of an extended ACL with action set to ALLOW. The rule specified in the ACL is used as a forwarding-session rule.

acl6name

Name of any configured ACL6 whose action is ALLOW. The rule of the ACL6 is used as an forwarding session rule.

connfailover

Synchronize connection information with the secondary appliance in a high availability (HA) pair. That is, synchronize all connection-related information for the forwarding session.

devno

count

stateflag

inat

Sep 22, 2015

The following operations can be performed on "inat":

add | rm | set | unset | stat | show

add inat

Adds an INAT rule to the NetScaler appliance. When a packet generated by a client matches the conditions specified in the INAT rule, the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

Synopsys

add inat <name>@ <publicIP>@ <privateIP>@ [-tcpproxy (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-tftp (ENABLED | DISABLED)] [-usip (ON | OFF)] [-usnip (ON | OFF)] [-proxyIP <ip_addr|ipv6_addr>] [-mode STATELESS] [-td <positive_integer>]

Arguments

name

Name for the Inbound NAT (INAT) entry. Leading character must be a number or letter. Other characters allowed, after the first character, are @ _ - . (period) : (colon) # and space ( ).

publicIP

Public IP address of packets received on the NetScaler appliance. Can be aNetScaler-owned VIP or VIP6 address.

privateIP

IP address of the server to which the packet is sent by the NetScaler. Can be an IPv4 or IPv6 address.

tcpproxy

Enable TCP proxy, which enables the NetScaler appliance to optimize the RNAT TCP traffic by using Layer 4 features.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ftp

Enable the FTP protocol on the server for transferring files between the client and the server.

Possible values: ENABLED, DISABLED

Default value: DISABLED

tftp

To enable/disable TFTP (Default DISABLED).

Possible values: ENABLED, DISABLED

Default value: DISABLED

usip

Enable the NetScaler appliance to retain the source IP address of packets before sending the packets to the server.

Possible values: ON, OFF

Default value: OFF

usnip

Enable the NetScaler appliance to use a SNIP address as the source IP address of packets before sending the packets to the server.

Possible values: ON, OFF

Default value: ON

proxyIP

Unique IP address used as the source IP address in packets sent to the server. Must be a MIP or SNIP address.

mode

Stateless translation.

Possible values: STATELESS

td

Traffic Domain Id.

Maximum value: 4094

Example

```
add nat mynat 1.2.3.4 192.168.1.100
```

---

rm inat

Remove the specified Inbound NAT configuration.

Synopsys

```
rm inat <name>@
```

Arguments

name

Name of the Inbound NAT entry to be removed from the NetScaler appliance.

Example

rm nat mynat.

---

set inat

Modifies parameters of an INAT rule.

Synopsys

set inat <name>@ [-privateIP <ip_addr|ipv6_addr>@] [-tcpproxy (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-tftp (ENABLED | DISABLED)] [-usip (ON | OFF)] [-usnip (ON | OFF)] [-proxyIP <ip_addr|ipv6_addr>] [-mode STATELESS]

Arguments

name

The name of the Inbound NAT (INAT) entry that you want to modify.

privateIP

IP address of the server to which the packet is sent by the NetScaler. Can be an IPv4 or IPv6 address.

tcpproxy

Enable TCP proxy, which enables the NetScaler appliance to optimize the RNAT TCP traffic by using Layer 4 features.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ftp

Enable the FTP protocol on the server for transferring files between the client and the server.

Possible values: ENABLED, DISABLED

Default value: DISABLED

tftp

To enable/disable TFTP (Default DISABLED).

Possible values: ENABLED, DISABLED

Default value: DISABLED

usip

Enable the NetScaler appliance to retain the source IP address of packets before sending the packets to the server.

Possible values: ON, OFF

Default value: OFF

usnip

Enable the NetScaler appliance to use a SNIP address as the source IP address of packets before sending the packets to the server.

Possible values: ON, OFF

Default value: ON

proxyIP

A unique IP address used as the source IP address in packets sent to the server. Must be a MIP or SNIP address.

mode

Stateless translation.

Possible values: STATELESS

Example

```
set nat mynat -tcpproxy ENABLED
```

---

unset inat

Use this command to remove inat settings.Refer to the set inat command for meanings of the arguments.

Synopsys

```
unset inat <name>@ [-tcpproxy] [-ftp] [-tftp] [-usip] [-usnip] [-proxyIP] [-mode]
```

---

stat inat

Display statistics for inat sessions.

Synopsys

```
stat inat [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats ( basic | full )]
```

Arguments

name

The INAT.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

Total IPV6 packets dropped.

TCP Packets translated (V4->V6) (inatNat46Tcp46)

TCP packets translated (V4->v6).

UDP Packets translated (V4->V6) (inatNat46Udp46)

UDP packets translated (V4->v6).

ICMP Packets translated (V4->V6) (inatNat46Icmp46)

ICMP packets translated (V4->v6).

IPV4 packets dropped (inatNat46drop46)

IPV4 packets dropped.

TCP Packets translated (V6->V4) (inatNat46Tcp64)

TCP packets translated (V6->v4).

UDP Packets translated (V6->V4) (inatNat46Udp64)

UDP packets translated (V6->v4).

ICMP Packets translated (V6->V4) (inatNat46Icmp64)

ICMP packets translated (V6->v4).

IPV6 packets dropped (inatNat46drop64)

IPV6 packets dropped.

Example

stat inat

---

show inat

show all configured inbound NAT.

Synopsys

show inat [<name>]

Arguments

name

Name for the Inbound NAT (INAT) entry. Leading character must be a number or letter. Other characters allowed, after the first character, are @ _ - . (period) : (colon) # and space ( ).

summary

fullValues

format

level

Outputs

publicIP

Public IP address of packets received on the NetScaler appliance. Can be aNetScaler-owned VIP or VIP6 address.

privateIP

IP address of the server to which the packet is sent by the NetScaler. Can be an IPv4 or IPv6 address.

proxyIP

Source IP address for connection to a server.

tcpproxy

Enable TCP proxy, which enables the NetScaler appliance to optimize the RNAT TCP traffic by using Layer 4 features.

ftp

Enable the FTP protocol on the server for transferring files between the client and the server.

tftp

To enable/disable TFTP (Default DISABLED).

usip

Enable the NetScaler appliance to retain the source IP address of packets before sending the packets to the server.

usnip

Enable the NetScaler appliance to use a SNIP address as the source IP address of packets before sending the packets to the server.

flags

Flags for different modes

mode

Stateless translation.

td

Traffic Domain Id.

devno

count

stateflag

Example

show nat

inatparam

Sep 22, 2015

The following operations can be performed on "inatparam":

set | unset | show

set inatparam

Set the inat parameter

Synopsys

set inatparam [-nat46v6Prefix <ipv6_addr|*>] [-nat46IgnoreTOS (YES | NO)] [-nat46ZeroCheckSum (ENABLED | DISABLED)] [-nat46v6Mtu <positive_integer>] [-nat46FragHeader (ENABLED | DISABLED)]

Arguments

nat46v6Prefix

The prefix used for translating packets received from private IPv6 servers into IPv4 packets. This prefix has a length of 96 bits (128-32 = 96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix. IPv6 packets addressed to this prefix have to be routed to the NetScaler appliance to ensure that the IPv6-IPv4 translation is done by the appliance.

nat46IgnoreTOS

Ignore TOS.

Possible values: YES, NO

Default value: NO

nat46ZeroCheckSum

Calculate checksum for UDP packets with zero checksum

Possible values: ENABLED, DISABLED

Default value: ENABLED

nat46v6Mtu

Calculate checksum for UDP packets with zero checksum

Default value: 1280

Minimum value: 1280

Maximum value: 1500

nat46FragHeader

When disabled, translator will not insert IPv6 fragmentation header for non fragmented IPv4 packets

Possible values: ENABLED, DISABLED

Default value: ENABLED

Example

set inat parameter -nat46ignoretos YES

---

unset inatparam

Use this command to remove inatparam settings.Refer to the set inatparam command for meanings of the arguments.

Synopsys

unset inatparam -nat46v6Prefix

---

show inatparam

Show the inat parameters.

Synopsys

show inatparam

Arguments

format

level

Outputs

nat46v6Prefix

The prefix used for translating packets received from private IPv6 servers into IPv4 packets. This prefix has a length of 96 bits (128-32 = 96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix. IPv6 packets addressed to this prefix have to be routed to the NetScaler appliance to ensure that the IPv6-IPv4 translation is done by the appliance.

nat46IgnoreTOS

Ignore TOS.

nat46ZeroCheckSum

Calculate checksum for UDP packets with zero checksum

nat46v6Mtu

Calculate checksum for UDP packets with zero checksum

nat46FragHeader

When disabled, translator will not insert IPv6 fragmentation header for non fragmented IPv4 packets

Example

show inat params

inatsession

Sep 22, 2015

The following operations can be performed on "inatsession":

stat inatsession

Display statistics for stateful inat sessions.

Synopsys

stat inatsession <name> [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

name

INAT name

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

INAT total sessions (inatTotHits)

INAT total sessions

INAT Current sessions (inatCurSessions)

INAT current sessions

INAT total Received Bytes (inatTotReceiveBytes)

INAT total Received Bytes

INAT total Sent Bytes (inatTotSentBytes)

INAT total Sent Bytes

INAT total Packets Received (inatTotpktreceived)

INAT total Packets Received

INAT total Packets Sent (inatTotpktsent)

INAT total Packets Sent

Example

```
stat inatsession inat_1
```

interface

Sep 22, 2015

The following operations can be performed on "interface":

clear | set | unset | enable | disable | reset | show | stat

clear interface

Resets the statistical counters of the specified interface.

Synopsys

clear interface <id>@

Arguments

id

Interface number, in C/U format, where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

* LA - Indicates a link aggregation port.

* LO - Indicates a loop back port.

U is a unique integer for representing an interface in a particular port group.

---

set interface

Modifies the parameters of an interface.

Synopsys

set interface <id>@ [-speed <speed>] [-duplex <duplex>] [-flowControl <flowControl>] [-autoneg (DISABLED | ENABLED)] [-haMonitor (ON | OFF)] [-tagall (ON | OFF)] [-lacpMode <lacpMode>] [-lacpKey <positive_integer>] [-lagtype (NODE | CLUSTER)] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]

Arguments

id

ID of the Interface whose parameters you want to modify.

For a NetScaler appliance, specify the interface in C/U notation (for example, 1/3).

For a cluster configuration, specify the interface in N/C/U notation (for example, 2/1/3).

where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

U is a unique integer for representing an interface in a particular port group.

N is the ID of the node to which an interface belongs in a cluster configuration.

Use spaces to separate multiple entries.

speed

Ethernet speed of the interface, in Mbps.

Notes:

* If you set the speed as AUTO, the NetScaler appliance attempts to auto-negotiate or auto-sense the link speed of the interface when it is UP. You must enable auto negotiation on the interface.

* If you set a speed other than AUTO, you must specify the same speed for the peer network device. Mismatched speed and duplex settings between the peer devices of a link lead to link errors, packet loss, and other errors.

Some interfaces do not support certain speeds. If you specify an unsupported speed, an error message appears.

Possible values: AUTO, 10, 100, 1000, 10000, 40000

Default value: NSA_DVC_SPEED_AUTO

duplex

The duplex mode for the interface.

Notes:

* If you set the duplex mode to AUTO, the NetScaler appliance attempts to auto-negotiate the duplex mode of the interface when it is UP. You must enable auto negotiation on the interface.

If you set a duplex mode other than AUTO, you must specify the same duplex mode for the peer network device. Mismatched speed and duplex settings between the peer devices of a link lead to link errors, packet loss, and other errors.

Possible values: AUTO, HALF, FULL

Default value: NSA_DVC_DUPLEX_AUTO

flowControl

802.3x flow control setting for the interface. The 802.3x specification does not define flow control for 10 Mbps and 100 Mbps speeds, but if a Gigabit Ethernet interface operates at those speeds, the flow control settings can be applied. The flow control setting that is finally applied to an interface depends on auto-negotiation. With the ON option, the peer negotiates the flow control, but the appliance then forces two-way flow control for the interface.

Possible values: OFF, RX, TX, RXTX

Default value: NSA_DVC_FC_OFF

autoneg

Auto-negotiation state of the interface.

With the ENABLED setting, the NetScaler appliance auto-negotiates the speed and duplex settings with the peer network device on the link.

The NetScaler appliance auto-negotiates the settings of only those parameters (speed or duplex mode) for which the value is set as AUTO.

Possible values: DISABLED, ENABLED

Default value: NSA_DVC_AUTONEG_ON

haMonitor

In a High Availability (HA) configuration, monitor the interface for failure events. In an HA configuration, an interface that has HA MON enabled and is not bound to any Failover Interface Set (FIS), is a critical interface. Failure or disabling of any critical interface triggers HA failover.

Possible values: ON, OFF

Default value: NSA_DVC_MONITOR_ON

tagall

Add a four-byte 802.1q tag to every packet sent on this interface. The ON setting applies the tag for this interface's native VLAN. OFF applies the tag for all VLANs other than the native VLAN.

Possible values: ON, OFF

Default value: NSA_DVC_VTRUNK_OFF

trunk

This argument is deprecated by tagall.

Possible values: ON, OFF

Default value: NSA_DVC_VTRUNK_OFF

lacpMode

Bind the interface to a LA channel created by the Link Aggregation control protocol (LACP).

Available settings function as follows:

* Active - The LA channel port of the NetScaler appliance generates LACPDU messages on a regular basis, regardless of any need expressed by its peer device to receive them.

* Passive - The LA channel port of the NetScaler appliance does not transmit LACPDU messages unless the peer device port is in the active mode. That is, the port does not speak unless spoken to.

* Disabled - Unbinds the interface from the LA channel. If this is the only interface in the LA channel, the LA channel is removed.

Possible values: DISABLED, ACTIVE, PASSIVE

Default value: NSA_LACP_DISABLE

lacpKey

Integer identifying the LACP LA channel to which the interface is to be bound.

For an LA channel of the NetScaler appliance, this digit specifies the variable x of an LA channel in LA/x notation, where x can range from 1 to 8. For example, if you specify 3 as the LACP key for an LA channel, the interface is bound to the LA channel LA/3.

For an LA channel of a cluster configuration, this digit specifies the variable y of a cluster LA channel in CLA/(y-4) notation, where y can range from 5 to 8. For example, if you specify 6 as the LACP key for a cluster LA channel, the interface is bound to the cluster LA channel CLA/2.

Minimum value: 1

Maximum value: 8

lagtype

Type of entity (NetScaler appliance or cluster configuration) for which to create the channel.

Possible values: NODE, CLUSTER

Default value: NSA_LAG_NODE

lacpPriority

LACP port priority, expressed as an integer. The lower the number, the higher the priority. The NetScaler appliance limits the number of interfaces in an LA channel to eight. If LACP is enabled on more than eight interfaces, the appliance selects eight interfaces, in descending order of port priority, to form a channel.

Default value: 32768

Minimum value: 1

Maximum value: 65535

lacpTimeout

Interval at which the NetScaler appliance sends LACPDU messages to the peer device on the LA channel.

Available settings function as follows:

LONG - 30 seconds.

SHORT - 1 second.

Possible values: LONG, SHORT

Default value: NSA_LACP_TIMEOUT_LONG

ifAlias

Alias name for the interface. Used only to enhance readability. To perform any operations, you have to specify the interface ID.

Default value: " "

throughput

Low threshold value for the throughput of the interface, in Mbps. In an HA configuration, failover is triggered if the interface has HA MON enabled and the throughput is below the specified the threshold.

Maximum value: 80000

bandwidthHigh

High threshold value for the bandwidth usage of the interface, in Mbps. The NetScaler appliance generates an SNMP trap message when the bandwidth usage of the interface is greater than or equal to the specified high threshold value.

Maximum value: 80000

---

unset interface

Use this command to remove interface settings.Refer to the set interface command for meanings of the arguments.

Synopsys

unset interface <id>@ [-speed] [-duplex] [-flowControl] [-autoneg] [-haMonitor] [-tagall] [-lacpMode] [-lacpKey] [-lacpPriority] [-lacpTimeout] [-ifAlias] [-throughput] [-bandwidthHigh] [-bandwidthNormal]

---

enable interface

Enables the interface. If the link is active, it can transmit and receive packets. Note: To view the status of an interface, use the show interface command.

Synopsys

enable interface <id>@

Arguments

id

Interface number, in C/U format, where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

* LA - Indicates a link aggregation port.

* LO - Indicates a loop back port.

U is a unique integer for representing an interface in a particular port group.

---

disable interface

Disables the interface from transmitting and receiving packets. The link remains active and the peer network device is unaware that the interface has been disabled. In a High Availability configuration, an interface that has HA MON enabled and is not bound to any Failover Interface Set (FIS), is a critical interface. Disabling or failure of any critical interface triggers HA failover. Note: To view the status of an interface, use the show interface command.

Synopsys

disable interface <id>@

Arguments

id

Interface number, in C/U format, where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

* LA - Indicates a link aggregation port.

* LO - Indicates a loop back port.

U is a unique integer for representing an interface in a particular port group.

---

reset interface

Restarts the interface but leaves the administrative state ENABLED or DISABLED and configuration unchanged. The link pertaining to the interface is reestablished with the existing settings.

Synopsys

reset interface <id>@

Arguments

id

Interface number, in C/U format, where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

* LA - Indicates a link aggregation port.

* LO - Indicates a loop back port.

U is a unique integer for representing an interface in a particular port group.

---

show interface

Displays the settings of all interfaces or of the specified interface on the NetScaler appliance. To display the settings of all interfaces, run the command without any parameters. To display the settings of a particular interface, specify the ID of the interface.

Synopsys

show interface [<id>@] show interface stats - alias for 'stat interface'

Arguments

id

Interface number, in C/U format, where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

* LA - Indicates a link aggregation port.

* LO - Indicates a loop back port.

U is a unique integer for representing an interface in a particular port group.

summary

fullValues

format

level

Outputs

stateflag

deviceName

Name of the interface.

unit

Unit number for this interface, signifying the sequence number in which this interface is discovered on this Netscaler.

description

Display the type of interface, the speeds at which this interface can operate, and, if applicable, the type of SFP,.

flags

Flags for this interface. Used for communicating the device states.

mtu

MTU for this interface (the largest frame that can transit this interface).

vlan

Native VLAN for this interface.

mac

MAC address for this interface.

uptime

Duration for which the interface has been UP (Example: 3 hours 1 minute 1 second). This value is reset when the interface state changes to DOWN..

downTime

Duration for which the interface has been DOWN. This value is reset when the interface state changes to UP.(Example: 3 hours 1 minute 1 second).

reqMedia

Requested media setting for this interface.

reqSpeed

Requested speed setting for this interface.

reqDuplex

Requested duplex setting for this interface.

reqFlowcontrol

Requested flow control setting for this interface.

media

Actual media setting for this interface.

speed

Actual speed setting for this interface.

duplex

Actual duplex setting for this interface.

flowControl

Actual flow control setting for this interface.

connDistr

Connection distribution setting on this interface.

macdistr

MAC distribution setting on this interface.

Mode

The mode(AUTO/MANNUAL) for the LA channel.

haMonitor

HA monitor enabled or disabled for this interface.

state

Link state of the interface (UP/DOWN).

autoneg

Interface autonegotiation enabled or disabled.

autonegResult

Actual auto-negotiation setting for this interface.

tagged

VLAN tags setting on this channel.

tagall

VLAN tagging behavior on this interface. With the ON setting,, packets are tagged with all the VLANs that are bound to this interface. With the OFF setting, packets are tagged with the native VLAN.

trunk

This argument is deprecated by tagall.NOTE: This attribute is deprecated.The "trunk" argument is confused with LA-trunk, renaming this to "tagall" instead.

taggedAny

Interface setting to accept/drop all tagged packets.

taggedAutolearn

Dynamic VLAN membership autolearning enabled or disabled on this interface.

hangDetect

Hang detection enabled or disabled for this interface.

hangReset

Hang reset enabled or disabled for this interface.

linkState

The current state of the link associated with the interface. For logical interfaces (LA), the state of the link is dependent on the state of the slave interfaces. For the link to be UP at least one of the slave interfaces needs to be UP.

intfState

Current state of the specified interface. The interface state set to UP only if the link state is UP and administrative state is ENABLED.

rxpackets

Number of packets received by an interface since the NetScaler appliance was started or the interface statistics were cleared.

rxbytes

Number of bytes received by an interface since the NetScaler appliance was started or the interface statistics were cleared.

rxerrors

Number of inbound packets dropped by the hardware on a specified interface since the NetScaler appliance was started or the interface statistics were cleared. Packets can be dropped because of CRC, length (undersize or oversize), or alignment errors.

rxdrops

Number of inbound packets dropped by the specified interface. Commonly dropped packets are multicast frames, spanning tree BPDUs, packets destined to a MAC not owned by the NetScaler appliance when L2 mode is disabled, or packets tagged for a VLAN that is not bound to the interface. In most healthy networks, this statistic increments at a steady rate regardless of traffic load. A sharp spike in dropped packets generally indicates an issue with connected L2 switches, such as a forwarding database overflow resulting in packets being broadcast on all ports.

txpackets

Number of packets transmitted by an interface since the NetScaler appliance was started or the interface statistics were cleared.

txbytes

Number of bytes transmitted by an interface since the NetScaler appliance was started or the interface statistics were cleared.

txerrors

Number of outbound packets dropped by the hardware on a specified interface since the NetScaler appliance was started or the interface statistics were

cleared. Packets can be dropped because of length (undersize or oversize) errors or a lack of resources. This statistic is available only for:

(1) Loop back interface (LO) of all platforms.

(2) All data ports on the NetScaler 12000 platform.

(3) Management ports on the Netscaler MPX 15000 and 17000 platforms.

txdrops

Number of packets dropped in transmission by the specified interface for one of the following reasons.

(1) VLAN mismatch.

(2) Oversized packets.

(3) Interface congestion.

(4) Loopback packets sent on non loop back interface.

inDisc

Number of error-free inbound packets discarded by the specified interface because of a lack of resources (for example, insufficient receive buffers).

outDisc

Number of error-free outbound packets discarded by the specified interface because of a lack of resources. This statistic is not available on:

(1) 10G ports of NetScaler MPX 12500/12500/15500-10G platforms.

(2) 10G data ports on NetScaler MPX 17500/19500/21500 platforms.

fctls

Number of times flow control is performed on the specified interface because of received pause frames.

hangs

Number of times the specified interface detected hangs in the transmit and receive paths since the NetScaler appliance was started or the interface statistics were cleared.

stsStalls

Number of times the status updates for a specified interface were stalled since the NetScaler appliance was started or the interface statistics were cleared. A status stall is detected when the status of the interface is not updated by the NIC hardware within 0.8 seconds of the last update.

txStalls

Number of times the interface stalled, when transmitting packets, since the NetScaler appliance was started or the interface statistics were cleared. Transmit (Tx) stalls are detected when a packet posted for transmission is not transmitted in 4 seconds.

rxStalls

Number of times the interface stalled, when receiving packets, since the NetScaler appliance was started or the interface statistics were cleared. Receive (Rx) stalls are detected when the following conditions are met:

(1)The link is up for more than 10 minutes.

(2)Packets are transmitted, but no packets are received for 16 seconds.

bdgMacMoved

Number of MAC moves between ports. A high rate of MAC moves typically indicates a bridge loop between two interfaces.

bdgMuted

Number of times the specified interface stopped transmitting and receiving packets because of MAC moves between ports.

vmac

Virtual MAC of this interface.

vmac6

Virtual MAC for IPv6 of this interface.

lacpMode

The LACP mode of the specified interface. The possible values are:

1. Active: A port in active mode generates LACP protocol messages on a regular basis, regardless of any need expressed by its partner to receive them.

2. Passive: A port in passive mode is generally not transmit LACP messages unless its partner is in the active mode; that is, it does not communicate to the other appliance unless other appliance communicates with this appliance.

lacpKey

Identifies the channel to which the interface is bound. The possible values are 1, 2, 3, and 4.

lacpPriority

LACP port priority, expressed as an integer. The lower the number, the higher the priority. The NetScaler appliance limits the number of interfaces in an LA channel to eight. If LACP is enabled on more than eight interfaces, the appliance selects eight interfaces, in descending order of port priority, to form a channel.

lacpTimeout

Time to wait for the LACPDU. If an LACPDU is not received within this interval, the NetScaler markes the link partner port as DOWN. Possible values; Long, Short. Long lacptimeout is 90 sec and Short LACP timeout is 3 sec.

lagtype

Type of entity (NetScaler appliance or cluster configuration) for which to create the channel.

ifAlias

Alias name for the interface. Used only to enhance readability. To perform any operations, you have to specify the interface ID.

reqThroughput

Minimum required throughput for an interface. Failover is triggered if the operating throughput of a Link Aggregation (LA) channel for which HAMON is ON falls below this value. The possible values are:

1. 1000Mbps for 1G interfaces.

2. 10000Mbps for 10G interfaces.

3. 80000Mbps for Link Aggregation channels.

throughput

Actual throughput for the interface.

bandwidthHigh

High threshold value for the bandwidth usage of the interface, in Mbps. The NetScaler appliance generates an SNMP trap message when the bandwidth usage of the interface is greater than or equal to the specified high threshold value.

bandwidthNormal

Normal threshold value for the bandwidth usage of the interface, in Mbps. When the bandwidth usage of the interface becomes less than or equal to the specified normal threshold after exceeding the high threshold, the NetScaler appliance generates an SNMP trap message to indicate that the bandwidth usage has returned to normal.

backplane

The cluster backplane status of the interface. If the status is enabled, the interface is part of the cluster backplane. By default, the backplane status is disabled.

ifnum

Contains the LA Master, if the interface is part of LA channel.

clearTime

Time since the interface stats are cleared last time.

slavestate

State of the member interfaces.

slavemedia

Media type of the member interfaces.

slavespeed

Speed of the member interfaces.

slaveduplex

Duplex of the member interfaces.

slaveflowctl

Flowcontrol of the member interfaces.

slavetime

UP time of the member interfaces.

intftype

Interface Type, this field will have the interface type either it is virtual, physical or loopback.

lacpActorMode

* Active - The LA channel port of the NetScaler appliance generates LACPDU messages on a regular basis, regardless of any need expressed by its peer

device to receive them.

* Passive - The LA channel port of the NetScaler appliance does not transmit LACPDU messages unless the peer device port is in the active mode. That is, the port does not speak unless spoken to.

* Disabled - Unbinds the interface from the LA channel. If this is the only interface in the LA channel, the LA channel is removed.

lacpActorTimeout

Interval at which the NetScaler appliance sends LACPDU messages to the peer device on the LA channel.

Available settings function as follows:

LONG - 30 seconds.

SHORT - 1 second.

lacpActorPriority

LACP Actor Priority. A LACP port priority is configured on each port using LACP. LACP uses the port priority with the port number to form the port identifier. The port priority determines which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

lacpActorPortno

LACP Actor port number. LACP uses the port priority with the port number to form the port identifier.

lacpPartnerState

LACP Partner State. Whether the port is in Active or Passive negotiating state.

lacpPartnerTimeout

The timeout value for the information revieved in LACPDUs. It can have values as SHORT or LONG. The SHORT timeout is 3s and the LONG timeout is 90s.

lacpPartnerAggregation

The Aggregation flag indicates that the participant will allow the link to be used as part of an aggregate. Otherwise the link is to be used as an individual link, i.e. not aggregated with any other.

lacpPartnerInsync

The Synchronization flag indicates that the transmitting participant.s mux component is in sync with the system id and key information transmitted.

lacpPartnerCollecting

The Collecting flag indicates that the participant.s collector, i.e. the reception component of the mux, is definitely on. If set the flag communicates collecting.

lacpPartnerDistributing

The Distributing flag indicates that the participant.s distributor is not definitely off. If reset the flag indicates not distributing.

lacpPartnerDefaulted

If the timer expires in the Expired state, the Receive Machine enters the Defaulted state.

lacpPartnerExpired

If the LACPDUs are received for timeout period, the Receive Machine enters the Expired state and the timer is restarted with the timeout value of SHORT timeout

lacpPartnerPriority

LACP Partner Priority. A LACP port priority is configured on each port using LACP. LACP uses the port priority with the port number to form the port identifier.

The port priority determines which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

lacpPartnerSystemMac

LACP Partner System MAC.

lacpPartnerSystemPriority

LACP Partner System Priority. The LACP partner's system priority. The values for the priority range from 0 to 65535. The lower the value, the higher the system priority. The switch with the lower system priority value determines which links between LACP partner are active and which are in the standby for each LACP Channel.

lacpPartnerPortno

LACP Partner Port number. LACP uses the port priority with the port number to form the port identifier.

lacpPartnerKey

LACP Partner Key. The LACP key used by the partner port.

lacpActorAggregation

The Aggregation flag indicates that the participant will allow the link to be used as part of an aggregate. Otherwise the link is to be used as an individual link, i.e. not aggregated with any other.

lacpActorInsync

The Synchronization flag indicates that the transmitting participant.s mux component is in sync with the system id and key information transmitted.

lacpActorCollecting

The Collecting flag indicates that the participant.s collector, i.e. the reception component of the mux, is definitely on. If set the flag communicates collecting.

lacpActorDistributing

The Distributing flag indicates that the participant.s distributor is not definitely off. If reset the flag indicates not distributing.

lacpPortMuxState

LACP Port MUX state. The state of the MUX control machine. The Mux Control Machine attaches the physical port to an aggregate port, using the Selection Logic to choose an appropriate port, and turns the distributor and collector for the physical port on or off as required by protocol information.

lacpPortRxStat

LACP Port RX state. The state of the Receive machine. The Receive Machine maintains partner information, recording protocol information from LACPDUs sent by remote partner(s). Received information is subject to a timeout, and if sufficient time elapses the receive machine will revert to using default partner information.

lacpPortSelectState

LACP Port SELECT state. The state of the SELECT state machine, It could be SELECTED or UNSELECTED.

devno

count

Example

The output for the show interface command is as follows: 1) Interface 0/1 (Gig Ethernet 10/100/1000 MBits) #4 flags=0x4021

---

stat interface

Displays the statistics of all interfaces or of the specified interface on the NetScaler appliance. To display the statistics of all interfaces, run the command without any parameters. To display the statistics of a particular interface, specify the ID of the interface.

Synopsys

stat interface [<id>@] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

id

Interface number, in C/U format, where C can take one of the following values:

* 0 - Indicates a management interface.

* 1 - Indicates a 1 Gbps port.

* 10 - Indicates a 10 Gbps port.

* LA - Indicates a link aggregation port.

* LO - Indicates a loop back port.

U is a unique integer for representing an interface in a particular port group.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Interface State (IntfState)

Current state of the specified interface. The interface state set to UP only if the link state is UP and administrative state is ENABLED .

Link uptime (UpTime)

Duration for which the link is UP. This statistic is reset when the state changes to DOWN.

Link downtime (DnTime)

Duration for which the link is DOWN. This statistic is reset when the state changes to UP.

Bytes received (Rx Bytes)

Number of bytes received by an interface since the NetScaler appliance was started or the interface statistics were cleared.

Bytes transmitted (Tx Bytes)

Number of bytes transmitted by an interface since the NetScaler appliance was started or the interface statistics were cleared.

Packets received (Rx Pkts)

Number of packets received by an interface since the NetScaler appliance was started or the interface statistics were cleared.

Packets transmitted (Tx Pkts)

Number of packets transmitted by an interface since the NetScaler appliance was started or the interface statistics were cleared.

Multicast packets (McastPkt)

Number of multicast packets received by the specified interface since the NetScaler appliance was started or the interface statistics were cleared.

NetScaler packets (NSPkt)

Number of packets, destined to the NetScaler, received by an interface since the NetScaler appliance was started or the interface statistics were cleared. The packets destined to NetScaler are those that have the same MAC address as that of an interface or a VMAC address owned by the NetScaler.

LACPDUs received (RxLacpdu)

Number of Link Aggregation Control Protocol Data Units(LACPDUs) received by the specified interface since the NetScaler appliance was started or the interface statistics were cleared.

LACPDUs transmitted (TxLacpdu)

Number of Link Aggregation Control Protocol Data Units(LACPDUs) transmitted by the specified interface since the NetScaler appliance was started or the interface statistics were cleared.

Error packets received (hw) (ErrRx)

Number of inbound packets dropped by the hardware on a specified interface once the NetScaler appliance starts or the interface statistics are cleared. This happens due to following reasons:

1) The hardware receives packets at a rate higher rate than that at which the software is processing packets. In this case, the hardware FIFO overruns and starts dropping the packets .

2) The specified interface fails to receive inbound packets from the appliance because of insufficient memory.

3) The specified interface receives packets with CRC errors (Alignment or Frame Check Sequence).

4) The specified interface receives overly long packets.

5) The specified interface receives packets with alignment errors.

6) The software does less buffering because it is running out of available memory. When hardware detects that there is no space into which to push newly arrived packets, it starts dropping them.

7) The specified interface receives packets with Frame Check Sequence (FCS) errors.

8) The specified interface receives packets smaller than 64 bytes.

9) The specified interface discards error-free inbound packets because of insufficient resources. For example: NIC buffers.

10) Packets are missed because of collision detection, link lost, physical decoding error, or MAC abort.

Error packets transmitted (hw) (ErrTx)

Number of outbound packets dropped by the hardware on a specified interface since the NetScaler appliance was started or the interface statistics were cleared. This could happen due to length (undersize or oversize) errors and lack of resources. This statistic is available only for:

(1) Loop back interface (LO) of all platforms.

(2) All data ports on the NetScaler 12000 platform.

(3) Management ports on the MPX 15000 and 17000 platforms.

Inbound packets discarded(hw) (InDisc)

Number of error-free inbound packets discarded by the specified interface due to a lack of resources, for example, insufficient receive buffers.

Outbound packets discarded(hw) (OutDisc)

Number of error-free outbound packets discarded by the specified interface due to a lack of resources. This statistic is not available on:

(1) 10G ports of NetScaler MPX 12500/12500/15500-10G platforms.

(2) 10G data ports on NetScaler MPX 17500/19500/21500 platforms.

Packets dropped in Rx (sw) (DrpRxPkt)

Number of inbound packets dropped by the specified interface. Commonly dropped packets are multicast frames, spanning tree BPDUs, packets destined to a MAC not owned by the NetScaler when L2 mode is disabled, or packets tagged for a VLAN that is not bound to the interface. This statistic will increment in most healthy networks at a steady rate regardless of traffic load. If a sharp spike in dropped packets occurs, it generally indicates an issue with connected L2 switches, such as a forwarding database overflow resulting in packets being broadcast on all ports.

Packets dropped in Tx (sw) (DrpTxPkt)

Number of packets dropped in transmission by the specified interface due to one of the following reasons.

(1) VLAN mismatch.

(2) Oversized packets.

(3) Interface congestion.

(4) Loopback packets sent on non loop back interface.

NIC hangs (Hangs)

Number of times the specified interface detected hangs in the transmit and receive paths since the NetScaler appliance was started or the interface statistics were cleared.

Status stalls (StsStall)

Number of times the status updates for a specified interface were stalled since the NetScaler appliance was started or the interface statistics were cleared. A status stall is detected when the status of the interface is not updated by the NIC hardware within 0.8 seconds of the last update.

Transmit stalls (TxStall)

Number of times the interface stalled, when transmitting packets, since the NetScaler appliance was started or the interface statistics were cleared. Transmit (Tx) stalls are detected when a packet posted for transmission is not transmitted in 4 seconds.

Receive stalls (RxStall)

Number of times the interface stalled, when receiving packets, since the NetScaler appliance was started or the interface statistics were cleared. Receive (Rx) stalls are detected when the following conditions are met:

(1)The link is up for more than 10 minutes.

(2)Packets are transmitted, but no packets is received for 16 seconds.

Error-disables (ErrDis)

Number of times the specified interface is disabled by the NetScaler, due to continuous Receive (Rx) or Transmit (Tx) stalls, since the NetScaler appliance was started or the interface statistics were cleared. The NetScaler disables an interface when one of the following conditions is met:

(1) Three consecutive transmit stalls occurs with at most gap of 10 seconds between any two stalls.

(2) Three consecutive receive stalls occurs with at most gap of 120 seconds between any two stalls.

Duplex mismatches (DupMism)

Number of times duplex mismatches were detected on the specified interface since the NetScaler appliance was started or the interface statistics were cleared. A mismatch will occur if the duplex mode is not identically set on both ends of the link. This statistic is only available on the NetScaler Classic edition.

Link re-initializations (LnkReint)

Number of times the link has been re-initialized. A re-initialization occurs due to link state change, configuration parameter change, or administrative reset operation.

MAC moves registered (MacMvd)

Number of MAC moves between ports. If a high rate of MAC moves is observed, it is likely that there is a bridge loop between two interfaces.

Times NIC became muted (ErrMtd)

Number of times the specified interface stopped transmitting and receiving packets due to MAC moves between ports.

Interface Alias (IntfAlias)

Alias Name for the Interface

Link State (State)

The current state of the link associated with the interface. For logical interfaces (LA), the state of the link is dependent on the state of the slave interfaces. For the link to be UP at least one of the slave interfaces needs to be UP.

ip6Tunnel

Sep 22, 2015

The following operations can be performed on "ip6Tunnel":

add | rm | show

add ip6Tunnel

Creates an IPv6 tunnel. An IP tunnel is a communication channel, using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent through the tunnel.

Synopsys

add ip6Tunnel <name> <remote> <local>

Arguments

name

Name for the IPv6 Tunnel. Cannot be changed after the service group is created. Must begin with a number or letter, and can consist of letters, numbers, and the @ _ - . (period) : (colon) # and space ( ) characters.

remote

An IPv6 address of the remote NetScaler appliance used to set up the tunnel.

local

An IPv6 address of the local NetScaler appliance used to set up the tunnel.

Example

```
add ip6tunnel tun6 9901::200/64 *
```

---

rm ip6Tunnel

Removes an IPv6 tunnel from the NetScaler appliance.

Synopsys

rm ip6Tunnel <name>

Arguments

name

Name of the IPv6 tunnel to be removed.

Example

```
rm ip6tunnel tun6
```

---

show ip6Tunnel

Displays the settings of all IPv6 tunnels configured on the NetScaler appliance, or of the specified IPv6 tunnel.

Synopsys

show ip6Tunnel [<name> | <remote>]

Arguments

name

Name of the IPv6 tunnel whose details you want to display.

remote

The IPv6 address at which the remote NetScaler appliance connects to the tunnel.

summary

fullValues

format

level

Outputs

remoteIP

The remote IP address or subnet of the tunnel.

local

An IPv6 address of the local NetScaler appliance used to set up the tunnel.

type

The type of this tunnel.

encapIp

The effective local IP address of the tunnel. Used as the source of the encapsulated packets.

```
1) Name.....: tun61    Remote.....:    9901::200/64 Local.....:        *    Encap.....:      ::0/128     Type.....:          C 2) Na
```

ip6TunnelParam

Sep 22, 2015

The following operations can be performed on "ip6TunnelParam":

set | unset | show

set ip6TunnelParam

Sets global parameters of IPv6 tunnels on the NetScaler appliance.

Synopsys

set ip6TunnelParam [-srcIP <ipv6_addr|null>] [-dropFrag (YES | NO)] [-dropFragCpuThreshold <positive_integer>] [-srcIPRoundRobin (YES | NO)]

Arguments

srcIP

Common source IPv6 address for all IPv6 tunnels. Must be a SNIP6 or VIP6 address.

dropFrag

Drop any packet that requires fragmentation.

Possible values: YES, NO

Default value: NO

dropFragCpuThreshold

Threshold value, as a percentage of CPU usage, at which to drop packets that require fragmentation. Applies only if dropFragparameter is set to NO.

Minimum value: 1

Maximum value: 100

srcIPRoundRobin

Use a different source IPv6 address for each new session through a particular IPv6 tunnel, as determined by round robin selection of one of the SNIP6 addresses. This setting is ignored if a common global source IPv6 address has been specified for all the IPv6 tunnels. This setting does not apply to a tunnel for which a source IPv6 address has been specified.

Possible values: YES, NO

Default value: NO

Example

```
set ip6TunnelParam -srcIP 9901::100 -dropFrag YES -dropFragCpuThreshold 95
```

---

unset ip6TunnelParam

Resets the specified global parameters of IPv6 tunnels to their default settings. Refer to the set ip6TunnelParam command for parameter descriptions..Refer to the set ip6TunnelParam command for meanings of the arguments.

Synopsys

unset ip6TunnelParam [-srcIP] [-dropFrag] [-dropFragCpuThreshold] [-srcIPRoundRobin]

Example

unset ip6TunnelParam -srcIP -dropFrag -dropFragCpuThreshold

---

show ip6TunnelParam

Displays the global settings of IPv6 tunnels on the NetScaler appliance.

Synopsys

show ip6TunnelParam

Arguments

format

level

Outputs

srcIP

Common source IPv6 address for all IPv6 tunnels. Must be a SNIP6 or VIP6 address.

dropFrag

Drop any packet that requires fragmentation.

dropFragCpuThreshold

Threshold value, as a percentage of CPU usage, at which to drop packets that require fragmentation. Applies only if dropFragparameter is set to NO.

srcIPRoundRobin

Use a different source IPv6 address for each new session through a particular IPv6 tunnel, as determined by round robin selection of one of the SNIP6 addresses. This setting is ignored if a common global source IPv6 address has been specified for all the IPv6 tunnels. This setting does not apply to a tunnel for which a source IPv6 address has been specified.

Example

Tunnel Source IP: 9901::100 Drop if Fragmentation Needed: YES CPU usage threshold to avoid fragmentation: 95

---

ipTunnel

Sep 22, 2015

The following operations can be performed on "ipTunnel":

add | rm | show

add ipTunnel

Creates an IPv4 tunnel. An IP tunnel is a communication channel, using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent through the tunnel.

Synopsys

add ipTunnel <name> <remote> <remoteSubnetMask> <local> [-protocol <protocol>] [-ipsecProfileName <string>]

Arguments

name

Name for the IP tunnel. Leading character must be a number or letter. Other characters allowed, after the first character, are @ _ - . (period) : (colon) # and space ( ).

remote

Public IPv4 address, of the remote device, used to set up the tunnel. For this parameter, you can alternativelyspecify a network address if you specify IPIP (IP over IP) for the Protocol parameter.

remoteSubnetMask

Subnet mask of the remote IP address of the tunnel.

local

Type ofNetScaler owned public IPv4 address, configured on the local NetScaler appliance and used to set up the tunnel.

protocol

The IP tunneling protocol.

Possible values: IPIP, GRE, IPSEC

Default value: TNL_IPIP

ipsecProfileName

Name of IPSec profile to be associated.

Default value: "ns_ipsec_default_profile"

Example

```
add iptunnel tunnel1 10.100.20.0 255.255.255.0 *
```

---

rm ipTunnel

Removes an IP tunnel configuration from the NetScaler appliance.

Synopsys

rm ipTunnel <name>

Arguments

name

Name of the IP Tunnel.

Example

```
rm iptunnel tunnel1
```

---

show ipTunnel

Display the configured IP tunnels.

Synopsys

show ipTunnel [(<remote> <remoteSubnetMask>) | <name>]

Arguments

remote

Public IPv4 address, of the remote device, used to set up the tunnel. For this parameter, you can alternativelyspecify a network address if you specify IPIP (IP over IP) for the Protocol

parameter.

name

Name for the IP tunnel. Leading character must be a number or letter. Other characters allowed, after the first character, are @ _ - . (period) : (colon) # and space ( ).

summary

fullValues

format

level

Outputs

name

Name for the PBR

local

Type of NetScaler owned public IPv4 address, configured on the local NetScaler appliance and used to set up the tunnel.

protocol

The IP tunneling protocol.

type

The type of this tunnel.

encapIp

The effective local IP address of the tunnel. Used as the source of the encapsulated packets.

channel

The tunnel that is bound to a netbridge.

ipsecProfileName

Name of IPSec profile to be associated.

tunnelType

Indicates that a tunnel is User-Configured, Internal or DELETE-IN-PROGRESS.

ipsecTunnelStatus

Whether the ipsec on this tunnel is up or down.

devno

Example

```
1) Name.....: t1    Remote.....:    10.102.33.0  Mask.....:  255.255.255.0    Local.....:          *  Encap.....:       0.0.0.0    P
```

ipTunnelParam

Sep 22, 2015

The following operations can be performed on "ipTunnelParam":

set | unset | show

set ipTunnelParam

Sets global parameters of IPv4 tunnels on the NetScaler appliance.

Synopsys

set ipTunnelParam [-srcIP <ip_addr>] [-dropFrag (YES | NO)] [-dropFragCpuThreshold <positive_integer>] [-srcIPRoundRobin (YES | NO)]

Arguments

srcIP

Common source-IP address for all tunnels. For a specific tunnel, this global setting is overridden if you have specified another source IP address. Must be a MIP or SNIP address.

dropFrag

Drop any IP packet that requires fragmentation before it is sent through the tunnel.

Possible values: YES, NO

Default value: NO

dropFragCpuThreshold

Threshold value, as a percentage of CPU usage, at which to drop packets that require fragmentation to use the IP tunnel. Applies only if dropFragparameter is set to NO. The default value, 0, specifies that this parameter is not set.

Minimum value: 1

Maximum value: 100

srcIPRoundRobin

Use a different source IP address for each new session through a particular IP tunnel, as determined by round robin selection of one of the SNIP addresses. This setting is ignored if a common global source IP address has been specified for all the IP tunnels. This setting does not apply to a tunnel for which a source IP address has been specified.

Possible values: YES, NO

Default value: NO

Example

```
set ipTunnelParam -srcIP 10.100.20.48 -dropFrag YES -dropFragCpuThreshold 95
```

---

unset ipTunnelParam

Use this command to remove ipTunnelParam settings.Refer to the set ipTunnelParam command for meanings of the arguments.

Synopsys

unset ipTunnelParam [-srcIP] [-dropFrag] [-dropFragCpuThreshold] [-srcIPRoundRobin]

---

show ipTunnelParam

Display the IP Tunnel global settings on the NetScaler

Synopsys

show ipTunnelParam

Arguments

format

level

Outputs

srcIP

Common source-IP address for all tunnels. For a specific tunnel, this global setting is overridden if you have specified another source IP address. Must be a MIP or SNIP address.

dropFrag

Drop any IP packet that requires fragmentation before it is sent through the tunnel.

dropFragCpuThreshold

Threshold value, as a percentage of CPU usage, at which to drop packets that require fragmentation to use the IP tunnel. Applies only if dropFragparameter is set to NO. The default value, 0, specifies that this parameter is not set.

srcIPRoundRobin

Use a different source IP address for each new session through a particular IP tunnel, as determined by round robin selection of one of the SNIP addresses. This setting is ignored if a common global source IP address has been specified for all the IP tunnels. This setting does not apply to a tunnel for which a source IP address has been specified.

Example

```
Tunnel Source IP: 10.100.20.48 Drop if Fragmentation Needed: YES CPU usage threshold to avoid fragmentation: 95
```

ipset

Sep 22, 2015

The following operations can be performed on "ipset":

add | rm | bind | unbind | show

add ipset

Creates an IP set to which you can bind subnet IP (SNIP) or mapped IP (MIP) addresses that have been configured on the NetScaler appliance.

Synopsys

add ipset <name> [-td <positive_integer>]

Arguments

name

Name for the IP set. Must begin with a letter, number, or the underscore character (_), and can consist of letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore characters. Cannot be changed after the IP set is created. Choose a name that helps identify the IP set.

td

Traffic Domain Id.

Maximum value: 4094

Example

```
add ipset pool1
```

---

rm ipset

Removes an IP set from the NetScaler appliance.

Synopsys

rm ipset <name> ...

Arguments

name

Name of the IP set to be removed.

Example

```
rm ipset pool1
```

bind ipset

Binds specified IP addresses to an IP set.

Synopsys

bind ipset <name> <IPAddress>@ ...

Arguments

name

Name of the IP set to which to bind IP addresses.

IPAddress

SNIP or MIP addresses, configured on the NetScaler appliance, to be bound to the IP set. (If using the CLI, use spaces to separate multiple addresses.)

Example

```
bind ipset ipset_1 10.102.1.10
```

unbind ipset

Unbinds the associated IP addresses from an IP set.

Synopsys

unbind ipset <name> <IPAddress>@ ...

Arguments

name

Name of the IP set from which to unbind IP addresses.

IPAddress

IP addresses to be unbound from the IP set. (If using the CLI, use spaces to separate multiple addresses.)

Example

```
unbind ipset ipset_1 10.102.1.10
```

show ipset

Displays the settings of all IP sets configured on the NetScaler appliance, or of the specified IP set.

Synopsys

show ipset [<name>]

Arguments

name

Name of the IP set whose details you want to display.

summary

fullValues

format

level

Outputs

td

Traffic Domain Id.

IPAddress

One or more IP addresses bound to the IP set.

stateflag

state flag

flags

show network ipset

ipv6

Sep 22, 2015

The following operations can be performed on "ipv6":

set | unset | show

set ipv6

Sets the IPv6-related parameters: RA Learning and IPv6 NAT Prefix.

Synopsys

set ipv6 [-ralearning (ENABLED | DISABLED)] [-routerRedirection (ENABLED | DISABLED)] [-ndBasereachTime <positive_integer>] [-ndRetransmissionTime <positive_integer>] [-natprefix <ipv6_addr|*>] [-doDAD (ENABLED | DISABLED)]

Arguments

ralearning

Enable the NetScaler appliance to learn about various routes from Router Advertisement (RA) and Router Solicitation (RS) messages sent by the routers.

Possible values: ENABLED, DISABLED

Default value: DISABLED

routerRedirection

Enable the NetScaler appliance to do Router Redirection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ndBasereachTime

ND6 base reachable time (ms)

Default value: 30000

ndRetransmissionTime

ND6 retransmission time (ms)

Default value: 1000

natprefix

Prefix used for translating packets from private IPv6 servers to IPv4 packets. This prefix has a length of 96 bits (128-32 = 96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as

the IPv6 NAT prefix. IPv6 packets addressed to this prefix have to be routed to the NetScaler appliance to ensure that the IPv6-IPv4 translation is done by the appliance.

doDAD

Enable the NetScaler appliance to do Duplicate Address Detection(DAD) for all the IPv6 addresses configured on NS, regardless of whether they are obtained through stateless autoconfiguration .DHCPv6, or manual configuration. RFC4862-sec 5.4.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

```
set ipv6 -natprefix 2000::/96
```

---

unset ipv6

Use this command to remove ipv6 settings.Refer to the set ipv6 command for meanings of the arguments.

Synopsys

```
unset ipv6 [-ralearning] [-routerRedirection] [-ndBasereachTime] [-ndRetransmissionTime] [-natprefix] [-doDAD]
```

---

show ipv6

Display IPv6 settings

Synopsys

```
show ipv6
```

Arguments

format

level

Outputs

ralearning

Enable the NetScaler appliance to learn about various routes from Router Advertisement (RA) and Router Solicitation (RS) messages sent by the routers.

routerRedirection

Enable the NetScaler appliance to do Router Redirection.

basereachtime

ND6 base reachable time (ms)NOTE: This attribute is deprecated.depricating "basereachtime" in favor of "ndBasereachTime" to accommodate larger value set

ndBasereachTime

ND6 base reachable time (ms)

reachtime

ND6 computed reachable time (ms)NOTE: This attribute is deprecated.depricating V6REACHTIME in favor of ND6REACHTIME to accommodate larger value set

ndreachtime

ND6 computed reachable time (ms)

retransmissiontime

ND6 retransmission time (ms)NOTE: This attribute is deprecated.depricating "retransmissiontime" in favor of "ndRetransmissionTime" to accommodate larger value set

ndRetransmissionTime

ND6 retransmission time (ms)

natprefix

Prefix used for translating packets from private IPv6 servers to IPv4 packets. This prefix has a length of 96 bits (128-32 = 96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix. IPv6 packets addressed to this prefix have to be routed to the NetScaler appliance to ensure that the IPv6-IPv4 translation is done by the appliance.

doDAD

Enable the NetScaler appliance to do Duplicate Address Detection(DAD) for all the IPv6 addresses configured on NS, regardless of whether they are obtained through stateless autoconfiguration .DHCPv6, or manual configuration. RFC4862-sec 5.4.

Example

show ipv6

lacp

Sep 22, 2015

The following operations can be performed on "lacp":

set | show

set lacp

Sets the Link Aggregation Control Protocol (LACP) system priority. Note: The NetScaler appliance automatically adds a parameter called mac in the configuration file (ns.conf) for this command entry. This parameter is set to the MAC address of one of the NetScaler appliance's interfaces and is used along with the system priority to form the system ID for the LACP channel.

Synopsys

set lacp -sysPriority <positive_integer> [-ownerNode <positive_integer>]

Arguments

sysPriority

Priority number that determines which peer device of an LACP LA channel can have control over the LA channel. This parameter is globally applied to all LACP channels on the NetScaler appliance. The lower the number, the higher the priority.

Default value: 32768

Minimum value: 1

Maximum value: 65535

ownerNode

The owner node in a cluster for which we want to set the lacp priority. Owner node can vary from 0 to 31. Ownernode value of 254 is used for Cluster.

Default value: 255

---

show lacp

Displays the settings of all channels created by the link aggregation control protocol (LACP) on the NetScaler appliance.

Synopsys

show lacp [-ownerNode <positive_integer>]

Arguments

ownerNode

The owner node in a cluster for which we want to set the lacp priority. Owner node can vary from 0 to 31. Ownernode value of 254 is used for Cluster.

Default value: 255

format

level

Outputs

deviceName

Name of the channel.

sysPriority

Priority number that determines which peer device of an LACP LA channel can have control over the LA channel. This parameter is globally applied to all LACP channels on the NetScaler appliance. The lower the number, the higher the priority.

mac

LACP system MAC.

flags

Flags of this channel.

lacpKey

LACP key of this channel.

clustersysPriority

LACP system (Cluster) priority

clusterMac

LACP system (Cluster) mac.

devno

count

stateflag

linkset

Sep 22, 2015

The following operations can be performed on "linkset":

add | rm | bind | unbind | show

add linkset

Adds a linkset to the NetScaler cluster.

Synopsys

add linkset <id>

Arguments

id

Unique identifier for the linkset. Must be of the form LS/x, where x can be an integer from 1 to 32.

Example

```
add linkset LS/1
```

---

rm linkset

Removes a linkset from the cluster.

Synopsys

rm linkset <id>

Arguments

id

ID of the linkset to be removed.

Example

```
rm linkset LS/1
```

---

bind linkset

Binds interfaces to the linkset.

Synopsys

bind linkset <id> -ifnum <interface_name> ...

Arguments

id

ID of the linkset to which to bind the interfaces.

ifnum

The interfaces to be bound to the linkset.

Example

```
bind linkset LS/1 -ifnum 1/1/1
```

---

unbind linkset

Unbinds interfaces from the linkset.

Synopsys

unbind linkset <id> -ifnum <interface_name> ...

Arguments

id

ID of the linkset from which to unbind the interfaces.

ifnum

Interfaces to be unbound from the linkset.

Example

```
unbind linkset LS/1 -ifnum 1/1/1
```

---

show linkset

Displays information about all linksets, or displays information about the specified linkset.

Synopsys

show linkset [<id>]

Arguments

id

ID of the linkset for which to display information. If an ID is not provided, the display includes information about all linksets that are available in the cluster.

summary

fullValues

format

level

Outputs

ifnum

The interfaces to be bound to the linkset.

nat64

Sep 22, 2015

The following operations can be performed on "nat64":

add | set | unset | rm | stat | show

add nat64

Configure a nat64 rule on the appliance.

Synopsys

add nat64 <name> <acl6name> [-netProfile <string>]

Arguments

name

Name of NAT64 rule.

acl6name

The ACL6 name.

netProfile

The name of the network profile.

---

set nat64

Set the configured nat64 rule.

Synopsys

set nat64 <name> [-acl6name <string>] [-netProfile <string>]

Arguments

name

Name of NAT64 rule.

acl6name

The ACL6 name.

netProfile

The name of the network profile.

Example

set nat64 rule1 -acl6name acl1 .

---

unset nat64

Use this command to remove nat64 settings.Refer to the set nat64 command for meanings of the arguments.

Synopsys

unset nat64 <name> -netProfile

---

rm nat64

Remove the configured nat64 rule.

Synopsys

rm nat64 <name>

Arguments

name

Name of NAT64 rule.

Example

rm nat64 name.

---

stat nat64

Display statistics for nat64 sessions.

Synopsys

stat nat64 [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

TCP Sessions (nat64TotTcpSessions)

Total number of TCP sessions created by NAT64.

UDP Sessions (nat64TotUdpSessions)

Total number of UDP sessions created by NAT64.

ICMP Sessions (nat64TotIcmpSessions)

Total number of ICMP sessions created by NAT64.

Total Sessions (nat64TotSessions)

Total number of sessions created by NAT64.

Example

stat nat64

---

show nat64

Display the nat64 configuration.

Synopsys

show nat64 [<name>]

Arguments

name

Name of NAT64 rule.

format

level

Outputs

acl6name

The ACL6 name.

netProfile

The name of the network profile.

devno

count

stateflag

---

nd6

Sep 22, 2015

The following operations can be performed on "nd6":

add | clear | rm | show

add nd6

Adds a static entry to the ND6 table of the NetScaler appliance.

Synopsys

add nd6 <neighbor> <mac> <ifnum> [-vlan <integer>] [-td <positive_integer>]

Arguments

neighbor

Link-local IPv6 address of the adjacent network device to add to the ND6 table.

mac

MAC address of the adjacent network device.

ifnum

Interface through which the adjacent network device is available, specified in slot/port notation (for example, 1/3). Use spaces to separate multiple entries.

vlan

Integer value that uniquely identifies the VLAN on which the adjacent network device exists.

Minimum value: 1

Maximum value: 4094

td

Traffic Domain Id.

Maximum value: 4094

Example

```
add nd6 2001::1 00:04:23:be:3c:06 5 1/1
```

---

clear nd6

Removes all IPv6 neighbour discovery entries from the NetScaler appliance.

Synopsys

clear nd6

---

rm nd6

Remove a static IPv6 neighbor discovery entry from the NetScaler appliance's ND6 table.

Synopsys

rm nd6 <neighbor> [-vlan <integer>] [-td <positive_integer>]

Arguments

neighbor

Link-local IPv6 address of the adjacent network device that you want to remove from the ND6 table.

vlan

Integer value that uniquely identifies the VLAN for the ND6 entry you want to remove.

Minimum value: 1

Maximum value: 4094

td

Traffic Domain Id.

Maximum value: 4094

Example

rm nd6 2001::1 5 1/1

---

show nd6

Display the neighbor discovery information.

Synopsys

show nd6 [<neighbor> [-td <positive_integer>]]

Arguments

neighbor

Link-local IPv6 address of the adjacent network device to add to the ND6 table.

summary

fullValues

format

level

Outputs

mac

MAC address of the adjacent network device.

state

ND6 state

timeout

Time elapsed

ifnum

Interface through which the adjacent network device is available, specified in slot/port notation (for example, 1/3). Use spaces to separate multiple entries.

vlan

Integer value that uniquely identifies the VLAN on which the adjacent network device exists.

flags

flag for static/permanent entry.

channel

The tunnel that is bound to a netbridge.

Following is an example of the output for the show nd6 command: Neighbor MAC-Address(Vlan, Interface) State TIME(hh:

---

nd6RAvariables

Sep 22, 2015

The following operations can be performed on "nd6RAvariables":

set | unset | show | bind | unbind

set nd6RAvariables

Set vlan specific Router Advertisment parameters in NetScaler.

Synopsys

set nd6RAvariables -vlan <positive_integer> [-ceaseRouterAdv (YES | NO)] [-sendRouterAdv (YES | NO)] [-srcLinkLayerAddrOption (YES | NO)] [-onlyUnicastRtAdvResponse (YES | NO)] [-managedAddrConfig (YES | NO)] [-otherAddrConfig (YES | NO)] [-currHopLimit <positive_integer>] [-maxRtAdvInterval <positive_integer>] [-minRtAdvInterval <positive_integer>] [-linkMTU <positive_integer>] [-reachableTime <positive_integer>] [-retransTime <positive_integer>] [-defaultLifeTime <integer>]

Arguments

vlan

The VLAN number.

Maximum value: 4094

ceaseRouterAdv

Cease router advertisements on this vlan.

Possible values: YES, NO

Default value: NO

sendRouterAdv

whether the router sends periodic RAs and responds to Router Solicitations.

Possible values: YES, NO

Default value: NO

srcLinkLayerAddrOption

Include source link layer address option in RA messages.

Possible values: YES, NO

Default value: YES

onlyUnicastRtAdvResponse

Send only Unicast Router Advertisements in respond to Router Solicitations.

Possible values: YES, NO

Default value: NO

managedAddrConfig

Value to be placed in the Managed address configuration flag field.

Possible values: YES, NO

Default value: NO

otherAddrConfig

Value to be placed in the Other configuration flag field.

Possible values: YES, NO

Default value: NO

currHopLimit

Current Hop limit.

Default value: 64

Maximum value: 255

maxRtAdvInterval

Maximum time allowed between unsolicited multicast RAs, in seconds.

Default value: 600

Minimum value: 4

Maximum value: 1800

minRtAdvInterval

Minimum time interval between RA messages, in seconds.

Default value: 198

Minimum value: 3

Maximum value: 1350

linkMTU

The Link MTU.

Maximum value: 1500

reachableTime

Reachable time, in milliseconds.

Maximum value: 3600000

retransTime

Retransmission time, in milliseconds.

defaultLifeTime

Default life time, in seconds.

Default value: 1800

Maximum value: 9000

Example

```
set nd6RAvariables -vlan 2 -maxRtAdvInterval 600
```

---

unset nd6RAvariables

Use this command to remove nd6RAvariables settings.Refer to the set nd6RAvariables command for meanings of the arguments.

Synopsys

```
unset nd6RAvariables -vlan <positive_integer> [-ceaseRouterAdv] [-sendRouterAdv] [-srcLinkLayerAddrOption] [-onlyUnicastRtAdvResponse] [-managedAddrConfig] [-otherAddrConfig] [-currHopLimit] [-maxRtAdvInterval] [-minRtAdvInterval] [-linkMTU] [-reachableTime] [-retransTime] [-defaultLifeTime]
```

---

show nd6RAvariables

Display Router Advertisement configuration variables.

Synopsys

```
show nd6RAvariables [-vlan <positive_integer>]
```

Arguments

vlan

The VLAN number.

Maximum value: 4094

format

level

Outputs

ceaseRouterAdv

Cease router advertisements on this vlan.

sendRouterAdv

whether the router sends periodic RAs and responds to Router Solicitations.

srcLinkLayerAddrOption

Include source link layer address option in RA messages.

onlyUnicastRtAdvResponse

Send only Unicast Router Advertisements in respond to Router Solicitations.

managedAddrConfig

Value to be placed in the Managed address configuration flag field.

otherAddrConfig

Value to be placed in the Other configuration flag field.

currHopLimit

Current Hop limit.

maxRtAdvInterval

Maximum time allowed between unsolicited multicast RAs, in seconds.

minRtAdvInterval

Minimum time interval between RA messages, in seconds.

linkMTU

The Link MTU.

reachableTime

Reachable time, in milliseconds.

retransTime

Retransmission time, in milliseconds.

defaultLifeTime

Default life time, in seconds.

stateflag

RA Param state flags.

lastRtAdvTime

Last RA sent timestamp.

nextRtAdvDelay

Next RA delay.

ipv6Prefix

Onlink prefixes for RA messages.

devno

count

---

bind nd6RAvariables

Bind on-link global prefixes to Router Advertisments variables.

Synopsys

bind nd6RAvariables -vlan <positive_integer> -ipv6Prefix <ipv6_addr|*>

Arguments

vlan

The VLAN number.

Maximum value: 4094

ipv6Prefix

Onlink prefixes for RA messages.

Example

```
bind nd6RAvariables -vlan 2 -ipv6Prefix 8000::/64
```

---

unbind nd6RAvariables

Unbind prefix from Router Advertisment parameters in NetScaler

Synopsys

unbind nd6RAvariables -vlan <positive_integer> -ipv6Prefix <ipv6_addr|*>

Arguments

vlan

The VLAN number.

Maximum value: 4094

ipv6Prefix

Onlink prefixes for RA messages.

Example

```
unbind nd6RAvariables -vlan 2 -ipv6Prefix 8000::/64
```

netProfile

Sep 22, 2015

The following operations can be performed on "netProfile":

add | rm | set | unset | show

add netProfile

Creates a net profile. A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the NetScaler appliance uses the addresses specified in the profile as the source IP address.

Synopsys

add netProfile <name> [-td <positive_integer>] [-srcIP <string>]

Arguments

name

Name for the net profile. Must begin with a letter, number, or the underscore character (_), and can consist of letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore characters. Cannot be changed after the profile is created. Choose a name that helps identify the net profile.

td

Traffic Domain Id.

Maximum value: 4094

srcIP

IP address or the name of an IP set.

Example

```
add netProfile prof1 -srcip 10.102.1.10
```

---

rm netProfile

Removes a net profile from the NetScaler appliance.

Synopsys

rm netProfile <name> ...

Arguments

name

Name of the net profile to be removed.

Example

rm netProfile prof1

---

set netProfile

Modifies the srcIP parameter of a net profile.

Synopsys

set netProfile <name> [-srcIP <string>]

Arguments

name

Name of the net profile whose parameter you want to modify.

srcIP

IP address or the name of an IP set.

Example

set netProfile prof_1 -srcIP 10.102.1.10

---

unset netProfile

Removes the srcIP attribute of a net profile..Refer to the set netProfile command for meanings of the arguments.

Synopsys

unset netProfile <name> [-srcIP]

Example

unset netProfile prof1 -srcIP

---

show netProfile

Displays the settings of all net profiles configured on the NetScaler appliance, or of the specified net profile.

Synopsys

show netProfile [<name>]

Arguments

name

Name of the net profile whose details you want to display.

summary

fullValues

format

level

Outputs

srcIP

Source IPaddress or IPSET name.

vpathEncap

enable/disable vPath Encapsulation

td

Traffic Domain Id.

devno

count

stateflag

Example

```
show netProfile
```

netbridge

Sep 22, 2015

The following operations can be performed on "netbridge":

add | rm | show | bind | unbind

add netbridge

Add a network bridge.

Synopsys

add netbridge <name>

Arguments

name

The name of the network bridge.

Example

```
add netbridge bridge1
```

---

rm netbridge

Remove a network bridge.

Synopsys

rm netbridge <name>

Arguments

name

The name of the network bridge.

Example

```
remove netbridge bridge1
```

---

show netbridge

Show configured network bridges.

Synopsys

show netbridge [<name>]

Arguments

name

The name of the network bridge.

format

level

Outputs

tunnel

The name of the tunnel that is a part of this bridge.

vlan

The VLAN that is extended by this network bridge.

IPAddress

The subnet that is extended by this network bridge.

netmask

The network mask for the subnet.

stateflag

Used internally for display.

devno

count

---

bind netbridge

Bind a network bridge to its attributes.

Synopsys

bind netbridge <name> [-tunnel <string> ...] [-vlan <positive_integer> ...] [-IPAddress <ip_addr|ipv6_addr|*> [<netmask>]]

Arguments

name

The name of the network bridge.

tunnel

The name of the tunnel that needs to be a part of this network bridge.

vlan

The VLAN that needs to be extended.

Minimum value: 1

Maximum value: 4094

IPAddress

The subnet that needs to be extended.

Example

```
bind netbridge bridge1 -tunnel tun0
```

---

unbind netbridge

Unbind a network bridge from its attributes.

Synopsys

unbind netbridge <name> [-tunnel <string> ...] [-vlan <positive_integer> ...] [-IPAddress <ip_addr|ipv6_addr|*> [<netmask>]]

Arguments

name

The name of the network bridge.

tunnel

The name of the tunnel that is part of this network bridge.

vlan

The vlan that is part of this network bridge.

Minimum value: 1

Maximum value: 4094

IPAddress

The subnet that is part of this network bridge.

Example

```
unbind netbridge bridge1 -tunnel tun0
```

---

onLinkIPv6Prefix

Sep 22, 2015

The following operations can be performed on "onLinkIPv6Prefix":

add | rm | set | unset | show

add onLinkIPv6Prefix

add a new on-link global prefix.

Synopsys

add onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix (YES | NO)] [-autonomusPrefix (YES | NO)] [-depricatePrefix (YES | NO)] [-decrementPrefixLifeTimes (YES | NO)] [-prefixValideLifeTime <positive_integer>] [-prefixPreferredLifeTime <positive_integer>]

Arguments

ipv6Prefix

Onlink prefixes for RA messages.

onlinkPrefix

RA Prefix onlink flag.

Possible values: YES, NO

Default value: YES

autonomusPrefix

RA Prefix Autonomus flag.

Possible values: YES, NO

Default value: YES

depricatePrefix

Depricate the prefix.

Possible values: YES, NO

Default value: NO

decrementPrefixLifeTimes

RA Prefix Autonomus flag.

Possible values: YES, NO

Default value: NO

prefixValideLifeTime

Valide life time of the prefix, in seconds.

Default value: 2592000

prefixPreferredLifeTime

Preferred life time of the prefix, in seconds.

Default value: 604800

Example

```
add onLinkIPv6Prefix 8000::/64
```

---

rm onLinkIPv6Prefix

remove an existing on-link global prefix.

Synopsys

```
rm onLinkIPv6Prefix <ipv6Prefix>
```

Arguments

ipv6Prefix

Onlink prefixes for RA messages.

Example

```
rm onLinkIPv6Prefix 8000::/64
```

---

set onLinkIPv6Prefix

set on-link global prefix's configuration variables.

Synopsys

```
set onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )] [-autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )] [-decrementPrefixLifeTimes ( YES | NO )] [-prefixValideLifeTime <positive_integer>] [-prefixPreferredLifeTime <positive_integer>]
```

Arguments

ipv6Prefix

Onlink prefixes for RA messages.

onlinkPrefix

RA Prefix onlink flag.

Possible values: YES, NO

Default value: YES

autonomusPrefix

RA Prefix Autonomus flag.

Possible values: YES, NO

Default value: YES

depricatePrefix

Depricate the prefix.

Possible values: YES, NO

Default value: NO

decrementPrefixLifeTimes

RA Prefix Autonomus flag.

Possible values: YES, NO

Default value: NO

prefixValideLifeTime

Valide life time of the prefix, in seconds.

Default value: 2592000

prefixPreferredLifeTime

Preferred life time of the prefix, in seconds.

Default value: 604800

Example

```
set onLinkIPv6Prefix 8000::/64 -prefixValideLifeTime 2592000
```

---

unset onLinkIPv6Prefix

Use this command to remove onLinkIPv6Prefix settings.Refer to the set onLinkIPv6Prefix command for meanings of the arguments.

Synopsys

```
unset onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix] [-autonomusPrefix] [-depricatePrefix] [-decrementPrefixLifeTimes] [-
```

prefixValideLifeTime] [-prefixPreferredLifeTime]

---

show onLinkIPv6Prefix

displays on-link global prefixes.

Synopsys

show onLinkIPv6Prefix [<ipv6Prefix>]

Arguments

ipv6Prefix

Onlink prefixes for RA messages.

format

level

Outputs

onlinkPrefix

RA Prefix onlink flag.

autonomusPrefix

RA Prefix Autonomus flag.

depricatePrefix

Depricate the prefix.

decrementPrefixLifeTimes

RA Prefix Autonomus flag.

prefixValideLifeTime

Valide life time of the prefix, in seconds.

prefixPreferredLifeTime

Preferred life time of the prefix, in seconds.

stateflag

RA Param state flags

prefixCurrValideLfT

Prefix current valid life time

prefixCurrPreferredLfT

Prefix current prefered life time

devno

count

ptp

Sep 22, 2015

The following operations can be performed on "ptp":

set | show

set ptp

Specifies whether to use Precision Time Protocol (PTP) to synchronize time across cluster nodes. This command is applicable in a cluster setup only. If you do not want to use PTP, you must disable PTP, by using this command, and instead enable NTP.

Synopsys

set ptp -state (DISABLE | ENABLE)

Arguments

state

Enables or disables Precision Time Protocol (PTP) on the appliance. If you disable PTP, make sure you enable Network Time Protocol (NTP) on the cluster.

Possible values: DISABLE, ENABLE

Default value: NSA_PTP_ENABLE

---

show ptp

Displays the status of Precision Time Protocol (PTP) on the appliance.

Synopsys

show ptp

Arguments

format

level

Outputs

state

Enables or disables Precision Time Protocol (PTP) on the appliance. If you disable PTP, make sure you enable Network Time Protocol (NTP) on the cluster.

---

rnat

Sep 22, 2015

The following operations can be performed on "rnat":

clear | set | unset | stat | show

clear rnat

Removes an RNAT rule from the NetScaler appliance.

Synopsys

clear rnat ((<network> [<netmask>]) | (<aclname> [-redirectPort])) [-natIP <ip_addr|*>@ ...] [-td <positive_integer>]

Arguments

network

The network address defined for the RNAT entry.

netmask

The subnet mask for the network address.

aclname

An extended ACL defined for the RNAT entry.

redirectPort

The port number to which the packets are redirected.

natIP

The NAT IP address defined for the RNAT entry.

td

Traffic Domain Id.

Maximum value: 4094

---

set rnat

Modifies parameters of an RNAT rule.

Synopsys

set rnat ((<network> [<netmask>] [-natIP <ip_addr|*>@ ...]) | (<aclname> [-redirectPort <port>] [-natIP <ip_addr|*>@ ...])) [-td <positive_integer>]

Arguments

network

IPv4 network address on whose traffic you want the NetScaler appliance to do RNAT processing.

aclname

Name of any configured extended ACL whose action is ALLOW. The condition specified in the extended ACL rule isused as the condition for the RNAT6 rule.

---

unset rnat

Use this command to modify the parameters of configured Reverse NAT on the system..Refer to the set rnat command for meanings of the arguments.

Synopsys

unset rnat ((<network> [<netmask>]) | (<aclname> [-redirectPort])) [-td <positive_integer>] [-natIP <ip_addr|*>@ ...]

---

stat rnat

Display statistics for rnat sessions.

Synopsys

stat rnat [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

Bytes Received (rnatRxBytes)

Bytes received during RNAT sessions.

Bytes Sent (rnatTxBytes)

Bytes sent during RNAT sessions.

Packets Received (rnatRxPkts)

Packets received during RNAT sessions.

Packets Sent (rnatTxPkts)

Packets sent during RNAT sessions.

Syn Sent (rnatTxSyn)

Requests for connections sent during RNAT sessions.

Current RNAT sessions (rnatSessions)

Currently active RNAT sessions.

Example

stat rnat

---

show rnat

Display the Reverse NAT configuration.

Synopsys

show rnat

Arguments

summary

fullValues

format

level

Outputs

network

The network address.

netmask

Subnet mask associated with the network address.

td

Traffic Domain Id.

natIP

Nat IP Address.

aclname

Name of any configured extended ACL whose action is ALLOW. The condition specified in the extended ACL rule isused as the condition for the RNAT6 rule.

redirectPort

The port number to which the packets are redirected.

cfgflags

This contains the flags for RNAT in DB

devno

count

rnat6

Sep 22, 2015

The following operations can be performed on "rnat6":

add | bind | unbind | set | unset | clear | show

add rnat6

Adds a Reverse Network Address Translation (RNAT6) rule for IPv6 traffic. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination.

Synopsys

add rnat6 <name> (<network> | (<acl6name> [-redirectPort <port>]))

Arguments

name

Name for the RNAT6 rule. Must begin with a letter, number, or the underscore character (_), and can consist of letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore characters. Cannot be changed after the rule is created. Choose a name that helps identify the RNAT6 rule.

network

IPv6 address of the network on whose traffic you want the NetScaler appliance to do RNAT processing.

acl6name

Name of any configured ACL6 whose action is ALLOW. The rule of the ACL6 is used as an RNAT6 rule.

Example

```
add rnat6 rnat6_name 2002::/64
```

---

bind rnat6

Binds specified IPv6 NAT IPs to an RNAT6 rule.

Synopsys

bind rnat6 <name> <natIP6>@ ...

Arguments

name

Name of the RNAT6 rule to which to bind NAT IPs.

natIP6

One or more IP addresses to be bound to the IP set.

Example

```
bind rnat6 <rnat6_name> <natIP6>@ ...
```

---

unbind rnat6

Unbinds the associated NAT IPv6 address(es) from an RNAT6 rule.

Synopsys

```
unbind rnat6 <name> <natIP6>@ ...
```

Arguments

name

Name of the RNAT6 rule from which to unbind the associated NAT IP address(es).

natIP6

IP address, or multiple addresses, to be unbound from the RNAT6rule. (If using the CLI, use spaces to separate multiple addresses.)

Example

```
unbind rnat6 <rnat6_name> <natIP6>@ ...
```

---

set rnat6

Modifies the specified parameters of an RNAT6 rule.

Synopsys

```
set rnat6 <name> [-redirectPort <port>]
```

Arguments

name

Name of the RNAT6 rule. Required for identifying the RNAT6 rule and cannot be modified.

redirectPort

Port number to which the IPv6 packets are redirected. Applicable to TCP and UDP protocols.

Minimum value: 1

Maximum value: 65535

---

unset rnat6

Resets the specified parameters of an RNAT6 rule to their default settings. Refer to the set rnat6 command for parameter descriptions..Refer to the set rnat6 command for meanings of the arguments.

Synopsys

unset rnat6 <name> [-redirectPort]

---

clear rnat6

Removes an RNAT6 rule from the NetScaler appliance.

Synopsys

clear rnat6 <name>

Arguments

name

Name of the RNAT6 rule to be removed.

---

show rnat6

Displays the settings of all RNAT6 rules configured on the NetScaler appliance, or of the specified RNAT6 rule.

Synopsys

show rnat6 [<name>]

Arguments

name

Name of the RNAT6 rule whose details you want to display.

format

level

Outputs

network

The network address.

acl6name

ACL6 name

natIP6

Nat IP Address.

redirectPort

Redirect Port Value

stateflag

devno

count

rnatip

Sep 22, 2015

The following operations can be performed on "rnatip":

stat rnatip

Display statistics for RNAT sessions.

Synopsys

stat rnatip [<rnatip>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

rnatip

Specifies the NAT IP address of the configured RNAT entry for which you want to see the statistics. If you do not specify an IP address, this displays the statistics for all the configured RNAT entries.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Traffic domain (td)

Traffic domain for ipaddr.

Bytes Received (rxBytes)

Bytes received on this IP address during RNAT sessions.

Bytes Sent (txBytes)

Bytes sent from this IP address during RNAT sessions.

Packets Received (rxPkts)

Packets received on this IP address during RNAT sessions.

Packets Sent (txPkts)

Packets sent from this IP address during RNAT sessions.

Syn Sent (txSyn)

Requests for connections sent from this IP address during RNAT sessions.

Current RNAT sessions (sessions)

Currently active RNAT sessions started from this IP address.

Example

```
stat rnatip 1.1.1.1
```

rnatparam

Sep 22, 2015

The following operations can be performed on "rnatparam":

set | unset | show

set rnatparam

Sets global parameters of RNAT rules on the NetScaler appliance.

Synopsys

set rnatparam -tcpproxy (ENABLED | DISABLED)

Arguments

tcpproxy

Enable TCP proxy, which enables the NetScaler appliance to optimize the RNAT TCP traffic by using Layer 4 features.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Example

set rnat parameter -tcpproxy ENABLED

---

unset rnatparam

Use this command to remove rnatparam settings.Refer to the set rnatparam command for meanings of the arguments.

Synopsys

unset rnatparam -tcpproxy

---

show rnatparam

Show the rnat parameter.

Synopsys

show rnatparam

Arguments

format

level

Outputs

tcpproxy

Enable TCP proxy, which enables the NetScaler appliance to optimize the RNAT TCP traffic by using Layer 4 features.

Example

```
show rnat parameter
```

route

Sep 22, 2015

The following operations can be performed on "route":

add | clear | rm | set | unset | show

add route

Adds an IPv4 static route to the routing table of the NetScaler appliance.

Synopsys

add route <network> <netmask> <gateway> [-td <positive_integer>] [-distance <positive_integer>] [-cost <positive_integer>] [-weight <positive_integer>] [-advertise (DISABLED | ENABLED)] [-protocol <protocol> ...] [-msr (ENABLED | DISABLED) [-monitor <string>]]

Arguments

network

IPv4 network address for which to add a route entry in the routing table of the NetScaler appliance.

netmask

The subnet mask associated with the network address.

gateway

IP address of the gateway for this route. Can be either the IP address of the gateway, or can be null to specify a null interface route.

cost

The cost of a route is used to compare routes of the same type. The route having the lowest cost is the most preferred route. Possible values: 0 through 65535. Default: 0.

Maximum value: 65535

td

Traffic Domain Id.

Maximum value: 4094

distance

Administrative distance of this route, which determines the preference of this route over other routes, with same destination, from different routing protocols. A lower value is preferred.

Default value: STATIC_ROUTE_DEFAULT_DISTANCE

Maximum value: 255

weight

Positive integer used by the routing algorithms to determine preference for this route over others of equal cost. The lower the weight, the higher the preference.

Default value: ROUTE_DEFAULT_WEIGHT

Minimum value: 1

Maximum value: 65535

advertise

Advertise this route.

Possible values: DISABLED, ENABLED

protocol

Routing protocol used for advertising this route.

Default value: ADV_ROUTE_FLAGS

msr

Monitor this route using a monitor of type ARP or PING.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

add route 10.10.10.0 255.255.255.0 10.10.10.1

---

clear route

Removes routes of the specifiedtype(protocol) from the routing table of the NetScaler appliance.

Synopsys

clear route <routeType>

Arguments

routeType

Protocol used by routes that you want to remove from the routing table of the NetScaler appliance.

---

rm route

Removes a static route from the NetScaler appliance. Note: You cannot use this command to remove routes that are part of a VLAN configuration. Use the rmvlan or clear vlan command instead.

Synopsys

rm route <network> <netmask> <gateway> [-td <positive_integer>]

Arguments

network

Network address specified in the route entry that you want to remove from the routing table of the NetScaler appliance.

netmask

Subnet mask associated with the network address.

gateway

IP address of the gateway for this route.

td

The Traffic Domain Id of the route to be removed.

Maximum value: 4094

---

set route

Modifies parameters of an IPv4 static route.

Synopsys

set route <network> <netmask> <gateway> [-td <positive_integer>] [-distance <positive_integer>] [-cost <positive_integer>] [-weight <positive_integer>] [-advertise (DISABLED | ENABLED)] [-protocol <protocol> ...] [-msr (ENABLED | DISABLED) [-monitor <string>]]

Arguments

network

Network address in the route entry that you want to modify.

netmask

Subnet mask associated with the network address.

gateway

IP address of the gateway for this route. Can be either the IP address of the gateway, or can be null to specify a null interface route.

td

Traffic Domain Id.

Maximum value: 4094

distance

Administrative distance of this route, which determines the preference of this route over other routes, with same destination, from different routing protocols. A lower value is preferred.

Default value: STATIC_ROUTE_DEFAULT_DISTANCE

Maximum value: 255

cost

The cost of a route is used to compare routes of the same type. The route having the lowest cost is the most preferred route. Possible values: 0 through 65535. Default: 0.

Maximum value: 65535

weight

Positive integer used by the routing algorithms to determine preference for this route over others of equal cost. The lower the weight, the higher the preference.

Default value: ROUTE_DEFAULT_WEIGHT

Minimum value: 1

Maximum value: 65535

advertise

Advertise this route.

Possible values: DISABLED, ENABLED

protocol

Routing protocol used for advertising this route.

Default value: ADV_ROUTE_FLAGS

msr

Monitor this route using a monitor of type ARP or PING.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

```
set route 10.10.10.0 255.255.255.0 10.10.10.1 -advertise enable
```

---

unset route

Unset the attributes of a route that were added by the add/set route command..Refer to the set route command for meanings of the arguments.

Synopsys

```
unset route <network> <netmask> <gateway> [-td <positive_integer>] [-advertise] [-distance] [-cost] [-weight] [-protocol] [-msr] [-monitor]
```

Example

```
unset route 10.10.10.0 255.255.255.0 10.10.10.1 -advertise enable
```

---

show route

Display the configured routing information.

Synopsys

```
show route [<network> <netmask> [<gateway>] [-td <positive_integer>]] [<routeType>] [-detail]
```

Arguments

network

The destination network or host.

routeType

The type of routes to be shown.

detail

Display a detailed view.

summary

fullValues

format

level

Outputs

gatewayName

The name of the gateway for this route. For a route other than a link load balancing (LLB) route, this value is null.

advertise

Enable advertisement.

type

State of the RNAT.

stateflag

dynamic

State of the route.

STATIC

PERMANENT

DIRECT

NAT

LBROUTE

ADV

TUNNEL

Show whether it is a tunnel route or not.

cost

The cost of a route is used to compare routes of the same type. The route having the lowest cost is the most preferred route. Possible values: 0 through 65535. Default: 0.

distance

Administrative distance of this route, which determines the preference of this route over other routes, with same destination, from different routing protocols. A lower value is preferred.

weight

The weight of this route.

protocol

Routing protocol used for advertising this route.

data

Internal data of this route.

data0

Internal route type is stored, used for get.

flags

If this route is dynamic, the name of the routing protocol from which it was learned.

routeOwners

Use this option with -dynamic and in a cluster only to specify the set of nodes from which this dynamic route has been learnt.

retain

OSPF

OSPF protocol.

ISIS

ISIS protocol.

RIP

RIP protocol.

BGP

BGP protocol.

DHCP

advOSPF

Advertised through OSPF protocol.NOTE: This attribute is deprecated.This argument is deprecated.Use protocol parameter to read advertise properties of route

advISIS

Advertised through ISIS protocol.NOTE: This attribute is deprecated.This argument is deprecated.Use protocol parameter to read advertise properties of route

advRIP

Advertised through RIP protocol.NOTE: This attribute is deprecated.This argument is

deprecated.Use protocol parameter to read advertise properties of route

advBGP

Advertised through BGP protocol.NOTE: This attribute is deprecated.This argument is deprecated.Use protocol parameter to read advertise properties of route

msr

Whether MSR is enabled or disabled.

monitor

Name of the monitor, of type ARP or PING, configured on the NetScaler appliance to monitor this route.

state

The state of the static route. Possible values: UP, DOWN.

peFlags

PE flags.

totalprobes

The total number of probes sent.

totalfailedprobes

The total number of failed probes.

failedprobes

Number of the current failed monitoring probes.

monStatCode

The code indicating the monitor response.

monStatParam1

First parameter used with the message code.

monStatParam2

Second parameter used with the message code.

monStatParam3

Third parameter used with the message code.

devno

count

Example

An example of the output of the show route command is as follows: 3 config

route6

Sep 22, 2015

The following operations can be performed on "route6":

add | clear | rm | set | unset | show

add route6

Adds an IPv6 static route to the routing table of the NetScaler appliance.

Synopsys

add route6 <network> [<gateway>] [-vlan <positive_integer>] [-weight <positive_integer>] [-distance <positive_integer>] [-cost <positive_integer>] [-advertise (DISABLED | ENABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-td <positive_integer>]

Arguments

network

IPv6 network address for which to add a route entry to the routing table of the NetScaler appliance.

gateway

The gateway for this route. The value for this parameter is either an IPv6 address or null.

vlan

Integer value that uniquely identifies a VLAN through which the NetScaler appliance forwards the packets for this route.

Maximum value: 4094

weight

Positive integer used by the routing algorithms to determine preference for this route over others of equal cost. The lower the weight, the higher the preference.

Default value: 1

Minimum value: 1

Maximum value: 65535

distance

Administrative distance of this route from the appliance.

Default value: 1

Minimum value: 1

Maximum value: 254

cost

Positive integer used by the routing algorithms to determine preference for this route. The lower the cost, the higher the preference.

Default value: 1

Maximum value: 65535

advertise

Advertise this route.

Possible values: DISABLED, ENABLED

msr

Monitor this route witha monitor of type ND6 or PING.

Possible values: ENABLED, DISABLED

Default value: DISABLED

td

Traffic Domain Id for IPv6 network.

Maximum value: 4094

Example

```
add route6 ::/0 2004::1  add route6 ::/0 FE80::67 -vlan 5
```

---

clear route6

Removes IPv6 routes of the specified type (protocol) from the routing table of the NetScaler appliance.

Synopsys

clear route6 <routeType>

Arguments

routeType

Type of IPv6 routes to remove from the routing table of the NetScaler appliance.

---

rm route6

Removes a static IPv6 route from the NetScaler appliance.

Synopsys

rm route6 <network> [<gateway>] [-vlan <positive_integer>] [-td <positive_integer>]

Arguments

network

The network of the route to be removed.

gateway

The gateway address of the route to be removed.

vlan

Integer that uniquely identifies the VLAN defined for this route.

Maximum value: 4094

td

Traffic Domain Id for IPv6 network.

Maximum value: 4094

Example

rm route6 ::/0 2004::1 rm route6 ::/0 FE80::67 -vlan 5

---

set route6

Modifies parameters of an IPv6 static route.

Synopsys

set route6 <network> [<gateway>] [-vlan <positive_integer>] [-weight <positive_integer>] [-distance <positive_integer>] [-cost <positive_integer>] [-advertise (DISABLED | ENABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-td <positive_integer>]

Arguments

network

IPv6 network address of the route entry to be modified.

gateway

The gateway for the route's destination network.

vlan

Integer value that uniquely identifies a VLAN through which the NetScaler appliance forwards the packets for this route.

Maximum value: 4094

weight

Positive integer used by the routing algorithms to determine preference for this route over others of equal cost. The lower the weight, the higher the preference.

Default value: 1

Minimum value: 1

Maximum value: 65535

distance

Administrative distance of this route from the appliance.

Default value: 1

Minimum value: 1

Maximum value: 254

cost

Positive integer used by the routing algorithms to determine preference for this route. The lower the cost, the higher the preference.

Default value: 1

Maximum value: 65535

advertise

Advertise this route.

Possible values: DISABLED, ENABLED

msr

Monitor this route witha monitor of type ND6 or PING.

Possible values: ENABLED, DISABLED

Default value: DISABLED

td

Traffic Domain Id for IPv6 network.

Maximum value: 4094

Example

```
set route6 1::1/100 2000::1 -advertise enable
```

---

unset route6

Unset the attributes of a route that were added by the add/set route command..Refer to the set route6 command for meanings of the arguments.

Synopsys

```
unset route6 <network> [<gateway>] [-vlan <positive_integer>] [-td <positive_integer>] [-weight] [-distance] [-cost] [-advertise] [-msr] [-monitor]
```

Example

```
unset route6 2000::1/100 3000::1 -advertise enable
```

---

show route6

Displays configuration and state information of all IPv6 routes in the NetScaler appliance's routing table, or of the specified IPv6 route.

Synopsys

```
show route6 [<network> [<gateway>] [-vlan <positive_integer>] [-td <positive_integer>]] [<routeType>] [-detail]
```

Arguments

network

IPv6 network address of the route entry for which to display details.

routeType

The type of IPv6 routes to be to be displayed.

detail

To get a detailed view.

summary

fullValues

format

level

Outputs

gatewayName

The name of the gateway for this route.

advertise

Any gateway of the route entry for which the details are to be displayed.

type

State of the RNAT.

stateflag

dynamic

Whether this route is dynamically learned or not.

weight

Weight of this route.

distance

Administrative distance of this route from the appliance.

cost

Positive integer used by the routing algorithms to determine preference for this route. The lower the cost, the higher the preference.

data

Internal data of this route.NOTE: This attribute is deprecated.This option is deprecated in favour of NSA_DATA1

flags

For a dynamic route, the routing protocol from which the route was learned.

msr

Whether MSR is enabled or disabled.

monitor

Name of the monitor, of type ND6 or PING, configured on the NetScaler appliance to monitor this route.

state

Whether this route is UP or DOWN.

totalprobes

The total number of probes sent.

totalfailedprobes

The total number of failed probes.

failedprobes

Current number of failed monitoring probes.

monStatCode

The code indicating the monitor response.

monStatParam1

First parameter for use with message code.

monStatParam2

Second parameter for use with message code.

monStatParam3

Third parameter for use with message code.

data1

Internal data of this route.

routeOwners

Use this option with -dynamic and in a cluster only to specify the set of nodes from which this dynamic route has been learnt.

retain

STATIC

Static route.

PERMANENT

Permanent Route.

connected

Connected Route.

OSPFV3

For a dynamic route, the routing protocol from which the route was learned.

ISIS

If this route is dynamic then which routing protocol was it learnt from.

active

For a dynamic route, the routing protocol from which the route was learned.

BGP

For a dynamic route, the routing protocol from which the route was learned.

RIP

For a dynamic route, the routing protocol from which the route was learned.

raRoute

For a dynamic route, the routing protocol from which the route was learned.

devno

count

Example

Following is an example of the output of the show route6 command: Flags: Static(S), Dynamic(D), Active(A) ----------

rsskeytype

Sep 22, 2015

The following operations can be performed on "rsskeytype":

set | show

set rsskeytype

Synopsys

set rsskeytype -rsstype (ASYMMETRIC | SYMMETRIC)

Arguments

rsstype

Type of RSS key, possible values ASYMMETRIC and SYMMETRIC.

Possible values: ASYMMETRIC, SYMMETRIC

Default value: NSA_RSSKEY_ASYM

---

show rsskeytype

Synopsys

show rsskeytype

Arguments

format

level

Outputs

rsstype

Type of RSS key, possible values ASYMMETRIC and SYMMETRIC.

---

tunnelip

Sep 22, 2015

The following operations can be performed on "tunnelip":

stat tunnelip

Display the statistics related to IP tunnel.

Synopsys

stat tunnelip [<tunnelip>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

tunnelip

remote IP address of the configured tunnel.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Packets received on tunnel (tnlRxPkts)

Total number of packets received on the tunnel.

Packets transmitted on tunnel (tnlTxPkts)

Total number of packets transmitted on the tunnel.

Bytes received on tunnel (tnlRxBytes)

Total number of bytes received on the tunnel.

Bytes transmitted on tunnel (tnlTxBytes)

Total number of bytes transmitted on the tunnel.

Example

```
stat tunnelip 2.1.1.1
```

tunnelip6

Sep 22, 2015

The following operations can be performed on "tunnelip6":

stat tunnelip6

Display the statistics related to IP tunnel.

Synopsys

stat tunnelip6 [<tunnelip6>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

tunnelip6

remote IPv6 address of the configured tunnel.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Packets received on tunnel (tnlRxPkts)

Total number of packets received on the tunnel.

Packets transmitted on tunnel (tnlTxPkts)

Total number of packets transmitted on the tunnel.

Bytes received on tunnel (tnlRxBytes)

Total number of bytes received on the tunnel.

Bytes transmitted on tunnel (tnlTxBytes)

Total number of bytes transmitted on the tunnel.

Example

```
stat tunnelip6 2001::1
```

vPathParam

Sep 22, 2015

The following operations can be performed on "vPathParam":

set | unset | show

set vPathParam

Sets the global parameters for vPath

Synopsys

set vPathParam [-srcIP <ip_addr>] [-offload (ENABLED | DISABLED)]

Arguments

srcIP

source-IP address used for all vPath L3 encapsulations. Must be a MIP or SNIP address.

offload

enable/disable vPath offload feature

Possible values: ENABLED, DISABLED

Default value: 2

Example

```
set vpathparam -srcip 2.2.2.2
```

---

unset vPathParam

Use this command to remove vPathParam settings.Refer to the set vPathParam command for meanings of the arguments.

Synopsys

unset vPathParam [-srcIP] [-offload]

---

show vPathParam

Display the global parameters for vPath

Synopsys

show vPathParam

Arguments

format

level

Outputs

srcIP

srcIP used for vPath encapsulation.

Encapsulation

Global vPath encapsulation .

offload

enable/disable vPath offload feature

Example

show vpathparam

---

vlan

Sep 22, 2015

The following operations can be performed on "vlan":

add | rm | set | unset | bind | unbind | show | stat

add vlan

Adds a VLAN to the NetScaler appliance.The newVLAN is not active unless interfaces are bound to it.

Synopsys

add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED | DISABLED)]

Arguments

id

ID of the VLAN whose parameters you want to modify.

Minimum value: 1

Maximum value: 4094

aliasName

A name for the VLAN. Must begin with a letter, a number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the VLAN. However, you cannot perform any VLAN operation by specifying this name instead of the VLAN ID.

ipv6DynamicRouting

Enable all IPv6 dynamic routing protocols on this VLAN. Note: For the ENABLED setting to work, you must configure IPv6 dynamic routing protocols from the VTYSH command line.

Possible values: ENABLED, DISABLED

Default value: DISABLED

---

rm vlan

Removes a VLAN from the NetScaler appliance. When the VLAN is removed, its interfaces are bound to VLAN 1. Note: VLAN 1 cannot be removed by any command.

Synopsys

rm vlan <id>

Arguments

id

Integer that uniquely identifies the VLAN to be removed from the NetScaler appliance. When the VLAN is removed, its interfaces become members of VLAN 1.

Minimum value: 2

Maximum value: 4094

---

set vlan

Modifies parameters of a VLAN on the NetScaler appliance.

Synopsys

set vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED | DISABLED)]

Arguments

id

ID of the VLAN whose parameters you want to modify.

Minimum value: 1

Maximum value: 4094

aliasName

A name for the VLAN. Must begin with a letter, a number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the VLAN. However, you cannot perform any VLAN operation by specifying this name instead of the VLAN ID.

ipv6DynamicRouting

Enable all IPv6 dynamic routing protocols on this bridge group. Note: For the ENABLED setting to work, you must configure IPv6 dynamic routing protocols from the VTYSH command line.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

set vlan 2 -dynamicRouting ENABLED

---

unset vlan

Use this command to remove vlan settings.Refer to the set vlan command for meanings of the arguments.

Synopsys

unset vlan <id> [-aliasName] [-ipv6DynamicRouting]

---

bind vlan

Binds the specified interfaces or IP addresses to a VLAN. An interface can be bound to a VLAN as a tagged or an untagged member. Adding an interface as an untagged member removes it from its current native VLAN and adds it to the new VLAN. If an interface is added as a tagged member to a VLAN, it still remains a member of its native VLAN.

Synopsys

bind vlan <id> [-ifnum <interface_name> ... [-tagged]] [-IPAddress <ip_addr|ipv6_addr|*> [<netmask>] [-td <positive_integer>]]

Arguments

id

Specifies the virtual LAN ID.

Minimum value: 1

Maximum value: 4094

ifnum

Interface to be bound to the VLAN, specified in slot/port notation (for example, 1/3).

Minimum value: 1

IPAddress

Network address to be associated with the VLAN. Should exist on the appliance before you associate it with the VLAN. To enable IP forwarding among VLANs, the specified address can be used as the default gateway by the hosts in the network.

---

unbind vlan

Unbinds the specified interfaces or IP addresses from a VLAN. If any of the interfaces are untagged members of the VLAN, they are automatically bound to VLAN 1.

Synopsys

unbind vlan <id> [-ifnum <interface_name> ... [-tagged]] [-IPAddress <ip_addr|ipv6_addr|*> [<netmask>] [-td <positive_integer>]]

Arguments

id

The virtual LAN (VLAN) id.

Minimum value: 1

Maximum value: 4094

ifnum

Interface to unbind from the VLAN, specified in slot/port notation (for example, 1/3).

Minimum value: 1

IPAddress

The IP Address associated with the VLAN configuration.

---

show vlan

Displays the settings of all VLANs configured on the NetScaler appliance, or of the specified VLAN. To display the settings of all the VLANs, run the command without any parameters. To display the settings of a particular VLAN, specify the ID of the VLAN.

Synopsys

show vlan [<id>] show vlan stats - alias for 'stat vlan'

Arguments

id

Integer that uniquely identifies the VLAN for which the details are to be displayed.

Minimum value: 1

Maximum value: 4094

summary

fullValues

format

level

Outputs

aliasName

A name for the VLAN. Must begin with a letter, a number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the VLAN. However, you cannot perform any VLAN operation by specifying this name instead of the VLAN ID.

IPAddress

The IP address assigned to the VLAN.

netmask

Subnet mask for the network address defined for this VLAN.

linklocalIPv6Addr

The link-local IP address assigned to the VLAN.

rnat

Temporary flag used for internal purpose.

stateflag

state flag

portbitmap

Member interfaces of this vlan.

lsbitmap

Member linksets of this vlan.

tagbitmap

Tagged members of this vlan.

lstagbitmap

Tagged linksets of this vlan.

ifaces

Names of all member interfaces of this vlan.

taglfaces

Names of all tagged member interfaces of this vlan.

ipv6DynamicRouting

Whether dynamic routing is enabled or disabled.

flag

ifnum

The interface to be bound to the VLAN, specified in slot/port notation (for example, 1/3).

tagged

Make the interface an 802.1q tagged interface. Packets sent on this interface on this VLAN have an additional 4-byte 802.1q tag, which identifies the VLAN. To use 802.1q tagging, you must also configure the switch connected to the appliance's interfaces.

td

Traffic Domain Id.

sdxVlan

SDX vlan.

devno

count

Example

An example of the output of the show vlan command is as follows: 1) VLAN ID: 5 VLAN Alias Name: Interfaces : 1/7 IPs

---

stat vlan

Display statistics for VLAN(s).

Synopsys

stat vlan [<id>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

id

An integer specifying the VLAN identification number (VID). Possible values: 1 through 4094.

Minimum value: 1

Maximum value: 4094

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Packets received (RxPkts)

Packets received on the VLAN.

Bytes received (RxBytes)

Bytes of data received on the VLAN.

Packets sent (TxPkts)

Packets transmitted on the VLAN.

Bytes sent (TxBytes)

Bytes of data transmitted on the VLAN.

Packets dropped (DropPkts)

Inbound packets dropped by the VLAN upon reception.

received (BcastPkt)

Broadcast packets sent and received on the VLAN.

Example

stat vlan 1

---

vpath

Sep 22, 2015

The following operations can be performed on "vpath":

add | rm | show | stat

add vpath

Adds vPath destination IP to which packets need to be vPath injected.

Synopsys

add vpath <name> (<destIP> [<netmask>] [<gateway>])

Arguments

name

Name for the vPath. Must begin with a letter, number, or the underscore character (_), and can consist of letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore characters. Cannot be changed after the profile is created. Choose a name that helps identify the net profile.

destIP

This is the destination ip, where vPath encapsulated packets needs to be sent

Example

```
add vpath vPath1 -destip 10.102.1.10
```

---

rm vpath

Remove vPath destination IP.

Synopsys

rm vpath <name> ...

Arguments

name

Name of the vPath to be removed.

Example

```
rm netProfile prof1
```

---

show vpath

List down all vPath destination IPs.

Synopsys

show vpath [<name>]

Arguments

name

Name of the vPath whose details you want to display.

summary

fullValues

format

level

Outputs

destIP

This is the destination ip, where vPath encapsulated packets needs to be sent

netmask

Subnet mask associated with the destination network.

gateway

Next hop gateway to reach the destination address.

devno

count

stateflag

Example

show vpath

---

stat vpath

Display vPath statistics.

Synopsys

stat vpath [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

L2 data packets received (TotL2DataRx)

Total number of non-fragmented vPath data packets decapsulated in L2 adjacency

L3 data packets received (TotL3DataRx)

Total number of non-fragmented vPath data packets decapsulated in L3 adjacency

L2 control packets received (TotL2CntrlPkts)

Total number of vPath control packets received in L2 adjacency

L3 control packets received (TotL3CntrlPkts)

Total number of vPath control packets received in L3 adjacency

Fragmented packets received (TotFragPkts)

Total number of vPath fragments received

L2 packets transmitted (TotL2EncapPkts)

Total number of L2 vPath encapsulated packets injected to VEM

L3 packets transmitted (TotL3EncapPkts)

Total number of L3 vPath encapsulated packets injected to VEM

Fragmented packets transmitted (TotFragEncapPkts)

Number of fragmented vPath packets transmitted

Offload packets transmitted (TotOffload)

Number of offloaded vPath packets transmitted

vrID

Sep 22, 2015

The following operations can be performed on "vrID":

add | rm | set | unset | bind | unbind | show

Adds a VMAC address to the NetScaler appliance. A Virtual MAC address (VMAC) is a floating entity, shared by the nodes in an HA configuration.

add vrID <id> [-priority <positive_integer>] [-preemption (ENABLED | DISABLED)] [-sharing (ENABLED | DISABLED)] [-tracking <tracking>]

id

Integer that uniquely identifies the VMAC address. The generic VMAC address is in the form of 00:00:5e:00:01:<VRID>. For example, if you add a VRID with a value of 60 and bind it to an interface, the resulting VMAC address is 00:00:5e:00:01:3c, where 3c is the hexadecimal representation of 60.

Minimum value: 1

Maximum value: 255

priority

Base priority (BP), in an active-active mode configuration, which ordinarily determines the master VIP address.

Default value: 255

Minimum value: 1

Maximum value: 255

preemption

In an active-active mode configuration, make a backup VIP address the master if its priority becomes higher than that of a master VIP address bound to this VMAC address.

If you disable pre-emption while a backup VIP address is the master, the backup VIP address remains master until the original master VIP's priority becomes higher than that of the current master.

Possible values: ENABLED, DISABLED

Default value: ENABLED

sharing

In an active-active mode configuration, enable the backup VIP address to process any traffic instead of dropping it.

Possible values: ENABLED, DISABLED

Default value: DISABLED

tracking

The effective priority (EP) value, relative to the base priority (BP) value in an active-active mode configuration. When EP is set to a value other than None, it is EP, not BP, which determines the master VIP address.

Available settings function as follows:

* NONE - No tracking. EP = BP

* ALL - If the status of all virtual servers is UP, EP = BP. Otherwise, EP = 0.

* ONE - If the status of at least one virtual server is UP, EP = BP. Otherwise, EP = 0.

* PROGRESSIVE - If the status of all virtual servers is UP, EP = BP. If the status of all virtual servers is DOWN, EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP address and K is the number of virtual servers for which the status is DOWN.

Default: NONE.

Possible values: NONE, ONE, ALL, PROGRESSIVE

Default value: TRACK_NONE

add vrID 1

Removes a specified VMAC entry or all VMAC entries from the NetScaler appliance.

rm vrID (<id> | -all)

id

Integer value that uniquely identifies the VMAC address.

Minimum value: 1

Maximum value: 255

all

Remove all the configured VMAC addresses from the NetScaler appliance.

Modifies parameters related to a VMAC address on the NetScaler appliance.

set vrID <id> [-priority <positive_integer>] [-preemption (ENABLED | DISABLED)] [-sharing (ENABLED | DISABLED)] [-tracking <tracking>]

id

Integer value that uniquely identifies the VMAC address. The generic VMACaddressis in the form of 00:00:5e:00:01:<VRID>. For example, if you add a VRID with a value of 60 and bind it to an interface, the resulting VMAC address is 00:00:5e:00:01:3c, where 3c is the hexadecimal representation of 60.

Minimum value: 1

Maximum value: 255

priority

Base priority (BP), in an active-active mode configuration, which ordinarily determines the master VIP address.

Default value: 255

Minimum value: 1

Maximum value: 255

preemption

In an active-active mode configuration, make a backup VIP address the master if its priority becomes higher than that of a master VIP address bound to this VMAC address.

If you disable pre-emption while a backup VIP address is the master, the backup VIP address remains master until the original master VIP's priority becomes higher than that of the current master.

Possible values: ENABLED, DISABLED

Default value: ENABLED

sharing

In an active-active mode configuration, enable the backup VIP address to process any traffic instead of dropping it.

Possible values: ENABLED, DISABLED

Default value: DISABLED

tracking

The effective priority (EP) value, relative to the base priority (BP) value in an active-active mode configuration. When

EP is set to a value other than None, it is EP, not BP, which determines the master VIP address.

Available settings function as follows:

* NONE - No tracking. EP = BP

* ALL - If the status of all virtual servers is UP, EP = BP. Otherwise, EP = 0.

* ONE - If the status of at least one virtual server is UP, EP = BP. Otherwise, EP = 0.

* PROGRESSIVE - If the status of all virtual servers is UP, EP = BP. If the status of all virtual servers is DOWN, EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP address and K is the number of virtual servers for which the status is DOWN.

Default: NONE.

Possible values: NONE, ONE, ALL, PROGRESSIVE

Default value: TRACK_NONE

```
set vrID 1 -priority 100
```

Use this command to remove vrID settings.Refer to the set vrID command for meanings of the arguments.

```
unset vrID <id> [-priority] [-preemption] [-sharing] [-tracking]
```

Binds the specified interfaces to a VMAC configuration.

```
bind vrID <id> -ifnum <interface_name> ...
```

id

Integer that uniquely identifies the VMAC address. The generic VMAC address is in the form of 00:00:5e:00:01:<VRID>. For example, if you add a VRID with a value of 60 and bind it to an interface, the resulting VMAC address is 00:00:5e:00:01:3c, where 3c is the hexadecimal representation of 60.

Minimum value: 1

Maximum value: 255

ifnum

Interfaces to bind to the VMAC, specified in (slot/port) notation (for example, 1/2).Use spaces to separate multiple entries.

add vrID 1

Unbinds specified interfaces from a VMAC configuration.

unbind vrID <id> -ifnum <interface_name> ...

id

Integer value that uniquely identifies the VMAC address. The generic VMAC address is in the form of 00:00:5e:00:01:<VRID>. For example, if you add a VRID with a value of 60 and bind it to an interface, the resulting VMAC address is 00:00:5e:00:01:3c, where 3c is the hexadecimal representation of 60.

Minimum value: 1

Maximum value: 255

ifnum

Interfaces to unbind from the VMAC, specified in (slot/port) notation (for example, 1/2). Use spaces to separate multiple entries.

Displays the settings of all VRIDs configured on the NetScaler appliance, or of the specified VRID. To display the settings of all the VRIDs, run the command without any parameters. To display the settings of a particular VRID, specify the VRID.

show vrID [<id>]

id

Integer value that uniquely identifies the VMAC address.

Minimum value: 1

Maximum value: 255

summary

fullValues

format

level

ifaces

Interfaces bound to this VRID.

type

Indicates whether this VRID entry was added manually or dynamically. When you manually add a VRID entry, the value for this parameter is STATIC. Otherwise, it is DYNAMIC.

vlan

The VLAN in which this VRID resides.

priority

Base priority (BP), in an active-active mode configuration, which ordinarily determines the master VIP address.

effectivePriority

The effective priority of this VRID.

preemption

In an active-active mode configuration, make a backup VIP address the master if its priority becomes higher than that of a master VIP address bound to this VMAC address.

If you disable pre-emption while a backup VIP address is the master, the backup VIP address remains master until the original master VIP's priority becomes higher than that of the current master.

sharing

In an active-active mode configuration, enable the backup VIP address to process any traffic instead of dropping it.

tracking

The effective priority (EP) value, relative to the base priority (BP) value in an active-active mode configuration. When EP is set to a value other than None, it is EP, not BP, which determines the master VIP address.

Available settings function as follows:

* NONE - No tracking. EP = BP

* ALL - If the status of all virtual servers is UP, EP = BP. Otherwise, EP = 0.

* ONE - If the status of at least one virtual server is UP, EP = BP. Otherwise, EP = 0.

* PROGRESSIVE - If the status of all virtual servers is UP, EP = BP. If the status of all virtual servers is DOWN, EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP address and K is the number of virtual servers for which the status is DOWN.

Default: NONE.

vrID6

Sep 22, 2015

The following operations can be performed on "vrID6":

add | rm | bind | unbind | show

Adds a VMAC6 address to the NetScaler appliance. A Virtual MAC address (VMAC6) is a floating entity, shared by the nodes in an HA configuration.

add vrID6 <id>

id

Integer value that uniquely identifies a VMAC6 address.

Minimum value: 1

Maximum value: 255

add vrID6 1

Removes a specified VMAC6 entry or all VMAC6 entries from the NetScaler appliance.

rm vrID6 (<id> | -all)

id

Integer value that uniquely identifies a VMAC6 address.

Minimum value: 1

Maximum value: 255

all

Remove all configured VMAC6 addresses from the NetScaler appliance.

Binds the specified interfaces to a VMAC6 configuration.

bind vrID6 <id> -ifnum <interface_name> ...

id

Integer value that uniquely identifies a VMAC6 address.

Minimum value: 1

Maximum value: 255

ifnum

Interfaces to bind tothe VMAC6, specified in (slot/port) notation (for example, 1/2).Use spaces to separate multiple entries.

add vrID6 1

Unbinds the specified interfaces from a VMAC6 configuration.

unbind vrID6 <id> -ifnum <interface_name> ...

id

Integer value that uniquely identifies a VMAC6 address.

Minimum value: 1

Maximum value: 255

ifnum

Interfaces to unbind from the VMAC6, specified in (slot/port) notation (for example, 1/2). Use spaces to separate multiple entries.

Displays the settings of all VRID6s configured on the NetScaler appliance, or of the specified VRID6. To display the settings of all the VRID6s, run the command without any parameters. To display the settings of a particular VRID6, specify the VRID6.

show vrID6 [<id>]

id

Integer value that uniquely identifies a VMAC6 address.

Minimum value: 1

Maximum value: 255

vrIDParam

Sep 22, 2015

The following operations can be performed on "vrIDParam":

set | unset | show

Sets global parameters of VMACs on the NetScaler appliance.

set vrIDParam -sendToMaster (ENABLED | DISABLED)

sendToMaster

Forward packets to the master node, in an active-active mode configuration, if the virtual server is in the backup state and sharing is disabled.

Possible values: ENABLED, DISABLED

Default value: DISABLED

set vrIDParam -sendToMaster ENABLED

Use this command to remove vrIDParam settings.Refer to the set vrIDParam command for meanings of the arguments.

unset vrIDParam -sendToMaster

Displays the VRID global settings on the NetScaler appliance.

show vrIDParam

format

level

sendToMaster

Forward packets to the master node, in an active-active mode configuration, if the virtual server is in the backup state and sharing is disabled.

NS Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- ns
- ns acl
- ns acl6
- ns acls
- ns acls6
- ns appflowCollector
- ns appflowParam
- ns aptlicense
- ns config
- ns connectiontable
- ns consoleloginprompt
- ns dhcpIp
- ns dhcpParams
- ns diameter
- ns encryptionParams
- ns events
- ns feature
- ns hardware
- ns hostName
- ns httpParam
- ns httpProfile
- ns idletimeout
- ns info
- ns ip
- ns ip6
- ns license
- ns limitIdentifier
- ns limitSelector
- ns limitSessions
- ns memory
- ns mode
- ns ns.conf
- ns param
- ns pbr
- ns pbr6
- ns pbrs
- ns persistencesession
- ns rateControl
- ns rollbackcmd
- ns rpcNode
- ns runningConfig

- ns savedConfig
- ns simpleacl
- ns simpleacl6
- ns spParams
- ns stats
- ns surgeQ
- ns tcpParam
- ns tcpProfile
- ns tcpbufParam
- ns timeout
- ns timer
- ns trafficDomain
- ns version
- ns weblogparam
- ns xmlnamespace
- reboot
- shutdown

ns

Sep 22, 2015

The following operations can be performed on "ns":

config | stat

Displays a menu to configure the basic parameters of a NetScaler appliance. Note: The appliance must be rebooted for these changes to take effect.

config ns

Displays generic statistics of the NetScaler appliance.

stat ns [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

Maximum Memory Available (MB) (MemTotAvail)

Total system memory available for PE to grab from the system.

Maximum memory(KB) Deprecated (MaxMem)

Largest amount of memory the NetScaler can dedicate to caching, up to 50% of available memory. A 0 value disables caching, but the caching module continues to run.

Delta compression ratio (DlCmpRt)

Ratio of compressible data received to compressed data transmitted.If this ratio is one (uncmp:1.0) that means compression is disabled or we are not able to compress even a single compressible packet.

Average CPU usage (CPU)

Shows average CPU utilization percentage if more than 1 CPU is present.

CPU usage (CPU)

CPU utilization: percentage * 10.

Memory usage (MemUsage)

Percentage of memory utilization on NetScaler.

Total HTTP compression ratio

Ratio of total HTTP data received to total HTTP data transmitted.

HTTP compression ratio

Ratio of the compressible data received from the server to the compressed data sent to the client.

Utilized memory(KB) (UtiMem)

Amount of memory the integrated cache is currently using.

Maximum memory active value(KB) (MaxMemActive)

Currently active value of maximum memory

Maximum memory(KB) (Max64Mem)

Largest amount of memory the NetScaler can dedicate to caching, up to 50% of available memory. A 0 value disables caching, but the caching module continues to run.

Origin bandwidth saved(%) (POrBan)

Percentage of origin bandwidth saved, expressed as number of bytes served from the integrated cache divided by all bytes served. The assumption is that all compression is done in the NetScaler.

Misses (TotMiss)

Intercepted HTTP requests requiring fetches from origin server.

Hits (TotHit)

Responses served from the integrated cache. These responses match a policy with a CACHE action.

SSL cards UP (SSLCardUP)

Number of SSL cards that are UP. If the number of cards UP is lower than a threshold, a failover is initiated.

InUse Memory (%) (MemUsage)

Percentage of memory utilization on NetScaler.

Memory usage (MB) (MemUseMB)

Main memory currently in use, in megabytes.

Management CPU usage (%) (CPU)

Management CPU utilization percentage.

Packet CPU usage (%) (CPU)

Average CPU utilization percentage for all packet engines excluding management PE.

Average CPU usage (%) (CPU)

Average CPU utilization percentage. Not applicable for a single-CPU system.

CPU usage (%) (CPU)

CPU utilization percentage.

Up since (Since)

Time when the NetScaler appliance was last started.

Last Transition time (TransTime)

Time when the last master state transition occurred. You can use this statistic for debugging.

System state (HAState)

State of the HA node, based on its health, in a high availability setup. Possible values are:

UP ? Indicates that the node is accessible and can function as either a primary or secondary node.

DISABLED ? Indicates that the high availability status of the node has been manually disabled. Synchronization and propagation cannot take place between the peer nodes.

INIT ? Indicates that the node is in the process of becoming part of the high availability configuration.

PARTIALFAIL ? Indicates that one of the high availability monitored interfaces has failed because of a card or link failure. This state triggers a failover.

COMPLETEFAIL ? Indicates that all the interfaces of the node are unusable, because the interfaces on which high availability monitoring is enabled are not connected or are manually disabled. This state triggers a failover.

DUMB ? Indicates that the node is in listening mode. It does not participate in high availability transitions or transfer configuration from the peer node. This is a configured value, not a statistic.

PARTIALFAILSSL ? Indicates that the SSL card has failed. This state triggers a failover.

ROUTEMONITORFAIL ? Indicates that the route monitor has failed. This state triggers a failover.

Master state (mastate)

Indicates the high availability state of the node. Possible values are:

STAYSECONDARY ? Indicates that the selected node remains the secondary node in a high availability setup. In this case a forced failover does not change the state but, instead, returns an appropriate error message. This is a configured value and not a statistic.

PRIMARY ? Indicates that the selected node is the primary node in a high availability setup.

SECONDARY ? Indicates that the selected node is the secondary node in a high availability setup.

CLAIMING ? Indicates that the secondary node is in the process of taking over as the primary node. This is the intermediate state in the transition of the secondary node to primary status.

FORCE CHANGE - Indicates that the secondary node is forcibly changing its status to primary due to a forced failover issued on the secondary node.

SSL cards present (SSLCards)

Number of SSL crypto cards present on the NetScaler appliance.

/flash Used (%) (disk0PerUsage)

Used space in /flash partition of the disk, as a percentage. This is a critical counter.

You can configure /flash Used (%) by using the Set snmp alarm DISK-USAGE-HIGH command.

/var Used (%) (disk1PerUsage)

Used space in /var partition of the disk, as a percentage. This is a critical counter. You can configure /var Used (%) by using the Set snmp alarm DISK-USAGE-HIGH command.

/flash Available (MB) (disk0Avail)

Available space in /flash partition of the hard disk.

/var Available (MB) (disk1Avail)

Available space in /var partition of the hard disk.

Megabits received (RxMb)

Number of megabytes received by the NetScaler appliance.

Megabits transmitted (TxMb)

Number of megabytes transmitted by the NetScaler appliance.

All client connections (CltCx)

Client connections, including connections in the Opening, Established, and Closing state.

Established client connections (CltCxE)

Current client connections in the Established state, which indicates that data transfer can occur between the NetScaler and the client.

All server connections (SvrCx)

Server connections, including connections in the Opening, Established, and Closing state.

Established server connections (SvrCxE)

Current server connections in the Established state, which indicates that data transfer can occur between the

NetScaler and the server.

Total requests (HTReqRx)

Total number of HTTP requests received.

Total responses (HTRspRx)

Total number of HTTP responses sent.

Request bytes received (HTReqbRx)

Total number of bytes of HTTP request data received.

Response bytes received (HTRspbRx)

Total number of bytes of HTTP response data received.

SSL transactions (SSLTrn)

Number of SSL transactions on the NetScaler appliance.

SSL session hits (SeHit)

Number of SSL session reuse hits on the NetScaler appliance.

requests (reqs)

HTTP/HTTPS requests sent to your protected web servers via the Application Firewall.

responses (resps)

HTTP/HTTPS responses sent by your protected web servers via the Application Firewall.

aborts

Incomplete HTTP/HTTPS requests aborted by the client before the Application Firewall could finish processing them.

redirects (redirect)

HTTP/HTTPS requests redirected by the Application Firewall to a different Web page or web server. (HTTP 302)

Misc. Counter 0 (misc0)

Miscellaneous Counter 0.

Misc. Counter 1 (misc1)

Miscellaneous Counter 1.

Management CPU usage (CPU)

Management CPU utilization: percentage * 10.

SSL crypto card status (SSLCardSt)

Status of the SSL card(s). The value should be interpreted in binary form, with each set bit indicates a card as UP.

304 hits (304Hit)

Object not modified responses served from the cache. (Status code 304 served instead of the full response.)

Non-304 hits (Non304Hit)

Total number of full (non-304) responses served from the cache. A 304 status code indicates that a response has not been modified since the last time it was served

sql hits (sqlHit)

sql response served from cache

Requests (CacReq)

Total cache hits plus total cache misses.

Compressed bytes transmitted

Number of bytes the NetScaler sends to the client after compressing the response from the server.

Compressible bytes received

Number of bytes that can be compressed, which the NetScaler receives from the server. This gives the content length of the response that the NetScaler receives from server.

Compressible bytes received (DlCmpRxB)

Total number of delta-compressible bytes received by NetScaler.

Compressed bytes transmitted (DlCmpTxB)

Total number of delta-compressed bytes transmitted by NetScaler.

ns acl

Sep 22, 2015

The following operations can be performed on "ns acl":

add | rm | set | unset | enable | disable | stat | rename | show

Adds an extended ACL rule to the NetScaler appliance. To commit this operation, you must apply the extended ACLs. Extended ACL rules filter data packets on the basis of various parameters, such as IP address, source port, action, and protocol.

add ns acl <aclname> <aclaction> [-td <positive_integer>] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-TTL <positive_integer>] [-srcMac <mac_addr>] [(-protocol <protocol> [-established]) | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-icmpType <positive_integer> [-icmpCode <positive_integer>]] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-logstate (ENABLED | DISABLED) [-ratelimit <positive_integer>]]

aclname

Name for the extended ACL rule. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the extended ACL rule is created.

aclaction

Action to perform on incoming IPv4 packets that match the extended ACL rule.

Available settings function as follows:

* ALLOW - The NetScaler appliance processes the packet.

* BRIDGE - The NetScaler appliance bridges the packet to the destination without processing it.

* DENY - The NetScaler appliance drops the packet.

Possible values: BRIDGE, DENY, ALLOW

td

Traffic Domain Id.

Maximum value: 4094

srcIP

IP address or range of IP addresses to match against the source IP address of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

srcPort

Port number or range of port numbers to match against the source port number of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

destIP

IP address or range of IP addresses to match against the destination IP address of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

destPort

Port number or range of port numbers to match against the destination port number of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

TTL

Number of seconds, in multiples of four, after which the extended ACL rule expires. If you do not want the extended ACL rule to expire, do not specify a TTL value.

Minimum value: 1

Maximum value: 2147483647

srcMac

MAC address to match against the source MAC address of an incoming IPv4 packet.

protocol

Protocol to match against the protocol of an incoming IPv4 packet.

Possible values: ICMP, IGMP, TCP, EGP, IGP, ARGUS, UDP, RDP, RSVP, EIGRP, L2TP, ISIS

protocolNumber

Protocol to match against the protocol of an incoming IPv4 packet.

Minimum value: 1

Maximum value: 255

vlan

ID of the VLAN. The NetScaler appliance applies the ACL rule only to the incoming packets of the specified VLAN. If you do not specify a VLAN ID, the appliance applies the ACL rule to the incoming packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance applies the ACL rule only to the incoming packets from the specified interface. If you do not specify any value, the appliance applies the ACL rule to the incoming packets of all interfaces.

established

Allow only incoming TCP packets that have the ACK or RST bit set, if the action set for the ACL rule is ALLOW and these packets match the other conditions in the ACL rule.

icmpType

ICMP Message type to match against the message type of an incoming ICMP packet. For example, to block DESTINATION UNREACHABLE messages, you must specify 3 as the ICMP type.

Note: This parameter can be specified only for the ICMP protocol.

Maximum value: 65536

icmpCode

Code of a particular ICMP message type to match against the ICMP code of an incoming ICMP packet. For example, to block DESTINATION HOST UNREACHABLE messages, specify 3 as the ICMP type and 1 as the ICMP code.

If you set this parameter, you must set the ICMP Type parameter.

Maximum value: 65536

priority

Priority for the extended ACL rule that determines the order in which it is evaluated relative to the other extended ACL rules. If you do not specify priorities while creating extended ACL rules, the ACL rules are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 100000

state

Enable or disable the extended ACL rule. After you apply the extended ACL rules, the NetScaler appliance compares incoming packets against the enabled extended ACL rules.

Possible values: ENABLED, DISABLED

Default value: XACLENABLED

logstate

Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.

Possible values: ENABLED, DISABLED

Default value: GENDISABLED

ratelimit

Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

Default value: 100

Minimum value: 1

Maximum value: 10000

```
add ns acl restrict DENY -srcport 45-1024 -destIP 192.168.1.1 -protocol TCP
```

Removes an extended ACL rule from the NetScaler appliance. To commit this operation, you must apply the extended ACLs.

```
rm ns acl <aclname> ...
```

aclname

Name of the extended ACL rule that you want to remove.

rm ns acl restrict

Modifies the parameters of an ACL rule. To commit this operation, you must apply the extended ACLs.

set ns acl <aclname> [-aclaction <aclaction>] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-icmpType <positive_integer> [-icmpCode <positive_integer>]] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-logstate (ENABLED | DISABLED)] [-ratelimit <positive_integer>] [-established]

aclname

Name of the ACL rule whose parameters you want to modify.

aclaction

Action to perform on incoming IPv4 packets that match the extended ACL rule.

Available settings function as follows:

* ALLOW - The NetScaler appliance processes the packet.

* BRIDGE - The NetScaler appliance bridges the packet to the destination without processing it.

* DENY - The NetScaler appliance drops the packet.

Possible values: BRIDGE, DENY, ALLOW

srcIP

IP address or range of IP addresses to match against the source IP address of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

srcPort

Port number or range of port numbers to match against the source port number of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

destIP

IP address or range of IP addresses to match against the destination IP address of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

destPort

Port number or range of port numbers to match against the destination port number of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

srcMac

MAC address to match against the source MAC address of an incoming IPv4 packet.

protocol

Protocol to match against the protocol of an incoming IPv4 packet.

Possible values: ICMP, IGMP, TCP, EGP, IGP, ARGUS, UDP, RDP, RSVP, EIGRP, L2TP, ISIS

protocolNumber

Protocol to match against the protocol of an incoming IPv4 packet.

Minimum value: 1

Maximum value: 255

icmpType

ICMP Message type to match against the message type of an incoming ICMP packet. For example, to block DESTINATION UNREACHABLE messages, you must specify 3 as the ICMP type.

Note: This parameter can be specified only for the ICMP protocol.

Maximum value: 65536

vlan

ID of the VLAN. The NetScaler appliance applies the ACL rule only to the incoming packets of the specified VLAN. If you do not specify a VLAN ID, the appliance applies the ACL rule to the incoming packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance applies the ACL rule only to the incoming packets from the specified interface. If you do not specify any value, the appliance applies the ACL rule to the incoming packets of all interfaces.

priority

Priority for the extended ACL rule that determines the order in which it is evaluated relative to the other extended ACL rules. If you do not specify priorities while creating extended ACL rules, the ACL rules are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 100000

logstate

Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.

Possible values: ENABLED, DISABLED

Default value: GENDISABLED

established

Allow only incoming TCP packets that have the ACK or RST bit set, if the action set for the ACL rule is ALLOW and these packets match the other conditions in the ACL rule.

```
set ns acl restrict -srcPort 50
```

Resets the attributes of the specified extended ACL rule. Attributes for which a default value is available revert to their default values. Refer to the set ns acl command for a description of the parameters..Refer to the set ns acl command for meanings of the arguments.

```
unset ns acl <aclname> [-srcIP] [-srcPort] [-destIP] [-destPort] [-srcMac] [-protocol] [-icmpType] [-icmpCode] [-vlan] [-interface] [-logstate] [-ratelimit] [-established]
```

```
unset ns acl rule1 -srcPort
```

Enables an extended ACL rule. To commit this operation, you must apply the extended ACLs. After you apply the extended ACL rules, the NetScaler appliance compares incoming packets against the enabled extended ACL rules.

```
enable ns acl <aclname> ...
```

aclname

Name of the extended ACL rule that you want to enable.

```
enable ns acl foo
```

Disables an extended ACL rule. To commit this operation, you must apply the extended ACLs. After you apply the ACL rules, the NetScaler appliance does not compare incoming packets against the disabled extended ACL rules.

```
disable ns acl <aclname> ...
```

aclname

Name of the extended ACL rule that you want to disable.

disable ns acl foo

Displays statistics related to the extended ACL rules. To display statistics of all the extended ACL rules, run the command without any parameters. To display statistics of a particular extended ACL rule, specify the name of the extended ACL rule.

stat ns acl [<aclname>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

aclname

Name of the extended ACL rule whose statistics you want the NetScaler appliance to display.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Bridge ACL hits (ACLBdg)

Packets matching a bridge ACL, which is in transparent mode and bypasses service processing.

Deny ACL hits (ACLDeny)

Packets dropped because they match ACLs with processing mode set to DENY.

Allow ACL hits (ACLAllow)

Packets matching ACLs with processing mode set to ALLOW. NetScaler processes these packets.

NAT ACL hits (ACLNAT)

Packets matching a NAT ACL, resulting in a NAT session.

ACL hits (ACLHits)

Packets matching an ACL.

ACL misses (ACLMiss)

Packets not matching any ACL.

ACL Count (ACLCount)

Total number of ACL rules configured.

Hits for this ACL (Hits)

Number of times the acl was hit

stat acl

Renames an extended ACL rule.

rename ns acl <aclname> <newName>

aclname

Name of the extended ACL rule that you want to rename.

newName

New name for the extended ACL rule. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

rename acl rule rule-new

Displays settings related to the extended ACL rules. To display settings of all the extended ACL rules, run the command without any parameters. To display settings of a particular extended ACL rule, specify the name of the extended ACL rule.

show ns acl [<aclname>]

aclname

Name of the extended ACL rule whose details you want the NetScaler appliance to display.

summary

fullValues

format

level

td

Traffic Domain Id.

aclaction

Action to perform on incoming IPv4 packets that match the extended ACL rule.

Available settings function as follows:

* ALLOW - The NetScaler appliance processes the packet.

* BRIDGE - The NetScaler appliance bridges the packet to the destination without processing it.

* DENY - The NetScaler appliance drops the packet.

srcMac

MAC address to match against the source MAC address of an incoming IPv4 packet.

stateflag

ACL state flag.

protocol

The protocol number in IP header or name.

protocolNumber

The protocol number in IP header or name.

srcPortVal

Port number or range of port numbers to match against the source port number of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

destPortVal

Port number or range of port numbers to match against the destination port number of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

srcIPVal

IP address or range of IP addresses to match against the source IP address of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

destIPVal

IP address or range of IP addresses to match against the destination IP address of an incoming IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

vlan

ID of the VLAN. The NetScaler appliance applies the ACL rule only to the incoming packets of the specified VLAN. If you do not specify a VLAN ID, the appliance applies the ACL rule to the incoming packets on all VLANs.

state

Enable or disable the extended ACL rule. After you apply the extended ACL rules, the NetScaler appliance compares incoming packets against the enabled extended ACL rules.

TTL

Number of seconds, in multiples of four, after which the extended ACL rule expires. If you do not want the extended ACL rule to expire, do not specify a TTL value.

icmpType

ICMP Message type to match against the message type of an incoming ICMP packet. For example, to block DESTINATION UNREACHABLE messages, you must specify 3 as the ICMP type.

Note: This parameter can be specified only for the ICMP protocol.

icmpCode

Code of a particular ICMP message type to match against the ICMP code of an incoming ICMP packet. For example, to block DESTINATION HOST UNREACHABLE messages, specify 3 as the ICMP type and 1 as the ICMP code.

If you set this parameter, you must set the ICMP Type parameter.

interface

ID of an interface. The NetScaler appliance applies the ACL rule only to the incoming packets from the specified interface. If you do not specify any value, the appliance applies the ACL rule to the incoming packets of all interfaces.

hits

The hits of this ACL.

established

This flag indicates that the ACL should be used for TCP response traffic only.

priority

Priority for the extended ACL rule that determines the order in which it is evaluated relative to the other extended ACL rules. If you do not specify priorities while creating extended ACL rules, the ACL rules are evaluated in the order in which they are created.

operator

Either the equals (=) or does not equal (!=) logical operator.

kernelstate

The commit status of the ACL.

logstate

Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.

ratelimit

Packet rate limit for acl logging

time

Time when this acl is applied.

devno

```

ns acl6

Sep 22, 2015

The following operations can be performed on "ns acl6":

add | rm | set | unset | enable | disable | stat | rename | show

Adds an ACL6 rule to the NetScaler appliance. To commit this operation, you must apply the ACL6s. ACL6 rules filter data packets on the basis of various parameters, such as IP address, source port, action, and protocol.

add ns acl6 <acl6name> <acl6action> [-td <positive_integer>] [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-TTL <positive_integer>] [-srcMac <mac_addr>] [(-protocol <protocol> [-established]) | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-icmpType <positive_integer> [-icmpCode <positive_integer>]] [-priority <positive_integer>] [-state (ENABLED | DISABLED)]

acl6name

Name for the ACL6 rule. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the ACL6 rule is created.

acl6action

Action to perform on the incoming IPv6 packets that match the ACL6 rule.

Available settings function as follows:

* ALLOW - The NetScaler appliance processes the packet.

* BRIDGE - The NetScaler appliance bridges the packet to the destination without processing it.

* DENY - The NetScaler appliance drops the packet.

Possible values: BRIDGE, DENY, ALLOW

td

Traffic Domain Id.

Maximum value: 4094

srcIPv6

IP address or range of IP addresses to match against the source IP address of an incoming IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

srcPort

Port number or range of port numbers to match against the source port number of an incoming IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

destIPv6

IP address or range of IP addresses to match against the destination IP address of an incoming IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

destPort

Port number or range of port numbers to match against the destination port number of an incoming IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

TTL

Time to expire this ACL6 (in seconds).

Minimum value: 1

Maximum value: 2147483647

srcMac

MAC address to match against the source MAC address of an incoming IPv6 packet.

protocol

Protocol, identified by protocol name, to match against the protocol of an incoming IPv6 packet.

Possible values: ICMPV6, TCP, UDP

protocolNumber

Protocol, identified by protocol number, to match against the protocol of an incoming IPv6 packet.

Minimum value: 1

Maximum value: 255

vlan

ID of the VLAN. The NetScaler appliance applies the ACL6 rule only to the incoming packets on the specified VLAN. If you do not specify a VLAN ID, the appliance applies the ACL6 rule to the incoming packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance applies the ACL6 rule only to the incoming packets from the specified interface. If you do not specify any value, the appliance applies the ACL6 rule to the incoming packets from all interfaces.

established

Allow only incoming TCP packets that have the ACK or RST bit set if the action set for the ACL6 rule is ALLOW and these packets match the other conditions in the ACL6 rule.

icmpType

ICMP Message type to match against the message type of an incoming IPv6 ICMP packet. For example, to block DESTINATION UNREACHABLE messages, you must specify 3 as the ICMP type.

Note: This parameter can be specified only for the ICMP protocol.

Maximum value: 65536

icmpCode

Code of a particular ICMP message type to match against the ICMP code of an incoming IPv6 ICMP packet. For example, to block DESTINATION HOST UNREACHABLE messages, specify 3 as the ICMP type and 1 as the ICMP code.

If you set this parameter, you must set the ICMP Type parameter.

Maximum value: 65536

priority

Priority for the ACL6 rule, which determines the order in which it is evaluated relative to the other ACL6 rules. If you do not specify priorities while creating ACL6 rules, the ACL6 rules are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 80000

state

State of the ACL6.

Possible values: ENABLED, DISABLED

Default value: XACLENABLED

```
add ns acl6 rule1 DENY -srcport 45-1024 -destIPv6 2001::45 -protocol TCP
```

Removes an ACL6 rule from the NetScaler appliance. To commit this operation, you must apply the ACL6s.

```
rm ns acl6 <acl6name> ...
```

acl6name

Name of the ACL6 rule that you want to remove.

```
rm ns acl6 rule1
```

Modifies the parameters of an ACL6 rule. To commit this operation, you must apply the ACL6s.

set ns acl6 <acl6name> [-aclaction <aclaction>] [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-icmpType <positive_integer> [-icmpCode <positive_integer>]] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-established]

acl6name

Name of the ACL6 rule whose parameters you want to modify.

aclaction

Action associated with the ACL6.

Possible values: BRIDGE, DENY, ALLOW

srcIPv6

IP address or range of IP addresses to match against the source IP address of an incoming IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

srcPort

Source Port (range).

destIPv6

IP address or range of IP addresses to match against the destination IP address of an incoming IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

destPort

Destination Port (range).

srcMac

MAC address to match against the source MAC address of an incoming IPv6 packet.

protocol

Protocol, identified by protocol name, to match against the protocol of an incoming IPv6 packet.

Possible values: ICMPV6, TCP, UDP

protocolNumber

Protocol, identified by protocol number, to match against the protocol of an incoming IPv6 packet.

Minimum value: 1

Maximum value: 255

icmpType

ICMP Message type to match against the message type of an incoming IPv6 ICMP packet. For example, to block DESTINATION UNREACHABLE messages, you must specify 3 as the ICMP type.

Note: This parameter can be specified only for the ICMP protocol.

Maximum value: 65536

vlan

ID of the VLAN. The NetScaler appliance applies the ACL6 rule only to the incoming packets on the specified VLAN. If you do not specify a VLAN ID, the appliance applies the ACL6 rule to the incoming packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance applies the ACL6 rule only to the incoming packets from the specified interface. If you do not specify any value, the appliance applies the ACL6 rule to the incoming packets from all interfaces.

priority

Priority for the ACL6 rule, which determines the order in which it is evaluated relative to the other ACL6 rules. If you do not specify priorities while creating ACL6 rules, the ACL6 rules are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 80000

established

Allow only incoming TCP packets that have the ACK or RST bit set if the action set for the ACL6 rule is ALLOW and these packets match the other conditions in the ACL6 rule.

set ns acl6 rule1 -srcPort 50

Resets the attributes of the specified ACL6 rule. To commit this operation, you must apply the ACL6s.Attributes for which a default value is available revert to their default values. Refer to the set ns acl6 command for descriptions of the parameters..Refer to the set ns acl6 command for meanings of the arguments.

unset ns acl6 <acl6name> [-srcIPv6] [-srcPort] [-destIPv6] [-destPort] [-srcMac] [-protocol] [-icmpType] [-icmpCode] [-vlan] [-interface] [-established]

unset ns acl6 rule1 -srcPort

Enables an ACL6 rule. To commit this operation, you must apply the ACL6s.After you apply the ACL6 rules, the NetScaler appliance compares incoming IPv6 packets to the enabled ACL6 rules.

enable ns acl6 <acl6name> ...

acl6name

Name of ACL6 rule that you want to enable.

enable ns acl6 rule1

Disables an ACL6 rule. To commit this operation, you must apply the ACL6s.After you apply the ACL6 rules, the NetScaler appliance does not compare incoming IPv6 packets to the disabled ACL6 rules.

disable ns acl6 <acl6name> ...

acl6name

Name of ACL6 rule that you want to disable.

disable ns acl6 rule1

Displays statistics related to the ACL6 rules. To display statistics of all the ACL6 rules, run the command without any parameters. To display statistics of a particular ACL6 rule, specify the name of the ACL6 rule.

stat ns acl6 [<acl6name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

acl6name

Name of the ACL6 rule whose statistics you want the NetScaler appliance to display.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Bridge ACL6 hits (ACL6Bdg)

Packets matching a bridge IPv6 ACL, which is in transparent mode and bypasses service processing.

Deny ACL6 hits (ACL6Deny)

Packets dropped because they match IPv6 ACLs with processing mode set to DENY.

Allow ACL6 hits (ACL6Allow)

Packets matching IPv6 ACLs with processing mode set to ALLOW. NetScaler processes these packets.

NAT ACL6 hits (ACL6NAT)

Packets matching a NAT ACL6, resulting in a NAT session.

ACL6 hits (ACL6Hits)

Packets matching an IPv6 ACL.

ACL6 misses (ACL6Miss)

Packets not matching any IPv6 ACL.

NAT64 ACL6 hits (ACL6NAT64)

Packets matching a NAT64 ACL6, resulting in a NAT64 translation.

ACL6 Count (ACL6Count)

Total number of ACL6 rules configured.

Hits for this ACL6 (Hits)

Number of times the acl6 was hit

stat acl6

Renames an ACL6 rule. To commit this operation, you must apply the ACL6s.

rename ns acl6 <acl6name> <newName>

acl6name

Name of the ACL6 rule that you want to rename.

newName

New name for the ACL6 rule. Must begin with an ASCII alphabetic or underscore \\(_\\) character, and must contain only ASCII alphanumeric, underscore, hash \\(\\#\\), period \\(.\\), space, colon \\(:\\), at \\(@\\), equals \\(=\\), and hyphen \\(-\\) characters.

rename acl6 rule rule-new

Displays settings related to the ACL6 rules. To display settings of all the ACL6 rules, run the command without any parameters. To display settings of a particular ACL6 rule, specify the name of the ACL6 rule.

show ns acl6 [<acl6name>]

acl6name

Name of the ACL6 rule whose details you want the NetScaler appliance to display.

summary

fullValues

format

level

acl6action

Action to perform on the incoming IPv6 packets that match the ACL6 rule.

Available settings function as follows:

* ALLOW - The NetScaler appliance processes the packet.

* BRIDGE - The NetScaler appliance bridges the packet to the destination without processing it.

* DENY - The NetScaler appliance drops the packet.

srcMac

MAC address to match against the source MAC address of an incoming IPv6 packet.

stateflag

ACL6 state flag.

protocol

Protocol number in IPv6 header or name.

protocolNumber

Protocol number in IPv6 header or name.

srcPortVal

Source port (range).

destPortVal

Destination port (range).

srcIPv6Val

Source IPv6 address (range).

destIPv6Val

Destination IPv6 address (range).

vlan

ID of the VLAN. The NetScaler appliance applies the ACL6 rule only to the incoming packets on the specified VLAN. If you do not specify a VLAN ID, the appliance applies the ACL6 rule to the incoming packets on all VLANs.

state

State of the ACL6.

kernelstate

Commit status of the ACL6.

TTL

Time left to expire ACL6 (in seconds).

icmpType

ICMP Message type to match against the message type of an incoming IPv6 ICMP packet. For example, to block DESTINATION UNREACHABLE messages, you must specify 3 as the ICMP type.

Note: This parameter can be specified only for the ICMP protocol.

icmpCode

Code of a particular ICMP message type to match against the ICMP code of an incoming IPv6 ICMP packet. For example, to block DESTINATION HOST UNREACHABLE messages, specify 3 as the ICMP type and 1 as the ICMP code.

If you set this parameter, you must set the ICMP Type parameter.

interface

ID of an interface. The NetScaler appliance applies the ACL6 rule only to the incoming packets from the specified interface. If you do not specify any value, the appliance applies the ACL6 rule to the incoming packets from all interfaces.

hits

Number of hits of this ACL6.

established

This flag indicates that the ACL6 should be used for TCP response traffic only.

priority

Priority for the ACL6 rule, which determines the order in which it is evaluated relative to the other ACL6 rules. If you do not specify priorities while creating ACL6 rules, the ACL6 rules are evaluated in the order in which they are created.

operator

Logical operator.

ns acls

Sep 22, 2015

The following operations can be performed on "ns acls":

renumber | clear | apply

Renumbers the priorities of extended ACL rules to multiples of 10. To commit this operation, you must apply the extended ACLs. Enables you to assign a new extended ACL rule a priority that is between two existing, consecutively numbered priorities. For example, if two extended ACLs, ACL1 and ACL2, have priorities 2 and 3 renumbering changes those priorities to 20 and 30. You can then add ACL3 with priority 25.

renumber ns acls

renumber acls

Removes all simple ACL rules from the NetScaler appliance. This operation does not require an explicit apply.

clear ns acls

clear ns acls

Updates the extended ACL rule's memory tree (lookup table), adding any new extended ACL rules and applying any modifications to existing ACL rules. The lookup table includes the configuration of all the extended ACL rules on the NetScaler appliance. The NetScaler appliance uses the lookup table (not the configuration file) to filter the incoming IPv4 packets.

apply ns acls

apply ns acls

ns acls6

Sep 22, 2015

The following operations can be performed on "ns acls6":

clear | apply | renumber

Removes all simple ACL6 rules from the NetScaler appliance. This operation does not require an explicit apply.

clear ns acls6

clear ns acls6

Updates the ACL6 rules' memory tree (lookup table), adding any new ACL6 rules and applying any modifications to existing ACL rules. The lookup table includes the configuration of all the ACL6 rules on the NetScaler appliance. The NetScaler appliance uses the lookup table (not the configuration file) to filter the incoming IPv4 packets.

apply ns acls6

apply ns acls6

Renumbers the priorities of ACL6 rules to multiples of 10. To commit this operation, you must apply the ACL6s. Enables you to assign a new ACL6 rule a priority that is between two existing, consecutively numbered priorities. For example, if two ACL6s, ACL6-1 and ACL6-2, have priorities 2 and 3 renumbering changes those priorities to 20 and 30. You can then add ACL6-3 with priority 25.

renumber ns acls6

renumber acls6

ns config

Sep 22, 2015

The following operations can be performed on "ns config":

clear | set | unset | save | show | diff

Clears the NetScaler running configurations based on different levels.

clear ns config [-force] <level>

force

Configurations will be cleared without prompting for confirmation.

level

Types of configurations to be cleared.

* basic: Clears all configurations except the following:

- NSIP, default route (gateway), MIPs, and SNIPs

- Network settings (DG, VLAN, RHI, NTP and DNS settings)

- Cluster settings

- HA node definitions

- Feature and mode settings

- nsroot password

* extended: Clears the same configurations as the 'basic' option. In addition, it clears the nsroot password and feature and mode settings.

* full: Clears all configurations except NSIP, default route, and interface settings.

Note: When you clear the configurations through the cluster IP address, by specifying the level as 'full', the cluster is deleted and all cluster nodes become standalone appliances. The 'basic' and 'extended' levels are propagated to the cluster nodes.

Possible values: basic, extended, full

Sets the NetScaler IP address and NetScaler VLAN. To set other NetScaler parameters, use the 'set ns param' command. Note: To change the NSIP address or the NSVLAN of an appliance that is part of a cluster, first remove the appliance from the cluster, change the NSIP or the NSVLAN, and then add the appliance back to the cluster.

set ns config [-IPAddress <ip_addr> -netmask <netmask>] [-nsvlan <positive_integer> -ifnum <interface_name> ... [-tagged (YES | NO)]] [-nwfwmode <nwfwmode>]

IPAddress

IP address of the NetScaler appliance. Commonly referred to as NSIP address. This parameter is mandatory to bring up the appliance.

nsvlan

VLAN (NSVLAN) for the subnet on which the IP address resides.

Minimum value: 2

Maximum value: 4094

httpPort

The HTTP ports on the Web server. This allows the system to perform connection off-load for any client request that has a destination port matching one of these configured ports.

Minimum value: 1

maxConn

The maximum number of connections that will be made from the system to the web server(s) attached to it. The value entered here is applied globally to all attached servers.

Maximum value: 4294967294

maxReq

The maximum number of requests that the system can pass on a particular connection between the system and a server attached to it. Setting this value to 0 allows an unlimited number of

requests to be passed.

Maximum value: 65535

cip

The option to control (enable or disable) the insertion of the actual client IP address into the HTTP header request passed from the client to one, some, or all servers attached to the system.

The passed address can then be accessed through a minor modification to the server.

l If cipHeader is specified, it will be used as the client IP header.

l If it is not specified, then the value that has been set by the set ns config CLI command will be used as the client IP header.

Possible values: ENABLED, DISABLED

cookieversion

The version of the cookie inserted by system.

Possible values: 0, 1

secureCookie

enable/disable secure flag for persistence cookie

Possible values: ENABLED, DISABLED

Default value: ENABLED

pmtuMin

The minimum Path MTU.

Default value: 576

Minimum value: 168

Maximum value: 1500

pmtuTimeout

The timeout value in minutes.

Default value: 10

Minimum value: 1

Maximum value: 1440

ftpPortRange

Port range configured for FTP services.

Minimum value: 1024

Maximum value: 64000

crPortRange

Port range for cache redirection services.

Minimum value: 1

Maximum value: 65535

timezone

Name of the timezone

grantQuotaMaxClient

The percentage of shared quota to be granted at a time for maxClient

Default value: 10

Maximum value: 100

exclusiveQuotaMaxClient

The percentage of maxClient to be given to PEs

Default value: 80

Maximum value: 100

grantQuotaSpillOver

The percentage of shared quota to be granted at a time for spillover

Default value: 10

Maximum value: 100

exclusiveQuotaSpillOver

The percentage of max limit to be given to PEs

Default value: 80

Maximum value: 100

nwfwmode

Network Firewall mode to be used.

NOFIREWALL - No Network firewall setting

BASIC - DENY-ALL behavior and DENY-ALL AT BOOTUP

EXTENDED - NS_NWFWMODE_BASIC + drop IP fragments + TCP and ACL logging + packet drop on closed port

EXTENDEDPLUS - NS_NWFWMODE_EXTENDED + block traffic on 3008-3011 + drop non-session packets

FULL - NS_NWFWMODE_EXTENDEDPLUS + drop non-ip packets.

Possible values: NOFIREWALL, BASIC, EXTENDED, EXTENDEDPLUS, FULL

Default value: NS_NWFWMODE_NO

Removes the attributes of the NetScaler appliance. Attributes for which a default value is available revert to their default values. Refer to the 'set ns config' command for a description of the parameters..Refer to the set ns config command for meanings of the arguments.

unset ns config [-nsvlan] [-IPAddress] [-netmask] [-ifnum] [-tagged] [-nwfwmode]

Save the configurations to the appliances FLASH memory in the /nsconfig/ns.conf file. Backup configuration files are named ns.conf.n. The most recent backup file has the smallest value for n.

save ns config

message

Displays the following details of the NetScaler appliance: * NetScaler IP address and subnet mask * Number of mapped IP addresses * Identifies the appliance as a standalone appliance, a part of a HA pair, or is a cluster node * Current time on the system and timestamp when the appliance was last updated Note: To view the complete configurations that have been executed on the appliance, run the 'show ns runningConfig' command.

show ns config

format

level

IPAddress

IP Address of the System.

netmask

The netmask corresponding to the IP address.

mappedIP

Mapped IP Address of the System.

range

The range of Mapped IP addresses to be configured.

nsvlan

The VLAN (NSVLAN) for the subnet on which the system IP resides.

ifnum

Bind the given ports to the NSVLAN.

tagged

Specifies that the interfaces will be added as 802.1q tagged interfaces. Packets sent on these interface on this VLAN will have an additional 4-byte 802.1q tag which identifies the VLAN.

To use 802.1q tagging, the switch connected to the appliance's interfaces must also be configured for tagging.

httpPort

The HTTP ports on the Web server.

maxConn

Maximum Number of Connections.

maxReq

Maxmimum Number of requests that can be handled.

cip

Insertion of client IP address into the HTTP header.

cipHeader

The text that will be used as the client IP header.

cookieversion

The version of the cookie inserted by system.

secureCookie

enable/disable secure flag for persistence cookie

failover

Standalone node.NOTE: This attribute is deprecated.

systemType

The type of the System. Possible Values: Standalone, HA, Cluster

primaryIP

HA Master Node IP address.

pmtuMin

The minimum Path MTU.

pmtuTimeout

The timeout value in minutes.

ftpPortRange

Port range configured for FTP services.

crPortRange

Port range for cache redirection services.

flags

The flags for this entry.

timezone

Name of the timezone

LastConfigChangedTime

Time when the configuration was last modified.

LastConfigSaveTime

Time when the configuration was last saved through savensconfig.

currentSytemTime

current system time in date format.

systemTime

current system time.

grantQuotaMaxClient

The percentage of shared quota to be granted at a time for maxClient

exclusiveQuotaMaxClient

The percentage of maxClient to be given to PEs

grantQuotaSpillOver

The percentage of shared quota to be granted at a time for spillover

exclusiveQuotaSpillOver

The percentage of max limit to be given to PEs

nwfwmode

Network Firewallmode

Difference between two configuration

diff ns config [<config1>] [<config2>] [-outtype (cli | xml)] [-template] [-ignoreDeviceSpecific]

config1

Location of the configurations.

config2

Location of the configurations.

outtype

Format to display the difference in configurations.

Possible values: cli, xml

template

File that contains the commands to be compared.

ignoreDeviceSpecific

Suppress device specific differences.

response

Generates the differences between two configurations. Note: If no parameters are provided, then the differences between the saved configurations and the runnin

---

ns connectiontable

Sep 22, 2015

The following operations can be performed on "ns connectiontable":

Displays the current TCP/IP connection table.

show ns connectiontable [<filterexpression>] [-detail <detail> ...]

filterexpression

Expression using which TCP/IP connections must be filtered. Maximum length of filter is 255 and it can be of the following format:

"<expression> \\[<relop> <expression>"\\]

where,

<relop> can be the && or the || relational operators.

<expression> is a string in the following format:

<qualifier> <operator> <qualifier-value>

where,

<operator> can be any one of the following (except the commas): ==, eq, !=, neq, >, gt, <, lt, >=, ge, <=, le, BETWEEN

Following are the valid qualifier - qualifier value combinations:

SOURCEIP - A valid IP address

SOURCEPORT - A valid port number

DESTIP - A valid IP address

DESTPORT - A valid port number

IP - A valid IP address

PORT - A valid port number

IDLETIME - A positive integer indicating the idle time

SVCNAME - The name of a service

VSVRNAME - The name of a vserver

STATE - CLOSE_WAIT, CLOSED, CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, LAST_ACK, LISTEN, SYN_RECEIVED, SYN_SENT, TIME_WAIT

SVCTYPE - HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, RPCSVRS, RPCCLNT, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, MONITOR, MONITOR_UDP, MONITOR_PING, SIP_UDP, MYSQL, MSSQL, UNKNOWN.

link

Display link information if available

name

Display name instead of IP for local entities

detail

Specify display options for the connection table.

* LINK - Displays the linked PCB (Protocol Control Block).

* NAME - Displays along with the service name.

* CONNFAILOVER - Displays PCB with connection failover.

* FULL - Displays all available details.

summary

fullValues

SOURCEIP

Source IP of the connection.

SOURCEPORT

Source port of the connection.

DESTIP

Destination IP of the connection.

DESTPORT

Destination port of the connection.

SVCTYPE

Protocol supported by the connection.

IDLETIME

Time since last activity was detected on the connection.

STATE

Current TCP/IP state of the connection.

linkSourceIP

Source IP of the link connection.

linkSourcePort

Source port of the link connection.

linkDestIP

Destination IP of the link connection.

linkDestPort

Destination port of the link connection.

linkServiceType

Protocol supported by the link connection.

linkIdleTime

Time since last activity was detected on link connection.

linkState

TCP/IP current state of link connection.

entityName

NetScaler entity name for the connection.

linkEntityName

NetScaler entity name for link connection.

connectionNumber

Connection numberNOTE: This attribute is deprecated.Deprecated in favour of NSA_CONNID.

linkConnectionNumber

Link connection numberNOTE: This attribute is deprecated.Deprecated in favour of NSA_LINK_CONNID.

connid

Unique transaction number for the connection.

linkConnid

Unique transaction number for the peer connection.

filterFlags

flags used to store display options

optionFlags

flags used to store TCP options like Sack, WS

nsWSvalue

netscaler window scaling value

peerWSvalue

peer window scaling value

mss

Client side MSS for the connection - used in server SYN.

retxRetryCnt

Retransmission retry count for the connection.

rcvWnd

Received Advertised Window for the connection.

advWnd

Sent advertised window for the connection.

sndCwnd

sent congestion window for the connection.

iss

Initial send sequence number for the connection.

irs

Initial receive sequence number for the connection.

rcvNxt

next expecting seq number for the connection.

maxAck

current running max ack sent for the connection.

sndNxt

next bytes seq number for the connection.

sndUnAck

Most recently received ACK for the connection.

httpEndSeq

HTTP parsing tracking seq number for the connection.

httpState

HTTP Protocol state for the connection.

trCount

Max reuests allowed per connection.

priority

priority of the connection.

httpReqVer

current HTTP request version on the connection.

httpRequest

current HTTP request type on the connection.

httpRspCode

current response type on the connection.

rttSmoothed

smoothed RTT value of the connection.

rttVariance

RTT variance for the connection.

outoforderPkts

held packets on the connection.

count

linkOptionFlag

Link connection's TCP option flag for Sack and WS

linknsWSvalue

Link connection-s netscaler window scaling value

linkpeerWSvalue

Link connection-s peer netscaler window scaling value

linkMSS

Client side MSS for the Link connection - used in server SYN

linkRetxRetryCnt

Retransmission retry count for the Link connection.

linkRcvWnd

Received Advertised Window for the Link connection.

linkAdvWnd

Sent advertised window for the Link connection.

linkSndCwnd

Send congestion window for the Link connection.

linkISS

Initial send seq number for the Link connection.

linkIRS

Initial receive seq number for the Link connection.

linkRcvNxt

Next expecting seq number on the Link connection.

linkMaxAck

Current running maximum ack sent on the Link connection.

linkSndNxt

Next bytes seq number for the Link connection.

linkSndUnAck

Most recently received ACK on the Link connection.

linkHttpEndSeq

HTTP parsing tracking seq number on the Link connection.

linkHttpState

HTTP protocol state on the Link connection.

linkTrCount

Max requests per connection for Link connection.

linkPriority

Priority for the Link connection.

linkHttpReqVer

HTTP current request version on Link connection.

linkHttpReq

HTTP current request type on Link connection.

linkHttpRspCode

Current response type on link connection.

linkRttSmoothed

Smoothed RTT value on link connection.

linkRttVariance

RTT variance on Link connection.

linkHeldPkts

Held packets on Link connection.

targetnodeidnnm

NNM connection target node ID.

sourcenodeidnnm

NNM connection source node ID.

channelidnnm

NNM connection channel ID.

msgversionnnm

nnm message version.

td

Traffic Domain Id.

ns consoleloginprompt

Sep 22, 2015

The following operations can be performed on "ns consoleloginprompt":

set | unset | show

set ns consoleloginprompt <promptString>

promptString

Console login prompt string

set ns consoleloginprompt <prompt_string>

Use this command to remove ns consoleloginprompt settings.Refer to the set ns consoleloginprompt command for meanings of the arguments.

unset ns consoleloginprompt -promptString

---

show ns consoleloginprompt

promptString

Console login prompt string

get ns consoleloginprompt

---

ns dhcpIp

Sep 22, 2015

The following operations can be performed on "ns dhcpIp":

Releases the IP address acquired by the DHCP client.

release ns dhcpIp

ns dhcpParams

Sep 22, 2015

The following operations can be performed on "ns dhcpParams":

set | unset | show

Sets the DHCP client parameters.

```
set ns dhcpParams [-dhcpClient ( ON | OFF )] [-saveroute ( ON | OFF )]
```

dhcpClient

Enables DHCP client to acquire IP address from the DHCP server in the next boot. When set to OFF, disables the DHCP client in the next boot.

Possible values: ON, OFF

Default value: OFF

saveroute

DHCP acquired routes are saved on the NetScaler appliance.

Possible values: ON, OFF

Default value: OFF

Use this command to remove ns dhcpParams settings.Refer to the set ns dhcpParams command for meanings of the arguments.

```
unset ns dhcpParams [-dhcpClient] [-saveroute]
```

Displays the parameters configured for the DHCP client.

```
show ns dhcpParams
```

format

level

dhcpClient

ON, if DHCP client active on next reboot, else OFF

IPAddress

DHCP acquired IP

netmask

DHCP acquired Netmask

hostRtGw

DHCP acquired Gateway

running

DHCP mode

saveroute

DHCP acquired gateway save flag

ns diameter

Sep 22, 2015

The following operations can be performed on "ns diameter":

set | unset | show

Set the diameter configuration on NS.

set ns diameter [-identity <string>] [-realm <string>] [-serverClosePropagation (YES | NO)]

identity

DiameterIdentity to be used by NS. DiameterIdentity is used to identify a Diameter node uniquely. Before setting up diameter configuration, Netscaler (as a Diameter node) MUST be assigned a unique DiameterIdentity.

example =>

set ns diameter -identity netscaler.com

Now whenever Netscaler system needs to use identity in diameter messages. It will use 'netscaler.com' as Origin-Host AVP as defined in RFC3588

realm

Diameter Realm to be used by NS.

example =>

set ns diameter -realm com

Now whenever Netscaler system needs to use realm in diameter messages. It will use 'com' as Origin-Realm AVP as defined in RFC3588

serverClosePropagation

when a Server connection goes down, whether to close the corresponding client connection if there were requests pending on the server.

Possible values: YES, NO

Default value: NO

Use this command to remove ns diameter settings.Refer to the set ns diameter command for meanings of the arguments.

unset ns diameter -serverClosePropagation

Displays the diameter parameters configured on the NetScaler appliance.

show ns diameter

format

level

identity

DiameterIdentity to be used by NS. DiameterIdentity is used to identify a Diameter node uniquely. Before setting up diameter configuration, Netscaler (as a Diameter node) MUST be assigned a unique DiameterIdentity.

example =>

set ns diameter -identity netscaler.com

Now whenever Netscaler system needs to use identity in diameter messages. It will use 'netscaler.com' as Origin-Host AVP as defined in RFC3588

realm

Diameter Realm to be used by NS.

serverClosePropagation

when a Server connection goes down, whether to close the corresponding client connection if there were requests pending on the server.

---

ns encryptionParams

Sep 22, 2015

The following operations can be performed on "ns encryptionParams":

set | show

Sets the parameters required for encrypting or decrypting content.

set ns encryptionParams -method <method> [-keyValue]

method

Cipher method (and key length) to be used to encrypt and decrypt content. The default value is AES256.

Possible values: NONE, RC4, DES3, AES128, AES192, AES256

keyValue

The base64-encoded key generation number, method, and key value.

Note:

* Do not include this argument if you are changing the encryption method.

* To generate a new key value for the current encryption method, specify an empty string \\(""\\) as the value of this parameter. The parameter is passed implicitly, with its automatically generated value, to the NetScaler packet engines even when it is not included in the command. Passing the parameter to the packet engines enables the appliance to save the key value to the configuration file and to propagate the key value to the secondary appliance in a high availability setup.

set ns encryptionParams -method aes128

Displays the encryption method configured on the NetScaler appliance.

show ns encryptionParams

format

level

method

The cipher method (and key length) used to encrypt and decrypt content.

keyValue

The base64-encoded key generation number, method, and key value.

Note:

* Do not include this argument if you are changing the encryption method.

* To generate a new key value for the current encryption method, specify an empty string \\(""\\) as the value of this parameter. The parameter is passed implicitly, with its automatically generated value, to the NetScaler packet engines even when it is not included in the command. Passing the parameter to the packet engines enables the appliance to save the key value to the configuration file and to propagate the key value to the secondary appliance in a high availability setup.

ns events

Sep 22, 2015

The following operations can be performed on "ns events":

Displays events that occur on the appliance.

show ns events [<eventNo>]

eventNo

Event number starting from which events must be shown.

time

Event no.

eventcode

event Code.

devid

Device Name.

devname

Device Name.

text

Event no.

data0

additional event information.

data1

additional event information.

data2

additional event information.

data3

additional event information.

devno

count

stateflag

show ns events

ns feature

Sep 22, 2015

The following operations can be performed on "ns feature":

enable | disable | show

enable ns feature

Enables NetScaler feature(s).

Synopsys

enable ns feature <feature> ...

Arguments

feature

Feature to be enabled. Multiple features can be specified by providing a blank space between each feature.

Example

enable ns feature sc This CLI command enables the SureConnect feature.

---

disable ns feature

Disables NetScaler feature(s).

Synopsys

disable ns feature <feature> ...

Arguments

feature

Feature to be disabled. Multiple features can be specified by providing a blank space between each feature.

---

show ns feature

Displays the current state of NetScaler features.

Synopsys

show ns feature

Outputs

feature

Feature to be enabled. Multiple features can be specified by providing a blank space between each feature.

WL

Web Logging.

SP

Surge Protection.

LB

Load Balancing.

CS

Content Switching.

CR

Cache Redirect.

SC

Sure Connect.

CMP

Compression.

PQ

Priority Queuing.

SSL

Secure Sockets Layer.

GSLB

Global Server Load Balancing.

HDOSP

DOS Protection.

Routing

Routing.NOTE: This attribute is deprecated.

CF

Content Filter.

IC

Integrated Caching.

SSLVPN

SSL VPN.

AAA

AAA

OSPF

OSPF Routing.

RIP

RIP Routing.

BGP

BGP Routing.

REWRITE

Rewrite.

IPv6PT

IPv6 protocol translation

AppFw

Application Firewall.

RESPONDER

Responder.

HTMLInjection

HTML Injection.

push

NetScaler Push.

AppFlow

AppFlow.

CloudBridge

CloudBridge.

ISIS

ISIS Routing.

CH

Call Home.

AppQoE

AppQoS

vPath

Vpath

ns hardware

Sep 22, 2015

The following operations can be performed on "ns hardware":

show ns hardware

Displays details of the appliance hardware and information such as the host ID and the serial number.

Synopsys

show ns hardware

Outputs

hwdescription

Hardware and it's ports detail.

sysId

System id.

manufactureDay

Manufacturing day.

manufactureMonth

Manufacturing month.

manufactureYear

Manufacturing year.

cpufrequncy

CPU Frequency.

hostId

host id.

host

host id.

serialNo

Serial no.

encodedSerialNo

Encoded serial no.

ns hostName

Sep 22, 2015

The following operations can be performed on "ns hostName":

set | show

set ns hostName

Sets the hostname for the NetScaler appliance. The hostname is displayed on the shell prompt.

Synopsys

set ns hostName <hostName> [-ownerNode <positive_integer>]

Arguments

hostName

Host name for the NetScaler appliance.

ownerNode

ID of the cluster node for which you are setting the hostname. Can be configured only through the cluster IP address.

Default value: 255

Maximum value: 31

Example

set ns hostname nspri

---

show ns hostName

Displays the host name of the system.

Synopsys

show ns hostName

Arguments

format

level

Outputs

hostName

Host name

ownerNode

ID of the cluster node for which you are setting the hostname. Can be configured only through the cluster IP address.

devno

count

stateflag

Example

show ns hostname

ns httpParam

Sep 22, 2015

The following operations can be performed on "ns httpParam":

set | unset | show

set ns httpParam

Sets the configurable HTTP parameters for the NetScaler appliance.

Synopsys

set ns httpParam [-dropInvalReqs (ON | OFF)] [-markHttp09Inval (ON | OFF)] [-markConnReqInval (ON | OFF)] [-insNsSrvrHdr (ON | OFF) [<nsSrvrHdr>]] [-logErrResp (ON | OFF)] [-conMultiplex (ENABLED | DISABLED)] [-maxReusePool <positive_integer>]

Arguments

dropInvalReqs

Drop invalid HTTP requests or responses.

Possible values: ON, OFF

Default value: OFF

markHttp09Inval

Mark HTTP/0.9 requests as invalid.

Possible values: ON, OFF

Default value: OFF

markConnReqInval

Mark CONNECT requests as invalid.

Possible values: ON, OFF

Default value: OFF

insNsSrvrHdr

Enable or disable NetScaler server header insertion for NetScaler generated HTTP responses.

Possible values: ON, OFF

Default value: OFF

logErrResp

Server header value to be inserted.

Possible values: ON, OFF

Default value: ON

conMultiplex

Reuse server connections for requests from more than one client connections.

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxReusePool

Maximum limit on the number of connections, from the NetScaler to a particular server that are kept in the reuse pool. This setting is helpful for optimal memory utilization and for reducing the idle connections to the server just after the peak time.

Maximum value: 360000

Example

```
set ns httpParam -dropInvalReqs ON
```

---

unset ns httpParam

Use this command to remove ns httpParam settings.Refer to the set ns httpParam command for meanings of the arguments.

Synopsys

```
unset ns httpParam [-dropInvalReqs] [-markHttp09Inval] [-markConnReqInval] [-insNsSrvrHdr] [-nsSrvrHdr] [-logErrResp] [-conMultiplex] [-maxReusePool]
```

---

show ns httpParam

Displays the HTTP parameters configured on the NetScaler appliance.

Synopsys

```
show ns httpParam
```

Arguments

format

level

Outputs

dropInvalReqs

Drop invalid HTTP requests or responses.

markHttp09Inval

Mark HTTP/0.9 requests as invalid.

markConnReqInval

Mark CONNECT requests as invalid.

insNsSrvrHdr

Enable or disable NetScaler server header insertion for NetScaler generated HTTP responses.

nsSrvrHdr

The server header value to be inserted. If no explicit header is specified then NSBUILD.RELEASE is used as default server header.

logErrResp

Whether to log HTTP error responses

conMultiplex

Reuse server connections for requests from more than one client connections.

maxReusePool

Maximum limit on the number of connections, from the NetScaler to a particular server that are kept in the reuse pool. This setting is helpful for optimal memory utilization and for reducing the idle connections to the server just after the peak time.

ns httpProfile

Sep 22, 2015

The following operations can be performed on "ns httpProfile":

add | rm | set | unset | show

add ns httpProfile

Adds an HTTP profile to the NetScaler appliance.

Synopsys

add ns httpProfile <name> [-dropInvalReqs (ENABLED | DISABLED)] [-markHttp09Inval (ENABLED | DISABLED)] [-markConnReqInval (ENABLED | DISABLED)] [-cmpOnPush (ENABLED | DISABLED)] [-conMultiplex (ENABLED | DISABLED)] [-maxReusePool <positive_integer>] [-dropExtraCRLF (ENABLED | DISABLED)] [-incompHdrDelay <positive_integer>] [-webSocket (ENABLED | DISABLED)] [-rtspTunnel (ENABLED | DISABLED)] [-reqTimeout <positive_integer>] [-adptTimeout (ENABLED | DISABLED)] [-reqTimeoutAction <string>] [-dropExtraData (ENABLED | DISABLED)] [-webLog (ENABLED | DISABLED)] [-clientIpHdrExpr <expression>] [-maxReq <positive_integer>] [-persistentETag (ENABLED | DISABLED)] [-spdy (ENABLED | DISABLED)] [-reusePoolTimeout <positive_integer>] [-maxHeaderLen <positive_integer>]

Arguments

name

Name for an HTTP profile. Must begin with a letter, number, or the underscore \\(_\\) character. Other characters allowed, after the first character, are the hyphen \\(-\\), period \\(.\\), hash \\(\\#\\), space \\(\\), at \\(@\\), and equal \\(=\\) characters. The name of a HTTP profile cannot be changed after it is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks \\(for example, "my http profile" or 'my http profile'\\).

dropInvalReqs

Drop invalid HTTP requests or responses.

Possible values: ENABLED, DISABLED

Default value: DISABLED

markHttp09Inval

Mark HTTP/0.9 requests as invalid.

Possible values: ENABLED, DISABLED

Default value: DISABLED

markConnReqInval

Mark CONNECT requests as invalid.

Possible values: ENABLED, DISABLED

Default value: DISABLED

cmpOnPush

Start data compression on receiving a TCP packet with PUSH flag set.

Possible values: ENABLED, DISABLED

Default value: DISABLED

conMultiplex

Reuse server connections for requests from more than one client connections.

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxReusePool

Maximum limit on the number of connections, from the NetScaler to a particular server that are kept in the reuse pool. This setting is helpful for optimal memory utilization and for reducing the idle connections to the server just after the peak time.

Maximum value: 360000

dropExtraCRLF

Drop any extra 'CR' and 'LF' characters present after the header.

Possible values: ENABLED, DISABLED

Default value: ENABLED

incompHdrDelay

Maximum time to wait, in milliseconds, between incomplete header packets. If the header packets take longer to arrive at NetScaler, the connection is silently dropped.

Default value: 7000

Maximum value: 360000

webSocket

HTTP connection to be upgraded to a web socket connection. Once upgraded, NetScaler does not process Layer 7 traffic on this connection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

rtspTunnel

Allow RTSP tunnel in HTTP. Once application/x-rtsp-tunnelled is seen in Accept or Content-Type header, NetScaler does not process Layer 7 traffic on this connection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

reqTimeout

Time, in seconds, within which the HTTP request must complete. If the request does not complete within this time, the specified request timeout action is executed.

Maximum value: 86400

adptTimeout

Adapts the configured request timeout based on flow conditions. The timeout is increased or decreased internally and applied on the flow.

Possible values: ENABLED, DISABLED

Default value: DISABLED

reqTimeoutAction

Action to take when the HTTP request does not complete within the specified request timeout duration. You can configure the following actions:

* RESET - Send RST (reset) to client when timeout occurs.

* DROP - Drop silently when timeout occurs.

* Custom responder action - Name of the responder action to trigger when timeout occurs, used to send custom message.

dropExtraData

Drop any extra data when server sends more data than the specified content-length.

Possible values: ENABLED, DISABLED

Default value: DISABLED

webLog

Enable or disable web logging.

Possible values: ENABLED, DISABLED

Default value: ENABLED

clientIpHdrExpr

Name of the header that contains the real client IP address.

maxReq

Maximum requests allowed on a single connection.

Maximum value: 65534

persistentETag

Generate the persistent NetScaler specific ETag for the HTTP response with ETag header.

Possible values: ENABLED, DISABLED

Default value: DISABLED

spdy

Allow SPDY over SSL vserver. SSL will advertise SPDY support during NPN Handshake.

Possible values: ENABLED, DISABLED

Default value: DISABLED

reusePoolTimeout

Idle timeout (in seconds) for server connections in re-use pool. Connections in the re-use pool are flushed, if they remain idle for the configured timeout.

Maximum value: 31536000

maxHeaderLen

Number of bytes to be queued to look for complete header before returning error. If complete header is not obtained after queuing these many bytes, request will be marked as invalid and no L7 processing will be done for that TCP connection.

Default value: 24820

Minimum value: 2048

Maximum value: 61440

Example

```
add httpprofile <profile name> -dropInvalReqs ON -markHttp09Inval ON
```

---

rm ns httpProfile

Removes an HTTP profile from the appliance.

Synopsys

```
rm ns httpProfile <name>
```

Arguments

name

Name of the HTTP profile to be removed.

Example

rm httpprofile <profile name>

---

set ns httpProfile

Modifies the attributes of an HTTP profile.

Synopsys

set ns httpProfile <name> [-dropInvalReqs (ENABLED | DISABLED)] [-markHttp09Inval (ENABLED | DISABLED)] [-markConnReqInval (ENABLED | DISABLED)] [-cmpOnPush (ENABLED | DISABLED)] [-conMultiplex (ENABLED | DISABLED)] [-maxReusePool <positive_integer>] [-dropExtraCRLF (ENABLED | DISABLED)] [-incompHdrDelay <positive_integer>] [-webSocket (ENABLED | DISABLED)] [-rtspTunnel (ENABLED | DISABLED)] [-reqTimeout <positive_integer>] [-adptTimeout (ENABLED | DISABLED)] [-reqTimeoutAction <string>] [-dropExtraData (ENABLED | DISABLED)] [-webLog (ENABLED | DISABLED)] [-clientIpHdrExpr <expression>] [-maxReq <positive_integer>] [-persistentETag (ENABLED | DISABLED)] [-spdy (ENABLED | DISABLED)] [-reusePoolTimeout <positive_integer>] [-maxHeaderLen <positive_integer>]

Arguments

name

Name of the HTTP profile to be modified.

dropInvalReqs

Drop invalid HTTP requests or responses.

Possible values: ENABLED, DISABLED

Default value: DISABLED

markHttp09Inval

Mark HTTP/0.9 requests as invalid.

Possible values: ENABLED, DISABLED

Default value: DISABLED

markConnReqInval

Mark CONNECT requests as invalid.

Possible values: ENABLED, DISABLED

Default value: DISABLED

cmpOnPush

Start data compression on receiving a TCP packet with PUSH flag set.

Possible values: ENABLED, DISABLED

Default value: DISABLED

conMultiplex

Reuse server connections for requests from more than one client connections.

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxReusePool

Maximum limit on the number of connections, from the NetScaler to a particular server that are kept in the reuse pool. This setting is helpful for optimal memory utilization and for reducing the idle connections to the server just after the peak time.

Maximum value: 360000

dropExtraCRLF

Drop any extra 'CR' and 'LF' characters present after the header.

Possible values: ENABLED, DISABLED

Default value: ENABLED

incompHdrDelay

Maximum time to wait, in milliseconds, between incomplete header packets. If the header packets take longer to arrive at NetScaler, the connection is silently dropped.

Default value: 7000

Maximum value: 360000

webSocket

HTTP connection to be upgraded to a web socket connection. Once upgraded, NetScaler does not process Layer 7 traffic on this connection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

rtspTunnel

Allow RTSP tunnel in HTTP. Once application/x-rtsp-tunnelled is seen in Accept or Content-Type header, NetScaler does not process Layer 7 traffic on this connection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

reqTimeout

Time, in seconds, within which the HTTP request must complete. If the request does not complete within this time, the specified request timeout action is executed.

Maximum value: 86400

adptTimeout

Adapts the configured request timeout based on flow conditions. The timeout is increased or decreased internally and applied on the flow.

Possible values: ENABLED, DISABLED

Default value: DISABLED

reqTimeoutAction

Action to take when the HTTP request does not complete within the specified request timeout duration. You can configure the following actions:

* RESET - Send RST (reset) to client when timeout occurs.

* DROP - Drop silently when timeout occurs.

* Custom responder action - Name of the responder action to trigger when timeout occurs, used to send custom message.

dropExtraData

Drop any extra data when server sends more data than the specified content-length.

Possible values: ENABLED, DISABLED

Default value: DISABLED

webLog

Enable or disable web logging.

Possible values: ENABLED, DISABLED

Default value: ENABLED

clientIpHdrExpr

Name of the header that contains the real client IP address.

maxReq

Maximum requests allowed on a single connection.

Maximum value: 65534

persistentETag

Generate the persistent NetScaler specific ETag for the HTTP response with ETag header.

Possible values: ENABLED, DISABLED

Default value: DISABLED

spdy

Allow SPDY over SSL vserver. SSL will advertise SPDY support during NPN Handshake.

Possible values: ENABLED, DISABLED

Default value: DISABLED

reusePoolTimeout

Idle timeout (in seconds) for server connections in re-use pool. Connections in the re-use pool are flushed, if they remain idle for the configured timeout.

Maximum value: 31536000

maxHeaderLen

Number of bytes to be queued to look for complete header before returning error. If complete header is not obtained after queuing these many bytes, request will be marked as invalid and no L7 processing will be done for that TCP connection.

Default value: 24820

Minimum value: 2048

Maximum value: 61440

Example

```
set httpprofile <profile name> -dropInvalReqs ON -markHttp09Inval ON
```

---

unset ns httpProfile

Removes the attributes of the HTTP profile. Attributes for which a default value is available revert to their default values. Refer to the 'set ns httpProfile' command for a description of the parameters..Refer to the set ns httpProfile command for meanings of the arguments.

Synopsys

```
unset ns httpProfile <name> [-dropInvalReqs] [-markHttp09Inval] [-markConnReqInval] [-cmpOnPush] [-conMultiplex] [-maxReusePool] [-dropExtraCRLF] [-incompHdrDelay] [-webSocket] [-dropExtraData] [-clientIpHdrExpr] [-reqTimeout] [-adptTimeout] [-reqTimeoutAction] [-webLog] [-maxReq] [-persistentETag] [-spdy] [-reusePoolTimeout] [-maxHeaderLen] [-rtspTunnel]
```

show ns httpProfile

Displays information about HTTP profiles configured on the appliance.

Synopsys

show ns httpProfile [<name>]

Arguments

name

Name of the HTTP profile to be displayed. If a name is not provided, information about all HTTP profiles is shown.

summary

fullValues

format

level

Outputs

dropInvalReqs

Dropping of invalid HTTP requests/responses

markHttp09Inval

Invalidating HTTP 0.9 requests

markConnReqInval

Invalidating CONNECT HTTP requests

cmpOnPush

Compression on PUSH packet

conMultiplex

Reuse server connections for requests from more than one client connections.

maxReusePool

Maximum connections in reusepool

webSocket

HTTP connection to be upgraded to a web socket connection. Once upgraded, NetScaler does not process Layer 7 traffic on this connection.

refCnt

Number of entities using this profile

stateflag

State flag

dropExtraCRLF

Drop any extra 'CR' and 'LF' characters present after the header.

incompHdrDelay

Maximum time to wait, in milliseconds, between incomplete header packets. If the header packets take longer to arrive at NetScaler, the connection is silently dropped.

reqTimeout

Time, in seconds, within which the HTTP request must complete. If the request does not complete within this time, the specified request timeout action is executed.

adptTimeout

Adapts the configured request timeout based on flow conditions. The timeout is increased or decreased internally and applied on the flow.

reqTimeoutAction

Action to take when the HTTP request does not complete within the specified request timeout duration. You can configure the following actions:

* RESET - Send RST (reset) to client when timeout occurs.

* DROP - Drop silently when timeout occurs.

* Custom responder action - Name of the responder action to trigger when timeout occurs, used to send custom message.

dropExtraData

Drop any extra data when server sends more data than the specified content-length.

webLog

Disabling weblog option

clientIpHdrExpr

Name of the header that contains the real client IP address.

maxReq

Maximum requests allowed on a single connection.

persistentETag

Generate the persistent NetScaler specific ETag for the HTTP response with ETag header.

spdy

Allow SPDY over SSL vserver. SSL will advertise SPDY support during NPN Handshake.

reusePoolTimeout

Idle timeout (in seconds) for server connections in re-use pool. Connections in the re-use pool are flushed, if they remain idle for the configured timeout.

maxHeaderLen

Number of bytes to be queued to look for complete header before returning error. If complete header is not obtained after queuing these many bytes, request will be marked as invalid and no L7 processing will be done for that TCP connection.

rtspTunnel

Allow RTSP tunnel in HTTP. Once application/x-rtsp-tunnelled is seen in Accept or Content-Type header, NetScaler does not process Layer 7 traffic on this connection.

devno

count

Example

```
show http profile [profile name]
```

ns idletimeout

Sep 22, 2015

The following operations can be performed on "ns idletimeout":

set | unset | show

set ns idletimeout

Set the pcb/natpcb idletimeout. NOTE: This command is deprecated.

Synopsys

Arguments

tcpsvr

Set the idletimeout for server side pcb.

tcpclt

Set the idletimeout for client side pcb.

nontcpsvrclt

Set the idletimeout for natpcb.

Default value: 120

Minimum value: 1

Example

```
set ns idletimeout -tcpsvr 120  set ns idletimeout -tcpclt 120  set ns idletimeout -nontcpsvrclt 120
```

---

unset ns idletimeout

Use this command to remove ns idletimeout settings.Refer to the set ns idletimeout command for meanings of the arguments.NOTE: This command is deprecated.

Synopsys

---

show ns idletimeout

Display the global setting of pcb/natpcb idletimeout. NOTE: This command is deprecated.This command is deprecated in favour of 'set ns timeout'

Synopsys

Arguments

format

level

Outputs

tcpsvr

Set the idletimeout for server side pcb.

tcpclt

Set the idletimeout for client side pcb.

nontcpsvrclt

Set the idletimeout for natpcb.

---

ns info

Sep 22, 2015

The following operations can be performed on "ns info":

show ns info

Displays the following details of the NetScaler appliance: * Software version * NetScaler IP address and subnet mask * Number of mapped IP addresses * Identifies the appliance as a standalone appliance, a part of an HA pair, or is a cluster node * Current time on the system and timestamp when the appliance was last updated * Features that are enabled or disabled * Modes that are enabled or disabled

Synopsys

show ns info

Example

An example of this command's output is shown below: System Rainier: Build 24, Date: Apr 25 2002, 21:13:25 System IP: 10.101.4.22 (mask: 255.255.0.0) Mapped IP: 10.1

ns ip

Sep 22, 2015

The following operations can be performed on "ns ip":

add | rm | set | unset | enable | disable | show

add ns ip

Creates an IPv4 address on the NetScaler appliance.

Synopsys

add ns ip <IPAddress>@ <netmask> [-type <type> [-hostRoute (ENABLED | DISABLED) [-hostRtGw <ip_addr>] [-metric <integer>] [-vserverRHILevel <vserverRHILevel>] [-ospfLSAType (TYPE1 | TYPE5) [-ospfArea <positive_integer>]]]] [-arp (ENABLED | DISABLED)] [-icmp (ENABLED | DISABLED)] [-vServer (ENABLED | DISABLED)] [-telnet (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-gui <gui>] [-ssh (ENABLED | DISABLED)] [-snmp (ENABLED | DISABLED)] [-mgmtAccess (ENABLED | DISABLED)] [-restrictAccess (ENABLED | DISABLED)] [-dynamicRouting (ENABLED | DISABLED)] [-state (ENABLED | DISABLED)] [-vrID <positive_integer>] [-icmpResponse <icmpResponse>] [-ownerNode <positive_integer>] [-arpResponse <arpResponse>] [-td <positive_integer>]

Arguments

IPAddress

IPv4 address to create on the NetScaler appliance. Cannot be changed after the IP address is created.

netmask

Subnet mask associated with the IP address.

type

Type of the IP address to create on the NetScaler appliance. Cannot be changed after the IP address is created.

Possible values: SNIP, VIP, MIP, NSIP, GSLBsiteIP, CLIP

Default value: NSADDR_SNIP

arp

Respond to respond to ARP requests for this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

icmp

Respond to ICMP requests for this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

vServer

Use this option to set (enable or disable) the vserver attribute for this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

telnet

Allow Telnet access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

ftp

Allow File Transfer Protocol (FTP) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

gui

Allow graphical user interface (GUI) access to this IP address.

Possible values: ENABLED, SECUREONLY, DISABLED

Default value: ENABLED

ssh

Allow secure shell (SSH) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

snmp

Allow Simple Network Management Protocol (SNMP) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

mgmtAccess

Allow access to management applications on this IP address.

Possible values: ENABLED, DISABLED

Default value: DISABLED

restrictAccess

Block access to nonmanagement applications on this IP. This option is applicable for MIPs, SNIPs, and NSIP, and is disabled by default. Nonmanagement applications can run on the underlying NetScaler Free BSD operating system.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dynamicRouting

Allow dynamic routing on the IP address. Specific to SNIP addresses.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ospf

Use this option to enable or disable OSPF on this IP address for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

bgp

Use this option to enable or disable BGP on this IP address for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

rip

Use this option to enable or disable RIP on this IP address for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

hostRoute

Advertise a route for the VIP address, using the dynamic routing protocols running on the NetScaler appliance.

Possible values: ENABLED, DISABLED

hostRtGw

IP address of the gateway for the route. If hostRtGw is not set(i.e. default value), VIP goes with MIP as the gateway(if MIP is present) or with 0.0.0.0 (if MIP is not present).

Default value: -1

metric

Integer value to add to or subtract from the cost of the route advertised for the VIP address.

Minimum value: -16777215

vserverRHILevel

Advertise the route for the Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

* NONE - Advertise the route for the VIP address, regardless of the state of the virtual servers associated with the address.

* ONE VSERVER - Advertise the route for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - Advertise the route for the VIP address if all of the associated virtual servers are in UP state.

Possible values: ONE_VSERVER, ALL_VSERVERS, NONE

Default value: RHI_STATE_ONE

ospfLSAType

Type of LSAs to be used by the OSPF protocol, running on the NetScaler appliance, for advertising the route for this VIP address.

Possible values: TYPE1, TYPE5

Default value: DISABLED

ospfArea

ID of the area in which the Type1 LSAs are to be advertised for this VIP address by the OSPF protocol running on the NetScaler appliance. When ospfArea is not set, the VIP is advertised on all areas.

Default value: -1

Maximum value: 4294967294LU

state

Enable or disable the IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

vrID

ID, which uniquely identifies a VMAC address, to bin to a VIP address. This binding is used to set up NetScaler appliances in an active-active configuration using VRRP.

Minimum value: 1

Maximum value: 255

icmpResponse

Respond to ICMP requests for a Virtual IP (VIP) address on the basis of the states of the virtual servers associated with that VIP. Available settings function as follows:

* NONE - The NetScaler appliance responds to any ICMP request for the VIP address, irrespective of the states of the virtual servers associated with the address.

* ONE VSERVER - The NetScaler appliance responds to any ICMP request for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - The NetScaler appliance responds to any ICMP request for the VIP address if all of the associated virtual servers are in UP state.

* VSVR_CNTRLD - The behavior depends on the ICMP VSERVER RESPONSE setting on all the associated virtual servers.

The following settings can be made for the ICMP VSERVER RESPONSE parameter on a virtual server:

* If you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.

* If you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds if even one virtual server is UP.

* When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds if even one virtual server set to ACTIVE is UP.

Possible values: NONE, ONE_VSERVER, ALL_VSERVERS, VSVR_CNTRLD

Default value: NS_IP_NONE

ownerNode

The owner node in a Cluster for this IP address. Owner node can vary from 0 to 31. If ownernode is not specified then the IP is treated as Striped IP.

Default value: 255

arpResponse

Respond to ARP requests for a Virtual IP (VIP) address on the basis of the states of the virtual servers associated with that VIP. Available settings function as follows:

* NONE - The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the states of the virtual servers associated with the address.

* ONE VSERVER - The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Possible values: NONE, ONE_VSERVER, ALL_VSERVERS

Default value: NS_IP_NONE

td

Traffic Domain Id

Maximum value: 4094

Example

```
add ns ip 10.102.4.123 255.255.255.0
```

rm ns ip

Removes an IPv4 address configured on the NetScaler appliance.

Synopsys

rm ns ip <IPAddress>@ [-td <positive_integer>]

Arguments

IPAddress

IPv4 address that you want to remove.

td

Traffic Domain Id

Maximum value: 4094

Example

rm ns ip 10.102.4.123

---

set ns ip

Modifies the parameters of an IPv4 address configured on the NetScaler appliance.

Synopsys

set ns ip (<IPAddress>@ [-td <positive_integer>]) [-netmask <netmask>] [-arp (ENABLED | DISABLED)] [-icmp (ENABLED | DISABLED)] [-vServer (ENABLED | DISABLED)] [-telnet (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-gui <gui>] [-ssh (ENABLED | DISABLED)] [-snmp (ENABLED | DISABLED)] [-mgmtAccess (ENABLED | DISABLED)] [-restrictAccess (ENABLED | DISABLED)] [-dynamicRouting (ENABLED | DISABLED)] [-hostRoute (ENABLED | DISABLED) [-hostRtGw <ip_addr>] [-metric <integer>] [-vserverRHILevel <vserverRHILevel>] [-ospfLSAType (TYPE1 | TYPE5) [-ospfArea <positive_integer>]]] [-vrID <positive_integer>] [-icmpResponse <icmpResponse>] [-arpResponse <arpResponse>]

Arguments

IPAddress

IPv4 address whose parameters you want to modify.

netmask

Subnet mask associated with the IP address.

arp

Respond to respond to ARP requests for this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

icmp

Respond to ICMP requests for this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

vServer

Use this option to set (enable or disable) the vserver attribute for this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

telnet

Allow Telnet access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

ftp

Allow File Transfer Protocol (FTP) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

gui

Allow graphical user interface (GUI) access to this IP address.

Possible values: ENABLED, SECUREONLY, DISABLED

Default value: ENABLED

ssh

Allow secure shell (SSH) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

snmp

Allow Simple Network Management Protocol (SNMP) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

mgmtAccess

Allow access to management applications on this IP address.

Possible values: ENABLED, DISABLED

Default value: DISABLED

restrictAccess

Block access to nonmanagement applications on this IP. This option is applicable for MIPs, SNIPs, and NSIP, and is disabled by default. Nonmanagement applications can run on the underlying NetScaler Free BSD operating system.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dynamicRouting

Allow dynamic routing on the IP address. Specific to SNIP addresses.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ospf

The state of OSPF on this IP address for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

bgp

The state of BGP on this IP address for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

rip

The state of RIP on this IP address for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

hostRoute

Advertise a route for the VIP address, using the dynamic routing protocols running on the NetScaler appliance.

Possible values: ENABLED, DISABLED

vrID

ID, which uniquely identifies a VMAC address, to bin to a VIP address. This binding is used to set up NetScaler appliances in an active-active configuration using VRRP.

Minimum value: 1

Maximum value: 255

icmpResponse

Respond to ICMP requests for a Virtual IP (VIP) address on the basis of the states of the virtual servers associated with that VIP. Available settings function as follows:

* NONE - The NetScaler appliance responds to any ICMP request for the VIP address, irrespective of the states of the virtual servers associated with the address.

* ONE VSERVER - The NetScaler appliance responds to any ICMP request for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - The NetScaler appliance responds to any ICMP request for the VIP address if all of the associated virtual servers are in UP state.

* VSVR_CNTRLD - The behavior depends on the ICMP VSERVER RESPONSE setting on all the associated virtual servers.

The following settings can be made for the ICMP VSERVER RESPONSE parameter on a virtual server:

* If you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.

* If you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds if even one virtual server is UP.

* When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds if even one virtual server set to ACTIVE is UP.

Possible values: NONE, ONE_VSERVER, ALL_VSERVERS, VSVR_CNTRLD

Default value: NS_IP_NONE

arpResponse

Respond to ARP requests for a Virtual IP (VIP) address on the basis of the states of the virtual servers associated with that VIP. Available settings function as follows:

* NONE - The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the states of the virtual servers associated with the address.

* ONE VSERVER - The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Possible values: NONE, ONE_VSERVER, ALL_VSERVERS

Default value: NS_IP_NONE

Example

```
set ns ip 10.102.4.123 -arp ENABLED
```

---

unset ns ip

Modifies the parameters of an IPv4 address configured on the NetScaler appliance..Refer to the set ns ip command for meanings of the arguments.

Synopsys

```
unset ns ip <IPAddress>@ [-td <positive_integer>] [-ospfArea] [-hostRtGw] [-netmask] [-arp] [-icmp] [-vServer] [-telnet] [-ftp] [-gui] [-ssh] [-snmp] [-mgmtAccess] [-restrictAccess] [-dynamicRouting] [-hostRoute] [-metric] [-vserverRHILevel] [-ospfLSAType] [-vrID] [-icmpResponse] [-arpResponse]
```

Example

```
unset ns ip 10.102.4.123 -ospfArea
```

---

enable ns ip

Enables the specified IP address configured on the NetScaler appliance.

Synopsys

```
enable ns ip (<IPAddress>@ [-td <positive_integer>])
```

Arguments

IPAddress

IP address that you want to enable.

Example

```
enable ns ip 10.10.10.10
```

---

disable ns ip

Disables the specified IP address configured on the NetScaler appliance.

Synopsys

```
disable ns ip (<IPAddress>@ [-td <positive_integer>])
```

Arguments

IPAddress

IP address that you want to disable.

Example

```
disable ns ip 10.10.10.10
```

---

show ns ip

Displays settings of all the IPv4 addresses or of the specified IPv4 address configured on the NetScaler appliance. To display settings of all the IPv4 addresses, run the command without any parameters. To display settings of a particular IPv4 address, specify the IPv4 address.

Synopsys

show ns ip [<IPAddress> [-td <positive_integer>]] [-type <type>]

Arguments

IPAddress

IPv4 address whose details you want the NetScaler appliance to display.

type

Display the settings of all IPv4 addresses of a particular type.

Possible values: SNIP, VIP, MIP, NSIP, GSLBsiteIP, CLIP

summary

fullValues

format

level

Outputs

netmask

The netmask of this IP.

flags

The flags for this entry.

ipAttribute

arp

Whether arp is enabled or disabled.

icmp

Whether icmp is enabled or disabled.

vServer

Whether vserver is enabled or disabled.

telnet

Whether telnet is enabled or disabled.

ssh

Whether ssh is enabled or disabled.

gui

Whether gui is (enabled | SecureOnly | disabled).

snmp

Whether snmp is enabled or disabled.

ftp

Whether ftp is enabled or disabled.

mgmtAccess

Whether management access is enabled or disabled.

restrictAccess

Blocking of all ports not used for management access enabled or disabled

dynamicRouting

Whether dynamic routing is enabled or disabled.

bgp

Whether bgp is enabled or disabled.NOTE: This attribute is deprecated.

ospf

Whether ospf is enabled or disabled.NOTE: This attribute is deprecated.

rip

Whether rip is enabled or disabled.NOTE: This attribute is deprecated.

hostRoute

Whether host route is enabled or disabled.

hostRtGw

Gateway used for advertising host route.

hostRtGwAct

Actual Gateway used for advertising host route.

metric

The metric value added or subtracted from the cost of the hostroute.

ospfArea

The area ID of the area in which OSPF Type1 LSAs are advertised. When ospfArea if not set, LSAs are advertised on all areas.NOTE: This attribute is deprecated.Replaced by ospfAreaval

ospfAreaval

The area ID of the area in which OSPF Type1 LSAs are advertised.

vserverRHILevel

The rhi level for this IP.

VIPrtadv2BSD

Whether this route is advertised to FreeBSD

VIPvserCount

Number of vservers bound to this VIP

VIPvserDownCount

Number of vservers bound to this VIP, which are down

ospfLSAType

The ospf lsa type to use while advertising this IP.

state

Whether this ip is enabled or disabled.

freePorts

Number of free Ports available on this IP

vrID

ID, which uniquely identifies a VMAC address, to bin to a VIP address. This binding is used to set up NetScaler appliances in an active-active configuration using VRRP.

ipType

icmpResponse

Respond to ICMP requests for a Virtual IP (VIP) address on the basis of the states of the virtual servers associated with that VIP. Available settings function as follows:

* NONE - The NetScaler appliance responds to any ICMP request for the VIP address, irrespective of the states of the virtual servers associated with the address.

* ONE VSERVER - The NetScaler appliance responds to any ICMP request for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - The NetScaler appliance responds to any ICMP request for the VIP address if all of the associated virtual servers are in UP state.

* VSVR_CNTRLD - The behavior depends on the ICMP VSERVER RESPONSE setting on all the associated virtual servers.

The following settings can be made for the ICMP VSERVER RESPONSE parameter on a virtual server:

* If you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.

* If you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds if even one virtual server is UP.

* When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds if even one virtual server set to ACTIVE is UP.

ownerNode

The owner node in a Cluster for this IP address. Owner node can vary from 0 to 31. If ownernode is not specified then the IP is treated as Striped IP.

arpResponse

Respond to ARP requests for a Virtual IP (VIP) address on the basis of the states of the virtual servers associated with that VIP. Available settings function as follows:

* NONE - The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the states of the virtual servers associated with the address.

* ONE VSERVER - The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

stateflag

cfgflags

This contains the flags for IP in DB

ipRefcount

Used to keep reference count of IP

ns ip6

Sep 22, 2015

The following operations can be performed on "ns ip6":

add | rm | set | unset | show

add ns ip6

Creates an IPv6 address on the NetScaler appliance.

Synopsys

add ns ip6 <IPv6Address>@ [-scope (global | link-local)] [-type <type> [-hostRoute (ENABLED | DISABLED) [-ip6hostRtGw <ipv6_addr|*>] [-metric <integer>] [-vserverRHILevel <vserverRHILevel>] [-ospf6LSAType (INTRA_AREA | EXTERNAL) [-ospfArea <positive_integer>]]]] [-vlan <positive_integer>] [-nd (ENABLED | DISABLED)] [-icmp (ENABLED | DISABLED)] [-vServer (ENABLED | DISABLED)] [-telnet (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-gui <gui>] [-ssh (ENABLED | DISABLED)] [-snmp (ENABLED | DISABLED)] [-mgmtAccess (ENABLED | DISABLED)] [-restrictAccess (ENABLED | DISABLED)] [-dynamicRouting (ENABLED | DISABLED)] [-state (DISABLED | ENABLED)] [-map <ip_addr>] [-ownerNode <positive_integer>] [-td <positive_integer>]

Arguments

IPv6Address

IPv6 address to create on the NetScaler appliance.

scope

Scope of the IPv6 address to be created. Cannot be changed after the IP address is created.

Possible values: global, link-local

Default value: NS_GLOBAL

type

Type of IP address to be created on the NetScaler appliance. Cannot be changed after the IP address is created.

Possible values: NSIP, VIP, SNIP, GSLBsiteIP, ADNSsvcIP, CLIP

Default value: NS_IPV6_SNIP

vlan

The VLAN number.

Maximum value: 4094

nd

Respond to Neighbor Discovery (ND) requests for this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

icmp

Respond to ICMP requests for this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

vServer

Enable or disable the state of all the virtual servers associated with this VIP6 address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

telnet

Allow Telnet access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

ftp

Allow File Transfer Protocol (FTP) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

gui

Allow graphical user interface (GUI) access to this IP address.

Possible values: ENABLED, SECUREONLY, DISABLED

Default value: ENABLED

ssh

Allow secure Shell (SSH) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

snmp

Allow Simple Network Management Protocol (SNMP) access to this IP address.

Possible values: ENABLED, DISABLED

Default value: ENABLED

mgmtAccess

Allow access to management applications on this IP address.

Possible values: ENABLED, DISABLED

Default value: DISABLED

restrictAccess

Block access to nonmanagement applications on this IP address. This option is applicable forMIP6s, SNIP6s, and NSIP6s, and is disabled by default. Nonmanagement applications can run on the underlying NetScaler Free BSD operating system.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dynamicRouting

Allow dynamic routing on the IP address. Specific to SNIP6 address.

Possible values: ENABLED, DISABLED

Default value: DISABLED

hostRoute

Advertise a route for the VIP6 address by using the dynamic routing protocols running on the NetScaler appliance.

Possible values: ENABLED, DISABLED

ip6hostRtGw

IPv6 address of the gateway for the route. If Gateway is not set, VIP uses :: as the gateway.

metric

Integer value to add to or subtract from the cost of the route advertised for the VIP6 address.

Minimum value: -16777215

vserverRHILevel

Advertise or do not advertise the route for the Virtual IP (VIP6) address on the basis of the state of the virtual servers associated with that VIP6.

* NONE - Advertise the route for the VIP6 address, irrespective of the state of the virtual servers associated with the address.

* ONE VSERVER - Advertise the route for the VIP6 address if at least one of the associated virtual servers is in UP

state.

* ALL VSERVER - Advertise the route for the VIP6 address if all of the associated virtual servers are in UP state.

Possible values: ONE_VSERVER, ALL_VSERVERS, NONE

Default value: RHI_STATE_ONE

ospf6LSAType

Type of LSAs to be used by the IPv6 OSPF protocol, running on the NetScaler appliance, for advertising the route for the VIP6 address.

Possible values: INTRA_AREA, EXTERNAL

Default value: DISABLED

ospfArea

ID of the area in which the Intra-Area-Prefix LSAs are to be advertised for the VIP6 address by the IPv6 OSPF protocol running on the NetScaler appliance. When ospfArea is not set, VIP6 is advertised on all areas.

Default value: -1

Maximum value: 4294967294LU

state

Enable or disable the IP address.

Possible values: DISABLED, ENABLED

Default value: ENABLED

map

Mapped IPV4 address for the IPV6 address.

ownerNode

ID of the cluster node for which you are adding the IP address. Must be used if you want the IP address to be active only on the specific node. Can be configured only through the cluster IP address. Cannot be changed after the IP address is created.

Default value: 255

td

Traffic Domain Id

Maximum value: 4094

Example

```
add ns ip6 2001::a/96 -scope GLOBAL
```

rm ns ip6

Removes an IPv6 address configured on the NetScaler appliance.

Synopsys

rm ns ip6 <IPv6Address>@ [-td <positive_integer>]

Arguments

IPv6Address

IPv6 address that you want to remove.

td

Traffic Domain Id

Maximum value: 4094

Example

rm ns ip6 2002::5

set ns ip6

Modifies the specified parameters of an IPv6 address configured on the NetScaler appliance.

Synopsys

set ns ip6 (<IPv6Address>@ [-td <positive_integer>]) [-nd (ENABLED | DISABLED)] [-icmp (ENABLED | DISABLED)] [-vServer (ENABLED | DISABLED)] [-telnet (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-gui <gui>] [-ssh (ENABLED | DISABLED)] [-snmp (ENABLED | DISABLED)] [-mgmtAccess (ENABLED | DISABLED)] [-restrictAccess (ENABLED | DISABLED)] [-state (DISABLED | ENABLED)] [-map <ip_addr>] [-dynamicRouting (ENABLED | DISABLED)] [-hostRoute (ENABLED | DISABLED) [-ip6hostRtGw <ipv6_addr|*>] [-metric <integer>] [-vserverRHILevel <vserverRHILevel>] [-ospf6LSAType (INTRA_AREA | EXTERNAL) [-ospfArea <positive_integer>]]]

Arguments

IPv6Address

IPv6 address whose parameters you want to modify.

nd

The state of ND responses for the entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

icmp

The state of ICMP responses for the entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

vServer

The state of vserver attribute for this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

telnet

The state of telnet access to this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

ftp

The state of ftp access to this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

gui

The state of GUI access to this IP entity.

Possible values: ENABLED, SECUREONLY, DISABLED

Default value: ENABLED

ssh

The state of SSH access to this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

snmp

The state of SNMP access to this IP entity.

Possible values: ENABLED, DISABLED

Default value: ENABLED

mgmtAccess

The state of management access to this IP entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

restrictAccess

Status of ports not used for management access (blocked/open) for the entity.

Possible values: ENABLED, DISABLED

Default value: DISABLED

state

Enable or disable the IP address.

Possible values: DISABLED, ENABLED

Default value: ENABLED

map

Mapped IPV4 address for the IPV6 address.

dynamicRouting

Allow dynamic routing on the IP address. Specific to SNIP6 address.

Possible values: ENABLED, DISABLED

Default value: DISABLED

hostRoute

Advertise a route for the VIP6 address by using the dynamic routing protocols running on the NetScaler appliance.

Possible values: ENABLED, DISABLED

Example

```
set ns ip6 2001::a -map 10.102.33.27
```

---

unset ns ip6

Modifies the parameters of an IPv6 address configured on the NetScaler appliance..Refer to the set ns ip6 command for meanings of the arguments.

Synopsys

unset ns ip6 <IPv6Address>@ [-td <positive_integer>] [-ospfArea] [-nd] [-icmp] [-vServer] [-telnet] [-ftp] [-gui] [-ssh] [-snmp] [-mgmtAccess] [-restrictAccess] [-state] [-map] [-dynamicRouting] [-hostRoute] [-ip6hostRtGw] [-metric] [-vserverRHILevel] [-ospf6LSAType]

Example

unset ns ip6 2001::a -ospfArea

---

show ns ip6

Displays settings of all the IPv6 addresses or of the specified IPv6 address configured on the NetScaler appliance. To display settings of all the IPv6 addresses, run the command without any parameters. To display settings of a particular IPv6 address, specify the IPv6 address.

Synopsys

show ns ip6 [<IPv6Address> [-td <positive_integer>]]

Arguments

IPv6Address

IPv6 address whose settings you want the NetScaler appliance to display.

summary

fullValues

format

level

Outputs

scope

Scope of the IPv6 address to be created. Cannot be changed after the IP address is created.

type

The type of the IPV6 addressNOTE: This attribute is deprecated.This option is deprecated in favour of ip6_type

ipType

The type of the IPv6 address

vlan

The VLAN number.

nd

Whether ND is enabled or disabled.

icmp

Whether icmp is enabled or disabled.

vServer

Whether vserver is enabled or disabled.

telnet

Whether telnet is enabled or disabled.

ssh

Whether ssh is enabled or disabled.

gui

Whether gui is (enabled | SecureOnly | disabled).

snmp

Whether snmp is enabled or disabled.

ftp

Whether ftp is enabled or disabled.

mgmtAccess

Whether management access is enabled or disabled.

restrictAccess

Blocking of all ports not used for management access enabled or disabled

state

Current state of this IP.

map

Mapped IPV4 address for the IPV6 address.

dynamicRouting

Allow dynamic routing on the IP address. Specific to SNIP6 address.

hostRoute

Advertise a route for the VIP6 address by using the dynamic routing protocols running on the NetScaler appliance.

ip6hostRtGw

IPv6 address of the gateway for the route. If Gateway is not set, VIP uses :: as the gateway.

metric

The metric value to be added or subtracted from the cost of the hostroute advertised for this IPv6 entity.

vserverRHILevel

Advertise or do not advertise the route for the Virtual IP (VIP6) address on the basis of the state of the virtual servers associated with that VIP6.

* NONE - Advertise the route for the VIP6 address, irrespective of the state of the virtual servers associated with the address.

* ONE VSERVER - Advertise the route for the VIP6 address if at least one of the associated virtual servers is in UP state.

* ALL VSERVER - Advertise the route for the VIP6 address if all of the associated virtual servers are in UP state.

VIPrtadv2BSD

Whether this route is advertised to FreeBSD

VIPvserCount

Number of vservers bound to this VIP

VIPvserDownCount

Number of vservers bound to this VIP, which are down

ospf6LSAType

The OSPF's route advertisement type.

ospfArea

The area ID of the area in which OSPF INTRA AREA PREFIX LSAs should be advertised. When ospfArea is not set, LSAs are advertised in all areas.

ownerNode

ID of the cluster node for which you are adding the IP address. Must be used if you want the IP address to be active only on the specific node. Can be configured only through the cluster IP address. Cannot be changed after the IP address is created.

stateflag

cfgflags

This contains the flags for IP in DB

ipRefcount

Used to keep reference count of IPv6

systemType

The type of the System. Possible Values: Standalone, HA, Cluster. Used for display purpose.

devno

count

Example

show ns ip6

ns license

Sep 22, 2015

The following operations can be performed on "ns license":

show ns license

Displays the state of all the licensed features.

Synopsys

show ns license

Outputs

WL

Web Logging.

SP

Surge Protection.

LB

Load Balancing.

CS

Content Switching.

CR

Cache Redirect.

SC

Sure Connect.

CMP

HWSSL

HW SSL

ns limitIdentifier

Sep 22, 2015

The following operations can be performed on "ns limitIdentifier":

add | rm | set | unset | show | stat

add ns limitIdentifier

Adds a limit identifier to check if the amount of traffic exceeds a specified value, within a particular time interval.

Synopsys

add ns limitIdentifier <limitIdentifier> [-threshold <positive_integer>] [-timeSlice <positive_integer>] [-mode <mode> [-limitType (BURSTY | SMOOTH)]] [-selectorName <string>] [-maxBandwidth <positive_integer>] [-trapsInTimeSlice <positive_integer>]

Arguments

limitIdentifier

Name for a rate limit identifier. Must begin with an ASCII letter or underscore (_) character, and must consist only of ASCII alphanumeric or underscore characters. Reserved words must not be used.

threshold

Maximum number of requests that are allowed in the given timeslice when requests (mode is set as REQUEST_RATE) are tracked per timeslice.

When connections (mode is set as CONNECTION) are tracked, it is the total number of connections that would be let through.

Default value: 1

Minimum value: 1

timeSlice

Time interval, in milliseconds, specified in multiples of 10, during which requests are tracked to check if they cross the threshold. This argument is needed only when the mode is set to REQUEST_RATE.

Default value: 1000

Minimum value: 10

mode

Defines the type of traffic to be tracked.

* REQUEST_RATE - Tracks requests/timeslice.

* CONNECTION - Tracks active transactions.

Examples

1. To permit 20 requests in 10 ms and 2 traps in 10 ms:

add limitidentifier limit_req -mode request_rate -limitType smooth -timeslice 1000 -Threshold 2000 -trapsInTimeSlice 200

2. To permit 50 requests in 10 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5000 -limitType smooth

3. To permit 1 request in 40 ms:

set limitidentifier limit_req -mode request_rate -timeslice 2000 -Threshold 50 -limitType smooth

4. To permit 1 request in 200 ms and 1 trap in 130 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5 -limitType smooth -trapsInTimeSlice 8

5. To permit 5000 requests in 1000 ms and 200 traps in 1000 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5000 -limitType BURSTY

Possible values: CONNECTION, REQUEST_RATE, NONE

Default value: PEMGMT_RLT_MODE_REQ_RATE

limitType

Smooth or bursty request type.

* SMOOTH - When you want the permitted number of requests in a given interval of time to be spread evenly across the timeslice

* BURSTY - When you want the permitted number of requests to exhaust the quota anytime within the timeslice.

This argument is needed only when the mode is set to REQUEST_RATE.

Possible values: BURSTY, SMOOTH

Default value: PEMGMT_RLT_REQ_RATE_TYPE_BURSTY

selectorName

Name of the rate limit selector. If this argument is NULL, rate limiting will be applied on all traffic received by the virtual server or the NetScaler (depending on whether the limit identifier is bound to a virtual server or globally) without any filtering.

maxBandwidth

Maximum bandwidth permitted, in kbps.

Maximum value: 4294967287

trapsInTimeSlice

Number of traps to be sent in the timeslice configured. A value of 0 indicates that traps are disabled.

Maximum value: 65535

Example

```
add ns limitIdentifier limit_id -threshold 2 -timeSlice 5000 -mode CONNECTION  -selectorName sel_1 -maxBandwidth 24 -trapsInTimeSlice 8
```

---

rm ns limitIdentifier

Removes a rate limit identifier from the appliance.

Synopsys

```
rm ns limitIdentifier <limitIdentifier>
```

Arguments

limitIdentifier

Name of the rate limit identifier to be removed.

Example

```
rm ns limitIdentifier limit_id
```

---

set ns limitIdentifier

Modifies the attributes of a rate limit identifier.

Synopsys

```
set ns limitIdentifier <limitIdentifier> [-threshold <positive_integer>] [-timeSlice <positive_integer>] [-mode <mode> [-limitType ( BURSTY | SMOOTH )]] [-selectorName <string>] [-maxBandwidth <positive_integer>] [-trapsInTimeSlice <positive_integer>]
```

Arguments

limitIdentifier

Name of the rate limit identifier to be modified.

threshold

Maximum number of requests that are allowed in the given timeslice when requests (mode is set as REQUEST_RATE) are tracked per timeslice.

When connections (mode is set as CONNECTION) are tracked, it is the total number of connections that would be let through.

Default value: 1

Minimum value: 1

timeSlice

Time interval, in milliseconds, specified in multiples of 10, during which requests are tracked to check if they cross the threshold. This argument is needed only when the mode is set to REQUEST_RATE.

Default value: 1000

Minimum value: 10

mode

Defines the type of traffic to be tracked.

* REQUEST_RATE - Tracks requests/timeslice.

* CONNECTION - Tracks active transactions.

Examples

1. To permit 20 requests in 10 ms and 2 traps in 10 ms:

add limitidentifier limit_req -mode request_rate -limitType smooth -timeslice 1000 -Threshold 2000 -trapsInTimeSlice 200

2. To permit 50 requests in 10 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5000 -limitType smooth

3. To permit 1 request in 40 ms:

set limitidentifier limit_req -mode request_rate -timeslice 2000 -Threshold 50 -limitType smooth

4. To permit 1 request in 200 ms and 1 trap in 130 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5 -limitType smooth -trapsInTimeSlice 8

5. To permit 5000 requests in 1000 ms and 200 traps in 1000 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5000 -limitType BURSTY

Possible values: CONNECTION, REQUEST_RATE, NONE

Default value: PEMGMT_RLT_MODE_REQ_RATE

selectorName

Name of the rate limit selector. If this argument is NULL, rate limiting will be applied on all traffic received by the virtual server or the NetScaler (depending on whether the limit identifier is bound to a virtual server or globally) without any filtering.

maxBandwidth

Maximum bandwidth permitted, in kbps.

Maximum value: 4294967287

trapsInTimeSlice

Number of traps to be sent in the timeslice configured. A value of 0 indicates that traps are disabled.

Maximum value: 65535

Example

```
set ns limitIdentifier limit_id -threshold 2 -timeSlice 5000 -mode CONNECTION  -selectorName sel_1 -maxBandwidth 24 -trapsInTimeSlice 8
```

unset ns limitIdentifier

Use this command to remove ns limitIdentifier settings.Refer to the set ns limitIdentifier command for meanings of the arguments.

Synopsys

unset ns limitIdentifier <limitIdentifier> [-selectorName] [-threshold] [-timeSlice] [-mode] [-limitType] [-maxBandwidth] [-trapsInTimeSlice]

---

show ns limitIdentifier

Displays information about a rate limit identifier.

Synopsys

show ns limitIdentifier [<limitIdentifier>]

Arguments

limitIdentifier

Name of the rate limit identifier about which to display information. If a name is not provided, information about all rate limit identifiers is shown.

summary

fullValues

format

level

Outputs

ngname

Nodegroup name to which this identifier belongs to.

threshold

Maximum number of requests that are allowed in the given timeslice when requests (mode is set as REQUEST_RATE) are tracked per timeslice.

When connections (mode is set as CONNECTION) are tracked, it is the total number of connections that would be let through.

timeSlice

Defines the time interval in msecs specified in multiples of 10 msec during which the requests are tracked to see if they cross the threshold. It is used and displayed only when the mode is REQUEST_RATE while tracking request rate and for defining the trap timeslice.

mode

Defines the type of traffic to be tracked.

* REQUEST_RATE - Tracks requests/timeslice.

* CONNECTION - Tracks active transactions.

Examples

1. To permit 20 requests in 10 ms and 2 traps in 10 ms:

add limitidentifier limit_req -mode request_rate -limitType smooth -timeslice 1000 -Threshold 2000 -trapsInTimeSlice 200

2. To permit 50 requests in 10 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5000 -limitType smooth

3. To permit 1 request in 40 ms:

set limitidentifier limit_req -mode request_rate -timeslice 2000 -Threshold 50 -limitType smooth

4. To permit 1 request in 200 ms and 1 trap in 130 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5 -limitType smooth -trapsInTimeSlice 8

5. To permit 5000 requests in 1000 ms and 200 traps in 1000 ms:

set limitidentifier limit_req -mode request_rate -timeslice 1000 -Threshold 5000 -limitType BURSTY

limitType

Smooth or bursty request type.

* SMOOTH - When you want the permitted number of requests in a given interval of time to be spread evenly across the timeslice

* BURSTY - When you want the permitted number of requests to exhaust the quota anytime within the timeslice.

This argument is needed only when the mode is set to REQUEST_RATE.

selectorName

Name of the rate limit selector. If this argument is NULL, rate limiting will be applied on all traffic received by the virtual server or the NetScaler (depending on whether the limit identifier is bound to a virtual server or globally) without any filtering.

stateflag

This is used internally to identify ip addresses returned.

hits

The number of times this identifier was evaluated.

drop

The number of times action was taken.

rule

Rule.

time

Time interval considered for rate limiting

total

Maximum number of requests permitted in the computed timeslice

maxBandwidth

The maximum bandwidth in kbps permitted

trapsInTimeSlice

The maximum bandwidth permitted in kbps

trapsComputedInTimeSlice

The number of traps that would be sent in the timeslice configured.

computedTrapTimeSlice

The time interval computed for sending traps.

referenceCount

Total number of transactions pointing to this entry.

devno

count

Example

```
show ns limitIdentifier limit_id
```

stat ns limitIdentifier

Display statistics of a identifier.

Synopsys

stat ns limitIdentifier [<name> [<pattern> ...]] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)] [-sortBy Hits [<sortOrder>]]

Arguments

name

The name of the identifier.

pattern

Pattern for the selector field, ? means field is required, * means field value does not matter, anything else is a regular pattern

clearstats

Clear the statsistics / counters

Possible values: basic, full

sortBy

use this argument to sort by specific key

Possible values: Hits

Outputs

count

devno

stateflag

Outputs

Rate Limit Identifier Hits (Hits)

Total hits.

Rate Limit Identifier Drops (Drops)

Total drops

Rate Limit Session Hits (Hits)

Total hits.

ns limitSelector

Sep 22, 2015

The following operations can be performed on "ns limitSelector":

add | rm | set | unset | show

add ns limitSelector

NOTE: This command is deprecated.Replaced by "stream selector"

Synopsys

Arguments

selectorName

rule

---

rm ns limitSelector

NOTE: This command is deprecated.Replaced by "stream selector"

Synopsys

Arguments

selectorName

---

set ns limitSelector

NOTE: This command is deprecated.

Synopsys

Arguments

selectorName

rule

---

unset ns limitSelector

Use this command to remove ns limitSelector settings.Refer to the set ns limitSelector command for meanings of the arguments.NOTE: This command is deprecated.

Synopsys

show ns limitSelector

NOTE: This command is deprecated.Replaced by "stream selector"

Synopsys

Arguments

selectorName

summary

fullValues

format

level

Outputs

rule

stateflag

devno

count

ns limitSessions

Sep 22, 2015

The following operations can be performed on "ns limitSessions":

show | clear

show ns limitSessions

Displays the rate limit sessions available on the appliance.

Synopsys

show ns limitSessions <limitIdentifier> [-detail]

Arguments

limitIdentifier

Name of the rate limit identifier for which to display the sessions.

detail

Show the individual hash values.

Outputs

timeout

The time remaining on the session before a flush can be attempted. If active transactions are present the session will not be flushed

hits

The number of times this entry was hit.

drop

The number of times action was taken.

number

The hash of the matched selectlets.

name

The string formed by gathering selectlet values.

unit

Total computed hash of the matched selectlets.

flags

Used internally to identify ip addresses.

referenceCount

Total number of transactions pointing to this entry. Its the sum total of the connection and bandwidth references

maxBandwidth

The current bandwidth

SelectorIPV61

First IPV6 address gathered.

SelectorIPV62

Second IPV6 address gathered.

flag

Used internally to identify ipv6 addresses.

devno

count

stateflag

---

clear ns limitSessions

Clears the rate limit sessions available on the appliance.

Synopsys

clear ns limitSessions <limitIdentifier>

Arguments

limitIdentifier

Name of the rate limit identifier for which the sessions must be cleared.

---

ns memory

Sep 22, 2015

The following operations can be performed on "ns memory":

stat ns memory

Displays memory statistics of NetScaler features.

Synopsys

stat ns memory [<pool>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

pool

Feature name for which to display memory statistics.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Maximum Memory Available (MB) (MemTotAvail)

Total system memory available for PE to grab from the system.

Allocation failure (AllocF)

Memory allocation failure for particular feature.

Percentage of memory allocated (Alloc(%))

Percentage of NetScaler memory used by the feature.

Total memory Allocated (KB) (CurAlloc(KB))

Total current NetScaler memory available for use by the feature, in kilobytes.

ns mode

Sep 22, 2015

The following operations can be performed on "ns mode":

enable | disable | show

enable ns mode

Enables NetScaler mode(s).

Synopsys

enable ns mode <Mode> ...

Arguments

Mode

Mode to be enabled. Multiple modes can be specified by providing a blank space between each mode.

Example

This CLI command enables the system's client keep-alive feature: enable ns mode CKA

---

disable ns mode

Disables NetScaler mode(s).

Synopsys

disable ns mode <Mode> ...

Arguments

Mode

Mode to be disabled. Multiple modes can be specified by providing a blank space between each mode.

Example

This example shows the command to disable the system's client keep-alive feature: disable ns mode CKA

---

show ns mode

Displays the current state of NetScaler modes.

Synopsys

show ns mode

Outputs

Mode

Mode to be enabled. Multiple modes can be specified by providing a blank space between each mode.

FR

Fast Ramp.

L2

Layer 2 mode.

USIP

Use Source IP.

CKA

Client Keep-alive.

TCPB

TCP Buffering.

MBF

MAC-based forwarding.

Edge

Edge configuration.

USNIP

Use Subnet IP.

L3

Layer 3 mode (ip forwarding).

PMTUD

Path MTU Discovery.

SRADV

Static Route Advertisement.

DRADV

Direct Route Advertisement.

IRADV

Intranet Route Advertisement.

SRADV6

Ipv6 Static Route Advertisement.

DRADV6

Ipv6 Direct Route Advertisement.

BridgeBPDUs

BPDU Bridging Mode.

ns ns.conf

Sep 22, 2015

The following operations can be performed on "ns ns.conf":

show ns ns.conf

Displays the saved configurations.

Synopsys

show ns ns.conf

Outputs

textBlob

Text of the last saved configuration.

ns param

Sep 22, 2015

The following operations can be performed on "ns param":

set | unset | show

set ns param

Sets the parameters of the NetScaler appliance.

Synopsys

set ns param [-httpPort <port> ...] [-maxConn <positive_integer>] [-maxReq <positive_integer>] [-cip (ENABLED | DISABLED) <cipHeader>] [-cookieversion (0 | 1)] [-secureCookie (ENABLED | DISABLED)] [-pmtuMin <positive_integer>] [-pmtuTimeout <mins>] [-ftpPortRange <int[-int]>] [-crPortRange <int[-int]>] [-timezone <timezone>] [-grantQuotaMaxClient <positive_integer>] [-exclusiveQuotaMaxClient <positive_integer>] [-grantQuotaSpillOver <positive_integer>] [-exclusiveQuotaSpillOver <positive_integer>] [-useproxyport (ENABLED | DISABLED)] [-internaluserlogin (ENABLED | DISABLED)] [-aftpAllowRandomSourcePort (ENABLED | DISABLED)] [-icaPorts <port> ...]

Arguments

httpPort

HTTP ports on the web server. This allows the system to perform connection off-load for any client request that has a destination port matching one of these configured ports.

Minimum value: 1

maxConn

Maximum number of connections that will be made from the appliance to the web server(s) attached to it. The value entered here is applied globally to all attached servers.

Maximum value: 4294967294

maxReq

Maximum number of requests that the system can pass on a particular connection between the appliance and a server attached to it. Setting this value to 0 allows an unlimited number of requests to be passed. This value is overridden by the maximum number of requests configured on the individual service.

Maximum value: 65535

cip

Enable or disable the insertion of the actual client IP address into the HTTP header request passed from the client to one, some, or all servers attached to the system. The passed address can then be accessed through a minor modification to the server.

* If the CIP header is specified, it will be used as the client IP header.

* If the CIP header is not specified, the value that has been set will be used as the client IP header.

Possible values: ENABLED, DISABLED

cookieversion

Version of the cookie inserted by the system.

Possible values: 0, 1

secureCookie

Enable or disable secure flag for persistence cookie.

Possible values: ENABLED, DISABLED

Default value: ENABLED

pmtuMin

Minimum path MTU value that NetScaler will process in the ICMP fragmentation needed message. If the ICMP message contains a value less than this value, then this value is used instead.

Default value: 576

Minimum value: 168

Maximum value: 1500

pmtuTimeout

Interval, in minutes, for flushing the PMTU entries.

Default value: 10

Minimum value: 1

Maximum value: 1440

ftpPortRange

Minimum and maximum port (port range) that FTP services are allowed to use.

Minimum value: 1024

Maximum value: 64000

crPortRange

Port range for cache redirection services.

Minimum value: 1

Maximum value: 65535

timezone

Time zone for the NetScaler appliance. Name of the time zone should be specified as argument.

Possible values: CoordinatedUniversalTime, GMT+01:00-CET-Europe/Andorra, GMT+04:00-GST-Asia/Dubai, GMT+04:30-AFT-Asia/Kabul, GMT-04:00-AST-America/Antigua, GMT-04:00-AST-America/Anguilla, GMT+01:00-CET-Europe/Tirane, GMT+04:00-AMT-Asia/Yerevan, GMT+01:00-WAT-Africa/Luanda, GMT+13:00-NZDT-Antarctica/McMurdo, GMT+13:00-NZDT-Antarctica/South_Pole, GMT-03:00-ROTT-Antarctica/Rothera, GMT-04:00-CLT-Antarctica/Palmer, GMT+05:00-MAWT-Antarctica/Mawson, GMT+07:00-DAVT-Antarctica/Davis, GMT+08:00-WST-Antarctica/Casey, GMT+06:00-VOST-Antarctica/Vostok, GMT+10:00-DDUT-Antarctica/DumontDUrville, GMT+03:00-SYOT-Antarctica/Syowa, GMT+11:00-MIST-Antarctica/Macquarie, GMT-03:00-ART-America/Argentina/Buenos_Aires, GMT-03:00-ART-America/Argentina/Cordoba, GMT-03:00-ART-America/Argentina/Salta, GMT-03:00-ART-America/Argentina/Jujuy, GMT-03:00-ART-America/Argentina/Tucuman, GMT-03:00-ART-America/Argentina/Catamarca, GMT-03:00-ART-America/Argentina/La_Rioja, GMT-03:00-ART-America/Argentina/San_Juan, GMT-03:00-ART-America/Argentina/Mendoza, GMT-03:00-WARST-America/Argentina/San_Luis, GMT-03:00-ART-America/Argentina/Rio_Gallegos, GMT-03:00-ART-America/Argentina/Ushuaia, GMT-11:00-SST-Pacific/Pago_Pago, GMT+01:00-CET-Europe/Vienna, GMT+11:00-LHST-Australia/Lord_Howe, GMT+11:00-EST-Australia/Hobart, GMT+11:00-EST-Australia/Currie, GMT+11:00-EST-Australia/Melbourne, GMT+11:00-EST-Australia/Sydney, GMT+10:30-CST-Australia/Broken_Hill, GMT+10:00-EST-Australia/Brisbane, GMT+10:00-EST-Australia/Lindeman, GMT+10:30-CST-Australia/Adelaide, GMT+09:30-CST-Australia/Darwin, GMT+08:00-WST-Australia/Perth, GMT+08:45-CWST-Australia/Eucla, GMT-04:00-AST-America/Aruba, GMT+02:00-EET-Europe/Mariehamn, GMT+04:00-AZT-Asia/Baku, GMT+01:00-CET-Europe/Sarajevo, GMT-04:00-AST-America/Barbados, GMT+06:00-BDT-Asia/Dhaka, GMT+01:00-CET-Europe/Brussels, GMT+00:00-GMT-Africa/Ouagadougou, GMT+02:00-EET-Europe/Sofia, GMT+03:00-AST-Asia/Bahrain, GMT+02:00-CAT-Africa/Bujumbura, GMT+01:00-WAT-Africa/Porto-Novo, GMT-04:00-AST-America/St_Barthelemy, GMT-03:00-ADT-Atlantic/Bermuda, GMT+08:00-BNT-Asia/Brunei, GMT-04:00-BOT-America/La_Paz, GMT-02:00-FNT-America/Noronha, GMT-03:00-BRT-America/Belem, GMT-03:00-BRT-America/Fortaleza, GMT-03:00-BRT-America/Recife, GMT-03:00-BRT-America/Araguaina, GMT-03:00-BRT-America/Maceio, GMT-03:00-BRT-America/Bahia, GMT-03:00-BRT-America/Sao_Paulo, GMT-04:00-AMT-America/Campo_Grande, GMT-04:00-AMT-America/Cuiaba, GMT-03:00-BRT-America/Santarem, GMT-04:00-AMT-America/Porto_Velho, GMT-04:00-AMT-America/Boa_Vista, GMT-04:00-AMT-America/Manaus, GMT-04:00-AMT-America/Eirunepe, GMT-04:00-AMT-America/Rio_Branco, GMT-04:00-EDT-America/Nassau, GMT+06:00-BTT-Asia/Thimphu, GMT+02:00-CAT-Africa/Gaborone, GMT+03:00-FET-Europe/Minsk, GMT-06:00-CST-America/Belize, GMT-02:30-NDT-America/St_Johns, GMT-03:00-ADT-America/Halifax, GMT-03:00-ADT-America/Glace_Bay, GMT-03:00-ADT-America/Moncton, GMT-03:00-ADT-America/Goose_Bay, GMT-04:00-AST-America/Blanc-Sablon, GMT-04:00-EDT-America/Montreal, GMT-04:00-EDT-America/Toronto, GMT-04:00-EDT-America/Nipigon, GMT-04:00-EDT-America/Thunder_Bay, GMT-04:00-EDT-America/Iqaluit, GMT-04:00-EDT-America/Pangnirtung, GMT-05:00-CDT-America/Resolute, GMT-05:00-EST-America/Atikokan, GMT-05:00-CDT-America/Rankin_Inlet, GMT-05:00-CDT-America/Winnipeg, GMT-05:00-CDT-America/Rainy_River, GMT-06:00-CST-America/Regina, GMT-06:00-CST-America/Swift_Current, GMT-06:00-MDT-America/Edmonton, GMT-06:00-MDT-America/Cambridge_Bay, GMT-06:00-MDT-America/Yellowknife, GMT-06:00-MDT-America/Inuvik, GMT-07:00-MST-America/Dawson_Creek, GMT-07:00-PDT-America/Vancouver, GMT-07:00-PDT-America/Whitehorse, GMT-07:00-PDT-America/Dawson, GMT+06:30-CCT-Indian/Cocos, GMT+01:00-WAT-Africa/Kinshasa, GMT+02:00-CAT-Africa/Lubumbashi, GMT+01:00-WAT-Africa/Bangui, GMT+01:00-WAT-Africa/Brazzaville, GMT+01:00-CET-Europe/Zurich, GMT+00:00-GMT-Africa/Abidjan, GMT-10:00-CKT-Pacific/Rarotonga, GMT-04:00-CLT-America/Santiago, GMT-06:00-EAST-Pacific/Easter, GMT+01:00-WAT-Africa/Douala, GMT+08:00-CST-Asia/Shanghai, GMT+08:00-CST-Asia/Harbin, GMT+08:00-CST-Asia/Chongqing, GMT+08:00-CST-Asia/Urumqi, GMT+08:00-CST-Asia/Kashgar, GMT-05:00-COT-America/Bogota, GMT-06:00-CST-America/Costa_Rica, GMT-04:00-CDT-America/Havana, GMT-01:00-CVT-Atlantic/Cape_Verde, GMT+07:00-CXT-Indian/Christmas, GMT+02:00-EET-Asia/Nicosia, GMT+01:00-CET-

grantQuotaMaxClient

Percentage of shared quota to be granted at a time for maxClient.

Default value: 10

Maximum value: 100

exclusiveQuotaMaxClient

Percentage of maxClient to be given to PEs.

Default value: 80

Maximum value: 100

grantQuotaSpillOver

Percentage of shared quota to be granted at a time for spillover.

Default value: 10

Maximum value: 100

exclusiveQuotaSpillOver

Percentage of maximum limit to be given to PEs.

Default value: 80

Maximum value: 100

useproxyport

Enable/Disable use_proxy_port setting

Possible values: ENABLED, DISABLED

Default value: ENABLED

internaluserlogin

Enables/disables the internal user from logging in to the appliance. Before disabling internal user login, you must have key-based authentication set up on the appliance. The file name for the key pair must be "ns_comm_key".

Possible values: ENABLED, DISABLED

Default value: ENABLED

aftpAllowRandomSourcePort

Allow the FTP server to come from a random source port for active FTP data connections

Possible values: ENABLED, DISABLED

Default value: DISABLED

icaPorts

The ICA ports on the Web server. This allows the system to perform connection off-load for any

client request that has a destination port matching one of these configured ports.

Minimum value: 1

---

unset ns param

Removes the attributes of the NetScaler parameters. Attributes for which a default value is available revert to their default values. Refer to the 'set ns param' command for a description of the parameters..Refer to the set ns param command for meanings of the arguments.

Synopsys

unset ns param [-ftpPortRange] [-crPortRange] [-timezone] [-aftpAllowRandomSourcePort] [-httpPort] [-maxConn] [-maxReq] [-cip] [-cipHeader] [-cookieversion] [-secureCookie] [-pmtuMin] [-pmtuTimeout] [-grantQuotaMaxClient] [-exclusiveQuotaMaxClient] [-grantQuotaSpillOver] [-exclusiveQuotaSpillOver] [-useproxyport] [-internaluserlogin] [-icaPorts]

---

show ns param

Displays the information of the parameters of the NetScaler appliance that were set by using the 'set ns param' command.

Synopsys

show ns param

Arguments

format

level

Outputs

httpPort

The HTTP ports on the Web server.

maxConn

Maximum Number of Connections.

maxReq

Maxmimum Number of requests that can be handled.

cip

Insertion of client IP address into the HTTP header.

cipHeader

The text that will be used as the client IP header.

cookieversion

Version of the cookie inserted by the system.

secureCookie

Enable or disable secure flag for persistence cookie.

pmtuMin

Minimum path MTU value that NetScaler will process in the ICMP fragmentation needed message. If the ICMP message contains a value less than this value, then this value is used instead.

pmtuTimeout

Interval, in minutes, for flushing the PMTU entries.

ftpPortRange

Minimum and maximum port (port range) that FTP services are allowed to use.

crPortRange

Port range for cache redirection services.

timezone

Time zone for the NetScaler appliance. Name of the time zone should be specified as argument.

grantQuotaMaxClient

Percentage of shared quota to be granted at a time for maxClient.

exclusiveQuotaMaxClient

Percentage of maxClient to be given to PEs.

grantQuotaSpillOver

Percentage of shared quota to be granted at a time for spillover.

exclusiveQuotaSpillOver

Percentage of maximum limit to be given to PEs.

useproxyport

Enable/Disable use_proxy_port setting

internaluserlogin

Enables/disables the internal user from logging in to the appliance. Before disabling internal user login, you

must have key-based authentication set up on the appliance. The file name for the key pair must be "ns_comm_key".

aftpAllowRandomSourcePort

Allow the FTP server to come from a random source port for active FTP data connections

icaPorts

The ICA ports on the Web server. This allows the system to perform connection off-load for any client request that has a destination port matching one of these configured ports.

ns pbr

Sep 22, 2015

The following operations can be performed on "ns pbr":

add | rm | set | unset | enable | disable | stat | show

add ns pbr

Adds a policy based route (PBR) to the NetScaler appliance. To commit this operation, you must apply the PBRs. A PBR specifies criteria for selecting outgoing IPv4 packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Note: The NetScaler appliance process PBRs before processing the RNAT rules.

Synopsys

add ns pbr <name> <action> [-td <positive_integer>] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] ((-nextHop <nextHopVal>) | (-ipTunnel <ipTunnelName>)) [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]

Arguments

name

Name for the PBR. Must begin with an ASCII alphabetic or underscore \\(_\\) character, and must contain only ASCII alphanumeric, underscore, hash \\(\\#\\), period \\(.\\), space, colon \\(:\\), at \\(@\\), equals \\(=\\), and hyphen \\(-\\) characters. Can be changed after the PBR is created.

action

Action to perform on the outgoing IPv4 packets that match the PBR.

Available settings function as follows:

* ALLOW - The NetScaler appliance sends the packet to the designated next-hop router.

* DENY - The NetScaler appliance applies the routing table for normal destination-based routing.

Possible values: ALLOW, DENY

td

Traffic Domain Id.

Maximum value: 4094

srcIP

IP address or range of IP addresses to match against the source IP address of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

srcPort

Port number or range of port numbers to match against the source port number of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

destIP

IP address or range of IP addresses to match against the destination IP address of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

destPort

Port number or range of port numbers to match against the destination port number of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

nextHop

IP address of the next hop router or the name of the link load balancing virtual server to which to send matching packets if action is set to ALLOW.

If you specify a link load balancing (LLB) virtual server, which can provide a backup if a next hop link fails, first make sure that the next hops bound to the LLB virtual server are actually next hops that are directly connected to the NetScaler appliance. Otherwise, the NetScaler throws an error when you attempt to create the PBR.

ipTunnel

The Tunnel name.

srcMac

MAC address to match against the source MAC address of an outgoing IPv4 packet.

protocol

Protocol, identified by protocol name, to match against the protocol of an outgoing IPv4 packet.

Possible values: ICMP, IGMP, TCP, EGP, IGP, ARGUS, UDP, RDP, RSVP, EIGRP, L2TP, ISIS

protocolNumber

Protocol, identified by protocol number, to match against the protocol of an outgoing IPv4 packet.

Minimum value: 1

Maximum value: 255

vlan

ID of the VLAN. The NetScaler appliance compares the PBR only to the outgoing packets on the specified VLAN. If you do not specify any interface ID, the appliance compares the PBR to the outgoing packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance compares the PBR only to the outgoing packets on the specified interface. If you do not specify any value, the appliance compares the PBR to the outgoing packets on all interfaces.

priority

Priority of the PBR, which determines the order in which it is evaluated relative to the other PBRs. If you do not specify priorities while creating PBRs, the PBRs are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 81920

msr

Monitor the route specified byte Next Hop parameter. This parameter is not applicable if you specify a link load balancing (LLB) virtual server name with the Next Hop parameter.

Possible values: ENABLED, DISABLED

Default value: DISABLED

state

Enable or disable the PBR. After you apply the PBRs, the NetScaler appliance compares outgoing packets to the enabled PBRs.

Possible values: ENABLED, DISABLED

Default value: XACLENABLED

Example

```
add ns pbr a allow -srcip 10.102.37.252 -destip 10.10.10.2 -nexthop 11.11.11.2
```

---

rm ns pbr

Removes a PBR from the NetScaler appliance. To commit this operation, you must apply the PBRs.

Synopsys

```
rm ns pbr <name> ...
```

Arguments

name

Name of the PBR that you want to remove.

Example

```
rm ns pbr a
```

---

set ns pbr

Modifies the specified parameters of a PBR. To commit this operation, you must apply the PBRs.

Synopsys

```
set ns pbr <name> [-action ( ALLOW | DENY )] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] ((-nextHop <nextHopVal>) | (-ipTunnel <ipTunnelName>)) [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr ( ENABLED | DISABLED ) [-monitor <string>]]
```

Arguments

name

Name of the PBR whose parameters you want to modify.

action

Action to perform on the outgoing IPv4 packets that match the PBR.

Available settings function as follows:

* ALLOW - The NetScaler appliance sends the packet to the designated next-hop router.

* DENY - The NetScaler appliance applies the routing table for normal destination-based routing.

Possible values: ALLOW, DENY

srcIP

IP address or range of IP addresses to match against the source IP address of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

srcPort

Port number or range of port numbers to match against the source port number of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

destIP

IP address or range of IP addresses to match against the destination IP address of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

destPort

Port number or range of port numbers to match against the destination port number of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

nextHop

IP address of the next hop router or the name of the link load balancing virtual server to which to send matching packets if action is set to ALLOW.

If you specify a link load balancing (LLB) virtual server, which can provide a backup if a next hop link fails, first make sure that the next hops bound to the LLB virtual server are actually next hops that are directly connected to the NetScaler appliance. Otherwise, the NetScaler throws an error when you attempt to create the PBR.

ipTunnel

The Tunnel name.

srcMac

MAC address to match against the source MAC address of an outgoing IPv4 packet.

protocol

Protocol, identified by protocol name, to match against the protocol of an outgoing IPv4 packet.

Possible values: ICMP, IGMP, TCP, EGP, IGP, ARGUS, UDP, RDP, RSVP, EIGRP, L2TP, ISIS

protocolNumber

Protocol, identified by protocol number, to match against the protocol of an outgoing IPv4 packet.

Minimum value: 1

Maximum value: 255

vlan

ID of the VLAN. The NetScaler appliance compares the PBR only to the outgoing packets on the specified VLAN. If you do not specify any interface ID, the appliance compares the PBR to the outgoing packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance compares the PBR only to the outgoing packets on the specified interface. If you do not specify any value, the appliance compares the PBR to the outgoing packets on all interfaces.

priority

Priority of the PBR, which determines the order in which it is evaluated relative to the other PBRs. If you do not specify priorities while creating PBRs, the PBRs are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 81920

msr

Monitor the route specified byte Next Hop parameter. This parameter is not applicable if you specify a link load balancing (LLB) virtual server name with the Next Hop parameter.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example

```
set ns pbr a -srcPort 50
```

---

unset ns pbr

Resets the attributes of the specified PBR. Attributes for which a default value is available revert to their default values. Refer to the set ns pbr command for descriptions of the parameters..Refer to the set ns pbr command for meanings of the arguments.

Synopsys

```
unset ns pbr <name> [-srcIP] [-srcPort] [-destIP] [-destPort] [-nextHop] [-ipTunnel] [-srcMac] [-protocol] [-vlan] [-interface] [-msr] [-monitor]
```

Example

```
unset ns pbr rule1 -srcPort
```

---

enable ns pbr

Enables a PBR. To commit this operation, you must apply the PBRs. After you apply the PBRs, the NetScaler appliance compares outgoing packets to the enabled PBRs.

Synopsys

```
enable ns pbr <name> ...
```

Arguments

name

Name of PBR that you want to enable.

Example

```
enable ns pbr foo
```

---

disable ns pbr

Disables a PBR. To commit this operation, you must apply the PBRs. After you apply the PBRs, the NetScaler appliance does not compare outgoing packets against the disabled PBRs

Synopsys

```
disable ns pbr <name> ...
```

Arguments

name

Name of PBR that you want to disable.

Example

```
disable ns pbr foo
```

---

stat ns pbr

Displays statistics related to the PBRs. To display statistics of all the PBRs, run the command without any parameters. To display statistics of a particular PBR, specify the name of the PBR.

Synopsys

```
stat ns pbr [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats ( basic | full )]
```

Arguments

name

Name of the PBR whose statistics you want the NetScaler appliance to display.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Allow PBR hits (PBRAllow)

Total packets that matched the PBR (Policy-Based Routes) with action ALLOW

Deny PBR hits (PBRDeny)

Total packets that matched the PBR with action DENY

PBR hits (PBRTotHits)

Total packets that matched one of the configured PBR

PBR misses (PBRMiss)

Total packets that did not match any PBR

Hits for this PBR (PBRHits)

Number of times the pbr was hit

Example

stat pbr

---

show ns pbr

Displays settings related to the PBRs. To display settings of all the PBRs, run the command without any parameters. To display settings of a particular PBR, specify the name of the PBR.

Synopsys

show ns pbr [<name>] [-detail]

Arguments

name

Name of the PBR whose details you want the NetScaler appliance to display.

detail

To get a detailed view.

summary

fullValues

format

level

Outputs

action

Action to perform on the outgoing IPv4 packets that match the PBR.

Available settings function as follows:

* ALLOW - The NetScaler appliance sends the packet to the designated next-hop router.

* DENY - The NetScaler appliance applies the routing table for normal destination-based routing.

srcMac

MAC address to match against the source MAC address of an outgoing IPv4 packet.

protocol

The protocol number in IP header or name.

protocolNumber

The protocol number in IP header or name.

srcPortVal

Port number or range of port numbers to match against the source port number of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

td

Traffic Domain Id.

destPortVal

Port number or range of port numbers to match against the destination port number of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

srcIPVal

IP address or range of IP addresses to match against the source IP address of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

destIPVal

IP address or range of IP addresses to match against the destination IP address of an outgoing IPv4 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [10.102.29.30-10.102.29.189].

vlan

ID of the VLAN. The NetScaler appliance compares the PBR only to the outgoing packets on the specified VLAN. If you do not specify any interface ID, the appliance compares the PBR to the outgoing packets on all VLANs.

state

If this route is UP/DOWN.

interface

ID of an interface. The NetScaler appliance compares the PBR only to the outgoing packets on the specified interface. If you do not specify any value, the appliance compares the PBR to the outgoing packets on all interfaces.

hits

The hits of this PBR.

priority

Priority of the PBR, which determines the order in which it is evaluated relative to the other PBRs. If you do not specify priorities while creating PBRs, the PBRs are evaluated in the order in which they are created.

operator

Logical operator.

kernelstate

The commit status of the PBR.

nextHopVal

The Next Hop IP address or gateway name.

ipTunnelName

The iptunnel name where packets need to be forwarded upon.

msr

Whether Monitored Static Route(MSR) is enabled or disabled.

monitor

Name of the monitor, of type PING or ARP, configured on the NetScaler appliance to monitor the route specified by the Next Hop parameter. You must enable the MSR parameter before setting this parameter.

totalprobes

The total number of probes sent.

totalfailedprobes

The total number of failed probes.

failedprobes

Number of the current failed monitoring probes.

monStatCode

The code indicating the monitor response.

monStatParam1

First parameter for use with message code.

monStatParam2

Second parameter for use with message code.

monStatParam3

Third parameter for use with message code.

data

Internal data of this route.

devno

count

stateflag

Example

```
show ns pbr a  Name: a                    Action: ALLOW    Hits: 0      srcIP = 10.102.37.252      destIP = 10.10.10.2
```

ns pbr6

Sep 22, 2015

The following operations can be performed on "ns pbr6":

add | renumber | rm | set | unset | enable | disable | stat | show | clear | apply

add ns pbr6

Adds an IPv6 policy based route (PBR6) to the NetScaler appliance. To commit this operation, you must apply the PBR6s. A PBR6 specifies criteria for selecting outgoing IPv6 packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Note: The NetScaler appliance process PBR6s before processing the RNAT rules.

Synopsys

add ns pbr6 <name> [-td <positive_integer>] <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]

Arguments

name

Name for the PBR6. Must begin with an ASCII alphabetic or underscore \\(_\\) character, and must contain only ASCII alphanumeric, underscore, hash \\(\\#\\), period \\(.\\), space, colon \\(:\\), at \\(@\\), equals \\(=\\), and hyphen \\(-\\) characters. Can be changed after the PBR6 is created.

td

Traffic Domain Id.

Maximum value: 4094

action

Action to perform on the outgoing IPv6 packets that match the PBR6.

Available settings function as follows:

* ALLOW - The NetScaler appliance sends the packet to the designated next-hop router.

* DENY - The NetScaler appliance applies the routing table for normal destination-based routing.

Possible values: ALLOW, DENY

srcIPv6

IP address or range of IP addresses to match against the source IP address of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

srcPort

Port number or range of port numbers to match against the source port number of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

destIPv6

IP address or range of IP addresses to match against the destination IP address of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

destPort

Port number or range of port numbers to match against the destination port number of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

srcMac

MAC address to match against the source MAC address of an outgoing IPv6 packet.

protocol

Protocol, identified by protocol name, to match against the protocol of an outgoing IPv6 packet.

Possible values: ICMPV6, TCP, UDP

protocolNumber

Protocol, identified by protocol number, to match against the protocol of an outgoing IPv6 packet.

Minimum value: 1

Maximum value: 255

vlan

ID of the VLAN. The NetScaler appliance compares the PBR6 only to the outgoing packets on the specified VLAN. If you do not specify an interface ID, the appliance compares the PBR6 to

the outgoing packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance compares the PBR6 only to the outgoing packets on the specified interface. If you do not specify a value, the appliance compares the PBR6 to the outgoing packets on all interfaces.

priority

Priority of the PBR6, which determines the order in which it is evaluated relative to the other PBR6s. If you do not specify priorities while creating PBR6s, the PBR6s are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 80000

state

Enable or disable the PBR6. After you apply the PBR6s, the NetScaler appliance compares outgoing packets to the enabled PBR6s.

Possible values: ENABLED, DISABLED

Default value: XACLENABLED

msr

Monitor the route specified by the Next Hop parameter.

Possible values: ENABLED, DISABLED

Default value: DISABLED

nextHop

IP address of the next hop router to which to send matching packets if action is set to ALLOW. This next hop should be directly reachable from the appliance.

nextHopVlan

VLAN number to be used for link local nexthop .

Minimum value: 1

Maximum value: 4094

Example

```
add ns pbr6 rule1 ALLOW -srcport 45-1024 -destIPv6 2001::45 -nexthop 2001::49
```

---

renumber ns pbr6

Renumbers the priorities of PBR6s to multiples of 10.To commit this operation, you must apply the PBR6s. Enables you to assign a new PBR6 a priority that is between two existing, consecutively numbered priorities. For example, if two PBR6s, PBR6-1 and PBR6-2, have priorities 2 and 3 renumbering changes those priorities to 20 and 30. You can then add PBR6-3 with priority 25.

Synopsys

```
renumber ns pbr6
```

Example

```
renumber pbr6
```

---

rm ns pbr6

Removes a PBR6 from the NetScaler appliance. To commit this operation, you must apply the PBR6s.

Synopsys

```
rm ns pbr6 <name> ...
```

Arguments

name

Name of the PBR6 that you want to remove.

Example

```
rm ns pbr6 rule1
```

---

set ns pbr6

Modifies the specified parameters of a PBR6.To commit this operation, you must apply the PBR6s.

Synopsys

set ns pbr6 <name> [-action (ALLOW | DENY)] [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]

Arguments

name

Name of the PBR6 whose parameters you want to modify.

action

Action to perform on the outgoing IPv6 packets that match the PBR6.

Available settings function as follows:

* ALLOW - The NetScaler appliance sends the packet to the designated next-hop router.

* DENY - The NetScaler appliance applies the routing table for normal destination-based routing.

Possible values: ALLOW, DENY

srcIPv6

IP address or range of IP addresses to match against the source IP address of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

srcPort

Source Port (range).

destIPv6

IP address or range of IP addresses to match against the destination IP address of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

destPort

Destination Port (range).

srcMac

MAC address to match against the source MAC address of an outgoing IPv6 packet.

protocol

Protocol, identified by protocol name, to match against the protocol of an outgoing IPv6 packet.

Possible values: ICMPV6, TCP, UDP

protocolNumber

Protocol, identified by protocol number, to match against the protocol of an outgoing IPv6 packet.

Minimum value: 1

Maximum value: 255

vlan

ID of the VLAN. The NetScaler appliance compares the PBR6 only to the outgoing packets on the specified VLAN. If you do not specify an interface ID, the appliance compares the PBR6 to the outgoing packets on all VLANs.

Minimum value: 1

Maximum value: 4094

interface

ID of an interface. The NetScaler appliance compares the PBR6 only to the outgoing packets on the specified interface. If you do not specify a value, the appliance compares the PBR6 to the outgoing packets on all interfaces.

priority

Priority of the PBR6, which determines the order in which it is evaluated relative to the other PBR6s. If you do not specify priorities while creating PBR6s, the PBR6s are evaluated in the order in which they are created.

Minimum value: 1

Maximum value: 80000

msr

Monitor the route specified by the Next Hop parameter.

Possible values: ENABLED, DISABLED

Default value: DISABLED

nextHop

IP address of the next hop router to which to send matching packets if action is set to ALLOW. This next hop should be directly reachable from the appliance.

nextHopVlan

VLAN number to be used for link local nexthop .

Minimum value: 1

Maximum value: 4094

Example

```
set ns pbr6 rule1 -srcPort 50
```

---

unset ns pbr6

Resets the attributes of the specified PBR6. Attributes for which a default value is available revert to their default values. Refer to the set ns pbr6 command for descriptions of the parameters..Refer to the set ns pbr6 command for meanings of the arguments.

Synopsys

```
unset ns pbr6 <name> [-srcIPv6] [-srcPort] [-destIPv6] [-destPort] [-srcMac] [-protocol] [-interface] [-vlan] [-msr] [-monitor] [-nextHop] [-nextHopVlan]
```

Example

```
unset ns pbr6 rule1 -srcPort
```

---

enable ns pbr6

Enables a PBR6. To commit this operation, you must apply the PBR6s.After you apply the PBR6s, the NetScaler appliance compares outgoing packets to the enabled PBR6.

Synopsys

```
enable ns pbr6 <name> ...
```

Arguments

name

Name of PBR6 that you want to enable.

Example

```
enable ns pbr6 rule1
```

---

disable ns pbr6

Disables a PBR6. To commit this operation, you must apply the PBR6s.After you apply the PBR6s, the NetScaler appliance does not compare outgoing packets to the disabled PBR6s.

Synopsys

```
disable ns pbr6 <name> ...
```

Arguments

name

Name of PBR6 that you want to disable.

Example

```
disable ns pbr6 rule1
```

---

stat ns pbr6

Displays statistics related to the PBR6s. To display statistics of all the PBR6s, run the command without any parameters. To display statistics of a particular PBR6, specify the name of the PBR6.

Synopsys

```
stat ns pbr6 [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats ( basic | full )]
```

Arguments

name

Name of the PBR6 whose statistics you want the NetScaler appliance to display.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Allow PBR6 hits (PBR6Allow)

Total packets that matched the PBR6 with action ALLOW

Deny PBR6 hits (PBR6Deny)

Total packets that matched PBR6 with action DENY

PBR6 hits (PBR6TotHits)

Total packets that matched one of the configured PBR6

PBR6 misses (PBR6Miss)

Total packets that did not match any PBR6

Hits for this PBR6 (PBR6Hits)

Number of times the pbr6 was hit

Example

stat pbr6

---

show ns pbr6

Displays settings related to the PBR6s. To display settings of all the PBR6s, run the command without any parameters. To display settings of a particular PBR6, specify the name of the PBR6.

Synopsys

show ns pbr6 [<name>] [-detail]

Arguments

name

Name of the PBR6 whose settings you want the NetScaler appliance to display.

detail

To get a detailed view.

summary

fullValues

format

level

Outputs

td

Traffic Domain Id.

action

Action to perform on the outgoing IPv6 packets that match the PBR6.

Available settings function as follows:

* ALLOW - The NetScaler appliance sends the packet to the designated next-hop router.

* DENY - The NetScaler appliance applies the routing table for normal destination-based routing.

srcMac

MAC address to match against the source MAC address of an outgoing IPv6 packet.

stateflag

PBR6 state flag.

protocol

Protocol number in IPv6 header or name.

protocolNumber

Protocol number in IPv6 header or name.

srcPortVal

Port number or range of port numbers to match against the source port number of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

destPortVal

Port number or range of port numbers to match against the destination port number of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets. For example: [40-90].

Note: The destination port can be specified only for TCP and UDP protocols.

srcIPv6Val

IP address or range of IP addresses to match against the source IP address of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

destIPv6Val

IP address or range of IP addresses to match against the destination IP address of an outgoing IPv6 packet. In the command line interface, separate the range with a hyphen and enclose within brackets.

vlan

ID of the VLAN. The NetScaler appliance compares the PBR6 only to the outgoing packets on the specified VLAN. If you do not specify an interface ID, the appliance compares the PBR6 to the outgoing packets on all VLANs.

state

If this route is UP/DOWN.

kernelstate

Commit status of the PBR6.

interface

ID of an interface. The NetScaler appliance compares the PBR6 only to the outgoing packets on the specified interface. If you do not specify a value, the appliance compares the PBR6 to the outgoing packets on all interfaces.

hits

Number of hits of this PBR6.

priority

Priority of the PBR6, which determines the order in which it is evaluated relative to the other PBR6s. If you do not specify priorities while creating PBR6s, the PBR6s are evaluated in the order in which they are created.

operator

Logical operator.

msr

Whether Monitored Static Route(MSR) is enabled or disabled.

monitor

Name of the monitor, of type PING6 or ARP, configured on the NetScaler appliance to monitor the route specified by the Next Hop parameter. You must enable the MSR parameter before setting the Monitor parameter.

totalprobes

The total number of probes sent.

totalfailedprobes

The total number of failed probes.

failedprobes

Number of the current failed monitoring probes.

monStatCode

The code indicating the monitor response.

monStatParam1

First parameter for use with message code.

monStatParam2

Second parameter for use with message code.

monStatParam3

Third parameter for use with message code.

nextHopVal

ID of the VLAN, if you have specified a link local address for the Next Hop parameter.

nextHopVlan

VLAN number to be used for link local nexthop .

data

Internal data of this route.

devno

count

Example

```
show ns pbr6 rule1 1)    Name: r1                Action: DENY      srcIPv6 = 2001::1      destIPv6      srcMac:
```

clear ns pbr6

Removes all PBR6s from the NetScaler appliance. This operation does not require an explicit apply.

Synopsys

```
clear ns pbr6
```

Example

```
clear ns pbr6
```

apply ns pbr6

Updates the PBR6's memory tree (lookup table), adding any new PBR6 and applying any modifications to the existing PBR6s. The lookup table includes the configuration of all the extended PBR6s on the NetScaler appliance. The NetScaler appliance uses the lookup table (not the configuration file) to filter the outgoing IPv6 packets.

Synopsys

```
apply ns pbr6
```

Example

```
apply ns pbr6
```

ns pbrs

Sep 22, 2015

The following operations can be performed on "ns pbrs":

renumber | clear | apply

renumber ns pbrs

Renumbers the priorities of PBRs to multiples of 10.To commit this operation, you must apply the PBRs. Enables you to assign a new PBR a priority that is between two existing, consecutively numbered priorities. For example, if two PBRs, PBR1 and PBR2, have priorities 2 and 3 renumbering changes those priorities to 20 and 30. You can then add PBR3 with priority 25.

Synopsys

renumber ns pbrs

Example

```
renumber pbrs
```

---

clear ns pbrs

Removes all PBRs from the NetScaler appliance. This operation does not require an explicit apply.

Synopsys

clear ns pbrs

Example

```
clear ns pbrs
```

---

apply ns pbrs

Updates the PBR's memory tree (lookup table), adding any new PBR and applying any modifications to existing PBRs. The lookup table includes the configuration of all the extended PBRs on the NetScaler appliance. The NetScaler appliance uses the lookup table (not the configuration file) to filter the outgoing IPv4 packets.

Synopsys

apply ns pbrs

Example

```
apply ns pbrs
```

---

ns persistencesession

Sep 22, 2015

The following operations can be performed on "ns persistencesession":

show | clear

show ns persistencesession

Get all Sessions corresponding to a Vserver NOTE: This command is deprecated.Moved to LB command group

Synopsys

Arguments

name

The name of the virtual server.

summary

fullValues

Outputs

type

The netmask of this IP.

srcIP

SOURCE IP.

srcIPv6

SOURCE IPv6 ADDRESS.

destIP

DESTINATION IP.

destIPv6

DESTINATION IPv6 ADDRESS.

flags

IPv6 FLAGS.

destPort

Destination port.

vServerName

Virtual server name.

timeout

Persistent Session timeout.

referenceCount

Reference Count.

sipCallID

SIP CALLID.NOTE: This attribute is deprecated.Replaced by "persistenceParam" field

persistenceParam

Specific persistence information . Callid in case of SIP_CALLID persistence entry , RTSP session id in case of RTSP_SESSIONID persistence entry.

devno

count

stateflag

Example

```
show ns persistencesession vipname
```

---

clear ns persistencesession

Use this command to clear/flush persistence sessions NOTE: This command is deprecated.Moved to LB command group

Synopsys

Arguments

vServer

The name of the LB vserver whose persistence sessions are to be flushed. If not specified, all persistence sessions will be flushed .

Example

```
clear persistenceSessions -vserver vip1
```

---

ns rateControl

Sep 22, 2015

The following operations can be performed on "ns rateControl":

set | unset | show

set ns rateControl

Sets the UDP/TCP/ICMP packet rate controls for any application that is not configured at System (direct access to the backend through System).

Synopsys

set ns rateControl [-tcpThreshold <positive_integer>] [-udpThreshold <positive_integer>] [-icmpThreshold <positive_integer>] [-tcprstThreshold <positive_integer>]

Arguments

tcpThreshold

Number of SYNs permitted per 10 milliseconds.

udpThreshold

Number of UDP packets permitted per 10 milliseconds.

icmpThreshold

Number of ICMP packets permitted per 10 milliseconds.

Default value: 100

tcprstThreshold

The number of TCP RST packets permitted per 10 milli second. zero means rate control is disabled and 0xffffffff means every thing is rate controlled

Default value: 100

Example

The following command will set the SYN rate to 100, icmp rate to 10 and the udp rate to unlimited. set ns ratecontrol -tcpThreshold 100 -udpThreshold 0 -icmpThreshol

---

unset ns rateControl

Use this command to remove ns rateControl settings.Refer to the set ns rateControl command for meanings of the arguments.

Synopsys

unset ns rateControl [-tcpThreshold] [-udpThreshold] [-icmpThreshold] [-tcprstThreshold]

---

show ns rateControl

Displays the values configured for rate control on the appliance.

Synopsys

show ns rateControl

Arguments

format

level

Outputs

tcpThreshold

Number of SYNs permitted per 10 milliseconds.

udpThreshold

Number of UDP packets permitted per 10 milliseconds.

icmpThreshold

Number of ICMP packets permitted per 10 milliseconds.

tcprstThreshold

The number of TCP RST packets permitted per 10 milli second. zero means rate control is disabled and 0xffffffff means every thing is rate controlled

Example

By default, there is no rate control for TCP/UDP and for ICMP it will be 100. The output of the "show ns ratecontrol" command, with default setting, > show ns ra

ns rollbackcmd

Sep 22, 2015

The following operations can be performed on "ns rollbackcmd":

show ns rollbackcmd

Generates the command(s) that can be used to roll back the command(s) that are specified in an input file. For example, if you want to roll back the creation of a load balancing virtual server named vserver_test, you must include the 'add lb vserver vserver_test ..' command in the input file. The output of this command is the 'rm lb vserver vserver_test' command.

Synopsys

show ns rollbackcmd [-fileName <input_filename>] [-outtype (cli | xml)]

Arguments

fileName

File that contains the commands for which the rollback commands must be generated. Specify the full path of the file name.

outtype

Format in which the rollback commands must be generated.

Possible values: cli, xml

Example

```
show ns rollbackcmd -file <file_name>
```

ns rpcNode

Sep 22, 2015

The following operations can be performed on "ns rpcNode":

set | unset | show

set ns rpcNode

Sets the authentication attributes associated with peer system node. All system nodes use Remote Procedure Calls (RPC) to communicate.

Synopsys

set ns rpcNode <IPAddress> {-password } [-srcIP <ip_addr|ipv6_addr|*>] [-secure (YES | NO)]

Arguments

IPAddress

IP address of the node. This has to be in the same subnet as the NSIP address.

password

Password to be used in authentication with the peer system node.

srcIP

Source IP address to be used to communicate with the peer system node. The default value is 0, which means that the appliance uses the NSIP address as the source IP address.

secure

State of the channel when talking to the node.

Possible values: YES, NO

Example

Example-1: Failover configuration In a failover configuration define peer NS as: add node 1 10.101.4.87 Set peer ha-unit's password as: set ns rpcnode 10.101.4.87 -p

---

unset ns rpcNode

Use this command to remove ns rpcNode settings.Refer to the set ns rpcNode command for meanings of the arguments.

Synopsys

unset ns rpcNode <IPAddress> [-password] [-srcIP] [-secure]

---

show ns rpcNode

Display a list of nodes currently communicating by using Remote Procedure Calls (RPC).

Synopsys

show ns rpcNode [<IPAddress>]

Arguments

IPAddress

IP address of the node.

summary

fullValues

format

level

Outputs

password

Password.

srcIP

The src ip used in communiction with the peer System node.

secure

State of the channel when talking to the node.

flags

Flags related to this rpcNode

devno

count

stateflag

Example

Following example shows list of nodes communicating using RPC: > sh rpcnode 1) IPAddress: 10.101.4.84 Password: ..8a7b474124

ns runningConfig

Sep 22, 2015

The following operations can be performed on "ns runningConfig":

show ns runningConfig

Displays all the configurations that have been executed on the appliance, including the configurations that have not yet been saved. Note: The unsaved configurations are lost when the appliance is rebooted or shut down.

Synopsys

show ns runningConfig [-withDefaults]

Arguments

withDefaults

Include default values of parameters that have not been explicitly configured. If this argument is disabled, such parameters are not included.

Outputs

response

running config data as text blob

ns savedConfig

Sep 22, 2015

The following operations can be performed on "ns savedConfig":

show ns savedConfig

Displays the saved configurations.

Synopsys

show ns savedConfig

Outputs

textBlob

Text of the last saved configuration.

ns simpleacl

Sep 22, 2015

The following operations can be performed on "ns simpleacl":

add | clear | rm | flush | show | stat

add ns simpleacl

Adds a simple ACL rule to the NetScaler appliance. Simple ACL rules filter IPv4 packets on the basis of their source IP addresses and, optionally, the destination port and/or protocol. Any packet with the characteristics specified in the simple ACL rule is dropped.

Synopsys

add ns simpleacl <aclname> <aclaction> [-td <positive_integer>] -srcIP <ip_addr> [-destPort <port> -protocol (TCP | UDP)] [-TTL <positive_integer>]

Arguments

aclname

Name for the simple ACL rule. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the simple ACL rule is created.

aclaction

Drop incoming IPv4 packets that match the simple ACL rule.

Possible values: DENY

td

Traffic Domain Id.

Maximum value: 4094

srcIP

IP address to match against the source IP address of an incoming IPv4 packet.

destPort

Port number to match against the destination port number of an incoming IPv4 packet.

Omitting the port number creates an all-ports simple ACL rule, which matches any port. In that case, you cannot create another simple ACL rule specifying a specific port and the same source IPv4 address.

TTL

Number of seconds, in multiples of four, after which the simple ACL rule expires. If you do not want the simple ACL rule to expire, do not specify a TTL value.

Minimum value: 4

Maximum value: 2147483647

Example

```
add simpleacl rule1 DENY -srcIP 1.1.1.1 -destPort 80 -protocol TCP add simpleacl rule2 DENY -srcIP 2.2.2.2 -TTL 600
```

---

clear ns simpleacl

Removes all simple ACL rules from the NetScaler appliance.

Synopsys

```
clear ns simpleacl
```

---

rm ns simpleacl

Removes a simple ACL rule from the NetScaler appliance.

Synopsys

rm ns simpleacl <aclname> ...

Arguments

aclname

Name of the simple ACL rule that you want to remove.

Example

```
rm ns simpleacl rule1
```

flush ns simpleacl

Terminates all established IPv4 connections that match any of the newly configured simple ACL rules. Note: If you plan to create more than one simple ACL rule and flush existing connections that match any of them, you can minimize the affect on performance by first creating all of the simple ACL rules and then running flush only once.

Synopsys

flush ns simpleacl -estSessions

Arguments

estSessions

show ns simpleacl

Displays settings of all the simple ACL rules or of the specified simple ACL rule. To display settings of all the simple ACL rules, run the command without any parameters. To display settings of a particular simple ACL rule, specify the name of the simple ACL rule.

Synopsys

show ns simpleacl [<aclname>]

Arguments

aclname

Name of the simple ACL rule whose details you want the NetScaler appliance to display.

summary

fullValues

format

level

Outputs

aclaction

Drop incoming IPv4 packets that match the simple ACL rule.

td

Traffic Domain Id.

srcIP

Source IP address.

stateflag

SACL state flag.

destPort

Destination Port.

protocol

Protocol associated with the ACL rule.

TTL

Time to expire this ACL rule(in seconds).

time

Time when this acl is added.

hits

Number of hits for this ACL rule.

devno

count

Example

```
show simpleacl rule1  Name: rule1                Action: DENY  srcIP = 10.102.1.150  Protocol = TCP                DestPort = 110  Hits:
```

stat ns simpleacl

Displays statistics related to the simple ACL rules.

Synopsys

stat ns simpleacl [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

SimpleACL hits (SACLHits)

Packets matching a SimpleACL.

SimpleACL misses (SACLMiss)

Packets not matching any SimpleACL.

SimpleACLs count (SACLsCount)

Number of SimpleACLs configured.

Allow SimpleACL hits (SACLAllow)

Total packets that matched a SimpleACL with action ALLOW and got consumed by NetScaler.

Bridge SimpleACL hits (SACLBdg)

Total packets that matched a SimpleACL with action BRIDGE and got bridged by NetScaler.

Deny SimpleACL hits (SACLDeny)

Packets dropped because they match SimpleACL (Access Control List) with processing mode set to DENY.

Example

stat simpleacl

ns simpleacl6

Sep 22, 2015

The following operations can be performed on "ns simpleacl6":

add | clear | flush | rm | show | stat

add ns simpleacl6

Adds a simple ACL6 rule to the NetScaler appliance. Simple ACL6 rules filter IPv6 packets on the basis of their source IP addresses and, optionally, the destination port and/or protocol. Any packet with the characteristics specified in the simple ACL6 rule is dropped.

Synopsys

add ns simpleacl6 <aclname> [-td <positive_integer>] <aclaction> -srcIPv6 <ipv6_addr|null> [-destPort <port> -protocol (TCP | UDP)] [-TTL <positive_integer>]

Arguments

aclname

Name for the simple ACL6 rule. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the simple ACL6 rule is created.

td

Traffic Domain Id.

Maximum value: 4094

aclaction

Drop incoming IPv6 packets that match the simple ACL6 rule.

Possible values: DENY

srcIPv6

IP address to match against the source IP address of an incoming IPv6 packet.

destPort

Port number to match against the destination port number of an incoming IPv6 packet.

Omitting the port number creates an all-ports simple ACL6 rule, which matches any port. In that case, you cannot create another simple ACL6 rule specifying a specific port and the same source IPv6 address.

TTL

Number of seconds, in multiples of four, after which the simple ACL6 rule expires. If you do not want the simple ACL6 rule to expire, do not specify a TTL value.

Minimum value: 4

Maximum value: 2147483647

Example

```
add simpleacl6 rule1 DENY -srcIP6 fe80::2c0:95ff:fec5:d9b8 -destPort 80 -protocol TCP add simpleacl rule2 DENY -srcIP6 3ffe:100:100::1 -TTL 600
```

---

clear ns simpleacl6

Removes all simple ACL6 rules from the NetScaler appliance.

Synopsys

clear ns simpleacl6

Example

```
clear ns simpleacl6
```

---

flush ns simpleacl6

Terminates all established IPv6 connections that match any of the newly configured simple ACL6 rules. Note: If you plan to create more than one simple ACL6 rule and flush existing connections that match any of them, you can minimize the affect on performance by first creating all of the simple ACL6 rules and then running flush only once.

Synopsys

flush ns simpleacl6 -estSessions

Arguments

estSessions

---

rm ns simpleacl6

Removes a simple ACL6 rule from the NetScaler appliance.

Synopsys

rm ns simpleacl6 <aclname> ...

Arguments

aclname

Name of the simple ACL6 rule that you want to remove.

Example

```
rm ns simpleacl6 rule1
```

---

show ns simpleacl6

Displays settings of all the simple ACL6 rules or of the specified simple ACL6 rule. To display settings of all the simple ACL6 rules, run the command without any parameters. To display settings of a particular simple ACL6 rule, specify the name of the simple ACL6 rule.

Synopsys

show ns simpleacl6 [<aclname>]

Arguments

aclname

Name of the simple ACL6 rule whose settings you want the NetScaler appliance to display.

summary

fullValues

format

level

Outputs

aclaction

Action associated with the SACL6 rule.

td

Traffic Domain Id.

srcIPv6

Source IP6 address.

stateflag

SACL6 state flag.

destPort

Destination Port.

protocol

Protocol associated with the ACL rule.

TTL

Time to expire this ACL rule(in seconds).

hits

Number of hits for this SACL6 rule.

time

Time when this acl is added.

devno

count

Example

```
show simpleacl6 rule1  Name: rule1    Action: DENY              Hits: 5  srcIP6 = 3ffe:100:100::1  Protocol = TCP             DestPort
```

---

stat ns simpleacl6

Displays statistics related to the simple ACL6 rules.

Synopsys

stat ns simpleacl6 [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

SimpleACL6 hits (SACL6Hits)

Packets matching a SimpleACL6.

SimpleACL6 misses (SACL6Miss)

Packets not matching any SimpleACL6.

SimpleACLs6 count (SACL6sCount)

Number of SimpleACL6s configured.

Allow SimpleACL6 hits (SACL6Allow)

Total packets that matched a SimpleACL6 with action ALLOW and got consumed by NetScaler.

Bridge SimpleACL6 hits (SACL6Bdg)

Total packets that matched a SimpleACL6 with action BRIDGE and got bridged by NetScaler.

Deny SimpleACL6 hits (SACL6Deny)

Packets dropped because they match SimpleACL6 with processing mode set to DENY.

Example

stat simpleacl6

ns spParams

Sep 22, 2015

The following operations can be performed on "ns spParams":

set | unset | show

set ns spParams

Sets surge protection attributes on the appliance.

Synopsys

set ns spParams [-baseThreshold <integer>] [-throttle <throttle>]

Arguments

baseThreshold

Maximum number of server connections that can be opened before surge protection is activated.

Default value: 200

Maximum value: 32767

throttle

Rate at which the system opens connections to the server.

Possible values: Aggressive, Normal, Relaxed

Default value: NORM_SP_TABLE

Example

```
set ns spparams -baseThreshold 1000 -throttle aggressive set ns spparams -throttle relaxed
```

---

unset ns spParams

Use this command to remove ns spParams settings.Refer to the set ns spParams command for meanings of the arguments.

Synopsys

```
unset ns spParams [-baseThreshold] [-throttle]
```

---

show ns spParams

Displays the surge protection configuration on the appliance. Surge protection parameters are set by using the 'set ns spParams' command.

Synopsys

show ns spParams

Arguments

format

level

Outputs

baseThreshold

The base threshold. This is the maximum number of server connections that can be open before surge protection is activated.

throttle

Rate at which the system opens connections to the server.

Table

Table.

Example

```
> show ns spparams   Surge Protection parameters:   BaseThreshold: 200   Throttle:  Normal   Done
```

ns stats

Sep 22, 2015

The following operations can be performed on "ns stats":

show | clear

show ns stats

show ns stats is an alias for stat ns

Synopsys

show ns stats - alias for 'stat ns'

---

clear ns stats

Clearing stats

Synopsys

clear ns stats <cleanuplevel>

Arguments

cleanuplevel

The level of stats to be cleared. 'global' option will clear global counters only, 'all' option will clear all device counters also along with global counters. For both the cases only 'ever incrementing counters' i.e. total counters will be cleared.

Possible values: global, all

---

ns surgeQ

Sep 22, 2015

The following operations can be performed on "ns surgeQ":

flush ns surgeQ

Flushes the connections that are waiting in SurgeQ. SurgeQ contains the client connections waiting for a server connection.

Synopsys

flush ns surgeQ [-name <string> [-serverName <string> <port>]]

Arguments

name

Name of a virtual server, service or service group for which the SurgeQ must be flushed.

serverName

Name of a service group member. This argument is needed when you want to flush the SurgeQ of a service group.

Example

To flush the surgeQ system wide, use the command: flush ns SurgeQ. To flush the surgeQ specific to a vserver/service/svcgrp use the command: flush ns SurgeQ -name <n

ns tcpParam

Sep 22, 2015

The following operations can be performed on "ns tcpParam":

set | unset | show

set ns tcpParam

Sets the TCP parameters for the NetScaler appliance.

Synopsys

set ns tcpParam [-WS (ENABLED | DISABLED)] [-WSVal <positive_integer>] [-SACK (ENABLED | DISABLED)] [-learnVsvrMSS (ENABLED | DISABLED)] [-maxBurst <positive_integer>] [-initialCwnd <positive_integer>] [-delayedAck <positive_integer>] [-downStateRST (ENABLED | DISABLED)] [-nagle (ENABLED | DISABLED)] [-limitedPersist (ENABLED | DISABLED)] [-oooQSize <positive_integer>] [-ackOnPush (ENABLED | DISABLED)] [-maxPktPerMss <integer>] [-pktPerRetx <integer>] [-minRTO <integer>] [-slowStartIncr <integer>] [-maxDynServerProbes <positive_integer>] [-synHoldFastGiveup <positive_integer>] [-maxSynholdPerprobe <positive_integer>] [-maxSynhold <positive_integer>] [-mssLearnInterval <positive_integer>] [-mssLearnDelay <positive_integer>] [-maxTimeWaitConn <positive_integer>] [-maxSynAckRetx <positive_integer>] [-synAttackDetection (ENABLED | DISABLED)] [-connFlushIfNoMem <connFlushIfNoMem>] [-connFlushThres <positive_integer>] [-mptcpConCloseOnPassiveSF (ENABLED | DISABLED)] [-mptcpChecksum (ENABLED | DISABLED)] [-mptcpSFtimeout <secs>] [-mptcpSFReplaceTimeout <secs>] [-mptcpMaxSF <positive_integer>] [-mptcpMaxPendingSF <positive_integer>] [-mptcpPendingJoinThreshold <positive_integer>] [-mptcpRTOsToSwitchSF <positive_integer>] [-mptcpUseBackupOnDSS (ENABLED | DISABLED)] [-TcpMaxRetries <positive_integer>] [-mptcpImmediateSFCloseOnFIN (ENABLED | DISABLED)]

Arguments

WS

Enable or disable window scaling.

Possible values: ENABLED, DISABLED

Default value: DISABLED

WSVal

Factor used to calculate the new window size.

This argument is needed only when the window scaling is enabled.

Default value: 4

Maximum value: 14

SACK

Enable or disable Selective ACKnowledgement (SACK).

Possible values: ENABLED, DISABLED

Default value: DISABLED

learnVsvrMSS

Enable or disable maximum segment size (MSS) learning for virtual servers.

Possible values: ENABLED, DISABLED

Default value: DISABLED

maxBurst

Maximum number of TCP segments allowed in a burst.

Default value: 6

Minimum value: 1

Maximum value: 255

initialCwnd

Initial maximum upper limit on the number of TCP packets that can be outstanding on the TCP link to the server.

Default value: 4

Minimum value: 1

Maximum value: 44

recvBuffSize

TCP Receive buffer size

Default value: 8190

Minimum value: 8190

Maximum value: 20971520

delayedAck

Timeout for TCP delayed ACK, in milliseconds.

Default value: 100

Minimum value: 10

Maximum value: 300

downStateRST

Flag to switch on RST on down services.

Possible values: ENABLED, DISABLED

Default value: DISABLED

nagle

Enable or disable the Nagle algorithm on TCP connections.

Possible values: ENABLED, DISABLED

Default value: DISABLED

limitedPersist

Limit the number of persist (zero window) probes.

Possible values: ENABLED, DISABLED

Default value: ENABLED

oooQSize

Maximum size of out-of-order packets queue. A value of 0 means infinite.

Default value: 64

Maximum value: 65535

ackOnPush

Send immediate positive acknowledgement (ACK) on receipt of TCP packets when doing Web 2.0 PUSH.

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxPktPerMss

Maximum number of TCP packets allowed per maximum segment size (MSS).

Maximum value: 1460

pktPerRetx

Maximum limit on the number of packets that should be retransmitted on receiving a partial ACK.

Default value: 1

Minimum value: 1

Maximum value: 100

minRTO

Minimum retransmission timeout, in milliseconds, specified in 10-millisecond increments (value must yield a whole number if divided by 10).

Default value: 1000

Minimum value: 10

Maximum value: 64000

slowStartIncr

Multiplier that determines the rate at which slow start increases the size of the TCP transmission window after each acknowledgement of successful transmission.

Default value: 2

Minimum value: 1

Maximum value: 100

maxDynServerProbes

Maximum number of probes that NetScaler can send out in 10 milliseconds, to dynamically learn a service. NetScaler probes for the existence of the origin in case of wildcard virtual server or services.

Default value: 7

Minimum value: 1

Maximum value: 65535

synHoldFastGiveup

Maximum threshold. After crossing this threshold number of outstanding probes for origin, the NetScaler reduces the number of connection retries for probe connections.

Default value: 1024

Minimum value: 256

Maximum value: 65535

maxSynholdPerprobe

Limit the number of client connections (SYN) waiting for status of single probe. Any new SYN packets will be dropped.

Default value: 128

Minimum value: 1

Maximum value: 255

maxSynhold

Limit the number of client connections (SYN) waiting for status of probe system wide. Any new SYN packets will be dropped.

Default value: 16384

Minimum value: 256

Maximum value: 65535

mssLearnInterval

Duration, in seconds, to sample the Maximum Segment Size (MSS) of the services. The NetScaler appliance determines the best MSS to set for the virtual server based on this sampling. The argument to enable maximum segment size (MSS) for virtual servers must be enabled.

Default value: 180

Minimum value: 1

Maximum value: 1048576

mssLearnDelay

Frequency, in seconds, at which the virtual servers learn the Maximum segment size (MSS) from the services. The argument to enable maximum segment size (MSS) for virtual servers must be enabled.

Default value: 3600

Minimum value: 1

Maximum value: 1048576

maxTimeWaitConn

Maximum number of connections to hold in the TCP TIME_WAIT state. New connections entering TIME_WAIT state are proactively cleaned up.

Default value: 7000

Minimum value: 1

KAprobeUpdateLastactivity

Update last activity for KA probes

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxSynAckRetx

When 'syncookie' is disabled in the TCP profile that is bound to the virtual server or service, and the number of TCP SYN+ACK retransmission by NetScaler for that virtual server or service crosses this threshold, the NetScaler appliance responds by using the TCP SYN-Cookie mechanism.

Default value: 100

Minimum value: 100

Maximum value: 1048576

synAttackDetection

Detect TCP SYN packet flood and send an SNMP trap.

Possible values: ENABLED, DISABLED

Default value: ENABLED

connFlushIfNoMem

Flush an existing connection if no memory can be obtained for new connection.

HALF_CLOSED_AND_IDLE: Flush a connection that is closed by us but not by peer, or failing that, a connection that is past configured idle time. New connection fails if no such connection can be found.

FIFO: If no half-closed or idle connection can be found, flush the oldest non-management connection, even if it is active. New connection fails if the oldest few connections are management connections.

Note: If you enable this setting, you should also consider lowering the zombie timeout and half-close timeout (see NSCLI command: set ns timeout).

See Also: connFlushThres argument below.

Possible values: NONE, HALFCLOSED_AND_IDLE, FIFO

Default value: NSA_CONNFLUSH_NONE

connFlushThres

Flush an existing connection (as configured through -connFlushIfNoMem FIFO) if the system has more than specified number of connections, and a new connection is to be established. Note: This value may be rounded down to be a whole multiple of the number of packet engines running.

Minimum value: 1

mptcpConCloseOnPassiveSF

Accept DATA_FIN/FAST_CLOSE on passive subflow

Possible values: ENABLED, DISABLED

Default value: ENABLED

mptcpChecksum

Use MPTCP DSS checksum

Possible values: ENABLED, DISABLED

Default value: ENABLED

mptcpSFtimeout

The timeout value in seconds for idle mptcp subflows. If this timeout is not set, idle subflows are cleared after cltTimeout of vserver

Maximum value: 31536000

mptcpSFReplaceTimeout

The minimum idle time value in seconds for idle mptcp subflows after which the sublow is replaced by new incoming subflow if maximum subflow limit is reached. The priority for replacement is given to those subflow without any transaction

Default value: 10

Maximum value: 31536000

mptcpMaxSF

Maximum number of subflow connections supported in established state per mptcp connection.

Default value: 4

Minimum value: 2

Maximum value: 6

mptcpMaxPendingSF

Maximum number of subflow connections supported in pending join state per mptcp connection.

Default value: 4

Maximum value: 4

mptcpPendingJoinThreshold

Maximum system level pending join connections allowed.

Maximum value: 4294967294

mptcpRTOsToSwitchSF

Number of RTO's at subflow level, after which MPCTP should start using other subflow.

Default value: 2

Minimum value: 1

Maximum value: 6

mptcpUseBackupOnDSS

When enabled, if NS receives a DSS on a backup subflow, NS will start using that subflow to send data. And if disabled, NS will continue to transmit on current chosen subflow. In case there is some error on a subflow (like RTO's/RST etc.) then NS can choose a backup subflow irrespective of this tunable.

Possible values: ENABLED, DISABLED

Default value: ENABLED

TcpMaxRetries

Number of RTO's after which a connection should be freed.

Default value: 7

Minimum value: 1

Maximum value: 7

mptcpImmediateSFCloseOnFIN

Allow subflows to close immediately on FIN before the DATA_FIN exchange is completed at mptcp level.

Possible values: ENABLED, DISABLED

Default value: DISABLED

---

unset ns tcpParam

Use this command to remove ns tcpParam settings.Refer to the set ns tcpParam command for meanings of the arguments.

Synopsys

unset ns tcpParam [-WS] [-WSVal] [-SACK] [-learnVsvrMSS] [-maxBurst] [-initialCwnd] [-delayedAck] [-downStateRST] [-nagle] [-limitedPersist] [-oooQSize] [-ackOnPush] [-maxPktPerMss] [-pktPerRetx] [-minRTO] [-slowStartIncr] [-maxDynServerProbes] [-synHoldFastGiveup] [-maxSynholdPerprobe] [-maxSynhold] [-mssLearnInterval] [-mssLearnDelay] [-maxTimeWaitConn] [-maxSynAckRetx] [-synAttackDetection] [-connFlushIfNoMem] [-connFlushThres] [-mptcpConCloseOnPassiveSF] [-mptcpChecksum] [-mptcpSFtimeout] [-mptcpSFReplaceTimeout] [-mptcpMaxSF] [-mptcpMaxPendingSF] [-mptcpPendingJoinThreshold] [-mptcpRTOsToSwitchSF] [-mptcpUseBackupOnDSS] [-TcpMaxRetries] [-mptcpImmediateSFCloseOnFIN]

---

show ns tcpParam

Displays the TCP parameters configured on the NetScaler appliance.

Synopsys

show ns tcpParam

Arguments

format

level

Outputs

WS

Enable or disable window scaling.

WSVal

Factor used to calculate the new window size.

This argument is needed only when the window scaling is enabled.

SACK

Enable or disable Selective ACKnowledgement (SACK).

learnVsvrMSS

Enable or disable maximum segment size (MSS) learning for virtual servers.

maxBurst

Maximum number of TCP segments allowed in a burst.

initialCwnd

Initial maximum upper limit on the number of TCP packets that can be outstanding on the TCP link to the server.

recvBuffSize

TCP Receive buffer sizeNOTE: This attribute is deprecated.This option is deprecated in favour of -buffersize

delayedAck

Timeout for TCP delayed ACK, in milliseconds.

downStateRST

Flag to switch on RST on down services.

nagle

Enable or disable the Nagle algorithm on TCP connections.

limitedPersist

Limit the number of persist (zero window) probes.

oooQSize

Maximum size of out-of-order packets queue. A value of 0 means infinite.

ackOnPush

Immediate ACK on PUSH packet

maxPktPerMss

Maximum packets per MSS

pktPerRetx

Maximum packets per retransmission

minRTO

Minimum retransmission timeout, in milliseconds, specified in 10-millisecond increments (value must yield a whole number if divided by 10).

slowStartIncr

TCP slowstart increment factor

maxDynServerProbes

Maximum number of probes that NetScaler can send out in 10 milliseconds, to dynamically learn a service. NetScaler probes for the existence of the origin in case of wildcard virtual server or services.

synHoldFastGiveup

Maximum threshold. After crossing this threshold number of outstanding probes for origin, the NetScaler reduces the number of connection retries for probe connections.

maxSynholdPerprobe

Limit the number of client connections (SYN) waiting for status of single probe. Any new SYN packets will be dropped.

maxSynhold

Limit the number of client connections (SYN) waiting for status of probe system wide. Any new SYN packets will be dropped.

mssLearnInterval

Duration, in seconds, to sample the Maximum Segment Size (MSS) of the services. The NetScaler appliance determines the best MSS to set for the virtual server based on this sampling. The argument to enable maximum segment size (MSS) for virtual servers must be enabled.

mssLearnDelay

Frequency, in seconds, at which the virtual servers learn the Maximum segment size (MSS) from the services. The argument to enable maximum segment size (MSS) for virtual servers must be enabled.

maxTimeWaitConn

Maximum number of connections to hold in the TCP TIME_WAIT state. New connections entering TIME_WAIT state are proactively cleaned up.

KAprobeUpdateLastactivity

Update last activity for KA probesNOTE: This attribute is deprecated.This option has been moved tcpProfile

maxSynAckRetx

When 'syncookie' is disabled in the TCP profile that is bound to the virtual server or service, and the number of TCP SYN+ACK retransmission by NetScaler for that virtual server or service crosses this threshold, the NetScaler appliance responds by using the TCP SYN-Cookie mechanism.

synAttackDetection

Detect TCP SYN packet flood and send an SNMP trap.

connFlushIfNoMem

Flush an existing connection if no memory can be obtained for new connection.

HALF_CLOSED_AND_IDLE: Flush a connection that is closed by us but not by peer, or failing that, a connection that is past configured idle time. New connection fails if no such connection can be found.

FIFO: If no half-closed or idle connection can be found, flush the oldest non-management connection, even if it is active. New connection fails if the oldest few connections are management connections.

Note: If you enable this setting, you should also consider lowering the zombie timeout and half-close timeout (see NSCLI command: set ns timeout).

See Also: connFlushThres argument below.

connFlushThres

Flush an existing connection (as configured through -connFlushIfNoMem FIFO) if the system has more than specified number of connections, and a new connection is to be established. Note: This value may be rounded down to be a whole multiple of the number of packet engines running.

mptcpConCloseOnPassiveSF

Accept DATA_FIN/FAST_CLOSE on passive subflow

mptcpChecksum

Use MPTCP DSS checksum

mptcpSFtimeout

The timeout value in seconds for idle mptcp subflows. If this timeout is not set, idle subflows are cleared after cltTimeout of vserver

mptcpSFReplaceTimeout

The minimum idle time value in seconds for idle mptcp subflows after which the sublow is replaced by new incoming subflow if maximum subflow limit is reached. The priority for replacement is given to those subflow without any transaction

mptcpMaxSF

Maximum number of subflow connections supported in established state per mptcp connection.

mptcpMaxPendingSF

Maximum number of subflow connections supported in pending join state per mptcp connection.

mptcpPendingJoinThreshold

Maximum system level pending join connections allowed.

mptcpRTOsToSwitchSF

Number of RTO's at subflow level, after which MPCTP should start using other subflow.

mptcpUseBackupOnDSS

When enabled, if NS receives a DSS on a backup subflow, NS will start using that subflow to send data. And if disabled, NS will continue to transmit on current chosen subflow. In case there is some error on a subflow (like RTO's/RST etc.) then NS can choose a backup subflow irrespective of this tunable.

TcpMaxRetries

Number of RTO's after which a connection should be freed.

mptcpImmediateSFCloseOnFIN

Allow subflows to close immediately on FIN before the DATA_FIN exchange is completed at mptcp level.

ns tcpProfile

Sep 22, 2015

The following operations can be performed on "ns tcpProfile":

add | rm | set | unset | show

add ns tcpProfile

Adds a TCP profile to the NetScaler appliance.

Synopsys

add ns tcpProfile <name> [-WS (ENABLED | DISABLED)] [-SACK (ENABLED | DISABLED)] [-WSVal <positive_integer>] [-nagle (ENABLED | DISABLED)] [-ackOnPush (ENABLED | DISABLED)] [-mss <positive_integer>] [-maxBurst <positive_integer>] [-initialCwnd <positive_integer>] [-delayedAck <positive_integer>] [-oooQSize <positive_integer>] [-maxPktPerMss <positive_integer>] [-pktPerRetx <positive_integer>] [-minRTO <positive_integer>] [-slowStartIncr <positive_integer>] [-bufferSize <positive_integer>] [-synCookie (ENABLED | DISABLED)] [-KAprobeUpdateLastactivity (ENABLED | DISABLED)] [-flavor (Default | Westwood)] [-dynamicReceiveBuffering (ENABLED | DISABLED)] [-KA (ENABLED | DISABLED)] [-KAconnIdleTime <positive_integer>] [-KAmaxProbes <positive_integer>] [-KAprobeInterval <positive_integer>] [-sendBuffsize <positive_integer>] [-mptcp (ENABLED | DISABLED)] [-EstablishClientConn <EstablishClientConn>]

Arguments

name

Name for a TCP profile. Must begin with a letter, number, or the underscore \\(_\\) character. Other characters allowed, after the first character, are the hyphen \\(-\\), period \\(.\\), hash \\(\\#\\), space \\(\\), at \\(@\\), and equal \\(=\\) characters. The name of a TCP profile cannot be changed after it is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks \\(for example, "my tcp profile" or 'my tcp profile'\\).

WS

Enable or disable window scaling.

Possible values: ENABLED, DISABLED

Default value: DISABLED

SACK

Enable or disable Selective ACKnowledgement (SACK).

Possible values: ENABLED, DISABLED

Default value: DISABLED

WSVal

Factor used to calculate the new window size.

This argument is needed only when window scaling is enabled.

Default value: 4

Maximum value: 14

nagle

Enable or disable the Nagle algorithm on TCP connections.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ackOnPush

Send immediate positive acknowledgement (ACK) on receipt of TCP packets when doing Web 2.0 PUSH.

Possible values: ENABLED, DISABLED

Default value: ENABLED

mss

Maximum number of octets to allow in a TCP data segment.

Maximum value: 1460

maxBurst

Maximum number of TCP segments allowed in a burst.

Default value: 6

Minimum value: 1

Maximum value: 255

initialCwnd

Initial maximum upper limit on the number of TCP packets that can be outstanding on the TCP link to the server.

Default value: 4

Minimum value: 1

Maximum value: 44

delayedAck

Timeout for TCP delayed ACK, in milliseconds.

Default value: 100

Minimum value: 10

Maximum value: 300

oooQSize

Maximum size of out-of-order packets queue. A value of 0 means infinite.

Default value: 64

Maximum value: 65535

maxPktPerMss

Maximum number of TCP packets allowed per maximum segment size (MSS).

Maximum value: 1460

pktPerRetx

Maximum limit on the number of packets that should be retransmitted on receiving a partial ACK.

Default value: 1

Minimum value: 1

Maximum value: 512

minRTO

Minimum retransmission timeout, in milliseconds.

Default value: 1000

Minimum value: 10

Maximum value: 64000

slowStartIncr

Multiplier that determines the rate at which slow start increases the size of the TCP transmission window after each acknowledgement of successful transmission.

Default value: 2

Minimum value: 1

Maximum value: 100

bufferSize

TCP buffering size, in bytes.

Default value: 8190

Minimum value: 8190

Maximum value: 4194304

synCookie

Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the NetScaler appliance.

Possible values: ENABLED, DISABLED

Default value: ENABLED

KAprobeUpdateLastactivity

Update last activity for the connection after receiving keep-alive (KA) probes.

Possible values: ENABLED, DISABLED

Default value: ENABLED

flavor

Set TCP congestion control algorithm.

Possible values: Default, Westwood

Default value: NS_TCP_DEFAULT

dynamicReceiveBuffering

Enable or disable dynamic receive buffering. When enabled, allows the receive buffer to be adjusted dynamically based on memory and network conditions.

Note: The buffer size argument must be set for dynamic adjustments to take place.

Possible values: ENABLED, DISABLED

Default value: ENABLED

KA

Send periodic TCP keep-alive (KA) probes to check if peer is still up.

Possible values: ENABLED, DISABLED

Default value: DISABLED

KAconnIdleTime

Duration, in seconds, for the connection to be idle, before sending a keep-alive (KA) probe.

Default value: NSTCP_KA_DEFAULT_CONN_IDLETIME

Minimum value: 1

Maximum value: 4095

KAmaxProbes

Number of keep-alive (KA) probes to be sent when not acknowledged, before assuming the peer to be down.

Default value: NSTCP_KA_DEFAULT_PROBE_COUNT

Minimum value: 1

Maximum value: 255

KAprobeInterval

Time interval, in seconds, before the next keep-alive (KA) probe, if the peer does not respond.

Default value: NSTCP_KA_DEFAULT_INTERVAL

Minimum value: 1

Maximum value: 4095

sendBuffsize

TCP Send Buffer Size

Default value: 8190

Minimum value: 8190

Maximum value: 4194304

mptcp

Enable/Disable Multi-Path TCP

Possible values: ENABLED, DISABLED

Default value: DISABLED

EstablishClientConn

Establishing Client Client connection on First data/ Final-ACK / Automatic

Possible values: AUTOMATIC, CONN_ESTABLISHED, ON_FIRST_DATA

Default value: NS_CONN_AUTOMATIC

Example

```
add tcpprofile <profile name> -WS ENABLED -WSVAL 4
```

---

rm ns tcpProfile

Removes a TCP profile from the appliance.

Synopsys

rm ns tcpProfile <name>

Arguments

name

Name of the TCP profile to be removed.

Example

rm tcpprofile <profile name>

---

set ns tcpProfile

Modifies the attributes of a TCP profile.

Synopsys

set ns tcpProfile <name> [-WS (ENABLED | DISABLED)] [-SACK (ENABLED | DISABLED)] [-WSVal <positive_integer>] [-nagle (ENABLED | DISABLED)] [-ackOnPush (ENABLED | DISABLED)] [-mss <positive_integer>] [-maxBurst <positive_integer>] [-initialCwnd <positive_integer>] [-delayedAck <positive_integer>] [-oooQSize <integer>] [-maxPktPerMss <positive_integer>] [-pktPerRetx <positive_integer>] [-minRTO <positive_integer>] [-slowStartIncr <positive_integer>] [-bufferSize <positive_integer>] [-synCookie (ENABLED | DISABLED)] [-KAprobeUpdateLastactivity (ENABLED | DISABLED)] [-flavor (Default | Westwood)] [-dynamicReceiveBuffering (ENABLED | DISABLED)] [-KA (ENABLED | DISABLED)] [-KAconnIdleTime <positive_integer>] [-KAmaxProbes <positive_integer>] [-KAprobeInterval <positive_integer>] [-sendBuffsize <positive_integer>] [-mptcp (ENABLED | DISABLED)] [-EstablishClientConn <EstablishClientConn>]

Arguments

name

Name of the TCP profile to be modified.

WS

Enable or disable window scaling.

Possible values: ENABLED, DISABLED

Default value: DISABLED

SACK

Enable or disable Selective ACKnowledgement (SACK).

Possible values: ENABLED, DISABLED

Default value: DISABLED

WSVal

Factor used to calculate the new window size.

This argument is needed only when window scaling is enabled.

Default value: 4

Maximum value: 14

nagle

Enable or disable the Nagle algorithm on TCP connections.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ackOnPush

Send immediate positive acknowledgement (ACK) on receipt of TCP packets when doing Web 2.0 PUSH.

Possible values: ENABLED, DISABLED

Default value: ENABLED

mss

Set Maximum Segment Size(MSS) to use for TCP Connection(0 forces use of global setting)

Maximum value: 1460

maxBurst

Maximum number of TCP segments allowed in a burst.

Default value: 6

Minimum value: 1

Maximum value: 255

initialCwnd

Initial maximum upper limit on the number of TCP packets that can be outstanding on the TCP link to the server.

Default value: 4

Minimum value: 1

Maximum value: 44

delayedAck

Timeout for TCP delayed ACK, in milliseconds.

Default value: 100

Minimum value: 10

Maximum value: 300

oooQSize

Maximum size of out-of-order packets queue. A value of 0 means infinite.

Default value: 64

Maximum value: 65535

maxPktPerMss

Maximum number of TCP packets allowed per maximum segment size (MSS).

Maximum value: 1460

pktPerRetx

Maximum limit on the number of packets that should be retransmitted on receiving a partial ACK.

Default value: 1

Minimum value: 1

Maximum value: 512

minRTO

Minimum retransmission timeout, in milliseconds.

Default value: 1000

Minimum value: 10

Maximum value: 64000

slowStartIncr

Multiplier that determines the rate at which slow start increases the size of the TCP transmission window after each acknowledgement of successful transmission.

Default value: 2

Minimum value: 1

Maximum value: 100

bufferSize

TCP buffering size, in bytes.

Default value: 8190

Minimum value: 8190

Maximum value: 4194304

synCookie

Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the NetScaler appliance.

Possible values: ENABLED, DISABLED

Default value: ENABLED

KAprobeUpdateLastactivity

Update last activity for the connection after receiving keep-alive (KA) probes.

Possible values: ENABLED, DISABLED

Default value: ENABLED

flavor

Set TCP congestion control algorithm.

Possible values: Default, Westwood

Default value: NS_TCP_DEFAULT

dynamicReceiveBuffering

Enable or disable dynamic receive buffering. When enabled, allows the receive buffer to be adjusted dynamically based on memory and network conditions.

Note: The buffer size argument must be set for dynamic adjustments to take place.

Possible values: ENABLED, DISABLED

Default value: ENABLED

KA

Send periodic TCP keep-alive (KA) probes to check if peer is still up.

Possible values: ENABLED, DISABLED

Default value: DISABLED

KAconnIdleTime

Duration, in seconds, for the connection to be idle, before sending a keep-alive (KA) probe.

Default value: NSTCP_KA_DEFAULT_CONN_IDLETIME

Minimum value: 1

Maximum value: 4095

KAmaxProbes

Number of keep-alive (KA) probes to be sent when not acknowledged, before assuming the peer to be down.

Default value: NSTCP_KA_DEFAULT_PROBE_COUNT

Minimum value: 1

Maximum value: 255

KAprobeInterval

Time interval, in seconds, before the next keep-alive (KA) probe, if the peer does not respond.

Default value: NSTCP_KA_DEFAULT_INTERVAL

Minimum value: 1

Maximum value: 4095

sendBuffsize

TCP Send Buffer Size

Default value: 8190

Minimum value: 8190

Maximum value: 4194304

mptcp

Enable/Disable Multi-Path TCP

Possible values: ENABLED, DISABLED

Default value: DISABLED

EstablishClientConn

Establishing Client Client connection on First data/ Final-ACK / Automatic

Possible values: AUTOMATIC, CONN_ESTABLISHED, ON_FIRST_DATA

Default value: NS_CONN_AUTOMATIC

Example

```
set tcpprofile <profile name> -WS ENABLED -WSVAL 4
```

---

unset ns tcpProfile

Removes the attributes of the TCP profile. Attributes for which a default value is available revert to their default values. Refer to the 'set ns tcpProfile' command for a description of the parameters..Refer to the set ns tcpProfile command for

meanings of the arguments.

Synopsys

unset ns tcpProfile <name> [-WS] [-SACK] [-WSVal] [-nagle] [-ackOnPush] [-mss] [-maxBurst] [-initialCwnd] [-delayedAck] [-oooQSize] [-maxPktPerMss] [-pktPerRetx] [-minRTO] [-slowStartIncr] [-bufferSize] [-synCookie] [-KAprobeUpdateLastactivity] [-flavor] [-dynamicReceiveBuffering] [-KA] [-KAmaxProbes] [-KAconnIdleTime] [-KAprobeInterval] [-sendBuffsize] [-mptcp] [-EstablishClientConn]

---

show ns tcpProfile

Displays information about TCP profiles configured on the appliance.

Synopsys

show ns tcpProfile [<name>]

Arguments

name

Name of the TCP profile to be displayed. If a name is not provided, information about all TCP profiles is shown.

summary

fullValues

format

level

Outputs

WS

Enable or disable window scaling.

SACK

Enable or disable Selective ACKnowledgement (SACK).

WSVal

Factor used to calculate the new window size.

This argument is needed only when window scaling is enabled.

nagle

Enable or disable the Nagle algorithm on TCP connections.

ackOnPush

Send immediate positive acknowledgement (ACK) on receipt of TCP packets when doing

Web 2.0 PUSH.

mss

Maximum Segment Size(MSS) to use for TCP Connection(0 forces use of global setting)

maxBurst

Maximum number of TCP segments allowed in a burst.

initialCwnd

Initial maximum upper limit on the number of TCP packets that can be outstanding on the TCP link to the server.

delayedAck

Timeout for TCP delayed ACK, in milliseconds.

oooQSize

Maximum size of out-of-order packets queue. A value of 0 means infinite.

maxPktPerMss

Maximum packet per MSS value

pktPerRetx

Maximum limit on the number of packets that should be retransmitted on receiving a partial ACK.

minRTO

TCP minimum RTO (in millisec)

slowStartIncr

TCP slowstart increment factor

bufferSize

TCP Buffer size

flavor

TCP algorithm

refCnt

Number of entities using this profile

synCookie

Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the NetScaler appliance.

KAprobeUpdateLastactivity

Update last activity for the connection after receiving keep-alive (KA) probes.

dynamicReceiveBuffering

Enable or disable dynamic receive buffering. When enabled, allows the receive buffer to be adjusted dynamically based on memory and network conditions.

Note: The buffer size argument must be set for dynamic adjustments to take place.

KA

Send periodic TCP keep-alive (KA) probes to check if peer is still up.

KAconnIdleTime

Duration, in seconds, for the connection to be idle, before sending a keep-alive (KA) probe.

KAmaxProbes

Number of keep-alive (KA) probes to be sent when not acknowledged, before assuming the peer to be down.

KAprobeInterval

Time interval, in seconds, before the next keep-alive (KA) probe, if the peer does not respond.

sendBuffsize

TCP Send Buffer size

mptcp

Enable/Disable Multi-Path TCP

EstablishClientConn

Allocating Client Connection On

Example

```
show tcp profile [profile name]
```

ns tcpbufParam

Sep 22, 2015

The following operations can be performed on "ns tcpbufParam":

set | unset | show

set ns tcpbufParam

Sets the attributes for the TCP buffering per connection.

Synopsys

set ns tcpbufParam [-size <KBytes>] [-memLimit <MBytes>]

Arguments

size

TCP buffering size per connection, in kilobytes.

Default value: 64

Minimum value: 4

Maximum value: 20480

memLimit

Maximum memory, in megabytes, that can be used for buffering.

Default value: 64

---

unset ns tcpbufParam

Use this command to remove ns tcpbufParam settings.Refer to the set ns tcpbufParam command for meanings of the arguments.

Synopsys

unset ns tcpbufParam [-size] [-memLimit]

---

show ns tcpbufParam

Displays the TCP buffering configuration on the appliance.

Synopsys

show ns tcpbufParam

Arguments

format

level

Outputs

size

TCP buffering size per connection, in kilobytes.

memLimit

Maximum memory, in megabytes, that can be used for buffering.

Example

An example of this command's output is as follows: TCP buffer size: 64KBytes TCP buffer percentage: 50%

ns timeout

Sep 22, 2015

The following operations can be performed on "ns timeout":

set | unset | show

set ns timeout

Sets timeout values for various aspects of the NetScaler appliance. Caution: Modifying these values can affect system performance.

Synopsys

set ns timeout [-zombie <positive_integer>] [-httpClient <positive_integer>] [-httpServer <positive_integer>] [-tcpClient <positive_integer>] [-tcpServer <positive_integer>] [-anyClient <positive_integer>] [-anyServer <positive_integer>] [-halfclose <positive_integer>] [-nontcpZombie <positive_integer>] [-ReducedFinTimeOut <positive_integer>] [-NewConnIdleTimeOut <positive_integer>]

Arguments

zombie

Interval, in seconds, at which the NetScaler zombie cleanup process must run. This process cleans up inactive TCP connections.

Default value: 120

Minimum value: 1

Maximum value: 600

client

Client idle timeout (in seconds). If zero, the service-type default value is taken when service is created.

Maximum value: 18000

server

Server idle timeout (in seconds). If zero, the service-type default is taken when service is created.

Maximum value: 18000

httpClient

Global idle timeout, in seconds, for client connections of HTTP service type. This value is over ridden by the client timeout that is configured on individual entities.

Maximum value: 18000

httpServer

Global idle timeout, in seconds, for server connections of HTTP service type. This value is over ridden by the server timeout that is configured on individual entities.

Maximum value: 18000

tcpClient

Global idle timeout, in seconds, for non-HTTP client connections of TCP service type. This value is over ridden by the client timeout that is configured on individual entities.

Maximum value: 18000

tcpServer

Global idle timeout, in seconds, for non-HTTP server connections of TCP service type. This value is over ridden by the server timeout that is configured on entities.

Maximum value: 18000

anyClient

Global idle timeout, in seconds, for non-TCP client connections. This value is over ridden by the client timeout that is configured on individual entities.

Maximum value: 31536000

anyServer

Global idle timeout, in seconds, for non TCP server connections. This value is over ridden by the server timeout that is configured on individual entities.

Maximum value: 31536000

halfclose

Idle timeout, in seconds, for connections that are in TCP half-closed state.

Default value: 10

Minimum value: 1

Maximum value: 600

nontcpZombie

Interval at which the zombie clean-up process for non-TCP connections should run. Inactive IP NAT connections will be cleaned up.

Default value: 60

Minimum value: 1

Maximum value: 600

ReducedFinTimeOut

Alternative idle timeout for new TCP NATPCB connections.

Default value: 30

Minimum value: 1

Maximum value: 300

NewConnIdleTimeOut

Timer interval(in seconds) for new NATPCB for tcp connections.

Default value: 4

Minimum value: 1

Maximum value: 120

Example

```
set ns timeout -zombie 200
```

---

unset ns timeout

Use this command to remove ns timeout settings.Refer to the set ns timeout command for meanings of the arguments.

Synopsys

```
unset ns timeout [-zombie] [-httpClient] [-httpServer] [-tcpClient] [-tcpServer] [-anyClient] [-anyServer] [-halfclose] [-nontcpZombie] [-ReducedFinTimeOut] [-NewConnIdleTimeOut]
```

---

show ns timeout

Displays the timeouts configured for various NetScaler entities. Note: The timeouts having default values are not displayed.

Synopsys

```
show ns timeout
```

Arguments

format

level

Outputs

zombie

Timer interval(in seconds) for zombie process that cleanup inactive TCP connections

Minimum value: 1

Maximum value: 600

Default value: 120

client

Client idle timeout (in seconds). If zero, the service-type default value is taken when service is created.

server

Server idle timeout (in seconds). If zero, the service-type default is taken when service is created.

httpClient

HTTP client idle timeout (in seconds)

Minimum value: 0

Maximum value: 18000

httpServer

HTTP server idle timeout (in seconds)

Minimum value: 0

Maximum value: 18000

tcpClient

TCP client idle timeout (in seconds)

Minimum value: 0

Maximum value: 18000

tcpServer

TCP server idle timeout (in seconds)

Minimum value: 0

Maximum value: 18000

anyClient

ANY client idle timeout (in seconds)

Minimum value: 0

Maximum value: 31536000

anyServer

ANY server idle timeout (in seconds)

Minimum value: 0

Maximum value: 31536000

halfclose

Half-closed connection timeout (in seconds)

Minimum value: 1

Maximum value: 600

Default value: 10

nontcpZombie

Timer interval(in seconds) for zombie process that cleanup inactive IP NAT connections

Minimum value: 1

Maximum value: 600

Default value: 60

ReducedFinTimeOut

Timer interval(in seconds) for NATPCB for tcp flow

NewConnIdleTimeOut

Timer interval(in seconds) for new NATPCB for tcp connections

Example

```
show ns timeout
```

ns timer

Sep 22, 2015

The following operations can be performed on "ns timer":

add | rm | set | unset | bind | unbind | show | rename

add ns timer

Create a Timer.

Synopsys

add ns timer <name> (-interval <integer> [<unit>]) [-comment <string>]

Arguments

name

Timer name.

interval

The frequency at which the policies bound to this timer are invoked. The minimum value is 20 msec. The maximum value is 20940 in seconds and 349 in minutes

Default value: 5

Minimum value: 1

Maximum value: 20940000

comment

Comments associated with this timer.

Example

```
add timer policy timer -comment "Timer that would be invoked at interval 10 sec apart."
```

---

rm ns timer

Remove a Timer.

Synopsys

rm ns timer <name>

Arguments

name

Timer name.

Example

```
rm ns timer timer
```

---

set ns timer

Set a argument values for existing timer.

Synopsys

set ns timer <name> [-interval <integer>] [<unit>] [-comment <string>]

Arguments

name

Timer name.

interval

The frequency at which the policies bound to this timer are invoked. The minimum value is 20 msec. The maximum value is 20940 in seconds and 349 in minutes

Default value: 5

Minimum value: 1

Maximum value: 20940000

unit

Timer interval unit

Possible values: SEC, MIN

Default value: NSTMUNT_SEC

comment

Comments associated with this timer.

Example

```
set ns timer timer -comment "Timer that would be invoked at interval 20 sec apart."
```

---

unset ns timer

Unset comment for existing timer..Refer to the set ns timer command for meanings of the arguments.

Synopsys

unset ns timer <name> [-interval <integer>] [<unit>] [-comment <string>]

Example

```
unset ns timer timer -comment
```

---

bind ns timer

Defines the binding relation among timer, and timer policy.

Synopsys

bind ns timer <name> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-vServer <string>] [-sampleSize <positive_integer>] [-threshold <positive_integer>]

Arguments

name

Timer name.

policyName

The timer policy associated with the timer.

Example

i) bind ns timer timer_trigger -policyName timer_pol -priority 1 ii) bind ns timer timer_trigger -policyName timer_pol -priority 1

---

unbind ns timer

Unbind entities from timer

Synopsys

unbind ns timer <name> -policyName <string>

Arguments

name

Timer name.

policyName

The timer policy associated with the timer.

Example

unbind ns timer timer -policyName timer_pol

---

show ns timer

Display the Timer entities.

Synopsys

show ns timer [<name>]

Arguments

name

Timer name.

summary

fullValues

format

level

Outputs

interval

The frequency at which the policies bound to this timer are invoked. The minimum value is 20 msec. The maximum value is 20940 in seconds and 349 in minutes

unit

Timer interval unit

comment

Comments associated with this timer.

policyName

The timer policy associated with the timer.

priority

Specifies the priority of the timer policy.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

vServer

Name of the vserver which provides the context for the rule in timer policy. When not specified it is treated as a Global Default context.

sampleSize

Denotes the sample size. Sample size value of 'x' means that previous '(x - 1)' policy's rule evaluation results and the current evaluation result are present with the binding. For example, sample size of 10 means that there is a state of previous 9 policy evaluation results and also the current policy evaluation result.

threshold

Denotes the threshold. If the rule of the policy in the binding relation evaluates 'threshold size' number of times in 'sample size' to true, then the corresponding action is taken. Its value needs to be less than or equal to the sample size value.

stateflag

bindPolicyType

devno

count

---

rename ns timer

Rename a timer.

Synopsys

rename ns timer <name>@ <newName>@

Arguments

name

The name of the timer.

newName

The new name of the timer.

Example

rename ns timer oldname newname

---

ns trafficDomain

Sep 22, 2015

The following operations can be performed on "ns trafficDomain":

add | rm | clear | bind | unbind | enable | disable | show | stat

add ns trafficDomain

Configure Traffic Domain on the system.

Synopsys

add ns trafficDomain <td> [-aliasName <string>]

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

aliasName

Name of traffic domain being added.

Example

```
add ns trafficDomain 1 -aliasName td1
```

---

rm ns trafficDomain

Remove Traffic Domain configured.

Synopsys

rm ns trafficDomain <td>

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

Example

```
rm ns trafficDomain 1
```

---

clear ns trafficDomain

Remove Traffic Domain configuration.

Synopsys

clear ns trafficDomain <td>

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

---

bind ns trafficDomain

bind vlan or bridgegroup entities with traffic domain.

Synopsys

bind ns trafficDomain <td> [-vlan <positive_integer>] [-bridgegroup <positive_integer>]

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

vlan

Names of all member vlans.

Minimum value: 1

Maximum value: 4094

bridgegroup

bridge group.

Minimum value: 1

Maximum value: 1000

Example

```
bind ns trafficDomain 1 -vlan 2
```

---

unbind ns trafficDomain

Unbind vlan or bridgegroup entities from traffic domain

Synopsys

```
unbind ns trafficDomain <td> [-vlan <positive_integer>] [-bridgegroup <positive_integer>]
```

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

vlan

Names of all member vlans.

Minimum value: 1

Maximum value: 4094

bridgegroup

bridge group.

Minimum value: 1

Maximum value: 1000

Example

```
unbind ns trafficDomain 1 -vlan 2
```

---

enable ns trafficDomain

Enable TrafficDomain.

Synopsys

```
enable ns trafficDomain <td> [-state ( ENABLED | DISABLED )]
```

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

state

The state of TrafficDmain.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Example

```
enable ns trafficdomain 1
```

---

disable ns trafficDomain

Disable TrafficDomain.

Synopsys

```
disable ns trafficDomain <td> [-state ( ENABLED | DISABLED )]
```

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

state

The state of TrafficDmain.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Example

```
disable ns trafficdomain 1
```

---

show ns trafficDomain

Display Traffic Domain configuration.

Synopsys

```
show ns trafficDomain [<td>]
```

Arguments

td

Traffic Domain Id.

Minimum value: 1

Maximum value: 4094

format

level

Outputs

aliasName

Name of traffic domain being added.

stateflag

Used internally for display.

vlan

Names of all member vlans.

bridgegroup

bridge group.

state

The state of TrafficDmain.

devno

count

Example

An example of the output of the show trafficDomain command is as follows: 1) Td: 1 Alias Name: State: ENABLED Vlans : 50 2) Td: 2 Ali

---

stat ns trafficDomain

Display statistics for Traffic Domains(s).

Synopsys

stat ns trafficDomain [<td>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

td

An integer specifying the Traffic Domain ID. Possible values: 1 through 4094.

Minimum value: 1

Maximum value: 4094

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Packets received (TdRxPkts)

Packets received on this TD.

Packets sent (TdTxPkts)

Packets transmitted from this TD.

Packets dropped (TdDropPkts)

Inbound packets dropped on this TD by reception.

Example

stat ns trafficdomain 1

---

ns version

Sep 22, 2015

The following operations can be performed on "ns version":

show ns version

Displays the version and build number of the appliance.

Synopsys

show ns version

Outputs

version

Version.

Mode

Kernel mode (KMPE/VMPE).

ns weblogparam

Sep 22, 2015

The following operations can be performed on "ns weblogparam":

set | unset | show

set ns weblogparam

Sets the Weblog parameters.

Synopsys

set ns weblogparam [-bufferSizeMB <positive_integer>] [-customReqHdrs <string> ...] [-customRspHdrs <string> ...]

Arguments

bufferSizeMB

Buffer size, in MB, allocated for log transaction data on the system. The maximum value is limited to the memory available on the system. Note: For the change in buffer size to take effect, you must disable and then re-enable the Web Server Logging feature on the appliance.

Default value: 16

Minimum value: 1

Maximum value: 4294967294LU

customReqHdrs

Name(s) of HTTP request headers whose values should be exported by the Web Logging feature. A maximum of two header names can be configured, with each header name having a maximum length of 31 characters.

customRspHdrs

Name(s) of HTTP response headers whose values should be exported by the Web Logging feature. A maximum of two header names can be configured, with each header name having a maximum length of 31 characters.

---

unset ns weblogparam

Use this command to remove ns weblogparam settings.Refer to the set ns weblogparam command for meanings of the arguments.

Synopsys

unset ns weblogparam [-bufferSizeMB] [-customReqHdrs] [-customRspHdrs]

---

show ns weblogparam

Displays the Weblog parameters.

Synopsys

show ns weblogparam

Arguments

format

level

Outputs

bufferSizeMB

Buffer size in MB.

customReqHdrs

Name(s) of HTTP request headers whose values should be exported by the Web Logging feature.

customRspHdrs

Name(s) of HTTP response headers whose values should be exported by the Web Logging feature.

ns xmlnamespace

Sep 22, 2015

The following operations can be performed on "ns xmlnamespace":

add | rm | set | unset | show

add ns xmlnamespace

Adds a mapping between an XML prefix and a namespace URI (Uniform Resource Identifier).

Synopsys

add ns xmlnamespace <prefix> <namespace>

Arguments

prefix

XML prefix.

namespace

Expanded namespace for which the XML prefix is provided.

Example

```
add ns xmlnamespace soap http://schemas.xmlsoap.org/soap/envelope/
```

---

rm ns xmlnamespace

Removes the mapping between an XML prefix and a namespace URI.

Synopsys

rm ns xmlnamespace <prefix>

Arguments

prefix

XML prefix for which the mapping must be removed.

Example

```
rm ns xmlnamespace soap
```

---

set ns xmlnamespace

Modifies the mapping between an XML prefix and a namespace URI.

Synopsys

set ns xmlnamespace <prefix> [<namespace>] [-description <string>]

Arguments

prefix

XML prefix for which the namespace or description must be added or updated.

namespace

Expanded namespace for which the XML prefix is provided.

description

Description for the prefix.

Example

```
set ns xmlnamespace soap -description SOAP/1.1
```

---

unset ns xmlnamespace

Use this command to remove ns xmlnamespace settings.Refer to the set ns xmlnamespace command for meanings of the arguments.

Synopsys

unset ns xmlnamespace <prefix> [-namespace] [-description]

---

show ns xmlnamespace

Displays the mappings between XML prefixes to namespace URIs.

Synopsys

show ns xmlnamespace [<prefix>]

Arguments

prefix

Name of the prefix for which the mappings must be displayed.

summary

fullValues

format

level

Outputs

namespace

Expanded namespace for which the XML prefix is provided.

description

Description for the prefix.

devno

count

stateflag

Example

```
show ns xmlnamespace soap
```

reboot

Sep 22, 2015

The following operations can be performed on "reboot":

Restarts the NetScaler appliance. Note: * When a standalone NetScaler appliance is rebooted, the unsaved configurations (configurations performed since the last 'save ns config' command was issued) are lost. * In the high availability mode, when the primary appliance is rebooted, the secondary system takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance. * In a cluster setup, this command can be executed only through the cluster IP address and it reboots only the configuration coordinator.

reboot [-warm]

warm

Restarts the NetScaler software without rebooting the underlying operating system. The session terminates and you must log on to the appliance after it has restarted.

Note: This argument is required only for nCore appliances. Classic appliances ignore this argument.

shutdown

Sep 22, 2015

The following operations can be performed on "shutdown":

Stops all operations and powers off the NetScaler appliance. Note: * When a standalone NetScaler appliance is shut down, the unsaved configurations (configurations performed since the last 'save ns config' command was issued) are lost. * In a high availability setup, when the primary appliance is shut down, the secondary appliance takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance. * In a cluster setup, this command can be executed only through the cluster IP address and it shuts down only the configuration coordinator.

shutdown

NTP Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- ntp param
- ntp server
- ntp status
- ntp sync

ntp param

Sep 22, 2015

The following operations can be performed on "ntp param":

set | unset | show

Modifies the values for NTP parameters on the NetScaler appliance.

set ntp param [-authentication (YES | NO)] [-trustedkey <positive_integer> ...] [-autokeyLogsec <positive_integer>] [-revokeLogsec <positive_integer>]

authentication

Apply NTP authentication, which enables the NTP client (NetScaler) to verify that the server is in fact known and trusted.

Possible values: YES, NO

Default value: YES

trustedkey

Key identifiers that are trusted for server authentication with symmetric key cryptography in the keys file.

Minimum value: 1

Maximum value: 65534

autokeyLogsec

Autokey protocol requires the keys to be refreshed periodically. This parameter specifies the interval between regenerations of new session keys. In seconds, expressed as a power of 2.

Default value: 12

Maximum value: 32

revokeLogsec

Interval between re-randomizations of the autokey seeds to prevent brute-force attacks on the autokey algorithms.

Default value: 16

Maximum value: 32

Use this command to remove ntp param settings.Refer to the set ntp param command for meanings of the arguments.

unset ntp param [-authentication] [-trustedkey] [-autokeyLogsec] [-revokeLogsec]

Displays information about the NTP parameters.

show ntp param

format

level

authentication

Apply NTP authentication, which enables the NTP client (NetScaler) to verify that the server is in fact known and trusted.

trustedkey

Key identifiers that are trusted for server authentication with symmetric key cryptography in the keys file.

autokeyLogsec

Autokey protocol requires the keys to be refreshed periodically. This parameter specifies the interval between regenerations of new session keys. In seconds, expressed as a power of 2.

revokeLogsec

Interval between re-randomizations of the autokey seeds to prevent brute-force attacks on the autokey algorithms.

---

ntp server

Sep 22, 2015

The following operations can be performed on "ntp server":

add | rm | set | unset | show

Adds an NTP server to the appliance. This server can be used to synchronize the time on the appliance to the network time.

add ntp server (<serverIP> | <serverName>) [-minpoll <positive_integer>] [-maxpoll <positive_integer>] [-autokey | -key <positive_integer>]

serverIP

IP address of the NTP server.

serverName

Fully qualified domain name of the NTP server.

minpoll

Minimum time after which the NTP server must poll the NTP messages. In seconds, expressed as a power of 2.

Default value: NS_NTP_MINPOLL_DEFAULT_VALUE

Minimum value: 4

Maximum value: 17

maxpoll

Maximum time after which the NTP server must poll the NTP messages. In seconds, expressed as a power of 2.

Default value: NS_NTP_MAXPOLL_DEFAULT_VALUE

Minimum value: 4

Maximum value: 17

autokey

Use the Autokey protocol for key management for this server, with the cryptographic values (for example, symmetric key, host and public certificate files, and sign key) generated by the ntp-keygen utility. To require authentication for communication with the server, you must set either the value of this parameter or the key parameter.

key

Key to use for encrypting authentication fields. All packets sent to and received from the server must include authentication fields encrypted by using this key. To require authentication for communication with the server, you must set either the value of this parameter or the autokey parameter.

Minimum value: 1

Maximum value: 65534

Removes an NTP server. You can specify the server by IP address or by name.

rm ntp server (<serverIP> | <serverName>)

serverIP

IP address of the NTP server to be removed.

serverName

Name of the NTP server to be removed.

Modifies the specified attributes of an NTP server.

set ntp server (<serverIP> | <serverName>) [-minpoll <positive_integer>] [-maxpoll <positive_integer>] [-preferredNtpServer (YES | NO)] [-autokey | -key <positive_integer>]

serverIP

IP address of the NTP server to be modified.

serverName

Name of the NTP server to be modified.

minpoll

Minimum time after which the NTP server must poll the NTP messages. In seconds, expressed as a power of 2.

Default value: NS_NTP_MINPOLL_DEFAULT_VALUE

Minimum value: 4

Maximum value: 17

maxpoll

Maximum time after which the NTP server must poll the NTP messages. In seconds, expressed as a power of 2.

Default value: NS_NTP_MAXPOLL_DEFAULT_VALUE

Minimum value: 4

Maximum value: 17

preferredNtpServer

Preferred NTP server. The NetScaler appliance chooses this NTP server for time synchronization among a set of correctly operating hosts.

Possible values: YES, NO

Default value: NO

autokey

Use the Autokey protocol for key management for this server, with the cryptographic values (for example, symmetric key, host and public certificate files, and sign key) generated by the ntp-keygen utility. To require authentication for communication with the server, you must set either the value of this parameter or the key parameter.

key

Key to use for encrypting authentication fields. All packets sent to and received from the server must include authentication fields encrypted by using this key. To require authentication for communication with the server, you must set either the value of this parameter or the autokey parameter.

Minimum value: 1

Maximum value: 65534

Use this command to remove ntp server settings.Refer to the set ntp server command for meanings of the arguments.

unset ntp server [<serverIP>] [<serverName>] [-minpoll] [-maxpoll] [-preferredNtpServer] [-autokey] [-key]

Displays information about an NTP server. You can specify the server by IP address or by name.

show ntp server [<serverIP> | <serverName>]

serverIP

IP address of the NTP server about which to display information.

serverName

Name of the NTP server about which to display information.

summary

fullValues

format

level

minpoll

Minimum poll interval of the server in secs.

maxpoll

Maximum poll interval of the server in secs.

preferredNtpServer

Preferred NTP server. The NetScaler appliance chooses this NTP server for time synchronization among a set of correctly operating hosts.

autokey

Use the Autokey protocol for key management for this server, with the cryptographic values (for example, symmetric key, host and public certificate files, and sign key) generated by the ntp-keygen utility. To require authentication for communication with the server, you must set either the value of this parameter or the key parameter.

key

Key to use for encrypting authentication fields. All packets sent to and received from the server must include authentication fields encrypted by using this key. To require authentication for communication with the server, you must set either the value of this parameter or the autokey parameter.

devno

count

stateflag

ntp status

Sep 22, 2015

The following operations can be performed on "ntp status":

Displays the NTP status on the appliance.

show ntp status

response

ntp sync

Sep 22, 2015

The following operations can be performed on "ntp sync":

enable | disable | show

Enables NTP synchronization. When NTP synchronization is enabled, the NTP daemon is spawned for time synchronization.

enable ntp sync

Disables NTP synchronization.

disable ntp sync

Displays the status of the NTP synchronization.

show ntp sync

state

Show NTP status

Policy Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- policy dataset
- policy evaluation
- policy expression
- policy httpCallout
- policy map
- policy patClass
- policy patset
- policy stringmap

policy dataset

Sep 22, 2015

The following operations can be performed on "policy dataset":

add | rm | bind | unbind | show

Adds a policy dataset to the appliance.

add policy dataset <name> <type> [-indexType (Auto-generated | User-defined)]

name

Name of the dataset. Must not exceed 127 characters.

type

Type of value to bind to the dataset.

Possible values: ipv4, number, ipv6

indexType

Index type.

```
add policy dataset ts1 -type IPV4
```

Removes a dataset from the appliance.

rm policy dataset <name>

name

Name of the dataset to remove.

```
rm policy dataset pat1
```

Binds a value of the specified type to the dataset. If the first value is bound by using an index label, the other bind statements to that set should also provide an index.

bind policy dataset <name> <value> [-index <positive_integer>]

name

Name of the dataset to which to bind the value.

value

Value of the specified type that is associated with the dataset.

```
bind policy dataset ts1 192.168.20.1 -index 2
```

Unbind string(s) from a dataset.

unbind policy dataset <name> <value>

name

Name of the dataset from which to unbind the value.

value

Value to unbind from the dataset.

```
unbind policy dataset pat1 bar xyz
```

Display the configured dataset(s).

show policy dataset [<name>]

name

Name of the dataset. Must not exceed 127 characters.

summary

fullValues

format

level

stateflag

value

Value of the specified type that is associated with the dataset.

index

The index of the value (ipv4, ipv6, number) associated with the set.

description

Description of the set

type

Type of value to bind to the dataset.

indexType

Index type.

MaxIndex

Maximum number of values bounded to dataset. The maxindex value will not be decreased when we unbind a value from the dataset. This field is used in auto-generated indexing type.

devno

count

show policy dataset set1

policy evaluation

Sep 22, 2015

The following operations can be performed on "policy evaluation":

Executes pixl expression or action and gives result. Result type can be zero or more of: -Bool -Num -Double -Unsigned long -String

show policy evaluation (-expression <expression> | -action <string>) -type <type> -input <string>

expression

Expression string. For example: http.req.body(100).contains("this").

action

Rewrite action name. Supported rewrite action types are:

-delete

-delete_all

-delete_http_header

-insert_after

-insert_after_all

-insert_before

-insert_before_all

-insert_http_header

-replace

-replace_all

type

Indicates request or response input packet

Possible values: HTTP_REQ, HTTP_RES, TEXT

input

Text representation of input packet.

summary

fullValues

stateflag

pitModifiedInputData

Text representation of packet after evaluating expression or rewrite action.

pitBoolResult

Result of the expression in bool format.

pitNumResult

Result of the expression in num format.

pitDoubleResult

Result of the expression in double format.

pitUlongResult

Result of the expression in unsigned long format.

pitRefResult

Result of the expression in string format.

isPitEmptyRefResult

Result of the expression is empty string.

pitOffsetResult

Offset of the resultant sting.

pitOffsetResultLen

Offset length of the resultant sting.

isTruncatedRefResult

Identify whether ref result is truncated result.

pitBoolEvalTime

Average evaluation time of bool type expression in nanoseconds.

pitNumEvalTime

Average evaluation time of num type expression in nanoseconds.

pitDoubleEvalTime

Average evaluation time of double type expression in nanoseconds.

pitUlongEvalTime

Average evaluation time of unsigned long type expression in nanoseconds.

pitRefEvalTime

Average evaluation time of string type expression in nanoseconds.

pitOffsetEvalTime

Average evaluation time in finding offset of the resultant string in the input. Time is in nanoseconds.

pitActionEvalTime

Average evaluation time of rewrite action in nanoseconds.

pitOperationPerformerArray

Details of the operation NS performed at various offsets during applying of rewrite action on input data. Operation can be insertion, modfication or deletion.

pitOldOffsetArray

Details of the offsets in the input data at which NS either inserted or modified or deleted data during applying of rewrite action.

pitNewOffsetArray

Details of the offsets in the output data at which NS either inserted or modified or deleted data during applying of rewrite action.

pitOffsetLengthArray

Details of the lengths of the data which NS either inserted or modified or deleted during applying of rewrite action.

pitBoolErrorResult

Result of the bool type expression if any error occurs during evaluation. Result will be in string format.

pitNumErrorResult

Result of the num type expression if any error occurs during evaluation. Result will be in string format.

pitDoubleErrorResult

Result of the double type expression if any error occurs during evaluation. Result will be in string format.

pitUlongErrorResult

Result of the unsigned long type expression if any error occurs during evaluation. Result will be in string format.

pitRefErrorResult

Result of the ref type expression if any error occurs during evaluation. Result will be in string format.

pitOffsetErrorResult

Result of the expression if any error occurs in calculating offset. Result will be in string format.

pitActionErrorResult

Result of the action if any error occurs in evaluation. Result will be in string format.

devno

count

Example 1: show policy evaluation -action rw_act_1 -type http_req -input 'GET / HTTP/1.1\\\\r\\\\nHost: abc.com\\\\r\\\\n\\\\r\\\\n' Example 2: show policy

policy expression

Sep 22, 2015

The following operations can be performed on "policy expression":

add | rm | set | unset | show

Creates a classic or default syntax named expression, which can be used in multiple policies. For example, you can create the following named expressions, ExpressionA and ExpressionB: ExpressionA: http.req.body(100).contains("A") ExpressionB: http.req.body(100).contains("B") You could then create an expression of the form: <ExpressionA || ExpressionB>

add policy expression <name> <value> [-comment <string>] [-clientSecurityMessage <string>]

name

Unique name for the expression. Not case sensitive. Must begin with an ASCII letter or underscore (_) character, and must consist only of ASCII alphanumeric or underscore characters. Must not begin with 're' or 'xp' or be a word reserved for use as a default syntax expression qualifier prefix (such as HTTP) or enumeration value (such as ASCII). Must not be the name of an existing named expression, pattern set, dataset, stringmap, or HTTP callout.

value

Expression string. For example: http.req.body(100).contains("this").

description

Description for the expression.

comment

Any comments associated with the expression. Displayed upon viewing the policy expression.

clientSecurityMessage

Message to display if the expression fails. Allowed for classic end-point check expressions only.

Removes a named policy expression. If the expression is used by a policy or filter, you must remove the policy or filter before removing the expression.

rm policy expression <name> ...

name

Name of the policy expression to be removed.

Modifies the attributes of a named policy expression.

```
set policy expression <name> [<value>] [-comment <string>] [-clientSecurityMessage <string>]
```

name

Name of the policy expression to be modified.

value

The expression string.

description

Description for the expression.

comment

Any comments associated with the expression. Displayed upon viewing the policy expression.

clientSecurityMessage

The client security message that will be displayed on failure of this expression. Only relevant for end point check expressions.

Use this command to remove policy expression settings.Refer to the set policy expression command for meanings of the arguments.

```
unset policy expression <name> [-comment] [-clientSecurityMessage]
```

Displays information about the available named policy expressions.

show policy expression [<name> | -type (CLASSIC | ADVANCED)]

name

Name of the policy expression to display. If a name is not provided, information about all policy expressions is shown.

type

Type of expression. Can be a classic or default syntax (advanced) expression.

Possible values: CLASSIC, ADVANCED

summary

fullValues

format

level

value

The expression string.

hits

The total number of hits.

piHits

The total number of hits.

type

The type of expression. This is for output only.

clientSecurityMessage

The client security message that will be displayed on failure of the client security check.

description

Description for the expression.NOTE: This attribute is deprecated.

comment

Any comments associated with the expression. Displayed upon viewing the policy expression.

stateflag

flag

isDefault

A value of true is returned if it is a default policy expression.

builtin

Indicates that a variable is a built-in (SYSTEM INTERNAL) type.

devno

count

policy httpCallout

Sep 22, 2015

The following operations can be performed on "policy httpCallout":

add | rm | set | unset | show

Adds a default syntax expression element that, when evaluated, sends an HTTP request to a specified service and receives an HTTP response from the service. Can be used to obtain additional information for use in evaluating policy rules and other expressions. This command only creates the HTTP callout. Use the 'set policy httpCallout' command to configure it.

add policy httpCallout <name>

name

Name for the HTTP callout. Not case sensitive. Must begin with an ASCII letter or underscore (_) character, and must consist only of ASCII alphanumeric or underscore characters. Must not begin with 're' or 'xp' or be a word reserved for use as a default syntax expression qualifier prefix (such as HTTP) or enumeration value (such as ASCII). Must not be the name of an existing named expression, pattern set, dataset, stringmap, or HTTP callout.

```
add policy httpcallout h1
```

Removes an HTTP callout. You cannot remove an HTTP callout that is used in any part of policy, action, or expression.

rm policy httpCallout <name>

name

Name of the HTTP callout to remove.

```
rm policy httpcallout h1
```

Configures an HTTP callout element. You can then invoke the HTTP callout from other policies and functions (for example, actions) that use default syntax expressions. The expression prefix SYS.HTTP_CALLOUT invokes an HTTP callout. You can construct the HTTP callout request in one of two ways: * Specify individual parts of the request by using the HTTP method, host expression, URL stem expression, and header parameters. These parts are evaluated at run time and concatenated to build the request. * Specify the entire HTTP request in a single expression.

set policy httpCallout <name> [-IPAddress <ip_addr|ipv6_addr>] [-port <port>] [-vServer <string>] [-returnType <returnType>] [-httpMethod (GET | POST)] [-hostExpr <string>] [-urlStemExpr <string>] [-headers <name(value)> ...] [-parameters <name(value)> ...] [-bodyExpr <string>] [-fullReqExpr <string>] [-scheme (http | https)] [-resultExpr <string>] [-cacheForSecs <secs>]

name

Name of the HTTP callout to configure.

IPAddress

IP Address of the server (callout agent) to which the callout is sent. Can be an IPv4 or IPv6 address.

Mutually exclusive with the Virtual Server parameter. Therefore, you cannot set the <IP Address, Port> and the Virtual Server in the same HTTP callout.

port

Server port to which the HTTP callout agent is mapped. Mutually exclusive with the Virtual Server parameter. Therefore, you cannot set the <IP Address, Port> and the Virtual Server in the same HTTP callout.

vServer

Name of the load balancing, content switching, or cache redirection virtual server (the callout agent) to which the HTTP callout is sent. The service type of the virtual server must be HTTP. Mutually exclusive with the IP address and port parameters. Therefore, you cannot set the <IP Address, Port> and the Virtual Server in the same HTTP callout.

returnType

Type of data that the target callout agent returns in response to the callout.

Available settings function as follows:

* TEXT - Treat the returned value as a text string.

* NUM - Treat the returned value as a number.

* BOOL - Treat the returned value as a Boolean value.

Note: You cannot change the return type after it is set.

Possible values: BOOL, NUM, TEXT

httpMethod

Method used in the HTTP request that this callout sends. Mutually exclusive with the full HTTP request expression.

Possible values: GET, POST

hostExpr

Default Syntax string expression to configure the Host header. Can contain a literal value (for example, 10.101.10.11) or a derived value (for example, http.req.header("Host")). The literal value can be an IP address or a fully qualified domain name. Mutually exclusive with the full HTTP request expression.

urlStemExpr

Default Syntax string expression for generating the URL stem. Can contain a literal string (for example, "/mysite/index.html") or an expression that derives the value (for example, http.req.url). Mutually exclusive with the full HTTP request expression.

headers

One or more headers to insert into the HTTP request. Each header is specified as "name(expr)", where expr is a default syntax expression that is evaluated at runtime to provide the value for the named header. You can configure a maximum of eight headers for an HTTP callout. Mutually exclusive with the full HTTP request expression.

parameters

One or more query parameters to insert into the HTTP request URL (for a GET request) or into the request body (for a POST request). Each parameter is specified as "name(expr)", where expr is an default syntax expression that is evaluated at run time to provide the value for the named parameter (name=value). The parameter values are URL encoded. Mutually exclusive with the full HTTP request expression.

bodyExpr

An advanced string expression for generating the body of the request. The expression can contain a literal string or an expression that derives the value (for example, client.ip.src). Mutually exclusive with -fullReqExpr.

fullReqExpr

Exact HTTP request, in the form of a default syntax expression, which the NetScaler appliance sends to the callout agent. If you set this parameter, you must not include HTTP method, host expression, URL stem expression, headers, or parameters.

The request expression is constrained by the feature for which the callout is used. For example, an HTTP.RES expression cannot be used in a request-time policy bank or in a TCP content switching policy bank.

The NetScaler appliance does not check the validity of this request. You must manually validate the request.

scheme

Type of scheme for the callout server.

Possible values: http, https

resultExpr

Expression that extracts the callout results from the response sent by the HTTP callout agent. Must be a response based expression, that is, it must begin with HTTP.RES. The operations in this expression must match the return type. For example, if you configure a return type of TEXT, the result expression must be a text based expression. If the return type is NUM, the result expression (resultExpr) must return a numeric value, as in the following example: http.res.body(10000).length.

cacheForSecs

Duration, in seconds, for which the callout response is cached. The cached responses are stored in an integrated caching content group named "calloutContentGroup". If no duration is configured, the callout responses will not be cached unless normal caching configuration is used to cache them. This parameter takes precedence over any normal caching configuration that would otherwise apply to these responses.

Note that the calloutContentGroup definition may not be modified or removed nor may it be used with other cache policies.

Minimum value: 1

Maximum value: 31536000

set policy httpcallout h1 -vServer v1

Use this command to remove policy httpCallout settings.Refer to the set policy httpCallout command for meanings of the arguments.

unset policy httpCallout <name> [-IPAddress] [-port] [-vServer] [-httpMethod] [-hostExpr] [-urlStemExpr] [-headers] [-parameters] [-bodyExpr] [-fullReqExpr] [-resultExpr] [-cacheForSecs]

Displays information about the configured HTTP callouts.

show policy httpCallout [<name>]

name

Name of the HTTP callout to display. If a name is not provided, information about all configured HTTP callouts is shown.

policy map

Sep 22, 2015

The following operations can be performed on "policy map":

add | rm | show

Creates a policy to map a publicly known domain name to a target domain name for a reverse proxy virtual server used by the cache redirection feature. Optionally, you can also specify a source and target URL. The map policy can be associated with a reverse proxy cache redirection virtual server by using the 'bind cr vserver' command. There can be only one default map policy for a domain.

add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]

mapPolicyName

Name for the map policy. Must begin with a letter, number, or the underscore (_) character and must consist only of letters, numbers, and the hash (#), period (.), colon (:), space ( ), at (@), equals (=), hyphen (-), and underscore (_) characters.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my map" or 'my map').

sd

Publicly known source domain name. This is the domain name with which a client request arrives at a reverse proxy virtual server for cache redirection. If you specify a source domain, you must specify a target domain.

su

Source URL. Specify all or part of the source URL, in the following format: /[[prefix] [*]] [.suffix].

td

Target domain name sent to the server. The source domain name is replaced with this domain name.

tu

Target URL. Specify the target URL in the following format: /[[prefix] [*]][.suffix].

Example 1 The following example creates a default map policy (map1) for the source domain www.a.com. Any client requests with this source domain in the host header is

---

Removes a map policy. Before removing the map policy, you must unbind the map policy from the reverse proxy virtual server.

rm policy map <mapPolicyName>

mapPolicyName

Name of the policy map to remove.

Displays information about the available policy maps.

show policy map [<mapPolicyName>]

mapPolicyName

Name of the policy map to display. If a name is not provided, information of all configured policy maps is shown.

show policy patclass pat1

policy patset

Sep 22, 2015

The following operations can be performed on "policy patset":

add | rm | bind | unbind | show

Adds a pattern set. A pattern set contains a name and one or more string patterns. Pattern sets can be used in default syntax expressions to match a set of strings. For example, HTTP.REQ.URL.EQUALS_ANY("test_urls"), where test_urls is a pattern set containing URL strings. Pattern sets can also be used in the search parameter of a rewrite action. Each string pattern is assigned an index that enables you to select the associated string from the set.

add policy patset <name> [-indexType (Auto-generated | User-defined)]

name

Unique name of the pattern set. Not case sensitive. Must begin with an ASCII letter or underscore (_) character and must contain only alphanumeric and underscore characters. Must not be the name of an existing named expression, pattern set, dataset, string map, or HTTP callout.

indexType

Index type.

add policy patset pat1

Removes a pattern set. If the pattern set is used by an expression in another object, such as a policy, you must remove the object before removing the pattern set.

rm policy patset <name>

name

Name of the pattern set to remove.

rm policy patset pat1

Binds a string to a pattern set.

bind policy patset <name> <string> [-index <positive_integer>] [-charset (ASCII | UTF_8)]

name

Name of the pattern set to which to bind the string.

string

String of characters that constitutes a pattern. For more information about the characters that can be used, refer to the character set parameter.

Note: Minimum length for pattern sets used in rewrite actions of type REPLACE_ALL, DELETE_ALL, INSERT_AFTER_ALL, and INSERT_BEFORE_ALL, is three characters.

bind policy patset pat1 bar -index 2

Unbinds a string from a pattern set.

unbind policy patset <name> <string> ...

name

Name of the pattern set from which to unbind a string.

string

String of characters to unbind from the pattern set.

unbind policy patset pat1 bar xyz

Displays the list of pattern sets configured on the appliance.

show policy patset [<name>]

name

Name of the pattern set for which to display the detailed information. If a name is not provided, a list of all pattern sets configured on the appliance is shown.

summary

show policy patset pat1

policy stringmap

Sep 22, 2015

The following operations can be performed on "policy stringmap":

add | rm | set | unset | bind | unbind | show

Creates a string map. You must use the 'bind policy stringmap' command to bind strings to this string map.

add policy stringmap <name> [-comment <string>]

name

Unique name for the string map. Not case sensitive. Must begin with an ASCII letter or underscore (_) character, and must consist only of ASCII alphanumeric or underscore characters. Must not begin with 're' or 'xp' or be a word reserved for use as a default syntax expression qualifier prefix (such as HTTP) or enumeration value (such as ASCII). Must not be the name of an existing named expression, pattern set, dataset, string map, or HTTP callout.

comment

Comments associated with the string map.

i) add stringmap custom_stringmap . This creates a new string map with name custom_stringmap.

Removes a string map. String maps can be removed only if not used in any part of policy, action, or expression.

rm policy stringmap <name>

name

Name of the string map to remove.

i) rm stringmap custom_stringmap . This removes a string map whose name is custom_stringmap

---

Modifies the attributes of an existing string map.

set policy stringmap <name> -comment <string>

name

Name of the string map to be modified.

comment

Comments associated with the string map.

i) set stringmap custom_stringmap -comment "custom string map is for URLs." . This updates the comment associated with the string map whose name is custom_stringma

---

Use this command to remove policy stringmap settings.Refer to the set policy stringmap command for meanings of the arguments.

unset policy stringmap <name> -comment

Binds a key and its associated value to a string map. If the key already exists and has a different value, the old value is overwritten with the new value.

bind policy stringmap <name> <key> <value>

name

Name of the string map to which to bind the key-value pair.

key

Character string constituting the key to be bound to the string map. The key is matched against the data processed by the operation that uses the string map. The default character set is ASCII. UTF-8 characters can be included if the character set is UTF-8. UTF-8 characters can be entered directly (if the UI supports it) or can be encoded as a sequence of hexadecimal bytes '\\xNN'. For example, the UTF-8 character '?' can be encoded as '\\xC3\\xBC'.

bind stringmap custom_stringmap "key-string" "value-string" . This adds the key "key-string" and its associated value "value-string" to the string map whose name is cus

---

Removes a key from the string map.

unbind policy stringmap <name> <key>

name

Name of the string map from which to remove a key.

key

Key to remove from the string map.

unbind stringmap custom_stringmap key1 . This removes the key "key1" and its associated value from the string map whose name is custom_stringmap.

Displays a list of available string maps.

show policy stringmap [<name>]

name

Name of the string map to display. If a name is not provided, a list of all the configured string maps is shown.

summary

PQ Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- pq
- pq binding
- pq policy
- pq stats

pq

Sep 22, 2015

The following operations can be performed on "pq":

Displays statistics of priority queuing.

stat pq [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

Policy hits (PolMatch)

Number of times the Netscaler appliance matched an incoming request using any priority queuing policy.

Threshold failed (ThrsFail)

Number of times the Netscaler appliance failed to match an incoming request to any of priority queing policy.

Priority 1 requests (Pri1Req)

Number of priority 1 requests that the Netscaler appliance received.

Priority 2 requests (Pri2Req)

Number of priority 2 requests that the Netscaler appliance received.

Priority 3 requests (Pri3Req)

Number of priority 3 requests that the Netscaler appliance received.

pq binding

Sep 22, 2015

The following operations can be performed on "pq binding":

Displays the information about the priority queuing policy bound to the virtual server. NOTE: This command is deprecated.Deprecated as cluster dont support reverse binding

vServerName

Name of the load balancing virtual server for which to display the priority queuing policy.

summary

fullValues

stateflag

policyName

The name of the priority queuing policy.

rule

The condition for applying the policy.

priority

The priority of queuing the request.

weight

Weight.

qDepth

Queue Depth.

polqDepth

Policy Queue Depth.

hits

Total number of hits.

devno

count

pq policy

Sep 22, 2015

The following operations can be performed on "pq policy":

add | rm | set | unset | show | stat

Adds a priority queuing policy to the appliance. Note: To use the priority queuing policy on a virtual server, the virtual server must have priority queuing enabled and the priority queuing policy must be bound to the load balancing virtual server. To enable priority queuing on the virtual server and to bind the policy, use the set lb vserver and bind lb vserver commands.

add pq policy <policyName> -rule <expression> -priority <positive_integer> [-weight <positive_integer>] [-qDepth <positive_integer> | -polqDepth <positive_integer>]

policyName

Name for the priority queuing policy. Must begin with a letter, number, or the underscore symbol (_). Other characters allowed, after the first character, are the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), and colon (:) characters.

rule

Expression or name of a named expression, against which the request is evaluated. The priority queuing policy is applied if the rule evaluates to true.

Note:

* On the command line interface, if the expression includes blank spaces, the entire expression must be enclosed in double quotation marks.

* If the expression itself includes double quotation marks, you must escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you will not have to escape the double quotation marks.

* Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

priority

Priority for queuing the request. If server resources are not available for a request that matches the configured rule, this option specifies a priority for queuing the request until the server resources are available again. Enter the value of positive_integer as 1, 2 or 3. The highest priority level is 1 and the lowest priority value is 3.

Minimum value: 1

Maximum value: 3

weight

Weight of the priority. Each priority is assigned a weight according to which it is served when server resources are available. The weight for a higher priority request must be set higher than that of a lower priority request.

To prevent delays for low-priority requests across multiple priority levels, you can configure weighted queuing for serving requests. The default weights for the priorities

are:

* Gold - Priority 1 - Weight 3

* Silver - Priority 2 - Weight 2

* Bronze - Priority 3 - Weight 1

Specify the weights as 0 through 101. A weight of 0 indicates that the particular priority level should be served only when there are no requests in any of the priority queues.

A weight of 101 specifies a weight of infinity. This means that this priority level is served irrespective of the number of clients waiting in other priority queues.

Maximum value: 101

qDepth

Queue depth threshold value. When the queue size (number of requests in the queue) on the virtual server to which this policy is bound, increases to the specified qDepth value, subsequent requests are dropped to the lowest priority level.

Maximum value: 4294967294

polqDepth

Policy queue depth threshold value. When the policy queue size (number of requests in all the queues belonging to this policy) increases to the specified polqDepth value, subsequent requests are dropped to the lowest priority level.

Maximum value: 4294967294

Removes a priority queuing policy from the appliance.

```
rm pq policy <policyName> ...
```

policyName

Name of the priority queuing policy to be removed.

Modifies the attributes of a priority queuing policy.

set pq policy <policyName> [-weight <positive_integer>] [-qDepth <positive_integer> | -polqDepth <positive_integer>]

policyName

Name of the priority queuing policy to be modified.

weight

Weight of the priority. Each priority is assigned a weight according to which it is served when server resources are available. The weight for a higher priority request must be set higher than that of a lower priority request.

To prevent delays for low-priority requests across multiple priority levels, you can configure weighted queuing for serving requests. The default weights for the priorities

are:

* Gold - Priority 1 - Weight 3

* Silver - Priority 2 - Weight 2

* Bronze - Priority 3 - Weight 1

Specify the weights as 0 through 101. A weight of 0 indicates that the particular priority level should be served only when there are no requests in any of the priority queues.

A weight of 101 specifies a weight of infinity. This means that this priority level is served irrespective of the number of clients waiting in other priority queues.

Maximum value: 101

qDepth

Queue depth threshold value. When the queue size (number of requests in the queue) on the virtual server to which this policy is bound, increases to the specified qDepth value, subsequent requests are dropped to the lowest priority level.

Maximum value: 4294967294

polqDepth

Policy queue depth threshold value. When the policy queue size (number of requests in all the queues belonging to

this policy) increases to the specified polqDepth value, subsequent requests are dropped to the lowest priority level.

Maximum value: 4294967294

Use this command to remove pq policy settings.Refer to the set pq policy command for meanings of the arguments.

unset pq policy <policyName> [-weight] [-qDepth] [-polqDepth]

Displays information about the priority queuing policy.

show pq policy [<policyName>]

policyName

Name of the priority queuing policy about which to display information. If a name is not provided, information about all priority queuing policies is shown.

Toatal queue wait time (QWaitTim)

Amount of time spent by priority queuing clients waiting in the priority queue.

Avg queue wait time (AvWtTime)

Average wait time for clients for this priority queuing

policy.

Avg clt transaction time (AvgTime)

Average time taken by a priority queuing client to complete its transaction for this priority queuing policy.

Vserver IP (VsIP)

IP address of the virtual server to which this priority queuing policy is bound.

Vserver port (VsPort)

Port number of the virtual server to which this priority queuing policy is bound.

Current queue depth (Qdepth)

Number of clients waiting currently for this priority queuing policy.

Current server connections (ServCons)

Current number of server connections established for serving clients for this priority queuing policy.

Server TCP connections (TotServCon)

Total number of server connections established for serving clients for this priority queuing policy.

Client requests dropped (Dropped)

Total number of dropped transactions for this priority queuing policy.

Client HTTP transactions (CltTrns)

Total number of client transactions for this priority queuing policy.

Queue depth (TotQLen)

Total number of waiting clients for this priority queuing policy.

Avg clt transaction time (us) (AvgTime)

Average time taken by a priority queuing client to complete its transaction for this priority queuing policy.

pq stats

Sep 22, 2015

The following operations can be performed on "pq stats":

show pq stats is an alias for stat pq

```
show pq stats - alias for 'stat pq'
```

Protocol Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- protocol http
- protocol httpBand
- protocol icmp
- protocol icmpv6
- protocol ip
- protocol ipv6
- protocol tcp
- protocol udp

protocol http

Sep 22, 2015

The following operations can be performed on "protocol http":

Displays statistics of the HTTP protocol.

stat protocol http [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

Total requests (HTReqRx)

Total number of HTTP requests received.

Total responses (HTRspRx)

Total number of HTTP responses sent.

Request bytes received (HTReqbRx)

Total number of bytes of HTTP request data received.

Response bytes received (HTRspbRx)

Total number of bytes of HTTP response data received.

GETs (HTGETs)

Total number of HTTP requests received with the GET method.

POSTs (HTPOSTs)

Total number of HTTP requests received with the POST method.

Other methods (HTOthers)

Total number of HTTP requests received with methods other than GET and POST. Some of the other well-defined HTTP methods are HEAD, PUT, DELETE, OPTIONS, and TRACE. User-defined methods are also allowed.

HTTP/1.0 requests (HT10ReqRx)

Total number of HTTP/1.0 requests received.

HTTP/1.1 requests (HT11ReqRx)

Total number of HTTP/1.1 requests received.

Content-length requests (HTCLnReq)

Total number of HTTP requests in which the Content-length field of the HTTP header has been set. Content-length specifies the length of the content, in bytes, in the associated HTTP body.

Chunked requests (HTChkReq)

Total number of HTTP requests in which the Transfer-Encoding field of the HTTP header has been set to chunked.

Request bytes transmitted (HTReqbTx)

Total number of bytes of HTTP request data transmitted.

HTTP/1.0 responses (HT10RspRx)

Total number of HTTP/1.0 responses sent.

HTTP/1.1 responses (HT11RspRx)

Total number of HTTP/1.1 responses sent.

Content-length responses (HTCLnRsp)

Total number of HTTP responses sent in which the Content-length field of the HTTP header has been set. Content-length specifies the length of the content, in bytes, in the associated HTTP body.

Chunked responses (HTChunk)

Total number of HTTP responses sent in which the Transfer-Encoding field of the HTTP header has been set to chunked. This setting is used when the server wants to start sending the response before knowing its total length. The server breaks the response into chunks and sends them in sequence, inserting the length of each chunk before the actual data. The message ends with a chunk of size zero.

Multi-part responses (HTMPrtHd)

Total number of HTTP multi-part responses sent. In multi-part responses, one or more entities are encapsulated within the body of a single message.

FIN-terminated responses (HTNoCLnChunk)

Total number of FIN-terminated responses sent. In FIN-terminated responses, the server finishes sending the data and closes the connection.

Response bytes transmitted (HTRspbTx)

Total number of bytes of HTTP response data transmitted.

Incomplete headers (HTIncHd)

Total number of HTTP requests and responses received in which the HTTP header spans more than one packet.

Incomplete request headers (HTIncReqHd)

Total number of HTTP requests received in which the header spans more than one packet.

Incomplete response headers (HTIncRspHd)

Total number of HTTP responses received in which the header spans more than one packet.

HTTP 500 Server-busy Responses (HT500Rsp)

Total number of HTTP error responses received. Some of the error responses are:

500 Internal Server Error

501 Not Implemented

502 Bad Gateway

503 Service Unavailable

504 Gateway Timeout

505 HTTP Version Not Supported

Large/Invalid messages (HTInvReq)

Total number of requests and responses received with large body.

Large/Invalid chunk requests (HTInvChkRx)

Total number of requests received with large chunk size, in which the Transfer-Encoding field of the HTTP header has been set to chunked.

Large/Invalid content-length (HTInvCLn)

Total number of requests received with large content, in which the Content-length field of the HTTP header has been set. Content-length specifies the length of the content, in bytes, in the associated HTTP body.

SPDYv2 requests (SPDY2Strm)

Total number of requests received over SPDY

protocol httpBand

Sep 22, 2015

The following operations can be performed on "protocol httpBand":

set | unset | show

Sets the band size for HTTP request/response band statistics.

set protocol httpBand [-reqBandSize <integer>] [-respBandSize <integer>]

reqBandSize

Band size, in bytes, for HTTP request band statistics. For example, if you specify a band size of 100 bytes, statistics will be maintained and displayed for the following size ranges:

0 - 99 bytes

100 - 199 bytes

200 - 299 bytes and so on.

Default value: 100

Minimum value: 50

respBandSize

Band size, in bytes, for HTTP response band statistics. For example, if you specify a band size of 100 bytes, statistics will be maintained and displayed for the following size ranges:

0 - 99 bytes

100 - 199 bytes

200 - 299 bytes and so on.

Default value: 1024

Minimum value: 50

set protocol httpBand -reqBandSize 200 -respBandSize 2048

Use this command to remove protocol httpBand settings.Refer to the set protocol httpBand command for meanings of the arguments.

unset protocol httpBand [-reqBandSize] [-respBandSize]

Displays statistics of the HTTP request/response band.

show protocol httpBand -type (REQUEST | RESPONSE)

type

Type of statistics to display.

Possible values: REQUEST, RESPONSE

format

level

BandRange

The range of the HTTP request/response size, in bytes.

TotalBandSize

The total size of all HTTP requests/responses in this size range.

AvgBandSize

The average size of all HTTP requests/responses in this size range.

BandData

The total size of all HTTP requests/responses in this size range, expressed as a percentage of the total size of all HTTP requests/responses.

AccessCount

The number of HTTP requests/responses in this size range.

AccessRatio

The number of HTTP requests/responses in this size range, expressed as a percentage of the total number of HTTP requests/responses.

protocol icmp

Sep 22, 2015

The following operations can be performed on "protocol icmp":

Displays statistics of the ICMP protocol.

stat protocol icmp [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

ICMP packets received (ICPktRx)

ICMP packets received.

ICMP bytes received (ICbRx)

Bytes of ICMP data received.

ICMP packets transmitted (ICPktTx)

ICMP packets transmitted.

ICMP bytes transmitted (ICbTx)

Bytes of ICMP data transmitted.

ICMP echo replies received (ECORepRx)

ICMP Ping echo replies received.

ICMP echo replies transmitted (ECORepTx)

ICMP Ping echo replies transmitted.

ICMP echos received (ECORx)

ICMP Ping Echo Request and Echo Reply packets received.

MTU lookup on dst ip info recvd (MTULkDst)

Total number of MTU lookup on destination IP info received on a need fragmentation ICMP error message failed.

ICMP rate threshold (pkts/sec) (ICThs)

Limit for ICMP packets handled every 10 milliseconds. Default value, 0, applies no limit.

This is a configurable value using the set rateControl command.

ICMP port unreachable received (PortUnRx)

ICMP Port Unreachable error messages received. This error is generated when there is no service is running on the port.

ICMP port unreachable generated (PortUnTx)

ICMP Port Unreachable error messages generated. This error is generated when there is no service is running on the port.

Need fragmentation received (NeedFrag)

ICMP Fragmentation Needed error messages received for packets that need to be fragmented but for which Don't Fragment is specified the header.

ICMP rate threshold exceeded (ICRtEx)

Times the ICMP rate threshold is exceeded. If this counter continuously increases, first make sure the ICMP packets received are genuine. If they are, increase the current rate threshold.

ICMP packets dropped (ICPktDr)

ICMP packets dropped because the rate threshold has been exceeded.

Bad ICMP checksum (BadCkSum)

ICMP Fragmentation Needed error messages received with an ICMP checksum error.

PMTU non-first IP fragments (PMTUerr)

ICMP Fragmentation Needed error messages received that were generated by an IP fragment other than the first one.

PMTU Invalid body len received (IvBdyLen)

ICMP Fragmentation Needed error messages received that specified an invalid body length.

PMTU no tcp connection (NoTcpCon)

ICMP Need Fragmentation error messages received for TCP packets. The state of the connection for these packets is not maintained on the NetScaler.

PMTU no udp conection (NoUdpCon)

ICMP Need Fragmentation error messages received for UDP packets. The state of the connection for these packets is not maintained on the NetScaler.

PMTU invalid tcp seqno recvd (InvSeqNo)

ICMP Fragmentation Needed error messages received for packets that contain an invalid TCP address.

Invalid next MTU value recvd (IvNxtMTU)

ICMP Fragmentation Needed error messages received in which the Maximum Transmission Unit (MTU) for the next hop is out of range. The range for the MTU is 576-1500.

Next MTU > Current MTU (BigNxMTU)

ICMP Fragmentation Needed error messages received in which the value for the next MTU is higher than that of the current MTU.

PMTU Invalid protocol recvd (IvPrtRx)

ICMP Fragmentation Needed error messages received that contain a protocol other than TCP and UDP.

PMTU IP check sum error (CkSumErr)

ICMP Fragmentation Needed error messages received with an IP checksum error.

PMTU pcb with no link (NoLnkErr)

ICMP Fragmentation Needed error messages received on a Protocol Control Block (PCB) with no link. The PCB maintains the state of the connection.

PMTU Discovery not enabled (PMTUdis)

ICMP Need Fragmentation error messages received when the PMTU Discovery mode is not enabled.

protocol icmpv6

Sep 22, 2015

The following operations can be performed on "protocol icmpv6":

Displays statistics of the ICMPv6 protocol.

stat protocol icmpv6 [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

ICMPv6 packets received (icmpv6RxPkts)

ICMPv6 packets received.

ICMPv6 bytes received (icmpv6RxBytes)

Bytes of ICMPv6 data received.

ICMPv6 packets transmitted (icmpv6TxPkts)

ICMPv6 packets transmitted.

ICMPv6 bytes transmitted (icmpv6TxBytes)

Bytes of ICMPv6 data transmitted.

ICMPv6 NA packets received (icmpv6RxNa)

ICMPv6 neighbor advertisement packets received. These packets are received in response to a neighbor solicitation message sent out by this node, or if the link layer address of a neighbor has changed.

ICMPv6 NS packets received (icmpv6RxNs)

ICMPv6 neighbor solicitation packets received. These packets are received if the link layer address of a neighbor has changed, or in response to a neighbor solicitation message sent out by this node.

ICMPv6 RA packets received (icmpv6RxRa)

ICMPv6 router advertisement packets received. These are received at defined intervals or in response to a router solicitation message.

ICMPv6 RS packets received (icmpv6RxRs)

ICMPv6 router solicitation packets received. These could be sent by a neighboring router to initiate address resolution.

ICMPv6 Echo Request packets received (icmpv6RxEchoReq)

ICMPv6 Ping Echo Request packets received.

ICMPv6 Echo Reply packets received (icmpv6RxEchoReply)

ICMPv6 Ping Echo Reply packets received.

ICMPv6 NA packets transmitted (icmpv6TxNa)

ICMPv6 neighbor advertisement packets transmitted. These packets are sent in response to a neighbor solicitation packet, or if the link layer address of this node has changed.

ICMPv6 NS packets transmitted (icmpv6TxNs)

ICMPv6 neighbor solicitation packets transmitted. These packets are sent to get the link layer addresses of neighboring nodes or to confirm that they are reachable.

ICMPv6 RA packets transmitted (icmpv6TxRa)

ICMPv6 router advertisement packets transmitted. These packets are sent at regular intervals or in response to a router solicitation packet from a neighbor.

ICMPv6 RS packets transmitted (icmpv6TxRs)

ICMPv6 router solicitation packets transmitted. These packets are sent to request neighboring routers to generate router advertisements immediately rather than wait for the next defined time.

ICMPv6 Echo Request packets transmitted (icmpv6TxEchoReq)

ICMPv6 Ping Echo Request packets transmitted.

ICMPv6 Echo Reply packets transmitted (icmpv6TxEchoReply)

ICMP Ping Echo Reply packets transmitted.

ICMPv6 RA error packets (Error in RA packet)

ICMPv6 router advertisement error packets received that contain an error in the header, such as an incorrect source IP address, destination IP address, or packet length.

ICMPv6 NA error packets (Error in NA packet)

ICMPv6 neighbor advertisement error packets received that contain an error in the header, such as an incorrect source IP address, destination IP address, or packet length.

ICMPv6 NS error packets (Error in NS packet)

ICMPv6 neighbor solicitation error packets received that contain an error in the header, such as an incorrect source IP address, destination IP address, or packet length.

ICMPv6 bad checksum (Cksumerr)

Packets received with an ICMPv6 checksum error.

unsupported ICMPv6 packets (icmpv6Unspt)

ICMPv6 packets received that are not supported by the NetScaler.

Rate threshold exceeded packets (icmpv6thsld)

Packets dropped because the default threshold of 100 requests per 10 milliseconds has been exceeded.

This is a configurable value using the set rateControl command.

protocol ip

Sep 22, 2015

The following operations can be performed on "protocol ip":

Displays statistics of the IP protocol.

stat protocol ip [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

IP packets received (IPPktRx)

IP packets received.

IP bytes received (IPbRx)

Bytes of IP data received.

IP packets transmitted (IPPktTx)

IP packets transmitted.

IP bytes transmitted (IPbTx)

Bytes of IP data transmitted.

Megabits received (IPMbRx)

Megabits of IP data received.

Megabits transmitted (IPMbTx)

Megabits of IP data transmitted.

Total routed IP packets (IPRoutedPkts)

Total routed packets.

Total routed IP Mbits (IPRoutedMbits)

Total routed Mbits

IP fragments received (IPFragRx)

IP fragments received.

Successful reassembly (reasSucc)

Fragmented IP packets successfully reassembled on the NetScaler.

Reassembly attempted (reasAtmp)

IP packets that the NetScaler attempts to reassemble. If one of the fragments is missing, the whole packet is dropped.

IP address lookups (IpLkUp)

IP address lookups performed by the NetScaler. When a packet is received on a non-established session, the NetScaler checks if the destination IP address is one of the NetScaler owned IP addresses.

IP address lookup failure (IpLkFail)

IP address lookups performed by the NetScaler that have failed because the destination IP address of the packet does not match any of the NetScaler owned IP addresses.

UDP fragments forwarded (udpFgFwd)

UDP fragments forwarded to the client or the server.

TCP fragments forwarded (tcpFgFwd)

TCP fragments forwarded to the client or the server.

Fragmentation packets created (frgPktCr)

Fragmented packets created by the NetScaler.

Bad IP checksums (badCksum)

Packets received with an IP checksum error.

Unsuccessful reassembly (reasFail)

Packets received that could not be reassembled. This can occur when there is a checksum failure, an identification field mismatch, or when one of the fragments is missing.

Reassembled data too big (reasBig)

Packets received for which the reassembled data exceeds the Ethernet packet data length of 1500 bytes.

Zero fragment length received (zeroLen)

Packets received with a fragment length of 0 bytes.

Duplicate fragments received (dupFrag)

Duplicate IP fragments received. This can occur when the acknowledgement was not received within the expected

time.

Out of order fragment received (oooFrag)

Fragments received that are out of order.

Unknown destination received (UnkDst)

Packets received in which the destination IP address was not reachable or not owned by the NetScaler.

Bad Transport (badTran)

Packets received in which the protocol specified in the IP header is unknown to the NetScaler.

VIP down (vipDown)

Packets received for which the VIP is down. This can occur when all the services bound to the VIP are down or the VIP is manually disabled.

Fix header failure (hdrFail)

Packets received that contain an error in one or more components of the IP header.

TTL expired during transit (ttlExp)

Packets for which the time-to-live (TTL) expired during transit. These packets are dropped.

max non-TCP clients (maxClt)

Attempts to open a new connection to a service for which the maximum limit has been exceeded. Default value, 0, applies no limit.

Unknown services (UnkSvc)

Packets received on a port or service that is not configured.

land-attacks (LndAtk)

Land-attack packets received. The source and destination addresses are the same.

Invalid IP header size (errHdrSz)

Packets received in which an invalid data length is specified, or the value in the length field and the actual data length do not match. The range for the Ethernet packet data length is 0-1500 bytes.

Invalid IP packet size (errPktLen)

Total number of packets received by NetScaler with invalid IP packet size.

Truncated IP packet (trIP)

Truncated IP packets received. An overflow in the routers along the path can truncate IP packets.

Truncated non-IP packet (trNonIp)

Truncated non-IP packets received.

ZERO next hop (zrNxtHop)

Packets received that contain a 0 value in the next hop field. These packets are dropped.

Packets with len > 1514 rcvd (BadLenTx)

Packets received with a length greater than the normal maximum transmission unit of 1514 bytes.

Packets with bad MAC sent (BadMacTx)

IP packets transmitted with a bad MAC address.

protocol ipv6

Sep 22, 2015

The following operations can be performed on "protocol ipv6":

Displays statistics of the IPv6 protocol.

stat protocol ipv6 [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

IPv6 packets received (ipv6RxPkts)

IPv6 packets received.

IPv6 bytes received (ipv6RxBytes)

Bytes of IPv6 data received.

IPv6 packets transmitted (ipv6TxPkts)

IPv6 packets transmitted

IPv6 bytes transmitted (ipv6TxBytes)

Bytes of IPv6 data transmitted.

Total Routed IPv6 packets (ipv6RoutePkts)

IPv6 packets routed.

Total Routed IPv6 Mbits (ipv6RouteMbits)

IPv6 total Mbits.

IPv6 Fragments received. (ipv6FragRxPkts)

IPv6 fragments received.

TCP Fragments reassembled. (ipv6FragTcpReass)

TCP fragments processed after reassembly.

UDP Fragments reassembled. (ipv6FragUdpReass)

UDP fragments processed after reassembly.

IPv6 Fragments processed without reassembly. (ipv6FragPktsProcessNoReass)

IPv6 fragments processed without reassembly.

IPv6 Fragments bridged. (ipv6FragPktsForward)

IPv6 fragments forwarded to the client or server without reassembly.

IPv6 error hdr packets (RxErrHdr)

Packets received that contain an error in one or more components of the IPv6 header.

IPv6 unsupported next header (Errnxthdr)

Packets received that contain an unsupported next header. The supported next headers are TCP, ICMP, UDP, OSPF, and FRAGMENT.

IPv6 Land-attacks (land attack)

Land-attack packets received. The source and destination addresses are the same. If not dropped, these packets can lock up the appliance.

Reassembled data too big (AssembledPktTooBig)

Packets received for which the reassembled data exceeds the Ethernet packet data length of 1500 bytes.

Zero fragment length received (ZeroLenFramentedPkt)

Packets received with a fragment length of 0 bytes.

ICMPv6 NA packets received

Number of ICMPv6 NA packets received by NetScaler (OBSOLETE).

ICMPv6 NS packets received

Number of ICMPv6 NS packets received by NetScaler (OBSOLETE).

ICMPv6 NA packets transmitted

Number of ICMPv6 NA packets transmitted by NetScaler (OBSOLETE).

ICMPv6 NS packets transmitted

Number of ICMPv6 NS packets transmitted by NetScaler (OBSOLETE).

ICMPv6 RA packets received

Number of ICMPv6 RA packets received by NetScaler (OBSOLETE).

ICMPv6 RS packets transmitted

Number of ICMPv6 RS packets transmitted by NetScaler (OBSOLETE).

ICMPv6 packets received

Number of ICMPv6 packets received by NetScaler (OBSOLETE).

ICMPv6 packets transmitted

Number of ICMPv6 packets transmitted by NetScaler (OBSOLETE).

IPv6 error hdr packets

Number of erroneous header packets received (OBSOLETE).

IPv6 error packets

Number of erroneous packets received (OBSOLETE).

IPv6 bad checksum

Number of bad checksum packets received (OBSOLETE).

ICMPv6 error packets

Number of erroneous ICMPv6 packets received (OBSOLETE).

unsupported ICMPv6 packets

Number of ICMPv6 unsupported packets received (OBSOLETE).

Rate threshold exceeded packets

Number of ICMPv6 packets dropped for rate threshold exceeded (OBSOLETE).

protocol tcp

Sep 22, 2015

The following operations can be performed on "protocol tcp":

Displays statistics of the TCP protocol.

stat protocol tcp [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

Server active connections (ActSvrCo)

Connections to a server currently responding to requests.

Opening server connections (SvrCxO)

Server connections in the Opening state, which indicates that the handshakes are not yet complete.

Opening client connections (CltCxO)

Client connections in the Opening state, which indicates that the handshakes are not yet complete.

Established client connections (CltCxE)

Current client connections in the Established state, which indicates that data transfer can occur between the NetScaler and the client.

Established server connections (SvrCxE)

Current server connections in the Established state, which indicates that data transfer can occur between the NetScaler and the server.

TCP packets received (TCPPktRx)

TCP packets received.

TCP bytes received (TCPbRx)

Bytes of TCP data received.

TCP packets transmitted (TCPPktTx)

TCP packets transmitted.

TCP bytes transmitted (TCPbTx)

Bytes of TCP data transmitted.

All client connections (CltCx)

Client connections, including connections in the Opening, Established, and Closing state.

Closing client connections (CltCxCl)

Client connections in the Closing state, which indicates that the connection termination process has initiated but is not complete.

Opened client connections (TotCltO)

Client connections opened by the NetScaler since startup (after three-way handshake). This counter is reset when the NetScaler is restarted.

All server connections (SvrCx)

Server connections, including connections in the Opening, Established, and Closing state.

Closing server connections (SvrCxCl)

Server connections in the Closing state, which indicates that the connection termination process has initiated but is not complete.

Opened server connections (TotSvrO)

Server connections initiated by the NetScaler since startup. This counter is reset when the NetScaler is restarted.

Surge queue (SQlen)

Connections in the surge queue. When the NetScaler cannot open a connection to the server, for example when maximum connections have been reached, the NetScaler queues these requests.

Spare connections (SpConn)

Spare connections available. To save time and resources in establishing another connection for a new client, the connection on the server is not closed after completing the request from the first client and is available for serving future requests.

Client idle flushed (ZomCltF)

Client connections that are flushed because the client has been idle for some time.

Client half opened flushed (ZCltFHo)

Half-opened client connections that are flushed because the three-way handshakes are not complete.

Client active half closed flushed (ZCltFAhc)

Active half-closed client connections that are flushed because the client has closed the connection and there has

been no activity on the connection.

Client passive half closed flushed (ZCltFPhc)

Passive half-closed client connections that are flushed because the NetScaler has closed the connection and there has been no activity on the connection.

Server idle connections flushed (ZSvrF)

Server connections that are flushed because there have been no client requests in the queue for some time.

Server half opened flushed (ZSvrFHo)

Half-opened server connections that are flushed because the three-way handshakes are not complete.

Server active half closed flushed (ZSvrFAhc)

Active half-closed server connections that are flushed because the server has closed the connection and there has been no activity on the connection.

Server passive half closed flushed (ZSrvFPhc)

Passive half-closed server connections that are flushed because the NetScaler has closed the connection and there has been no activity on the connection.

Zombie cleanup calls (ZmbCall)

Times the Zombie cleanup function is called. Every time a connection is flushed, it is marked for cleanup. The Zombie cleanup function clears all these connections at predefined intervals.

SYN packets received (TCPSYN)

SYN packets received

Server probes (SYNProbe)

Probes from the NetScaler to a server. The NetScaler sends a SYN packet to the server to check its availability and expects a SYN_ACK packet from the server before a specified response timeout.

FIN packets from server (SvrFin)

FIN packets received from the server.

FIN packets from client (CltFin)

FIN packets received from the clients.

Time wait to SYN (WaToSyn)

SYN packets (packets used to initiate a TCP connection) received on connections that are in the TIME_WAIT state. Packets cannot be transferred on a connection in this state.

Data in TIME_WAIT (WaDat)

Bytes of data received on connections that are in the TIME_WAIT state. Data cannot be transferred on a

connection that is in this state.

SYN packets held (SYNHeld)

SYN packets held on the NetScaler that are waiting for a server connection.

SYN packets flushed (SYNFlush)

SYN packets flushed on the NetScaler because of no response from the server for three or more seconds.

TIME_WAIT connections closed (FinWaitC)

Connections closed on the NetScaler because the number of connections in the TIME_WAIT state has exceeded the default value of 7000.

Bad TCP checksum (TCPBadCk)

Packets received with a TCP checksum error.

Data after FIN (TCPDtFin)

Packets received following a connection termination request. This error is usually caused by a reordering of packets during transmission.

SYN in SYN_RCVD state (TCPSYNRv)

SYN packets received on a connection that is in the SYN_RCVD state. A connection goes into the SYN_RCVD state after receiving a SYN packet.

SYN in ESTABLISHED state (TCPSYNEs)

SYN packets received on a connection that is in the ESTABLISHED state. A SYN packet is not expected on an ESTABLISHED connection.

SYN_SENT incorrect ACK packet (TCPBadAk)

Incorrect ACK packets received on a connection that is in the SYN_SENT state. An incorrect ACK packet is the third packet in the three-way handshake that has an incorrect sequence number.

RST packets received (TCPRST)

Reset packets received from a client or a server.

RST on not ESTABLISHED (TCPRSTNE)

Reset packets received on a connection that is not in the ESTABLISHED state.

RST out of window (TCPRSTOW)

Reset packets received on a connection that is out of the current TCP window.

RST in TIME_WAIT (TCPRSTTi)

Reset packets received on a connection that is in the TIME_WAIT state. Packets cannot be transferred on a connection in the TIME_WAIT state.

Server out of order packets (SvrOOO)

Out of order TCP packets received from a server.

Client out of order packets (CltOOO)

Out of order TCP packets received from a client.

TCP hole on client connection (CltHole)

TCP holes created on a client connection. When out of order packets are received from a client, a hole is created on the NetScaler for each group of missing packets.

TCP hole on server connection (SvrHole)

TCP holes created on a server connection. When out of order packets are received from a server, a hole is created on the NetScaler for each group of missing packets.

Seq number SYN cookie reject (CSeqRej)

SYN cookie packets rejected because they contain an incorrect sequence number.

Signature SYN cookie reject (CSigRej)

SYN cookie packets rejected because they contain an incorrect signature.

Seq number SYN cookie drop (CSigDrp)

SYN cookie packets dropped because the sequence number specified in the packets is outside the current window.

MSS SYN cookie reject (CMssRej)

SYN cookie packets rejected because the maximum segment size (MSS) specified in the packets is incorrect.

Any IP port allocation failure (PortFal)

Port allocations that have failed on a mapped IP address because the maximum limit of 65536 has been exceeded.

IP port allocation failure (PortFall)

Port allocations that have failed on a subnet IP address or vserver IP address because the maximum limit of 65536 has been exceeded.

Stray packets (StrayPkt)

Number of stray or misrouted packets.

RST packets sent (SentRst)

Reset packets sent to a client or a server.

Bad state connections (BadConn)

Connections that are not in a valid TCP state.

RST threshold dropped (RstThre)

Reset packets dropped because the default threshold of 100 resets per 10 milliseconds has been exceeded. This is a configurable value using the set rateControl command.

Packets out of window (OOWPkt)

Packets received that are out of the current advertised window.

SYNs dropped (Congestion) (SynCng)

SYN packets dropped because of network congestion.

Client retransmissions (TCPCltRe)

Packets retransmitted by a client. This usually occurs because the acknowledgement from the NetScaler has not reached the client.

Full packet retransmissions (TCPFulRe)

Full packets retransmitted by the client or the server.

SYN packet retries (TCPSYNRe)

SYN packets resent to a server.

SYN packets timeout (TCPSYNG)

Attempts to establish a connection on the NetScaler that timed out.

TCP retransmission (Retr)

TCP packets retransmitted. The NetScaler attempts to retransmit the packet up to seven times, after which it resets the other half of the TCP connection.

1st retransmission (1stRetr)

Packets retransmitted once by the NetScaler.

3rd retransmission (3rdRetr)

Packets retransmitted three times by the NetScaler.

5th retransmission (5thRetr)

Packets retransmitted five times by the NetScaler.

7th retransmission (7thRetr)

Packets retransmitted seven times by the NetScaler. If this fails, the NetScaler terminates the connection.

Fast retransmits (FastRetr)

TCP packets on which the NetScaler performs a fast retransmission in response to three duplicate acknowledgements or a partial acknowledgement. The NetScaler assumes that the packet is lost and retransmits the packet before its time-out.

Server retransmissions (TCPSvrRe)

Packets retransmitted by a server. This usually occurs because the acknowledgement from the NetScaler has not reached the server.

Partial packet retransmissions (TCPParRe)

Partial packet retransmits by a client or server due to congestion on the connection. This usually occurs because the window advertised by the NetScaler is not big enough to hold the full packet.

FIN packet retries (TCPFINRe)

FIN packets resent to a server or a client.

FIN packets timeout (TCPFING)

Connections that were timed out by the NetScaler because of not receiving the ACK packet after retransmitting the FIN packet four times.

2nd retransmission (2ndRetr)

Packets retransmitted twice by the NetScaler.

4th retransmission (4thRetr)

Packets retransmitted four times by the NetScaler.

6th retransmission (6thRetr)

Packets retransmitted six times by the NetScaler.

TCP retransmission giveup (RetrG)

Number of times NetScaler terminates a connection after retransmitting the packet seven times on that connection.Retrasnmission happens when recieving end doesn't acknowledges the packet.

TCP level cip failure (CltHdrEr)

Number of times TCP level client header insertion failure

protocol udp

Sep 22, 2015

The following operations can be performed on "protocol udp":

Displays statistics of the UDP protocol.

stat protocol udp [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

Packets received (UDPPktRx)

Total number of UDP packets received.

Bytes received (UDPbRx)

Total number of UDP data received in bytes.

Packets transmitted (UDPPktTx)

Total number of UDP packets transmitted.

Bytes transmitted (UDPbTx)

Total number of UDP data transmitted in bytes.

Current rate threshold (UDPThs)

Limit for UDP packets handled every 10 milliseconds. Default value, 0, applies no limit.

This is a configurable value using the set rateControl command.

Unknown service (UDPUnSvc)

Stray UDP packets dropped due to no configured listening service.

Bad UDP checksum (UDPBadCkSum)

Packets received with a UDP checksum error.

Rate threshold exceeded (UDPRtEx)

Number of times the UDP rate threshold is exceeded. If this counter continuously increases, first make sure the UDP packets received are genuine.

If they are, increase the current rate threshold. This is a configurable value using the set rateControl command.

QOS Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- qos
- qos stats

qos

Sep 22, 2015

The following operations can be performed on "qos":

Display QoS statistics.

stat qos [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

IPC messages sent from QoS (ipcsent)

IPC messages sent from qos system.

IPC messages QoS failed to send (ipcfailed)

IPC messages failed to send from qos system.

IPC messages QoS received (ipcrcvd)

IPC messages received by qos.

IPC messages sent to QoS (pe2qsent)

IPC messages sent to qos system.

IPC messages failed to send QoS (pe2qfail)

IPC messages failed to send to qos system.

IPC messages received from QoS (pe2qrecv)

IPC messages received from qos system.

Bytes QoS marked for drop (bytsdrop)

Bytes QoS marked for drop

QoS bytes sent not classified (bytsntnc)

Bytes scheduled by QoS that were not classified.

QoS bytes dropped no connection (bytdrpnc)

Bytes dropped by QoS when no connection was found.

Packets sent to QoS (qosinpkt)

Packets sent to QoS for scheduling.

Packets from QoS to be sent (qosotpkt)

Packets from QoS to be sent

Packets Dropped by QoS (qosdrpkt)

Packets Dropped by QoS.

Classified source MAC rewritten (qosrwmac)

Number of packets with inband classification in source MAC.

QoS packets unclassified (qosuclas)

Number of packets without classification.

QoS packets classified (qosclas)

Number of packets with classification.

QoS learned true MAC (qoslm)

QoS learned true MAC

QoS Input Bytes (qosib)

Bytes sent to QoS for scheduling

QoS Output Bytes (qosob)

Bytes received from QoS to be sent

QoS Free Held List (qosfc)

No. more packets QoS can hold onto.

QoS Link 00 Bytes Sent (qosl00sd)

QoS bytes sent on Link 00

QoS Link 00 Bytes Dropped (qosl00dr)

QoS bytes dropped on Link 00

QoS Link 01 Bytes Sent (qosl01sd)

QoS bytes sent on Link 01

QoS Link 01 Bytes Dropped (qosl01dr)

QoS bytes dropped on Link 01

qos stats

Sep 22, 2015

The following operations can be performed on "qos stats":

show qos stats is an alias for stat qos

show qos stats - alias for 'stat qos'

Rewrite Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- rewrite action
- rewrite global
- rewrite param
- rewrite policy
- rewrite policylabel

rewrite action

Sep 22, 2015

The following operations can be performed on "rewrite action":

add | rm | set | unset | show | rename

Creates a rewrite action, which specifies exactly what modifications to make to a request or response before forwarding that request or response to the protected web server or to the user. In addition to user-defined actions, the rewrite feature has the following three built-in actions: * NOREWRITE - Sends the request or response to the user without rewriting it. * RESET - Resets the connection and notifies the user?s browser, so that the user can resend the request. * DROP - Drops the connection without sending a response to the user. One of the following three flow types is implicitly associated with every action: * Request - Action applies to the request. * Response - Action applies to the response. * Neutral - Action applies to both requests and responses.

add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-pattern <expression> | -search <expression>] [-bypassSafetyCheck (YES | NO)] [-refineSearch <string>] [-comment <string>]

name

Name for the user-defined rewrite action. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the rewrite policy is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rewrite action" or ?my rewrite action?).

type

Type of user-defined rewrite action. The information that you provide for, and the effect of, each type are as follows::

* REPLACE <target> <string_builder_expr>. Replaces the string with the string-builder expression.

* REPLACE_ALL <target> <string_builder_expr1> -(pattern|search) <string_builder_expr2>. In the request or response specified by <target>, replaces all occurrences of the string defined by <string_builder_expr1> with the string defined by <string_builder_expr2>. You can use a PCRE-format pattern or the search facility to find the strings to be replaced.

* REPLACE_HTTP_RES <string_builder_expr>. Replaces the complete HTTP response with the string defined by the string-builder expression.

* REPLACE_SIP_RES <target> - Replaces the complete SIP response with the string specified by <target>.

* INSERT_HTTP_HEADER <header_string_builder_expr> <contents_string_builder_expr>. Inserts the HTTP header specified by <header_string_builder_expr> and header contents specified by <contents_string_builder_expr>.

* DELETE_HTTP_HEADER <target>. Deletes the HTTP header specified by <target>.

* CORRUPT_HTTP_HEADER <target>. Replaces the header name of all occurrences of the HTTP header specified by <target> with a corrupted name, so that it will not be recognized by the receiver Example: MY_HEADER is changed to MHEY_ADER.

* INSERT_BEFORE <string_builder_expr1> <string_builder_expr1>. Finds the string specified in <string_builder_expr1> and inserts the string in <string_builder_expr2> before it.

* INSERT_BEFORE_ALL <target> <string_builder_expr1> -(pattern|search) <string_builder_expr2>. In the request or response specified by <target>, locates all occurrences of the string specified in <string_builder_expr1> and inserts the string specified in <string_builder_expr2> before each. You can use a PCRE-format pattern or the search facility to find the strings.

* INSERT_AFTER <string_builder_expr1> <string_builder_expr2>. Finds the string specified in <string_builder_expr1>, and inserts the string specified in <string_builder_expr2> after it.

* INSERT_AFTER_ALL <target> <string_builder_expr1> -(pattern|search) <string_builder_expr>. In the request or response specified by <target>, locates all occurrences of the string specified by <string_builder_expr1> and inserts the string specified by <string_builder_expr2> after each. You can use a PCRE-format pattern or the search facility to find the strings.

* DELETE <target>. Finds and deletes the specified target.

* DELETE_ALL <target> -(pattern|search) <string_builder_expr>. In the request or response specified by <target>, locates and deletes all occurrences of the string specified by <string_builder_expr>. You can use a PCRE-format pattern or the search facility to find the strings.

Possible values: noop, delete, insert_http_header, delete_http_header, corrupt_http_header, insert_before, insert_after, replace, replace_http_res, delete_all, replace_all, insert_before_all, insert_after_all, clientless_vpn_encode, clientless_vpn_encode_all, clientless_vpn_decode, clientless_vpn_decode_all, insert_sip_header, delete_sip_header, corrupt_sip_header, replace_sip_res

target

Default syntax expression that specifies which part of the request or response to rewrite.

stringBuilderExpr

Default syntax expression that specifies the content to insert into the request or response at the specified location, or that replaces the specified string.

pattern

Pattern that is used to match multiple strings in the request or response. The pattern may be a string literal (without quotes) or a PCRE-format regular expression with a delimiter that consists of any printable ASCII non-alphanumeric character except for the underscore (_) and space ( ) that is not otherwise used in the expression. Example: re~https?://|HTTPS?://~ The preceding regular expression can use the tilde (~) as the delimiter because that character does not appear in the regular expression itself. Used in the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types.

search

Search facility that is used to match multiple strings in the request or response. Used in the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types. The following search types are supported:

* Text ("text(string)") - A literal string. Example: -search text("hello")

* Regular expression (?regex(re<delimiter>regular exp<delimiter>)?) - Pattern that is used to match multiple strings in the request or response. The pattern may be a string literal (without quotes) or a PCRE-format regular expression with a delimiter that consists of any printable ASCII non-alphanumeric character except for the underscore (_) and space ( ) that is not otherwise used in the expression. Example: -search regex(re~^hello~) The preceding regular expression can use the tilde (~) as the delimiter because that character does not appear in the regular expression itself.

* XPath ("xpath(xp<delimiter>xpath expression<delimiter>)") - An XPath expression. Example: -search xpath(xp%/a/b%)

* JSON ("xpath_json(xp<delimiter>xpath expression<delimiter>)") - An XPath JSON expression. Example: -search xpath_json(xp%/a/b%)

NOTE: JSON searches use the same syntax as XPath searches, but operate on JSON files instead of standard XML files.

* Patset ("patset(patset)") - A predefined pattern set. Example: -search patset("patset1")

bypassSafetyCheck

Bypass the safety check and allow unsafe expressions. An unsafe expression is one that contains references to message elements that might not be present in all messages. If an expression refers to a missing request element, an empty string is used instead.

Possible values: YES, NO

Default value: NO

refineSearch

Specify additional criteria to refine the results of the search.

Always starts with the "extend(m,n)" operation, where 'm' specifies number of bytes to the left of selected data and 'n' specifies number of bytes to the right of selected data.

You can use refineSearch only on body expressions, and for the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types.

comment

Comment. Can be used to preserve information about this rewrite action.

i) add rewrite action act_insert INSERT_HTTP_HEADER change_req "\\\\"no change\\\\"" . This Adds to http header will add the header change_req: no change. ii) add rewri

---

Removes a rewrite action.

rm rewrite action <name>

name

Name of the rewrite action to remove.

rm rewrite action act_before

Modifies the specified parameters of a rewrite action.

set rewrite action <name> [-target <string>] [-stringBuilderExpr <string>] [-pattern <expression> | -search <expression>] [-bypassSafetyCheck (YES | NO)] [-refineSearch <string>] [-comment <string>]

name

Name of the rewrite action to modify.

target

Expression that specifies which part of the connection to rewrite.

stringBuilderExpr

Default syntax expression that specifies the content to insert into the request or response at the specified location, or that replaces the specified string.

pattern

Pattern that is used to match multiple strings in the request or response. The pattern may be a string literal (without quotes) or a PCRE-format regular expression with a delimiter that consists of any printable ASCII non-alphanumeric character except for the underscore (_) and space ( ) that is not otherwise used in the expression. Example: re~https?://|HTTPS?://~ The preceding regular expression can use the tilde (~) as the delimiter because that character does not appear in the regular expression itself. Used in the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types.

search

Search facility that is used to match multiple strings in the request or response. Used in the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types. The following search types are supported:

* Text ("text(string)") - A literal string. Example: -search text("hello")

* Regular expression (?regex(re<delimiter>regular exp<delimiter>)?) - Pattern that is used to match multiple strings in the request or response. The pattern may be a string literal (without quotes) or a PCRE-format regular expression with a delimiter that consists of any printable ASCII non-alphanumeric character except for the underscore (_) and space ( ) that is not otherwise used in the expression. Example: -search regex(re~^hello~) The preceding regular expression can use the tilde (~) as the delimiter because that character does not appear in the regular expression itself.

* XPath ("xpath(xp<delimiter>xpath expression<delimiter>)") - An XPath expression. Example: -search xpath(xp%/a/b%)

* JSON ("xpath_json(xp<delimiter>xpath expression<delimiter>)") - An XPath JSON expression. Example: -search xpath_json(xp%/a/b%)

NOTE: JSON searches use the same syntax as XPath searches, but operate on JSON files instead of standard XML files.

* Patset ("patset(patset)") - A predefined pattern set. Example: -search patset("patset1")

bypassSafetyCheck

Bypass the safety check and allow unsafe expressions. An unsafe expression is one that contains references to message elements that might not be present in all messages. If an expression refers to a missing request element, an empty string is used instead.

Possible values: YES, NO

Default value: NO

refineSearch

Specify additional criteria to refine the results of the search.

Always starts with the "extend(m,n)" operation, where 'm' specifies number of bytes to the left of selected data and 'n' specifies number of bytes to the right of selected data.

You can use refineSearch only on body expressions, and for the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types.

comment

Comment. Can be used to preserve information about this rewrite action.

```
set rewrite action rwact1 -target "HTTP.REQ.HEADER(\\\"MyHdr\\\")" -stringBuilderExpr "HTTP.REQ.URL.MARK_SAFE"
```

Use this command to remove rewrite action settings.Refer to the set rewrite action command for meanings of the arguments.

```
unset rewrite action <name> [-stringBuilderExpr] [-refineSearch] [-comment]
```

Displays the current settings for the specified rewrite action. If no rewrite action name is provided, displays a list of all rewrite actions currently configured on the NetScaler appliance.

```
show rewrite action [<name>]
```

name

Name of the rewrite action.

summary

level

stateflag

type

Type of rewrite action. It can be: (delete | replace | insert_http_header | insert_before | insert_after | replace_http_res).

target

Expression specifying which part of HTTP header needs to be rewritten.

stringBuilderExpr

Expression specifying the value of rewritten HTTP header.

pattern

Pattern used for insert_before_all, insert_after_all, replace_all, delete_all action types.

search

Search facility that is used to match multiple strings in the request or response. Used in the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types. The following search types are supported:

* Text ("text(string)") - A literal string. Example: -search text("hello")

* Regular expression (?regex(re<delimiter>regular exp<delimiter>)?) - Pattern that is used to match multiple strings in the request or response. The pattern may be a string literal (without quotes) or a PCRE-format regular expression with a delimiter that consists of any printable ASCII non-alphanumeric character except for the underscore (_) and space ( ) that is not otherwise used in the expression. Example: -search regex(re~^hello~) The preceding regular expression can use the tilde (~) as the delimiter because that character does not appear in the regular expression itself.

* XPath ("xpath(xp<delimiter>xpath expression<delimiter>)") - An XPath expression. Example: -search xpath(xp%/a/b%)

* JSON ("xpath_json(xp<delimiter>xpath expression<delimiter>)") - An XPath JSON expression. Example: -search xpath_json(xp%/a/b%)

NOTE: JSON searches use the same syntax as XPath searches, but operate on JSON files instead of standard XML files.

* Patset ("patset(patset)") - A predefined pattern set. Example: -search patset("patset1")

bypassSafetyCheck

The safety check to allow unsafe expressions.

refineSearch

Specify additional criteria to refine the results of the search.

Always starts with the "extend(m,n)" operation, where 'm' specifies number of bytes to the left of selected data and 'n' specifies number of bytes to the right of selected data.

You can use refineSearch only on body expressions, and for the INSERT_BEFORE_ALL, INSERT_AFTER_ALL, REPLACE_ALL, and DELETE_ALL action types.

hits

The number of times the action has been taken.

undefHits

The number of times the action resulted in UNDEF.

referenceCount

The number of references to the action.

description

Description of the action

flags

isDefault

A value of true is returned if it is a default rewriteaction.

comment

Comment. Can be used to preserve information about this rewrite action.

builtin

Flag to determine whether rewrite action is built-in or not

devno

count

1. show rewrite action 2. show rewrite action act_insert

Renames a rewrite action.

rename rewrite action <name>@ <newName>@

name

Existing name of the rewrite action.

newName

New name for the rewrite action.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the rewrite policy is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rewrite action" or ?my rewrite action?).

rename rewrite action oldname newname

rewrite global

Sep 22, 2015

The following operations can be performed on "rewrite global":

bind | unbind | show

Activates the specified rewrite policy globally.

bind rewrite global <policyName> <priority> [<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]

policyName

Name of the rewrite policy to activate.

i) bind rewrite global pol9 9 ii) bind rewrite global pol9 9 120 iii) bind rewrite global pol9 9 "HTTP.REQ.HEADER(\\\\"qh3\\\\").TYPECAST_NUM_T(DECIMAL)"

Unbinds the specified rewrite policy from rewrite global. See the bind rewrite global command for a description of the parameters.

unbind rewrite global <policyName> [-type <type>] [-priority <positive_integer>]

policyName

Name of the rewrite policy to deactivate.

priority

Priority of the NOPOLICY to be unbound.

Minimum value: 1

Maximum value: 2147483647

unbind rewrite global pol9

Displays the list of policies bound to the specified rewrite global policy bank. If no policy bank is specified, displays a list of all policies bound to rewrite global.

show rewrite global [-type <type>]

type

The bindpoint to which to policy is bound.

Possible values: REQ_OVERRIDE, REQ_DEFAULT, RES_OVERRIDE, RES_DEFAULT, OTHERTCP_REQ_OVERRIDE, OTHERTCP_REQ_DEFAULT, OTHERTCP_RES_OVERRIDE, OTHERTCP_RES_DEFAULT, SIPUDP_REQ_OVERRIDE, SIPUDP_REQ_DEFAULT, SIPUDP_RES_OVERRIDE, SIPUDP_RES_DEFAULT

summary

format

level

stateflag

policyName

Name of the rewrite policy.

priority

Specifies the priority of the policy.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

invoke

Terminate evaluation of policies bound to the current policy label, and then forward the request to the specified virtual server or evaluate the specified policy label.

labelType

Type of invocation. Available settings function as follows:

* reqvserver - Forward the request to the specified request virtual server.

* resvserver - Forward the response to the specified response virtual server.

* policylabel - Invoke the specified policy label.

labelName

* If labelType is policylabel, name of the policy label to invoke.

* If labelType is reqvserver or resvserver, name of the virtual server to which to forward the request of response.

numpol

The number of policies bound to the bindpoint.

flowType

flowtype of the bound rewrite policy.

flags

devno

count

show rewrite global

rewrite param

Sep 22, 2015

The following operations can be performed on "rewrite param":

set | unset | show

Sets the default rewrite undefined action. If an UNDEF event is triggered during policy evaluation and if no undefAction is specified for the current policy, this value is used.

set rewrite param -undefAction <string>

undefAction

Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition.

Available settings function as follows:

* NOOP - Send the request to the protected server instead of responding to it.

* RESET - Reset the request and notify the user?s browser, so that the user can resend the request.

* DROP - Drop the request without sending a response to the user.

Default value: "NOREWRITE"

set rewrite param -undefAction RESET

Resets the global undefAction to NOREWRITE..Refer to the set rewrite param command for meanings of the arguments.

unset rewrite param -undefAction

unset rewrite param -undefAction

Displays the default rewrite undefAction.

show rewrite param

format

level

undefAction

Name of the rewrite action.

show rewrite param

rewrite policy

Sep 22, 2015

The following operations can be performed on "rewrite policy":

add | rm | set | unset | show | stat | rename

Creates a rewrite policy, which specifies which requests or responses to rewrite.

add rewrite policy <name> <rule> <action> [<undefAction>] [-comment <string>] [-logAction <string>]

name

Name for the rewrite policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the rewrite policy is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rewrite policy" or ?my rewrite policy?).

rule

Expression against which traffic is evaluated. Written in default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

(Classic expressions are not supported in the cluster build.)

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Name of the rewrite action to perform if the request or response matches this rewrite policy.

undefAction

Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition.

Available settings function as follows:

* NOREWRITE - Send the request to the protected server without rewriting.

* RESET - Reset the request and notify the user?s browser, so that the user can resend the request.

* DROP - Drop the request without sending a response to the user.

comment

Any comments to preserve information about this rewrite policy.

logAction

Name of messagelog action to use when a request matches this policy.

i) add rewrite policy pol9 "HTTP.REQ.HEADER(\\\"header\\\").CONTAINS(\\\"qh3\\\")" act_insert ii) add rewrite policy pol9 "HTTP.REQ.HEADER(\\\"header\\\").CONTAIN

Removes the specified rewrite policy.

rm rewrite policy <name>

name

Name of the rewrite policy to be removed.

rm rewrite policy pol9

Modifies the specified parameters of a rewrite policy.

set rewrite policy <name> [-rule <expression>] [-action <string>] [-undefAction <string>] [-comment <string>] [-logAction <string>]

name

Name of the rewrite policy to modify.

rule

Expression against which traffic is evaluated. Written in default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

(Classic expressions are not supported in the cluster build.)

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Name of the rewrite action to perform if the request or response matches this rewrite policy.

undefAction

Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition.

Available settings function as follows:

* NOREWRITE - Send the request to the protected server without rewriting.

* RESET - Reset the request and notify the user?s browser, so that the user can resend the request.

* DROP - Drop the request without sending a response to the user.

comment

Any comments to preserve information about this rewrite policy.

logAction

Name of messagelog action to use when a request matches this policy.

set rewrite policy pol9 -rule "HTTP.REQ.HEADER(\\\"header\\\").CONTAINS(\\\"qh2\\\")"

Removes the settings of an existing rewrite policy. Attributes for which a default value is available revert to their default values. See the set rewrite policy command for a description of the parameters..Refer to the set rewrite policy command for meanings of the arguments.

unset rewrite policy <name> [-undefAction] [-comment] [-logAction]

unset rewrite policy pol9 -undefAction

Displays the current settings for the specified rewrite policy. If no policy name is provided, displays a list of all rewrite policies currently configured on the NetScaler appliance.

show rewrite policy [<name>] show rewrite policy stats - alias for 'stat rewrite policy'

name

Name of the rewrite policy.

count

show rewrite policy

Displays statistics for the specified rewrite policy. If no policy name is specified, displays abbreviated statistics for all rewrite policies currently configured on the NetScaler appliance.

stat rewrite policy [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

name

Name of the rewrite policy.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Policy hits (Hits)

Number of hits on the policy

Policy undef hits (Undefhits)

Number of undef hits on the policy

stat rewrite policy

Renames the specified rewrite policy. You must restart the NetScaler appliance to put new name in effect.

rename rewrite policy <name>@ <newName>@

name

Existing name of the rewrite policy.

newName

New name for the rewrite policy.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rewrite policy" or ?my rewrite policy?).

rename rewrite policy oldname newname

rewrite policylabel

Sep 22, 2015

The following operations can be performed on "rewrite policylabel":

add | rm | bind | unbind | show | stat | rename

Creates a user-defined rewrite policy label.

add rewrite policylabel <labelName> <transform>

labelName

Name for the rewrite policy label. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the rewrite policy label is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rewrite policy label" or ?my rewrite policy label?).

transform

Types of transformations allowed by the policies bound to the label. For Rewrite, the following types are supported:

* http_req - HTTP requests

* http_res - HTTP responses

* othertcp_req - Non-HTTP TCP requests

* othertcp_res - Non-HTTP TCP responses

* url - URLs

* text - Text strings

* clientless_vpn_req - NetScaler clientless VPN requests

* clientless_vpn_res - NetScaler clientless VPN responses

* sipudp_req - SIP requests

* sipudp_res - SIP responses

Possible values: http_req, http_res, othertcp_req, othertcp_res, url, text, clientless_vpn_req, clientless_vpn_res, sipudp_req, sipudp_res

add rewrite policylabel trans_http_url http_req

Removes the specified rewrite policy label.

rm rewrite policylabel <labelName>

labelName

Name of the rewrite policy label to remove.

rm rewrite policylabel trans_http_url

Binds the specified rewrite policy to the specified policy label.

bind rewrite policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]

labelName

Name of the rewrite policy label to which to bind the policy.

policyName

Name of the rewrite policy to bind to the policy label.

i) bind rewrite policylabel trans_http_url pol_1 1 2 -invoke reqvserver CURRENT ii) bind rewrite policylabel trans_http_url pol_2 2

Unbinds the specified rewrite policy from the specified policy label. See the bind rewrite policylabel command for a description of the parameters.

unbind rewrite policylabel <labelName> <policyName> [-priority <positive_integer>]

labelName

Name for the rewrite policy label. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the rewrite policy label is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my rewrite policy label" or ?my rewrite policy label?).

policyName

Name of the rewrite policy to bind to the policy label.

priority

Priority of the NOPOLICY to be unbound.

Minimum value: 1

Maximum value: 2147483647

unbind rewrite policylabel trans_http_url pol_1

Displays the current settings for the specified rewrite policy label. If no policy label is specified, displays a list of all rewrite policy labels currently configured on the NetScaler appliance.

show rewrite policylabel [<labelName>]

labelName

Name of the rewrite policy label.

summary

fullValues

format

level

stateflag

transform

Types of transformations allowed by the policies bound to the label. For Rewrite, the following types are supported:

* http_req - HTTP requests

* http_res - HTTP responses

* othertcp_req - Non-HTTP TCP requests

* othertcp_res - Non-HTTP TCP responses

* url - URLs

* text - Text strings

* clientless_vpn_req - NetScaler clientless VPN requests

* clientless_vpn_res - NetScaler clientless VPN responses

* sipudp_req - SIP requests

* sipudp_res - SIP responses

numpol

Number of polices bound to label.

hits

Number of times policy label was invoked.

policyName

Name of the rewrite policy to bind to the policy label.

priority

Specifies the priority of the policy.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

invoke

Suspend evaluation of policies bound to the current policy label, and then forward the request to the specified virtual server or evaluate the specified policy label.

labelType

Type of invocation. Available settings function as follows:

* reqvserver - Forward the request to the specified request virtual server.

* resvserver - Forward the response to the specified response virtual server.

* policylabel - Invoke the specified policy label.

labelName

* If labelType is policylabel, name of the policy label to invoke.

* If labelType is reqvserver or resvserver, name of the virtual server to which to forward the request or response.

flowType

Flowtype of the bound rewrite policy.

description

Description of the policylabel

isDefault

A value of true is returned if it is a default rewritepolicylabel.

flags

devno

count

i) show rewrite policylabel trans_http_url ii) show rewrite policylabel

---

Displays statistics for the specified rewrite policy label. If no policy label name is provided, displays abbreviated statistics for all rewrite policy labels currently configured on the NetScaler appliance.

stat rewrite policylabel [<labelName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

labelName

Name of the rewrite policy label.

clearstats

Clear the statsistics / counters

Possible values: basic, full

count

devno

stateflag

Policy Label Hits (Hits)

Number of times policy label was invoked.

Renames a rewrite policy label.

rename rewrite policylabel <labelName>@ <newName>@

labelName

Current name of the policy label.

newName

New name for the rewrite policy label.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy label" or ?my policy label?).

rename rewrite policylabel oldname newname

Responder Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- responder action
- responder global
- responder htmlpage
- responder param
- responder policy
- responder policylabel

responder action

Sep 22, 2015

The following operations can be performed on "responder action":

add | rm | set | unset | show | rename

Creates a responder action, which specifies how to respond to a request.

add responder action <name> <type> (<target> | <htmlpage>) [-bypassSafetyCheck (YES | NO)] [-comment <string>]

name

Name for the responder action. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the responder policy is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder action" or 'my responder action').

type

Type of responder action. Available settings function as follows:

* respondwith <target> - Respond to the request with the expression specified as the target.

* respondwithhtmlpage - Respond to the request with the uploaded HTML page object specified as the target.

* redirect - Redirect the request to the URL specified as the target.

* sqlresponse_ok - Send an SQL OK response.

* sqlresponse_error - Send an SQL ERROR response.

Possible values: noop, respondwith, redirect, respondwithhtmlpage, sqlresponse_ok, sqlresponse_error

target

Expression specifying what to respond with. Typically a URL for redirect policies or a default-syntax expression. In addition to NetScaler default-syntax expressions that refer to information in the request, a stringbuilder expression can contain text and HTML, and simple escape codes that define new lines and paragraphs. Enclose each stringbuilder expression element (either a NetScaler default-syntax expression or a string) in double quotation marks. Use the plus (+) character to join the elements.

Examples:

1) Respondwith expression that sends an HTTP 1.1 200 OK response:

"HTTP/1.1 200 OK\\r\\n\\r\\n"

2) Redirect expression that redirects user to the specified web host and appends the request URL to the redirect.

"http://backupsite2.com" + HTTP.REQ.URL

3) Respondwith expression that sends an HTTP 1.1 404 Not Found response with the request URL included in the response:

"HTTP/1.1 404 Not Found\\r\\n\\r\\n"+ "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."

The following requirement applies only to the NetScaler CLI:

Enclose the entire expression in single quotation marks. (NetScaler default expression elements should be included inside the single quotation marks for the entire expression, but do not need to be enclosed in double quotation marks.)

htmlpage

For respondwithhtmlpage policies, name of the HTML page object to use as the response. You must first import the page object.

bypassSafetyCheck

Bypass the safety check, allowing potentially unsafe expressions. An unsafe expression in a response is one that contains references to request elements that might not be present in all requests. If a response refers to a missing request element, an empty string is used instead.

Possible values: YES, NO

Default value: NO

comment

Comment. Any type of information about this responder action.

1) add responder action act1 respondwith "\\\"HTTP/1.1 200 OK\\\\r\\\\n\\\\r\\\\n\\\"" 2) add responder action resp respondwithhtmlpage my-responder-page, 3) add responde

Removes the specified responder action.

rm responder action <name>

name

Name of the responder action to remove.

rm responder action act_before

Modifies the specified parameters of a responder action.

set responder action <name> [-target <string> [-bypassSafetyCheck (YES | NO)]] [-htmlpage <string>] [-comment <string>]

name

Name of the responder action to be modified.

target

Expression specifying what to respond with. Typically a URL for redirect policies or a default-syntax expression. In addition to NetScaler default-syntax expressions that refer to information in the request, a stringbuilder expression can contain text and HTML, and simple escape codes that define new lines and paragraphs. Enclose each stringbuilder expression element (either a NetScaler default-syntax expression or a string) in double quotation marks. Use the plus (+) character to join the elements.

Examples:

1) Respondwith expression that sends an HTTP 1.1 200 OK response:

"HTTP/1.1 200 OK\\r\\n\\r\\n"

2) Redirect expression that redirects user to the specified web host and appends the request URL to the redirect.

"http://backupsite2.com" + HTTP.REQ.URL

3) Respondwith expression that sends an HTTP 1.1 404 Not Found response with the request URL included in the response:

"HTTP/1.1 404 Not Found\\r\\n\\r\\n"+ "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."

The following requirement applies only to the NetScaler CLI:

Enclose the entire expression in single quotation marks. (NetScaler default expression elements should be included inside the single quotation marks for the entire expression, but do not need to be enclosed in double quotation marks.)

htmlpage

For respondwithhtmlpage policies, name of the HTML page object to use as the response. You must first import the page object.

comment

Comment. Any type of information about this responder action.

1. set responder action act_responder -target 'HTTP.REQ.HEADER(MYURL)' -bypassSafetyCheck YES/, 2. set responder action act_responder -htmlpage my-local-file

---

Use this command to remove responder action settings.Refer to the set responder action command for meanings of the arguments.

unset responder action <name> -comment

Displays the current settings for the specified responder action. If no action name is provided, displays a list of all responder actions currently configured on the NetScaler appliance, with abbreviated settings.

show responder action [<name>]

name

Name of the responder action.

The number of times the action has been taken.

referenceCount

The number of references to the action.

undefHits

The number of times the action resulted in UNDEF.

comment

Comment. Any type of information about this responder action.

builtin

Flag to determine whether responder action is built-in or not

devno

count

1. show responder action 2. show responder action act_insert

Renames a responder action.

rename responder action <name>@ <newName>@

name

Existing name of the responder action.

newName

New name for the responder action.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder action" or my responder action').

rename responder action oldname newname

responder global

Sep 22, 2015

The following operations can be performed on "responder global":

bind | unbind | show

Activates the specified responder policy for all requests sent to the NetScaler appliance.

bind responder global <policyName> <priority> [<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]

policyName

Name of the responder policy to activate. If you want to create the policy as well as activate it, specify a name for the responder policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder policy" or 'my responder policy').

i) bind responder global pol9 9

Unbind the specified responder policy from responder global.

unbind responder global <policyName> [-type <type>] [-priority <positive_integer>]

policyName

Name of the policy to unbind.

priority

Priority of the NOPOLICY to be unbound.

Minimum value: 1

Maximum value: 2147483647

unbind responder global pol9

Displays the list of policies bound to the specified responder global bind point. If no bind point is specified, displays a list of all policies bound to responder global.

show responder global [-type <type>]

type

Specifies the bind point whose policies you want to display. Available settings function as follows:

* REQ_OVERRIDE - Request override. Binds the policy to the priority request queue.

* REQ_DEFAULT - Binds the policy to the default request queue.

* OTHERTCP_REQ_OVERRIDE - Binds the policy to the non-HTTP TCP priority request queue.

* OTHERTCP_REQ_DEFAULT - Binds the policy to the non-HTTP TCP default request queue..

* SIPUDP_REQ_OVERRIDE - Binds the policy to the SIP UDP priority response queue..

* SIPUDP_REQ_DEFAULT - Binds the policy to the SIP UDP default response queue.

* MSSQL_REQ_OVERRIDE - Binds the policy to the Microsoft SQL priority response queue..

* MSSQL_REQ_DEFAULT - Binds the policy to the Microsoft SQL default response queue.

* MYSQL_REQ_OVERRIDE - Binds the policy to the MySQL priority response queue.

* MYSQL_REQ_DEFAULT - Binds the policy to the MySQL default response queue.

Possible values: REQ_OVERRIDE, REQ_DEFAULT, OVERRIDE, DEFAULT, OTHERTCP_REQ_OVERRIDE, OTHERTCP_REQ_DEFAULT, SIPUDP_REQ_OVERRIDE, SIPUDP_REQ_DEFAULT, MSSQL_REQ_OVERRIDE, MSSQL_REQ_DEFAULT, MYSQL_REQ_OVERRIDE, MYSQL_REQ_DEFAULT

responder htmlpage

Sep 22, 2015

The following operations can be performed on "responder htmlpage":

import | rm | update | show

Imports the specified HTML page to the NetScaler appliance, assigns it the specified name, and stores it in the list of Responder HTML page objects.

import responder htmlpage [<src>] <name> [-comment <string>] [-overwrite]

src

Local path to and name of, or URL \\(protocol, host, path, and file name\\) for, the file in which to store the imported HTML page.

NOTE: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access.

name

Name to assign to the HTML page object on the NetScaler appliance.

comment

Any comments to preserve information about the HTML page object.

overwrite

Overwrites the existing file

import responder htmlpage http://www.example.com/page.html my-responder-page

---

Removes the specified HTML page object.

rm responder htmlpage <name>

name

Name of the HTML page object to remove.

rm responder htmlpage <name>

Updates the specified HTML page object from the source.

update responder htmlpage <name>

name

Name to assign to the HTML page object on the NetScaler appliance.

update responder htmlpage my-responder-page

Displays the specified HTML page object. If no HTML page object is specified, lists all HTML page objects on the NetScaler appliance.

show responder htmlpage [<name>]

name

Name of the HTML page object to display.

response

show responder htmlpage

---

responder param

Sep 22, 2015

The following operations can be performed on "responder param":

set | unset | show

Sets the default responder undefined action. If an UNDEF event is triggered during policy evaluation and if no undefAction is specified for the current policy, this value is used.

set responder param -undefAction <string>

undefAction

Action to perform when policy evaluation creates an UNDEF condition. Available settings function as follows:

* NOOP - Send the request to the protected server.

* RESET - Reset the request and notify the user's browser, so that the user can resend the request.

* DROP - Drop the request without sending a response to the user.

Default value: "NOOP"

set responder param -undefAction RESET

Resets the global undefAction to NOOP..Refer to the set responder param command for meanings of the arguments.

unset responder param -undefAction

unset responder param -undefAction

Displays the default responder undefAction.

show responder param

format

level

undefAction

Name of the responder action.

show responder param

responder policy

Sep 22, 2015

The following operations can be performed on "responder policy":

add | rm | set | unset | show | rename | stat

Creates a responder policy, which specifies requests that the NetScaler appliance intercepts and responds to directly instead of forwarding them to a protected server.

add responder policy <name> <rule> <action> [<undefAction>] [-comment <string>] [-logAction <string>] [-appflowAction <string>]

name

Name for the responder policy.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the responder policy is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder policy" or 'my responder policy').

rule

Default syntax expression that the policy uses to determine whether to respond to the specified request.

action

Name of the responder action to perform if the request matches this responder policy.

undefAction

Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition.

Available settings function as follows:

* NOOP - Send the request to the protected server instead of responding to it.

* RESET - Reset the request and notify the user's browser, so that the user can resend the request.

* DROP - Drop the request without sending a response to the user.

comment

Any type of information about this responder policy.

logAction

Name of the messagelog action to use for requests that match this policy.

appflowAction

AppFlow action to invoke for requests that match this policy.

i) add responder policy pol9 "HTTP.REQ.HEADER(\\\"header\\\").CONTAINS(\\\"qh3\\\")" act_respondwith

---

Removes the specified responder policy.

rm responder policy <name>

name

Name of the responder policy to remove.

rm responder policy pol9

Modifies the rule or action portion of the specified responder policy.

set responder policy <name> [-rule <expression>] [-action <string>] [-undefAction <string>] [-comment <string>] [-logAction <string>] [-appflowAction <string>]

name

Name of the responder policy.

rule

Default syntax expression that the policy uses to determine whether to respond to the specified request.

action

Name of the responder action to perform if the request matches this responder policy.

undefAction

Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition.

Available settings function as follows:

* NOOP - Send the request to the protected server instead of responding to it.

* RESET - Reset the request and notify the user's browser, so that the user can resend the request.

* DROP - Drop the request without sending a response to the user.

comment

Any type of information about this responder policy.

logAction

Name of the messagelog action to use for requests that match this policy.

appflowAction

AppFlow action to invoke for requests that match this policy.

```
set responder policy pol9 -rule "HTTP.REQ.HEADER(\\\"header\\\").CONTAINS(\\\"qh2\\\")"
```

Removes the settings of an existing responder policy. Attributes for which a default value is available revert to their default values. See the set responder policy command for descriptions of the parameters..Refer to the set responder policy command for meanings of the arguments.

```
unset responder policy <name> [-undefAction] [-comment] [-logAction] [-appflowAction]
```

```
unset responder policy respol9 -undefAction
```

Displays the current settings for the specified responder policy. If no policy name is specified, displays a list of all responder policies currently configured on the NetScaler appliance, with abbreviated settings.

show responder policy [<name>] show responder policy stats - alias for 'stat responder policy'

name

Name of the responder policy for which to display settings.

Policy undef hits (Undefhits)

Number of undef hits on the policy

responder policylabel

Sep 22, 2015

The following operations can be performed on "responder policylabel":

add | rm | bind | unbind | show | stat | rename

Creates a user-defined responder policy label, to which you can bind policies. A policy label is a tool for evaluating a set of policies in a specified order. By using a policy label, you can configure the responder feature to choose the next policy, invoke a different policy label, or terminate policy evaluation completely by looking at whether the previous policy evaluated to TRUE or FALSE.

add responder policylabel <labelName> [-policylabeltype <policylabeltype>]

labelName

Name for the responder policy label. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the responder policy label is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder policy label" or my responder policy label').

policylabeltype

Type of responses sent by the policies bound to this policy label. Types are:

* HTTP - HTTP responses.

* OTHERTCP - NON-HTTP TCP responses.

* SIP_UDP - SIP responses.

* MYSQL - SQL responses in MySQL format.

* MSSQL - SQL responses in Microsoft SQL format.

Possible values: HTTP, OTHERTCP, SIP_UDP, MYSQL, MSSQL

Default value: NS_PLTMAP_RSP_REQ

```
add responder policylabel resp_lab
```

Removes a responder policy label.

rm responder policylabel <labelName>

labelName

Name of the responder policy label to remove.

rm responder policylabel resp_lab

Binds the specified responder policy to the specified policy label.

bind responder policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]

labelName

Name of the responder policy label to which to bind the policy.

policyName

Name of the policy to bind to the responder policy label.

i) bind responder policylabel resp_lab pol_resp 1 2 ii) bind responder policylabel resp_lab pol_resp 1 2 -invoke vserver CURRENT

Unbinds the specified responder policy from the specified policy label.

unbind responder policylabel <labelName> <policyName> [-priority <positive_integer>]

labelName

Name for the responder policy label. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the responder policy label is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder policy label" or my responder policy label').

policyName

The name of the policy to be unbound.

priority

Priority of the NOPOLICY to be unbound.

Minimum value: 1

Maximum value: 2147483647

unbind responder policylabel resp_lab pol_resp

Displays the current settings for the specified responder policy label. If no policy label is specified, displays a list of all responder policy labels currently configured on the NetScaler appliance, with abbreviated settings.

show responder policylabel [<labelName>]

Router Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- router bgp
- router ospf
- router rip
- vtysh

router bgp

Sep 22, 2015

The following operations can be performed on "router bgp":

add | clear | rm | set | unset | show

NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

autonomousSystem

The BGP autonomous system.

Minimum value: 1

routerID

The router ID of the router.

learnRoute

The state of route learning from BGP.

staticRedistribute

The state of router in redistribution of static routes.

kernelRedistribute

The state of router in redistribution of kernel routes.

conRedistribute

The state of router in redistribution of connected routes.

neighbor

Add a BGP neighbor.

network

The neighbor to be advertised.

NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

autonomousSystem

The autonomous system for BGP.

Minimum value: 1

neighbor

The neighbor associated with the connection that needs to be torn down.

all

Reset TCP connections to all neighbors.

NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

autonomousSystem

The autonomous system for BGP.

Minimum value: 1

neighbor

To remove a particular neighbor.

NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

autonomousSystem

The autonomous system for BGP.

Minimum value: 1

routerID

The Router ID of this router.

learnRoute

The state of the router in learning routes from BGP. Use this option to enable route learning and installation from BGP.

staticRedistribute

The state of the router in redistributing static routes. Use this option to enable the redistribution of static routes.

kernelRedistribute

The state of the router in redistribution of kernel routes.

conRedistribute

The state of the router in redistributing connected routes. Use this option to enable the redistribution of connected routes into the BGP domain.

neighbor

The IP address of a BGP peer for the router.

network

The network to be advertized.

Use this command to remove router bgp settings.Refer to the set router bgp command for meanings of the arguments.NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

router ospf

Sep 22, 2015

The following operations can be performed on "router ospf":

set | unset | show

Configure different OSPF parameters. NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

routerID

The router ID.

passiveInterface

The mode of the Interface. Use this option to change the mode of the interface to listen only.

staticRedistribute

The state of the router in redistributing static routes. Use this option to enable the redistribution of static routes.

kernelRedistribute

The state of the router in redistributing kernel routes. Use this option to enable the redistribution of kernel routes.

conRedistribute

The state of the router in redistributing connected routes. Use this option to enable the redistribution of connected routes.

learnRoute

The state of the router in learning routes from OSPF. Use this option to enable route learning from OSPF.

network

The broadcast network on which OSPF is to be run.

host

The stub link.

```
set ospf -routerID 1.2.3.4
```

Unset the OSPF parameters that were configured using the ###set ospf### command..Refer to the set router ospf command for meanings of the arguments.NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

unset ospf -router-id

Display the state of the OSPF daemon. NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

ospfoptions

The Router OSPF option. Use this option to display one of border-routers, database, interface, neighbor, route, and virtual-links.

Possible values: border-routers, database, interface, neighbor, route, virtual-links

format

level

network

The network on which OSPF is running.

netmask

Netmask of the network on which OSPF is running

show ospf neighbor

---

router rip

Sep 22, 2015

The following operations can be performed on "router rip":

set | unset | show

Configure the RIP daemon. NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

defaultMetric

The default metrics when advertising routes.

Default value: 1

Minimum value: 1

Maximum value: 16

passiveInterface

The mode of the interface to listen only.

learnRoute

The state of Route learning. Use this option to enable route learning and installation in the kernel.

staticRedistribute

The state of redistributing static routes.

kernelRedistribute

The state of redistributing kernel routes.

network

The broadcast network on which RIP must run.

set router rip -kernelRedistribute

Unset the RIP parameters..Refer to the set router rip command for meanings of the arguments.NOTE: This command is

deprecated.All routing configurations have now been moved to vtysh

unset rip -default-metric

Display the RIP configuration. NOTE: This command is deprecated.All routing configurations have now been moved to vtysh

ripOptions

RIP option in show command, one of database or interface.

Possible values: database, interface

format

level

network

The broadcast network on which RIP must run.

netmask

show rip interface

---

vtysh

Sep 22, 2015

The following operations can be performed on "vtysh":

Enters into the Virtual Teletype Shell (VTYSH) prompt, at which you can configure all the dynamic routing protocols. The NetScaler dynamic routing suite is based on ZebOS, the commercial version of GNU Zebra.

vtysh

SureConnect Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- sc
- sc parameter
- sc policy
- sc stats

SC

Sep 22, 2015

The following operations can be performed on "sc":

Displays SureConnect statistics.

stat sc [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

SC condition triggered (ScTrigd)

Number of times that SureConnect conditions were triggered.

SC trigger condition failed

Total number of times SureConnect was not triggered because the thresholds conditions failed.

Policy matches

Total number of incoming requests that matched configured sureconnect policies.

SC responses sent

Total number of in-memory java script served which throws the pop-up window.

Reissued requests (ReissReq)

Total number of reissued SureConnect requests.

Valid reissued requests

Total number of requests that were handled in a single SureConnect session.

Alternate content requests

Total number of alternate content served which throws the pop-up window.

SC POST requests

Total number of HTTP POST requests that triggered SureConnect feature.

SC statistics timeout

Toal number of times that SureConnect statistics were reset.

Unsupported browsers

Total number of requests that came from all unsupported browsers.

Tampered SC cookies

Total number of corrupted SureConnect cookies.

sc parameter

Sep 22, 2015

The following operations can be performed on "sc parameter":

set | unset | show

Sets the parameters for displaying SureConnect information.

set sc parameter [-sessionLife <secs>] [-vsr <input_filename>]

sessionLife

Time, in seconds, between the first time and the next time the SureConnect alternative content window is displayed. The alternative content window is displayed only once during a session for the same browser accessing a configured URL, so this parameter determines the length of a session.

Default value: 300

Minimum value: 1

Maximum value: 4294967294

vsr

File containing the customized response to be displayed when the ACTION in the SureConnect policy is set to NS.

Default value: "DEFAULT"

set sc parameter -sessionlife 200 -vsr /etc/vsr.htm

Use this command to remove sc parameter settings.Refer to the set sc parameter command for meanings of the arguments.

unset sc parameter [-sessionLife] [-vsr]

Displays the values of the session life and vsr filename parameters.

show sc parameter

format

level

sessionLife

The time between first time the Sureconnect aternate content window displays and the next time it displays.The SureConnect alternate content window is displayed only once during a session. For the same browser accessing a configured URL.The value is in seconds.

vsr

The customized response will be displayed to the user if the alternate content server has been determined by the system to have failed.

If you have created a customized response that you want the system to use, enter its filename (if you renamed the vsr.htm file supplied by system). If you have not renamed the file, enter /etc/vsr.htm as the filename.

> show sc parameter Sure Connect Parameters: Sessionlife: 300 Vsr: DEFAULT Done

sc policy

Sep 22, 2015

The following operations can be performed on "sc policy":

add | rm | set | unset | show | stat

Creates a new SureConnect policy.

add sc policy <name> [-url <URL> | -rule <expression>] [-delay <usecs>] [-maxConn <positive_integer>] [-action <action> (<altContentSvcName> <altContentPath>)]

name

Name for the policy. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

url

URL against which to match incoming client request.

rule

Expression against which the traffic is evaluated.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

delay

Delay threshold, in microseconds, for requests that match the policy's URL or rule. If the delay statistics gathered for the matching request exceed the specified delay, SureConnect is triggered for that request.

Minimum value: 1

Maximum value: 599999999

maxConn

Maximum number of concurrent connections that can be open for requests that match the policy's URL or rule.

Minimum value: 1

Maximum value: 4294967294

action

Action to be taken when the delay or maximum-connections threshold is reached. Available settings function as follows:

ACS - Serve content from an alternative content service.

NS - Serve alternative content from the NetScaler appliance.

NO ACTION - Serve no alternative content. However, delay statistics are still collected for the configured URLs, and, if the Maximum Client Connections parameter is set, the number of connections is limited to the value specified by that parameter. (However, alternative content is not served even if the maxConn threshold is met).

Possible values: ACS, NS, NOACTION

altContentSvcName

Name of the alternative content service to be used in the ACS action.

altContentPath

Path to the alternative content service to be used in the ACS action.

add sc policy scpol_ns -delay 1000000 -url /delay.asp -action NS add policy expression exp_acs "url == /mc_acs.asp" add service svc_acs 10.110.100.253 http 80 add scp

---

Removes the specified SureConnect policy.

rm sc policy <name>

name

Name of the policy to be removed.

rm sc policy scpol_ns rm sc policy scpol_acs

Modifies the specified settings of a SureConnect policy.

set sc policy <name> [-url <URL> | -rule <expression>] [-delay <usecs>] [-maxConn <positive_integer>] [-action <action> (<altContentSvcName> <altContentPath>)]

name

Name of the policy to be modified.

url

URL against which to match requests. URLs take precedence over rules in SureConnect policies.

rule

Expression against which the traffic is evaluated.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

delay

Delay threshold, in microseconds, for requests that match the policy's URL or rule. If the delay statistics gathered for the matching request exceed the specified delay, SureConnect is triggered for that request.

Minimum value: 1

Maximum value: 599999999

maxConn

Maximum number of concurrent connections that can be open for the configured URL or rule.

Minimum value: 1

Maximum value: 4294967294

action

Action to be taken when the delay or maximum-connections threshold is reached. Available settings function as follows:

ACS - Serve content from an alternative content service.

NS - Serve alternative content from the NetScaler appliance.

NO ACTION - Serve no alternative content. However, delay statistics are still collected for the configured URLs, and, if the Maximum Client Connections parameter is set, the number of connections is limited to the value specified by that parameter. (However, alternative content is not served even if the maxConn threshold is met).

Possible values: ACS, NS, NOACTION

set sc policy scpol_ns -delay 2000000 set sc policy scpol_acs -maxconn 100

Use this command to remove sc policy settings.Refer to the set sc policy command for meanings of the arguments.

unset sc policy <name> [-delay] [-maxConn]

Displays information about the SureConnect policies.

show sc policy [<name>]

name

Name of a policy about which to display detailed information. To display information about all the SureConnect policies, do not set this parameter.

summary

fullValues

format

level

url

The URL name. The system matches the incoming client request against the URL you enter here.

rule

The rule that the system matches with the incoming request.

The system matches the incoming request against the rules you enter here. Before matching against the configured rules, the NetScaler 9000 system matches the requests with any of the configured URLs. Thus, URLs have a higher precedence over rules. If the incoming request does not match any of the configured URLs or the rules that have been configured, then SureConnect does not trigger.

Expression logic is expression names, separated by the logical operators | | and && , and possibly grouped using parenthesis. If the expression contains blanks (for example, between an expression name and a logical operator), then the entire argument must be enclosed in double quotes.The following are valid expression logic:

ns_ext_cgi| |ns_ext_asp

ns_non_get && (ns_header_cookie| |ns_header_pragma)

delay

Delay threshold, in microseconds, for requests that match the policy's URL or rule. If the delay statistics gathered for the matching request exceed the specified delay, SureConnect is triggered for that request.

maxConn

Maximum number of concurrent connections that can be open for requests that match the policy's URL or rule.

action

The action to be taken when the thresholds are met. The valid options are ACS , NS and NOACTION .

ACS - Specifies that alternate content is to be served from altContSvcName with the path altContPath .

NS - Specifies that alternate content is to be served from the NetScaler 9000 system. See the set sc parameter command to customize the response served from the system.

NOACTION - Specifies that no alternate content is to be served. However, delay statistics are still collected for the configured URLs. If the - maxconn argument is specified, the number of connections is limited to that specified value for that configured URL or rule (alternate content will not served even if the - maxconn threshold is met).

altContentSvcName

Name of the alternative content service to be used in the ACS action.

altContentPath

Path to the alternative content service to be used in the ACS action.

stateflag

Server TTLB (SvrTTLB)

Server Time-To-Last-Byte in seconds calculated for this SureConnect policy.

Average server TTLB

Average server transaction time in seconds for this SureConnect Policy.

Average client TTLB (AvClTTLB)

Average value of the client Time-To-Last-Byte in seconds for this SureConnect policy.

Physical service IP (SvcIP)

IP address of the service in dotted notation for which these statistics are maintained.

Physical service port (SvcPort)

Port of the service for which these statistics are maintained.

Current client connections (CurClts)

Number of clients currently allowed a server connection by this SureConnect policy.

Current SC queue length (WaitClts)

Current number of SureConnect priority clients that are waiting for a server connection.

Current server connections (CurSvrs)

Current number of open connections to the servers matching this policy.

Estimated waiting time (Sec) (WaitTime)

Value of the currently estimated waiting time in seconds for the configured URL.

Client TCP connections (TotClt)

Total number of clients that were allowed a server connection by this SureConnect policy.

Server TCP connections (TotSvr)

Total number of server connections that were established through this SureConnect policy.

Client HTTP transactions

Total number of client transactions processed by this SureConnect policy.

Server HTTP transactions (SrvTrans)

Number of 200 OK responses received from the web server by this SureConnect policy.

Requests received (TotReq)

Total number of requests received by this SureConnect policy.

Request bytes received (ReqBytes)

Total number of request bytes received by this SureConnect policy.

Server responses received (TotResp)

Total number of server responses received by this SureConnect policy.

Response bytes received (RspBytes)

Total number of response bytes received by this SureConnect policy.

sc stats

Sep 22, 2015

The following operations can be performed on "sc stats":

show sc stats is an alias for stat sc

show sc stats - alias for 'stat sc'

SNMP Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- snmp
- snmp alarm
- snmp community
- snmp engineId
- snmp group
- snmp manager
- snmp mib
- snmp oid
- snmp option
- snmp stats
- snmp trap
- snmp user
- snmp view

snmp

Sep 22, 2015

The following operations can be performed on "snmp":

Display the statistics related to SNMP.

stat snmp [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

SNMP packets received (PktsRx)

SNMP packets received.

SNMP packets sent (PktsTx)

SNMP packets transmitted.

Get requests receieved (GetReqRx)

SNMP Get-Request PDUs that have been accepted and processed.

Get-next requests receieved (GtNextRx)

SNMP Get-Next PDUs that have been accepted and processed.

Get-bulk requests received (GtBulkRx)

SNMP Get-Bulk PDUs that have been accepted and pro?cessed.

Responses sent (RspTx)

SNMP Get-Response PDUs that have been generated by the NetScaler.

Traps messages sent (TrapsTx)

SNMP Trap PDUs that have been generated by the NetScaler.

Requests dropped (ReqDrop)

SNMP requests dropped.

ASN.1/BER errors in requests (PrsErrRx)

Number of ASN.1 or BER errors encountered when decoding received SNMP Messages.

Unsupported SNMP version (UnkVrsRx)

Number of SNMP messages received, which were for an unsupported SNMP version.

Unknown community name (UnkCNRx)

SNMP messages received, which used an SNMP community name not known to the NetScaler.

No permission on community (BadCURx)

The total number of SNMP Messages received that represented an SNMP operation which was not allowed by the SNMP community named in the Message.

Unsupported security level (UnkSecLv)

SNMP packets that were dropped because they requested a security level that was

unknown to the NetScaler or otherwise unavailable.

Not in time window (NtTimeWd)

SNMP packets that were dropped because they appeared outside of the authoritative SNMP engine's window.

Unknown user name (UnkUser)

SNMP packets that were dropped because they referenced a user that was not known to the SNMP engine.

Unknown engine Id (UnkEngId)

SNMP packets that were dropped because they referenced an SNMP engine ID that was not known to the NetScaler.

Wrong digest value (WrgDgst)

SNMP packets that were dropped because they did not contain the expected digest value.

Decryption errors (DcrptErr)

SNMP packets that were dropped because they could not be decrypted.

stat snmp

snmp alarm

Sep 22, 2015

The following operations can be performed on "snmp alarm":

set | unset | enable | disable | show

Configures an SNMP alarm. You must enable and configure alarms to generate enterprise-specific trap messages. The NetScaler appliance sends these trap messages only to trap listeners of type (class) SPECIFIC. The SNMP alarms are either event based or threshold based. The NetScaler appliance supports the following user configurable alarms: HA-STATE-CHANGE: Change to primary/secondary CPU-USAGE: Individual CPU usage AVERAGE-CPU: Average CPU usage MGMT-CPU: Management CPU usage ENTITY-STATE: Entity state change SYNFLOOD: Global unacknowledged SYN count MEMORY: Memory usage VSERVER-REQRATE: Vserver specific request rate SERVICE-REQRATE: Service specific request rate ENTITY-RXRATE: Entity specific Rx bytes per sec ENTITY-TXRATE: Entity specific Tx bytes per sec ENTITY-SYNFLOOD: Entity specific unacknowledged SYN count CONFIG-CHANGE: System configuration changed SERVICE-MAXCLIENTS: Service hit max-client limit CONFIG-SAVE: System configuration was saved SERVICEGROUP-MEMBER-REQRATE: Request rate on a service group member SERVICEGROUP-MEMBER-MAXCLIENTS: Service group member hits max-client MONITOR-RTO-THRESHOLD: Monitor probe response timeout LOGIN-FAILURE: GUI/CLI/API login failure SSL-CERT-EXPIRY: Certificate expiry FAN-SPEED-LOW: Low fan speed VOLTAGE-LOW: Low voltage VOLTAGE-HIGH: High Voltage TEMPERATURE-HIGH: High temperature CPU-TEMPERATURE-HIGH: High CPU temperature POWER-SUPPLY-FAILURE: Power supply failure DISK-USAGE-HIGH: High disk usage INTERFACE-THROUGHPUT-LOW: Low Interface throughput MON_PROBE_FAILED: Monitor probe failure HA-VERSION-MISMATCH: HA netscaler's OS version mismatch HA-SYNC-FAILURE: HA config synchronization failure HA-NO-HEARTBEATS: No HA hearbeats HA-BAD-SECONDARY-STATE: Secondary state DOWN/UNKNOWN/STAY SECONDARY INTERFACE-BW-USAGE: System aggregate BW usage RATE-LIMIT-THRESHOLD-EXCEEDED: Client exceed rate-limit threshold ENTITY-NAME-CHANGE: Entity name change HA-PROP-FAILURE: HA config propagation failure IP-CONFLICT: IP conflict PF-RL-RATE-THRESHOLD: Platform rate limit in Mbps PF-RL-PPS-THRESHOLD: Platform packets per second limit PF-RL-RATE-PKTS-DROPPED: Packet Drops due to platform rate limit PF-RL-PPS-PKTS-DROPPED: Packet Drops due to platform packet per sec limit APPFW-START-URL: AppFirewall Start URL violation APPFW-DENY-URL: AppFirewall Deny URL violation APPFW-REFERER-HEADER: AppFirewall Referer Header violation APPFW-CSRF-TAG: AppFirewall CSRF Tag violation APPFW-COOKIE: AppFirewall Cookie violation APPFW-FIELD-CONSISTENCY: AppFirewall Field Consistency violation APPFW-BUFFER-OVERFLOW: AppFirewall Buffer Overflow violation APPFW-FIELD-FORMAT: AppFirewall Field Format violation APPFW-SAFE-COMMERCE: AppFirewall Safe Commerce violation APPFW-SAFE-OBJECT: AppFirewall Safe Object violation APPFW-POLICY-HIT: AppFirewall Policy Hit APPFW-VIOLATIONS-TYPE: AppFirewall Content Type violation APPFW-XSS: AppFirewall Cross Site Scripting violation APPFW-XML-XSS: AppFirewall XML Cross Site Scripting violation APPFW-SQL: AppFirewall SQL violation APPFW-XML-SQL: AppFirewall XML SQL violation APPFW-XML-ATTACHMENT: AppFirewall XML Attachment violation APPFW-XML-DOS: AppFirewall XML DoS violation APPFW-XML-VALIDATION: AppFirewall XML Validation violation APPFW-XML-WSI: AppFirewall XML WSI violation APPFW-XML-SCHEMA-COMPILE: AppFirewall XML Schema Compile violation APPFW-XML-SOAP-FAULT: AppFirewall XML Soap Fault violation DNSKEY-EXPIRY: DNSKEY expiry DATASTREAM-RATE-LIMIT-HIT: DataStream Rate Limit Hit HA-LICENSE-MISMATCH: HA netscaler's license mismatch SSL-CARD-FAILED: SSL Card Failed SSL-CARD-NORMAL: SSL Card Normal WARM-RESTART-EVENT: Warm Restart Event Occurred HARD-DISK-DRIVE-ERRORS: Hard Disk Drive Errors COMPACT-FLASH-ERRORS: Compact Flash Errors CALLHOME-UPLOAD-EVENT: Attempt to upload Show Tech Support Archive 1024KEY-EXCHANGE-RATE: 1024 Key Exchange Rate 2048KEY-EXCHANGE-RATE: 2048 Key Exchange Rate 4096KEY-EXCHANGE-RATE: 4096 Key Exchange Rate SSL-CUR-SESSION-INUSE: SSL Current Sessions In Use CLUSTER-NODE-

HEALTH: Cluster Node Health State Change CLUSTER-NODE-QUORUM: Cluster Node View has Quorum CLUSTER-VERSION-MISMATCH: Cluster Node Version Mismatch CLUSTER-CCO-CHANGE: Cluster Configuration Coordinator Change CLUSTER-OVS-CHANGE: Cluster Operational View Set Change CLUSTER-SYNC-FAILURE: Cluster Config Synchronization Failure CLUSTER-PROP-FAILURE: Cluster Config Propagation Failure HA-STICKY-PRIMARY: Fixed primary state owing to max HA flips INBAND-PROTOCOL-VERSION-MISMATCH: Inband protocol mismatch between BR and QoSd SSL-CHIP-REINIT: SSL Chip Reinit VRID-STATE-CHANGE: VRID State Change For the purposes of this command, entity includes vservers and services.

set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-time <secs>] [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging (ENABLED | DISABLED)]

trapName

Name of the SNMP alarm. This parameter is required for identifying the SNMP alarm and cannot be modified.

Possible values: CPU-USAGE, AVERAGE-CPU, MEMORY, MGMT-CPU-USAGE, SYNFLOOD, VSERVER-REQRATE, SERVICE-REQRATE, ENTITY-RXRATE, ENTITY-TXRATE, ENTITY-SYNFLOOD, SERVICE-MAXCLIENTS, HA-STATE-CHANGE, ENTITY-STATE, CONFIG-CHANGE, CONFIG-SAVE, SERVICEGROUP-MEMBER-REQRATE, SERVICEGROUP-MEMBER-MAXCLIENTS, MONITOR-RTO-THRESHOLD, LOGIN-FAILURE, SSL-CERT-EXPIRY, FAN-SPEED-LOW, VOLTAGE-LOW, VOLTAGE-HIGH, TEMPERATURE-HIGH, CPU-TEMPERATURE-HIGH, POWER-SUPPLY-FAILURE, DISK-USAGE-HIGH, INTERFACE-THROUGHPUT-LOW, MON_PROBE_FAILED, HA-VERSION-MISMATCH, HA-SYNC-FAILURE, HA-NO-HEARTBEATS, HA-BAD-SECONDARY-STATE, INTERFACE-BW-USAGE, RATE-LIMIT-THRESHOLD-EXCEEDED, ENTITY-NAME-CHANGE, HA-PROP-FAILURE, IP-CONFLICT, PF-RL-RATE-THRESHOLD, PF-RL-PPS-THRESHOLD, PF-RL-RATE-PKTS-DROPPED, PF-RL-PPS-PKTS-DROPPED, APPFW-START-URL, APPFW-DENY-URL, APPFW-VIOLATIONS-TYPE, APPFW-REFERER-HEADER, APPFW-CSRF-TAG, APPFW-COOKIE, APPFW-FIELD-CONSISTENCY, APPFW-BUFFER-OVERFLOW, APPFW-FIELD-FORMAT, APPFW-SAFE-COMMERCE, APPFW-SAFE-OBJECT, APPFW-POLICY-HIT, APPFW-XSS, APPFW-XML-XSS, APPFW-SQL, APPFW-XML-SQL, APPFW-XML-ATTACHMENT, APPFW-XML-DOS, APPFW-XML-VALIDATION, APPFW-XML-WSI, APPFW-XML-SCHEMA-COMPILE, APPFW-XML-SOAP-FAULT, DNSKEY-EXPIRY, DATASTREAM-RATE-LIMIT-HIT, HA-LICENSE-MISMATCH, SSL-CARD-FAILED, SSL-CARD-NORMAL, WARM-RESTART-EVENT, HARD-DISK-DRIVE-ERRORS, COMPACT-FLASH-ERRORS, CALLHOME-UPLOAD-EVENT, 1024KEY-EXCHANGE-RATE, 2048KEY-EXCHANGE-RATE, 4096KEY-EXCHANGE-RATE, SSL-CUR-SESSION-INUSE, CLUSTER-NODE-HEALTH, CLUSTER-NODE-QUORUM, CLUSTER-VERSION-MISMATCH, CLUSTER-CCO-CHANGE, CLUSTER-OVS-CHANGE, CLUSTER-SYNC-FAILURE, CLUSTER-PROP-FAILURE, HA-STICKY-PRIMARY, INBAND-PROTOCOL-VERSION-MISMATCH, SSL-CHIP-REINIT, VRID-STATE-CHANGE

thresholdValue

Value for the high threshold. The NetScaler appliance generates an SNMP trap message when the value of the attribute associated with the alarm is greater than or equal to the specified high threshold value.

Minimum value: 1

time

Interval, in seconds, at which the NetScaler appliance generates SNMP trap messages when the conditions

specified in the SNMP alarm are met.Can be specified for the following alarms: SYNFLOOD, HA-VERSION-MISMATCH, HA-SYNC-FAILURE, HA-NO-HEARTBEATS,HA-BAD-SECONDARY-STATE, CLUSTER-NODE-HEALTH, CLUSTER-NODE-QUORUM, CLUSTER-VERSION-MISMATCH, PORT-ALLOC-FAILED and APPFW traps. Default trap time intervals: SYNFLOOD and APPFW traps = 1sec, PORT-ALLOC-FAILED = 3600sec(1 hour), Other Traps = 86400sec(1 day)

Default value: 1

state

Current state of the SNMP alarm. The NetScaler appliance generates trap messages only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

Possible values: ENABLED, DISABLED

Default value: ENABLED

severity

Severity level assigned to trap messages generated by this alarm. The severity levels are, in increasing order of severity, Informational, Warning, Minor, Major, and Critical.

This parameter is useful when you want the NetScaler appliance to send trap messages to a trap listener on the basis of severity level. Trap messages with a severity level lower than the specified level (in the trap listener entry) are not sent.

Possible values: Critical, Major, Minor, Warning, Informational

Default value: SNMP_SEV_UNKNOWN

logging

Logging status of the alarm. When logging is enabled, the NetScaler appliance logs every trap message that is generated for this alarm.

Possible values: ENABLED, DISABLED

Default value: ENABLED

```
set snmp alarm VSERVER-REQRATE -thresholdValue 10000 -normalValue 100
```

Resets the specified parameters of an SNMP alarm to their default settings..Refer to the set snmp alarm command for meanings of the arguments.

```
unset snmp alarm <trapName> [-thresholdValue] [-normalValue] [-time] [-state] [-severity] [-logging]
```

unset snmp alarm VSERVER-REQRATE

Enables or disables an SNMP alarm. The NetScaler appliance looks for conditions specified in the enabled SNMP alarms. When the condition in any enabled SNMP alarm is met, the appliance generates an SNMP trap message. It does not look for conditions specified in disabled SNMP alarms and therefore does not generate an SNMP trap message when the condition in any disabled SNMP alarm is met. Some alarms are enabled by default, but you can disable them.

enable snmp alarm <trapName> ...

trapName

Name of the SNMP alarm. This parameter is required for identifying the SNMP alarm.

Possible values: CPU-USAGE, AVERAGE-CPU, MEMORY, MGMT-CPU-USAGE, SYNFLOOD, VSERVER-REQRATE, SERVICE-REQRATE, ENTITY-RXRATE, ENTITY-TXRATE, ENTITY-SYNFLOOD, SERVICE-MAXCLIENTS, HA-STATE-CHANGE, ENTITY-STATE, CONFIG-CHANGE, CONFIG-SAVE, SERVICEGROUP-MEMBER-REQRATE, SERVICEGROUP-MEMBER-MAXCLIENTS, MONITOR-RTO-THRESHOLD, LOGIN-FAILURE, SSL-CERT-EXPIRY, FAN-SPEED-LOW, VOLTAGE-LOW, VOLTAGE-HIGH, TEMPERATURE-HIGH, CPU-TEMPERATURE-HIGH, POWER-SUPPLY-FAILURE, DISK-USAGE-HIGH, INTERFACE-THROUGHPUT-LOW, MON_PROBE_FAILED, HA-VERSION-MISMATCH, HA-SYNC-FAILURE, HA-NO-HEARTBEATS, HA-BAD-SECONDARY-STATE, INTERFACE-BW-USAGE, RATE-LIMIT-THRESHOLD-EXCEEDED, ENTITY-NAME-CHANGE, HA-PROP-FAILURE, IP-CONFLICT, PF-RL-RATE-THRESHOLD, PF-RL-PPS-THRESHOLD, PF-RL-RATE-PKTS-DROPPED, PF-RL-PPS-PKTS-DROPPED, APPFW-START-URL, APPFW-DENY-URL, APPFW-VIOLATIONS-TYPE, APPFW-REFERER-HEADER, APPFW-CSRF-TAG, APPFW-COOKIE, APPFW-FIELD-CONSISTENCY, APPFW-BUFFER-OVERFLOW, APPFW-FIELD-FORMAT, APPFW-SAFE-COMMERCE, APPFW-SAFE-OBJECT, APPFW-POLICY-HIT, APPFW-XSS, APPFW-XML-XSS, APPFW-SQL, APPFW-XML-SQL, APPFW-XML-ATTACHMENT, APPFW-XML-DOS, APPFW-XML-VALIDATION, APPFW-XML-WSI, APPFW-XML-SCHEMA-COMPILE, APPFW-XML-SOAP-FAULT, DNSKEY-EXPIRY, DATASTREAM-RATE-LIMIT-HIT, HA-LICENSE-MISMATCH, SSL-CARD-FAILED, SSL-CARD-NORMAL, WARM-RESTART-EVENT, HARD-DISK-DRIVE-ERRORS, COMPACT-FLASH-ERRORS, CALLHOME-UPLOAD-EVENT, 1024KEY-EXCHANGE-RATE, 2048KEY-EXCHANGE-RATE, 4096KEY-EXCHANGE-RATE, SSL-CUR-SESSION-INUSE, CLUSTER-NODE-HEALTH, CLUSTER-NODE-QUORUM, CLUSTER-VERSION-MISMATCH, CLUSTER-CCO-CHANGE, CLUSTER-OVS-CHANGE, CLUSTER-SYNC-FAILURE, CLUSTER-PROP-FAILURE, HA-STICKY-PRIMARY, INBAND-PROTOCOL-VERSION-MISMATCH, SSL-CHIP-REINIT, VRID-STATE-CHANGE

enable snmp alarm VSERVER-REQRATE enable snmp alarm CPU SYNFLOOD

Disables an SNMP alarm. The NetScaler appliance does not generate trap messages for SNMP alarms that are disabled. Some alarms are enabled by default, but you can disable them.

disable snmp alarm <trapName> ...

trapName

Name of the SNMP alarm. This parameter is required for identifying the SNMP alarm.

Possible values: CPU-USAGE, AVERAGE-CPU, MEMORY, MGMT-CPU-USAGE, SYNFLOOD, VSERVER-REQRATE, SERVICE-REQRATE, ENTITY-RXRATE, ENTITY-TXRATE, ENTITY-SYNFLOOD, SERVICE-MAXCLIENTS, HA-STATE-CHANGE, ENTITY-STATE, CONFIG-CHANGE, CONFIG-SAVE, SERVICEGROUP-MEMBER-REQRATE, SERVICEGROUP-MEMBER-MAXCLIENTS, MONITOR-RTO-THRESHOLD, LOGIN-FAILURE, SSL-CERT-EXPIRY, FAN-SPEED-LOW, VOLTAGE-LOW, VOLTAGE-HIGH, TEMPERATURE-HIGH, CPU-TEMPERATURE-HIGH, POWER-SUPPLY-FAILURE, DISK-USAGE-HIGH, INTERFACE-THROUGHPUT-LOW, MON_PROBE_FAILED, HA-VERSION-MISMATCH, HA-SYNC-FAILURE, HA-NO-HEARTBEATS, HA-BAD-SECONDARY-STATE, INTERFACE-BW-USAGE, RATE-LIMIT-THRESHOLD-EXCEEDED, ENTITY-NAME-CHANGE, HA-PROP-FAILURE, IP-CONFLICT, PF-RL-RATE-THRESHOLD, PF-RL-PPS-THRESHOLD, PF-RL-RATE-PKTS-DROPPED, PF-RL-PPS-PKTS-DROPPED, APPFW-START-URL, APPFW-DENY-URL, APPFW-VIOLATIONS-TYPE, APPFW-REFERER-HEADER, APPFW-CSRF-TAG, APPFW-COOKIE, APPFW-FIELD-CONSISTENCY, APPFW-BUFFER-OVERFLOW, APPFW-FIELD-FORMAT, APPFW-SAFE-COMMERCE, APPFW-SAFE-OBJECT, APPFW-POLICY-HIT, APPFW-XSS, APPFW-XML-XSS, APPFW-SQL, APPFW-XML-SQL, APPFW-XML-ATTACHMENT, APPFW-XML-DOS, APPFW-XML-VALIDATION, APPFW-XML-WSI, APPFW-XML-SCHEMA-COMPILE, APPFW-XML-SOAP-FAULT, DNSKEY-EXPIRY, DATASTREAM-RATE-LIMIT-HIT, HA-LICENSE-MISMATCH, SSL-CARD-FAILED, SSL-CARD-NORMAL, WARM-RESTART-EVENT, HARD-DISK-DRIVE-ERRORS, COMPACT-FLASH-ERRORS, CALLHOME-UPLOAD-EVENT, 1024KEY-EXCHANGE-RATE, 2048KEY-EXCHANGE-RATE, 4096KEY-EXCHANGE-RATE, SSL-CUR-SESSION-INUSE, CLUSTER-NODE-HEALTH, CLUSTER-NODE-QUORUM, CLUSTER-VERSION-MISMATCH, CLUSTER-CCO-CHANGE, CLUSTER-OVS-CHANGE, CLUSTER-SYNC-FAILURE, CLUSTER-PROP-FAILURE, HA-STICKY-PRIMARY, INBAND-PROTOCOL-VERSION-MISMATCH, SSL-CHIP-REINIT, VRID-STATE-CHANGE

disable snmp alarm VSERVER-REQRATE disable snmp alarm CPU SYNFLOOD

Displays the settings of all SNMP alarms or of the specified SNMP alarm. To display the settings of all the SNMP alarms, run the command without any parameters. To display the settings of a particular SNMP alarm, specify the trapName (Alarm name) of the SNMP alarm.

show snmp alarm [<trapName>]

trapName

Name of the SNMP alarm whose details you want the NetScaler appliance to display.

Possible values: CPU-USAGE, AVERAGE-CPU, MEMORY, MGMT-CPU-USAGE, SYNFLOOD, VSERVER-REQRATE, SERVICE-REQRATE, ENTITY-RXRATE, ENTITY-TXRATE, ENTITY-SYNFLOOD, SERVICE-MAXCLIENTS, HA-STATE-CHANGE, ENTITY-STATE, CONFIG-CHANGE, CONFIG-SAVE, SERVICEGROUP-MEMBER-REQRATE, SERVICEGROUP-MEMBER-MAXCLIENTS, MONITOR-RTO-THRESHOLD, LOGIN-FAILURE, SSL-CERT-EXPIRY, FAN-SPEED-LOW, VOLTAGE-LOW, VOLTAGE-HIGH, TEMPERATURE-HIGH, CPU-TEMPERATURE-HIGH, POWER-SUPPLY-FAILURE, DISK-USAGE-HIGH, INTERFACE-THROUGHPUT-LOW, MON_PROBE_FAILED, HA-VERSION-MISMATCH, HA-SYNC-FAILURE, HA-NO-HEARTBEATS, HA-BAD-SECONDARY-STATE, INTERFACE-BW-USAGE, RATE-LIMIT-THRESHOLD-EXCEEDED, ENTITY-NAME-CHANGE, HA-PROP-FAILURE, IP-CONFLICT, PF-RL-RATE-THRESHOLD, PF-RL-PPS-THRESHOLD, PF-RL-RATE-PKTS-DROPPED, PF-RL-PPS-PKTS-DROPPED, APPFW-START-URL, APPFW-DENY-URL, APPFW-VIOLATIONS-TYPE, APPFW-REFERER-HEADER, APPFW-CSRF-TAG, APPFW-COOKIE, APPFW-FIELD-CONSISTENCY, APPFW-BUFFER-OVERFLOW, APPFW-FIELD-FORMAT, APPFW-SAFE-COMMERCE, APPFW-SAFE-OBJECT, APPFW-POLICY-HIT, APPFW-XSS, APPFW-XML-XSS, APPFW-SQL, APPFW-XML-SQL, APPFW-XML-ATTACHMENT, APPFW-XML-DOS, APPFW-XML-VALIDATION, APPFW-XML-WSI, APPFW-XML-SCHEMA-COMPILE, APPFW-XML-SOAP-FAULT, DNSKEY-EXPIRY, DATASTREAM-RATE-LIMIT-HIT, HA-LICENSE-MISMATCH, SSL-CARD-FAILED, SSL-CARD-NORMAL, WARM-RESTART-EVENT, HARD-DISK-DRIVE-ERRORS, COMPACT-FLASH-ERRORS, CALLHOME-UPLOAD-EVENT, 1024KEY-EXCHANGE-RATE, 2048KEY-EXCHANGE-RATE, 4096KEY-EXCHANGE-RATE, SSL-CUR-SESSION-INUSE, CLUSTER-NODE-HEALTH, CLUSTER-NODE-QUORUM, CLUSTER-VERSION-MISMATCH, CLUSTER-CCO-CHANGE, CLUSTER-OVS-CHANGE, CLUSTER-SYNC-FAILURE, CLUSTER-PROP-FAILURE, HA-STICKY-PRIMARY, INBAND-PROTOCOL-VERSION-MISMATCH, SSL-CHIP-REINIT, VRID-STATE-CHANGE

summary

fullValues

format

level

thresholdValue

The high threshold value.

normalValue

The normal threshold value.

time

The time interval for the SYNFLOOD alarm.

state

Current state of the SNMP alarm. The NetScaler appliance generates trap messages only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

severity

The severity of this alarm.

logging

The log status of the alarm.

flags

timeout

If DB is enabled and clear config is fired, then to reset timeinterval of alarm, corresponding default time value is needed. This hidden argument holds the default time value for the corresponding alarm.

devno

count

snmp community

Sep 22, 2015

The following operations can be performed on "snmp community":

add | rm | show

Creates an SNMP community, which is a password (string) used to authenticate SNMP queries from SNMP managers. You can associate it with any of the following SNMP query types: GET, GET NEXT, ALL, GET BULK. You can associate one or more community strings with each query type. For example, if you associate two community strings, such as Example and Test, with the query type GET NEXT, the NetScaler appliance considers only those GET NEXT SNMP query packets that contain Example or Test as the community string.

add snmp community <communityName> <permissions>

communityName

The SNMP community string. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and special characters.

The following requirement applies only to the NetScaler CLI:

If the string includes one or more spaces, enclose the name in double or single quotation marks (for example, "my string" or 'my string').

permissions

The SNMP V1 or V2 query-type privilege that you want to associate with this SNMP community.

Possible values: GET, GET_NEXT, GET_BULK, SET, ALL

add snmp community public ALL add snmp community a#12ab GET_BULK

Removes an SNMP community from the NetScaler appliance. After you remove the SNMP community, the appliance does not respond to any SNMP queries that contain that community string.

rm snmp community <communityName>

communityName

The name of the SNMP community.

rm snmp community public

Displays the SNMP v1 or v2 query-type privileges (such as GET, GET NEXT, ALL, or GET BULK) that have been set for all SNMP communities or for the specified SNMP community. To display the settings of all the SNMP communities, run the command without any parameters. To display the settings of a particular SNMP community, specify the name of the SNMP community.

show snmp community [<communityName>]

communityName

The name of the SNMP community whose SNMP v1 or v2 query type privilege setting, such as GET, GET NEXT, ALL, or GET BULK, you want the NetScaler appliance to display.

summary

show snmp community

---

snmp engineId

Sep 22, 2015

The following operations can be performed on "snmp engineId":

set | unset | show

set snmp engineId

Modifies the SNMPv3 engine identification (ID) on the NetScaler appliance. Caution: Changing the ID of the SNMPv3 engine invalidates the current SNMP users. You have to reconfigure the SNMP users in the SNMP managers. The SNMPv3 engine has an identification (ID) that uniquely identifies it on the appliance and is used in the communication between the SNMPv3 user and the SNMPv3 engine. The engine ID is preconfigured by Citrix and is based on the MAC address of one of its interfaces. Overriding the engine ID is not necessary, but you can change it.

Synopsys

set snmp engineId <engineID> [-ownerNode <positive_integer>]

Arguments

engineID

A hexadecimal value of at least 10 characters, uniquely identifying the engineid

ownerNode

ID of the cluster node for which you are setting the engineid

Default value: -1

Maximum value: 31

---

unset snmp engineId

Resets the SNMPv3 engine identification (ID) on the NetScaler appliance to its default value. The NetScaler appliance derives the engine ID from the MAC address of one of its interfaces. Caution: Changing the ID of the SNMPv3 engine invalidates the current SNMP users. You have to reconfigure the SNMP users in the SNMP managers..Refer to the set snmp engineId command for meanings of the arguments.

Synopsys

unset snmp engineId [-ownerNode <positive_integer>]

---

show snmp engineId

Displays the ID of the SNMPv3 engine of the NetScaler appliance.

Synopsys

show snmp engineId [-ownerNode <positive_integer>]

Arguments

ownerNode

ID of the cluster node for which you are setting the engineid

Default value: -1

Maximum value: 31

format

level

Outputs

engineID

A hexadecimal value of at least 10 characters, uniquely identifying the engineid

defaultEngineID

Unique identifier to assign to the SNMPv3 engine. Should be a hexadecimal value with a minimum length of 10 hex characters.

count

stateflag

snmp group

Sep 22, 2015

The following operations can be performed on "snmp group":

add | rm | set | show

add snmp group

Adds an SNMPv3 user group on the NetScaler appliance. SNMPv3 groups are logical aggregations of SNMPv3 users. SNMPv3 groups are used to implement access control and define the security levels for the users. You can add a maximum of 1000 SNMPv3 groups to the NetScaler appliance.

Synopsys

add snmp group <name> <securityLevel> -readViewName <string>

Arguments

name

Name for the SNMPv3 group. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 group.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose it in double or single quotation marks (for example, "my name" or 'my name').

securityLevel

Security level required for communication between the NetScaler appliance and the SNMPv3 users who belong to the group. Specify one of the following options:

noAuthNoPriv. Require neither authentication nor encryption.

authNoPriv. Require authentication but no encryption.

authPriv. Require authentication and encryption.

Note: If you specify authentication, you must specify an encryption algorithm when you assign an SNMPv3 user to the group. If you also specify encryption, you must assign both an authentication and an encryption algorithm for each group member.

Possible values: noAuthNoPriv, authNoPriv, authPriv

readViewName

Name of the configured SNMPv3 view that you want to bind to this SNMPv3 group. An SNMPv3 user bound to this group can access the subtrees that are bound to this SNMPv3 view as type INCLUDED, but cannot access the ones that are type EXCLUDED. If the NetScaler appliance has multiple SNMPv3 view entries with the same name,

all such entries are associated with the SNMPv3 group.

---

rm snmp group

Removes an SNMPv3 group entry from the NetScaler appliance. The appliance can have multiple SNMPv3 groups with the same name, differentiated by the securityLevel (Security level) parameter setting. Therefore, to identify an SNMPv3 group entry that you want to remove, you have to specify both the name and security level of the SNMPv3 group.

Synopsys

rm snmp group <name> <securityLevel>

Arguments

name

Name of the SNMPv3 group.

securityLevel

Security level of the SNMPv3 group.

Possible values: noAuthNoPriv, authNoPriv, authPriv

---

set snmp group

Modifies the specified parameters of an SNMPv3 group entry on the NetScaler appliance.

Synopsys

set snmp group <name> <securityLevel> -readViewName <string>

Arguments

name

The name specified in the SNMPv3 group entry that you want to modify. This parameter cannot be modified.

securityLevel

Security level required for communication between the NetScaler appliance and the SNMPv3 users who belong to the group. Specify one of the following options:

noAuthNoPriv. Require neither authentication nor encryption.

authNoPriv. Require authentication but no encryption.

authPriv. Require authentication and encryption.

Note: If you specify authentication, you must specify an encryption algorithm when you assign an SNMPv3 user to the group. If you also specify encryption, you must assign both an authentication and an encryption algorithm for

each group member.

Possible values: noAuthNoPriv, authNoPriv, authPriv

readViewName

Name of the configured SNMPv3 view that you want to bind to this SNMPv3 group. An SNMPv3 user bound to this group can access the subtrees that are bound to this SNMPv3 view as type INCLUDED, but cannot access the ones that are type EXCLUDED. If the NetScaler appliance has multiple SNMPv3 view entries with the same name, all such entries are associated with the SNMPv3 group.

---

show snmp group

Displays the settings of all SNMPv3 groups or of the specified SNMPv3 group. To display the settings of all SNMPv3 groups, run the command without any parameters. To display the settings of a particular SNMPv3 group, specify the name of the SNMPv3 group and securityLevel (Security level). The NetScaler appliance can have multiple SNMPv3 groups with the same name, differentiated by the securityLevel (Security level) parameter setting.

Synopsys

show snmp group [<name> <securityLevel>]

Arguments

name

Name of the SNMPv3 group whose details you want the NetScaler appliance to display.

securityLevel

Security level of the SNMPv3 group whose details you want the NetScaler appliance to display.

Possible values: noAuthNoPriv, authNoPriv, authPriv

summary

snmp manager

Sep 22, 2015

The following operations can be performed on "snmp manager":

add | rm | set | unset | show

add snmp manager

Specifies an SNMP manager to query the NetScaler appliance. The added manager complies with SNMP V1, V2, and V3. If you specify one or more SNMP managers, the appliance does not accept SNMP queries from any hosts except the specified SNMP managers. You can specify up to a maximum of 100 IP based SNMP managers or networks and a maximum of 5 host-name based SNMP managers.

Synopsys

add snmp manager <IPAddress> ... [-netmask <netmask>] [-domainResolveRetry <integer>]

Arguments

IPAddress

IP address of the SNMP manager. Can be an IPv4 or IPv6 address. You can instead specify an IPv4 network address or IPv6 network prefix if you want the NetScaler appliance to respond to SNMP queries from any device on the specified network. Alternatively, instead of an IPv4 address, you can specify a host name that has been assigned to an SNMP manager. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address.

Note: The NetScaler appliance does not support host names for SNMP managers that have IPv6 addresses.

netmask

Subnet mask associated with an IPv4 network address. If the IP address specifies the address or host name of a specific host, accept the default value of 255.255.255.255.

Default value: 0xFFFFFFFF

domainResolveRetry

Amount of time, in seconds, for which the NetScaler appliance waits before sending another DNS query to resolve the host name of the SNMP manager if the last query failed. This parameter is valid for host-name based SNMP managers only. After a query succeeds, the TTL determines the wait time.

Minimum value: 5

Maximum value: 20939

Example

```
add snmp manager 192.168.1.20 192.168.2.42 add snmp manager 192.168.2.16 -netmask 255.255.255.240 add snmp manager hostnamemanager.com
```

---

rm snmp manager

Removes an SNMP manager from the list of managers that are allowed to access the NetScaler appliance.

Synopsys

rm snmp manager <IPAddress> ... [-netmask <netmask>]

Arguments

IPAddress

IPv4 or IPv6 address (or IPv4 host name) of the SNMP manager, or the IPv4 network address or IPv6 network prefix of the SNMP managers.

netmask

Subnet mask associated with an IPv4 SNMP manager entry. For a specific host, the subnet mask is 255.255.255.255.

Default value: 0xFFFFFFFF

Example

```
rm snmp manager 192.168.1.20 rm snmp manager 192.168.2.16 -netmask 255.255.255.240 rm snmp manager hostnamemanager.com
```

---

set snmp manager

Modifies the Domain Resolve Retry parameter of any host-name based SNMP manager configured on the NetScaler appliance.

Synopsys

set snmp manager <IPAddress> [-netmask <netmask>] [-domainResolveRetry <integer>]

Arguments

IPAddress

Host name of the SNMP manager for which you want to modify the Domain Resolve Retry parameter.

netmask

Subnet mask associated with an IPv4 network address. If the IP address specifies the address or host name of a specific host, accept the default value of 255.255.255.255.

Default value: 0xFFFFFFFF

domainResolveRetry

Amount of time, in seconds, for which the NetScaler appliance waits before sending another DNS query to resolve the host name of the SNMP manager if the last query failed. This parameter is valid for host-name based SNMP managers only. After a query succeeds, the TTL determines the wait time.

Minimum value: 5

Maximum value: 20939

Example

```
set snmp manager www.example.com -domainResolveRetry 7
```

---

unset snmp manager

Use this command to remove snmp manager settings.Refer to the set snmp manager command for meanings of the arguments.

Synopsys

unset snmp manager <IPAddress> -netmask <netmask> -domainResolveRetry

---

show snmp manager

Displays configuration information about all SNMP managers on the NetScaler appliance, or detailed information about the specified manager.

Synopsys

show snmp manager [<IPAddress> [-netmask <netmask>]]

Arguments

IPAddress

IPv4 or IPv6 address (or IPv4 host name) of the SNMP manager, or the IPv4 network address or IPv6 network prefix of the SNMP managers, about which to display information.

summary

fullValues

format

level

Outputs

IP

The resolved IP address of the hostname manager

domain

IP address of manager. It will be zero for hostname manager

domainResolveRetry

Amount of time, in seconds, for which the NetScaler appliance waits before sending another DNS query to resolve the host name of the SNMP manager if the last query failed. This parameter is valid for host-name based SNMP managers only. After a query succeeds, the TTL determines the wait time.

Example

show snmp manager

snmp mib

Sep 22, 2015

The following operations can be performed on "snmp mib":

set | unset | show

set snmp mib

Configures the SNMP agent of the NetScaler appliance with information that identifies the appliance, such as the name of the administrator for this NetScaler appliance, a name for the appliance, and the location of the appliance. SNMP managers can query the NetScaler appliance for this information.

Synopsys

set snmp mib [-contact <string>] [-name <string>] [-location <string>] [-customID <string>]

Arguments

contact

Name of the administrator for this NetScaler appliance. Along with the name, you can include information on how to contact this person, such as a phone number or an email address. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the information includes one or more spaces, enclose it in double or single quotation marks (for example, "my contact" or 'my contact').

Default value: "WebMaster (default)"

name

Name for this NetScaler appliance. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the NetScaler appliance.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose it in double or single quotation marks (for example, "my name" or 'my name').

Default value: "NetScaler"

location

Physical location of the NetScaler appliance. For example, you can specify building name, lab number, and rack number. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the location includes one or more spaces, enclose it in double or single quotation marks (for example, "my location" or 'my location').

Default value: "POP (default)"

customID

Custom identification number for the NetScaler appliance. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a custom identification that helps identify the NetScaler appliance.

The following requirement applies only to the NetScaler CLI:

If the ID includes one or more spaces, enclose it in double or single quotation marks (for example, "my ID" or 'my ID').

Default value: "Default"

---

unset snmp mib

Use this command to remove snmp mib settings.Refer to the set snmp mib command for meanings of the arguments.

Synopsys

unset snmp mib [-contact] [-name] [-location] [-customID]

---

show snmp mib

Displays the information that has been configured on the SNMP agent for the purpose of identifying the NetScaler appliance, such as the name of the appliance, administrator, and location.

Synopsys

show snmp mib

Arguments

format

level

Outputs

contact

Name of the administrator for this NetScaler appliance. Along with the name, you can include information on how to contact this person, such as a phone number or an email address. Can consist of 1 to 127

characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the information includes one or more spaces, enclose it in double or single quotation marks (for example, "my contact" or 'my contact').

name

Name for this NetScaler appliance. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the NetScaler appliance.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose it in double or single quotation marks (for example, "my name" or 'my name').

location

Physical location of the NetScaler appliance. For example, you can specify building name, lab number, and rack number. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the location includes one or more spaces, enclose it in double or single quotation marks (for example, "my location" or 'my location').

sysDesc

The description of the system.

sysUptime

The UP time of the system in 100th of a second.

sysServices

The services offered by the system.

sysOID

The OID of the system's management system.

customID

Custom identification number for the NetScaler appliance. Can consist of 1 to 127 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a custom identification that helps identify the NetScaler appliance.

The following requirement applies only to the NetScaler CLI:

If the ID includes one or more spaces, enclose it in double or single quotation marks (for example, "my ID" or 'my ID').

Example

```
show snmp mib
```

snmp oid

Sep 22, 2015

The following operations can be performed on "snmp oid":

show snmp oid

Displays the corresponding SNMP OIDs for the virtual servers, services, and service groups configured on the NetScaler appliance. To display the SNMP OID of all entities of a particular type, such as virtual servers, run the command with only that entity type specified. To display the SNMP of a particular entity, specify the entity type and the entity name.

Synopsys

show snmp oid <entityType> [<name>]

Arguments

entityType

The type of entity whose SNMP OIDs you want to displayType of entity whose SNMP OIDs you want the NetScaler appliance to display.

Possible values: VSERVER, SERVICE, SERVICEGROUP

name

Name of the entity whose SNMP OID you want the NetScaler appliance to display.

summary

snmp option

Sep 22, 2015

The following operations can be performed on "snmp option":

set | unset | show

set snmp option

Enables or disables SNMP options for SNMP SET and SNMP trap logging.

Synopsys

set snmp option [-snmpset (ENABLED | DISABLED)] [-snmpTrapLogging (ENABLED | DISABLED)]

Arguments

snmpset

Accept SNMP SET requests sent to the NetScaler appliance, and allow SNMP managers to write values to MIB objects that are configured for write access.

Possible values: ENABLED, DISABLED

Default value: DISABLED

snmpTrapLogging

Log any SNMP trap events (for SNMP alarms in which logging is enabled) even if no trap listeners are configured. With the default setting, SNMP trap events are logged if at least one trap listener is configured on the appliance.

Possible values: ENABLED, DISABLED

Default value: DISABLED

---

unset snmp option

Use this command to remove snmp option settings.Refer to the set snmp option command for meanings of the arguments.

Synopsys

unset snmp option [-snmpset] [-snmpTrapLogging]

---

show snmp option

Displays the settings for the following SNMP options: SNMP SET and SNMP trap Logging.

Synopsys

show snmp option

Arguments

format

level

Outputs

snmpset

Accept SNMP SET requests sent to the NetScaler appliance, and allow SNMP managers to write values to MIB objects that are configured for write access.

snmpTrapLogging

Log any SNMP trap events (for SNMP alarms in which logging is enabled) even if no trap listeners are configured. With the default setting, SNMP trap events are logged if at least one trap listener is configured on the appliance.

snmp stats

Sep 22, 2015

The following operations can be performed on "snmp stats":

show snmp stats

show snmp stats is an alias for stat snmp Displays the statistics related to SNMP.

Synopsys

show snmp stats - alias for 'stat snmp'

snmp trap

Sep 22, 2015

The following operations can be performed on "snmp trap":

add | rm | set | unset | show

add snmp trap

Adds an SNMP trap listener. You can configure the NetScaler appliance to generate asynchronous events (trap messages) to report abnormal conditions. The trap messages are sent to a remote device (trap listener) to help administrators monitor the appliance and respond promptly to any issues.

Synopsys

add snmp trap <trapClass> <trapDestination> ... [-version (V1 | V2)] [-destPort <port>] [-communityName <string>] [-srcIP <ip_addr|ipv6_addr>] [-severity <severity>]

Arguments

trapClass

Type of trap messages that the NetScaler appliance sends to the trap listener: Generic or the enterprise-specific messages defined in the MIB file.

Possible values: generic, specific

trapDestination

IPv4 or the IPv6 address of the trap listener to which the NetScaler appliance is to send SNMP trap messages.

version

SNMP version, which determines the format of trap messages sent to the trap listener.

This setting must match the setting on the trap listener. Otherwise, the listener drops the trap messages.

Possible values: V1, V2

Default value: TRAP_VERSION_2

destPort

UDP port at which the trap listener listens for trap messages. This setting must match the setting on the trap listener. Otherwise, the listener drops the trap messages.

Default value: 162

Minimum value: 1

Maximum value: 65534

communityName

Password (string) sent with the trap messages, so that the trap listener can authenticate them. Can include 1 to 31 uppercase or lowercase letters, numbers, and hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) characters.

You must specify the same community string on the trap listener device. Otherwise, the trap listener drops the trap messages.

The following requirement applies only to the NetScaler CLI:

If the string includes one or more spaces, enclose the name in double or single quotation marks (for example, "my string" or 'my string').

Default value: "public"

srcIP

IPv4 or IPv6 address that the NetScaler appliance inserts as the source IP address in all SNMP trap messages that it sends to this trap listener. By default this is the appliance's NSIP or NSIP6 address, but you can specify an IPv4 MIP or SNIP address or a SNIP6 address.

severity

Severity level at or above which the NetScaler appliance sends trap messages to this trap listener. The severity levels, in increasing order of severity, are Informational, Warning, Minor, Major, Critical. This parameter can be set for trap listeners of type SPECIFIC only. The default is to send all levels of trap messages.

Important: Trap messages are not assigned severity levels unless you specify severity levels when configuring SNMP alarms.

Possible values: Critical, Major, Minor, Warning, Informational

Default value: SNMP_SEV_UNKNOWN

---

rm snmp trap

Removes a trap listener entry from the NetScaler appliance.

Synopsys

rm snmp trap <trapClass> <trapDestination> ...

Arguments

trapClass

Trap type specified in the trap listener entry that you want to remove.

Possible values: generic, specific

trapDestination

IP address of the trap listener specified in the trap listener entry that you want to remove.

set snmp trap

Modifies the specified parameters in a trap-listener entry.

Synopsys

set snmp trap <trapClass> <trapDestination> [-destPort <port>] [-version (V1 | V2)] [-communityName <string>] [-srcIP <ip_addr|ipv6_addr>] [-severity <severity>]

Arguments

trapClass

Type of trap specified in the trap-listener entry. Because this parameter is used for identifying the trap listener entry, it cannot be modified after the entry has been created.

Possible values: generic, specific

trapDestination

IPv4 or the IPv6 address of the trap listener to which the NetScaler appliance is to send SNMP trap messages.

destPort

UDP port at which the trap listener listens for trap messages. This setting must match the setting on the trap listener. Otherwise, the listener drops the trap messages.

Default value: 162

Minimum value: 1

Maximum value: 65534

version

SNMP version, which determines the format of trap messages sent to the trap listener.

This setting must match the setting on the trap listener. Otherwise, the listener drops the trap messages.

Possible values: V1, V2

Default value: TRAP_VERSION_2

communityName

Password (string) sent with the trap messages, so that the trap listener can authenticate them. Can include 1 to 31 uppercase or lowercase letters, numbers, and hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) characters.

You must specify the same community string on the trap listener device. Otherwise, the trap listener drops the trap messages.

The following requirement applies only to the NetScaler CLI:

If the string includes one or more spaces, enclose the name in double or single quotation marks (for example, "my string" or 'my string').

Default value: "public"

srcIP

IPv4 or IPv6 address that the NetScaler appliance inserts as the source IP address in all SNMP trap messages that it sends to this trap listener. By default this is the appliance's NSIP or NSIP6 address, but you can specify an IPv4 MIP or SNIP address or a SNIP6 address.

severity

Severity level at or above which the NetScaler appliance sends trap messages to this trap listener. The severity levels, in increasing order of severity, are Informational, Warning, Minor, Major, Critical. This parameter can be set for trap listeners of type SPECIFIC only. The default is to send all levels of trap messages.

Important: Trap messages are not assigned severity levels unless you specify severity levels when configuring SNMP alarms.

Possible values: Critical, Major, Minor, Warning, Informational

Default value: SNMP_SEV_UNKNOWN

Example

```
set snmp trap generic 192.168.3.4 -version V1
```

---

unset snmp trap

Resets the specified parameters to their default settings in a trap-listener entry..Refer to the set snmp trap command for meanings of the arguments.

Synopsys

```
unset snmp trap <trapClass> <trapDestination> [-destPort] [-version] [-communityName] [-srcIP] [-severity]
```

Example

```
unset snmp trap generic 192.168.3.4 -version
```

---

show snmp trap

Displays the settings of all trap listeners or of the specified trap listener. To display the settings of all the trap listeners, run the command without any parameters. To display the settings of a particular trap listener, specify the trapClass (Trap Type) and trapDestination (IP Address) of the trap listener.

Synopsys

```
show snmp trap [<trapClass> <trapDestination>]
```

Arguments

trapClass

Trap type specified in the trap listener entry.

Possible values: generic, specific

summary

fullValues

format

level

Outputs

destPort

The destination port of the SNMP trap.

version

The SNMP version of the trap to be sent.

communityName

Password (string) sent with the trap messages, so that the trap listener can authenticate them. Can include 1 to 31 uppercase or lowercase letters, numbers, and hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) characters.

You must specify the same community string on the trap listener device. Otherwise, the trap listener drops the trap messages.

The following requirement applies only to the NetScaler CLI:

If the string includes one or more spaces, enclose the name in double or single quotation marks (for example, "my string" or 'my string').

srcIP

The source IP of the SNMP trap to be sent.

severity

The minimum severity of traps to be sent to this destination.

Example

snmp user

Sep 22, 2015

The following operations can be performed on "snmp user":

add | rm | set | unset | show

add snmp user

Adds an SNMPv3 user who can send SNMP queries to the NetScaler appliance. You can add a maximum of 1000 SNMPv3 users.

Synopsys

add snmp user <name> -group <string> [-authType (MD5 | SHA) {-authPasswd } [-privType (DES | AES) {-privPasswd }]]

Arguments

name

Name for the SNMPv3 user. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose it in double or single quotation marks (for example, "my user" or 'my user').

group

Name of the configured SNMPv3 group to which to bind this SNMPv3 user. The access rights (bound SNMPv3 views) and security level set for this group are assigned to this user.

authType

Authentication algorithm used by the NetScaler appliance and the SNMPv3 user for authenticating the communication between them. You must specify the same authentication algorithm when you configure the SNMPv3 user in the SNMP manager.

Possible values: MD5, SHA

privType

Encryption algorithm used by the NetScaler appliance and the SNMPv3 user for encrypting the communication between them. You must specify the same encryption algorithm when you configure the SNMPv3 user in the SNMP manager.

Possible values: DES, AES

rm snmp user

Removes an SNMPv3 user entry from the NetScaler appliance.

Synopsys

rm snmp user <name>

Arguments

name

Name of the SNMPv3 user.

---

set snmp user

Modifies the specified parameters of an SNMPv3 user entry on the NetScaler appliance.

Synopsys

set snmp user <name> [-group <string>] [-authType (MD5 | SHA) {-authPasswd }] [-privType (DES | AES) {-privPasswd }]

Arguments

name

Name specified in the SNMPv3 user entry that you want to modify. Because this parameter is used for identifying the SNMPv3 user entry, it cannot be modified after the entry has been created.

group

Name of the configured SNMPv3 group to which to bind this SNMPv3 user. The access rights (bound SNMPv3 views) and security level set for this group are assigned to this user.

authType

Authentication algorithm used by the NetScaler appliance and the SNMPv3 user for authenticating the communication between them. You must specify the same authentication algorithm when you configure the SNMPv3 user in the SNMP manager.

Possible values: MD5, SHA

privType

Encryption algorithm used by the NetScaler appliance and the SNMPv3 user for encrypting the communication between them. You must specify the same encryption algorithm when you configure the SNMPv3 user in the SNMP manager.

Possible values: DES, AES

---

unset snmp user

Resets the specified parameters of an SNMPv3 user entry to their default settings..Refer to the set snmp user command for meanings of the arguments.

Synopsys

unset snmp user <name> (-authType | -privType) [-authPasswd] [-privPasswd]

---

show snmp user

Displays the settings of all SNMPv3 users or of the specified SNMPv3 user. To display the settings of all the SNMPv3 users, run the command without any parameters. To display the settings of a particular SNMPv3 user, specify the name of the SNMPv3 user.

Synopsys

show snmp user [<name>]

Arguments

name

Name of the SNMPv3 user whose details you want the NetScaler appliance to display.

summary

fullValues

format

level

Outputs

group

Name of the configured SNMPv3 group to which to bind this SNMPv3 user. The access rights (bound SNMPv3 views) and security level set for this group are assigned to this user.

authType

Authentication algorithm used by the NetScaler appliance and the SNMPv3 user for authenticating the communication between them. You must specify the same authentication algorithm when you configure the SNMPv3 user in the SNMP manager.

authPasswd

Plain-text pass phrase to be used by the authentication algorithm specified by the authType (Authentication Type) parameter. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the pass phrase includes one or more spaces, enclose it in double or single quotation marks (for example, "my phrase" or 'my phrase').

privType

Encryption algorithm used by the NetScaler appliance and the SNMPv3 user for encrypting the communication between them. You must specify the same encryption algorithm when you configure the SNMPv3 user in the SNMP manager.

privPasswd

Encryption key to be used by the encryption algorithm specified by the privType (Encryption Type) parameter. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters.

The following requirement applies only to the NetScaler CLI:

If the key includes one or more spaces, enclose it in double or single quotation marks (for example, "my key" or 'my key').

engineID

The context engine ID of the user.

storageType

The storage type for this user.

status

The status of this user.

devno

count

stateflag

snmp view

Sep 22, 2015

The following operations can be performed on "snmp view":

add | rm | set | show

add snmp view

Adds an SNMPv3 view. Used to implement access control for the SNMPv3 user, SNMPv3 views restrict user access to specific portions of the MIB. The NetScaler appliance can have multiple SNMPv3 views with the same name, differentiated by subtree parameter settings. You can add a maximum of 1000 SNMPv3 views.

Synopsys

add snmp view <name> <subtree> -type (included | excluded)

Arguments

name

Name for the SNMPv3 view. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 view.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose it in double or single quotation marks (for example, "my view" or 'my view').

subtree

A particular branch (subtree) of the MIB tree that you want to associate with this SNMPv3 view. You must specify the subtree as an SNMP OID.

type

Include or exclude the subtree, specified by the subtree parameter, in or from this view. This setting can be useful when you have included a subtree, such as A, in an SNMPv3 view and you want to exclude a specific subtree of A, such as B, from the SNMPv3 view.

Possible values: included, excluded

---

rm snmp view

Removes an SNMPv3 view entry from the NetScaler appliance. The appliance can have multiple SNMPv3 views with the same name, differentiated by the subtree parameter setting. Therefore, to identify an SNMPv3 group subtree that you want to remove, you have to specify both the name and subtree of the SNMPv3 view.

Synopsys

rm snmp view <name> <subtree>

Arguments

name

Name of the SNMPv3 view. Note: If multiple views have the same name, specify the subtree to identify the view to be removed.

subtree

A MIB subtree of the SNMPv3 view.

---

set snmp view

Modifies the type (Type) parameter of an SNMPv3 view configured on the NetScaler appliance.

Synopsys

set snmp view <name> <subtree> -type (included | excluded)

Arguments

name

The name specified in the SNMPv3 view entry. This parameter cannot be modified.

subtree

A MIB subtree of the SNMPv3 view entry. This parameter cannot be modified.

type

Include or exclude the subtree, specified by the subtree parameter, in or from this view. This setting can be useful when you have included a subtree, such as A, in an SNMPv3 view and you want to exclude a specific subtree of A, such as B, from the SNMPv3 view.

Possible values: included, excluded

---

show snmp view

Displays the settings of all SNMPv3 views or of the specified SNMPv3 view. To display the settings of all the SNMPv3 views, run the command without any parameters. To display the settings of a particular SNMPv3 view, specify the name of the SNMPv3 view and subtree (the associated subtree of the MIB). The NetScaler appliance can have multiple SNMPv3 views with the same name, differentiated by the subtree parameter settings.

Synopsys

show snmp view [<name> [<subtree>]]

Arguments

name

Name of the SNMPv3 view.

summary

fullValues

format

level

Outputs

type

The type of sutree.

storageType

The storage type for this view.

Spillover Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- spillover action
- spillover policy

spillover action

Sep 22, 2015

The following operations can be performed on "spillover action":

add | rm | show | rename

add spillover action

Creating spillover action

Synopsys

add spillover action <name> -action SPILLOVER

Arguments

name

Name of the spillover action.

action

Spillover action. Currently only type SPILLOVER is supported

Possible values: SPILLOVER

---

rm spillover action

Removes a spillover policy.

Synopsys

rm spillover action <name>

Arguments

name

Name of the spillover action.

---

show spillover action

Displaying spillover actions

Synopsys

show spillover action [<name>]

Arguments

name

Name of the spillover action.

summary

fullValues

format

level

Outputs

action

Spillover action. Currently only type SPILLOVER is supported

builtin

Flag to determine whether compression is default or not

devno

count

stateflag

---

rename spillover action

Renames a spillover action.

Synopsys

rename spillover action <name>@ <newName>@

Arguments

name

Existing name of the action.

newName

New name for the spillover action. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at

(@), equals (=), and hyphen (-) characters.

Choose a name that can be correlated with the function that the action performs.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

Example

```
rename spillover policy oldname newname
```

spillover policy

Sep 22, 2015

The following operations can be performed on "spillover policy":

add | rm | set | unset | show | rename | stat

add spillover policy

Add a spillover policy. SPILLOVER policies that can be added are based on vserver expressions.

Synopsys

add spillover policy <name> -rule <expression> -action <string> [-comment <string>]

Arguments

name

Name of the spillover policy.

rule

Expression to be used by the spillover policy.

action

Action for the spillover policy. Action is created using add spillover action command

comment

Any comments that you might want to associate with the spillover policy.

Example

add spillover policy pol1 -rule "SYS.VSERVER("abc").ACTIVESERVICES.LE(2) -action act1 add spillover policy pol2 -rule "SYS.VSERVER("abc").CONNECTIONS.GT(500) -ac

---

rm spillover policy

Removes a spillover policy.

Synopsys

rm spillover policy <name>

Arguments

name

Name of the spillover policy.

---

set spillover policy

Used to change the expression or other parameters of an existing policy.

Synopsys

set spillover policy <name> [-rule <expression>] [-action <string>] [-comment <string>]

Arguments

name

Name of the spillover policy.

rule

Expression to be used by the spillover policy.

action

Action for the spillover policy. Action is created using add spillover action command

comment

Any comments that you might want to associate with the spillover policy.

Example

set spillover policy pol1 -rule "SYS.VSERVER("abc").ACTIVESERVICS.LE(1)" set spillover policy pol2 -action act4"

---

unset spillover policy

Use this command to remove spillover policy settings.Refer to the set spillover policy command for meanings of the arguments.

Synopsys

unset spillover policy <name> -comment

---

show spillover policy

Displaying the policy-related information.

Synopsys

show spillover policy [<name>]

Arguments

name

Name of the spillover policy.

summary

fullValues

format

level

Outputs

stateflag

rule

Expression to be used by the spillover policy.

action

Action for the spillover policy. Action is created using add spillover action command

boundTo

The name of the entity to which the policy is bound.

hits

The number of times the policy has been hit.

undefHits

Number of policy UNDEF hits.

activePolicy

Indicates whether policy is bound or not.

priority

Specifies the priority of the policy.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

labelType

Type of policy label invocation.

labelName

Name of the label to invoke if the current policy rule evaluates to TRUE.

comment

Any comments that you might want to associate with the spillover policy.

builtin

Flag to determine if compression policy is builtin or not

devno

count

---

rename spillover policy

Renames a spillover policy.

Synopsys

rename spillover policy <name>@ <newName>@

Arguments

name

Existing name of the policy.

newName

New name for the spillover policy. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

Choose a name that reflects the function that the policy performs.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy').

Example

rename spillover policy oldname newname

---

stat spillover policy

Displays statistics for all spillover policies currently configured on the NetScaler appliance, or detailed statistics for the specified policy.

Synopsys

stat spillover policy [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

name

Name of the spillover policy for which to show detailed statistics.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

Policy hits (Hits)

Number of hits on the policy

Policy undef hits (Undefhits)

Number of undef hits on the policy

SSL Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- ssl
- ssl action
- ssl cert
- ssl certKey
- ssl certLink
- ssl certReq
- ssl cipher
- ssl ciphersuite
- ssl crl
- ssl dhParam
- ssl dsaKey
- ssl dtlsProfile
- ssl fips
- ssl fipsKey
- ssl fipsSIMSource
- ssl fipsSIMTarget
- ssl global
- ssl ocspResponder
- ssl parameter
- ssl pkcs12
- ssl pkcs8
- ssl policy
- ssl policylabel
- ssl rsakey
- ssl service
- ssl serviceGroup
- ssl stats
- ssl vserver
- ssl wrapkey

ssl

Sep 22, 2015

The following operations can be performed on "ssl":

stat ssl

Displays SSL statistics.

Synopsys

stat ssl [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

 # SSL cards UP (SSLCardUP)

Number of SSL cards that are UP. If the number of cards UP is lower than a threshold, a failover is initiated.

SSL crypto card status (SSLCardSt)

Status of the SSL card(s). The value should be interpreted in binary form, with each set bit indicates a card as UP.

 # SSL cards present (SSLCards)

Number of SSL crypto cards present on the NetScaler appliance.

SSL engine status (SSLEngSt)

State of the SSL Engine (1=UP/0=DOWN). This state is decided based on SSL Feature/License status and minimum number of cards UP.

SSL sessions (SSLSe)

Number of SSL sessions on the NetScaler appliance.

SSL transactions (SSLTrn)

Number of SSL transactions on the NetScaler appliance.

SSLv2 transactions (SSL2Trn)

Number of SSLv2 transactions on the NetScaler appliance.

SSLv3 transactions (SSL3Trn)

Total number of SSLv3 transactions on the NetScaler appliance.

TLSv1 transactions (TLS1Trn)

Number of TLSv1 transactions on the NetScaler appliance.

SSLv2 sessions (SSL2Se)

Number of SSLv2 sessions on the NetScaler appliance.

SSLv3 sessions (SSL3Se)

Number of SSLv3 sessions on the NetScaler appliance.

TLSv1 sessions (TLS1Se)

Number of TLSv1 sessions on the NetScaler appliance.

new SSL sessions (NewSe)

Number of new SSL sessions created on the NetScaler appliance.

SSL session misses (SeMiss)

Number of SSL session reuse misses on the NetScaler appliance.

SSL session hits (SeHit)

Number of SSL session reuse hits on the NetScaler appliance.

SSL sessions (BSSLSe)

Number of back-end SSL sessions on the NetScaler appliance.

SSLv3 sessions (BSSL3Se)

Number of back-end SSLv3 sessions on the NetScaler appliance.

TLSv1 sessions (BTLS1Se)

Number of back-end TLSv1 sessions on the NetScaler appliance.

Session multiplex attempts (BSeMx)

Number of back-end SSL session multiplex attempts on the NetScaler appliance.

Session multiplex successes (BSeMxS)

Number of back-end SSL session multiplex successes on the NetScaler appliance.

Session multiplex failures (BSeMxF)

Number of back-end SSL session multiplex failures on the NetScaler appliance.

Bytes encrypted (Enc)

Number of bytes encrypted on the NetScaler appliance.

Bytes decrypted (Dec)

Number of bytes decrypted on the NetScaler appliance.

SSL session renegotiations (SSLRn)

Number of SSL session renegotiations on the NetScaler appliance.

SSLv3 session renegotiations (SSL3Rn)

Number of session renegotiations done on SSLv3.

TLSv1 session renegotiations (TLS1Rn)

Number of SSL session renegotiations done on TLSv1.

RSA 512-bit key exchanges (RSAKx5)

Number of RSA 512-bit key exchanges on the NetScaler appliance.

RSA 1024-bit key exchanges (RSAKx1)

Number of RSA 1024-bit key exchanges on the NetScaler appliance.

RSA 2048-bit key exchanges (RSAKx2)

Number of RSA 2048-bit key exchanges on the NetScaler appliance.

RSA 4096-bit key exchanges (RSAKx4)

Number of RSA 4096-bit key exchanges on the NetScaler appliance.

DH 512-bit key exchanges (DHKx5)

Number of Diffie-Helman 512-bit key exchanges on the NetScaler appliance.

DH 1024-bit key exchanges (DHKx1)

Number of Diffie-Helman 1024-bit key exchanges on the NetScaler appliance.

DH 2048-bit key exchanges (DHKx2)

Number of Diffie-Helman 2048-bit key exchanges on the NetScaler appliance.

ECDHE 521 curve key exchanges (ECDHEKx521)

Number of 521 Elliptical Curve Diffie-Helman on the NetScaler appliance.

ECDHE 384 curve key exchanges (ECDHEKx384)

Number of 384 Elliptical Curve Diffie-Helman on the NetScaler appliance.

ECDHE 256 curve key exchanges (ECDHEKx256)

Number of 256 Elliptical Curve Diffie-Helman on the NetScaler appliance.

ECDHE 224 curve key exchanges (ECDHEKx224)

Number of 224 Elliptical Curve Diffie-Helman on the NetScaler appliance.

RC4 40-bit encryptions (RC4En4)

Number of RC4 40-bit cipher encryptions on the NetScaler appliance.

RC4 56-bit encryptions (RC4En5)

Number of RC4 56-bit cipher encryptions on the NetScaler appliance.

RC4 64-bit encryptions (RC4En6)

Number of RC4 64-bit cipher encryptions on the NetScaler appliance.

RC4 128-bit encryptions (RC4En1)

Number of RC4 128-bit cipher encryptions on the NetScaler appliance.

DES 40-bit encryptions (DESEn4)

Number of DES 40-bit cipher encryptions on the NetScaler appliance.

DES 56-bit encryptions (DESEn5)

Number of DES 56-bit cipher encryptions on the NetScaler appliance.

3DES 168-bit encryptions (3DESEn1)

Number of DES 168-bit cipher encryptions on the NetScaler appliance.

AES 128-bit encryptions (AESEn1)

Number of AES 128-bit cipher encryptions on the NetScaler appliance.

AES 256-bit encryptions (AESEn2)

Number of AES 256-bit cipher encryptions on the NetScaler appliance.

RC2 40-bit encryptions (RC2En4)

Number of RC2 40-bit cipher encryptions on the NetScaler appliance.

RC2 56-bit encryptions (RC2En5)

Number of RC2 56-bit cipher encryptions on the NetScaler appliance.

RC2 128-bit encryptions (RC2En1)

Number of RC2 128-bit cipher encryptions on the NetScaler appliance.

Null cipher encryptions (NullEn)

Number of Null cipher encryptions on the NetScaler appliance.

MD5 hashes (MD5Hsh)

Number of MD5 hashes on the NetScaler appliance.

SHA hashes (SHAHsh)

Number of SHA hashes on the NetScaler appliance.

SSLv2 SSL handshakes (SSL2Hs)

Number of handshakes on SSLv2 on the NetScaler appliance.

SSLv3 SSL handshakes (SSL3Hs)

Number of handshakes on SSLv3 on the NetScaler appliance.

TLSv1 SSL handshakes (TLS1Hs)

Number of SSL handshakes on TLSv1 on the NetScaler appliance.

SSLv2 client authentications (SSL2CAt)

Number of client authentications done on SSLv2.

SSLv3 client authentications (SSL3CAt)

Number of client authentications done on SSLv3.

TLSv1 client authentications (TLS1CAt)

Number of client authentications done on TLSv1.

RSA authentications (RSAAt)

Number of RSA authentications on the NetScaler appliance.

DH authentications (DHAt)

Number of Diffie-Helman authentications on the NetScaler appliance.

DSS (DSA) authentications (DSSAt)

Total number of times DSS authorization is used on the NetScaler appliance.

Null authentications (NullAt)

Number of Null authentications on the NetScaler appliance.

SSL session renegotiations (BSSLRn)

Number of back-end SSL session renegotiations on the NetScaler appliance.

SSLv3 session renegotiations (BSSL3Rn)

Number of back-end SSLv3 session renegotiations on the NetScaler appliance.

TLSv1 session renegotiations (BTLS1Rn)

Number of back-end TLSv1 session renegotiations on the NetScaler appliance.

RSA 512-bit key exchanges (BRSAKx5)

Number of back-end RSA 512-bit key exchanges on the NetScaler appliance.

RSA 1024-bit key exchanges (BRSAKx1)

Number of back-end RSA 1024-bit key exchanges on the NetScaler appliance.

RSA 2048-bit key exchanges (BRSAKx2)

Number of back-end RSA 2048-bit key exchanges on the NetScaler appliance.

DH 512-bit key exchanges (BDHKx5)

Number of back-end DH 512-bit key exchanges on the NetScaler appliance.

DH 1024-bit key exchanges (BDHKx1)

Number of back-end DH 1024-bit key exchanges on the NetScaler appliance.

DH 2048-bit key exchanges (BDHKx2)

Number of back-end DH 2048-bit key exchanges on the NetScaler appliance.

RC4 40-bit encryptions (BRC4En4)

Number of back-end RC4 40-bit cipher encryptions on the NetScaler appliance.

RC4 56-bit encryptions (BRC4En5)

Number of back-end RC4 56-bit cipher encryptions on the NetScaler appliance.

RC4 64-bit encryptions (BRC4En6)

Number of back-end RC4 64-bit cipher encryptions on the NetScaler appliance.

RC4 128-bit encryptions (BRC4En1)

Number of back-end RC4 128-bit cipher encryptions on the NetScaler appliance.

DES 40-bit encryptions (BDESEn4)

Number of back-end DES 40-bit cipher encryptions on the NetScaler appliance.

DES 56-bit encryptions (BDESEn5)

Number of back-end DES 56-bit cipher encryptions on the NetScaler appliance.

3DES 168-bit encryptions (B3DESE1n)

Number of back-end 3DES 168-bit cipher encryptions on the NetScaler appliance.

AES 128-bit encryptions (BAESEn1)

Back-end AES 128-bit cipher encryptions on the NetScaler appliance.

AES 256-bit encryptions (BAESEn2)

Back-end AES 256-bit cipher encryptions on the NetScaler appliance.

RC2 40-bit encryptions (BRC2En4)

Number of back-end RC2 40-bit cipher encryptions on the NetScaler appliance.

RC2 56-bit encryptions (BRC2En5)

Number of back-end RC2 56-bit cipher encryptions on the NetScaler appliance.

RC2 128-bit encryptions (BRC2En1)

Number of back-end RC2 128-bit cipher encryptions on the NetScaler appliance.

null encryptions (BNullEn)

Number of back-end null cipher encryptions on the NetScaler appliance.

MD5 hashes (BMD5Hsh)

Number of back-end MD5 hashes on the NetScaler appliance.

SHA hashes (BSHAHsh)

Number of back-end SHA hashes on the NetScaler appliance.

SSLv3 handshakes (BSSL3Hs)

Number of back-end SSLv3 handshakes on the NetScaler appliance.

TLSv1 handshakes (BTLS1Hs)

Number of back-end TLSv1 handshakes on the NetScaler appliance.

SSLv3 client authentications (BSSL3CAt)

Number of back-end SSLv3 client authentications on the NetScaler appliance.

TLSv1 client authentications (BTLS1CAt)

Number of back-end TLSv1 client authentications on the NetScaler appliance.

RSA authentications (BRSAAt)

Number of back-end RSA authentications on the NetScaler appliance.

DH authentications (BDHAt)

Number of back-end DH authentications on the NetScaler appliance.

DSS authentications (BDSSAt)

Number of back-end DSS authentications on the NetScaler appliance.

Null authentications (BNullAt)

Number of back-end null authentications on the NetScaler appliance.

RSA key exchanges offloaded (RSAkxOf)

Number of RSA key exchanges offloaded to the cryptography card.

RSA sign operations offloaded (RSASnOf)

Number of RSA sign operations offloaded to the cryptography card.

DH key exchanges offloaded (DHkxOf)

Number of DH key exchanges offloaded to the cryptography card.d

RC4 encryptions offloaded (RC4EnOf)

Number of RC4 encryptions offloaded to the cryptography card.

DES encryptions offloaded (DESEnOf)

Number of DES encryptions offloaded to the cryptography card.

AES encryptions offloaded (AESEnOf)

Number of AES encryptions offloaded to the cryptography card.

Bytes encrypted in hardware (EncHw)

Number of bytes encrypted in hardware.

Bytes encrypted in software. (EncSw)

Number of bytes encrypted in software.

Bytes encrypted on the front end. (EncFe)

Number of bytes encrypted on the front end.

Bytes encrypted in hardware on the front end. (EncHwFe)

Number of bytes encrypted in hardware on the front end.

Bytes encrypted in software on front-end (EncSwFe)

Number of bytes encrypted in software on the front end.

Bytes encrypted on back-end (EncBe)

Number of bytes encrypted on the back end.

Bytes encrypted in hardware on back-end (EncHwBe)

Number of bytes encrypted in hardware on the back end.

Bytes encrypted in software on back-end (EncSwBe)

Number of bytes encrypted in software on the back end.

Bytes decrypted in hardware (DecHw)

Number of bytes decrypted in hardware.

Bytes decrypted in software (DecSw)

Number of bytes decrypted in software.

Bytes decrypted on front-end (DecFe)

Number of bytes decrypted on the front end.

Bytes decrypted in hardware on front-end (DecHwFe)

Number of bytes decrypted in hardware on the front end.

Bytes decrypted in software on front-end (DecSwFe)

Number of bytes decrypted in software on the front end.

Bytes decrypted on back-end (DecBe)

Number of bytes decrypted on the back end.

Bytes decrypted in hardware on back-end (DecHwBe)

Number of bytes decrypted in hardware on the back end.

Bytes decrypted in software on the back end. (DecSwBe)

Number of bytes decrypted in software on back-end

Backend SSL sessions reused (BSeRe)

Number of back-end SSL sessions reused on the NetScaler appliance.

IDEA 128-bit encryptions (IDEAEn1)

Number of IDEA 128-bit cipher encryptions on the NetScaler appliance.

IDEA 128-bit encryptions (BIDEAEn1)

Number of back-end IDEA 128-bit cipher encryptions on the NetScaler appliance.

ssl action

Sep 22, 2015

The following operations can be performed on "ssl action":

add | rm | show

add ssl action

Creates a new SSL action. An SSL action defines SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule (expression) specified in the policy, and the action is applied to connections that match the rule.

Synopsys

add ssl action <name> [-clientAuth (DOCLIENTAUTH | NOCLIENTAUTH)] [-clientCert (ENABLED | DISABLED) -certHeader <string>] [-clientCertSerialNumber (ENABLED | DISABLED) -certSerialHeader <string>] [-clientCertSubject (ENABLED | DISABLED) -certSubjectHeader <string>] [-clientCertHash (ENABLED | DISABLED) -certHashHeader <string>] [-clientCertIssuer (ENABLED | DISABLED) -certIssuerHeader <string>] [-sessionID (ENABLED | DISABLED) -sessionIDHeader <string>] [-cipher (ENABLED | DISABLED) -cipherHeader <string>] [-clientCertNotBefore (ENABLED | DISABLED) -certNotBeforeHeader <string>] [-clientCertNotAfter (ENABLED | DISABLED) -certNotAfterHeader <string>] [-OWASupport (ENABLED | DISABLED)]

Arguments

name

Name for the SSL action. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

clientAuth

Perform client certificate authentication.

Possible values: DOCLIENTAUTH, NOCLIENTAUTH

clientCert

Insert the entire client certificate into the HTTP header of the request being sent to the web server. The certificate is inserted in ASCII (PEM) format.

Possible values: ENABLED, DISABLED

clientCertSerialNumber

Insert the entire client serial number into the HTTP header of the request being sent to the web server.

Possible values: ENABLED, DISABLED

clientCertSubject

Insert the client certificate subject, also known as the distinguished name (DN), into the HTTP header of the request being sent to the web server.

Possible values: ENABLED, DISABLED

clientCertHash

Insert the certificate signature (hash) into the HTTP header of the request being sent to the web server.

Possible values: ENABLED, DISABLED

clientCertIssuer

Insert the certificate issuer details into the HTTP header of the request being sent to the web server.

Possible values: ENABLED, DISABLED

sessionID

Insert the SSL session ID into the HTTP header of the request being sent to the web server. Every SSL connection that the client and the NetScaler share has a unique ID that identifies the specific connection.

Possible values: ENABLED, DISABLED

cipher

Insert the cipher suite that the client and the NetScaler appliance negotiated for the SSL session into the HTTP header of the request being sent to the web server. The appliance inserts the cipher-suite name, SSL protocol, export or non-export string, and cipher strength bit, depending on the type of browser connecting to the SSL virtual server or service (for example, Cipher-Suite: RC4- MD5 SSLv3 Non-Export 128-bit).

Possible values: ENABLED, DISABLED

clientCertNotBefore

Insert the date from which the certificate is valid into the HTTP header of the request being sent to the web server. Every certificate is configured with the date and time from which it is valid.

Possible values: ENABLED, DISABLED

clientCertNotAfter

Insert the date of expiry of the certificate into the HTTP header of the request being sent to the web server. Every certificate is configured with the date and time at which the certificate expires.

Possible values: ENABLED, DISABLED

OWASupport

If the appliance is in front of an Outlook Web Access (OWA) server, insert a special header field, FRONT-END-HTTPS: ON, into the HTTP requests going to the OWA server. This header communicates to the server that the transaction is HTTPS and not HTTP.

Possible values: ENABLED, DISABLED

Example

```
add ssl action certInsert_act -clientCert ENABLED -certHeader CERT
```

---

rm ssl action

Removes the specified SSL action.

Synopsys

```
rm ssl action <name>
```

Arguments

name

Name of the SSL action to remove.

Example

```
rm ssl action certInsert_act
```

---

show ssl action

Displays information about all the SSL actions configured on the appliance, or displays detailed information about the specified SSL action.

Synopsys

```
show ssl action [<name>]
```

Arguments

name

Name of the SSL action for which to show detailed information.

summary

fullValues

format

level

Outputs

stateflag

clientAuth

Perform client certificate authentication.

clientCert

Insert the entire client certificate into the HTTP header of the request being sent to the web server. The certificate is inserted in ASCII (PEM) format.

certHeader

clientCertSerialNumber

Insert the entire client serial number into the HTTP header of the request being sent to the web server.

certSerialHeader

clientCertSubject

Insert the client certificate subject, also known as the distinguished name (DN), into the HTTP header of the request being sent to the web server.

certSubjectHeader

clientCertHash

Insert the certificate signature (hash) into the HTTP header of the request being sent to the web server.

certHashHeader

clientCertIssuer

Insert the certificate issuer details into the HTTP header of the request being sent to the web server.

certIssuerHeader

sessionID

Insert the SSL session ID into the HTTP header of the request being sent to the web server. Every SSL connection that the client and the NetScaler share has a unique ID that identifies the specific connection.

sessionIDHeader

cipher

Insert the cipher suite that the client and the NetScaler appliance negotiated for the SSL session into the HTTP header of the request being sent to the web server. The appliance inserts the cipher-suite name, SSL protocol, export or non-export string, and cipher strength bit, depending on the type of browser connecting to the SSL virtual server or service (for example, Cipher-Suite: RC4- MD5 SSLv3 Non-Export 128-bit).

cipherHeader

OWASupport

If the appliance is in front of an Outlook Web Access (OWA) server, insert a special header field, FRONT-END-HTTPS: ON, into the HTTP requests going to the OWA server. This header communicates to the server that the transaction is HTTPS and not HTTP.

clientCertNotBefore

Insert the date from which the certificate is valid into the HTTP header of the request being sent to the web server. Every certificate is configured with the date and time from which it is valid.

certNotBeforeHeader

clientCertNotAfter

Insert the date of expiry of the certificate into the HTTP header of the request being sent to the web server. Every certificate is configured with the date and time at which the certificate expires.

certNotAfterHeader

hits

The number of times the action has been taken.

undefHits

The number of times the action resulted in UNDEF.

referenceCount

The number of references to the action.

description

Description of the action

flags

builtin

Flag to determine whether ssl action is built-in or not

devno

count

Example

show ssl action 1 Configured SSL action: 1) Name: certIns

ssl cert

Sep 22, 2015

The following operations can be performed on "ssl cert":

create ssl cert

Generates a signed X509 Certificate.

Synopsys

create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM) {-PEMPassPhrase }] [-days <positive_integer>] [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (DER | PEM)] [-CAkey <input_filename>] [-CAkeyForm (DER | PEM)] [-CAserial <output_filename>]

Arguments

certFile

Name for and, optionally, path to the generated certificate file. /nsconfig/ssl/ is the default path.

Maximum value: 63

reqFile

Name for and, optionally, path to the certificate-signing request (CSR). /nsconfig/ssl/ is the default path.

Maximum value: 63

certType

Type of certificate to generate. Specify one of the following:

* ROOT_CERT - Self-signed Root-CA certificate. You must specify the key file name. The generated Root-CA certificate can be used for signing end-user client or server certificates or to create Intermediate-CA certificates.

* INTM_CERT - Intermediate-CA certificate.

* CLNT_CERT - End-user client certificate used for client authentication.

* SRVR_CERT - SSL server certificate used on SSL servers for end-to-end encryption.

Possible values: ROOT_CERT, INTM_CERT, CLNT_CERT, SRVR_CERT

keyFile

Name for and, optionally, path to the private key. You can either use an existing RSA or DSA key that you own or create a new private key on the NetScaler appliance. This file is required only when creating a self-signed Root-CA certificate. The key file is stored in the /nsconfig/ssl directory by default.

If the input key specified is an encrypted key, you are prompted to enter the PEM pass phrase that was used for encrypting the key.

Maximum value: 63

keyform

Format in which the key is stored on the appliance.

Possible values: DER, PEM

Default value: FORMAT_PEM

PEMPassPhrase

days

Number of days for which the certificate will be valid, beginning with the time and day (system time) of creation.

Default value: 365

Minimum value: 1

Maximum value: 3650

certForm

Format in which the certificate is stored on the appliance.

Possible values: DER, PEM

Default value: FORMAT_PEM

CAcert

Name of the CA certificate file that issues and signs the Intermediate-CA certificate or the end-user client and server certificates.

Maximum value: 63

CAcertForm

Format of the CA certificate.

Possible values: DER, PEM

Default value: FORMAT_PEM

CAkey

Private key, associated with the CA certificate that is used to sign the Intermediate-CA certificate or the end-user client and server certificate. If the CA key file is password protected, the user is prompted to enter the pass phrase that was used to encrypt the key.

Maximum value: 63

CAkeyForm

Format for the CA certificate.

Possible values: DER, PEM

Default value: FORMAT_PEM

CAserial

Serial number file maintained for the CA certificate. This file contains the serial number of the next certificate to be issued or signed by the CA. If the specified file does not exist, a new file is created, with /nsconfig/ssl/ as the default path. If you do not specify a proper path for the existing serial file, a new serial file is created. This might change the certificate serial numbers assigned by the CA certificate to each of the certificates it signs.

Maximum value: 63

Example

1) create ssl cert /nsconfig/ssl/root_cert.pem /nsconfig/ssl/root_csr.pem ROOT_CERT -keyFile /nsconfig/ssl/root_key.pem -days 1000 The above example creates a self sign

ssl certKey

Sep 22, 2015

The following operations can be performed on "ssl certKey":

add | rm | set | unset | bind | unbind | link | unlink | show | update

add ssl certKey

Adds a certificate-key pair to memory. After it is bound to a virtual server or service, it is used for processing SSL transactions. In a high-availability configuration, the path to the certificate and the optional private key must be the same on the primary and the secondary appliance. For a server certificate, a private key is required.

Synopsys

add ssl certKey <certkeyName> -cert <string> [(-key <string> [-password]) | -fipsKey <string>] [-inform (DER | PEM)] [-expiryMonitor (ENABLED | DISABLED) [-notificationPeriod <positive_integer>]] [-bundle (YES | NO)]

Arguments

certkeyName

Name for the certificate and private-key pair. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the certificate-key pair is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my cert" or 'my cert').

cert

Name of and, optionally, path to the X509 certificate file that is used to form the certificate-key pair. The certificate file should be present on the appliance's hard-disk drive or solid-state drive. Storing a certificate in any location other than the default might cause inconsistency in a high availability setup. /nsconfig/ssl/ is the default path.

key

Name of and, optionally, path to the private-key file that is used to form the certificate-key pair. The certificate file should be present on the appliance's hard-disk drive or solid-state drive. Storing a certificate in any location other than the default might cause inconsistency in a high availability setup. /nsconfig/ssl/ is the default path.

fipsKey

Name of the FIPS key that was created inside the Hardware Security Module (HSM) of a FIPS appliance, or a key that was imported into the HSM.

inform

Input format of the certificate and the private-key files. The two formats supported by the appliance are:

PEM - Privacy Enhanced Mail

DER - Distinguished Encoding Rule

Possible values: DER, PEM

Default value: FORMAT_PEM

passplain

Pass phrase used to encrypt the private-key. Required when adding an encrypted private-key in PEM format.

expiryMonitor

Issue an alert when the certificate is about to expire.

Possible values: ENABLED, DISABLED

notificationPeriod

Time, in number of days, before certificate expiration, at which to generate an alert that the certificate is about to expire.

Minimum value: 10

Maximum value: 100

bundle

Parse the certificate chain as a single file after linking the server certificate to its issuer's certificate within the file.

Possible values: YES, NO

Default value: NO

Example

1) add ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /nsconfig/ssl/pkey.pem The above command loads a certificate and private key file. 2) add ssl certkey site.

---

rm ssl certKey

Removes all the certificate-key pairs, or the specified certificate-key pair, from the appliance. The certificate-key pair is removed only if it is not referenced by any other object. The reference count is updated when the certificate-key pair is bound to an SSL virtual server or linked to another certificate-key pair.

Synopsys

rm ssl certKey <certkeyName> ...

Arguments

certkeyName

Name of the certificate-key pair to remove.

Example

1) rm ssl certkey siteAcertkey The above command removes the certificate-key pair siteAcertkey from the system.

---

set ssl certKey

Modifies the specified attributes of a certificate-key pair.

Synopsys

set ssl certKey <certkeyName> [-expiryMonitor (ENABLED | DISABLED) [-notificationPeriod <positive_integer>]]

Arguments

certkeyName

Name of the certificate-key pair to modify.

expiryMonitor

Issue an alert when the certificate is about to expire.

Possible values: ENABLED, DISABLED

---

unset ssl certKey

Use this command to remove ssl certKey settings.Refer to the set ssl certKey command for meanings of the arguments.

Synopsys

unset ssl certKey <certkeyName> [-expiryMonitor] [-notificationPeriod]

---

bind ssl certKey

Binds a certificate-key pair to an SSL virtual server or an SSL service.

Synopsys

bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]

Arguments

certkeyName

Name of the certificate-key pair.

ocspResponder

Name of the OCSP responder to be associated with the CA certificate.

vServerName

The name of the SSL virtual server name to which the certificate-key pair needs to be bound.

serviceName

The name of the SSL service to which the certificate-key pair needs to be bound. Use the ###add service### command to create this service.

serviceGroupName

The name of the SSL service group to which the certificate-key pair needs to be bound. Use the "add servicegroup" command to create this service.

CA

If this option is specified, it indicates that the certificate-key pair being bound to the SSL virtual server is a CA certificate. If this option is not specified, the certificate-key pair is bound as a normal server certificate.

Note: In case of a normal server certificate, the certificate-key pair should consist of both the certificate and the private-key.

Example

1) bind ssl certkey cacert -ocspResponder ocsp_ca -priority 1 In the above example, the CA certificate cacert is bound with the OCSP responder ocsp_ca with priority 1, wh

---

unbind ssl certKey

Unbinds the specified certificate-key pair from the SSL virtual server or service.

Synopsys

unbind ssl certKey <certkeyName> -ocspResponder <string>

Arguments

certkeyName

Name of the certificate-key pair to unbind.

ocspResponder

Name of the OCSP responder.

vServerName

The name of the SSL virtual server.

serviceName

The name of the SSL service

serviceGroupName

The name of the service group.

CA

The certificate-key pair being unbound is a Certificate Authority (CA) certificate. If you choose this option, the certificate-key pair is unbound from the list of CA certificates that were bound to the specified SSL virtual server or SSL service.

Example

1) unbind ssl certkey sslvip siteAcertkey In the above example, the server certificate siteAcertkey is unbound from the SSL virtual server. 2) unbind ssl certkey sslvip CAc

---

link ssl certKey

Links a certificate-key pair to its Certificate Authority (CA) certificate-key pair.

Synopsys

link ssl certKey <certkeyName> <linkCertKeyName>

Arguments

certkeyName

Name of the certificate-key pair to link to its issuer's certificate-key pair in the chain.

linkCertKeyName

Name of the Certificate Authority certificate-key pair to which to link a certificate-key pair.

Example

1) link ssl certkey siteAcertkey CAcertkey In the above example, the certificate-key siteAcertkey is bound to its issuer certificate-key pair CAcertkey.

---

unlink ssl certKey

Unlinks the certificate-key pair from its Certificate-Authority (CA) certificate-key pair.

Synopsys

unlink ssl certKey <certkeyName>

Arguments

certkeyName

Name of the certificate-key pair to unlink.

Example

1) unlink ssl certkey siteAcertkey The above example unlinks the certificate 'siteAcertkey' from its Certificate-Authority (CA) certificate.

---

show ssl certKey

Displays information about all the certificate-key pairs configured on the appliance, or displays detailed information about the specified certificate-key pair.

Synopsys

show ssl certKey [<certkeyName>]

Arguments

certkeyName

Name of the certificate-key pair for which to show detailed information.

summary

fullValues

format

level

Outputs

cert

The name and location of the file containing the certificate.

key

The name and location of the file containing the key.

The encoding format of the certificate and key (PEM or DER).

signatureAlg

Signature algorithm.

serial

Serial number.

issuer

Issuer name.

clientCertNotBefore

Not-Before date.

clientCertNotAfter

Not-After date.

daysToExpiration

Days remaining for the certificate to expire.

subject

Subject name.

publickey

Public key algorithm.

publickeysize

Size of the public key.

version

Version.

priority

ocsp priority

status

Status of the certificate.

fipsKey

FIPS key ID.

passcrypt

Passcrypt.

data

Vserver Id

serverName

Vserver name to which the certificate key pair is bound.

serviceName

Service name to which the certificate key pair is bound.

ocspResponder

OCSP responders bound to this certkey

expiryMonitor

Certificate expiry monitor

notificationPeriod

Certificate expiry notification period

linkCertKeyName

The name of the Certificate-Authority.

Example

1) An example of the output of the show ssl certkey command is shown below: 2 configured certkeys: 1) Name: siteAcertkey Cert Path

---

update ssl certKey

Updates the certificate or private key in a certificate-key pair. In a high availability configuration, the path to the certificate and the optional private key must be the same on the primary and secondary nodes.

Synopsys

update ssl certKey <certkeyName> [-cert <string>] [(-key <string> [-password]) | -fipsKey <string>] [-inform (DER | PEM)] [-noDomainCheck]

Arguments

certkeyName

Name of the certificate-key pair to update.

cert

Name of and, optionally, path to the X509 certificate file that is used to form the certificate-key pair. The certificate file should be present on the appliance's hard-disk drive or solid-state drive. Storing a certificate in any location other than the default might cause inconsistency in a high availability setup. /nsconfig/ssl/ is the default path.

key

Name of and, optionally, path to the private-key file that is used to form the certificate-key pair. The certificate file should be present on the appliance's hard-disk drive or solid-state drive. Storing a certificate in any location other than the default might cause inconsistency in a high availability setup. /nsconfig/ssl/ is the default path.

fipsKey

Name of the FIPS key that was created inside the Hardware Security Module (HSM) of a FIPS appliance, or a key that was imported into the HSM.

inform

Input format of the certificate and the private-key files. The two formats supported by the appliance are:

PEM - Privacy Enhanced Mail

DER - Distinguished Encoding Rule

Possible values: DER, PEM

Default value: FORMAT_PEM

passplain

Pass phrase used to encrypt the private-key. Required when adding an encrypted private-key in PEM format.

noDomainCheck

Override the check for matching domain names during a certificate update operation.

Example

1) update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /nsconfig/ssl/pkey.pem The above command updates a certificate

ssl certLink

Sep 22, 2015

The following operations can be performed on "ssl certLink":

show ssl certLink

Displays information about all the linked certificate-key pairs on the appliance.

Synopsys

show ssl certLink

Arguments

summary

fullValues

format

level

Outputs

certkeyName

Certificate key name.

linkCertKeyName

Name of the Certificate-Authority.

devno

count

stateflag

Example

The following shows an example of the output of the show ssl certlink command: linked certificate: 1) Cert Name: siteAcertkey CA Cer

ssl certReq

Sep 22, 2015

The following operations can be performed on "ssl certReq":

create ssl certReq

Generates a new Certificate Signing Request (CSR). A CSR is a collection of information including the domain name, company details, and the private key to be used to create the certificate. Send the CSR to a Certificate Authority (CA) to obtain an X509 certificate for the user domain (web site).

Synopsys

create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName <string>) [-keyform (DER | PEM) {-PEMPassPhrase }] -countryName <string> -stateName <string> -organizationName <string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] {-challengePassword } [-companyName <string>]

Arguments

reqFile

Name for and, optionally, path to the certificate signing request (CSR). /nsconfig/ssl/ is the default path.

Maximum value: 63

keyFile

Name of and, optionally, path to the private key used to create the certificate signing request, which then becomes part of the certificate-key pair. The private key can be either an RSA or a DSA key. The key must be present in the appliance's local storage. /nsconfig/ssl is the default path.

Maximum value: 63

fipsKeyName

Name of the FIPS key used to create the certificate signing request. FIPS keys are created inside the Hardware Security Module of the FIPS card.

keyform

Format in which the key is stored on the appliance.

Possible values: DER, PEM

Default value: FORMAT_PEM

countryName

Two letter ISO code for your country. For example, US for United States.

stateName

Full name of the state or province where your organization is located.

Do not abbreviate.

organizationName

Name of the organization that will use this certificate. The organization name (corporation, limited partnership, university, or government agency) must be registered with some authority at the national, state, or city level. Use the legal name under which the organization is registered.

Do not abbreviate the organization name and do not use the following characters in the name:

Angle brackets (< >) tilde (~), exclamation mark, at (@), pound (#), zero (0), caret (^), asterisk (*), forward slash (/), square brackets ([ ]), question mark (?).

organizationUnitName

Name of the division or section in the organization that will use the certificate.

localityName

Name of the city or town in which your organization's head office is located.

commonName

Fully qualified domain name for the company or web site. The common name must match the name used by DNS servers to do a DNS lookup of your server. Most browsers use this information for authenticating the server's certificate during the SSL handshake. If the server name in the URL does not match the common name as given in the server certificate, the browser terminates the SSL handshake or prompts the user with a warning message.

Do not use wildcard characters, such as asterisk (*) or question mark (?), and do not use an IP address as the common name. The common name must not contain the protocol specifier <http://> or <https://>.

emailAddress

Contact person's e-mail address. This address is publically displayed as part of the certificate. Provide an e-mail address that is monitored by an administrator who can be contacted about the certificate.

challengePassword

Pass phrase, embedded in the certificate signing request that is shared only between the client or server requesting the certificate and the SSL certificate issuer (typically the certificate authority). This pass phrase can be used to authenticate a client or server that is requesting a certificate from the certificate authority.

companyName

Additional name for the company or web site.

Example

```
create ssl certreq /nsconfig/ssl/csr.pem -keyFile /nsconfig/ssl/rsa1024.pem
```

ssl cipher

Sep 22, 2015

The following operations can be performed on "ssl cipher":

add | bind | show | rm | unbind

add ssl cipher

Creates a user-defined cipher group, which you can bind to an SSL virtual server instead of binding ciphers individually. Although you cannot modify a built-in cipher group, you can add built-in cipher groups as well as individual ciphers to a user-defined cipher group.

Synopsys

add ssl cipher <cipherGroupName>

Arguments

cipherGroupName

Name for the user-defined cipher group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the cipher group is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my ciphergroup" or 'my ciphergroup').

cipherAliasName/cipherName/cipherGroupName

The individual cipher name(s), a user-defined cipher group, or a system predefined cipher alias that will be added to the predefined cipher alias that will be added to the group cipherGroupName.

If a cipher alias or a cipher group is specified, all the individual ciphers in the cipher alias or group will be added to the user-defined cipher group.

Example

1) add ssl cipher mygroup SSL2-RC4-MD5 SSL2-EXP-RC4-MD5 The above command creates a new cipher-group by the name: mygroup, with the two ciphers SSL2-RC4-MD5

---

bind ssl cipher

Adds ciphers to a user-defined cipher group. You can add an existing cipher group to a user-defined cipher group but you cannot modify a built-in cipher group.

Synopsys

bind ssl cipher [<cipherGroupName>@] [-cipherName <string>]

Arguments

cipherGroupName

Name of the user-defined cipher group.

vServerName

The name of the SSL virtual server to which the cipher-suite is to be bound.

serviceName

The name of the SSL service name to which the cipher-suite is to be bound.

serviceGroupName

The name of the SSL service name to which the cipher-suite is to be bound.

cipherOperation

The operation that is performed when adding the cipher-suite.

Possible cipher operations are:

ADD - Appends the given cipher-suite to the existing one configured for the virtual server.

REM - Removes the given cipher-suite from the existing one configured for the virtual server.

ORD - Overrides the current configured cipher-suite for the virtual server with the given cipher-suite.

Possible values: ADD, REM, ORD

cipherAliasName/cipherName/cipherGroupName

A cipher-suite can consist of an individual cipher name, the system predefined cipher-alias name, or user defined cipher-group name.

cipherName

Name of the individual cipher, user-defined cipher group, or predefined (built-in) cipher alias to add to the cipher group.

Example

1) bind ssl cipher sslvip ADD SSL3-RC4-SHA The above example appends the cipher SSL3-RC4-SHA to the cipher-suite already configured for the SSL virtual server sslvip.

---

show ssl cipher

Displays information about all the cipher groups defined on the appliance, or displays detailed information about the specified cipher group.

Synopsys

show ssl cipher [<cipherGroupName>]

Arguments

cipherGroupName

Name of the cipher group for which to show detailed information.

summary

fullValues

format

level

Outputs

description

Cipher suite description.

cipherName

Cipher name.

count

Example

1) An example of the output of the show ssl cipher SSL3-RC4-MD5 command is as follows: Cipher Name: SSL3-RC4-MD5

---

rm ssl cipher

Removes a user-defined cipher group from the appliance.

Synopsys

rm ssl cipher <cipherGroupName>

Arguments

cipherGroupName

Name of the user-defined cipher group to remove.

cipherName

The cipher(s) to be removed from the cipher group.

Example

1) rm ssl cipher mygroup SSL2-RC4-MD5 The above example removes the cipher SSL2-RC4-MD5 from the cipher group m

---

unbind ssl cipher

Removes all the ciphers from a user-defined cipher group. You can only remove individual ciphers from a user-defined cipher group. Removing groups is not supported.

Synopsys

unbind ssl cipher <cipherGroupName> [-cipherName <string> ...]

Arguments

cipherGroupName

Name of the user-defined cipher group.

cipherName

Name(s) of the cipher(s) to be removed from the user-defined cipher group.

Example

1) rm ssl cipher mygroup SSL2-RC4-MD5 The above example removes the cipher SSL2-RC4-MD5 from the cipher group m

ssl ciphersuite

Sep 22, 2015

The following operations can be performed on "ssl ciphersuite":

show ssl ciphersuite

Displays information about all the cipher suites configured on the appliance, or displays detailed information about the specified cipher-suite. A cipher suite comprises a protocol and the following algorithms: key exchange (Kx), authentication (Au), encryption (Enc), and message authentication code (Mac).

Synopsys

show ssl ciphersuite [<cipherName>]

Arguments

cipherName

Name of the cipher suite for which to show detailed information.

ssl crl

Sep 22, 2015

The following operations can be performed on "ssl crl":

add | create | rm | set | unset | show

add ssl crl

Adds a Certificate Revocation List (CRL). A CRL identifies invalid certificates by serial number and issuer. In a high availability configuration, the CRL must be in the same location on the primary and secondary nodes.

Synopsys

add ssl crl <crlName> <crlPath> [-inform (DER | PEM)] [-refresh (ENABLED | DISABLED)] [-CAcert <string>] [-method (HTTP | LDAP)] [-server <ip_addr|ipv6_addr|*> | -url <URL>] [-port <port>] [-baseDN <string>] [-scope (Base | One)] [-interval <interval>] [-day <integer>] [-time <HH:MM>] [-bindDN <string>] {-password } [-binary (YES | NO)]

Arguments

crlName

Name for the Certificate Revocation List (CRL). Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CRL is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my crl" or 'my crl').

crlPath

Path to the CRL file. /var/netscaler/ssl/ is the default path.

inform

Input format of the CRL file. The two formats supported on the appliance are:

PEM - Privacy Enhanced Mail.

DER - Distinguished Encoding Rule.

Possible values: DER, PEM

Default value: FORMAT_PEM

refresh

Set CRL auto refresh.

Possible values: ENABLED, DISABLED

CAcert

CA certificate that has issued the CRL. Required if CRL Auto Refresh is selected. Install the CA certificate on the appliance before adding the CRL.

method

Method for CRL refresh. If LDAP is selected, specify the method, CA certificate, base DN, port, and LDAP server name. If HTTP is selected, specify the CA certificate, method, URL, and port. Cannot be changed after a CRL is added.

Possible values: HTTP, LDAP

server

IP address of the LDAP server from which to fetch the CRLs.

url

URL of the CRL distribution point.

port

Port for the LDAP server.

Minimum value: 1

baseDN

Base distinguished name (DN), which is used in an LDAP search to search for a CRL. Citrix recommends searching for the Base DN instead of the Issuer Name from the CA certificate, because the Issuer Name field might not exactly match the LDAP directory structure's DN.

scope

Extent of the search operation on the LDAP server. Available settings function as follows:

One - One level below Base DN.

Base - Exactly the same level as Base DN.

Possible values: Base, One

Default value: NSAPI_ONESCOPE

interval

CRL refresh interval. Use the NONE setting to unset this parameter.

Possible values: MONTHLY, WEEKLY, DAILY, NONE

day

Day on which to refresh the CRL, or, if the Interval parameter is not set, the number of days after which to refresh the CRL. If Interval is set to MONTHLY, specify the date. If Interval is set to WEEKLY, specify the day of the week (for example, Sun=0 and Sat=6). This parameter is not applicable if the Interval is set to DAILY.

Maximum value: 31

time

Time, in hours (1-24) and minutes (1-60), at which to refresh the CRL.

bindDN

Bind distinguished name (DN) to be used to access the CRL object in the LDAP repository if access to the LDAP repository is restricted or anonymous access is not allowed.

password

Password to access the CRL in the LDAP repository if access to the LDAP repository is restricted or anonymous access is not allowed.

binary

Set the LDAP-based CRL retrieval mode to binary.

Possible values: YES, NO

Default value: NO

Example

1) add ssl certkey CAcert -cert /nsconfig/ssl/ca_cert.pem add ssl crl crl_file /var/netscaler/ssl/crl.pem -cacert CAcert The above command adds a CRL from local storage sys

---

create ssl crl

Revokes a certificate, or list of certificates, or generates a CRL for the list of revoked certificates.

Synopsys

create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <input_filename> | -genCRL <output_filename>) {-password }

Arguments

CAcertFile

Name of and, optionally, path to the CA certificate file.

/nsconfig/ssl/ is the default path.

Maximum value: 63

CAkeyFile

Name of and, optionally, path to the CA key file. /nsconfig/ssl/ is the default path

Maximum value: 63

indexFile

Name of and, optionally, path to the file containing the serial numbers of all the certificates that are revoked. Revoked certificates are appended to the file. /nsconfig/ssl/ is the default path

Maximum value: 63

revoke

Name of and, optionally, path to the certificate to be revoked. /nsconfig/ssl/ is the default path.

Maximum value: 63

genCRL

Name of and, optionally, path to the CRL file to be generated. The list of certificates that have been revoked is obtained from the index file. /nsconfig/ssl/ is the default path.

Maximum value: 63

password

Password for the CA key file.

Maximum value: 31

Example

1) create crl /nsconfig/ssl/cacert.pem /nsconfig/ssl/cakey.pem /nsconfig/ssl/index.txt -gencrl /var/netscaler/ssl/crl.pem

---

rm ssl crl

Removes the specified CRL from the appliance.

Synopsys

rm ssl crl <crlName> ...

Arguments

crlName

Name of the CRL to remove.

Example

1) rm ssl crl ca_crl The above CLI command to delete the CRL object ca_crl from the system is.

---

set ssl crl

Modifies all the parameters of a CRL, except the CRL name and method.

Synopsys

set ssl crl <crlName> [-refresh (ENABLED | DISABLED)] [-CAcert <string>] [-server <ip_addr|ipv6_addr|*> | -url <URL>] [-method (HTTP | LDAP)] [-port <port>] [-baseDN <string>] [-scope (Base | One)] [-interval <interval>] [-day <integer>] [-time <HH:MM>] [-bindDN <string>] { -password } [-binary (YES | NO)]

Arguments

crlName

Name of the CRL to be modified.

refresh

Set CRL auto refresh.

Possible values: ENABLED, DISABLED

CAcert

CA certificate that has issued the CRL. Required if CRL Auto Refresh is selected. Install the CA certificate on the appliance before adding the CRL.

server

IP address of the LDAP server from which to fetch the CRLs.

method

Method for CRL refresh. If LDAP is selected, specify the method, CA certificate, base DN, port, and LDAP server name. If HTTP is selected, specify the CA certificate, method, URL, and port. Cannot be changed after a CRL is added.

Possible values: HTTP, LDAP

port

Port for the LDAP server.

Minimum value: 1

baseDN

Base distinguished name (DN), which is used in an LDAP search to search for a CRL. Citrix recommends searching for the Base DN instead of the Issuer Name from the CA certificate, because the Issuer Name field might not exactly match the LDAP directory structure's DN.

scope

Extent of the search operation on the LDAP server. Available settings function as follows:

One - One level below Base DN.

Base - Exactly the same level as Base DN.

Possible values: Base, One

Default value: NSAPI_ONESCOPE

interval

CRL refresh interval. Use the NONE setting to unset this parameter.

Possible values: MONTHLY, WEEKLY, DAILY, NOW, NONE

day

Day on which to refresh the CRL, or, if the Interval parameter is not set, the number of days after which to refresh the CRL. If Interval is set to MONTHLY, specify the date. If Interval is set to WEEKLY, specify the day of the week (for example, Sun=0 and Sat=6). This parameter is not applicable if the Interval is set to DAILY.

Maximum value: 31

time

Time, in hours (1-24) and minutes (1-60), at which to refresh the CRL.

bindDN

Bind distinguished name (DN) to be used to access the CRL object in the LDAP repository if access to the LDAP repository is restricted or anonymous access is not allowed.

password

Password to access the CRL in the LDAP repository if access to the LDAP repository is restricted or anonymous access is not allowed.

binary

Set the LDAP-based CRL retrieval mode to binary.

Possible values: YES, NO

Default value: NO

Example

1) set ssl crl crl_file -refresh ENABLE -interval MONTHLY -days 10 -time 12:00 The above example sets the CRL refresh to every Month, on date=10, and time=12:00hrs. 2

---

unset ssl crl

Use this command to remove ssl crl settings.Refer to the set ssl crl command for meanings of the arguments.

Synopsys

unset ssl crl <crlName> [-refresh] [-CAcert] [-server] [-method] [-url] [-port] [-baseDN] [-scope] [-interval] [-day] [-time] [-bindDN] [-password] [-binary]

---

show ssl crl

Displays information about all the CRLs configured on the appliance, or displays detailed information about the specified CRL.

Synopsys

show ssl crl [<crlName>]

Arguments

crlName

Name of the CRL for which to show detailed information.

summary

fullValues

format

level

Outputs

crlPath

The name and path to the file containing the CRL.

inform

The encoding format of the CRL (PEM or DER).

CAcert

The CA certificate that issued the CRL.

refresh

The state of the auto refresh feature for the CRL.

scope

Extent of the search operation on the LDAP server.

Base: Exactly the same level as basedn

One : One level below basedn.

server

The IP address of the LDAP/HTTP server from which the CRLs are to be fetched.

port

The port of the LDAP/HTTP server.

url

URL of the CRL distribution point.

method

The method for CRL refresh (LDAP or HTTP).

baseDN

The baseDN to be used to fetch the CRL object from the LDAP server.

interval

The CRL refresh interval.

day

The day when the CRL is to be refreshed.

time

The time when the CRL is to be refreshed.

bindDN

The bindDN to be used to access the CRL object in the LDAP repository.

password

The password to be is used to access the CRL object in the LDAP repository.

flags

CRL status flag.

lastupdatetime

Last CRL refresh time.

version

CRL version.

signaturealgo

Signature algorithm.

issuer

Issuer name.

lastupdate

Last update time.

nextupdate

Next update time.

date

Certificate Revocation date

number

Certificate Serial number.

binary

Mode of retrieval of CRL from LDAP server.

daysToExpiration

Number of days remaining for the CRL to expire.

devno

count

stateflag

Example

1) An example output of the show ssl crl command is as follows: 1 configured CRL(s) 1 Name: ca_crl CRL Path: /var/netscaler/ssl/cr1.d

ssl dhParam

Sep 22, 2015

The following operations can be performed on "ssl dhParam":

create ssl dhParam

Generates a Diffie-Hellman (DH) key.

Synopsys

create ssl dhParam <dhFile> [<bits>] [-gen (2 | 5)]

Arguments

dhFile

Name of and, optionally, path to the DH key file. /nsconfig/ssl/ is the default path.

Maximum value: 63

bits

Size, in bits, of the DH key being generated.

Minimum value: 512

Maximum value: 2048

gen

Random number required for generating the DH key. Required as part of the DH key generation algorithm.

Possible values: 2, 5

Default value: 2

Example

1) create ssl dhparam /nsconfig/ssl/dh1024.pem 1024 -gen 5

ssl dsaKey

Sep 22, 2015

The following operations can be performed on "ssl dsaKey":

create ssl dsaKey

Generates a DSA key.

Synopsys

create ssl dsaKey <keyFile> <bits> [-keyform (DER | PEM)] [-des | -des3] {-password }

Arguments

keyFile

Name for and, optionally, path to the DSA key file. /nsconfig/ssl/ is the default path.

Maximum value: 63

bits

Size, in bits, of the DSA key.

Minimum value: 512

Maximum value: 2048

keyform

Format in which the DSA key file is stored on the appliance.

Possible values: DER, PEM

Default value: FORMAT_PEM

des

Encrypt the generated DSA key by using the DES algorithm. On the command line, you are prompted to enter the pass phrase (password) that will be used to encrypt the key.

des3

Encrypt the generated DSA key by using the Triple-DES algorithm. On the command line, you are prompted to enter the pass phrase (password) that will be used to encrypt the key.

password

Pass phrase to use for encryption if DES or DES3 option is selected.

Maximum value: 31

Example

```
create ssl dsakey /nsconfig/ssl/dsa1024.pem 1024
```

ssl dtlsProfile

Sep 22, 2015

The following operations can be performed on "ssl dtlsProfile":

add | rm | set | unset | show

add ssl dtlsProfile

Add a new DTLS profile on the Netscaler

Synopsys

add ssl dtlsProfile <name> [-pmtuDiscovery (ENABLED | DISABLED)] [-maxRecordSize <positive_integer>] [-maxRetryTime <positive_integer>] [-helloVerifyRequest (ENABLED | DISABLED)] [-terminateSession (ENABLED | DISABLED)] [-maxPacketSize <positive_integer>]

Arguments

name

Name of the DTLS profile

pmtuDiscovery

Enable/disable PMTU discovery

Possible values: ENABLED, DISABLED

Default value: DISABLED

maxRecordSize

Maximum record size

Default value: 1460

Maximum value: 1472

maxRetryTime

Maximum retry time

Default value: 3

helloVerifyRequest

Enable/disable sending of hello verify request

Possible values: ENABLED, DISABLED

Default value: DISABLED

terminateSession

Option to decide whether to terminate the session if bad MAC decode error happens.

Possible values: ENABLED, DISABLED

Default value: DISABLED

maxPacketSize

Max packet count to reassemble for a fragmented record ? attack protection if client send small packets

Default value: 120

Maximum value: 86400

Example

```
add dtlsProfile dtls1 -helloVerifyRequest  ENABLED -maxRetryTime 4
```

---

rm ssl dtlsProfile

Remove a DTLS profile on the Netscaler

Synopsys

```
rm ssl dtlsProfile <name>
```

Arguments

name

Name of the DTLS profile

Example

```
rm dtlsprofile <profile name>
```

---

set ssl dtlsProfile

Set/modify DTLS profile values

Synopsys

```
set ssl dtlsProfile <name> [-pmtuDiscovery ( ENABLED | DISABLED )] [-maxRecordSize <positive_integer>] [-maxRetryTime <positive_integer>] [-helloVerifyRequest ( ENABLED | DISABLED )] [-terminateSession ( ENABLED | DISABLED )] [-maxPacketSize <positive_integer>]
```

Arguments

name

Name of the DTLS profile

pmtuDiscovery

Enable/disable PMTU discovery

Possible values: ENABLED, DISABLED

Default value: DISABLED

maxRecordSize

Maximum record size

Default value: 1460

Maximum value: 1472

maxRetryTime

Maximum retry time

Default value: 3

helloVerifyRequest

Enable/disable sending of hello verify request

Possible values: ENABLED, DISABLED

Default value: DISABLED

terminateSession

Option to decide whether to terminate the session if bad MAC decode error happens.

Possible values: ENABLED, DISABLED

Default value: DISABLED

maxPacketSize

Max packet count to reassemble for a fragmented record ? attack protection if client send small packets

Default value: 120

Maximum value: 86400

Example

```
set dtlsprofile <profile name> -dropInvalReqs ON -markHttp09Inval ON
```

---

unset ssl dtlsProfile

Use this command to remove ssl dtlsProfile settings.Refer to the set ssl dtlsProfile command for meanings of the arguments.

Synopsys

unset ssl dtlsProfile <name> [-pmtuDiscovery] [-maxRecordSize] [-maxRetryTime] [-helloVerifyRequest] [-terminateSession] [-maxPacketSize]

---

show ssl dtlsProfile

Display all the configured DTLS profiles in the system. If a name is specified, then only that profile is shown.

Synopsys

show ssl dtlsProfile [<name>]

Arguments

name

Name of the DTLS profile.

summary

fullValues

format

level

Outputs

pmtuDiscovery

PMTU Discovery

maxRecordSize

Maximum record size

maxRetryTime

Maximum retry time

helloVerifyRequest

Hello Verify Request

terminateSession

Terminate Session

Example

show dtls profile [profile name]

ssl fips

Sep 22, 2015

The following operations can be performed on "ssl fips":

set | unset | reset | show | update

set ssl fips

Initializes the Hardware Security Module (HSM) on the FIPS card and sets a new security officer password and user password. CAUTION: This command erases all data on the FIPS card. You are prompted before proceeding with the command execution. A restart is required before and after executing this command for the changes to apply. Save the configuration after executing this command and before restarting the appliance.

Synopsys

set ssl fips -initHSM Level-2 [-hsmLabel <string>]

Arguments

initHSM

FIPS initialization level. The appliance currently supports Level-2 (FIPS 140-2).

Possible values: Level-2

soPassword

Security officer password that will be in effect after you have configured the HSM.

oldSoPassword

Old password for the security officer.

userPassword

The Hardware Security Module's (HSM) User password.

hsmLabel

Label to identify the Hardware Security Module (HSM).

Example

1) set fips -initHSM Level-2 fipsso123 oldfipsso123 fipuser123 -hsmLabel FIPS-140-2 >This command will erase all data on the FIPS card. You must save the configuratio

---

unset ssl fips

Use this command to remove ssl fips settings.Refer to the set ssl fips command for meanings of the arguments.

Synopsys

unset ssl fips -hsmLabel

---

reset ssl fips

Resets the FIPS card to the default password for Security Officer and User accounts. This command can be used only if the FIPS card has been locked because of three or more unsuccessful login attempts.

Synopsys

reset ssl fips

Example

reset fips

---

show ssl fips

Displays the information on the FIPS card.

Synopsys

show ssl fips

Arguments

format

level

Outputs

initHSM

The level of the FIPS initialization.

soPassword

Security officer password that will be in effect after you have configured the HSM.

userPassword

The Hardware Security Module's (HSM) User password.

oldSoPassword

Old password for the security officer.

eraseData

Erase data.

hsmLabel

FIPS card (HSM) label

serial

FIPS card serial number.

majorVersion

Firmware major version.

minorVersion

Firmware minor version.

FipsHwMajorVersion

FIPS card hardware major version.

FipsHwMinorVersion

FIPS card hardware minor version.

FipsHwVersionString

FIPS card hardware extended version string.

flashMemoryTotal

Total size of the flash memory on card.

flashMemoryFree

Total size of free flash memory.

sramTotal

Total size of the SRAM memory on card.

sramFree

Total size of free SRAM memory.

status

Status.

flag

Internal Flags.

serialNo

FIPS card serial number.

state

FIPS card state.

firmwareReleaseDate

FIPS card firmware revision date.

coresMax

Maximum number of crypto cores present in the FIPS card.

coresEnabled

Number of crypto cores enabled in the FIPS card.

Example

An example of the output for show ssl fips command is as follows: FIPS HSM Info: HSM Label : FIPS1 Initialization : FIPS-140-2 Level-2 HSM Seria

---

update ssl fips

Updates the FIPS firmware. Note: Only compatible firmware version upgrade is allowed. For example, 4.6.0 to 4.6.1

Synopsys

update ssl fips -fipsFW 4.6.1

Arguments

fipsFW

FIPS firmware update.

Possible values: 4.6.1

Example

update ssl fips -fipsFW 4.6.1

---

ssl fipsKey

Sep 22, 2015

The following operations can be performed on "ssl fipsKey":

create | rm | show | import | export

create ssl fipsKey

Generates a FIPS key within the Hardware Security Module (HSM) of the FIPS card.

Synopsys

create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent (3 | F4)]

Arguments

fipsKeyName

Name for the FIPS key. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the FIPS key is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my fipskey" or 'my fipskey').

modulus

Modulus, in multiples of 64, of the FIPS key to be created.

Minimum value: 1024

Maximum value: 4096

exponent

Exponent value for the FIPS key to be created. Available values function as follows:

3=3 (hexadecimal)

F4=10001 (hexadecimal)

Possible values: 3, F4

Default value: 3

Example

```
create fipskey fips1 -modulus 1024 -exp f4
```

---

rm ssl fipsKey

Removes all the FIPS keys, or the specified FIPS key, from the appliance.

Synopsys

rm ssl fipsKey <fipsKeyName> ...

Arguments

fipsKeyName

Name of the FIPS key to remove.

Example

```
rm fipskey fips1
```

---

show ssl fipsKey

Displays information about all the FIPS keys configured on the appliance, or displays detailed information about the specified FIPS key.

Synopsys

show ssl fipsKey [<fipsKeyName>]

Arguments

fipsKeyName

Name of the FIPS key for which to show detailed information.

summary

fullValues

format

level

Outputs

modulus

The modulus of the key.

exponent

The exponent value for the key.

size

Size.

devno

count

stateflag

Example

1) An example of output of show ssl fipskey command is as follows: show fipskey 2 FIPS keys: 1) FIPS Key Name: fips1 2) FIPS K

---

import ssl fipsKey

Imports a FIPS key into the Hardware Security Module (HSM) of the FIPS card. Can import an existing FIPS key, or can import, as a FIPS key, an external private key, such as a key that was created on an Apache or IIS external Web server.

Synopsys

import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv <string>] [-exponent (3 | F4)]

Arguments

fipsKeyName

Name for the FIPS key to be imported. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the FIPS key is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my fipskey" or 'my fipskey').

key

Name of and, optionally, path to the key file to be imported.

/nsconfig/ssl/ is the default path.

inform

Input format of the key file. Available formats are:

SIM - Secure Information Management; select when importing a FIPS key. If the external FIPS key is encrypted, first decrypt it, and then import it.

PEM - Privacy Enhanced Mail; select when importing a non-FIPS key.

Possible values: SIM, DER, PEM

Default value: FORMAT_SIM

wrapKeyName

Name of the wrap key to use for importing the key. Required for importing a non-FIPS key.

iv

Initialization Vector (IV) to use for importing the key. Required for importing a non-FIPS key.

exponent

Exponent value for the FIPS key to be created. Available values function as follows:

3=3 (hexadecimal)

F4=10001 (hexadecimal)

Possible values: 3, F4

Default value: 3

Example

1) import fipskey fips1 -key /nsconfig/ssl/fipskey.sim The above example imports a FIPS key stored in the file fipskey.sim in the systen

---

export ssl fipsKey

Exports a FIPS key from one appliance to another or backs up a FIPS key in a secure manner. The exported key is secured by using a strong asymmetric key encryption method.

Synopsys

export ssl fipsKey <fipsKeyName> -key <string>

Arguments

fipsKeyName

Name of the FIPS key to export.

key

Name of and, optionally, path to the exported key file.

/nsconfig/ssl/ is the default path.

Example

export fipskey fips1 -key /nsconfig/ssl/fips1.key

---

ssl fipsSIMSource

Sep 22, 2015

The following operations can be performed on "ssl fipsSIMSource":

enable | init

enable ssl fipsSIMSource

Enable the source FIPS appliance to participate in a secure exchange of keys with the target (secondary) FIPS appliance.

Synopsys

enable ssl fipsSIMSource <targetSecret> <sourceSecret>

Arguments

targetSecret

Name of and, optionally, path to the target FIPS appliance's secret data. /nsconfig/ssl/ is the default path.

sourceSecret

Name for and, optionally, path to the source FIPS appliance's secret data. /nsconfig/ssl/ is the default path.

Example

```
enable fipsSIMsource /nsconfig/ssl/target.secret /nsconfig/ssl/source.secret
```

---

init ssl fipsSIMSource

Initialize the source FIPS appliance for participating in a secure exchange of keys with the target (secondary) FIPS appliance.

Synopsys

init ssl fipsSIMSource <certFile>

Arguments

certFile

Name for and, optionally, path to the source FIPS appliance's certificate file. /nsconfig/ssl/ is the default path.

Example

```
init fipsSIMsource /nsconfig/ssl/source.cert
```

---

ssl fipsSIMTarget

Sep 22, 2015

The following operations can be performed on "ssl fipsSIMTarget":

enable | init

enable ssl fipsSIMTarget

Enables secure transfer of FIPS keys in a high availability setup from the primary appliance to the secondary appliance.

Synopsys

enable ssl fipsSIMTarget <keyVector> <sourceSecret>

Arguments

keyVector

Name of and, optionally, path to the target FIPS appliance's key vector. /nsconfig/ssl/ is the default path.

sourceSecret

Name of and, optionally, path to the source FIPS appliance's secret data. /nsconfig/ssl/ is the default path.

Example

```
enable fipsSIMtarget /nsconfig/ssl/target.key /nsconfig/ssl/source.secret
```

---

init ssl fipsSIMTarget

Initialize the target (secondary) FIPS appliance for participating in a secure exchange of keys with the primary FIPS appliance.

Synopsys

init ssl fipsSIMTarget <certFile> <keyVector> <targetSecret>

Arguments

certFile

Name of and, optionally, path to the source FIPS appliance's certificate file. /nsconfig/ssl/ is the default path.

keyVector

Name for and, optionally, path to the target FIPS appliance's key vector. /nsconfig/ssl/ is the default path.

targetSecret

Name for and, optionally, path to the target FIPS appliance's secret data. The default input path for the secret data is /nsconfig/ssl/.

Example

```
init fipsSIMtarget /nsconfig/ssl/source.cert /nsconfig/ssl/target.key /nsconfig/ssl/target.secret
```

ssl global

Sep 22, 2015

The following operations can be performed on "ssl global":

bind | unbind | show

bind ssl global

Binds an SSL policy globally.

Synopsys

bind ssl global [-policyName <string>] [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type <type>] [-invoke (<labelType> <labelName>)]

Arguments

policyName

Name of the SSL policy.

Example

```
bind ssl global -policyName certInsert_pol -priority 100
```

---

unbind ssl global

Unbinds a globally bound SSL policy.

Synopsys

unbind ssl global [-policyName <string> [-type <type>] [-priority <positive_integer>]]

Arguments

policyName

Name of the SSL policy to unbind.

Example

```
unbind ssl global -policyName certInsert_pol
```

---

show ssl global

Displays globally bound SSL policies.

Synopsys

show ssl global [-type <type>]

Arguments

type

Global bind point to which the policy is bound.

Possible values: CONTROL_OVERRIDE, CONTROL_DEFAULT, DATA_OVERRIDE, DATA_DEFAULT

summary

fullValues

format

level

Outputs

stateflag

policyName

The name for the SSL policy.

priority

The priority of the policy binding.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE

invoke

Invoke flag. This attribute is relevant only for ADVANCED policies

labelType

Type of policy label invocation.

labelName

Name of the label to invoke if the current policy rule evaluates to TRUE.

numpol

The number of policies bound to the bindpoint.

devno

count

Example

show ssl global 1 Globally Active SSL Policy: 1) Name: certInsert_pol Priority: 100

ssl ocspResponder

Sep 22, 2015

The following operations can be performed on "ssl ocspResponder":

add | rm | set | unset | show

add ssl ocspResponder

Adds an OCSP responder. An OCSP responder identifies the OCSP server that validates a certificate. NetScaler appliances support OCSP as defined in RFC 2560.

Synopsys

add ssl ocspResponder <name> -url <URL> [-cache (ENABLED | DISABLED) [-cacheTimeout <positive_integer>]] [-batchingDepth <positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce (YES | NO)] [-insertClientCert (YES | NO)]

Arguments

name

Name for the OCSP responder. Cannot begin with a hash (#) or space character and must contain only ASCII alphanumeric, underscore (_), hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the responder is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my responder" or 'my responder').

url

URL of the OCSP responder.

cache

Enable caching of responses. Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder.

Possible values: ENABLED, DISABLED

cacheTimeout

Timeout for caching the OCSP response. After the timeout, the NetScaler sends a fresh request to the OCSP responder for the certificate status. If a timeout is not specified, the timeout provided in the OCSP response applies.

Default value: 1

Minimum value: 1

Maximum value: 1440

batchingDepth

Number of client certificates to batch together into one OCSP request. Batching avoids overloading the OCSP responder. A value of 1 signifies that each request is queried independently. For a value greater than 1, specify a timeout (batching delay) to avoid inordinately delaying the processing of a single certificate.

Minimum value: 1

Maximum value: 8

batchingDelay

Maximum time, in milliseconds, to wait to accumulate OCSP requests to batch. Does not apply if the Batching Depth is 1.

Maximum value: 10000

resptimeout

Time, in milliseconds, to wait for an OCSP response. When this time elapses, an error message appears or the transaction is forwarded, depending on the settings on the virtual server. Includes Batching Delay time.

Maximum value: 120000

responderCert

producedAtTimeSkew

Time, in seconds, for which the NetScaler waits before considering the response as invalid. The response is considered invalid if the Produced At time stamp in the OCSP response exceeds or precedes the current NetScaler clock time by the amount of time specified.

Default value: 300

Maximum value: 86400

signingCert

Certificate-key pair that is used to sign OCSP requests. If this parameter is not set, the requests are not signed.

useNonce

Enable the OCSP nonce extension, which is designed to prevent replay attacks.

Possible values: YES, NO

insertClientCert

Include the complete client certificate in the OCSP request.

Possible values: YES, NO

Example

1) add ssl ocspResponder -url http://ocsp.example.com -producedAtTimeSkew 0 The above command will only allow responses that were generated in the same second to l

---

rm ssl ocspResponder

Removes the specified OCSP responder from the appliance.

Synopsys

rm ssl ocspResponder <name> ...

Arguments

name

Name of the OCSP responder to remove. The OCSP responder is removed only if it is not referenced by any other object.

Example

1) rm ssl ocspResponder o1 The above command removes the OCSP responder o1 from the system.

---

set ssl ocspResponder

Modifies the parameters of an OCSP responder.

Synopsys

set ssl ocspResponder <name> [-url <URL>] [-cache (ENABLED | DISABLED)] [-cacheTimeout <positive_integer>] [-batchingDepth <positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce (YES | NO)] [-insertClientCert (YES | NO)]

Arguments

name

Name of the OCSP responder to modify.

url

URL of the OCSP responder.

cache

Enable caching of responses. Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder.

Possible values: ENABLED, DISABLED

cacheTimeout

Timeout for caching the OCSP response. After the timeout, the NetScaler sends a fresh request to the OCSP responder for the certificate status. If a timeout is not specified, the timeout provided in the OCSP response applies.

Default value: 1

Minimum value: 1

Maximum value: 1440

batchingDepth

Number of client certificates to batch together into one OCSP request. Batching avoids overloading the OCSP responder. A value of 1 signifies that each request is queried independently. For a value greater than 1, specify a timeout (batching delay) to avoid inordinately delaying the processing of a single certificate.

Minimum value: 1

Maximum value: 8

batchingDelay

Maximum time, in milliseconds, to wait to accumulate OCSP requests to batch. Does not apply if the Batching Depth is 1.

Maximum value: 10000

resptimeout

Time, in milliseconds, to wait for an OCSP response. When this time elapses, an error message appears or the transaction is forwarded, depending on the settings on the virtual server. Includes Batching Delay time.

Maximum value: 120000

responderCert

producedAtTimeSkew

Time, in seconds, for which the NetScaler waits before considering the response as invalid. The response is considered invalid if the Produced At time stamp in the OCSP response exceeds or precedes the current NetScaler clock time by the amount of time specified.

Default value: 300

Maximum value: 86400

signingCert

Certificate-key pair that is used to sign OCSP requests. If this parameter is not set, the requests are not signed.

useNonce

Enable the OCSP nonce extension, which is designed to prevent replay attacks.

Possible values: YES, NO

insertClientCert

Include the complete client certificate in the OCSP request.

Possible values: YES, NO

Example

1) add ssl ocspResponder -url http://ocsp.example.com -producedAtTimeSkew 0 The above command will only allow responses that were generated in the same second to l

---

unset ssl ocspResponder

Removes the attributes of an OCSP responder. Attributes for which a default value is available revert to their default values. Refer to the set ssl ocspResponder command for descriptions of the arguments..Refer to the set ssl ocspResponder command for meanings of the arguments.

Synopsys

unset ssl ocspResponder <name> [-trustResponder] [-insertClientCert (YES | NO)] [-cache] [-cacheTimeout] [-batchingDepth] [-batchingDelay] [-resptimeout] [-responderCert] [-producedAtTimeSkew] [-signingCert] [-useNonce]

---

show ssl ocspResponder

Displays information about all the OCSP responders configured on the appliance, or displays detailed information about the specified OCSP responder.

Synopsys

show ssl ocspResponder [<name>]

Arguments

name

Name of the OCSP responder for which to show detailed information.

summary

fullValues

format

level

Outputs

url

URL of the OCSP responder.

useAIA

Only use the URL present in the certificate.

cache

Enable caching of responses. Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder.

cacheTimeout

Timeout for caching the OCSP response. After the timeout, the NetScaler sends a fresh request to the OCSP responder for the certificate status. If a timeout is not specified, the timeout provided in the OCSP response applies.

batchingDepth

Number of client certificates to batch together into one OCSP request. Batching avoids overloading the OCSP responder. A value of 1 signifies that each request is queried independently. For a value greater than 1, specify a timeout (batching delay) to avoid inordinately delaying the processing of a single certificate.

batchingDelay

Maximum time, in milliseconds, to wait to accumulate OCSP requests to batch. Does not apply if the Batching Depth is 1.

resptimeout

Maximum time, in mS, to wait for an OCSP response before giving up. Defaults to 2000 mS. If this is set to 0, NetScaler will wait for an indefinite amount of time.

producedAtTimeSkew

Time, in seconds, for which the NetScaler waits before considering the response as invalid. The response is considered invalid if the Produced At time stamp in the OCSP response exceeds or precedes the current NetScaler clock time by the amount of time specified.

responderCert

trustResponder

A certificate to use to validate OCSP responses. Alternatively, if -trustResponder is specified, no verification will be done on the reponse. If both are omitted, only the response times (producedAt, lastUpdate, nextUpdate) will be verified.

signingCert

Certificate-key pair that is used to sign OCSP requests. If this parameter is not set, the requests are not signed.

useNonce

Add a nonce to the OCSP request. Protects against replay attacks.

dns

Was DNS resolution successful for a domain-based OCSP responder

insertClientCert

Include the complete client certificate in the OCSP request.

IPAddress

The IPv6 address of the ocsp responder.

devno

count

stateflag

ssl parameter

Sep 22, 2015

The following operations can be performed on "ssl parameter":

set | unset | show

set ssl parameter

Synopsys

set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout <positive_integer>] [-sendCloseNotify (YES | NO)] [-encryptTriggerPktCount <positive_integer>] [-denySSLReneg <denySSLReneg>] [-insertionEncoding (Unicode | UTF-8)] [-ocspCacheSize <positive_integer>] [-pushFlag <positive_integer>] [-dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <positive_integer>] [-cryptodevDisableLimit <positive_integer>] [-undefActionControl <string>] [-undefActionData <string>]

Arguments

quantumSize

Amount of data to collect before the data is pushed to the crypto hardware for encryption. For large downloads, a larger quantum size better utilizes the crypto resources.

Possible values: 4096, 8192, 16384

Default value: 8192

crlMemorySizeMB

Maximum memory size to use for certificate revocation lists (CRLs). This parameter reserves memory for a CRL but sets a limit to the maximum memory that the CRLs loaded on the appliance can consume.

Default value: 256

Minimum value: 10

Maximum value: 1024

strictCAChecks

Enable strict CA certificate checks on the appliance.

Possible values: YES, NO

Default value: NO

sslTriggerTimeout

Time, in milliseconds, after which encryption is triggered for transactions that are not tracked on the NetScaler appliance because their length is not known. There can be a delay of up to 10ms from the specified timeout value before the packet is pushed into the queue.

Default value: 100

Minimum value: 1

Maximum value: 200

sendCloseNotify

Send an SSL Close-Notify message to the client at the end of a transaction.

Possible values: YES, NO

Default value: YES

encryptTriggerPktCount

Maximum number of queued packets after which encryption is triggered. Use this setting for SSL transactions that send small packets from server to NetScaler.

Default value: 45

Minimum value: 10

Maximum value: 50

denySSLReneg

Deny renegotiation in specified circumstances. Available settings function as follows:

* NO - Allow SSL renegotiation.

* FRONTEND_CLIENT - Deny secure and nonsecure SSL renegotiation initiated by the client.

* FRONTEND_CLIENTSERVER - Deny secure and nonsecure SSL renegotiation initiated by the client or the NetScaler during policy-based client authentication.

* ALL - Deny all secure and nonsecure SSL renegotiation.

* NONSECURE - Deny nonsecure SSL renegotiation. Allows only clients that support RFC 5746.

Possible values: NO, FRONTEND_CLIENT, FRONTEND_CLIENTSERVER, ALL, NONSECURE

Default value: NO

insertionEncoding

Encoding method used to insert the subject or issuer's name in HTTP requests to servers.

Possible values: Unicode, UTF-8

Default value: UNICODE_INSERTION

ocspCacheSize

Size, per packet engine, in megabytes, of the OCSP cache. A maximum of 10% of the packet engine memory can be assigned. Because the maximum allowed packet engine memory is 4GB, the maximum value that can be assigned to

the OCSP cache is approximately 410 MB.

Default value: 10

Maximum value: 512

pushFlag

Insert PUSH flag into decrypted, encrypted, or all records. If the PUSH flag is set to a value other than 0, the buffered records are forwarded on the basis of the value of the PUSH flag. Available settings function as follows:

0 - Auto (PUSH flag is not set.)

1 - Insert PUSH flag into every decrypted record.

2 -Insert PUSH flag into every encrypted record.

3 - Insert PUSH flag into every decrypted and encrypted record.

Maximum value: 3

dropReqWithNoHostHeader

Host header check for SNI enabled sessions. If this check is enabled and the HTTP request does not contain the host header for SNI enabled sessions, the request is dropped.

Possible values: YES, NO

Default value: NO

pushEncTriggerTimeout

PUSH encryption trigger timeout value. The timeout value is applied only if you set the Push Encryption Trigger parameter to Timer in the SSL virtual server settings.

Default value: 1

Minimum value: 1

Maximum value: 200

cryptodevDisableLimit

Disabled Crypto Device Limit reboots the system once reached. A value of zero(0) implies no reboot.

undefActionControl

Name of the undefined built-in control action: CLIENTAUTH, NOCLIENTAUTH, NOOP, RESET, or DROP.

Default value: "CLIENTAUTH"

undefActionData

Name of the undefined built-in data action: NOOP, RESET or DROP.

Default value: "NOOP"

unset ssl parameter

Use this command to remove ssl parameter settings.Refer to the set ssl parameter command for meanings of the arguments.

Synopsys

unset ssl parameter [-quantumSize] [-crlMemorySizeMB] [-strictCAChecks] [-sslTriggerTimeout] [-sendCloseNotify] [-encryptTriggerPktCount] [-denySSLReneg] [-insertionEncoding] [-ocspCacheSize] [-pushFlag] [-dropReqWithNoHostHeader] [-pushEncTriggerTimeout] [-cryptodevDisableLimit] [-undefActionControl] [-undefActionData]

show ssl parameter

Displays information about advanced SSL parameters.

Synopsys

show ssl parameter

Arguments

format

level

Outputs

quantumSize

Amount of data to collect before the data is pushed to the crypto hardware for encryption. For large downloads, a larger quantum size better utilizes the crypto resources.

crlMemorySizeMB

Maximum memory size to use for certificate revocation lists (CRLs). This parameter reserves memory for a CRL but sets a limit to the maximum memory that the CRLs loaded on the appliance can consume.

strictCAChecks

Memory size to use for CRLs

sslTriggerTimeout

Encryption trigger timer. Set the encryption trigger timeout for transactions, which are not trackable by Netscaler. NetScaler will use this setting to accumulate data received from the server for the configured time period before pushing it to the crypto hardware for encryption.

sendCloseNotify

Send an SSL Close-Notify message to the client at the end of a transaction.

encryptTriggerPktCount

Maximum number of queued packets after which encryption is triggered. Use this setting for SSL transactions that send small packets from server to NetScaler.

denySSLReneg

SSL Renegotiation setting

insertionEncoding

Encoding method used to insert the subject or issuer's name in HTTP requests to servers.

ocspCacheSize

Size, per packet engine, in megabytes of the OCSP cache

pushFlag

Insert PUSH flag into decrypted, encrypted, or all records. If the PUSH flag is set to a value other than 0, the buffered records are forwarded on the basis of the value of the PUSH flag. Available settings function as follows:

0 - Auto (PUSH flag is not set.)

1 - Insert PUSH flag into every decrypted record.

2 -Insert PUSH flag into every encrypted record.

3 - Insert PUSH flag into every decrypted and encrypted record.

dropReqWithNoHostHeader

Host header check for SNI enabled sessions. If this check is enabled and the HTTP request does not contain the host header for SNI enabled sessions, the request is dropped.

pushEncTriggerTimeout

PUSH encryption trigger timeout value. The timeout value is applied only if you set the Push Encryption Trigger parameter to Timer in the SSL virtual server settings.

cryptodevDisableLimit

Disabled Crypto Device Limit reboots the system once reached. A value of zero(0) implies no reboot

undefActionControl

Global undef action for SSL control policies

undefActionData

Global undef action for SSL data policies

ssl pkcs12

Sep 22, 2015

The following operations can be performed on "ssl pkcs12":

convert ssl pkcs12

Converts the end-user certificate from PEM encoding format to PKCS#12 format. This certificate can then be distributed and installed in browsers as client certificates.

Synopsys

convert ssl pkcs12 <outfile> [-import [-pkcs12File <input_filename>] [-des | -des3]] [-export [-certFile <input_filename>] [-keyFile <input_filename>]] {-password } {-PEMPassPhrase }

Arguments

outfile

Name for and, optionally, path to, the output file that contains the certificate and the private key after converting from PKCS#12 to PEM format. /nsconfig/ssl/ is the default path.

If importing, the certificate-key pair is stored in PEM format. If exporting, the certificate-key pair is stored in PKCS#12 format.

Maximum value: 63

import

Convert the certificate and private-key from PKCS#12 format to PEM format.

export

Convert the certificate and private key from PEM format to PKCS#12 format. On the command line, you are prompted to enter the pass phrase.

password

PEMPassPhrase

Example

1) convert ssl pkcs12 /nsconfig/ssl/client_certkey.p12 -export -cert /nsconfig/ssl/client_certcert.pem -key /nsconfig/ssl/client_key.pem The above example CLI cor

ssl pkcs8

Sep 22, 2015

The following operations can be performed on "ssl pkcs8":

convert ssl pkcs8

Convert a PEM or DER format key file to PKCS#8 format before importing it into the FIPS appliance.

Synopsys

convert ssl pkcs8 <pkcs8File> <keyFile> [-keyform (DER | PEM)] {-password }

Arguments

pkcs8File

Name for and, optionally, path to, the output file where the PKCS#8 format key file is stored. /nsconfig/ssl/ is the default path.

Maximum value: 63

keyFile

Name of and, optionally, path to the input key file to be converted from PEM or DER format to PKCS#8 format. /nsconfig/ssl/ is the default path.

Maximum value: 63

keyform

Format in which the key file is stored on the appliance.

Possible values: DER, PEM

Default value: FORMAT_PEM

password

Password to assign to the file if the key is encrypted. Applies only for PEM format files.

Maximum value: 31

Example

```
convert ssl pkcs8 /nsconfig/ssl/key.pk8 /nsconfig/ssl/key.pem
```

ssl policy

Sep 22, 2015

The following operations can be performed on "ssl policy":

add | rm | set | unset | show

add ssl policy

Adds an SSL policy. An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). You have to configure the actions before creating the policies, so that you can specify an action when you create a policy.

Synopsys

add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]

Arguments

name

Name for the new SSL policy. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the policy is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy').

rule

Expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

(Classic expressions are not supported in the cluster build.)

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

reqAction

The name of the action to be performed on the request. Refer to 'add ssl action' command to add a new action. Builtin actions like NOOP, RESET, DROP, CLIENTAUTH and NOCLIENTAUTH are also allowed.

action

Name of the built-in or user-defined action to perform on the request. Available built-in actions are NOOP, RESET, DROP, CLIENTAUTH, and NOCLIENTAUTH.

undefAction

Name of the action to be performed when the result of rule evaluation is undefined. Possible values for control policies: CLIENTAUTH, NOCLIENTAUTH, NOOP, RESET, DROP. Possible values for data policies: NOOP, RESET or DROP.

comment

Any comments associated with this policy.

Example

```
add ssl action certInsert_act -clientCert ENABLED -certHeader CERT  add ssl policy certInsert_pol -rule 'HTTP.REQ.URL.STARTSWITH("/secure/")' -reqAction certInsert_
```

---

rm ssl policy

Removes an SSL policy.

Synopsys

rm ssl policy <name>

Arguments

name

Name of the SSL policy to be removed.

Example

```
rm ssl policy certInsert_pol
```

set ssl policy

Modifies the parameters of an SSL default syntax policy.

Synopsys

set ssl policy <name> [-rule <expression>] [-action <string>] [-undefAction <string>] [-comment <string>]

Arguments

name

Name of the SSL policy to modify.

rule

Expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

(Classic expressions are not supported in the cluster build.)

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Name of the built-in or user-defined action to perform on the request. Available built-in actions are NOOP, RESET, DROP, CLIENTAUTH, and NOCLIENTAUTH.

undefAction

Name of the action to be performed when the result of rule evaluation is undefined. Possible values for control policies: CLIENTAUTH, NOCLIENTAUTH, NOOP, RESET, DROP. Possible values for data policies: NOOP, RESET or DROP.

comment

Any comments associated with this policy.

Example

```
set ssl policy pol1 -rule "HTTP.REQ.HEADER(\\\"header\\\").CONTAINS(\\\"qh2\\\")"
```

unset ssl policy

Removes the attributes of an SSL default syntax policy. Attributes for which a default value is available revert to their default values. Refer to the set ssl policy command for a description of the parameters..Refer to the set ssl policy command for meanings of the arguments.

Synopsys

unset ssl policy <name> [-undefAction] [-comment]

Example

```
unset ssl policy pol1 -undefAction
```

show ssl policy

Displays information about all the SSL policies configured on the appliance, or displays detailed information about the specified SSL policy.

Synopsys

show ssl policy [<name>]

Arguments

name

Name of the SSL policy for which to display detailed information.

summary

fullValues

format

level

Outputs

stateflag

rule

The expression that sets the condition for application of the SSL policy.

action

The name of the action to be performed on the request.

undefAction

Undef Action associated with the policy.

hits

Number of hits for this policy.

piHits

Number of hits.

undefHits

Number of Undef hits.

activePolicy

boundTo

The entity name to which policy is bound

priority

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

labelType

Type of policy label invocation.

labelName

Name of the label to invoke if the current policy rule evaluates to TRUE.

ssl policylabel

Sep 22, 2015

The following operations can be performed on "ssl policylabel":

add | rm | bind | unbind | show

add ssl policylabel

Creates an SSL policy label. An SSL policy label can be a control label or a data label.

Synopsys

add ssl policylabel <labelName> -type (CONTROL | DATA)

Arguments

labelName

Name for the SSL policy label. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the policy label is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my label" or 'my label').

type

Type of policies that the policy label can contain.

Possible values: CONTROL, DATA

Example

```
add ssl policylabel ssl_pol_label -type REQ
```

---

rm ssl policylabel

Removes an SSL policy label.

Synopsys

rm ssl policylabel <labelName>

Arguments

labelName

Name of the SSL policy label to remove.

Example

```
rm ssl policylabel ssl_pol_label
```

---

bind ssl policylabel

Binds an SSL policy to an SSL policy label and specifies the order in which the policies in the label are to be evaluated.

Synopsys

```
bind ssl policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>) ]
```

Arguments

labelName

Name of the SSL policy label to which to bind policies.

policyName

Name of the SSL policy to bind to the policy label.

Example

```
bind ssl policylabel ssl_pol_label -policyName ssl_pol -priority 1
```

---

unbind ssl policylabel

Unbinds an SSL policy from an SSL policy label.

Synopsys

```
unbind ssl policylabel <labelName> <policyName> [-priority <positive_integer>]
```

Arguments

labelName

Name of the SSL policy label from which to unbind policies.

policyName

Name of the SSL policy to unbind.

Example

```
unbind ssl policylabel ssl_pol_label ssl_pol
```

---

show ssl policylabel

Displays information about all the SSL policy labels, or displays detailed information about the specified policy label.

Synopsys

show ssl policylabel [<labelName>]

Arguments

labelName

Name of the SSL policy label for which to show detailed information.

summary

ssl rsakey

Sep 22, 2015

The following operations can be performed on "ssl rsakey":

create ssl rsakey

Generates an RSA key.

Synopsys

create ssl rsakey <keyFile> <bits> [-exponent (3 | F4)] [-keyform (DER | PEM)] [-des | -des3] {-password }

Arguments

keyFile

Name for and, optionally, path to the RSA key file. /nsconfig/ssl/ is the default path.

Maximum value: 63

bits

Size, in bits, of the RSA key.

Minimum value: 512

Maximum value: 4096

exponent

Public exponent for the RSA key. The exponent is part of the cipher algorithm and is required for creating the RSA key.

Possible values: 3, F4

Default value: FIPSEXP_F4

keyform

Format in which the RSA key file is stored on the appliance.

Possible values: DER, PEM

Default value: FORMAT_PEM

des

Encrypt the generated RSA key by using the DES algorithm. On the command line, you are prompted to enter the pass phrase (password) that is used to encrypt the key.

des3

Encrypt the generated RSA key by using the Triple-DES algorithm. On the command line, you are prompted to enter

the pass phrase (password) that is used to encrypt the key.

password

Pass phrase to use for encryption if DES or DES3 option is selected.

Maximum value: 31

Example

```
create ssl rsakey /nsconfig/ssl/rsa1024.pem 1024 -exp F4
```

ssl service

Sep 22, 2015

The following operations can be performed on "ssl service":

set | unset | bind | unbind | show

set ssl service

Sets the advanced SSL configuration for an SSL service.

Synopsys

set ssl service <serviceName>@ [-dh (ENABLED | DISABLED) -dhFile <string>] [-dhCount <positive_integer>] [-eRSA (ENABLED | DISABLED) [-eRSACount <positive_integer>]] [-sessReuse (ENABLED | DISABLED) [-sessTimeout <positive_integer>]] [-cipherRedirect (ENABLED | DISABLED) [-cipherURL <URL>]] [-sslv2Redirect (ENABLED | DISABLED) [-sslv2URL <URL>]] [-clientAuth (ENABLED | DISABLED) [-clientCert (Mandatory | Optional)]] [-sslRedirect (ENABLED | DISABLED)] [-redirectPortRewrite (ENABLED | DISABLED)] [-nonFipsCiphers (ENABLED | DISABLED)] [-ssl2 (ENABLED | DISABLED)] [-ssl3 (ENABLED | DISABLED)] [-tls1 (ENABLED | DISABLED)] [-tls11 (ENABLED | DISABLED)] [-tls12 (ENABLED | DISABLED)] [-SNIEnable (ENABLED | DISABLED)] [-serverAuth (ENABLED | DISABLED) [-commonName <string>]] [-pushEncTrigger <pushEncTrigger>] [-sendCloseNotify (YES | NO)] [-dtlsProfileName <string>]

Arguments

serviceName

Name of the SSL service.

dh

State of Diffie-Hellman (DH) key exchange. This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

dhCount

Number of interactions, between the client and the NetScaler appliance, after which the DH private-public pair is regenerated. A value of zero (0) specifies infinite use (no refresh). This parameter is not applicable when configuring a backend service.

Maximum value: 65534

eRSA

State of Ephemeral RSA (eRSA) key exchange. Ephemeral RSA allows clients that support only export ciphers to communicate with the secure server even if the server certificate does not support export clients. The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted. It is reused at a later date when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the appliance restarts.

This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sessReuse

State of session reuse. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the ENABLED setting, session key exchange is avoided for session resumption requests received from the client.

Possible values: ENABLED, DISABLED

Default value: ENABLED

cipherRedirect

State of Cipher Redirect. If this parameter is set to ENABLED, you can configure an SSL virtual server or service to display meaningful error messages if the SSL handshake fails because of a cipher mismatch between the virtual server or service and the client.

This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sslv2Redirect

State of SSLv2 Redirect. If this parameter is set to ENABLED, you can configure an SSL virtual server or service to display meaningful error messages if the SSL handshake fails because of a protocol version mismatch between the virtual server or service and the client.

This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

clientAuth

State of client authentication. In service-based SSL offload, the service terminates the SSL handshake if the SSL client does not provide a valid certificate.

This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sslRedirect

State of HTTPS redirects for the SSL service.

For an SSL session, if the client browser receives a redirect message, the browser tries to connect to the new location. However, the secure SSL session breaks if the object has moved from a secure site (https://) to an unsecure site (http://). Typically, a warning message appears on the screen, prompting the user to continue or disconnect.

If SSL Redirect is ENABLED, the redirect message is automatically converted from http:// to https:// and the SSL session does not break.

This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

redirectPortRewrite

State of the port rewrite while performing HTTPS redirect. If this parameter is set to ENABLED, and the URL from the server does not contain the standard port, the port is rewritten to the standard.

Possible values: ENABLED, DISABLED

Default value: DISABLED

nonFipsCiphers

State of usage of ciphers that are not FIPS approved. Valid only for an SSL service bound with a FIPS key and certificate.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssl2

State of SSLv2 protocol support for the SSL service.

This parameter is not applicable when configuring a backend service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssl3

State of SSLv3 protocol support for the SSL service.

Possible values: ENABLED, DISABLED

Default value: ENABLED

tls1

State of TLSv1.0 protocol support for the SSL service.

Possible values: ENABLED, DISABLED

Default value: ENABLED

tls11

State of TLSv1.1 protocol support for the SSL service.Enabled for Front-end service on MPX-CVM platform only.

Possible values: ENABLED, DISABLED

Default value: ENABLED

tls12

State of TLSv1.2 protocol support for the SSL service.Enabled for Front-end service on MPX-CVM platform only.

Possible values: ENABLED, DISABLED

Default value: ENABLED

SNIEnable

State of the Server Name Indication (SNI) feature on the virtual server and service-based offload. SNI helps to enable SSL encryption on multiple domains on a single virtual server or service if the domains are controlled by the same organization and share the same second-level domain name. For example, *.sports.net can be used to secure domains such as login.sports.net and help.sports.net.

Possible values: ENABLED, DISABLED

Default value: DISABLED

serverAuth

State of server authentication support for the SSL service.

Possible values: ENABLED, DISABLED

Default value: DISABLED

pushEncTrigger

Trigger encryption on the basis of the PUSH flag value. Available settings function as follows:

* ALWAYS - Any PUSH packet triggers encryption.

* IGNORE - Ignore PUSH packet for triggering encryption.

* MERGE - For a consecutive sequence of PUSH packets, the last PUSH packet triggers encryption.

* TIMER - PUSH packet triggering encryption is delayed by the time defined in the set ssl parameter command or in the Change Advanced SSL Settings dialog box.

Possible values: Always, Merge, Ignore, Timer

sendCloseNotify

Enable sending SSL Close-Notify at the end of a transaction

Possible values: YES, NO

Default value: YES

dtlsProfileName

Name of the DTLS profile whose settings are to be applied to the virtual server.

Example

1) set ssl service sslsvc -dh ENABLED -dhFile /nsconfig/ssl/dh1024.pem -dhCount 500 The above example sets the DH parameters for the SSL service 'sslsvc'. 2. set ssl se

---

unset ssl service

Use this command to remove ssl service settings.Refer to the set ssl service command for meanings of the arguments.

Synopsys

unset ssl service <serviceName>@ [-dh] [-dhFile] [-dhCount] [-eRSA] [-eRSACount] [-sessReuse] [-sessTimeout] [-cipherRedirect] [-cipherURL] [-sslv2Redirect] [-sslv2URL] [-clientAuth] [-clientCert] [-sslRedirect] [-redirectPortRewrite] [-nonFipsCiphers] [-ssl2] [-ssl3] [-tls1] [-tls11] [-tls12] [-SNIEnable] [-serverAuth] [-commonName] [-sendCloseNotify] [-dtlsProfileName]

---

bind ssl service

Binds an SSL certificate-key pair or an SSL policy to a transparent SSL service.

Synopsys

bind ssl service <serviceName>@ ((-policyName <string> [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-invoke (<labelType> <labelName>)]) | ((-certkeyName <string> [(-CA [-crlCheck (Mandatory | Optional) | -ocspCheck (Mandatory | Optional)] [-skipCAName]) | -SNICert]) | -cipherName <string>))

Arguments

serviceName

Name of the SSL service for which to set advanced configuration.

policyName

Name of the SSL policy to bind to the service.

certkeyName

Name of the certificate-key pair.

cipherName

Name of the individual cipher, user-defined cipher group, or predefined (built-in) cipher alias.

Example

bind ssl service ssl_svc -policyName certInsert_pol -priority 10

---

unbind ssl service

Unbinds an SSL policy, cipher, and certificate-key pair from an SSL service.

Synopsys

unbind ssl service <serviceName>@ ((-policyName <string> [-priority <positive_integer>]) | ((-certkeyName <string> [(-CA [-crlCheck (Mandatory | Optional)]) | -SNICert]) | -cipherName <string>))

Arguments

serviceName

Name of the SSL service.

policyName

Name of the SSL policy to unbind from the SSL service.

certkeyName

The certificate key pair binding.

cipherName

Name of the individual cipher, user-defined cipher group, or predefined (built-in) cipher alias.

Example

```
unbind ssl service ssl_svc -policyName certInsert_pol
```

---

show ssl service

Displays information about SSL-specific configuration information for all SSL services, or displays detailed information about the specified SSL service.

Synopsys

show ssl service [<serviceName>] [-cipherDetails]

Arguments

serviceName

Name of the SSL service for which to show detailed information.

cipherDetails

Display details of the individual ciphers bound to the SSL service.

summary

fullValues

format

level

Outputs

crlCheck

The state of the CRL check parameter. (Mandatory/Optional)

dh

The state of Diffie-Hellman (DH) key exchange support.

dhFile

The file name and path for the DH parameter.

dhCount

The refresh count for regeneration of DH public-key and private-key from the DH parameter.

eRSA

The state of Ephemeral RSA key exchange support. Ephemeral RSA is used for export ciphers

eRSACount

The refresh count for re-generation of RSA public-key and pri-vate-key pair.

sessReuse

The state of session reuse support.

sessTimeout

The session timeout value in seconds.

cipherRedirect

The state of Cipher Redirect feature.Cipher Redirect feature can be used to provide more readable information to SSL clients about mismatch in ciphers between

the client and the SSL vserver.

cipherURL

The redirect URL to be used with the Cipher Redirect feature.

sslv2Redirect

The state of SSLv2 Redirect feature.SSLv2 Redirect feature can be used to provide more readable information to SSL client about non-support of SSLv2 protocol on the SSL vserver.

sslv2URL

The redirect URL to be used with the SSLv2 Redirect feature.

clientAuth

The state of Client-Authentication support.

clientCert

The rule for client certificate requirement in client authentication.

sslRedirect

The state of HTTPS redirect feature.

redirectPortRewrite

The state of port rewrite feature.

nonFipsCiphers

The state of usage of non FIPS approved ciphers.

ssl2

The state of SSLv2 protocol support.

ssl3

The state of SSLv3 protocol support.

tls1

The state of TLSv1.0 protocol support.

tls11

The state of TLSv1.1 protocol support.

tls12

The state of TLSv1.2 protocol support.

SNIEnable

The state of SNI extension. Server Name Indication (SNI) helps to enable SSL encryption on multiple subdomains if the domains are controlled by the same organization and share the same second-level domain name.

serverAuth

The state of Server-Authentication support.

commonName

Name to be checked against the CommonName (CN) field in the server certificate bound to the SSL server

cipherAliasName/cipherName/cipherGroupName

The cipher group/alias/individual cipher configuration.

cipherName

The cipher group/alias/individual cipher configuration

description

The cipher suite description.

certkeyName

The certificate key pair binding.

policyName

The SSL policy binding.

invoke

Invoke flag. This attribute is relevant only for ADVANCED policies

labelType

Type of policy label invocation.

labelName

Name of the label to invoke if the current policy rule evaluates to TRUE.

clearTextPort

The clearTextPort settings.

service

priority

The priority of the policies bound to this SSL service

polinherit

Whether the bound policy is a inherited policy or not

ocspCheck

Rule to use for the OCSP responder associated with the CA certificate during client authentication. If MANDATORY is specified, deny all SSL clients if the OCSP check fails because of connectivity issues with the remote OCSP server, or any other reason that prevents the OCSP check. With the OPTIONAL setting, allow SSL clients even if the OCSP check fails except when the client certificate is revoked.

pushEncTrigger

PUSH packet triggering encryption: Always, Ignore, Merge

CA

CA certificate.

SNICert

The name of the CertKey. Use this option to bind Certkey(s) which will be used in SNI processing.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

stateflag

skipCAName

The flag is used to indicate whether this particular CA certificate's CA_Name needs to be sent to the SSL client while requesting for client certificate in a SSL handshake

sendCloseNotify

Enable sending SSL Close-Notify at the end of a transaction

dtlsProfileName

Name of the DTLS profile whose settings are to be applied to the virtual server.

dtlsFlag

The flag is used to indicate whether DTLS is set or not

devno

count

Example

An example of output of show ssl service command is as shown below show ssl service svc1 Advanced SSL configuration f

ssl serviceGroup

Sep 22, 2015

The following operations can be performed on "ssl serviceGroup":

set | unset | bind | unbind | show

set ssl serviceGroup

Sets the advanced SSL configuration for an SSL service group.

Synopsys

set ssl serviceGroup <serviceGroupName>@ [-sessReuse (ENABLED | DISABLED) [-sessTimeout <positive_integer>]] [-nonFipsCiphers (ENABLED | DISABLED)] [-ssl3 (ENABLED | DISABLED)] [-tls1 (ENABLED | DISABLED)] [-serverAuth (ENABLED | DISABLED) [-commonName <string>]] [-sendCloseNotify (YES | NO)]

Arguments

serviceGroupName

Name of the SSL service group for which to set advanced configuration.

sessReuse

State of session reuse. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the ENABLED setting, session key exchange is avoided for session resumption requests received from the client.

Possible values: ENABLED, DISABLED

Default value: ENABLED

nonFipsCiphers

State of usage of ciphers that are not FIPS approved. Valid only for an SSL service bound with a FIPS key and certificate.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssl3

State of SSLv3 protocol support for the SSL service group.

Possible values: ENABLED, DISABLED

Default value: ENABLED

tls1

State of TLSv1.0 protocol support for the SSL service group.

Possible values: ENABLED, DISABLED

Default value: ENABLED

serverAuth

State of server authentication support for the SSL service group.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sendCloseNotify

Enable sending SSL Close-Notify at the end of a transaction

Possible values: YES, NO

Default value: YES

Example

1) set ssl servicegroup svcg1 -sessReuse DISABLED The above example disables session reuse for the service group 'svcg1'.

---

unset ssl serviceGroup

Use this command to remove ssl serviceGroup settings.Refer to the set ssl serviceGroup command for meanings of the arguments.

Synopsys

unset ssl serviceGroup <serviceGroupName>@ [-sessReuse] [-sessTimeout] [-nonFipsCiphers] [-ssl3] [-tls1] [-serverAuth] [-commonName] [-sendCloseNotify]

---

bind ssl serviceGroup

Bind a SSL certkey or a SSL policy to a SSL service.

Synopsys

bind ssl serviceGroup <serviceGroupName>@ ((-certkeyName <string> [(-CA [-crlCheck (Mandatory | Optional) | -ocspCheck (Mandatory | Optional)]) | -SNICert]) | -cipherName <string>)

Arguments

serviceGroupName

The name of the SSL service to which the SSL policy needs to be bound.

certkeyName

The name of the CertKey

cipherName

A cipher-suite can consist of an individual cipher name, the system predefined cipher-alias name, or user defined cipher-group name.

Example

```
bind ssl service ssl_svc -policyName certInsert_pol -priority 10
```

---

unbind ssl serviceGroup

Unbind a SSL policy from a SSL service.

Synopsys

unbind ssl serviceGroup <serviceGroupName>@ ((-certkeyName <string> [(-CA [-crlCheck (Mandatory | Optional)]) | -SNICert]) | -cipherName <string>)

Arguments

serviceGroupName

The name of the SSL service from which the SSL policy needs to be unbound.

certkeyName

The name of the certificate bound to the SSL service group.

cipherName

A cipher-suite can consist of an individual cipher name, the system predefined cipher-alias name, or user defined cipher-group name.

Example

```
unbind ssl service ssl_svc -policyName certInsert_pol
```

---

show ssl serviceGroup

Displays information about SSL-specific configuration for all SSL service groups, or displays detailed information about the specified SSL service group.

Synopsys

show ssl serviceGroup [<serviceGroupName>] [-cipherDetails]

Arguments

serviceGroupName

Name of the SSL service group for which to show detailed information.

cipherDetails

Display details of the individual ciphers bound to the SSL service group.

summary

fullValues

format

level

Outputs

dh

The state of DH key exchange support for the SSL service group.

dhFile

The file name and path for the DH parameter.

dhCount

The refresh count for the re-generation of DH public-key and private-key from the DH parameter.

eRSA

The state of Ephemeral RSA key exchange support for the SSL service group.Ephemeral RSA is used for export ciphers.

eRSACount

The refresh count for the re-generation of RSA public-key and private-key pair.

sessReuse

The state of session re-use support for the SSL service group.

sessTimeout

The Session timeout value in seconds.

cipherRedirect

The state of Cipher Redirect feature. Cipher Redirect feature can be used to provide more readable information to SSL clients about mismatch in ciphers between the client and the SSL vserver.

cipherURL

The redirect URL to be used with the Cipher Redirect feature.

sslv2Redirect

The state of SSLv2 Redirect feature.SSLv2 Redirect feature can be used to provide more readable information to SSL client about non-support of SSLv2 protocol on the SSL vserver.

sslv2URL

The redirect URL to be used with SSLv2 Redirect feature.

clientAuth

The state of Client-Authentication support for the SSL service group.

clientCert

The rule for client certificate requirement in client authentication.

sslRedirect

The state of HTTPS redirects for the SSL service group.

This is required for the proper functioning of the redirect messages from the server. The redirect message from the server provides the new location for the moved object. This is contained in the HTTP header field: Location, e.g. Location: http://www.moved.org/here.html

For the SSL session, if the client browser receives this message, the browser will try to connect to the new location. This will break the secure SSL session, as the object has moved from a secure site (https://) to an un-secure one (http://). Generally browsers flash a warning message on the screen and prompt the user, either to continue or disconnect.

The above feature, when enabled will automatically convert all such http:// redirect message to https://. This will not break the client SSL session.

Note: The set ssl service command can be used for configuring a front-end SSL service for service based SSL Off-Loading, or a backend SSL service for backend-encryption setup.

redirectPortRewrite

The state of port-rewrite feature.

nonFipsCiphers

The state of usage of non FIPS approved ciphers.

ssl2

The state of SSLv2 protocol support for the SSL service group.

ssl3

State of SSLv3 protocol support for the SSL service group.

tls1

State of TLSv1.0 protocol support for the SSL service group.

serverAuth

The state of the server authentication configuration for the SSL service group. For SSL deployments where data is encrypted end-to-end using SSL, you can authenticate the server.

commonName

Name to be checked against the CommonName (CN) field in the server certificate bound to the SSL server

cipherAliasName/cipherName/cipherGroupName

The name of the cipher group/alias/name configured for the SSL service group.

cipherName

The name of the cipher group/alias/name configured for the SSL service group.

ocspCheck

The state of the OCSP check parameter. (Mandatory/Optional)

crlCheck

The state of the CRL check parameter. (Mandatory/Optional)

description

The description of the cipher.

certkeyName

The name of the certificate bound to the SSL service group.

clearTextPort

The port on the back-end web-servers where the clear-text data is sent by system. Use this setting for the wildcard IP based SSL Acceleration configuration (*:443).

serviceName

The service name.

CA

CA certificate.

SNICert

The name of the CertKey. Use this option to bind Certkey(s) which will be used in SNI processing.

stateflag

sendCloseNotify

Enable sending SSL Close-Notify at the end of a transaction

devno

system eventhistory

Sep 22, 2015

The following operations can be performed on "system eventhistory":

Display events in historical data.

show system eventhistory [-startTime <string> | (-last <integer> [<unit>])] [-endTime <string>] -dataSource <string>

startTime

Specify start time in mmddyyyyhhmm to start collecting values from that timestamp.

endTime

Specify end time in mmddyyyyhhmm upto which values have to be collected.

last

Last is literal way of saying a certain time period from the current moment. Example: -last 1 hour, -last 1 day, et cetera.

Default value: 1

dataSource

Specifies the source which contains all the stored counter values.

response

system global

Sep 22, 2015

The following operations can be performed on "system global":

bind | unbind | show

Binds policies globally.

bind system global [<policyName> [-priority <positive_integer>]]

policyName

Name of the policy to bind globally.

Unbinds a globally bound policy.

unbind system global <policyName>

policyName

Name of the globally bound policy to unbind.

Displays information about all global policy bindings.

show system global

system group

Sep 22, 2015

The following operations can be performed on "system group":

add | rm | bind | unbind | show | set | unset

Creates a system-user group, to which you can bind individual users by using the bind system group command.

add system group <groupName> [-promptString <string>] [-timeout <secs>]

groupName

Name for the group. Must begin with a letter, number, or the underscore (_) character, and must contain only alphanumeric, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), and underscore characters. Cannot be changed after the group is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my group" or 'my group').

promptString

String to display at the command-line prompt. Can consist of letters, numbers, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), underscore (_), and the following variables:

* %u - Will be replaced by the user name.

* %h - Will be replaced by the hostname of the NetScaler appliance.

* %t - Will be replaced by the current time in 12-hour format.

* %T - Will be replaced by the current time in 24-hour format.

* %d - Will be replaced by the current date.

* %s - Will be replaced by the state of the NetScaler appliance.

Note: The 63-character limit for the length of the string does not apply to the characters that replace the variables.

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

Maximum value: 100000000

Removes a system group from the appliance.

rm system group <groupName>

groupName

Name of the system group to remove.

Binds a system user to a system group.

bind system group <groupName> [-userName <string>] [-policyName <string> <priority>]

groupName

Name of the system group.

userName

Name of a system user to bind to the group.

policyName

Name of the command policy to be bind to the group.

Unbinds a system user from a group.

unbind system group <groupName> [-userName <string>] [-policyName <string>]

groupName

Name of the system group from which to unbind the user.

userName

Name of the system user to unbind from the group.

policyName

Command policy to unbind from the group.

Displays information about all system groups configured on the appliance, or about the specified group.

show system group [<groupName>]

groupName

Name of the system group about which to display information.

summary

fullValues

format

level

userName

The system user.

policyName

The name of command policy.

priority

The priority of the command policy.

promptString

String to display at the command-line prompt. Can consist of letters, numbers, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), underscore (_), and the following variables:

* %u - Will be replaced by the user name.

* %h - Will be replaced by the hostname of the NetScaler appliance.

* %t - Will be replaced by the current time in 12-hour format.

* %T - Will be replaced by the current time in 24-hour format.

* %d - Will be replaced by the current date.

* %s - Will be replaced by the state of the NetScaler appliance.

Note: The 63-character limit for the length of the string does not apply to the characters that replace the variables.

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

devno

count

stateflag

Modifies the specified parameters of a system group.

set system group <groupName> [-promptString <string>] [-timeout <secs>]

groupName

Name of system group to be modified.

promptString

String to display at the command-line prompt. Can consist of letters, numbers, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), underscore (_), and the following variables:

* %u - Will be replaced by the user name.

* %h - Will be replaced by the hostname of the NetScaler appliance.

* %t - Will be replaced by the current time in 12-hour format.

* %T - Will be replaced by the current time in 24-hour format.

* %d - Will be replaced by the current date.

* %s - Will be replaced by the state of the NetScaler appliance.

Note: The 63-character limit for the length of the string does not apply to the characters that replace the variables.

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

Maximum value: 100000000

Use this command to remove system group settings.Refer to the set system group command for meanings of the arguments.

unset system group <groupName> [-promptString] [-timeout]

---

system memory

Sep 22, 2015

The following operations can be performed on "system memory":

Displays system-memory statistics.

stat system memory [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

clearstats

Clear the statsistics / counters

Possible values: basic, full

Shared Memory InUse (%) (shMemAllocpcnt)

Shared memory insue percent.

Shared Memory InUse (MB) (shMemAllocMB)

Shared memory insue, in megabytes.

Total Shared Memory (MB) (shMemtotMB)

Total shared memory allowed to allocate, in megabytes.

Free Memory (MB) (MemTotFree)

Total Free PE Memory in the System.

InUse Memory (%) (MemUsage)

Percentage of memory utilization on NetScaler.

InUse Memory (MB) (MemTotUseMB)

Total NetScaler Memory in use, in megabytes.

Memory Allocated (%) (MemTotAlloc(%))

Currently allocated memory in percent.

Memory Allocated (MB) (MemTotAlloc)

Currently allocated memory, in megabytes.

Memory Currently Available (MB) (MemTotMB)

Total memory available (grabbed) for use by packet engine (PE), in megabytes.

Maximum Memory Available (MB) (MemTotAvail)

Total system memory available for PE to grab from the system.

stat system memory

system parameter

Sep 22, 2015

The following operations can be performed on "system parameter":

set | unset | show

Modifies the specified system parameters.

set system parameter [-rbaOnResponse (ENABLED | DISABLED)] [-promptString <string>] [-natPcbForceFlushLimit <positive_integer>] [-natPcbRstOnTimeout (ENABLED | DISABLED)] [-timeout <secs>]

rbaOnResponse

Enable or disable Role-Based Authentication (RBA) on responses.

Possible values: ENABLED, DISABLED

Default value: ENABLED

promptString

String to display at the command-line prompt. Can consist of letters, numbers, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), underscore (_), and the following variables:

* %u - Will be replaced by the user name.

* %h - Will be replaced by the hostname of the NetScaler appliance.

* %t - Will be replaced by the current time in 12-hour format.

* %T - Will be replaced by the current time in 24-hour format.

* %d - Will be replaced by the current date.

* %s - Will be replaced by the state of the NetScaler appliance.

Note: The 63-character limit for the length of the string does not apply to the characters that replace the variables.

natPcbForceFlushLimit

Flush the system if the number of Network Address Translation Protocol Control Blocks (NATPCBs) exceeds this value.

Default value: 2147483647

Minimum value: 1000

natPcbRstOnTimeout

Send a reset signal to client and server connections when their NATPCBs time out. Avoids the buildup of idle TCP connections on both the sides.

Possible values: ENABLED, DISABLED

Default value: DISABLED

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

Maximum value: 100000000

Use this command to remove system parameter settings.Refer to the set system parameter command for meanings of the arguments.

unset system parameter [-rbaOnResponse] [-promptString] [-natPcbForceFlushLimit] [-natPcbRstOnTimeout] [-timeout]

Displays information about the system parameters.

show system parameter

format

level

rbaOnResponse

Enable or disable Role-Based Authentication (RBA) on responses.

promptString

The global system prompt.

natPcbForceFlushLimit

Flush the system if the number of Network Address Translation Protocol Control Blocks (NATPCBs)

exceeds this value.

natPcbRstOnTimeout

Send RST to client and server connections when the natpcbs timeout.This avoids the buildup of idle TCP connections on the both the sides.

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

maxClient

Maximum number of client connection allowed by the system

system session

Sep 22, 2015

The following operations can be performed on "system session":

show | kill

Displays information about all current system sessions, or about the specified session. The system might reclaim sessions with no active connections before expiry time.

show system session [<sid>]

sid

ID of the system session about which to display information.

Minimum value: 1

summary

fullValues

userName

user name of the session

logintime

logged-in time of this session

lastactivitytime

last activity time of on this session

expirytime

Time left in expire the session in seconds

numOfconnections

number of connection using this token

currentconn

True if the token is used for current session

devno

count

stateflag

Kills one system session, or all system sessions except the current session.

kill system session (<sid> | -all)

sid

ID of the system session to terminate.

CLI users: You can get the session ID by using the show system session command.

Minimum value: 1

all

Terminate all the system sessions except the current session.

---

system user

Sep 22, 2015

The following operations can be performed on "system user":

add | rm | set | unset | bind | unbind | show

Adds a new user to the system. Note: You must provide the password after the user name.

add system user <userName> [-externalAuth (ENABLED | DISABLED)] [-promptString <string>] [-timeout <secs>]

userName

Name for a user. Must begin with a letter, number, or the underscore (_) character, and must contain only alphanumeric, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), and underscore characters. Cannot be changed after the user is added.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my user" or 'my user').

password

Password for the system user. Can include any ASCII character.

externalAuth

Whether to use external authentication servers for the system user authentication or not

Possible values: ENABLED, DISABLED

Default value: ENABLED

promptString

String to display at the command-line prompt. Can consist of letters, numbers, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), underscore (_), and the following variables:

* %u - Will be replaced by the user name.

* %h - Will be replaced by the hostname of the NetScaler appliance.

* %t - Will be replaced by the current time in 12-hour format.

* %T - Will be replaced by the current time in 24-hour format.

* %d - Will be replaced by the current date.

* %s - Will be replaced by the state of the NetScaler appliance.

Note: The 63-character limit for the length of the string does not apply to the characters that replace the variables.

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

Maximum value: 100000000

Removes a system user from the appliance.

```
rm system user <userName>
```

userName

Name of the system user to remove.

Modifies the specified parameters of a system-user entry.

```
set system user <userName> {-password } [-externalAuth ( ENABLED | DISABLED )] [-promptString <string>] [-timeout <secs>]
```

userName

Name of the system-user entry to modify.

password

Password for the system user. Can include any ASCII character.

externalAuth

Whether to use external authentication servers for the system user authentication or not

Possible values: ENABLED, DISABLED

Default value: ENABLED

promptString

String to display at the command-line prompt. Can consist of letters, numbers, hyphen (-), period (.), hash (#), space ( ), at (@), equal (=), colon (:), underscore (_), and the following variables:

* %u - Will be replaced by the user name.

* %h - Will be replaced by the hostname of the NetScaler appliance.

* %t - Will be replaced by the current time in 12-hour format.

* %T - Will be replaced by the current time in 24-hour format.

* %d - Will be replaced by the current date.

* %s - Will be replaced by the state of the NetScaler appliance.

Note: The 63-character limit for the length of the string does not apply to the characters that replace the variables.

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and 9.

Maximum value: 100000000

Use this command to remove system user settings.Refer to the set system user command for meanings of the arguments.

```
unset system user <userName> [-externalAuth] [-promptString] [-timeout]
```

Binds a command policy to a system user.

```
bind system user <userName> <policyName> <priority>
```

userName

Name of the system-user entry to which to bind the command policy.

policyName

Name of the command policy to bind to the system user.

Unbinds a command policy from the system user.

unbind system user <userName> <policyName>

userName

Name of the user entry from which to unbind the command policy.

policyName

Name of the command policy to unbind.

Displays information about all system users configured on the appliance, or about the specified user.

show system user [<userName>]

userName

Name of a system user about whom to display information.

summary

fullValues

format

level

groupName

The system group.

Traffic Management Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- tm formSSOAction
- tm global
- tm samlSSOProfile
- tm sessionAction
- tm sessionParameter
- tm sessionPolicy
- tm trafficAction
- tm trafficPolicy

tm formSSOAction

Sep 22, 2015

The following operations can be performed on "tm formSSOAction":

add | rm | set | unset | show

Creates a form-based single sign-on traffic profile (action.) Form-based single sign-on allows users to access web applications that require an HTML form-based logon without having to type their password again for each new application.

add tm formSSOAction <name> -actionURL <URL> -userField <string> -passwdField <string> -ssoSuccessRule <expression> [-nameValuePair <string>] [-responsesize <positive_integer>] [-nvtype (STATIC | DYNAMIC)] [-submitMethod (GET | POST)]

name

Name for the new form-based single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

actionURL

URL to which the completed form is submitted.

userField

Name of the form field in which the user types in the user ID.

passwdField

Name of the form field in which the user types in the password.

ssoSuccessRule

Expression, that checks to see if single sign-on is successful.

nameValuePair

Name-value pair attributes to send to the server in addition to sending the username and password. Value names are separated by an ampersand (&) (for example, name1=value1&name2=value2).

responsesize

Number of bytes, in the response, to parse for extracting the forms.

Default value: 8096

nvtype

Type of processing of the name-value pair. If you specify STATIC, the values configured by the administrator are used. For DYNAMIC, the response is parsed, and the form is extracted and then submitted.

Possible values: STATIC, DYNAMIC

Default value: NS_ACT_FSSO_NV_DYNAMIC

submitMethod

HTTP method used by the single sign-on form to send the logon credentials to the logon server. Applies only to STATIC name-value type.

Possible values: GET, POST

Default value: NS_ACT_FSSO_SUBMIT_GET

Deletes an existing form-based single sign-on traffic profile (action.)

rm tm formSSOAction <name>

name

Name of the form-based single sign-on profile to delete.

Modifies the specified attributes of a form-based single sign-on traffic profile (action.)

set tm formSSOAction <name> [-actionURL <URL>] [-userField <string>] [-passwdField <string>] [-ssoSuccessRule <expression>] [-responsesize <positive_integer>] [-nameValuePair <string>] [-nvtype (STATIC | DYNAMIC)] [-submitMethod (GET | POST)]

name

Name of the form-based single sign-on profile (action) to modify.

actionURL

URL to which the completed form is submitted.

userField

Name of the form field in which the user types in the user ID.

passwdField

Name of the form field in which the user types in the password.

ssoSuccessRule

Expression, that checks to see if single sign-on is successful.

responsesize

Number of bytes, in the response, to parse for extracting the forms.

Default value: 8096

nameValuePair

Name-value pair attributes to send to the server in addition to sending the username and password. Value names are separated by an ampersand (&) (for example, name1=value1&name2=value2).

nvtype

Type of processing of the name-value pair. If you specify STATIC, the values configured by the administrator are used. For DYNAMIC, the response is parsed, and the form is extracted and then submitted.

Possible values: STATIC, DYNAMIC

Default value: NS_ACT_FSSO_NV_DYNAMIC

submitMethod

HTTP method used by the single sign-on form to send the logon credentials to the logon server. Applies only to STATIC name-value type.

Possible values: GET, POST

Default value: NS_ACT_FSSO_SUBMIT_GET

Use this command to remove tm formSSOAction settings.Refer to the set tm formSSOAction command for meanings of the arguments.

unset tm formSSOAction <name> [-responsesize] [-nameValuePair] [-nvtype] [-submitMethod]

Displays information about all configured form-based single sign-on actions, or displays detailed information about the specified action.

show tm formSSOAction [<name>]

name

Name of the SSO action for which to display detailed information.

summary

fullValues

format

level

actionURL

URL to which the completed form is submitted.

userField

Username field.

passwdField

Password field.

responsesize

Number of bytes, in the response, to parse for extracting the forms.

tm global

Sep 22, 2015

The following operations can be performed on "tm global":

bind | unbind | show

Binds traffic, sessions, nslog, and syslog policies to traffic management (TM) Global.

bind tm global [-policyName <string> [-priority <positive_integer>]]

policyName

Name of the policy that you are binding.

Unbinds a globally bound traffic session policy.

unbind tm global -policyName <string>

policyName

Name of the policy to unbind.

Displays information about TM global bindings.

show tm global

summary

bindPolicyType

Bound policy type

devno

count

tm samlSSOProfile

Sep 22, 2015

The following operations can be performed on "tm samlSSOProfile":

add | rm | set | unset | show

Creates a SAML single sign-on profile. This profile is employed in triggering saml assertion to a target service based on traffic profile.

add tm samlSSOProfile <name> -samlSigningCertName <string> -assertionConsumerServiceURL <URL> -relaystateRule <expression> [-sendPassword (ON | OFF)] [-samlIssuerName <string>]

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

samlSigningCertName

Name of the signing authority as given in the SAML server?s SSL certificate.

assertionConsumerServiceURL

URL to which the assertion is to be sent.

relaystateRule

Expression to extract relaystate to be sent along with assertion.

sendPassword

Option to send password in assertion.

Possible values: ON, OFF

Default value: OFF

samlIssuerName

The name to be used in requests sent from Netscaler to IdP to uniquely identify Netscaler.

Deletes an existing saml single sign-on traffic profile.

rm tm samlSSOProfile <name>

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

Modifies the specified attributes of a saml single sign-on traffic profile.

set tm samlSSOProfile <name> [-samlSigningCertName <string>] [-assertionConsumerServiceURL <URL>] [-sendPassword (ON | OFF)] [-samlIssuerName <string>] [-relaystateRule <expression>]

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

tm sessionAction

Sep 22, 2015

The following operations can be performed on "tm sessionAction":

add | rm | set | unset | show

Creates a session action (profile) that allows you to override global settings for any of the session parameters.

add tm sessionAction <name> [-sessTimeout <mins>] [-defaultAuthorizationAction (ALLOW | DENY)] [-SSO (ON | OFF)] [-ssoCredential (PRIMARY | SECONDARY)] [-ssoDomain <string>] [-httpOnlyCookie (YES | NO)] [-kcdAccount <string>] [-persistentCookie (ON | OFF)] [-persistentCookieValidity <mins>] [-homePage <URL>]

name

Name for the session action. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after a session action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

sessTimeout

Session timeout, in minutes. If there is no traffic during the timeout period, the user is disconnected and must reauthenticate to access intranet resources.

Minimum value: 1

defaultAuthorizationAction

Allow or deny access to content for which there is no specific authorization policy.

Possible values: ALLOW, DENY

SSO

Use single sign-on (SSO) to log users on to all web applications automatically after they authenticate, or pass users to the web application logon page to authenticate to each application individually.

Possible values: ON, OFF

Default value: OFF

ssoCredential

Use the primary or secondary authentication credentials for single sign-on (SSO).

Possible values: PRIMARY, SECONDARY

ssoDomain

Domain to use for single sign-on (SSO).

httpOnlyCookie

Allow only an HTTP session cookie, in which case the cookie cannot be accessed by scripts.

Possible values: YES, NO

kcdAccount

Kerberos constrained delegation account name

persistentCookie

Enable or disable persistent SSO cookies for the traffic management (TM) session. A persistent cookie remains on the user device and is sent with each HTTP request. The cookie becomes stale if the session ends. This setting is overwritten if a traffic action sets persistent cookie to OFF.

Note: If persistent cookie is enabled, make sure you set the persistent cookie validity.

Possible values: ON, OFF

persistentCookieValidity

Integer specifying the number of minutes for which the persistent cookie remains valid. Can be set only if the persistent cookie setting is enabled.

Minimum value: 1

homePage

Web address of the home page that a user is displayed when authentication vserver is bookmarked and used to login.

Deletes an existing session action.

rm tm sessionAction <name>

name

Name of the session action to delete.

Modifies the specified parameters of an existing session action.

set tm sessionAction <name> [-sessTimeout <mins>] [-defaultAuthorizationAction (ALLOW | DENY)] [-SSO (ON | OFF)] [-ssoCredential (PRIMARY | SECONDARY)] [-ssoDomain <string>] [-kcdAccount <string>] [-httpOnlyCookie (YES | NO)] [-persistentCookie (ON | OFF)] [-persistentCookieValidity <positive_integer>] [-homePage <URL>]

name

Name of the session action to modify.

sessTimeout

Session timeout, in minutes. If there is no traffic during the timeout period, the user is disconnected and must reauthenticate to access intranet resources.

Minimum value: 1

defaultAuthorizationAction

Allow or deny access to content for which there is no specific authorization policy.

Possible values: ALLOW, DENY

SSO

Use single sign-on (SSO) to log users on to all web applications automatically after they authenticate, or pass users to the web application logon page to authenticate to each application individually.

Possible values: ON, OFF

Default value: OFF

ssoCredential

Use the primary or secondary authentication credentials for single sign-on (SSO).

Possible values: PRIMARY, SECONDARY

ssoDomain

Domain to use for single sign-on (SSO).

kcdAccount

Kerberos constrained delegation account name

httpOnlyCookie

Allow only an HTTP session cookie, in which case the cookie cannot be accessed by scripts.

Possible values: YES, NO

persistentCookie

Enable or disable persistent SSO cookies for the traffic management (TM) session. A persistent cookie remains on the user device and is sent with each HTTP request. The cookie becomes stale if the session ends. This setting is overwritten if a traffic action sets persistent cookie to OFF.

Note: If persistent cookie is enabled, make sure you set the persistent cookie validity.

Possible values: ON, OFF

persistentCookieValidity

Integer specifying the number of minutes for which the persistent cookie remains valid. Can be set only if the persistent cookie setting is enabled.

Minimum value: 1

homePage

Web address of the home page that a user is displayed when authentication vserver is bookmarked and used to login.

Use this command to remove tm sessionAction settings.Refer to the set tm sessionAction command for meanings of the arguments.

unset tm sessionAction <name> [-sessTimeout] [-defaultAuthorizationAction] [-SSO] [-ssoCredential] [-ssoDomain] [-kcdAccount] [-httpOnlyCookie] [-persistentCookie] [-persistentCookieValidity] [-homePage]

Displays information about all configured traffic management (TM) session actions, or detailed information about the specified TM session action.

show tm sessionAction [<name>]

name

Name of the existing traffic management (TM) session action for which to display detailed information.

summary

fullValues

Use primary or secondary authentication credentials for single sign-on.

ssoDomain

Domain to use for single sign-on.

kcdAccount

Kerberos constrained delegation account name

httpOnlyCookie

Allow only an HTTP session cookie, in which case the cookie cannot be accessed by scripts.

homePage

Web address of the home page that a user is displayed when authentication vserver is bookmarked and used to login.

persistentCookie

Use persistent SSO cookies for the traffic session. A persistent cookie remains on the user device and is sent with each HTTP request. The cookie becomes stale if the session ends.

persistentCookieValidity

Integer specifying the number of minutes for which the persistent cookie remains valid. Can be set only if the persistence cookie setting is enabled.

tm sessionPolicy

Sep 22, 2015

The following operations can be performed on "tm sessionPolicy":

add | rm | set | unset | show

Creates a traffic management (TM) session policy, which is applied after the user logs on to the AAA virtual server, to customize user sessions.

add tm sessionPolicy <name> <rule> <action>

name

Name for the session policy. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign (@), equal sign (=), and hyphen (-) characters. Cannot be changed after a session policy is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy').

rule

Expression, against which traffic is evaluated. Written in the classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Action to be applied to connections that match this policy.

Removes an existing traffic management (TM) session policy.

rm tm sessionPolicy <name>

name

Name of the session policy to remove.

Modifies the rule or action of an existing traffic management (TM) session policy.

set tm sessionPolicy <name> [-rule <expression>] [-action <string>]

name

Name of the session policy to modify.

rule

Expression, against which traffic is evaluated. Written in the classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Action to be applied to connections that match this policy.

Use this command to remove tm sessionPolicy settings.Refer to the set tm sessionPolicy command for meanings of the arguments.

unset tm sessionPolicy <name> [-rule] [-action]

Displays information about all the configured traffic management (TM) session policies, or displays detailed information about the specified TM session policy.

show tm sessionPolicy [<name>]

name

Name of the session policy for which to display detailed information.

tm trafficAction

Sep 22, 2015

The following operations can be performed on "tm trafficAction":

add | rm | set | unset | show

Creates a traffic action to set traffic characteristics at run time. You can create a traffic action for an application that is installed in the internal network (for example, an action that defines the destination IP address and destination port, and sets the amount of time a user can stay logged on to the application, such as 15 minutes).

add tm trafficAction <name> [-appTimeout <mins>] [-SSO (ON | OFF) [-formSSOAction <string>]] [-persistentCookie (ON | OFF)] [-InitiateLogout (ON | OFF)] [-kcdAccount <string>] [-samlSSOProfile <string>]

name

Name for the traffic action. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after a traffic action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

appTimeout

Time interval, in minutes, of user inactivity after which the connection is closed.

Minimum value: 1

Maximum value: 715827

SSO

Use single sign-on for the resource that the user is accessing now.

Possible values: ON, OFF

formSSOAction

Name of the configured form-based single sign-on profile.

persistentCookie

Use persistent cookies for the traffic session. A persistent cookie remains on the user device and is sent with each HTTP request. The cookie becomes stale if the session ends.

Possible values: ON, OFF

InitiateLogout

Initiate logout for the traffic management (TM) session if the policy evaluates to true. The session is then terminated after two minutes.

Possible values: ON, OFF

kcdAccount

Kerberos constrained delegation account name

Default value: "None"

samlSSOProfile

Profile to be used for doing SAML SSO to remote relying party

---

Removes an existing traffic action.

rm tm trafficAction <name>

name

Name of the traffic action to remove.

Modifies the specified parameters of an existing traffic action.

set tm trafficAction <name> [-appTimeout <mins>] [-SSO (ON | OFF)] [-formSSOAction <string>] [-persistentCookie (ON | OFF)] [-InitiateLogout (ON | OFF)] [-kcdAccount <string>] [-samlSSOProfile <string>]

name

Name of the traffic action to modify.

appTimeout

Time interval, in minutes, of user inactivity after which the connection is closed.

Minimum value: 1

Maximum value: 715827

SSO

Use single sign-on for the resource that the user is accessing now.

Possible values: ON, OFF

formSSOAction

Name of the configured form-based single sign-on profile.

persistentCookie

Use persistent cookies for the traffic session. A persistent cookie remains on the user device and is sent with each HTTP request. The cookie becomes stale if the session ends.

Possible values: ON, OFF

InitiateLogout

Initiate logout for the traffic management (TM) session if the policy evaluates to true. The session is then terminated after two minutes.

Possible values: ON, OFF

tm trafficPolicy

Sep 22, 2015

The following operations can be performed on "tm trafficPolicy":

add | rm | set | unset | show | stat

Adds a traffic policy to use for setting connection timeout, single sign-on, and initiating logout. The policy sets the characteristics of application traffic at run time.

add tm trafficPolicy <name> <rule> <action>

name

Name for the traffic policy. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the policy is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy').

rule

Expression, against which traffic is evaluated. Written in the classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Name of the action to apply to requests or connections that match this policy.

Removes an existing traffic policy.

rm tm trafficPolicy <name>

name

Name of the traffic policy to remove.

Modifies the specified parameters of an existing traffic policy.

set tm trafficPolicy <name> [-rule <expression>] [-action <string>]

name

Name of the traffic policy to modify.

Transform Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- transform action
- transform global
- transform policy
- transform policylabel
- transform profile

transform action

Sep 22, 2015

The following operations can be performed on "transform action":

add | rm | set | unset | show

Creates a URL Transformation action, which defines how a specific element in URLs in the request or response is to be modified. NOTE: In the URL Transformation feature (unlike all other NetScaler features), ?profile? and ?action? are not synonymous but refer to distinct entities. You must create the profile first, and then the actions.

add transform action <name> <profileName> <priority> [-state (ENABLED | DISABLED)]

name

Name for the URL transformation action.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the URL Transformation action is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform action? or ?my transform action).

profileName

Name of the URL Transformation profile with which to associate this action.

priority

Positive integer specifying the priority of the action within the profile. A lower number specifies a higher priority. Must be unique within the list of actions bound to the profile. Policies are evaluated in the order of their priority numbers, and the first policy that matches is applied.

Minimum value: 1

Maximum value: 2147483647

state

Enable or disable this action.

Possible values: ENABLED, DISABLED

Default value: GENENABLED

Removes a URL Transformation action.

rm transform action <name>

name

Name of the action.

Modifies the settings of the specified URL Transformation action.

set transform action <name> [-priority <positive_integer>] [-reqUrlFrom <expression>] [-reqUrlInto <expression>] [-resUrlFrom <expression>] [-resUrlInto <expression>] [-cookieDomainFrom <expression>] [-cookieDomainInto <expression>] [-state (ENABLED | DISABLED)] [-comment <string>]

name

Name of the URL Transformation action to modify.

priority

Positive integer specifying the priority of the action within the profile. A lower number specifies a higher priority. Must be unique within the list of actions bound to the profile. Policies are evaluated in the order of their priority numbers, and the first policy that matches is applied.

Minimum value: 1

Maximum value: 2147483647

reqUrlFrom

PCRE-format regular expression that describes the request URL pattern to be transformed.

reqUrlInto

PCRE-format regular expression that describes the transformation to be performed on URLs that match the reqUrlFrom pattern.

resUrlFrom

PCRE-format regular expression that describes the response URL pattern to be transformed.

resUrlInto

PCRE-format regular expression that describes the transformation to be performed on URLs that match the resUrlFrom pattern.

cookieDomainFrom

Pattern that matches the domain to be transformed in Set-Cookie headers.

cookieDomainInto

PCRE-format regular expression that describes the transformation to be performed on cookie domains that match the cookieDomainFrom pattern.

NOTE: The cookie domain to be transformed is extracted from the request.

state

Enable or disable this action.

Possible values: ENABLED, DISABLED

Default value: GENENABLED

comment

Any comments to preserve information about this URL Transformation action.

Use this command to remove transform action settings.Refer to the set transform action command for meanings of the arguments.

unset transform action <name> [-reqUrlFrom] [-reqUrlInto] [-resUrlFrom] [-resUrlInto] [-cookieDomainFrom] [-cookieDomainInto] [-state] [-comment]

Displays a list of all URL Transformation actions currently assigned to the specified profile.

show transform action [<name>]

name

Name of the profile.

summary

transform global

Sep 22, 2015

The following operations can be performed on "transform global":

bind | unbind | show

Activates the specified URL Transformation policy for all traffic received by this NetScaler appliance. If you set policyName to a name that does not match an existing URL Transformation policy name, this command creates the policy, with the configuration that you specify.

bind transform global <policyName> <priority> [<gotoPriorityExpression>] [-type (REQ_OVERRIDE | REQ_DEFAULT)] [-invoke (<labelType> <labelName>)]

policyName

Name of the policy.

If you want to create the policy as well as activate it, specify a name for the policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform policy? or ?my transform policy).

bind transform global pol9 9

Unbinds the specified URL Transformation policy from URL Transformation global.

unbind transform global <policyName> [-type (REQ_OVERRIDE | REQ_DEFAULT)] [-priority <positive_integer>]

policyName

The name of the policy to be unbound.

priority

Priority of the NOPOLICY to be unbound.

Minimum value: 1

Maximum value: 2147483647

unbind transform global pol9

Displays the policies bound to the specified URL Transformation global bind point. If no bind point is specified, displays a list of all policies bound to URL Transformation global.

show transform global [-type (REQ_OVERRIDE | REQ_DEFAULT)]

type

Specifies the bind point to which to bind the policy. Available settings function as follows:

* REQ_OVERRIDE. Request override. Binds the policy to the priority request queue.

* REQ_DEFAULT. Binds the policy to the default request queue.

Possible values: REQ_OVERRIDE, REQ_DEFAULT

summary

fullValues

format

level

stateflag

policyName

Name of the transform policy.

priority

Specifies the priority of the policy.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the current policy rule evaluates to TRUE.

invoke

If the current policy evaluates to TRUE, terminate evaluation of policies bound to the current policy label, and then forwards the request or response to the specified virtual server or evaluates the specified policy label.

labelType

Type of invocation. Available settings function as follows:

* reqvserver - Send the request to the specified request virtual server.

* resvserver - Send the response to the specified response virtual server.

* policylabel - Invoke the specified policy label.

labelName

Name of the policy label to invoke if the current policy evaluates to TRUE, the invoke parameter is set, and the label type is Policy Label.

flowType

flowtype of the bound transform policy.

numpol

The number of policies bound to the bindpoint.

flags

devno

count

show transform global

transform policy

Sep 22, 2015

The following operations can be performed on "transform policy":

add | rm | set | unset | show | stat | rename

Creates a URL Transformation policy, which specifies the requests and responses to be transformed by the associated profile.

add transform policy <name> <rule> <profileName> [-comment <string>] [-logAction <string>]

name

Name for the URL Transformation policy.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the URL Transformation policy is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform policy? or ?my transform policy).

rule

Expression, or name of a named expression, against which to evaluate traffic. Can be written in either default or classic syntax. Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes blank spaces, the entire expression must be enclosed in double quotation marks.

* If the expression itself includes double quotation marks, you must escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

profileName

Name of the URL Transformation profile to use to transform requests and responses that match the policy.

comment

Any comments to preserve information about this URL Transformation policy.

logAction

Log server to use to log connections that match this policy.

Removes the specified URL Transformation policy.

rm transform policy <name>

name

Name of the policy to remove.

rm transform policy trans_pol

Modifies the specified parameters of a URL Transformation policy.

set transform policy <name> [-rule <expression>] [-profileName <string>] [-comment <string>] [-logAction <string>]

name

Name of the policy to modify.

rule

Expression, or name of a named expression, against which to evaluate traffic. Can be written in either default or classic syntax. Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

* If the expression itself includes double quotation marks, you must escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

profileName

Name of the URL Transformation profile to use to transform requests and responses that match the policy.

comment

Any comments to preserve information about this URL Transformation policy.

logAction

Log server to use to log connections that match this policy.

```
set transform policy pol9 -rule "HTTP.REQ.HEADER(\\\"header\\\").CONTAINS(\\\"qh2\\\")"
```

Removes the settings of an existing URL Transformation policy. Attributes for which a default value is available revert to their default values. See the set transform policy command for a description of the parameters..Refer to the set transform policy command for meanings of the arguments.

```
unset transform policy <name> [-comment] [-logAction]
```

```
unset transform policy pol9 -undefAction
```

Displays the current settings for the specified URL Transformation policy. If no policy name is specified, displays a list of all URL Transformation policies currently configured on the NetScaler appliance.

```
show transform policy [<name>]
```

name

Name of the URL Transformation policy.

Policy hits (Hits)

Number of hits on the policy

Policy undef hits (Undefhits)

Number of undef hits on the policy

stat transform policy

Renames a URL Transformation policy.

rename transform policy <name>@
<newName>@

name

Existing name of the policy.

newName

New name for the policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform policy? or ?my transform policy).

rename transform policy oldname newname

transform policylabel

Sep 22, 2015

The following operations can be performed on "transform policylabel":

add | rm | bind | unbind | show | stat | rename

Creates a URL Transformation policy label. A policy label is a tool for evaluating a set of policies in a specified order. By using a policy label, you can configure the URL Transformation feature to choose the next policy, invoke a different policy label, or terminate policy evaluation completely by looking at whether the previous policy evaluated to TRUE or FALSE.

add transform policylabel <labelName> <policylabeltype>

labelName

Name for the policy label. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the URL Transformation policy label is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform policylabel? or ?my transform policylabel).

policylabeltype

Types of transformations allowed by the policies bound to the label. For URL transformation, always http_req (HTTP Request).

Possible values: http_req

```
add transform policylabel trans_policylabel http_req
```

Removes a URL Transformation policy label.

rm transform policylabel <labelName>

labelName

Name of the policy label to remove.

```
rm transform policylabel trans_policylabel
```

Binds the specified URL Transformation policy to the specified policy label.

bind transform policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]

labelName

Name of the URL Transformation policy label to which to bind the policy.

policyName

Name of the URL Transformation policy to bind to the policy label.

```
i) bind transform policylabel trans_policylabel pol_1 1 2 -invoke reqvserver CURRENT  ii) bind transform policylabel trans_policylabel pol_2 2
```

Unbinds the specified URL Transformation policy from the specified policy label.

```
unbind transform policylabel <labelName> <policyName> [-priority <positive_integer>]
```

labelName

Name of the label from which to unbind the policy.

policyName

Name of the label to which to bind the policy.

priority

Priority of the NOPOLICY to be unbound.

Minimum value: 1

Maximum value: 2147483647

```
unbind transform policylabel trans_policylabel pol_1
```

Displays the current settings for the specified URL Transformation policy label. If no policy label is specified, displays a list of all URL Transformation policy labels currently configured on the NetScaler appliance.

```
show transform policylabel [<labelName>]
```

labelName

Name for the policy label. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the URL Transformation policy label is added.

Policy Label Hits (Hits)

Number of times policy label was invoked.

Renames a URL Transformation policy label.

rename transform policylabel <labelName>@ <newName>@

labelName

Current name of the policy label.

newName

New name for the policy label.

Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform policylabel? or ?my transform policylabel).

rename transform policylabel oldname newname

---

transform profile

Sep 22, 2015

The following operations can be performed on "transform profile":

add | rm | set | unset | show

Creates a URL transformation profile, which contains a list of actions that define how the URLs in a request or response are to be modified. NOTE: In the URL Transformation feature (unlike all other NetScaler features), ?profile? and ?action? are not synonymous but refer to distinct entities. You must create the profile first, and then the actions.

add transform profile <name> [-type URL]

name

Name for the URL transformation profile. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the URL transformation profile is added.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, ?my transform profile? or ?my transform profile?).

type

Type of transformation. Always URL for URL Transformation profiles.

Possible values: URL

Removes a URL Transformation profile.

rm transform profile <name>

name

Name of the profile to remove.

Modifies the settings of a URL Transformation profile.

```
set transform profile <name> [-type URL] [-onlyTransformAbsURLinBody ( ON | OFF )] [-comment <string>]
```

name

Name of the profile to be modified.

type

Type of transformation. Always URL for URL Transformation profiles.

Possible values: URL

onlyTransformAbsURLinBody

In the HTTP body, transform only absolute URLs. Relative URLs are ignored.

Possible values: ON, OFF

comment

Any comments to preserve information about this URL Transformation profile.

Use this command to remove transform profile settings.Refer to the set transform profile command for meanings of the arguments.

```
unset transform profile <name> [-type] [-onlyTransformAbsURLinBody] [-comment]
```

Displays the current settings for the specified URL Transformation profile. If no URL Transformation profile name is specified, displays a list of all URL Transformation profiles currently configured on the NetScaler appliance.

```
show transform profile [<name>]
```

name

Name of the profile.

summary

fullValues

format

level

actionName

URL Transformation action name.

stateflag

type

Type of transformation. Always URL for URL Transformation profiles.

RegexForFindingURLinJavaScript

Patclass having regexes to find the URLs in JavaScript.

RegexForFindingURLinCSS

Patclass having regexes to find the URLs in CSS.

RegexForFindingURLinXComponent

Patclass having regexes to find the URLs in X-Component.

RegexForFindingURLinXML

Patclass having regexes to find the URLs in XML.

additionalReqHeadersList

Patclass having a list of additional request header names that should transformed.

additionalRespHeadersList

Patclass having a list of additional response header names that should transformed.

onlyTransformAbsURLinBody

In the HTTP body, transform only absolute URLs. Relative URLs are ignored.

comment

Any comments to preserve information about this URL Transformation profile.

priority

Priority of the Action within the Profile.

state

Enabled flag.

profileName

URL Transformation profile name.

reqUrlFrom

Pattern of original request URLs. It corresponds to the way external users view the server, and acts as a source for request transformations.

reqUrlInto

Pattern of transformed request URLs. It corresponds to internal addresses and indicates how they are created.

resUrlFrom

Pattern of original response URLs. It corresponds to the way external users view the server, and acts as a source for response transformations.

resUrlInto

Pattern of transformed response URLs. It corresponds to internal addresses and indicates how they are created.

cookieDomainFrom

Pattern of the original domain in Set-Cookie headers.

cookieDomainInto

Pattern of the transformed domain in Set-Cookie headers.

actionComment

Comments.

Tunnel Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- tunnel global
- tunnel trafficPolicy

tunnel global

Sep 22, 2015

The following operations can be performed on "tunnel global":

bind | unbind | show

Activates an existing tunnel traffic policy globally.

bind tunnel global (<policyName> [-priority <positive_integer>]) [-state (ENABLED | DISABLED)]

policyName

Name of the tunnel traffic policy to activate or bind.

add tunnel trafficpolicy cmp_all_destport "REQ.TCP.DESTPORT == 0-65535" GZIP After creating above tunnel policy, it can be activated by binding it globally: bind tun

---

Deactivates an active tunnel traffic policy.

unbind tunnel global <policyName>

policyName

Name of the tunnel traffic policy to unbind or deactivate.

Globally active tunnel policies can be seen using command: > show tunnel global 1 Globally Active Tunnel Policies: 1) Policy Name: cmp_all_destport Priority: 0 Don

---

Displays globally active tunnel policies.

show tunnel global

summary

fullValues

format

level

policyName

Policy name.

priority

Priority.

state

Current state of the binding. If the binding is enabled, the policy is active.

builtin

Indicates that a variable is a built-in (SYSTEM INTERNAL) type.

devno

count

stateflag

```
> sh tunnel global 1) Policy Name: cmp_all_destport   Priority: 0 2) Policy Name: local_sub_nocmp   Priority: 500  Done
```

tunnel trafficPolicy

Sep 22, 2015

The following operations can be performed on "tunnel trafficPolicy":

add | rm | set | unset | show

Creates a tunnel traffic policy. A tunnel traffic policy defines the type of compression to be used for the tunneled traffic.

add tunnel trafficPolicy <name> <rule> <action>

name

Name for the tunnel traffic policy.

Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the policy is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy)'.

rule

Expression, against which traffic is evaluated. Written in classic or default syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes blank spaces, the entire expression must be enclosed in double quotation marks.

* If the expression itself includes double quotation marks, you must escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Name of the built-in compression action to associate with the policy.

Example 1: add tunnel trafficpolicy cmp_all_destport "REQ.TCP.DESTPORT == 0-65535" GZIP After creating above tunnel policy, it can be activated by binding it global

---

Removes a tunnel traffic policy.

rm tunnel trafficPolicy <name>

name

Name of the tunnel traffic policy to remove.

rm tunnel trafficpolicy tunnel_policy_name The "show tunnel trafficpolicy" command shows all tunnel policies that are currently defined.

Modifies the specified parameters of an existing tunnel traffic policy.

set tunnel trafficPolicy <name> [-rule <expression>] [-action <string>]

name

Name of the tunnel traffic policy to modify.

rule

Expression, against which traffic is evaluated. Written in classic or default syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes blank spaces, the entire expression must be enclosed in double quotation marks.

* If the expression itself includes double quotation marks, you must escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Name of the built-in compression action to associate with the policy.

```
add tunnel trafficpolicy cmp_all_destport "REQ.TCP.DESTPORT == 0-65535" GZIP  set tunnel trafficpolicy cmp_all_destport -action NOCOMPRESS  Above 'set' comman
```

Use this command to remove tunnel trafficPolicy settings.Refer to the set tunnel trafficPolicy command for meanings of the arguments.

```
unset tunnel trafficPolicy <name> [-rule] [-action]
```

Displays information about all the configured tunnel traffic policies, or displays detailed information about the specified tunnel traffic policy.

```
show tunnel trafficPolicy [<name>]
```

name

Name of the tunnel traffic policy for which to show detailed information.

summary

Utility Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- audit
- callhome
- grep
- install
- nstrace
- ping
- ping6
- raid
- scp
- shell
- techsupport
- traceroute
- traceroute6

audit

Sep 22, 2015

The following operations can be performed on "audit":

audit and verify the commands in file against running config. NOTE: This command is deprecated.Command deprecated. Use diff ns config command

commandStr

specify the options.

```
config audit -diff -f <filename>
```

callhome

Sep 22, 2015

The following operations can be performed on "callhome":

show | set | unset

Displays the trigger events configured and the time when these events were triggered.

show callhome

format

level

emailAddress

The contact person's E-mail address.

proxyMode

Deploy the callhome proxy mode

IPAddress

Proxy Server IP address

port

Proxy Server Port

sslcardfirstfailure

First occurrence SSL card failure.

sslcardlatestfailure

Latest occurrence SSL card failure.

powfirstfail

First occurrence power supply unit failure.

powlatestfailure

Latest occurrence power supply unit failure.

HDDfirstfail

First occurrence hard disk drive failure.

HDDlatestfailure

Latest occurrence hard disk drive failure.

FLASHfirstfail

First occurrence compact flash failure.

FLASHlatestfailure

Latest occurrence compact flush failure.

restartLatestfail

Latest occurrence warm restart failure.

callhomestatus

Callhome feature enabled/disable, register with upload server successful/failed

show callhome E-mail address configured:xxx@yahoo.com Trigger event State First occurrence Latest occurrence ---------- ----- -----

Sets the contact person's E-mail address

set callhome -emailAddress e-mailaddress

emailAddress

The contact person's E-mail address.

proxyMode

Deploy the callhome proxy mode

Possible values: YES, NO

Default value: NO

```
set callhome -emailAddress xxxx@yahoo.com
```

Use this command to remove callhome settings.Refer to the set callhome command for meanings of the arguments.

```
unset callhome [-emailAddress] [-proxyMode] [-IPAddress] [-port]
```

---

grep

Sep 22, 2015

The following operations can be performed on "grep":

Searches files or output for lines containing a match to the specified <pattern>. By default, grep prints the matching lines.

grep [-c] [-E] [-i] [-v] [-w] [-x] <pattern>

c

Suppress normal output. Instead print a count of matching lines.

With the -v option, count non-matching lines.

E

Interpret <pattern> as an extended regular expression.

i

Ignore case distinctions.

v

Invert the sense of matching, to select non-matching lines.

w

Select only those lines containing matches that form whole words.

x

Select only those matches that exactly match the whole line.

pattern

The pattern (regular expression or text string) for which to search.

```
show ns info | grep off -i
```

install

Sep 22, 2015

The following operations can be performed on "install":

Installs a version of NetScaler software on the system.

install <url> [-c] [-y]

url

http://[user]:[password]@host/path/to/file

https://[user]:[password]@host/path/to/file

sftp://[user]:[password]@host/path/to/file

scp://[user]:[password]@host/path/to/file

ftp://[user]:[password]@host/path/to/file

file://path/to/file

c

Back up existing kernel.

y

Do not prompt for yes/no before rebooting.

```
install http://host.netscaler.com/ns-6.0-41.2.tgz
```

nstrace

Sep 22, 2015

The following operations can be performed on "nstrace":

Invokes the nstrace program to log traffic flowing through the NetScaler appliance.

nstrace [-nf <positive_integer>] [-time <secs>] [-size <positive_integer>] [-mode <mode> ...] [-tcpdump (ENABLED | DISABLED) [-perNIC (ENABLED | DISABLED)]] [-name <string> [-id <string>]] [-filter <expression> [-link (ENABLED | DISABLED)]]

h

prints this message - exclusive option

nf

Number of files to be generated in a single run of the command.

Default value: 24

time

Number of seconds for which to log to trace file. Can be a mathematical expression. For example, to log to trace files for 2 hours, you can specify 2*60*60.

Default value: 3600

size

Size of the packet to be logged (should be in the range of 60 to 1514 bytes). Set to 0 for full packet trace.

Default value: 164

Maximum value: 1514

m

Capturing mode: sum of the values:

1 - Transmitted packets (TX)

2 - Packets buffered for transmission (TXB)

4 - Received packets (RX)

Default value: 6

tcpDump

Log files in TCP dump format (instead of nstrace format).

Possible values: NSTRACE, TCPDUMP

mode

Capturing mode for trace. Can be any of the following values, or a combination of these values:

* RX - Received packets before NIC pipelining

* NEW_RX - Received packets after NIC pipelining (packets that are not dropped)

* TX - Transmitted packets

* TXB - Packets buffered for transmission

* IPV6 - Translated IPv6 packets

* C2C - Capture core-to-core messages

* NS_FR_TX - Flow receiver does not capture the TX/TXB packets. Applicable only for a cluster setup.

You can also provide a combination of modes. For example:

* -mode NEW_RX TXB: Capture RX packets after NIC handling and packets that are buffered for actual transmission.

* -mode RX TX: Capture packet during NIC pipeline (filter expressions will not work for RX mode).

* -mode NEW_RX TXB NS_FR_TX: Default mode except that TX/TXB packets on the flow receiver are not captured.

Default value: DEFAULT_MODE

tcpdump

Log files format supported:nstrace-format, tcpdump-format. default:nstrace-format

Possible values: ENABLED, DISABLED

Default value: DISABLED

name

Custom file name for nstrace files.

filter

Filter expression for nstrace. Maximum length of filter is 255 and it can be of the following format:

"<expression> [<relop> <expression>"]

where,

<relop> can be the && or the || relational operators.

<expression> is a string in the following format: <qualifier> <operator> <qualifier-value>

where,

<operator> can be any one of the following (except the commas): ==, eq, !=, neq, >, gt, <, lt, >=, ge, <=, le, BETWEEN

Following are the valid qualifiers for the command: SOURCEIP, SOURCEPORT, DESTIP, DESTPORT, IP, PORT, SVCNAME, VSVRNAME, CONNID, VLAN, INTF.

Example:

nstrace -filter "SOURCEIP==10.102.34.201 || SVCNAME !=s1 && SOURCEPORT >80"

```
nstrace -nf 10 -time 100 -mode RX IPV6 TXB -name abc -tcpdump ENABLED -perNIC ENABLED
```

ping

Sep 22, 2015

The following operations can be performed on "ping":

Invokes the UNIX ping command. The hostName parameter must be used if the name is in the /etc/hosts file directory or is otherwise known in DNS.

ping [-c <count>] [-i <interval>] [-I <interface>] [-n] [-p <pattern>] [-q] [-s <size>] [-S <src_addr>] [-T <td>] [-t <timeout>] <hostname>

c

Number of packets to send. The default value is infinite.

Minimum value: 1

Maximum value: 65535

i

Waiting time, in seconds. The default value is 1 second.

Maximum value: 65535

I

Network interface on which to ping, if you have multiple interfaces.

n

Numeric output only. No name resolution.

p

Pattern to fill in packets. Can be up to 16 bytes, useful for diagnosing data-dependent problems.

q

Quiet output. Only the summary is printed.

s

Data size, in bytes. The default value is 56.

Maximum value: 65507

S

Source IP address to be used in the outgoing query packets. If the IP addrESS does not belongs to this appliance, an error is returned and nothing is sent.

T

Traffic Domain Id

Minimum value: 1

Maximum value: 4094

t

Time-out, in seconds, before ping exits.

Minimum value: 1

Maximum value: 3600

hostName

Address of host to ping.

```
ping -p ff -c 4 10.102.4.107
```

ping6

Sep 22, 2015

The following operations can be performed on "ping6":

Invokes the UNIX ping6 command. The hostName parameter must be used if the name is in the /etc/hosts file directory or is otherwise known in DNS.

ping6 [-c <count>] [-i <interval>] [-I <interface>] [-n] [-p <pattern>] [-q] [-S sourceaddr] [-V <vlanid>] [-T <td>] [-s <size>] Hostname

c

Number of packets to send. The default value is infinite.

Minimum value: 1

Maximum value: 65535

i

Waiting time, in seconds. The default value is 1 second.

Maximum value: 65535

I

Network interface on which to ping, if you have multiple interfaces.

n

Numeric output only. No name resolution.

p

Pattern to fill in packets. Can be up to 16 bytes, useful for diagnosing data-dependent problems.

q

Quiet output. Only summary is printed.

s

Data size, in bytes. The default value is 56.

Maximum value: 65507

V

VLAN ID for link local address.

Minimum value: 1

Maximum value: 4094

S

Source IP address to be used in the outgoing query packets.

T

Traffic Domain Id

Minimum value: 1

Maximum value: 4094

t

Timeout in seconds before ping6 exits

hostName

Address of host to ping.

```
ping6 -p ff -I 1/1 -c 4 2002::1
```

raid

Sep 22, 2015

The following operations can be performed on "raid":

Provides status of raid

show raid

status raid

scp

Sep 22, 2015

The following operations can be performed on "scp":

Securely copies data from one computer to another, in SSH protocol.

scp [-r] [-C] [-q] <sourceString> <destString>

r

Recursively copy subdirectories.

C

Enable compression.

q

Quiet output. Disable the progress meter.

sourceString

Source user, host, and file path, specified as <user>@<host>:<path_to_copy_from>. The user and host parts are optional.

destString

Destination user, host, and file path, specified as

<user>@<host>:<path_to_copy_to>. The user and host parts are optional.

```
scp /nsconfig/ns.conf nsroot@10.102.4.107:/nsconfig/
```

shell

Sep 22, 2015

The following operations can be performed on "shell":

Exits to the FreeBSD command prompt. Press Control + D or type exit to return to the NetScaler command prompt. Note: The shell can be accessed only by users who have write access to the NetScaler appliance.

shell [(command)]

command

Shell command(s) to be invoked.

techsupport

Sep 22, 2015

The following operations can be performed on "techsupport":

Generates a tar of system configuration data and statistics. This file must be submitted to Citrix technical support with file name collector_<NS IP>_<P/S>_<DateTime>.tgz. The archive is always pointed by the symbolic link /var/tmp/support/support.tgz for each invocation of the command.

show techsupport [-scope (NODE | CLUSTER)]

scope

Use this option to run showtechsupport on present node or all cluster nodes.

Possible values: NODE, CLUSTER

Default value: NS_TECH_NODE

serverName

show techsupport

traceroute

Sep 22, 2015

The following operations can be performed on "traceroute":

Invokes the UNIX traceroute command. This command attempts to track the route that the packets follow to reach the destination host.

traceroute [-S] [-n] [-r] [-v] [-M <min_ttl] [-m <max_ttl>] [-P <protocol>][-p <portno>] [-q <nqueries>] [-s <src_addr>] [-T <td>] [-t <tos>] [-w <wait>] <host> [<packetlen>]

S

Print a summary of how many probes were not answered for each hop.

n

Print hop addresses numerically instead of symbolically and numerically.

r

Bypass normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned.

v

Verbose output. List received ICMP packets other than TIME_EXCEEDED and UNREACHABLE.

M

Minimum TTL value used in outgoing probe packets.

Default value: 1

Minimum value: 1

Maximum value: 255

m

Maximum TTL value used in outgoing probe packets.

Default value: 64

Minimum value: 1

Maximum value: 255

P

Send packets of specified IP protocol. The currently supported protocols are UDP and ICMP.

p

Base port number used in probes.

Default value: 33434

Minimum value: 1

Maximum value: 65535

q

Number of queries per hop.

Default value: 3

Minimum value: 1

Maximum value: 65535

s

Source IP address to use in the outgoing query packets. If the IP address does not belong to this appliance, an error is returned and nothing is sent.

T

Traffic Domain Id

Minimum value: 1

Maximum value: 4094

t

Type-of-service in query packets.

Maximum value: 255

w

Time (in seconds) to wait for a response to a query.

Default value: 5

Minimum value: 2

Maximum value: 86399

host

Destination host IP address or name.

packetlen

Length (in bytes) of the query packets.

Default value: 44

Minimum value: 44

Maximum value: 32768

traceroute 10.102.4.107

traceroute6

Sep 22, 2015

The following operations can be performed on "traceroute6":

Invokes the UNIX traceroute6 command. Traceroute6 attempts to track the route that the packets follow to reach the destination host.

traceroute6 [-n] [I] [-r] [-v] [-m <hoplimit>] [-p <port>] [-q <probes>] [-s <src_addr>] [-T <td>] [-w <waittime>] <target> [<packetlen>]

n

Print hop addresses numerically rather than symbolically and numerically.

I

Use ICMP ECHO for probes.

r

Bypass normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned.

v

Verbose output. List received ICMP packets other than TIME_EXCEEDED and UNREACHABLE.

m

Maximum hop value for outgoing probe packets.

Default value: 64

Minimum value: 1

Maximum value: 255

p

Base port number used in probes.

Default value: 33434

Minimum value: 1

Maximum value: 65535

q

Number of probes per hop.

Default value: 3

Minimum value: 1

Maximum value: 65535

s

Source IP address to use in the outgoing query packets. If the IP address does not belong to this appliance, an error is returned and nothing is sent.

T

Traffic Domain Id

Minimum value: 1

Maximum value: 4094

w

Time (in seconds) to wait for a response to a query.

Default value: 5

Minimum value: 2

Maximum value: 86399

host

Destination host IP address or name.

packetlen

Length (in bytes) of the query packets.

Default value: 44

Minimum value: 44

Maximum value: 32768

```
traceroute6 2002::7
```

VPN Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- vpn
- vpn clientlessAccessPolicy
- vpn clientlessAccessProfile
- vpn formSSOAction
- vpn global
- vpn icaConnection
- vpn intranetApplication
- vpn nextHopServer
- vpn parameter
- vpn samlSSOProfile
- vpn sessionAction
- vpn sessionPolicy
- vpn stats
- vpn trafficAction
- vpn trafficPolicy
- vpn url
- vpn vserver

vpn

Sep 22, 2015

The following operations can be performed on "vpn":

stat vpn

Displays the statistics for Access Gateway usage. Displays event information, such as the event that generated the message, a time stamp, the message type, and predefined log levels and message information.

Synopsys

stat vpn [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

Login-page requests received (iHtHit)

Number of requests for VPN login page.

Login-page delivery failures (iHtFail)

Number of failures to display VPN login page.

Client-configuration requests (cfgHit)

Number of client configuration requests received by VPN server.

DNS queries resolved (dnsHit)

Number of DNS queries resolved by VPN server.

WINS queries resolved (winsHit)

Number of WINS queries resolved by VPN server.

Number of SSLVPN tunnels (csHit)

Number of SSL VPN tunnels formed between VPN server and client.

Backend non-HTTP server probes (csNoHttp)

Number of probes from VPN to back-end non-HTTP servers that have been accessed by the VPN client.

Backend HTTP server probes (csHttp)

Number of probes from VPN to back-end HTTP servers that have been accessed by the VPN client.

Backend server probe successes (csConSuc)

Number of successful probes to all back-end servers.

File-system requests received (totFsHit)

Number of file system requests received by VPN server.

IIP disabled and MIP used (IIPdMIPu)

Number of times MIP is used as IIP is disabled.

IIP failed and MIP used (IIPfMIPu)

Number of times MIP is used as IIP assignment failed.

IIP spillover and MIP used (IIPsMIPu)

Number of times MIP is used on IIP Spillover.

IIP disabled and MIP disabled (IIPdMIPd)

Both IIP and MIP is disabled.

IIP failed and MIP disabled (IIPfMIPd)

Number of times IIP assignment failed and MIP is disabled.

SOCKS method request received (SOCKSmReqR)

Number of received SOCKS method request.

SOCKS method request sent (SOCKSmReqS)

Number of sent SOCKS method request.

SOCKS method response received (SOCKSmRespR)

Number of received SOCKS method response.

SOCKS method response sent (SOCKSmRespS)

Number of sent SOCKS method response.

SOCKS connect request received (SOCKScReqR)

Number of received SOCKS connect request.

SOCKS connect request sent (SOCKScReqS)

Number of sent SOCKS connect request.

SOCKS connect response received (SOCKScRespR)

Number of received SOCKS connect response.

SOCKS connect response sent (SOCKScRespS)

Number of sent SOCKS connect response.

SOCKS server error (SOCKSserverErr)

Number of SOCKS server error.

SOCKS client error (SOCKSclientErr)

Number of SOCKS client error.

STA connection success (STAconnSucc)

Number of STA connection success.

STA connection failure (STAconnFail)

Number of STA connection failure.

CPS connection success (CPSconnSucc)

Number of CPS connection success.

CPS connection failure (CPSconnFail)

Number of CPS connection failure.

STA request sent (STAreqSent)

Number of STA request sent.

STA response received (STArespRecvd)

Number of STA response received.

ICA license failure (ICAlicenseFail)

Number of ICA license failure.

vpn clientlessAccessPolicy

Sep 22, 2015

The following operations can be performed on "vpn clientlessAccessPolicy":

add | rm | set | show

add vpn clientlessAccessPolicy

Adds a clientless access policy, which enables users to log on using a web browser and connect to the bookmarked web address without requiring the user to install a software plug-in.

Synopsys

add vpn clientlessAccessPolicy <name> <rule> <profileName>

Arguments

name

Name of the new clientless access policy.

rule

Expression, or name of a named expression, specifying the traffic that matches the policy. Can be written in either default or classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

profileName

Name of the profile to invoke for the clientless access.

---

rm vpn clientlessAccessPolicy

Removes a clientless access policy.

Synopsys

rm vpn clientlessAccessPolicy <name>

Arguments

name

Name of the clientless access policy to remove.

---

set vpn clientlessAccessPolicy

Adds a new rule to be used by an existing clientless access policy that includes a simple expression that specifies the conditions for which the policy is enforced.

Synopsys

set vpn clientlessAccessPolicy <name> [-rule <expression>] [-profileName <string>]

Arguments

name

Name of the existing clientless access policy to modify.

rule

Expression, or name of a named expression, specifying the traffic that matches the policy. Can be written in either default or classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: "'<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

profileName

Name of the profile to invoke for the clientless access.

---

show vpn clientlessAccessPolicy

Displays a clientless access policy.

Synopsys

show vpn clientlessAccessPolicy [<name>]

Arguments

name

Name of the clientless access policy to display.

summary

fullValues

format

level

Outputs

rule

The rule used by the clientless access policy. Rules are combinations of Expressions. Expressions are simple conditions, such as a test for equality, applied to operands, such as a URL string or an IP address. Expression syntax is described in the Installation and Configuration Guide

profileName

The profile to invoked for the clientless access.

undefAction

The UNDEF action.

hits

The number of times the policy evaluated to true.

undefHits

The number of times the policy evaluation resulted in undefined processing.

activePolicy

Indicates whether policy is bound or not.

boundTo

Location where policy is bound.

priority

Specifies the priority of the policy.

description

Description of the clientless access policy.

isDefault

A value of true is returned if it is a default vpnclientlessrwpolicy.

count

vpn clientlessAccessProfile

Sep 22, 2015

The following operations can be performed on "vpn clientlessAccessProfile":

add | rm | set | unset | show

add vpn clientlessAccessProfile

Adds a collection of settings that allows clientless access to a given application. Settings include the policies to specify whether to rewrite a URL, rules to find the URLs within various web content-types, and a set of cookies that are required to be present on the client machine.

Synopsys

add vpn clientlessAccessProfile <profileName>

Arguments

profileName

Name for the Access Gateway clientless access profile. Must begin with an ASCII alphabetic or underscore (_) character, and must consist only of ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the profile is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my profile" or 'my profile').

---

rm vpn clientlessAccessProfile

Removes a clientless access profile.

Synopsys

rm vpn clientlessAccessProfile <profileName>

Arguments

profileName

Name of the clientless access profile to remove.

---

set vpn clientlessAccessProfile

Modifies the settings for an existing clientless access profile.

Synopsys

set vpn clientlessAccessProfile <profileName> [-URLRewritePolicyLabel <string>] [-JavaScriptRewritePolicyLabel <string>] [-ReqHdrRewritePolicyLabel <string>] [-ResHdrRewritePolicyLabel <string>] [-RegexForFindingURLinJavaScript <string>] [-RegexForFindingURLinCSS <string>] [-RegexForFindingURLinXComponent <string>] [-RegexForFindingURLinXML <string>] [-RegexForFindingCustomURLs <string>] [-ClientConsumedCookies <string>] [-requirePersistentCookie (ON | OFF)]

Arguments

profileName

Name of the clientless access profile to modify.

URLRewritePolicyLabel

Name of the configured URL rewrite policy label. If you do not specify a policy label name, then URLs are not rewritten.

JavaScriptRewritePolicyLabel

Name of the configured JavaScript rewrite policy label. If you do not specify a policy label name, then JAVA scripts are not rewritten.

ReqHdrRewritePolicyLabel

Name of the configured Request rewrite policy label. If you do not specify a policy label name, then requests are not rewritten.

ResHdrRewritePolicyLabel

Name of the configured Response rewrite policy label.

RegexForFindingURLinJavaScript

Name of the pattern set that contains the regular expressions, which match the URL in Java script.

RegexForFindingURLinCSS

Name of the pattern set that contains the regular expressions, which match the URL in the CSS.

RegexForFindingURLinXComponent

Name of the pattern set that contains the regular expressions, which match the URL in X Component.

RegexForFindingURLinXML

Name of the pattern set that contains the regular expressions, which match the URL in XML.

RegexForFindingCustomURLs

Name of the pattern set that contains the regular expressions, which match the URLs in the custom content type other than HTML, CSS, XML, XCOMP, and JavaScript. The custom content type should be included in the patset ns_cvpn_custom_content_types.

ClientConsumedCookies

Specify the name of the pattern set containing the names of the cookies, which are allowed between the client

and the server. If a pattern set is not specified, Access Gateway does not allow any cookies between the client and the server. A cookie that is not specified in the pattern set is handled by Access Gateway on behalf of the client.

requirePersistentCookie

Specify whether a persistent session cookie is set and accepted for clientless access. If this parameter is set to ON, COM objects, such as MSOffice, which are invoked by the browser can access the files using clientless access. Use caution because the persistent cookie is stored on the disk.

Possible values: ON, OFF

Default value: OFF

---

unset vpn clientlessAccessProfile

Resets the attributes of the specified clientless access profile. Attributes for which a default value is available revert to their default values. Refer to the set vpn clientlessAccessProfile command for a description of the parameters..Refer to the set vpn clientlessAccessProfile command for meanings of the arguments.

Synopsys

unset vpn clientlessAccessProfile <profileName> [-URLRewritePolicyLabel] [-JavaScriptRewritePolicyLabel] [-ReqHdrRewritePolicyLabel] [-ResHdrRewritePolicyLabel] [-RegexForFindingURLinJavaScript] [-RegexForFindingURLinCSS] [-RegexForFindingURLinXComponent] [-RegexForFindingURLinXML] [-RegexForFindingCustomURLs] [-ClientConsumedCookies] [-requirePersistentCookie]

---

show vpn clientlessAccessProfile

Displays information about all the configured clientless access profiles, or displays detailed information about the specified clientless access profile.

Synopsys

show vpn clientlessAccessProfile [<profileName>]

Arguments

profileName

Name of the clientless access profile for which to display detailed information.

summary

fullValues

format

level

Outputs

stateflag

URLRewritePolicyLabel

Name of the configured URL rewrite policy label. If you do not specify a policy label name, then URLs are not rewritten.

JavaScriptRewritePolicyLabel

Name of the configured JavaScript rewrite policy label. If you do not specify a policy label name, then JAVA scripts are not rewritten.

CSSRewritePolicyLabel

The configured CSS rewrite policylabel.

XMLRewritePolicyLabel

The configured XML rewrite policylabel.

XComponentRewritePolicyLabel

The configured X-Component rewrite policylabel.

ReqHdrRewritePolicyLabel

Name of the configured Request rewrite policy label. If you do not specify a policy label name, then requests are not rewritten.

ResHdrRewritePolicyLabel

Name of the configured Response rewrite policy label.

RegexForFindingURLinJavaScript

Name of the pattern set that contains the regular expressions, which match the URL in Java script.

RegexForFindingURLinCSS

Name of the pattern set that contains the regular expressions, which match the URL in the CSS.

RegexForFindingURLinXComponent

Name of the pattern set that contains the regular expressions, which match the URL in X Component.

RegexForFindingURLinXML

Name of the pattern set that contains the regular expressions, which match the URL in XML.

RegexForFindingCustomURLs

Name of the pattern set that contains the regular expressions, which match the URLs in the custom content type other than HTML, CSS, XML, XCOMP, and JavaScript. The custom content type should be included in the patset ns_cvpn_custom_content_types.

ClientConsumedCookies

Specify the name of the pattern set containing the names of the cookies, which are allowed between the client and the server. If a pattern set is not specified, Access Gateway does not allow any cookies between the client and the server. A cookie that is not specified in the pattern set is handled by Access Gateway on behalf of the client.

requirePersistentCookie

Specify whether a persistent session cookie is set and accepted for clientless access. If this parameter is set to ON, COM objects, such as MSOffice, which are invoked by the browser can access the files using clientless access. Use caution because the persistent cookie is stored on the disk.

isDefault

A value of true is returned if it is a default vpnclientlessrwprofile.

vpn formSSOAction

Sep 22, 2015

The following operations can be performed on "vpn formSSOAction":

add | rm | set | unset | show

add vpn formSSOAction

Creates a form-based single sign-on profile. Form based single sign-on allows users to log on one time to all protected applications in your network. Users can access web applications that require an HTML form-based logon without having to type their password again.

Synopsys

add vpn formSSOAction <name> -actionURL <URL> -userField <string> -passwdField <string> -ssoSuccessRule <expression> [-nameValuePair <string>] [-responsesize <positive_integer>] [-nvtype (STATIC | DYNAMIC)] [-submitMethod (GET | POST)]

Arguments

name

Name for the form based single sign-on profile.

actionURL

Root-relative URL to which the completed form is submitted.

userField

Name of the form field in which the user types in the user ID.

passwdField

Name of the form field in which the user types in the password.

ssoSuccessRule

Use a frequently used expression or create a custom expression describing the action that the form-based single sign-on profile takes when invoked by a policy. Used for verifying successful single sign-on.

nameValuePair

Other name-value pair attributes to send to the server, in addition to sending the user name and password. Value names are separated by an ampersand (&), such as in name1=value1&name2=value2.

responsesize

Maximum number of bytes to allow in the response size. Specifies the number of bytes in the response to be parsed for extracting the forms.

Default value: 8096

nvtype

How to process the name-value pair. Available settings function as follows:

* STATIC - The administrator-configured values are used.

* DYNAMIC - The response is parsed, the form is extracted, and then submitted.

Possible values: STATIC, DYNAMIC

Default value: NS_ACT_FSSO_NV_DYNAMIC

submitMethod

HTTP method (GET or POST) used by the single sign-on form to send the logon credentials to the logon server.

Possible values: GET, POST

Default value: NS_ACT_FSSO_SUBMIT_GET

---

rm vpn formSSOAction

Removes a configured form-based single sign-on profile.

Synopsys

rm vpn formSSOAction <name>

Arguments

name

Name of the form-based single sign-on profile to remove.

---

set vpn formSSOAction

Modifies the parameters of an existing form-based single sign-on profile (or action).

Synopsys

set vpn formSSOAction <name> [-actionURL <URL>] [-userField <string>] [-passwdField <string>] [-ssoSuccessRule <expression>] [-responsesize <positive_integer>] [-nameValuePair <string>] [-nvtype (STATIC | DYNAMIC)] [-submitMethod (GET | POST)]

Arguments

name

Name for the form based single sign-on profile.

actionURL

Root-relative URL to which the completed form is submitted.

userField

Name of the form field in which the user types in the user ID.

passwdField

Name of the form field in which the user types in the password.

ssoSuccessRule

Use a frequently used expression or create a custom expression describing the action that the form-based single sign-on profile takes when invoked by a policy. Used for verifying successful single sign-on.

responsesize

Maximum number of bytes to allow in the response size. Specifies the number of bytes in the response to be parsed for extracting the forms.

Default value: 8096

nameValuePair

Other name-value pair attributes to send to the server, in addition to sending the user name and password. Value names are separated by an ampersand (&), such as in name1=value1&name2=value2.

nvtype

How to process the name-value pair. Available settings function as follows:

* STATIC - The administrator-configured values are used.

* DYNAMIC - The response is parsed, the form is extracted, and then submitted.

Possible values: STATIC, DYNAMIC

Default value: NS_ACT_FSSO_NV_DYNAMIC

submitMethod

HTTP method (GET or POST) used by the single sign-on form to send the logon credentials to the logon server.

Possible values: GET, POST

Default value: NS_ACT_FSSO_SUBMIT_GET

---

unset vpn formSSOAction

Use this command to remove vpn formSSOAction settings.Refer to the set vpn formSSOAction command for meanings of the arguments.

Synopsys

unset vpn formSSOAction <name> [-responsesize] [-nameValuePair] [-nvtype] [-submitMethod]

---

show vpn formSSOAction

Displays the attributes of a form-based single sign-on profile.

Synopsys

show vpn formSSOAction [<name>]

Arguments

name

Name of the form-based single sign-on profile.

summary

fullValues

format

level

Outputs

actionURL

Root-relative URL to which the completed form is submitted.

userField

Username field.

stateflag

vpn global

Sep 22, 2015

The following operations can be performed on "vpn global":

bind | unbind | show

bind vpn global

Binds Access Gateway entities, including policies, globally.

Synopsys

bind vpn global [-policyName <string> [-priority <positive_integer>] [-secondary] [-groupExtraction]] [-intranetDomain <string>] [-intranetApplication <string>] [-nextHopServer <string>] [-urlName <string>] [-intranetIP <ip_addr> <netmask>] [-staServer <URL>] [-appController <URL>] [-sharefile <string>]

Arguments

policyName

Name of the policy to bind globally.

intranetDomain

Intranet domain name for single sign-on.

intranetApplication

Name of the intranet application to bind globally.

nextHopServer

Name of the next hop server to bind globally.

urlName

Name of the URL of the virtual server to bind globally.

intranetIP

Range of IP addresses in an address pool or individual IP addresses to bind globally.

staServer

Web address of the Secure Ticketing Authority (STA) server to be bound globally, in the following format:

'http(s)://FQDN/URLPATH'

appController

AppController server, in the format 'http(s)://IP/FQDN'

sharefile

Sharefile server, in the format 'IP:PORT / FQDN:PORT'

---

unbind vpn global

Unbinds Access Gateway policies to the virtual server globally.

Synopsys

unbind vpn global [-policyName <string> [-secondary] [-groupExtraction]] [-intranetDomain <string>] [-intranetApplication <string>] [-nextHopServer <string>] [-urlName <string>] [-intranetIP <ip_addr> <netmask>] [-staServer <URL>] [-appController <URL>] [-sharefile <string>]

Arguments

policyName

Name of the policy to unbind globally.

intranetDomain

A conflicting intranet domain name to be unbound.

intranetApplication

The name of a vpn intranet application to be unbound.

nextHopServer

The name of the next hop server to be unbound globally.

urlName

The name of a vpn url to be unbound from vpn global.

intranetIP

The intranet ip address or range to be unbound.

staServer

Secure Ticketing Authority (STA) server to be removed, in the format 'http(s)://IP/FQDN/URLPATH'

appController

AppController server to be removed, in the format 'http(s)://IP/FQDN'

sharefile

Sharefile server to be removed, in the format 'IP:PORT / FQDN:PORT'

---

show vpn global

Shows the Access Gateway policies that are bound to the virtual server globally.

Synopsys

show vpn global

Arguments

summary

fullValues

format

level

Outputs

stateflag

policyName

The name of the policy.

priority

The priority of the policy.

intranetDomain

The conflicting intranet domain name.

intranetApplication

The intranet vpn application.

nextHopServer

The name of the next hop server bound to vpn global.

urlName

The intranet url.

intranetIP

The intranet ip address or range.

netmask

The intranet ip address or range's netmask.

staServer

Configured Secure Ticketing Authority (STA) server.

staAuthID

Authority ID of the STA Server. Authority ID is used to match incoming STA Tickets in the SOCKS/CGP protocol with the right STA Server.

appController

Configured AppController server.

sharefile

Configured Sharefile server, in the format IP:PORT / FQDN:PORT

type

Bindpoint to which the policy is bound

policySubType

builtin

Indicates that a variable is a built-in (SYSTEM INTERNAL) type.

secondary

Bind the authentication policy as the secondary policy to use in a two-factor configuration. A user must then authenticate not only to a primary authentication server but also to a secondary authentication server. User groups are aggregated across both authentication servers. The user name must be exactly the same on both authentication servers, but the authentication servers can require different passwords.

groupExtraction

Bind the Authentication policy to a tertiary chain which will be used only for group extraction. The user will not authenticate against this server, and this will only be called it primary and/or secondary authentication has succeeded.

devno

count

vpn icaConnection

Sep 22, 2015

The following operations can be performed on "vpn icaConnection":

show vpn icaConnection

Displays active connections that use the ICA proxy.

Synopsys

show vpn icaConnection [-userName <string>]

Arguments

userName

User name for which to display connections.

summary

fullValues

Outputs

domain

The domain name.

srcIP

The client IP address.

srcPort

The client port.

destIP

The CPS server IP address.

destPort

The CPS server port.

peId

Core id of the session owner

stateflag

devno

count

vpn intranetApplication

Sep 22, 2015

The following operations can be performed on "vpn intranetApplication":

add | rm | show

add vpn intranetApplication

Defines intranet applications to be made accessible through the Access Gateway.

Synopsys

add vpn intranetApplication <intranetApplication> [<protocol>] ((<destIP> [-netmask <netmask>]) | <IPRange> | <hostName> | (-clientApplication <string> ... [-spoofIIP (ON | OFF)])) [-destPort <port[-port]>] [-interception (PROXY | TRANSPARENT) [-srcIP <ip_addr>] [-srcPort <port>]]

Arguments

intranetApplication

Name of the intranet application.

protocol

Protocol used by the intranet application. If protocol is set to BOTH, TCP and UDP traffic is allowed.

Possible values: TCP, UDP, ANY

destIP

Destination IP address, IP range, or host name of the intranet application. This address is the server IP address.

clientApplication

Names of the client applications, such as PuTTY and Xshell.

destPort

Destination TCP or UDP port number for the intranet application. Use a hyphen to specify a range of port numbers, for example 90-95.

Minimum value: 1

interception

Interception mode for the intranet application or resource. Correct value depends on the type of client software used to make connections. If the interception mode is set to TRANSPARENT, users connect with the Access Gateway Plug-in for Windows. With the PROXY setting, users connect with the Access Gateway Plug-in for Java.

Possible values: PROXY, TRANSPARENT

srcIP

Source IP address. Required if interception mode is set to PROXY. Default is the loopback address, 127.0.0.1.

srcPort

Source port for the application for which the Access Gateway virtual server proxies the traffic. If users are connecting from a device that uses the Access Gateway Plug-in for Java, applications must be configured manually by using the source IP address and TCP port values specified in the intranet application profile. If a port value is not set, the destination port value is used.

Minimum value: 1

---

rm vpn intranetApplication

Removes a configured intranet resource.

Synopsys

rm vpn intranetApplication <intranetApplication>

Arguments

intranetApplication

Name of the intranet resource to remove.

---

show vpn intranetApplication

Displays information about all the configured intranet resources, or displays detailed information about the specified intranet resource.

Synopsys

show vpn intranetApplication [<intranetApplication>]

Arguments

intranetApplication

Name of the intranet resource for which to display detailed information.

summary

fullValues

format

level

Outputs

protocol

The IP protocol, e.g. TCP, UDP or ANY

destIP

The destination IP address.

netmask

The destination netmask.

IPAddress

The IP address for the application. This address is the real application server IP address.

hostName

Name based interception. Names should be valid dns or wins names and will be resolved during interception on the sslvpn.

destPort

The destination port.

clientApplication

Names of the client applications, such as PuTTY and Xshell.

spoofIIP

This specifies whether to spoof this application on the client.

interception

The interception type, e.g. proxy or transparent.

srcIP

The source IP address.

srcPort

The source port.

vpn nextHopServer

Sep 22, 2015

The following operations can be performed on "vpn nextHopServer":

add | rm | show

add vpn nextHopServer

Enables an Access Gateway appliance in the first DMZ to communicate with one or more Access Gateway appliances in the second DMZ.

Synopsys

add vpn nextHopServer <name> <nextHopIP> <nextHopPort> [-secure (ON | OFF)]

Arguments

name

Name for the Access Gateway appliance in the first DMZ.

Maximum value: 32

nextHopIP

IP address or FQDN of the Access Gateway proxy in the second DMZ.

nextHopPort

Port number of the Access Gateway proxy in the second DMZ.

Minimum value: 1

Maximum value: 65535

secure

Use of a secure port, such as 443, for the double-hop configuration.

Possible values: ON, OFF

Default value: OFF

Example

```
add vpn nexthopserver dh1 10.1.1.1 80 -secure OFF
```

---

rm vpn nextHopServer

Removes a configured next hop server.

Synopsys

rm vpn nextHopServer <name>

Arguments

name

Name of the next hop server to remove.

Maximum value: 32

Example

rm vpn nexthopserver dh1

---

show vpn nextHopServer

Displays information about all the configured next Access Gateway hop servers, or detailed information about the specified Access Gateway next hop server.

Synopsys

show vpn nextHopServer [<name>]

Arguments

name

Name of the Access Gateway next hop server for which to display detailed information.

Maximum value: 32

summary

fullValues

format

level

Outputs

nextHopIP

Next hop IP address.

nextHopPort

Next hop port number.

secure

Next hop over secure connection.

stateflag

show vpn nexthopserver dh1

vpn parameter

Sep 22, 2015

The following operations can be performed on "vpn parameter":

set | unset | show

set vpn parameter

Sets global parameters for Access Gateway.

Synopsys

set vpn parameter [-httpPort <port> ...] [-winsIP <ip_addr>] [-dnsVserverName <string>] [-splitDns <splitDns>] [-sessTimeout <mins>] [-clientSecurity <expression> [-clientSecurityGroup <string>] [-clientSecurityMessage <string>]] [-clientSecurityLog (ON | OFF)] [-splitTunnel <splitTunnel>] [-localLanAccess (ON | OFF)] [-rfc1918 (ON | OFF)] [-spoofIIP (ON | OFF)] [-killConnections (ON | OFF)] [-transparentInterception (ON | OFF)] [-defaultAuthorizationAction (ALLOW | DENY)] [-authorizationGroup <string>] [-clientIdleTimeout <mins>] [-proxy <proxy>] [-allProtocolProxy <string> | -httpProxy <string> | -ftpProxy <string> | -socksProxy <string> | -gopherProxy <string> | -sslProxy <string>] [-proxyException <string>] [-proxyLocalBypass (ENABLED | DISABLED)] [-clientCleanupPrompt (ON | OFF)] [-forceCleanup <forceCleanup> ...] [-clientOptions <clientOptions> ...] [-clientConfiguration <clientConfiguration> ...] [-SSO (ON | OFF)] [-ssoCredential (PRIMARY | SECONDARY)] [-windowsAutoLogon (ON | OFF)] [-useMIP (NS | OFF)] [-useIIP <useIIP>] [-clientDebug <clientDebug>] [-loginScript <input_filename>] [-logoutScript <input_filename>] [-homePage <URL>] [-icaProxy (ON | OFF)] [-wihome <URL>] [-citrixReceiverHome <URL>] [-wiPortalMode (NORMAL | COMPACT)] [-ClientChoices (ON | OFF)] [-iipDnsSuffix <string>] [-forcedTimeout <mins>] [-forcedTimeoutWarning <mins>] [-ntDomain <string>] [-clientlessVpnMode <clientlessVpnMode>] [-clientlessModeUrlEncoding <clientlessModeUrlEncoding>] [-clientlessPersistentCookie <clientlessPersistentCookie>] [-emailHome <URL>] [-allowedLoginGroups <string>] [-encryptCsecExp (ENABLED | DISABLED)] [-appTokenTimeout <positive_integer>] [-mdxTokenTimeout <positive_integer>] [-UITHEME <UITHEME>] [-SecureBrowse (ENABLED | DISABLED)] [-storefronturl <string>] [-kcdAccount <string>]

Arguments

httpPort

Destination port numbers other than port 80, added as a comma-separated list. Traffic to these ports is processed as HTTP traffic, which allows functionality, such as HTTP authorization and single sign-on to a web application to work.

Minimum value: 1

winsIP

WINS server IP address to add to Access Gateway for name resolution.

dnsVserverName

Name of the DNS virtual server for the user session.

splitDns

Route the DNS requests to the local DNS server configured on the user device, or Access Gateway (remote), or both.

Possible values: LOCAL, REMOTE, BOTH

sessTimeout

Number of minutes after which the session times out.

Default value: 30

Minimum value: 1

clientSecurity

Specify the client security check for the user device to permit an Access Gateway session. The web address or IP address is not included in the expression for the client security check.

clientSecurityLog

Set the logging of client security checks.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_ON

splitTunnel

Send, through the tunnel, traffic only for intranet applications that are defined in Access Gateway. Route all other traffic directly to the Internet. The OFF setting routes all traffic through Access Gateway. With the REVERSE setting, intranet applications define the network traffic that is not intercepted. All network traffic directed to internal IP addresses bypasses the VPN tunnel, while other traffic goes through Access Gateway. Reverse split tunneling can be used to log all non-local LAN traffic. For example, if users have a home network and are logged on through the Access Gateway Plug-in, network traffic destined to a printer or another device within the home network is not intercepted.

Possible values: ON, OFF, REVERSE

Default value: VPN_SESS_ACT_OFF

localLanAccess

Set local LAN access. If split tunneling is OFF, and you set local LAN access to ON, the local client can route traffic to its local interface. When the local area network switch is specified, this combination of switches is useful. The client can allow local LAN access to devices that commonly have non-routable addresses, such as local printers or local file servers.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

rfc1918

As defined in the local area network, allow only the following local area network addresses to bypass the VPN

tunnel when the local LAN access feature is enabled:

* 10.*.*.*,

* 172.16.*.*,

* 192.168.*.*

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

spoofIIP

Indicate whether or not the application requires IP spoofing, which routes the connection to the intranet application through the virtual adapter.

Possible values: ON, OFF

Default value: ON

killConnections

Specify whether the Access Gateway Plug-in should disconnect all preexisting connections, such as the connections existing before the user logged on to Access Gateway, and prevent new incoming connections on the Access Gateway Plug-in for Windows and MAC when the user is connected to Access Gateway and split tunneling is disabled.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

transparentInterception

Allow access to network resources by using a single IP address and subnet mask or a range of IP addresses. The OFF setting sets the mode to proxy, in which you configure destination and source IP addresses and port numbers. If you are using the Access Gateway Plug-in for Windows, set this parameter to ON, in which the mode is set to transparent. If you are using the Access Gateway Plug-in for Java, set this parameter to OFF.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_ON

windowsClientType

The Windows client type. Choose between two types of Windows Client\\

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed\\

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.

Possible values: AGENT, PLUGIN

Default value: VPN_SESS_ACT_CLT_AGENT

defaultAuthorizationAction

Specify the network resources that users have access to when they log on to the internal network. The default setting for authorization is to deny access to all network resources. Citrix recommends using the default global setting and then creating authorization policies to define the network resources users can access. If you set the default authorization policy to DENY, you must explicitly authorize access to any network resource, which improves security.

Possible values: ALLOW, DENY

authorizationGroup

Comma-separated list of groups in which the user is placed when none of the groups that the user is a part of is configured on Access Gateway. The authorization policy can be bound to these groups to control access to the resources.

clientIdleTimeout

Time, in minutes, after which to time out the user session if Access Gateway does not detect mouse or keyboard activity.

Minimum value: 1

Maximum value: 9999

proxy

Set options to apply proxy for accessing the internal resources. Available settings function as follows:

* BROWSER - Proxy settings are configured only in Internet Explorer and Firefox browsers.

* NS - Proxy settings are configured on the NetScaler appliance.

* OFF - Proxy settings are not configured.

Possible values: BROWSER, NS, OFF

allProtocolProxy

IP address of the proxy server to use for all protocols supported by Access Gateway.

httpProxy

IP address of the proxy server to be used for HTTP access for all subsequent connections to the internal network.

ftpProxy

IP address of the proxy server to be used for FTP access for all subsequent connections to the internal network.

socksProxy

IP address of the proxy server to be used for SOCKS access for all subsequent connections to the internal network.

gopherProxy

IP address of the proxy server to be used for GOPHER access for all subsequent connections to the internal network.

sslProxy

IP address of the proxy server to be used for SSL access for all subsequent connections to the internal network.

proxyException

Proxy exception string that will be configured in the browser for bypassing the previously configured proxies. Allowed only if proxy type is Browser.

proxyLocalBypass

Bypass proxy server for local addresses option in Internet Explorer and Firefox proxy server settings.

Possible values: ENABLED, DISABLED

Default value: VPN_SESS_ACT_DISABLED

clientCleanupPrompt

Prompt for client-side cache clean-up when a client-initiated session closes.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_ON

forceCleanup

Force cache clean-up when the user closes a session. You can specify all, none, or any combination of the client-side items.

clientOptions

Display only the configured menu options when you select the "Configure Access Gateway" option in the Access Gateway Plug-in's system tray icon for Windows.

clientConfiguration

Display only the configured tabs when you select the "Configure Access Gateway" option in the Access Gateway Plug-in's system tray icon for Windows.

SSO

Set single sign-on (SSO) for the session. When the user accesses a server, the user's logon credentials are passed to the server for authentication.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

ssoCredential

Specify whether to use the primary or secondary authentication credentials for single sign-on to the server.

Possible values: PRIMARY, SECONDARY

Default value: VPN_SESS_ACT_USE_PRIMARY_CREDENTIALS

windowsAutoLogon

Enable or disable the Windows Auto Logon for the session. If a VPN session is established after this setting is enabled, the user is automatically logged on by using Windows credentials after the system is restarted.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

useMIP

Enable or disable the use of a unique IP address alias, or a mapped IP address, as the client IP address for each client session. Allow Access Gateway to use the mapped IP address as an intranet IP address when all other IP addresses are not available.

When IP pooling is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

Possible values: NS, OFF

Default value: VPN_SESS_ACT_NS

useIIP

Define IP address pool options. Available settings function as follows:

* SPILLOVER - When an address pool is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

* NOSPILLOVER - When intranet IP addresses are enabled and the mapped IP address is not used, the Transfer Login page appears for users who have used all available intranet IP addresses.

* OFF - Address pool is not configured.

Possible values: NOSPILLOVER, SPILLOVER, OFF

Default value: VPN_SESS_ACT_NOSPILLOVER

clientDebug

Set the trace level on Access Gateway. Technical support technicians use these debug logs for in-depth debugging and troubleshooting purposes. Available settings function as follows:

* DEBUG - Detailed debug messages are collected and written into the specified file.

* STATS - Application audit level error messages and debug statistic counters are written into the specified file.

* EVENTS - Application audit-level error messages are written into the specified file.

* OFF - Only critical events are logged into the Windows Application Log.

Possible values: debug, stats, events, OFF

Default value: VPN_FLAG_TRACE_OFF

loginScript

Path to the logon script that is run when a session is established. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

logoutScript

Path to the logout script. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

homePage

Web address of the home page that appears when users log on. Otherwise, users receive the default home page for Access Gateway, which is the Access Interface.

icaProxy

Enable ICA proxy to configure secure Internet access to servers running Citrix XenApp or XenDesktop by using Citrix Receiver instead of the Access Gateway Plug-in.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

wihome

Web address of the Web Interface server, such as http://<ipAddress>/Citrix/XenApp, or Receiver for Web, which enumerates the virtualized resources, such as XenApp, XenDesktop, and cloud applications. This web address is used as the home page in ICA proxy mode.

If Client Choices is ON, you must configure this setting. Because the user can choose between FullClient and ICAProxy, the user may see a different home page. An Internet web site may appear if the user gets the FullClient option, or a Web Interface site if the user gets the ICAProxy option. If the setting is not configured, the XenApp option does not appear as a client choice.

citrixReceiverHome

Web address for the Citrix Receiver home page. Configure Access Gateway so that when users log on to the appliance, the Access Gateway Plug-in opens a web browser that allows single sign-on to the Citrix Receiver home page.

wiPortalMode

Layout on the Access Interface. The COMPACT value indicates the use of small icons.

Possible values: NORMAL, COMPACT

ClientChoices

Provide users with multiple logon options. With client choices, users have the option of logging on by using the Access Gateway Plug-in for Windows, Access Gateway Plug-in for Java, the Web Interface, or clientless access from one location. Depending on how Access Gateway is configured, users are presented with up to three icons for logon choices. The most common are the Access Gateway Plug-in for Windows, Web Interface, and clientless access.

Possible values: ON, OFF

Default value: VPN_SESS_ACT_OFF

epaClientType

Choose between two types of End point Windows Client

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.

Possible values: AGENT, PLUGIN

iipDnsSuffix

An intranet IP DNS suffix. When a user logs on to Access Gateway and is assigned an IP address, a DNS record for the user name and IP address combination is added to Access Gateway DNS cache. You can configure a DNS suffix to append to the user name when the DNS record is added to the cache. You can reach to the host from where the user is logged on by using the user's name, which can be easier to remember than an IP address. When the user logs off from Access Gateway, the record is removed from the DNS cache.

forcedTimeout

Force a disconnection from the Access Gateway Plug-in with Access Gateway after a specified number of minutes. If the session closes, the user must log on again.

Minimum value: 1

Maximum value: 65535

forcedTimeoutWarning

Number of minutes to warn a user before the user session is disconnected.

Minimum value: 1

Maximum value: 255

ntDomain

Single sign-on domain to use for single sign-on to applications in the internal network. This setting can be overwritten by the domain that users specify at the time of logon or by the domain that the authentication server returns.

clientlessVpnMode

Enable clientless access for web, XenApp or XenDesktop, and FileShare resources without installing the Access Gateway Plug-in. Available settings function as follows:

* ON - Allow only clientless access.

* OFF - Allow clientless access after users log on with the Access Gateway Plug-in.

* DISABLED - Do not allow clientless access.

Possible values: ON, OFF, DISABLED

Default value: VPN_SESS_ACT_CVPNMODE_OFF

clientlessModeUrlEncoding

When clientless access is enabled, you can choose to encode the addresses of internal web applications or to leave the address as clear text. Available settings function as follows:

* OPAQUE - Use standard encoding mechanisms to make the domain and protocol part of the resource unclear to users.

* CLEAR - Do not encode the web address and make it visible to users.

* ENCRYPT - Allow the domain and protocol to be encrypted using a session key. When the web address is encrypted, the URL is different for each user session for the same web resource. If users bookmark the encoded web address, save it in the web browser and then log off, they cannot connect to the web address when they log on and use the bookmark. If users save the encrypted bookmark in the Access Interface during their session, the bookmark works each time the user logs on.

Possible values: TRANSPARENT, OPAQUE, ENCRYPT

Default value: VPN_SESS_ACT_CVPN_ENC_OPAQUE

clientlessPersistentCookie

State of persistent cookies in clientless access mode. Persistent cookies are required for accessing certain features of SharePoint, such as opening and editing Microsoft Word, Excel, and PowerPoint documents hosted on the SharePoint server. A persistent cookie remains on the user device and is sent with each HTTP request. Access Gateway encrypts the persistent cookie before sending it to the plug-in on the user device, and refreshes the cookie periodically as long as the session exists. The cookie becomes stale if the session ends. Available settings function as follows:

* ALLOW - Enable persistent cookies. Users can open and edit Microsoft documents stored in SharePoint.

* DENY - Disable persistent cookies. Users cannot open and edit Microsoft documents stored in SharePoint.

* PROMPT - Prompt users to allow or deny persistent cookies during the session. Persistent cookies are not required for clientless access if users do not connect to SharePoint.

Possible values: ALLOW, DENY, PROMPT

Default value: VPN_SESS_ACT_CVPN_PERSCOOKIE_DENY

emailHome

Web address for the web-based email, such as Outlook Web Access.

allowedLoginGroups

Specify groups that have permission to log on to Access Gateway. Users who do not belong to this group or groups are denied access even if they have valid credentials.

encryptCsecExp

Enable encryption of client security expressions.

Possible values: ENABLED, DISABLED

Default value: VPN_SESS_ACT_ENABLED

appTokenTimeout

The timeout value in seconds for tokens to access cloud gateway applications

Default value: 100

Minimum value: 1

Maximum value: 255

mdxTokenTimeout

Validity of MDX Token in minutes. This token is used for mdx services to access backend and valid HEAD and GET request.

Default value: 10

Minimum value: 1

Maximum value: 1440

UITHEME

Set VPN UI Theme to Green-Bubble, Caxton or Custom; default is Caxton.

Possible values: DEFAULT, GREENBUBBLE, CUSTOM

SecureBrowse

Allow users to connect through Access Gateway to network resources from iOS and Android mobile devices with Citrix Receiver. Users do not need to establish a full VPN tunnel to access resources in the secure network.

Possible values: ENABLED, DISABLED

Default value: VPN_SESS_ACT_ENABLED

storefronturl

Web address for StoreFront to be used in this session for enumeration of resources from XenApp or XenDesktop.

kcdAccount

The kcd account details to be used in SSO

Example

set vpn parameter -httpport 80 90 -winsIP 192.168.0.220 -dnsVserverName mydns -sessTimeout 240

---

unset vpn parameter

Removes global parameters for Access Gateway..Refer to the set vpn parameter command for meanings of the arguments.

Synopsys

unset vpn parameter [-httpPort] [-winsIP] [-dnsVserverName] [-splitDns] [-sessTimeout] [-clientSecurity] [-clientSecurityGroup] [-clientSecurityMessage] [-clientSecurityLog] [-authorizationGroup] [-clientIdleTimeout] [-allProtocolProxy | -httpProxy | -ftpProxy | -socksProxy | -gopherProxy | -sslProxy] [-proxyException] [-forceCleanup] [-clientOptions] [-clientConfiguration] [-loginScript] [-logoutScript] [-homePage] [-proxy] [-wihome] [-citrixReceiverHome] [-wiPortalMode] [-iipDnsSuffix] [-forcedTimeout] [-forcedTimeoutWarning] [-defaultAuthorizationAction] [-ntDomain] [-clientlessVpnMode] [-emailHome] [-clientlessModeUrlEncoding] [-clientlessPersistentCookie] [-allowedLoginGroups] [-appTokenTimeout] [-mdxTokenTimeout] [-storefronturl] [-UITHEME] [-kcdAccount] [-splitTunnel] [-localLanAccess] [-rfc1918] [-spoofIIP] [-killConnections] [-transparentInterception] [-proxyLocalBypass] [-clientCleanupPrompt] [-SSO] [-ssoCredential] [-windowsAutoLogon] [-useMIP] [-useIIP] [-clientDebug] [-icaProxy] [-ClientChoices] [-encryptCsecExp] [-SecureBrowse]

---

show vpn parameter

Displays the configured Access Gateway parameters.

Synopsys

show vpn parameter

Arguments

format

level

Outputs

name

The VPN name.

httpPort

The HTTP Port.

winsIP

The WINS server IP address used for WINS host resolution by the VPN.

dnsVserverName

The configured DNS vserver used for DNS host resolution by the VPN.

splitDns

The VPN client SplitDns state.

sessTimeout

The session timeout, in minutes.

clientSecurity

The client security check applied to client sessions. This is in the form of an Expression. Expressions are simple conditions, such as a test for equality, applied to operands, such as a URL string or an IP address. Expression syntax is described in the Installation and Configuration Guide.

clientSecurityGroup

The client security group that will be assigned on failure of the client security check. Users can in general be organized into Groups. In this case, the Client Security Group may have a more restrictive security policy.

clientSecurityMessage

The client security message that will be displayed on failure of the client security check.

clientSecurityLog

Set the logging of client security checks.

splitTunnel

Send, through the tunnel, traffic only for intranet applications that are defined in Access Gateway. Route all other traffic directly to the Internet. The OFF setting routes all traffic through Access Gateway. With the REVERSE setting, intranet applications define the network traffic that is not intercepted. All network traffic directed to internal IP addresses bypasses the VPN tunnel, while other traffic goes through Access Gateway. Reverse split tunneling can be used to log all non-local LAN traffic. For example, if users have a home network and are logged on through the Access Gateway Plug-in, network traffic destined to a printer or another device within the home network is not intercepted.

localLanAccess

Set local LAN access. If split tunneling is OFF, and you set local LAN access to ON, the local client can route traffic to its local interface. When the local area network switch is specified, this combination of switches is useful. The client can allow local LAN access to devices that commonly have non-routable addresses, such as local printers or local file servers.

rfc1918

Only allow RFC1918 local addresses when local LAN access feature is enabled.

spoofIIP

Controls the Spoofing of Intranet IP to the Windows Applications by Windows VPN client when the end-user is connected to SSL VPN in '-splittunnel OFF' mode.

killConnections

Determines whether Windows VPN client should kill all pre-existing connections (ie, the connections existing before the end user logged in to SSL VPN) and prevent new incoming connections on the Windows Client system when the end-user is connected to SSL VPN in '-splittunnel OFF' mode.

transparentInterception

Allow access to network resources by using a single IP address and subnet mask or a range of IP addresses. The OFF setting sets the mode to proxy, in which you configure destination and source IP addresses and port numbers. If you are using the Access Gateway Plug-in for Windows, set this parameter to ON, in which the mode is set to transparent. If you are using the Access Gateway Plug-in for Java, set this parameter to OFF.

windowsClientType

The windows client type.NOTE: This attribute is deprecated.This argument is deprecated since ActiveX is no longer supported.

defaultAuthorizationAction

The Authentication Action, e.g. allow or deny.

authorizationGroup

The authorization group applied to the session.

clientIdleTimeout

The client idle timeout, in minutes.

clientIdleTimeoutWarning

The time after which the client gets a timeout warning, in minutes.

proxy

Proxy configuration for the session.

allProtocolProxy

Address set for all proxies.

httpProxy

IP address of the proxy server to be used for HTTP access for all subsequent connections to the internal network.

ftpProxy

IP address of the proxy server to be used for FTP access for all subsequent connections to the internal network.

socksProxy

IP address of the proxy server to be used for SOCKS access for all subsequent connections to the internal network.

gopherProxy

IP address of the proxy server to be used for GOPHER access for all subsequent connections to the internal network.

sslProxy

IP address of the proxy server to be used for SSL access for all subsequent connections to the internal network.

proxyException

The Proxy Exception string that is configured in the Browser for bypassing the previously configured proxies. Allowed only if proxy type is Browser.

proxyLocalBypass

Bypass proxy server for local addresses option in Internet Explorer and Firefox proxy server settings.

clientCleanupPrompt

Prompt for client-side cache clean-up when a client-initiated session closes.

forceCleanup

Whether or not to force a cleanup on exit from the VPN session.

clientOptions

List of configured buttons(and/or menu options in the docked client) in the Windows VPN client.

clientConfiguration

List of configured tabs in the Windows VPN client.

SSO

Enable or Disable Single Sign-On.

ssoCredential

Specify whether to use the primary or secondary authentication credentials for single sign-on to the server.

windowsAutoLogon

Enable or Disable Windows Auto Logon.

useMIP

Enables or disables the use of a Mapped IP address for the session.

useIIP

Define IP address pool options. Available settings function as follows:

* SPILLOVER - When an address pool is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

* NOSPILLOVER - When intranet IP addresses are enabled and the mapped IP address is not used, the Transfer Login page appears for users who have used all available intranet IP addresses.

* OFF - Address pool is not configured.

clientDebug

Whether or not to add debugging information to the activity log on the client.

loginScript

Path to the logon script that is run when a session is established. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

logoutScript

Path to the logout script. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

homePage

The home page URL, or 'none'. 'none' is case sensitive.

icaProxy

Enable ICA proxy to configure secure Internet access to servers running Citrix XenApp or XenDesktop by using Citrix Receiver instead of the Access Gateway Plug-in.

wihome

Web address of the Web Interface server, such as http://<ipAddress>/Citrix/XenApp, or Receiver for Web, which enumerates the virtualized resources, such as XenApp, XenDesktop, and cloud applications. This web address is used as the home page in ICA proxy mode.

If Client Choices is ON, you must configure this setting. Because the user can choose between FullClient and ICAProxy, the user may see a different home page. An Internet web site may appear if the user gets the FullClient option, or a Web Interface site if the user gets the ICAProxy option. If the setting is not configured, the XenApp option does not appear as a client choice.

citrixReceiverHome

Web address for the Citrix Receiver home page. Configure Access Gateway so that when users log on to the appliance, the Access Gateway Plug-in opens a web browser that allows single sign-on to the Citrix

Receiver home page.

wiPortalMode

Layout on the Access Interface. The COMPACT value indicates the use of small icons.

ClientChoices

Provide users with multiple logon options. With client choices, users have the option of logging on by using the Access Gateway Plug-in for Windows, Access Gateway Plug-in for Java, the Web Interface, or clientless access from one location. Depending on how Access Gateway is configured, users are presented with up to three icons for logon choices. The most common are the Access Gateway Plug-in for Windows, Web Interface, and clientless access.

epaClientType

Choose between two types of End point Windows Client

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.NOTE: This attribute is deprecated.This argument is not supported

iipDnsSuffix

The DNS suffix for the intranet IP address.

forcedTimeout

The time, in minutes after which a timeout is forced.

forcedTimeoutWarning

The time, in minutes, after which a timeout warning is issued.

ntDomain

Single sign-on domain to use for single sign-on to applications in the internal network. This setting can be overwritten by the domain that users specify at the time of logon or by the domain that the authentication server returns.

clientlessVpnMode

Whether clientlessVPN is available to the session.

clientlessModeUrlEncoding

URL encoding to be used for clientless mode.

clientlessPersistentCookie

State of persistent cookies in clientless access mode. Persistent cookies are required for accessing certain features of SharePoint, such as opening and editing Microsoft Word, Excel, and PowerPoint documents

hosted on the SharePoint server. A persistent cookie remains on the user device and is sent with each HTTP request. Access Gateway encrypts the persistent cookie before sending it to the plug-in on the user device, and refreshes the cookie periodically as long as the session exists. The cookie becomes stale if the session ends. Available settings function as follows:

* ALLOW - Enable persistent cookies. Users can open and edit Microsoft documents stored in SharePoint.

* DENY - Disable persistent cookies. Users cannot open and edit Microsoft documents stored in SharePoint.

* PROMPT - Prompt users to allow or deny persistent cookies during the session. Persistent cookies are not required for clientless access if users do not connect to SharePoint.

emailHome

Web address for the web-based email, such as Outlook Web Access.

allowedLoginGroups

Specify groups that have permission to log on to Access Gateway. Users who do not belong to this group or groups are denied access even if they have valid credentials.

encryptCsecExp

Enable encryption of client security expressions.

appTokenTimeout

The timeout value in seconds for tokens to access cloud gateway applications

mdxTokenTimeout

Validity of MDX Token in minutes. This token is used for mdx services to access backend and valid HEAD and GET request.

UITHEME

Set VPN UI Theme to Green-Bubble, Caxton or Custom; default is Caxton.

SecureBrowse

Allow users to connect through Access Gateway to network resources from iOS and Android mobile devices with Citrix Receiver. Users do not need to establish a full VPN tunnel to access resources in the secure network.

storefronturl

Web address for StoreFront to be used in this session for enumeration of resources from XenApp or XenDesktop.

kcdAccount

The kcd account details to be used in SSO

vpn samlSSOProfile

Sep 22, 2015

The following operations can be performed on "vpn samlSSOProfile":

add | rm | set | unset | show

add vpn samlSSOProfile

Creates a SAML single sign-on profile. This profile is employed in triggering saml assertion to a target service based on traffic profile.

Synopsys

add vpn samlSSOProfile <name> -samlSigningCertName <string> -assertionConsumerServiceURL <URL> -relaystateRule <expression> [-sendPassword (ON | OFF)] [-samlIssuerName <string>]

Arguments

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

samlSigningCertName

Name of the signing authority as given in the SAML server?s SSL certificate.

assertionConsumerServiceURL

URL to which the assertion is to be sent.

relaystateRule

Expression to extract relaystate to be sent along with assertion.

sendPassword

Option to send password in assertion.

Possible values: ON, OFF

Default value: OFF

samlIssuerName

The name to be used in requests sent from Netscaler to IdP to uniquely identify Netscaler.

rm vpn samlSSOProfile

Deletes an existing saml single sign-on traffic profile.

Synopsys

rm vpn samlSSOProfile <name>

Arguments

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

---

set vpn samlSSOProfile

Modifies the specified attributes of a saml single sign-on traffic profile.

Synopsys

set vpn samlSSOProfile <name> [-samlSigningCertName <string>] [-assertionConsumerServiceURL <URL>] [-sendPassword (ON | OFF)] [-samlIssuerName <string>] [-relaystateRule <expression>]

Arguments

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

samlSigningCertName

Name of the signing authority as given in the SAML server?s SSL certificate.

assertionConsumerServiceURL

URL to which the assertion is to be sent.

sendPassword

Option to send password in assertion.

Possible values: ON, OFF

Default value: OFF

samlIssuerName

The name to be used in requests sent from Netscaler to IdP to uniquely identify Netscaler.

relaystateRule

Expression to extract relaystate to be sent along with assertion.

---

unset vpn samlSSOProfile

Use this command to remove vpn samlSSOProfile settings.Refer to the set vpn samlSSOProfile command for meanings of the arguments.

Synopsys

unset vpn samlSSOProfile <name> [-samlSigningCertName] [-sendPassword] [-samlIssuerName]

---

show vpn samlSSOProfile

Displays information about all configured saml single sign-on profiles, or displays detailed information about the specified action.

Synopsys

show vpn samlSSOProfile [<name>]

Arguments

name

Name for the new saml single sign-on profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after an SSO action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

summary

fullValues

format

level

Outputs

samlSigningCertName

Name of the signing authority as given in the SAML server?s SSL certificate.

assertionConsumerServiceURL

URL to which the assertion is to be sent.

sendPassword

Option to send password in assertion.

samlIssuerName

The name to be used in requests sent from Netscaler to IdP to uniquely identify Netscaler.

relaystateRule

Expression to extract relaystate to be sent along with assertion.

devno

count

stateflag

vpn sessionAction

Sep 22, 2015

The following operations can be performed on "vpn sessionAction":

add | rm | set | unset | show

add vpn sessionAction

Adds a session profile (action) to bind to a session policy that is applied to a user session if the policy expression conditions are met.

Synopsys

add vpn sessionAction <name> [-httpPort <port> ...] [-winsIP <ip_addr>] [-dnsVserverName <string>] [-splitDns <splitDns>] [-sessTimeout <mins>] [-clientSecurity <expression> [-clientSecurityGroup <string>] [-clientSecurityMessage <string>]] [-clientSecurityLog (ON | OFF)] [-splitTunnel <splitTunnel>] [-localLanAccess (ON | OFF)] [-rfc1918 (ON | OFF)] [-spoofIIP (ON | OFF)] [-killConnections (ON | OFF)] [-transparentInterception (ON | OFF)] [-defaultAuthorizationAction (ALLOW | DENY)] [-authorizationGroup <string>] [-clientIdleTimeout <mins>] [-proxy <proxy>] [-allProtocolProxy <string> | -httpProxy <string> | -ftpProxy <string> | -socksProxy <string> | -gopherProxy <string> | -sslProxy <string>] [-proxyException <string>] [-proxyLocalBypass (ENABLED | DISABLED)] [-clientCleanupPrompt (ON | OFF)] [-forceCleanup <forceCleanup> ...] [-clientOptions <clientOptions> ...] [-clientConfiguration <clientConfiguration> ...] [-SSO (ON | OFF)] [-ssoCredential (PRIMARY | SECONDARY)] [-windowsAutoLogon (ON | OFF)] [-useMIP (NS | OFF)] [-useIIP <useIIP>] [-clientDebug <clientDebug>] [-loginScript <input_filename>] [-logoutScript <input_filename>] [-homePage <URL>] [-icaProxy (ON | OFF)] [-wihome <URL>] [-citrixReceiverHome <URL>] [-wiPortalMode (NORMAL | COMPACT)] [-ClientChoices (ON | OFF)] [-iipDnsSuffix <string>] [-forcedTimeout <mins>] [-forcedTimeoutWarning <mins>] [-ntDomain <string>] [-clientlessVpnMode <clientlessVpnMode>] [-emailHome <URL>] [-clientlessModeUrlEncoding <clientlessModeUrlEncoding>] [-clientlessPersistentCookie <clientlessPersistentCookie>] [-allowedLoginGroups <string>] [-SecureBrowse (ENABLED | DISABLED)] [-storefronturl <string>] [-kcdAccount <string>]

Arguments

name

Name for the Access Gateway profile (action). Must begin with an ASCII alphabetic or underscore (_) character, and must consist only of ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the profile is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

httpPort

Destination port numbers other than port 80, added as a comma-separated list. Traffic to these ports is processed as HTTP traffic, which allows functionality, such as HTTP authorization and single sign-on to a web application to work.

Minimum value: 1

winsIP

WINS server IP address to add to Access Gateway for name resolution.

dnsVserverName

Name of the DNS virtual server for the user session.

splitDns

Route the DNS requests to the local DNS server configured on the user device, or Access Gateway (remote), or both.

Possible values: LOCAL, REMOTE, BOTH

sessTimeout

Number of minutes after which the session times out.

Minimum value: 1

clientSecurity

Specify the client security check for the user device to permit an Access Gateway session. The web address or IP address is not included in the expression for the client security check.

clientSecurityLog

Set the logging of client security checks.

Possible values: ON, OFF

splitTunnel

Send, through the tunnel, traffic only for intranet applications that are defined in Access Gateway. Route all other traffic directly to the Internet. The OFF setting routes all traffic through Access Gateway. With the REVERSE setting, intranet applications define the network traffic that is not intercepted. All network traffic directed to internal IP addresses bypasses the VPN tunnel, while other traffic goes through Access Gateway. Reverse split tunneling can be used to log all non-local LAN traffic. For example, if users have a home network and are logged on through the Access Gateway Plug-in, network traffic destined to a printer or another device within the home network is not intercepted.

Possible values: ON, OFF, REVERSE

localLanAccess

Set local LAN access. If split tunneling is OFF, and you set local LAN access to ON, the local client can route traffic to its local interface. When the local area network switch is specified, this combination of switches is useful. The client can allow local LAN access to devices that commonly have non-routable addresses, such as local printers or local file servers.

Possible values: ON, OFF

rfc1918

As defined in the local area network, allow only the following local area network addresses to bypass the VPN tunnel when the local LAN access feature is enabled:

* 10.*.*.*,

* 172.16.*.*,

* 192.168.*.*

Possible values: ON, OFF

spoofIIP

IP address that the intranet application uses to route the connection through the virtual adapter.

Possible values: ON, OFF

killConnections

Specify whether the Access Gateway Plug-in should disconnect all preexisting connections, such as the connections existing before the user logged on to Access Gateway, and prevent new incoming connections on the Access Gateway Plug-in for Windows and MAC when the user is connected to Access Gateway and split tunneling is disabled.

Possible values: ON, OFF

transparentInterception

Allow access to network resources by using a single IP address and subnet mask or a range of IP addresses. The OFF setting sets the mode to proxy, in which you configure destination and source IP addresses and port numbers. If you are using the Access Gateway Plug-in for Windows, set this parameter to ON, in which the mode is set to transparent. If you are using the Access Gateway Plug-in for Java, set this parameter to OFF.

Possible values: ON, OFF

windowsClientType

Choose between two types of Windows Client\\

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed\\

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.

Possible values: AGENT, PLUGIN

defaultAuthorizationAction

Specify the network resources that users have access to when they log on to the internal network. The default setting for authorization is to deny access to all network resources. Citrix recommends using the default global setting and then creating authorization policies to define the network resources users can access. If you set the default authorization policy to DENY, you must explicitly authorize access to any network resource, which improves

security.

Possible values: ALLOW, DENY

authorizationGroup

Comma-separated list of groups in which the user is placed when none of the groups that the user is a part of is configured on Access Gateway. The authorization policy can be bound to these groups to control access to the resources.

clientIdleTimeout

Time, in minutes, after which to time out the user session if Access Gateway does not detect mouse or keyboard activity.

Minimum value: 1

Maximum value: 9999

proxy

Set options to apply proxy for accessing the internal resources. Available settings function as follows:

* BROWSER - Proxy settings are configured only in Internet Explorer and Firefox browsers.

* NS - Proxy settings are configured on the NetScaler appliance.

* OFF - Proxy settings are not configured.

Possible values: BROWSER, NS, OFF

allProtocolProxy

IP address of the proxy server to use for all protocols supported by Access Gateway.

httpProxy

IP address of the proxy server to be used for HTTP access for all subsequent connections to the internal network.

ftpProxy

IP address of the proxy server to be used for FTP access for all subsequent connections to the internal network.

socksProxy

IP address of the proxy server to be used for SOCKS access for all subsequent connections to the internal network.

gopherProxy

IP address of the proxy server to be used for GOPHER access for all subsequent connections to the internal network.

sslProxy

IP address of the proxy server to be used for SSL access for all subsequent connections to the internal network.

proxyException

Proxy exception string that will be configured in the browser for bypassing the previously configured proxies. Allowed only if proxy type is Browser.

proxyLocalBypass

Bypass proxy server for local addresses option in Internet Explorer and Firefox proxy server settings.

Possible values: ENABLED, DISABLED

clientCleanupPrompt

Prompt for client-side cache clean-up when a client-initiated session closes.

Possible values: ON, OFF

forceCleanup

Force cache clean-up when the user closes a session. You can specify all, none, or any combination of the client-side items.

clientOptions

Display only the configured menu options when you select the "Configure Access Gateway" option in the Access Gateway Plug-in's system tray icon for Windows.

clientConfiguration

Display only the configured tabs when you select the "Configure Access Gateway" option in the Access Gateway Plug-in's system tray icon for Windows.

SSO

Set single sign-on (SSO) for the session. When the user accesses a server, the user's logon credentials are passed to the server for authentication.

Possible values: ON, OFF

ssoCredential

Specify whether to use the primary or secondary authentication credentials for single sign-on to the server.

Possible values: PRIMARY, SECONDARY

windowsAutoLogon

Enable or disable the Windows Auto Logon for the session. If a VPN session is established after this setting is enabled, the user is automatically logged on by using Windows credentials after the system is restarted.

Possible values: ON, OFF

useMIP

Enable or disable the use of a unique IP address alias, or a mapped IP address, as the client IP address for each client session. Allow Access Gateway to use the mapped IP address as an intranet IP address when all other IP addresses are not available.

When IP pooling is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

Possible values: NS, OFF

useIIP

Define IP address pool options. Available settings function as follows:

* SPILLOVER - When an address pool is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

* NOSPILLOVER - When intranet IP addresses are enabled and the mapped IP address is not used, the Transfer Login page appears for users who have used all available intranet IP addresses.

* OFF - Address pool is not configured.

Possible values: NOSPILLOVER, SPILLOVER, OFF

clientDebug

Set the trace level on Access Gateway. Technical support technicians use these debug logs for in-depth debugging and troubleshooting purposes. Available settings function as follows:

* DEBUG - Detailed debug messages are collected and written into the specified file.

* STATS - Application audit level error messages and debug statistic counters are written into the specified file.

* EVENTS - Application audit-level error messages are written into the specified file.

* OFF - Only critical events are logged into the Windows Application Log.

Possible values: debug, stats, events, OFF

loginScript

Path to the logon script that is run when a session is established. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

logoutScript

Path to the logout script. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

homePage

Web address of the home page that appears when users log on. Otherwise, users receive the default home page for Access Gateway, which is the Access Interface.

icaProxy

Enable ICA proxy to configure secure Internet access to servers running Citrix XenApp or XenDesktop by using Citrix Receiver instead of the Access Gateway Plug-in.

Possible values: ON, OFF

wihome

Web address of the Web Interface server, such as http://<ipAddress>/Citrix/XenApp, or Receiver for Web, which enumerates the virtualized resources, such as XenApp, XenDesktop, and cloud applications. This web address is used as the home page in ICA proxy mode.

If Client Choices is ON, you must configure this setting. Because the user can choose between FullClient and ICAProxy, the user may see a different home page. An Internet web site may appear if the user gets the FullClient option, or a Web Interface site if the user gets the ICAProxy option. If the setting is not configured, the XenApp option does not appear as a client choice.

citrixReceiverHome

Web address for the Citrix Receiver home page. Configure Access Gateway so that when users log on to the appliance, the Access Gateway Plug-in opens a web browser that allows single sign-on to the Citrix Receiver home page.

wiPortalMode

Layout on the Access Interface. The COMPACT value indicates the use of small icons.

Possible values: NORMAL, COMPACT

ClientChoices

Provide users with multiple logon options. With client choices, users have the option of logging on by using the Access Gateway Plug-in for Windows, Access Gateway Plug-in for Java, the Web Interface, or clientless access from one location. Depending on how Access Gateway is configured, users are presented with up to three icons for logon choices. The most common are the Access Gateway Plug-in for Windows, Web Interface, and clientless access.

Possible values: ON, OFF

epaClientType

Choose between two types of End point Windows Client

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.

Possible values: AGENT, PLUGIN

iipDnsSuffix

An intranet IP DNS suffix. When a user logs on to Access Gateway and is assigned an IP address, a DNS record for the user name and IP address combination is added to Access Gateway DNS cache. You can configure a DNS suffix

to append to the user name when the DNS record is added to the cache. You can reach to the host from where the user is logged on by using the user's name, which can be easier to remember than an IP address. When the user logs off from Access Gateway, the record is removed from the DNS cache.

forcedTimeout

Force a disconnection from the Access Gateway Plug-in with Access Gateway after a specified number of minutes. If the session closes, the user must log on again.

Minimum value: 1

Maximum value: 65535

forcedTimeoutWarning

Number of minutes to warn a user before the user session is disconnected.

Minimum value: 1

Maximum value: 255

ntDomain

Single sign-on domain to use for single sign-on to applications in the internal network. This setting can be overwritten by the domain that users specify at the time of logon or by the domain that the authentication server returns.

clientlessVpnMode

Enable clientless access for web, XenApp or XenDesktop, and FileShare resources without installing the Access Gateway Plug-in. Available settings function as follows:

* ON - Allow only clientless access.

* OFF - Allow clientless access after users log on with the Access Gateway Plug-in.

* DISABLED - Do not allow clientless access.

Possible values: ON, OFF, DISABLED

emailHome

Web address for the web-based email, such as Outlook Web Access.

clientlessModeUrlEncoding

When clientless access is enabled, you can choose to encode the addresses of internal web applications or to leave the address as clear text. Available settings function as follows:

* OPAQUE - Use standard encoding mechanisms to make the domain and protocol part of the resource unclear to users.

* CLEAR - Do not encode the web address and make it visible to users.

* ENCRYPT - Allow the domain and protocol to be encrypted using a session key. When the web address is

encrypted, the URL is different for each user session for the same web resource. If users bookmark the encoded web address, save it in the web browser and then log off, they cannot connect to the web address when they log on and use the bookmark. If users save the encrypted bookmark in the Access Interface during their session, the bookmark works each time the user logs on.

Possible values: TRANSPARENT, OPAQUE, ENCRYPT

clientlessPersistentCookie

State of persistent cookies in clientless access mode. Persistent cookies are required for accessing certain features of SharePoint, such as opening and editing Microsoft Word, Excel, and PowerPoint documents hosted on the SharePoint server. A persistent cookie remains on the user device and is sent with each HTTP request. Access Gateway encrypts the persistent cookie before sending it to the plug-in on the user device, and refreshes the cookie periodically as long as the session exists. The cookie becomes stale if the session ends. Available settings function as follows:

* ALLOW - Enable persistent cookies. Users can open and edit Microsoft documents stored in SharePoint.

* DENY - Disable persistent cookies. Users cannot open and edit Microsoft documents stored in SharePoint.

* PROMPT - Prompt users to allow or deny persistent cookies during the session. Persistent cookies are not required for clientless access if users do not connect to SharePoint.

Possible values: ALLOW, DENY, PROMPT

allowedLoginGroups

Specify groups that have permission to log on to Access Gateway. Users who do not belong to this group or groups are denied access even if they have valid credentials.

SecureBrowse

Allow users to connect through Access Gateway to network resources from iOS and Android mobile devices with Citrix Receiver. Users do not need to establish a full VPN tunnel to access resources in the secure network.

Possible values: ENABLED, DISABLED

storefronturl

Web address for StoreFront to be used in this session for enumeration of resources from XenApp or XenDesktop.

kcdAccount

The kcd account details to be used in SSO

---

rm vpn sessionAction

Removes an action that was previously added to a session policy.

Synopsys

rm vpn sessionAction <name>

Arguments

name

Name of the action to remove.

---

set vpn sessionAction

Modifies an action that was previously added to a session policy that is applied to a user session if the policy expression conditions are met.

Synopsys

set vpn sessionAction <name> [-httpPort <port> ...] [-winsIP <ip_addr>] [-dnsVserverName <string>] [-splitDns <splitDns>] [-sessTimeout <mins>] [-clientSecurity <expression> [-clientSecurityGroup <string>] [-clientSecurityMessage <string>]] [-clientSecurityLog (ON | OFF)] [-splitTunnel <splitTunnel>] [-localLanAccess (ON | OFF)] [-rfc1918 (ON | OFF)] [-spoofIIP (ON | OFF)] [-killConnections (ON | OFF)] [-transparentInterception (ON | OFF)] [-defaultAuthorizationAction (ALLOW | DENY)] [-authorizationGroup <string>] [-clientIdleTimeout <mins>] [-proxy <proxy>] [-allProtocolProxy <string> | -httpProxy <string> | -ftpProxy <string> | -socksProxy <string> | -gopherProxy <string> | -sslProxy <string>] [-proxyException <string>] [-proxyLocalBypass (ENABLED | DISABLED)] [-clientCleanupPrompt (ON | OFF)] [-forceCleanup <forceCleanup> ...] [-clientOptions <clientOptions> ...] [-clientConfiguration <clientConfiguration> ...] [-SSO (ON | OFF)] [-ssoCredential (PRIMARY | SECONDARY)] [-windowsAutoLogon (ON | OFF)] [-useMIP (NS | OFF)] [-useIIP <useIIP>] [-clientDebug <clientDebug>] [-loginScript <input_filename>] [-logoutScript <input_filename>] [-homePage <URL>] [-icaProxy (ON | OFF)] [-wihome <URL>] [-citrixReceiverHome <URL>] [-wiPortalMode (NORMAL | COMPACT)] [-ClientChoices (ON | OFF)] [-iipDnsSuffix <string>] [-forcedTimeout <mins>] [-forcedTimeoutWarning <mins>] [-ntDomain <string>] [-clientlessVpnMode <clientlessVpnMode>] [-emailHome <URL>] [-clientlessModeUrlEncoding <clientlessModeUrlEncoding>] [-clientlessPersistentCookie <clientlessPersistentCookie>] [-allowedLoginGroups <string>] [-SecureBrowse (ENABLED | DISABLED)] [-storefronturl <string>] [-kcdAccount <string>]

Arguments

name

The name of the vpn session action.

httpPort

Destination port numbers other than port 80, added as a comma-separated list. Traffic to these ports is processed as HTTP traffic, which allows functionality, such as HTTP authorization and single sign-on to a web application to work.

Minimum value: 1

winsIP

The WINS server ip address.

dnsVserverName

Name of the DNS virtual server for the user session.

splitDns

Route the DNS requests to the local DNS server configured on the user device, or Access Gateway (remote), or both.

Possible values: LOCAL, REMOTE, BOTH

sessTimeout

Number of minutes after which the session times out.

Minimum value: 1

clientSecurity

Specify the client security check for the user device to permit an Access Gateway session. The web address or IP address is not included in the expression for the client security check.

clientSecurityLog

Set the logging of client security checks.

Possible values: ON, OFF

splitTunnel

Send, through the tunnel, traffic only for intranet applications that are defined in Access Gateway. Route all other traffic directly to the Internet. The OFF setting routes all traffic through Access Gateway. With the REVERSE setting, intranet applications define the network traffic that is not intercepted. All network traffic directed to internal IP addresses bypasses the VPN tunnel, while other traffic goes through Access Gateway. Reverse split tunneling can be used to log all non-local LAN traffic. For example, if users have a home network and are logged on through the Access Gateway Plug-in, network traffic destined to a printer or another device within the home network is not intercepted.

Possible values: ON, OFF, REVERSE

localLanAccess

Set local LAN access. If split tunneling is OFF, and you set local LAN access to ON, the local client can route traffic to its local interface. When the local area network switch is specified, this combination of switches is useful. The client can allow local LAN access to devices that commonly have non-routable addresses, such as local printers or local file servers.

Possible values: ON, OFF

rfc1918

As defined in the local area network, allow only the following local area network addresses to bypass the VPN tunnel when the local LAN access feature is enabled:

* 10.*.*.*,

* 172.16.*.*,

* 192.168.*.*

Possible values: ON, OFF

spoofIIP

IP address that the intranet application uses to route the connection through the virtual adapter.

Possible values: ON, OFF

killConnections

Specify whether the Access Gateway Plug-in should disconnect all preexisting connections, such as the connections existing before the user logged on to Access Gateway, and prevent new incoming connections on the Access Gateway Plug-in for Windows and MAC when the user is connected to Access Gateway and split tunneling is disabled.

Possible values: ON, OFF

transparentInterception

Allow access to network resources by using a single IP address and subnet mask or a range of IP addresses. The OFF setting sets the mode to proxy, in which you configure destination and source IP addresses and port numbers. If you are using the Access Gateway Plug-in for Windows, set this parameter to ON, in which the mode is set to transparent. If you are using the Access Gateway Plug-in for Java, set this parameter to OFF.

Possible values: ON, OFF

windowsClientType

Choose between two types of Windows Client\\

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed\\

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.

Possible values: AGENT, PLUGIN

defaultAuthorizationAction

Specify the network resources that users have access to when they log on to the internal network. The default setting for authorization is to deny access to all network resources. Citrix recommends using the default global setting and then creating authorization policies to define the network resources users can access. If you set the default authorization policy to DENY, you must explicitly authorize access to any network resource, which improves security.

Possible values: ALLOW, DENY

authorizationGroup

Comma-separated list of groups in which the user is placed when none of the groups that the user is a part of is

configured on Access Gateway. The authorization policy can be bound to these groups to control access to the resources.

clientIdleTimeout

Time, in minutes, after which to time out the user session if Access Gateway does not detect mouse or keyboard activity.

Minimum value: 1

Maximum value: 9999

proxy

Set options to apply proxy for accessing the internal resources. Available settings function as follows:

* BROWSER - Proxy settings are configured only in Internet Explorer and Firefox browsers.

* NS - Proxy settings are configured on the NetScaler appliance.

* OFF - Proxy settings are not configured.

Possible values: BROWSER, NS, OFF

allProtocolProxy

IP address of the proxy server to use for all protocols supported by Access Gateway.

httpProxy

IP address of the proxy server to be used for HTTP access for all subsequent connections to the internal network.

ftpProxy

IP address of the proxy server to be used for FTP access for all subsequent connections to the internal network.

socksProxy

IP address of the proxy server to be used for SOCKS access for all subsequent connections to the internal network.

gopherProxy

IP address of the proxy server to be used for GOPHER access for all subsequent connections to the internal network.

sslProxy

IP address of the proxy server to be used for SSL access for all subsequent connections to the internal network.

proxyException

Proxy exception string that will be configured in the browser for bypassing the previously configured proxies. Allowed only if proxy type is Browser.

proxyLocalBypass

Bypass proxy server for local addresses option in Internet Explorer and Firefox proxy server settings.

Possible values: ENABLED, DISABLED

clientCleanupPrompt

Prompt for client-side cache clean-up when a client-initiated session closes.

Possible values: ON, OFF

forceCleanup

Force cache clean-up when the user closes a session. You can specify all, none, or any combination of the client-side items.

clientOptions

Display only the configured menu options when you select the "Configure Access Gateway" option in the Access Gateway Plug-in's system tray icon for Windows.

clientConfiguration

Display only the configured tabs when you select the "Configure Access Gateway" option in the Access Gateway Plug-in's system tray icon for Windows.

SSO

Set single sign-on (SSO) for the session. When the user accesses a server, the user's logon credentials are passed to the server for authentication.

Possible values: ON, OFF

ssoCredential

Specify whether to use the primary or secondary authentication credentials for single sign-on to the server.

Possible values: PRIMARY, SECONDARY

windowsAutoLogon

Enable or disable the Windows Auto Logon for the session. If a VPN session is established after this setting is enabled, the user is automatically logged on by using Windows credentials after the system is restarted.

Possible values: ON, OFF

useMIP

Enable or disable the use of a unique IP address alias, or a mapped IP address, as the client IP address for each client session. Allow Access Gateway to use the mapped IP address as an intranet IP address when all other IP addresses are not available.

When IP pooling is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

Possible values: NS, OFF

useIIP

Define IP address pool options. Available settings function as follows:

* SPILLOVER - When an address pool is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

* NOSPILLOVER - When intranet IP addresses are enabled and the mapped IP address is not used, the Transfer Login page appears for users who have used all available intranet IP addresses.

* OFF - Address pool is not configured.

Possible values: NOSPILLOVER, SPILLOVER, OFF

clientDebug

Set the trace level on Access Gateway. Technical support technicians use these debug logs for in-depth debugging and troubleshooting purposes. Available settings function as follows:

* DEBUG - Detailed debug messages are collected and written into the specified file.

* STATS - Application audit level error messages and debug statistic counters are written into the specified file.

* EVENTS - Application audit-level error messages are written into the specified file.

* OFF - Only critical events are logged into the Windows Application Log.

Possible values: debug, stats, events, OFF

loginScript

Path to the logon script that is run when a session is established. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

logoutScript

Path to the logout script. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

homePage

Web address of the home page that appears when users log on. Otherwise, users receive the default home page for Access Gateway, which is the Access Interface.

icaProxy

Enable ICA proxy to configure secure Internet access to servers running Citrix XenApp or XenDesktop by using Citrix Receiver instead of the Access Gateway Plug-in.

Possible values: ON, OFF

Default value: OFF

wihome

Web address of the Web Interface server, such as http://<ipAddress>/Citrix/XenApp, or Receiver for Web, which enumerates the virtualized resources, such as XenApp, XenDesktop, and cloud applications. This web address is used as the home page in ICA proxy mode.

If Client Choices is ON, you must configure this setting. Because the user can choose between FullClient and ICAProxy, the user may see a different home page. An Internet web site may appear if the user gets the FullClient option, or a Web Interface site if the user gets the ICAProxy option. If the setting is not configured, the XenApp option does not appear as a client choice.

citrixReceiverHome

Web address for the Citrix Receiver home page. Configure Access Gateway so that when users log on to the appliance, the Access Gateway Plug-in opens a web browser that allows single sign-on to the Citrix Receiver home page.

wiPortalMode

Layout on the Access Interface. The COMPACT value indicates the use of small icons.

Possible values: NORMAL, COMPACT

ClientChoices

Provide users with multiple logon options. With client choices, users have the option of logging on by using the Access Gateway Plug-in for Windows, Access Gateway Plug-in for Java, the Web Interface, or clientless access from one location. Depending on how Access Gateway is configured, users are presented with up to three icons for logon choices. The most common are the Access Gateway Plug-in for Windows, Web Interface, and clientless access.

Possible values: ON, OFF

epaClientType

Choose between two types of End point Windows Client

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.

Possible values: AGENT, PLUGIN

iipDnsSuffix

An intranet IP DNS suffix. When a user logs on to Access Gateway and is assigned an IP address, a DNS record for the user name and IP address combination is added to Access Gateway DNS cache. You can configure a DNS suffix to append to the user name when the DNS record is added to the cache. You can reach to the host from where the user is logged on by using the user's name, which can be easier to remember than an IP address. When the user logs off from Access Gateway, the record is removed from the DNS cache.

forcedTimeout

Force a disconnection from the Access Gateway Plug-in with Access Gateway after a specified number of minutes. If the session closes, the user must log on again.

Minimum value: 1

Maximum value: 65535

forcedTimeoutWarning

Number of minutes to warn a user before the user session is disconnected.

Minimum value: 1

Maximum value: 255

ntDomain

Single sign-on domain to use for single sign-on to applications in the internal network. This setting can be overwritten by the domain that users specify at the time of logon or by the domain that the authentication server returns.

clientlessVpnMode

Enable clientless access for web, XenApp or XenDesktop, and FileShare resources without installing the Access Gateway Plug-in. Available settings function as follows:

* ON - Allow only clientless access.

* OFF - Allow clientless access after users log on with the Access Gateway Plug-in.

* DISABLED - Do not allow clientless access.

Possible values: ON, OFF, DISABLED

Default value: VPN_SESS_ACT_CVPNMODE_OFF

emailHome

Web address for the web-based email, such as Outlook Web Access.

clientlessModeUrlEncoding

When clientless access is enabled, you can choose to encode the addresses of internal web applications or to leave the address as clear text. Available settings function as follows:

* OPAQUE - Use standard encoding mechanisms to make the domain and protocol part of the resource unclear to users.

* CLEAR - Do not encode the web address and make it visible to users.

* ENCRYPT - Allow the domain and protocol to be encrypted using a session key. When the web address is encrypted, the URL is different for each user session for the same web resource. If users bookmark the encoded web address, save it in the web browser and then log off, they cannot connect to the web address when they log on and use the bookmark. If users save the encrypted bookmark in the Access Interface during their session, the

bookmark works each time the user logs on.

Possible values: TRANSPARENT, OPAQUE, ENCRYPT

clientlessPersistentCookie

State of persistent cookies in clientless access mode. Persistent cookies are required for accessing certain features of SharePoint, such as opening and editing Microsoft Word, Excel, and PowerPoint documents hosted on the SharePoint server. A persistent cookie remains on the user device and is sent with each HTTP request. Access Gateway encrypts the persistent cookie before sending it to the plug-in on the user device, and refreshes the cookie periodically as long as the session exists. The cookie becomes stale if the session ends. Available settings function as follows:

* ALLOW - Enable persistent cookies. Users can open and edit Microsoft documents stored in SharePoint.

* DENY - Disable persistent cookies. Users cannot open and edit Microsoft documents stored in SharePoint.

* PROMPT - Prompt users to allow or deny persistent cookies during the session. Persistent cookies are not required for clientless access if users do not connect to SharePoint.

Possible values: ALLOW, DENY, PROMPT

Default value: VPN_SESS_ACT_CVPN_PERSCOOKIE_DENY

allowedLoginGroups

Specify groups that have permission to log on to Access Gateway. Users who do not belong to this group or groups are denied access even if they have valid credentials.

SecureBrowse

Allow users to connect through Access Gateway to network resources from iOS and Android mobile devices with Citrix Receiver. Users do not need to establish a full VPN tunnel to access resources in the secure network.

Possible values: ENABLED, DISABLED

storefronturl

Web address for StoreFront to be used in this session for enumeration of resources from XenApp or XenDesktop.

kcdAccount

The kcd account details to be used in SSO

---

unset vpn sessionAction

Use this command to remove vpn sessionAction settings.Refer to the set vpn sessionAction command for meanings of the arguments.

Synopsys

unset vpn sessionAction <name> [-httpPort] [-winsIP] [-dnsVserverName] [-splitDns] [-sessTimeout] [-clientSecurity] [-

clientSecurityGroup] [-clientSecurityMessage] [-clientSecurityLog] [-splitTunnel] [-localLanAccess] [-rfc1918] [-spoofIIP] [-killConnections] [-transparentInterception] [-defaultAuthorizationAction] [-authorizationGroup] [-clientIdleTimeout] [-proxy] [-allProtocolProxy] [-httpProxy] [-ftpProxy] [-socksProxy] [-gopherProxy] [-sslProxy] [-proxyException] [-proxyLocalBypass] [-clientCleanupPrompt] [-forceCleanup] [-clientOptions] [-clientConfiguration] [-SSO] [-ssoCredential] [-windowsAutoLogon] [-useMIP] [-useIIP] [-clientDebug] [-loginScript] [-logoutScript] [-homePage] [-icaProxy] [-wihome] [-citrixReceiverHome] [-wiPortalMode] [-ClientChoices] [-iipDnsSuffix] [-forcedTimeout] [-forcedTimeoutWarning] [-ntDomain] [-clientlessVpnMode] [-emailHome] [-clientlessModeUrlEncoding] [-clientlessPersistentCookie] [-allowedLoginGroups] [-SecureBrowse] [-storefronturl] [-kcdAccount]

---

show vpn sessionAction

Displays a session action that is applied to a user session if the policy expression conditions are met.

Synopsys

show vpn sessionAction [<name>]

Arguments

name

Name of the session action to display.

summary

fullValues

format

level

Outputs

httpPort

The HTTP port for this session action

winsIP

The WINS server IP address for this session action.

dnsVserverName

The name of the DNS vserver configured by the session action.

splitDns

The VPN client SplitDns state.

sessTimeout

The session timeout, in minutes, set by the action.

clientSecurity

The client security check string being applied. This is in the form of an Expression. Expressions are simple conditions, such as a test for equality, applied to operands, such as a URL string or an IP address. Expression syntax is described in the Installation and Configuration Guide.

clientSecurityGroup

The client security group that will be assigned on failure of the client security check. Users can in general be organized into Groups. In this case, the Client Security Group may have a more restrictive security policy.

clientSecurityMessage

The client security message that will be displayed on failure of the client security check.

clientSecurityLog

Set the logging of client security checks.

splitTunnel

Send, through the tunnel, traffic only for intranet applications that are defined in Access Gateway. Route all other traffic directly to the Internet. The OFF setting routes all traffic through Access Gateway. With the REVERSE setting, intranet applications define the network traffic that is not intercepted. All network traffic directed to internal IP addresses bypasses the VPN tunnel, while other traffic goes through Access Gateway. Reverse split tunneling can be used to log all non-local LAN traffic. For example, if users have a home network and are logged on through the Access Gateway Plug-in, network traffic destined to a printer or another device within the home network is not intercepted.

localLanAccess

Set local LAN access. If split tunneling is OFF, and you set local LAN access to ON, the local client can route traffic to its local interface. When the local area network switch is specified, this combination of switches is useful. The client can allow local LAN access to devices that commonly have non-routable addresses, such as local printers or local file servers.

rfc1918

As defined in the local area network, allow only the following local area network addresses to bypass the VPN tunnel when the local LAN access feature is enabled:

* 10.*.*.*,

* 172.16.*.*,

* 192.168.*.*

spoofIIP

IP address that the intranet application uses to route the connection through the virtual adapter.

killConnections

Specify whether the Access Gateway Plug-in should disconnect all preexisting connections, such as the connections existing before the user logged on to Access Gateway, and prevent new incoming connections on the Access Gateway Plug-in for Windows and MAC when the user is connected to Access Gateway and split tunneling is disabled.

transparentInterception

Allow access to network resources by using a single IP address and subnet mask or a range of IP addresses. The OFF setting sets the mode to proxy, in which you configure destination and source IP addresses and port numbers. If you are using the Access Gateway Plug-in for Windows, set this parameter to ON, in which the mode is set to transparent. If you are using the Access Gateway Plug-in for Java, set this parameter to OFF.

windowsClientType

Windows client type, e.g. Agent or ActiveXNOTE: This attribute is deprecated.This argument is deprecated since ActiveX is no longer supported.

defaultAuthorizationAction

The Authorization Action, e.g. allow or deny

authorizationGroup

The authorization group applied to client sessions.

clientIdleTimeout

The client idle timeout, in minutes.

clientIdleTimeoutWarning

The time after which the client gets a timeout warning, in minutes.

proxy

The state of proxy configuration for the session.

allProtocolProxy

The address set for all proxies.

httpProxy

The HTTP proxy IP address.

ftpProxy

The FTP proxy IP address.

socksProxy

IP address of the proxy server to be used for SOCKS access for all subsequent connections to the internal network.

gopherProxy

The Gopher proxy IP address.

sslProxy

The HTTPS proxy IP address.

proxyException

Proxy exception string that will be configured in the browser for bypassing the previously configured proxies. Allowed only if proxy type is Browser.

proxyLocalBypass

Bypass proxy server for local addresses option in Internet Explorer and Firefox proxy server settings.

clientCleanupPrompt

Prompt for client-side cache clean-up when a client-initiated session closes.

forceCleanup

Force cache clean-up when the user closes a session. You can specify all, none, or any combination of the client-side items.

clientOptions

List of configured buttons(and/or menu options in the docked client) in the Windows VPN client.

clientConfiguration

List of configured tabs in the Windows VPN client.

SSO

Whether or not Single Sign-On is used for this session.

ssoCredential

Specify whether to use the primary or secondary authentication credentials for single sign-on to the server.

windowsAutoLogon

Whether or not Windows Auto Logon is enabled for this session.

useMIP

Whether or not a Mapped IP address is used for the session

useIIP

Define IP address pool options. Available settings function as follows:

* SPILLOVER - When an address pool is configured and the mapped IP is used as an intranet IP address, the mapped IP address is used when an intranet IP address cannot be assigned.

* NOSPILLOVER - When intranet IP addresses are enabled and the mapped IP address is not used, the Transfer Login page appears for users who have used all available intranet IP addresses.

* OFF - Address pool is not configured.

clientDebug

Trace level on the Windows VPN Client.

loginScript

Path to the logon script that is run when a session is established. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

logoutScript

Path to the logout script. Separate multiple scripts by using comma. A "$" in the path signifies that the word following the "$" is an environment variable.

homePage

The client home page.

icaProxy

Enable ICA proxy to configure secure Internet access to servers running Citrix XenApp or XenDesktop by using Citrix Receiver instead of the Access Gateway Plug-in.

wihome

Web address of the Web Interface server, such as http://<ipAddress>/Citrix/XenApp, or Receiver for Web, which enumerates the virtualized resources, such as XenApp, XenDesktop, and cloud applications. This web address is used as the home page in ICA proxy mode.

If Client Choices is ON, you must configure this setting. Because the user can choose between FullClient and ICAProxy, the user may see a different home page. An Internet web site may appear if the user gets the FullClient option, or a Web Interface site if the user gets the ICAProxy option. If the setting is not configured, the XenApp option does

not appear as a client choice.

citrixReceiverHome

Web address for the Citrix Receiver home page. Configure Access Gateway so that when users log on to the appliance, the Access Gateway Plug-in opens a web browser that allows single sign-on to the Citrix Receiver home page.

wiPortalMode

Layout on the Access Interface. The COMPACT value indicates the use of small icons.

ClientChoices

Provide users with multiple logon options. With client choices, users have the option of logging on by using the Access Gateway Plug-in for Windows, Access Gateway Plug-in for Java, the Web Interface, or clientless access from one location. Depending on how Access Gateway is configured, users are presented with up to three icons for logon choices. The most common are the Access Gateway Plug-in for Windows, Web Interface, and clientless access.

epaClientType

Choose between two types of End point Windows Client

a) Application Agent - which always runs in the task bar as a standalone application and also has a supporting service which runs permanently when installed

b) Activex Control - ActiveX control run by Microsoft's Internet Explorer.NOTE: This attribute is deprecated.This argument is not supported

iipDnsSuffix

The IntranetIP DNS suffix.

forcedTimeout

Force a disconnection from the Access Gateway Plug-in with Access Gateway after a specified number of minutes. If the session closes, the user must log on again.

forcedTimeoutWarning

Number of minutes to warn a user before the user session is disconnected.

ntDomain

Single sign-on domain to use for single sign-on to applications in the internal network. This setting can be overwritten by the domain that users specify at the time of logon or by the domain that the authentication server returns.

clientlessVpnMode

Whether clientlessVPN is available to the session.

clientlessModeUrlEncoding

URL encoding used in clientless mode.

clientlessPersistentCookie

State of persistent cookies in clientless access mode. Persistent cookies are required for accessing certain features of SharePoint, such as opening and editing Microsoft Word, Excel, and PowerPoint documents hosted on the SharePoint server. A persistent cookie remains on the user device and is sent with each HTTP request. Access Gateway encrypts the persistent cookie before sending it to the plug-in on the user device, and refreshes the cookie periodically as long as the session exists. The cookie becomes stale if the session ends. Available settings function as follows:

* ALLOW - Enable persistent cookies. Users can open and edit Microsoft documents stored in SharePoint.

* DENY - Disable persistent cookies. Users cannot open and edit Microsoft documents stored in SharePoint.

* PROMPT - Prompt users to allow or deny persistent cookies during the session. Persistent cookies are not required for clientless access if users do not connect to SharePoint.

emailHome

The EMail home for the portal

stateflag

allowedLoginGroups

Specify groups that have permission to log on to Access Gateway. Users who do not belong to this group or groups are denied access even if they have valid credentials.

SecureBrowse

Allow users to connect through Access Gateway to network resources from iOS and Android mobile devices with Citrix Receiver. Users do not need to establish a full VPN tunnel to access resources in the secure network.

storefronturl

Web address for StoreFront to be used in this session for enumeration of resources from XenApp or XenDesktop.

kcdAccount

The kcd account details to be used in SSO

builtin

Indicates that a variable is a built-in (SYSTEM INTERNAL) type.

count

vpn sessionPolicy

Sep 22, 2015

The following operations can be performed on "vpn sessionPolicy":

add | rm | set | unset | show

add vpn sessionPolicy

Creates a new session policy that, if bound, is applied after the user logs on to Access Gateway, and that determines the properties of the user session.

Synopsys

add vpn sessionPolicy <name> <rule> <action>

Arguments

name

Name for the new session policy that is applied after the user logs on to Access Gateway.

rule

Expression, or name of a named expression, specifying the traffic that matches the policy. Can be written in either default or classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Action to be applied by the new session policy if the rule criteria are met.

---

rm vpn sessionPolicy

Removes the session policy that is applied after the user logs on to Access Gateway.

Synopsys

rm vpn sessionPolicy <name>

Arguments

name

Name of the session policy to remove.

---

set vpn sessionPolicy

Modifies the rule or action of a session policy.

Synopsys

set vpn sessionPolicy <name> [-rule <expression>] [-action <string>]

Arguments

name

Name of the session policy to modify.

rule

Expression, or name of a named expression, specifying the traffic that matches the policy. Can be written in either default or classic syntax.

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Action to be applied by the new session policy if the rule criteria are met.

---

unset vpn sessionPolicy

Use this command to remove vpn sessionPolicy settings.Refer to the set vpn sessionPolicy command for meanings of the arguments.

Synopsys

unset vpn sessionPolicy <name> [-rule] [-action]

show vpn sessionPolicy

Displays a session policy.

Synopsys

show vpn sessionPolicy [<name>]

Arguments

name

Name of the session policy to display.

summary

fullValues

format

level

Outputs

rule

The new rule associated with the policy. Rules are combinations of Expressions. Expressions are simple conditions, such as a test for equality, applied to operands, such as a URL string or an IP address. Expression syntax is described in the Installation and Configuration Guide.

action

The new vpn session action the policy is using.

boundTo

The entity name to which policy is bound

activePolicy

priority

bindPolicyType

policyType

builtin

Indicates that a variable is a built-in (SYSTEM INTERNAL) type.

devno

count

stateflag

vpn stats

Sep 22, 2015

The following operations can be performed on "vpn stats":

show vpn stats

show vpn stats is an alias for stat vpn

Synopsys

show vpn stats - alias for 'stat vpn'

vpn trafficAction

Sep 22, 2015

The following operations can be performed on "vpn trafficAction":

add | rm | set | unset | show

add vpn trafficAction

Creates an action to be applied by a policy that matches the traffic being processed.

Synopsys

add vpn trafficAction <name> <qual> [-appTimeout <mins>] [(-SSO (ON | OFF) [-formSSOAction <string>]) | -wanscaler (ON | OFF)] [-fta (ON | OFF)] [-kcdAccount <string>] [-samlSSOProfile <string>]

Arguments

name

Name for the traffic action. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after a traffic action is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my action" or 'my action').

qual

Protocol, either HTTP or TCP, to be used with the action. If you specify TCP, single sign-on cannot be configured.

Possible values: http, tcp

appTimeout

Maximum amount of time, in minutes, a user can stay logged on to the web application.

Minimum value: 1

Maximum value: 715827

SSO

Provide single sign-on to the web application.

Possible values: ON, OFF

formSSOAction

Name of the form-based single sign-on profile. Form-based single sign-on allows users to log on one time to all protected applications in your network, instead of requiring them to log on separately to access each one.

fta

Specify file type association, which is a list of file extensions that users are allowed to open.

Possible values: ON, OFF

wanscaler

Use the Repeater Plug-in to optimize network traffic.

Possible values: ON, OFF

kcdAccount

Kerberos constrained delegation account name

Default value: "None"

samlSSOProfile

Profile to be used for doing SAML SSO to remote relying party

---

rm vpn trafficAction

Removes a previously created traffic policy action.

Synopsys

rm vpn trafficAction <name>

Arguments

name

Name of the traffic policy action to remove.

---

set vpn trafficAction

Modifies a traffic policy action to be applied by the policy if the rule criteria are met.

Synopsys

set vpn trafficAction <name> [-appTimeout <mins>] [-SSO (ON | OFF) | -wanscaler (ON | OFF)] [-formSSOAction <string>] [-fta (ON | OFF)] [-kcdAccount <string>] [-samlSSOProfile <string>]

Arguments

name

Name of the traffic policy action to modify.

appTimeout

Maximum amount of time, in minutes, a user can stay logged on to the web application.

Minimum value: 1

Maximum value: 715827

SSO

Provide single sign-on to the web application.

Possible values: ON, OFF

formSSOAction

Name of the form-based single sign-on profile. Form-based single sign-on allows users to log on one time to all protected applications in your network, instead of requiring them to log on separately to access each one.

fta

Specify file type association, which is a list of file extensions that users are allowed to open.

Possible values: ON, OFF

wanscaler

Use the Repeater Plug-in to optimize network traffic.

Possible values: ON, OFF

kcdAccount

Kerberos constrained delegation account name

Default value: "None"

samlSSOProfile

Profile to be used for doing SAML SSO to remote relying party

---

unset vpn trafficAction

Use this command to remove vpn trafficAction settings.Refer to the set vpn trafficAction command for meanings of the arguments.

Synopsys

unset vpn trafficAction <name> [-wanscaler] [-kcdAccount]

---

show vpn trafficAction

Displays information about all the configured traffic actions, or displays detailed information about the specified traffic

action.

Synopsys

show vpn trafficAction [<name>]

Arguments

name

Name of the traffic policy action for which to display detailed information.

summary

fullValues

format

level

Outputs

qual

The protocol that is set with the action, e.g. http or tcp.

appTimeout

The application timeout

SSO

Whether or not Single Sign On is enabled.

formSSOAction

Name of the form-based single sign-on profile. Form-based single sign-on allows users to log on one time to all protected applications in your network, instead of requiring them to log on separately to access each one.

fta

Whether or not file-type association is enabled.

wanscaler

Use the Repeater Plug-in to optimize network traffic.

kcdAccount

Kerberos constrained delegation account name

samlSSOProfile

Profile to be used for doing SAML SSO to remote relying party

devno

count

vpn trafficPolicy

Sep 22, 2015

The following operations can be performed on "vpn trafficPolicy":

add | rm | set | unset | show

add vpn trafficPolicy

Creates a traffic policy. A traffic policy conditionally sets Access Gateway traffic characteristics at run time. For an intranet resource, for example, the traffic policy parameters define the destination IP address, destination port, amount of time a user can stay logged on to the application, and HTTP compression.

Synopsys

add vpn trafficPolicy <name> <rule> <action>

Arguments

name

Name for the traffic policy. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the policy is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy').

rule

Expression, or name of a named expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: '"<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Action to apply to traffic that matches the policy.

rm vpn trafficPolicy

Removes an existing traffic policy from Access Gateway.

Synopsys

rm vpn trafficPolicy <name>

Arguments

name

Name of the traffic policy to remove.

set vpn trafficPolicy

Modifies the specified parameters of an existing traffic policy.

Synopsys

set vpn trafficPolicy <name> [-rule <expression>] [-action <string>]

Arguments

name

Name of the traffic policy to modify.

rule

Expression, or name of a named expression, against which traffic is evaluated. Written in the classic or default syntax.

Note:

Maximum length of a string literal in the expression is 255 characters. A longer string can be split into smaller strings of up to 255 characters each, and the smaller strings concatenated with the + operator. For example, you can create a 500-character string as follows: "'<string of 255 characters>" + "<string of 245 characters>"'

The following requirements apply only to the NetScaler CLI:

* If the expression includes one or more spaces, enclose the entire expression in double quotation marks.

* If the expression itself includes double quotation marks, escape the quotations by using the \\ character.

* Alternatively, you can use single quotation marks to enclose the rule, in which case you do not have to escape the double quotation marks.

action

Action to apply to traffic that matches the policy.

unset vpn trafficPolicy

Use this command to remove vpn trafficPolicy settings.Refer to the set vpn trafficPolicy command for meanings of the arguments.

Synopsys

unset vpn trafficPolicy <name> [-rule] [-action]

show vpn trafficPolicy

Displays information about all Access Gateway traffic policies, or detailed information about the specified policy.

Synopsys

show vpn trafficPolicy [<name>]

Arguments

name

Name of the traffic policy for which to display detailed information.

summary

fullValues

format

level

Outputs

rule

The rule used by the vpn traffic policy. Rules are combinations of Expressions. Expressions are simple conditions, such as a test for equality, applied to operands, such as a URL string or an IP address. Expression syntax is described in the Installation and Configuration Guide

action

The action to be performed when the rule is matched.

vpn url

Sep 22, 2015

The following operations can be performed on "vpn url":

add | rm | set | unset | show

add vpn url

Creates a bookmark link to an external or internal resource that appears on the Access Interface, according to type, as a web site link or file share link.

Synopsys

add vpn url <urlName> <linkName> <actualURL> [-clientlessAccess (ON | OFF)] [-comment <string>]

Arguments

urlName

Name of the bookmark link.

linkName

Description of the bookmark link. The description appears in the Access Interface.

actualURL

Web address for the bookmark link.

clientlessAccess

If clientless access to the resource hosting the link is allowed, also use clientless access for the bookmarked web address in the Secure Client Access based session. Allows single sign-on and other HTTP processing on Access Gateway for HTTPS resources.

Possible values: ON, OFF

Default value: OFF

comment

Any comments associated with the bookmark link.

Example

add vpn url ggl search www.google.com.

---

rm vpn url

Removes a bookmark link to an internal resource that appears in the Access Interface.

Synopsys

rm vpn url <urlName>

Arguments

urlName

Name of the bookmark link to remove.

Example

rm vpn url ggl

---

set vpn url

Modifies the specified parameters of a bookmark link to an internal resource that appears in the Access Interface.

Synopsys

set vpn url <urlName> [-linkName <string>] [-actualURL <string>] [-clientlessAccess (ON | OFF)] [-comment <string>]

Arguments

urlName

Name of the bookmark link.

linkName

Description of the bookmark link. The description appears in the Access Interface.

actualURL

Web address for the bookmark link.

clientlessAccess

If clientless access to the resource hosting the link is allowed, also use clientless access for the bookmarked web address in the Secure Client Access based session. Allows single sign-on and other HTTP processing on Access Gateway for HTTPS resources.

Possible values: ON, OFF

Default value: OFF

comment

Any comments associated with the bookmark link.

Example

set vpn url wiurl -clientlessAccess on

unset vpn url

Use this command to remove vpn url settings.Refer to the set vpn url command for meanings of the arguments.

Synopsys

unset vpn url <urlName> [-clientlessAccess] [-comment]

show vpn url

Displays information about all the configured bookmark links to internal resources that appear in the Access Interface, or displays detailed information about the specified bookmark link.

Synopsys

show vpn url [<urlName>]

Arguments

urlName

Name of the bookmark link for which to display detailed information.

summary

fullValues

format

level

Outputs

linkName

Description of the bookmark link. The description appears in the Access Interface.

actualURL

Web address for the bookmark link.

clientlessAccess

Whether clientless access is enabled for the url in other modes or not.

comment

Comments associated with this virtual server.

count

stateflag

vpn vserver

Sep 22, 2015

The following operations can be performed on "vpn vserver":

add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename

add vpn vserver

Creates an Access Gateway virtual server to allow authenticated users to access intranet resources, such as XenApp, XenDesktop, and web servers.

Synopsys

add vpn vserver <name> <serviceType> (<IPAddress> [-range <positive_integer>]) <port> [-state (ENABLED | DISABLED)] [-authentication (ON | OFF)] [-doubleHop (ENABLED | DISABLED)] [-maxAAAUsers <positive_integer>] [-icaOnly (ON | OFF)] [-downStateFlush (ENABLED | DISABLED)] [-Listenpolicy <expression> [-Listenpriority <positive_integer>]] [-tcpProfileName <string>] [-httpProfileName <string>] [-comment <string>] [-appflowLog (ENABLED | DISABLED)] [-icmpVsrResponse (PASSIVE | ACTIVE)] [-netProfile <string>] [-cginfraHomePageRedirect (ENABLED | DISABLED)] [-maxLoginAttempts <positive_integer> [-failedLoginTimeout <positive_integer>]] [-deploymentType <deploymentType>]

Arguments

name

Name for the Access Gateway virtual server. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the virtual server is created.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my server" or 'my server').

serviceType

Protocol used by the Access Gateway virtual server.

Possible values: SSL

Default value: NSSVC_SSL

IPAddress

IPv4 or IPv6 address of the Access Gateway virtual server. Usually a public IP address. User devices send connection requests to this IP address.

port

TCP port on which the virtual server listens.

Minimum value: 1

state

State of the virtual server. If the virtual server is disabled, requests are not processed.

Possible values: ENABLED, DISABLED

Default value: ENABLED

authentication

Require authentication for users connecting to Access Gateway.

Possible values: ON, OFF

Default value: ON

doubleHop

Use the Access Gateway appliance in a double-hop configuration. A double-hop deployment provides an extra layer of security for the internal network by using three firewalls to divide the demilitarized zone (DMZ) into two stages. Such a deployment can have one appliance in the DMZ and one appliance in the secure network.

Possible values: ENABLED, DISABLED

Default value: DISABLED

maxAAAUsers

Maximum number of concurrent user sessions allowed on this virtual server. The actual number of users allowed to log on to this virtual server depends on the total number of user licenses.

icaOnly

User can log on in basic mode only, through either Citrix Receiver or a browser. Users are not allowed to connect by using the Access Gateway Plug-in.

Possible values: ON, OFF

Default value: OFF

downStateFlush

Close existing connections when the virtual server is marked DOWN, which means the server might have timed out. Disconnecting existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups. Enable this setting on servers whose connections can safely be closed when they are marked DOWN. Do not enable DOWN state flush

on servers that must complete their transactions.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Listenpolicy

String specifying the listen policy for the Access Gateway virtual server. Can be either a named expression or a default syntax expression. The Access Gateway virtual server processes only the traffic for which the expression evaluates to true.

Default value: "none"

Listenpriority

Integer specifying the priority of the listen policy. A higher number specifies a lower priority. If a request matches the listen policies of more than one virtual server, the virtual server whose listen policy has the highest priority (the lowest priority number) accepts the request.

Default value: 101

Maximum value: 100

tcpProfileName

Name of the TCP profile to assign to this virtual server.

httpProfileName

Name of the HTTP profile to assign to this virtual server.

comment

Any comments associated with the virtual server.

appflowLog

Log AppFlow records that contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. Also log records that contain application-level information, such as HTTP web addresses, HTTP request methods and response status codes, server response time, and latency.

Possible values: ENABLED, DISABLED

Default value: DISABLED

icmpVsrResponse

Criterion for responding to PING requests sent to this virtual server. If this parameter is set to ACTIVE, respond only if the virtual server is available. With the PASSIVE setting, respond even if the virtual server is not available.

Possible values: PASSIVE, ACTIVE

Default value: NS_VSR_PASSIVE

netProfile

The name of the network profile.

cginfraHomePageRedirect

When client requests for Sharefile resource and AGEE finds that the user is unauthenticated or the user-session has expired then, disabling this option will take the user to the originally requested Sharefile resource after authentication (instead of taking the user to the default vpn homepage)

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxLoginAttempts

Maximum Number of login Attempts

Minimum value: 1

Maximum value: 255

deploymentType

Example

The following example creates a VPN vserver named myvpnvip which supports SSL portocol and with AAA functionality enabled: vserver myvpnvip SSL 65.219.17.34 443 -

---

rm vpn vserver

Removes an Access Gateway virtual server. Policies that are bound to the virtual server are automatically unbound.

Synopsys

rm vpn vserver <name>@ ...

Arguments

name

Name of the virtual server to remove.

Example

rm vserver vpn_vip

---

set vpn vserver

Modifies the specified parameters of an Access Gateway virtual server.

Synopsys

set vpn vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-authentication (ON | OFF)] [-doubleHop (ENABLED | DISABLED)] [-icaOnly (ON | OFF)] [-maxAAAUsers <positive_integer>] [-downStateFlush (ENABLED | DISABLED)] [-Listenpolicy <expression>] [-Listenpriority <positive_integer>] [-tcpProfileName <string>] [-httpProfileName <string>] [-comment <string>] [-appflowLog (ENABLED | DISABLED)] [-icmpVsrResponse (PASSIVE | ACTIVE)] [-netProfile <string>] [-cginfraHomePageRedirect (ENABLED | DISABLED)] [-maxLoginAttempts <positive_integer>] [-failedLoginTimeout <positive_integer>]

Arguments

name

Name of the virtual server to modify.

IPAddress

IPv4 or IPv6 address of the Access Gateway virtual server. Usually a public IP address. User devices send connection requests to this IP address.

authentication

Require authentication for users connecting to Access Gateway.

Possible values: ON, OFF

Default value: ON

doubleHop

Use the Access Gateway appliance in a double-hop configuration. A double-hop deployment provides an extra layer of security for the internal network by using three firewalls to divide the demilitarized zone (DMZ) into two stages. Such a deployment can have one appliance in the DMZ and one appliance in the secure network.

Possible values: ENABLED, DISABLED

Default value: DISABLED

icaOnly

User can log on in basic mode only, through either Citrix Receiver or a browser. Users are not allowed to connect by using the Access Gateway Plug-in.

Possible values: ON, OFF

Default value: OFF

maxAAAUsers

Maximum number of concurrent user sessions allowed on this virtual server. The actual number of users allowed to log on to this virtual server depends on the total number of user licenses.

downStateFlush

Close existing connections when the virtual server is marked DOWN, which means the server might have timed out. Disconnecting existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups. Enable this setting on servers whose connections can safely be closed when they are marked DOWN. Do not enable DOWN state flush on servers that must complete their transactions.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Listenpolicy

String specifying the listen policy for the Access Gateway virtual server. Can be either a named expression or a default syntax expression. The Access Gateway virtual server processes only the traffic for which the expression evaluates to true.

Default value: "none"

Listenpriority

Integer specifying the priority of the listen policy. A higher number specifies a lower priority. If a request matches the listen policies of more than one virtual server, the virtual server whose listen policy has the highest priority (the lowest priority number) accepts the request.

Default value: 101

Maximum value: 100

tcpProfileName

Name of the TCP profile to assign to this virtual server.

httpProfileName

Name of the HTTP profile to assign to this virtual server.

comment

Any comments associated with the virtual server.

appflowLog

Log AppFlow records that contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. Also log records that contain application-level information, such as HTTP web addresses, HTTP request methods and response status codes, server response time, and latency.

Possible values: ENABLED, DISABLED

Default value: DISABLED

icmpVsrResponse

Criterion for responding to PING requests sent to this virtual server. If this parameter is set to ACTIVE, respond only if the virtual server is available. With the PASSIVE setting, respond even if the virtual server is not available.

Possible values: PASSIVE, ACTIVE

Default value: NS_VSR_PASSIVE

netProfile

The name of the network profile.

cginfraHomePageRedirect

When client requests for Sharefile resource and AGEE finds that the user is unauthenticated or the user-session has expired then, disabling this option will take the user to the originally requested Sharefile resource after authentication (instead of taking the user to the default vpn homepage)

Possible values: ENABLED, DISABLED

Default value: ENABLED

maxLoginAttempts

Maximum Number of login Attempts

Minimum value: 1

Maximum value: 255

failedLoginTimeout

Failed Login timeout

Minimum value: 1

---

unset vpn vserver

Use this command to remove vpn vserver settings.Refer to the set vpn vserver command for meanings of the arguments.

Synopsys

unset vpn vserver <name> [-authentication] [-doubleHop] [-icaOnly] [-maxAAAUsers] [-downStateFlush] [-Listenpolicy] [-Listenpriority] [-tcpProfileName] [-httpProfileName] [-comment] [-appflowLog] [-icmpVsrResponse] [-netProfile] [-cginfraHomePageRedirect] [-maxLoginAttempts]

---

bind vpn vserver

Binds attributes to the specified Access Gateway virtual server.

Synopsys

bind vpn vserver <name> [-policy <string> [-priority <positive_integer>] [-secondary] [-groupExtraction] [-gotoPriorityExpression <expression>] [-type <type>]] [-intranetApplication <string>] [-nextHopServer <string>] [-urlName <string>] [-intranetIP <ip_addr> <netmask>] [-staServer <URL>] [-appController <URL>] [-sharefile <string>]

Arguments

name

Name of the virtual server.

policy

Name of a policy to bind to the virtual server (for example, the name of an authentication, session, or endpoint analysis policy).

intranetApplication

Name of the application to bind to the virtual server. Intranet applications are used to enable access to selected applications located in the internal network. They are required for any user connecting with the Access Gateway Plug-in for Java.

nextHopServer

Name of the next hop server to bind to the virtual server.

urlName

Web address of the next hop virtual server to bind to the virtual server.

intranetIP

The network id for the range of intranet IP addresses or individual intranet ip to be bound to the vserver.

staServer

Web address of the Secure Ticket Authority (STA) server, in the following format: 'http(s)://FQDN/URLPATH'

appController

AppController server, in the format 'http(s)://IP/FQDN'

sharefile

Sharefile server, in the format 'IP:PORT / FQDN:PORT'

---

unbind vpn vserver

Unbinds the specified attributes from a virtual server.

Synopsys

unbind vpn vserver <name> [-policy <string> [-secondary] [-groupExtraction] [-type <type>]] [-intranetApplication <string>] [-nextHopServer <string>] [-urlName <string>] [-intranetIP <ip_addr> <netmask>] [-staServer <URL>] [-appController <URL>] [-sharefile <string>]

Arguments

name

Name of the virtual server from which to unbind an attribute.

policy

Name of the policy to unbind from the virtual server.

intranetApplication

Name of intranet application to unbind from the virtual server.

nextHopServer

Name of the next hop server to remove.

urlName

Web address of the next hop virtual server to unbind.

intranetIP

The range of IP addresses to unbind from the virtual server.

staServer

Web address of the Secure Ticket Authority (STA) server to remove, in the following format: 'http(s)://FQDN/URLPATH'

appController

AppController server to be removed, in the format 'http(s)://IP/FQDN'

sharefile

Sharefile server to be removed, in the format 'IP:PORT / FQDN:PORT'

---

enable vpn vserver

Enables an Access Gateway virtual server. Note: Virtual servers, when added, are enabled by default.

Synopsys

enable vpn vserver <name>@

Arguments

name

Name of the virtual server to be enabled.

Example

```
enable vserver vpn1
```

---

disable vpn vserver

Disables an Access Gateway virtual server. The virtual server is taken out of service.

Synopsys

disable vpn vserver <name>@

Arguments

name

Name of the virtual server to be disabled. The Access Gateway still responds to ARP and/or ping requests for the IP address of the virtual server. You can enable the Access Gateway virtual server again at any time, because the virtual server is still configured.

Example

```
disable vserver lb_vip
```

---

show vpn vserver

Displays information about all the configured Access Gateway virtual servers, or displays detailed information about the specified Access Gateway virtual server.

Synopsys

show vpn vserver [<name>] show vpn vserver stats - alias for 'stat vpn vserver'

Arguments

name

Name of the Access Gateway virtual server for which to show detailed information.

summary

fullValues

format

level

Outputs

IPAddress

The IP address of the virtual server.

value

Indicates whether or not the certificate is bound or if SSL offload is disabled.

port

The virtual TCP port of the VPN vserver.

range

The range of vpn vserver IP addresses. The new range of vpn vservers will have IP addresses consecutively numbered, starting with the primary address specified with the <ipaddress> argument.

serviceType

The vpn vserver's protocol type, Currently the only possible value is SSL.

type

Bindpoint to which the policy is bound

state

The current state of the Virtual server, e.g. UP, DOWN, BUSY, etc.

status

Whether or not this vserver responds to ARPs and whether or not round-robin selection is temporarily in effect.

cacheType

Virtual server's cache type. The options are: TRANSPARENT, REVERSE and FORWARD.

redirect

The cache redirect policy.

The valid redirect policies are:

l. CACHE - Directs all requests to the cache.

2. POLICY - Applies cache redirection policy to determine whether the request should be directed to the cache or origin. This is the default setting.

3. ORIGIN - Directs all requests to the origin server.

precedence

This argument is used only when configuring content switching on the specified virtual server. This is applicable only

if both the URL and RULE-based policies have been configured on the same virtual server.

It specifies the type of policy (URL or RULE) that takes precedence on the content switching virtual server. The default setting is RULE.

l URL - In this case, the incoming request is matched against the URL-based policies before the rule-based policies.

l RULE - In this case, the incoming request is matched against the rule-based policies before the URL-based policies.

For all URL-based policies, the precedence hierarchy is:

1. Domain and exact URL

2. Domain, prefix and suffix

3. Domain and suffix

4. Domain and prefix

5. Domain only

6. Exact URL

7. Prefix and suffix

8. Suffix only

9. Prefix only

10. Default

redirectURL

The URL where traffic is redirected if the virtual server in system becomes unavailable. WARNING! Make sure that the domain you specify in the URL does not match the domain specified in the -d domainName argument of the ###add cs policy### command. If the same domain is specified in both arguments, the request will be continuously redirected to the same unavailable virtual server in the system. If so, the user may not get the requested content.

authentication

Indicates whether or not authentication is being applied to incoming users to the VPN.

doubleHop

Indicates whether double hop functionality is enabled or not.

icaOnly

Indicates whether or ica only license feature is enabled or not.

maxAAAUsers

The maximum number of concurrent users allowed to login into this vserver at a time.

curAAAUsers

The number of current users logged in to this vserver.

curTotalUsers

The total number of current users connected through this virtual server.

domain

The domain name of the server for which a service needs to be added. If the IP Address has been specified, the domain name does not need to be specified.

rule

The name of the rule, or expression, if any, that policy for the vpn server is to use. Rules are combinations of Expressions. Expressions are simple conditions, such as a test for equality, applied to operands, such as a URL string or an IP address. Expression syntax is described in the Installation and Configuration Guide. The default rule is ns_true.

policyName

The name of the policy, if any, bound to the vpn vserver.NOTE: This attribute is deprecated.Replaced by Policy field

policy

The name of the policy, if any, bound to the vpn vserver.

serviceName

The name of the service, if any, to which the vserver policy is bound.

weight

Weight for this service, if any. This weight is used when the system performs load balancing, giving greater priority to a specific service. It is useful when the services bound to a virtual server are of different capacity.

cacheVserver

The name of the default target cache virtual server, if any, to which requests are redirected.

backupVServer

The name of the backup vpn virtual server for this vpn virtual server.

priority

The priority, if any, of the vpn vserver policy.

cltTimeout

The idle time, if any, in seconds after which the client connection is terminated.

soMethod

VPN client applications are allocated from a block of Intranet IP addresses.

That block may be exhausted after a certain number of connections. This switch specifies the

method used to determine whether or not a new connection will spillover, or exhaust, the allocated block of

Intranet IP addresses for that application. Possible values are CONNECTION or DYNAMICCONNECTION.

CONNECTION means that a static integer value is the hard limit for the spillover threshold. The spillover

threshold is described below. DYNAMICCONNECTION means that the spillover threshold is set according to

the maximum number of connections defined for the vpn vserver.

soThreshold

VPN client applications are allocated from a block of Intranet IP addresses.

That block may be exhausted after a certain number of connections.

The value of this option is number of client connections after which the Mapped IP address is used

as the client source IP address instead of an address from the allocated block of Intranet IP addresses.

soPersistence

Whether or not cookie-based site persistance is enabled for this VPN vserver. Possible values are 'ConnectionProxy', HTTPRedirect, or NONE

soPersistenceTimeOut

The timeout, if any, for cookie-based site persistance of this VPN vserver.

actType

intranetApplication

The intranet vpn application.

nextHopServer

The name of the next hop server bound to vpn vserver.

urlName

The intranet url.

intranetIP

The network id for the range of intranet IP addresses or individual intranet ip to be bound to the vserver.

netmask

The netmask of the intranet ip or range.

staServer

Configured Secure Ticketing Authority (STA) server.

staAuthID

Authority ID of the STA Server. Authority ID is used to match incoming STA Tickets in the SOCKS/CGP protocol with the right STA Server.

appController

Configured AppController server in Cloud Gateway deployment.

sharefile

Configured Sharefile server in Cloud Gateway deployment. Format IP:PORT / FQDN:PORT

useMIP

Deprecated. See 'map' below.

map

Whether or not Mapped IP Addresses are ON or OFF. Mapped IP addresses are source IP addresses

for the virtual servers running on the NetScaler. Mapped IP addresses are used by the system to connect to the backend servers.

downStateFlush

Close existing connections when the virtual server is marked DOWN, which means the server might have timed out. Disconnecting existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups. Enable this setting on servers whose connections can safely be closed when they are marked DOWN. Do not enable DOWN state flush on servers that must complete their transactions.

gotoPriorityExpression

Next priority expression.

disablePrimaryOnDown

Tells whether traffic will continue reaching backup vservers even after primary comes UP from DOWN state.

Listenpolicy

The string is listenpolicy configured for VPN vserver

Listenpriority

This parameter is the priority for listen policy of VPN Vserver.

tcpProfileName

Name of the TCP profile to assign to this virtual server.

httpProfileName

Name of the HTTP profile to assign to this virtual server.

policySubType

stateflag

flags

comment

Any comments associated with the virtual server.

appflowLog

Log AppFlow records that contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. Also log records that contain application-level information, such as HTTP web addresses, HTTP request methods and response status codes, server response time, and latency.

icmpVsrResponse

Criterion for responding to PING requests sent to this virtual server. If this parameter is set to ACTIVE, respond only if the virtual server is available. With the PASSIVE setting, respond even if the virtual server is not available.

netProfile

The name of the network profile.

cginfraHomePageRedirect

When client requests for Sharefile resource and AGEE finds that the user is unauthenticated or the user-session has expired then, disabling this option will take the user to the originally requested Sharefile resource after authentication (instead of taking the user to the default vpn homepage)

maxLoginAttempts

Maximum Number of login Attempts

failedLoginTimeout

Failed Login timeout

secondary

Bind the authentication policy as the secondary policy to use in a two-factor configuration. A user must then authenticate not only via a primary authentication method but also via a secondary authentication method. User groups are aggregated across both. The user name must be exactly the same for both authentication methods, but they can require different passwords.

groupExtraction

Bind the Authentication policy to a tertiary chain which will be used only for group extraction. The user will not authenticate against this server, and this will only be called if primary and/or secondary authentication has succeeded.

deploymentType

devno

count

Example

show vpn vserver

---

stat vpn vserver

Displays statistics for all Access Gateway virtual servers, or displays detailed statistics for the specified Access Gateway virtual server.

Synopsys

stat vpn vserver [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>] [-clearstats (basic | full)]

Arguments

name

Name of the virtual server for which to show detailed statistics.

clearstats

Clear the statsistics / counters

Possible values: basic, full

Outputs

count

devno

stateflag

Outputs

IP address (IP)

The IP address on which the service is running.

Port (port)

The port on which the service is running.

Vserver protocol (Protocol)

Protocol associated with the vserver

State

Current state of the server. Possible values are UP, DOWN, UNKNOWN, OFS(Out of Service), TROFS(Transition Out of Service), TROFS_DOWN(Down When going Out of Service)

Requests (Req)

Total number of requests received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Responses (Rsp)

Number of responses received on this service or virtual server. (This applies to HTTP/SSL services and servers.)

Request bytes (Reqb)

Total number of request bytes received on this service or virtual server.

Response bytes (Rspb)

Number of response bytes received by this service or virtual server.

rename vpn vserver

Renames an Access Gateway virtual server.

Synopsys

rename vpn vserver <name>@ <newName>@

Arguments

name

Name of the Access Gateway virtual server.

newName

New name for the Access Gateway virtual server. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

The following requirement applies only to the NetScaler CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my server" or 'my server').

Example

```
rename vpn vserver vpn1 vpn1new
```

WebInterface Commands

Sep 22, 2015

The entities on which you can perform NetScaler CLI operations:

- wi package
- wi site

wi package

Sep 22, 2015

The following operations can be performed on "wi package":

install | uninstall

install wi package

Installs Web Interface and JRE tar files on the NetScaler appliance.

Synopsys

install wi package [-jre <URL>] [-wi <URL>] [-maxSites <maxSites>]

Arguments

jre

Complete path to the JRE tar file.

You can use the Diablo Latte JRE version 1.6.0-7 for 64-bit FreeBSD 6.x/amd64 platform available on the FreeBSD Foundation web site.

Alternatively, you can use OpenJDK6 package for FreeBSD 6.x/amd63.The Java package can be downloaded from https://citrix.sharefile.com/d/c85aeefcc05643f8 or http://www.freebsdfoundation.org/java/java16

Default value: "file://tmp/diablo-jdk-freebsd6.amd64.1.6.0.07.02.tbz"

wi

Complete path to the Web Interface tar file for installing the Web Interface on the NetScaler appliance. This file includes Apache Tomcat Web server. The file name has the following format: nswi-<version number>.tgz (for example, nswi-1.5.tgz).

Default value: "http://citrix.com/downloads/nswi-1.7.tgz"

maxSites

Maximum number of Web Interface sites that can be created on the NetScaler appliance; changes the amount of RAM reserved for Web Interface usage; changing its value results in restart of Tomcat server and invalidates any existing Web Interface sessions.

Possible values: 3, 25, 50, 100, 200, 500

Example

```
install wi package -jre http://10.102.1.10/diablo-latte-freebsd6-amd64-1.6.0_07-b02.tar.bz2 -wi http://citrix.com/downloads/nswi-1.7.tgz -maxSites 25
```

---

uninstall wi package

Removes the Web Interface and JRE tar files, and the entire Web Interface related configuration, from the NetScaler appliance.

Synopsys

uninstall wi package

Example

```
uninstall wi package
```

---

wi site

Sep 22, 2015

The following operations can be performed on "wi site":

add | rm | set | unset | bind | unbind | show

add wi site

Creates a Web Interface site on the NetScaler appliance. The NetScaler Web Interface feature provides access to Citrix XenApp and Citrix XenDesktop applications. Users access resources through a standard web browser or by using the Citrix XenApp plug-in.

Synopsys

add wi site <sitePath> [<agURL> [<staURL> [-secondSTAURL <string> [-useTwoTickets (ON | OFF)]] [-sessionReliability (ON | OFF)]] [-authenticationPoint (WebInterface | AccessGateway) [-agAuthenticationMethod (Explicit | SmartCard)]]] [-wiAuthenticationMethods (Explicit | Anonymous) ...] [-defaultCustomTextLocale <defaultCustomTextLocale>] [-webSessionTimeout <positive_integer>] [-defaultAccessMethod <defaultAccessMethod>] [-loginTitle <string>] [-appWelcomeMessage <string>] [-welcomeMessage <string>] [-footerText <string>] [-loginSysMessage <string>] [-preLoginButton <string>] [-preLoginMessage <string>] [-preLoginTitle <string>] [-domainSelection <string>] [-siteType (XenAppWeb | XenAppServices) [-ShowSearch (ON | OFF)] [-ShowRefresh (ON | OFF)] [-wiUserInterfaceModes (SIMPLE | ADVANCED)] [-UserInterfaceLayouts <UserInterfaceLayouts>]] [-userInterfaceBranding (Desktops | Applications)] [-publishedResourceType <publishedResourceType>] [-kioskMode (ON | OFF)] [-restrictDomains (ON | OFF)] [-loginDomains <string>] [-hideDomainField (ON | OFF)] [-agCallbackURL <string>]

Arguments

sitePath

Path to the Web Interface site being created on the NetScaler appliance.

agURL

Call back URL of the Gateway.

wiAuthenticationMethods

The method of authentication to be used at Web Interface

Default value: WI_EXPLICIT

defaultCustomTextLocale

Default language for the Web Interface site.

Possible values: German, English, Spanish, French, Japanese, Korean, Russian, Chinese_simplified, Chinese_traditional

Default value: LANG_EN

webSessionTimeout

Time-out, in minutes, for idle Web Interface browser sessions. If a client's session is idle for a time that exceeds the time-out value, the NetScaler appliance terminates the connection.

Default value: 20

Minimum value: 1

Maximum value: 1440

defaultAccessMethod

Default access method for clients accessing the Web Interface site.

Note: Before you configure an access method based on the client IP address, you must enable USIP mode on the Web Interface service to make the client?s IP address available with the Web Interface.

Depending on whether the Web Interface site is configured to use an HTTP or HTTPS virtual server or to use access gateway, you can send clients or access gateway the IP address, or the alternate address, of a XenApp or XenDesktop server. Or, you can send the IP address translated from a mapping entry, which defines mapping of an internal address and port to an external address and port.

Note: In the NetScaler command line, mapping entries can be created by using the bind wi site command.

Possible values: Direct, Alternate, Translated, GatewayDirect, GatewayAlternate, GatewayTranslated

loginTitle

A custom login page title for the Web Interface site.

Default value: "Welcome to Web Interface on NetScaler"

appWelcomeMessage

Specifies localized text to appear at the top of the main content area of the Applications screen. LanguageCode is en, de, es, fr, ja, or any other supported language identifier.

welcomeMessage

Localized welcome message that appears on the welcome area of the login screen.

footerText

Localized text that appears in the footer area of all pages.

loginSysMessage

Localized text that appears at the bottom of the main content area of the login screen.

preLoginButton

Localized text that appears as the name of the pre-login message confirmation button.

preLoginMessage

Localized text that appears on the pre-login message page.

preLoginTitle

Localized text that appears as the title of the pre-login message page.

domainSelection

Domain names listed on the login screen for explicit authentication.

siteType

Type of access to the Web Interface site. Available settings function as follows:

* XenApp/XenDesktop web site - Configures the Web Interface site for access by a web browser.

* XenApp/XenDesktop services site - Configures the Web Interface site for access by the XenApp plug-in.

Possible values: XenAppWeb, XenAppServices

Default value: WI_XENAPPWEB

userInterfaceBranding

Specifies whether the site is focused towards users accessing applications or desktops. Setting the parameter to Desktops changes the functionality of the site to improve the experience for XenDesktop users. Citrix recommends using this setting for any deployment that includes XenDesktop.

Possible values: Desktops, Applications

Default value: WI_UIBRAND_APP

publishedResourceType

Method for accessing the published XenApp and XenDesktop resources.

Available settings function as follows:

* Online - Allows applications to be launched on the XenApp and XenDesktop servers.

* Offline - Allows streaming of applications to the client.

* DualMode - Allows both online and offline modes.

Possible values: Online, Offline, DualMode

Default value: WI_ONLINE

kioskMode

User settings do not persist from one session to another.

Possible values: ON, OFF

Default value: OFF

ShowSearch

Enables search option on XenApp websites

Possible values: ON, OFF

Default value: OFF

ShowRefresh

Provides the Refresh button on the applications screen.

Possible values: ON, OFF

Default value: OFF

wiUserInterfaceModes

Appearance of the login screen.

* Simple - Only the login fields for the selected authentication method are displayed.

* Advanced - Displays the navigation bar, which provides access to the pre-login messages and preferences screens.

Possible values: SIMPLE, ADVANCED

Default value: WI_SIMPLE

UserInterfaceLayouts

Specifies whether or not to use the compact user interface.

Possible values: AUTO, NORMAL, COMPACT

Default value: WI_AUTO

restrictDomains

The RestrictDomains setting is used to enable/disable domain restrictions. If domain restriction is enabled, the LoginDomains list is used for validating the login domain. It is applied to all the authentication methods except Anonymous for XenApp Web and XenApp Services sites

Possible values: ON, OFF

Default value: OFF

loginDomains

[List of NetBIOS domain names], Domain names to use for access restriction.

Only takes effect when used in conjunction with the RestrictDomains setting.

hideDomainField

The HideDomainField setting is used to control whether the domain field is displayed on the logon screen.

Possible values: ON, OFF

Default value: OFF

agCallbackURL

Callback AGURL to which Web Interface contacts.

Example

```
add wi site /Citrix/PNAgent -siteType XenAppServices
```

---

rm wi site

Removes a Web Interface site from the NetScaler appliance.

Synopsys

```
rm wi site <sitePath>
```

Arguments

sitePath

Path to the Web Interface site being created on the NetScaler appliance.

Example

```
rm wi site /Citrix/PNAgent
```

---

set wi site

Modifies the parameters of a Web Interface site configured on the NetScaler appliance.

Synopsys

```
set wi site <sitePath> [-agURL <string>] [-staURL <string>] [-sessionReliability ( ON | OFF )] [-useTwoTickets ( ON | OFF )] [-secondSTAURL <string>] [-wiAuthenticationMethods ( Explicit | Anonymous ) ...] [-defaultAccessMethod <defaultAccessMethod>] [-defaultCustomTextLocale <defaultCustomTextLocale>] [-webSessionTimeout <positive_integer>] [-loginTitle <string>] [-appWelcomeMessage <string>] [-welcomeMessage <string>] [-footerText <string>] [-loginSysMessage <string>] [-preLoginButton <string>] [-preLoginMessage <string>] [-preLoginTitle <string>] [-domainSelection <string>] [-userInterfaceBranding ( Desktops | Applications )] [-authenticationPoint ( WebInterface | AccessGateway )] [-agAuthenticationMethod ( Explicit | SmartCard )] [-publishedResourceType <publishedResourceType>] [-kioskMode ( ON | OFF )] [-ShowSearch ( ON | OFF )] [-ShowRefresh ( ON | OFF )] [-wiUserInterfaceModes ( SIMPLE | ADVANCED )] [-UserInterfaceLayouts <UserInterfaceLayouts>] [-restrictDomains ( ON | OFF )] [-loginDomains <string>] [-hideDomainField ( ON | OFF )] [-agCallbackURL <string>]
```

Arguments

sitePath

Path to the Web Interface site being created on the NetScaler appliance.

agURL

Call back URL of the Gateway.

staURL

URL of the Secure Ticket Authority (STA) server.

sessionReliability

Enable session reliability through Access Gateway.

Possible values: ON, OFF

Default value: OFF

useTwoTickets

Request tickets issued by two separate Secure Ticket Authorities (STA) when a resource is accessed.

Possible values: ON, OFF

Default value: OFF

secondSTAURL

URL of the second Secure Ticket Authority (STA) server.

wiAuthenticationMethods

The method of authentication to be used at Web Interface

Default value: WI_EXPLICIT

defaultAccessMethod

Default access method for clients accessing the Web Interface site.

Note: Before you configure an access method based on the client IP address, you must enable USIP mode on the Web Interface service to make the client?s IP address available with the Web Interface.

Depending on whether the Web Interface site is configured to use an HTTP or HTTPS virtual server or to use access gateway, you can send clients or access gateway the IP address, or the alternate address, of a XenApp or XenDesktop server. Or, you can send the IP address translated from a mapping entry, which defines mapping of an internal address and port to an external address and port.

Note: In the NetScaler command line, mapping entries can be created by using the bind wi site command.

Possible values: Direct, Alternate, Translated, GatewayDirect, GatewayAlternate, GatewayTranslated

defaultCustomTextLocale

Default language for the Web Interface site.

Possible values: German, English, Spanish, French, Japanese, Korean, Russian, Chinese_simplified, Chinese_traditional

Default value: LANG_EN

webSessionTimeout

Time-out, in minutes, for idle Web Interface browser sessions. If a client's session is idle for a time that exceeds the time-out value, the NetScaler appliance terminates the connection.

Default value: 20

Minimum value: 1

Maximum value: 1440

loginTitle

A custom login page title for the Web Interface site.

Default value: "Welcome to Web Interface on NetScaler"

appWelcomeMessage

Specifies localized text to appear at the top of the main content area of the Applications screen. LanguageCode is en, de, es, fr, ja, or any other supported language identifier.

welcomeMessage

Localized welcome message that appears on the welcome area of the login screen.

footerText

Localized text that appears in the footer area of all pages.

loginSysMessage

Localized text that appears at the bottom of the main content area of the login screen.

preLoginButton

Localized text that appears as the name of the pre-login message confirmation button.

preLoginMessage

Localized text that appears on the pre-login message page.

preLoginTitle

Localized text that appears as the title of the pre-login message page.

domainSelection

Domain names listed on the login screen for explicit authentication.

userInterfaceBranding

Specifies whether the site is focused towards users accessing applications or desktops. Setting the parameter to Desktops changes the functionality of the site to improve the experience for XenDesktop users. Citrix

recommends using this setting for any deployment that includes XenDesktop.

Possible values: Desktops, Applications

Default value: WI_UIBRAND_APP

authenticationPoint

Authentication point for the Web Interface site.

Possible values: WebInterface, AccessGateway

agAuthenticationMethod

Method for authenticating a Web Interface site if you have specified Web Interface as the authentication point.

Available settings function as follows:

* Explicit - Users must provide a user name and password to log on to the Web Interface.

* Anonymous - Users can log on to the Web Interface without providing a user name and password. They have access to resources published for anonymous users.

Possible values: Explicit, SmartCard

publishedResourceType

Method for accessing the published XenApp and XenDesktop resources.

Available settings function as follows:

* Online - Allows applications to be launched on the XenApp and XenDesktop servers.

* Offline - Allows streaming of applications to the client.

* DualMode - Allows both online and offline modes.

Possible values: Online, Offline, DualMode

Default value: WI_ONLINE

kioskMode

User settings do not persist from one session to another.

Possible values: ON, OFF

Default value: OFF

ShowSearch

Enables search option on XenApp websites

Possible values: ON, OFF

Default value: OFF

ShowRefresh

Provides the Refresh button on the applications screen.

Possible values: ON, OFF

Default value: OFF

wiUserInterfaceModes

Appearance of the login screen.

* Simple - Only the login fields for the selected authentication method are displayed.

* Advanced - Displays the navigation bar, which provides access to the pre-login messages and preferences screens.

Possible values: SIMPLE, ADVANCED

Default value: WI_SIMPLE

UserInterfaceLayouts

Specifies whether or not to use the compact user interface.

Possible values: AUTO, NORMAL, COMPACT

Default value: WI_AUTO

restrictDomains

The RestrictDomains setting is used to enable/disable domain restrictions. If domain restriction is enabled, the LoginDomains list is used for validating the login domain. It is applied to all the authentication methods except Anonymous for XenApp Web and XenApp Services sites

Possible values: ON, OFF

Default value: OFF

loginDomains

[List of NetBIOS domain names], Domain names to use for access restriction.

Only takes effect when used in conjunction with the RestrictDomains setting.

hideDomainField

The HideDomainField setting is used to control whether the domain field is displayed on the logon screen.

Possible values: ON, OFF

Default value: OFF

agCallbackURL

Callback AGURL to which Web Interface contacts.

Example

```
set wi site /Citrix/PNAgent -staURL http://myStaServer
```

---

unset wi site

Use this command to remove wi site settings.Refer to the set wi site command for meanings of the arguments.

Synopsys

```
unset wi site <sitePath> [-appWelcomeMessage] [-welcomeMessage] [-footerText] [-loginSysMessage] [-preLoginButton] [-preLoginMessage] [-preLoginTitle] [-userInterfaceBranding] [-loginDomains]
```

---

bind wi site

Binds XenApp or XenDesktop farms to a Web Interface site and optionally, defines access methods for different client IP addresses or networks.

Synopsys

```
bind wi site <sitePath> ((<farmName> <xmlServerAddresses> [-groups <string>] [-recoveryFarm ( ON | OFF )] [-xmlPort <positive_integer>] [-transport <transport> [-sslRelayPort <positive_integer>]] [-loadBalance ( ON | OFF )]) | ((-accessMethod <accessMethod> (-clientIpAddress <ip_addr> -clientNetMask <netmask>)) | (-translationInternalIp <ip_addr> -translationInternalPort <port | *> -translationExternalIp <ip_addr> -translationExternalPort <port | *> [-accessType <accessType>])))
```

Arguments

sitePath

Path to the Web Interface site.

farmName

Name for the logical representation of a XenApp or XenDesktop farm to be bound to the Web Interface site. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

accessMethod

Secure access method to be applied to the IPv4 or network address of the client specified by the Client IP Address parameter.

Depending on whether the Web Interface site is configured to use an HTTP or HTTPS virtual server or to use access gateway, you can send clients or access gateway the IP address, or the alternate address, of a XenApp or XenDesktop server. Or, you can send the IP address translated from a mapping entry, which defines mapping of an internal address and port to an external address and port.

Possible values: Direct, Alternate, Translated, GatewayDirect, GatewayAlternate, GatewayTranslated

translationInternalIp

IP address of the server for which you want to associate an external IP address. (Clients access the server through the associated external address and port.)

Example

```
bind wi site /Citrix/XenApp Farm2 10.10.10.11
```

---

unbind wi site

Unbinds XenApp or XenDesktop farms from the Web Interface site and removes the existing access method definition for a client IP address or network.

Synopsys

```
unbind wi site <sitePath> (<farmName> | ((-clientIpAddress <ip_addr> -clientNetMask <netmask>) | (-translationInternalIp <ip_addr> -translationInternalPort <port | *> -translationExternalIp <ip_addr> -translationExternalPort <port | *>)))
```

Arguments

sitePath

Path to the Web Interface site.

farmName

Name of the XenApp farm to be unbound from the Web Interface site.

clientIpAddress

IPv4 address or network address of the client for which you want to remove the defined access method.

translationInternalIp

Internal IP address of a mapping entry to be removed.

Example

```
unbind wi site  /Citrix/XenApp Farm2
```

---

show wi site

Displays settings of all the Web Interface sites, or of a specified site. To display settings of all the Web Interface sites, run the command without any parameters.

Synopsys

```
show wi site [<sitePath>]
```

Arguments

sitePath

Path of a Web Interface site whose details you want the NetScaler appliance to display.

format

level

Outputs

stateflag

agURL

Call back URL of the Gateway.

staURL

The URL of Secure Ticketing Authortity server

wiAuthenticationMethods

The method of authentication to be used at Web Interface

loginTitle

A custom login page title for the Web Interface site.

appWelcomeMessage

Specifies localized text to appear at the top of the main content area of the Applications screen. LanguageCode is en, de, es, fr, ja, or any other supported language identifier.

welcomeMessage

Localized welcome message that appears on the welcome area of the login screen.

footerText

Localized text that appears in the footer area of all pages.

loginSysMessage

Localized text that appears at the bottom of the main content area of the login screen.

preLoginButton

Localized text that appears as the name of the pre-login message confirmation button.

preLoginMessage

Localized text that appears on the pre-login message page.

preLoginTitle

Localized text that appears as the title of the pre-login message page.

domainSelection

Domain names listed on the login screen for explicit authentication.

defaultCustomTextLocale

Default language for the Web Interface site.

webSessionTimeout

Time-out, in minutes, for idle Web Interface browser sessions. If a client's session is idle for a time that exceeds the time-out value, the NetScaler appliance terminates the connection.

siteType

Type of access to the Web Interface site. Available settings function as follows:

* XenApp/XenDesktop web site - Configures the Web Interface site for access by a web browser.

* XenApp/XenDesktop services site - Configures the Web Interface site for access by the XenApp plug-in.

userInterfaceBranding

Specifies whether the site is focused towards users accessing applications or desktops. Setting the parameter to Desktops changes the functionality of the site to improve the experience for XenDesktop users. Citrix recommends using this setting for any deployment that includes XenDesktop.

ShowSearch

Enables search option on XenApp websites

ShowRefresh

Provides the Refresh button on the applications screen.

wiUserInterfaceModes

Appearance of the login screen.

* Simple - Only the login fields for the selected authentication method are displayed.

* Advanced - Displays the navigation bar, which provides access to the pre-login messages and preferences screens.

UserInterfaceLayouts

Specifies whether or not to use the compact user interface.

publishedResourceType

Method for accessing the published XenApp and XenDesktop resources.

Available settings function as follows:

* Online - Allows applications to be launched on the XenApp and XenDesktop servers.

* Offline - Allows streaming of applications to the client.

* DualMode - Allows both online and offline modes.

defaultAccessMethod

Default access method for clients accessing the Web Interface site.

Note: Before you configure an access method based on the client IP address, you must enable USIP mode on the Web Interface service to make the client?s IP address available with the Web Interface.

Depending on whether the Web Interface site is configured to use an HTTP or HTTPS virtual server or to use access gateway, you can send clients or access gateway the IP address, or the alternate address, of a XenApp or XenDesktop server. Or, you can send the IP address translated from a mapping entry, which defines mapping of an internal address and port to an external address and port.

Note: In the NetScaler command line, mapping entries can be created by using the bind wi site command.

farmName

Name for the logical representation of a XenApp or XenDesktop farm to be bound to the Web Interface site. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

accessMethod

Secure access method to be applied to the IPv4 or network address of the client specified by the Client IP Address parameter.

Depending on whether the Web Interface site is configured to use an HTTP or HTTPS virtual server or to use access gateway, you can send clients or access gateway the IP address, or the alternate address, of a XenApp or XenDesktop server. Or, you can send the IP address translated from a mapping entry, which defines mapping of an internal address and port to an external address and port.

clientIpAddress

IPv4 or network address of the client for which you want to associate an access method.

clientNetMask

Subnet mask associated with the IPv4 or network address specified by the Client IP Address parameter.

translationInternalIp

IP address of the server for which you want to associate an external IP address. (Clients access the server through the associated external address and port.)

translationInternalPort

Port number of the server for which you want to associate an external port. (Clients access the server through the associated external address and port.)

translationExternalIp

External IP address associated with server's IP address.

translationExternalPort

External port number associated with the server's port number.

accessType

Type of access to the XenApp or XenDesktop server.

Available settings function as follows:

* User Device - Clients can use the translated address of the mapping entry to connect to the XenApp or XenDesktop server.

* Gateway - Access Gateway can use the translated address of the mapping entry to connect to the XenApp or XenDesktop server.

* User Device and Gateway - Both clients and Access Gateway can use the translated address of the mapping entry to connect to the XenApp or XenDesktop server.

xmlServerAddresses

Comma-separated IP addresses or host names of XenApp or XenDesktop servers providing XML services.

xmlPort

Port number at which to contact the XML service.

transport

Transport protocol to use for transferring data, related to the Web Interface site, between the NetScaler appliance and the XML service.

sslRelayPort

TCP port at which the XenApp or XenDesktop servers listenfor SSL Relay traffic from the NetScaler appliance. This parameter is required if you have set SSL Relay as the transport protocol.

Web Interface uses root certificates when authenticating a server running SSL Relay. Make sure that all the servers running SSL Relay are configured to listen on the same port.

agAuthenticationMethod

Method for authenticating a Web Interface site if you have specified Web Interface as the authentication point.

Available settings function as follows:

* Explicit - Users must provide a user name and password to log on to the Web Interface.

* Anonymous - Users can log on to the Web Interface without providing a user name and password. They have access to resources published for anonymous users.

groups

Active Directory groups that are permitted to enumerate resources from server farms. Including a setting for this parameter activates the user roaming feature. A maximum of 512 user groups can be specified for each farm defined with the Farm<n> parameter. The groups must be comma separated.

recoveryFarm

Binded farm is set as a recovery farm.

sessionReliability

Enable session reliability through Access Gateway.

useTwoTickets

Request tickets issued by two separate Secure Ticket Authorities (STA) when a resource is accessed.

secondSTAURL

URL of the second Secure Ticket Authority (STA) server.

loadBalance

Use all the XML servers (load balancing mode) or only one server (failover mode).

authenticationPoint

Authentication point for the Web Interface site.

kioskMode

User settings do not persist from one session to another.

restrictDomains

The RestrictDomains setting is used to enable/disable domain restrictions. If domain restriction is enabled, the LoginDomains list is used for validating the login domain. It is applied to all the authentication methods except Anonymous for XenApp Web and XenApp Services sites

loginDomains

[List of NetBIOS domain names], Domain names to use for access restriction.

Only takes effect when used in conjunction with the RestrictDomains setting.

hideDomainField

The HideDomainField setting is used to control whether the domain field is displayed on the logon screen.

agCallbackURL

Callback AGURL to which Web Interface contacts.

Glossary

Jan 28, 2011

A

AAA

A NetScaler feature providing authentication, authorization, and auditing for all application traffic.

AAA-TM

See AAA. The configuration utility displays AAA as AAA-TM, meaning AAA traffic management.

access control

A general term denoting something that controls access to a resource. A more specific term is usually preferable.

Access Gateway

Former name of NetScaler Gateway.

action

A policy element that specifies what to do with a request or response that matches the expression in the policy. For example, if an expression in a policy matches a particular source IP address in a request, the action associated with the policy determines whether the connection is permitted.

action analytics

A NetScaler data-collection feature that can automatically optimize traffic in real time.

active-active mode

A deployment mode that, in addition to preventing downtime, makes efficient use of all the NetScaler ADCs in the deployment. In active-active deployment mode, the same virtual IP (VIP) addresses are assigned to all NetScaler ADCs in the configuration, but with different priorities, so that a given VIP can be active on only one ADC at a time. The ADCs can be configured so that no NetScaler ADC is idle.

ADC

See application delivery controller.

Amazon Elastic Block Store (EBS)

AWS feature that provides storage volumes that can be attached to EC2 instances.

Amazon Machine Image (AMI)

A special type of virtual appliance used to instantiate (create) a virtual machine within the Amazon Elastic Compute Cloud (EC2). It serves as the basic unit of deployment for services delivered through EC2.

AMI

See Amazon Machine Image.

AppFlow

A NetScaler feature that provides transaction-level visibility into HTTP, SSL, TCP, and SSL_TCP traffic flows.

application delivery controller (ADC)

A product, such as Citrix NetScaler, that optimizes delivery of applications. An ADC provides advanced features in addition to basic load balancing.

application visualizer

A graphical representation of an AppExpert application. Displays the public endpoints, application units, backend services, and policies that are configured for the application. You can use the Visualizer to obtain a visual overview of an AppExpert application's configuration and configure some of the displayed entities. By default, the Visualizer displays application units, services, and monitors for the selected application.

AVP

See Attribute-Value Pair.

Attribute-Value Pair (AVP)

AVPs are the basic units inside a Diameter and Radius message that carry authentication, security, and any other data pertaining to the application. There must be at least one AVP inside a Diameter or RADIUS message.

auditing

Feature that keeps a record of each user's activity on a protected server.

authentication

Feature for verifying client credentials, either locally or with a third-party authentication server, and allowing only approved users to access protected servers.

authorization

Feature for verifying which content on a protected server each user is allowed to access.

AWS region

Amazon EC2 is hosted in multiple locations world-wide. These locations are composed of regions and Availability Zones. Each region is a separate geographic area. Each region has multiple, isolated locations known as Availability Zones. Amazon EC2 gives you the ability to place resources, such as instances, and data in multiple locations. Resources are not replicated across regions unless you do so specifically.

B

back end

The server-facing side of a network.

bind point

An entity, or a stage of traffic processing, at which traffic is examined to see if it matches a policy. For example, a bind point can be a load balancing virtual server, or it can apply to all traffic at given stage of processing, such as when a request is received or when a response is sent.

bridge group

A NetScaler feature for merging multiple VLANs into a single broadcast domain.

C

cache redirection

A policy and virtual-server based NetScaler feature that evaluates the type of content requested and directs requests to a cache instead of a server.

call home

A NetScaler feature that monitors the appliance and automatically uploads data to the Support server if an error condition is detected.

CEA

Capabilities Exchange Answer. A message used by the Diameter protocol to establish a connection.

CER

Capabilities Exchange Request. A message used by the Diameter protocol to establish a connection.

certificate-key pair

An SSL certificate and its corresponding private key. Stored on a NetScaler ADC that offloads SSL processing from servers.

classic policy

The older, less robust type of NetScaler policy.

CLI

Command-line interface.

client

A computer that receives data from a server. Can also refer to a person.

client data plane

The logical grouping of the physical connections between the cluster nodes and the client-side connecting device.

client drive mapping

A method that enables users to access some or all of their clients' drives from an application running on an application server.

client keep-alive

A setting that enables receiving multiple client requests on a single client connection. Applies only to HTTP and HTTPS services.

CloudBridge Connector

A NetScaler feature for connecting a datacenter to a cloud or another datacenter. The feature establishes a "CloudBridge Connector tunnel" between the connected entities.

CloudFormation

An Amazon Web Services (AWS) feature for managing cloud resources. Uses templates to manage groups of resources, which are called "stacks."

CloudPlatform

A Citrix software platform (powered by Apache CloudStack) that pools computing resources to build public, private, and hybrid Infrastructure as a Service (IaaS) clouds.

cluster

A group of nCore appliances working together as a single system image. The cluster can include as few as 2 or as many as 32 NetScaler nCore hardware or virtual appliances as nodes. The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

cluster backplane

The logical grouping of the physical connections between the cluster nodes and the cluster backplane switch. The nodes of a cluster communicate with each other over the cluster backplane.

cluster backplane switch

A switch through which cluster nodes communicate with each other.

cluster instance

A logical entity created on the first node added to a NetScaler cluster. The cluster instance is assigned a cluster ID, which uniquely identifies the cluster.

cluster IP address

The management IP address of a cluster, through which configuration tasks must be performed. This IP address is owned by the cluster's configuration coordinator.

cluster link aggregation

A feature combining groups of cluster interfaces into channels. Similar to NetScaler link aggregation, but without the requirement that all interfaces be on the same appliance. The interfaces can be on different nodes of the same cluster.

cluster node

A NetScaler ADC that is part of a cluster.

cluster propagation

The process through which configurations that are performed on the cluster IP address are propagated to all the nodes of the cluster.

cluster synchronization

The process through which cluster configurations are synchronized to appliances that are added as cluster nodes or to nodes that rejoin the cluster.

clustering

The process of creating a cluster of NetScaler ADCs.

collector

An AppFlow entity that receives flow records generated by a NetScaler appliance.

community string

A password for authenticating SNMP queries from SNMP managers.

configuration coordinator

The cluster node on which cluster configurations are performed and then propagated to the other cluster nodes. The configuration coordinator owns the cluster IP address.

configuration utility

The NetScaler graphical user interface (GUI).

console

The command line interface accessed through the console port of a NetScaler appliance.

content filtering

A NetScaler feature that takes a user-specified action when the something in the header of a request or response matches a policy.

content group

A group of all virtual servers and policies involved in a particular content switching configuration.

content switching

Load balancing that bases server selection on the type of content requested.

critical interface

A NetScaler interface that, if it fails or is disabled, triggers a high-availability (HA) failover.

crossover cable

An Ethernet cable in which the sending and receiving wires are crossed.

D

dashboard

An interface element that displays performance data in graphical form.

data set

A specialized form of pattern set, consisting of an array of patterns of type number (integer), IPv4 address, or IPv6 address.

datacenter

A facility housing computer systems and associated components, such as telecommunications and storage systems. Usually includes redundant or backup power supplies, redundant data communications connections, environmental controls such as air conditioning and fire suppression, and security devices.

DataStream

NetScaler feature for load balancing database servers.

default syntax policies

The newer type of NetScaler policies, which provide more capabilities than do classic policies. Most NetScaler features are migrating from classic to default syntax policies.

Desktop Director

A Citrix product that provides a detailed and intuitive overview of XenDesktop environments.

Diameter

An Authentication, Authorization, and Accounting (AAA) protocol derived from RADIUS.

direct server return (DSR)

A NetScaler load balancing mode in which servers send responses directly to the clients, instead of through the NetScaler ADC.

Disconnect Peer Acknowledgment (DPA)

A response acknowledging a DPR.

Disconnect Peer Request (DPR)

A Diameter request sent to a peer to initiate session termination.

down state flush

A NetScaler feature for delayed cleanup of a virtual-server's connections. Connections remain open until the virtual server enters the DOWN state.

DPA

See Disconnect Peer Acknowledgment.

DPR

See Disconnect Peer Request.

DSR

See direct server return.

E

EBS

See Amazon Elastic Block Store.

EC2

See Elastic Cloud Compute.

effective state

Cumulative state of the primary and backup virtual servers. If any of virtual servers in the chain is UP, the effective state is UP. For a GSLB service, the effective state reflects the effective state of the corresponding load balancing virtual server. (A load balancing *service* has no effective state.)

Elastic Cloud Compute (EC2)

Amazon Web Services (AWS) feature with which users create virtual computers (instances).

Elastic Network Interface (ENI)

An Amazon Web Services (AWS) virtual network interface that you can attach to an instance in a virtual private cloud (VPC).

ENI

See Elastic Network Interface.

ETag

An identifier assigned by a web server to a specific resource at a URL. Useful for cache validation and for preventing one simultaneous update of a resource from overwriting another.

expression

A logic statement, such as a Perl Compatible Regular Expression (PCRE), specifying the characteristics of requests or responses that match the policy of which the expression is a part. Also called a rule.

F

failover interface set

A pair of interfaces, with each interface on a different appliance. If one appliance fails, process is transferred to the other appliance without triggering a failover event.

Federal Information Processing Standards (FIPS)

Standards developed by the National Institute for Standards and Technology (NIST) to ensure compliance with federal security and data-privacy requirements.

field replaceable unit (FRU)

A NetScaler component that can be replaced by the user.

FIPS

See Federal Information Processing Standards.

FRU

See field replaceable unit.

flow processor

The cluster node that is selected as the node to process the traffic. The flow processor receives the traffic from the flow receiver through the cluster backplane.

flow receiver

The cluster node that receives traffic from the external network. The flow receiver node steers or forwards the traffic to the flow processor through the cluster backplane.

front end

The client-facing side of a network.

G

global server load balancing (GSLB)

A NetScaler feature that performs load balancing across data centers in a WAN.

GSLB

See global server load balancing.

GUI

See configuration utility.

H

HDX Insight

NetScaler Insight Center component that monitors ICA traffic.

high availability (HA)

A deployment mode in which one appliance (the primary) is backed up by another appliance (the secondary). If the primary appliance fails, a failover event transfers control to the secondary appliance.

HA

See high availability.

I

IAM

See Identity and Access Management.

INC

See Independent Network Configuration (INC) mode.

Identity and Access Management (IAM)

An Amazon Web Services (AWS) feature with which you can control access to AWS services and resources for your users. Using IAM, you can create and manage AWS users and groups and use permissions to allow or deny their access to AWS resources.

ICA

See Independent Computing Architecture (ICA)

Independent Computing Architecture (ICA)

Citrix proprietary protocol for XenApp and XenDesktop traffic.

Independent Network Configuration (INC) mode

A type of High availability deployment in which the two HA nodes reside in different networks. The following independent network entities and configurations are neither propagated nor synced to the other node: MIPs, SNIPs, VLANs, routes (except LLB routes), route monitors, RNAT rules (except any RNAT rule with a VIP as the NAT IP), and dynamic routing configurations.

information element

A description of an attribute that can appear in an IPFIX Record. RFC5102 defines the base set of IPFIX information elements.

inline mode

A two-arm deployment mode in which the traffic between clients and servers passes through the deployed appliance.

IP set

A set of subnet IP (SNIP) addresses and virtual IP (VIP) addresses, identified with a meaningful name indicating the usage of the IP addresses contained in the set.

L

link load balancing (LLB)

A NetScaler feature that balances outbound traffic across multiple Internet connections provided by different service providers.

Linkset

An entity specifying interfaces through which a node can connect to the external switch through the cluster backplane. Linksets must be used for traffic distribution in an asymmetric (some nodes not connected to the external switch) cluster topology. Linksets can be used exclusively or combined with ECMP or cluster link aggregation.

load balancing

A core NetScaler feature that distributes user requests for web pages and other protected applications across multiple

servers that all host (or mirror) the same content.

load balancing virtual server

The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the local area network (LAN) or wide area network (WAN), the VIP is usually a private (ICANN non-routable) IP address.

M

management service

The graphical user interface (GUI) of a NetScaler SDX appliance. Also used on some CloudBridge appliances.

mapped IP (MIP)

Mapped IP address. A NetScaler IP address used for server-side connections. Citrix recommends using a subnet IP (SNIP) address instead.

MEP

Metric Exchange Protocol, a Citrix protocol used for GSLB.

MIP

See mapped IP.

MIR

See multiple IP response.

monitor

A NetScaler entity that periodically probes each service to which you assign it. If a service does not respond within a specified interval, and the specified number of probes fail, the service is marked DOWN. In that case, the monitor continues to send probes, and can change the status to UP.

multiple IP response (MIR)

A GSLB option for the NetScaler ADC to send multiple IP addresses in response to a DNS request.

multitenant

A configuration in which multiple clients are served from the same platform.

N

named expression

An expression that has been assigned a name, which is used instead of the expression itself in a policy.

nCore

The multiple-core, 64-bit version of the NetScaler operating system.

negative caching

The caching of negative responses from servers in a domain, to speed up responses to queries.

net profile

An information set that contains NetScaler owned IP addresses (IP set) or an IP address. During communication with

physical servers or peers, the NetScaler ADC uses the addresses specified in the profile as source IP addresses.

netbridge

A logical container that holds or represents a CloudBridge Connector tunnel configuration on a NetScaler appliance. A GRE tunnel entity is associated with the netbridge. A particular CloudBridge Connector tunnel configuration on a NetScaler appliance is identified by the name of the netbridge entity.

netmask

A network mask. Also called a subnet mask.

NetScaler Gateway

A NetScaler feature (also available as a standalone appliance) that provides secure access to a LAN or WAN from any location on the Internet.

NetScaler Insight Center

A Citrix virtual appliance that can monitor NetScaler appliances.

NetScaler IP (NSIP)

NetScaler IP address. The IP address for management and general system access to the NetScaler appliance.

NetScaler owned IP address

An IP address that exists only on a NetScaler ADC. NetScaler owned IP addresses can be of the following types: NetScaler IP address (NSIP), Virtual IP addresses (VIPs), Subnet IP addresses (SNIPs), and global server load balancing site IP addresses (GSLBIPs). The NetScaler IP address (NSIP) uniquely identifies the NetScaler ADC on your network, and it provides access to the ADC. A Virtual IP address (VIP) is a public IP address to which a client sends requests. The NetScaler ADC terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a subnet IP address (SNIP) as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique global server load balancing site IP address (GSLBIP).

NetScaler software

The NetScaler operating system.

NetScaler VPX

A NetScaler virtual machine image that can be installed on a virtualization platform.

NetScaler Web Logging (NSWL) client

Software installed on the client system to collect logs of HTTP and HTTPS requests.

network visualizer

A Network feature that displays the network configuration of a NetScaler ADC, including the network configuration of the nodes in a high availability (HA) deployment. You can also modify the configuration of VLANs, interfaces, channels, and bridge groups, and perform HA configuration tasks.

Next Secure (NSEC)

A DNS record showing that no records exist between two points.

NITRO

The NetScaler API suite.

node group

A group of cluster nodes that have a specific set of cluster configurations. Node groups are used to define partially striped configurations.

node instance

A logical entity on a cluster node. The node instance is assigned a node ID, which uniquely identifies the node.

non-INC mode

A high availability-deployment mode in which both HA nodes are in the same network.

NSIP

See NetScaler IP.

NSVLAN

The virtual LAN (VLAN) to which the subnet that includes the NetScaler management IP (NSIP) address is bound. This subnet is available only on interfaces that are associated with NSVLAN.

O

one-arm mode

Configuration in which only one NetScaler interface is connected to an Ethernet segment.

P

partially striped configuration

A configuration available on a subset of cluster nodes. The subset is defined by the node group.

pattern set

An array of indexed patterns used for string matching during default syntax policy evaluation. Example of a pattern set: image types {svg, bmp, png, gif, tiff, jpg}. Also called a patset.

policy

An entity that identifies requests or responses on which to perform specified actions. A policy is essentially of the form: if <expression>, do <action>

policy binding

The act of binding a policy to a bind point, which determines the instant at which the policy is invoked. A policy can be bound to a virtual server or globally to the NetScaler appliance.

pre-shared key

A text string manually configured on CloudBridge peers. The strings are matched against each other for authentication before security associations are established.

profile

A collection of settings that enable a feature to perform a complex function. For example, in the application firewall, a profile for XML data can perform multiple screening operations, such as examining the data for illegal XML syntax or evidence of SQL injection.

R

rate limit identifier

A named entity that specifies numeric rate-limiting thresholds, such as the maximum number of requests or connections (of a particular type) that are permitted in a specified period called a *time slice*.

rate limiting

A NetScaler feature with which you can configure the appliance to monitor the rate of traffic associated with an entity and take preventive action, in real time, when the rate reaches a specified value.

reboot

To restart an appliance.

redirection

Sending a client request to a different web page or server.

Request Switching

Citrix technology that enables an appliance to multiplex and offload TCP connections, maintain persistent connections, and manage traffic at the request (application layer) level.

responder

NetScaler feature that sends an automatic response based on who sent the request, where it is from, and other criteria with security and system-management implications.

REST interface

REpresentational State Transfer interface. A software architecture for using simple HTML calls to create or modify information on a server.

rewrite

NetScaler feature that modifies information in the headers or bodies of requests or responses.

rule

A policy element consisting of a logical expression used to evaluate requests or responses. If the evaluation returns TRUE, the action that is bound to the policy is performed.

S

SDX

An advanced NetScaler or CloudBridge platform hosting virtual machines (VMs). NetScaler SDX hosts multiple NetScaler VMs. CloudBridge SDX hosts a NetScaler VM and multiple CloudBridge VMs.

Secure Ticket Authority (STA)

The XenApp/XenDesktop entity responsible for issuing session tickets in response to connection requests for published applications on XenApp and published desktops on XenDesktop. These session tickets form the basis of authentication and authorization for access to published resources.

selectlets

A group of non-compound, default syntax expressions, each of which is called a selectlet. A traffic stream selector can contain up to five selectlets. Each selectlet is considered to be in an AND relationship with the other expressions.

selector

A filter for identifying requests, or for identifying objects in a content group.

server data plane

The logical grouping of the physical connections between cluster nodes and the server-side connecting device.

server object

A virtual entity representing a physical server. Enables naming a server, rather than identifying it by its IP address.

service

The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a virtual server.

sessionless load balancing

Load balancing on a per packet basis, without storing session information. Reduces NetScaler resource requirements. Used in DSR mode.

shell

Refers to the BSD command shell unless otherwise stated.

single sign-on (SSO)

A method of providing access to multiple password-protected information systems without requiring multiple authentications. Supported by the Citrix password manager.

single-hop mode

The mode in which NetScaler Insight Center collects data from NetScaler appliances handling connections in which users connect to XenApp and XenDesktop applications through a NetScaler Gateway appliance.

slow start

A NetScaler feature that avoids assigning all new connections to a server when it is added to the network.

spotted configuration

A configuration that is available on only a single cluster node.

SSO profile

In forms-based single signon (SSO), the profile that defines how to handle an authentication request that matches the associated policy.

start

To start an appliance (formerly "boot").

stream selector

A filter for identifying an entity for which you want to throttle access.

string map

A NetScaler entity, consisting of key-value pairs, that can be used for pattern matching in all NetScaler features that use the default policy syntax.

striped configuration

A configuration available on all nodes of a cluster.

subnet IP (SNIP)

Subnet IP address. A NetScaler-owned IP address used for server-side connections.

SureConnect

A NetScaler feature that directs requests to an alternative web page if the primary page is DOWN.

Sysid

See system ID

SYSLOG

A standard logging protocol, implemented on a SYSLOG auditing module, (which runs on the monitored appliance), and a SYSLOG server, which can run on a remote system. SYSLOG uses User Data Protocol (UDP) for data transfer.

system ID (sysid)

A number, or possibly characters, identifying an appliance or virtual appliance.

T

thick provisioned format

VMDK format in which all physical disk space required for a virtual disk is allocated and zeroed out (wiped) when the disk is first created. In other words, space for a thick provisioned VMDK is reserved in advance for that VMDK only. You cannot overallocate physical disk space if you use thick provisioned VMDKs, which limits the number and size of VMDKs and can waste physical disk space, but ensures that you will have enough physical disk space in all circumstances.

thin provisioned format

VMDK format in which physical disk space needed for a virtual disk is allocated and zeroed out (wiped) only when the VMDK is written to the physical disk. In other words, space for a thin provisioned VMDK is allocated dynamically as needed; physical disk space is not allocated and reserved in advance. You can overallocate physical disk space if you use thin provisioned VMDKs, which allows you to put more and larger VMDKs on a given physical disk and avoid wasting unused space, but risks running out of physical disk space if your VMDKs are too full.

time stamp

Data indicating when an event occurred.

timeout

A setting indicating when an entity is to become unavailable (for example, how long a connection can remain idle without being closed). Also, the act of becoming unavailable after the specified period of time.

tracing

The use of trace files to debug problems in the flow of packets to the cluster nodes. The NetScaler operating system includes a utility called nstrace, which provides a dump of the packets received and sent by the appliance, and stores the packets in trace files. You use the Wireshark application to view the trace files.

traffic domains

A NetScaler feature with which you can create multiple isolated environments within a the appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. You can, for example, use the same IP address in different domains.

transparent mode

An operational mode in which an appliance between the end points of a connection does not have its own IP address. The appliance intercepts packets that one end point sends to the other.

two-arm mode

A deployment mode in which two network interfaces on the deployed appliance are connected to different Ethernet segments.

U

Use Source IP (USIP)

A NetScaler mode in which the ADC uses the client's IP address, instead of a SNIP address, in packets sent to the server.

USNIP

NetScaler mode that uses a subnet IP (SNIP) address as the source IP address of packets sent to the server, and as the address at which packets are received from the server. This mode is enabled by default.

V

view based access control model (VACM)

An SNMPv3 feature that enables you to configure access rights to a specific subtree of the MIB on the basis of various parameters, such as security level, security model, user name, and view type. You can configure agents to provide different levels of MIB access to different managers.

virtual IP (VIP)

A virtual IP (VIP) address is the IP address associated with a virtual server. It is the IP address to which clients connect for access to one of the servers represented by the virtual server. An appliance managing a wide range of traffic might have many virtual servers, each configured with its own VIP address. Some of the attributes of a VIP address are customized to meet the requirements of the virtual server.

virtual machine disk (VMDK)

File format for virtual disk drives. Originally developed by VMWare, but now an open format that is widely used in many types of clouds and virtual machines (VMs).

VMDK

See virtual machine disk

virtual server

A NetScaler entity with an IP address to which clients send requests. Distributes the requests to physical servers.

VPX

See NetScaler VPX.

W

waterfall chart

A NetScaler Insight Center chart that shows the cumulative effect of sequentially introduced positive or negative values.

Web 2.0 push

A NetScaler feature in which the NetScaler ADC functions as a proxy server to offload long-lived client TCP connections

and maintain relatively fewer, reusable connections to the server.

Web Insight

A component of NetScaler Insight Center. Monitors HTTP traffic.

Web Interface

The XenApp/XenDesktop component with which users access their applications, content, and desktops through a web browser. Also supports access through the Citrix XenApp plug-in. A NetScaler ADC can manage Web Interface access to XenApp or XenDesktop server farms.

web server logging

A NetScaler feature that sends logs of HTTP and HTTPS requests to a client system for storage and retrieval.

wildcard virtual server

A virtual server that accepts all traffic.

X

XenApp

A Citrix on-demand application delivery solution that enables any Windows application to be virtualized, centralized, and managed in the datacenter, and instantly delivered as a service to users anywhere on any device.

XenCenter

Management application for XenServer. You can use XenCenter to create, deploy, manage, and monitor virtual machines (VMs) from a Windows computer.

XenDesktop

A Citrix desktop virtualization and VDI solution that delivers a complete Windows desktop experience as an on-demand service to any user, anywhere.

XenServer

The Citrix open-source virtualization platform.
